PREFACE

This is the **One Hundred Thirty Ninth** Issue of Current Awareness Bulletin started by Delhi Technological University, Central Library. The aim of the bulletin is to compile, preserve and disseminate information published by the faculty, students and alumni for mutual benefits. The bulletin also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **July, 2024**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A Comparative Study of Machine Learning Models for Network Traffic Classification in the IoT Landscape, ***8.Divyanshu Thakur***, ***8.Srijan Sah***, ***8.Priyansh Ailsinghani*** and ***3.Virender Ranga***, IT, DTU

2. A fexible memory device made of SnO2-hBN nanocomposite exhibits stable resistive switching application, ***6.Km. Komal***, ***3.Mukhtiyar Singh*** and ***3.Bharti Singh***, Applied Physics, DTU

3. A NEW DIFFERENTIAL SUBORDINATION TECHNIQUE FOR A SUBCLASS OF STARLIKE FUNCTIONS, ***3.S. SIVAPRASAD KUMAR*** AND ***6.POOJA YADAV***, Applied Mathematics, DTU

4. A novel hybrid intelligent approach for solar photovoltaic power prediction considering UV index and cloud cover, ***6.Rahma Aman***, ***3.M. Rizwan*** and Astitva Kumar, Electrical, DTU

5. A novel investigation on single-loop pulsating heat pipe filling with hybrid nanofluids: numerical and experimental, ***6.Prem shanker yadav***, Jitendra sharma, Mohd Hussain, Imran ahmed Khan, Kartik Goyal and Samer Fikry Ahmed, Mechanical, DTU

6. A uniformly convergent method for two-parameter singularly perturbed parabolic partial differential equations with a large shift, ***3.Aditya Kaushik***, ***6.Nitika Sharma***, Manju Sharma, Monika Arora and ***6.Shivani Jain***, Applied Mathematics, DTU

7. Addressing Health Disparities through Community-Based Public Health Initiatives, ***6.Naima Tiwari***, Public Health, DTU

8. An experimental study of game theory with various word embeddings for automatic extractive text summarization, ***3.Minni Jain***, ***3.Rajni Jindal*** and Amita Jain, CSE, DTU

9. An Implementation of a Frequency Decomposition Algorithm for Power Quality Smoothening in a Hybrid SPVA-BES Microgrid, ***7.1, Divyank Srivastava***, Vivek Narayanan, Bhim Singh, and Arunima Verma, Power Systems, DTU

10. Analysis of PCE-based Superplasticiser for the Different Types of Cement using Marsh Cone Test, Rahul Kumar, Manvendra Verma and ***3.Nirendra Dev***, Civil, DTU

11. Analyzing Yoga Pose Recognition: A Comparison of MediaPipe and YOLO Keypoint Detection with Ensemble Techniques, ***7.Debashree Debalaxmi***, ***3.Dinesh Kumar Vishwakarma*** and ***3.Virender Ranga***, IT, DTU

12. Assessing Gender Bias in Machine Translation, ***7.Rishabh Jain***, CSE, DTU

13. Barrow holographic dark energy model in f (R,T) theory, Kanchan Devi, ***6.Ajay Kumar*** and Pankaj Kumar, Applied Mathematics, DTU

14. Base and Exponent Prediction in Mathematical Expressions using Multi-Output CNN, ***8.Md Laraib Salam***, Akash S Balsaraf and Gaurav Gupta, Electrical, DTU

15. Camera-based Mobility Framework for Visually Impaired Pedestrians in Unstructured Environments, Aditya Kumar, Anwesha Chakravarty, ***6.Ayesha Choudhary*** and ***3.S. Indu***, ECE, DTU

16. Carboxymethyl Guar Gum-Based Bioactive and Biodegradable Film for Food Packaging, ***6.Tanvi Singh***, ***6.Meenakshi Tanwar*** and ***3.Rajinder K. Gupta***, Chemistry, DTU

17. Classification of Banana Plant Leaves Based on Nutrient Deficiency Using Vision Transformer, ***6.Sumit Kumar Sharma*** & ***3.Prof. Dinesh Kumar Vishwakarma***, IT, DTU

18. Comparative Analysis of various Slot in Patch Antennas: A Review, ***3.Sumit Kumar Khandelwal***, ***8.1Anupam Verma, 8.1Amarnath Yadav*** and ***8.1Arpan Goyal, ECE, DTU***

19. Complementary Dynamics of Global and Local Centrality for Influence Maximization in Social Networks, ***3.Rajesh Kumar Yadav***, ***8.Aaryan Arora***, ***8.Aayush Patel*** and ***8.Aditya Gupta***, CSE, DTU

20. Cosmological tests of the dark energy models in Finsler-Randers Space-time, Z. Nekouee, ***7.Himanshu Chaudhary***, S. K. Narasimhamurthy, S. K. J. Pacif and Manjunath Malligawad, Applied Mathematics, DTU

21. Curcumin and ZnO-NPs loaded xanthan gum and hydroxypropyl guar gum-based hydrogel film for food packaging, ***8.Ishita Parmar***, ***6.Meenakshi Tanwar*** and ***3.Rajinder K. Gupta***, Applied Chemistry, DTU

22. Design and theoretical study of rectangular photonic crystal fiber based sensor for chemical sensing in terahertz regime, ***8.1 D Garg, 8.1 J Singh,*** and ***3.A Kumar,*** Applied Physics, DTU

23. Document Information Retrieval with Deep Learning, ***3.Abhilasha Sharma*** and ***7.Aparna Arya***, Software Engineering, DTU

24. DoSLex: automatic generation of all domain semantically rich sentiment lexicon **3.** ***Minni Jain, 3. Rajni Jindal*** ,Amita Jain,CSE, DTU

25. Ecological Representation in the Maithili Songs of Vidyapati, ***6.Mallika Tosha*** and ***3.Dr. Rajiv Ranjan Dwivedi***, Humanities, DTU

26. Effect of various energy storage phase change materials (PCMs) and nano-enhanced PCMs on the performance of solar stills: A review ***6.Aseem Dubey*** and ***3.Akhilesh Arora***, Mechanical, DTU

27. Efficient hashing technique for malicious profle detection at hypervisor environment, Anumukonda Naga ***6.Seshu Kumar***, ***3.Rajesh Kumar Yadav*** and ***3.Nallanthighal Srinivasa Raghava***, CSE and Electronics, DTU

28. Enhancement in sugar extraction from Pistia stratiotes through statistical optimization of alkaline pre-treatment and enzymatic hydrolysis, ***6.Sweeti Mann***, ***3.Jai Gopal Sharma*** and Rashmi Kataria, Biotechnology, DTU

29. Enhancing concrete durability and strength: An innovative approach integrating abrasion and cement slurry treatment for recycled coarse aggregates, ***6.Harish Panghal*** and ***3.Awadhesh Kumar***, Civil, DTU

30. Evaluation of the role of process parameters of CMT welding and their statistical behaviour on the tensile properties of weld joint of novel aluminium hybrid composite, ***6.Vibhu Singh***, ***3.M. S. Niranjan*** and ***3.Qasim Murtaza***, Mechanical, DTU

31. Evaluation of Tribological and Cooling Performance of TiN and DLCCoated Pistons for Miniature Stirling Cryocooler ***8.M.Singhal***, R. Kumar, R.S.Walia,,S. K. Pandey, Mechanical Engineering,DTU

32. Experimental analysis of GMAW welded AA7475 T7351 alloy joints, Hari Shanker, ***3.Reeta Wattal***, Mechanical Engineering ,DTU

33. "Explainable AI" Disease Detection with Reasoning, ***3.Manoj Kumar***, ***8.Kanishk Ramrakhiyani*** and ***8.Harsh Garg***, CSE, DTU

34. Exploring the potential of dual-metallized PET towards improving the efficiency of outermost reflective layer in fire proximity clothing, Shivangi Dwivedi, ***3.Richa Srivastava*** and Prasun Kumar Roy, Applied Chemistry, DTU

35. Exploring the wear behaviour of Al6351-Gr composite reinforced with B4C, TiC, and WC particles, Shahazad Ali, ***3.Qasim Murtaza***, Pallav Gupta, Mechanical, Production and Industrial Engineering Department, DTU

36. Geographical variability of ultrafine particle concentrations in urban and background regions in India, ***6.Vignesh Mohan***,Vijay Kumar Soni, ***3.Rajeev Kumar Mishra,*** Environmental Engineering, DTU

37. Ge-Se-Te based Penrose Photonic Quasi-Crystal fiber for SCG covering 2-21 μm MIR Regime, ***6.Akash Khamaru*** and ***3.Ajeet Kumar***, Applied Physics, DTU

38. Hate Speech Detection using CoT and Post-hoc Explanation through Instruction-based Fine Tuning in Large Language Models, ***8.Palak Gupta***, ***8.Nikhilesh Jain*** and ***3.Aruna Bhat***, CSE, DTU

39. Impact of flexible vegetation on hydraulic characteristics in compound channels with converging floodplains, ***6.Noopur Awasthi, 3.Munendra Kumar*** & ***3.Ritu Raj***, Civil, DTU

40. Impact of Health Insurance on Accessibility, Utilization of Inpatient Care, and Financial Risk Protection Across States/Union Territories of India, ***6.Aashima***, ***6.Mehak Nanda*** and Rajesh Sharma, USME, DTU

41. Improved optical characteristics in BaBi2Nb2O9 ferroelectric ceramic infused with transition metal ion (W6+) and rare earth ions (Er3+/Yb3+), ***6.Ankita Banwal***, ***6.Bhavya Kumar***, Manoj Verma, Ankur Shandilya, ***3.Bharti Singh*** and ***3.Renuka Bokolia***, Applied Physics, DTU

42. Improving Intrusion Detection in a Software Defined Network using Hybrid CNN and Bi-LSTM, ***8.Ashutosh Bhattarai***, ***8.Unmik Gyawali***, ***6.Abhishek Verma*** and ***3.Virender Ranga***, IT, DTU

43. Innovative Channel Estimation Method for Rayleigh, Rician, and Nakagami Channels: The Modified M-Estimator-I, Prakhar Hari, Sanjay Mathur, Prachi Mishra, ***6.Pooja Singh*** and Hari Kumar Singh, Electrical, DTU

44. Integration of Deep Learning and Plant Biosecurity Toward Sustainable Agriculture: A SWOT Analysis, ***3.Abhilasha Sharma*** and ***6.Parul Sharma***, Software, DTU

45. Investigating the effect of scaling and temperature on the performance of improved junctionless nanowire FET through simulation analysis***, 3.Bharti,*** Applied Physics,DTU ***and 3.Poornima Mittal,*** ECE, DTU

46. Iris and Palmprint Multimodal Biometric Recognition using Novel Preactivated Inverted ResNet and Hybrid Metaheuristic Optimized DenseNet, ***3.Indu Singh***, ***8.Shruti Khatri***, ***8.Sunaina Luthra***, ***8.Tanvi Singh*** & Gunbir Singh Baveja, CSE, DTU

47. Mechanical characterization of Al6351 reinforced with TiC, B4C, and WC: Proportional effects and microstructural analysis, Shahazad Ali,***3.Qasim Murtaza***, and Pallav Gupta, Mechanical Engineering,DTU

48. Motor Imagery Features Selection with Grey Wolf Optimization for Brain Computer Interface, Pawan, Rohtash Dhiman, Jasbir Singh Saini, Ankur Saxena and ***6.Vikas Sharma***, IT, DTU

49. Multifaceted Discrete Emotion Recognition from EEG Physiological Signals via Machine Learning Techniques, ***8.Amriti Gupta***, Software Engineering, ***8.Kunal Nayyar***, ECE, ***8.Harshit Chopra*** Computer Engineering, ***6.Neha Gahlan***, Software Engineering, ***3.Divyashikha Sethia***, Software Engineering, DTU

50. Municipal organic solid waste management in the concept of urban mining and circular economy: a model from Palestine, ***6.Majed Ibrahim Al-Sari*** and ***3.A. K. Haritash***, Environmental, DTU

51. Observational Constraints on the Parameters of Hoˇrava–Lifshitz Gravity, ***6.Himanshu Chaudhary***, , Ujjal Debnath, Shibesh Kumar Jas Pacif, Niyaz Uddin Molla, Ghulam Mustafa, and Sunil Kumar Maurya, Applied Mathmatics, DTU

52. Performance analysis of fractional-order modified SRF PLL under grid abnormalities, ***6.Oinam Lotika Devi*** and ***3.Alka Singh***, Electrical, DTU

53. Phytoremediation of Chromium (VI)-Contaminated Soil by Euphorbia tithymaloides L. and Metagenomic Analysis of Rhizospheric Bacterial Community, ***6.Deepika*** and ***3.Anil Kumar Haritash***, Environmental, DTU

54. Plasma-assisted carbon nanotube for solar cell application, ***7.Suraj Kumar Singh***, ***7.Ishu Sharma*** and ***3.Suresh C. Sharma***, Applied Physics, DTU

55. Predicting Cardiovascular Disease with Machine Learning: A Comparative Analysis of Classification Models, ***7.Diya Malhotra*** and ***7.Aarushi Saini***, Applied Mathematics, DTU

56. Predictive design of KSnI3-based perovskite solar cells using SCAPS and machine learning model, ***6.Rahul Kundara*** and ***3.Sarita Baghel***, Applied Physics, DTU

57. Primary Microplastics in the Ecosystem: Ecological Effects, Risks, and Comprehensive Perspectives on Toxicology and Detection Methods, ***6.Pooja Singh***, ***6.Gunjan Varshney*** and ***3.Raminder Kaur***, Applied Chemistry, DTU

58. Quadrupole mode plasmon resonance enabled dual-band metamaterial for refractive index sensing application, ***6.Ankit***, Monu Nath Baitha, ***3.Kamal Kishor*** and ***3.Ravindra Kumar Sinha***, Applied Physics, DTU

59. Quantum Computational and Spectroscopic Investigation of 3-aminosalicylic Acid, Shahid Husain, Nupur Pandey, Nisha Fatma, Sanjay Pant and ***3.Mohan Singh Mehata***, Applied Physics, DTU

60. Quantum Resistant Blockchain-based Architecture for Secure Medical Data Sharing, ***8.Kanupriya Jain***, ***8.Mahima Singh***, ***8.Harshita Gupta*** and ***3.Aruna Bhat***, CSE, DTU

61. Quitting silently: A longitudinal research on the impact of workplace conflict and nonviolent work behavior, ***6.Suhans Bansal*** and ***3.Naval Garg***, USME, DTU

62. Real-time investigation of grid-interactive EV charger with two-stage bidirectional converter under wide voltage range scenarios, ***8.Gaurav Yadav***, ECE, ***3.Mukhtiar Singh***, Electrical Engineering, DTU

63. Rheological Behaviour Analysis of Prepared NanoCutting Fluids from Al2O3 and Tio2, Anurag Sharma, ***3.R. C. Singh***, ***3.Ranganath M. Singari*** and S. L. Bhandarkar, Mechanical and Design, DTU

64. Second generation current conveyor based capacitorless floating memristor emulator, ***6.Navnit Kumar, 3.Manjeet Kumar*** ECE, ***3.Neeta Pandey*** ECE, DTU

65. Sentiment Analysis of Unified Payments Interface (UPI) Payment App Review using Machine Learning Algorithm, ***8.Kunal Jaluthria***, ***8.Karandeep Singh***, ***8.Manik Sharma***, ***3.Rajni Jindal***, Computer Science and Engineering, DTU

66. Shapley Explainable Deep Learning based Knowledge Distillation Framework for Student's Performance Prediction, ***3.Rahul*** and ***3.Rahul Katarya***, CSE, DTU

67. Size Optimization of Grid-Tied Hybrid Energy System by Employing Forecasted Meteorological Data, P. Anand, ***6.B. Sharma*** and ***3.M. Rizwan***, Electrical, DTU

68. Strategic Pseudo-Goal Perturbation for Deadlock-Free Multi-Agent Navigation in Social Mini-Games, ***8.Abhishek Jha***, ***8.Tanishq Gupta***, ***8.Sumit Singh Rawat*** and ***3.Girish Kumar***, Mechanical, DTU

69. The collisional study of EIC waves in a magnetized dusty plasma with the inclusion of a DC electric field, ***6.Anshu***, Jyotsna Sharma and ***3.Suresh C Sharma***, Applied Physics, DTU

70. TILING SPACES AND THE EXPANDING UNIVERSE: BRIDGING QUANTUM MECHANICS AND COSMOLOGY, ***8.Aman Yadav*** and Marcelo Maciel Amaral, Civil, DTU

71. Towards optimal score level fusion for adaptive multi-biometric authentication system, ***6.Kavita***, ***3.Rajesh Rohilla*** and Gurjit Singh Walia, Electronics, DTU

72. UDCT: lung Cancer detection and classifcation using U-net and DARTS for medical CT images, Aakanksha Gupta, Ashwni Kumar and ***6.Kamakshi Rautela***, ECE, DTU

73. Utilising NLP for Enhanced Clinical Text Mining, ***8.Gaurav Gulati*** and ***8.Gaurav Upreti***, CSE, DTU

74. VEDANet: A dense blocked network for visual emotion analysis in multimedia retrieval, Kirti Sharma, Rainu Nandal, ***3.Shailender Kumar*** and Kamaldeep Joshi1, CSE, DTU

75. VRFNet-ASLiT: Fused Deep CNN and Adaptive Super Resolution Transform Based Hand Gesture Recognition, ***6.Roli Kushwaha***, ***3.Manjeet Kumar*** and ***3.Dinesh Kumar***, Electronics, DTU

76. Workplace gratitude studies: Review and future agenda using bibliometric analysis, ***3.Naval Garg*** and ***6.B. K. Punia***, USME, DTU

***Abstract*— Network security is a top priority in today's digital economy, where intrusions grow in sophistication and size. To safeguard network infrastructure and data, it is critical to discern between legitimate and malicious network traffic. Machine learning classification models have proven useful in this task, with decision trees, random forests, and support vector machines among the most common options. This study analyzes six machine learning techniques for determining whether network data is benign or malicious. The performance evaluation is based on the accuracy, precision, F1-score, AUC ROC score, and computational efficiency of the latest IoT dataset, the TII-SSRC-23 Dataset from Kaggle. The findings shed light on each technique's strengths and drawbacks, as well as recommendations for choosing the best approach for network traffic classification.**

Keywords*— *Machine Learning, Benign Traffic, Malicious Traffic, Classifiers, Attacks, Dataset

I. INTRODUCTION

In today's hyperconnected environment, IoT gadget proliferation is a widespread trend. However, increased connection leaves organizations and individuals vulnerable to cyber dangers. Despite the availability of tools and strategies for improving security and detecting aberrant online behavior, attackers continue to violate confidentiality and compromise sensitive data. The rapid proliferation of varied IoT devices and applications complicates the network, resulting in varying capabilities, communication protocols, and data formats.[1] [2]. Machine learning-based intrusion detection systems have gained importance for adapting to this evolving IoT landscape.

Machine learning algorithms analyze massive network data and traffic patterns to automate real-time threat detection and adaptation to evolving threats. This research focuses on developing a robust solution for network traffic classification using machine learning models to improve accuracy and adaptability in network security. Malware assaults occur when dangerous software infiltrates computer systems, networks, and devices, appearing as viruses, worms, trojans, ransomware, spyware, and adware. In cybersecurity, data is divided into benign and harmful categories. Audio, background, text, and video are examples of benign data that is both safe and legal. They are essential for authorized activities. In contrast, malicious data with detrimental intent includes brute force assaults (DNS, FTP, SSH), Denial of Service attacks (ACK, FIN, HTTP), information collecting, and Mirai (Malware).[2] Cybercriminals use malicious data to compromise system integrity, confidentiality, and availability, often aiming to gain unauthorized access, steal data, disrupt services, or extort victims.

Even with multiple safeguards, malware threats can breach a user's system, requiring machine learning-based intrusion detection systems using data-driven modeling and pattern recognition for defense.[3] Relevant machine learning classifiers for network traffic classification include:

A. Support Vector Machines (SVM):

SVMs are employed in malware analysis for binary classification tasks, with the goal of establishing the appropriate boundary between malicious and benign samples. They excel at separating complex data and can categorize malware samples based on a variety of criteria, such as opcode sequences or API call patterns. SVM is suitable for binary classification because it seeks to find the optimal hyperplane that maximizes the margin between two classes, effectively enhancing class separability[4] [5].

B. Random Forest

Random Forest is frequently used for feature selection and classification in malware investigation. It can distinguish between benign and malicious files using a variety of features including as file behavior, code characteristics, and API calls.[6] Its ensemble nature helps reduce false positives and negatives, making it suited for detecting new and emerging malware strains. Random Forest is suitable for binary classification because it combines multiple decision trees to enhance accuracy and reduce overfitting.[6]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:36:59 UTC from IEEE Xplore. Restrictions apply.

C. XGBoost

XGBoost's robust performance and ability to handle imbalanced datasets make it valuable for malware classification tasks. It can process various types of data, such as static file features and dynamic behavioural analysis results, to detect malware with high accuracy. XGBoost is suitable for binary classification because it utilizes gradient boosting to optimize a loss function, enhancing prediction accuracy and handling diverse data effectively. [7]

D. Multilayer Perceptron (MLP)

MLPs, a form of neural network, are used for deep learning in malware research. It can discover sophisticated patterns and relationships from vast datasets[8], [9]. MLP models are used for tasks such as malware family classification, which involves recognizing similarities and differences between malware samples. MLP is suitable for binary classification because it uses multiple layers of neurons to learn complex patterns and non-linear decision boundaries from data.[10]

E. Decision Tree

Decision trees are useful in malware research because they help choose traits and explain them. They can help to visualize the decision-making process and discover key markers of hostile behavior. Decision trees improve the overall performance of models using ensemble techniques like Random Forest. A decision tree is suitable for binary classification because it recursively splits data into homogenous subsets, making it intuitive and effective for distinguishing between two classes.[11]

F. Extra Trees

Extra trees are useful for feature selection and classification tasks. It operates by generating several decision trees using randomized feature selection, making it resistant to overfitting. Extra Trees is commonly used to detect and categorize malware based on various static and dynamic data, such as file properties, code behavior, and API call patterns. Extra Trees is suitable for binary classification because it builds multiple de-correlated trees using random splits and samples, which improves accuracy and robustness against overfitting. [12]

Selecting the appropriate technique involves considering various critical issues. For instance, the research objective is to categorize network traffic as benign or malicious, which requires techniques capable of handling binary classification tasks. The nature of the data, such as its volume, complexity, and mix of categorical and numerical features, necessitates techniques robust to such characteristics. Scalability and efficiency are crucial due to potentially large datasets, as indicated by the hardware specifications mentioned in the paper. Model interpretability is essential for understanding cybersecurity threats, making techniques like Random Forest and Decision Trees valuable. Additionally, ethical considerations arise concerning the use of sensitive network data. By addressing these critical issues, the researchers can select appropriate techniques like Random Forest or XGBoost for effective network traffic classification while ensuring alignment with research objectives, data characteristics, and practical constraints.

The research explores the predictive capabilities of machine learning classification models for distinguishing between malicious and benign traffic. It applies six ML algorithms to an IOT based public dataset, TII-SSRC-23 dataset, which are Random Forest, XGBoost, Decision Tree, Multilayer Perceptron (MLP)[13], Extra Trees, and Support Vector Machine (SVM). The model's performance was tested using the parameters accuracy, precision, F1-score, and AUC_ROC score. Accuracy measures the overall correctness of the model's classifications, whereas precision offers information about false positives and false negatives, respectively.[14] The F1-Score combines precision and recall to provide a balanced model performance. Collectively, these features provide a detailed assessment of the model's ability to consistently identify hostile traffic while lowering the risk of false alarms, thus contributing to effective cybersecurity policy.[15]

II. LITERATURE REVIEW

Previously there have been many studies done on the implementation of Machine Learning in malware analysis, such as Sai Tejaswi's research on 'Malicious Attacks Detection Using Machine Learning' focuses on using machine learning techniques, specifically the KMEANS algorithm, to detect malicious attacks, particularly botnet attacks.[16] Traditional methods include manual packet analysis and signature-based procedures. The paper presents a graphical user interface (GUI) for the system, allowing users to upload datasets, apply KMEANS, perform flow integration, feature extraction, normalization, and employ a decision tree method for detection. [16]. The goal is to enhance the detection of botnet attacks in web-based environments using graph-based features and machine learning, offering a promising solution for improved cybersecurity.

Rastogi's study addresses the growing cybercrime threat and the need to detect malicious URLs using machine learning. The authors propose a model that employs various machine learning algorithms, including Random Forest, Support Vector Machine (SVM), Deep Neural Network (DNN), and Convolutional Neural Network (CNN), to identify malicious URLs in datasets containing both malicious and benign URLs.[17] The results show that this strategy is successful for identifying malicious URLs based on their behavior and features. The research also goes into deep learning approaches such as CNN for detecting fraudulent URLs, providing a comprehensive comparison of algorithms for this purpose.[17]

Not just URLs but QR codes have been in malicious streams as well as addressed by Rosario Lourenco's publication which focused on classifying malicious URLs and QR codes used for spreading malware and phishing.[18] It introduces two methods:

Malware URL Categorization: Using machine learning models to classify URLs as dangerous or benign.

Malicious QR Code Classification: Utilizing deep learning techniques, including CNN and ResNet, to detect malicious QR codes.

The research identifies gaps in malicious URL detection, emphasizing the need for improved datasets and model interpretability.[18] Deep learning models, such as CNNs and

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:36:59 UTC from IEEE Xplore. Restrictions apply.

ResNet, outperform classical approaches. The paper highlights the difficulties of dealing with malware, as well as the benefits of early identification. While machine learning shows promise, it has limits, such as vulnerability to adversarial assaults. QR code classification models such as CNN, ResNet, and VGG are recommended, depending on dataset size and available resources. The authors achieved great accuracy using several machine learning and deep learning models, highlighting the promise of these techniques in improving security.[18]

Websites play a significant role in phishing and generating malicious network traffic, as emphasized in Sanaa Kaddoura's research on early malicious website detection. The study utilizes supervised machine learning models, including Random Forest, Artificial Neural Network, K-nearest neighbors, and Support Vector Machine, to analyze a dataset containing application layer and network attributes[19], [20],[21]. The experiments yield strong predictive performance, with the Support Vector Machine achieving 92% accuracy in detecting malicious websites. This research is essential for bolstering internet security by effectively identifying malicious websites. [21].Future work could explore the detection of specific cyberattack types and the implementation of hybrid techniques to enhance website classification.

The research focuses on the TI-SSRC dataset which is extracted from a recent paper emphasizing the importance of diverse and robust datasets for enhancing network intrusion detection systems, driven by machine learning.[22] Many existing datasets lack diversity and relevance to current network conditions, limiting intrusion detection effectiveness. To address this, the paper introduces the TII-SSRC-23 dataset with a wide range of traffic types.[22]. The research includes a feature importance analysis and establishes strong baseline performance for both supervised and unsupervised intrusion detection, contributing to the advancement of intrusion detection models in the ever-changing network security landscape.

III. METHODOLOGY

A. Proposed Workflow

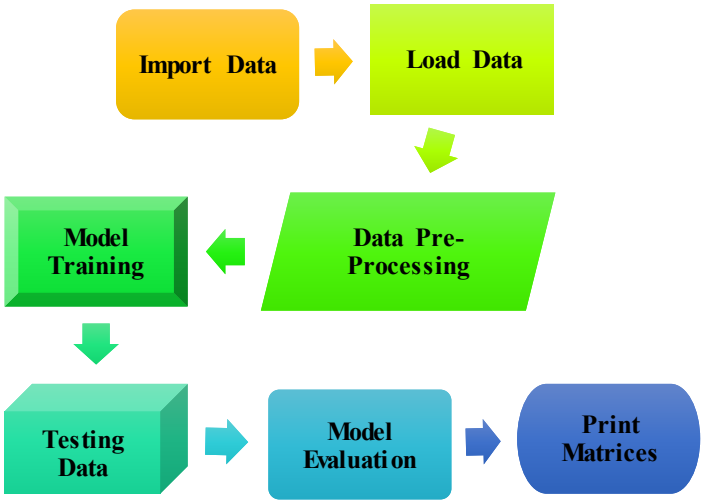

Fig 1: Workflow

The workflow diagram illustrates the research process, beginning with the collection of TII-SSRC-23 network traffic data from Kaggle. Primarily focusing on this data, employing six distinct machine learning models to assess and compare their performance metrics for model efficiency as shown in fig 1.

B. Dataset Used

In this study, the TII-SSRC-23 dataset was used from Kaggle, which contains both benign and malicious network traffic. The benign category has subtypes like audio, background, text, and video, totaling 1300 entries. The malicious category consists of over 1,000,000 datasets, categorized into 4 malicious traffic types with 24 subtypes, including brute force (20%), Dos attack (50%), information gathering (0.04%), and Mirai attack (33%).

Feature Extraction for ML Model:

The dataset contains 1,500,000+ data entries with 81 features. The extracted columns were only 'Label,' 'Traffic Type,' and 'Traffic Subtype' from the network traffic as relevant features. Columns which were excluded were 'Flow ID,' 'Src IP,' 'Src Port,' 'Dst IP,' 'Dst Port,' and 'Timestamp' due to their identifier or time-based nature, which are not relevant for classification. 'Traffic Type' and 'Traffic Subtype' represent network characteristics, while 'Label' is the binary feature indicating benign or malicious. The authors extracted features from each network traffic entry in the training dataset to label them for the ML model. Used a Label Encoder to assign 0 for benign and 1 for malicious labels.

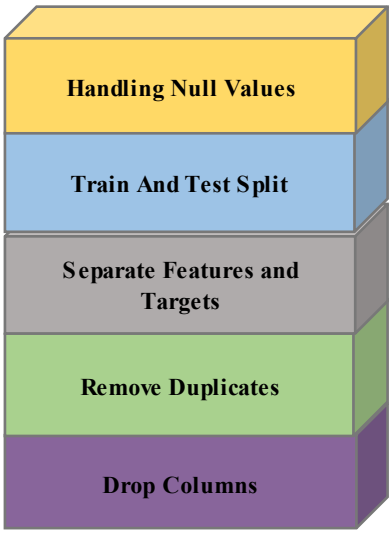
C. Proposed Methodology

1. Import and Load data: Begin by importing essential Python libraries in Jupyter and specifying the columns to drop and the target variables. Then, load the CSV file into the code. Group the data frame by the columns designated as target variables, creating

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:36:59 UTC from IEEE Xplore. Restrictions apply.

separate data frames for each unique occurrence with these target variables.

2. Data Processing:



To prepare the dataset for classification, process the data by removing unnecessary columns, round data to three decimal places, eliminate duplicates, and exclude additional columns based on the target variable. Then, it split the dataset into features (X) and the target variable (y), encode the target variable, and create training and testing sets while preserving the target variable's distribution as shown in fig 2. Duplicates are excluded by feature transformation and preprocessing.

3. Feature transformation and preprocessing: Categorize columns into numerical and categorical groups, even reclassifying the 'Protocol' column. Then, created two preprocessing pipelines: one for numerical columns, handling missing values with mean imputation and standardization, and another for categorical columns, filling missing values with mode and applying one-hot encoding. Using a Column Transformer, streamlined these transformations, fitting it to the training data to learn the process. Finally, apply the preprocessor to both training and testing datasets for further analysis and modeling.
4. Model Training and matrices evaluation:

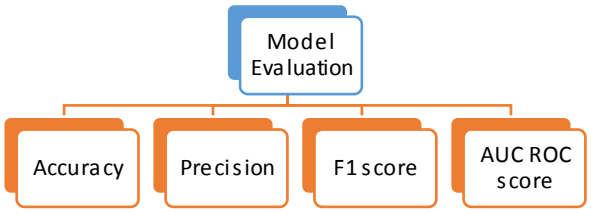


Fig 3: Model Evaluation Matrices

A Random Forest Classifier with 100 trees was utilized, a fixed random state for reproducibility, and optimized CPU core usage for faster training. Following the training, the model was evaluated using sklearn's standard metrics, including accuracy, precision, F1 score, and AUC-ROC score as shown in fig 3.

IV. EXPERIMENTAL ANALYSIS

After analysing the TI-SSRC-23 dataset using various supervised learning models, various calculated evaluation matrices were calculated to measure the performance of each model in classifying the network data as benign or malicious. These matrices are listed below:

- Precision is calculated by:

$$Precision = \frac{T_P}{T_P + F_P} \times 100 \quad -(1)$$

- Recall is calculated by:

$$Recall = \frac{T_P}{T_P + F_N} \times 100 - (2)$$

- F1-Score is calculated by:

$$F1 - Score = \frac{2 \times Recall \times Precision}{Recall \times Precision} \times 100 - (3)$$

Higher the F1-score, better the prediction rate. The capacity to discriminate between the various classes is represented by the AUC-ROC measure. The classifier's ability to distinguish between benign and malicious networks is stronger when the AUC-ROC value is higher. This number ought to be less than one and positive.

TABLE I. PERFORMANCE MEASURES

Models	**Accuracy (%)**	**Precision (%)**	**F1-Score**	**AUC-ROC Score**
SVM	99.9	97.1	0.97	0.97
Random Forest	99.7	93.0	0.93	0.99
Decision Tree	99.7	88.7	0.88	0.94
Extra Tree	99.7	93.3	0.93	0.98
MLP	99.7	79.1	0.77	0.98
XGBoost	99.8	93.6	0.92	0.99

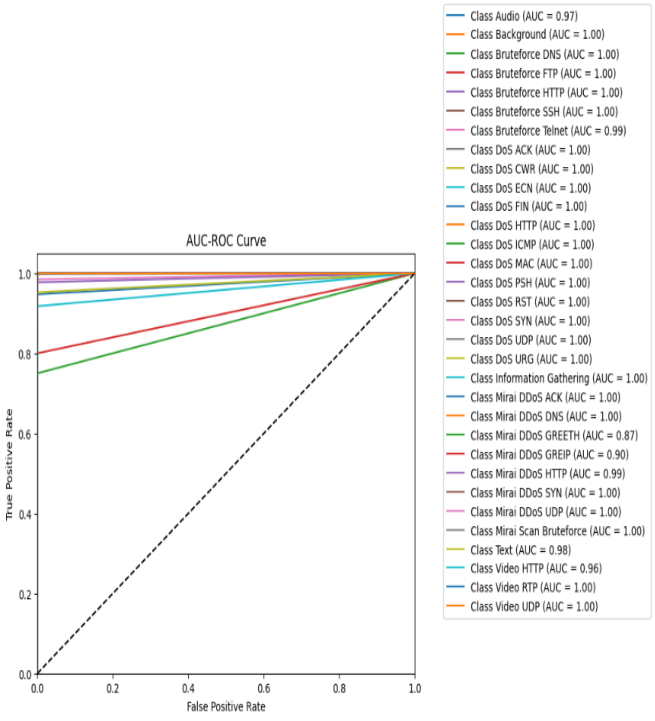

Fig 4: AUC-ROC Curve for Random Forest

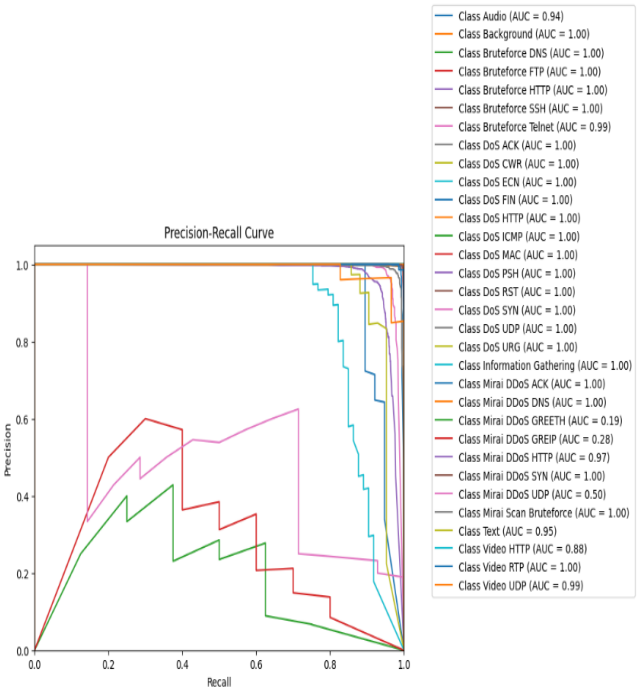

Fig 5: Precision-Recall Curve for Random Forest

The hardware requirements for executing these models are Google Collab Pro with a K80 GPU, 2 x vCPU CPU, 32GB RAM, and a Tesla T4. This approach ensures that the models are processed efficiently and accurately. These specifications are ideal for running such large datasets without encountering any software issues.

V. RESULTS AND DISCUSSION

Using the TII-SSRC-23 dataset, the study compares the effectiveness of six machine learning models in categorizing network traffic as benign or malicious. Random Forest, Decision Tree, Extra Tree, Multilayer Perceptron (MLP), XGBoost, and Support Vector Machine (SVM) were the models tested. The evaluation measures include accuracy, precision, F1-score, and AUC-ROC score, and the analysis provides insight into the performance of each model. The findings show that all models were highly accurate, with the following values:

a) Random Forest: 99.7%
b) Decision Tree: 99.7%
c) Extra Tree: 99.7%
d) MLP: 99.7%
e) XGBoost: 99.8%
f) Support Vector Machine (SVM): 99.9%

As a result, it was determined that the Support Vector Machine had the highest accuracy at 99.9%. Precision, which assesses the true positive rate among anticipated positives, shows that the Support Vector Machine had 97.1%. The F1-score, which balances precision and recall, ranks Support Vector Machine and Random Forest as the top performers,

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:36:59 UTC from IEEE Xplore. Restrictions apply.

with 0.97 and 0.93, respectively. The AUC-ROC score, which measures the classifier's ability to distinguish between benign and malicious networks, identifies Random Forest and XGBoost as the most robust models, with both earning 0.99. As a result, since Random Forest and XGBoost have the largest AUC-ROC curves, they are both the most effective classifiers for determining whether a network is benign or malevolent. By further comparing results it can be concluded that Random Forst is slightly better than XGBoost as it has a higher F1-score. The Precision-Recall curve, fig 5, and AUC-ROC curve, fig4, for Random Forest illustrate the model's excellent performance in distinguishing between benign and malicious instances. Along with the accuracy it is also important to calculate the classification error which is defined as the compliment of accuracy. The classification error is calculated by subtracting accuracy from 100%. Here, random forest has the accuracy which is 99.7%. Hence its classification error would be 100-99.7=0.3%. SVM has the least classification error with only 0.1%.

The experimental analysis suggests that Random Forest and XGBoost are highly effective in classifying network traffic as benign or malicious based on the TII-SSRC-23 dataset. These models demonstrate robustness in accuracy, precision, and overall performance. However, the paper also acknowledges the potential of neural networks and suggests future work that explores the use of the latest classifiers and hybrid approaches for improved network categorization. The focus on recognizing specific cyberattack types and identifying harmful behavior in incoming network traffic indicates a forward-looking approach to enhancing cybersecurity measures. Overall, the study contributes valuable insights into the application of machine learning models for network security in the evolving landscape of cyber threats.

VI. Conclusion and Future Work

The research has applied six different supervised machine learning models to binary classify the incoming network dataset as either benign or malicious on the publicly available dataset of TI-SSRC-23. All these models were trained on the same dataset by which their accuracy, precision, F1-score, and AUC-ROC scores have been evaluated and analysed. The experimental analysis for classifying the network as benign or malicious showed that the highest F1-score metric among all the algorithms was for support vector machine with 0.97. But when compared with AUC-ROC score, Random Forest and XGBoost had the highest score above all other algorithms with 0.99. Overall, on average all performance matrices, Random Forest showed the best results for predicting the outcome therefore the model loss curve and training curve was plotted.

Since this research used the state-of-art machine learning models, for future work it would be more efficient to use neural network and latest classifiers to predict the network traffics. Not only is it important to identify dangerous networks, but it's also critical to identify the harmful behaviour of the incoming network traffic in order to deliver the exact countermeasure in the shortest amount of time. Future research will take into account creating a system that can recognize and identify the kind of cyberattack that a person could experience. Secondly, employing hybrid approaches provides an additional avenue for improving network categorization.

ABSTRACT

Recent developments in flexible memories, neuromorphic computing, and other fields have generated a lot of interest in memristive devices based on two-dimensional materials. Due to its capacity for data storage and quick working speed, two-terminal non-volatile memory devices are more efficient and incredible. The need for memory that is flexible, low-powered, and ultra-thin is rising as a result of the rapidly developing fields of healthcare, wearable electronics, and the Internet of Things. The current study observes the effects of pure hexagonal boron nitride (hBN) inclusion on the resistive switching properties of tin oxide (SnO_2)-based flexible resistive memory device, which was synthesized by a straightforward hydrothermal method. The synthesized nanocomposite powders were characterized by X-ray diffraction and Raman spectroscopic methods. A pure SnO_2 and SnO_2-hBN (5, 7, and 10 wt.%) nanocomposite film was spin-coated on an ITO-PET flexible substrate to create the memory device. To finish the memory device, thermal evaporation was used to create Al top electrodes with a thickness of less than 100 nm. After comparing the resistive switching performance of the created devices, it was found that the memory device using 7% hBN in SnO_2 had a higher I_{ON}/I_{OFF} ratio of 1000, whereas the samples including 5 and 10 wt.% hBN had ratios of 96 and 10, respectively. In addition, the retention and endurance behaviour of the fabricated 7%SnO_2-hBN composite film-based device was studied for up to 1.5×10^4 and 100 cycles, respectively, with no degradation in the memory window. It has been noted that the current metal oxide–2D hybrid nanocomposite is a promising option for low-power, flexible, and enduring non-volatile memory applications.

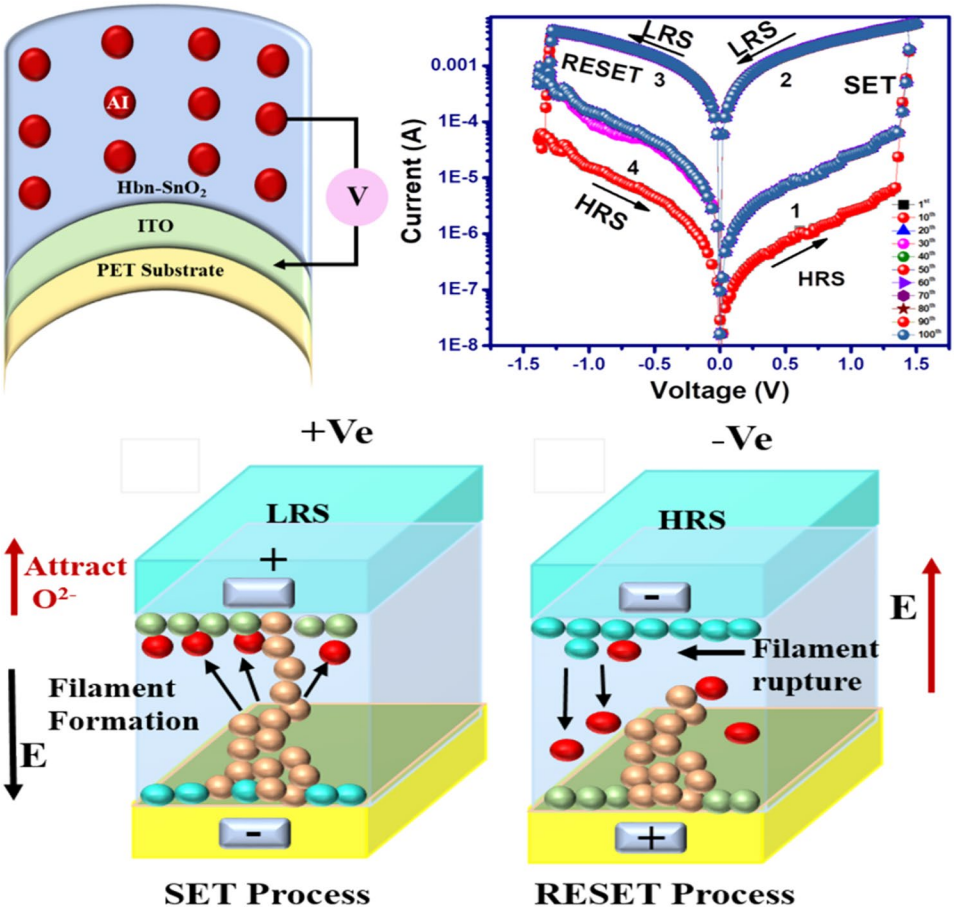
GRAPHICAL ABSTRACT



Introduction

To address the issue of huge information storage and memory scalability, both the industrial and academic groups are working to develop innovative non-volatile memory technologies to replace the current flash memory [1]. The fact, that flexible devices can be bent, stretched, and used in wearable electronics, has undoubtedly drawn a lot of interest in these gadgets [2]. Recently, there has been a growth in the requirement for flexible, wearable, foldable, lightweight, and transparent electronic devices in many aspects of modern life. Intelligent devices are gaining popularity as a result of the introduction of 5G communication networks, and nonlinear electric transport materials are now seen as a significant boost for smart devices [3]. Examples of these devices include mobile phones, radio frequency identification tags, sensors, displays, and watches. The essential component of intelligent flexible electronics is the data processing and storage systems. In order to address the demands of wearable gadgets, researchers are dedicated to creating flexible mersistors [4]. An increasing number of people are becoming interested in novel non-volatile memory devices with bright futures, such as resistive random access memory (RRAM), ferroelectric random access memory (FeRAM), magnetoresistive random access memory (MRAM), and phase-change random access memory (PCRAM) [5]. Recent research has focused more and more on RRAM due to its higher memory performance, and it is expected to be one of the most promising options for next-generation memory. However, the small memory window, precise material and structure, and other reasons limit MRAM. Because of this, there are still several problems in the way of applying the three previously mentioned types of memories in large-scale memory [6]. The

RRAM device, which can be reduced down to less than 10 nm and provides high write/erase speed, high durability, and low-power consumption, has drawn great interest and has the potential to substitute charge-based memory devices [7]. A wide range of materials showing resistive switching behaviours, including metal oxides, organic polymers, amino acids, chalcogenides, and 2D nanotechnologies, have been studied as potential candidates for memory devices [8]. Hickmott originally reported the resistive switching phenomenon in 1962. This was confirmed when Hickmott found the hysteretic current–voltage (I–V) property in a metal–insulator–metal (MIM) structure [1]. Thus, the 1970s and 1980s marked the beginning of a period of intense research into the resistive switching phenomenon. Early studies primarily addressed and elucidated the physical mechanism of electrically stimulated resistive switching. The second resistive switching research surge began in the late 1990s when scientists realized that resistive switching behaviour has the potential to be used as an ultimate NVM as microelectronics processing technology developed [9]. Metal–insulator–metal (MIM) capacitor structures are a usual form of resistive switching (RS) device. By putting a device under electrical stress, it is possible to switch its resistance state from high resistance (HRS) to low resistance (LRS). This RS behaviour is caused by the assembly of metal ions moving away from a working metal electrode or donor-type point defects, which results in the creation and destruction of conducting filaments (CFs) in the dielectric [10]. To create a high-performance RRAM device, the RS phenomenon has been investigated in several material categories. The main contributors include low-dimensional materials such as graphene oxide (GO), molybdenum disulphide (MoS_2), reduced GO, tungsten disulphide, and hexagonal boron nitride; polymer dielectrics such as poly(4-vinylphenol) (PVP), polyvinyl carbazole, polymethyl methacrylate, and polyvinyl alcohol; and metal oxides such as HfOx, TiOx, AlOx, TaOx, and ZnO; these materials are among the main contributors [11]. In recent times, hybrid RRAMs have gained significant attention, mainly due to their reliable and low-power switching operations [12]. The term hybrid RRAM is attributed to the nonconventional multilayer structure of the device with either organic polymer composites or metal oxide or both, where the metal oxide layer enhances the memory window, and the polymer composite contributes towards improved reliability [13]. However, these devices high ON-current remains an important problem that needs to be fixed to increase their power efficiency.

In recent times, two-dimensional (2D) materials have gained tremendous attention and growth owing to their excellent performance in applications not limited to field effect transistors, sensors, photodetectors, non-volatile memories, and solar cells [14]. Hexagonal boron nitride (hBN) is an intriguing ultra-wide bandgap insulating material with a crystal structure resembling graphite [15], where boron and nitrogen atoms alternately replace the sp^2-hybridized carbon atoms. Because of its graphite-like structure, hBN has great chemical and thermal stability and strong thermal conductivity, making it a viable choice for oxidation resistance and heat spreading [16]. Additionally, hBN provides a notable improvement in the confinement effects of chemical and physical characteristics, as well as a high number of active sites. Very few studies have been reported on hexagonal boron nitride (hBN), despite most of the studies on the resistive switching effect in 2D materials primarily focuses on graphene and molybdenum disulphide (MoS_2). Flexible resistive switching applications for hBN and its nanocomposites still have a lot of unexplored potential. These hybrid nanocomposites are expected to have a configurable bandgap, a high level of flexibility, and a combination of unusual electrical and mechanical properties as a result more research is required to extract more insightful conclusions [17]. Additionally, Table 1 compares the findings from our study with those from other published research.

SnO_2 was chosen as a switching material because it is an n-type semiconductor that is conducted by oxygen vacancies and was reported to have high thermal stability [26]. In the literature, SnO_2-based sensors have demonstrated good endurance. Because the Frenkel defect energy (7 eV) is substantially greater than the bandgap (3.6 eV), SnO_2 is resistant to displacement damage. Because of these features, SnO_2 is an excellent contender for resistive memory applications in radiation-hard situations. However, further research is required to completely comprehend the MIM devices filament and current mechanisms and to increase its reliability. For this reason, SnO_2 has received limited attention even though it has shown promising properties for resistive switching [27]. SnO_2 is an n-type broadband semiconductor in its purest form, and the electrical conductivity of

this material is caused by structural flaws or, more specifically, departures from stoichiometry in the lattice. It has been demonstrated that oxygen vacancies in the SnO_2 lattice are the predominant structural flaws in pure SnO_2 thin films, suggesting that tin atoms across the lattice may exist on a microscopic level as well. The electrically conductive properties of transparent SnO_2 semiconductors thin layers can be increased by adding donor impurities. In thin layers of SnO_2, the amount of free electrons is decreased upon the addition of impurities with a valence of less than four, such as zinc (Zn), which lowers the thin film's electrical conductivity. However, the converse happens when impurities like Sb, which have a valence of more than four, are added; as a result, thin films conduct electricity more readily. Antimony (Sb) and fluorine (F) are common contaminants for SnO_2 thin films. The thin coating's electrical conductivity becomes more thermally stable when Sb is added to SnO_2. Also, the electrical conductivity of transparent SnO_2 semiconductor thin films can be tailored by adding hexagonal boron nitride (hBN) in its matrix [28].

In the current study, pure SnO_2 and SnO_2-hBN with the different wt.% of hBN nanocomposite powder was made using the simple hydrothermal process [22] and was used further for spin coating the active memory layer in MIM configuration. The resistive switching performance of devices based on Al/SnO_2/ITO-PET and Al/SnO_2-hBN/ITO-PET was observed in relation to hysteresis loop, durability, and retention tests. The logarithmic plot of I–V characteristics allowed for a comprehensive analysis of the electrical charge transport mechanism responsible for the resistive switching behaviour. The ability to get constant resistive switching outcomes even after bending down 100 times was used to illustrate the flexibility of the ReRAM devices that were created.

Experimental

Substances

The ingredients used to make tin (IV) chloride pentahydrate ($SnCl_4.5H_2O$) are as follows: 98% of the boron nitride powder (BN) comes from Sigma-Aldrich. Sodium hydroxide (NaOH, 98%), ethanol (C_2H_5OH, 99.9%), isopropanol (C_3H_7OH, IPA), and hydrazine hydrate ($N_2H_4H_2O$, > 99%) are purchased from Fisher Scientific. Since the compounds were in analytic purity, no more purification was necessary.

Synthesis of hBN flakes

A simple in situ hydrothermal process has been used to produce hexagonal boron nitride nanosheets. The dispersion is typically made by mixing 50 ml of isopropyl alcohol (C_3H_7OH) and 10 ml of hydrazine hydrate ($N_2H_4.H_2O$) with 0.75 g of bulk hBN powder. Add 50 ml of deionized (DI) water to this dispersion and mix for 2 h. The final step is to transfer the resulting dispersion into a 100-ml Teflon-lined stainless steel autoclave vessel and seal it. An oven with a high temperature is used to keep the autoclave at 220 °C for 20 h. The bulk BN powder nanosheets were exfoliated in a stainless steel autoclave. Ultimately, the finished product was dried for 12 h at 90 °C after being repeatedly cleaned with DI water. The white powder in Eppendorf is gathered and kept until it is required at room temperature (RT-25 °C).

hBN-SnO_2 nanocomposite synthesis

To synthesize 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposites, firstly, synthesized hBN (200 mg, 280 mg, and 400 mg) was dissolved in 4 ml of DI water, then ultrasonically sonicated for 30 min. Furthermore, $SnCl_4{\cdot}5H_2O$ (1.76 g) and NaOH (2 g) were dissolved in a mixture of ethylene glycol (12 ml) added into 88 ml DI water and magnetically stirred for 1 h to get a homogeneous solution [29]. The SnO_2 solution was then added to the hBN resolution after 1 h of stirring and stirred for 30 min. After the suspension was prepared, it was placed inside a 100-mL Teflon-lined stainless steel autoclave and heated to 180 °C for 18 h. Both ethanol and DI water were used for three centrifugations of the material. The leftovers were dried for 5 h at 50 °C in a vacuum oven [30]. The two-step hydrothermal process for making SnO_2-hBN nanocomposite is depicted in Fig. 1.

Fabrication of films

On top of ITO-PET substrates, a thin layer of SnO_2-hBN nanocomposite was placed. First, a normal wet cleaning process was used to clean the ITO-PET substrates. After washing, the materials were dried by heating them to 100 °C for 20 min. The solution was created by ultrasonically mixing 100 mg of SnO_2-hBN powder with 3 ml of ethanol solution for 45 min, then applying the mixture to the ITO-PET substrate (2 cm × 1 cm) and spinning it for 60 s at 2000 rpm. The sample covered in coatings was placed on a heated plate for 10 min at 100 °C. After seven cycles of spin coating, a homogeneous layer of SnO_2-hBN was formed. Finally, the top aluminium electrodes were deposited through the shadow mask using the thermal evaporation process under vacuum conditions of 10^{-5} bar [20]. The fabrication process of the Al/SnO_2-hBN/ITO-PET-based MIM device is schematically shown in Fig. 1 [31].

Materials characterization techniques

First, made-up samples are examined with the WiTec alpha 300RA Raman Spectrometer, which uses a laser source with a wavelength of 530 nm. An X-ray diffractometer (Bruker D8 Advance) and a Cu Kα source (λ = 1.54 Å) were used to study the structural phase of hBN, SnO_2, and SnO_2-hBN (5%, 7%, and 10%) materials. The hBN, SnO_2, and SnO_2-hBN nanocomposite materials surface morphologies were investigated using electron microscopy (FESEM; ZEISS). Using a monochromatic Al Kα source and a Perkin Elmer ultra-high vacuum XPS machine (Model 1257 PHI), the interfacial analysis of hBN, SnO_2, and SnO_2-hBN nanocomposite structures was achieved. The thin layer of synthesized SnO_2-hBN nanocomposite film is deposited using the spin coating process. Aluminium electrodes less than 100 nm were made for memory devices using the thermal evaporation technique. After that, I–V measurements were performed on the created thin-film memory cells (Al/SnO_2/ITO, Al/hBN-SnO_2/ITO) using a Keithley Source Metre 2450. First,

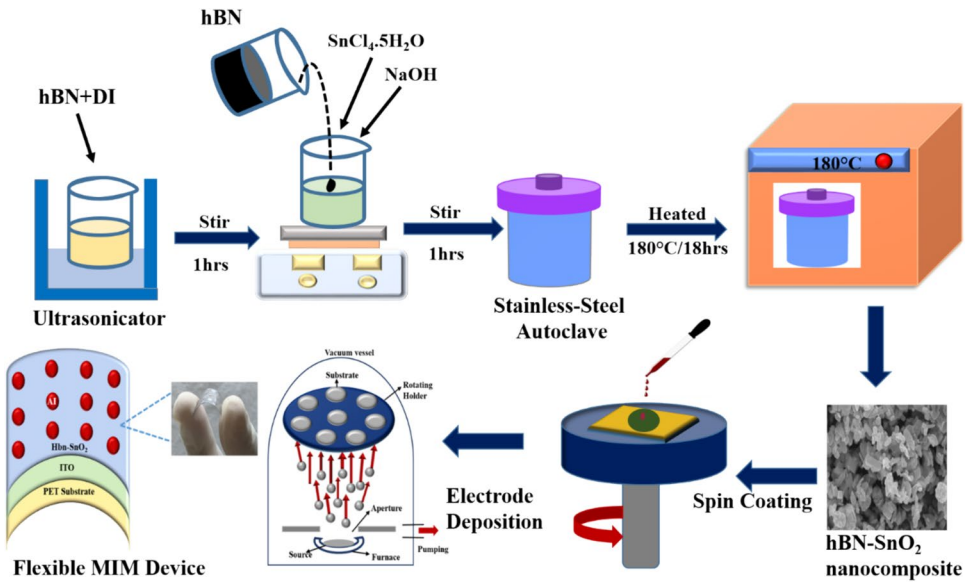

Figure 1 A visual representation showing the synthesis of hBN-SnO_2 (5%, 7%, and 10%) nanocomposite powder using the hydrothermal method and the pictorial presentation of steps involved in the fabrication of resistive memory devices.

we tested the dielectric using the capacitance method on a sample that had been heated to 260 °C for 2 h and covered with silver paste on both sides. With an Agilent LCR metre (Model E4980A), the frequency (20–10^6 Hz) and loss tangent ($D = \tan\delta$) measurements were compared to one another.

Results and discussion

X-ray diffraction

The XRD technique was used to examine the crystal structure of synthesized pure hBN, pure SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposite powder. As illustrated in Fig. 2a, XRD spectra verify that hBN and SnO_2 exist in the SnO_2-hBN nanocomposite. The existence of tetragonal rutile structure in pure SnO_2 is confirmed by its XRD spectra, which show peaks at 26°, 34°, 52°, and 65°, corresponding to the (110), (101), (211), and (202) planes. Similar to this, the as-synthesized hBN samples peaks are indexed at 26.86°, 41.8°, 44.01°, 50.5°, 55.34°, and 76.1°, which correspond to the hexagonal boron nitride (002), (100), (101), (102), (004), and (110) distinctive hkl planes. The XRD data showed the development of a pure hexagonal phase of BN with good crystallinity, with no extra impurity peaks detected. In comparison with the diffraction planes (100), (101), (102), (004), and (110), the intensity of the peak connected to the (002) diffraction plane shown in Fig. 2a is significantly higher. This suggests that the hBN (002) crystal plane is more exposed. The tetragonal rutile phase of SnO_2 is further confirmed for the SnO_2-hBN nanocomposite, which displays peaks at 26°, 34°, 52°, and 65° that are related to the (110), (101), (211), and (202) planes.

Because hBN has a low crystallinity, the peaks of pristine hBN are not visible in the SnO_2-hBN nanocomposite. The pristine SnO_2 diffraction peak, which corresponds to the (110) plane, dominates the hBN peak in the composite sample, which is visible at 26° (002). It could be explained by the SnO_2-hBN samples transformation of Sn^{4+} into SnO_2 nanoparticles [32]. The addition of hBN was found to cause the SnO_2 diffraction peaks to expand. As crystallinity depends on crystallite size, the crystallite size was calculated by using the Scherrer formula for pure hBN, pure SnO_2, and SnO_2-hBN nanocomposite [20, 33];

$$D = k\lambda/(\beta\cos\theta) \quad (1)$$

where λ denotes the wavelength of X-ray, β denotes the broadening of the diffraction peak measured at half maximum intensity (FWHM), θ denotes the angle corresponding to peak position, crystallite size is D, and k denotes the shape factor ($k = 0.94$).

The average crystal size determined for pure SnO_2, pure hBN, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposites are calculated to be 13.2 nm, 19.5 nm, 26.1 nm, 20.8 nm, and 20.7 nm, respectively. It has been observed that the average crystallite size of SnO_2-hBN nanocomposite decreases owing to the growth and nucleation of SnO_2 crystals, which was hindered by hBN [34, 35].

Raman characterization

As Raman scattering is an effective process for examining the structure of hBN-based substances, it was used to investigate the SnO_2-hBN nanocomposite structure in more detail. Figure 2b displays the Raman spectra of SnO_2-hBN nanocomposites and SnO_2 nanoparticles at different hBN concentrations. The Raman peak of SnO_2 nanoparticles at the peak position of 630 cm^{-1} corresponds to the A_{1g} vibration mode [36], whereas, for the bulk hBN, the characteristics peak is observed at 1363 cm^{-1}, corresponding to in-plane vibrational mode (E_{2g}), respectively [15, 17]. Raman spectra for SnO_2-hBN nanocomposite powder reveal distinct peaks at different hBN concentrations (5, 7, and 10%). For the 5%SnO_2-hBN nanocomposite sample, the Raman spectrum is a simple superposition of the single vibration modes of hBN and SnO_2, which is consistent with the literature [37]. Peak positions remain unchanged, but the hBN vibration modes E_{2g} and A_{1g} have significantly lower peak intensities. As the hBN content increases, the peak intensity of the SnO_2 A_{1g} mode decreases, signifying the successful creation of the nanocomposite material with a variable hBN content.

FTIR spectra

The chemical interactions and advantageous groups present in a substance can be further investigated using the FTIR method. Since it shows the composition of the material, knowing which functional groups are adsorbed at certain occurrences under the transmission method is very useful. Band locations and the number of absorption peaks are determined by morphology, chemical composition, and crystalline structure [38]. The surface of nanoscale materials is extremely sensitive and easily altered. An FTIR study at room temperature was performed to examine the compound structures on the outer layer of the materials over a wavenumber between 400 and 4000 cm^{-1}. Figure 2c displays the FTIR spectra of pure hBN, pure SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposites. Pure hBN exhibits two strong peaks in its FTIR spectra at 790 and 1378 cm^{-1}, respectively. The broad B-N stretching was observed, including in-plane stretching vibration (B-N, 1378 cm^{-1}) and the out-of-plane bending mode (B-N, 809 cm^{-1}), as shown in Fig. 2c [39]. The band exhibited in the low wavenumber region 610 cm^{-1} is attributed to the Sn–O stretching vibration [38, 40]. Characteristic peaks of SnO_2-hBN occurred at 1378 cm^{-1}, 709 cm^{-1} (B-N stretching vibration), and 610 cm^{-1} (Sn–O vibration); furthermore, the peak positions do not change; however, the peak intensities of the hBN vibration modes B-N are dramatically reduced and also the peaks are broadened. With the increase in hBN content, the peak intensity for the Sn–O mode of SnO_2 decreases, indicating the successful fabrication of the nanocomposite substance with variable hBN content [41].

Ultraviolet–visible spectroscopy

In Fig. 3, using the diffused UV–Vis reflection spectrum, the optical characteristics of the hBN, SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposites powder have been evaluated. With the exception of a small amount of absorption in the visible range (200–800 nm), SnO_2 mostly absorbs ultraviolet light. UV–visible spectra have been used to quantify a move in the bandgap energy of materials evenly

dispersed in ethanol–water. Boron nitride is a material having a high direct bandgap ($n = 2$) and the capacity to transition. Bulk hBN has the lowest value of E_g whereas h-BNNS holds the highest value of E_g [42]. A wider bandgap emphasizes quantum confinement in the substance and results in smaller crystallite sizes. The synthesized samples bandgap was also analysed using Tauc's figure;

$$(\alpha h\nu) = A(h - Eg)^{1/2} \quad (2)$$

In this equation, E_g is the bandgap, α is the absorption coefficient, A is a constant, and E is the photon energy obtained from $E = h\nu$, where h is Planck's constant, and ν is the UV–visible spectrum occurrence. Plotting $(\alpha h\nu)^2$ against $h\nu$ allowed for the calculation of the optical bandgap for pure hBN, pure SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposites. The calculated bandgap energies for pure SnO_2, hBN, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN were found to be 4.8 eV, 3.65 eV, 2.82 eV, 2.72 eV, and 2.69 eV. Once hBN is added to the SnO_2 nanoparticles, the bandgap value in the SnO_2-hBN nanocomposites drops, and the hump in the absorption spectrum keeps moving downward in wavelength.

Field emission scanning electron microscope

Figure 4 depicts the morphology of pure hBN, pure SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposite. It is feasible to verify that the morphology of the nanoflakes produced during the hydrothermal exfoliation of hBN was successfully synthesized using field emission scanning electron microscopy (FESEM). Figure 4a displaying FESEM image of hBN which is synthesized at reaction temperature 220 °C for 18 h displays large lateral size nanoflakes [43, 44]. Furthermore, aggregated hBN sheets are displayed at random. The FESEM picture of nanocrystalline SnO_2 is shown in Fig. 4b. It demonstrates the homogeneous and uniform dispersion of SnO_2 nanocrystallites [45]. Moreover, the FESEM image of the SnO_2-hBN (5%, 7%, and 10%) nanocomposite, as displayed in Fig. 4c–e, specifies that SnO_2 nanoparticles adhere consistently to the surface of hBN sheets. It indicates that hydrothermal treatment of hBN and $SnCl_4$ solution is a successful approach for the synthesis of the SnO_2-hBN nanocomposite [37]. The combination of SnO_2 with hBN nanocomposite demonstrates irregular shape particles combined with lateral size nanoflakes that could be favourable for electron transfer properties [43]. Energy-dispersive X-ray spectra, or EDX, are among the best methods available for determining sample purity. The SnO_2-hBN (5, 7, and 10%) nanocomposite is depicted in Fig. 5 and contains elements such as tin (Sn), oxygen (O), boron (B), and nitrogen (N), verified.

X-ray photoelectron spectroscopy

Furthermore, X-ray photoelectron spectroscopy (XPS) is employed to analyse the element configuration of the synthesized hBN, SnO_2, and SnO_2-hBN nanocomposite powder. In the absence of any other impurity, the survey spectra in Fig. 6a support the existence of B, N, C, Sn, and O. The high-resolution core level spectra of Sn 3d, B1s, N1s, C1s, and O1s are given in Fig. 6b–e.

B spectra

Figure 6b shows the B1s core level spectra for pure hBN and SnO_2-hBN nanocomposite, where high-resolution B1s spectrum with the main peak located at 190.2 eV which corresponds to BN bonds and a smaller peak at 190.6 eV assigned to BO bonds [43]. In the case of SnO_2-hBN nanocomposite powder, the majority of the B signal comes from the peaks at around 190 and 190.3 eV, which correspond to BN and BO, respectively [46]. The shift towards the lower binding energy side corresponds to electronic interaction at the interface of hBN and SnO_2 [47].

N spectra

Figure 6c displays the N1s core level spectra of the hBN and SnO_2-hBN nanocomposite. It is also possible to fit the broad peak surrounding the nitrogen 1 s lines with two distinct peaks at 397.9 and 398.2 eV, which are in good contact with the B–N and N–C bonds. These results show good agreement with the previous studies, suggesting that hBN nanosheets fabricated by the hydrothermal method display functional groups on their surface [48]. The deconvolution of N1s

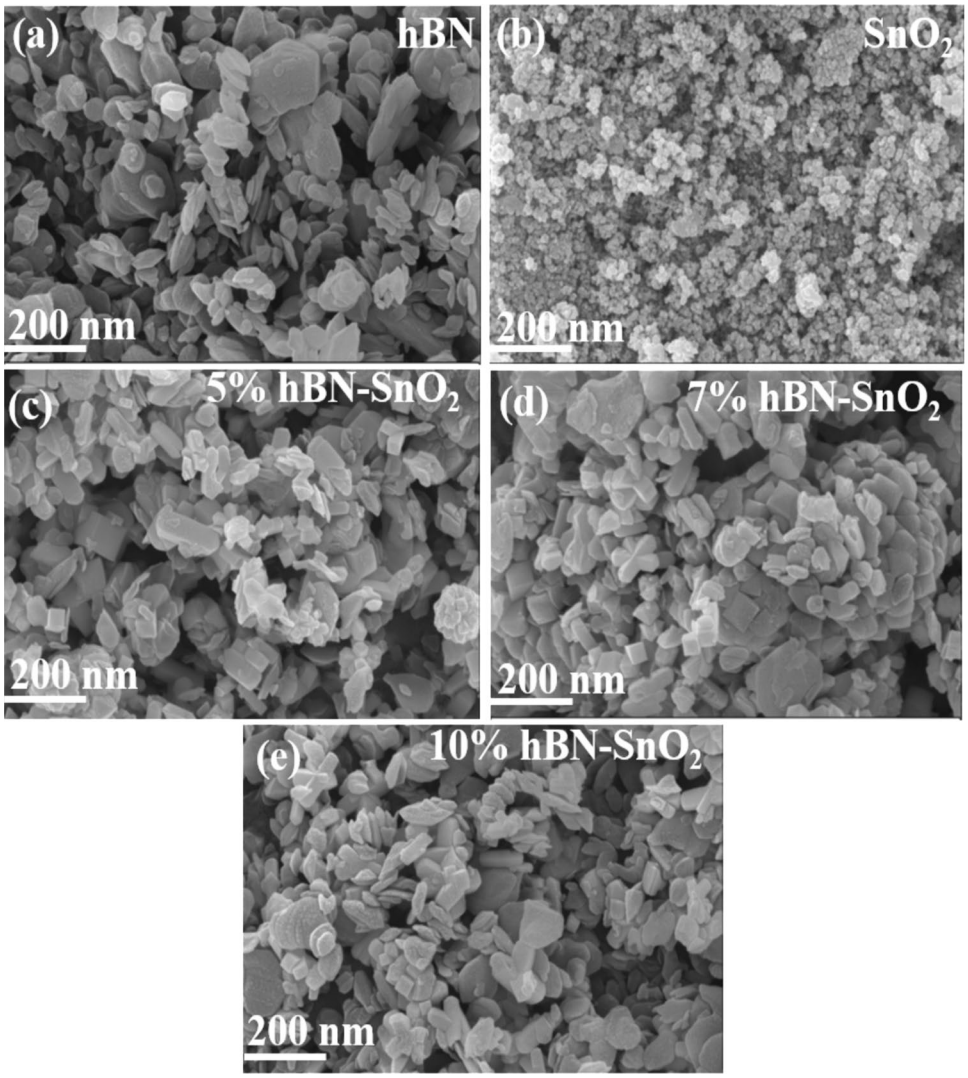

Figure 4 FESEM images of hBN, SnO_2, and hBN-SnO_2 nanocomposites with the different weight percentages of hBN: **a** hBN, **b** SnO_2, **c** 5%hBN-SnO_2, **d** 7%hBN-SnO_2, and **e** 10%hBN-SnO_2.

(SnO_2-hBN) spectra yielded two primary peaks at a binding energy of 397.6 and 397.8 eV (Fig. 6c). The peak located at 397.6 eV corresponds to the B–N bond of hBN whereas the peak located at lower energy (397.8 eV) can be attributed to the N–C bond, respectively [49].

Tin spectra

The Sn 3d positions of the SnO_2 and SnO_2-hBN compound samples are displayed in Fig. 6(d). In the case of pure SnO_2, two characteristic peaks of $Sn3d_{5/2}$ and $Sn3d_{3/2}$ are observed at 485.4 and 493.8 eV, respectively, which correspond to the typical oxidized form of Sn^{4+} [50, 51]. XPS peaks in the Sn 3d spectrum of the SnO_2-hBN nanocomposite show more substantial Sn $3d_{5/2}$ and Sn $3d_{3/2}$ peaks with binding energy changes of 1.3 eV, etc. These peaks are detected at 486.7 eV and 495.1 eV, respectively. The characteristic SnO_2 peaks are separated from one another by 8.4 eV, which is in line with the previous findings. The above-observed shift indicates that the SnO_2 nanoparticles are connected to the hBN nanosheets, and have also been confirmed in the literature [52]. A significant interfacial interaction between SnO_2 and hBN was required to improve resistive switching performance, as indicated by the formation of the Sn–O link between the two materials. As a result, the SnO_2-hBN and Sn 3d peaks have been moved to a higher binding energy position. Because SnO_2 has a smaller work function than hBN, the electrons in SnO_2-hBN hybrids can generally flow (SnO_2 to hBN) [20, 53]. Therefore, the hBN-SnO_2 Sn 3d peaks have been shifted to have a higher binding

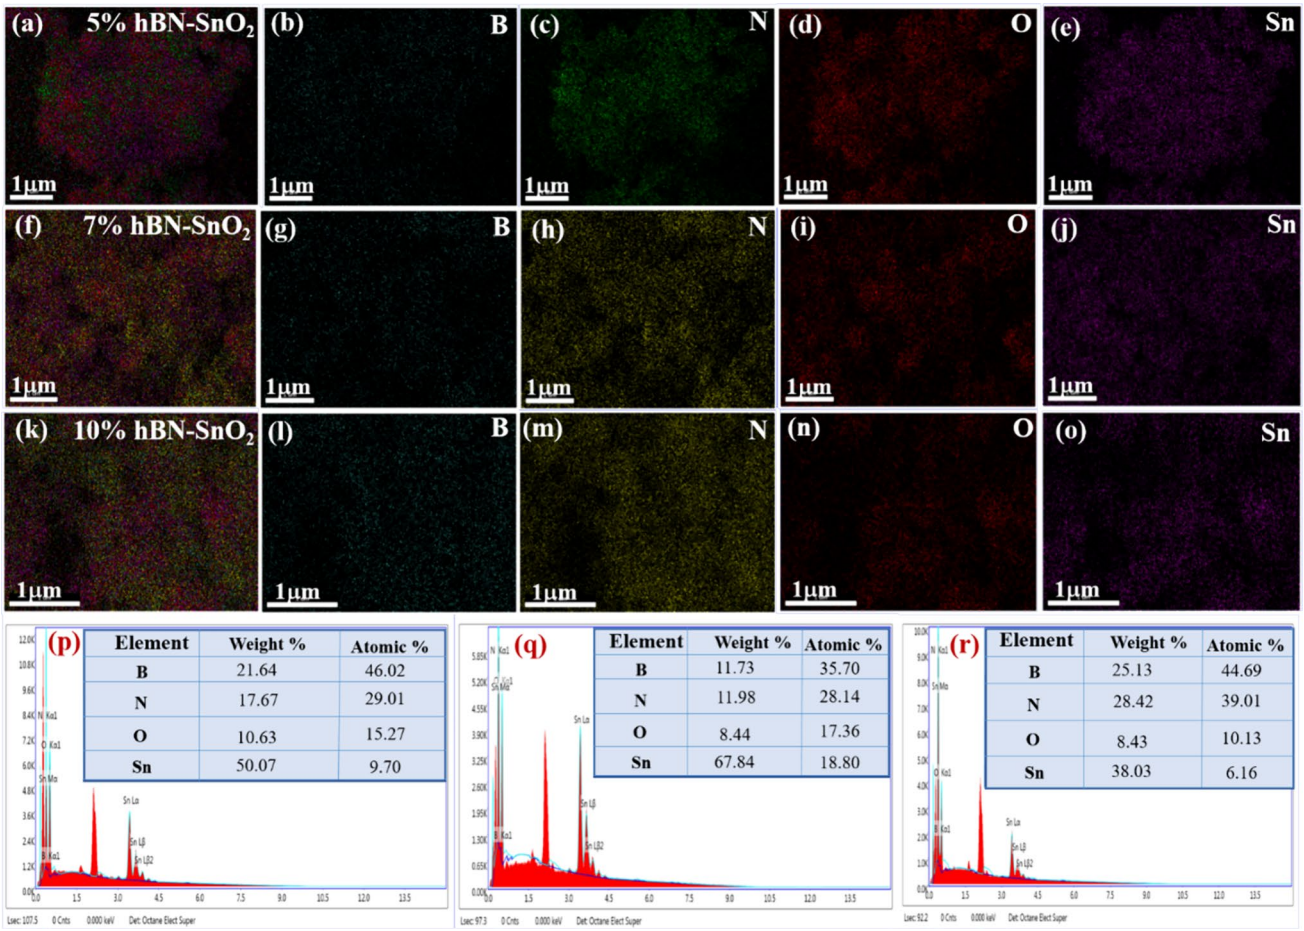

Figure 5 **a–o** Elemental mapping, **p–r** the synthesized EDX spectra of 5% hBN-SnO_2, 7% hBN-SnO_2, and 10% hBN-SnO_2 nanocomposites showing the purity of the synthesized powder.

energy. The electrostatic repulsive contact between O and a negative charge in the matrix allows Sn to generate more energy. The shift in the Sn electronic orbit will impact the binding energy of O1s [54]. Remarkably, when the SnO_2-hBN nanocomposite is synthesized, the associated peaks of B1s, N1s, and Sn 3d change positively, whilst the peaks of O1s move positively, indicating a significant interface among SnO_2 and hBN. The XPS results also show that ultrafine hBN flakes are agglomerated on the SnO_2 surfaces.

O1s spectra

The deconvoluted O1s core level spectra were found to consist of two peaks, as shown in Fig. 6e. Considering the information of lattice O, tetravalent Sn ions in the O vault are responsible for the peak for pure SnO_2 at the binding energy location of 530.3 eV. Another peak at 530.9 eV indicates that the surface is surrounded by hydroxide OH groups and corresponds to nonlattice oxygen [55]. Additionally, two peaks at 530.2 eV and 531.1 eV in the O1s spectra, corresponding to B–O and C–O bonds, are visible in the case of SnO_2-hBN, and they are displaced towards the lower binding energy side. BN from hBN and the oxygen species from SnO_2 likely interacted at the interface, as evidenced by the opposite direction shift in binding energy position for the O1s and BN peak [56].

Dielectric characteristics

Important details on the material relaxation method are revealed by the frequency dependence of the dielectric measurements. It gives details on the materials two primary physical properties, which are electric permittivity (sometimes referred to as the dielectric constant) and dielectric loss. A delay in polarity called

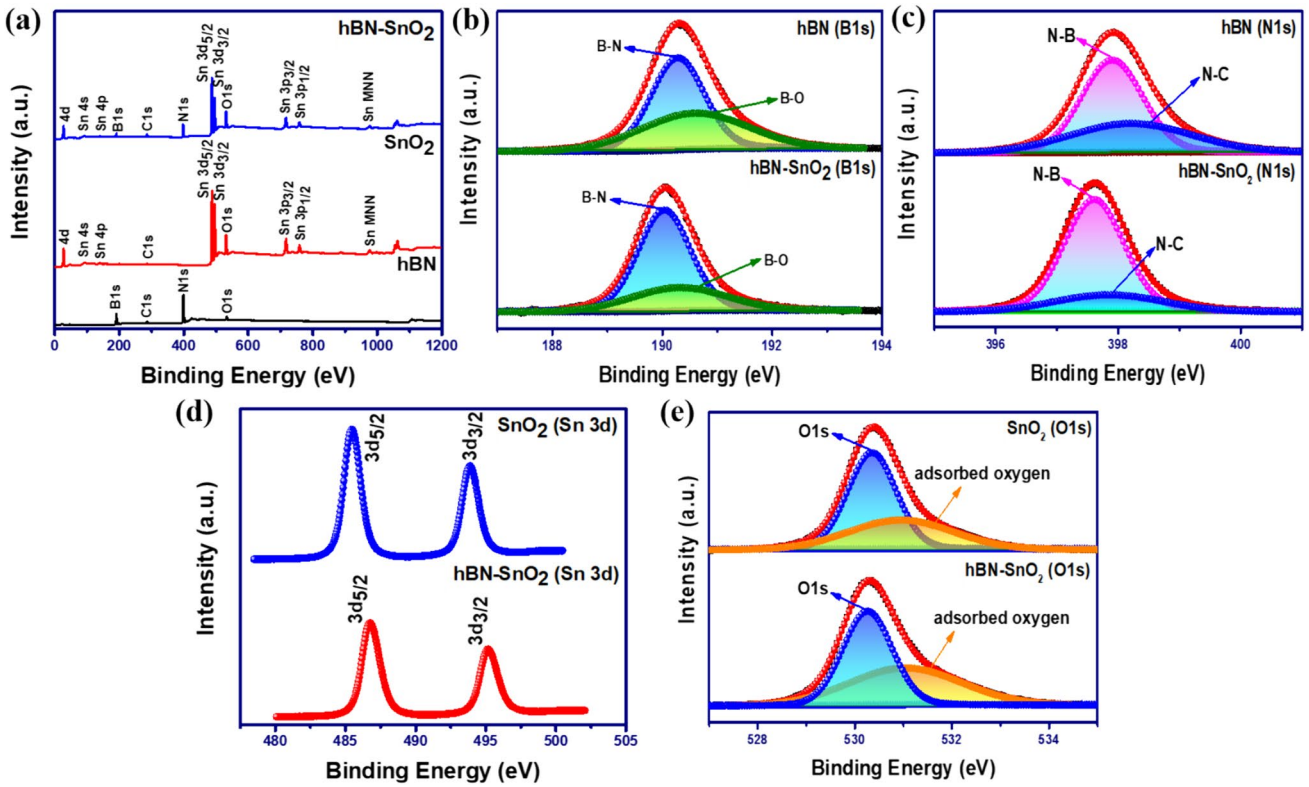

Figure 6 **a** An XPS survey scan of hBN-SnO_2 reveals the existence of elements such as B, N, Sn, and O, as well as increased resolution spectrums of **b** B1s, **c** N1s, **d** Sn 3d, and **e** O1s.

"dielectric loss" ($D = \tan\delta$) causes charge carriers to produce heat after a changing field is applied through the sample. The combined actions of electrical conduction and dielectric relaxation result in dielectric loss inside a material [57]. Figure 7a and b illustrates how the dielectric constant, also known as electric permittivity, varies with frequency in relation to its real ($\varepsilon' r$) and imaginary ($\varepsilon'' r$) components. Based on the Maxwell–Wagner model, it can be seen that $\varepsilon' r$ decreases with increasing frequency of applied field for all samples [58]. Space charge polarization enables nanodipoles that oscillate to facilitate easy orientation in the direction of the supplied electrical field; therefore, a high value of $\varepsilon' r$ is detected in the low-frequency zone [3]. Dipoles can travel to the grain boundaries at low frequencies, wherever charge carriers figure up and significantly polarize the material. The charge carriers are unable to keep up with the rapid changes in field direction that occurs at high frequencies. As a result, carriers are unable to reach the grain boundaries, and as a result, no polarizations occur [59]. Since composites have a larger surface area due to their small size (more grains), the dielectric constant in 7%SnO_2-hBN composite is higher than in 5%SnO_2-hBN, 10%SnO_2-hBN, pure SnO_2, and hBN [60]. In composites, more oxygen vacancies are formed, resulting in increased space charge polarization (SCP) and rotational direction polarization (RDP), which raises the dielectric constant. Furthermore, polarization occurs at the interface of SnO_2 and hBN, which contributes to the rise in the dielectric constant. This causes an increase in the dielectric constant value. Because hBN plays an important role in the alignment of the dipoles and facilitates the development of a microcapacitor within the composite. Furthermore, the hBN sheet has a very wide surface area, which causes a huge number of dipoles to form, improving charge generation and storage capability. As a result, the increase in dielectric constant seen following the addition of hBN could be attributed to the development of many micro-capacitors within the composite [61]. Furthermore, the presence of the interaction between SnO_2 and hBN, as well as the defects caused by the rearrangement of hBN sheets in the nanocomposite, generates free charge carriers in SnO_2-hBN, which accumulate at the interface and contribute to a strong interfacial polarization,

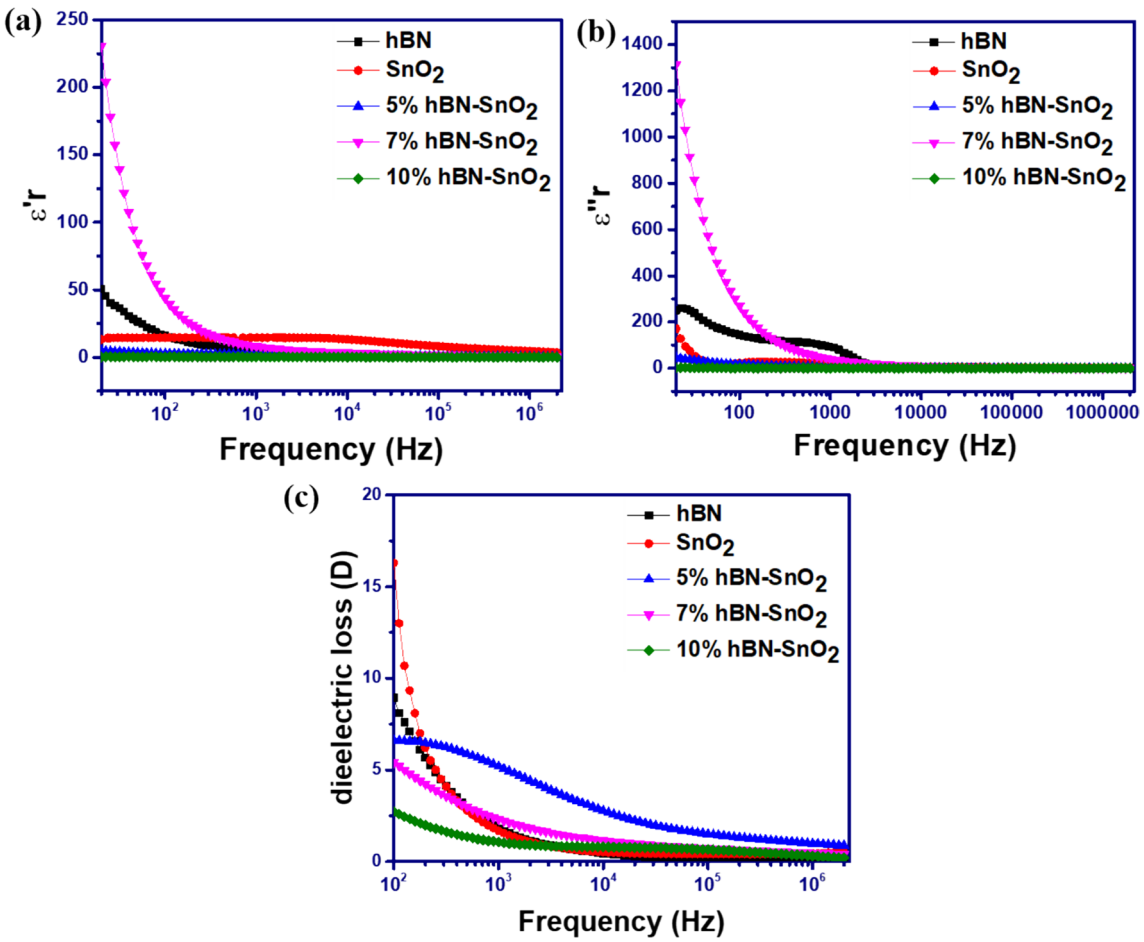

Figure 7 Dielectric constant variation **a** real and **b** imaginary parts, and dielectric loss (**c**) for pure hBN, SnO_2, 5% hBN-SnO_2, 7% hBN-SnO_2, and 10% hBN-SnO_2 nanocomposite as a function of the frequency.

resulting in an improvement in the composite's dielectric constant. It can also be shown from Fig. 7a and b that when hBN loading increases, the dielectric constant for SnO_2-hBN nanocomposite increases. However, once hBN loading reaches a threshold, the dielectric constant drops. Additionally, the highest dielectric constant is observed close to the percolation threshold, which is reached at the most efficient hBN adding in the SnO_2-hBN nanocomposite. In contrast, a tunnelling percolation method has been created within the material of the composite with higher hBN transferring beyond the percolation threshold, rendering the composites semiconductive [62]. Therefore, it is necessary to take into account charge injection at the contacts between metallic electrodes and composite materials. As a result, space charge polarization at the sample–electrode interfaces, together with interfacial polarization, reduces the dielectric constant.

A process called dielectric loss (tanδ) occurs in the dielectric system when energy is lost. Based on a frequency range of 20–10^6 Hz, Fig. 7c displays the dielectric loss for the room temperature nanocomposite of hBN, SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN. When the charge transporters in dielectric material fail to keep up with the changes in the electric field, dielectric loss occurs. For every sample, dielectric losses decrease as the applied field frequency increases. Due to domain wall inhibition-induced forced clockwise shift of magnetization, smaller electrical losses are observed at higher frequencies. At higher frequencies, lower values could indicate Maxwell–Wagner relaxation. As shown in Fig. 7c, lower frequencies cause the greatest dielectric loss. This is caused by space charge polarization, which can be explained by the Shockley–Read mechanism [63]. The variation of dielectric loss factor (tan δ) of pure hBN, 5%SnO_2-hBN, 7%SnO_2-hBN, and

10%SnO_2-hBN is discovered to be considerably lower than that of SnO_2. The dielectric constant (ε'') imaginary fraction denotes the quantity of energy dissipation, and tan δ is proportional to ε''. Figure 7c clearly shows that the SnO_2-hBN nanocomposite has low dielectric loss [58]. Furthermore, the decreased loss in the composite compared to SnO_2 could be attributable to significant interfacial polarization. In the case of SnO_2-hBN nanocomposite, the rise in dielectric loss may be due to the significant leakage current generated by the direct interaction between hBN sheets over the percolation threshold [59]. The high dielectric constant and low dielectric loss in the SnO_2-hBN sample may undoubtedly be attributed to the synergic impact of the hBN sheets and SnO_2 nanoparticle decoration in the composite. From Fig. 7c, it is observed that the dielectric loss tangent of SnO_2-hBN (5–10%) samples decreases from pure SnO_2 and pure hBN; thus, composites sample will be better in case of dielectric application [64, 65].

Impedance spectroscopy

To investigate numerous electrical properties, such as the impact of grain and grain borders on total impedance, relaxation time distribution, and the type of relaxation mechanism [57], the complicated behaviour of total impedance with frequency can be examined. Use the formula below to describe the whole composite impedance:

$$Z^* = Z' + jZ'' \tag{3}$$

wherever the real (Z′) and imaginary (Z′′) modules of the whole impedance are provided by Eq. 4.

$$Z'' = Z \times \sin\theta \quad \text{and} \quad Z' = Z \times \cos\theta \tag{4}$$

Here Z stands for the entire measured impedance or the observed phase angle (measured in radians). Figure 8a and b shows how the used field frequency

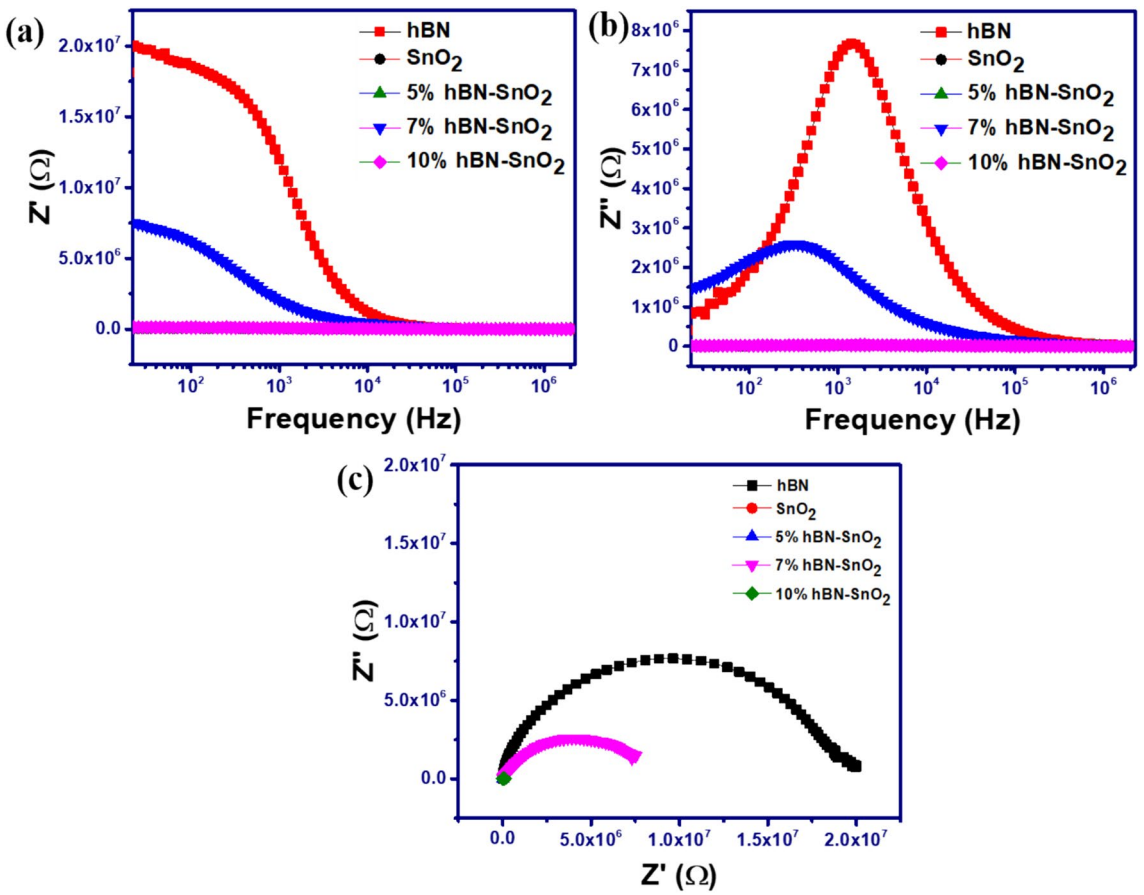

Figure 8 Impedance variation for the hBN, SnO_2, 5%hBN-SnO_2, 7%hBN-SnO_2, and 10%hBN-SnO_2 nanocomposite powder as a function of frequency (20–10^6 Hz) in both **a** real and **b** imaginary sections. **c** Nyquist plot of hBN, SnO_2, 5% hBN-SnO_2, 7% hBN-SnO_2, and 10% hBN-SnO_2 nanocomposite samples.

affects the fluctuation in the resistance or real part (Z') and the capacitance or imaginary part. Impedance levels at lower frequencies are considerable, but they get smaller as frequency rises. Because of increasing mobility and the dissipation of stationary charges, impedance has decreased as frequency has increased. At higher frequencies, there is a tendency for all the curves to merge due to a decrease in space charge and the cancellation of the dipole orientation effect [57]. Nyquist plots were used to separate the effects of grain boundaries at room temperature and grain temperature, as Fig. 8c illustrates. In materials used to create hBN, SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN nanocomposite, conductive grain boundaries are necessary at higher frequencies, whereas resistive grain boundaries are significant at lower frequencies. The semicircle shows exceptionally robust grain boundaries at low occurrences. Low resistance and high-frequency semicircles are produced by the conducting grains. In our situation, all of the samples display just one semicircle, which is caused by the contribution of the grain boundaries [64], as shown in Fig. 8c. Due to their higher resistance than the grain itself, grain boundaries are thought to play a significant role in impedance [66]. The SnO_2-hBN nanocomposite has less resistance than SnO_2 because of hBN strong conductivity.

AC conductivity

To better understand the conduction process, the frequencies-dependent AC electrical conductivity of hBN, SnO_2, 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN composites specimens was examined at ambient temperature in the occurrence range of 20–10^6 Hz. It has been noted that when the conductivity decreases with an increase in frequency, the free charge carriers make the majority contribution, whereas when the conductivity increases with frequency, the bound charge carriers make the majority contribution [67]. The carriers change from one faulty state to another as a result of the oscillating field over the sample. Figure 9a displays the calculated AC conductivity using the formula $\sigma(\omega) = \omega\varepsilon_0\varepsilon_0 \tan\delta$. It determines that conductivity rises with the occurrence, demonstrating the existence of bonded charge carriers and providing insight into the behaviour of considerable occurrence dependency. Carriers offer frequency-independent conductivity and can go farther since they can hop at lower frequencies for longer periods. Because carriers have shorter lifetimes, failure and successful processes conflict at higher frequencies. Higher frequency conductivity exhibits dispersion behaviour due to the ratio of failed to successful hops. Equation 5 is used to fit the frequency dependence of the AC conductivity data using Jonscher's power law [57].

$$\sigma_{ac}(\omega) = \sigma_{dc} + A\omega^s \tag{5}$$

where DC contribution is frequency-independent, s is a supporter describing the lattice–mobile ion interface based on the applied field occurrence, and A is the polarization strength. Moreover, $A\omega^s$ indicates the frequency-dependent contribution, whilst $\sigma_{ac}(\omega)$ reflects the overall observed conductivity. The shift between the frequency-independent and frequency-dependent regions demonstrates the transformation from long-range hopping across barriers to the short-range motion of carriers [57, 68]. An examination of AC conductivity reveals a sharp increase at higher frequencies, supporting Jonscher's power law and suggesting the potential of other conduction pathways. As shown in Fig. 9b–f, we estimate the AC conductivity values using Jonscher's power law. The fitting parameters derived from the data are presented in Table 2. Figure 9a shows that the addition of hBN to SnO_2 results in an increase in AC conductivity. Figure 9f shows that when the amount of hBN in SnO_2 increases, the AC conductivity decreases. Substituting hBN ions for SnO_2 ions hindered Verwey's hopping mechanism, resulting in reduced AC conductivity. Similar behaviour has already been observed by various researchers [69]. hBN ions at hexagonal boron and nitrogen sites serve a significant and dominant role in the conduction mechanism of 2D materials. SnO_2 with large ionic radii likes to be found on hexagonal sites. This reduces the quantity of hBN ions at the hexagonal boron and nitrogen sites, causing conductivity to drop [70].

I–V characteristics

The impact of hBN inclusion on SnO_2 electrical qualities is investigated using ambient temperature I–V characteristics measured with a Keithley 2450 Source Metre Unit. Figure 10 shows a diagram of the metal–insulator–metal (MIM) structure used to investigate I–V properties.

Figure 11a–d shows the I–V properties of Al/SnO_2/ITO-PET and Al/SnO_2-hBN/ITO-PET layers

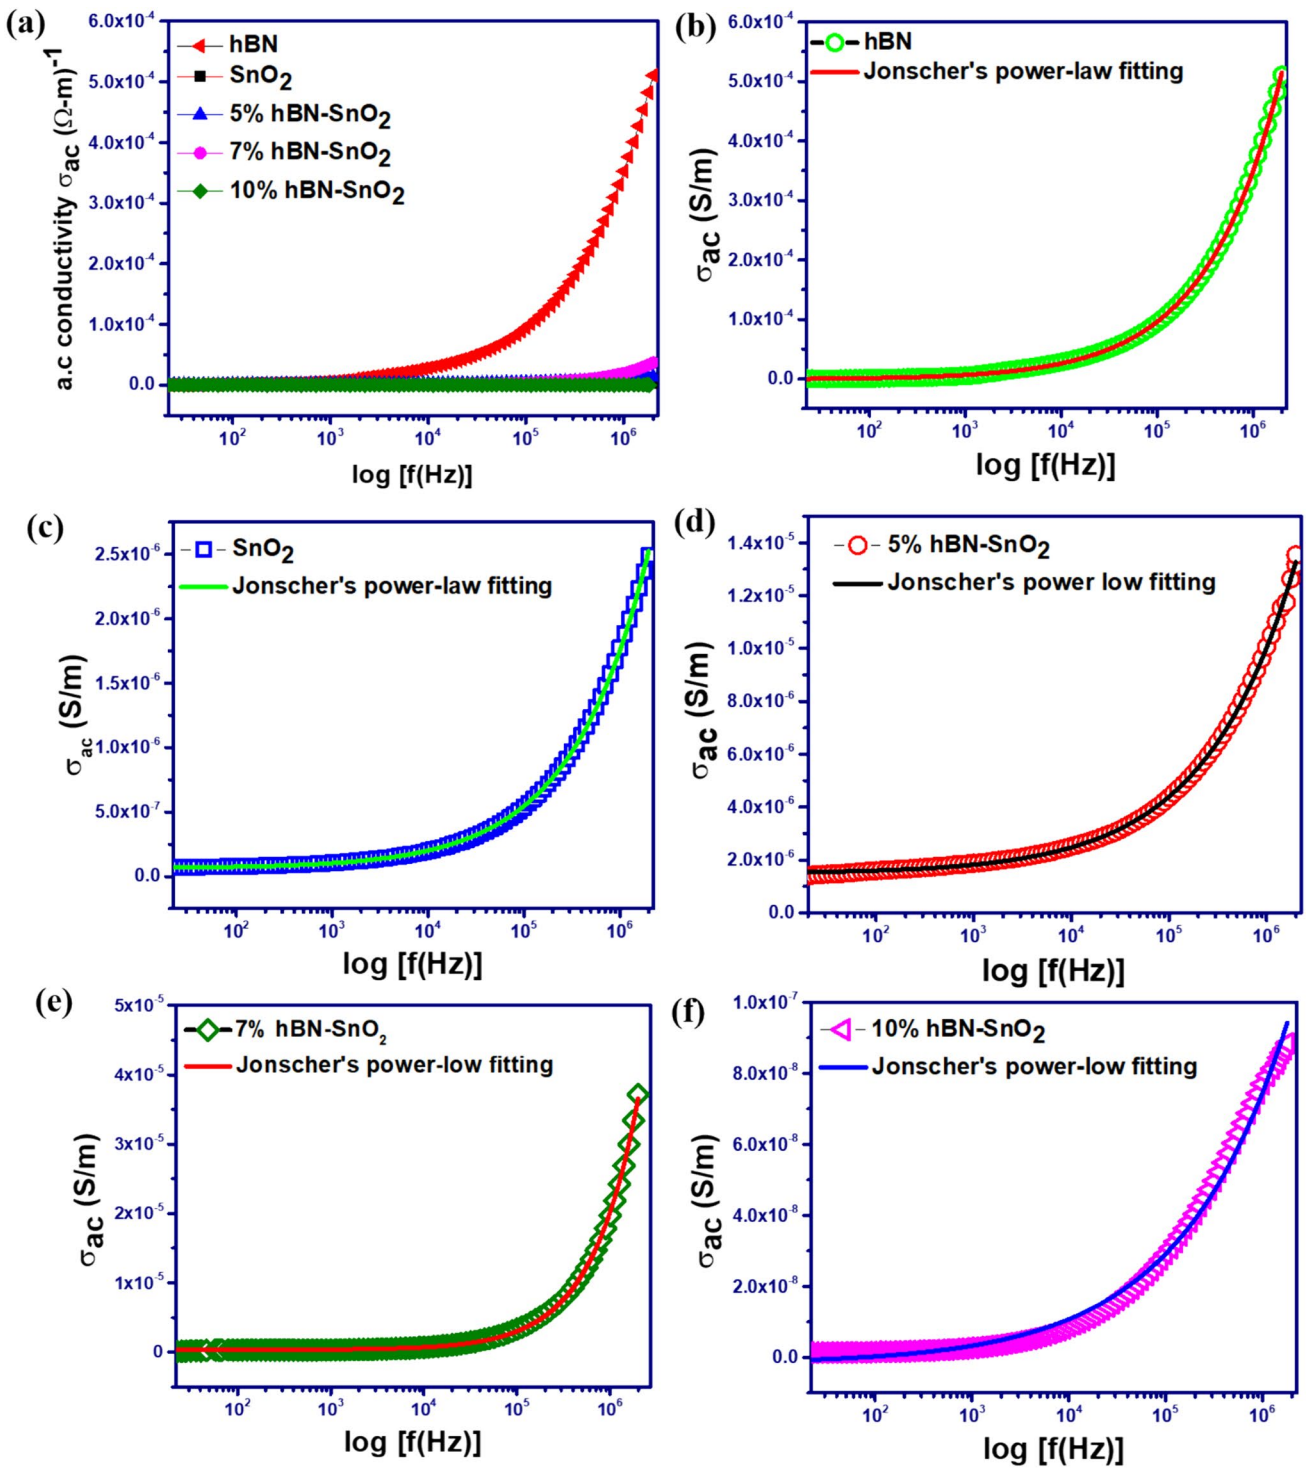

Figure 9 **a** The relationship between frequency and AC conductivity (σ_{ac}). **b–d** The graphs of curve fitting for hBN, SnO_2, 5% hBN-SnO_2, 7% hBN-SnO_2, and 10% hBN-SnO_2 nanocomposite were created using Jonscher's power law.

with different hBN wt.% in SnO_2 when the voltage is improved from − 1 to + 1 V. All of the fabricated memory devices resistive switching behaviour are shown in Fig. 11e–h. The device including the nanocomposite based on SnO_2-hBN exhibits distinct behaviour from the pure SnO_2-based device,

Table 2 Parameters are derived from Jonscher's power law fitting for each sample

Materials	Frequency exponents (s)	Pre-exponent A
SnO_2	0.543	9.22×10^{-10}
hBN	0.558	1.56×10^{-7}
5% hBN-SnO_2	0.467	1.33×10^{-8}
7% hBN-SnO_2	0.870	1.17×10^{-10}
10% hBN-SnO_2	0.391	3.40×10^{-10}

as demonstrated, suggesting the presence of interaction at the SnO_2-hBN interface. To investigate the memory phenomenon, the power is raised. It is found that the device enters the SET state (6.5 V) for pure SnO_2-based devices (Al/SnO_2/ITO-PET), transitioning from the early HRS to the LRS. However, whilst the voltage continues to rise in the same direction, as shown in Fig. 11e, the changeover from LRS to HRS does not occur. For the device to complete the reset transition, it is necessary to reverse the voltage polarity. The bipolar resistive switching behaviour is demonstrated by the device, which has been found to occur at − 5.5 V. The direction of the voltage sweep is shown by the arrow. SnO_2-based memory devices are not suited for real-world applications because of their greater switching voltages and less hysteresis. Consequently, more research was done on the device using an active layer made of SnO_2-hBN nanocomposite. To further comprehend the influence of 2D hBN in SnO_2 on memory device applications, various wt.% of hBN in SnO_2-based devices were investigated. Every SnO_2-hBN nanocomposite device exhibited the properties of bipolar resistive switching (BRS), as shown in Fig. 11f–h. Moreover, as shown in Fig. 11g, the memory phenomena with 7 wt.% hBN in SnO_2 show a greater ON/OFF current ratio. When comparing the nanocomposite-based memory device to a pure SnO_2-based memory device, the HRS to LRS transition occurs at a voltage of 0.5 V, whereas the LRS to HRS transition occurs at -0.7 V. The device made of SnO_2-hBN has better resistive switching characteristics. The I_{ON}/I_{OFF} ratios at a read voltage of 0.5 V are 2, 96, 1000, and 10 for pure SnO_2, 5%, 7%, and 10% SnO_2-hBN devices, respectively. This suggests that the composite 7 wt.% hBN-SnO_2 device performs better when it comes to resistive switching. After comparing to pure SnO_2, the interfacial contact between hBN and SnO_2 nanoparticles may explain the greater resistive switching ratio (I_{ON}/I_{OFF}). The dielectric constant of a substance determines its ability to hold charges and has been found that a device having a 7%SnO_2-hBN nanocomposite has a higher dielectric constant, which allows for additional charge storage, potentially extending the memory window. It should be mentioned that the composite made of SnO_2 and hBN

◂**Figure 11** **a–d** The I–V properties and **e–h** the resistive switching properties observed for pure SnO_2 and hBN-SnO_2 nanocomposite with the different weight percentages of hBN powder. The inset of resistive switching figures shows the logarithmic I–V curves.

also considerably increases the switching parameter, as seen by the XPS spectra. According to Singh et al., resistive memory-based metal oxide nanocomposite applications have two advantages: They not only serve as an oxygen reservoir but also as a blocking layer to stop oxygen from diffusing into the switching layers, improving the switching ratio [71].

As shown in Fig. 12a, the positive side characteristics of I–V are presented on a dual logarithmic scale to help better understand the switching operations in Al/7%SnO_2-hBN/ITO-PET. Because the device-fitted I–V curve in the HRS has a slope of 1, the ohmic conduction mechanism dominates at lower voltages, as demonstrated in Fig. 12a. The density of thermally generated charged particles in dielectric materials is significantly higher than the density of introduced charge particles since metal electrodes at lesser voltage values, as per the ohmic conduction process. A dielectric or insulator's electrical properties and the applied voltage influence how much generated or inserted charge is produced by metallic electrodes. The charge transporters produced by metal electrodes frequently pass over the entire depth of the sample due to the long relaxation period. This state is referred to as high resistance (HRS). Injecting additional electricity from the metal electrode results in a rise in the applied voltage. The quantity of charge carriers injected exceeds the quantity of charge carriers produced by heat. All available trap sites are filled with induced or injected charge carriers, which causes a large rise in current. In this area, the present correlates to the square of the voltage, and space charge-limited conduction (SCLC) has replaced ohmic conduction. The induced charge carriers move through the materials upon filling every vacant trap site. Current flowing through the material increases dramatically as a result [69] (see Fig. 12a). Subsequently, due to space charge-limited conduction, injected electrons fill every trap in the active film of the 7%SnO_2-hBN material, and the current is determined by squaring the voltage. Thus, in the high-voltage area, the slope rises close to 2.5 based on the I–V curves. This is confirmed by applying the Schottky emission concept to the high-voltage area I–V characteristics (a slope of 2.5 on the log (I) vs. log (V) graph). The resulting SnO_2-hBN nanocomposites and the electrode differing work functions, as indicated by the equation below, are what cause this interface-limited conduction mechanism.

$$\ln I \propto \sqrt{\frac{e^3}{4\pi\varepsilon_r\varepsilon_0 d}}\sqrt{V}/kT \tag{6}$$

In the higher voltage area of HRS, Schottky emission is the predominant charge transport method, as indicated by the linear plot between log (I) versus $V^{1/2}$ displayed in the inset of Fig. 12a. The excellent fit of the I–V curve at a higher voltage by the Schottky model indicates that multiple charge transport mechanisms are operational in HRS [1, 72]. Additionally, the entire region of LRS is equipped with an ohmic conduction slope of roughly 1.2. This type of mechanism is seen in devices where the contact at the junction is ohmic, allowing carriers to enter and move freely inside the insulating layer [73]. When a material conduction band is injected with electrons more quickly than they are reabsorbed, the SCLC mechanism takes place. This huge amount of electrons limits the devices current flow due to electron scattering. The HRS area, which comprises this SCLC mechanism, may be caused by oxygen vacancies within the hBN thin layer.

A sequence of durability examinations was carried out to assess the device constancy with the largest memory window (Al/7%SnO_2-hBN/ITO-PET). Figure 12b shows that the device performance remains stable even after 100 cycles. The set and reset functions were performed with sweeping voltages ranging from 0 to + 1.5 V and 0 to − 1.5 V, respectively. At ambient temperature, we used a 0.5-V read voltage to evaluate the resistance across ON and OFF. The retention parameters displayed in Fig. 12d demonstrate that HRS and LRS may be retained by the 7%SnO_2-hBN-based device for more than 1.5×10^4 s without suffering any significant degradation. As illustrated in Fig. 12c, the device memory window is 1000, as represented by R_{ON}/R_{OFF}. It is obvious from these results that constant after several cycles, the Al/7%SnO_2-hBN/ITO-PET device does not degrade. According to these findings, the change from the OFF to the ON state is reversible and repeatable. At the read voltage of 0.5 V, both HRS and LRS remain unchanged when the resistance ratio of LRS/HRS stays constant throughout 100 cycles. According to the results overhead,

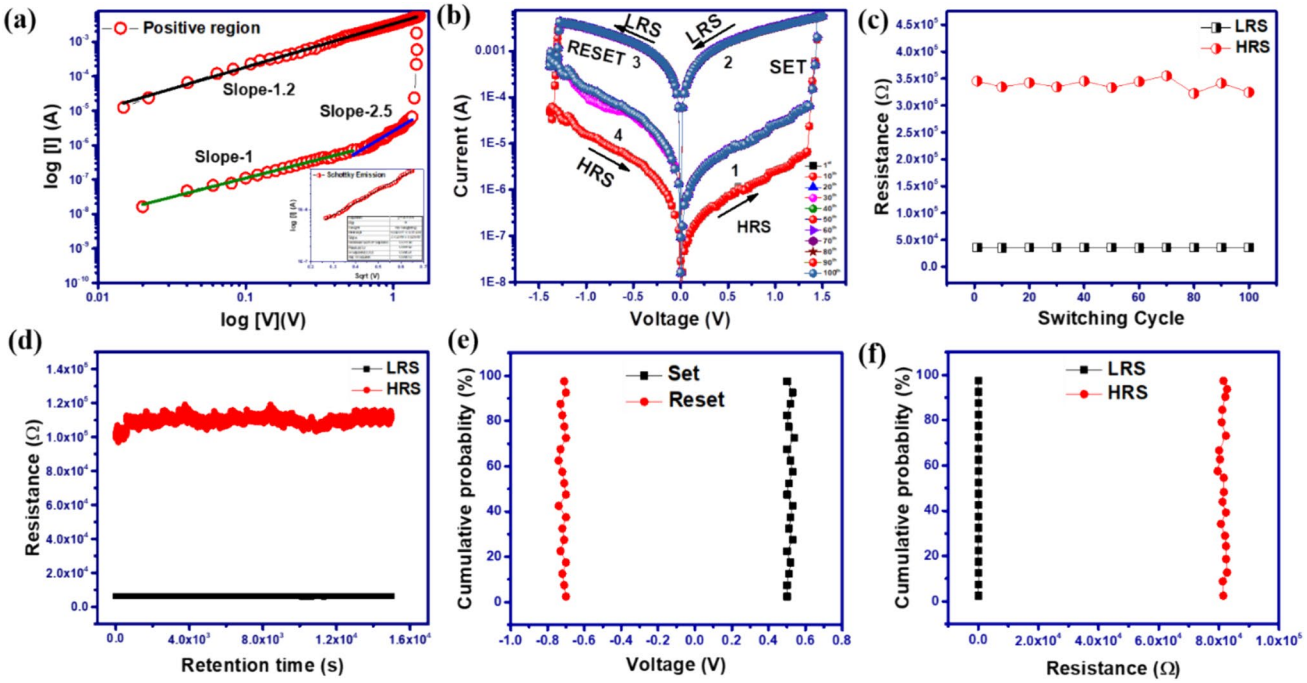

Figure 12 **a** Positive LRS, HRS at log–log scale. **b**, **c** The hBN-SnO_2-based device endurance performance over 100 resistive switching cycles. **d** Sustained resistance in HRS and LRS for roughly 1.6×10^4 s stipulating robust performance. **e**, **f** The device-to-device cumulative probability distributions of Vset–Vreset and HRS-LRS of 7%hBN-SnO_2 RRAM devices.

the Al/7%SnO_2-hBN/ITO-PET device performs consistently and durably, and switching between HRS and LRS is improved. We also examined device-to-device continuous probability distributions for the $V_{SET} - V_{RESET}$, LRS, and HRS for the 7%SnO_2-hBN RRAM devices, which are displayed in Fig. 12e, f, and so on. The operating voltages for the device-to-device distribution were calculated using the average of the first 10 cycles of each of the 20 tested devices [74]. Since the filament rupture process can be unpredictable, it is vital to handle the little variance in the RESET process for a practical memory application. Across devices, there is virtually little variation in the SET voltage variability. The fact that the device-to-device LRS and HRS vary very little should be addressed as they demonstrate the fabricated memory devices dependability [75].

Summary

In conclusion, an Al/SnO_2-hBN/ITO-PET-based memory device has been fabricated in the current study, where the percentage of hBN was varied to understand its influence on resistive switching properties. The nanocomposite powder with 5%SnO_2-hBN, 7%SnO_2-hBN, and 10%SnO_2-hBN with average crystallize sizes of 26.1 nm, 20.8 nm, and 20.7 nm is successfully synthesized via hydrothermal synthesis. XRD, Raman, FTIR, FESEM, EDX, and XPS analysis are used systematically to investigate the phase structure, composite formation, surface structure, chemical distribution, and valance state of SnO_2-hBN nanocomposite. When comparing the SnO_2-hBN nanocomposite to pure SnO_2 and hBN, the shift in the B1s, N1s, C1s, O1s, and Sn 3d peaks indicates an interfacial interaction. The dielectric constant, dielectric loss factor, and AC conductivity were found to decrease with increasing hBN quantity and frequency. In comparison with SnO_2, 5%SnO_2-hBN, and 10%SnO_2-hBN nanocomposites, the 7%SnO_2-hBN nanocomposite had a higher dielectric constant and lower loss. The percolation theory of conductive filler may explain dramatic variations in the dielectric characteristics of SnO_2-hBN. One semicircle is displayed in the Nyquist plots only because of the grain boundary contribution to the conduction process. AC conductivity was shown to be substantially dependent on frequency, with conductivity increasing at higher frequencies. The power law of Jonscher's is universally applicable to AC

conductivity. Later, the fabricated devices made up of pure SnO_2 and SnO_2-hBN (5, 7, and 10 wt.%) nanocomposite powder were tested for resistive switching applications. The resistive memory device based on SnO_2-hBN nanocomposite further demonstrated its altered electrical properties with a decrease in switching parameters and an increase in the current ratio. After comparing the resistive switching performance of the created device, it was found that the device with 7% hBN in SnO_2 had a higher I_{ON}/I_{OFF} ratio of ~ 1000, whereas the devices with 5 and 10 wt.% hBN in SnO_2 had higher ratios of ~ 96 and ~ 10, respectively. The Al/7%SnO_2-hBN/ITO-PET device also showed good durability behaviour up to 100 cycles and switching characteristics with a lower switching voltage. Retention time, which is an important consideration for RRAM devices, was measured for this device up to 1.5×10^4 s. The increased electrical properties of the presented flexible device indicate possibilities for future RRAM memory.

A NEW DIFFERENTIAL SUBORDINATION TECHNIQUE FOR A SUBCLASS OF STARLIKE FUNCTIONS

S. SIVAPRASAD KUMAR AND POOJA YADAV

Abstract. In the present investigation, we employ a new technique to find several first and second order differential subordination implications involving the following starlike class associated with a bean shaped domain:

$$\mathcal{S}^*_{\mathfrak{B}} := \left\{ f \in \mathcal{S} : \frac{zf'(z)}{f(z)} \prec \sqrt{1+\tanh z} =: \mathfrak{B}(z) \right\}.$$

Also, we give several applications stemming from our derived results.

1. Introduction

Let $\mathbb{D} = \{z \in \mathbb{C} : |z| < 1\}$ and $\mathcal{H}$ be the class of functions f analytic in $\mathbb{D}$ with $f(z) = 1+a_1z+a_2z^2+\cdots$. Also, let $\mathcal{A}$ be the class of analytic functions f normalized by $f(0) = f'(0)-1 = 0$ in $\mathbb{D}$ and $\mathcal{S}$ be the subclass of $\mathcal{A}$ consisting of all univalent functions. Further $\mathcal{S}^*$ is a subclass of $\mathcal{S}$, which consists of all functions f such that $f(\mathbb{D})$ is starshaped with respect to origin and these functions are known as starlike functions with respect to origin. Analytically, $f \in \mathcal{S}^*$ if we have $\operatorname{Re} zf'(z)/f(z) > 0$ Furthermore, to compare the inclusion properties of two analytic functions f and g, having same origin, i.e. $f(0) = g(0)$, we say that f is subordinate to g, written as $f \prec g$, if and only if $f(z) = g(w(z))$ where $w(z)$ is a Schwarz function. In terms of subordination, Ma and Minda [9] unified all the subclasses of $\mathcal{S}^*$ by defining the following class:

$$\mathcal{S}^*(\phi) = \left\{ f \in \mathcal{S} : \frac{zf'(z)}{f(z)} \prec \phi(z) \right\}, \tag{1.1}$$

where ϕ is a univalent and analytic function with positive real part, starlike with respect to $\phi(0) = 1$, $\phi'(0) > 0$ and $\phi(\mathbb{D})$ is symmetric with respect to the real axis. Several well-known classes can be obtained by specializing ϕ, such as the Janowski strongly starlike class of order α $\mathcal{SS}^*(A, B, \alpha) := \mathcal{S}^*(((1+Az)/(1+Bz))^\alpha)$ where $\alpha \in (0, 1]$ and $A, B \in \mathbb{C}$ with $|B| \leq 1$ and $A \neq B$, studied by Kumar and Yadav in [7]. Here $\mathcal{SS}^*(1, -1, \alpha) =: \mathcal{SS}^*(\alpha)$; the class of strongly starlike functions of order α. And for $A, B \in [-1, 1]$ and $\alpha = 1$ we obtain the class of Janowski starlike functions, denoted as $\mathcal{S}^*(A, B)$, which specifically reduces to many well-known classes, for instance see [5]. Sokól and Stankiewicz [15] considered the class $\mathcal{S}^*_L$ by opting $\phi(z) = \sqrt{1+z}$. Geometrically $\mathcal{S}^*_L = \{f \in \mathcal{S}; |(zf'(z)/f(z))^2 - 1| < 1\}$, that is, $zf'(z)/f(z)$ lies in the domain bounded by the right lemniscate of Bernoulli. Moreover, Goel and Kumar [4] studied the starlike class associated with sigmoid, $\mathcal{S}^*(2/(1+e^{-z})) =: \mathcal{S}^*_{SG}$ and Mendiratta et al. [11] introduced and studied the class associated with exponential, $\mathcal{S}^*(e^z) =: \mathcal{S}^*_e$. Similarly, in [8] the following class was introduced by Kumar and Yadav:

$$\mathcal{S}^*_{\mathfrak{B}} := \left\{ f \in \mathcal{S} : \frac{zf'(z)}{f(z)} \prec \sqrt{1+\tanh z} =: \mathfrak{B}(z) \right\}.$$

2010 *Mathematics Subject Classification.* 30C45, 30C80.

Key words and phrases. Analytic functions, Starlike functions, Subordination, Admissibility condition.

Observe that the function $\mathfrak{B}(z) := \sqrt{1+\tanh z} = \sqrt{2/(1+e^{-2z})}$ conformally maps $\mathbb{D}$ onto the following bean shaped region

$$\Omega_{\mathfrak{B}} := \left\{ w \in \mathbb{C} : \left| \log\left(\frac{w^2}{2-w^2}\right) \right| < 2 \right\}. \tag{1.2}$$

In [8], authors obtained various geometric characteristics of $\mathfrak{B}(z)$ and derived several inclusion and radii results associated with $\mathcal{S}^*_{\mathfrak{B}}$. The present article is an extension of that work in terms of differential subordination. Here, we are establishing certain first and second order differential subordination implications related to the function $\mathfrak{B}(z)$, utilizing a lemma that significantly simplifies the calculations. Differential subordination, analogous to differential inequalities in real analysis, has numerous applications. A pivotal contribution to this field was made by Miller and Mocanu's influential monograph [12], which sparked a major revolution in the geometric function theory research community. Many researchers have addressed problems related to differential subordination, such as those in [3, 6, 13, 14, 16]. Chapter 2 of the aforementioned monograph presents a set of results that establish admissibility conditions for second-order differential subordination. Significant work has been built upon these results. For instance, Madaan et al. [10] investigated the class of admissible functions associated with the lemniscate of Bernoulli and proved several first- and second-order differential subordination implications. In [16], the author established various second- and third-order differential subordination implications by defining admissibility conditions for the exponential function. In [1], the authors modified the concept of second-order differential subordination by introducing β-admissible functions, and in [2], the authors extended the concept of differential subordination and admissibility conditions to third order.

We now present essential definitions, lemmas, and notations necessary for further discussion.

Lemma 1.1. [8] *Let $w \in \mathbb{C}$ such that $|w| > \sqrt{2}$ and $R_0 = e\sqrt{2/(e^2-1)} \simeq 1.5208$. Then*

$$\left| \log\left(\frac{w^2}{2-w^2}\right) \right| \geq 2, \quad \textit{whenever} \quad |w| \geq R_0.$$

Definition 1.2. [12] Let $\mathcal{Q}$ denotes the set of functions q that are analytic and univalent on $\overline{\mathbb{D}}\backslash\mathcal{E}(q)$, where

$$\mathcal{E}(q) = \left\{ \zeta \in \partial\mathbb{D} : \lim_{z\to\zeta} q(z) = \infty \right\}$$

such that $q'(\zeta) \neq 0$ for $\zeta \in \partial\mathbb{D}\backslash\mathcal{E}(q)$.

Definition 1.3. [12] Let Ω be a set in $\mathbb{C}$, $q \in \mathcal{Q}$ and n be a positive integer, the class of admissible functions $\Psi_n(\Omega, q)$, consists of those functions $\psi : \mathbb{C}^3 \times \mathbb{D} \to \mathbb{C}$ that satisfy the admissibility condition $\psi(r, s, t; z) \notin \Omega$, whenever $r = q(\zeta)$, $s = m\zeta q'(\zeta)$,

$$\operatorname{Re}\left(\frac{t}{s}+1\right) \geq m \operatorname{Re}\left(\frac{\zeta q''(\zeta)}{q'(\zeta)}+1\right),$$

$z \in \mathbb{D}$, $\zeta \in \partial\mathbb{D}\backslash\mathcal{E}(q)$ and $m \geq n$. In particular, we denote $\Psi_1(\Omega, q)$ as $\Psi(\Omega, q)$.

Lemma 1.4. [12] *Let $\psi \in \Psi(\Omega, q)$ with $q(0) = 1$. If $p \in \mathcal{H}$ satisfies*

$$\psi(p(z), zp'(z), z^2p''(z); z) \in \Omega,$$

then $p \prec q$.

Throughout this article, we consider the function $q(z) = \mathfrak{B}(z)$ and define the admissibility class $\Psi(\Omega, q)$, where $\Omega \subset \mathbb{C}$. Since $\mathcal{E}(\mathfrak{B}) = \varnothing$, therefore $\mathfrak{B} \in \mathcal{Q}$. For $\zeta = e^{i\theta}$ $(0 \leq \theta < 2\pi)$ we have,

$$q(\zeta) = \sqrt{\frac{2}{1+e^{-2e^{i\theta}}}}, \quad \zeta q'(\zeta) = \frac{\sqrt{2}e^{i\theta}e^{-2e^{i\theta}}}{(1+e^{-2e^{i\theta}})^{3/2}}$$

and

$$\operatorname{Re}\left(\frac{\zeta q''(\zeta)}{q'(\zeta)}\right) = \frac{\cos\theta - 2e^{4\cos\theta}\cos\theta + e^{2\cos\theta}(\cos(\theta - 2\sin\theta) - 2\cos(\theta + 2\sin\theta))}{1 + e^{4\cos\theta} + 2e^{2\cos\theta}\cos(2\sin\theta)} =: g(\theta). \quad (1.3)$$

Here,

$$|q(\zeta)| = \frac{\sqrt{2}}{(1 + e^{-4\cos\theta} + 2e^{-2\cos\theta}\cos(2\sin\theta))^{\frac{1}{4}}} =: \omega(\theta). \quad (1.4)$$

From [8], we obtain that the minimum value of $\omega(\theta)$ is $\omega(\pi) = \sqrt{2/(1+e^2)}$ and maximum is $\omega(\theta_0) =: \omega_{\theta_0} \simeq 1.438$, where $\theta_0 \simeq 1.31364$. By simple analysis we also obtain that $\min g(\theta) = g(0)$, and

$$|\zeta q'(\zeta)| = \frac{\sqrt{2}e^{-2\cos\theta}}{(1 + e^{-4\cos\theta} + 2e^{-2\cos\theta}\cos(2\sin\theta))^{3/4}} := d(\theta). \quad (1.5)$$

Further, a computation shows that $d'(\theta) = 0$ if and only if $\theta \in \{0, \theta_1, \pi\}$ where $\theta_1 \simeq 1.639$. We observe that $d(\theta)$ is increasing in $[0, \theta_1]$ and decreasing in $[\theta_1, \pi]$. Therefore, $\max d(\theta) = d(1.639) =: d_{\theta_1} \simeq 0.905$ and $\min d(\theta) = \min\{d(0), d(\pi)\} = \min\{0.158, 0.304\} = d(0)$. Moreover, $\Psi(\Omega, \mathfrak{B})$ is defined to be the class of functions $\psi : \mathbb{C}^3 \times \mathbb{D} \to \mathbb{C}$, which satisfies the following conditions:

$$\psi(r, s, t; z) \notin \Omega,$$

whenever

$$r = \mathfrak{B}(\zeta) = \sqrt{\frac{2}{1 + e^{-2e^{i\theta}}}}; \quad s = m\zeta\mathfrak{B}'(\zeta) = \frac{\sqrt{2}me^{i\theta}e^{-2e^{i\theta}}}{(1 + e^{-2e^{i\theta}})^{3/4}}; \quad \operatorname{Re}\left(1 + \frac{s}{t}\right) = m(1 + g(\theta)),$$

where $z \in \mathbb{D}$, $0 \le \theta < 2\pi$ and $m \ge 1$. Here, we start from first order differential subordination.

2. First order differential subordination

We first establish the following lemmas to prove our main results:

Lemma 2.1. *Let $-1 < B \le 0 < A \le 1$ and $w \in \mathbb{C}$ such that $|w| > 1$, then*

$$\left|\frac{w - 1}{A - Bw}\right| \ge 1, \quad \text{whenever} \quad |w| \ge \frac{1 + A}{1 + B}.$$

Proof. Let $w = Re^{i\theta}$ where $R > 1$ and $\theta \in (0, 2\pi]$. Then

$$\left|\frac{w - 1}{A - Bw}\right| \ge 1$$

is equivalent to

$$g(R, \theta) := \frac{1 + R^2 - 2R\cos\theta}{A^2 + B^2R^2 - 2ABR\cos\theta} \ge 1.$$

A simple computation shows that $g(R, \theta)$ attains its minimum at $\theta = 0$. Thus the above inequality holds if $g(R, 0) \ge 1$, i.e.

$$\frac{(R - 1)^2}{(A - BR)^2} \ge 1. \quad (2.1)$$

Since $|w| = R > 1$ and $B \le 0$ then $BR \le B < A$, thus (2.1) reduces to

$$\frac{R - 1}{A - BR} \ge 1 \implies R \ge \frac{1 + A}{1 + B}.$$

Thus the result holds. ∎

Lemma 2.2. *Let $w \in \mathbb{C}$ such that $|w| > 1$, then*

$$\left|w^2 - 1\right| \ge 1, \quad \text{whenever} \quad |w| \ge \sqrt{2}.$$

Proof. Let $w = Re^{i\theta}$ where $R > 1$ and $\theta \in (0, 2\pi]$. Then

$$\left|w^2 - 1\right| \geq 1$$

is equivalent to

$$L(R, \theta) := 1 + R^4 - 2R^2 \cos 2\theta \geq 1.$$

Clearly, the above inequality holds if $\min L(R, \theta) \geq 1$. Since, $\min L(R, \theta) = L(R, 0)$ and $R > 1$, thus the result holds. ∎

In this section, we find conditions on $\psi(p(z), zp'(z); z)$, so that the following implication holds:

$$\psi(p(z), zp'(z); z) \prec h(z) \implies p(z) \prec \mathfrak{B}(z),$$

where $h(z)$ is either $\mathfrak{B}(z)$, $(1 + Az)/(1 + Bz)$ $(-1 < B \leq 0 < A \leq 1)$ or $\sqrt{1+z}$. Here, $\psi(p(z), zp'(z); z)$ is taken to be as follows: $(p(z))^\delta + \beta(zp'(z))^n$, $(p(z))^\delta + \beta zp'(z)/(p(z))^n$ and $p(z) + zp'(z)/(\beta p(z) + \gamma)$.

Theorem 2.3. *Let n be a positive integer, $\delta \in \{0, 1\}$, $R_0 = e\sqrt{2/(e^2 - 1)}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta \in \mathbb{C}$ such that $|\beta| \geq (R_0 + \omega_{\theta_0}^\delta)(1 + e^2)^{3n/2}/(\sqrt{2}e)^n$. Suppose $p(z) \in \mathcal{H}$ and satisfies the subordination*

$$(p(z))^\delta + \beta(zp'(z))^n \prec \mathfrak{B}(z),$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1 + e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = q(\mathbb{D}) = \Omega_{\mathfrak{B}}$. Now consider $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ defined by $\psi(r, s; z) = r^\delta + \beta s^n$. For ψ to lie in the admissible class $\Psi(\Omega_{\mathfrak{B}}, \mathfrak{B})$,it must satisfy

$$\psi\left(\sqrt{\frac{2}{1 + e^{-2e^{i\theta}})}}, \frac{\sqrt{2}me^{i\theta}e^{-2e^{i\theta}}}{(1 + e^{-2e^{i\theta}})^{3/2}}; z\right) \notin \Omega_{\mathfrak{B}} \qquad (z \in \mathbb{D}, 0 \leq \theta < 2\pi, m \geq 1),$$

which is equivalent to

$$\left|\log\left(\frac{(r^\delta + \beta s^n)^2}{2 - (r^\delta + \beta s^n)^2}\right)\right| \geq 2.$$

We now use the Lemma 1.1 to prove the result, for which, let us assume $w = r^\delta + \beta s^n$. From (1.4) and (1.5) respectively, we have $|r| = |\mathfrak{B}(\zeta)| = |q(\zeta)| = \omega(\theta) \leq \max \omega(\theta) = \omega_{\theta_0}$ and $|s|/m = |\zeta\mathfrak{B}'(\zeta)| = |\zeta q'(\zeta)| = d(\theta) \geq \min d(\theta) = d(0)$. Thus

$$\begin{aligned} |w| &= |r^\delta + \beta s^n| \\ &\geq |\beta||s|^n - |r|^\delta \\ &\geq |\beta| m^n \left(d(0)\right)^n - \omega_{\theta_0}^\delta. \end{aligned}$$

Since $m \geq 1$ and $|\beta| \geq (R_0 + \omega_{\theta_0}^\delta)(1 + e^2)^{3n/2}/(\sqrt{2}e)^n$, we have

$$|w| \geq |\beta|\left(\frac{\sqrt{2}e}{(1 + e^2)^{3/2}}\right)^n - \omega_{\theta_0}^\delta \geq R_0 > \sqrt{2},$$

therefore the result follows at once by Lemma 1.1. ∎

Corollary 2.4. *Let n be a positive integer, $\delta \in \{0, 1\}$, $R_0 = e\sqrt{2/(e^2 - 1)}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta \in \mathbb{C}$ such that $|\beta| \geq (R_0 + \omega_{\theta_0}^\delta)(1 + e^2)^{3n/2}/(\sqrt{2}e)^n$. Suppose $f \in \mathcal{A}$ such that*

$$\left(\frac{zf'(z)}{f(z)}\right)^\delta + \beta\left(\frac{zf'(z)}{f(z)}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right)\right)^n \prec \mathfrak{B}(z),$$

then $f \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$(p(z))^{\delta} + \beta(zp'(z))^{n} = \left(\frac{zf'(z)}{f(z)}\right)^{\delta} + \beta\left(\frac{zf'(z)}{f(z)}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right)\right)^{n}.$$

Therefore the result holds using Theorem 2.3. ∎

Theorem 2.5. *Let n be a positive integer, $\delta \in \{0,1\}$, $R_0 = e\sqrt{2/(e^2-1)}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta \in \mathbb{C}$ such that $|\beta| \geq (R_0 + \omega_{\theta_0}^{\delta})(1+e^2)^{(3-n)/2}/(\sqrt{2}e)^{1-n}$. Suppose $p(z) \in \mathcal{H}$ and satisfies the subordination*

$$(p(z))^{\delta} + \beta\frac{zp'(z)}{(p(z))^{n}} \prec \mathfrak{B}(z),$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = q(\mathbb{D}) = \Omega_{\mathfrak{B}}$. Now consider $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be as $\psi(r,s;z) = r^{\delta} + \beta s/r^{n}$. For ψ to lie in the admissible class $\Psi(\Omega_{\mathfrak{B}}, \mathfrak{B})$, we must have

$$\psi\left(\sqrt{\frac{2}{1+e^{-2e^{i\theta}})}}, \frac{\sqrt{2}me^{i\theta}e^{-2e^{i\theta}}}{(1+e^{-2e^{i\theta}})^{3/2}}; z\right) \notin \Omega_{\mathfrak{B}} \qquad (z \in \mathbb{D}, 0 \leq \theta < 2\pi, m \geq 1),$$

which is equivalent to

$$\left|\log\left(\frac{(r^{\delta} + \beta s/r^{n})^2}{2 - (r^{\delta} + \beta s/r^{n})^2}\right)\right| \geq 2.$$

We now use the Lemma 1.1 to prove the result, for which, let us assume $w = r^{\delta} + \beta s/r^{n}$. From (1.4), we have $|r| = \omega(\theta) \leq \omega_{\theta_0}$. Thus

$$\begin{aligned} |w| &= \left|r^{\delta} + \beta\frac{s}{r^{n}}\right| \\ &\geq |\beta|\left(\frac{2^{\frac{1-n}{2}}me^{-2\cos\theta}}{(1+e^{-4\cos\theta} + 2e^{-2\cos\theta}\cos(2\sin\theta))^{\frac{3-n}{4}}}\right) - (\omega(\theta))^{\delta} \\ &\geq |\beta|m\chi_n(\theta) - (\omega(\theta))^{\delta}, \end{aligned}$$

where

$$\chi_n(\theta) := \frac{2^{\frac{1-n}{2}}e^{-2\cos\theta}}{(1+e^{-4\cos\theta} + 2e^{-2\cos\theta}\cos(2\sin\theta))^{\frac{3-n}{4}}}.$$

After a simple computation we obtain that $\min\chi_n(\theta) = \chi_n(0)$ for all $n \geq 1$. Since $m \geq 1$ and $|\beta| \geq (R_0 + \omega_{\theta_0}^{\delta})(1+e^2)^{(3-n)/2}/(\sqrt{2}e)^{1-n}$, we have

$$|w| \geq |\beta|\left(\frac{(\sqrt{2}e)^{1-n}}{(1+e^2)^{\frac{3-n}{2}}}\right) - \omega_{\theta_0}^{\delta} \geq R_0 > \sqrt{2}.$$

Therefore, the result follows immediately from Lemma 1.1. ∎

Corollary 2.6. *Let n be a positive integer, $\delta \in \{0,1\}$, $R_0 = e\sqrt{2/(e^2-1)}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta \in \mathbb{C}$ such that $|\beta| \geq (R_0 + \omega_{\theta_0}^{\delta})(1+e^2)^{(3-n)/2}/(\sqrt{2}e)^{1-n}$. Suppose f be a function in $\mathcal{A}$ such that*

$$\left(\frac{zf'(z)}{f(z)}\right)^{\delta} + \beta\left(\frac{zf'(z)}{f(z)}\right)^{1-n}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right) \prec \mathfrak{B}(z),$$

then $f \in \mathcal{S}^{*}_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$(p(z))^{\delta} + \beta\frac{zp'(z)}{(p(z))^n} = \left(\frac{zf'(z)}{f(z)}\right)^{\delta} + \beta\left(\frac{zf'(z)}{f(z)}\right)^{1-n}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right).$$

Now the result follows by an application of Theorem 2.5. ∎

Theorem 2.7. *Let $R_0 = e\sqrt{2/(e^2-1)}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta, \gamma \in \mathbb{C}$ such that $\beta \neq 0$ with $|\beta|\omega_{\theta_0} + |\gamma| \leq \sqrt{2}e/((1+e^2)^{3/2}(R_0 + \omega_{\theta_0}))$. Suppose $p(z) \in \mathcal{H}$ and satisfies the subordination*

$$p(z) + \frac{zp'(z)}{\beta p(z) + \gamma} \prec \mathfrak{B}(z),$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = q(\mathbb{D}) = \Omega_{\mathfrak{B}}$. Now consider $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be as $\psi(r, s; z) = r + s/(\beta r + \gamma)$. For ψ to lie in the admissible class $\Psi(\Omega_{\mathfrak{B}}, \mathfrak{B})$, we must have

$$\psi\left(\sqrt{\frac{2}{1+e^{-2e^{i\theta}}}}, \frac{\sqrt{2}me^{i\theta}e^{-2e^{i\theta}}}{(1+e^{-2e^{i\theta}})^{3/2}}; z\right) \notin \Omega_{\mathfrak{B}} \qquad (z \in \mathbb{D}, 0 \leq \theta < 2\pi, m \geq 1),$$

which is equivalent to

$$\left|\log\left(\frac{(r + s/(\beta r+\gamma))^2}{2 - (r + s/(\beta r+\gamma))^2}\right)\right| \geq 2.$$

We now use the Lemma 1.1 to prove the result, for which, let us assume $w = r + s/(\beta r + \gamma)$. From (1.4) and (1.5), we have $|r| = \omega(\theta) \leq \omega_{\theta_0}$ and $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$. Thus

$$\begin{aligned} |w| &= \left|r + \frac{s}{\beta r + \gamma}\right| \\ &\geq \frac{|s|}{|\beta||r| + |\gamma|} - |r| \\ &\geq \frac{md(0)}{|\beta|\omega_{\theta_0} + |\gamma|} - \omega_{\theta_0}. \end{aligned}$$

Since $m \geq 1$ and $|\beta|\omega_{\theta_0} + |\gamma| \leq \sqrt{2}e/((1+e^2)^{3/2}(R_0 + \omega_{\theta_0}))$, we have

$$|w| \geq \frac{\sqrt{2}e}{(1+e^2)^{3/2}(|\beta|\omega_{\theta_0} + |\gamma|)} - \omega_{\theta_0} \geq R_0 > \sqrt{2},$$

therefore the result follows at once by Lemma 1.1. ∎

Corollary 2.8. *Let $R_0 = e\sqrt{2/(e^2-1)}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta, \gamma \in \mathbb{C}$ such that $\beta \neq 0$ with $\omega_{\theta_0}|\beta| + |\gamma| \leq \sqrt{2}e/((1+e^2)^{3/2}(R_0 + \omega_{\theta_0}))$. Suppose f be a function in $\mathcal{A}$ such that*

$$\frac{zf'(z)}{f(z)}\left(1 + \left(\beta\frac{zf'(z)}{f(z)} + \gamma\right)^{-1}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right)\right) \prec \mathfrak{B}(z),$$

then $f \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$p(z) + \frac{zp'(z)}{\beta p(z) + \gamma} = \frac{zf'(z)}{f(z)}\left(1 + \left(\beta\frac{zf'(z)}{f(z)} + \gamma\right)^{-1}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right)\right).$$

Therefore the result holds using Theorem 2.7. ∎

Theorem 2.9. *Let $n \in \mathbb{N}$, $\delta \in \{0,1\}$, $\beta \in \mathbb{C}\backslash\{0\}$, $\omega_{\theta_0} \simeq 1.438$ and $-1 < B \leq 0 < A \leq 1$. Suppose $p \in \mathcal{H}$ such that it satisfies*

$$(p(z))^\delta + \beta(zp'(z))^n \prec \frac{1+Az}{1+Bz}$$

where

$$|\beta| \geq \left(\frac{(1+e^2)^{3/2}}{\sqrt{2}e}\right)^n \left(\frac{1+A}{1+B} + \omega_{\theta_0}^\delta\right) \tag{2.2}$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = \{w \in \mathbb{C} : |(w-1)/(A-Bw)| < 1\}$. Let $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be defined as $\psi(r,s;z) = r^\delta + \beta s^n$ where $r = \mathfrak{B}(\xi)$, $s = m\xi\mathfrak{B}'(\xi) = m\sqrt{2}\xi e^{-2\xi}/(1+e^{-2\xi})^{3/2}$ for $z \in \mathbb{D}$, $\xi \in \overline{\mathbb{D}}$ and $m \geq 1$. For ψ to be an admissible function and for $\psi \in \Psi[\Omega, \mathfrak{B}]$ we need to show $\psi(\mathbb{D}) \not\subseteq \Omega$, which is equivalent to

$$\left|\frac{r^\delta + \beta s^n - 1}{A - B(r^\delta + \beta s^n)}\right| \geq 1.$$

We now use the Lemma 2.1 to prove the result, for which, let us assume $w = r^\delta + \beta s^n$. From (1.4) and (1.5), we have $|r| = \omega(\theta) \leq \omega_{\theta_0}$ and $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$. Thus

$$\begin{aligned} |w| &= |r^\delta + \beta s^n| \\ &\geq |\beta||s|^n - |r|^\delta \\ &\geq |\beta| m^n (d(0))^n - \omega_{\theta_0}^\delta \end{aligned}$$

Since $m \geq 1$ and using (2.2), we have

$$|w| \geq |\beta| \left(\frac{\sqrt{2}e}{(1+e^2)^{3/2}}\right)^n - \omega_{\theta_0}^\delta \geq \frac{1+A}{1+B} > 1,$$

therefore the result follows at once from Lemma 2.1. ∎

Corollary 2.10. *Let $n \in \mathbb{N}$, $\delta \in \{0,1\}$ and $\beta \in \mathbb{C}\backslash\{0\}$ such that β satisfies inequality (2.2). Moreover, let $\omega_{\theta_0} \simeq 1.438$ and $-1 < B \leq 0 < A \leq 1$. Suppose $f \in \mathcal{A}$ such that*

$$\left(\frac{zf'(z)}{f(z)}\right)^\delta + \beta\left(\frac{zf'(z)}{f(z)}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right)\right)^n \prec \frac{1+Az}{1+Bz},$$

then $f \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$(p(z))^\delta + \beta(zp'(z))^n = \left(\frac{zf'(z)}{f(z)}\right)^\delta + \beta\left(\frac{zf'(z)}{f(z)}\left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right)\right)^n.$$

Now the result follows directly from Theorem 2.9. ∎

Theorem 2.11. *Let $n \in \mathbb{N}$, $\delta \in \{0,1\}$, $\beta \in \mathbb{C}\backslash\{0\}$, $\omega_{\theta_0} \simeq 1.438$ and $-1 \leq B < 0 \leq A \leq 1$. Suppose $p \in \mathcal{H}$ such that it satisfies*

$$(p(z))^\delta + \beta\frac{zp'(z)}{(p(z))^n} \prec \frac{1+Az}{1+Bz},$$

where

$$|\beta| \geq \left(\frac{(1+e^2)^{\frac{3-n}{2}}}{(\sqrt{2}e)^{1-n}}\right)\left(\frac{1+A}{1+B} + \omega_{\theta_0}^\delta\right). \tag{2.3}$$

Then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = \{w \in \mathbb{C} : |(w-1)/(A-Bw)| < 1\}$. Let $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be defined as $\psi(r,s;z) = r^\delta + \beta s/r^n$ where $r = \mathfrak{B}(\xi)$, $s = m\xi\mathfrak{B}'(\xi) = m\sqrt{2}\xi e^{-2\xi}/(1+e^{-2\xi})^{3/2}$ for $z \in \mathbb{D}$, $\xi \in \overline{\mathbb{D}}$ and $m \geq 1$. For ψ to be an admissible function and for $\psi \in \Psi[\Omega, \mathfrak{B}]$ we need to show $\psi(\mathbb{D}) \not\subseteq \Omega$, which is equivalent to

$$\left| \frac{r^\delta + \beta\frac{s}{r^n} - 1}{A - B(r^\delta + \beta\frac{s}{r^n})} \right| \geq 1.$$

We now use the Lemma 2.1 to prove the result, for which, let us assume $w = r^\delta + \beta s/r^n$. From (1.4), we have $|r| = \omega(\theta) \leq \omega_{\theta_0}$. Thus

$$\begin{aligned} |w| &= \left| r^\delta + \beta\frac{s}{r^n} \right| \\ &\geq |\beta| \left(\frac{2^{\frac{1-n}{2}} m e^{-2\cos\theta}}{(1 + e^{-4\cos\theta} + 2e^{-2\cos\theta}\cos(2\sin\theta))^{\frac{3-n}{4}}} \right) - (\omega(\theta))^\delta \\ &\geq |\beta| m \chi_n(\theta) - (\omega(\theta))^\delta, \end{aligned}$$

where

$$\chi_n(\theta) := \frac{2^{\frac{1-n}{2}} e^{-2\cos\theta}}{(1 + e^{-4\cos\theta} + 2e^{-2\cos\theta}\cos(2\sin\theta))^{\frac{3-n}{4}}}.$$

After a simple computation we obtain that $\min \chi_n(\theta) = \chi_n(0)$ for all $n \geq 1$. Since $m \geq 1$ and using (2.3), we have

$$|w| \geq |\beta| \left(\frac{(\sqrt{2}e)^{1-n}}{(1+e^2)^{\frac{3-n}{2}}} \right) - \omega_{\theta_0}^\delta \geq \frac{1+A}{1+B} > 1,$$

therefore the result follows from Lemma 2.1. ∎

Corollary 2.12. *Let $n \in \mathbb{N}$, $\delta \in \{0,1\}$ and $\beta \in \mathbb{C}\backslash\{0\}$ such that β satisfies inequality (2.3). Moreover, let $\omega_{\theta_0} \simeq 1.438$ and $-1 < B \leq 0 < A \leq 1$. Suppose f be a function in $\mathcal{A}$ such that*

$$\left(\frac{zf'(z)}{f(z)}\right)^\delta + \beta \left(\frac{zf'(z)}{f(z)}\right)^{1-n} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right) \prec \frac{1+Az}{1+Bz},$$

then $f \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$(p(z))^\delta + \beta\frac{zp'(z)}{(p(z))^n} = \left(\frac{zf'(z)}{f(z)}\right)^\delta + \beta \left(\frac{zf'(z)}{f(z)}\right)^{1-n} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right).$$

Now the result follows by an application of Theorem 2.11. ∎

Theorem 2.13. *Let $\beta, \gamma \in \mathbb{C}$ such that $\beta \neq 0$, $\omega_{\theta_0} \simeq 1.438$ and $-1 < B \leq 0 < A \leq 1$. Suppose $p \in \mathcal{H}$ such that it satisfies*

$$p(z) + \frac{zp'(z)}{\beta p(z) + \gamma} \prec \frac{1+Az}{1+Bz}$$

provided

$$|\beta|\omega_{\theta_0} + |\gamma| \leq \left(\frac{(1+e^2)^{3/2}}{\sqrt{2}e} \left(\frac{1+A}{1+B} + \omega_{\theta_0} \right) \right)^{-1} \tag{2.4}$$

where Then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = \{w \in \mathbb{C} : |(w-1)/(A-Bw)| < 1\}$. Let $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be defined as $\psi(r,s;z) = r + s/(\beta r + \gamma)$ where $r = \mathfrak{B}(\xi)$, $s = m\xi\mathfrak{B}'(\xi) = m\sqrt{2}\xi e^{-2\xi}/(1+e^{-2\xi})^{3/2}$ for $z \in \mathbb{D}$, $\xi \in \overline{\mathbb{D}}$ and $m \geq 1$. For ψ to be an admissible function and for $\psi \in \Psi[\Omega, \mathfrak{B}]$ we need to show $\psi(\mathbb{D}) \not\subseteq \Omega$, which is equivalent to

$$\left| \frac{r + \frac{s}{\beta r+\gamma}}{A - B(r + \frac{s}{\beta r+\gamma})} \right| \geq 1.$$

We now use the Lemma 2.1 to prove the result, for which, let us assume $w = r + s/(\beta r + \gamma)$. From (1.4) and (1.5), we have $|r| = \omega(\theta) \leq \omega_{\theta_0}$ and $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$. Thus

$$\begin{aligned} |w| &= \left| r + \frac{s}{\beta r + \gamma} \right| \\ &\geq \frac{|s|}{|\beta||r|+|\gamma|} - |r| \\ &\geq \frac{md(0)}{|\beta|\omega_{\theta_0} + |\gamma|} - \omega_{\theta_0}. \end{aligned}$$

Since $m \geq 1$ and using (2.4), we have

$$|w| \geq \frac{\sqrt{2}e}{(1+e^2)^{3/2}(|\beta|\omega_{\theta_0} + |\gamma|)} - \omega_{\theta_0} \geq \frac{1+A}{1+B} > 1,$$

therefore the result follows at once from Lemma 2.1. ∎

Corollary 2.14. *Let $\beta, \gamma \in \mathbb{C}$ such that $\beta \neq 0$ and satisfies inequality (2.4). Moreover, let $\omega_{\theta_0} \simeq 1.438$ and $-1 < B \leq 0 < A \leq 1$. Suppose f be a function in $\mathcal{A}$ such that*

$$\frac{zf'(z)}{f(z)} \left(1 + \left(\beta \frac{zf'(z)}{f(z)} + \gamma \right)^{-1} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)} \right) \right) \prec \frac{1+Az}{1+Bz},$$

then $f \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$p(z) + \frac{zp'(z)}{\beta p(z) + \gamma} = \frac{zf'(z)}{f(z)} \left(1 + \left(\beta \frac{zf'(z)}{f(z)} + \gamma \right)^{-1} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)} \right) \right).$$

Thus the result follows by an application of Theorem 2.13. ∎

Theorem 2.15. *Let $n \in \mathbb{N}$, $\delta \in \{0, 1\}$, $\beta \in \mathbb{C}\backslash\{0\}$ and $\omega_{\theta_0} \simeq 1.438$. Suppose $p \in \mathcal{H}$ such that it satisfies*

$$(p(z))^\delta + \beta(zp'(z)^n \prec \sqrt{1+z}$$

where

$$|\beta| \geq \left(\frac{(1+e^2)^{3/2}}{\sqrt{2}e} \right)^n \left(\sqrt{2} + \omega_{\theta_0}^\delta \right), \tag{2.5}$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = \{w \in \mathbb{C} : |w^2 - 1| < 1\}$. Let $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be defined as $\psi(r,s;z) = r^\delta + \beta s^n$ where $r = \mathfrak{B}(\xi)$, $s = m\xi\mathfrak{B}'(\xi) = m\sqrt{2}\xi e^{-2\xi}/(1+e^{-2\xi})^{3/2}$ for $z \in \mathbb{D}$, $\xi \in \overline{\mathbb{D}}$ and $m \geq 1$. For ψ to be an admissible function and for $\psi \in \Psi[\Omega, \mathfrak{B}]$ we need to show $\psi(\mathbb{D}) \not\subseteq \Omega$, which is equivalent to

$$\left| (r^\delta + \beta s^n)^2 - 1 \right| \geq 1.$$

We now use the Lemma 2.2 to prove the result, for which, let us assume $w = r^\delta + \beta s^n$. From (1.4) and (1.5), we have $|r| = \omega(\theta) \leq \omega_{\theta_0}$ and $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$. Thus

$$\begin{aligned} |w| &= |r^\delta + \beta s^n| \\ &\geq |\beta||s|^n - |r|^\delta \\ &\geq |\beta| m^n (d(0))^n - \omega_{\theta_0}^\delta. \end{aligned}$$

Since $m \geq 1$ and using (2.5), we have

$$|w| \geq |\beta| \left(\frac{\sqrt{2}e}{(1+e^2)^{3/2}} \right)^n - \omega_{\theta_0}^\delta \geq \sqrt{2} > 1,$$

therefore the result follows from Lemma 2.2. ∎

Corollary 2.16. *Let $n \in \mathbb{N}$, $\delta \in \{0, 1\}$, $\beta \in \mathbb{C}\backslash\{0\}$ such that it satisfies (2.5) and $\omega_{\theta_0} \simeq 1.438$. Further if $f \in \mathcal{A}$ and satisfies*

$$\left(\frac{zf'(z)}{f(z)} \right)^\delta + \beta \left(\frac{zf'(z)}{f(z)} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)} \right) \right)^n \prec \sqrt{1+z}$$

Then $p(z) \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$(p(z))^\delta + \beta (zp'(z))^n = \left(\frac{zf'(z)}{f(z)} \right)^\delta + \beta \left(\frac{zf'(z)}{f(z)} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)} \right) \right)^n.$$

Now the result follows from Theorem 2.15. ∎

Theorem 2.17. *Let $n \in \mathbb{N}$, $\delta \in \{0, 1\}$, $\beta \in \mathbb{C}\backslash\{0\}$ and $\omega_{\theta_0} \simeq 1.438$. Suppose $p \in \mathcal{H}$ such that it satisfies*

$$(p(z))^\delta + \beta \frac{zp'(z)}{(p(z))^n} \prec \sqrt{1+z}$$

where

$$|\beta| \geq \left(\frac{(1+e^2)^{\frac{3-n}{2}}}{(\sqrt{2}e)^{1-n}} \right) \left(\sqrt{2} + \omega_{\theta_0}^\delta \right) \tag{2.6}$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = \{w \in \mathbb{C} : |w^2 - 1| < 1\}$. Let $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be defined as $\psi(r, s; z) = r^\delta + \beta s/r^n$ where $r = \mathfrak{B}(\xi)$, $s = m\xi\mathfrak{B}'(\xi) = m\sqrt{2}\xi e^{-2\xi}/(1+e^{-2\xi})^{3/2}$ for $z \in \mathbb{D}$, $\xi \in \overline{\mathbb{D}}$ and $m \geq 1$. For ψ to be an admissible function and for $\psi \in \Psi[\Omega, \mathfrak{B}]$ we need to show $\psi(\mathbb{D}) \not\subseteq \Omega$, which is equivalent to

$$\left| \left(r^\delta + \beta \frac{s}{r^n} \right)^2 - 1 \right| \geq 1.$$

We now use the Lemma 2.2 to prove the result, for which, let us assume $w = r^\delta + \beta s/r^n$. From (1.4), we have $|r| = \omega(\theta) \leq \omega_{\theta_0}$. Thus

$$\begin{aligned} |w| &= \left| r^\delta + \beta \frac{s}{r^n} \right| \\ &\geq |\beta| \left(\frac{2^{\frac{1-n}{2}} m e^{-2\cos\theta}}{(1 + e^{-4\cos\theta} + 2e^{-2\cos\theta}\cos(2\sin\theta))^{\frac{3-n}{4}}} \right) - (\omega(\theta))^\delta \\ &\geq |\beta| m \chi_n(\theta) - (\omega(\theta))^\delta, \end{aligned}$$

where

$$\chi_n(\theta) := \frac{2^{\frac{1-n}{2}} e^{-2\cos\theta}}{(1+e^{-4\cos\theta}+2e^{-2\cos\theta}\cos(2\sin\theta))^{\frac{3-n}{4}}}.$$

After a simple computation we obtain that $\min \chi_n(\theta) = \chi_n(0)$ for all $n \geq 1$. Since $m \geq 1$ and using (2.6), we have

$$|w| \geq |\beta| \left(\frac{(\sqrt{2}e)^{1-n}}{(1+e^2)^{\frac{3-n}{2}}} \right) - \omega_{\theta_0}^{\delta} \geq \sqrt{2} > 1,$$

therefore the result follows from Lemma 2.2. ∎

Corollary 2.18. *Let $n \in \mathbb{N}$, $\delta \in \{0,1\}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta \in \mathbb{C}\backslash\{0\}$ such that β satisfies inequality (2.6). Suppose f be a function in $\mathcal{A}$ such that*

$$\left(\frac{zf'(z)}{f(z)}\right)^{\delta} + \beta \left(\frac{zf'(z)}{f(z)}\right)^{1-n} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right) \prec \sqrt{1+z},$$

then $f \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$(p(z))^{\delta} + \beta \frac{zp'(z)}{(p(z))^n} = \left(\frac{zf'(z)}{f(z)}\right)^{\delta} + \beta \left(\frac{zf'(z)}{f(z)}\right)^{1-n} \left(1 + \frac{zf''(z)}{f'(z)} - \frac{zf'(z)}{f(z)}\right).$$

Now the result follows as an application of Theorem 2.17. ∎

Theorem 2.19. *Let $\beta, \gamma \in \mathbb{C}$ such that $\beta \neq 0$ and $\omega_{\theta_0} \simeq 1.438$. Suppose $p \in \mathcal{H}$ such that it satisfies*

$$p(z) + \frac{zp'(z)}{\beta p(z) + \gamma} \prec \sqrt{1+z}$$

provided

$$|\beta|\omega_{\theta_0} + |\gamma| \leq \left(\frac{(1+e^2)^{3/2}}{\sqrt{2}e} \left(\sqrt{2} + \omega_{\theta_0}\right) \right)^{-1} \tag{2.7}$$

where Then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \sqrt{2/(1+e^{-2z})} =: \mathfrak{B}(z)$ and $\Omega = \{w \in \mathbb{C} : |w^2 - 1| < 1\}$. Let $\psi : \mathbb{C}^2 \times \mathbb{D} \to \mathbb{C}$ be defined as $\psi(r, s; z) = r + s/(\beta r + \gamma)$ where $r = \mathfrak{B}(\xi)$, $s = m\xi\mathfrak{B}'(\xi) = m\sqrt{2}\xi e^{-2\xi}/(1+e^{-2\xi})^{3/2}$ for $z \in \mathbb{D}$, $\xi \in \overline{\mathbb{D}}$ and $m \geq 1$. For ψ to be an admissible function and for $\psi \in \Psi[\Omega, \mathfrak{B}]$ we need to show $\psi(\mathbb{D}) \not\subseteq \Omega$, i.e.

$$\left| \left(r + \frac{s}{\beta r + \gamma}\right)^2 - 1 \right| \geq 1.$$

We now use the Lemma 2.2 to prove the result, for which, let us assume $w = r + s/(\beta r + \gamma)$. From (1.4) and (1.5), we have $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$ and $|r| = \omega(\theta) \leq \omega_{\theta_0}$. Thus

$$\begin{aligned} |w| &= \left| r + \frac{s}{\beta r + \gamma} \right| \\ &\geq \frac{|s|}{|\beta||r| + |\gamma|} - |r| \\ &\geq \frac{md(0)}{|\beta|\omega_{\theta_0} + |\gamma|} - \omega_{\theta_0}. \end{aligned}$$

Since $m \geq 1$ and using (2.7), we have

$$|w| \geq \frac{\sqrt{2}e}{(1+e^2)^{3/2}(|\beta|\omega_{\theta_0}+|\gamma|)} - \omega_{\theta_0} \geq \sqrt{2} > 1,$$

therefore, by Lemma 2.2, the result holds. ∎

Corollary 2.20. *Let $\omega_{\theta_0} \simeq 1.438$ and $\beta, \gamma \in \mathbb{C}$ such that $\beta \neq 0$ and satisfies inequality (2.7). Suppose f be a function in $\mathcal{A}$ such that*

$$\frac{zf'(z)}{f(z)}\left(1+\left(\beta\frac{zf'(z)}{f(z)}+\gamma\right)^{-1}\left(1+\frac{zf''(z)}{f'(z)}-\frac{zf'(z)}{f(z)}\right)\right) \prec \sqrt{1+z},$$

then $f \in \mathcal{S}^*_{\mathfrak{B}}$.

Proof. Let $p(z) = zf'(z)/f(z)$, then

$$p(z)+\frac{zp'(z)}{\beta p(z)+\gamma} = \frac{zf'(z)}{f(z)}\left(1+\left(\beta\frac{zf'(z)}{f(z)}+\gamma\right)^{-1}\left(1+\frac{zf''(z)}{f'(z)}-\frac{zf'(z)}{f(z)}\right)\right).$$

Therefore the result holds using Theorem 2.19. ∎

3. Second order differential subordination

In this section, we consider the following second order differential subordination implication

$$(p(z))^\delta + \gamma z p'(z) + \beta z^2 p''(z) \prec h(z) \implies p(z) \prec \mathfrak{B}(z).$$

Taking $h(z)$ as $\mathfrak{B}(z)$, $(1+Az)/(1+Bz)$ $(-1 < B \leq 0 < A \leq 1)$ and $\sqrt{1+z}$.

Theorem 3.1. *Let $\delta \in \{0,1\}$, $R_0 = e\sqrt{2/(e^2-1)}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta, \gamma \in \mathbb{C}\backslash\{0\}$. If $p(z) \in \mathcal{H}$ such that*

$$(p(z))^\delta + \gamma z p'(z) + \beta z^2 p''(z) \prec \mathfrak{B}(z),$$

provided

$$\sqrt{2}e(\gamma(1+e^2)^2 + \beta(1-2e^4-e^2)) \geq (R_0+\omega^\delta_{\theta_0})(e^2+1)^{7/2} \tag{3.1}$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Let $q(z) = \mathfrak{B}(z)$ and $\Omega = q(\mathbb{D}) = \Omega_{\mathfrak{B}}$. Now consider $\psi : \mathbb{C}^3 \times \mathbb{D} \to \mathbb{C}$ be as $\psi(r,s,t;z) = r^\delta + \gamma s + \beta t$. For ψ to lie in the admissible class $\Psi(\Omega_{\mathfrak{B}}, \mathfrak{B})$, we must have

$$\psi(r,s,t;z) \notin \Omega_{\mathfrak{B}},$$

whenever

$$r = \mathfrak{B}(\zeta) = \sqrt{\frac{2}{1+e^{-2e^{i\theta}}}}; \quad s = m\zeta\mathfrak{B}'(\zeta) = \frac{\sqrt{2}me^{i\theta}e^{-2e^{i\theta}}}{(1+e^{-2e^{i\theta}})^{3/4}}; \quad \mathrm{Re}\left(1+\frac{s}{t}\right) = m(1+g(\theta)),$$

where $z \in \mathbb{D}$, $0 \leq \theta < 2\pi$ and $m \geq 1$. Thus, it is sufficient to show that

$$\left|\log\left(\frac{(r^\delta+\gamma s+\beta t)^2}{2-(r^\delta+\gamma s+\beta t)^2}\right)\right| \geq 2.$$

We now use the Lemma 1.1 to prove the result, for which, let us assume $w = r^\delta + \gamma s + \beta t$. From (1.3), (1.4) and (1.5), we have $\min g(\theta) = g(0)$, $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$ and

$|r|= \omega(\theta) \leq \omega_{\theta_0}$. Thus

$$\begin{aligned}|w| &= |r^\delta + \gamma s + \beta t| \\ &\geq \gamma|s|\mathrm{Re}\left(1+\frac{\beta}{\gamma}\frac{t}{s}\right) - |r|^\delta \\ &\geq \gamma m d(\theta)\left(1+\frac{\beta}{\gamma}(mg(\theta)+m-1)\right) - (\omega(\theta))^\delta \\ &\geq m\frac{\sqrt{2}e}{(e^2+1)^{3/2}}\left(\gamma+\beta\left(m\frac{1-2e^4-e^2}{(e^2+1)^2}+m-1\right)\right) - \omega_{\theta_0}^\delta.\end{aligned}$$

Since $m \geq 1$ and using (3.1), we have

$$|w| \geq \frac{\sqrt{2}e}{(e^2+1)^{3/2}}\left(\gamma+\beta\left(\frac{1-2e^4-e^2}{(e^2+1)^2}\right)\right) - \omega_{\theta_0}^\delta \geq R_0 > \sqrt{2},$$

therefore the result follows at once by Lemma 1.1. ∎

Theorem 3.2. *Let $\delta \in \{0,1\}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta, \gamma \in \mathbb{C}\backslash\{0\}$. If $p(z) \in \mathcal{H}$ such that*

$$(p(z))^\delta + \gamma z p'(z) + \beta z^2 p''(z) \prec \frac{1+Az}{1+Bz}, \quad -1 < B \leq 0 < A \leq 1,$$

provided

$$\sqrt{2}e(\gamma(1+e^2)^2 + \beta(1-2e^4-e^2)) \geq \left(\frac{1+A}{1+B} + \omega_{\theta_0}^\delta\right)(e^2+1)^{7/2} \tag{3.2}$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Here $q(z) = \mathfrak{B}(z)$ and $h(z) = (1+Az)/(1+Bz)$, thus

$$\Omega = h(\mathbb{D}) = \left\{w \in \mathbb{C} : \left|\frac{w-1}{A-Bw}\right| < 1\right\},$$

Now consider $\psi : \mathbb{C}^3 \times \mathbb{D} \to \mathbb{C}$ be as $\psi(r,s,t;z) = r^\delta + \gamma s + \beta t$. For ψ to lie in the admissible class $\Psi(\Omega, \mathfrak{B})$, we must have

$$\psi(r,s,t;z) \notin \Omega,$$

whenever

$$r = \mathfrak{B}(\zeta) = \sqrt{\frac{2}{1+e^{-2e^{i\theta}}}}; \quad s = m\zeta\mathfrak{B}'(\zeta) = \frac{\sqrt{2}me^{i\theta}e^{-2e^{i\theta}}}{(1+e^{-2e^{i\theta}})^{3/4}}; \quad \mathrm{Re}\left(1+\frac{s}{t}\right) = m(1+g(\theta)),$$

where $z \in \mathbb{D}$, $0 \leq \theta < 2\pi$ and $m \geq 1$. i.e. it is sufficient to show that

$$\left|\frac{r^\delta + \gamma s + \beta t - 1}{A - B(r^\delta + \gamma s + \beta t)}\right| \geq 1.$$

We now use the Lemma 2.1 to prove the result, for which, let us assume $w = r^\delta + \gamma s + \beta t$. From (1.3), (1.4) and (1.5), we have $\min g(\theta) = g(0)$, $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$ and $|r|= \omega(\theta) \leq \omega_{\theta_0}$. Thus

$$\begin{aligned}|w| &= |r^\delta + \gamma s + \beta t| \\ &\geq \gamma|s|\mathrm{Re}\left(1+\frac{\beta}{\gamma}\frac{t}{s}\right) - |r|^\delta \\ &\geq \gamma m d(\theta)\left(1+\frac{\beta}{\gamma}(mg(\theta)+m-1)\right) - (\omega(\theta))^\delta \\ &\geq m\frac{\sqrt{2}e}{(e^2+1)^{3/2}}\left(\gamma+\beta\left(m\frac{1-2e^4-e^2}{(e^2+1)^2}+m-1\right)\right) - \omega_{\theta_0}^\delta.\end{aligned}$$

Since $m \geq 1$ and by (3.2), we have

$$|w| \geq \frac{\sqrt{2}e}{(e^2+1)^{3/2}}\left(\gamma+\beta\left(\frac{1-2e^4-e^2}{(e^2+1)^2}\right)\right)-\omega_{\theta_0}^{\delta} \geq \frac{1+A}{1+B} > 1,$$

therefore, by Lemma 2.1, the result holds. ∎

Theorem 3.3. *Let $\delta \in \{0,1\}$, $\omega_{\theta_0} \simeq 1.438$ and $\beta, \gamma \in \mathbb{C}\backslash\{0\}$. If $p(z) \in \mathcal{H}$ such that*

$$(p(z))^{\delta} + \gamma z p'(z) + \beta z^2 p''(z) \prec \sqrt{1+z},$$

provided

$$\sqrt{2}e(\gamma(1+e^2)^2+\beta(1-2e^4-e^2)) \geq \left(\sqrt{2}+\omega_{\theta_0}^{\delta}\right)(e^2+1)^{7/2} \tag{3.3}$$

then $p(z) \prec \mathfrak{B}(z)$.

Proof. Here $q(z) = \mathfrak{B}(z)$ and $h(z) = \sqrt{1+z}$, thus

$$\Omega = h(\mathbb{D}) = \left\{w \in \mathbb{C} : \left|w^2-1\right| < 1\right\},$$

Now consider $\psi : \mathbb{C}^3 \times \mathbb{D} \to \mathbb{C}$ be as $\psi(r,s,t;z) = r^{\delta} + \gamma s + \beta t$. For ψ to lie in the admissible class $\Psi(\Omega, \mathfrak{B})$, we must have

$$\psi(r,s,t;z) \notin \Omega,$$

whenever

$$r = \mathfrak{B}(\zeta) = \sqrt{\frac{2}{1+e^{-2e^{i\theta}}}}; \quad s = m\zeta\mathfrak{B}'(\zeta) = \frac{\sqrt{2}me^{i\theta}e^{-2e^{i\theta}}}{(1+e^{-2e^{i\theta}})^{3/4}}; \quad \mathrm{Re}\left(1+\frac{s}{t}\right) = m(1+g(\theta)),$$

where $z \in \mathbb{D}$, $0 \leq \theta < 2\pi$ and $m \geq 1$. i.e. it is sufficient to show that

$$\left|\left(r^{\delta}+\gamma s+\beta t\right)^2 - 1\right| \geq 1.$$

We now use the Lemma 2.2 to prove the result, for which, let us assume $w = r^{\delta} + \gamma s + \beta t$. From (1.3), (1.4) and (1.5), we have $\min g(\theta) = g(0)$, $|s|/m = d(\theta) \geq \min d(\theta) = d(0)$ and $|r| = \omega(\theta) \leq \omega_{\theta_0}$. Thus

$$\begin{aligned}
|w| &= |r^{\delta} + \gamma s + \beta t| \\
&\geq \gamma|s|\mathrm{Re}\left(1+\frac{\beta}{\gamma}\frac{t}{s}\right) - |r|^{\delta} \\
&\geq \gamma m d(\theta)\left(1+\frac{\beta}{\gamma}(mg(\theta)+m-1)\right) - (\omega(\theta))^{\delta} \\
&\geq m\frac{\sqrt{2}e}{(e^2+1)^{3/2}}\left(\gamma+\beta\left(m\frac{1-2e^4-e^2}{(e^2+1)^2}+m-1\right)\right) - \omega_{\theta_0}^{\delta}.
\end{aligned}$$

Since $m \geq 1$ and by (3.3), we have

$$|w| \geq \frac{\sqrt{2}e}{(e^2+1)^{3/2}}\left(\gamma+\beta\left(\frac{1-2e^4-e^2}{(e^2+1)^2}\right)\right)-\omega_{\theta_0}^{\delta} \geq \sqrt{2} > 1,$$

therefore, by Lemma 2.2, the result holds. ∎

ORIGINAL PAPER

A novel hybrid intelligent approach for solar photovoltaic power prediction considering UV index and cloud cover

Abstract
The power generation from photovoltaic plants depends on varying meteorological conditions. These meteorological conditions such as solar irradiance, temperature, and wind speed are nonlinear and stochastic, thus affecting the estimation of solar photovoltaic (PV) power. Accurate estimation of photovoltaic power is essential for enhancing the functioning of solar power installations. The paper aims to develop a novel deep learning-based photovoltaic power prediction model on different weather conditions. The proposed model utilises a two-stage deep learning framework for accurate solar PV power prediction, which combines the long short-term memory (LSTM) and convolutional neural network (CNN) deep learning architectures. The key role of CNN layer is to identify the weather conditions, i.e., sunny, partially cloudy, and extremely cloudy, while the LSTM layer learns the patterns of solar power generation that depend on weather variations to estimate photovoltaic power. The proposed hybrid models consider meteorological factors, such as wind speed, irradiance, temperature, and humidity, including cloud cover and UV index to provide precise solar PV power prediction. The presented hybrid model has better performance metrices having root mean square error of 0.0254, 0.03465, and 0.0824, mean square error of 0.000645, 0.00120, and 0.00679, R^2 of 0.9898, 0.9872, and 0.9358, and mean average error of 0.0163, 0.0236, and 0.2521 for sunny, partially cloudy, and extremely cloudy weather conditions, respectively. The results demonstrate that presented deep learning-based novel solar PV power prediction model can accurately predict solar PV power based on instantaneous changes in generated power patterns and aid in the optimisation of PV power plant operations. The paper presents an effective methodology for prediction of solar power that can contribute to the improvement of solar power generation and management.

1 Introduction

In response to environmental concerns about greenhouse gas emissions and fossil fuel finiteness, renewable energy sources including solar, wind, hydropower, geothermal, and biomass have grown in popularity over the past several decades. Renewable energy sources are a sustainable alternative to fossil fuels due to their low carbon emissions and environmental effect, according to science. PV power is widely regarded as one of the most promising forms of renewable energy that has the potential to meet the requirements for energy production on a global scale [1]. According to reports, the renewable energy sector experienced a challenging phase in the first half of 2020, coinciding with the start of the COVID-19 epidemic. Nonetheless, the PV industry achieved a new record for new capacity in the second half of 2020, bringing the solar sector to its greatest level of more than 800 Gigawatts. Nevertheless, because solar energy is stochastic and unpredictable, it has created a variety of issues, such as voltage variations and uncertainties in a power grid, making it difficult to maintain a balance between power generation and load demand [2]. The fluctuation of solar irradiance received by PV modules demonstrates significant variability on days with cloud cover, mostly due to the dynamic

movement of clouds. The presence of stochastic variations significantly influences the production of solar PV systems. Given the non-stationary and nonlinear characteristics of this phenomenon, it is crucial to accurately forecast solar irradiance. The employment of accurate predictions is crucial in improving the dependability of photovoltaic plants and enabling efficient management of supply and demand in the realm of solar energy utilisation. There are multiple approaches available for predicting solar radiation, each designed to account for the nuances and complexity inherent in this dynamic process [3, 4]. Similarly, the demand for solar PV power forecasting arises from the inherent dynamism and intermittent characteristics of solar energy. Precise predictions facilitate the dependable and effective incorporation of solar energy into the wider energy framework, yielding advantages for grid management, energy strategizing, market transactions, and sustainability endeavours as a whole.

Due to the rising prevalence of solar PV systems in built environments, accurate forecasting is simultaneously becoming more essential and more difficult to achieve.

Accurate forecasting requires two critical components: minimising the negative impact of random solar PV power on the power system and giving and predicting solar PV power output data to grid operators. As a result, anticipating the output power of solar systems is essential for the effective operation of the electrical grid. The estimation of reserves is strongly reliant on the efficient administration and scheduling of a power system. It should be emphasised that solar forecasting is becoming increasingly relevant owing to the worldwide expansion in solar PV power output [5]. For this reason, the researchers looked at a number of different methods for predicting solar PV power. Statistical techniques (ST), artificial intelligence techniques (AI), and hybrid method techniques (HM) are the major categories that these approaches fall under [6]. Interdependence and correlation studies examined how climatic conditions affect performance metrics. Some variables are interdependent, but separating their correlation effects is challenging [7].

Predicting electricity generation from meteorological factors using random forest approach and pre-processing methods like feature selection and principal component analysis, forecasting models were assessed for computation time, accuracy, and statistical indicators [8]. In order to forecast the power output of a 960 kW_P grid-connected photovoltaic (PV) plant that was erected in Italy, statistical approaches that were developed on the basis of multiregression analysis and the Elmann artificial neural network (ANN) were used. Several inputs into the artificial neural network (ANN) included time series of both the PV power that was generated and the meteorological factors that were monitored [9]. This study investigates time series statistical, physical, ensemble, machine, and deep learning solar PV power forecasting approaches. Moreover, model parameter optimisation processes, major factors influencing solar PV power predictions, and input selection for solar PV power generation forecasting models are investigated. This research compares deterministic and probabilistic forecasting approaches to help solar PV power forecasting meet current grid system issues [10]. Authors in [11] proposed a simple yet accurate short-term power forecasting method for large-scale grid-connected photovoltaic plant (LS-GCPVs.) Three artificial neural network (ANN) models for bright, partly cloudy, and overcast days are developed using a 1-year record of solar irradiance, cell temperature, and power production from a 1-MWp photovoltaic facility in Southern Italy. Some statistical methods used for solar prediction, in [12, 13] statistical models, on the other hand, can only learn from linear data since they are incapable of processing complex information. As a result, ST-based techniques are not recommended for tackling problems that need nonlinear predictions, such as those related to solar PV power. It has become clear that AI-based models perform far better than their physical and statistical counterparts. It has been shown that AI-based models are more effective than physical and statistical ones. Author in [14] proposed incident solar radiation using limited meteorological dataset, and a wavelet-coupled support vector machine (W-SVM) model was utilised to forecast global incident solar radiation. The predictor variables for this model included sunshine hours (St), minimum temperature (T_{min}), maximum temperature (T_{max}), wind speed (U), evaporation (E), and precipitation (P). Author in [15] uses wavelet transform (WT) and artificial intelligence (AI) to anticipate a PV system's one-hour power production using solar radiation and temperature data. The suggested approach uses WT to improve PV power time series data and AI to better capture nonlinear PV variability. Modern machine learning methods are used to increase PV system dependability and stability. Time series long short-term memory (LSTM) network, ConvLSTM, CNN, RF, SVM, and XGBoost regression models predicted Johannesburg's sun irradiance [16]. AI-based approaches outperform traditional ones. AI-based approaches can handle imperfect inputs, update and maintain easily, and reason. A deep learning model using a group of gated recurrent units (GRU) and optimised hyperparameters uses sub-signals from similar days as network inputs. The solar PV power forecasting is calculated by integrating each sub-signal's projection. Author in [17] develops the random forest combines present and previous solar PV power predictions from different models and meteorological data to enhance day-ahead solar PV power estimates. The year-long performance of the combined model is compared to different combining methods. Smart persistence, artificial neural network, and random forest are compared to forecast global horizontal, beam normal, and diffuse horizontal sun irradiance in Odeillo, France, a place with significant

weather variability [18]. Author in [19] proposes a five-layer CNN-LSTM model for solar PV power projections using data from Temixco, Morelos, Mexico. In the hybrid model, the convolutional layer filters local data features, while the long short-term memory network extracts temporal characteristics. Finally, the five-layer hybrid model is compared against a single LSTM, a two-layer CNN-LSTM hybrid model, and two prominent benchmarks. Author in [20] introduces hybrid deep learning forecasting. Levy-flight beetle antennae search technique is used to find prior days comparable to the projected day from real-time large data.

CNNs and LSTM networks dominate deep learning. Time series data are used for such models because LSTM networks can capture sequence pattern information and CNN models can extract important features and filter out noise. CNNs can extract patterns of local trend and the same pattern that appears in different regions of time series data, but they are not usually adapted for long temporal dependencies. LSTM networks, on the other hand, are designed to work with temporal correlations but only use the attributes provided in the training set. Hence, a hybrid model using both deep learning techniques may increase forecasting accuracy. Hybrid model forecasting predicts power effectively.

The authors in [21] proposed a CNN-LSTM model to predict irregularities in PV power generation (PVPG) that other machine learning models could not learn well. The hybrid model can accurately predict how much solar PV power will be made by taking features from the things that affect how much solar PV power will be made. Then, to show how useful the model was, they compared it to other machine learning methods. From multivariate time series, the model learns trends in the PVPG and information about how time changes over time. The results show that the 5D CNN-LSTM model predicts PVPG very well and does better than the single LSTM model and the 2D CNN-LSTM model. In [22] day-ahead solar photovoltaic energy forecasting is performed using three different long short-term memory (LSTM) networks: LSTM, bidirectional long short-term memory (BiLSTM), and stacked LSTM, taking into account the power of the PV panels, the solar energy value produced, and the weather-related features. Chen et al. [23] proposed a photovoltaic power forecasting (PVPF) model that predicts the next day's production by grouping days by their weather conditions (sunny, cloudy, or rainy) and weather variables (solar radiation, total, and low cloud coverage). Accurate forecasting of solar radiation is required for predicting the output power of a photovoltaic power plant. This article assesses the possibility of a 20 MW solar photovoltaic power plant in Zahedan for this purpose. MLP, LSTM, GRU, CNN, and CNN-LSTM models are used to forecast solar radiation and temperature for the next 10 years (1984-2021) using monthly data. CNN outperforms other models with four input parameters: global horizontal irradiance, temperature, surface pressure, relative humidity (RH), and two output parameters: temperature and radiation [24]. To address the intermittent and stochastic character of photovoltaic (PV) power generation, [25] provides an ultra-short-term prediction technique employing a convolutional neural network (CNN) and long short-term memory (LSTM) hybrid model powered by empirical wavelet transform (EWT). An LSTM-ARMA combination model driven by ensemble empirical mode decomposition (EEMD) is suggested for ultra-short-term PV output prediction to minimise solar PV power generation intermittency and uncertainty [26]. In advanced concentrated solar power system management, short-term forecasting of direct normal irradiance (DNI), photons that did not interact with the environment on their approach to the observer, is important. Hybrid model for intra-hour DNI forecasting (5, 10, and 15 min). This hybrid technique uses a knowledge-based methodology for clear-sky DNI predictions using DNI data and a machine learning algorithm [27]. As the primary input, the proposed model employs a series of time-dependent irradiance estimates near the target location. These estimates are derived from satellite images and combined with other secondary inputs in an advanced neural network with convolutional and dense layers that has been trained using a deep learning technique [28].

The construction of renewable energy power plants is currently underway, resulting in a significant increase in energy production. The prediction of power output holds significant importance from an economic standpoint. Moreover, the act of predicting solar PV power output plays a crucial role in the strategic organisation of power production, enabling effective mitigation of challenges related to system stability and power-generating equilibrium. The field of renewable energy power production forecasting has been widely investigated using various methodologies, including physical, statistical, machine learning (ML), and artificial neural network (ANN) approaches.

Table 1 represents work considering artificial intelligence model models like ANN and deep learning LSTM and CNN are most accurate model for predicting irradiance, most of the authors have considered input parameters like wind speed, temperature, irradiance, and humidity for training the model for accurate prediction very few works is been done considering the cloud cover parameters and UV index for precise prediction. As reviewed, the above combination of LSTM and CNN models is best for precise solar PV power prediction.

Motivated by the above-discussed papers, we propose a CNN-LSTM model that tries to fully use CNN's superiority for extracting spatial features and the LSTM network's superiority for extracting time series features in order to increase the performance. The model that uses both temporal and spatial for training the deep learning models is proposed.

Table 1 Solar PV power prediction and irradiance prediction using deep learning approach

Ref	Method Proposed	Input Parameters	Dataset	Performance Metric	Observation
[29]	LSTM-CNN	Relative humidity, temperature, pressure, global horizontal irradiance (GHI), wind speed, and cloud type	1 Year	27.38 Wm − 2 – 37.02 Wm − 2 (MAE)	In several seasons across a year and under three distinct sky conditions, the suggested model outperforms the standard model in predicting accuracy
[30]	LSTM & ANN	Temperature, humidity, cloudiness, radiation, and two seasonal months (month of year and day of month)	1 Year	LSTM;1.23–1.82% (RMSE) ANN; 1.67–8.02% (RMSE)	When the offered methods were compared, LSTM outperformed ANN (single and multi-layer)
[31]	LSTM-PVPF	Wind speed, ambient temperature, global horizontal radiation, wind direction, air pressure, and daily rainfall	3 years	6 ~ 9 (MAPE)	The suggested models were less computationally costly and proved consistency, excellent accuracy, feasibility, and applicability for applications requiring large dataset sets
[32]	CLSTM	Solar irradiance	12 years	≈1.515% (RMSE) ≈4.672% (MAE) ≈1.233% (APB)	The suggested model outperformed other competing models in terms of percentage error; it had higher prediction performance and outperformed standalone models such as CNN, LSTM, and DNN
[33]	DWT-CNN-LSTM	Solar irradiance	8 years	32.411% (RMSE)	The enhanced forecasting accuracy of the proposed method via a comparison with traditional and single DL models
[34]	CNN–LSTM	Irradiation, Wind speed Temperature	6 years	5.1% (RMSE) 1 day 29.7% (RMSE) 1 h 10% (RMSE) 1 week	CNN-simple and CNN-LSTM perform best for 1-h, 1-day, and 1-week forecasts, with CNN-LSTM sometimes outperforming
[35]	CNN–LSTM	Relative humidity, GHI, DHI Wind direction, temperature	4 years	34.3% (RMSE)	This paper's deep learning model for solar power prediction shows that deep learning improves accuracy
[36]	GRU model LSTM model	GHI, Solar zenith angle, Relative humidity And Air Temperature	10 years	66% (RMSE) 67% (RMSE)	GRU is compared to long short-term memory (LSTM) utilising historical sun irradiance data and exogenous meteorological factors in GRU and LSTM considerably increased predicting accuracy, outperforming univariate and statistical models
[37]	LSTM-RNN	Humidity, Temperature, Wind speed, Precipitation - Cloud cover, Wind direction	14 years	60.139%(RMSE)	The suggested method is more accurate and saves 2% more energy than Feed forward neural network

The proposed model predicts the solar PV power output by looking at both historical PV power output data further the prediction based on local weather data, i.e., sunny, partially cloudy, and extremely cloudy which is considered in very few research papers. The temporal data show the long-term patterns and trends in the PV power output, while the local meteorological data show how the output changes over short periods of time. Generally, univariant time series prediction is done where mostly solar irradiance and solar PV power are forecasted here; in this paper, multi-inputs are used in intra-hour prediction solar PV power by using CNN-LSTM hybrid models. Many papers found have trained the models with hourly dataset which is very common in the literature review; intra-hour solar PV power prediction is found in very few papers; this paper uses 10-minute dataset to train the prediction models. Further according to the literature review, cloud cover and UV index are incorporated as inputs for predicting solar PV power in very few articles since they are an essential element that affects solar PV power prediction, the cloud cover and UV index have been modelled and then used as an input to train the deep learning models, and these parameters are included with common meteorological inputs for prediction the solar PV power. Further comparison of the proposed hybrid model is done with traditional ARIMA model and deep learning models, i.e., CNN and LSTM are done based on statistical indicators, i.e., RMSE, MSE, R^2, and MAE are done.

Main contribution of this work is as follows.

This research aims in design and implementation of a new hybrid deep learning model, i.e., CNN-LSTM for predicting solar PV power output that uses both temporal and local weather data at every 10 min aiming to enhance accuracy by capturing spatiotemporal dependencies.

The proposed work helps in improving the prediction accuracy of solar PV power, by considering the meteorological parameters such as irradiance, temperature, humidity, wind speed, cloud cover, and UV index, where the cloud cover and UV index play a significant role in the development of efficient model.

The developed model is validated for various seasons and weather scenarios such as sunny, partially cloudy, and extremely cloudy, and the performance found more accurate as compared to the existing models, i.e., LSTM and CNN.

The remaining paper is organised in five sections: Sect. 1 is the literature survey which helps in finding the gaps. In Sect. 2, the proposed hybrid CNN-LSTM model is introduced and the overview of the proposed analytical method is discussed, in Sect. 3 data preparation is given, Sect. 4 discusses the results, and Sect. 5 concludes the paper.

2 Proposed methods

2.1 CNN for feature extraction

CNN, a frequently used deep learning system for image, text, and signal inputs, comprises layers that extract object attributes. Fig. 1 displays the core construction of a CNN. In CNNs, feature extraction comprises a series of convolutional, activation, and pooling processes that gradually convert raw input data into hierarchical and useful features, allowing the network to learn and generalise from complicated patterns in the data.

The performance of models is determined by the number of stacked layers as well as the kind and size of the kernel. Convolution and pooling layers are utilised to extract deep features from the input layer data. These attributes are then passed into the fully linked layer, which categorises the result values. A CNN is used to extract hierarchical picture characteristics. Thus, a CNN is able to extract relevant information from sequential and two-dimensional input data [38]. In essence, a CNN aims to build several filters capable of extracting hidden characteristics via layer-by-layer convolution and data pooling as shown in Fig. 1. Finally, the fully connected layer merges these abstract features, and an activation function is employed to solve the classification or regression problem. The previous layer's feature maps are convolved with a convolution kernel in the convolution layer, and the output feature maps are generated using an activation function [39]. The previous layer's feature maps are convolved using a convolution kernel in the convolution layer, and the output feature maps are generated. 1D-CNNs are often used to process natural language or time series since they can handle sequential data. 1D-CNNs are different from 2D-CNNs because both the kernel that does the convolution and the sequence of data used have a one-dimensional structure. As seen in Fig. 2, the kernel of a 1D-CNN moves along a single dimension.

2.2 LSTM Model

The LSTM network is a type of recurrent network. Unlike "regular" MLP, RNNs use the input data's temporal context. The LSTM network is made up of layers that allow for the modelling of long-term dependencies in sequential data. The network has been trained to recognise patterns and trends in solar PV power, including temporal dependencies that lead to accurate forecasts. The LSTM output provides insights into the temporal dynamics of solar PV power production. This is possible in an RNN because the neurons are connected to each other in the same way more than once. An LSTM is able to store and recall information because of how the neurons in a memory cell are set up. These memory cells can hold information for an indefinite amount of time. As shown in

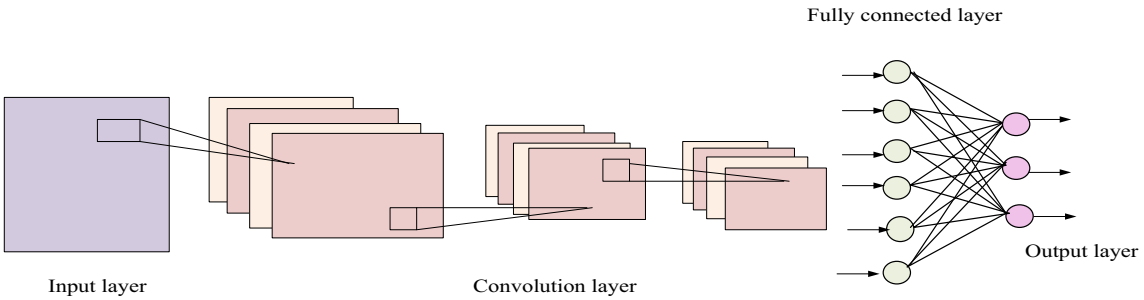

Fig. 1 Convolutional neural networks architecture

Fig. 2. 1D-CNN computation method

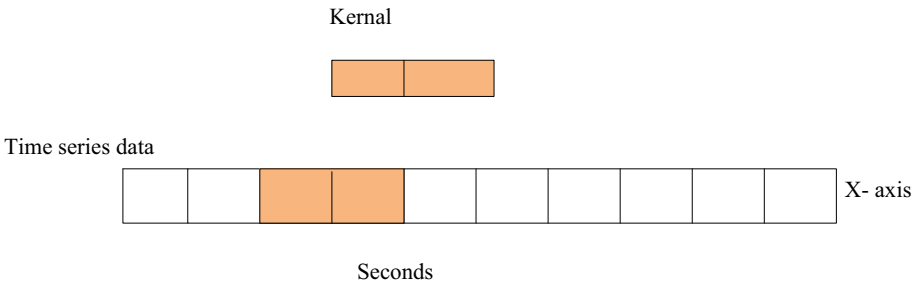

Fig. 3 Cell diagram of LSTM

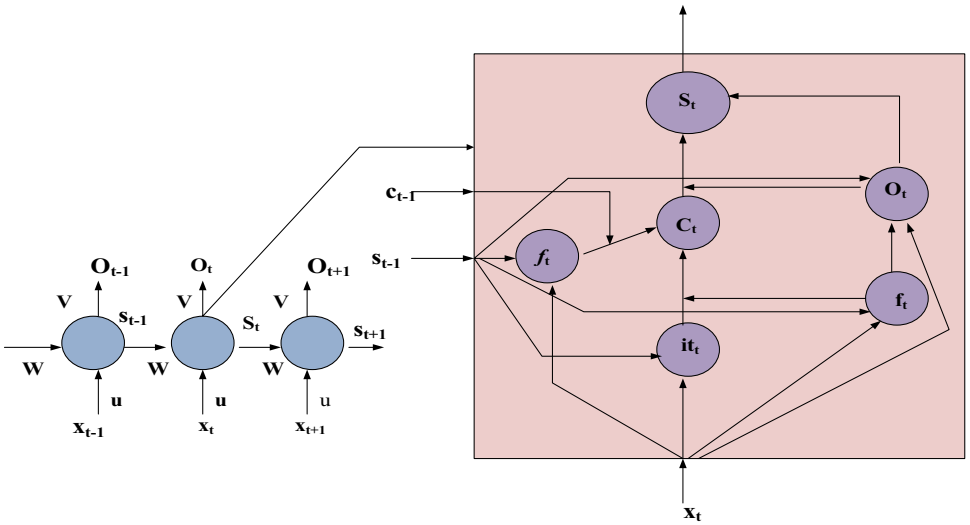

Fig. 3, the memory unit is made up of three gates labelled "Input gate (i_t)," "Forget gate (f_t)," and "Output gate (o_t)," as well as a recurrent connection. It controls how information comes into and goes out of the cell. Each gate in the LSTM gets information from the input neuron. Also, each gate has a function for turning it on and off. It has a single input, x_t, and two feedbacks from the previous state, s_{t-1} and c_{t-1}. The sigmoid activation function (g) is used by gates, while the tanh function is used by states. The LSTM's memory unit can be explained by a set of equations, where w is the weight parameter and b is the bias. An LSTM has a general structure of three layers: forget, input, and output. First, x_t and s_{t-1} are put into the LSTM architecture. Then, a decision is made about whether or not to keep the information. All of the tasks are done by the forget layer f_t [40].

$$f_t = g\left(w_{xf}\, x_t + w_{hf} s_{t-1} + b_f\right) \tag{1}$$

where activation function (g). Also, the input layer i_t is given by Eq. 2.

$$i_t = g(w_{xi} x_t + w_{hi} s_{t-1} + b_i) \tag{2}$$

$$c_t = f_t c_{t-1} + i_t i t_t \tag{3}$$

$$i t_t = \tanh(w_{xc} x_t + w_{hc} s_{t-1} + b_i t_i \tag{4}$$

Table 2 Hybrid CNN-LSTM Model parameters

Model layers		
Inputs	Size	3,7
Conv1D	Kernal Size	2
Max pooling	Pooling size	2
Conv1D	Kernal size	2
Max pooling	Pooling size	2
Flatten	–	–
LSTM layers	Hidden Neurons/Activation	64/ Relu
LSTM layers	Hidden Neurons/Activation	64/ Relu
Learning rate		0.0001
No. of epochs		500
Optimiser		Adam

The last step is to use the following expressions in the output layer to get the output data.

$$o_t = g(w_{xo}x_t + w_{ho}s_{t-1} + b_0) \tag{5}$$

$$s_t = o_t \tanh(c_t) \tag{6}$$

The process described above keeps going back and forth. This model learns weight parameters (w) and bias parameters (b) to minimise the difference between actual training values and LSTM output values.

2.3 CNN-LSTM model

In this method CNN and LSTM layers are combined as shown in Fig. 4; here, the selected inputs are sent to the CNN layer first for feature extraction, then to the flatten layer, and finally to the LSTM layer for prediction. After pre-processing, the CNN layer uses time series to find local features. The one-dimensional CNN works well for time series applications because the convolution kernel moves in a clear direction. This allows it to automatically pull out the unobserved data characteristics in the time direction. The retrieved features from the encoder (CNN) are fed into the LSTM architecture. The training data, as well as the various gates of the LSTM network, are constantly changed so that the LSTM model may find the relationships between the input and output sequence [41]. The proposed model parameters considered are shown in Table 2, and the proposed work is shown in Fig. 5.

Following are the steps for proposed work.

Stage 1—Input dimension reconstruction.

1. Inputs are selected that are correlated with the solar PV power six inputs are considered for training the models.
2. The reconstruction of inputs such as cloud cover, UV index, wind speed, irradiance, temperature, and humidity is done to extract spatial features, while historical solar PV power to obtain temporal features.
3. These inputs are given in the proposed model CNN-LSTM and LSTM and CNN deep learning model

Stage 2—Model development.

1. The deep learning models are developed with the help of Jupyter notebook platform.
2. The three deep learning models are trained individually by giving the inputs
3. Fine-tuning of parameters is done in this stage to make the model more accurate to predict solar PV power

Step 3—Evaluation and assessment.

The three deep learning models are employed for evaluating the performance in terms of three weather conditions Sunny, partially cloudy, and extremely cloudy and four different seasons (winter, summer, rainy, and post monsoon)

Stage 4—Interpret Results.

The best solar PV power prediction among the three deep learning models is analysed based on the performance metrices such as RMSE, MSE, MAE, and R^2.

3 Data preparation

This study uses dataset where irradiance and temperature are obtained from solar analyser 9018 T, humidity and wind speed are obtained from the solcast site, and cloud cover, UV index, and solar PV power are mathematically modelled for obtaining higher accuracy results. Solcast has access high-resolution historical time series and TMY data with minimal uncertainty for energy simulations and reliable solar resource assessments. Prepared for integration through API and the solar analyser is a portable instrument utilised for troubleshooting, monitoring, measuring, and analysing a variety of solar system parameters (Fig. 6). The data used are for one year from 24 November 2021 to 24 November 2022 containing 52,560 data, i.e., $365 \times 24 \times 6$, the data collected are at 10-min interval, and the dataset comprises inputs having irradiance, humidity, wind speed, cloud cover, temperatures, solar PV power, and UV index as shown in Fig. 7.

Figure 8 is a correlation matrix from where the correlation of several meteorological parameters with power has been shown, and in this proposed deep learning model from the

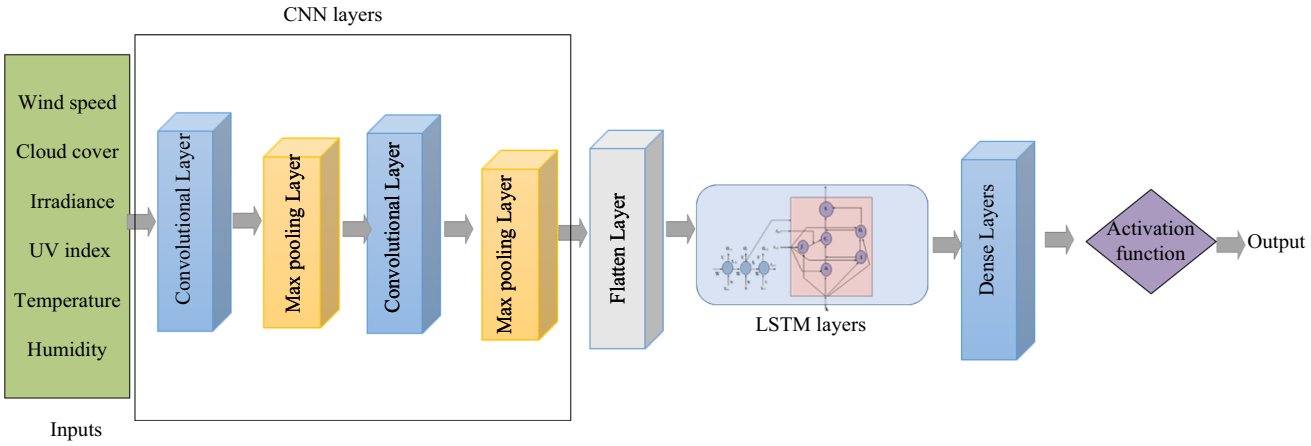

Fig. 4 Structure of CNN-LSTM hybrid model

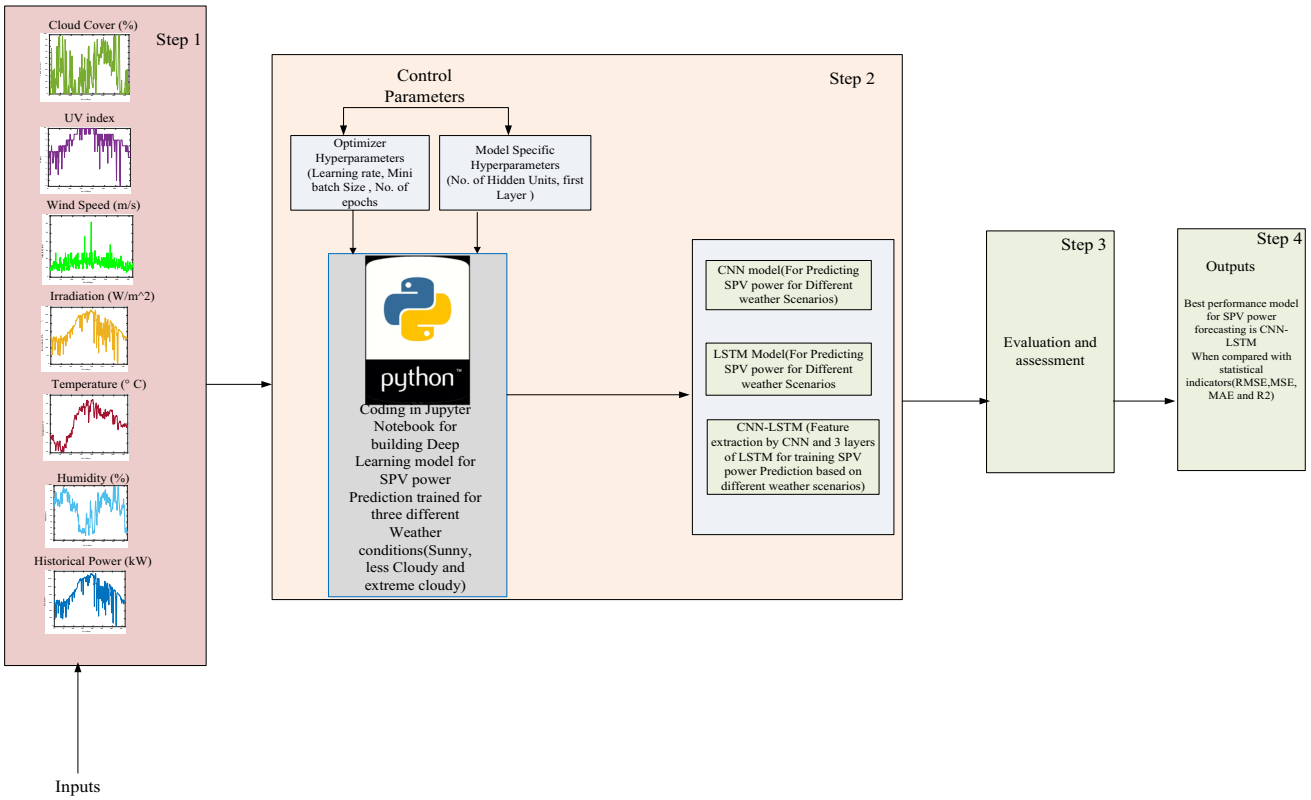

Fig. 5 Flowchart of Proposed work

correlation matrix, the inputs which are having highest correlation with solar PV power are considered as an input for prediction of solar PV power. The multi-inputs chosen in this paper are humidity, temperature, UV index, irradiance, wind speed, cloud cover, and solar PV power which are provided to the CNN, LSTM, and CNN-LSTM model for prediction of solar PV power.

3.1 Selection of inputs-based co-relation matrix

This section explains the inputs used to construct the solar PV power prediction model. The choice of input variables and location is critical to the operation of the PV system.

Despite the flat terrain, the movement of clouds and the kind of clearness index in the sky have an influence on the power output of the PV system. Solar PV power is affected by changes in ambient temperature, humidity, wind speed, cloud cover, UV index, and irradiance. Mathematical computation

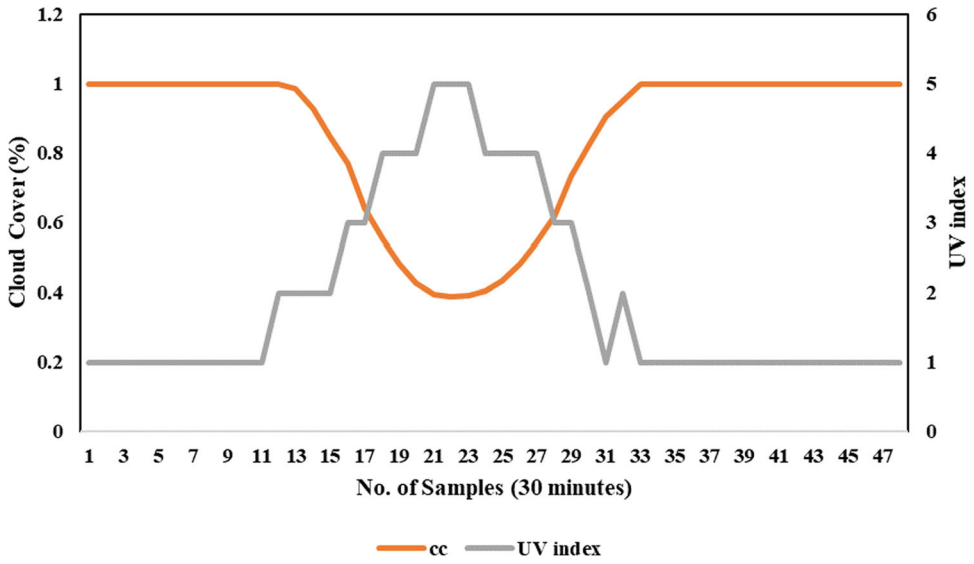

Fig. 6 Cloud cover and UV index relation for 24 h

of cloud cover and UV index is done in this section. The modelling of cloud cover and UV index was done with the help of meteorological parameters such as wind speed, irradiance, humidity, and temperature; these data are recorded on intra-hourly basis so as to get the cloud cover and UV index at 10 min of intervals. The usage of proper sorts of input parameters results in better performing prediction models. The inputs considered for prediction are shown in Fig. 7. This figure is plotted considering one year of data.

If the inputs used are redundant, have a low correlation factor, or essential parameters are missing, the prediction results will be complicated [42].

(A) Modelling of solar PV power

To forecast solar PV power, the real irradiance incident on the PV panel, the exact wind speed on the PV panel, and the PV panel temperature must be estimated. The solar power equation is as follows [16]:

$$P_{\mathrm{c}} = P_{\mathrm{r}} S_m \Big(1 + K_1 \log(S_m) + K_2 \log(S_m)^2 + K_3 T_{\mathrm{a}} + K_4 T_{\mathrm{a}} \log(S_m) + K_5 T_{\mathrm{a}} \log(S_m)^2 + K_6 {T_{\mathrm{a}}}^2 \Big)) \tag{7}$$

$$T_{\mathrm{a}} = \frac{S_m}{26.9 + 6.2 * w_{\mathrm{in}}} \tag{8}$$

$$S_m = \frac{S_{m1}}{1000} \tag{9}$$

$$T_a = T_{a1} - 25^o C \tag{10}$$

$$W_{\mathrm{in}} = \frac{{D_m}^{0.2}}{D_a} * w_s \tag{11}$$

Table 3 Parameters for calculating solar PV power

Parameters	Values
K_1	−0.046689
K_2	−0.072844
K_3	−0.002262
K_4	0.000276
K_5	0.000159
K_6	−0.000006
D_{m}	10 m
D_{a}	7.2 m

where P_c is the real time module estimated power, w_{in} is the speed of wind on the panel, T_{a} is the change in temperature caused by wind speed, and K_1–K_6 are PV module constants. D_{a} is the distance between the PV panel and the ground surface, and D_{m} is the distance between the anemometer and the ground surface. Table 3 shows the values of the constants used to calculate solar PV power. The power received for one year is displayed in Fig. 7g) when P_{r} is set to 5 kW.

(B) Modelling of Cloud Cover.

Cloud cover is the percentage of the sky that is obscured by clouds at a given place and time. It is frequently stated as a percentage or fraction range from 0 to 1, with 0 representing clear sky with no clouds and 1 representing totally overcast sky with clouds covering the whole sky.

Authors in [43] included cloud cover, temperature, relative humidity, and wind speed to develop a model for estimating global solar irradiance. The correlation can be expressed as

$$H = \frac{\left[H_o \sin\alpha_s \left(a_0 + a_1 \frac{N}{10} + a_2 \left(\frac{N}{10}\right)^2 + a_3(T_{\mathrm{a}}) + a_4.RH + a_5 w_s + d\right)\right]}{k} \tag{12}$$

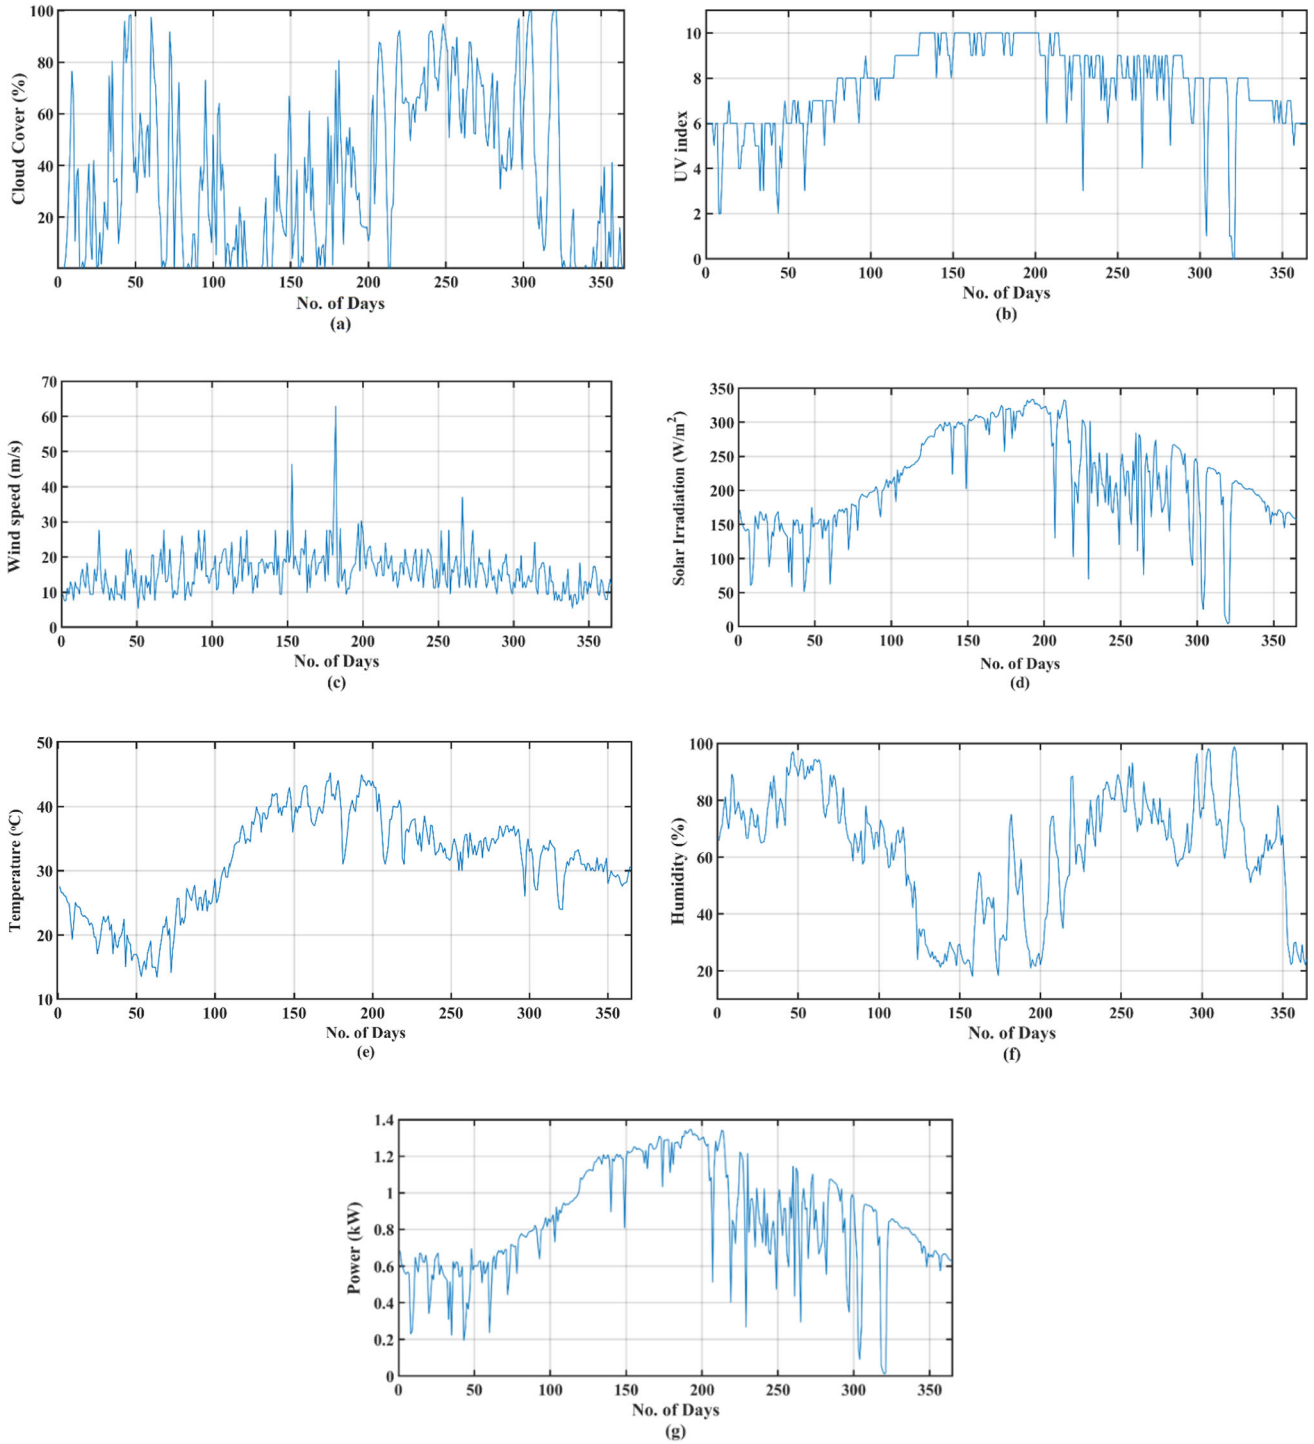

Fig. 7 Daily plots of 1 year for **a** cloud cover (%) **b** UV index **c** wind speed (m/s) **d** Irradiance (W/m.^{2}) **e** Temperature ° C **f** Humidity (%) and **g** power (kW)

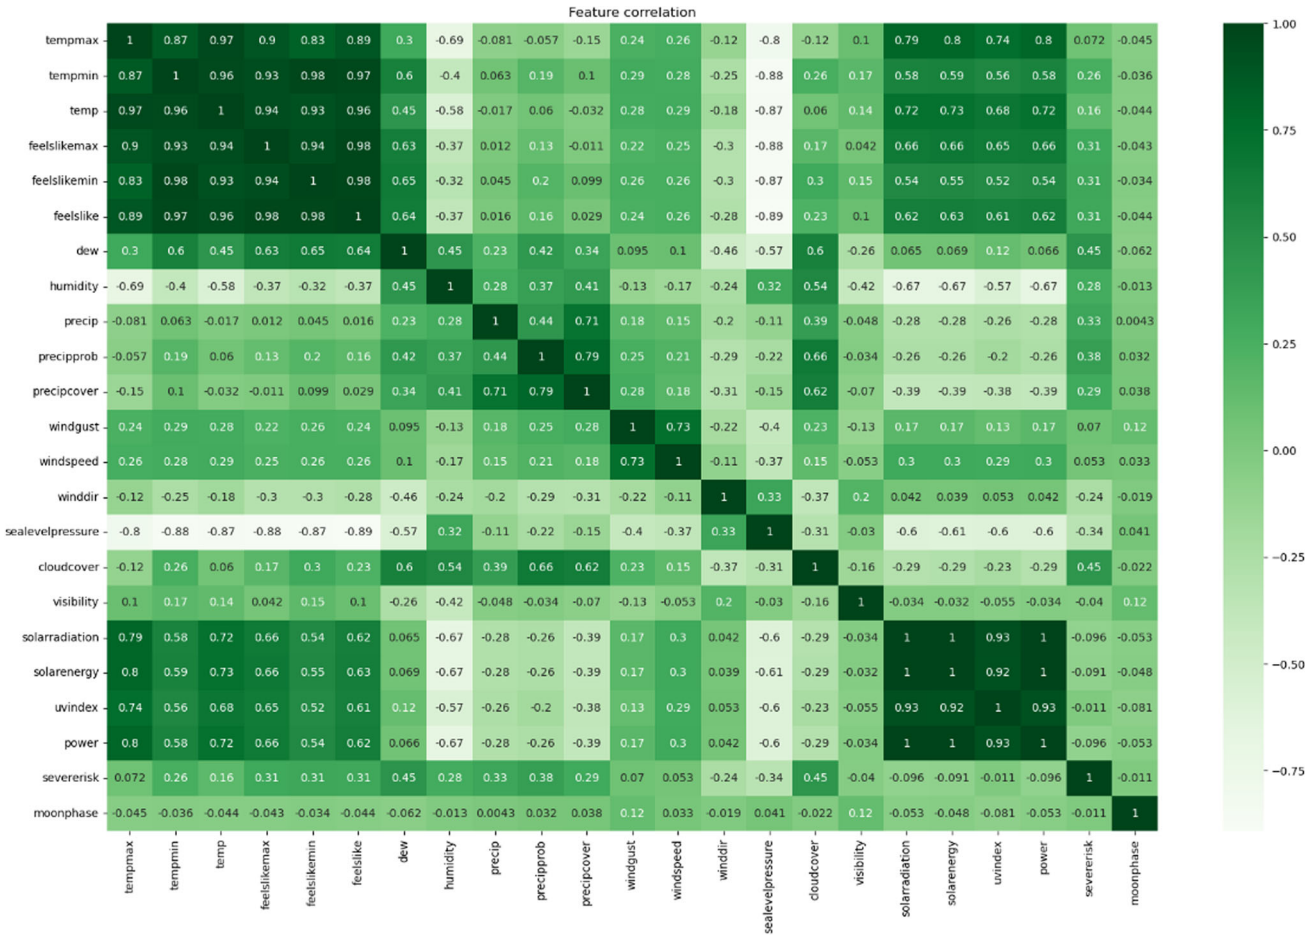

Fig. 8 Feature correlation matrix

There is an inverse relation between cloud cover and irradiance which means more the cloud less will be the irradiance.

where a_0, a_1, a_2, a_3, a_4, a_5, d, and k are regression coefficients; N is the cloud cover in tenths; T_a is the ambient temperature (°C). Here H is hourly global solar radiation (GSR) and H_o is GSR on any horizontal surface under clear sky [44]

There is an inverse relation between cloud cover and Irradiance which means more the percentage of cloud cover less will be the irradiance

$$H = H_o[1 - (1 - k)C] \tag{13}$$

where H_0 represents the expected daily global radiation for a clear sky, C represents the monthly average proportion of the daylight sky covered by clouds, and k represents a constant defining solar radiation transmission inside clouds. This formula has a structure similar to the Angstrom–Prescott (A-P) formula, which describes the relationship between sunlight duration (S) and global solar radiation (H) as:

Calculate H from Eq. (12)

Relation between H and S is as below

$$H = H_o\left[a + b\left(\frac{S}{S_o}\right)\right] \tag{14}$$

a and b are regression coefficients to be found. If the estimate is exact and devoid of aesthetic flaws, the total cloud amount should follow the relationship as [45]:

$$C = \left[1 - \left(\frac{S}{S_o}\right)\right] \tag{15}$$

Nonlinearity was discovered in the connection between C and $(1\text{-}\frac{H}{H_o})$, where H_o represents extraterrestrial solar radiation.

In this work, a relationship between cloud cover and sunlight every 10 min for a one-year New Delhi location data is considered having latitude is 28.749493 longitude is 77.118361. For more accurate cloud cover estimation, sunshine hour data are required.

We can estimate S/S_0 using the correlations reported in (13). Then, multiplying this amount by S_0 gives us the value of S. Cloud cover is calculated from (14).

(C) Modelling of UV index

Table 4 UV index scale range

UV index	Rating
11 or higher	Extreme
8 to 10	Very high
6 to 7	High
3 to 5	Moderate
2 or less	Low

The UV index is scaled from 0 to 11, with 0 being the lowest and 11 being the most intense. These figures are organised as follows:

UV index 2 or less means low, 3 to 5 means moderate, 6 to 7 means high, 8 to 10 means very high, and 11 or higher means extreme as in Table 4; ultraviolet (UV) radiation affects the solar PV power as the correlation with power is 0.8574.

UV relation with solar PV power is linear as the UV is more, power production will be high, and UV index is related to irradiance as in Eq. (16)

$$\mathrm{UVI} = \frac{1}{25}\mathrm{mWm^2UVE} \tag{16}$$

$$\mathrm{UVE} = 40\int_{0.28}^{0.40} E_{\mathrm{gl}}(\lambda)\varepsilon(\lambda)\mathrm{d}\lambda \tag{17}$$

where $E_{gl}(\lambda)$ and $\varepsilon(\lambda)$ are UV global irradiation at the surface and erythemal photobiological global radiation at the surface and the erythemal photobiological reaction action spectrum for human skin at the wavelength (λ). Micrometres (μm) are used to talk about the boundaries of the integral. Each UVI measure is equal to 25 milliwatts per square metre of broadband ultraviolet erythemal energy (UVE). The conversion from UVE (unit in W/m2) to UVI (unitless) makes it easier for people to understand UV levels (WHO—World Health Organisation World Meteorological Organisation United Nations Environment Programme International Commission on Non-Ionizing Radiation Protection, 2002). Since there aren't many UV radiometric standard readings, modelling and satellite remote sensing have been used to determine UVI.

Considering UV index will help in knowing the impact of UV index on solar modules performance. Its correlation with solar PV power is shown in Table 5.

The cloud cover and UV index from Fig. 6 show that when the cloud cover is 1, UV index is minimum, and vice versa, the cloud cover and UV index are modelled with the help of the meterological inputs and the data obtained is at every 30 min.

The correlation of the inputs with solar PV power is shown in Fig. 9 where the irradiance is the best factor which affects the solar PV power as in Table 5. UV index also has high correlation with solar PV power of 0.8574, temperature correlation with solar PV power is 0.6315, and wind speed correlation with power is about 0.08937. Sea-level pressure correlation with solar PV power is 0.3591, humidity and cloud cover show negative correlation which means higher the humidity solar PV power is reduced, and as the percentage of cloud cover increases, the solar PV power is reduced so its impact on solar power for prediction is an important factor. Dataset taken from solcast site has several parameters, and the feature correlation matrix is shown in Fig. 8. Table 5 depicts the relationship between the six specified inputs and the power of the PV system.

Table 5 Correlation coefficient between the six selected inputs to the solar PV power

Inputs	Correlation Coefficient (R^2)
Irradiance	1
Temperature	0.6315
Humidity	−0.6509
Wind Speed	0.3937
Cloud cover	−0.2931
UV index	0.8574

4 Results and discussion

Deep learning models and proposed hybrid models are employed for the prediction of solar power using multivariate time series data. The selection of the inputs that are utilised in the models that are run through deep learning is covered in Sect. 4. In the first place, a hybrid model that consists of CNN and LSTM features is presented. The dataset that was used for this analysis spanned one year containing 52,560 (365*24*6), and additional LSTM layers were connected in order to learn the pattern of solar PV power prediction based on weather scenarios, i.e. sunny, partially cloudy, and extremely cloudy. The CNN model assisted in the extraction of features from the dataset. The outcomes that were predicted are then compared with the LSTM and CNN models. In this section, the dataset was divided into four seasons: winter, summer (pre monsoon), rainy, and post-monsoon. Deep learning models such as CNN, LSTM, CNN-LSTM, and ARIMA are trained to predict solar power based on the seasonally divided dataset. To further improve the accuracy of solar power predictions, the models were trained on data divided by different weather patterns. This section is divided into three parts: The first part discusses the prediction based on seasonal patterns, i.e. (winter, summer, rainy, and post monsoon), and then the second shows the prediction based

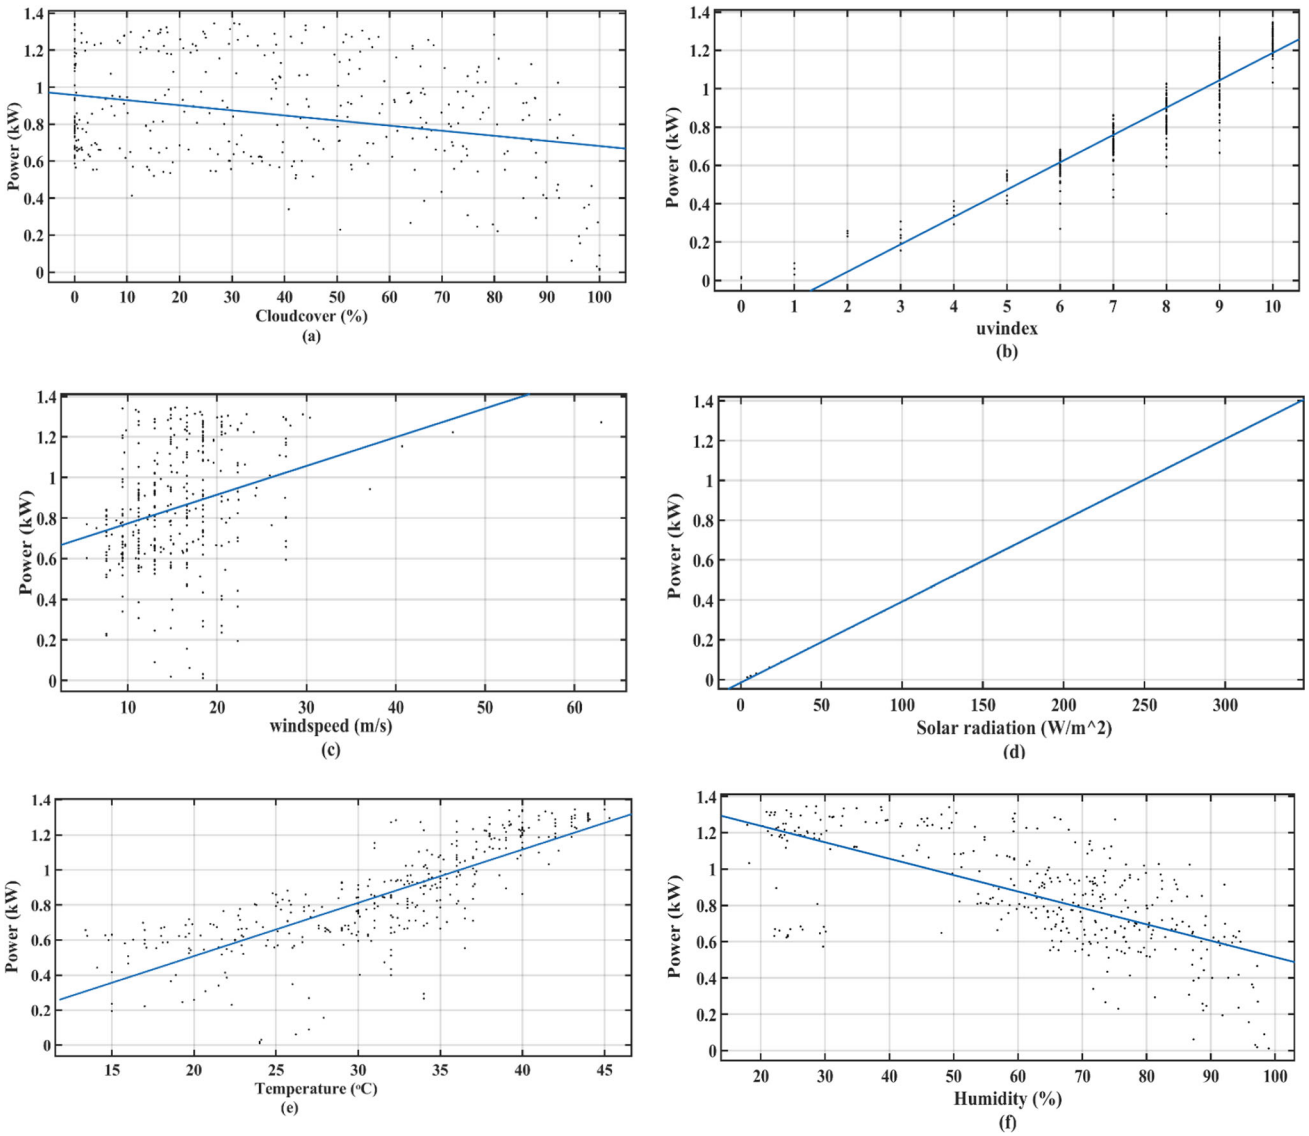

Fig. 9 Correlation plot of solar power with **a** cloud cover **b** UV index **c** wind speed **d** Irradiance **e** Temperature **f** Humidity

on three weather conditions, and the third part discusses the performance metrices.

Data are collected throughout a year and used to train deep learning models such as CNN-LSTM, CNN, and LSTM. In addition, the ARIMA model is trained to predict solar power. The dataset contains 365 data points for a year. Figure 10a depicts a comparison prediction plot of deep learning models. The error plots are shown in Fig. 10b. Based on the data shown in Fig. 10a, it can be concluded that the CNN-LSTM model is a better approach for predicting solar output, with less mistakes than other proposed methods.

4.1 Solar power prediction based on different seasons

The complete dataset is divided in four different seasons—winter, summer (pre monsoon), rainy (monsoon) and post monsoon—

The winter season encompasses the months of December to March.

The summer (premonsoon) season spans from April to June.

The monsoon season, known as the rainy season, spans from June to September.

And the post-monsoon season spans from October to December.

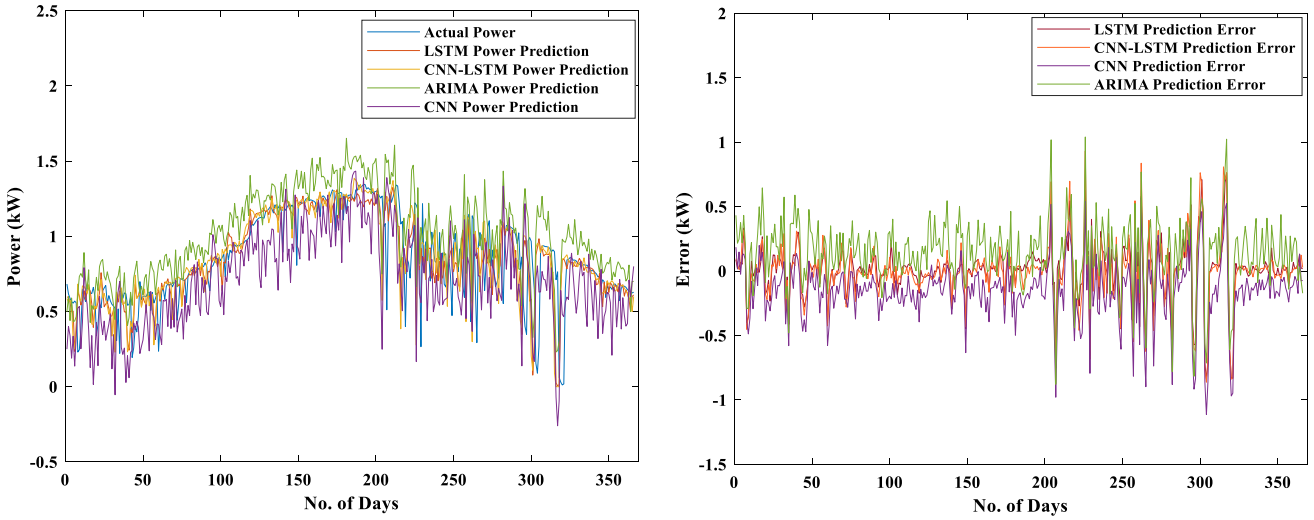

Fig. 10 Comparison of CNN-LSTM, LSTM, CNN and ARIMA models for one year data **a** solar PV power prediction plot with actual power **b** error plots

Table 6 Distributions of different weather conditions

UV index	Type of weather conditions
0% to 20%	Clear day (sunny)
21% to 60%	Partially Cloudy
61% to 100%	Extremely Cloudy

These different seasonal pattern datasets are used to train the deep learning models for different seasons. The deep learning models are trained based on different seasonal pattern and solar power prediction is made according to different seasons. From Fig. 11 it can be observed that maximum power is obtained in months of summer the variations are also less as compared to rainy, post-monsoon and winter conditions. Figure 11 shows the solar power prediction comparison plot and error plot of various deep learning models with the traditional model i.e. ARIMA.

4.2 Solar power prediction based on weather conditions

One year of solar power data is analysed based on three different weather conditions; these weather conditions are obtained based on Table 6.

Based on Table 6 the dataset is divided into 3 different weather scenarios. The sunny dataset has 144 data points, the partially cloudy dataset has 141 days, and the extremely cloudy dataset has 81 days.

4.2.1 Solar PV power prediction for sunny day

The data were collected from solcast site for one year where sunny condition data were used to train the three models, i.e. CNN, LSTM and the proposed hybrid CNN-LSTM. The sunny data are 144; these data are used to train the deep learning models for solar PV power prediction. From Fig. 12a it can be observed when there is sun in sky, power increases or decreases gradually in the sky. Seven inputs were given to all the three model for analysing; they were humidity, temperature, wind speed, solar radiation, UV index cloud cover, and solar PV power; the predicted output is solar PV power; the forecasted results for all the three models are shown in Fig. 12a; and it is observed that CNN-LSTM predicted more accurately than CNN model and LSTM model. The error between all the three models has been compared which shows CNN-LSTM has less errors than the other two models, the error plot is shown in Fig. 12b, and it is observed that CNN-LSTM have less error than other CNN and LSTM model.

Traditional methods of prediction are compared for sunny conditions in order to show that the proposed deep learning model performs much better than traditional model; the traditional model considered is ARIMA (auto-regressive integrated average). For comparison MSE is calculated for ARIMA model, it comes out to be 0.00220, and MSE for proposed CNN-LSTM model comes out to be 0.000645. The comparison is shown in Fig. 12a.

Additionally, the models are compared using root mean square error, mean absolute error, mean square error, and R^2 for the goal of conducting more accurate analyses.

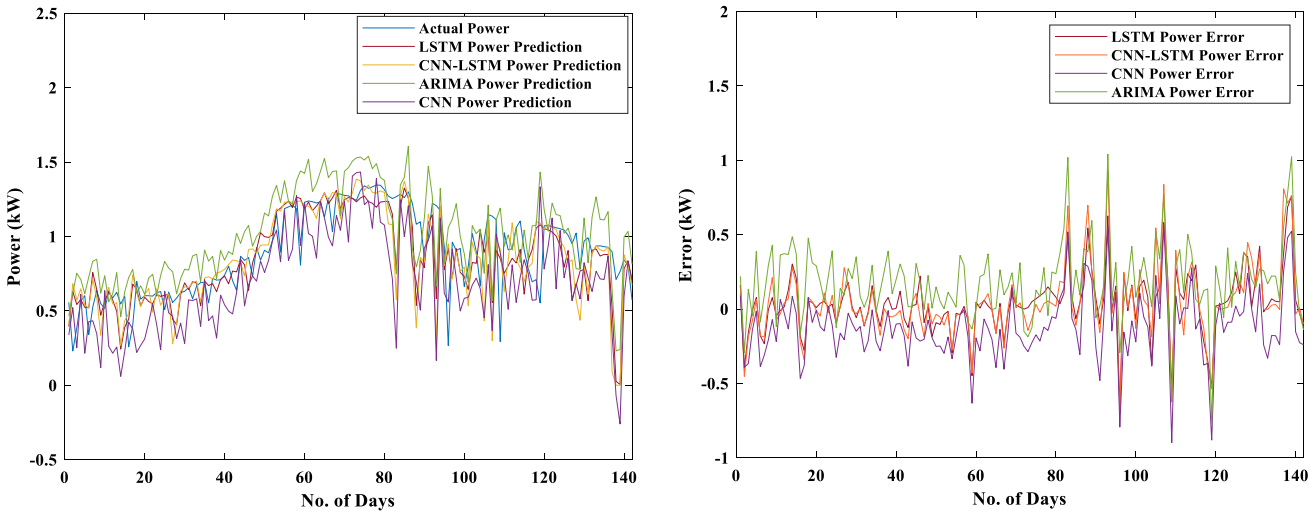
4.2.2 Solar PV power prediction with partially cloudy conditions

The data were collected from solcast site for one years where partially cloudy condition data were used to train the three models, i.e. CNN, LSTM and the proposed hybrid CNN-LSTM. The partially cloudy data are 141; these data are used to train the deep learning models for solar PV power prediction. From Fig. 13a it can be observed when there are clouds in the sky, there is an immediate shift in the amount of fluctuation in the power generation. In cloudy conditions the solar PV power fluctuated more as compared to Sunny conditions. Seven inputs were given to all the three models for analysing; they were humidity, temperature, wind speed, solar radiation, UV index cloud cover, solar PV power and the predicted output solar PV power; the forecasted results for all the three models are shown in Fig. 13. It is observed that CNN-LSTM predicted more accurately than CNN model and LSTM model. The error between all the three models has been compared which shows CNN-LSTM has less errors than the other two models and the error plot is shown in Fig. 13b. It



(a) (b)

Fig. 13 Comparison of CNN-LSTM, LSTM, CNN, and ARIMA model in partially cloudy conditions **a** Solar PV power prediction plot with actual power **b** error plots

can be observed that CNN-LSTM error is very less compared to CNN and LSTM model.

4.2.3 Solar PV power prediction with extremely cloudy conditions

The data were collected from solcast site for one years where extremely cloudy condition data were used to train the three models, i.e. CNN, LSTM, and the proposed hybrid CNN-LSTM. The extremely cloudy data are 81; these data are used to train the deep learning models for solar PV power prediction. In extremely cloudy condition, frequent fluctuation of solar PV power is observed. And the solar PV power generated is less in extremely cloudy conditions. From Fig. 14a it can be observed when there are clouds in the sky, there is an immediate shift in the amount of fluctuation in the power generation. Seven inputs were given to all the three models for analysing; they were humidity, temperature, wind speed, solar radiation, UV index cloud cover, solar PV power, and the predicted output solar PV power. The forecasted results for all the three models are shown in Fig. 14; it is observed that CNN-LSTM predicted more accurately than CNN model and LSTM model. The error between all the three models has been compared which shows CNN-LSTM has less errors than the other two models; the error plot is shown in Fig. 14b. It can be observed that CNN-LSTM error is very less compared to CNN and LSTM model. Traditional methods of prediction are compared for extremely cloudy conditions in order to show that the proposed deep learning model performs much better than traditional model; the traditional model considered is ARIMA. For comparison MSE is calculated for ARIMA model, it comes out to be 0.00820, and MSE for proposed CNN-LSTM model comes out to be 0.0012. The comparison is shown in Fig. 14.

4.3 Performance Evaluation

Performance estimation is an essential factor for determining a model's prediction accuracy. Root means square error (RMSE), moving average error (MAE), mean square error (MSE), and R^2 are variables used for comparison analysis. MAE aids in analysing the prediction model's constant prediction errors, RMSE assesses the model's overall accuracy, and R^2 represents the relationship strength between the predicted and actual values of the models. Table 7 shows partially cloudy, extremely cloudy, and sunny prediction error.

$$\mathrm{MAE} = \frac{1}{N}\sum_{i=1}^{N}|A_i - P_i| \tag{18}$$

$$\mathrm{NMAE} = \frac{\mathrm{MAE}}{\mathrm{Range}(A_i)} \tag{19}$$

$$\mathrm{MSE} = \frac{1}{N}\sum_{i=1}^{N}(A_i - P_i)^2 \tag{20}$$

$$\mathrm{NMSE} = \frac{\mathrm{MSE}}{\mathrm{Range}(A_i)} \tag{21}$$

$$\mathrm{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(A_i - Pi)^2} \tag{22}$$

$$\mathrm{NRMSE} = \frac{\mathrm{RMSE}}{\mathrm{Range}(A_i)} \tag{23}$$

where "N" number of windows, "A_i" actual value, and P_i does the Predicted value. The arithmetic mean of the actual value is $\overline{A}$.

Tables 7 and 8 analyse the performance of proposed methodology for varying weather conditions and seasons, respectively. According to Table 7, the CNN-LSTM algorithm's performance is superior than that of both CNN and LSTM which performs better than LSTM in the majority of deep learning applications; nevertheless, when compared with the CNN-LSTM model, its performance is less accurate in terms of performance evaluation. It is possible to draw the conclusion from Table 7 that the deep learning model is superior to cloudy weather circumstances in terms of its ability to forecast. Furthermore, it is possible to deduce from Table 8 that the models have a high level of accuracy when applied to the winter and post-monsoon datasets. In Tables 7 and 8, deep learning models perform better than the ARIMA.

CNN-LSTM is the deep learning model that performs the best across all of the weather patterns and seasons that were taken into consideration. In Table 9, the work of previous

author is compared with the proposed, and the results show that the proposed model is more effective.

5 Conclusion

A prediction model for PV power generation can enhance the design, operation, and stability of PV power plants by making more accurate forecasts based on meteorological data. But because the weather changes all the time, it is difficult to know how much PV power is produced. To make a good prediction model that only uses past data and leaves out data on solar radiation that is highly correlated with PV power production, you need a statistical method for figuring out how past and short-term data depend on each other. In this study, a CNN-LSTM hybrid model is proposed for estimating how much PV power is produced. The suggested model addresses the shortcomings of the previous models while retaining their benefits. The proposed model has been compared to other deep learning models in which only LSTM and CNN models are given multiple inputs. However, their performance is less accurate than the hybrid model because in the proposed hybrid model, the CNN model first learns the pattern of different weather conditions and then separates LSTMs for prediction solar PV power which help the model make more accurate prediction of PV power. A quantitative evaluation also showed that the proposed model has RMSE of 0.0254, 0.03465, and 0.0824, MAE of 0.0163, 0.0236, and 0.2521, MSE of 0.000645, 0.00120, and 0.00679, and R^2 of 0.9898, 0.9872, and 0.9358 for sunny, partially cloudy, and extremely cloudy day data, respectively. The normalised RMSE, MAE, and MSE came out to be 0.0176, 0.02739, and 0.00069 for sunny conditions. For partially cloudy conditions the normalised RMSE, MAE, and MSE came out to be 0.0175, 0.0258, and 0.00089 and for extremely cloudy conditions the normalised RMSE, MAE, and MSE came out to be 0.1947, 0.06366, and 0.00524. This model works better when the weather is sunny. When different season datasets are considered, the proposed CNN-LSTM models perform better in winter seasons and worst in rainy season. It is seen that PV power is increased in sunny conditions and decreased in non-ideal conditions, i.e. partially cloudy and extremely cloudy. The amount of power a PV power plant can make depends on the size of the installation and the weather, so the model needs to be changed. In a future study, the power-generating capacity of PV power plants should be changed to predict solar PV power. To make forecasts more accurate, optimisation methods automatically change models based on data from the system. Solar radiation and the properties of PV panels must also be analysed.

Table 9 Comparison of the proposed CNN-LSTM method with previous work

Ref	Method Proposed	Input Parameters	Dataset	Performance Metric	Observation
[46]	CNN-LSTM with a Semi Asynchronous Personalised Federated Learning Framework	Not given	990 days	0.689 (RMSE)	The suggested system greatly enhanced performance without exchanging raw data and further improved the PV power production performance projection
[47]	CNN-LSTM	Time sampling	1 month	0.03105 (RMSE)	CNN LSTM outperforms LSTM method
[48]	Deep ESN and CNN-Dee ESN	Wind speed, humidity, output power, global horizontal radiation, diffuse radiation, average phase current, and temperature	11 months	0.04101(RMSE) 0.0381(MAE) 3.3313 (MAPE)	In solar power generation prediction, the suggested hybrid model beat other single models and attained the lowest performance measure
[19]	CNN-LSTM	Solar power	1 year	0.485 and 0.2775 RMSE for sunny and cloudy, respectively	CNN-LSTM Outperforms in sunny Weather conditions
[49]	CNN-LSTM	Humidity Wind speed, output power, diffuse radiation, global horizontal radiation, average phase current, and temperature	–	O.623 (RMSE)	The suggested hybrid prediction model outperforms the single model LSTM, CNN
[50]	MODWT-LSTM	Wind speed, wind direction, Active power, temperature, humidity, global horizontal radiation, diffuse horizontal radiation, and daily rainfall	1 year	0.1231 (RMSE)	As compared to 1 day and 10 days, the suggested technique is found to be more dependable and to have the best produced efficient accuracy over a long-term prediction horizon of 1 month
	Proposed model	Temperature, humidity, wind speed, cloud cover, UV index, solar irradiance, Solar power	12 Months	0.025407 RMSE (sunny) 0.03465 RMSE (partially cloudy) 0.0824 RMSE (Extremely cloudy)

RESEARCH

A novel investigation on single-loop pulsating heat pipe filling with hybrid nanofluids: numerical and experimental

Abstract
Pulsating heat pipes (PHPs) employ to multiphase heat transfer between condensers and evaporators. The efficacy of PHP is predominantly contingent upon the thermos-physical property exhibited by its working fluid. The exergy analysis of evaporator, adiabatic and condenser system were performed to evaluate the efficiency and sustainability of energy conversion processes, it was also seen that exergy loss of condenser was 1.01% higher than evaporator. Further, 2-D numerical simulation of a cryogenic pulsating heat pipe (CPHP) was conducted and also numerical and experimental simulation was conducted, where simulation results agreed with experimental results with 10% similarity. The simulation employs the volume of fluid (VOF) model to capture the dynamics of two-phase liquid–vapor flow within the CPHP employing liquid acetone – Al_2O_3 as the working fluid. The diameter of the single turn is systematically varied, ranging from 1 mm to 2.5 mm, while maintaining the filling ratio (FR) within the range of 25% to 75%. The evaporator temperature is adjusted within the span of 85 K to 115 K. The PHP exhibited best thermal performance at inner diameter of 2 mm among (1, 1.5, 2, 2.5 mm) and filling ratio of 55% among (25%, 45%, 55%, 65% and 75%).

Abbreviations

PHP	Pulsating Heat Pipe
CLPHP	Closed loop pulsating heat pipe
Al_2O_3	Aluminum oxide
BP	Boiling point
LHv	Latent heat of vaporization
D	Diameter
ρ_l	Density of liquid
ρ_v	Density of vapor
µm	Micro - meter
d_{crit}	Critical diameter
T_{max}	Maximum Temperature
Cp	Specific heat capacity
$T_{e,o}$	Temperature of working fluid exiting evaporator
σ	Boltzman constant
CFD	Computational Fluid Dynamics
d	Internal diameter
σ	Surface Tension
FR	Filling ratio
g/s	gram/second
mm	millimeter
MPa	Mega Pascal
nm	Nano - meter
VOF	Volume of fluid
Te	Evaporator Temperature
Tsat	Saturated Temperature
Te,i	Temperature of working fluid before entering evaporator
Tc,i	Temperature of working fluid before entering condenser
ε	Emissivity
Evap	Evaporator

1 Introduction

The Pulsating Heat Pipe (PHP), a passive heat transmission system, has been utilized for approximately 30 years. In regards to its structure, the PHP can be described as a hollow and winding pipe. Khandekar and Groll [1] is credited with the development of these devices, which exhibit tremendous

potential in various applications such as solar energy utilization, waste heat recovery, aircraft thermal management, and electronics cooling as shown in Fig. 1 [2]. PHPs are passive cooling systems that operate with two-phase flow, providing rapid heat transfer. They consist of 3—sections: the adiabatic, evaporator section and the condenser. The condenser as well as evaporator parts are thermally connected to a cold sink and a heat source respectively, using thermal anchors. Capillary tubing is employed to connect the condenser and evaporator part, these are bent back and forth repeatedly. There are three primary types of PHPs: Closed-loop with a check valve, Closed Loop, and Closed-ended PHPs [3]. In a CLPHP, a slug flow pattern is observed, characterized by the presence of vapor and liquid slugs, as depicted in Fig. 1. As vapor plugs move towards the condenser section, they undergo a reduction in volume caused by re-condensation and temperature influences, with certain vapor bubbles fully transitioning into the liquid phase. Boiling in the evaporator region results in the growth of existing vapor bubbles and the formation of new ones. These expansions and contractions of the two-phase fluid generate pressure fluctuations necessary for driving the flow. Fluids characterized by a high $(dP/dT)_{sat}$ are considered preferable due to the substantial pressure shift observed in vapor bubbles with only a slight temperature adjustment at saturation levels [4].

However, the selection of the working fluid plays a crucial role in determining the performance of a PHP. Selecting a suitable working fluid that meets the operating temperature range, heat transfer requirements, and compatibility with the materials used in the PHP can be a challenge. Furthermore, the availability and cost of the chosen fluid can also impact

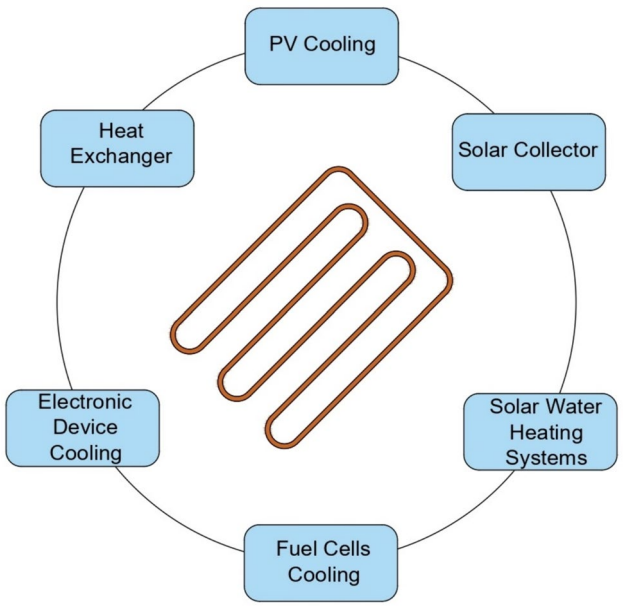

Fig. 1 Applications of PHP

the practicality of PHP implementation [5, 6]. Further, Zhang et al. [7] examined that it is simpler to start up a working fluid with low surface tension, low dynamic viscosity and high thermal conductivity. Acetone's low latent heat and low surface tension make it simpler to dry out than other working fluids [8]. The increased flow speed of nanofluids in PHP was noted by Zhang et al. [9]. PHP can typically start and run between 20 and 80% of the filling ratio. While, high filling ratio prevents the production of vapor plugs and impedes flow, whereas a low filling ratio makes it difficult to cause oscillation of the operational fluid [10, 11].

The sensible heat also plays a crucial role in dissipating a significant amount of heat as the heat flux supplied to the evaporation section is minimal. In such cases, where the heat transfer rate is relatively small, the majority of heat transfer occurs through the sensible heat mechanism. Further, the ability to maintain the oscillation motion at a lower required heat flux is crucial for the performance and effectiveness of the PHP. Therefore, opting for a working fluid with lower viscosity can contribute to enhancing the overall heat transfer efficiency of the system [12, 13]. The results of Qu et al. [14] demonstrated that among the tested working fluids such as acetone, methanol and water, acetone exhibited the best heat transfer performance in the PHP system. Despite the low heat flux input, acetone proved to be the most effective choice in terms of facilitating heat transfer within the PHP. The major portion of heat transfer is accomplished through the sensible heat of the liquid, while the latent heat of vaporization plays a secondary role [15]. Liang et al. [16] investigated the thermal performance of a cryogenic PHP and specifically examined the influence of condenser temperature and filling ratio. The findings demonstrated that a lower filling ratio led to a dry-out phenomenon occurring at lower heat inputs. Zhang et al. [17] conducted experiments taking FC-72, ethanol, and water as working fluid, and found that the best fill ratio for all three fluids was around 70%, with lower and higher fill ratios resulting in lower thermal performance. At this fill ratio, the mean temperatures in the heating section were lowest and the thermal performance was highest. In an experimental study conducted by Saha et al. [18], two open PHPs were examined. The results of the experiment indicated that the PHP with a 0.9 mm inner diameter exhibited superior performance compared to the PHP with a 1.5 mm inner diameter. It is worth noting that the physical properties of the working fluid can influence the impact of the inner diameter on the PHP's performance, as highlighted by Rittidech et al. [3]. Specifically, it was observed that a larger inner diameter resulted in improved heat transfer performance for R123, while it led to poorer performance for ethanol. Hybrid nanofluids, which are a combination of base fluids and nanoparticles, are being

increasingly explored for use in PHPs due to their potential to enhance thermal performance. The addition of nanoparticles to the base fluid in PHPs can offer several benefits such as improved thermal conductivity and heat transfer coefficient, reduced thermal resistance and controlled fluid flow. However, there are some challenges in utilization of nanofluids such as particle agglomeration, difficulty in nanoparticle dispersion [19–21].

Karthikeyan et al. [22] explored the use of nano-fluids, specifically Ag-deionized water and Cu-deionized water, within the range of heating power from 50 to 240 W. Their findings indicated a noteworthy 33.3% increase in the heat transfer capacity of the PHP when employing nano-fluids compared to the utilization of pure deionized water. Ji et al. [23] scrutinized the heat transfer characteristics of the PHP utilizing Al_2O_3-water with varying particle sizes (80 nm, 50 nm, 22 µm, and 2.2 µm). Their observations revealed that the initiation power of the PHP decreased proportionally with the reduction in particle size. Tanshen et al. [24] examined the thermal resistance of the PHP employing nano-fluids containing multi-walled carbon nanotubes (MWCNT) across four mass ratios (0.2, 0.3, 0.05, and 0.1 wt%). The outcomes they obtained suggested that the PHP attained its peak inner evaporation pressure, and concurrently, the thermal resistance of the PHP reached its minimum at a mass ratio of 0.2 wt%. Changes in boiling performance in heat pipes directly affect the surface properties, as indicated in relevant literature sources [25–27]. The presence of nanoparticles in the base fluid does not significantly increase the thermal conductivity of the working fluid. However, the oscillatory movement of particles within the working fluids may offer additional enhancement to the thermal performance of the CLPHP.

From this comprehensive review, it becomes evident that there are two significant research gaps noticed.

(a) No previous studies have explored the effects of acetone- Al2O3 on the exergy and sustainability. These analyses serve as contemporary tools for evaluating the effectiveness of systems, offering valuable insights and conclusions.
(b) Additionally, there is a notable absence of research investigating the optimum diameter and filling ratio for acetone- Al2O3 fluid to get maximum performance.

The first section of the study evaluates the thermodynamic analysis and sustainability analysis. The subsequent section outlines the governing equations and computational techniques utilized for the CFD analysis at various diameter to analyze the flow characteristics within a PHP. Getting optimum diameter, filling ratio was varied to get the enhanced performance of PHP.

2 Experimental setup and description of operation of a PHP

The internal pipe diameter, represented by the Bond dimensionless number ($B_0 = (\rho_l - \rho_v)gd/\sigma$) plays a crucial role in characterizing phase separation within the PHP device [28]. In Taylor bubble-rising experiments involving water boiling in vertical tubes, it has been observed that when the bond number is less than 2, the vapor bubble and the wall film maintain radial symmetry due to the dominant influence of surface tension over gravitational force [29]. PHPs exhibit remarkable operational stability across various orientations, allowing them to function successfully. The stability is attributed to the diverse flow regimes that can be observed in a PHP, as depicted in Fig. 2. Under low heat loads, the vapor phase diffuses into the liquid phase, leaving the nucleation sites on the walls. As evaporation intensifies, the number of small and micro-bubbles increases, with the smaller bubbles migrating towards the core region. These bubbles engage in interactions with each other and frequently merge, forming

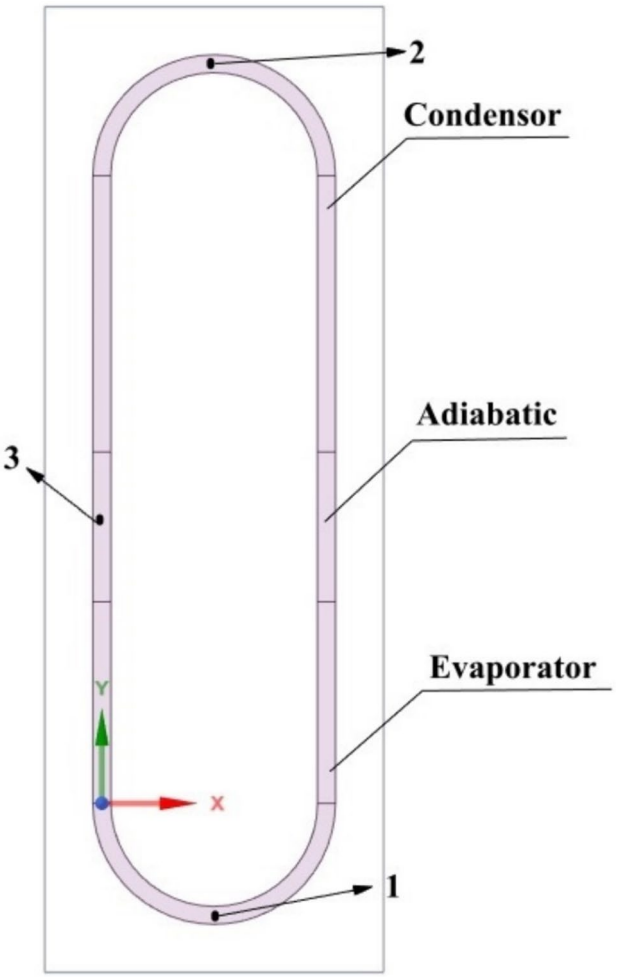

Fig. 2 Single loop pulsating heat pipe model

larger bubbles. With a continued rise in heat load, the dimensions of these aggregations of bubbles progressively enlarge, eventually resulting in the separation of the mixed-phase fluid into alternating liquid segments known as slugs and vapor segments referred to as plugs. When the capillary length is larger than internal diameter of the pipe, the aforementioned formations spread radially and occupy the pipe's core space. With increased energy input, the phase change intensifies the turbulence and movement, making the segments unstable. In such unstable conditions, the structures have a tendency to break down into chaotic swirls, eventually forming small droplets. This phenomenon gives rise to a flow regime with enhanced heat transmission capabilities, known as annular flow [30, 31]. Within such a regime, the flow field within The PHP can be segmented into two clearly defined regions. The core region comprises a liquid film wall layer along with a mixture of dispersed liquid and vapor phase. Notably, significant interactions occur between the wall and core regions in this mode. At extremely elevated levels of core flux, droplets carried along in the core flow have the potential to condense into liquid masses, akin to vapor conglomerates. This condensation process contributes to pressure instability [32]. PHPs leverage these instabilities to generate a unique mixed-phase flow, setting them apart from conventional heat pipes. The fluid within the PHP is propelled along the serpentine tube by a pressure gradient, which arises due to local variations in the rates of condensation and evaporation. Pulsation is initiated by the shifting direction of chains of slugs and plugs due to an imbalance in the total force [33]. The areas of a PHP have varying velocities due to expansion from liquid evaporation and contraction from vapor condensation, respectively. These localized motion fields have the potential to interact with each other as waves and change in strength as a result.

A region exhibiting alike flow velocity and direction can form if certain locations are connected as the heat load rises. The circular flow regime, which enhances heat capacity and can withstand a large heat load, tends to emerge in the single-directional field [34]. The robust interactions of the wall boundary layer also contribute to heat transmission. A bubble traveling through the channel exhibits an unbalanced head and a less orderly tail. The bubble having thin liquid film is disrupted by the turbulence created in the wake zone, leading to a local increase in the heat transfer coefficient. This enhanced convection is primarily responsible for thermal transfer that surpasses conduction within the solid wall by orders of magnitude [35].

Figure 3 illustrates the experimental apparatus employed in the present study. The condensation, adiabatic and evaporation sections comprise a length of 50 mm each. The pulsating heat pipe is constructed using quartz glass having 6 mm outer diameter. For visualization purposes, it has an inner diameter of 3.8 mm. The current PHP has a sufficiently small inner diameter, allowing the working fluid, water, to spontaneously disperse as liquid–vapor slugs. It is oriented vertically, with the bottom-heating pattern. A heating wire, measuring 0.4 mm in diameter, is wrapped around the surface of the evaporation section. Additionally, a water cooler is submerged in the condensation area. The water cooler's inlet temperature is maintained at 25 °C, while a fix flow rate of 4.69 g/s is prescribed. The current PHPs undergo evacuation to 0.079 MPa using a vacuum pump. Subsequently, water is introduced into the PHPs through the injection entrance, as illustrated in Fig. 3. In this study, different filling ratios of 30%, 40%, 50%, and 60% are employed for the PHPs. Furthermore, the heating power can be adjusted within the range of 5W to 40W by modifying the output voltage. The experimental setup depicted in Fig. 3 includes six T-type thermocouples positioned on the outer wall of the PHP. These thermocouples are specifically labeled as Te_1 and Te_2 for the evaporation section, Ta_1 and Ta_2 for the adiabatic section, and Tc_1 and Tc_2 for the condensation section. Real-time temperature data is collected using an agilent 34970A data acquisition system, which is connected to a computer and programmed to scan the temperatures at intervals of 5 s. This continuous data acquisition enables the determination of the experimental thermal resistance (Rex) of the PHP. The average temperatures of the evaporation and condensation sections are denoted as T_e and T_c, respectively. The input heating power is represented by Q in the equation $Rex = \frac{(T_e - T_c)}{Q}$.

The working fluids having minimum latent heat of vaporization, lower boiling point and liquid specific heat can begin pulsating very readily inside the pulsating heat pipe, however, they are low energy carrier. Further, low dynamic viscosity fluids experience lesser flow resistance resulting strong pulsating effects due to high flow rate [33]. Table 1 shows the thermos-physical properties of water, acetone and acetone-Al_2O_3 and it was observed that acetone-Al2O3 consist of low dynamic viscosity, liquid specific heat and latent heat of vaporization and that improves pulsating effects in PHPs. The diameter is varied from 1 mm to 2.5 mm based on bond no which shows the critical diameter 2.1 mm. Further, investigation is performed order to get the optimum filling ratio which is considered from 25 to 75%.

Uncertainty analysis involves estimating the true value from the mean of repeated measurements. The errors observed in the test data primarily stem from the heating procedure and the subsequent recording of temperature data. For a given parameter, six experiments were conducted, and the average was used for error analysis. The uncertainty associated with the total thermal resistance of PHP can be estimated using Holman's square root rule as shown in Eq. 1 [36].

Water	2257	72.8	100	998	0.599	4.18	1.01	1.92	[33]
Acetone	523	23.7	56.2	792	0.170	2.35	0.32	6.27	[33]
Acetone-Al_2O_3	516	24.8	-	798	0.206	2.32	0.28	-	Present

represent the uncertainties associated with these measurements. Consequently, the comprehensive uncertainty of the experimental findings can be described as following Eq. (2).

$$\frac{\Delta R}{R} = \sqrt{\left(\frac{\Delta(T_{ave,e} - T_{ave,c})}{Q_{in}}\right)^2} = \pm 1.96\% \tag{2}$$

The change in thermal resistance (ΔR), when considered, reveals that the maximum uncertainty in the overall heat input and thermal resistance in PHP falls well within the ± 1.96% range.

The total uncertainty value is ± 1.96%, which falls within the range reported by prior studies [37].

3 Exergy analysis

This is a thermodynamic approach employed to evaluate the quality or usefulness of energy within a system. It takes into account both the energy content and the thermodynamic irreversibility in the system [38]. In the case of a PHP, two-phase heat transfer passive device, it can be performing an exergy analysis to evaluate the efficiency and losses within the system. Here a single turn PHP with an adiabatic, evaporator, and a condenser section. The exergy balance equations for each section are as follows:

Evaporator section

The heat transfer in a PHP involves two main components: liquid slug flow and vapor flow. The exergy change in the evaporator section is given by Eq. 3 [3]:

$$\Delta Ex_E = mC_p[(Te, i - Te, o) - To \ln\left(\frac{Te, i}{Te, o}\right)\}] \tag{3}$$

The heat loss can be expressed as the sum of convective heat transfer and radiative heat transfer as in Eqs. 4 and 5 [39]

$$\Delta Ex_{e,1} = \Delta Ex_{co,1} + \Delta Ex_{ra,1} \tag{4}$$

$$\Delta Ex_{co,1} = hco \times As \times \Delta T \tag{5}$$

where, $\Delta Ex_{e,}$ $\Delta Ex_{e,l}$, $\Delta Ex_{co,l}$,, $\Delta Ex_{ra,l}$ are net exergy change across evaporator, exergy loss through evaporator, convective exergy loss and radiative exergy loss respectively.

Radiative heat transfer in a PHP evaporator occurs through thermal radiation between the evaporator surface and the surroundings. The radiative heat transfer rate can be estimated using the following Eq. 6 [39]

$$\Delta Ex_{ra,1} = \sigma \times \varepsilon \times As \times (T_{sf}^4 - T_{sr}^4) \tag{6}$$

Adiabatic section

Since the adiabatic section does not involve any heat transfer, the exergy change is only due to the fluid friction losses:

$$\Delta Ex_adiabatic = W_friction$$

where:

$\Delta Ex_adiabatic$ is the change in exergy in the adiabatic section,

$W_friction$ is the work done against fluid friction losses. It is assumed that the pressure drop is very less throughout the adiabatic section therefore the losses in adiabatic section is negligible.

Condenser section

Similar to the evaporator section, the exergy change in the condenser section can be expressed as per Eq. 7 [7]:

$$\Delta Ex_c = mC_p[(Tc, i - Tc, o) - To \ln\left(\frac{Tc, i}{Tc, o}\right)\}] \tag{7}$$

where:

The heat loss can be expressed as the sum of convective heat transfer and radiative heat transfer as in Eqs. 8 and 9 [9].

$$\Delta Ex_{c,1} = \Delta Ex_{co,1} + \Delta Ex_{ra,1} \tag{8}$$

$$\Delta Ex_{co,1} = hco \times Asc \times \Delta T \tag{9}$$

where, ΔEx_c $\Delta Ex_{c,1}$, $\Delta Ex_{co,1}$, $\Delta Ex_{ra,1}$ are net exergy change across condenser, exergy loss through condenser, convective exergy loss and radiative exergy loss respectively. Radiative heat transfer in a PHP evaporator occurs through thermal radiation between the evaporator surface and the surroundings. The radiative heat transfer rate can be estimated using the following Eq. 10 [40]

$$\Delta Ex_{ra,1} = \sigma \times \varepsilon \times Asc \times (T_{sf}^4 - T_{sr}^4) \tag{10}$$

The exergy efficiency of a PHP can be calculated by comparing the actual exergy transfer in the system to the maximum possible exergy transfer. The exergy efficiency $\eta_{\Delta E_X}$ is defined as the ratio of the actual exergy transfer to the maximum exergy transfer as given in Eq. 11 [39, 40]:

$$\eta_{\Delta E_x} = \frac{(Ex_out - Ex_in)}{Ex_in_\max} \tag{11}$$

Sustainability Assessment Sustainable development requires the resources to be used efficiently. Employing the exergy analysis method proves to be a valuable tool for optimizing advantages and utilizing resources efficiently. In this analysis, the SI method directly related to exergy efficiency $\eta_{\Delta E_x}$ is used to improve and contribute to the sustainable development as follows [41] as in Eq. 12:

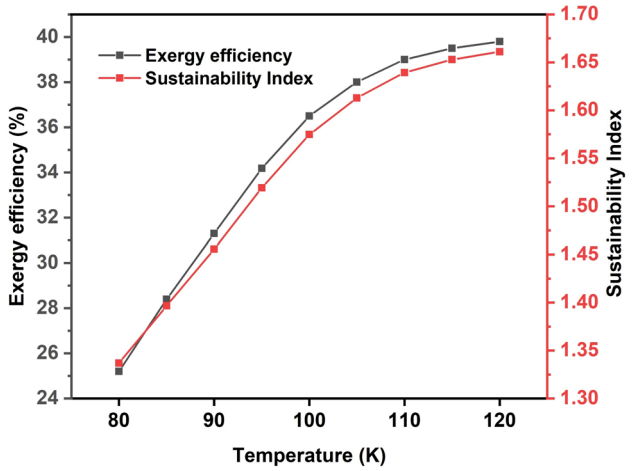

Fig. 4 Exergy efficiency and sustainability vs temperature

$$SA = \frac{1}{(1 - \eta_{\Delta EX})} \tag{12}$$

Figure 4 demonstrate the sustainability index and exergy efficiency in terms of reference temperature. It can be observed that exergy efficiency initially increased and further rate of increment got decrease. This is due to rise in exergy loss. In the given range of reference temperature, the exergy efficiency is highest at 120 K of temperature.

The sustainability index also showed the similar pattern of exergy efficiency and that confirms the resources can be utilized efficiently.

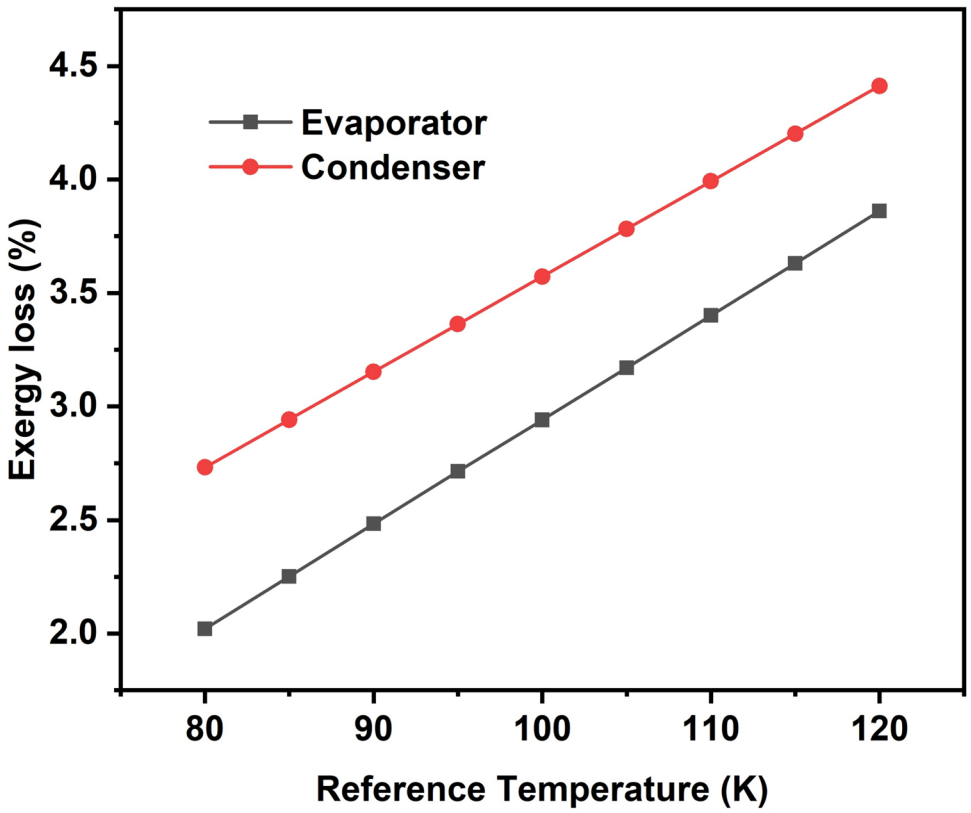
In the evaporator, as the reference temperature rises, the temperature difference between the working fluid and the surroundings also increases. This larger temperature gradient results in higher heat transfer irreversibilities and, consequently, higher exergy losses as shown in Fig. 5.

Similarly, in the condenser, a higher reference temperature means a higher temperature difference between the working fluid and the surroundings during heat rejection. This increased temperature gap results in greater irreversibilities and higher exergy losses.

4 Simulation and modeling

Figure 6 illustrates a 2-D physical model of a single loop PHP, where acetone – Al_2O_3 serves as the operating fluid. The PHP is positioned for bottom heating, and it has an overall length span of 57 mm. In order to ensure that the dominance of surface tension force over gravitational force is evident within the channel, which measures 1 mm, the calculation of the inner critical diameter of the PHP involves the use of the Bond number (Eq. 1, The inner diameter (D) of the CPHP must be smaller than the critical diameter (D_c) for proper functionality). Thus, the current CPHP model's inner diameter is set at 1 mm.

Fig. 5 Exergy loss vs reference temperature



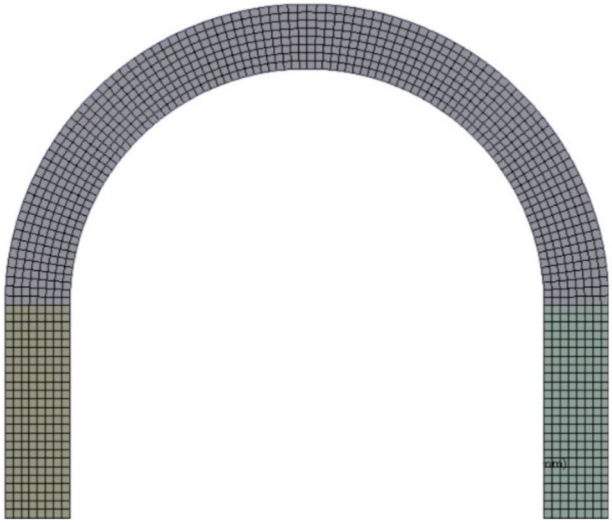


Fig. 6 A mesh structure adopted in a 2-D CPHP model

To accurately account for the surface tension effect, a quadrilateral mesh is favored over tetrahedral and triangular meshes [42]. Accordingly, quadrilateral structured mesh has been employed. Figure 6 illustrates the utilized quadrilateral mesh in the 2-D PHP model. The thickness of the first layer adjacent to the wall is set at 0.18 mm.

The flow dynamics in a PHP can be described as a two-phase gas-liquid flow regime. This regime is characterized by the presence of gas bubbles interspersed with liquid slugs [43]. The VOF approach enables the modeling of the two-phase flow by tracking the interface between the gas and liquid phases. The VOF approach ensures that the distinct gas and liquid phases within a PHP, characterized by bubbles and liquid slugs, are appropriately represented without mixing or overlapping. The variables are integrated for each introduced phase in the model, ensuring that the total sum of volume fractions for all phases within a computational cell equals unity. The properties and variables in a cell exhibit either two phase mixture or single phase and that relies on volume fraction values (Table 2).

Consider the fluid volume fraction in a cell, denoted as αq, representing the volume percentage of the fluid labeled as "qth.". There are three possible conditions: $\alpha q = 1$, $\alpha q = 0$ and $0 < \alpha q < 1$ are indicated as full cell, empty cell (for qth fluid) and interface between two fluids. Depending on the value of αq, appropriate variables and properties are assigned to every control volume within the domain. Further, it is postulated that phase transition transpires at the saturation temperature when transitioning between the vapor and liquid phases. Equation (13) represents mass conservation equation [44].

$$\frac{\partial(\alpha_v \rho_v)}{\partial t} + \nabla.(\alpha_v \rho_v \upsilon_v) = m_{lv} - \dot{m}_{vl} \tag{13}$$

The interphase mass transfer is described as in Eqs. 14 and 15 [44].

Here, $T_l > T_{sat}$ (for evaporation)

$$\dot{m}_{lv} = r_{lv}.\alpha_l \rho_l \frac{(T_l - T_{sat})}{T_{sat}} \tag{14}$$

If, $T_{sat} > T_v$ (for condensation)

$$\dot{m}_{vl} = r_{vl}.\alpha_l \rho_l \frac{(T_l - T_{sat})}{T_{sat}} \tag{15}$$

where, r indicates relaxation factor,

The relaxation factor, denoted as 'r,' is set to a default value of 0.1 s-1 to ensure the interface temperature remains in proximity to the saturation temperature of the working fluid [45]. Throughout the domain, the momentum equation (Eq. 16) is computed, the momentum equation's outcome is influenced by the volume fractions of each phase [46].

$$\frac{\partial(\rho\vec{v})}{\partial t} + \nabla.(\rho\vec{v}\vec{v}) = -\nabla P + \nabla.[\mu(\nabla\vec{v} + \nabla\vec{v}^T)] + \rho\vec{g} + \vec{F}_{vol} \tag{16}$$

Surface tension emerges due to the cohesive forces among molecules present in the fluid. These surface forces become dominant, particularly in mini channels. The CSF model is employed for surface tension modelling in FLUENT. Incorporating surface tension into the VOF formulation introduces it as a source term in the momentum equation. The volume force acts on the surface are given by Eq. (17) [47].

$$F_{vol} = \sigma_{lv} \frac{\alpha_v \rho_v k_l \nabla\alpha_l + \alpha_l \rho_l k_v \nabla\alpha_v}{\frac{1}{2}(\rho_v + \rho_l)} \tag{17}$$

Table 2 Numerical simulation matrix

Items	Content	Items	Content
Multiphase model	VOF Implicit /Explicit	Volume Fraction	Geo-Reconstruct
Viscous model	k-epslion	Model	2D transient
Energy and Momentum and	Upwind second Order	Mesh	Quadrilateral
Pressure interpolation	PRESTO	First layer thickness	0.18 mm
Gravitational acceleration	-9.81 m/s 2, Y axis	Modeling of surface tension force	CSF

The curvature (k) is mathematically represented as follows: $k_l = \frac{\nabla \alpha_l}{\nabla \alpha_v}$, $k_v = \frac{\nabla \alpha_v}{\nabla \alpha_l}$.

Further, the Eq. (18) shows the energy equation contributed among phases [48]. Where, Sh exhibits the energy source due to phase change. It is acquired by multiplying the latent heat by the rate of mass transfer such as

$$S_h = -h_{LH}\, m_{lv} = h_{LH}\, \dot{m}_{vl}$$

$$\frac{\partial}{\partial t}(\rho E) + \nabla.(\vec{v}(\rho E + P)) = \nabla.(K.\nabla T + (\overline{\overline{\tau}}.\vec{v})) + S_h \tag{18}$$

The two terms of Eq. (18) in right side are the sum of energy transfer through viscous dissipation and conduction.

In Eq. (19), the temperature (T) and energy (E) are considered as mass-averaged variables in volume of fluid (VOF) model [47].

$$E = \frac{\alpha_v \rho_v E_v + \alpha_l \rho_l E_l}{\alpha_v \rho_v + \alpha_l \rho_l} \tag{19}$$

where, Ev and E_l are depends on specific heat of phases and shared temperature as in Eqs. 20 and 21.

$$E_v = C_{v,v}(T - T_{sat}) \tag{20}$$

$$E_l = C_{v,l}(T - T_{sat}) \tag{21}$$

The properties K, ρ and μ are common to all phases, as presented below:

$$K = \alpha_v K_V + \alpha_l K_l,\ \rho = \alpha_v \rho_v + \alpha_l \rho_l,\ \mu = \alpha_v \mu_v + \alpha_l \mu_l$$

5 Results and discussion

5.1 Validation of model and grid sensitivity test

The results of laboratory research on a PHP were compared with previous simulations to verify the accuracy of the current numerical method [28]. The geometry used in the laboratory investigation is completely consistent with that of the numerical study, with a filling ratio of 55% and having ethylene glycol as working fluid. The thermal resistance measured in the laboratory study differs from that in the current numerical study by less than 5% as shown in Fig. 7. The concordance between the simulation and experiment findings shows that the current numerical simulations can accurately represent the two-phase liquid/vapor flow in the oscillatory heat pipe. Where Q and Te represents the heat input and evaporator temperature.

Moreover, based on our current understanding, the quantity of grids exerts a somewhat indirect influence

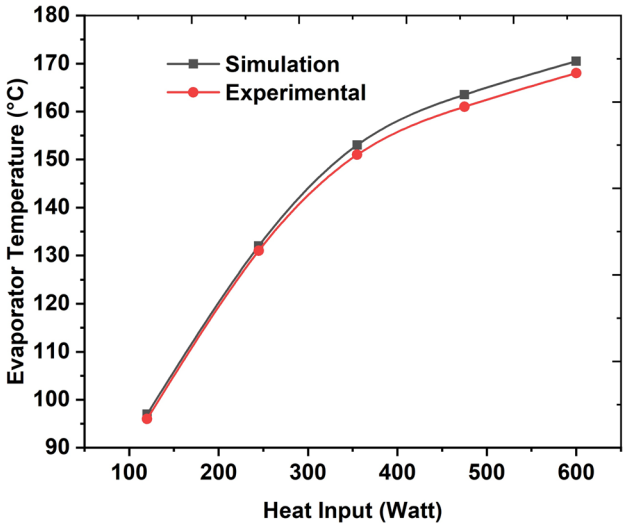

Fig. 7 Fluid temperature vs time (Evaporator and condenser) at FR (42%)

on the outcomes of numerical simulations. Four distinct grid numbers— 75,623, 55,545, 22,323 and 38,432— are employed to assess grid independence and meet the requisite criteria. Throughout the testing, all parameters remain constant, except for the grid count. When utilizing grid numbers 75623 and 55,545, as depicted in Fig. 8, the simulation results demonstrate nearly identical consistency, with a relative variance of approximately 1%. Consequently, due to the numerical precision and computational efficiency, grid number 55545 is selected for use in this study.

5.2 Effect of internal diameter

The viscous force and surface tension are directly affected by internal diameter of PHP. Where, bond no limits the

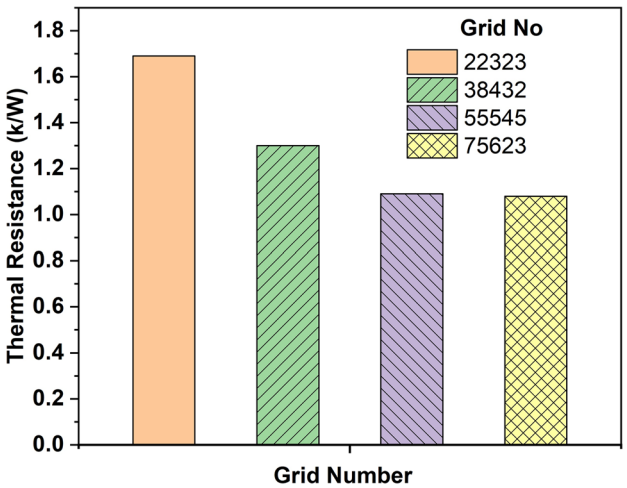

Fig. 8 Grid independence test (Q = 45 W)

maximum diameter for sustained liquid slugs [1]. The critical diameter of a pulsating heat pipe is presented in Eq. 22

$$d_{crit} = 2\sqrt{\frac{\sigma}{g(\rho_l - \rho_v)}} \tag{22}$$

The critical diameter for a pulsating heat pipe (PHP) with acetone-Al_2O_3 as the working fluid can be calculated using the eq. 2. The critical diameter comes out to be 2.1 mm. When the diameter of the PHP (Pulsating Heat Pipe) channels is smaller, the capillary forces tend to be stronger. As a result, there is an increase in liquid-vapor phase separation and the formation and growth of bubbles are promoted. This phenomenon has been distinctly observed in the PHP illustrated in the Figs. (9 and 10). When the channel diameter is closer to the critical diameter (D_{crit}), the PHP exhibits better slug-plug characteristics, leading to an improvement in overall performance. However, the minimum diameter to which a PHP can be reduced depends on several factors, including the properties of the working fluid, surface tension, fluid viscosity, channel geometry, and the desired operating conditions but there is no universal minimum diameter for a PHP [49] (Fig. 9).

Though, the figures show that the benefit of reducing the total thermal resistance, achieved by expanding the range of movement, is maintained up to a 1 mm internal diameter. The longer periods of standstill indicate a decline in surface tension forces beyond this point. The most noticeable difference is that the tiny internal diameter has more short bubbles than the large internal diameter. However, the smaller diameter leads to increased thermal resistance within the PHP, as heat transfer area decreases while the flow resistance increases as shown in Fig. 10. The rationale of above is also suggested by study [50] (Fig. 11).

It was also observed that capillary became more influential with decrease in internal diameter. A decrease in diameter enhanced capillary action due to increased surface tension effects, which may aid in overcoming gravitational forces, thus facilitating better fluid circulation. In contrast to other inner tube sizes, the lower thermal resistance value was also found for an inner diameter of 2 mm and this result is align with studies [51].

5.3 Effect of filling ratio

The transient fluid temperature variation as well as pressure drop with time in evaporator for FR 25%-75% at evaporator temperature Te = 105 K is shown in Figs. (11, 12, 13, 14, 15, 16, 17, 18, 19 and 20). It's also presumed that this filling ratio remains consistent over time. and flow is incompressible since small temperature variation. Figure 12 illustrates the T_{max} graph acquired at 0.25 FR. The oscillations observed in T_{max} over time exhibit a similar nature across various filling ratios. Yet, deviating from the norm, an intriguing trend emerges for a filling ratio of 0.55, as depicted in Fig. 13. It was observed that At a filling ratio of 25%, there exists a greater abundance of vapor plugs within the evaporator. Therefore, the time

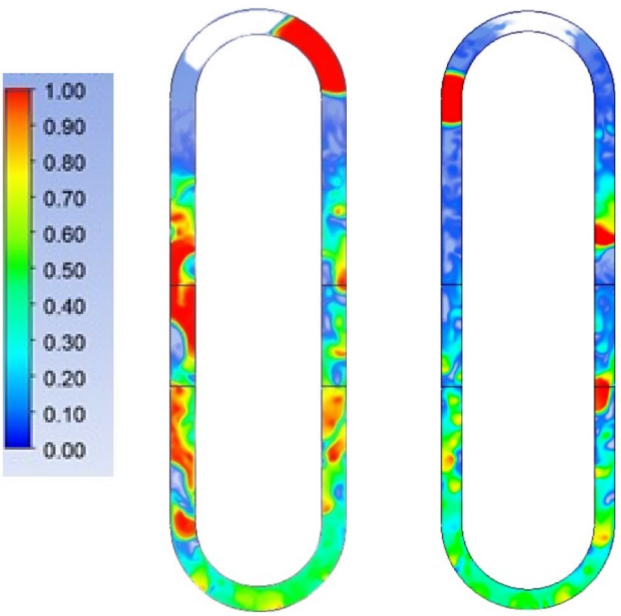

Fig. 9 Volume liquid fraction vs time value (D: 2.5 mm and 2 mm) (left to right)

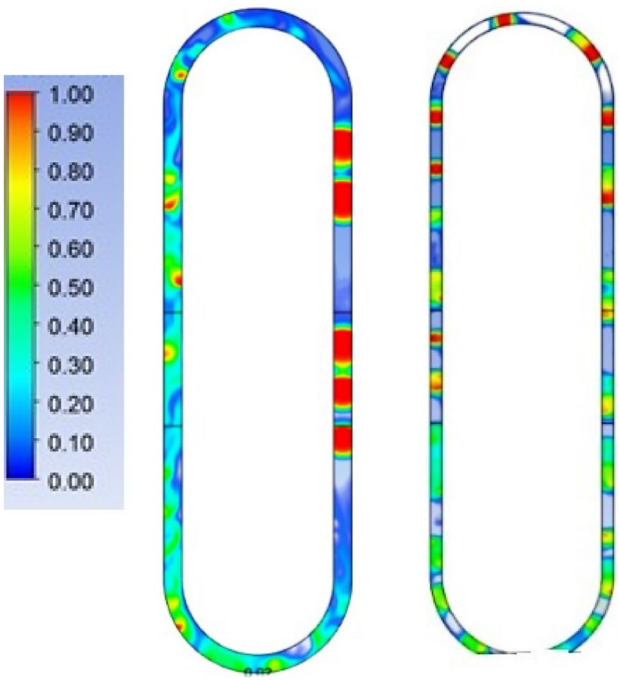

Fig. 10 Volume liquid fraction vs time value (D: 1.5 mm and 1 mm) (left to right)

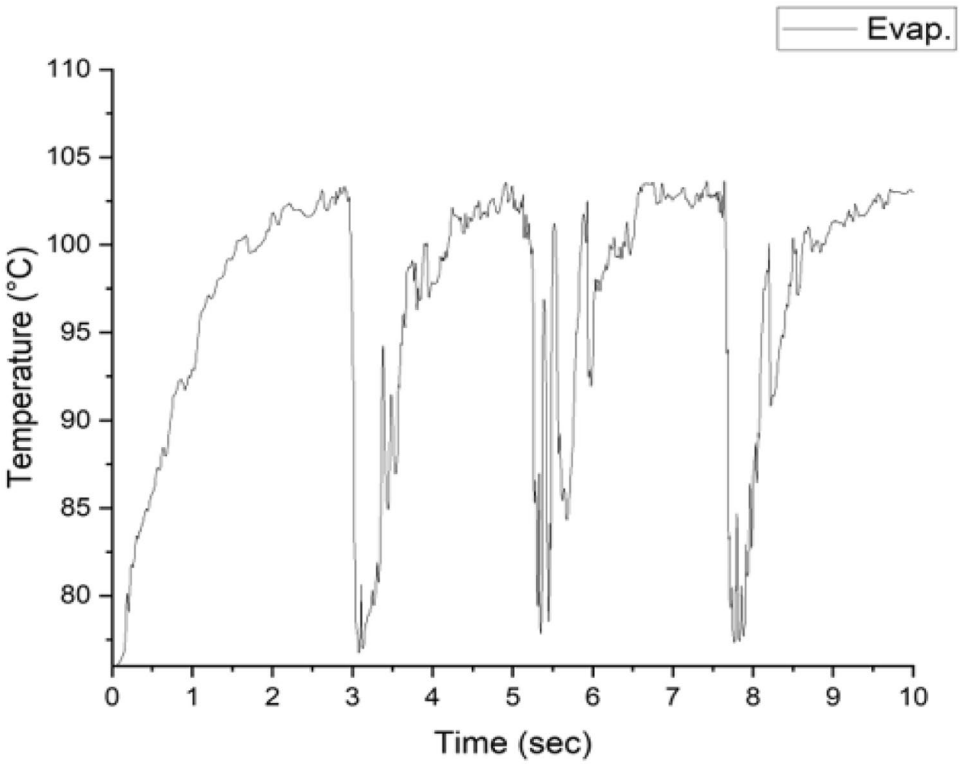

Fig. 11 Temperature Vs Time graph for Fill ratio 25%

averaged temperature of the acetone-Al_2O_3 in the evaporator section is notably elevated. In Figs. 12, 13 and 14, with the increase in filling ratio from 45 to 75%, there is a corresponding decrease in the time-averaged temperature difference of the working fluid. This phenomenon is primarily attributed to the higher.

quantity of liquid slugs presents at increased filling ratios (45% to 75%), accompanied by a higher circulation velocity of the slug flow. Since, the filling ratio determines the amount of working fluid available for heat transfer (Fig. 15).

A higher filling ratio allows for a larger amount of working fluid, resulting in higher heat transfer capability. This is because a larger volume of working fluid can absorb more heat before reaching a critical temperature [2]. It is worth to note that the temperature gradient with time decreased with increasing filling ration.

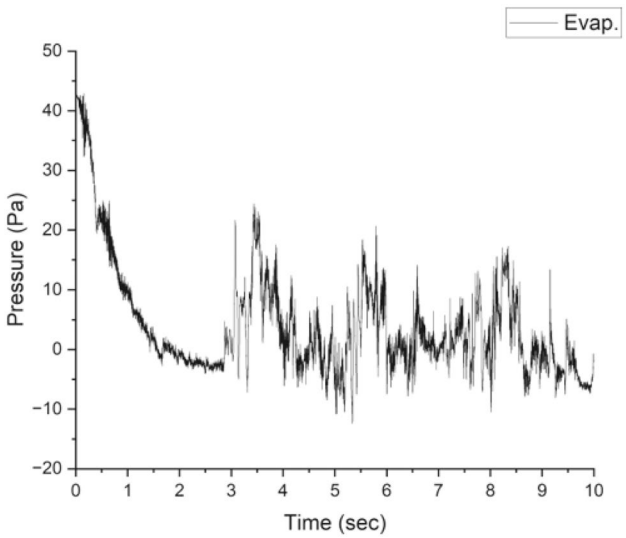

Fig. 12 Pressure vs time graph for fill ratio 25%

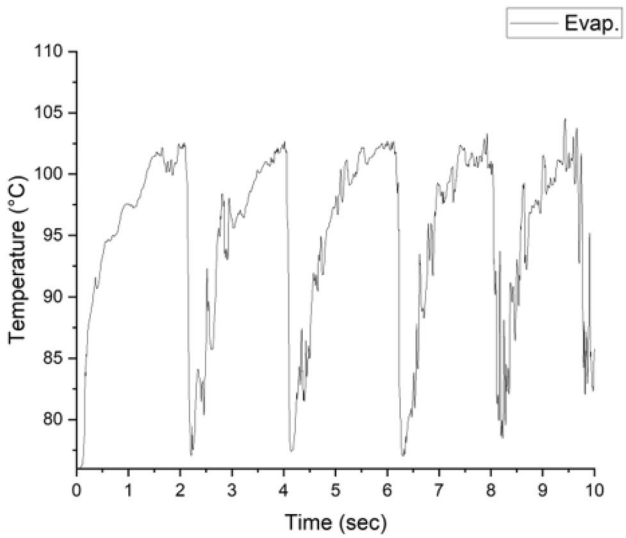

Fig. 13 Temperature vs time graph for Fill ratio 45%

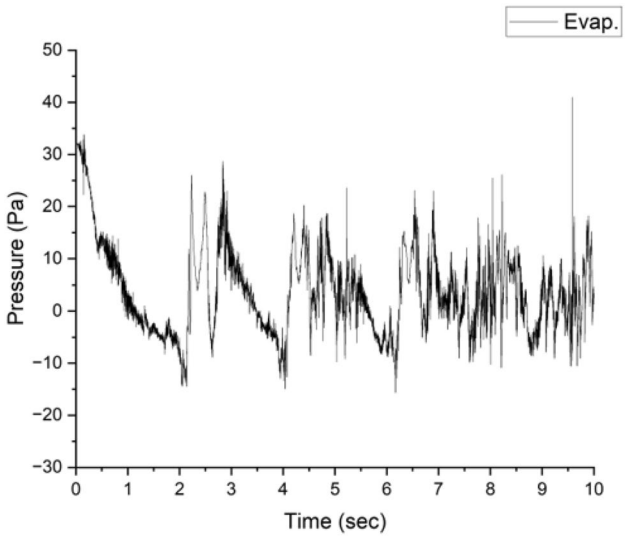

Fig. 14 Pressure vs time graph for fill ratio 45%

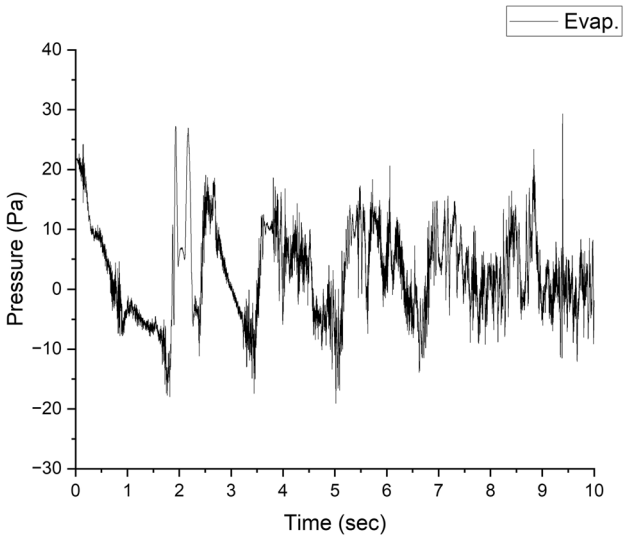

Fig. 16 Pressure vs time graph for fill ratio 55%

However, after FR = 55%, the maximum temperature also increased. At a constant filling ratio, the temperature gradient of the working fluid (the temperature difference between condenser and evaporator) rises proportionally with the improve in heat input. Nevertheless, when the filling ratio was elevated at a constant heat load, the fluid temperature gradient reduced. Hence at high heat input situation, high FR is more suitable to avoid dry out in a PHP (Fig. 16).

As the liquid content within the PHP steadily diminishes (accompanied by a corresponding increase in vapor volume), the heat transfer experiences an initial boost owing to the heightened movement of vapor plugs. Nonetheless, concurrently, the quantity of sensible heat transfer undergoes a continuous decline as a result of the diminishing liquid content. Therefore, an optimum point exists at a specific filling ratio (here, FR = 55%). The rationale of above study is also suggested by [52] Since, PHPs rely on capillary forces to transport the working fluid between the condenser and evaporator section (Fig. 17).

Capillary forces are generated by the interaction between the working fluid and the inner walls of the tube. A lower filling ratio may result in reduced capillary forces due to a smaller amount of fluid available for generating these forces [53] (Fig. 18).

Figures 12, 13 and 14 shows the pressure drop with time, and was observed that filling ratio having 75% exhibited on average highest pressure drop among all filling ratio. This is due to higher filling ratios generally lead to higher pressure

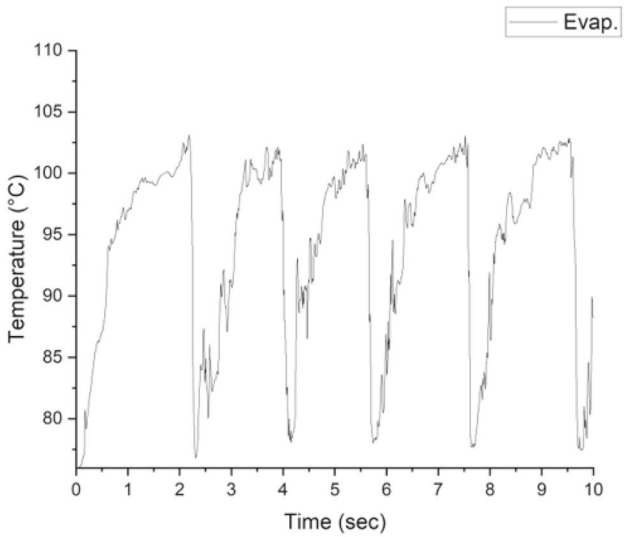

Fig. 15 Temperature vs time graph for fill ratio 55%

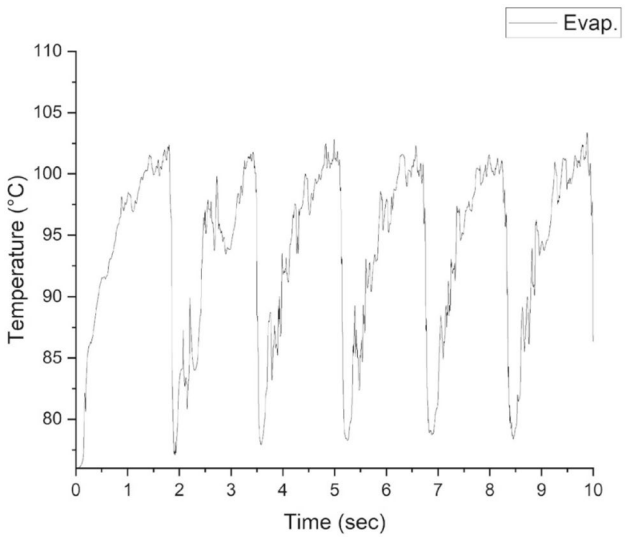

Fig. 17 Temperature vs time graph for fill ratio 65%

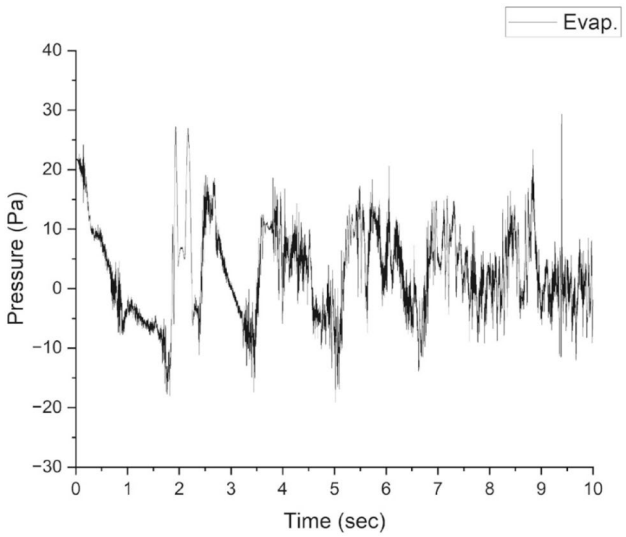

Fig. 18 Pressure vs time graph for fill ratio 65%

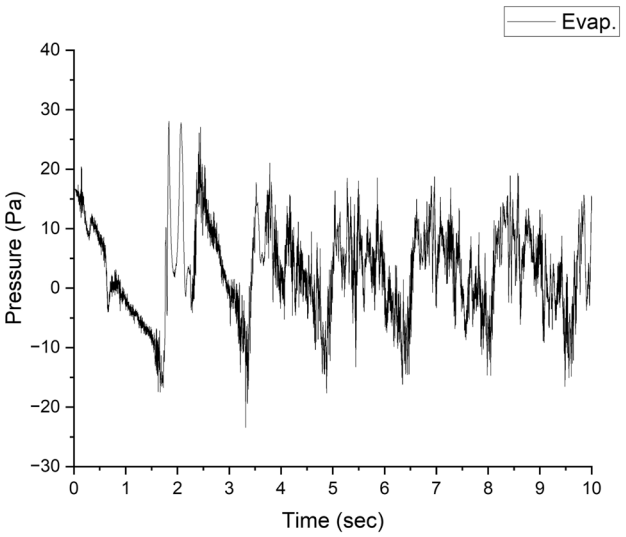

Fig. 20 Pressure vs time graph for fill ratio 75%

drops due to increased frictional resistance between the working fluid and the tube walls. This can impact the fluid flow rate and the overall system performance [54]. However, maximum pressure drop was seen for 25% filling ratio at initially small duration. It occurs due to gas entrainment: The gas plugs formed in slug flow can get entrained with the liquid slugs (Fig. 19).

As the PHP operates, these gas plugs can become dislodged from the liquid slugs, creating gas bubbles that travel through the system. The movement of gas bubbles along with the liquid slugs contributes to the overall pressure drop [55] and frictional effects: Slug flow introduces a high interfacial area between the liquid and gas phases. This increased interfacial area leads to increased frictional effects as the liquid and gas flow past each other. Frictional pressure losses occur due to the shearing forces between the two phases, resulting in additional pressure drop [56]. It is worth to note that the time averaged working fluid temperature difference (thick straight lines) evaporator decreases as FR is raised from 25 to 75%.

Additionally, there is an increased number of vapor plugs within the evaporator depicted in Fig. 20 when FR = 25%. Consequently, the time-averaged temperature of the working fluid within the evaporator section is significantly elevated as there in [57]. The time-averaged temperature differential of the working fluid decreases in Figs. 15, 16, 17, 18, 19, and 20 as FR increases from 45 to 75%. This shift is primarily attributable to the greater presence of liquid slugs at higher filling ratios (45% to 70%) and increased circulation velocities of slug flow.

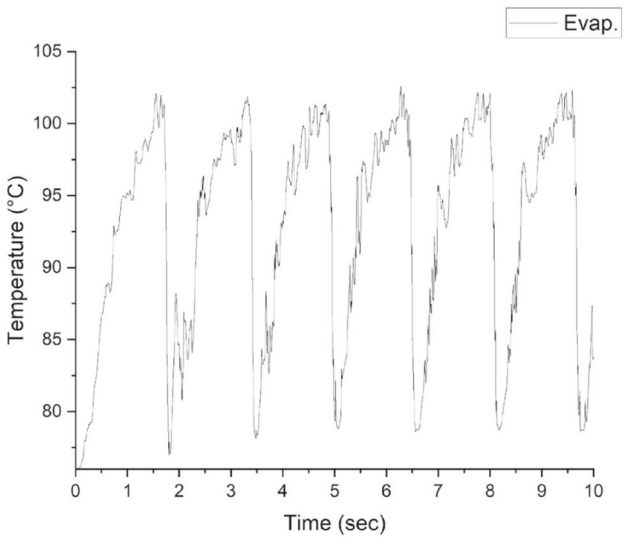

Fig. 19 Temperature vs time graph for fill ratio 75%

6 Conclusion

The pulsating heat pipe utilizing an Acetone – Al_2O_3 mixture, single turn tube, and cylindrical geometry demonstrated successful operation across various diameters and fill ratios under closed PHP valve conditions. The following conclusions are drawn from the study.

1. Increasing the diameter in a pulsating heat pipe involves a trade-off. While it can enhance heat transfer area and fluid flow dynamics, there's a limit beyond which capillary forces may become less effective. Therefore, PHP showed highest performance at 2 mm internal diameter among (1 mm, 1.5 mm, 2 mm and 2.5 mm)

2. In mixtures, the inhibition of phase transitions can significantly delay the onset of dry-out in the PHP, even when operating at low filling ratios (25%, 45%), while, Due to the reduced flow rate, the heat transmission capabilities of the PHP with acetone-Al2O3 mixtures are less effective at higher filling ratios (65 and 75%).
3. As the temperature increased, the exergy efficiency also increased linearly. However, it became nearly constant at higher temperature. Sustainability index also showed similar trends to exergy efficiency.
4. Exergy loss was lower for evaporator than condenser for a range of temperature. This is due to low temperature difference in evaporator, which can contribute to lower exergy losses.

7 Future scope

Investigate the implementation of optimal PHP configurations in real-world scenarios, considering external factors such as fluctuations in temperature. Evaluate the reliability and enduring stability of continuously operating PHP systems. Extend the investigation to explore the potential for enhancing optimization through the utilization of diverse nanoparticles and alternative working fluids. Enhance the practical applicability of PHP technology by assessing its scalability and adaptability across various industrial sectors.

ABSTRACT

A class of singularly perturbed two-parameter parabolic partial differential equations with a large shift is studied. These equations include time-dependent variables and exhibit sensitivity to small perturbations in the system parameters. Moreover, the shift captures the influence of neighbouring states or events on the current evolution of the system. It adds memory-like behaviour to the problem, making their analysis and numerical solution more intricate. The solution of these equations exhibits a multiscale character. The interior and boundary layers exist across which the solution has a steep gradient. A higher-order accurate numerical method is proposed on a non-uniform mesh to solve the problem. The method combines an upwind difference scheme in space and a Crank-Nicolson scheme in time. The method is unconditionally stable, and parameters uniformly convergent with second-order accuracy in time and first-order accuracy in the space variable. Besides, the paper presents numerical results and illustrations to support theoretical estimates.

1. Introduction

The problem we consider involves a singularly perturbed parabolic equation with two small parameters which control the system's behaviour and a large shift. This type of problem forms an essential basis for several physical [17], biological and chemical processes [18], including chemical flow [8], lubrication theory [10], and reactor theory [24], to name a few among numerous others. The presence of two small parameters leads to interesting phenomena and challenges in the analysis and numerical solution of these problems. The solution exhibits twin boundary layers due to the presence of two parameters and an interior layer due to the large shift. O'Malley has started the study of singular perturbation problems [23–25]. He has shown that the nature of the problem and the occurrence of boundary layers in the solution is affected by the magnitude of the two parameters involved. The nature of these layers depends on the ratio of μ^2 and ε [26].

Many researchers have worked to develop uniformly convergent numerical methods for the solution of two-parameter singularly perturbed parabolic problems [4,5,7,32]. In [21], the researchers consider a two-parameter singularly perturbed time-delay parabolic equation. They employ a fitted operator finite difference scheme to approximate the numerical solution. The first step involves discretising the time variables using the Crank-Nicolson method. The semidiscrete problem is further discretized in space using the exponentially fitted tension-spline finite difference method. The study reveals that the numerical scheme exhibits almost second-order uniform convergence in space and time variables. In [22], they consider a two-parameter singularly perturbed parabolic problem with time-delay. They discretized the problem using an exponentially fitted scheme in the spatial direction and the Crank-Nicolson method in the time direction on a uniform mesh. In [3], the authors employ a fitted cubic spline scheme to solve a two-parameter singularly perturbed time-delayed problem. This scheme combines the θ-method on a uniform mesh in the time direction and a cubic spline scheme on a uniform mesh in the spatial direction. In [1], the authors focus on a two-parameter singularly perturbed system of partial differential equations with discontinuous coefficients. This discontinuity and small values of the perturbation parameters cause interior and boundary layers to appear in the solution. They employ a central finite-difference approach on a piecewise uniform Shishkin mesh in the spatial direction and an implicit Euler scheme on a uniform mesh in the time direction. In [29], the authors used a Hermite wavelet-based numerical method to solve two parameters singularly perturbed non-linear Benjamina-Bona-Mohany equation. The method involves time discretisation of Hermite wavelet series approximations with collocation technique. In [32], the authors used a finite element method on a Bakhvalov-type mesh to solve a two-parameter singularly perturbed two-point boundary value problem. Utilising individual interpolation, they obtain the errors for Lagrange interpolation and then prove the optimal order of convergence. In [2], the authors consider a singularly perturbed initial-boundary value problem with two parameters. They propose a fully-discrete numerical method combining the Crank-Nicolson scheme for time variables and the streamline-diffusion finite element method for the spatial variable. In [30], the authors consider a two-dimensional singularly perturbed convection-reaction-diffusion elliptic type problem with two parameters. Furthermore, the authors assume that jump discontinuities exist in the source term along the x-axis and y-axis. They employ an upwind finite-difference technique with an appropriate layer-adapted piecewise uniform Shishkin mesh to approximate the numerical solution.

In [26], the author proposed a numerical method based on an upwind finite difference operator to solve a two-parameter problem. They proved that the method is first-order convergent in space and time. The paper [15] presents a higher-order uniformly convergent method based on finite elements for a two-parameter parabolic singular perturbation problem. In [13], researchers have developed a hybrid scheme for one-dimensional singularly perturbed parabolic problems with two small parameters. The method presented is a composition of an upwind, midpoint upwind and central difference operator on a piecewise uniform Shishkin mesh. In contrast, the implicit Euler method is used for time stepping on a uniform mesh. A numerical approximation of a two-parameter parabolic problem with discontinuous data is proposed in [6]. In [11], the authors present an almost first-order convergent scheme for a two-parameter singularly perturbed problem with a time-delay. The method combines an upwind scheme for spatial discretisation and the implicit Euler

scheme for time discretisation. A hybrid difference approach for time dependent problems is studied in [14,27,31]. The author established almost second-order convergence in space direction and first-order convergence in time.

Due to their large applications, it is essential to develop robust numerical methods for solving two-parameter singular perturbation problems. This field of research is still developing, and this paper is a step forward in developing a parameter-uniform numerical method to solve a two-parameter singular perturbation problem with a large spatial delay or shift. Moreover, the paper presents rigorous consistency, stability and convergence analysis of the proposed method and illustrates numerical results to support theoretical estimates.

2. Continuous problem

Let $D = \Omega \times \Delta := (0,2) \times (0,T]$ and consider the following two-parameter, non-homogeneous initial boundary value problem

$$\left.\begin{aligned} &\mathcal{L}u(x,t) = \varepsilon u_{xx}(x,t) + \mu p(x,t)u_x(x,t) - q(x,t)u(x,t) + r(x,t)u(x-1,t) - u_t(x,t)\\ &\quad = g(x,t) \text{ in } D,\\ &u(x,t) = \psi_1(x,t) \text{ in } \Gamma_1 := \{(x,t),\ x \in [-1,0],\ t \in [0,T]\},\\ &u(x,t) = \psi_2(x,t) \text{ on } \Gamma_2 := \{(x,0),\ x \in [0,2]\},\\ &u(x,t) = \psi_3(x,t) \text{ on } \Gamma_3 := \{(2,t),\ t \in [0,T]\}, \end{aligned}\right\} \tag{1}$$

where $0 < \varepsilon < 1$ and $0 < \mu < 1$ are small parameters, $g(x,t)$, $p(x,t)$, $q(x,t)$ and $r(x,t)$ are sufficiently smooth functions such that

$$p(x,t) \geq p_0 > 0, \quad q(x,t) \geq q_0 > 0, \quad r(x,t) \geq r_0 > 0, \quad (q-r)(x,t) \geq \kappa > 0. \tag{2}$$

Moreover, we assume that the initial-boundary data ψ_1, ψ_2 and ψ_3 are smooth functions on their respective domain and satisfy the compatibility conditions given below

$$\begin{cases} \psi_2(0,0) = \psi_1(0,0), \quad \psi_2(2,0) = \psi_3(2,0),\\ \varepsilon\dfrac{\partial^2\psi_2(0,0)}{\partial x^2} + \mu p(0,0)\dfrac{\partial\psi_2(0,0)}{\partial x} - q(0,0)\psi_2(0,0)\\ \quad + r(0,0)\psi_1(-1,0) - \dfrac{\partial\psi_1(0,0)}{\partial t} = g(0,0),\\ \varepsilon\dfrac{\partial^2\psi_2(2,0)}{\partial x^2} + \mu p(2,0)\dfrac{\partial\psi_2(2,0)}{\partial x} - q(2,0)\psi_2(2,0)\\ \quad + r(2,0)\psi_2(1,0) - \dfrac{\partial\psi_3(2,0)}{\partial t} = g(2,0). \end{cases} \tag{3}$$

Let $D_1 = \Omega_1 \times \Delta := (0,1) \times (0,T]$ and $D_2 = \Omega_2 \times \Delta := [1,2) \times (0,T]$. Rewriting (1) as

$$\mathcal{L}u(x,t) = \mathcal{G}(x,t),$$

where

$$\mathcal{L}u(x,t) = \begin{cases} \mathcal{L}_1 u = \varepsilon u_{xx}(x,t) + \mu p(x,t)u_x(x,t) - q(x,t)u(x,t) \\ \qquad\qquad - u_t(x,t) \quad \text{if } (x,t) \in D_1, \\ \mathcal{L}_2 u = \varepsilon u_{xx}(x,t) + \mu p(x,t)u_x(x,t) - q(x,t)u(x,t) + r(x,t)u(x-1,t) \\ \qquad\qquad - u_t(x,t) \quad \text{if } (x,t) \in D_2, \end{cases} \tag{4}$$

and

$$\mathcal{G}(x,t) = \begin{cases} g(x,t) - r(x,t)\psi_1(x-1,t) & \text{if } (x,t) \in D_1, \\ g(x,t) & \text{if } (x,t) \in D_2 \end{cases} \tag{5}$$

with

$$\begin{cases} u(0,t) = \psi_1(0,t), \quad u(1^-,t) = u(1^+,t), \quad u_x(1^-,t) = u_x(1^+,t), \\ u(2,t) = \psi_3(2,t), \quad u(x,0) = \psi_2(x,0). \end{cases} \tag{6}$$

Under these assumptions, the solution of (1) exists and is unique [19]. The solution exhibits twin boundary layers due to the presence of perturbation parameters and an interior layer due to the presence of the shift [26]. Let $\gamma = \min\limits_{(x,t)\in\bar{D}} \left(\frac{q(x,t)-r(x,t)}{p(x,t)}\right)$. If $\frac{\mu^2}{\varepsilon} \leq \frac{\gamma}{p_0}$, the boundary layers of width $\mathcal{O}(\sqrt{\varepsilon})$ appear near the boundaries $x = 0$ and $x = 2$, as well as on the left and right neighbourhoods of $x = 1$ due to the large shift. If $\frac{\mu^2}{\varepsilon} \geq \frac{\gamma}{p_0}$, the boundary layers of width $\mathcal{O}(\mu)$ appear in a left neighbourhood of $x = 1$ and $x = 2$, while a boundary layer of width $\mathcal{O}\left(\frac{\varepsilon}{\mu}\right)$ appears in a right neighbourhood of $x = 0$ and $x = 1$.

Lemma 2.1: *Suppose* $\mathcal{P}(x,t) \in C^0(\bar{D}) \cap C^2(D)$ *satisfies* $\mathcal{P}(0,t) \geq 0, \mathcal{P}(2,t) \geq 0, \mathcal{P}(x,0) \geq 0$ *with* $\mathcal{L}_1\mathcal{P}(x,t) \leq 0$ *for all* $(x,t) \in (0,1) \times [0,T]$ *and* $\mathcal{L}_2\mathcal{P}(x,t) \leq 0$ *for all* $(x,t) \in [1,2) \times [0,T]$. *Then* $\mathcal{P}(x,t) \geq 0$ *for all* $(x,t) \in \bar{D}$.

Proof: Choose $(x^k,t^k) \in \bar{D}$ such that $\mathcal{P}(x^k,t^k) = \min\limits_{(x,t)\in\bar{D}} \mathcal{P}(x,t)$. Consequently,

$$\mathcal{P}_x(x^k,t^k) = 0, \quad \mathcal{P}_t(x^k,t^k) = 0 \quad \text{and} \quad \mathcal{P}_{xx}(x^k,t^k) > 0. \tag{7}$$

Suppose $\mathcal{P}(x^k,t^k) < 0$ and it follows that $(x^k,t^k) \notin \Gamma^* := \Gamma_1^* \cup \Gamma_2 \cup \Gamma_3$, where $\Gamma_1^* := \{(0,t),\ t \in [0,T]\}$.

Case I: If $(x^k,t^k) \in (0,1) \times [0,T]$, then

$$\begin{aligned} \mathcal{L}_1\mathcal{P}(x^k,t^k) &= \varepsilon\mathcal{P}_{xx}(x^k,t^k) + \mu p(x^k,t^k)\mathcal{P}_x(x^k,t^k) - q(x^k,t^k)\mathcal{P}(x^k,t^k) - \mathcal{P}_t(x^k,t^k) \\ &> 0, \text{ from (2) and (7).} \end{aligned}$$

Case II: If $(x^k, t^k) \in [1,2) \times [0,T]$, then

$$\begin{aligned}\mathcal{L}_2\mathcal{P}(x^k,t^k) &= \varepsilon\mathcal{P}_{xx}(x^k,t^k) + \mu p(x^k,t^k)\mathcal{P}_x(x^k,t^k) - q(x^k,t^k)\mathcal{P}(x^k,t^k)\\ &\quad + r(x^k,t^k)\mathcal{P}(x^k-1,t^k) - \mathcal{P}_t(x^k,t^k)\\ &\geq \varepsilon\mathcal{P}_{xx}(x^k,t^k) - (q-r)(x^k,t^k)\mathcal{P}(x^k,t^k)\\ &> 0, \text{ from (2) and (7).}\end{aligned}$$

A contradiction to the assumption that $\mathcal{L}_1\mathcal{P} \leq 0$ for all $(x,t) \in (0,1) \times [0,T]$ and $\mathcal{L}_2\mathcal{P} \leq 0$ for all $(x,t) \in [1,2) \times [0,T]$. Consequently, the required result follows from a contradiction. ■

As a consequence of Lemma 2.1, obtaining the following stability estimate is straightforward.

Lemma 2.2: *Let u be the solution of (1). Then* $\|u\|_{\bar{D}} \leq \|u\|_{\Gamma^*} + \frac{1}{\kappa}\|\mathcal{G}\|_{\bar{D}}$.

Proof: Define $\theta_\pm(x,t) = \|u\|_{\Gamma^*} + \dfrac{1}{\kappa}\|\mathcal{G}\|_{\bar{D}} \pm u(x,t)$, $(x,t) \in \bar{D}$. Then $\theta_\pm(x,t) \geq 0$ for all $(x,t) \in \Gamma^*$ and if $(x,t) \in (0,1) \times [0,T]$, it follows that

$$\begin{aligned}\mathcal{L}_1\theta_\pm(x,t) &= -q(x,t)\left(\|u\|_{\Gamma^*} + \frac{\|\mathcal{G}\|_{\bar{D}}}{\kappa}\right) \pm \mathcal{L}_1 u(x,t)\\ &= -q(x,t)\left(\|u\|_{\Gamma^*} + \frac{\|\mathcal{G}\|_{\bar{D}}}{\kappa}\right) \pm \mathcal{G}(x,t) \leq 0\end{aligned}$$

Similarly, for $(x,t) \in [1,2) \times [0,T]$

$$\mathcal{L}_2\theta_\pm(x,t) = -(q-r)(x,t)\left(\|u\|_{\Gamma^*} + \frac{\|\mathcal{G}\|_{\bar{D}}}{\kappa}\right) \pm \mathcal{L}_2 u(x,t) \leq 0.$$

The required result thus follows from Lemma 2.1. ■

Lemma 2.3: *Let u be the solution of (1). Then, for* $1 \leq k + 2m \leq 3$

$$\left\|\frac{\partial^{k+m}u}{\partial x^k \partial t^m}\right\|_{\bar{D}} \leq \begin{cases}\dfrac{C}{(\sqrt{\varepsilon})^k} & \text{if } p_0\mu^2 \leq \gamma\,\varepsilon,\\ C\left(\dfrac{\mu}{\varepsilon}\right)^k\left(\dfrac{\mu^2}{\varepsilon}\right)^m & \text{if } p_0\mu^2 \geq \gamma\,\varepsilon,\end{cases}$$

where C is a constant independent of ε *and* μ.

Proof: We obtain the bounds of the solution and its derivatives by splitting the argument into two cases $p_0\mu^2 \leq \gamma\,\varepsilon$ and $p_0\mu^2 \geq \gamma\,\varepsilon$.

Case I: Let $p_0\mu^2 \le \gamma\,\varepsilon$. Consider the stretching variables $\tilde{x} = \dfrac{x}{\sqrt{\varepsilon}}$, $\tilde{t} = t$ to obtain the transformed problem on the domain $\tilde{D} = (0, 2/\sqrt{\varepsilon}) \times (0, T]$:

$$\begin{cases} \left(\tilde{u}_{\tilde{x}\tilde{x}} + \frac{\mu}{\sqrt{\varepsilon}}\tilde{p}\tilde{u}_{\tilde{x}} - \tilde{q}\tilde{u} - \tilde{u}_{\tilde{t}}\right)(\tilde{x},\tilde{t}) + \tilde{r}(\tilde{x},\tilde{t})\tilde{u}(\tilde{x}-1,\tilde{t}) = \tilde{g}(\tilde{x},\tilde{t}) \text{ in } \tilde{D}, \\ \tilde{u}(\tilde{x},\tilde{t}) = \tilde{\psi_1}(\tilde{x},\tilde{t}) \text{ on } \tilde{\Gamma_1}, \\ \tilde{u}(\tilde{x},\tilde{t}) = \tilde{\psi_2}(\tilde{x},\tilde{t}) \text{ on } \tilde{\Gamma_2}, \\ \tilde{u}(\tilde{x},\tilde{t}) = \tilde{\psi_3}(\tilde{x},\tilde{t}) \text{ on } \tilde{\Gamma_3}. \end{cases}$$

Using the condition $p_0\mu^2 \le \gamma\,\varepsilon$ and result from [19], we have

$$\left\| \frac{\partial^{k+m}\tilde{u}}{\partial\tilde{x}^k\partial\tilde{t}^m} \right\|_{N_{\lambda,\xi}} \le C(1 + \|\tilde{u}\|_{\tilde{D}}), \quad 1 \le k + 2m \le 3,$$

where $N_{\lambda,\xi}$ is the rectangle $(\lambda - \xi, \lambda + \xi) \times (0, T] \cap \tilde{D}$ for any $\lambda \in (0, 2/\sqrt{\varepsilon})$ and $\xi > 0$. Now, we return back to the original variable to get

$$\begin{aligned} \left\| \frac{\partial^{k+m}u}{\partial x^k\partial t^m} \right\|_{\bar{D}} &\le C\varepsilon^{\frac{-k}{2}}(1 + \|u\|_{\bar{D}}), \quad 1 \le k + 2m \le 3 \\ &\le \frac{C}{(\sqrt{\varepsilon})^k}, \text{ from Lemma 2.2.} \end{aligned}$$

Case II: Let $p_0\mu^2 \ge \gamma\,\varepsilon$. Consider the stretching variables $\tilde{x} = \dfrac{\mu x}{\varepsilon}$, $\tilde{t} = \dfrac{\mu^2 t}{\varepsilon}$ to obtain the following transformed problem on the domain $\tilde{D} = (0, 2\mu/\varepsilon) \times (0, \mu^2 T/\varepsilon]$:

$$\begin{cases} \left(\tilde{u}_{\tilde{x}\tilde{x}} + \tilde{p}\tilde{u}_{\tilde{x}} - \dfrac{\tilde{q}\varepsilon}{\mu^2}\tilde{u} - \tilde{u}_{\tilde{t}}\right)(\tilde{x},\tilde{t}) + \dfrac{\tilde{r}\varepsilon}{\mu^2}(\tilde{x},\tilde{t})\tilde{u}(\tilde{x}-1,\tilde{t}) = \dfrac{\varepsilon}{\mu^2}\tilde{g}(\tilde{x},\tilde{t}) \text{ in } \tilde{D}, \\ \tilde{u}(\tilde{x},\tilde{t}) = \tilde{\psi_1}(\tilde{x},\tilde{t}) \text{ on } \tilde{\Gamma_1}, \\ \tilde{u}(\tilde{x},\tilde{t}) = \tilde{\psi_2}(\tilde{x},\tilde{t}) \text{ on } \tilde{\Gamma_2}, \\ \tilde{u}(\tilde{x},\tilde{t}) = \tilde{\psi_3}(\tilde{x},\tilde{t}) \text{ on } \tilde{\Gamma_3}. \end{cases}$$

Repeating the argument given in Case I, we get

$$\left\| \frac{\partial^{k+m}u}{\partial x^k\partial t^m} \right\|_{\bar{D}} \le C\left(\frac{\mu}{\varepsilon}\right)^k\left(\frac{\mu^2}{\varepsilon}\right)^m, \quad 1 \le k + 2m \le 3. \qquad \blacksquare$$

Corollary 2.4: *Let $u(x,t)$ be the solution of* (1) *and Lemmas 2.1 and 2.2 hold. Then*

$$\|u_{tt}\|_{\bar{D}} \le \begin{cases} C & \text{if } p_0\mu^2 \le \gamma\,\varepsilon, \\ C\mu^4\varepsilon^{-2} & \text{if } p_0\mu^2 \ge \gamma\,\varepsilon. \end{cases}$$

3. Time discretization

Let $\mathbb{T}_t^M = \{t_k = kT/M, k = 0, \ldots, M\}$ be an equidistant mesh in the time direction. We use the Crank-Nicolson method to discretize the problem (1) in the time variable. The semidiscrete problem on $\mathbb{T}_t^M$ thus reads

$$\left.\begin{aligned}&\left(\varepsilon U_{xx} + \mu p U_x - lU\right)(x, t_{k+1}) + r(x, t_{k+1})U(x-1, t_{k+1})\\&\quad = \left(-\varepsilon U_{xx} - \mu p U_x + mU\right)(x, t_k) - r(x, t_k)U(x-1, t_k) + g(x, t_{k+1}) + g(x, t_k),\\&\quad x \in \Omega,\ k = 0, 1, \ldots, M-1\end{aligned}\right\} \tag{8}$$

such that

$$\left.\begin{aligned}&U(x, t_{k+1}) = \psi_1(x, t_{k+1}), \quad -1 \le x \le 0, \quad -1 \le k \le M-1,\\&U(x, 0) = \psi_2(x, 0), \quad 0 \le x \le 2,\\&U(2, t_{k+1}) = \psi_3(2, t_{k+1}), \quad -1 \le k \le M-1,\end{aligned}\right\} \tag{9}$$

where $l(x, t_{k+1}) = q(x, t_{k+1}) + \dfrac{2}{\Delta t}$, $m(x, t_k) = q(x, t_k) - \dfrac{2}{\Delta t}$ and $U(x, t_{k+1})$ is the numerical approximation of the continuous solution $u(x, t)$ at $(k+1)$th time step.

Let us rewrite (8) as

$$\tilde{\mathcal{L}}_n U(x, t_{k+1}) = \tilde{\mathcal{G}}_n(x, t_{k+1}), \quad n = 1, 2, \tag{10}$$

where

$$\begin{aligned}\tilde{\mathcal{L}}_1 U(x, t_{k+1}) &= \left(\varepsilon U_{xx} + \mu p U_x - lU\right)(x, t_{k+1}) \quad \text{if } x \in (0, 1),\\ \tilde{\mathcal{L}}_2 U(x, t_{k+1}) &= \left(\varepsilon U_{xx} + \mu p U_x - lU\right)(x, t_{k+1}) + r(x, t_{k+1})U(x-1, t_{k+1}) \quad \text{if } x \in [1, 2),\end{aligned}$$

and

$$\begin{aligned}\tilde{\mathcal{G}}_1(x, t_{k+1}) &= \left(-\varepsilon U_{xx} - \mu p U_x + mU\right)(x, t_k) - r(x, t_{k+1})\psi_1(x-1, t_{k+1})\\&\quad - r(x, t_k))\psi_1(x-1, t_k) + g(x, t_{k+1}) + g(x, t_k) \quad \text{if } x \in (0, 1),\\ \tilde{\mathcal{G}}_2(x, t_{k+1}) &= \left(-\varepsilon U_{xx} - \mu p U_x + mU\right)(x, t_k) - r(x, t_k))\psi_1(x-1, t_k)\\&\quad + g(x, t_{k+1}) + g(x, t_k) \quad \text{if } x \in [1, 2).\end{aligned}$$

The operator $\tilde{\mathcal{L}}_n$ satisfies the following minimum principle.

Lemma 3.1: *Let $\chi(x, t_{k+1})$ be a smooth function such that $\chi(x, t_{k+1}) \ge 0$ for $x = 0, 2$ with $\tilde{\mathcal{L}}_1\chi(x, t_{k+1}) \le 0$ for all $x \in (0, 1)$ and $\tilde{\mathcal{L}}_2\chi(x, t_{k+1}) \le 0$ for all $x \in [1, 2)$. Then $\chi(x, t_{k+1}) \ge 0$ for all $x \in \bar{\Omega}$.*

Proof: Let $\chi(\alpha, t_{k+1}) = \min_{x\in\bar{\Omega}} \chi(x, t_{k+1})$ for some $\alpha \in \bar{\Omega}$. Then

$$\chi_x(\alpha, t_{k+1}) = 0 \quad \text{and} \quad \chi_{xx}(\alpha, t_{k+1}) > 0. \tag{11}$$

Suppose $\chi(\alpha, t_{k+1}) < 0$, therefore $\alpha \notin \{0, 2\}$ because $\chi(x, t_{k+1}) \ge 0$ for $x = 0, 2$.

Case I: If $\alpha \in (0,1)$

$$\begin{aligned}\tilde{\mathcal{L}}_1\chi(\alpha,t_{k+1}) &= \left(\varepsilon\chi_{xx}+\mu p\chi_x - l\chi\right)(\alpha,t_{k+1})\\ &> 0, \quad \text{from (2) and (11).}\end{aligned}$$

Case II: If $\alpha \in [1,2)$

$$\begin{aligned}\tilde{\mathcal{L}}_2\chi(\alpha,t_{k+1}) &= \left(\varepsilon\chi_{xx}+\mu p\chi_x - l\chi\right)(\alpha,t_{k+1}) + r(\alpha,t_{k+1})\chi(\alpha-1,t_{k+1})\\ &\geq \varepsilon\chi_{xx}(\alpha,t_{k+1}) - l(\alpha,t_{k+1})\chi(\alpha,t_{k+1}) + r(\alpha,t_{k+1})\chi(\alpha,t_{k+1})\\ &\geq \varepsilon\chi_{xx}(\alpha,t_{k+1}) - \left(q(\alpha,t_{k+1}) + \frac{2}{\Delta t} - r(\alpha,t_{k+1})\right)\chi(\alpha,t_{k+1})\\ &= \varepsilon\chi_{xx}(\alpha,t_{k+1}) - (q-r)(\alpha,t_{k+1})\chi(\alpha,t_{k+1}) - \frac{2}{\Delta t}\chi(\alpha,t_{k+1})\\ &> 0, \quad \text{from (2) and (11).}\end{aligned}$$

It contradicts the assumption, and hence the result follows from a contradiction. ■

Lemma 3.2: *Let $U(x,t_{k+1})$ be the solution of* (10)*. Then*

$$\|U(x,t_{k+1})\|_{\bar{\Omega}} \leq \max\left\{|U(0,t_{k+1})|, |U(2,t_{k+1})|, \frac{1}{\kappa}\|\tilde{\mathcal{G}}\|_{\bar{\Omega}}\right\} \quad \text{for all } x \in [0,2].$$

Proof: Consider $M_{\pm}(x,t_{k+1}) = \max\{|U(0,t_{k+1})|, \frac{1}{\kappa}\|\tilde{\mathcal{G}}_1\|_{\bar{\Omega}_1}\} \pm U(x,t_{k+1})$ for all $x \in (0,1)$. Then, $M_{\pm}(0,t_{k+1}) \geq 0$. Moreover, for $x \in (0,1)$

$$\begin{aligned}\tilde{\mathcal{L}}_1 M_{\pm}(x,t_{k+1}) &= -l(x,t_{k+1})\max\left\{|U(0,t_{k+1})|, \frac{1}{\kappa}\|\tilde{\mathcal{G}}_1\|_{\bar{\Omega}_1}\right\} \pm \tilde{\mathcal{L}}_1 U(x,t_{k+1})\\ &= -l(x,t_{k+1})\max\left\{|U(0,t_{k+1})|, \frac{1}{\kappa}\|\tilde{\mathcal{G}}_1\|_{\bar{\Omega}_1}\right\} \pm \tilde{\mathcal{G}}_1(x,t_{k+1})\\ &\leq 0, \quad \text{from (2).}\end{aligned}$$

Similarly, consider $M_{\pm}(x,t_{k+1}) = \max\{|U(2,t_{k+1})|, \frac{1}{\kappa}\|\tilde{\mathcal{G}}_2\|_{\bar{\Omega}_2}\} \pm U(x,t_{k+1})$ for all $x \in [1,2)$. Then, $M_{\pm}(2,t_{k+1}) \geq 0$ and for $x \in [1,2)$ we compute

$$\begin{aligned}&\tilde{\mathcal{L}}_2 M_{\pm}(x,t_{k+1})\\ &= -(l-r)(x,t_{k+1})\max\left\{|U(2,t_{k+1})|, \frac{1}{\kappa}\|\tilde{\mathcal{G}}_2\|_{\bar{\Omega}_2}\right\} \pm \tilde{\mathcal{L}}_2 U(x,t_{k+1})\\ &= -\left(q(x,t_{k+1}) + \frac{2}{\Delta t} - r(x,t_{k+1})\right)\max\left\{|U(2,t_{k+1})|, \frac{1}{\kappa}\|\tilde{\mathcal{G}}_2\|_{\bar{\Omega}_2}\right\} \pm \tilde{\mathcal{G}}_2(x,t_{k+1})\\ &\leq 0, \quad \text{from (2).}\end{aligned}$$

Consequently, from Lemma 3.1 the required result follows. ■

The local truncation error of the semidiscretized problem (10) is given by $e_{k+1} := \hat{U}(x, t_{k+1}) - u(x, t_{k+1})$, where $\hat{U}$ is the solution of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_n \hat{U}(x, t_{k+1}) = \hat{\mathcal{G}}(x, t_{k+1}), \quad x \in \Omega, \quad 0 \le k \le M-1, \\ &\hat{U}(x, t_{k+1}) = \psi_1(x, t_{k+1}), \quad -1 \le x \le 0, \quad -1 \le k \le M-1, \\ &\hat{U}(x, 0) = \psi_2(x, 0), \quad x \in \bar{\Omega}, \\ &\hat{U}(2, t_{k+1}) = \psi_3(2, t_{k+1}), \quad -1 \le k \le M-1, \end{aligned}\right\} \tag{12}$$

where $\tilde{\mathcal{L}}_n$ is defined in (10), and

$$\hat{\mathcal{G}} = \begin{cases} \left(-\varepsilon u_{xx} - \mu p u_x + mu\right)(x, t_k) - r(x, t_{k+1})\psi_1(x-1, t_{k+1}) \\ \quad -r(x, t_k)\psi_1(x-1, t_k) + g(x, t_{k+1}) + g(x, t_k) & \text{if } x \in (0, 1), \\ \left(-\varepsilon u_{xx} - \mu p u_x + mu\right)(x, t_k) - r(x, t_k))\psi_1(x-1, t_k) \\ \quad +g(x, t_{k+1}) + g(x, t_k) & \text{if } x \in [1, 2). \end{cases}$$

Lemma 3.3: *For some constant C, the local truncation error at* $(k+1)$*th time step satisfies the following bound*

$$\left\| e_{k+1} \right\|_\infty \le C(\Delta t)^3, \quad -1 \le k \le M-1.$$

Proof: For proof, see [9]. ■

The global error $E_k := u(x, t_k) - U(x, t_k)$ of the semidiscretized problem is the contribution of the local truncation error at each time step. Then, it follows that

$$\left\| E_{k+1} \right\|_\infty = \left\| \sum_{i=1}^{k} \hat{e}_i \right\|_\infty \le \left\| \hat{e}_1 \right\|_\infty + \left\| \hat{e}_2 \right\|_\infty + \ldots + \left\| \hat{e}_k \right\|_\infty \le C\Delta t^2. \tag{13}$$

This in turn ensures the uniform convergence of the time semidiscretization process.

Lemma 3.4: *Let* $U(x, t_{k+1})$ *be the solution of* (10). *Then*

$$\left\| \frac{d^k U}{dx^k} \right\| \le \frac{C}{(\sqrt{\varepsilon})^k} \left(1 + \left(\frac{\mu}{\sqrt{\varepsilon}}\right)^k\right) \max\left\{ \|U\|, \|\tilde{\mathcal{G}}\| \right\}, \quad k = 1, 2,$$

$$\left\| \frac{d^3 U}{dx^3} \right\| \le \frac{C}{(\sqrt{\varepsilon})^3} \left(1 + \left(\frac{\mu}{\sqrt{\varepsilon}}\right)^3\right) \max\left\{ \|U\|, \|\tilde{\mathcal{G}}\| \right\} + \frac{1}{\varepsilon} \left\| \frac{\mathrm{d}\tilde{\mathcal{G}}}{\mathrm{d}x} \right\|,$$

where C is the constant independent of μ *and* ε.

Proof: For proof, see [16]. ■

The solution $U(x, t_{k+1})$ of the semidiscretized problem (10) admit a decomposition into smooth and singular components [20]. We write

$$U(x, t_{k+1}) := X(x, t_{k+1}) + Z(x, t_{k+1}),$$

where

$$X(x, t_{k+1}) = \begin{cases} b(x, t_{k+1}), & x \in [0, 1), \\ c(x, t_{k+1}), & x \in [1, 2], \end{cases} \tag{14}$$

and

$$Z(x, t_{k+1}) = \begin{cases} z_1(x, t_{k+1}), & x \in [0, 1), \\ z_2(x, t_{k+1}), & x \in [1, 2]. \end{cases} \tag{15}$$

Here, the smooth component $b(x, t_{k+1})$ is the solution of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_1 b(x, t_{k+1}) = \tilde{\mathcal{G}}_1(x, t_{k+1}), \quad x \in (0, 1), \\ &b(0, t_{k+1}), \quad b(1, t_{k+1}) \text{ are to be chosen lately,} \end{aligned}\right\} \tag{16}$$

and $c(x, t_{k+1})$ is the solution of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_2 c(x, t_{k+1}) = \tilde{\mathcal{G}}_2(x, t_{k+1}), \quad x \in (1, 2), \\ &c(x, t_{k+1}) = b(x, t_{k+1}) \text{ on } [0, 1), \\ &c(1, t_{k+1}), \quad c(2, t_{k+1}) \text{ are to be chosen lately.} \end{aligned}\right\} \tag{17}$$

Moreover, the singular components $z_1(x, t_{k+1})$ and $z_2(x, t_{k+1})$ satisfy the following

$$\tilde{\mathcal{L}}_1 z_1(x, t_{k+1}) = 0, \quad x \in (0, 1), \quad \tilde{\mathcal{L}}_2 z_2(x, t_{k+1}) = 0, \quad x \in (1, 2), \tag{18}$$

$$z_1(0, t_{k+1}) = U(0, t_{k+1}) - b(0, t_{k+1}),$$

$$z_2(1, t_{k+1}) - z_1(1, t_{k+1}) = b(1, t_{k+1}) - c(1, t_{k+1}), \tag{19}$$

$$\frac{\mathrm{d}z_2}{\mathrm{d}x}(1, t_{k+1}) - \frac{\mathrm{d}z_1}{\mathrm{d}x}(1, t_{k+1}) = \frac{\mathrm{d}b}{\mathrm{d}x}(1, t_{k+1}) - \frac{\mathrm{d}c}{\mathrm{d}x}(1, t_{k+1}), \tag{20}$$

$$z_2(2, t_{k+1}) = U(2, t_{k+1}) - c(2, t_{k+1}).$$

The next lemmas provide bounds on the derivatives of $X(x, t_{k+1})$ and $Z(x, t_{k+1})$ with respect to x. We derive bounds for these components separately for $p_0\mu^2 \le \gamma\,\varepsilon$ and $p_0\mu^2 \ge \gamma\,\varepsilon$.

3.1. Estimates for the smooth components when $p_0\mu^2 \le \gamma\,\varepsilon$

Lemma 3.5: *Let $b(x, t_{k+1})$ and $c(x, t_{k+1})$ be the solutions of* (16) *and* (17)*, respectively. Then for $p_0\mu^2 \le \gamma\,\varepsilon$ and $k = 0, 1, 2, 3$*

$$\|b^{(k)}\|_{\bar{\Omega}_1} \le C, \quad \|c^{(k)}\|_{\bar{\Omega}_2} \le C.$$

Proof: Decompose the smooth components $b(x,t_{k+1})$ and $c(x,t_{k+1})$ as

$$\begin{aligned} b(x,t_{k+1}) &= b_0(x,t_{k+1}) + \sqrt{\varepsilon}b_1(x,t_{k+1}) + (\sqrt{\varepsilon})^2 b_2(x,t_{k+1}) \\ &\quad + (\sqrt{\varepsilon})^3 b_3(x,t_{k+1}), \quad x \in \bar{\Omega}_1, \\ c(x,t_{k+1}) &= c_0(x,t_{k+1}) + \sqrt{\varepsilon}c_1(x,t_{k+1}) + (\sqrt{\varepsilon})^2 c_2(x,t_{k+1}) \\ &\quad + (\sqrt{\varepsilon})^3 c_3(x,t_{k+1}), \quad x \in \bar{\Omega}_2, \end{aligned}$$

where the functions b_0 and c_0 are the solutions of

$$\left.\begin{aligned} -(lb_0)(x,t_{k+1}) &= (mb_0)(x,t_k) - r(x,t_{k+1})\psi_1(x-1,t_{k+1}) - r(x,t_k)\psi_1(x-1,t_k) \\ &\quad + g(x,t_k) + g(x,t_{k+1}), \quad x \in \bar{\Omega}_1, \\ -(lc_0)(x,t_{k+1}) + r(x,t_{k+1})b_0(x-1,t_{k+1}) &= (mc_0)(x,t_k) - r(x,t_k)b_0(x-1,t_k) \\ &\quad + g(x,t_k) + g(x,t_{k+1}), \quad x \in \bar{\Omega}_2, \end{aligned}\right\}$$

the functions b_1 and c_1 are the solutions of

$$\left.\begin{aligned} (lb_1)(x,t_{k+1}) &= \left(\sqrt{\varepsilon}b_0'' + \frac{\mu}{\sqrt{\varepsilon}}pb_0'\right)(x,t_{k+1}) \\ &\quad + \left(\sqrt{\varepsilon}b_0'' + \frac{\mu}{\sqrt{\varepsilon}}pb_0' - mb_1\right)(x,t_k), \quad x \in \bar{\Omega}_1, \\ (lc_1)(x,t_{k+1}) - r(x,t_{k+1})b_1(x-1,t_{k+1}) &= \left(\sqrt{\varepsilon}c_0'' + \frac{\mu}{\sqrt{\varepsilon}}pc_0'\right)(x,t_{k+1}) \\ &\quad + r(x,t_k)b_1(x-1,t_k) + \left(\sqrt{\varepsilon}c_0'' + \tfrac{\mu}{\sqrt{\varepsilon}}pc_0' - mc_1\right)(x,t_k), \quad x \in \bar{\Omega}_2, \end{aligned}\right\}$$

the functions b_2 and c_2 are the solutions of

$$\left.\begin{aligned} (lb_2)(x,t_{k+1}) &= \left(\sqrt{\varepsilon}b_1'' + \frac{\mu}{\sqrt{\varepsilon}}pb_1'\right)(x,t_{k+1}) \\ &\quad + \left(\sqrt{\varepsilon}b_1'' + \frac{\mu}{\sqrt{\varepsilon}}pb_1' - mb_2\right)(x,t_k), \quad x \in \bar{\Omega}_1, \\ &(lc_2)(x,t_{k+1}) - r(x,t_{k+1})b_2(x-1,t_{k+1}) \\ &\quad = \left(\sqrt{\varepsilon}c_1'' + \frac{\mu}{\sqrt{\varepsilon}}pc_1'\right)(x,t_{k+1}) + r(x,t_k)b_2(x-1,t_k) \\ &\qquad + \left(\sqrt{\varepsilon}c_1'' + \tfrac{\mu}{\sqrt{\varepsilon}}pc_1' - mc_2\right)(x,t_k), \quad x \in \bar{\Omega}_2, \end{aligned}\right\}$$

and lastly, the functions b_3 and c_3 are the solutions of

$$\left.\begin{aligned} \tilde{\mathcal{L}}_1 b_3(x,t_{k+1}) &= \left(-\sqrt{\varepsilon}b_2'' - \frac{\mu}{\sqrt{\varepsilon}}pb_2'\right)(x,t_{k+1}) + \left(-\sqrt{\varepsilon}b_2'' - \frac{\mu}{\sqrt{\varepsilon}}pb_2'\right)(x,t_k) \\ &\quad - (\varepsilon b_3'' + \mu p b_3' - mb_3)(x,t_k), \quad x \in \Omega_1, \\ b_3(0,t_{k+1}) &= 0, \quad b_3(1,t_{k+1}) = 0, \end{aligned}\right\} \tag{22}$$

and

$$\left.\begin{aligned}\tilde{\mathcal{L}}_2 c_3(x,t_{k+1}) &= \left(-\sqrt{\varepsilon}c_2'' - \frac{\mu}{\sqrt{\varepsilon}}pc_2'\right)(x,t_{k+1}) - \left(\sqrt{\varepsilon}c_2'' + \frac{\mu}{\sqrt{\varepsilon}}pc_2'\right)(x,t_k)\\ &-(\varepsilon c_3'' + \mu p c_3' - m c_3)(x,t_k) - r(x,t_k)b_3(x-1,t_k), \quad x \in \Omega_2,\\ c_3(1,t_{k+1}) &= 0, \quad c_3(2,t_{k+1}) = 0, \quad c_3(x,t_{k+1}) = b_3(x,t_{k+1}) \text{ on } [0,1).\end{aligned}\right\} \tag{23}$$

Since, the functions $p(x,t_{k+1})$, $r(x,t_{k+1})$, $m(x,t_{k+1})$, $l(x,t_{k+1})$, $\psi_1(x,t_{k+1})$ and $g(x,t_{k+1})$ are sufficiently smooth and $p_0\mu^2 \le \gamma\,\varepsilon$, we have

$$\begin{aligned}\|b_0^{(k)}\|_{\bar{\Omega}_1} \le C, \quad \|c_0^{(k)}\|_{\bar{\Omega}_2} \le C, \quad &\text{for } 0 \le k \le 7,\\ \|b_1^{(k)}\|_{\bar{\Omega}_1} \le C, \quad \|c_1^{(k)}\|_{\bar{\Omega}_2} \le C, \quad &\text{for } 0 \le k \le 5,\\ \|b_2^{(k)}\|_{\bar{\Omega}_1} \le C, \quad \|c_2^{(k)}\|_{\bar{\Omega}_2} \le C, \quad &\text{for } 0 \le k \le 3.\end{aligned}$$

Now, using Lemma 2 from [12] to obtain $\|b_3\|_{\bar{\Omega}_1} \le C$ and $\|c_3\|_{\bar{\Omega}_2} \le C$. Since $p_0\mu^2 \le \gamma\,\varepsilon$, Lemma 3.4 asserts that $\|b_3'\|_{\bar{\Omega}_1} \le \frac{C}{\sqrt{\varepsilon}}$ and $\|c_3'\|_{\bar{\Omega}_2} \le \frac{C}{\sqrt{\varepsilon}}$. Moreover, from (22) and (23), we obtain

$$\|b_3^{(k)}\|_{\bar{\Omega}_1} \le \frac{C}{(\sqrt{\varepsilon})^k}, \quad \|c_3^{(k)}\|_{\bar{\Omega}_2} \le \frac{C}{(\sqrt{\varepsilon})^k}, \quad \text{for } k = 2,3.$$

Next, we choose $b(0,t_{k+1})$, $b(1,t_{k+1})$, $c(1,t_{k+1})$ and $c(2,t_{k+1})$ to be

$$\begin{aligned}b(0,t_{k+1}) &= (b_0 + \sqrt{\varepsilon}b_1 + \varepsilon b_2)(0,t_{k+1}), \quad b(1,t_{k+1}) = (b_0 + \sqrt{\varepsilon}b_1 + \varepsilon b_2)(1,t_{k+1}),\\ c(1,t_{k+1}) &= (c_0 + \sqrt{\varepsilon}c_1 + \varepsilon c_2)(1,t_{k+1}), \quad c(2,t_{k+1}) = (c_0 + \sqrt{\varepsilon}c_1 + \varepsilon c_2)(2,t_{k+1}).\end{aligned}$$

Since $b = b_0 + \sqrt{\varepsilon}b_1 + \varepsilon b_2 + \varepsilon^{3/2}b_3$, for $k = 0, 1, 2, 3$, we have

$$\|b^{(k)}\|_{\bar{\Omega}_1} \le \|b_0^{(k)}\|_{\bar{\Omega}_1} + \sqrt{\varepsilon}\|b_1^{(k)}\|_{\bar{\Omega}_1} + \varepsilon\|b_2^{(k)}\|_{\bar{\Omega}_1} + \varepsilon^{3/2}\|b_3^{(k)}\|_{\bar{\Omega}_1} \le C.$$

Similarly, we get $\|c^{(k)}\|_{\bar{\Omega}_2} \le C$, for $k = 0, 1, 2, 3$. ■

3.2. Estimates for the smooth components when $p_0\mu^2 \ge \gamma\varepsilon$

Similar to the previous case, here also, the decomposition of $b(x,t_{k+1})$ and $c(x,t_{k+1})$ is considered, but at two levels. We define operators $\tilde{\mathcal{L}}_1^*$, $\tilde{\mathcal{L}}_2^*$, $\tilde{\mathcal{L}}_3$, $\tilde{\mathcal{L}}_3^*$, $\tilde{\mathcal{L}}_4$, and $\tilde{\mathcal{L}}_4^*$ for this purpose. These operators are defined as:

$$\begin{aligned}&\tilde{\mathcal{L}}_1^* = \varepsilon D^2 + \mu p(x,t_k)D - m(x,t_k)I, \quad \tilde{\mathcal{L}}_2^* = \varepsilon D^2 + \mu p(x,t_k)D - m(x,t_k)I + r(x,t_k)E,\\ &\tilde{\mathcal{L}}_3 = \mu p(x,t_k)D - l(x,t_k)I, \quad \tilde{\mathcal{L}}_3^* = \mu p(x,t_k)D - m(x,t_k)I,\\ &\tilde{\mathcal{L}}_4 = \mu p(x,t_k)D - l(x,t_k)I + r(x,t_k)E \quad \text{and} \quad \tilde{\mathcal{L}}_4^* = \mu p(x,t_k)D - m(x,t_k)I + r(x,t_k)E.\end{aligned}$$

Here, $DU(x,t_k) = \dfrac{\mathrm{d}U}{\mathrm{d}x}(x,t_k)$ and $D^2U(x,t_k) = \dfrac{\mathrm{d}^2U}{\mathrm{d}x^2}(x,t_k)$ are the differential operators. Additionally, $IU(x,t_k) = U(x,t_k)$ is the identity operator and $EU(x,t_k) = EU(x-1,t_k)$ is

the shift operator. Finally, we consider the decomposition of $b(x, t_{k+1})$ and $c(x, t_{k+1})$ as

$$\begin{aligned} b(x, t_{k+1}; \varepsilon, \mu) &= b_0(x, t_{k+1}) + \varepsilon b_1(x, t_{k+1}; \mu) + \varepsilon^2 b_2(x, t_{k+1}; \mu) \\ &\quad + \varepsilon^3 b_3(x, t_{k+1}; \mu), \quad x \in \bar{\Omega}_1, \\ c(x, t_{k+1}; \varepsilon, \mu) &= c_0(x, t_{k+1}) + \varepsilon c_1(x, t_{k+1}; \mu) + \varepsilon^2 c_2(x, t_{k+1}; \mu) \\ &\quad + \varepsilon^3 c_3(x, t_{k+1}; \mu), \quad x \in \bar{\Omega}_2, \end{aligned}$$

where the functions b_0 and c_0 are the solutions of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_3 b_0(x, t_{k+1}) = -\tilde{\mathcal{L}}_3^* b_0(x, t_k) - r(x, t_{k+1})\psi_1(x-1, t_{k+1}) \\ &\quad -r(x, t_k)\psi_1(x-1, t_k) + g(x, t_k) + g(x, t_{k+1}), \quad x \in [0, 1), \\ &b_0(1, t_{k+1}) \text{ is to be chosen lately,} \end{aligned}\right\} \tag{24}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_4 c_0(x, t_{k+1}) = -\tilde{\mathcal{L}}_4^* c_0(x, t_k) + g(x, t_k) + g(x, t_{k+1}), \quad x \in [1, 2), \\ &c_0(2, t_{k+1}) \text{ is to be chosen lately,} \\ &c_0(x, t_{k+1}) = b_0(x, t_{k+1}) \text{ on } [0, 1), \end{aligned}\right\} \tag{25}$$

the functions b_1 and c_1 are the solutions of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_3 b_1(x, t_{k+1}) = -b_0''(x, t_{k+1}) - b_0''(x, t_k) - \tilde{\mathcal{L}}_3^* b_1(x, t_k), \quad x \in [0, 1), \\ &b_1(1, t_{k+1}) \text{ is to be chosen lately,} \end{aligned}\right\} \tag{26}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_4 c_1(x, t_{k+1}) = -c_0''(x, t_{k+1}) - c_0''(x, t_k) - \tilde{\mathcal{L}}_4^* c_1(x, t_k), \quad x \in [1, 2), \\ &c_1(2, t_{k+1}) \text{ is to be chosen lately,} \\ &c_1(x, t_{k+1}) = b_1(x, t_{k+1}) \text{ on } [0, 1), \end{aligned}\right\} \tag{27}$$

the functions b_2 and c_2 are the solutions of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_3 b_2(x, t_{k+1}) = -b_1''(x, t_{k+1}) - b_1''(x, t_k) - \tilde{\mathcal{L}}_3^* b_2(x, t_k), \quad x \in [0, 1), \\ &b_2(1, t_{k+1}) = 0, \end{aligned}\right\} \tag{28}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_4 c_2(x, t_{k+1}) = -c_1''(x, t_{k+1}) - c_1''(x, t_k) - \tilde{\mathcal{L}}_4^* c_2(x, t_k), \quad x \in [1, 2), \\ &c_2(2, t_{k+1}) = 0, \\ &c_2(x, t_{k+1}) = b_2(x, t_{k+1}) \text{ on } [0, 1), \end{aligned}\right\} \tag{29}$$

and lastly, the functions b_3 and c_3 are the solutions of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_1 b_3(x, t_{k+1}) = -b_2''(x, t_{k+1}) - b_2''(x, t_k) - \tilde{\mathcal{L}}_1^* b_3(x, t_k), \quad x \in (0, 1), \\ &b_3(0, t_{k+1}) = 0, \quad b_3(1, t_{k+1}) = 0, \end{aligned}\right\} \tag{30}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_2 c_3(x,t_{k+1}) = -c_2''(x,t_{k+1}) - c_2''(x,t_k) - \tilde{\mathcal{L}}_2^* c_3(x,t_k), \quad x \in (1,2),\\ &c_3(1,t_{k+1}) = 0, \quad c_3(2,t_{k+1}) = 0,\\ &c_3(x,t_{k+1}) = b_3(x,t_{k+1}) \text{ on } [0,1). \end{aligned}\right\} \tag{31}$$

Lemma 3.6: *Let $\psi(x,t_{k+1})$ satisfies $\psi(1,t_{k+1}) \geq 0$ and $\tilde{\mathcal{L}}_3\psi(x,t_{k+1}) \leq 0$ for all $x \in [0,1)$. Then $\psi(x,t_{k+1}) \geq 0$ for all $x \in [0,1]$.*

Proof: Define $\psi(\alpha,t_{k+1}) = \min_{\alpha\in\bar{\Omega}_1} \psi(x,t_{k+1})$ for some $\alpha \in \bar{\Omega}_1$. Let $\psi(\alpha,t_{k+1}) < 0$, then $\alpha \neq 1$ and $\psi'(\alpha,t_{k+1}) = 0$. For $\alpha \in [0,1)$, we have $\tilde{\mathcal{L}}_3\psi(\alpha,t_{k+1}) = (\mu p\psi'(\alpha,t_{k+1}) - l\psi(\alpha,t_{k+1})) > 0$, which contradicts the assumption. Therefore, we can conclude that $\psi(\alpha,t_{k+1}) \geq 0$ which implies $\psi(x,t_{k+1}) \geq 0$ for all $x \in [0,1]$. ■

Lemma 3.7: *Let $b(x,t_{k+1})$ and $c(x,t_{k+1})$ be the solutions of* (24)–(31). *Then for $p_0\mu^2 \geq \gamma\,\varepsilon$ and $k = 0, 1, 2, 3$*

$$\|b^{(k)}\|_{\bar{\Omega}_1} \leq C\left(1 + \left(\frac{\varepsilon}{\mu}\right)^{3-k}\right), \quad \|c^{(k)}\|_{\bar{\Omega}_2} \leq C\left(1 + \left(\frac{\varepsilon}{\mu}\right)^{3-k}\right).$$

Proof: To establish the bounds for the derivatives of the smooth components b and c, we use the bounds for the derivatives of b_0, b_1, b_2, b_3, c_0, c_1, c_2 and c_3. Let's first establish the bounds for b_0 and c_0. To do this, we consider the decomposition of b_0 and c_0 as

$$\begin{aligned} b_0(x,t_{k+1};\mu) &= b_{0,0}(x,t_{k+1}) + \mu b_{0,1}(x,t_{k+1}) + \mu^2 b_{0,2}(x,t_{k+1})\\ &\quad + \mu^3 b_{0,3}(x,t_{k+1};\mu) \quad \text{for } x \in \bar{\Omega}_1,\\ c_0(x,t_{k+1};\mu) &= c_{0,0}(x,t_{k+1}) + \mu c_{0,1}(x,t_{k+1}) + \mu^2 c_{0,2}(x,t_{k+1})\\ &\quad + \mu^3 c_{0,3}(x,t_{k+1};\mu) \quad \text{for } x \in \bar{\Omega}_2, \end{aligned}$$

where the functions $b_{0,0}$ and $c_{0,0}$ are the solutions of

$$\left.\begin{aligned} &-(lb_{0,0})(x,t_{k+1}) = (mb_{0,0})(x,t_k) - r(x,t_{k+1})\psi_1(x-1,t_{k+1}) - r(x,t_k)\psi_1(x-1,t_k)\\ &\quad + g(x,t_k) + g(x,t_{k+1}), \quad x \in \bar{\Omega}_1,\\ &-(lc_{0,0})(x,t_{k+1}) + r(x,t_{k+1})b_{0,0}(x-1,t_{k+1}) = (mc_{0,0})(x,t_k) - r(x,t_k)b_{0,0}(x-1,t_k)\\ &\quad + g(x,t_k) + g(x,t_{k+1}), \quad x \in \bar{\Omega}_2, \end{aligned}\right\}$$

the functions $b_{0,1}$ and $c_{0,1}$ are the solutions of

$$\left.\begin{aligned} &(lb_{0,1})(x,t_{k+1}) = (pb_{0,0}')(x,t_{k+1}) + (pb_{0,0}' - mb_{0,1})(x,t_k), \quad x \in \bar{\Omega}_1,\\ &(lc_{0,1})(x,t_{k+1}) - r(x,t_{k+1})b_{0,1}(x-1,t_{k+1}) = (pc_{0,0}')(x,t_{k+1}) + (pc_{0,0}' - mc_{0,1})(x,t_k)\\ &\quad + r(x,t_k)b_{0,1}(x-1,t_k), \quad x \in \bar{\Omega}_2, \end{aligned}\right\}$$

the functions $b_{0,2}$ and $c_{0,2}$ are the solutions of

$$\left.\begin{aligned}&(lb_{0,2})(x,t_{k+1}) = (pb'_{0,1})(x,t_{k+1}) + (pb'_{0,1} - mb_{0,2})(x,t_k), \quad x \in \bar{\Omega}_1,\\ &(lc_{0,2})(x,t_{k+1}) - r(x,t_{k+1})b_{0,2}(x-1,t_{k+1}) = (pc'_{0,1})(x,t_{k+1}) + (pc'_{0,1} - mc_{0,2})(x,t_k)\\ &\quad + r(x,t_k)b_{0,2}(x-1,t_k), \quad x \in \bar{\Omega}_2,\end{aligned}\right\}$$

and lastly, the functions $b_{0,3}$ and $c_{0,3}$ are the solutions of

$$\left.\begin{aligned}&\tilde{\mathcal{L}}_3 b_{0,3}(x,t_{k+1}) = -(pb'_{0,2})(x,t_{k+1}) - (pb'_{0,2})(x,t_k) - \tilde{\mathcal{L}}_3^* b_{0,3}(x,t_k), \quad x \in [0,1),\\ &b_{0,3}(1,t_k) = 0,\end{aligned}\right\} \tag{32}$$

and

$$\left.\begin{aligned}&\tilde{\mathcal{L}}_4 c_{0,3}(x,t_{k+1}) = -(pc'_{0,2})(x,t_{k+1}) - (pc'_{0,2})(x,t_k) - \tilde{\mathcal{L}}_4^* c_{0,3}(x,t_k), \quad x \in [1,2),\\ &c_{0,3}(2,t_k) = 0,\\ &c_{0,3}(x,t_{k+1}) = b_{0,3}(x,t_{k+1}), \quad x \in [0,1).\end{aligned}\right\} \tag{33}$$

Since, the functions $l(x,t_{k+1})$, $m(x,t_{k+1})$, $r(x,t_{k+1})$, $\psi_1(x,t_{k+1})$, $\psi_2(x,t_{k+1})$, $\psi_3(x,t_{k+1})$, and $g(x,t_{k+1})$ are sufficiently smooth on their respective domain. Thus, we have

$$\begin{aligned}&\|b_{0,0}^{(k)}\|_{\bar{\Omega}_1} \le C, \quad \|c_{0,0}^{(k)}\|_{\bar{\Omega}_2} \le C, \quad \text{for } 0 \le k \le 10,\\ &\|b_{0,1}^{(k)}\|_{\bar{\Omega}_1} \le C, \quad \|c_{0,1}^{(k)}\|_{\bar{\Omega}_2} \le C, \quad \text{for } 0 \le k \le 9,\\ &\|b_{0,2}^{(k)}\|_{\bar{\Omega}_1} \le C, \quad \|c_{0,2}^{(k)}\|_{\bar{\Omega}_2} \le C, \quad \text{for } 0 \le k \le 8.\end{aligned} \tag{34}$$

Define $\psi^{\pm}(x,t_{k+1}) = C \pm b_{0,3}(x,t_{k+1})$, $x \in \bar{\Omega}_1$. Now, apply Lemma 3.6 to $\psi^{\pm}(x,t_{k+1})$ to obtain $\|b_{0,3}\|_{\bar{\Omega}1} \le C$. Then, we use (32) to get

$$\|b_{0,3}^{(k)}\|_{\bar{\Omega}_1} \le \frac{C}{\mu^k}, \quad \text{for } 0 \le k \le 8. \tag{35}$$

Similarly, consider the function $\psi^{\pm}(x,t_{k+1}) = C \pm c_{0,3}(x,t_{k+1})$, $x \in \bar{\Omega}_2$. Applying Lemma 3.6 to $\psi^{\pm}(x,t_{k+1})$ yields $\|c_{0,3}\|_{\bar{\Omega}_2} \le C$. Using (33), we have

$$\|c_{0,3}^{(k)}\|_{\bar{\Omega}_2} \le \frac{C}{\mu^k}, \quad \text{for } 0 \le k \le 8. \tag{36}$$

As defined in (24) and (25), choose $b_0(1,t_{k+1})$ and $c_0(2,t_{k+1})$ to be

$$\begin{aligned}b_0(1,t_{k+1}) &= (b_{0,0} + \mu b_{0,1} + \mu^2 b_{0,2})(1,t_{k+1}),\\ c_0(2,t_{k+1}) &= (c_{0,0} + \mu c_{0,1} + \mu^2 c_{0,2})(2,t_{k+1}).\end{aligned}$$

Therefore, using (34)–(36) to obtain

$$\|b_0^k\|_{\bar{\Omega}_1} \le C\left(1 + \frac{1}{\mu^{k-3}}\right), \quad \|c_0^k\|_{\bar{\Omega}_2} \le C\left(1 + \frac{1}{\mu^{k-3}}\right), \quad 0 \le k \le 8. \tag{37}$$

Now, decompose the functions b_1 and c_1 as

$$b_1(x,t_{k+1};\mu) = b_{1,0}(x,t_{k+1}) + \mu b_{1,1}(x,t_{k+1}) + \mu^2 b_{1,2}(x,t_{k+1};\mu), \quad x \in \bar{\Omega}_1,$$
$$c_1(x,t_{k+1};\mu) = c_{1,0}(x,t_{k+1}) + \mu c_{1,1}(x,t_{k+1}) + \mu^2 c_{1,2}(x,t_{k+1};\mu), \quad x \in \bar{\Omega}_2,$$

where the functions $b_{1,0}$ and $c_{1,0}$ are the solution of

$$\left.\begin{aligned}
&(lb_{1,0})(x,t_{k+1}) = b_0''(x,t_{k+1}) + b_0''(x,t_k) - (mb_{1,0})(x,t_k), \quad x \in \bar{\Omega}_1,\\
&(lc_{1,0})(x,t_{k+1}) - r(x,t_{k+1})c_{1,0}(x-1,t_{k+1}) = c_0''(x,t_{k+1}) + c_0''(x,t_k) - (mc_{1,0})(x,t_k)\\
&\quad + r(x,t_k)c_{1,0}(x-1,t_k), \quad x \in \bar{\Omega}_2,
\end{aligned}\right\}$$

the functions $b_{1,1}$ and $c_{1,1}$ are the solutions of

$$\left.\begin{aligned}
&(lb_{1,1})(x,t_{k+1}) = (pb_{1,0}')(x,t_{k+1}) + (pb_{1,0}' - mb_{1,1})(x,t_k), \quad x \in \bar{\Omega}_1,\\
&(lc_{1,1})(x,t_{k+1}) - r(x,t_{k+1})b_{1,1}(x-1,t_{k+1}) = (pc_{1,0}')(x,t_{k+1}) + (pc_{1,0}' - mc_{1,1})(x,t_k)\\
&\quad + r(x,t_k)b_{1,1}(x-1,t_k), \quad x \in \bar{\Omega}_2,
\end{aligned}\right\}$$

and the functions $b_{1,2}$ and $c_{1,2}$ are the solution of

$$\left.\begin{aligned}
&\tilde{\mathcal{L}}_3 b_{1,2}(x,t_{k+1}) = -(pb_{1,1}')(x,t_{k+1}) - (pb_{1,1}')(x,t_k) - \tilde{\mathcal{L}}_3^* b_{1,2}(x,t_k), \quad x \in [0,1),\\
&b_{1,2}(1,t_k) = 0,\\
&\tilde{\mathcal{L}}_4 c_{1,2}(x,t_{k+1}) = -(pc_{1,1}')(x,t_{k+1}) - (pc_{1,1}')(x,t_k) - \tilde{\mathcal{L}}_4^* c_{1,2}(x,t_k), \quad x \in [1,2),\\
&c_{1,2}(2,t_k) = 0,\\
&c_{1,2}(x,t_{k+1}) = b_{1,2}(x,t_{k+1}), \quad x \in [0,1).
\end{aligned}\right\}$$

To establish the bounds for the derivatives of b_1 and c_1, we use a similar argument as we did for b_0 and c_0. We apply Lemma 3.6 to suitable barrier functions and obtain the bounds for the derivatives of the components of b_1 and c_1 as follows

$$\|b_{1,0}^{(k)}\|_{\bar{\Omega}_1} \le C\left(1 + \frac{1}{\mu^{k-1}}\right), \quad \|c_{1,0}^{(k)}\|_{\bar{\Omega}_2} \le C\left(1 + \frac{1}{\mu^{k-1}}\right), \quad 0 \le k \le 6,$$
$$\|b_{1,1}^{(k)}\|_{\bar{\Omega}_1} \le C\left(1 + \frac{1}{\mu^{k}}\right), \quad \|c_{1,1}^{(k)}\|_{\bar{\Omega}_2} \le C\left(1 + \frac{1}{\mu^{k}}\right), \quad 0 \le k \le 5,$$
$$\|b_{1,2}^{(k)}\|_{\bar{\Omega}_1} \le \left(\frac{C}{\mu^{k+1}}\right), \quad \|c_{1,2}^{(k)}\|_{\bar{\Omega}_2} \le \left(\frac{C}{\mu^{k+1}}\right), \quad 0 \le k \le 5.$$

Therefore, we get the following bounds for the derivatives of b_1 and c_1

$$\|b_1^{(k)}\|_{\bar{\Omega}_1} \le C\left(1 + \frac{1}{\mu^{k-1}}\right), \quad \|c_1^{(k)}\|_{\bar{\Omega}_2} \le C\left(1 + \frac{1}{\mu^{k-1}}\right), \quad 0 \le k \le 5.$$

Similarly, we can establish the bounds for the derivatives of b_2 and c_2 as given below

$$\|b_2^{(k)}\|_{\bar{\Omega}_1} \le \left(\frac{C}{\mu^{k+1}}\right), \quad \|c_2^{(k)}\|_{\bar{\Omega}_2} \le \left(\frac{C}{\mu^{k+1}}\right), \quad 0 \le k \le 3. \tag{38}$$

From (30) and (31) and Lemma 2 of [12], we get the following bounds for b_3 and c_3

$$\|b_3\|_{\bar{\Omega}_1} \leq \left(\frac{C}{\mu^3}\right), \quad \|c_3\|_{\bar{\Omega}_2} \leq \left(\frac{C}{\mu^3}\right).$$

From Lemma 2.3, it follows that

$$\|b_3'\|_{\bar{\Omega}_1} \leq \left(\frac{C}{\varepsilon\mu^2}\right), \quad \|c_3'\|_{\bar{\Omega}_2} \leq \left(\frac{C}{\varepsilon\mu^2}\right), \tag{39}$$

and from (30) and (31), we have

$$\|b_3''\|_{\bar{\Omega}_1} \leq \left(\frac{C}{\varepsilon^2\mu}\right), \quad \|c_3''\|_{\bar{\Omega}_2} \leq \left(\frac{C}{\varepsilon^2\mu}\right). \tag{40}$$

Differentiating Equations (30) and (31) and using $p_0\mu^2 \geq \gamma\,\varepsilon$, we compute

$$\|b_3^{(3)}\|_{\bar{\Omega}_1} \leq \left(\frac{C}{\varepsilon^3}\right), \quad \|c_3^{(k)}\|_{\bar{\Omega}_2} \leq \left(\frac{C}{\varepsilon^3}\right). \tag{41}$$

Therefore, we can write

$$\|b_3^{(k)}\|_{\bar{\Omega}_1} \leq \left(\frac{C}{\varepsilon^k\mu^{3-k}}\right), \quad \|c_3^{(k)}\|_{\bar{\Omega}_2} \leq \left(\frac{C}{\varepsilon^k\mu^3 - k}\right), \quad k = 0, 1, 2, 3.$$

As defined in (16), choose $b(0, t_{k+1})$ and $b(1, t_{k+1})$ to be

$$\begin{aligned} b(0, t_{k+1}) &= b_0(0, t_{k+1}) + \varepsilon b_1(0, t_{k+1}) + \varepsilon^2 b_2(0, t_{k+1}), \\ b(1, t_{k+1}) &= b_0(1, t_{k+1}) + \varepsilon b_1(1, t_{k+1}), \end{aligned}$$

and from (17), choose $c(1, t_{k+1})$ and $c(2, t_{k+1})$ to be

$$\begin{aligned} c(1, t_{k+1}) &= c_0(1, t_{k+1}) + \varepsilon c_1(1, t_{k+1}) + \varepsilon^2 c_2(1, t_{k+1}), \\ c(2, t_{k+1}) &= c_0(2, t_{k+1}) + \varepsilon c_1(2, t_{k+1}). \end{aligned}$$

We now obtain the bounds for the functions b and c by using the estimates for their components b_0, b_1, b_2, b_3, c_0, c_1, c_2 and c_3 and get

$$\|b^{(k)}\|_{\bar{\Omega}_1} \leq C\left(1 + \left(\frac{\varepsilon}{\mu}\right)^{3-k}\right), \quad \|c^{(k)}\|_{\bar{\Omega}_2} \leq C\left(1 + \left(\frac{\varepsilon}{\mu}\right)^{3-k}\right). \qquad \blacksquare$$

3.3. Estimates for the singular components

Let us decompose the singular component $Z(x, t_{k+1})$ defined in (15) as

$$\begin{aligned} Z(x, t_{k+1}) &:= Z_L(x, t_{k+1}) + Z_R(x, t_{k+1}) \\ &:= (z_1^L + z_2^L)(x, t_{k+1}) + (z_1^R + z_2^R)(x, t_{k+1}), \end{aligned}$$

where the functions z_1^L and z_2^L satisfy

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_1 z_1^L(x, t_{k+1}) = 0, \quad x \in (0, 1), \\ &z_1^L(0, t_{k+1}) = U(0, t_{k+1}) - X(0, t_{k+1}) - j_1(\varepsilon, \mu), \quad z_1^L(1, t_{k+1}) = 0, \end{aligned}\right\} \tag{42}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_2 z_2^L(x, t_{k+1}) = 0, \quad x \in (1, 2), \\ &z_2^L(1, t_{k+1}) = k_1(\varepsilon, \mu) - j_2(\varepsilon, \mu), \quad z_2^L(2, t_{k+1}) = 0, \\ &z_2^L(x, t_{k+1}) = z_1^L(x, t_{k+1}), \quad x \in [0, 1), \end{aligned}\right\} \tag{43}$$

and the functions z_1^R and z_2^R satisfy

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_1 z_1^R(x, t_{k+1}) = 0, \quad x \in (0, 1), \\ &z_1^R(0, t_{k+1}) = j_1(\varepsilon, \mu), \quad z_1^R(1, t_{k+1}) = k_2(\varepsilon, \mu), \end{aligned}\right\} \tag{44}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_2 z_2^R(x, t_{k+1}) = 0, \quad x \in (1, 2), \\ &z_2^R(1, t_{k+1}) = j_2(\varepsilon, \mu), \quad z_2^R(2, t_{k+1}) = U(2, t_{k+1}) - X(2, t_{k+1}), \\ &z_2^R(x, t_{k+1}) = z_1^R(x, t_{k+1}), \quad x \in [0, 1). \end{aligned}\right\} \tag{45}$$

Here, $k_1(\varepsilon, \mu)$ and $k_2(\varepsilon, \mu)$ are constants to be chosen to satisfy the jump conditions at $x = 1$ given in (19) and (20). Moreover, constants $j_1(\varepsilon, \mu)$ and $j_2(\varepsilon, \mu)$ are to be chosen separately for the cases $p_0\mu^2 \le \gamma\,\varepsilon$ and $p_0\mu^2 \ge \gamma\,\varepsilon$ to satisfy the requirements for the bounds of the singular component.

Lemma 3.8: *Let $Z_L(x, t_{k+1})$ and $Z_R(x, t_{k+1})$ be the solutions of* (42)–(45). *Then for $p_0\mu^2 \ge \gamma\,\varepsilon$ and $k = 0, 1, 2, 3$*

$$\begin{aligned} &\|z_1^{L,(k)}\|_{\bar{\Omega}_1} \le C\left(\frac{\mu}{\varepsilon}\right)^k, \quad \|z_2^{L,(k)}\|_{\bar{\Omega}_2} \le C\left(\frac{\mu}{\varepsilon}\right)^k, \\ &\|z_1^{R,(k)}\|_{\bar{\Omega}_1} \le \frac{C}{\mu^k}, \quad \|z_2^{R,(k)}\|_{\bar{\Omega}_2} \le \frac{C}{\mu^k}. \end{aligned}$$

Proof: Since $U(0, t_{k+1})$ and $U(1, t_{k+1})$ are bounded by constants independent of ε and μ, $|j_1|$, $|j_2|$, $|k_1|$ and $|k_2|$ are also bounded by constants independent of ε and μ. Next, we use

Lemma 3.4 to compute

$$\|z_1^{L,(k)}(x,t_{k+1})\|_{\bar{\Omega}_1} \le C\left(\frac{\mu}{\varepsilon}\right)^k, \quad \|z_2^{L,(k)}(x,t_{k+1})\|_{\bar{\Omega}_2} \le C\left(\frac{\mu}{\varepsilon}\right)^k.$$

To find bounds for z_1^R and z_2^R, consider the following decomposition of z_1^R and z_2^R as

$$\begin{aligned} z_1^R(x,t_{k+1};\varepsilon,\mu) &= z_{1,0}^R(x,t_{k+1};\mu) + \varepsilon z_{1,1}^R(x,t_{k+1};\mu) + \varepsilon^2 z_{1,2}^R(x,t_{k+1};\mu) \\ &\quad + \varepsilon^3 z_{1,3}^R(x,t_{k+1};\varepsilon,\mu), \\ z_2^R(x,t_{k+1};\varepsilon,\mu) &= z_{2,0}^R(x,t_{k+1};\mu) + \varepsilon z_{2,1}^R(x,t_{k+1};\mu) + \varepsilon^2 z_{2,2}^R(x,t_{k+1};\mu) \\ &\quad + \varepsilon^3 z_{2,3}^R(x,t_{k+1};\varepsilon,\mu), \end{aligned} \tag{46}$$

where the functions $z_{1,0}^R$ and $z_{2,0}^R$ are the solutions of

$$\tilde{\mathcal{L}}_3 z_{1,0}^R(x,t_{k+1}) = 0, \quad x \in [0,1), \quad z_{1,0}^R(1,t_{k+1}) = k_2, \tag{47}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_4 z_{2,0}^R(x,t_{k+1}) = 0, \quad x \in [1,2), \quad z_{2,0}^R(2,t_{k+1}) = U(2,t_{k+1}) - X(2,t_{k+1}), \\ &z_{2,0}^R(x,t_{k+1}) = z_{1,0}^R(x,t_{k+1}), \quad x \in [0,1), \end{aligned}\right\} \tag{48}$$

the functions $z_{1,1}^R$ and $z_{2,1}^R$ are the solutions of

$$\tilde{\mathcal{L}}_3 z_{1,1}^R(x,t_{k+1}) = -z_{1,0}^{R,(2)}(x,t_{k+1}), \quad x \in [0,1), \quad z_{1,1}^R(1,t_{k+1}) = 0, \tag{49}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_4 z_{2,1}^R(x,t_{k+1}) = -z_{2,0}^{R,(2)}(x,t_{k+1}), \quad x \in [1,2), \quad z_{2,1}^R(2,t_{k+1}) = 0, \\ &z_{2,1}^R(x,t_{k+1}) = z_{1,1}^R(x,t_{k+1}), \quad x \in [0,1), \end{aligned}\right\} \tag{50}$$

the functions $z_{1,2}^R$ and $z_{2,2}^R$ are the solutions of

$$\tilde{\mathcal{L}}_3 z_{1,2}^R(x,t_{k+1}) = -z_{1,1}^{R,(2)}(x,t_{k+1}), \quad x \in [0,1), \quad z_{1,2}^R(1,t_{k+1}) = 0, \tag{51}$$

and

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_4 z_{2,2}^R(x,t_{k+1}) = -z_{2,1}^{R,(2)}(x,t_{k+1}), \quad x \in [1,2), \quad z_{2,2}^R(2,t_{k+1}) = 0, \\ &z_{2,2}^R(x,t_{k+1}) = z_{1,2}^R(x,t_{k+1}), \quad x \in [0,1), \end{aligned}\right\} \tag{52}$$

and lastly, the functions $z_{1,3}^R$ and $z_{2,3}^R$ are the solutions of

$$\left.\begin{aligned} &\tilde{\mathcal{L}}_1 z_{1,3}^R(x,t_{k+1}) = -z_{1,2}^{R,(2)}(x,t_{k+1}), \quad x \in (0,1),\ z_{1,3}^R(0,t_{k+1}) = 0,\ z_{1,3}^R(1,t_{k+1}) = 0, \\ &\tilde{\mathcal{L}}_2 z_{2,3}^R(x,t_{k+1}) = -z_{2,2}^{R,(2)}(x,t_{k+1}), \quad x \in (1,2),\ z_{2,3}^R(1,t_{k+1}) = 0,\ z_{2,3}^R(2,t_{k+1}) = 0, \\ &z_{2,3}^R(x,t_{k+1}) = z_{1,3}^R(x,t_{k+1}), \quad x \in [0,1). \end{aligned}\right\}$$

Define $\psi^{\pm}(x,t_{k+1}) = C \pm z_{1,0}^R(x,t_{k+1})$, $x \in [0,1]$ and apply Lemma 3.6 to the function $\psi^{\pm}(x,t_{k+1})$ to obtain $\|z_{1,0}^R(x,t_{k+1})\|_{\bar{\Omega}_1} \le C$. Now we use (47) to find

$$\|z_{1,0}^{R,(k)}\|_{\bar{\Omega}_1} \le \frac{C}{\mu^k}, \quad 0 \le k \le 5. \tag{53}$$

Similarly, it is easy to follow that

$$\|z_{2,0}^{R,(k)}\|_{\bar{\Omega}_2} \leq \frac{C}{\mu^k}, \quad 0 \leq k \leq 5. \tag{54}$$

Now, define $\psi^{\pm}(x, t_{k+1}) = C\|z_{1,0}^{R,(2)}\|_{\Omega_1} \pm z_{1,1}^{R}(x, t_{k+1})$, $x \in [0, 1]$ and apply Lemma 3.6 to the function $\psi^{\pm}$ we find $\|z_{1,1}^{R}\|_{\bar{\Omega}_1} \leq \frac{C}{\mu^2}$. From (49), we have

$$\|z_{1,1}^{R,(k)}\|_{\bar{\Omega}_1} \leq \frac{C}{\mu^{k+2}}, \quad 0 \leq k \leq 4. \tag{55}$$

Similarly, we can obtain the following bounds for $z_{1,2}^{R}$, $z_{2,1}^{R}$ and $z_{2,2}^{R}$

$$\|z_{1,2}^{R,(k)}\|_{\bar{\Omega}_1} \leq \frac{C}{\mu^{k+4}}, \quad 0 \leq k \leq 3, \tag{56}$$

$$\|z_{2,1}^{R,(k)}\|_{\bar{\Omega}_2} \leq \frac{C}{\mu^{k+2}}, \quad 0 \leq k \leq 4, \quad \|z_{2,2}^{R,(k)}\|_{\bar{\Omega}_2} \leq \frac{C}{\mu^{k+4}}, \quad 0 \leq k \leq 3. \tag{57}$$

Now, we apply Lemma 1 from [12] to the function $\psi^{\pm}(x, t_{k+1}) = C\|z_{1,2}^{R,(2)}\|_{\Omega_1} \pm z_{1,3}^{R}(x, t_{k+1})$, $x \in [0, 1]$, we get $\|z_{1,3}^{R}\|_{\bar{\Omega}_1} \leq \frac{C}{\mu^6}$. Using Lemma 3.4 to write

$$\|z_{1,3}^{R,(k)}\|_{\bar{\Omega}_1} \leq \frac{C}{(\sqrt{\varepsilon})^k \mu^6}\left(1 + \left(\frac{\mu}{\sqrt{\varepsilon}}\right)^k\right), \quad k = 1, 2, \tag{58}$$

$$\|z_{1,3}^{R,(3)}\|_{\bar{\Omega}_1} \leq \frac{C}{(\sqrt{\varepsilon})^3 \mu^6}\left(1 + \left(\frac{\mu}{\sqrt{\varepsilon}}\right)^3\right) + \frac{C}{\varepsilon \mu^7}. \tag{59}$$

Similarly, we can estimate the following bounds for $z_{2,3}^{R}$

$$\|z_{2,3}^{R,(k)}\|_{\bar{\Omega}_2} \leq \frac{C}{(\sqrt{\varepsilon})^k \mu^6}\left(1 + \left(\frac{\mu}{\sqrt{\varepsilon}}\right)^k\right), \quad k = 0, 1, 2, \tag{60}$$

$$\|z_{2,3}^{R,(3)}\|_{\bar{\Omega}_2} \leq \frac{C}{(\sqrt{\varepsilon})^3 \mu^6}\left(1 + \left(\frac{\mu}{\sqrt{\varepsilon}}\right)^3\right) + \frac{C}{\varepsilon \mu^7}, \quad k = 1, 2. \tag{61}$$

Since $p_0\mu^2 \geq \gamma\,\varepsilon$ and using (53)–(61) in (46), we get

$$\|z_1^{R,(k)}\|_{\bar{\Omega}_1} \leq \frac{C}{\mu^k} \quad \text{and} \quad \|z_2^{R,(k)}\|_{\bar{\Omega}_2} \leq \frac{C}{\mu^k}, \quad 0 \leq k \leq 3. \qquad \blacksquare$$

Lemma 3.9: *Let $Z_L(x, t_{k+1})$ and $Z_R(x, t_{k+1})$ be the solutions of* (42)–(45). *Then for $p_0\mu^2 \leq \gamma\,\varepsilon$ and $k = 0, 1, 2, 3$*

$$\|z_1^{L,(k)}(x, t_{k+1})\|_{\bar{\Omega}_1} \leq C\varepsilon^{\frac{-k}{2}}, \quad \|z_2^{L,(k)}(x, t_{k+1})\|_{\bar{\Omega}_2} \leq C\varepsilon^{\frac{-k}{2}},$$
$$\|z_1^{R,(k)}(x, t_{k+1})\|_{\bar{\Omega}_1} \leq C\varepsilon^{\frac{-k}{2}}, \quad \|z_2^{R,(k)}(x, t_{k+1})\|_{\bar{\Omega}_2} \leq C\varepsilon^{\frac{-k}{2}}.$$

Proof: Using Lemma 3.4, we note that z_1^L and z_2^L satisfy

$$\|z_1^{L,(k)}(x,t_{k+1})\|_{\bar{\Omega}_1} \leq C\varepsilon^{\frac{-k}{2}}, \quad \|z_2^{L,(k)}(x,t_{k+1})\|_{\bar{\Omega}_2} \leq C\varepsilon^{\frac{-k}{2}}, \quad 0 \leq k \leq 3.$$

For the bounds of z_1^R and z_2^R, choose $j_1(\varepsilon,\mu)$ and $j_2(\varepsilon,\mu)$ to be zero and using Lemma 3.4, we get

$$\|z_1^{R,(k)}\|_{\bar{\Omega}_1} \leq C\varepsilon^{\frac{-k}{2}} \quad \text{and} \quad \|z_2^{R,(k)}\|_{\bar{\Omega}_2} \leq C\varepsilon^{\frac{-k}{2}}, \quad 0 \leq k \leq 3. \qquad \blacksquare$$

The following Lemma establishes sharper estimates for the bounds of the singular components.

Lemma 3.10: *Let the layer components z_1^L, z_2^L, z_1^R and z_2^R be the solutions of* (42)–(45). *Then*

$$|z_1^L(x,t_{k+1})| \leq Ce^{-\theta_1 x},\ x \in [0,1], \quad |z_2^L(x,t_{k+1})| \leq Ce^{-\theta_1(x-1)},\ x \in [1,2],$$
$$|z_1^R(x,t_{k+1})| \leq Ce^{-\theta_2(1-x)},\ x \in [0,1], \quad |z_2^R(x,t_{k+1})| \leq Ce^{-\theta_2(2-x)},\ x \in [1,2],$$

where

$$\theta_1 = \begin{cases} \dfrac{\sqrt{\gamma p_0}}{\sqrt{\varepsilon}} & \text{if } \mu^2 \leq \dfrac{\gamma\varepsilon}{p_0}, \\ \dfrac{p_0\mu}{\varepsilon} & \text{if } \mu^2 \geq \dfrac{\gamma\varepsilon}{p_0}, \end{cases} \quad \text{and} \quad \theta_2 = \begin{cases} \dfrac{\sqrt{\gamma p_0}}{2\sqrt{\varepsilon}} & \text{if } \mu^2 \leq \dfrac{\gamma\varepsilon}{p_0}, \\ \dfrac{\gamma}{2\mu} & \text{if } \mu^2 \geq \dfrac{\gamma\varepsilon}{p_0}. \end{cases}$$

Proof: For proof, see [16]. $\blacksquare$

4. Spatial discretization

The solution of the problem exhibits boundary layers at $x = 0, x = 2$ and an interior layer at $x = 1$ [26]. To resolve the layers, we design the mesh to condense in the inner layer regions and to remain coarse in the outer regions, away from the layers. Consequently, to generate a piecewise-uniform meh $\bar{\mathbb{D}}_x^N$, we partition the interval $[0,2]$ into six subintervals as

$$[0,2] = [0,\beta_1] \cup [\beta_1, 1-\beta_2] \cup [1-\beta_2, 1] \cup [1, 1+\beta_1] \cup [1+\beta_1, 2-\beta_2] \cup [2-\beta_2, 2],$$

where β_1 and β_2 are the mesh transition parameters defined as

$$\beta_1 = \begin{cases} \min\left\{\dfrac{1}{4}, \dfrac{2\sqrt{\varepsilon}}{\sqrt{\gamma p_0}} \ln N\right\} & \text{if } \mu^2 \leq \dfrac{\gamma\varepsilon}{p_0}, \\ \min\left\{\dfrac{1}{4}, \dfrac{2\varepsilon}{p_0\mu} \ln N\right\} & \text{if } \mu^2 \geq \dfrac{\gamma\varepsilon}{p_0}, \end{cases} \quad \text{and}$$

$$\beta_2 = \begin{cases} \min\left\{\dfrac{1}{4}, \dfrac{2\sqrt{\varepsilon}}{\sqrt{\gamma p_0}} \ln N\right\} & \text{if } \mu^2 \leq \dfrac{\gamma\varepsilon}{p_0}, \\ \min\left\{\dfrac{1}{4}, \dfrac{2\mu}{\varepsilon} \ln N\right\} & \text{if } \mu^2 \geq \dfrac{\gamma\varepsilon}{p_0}. \end{cases}$$

We place $N/8$ mesh points each in intervals $[0, \beta_1]$, $[1-\beta_2, 1]$, $[1, 1+\beta_1]$, $[2-\beta_2, 2]$ and $N/4$ mesh points in intervals $[\beta_1, 1-\beta_2]$ and $[1+\beta_1, 2-\beta_2]$. Consequently, we obtain

$$\bar{\mathbb{D}}_x^N = \{x_i\}_0^N = \begin{cases} ih_1 & \text{for } i = 0, \ldots, N/8, \\ \beta_1 + \left(i - \dfrac{N}{8}\right) h_2 & \text{for } i = N/8+1, \ldots, 3N/8, \\ (1-\beta_2) + \left(i - \dfrac{3N}{8}\right) h_3 & \text{for } i = 3N/8+1, \ldots, N/2, \\ 1 + \left(i - \dfrac{N}{2}\right) h_1 & \text{for } i = N/2+1, \ldots, 5N/8, \\ (1+\beta_1) + \left(i - \dfrac{5N}{8}\right) h_2 & \text{for } i = 5N/8+1, \ldots, 7N/8, \\ (2-\beta_2) + \left(i - \dfrac{7N}{8}\right) h_3 & \text{for } i = 7N/8+1, \ldots, N, \end{cases}$$

where

$$h_i = \begin{cases} h_1 = \dfrac{4\beta_1}{N} & \text{for } i = 1, \ldots, N/8, N/2+1, \ldots, 5N/8, \\ h_2 = \dfrac{4}{N}(1-\beta_1-\beta_2) & \text{for } i = N/8+1, \ldots, 3N/8, 5N/8+1, \ldots, 7N/8, \\ h_3 = \dfrac{8\beta_2}{N} & \text{for } i = 3N/8+1, \ldots, N/2, 7N/8+1, \ldots, N. \end{cases}$$

The fully discrete problem on $\bar{\mathbb{D}}_x^N \times \mathbb{T}_t{}^M$ thus reads

$$\hat{\mathcal{L}}_n \tilde{U}(x_i, t_{k+1}) = \hat{\mathcal{G}}_n(x_i, t_{k+1}), \quad n = 1, 2, \tag{62}$$

where

$$\begin{aligned} \hat{\mathcal{L}}_1 \tilde{U}_{i,k+1} &= \varepsilon \delta_x^2 \tilde{U}_{i,k+1} + \mu p_{i,k+1} D_x^+ \tilde{U}_{i,k+1} - l_{i,k+1} \tilde{U}_{i,k+1} \quad \text{for } i = 1, \ldots, N/2-1, \\ \hat{\mathcal{L}}_2 \tilde{U}_{i,k+1} &= \varepsilon \delta_x^2 \tilde{U}_{i,k+1} + \mu p_{i,k+1} D_x^+ \tilde{U}_{i,k+1} - l_{i,k+1} \tilde{U}_{i,k+1} \\ &\quad + r_{i,k+1} \tilde{U}_{i-N/2,k+1} \quad \text{for } i = N/2, \ldots, N-1 \end{aligned}$$

and

$$\begin{aligned} \hat{\mathcal{G}}_1(x_i, t_{k+1}) &= -\varepsilon \delta_x^2 \tilde{U}_{i,k} - \mu p_{i,k} D_x^+ \tilde{U}_{i,k} + m_{i,k} \tilde{U}_{i,k} - r_{i,k} \psi_1(x_i - 1, t_k) \\ &\quad - r_{i,k+1} \psi_1(x_i - 1, t_{k+1}) + g_{i,k+1} + g_{i,k} \quad \text{for } i = 1, \ldots, N/2-1, \\ \hat{\mathcal{G}}_2(x_i, t_{k+1}) &= -\varepsilon \delta_x^2 \tilde{U}_{i,k} - \mu p_{i,k} D_x^+ \tilde{U}_{i,k} + m_{i,k} \tilde{U}_{i,k} - r_{i,k} \tilde{U}(x_i - 1, t_k) \\ &\quad + g_{i,k+1} + g_{i,k} \quad \text{for } i = N/2, \ldots, N-1 \end{aligned}$$

with

$$\begin{cases} \tilde{U}(x_i, t_{k+1}) = \psi_1(x_i - 1, t_{k+1}) & \text{for } i = 0, 1, \ldots N/2, \quad k = 0, \ldots, M-1, \\ \tilde{U}(x_i, t_0) = \psi_2(x_i, 0) & \text{for } i = 0, 1, \ldots, N, \\ \tilde{U}(x_N, t_{k+1}) = \psi_3(x_N, t_{k+1}) & \text{for } k = 0, \ldots, M-1. \end{cases}$$

The operator $\hat{\mathcal{L}}_n$ satisfies the following discrete minimum principle.

Lemma 4.1: *Let $Z_{i,k+1}$ be a mesh function such that $Z_{i,k+1} \geq 0$ for $i = \{0, N\}$, $\hat{\mathcal{L}}_1 Z_{i,k+1} \leq 0$ for $i = 1, \ldots, N/2 - 1$ and $\hat{\mathcal{L}}_2 Z_{i,k+1} \leq 0$ for $i = N/2, \ldots, N-1$. Then $Z_{i,k+1} \geq 0$ for $i = 0, 1, \ldots, N$.*

Proof: Choose $q^* \in \{0, 1, \ldots, N\}$ such that $Z_{q^*,k+1} = \min_{\bar{\mathbb{D}}_x^N \times \mathbb{T}_t^M} Z_{i,k+1}$. Suppose $Z_{q^*,k+1} < 0$ and it follows that $q^* \notin \{0, N\}$, $Z_{q^*+1,k+1} - Z_{q^*,k+1} \geq 0$ and $Z_{q^*,k+1} - Z_{q^*-1,k+1} \leq 0$.

Case I: For $q^* \in \{1, 2, \ldots, N/2 - 1\}$

$$\begin{aligned}
\hat{\mathcal{L}}_1 Z_{q^*,k+1} &= \varepsilon \delta_x^2 Z_{q^*,k+1} + \mu p_{q^*,k+1} D_x^+ Z_{q^*,k+1} - l_{q^*,k+1} Z_{q^*,k+1} \\
&= \frac{2\varepsilon}{h_{q^*} + h_{q^*+1}} \left\{ \frac{Z_{q^*+1,k+1} - Z_{q^*,k+1}}{h_{q^*+1}} - \frac{Z_{q^*,k+1} - Z_{q^*-1,k+1}}{h_{q^*}} \right\} \\
&\quad + \mu p_{q^*,k+1} \left\{ \frac{Z_{q^*+1,k+1} - Z_{q^*,k+1}}{h_{q^*+1}} \right\} - l_{q^*,k+1} Z_{q^*,k+1} \\
&> 0.
\end{aligned}$$

Case II: For $q^* \in \{N/2, \ldots, N-1\}$

$$\begin{aligned}
\hat{\mathcal{L}}_2 Z_{q^*,k+1} &= \varepsilon \delta_x^2 Z_{q^*,k+1} + \mu p_{q^*,k+1} D_x^+ Z_{q^*,k+1} - l_{q^*,k+1} Z_{q^*,k+1} + r_{q^*,k+1} Z_{q^*-N/2,k+1} \\
&\geq (r_{q^*,k+1} - l_{q^*,k+1}) Z_{q^*,k+1} \\
&> 0.
\end{aligned}$$

The required result follows from a contradiction. ■

Consequently, we can prove the following stability estimate for discrete operator $\hat{\mathcal{L}}_n$.

Lemma 4.2: *Let $Z_{i,k+1}$ be the solution of* (62). *Then*

$$|Z_{i,k+1}| \leq \max \left\{ |Z_{0,k+1}|, |Z_{N,k+1}|, \|\hat{\mathcal{L}}_1 Z_{i,k+1}\|, \|\hat{\mathcal{L}}_2 Z_{i,k+1}\| \right\}.$$

Proof: For proof, see [28]. ■

5. Error estimates

Let us decompose $\tilde{U}_{i,k+1}$ into smooth and singular components to obtain parameter uniform error estimates. We write $\tilde{U}_{i,k+1} := \tilde{X}_{i,k+1} + \tilde{Z}_{i,k+1}$, where

$$\tilde{X}(x_i, t_{k+1}) = \begin{cases} \tilde{X}_1(x_i, t_{k+1}) & \text{for } 0 \leq i \leq N/2 - 1, \\ \tilde{X}_2(x_i, t_{k+1}) & \text{for } N/2 \leq i \leq N, \end{cases}$$

and

$$\tilde{Z}(x_i, t_{k+1}) = \begin{cases} \tilde{Z}_1(x_i, t_{k+1}) & \text{for } 0 \leq i \leq N/2 - 1, \\ \tilde{Z}_2(x_i, t_{k+1}) & \text{for } N/2 \leq i \leq N. \end{cases}$$

The smooth component $\tilde{X}$ satisfies

$$\left.\begin{aligned}
&\hat{\mathcal{L}}_1\tilde{X}_1(x_i,t_{k+1}) = \hat{\mathcal{G}}_1(x_i,t_{k+1}) \quad \text{for } i\in\{1,2,\ldots,N/2-1\},\\
&\tilde{X}_1(x_0,t_{k+1}) = b(0,t_{k+1}), \quad \tilde{X}_1(x_{N/2},t_{k+1}) = b(1,t_{k+1}),\\
&\hat{\mathcal{L}}_2\tilde{X}_2(x_i,t_{k+1}) = \hat{\mathcal{G}}_2(x_i,t_{k+1}) \quad \text{for } i\in\{N/2+1,\ldots,N-1\},\\
&\tilde{X}_2(x_{N/2},t_{k+1}) = c(1,t_{k+1}), \quad \tilde{X}_2(x_N,t_{k+1}) = c(2,t_{k+1}),\\
&\tilde{X}_2(x_i-1,t_{k+1}) = \tilde{X}_1(x_{i-N/2},t_{k+1}), \quad \text{for } i\in\{N/2,\ldots,N-1\},
\end{aligned}\right\} \tag{63}$$

and the singular component $\tilde{Z}$ satisfies

$$\left.\begin{aligned}
&\hat{\mathcal{L}}_1\tilde{Z}_1(x_i,t_{k+1}) = 0 \quad \text{for } i\in\{1,2,\ldots,N/2-1\},\\
&\tilde{Z}_1(x_0,t_{k+1}) = z_1(0,t_{k+1}), \quad \tilde{Z}_1(x_{N/2},t_{k+1}) = Z_1(1,t_{k+1}),\\
&\hat{\mathcal{L}}_2\tilde{Z}_2(x_i,t_{k+1}) = 0 \quad \text{for } i\in\{N/2+1,\ldots,N-1\},\\
&\tilde{Z}_2(x_{N/2},t_{k+1}) = z_2(1,t_{k+1}), \quad \tilde{Z}_2(x_N,t_{k+1}) = z_2(2,t_{k+1}).
\end{aligned}\right\} \tag{64}$$

Moreover, the error $e_{i,k+1}$ is given by

$$e_{i,k+1} = \tilde{U}_{i,k+1} - U_{i,k+1} = (\tilde{X}_{i,k+1} - X_{i,k+1}) + (\tilde{Z}_{i,k+1} - Z_{i,k+1}).$$

Lemma 5.1: *Let* $X(x_i,t_{k+1})$ *and* $\tilde{X}_{i,k+1}$ *be the solutions of* (14), (16), (17) *and* (63), *respectively. Then*

$$|\tilde{X}_{i,k+1} - X(x_i,t_{k+1})| \le CN^{-1}, \quad 0\le i\le N.$$

Proof: Consider

$$\begin{aligned}
|\tilde{X}(x_i,t_{k+1}) - X(x_i,t_{k+1})| &= |(\tilde{X}_1+\tilde{X}_2)(x_i,t_{k+1}) - (b+c)(x_i,t_{k+1})|\\
&= |(\tilde{X}_1 - b)(x_i,t_{k+1}) + (\tilde{X}_2 - c)(x_i,t_{k+1})|\\
&\le |(\tilde{X}_1 - b)(x_i,t_{k+1})| + |(\tilde{X}_2 - c)(x_i,t_{k+1})|. \qquad (65)
\end{aligned}$$

For $i = 1,\ldots,N/2-1$

$$\begin{aligned}
&|\hat{\mathcal{L}}_1(\tilde{X}_1 - b)(x_i,t_{k+1})|\\
&\quad = |\hat{\mathcal{L}}_1\tilde{X}_1(x_i,t_{k+1}) - \hat{\mathcal{L}}_1 b(x_i,t_{k+1})|\\
&\quad \le \varepsilon\left|\left(\delta_x^2 - \frac{\mathrm{d}^2}{\mathrm{d}x^2}\right)b(x_i,t_{k+1})\right| + \mu|p(x_i,t_{k+1})|\left|\left(D_x^+ - \frac{\mathrm{d}}{\mathrm{d}x}\right)b(x_i,t_{k+1})\right|\\
&\quad \le C\max_{1\le i\le \frac{N}{2}-1} h_i(\varepsilon\|b\|_3 + \mu\|b\|_2).
\end{aligned}$$

Case I: For $p_0\mu^2 \le \gamma\,\varepsilon$. Lemma 3.5 leads to

$$|\hat{\mathcal{L}}_1(\tilde{X}_1 - b)(x_i,t_{k+1})| \le CN^{-1}.$$

Case II: For $p_0\mu^2 \geq \gamma\,\varepsilon$. Lemma 3.7 leads to

$$|\hat{\mathcal{L}}_1(\tilde{X}_1 - b)(x_i, t_{k+1})| \leq CN^{-1}.$$

Define $\psi^{\pm}(x_i, t_{k+1}) = CN^{-1} \pm (\tilde{X}_1 - b)(x_i, t_{k+1})$, $0 \leq i \leq N/2 - 1$ for sufficiently large C. Then $\psi^{\pm}(x_0, t_{k+1}) \geq 0$, $\psi^{\pm}(x_{N/2}, t_{k+1}) \geq 0$ and $\hat{\mathcal{L}}_1\psi^{\pm}(x_i, t_{k+1}) \leq 0$. Now, using Lemma 4.1, we obtain

$$|(\tilde{X}_1 - b)(x_i, t_{k+1})| \leq CN^{-1}, \quad 0 \leq i \leq N/2.$$

A similar argument for $(\tilde{X}_2 - c)$ leads us to the following estimates

$$|(\tilde{X}_2 - c)(x_i, t_{k+1})| \leq CN^{-1}, \quad N/2 \leq i \leq N.$$

Therefore, from (65), it follows that $|\tilde{X}(x_i, t_{k+1}) - X(x_i, t_{k+1})| \leq CN^{-1}$, $0 \leq i \leq N$. ■

Let us decompose $\tilde{Z}_1(x, t_{k+1})$ and $\tilde{Z}_2(x, t_{k+1})$ further as $\tilde{Z}_1(x_i, t_{k+1}) := (\tilde{Z}_1^L + \tilde{Z}_1^R)(x_i, t_{k+1})$ and $\tilde{Z}_2(x_i, t_{k+1}) := (\tilde{Z}_2^L + \tilde{Z}_2^R)(x_i, t_{k+1})$, where $\tilde{Z}_1^L$ and $\tilde{Z}_2^L$ satisfy

$$\left.\begin{aligned}
&\hat{\mathcal{L}}_1\tilde{Z}_1^L(x_i, t_{k+1}) = 0, \quad 0 < i < N/2,\\
&\tilde{Z}_1^L(x_0, t_{k+1}) = z_1^L(0, t_{k+1}), \quad \tilde{Z}_1^L(x_{N/2}, t_{k+1}) = 0,\\
&\hat{\mathcal{L}}_2\tilde{Z}_2^L(x_i, t_{k+1}) = 0, \quad N/2 < i < N,\\
&\tilde{Z}_2^L(x_{N/2}, t_{k+1}) = z_2^L(1, t_{k+1}), \quad \tilde{Z}_2^L(x_N, t_{k+1}) = 0,\\
&\tilde{Z}_2^L(x_{N/2} - 1, t_{k+1}) = \tilde{Z}_1^L(x_{i-N/2}, t_{k+1}), \quad N/2 \leq i < N,
\end{aligned}\right\} \tag{66}$$

and $\tilde{Z}_1^R$ and $\tilde{Z}_2^R$ satisfy

$$\left.\begin{aligned}
&\hat{\mathcal{L}}_1\tilde{Z}_1^R(x_i, t_{k+1}) = 0, \quad 0 < i < N/2,\\
&\tilde{Z}_1^R(x_0, t_{k+1}) = z_1^R(0, t_{k+1}), \quad \tilde{Z}_1^R(x_{N/2}, t_{k+1}) = z_1^R(1, t_{k+1}),\\
&\hat{\mathcal{L}}_2\tilde{Z}_2^R(x_i, t_{k+1}) = 0, \quad N/2 < i < N,\\
&\tilde{Z}_2^R(x_{N/2}, t_{k+1}) = z_2^R(1, t_{k+1}), \quad \tilde{Z}_2^R(x_N, t_{k+1}) = z_2^R(2, t_{k+1}),\\
&\tilde{Z}_2^R(x_i - 1, t_{k+1}) = \tilde{Z}_1^R(x_{i-N/2}, t_{k+1}), \quad 0 \leq i < N/2.
\end{aligned}\right\} \tag{67}$$

Define the mesh functions

$$I_{1,i} = \begin{cases} \displaystyle\prod_{j=1}^{i}(1 + \theta_1 h_j)^{-1}, & 1 < i \leq N/2,\\ 1, & i = 0, \end{cases} \quad \text{and}$$

$$I_{2,i} = \begin{cases} \displaystyle\prod_{j=i+1}^{N/2}(1 + \theta_2 h_j)^{-1}, & 0 \leq i < N/2,\\ 1, & i = N/2, \end{cases}$$

where θ_1 and θ_2 are defined in Lemma 3.10. For $i = N/8, \ldots, N/2$

$$\begin{aligned} I_{1,i} &\le I_{1,N/8} \\ &= \prod_{j=1}^{N/8} (1 + \theta_1 h_{N/8})^{-1} \\ &= (1 + \theta_1 h_{N/8})^{-N/8} \\ &= \left(1 + \theta_1 \frac{8\beta_1}{N}\right)^{-N/8} \\ &\le (1 + 8N^{-1} \ln N)^{-N/8} \le CN^{-1}, \end{aligned} \tag{68}$$

and for $i = 0, \ldots, 3N/8$

$$\begin{aligned} I_{2,i} &\le I_{2,3N/8} \\ &= \left(1 + \theta_2 \frac{8\beta_2}{N}\right)^{-N/8} \\ &\le (1 + 8N^{-1} \ln N)^{-N/8} \\ &\le CN^{-1}. \end{aligned} \tag{69}$$

Lemma 5.2: *Let $\tilde{Z}_1^L$, $\tilde{Z}_2^L$, $\tilde{Z}_1^R$ and $\tilde{Z}_2^R$ be the solutions of* (66) *and* (67). *Then*

$$|\tilde{Z}_1^L(x_i, t_{k+1})| \le CI_{1,i}, \quad |\tilde{Z}_1^R(x_i, t_{k+1})| \le CI_{2,i}, \quad 0 \le i \le N/2 \quad \text{and}$$
$$|\tilde{Z}_2^L(x_i, t_{k+1})| \le CI_{1,i-\frac{N}{2}}, \quad |\tilde{Z}_2^R(x_i, t_{k+1})| \le CI_{2,i-\frac{N}{2}}, \quad N/2 \le i \le N.$$

Proof: For $i = 0, \ldots N/2$, define $\mathcal{Q}^{\pm}(x_i, t_{k+1}) = |\tilde{Z}_1^L(x_0, t_{k+1})| I_{1,i} \pm \tilde{Z}_1^L(x_i, t_{k+1})$. Then, $\mathcal{Q}^{\pm}(x_0, t_{k+1}) = |\tilde{Z}_1^L(x_0, t_{k+1})| \pm \tilde{Z}_1^L(x_0, t_{k+1}) \ge 0$ and $\mathcal{Q}^{\pm}(x_{N/2}, t_{k+1}) \ge 0$. Also, note that $\hat{\mathcal{L}}_1 I_{1,i} = (\varepsilon \delta_s^2 + \mu p D_s^+ - l) I_{1,i} \le 0$ which implies $\hat{\mathcal{L}}_1 \mathcal{Q}^{\pm}(x_i, t_{k+1}) \le 0$. Using Lemma 4.1, we have

$$|\tilde{Z}_1^L(x_i, t_{k+1})| \le CI_{1,i}, \quad 0 \le i \le N/2.$$

A similar argument for $\tilde{Z}_1^R$, $\tilde{Z}_2^L$ and $\tilde{Z}_2^R$ leads to the following estimates

$$\begin{aligned} &|\tilde{Z}_1^R(x_i, t_{k+1})| \le CI_{2,i}, \quad 0 \le i \le N/2, \\ &|\tilde{Z}_2^L(x_i, t_{k+1})| \le CI_{1,i-N/2}, \quad N/2 \le i \le N, \\ &|\tilde{Z}_2^R(x_i, t_{k+1})| \le CI_{2,i-N/2}, \quad N/2 \le i \le N. \end{aligned}$$

■

To estimate the error bound for $(\tilde{Z} - Z) = (\tilde{Z}_L - Z_L) + (\tilde{Z}_R - Z_R)$, we compute the error bound for $(\tilde{Z}_L - Z_L)$ and $(\tilde{Z}_R - Z_R)$, separately. For this, define $\tilde{Z}_L$ and $\tilde{Z}_R$ as

$$\tilde{Z}_L(x_i, t_{k+1}) = \begin{cases} \tilde{Z}_1^L, & 0 \le i \le N/2 - 1, \\ \tilde{Z}_2^L, & N/2 \le i \le N, \end{cases} \qquad \text{and}$$

$$\tilde{Z}_R(x_i, t_{k+1}) = \begin{cases} \tilde{Z}_1^R, & 0 \le i \le N/2 - 1, \\ \tilde{Z}_2^R, & N/2 \le i \le N. \end{cases}$$

Therefore

$$(\tilde{Z}_L - Z_L)(x_i, t_{k+1}) = \begin{cases} (\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1}), & 0 \le i \le N/2 - 1, \\ (\tilde{Z}_2^L - z_2^L)(x_i, t_{k+1}), & N/2 \le i \le N, \end{cases}$$

and

$$(\tilde{Z}_R - Z_R)(x_i, t_{k+1}) = \begin{cases} (\tilde{Z}_1^R - z_1^R)(x_i, t_{k+1}), & 0 \le i \le N/2 - 1, \\ (\tilde{Z}_2^R - z_2^R)(x_i, t_{k+1}), & N/2 \le i \le N. \end{cases}$$

Lemma 5.3: *Let Z_L, Z_R be the solutions of* (42)–(45) *and $\tilde{Z}_L, \tilde{Z}_R$ be the solutions of* (66)–(67), *respectively. Then*

$$|(\tilde{Z}_L - Z_L)(x_i, t_{k+1})| \le \begin{cases} CN^{-1} \ln N & \text{if } p_0 \mu^2 \le \gamma\, \varepsilon, \\ CN^{-1} (\ln N)^2 & \text{if } p_0 \mu^2 \ge \gamma\, \varepsilon, \end{cases}$$

$$|(\tilde{Z}_R - Z_R)(x_i, t_{k+1})| \le \begin{cases} CN^{-1} \ln N & \text{if } p_0 \mu^2 \le \gamma\, \varepsilon, \\ CN^{-1} \ln N & \text{if } p_0 \mu^2 \ge \gamma\, \varepsilon. \end{cases}$$

Proof: Using (68), (69) and Lemma 5.2, we have

$$|\tilde{Z}_1^L(x_i, t_{k+1})| \le CN^{-1}, \quad \text{for } N/8 \le i \le N/2, \tag{70}$$

$$|\tilde{Z}_1^R(x_i, t_{k+1})| \le CN^{-1}, \quad \text{for } 0 \le i \le 3N/8, \tag{71}$$

$$|\tilde{Z}_2^L(x_i, t_{k+1})| \le CN^{-1}, \quad \text{for } 5N/8 \le i \le N, \tag{72}$$

$$|\tilde{Z}_2^R(x_i, t_{k+1})| \le CN^{-1}, \quad \text{for } N/2 \le i \le 7N/8. \tag{73}$$

Case I: For $p_0 \mu^2 \le \gamma\, \varepsilon$ and $1 \le i \le N/8 - 1$

$$\begin{aligned} |\hat{\mathcal{L}}_1(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| &= |\hat{\mathcal{L}}_1 \tilde{Z}_1^L(x_i, t_{k+1}) - \hat{\mathcal{L}} z_1^L(x_i, t_{k+1})| \\ &= |\hat{\mathcal{L}}_1 \tilde{Z}_1^L(x_i, t_{k+1}) - \tilde{\mathcal{L}}_1 z_1^L(x_i, t_{k+1})| \\ &\le \varepsilon \left(\delta_x^2 - \frac{d^2}{dx^2} \right) |z_1^L(x_i, t_{k+1})| + \mu \left(D_x^+ - \frac{d}{dx} \right) |z_1^L(x_i, t_{k+1})| \\ &\le Ch_i \left(\varepsilon |z_1^L|_3 + \mu |z_1^L|_2 \right) \\ &\le Ch_i \left(\frac{1}{\sqrt{\varepsilon}} + \frac{\mu}{\sqrt{\varepsilon}} \right) \\ &\le \frac{Ch_i}{\sqrt{\varepsilon}}. \end{aligned}$$

In case $\beta_1 = \dfrac{1}{4}$, we have $\dfrac{1}{4} \le \dfrac{2\sqrt{\varepsilon}}{\sqrt{\gamma\, p_0}} \ln N$, which implies $\dfrac{1}{\sqrt{\varepsilon}} \le C \ln N$. Thus

$$|\hat{\mathcal{L}}_1(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| \le CN^{-1} \ln N.$$

In case $\beta_1 = \dfrac{2\sqrt{\varepsilon}}{\sqrt{\gamma\, p_0}} \ln N$, we compute

$$|\hat{\mathcal{L}}_1(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| \leq \frac{Ch_i}{\sqrt{\varepsilon}} \leq \frac{C}{\sqrt{\varepsilon}} \frac{8\beta_1}{N} \leq CN^{-1} \ln N.$$

Let us next consider $\phi^{\pm}(x_i, t_{k+1}) = CN^{-1} \ln N \pm (\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})$ for $0 \leq i \leq N/8$. Then $\phi^{\pm}(x_i, t_{k+1}) \geq 0$ for $i = \{0, N/8\}$ and $\hat{\mathcal{L}}_1 \phi^{\pm}(x_i, t_{k+1}) \leq 0$. Using Lemma 4.1, we get

$$|(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| \leq CN^{-1} \ln N, \quad 0 \leq i \leq N/8. \tag{74}$$

For $N/8 \leq i \leq N/2 - 1$, using (70) and Lemma 3.10, we calculate that

$$|(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1}) \leq |\tilde{Z}_1^L(x_i, t_{k+1})| + |z_1^L(x_i, t_{k+1})| \leq CN^{-1}. \tag{75}$$

Thus from (74) and (75), we get

$$|(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1}) \leq CN^{-1} \ln N, \quad 0 \leq i \leq N/2 - 1.$$

Similarly, we can compute that

$$|(\tilde{Z}_2^L - z_2^L)(x_i, t_{k+1})| \leq CN^{-1} \ln N, \quad N/2 \leq i \leq N.$$

Case II: For $p_0 \mu^2 \geq \gamma\, \varepsilon$ and $1 \leq i \leq N/8 - 1$

$$\begin{aligned} |\hat{\mathcal{L}}_1(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| &= |\hat{\mathcal{L}}_1 \tilde{Z}_1^L(x_i, t_{k+1}) - \tilde{\mathcal{L}}_1 z_1^L(x_i, t_{k+1})| \\ &\leq Ch_i \left(\varepsilon |z_1^L|_3 + \mu |z_1^L|_2\right) \\ &\leq Ch_i \left(\frac{\mu^3}{\varepsilon^2} + \frac{\mu^3}{\varepsilon^2}\right) \\ &\leq Ch_i \mu \left(\frac{\mu}{\varepsilon}\right)^2. \end{aligned}$$

In case $\beta_1 = \dfrac{1}{4}$, we have $\dfrac{1}{4} \leq \dfrac{2\varepsilon}{p_0 \mu} \ln N$, which implies $\dfrac{\mu}{\varepsilon} \leq C \ln N$. Thus

$$|\hat{\mathcal{L}}_1(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| \leq CN^{-1} (\ln N)^2.$$

If $\beta_1 = \dfrac{2\varepsilon}{p_0 \mu} \ln N$, then we compute

$$|\hat{\mathcal{L}}_1(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| \leq Ch_i \mu \left(\frac{\mu}{\varepsilon}\right)^2 \leq C \frac{\mu^2}{\varepsilon} N^{-1} \ln N.$$

Consider,

$$\begin{aligned} \phi^{\pm}(x_i, t_{k+1}) = CN^{-1} + CN^{-1} \ln N (\beta_1 - x_i) \frac{\mu}{\varepsilon} \\ \pm (\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1}), \quad 0 \leq i \leq N/8. \end{aligned}$$

Then, $\hat{\mathcal{L}}_1\phi^{\pm}(x_i, t_{k+1}) \leq 0$ for $1 \leq i \leq N/8 - 1$ and $\phi^{\pm}(x_i, t_{k+1}) \geq 0$ for $i = \{0, N/8\}$. Using Lemma 4.1 to get

$$|(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1})| \leq CN^{-1} + CN^{-1} \ln N \beta_1 \frac{\mu}{\varepsilon}$$
$$\leq CN^{-1}(\ln N)^2, \quad 0 \leq i \leq N/8. \tag{76}$$

For $N/8 \leq i \leq N/2 - 1$, it follows from (70) and Lemma 3.10 that

$$|(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1}) \leq CN^{-1}. \tag{77}$$

Thus, from (76) and (77)

$$|(\tilde{Z}_1^L - z_1^L)(x_i, t_{k+1}) \leq CN^{-1}(\ln N)^2, \quad 0 \leq i \leq N/2 - 1. \tag{78}$$

Similarly, for $N/2 \leq i \leq N$, we obtain

$$|(\tilde{Z}_2^L - z_2^L)(x_i, t_{k+1})| \leq CN^{-1}(\ln N)^2.$$

Thus,

$$|(\tilde{Z}_L - Z_L)(x_i, t_{k+1})| \leq \begin{cases} CN^{-1} \ln N & \text{if } p_0\mu^2 \leq \gamma\,\varepsilon, \\ CN^{-1}(\ln N)^2 & \text{if } p_0\mu^2 \geq \gamma\,\varepsilon. \end{cases}$$

Following the similar steps and argument for $(\tilde{Z}_R - Z_R)$, it is straightforward to establish that for $p_0\mu^2 \leq \gamma\,\varepsilon$ and $p_0\mu^2 \geq \gamma\,\varepsilon$,

$$|(\tilde{Z}_R - Z_R)(x_i, t_{k+1})| \leq CN^{-1} \ln N, \quad 0 \leq i \leq N. \qquad \blacksquare$$

Theorem 5.4: *Let* $\tilde{U}(x_i, t_{k+1})$ *and* $U(x_i, t_{k+1})$ *be the solutions of* (62) *and* (10)*, respectively. Then for* $0 \leq i \leq N$

$$\left|(\tilde{U} - U)(x_i, t_{k+1})\right| \leq C \begin{cases} N^{-1} \ln N & \text{if } p_0\mu^2 \leq \gamma\,\varepsilon \\ N^{-1}(\ln N)^2 & \text{if } p_0\mu^2 \geq \gamma\,\varepsilon. \end{cases}$$

Proof: The proof follows from Lemmas 5.1 and 5.3. $\blacksquare$

Finally, we combine (13) and Theorem 5.4 to obtain the principle convergence estimate that reads.

Theorem 5.5: *Let* u *and* $\tilde{U}$ *be the solutions of the continuous problem* (1) *and the discrete problem* (62)*, respectively. Then*

$$\left|\tilde{U}(x_i, t_{k+1}) - u(x_i, t_{k+1})\right| \leq C \begin{cases} (\Delta t^2 + N^{-1} \ln N) & \text{if } p_0\mu^2 \leq \gamma\,\varepsilon \\ (\Delta t^2 + N^{-1}(\ln N)^2) & \text{if } p_0\mu^2 \geq \gamma\,\varepsilon \end{cases}$$

for $0 \leq i \leq N$ *and* $0 \leq k \leq M$.

Table 1. Maximum absolute error and order of convergence for Example 6.1 for different values of μ, M and N when $\varepsilon = 2^{-10}$.

6. Numerical illustrations

In this section, we consider two model problems, present numerical results using the proposed method, and verify the theoretical estimates numerically.

Example 6.1: Consider the following two-parameter singularly perturbed problem:

$$\begin{cases} [\varepsilon u_{xx} + \mu(1+x)u_x - (4+\sin x)u - u_t](x,t) + u(x-1,t) \\ \quad = -e^x, \quad (x,t) \in (0,2) \times (0,2], \\ u(x,t) = 5 + t^2, \quad (x,t) \in \Gamma_1, \\ u(x,t) = 5, \quad (x,t) \in \Gamma_2, \\ u(x,t) = 5, \quad (x,t) \in \Gamma_3. \end{cases}$$

	0.7193	1.1601	1.3501	1.3417	1.4248	1.5904

Example 6.2: Consider the following two-parameter singularly perturbed problem:

$$\begin{cases} [\varepsilon u_{xx} + \mu(2 + x + t)u_x - (2 + xt)u - u_t](x,t) + u(x-1,t) = (e^{t^2} - 1)(1 + xt), \\ (x,t) \in (0,2) \times (0,2], \\ u(x,t) = 0, \quad (x,t) \in \Gamma_1, \\ u(x,t) = 0, \quad (x,t) \in \Gamma_2, \\ u(x,t) = 0, \quad (x,t) \in \Gamma_3. \end{cases}$$

The exact solutions of the above examples are not known for comparison. Therefore, the double mesh principle [20] is used to estimate the maximum absolute error and rate of convergence. The maximum absolute error ($E_\varepsilon^{N,\Delta t}$) and order of convergence ($R_\varepsilon^{N,\Delta t}$) are

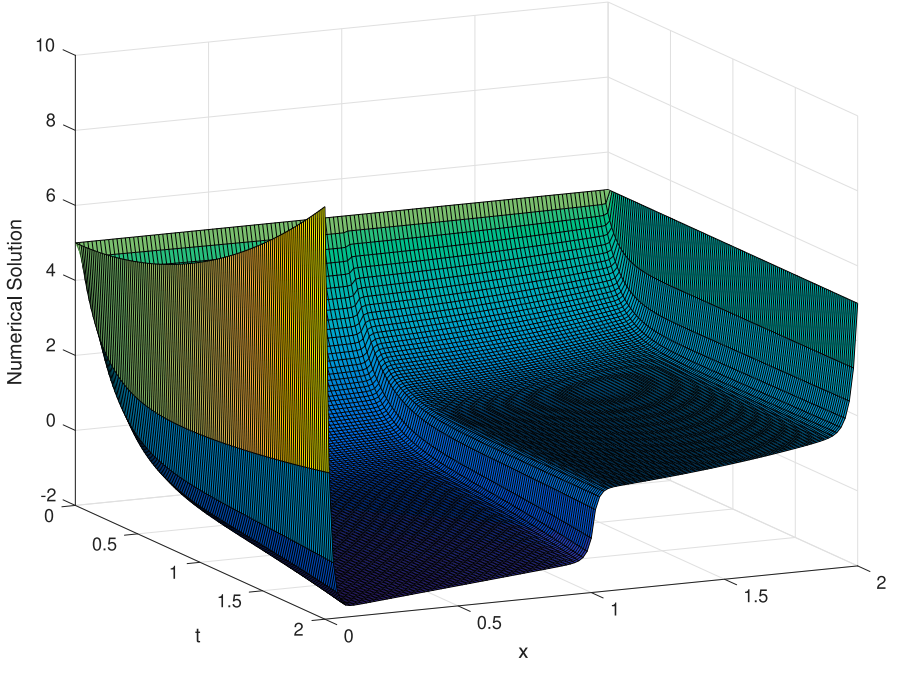

Figure 1. Numerical solution of Example 6.1 with $M = N = 128$, $\mu = 2^{-22}$ and $\varepsilon = 2^{-17}$.

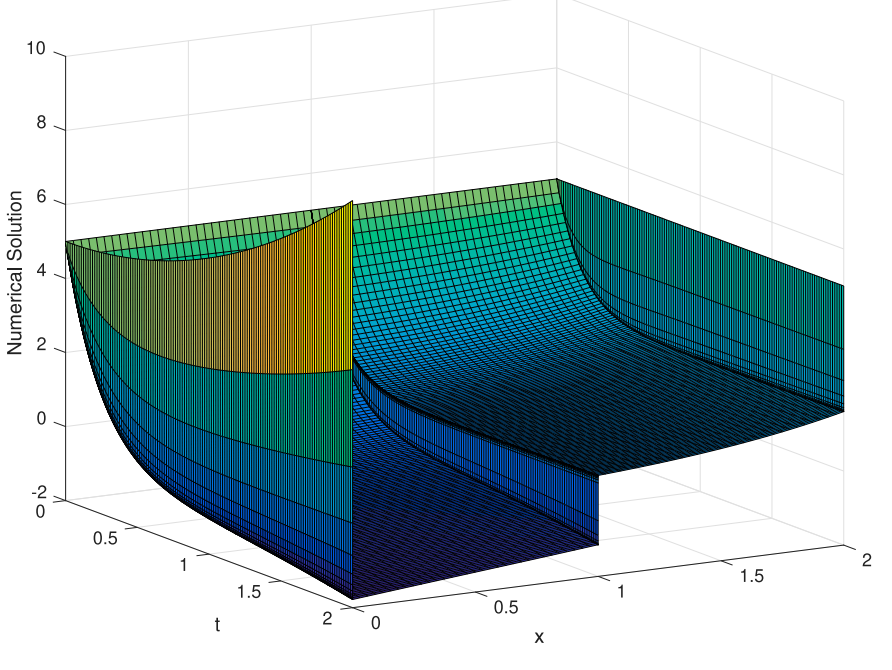

Figure 2. Numerical solution of Example 6.1 with $M = N = 128$, $\mu = 2^{-6}$ and $\varepsilon = 2^{-14}$.

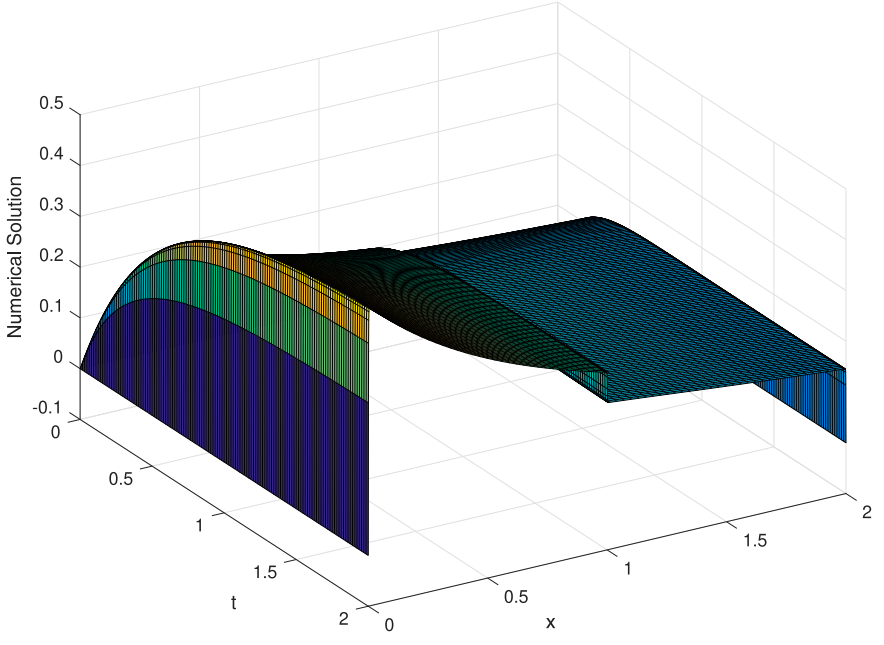

Figure 3. Numerical solution of Example 6.2 with $M = N = 128$, $\mu = 2^{-18}$ and $\varepsilon = 2^{-20}$.

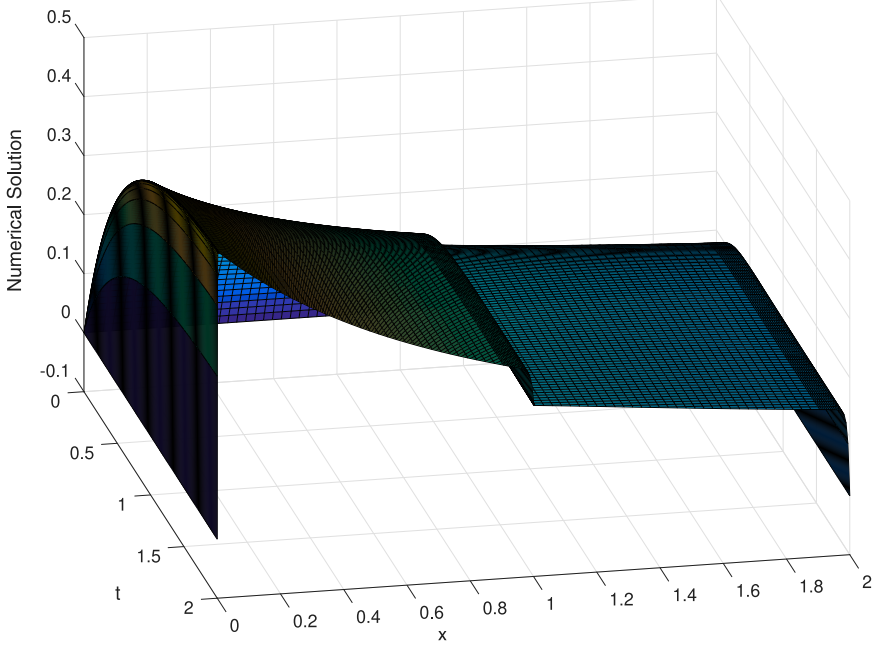

Figure 4. Numerical solution of Example 6.2 with $M = N = 128$, $\mu = 2^{-8}$ and $\varepsilon = 2^{-18}$.

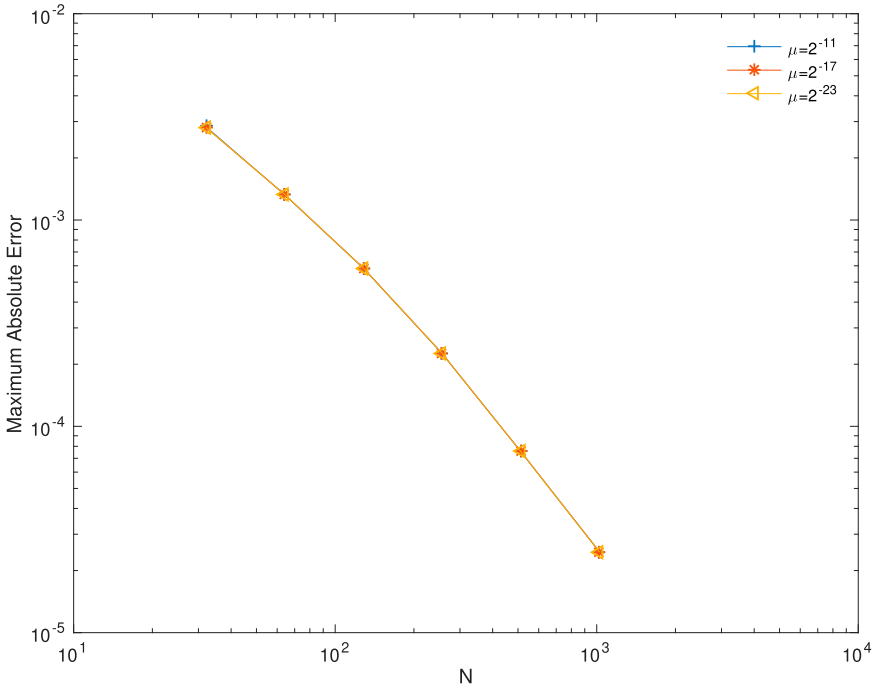

Figure 5. Error plot for Example 6.1 for Case 1 when $\varepsilon = 2^{-10}$.

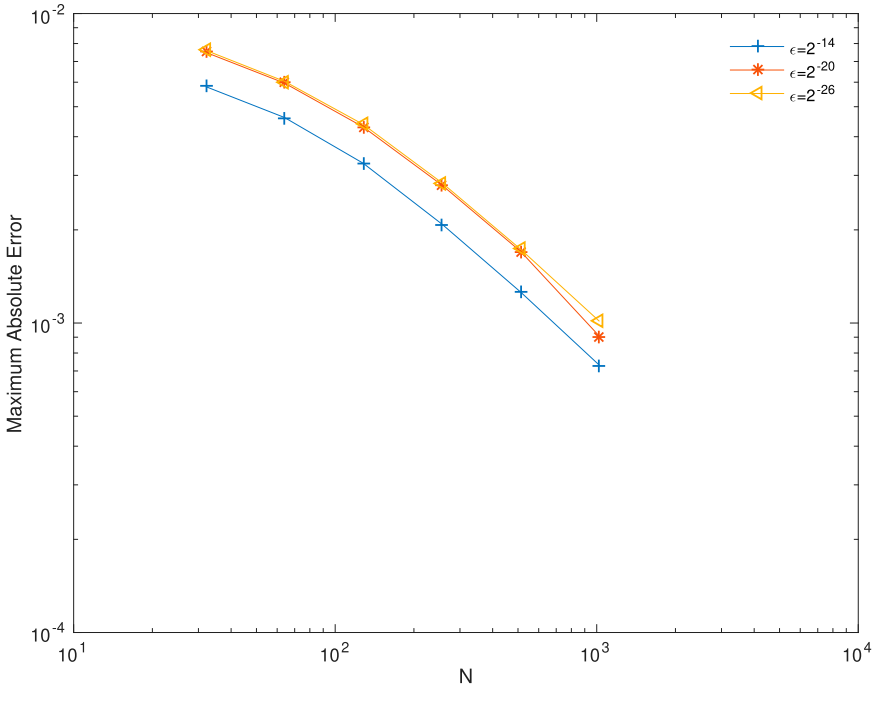

Figure 6. Error plot for Example 6.1 for Case 2 when $\mu = 2^{-6}$.

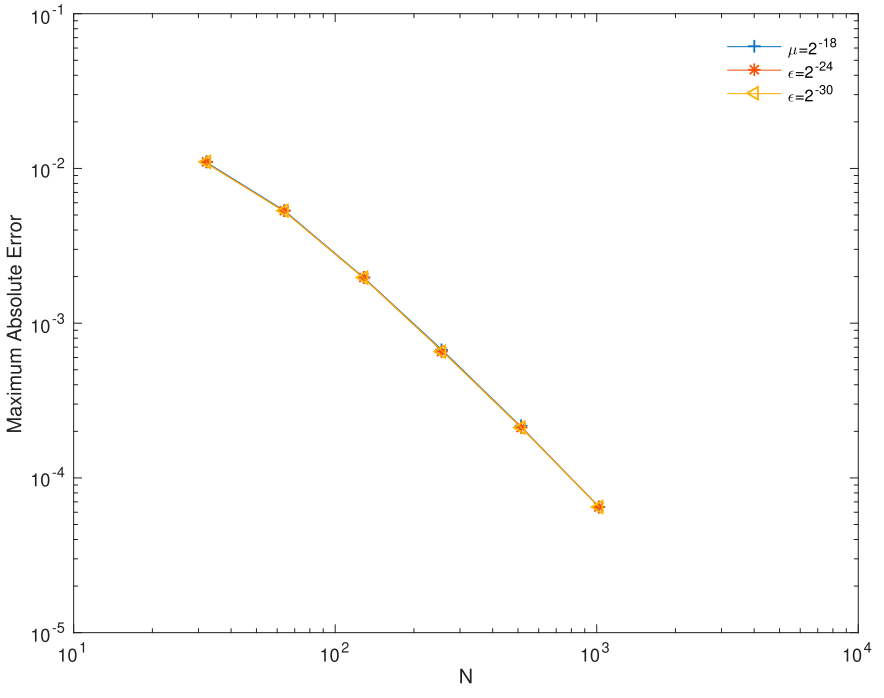

Figure 7. Error plot for Example 6.2 for Case 1 when $\varepsilon = 2^{-20}$.

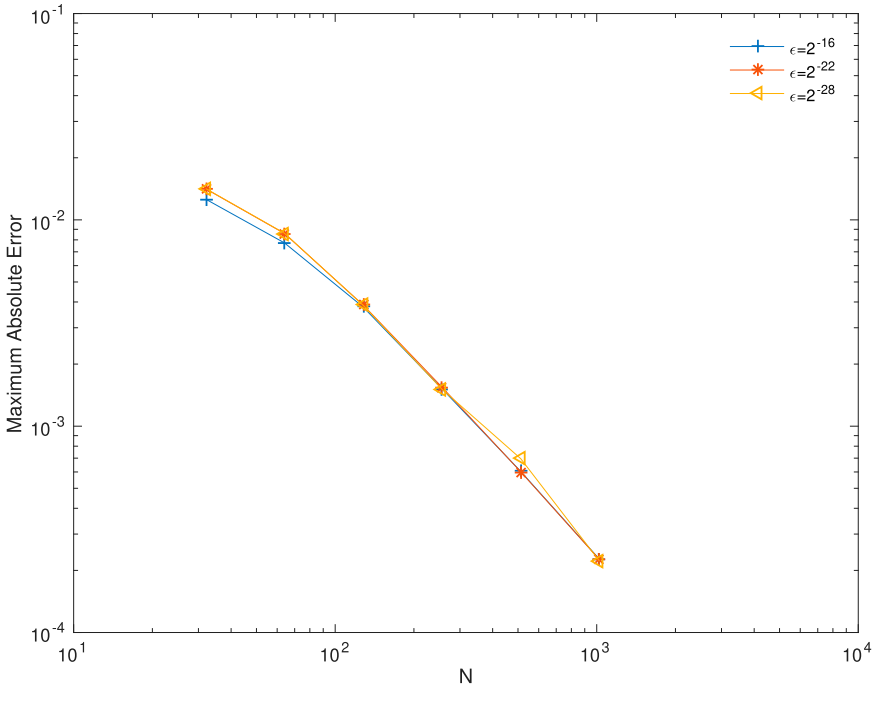

Figure 8. Error plot for Example 6.2 for Case 2 when $\mu = 2^{-8}$.

defined as

$$E_{\varepsilon}^{N,\Delta t} := \max \left| U_{N,\Delta t}(x_i, t_{k+1}) - \tilde{U}_{2N,\Delta t/2}(x_i, t_{k+1}) \right| \quad \text{and}$$

$$R_{\varepsilon}^{N,\Delta t} := \log_2 \left(\frac{E_{\varepsilon}^{N,\Delta t}}{E_{\varepsilon}^{2N,\Delta t/2}} \right).$$

Here, $U_{N,\Delta t}(x_i, t_{k+1})$ and $\tilde{U}_{2N,\Delta t/2}(x_i, t_{k+1})$ denotes the numerical solutions on $\bar{\mathbb{D}}_x^N \times \mathbb{T}_t{}^M$ and $\bar{\mathbb{D}}_x^{2N} \times \mathbb{T}_t{}^{2M}$, respectively.

The maximum absolute error ($E_{\varepsilon}^{N,\Delta t}$) and corresponding order of convergence ($R_{\varepsilon}^{N,\Delta t}$) for Examples 6.1 and 6.2 are tabulated for different values of ε, μ, M, and N in Tables 1–4. Moreover, the log-log plot of the maximum absolute error can be had from Figures 5–8. It is evident that the errors decrease monotonically as N increases.

The presence of both interior and boundary layers is apparent from the surface plots of the numerical solution of Examples 6.1 and 6.2 are displayed in Figures 1–4, for different values of ε and μ.

7. Concluding remark

This work proposed a higher-order difference method on a non-uniform mesh to solve singularly perturbed two-parameter parabolic problems with a large shift. The problem is characterized by the presence of two small parameters, leading to multiple timescales within the system. The interplay between fast and slow dynamics and non-local effects induced by shift gives rise to the boundary and interior layers. These layers are regions of rapid variation in the solution, and they can pose significant challenges for numerical solutions. The method combines an upwind difference scheme over a non-uniform mesh in space and a Crank-Nicolson scheme in time. A rigorous theoretical analysis is performed to establish the proposed method's consistency, stability, and convergence. The method is unconditionally stable, free from directional bias and parameters uniformly convergent with second-order accuracy in time and first-order accuracy in the space variable. Numerical results and illustrations are presented for two test problems which support theoretical estimates.

Abstract

This research article explores the critical role of community-based public health initiatives in addressing health disparities. Health disparities, defined as differences in health outcomes between various populations, remain a significant challenge worldwide, affecting individuals across socioeconomic, racial, ethnic, and geographic lines. Despite advancements in medical technology and healthcare delivery, disparities persist, highlighting the need for innovative approaches to promote health equity. Community-based public health initiatives leverage local resources, knowledge, and partnerships to develop targeted interventions that address the unique needs of diverse populations. This article examines the principles, strategies, and outcomes of community-based public health initiatives in reducing health disparities and promoting population health. Drawing upon examples from various communities, the article highlights successful approaches, challenges, and opportunities for collaboration among stakeholders. Additionally, it discusses the importance of cultural competence, community engagement, and sustainability in designing and implementing effective interventions. By fostering partnerships, empowering communities, and advocating for policy change, community-based public health initiatives offer promising solutions to mitigate health disparities and advance health equity.

Introduction

Health disparities, defined as differences in health outcomes between various populations, persist as a significant public health challenge globally. Despite advancements in medical science and healthcare delivery, disparities in access to care, health outcomes, and health behaviours continue to affect individuals across socioeconomic, racial, ethnic, and geographic lines [1]. These disparities not only undermine the well-being of affected populations but also pose challenges to achieving health equity a fundamental principle of public health. Addressing health disparities requires multifaceted strategies that go beyond clinical interventions to address the social, economic, and environmental determinants of health. Community-based public health initiatives play a crucial role in this endeavour by leveraging local resources, partnerships, and cultural insights to develop targeted interventions that address the unique needs of diverse communities. This article examines the principles, strategies, and outcomes of community-based public health initiatives in addressing health disparities and promoting health equity. Health disparities, characterized by differences in health outcomes among various population groups, persist as a profound challenge in public health worldwide. Despite advancements in medical science and healthcare delivery, these disparities continue to affect individuals across socioeconomic, racial, ethnic, and geographic divides, undermining the overarching goal of achieving health equity. Addressing health disparities requires comprehensive strategies that extend beyond traditional clinical interventions to tackle the social, economic, and environmental determinants of health. In this context, community-based public health initiatives emerge as pivotal mechanisms for reducing disparities and promoting health equity. Community-based public health initiatives represent a proactive approach to health promotion and disease prevention, leveraging local resources [2], knowledge, and partnerships to address the unique needs of diverse communities. By engaging stakeholders at the grassroots level, including community members, healthcare providers, government agencies, and non-profit organizations, these initiatives develop tailored interventions that target the underlying drivers of health disparities. From enhancing access to healthcare services to promoting healthy behaviours and addressing social determinants, community-based initiatives play a critical role in creating environments that support health and well-being for all. This research aims to explore the principles, strategies, and outcomes of community-based public health initiatives in addressing health disparities. Through a comprehensive review

Abstract
Text Summarization is a process to abridge a long-size document into condensed form by comprising all the prime information and central theme. Researchers proposed numerous approaches for automatic text summarization, but still state of art methods are not able to capture semantic information of input text and preserve the text cohesiveness properly. To incorporate these features the proposed novel hybrid approach integrates evolutionary game theory with word embedding models. Here each sentence acts as a player and the meaning (senses) of words of sentences form strategy for the respective games. The payoff is determined using word embedding similarity measures between words and senses of sentences. The proposed hybrid method is capable of having the sentences (in summary) from the sentences (in the document) that share a strong relationship. This idea preserves textual cohesiveness effectively by modelling the interdependence between the sentences. The proposed work is evaluated and compared with existing state-of-the-art approaches on DUC02 (Task 1) datasets using the ROUGE-1, ROUGE-2, ROUGE-SU4 and cohesion score metric. The experimental results show the proposed method outperforms the state-of-art approaches.

1 Introduction

With the rapid development of the Internet and information-communication technologies, the volume of documents on the Internet is growing exponentially. Human beings can't analyse and mine the useful information from this massive unstructured data

✉ Amita Jain

within the desired time. Therefore, it is required to provide the succinct form of data without losing its significance. Automatic Text Summarization (ATS) is an effective technique for producing a concise variant of a text that preserves the pertinent information of the text [1]. It reduces the human efforts and helps the user to get the desired information easily.

In literature, text summarization approaches can be categorised in to *Extractive* and *Abstractive*. Extractive summarization is hinged on taking out salient units (important sentences) from the document(s) and restructuring these extracted units to produce the desired summary. Extractive text summarization can be assumed to provide natural summaries by not altering the original structure of the text [1]. Abstractive summarization, on the contrary, is an approach in which summaries are produced by either rephrasing the words of the text or using new words, keeping the essence of the original text intact [2]. In this paper, the primary focus is on extractive summarization to produce indicative and generic summaries.

Research on text summarization started with the use of techniques like term or phrase frequency [3], key phrases [4], the significance of each term [5] and latent semantic analysis of the terms or phrases [6] to identify the relevant sentence(s) from a document. As time passed, significant efforts were put in to improve these automatic summarization techniques. Today, many of the techniques have graph scoring methods as their base [7] such as the semantic similarity of phrases based on WordNet [8], use local and global importance to identify the relevant sentence(s) [9] and generation of consistent extractive summaries by ranking the sentences [10, 11]. Text summarization research point towards handling the summarization task with the help of neural networks [12–14] and metaheuristic approaches [15–20].

Despite a lot of progress in recent years in the field of text summarization, the problem of producing consonant narrative summaries has still not been completely solved. The main disadvantages of existing approaches for automatic text summarization systems are that 1) ignore the semantics of text as they only focus on statistical rules such as the position of a sentence, and frequency of a word rather than the semantic/sematic of text in documents. 2) ignores the cohesion i.e., the relationships of the contexts that the sentences have with their neighbouring sentences. The proposed approach is to introduce a novel hybrid method that uses game theory with word embeddings to capture the semantic information of text and preserve the cohesiveness of the final summary. The motivation comes from the fact that game theory has proven to have predictive powers in collective decision-making scenarios and can perform consistent labelling of the data [21]. It was first initiated by Von Neumann and Morgenstern in 1994 as a mathematical framework to model the fundamentals of decision-making in like situations. Game-theoretic frameworks have since been used in various ways to gain knowledge on the use of language and evolution [22]. In literature various approaches utilized WordNet to find out the relationship between words [23]. However, WordNet has very limited coverage of words and does not involve word context. Unlike traditional approaches based on WordNet, word embeddings provide semantic and contextual-based similarity and incorporate large and real-world words. This is the main reason to combine word embeddings with the game theory approach. The proposed method is the first attempt to use game theory with word embedding models to accomplish the task of.

The approach introduced in this work finds and discusses the importance of each sentence using its similarity with every other sentence. The word embeddings (Word-2Vec, GloVe, BERT, ELMo and FastText) based similarities are calculated, taking into

account the meanings of the words of the sentences. Each sentence acts as a player and the meaning of words form strategy for the respective games. The approach follows the idea that if the senses (meanings) of the words of a sentence are strongly bonded with the senses (meanings) of the words of another sentence, then the two sentences must be similar. This preserves the cohesiveness in the resultant summary. The idea is expressed through an example in a later section.

On the evaluation front, manual assessment is subjective, costly and not suitable for real-time data collection. The approach proposed in this work is tested on the datasets introduced by DUC (Document Understanding Conferences) [24]. The dataset used in this work is DUC 2002. ROUGE scores have been computed for the evaluation using the Rogue Evaluation Toolkit [25]. Results produced by the algorithm are significant and beat the baseline scores claimed by DUC. In comparison with the various DUC claimed top performing systems, our approach shows better results and proves to be flexible and scalable despite being unsupervised. The summarization process, in general, serves as a useful tool for a range of applications varying from document indexing [26], to question-answering systems [27] and aiding information retrieval systems for document classification [28].

Problem statement: The ignorance of text semantics and cohesion in text summarization leads to work in hybrid approaches for better performance.

The objective of the proposed approach is to introduce a novel hybrid method that uses game theory with word embeddings to capture the semantic information of text and preserve the cohesiveness of the final summary.

The key contributions of the proposed work are:

1. For the first time, the proposed hybrid approach captures semantic/contextual information of input sentences in the text and preserves cohesiveness in the final summary using game theory and various word embeddings.
2. This is the first approach that amalgamates word embeddings with game theory for automatic text summarization.
3. The proposed approach investigates various word embedding models such as Word2Vec, FastText, GloVe, BERT and ELMo with game theory on the DUC2002 dataset.
4. Experimental results reveal that on evaluation matrices viz. ROUGE-1, ROUGE-2, ROUGE-SU4 and cohesiveness scores, the proposed approach outperforms the state-of-art methods on the DUC2002 standard dataset.

Roadmap: In Sect. 2, we demonstrate past work akin to text summarization. Section 3 states the prerequisite knowledge required to understand the algorithm proposed in this text. The proposed algorithm is then described in Sect. 4. Section 5 illustrates the method through an example. Section 6 describes the experimental setup and the evaluation results. In the last Sect. 7 discusses the conclusion of the work.

2 Related work

Text summarization has been an active area of interest in the research community for a very long time. Most of the studies in this area focus on extractive summarization. This literature review encompasses high-quality research conducted between 1996 and 2023. Over the years, the foundation of natural language has shifted towards mathematical models.

Applications of statistical techniques include language modelling for automatic speech recognition using smoothed n-grams, part-of-speech tagging using hidden markov models, syntactic parsing using probabilistic grammars and word sense disambiguation. The recent robust graph-based methods have proven to be beneficial in areas of natural language processing like keyword extraction [29], text summarization using lexical centrality [5] and word clustering [30]. The search for an optimal solution to the summarization problem has led to an extensive exploration of both extractive and abstractive methods.

Early methods of extractive summarization were based on simple features like the frequency of the words of the sentence, the semantic nature of the sentences in a document and the key phrases indicating the importance of those sentences. Approaches that were explored involved the representation of the documents and their positions, lexical chains [31, 32] and cue and stigma words [4].

The machine learning approach for text summarization involved classifying the sentences of the text as summary and non-summary sentences. The model was trained using a reference dataset, learning the classification probabilities at the time of training. This approach includes both unsupervised clustering methods [25] as well as supervised learning methods such as classification-based techniques [33]. The supervised learning-based approaches [12, 14, 34] require labelled summaries at the training phase whereas the unsupervised systems [35, 36] mostly rank sentences using some heuristics and do not require manually labelled summaries for training.

A common method known as term frequency-inverse document frequency (tf-idf) [37] reflects on how important a word in a document is using the measure inverse document frequency or *idf* (formulated as $\log(N/n_i)$, where N denotes the count of the documents in a collection and n_i denotes the count of the documents comprising of the word i). The system CLASSY [38] used *tf-idf* scores to rank sentences and is currently the best-performing system on the dataset DUC 2004 in terms of *ROUGE-1* score.

Approaches like the cluster-based method [39] involved the semantic nature of a document (expressed in a natural language like English). The system MEAD [8] used document clustering to obtain salient words (highly similar to the topic) called centroids. These centroids further helped in the selection of sentences for summarization.

The methods, CLASSY and MEAD are similar to Google's *PageRank* algorithm [40] and Kleinberg's *HITS* algorithm [41]. However, the systems mentioned above proceed without considering the global frame of reference. Hence, an optimization method has been proposed based on Integer Linear Programming (ILP) which treats text summarization as a knapsack problem [42]. The authors also mention the use of the ILP optimization for this task.

Graph-theoretic approaches, including *TextRank* [43] and *LexRank* [5] introduced connections between the sentences (nodes) by an edge if the two sentences share common words. These approaches can visualize inter-document and intra-document similarities. Researchers mentioned the use of a graph-theoretic approach based on a weighted graphical representation of the documents obtained by topic modelling [10]. Another renowned classical approach, Latent Semantic Analysis uses Singular Value Decomposition (SVD) to find the important sentences in the document [44]. In KLSum [45], the summary is built using the criteria of Kullback-Lieber (KL) divergence. Biased centrality ranking called KP-centrality works by grouping semantically related sentences based on some known similarity measure. The size of the group that a sentence belongs to determines the rank of its importance [46]. The sentences' relationships are modelled as a graph by the graph-based ranking methods, which then use random walk algorithms to rate the sentences [43]. The unsupervised graph-based ranking is expanded upon by the CoRank model [35]. To assess

sentences collectively, it can take into account data from numerous viewpoints, such as relationships between words and sentences and sentence-sentence interactions.

Other methods include HMM [12] and CRF [47] based approaches, support vector regression-based methods [48], latent semantic analysis (LSA) and relevance measures. The authors mention the use of a greedy approach to evaluate sentences for summarization [49]. An algorithm based on rhetorical statuses is used for summarizing scientific articles [24]. More advanced techniques have also been introduced to measure the similarity of a sentence with the discourse by using synonyms and anaphoric relations. Researchers have also tried to integrate fuzzy logic and neural networks [12] to find a solution to the problem of text summarization. One specific area is covered by Parihar et. al. in which authors summarized the scientific papers based on citation and utilized the game theory approach [50]. A method based on topic modelling and word embeddings for the extractive summarization of single documents [51]. For Hindi text summarization, a combination of the Title feature, Sentence length, Sentence position, Numerical Data, Thematic word, Proper Noun and Term frequency & Inverse Sentence Frequency is used by the authors [52]. To target summarizing legal documents, authors present an automated optimal DL-based legal text summarization (ODL-LTS) approach [53]. In a work, authors provided brief overview of challenges, application area, benefits of graph interpretation, summarization, and visualization, while providing existing tools and datasets available for graph processing and learning [54].

In the literature, different methodologies have employed WordNet to ascertain relationships between words. Nevertheless, WordNet is constrained by its limited coverage of words and the absence of consideration for word context. In contrast to conventional approaches relying on WordNet, word embeddings offer semantic and context-driven similarity, encompassing a vast array of real-world words.

The existing literature also demonstrates a lack in capturing semantic nuances and maintaining cohesiveness in the summarized content.

3 Preliminaries

In this section, an introduction to evolutionary game theory, Nash equilibrium and word embedding models is presented, which are a pre-requisite to understanding the algorithm proposed in this work.

3.1 Evolutionary game theory

Evolutionary Game Theory was first brought to light by Smith and Price in 1973. Evolutionary game theory induces an *inductive learning* process wherein a set of entities play games with other entities (called neighbors) repeatedly. The players update their understanding of the shape of the game at each iteration. Further strategies are developed according to what has proven to be fruitful previously. The strategy space of a player i can be defined as a mixed strategy profile $x_i = (x_1, \ldots, x_m)$, where m is the count of pure strategies and x_h denotes the probability of player i choosing the hth pure strategy. In every iteration, a player updates its strategy space in accordance with the payoffs obtained as a result of the games. It then assigns greater probability to the strategy which has gained higher payoff and the process is continued until a point of equilibrium is achieved – Nash Equilibrium [21, 23].

3.1.1 Nash Equilibrium

In a non-cooperative game involving two or more players, Nash Equilibrium—so named after the mathematician John Forbes Nash Jr.—is a suggested solution where each player is assumed to be aware of the equilibrium strategies of the other players and no player stands to gain by changing only their own strategy [55, 56]. Each player has a plan they want to use, and according to game theory, no person can gain anything by changing their strategy while the others' stay the same. This combination of tactics and their associated rewards form a Nash equilibrium.

we have used the discrete time version of the replicator dynamics equation to conduct the experiments in this work:

$$x^h(t+1) = x^h(t)\frac{u\left(e^h, x\right)}{u(x,x)}\forall h \in S \tag{1}$$

where at each quantum of time t, the players update their strategy space observing the developing environment until equilibrium is attained. x^h denotes the probability that player i chooses its hth pure strategy and e^h is the expected payoff of a pure strategy e.

3.2 Word embedding models

As we all know computers do not understand text, they only understand numbers. Thus we need word embeddings to transform the text into a digital representation for computers to understand and perform the required calculations. Some of the famous word embedding techniques are: Word2vec—It was the first technique to predict embeddings of the words [57]. It uses a small neural network architecture to calculate the similarity between words in the corpus. It determines which words in the corpus occur more frequently with the target word and calculates the embeddings. Glove—It was introduced as an advancement to the word2vec algorithm. Because we compare each word with all the words in the corpus in word2vec, with a large corpus size our algorithm is very slow. In Glove, it focuses on the word co-occurrence and creates word embeddings by combining the embeddings of related words. FastText—It adopted its idea of generating word embeddings from the word2vec algorithm but rather than comparing the words in the corpus, it goes one level deeper and compares the part of words and characters. This allows us to create more generalized versions of embeddings. Elmo—It stands for "Embeddings from Language Model ". In this architecture, it uses the character level tokens and processes them in a bidirectional LSTM to make the word-level embeddings. The LSTM processes the tokens in a right-to-left and left-to-right approach. BERT—The idea of embeddings in BERT is the same as Elmo. But instead of using LSTM, it uses a deeply connected bidirectional architecture to have a more concentrated embedding of the words.

4 Proposed work: automatic text summarization using game theory and word embeddings

This section outlines the methodology for automatic extractive text summarization, employing game theory and word embeddings. In this framework, each sentence (player) in the text is denoted as $s \in T$, with strategies corresponding to different word senses of

the sentence. The initial strategy profile $S_i = \{1, \ldots, c\}$, for each player, is uniformly and normally distributed, ranging from 1 to c, where c represents the total number of strategies for that player. This distribution, indicating the likelihood of selecting specific strategies, undergoes iterative updates until it converges to the optimal distribution.

The games are conducted utilizing pay-off matrices and sentence-similarity matrices for pairs of sentences, detailed later in the text. Scores are assigned to sentences based on the outcomes of these games, leading to a ranking of sentences in descending order of importance. The algorithm's stepwise implementation is described in the subsequent sections.

Step 1: Extract a list of all the tokens (sentences) from the text (document) (please refer to Algorithm 1).
Step 2: Compute the sentence-similarity matrix using word embeddings, which contains pairwise similarities between all the sentences and depicts each sentences' interaction with every other sentence (neighbour) (please refer to Algorithm 2).
Step 3: Compute the sense-similarity matrix between each pair of senses extracted from each word of every sentence. This will further be required to extract the payoff matrices (please refer to Algorithm 3).
Step 4: Construct a strategy profile for each sentence and assign it a probability distribution i.e., distribute a set of probabilities over all the viable strategies (senses) for each sentence (player) (please refer to Algorithm 4).
Step 5: Start the games using the mathematical equations of replicator dynamics. Every player is required to play a game with every other player in each iteration. Continue the games until Nash Equilibrium is achieved (please refer to Algorithm 5).
Step 6: The strategy profile of each player is updated as a result of these games. Use these updated profiles to assign scores to the sentences (please refer to Algorithm 6).
Step 7: Rank the sentences according to these scores to form the desired summary. Figure 1 Shows the overall flow of the proposed method.

Algorithm 1 divides the given text into tokens. Each token consists of a sentence from the text. All such tokens are saved into a list. The list of sentences is denoted by *list* and the total number of sentences is given by n. Using *list*, we compute an $n \times n$ similarity matrix

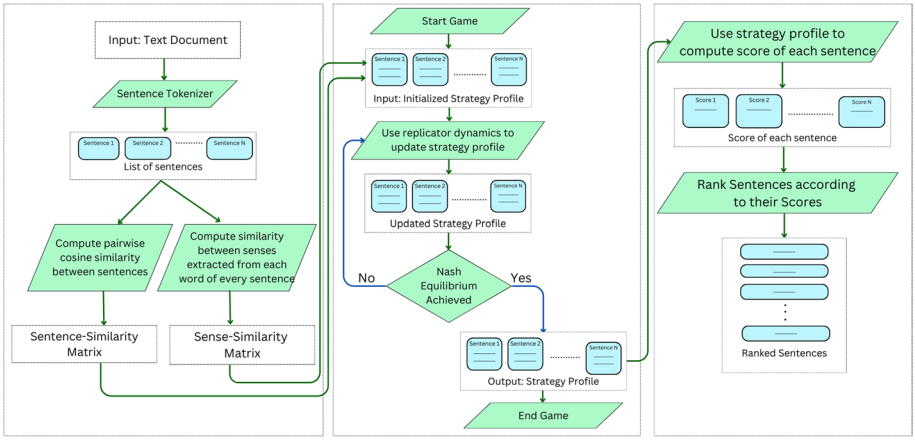

Fig. 1 Overall flow of the proposed text summarization method

– *sentence_matrix,* where every element w_{ij} denotes the similarity value between the sentences i and j. Proximity relations are taken into account by increasing the similarity value between two neighbouring sentences (can be checked using bi-gram) by a factor of the mean value of the *sentence_matrix*, as depicted in Algorithm 2.

Algorithm 1 Pre-Processing

Input: A text T
Output: A list of tokens (sentences) extracted from T – *list*
1. Input a text T
2. Extract from the text all the sentences into a *list*
3. Return the *list* of sentences

Algorithm 2 Sentence similarity matrix

Input: List *list* = (S_1, S_2, S_3, … , S_i, … , S_n) extracted from the text T
Output: A 2-D matrix (number_of_sentences × number_of_sentences) denoting the similarity

```
Let n = |list|, average = 0
Let sentence_matrix = 1 for all n * n values
for i = 1 to n do
    for j = 1 to n do
        Let score = 0, count = 0
        if (S_i is not equal to S_j)    // similarity between the same pair of sentences are ignored
            sentence1 = tokenize the sentence S_i and tag its words accordingly
            sentence2 = tokenize the sentence S_j and tag its words accordingly
            for each word1 in sentence1 do
                best_score = 0
                Let similarity_value_list = None
                for each word2 in sentence2 do
                    val = similarity-measure (word1, word2) using word embeddings
                    similarity_value_list. append(val)
                for k = 1 to | similarity_value_list | do   // filter out the 'None' values
                    if (similarity_value_list [k] is equal to 'None')
                        similarity_value_list [k] = 0.0
                best_score = Extract the maximum value from the similarity_value_list
                Add best_score to score
                Increment count by 1
            Divide score by count
            set sentence_matrix[i][j] = score
            add sentence_matrix[i][j] to average
Divide average by n * n
for i = 1 to n do
    for j = 1 to n do
        if (S_i is adjacent to S_j in list)
            add average to sentence_matrix[i][j]
Return sentence_matrix
```

The similarity value between a pair of sentences is determined through the following approach: for each word in a sentence, we compute its similarity with every word in the other sentence, employing diverse word embeddings such as word2vec, gloVe, fastText,

ELMo, and BERT. The highest obtained similarity value for each word pair is recorded. The average of these maximum values yields the overall similarity value between the two sentences. The comparison of these embeddings within the context of game theory for text summarization is elaborated upon in the results section (refer to Sect. 6).

The most popular, cosine similarity is used in Word2Vec word embedding models. Using this paradigm, the cosine similarity between the vectors of two words can be used to determine how similar the two words are. The cosine angles of the two vectors are multiplied to determine the cosine similarity.

$$\cos\alpha = \frac{AXB}{|A|X|B|} = \frac{\sum_{i=1}^{n} A_i X B_i}{\sqrt{\sum_{i=1}^{n} (A_i)^2} X \sqrt{\sum_{i=1}^{n} (B_i)^2}} \tag{2}$$

where A_i and B_i, respectively, are the elements of vectors A and B.

A list of unique senses (synsets) for every word of the text is extracted using a lexical database (WordNet 3.0 in this case) of the corresponding natural language. Let c denote the total number of available senses corresponding to all the words of the text. The payoff matrices are extracted from a $c \times c$ similarity matrix – *sense_matrix* constructed using the pairwise similarities of all the available senses. The reference knowledge base used in this work is WordNet 3.0 [58].

For each synset, we calculate its similarity with all other synsets. Again, to calculate the similarity measure between senses of words above mentioned word embeddings are used. Algorithm 3 gives a more computational and mathematical view for the same.

Algorithm 3 Sense Similarity Matrix

Input: List *list* = (S_1, S_2, S_3, ... , S_i, ... , S_n) extracted from the text *T*
Output: A 2-D matrix (number_of_synsets × number_of_synsets) denoting the pairwise similarities between all the synsets of all the words of the text – *sense_matrix*

```
Let all_synsets = None
for each sentence S_i in list do
    Tokenize the sentence and tag its words accordingly
    W = Extract all the words from sentence that are present in a lexical database W = (w_1, w_2, w_3, ... , w_i, ... , w_n)
    for each word in W do
        Extract all the unique synsets corresponding to word from the same lexical database – word-synsets
        for synset in word-synsets do
            all_synsets.append (synset)
Let len = |all_synsets|, sense_matrix = 0 for all len * len values
// all_synsets = (synset_1, synset_2, synset_3, ... , synset_i, ... , synset_j, ... , synset_len)
for i = 1 to len do
    for j = 1 to len do
        Set sense_matrix[i][j] = similarity-measure (synset_i, synset_j)
Return sense_matrix
```

The partial payoff matrix – Z_{ij} for each game between the players i and j can be obtained by extracting a sub-matrix from the sense similarity matrix (*sense_matrix*) corresponding to the entries corresponding to the senses of the two players. The $m_i \times m_j$ sub-matrix, thus obtained, is called the *payoff_matrix* for the game between players i and j, where m_i and m_j are the count of the senses of players i and j respectively. Greater the similarity value between the senses of the two words, greater is the motivation for the word to take that sense, and hence, utilize the strategy linked to that sense.

The more detailed explanation of how the payoff is determined using word embedding similarity measures between words and senses of sentences, emphasises the distinctiveness and effectiveness of this measure in capturing semantic relationships. The payoff determination in our approach is intricately tied to the semantic relationships between words and senses of sentences. We leverage word embedding similarity measures, utilizing embeddings from various models such as word2vec, gloVe, fastText, ELMo, and BERT. For each word in a sentence, we calculate its similarity with every word in the other sentence across these embeddings. This process is conducted comprehensively, considering all possible word pairs.

The uniqueness of our approach lies in its ability to capture semantic relationships. Word embeddings encode semantic information, and by assessing similarity across different models, we attain a more comprehensive understanding of the semantic space. The highest similarity value for each word pair is recorded, reflecting the strength of their semantic connection.

Aggregating these maximum similarity values and calculating their average yields the overall similarity measure between two sentences. This approach offers an effective means of determining payoff by considering the rich semantic associations embedded in various word embeddings. It allows us to encapsulate the intricacies of word meanings and sentence senses, contributing to a more robust and context-aware summarization process.

The sense inventories of the words of the text are used to create the strategy space for the games. A list $C = (1,..., c)$ comprising of all the unique senses is created marking the total space for the games. This strategy space S for the games can be defined in the following manner:

$$\begin{matrix} si1 & si2 & \ldots & sic \\ . & . & & . \\ . & . & \ldots & . \\ . & . & & . \\ sn1 & sn2 & \ldots & snc \end{matrix}$$

Each row corresponds to the strategy space of one particular player and each column corresponds to one particular sense. The components s_{ih} denote the probability with which a player i decides to move ahead with its hth pure strategy over all its other strategies i.e. the probability that the sentence s_i (player) chooses the sense s_h (strategy). Algorithm 4 describes the same.

Algorithm 4 Strategy Space

Input: List $list = (S_1, S_2, S_3, \ldots, S_i, \ldots, S_n)$ extracted from the text T
Output: A 2-D matrix (number_of_words x number_of_synsets) denoting the strategy profile of each sentence against all the available senses – *strategy_space*

1. Let *strategy_space* = 0 for all n * *len* values
2. for $i = 1$ to n do
3. for $j = 1$ to *len* do // Assigning a Normal Distribution to our Strategy Space
4. $$strategy_space[i][j] = \begin{cases} |M_i|^{-1} & \text{if sense } j \text{ comes from the sentence } i \\ & \text{where } |M_i| \text{ is the total sense-count of sentence } i \\ 0 & \text{otherwise} \end{cases}$$
5. Return *strategy_space*

The initial distribution of the mixed strategy space can be done either uniformly (normal distribution as in unsupervised learning) or can extract information from a sense-tagged corpus with pre-labelled values (supervised learning).

Normal distribution follows the following approach:

$$s_{ij} = \begin{cases} |M_i|^{-1}, if\ senses_{ij} \in M_i \\ 0, otherwise \end{cases} \tag{3}$$

where $M_i = \{1,..., m_i\}$ is the sense inventories of each word in a text, where m_i is the number of senses associated with the word i. The supervised initialization is explained in (Tripodi & Pelillo, 2017).

The system dynamics can now be started. Algorithm 5 gives a better understanding of the mathematics involved in the process. In each iteration, a player plays a game with each of its neighbors one by one. The payoff for the hth strategy is calculated as:

Algorithm 5 Replicator Dynamics

Input: *list*, *sentence_matrix*, *sense_matrix*, *strategy_space*
Output*: strategy_space* gets updated

```
Let number_of_iterations = 100                    // Assumption
for i = 1 to number_of_iterations do
    for j = 1 to n do                             // Player
        for k = 1 to n do                         // Neighbour
            Let payoff_matrix = a (sense_count_of_player x sense_count_of_neighbour)
            submatrix extracted accordingly from the sense_matrix
            The payoff for each strategy (current_payoff) is calculated according to the following equation:
            sentence_matrix[j][k] * dot-product (payoff_matrix, strategy_space[k])
            The strategy_payoff is calculated as Σ current_payoff
        The player_payoff is calculated as Σ dot-product (current_payoff, strategy_space[j]^T)
        Let updation_values for a player j = strategy_payoff / player_payoff
        Update strategy_space[j] according to the obtained updation_values
```

$$u_i\left(e^h, x\right) = \sum_{j \epsilon N_i} \left(w_{ij} Z_{ij} x_j\right)_h \tag{4}$$

The player's payoff for the iteration is calculated as:

$$u_i(x) = \sum_{j \epsilon N_i} x_i^T \left(w_{ij} Z_{ij} x_j\right) \tag{5}$$

Using this method, we can weigh the impact that each sentence has on the options that a candidate sentence has to consider to select its own meaning. The obtained payoff for a sentence i takes into account its own similarity with the sentence $j - w_{ij}$; the similarities among the senses of its words and the words of the sentence $j - Z_{ij}$, and the sense predilection of sentence $j - x_j$. Strategies pertaining to higher payoffs emerge at every iteration as a result of the selection criterion. After the process terminates, each player chooses its sense according to these restrictions.

The system may run for a pre-defined number of iterations or until convergence, as achieved by the following equation of Nash Equilibrium:

$$\phi_i = arg \max_{h=1,\ldots,c} x_{ih} \tag{6}$$

The result of the replicator dynamics assigns to each word of each sentence the sense that the word is most likely to assume in the given context. The top few senses of each word are taken to form the overall meaning of the sentence.

Now that we have the updated strategy profiles of the players, we know the optimal senses corresponding to each sentence. For each sentence, we compare its top senses (strategies) with every sense (strategy) of the other sentence to find the similarity between the two. Using the mean of the obtained data, we assign each sentence a similarity score as depicted in Algorithm 6. The sentence which has the maximum similarity is given the highest score. A descending order of the scores gives the final ranking of the sentences for the summary.

Algorithm 6 Assignment of Scores

```
Input: List list = (S1, S2, S3, ... , Si, ... , Sn) extracted from the text T, strategy_space
Output: An output array scores containing the similarity scores of each sentence
    Let sentence_synsets = None
    for each sentence in T do
        important_senses = Extract a list of the top important senses (synsets) using the strategy_space matrix
        sentence_synsets.append (important_senses)
    Let scores = []
    for each sentence Si in T do
        val = 0
        for each sentence Sj in T do
            for each sense si in sentence_synsets[i] do
                for each sense sj in sentence_synsets[j] do
                    add similarity_measure (sense Si, sense Sj) to val
        val = val / (|sentence_synsets|*|sentence_synsets|)
        scores.append (val)
    Return scores
```

5 Illustration through an Example

This section discusses an example to illustrate the algorithm proposed in this work. The following document has been taken as input to the algorithm:

A smart home speaker was the need of the hour. I was looking for the same on the Internet when I stumbled upon the perfect recommendation—the Echo Dot 3rd generation from Amazon. I immediately decided to move forward with it. The package containing the product was delivered to me within two days of its purchase. After using the product, I realised that the new Echo Dot from Amazon is the best compact smart speaker in the market by a wide margin. The quality of sound is extraordinary. Alexa has become smarter than ever with reasonable introduction to smart home control. The microphone sensitivity has also been improved significantly. However, I do feel that over a period of time the outer fabric cover might get dusty and the new power port is not as universal as it could have been.

The document is a review of the "Echo Dot 3rd Generation" from Amazon. The following steps illustrate the procedure to be followed to rank the sentences in order to produce a summary.

Algorithm 1 requires to divide the input text into nine sentences – S0, S1, S2, S3, S4, S5, S6, S7 and S8. We then proceed to calculate the sentence similarity matrix as illustrated in *Algorithm* 2. The sentence similarity matrix obtained for this example is shown in Table 1.

Algorithm 3 states the procedure to calculate the sense similarity matrix using word embeddings (Word2Vec in this illustration). The output obtained after this step is depicted in Table 2.

After this step we initialize our strategy space according to *Algorithm* 4 and assign normal probabilities to all the strategies (senses) corresponding to each player (sentence). We then proceed to perform Replicator Dynamics (*Algorithm* 5) as we initiate the games between the sentences. The scores assigned to each strategy (sense) of every sentence is shown in Table 3.

We now have the important strategies (senses) corresponding to every sentence in the text – Table 4. The score of every sentence is impacted by the very sense that is categorized as important for it. The scores thus assigned are shown in Table 5.

After the assignment of scores, a summary of size (the required number of sentences) '*k*' is expected to be generated. The top '*k*' sentences are then extracted on the basis of their scores and are given as the output. Let the required number of sentences for the summary ('*k*') be 5. Table 6 shows a summary of length five.

1	However, I do feel that over a period of time the outer fabric cover might get dusty and the new power port is not as universal as it could have been
2	The quality of sound is extraordinary
3	Alexa has become smarter than ever with reasonable introduction to smart home control
4	After using the product, I realised that the new Echo Dot from Amazon is the best compact smart speaker in the market by a wide margin
5	The microphone sensitivity has also been improved significantly

6 Experimental setup, results and discussion

This section discusses datasets description, evolutionary metrics, and comparison with state-of-art methodologies.

6.1 Evaluation dataset description and metrices

We have conducted various experiments using the DUC 2002 dataset, which is part of the Document Understanding Conference (DUC). DUC 2002 comprises 567 news stories in the English language, organized into 59 clusters.

The ROUGE package was utilized in the suggested study to automatically evaluate the algorithm [21, 25]. DUC has assumed the toolset for evaluations of automatic summarization. A measure of the summary's quality can be found in the number of overlapping units, such as n-grams, word sequences, and word pairs between the reference summary and the candidate summary.

ROUGE-N is an *n*-gram recall measure and is computed as follows:

$$ROUGE - N = \frac{\sum_{S\in\{Ref\sum\}}\sum_{n-gram\in S}Count_{match}(n-gram)}{\sum_{S\in\{Ref\sum\}}\sum_{n-gram\in S}Count(n-gram)} \tag{7}$$

where n is the n-gram's size, Countmatch (n-gram) returns the greatest number of n-grams that appear simultaneously in a set of reference summaries and a candidate summary, and Count (n-gram) returns the number of n-grams that appear in the reference summaries.

The evaluation of summaries was previously done using a score based on recall in the older ROUGE packages. However, the evaluation is now done using three metrics: ROUGE-N Precision, ROUGE-N Recall, and ROUGE-N F-Score, where N can be any number between one and four. The ROUGE toolbox reports distinct scores for each of the following: 1, 2, 3, and 4 g as well as the SU4: skip bigram. The longest subsequence between generated and standard summaries is examined by ROUGE-L. The ROUGE Version 1.5.5 has been used for the evaluation of our system.

6.2 Comparison with DUC systems on DUC 2002 dataset

This section compares the proposed method with popular five DUC systems on DUC 2002 dataset. Brief description of these five-systems sys code 21, sys 27, sys 28, sys 29 and sys31 is given in Table 7. These systems are considered to have the best ROGUE scores and have been widely used for comparisons. Their summaries have been listed on the DUC-NIST

Table 7 A brief description of the top five systems participating in DUC 2002

System Code	System ID	System Description
21	Wpdv-xtr.v1	Supervised sentence classification with WPDV (Weighted Probability Distribution Voting)
27	Ntt.duc02	Supervised sentence classification with SVM (Support Vector Machines)
28	Ccsnsa.v2	Supervised sentence extraction with the Hidden Markov Model (HMM) and the LRM (Logistic Regression Model)
29	Kul.2002	Unsupervised sentence extraction + topic segmentation
31	ULeth 131 m	Unsupervised sentence extraction + text segmentation

website. A comparison-based evaluation of ROGUE-1, ROGUE- 2 and ROGUE-SU4 scores of proposed approach, the baseline and the top DUC mentioned systems is performed. The results are shown in Table 8 and Fig. 2. It is very clear that the proposed system based on word embedding and Game Theory (TSWE&GT) outperforms the others.

6.3 Performance comparison on DUC 2002 dataset

We have performed a comparative evaluation of our proposed system with widely used baseline approaches and state-of-the-art systems published in the literature on DUC 2002, as shown in Table 9.

Description of Baseline approaches are as follows:

TextRank [59] a graph-based algorithm depicts a document as a graph of sentences, with the edges connecting two sentences based on how similar they are.

LexRank [5] is to determine the significance of each sentence in the document, LexRank applies the idea of eigenvector centrality to the graph representation of sentences.

Table 8 Results on the DUC 2002 dataset (Stop-words included)

System	ROGUE-1	ROGUE-2	ROGUE-SU4
TSWE&GT (proposed)	**53.4**	**28.1**	**28.9**
System 27	50.1	24.1	25.3
System 31	49.1	23.8	25.1
System 28	48.3	23.2	24.7
System 21	47.9	22.8	24.1
DUC 2002 Baseline (Lead)	47.5	22.6	24.4
System 29	46.7	21.7	23.5

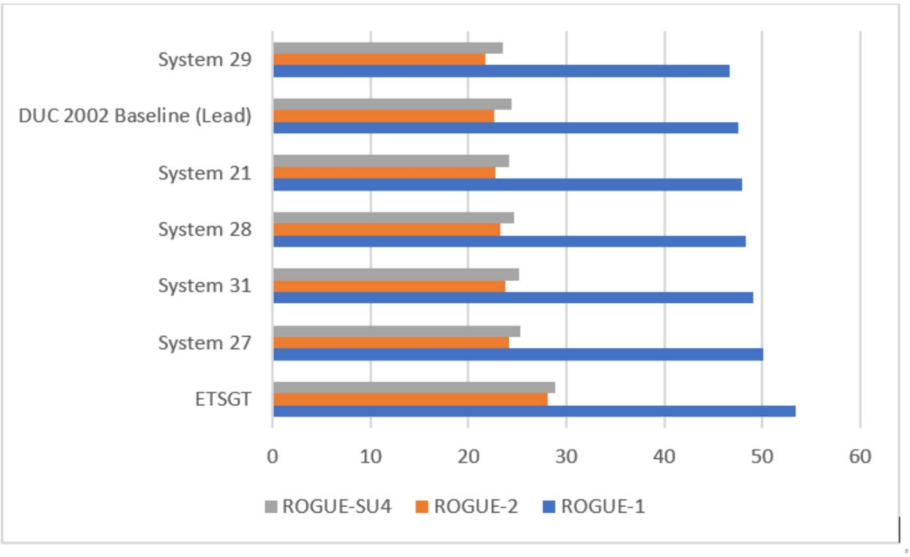

Fig. 2 Results for system comparison on DUC 2002 data (stop words included)

Table 9 ROUGE Scores on DUC 2002 using baseline, State-of-art and TSWE&GT approach

Methods	ROUGE-1	ROUGE-2	ROUGE-SU4
TextRank [59]	47.0	19.5	42.8
LexRank [5]	42.9	21.1	37.1
LSA [6]	43.0	21.3	40.0
KLSum [45]	38.3	16.9	32.2
SumBAsic [60]	39.6	17.3	35.1

Egraph + coh [10]	47.9	23.8	-
Tgraph + coh [10]	48.1	24.3	-
URANK [9]	48.5	21.5	-
CoRank [35]	52.6	25.8	45.1
SummCoder [62]	51.7	27.5	44.6
KP-centrality [46]	49.8	24.5	43.7
GT_TS by Ahemed [63]	-	35.5	-
PE_MSC [51]	50.0	22.1	22.8
TSWE&GT (proposed)	53.4	28.1	46.7

LSA (Latent Semantic Analysis) [6]: By applying Singular Value Decomposition (SVD) on a document matrix D of size m x n, consisting of m sentences and n number of terms, LSA (Latent Semantic Analysis), attempts to identify salient sentences in the document.

KLSum [45]:The output summary of the document is produced by the text summarization algorithm KLSum based on the Kullback-Lieber (KL) divergence criterion.

SumBasic [60] is a greedy search approximation technique that combines a component to re-weight the word probabilities with a frequency-based phrase selection component to reduce redundancy.

Integer Linear Programming [61] A phrase-based summarization technique that uses integer linear programming to encapsulate the grammaticality restrictions across phrase dependencies.

The entity graph-based system Egraph [10] represents documents using a bipartite graph of phrase and entity nodes. They created a system called "Egraph + Coh." that has a coherence metric that is determined by utilising the average outdegree of an unweighted projection graph.

Tgraph [10] is a graph-based, unsupervised text summarising system that models topics using Latent Dirichlet Allocation (LDA). Parveen et al."Tgraph.'s + coh" proposal generates a summary by taking into account coherence determined using a weighted projection graph.

URANK [9] is a unified rank methodology built on a graph model that manages multi-document summarization at the same time.

The graph-based unsupervised extractive text summarization method CoRank [35] combines the graph-based ranking model with the word-sentence relationship.

SummerCoder [62] is an unsupervised framework for extractive text summarization based on deep auto-encoders.

GT_AS [63] is a game theory-based approach for text summarization. PE_MSC [51] is a text summarization approach using Entailment based minimum set cover.

The proposed approach demonstrated outstanding performance in extractive text summarization on the DUC 2002 dataset, as evidenced by impressive ROUGE scores, as

depicted in Fig. 3. Specifically, we achieved a ROUGE-1 score of 53.4, a ROUGE-2 score of 28.1, and a ROUGE-SU4 score of 46.7. When compared to baseline methods and state-of-the-art summarizers, including ILP, graph-based approaches like Tgraph, Egraph, URANK, and deep auto-encoder-based methods like SummerCoder, our proposed framework (TSWE&GT) surpassed them in terms of ROUGE-1, ROUGE-2, and ROUGE-SU4 scores on the DUC 2002 dataset. Table 10 presents the ROUGE scores for game theory hybridising with various word embedding models including Word2Vec, FastText, GloVe, BERT and ELMo on the DUC 2002 dataset. Figure 4 illustrates the graphical impact of these models. Notably, the ensemble Bert with game theory method exhibited superior performance compared to other models. Reason behind is that BERT considers both left and right context in its representations. It captures contextual information from the entire sentence. One limitation of this work lies in its reliance on the performance of embeddings for generating payoff matrices, a crucial aspect of the proposed text summarization approach. The effectiveness may be compromised when dealing with sentences containing metaphors, slang terms, and abbreviations, as the current approach does not address these linguistic elements.

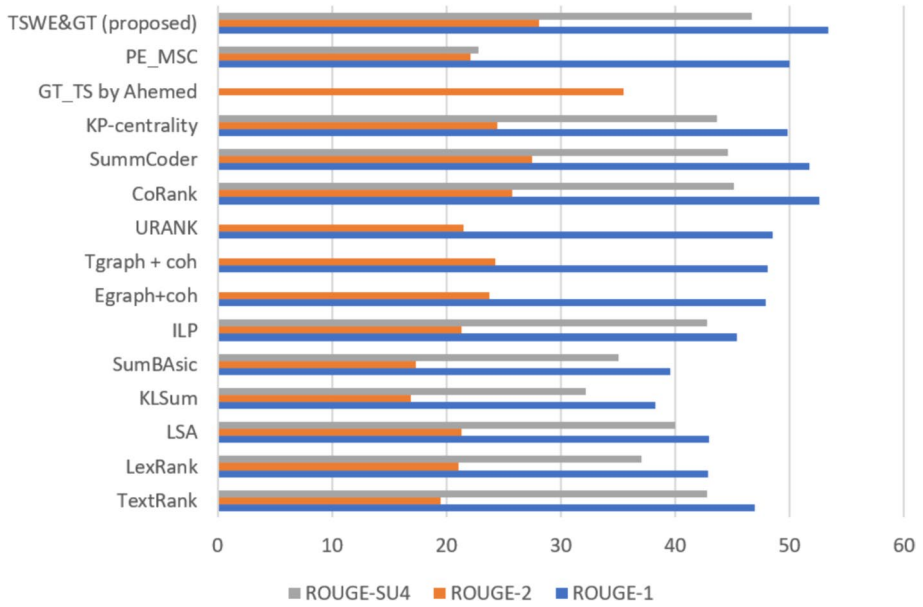

Fig. 3 ROUGE scores on DUC 2002 using baseline, state-of-the-art and TSWE&GT approach

Table 10 ROUGE scores for various word embedding models on DUC 2002 dataset

Word Embeddings	ROUGE-1	ROUGE-2	ROUGE-SU4
Word2Vec + GT	52.8	26.5	26.3
GloVe + GT	51.9	25.7	25.7
FastText + GT	52.3	26.2	26.8
BERT + GT	**53.4**	**28.1**	**28.9**
ELMo + GT	53.0	27.4	27.2

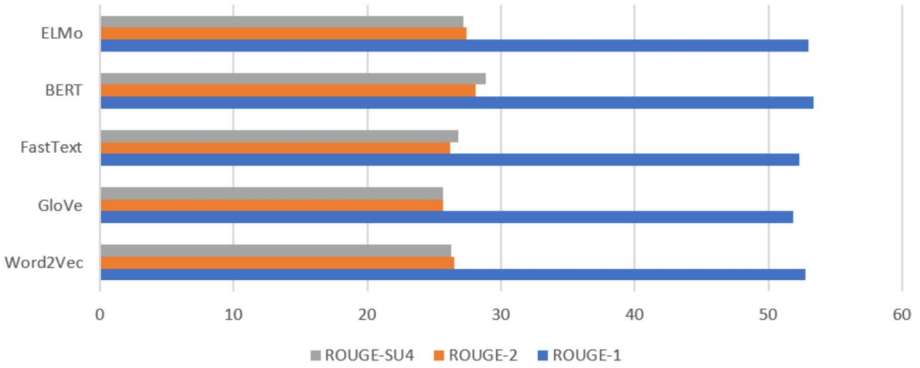

Fig. 4 Graphical Representation of results for word embedding models with game theory

6.4 Cohesiveness Assessment (S_{Coh})

This part compares the cohesion score of proposed methodology and above-mentioned state-of-art methods on DUC 2002 dataset. Cohesion is an essential element in text summarization. It refers to the degree to which sentences of resultant summary are connected for the smooth flow of reading and understanding. Cohesiveness in summary does not only mean grammatical correctness of sentences but it refers to the linking of the sentences at the both sentence level and passage level. The most used metric to compute cohesiveness of summary is cosine similarity.

$$SCoh = CosSim(Si, Sj) i \neq j = 1,2, \ldots k \tag{8}$$

where, S_i, S_j are the summary sentences. Higher the value of S_{Coh}, higher the connectivity between summary sentence and vice versa. Figure 5. shows the cohesion score of proposed method and baseline methods on DUC datasets (For simplicity four baseline methods with

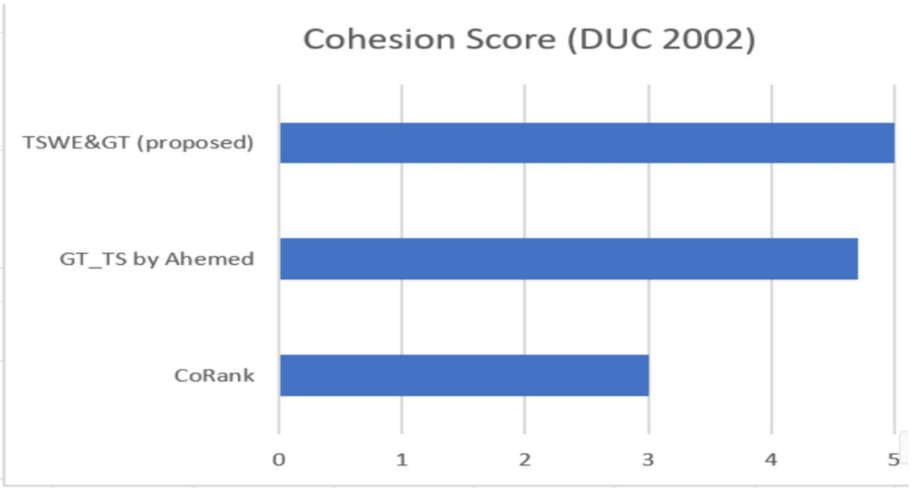

Fig. 5 Cohesiveness Assessment on DUC 2002 Dataset

highest rouge score are considered for cohesiveness comparison). It is observed from the analysis that proposed hybrid approach for text summarization using game theory and word embeddings has shown better cohesion value than the state-of-art for both datasets.

7 Conclusion and future work

A hybrid approach using evolutionary game theory and various word embedding models is capable to incorporate the semantic of input text and preserve the cohesiveness of the resultant summary. It is found that the proposed method successfully ranks each sentence in an order of importance by finding the mutual similarity of that sentence with all other sentences. The performance of generated summaries has been evaluated using ROUGE score on DUC 2002 dataset. Several experiments are performed and it has been found that proposed technique outperformed the state-of-art techniques on ROUGE-1, ROUGE-1 and ROUGE-SU4. Finally, cohesiveness is evaluated on DUC 2002 dataset and the result showed that proposed method preserves cohesiveness in final resultant summary.

An interesting future work direction can be the use of fuzzy game theory for text summarization. Hybridization of game theory with word embedding models can also enhance the performance of keyword extraction, query expansion, rumour detection etc. This work can be extended to cater to multi-document summarization with expectations of better results and greater efficiency.

Authors' contributions A.B. and B.C. conceived of the presented idea. A.C. developed the theory and performed the computations. A.B. and B.C. verified the analytical methods. B.C. encouraged A.B. to investigate and supervised the findings of this work. All authors discussed the results and contributed to the final manuscript.

An Implementation of a Frequency Decomposition Algorithm for Power Quality Smoothening in a Hybrid SPVA-BES Microgrid

Divyank Srivastava, *Graduate Student Member, IEEE*, Vivek Narayanan, *Senior Member, IEEE*, Bhim Singh, *Fellow, IEEE*, and Arunima Verma, *Senior Member, IEEE*

***Abstract*—This article presents a novel application of Fourier decomposition method in a double-stage grid-tied microgrid integrating a solar photovoltaic array (SPVA) and battery energy storage (BES). Due to intermittent nature of SPVA generation and the nonlinearity of local loads connected at point of common coupling, the grid is subject to harmonic distortions. The proposed control method decomposes nonlinear and nonstationary signals to extract fundamental components necessary for generating switching pulses for voltage source converter. To ensure reliable operation during grid outages, system incorporates a BES, managed using a bidirectional dc–dc converter. This configuration maintains high-quality power delivery, and facilitates a smooth transition between grid-connected mode and standalone mode. Simulation and hardware prototype results validate effective operation of proposed control strategy.**

***Index Terms*—Adaptive control, battery energy storage (BES), frequency decomposition, IEEE Std. 519, power quality, solar photovoltaic array (SPVA).**

NOMENCLATURE

ANFIS	Adaptive neuro fuzzy interference system.
BES, BDDC	Battery energy storage, bidirectional dc–dc converter.
CEEMD	Complete ensemble empirical mode decomposition.
EMD, EEMD	Empirical mode decomposition, ensemble empirical mode decomposition.
FDM, FIBF	Fourier decomposition method, Fourier intrinsic band functions.
GCM	Grid-connected mode.
HTL, HCC	High to low, hysteresis current controller.
IRPT, InC	Instantaneous reactive power theory, incremental conductance.
LTH, LMS, LMS-LMF	Low to high, least mean square, least mean square-least mean fourth.
MG, MPP, MPPT	Microgrid, maximum power point, maximum power point tracking.
P&O, PSO, PR, PLL, PQ	Perturb and observe, particle swarm optimization, proportional resonant, phase locked loop, power quality.
RESs, ROGI	Renewable energy sources, reduced order generalized integrator.
SAM, SNR, SOGI, SPVA, SRFT, STS	Standalone mode, signal to noise ratio, second-order generalized integrator, solar photovoltaic array, synchronous reference frame theory, state transition switches.
THD, TOGI	Total harmonic distortion, third order generalized integrator.
VMD, VSC, VSSLMS	Variational mode decomposition, voltage source converter, variable step-size least mean square.
f_g	Grid frequency.
i_{ga}, i_{gb}, i_{gc}	Grid currents.
$i^*_{ga}, i^*_{gb}, i^*_{gc}$	Reference grid currents.
i_{La}, i_{Lb}, i_{Lc}	Load currents.
$i_{\mathrm{VSC}a}, i_{\mathrm{VSC}b}, i_{\mathrm{VSC}c}$	VSC currents.
$i_{Lae}, i_{Lbe}, i_{Lce}$	Extracted fundamental components of load currents.
I_{pv}, P_{pv}	SPVA current, SPVA power.
$K_{pd}, K_{id}, K_{pb}, K_{ib}$	Proportional and integral gains of PI controllers of BDDC.
$u_{gae}, u_{gbe}, u_{gce}$	In-phase positive sequence unit templates.
$u_{gqa}, u_{gqb}, u_{gqc}$	Quadrature positive sequence unit templates.
v_{ga}, v_{gb}, v_{gc}	Grid phase voltages.
$v_{gae}, v_{gbe}, v_{gce}$	Fundamental frequency extracted grid phase voltages from FDM control.
$v^{ref}_{La}, v^{ref}_{Lb}, v^{ref}_{Lc}$	Reference load voltages.
v_{La}, v_{Lb}, v_{Lc}	Load voltages.

V_{term}	Amplitude of extracted PCC voltage.
V_L^{ref}	Amplitude of reference load voltages.
V_{dc}, V_{mpp}, $V_{\text{dc}ref}$	DC-link voltage, maximum power point voltage, reference dc-link voltage.
W_{Le}, W_{pvff}, W_{ge}	Average weight of fundamental load current, weight of SPVA feedforward component, grid weight.
ω_o	Frequency of reference load voltages.
θ_g, θ_L	Phase angle of grid voltage, phase angle of load voltage.

I. Introduction

THE climate change motivates to upgrade electricity industry and creates a low-carbon economy to support future economic growth [1]. Researchers focus on RES because of environmental effects and depleting nature of conventional energy sources. microgrids (MGs) are formed by integrating nonconventional energy sources, like solar photovoltaic array (SPVA), wind turbines, fuel cells, and electric vehicles with existing loads on distributed networks. SPVA has significant advantages over other nonconventional sources [2].

One of major issues addressed while integrating SPVA into utility grid is its intermittent nature, as it is climate-dependent and highly stochastic. As a result, the load demand during peak times may be greater than rated limit, thus resulting in destabilization or even an outage. Pump storage or diesel generators are often employed to reduce peak load demand during an imbalance. Nowadays, batteries replace these storage sources for peak load management as a temporary storage source because of advancements in battery technology [3]. When battery energy storage (BES) is linked directly to dc-link, it experiences issues with a second harmonic and unregulated battery current, causing degradation to its effective lifespan. BES is incorporated into MG using a bidirectional dc–dc converter (BDDC). It protects BES from second harmonic issue during imbalanced loads [4].

Two major categories of SPVA transformer-less designs in the literature are double-stage and single-stage topologies [5]. Even though single-stage topologies possess some merits over double-stage, such as compactness, lower component count, and cheaper, they experience much strain on primary dc–ac voltage source converter (VSC), hence reducing overall reliability [6].

A maximum power point tracking (MPPT) algorithm is implemented in SPVA to improve energy production by monitoring and modifying solar panel's operating point equal to maximum power point (MPP) [7]. MPPT controller collects SPVA output voltage and current, determines output's power, and compares it with operating power. The controller modifies voltage to maintain SPVA output at MPP and ensures that SPVA generates most electricity possible [8], [9]. To estimate MPP of SPVA, numerous researchers have put forth various sorts of methodologies. Due to their simplicity, extensively used methods are Perturb and observe (P&O) and InC. Alternatively, artificial intelligence strategies like particle swarm optimization and adaptive neuro fuzzy interference system are developed for MPPT operation of SPVA [10], [11].

As MGs are situated near distribution end, they can be integrated and controlled so that they can operate in grid-connected mode (GCM) and standalone mode (SAM). There should be proper synchronization control following the IEEE std. [12], [13], which enables the system to switch smoothly between GCM and SAM. Using ac–dc power electronic converters, equipment that uses dc power includes computers, microwaves, battery chargers, and lighting systems in commercial and residential areas are operated and they are highly nonlinear and inject harmonics into grid [14]. Various control algorithms for VSC have been proposed in the literature to ensure the injection of high-quality power into grid and smooth operation of MG. Table I provides a comparison of these methods. Conventional control techniques, such as synchronous reference frame theory (SRFT) and Instantaneous reactive power theory (IRPT), as discussed in [15] and [16], have been utilized for power quality improvement. However, these techniques exhibit limitations, including poor harmonic rejection capabilities, inability to reject dc-offsets, suboptimal dynamic response, and high complexity. To address these shortcomings, adaptive-based control techniques, such as least mean square (LMS), variable step-size least mean square (VSSLMS), and LMS-least mean fourth (LMF), have been introduced in [17] and [18]. Despite their advancements, these adaptive methods also face challenges, including the inability to reject dc-offsets, slow convergence rates, and difficulties in accurately determining the phase and frequency of load and grid voltages. For estimation of phase and rejection of dc-offset, some generalized integrator-based controls have been developed like second-order generalized integrator (SOGI), CSOGI, third order generalized integrator (TOGI), and reduced order generalized integrator (ROGI) [19], [20]. Using abovementioned controls for low signal to noise ratio (SNR) signals, fundamental frequency can be extracted from load currents and grid voltages, but noise and distortion are still present in signals. Hence, decomposition approach is employed to solve this issue. Several techniques are available for analysis of nonstationary and nonlinear signals. Most popular and significant method for these signals is empirical mode decomposition (EMD), but certain drawbacks have been acknowledged in [21] and [22]. Furthermore, ensemble empirical mode decomposition [23] and complete ensemble empirical mode decomposition [24] have been developed. However, modifications done on EMD do not fundamentally or completely check problem of mode mixing, aliasing, and end effects. Ning et al. [25] presented variational mode decomposition (VMD) technique based on generalization of Wiener filters. But, it suffers in decomposing nearly lined-up modes when SNR is varied. An adaptive nonstationary and nonlinear decomposition method, namely Fourier decomposition method (FDM), is presented by Singh et al. [22]. Using Fourier method and Hilbert transform, FDM decomposes signal into a small set of Fourier intrinsic band functions (FIBFs).

This work introduces a novel application of FDM on a double-stage grid-tied SPVA-BES hybrid MG. Using this, power quality issues are resolved in VSC, and proper synchronization is implemented with smooth mode transfer between GCM and SAM.

Key contributions to this work are outlined here as follows.

1) FDM is employed in MG to extract fundamental component of grid voltages, thereby achieving higher-quality grid currents. FDM addresses harmonic distortion challenges prevalent in microgrids with substantial penetration of SPVA. Unlike previous studies, this method enhances FDM for dynamic frequency response analysis, crucial for stabilizing microgrids with fluctuating renewable energy outputs.

TABLE I
COMPARISON OF DIFFERENT CONTROL METHODS

Sl. No	Algorithms	Example	Nature of control	Load balancing	Harmonics rejection	DC offset rejection	Dynamic response	Frequency and phase estimation	For Low SNR	
									Elimination of mode mixing	Aliasing and end effect rejection
1.	Conventional control methods	SRFT, IRPT [15-16]	Non-adaptive	Good	Poor	NO	Poor (takes 3-4 cycles to settle)	NO, Requires PLL and FLL	NO	NO
2.	Adaptive filter-type control methods	LMS, LMS-LMF, VSSLMS [17-18]	Adaptive	Very good	Better	NO	Good (takes 2-3 cycles to settle)	NO, Requires PLL and FLL	NO	NO
3.	GI-based control methods	SOGI [19]	Non-adaptive	Excellent	Good (Improves with cascading)	NO	Best (takes 1-2 cycles to settle)	YES, but for frequency estimation, FLL is required	NO	NO
		CSOGI [19]				NO				
		TOGI [19]	Adaptive			YES				
		ROGI [20]				YES				
4.	Decomposition based control methods	EMD [21]	Adaptive	Excellent	Good (Improves with cascading)	YES	Best (takes 1-2 cycles to settle)	NO, Requires PLL and FLL	NO	NO
		VMD [25]				YES			NO	NO
		FDM [22]				YES			YES	YES

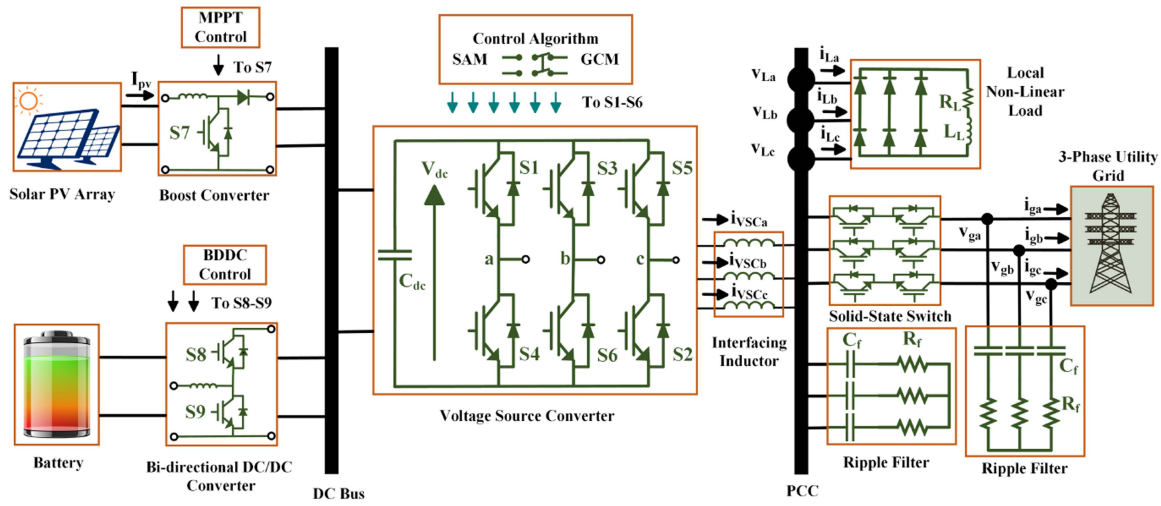

Fig. 1. System topology.

2) During transition between GCM and SAM, load currents experience significant transients, resulting in low SNR load currents. FDM technique decomposes load current into its fundamental components, noise, and harmonics. The fundamental component is then effectively extracted to maintain improved power quality. Furthermore, smooth synchronization between different operating modes is achieved. The authors have integrated FDM with control algorithms not extensively explored in existing literature, allowing for more precise and adaptive control of power flow, thereby improving the overall efficiency and reliability of microgrid operations.
3) FDM is refined to increase computational efficiency and accuracy. The authors have achieved this through parameter tuning, which reduces computation time while increasing the resolution of harmonic analysis. This refinement is critical for real-time grid management, ensuring the system operates efficiently and reliably.

II. SYSTEM LAYOUT

Fig. 1 presents system topology. It comprises an SPVA and BES. They are integrated to point of common coupling (PCC) using VSC, which transforms dc–ac conversion. SPVA is integrated at dc link using a dc–dc converter. BES is integrated using BDDC, which controls its charging and discharging currents. MG is integrated into the utility grid using STS, which are controlled to realize smooth synchronization and desynchronization of MG with the grid. To dampen ripples in PCC voltages, a parallel combination of resistor and capacitor is used at the grid and PCC. Nonlinear loads are composed of a diode bridge rectifier with resistive and inductive loads connected at PCC.

III. SYSTEM CONTROL DESIGN

MG consists of a distributed centralized controller that coordinates control and monitors overall operations of MG. Primary function of centralized controller is to determine if system can meet unanticipated load demand and to plan smooth transition between GCM and SAM. Overall control is subdivided into several specific controls: control of dc–dc boost converter, control of VSC during GCM, control of VSC during SAM, and control of BDDC.

A. Control of DC–DC Boost Converter

Due to intermittent nature of SPVA, its MPP is affected by changes in irradiance and temperature. As presented topology is a double-stage, a dc–dc boost converter is implemented for harvesting maximum power from SPVA. Fig. 2 demonstrates

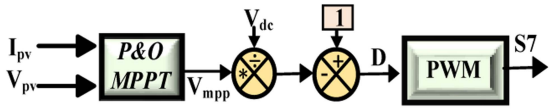

Fig. 2. DC–DC boost converter control.

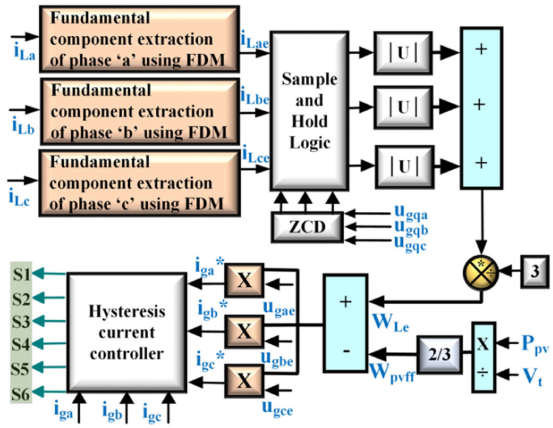

Fig. 3. Control of VSC in GCM.

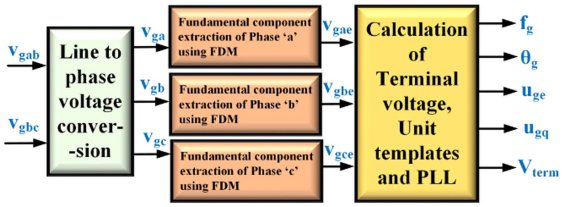

Fig. 4. Extraction of FIBFs of grid voltages.

control of dc–dc boost converter. For generating switching pulses of boost converter, a P&O MPPT algorithm is used, which gives MPP voltage (V_{mpp}), and using that, the duty cycle is generated for boost converter

$$D = 1 - \frac{V_{mpp}}{V_{\rm dc}}. \tag{1}$$

B. Control Strategy of VSC in GCM

In GCM, system encounters irregularities such as harmonics, voltage sags and swells, and nonlinearity in load currents. As depicted in Fig. 3, control strategy is designed to ensure delivery of high-quality power to grid while continuously supplying critical loads. Steps involved in GCM control are outlined as follows. By utilizing sensed line voltages (v_{gab}, v_{gbc}), grid phase voltages (v_{ga}, v_{gb}, v_{gc}) are determined

$$\begin{pmatrix} v_{ga} \\ v_{gb} \\ v_{gc} \end{pmatrix} = \frac{1}{3}\begin{pmatrix} 2 & 1 \\ -1 & 1 \\ -1 & 2 \end{pmatrix}\begin{pmatrix} v_{gab} \\ v_{gbc} \end{pmatrix}. \tag{2}$$

The application of FDM to grid voltages is utilized to extract fundamental components, as illustrated in Fig. 4. Using FDM, any data can be decomposed into a limited number of FIBFs. FDM provides a generalized Fourier expansion of a time series with varying amplitudes and frequencies. It is well-established that Fourier method is an ideal tool for time-frequency and spectrum analysis when processing signals. Fourier transform inherently provides an analytical representation of a signal, which, along with its Hilbert transform, elucidates its effectiveness.

As a result of this method, multicomponent and multifrequency signals are decomposed and extracted into fundamental and other FIBFs mono signals, which can be modeled as follows:

$$x(t) = \sum_{i=1}^{K} y_i(t) + N \tag{3}$$

where N represents noise or any residue components. $y_i(t)$ is K number of mono-component signals, which would be FIBFs in this framework. For FIBF $y_i(t)$ to proceed with nonstationary and nonlinear decomposition, it must meet requirements listed here.

1) FIBFs are zero mean function

$$\int_a^b y_i(t)dt = 0. \tag{4}$$

2) FIBFs are orthogonal functions

$$\int_a^b y_i(t)y_j(t)dt = 0; \quad i \neq j. \tag{5}$$

3) FIBFs provide analytic FIBFs with instantaneous frequency and amplitude always greater than zero

$$y_i(t) + jH(y_i(t)) = a_i(t)\exp(jj_i(t)) = z(t) \tag{6}$$

$$\text{where, } a_i(t), \frac{\partial}{\partial t}\phi_i(t) \geq 0 \,\forall t. \tag{7}$$

Followings are steps involved in decomposing a nonstationary, nonlinear signal using FDM.

Step 1: Use Fourier transform to get Fourier spectrum of signal $x(t)$.
Step 2: Utilizing spectrum of $x(t)$ acquired in Step 1 to express $z(t)$.
Step 3: Using LTH and HTL scan, obtain $z_k(t)$.
Step 4: From real part of $z_k(t)$ obtained in Step 3, obtain FIBFs $y_k(t)$.
Step 5: Reconstruct $x(t)$ as a summation of FIBFs $y_k(t)$ obtained in Step 4.

To generate FIBFs, two frequency scan techniques named LTH and HTL are used, as shown in Figs. 5 and 6.

Using FDM, fundamental grid voltage and load current can be extracted. Flowchart of FDM is shown in Fig. 7. Following extraction of the FIBFs of grid voltages (v_{ge}), amplitude of PCC voltages (V_{term}), along with in-phase (u_{ge}), and quadrature unit templates (u_{gq}), can be computed as outlined in [26].

Subsequently, SPVA feed-forward component and active weight of extracted fundamental load current are calculated to determine grid weight. SPVA feed-forward component is computed as follows:

$$W_{pvff}(k) = \frac{2}{3}\left\{\frac{P_{pv}(k)}{V_{\rm term}}\right\}. \tag{8}$$

For calculating active weight of fundamental extracted load currents, each current is processed with sample and hold block and then average weight is calculated as follows:

$$W_{Le}(k) = \frac{W_{Lae}(k) + W_{Lbe}(k) + W_{Lce}(k)}{3}. \tag{9}$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 04:51:24 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

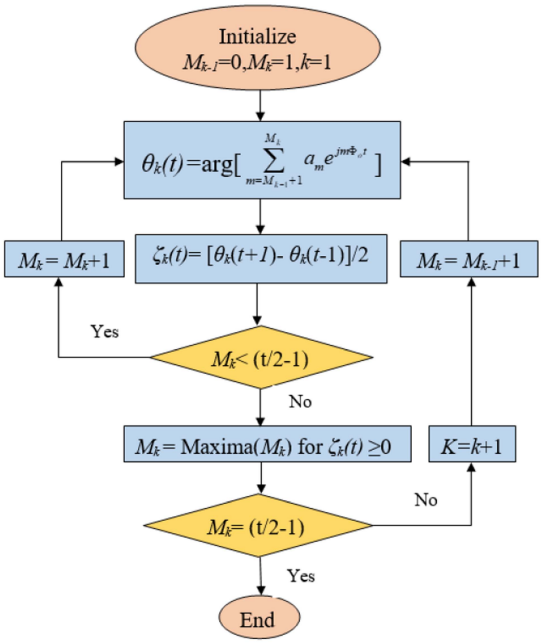

Fig. 5. Flowchart of LTH scan.

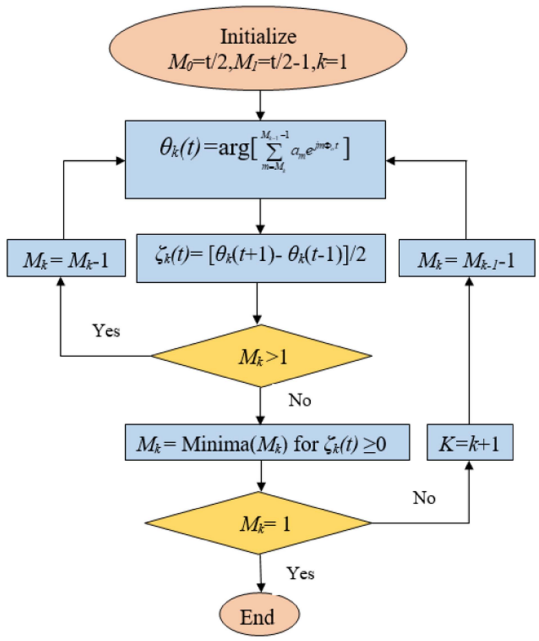

Fig. 6. Flowchart of HTL scan.

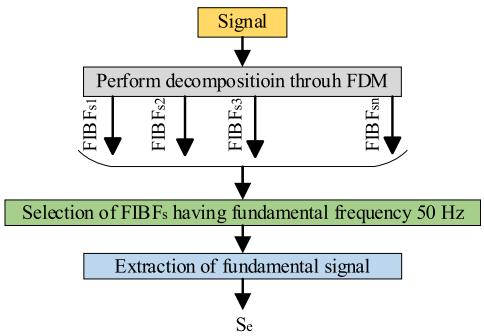

Fig. 7. Flowchart of FDM.

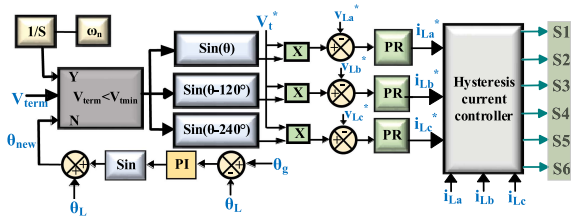

Fig. 8. VSC control during SAM.

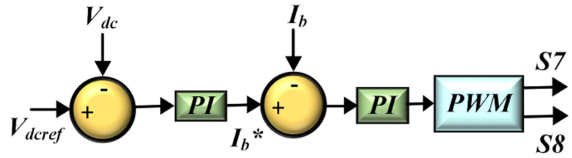

Fig. 9. BDDC control.

Grid current weight can be computed as

$$W_{ge}(k) = W_{Le}(k) - W_{pvff}(k). \tag{10}$$

For getting reference grid currents, grid currents' weight is multiplied with unit templates as follows:

$$i_{ga}{}^{*} = W_{ge} \times u_{gae}, i_{gb}{}^{*} = W_{ge} \times u_{gbe}, i_{gc}{}^{*} = W_{ge} \times u_{gce}. \tag{11}$$

To produce switching pulses of VSC in GCM, reference grid currents ($i_{ga}{}^{*}, i_{gb}{}^{*}, i_{gc}{}^{*}$) and sensed grid currents (i_{ga}, i_{gb}, i_{gc}) are given to hysteresis current controller (HCC).

C. Control Strategy of VSC in SAM

During SAM operation, primary objective of the VSC is to ensure uninterrupted power to load while maintaining high-quality load voltage in compliance with the IEEE-519 standards. Fig. 8 illustrates control mechanism of VSC during SAM. Reference load voltages are generated as follows:

$$v_{La}{}^{ref} = V_L{}^{ref} \sin(\omega_o t), v_{Lb}{}^{ref} = V_L{}^{ref} \sin(\omega_o t - 120^{\circ})$$
$$v_{Lc}{}^{ref} = V_L{}^{ref} \sin(\omega_o t - 240^{o}) \tag{12}$$

where $V_L{}^{ref}$ is desired magnitude of PCC voltages, and ω_o is equal to $2 \times \pi \times 50$ rad/s. When terminal voltage is greater than specified limit, then load phase angle is calculated as follows:

$$\theta_{\text{new}} = \theta_L + \sin\{k_p \times (\theta_g - \theta_L) + k_i \times (\theta_g - \theta_L)\}. \tag{13}$$

After computation of reference load voltages, these voltages are compared with sensed load voltages and then input into PR controller. PR controller subsequently generates reference currents for VSC. The advantage of using a PR controller over a PI controller is that it eliminates oscillations. Afterward, calculated reference VSC currents and actual VSC currents are sent to HCC to generate VSC switching pulses during SAM.

D. BDDC Control

Prime objective of BDDC is to control dc-link voltage. It also controls charging and discharging of battery during different dynamic conditions. Fig. 9 depicts BDDC control in which, first, $V_{\text{dc}ref}$ is compared with dc-link voltage, and it produces reference battery current. Afterward, resultant obtained by comparing reference battery current with sensed

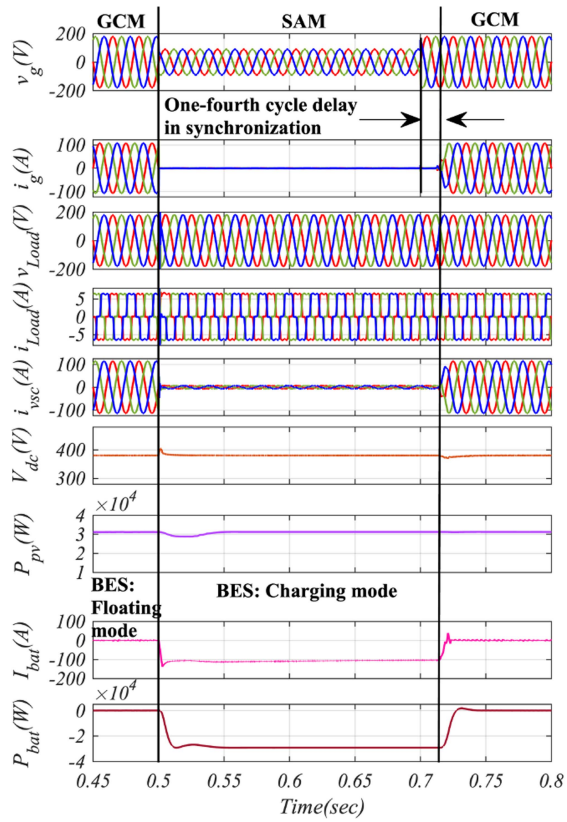

Fig. 11. Operation of the MG in a steady state during GCM and SAM, with smooth transition between these modes.

battery current is fed to PWM dc–dc block, which generates a switching pulse for S8 and S9 switches.

IV. Simulation Results

To illustrate dynamic function of control, performance of SPVA-interfaced MG is explored through simulation in MATLAB platform. Following modes show how well application of this FDM control on MG.

A. Operation of MG During GCM and SAM

Fig. 10(a) depicts nature of load current before and after extraction using FDM, respectively. These results clearly show that FDM is extracting pure fundamental load current, which is processed to generate reference grid current. Fig. 10(b) presents time-frequency energy estimate (TFEE) when extraction is done in HTL Fourier series, which indicates that fundamental component has highest energy, shown by red band and harmonics and noise having very less energy, shown from blue and gray color.

Fig. 11 illustrates the operation of MG in a steady-state during GCM and SAM, as well as smooth transition between these modes. It depicts utility grid voltages (v_g) and currents (i_g), load voltages ($v_{\rm Load}$) and currents ($i_{\rm Load}$), VSC currents ($i_{\rm vsc}$), dc-link voltage ($V_{\rm dc}$), SPVA power (P_{pv}), and battery current (I_{bat}) and power (P_{bat}). During both operational modes, MG functions smoothly, and THDs of load voltages and grid currents comply with IEEE 519 standard. In GCM, SPVA supplies power to the load, with any excess power injected into grid, while battery remains floating. In SAM, SPVA powers the load, and any surplus power is used to charge battery. At 0.5 s, a drop in grid voltage violates synchronization conditions, causing the system to seamlessly transition to SAM. At 0.7 s, although the grid voltage recovers, phase angle difference (θ_g - θ_L) does not meet the synchronization condition, so system continues to operate in SAM. After a one-fourth cycle delay, system transitions smoothly back to GCM.

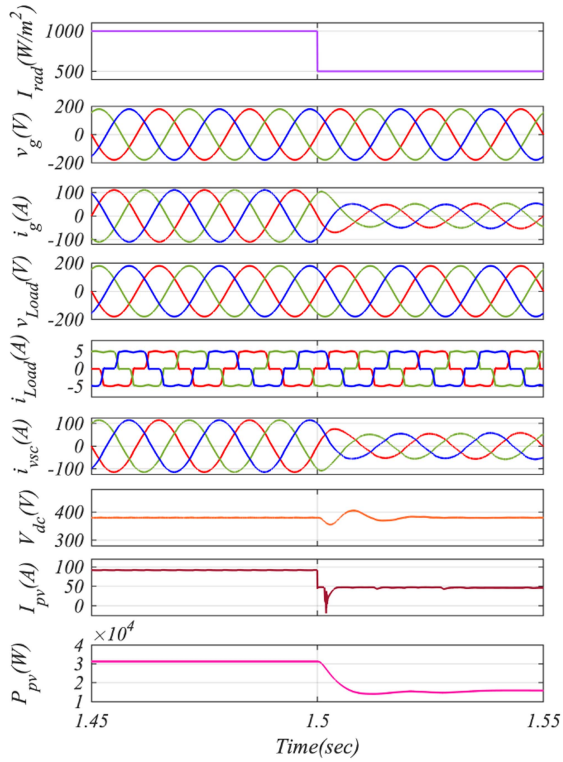

Fig. 12. Operation of MG under varying irradiance during GCM.

B. Operation of MG Under Varying Irradiance During GCM

Fig. 12 presents MG operation under varying irradiance on SPVA during GCM. Following results show solar irradiance (I_{rad}), grid voltages (v_g) and currents (i_g), load voltages ($v_{\rm Load}$) and currents ($i_{\rm Load}$), VSC currents ($i_{\rm vsc}$), dc-link voltage ($V_{\rm dc}$), and SPVA current (I_{pv}) and power (P_{pv}). At 1.5 s, the irradiance intensity decreases by 50%. The power produced by SPVA system decreases from 32 kW to 16.1 kW because of drop in irradiation. VSC performs multifunctional task of balancing load and maintaining dc-link voltage equal to $V_{{\rm dc}ref}$ using BDDC control. Grid currents waveforms are sinusoidal and adhere to the IEEE-519 standard.

C. Operation of MG During Load Unbalancing in GCM

Operation of MG under load unbalancing during GCM is shown in Fig. 13. It shows irradiation (I_{rad}), grid voltages (v_g) and currents (i_g), load voltages ($v_{\rm Load}$) and currents ($i_{\rm Load}$), VSC

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 04:51:24 UTC from IEEE Xplore. Restrictions apply.

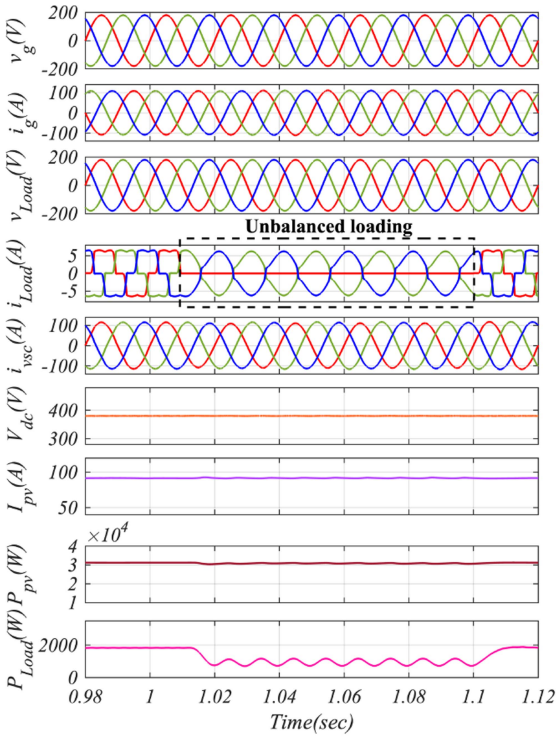

Fig. 13. Operation of MG under load unbalancing during GCM.

currents ($i_{\rm vsc}$), dc-link voltage ($V_{\rm dc}$), SPVA current (I_{pv}), SPVA power (P_{pv}), and load power ($P_{\rm Load}$). During removal of load in phase "a," loads connected to phases "b" and "c" function as a single-phase load. Reduction of phase "a" weight to zero leads to a decrease in fundamental active weight of load current. Despite these dynamic conditions, loads in the other two phases continue to operate smoothly, and grid currents are maintained as sinusoidal, in compliance with the IEEE-519 standard.

D. Operation of MG at Polluted Grid

Numerous MGs are connected to grid using power electronic converters, which consequently inject lower-order harmonics into grid. Additionally, harmonics are introduced into electrical system by nonlinear electronic switching components such as rectifiers, variable-speed drives, and electronic devices like computers, printers, TVs, servers, and telecom systems. The extensive connectivity of nonlinear loads to grid results in contamination of grid voltages by harmonics. Consequently, grid voltages at PCC are found to be polluted. Due to these polluted grid voltages, inaccurate unit templates and reference grid currents are generated. To address this issue, fundamental component of the grid voltages is extracted by processing polluted grid voltages using FDM, as illustrated in Fig. 14(a). Fig. 14(b) shows time-frequency energy estimate when extraction is performed in HTL scan, indicating that fundamental component has highest energy, represented by red band, while harmonics and noise exhibit significantly lower energy, represented by blue, light blue, and light green colors. Fig. 15 demonstrates extracted unit templates (u_{eabc}) and grid currents (i_{ge}) using extracted fundamental grid voltages, which are sinusoidal and comply with IEEE-519 standard.

V. Hardware Results

FDM control is tested on a prototype of a double-stage grid-connected system, developed in the laboratory, which validates

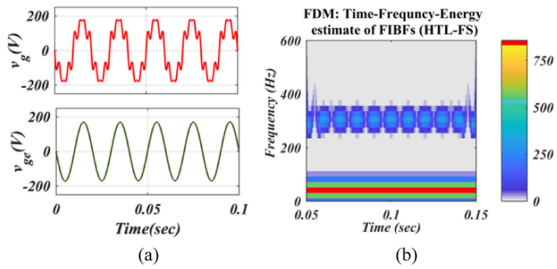

Fig. 14. (a) Extraction of grid voltages using FDM. (b) TFEE of grid voltage.

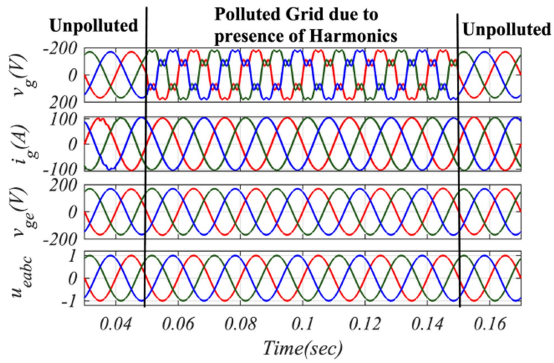

Fig. 15. Operation of MG with polluted grid.

Fig. 16. Hardware prototype.

its effectiveness and efficacy. A laboratory setup for MG prototype under investigation, used for experimental analysis, is shown in Fig. 16. Along with AMETAKE ETS 600/17 (SPVA), a battery bank is used to make a hybrid MG. Hall-effect based current (LEM LA55P) and voltage (LEM LV25P) sensors are used to detect signals. A dSPACE-1202 MicroLabBox DSP is used to deploy sensed signals to apply control. A power quality analyzer, HIOKI PQ3100, FLUKE-43B, and digital storage oscilloscope (MSOX3024T) are used.

A. Operation of MG in GCM at Steady-State

Fig. 17(a)–(f) presents operation of MG at a steady state in GCM. Fig. 17(a) and (b) presents waveforms of grid voltages and currents and analytical profile of grid voltages and currents. From analytical profile, it can be analyzed that grid voltage and grid currents THDs are 1.41% and 3.06%, which follows the IEEE 519 std. Fig. 17(c) presents the load voltages and currents waveform depicting that VSC successfully maintains uninterrupted power to critical load during GCM. Fig. 17(d)–(f) presents SPVA voltage and current, dc-link voltage, and SPVA

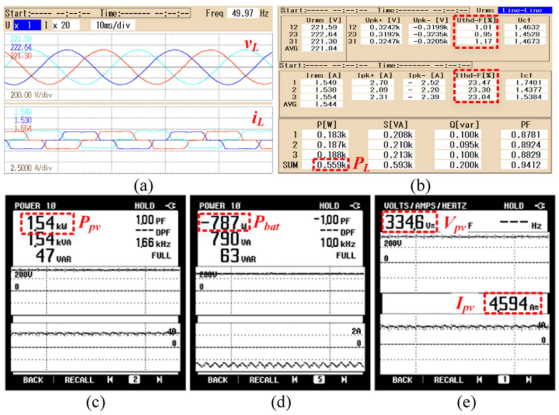

Fig. 18. Steady-state performance during SAM.

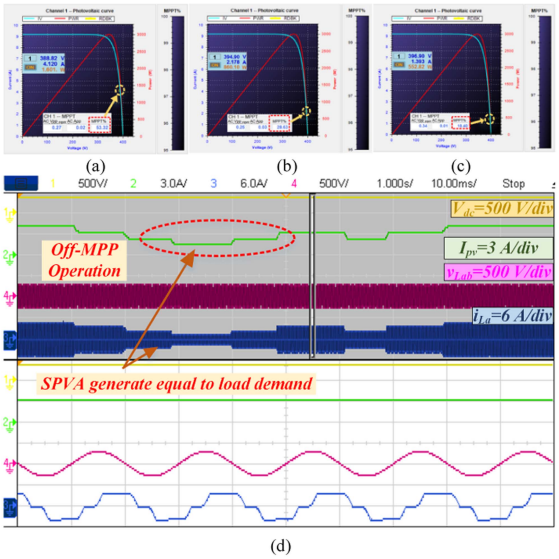

Fig. 19. Off-MPP operation of SPVA during SAM.

power. These show that dc-link voltage is regulated to desired voltage, and SPVA generates 3 kW power.

B. Operation of MG in SAM at Steady State

Fig. 18(a)–(e) presents operation of MG at steady state in SAM. Fig. 18(a) and (b) presents waveforms of load voltages and currents, load power, and harmonics spectra of load voltages and currents. Harmonics spectra show that PCC voltage THD is 1%, which follows the IEEE 519 standard. Fig. 18(c)–(e) presents SPVA voltage, current, and power (1.5 kW @500

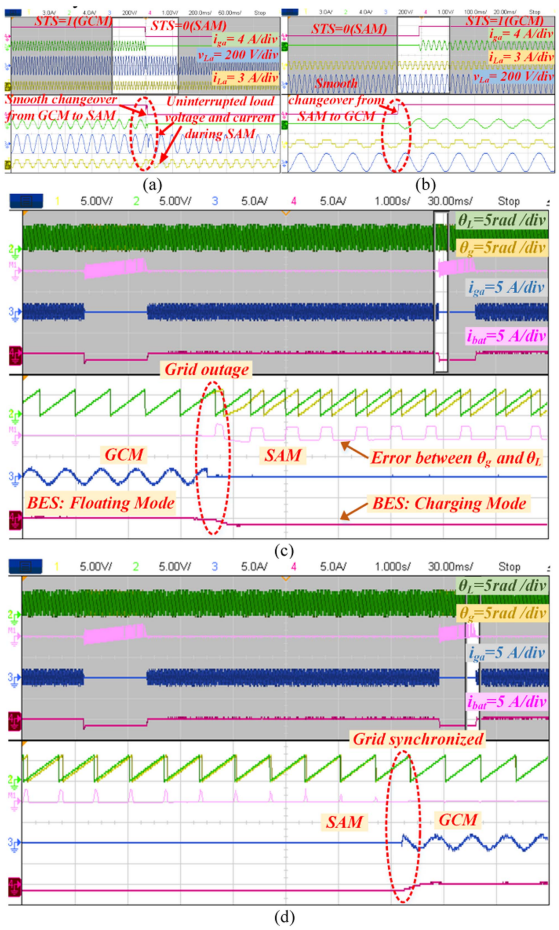

Fig. 20. Smooth changeover between GCM and SAM.

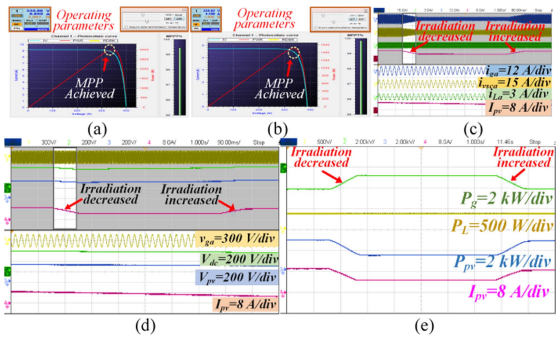

Fig. 21. Dynamic performance under varying solar irradiance.

W/m^2 irradiance), and power of battery. It shows that BES is charging. In the case of a fully charged battery during SAM, SPVA starts to work in OFF-MPP mode and generates power equal to load demand. Fig. 19(a)–(d) presents OFF-MPP operation. Fig. 19(a)–(c) shows OFF-MPP operating characteristics of SPVA at different loads. Fig. 19(d) represents dc-link voltage ($V_{\rm dc}$), SPVA current (I_{pv}), and load indices (v_{Lab}, i_{La}). It shows SPVA current change according to load currents, hence working in OFF-MPP mode.

C. Smooth Mode Changeover Between GCM and SAM

Fig. 20(a) and (b) shows an autonomous and seamless mode changeover of MG. It presents *STS*, i_{ga}, i_{La}, and v_{La}. It demonstrates how MG is safely separated from grid and runs in SAM during a power failure. The synchronization of MG

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 04:51:24 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

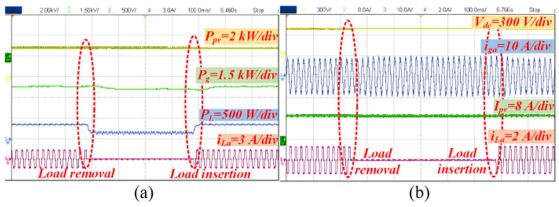

Fig. 22. (a) and (b) Dynamic performance under load unbalanced.

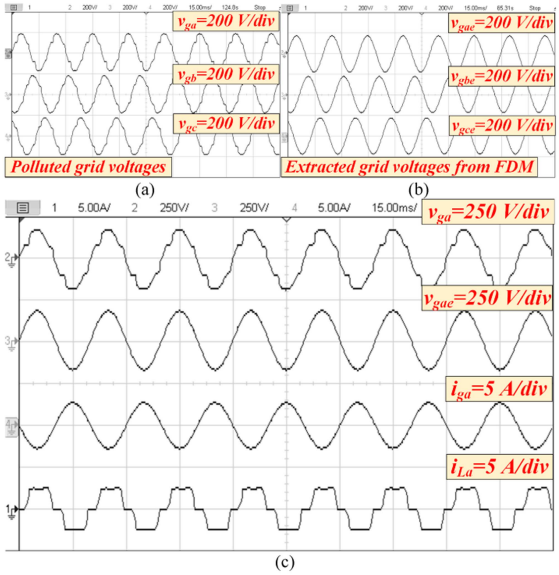

Fig. 23. Performance during polluted grid voltages.

into grid starts once grid voltages are recovered. When all synchronization requirements are met, MG is synchronized to grid by changing control pulse of STS to 1. Furthermore, it demonstrates that loads are being received in an uninterrupted power. Fig. 20(c) and (d) presents grid and load voltage phase angle (θ_g/θ_L), error between θ_g and θ_L, grid current (i_{ga}), and battery current (I_{bat}). It demonstrates that during transition from GCM to SAM, a phase angle mismatch occurs between θ_g and θ_L, and BES mode shifts from floating to charging. When grid is resynchronized, θ_g and θ_L realign, and system smoothly transitions back to GCM.

D. Operation of MG Under Varying Irradiance in GCM

Fig. 21(a)–(e) presents dynamic performance of this control under varying solar irradiance. Fig. 21(a) and (b) presents MPPT operation of SPVA at irradiation levels of 1000 W/m^2 and 500 W/m^2. Fig. 21(c) presents I_{pv}, i_{La}, $i_{\mathrm{vsc}\,a}$, and i_{ga}, from which it can be analyzed that when irradiance is decreased, SPVA current decreases, which results in decreased grid current and unchanged load current. Fig. 21(d) presents I_{pv}, V_{dc}, V_{pv}, and V_{ga}, from which it can be analyzed that when irradiance is decreased, all other three parameters remain unchanged. Fig. 21(e) presents I_{pv}, P_{pv}, P_L, and P_g, from which it can be analyzed that when irradiance is decreased, SPVA current decreases, due to which power produced by SPVA becomes half and power injected into grid also decreases. However, due to robust control, VSC is performing its objective of maintaining load power.

E. Operation of MG Under Load Unbalancing in GCM

Fig. 22(a) and (b) presents dynamic performance at load unbalancing. When load "a" is disconnected by a breaker due to a fault in phase "a," load current in that phase drops to zero. Consequently, remaining phases, "b" and "c," operate as a single-phase load, causing an increase in grid currents during this period. Fig. 22(a) presents i_{La}, P_L, P_g, and P_{pv}, illustrating that upon disconnection of phase "a" load, grid power increases, load power decreases, and the SPVA power remains unchanged. Fig. 22(b) presents i_{La}, i_{ga}, I_{pv}, and V_{dc}. It demonstrates that when phase "a" load is disconnected, SPVA current and dc-link

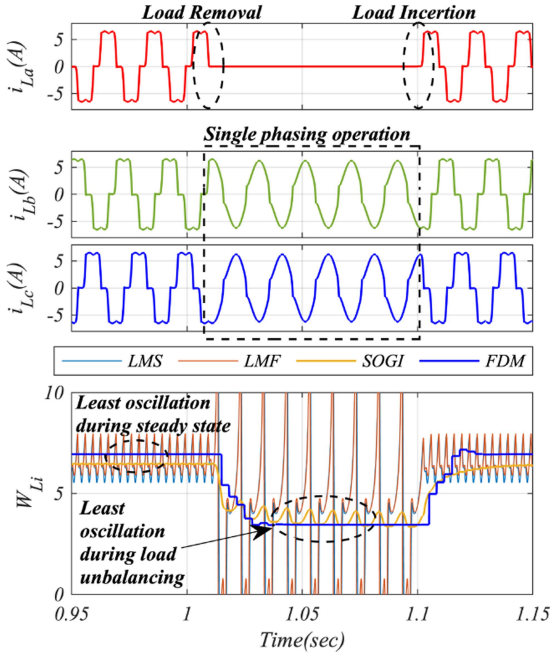

Fig. 24. Comparison of FDM with LMS, LMF, and SOGI controls.

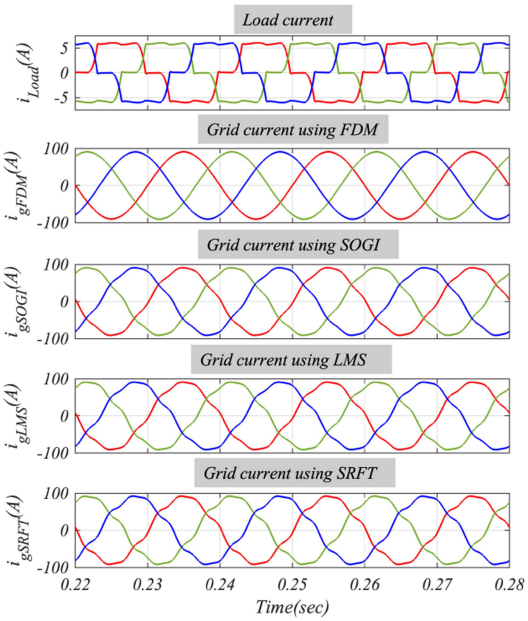

Fig. 26. Comparison of FDM with SOGI, LMS, and SRFT controls.

voltage remain unchanged. This indicates that SPVA continues to operate at its MPP regardless of operating conditions.

F. Operation of MG Under Polluted Grid Voltages

Fig. 23(a)–(c) presents experimental results under polluted grid conditions. Fig. 23(a) depicts polluted grid voltage waveforms for each phase. Fig. 23(b) shows extracted filtered grid voltage waveforms using an FDM filter, which is sinusoidal and complies with the IEEE-519 standard for THD. Fig. 23(c) presents polluted grid voltage (v_{ga}), extracted grid voltage (v_{gae}), generated grid current (i_{ga}), and load current (i_{La}). It is observed that generated grid current using filtered grid voltage is purely sinusoidal and adheres to the IEEE-519 standard, ensuring uninterrupted load supply.

G. Comparative Performance

A comparative performance of FDM over existing techniques during load unbalancing is shown in Fig. 24. It is observed that during steady-state, oscillation in the average load weight is least using FDM control as compared to LMS, LMF, and SOGI controls. Moreover, during load unbalancing, oscillation in average load weight is least using FDM control as compared to LMS, LMF, and SOGI controls.

The decomposition of load current using FDM and EMD is shown in Fig. 25. End effects are observed in EMD decomposition, while there is no end effect in FDM decomposition. Fig. 26 presents the grid current using FDM, SOGI, LMS, and SRFT controls. The grid currents using FDM are pure sinusoidal and free from harmonics, whereas harmonics are present in grid currents using SOGI, LMS, and SRFT controls.

VI. Conclusion

An SPVA-BES hybrid microgrid with a double-stage grid-connected system was developed in this work to demonstrate application of FDM technique. FDM technique eliminated effects of all harmonics and noises in grid voltages and load currents to estimate grid currents and provides fundamental sinusoidal components. The quality of extracted grid voltages, unit templates, and grid currents in GCM and load voltages in SAM follow the IEEE 519 standard. FDM technique presented efficient outcomes concerning performance in low SNR, oscillations, and convergence. BDDC control maintained dc-link voltage to desired value under all operating conditions; thus, it enhances reliability of the system. In SAM, a proportional resonant controller was used; hence, it reduces oscillations in load voltages. VSC performs multiobjective functions such as load balancing, smooth operation of system in both GCM and SAM, and seamless mode transition between grid-connected and standalone operations. Simulated responses of control technique were validated using a hardware prototype developed in the laboratory operating conditions.

Appendix

Parameters	Simulation	Hardware
Utility grid	220 V (L-L), 50 *Hz*	220 V (L-L), 50 *Hz*
SPVA	P_{mpp} = 32 *kW*, V_{mpp} = 342 *V*, I_{mpp} = 91.32 *A* (@1000 W/m^2)	P_{mpp} = 3 *kW*, V_{mpp} = 340 *V*, I_{mpp} = 8.7 *A* (@1000 W/m^2)

Divyank Srivastava (Graduate Student Member, IEEE) was born in Lucknow, India, in 1995. He received the B.Tech. degree in electrical from the Institute of Engineering and Technology (IET), Lucknow, India, in 2016, and the M.Tech. degree in power systems from Delhi Technological University, New Delhi, India, in 2018. He is currently working toward the Ph.D. degree in electrical engineering from the IET, Lucknow, India.

His research interests include power system, power electronics, solar conversion systems, energy storage, power quality mitigation in distribution systems, and microgrids.

Vivek Narayanan (Senior Member, IEEE) was born in Kerala, India, in 1993. He received the B.Tech. degree in electrical and electronics engineering from the College of Engineering Thalassery, Kerala, India, in 2015, the M.Tech. degree in power electronics and drives from the Government College of Engineering Kannur, Kerala, India, in 2017, and the Ph.D. degree in power electronics and drives from the Department of Electrical Engineering, Indian Institute of Technology Delhi, New Delhi, India, in 2024.

He is currently a Postdoctoral Research Fellow with the National University of Singapore, Singapore. His research interests include power electronics, solar and wind energy conversion systems, energy storage, power quality improvement in distribution systems, and microgrids.

Dr. Narayanan was the recipient of the IEEE International Conference on Environment and Electrical Engineering /I&CPS Europe Best Poster Award and the IEEE ICPC2T Best Paper Award in 2019 and 2022.

Bhim Singh (Fellow, IEEE) received the B.E. degree in electrical from the University of Roorkee (Now Indian Institute of Technology Roorkee), Roorkee, India, in 1977, and the M.Tech. degree in power apparatus and systems and Ph.D. degree in electrical engineering from the Indian Institute of Technology Delhi (IIT Delhi), New India, in 1979 and 1983, respectively.

In 1983, he was with the Department of Electrical Engineering, University of Roorkee, as a Lecturer. He became a Reader there in 1988. In Dec. 1990, he was with the Department of Electrical Engineering, IIT Delhi, India, as an Assistant Professor, where he became an Associate Professor in 1994 and a Professor in 1997. He was ABB Chair Professor from Sep. 2007 to Sep. 2012. He was CEA Chair Professor from Oct. 2012 to Sep. 2017. He was the Head with the Department of Electrical Engineering, IIT Delhi from Jul. 2014 to Aug. 2016. He has been the Dean, Academics with the IIT Delhi from Aug. 2016 to Aug. 2019. He was JC Bose Fellow with DST, Government of India from Dec. 2015 to Jun. 2021. He is currently an Emeritus Professor and SERB National Science Chair at IIT Delhi since July 2021. He has guided 121 Ph.D. dissertations, and 182 M.E./M.Tech./M.S.(R) theses. He has 62 granted patents and 46 filed patents. He has executed more than ninety sponsored and consultancy projects. He has coauthored a textbook on power quality: *Power Quality Problems and Mitigation Techniques* (Wiley, New York, NY, USA, 2015). His research interests include solar PV grid interface systems, microgrids, power quality monitoring and mitigation, solar PV water pumping systems, improved power quality ac–dc converters, power electronics, electrical machines, drives, and electric vehciles.

Arunima Verma (Senior Member, IEEE) received the B.Tech. degree in electrical from Priyadarshini College of Engineering and Architecture, Nagpur University, Nagpur, India, in 2000, the M.Tech. degree in power systems from Malaviya National Institute of Technology Jaipur, Jaipur, India, in 2002, and the Ph.D. degree in electric drive and control from Dr. A.P.J. Abdul Kalam Technical University, Lucknow, India, in 2011.

In 2003, she was an Assistant Professor with the Department of Electrical Engineering, Institute of Engineering and Technology, Lucknow. She became an Associate Professor in 2017 and a Professor in 2020. She has guided six Ph.D. dissertations and 12 M.E./M.Tech. thesis. Her areas of research interests include solar PV grid interface systems, microgrids, power quality mitigation, improved power quality ac–dc converters, and electric drives and control.

(Received December 13, 2023; Revised March 22, 2024; Accepted April 17, 2024).

Abstract: The Marsh cone test is a direct and straightforward technique for examining the fluidity of cement paste using a superplasticiser. Polycarboxylate ether (PCE) based Auramix 400 superplasticiser, portland pozzolana cement, and ordinary Portland cement are used for finding the optimum dosage of superplasticiser with specific cement. The optimum dosage and the superplasticiser's efficiency are determined by the marsh cone test for two types of cement. The fresh and mechanical properties and non-destructive testing of the concrete mixes made by two cement types have been compared. The water-cement ratio is kept constant for both types of cement. Results show that the optimum dosage of superplasticiser depends upon the different types of cement. After the saturation point, the fluidity of cement paste doesn't affect increasing the quantity of superplasticiser. Both concrete mixes' fresh and mechanical properties of the same grade are similar, but the fine aggregate and coarse aggregate requirements are higher in OPC (Ordinary Portland Cement) mix concrete than in PPC (Portland Pozzolana Cement) mix concrete. The requirement of superplasticiser is more when used with PPC than the OPC concrete mix.

Keywords: Mechanical Properties; Marsh cone funnel; Workability; Superplasticizer; Saturation point.

1. Introduction

The need for good workability is the primary goal of the concrete. Different conditions necessitate varying degrees of workability in concrete. Structures where thin walls are required, beam-column joints, roof and foundation systems with congestion of reinforcement, deep beams, and columns or pillar junctions all need a high degree of workability [1,2]. In most circumstances, the simple solution is to use more water on the site, but excess water can harm concrete's strength and durability. Due to this issue, the SP (superplasticiser) should be used to enhance the workability of the concrete. The use of SP can permit water reduction by up to 30 percent without dropping the concrete's workability [3–5].

These are some properties of superplasticisers:

- It created significantly more workable concrete than plain concrete at the same w/c ratio.
- For the same workability, it allows the use of a lower w/c ratio.
- It decreases cement content due to greater strength with a reduced w/c ratio.

SP also creates homogeneous, cohesive concrete, i.e., free of segregation and bleeding.

The paste's flow behaviour and the dispersion of cement particles by the SP determine high-performance concrete's fresh properties. Various types and quantities of SP are employed to assess the flow properties of cement paste. “The viscous nature of the paste is characterized using the Bingham and Herschel-Bulkley models. The analysis reveals a consistent pattern across alterations in SP dosage, Marsh cone flow period, mini-slump spread, and rheological parameters” [6]. The marsh cone flow is investigated on glycerol-water mixtures using rheological measurements and digital image analysis [7–10]. The viscous Newtonian fluid used in the computations to solve the flow problem is discussed. It is discovered that flow time is relative to Newtonian viscosity, and the relationship between flow duration and apparent viscosity is only applicable for cement pastes with no yield stress [11]. The investigation is done on the effects of a polycarboxylate SP on the mechanical, mineralogical, microstructural, and rheological properties of Portland cement paste. The SP presence is found to slow down the initial cement hydration processes, and a low polycarboxylate SP dosage resulted in a significant reduction in yield stress [12]. The impact of water/cement ratio, mineral admixture composition, and SP type is analysed on cement pastes with varying SP dosages. It is discovered that there is an SP saturation dosage above which no substantial rise in

fluidity occurs [13]. Admixtures in concrete have certain potential benefits with the cement paste, such as air entrainment, water reduction, and plasticity [14]. Furthermore, the use of admixtures may be used to control the setting time, such as acceleration or retardation. Amounts of admixture added beyond a certain point can cause incompatibilities such as concrete's performance characteristics and setting time and strength gain issues [15–17]. The marsh cone analysis finds the admixture's optimum dosage for a given cement [18]. The study is conducted on how mineral admixtures and pozzolanic content are used to produce self-compacting concrete. After lowering the aggregate volume ratio, it is determined that fly ash and the proper quantity of SP are used to create the self-compacting concrete [19]. Polyethylene Glycol 4000 admixture is used to analyse self-compacting self-curing concrete and is found well-performed compared to conventional concrete [10]. "A Marsh cone coupled with a Plexiglas horizontal channel can produce a trend similar to that of a rheometer" [20]. The increase in water temperature resulted in a rise in flow time due to increased plastic viscosity and a faster hydration rate [21]. With increasing temperature, cement paste's yield stress and plastic viscosity improved. Since cement hydration reactions accelerate at higher temperatures, the rate of increase becomes steeper [22].

2. Materials

2.1 Cement

JK Laxmi Pro+ (fly ash) pozzolanic material-based PPC and Wonder cement OPC, both types of cement, are purchased from a material plant located alongside Delhi, India, which are used in this analysis[3,23]. The PPC and OPC are subjected to various methods of testing based on several IS codes (Indian Standard). The outcomes from the PPC and OPC are presented in Table 1.

Table 1. Characteristics of PPC (J.K Laxmi pro+ cement).

Cement type	Cement properties	Results
PPC	28 days compressive strength	42 MPa
	Normal consistency	33%
	Sp. Gr.	2.97
	Setting time (Initial)	90 min
	Setting time (Final)	155 min
	Cement expansion (soundness)	3 mm
OPC	28 days compressive strength	44 MPa
	Normal consistency	29.5%
	Sp. Gr.	3.14
	Setting time (Initial)	93 minutes
	Setting time (Final)	182 minutes
	Cement expansion (soundness)	2 mm

2.2 Aggregates

"FA (Fine aggregate) in the form of crushed stone (stone dust) and CA (Coarse aggregate) in 10 mm and 20 mm sizes are purchased from a building material plant located alongside Delhi, India. The testing of FA and CA are done within standard parameters specified in the IS code, and all outcomes associated with properties of aggregate are available in table 2. The sieve analysis method is used to find FA's gradation and particle size distribution, and the results are demonstrated in Fig 1" [14–17,24,25].

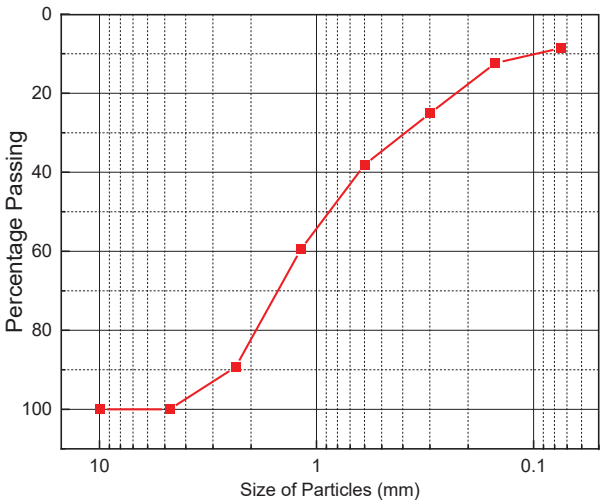

Fig. 1: Grain size distribution curve of fine aggregate

Table 2. Properties of FA and CA.

Material	Properties	Results
FA	Zone	II
	Fineness modulus	2.756
	Sp. Gr.	2.62
	Water absorption	1.21 %
CA	Sp. Gr.	2.79
	Water absorption	0.2 %
	Fineness modulus	7.29
	Impact value	26.3 %
	Loss angel abrasion Value	36 %

2.3 Superplasticiser

Fosroc Chemicals (India) Ltd. provides Auramix 400, a PCE (polycarboxylate ether) based SP that is used to provide concrete with the appropriate workability. SP has an Sp. Gr. of 1.09 and a pH value of 6, according to the Fosroc Chemicals. SP's optimal dose and efficiency are obtained with marsh cone equipment using a nozzle aperture diameter of 8 mm [26–28].

3. Mix Proportions

Based on trial results, a water-to-cement (w/c) ratio of 0.38 was chosen for the concrete in this investigation. The concrete's workability and compressive strength were

both evaluated as part of the examination. The Marsh cone test recommends a dose of 1.4 percent for Portland Pozzolana Cement (PPC) and 1 percent for Ordinary Portland Cement (OPC) in order to ensure a moderate degree of workability. The marsh cone test determines the optimum dosage of SP[4,5]. Proportions for the mix design of M40 grade concrete are presented in Table 3. Mix R1 is made by PPC, while R2 mix is made by OPC. In this analysis, a mechanical vibrator is used to achieve perfect compaction, minimise voids in the concrete, and ensure a consistent mix throughout. The concrete mixtures are prepared at a temperature of 29 degrees Celsius and under a relative humidity of 36%. Afterward 24 hours, the samples are demoulded and placed into the curing tank to achieve the strength of concrete at different ages [23,29]. The curing water is free from oils and other chemicals. The curing water is changed after every seven days to maintain the pH of the water. The mix proportion of M40 and all the materials used are presented in Table 3.

Table 3. Mix proportion for concrete.

Mix No.		**R1**	**R2**
Cement (kg/m^3)		390	390
FA (kg/m^3)		666	676
CA (kg/m^3)	(20 mm)	769.8	781.2
	(10 mm)	513.2	520.8
w/c ratio		0.38	0.38
SP (%)		1.4	1.0
Slump (mm)		97	99

4. Testing Procedure

Concrete's fresh and hardened properties are evaluated in this study, such as workability, compressive strength, and flexural strength non-destructive tests. For testing the hardened properties of concrete, three specimens are prepared for both sets of the mix. A UTM (universal testing machine) with a maximum loading capacity of 2000 tons is utilised to assess concrete's compressive and flexural strength. The specimen's dimension for compressive strength is 150X150X150 mm and for flexural strength is 100 mm x 100 mm x 500 mm as per IS code [30]. 140 kg/cm^2/min gradual loading rate is applied to the sample for testing compressive strength, and the 180 kg/min gradual loading rate is applied for flexural strength.

5. Results and Discussion

5.1 The Optimum dosage of superplasticizer

With the use of a marsh cone apparatus, the optimal amount and efficacy of SP are determined. The diameter of the nozzle aperture is 8 mm. There are many aperture sizes available, say 5, 6, 8, and 11 mm, to perform this test; however, the selection of the appropriate nozzle is based on cement paste fluidity. Other attachments with a bigger diameter aperture can be used according to different slurry types and different w/c ratios. In this test, w/c is taken 0.38 according to the prescribed mix design of concrete. The dosage of SP is taken 0.2% in the first test, then increased with an interval of 0.2% until the flow time becomes almost constant. Mix them thoroughly in the Hobart mixer for 2 min to avoid the lumps in the mixture. If hand mixing is done, then the slurry should pass through a 1.18 mm sieve before the marsh cone test to avoid lumps in the slurry. The SP's optimum dosage is selected when the slurry takes minimum time to complete out from the marsh cone. After the SP's optimum dosage (saturation point), the slurry's outcome time becomes almost constant for the particular cement and specified w/c ratio. After the saturation point, the addition of SP doesn't influence the fluidity of cement paste. The testing setup for determining the optimum dosage of SP is illustrated in Fig. 2(a). The slurry's flow time with different dosages is shown in Fig. 2(b). SP dosages of 1.4 percent for PPC and 1% for OPC are determined to be the most effective.

(b)

Fig. 2: a) Testing setup of marsh cone apparatus; **b)** The optimum dosage of superplasticizer with different cement

5.2 Efficiency of Superplasticiser

The marsh cone apparatus with an 8 mm aperture diameter is used for finding the SP's efficiency. The

efficiency of the SP is essential for making the mix design of desired strength. SP's efficiency indicates that the required amount of water for the concrete design mix can be reduced up to a specific limit. The test procedure for finding the SP's efficiency is taken from the book concrete technology (theory and practice)[31]. In this process, the cement quantity remains constant, but the water amount is changed in all the tests. The flow time of slurry without SP, having 1100 gm of water should be the same as another slurry with 1% of SP dosage having a less amount of water, as shown in Fig 3. The efficiency of the auramix-400 SP for PPC and OPC permits the decrement of 22.73% of water. Different kinds of SP may be used for the same nature of cement, and the SP efficiency will be dissimilar. To find the efficiency of the SP flow table test can be used in place of the marsh cone apparatus.

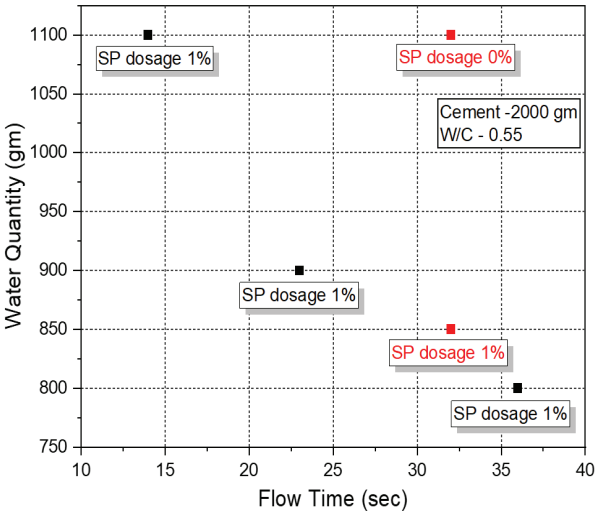

Fig. 3: The efficiency of SP

$$\text{The efficiency of SP} = \frac{\text{The difference in water content}}{\text{Original water content}} X100$$

$$= 22.73\%$$

5.3 Workability

The slump cone test measures the workability of concrete. SP is utilised by the weight of cement for ensuring the required workability of concrete. The slump cone results of the PPC and OPC mix are revealed in Fig 4. After the outcomes, it is assessed that the concrete workability of both mixes is nearly similar. The concrete mixes of the same grade made by PPC and OPC having the optimum dosage of SP exhibit similar workability. The slump value for medium workable concrete should be 50-100 mm, ensuring that both mixes are workable in the medium range.

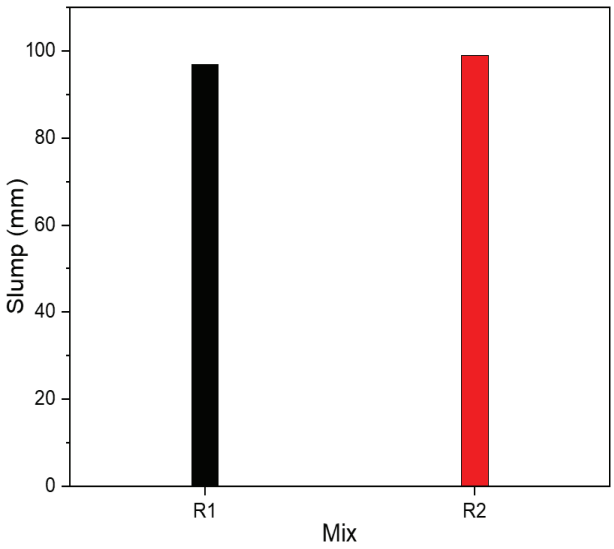

Fig. 4: Results of slump cone for mixes

5.4 Compressive Strength

The compressive strength of concrete is tested according to [32]. The compressive strength results of both mixtures are revealed in Fig 5. After analysing the results, it is found that the OPC mix's compressive strength is slightly larger at 28 days of curing and slightly lower at seven days and 14 days of curing as compared to the PPC mix. Both concrete mixes of the same grade show nearly similar results. The compressive strength of the PPC mix and OPC mix for the same SP would be almost similar, but the dosage of SP varies [33–38]. The dosage of SP in the PPC mix is slightly higher than the OPC mix, but the amount of FA and CA is lower.

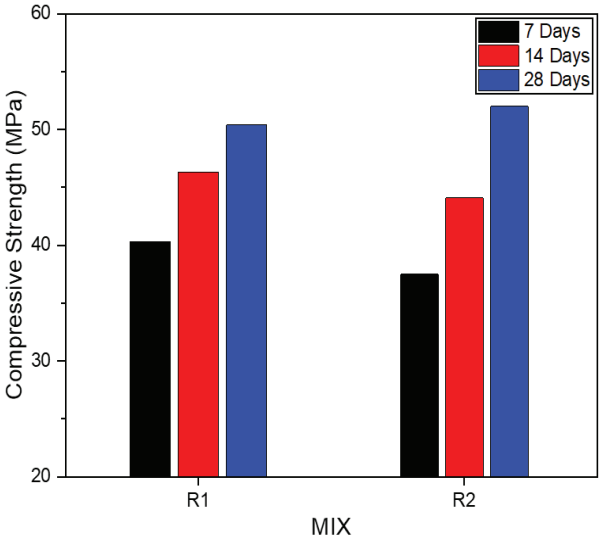

Fig. 5: Compressive strength of standard concrete of different mix

5.5 Flexural Strength

The Flexural strength of concrete is tested according to IS code [32]. The prism specimen's failure pattern is shown in Fig. 6(a), and the failure condition is in the range prescribed in IS code [32]. The results of the flexural strength of both mixtures are revealed in Fig. 6(b). Afterwards, evaluating the results, it is found that the OPC mix's flexural strength is slightly larger at 28 days of curing and slightly lower at seven days and 14 days of curing as compared to the PPC mix [39–41]. Both concrete mixes of the same grade show nearly similar results[42].

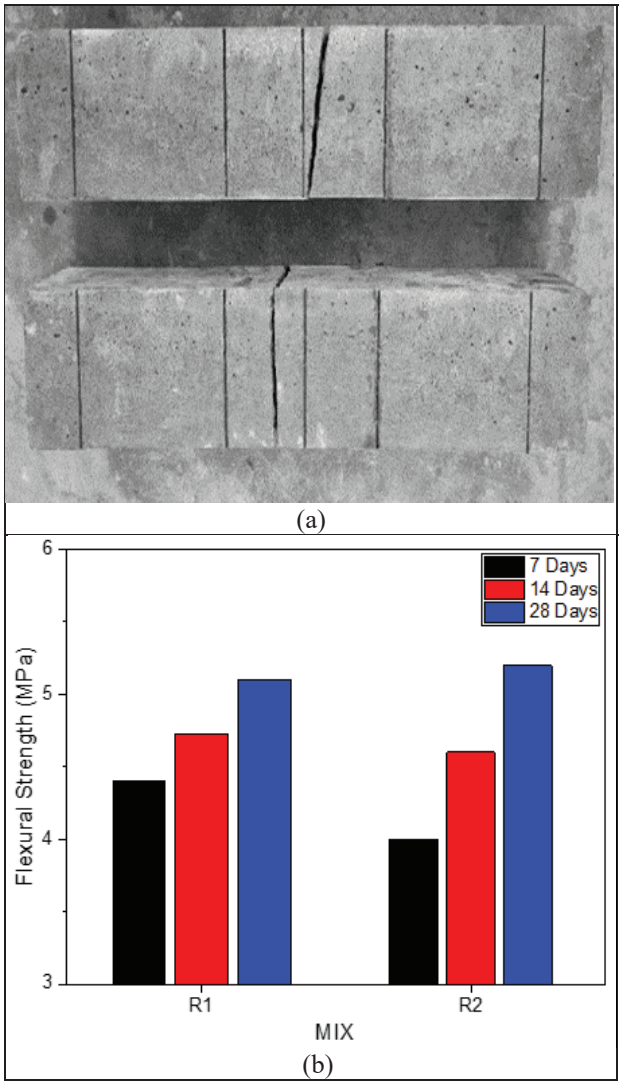

Fig. 6: a) Failure pattern of prism specimen; b) Flexural strength of standard concrete of different mix

5.6 Compressive strength of concrete mixes by Rebound hammer

Fig 7(a) shows the Proceq Schmidt Digital Concrete Test Hammer, utilised to assess the concrete's compressive strength according to [43]. The compressive strength results from the rebound hammer of both mixes are revealed in Fig.7(b). After examining the results, it is discovered that the compressive strength of concrete mixtures measured using a rebound hammer is 2-8 percent higher than the results obtained with UTM.

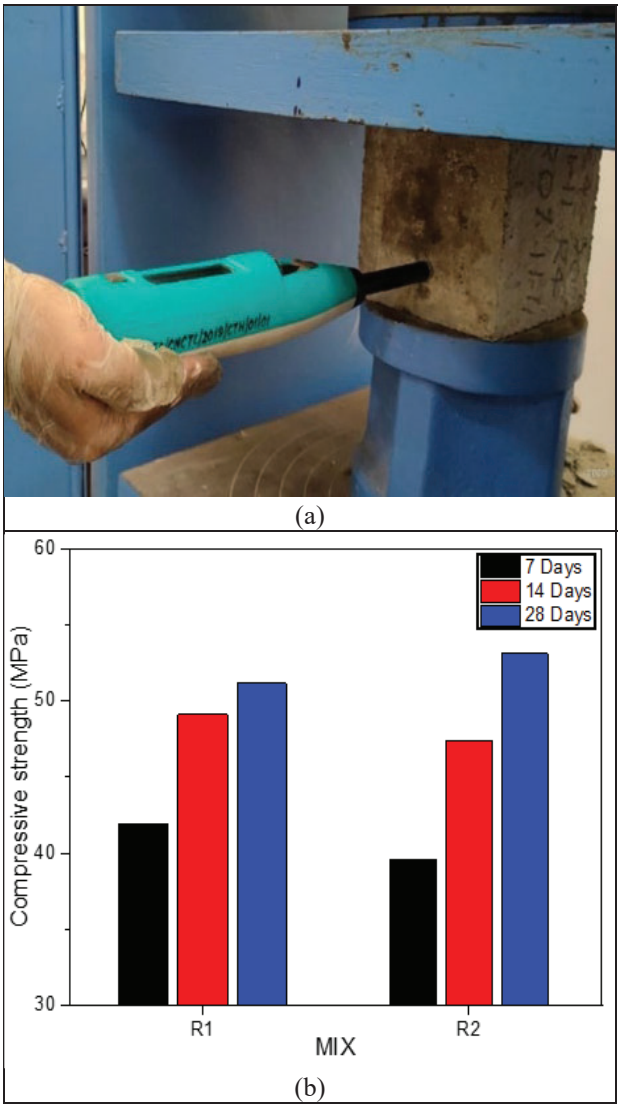

Fig. 7: a) Rebound hammer testing of the cube for the compressive strength test; **b)** Compressive strength of standard concrete by rebound hammer with age

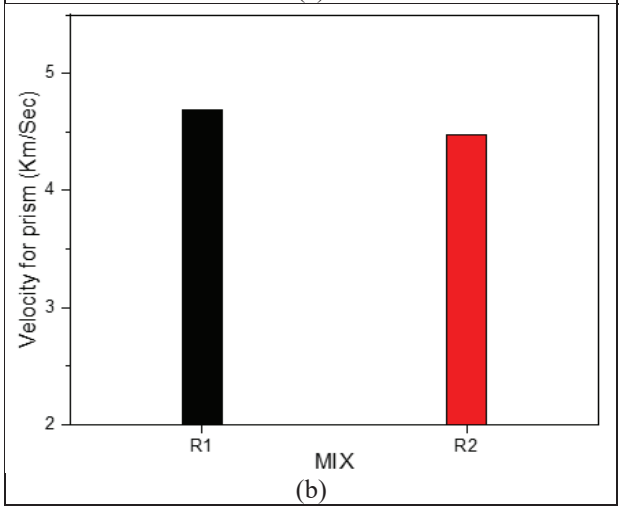
5.7 Ultrasonic Pulse Velocity

The UPV of both concrete mixes is tested by a 'MATEST' UPV tester and 2 transducers with a frequency of 54 kHz on the prism specimens, as shown in Fig. 8(a) according to [44]. An adequate amount of gel is applied between the concrete prism's surface and the transducer to confirm the proper connection. The UPV results of both mixes are shown in Fig. 8(b). The PPC concrete mix has UPV greater than 4.5 km/sec, which shows that the concrete is in excellent condition, but the OPC concrete mix has UPV of less than 4.5km/sec, and it offers good condition [45,46].

(a)



(b)

Fig. 8: a) Ultrasonic pulse velocity test of standard concrete; **b)** Ultrasonic pulse velocity of mixes at 28 days

6. Conclusion

The optimum dosage of polycarboxylate ether-based SP auramix 400 is found 1.4% with PPC and 1% with OPC. The optimum dosage of SP depends upon the type of SP and type of cement. If the cement or SP is different, then the optimum dosage will be changed. The optimum dosage of SP also depends upon the water-cement ratio. If the water ratio is changed, the optimum dosage will be different. If the SP is used with PPC, it requires more SP than the requirement of SP with OPC. However, FA and CA's requirement is more in OPC mix concrete than PPC mix concrete. The fresh and mechanical properties of concrete mixes of the same grade of concrete made by PPC and OPC with the SP's optimum dosage are approximately similar. The UPV is slightly higher in PPC concrete than in OPC concrete.

Acknowledgement

We would like to express our gratitude to Delhi Technological University's Civil Engineering Department for their kind help in making this effort possible and improved. The calibre and extent of our efforts have been greatly enhanced by their priceless contributions.

***Abstract*— The practice of yoga encompasses mental, physical, and spiritual dimensions, aiming for holistic well-being. Accurate alignment in yoga enhances the effectiveness of each pose by targeting specific muscle groups, reducing strain on muscles and joints, and improving stability and balance. This research employs advanced computer vision techniques, YOLO (You Only Look Once) and MediaPipe to identify critical keypoints from the skeletal structures of yoga practitioners, thereby providing a detailed representation of body alignment for posture recognition. Augmented using the SMOTE technique, the skeletal data serves as input for various Machine Learning and ensemble models during the training process. The study utilizes a 2D image dataset comprising 20 well-known yoga poses. Among the models tested, the LightGBM ensemble classifier using MediaPipe keypoints achieved the highest accuracy at 96.52%. Further analysis included the evaluation of the model through a confusion matrix, learning curve, and pose-wise accuracy, even for similar-looking exercises. These findings highlight the potential of integrating computer vision and machine learning to enhance yoga practice through precise posture recognition and alignment analysis.**

Keywords—pose recognition, yoga, machine learning, MediaPipe, YOLOv8

I. INTRODUCTION

In today's world, the pursuit of holistic well-being has grown in importance, and yoga serves as a beacon, offering a means to find balance amidst the chaos. By adhering to correct postures, techniques, and sequences, yoga practitioners can maximize health benefits. Various methods to learn yoga include attending classes at yoga centers, watching videos, looking at images, or reading books. Given the fast-paced lifestyles of many, practicing yoga at home has become a preferred option. However, it can be challenging for individuals to identify flaws in their own postures. Incorrect postures can lead to various health issues such as joint pain, muscle strain, and sprains. Therefore, ensuring proper technique is crucial to avoid these potential problems and to fully reap the benefits of yoga [1]. Therefore, to assist people to perform yoga in an effective manner, there is a need for scientific evaluation of improper yoga posture identification and rectification by providing feedback. To support self-learning, this research tackles a critical component of self-learning in yoga practice, which is the requirement for precise yoga position recognition.

This research study has incorporated keypoint detection to construct a skeletal framework, thereby advancing the accuracy and depth of yoga pose detection. This study has conducted a comparative analysis between two leading methodologies, YOLOv8 and MediaPipe [2], to assess their accuracies in the context of yoga pose detection. YOLOv8 is well-known for its real-time object identification, which performs accurately, and MediaPipe, a precision-focused framework, performs exceptionally well. To mitigate imbalanced classes, SMOTE oversamples minority classes to provide a representation of postures. Next, the yoga positions is classified using a variety of machine learning techniques, namely Naïve Bayes, Support Vector Machine, KNN and Decision Trees. Afterwards, different ensembling classifiers like LightGBM, Random Forest, XGBoost and Bagging are used to improve the model performance. Various accuracy levels offer useful comparison points for assessing how well various approaches work in the particular area of yoga position recognition. This programme helps people practice yoga without the need for a trainer. The proposed system's dependability and performance are enhanced through this iterative process, ensuring that practitioners may rely on its guidance for the safest and most optimal yoga experience.

II. RELATED WORKS

To gain knowledge on various techniques for estimating yoga poses, some of the most recent works in this field are studied. A variety of techniques have been employed to estimate yoga posture. Skeletal and non-skeletal approaches are commonly employed in yoga pose recognition and classification systems. Skeletal yoga pose recognition identifies joint positions using models like OpenPose, PoseNet etc while non-skeletal classification recognizes poses based on overall visual features using architectures like ResNet, DenseNet etc.

Chen et al. [3] proposed a yoga training system in their research that studies participant's stances using the Y-system. Prominent axes, skeleton-based characteristics, and contour-based interest points were all incorporated in this system. For performance comparison, Microsoft Kinect and the OpenNI library were used to build skeletal diagram for yoga positions. The system used a depth sensor and RGB camera to gather depth data for tracking and estimating human body posture. This approach was good, but its fundamental drawback was the exorbitant cost and lack of user-friendliness nature of the Kinect device.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:42:56 UTC from IEEE Xplore. Restrictions apply.

Extreme Gradient Boosting (XGBoost) was applied to the OpenPose tool by Kakulapati et al. [4] in order to categorize photos of five different stances. They divided the dataset where 80% were reserved to train the model, while the remaining is for testing, treating the X and Y coordinates as crucial features. With an accuracy of 88%, the XGBoost classification earned the greatest result.

Ajay et al. [5] included five yoga postures, namely Natarajasana, Virbhadrasana 1, Virbhadrasana 2, Vrikshasana, Trikonasana, and Utkatasana in a dataset that was assembled using web resources and contributions from system developers. In order to identify posture mistakes, the proposed deep learning approach incorporated a human joints localization model into its convolutional neural networks (CNN) for yoga posture identification. The limitation of this research was the dataset used which comprises of a very few categories.

In order to create a random forest classifier for evaluating yoga asanas, Mustafa et al. [6] used transfer human learning position estimation techniques to identify 136 body-wide essential points. They use the popular posture estimation method AlphaPose in the first stage and then a random forest classifier in the second. They created a brand-new dataset that emphasizes different viewpoints in order to categorize yoga poses. They relied on accurate keypoint recognition and posture estimation.

In a work published in 2022, Ujjayanta et al. [7] presented a trained model built using the COCO keypoint identification dataset technique. A well-known search engine was used to automatically generate the dataset, which was then divided keeping three-fourth of it in train sets. However, a more extensive dataset is required.

Debabrata et al. [8] proposed a system for tracking the different yoga stances. They extracted the 33 keypoints obtained from MediaPipe package and followed by training of a combined classifier of CNN and LSTM. Vivek et al. [9], developed a deep learning-based Yoga position estimation system that can recognize posture while also providing comments on how to improve it. A total of 18 keypoints are extracted from the dataset. Nevertheless, imprecise body map segmentations lead to errors in displayed guidelines.

Ranjana et al. [10] provide a system for recognizing and correcting yoga postures that makes use of the OpenCV computer vision module as well as a kinematic description of the body. On a 7-yoga position dataset, the system uses 17 keypoints mapped using a method known as tf-pose estimation. This kypoint recognition model was developed with Keras and then trained with TensorFlow's MoveNet.

Janardhana et al. [11] used deep learning techniques to recognize yoga positions, allowing practitioners to monitor and improve their form. A combination of OpenCV and MediaPipe architecture has been used to detect important body parts, allowing yoga poses to be classified and feedback to be provided in real time. Their proposed model exceeds performance of cutting-edge techniques with 99.53% accuracy using a dataset of six yoga poses.

Deepak et al. [12] provide a deep learning approach based on MediaPipe and MoveNet for automatic yoga stance recognition. Our method extracts each person's key points and skeletons from input yoga photos by utilizing MediaPipe for key point-based skeletonization. After processing, the photos are sent into the MoveNet model, which guarantees accurate identification of the yoga stance.

To identify five different yoga positions with minimal data, Ashraf et al. [13] suggested a deep learning method inspired from Xception model. Their YoNet architecture deliberately leverages dimensional and spatial information out of the picture and uses them to aid with classification.

The previous research generally concentrated on a very limited set of well-liked yoga poses, often taking into account about five to seven popular poses. Moreover, those chosen poses differ significantly from one another in terms of body alignment, resulting in higher accuracy for the recognition models. However there are numerous variations of yoga which share similarities in appearance for which we can actually test the model's robustness and generalizability. More diversified datasets are thus required in order to train and evaluate the systems. Also, due to the inherent variety of yoga poses and similarity in movements, yoga pose classification may benefit from ensemble learning approaches, which has seen limited use in this area.

III. Proposed Approach

To properly categorize yoga postures, the suggested method includes dataset preprocessing, skeletal keypoint extraction, data augmentation, training of machine learning as well as ensemble models and then followed by testing and model evaluation as shown in

Figure **1**.

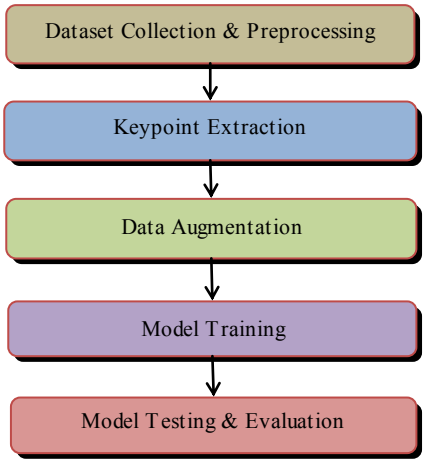

Figure 1 Proposed Approach

A. Dataset Collection and Preprocessing

We carefully selected a total of 1248 images of 20 yoga postures, each with a range of 50 to 90 photos, using the dataset we obtained from Kaggle [14]. We present a consolidated dataset with a variety of yoga poses from varied backdrops, lighting conditions, and viewpoints. Important meta data is attached to every image, including the file path, pixel values, and label that corresponds to the asana index. The yoga poses used here are 'Virabhadrasana i', 'Vajrasana', 'Savasana', 'Balasana', 'Bakasana', 'Setu bandha sarvangasana', 'Salabhasana', 'Vriksasana', 'Paschimottanasana', 'Uttanasana', 'Trikonasana', 'Virasana', 'Tadasana', 'Matsyasana', 'Virabhadrasana ii', 'Ardha matsyendrasana', 'Kapotasana', 'Adho mukha svanasana', 'Bhujangasana' and 'Dhanurasana'. The proposed method

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:42:56 UTC from IEEE Xplore. Restrictions apply.

seeks to include a greater variety of poses than existing work, including poses with similar alignments, like 'vajrasana' and 'virasana'. This varied dataset will aid in better understanding for evaluation of the models as they may misclassify and get confused.

To guarantee consistency and quality, certain preprocessing measures are implemented as soon as the dataset is gathered. These include image scaling, normalization, and label encoding. A split of 80:20 is followed, which means 80% data is used to train the model, and 20% is reserved for testing the model.

B. Keypoint Extraction

After preprocessing, two distinct keypoint extraction methods, namely YOLOv8 and MediaPipe are applied to extract skeletal keypoints from the images [14] as depicted in

Figure 2. These landmarks stand in for important anatomical regions, including the shoulders, wrists, elbows, knees, hips, and ankles. These landmarks' x, y, and z coordinates are also kept in arrays.

YOLOv8 functions through developing a grid based upon the input image. It enables fast and precise object detection via the use of only one neural network to forecast several bounding boxes and the class probabilities that correspond to them for every cell in the grid.

MediaPipe utilises deep learning algorithms trained on massive datasets to locate and monitor keypoints of interest, such as facial marking or joints on the human body. Convolutional neural network is used to identify traits from the input images and estimate the coordinates of landmarks, enabling continuous monitoring and evaluation.

These two keypoint extraction methods have been used due to their popularity in multiple classification tasks [2], [15].

Figure 2 Landmark detection in a yoga image [14]

C. Data Augmentation

A variety of methods, including rotation, scaling, flipping, cropping, translating, adding noise, varying brightness and contrast, color jittering, random erasing, and cutting, are included in data augmentation. By producing synthetic examples, these techniques are used to diversity the dataset, improve the model's capacity for generalization, and lower the likelihood of overfitting. It also has the benefit of permitting the model to perform generalisation on future unidentified images.

One method that is widely used for this is SMOTE, which is an abbreviation for 'Synthetic Minority Over-sampling Technique'. By interpolating between the current instances and their closest neighbors, SMOTE creates artificial training records for the minority class [16]. For each observation, after determining the k-nearest neighbors, we generate synthetic data points by interpolating between them. First, a stochastic sample is used to select the minority class. Then, SMOTE oversamples the minority class, and due to this successfully addresses class imbalance, decreases overfitting, and enhances model performance.

D. Model Training

The skeletal data is used to train a variety of machine learning and ensemble algorithms, to identify underlying patterns between the extracted keypoints and yoga position labels [17]. GridSearchCV is employed to methodically adjust the models' hyperparameters to find the optimal values which provide the best results during prediction. It operates by sifting through a predetermined set of parameters and assessing the effectiveness of each combination using cross-validation. The models that were utilized are as follows.

Linear SVM: The linear support vector machine (SVM) [18] determines the ideal hyperplane that maximizes margin between various stance classes. High-dimensional data, such as keypoints retrieved from pose photos, benefit greatly from its use.

Decision Tree: Decision Trees are trained to recursively partition the feature space based on landmark values in the classification of yoga poses .

K-Nearest Neighbors (KNN): KNN uses a distance measure between feature vectors for each sample [19]. This makes precise categorization based on important body positions and angles.

Multi-Layer Perceptron (MLP): MLP uses hidden layers in their multi-layered network to recognize complex details. In our context, the complexity comes from the variety of yoga postures in the dataset.

Gaussian Naive Bayes: It determines the probability that a given pose falls into a given category using the given keypoints. It simplifies the estimate of mean and standard deviation per pose by assuming a Gaussian data distribution.

Random Forest (RF): Random Forest builds and applies different feature subsets to train various decision trees. Every tree makes an individual pose class prediction during classification, and the final classification is the result of combining these predictions .

Bagging: Bagging improves accuracy by bootstrapping data. This means selecting subsets of data sampled with replacement. Each subset is also simultaneously trained on classifiers. Predictions are then aggregated to produce insights that increase robustness and accuracy.

eXtreme Gradient Boosting (XGBoost): It follows a boosting strategy of successively creating an ensemble of decision trees. It also handles missing data and is a well-used option because of its advantages which include maximizing precision and speed [20].

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:42:56 UTC from IEEE Xplore. Restrictions apply.

LightGBM: LightGBM builds an ensemble of decision trees sequentially. It uses histogram-based techniques and leaf-wise tree growth, unlike traditional decision trees based gradient boosting. This results in a faster and more precise model while also lowering memory usage.

E. Model Testing & Evaluation

After rigorous training phase, model performance is evaluated using the test set. Various measures like test accuracy, F1-score, precision, recall and ROC-AUC score are determined. To gain more insight into the performance of each model in relation to the landmark detection methods employed, a comparative study is performed. The weights of the model that outperformed the others in terms of accuracy highest test accuracy are then saved.

IV. Experimental Analysis

A. Requirements and Specification

The experimenting method was conducted using Python 3.10 to guarantee dependability. Various machine learning and ensemble models were trained on the provided dataset, which comprises 20 classes representing different yoga poses. The hardware prerequisites for these models include Tesla T4 GPU, two virtual CPUs, 32GB of RAM, all accessible via Google Colab's network.

B. Experimental Study and Results

For pose estimation, YOLOv8 detects 32 keypoints, while the MediaPipe framework detects 33 keypoints. After training on each set of skeletal data, a list of optimal hyperparameters for each model is provided in Table I. These were obtained using Grid Search technique and the given values yielded the best performance.

TABLE I OPTIMAL HYPERPARAMETERS DETECTED

Model	Parameter	YOLOv8	MediaPipe
Linear SVM	penalty	L1	L2
	loss	hinge	hinge
	multi_class	ovr	ovr
Decision Tree	min_samples_leaf	2	1
	max_depth	40	30
	criterion	entropy	entropy
	splitter	best	best
K-Nearest Neighbors	p	2	2
	n_neighbors	3	3
	algorithm	auto	auto
Multi-Layer Perceptron	activation	relu	relu
	solver	adam	adam
	early_stopping	True	False
GaussianNB	priors	None	None
	var_smoothing	1e-09	1e-09
Random Forest	bootstrap	False	False
	max_features	sqrt	sqrt
	criterion	gini	entropy
	oob_score	False	False
Bagging	oob_score	False	False
	n_estimators	164	100
XGBoost	max_depth	8	6
	learning_rate	0.005	0.001
LightGBM	learning_rate	0.005	0.001
	boosting_type	gbdt	rf
	num_leaves	31	31

The accuracy of trained models for yoga position categorization utilizing keypoints found by MediaPipe and YOLOv8 is summarized in the Table II. All things considered, MediaPipe routinely beats YOLOv8 for all the models trained. With YOLOv8 keypoints, the LightGBM obtains the best accuracy (82%) but with MediaPipe landmarks, it shows remarkably higher accuracy (96.52%), closely followed by Random Forest (95.65%). All other ensemble methods also showed consistently good accuracy of over 90% using MediaPipe keypoints. Multi-Layer Perceptron also exhibits notable accuracy gains with both YOLOv8 and MediaPipe keypoints. It is also observed that ensemble learning methods consistently outperformed the base ML models.

TABLE II ACCURACY TABLE WITH RESPECT TO TWO DIFFERENT KEYPOINT DETECTION APPROACHES

Base Models	Accuracy (YOLOv8)	Accuracy (MediaPipe)
Linear SVM	65.28%	85.65%
Decision Tree	64.94%	81.73%
K-Nearest Neighbors	70.00%	70.00%
Multi-Layer Perceptron	80.00%	87.39%
GaussianNB	65.45%	88.69%
Random Forest	81.00%	95.65%
Bagging	80.94%	94.78%
XGBoost	79.28%	93.91%
LightGBM	**82.00%**	**96.52%**

Table III shows performance metrics like precision, recall, F1-score of all the models trained with MediaPipe keypoints. With LightGBM being the best, other ensembles-Random Forest, XGBoost and Bagging also exhibit remarkable results, with precision, recall and F1-scores over 0.94. Looking at Table II and TABLE III, overall it was discovered that LightGBM with MediaPipe keypoints was the best model.

TABLE III PERFORMANCE METRICS WITH RESPECT TO MEDIAPIPE

Algorithm	Precision	Recall	F1 score
Linear SVM	0.86	0.85	0.85
Decision Tree	0.82	0.81	0.81
K-Nearest Neighbors	0.70	0.69	0.69
Multi-Layer Perceptron	0.87	0.87	0.86
GaussianNB	0.90	0.89	0.88
Random Forest	0.96	0.96	0.96
Bagging	0.95	0.95	0.95
XGBoost	0.94	0.94	0.94
LightGBM	0.97	0.96	0.96

Figure 3 shows the confusion matrix, wherein a visualization of pose-wise accuracy of each yoga pose is shown. The diagonals in the matrix counts the number of

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:42:56 UTC from IEEE Xplore. Restrictions apply.

correct predictions. 14 poses, namely 'Adho mukha svanasana', 'Ardha matsyendrasana', 'Bhujangasana', 'Kapotasana', 'Paschimottanasana', 'Salabhasana', 'Savasana', 'Tadasana', 'Uttanasana', 'Vajrasana', 'Virabhadrasana i', 'Virabhadrasana ii', 'Virasana', 'Vriksasana' show an accuracy of 100%, meaning all test images were classified correctly. The other elements in the matrix denote incorrect classifications for every exercise. It is because some poses are too intricate to be photographed from one single shot. Some poses carry many similarities like how the torso is oriented and the legs are positioned. For instance, in the 9th row, 'matsyasana' has been correctly predicted 7 times and misclassified as 'bhujangasana' once. This visualization helps in identifying problematic classes and defining scope for future improvements. Accuracy of the other yoga poses are: 'bakasana' (93.33%), ;setu bandha sarvangasana' (93.33%), 'matsyasana' (87.5%), 'trikonasana' (87.5%), 'balasana' (85.71%) and 'dhanurasana' (77.77%). For the exercises where comparatively lower accuracy is obtained, more images can be added to the dataset taken from various angles and direction for overall understanding of the pose by the model.

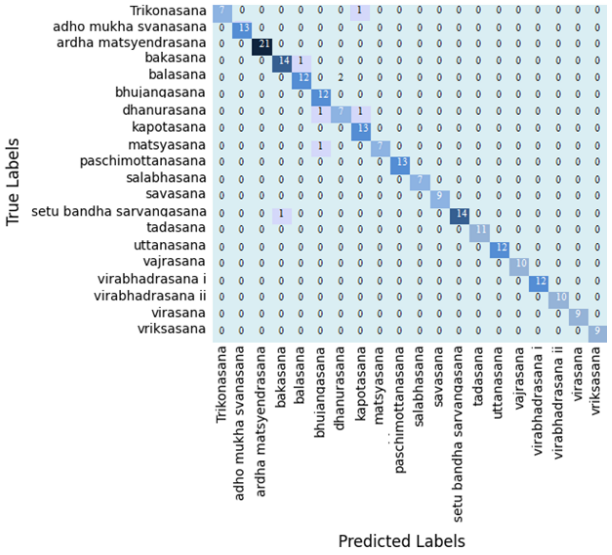

Figure 3 Confusion Matrix using MediaPipe+LightGBM model

In Figure 4 shows the accuracy and loss graphs of the MediaPipe+LightGBM model. The number of epochs, or one whole run across the training set, is shown on the x-axis. The left graph's y-axis denotes accuracy whereas the right one's represents loss. The accuracy curve starts at around 0.4 and increases to nearly 0.96 over the 25 epochs. This shows that the predictive algorithm is boosting its rate of accuracy in identifying the data points. The initial high loss (around 3.0) signifies significant discrepancies across the predictions to the true data points. The loss steadily decreasing towards 0 over 25 epochs indicates the model is progressively refining its predictions to better match the actual data.

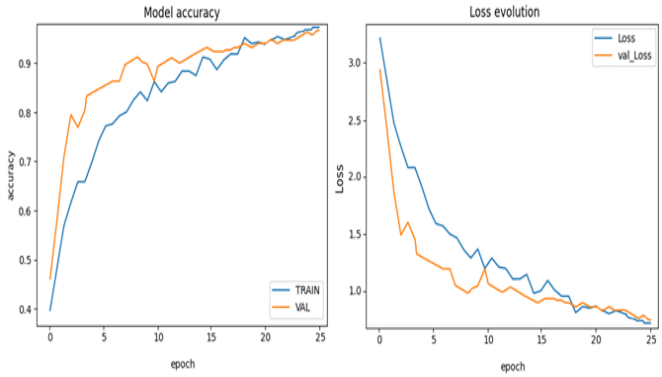

Figure 4 Accuracy and Loss curves using MediaPipe+LightGBM model

The learning curve of the LightGBM model with MediaPipe keypoints is shown in Figure 5, where the x-axis represents the count of training images and y-axis represents the cross-validation score, which rises quickly from roughly 0.65 to 0.96 as more training samples are added. Beyond a score of 0.96 improvement flattens and settles around a remarkable score of 0.97, which signifies a well-trained model. Also, the flattening of the curve indicates that after around 1200 samples, the model performance stays the same. As more samples are used for training, the shaded region encompassing the cross-validation score line diminishes, signifying a drop in uncertainty in the model's performance.

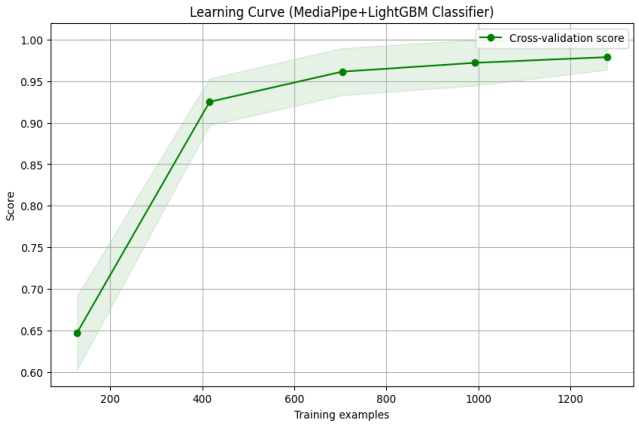

Figure 5 Learning Curve for LightGBM model

A graph of Receiver Operating Characteristic (ROC) is also shown for each class in Figure 6. AUC, which is the Area Under the Curve, quantifies classifier performance, with 1.0 indicating perfection classification. Classes like 'Trikonasana', 'adho mukha svanasana', and 'ardha matsyendrasana' have AUCs of 1.0. 'Bakasana' and 'setu bandha sarvangasana' achieve AUCs of 0.99, indicating high performance. Analysis of ROC curves and AUC values guides identification of classes necessitating improvement or more training data.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:42:56 UTC from IEEE Xplore. Restrictions apply.

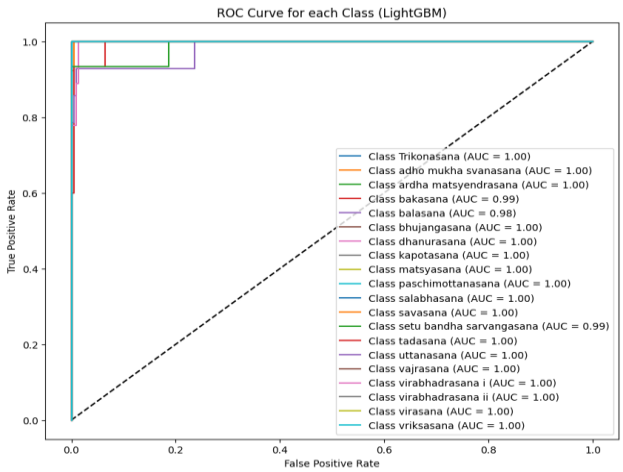

Figure 6 AUC-ROC curve using MediaPipe+LightGBM model

C. *Class prediction*

The true and predicted labels with landmarks indicated for pictures from the testing dataset showing different yoga positions are shown in Figure 7. From the six test images, five of them are correctly classified and one image of 'Trikonasona' pose is misclassified as 'kapotasana'.

Figure 7 True vs Predicted labels of some test images of poses [14]

V. Conclusion and Future Work

In summary, this study focuses on using YOLOv8 and MediaPipe keypoint detection for classifying yoga poses. Classification was performed using multiple base models and ensemble learning models on a custom dataset of varied yoga poses. For accurate posture identification, models using MediaPipe keypoints regularly outperformed their YOLOv8 counterparts. These results show how crucial accurate keypoint identification is to enhancing classification performance. Further, ensemble learning classifiers consistently showed better performance compared to base models which show the power of ensemble algorithms in collectively improving performance. LightGBM using MediaPipe keypoints showed the best performance. This model was further analyzed using to confirm the authenticity and correctness of results. Moreover, with this approach we can see that similar looking poses are also being distinguished and classified almost correctly.

In the future, more complex deep learning architectures such as CNNs or GNNs can be used for pose categorization. Also, using real-time inference, the proposed system can be enhanced to get interactive feedback. Also, more number of yoga poses should be considered to make a standard and large dataset. Moreover, the yoga posture classification task can be made more accessible when user-friendly mobile applications are developed.

Assessing Gender Bias in Machine Translation

Rishabh Jain
Computer Science and Engineering
Delhi Technological University
Delhi, India
jrishabh720@gmail.com

***Abstract*—Machine translation systems, such as Google Translate and Bing Microsoft Translator, are widely utilized for translating text from one language to another. This study undertakes a comprehensive evaluation of Google Translate and Bing Microsoft Translator with a specific focus on natural gender translation. Through rigorous analysis, it assesses the occurrence of female, male, and neutral forms in the translations of personality adjectives, professions, and nouns. Emphasizing the English to Hindi language pair, the evaluation meticulously examines how effectively these translation systems handle gendered language nuances, particularly in professions where biases may exist. By providing statistical insights into the translation outputs, the study aims to shed light on potential biases and accuracy levels within these machine translation systems. Ultimately, this evaluation contributes to a deeper understanding of the capabilities and limitations of automated translation tools in accurately representing gender-specific language constructs, thereby facilitating more nuanced and sensitive cross-lingual communication.**

***Index Terms*—Gender bias, Machine Translation, N-grams, Natural Language Processing (NLP)**

I. Introduction

The growing connectivity of our world has made the ability to communicate across linguistic boundaries more crucial than ever. Language diversity poses a formidable barrier to connectivity. With the increasing interconnectedness through trade, travel, and digital communication, there is a burgeoning demand for machine translation that is both unbiased and accurate. Machine Translation (MT) Systems are important for breaking down language barriers when we talk to people worldwide. For translating text or speech from one language to another language these system use advance algorithms and NLP(Natural Language Processing) techniques. Although the development of reliable machine translators is challenging, MT systems are continuously improving and expanding their functionalities. They are constantly evolving and getting closer to achieving translation accuracy comparable to that of human expertise.

MT systems can show gender bias by favoring one gender over another based on professions, pronouns, and verbs. Mitigating these biases enhances fairness and equity, resulting in better user experience and equal treatment based on gender.

This study evaluates the gender bias in Machine Translation (MT) systems. When translating from a gender-neutral language like Hindi to a language with grammatical gender like English, which manifests in various ways across different languages. Languages classify words as masculine, feminine, or neutral in grammatical gender which varies between Hindi to English. For example, ‘doctor’ or ‘nurse’ might be perceived as typically male or female roles. It reflects both the real-world makeup of the data and the biases found in everyday communication. Sentence-by-sentence translation is a common feature of most modern MT systems. For managing the gender aspect in translation, these systems depend on the patterns they learned during training, but it becomes challenging when it comes to translating from a gender-neutral language like Hindi to a language with grammatical gender like English. A language with grammatical genders requires additional information to translate gender accurately. MT systems can be biassed based on recent studies but very little work is done in the Hindi language. For example, Google Translate favors masculine translations [1]. It doesn’t matter whether the source text is gender-neutral or not. There seems a bias in the machine translation system. To address this issue, Systematically evaluating bias in machine translation systems, the study concludes by comparing the original English sentences with their translated counterparts to identify any gender bias introduced during translation and to observe the influence of professions on bias.

Fig. 1. Occupation gender bias shown in some HI- EN (Hindi-English) translation systems

II. Related Work

Recent literature on bias in Natural Language Processing (NLP) has garnered attention, particularly focusing on con-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 09:38:07 UTC from IEEE Xplore. Restrictions apply.

trolling gender fluctuations in translations by major Machine Translation (MT) providers, with neural approaches gaining prominence. Rabinovich [2] conducted extensive experiments akin to Bawden [3], emphasizing gender preservation in PB-SMT systems through domain adaptation, treating female and male genders as separate domains. In Neural Machine Translation (NMT), Vanmassenhove [4] experimented with inserting artificial tokens at the sentence start to denote speaker gender, akin to Sennrich [5], who introduced 'informal' or 'polite' tags to training sentences. Elaraby [6] introduced a technique for speech-like text translation, particularly English-to-Arabic, training on generic data and fine-tuning with gender-labeled sentences for correct gender agreement. Moryossef [7] proposed a black-box method to control NMT translations in cases of gender ambiguity by concatenating unambiguous artificial antecedents with speaker and interlocutor information. Recent studies, recognizing the scarcity of publicly available corpora, designed corpora specifically to evaluate MT performance in gender translation (Font and Costa-Jussa [8]; Di Gangi [9]). Monti [10] provided an overview of gender-related issues in MT, while Sun [11] conducted a literature review on gender bias in NLP. Social bias within language models arises from unintended associations in data. Previous works addressing bias include Bolukbasi [12], employing gender-definition pairs and principal component analysis for bias direction inference, but Gonen and Goldberg [13] noted incomplete debiasing. Huang [14] measured bias by evaluating if sentiment changed with entity alterations, while Kurita [15] introduced a metric based on WEAT to measure BERT bias. Stanovsky devised a method to automatically evaluate gender bias in 8 languages, aligning translations with source text and extracting gender. Work on mitigating bias has primarily focused on English, despite being non-gendered. Zhou and Gonen [16] measured bias in Spanish and French, considering animate and inanimate nouns, and neutralizing gender signals in training, respectively. Research in quantifying and mitigating bias in NLP is extensive but lacks emphasis on Hindi and other Indic languages, possibly due to resource constraints. Pujari [17] pioneered geometric debiasing, defining a bias subspace to decompose words into gendered and neutral components, later classified using SVMs. Research efforts address gender bias in MT and language models through domain adaptation, token insertion, fine-tuning, black-box methods, and corpus design. Despite progress, mitigating bias in Indic languages remains underexplored, highlighting the need for further research in this area.

III. Methodology

A. Dataset

The dataset used in this study comprises 3888 sentences collected from https://github.com/argentina-res/gender_project and generated using Large Language Models (LLMs) tools. Each sentence is tagged with one of three genders: male (1821 sentences), female (1814 sentences), or neutral (253 sentences). This balanced dataset ensures fair evaluation of bias, as each sentence contains only one gender. Additionally, the dataset includes Hindi translations of the sentences, along with their respective gender labels.

B. Description of the MT Systems

Machine translation is a computerized process utilizing statistical or neural machine learning models to convert text from a source language to a target language.

1) Google Translator (GT): GT, launched in 2003 as a statistical MT system and transitioning to a neural system in 2016, provides translations at the sentence level. Since 2018, GT offers alternatives for ambiguous or under-specified English words in certain languages with male-female alternatives. However, this feature is not available for Hindi.

2) Bing Microsoft Translator (BMT): BMT is a machine translation system that is owned by Microsoft. Initially, it used a statistical approach (Monti, 2017), but later it switched to a neural system (Alma-hasees, 2018). Unlike GT, BMT does not offer alternatives in the translation box itself [18].

After generating translations using Google Translator and Bing Microsoft Translator, an analysis was conducted to determine the frequency of occurrences of female, male, and neutral forms. The focus was on gender-specific terms such as personality adjectives, professions, and nouns.

C. Bias Statement

Bias refers to the tendency to show preference or inequity towards certain groups. In the context of machine translation, bias can lead to unfair or inaccurate representations of different genders or identities. Biased translations may perpetuate stereotypes and exclude certain groups from the conversation. Addressing bias in machine translation is crucial for creating more inclusive and equitable representations that benefit all individuals and promote diversity and respect.

D. Detection of gender

The detection of gender in a given text can be accomplished by using N-grams (Uni-grams, Bi-grams, Tri-grams) and Transformers. However, this method may produce comparable outcomes for both the original English sentences and their translations, as the sentences include only one gender. The process begins with the tokenization of text during the preprocessing stage, which involves dividing it into individual words (tokens) for both the English and its translated versions. Then converting all the tokens to lowercase. This ensures that the analysis is completely insensitive to case. This stage also includes stemming or lemmatization techniques, which are used to normalize the words to their root form. The gender detection algorithm identifies words such as 'He', 'His', 'Him', and 'Himself', which indicate male gender, and cross-references them with pre-defined gender-specific lists. Similarly, for the female gender, words like 'She', 'Her', 'Hers', and 'Herself' are checked, while for the neutral gender, terms like 'They', 'We', 'Our', and 'Themselves' are considered. Depending on

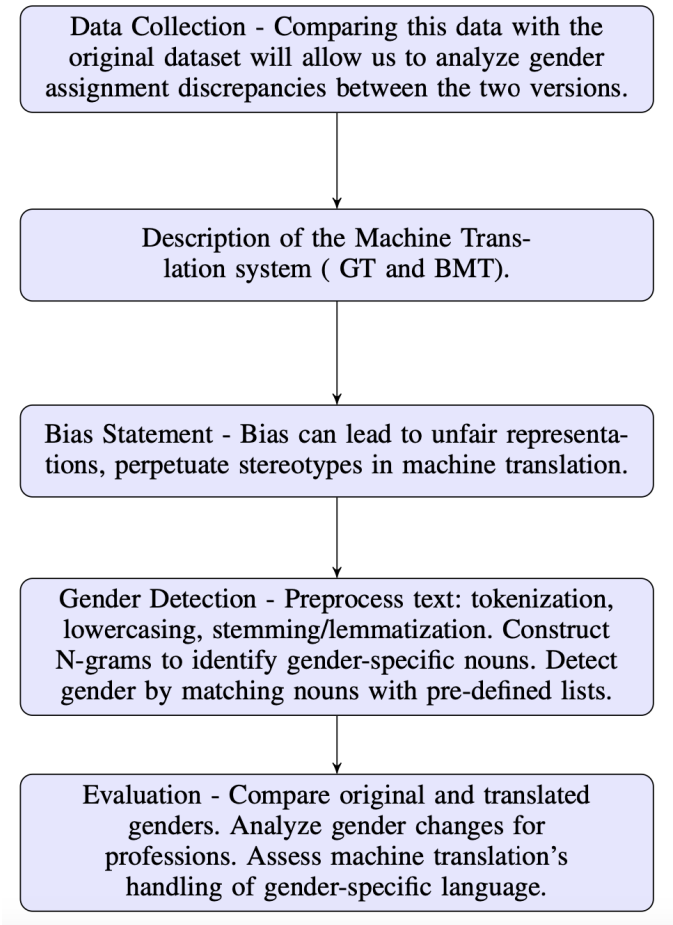

Fig. 2. Flow Diagram of Methodology

the match found in these lists, a gender label is assigned, categorizing the noun as ”male,” ”female,” or ”neutral.”

E. Evaluation

To evaluate the genders of the original data, comparisons are made with the genders of the translated data generated by Google Translator and Microsoft Bing Translator. Using various combinations, including comparing the results of the Original and Google Translator, Original and Bing Microsoft Translator, and Original, Google Translator, and Bing Microsoft Translator, patterns and correlations between professions and gender changes during translation are determined. The Natural Language Toolkit (NLTK) is utilized to extract professions from the dataset. This analysis aims to provide insights into how machine translation systems handle gender-specific language and its significance for professions during translation.

IV. Results

In this section, I intend to present the results and subsequent evaluation of the study. A comprehensive analysis and concrete examples will be provided. It is important to note that all evaluations were conducted in April 2024.

TABLE I
Gender Distribution in Dataset.

Data Gender	Value Count
Male	1821
Female	1814
Neutral	253

Table I distribution guarantees a fair evaluation across gender categories. The table provides a visual representation of these counts for easy comparison and analysis of gender distribution within the dataset.

TABLE II
Gender Distribution After Google Translation.

Google Translated Gender	Value Count
Male	2976
Female	386
Neutral	526

TABLE III
Gender Distribution After Bing Microsoft Translation.

BMT Gender	Value Count
Male	2946
Female	543
Neutral	399

Table II shows the Google translation's gender distribution across sentences. This provides insight into how gender-specific data is interpreted and categorized by the Google translation algorithm. By comparing this distribution with the original dataset, we can examine any disparities or similarities in gender assignment between the two versions and Table III shows the gender distribution of sentences translated by Bing Microsoft Translator.

between the original and translated data, providing insights into the impact of translation on gender assignment. Google Translator often fails to appropriately translate gender-specific terms which can result in misclassification. For example, neutral roles may be erroneously rendered as male-dominated or vice versa. Google Translator may perpetuate gender biases and stereotypes by assigning incorrect gender to certain professions in certain languages. For instance, it may assign a male gender to gender-neutral professions like 'Mechanic,' 'Developer,' 'Doctor,' and 'Guard' in certain English languages. Similarly, it may assign a female gender to professions like 'Nurse,' 'Veterinarian,' 'Teacher,' when translating from Hindi to English where gendered pronouns are prevalent. Table IV and Table V show that the gender distribution in the original dataset and the translated versions using Bing Microsoft Translator and Google Translator.

Table VI shows the gender distribution and comparison

The physician told the farmer that she tried the best.(F)	चिकित्सक ने किसान को बताया कि उसने सबसे अच्छी कोशिश की। (N)	The doctor told farmer that he tried his best.(M)	The therapist told farmer that he tried the best.(M)
The manager told the hairdresser that she expected something better.(F)	प्रबंधक ने हेयरड्रेसर को बताया कि उसे कुछ बेहतर होने की उम्मीद थी। (N)	The manager told the hairdresser that he expected something better.(M)	The manager told the hairdresser that he expected something better.(M)

Fig. 3. Example Sentences and Their Translations

across the original dataset, Google translated dataset, and Bing Microsoft Translator (BMT) translated dataset. Each row refers to a distinct combination of genders, with counts. The first character represents the gender of the original dataset, the second character represents the gender of the Google-translated dataset, and the third character represents the gender of the BMT-translated dataset. Counts in the table give an idea of gender assignment differences or similarities between the translation models. As one example, the combination of male-male-male, denoted by the code 'MMM,' has 1464, indicating that classify a sentence as male. Such comparative study will provide some insight into how rightly or wrongly different translation models translate gender and shed some light on the introduction of discrepancies or bias during the translation process.

The study examined the gender translation performance of two leading models of translation across a range of professions. The models, though very advanced in their algorithms, in the translation process based on profession convert gender from female to male or male to female. These are indications that improvements are needed in automated translation systems. Enhancing the accuracy of gender translation is crucial for promoting fair representation and inclusivity across linguistic contexts.

In this study, accuracy is defined as the absence of bias in the translated text compared to the original data. To calculate the accuracy, the counts of correctly translated sentences are summed and then divided by the total number of sentences in the dataset (3888 in this case).

For the Google translation system and Bing Microsoft translation system, the accuracy is calculated as follows:

$$\text{Accuracy (Google)} = \frac{1587 + 361 + 113}{3888} \approx 53.03\%$$

$$\text{Accuracy (Bing)} = \frac{1627 + 465 + 207}{3888} \approx 59.12\%$$

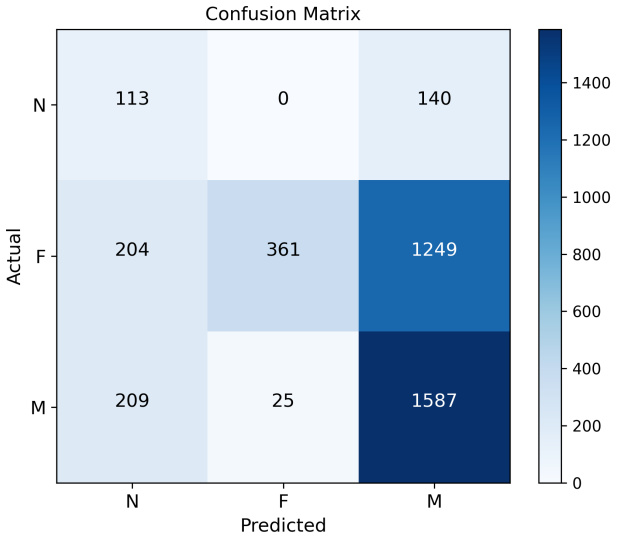

Fig. 4. Confusion Matrix for Google Translator(GT)

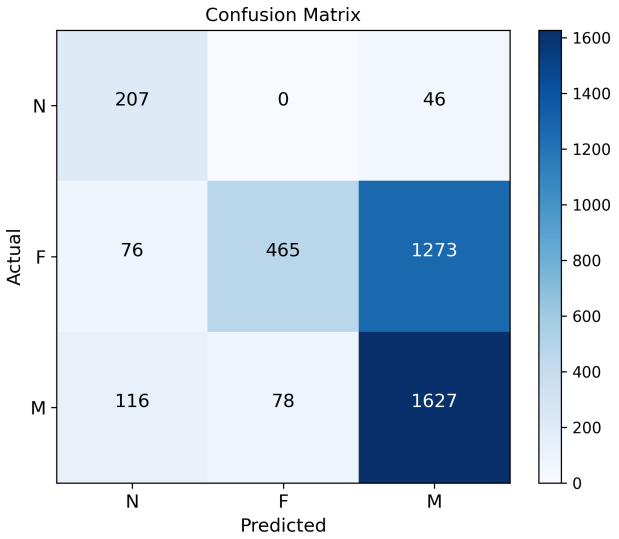

Fig. 5. Confusion Matrix for Bing Microsoft Translator

Comparing the two, it's observed that the Bing Microsoft translation system achieves a slightly higher accuracy compared to Google. However, it's important to note that both systems exhibit similar performance in accurately translating sentences without introducing bias.

V. Conclusion and Future Work

In this study aimed to evaluate the gender translation performance of two major translation models across different professions. Despite their advanced algorithms, both systems struggled to accurately translate professions and often misinterpreted gender. The accuracy of Bing Microsoft and Google translation systems was compared by assessing their ability to translate sentences without introducing bias. Although Bing Microsoft showed slightly higher accuracy, both systems performed similarly in this regard.

In future work, the aim is to expand the evaluation to include a broader range of language pairs and a more diverse vocabulary. Additionally, plans are in place to develop a challenge set that specifically targets gender-related phenomena in language, enabling automatic evaluation of translation systems. The goal is to train a state-of-the-art machine translation (MT) system to investigate the impact of machine bias on translation outputs and explore potential mitigation strategies. Various approaches will be explored, drawing on methods proposed for other languages, to address and reduce biases in machine translation. Furthermore, accuracy can be improved by mitigating bias through gender tagging at the sentence or word level, thereby enhancing the performance and reliability of the translator.

Abstract

We consider a recently modified version of holographic dark energy, known as Barrow holographic dark energy, in the framework of $f(R,T)$ gravity and consider a flat Friedmann-Lemaitre-Robertson-Walker line element for our study. We solve the field equations of the model to obtain the values of Hubble parameter and scale factor of the universe. We obtain the values of deceleration parameter and effective equation of state to discuss the evolution of the universe. Further, we constrain the model parameters using various data sets like type Ia supernova, observational Hubble data, SH0ES data etc. We use the Monte Carlo Markov Chain method to obtain the best fit values of the model parameters. We observe that the best fit present values of Hubble parameter $H_0 = 67.764^{+1.274}_{-1.354}$ and $H_0 = 70.440^{+0.816}_{-0.869}$, obtained for two different combinations of observational data, are in agreement with recent observations. We also constrain the case in which our model converts to the Barrow holographic dark energy model in general relativity and compare the results of both models. We compare the results with Λ-CDM model wherever required. We plot deceleration parameter against redshift parameter for best fit values of the model parameters. We observe a smooth phase transition of the universe from early time decelerated expansion to accelerated expansion which shows compatibility with recent observations. The values of equation of state parameter ω_h of Barrow holographic dark energy are found to be $-0.873^{+0.115}_{-0.078}$ and $-0.866^{+0.156}_{-0.130}$, and age of the universe are found to be 14.09 Gyr and 15.43 Gyr for two combination of data sets for Barrow holographic dark energy model in $f(R,T)$ gravity. Furthermore, we apply statefinder and Om diagnostic to discriminate our model from existing dark energy models.

Keywords Barrow holographic dark energy · $f(R,T)$ theory · Accelerated expansion · Observational estimation · Statefinder analysis · Om diagnostic

1 Introduction

The cosmological observations have changed our understanding about the universe in a significant way specially the observations of last three decades have made overwhelming changes in our knowledge of the universe. In the year 1998, the observations of type Ia supernovae changed our understanding about cosmic evolution. The accelerated expansion of the universe was observed by Riess et al. (1998) and Perlmutter et al. (1999), and this observational discovery presented a challenge in front of cosmologists to explain it theoretically. The observations of various cosmological probes like Wilkinson Microwave Anisotropy Probe (WMAP) (Spergel et al. 2003, 2007), Sloan Digital Sky Survey (SDSS) (Tegmark et al. 2004a, 2004b) and Planck data (Ade et al. 2014; Aghanim et al. 2020) etc. have confirmed the accelerated expansion of the universe. These observations suggest a mysterious type of energy, the so called dark energy (DE), which exerts a negative pressure required to accelerate the universe. According to recent observations, the universe should consist about 68.3% DE, 26.8% cold dark matter (CDM), and only 4.9% usual baryonic matter which can be described by the well-known particle theory (Aghanim et al. 2020). Till now, DE is a hypothetical form of energy because no evidences of it's true nature and origin are available. It behaves opposite of gravity and supposed to be the energy of the empty space. The simplest DE model

that fits the cosmological observations in a significant way is the Λ-CDM model, where Λ is the cosmological constant (Carroll 2001; Peebles and Ratra 2003). However, a number of DE models have been proposed in the literature but the Λ-CDM model is the most successful model of DE till date and known as the standard model of cosmic evolution. However, this model is not free from problems and the problems it is facing are cosmic coincidence, fine-tuning and H_0 tension (Copeland et al. 2006; Sahni et al. 2014; Valentino et al. 2021a,b).

The second possibility to explain accelerated expansion of the universe is by assuming that the General Relativity (GR) breaks down at large scales and a more general action is required to describe the gravitational field. The modified theories of gravity have been obtained by modifying the Einstein-Hilbert (EH) action of GR. The study on evolution of the universe through modified theories of gravity have become a popular area of research in recent years. The $f(R)$ theory is considered one of the simplest modifications of GR in which the gravitational Lagrangian depends on a general function of Ricci curvature scalar R (Bamba et al. 2008; Nojiri and S.D. Odintsov 2011; Matos et al. 2021). Buchdahl (1970) was first who considered the general function $f(R)$ in the EH action to present a more general model of gravity. It is natural to look beyond the dependence of gravitational Lagrangian on a function of R alone, it might be a function of two or more terms. Considering the fact, a number of theories such as $f(R, G)$ gravity (Bamba et al. 2010; Elizalde et al. 2010; Odintsov et al. 2019), $f(R, T)$ gravity (Singh and Kumar 2014), $f(Q, T)$ gravity (Xu et al. 2019), $f(T, B)$ gravity (Bahamonde et al. 2015; Wright 2016) etc. have been proposed to explain the recent accelerated expansion and other phenomena of the universe. Clifton et al. (2012) have provided a detailed review on modified theories of gravity.

In the present work, we are interested in $f(R, T)$ gravity which was proposed by Harko et al. (2011), where R as usual stands for Ricci curvature scalar and T denotes the trace of energy-momentum tensor. The dependence on T may be induced by exotic imperfect fluids or quantum effects (conformal anomaly). The authors have shown that a particular class of models in $f(R, T)$ gravity may produce an effective cosmological constant $\Lambda(t)$. Thus, the $f(R, T)$ gravity may provide a richer cosmological theory of gravity which also provides the space for imperfect fluids and quantum effects in its formalism. In a very recent paper, Bouali et al. (2023) have shown that a cosmological model in scalar-tensor $f(R, T)$ gravity is better than the Λ-CDM model in the light of recent observations. A number of authors have discussed the $f(R, T)$ gravity in different context to explain the early and late time evolution of the universe (Nojiri and Odintsov 2011; Houndjo 2012; Naser and Pradhan 2014). The reconstruction of $f(R, T)$ gravity has been carried out by Singh and Singh (2014) for two well-known scale factors. The cosmological implications of bulk viscosity and particle creation in the framework of $f(R, T)$ gravity was studied by Singh and Kumar (2014) and Kumar and Singh (2015). Sahoo et al. (2016) studied the Kaluza Klein cosmology in $f(R, T)$ theory. The holographic Ricci dark energy and generalized second law of thermodynamics has been discussed by Singh and Kumar (2018) within the framework of $f(R, T)$ gravity. Aktas (2019) has described various DE models in $f(R, T)$ theory like the k-essence, tachyon field. In recent papers, Bhattacharjee et al. (2020) have presented an inflationary model in $f(R, T)$ theory, energy conditions in unimodular $f(R, T)$ gravity have been discussed in (Rajabia and Nozarib 2021) and observational constraints have been obtained on $f(R, T)$ gravity using a particular form $f(R, T) = R + h(T)$ by Sardar et al. (2023).

To have a more accurate and general theory of gravity, the quantum physics should be included in the theory of gravity. Some efforts have been made but still we are far from the accurate theory of quantum gravity. Some DE candidates have been proposed in the literature which contains some properties of quantum gravity. A particularly interesting DE candidate featuring the properties of quantum gravity is the holographic dark energy (HDE). As the name suggests, this model is based on the holographic principle which was proposed by 't Hooft (1993). The energy density $\rho_h = 3c^2 M_p^2 L^{-2}$ of the HDE can be described by only two physical quantities which are the Planck mass M_p and the cosmic length scale L (Li 2004). Saridakis (2020) proposed a general version of HDE using the Barrow entropy instead of the standard Bekenstein-Hawking one which is known as Barrow holographic dark energy (BHDE). In a recent paper (Anagnostopoulos et al. 2020), observational constraints have been found on BHDE in flat FLRW universe taking GR as theory of evolution. Some recent works on BHDE are given in refs. (Srivastava and Sharma 2020; Mamon et al. 2021; Adhikary et al. 2021; Oliveros et al. 2022; Paul et al. 2022).

Singh and Kumar (2016) have discussed HDE in the framework of $f(R, T)$ gravity and applied statefinder analysis to the model. Saridakis (2020) found that BHDE exhibits more interesting and richer phenomenology comparing to the standard HDE scenario, therefore, it is worthy to study BHDE in $f(R, T)$ gravity. In the case of HDE, Hsu (2004) and Li (2004) have shown that Hubble horizon as an IR cut-off leads to a wrong equation of state, therefore, the accelerated expansion can not be achieved in the formalism of GR. Later on, Pavón and Zimdahl (2005) showed that interacting HDE may solve the problem and we may explain the accelerated expansion of the universe. Further, it was shown in a number of papers (Zimdahl and Pavón 2007; Campo et al. 2011; Singh and Kumar 2017) that the Hubble horizon as an IR cut-off is a suitable candidate to explain the recent accelerated expansion and it is also free from causality problem.

Moreover, it has been shown that Hubble horizon as an IR cut-off may explain the accelerated expansion of the universe without interaction in the formalism of $f(R,T)$ gravity (Singh and Kumar 2016). Therefore, we consider Hubble horizon as an IR cut-off in the present model. Tsallis HDE, generalization of HDE using Tsallis entropy, has also been discussed in $f(R,T)$ gravity. The authors studied Tsallis HDE for various IR cut-off and observed instability in the models (Zubair and Durrani 2021).

Sahni et al. (2003) proposed a new geometrical diagnostic pair {r, s} to discriminate among DE models called the statefinder. Further, Alam et al. (2003) discussed the diagnostic pair {r, s} in details. The statefinder is a geometrical diagnostic and allows us to characterize the properties of DE in a model-independent manner. The statefinder is dimensionless and is constructed from the scale factor of the cosmic expansion and its time derivatives only. The parameter r comes next in the hierarchy of geometrical cosmological parameters after the Hubble parameter H and the deceleration parameter q, while s is a linear combination of q and r. The ΛCDM and standard cold dark matter (SCDM) models have fixed values $\{1, 0\}$ and $\{1, 1\}$ of the statefinder pair {r, s}, respectively. Another geometrical diagnostic is the Om diagnostic which was proposed by Sahni et al. (2008). This diagnostic also applies to discriminate among DE models. We can discriminate among DE models on the basis of positive and negative slope of trajectories in $Om(z)$-z plane.

The main motive of the paper is to discuss BHDE model in the framework of $f(R,T)$ gravity whereas HDE model has been discussed in the theory. In the framework of GR, the BHDE model has been discussed by several authors showing the recent accelerated expansion successfully (Srivastava and Sharma 2020; Adhikary et al. 2021; Oliveros et al. 2022; Paul et al. 2022). But, problems like H_0 tension remain intact with this DE model also in GR as it can be observed in an observational analysis done in the paper (Anagnostopoulos et al. 2020). As we have discussed above $f(R,T)$ gravity presents a richer theory of gravity than GR, therefore, it is important to discuss the BHDE model in the framework of $f(R,T)$ gravity. It will be interesting to see whether the BHDE model in $f(R,T)$ gravity may resolve problems like H_0 tension, age problem, etc or not. In the era of observational precision, the cosmological model should be tested in light of recent observations. Therefore, we apply Monte Carlo Markov Chain (MCMC) method to find the best fit values of model parameters. Then, we use the best fit values to discuss the evolution of the universe within our model using cosmological parameters. Moreover, we also constrain our model for the case in which it converts into the BHDE model in GR. However, the BHDE model in GR has been constrained in the paper (Anagnostopoulos et al. 2020) but we use the latest observational data to constrain it. Then, we compare the results of our model with the results of this model. We also apply statefinder and Om diagnostic to our model to discuss similarities and differences between our model and existing DE models.

The paper is organized as follows. Section 2 is devoted to model and field equations. In Sect. 3, we provide the solution of the field equations where we obtain the values of Hubble parameter H, cosmic scale factor a, deceleration parameter q and effective equation of state parameter ω_{eff}. In Sect. 4, we estimate the best fit values of the model parameters. The evolution of the universe is the topic of the Sect. 5 where we discuss the evolution of the universe through cosmological parameters using the best fit values of model parameter and use geometric diagnostics to compare our model with existing ones. Section 6 is devoted to the conclusion of the paper.

2 Model and field equations

The general form of the EH action for the $f(R,T)$ gravity is as follows (in the unit $8\pi G = 1$)

$$S = \frac{1}{2}\int [f(R,T) + 2\mathcal{L}_m]\sqrt{-g}d^4x, \tag{1}$$

where g stands for the determinant of the metric tensor $g_{\mu\nu}$, R denotes Ricci curvature scalar and $\mathcal{L}_m$ denotes the matter Lagrangian density. Here, T represents the trace of energy-momentum tensor, i.e $T = g^{\mu\nu}T_{\mu\nu}$, and energy-momentum tensor $T_{\mu\nu}$ can be obtained from matter Lagrangian density as

$$T_{\mu\nu} = \frac{-2\delta(\sqrt{-g}\mathcal{L}_m)}{\sqrt{-g}\delta g^{\mu\nu}}. \tag{2}$$

It has been considered in $f(R,T)$ gravity that $\mathcal{L}_m$ depends only on $g_{\mu\nu}$, not on its derivatives. Now, the above form of $T_{\mu\nu}$ simplifies to

$$T_{\mu\nu} = g_{\mu\nu}\mathcal{L}_m - 2\frac{\partial\mathcal{L}_m}{\partial g^{\mu\nu}}. \tag{3}$$

Varying the action (1) with respect to the metric tensor $g^{\mu\nu}$, we obtain the field equations of the theory as

$$f_R(R,T)R_{\mu\nu} - \frac{1}{2}f(R,T)g_{\mu\nu} + (g_{\mu\nu}\Box - \nabla_\mu\nabla_\nu)f_R(R,T) = T_{\mu\nu} - f_T(R,T)T_{\mu\nu} - f_T(R,T)\Theta_{\mu\nu}, \tag{4}$$

where f_R and f_T denote the derivatives of the functional $f(R,T)$ with respect to R and T, respectively. Here, $\Box$ denotes the d'Alembert operator and ∇_μ denotes the covariant derivative. The term Θ present in the field equation is given by

$$\Theta\mu\nu = -2T_{\mu\nu} + g_{\mu\nu}\mathcal{L}_m - 2g^{\alpha\beta}\frac{\partial^2\mathcal{L}_m}{\partial g^{\mu\nu}\partial g^{\alpha\beta}}. \tag{5}$$

A number of forms of the functional $f(R,T)$ can be used to obtain various classes of $f(R,T)$ gravity models. The popular forms of the functional $f(R,T)$ are $R+f(T)$, $f_1(R)+f_2(T)$, $f_1(R)+f_2(R)f_3(T)$ etc. which have been taken to discuss various aspects of cosmological evolution. In the present paper, we are interested in the form $f(R,T)=R+f(T)$, where the term $f(T)$ is modifying GR by including geometry and matter coupling. The Eq. (4) for $f(R,T)=R+f(T)$ get converted into following equation

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu} = T_{\mu\nu}-(T_{\mu\nu}+\Theta_{\mu\nu})f'(T)+\frac{1}{2}f(T)g_{\mu\nu}, \tag{6}$$

where a prime denotes derivative with respect to the argument. The matter lagrangian $\mathcal{L}_m$ may be chosen as $\mathcal{L}_m=-p$, where p is the thermodynamic pressure of matter content of the universe. Now Eq. (5) gives $\Theta_{\mu\nu}=-2T_{\mu\nu}-pg_{\mu\nu}$. Using this result, Eq. (6) reduces to

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu} = T_{\mu\nu}+(T_{\mu\nu}+pg_{\mu\nu})f'(T)+\frac{1}{2}f(T)g_{\mu\nu}. \tag{7}$$

In $f(R,T)$ gravity, it is interesting to note that energy-momentum tensor does not conserve ($\nabla_v T_{\mu\nu}\neq 0$) which leads to some interesting cosmological consequences. One of the important consequences is the particle production through an open system irreversible process from the gravitational field (Harko 2014). Recently, a scalar-tensor representation of $f(R,T)$ gravity has been proposed which reduces mathematical complexity of the theory and presents some interesting features (Rosa 2021; Rosa and Kull 2022). It has been shown in a recent paper (Pinto et al. 2022) that the scalar-tensor $f(R,T)$ gravity shows capabilities of explaining particle production and the entropy production, which can explain the accelerated expansion of the universe. But, in the present paper, we are not considering the possibility of irreversible particle production.

In the present work, we consider a spatially homogenous and isotropic flat Friedmann-Lemaitre-Robertson-Walker (FLRW) space-time which is expressed in co-moving coordinates by the line element

$$ds^2=dt^2-a^2(t)(dx^2+dy^2+dz^2). \tag{8}$$

For the line element (8), the Eq. (7) produces the following equations

$$3H^2=\rho+(\rho+p)f'(T)+\frac{1}{2}f(T), \tag{9}$$

$$2\dot{H}+3H^2=-p+\frac{1}{2}f(T), \tag{10}$$

where ρ and p denote total content density and pressure of the universe, respectively. We assume $f(T)=\alpha T$, where α is a coupling parameter. Thus, the functional has the form $f(R,T)=R+\alpha T$ which represents a linear coupling between matter and geometry. This linear functional is important because it can produce effective cosmological constant model as a special case. Further, it may provide additional quantum corrections required to explain the problems like coincidence problem and H_0 tension associated with the concordance model. For this linear functional, the field equations (9) and (10) reduce as

$$3H^2=\rho+\alpha(\rho+p)+\frac{1}{2}\alpha T, \tag{11}$$

$$2\dot{H}+3H^2=-p+\frac{1}{2}\alpha T. \tag{12}$$

Now, the matter aries to choose the components of energy budget of the universe. However, the modified theories were considered to provide an alternative to DE still there are a number of DE candidates which naturally exit in the universe like holographic dark energy (HDE) and logical to be considered in the framework of modified theories of gravity. Moreover, the evolution of the universe is a very complex phenomenon and it is very possible that it may not be explained entirely by one theory. Taking into consideration of this fact, a number of DE candidates have been studies in the framework of modified theories of gravity (Sheykhi 2009; Sharif and Nawazish 2017; Samart et al. 2021; Zubair and Durrani 2021; Pinki and Kumar 2023). The HDE is based on holographic principle, contains some significant properties of quantum gravity and it appears from bound on zero point energy coming from black hole formation. Saridakis (2020) proposed a general version of HDE, using the Barrow entropy instead of the standard Bekenstein-Hawking one, which is known as BHDE. Author found that BHDE exhibits more interesting and richer phenomenology comparing to the standard HDE scenario. Therefore, it is worthy to study BHDE model in $f(R,T)$ gravity, however, HDE models have already been discussed in this theory. The energy density of BHDE ρ_h is given by

$$\rho_h=3c^2H^{2-\Delta}, \tag{13}$$

where $0\leq\Delta\leq 1$. Here, we have considered Hubble horizon as IR cut-off which is the simplest choice and free from causality problem. Also, we have considered $M_p^2=1$. It is to be noted that for $\Delta=0$, we obtain the energy density of HDE.

We consider that the universe is filled with BHDE and Dark Matter (DM), and we don't consider baryonic matter due to it's negligible contribution to the late time evolution. Thus, total energy density is given by $\rho=\rho_h+\rho_m$, where ρ_h

and ρ_m denote density of BHDE and density of DM, respectively. As DM is a pressureless component, the total pressure is given by $p = p_h$, where p_h denotes pressure of BHDE. In the literature, the study of DE and DM has been considered in two ways, interacting or non-interacting. We can deal with the interaction between dark components through energy conservation equations. In general, the energy-momentum tensor does not conserve in $f(R,T)$ gravity, although, it conserves for particular classes of $f(R,T)$ gravity (Bertini and Velten 2023). One can easily discuss the interaction between dark components in those classes of $f(R,T)$ gravity where conservation holds. But, in the classes where it does not hold, the problem is that how to write the separate conservation equations of dark components like for BHDE and DM in the present case. However, the part avoiding conservation of energy-momentum tensor may be considered either in the conservation equation of BHDE or DM, or may be divided into conservation equations of both. So, it is quite possible to study the interaction between dark components in the classes of $f(R,T)$ gravity where the energy-momentum tensor does not conserve. There is no compelling evidence of interaction between dark components, therefore, we are not considering interaction between BHDE and DM in the present work. Now, the field equations (11) and (12) takes the form

$$3H^2 = \rho_h + \rho_m + \alpha(\rho_h + \rho_m + p_h) + \frac{1}{2}\alpha T, \tag{14}$$

$$2\dot{H} + 3H^2 = -p_h + \frac{1}{2}\alpha T. \tag{15}$$

The above two equations are independent field equations of our model. Here, we have mainly three unknown quantities H, ρ_m and p_h, and only two field equations. Therefore, we have to either assume a quantity or assume a relation between any two quantities to solve equations. In the next section, we assume a relation between ρ_h and p_h to solve equations.

3 Solution of field equations

Let us consider a barotropic equation of state (EoS) of BHDE given by $p_h = \omega_h \rho_h$, where ω_h denotes the EoS parameter. The barotropic EoS is a direct relationship between density ρ_h and pressure p_h which allows for analytical solutions of the field equations and makes the study of evolution of the universe easy. Furthermore, it provides a way to classify the type of fluids depending on the values of the EoS parameter ω_h. It makes also possible to explain the accelerated or decelerated expansion of the universe using the values of ω_h. Thus, barotropic EoS plays an important role in cosmological modelling of the universe. The trace of energy-momentum tensor is given by $T = \rho_m + \rho_h - 3p_h$. After combining (14) and (15), we obtain a single evolution equation of H as

$$2\dot{H} + (1+\alpha)[(1+\omega_h)\rho_h + \rho_m] = 0. \tag{16}$$

Let us solve Eq. (16) to obtain the value of H. To solve this equation, we require the value of ρ_m which can be obtained using (13) into (14) as

$$\rho_m = \frac{6H^2 - 3c^2(2+3\alpha-\alpha\omega_h)H^{2-\Delta}}{(3\alpha+2)}. \tag{17}$$

We observe that the matter density depends on the model parameters. If we observe the numerator term, which may be written as $6H^2 - 3c^2H^{2-\Delta}[2+\alpha(3-\omega_h)]$, it is easy to observe for $\alpha > 0$ that as we increase the value of α the value of the numerator term decreases. As α increases the value of denominator term $3\alpha+2$ increases. Thus, the large value of parameter α slows down the evolution of matter density ρ_m. This also shows that the evolution of matter density ρ_m in $f(R,T)$ gravity is slower than GR where $\alpha = 0$. For negative values of parameter α, such that we must observe $\rho_m > 0$, we observe the reverse effect on the evolution of ρ_m. In this case, the evolution of matter density ρ_m in $f(R,T)$ gravity is faster than GR. It is easy to observe that the small value of parameter Δ slows down the evolution of matter density ρ_m and vice-versa. Similarly, the large value of c also slows down the evolution of matter density ρ_m and vice-versa. Further, we observe for $\alpha > 0$ that a large negative value of EoS of BHDE ω_h slows down the evolution of matter density ρ_m and vice-versa. And for $\alpha < 0$, this effect is reversed.

Now, using the values of ρ_h and ρ_m from (13) and (17), the Eq. (16) can be simplified as

$$\dot{H} + \frac{3(\alpha+1)}{(3\alpha+2)}\left[H^2 + (2\alpha+1)c^2\omega_h H^{2-\Delta}\right] = 0. \tag{18}$$

Here, we have obtained a single evolution equation of H. For $\Delta = 0$ the BHDE get converted in HDE, thus we will obtain the same results as obtained for HDE (Singh and Kumar 2016). In the present model, we consider a maximal deformation from the standard Bekenstein-Hawking entropy which is given by $\Delta = 1$. On solving Eq. (18) for $\Delta = 1$, we obtain the value of H as give by

$$H = \frac{(2\alpha+1)c^2\omega_h}{c_0(2\alpha+1)c^2\omega_h e^{\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h t}{(3\alpha+2)}} - 1}, \tag{19}$$

where $\alpha \neq -\frac{2}{3}$ and c_0 is a constant of integration. Equation (19) can be rewritten as

$$H = ((2\alpha+1)c^2\omega_h H_0 e^{-\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_0)}{(3\alpha+2)}})$$

$$/((2\alpha+1)c^2\omega_h + H_0(1-e^{-\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_0)}{(3\alpha+2)}})), \quad (20)$$

where H_0 is the value of the Hubble parameter at the present cosmic time $t = t_0$, the time where the BHDE starts to dominate. Using $H = \frac{\dot{a}}{a}$ in Eq. (20), the cosmic scale factor a is obtained as

$$a = c_1\Big[(2\alpha+1)\omega_h c^2 + H_0\Big(1-e^{-\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_0)}{(3\alpha+2)}}\Big)\Big]^{\frac{(3\alpha+2)}{3(1+\alpha)}}, \quad (21)$$

where c_1 is an another constant of integration. One can rewrite Eq. (21) as follows

$$a = a_0\Big[1+\frac{H_0}{(2\alpha+1)\omega_h c^2}\times\Big(1-e^{-\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_0)}{(3\alpha+2)}}\Big)\Big]^{\frac{(3\alpha+2)}{3(1+\alpha)}} \quad (22)$$

where a_0 is the value of the scale factor at the present cosmic time $t = t_0$. Now, using Eq. (22) the value of H given by Eq. (20) can be written in terms of redshift z as

$$H(z) = \frac{H_0 - (2\alpha+1)\omega_h c^2[(1+z)^{-\frac{3(\alpha+1)}{(3\alpha+2)}} - 1]}{(1+z)^{-\frac{3(\alpha+1)}{(3\alpha+2)}}}. \quad (23)$$

After Hubble parameter H, the next important parameter is deceleration parameter (DP) q. The DP q, which is defined as $q = -\frac{\ddot{a}a}{\dot{a}^2}$, is a geometric parameter which describes the acceleration or deceleration of the universe depending on its negative or positive value, respectively. We have obtained the value of q as

$$q = \frac{3(1+\alpha)}{(3\alpha+2)}\Big[-1+\frac{1}{3(1+\alpha)} + \Big(\frac{(2\alpha+1)\omega_h c^2}{H_0}+1\Big)e^{\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_o)}{(3\alpha+2)}}\Big], \quad (24)$$

and in the term of redshift parameter z, the value of q can be written as

$$q(z) = \frac{3(1+\alpha)}{(3\alpha+2)}\Big[-1+\frac{1}{3(1+\alpha)} + \frac{(2\alpha+1)\omega_h c^2 + H_0}{H_0 - (2\alpha+1)\omega_h c^2((1+z)^{\frac{-3(1+\alpha)}{(3\alpha+2)}} - 1)}\Big]. \quad (25)$$

We have obtained a non-constant value of q which may explain the recent phase transition of the universe. It is evident from (24) that accelerated expansion may be obtained if $\frac{3(1+\alpha)(H_0^2+(2\alpha+1)c^2\omega_h)}{H_0(3\alpha+2)} < e^{\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t_0-t)}{(3\alpha+2)}}$. Moreover, we observe a constant value $q = -1$ throughout the evolution for coupling parameter $\alpha = -1$, i.e, a specific type of coupling between matter and geometry can accelerate the universe throughout the evolution.

We can define the effective EoS parameter using the relation

$$\omega_{\text{eff}} = -1 - \frac{1}{3}\frac{2a}{h}\frac{dh}{da}, \quad (26)$$

where $h = \frac{H}{H_0}$ is the weighted Hubble parameter. Using (23) into (26), we obtain

$$\omega_{\text{eff}} = -\Big(H_0\alpha(1+z)^{\frac{3(1+\alpha)}{2+3\alpha}} + c^2\omega_h(1+2\alpha)\Big(-2+\alpha\Big(-3+(1+z)^{\frac{3(1+\alpha)}{2+3\alpha}}\Big)\Big)\Big) / \Big((2+3\alpha)\Big(H_0(1+z)^{\frac{3(1+\alpha)}{2+3\alpha}} + c^2\omega_h(1+2\alpha)\Big(-1+(1+z)^{\frac{3(1+\alpha)}{2+3\alpha}}\Big)\Big)\Big). \quad (27)$$

From the above equation, it can be observed that as $z \to -1$ in the late-time ω_{eff} approaches to -1. It is to be noted that the ω_{eff} represents EoS contributed by all components of the universe. Thus, if $\omega_{\text{eff}} \to -1$ then it does not mean that the model is converging to Λ-CDM model.

Observational cosmology has emerged as a game changer in the field of cosmology. To check the viability of a cosmological model, it's observational confrontation is required. Therefore, we constrain the model parameters using MCMC method in next section where we use the observational data obtained from various observational probes. We will use observational constraining of these model parameters to discuss the evolution of the universe within our model in details.

4 Parameters estimation

In the domain of observational cosmology, a critical component involves the development of ideal cosmological models. Achieving this necessitates constraining the parameters of the model via thorough analysis of observational data. In this paper, the data set of choice is combination of measurements obtained with the latest pantheon+ data sample derived from type Ia supernovae observations, observational Hubble data and local Hubble constant from SH0ES.

4.1 Type Ia supernovae (Pantheon+ data)

A recent compilation of spectroscopically confirmed type Ia supernovae (SNIa), referred to as Pantheon+, has emerged. This dataset directly builds upon the Pantheon analysis

Table 1 Best-fit values of the model parameters

	c	ω_h	α	H_0	M
SNIa+HD	$-9.008^{+0.465}_{-0.671}$	$-0.873^{+0.115}_{-0.078}$	$-0.181^{+0.037}_{-0.032}$	$67.764^{+1.274}_{-1.354}$	$23.831^{+0.009}_{-0.007}$
SNIa+HD+SH0ES	$-9.474^{+0.809}_{-0.349}$	$-0.866^{+0.156}_{-0.130}$	$-0.170^{+0.069}_{-0.044}$	$70.440^{+0.816}_{-0.869}$	$23.823^{+0.009}_{-0.008}$
SNIa+HD+SH0ES (GR)	$-8.587^{+1.184}_{-0.924}$	$-0.577^{+0.105}_{-0.178}$	–	$70.646^{+1.054}_{-1.152}$	$23.832^{+0.008}_{-0.006}$

(Scolnic et al. 2018) and its predecessor, the Joint Light-curve Analysis. In the realm of cosmology, the key disparity between the Pantheon+ study and the original Pantheon analysis lies in the incorporation of new datasets. The Pantheon+ dataset comprises 1701 SNIa samples, an increase from the 1048 samples in the original Pantheon analysis. These 1701 light curves, representing 1550 unique SNIa within the redshift range of $0.001 < z < 2.26$, constitute the Pantheon+ dataset (Brout et al. 2022; Scolnic et al. 2022). The efficacy of SNIa as standard candles becomes apparent when assessing their constraining power.

The χ^2 for SNIa is defined as

$$\chi^2_{SNIa} = m^T C^{-1} m \tag{28}$$

where $m = m_B - m_{th}$ with

$$m_{th} = 5\, log_{10} D_L + M, \tag{29}$$

and C is the covariance matrix of μ_{obs}. The luminosity distance d_L is defined by $d_L = (c/H_0) D_L$, where

$$D_L = (1 + z_{hel}) \int_0^{z_{cmb}} \frac{H_0 dz'}{H(z', \theta)} \tag{30}$$

where θ represents the set of model parameters, z_{hel} is the heliocentric redshift and z_{cmb} is the redshift of the CMB rest frame.

4.2 Observational Hubble data (HD)

The investigation into the cosmic expansion history has drawn considerable interest from researchers, primarily due to the model-independent nature of measuring the Hubble parameter $H(z)$. In this paper, we utilize 36 measurements of $H(z)$, where the initial 31 measurements are derived from the cosmic chronometric method (Moresco et al. 2012), three measurements are correlated with the Baryon Acoustic Oscillations (BAO) signal in galaxy distribution (Alam et al. 2017), and the final two measurements are determined from the BAO signal in Lyman-alpha forest distribution alone or cross-correlated with quasistellar objects (QSOs) (Font-Ribera et al. 2014; Delubac et al. 2015).

The χ^2 for 33 Hubble measurement is given by

$$\chi^2_{CC+Ly\alpha} = \sum_{i=1}^{33} \frac{[H_{obs}(z_i) - H_{th}(z_i)]^2}{\sigma_i^2}, \tag{31}$$

In this context, $H_{th}(z_i)$ and $H_{obs}(z_i)$ denote the theoretical and observed values, respectively, while σ_i^2 represents the standard deviation associated with each $H_{obs}(z_i)$.

The χ^2 for the 3 galaxy distribution measurements is given by

$$\chi^2_{gal} = A^T C^{-1} A \tag{32}$$

where C is the covariance matrix given by (Alam et al. 2017)

$$C = \begin{bmatrix} 3.65 & 1.78 & 0.93 \\ 1.78 & 3.65 & 2.20 \\ 0.93 & 2.20 & 4.45 \end{bmatrix}$$

and

$$A = \begin{bmatrix} H_{obs}(0.38) - H_{th}(0.38) \\ H_{obs}(0.51) - H_{th}(0.51) \\ H_{obs}(0.61) - H_{th}(0.61) \end{bmatrix}$$

So, the combined χ^2 for HD is

$$\chi^2_{HD} = \chi^2_{CC+Ly\alpha} + \chi^2_{gal} \tag{33}$$

4.3 Local Hubble constant

Moreover, we incorporate the recent measurement of the local Hubble constant, denoted by $H_0 = 73.5 \pm 1.4$ km s^{-1} Mpc^{-1}, provided by the SH0ES collaboration, as documented in (Reid et al. 2019). Throughout this paper, we use the unit km s^{-1} Mpc^{-1} of Hubble constant.

In order to explore the parameter space, we employ python EMCEE package (Foreman-Mackey et al. 2013) and the MCMC sample technique. Upon minimization of a total χ^2, it will produce the best fits of model parameters $\{c, \omega_h, \alpha, H_0\}$ and M, which is a free normalization parameter used in SNIa observation. Further, we have considered the combinations $SNIa + HD$ and $SNIa + HD + SH0ES$ separately to constrain the model parameters. We have also obtained the best fit values of the model parameters in the case when $\alpha = 0$, i.e., in the case of GR. We present the observational summary in Table 1 and the contour plots for the same are shown in Figs. 1–3 with $1\sigma(68.3\%)$ and $2\sigma(95.4\%)$ confidence level. It is important to notice from contour plots for BHDE model in $f(R,T)$ gravity shown in Figs. 1-2 that the case $\alpha = 0$ is excluded at 2σ confidence level, i.e., the recent observations used in the present

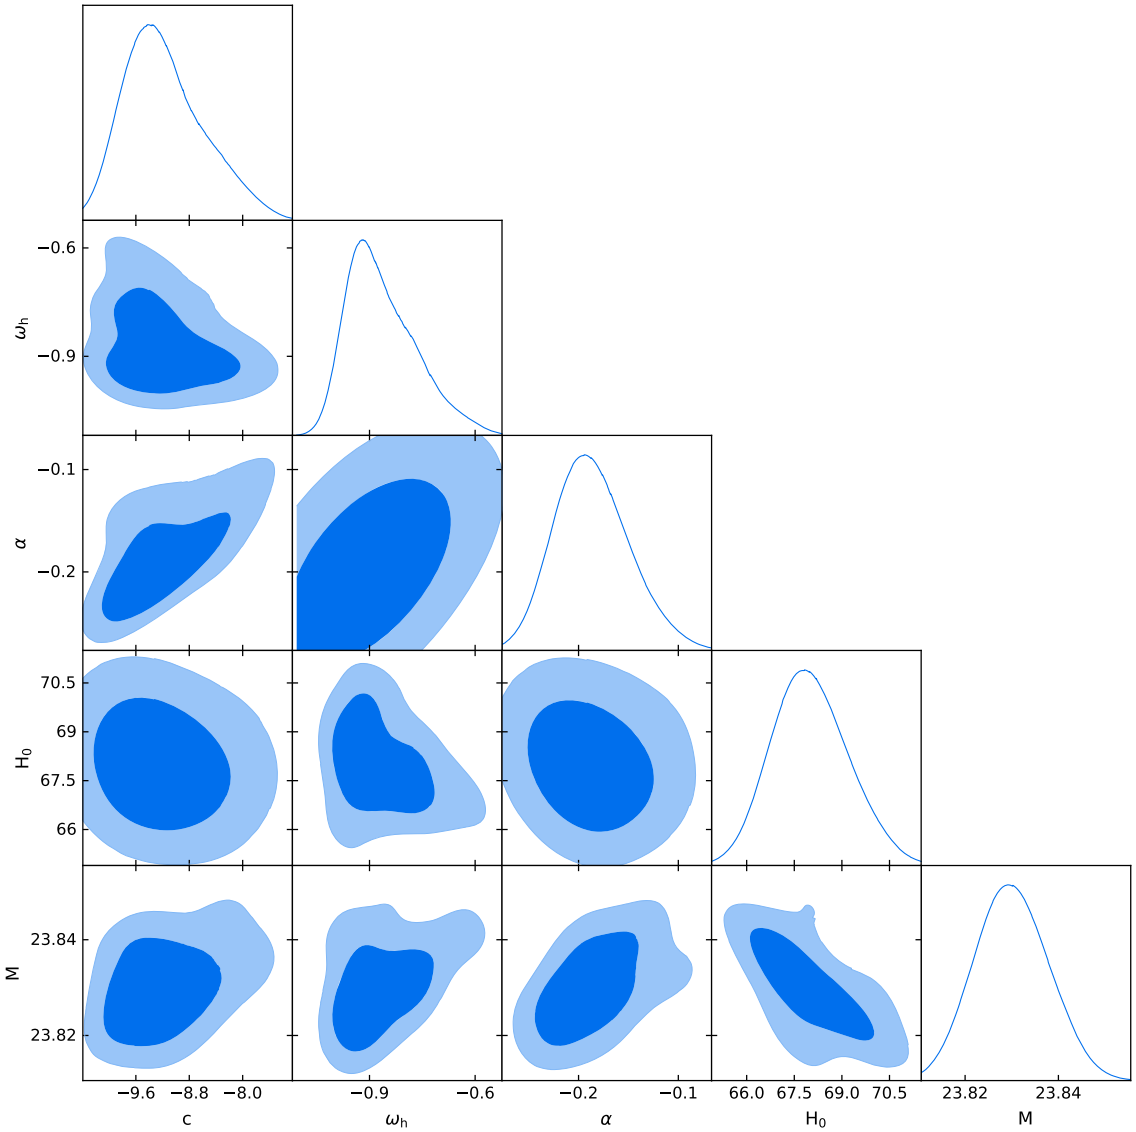

Fig. 1 1σ (68.3%) and 2σ (95.4%) confidence level contour plots for the model parameters using the observational data SNIa+HD

work are favoring $f(R,T)$ gravity over GR. It has also been shown in a recent paper (Bouali et al. 2023) that recent observations favor $f(R,T)$ gravity over GR.

5 Evolution of the model

In the Sect. 3, we have obtained the value of cosmological parameters like Hubble parameter H, DP q and effective EoS parameter ω_{eff} and discussed these parameters to some extent. Then, in Sect. 4, we applied two different combinations of recent observations to estimate the best fit values of the model parameter. Now, in the present section, we are interested to discuss the evolution of the universe through the obtained cosmological parameters in the light of obtained best fit values of the model parameters. We have divided the section into two subsections where in first subsection we discuss cosmological analysis through cosmological parameters and in second subsection we perform diagnostic analysis using statefinder and Om diagnostic.

5.1 Cosmological analysis

To study the cosmic evolution, there are many cosmological parameters which play an important role. Firstly, we plot the Hubble parameter along with the error bar and uncertainty region for the best fit values of the model parameters in Fig. 4. We compare our model with BHDE model in GR and Λ-CDM model. We find that the fitting achieved is compatible with the observational Hubble data at the low redshifts but their evolution with increasing z differs appreciably. For our BHDE model in $f(R,T)$ gravity, we have

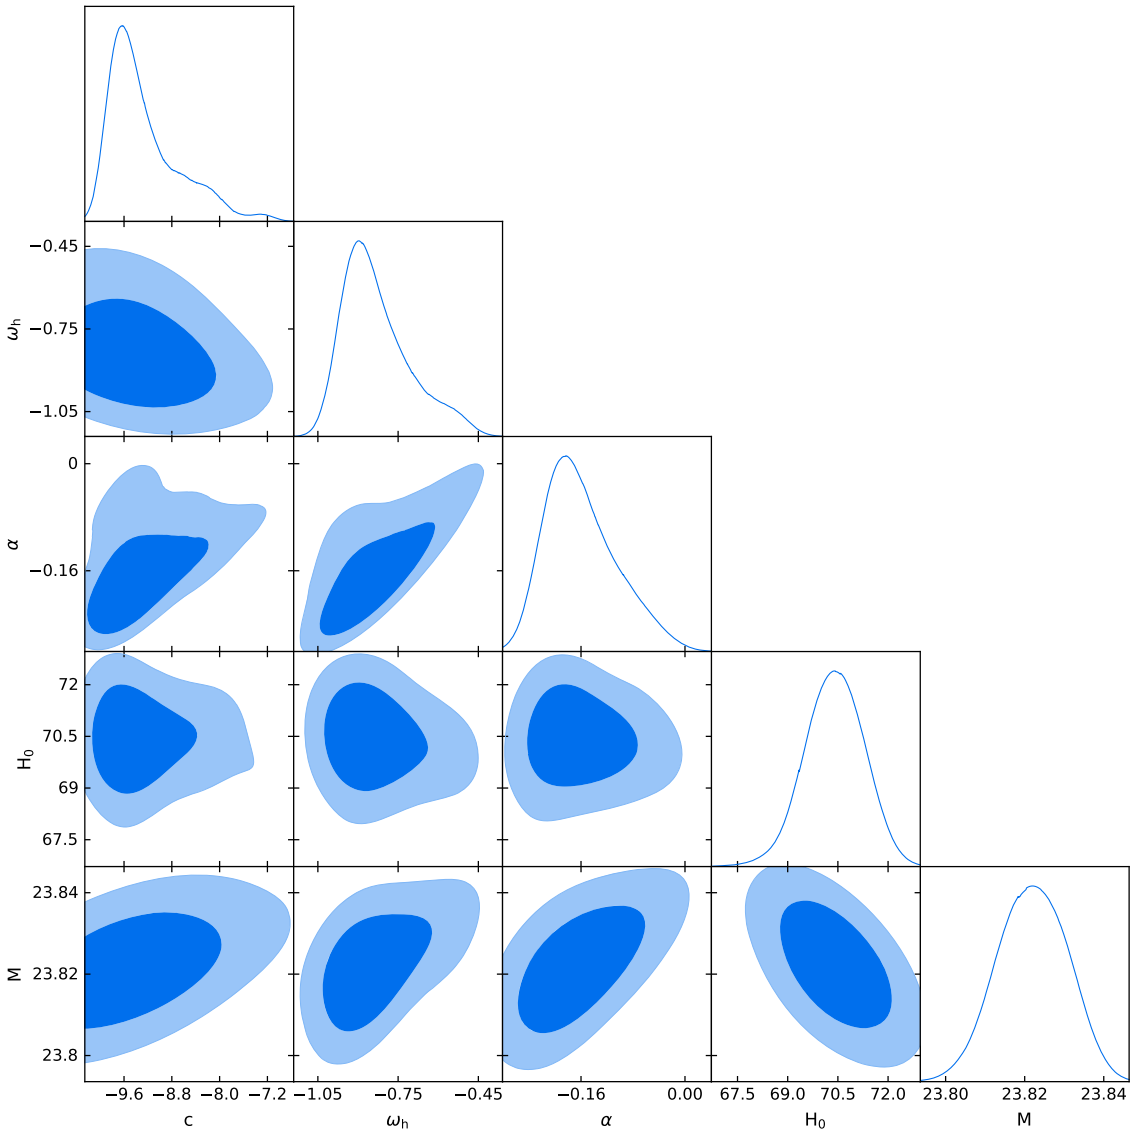

Fig. 2 1σ (68.3%) and 2σ (95.4%) confidence level contour plots for the model parameters using the observational data SNIa+HD+SH0ES

obtained the value of hubble constant $H_0 = 67.764^{+1.274}_{-1.354}$ when we consider combined data $SNIa + HD$ and we have obtained $H_0 = 70.440^{+0.816}_{-0.869}$ for $SNIa + HD + SH0ES$ data. We are observing a significant change in the value of H_0 when we add the data of $SH0ES$ collaboration. In the case of BHDE model in GR, we are getting almost same value $H_0 = 70.646^{+1.054}_{-1.152}$ for $SNIa + HD + SH0ES$ data but with large uncertainty region. The final data of Planck collaboration provided the value $H_0 = 67.4 \pm 0.5$ (Aghanim et al. 2020) taking Λ-CDM model as the model of evolution. In a very recent paper, authors (Riess 2022) have obtained $H_0 = 73.04 \pm 1.04$ using latest Cepheid+SNIa sample in a model independent analysis. We observe that the value of H_0 in our model for $SNIa + HD$ date is very close to the value from Λ-CDM model for Planck data. The value $H_0 = 70.440^{+0.816}_{-0.869}$ obtained from the data $SNIa + HD + SH0ES$ in our model is lying in between the values $H_0 = 67.4 \pm 0.5$ obtained from Λ-CDM model and the model independent value $H_0 = 73.04 \pm 1.04$. The significant difference between the values $H_0 = 67.4 \pm 0.5$ obtained from Λ-CDM model using Planck data and the model independent value $H_0 = 73.04 \pm 1.04$ is the reason of so called H_0 tension. Therefore, the BHDE model in $f(R,T)$ gravity could decrease the H_0 tension, bringing it to an acceptable range of error. It may be observed that the BHDE model in GR also able to decrease the H_0 tension. It has also been shown that HDE may explain the H_0 tension and authors obtained $H_0 = 71.54 \pm 1.78$ using Planck $CMB + BAO$ data (Dai et al. 2020). A detailed review of H_0 tension with the efforts that have been made to resolve it can be seen in (Valentino et al. 2021a,b).

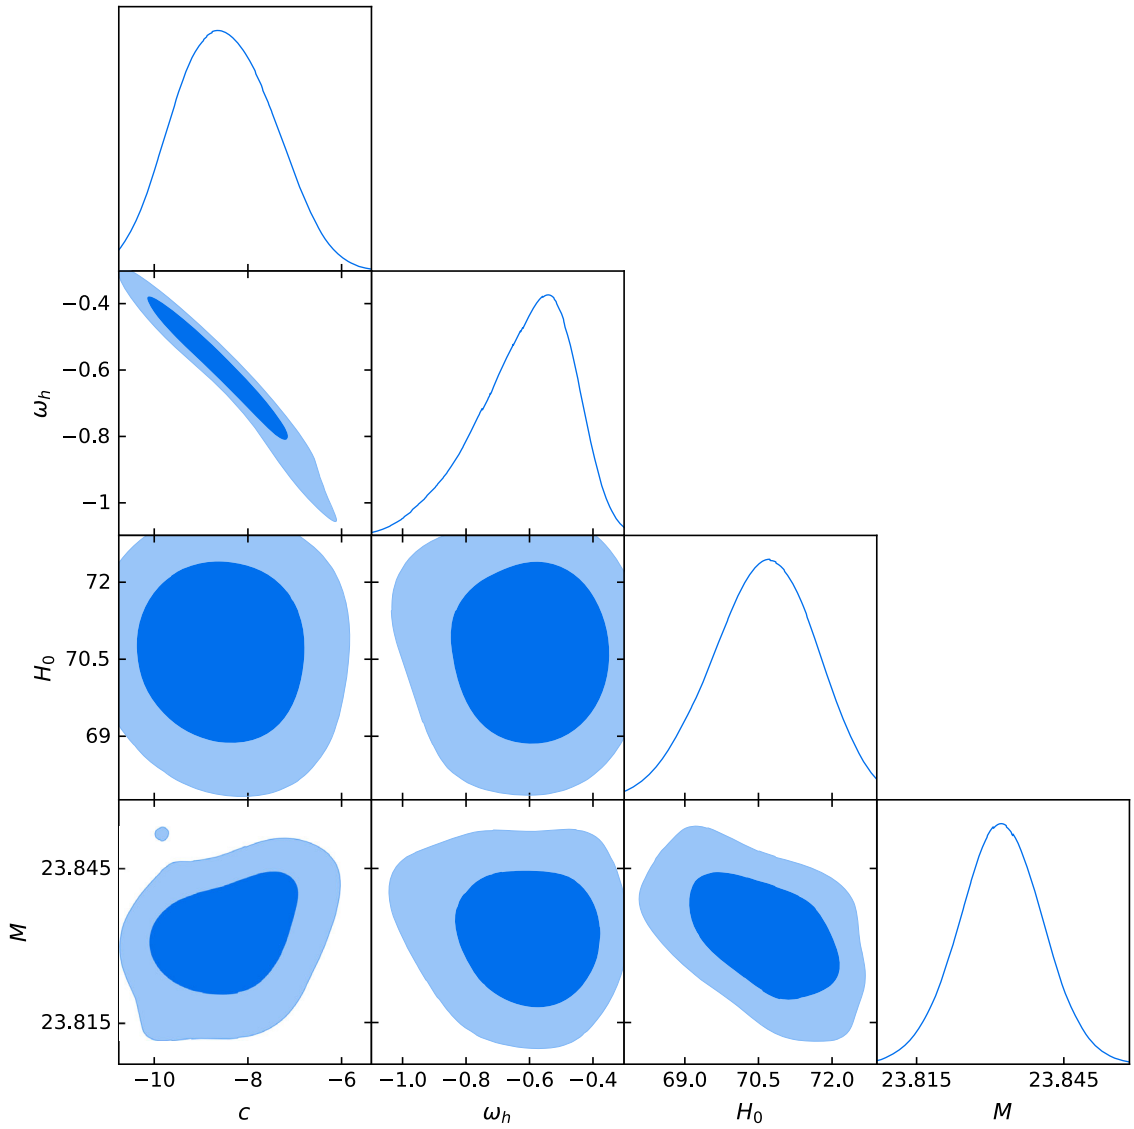

Fig. 3 1σ (68.3%) and 2σ (95.4%) confidence level contour plots for the model parameters using the observational data SNIa+HD+SH0ES for BHDE model in GR

We have plotted the graphs of $q(z)$ for obtained best fit values of the model parameters shown in Fig. 5. We observe a smooth phase transition of the universe from decelerated expansion to accelerated expansion which is compatible with recent observations. The phase transition occurs at transition redshift $z_t = 0.9$ for best fit value of the model parameters obtained from $SNIa + HD$ data and at $z_t = 1.3$ for $SNIa + HD + SH0ES$ data in our model. The transition redshift for the Λ-CDM model has been obtained as $z_t = 0.761 \pm 0.055$ (Lu et al. 2011) and we get $z_t = 1.1$ for $SNIa + HD + SH0ES$ data for BHDE model in GR. The present observational value of DP is given by $q_0 = -0.51 \pm 0.024$ (Riess 2022). One can observe from the Fig. 5 that the values of q_0 in our model is very close to the observational value.

Further, we have plotted effective EoS parameter for best fit values of the model parameters in Fig. 6 which shows that $\omega_{\text{eff}} \to -1$ in the far future ($z \to -1$) for BHDE model in $f(R, T)$ gravity and GR. It is also observed from the figure that our model is free from big-rip singularity as the curve does not cross phantom divide line. It is also important to note that ω_{eff} in not changing the sign in the case of BHDE model in GR as it is changing for $f(R, T)$ gravity, see Fig. 6. If we discuss about the EoS parameter of BHDE ω_h, the current value of ω_h is found to be $-0.873^{+0.115}_{-0.078}$ for $SNIa + HD$ data and $-0.866^{+0.156}_{-0.130}$ for $SNIa + HD + SH0ES$ data, which are in agreement with the value -0.93 predicted by the joint analysis of $WMAP + BAO + H_0 + SNIa$ data (Komatsu et al. 2011), while the value obtained from BHDE model in GR (taking $\alpha = 0$) using $SNIa + HD + SH0ES$

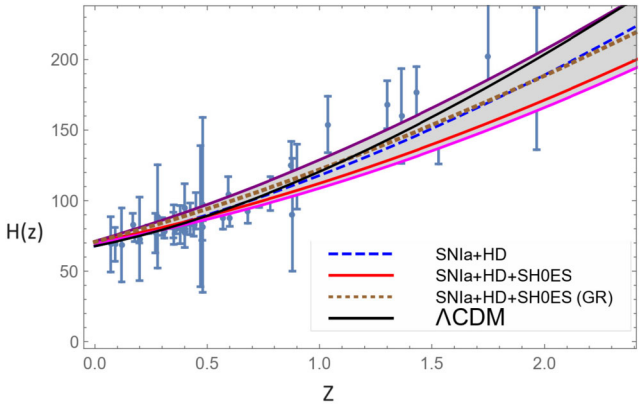

Fig. 4 The evolution of the Hubble parameter as a function of redshift z is depicted for the best-fit values of the BHDE model in both $f(R,T)$ gravity and GR for various data combinations. The uncertainty region for the SNIa+HD+SH0ES dataset is included at 1σ (68.3%) confidence level. The 36 observational $H(z)$ points are shown with grey error bars. Additionally, the variation of the Hubble function in the standard Λ-CDM model is represented by the black solid curve

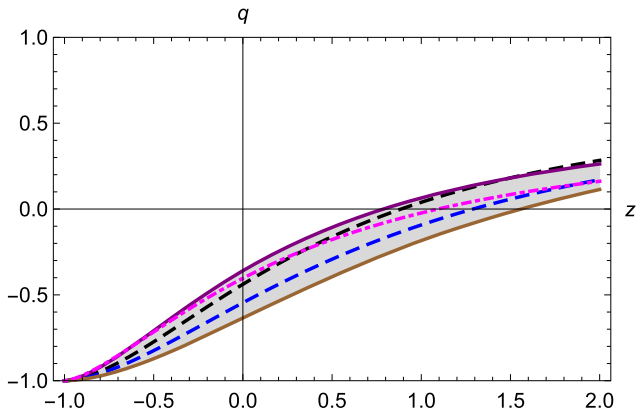

Fig. 5 We have plotted deceleration parameter against redshift z for best fit values of the model parameters where black dashed line corresponds to SNIa+HD data, blue dashed line correspond to SNIa+HD+SH0ES data and magenta dashed line represents trajectory for BHDE in GR for SNIa+HD+SH0ES data. The uncertainty region for the SNIa+HD+SH0ES dataset is included at 1σ (68.3%) confidence level

data is $-0.577^{+0.178}_{-0.105}$ which is very low in comparison of the observed value. Thus, BHDE model behaving significantly different in GR and $f(R,T)$ gravity on the basis of EoS parameters.

Next, we can calculate the age of the universe at the redshift z, which is given by $t(z) = T(z)/H_0$, where

$$T(z) = \int_z^\infty \frac{dz'}{(1+z')(H(z')/H_0)} \tag{34}$$

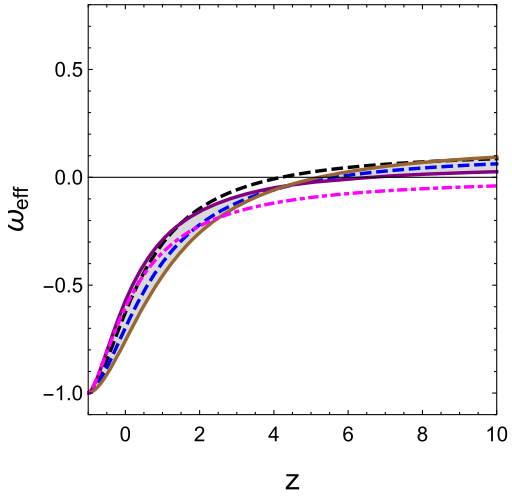

Fig. 6 The behavior of effective equation of state parameter as a function of z for best fit values of the model parameters has been plotted. The black dashed line corresponds to SNIa+HD data, blue dashed line correspond to SNIa+HD+SH0ES data and magenta dashed line represents trajectory for BHDE in GR for SNIa+HD+SH0ES data. The uncertainty region for the SNIa+HD+SH0ES dataset is included at 1σ (68.3%) confidence level

is dimensionless age parameter. For Λ-CDM model, the age parameter is (Feng and Li 2009)

$$T(z) = \int_z^\infty \frac{dz'}{(1+z')[\Omega_{m0}(1+z')^3 + (1-\Omega_{m0})]^{1/2}}. \tag{35}$$

With the help of above equations, we have plotted the age of the universe against the redshift z in Fig. 7. We have also plotted the age of the universe corresponding to concordance model (Λ-CDM model) for comparison with our model. The current age of the universe is found to be $t_0 = 14.09$ Gyr corresponding to $SNIa + HD$ data whereas it is found to be $t_0 = 15.43$ Gyr corresponding to $SNIa + HD + SH0ES$ data. It is observed that the age corresponding to the $SNIa + HD$ data is slightly higher but the age corresponding to $SNIa + HD + SH0ES$ data is comparatively much higher than the concordance model ($t_0 \sim 13.8$ Gyr). The age for BHDE model in GR is found to be $t_0 = 14.72$ Gyr corresponding to $SNIa + HD + SH0ES$ data which is also higher than the concordance model. The Λ-CDM model faces the age problem because stars have been found in the universe having age more than the age of universe predicted by the model. Moreover, the existence of early galaxies is also not compatible with the age of universe provided by the Λ-CDM model (see Gupta 2023 and references therein). The age of universe for the BHDE model in $f(R,T)$ gravity is higher than in GR corresponding to $SNIa + HD + SH0ES$ data. However, both models are able to resolve the age problem of Λ-CDM model but the BHDE model in $f(R,T)$ gravity seems more suitable as it provides higher value $t_0 = 15.43$ Gyr of the age of universe.

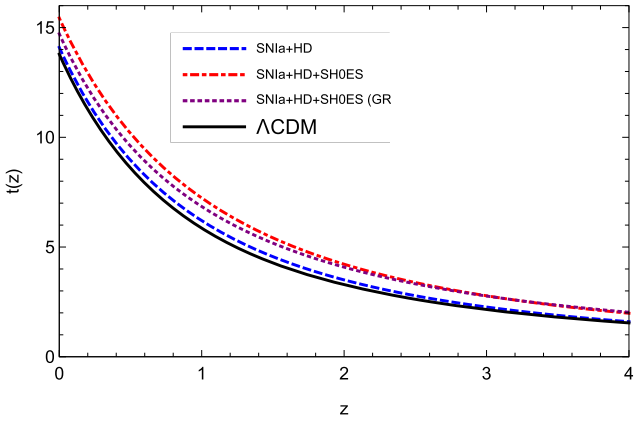

Fig. 7 The age of universe as a function of z plotted for best fit values of the model parameters. The blue dashed line corresponds to SNIa+HD data, red dot dashed line correspond to SNIa+HD+SH0ES data, violate dashed line represents trajectory for BHDE in GR for SNIa+HD+SH0ES data and solid black line corresponds to Λ-CDM model

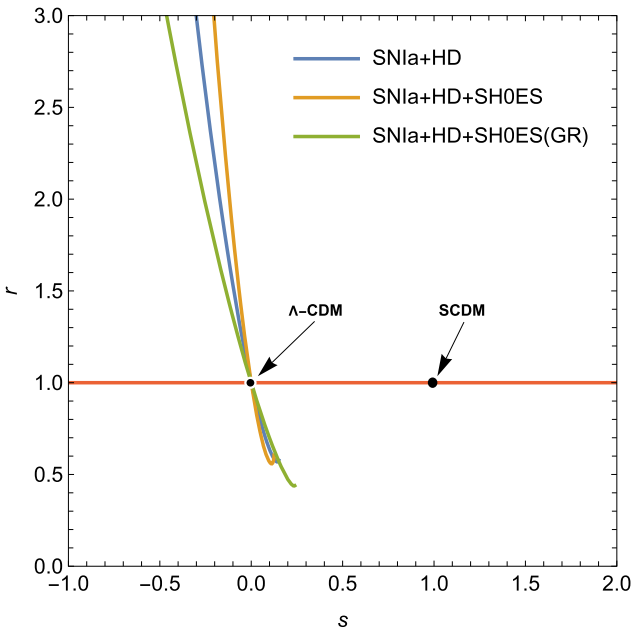

Fig. 8 The trajectories in $r - s$ plane are plotted for best fit values of the model parameters. The blue line corresponds to SNIa+HD data, magenta line corresponds to SNIa+HD+SH0ES data and green line represents trajectory for BHDE in GR for SNIa+HD+SH0ES data

Moreover, the observations also favouring $f(R,T)$ gravity over GR which has been discussed in Sect. 4.

5.2 Diagnostic analysis

Sahni et al. (2003) proposed a new diagnostic pair {r, s} to discriminate among DE models and the analysis is called the statefinder analysis. Alam et al. (2003) presented a detailed study on statefinder analysis. The statefinder is a geometrical diagnostic and allows us to characterize the properties of DE in a model-independent manner. The standard Λ-CDM model has the value of the statefinder pair {1, 0} and SCDM model has the value {1, 1}. Based on the behavior of trajectories in $r - s$ plane for a model, we can discriminate the model with other DE models. The statefinder pair {r, s} is defined as follows (Sahni et al. 2003)

$$r = \frac{\dddot{a}}{aH^3}, \quad s = \frac{(r-1)}{3(q-\frac{1}{2})}, \tag{36}$$

where the notations have their usual meaning. We have obtained the values of the statefinder parameters r and s for our model which are given by

$$r = \frac{e^{\frac{-6(1+\alpha)(2\alpha+1)c^2\omega_h t_0}{(3\alpha+2)}}}{H_0^2(2+3\alpha)^2}\Big[e^{\frac{6(1+\alpha)(2\alpha+1)c^2\omega_h t_0}{(3\alpha+2)}} H_0^2(2+3\alpha)^2$$
$$- 9e^{\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h (t+t_0)}{(3\alpha+2)}}$$
$$\times H_0(1+3\alpha+2\alpha^2)(H_0+c^2\omega_h(1+2\alpha))$$
$$+ 9e^{\frac{6(1+\alpha)(2\alpha+1)c^2\omega_h t}{(3\alpha+2)}}(1+\alpha)^2(H_0+c^2\omega_h(1+2\alpha))^2\Big],$$

$$s = 1/\Big(3H_0^2(2+3\alpha)^2$$
$$\times \Big(-\frac{1}{2}$$
$$+ \frac{e^{\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_0)}{(3\alpha+2)}}(H_0+3c^2\omega_h(1+3\alpha+2\alpha)^2)}{H_0(2+3\alpha)}\Big)\Big)$$
$$\Big[-9e^{\frac{3(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_0)}{(3\alpha+2)}}$$
$$\times H_0(1+3\alpha+2\alpha^2)(H_0+c^2\omega_h(1+2\alpha))$$
$$+9e^{\frac{6(1+\alpha)(2\alpha+1)c^2\omega_h(t-t_0)}{(3\alpha+2)}}(1+\alpha)^2(H_0+c^2\omega_h(1+2\alpha))^2\Big].$$

We have plotted trajectories in $r - s$ plane for our model shown in Fig. 8. The trajectories show Chaplygin gas type of behavior in starting, pass through Λ-CDM fixed point (1,0) during the evolution and then show quintessence type of behavior in the late evolution. Two trajectories in the figure have been plotted for best fit values of the model parameters obtained from $SNIa + HD$ data and $SNIa + HD + SH0ES$ data, where $t_0 = 1$ has been considered to plot the trajectories. We have also plotted trajectory of BHDE model in GR for best fit values of the model obtained from $SNIa + HD + SH0ES$ data. The trajectory shows qualitatively same behavior as in $f(R,T)$ gravity. We observe that the trajectories show small deviation in Chaplygin gas region but overall behavior of the trajectories remain same.

We have used another diagnostic parameter, called Om, which was introduced by Sahni et al. (2008) to distinguish various DE models from the Λ-CDM model. The slope of

$Om(z)$ can differentiate between different models of DE even if the value of the matter density is not accurately known. The Om diagnostic depends explicitly on the Hubble parameter H and is defined by

$$Om(z) = \frac{\frac{H^2(z)}{H_0^2} - 1}{(1+z)^3 - 1}. \tag{37}$$

With the help of (23), $Om(z)$ for our model can be obtained as

$$Om(z) = \frac{1}{(1+z)^3 - 1}\left[-1 + \frac{1}{H_0^2}\left\{ H_0(1+z)^{\frac{3(1+\alpha)}{2+3\alpha}} + c^2\omega_h(1+2\alpha)\left(-1 + (1+z)^{\frac{3(1+\alpha)}{2+3\alpha}} \right) \right\}^2 \right]. \tag{38}$$

To analyse the behavior of $Om(z)$, we plot the graph in $Om(z) - z$ plane for the best fit values of model parameters in Fig. 9. It is to be noted that the positive slope of $Om(z)$ represents phantom like behavior of DE whereas the negative slope represents the quintessence behavior. It can be observed from the figure that the trajectories of $Om(z)$ have the negative slope which represents the behavior similar to the quintessence model. The trajectory of the BHDE model in GR also shows similar behavior but it has more negative slope.

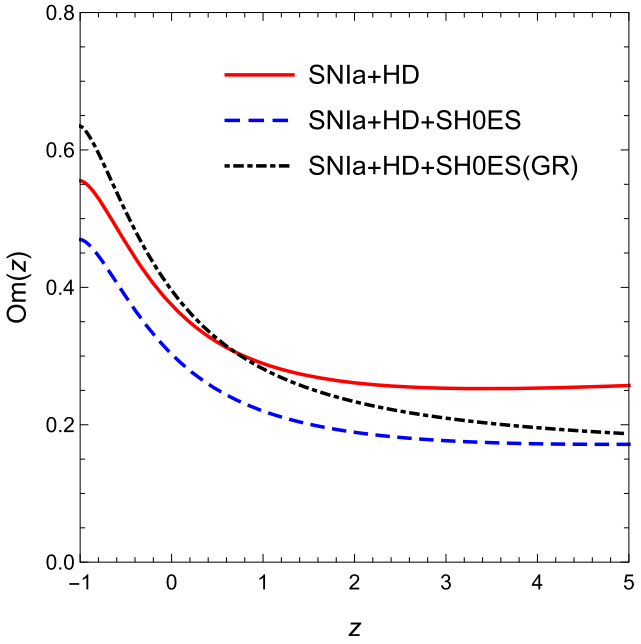

Fig. 9 The trajectories in $Om(z) - z$ plane are plotted for best fit values of the model parameters. The solid red line corresponds to SNIa+HD data, blue dashed line correspond to SNIa+HD+SH0ES data and black dot dashed line represents trajectory for BHDE in GR for SNIa+HD+SH0ES data

6 Conclusion

In the present work, we have analyzed a modified version of HDE based on Barrow entropy known as BHDE in the framework of $f(R,T)$ theory. We have considered a flat FLRW universe to discuss the model which is filled with BHDE and DM. The Hubble horizon has been considered as IR cut-off to obtain the energy density of BHDE because it is simplest and causal free choice for IR cut-off. We obtained the field equation of BHDE model in the framework of $f(R,T)$ theory and observed that the field equations can be solved analytically for only two values of BHDE parameter $\Delta = 0, 1$. For $\Delta = 0$, BHDE reduces to HDE and one will get the same result as obtained in (Singh and Kumar 2016). We consider a maximal deformation from the standard Bekenstein-Hawking entropy which is given by $\Delta = 1$ to obtain analytical solution of the field equations. In process to analyse the cosmic evolution, we have obtained the values of Hubble parameter and cosmic scale factor. Further, we have obtained the DP q and effective EoS parameter ω_{eff} using the values of Hubble parameter and cosmic scale factor.

In the present scenario, the observations are playing a crucial role in cosmology. Enormous amount of data being received every year and new probes being launched to explore every aspects of the universe. Therefore, it becomes utmost important to explore a theoretical model of cosmic evolution using available observational data. We have explored the model observationally and obtained best fit values of the model parameters using the MCMC method. The BHDE model in the framework of GR has been discussed (Adhikary et al. 2021; Oliveros et al. 2022) and has been constrained using observational data (Anagnostopoulos et al. 2020). Our BHDE model in $f(R,T)$ gravity gets converted in the BHDE model in GR for the parameter value $\alpha = 0$. Therefore, we have also constrained the BHDE model in GR taking $\alpha = 0$ in our model using the latest observational data to compare the results of both models. We have used two combinations $SNIa + HD$ and $SNIa + HD + SH0ES$ of the latest observational data to constrain model parameters. We observed that the best fit values of H_0 and ω_h with in BHDE model in $f(R,T)$ gravity are in good agreement with latest observational values of the parameters. Contour plots for the same are shown in Figs. 1–3 with $1\sigma(68.3\%)$ and $2\sigma(95.4\%)$ confidence level. The BHDE model in $f(R,T)$ gravity is able to reduce the Hubble tension. It is important to note that the case $\alpha = 0$, where $f(R,T)$ gravity gets converted in GR, is excluded at 2σ confidence level, i.e., the recent observations are favoring $f(R,T)$ gravity over GR.

We have plotted graphs of q against redshift parameter z for observationally estimated values of model parameters. The graphs show a smooth phase transition from early decelerated expansion to recent accelerated expansion. We have observed that the phase transition occurs at $z_t = 0.9$ for best fit value of the model parameters obtained from $SNIa + HD$ data and at $z_t = 1.3$ for $SNIa + HD + SH0ES$ data which shows compatibility with the observations. The current value of ω_h is found to be $-0.873^{+0.115}_{-0.078}$ for $SNIa + HD$ data and $-0.866^{+0.156}_{-0.130}$ for $SNIa + HD + SH0ES$ data, which are in agreement with the value -0.93 predicted by the joint analysis of $WMAP + BAO + H_0 + SNIa$ data (Komatsu et al. 2011). While, the value $-0.577^{+0.105}_{-0.178}$ obtained for BHDE model in GR for $SNIa + HD + SH0ES$ data is not compatible with the above values.

The current age of the universe is found to be $t_0 = 14.09\ Gyr$ corresponding to $SNIa + HD$ data set whereas it is found to be $t_0 = 15.43\ Gyr$ corresponding to $SNIa + HD + SH0ES$ data set. It is found to be $t_0 = 14.72\ Gyr$ corresponding to $SNIa + HD + SH0ES$ data set for BHDE model in GR. The age of the universe for BHDE model within $f(R, T)$ gravity is higher than in GR corresponding to $SNIa + HD + SH0ES$ data. However, both the model are able to resolve the age problem of Λ-CDM model but the BHDE model in $f(R, T)$ gravity seems more suitable. Moreover, we have analyzed our model using statefinder analysis and Om diagnostic to compare our model with other existing DE models. The statefinder analysis shows that the model shows similarity with Chaplygin gas in early phase evolution, go through the fixed point value of Λ-CDM model and shows quintessence type of behavior in late time evolution. It is to be noted that statefinder analysis of HDE model in $f(R, T)$ gravity has showed that the model behaves like quintessence model throughout the evolution (Singh and Kumar 2016). Thus, BHDE presents more richer phenomenon than HDE as discussed by Saridakis (2020). The BHDE model in GR presents qualitatively similar behavior as in $f(R, T)$ gravity as far as the statefinder and Om diagnostics are concerned.

Acknowledgements We are grateful to Prof. A. Beesham for fruitful discussion and help to improve the quality of the manuscript. We are thankful to the anonymous referees for their helpful comments and suggestions, which have enhanced the completeness of this manuscript.

Author contributions K.D. wrote the main manuscript text and all other authors contributed to the final version of it. A.K. complied with the observational data analysis. The analysis of the manuscript was completed by all authors. The graphs was made by all the authors.

Funding No funding was obtained to complete this research work.

Data Availability No datasets were generated or analysed during the current study.

***Abstract*—The use of neural networks and deep learning techniques in image processing has significantly advanced the field, enabling highly accurate recognition results. However, achieving high recognition rates often necessitates complex network models, which can be challenging to train and require substantial computational resources. This research presents a simplified yet effective approach to predicting both the base and exponent from images of mathematical expressions using a multi-output Convolutional Neural Network (CNN). The model is trained on 10,900 synthetically generated images containing exponent expressions, incorporating random noise, font size variations, and blur intensity to simulate real-world conditions. The proposed CNN model demonstrates robust performance with efficient training time. The experimental results indicate that the model achieves high accuracy in predicting the base and exponent values, proving the efficacy of this approach in handling noisy and varied input images.**

I. Introduction

Optical character recognition (OCR) technology encompasses both handwritten and printed character recognition, with applications ranging from postal code and financial value identification to tax form recognition and e-commerce digital processing. While significant progress has been made in these areas, achieving perfect recognition accuracy remains an ongoing challenge due to the variability and complexity of input images. In recent years, deep learning techniques, particularly Convolutional Neural Networks (CNNs), have revolutionized the field of image processing. CNNs are characterized by their local connectivity, weight sharing, and pooling operations, which enable them to extract robust and descriptive features from images. These attributes make CNNs well-suited for tasks requiring high accuracy in image recognition. This research focuses on a specialized application of CNNs: predicting the base and exponent values from images of mathematical expressions. Traditional approaches to OCR often struggle with the unique challenges posed by these images, which can include random noise, varying font sizes, and blur intensity. To address these challenges, we propose a multi-output CNN model that can simultaneously predict both the base and exponent from a single image. Our model is trained on a synthetically generated dataset of 10,900 images containing exponent expressions, designed to simulate real-world conditions with added noise and variations. Data augmentation techniques are employed to further enhance the model's generalization capabilities. The results demonstrate that our approach achieves high accuracy, offering a practical solution for recognizing mathematical expressions in noisy and varied contexts. This paper outlines the design and implementation of the multi-output CNN, detailing the pre processing steps, model architecture, and training process. Experimental results validate the effectiveness of our approach, highlighting the potential for applying similar techniques to other complex image recognition tasks.

II. Principles of the Method

A. Multi-Output CNN for Exponential Expression Recognition

In this paper, the methodology is divided into two main parts: model training and model testing. For model training, the Convolutional Neural Network (CNN) continuously updates the network parameters based on a synthetic dataset of 10,900 images. The dataset includes various forms of noise, font size variations, and blur to enhance the model's robustness. For model testing, the system evaluates the performance of the trained network on unseen images, predicting the base and exponent values, and demonstrates the model's generalization capability.

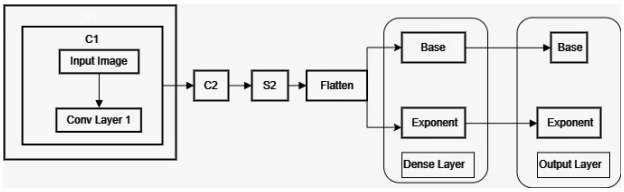

Fig. 1. CNN architecture for mathematical expression recognition.

B. Structure of the CNN

The CNN architecture is designed to process two-dimensional input matrices and is composed of several key layers:

- **Convolutional Layers**: The network begins with convolutional layers that extract hierarchical features from input images. Each convolutional layer applies filters to the input to produce feature maps.

1) Convolution Operation:

$$z_{i,j,k} = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} x_{i+m,j+n} \cdot w_{m,n,k} + b_k \quad (1)$$

where:

- $z_{i,j,k}$ is the output of the k-th filter at position (i, j),
- $x_{i+m,j+n}$ is the input pixel value at position $(i + m, j + n)$,
- $w_{m,n,k}$ is the weight of the k-th filter at position (m, n),
- b_k is the bias term for the k-th filter,
- $M \times N$ is the filter size.

- **Pooling Layers**: After convolution, pooling layers downsample the feature maps, reducing spatial dimensions while retaining important features. Max pooling is used in this architecture.
- **Fully Connected Layers**: Flattened outputs from the convolutional and pooling layers are passed through fully connected layers to generate the final predictions for base and exponent.

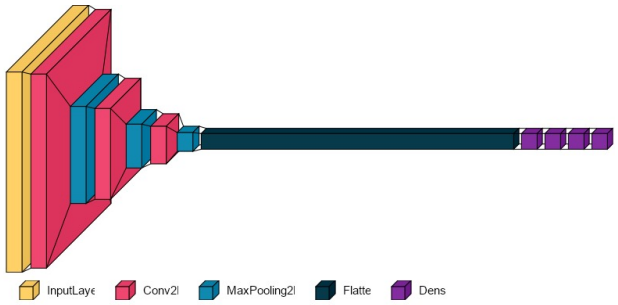

Fig. 2. Detailed CNN architecture of the model.

The convolution operation in a single layer is defined as:

$$(I * K)(i, j) = \sum_m \sum_n I(i + m, j + n)K(m, n) \quad (2)$$

where I is the input image and K is the convolution kernel. The Rectified Linear Unit (ReLU) activation function is used:

$$\text{ReLU}(x) = \max(0, x) \quad (3)$$

The CNN consists of multiple convolutional and pooling layers. The input pixel matrix is processed through convolution layers with various filters, followed by pooling operations to reduce dimensions. The final output is vectorized for classification. The convolution and pooling layers are trained to optimize the model's performance using algorithms like gradient descent.

C. Forward Propagation and Softmax Function

Forward propagation in the CNN involves passing the input through the network layers to obtain the output predictions. This process includes convolution, activation, pooling, and fully connected layers.

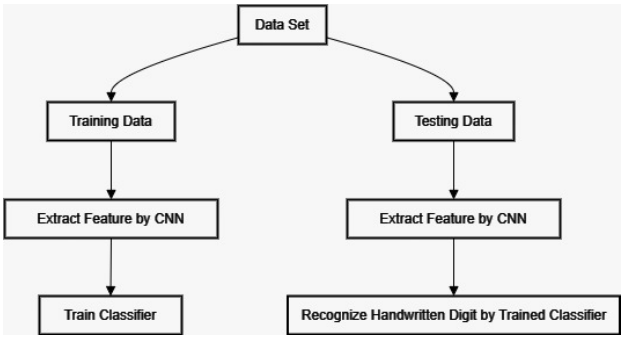

Fig. 3. Forward propagation through the CNN.

The softmax function is used to map the CNN's output into probability distributions:

$$\text{softmax}(V_i) = \frac{e^{V_i}}{\sum_j e^{V_j}} \quad (4)$$

where V_i represents the score for class i.

For multi-class classification, the loss function employed is sparse categorical cross-entropy:

$$\text{Loss} = -\sum_i y_i \log(\hat{y}_i) \quad (5)$$

where y_i is the true label and $\hat{y}_i$ is the predicted probability. The gradient descent method is used to optimize the model by updating the gradients with respect to the loss function.

III. Datasets

The dataset used for training and testing the CNN consists of 10,900 synthetic images of exponential expressions. These images are generated to include variations in noise, font size, and blur, designed to challenge and evaluate the model's performance. Each image is labeled with the base and exponent values to facilitate supervised learning.

IV. Experiments

Our experiments are divided into two main parts: training and testing.

A. Training

For the training phase, we utilized a convolutional neural network (CNN) model to learn from a dataset of 10,000 synthetically generated images. These images were created to simulate real-world conditions, incorporating variations in random noise, font size, and blur intensity. The CNN was trained using this dataset with the goal of predicting both the base and exponent values from images of mathematical expressions.

The network was trained over a total of 50 epochs. During training, the model's parameters were updated based on the loss function, which was computed using the cross-entropy loss for both the base and exponent outputs. The training process involved optimizing the model using the Adam optimizer and monitored with early stopping to prevent overfitting.

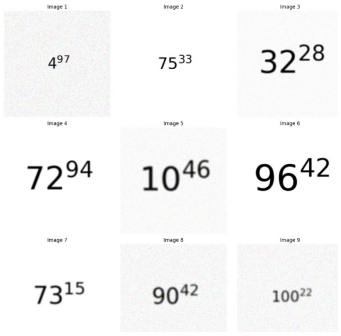

Fig. 4. Sample images from the test dataset with varying levels of noise and blur.

B. Testing

For the testing phase, we evaluated the performance of the trained CNN model using a separate test dataset. This dataset consisted of 1,000 images that were not seen by the model during the training phase. The test images were processed similarly to the training images, including normalization and resizing.

The performance of the model was assessed based on its accuracy in predicting the base and exponent values from the test images. Additionally, we evaluated the model's robustness by introducing varying levels of noise and blur to the test images to simulate real-world conditions.

Figure 4 shows some of the images from our test dataset, which include various levels of noise and blur to test the model's robustness.

We also analyzed the distribution of the base and exponent values in the test dataset to ensure a balanced representation. Figure 5 and Figure 6 illustrate these distributions.

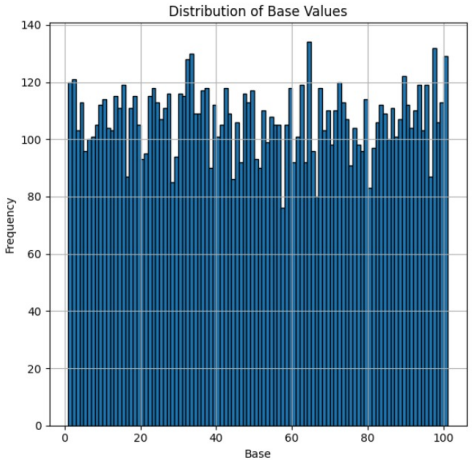

Fig. 5. Distribution of base values in the test dataset.

To further evaluate the model's performance, we examined the distribution of image attributes such as blur and noise levels in the test dataset. Figure 7 and Figure 8 show these distributions.

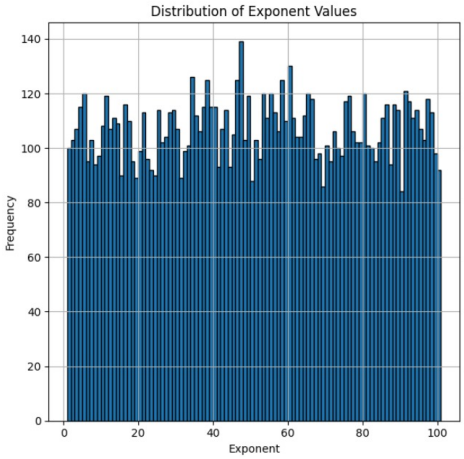

Fig. 6. Distribution of exponent values in the test dataset.

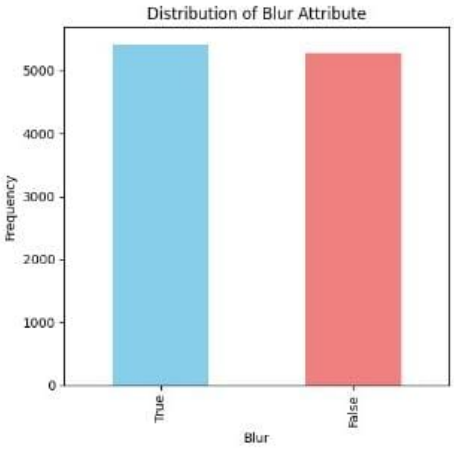

Fig. 7. Distribution of blur levels in the test dataset.

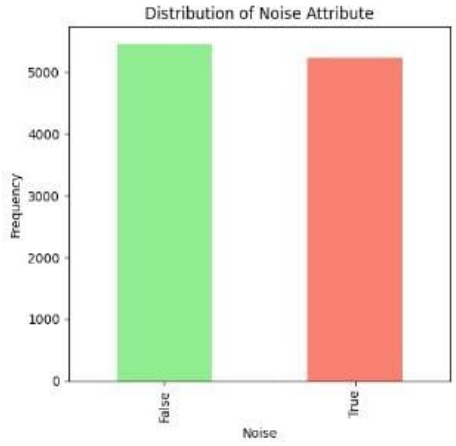

Fig. 8. Distribution of noise levels in the test dataset.

The model is able to accurately predict the base and exponent values from the images, demonstrating its robustness and effectiveness in handling real-world conditions. The results

from the testing phase confirm that the trained CNN model performs well even with variations in noise and blur levels, maintaining a high level of accuracy in its predictions.

The experimental results showed that the model achieved high accuracy in predicting both the base and exponent values. The effectiveness of the CNN was demonstrated through its ability to handle noisy and varied input images, maintaining a high level of performance across different test scenarios.

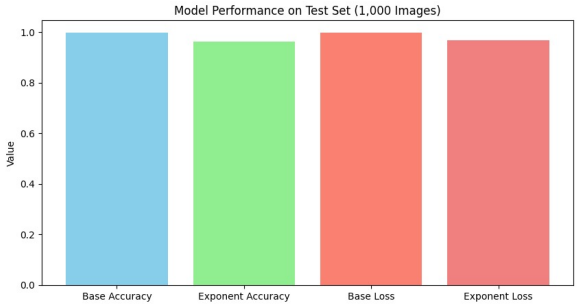

Fig. 9. Results of the testing phase showing model performance on various test scenarios.

V. Conclusion

In this paper, we have presented a comprehensive system for predicting base and exponent values from images of mathematical expressions using a multi-output Convolutional Neural Network (CNN). Our method demonstrates high accuracy and robustness in recognizing and predicting these values, even under varying conditions such as different levels of noise and blur.

The trained model was evaluated using a Python-generated dataset of 10,000 images, and testing showed that the model maintained high performance in predicting the desired outputs. The experimental results confirmed that our approach is effective and efficient, handling real-world variations and maintaining a high level of accuracy.

Compared to traditional methods, such as Histogram of Oriented Gradient (HOG), our CNN-based approach provides significant advantages in terms of accuracy, speed, and robustness. The ability of the model to generalize well to unseen data and to handle different image attributes makes it a strong candidate for practical applications in various fields.

In the future, we plan to extend our work by incorporating more diverse datasets to further improve the model's generalizability. Additionally, we aim to optimize the model architecture and explore advanced techniques such as transfer learning to enhance the performance and efficiency of the system. We also intend to integrate real-time processing capabilities to facilitate immediate feedback and predictions, making the system more applicable in dynamic and interactive environments.

Overall, our research demonstrates the potential of deep learning techniques in solving complex recognition tasks, and we are optimistic about the future advancements and applications of our work.

Acknowledgments

The authors would like to express their sincere gratitude to the anonymous reviewers and the editor for their insightful comments and suggestions, which have significantly contributed to enhancing the presentation and theoretical aspects of this paper. Their valuable feedback has been instrumental in improving the quality and clarity of this work.

Camera-based Mobility Framework for Visually Impaired Pedestrians in Unstructured Environments

Aditya Kumar[1*], Anwesha Chakravarty[1*], Ayesha Choudhary[1], S. Indu[2]

2024 IEEE Intelligent Vehicle Symposium (IV) | 979-8-3503-4881-1/24/$31.00 ©2024 IEEE | DOI: 10.1109/IV55156.2024.10588516

Abstract— **Developing automatic mobility assistance systems for the safe navigation of visually impaired pedestrians in unstructured environments presents several complex challenges. The dynamic and unpredictable conditions and the diverse range of obstacles encountered by a pedestrian walking on an unstructured road add to the difficulties of automatic navigation. Another significant aspect of safe mobility assistance is real-time performance, which demands lightweight architectures and fast processing. In this paper, we propose an obstacle detection framework combining a road object detection model and a road anomaly detection model, using parallel processing for fast real-time performance. The models are based on convolutional neural network backbones, use transfer learning, and are trained on custom datasets manually collected in unstructured environments. The proposed system addresses the challenges of the complexities of the camera-based automatic navigation to detect obstacles and, based on their position and size, alerts the user via audio feedback.**

I. Introduction

In this paper, we propose a novel, deep learning and computer vision-based framework for automatically detecting outdoor objects and road anomalies for the safe mobility of visually impaired pedestrians in unstructured environments. We construct two novel image datasets of various kinds of road anomalies, such as puddles and potholes, and different road objects, such as trees, poles and signboards, that can cause distress and harm to visually impaired pedestrians, both captured manually from unstructured environments. We train object detection models on the curated datasets. Finally, we design a parallelly combined real-time system for fast and reliable detection of obstacles that notifies the user based on the risks posed by their surroundings.

Unstructured environments include road systems and cityscapes with inconsistent layouts. They are often characterised by an unpredictable road structure, absent pavements and sidewalks, and makeshift paths. These are often accompanied by poorly maintained roads and varying road conditions due to weather, ongoing construction work, irregular traffic, etc. Unstructured road systems are challenging to navigate because of the unpredictable and dynamic conditions, as shown in Figure 1. Such road systems are particularly inaccessible and risky for visually impaired pedestrians and can lead to accidents.

On the other hand, structured environments are well-planned, often comprising organised streets, designated zones for vehicles to pass, cycles, parking and pedestrian pathways, and an overall standardised infrastructure. Such environments are more accessible to navigate because of the clearly defined structure. Most existing mobility assistance systems are trained on data captured from structured environments because they are easier to work on and due to a lack of diverse and reliable datasets of unstructured environments. As a result, most of the mobility assistance systems fail in unstructured environments. This gives rise to the paramount need for datasets captured from unstructured environments and mobility assistance systems trained on such datasets to function in outdoor environments, irrespective of their structure.

Fig. 1: Unstructured roads with limited walkable area with (a) a pothole and two-wheeler, and (b) puddles and a tree.

Visually impaired pedestrians face numerous difficulties while navigating unstructured roads, posing significant challenges to their mobility and independence. Uneven surfaces like potholes, puddles or sudden depressions can cause tripping, stumbling, or falls, leading to injuries. Detecting them in advance is highly challenging without vision. Identifying parked or moving vehicles, poles, trees, signboards, etc. and navigating these obstructions can be difficult and pose a collision risk. Judging the distance and speed of moving vehicles without sight is challenging and can lead to severe accidents. The severity of these difficulties can vary depending on the individual's level of vision impairment, their mobility aids, and their familiarity with the environment. Weather conditions like rain and other circumstantial factors can further exacerbate these challenges. Overcoming these barriers requires improving the infrastructure design and assistive technologies that can adapt to unstructured environments.

Visually impaired people primarily rely on the traditional white cane for navigation. While undoubtedly instrumental, the white cane encounters significant limitations in unstructured environments, amplifying the existing navigational challenges. Firstly, the cane's limited reach restricts sensory input to the immediate ground, leaving potholes and broken roads undetected. Gauging the distance and size of more considerable obstacles like vehicles or poles proves challenging, hindering safe manoeuvring around them. Furthermore, the lack of defined paths or designated pedestrian zones on unstructured roads can throw navigation into disarray. Accurately judging the movement and speed of oncoming vehicles, which is crucial for safe road crossing, with a cane can be extremely risky. While the white cane remains a valuable tool, camera-based assistive systems are increasingly necessary to address its limitations on complex and unstructured terrains, ensuring more excellent safety and independence for visually impaired individuals.

While promising for visually impaired individuals, camera-based assistive systems come with their challenges. Obstacle detection is difficult amidst shadows, varying lighting, diverse backgrounds, and occlusion. Another major challenge is real-time processing and high computation demands, which is crucial for safety. In this work, we have considered road anomalies such as potholes, puddles, cracks, and patches, and road objects such as trees, poles, signboards, two-wheelers, vehicles and stairs for detection using two separate obstacle detection models, each of which comes with a different level of complexity due to their inherent structure, size and shape, as shown in Figure 1. We have addressed the problem of slow computation using a parallel processing framework and developed a real-time obstacle detection system that works efficiently in unstructured conditions.

II. Related Work

Blind and visually impaired people (BVIP) face significant challenges navigating urban environments, limiting their independence and mobility. [1] provides a comprehensive review of the overall state of research in outdoor navigation for BVIP. Some navigation systems for BVIP show promising results, but there are limitations in accuracy, reliability and user-friendliness. [2] reviews various assistive tools and technologies designed to help BVIP navigate their surroundings and categorises them into three main groups: Electronic Travel Aids that use sensors like ultrasound, LiDAR, or cameras, Position Locator Devices that use GPS and GIS technology for navigation, and Electronic Orientation Aids to understand the surrounding environment and spatial orientation using tools like talking maps, 3D tactile maps, and indoor positioning systems based on Bluetooth beacons.

Sensors and cameras have been used together to help visually impaired people navigate using sound or vibration to avoid collision[3]. However, more research is needed to see how well the system would work with larger groups of people and in different environments. [4] proposes an automated walking guide system designed explicitly as spectacles for visually impaired individuals. The system utilises three ultrasonic sensors to detect obstacles in the front, left, and right directions, along with a Convolutional Neural Network to identify potholes on the walking surface. The research is in its early stages, and further testing and development are needed before real-world implementation.

While sensors and wearable devices have made significant strides in assisting visually impaired individuals with mobility, they still face limitations due to their limited range of functioning, sensitivity to environmental challenges like rain, dust, etc., and difficulty differentiating between obstacles and harmless objects. Camera-based systems can adapt better to complex environments, the visual data allowing for a better understanding of surroundings, and are cost-effective and more accessible to carry, hence, user-friendly. [5] introduces a computer vision-based visual assistance system for the visually impaired, leveraging mobile edge computing and deep learning for advanced perception tasks like detecting and identifying various road elements, providing audio feedback, and utilising affordable hardware and mobile edge computing for broader accessibility.

[6] proposes an assistive device designed to aid visually impaired people with mobility and object recognition, combining camera and sensor data for richer information and robustness. However, processing camera data and performing object recognition require significant computational power, draining the battery life of devices and potentially limiting real-time performance. This can be a significant hurdle, especially for visually impaired users who rely on this technology for safe and independent navigation. [7] proposes a new framework to aid visually impaired people with outdoor mobility and provide rich auditory descriptions of their surroundings. It processes real-time video and multisensor data streams to identify the type of obstacles and the surrounding scene. It automatically generates the description of obstacles, their spatial information and corresponding instructions.

[8] leverages real-time image analysis to identify surroundings, transforming visual data into audio descriptions, in which users receive obstacle alerts, object recognition details, and spatial awareness through intuitive audio cues. The system personalises descriptions based on user preferences, granting control over the information received, but its accuracy relies on image clarity, and object misidentification can occur, posing safety risks. Additionally, processing power demands need to be addressed for wider adoption.

[9] proposes a framework by combining an object recognition module based on YOLOv-3 and a sensor-based obstacle detection system that works at chest level, waist level, knee level and foot level of the visually impaired individual. The information from both these modules is then fused to create a comprehensive understanding of the surroundings and translated into audio descriptions. [10] also uses the YOLOv-3 obstacle detection model to train on the Pascal VOC dataset and proposes an application that gives audio alerts for the detected obstacles. [11] emphasizes uncertainty awareness for robust obstacle detection and spatial understanding by

leveraging just a stereo camera system to predict salient regions in the image and combining it with 3D spatial information from the camera for robust obstacle assessment.

There has been remarkable progress in the development of assistive technologies for the visually impaired in recent times, with the evolution of deep learning and computer vision technologies, sensors and other perception technologies. In this paper, we aim to address the shortcomings of the existing works and propose a real-time obstacle detection architecture combining two deep learning-based models for the detection of road objects and road anomalies, especially in unstructured environments. We use parallel processing in the combined system to tackle the challenges of high computation time and lower detection accuracy. Moreover, the proposed system is trained on datasets manually captured from unstructured environments for reliable obstacle detection and safe navigation of visually impaired pedestrians on unstructured roads.

III. Proposed Work

In this section, we describe the pipeline of our proposed obstacle detection system in detail. The framework consists of two obstacle detection models trained on separate manually curated datasets of various classes of road anomalies and road objects. The collected video data is split into image frames, pre-processed and carefully annotated. Then, deep learning-based models with a CNN backbone are trained to perform object detection and classification as per the chosen classes. We combine these two models in different ways to create an efficient mobility assistance architecture that detects obstacles and warns the user about objects ahead or nearby road anomalies.

A. Custom Datasets

The performance and accuracy of deep learning models directly depend on the quality, diversity, and variability of the dataset on which they are trained. The unavailability of adequate, reliable datasets of various obstacles and road anomalies in unstructured environments captured from the perspective of visually impaired pedestrians gives rise to the need for tailoring a custom dataset. In this work, we have created a novel image dataset of obstacles and road anomalies commonly encountered on the road, which can cause distress and accidents for visually impaired pedestrians.

The custom dataset for road anomalies contains four classes: potholes, puddles, cracks, and patches, and the road obstacles dataset includes six classes of road obstacles: vehicles, two-wheelers, poles, signboards, trees, and stairs. The image frames in the datasets have been extracted from videos manually captured using mobile cameras while walking on pavements and lanes and from inside a vehicle while driving on various roads. The data is captured from multiple regions in urban settings, at different times of the day, and under various weather conditions to infuse a broad range of variability in terms of surrounding illumination, complex backgrounds and image quality. The original datasets contain over 3500 images, each with one or more object class instances.

Fig. 2: Samples of image frames from the custom datasets for road objects and road anomalies.

In real-life scenarios, the significant issues visually impaired people face in obstacle detection while walking arise due to difficulties of camera focusing and different angles of holding the camera. As a result, the captured image frames are often blurry and out of focus, worsened due to motion. These challenges can be significantly overcome by incorporating data augmentation steps, such as adding blur, flipping and rotating the frames up to an angle, differing the brightness and exposure, and so on. We have augmented the original dataset to obtain a more diverse dataset of over 15000 frames, which is robust to the mentioned challenges. Data augmentation also helps in addressing the problem of overfitting. It improves the model's generalisation upon training on previously unseen data, which is crucial, especially for unstructured environments due to unpredictable and changing conditions.

B. Data Preparation and Annotation

The captured videos are split into frames, and only the relevant frames containing helpful information for training are extracted for annotation. Null frames with backgrounds without any obstacle or anomaly of interest are also included, indicating a safe and clear path. Each frame may contain multiple instances of the same or different classes. The type of instances and their position in the frames should be chosen carefully to be annotated for optimal model performance in real-life scenarios. We have selected only the instances that can pose an obstacle or cause disturbance to a pedestrian, such as objects in the same lane as the pedestrian, mobile obstacles that are approaching or obstructing their path, or a pothole ahead, before proceeding to annotation.

Each frame is resized to a uniform dimension of 640x640 square pixels for even faster training. After manually marking them using bounding boxes and smart polygons, we carefully annotated each relevant instance in the pre-processed frames according to the ten corresponding classes. Correct and accurate annotation of instances is crucial for extracting features and training deep learning models on the dataset.

C. Object Detection and Classification

In the proposed pipeline, we have performed object detection on images using a supervised deep learning model based on the YOLOv-8 (You Only Look Once) architecture to train on the curated datasets. YOLO [12] is a series of widespread object detection and image segmentation models known for its low cost of deployment, fast training and state-of-the-art object detection performance. YOLO uses an end-to-end Convolutional Neural Network consisting of 24 convolutional layers, followed by two fully connected layers. It uses a single-shot object detection algorithm that detects the location of objects in a single pass of the image, making it computationally efficient and suitable for real-time usage. YOLOv-8, the latest in the YOLO series, uses different augmentation methods while training, such as mosaic augmentation, and uses an anchor-free model for predicting the centre of an object directly. Additionally, YOLOv-8 has achieved extraordinary accuracy for object detection [13] according to the standard COCO (Common Objects in Context) [14] benchmark.

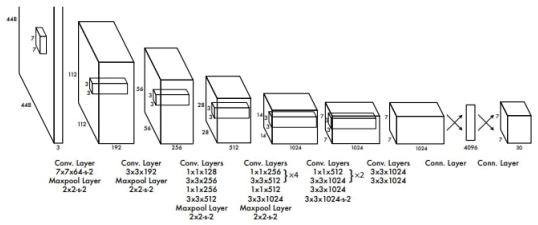

Fig. 3: YOLO Architecture [12]

The models are trained using transfer learning to achieve higher accuracy for all the different classes and then validated on validation datasets. The models are also tested separately on previously unseen video data. The two trained models can detect the obstacles and anomalies that appear in images and videos within bounding boxes and classify them as per the corresponding object class. The detection is accompanied by a confidence value. The object detection and classification on our novel datasets using YOLOv-8 show satisfactory results individually.

D. Proposed Parallel Architecture

Traditional object detection algorithms involve sequential information processing that becomes computationally expensive, especially with high-resolution images or videos. Parallel processing allows simultaneous data processing, significantly increasing speed and making real-time detection feasible. Our research employs two distinct models, each trained on a tailored dataset to tackle specific aspects of road safety. One model focuses on detecting road objects, while the other specialises in identifying road anomalies, both models addressing unique complexities inherent to their respective tasks. We evaluated three frameworks for object detection in input videos: (i) a sequential model architecture, (ii) a parallel model architecture, and (iii) a combined model architecture, comparing their performance in terms of both detection accuracy and execution time.

In the sequential architecture, a pre-processed frame is fed as input to one model, and the obtained output frame with detections is then provided as input to the other model. Then, in the parallel approach, we deploy our framework to test both models on the input frame in parallel using multi-threading to optimise the performance of both models and reduce execution time. The proposed parallel architecture is demonstrated in detail in Figure 4. In the combined approach, we combine both datasets into a single dataset of road objects and anomalies and train a single object detection model to detect the different classes at once.

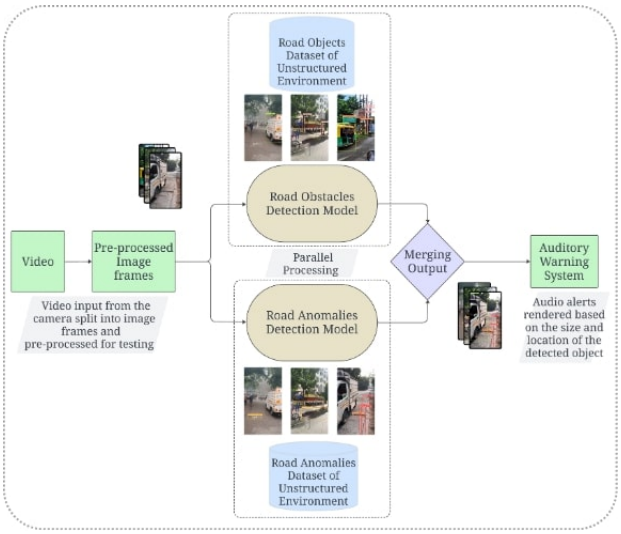

Fig. 4: The parallel architecture to test a video for road objects and road anomalies to achieve faster performance as compared to series architecture.

We observe and quantitatively elaborate in Section IV that among the three approaches, the parallel architecture gives optimal computation speed, along with accurate detections for all classes. The output detections of the models obtained in parallel are fused and integrated with the frame, resulting in faster and more efficient detection of obstacles. The user can switch between the parallel model framework and each of the distinct models at their convenience and depending on the environment they are navigating.

E. Audio Warning System

We integrate an audio-based alarm system with the parallel obstacle detection framework that notifies visually impaired pedestrians about the obstacle ahead based on its size and location, helping with safe navigation. If the area of the detected obstacle is more than 0.7 times the area of the frame, we empirically conclude that the obstacle is huge and close and can pose an immediate danger. Additionally, the centre of the detected obstacle being on the bottom two-thirds of the frame implies that the obstacle is close by and requires urgent attention. If the object's centre is near the centre of the image and the area is less than 0.7 times the area of the image, we

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 10:33:05 UTC from IEEE Xplore. Restrictions apply.

can deduce that the object is not obstructing the immediate path, which does not require immediate concern. Based on the threat level, the system sends either a high-priority critical or low-priority alert to trigger the user's attention. Figure 7 shows samples of high-priority and low-priority notifications issued based on the obstacles detected.

Visually impaired people rely heavily on ambient sounds to navigate their environment, gather information, and understand the surrounding activities. Moreover, a loud and repetitive alert can trigger a startled response and cause distress and disorientation in unfamiliar environments, leading to severe accidents. It is important to use calming and clear tones for notifications, and assistive devices should always have the option to regulate the volume and switch off the audio at the user's convenience.

IV. Experimentation Results and Discussion

Fig. 5: Low and inaccurate results of the combined model architecture with bounding box detections, class labels and confidence scores.

We have trained our models using object detection and transfer learning algorithms on our annotated datasets in an integrated GPU environment for faster training. The models have been configured in a parallel architecture on a system configured with AMD Ryzen 5 5600H and 8GB RAM, as shown in Figure 4. This architecture helped us achieve faster

Fig. 6: Accurate qualitative results of the proposed parallel architecture with bounding box detections, class labels and confidence scores.

TABLE I: A comparison of total run time and accuracy of different combinations of models.

Architecture	Duration (s)	Accuracy (F1-score)
Parallel Model	61.67	Object Accuracy - 0.88 @ 0.501 Anomalies Accuracy- 0.43 @ 0.286
Series Model	73.32	Object Accuracy - 0.88 @ 0.501 Anomalies Accuracy - 0.43 @ 0.286
Combined Model	49.49	0.54 @ 0.22

performance compared to a sequential implementation of the same models. We also compared the performance of the parallel architecture with a single object detection model trained on combining both datasets together. The parallel architecture gave a much higher accuracy compared to the single model, as shown in Table I.

Table I shows the overall time the different architectures take to run on the same video. The sequential model architecture that uses the models serially takes the longest time among the three. This is because both the models are inferenced one by one, which requires more computational time. The parallel model architecture takes slightly less time since it uses multiple threads simultaneously for computation.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 10:33:05 UTC from IEEE Xplore. Restrictions apply.

The combined model architecture in which a single model is trained on the combined dataset has a faster execution time but has the lowest accuracy due to the combination of complexities of ten different classes of objects. While the combined model fails, the parallel architecture takes slightly more computation time but achieves good detection and classification accuracy.

Figure 5 and 6 show the overall qualitative comparison of the same scenes using the parallel model architecture in Section III-D and the combined model architecture, respectively. From the images, we can infer that there is high complexity in detecting ten different classes of objects compared to using two different models to detect 4 & 6 classes each. The parallel model can detect all the various classes with high confidence because there are two different models doing two tasks individually. One detects all the road anomalies, and the second detects all the road obstacles, and the obtained results are merged, thus reducing the overall complexity.

(a) (b)

Fig. 7: Qualitative results with a textual warning based on the location of the road anomalies and obstacles. (a) Showing High Alert based on the location of the pothole and the size of the bounding box of the vehicle. (b) Showing Low Alert based on the location of the puddle and the vehicle.

The audio cues for the warning system have been changed here to textual cues, as shown in Figure 7 for better representation. The warning system works well in real time for all the anomalies and obstacles. It detects objects in each frame based on the overall image size and the bounding box location and size.

V. Conclusion

Unstructured environments present heightened challenges for the safe and independent mobility of visually impaired individuals. Our research underscores the immense potential of camera-based obstacle detection systems with audio alerts tailored to the complex landscapes and obstructions posed by unstructured environments. By leveraging obstacle detection algorithms, fast and real-time processing, and customised datasets, our findings demonstrate that the proposed obstacle detection framework can reliably identify and communicate obstacles and road anomalies, empowering individuals with spatial awareness and improved independent mobility.

Abstract—The study aimed to synthesize ascorbic acid (AA) loaded carboxymethyl guar gum (CMG) hydrogel based film cross linked by citric acid (CA). Bioactive films (CMG-CA and CMG-CA-AA) were synthesized by solvent casting method. The flexibility and mechanical strength of the bioactive film (CMG-CA-AA) were enhanced by the addition of glycerol and optimized by analyzing tensile strength. The structural, morphological and thermal analysis was done by FTIR, XRD, SEM and TGA. Further, the films were evaluated for its anti-oxidant, anti-microbial property and cytotoxicity. Barrier properties, biodegradability and fruit shelf life-enhancer capability were also assessed. The outcomes of the testings demonstrated favorable results and confirms the potential of CMG-CA-AA film in food packaging.

DOI: 10.1134/S0965545X24600388

INTRODUCTION

In recent years, plastic packaging has raised serious disposal and environmental challenges that endanger human health and development [1]. A significant amount of these plastic materials is used in food packaging [2]. Merely 9% of plastic waste is recycled globally, while 22% is mishandled [3]. It is vital to investigate innovative food packaging with varied functional features which can provide enhanced food product protection [4]. Consumers prefer the naturality of food and extended shelf life when it comes to packaged food. People would prefer one product over another if it has a longer shelf life [5]. Synthetic polymers or plastics have low biodegradability, minimal reuse and recycling options, and other negative environmental effects [6]. The utilization of bioactive packing materials as a substitute of plastic packaging may be the solution to such problems [7]. Natural polymer-based hydrogel films (bio-based films) as food packaging materials can serve as a great alternative [8]. Natural materials are emphasized and urged to be used instead of other options since they are environmentally beneficial [9]. Lipids, proteins, polysaccharides, or a mixture of such substances could be used to make bio-based films [10]. Carbohydrate polymers stand out among them as promising materials for food packaging due to their superior mechanical qualities (such as tensile strength, toughness, and elongation) [11].

In this context, carboxymethyl guar gum hydrogel based film (CMG-CA-AA) is being considered as a suitable substitute. The film was prepared from carboxymethyl guar gum cross-linked by citric acid, loaded with ascorbic acid, where glycerol is used as a plasticizer. All of the raw materials used in preparing CMG-CA-AA films are non-toxic and inexpensive, and the preparation process is simple and cost-effective.

Guar gum (GG) is a seed gum made from *Cyamopsis tetragonolobus* embryos of the Leguminosae family [12–14]. Carboxymethyl guar gum (CMG) is a derivative of GG, which is preferred over the pure form due to GG's low thermal stability, irregular hydration rate, decreased viscosity upon storage, and higher risk of microbial contamination [15]. Carboxymethylation is the chemical technique used here for attaching pendant carboxymethyl groups to pure GG [16].

Cross-linking is a typical method for enhancing the performance of polymers [17]. Citric acid, a polycarboxylic acid naturally found in citrus fruits like lemons, is a cost-effective and non-toxic example that has been utilized to enhance the characteristic properties of polymers [18, 19].

CMG cross-linked CA hydrogel films lack innate antioxidant and antimicrobial properties. AA was loaded in the bioactive film to incorporate these properties. Films possessing antimicrobial and antioxidant properties used in food packaging can improve the quality of food items and prevent microbial development [20, 21]. Ascorbic acid (AA) is a naturally occurring compound with strong polarity and significant antioxidant action found in many foods, including mangoes, oranges, lemons, blackberries, and vegetables [22, 23]. The mechanical strength of a material is a crucial factor to consider when creating packaging

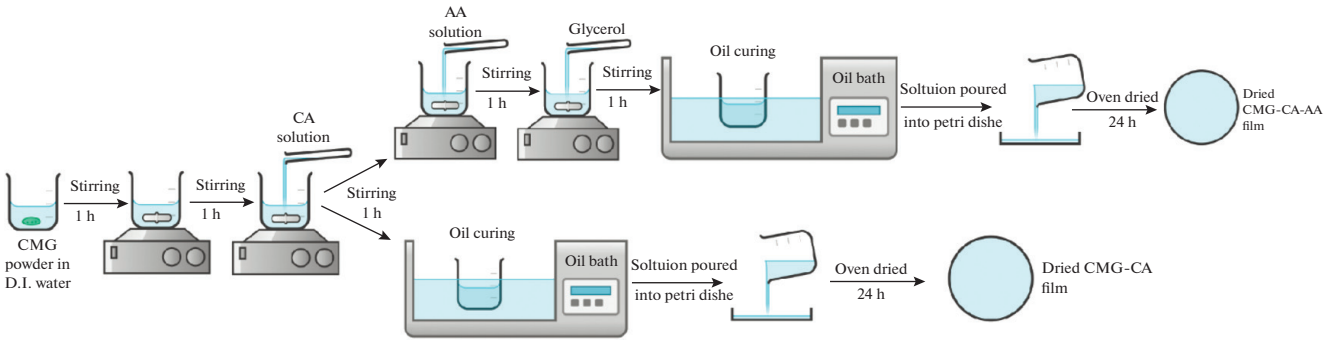

Fig. 1. Preparation method of (*1*) CMG-CA and (*2*) CMG-CA-AA films.

material. To improve this property of the prepared biofilm, a plasticizing agent, glycerol, was incorporated. Glycerol is a naturally occurring alcohol that is odorless, colorless, and slightly sweet to taste, and it was found to enhance the mechanical strength and elasticity of the films [24, 25].

In addition to being biodegradable, non-toxic, colorless, and odorless, the film also exhibits high barrier properties. Materials with high transmission barrier materials are highly suitable for providing package protection.

EXPERIMENTAL

Materials

CMG powder was purchased from the local market and CA was purchased from CDH, New Delhi. AA was purchased from CDH. Glycerol used in the preparation was from Fisher chemical, UK.

Preparation of CMG-CA-AA Films

Fabrication of CA cross-linked CMG bio active films was achieved through the solvent casting method (Fig. 1). Firstly, CMG 0.1% (w/v) was weighed and dissolved in distilled water to make a homogenized solution. 0.1% (w/v) CA dissolved in distilled water was added to the homogenized gum solution and stirred for 1 hour. 0.1% (w/v) AA dissolved in distilled water was added to the cross-linked CMG. After 1 h of stirring, 1 mL of glycerol was added and further stirred until a homogenized solution was obtained. Oil curing of the final solution was performed at a constant temperature of 140°C for 5–7 min. Controlled CMG-CA films were prepared by the same procedure, except the addition of AA. The prepared solution was transferred into Petri dishes and left to dry at 45°C for 24 h. After complete drying, the films were removed by peeling from the Petri dish.

Rheological Analysis

Rheology is an effective method for assessing the flow and deformation of matter by combining its principles with different properties [26]. Rheological studies of liquid CMG-CA-AA were performed on Anton Paar Modular Compact Rheometer 302 (MCR) at 25°C. Parallel plates of 40 mm were used for the testing. The constant shear rate for the steady shear rheology experiments varied between 0.1 and 500 s^{-1}, while the variable shear rate spans from 10 to 100 s^{-1}.

Mechanical Properties

The mechanical properties such as the thickness of films, maximum force, elongation at break (EB%), and tensile strength (TS) of the CMG-CA and CMG-CA-AA films were studied using, Universal Testing Machine (UTM), LLOYD LR 5K. The load range of the machine was 1–50 N with a 1000 mm extension range and 5 mm gauge length. The test and approach speed was 500 mm/min with no preload. A strip of 15 mm width and 150 mm length was cut from each film for mechanical testing. Each sample had three readings taken under air conditions, and the average result was taken into account in analyzing the mechanical characteristic. The *EB%* was calculated using the Eq. (1) [27]:

$$EB\% = \frac{E}{L} \times 100, \quad (1)$$

where E is the extent at which the film breaks and L is the initial length of the film.

The TS of the films were calculated using the Eq. (2) [28]:

$$TS = \frac{F}{A} \text{ (SI unit of TS is MPa)}, \quad (2)$$

where F is the force required to break the film and A is the cross-sectional area of the film.

Fourier Transform Infrared (FTIR) Spectroscopy

The FTIR spectra of CMG, CMG-CA and CMG-CA-AA were obtained through a Fourier transform infrared spectrophotometer (Perkin-Elmer model 2000). The range of spectra recorded was kept between 4000–400 cm^{-1} at room temperature [29].

X-ray Diffraction (XRD)

XRD analysis of CA, CMG, CMG-CA and CMG-CA-AA was performed using an Expert Pro MDR, Panalytical X-Ray diffractometer to get crucial information about its solid-state structure [30]. The scan rate was 1° per minute in the range of $2\theta = 5°$ to 80° using a copper diode with K_α radiation λ = 1.5406 Å.

Thermogravimetric Analysis (TGA)

Thermal degradation of CA, CMG, CMG-CA and CMG-CA-AA was determined by Thermo Gravimetric Analysis (TGA 4000, Perkin Elmer, USA). In a platinum crucible, approximately 4 mg of each sample was heated in a range of 25–800°C at a heating rate of 10 grad/min in N_2 gas atmosphere [31].

Scanning Electron Microscopy (SEM)

The morphology and physical properties of CMG-CA and CMG-CA-AA films were analyzed through a scanning electron microscope (SEM) (ZESIS EVO MA15). The samples were coated with gold to prevent electrostatic charge under a strong electron beam and low resolution during the investigation [32]. Film samples were observed at an accelerating voltage of 5.0 kV at 5000× and 10000× magnification.

Tests to Evaluate the Efficacy of the Hydrogel Film As a Potential Food Packaging Material

In vitro antibacterial activity. A disc diffusion susceptibility test was carried out to check the antimicrobial activity of the films [33]. The testing was done on agar plates for two different bacteria; gram-positive *Staphylococcus aureus* and gram-negative bacteria *Escherichia coli*. Overnight broth cultures of both bacteria were used for the assay. Under sterile conditions, the agar solution was poured and kept in Petri dishes to solidify. Bacterial inoculum was individually spread on the agar plates in an even manner. A disc of 1 cm diameter was cut from CMG-CA and CMG-CA-AA films and placed on agar plates with bacterial spread [34]. These plates were sealed and kept in an incubator at a temperature of 37°C for 24 h. The width of the inhibition zone (mm) around each sample was noted. Using a digital ruler, the sizes of the inhibition zones were calculated in millimeters (mm).

Antioxidant assay by DPPH radical scavenging. DPPH (2,2-diphenyl-1-picrylhydrazyl) is a free radical with an absorption maximum at 515 nm [35]. Antioxidants reduce the absorbance of DPPH. The samples' $DPPH^+$ free radical scavenging capacity was evaluated by using the $DPPH^+$ radical scavenging assay [36]. 1 mg $DPPH^+$ dissolved in 20 mL of methanol was prepared to be used as a radical solution. In methanol solution, DPPH gives a violet or purple color to the solution. The violet color fades to light yellow in the presence of an antioxidant. The antioxidant solution was prepared by mixing 1 mL of CMG-CA-AA homogeneous solution with 3 mL of methanol. Sample solutions were prepared with 1 mL $DPPH^+$ radical solution added to 4 mL antioxidant solution for the photometric assay [37]. At first, the absorbance of 1 mL $DPPH^+$ radical solution was recorded [using Ultraviolet–visible spectroscopy (Shimadzu UV spectrophotometer UV-1800)] as a blank, after that the $DPPH^+$ radical solution was added to the antioxidant solution. Then the readings were measured, one instantly and another at an interval of 30 min. The same procedure was repeated for all five different concentrations of CMG-CA-AA. The antioxidant activity was evaluated by analyzing and calculating the reduction in absorbance of $DPPH^+$ at different concentrations [38]. The following Eq. (3) was used to calculate the percentage $DPPH^+$ radical scavenging [39]:

$$DPPH^+ \text{ scavenging activity} = \left[1-\left(\frac{a-b}{c}\right)\right]\times 100, \quad (3)$$

where, a is the absorbance of sample solution, b is the absorbance of blank solution and c is the absorbance of $DPPH^+$.

A percentage higher than 85% indicates antioxidant activity [40].

Biodegradability test using burial method. The loaded bioactive film was subjected to degradation tests by the method of burring the sample in standard soil (ISO 17556 standard soil) for 25 days at room temperature and moisture controlled conditions. The sample was buried 2 cm under the soil. At intervals of 5 days, the buried film was taken out of the soil, gently washed with distilled water, dried and weight changes were noted [41]. The extent of degradation was evaluated by examining the changes in appearance, weight change and chemical changes through TGA. TGA was performed on a piece of bioactive film that had been buried in the soil for 15 days [42]. The results were compared with the TGA results of a freshly prepared bioactive film. The $\%D$ that is percentage weight loss

(at an interval of every 5 days) was calculated by Eq. (4) [43]:

$$\%D = \left(\frac{W - w}{W}\right) \times 100, \quad (4)$$

where W is the initial weight of the film and w is the weight after every 5 days.

Permeability Properties

Microbial penetration/microbial Barrier test. To determine the microbial penetration ability of the bioactive films, 2 vials of 5 mL were filled half (2.5 mL) with sterile nutrient agar broth. A circularly cut bioactive film (about 2 cm in radius) was fixed at the mouth of one of the vials [44]. The film was secured using rubber ties. The second vial was left uncovered and was used as a positive control for comparison. Both the vials were kept undisturbed for 24 h of incubation. After incubation, any cloudiness and turbidity observed in the nutrient agar broth in the vial was considered to be an indication of microbial contamination [45].

Water vapor permeability test. Using the desiccant method, the water vapor permeability of the bioactive films was evaluated. Two 5 mL vials were filled with 5 g of anhydrous $CaCl_2$ each. A circularly cut bioactive film (about 2 cm in radius) was fixed at the mouth of one of the vials (2.50 ± 0.05 m^2). The film was secured using parafilm and rubber ties. The second vial was left uncovered and was used as a reference for comparison [46]. The vials were put in a desiccator with a saturated NaCl solution at 37°C. The vials were weighed initially and after an interval of 24 h. The water vapor transmission rate (WVTR) can be calculated through Eq. (5):

$$WVTR = \frac{L}{A}\frac{\Delta m}{\Delta t}, \quad (5)$$

where Δm is the change in mass due to water vapor absorption (g), Δt is the time interval, L is the thickness (m) of the material through which water vapor passes and A is the exposed surface area of the material (m^2) [47].

Cytotoxicity evaluation by SRB assay. The cytotoxicity of the films on Hepatic (HepG2) cell line was analyzed by a Sulforhodamine B (SRB) assay. The cells were grown on 96-well plates for 24 h at 37°C with 5% CO_2 in Dulbecco's Modified Eagle's (DMEM) medium supplemented with 10% fetal bovine serum (FBS) and 1% antibiotic solution. Cells were treated with various doses of concentration the following day (0.075–1.25%). (In an insufficient medium, several concentrations were created) Tri-chloro acetic acid (TCA, 10%) was added to each well and incubated for an additional hour after being incubated for 24 h [48]. The plate was then rinsed with demineralized water (DM) water and allowed to air dry at room temperature. Each well received 0.04% SRB Solution, which was then added and allowed to sit for an hour. The plates were allowed to air-dry at room temperature after being incubated for 1 h. To remove any remaining unbound dye, they were then washed with 1% (v/v) acetic acid. In order to solubilize the protein-bound dye, tris base solution (pH 5) was added, agitated for 10 min on an orbital shaker, and then read at 510 nm in an Elisa plate reader (iMark, Biorad, USA).

Shelf life analysis (oranges). Packaging trials of shelf life on fresh fruit (orange) were done to examine the preservation capability of the bioactive films. Commercially, oranges are stored at a temperature of 3–9°C with 90–95% optimum humidity, to avoid spoilage and extend shelf life [49]. Inaccessibility to such optimum conditions results in spoilage and waste of food. The fabricated bioactive film is an attempt to provide sustainable packaging material with the least additional storage conditions. Three oranges were taken and placed in a separate petri dish. The first orange was left unpacked, i.e., without any film covering. Second, was packed with the CMG-CA film. Third was packed with the bioactive CMG-CA-AA film. Fruits were completely sealed in the films. All the samples were examined for 8 days. The samples were kept at room temperature in proper natural lighting [50]. Changes in the samples regarding spoilage and freshness were compared between the initial and last day (8th). These changes were analyzed to deduce a result regarding the preservation ability of the fabricated bioactive film (CMG-CA-AA) [51].

RESULTS AND DISCUSSION

Rheological Properties

Viscosity. Rheological analysis, clarifies the reaction between force, deformation, and time [52]. The experimental method of rheology is used to ascertain the rheological characteristics of materials [53]. Figure 2 shows the viscosity sweep of CMG-CA and CMG-CA-AA solutions. In comparison to the CMG-CA solution, the CMG-CA-AA solution was found to have a stronger shear thinning behavior [54]. The results suggest that with the introduction of AA into the hydrogel system a decrease in viscosity is observed. This could be as a result of the introduction of another acid, AA, which interrupted the intermolecular connections within the hydrogel system [55].

Mechanical Properties

The CMG-CA and CMG-CA-AA films were found to be 0.08 ± 0.005 and 0.03 ± 0.005 mm thick, respectively. Table 1 shows the results of mechanical testing for both films. Figure 3 shows the prepared hydrogel based films. The maximum load CMG-CA could hold was 10.60 N, while CMG-CA-AA could hold up to 39.90 N. The tensile strengths of CMG-CA and CMG-CA-AA were 7.20 and 29.08 MPa, respectively. This indicates that the bioactive film CMG-

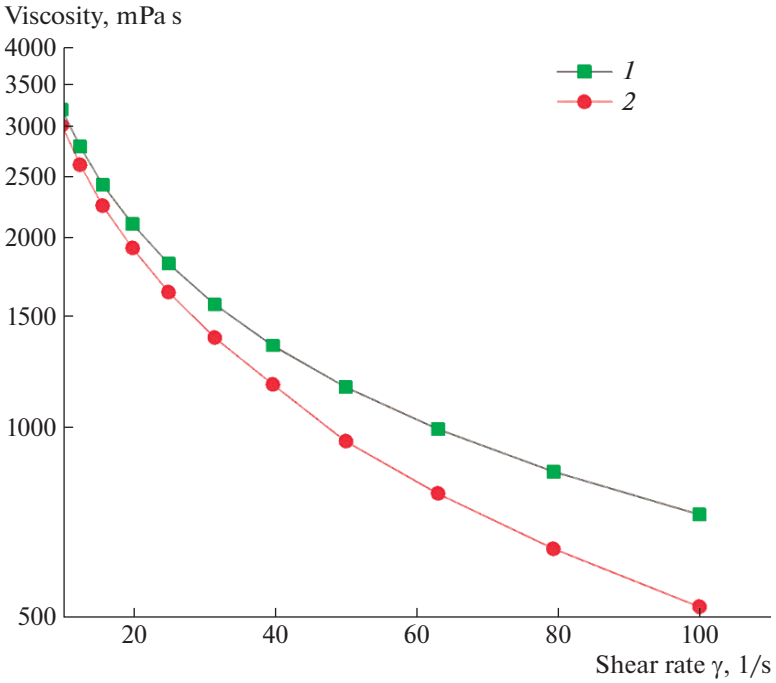

Fig. 2. Viscosity sweeps of (*1*) CMG-CA and (*2*) CMG-CA-AA solutions.

CA-AA has a higher tensile strength in comparison to CMG-CA, which proves that it can endure more force without breaking. The presence of glycerol and cross-linking of polymer chains in the bioactive films is the reason for their enhanced mechanical properties [56]. The results show the mechanical properties of the prepared bioactive film is greater than the controlled film. Such flexible and strong films could be used as a packaging film.

Fourier Transform Infrared (FTIR) Spectroscopy

FTIR spectroscopy was done to determine the functional groups of the films. Figure 4 shows the spectra of CMG, CMG-CA and CMG-CA-AA films. The vibrational stretching of –OH was shown by large, prominent peaks in the CMG spectrum between 3500 and 3000 cm^{-1}. The medium's peaks at 2852 and 2925 cm^{-1} demonstrated the asymmetric stretching of $-CH_2$ [57]. The –CO of ester group was said to be responsible for the highest peak presence at 1720 cm^{-1}. The C–O–C length of the glycoside link of CMG that resulted in the peak at 1023 cm^{-1}. The FTIR spectra of the cross-linked films CMG-CA and CMG-CA-AA showed the ester cross-links and carbonyl bond of free carboxylic acid at 1738 and 1726 cm^{-1} [58].

X-ray Diffraction (XRD) Analysis

The XRD data give important information on how composition affects crystal structure and shape. Figure 5 shows the X-ray diffractograms of CA, CMG, CMG-CA, and CMG-CA-AA. CMG powder show a broad peak at 19.08°. The CMG-CA and CMG-CA-AA films showed broad peaks at 2θ value 18.16° and 17.66°, respectively, indicating the amorphous structure of both films. Powder CMG shows a lower amorphous nature, indicated by the broad peak at 19.08°. Crosslinking via CA resulted in the substitution of the hydroxyl groups by the carboxymethyl groups in CMG-CA and CMG-CA-AA, caused an increase in amorphous structure. A reflex that is observed in the 40° region is also shown in the hydrogels of the gum (CMG-CA and CMG-CA-AA), confirming the

Table 1. Mechanical properties of the films

Film	Width, mm	Thickness, mm	Max force, N	Tensile strength, MPa	Elongation at break, %
CMG-CA	15.00	0.08 ± 0.005	10.60	7.20	47.50
CMG-CA-AA	15.00	0.03 ± 0.005	39.90	29.08	32.80

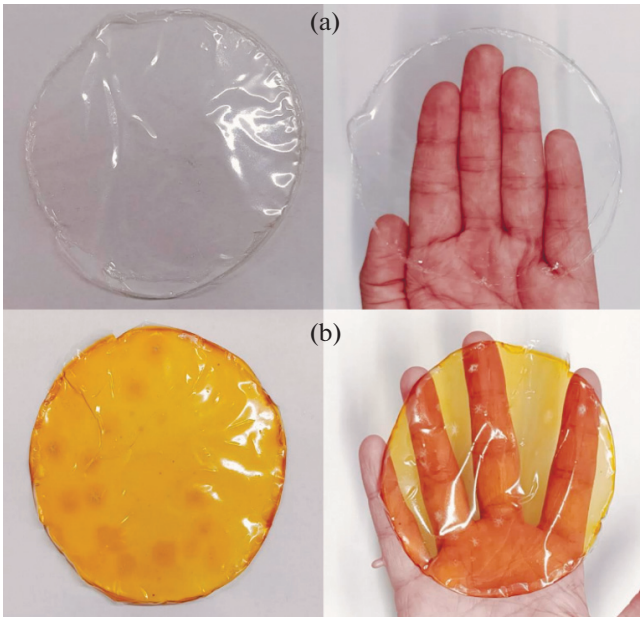

Fig. 3. (a) CMG-CA film, (b) CMG-CA-AA film.

cross-linking of the gum (CMG) and the citric acid. The breakage of hydrogen bonds of CMG crystals by cross linking increases the amorphous nature [59]. The moderately broader peak of CMG-CA-AA in comparison to CMG-CA at 18.36° suggests a smaller particle size which in turn suggests a higher amorphous nature of CMG-CA-AA [60].

Thermogravimetric Analysis (TGA)

The TGA curves shown in Fig. 6 of CA, CMG, CMG-CA, and CMG-CA-AA were studied to determine the thermal stability of the bioactive film. CMG-CA and CMG-CA-AA films showed a multi-step thermal degradation due to water evaporation, decomposition of CA and AA, breaking of polymer linkage bonds, and degradation of the polymer backbone. The 1st stage of mass loss is due to the evaporation of water molecules in all the samples tested [58].

In CA, the initial weight loss of 77.5% was observed between 172.89–237.55°C. CA completely degraded by the end of the analysis and no residual content was left.

In CMG gum 1st stage of degradation with 22.50 wt % loss was observed between 29.89–252.43°C. 2nd stage occurred between 252.43–555.88°C with a 50.42 wt % loss. And the final degradation was between 555.88–789.93°C with 23.53% and a residual content of 3.55 wt %.

In CMG-CA 1st stage of degradation was observed between 32.09– 229.99°C with a 11.29 wt % loss. 2nd stage was observed between 229.99–425.72°C(51.40%). The 3rd stage degradation at 425.72–780.62°C(32.47%). The residual content was of 4.84 wt %.

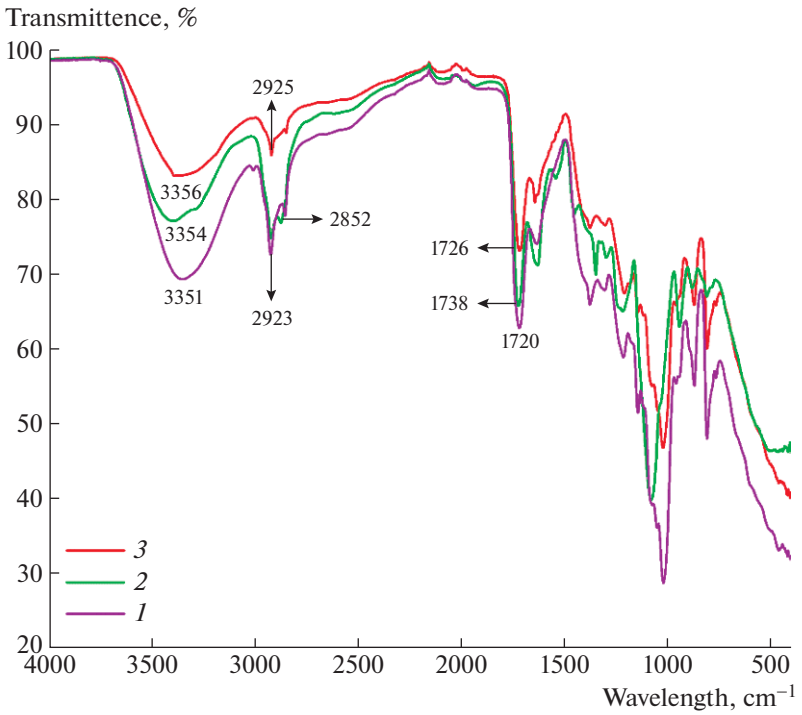

Fig. 4. FTIR graphs of (*1*) CMG, (*2*) CMG-CA and (*3*) CMG-CA-AA.

In CMG-CA-AA 1st stage of degradation was observed between 33.18–235.03°C with a 15.47 wt % loss. 2nd stage was observed between 235.03–502.86°C (53.16%). The 3rd stage degradation ranged between 502.86–615.33°C (11.19%). The 4th and final stage of decomposition was till 615.33–794.41°C (4.28%). The residual content was 15.90%.

In CMG-CA-AA, a slower thermal degradation occurred initially. Cross linking decreased the initial mass loss in both films in comparison to CMG. The initial temperature at which degradation starts was observed to be higher in cross linked films as compared to that of gum, indicating improved thermal stability. The residual content was found to be more in cross-linked films (CMG-CA and CMG-CA-AA) in comparison to CMG. CMG-CA-AA showed higher thermal stability than CMG-CA. The results of TGA give an idea about the thermal stability of the bioactive films which should be acknowledged while creating food packaging films.

Scanning Electron Microscopy (SEM)

The scanning electron micrographs of the surface morphology of CMG powder, CMG-CA and CMG-CA-AA films are presented in Fig. 7. CMG showed a globular structure. Both films exhibit small particle sizes and irregular particle shapes. SEM image analysis indicates that the CMG-CA film has compact surface with a few clusters of particles observed on the surface. On the other hand, CMG-CA-AA active films display a smoother, more compact and homogeneous surface with a patterned distribution of particle clusters which are favorable as a packaging film material [61]. Compared to the powder CMG, image of the CMG-CA-AA film at 1000× reveal smaller globular formations. This might have occurred due to cross-linking of the gum.

Tests to Evaluate the Efficacy of the Hydrogel Film As a Potential Food Packaging Material

In vitro antibacterial activity. Figure 8 illustrates the antibacterial activity of CMG-CA and CMG-CA-AA films. The images indicate that controlled CMG films did not exhibit any antibacterial activity, while CMG-CA-AA demonstrated good antibacterial activity. CMG-CA-AA showed a distinct zone of inhibition against both gram-positive (*Staphylococcus aureus*) and gram-negative (*Escherichia coli*) bacteria. The presence of AA contributed to the bacterial growth inhibition property exhibited by CMG-CA-AA. Incorporating 0.5 mg of AA into CMG-CA films produced a zone of inhibition of 15 mm (in diameter) against *Staphylococcus aureus* and 18 mm (in diameter) against *Escherichia coli*. Therefore, it can be inferred from the results that CMG-CA-AA films can prevent the growth of bacterial strains [62]. The antibacterial properties of CMG-CA-AA films can be significant for their application as a food packaging material [63].

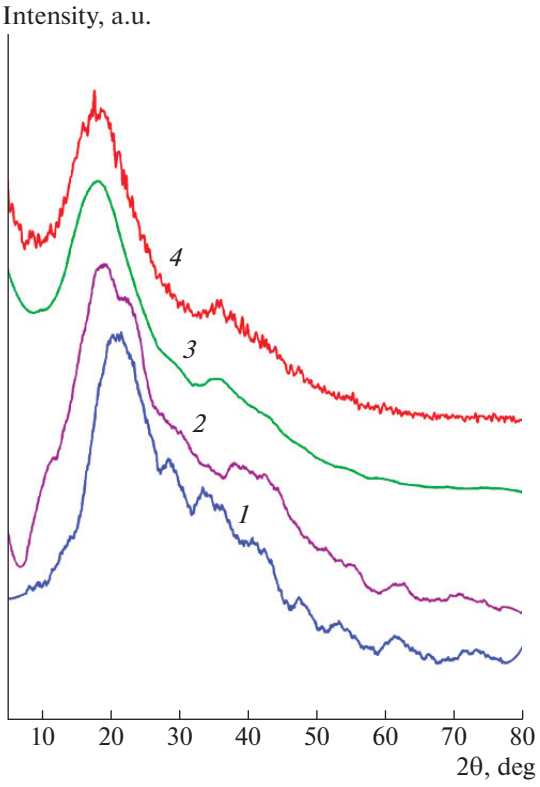

Fig. 5. XRD graphs of (*1*) CA, (*2*) CMG, (*3*) CMG-CA and (*4*) CMG-CA-AA.

Antioxidant assay by DPPH radical scavenging. Five different concentrations of CMG-CA-AA solution were tested to evaluate their antioxidant activity by analyzing the reduction of $DPPH^+$ radicals. The percentage radical scavenging activity of these sample solutions is shown in Table 2. The graphs of percentage $DPPH^+$ scavenging against concentration are presented in Fig. 9. The absorbance of $DPPH^+$ corresponding to the maximum wavelength ($\lambda_{max} = 515$ nm) was found to be 0.863. The scavenging percentage was highest (95%) at 500 μL/mL concentration and lowest (85.2%) at 100 μL/mL. Hence, higher scavenging was observed with an increase in concentration. The scavenging activity of the samples followed the order: 100 < 200 < 300 < 400 < 500 μL/mL. Antioxidants can reduce DPPH free radicals by donating hydrogen, which is essential to prevent the harmful role of free radicals in various disorders, including cancer [64]. The results suggest that all the loaded CMG-CA-AA samples exhibit antioxidant properties or radical scavenging activity due to their hydrogen donating or electron transfer ability. Antioxidant property in a food packaging film is a crucial requirement.

Biodegradability test using burial method. It was observed that the bioactive film started to degrade around the 5th day (week 1) after burial. The film started to develop cracks throughout and became softer. On reaching week 2 the film was seen to have broken down into a few pieces. In week 3 the film broke down into even smaller pieces. Most of the film had degraded by the starting of week 4 and only some of it could be seen in the soil with close observation. By the 25th day (week 4) no visible film particles could be observed and it was concluded that the majority of the film has degraded in the soil. At an interval of five days, the film was weighed to calculate the weight loss over the period of degradation [65]. The results are mentioned in Table 3.

During the evaluation, around 10th day (week 2) a fragment of the film was taken from the soil gently dusted, washed with distilled water and a thermal degradation analysis (TGA) was performed. The results of which was compared with a freshly prepared bioactive film (Fig. 10). CMG-CA-AA film showed a multi stage degradation while the degraded film has reduced to a single stage degradation. Shifts in the characteristic peaks and loss of residual contents in comparison to the initial film can be observed [66]. The results suggest that the components of the film have been broken down by the soil and is undergoing the process of natural decomposition. TGA results support the changes in the chemical structure of the degraded film. Figure 11 shows the degradation (change in

Table 2. Percentage radical scavenging activity

Concentration, μL/mL	Absorbance (after 30 min)	Percentage scavenging activity
100	0.128	85.2%
200	0.113	86.8%
300	0.103	88.1%
400	0.077	91.1%
500	0.044	95.0%

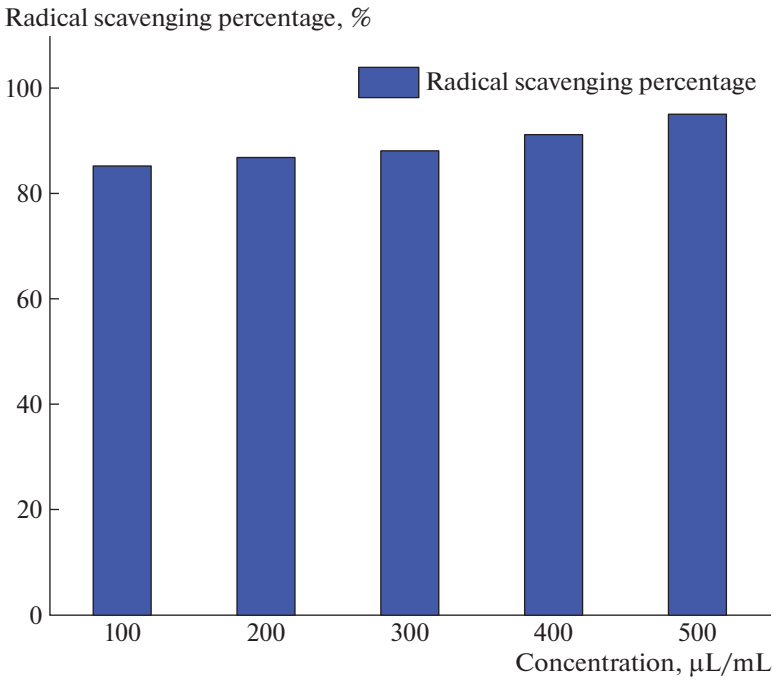

Fig. 9. DPPH+ scavenging percentage (antioxidant activity) graph of CMG-CA-AA.

shape and size) of the bioactive films over the course of 25 days. The results of the testing conclude that the prepared bioactive films are biodegradable and have significance in packaging film.

Permeability Properties

Microbial penetration/microbial Barrier test. After 24 hours, microbial growth in the uncovered vial was observed while the vial sealed with bioactive film showed no microbial growth. Figure 12 shows the observations of the test. White colored turbidity indicating microbial colonies can be observed in the nutrient medium of uncovered vial [67]. The nutrient medium of the bioactive film covered vial remains the same as in the beginning of the test that is a clear medium without any microbial growth. Through the findings of this test, it can be concluded that bioactive films inhibit the penetration of microbes through it. The presence of ascorbic acid in the bioactive films acts as an antimicrobial agent, which prevented the microbes from adhering to or growing on the surface of the film and also inhibiting the penetration of microbes through the film.

Table 3. Biodegradability assay: CMG-CA-AA film weight loss

Day	Initial weight, g	Final weight, g	Percentage weight loss, %
5	0.467	0.315	32.5%
10	0.315	0.204	35.2%
15	0.204	0.083	59.3%
20	0.083	0.019	77.1%
25	0.019	0.000	99%

Water vapor permeability test. There was a negligible change in the weight of the vial having bioactive film fixed on its mouth. Table 4 shows the change in weights of the vials used for testing. This indicates that the water vapor transmission rate (WVTR) of the bioactive film is negligible. For packaging films, high moist environment is considered to be unsuitable since moisture can promote degradation and contamination of food. The films will be effective in preventing a moist environment for the food [68]. The results suggest towards a favorable water permeable condition of the bioactive films as a food packaging material.

Cytotoxicity evaluation by SRB assay. Human hepatic cells (HepG2) were used as a model cell line to evaluate the cytocompatibility of CMG-CA-AA film. The cytotoxicity results for different concentrations are shown in Fig. 13. According to the results of the HepG2 cell culture experiment, the cells could adhere to the film surfaces, spread, and proliferate there [69]. Compared to the control, the cells on the CMG-CA-AA film showed a normal shape after incubation. It can be observed from Fig. 13 that all film samples of different concentrations exhibited cell viability values of more than 80%. This indicates the good biocompatibility of the films with HepG2 cells. Therefore, the

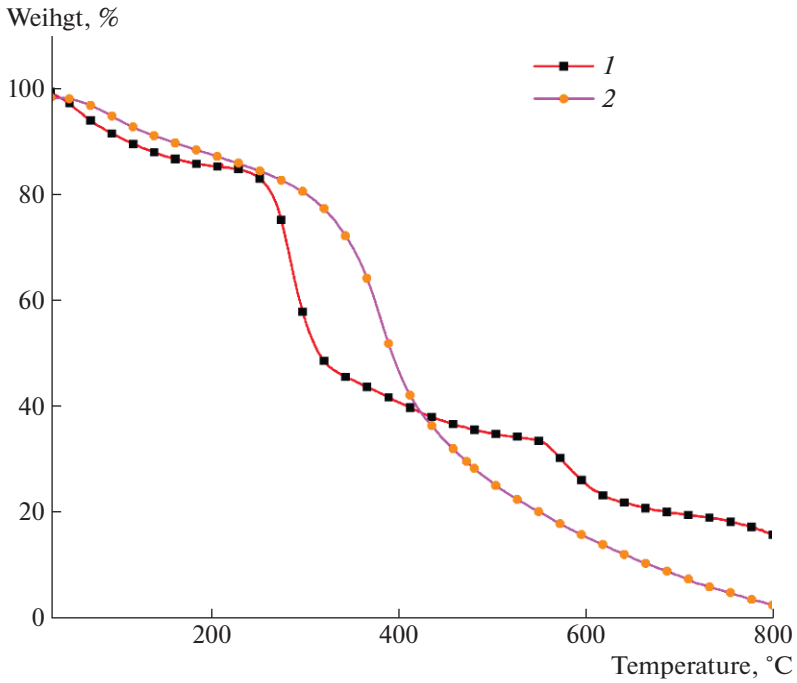

Fig. 10. TGA graph of (*1*) initial CMG-CA-AA and (*2*) the same film in degradation CMG-B.

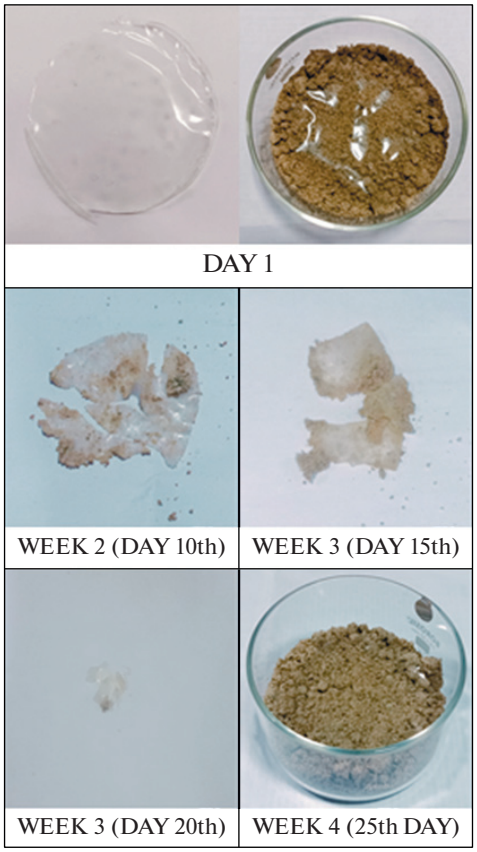

Fig. 11. Biodegradation of CMG-CA-AA film.

lower cytotoxicity of CMG-CA-AA film confirms the cytocompatibility of the bioactive film. The biocompatibility of the bioactive packaging film can be signified from this test.

Shelf life analysis (oranges). The food trials were conducted for 8 days to obtain accurate results [70]. Fruit trials are shown in Fig. 14. On day 1, all fruit samples appeared fresh, with an orange color and no microbial growth. On day 2, the oranges in the first and second Petri dishes began to ripen, while the third one remained unchanged. On day 3, the color of the oranges in the first two Petri dishes started to darken, but the third orange remained the same. On days 4 and 5, brown spots began to develop on the oranges in the first and second petri dishes, while there were no noticeable changes in the third orange. On days 6 and 7, the brown spots on the first and second oranges increased in size, and white microbial growth was observed on the first orange. The third orange started to ripen. On day 8, the first two oranges deteriorated significantly and were no longer suitable for consumption, while the third orange, covered with the bioactive film, looked similar to day 1 and was in perfect condition for consumption. These results indicate that the bioactive film successfully preserved the fruit and could be used as a packaging material.

CONCLUSIONS

The findings show that the CMG fabrication was effective in creating a bioactive film. In comparison to

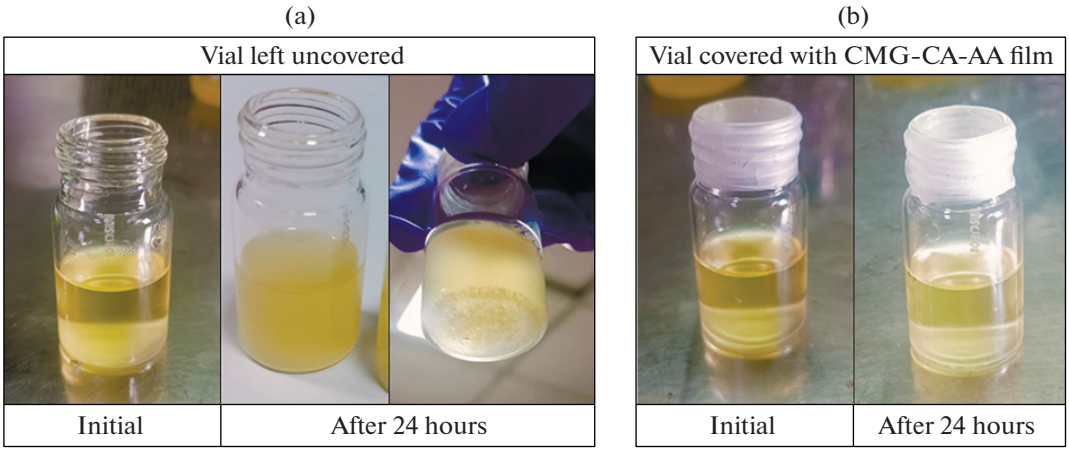

Fig. 12. Microbial barrier assay: (a) Vials left uncovered containing nutrient medium, (b) vials covered with CMG-CA-AA films containing nutrient medium.

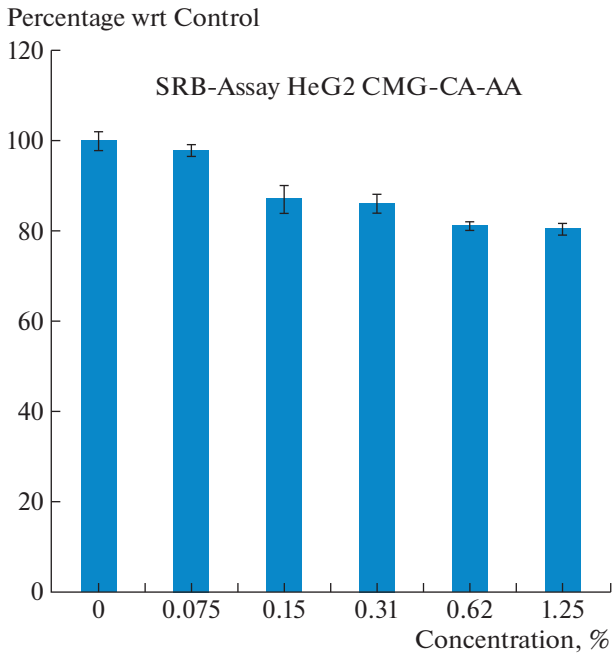

Fig. 13. Cytotoxicity evaluation, SRB assay-HepG2 of CMG-CA-AA at different concentrations.

the controlled film, the developed biofilm showed improved thermal stability and tensile strength. Granular particle was suggested by SEM pictures, and cross linking in the films was confirmed by FTIR measurements. The XRD results demonstrated the amorphous character of synthesized film. It also confirmed the cross-linking in CMC-CA-AA through a shift in the peaks. Effective suppression of both grams positive (*Staphylococcus aureus*) and gram negative (*Escherichia coli*) bacterial growth was demonstrated using CMG-CA-AA films. The films have antioxidant, biocompatible and biodegradable properties. The bioactive films appeared to be an effective barrier against microbial growth and water vapor based on studies of their barrier property analysis. The findings on food packaging demonstrated its usefulness as a packaging material by prolonging the freshness of fruits and extending their shelf life. Overall, CMG-CA-AA bio-

***Abstract*— Banana is one of major fruit crop consumed in India and its production is merely impacted over the year by many factors where malnutrition is one of the key causes which impact banana plants growth and production of banana. Identification of particular type of malnutrition in early stage avoids the diseases and lower the impact of that particular malnutrition on the plant. Traditional monitoring of plants requires intensive time and relies on humans to judge the type of malnutrition suffered a plant, whereas computer vision techniques currently using in similar tasks such as diseases detection, computer vision also performs well on the discussed task which discloses in this study here we proposes a vision transformers-based solution to classify the leaves based on the particular type of malnutrition it has. Vision transformer models have low inductive biases which makes them not to focus on local regions but also consider global patterns in image which makes to produce better results over images taken from real world crop fields. Due to which classification task able to classify with accuracy of 90 percentage on the benchmark dataset which is taken from Maland university of India in Karnataka, which includes 7000 plus images of banana plant leaves when leaves are under deficiency of 8 unique nutrition.**

Keywords*— nutrient deficiency, computer vision, Image classification, vision transformers

I. INTRODUCTION

Banana is one of the important majorly grown fruit in India, plants having different stages which includes consistently monitoring and care, lack of which introduces diseases or reduction in production [1]. And managing using existing methods requires huge time and cost as it is completely depend upon human labor which is not effective in terms of time and cost, whereas artificial intelligence able to solve similar kind of problems such as diseases detection where computer vision detects particular type of diseases on plant leave and helps to protect plant even in early stages of particular diseases associated with plant leaves [2]. In similar to diseases detection image processing is used to classify the leaves based on the deficiency of nutrient [4].There are various different types of image classification models which able to perform classification tasks over input images and classified them based on particular features like here classification of banana leaves performed based on the type of nutrient which a plant having deficiency, for classification tasks several benchmarking models were exist such as LeNet which was released in 1998 which uses pooling layers with smaller number of convolution layers[10]. In 2012 AlexNet another image classification model with introduces usage of ReLU activation, drop and level up the accuracy of image classifications tasks [11]. After that in 2014 VGGNet with uses small 3X3 filters for feature extraction with deep architecture based solution which surpass the AlexNet in image classification task over benchmarking datasets [12]. In same year GooLeNet popularly known as inception lunched which surpasses even VGGNet in some areas of image classification task as it enables extraction of features at multiple scales with reducing in the computational efforts [13]. Then in 2015 ResNEt introduces for image classification task which solves the problem of vanishing gradient, it was basically residual learning architecture with deep networks [14].Then in next year which is 2016 Densenet comes out which uses connected layers where each layers receives input from all the existing previous layers which promotes feature reuse, and it surpass the ResNEt in classification over benchmarking dataset [15]. After that in year 2017 NasNet and mobileNEt were introduced which perform classification task more accurate and even number of dense layers were also increases as we were moving one to another models [16, 17]. After 2 year another model which is EfficentNEt in 2019 was introduces which basically starting of balancing the model size as till now model gets deeper and deeper to generate better results [18]. These all are CNN based image classification models but vision transformers surpass the image classification task over the discussed CNN models as it captures the relationships between long range and different patches of input image which makes classification better over the benchmarking dataset [19]. Popular classifications models discussed above majority of them use ImageNet dataset [20] as benchmarking dataset for classification task. Motivation of the study is that nutrient deficiency detection in plants is requirement of current era where AgriTech sector entering into unmanned farming, The model must be in lesser resource intensive which makes it consumable in form of simpler API used for real time apps with lower response time and latency rates, transformers looks best solution potentially, as vision transformers attains excellent results compared to generally using convolutional networks while requiring substantially fewer computational resources to train[19]. The primary goal of the study to classify the banana plant leaves based on type of nutrients deficiency a particular leaf suffered from. Another goal is that solution should be less resource intensive and less image-specific inductive bias which means features are not restricted to focus on local regions they also include global patterns in making decisions. The study begins with discussion about existing models and problem definition with its purpose. The remaining part of the study as following sections related work shows studies utilize computer vision to solve the similar

problems. proposed section comprises detailed information about dataset, models and the implementation methodology, experimentation gives glimpse of implementation environment, sample data images and training curve, result section shows performance of proposed solution with sample outputs, and conclusion section conclude the study and share future direction for the study.

II. RELATED WORK

In past years researchers have proposed various studies on classification task on plants. These proposed studies operate on distinct datasets. Some of them are studied and discussed below. The importance of detecting malnutrition into leaves and uses convolution neural network for classification between healthy leaves and leaves based on the type of nutrient deficient in particular plant is highlighted in [1]. Reference [2] discussed various open opportunities for computer vision in managing and monitoring the stresses and diseases where they highlighted that some diseases are because of malnutrition in plant leaves if it was detected on early stage than it might be not reached to state where diseases starts affecting the production of the crop. Dataset of Indian state banana crops leaves images suffered from 8 different type of malnutrition and a class for healthy leaves, dataset opens new door for research in agriculture monitoring part which gives room to test and train diseases detection, classification leaves and predict survival for particular plant is discussed by [3]. Reference [4] worked with convolution neural network with fine tuning to classify the leaves in different classes based on deficiency of the nutrient and healthy status of the leaves, used the dataset of banana leaves having raw and augmented images releases from Indian banana tree fields. Reference [5] studied accuracy of the DCNN in nutrient deficient detection in rice crop images having 10 different classes based on type of malnutrition those plant leaves have, and fine tune the benchmarked DCNN models and perform experiments on different DCNN models. This experiment shows that nutrient deficiency detection is important step in monitoring and predicting crop yields.The applications of computer vision in agriculture sector to monitor crop nutrients using computer vision technology, study emphasis on tracking malnutrition of crop which in future may help to predict when fertilizers need to supplied into fields and based on nutrient what kind of fertilizer needs to be use is given by [6]. The role of the computer vision and machine learning in agriculture sector study which shows that computer vision alone plays vital role in monitoring of the crops in autonomous method, where detecting diseases on leaves, weed detection are areas in which computer vision is under testing and sooner will be available in real time systems is highlighted by [7]. A fine-tuned vision transform model for detecting infections and diseases over the plant leaves, and shows that vision transformer method which processes the images in patches surpasses the previous models in detecting diseases even having smaller regions affected through infection on plant leaves is proposed by [8]. A transformer leaf disease detection model which effective in terms of model size, even though transformer model in smaller size then also it outperforms over the existing CNN models in leaf regions detection task is given by [9].

III. PROPOSED SECTION

A. Dataset

Dataset was taken from Mendeley Data platform which was published on 24 oct 2022 by researchers from Malnad College of Engineering, Agriculture College, Tarekere, Hassan, Karnataka, India all the images were captured from high resolution mobile cameras from different locations which were Hassan , Ramnagara, Shimoga, Davangere and Hosapete districts of Karnataka, India. Original images dimensions are 3072 × 4096, 3096 × 4128, 30 0 0 × 40 0 0 but these all images are resized into 225 x 225 using adobe Photoshop as image processing tool. Dataset contains boron, calcium, potassium, iron, magnesium, manganese, sulphur, zinc classes which represents the deficiency of mentioned nutrient in each leaf. Natural background removed from all images and replaced with black background to avoid noises due capturing of other plants leafs and overlapping of background environment. Augmentations such as horizontal flip, vertical flip, and rotations were performed over the images to balance the number of samples for each class. Table 1 shows, number of samples of banana plant leafs based on type of deficiency of nutrient and in raw dataset number of image samples varies a lot which shows dataset was imbalanced, to make number around each other data augmentation such as horizontal and vertical flip, rotation, Gaussian blur and etc. were used. Dataset contains image samples for nutrient deficiency against boron, calcium, potassium, iron, zinc, manganese, magnesium and sulphur those counts were mentioned in table 1 against rows for raw and augmented samples. Total number of images in raw dataset were 3000 and after augmentation this count reaches to 8040.

TABLE I. SHOWS NUMBER OF IMAGE SAMPLES PER CLASS

Deficient nutrient	Number of image samples in raw form	Number of image samples after applying augmentation
Boron	100	900
Calcium	440	900
Potassium	86	900
Iron	160	900
Zinc	24	840
Manganese	210	900
Magnesium	730	900
Sulphur	400	900
Healthy	850	900
Total number of image samples	3000	8040

B. Pre-processing

Once difference between counts of images belongs to different malnutrion class looks balance, then multiple image preprocessing filters are operated over the dataset which highlights the pattern signifies the presence of particular type of nutrient deficiency. Images are taken under various lighting conditions to reduce the skew behavior of contrast histogram

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:51:39 UTC from IEEE Xplore. Restrictions apply.

equalization is applied over the greyscale version of the image which eliminates noises which creates false positives during classification. And then sharpening filter is applied over the images which highlight the areas effected with malnutrion in images.

C. Vision transformer

Core of the vision transformer is transformer based architecture for image handling tasks, where in order to process each part of the image it divides the images into patches then apply self-attention mechanism on each of these patches to get relationship between these different patches. Reducing dimensions of the patches is crucial part to handle, where vision transformer uses linear projections then leaned positions embedding's are added into encoder to encode the 2 dimensional topology of the image. Mathematically vision information transformer represented as $X \in \mathbb{R}^{H*W*C}$ which represents input image having height H, width W and channel C, where each such image divided into non-overlapping patches and each batch is linearized into a vector. Assuming P be a patches and D is the dimension of each patch after linearization.

$E \in \mathbb{R}^{P*D}$ is input embedding which is obtained by applying linear projection over each patch vectors.

$$E = X.W_{patch} + b_{patch} \quad (1)$$

Here in (1) b_{patch} is bais term and $W_{patch} \in \mathbb{R}^{P*D}$ is weighted matrix.In-order to incorporate spatial information E embeddings are added into positional embedding $PE \in \mathbb{R}^{P*D}$.

$$E_{pos} = E + PE \quad (2)$$

Then in (2) Epos is given as input into a transformer encoder in order to produce an output $Y \in \mathbb{R}^{P*D}$ .Y equals to TransformerEncoder(Epos) then ouput Y is classified using linear layer.

$$Z = Y.W_{class} + b_{class} \quad (3)$$

Here, $W_{class} \in \mathbb{R}^{D*num_classes}$ is weight matrix and b_{class} bias term. These equations represent the high-level mathematical model behind the working of vision information transformer, in proposed study ViT (vision information transformer) imported using transfer learning and then hyper parameters of baseline model are updated for specific use case of banana leaves classification based on malnutrition deficiency in leaf.

D. Dataset directory structure

Dataset divided into training, Validation and testing sets, directory structure for each split were created where training, validation and test splits samples were kept in folder names as per their nutrient deficiency. In final repositories each training, validation and test contains 9 folders where 8 against each nutrient deficiency and 1 for healthy leaf samples.

E. Transfer learning

Transfer learning is used to classification of image leafs based on deficiency of each nutrient in leafs. Here vit-base-patch16_224 pre-trained model is used on top of that model is fine tuned for leaf classification based on nutrient defiance task by adjusting model size, layer depth , optimization function and learning rate. In optimizing terms some layered are freeze as pertained model was trained on black color correctly in pre-processing stage backgrounds of all images were removed and replaced with black color so freezing some layer makes results better in terms of scores.

F. Hyper parameters tuning

Once pre-trained model imported parameters such as Patch size was tined for smaller size as a smaller patch size, like 16x16 able to capture the finer details in the leaf images, which makes model to identify complex patterns of diseases over leaf with better accuracy, moderate number of layers 10 was chosen for model which makes model to capture both low-level and high-level features from images even without making model computationally expensive. Feed forward dimensions set to 2048 as representation capacity needs to be balanced, 12 number of attention heads were used which capture various dependencies within the leaf images effectively, in order to generalize the model and avoiding over fitting drop rate set at 0.2 with all above defined values and values for weight decay was taken as 0.01, which helped in preventing over fitting and control the model's complexity during training. Values of all these final parameters were summarized in table 2.

TABLE II. SHOWS VALUES OF ALL FINAL PARAMETERS

Parameters	Values
Patch size	16X16
Number of layers	10
Feed-forward dimensions	2048
Attention heads	12
Drop rate	0.2
Weight decay	0.01

IV. EXPERIMENTATION

A. Implementation

Implementation of the proposed study begins with preprocessing the images which includes processes such as filtering noisy images, and resizing, after that images belongs to each class were count and if there was large gaps between the counting figures then augmentation was performed over the images, images augmented by rotations, translations , horizontals and verticals slicing after that complete dataset was divided into segments one for training and another for testing then arranging data into defined directory structure in which each training/testing had samples of ratios defined for each class, means difference between number of images of each class is lower for each training/testing sample set. Once dataset was prepared now, pertained model was loaded and parameters were finalized as defined in table 2 then start the training process over training set of data by initializing the model, then save the model file to perform testing over unseen data points which were in testing samples results of those were saved for evaluation purpose.

B. System

Experiment was performed over the system on windows 10 pro machine having 16 GB DDR4 Ram, and 512 GB SSD with

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:51:39 UTC from IEEE Xplore. Restrictions apply.

Nvidia GPU of 2 GB. On python version 8.5 with required packages such as numpy, pytroch, pandas, os, opencv, and tensorboard.

C. Data samples with labels

Images of each type of nutrient deficiency was coded in order to simplify the class labels, fig. 1 shows assigned labels for samples belongs to each class, with their labels such as boron represented by label 0, Calcium as label 1, Healthy as label 2, Iron as label 3 Magnesium as Label 4, Manganese as Label 5, Potassium as Label 6, Sulphur as Label 7 and Zinc as Label 8.

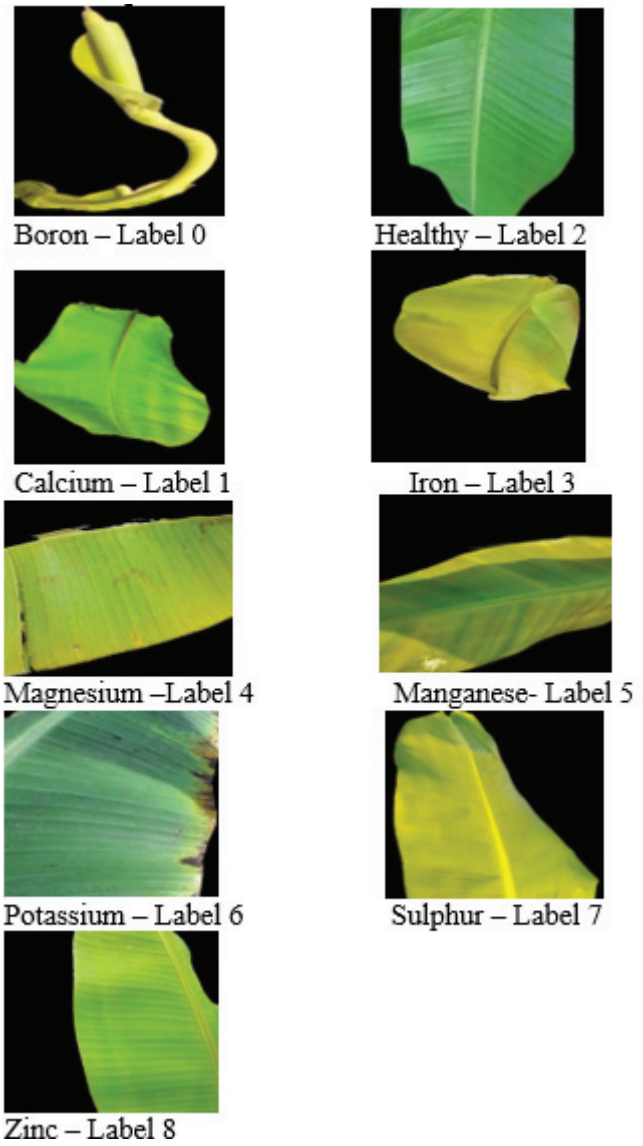

Fig. 1. Shows sample data images and their respective label classes

Images are pre-processed and augmented in order to balance the class labels so that model was not produce results which are biased for any particular class, and each sample's background was removed and replaced with black color background in-order to remove background noise, color variations and textures which makes model less complex and generic in nature.

D. Training loss curve

Once images were pre-processed, images were passed into initialized model for training. During training performance of the model was monitored through the logs generated corresponding to each epochs, here fig. 2 shows loss curve generated from logs saved during training in tensor scalar board which shows that reduction in training loss with respect to each epoch, it is observable from the curve that loss was reduced at every iteration and reached minimum and stable value at epoch 278, which makes to stop the training stage as there is no further updates in loss occur after iteration number 278, where loss seems to 0.06, and makes model stable. In curve vertical axis represented loss figures and horizontal axis represented the number of epochs.

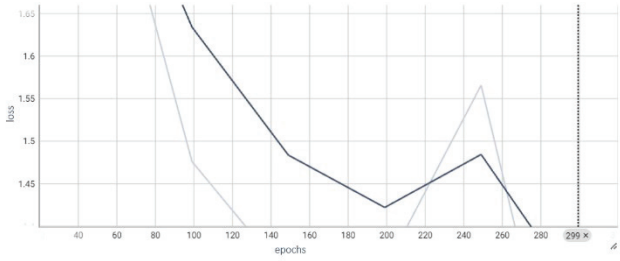

Fig. 2. Shows loss curves generated from logs saved during training in tensor scalar board

V. RESULTS

Once the model was trained testing set image predicted over the saved model file and performance was evaluated here table 3 shows proposed model performance scores for various classes which are different types of malnutrition in particular banana plant leaf, it is observable from the table that average accuracy for classes is around 90, for both training and testing sets of data which shows that model is generalized in nature and able to manage trade of between bias and variance.

TABLE III. SHOWS ACCURACY, PRECISION AND RECALL SCORES FOR EACH CLASS LABEL

Metrics / Class label	Training			Testing		
	Accuracy	*Precision*	*Recall*	*Accuracy*	*Precision*	*Recall*
Label 0	93	90	91	91	89	90
Label 1	91	89	90	90	87	89
Label 2	92	90	91	90	89	91
Label 3	92	90	89	92	90	89
Label 4	90	88	89	88	87	89
Label 5	91	89	87	87	90	88
Label 6	90	91	89	90	90	90
Label 7	91	89	90	89	88	89
Label 8	87	88	87	89	87	90

A. Illustrative examples

Fig. 3 shows the examples of output produced by the proposed model with their ground truth class and predicted label over some of the randomly selected image sample from testing set of the dataset, through illustrative examples it is observable that model performs quiet well even the images of the leafs looks similar such as in b part of figure 3 where samples of label 1 and label 2 looks similar but model able to classify.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:51:39 UTC from IEEE Xplore. Restrictions apply.

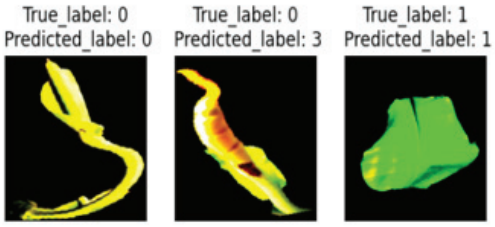

Fig. 3a Samples images of plants lacking boron and calcium

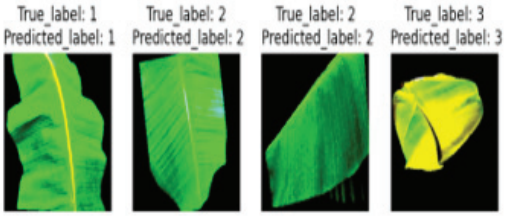

Fig. 3b Samples of healthy plant images, calcium and iron lacking images

Fig. 3. Shows sample output images and their respective label for both cases ground truth and predicted classes

Once results were evaluated for both training and testing set of images then scores of the convolutional neural network based existing solution[1] compared with proposed one here, table 4 compares the performance of convolutional neural network (CNN) [1] based classification model for classifying banana plant leaves based on nutrient deficiency with the vision information transformer based model, which surpass over the CNN model [1] in terms of recall and precision values, even with lower computational power, which shows that vision transformer are potential solutions for making decision over image taken from complex environments.

TABLE IV. SHOWS COMPARISON OF TEST RESULTS WITH CNN BASED SOLUTION

Metrics / Class label	CNN[1]		Proposed ViT	
	Precision	*Recall*	*Precision*	*Recall*
Label 0	79.73	97.4	89	90
Label 1	79.84	71.13	87	89
Label 2	85.32	94.89	89	91
Label 3	89.96	92.02	90	89
Label 4	73.95	81.09	87	89
Label 5	92.94	97.93	90	88
Label 6	96.74	96.88	90	90
Label 7	92.74	77.57	88	89
Label 8	87.57	63.79	87	90

TABLE V. SHOWS COMPARISON OF TEST RESULTS WITTH EXISTING SIMILAR STUDIES

Models	Accuracy	Recall	Precision
CNN[1]	80.1	85.85	86.53
ShuffleNet [4]	82.1	80	78.8
Inceptionv3[5]	79.84	80.6	87
ResNet50[5]	85.32	88.89	89
EfficientNet[18]	89.96	92.02	86
Proposed ViT	91	90	87

Table 5 represents comparison of the evaluation metrics between existing classification models based on deep convolutional neural networks with the proposed vision information transformer (ViT) based solution, and table 5 shows that creation of patches of images for understanding global pattern strategy of ViT makes it performs well over existing solution in terms of accuracy, precision and recall with handling tradeoff between precision and recall for similar task along with lower computational resources.

VI. CONCLUSION AND FUTURE SCOPE

Proposed study performed well for classification of bananas leaf's based on deficiency of multiple nutrients in the leaf's which ultimately helps in identification of reasons behind slow rate of improve in phenotype growth of plant and fruits with diseases. Proposed study uses transfer learning and pertained transformers to classify leaves, and generate models which were compact in size of existing solutions and better accuracy scores both at same time makes effective solution for mobile like portable devices applications even with lower hardware configuration.

***Abstract*—In the ever-evolving landscape of wireless communication, the demand for compact, high-performance antennas spanning a broad frequency range has become paramount. Microstrip patch antennas have emerged as a promising solution for fulfilling this demand, offering versatility and adaptability in various configurations. This research delves into a comparative analysis of different microstrip patch antenna designs tailored for broadband applications in the 2.4-6 GHz frequency range. As wireless technologies continue to advance, understanding the nuances of antenna performance becomes pivotal in achieving optimal communication systems. By scrutinizing the characteristics of E-shaped, U-shaped, Hexagonal, Circular, H-slot, Octagonal, and Rectangular microstrip patch antennas, this study aims to provide valuable insights that will inform the selection and design process for future wireless communication applications. The investigation spans crucial parameters such as bandwidth, gain, radiation pattern, return loss, impedance matching, and antenna efficiency, aiming to distill practical considerations for engineers and researchers working on the forefront of electronics and communication engineering.**

Keywords—Microstrip Patch Antenna, Gain, Return Loss, Impedance Matching, Antenna Efficiency, Bandwidth, U-shaped, Rectangular, E-shaped, Hexagonal, Circular, H-slot, Octagonal Microstrip Antenna.

I. INTRODUCTION

The microstrip antenna, a pivotal innovation in the domain of radio frequency engineering, has played a transformative role in the evolution of wireless communication systems. Its inception can be traced back to the mid-20th century when researchers began exploring planar transmission line technologies for antenna applications. The microstrip antenna, as we recognize it today, emerged as a result of continuous refinement and adaptation to meet the demands of modern communication.

The roots of the microstrip antenna can be found in the development of microstrip transmission lines in the 1950s. Initially conceived for microwave integrated circuits, researchers soon recognized the potential of these planar structures for radiating electromagnetic waves. The transition from transmission lines to antennas marked a significant shift, with notable contributions from innovators like Robert E. Munson and George F. Engen in the 1970s, who played key roles in refining the microstrip antenna design.

The fundamental structure of a microstrip antenna typically consists of a metallic radiating patch positioned on one side of a dielectric substrate, separated by an air or dielectric gap from a conductive ground plane on the other side. This planar configuration not only simplifies manufacturing processes but also lends itself to compact and lightweight designs.

II. LITERATURE SURVEY

The continual reduction in the size of mobile devices has spurred a significant surge in the development of compact antenna structures, supplanting conventional counterparts in mobile communication. Microstrip patch antennas have emerged as a highly promising solution for handheld electronic devices, thanks to their multiband capabilities and compact configurations. Comprising a rectangular patch on a dielectric substrate over a ground plane, these antennas can take diverse shapes, including octagonal configurations. Commonly fabricated with conducting materials such as Copper or Gold, microstrip patch antennas offer advantages like lightweight construction, cost-effectiveness, and simplicity in fabrication. However, despite their numerous merits, these antennas confront a substantial challenge in terms of low gain. [6] Leveraging the octagonal shape in microstrip patch antenna design optimally addresses the challenge of low gain, capitalizing on its compact and versatile configuration. This strategic utilization enhances antenna performance, offering a refined solution for efficient signal transmission in the evolving landscape of compact electronic devices.

A Microstrip patch antenna for 5G WLAN applications is proposed, operating at a frequency of 4.8 GHz and featuring an H-shaped slot within its rectangular patch. The incorporation of the H-shaped slot serves to enhance key antenna parameters such as VSWR, reflection coefficient, gain, and bandwidth.[4] The design is meticulously crafted to adhere to industrial standards set for 5G WLAN applications, ensuring optimal performance within this advanced communication context. The thin planar profile of the Microstrip patch antenna adds to its appeal, allowing for easy integration onto the flat surfaces of space-borne platforms such as aircraft and missiles. Notably, the antenna design yields a reflection coefficient of -25.44 dB and a VSWR of 1.11 at the specified frequency of 4.8 GHz, demonstrating its

2024 5th International Conference for Emerging Technology (INCET) | 979-8-3503-6115-5/24/$31.00 ©2024 IEEE | DOI: 10.1109/INCET61516.2024.10593030

effectiveness in meeting stringent performance criteria for 5G WLAN applications.

In biomedical applications, the imperative for low-latency, high-bandwidth transmission of patient information necessitates advanced antenna solutions. This paper proposes a multi-band Hexagonal Shaped Meandering Antenna (HSMP) with a defected ground structure designed to enhance the bandwidth, return loss, and gain characteristics of a Microstrip Patch (MSP) antenna. Leveraging a slotted meandering approach for optimization, our experimental analysis reveals that the suggested HSMP technique outperforms other MSP antennas, exhibiting greater bandwidth and consistently higher gain.[2] Additionally, we advocate for the use of a single-layer substrate to craft a compact, shallow-rejection, low-profile microstrip patch antenna tailored for high-selectivity differential filtering. This research aims to contribute to the evolution of efficient data transmission in biomedical contexts.

The E-shaped microstrip antenna emerges as a distinctive and innovative variant in the realm of microstrip antenna designs, featuring a unique radiating element shaped like the letter 'E.' This configuration departs from traditional patch antenna shapes, providing engineers with an additional degree of freedom to tailor antenna characteristics.[3] The intricacies of the E-shaped microstrip antenna's design significantly influence key parameters such as resonance frequency, bandwidth, and radiation pattern, making it a compelling subject for in-depth exploration. As we delve into the analysis of this specific microstrip antenna type, the goal is to unravel the nuanced performance aspects that contribute to its suitability for various wireless communication applications. Understanding both the strengths and limitations of the E-shaped microstrip antenna is pivotal for engineers aiming to optimize antenna performance in the ever-evolving landscape of radio frequency engineering.

The U-shaped microstrip antenna stands out as an innovative configuration in microstrip antenna designs, featuring a distinctive radiating element shaped like the letter 'U.' This departure from traditional patch antenna shapes offers engineers a novel approach to tailor antenna performance for specific applications. The U-shaped design's structural intricacies play a crucial role in determining key parameters such as resonance frequency, bandwidth, and radiation pattern.[1] In exploring this microstrip antenna variant, the goal is to uncover nuanced performance characteristics that define its utility in modern communication needs. Notably, the U-shaped microstrip antenna presents advantages such as enhanced bandwidth, addressing wideband performance requirements. Its compact and space-efficient nature makes it ideal for integration into portable devices or systems with limited space. Additionally, the U-shaped geometry influences radiation characteristics, leading to improved directivity and radiation efficiency, further enhancing its appeal in wireless communication applications.

The circular microstrip antenna emerges as a notable and versatile design within the microstrip antenna landscape, characterized by its circular radiating element. This configuration has garnered attention for its unique advantages in wireless communication systems, particularly its ability to achieve an omnidirectional radiation pattern, making it well-suited for applications requiring consistent signal coverage in all directions. Delving into the intricacies of the circular microstrip antenna, we explore its design principles, fabrication simplicity, and performance attributes. Notably, the circular shape not only streamlines the fabrication process by eliminating complex structures but also contributes to cost reduction. Beyond its simplicity, these antennas often exhibit robust impedance matching, facilitating efficient power transfer between the antenna and the transmission line.[5] This multifaceted appeal positions circular microstrip antennas as valuable components in diverse communication scenarios, especially where signal uniformity, ease of fabrication, and impedance matching are paramount.

III. PARAMETERS

A. Gain

The review paper explores various antenna designs, each tailored to optimize specific parameters such as gain, return loss, and directivity. The hexagon-shaped antenna is crafted for high throughput biomedical applications, operating at 2.4 GHz with a VSWR less than 2 and achieving a gain of 3 dB[2]. This superior gain can be attributed to the hexagon's geometric characteristics, providing an increased aperture size that captures and concentrates more electromagnetic energy. The enhanced directivity, a result of the hexagon's complexity, further amplifies the gain. The optimization of return loss characteristics and the incorporation of sophisticated matching networks contribute to the overall efficiency of power transfer, making the hexagon-shaped antenna well-suited for higher gain applications.

Similarly, the circular microstrip patch antenna designed for 5G applications at 3 GHz stands out with a high gain of 10.0 dB[5]. Circular patch antennas achieve this high gain through their circular geometry, ensuring a uniform radiation pattern for omni-directional coverage. Symmetry in design facilitates focused and directive radiation, while resonance at the desired frequency ensures efficient energy radiation. Low cross-polarization and low side lobes contribute to the concentration of energy in the main lobe. Surface wave suppression minimizes energy loss, and the simplicity of their structure makes circular patch antennas cost-effective and easy to integrate.

In contrast, the U-shaped antenna excels in gain with a transmitter gain value of 8.019 dBi at the resonating frequency band of 2 to 4 GHz[1]. The U-shaped structure creates a resonant cavity that enhances radiation efficiency, allowing for the concentration and redirection of electromagnetic waves. This results in a more focused radiation pattern, promoting impedance matching, and maximizing power transfer. The curved arms of the U-shaped antenna act as directors, further concentrating radiation in the desired direction. This overall geometry allows for fine-tuning, optimizing performance for specific frequency bands, making the U-shaped antenna a robust choice for applications where high gain and directional radiation are crucial.

The E-shaped antenna, operating at about 6.23 dB gain over its frequency range, showcases its ability to achieve high gain attributed to several key factors[3]. The E-shaped configuration creates multiple radiating arms, increasing the effective aperture of the antenna. This larger aperture allows for the capture and concentration of more electromagnetic energy, resulting in improved gain. The arms of the E-shaped antenna act as directors, aiding in focusing radiation in a specific direction. The geometry allows better control and manipulation of the electric field, contributing to enhanced

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:50:53 UTC from IEEE Xplore. Restrictions apply.

radiation efficiency. Additionally, the design facilitates impedance matching, minimizing signal reflections, and optimizing power transfer, making the E-shaped antenna versatile and effective for applications requiring directional and efficient signal propagation.

Examining the octagonal patch antenna, the array reveals a gain increase of 6.25 dB compared to the single patch on the FR4 substrate[6]. The choice of substrate material significantly impacts the antenna's resonance frequencies and gain, with FR4 exhibiting better performance. The octagonal patch antenna demonstrates the importance of substrate selection and geometry in achieving higher gain, as well as the potential for array configurations to further enhance performance.

Lastly, the 4x1 array of rectangular patch antennas radiates with higher gain in the forward direction compared to the single patch. The array achieves a gain of 5.284 dBi, surpassing the 1.369 dBi gain of the single patch. The directivity of the array, measured at 10.59 dBi, outperforms the 6.759 dBi directivity of the single patch. This underscores the advantage of array configurations in achieving higher gain and directivity, crucial for specific applications.

In summary, each antenna design demonstrates its unique attributes in optimizing gain and related parameters. The hexagon-shaped antenna leverages its geometric characteristics, the circular patch antenna excels in uniform radiation, the U-shaped antenna emphasizes resonance and directional focus, the E-shaped antenna utilizes multiple radiating arms, the octagonal patch antenna emphasizes substrate material, and the rectangular patch array showcases the advantage of array configurations. These findings collectively contribute to the understanding of antenna design considerations for various applications, highlighting the significance of geometry, resonance, substrate material, and array configurations in achieving higher-gain

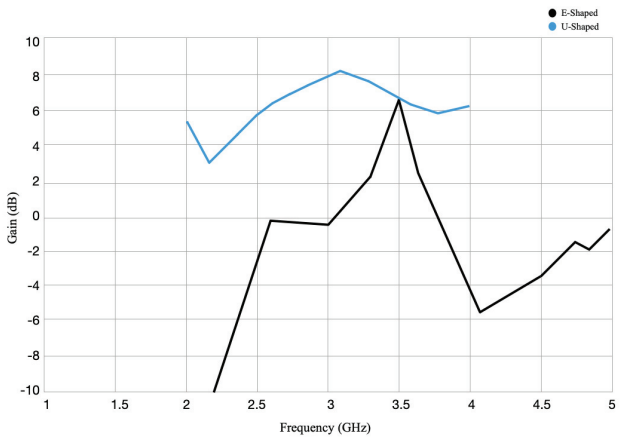

Fig. 1. E-Shaped vs U-Shaped Gain Comparison

B. Return Loss

Return loss is a measure of how much signal is reflected back to the source in a transmission system. It is commonly expressed in decibels (dB) and is defined as the ratio of the power of the reflected signal to the power of the incident signal, expressed as a negative dB value.

Return Loss (RL) can be calculated using the following formula:

$$RL\ (dB) = -20 * log10(\frac{Preflected}{Pincident})$$

•RL is the return loss in decibels (dB).

•$P_{reflected}$ is the power of the reflected signal.

•$P_{incident}$ is the power of the incident signal.

Return loss is an important parameter in the characterization of transmission systems, antennas, and other RF (Radio Frequency) components. It provides information about the amount of power that is not effectively transmitted through the system and is instead reflected back.

The U-slot antenna exhibits a remarkable -45.6 dB return loss, attributed to its innovative design that introduces an extra degree of freedom, facilitating enhanced impedance matching and a broader bandwidth[1]. Through simulations, the antenna demonstrates resonance at 3.145 GHz with an impressive bandwidth resolution of approximately 19.5%. Optimal dimensions, specifically an 18 mm length and 2 mm width for the U-slot, are identified, underscoring the significance of these parameters for optimal performance.

Comparatively, the hexagonal patch antenna achieves a return loss of -24.4 dB[2], although the paper doesn't explicitly detail the reasons. Presumably, the hexagonal shape and meandering design, coupled with a defected ground structure and slotted meandering approach, contribute synergistically to improved performance. Meanwhile, the octagonal counterpart exhibits a slightly lower -23.9 dB return loss[6], suggesting a close performance to the hexagonal shape, potentially hinting at the influence of shape geometry on the antenna's characteristics. Overall, the study underscores the importance of geometric variations in achieving superior antenna performance.

C. Impedance Matching

Impedance matching is a crucial concept in electronics, particularly in antenna design, to ensure efficient power transfer between components. It involves adjusting the electrical impedance of connected elements to achieve maximum energy transfer and minimize signal reflections. In the context of antennas, proper impedance matching enhances performance, optimizing signal strength and minimizing losses. Achieving impedance matching involves tuning parameters such as the dimensions of antenna elements and transmission lines. This ensures that the source

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:50:53 UTC from IEEE Xplore. Restrictions apply.

and load impedances align, preventing signal degradation and enhancing overall system efficiency, a vital consideration for reliable communication systems and electronic devices.

In antenna design, achieving optimal impedance matching is pivotal, and the U-slot antenna presented in this paper exemplifies a successful approach. Operating at 3.1245 GHz, it attains a notable impedance matching bandwidth of 19.5%, a result of meticulous adjustments to the U-slot and patch dimensions[1]. The prescribed slot length and width of 18 mm and 2 mm, respectively, emerge as optimal values for heightened performance, underscoring the critical role of these parameters in impedance optimization. Notably, the designed patch impedance aligns precisely with the resonant frequency, further contributing to effective impedance matching. The reported VSWR of 1.01 at the resonant frequency of 3.1245 GHz adds quantitative support to the antenna's impedance-matching prowess.

In contrast, the E-shaped antenna in the same study focuses on impedance matching between the radiating patch and the transmission feed line[3]. The authors highlight successful impedance matching to a 50Ω standard within the frequency range of the WiMAX operational band, ensuring good efficiency assets for the lanthanides-doped Magnesium ferrite antenna. This emphasizes the versatility of approaches employed in achieving impedance matching across different antenna designs.

D. Antenna Efficiency

Antenna efficiency is a critical metric that gauges the effectiveness of an antenna in converting electrical power into radiated electromagnetic waves. Expressed as a percentage, antenna efficiency accounts for various losses encountered in the antenna system, such as ohmic losses in the conductive elements, dielectric losses in the surrounding materials, and mismatch losses due to impedance mismatches. A highly efficient antenna optimally converts electrical signals into radiation, ensuring that a significant portion of the input power contributes to the desired electromagnetic field. Efficient antennas are pivotal in communication systems, as they enhance signal transmission range, improve overall system performance, and contribute to minimizing power consumption. Design considerations, material selection, and impedance matching are key factors influencing antenna efficiency, making it a crucial parameter in the development of reliable and high-performance wireless communication systems.

The review paper on the E-shaped antenna reports an efficiency of 73.32%[3]. The E-shaped antenna likely achieves this relatively high efficiency due to its carefully designed geometry. The distinctive shape of the E antenna is known for promoting desirable radiation characteristics, including improved directivity and radiation pattern control. The geometric configuration of the E-shaped antenna allows for better impedance matching, reduced losses, and enhanced radiation efficiency compared to some other antenna shapes. On the other hand, the H-slot antenna, with its increased directivity, experiences a boost in efficiency. This is because higher directivity often leads to a more focused and efficient use of radiated power[4]. In contrast, circular microstrip antennas may exhibit lower efficiency[5], possibly owing to broader radiation patterns and impedance matching challenges associated with their circular geometry. These differences highlight the importance of antenna design considerations in achieving optimal performance for specific applications, taking into account factors such as geometry, directivity, and impedance matching.

E. Bandwidth

The bandwidth of an antenna is a fundamental parameter that defines its ability to operate effectively across a range of frequencies. It represents the frequency span within which the antenna can maintain satisfactory performance, typically characterized by parameters such as acceptable radiation patterns, impedance matching, and gain. A wider bandwidth is desirable in communication systems as it allows the antenna to accommodate a broader range of frequencies, facilitating versatility in signal transmission and reception. Bandwidth considerations are particularly crucial in the context of modern wireless communication standards, where diverse frequency bands are allocated for different services. Antennas with broader bandwidths are better equipped to adapt to dynamic and evolving communication environments, making them essential components in systems requiring flexibility and adaptability to various frequency allocations and standards. Achieving optimal bandwidth often involves careful design considerations, including antenna geometry, feeding techniques, and impedance matching strategies, ensuring the antenna's effectiveness across a diverse spectrum of frequencies.

The bandwidth analysis of various microstrip antenna configurations reveals intriguing insights into their performance characteristics. The U-slot microstrip antenna, examined through S-parameter curves at a 10dB threshold[1], demonstrates a bandwidth of approximately 450MHz. However, the proposed Hexagonal patch antenna (HSPA) outshines this with a measured bandwidth of 3.2GHz, constituting a substantial 64% impedance bandwidth[4]. This improvement underscores the efficacy of the HSPA design in achieving a significantly wider frequency range, aligning well with the demands of High-Speed Packet Access (HSPA) technologies. Similarly, the utilization of an E-shaped slot proves advantageous, exhibiting enhanced bandwidth compared to a conventional microstrip antenna.

Moreover, the integration of an H-shaped patch contributes to bandwidth augmentation, with a bandwidth of approximately 140MHz derived from the S-parameter vs frequency curve[4]. Moving beyond shape variations, substrate choices also exert a considerable impact on bandwidth. For octagonal microstrip antennas across different substrates, variations in resonance frequencies and corresponding bandwidths are evident. For instance, the FR4 substrate resonates at two frequencies, resulting in a bandwidth of 200MHz and 500MHz[6], showcasing its versatility. Duroid resonates once but boasts a substantial bandwidth of 1200MHz, highlighting its superior frequency range coverage. Arlon resonates once with a bandwidth of 500MHz, and Rogers resonates once with a bandwidth of 100MHz, further emphasizing the influence of substrate selection on antenna bandwidth. These findings collectively underscore the importance of thoughtful design and material choices in optimizing the bandwidth of microstrip antennas for diverse communication applications.

Octagonal[6]	4.7-4.9	3.6	-	-10.5	0.2
Octagonal[6]	5.3-5.8	3.6	-	-23.9	0.5

IV. CONCLUSION

The review paper delves into various antenna designs, each tailored to optimize specific parameters such as gain, return loss, and directivity. The hexagon-shaped antenna emerges as a frontrunner for high throughput biomedical applications, operating at 2.4 GHz with a VSWR less than 2 and achieving a gain of 3 dB. This superior gain stems from the hexagon's geometric characteristics, providing an increased aperture size that captures and concentrates more electromagnetic energy. The enhanced directivity, a result of the hexagon's complexity, further amplifies the gain.

The circular microstrip patch antenna, designed for 5G applications at 3 GHz, stands out with a high gain of 10.0 dB. Circular patch antennas achieve this high gain through their circular geometry, ensuring a uniform radiation pattern for omni-directional coverage. Symmetry in design facilitates focused and directive radiation, while resonance at the desired frequency ensures efficient energy radiation. Low cross-polarization and low side lobes contribute to the concentration of energy in the main lobe. Surface wave suppression minimizes energy loss, and the simplicity of their structure makes circular patch antennas cost-effective and easy to integrate.

In contrast, the U-shaped antenna excels in gain with a transmitter gain value of 8.019 dBi at the resonating frequency band of 2 to 4 GHz. The U-shaped structure creates a resonant cavity that enhances radiation efficiency, allowing for the concentration and redirection of electromagnetic waves. This results in a more focused radiation pattern, promoting impedance matching, and maximizing power transfer. The curved arms of the U-shaped antenna act as directors, further concentrating radiation in the desired direction. This overall geometry allows for fine-tuning, optimizing performance for specific frequency bands, making the U-shaped antenna a robust choice for applications where high gain and directional radiation are crucial.

***Abstract*—With the growing interest and ease of communication, the number of people using various social networks to disseminate information daily has increased exponentially. Social networking platforms have experienced exponential growth in recent years. To maximize the reach of information, there is a need to effectively identify influential nodes in social networks. Still, existing centrality measures and other methods have drawbacks relating to generalizing across networks and providing consistently accurate identification. In this study, a novel method is proposed by using the Global Local Influence (GLI) approach in particular combining closeness centrality and eigenvector centrality respectively. This aims to get more accurate identification of influential nodes across various networks. To evaluate the performance of the proposed work, experiments were conducted on synthetic and real-world datasets. The results were evaluated with the help of the diffusion models, namely Susceptible-Infected-Recovered (SIR) model and Node Removal Procedure (NRP). The results showed that the proposed algorithm outperforms the existing centrality measures by over 9% across the datasets supported by both the evaluation metrics used.**

Keywords—Closeness Centrality, Eigenvector Centrality, Social Networks, Node Removal Procedure (NRP), Susceptible-Infected-Recovered (SIR) Model

I. INTRODUCTION

In recent times, social networking has become an increasingly important way to establish interpersonal connections and for sharing information. It plays a vital role in modern society by providing the seamless sharing of information. The social networking platforms like Facebook, X, Instagram and LinkedIn have experienced exponential growth in the last few years. Currently, worldwide there are overall 4.95 billion global users across more than 130 social media platforms and is expected to reach 5.85 billion by 2027 [1].

A social network can be defined as a collection of nodes (individuals, clubs, organizations, etc.) which are connected by edges/links that indicate the association between them. It has many applications in various areas such as organisational studies, psychology, economics, information science and criminology [1] thus providing new avenues for the application of social network analysis (SNA) methods.

SNA focuses on information exchange among individuals/groups/organizations, with applications in identifying influential nodes within complex systems like social networks. This method helps to track the spread of information by considering influential nodes/users in message dissemination, offering insights into the diffusion of rumours and potential interventions to control the spread of rumours [2].

The existing methodologies for identifying influential nodes incorporate measures such as degree, closeness, and betweenness centrality [3]. While degree centrality considers the number of connections of a node, it has drawbacks in terms of accurately assessing centrality, especially when nodes with higher connections are additionally compared to more central nodes with fewer connections [4]. Closeness centrality measures the distance between nodes, while betweenness centrality evaluates a node's role as a bridge between other nodes in the network. While these measures outperform degree centrality, their use in large complex networks is difficult because of their high computational complexity [3].

In k-shell algorithm [5], the outer layers of a network are stripped away, and the core nodes are considered to be more influential. However, in the case of some special networks, it has the drawback of assigning the same influence value to a large number of nodes.

The discussed approach above assumes a node's influence is only dependent on its importance. Information entropy [8] introduces the consideration of neighbours' importance in assessing a node's influence. Also, various random walk models like PageRank [5] and LeaderRank [6] are used in identifying influential nodes in directed networks but are unable to work effectively in undirected networks.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 19,2024 at 05:53:46 UTC from IEEE Xplore. Restrictions apply.

While there have been many efforts to identify influential nodes in social networks, there is still room for improvement in terms of accuracy and efficiency. Further research is needed to address the limitations of existing methods and to develop new approaches to better understand the importance of nodes in real-world networks. This study explores the use of Global Local information [3] for identifying influential nodes and evaluates its performance through experiments on real-world and synthetic datasets using SIR and NRP evaluation metrics.

The Global Local Information approach represents a novel method for analysing complex networks, specifically for identifying influential nodes. It addresses limitations in existing key node identification methods that consider either local or global information. The proposed method incorporates both global and local influences as two main factors, the local influence of a node is calculated using eigen vector centrality and closeness centrality has been used to evaluate the global influence of a node over the network [7]. This provides more accurate node influence estimation compared to a single centrality measure/algorithm. Global information is utilized to calculate the overall influence of nodes, while local information is employed to calculate their influence and that of their adjacent nodes. Distinguishing nodes with the same global influence enhance the differentiation effect [14].

The key contributions of the proposed research are as follows:

- This paper introduces a comprehensive evaluation of the proposed algorithm for identifying influential nodes in social networks.
- The proposed algorithm will identify influential nodes with a substantial impact on network structure and properties when removed from the network.
- The exploration of influential nodes in complex networks, allows targeted interventions to leverage their influence.
- The GLI approach makes noteworthy contributions to the field of SNA, particularly in dealing with extensive and intricate networks by incorporating both global and local information.

The subsequent sections of this paper are organized as follows: Section II reviews previous work in this field, Section III elucidates preliminary concepts, Section IV details the proposed methodology, Section V discusses the analysis results, and finally, Section VI provides concluding remarks and outlines the scope for future work.

II. Related work

This section includes research done in past in the field of identifying influential nodes in SNA. Already work has been done to quantify the significance of nodes in complex networks in several studies.

Centrality measures like degree, betweenness, closeness, and eigen vector centrality [2] are used to gather information on influential nodes based on their position and connections in the network. The clustered local degree centrality identifies important nodes by evaluating the local clustering of a node and the degree of its neighboring nodes [9].

In the heuristic clustering method, it allocates nodes into clusters based on the similarity between each pair of nodes present in the network. The most influential node in each cluster is chosen as a seed member. Despite its low time complexity, it has low accuracy in terms of identifying the optimal set of influential nodes [10] due to its possibility of getting trapped in locally optimal solutions.

Prior methods fall short of capturing the complete dynamics, that's why random walk models are used. These measures are integrated through preference analysis in the random walk algorithm [6] to rank influential nodes in a network. Also, the PageRank algorithm to address influence maximization problems is proposed. Zareie [11] proposed the gray wolf optimization algorithm as an optimization problem-solving approach, that considers the influence of nodes along with the distance between them. This shows improved performance with lower computational time compared to earlier heuristic methods used in SNA.

Panfeng et al. [12] introduced the VoteRank++ algorithm, which iteratively selects influential nodes where nodes with different degrees are assigned different numbers of votes. It prioritizes the nodes in terms of their voting ability, allowing each node to vote differently for its neighboring nodes. The Explosion-Trust (ET) Game Model [13] emphasizes how degrees of rumor explosion and trust in the source node can build a rumor-spreading model with the help of game theory.

While each measure is reasonable from its perspective, a comprehensive evaluation cannot be achieved individually. Hence, multiple hybrid approaches should be considered for the influence maximization problem. Utilizing deep learning techniques [13] with network embedding and deep reinforcement learning has also been considered for improved results. Liqing [7] emphasizes global selection based on the local influence algorithm, highlighting its two-stage filtering strategy and submodular property for enhanced efficiency and accuracy.

Within the research community, one can see that considerable work has already been done to find the influential nodes in complex networks. Despite the advances, there are still some drawbacks to the current studies. For example, centrality measures can be unreliable in capturing the true influence of a node in a network because they are based on limited information and can be influenced by the structure of the network itself.

This limitation has been addressed by a recent addition to the literature, Global Local Information. In this study, the GLI algorithm is used to identify influential nodes in a network based on existing literature. To achieve a balanced trade-off between effectiveness and efficiency, this paper proposes a local-global influence indicator-based algorithm and compares its performance to traditional centrality measures using real-world and synthetic datasets.

III. Preliminaries

This section provides foundational knowledge of the concepts necessary for a deeper comprehension of the proposed research.

A. Global and Local Influence

In network analysis, a node's influence is assessed on both global and local scales. This evaluation is crucial for understanding the node's significance in shaping network dynamics and behaviours.

Globally, a node's influence is determined by its impact on the overall network structure. This is quantified using centrality measures such as closeness, betweenness, and eigenvector. These metrics assess the node's importance in facilitating communication or information flow across the entire network. On a local scale, a node's influence is evaluated within its immediate neighbourhood or community using metrics such as degree centrality and PageRank. These measures help understand how a node contributes to the cohesion and dynamics of its local network surroundings.

Understanding both global and local influence is essential for gaining comprehensive insights into the role of nodes within a network, facilitating the analysis of network structure, dynamics, and the implications for various network-driven phenomena.

B. Information Diffusion Models

Information diffusion models are mathematical frameworks extensively employed to examine how information propagates within social networks. These models enable the study of the dynamics of information flow and the factors influencing the speed and scope of diffusion in social networks. To validate the proposed method's effectiveness, Node Removal Procedure (NRP) and Susceptible Infected Recovered (SIR) models have been utilised to evaluate the rationality of node ranking outcomes.

a. Susceptible Infected Recovered (SIR)

The SIR model is a predominant, deterministic diffusion model utilised in social network analysis, exploring the dissemination of infectious diseases, rumours, and information within networks. This model assesses the entire population susceptible to the disease, estimating the number of infected individuals over a given period to forecast disease progression. Individuals or nodes within the network are categorised into three distinct states:

- Susceptible (S(t)): Number of people who are susceptible at time *t*
- Infected (I(t)): Number of infected people who can transmit disease at time *t*
- Recovered (R(t)): Number of recovered people at time *t*

The set of differential equations that describe the dynamics of disease transmission and recovery in a network can be expressed as follows:

$$\frac{dS}{dt} = -\beta SI \tag{1}$$

$$\frac{dI}{dt} = \beta S I - \gamma I \tag{2}$$

$$\frac{dR}{dt} = \gamma I \tag{3}$$

The transmission coefficient, denoted by β, governs the infection rate, and γ signifies the recovery rate. It is assumed that recovered nodes maintain permanent immunity. Temporal variations in the susceptible (S), infected (I), and recovered (R) populations can be examined.

b. Node Removal Procedure (NRP)

Node Removal Procedure (NRP) is a method employed in social network analysis to evaluate the impact of removing specific nodes from a network. It involves systematically removing nodes based on certain criteria, such as centrality measures or other relevant indicators. By observing the changes in network dynamics after each node removal, insights can be made into the influence of nodes within the network.

IV. Proposed Methodology

A. Brief Description of Proposed Algorithm

Within the domain of social network analysis, many centrality algorithms play a pivotal role in explaining the influence of nodes within the network. Each algorithm has a distinct methodology and provides a singular perspective on the significance of nodes. These algorithms consider variables such as connectivity, proximity, and the structure of the network.

The proposed algorithm makes use of the centrality algorithms to generate a GLI score for the nodes in the network. The GLI score is derived by combining a global and a local centrality measure. For the study, closeness centrality is taken to account for global influence of the nodes and eigen vector centrality is considered for local influence of a node.

a. Closeness Centrality

Closeness centrality measures how close a vertex is to all other vertices in the graph [15]. It quantifies how quickly information can spread in a network, indicating the efficiency of communication pathways. It is computed by finding the average of the shortest path lengths from the node to all other nodes and then taking the reciprocal. Mathematically, for a graph of vertices, V, and

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 19,2024 at 05:53:46 UTC from IEEE Xplore. Restrictions apply.

edges, E, $G = (V, E)$, the closeness score of a vertex v, $C_s(v)$, can be defined as:

$$C_s(v) = \frac{V\text{-}1}{(\sum_{u_j \in V,\ u_j \neq v} d(vu_j))} \quad (4)$$

where d(vu) is the distance between vertices v and u.

Nodes with higher closeness centrality are considered more central, facilitating quicker information dissemination. This metric is valuable for assessing network resilience and efficiency across various contexts. This study utilises closeness centrality as a measure of global influence. The selection of closeness centrality was driven by two factors: (a) it indicates nodes as more central if they are closer to most of the nodes in the graph, corresponding to visual centrality [16], and (b) it considers both direct connections and the efficiency of communication pathways.

b. Eigen Vector Centrality

Eigenvector centrality quantifies a node's influence in a network, emphasizing the quality of connections over mere quantity. It posits that links to highly connected nodes enhance a node's centrality more significantly. It is computed by solving an eigenvector equation, involving the network's adjacency matrix, A; the centrality score matrix, x; and, the largest eigenvalue, λ. Formally,

$$Ax = \lambda x \quad (5)$$

The solution of (5) gives the eigenvector centrality for a node v, x_v.

This approach is adept at pinpointing key influencers in networks where connections vary in importance, such as in social or citation networks. By focusing on the principle that a node's significance is bolstered by its connections to other influential nodes, eigenvector centrality offers a nuanced perspective on node importance, balancing the insights into a node's network value beyond simple connectivity. Hence, eigenvector centrality is used to compute the local influence of a node in this study.

B. Algorithm Description

The suggested algorithm finds influential nodes within an intricate network by incorporating the concept of appraising the complementary impact of a node's global and local influence. The research objectives outlined in this report primarily pertain to undirected and unweighted networks, denoted as $G = (V, E)$. This section introduces the key definitions and the proposed algorithm which are specifically relevant to an undirected, unweighted network concerning a node (v_i).

- Global Influence, $GI(v_i)$: The global influence of a node can be calculated using the closeness centrality. Mathematically,

$$GI(v_i) = C_s(v_i) \quad (6)$$

- Local influence, $LI(v_i)$: The local influence of a node quantifies its influence on its immediate neighbourhood. In this research, this definition is extended to consider the influence of a node on its community. In a social network, communities exhibit strong internal connections while having weaker connections to nodes outside it. To calculate the community (or local) influence of a node, the eigenvector centralities of its immediate neighbours are considered. If Z is the set of neighbors of v_i,

$$LI(v_i) = Harmonic_Mean(x_u,\ u \in Z) \quad (7)$$

The choice of the harmonic mean is justified by its reduced sensitivity [17] to extreme values compared to other averages, such as the arithmetic mean. This property makes it particularly suitable for analysing networks so that extreme values do not bias the results.

The node influence $NI(v_i)$ depends on $LI(v_i)$ and $GI(v_i)$ and is calculated as:

$$NI(v_i) = LI(v_i) + GI(v_i) \quad (8)$$

Higher *NI* score is desirable. A node with higher *NI* score is considered more influential. Conversely, a node with lower *NI* score is considered less influential.

V. Results

This section lists the results analysis of the experiments conducted as part of the study. SIR model was used to simulate how well the top K% influential nodes identified by each algorithm were able to spread influence in the network. Initially, top 1% nodes were infected with the rest of the nodes considered as susceptible. The infection factor, β, was set to 0.15 and the recovery factor, γ, was set to 0.1. An average of 100 runs was considered to determine the results of the model.

NRP is used for evaluating the accuracy of identified influential nodes in a network. The algorithms considered for the study provide a ranked list of influential nodes. Nodes are removed in sequence from the network according to this ranking. At each step, two key metrics of the resulting graph are assessed: the size of the Giant Component (GC) and the number of Connected Components (CC). An algorithm is deemed superior if it has a higher number of connected components while having a lower size of the giant component.

A. SIR

Fig. 1 shows the results obtained with SIR simulations. The graphs shown are plotted: where x-axis representing epochs and y-axis representing the sum of infected and recovered nodes. The plotted graphs depict the spread of information in the network with epochs. A steeper slope in the graph denotes a faster information spread which in turn indicates more accurate identification of initial influential nodes.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 19,2024 at 05:53:46 UTC from IEEE Xplore. Restrictions apply.

As shown in fig. 1, the proposed algorithm shows a slightly faster rate of information diffusion than the other algorithms, indicated by its steeper slope. Additionally, the initial spread is much faster showcasing the superiority of the proposed algorithm in quick information spread before saturation. It reaches the peak faster than the rest of the algorithms in all datasets.

B. Node Removal Procedure

In fig. 2, the graphs show the results obtained after performing the node removal procedure on the datasets as discussed previously. Area under the curve (AUC) for size of GC and number of CC is plotted to perform a comprehensive comparison between the algorithms.

The proposed algorithm outperforms all algorithms in fig. 2(a) and (b) and fig.2 (e) and (f) datasets using both AUC - size of GC and AUC – number of CC. It has the highest AUC for the number of CC and the lowest size of GC amongst all the algorithms in these datasets. Additionally, in fig.2 (c) and (d), it shows superior performance according to the number of CC and just slightly worse than closeness according to the size of GC. This result highlights the superior performance of the proposed algorithm in identifying the influence spreading ability of the nodes and ranking them.

One limitation of the proposed approach is also highlighted where due to its focus on considering both the local and global factors it may perform worse than individual algorithms in specific datasets. Though due to its use of both the factors, it has less variable performance across datasets and performs better by 9% on average from the algorithms compared.

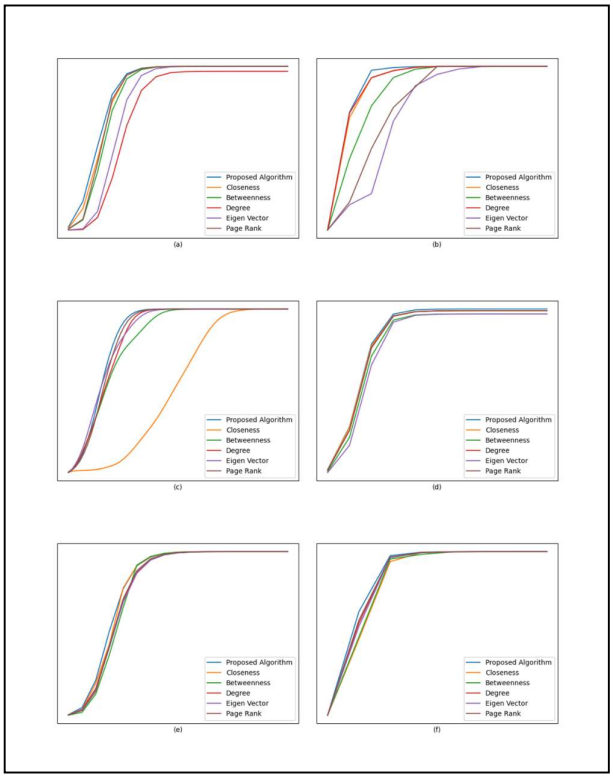

Fig.1: Results for NRP for various datasets

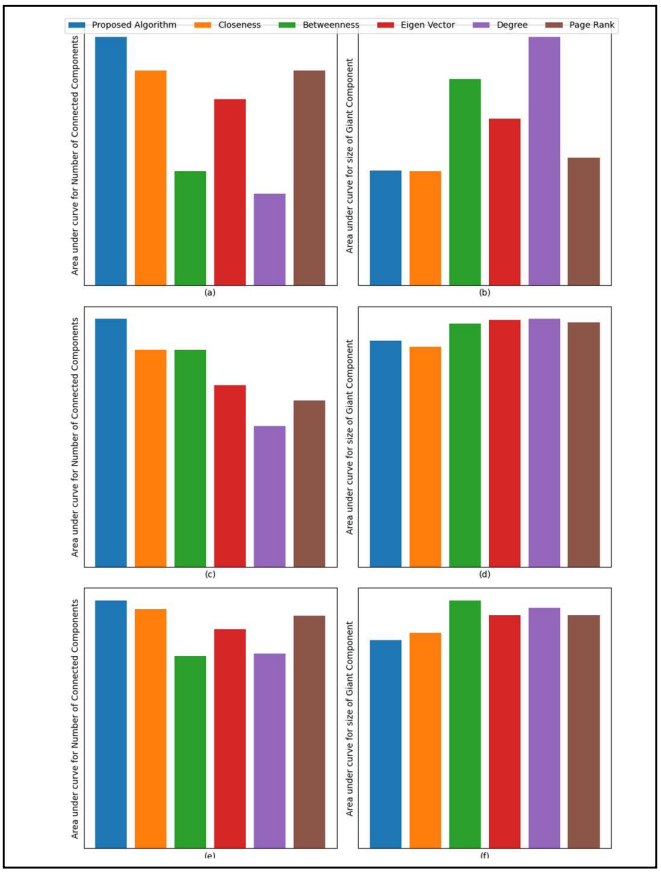

Fig.2: Results for SIR for various datasets

VI. Conclusion

SNA has shown increasing importance thanks to the era of online social networks having billions of daily active users engaging with multiple users. These networks have become very complex making it a challenge to effectively identify influential nodes. The role of influencers in the current society highlights their importance and in turn their power in the dissemination of information. In this study, a novel methodology is proposed using the GLI approach in particular combining closeness centrality and eigenvector centrality respectively.

The proposed algorithm was evaluated against multiple influential node identification algorithms using both real-world and synthetic datasets. The two diffusion models used for the comparison were SIR and NRP evaluation metrics. The results illustrated that the proposed algorithm performs better across all datasets supported by both the evaluation metrics used.

Though it does have its limitations where it was observed that it occasionally performs worse than its counterparts marginally. Additionally, as it requires the computation of both global and local measures namely closeness centrality and eigenvector centrality, it suffers from higher computation time than both of them.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 19,2024 at 05:53:46 UTC from IEEE Xplore. Restrictions apply.

Further study in the field of influential nodes is required to find an algorithm that offers greater accuracy more efficiently and is a field of constant research as no single solution exists. The need to select the suitable algorithm for a specific use case is still required with not a single algorithm available to rank influential nodes effectively and efficiently in varying network structures, sizes and complexities.

The Finsler-Randers space-time offers a novel perspective on cosmic dynamics, departing from the constraints of General Relativity. This paper thoroughly investigates two dark energy models resulting from the parametrization of H within this geometric framework. We have conducted some geometrical and physical analysis of the dark energy models in Finslerian geometry. First, We have derived the field equations governing the universe's evolution within the Finsler-Randers formalism, incorporating the presence of dark energy. Through this, we explore its implications on cosmological phenomena, including cosmic expansion, late-time behavior of the universe, cosmological phase transition, and a few more. Also, we employ observational data such as Cosmic Chronometer, Supernovae, Gamma-Ray Bursts, Quasar, and baryon acoustic oscillations to constrain the parameters associated with dark energy in the Finsler-Randers universe. Comparing theoretical predictions with empirical observations, we assess the model viability and discern any deviations from the standard ΛCDM cosmology. Our findings offer intriguing insights into the nature of dark energy within this alternative gravitational framework, providing a deeper understanding of its role in shaping cosmic evolution. The implications of our results extend to fundamental cosmology, hinting at new avenues for research to unravel the mysteries surrounding dark energy and the geometric structure of the universe within non-standard gravitational theories.

I. INTRODUCTION

Dark energy constitutes about 68 % of the total energy content of the universe, a mysterious force thought to be responsible for the universe's accelerated expansion. There are numerous dark energy (DE) models in the literature. However, the most straightforward and widely accepted candidate for DE is Einstein's cosmological constant Λ [1–3]. The Hubble parameter (H) is an essential quantity in cosmology, representing the universe's expansion rate. The concept of cosmic acceleration was initially supported by the findings from observing distant supernovae of type Ia with high redshifts [4, 5]. The motivation for the concept of acceleration stemmed from the independent observations conducted by the supernova teams directed by Perlmutter and Riess, employing diverse methodologies. These observations, along with data gathered from cosmic microwave background (CMB) [6, 7] and studies on large-scale structures [8, 9], contributed to the development of the concept. Researchers provide strong evidence, indicating a more precise comprehension of the universe's accelerating expansion [10–14]. The finding of cosmic acceleration has significant implications for physics and cosmology and has sparked investigations into the basic ideas that underlie cosmological theories. In recent years, many cosmological models have been proposed by researchers, either by changing the gravity theory itself or by modifying the energy-momentum tensor in Einstein's field equations (EFEs) [15–17]. The development of EFEs played a pivotal role in the quest for precise solutions. As a direct outcome, the Schwarzschild exterior solution [18] emerged as the inaugural exact solution. This solution was derived by incorporating the perfect fluid equation of state as a supplementary condition. Efforts in exact solutions development utilizing Einstein's field equations (EFEs) have been concentrated on specific cases, such as solutions for static and spherically symmetric metrics. Numerous noteworthy examples have been derived, including Einstein's static solution, Tolman's solutions [19], the de-Sitter solution [20], Adler's solutions [21], Vaidya and Tikekar solution [22], Knutsen's solutions [23], Buchdahl's solution [24], and Durgapal's solutions [25]. These solutions represent a comprehensive exploration of the possibilities within the framework of EFEs, showcasing the versatility of the equations in capturing various physical scenarios. The observational data is a pivotal inclusion in the cosmology examination, enhancing the credibility and

* zohrehnekouee@gmail.com

‡ nmurthysk@gmail.com
§ shibesh.math@gmail.com
¶ manjunathmalligawad91@gmail.com

applicability of models. Another alternative avenue contributing substantially to modern cosmological investigations is using numerical computation.

In recent advancements in dark energy models, the integration of observational data has significantly improved accuracy in understanding the universe's expansion. A notable contribution to this field is S. K. J. Pacif's [26] study, where two DE cosmological models are investigated. The study involved obtaining exact solutions of the EFEs through cosmological parametrization, specifically utilizing the Hubble parameter (H) within a flat FLRW background. J. K. Singh [27] has investigated a cosmological model within the FLRW framework by employing the Energy Density Scalar Field Differential Equation (EDSFD) parametrization. Constraints derived from observational data are applied to a specific f(Q, T) gravity model [28] characterized by the Hubble parameter transition. Numerical analysis is crucial in investigating the cubic parametrization of the deceleration parameter within the $f(R,T)$ gravitational theory [29]. This study leverages observational data, specifically from $H(z)$ and SNIa datasets, to determine optimal model parameters and the Hubble constant through best-fit values. The brief analysis of three dark energy models, derived from deceleration parameter parametrization [30], reveals noteworthy traits like late-time acceleration and a cosmological transition from early deceleration to late acceleration. Abdulla A. M. [31] investigates the Barrow holographic dark energy model with the Granda–Oliveros infrared cutoff in the recent examination. Ashley Chraya, [32] uses the most recent available observational data to explore the cosmological constraints on the Variable Chaplygin gas model. Vinod Kumar Bhardwaj [33] conducted an investigation into an isotropic and homogeneous cosmological model of the universe within the framework of f(R, T) gravity. Recent studies have delved into various types of dark energy models, including those featuring nonmonotonic energy densities known as omnipotent dark energy (DE) models[34]. Additionally, investigations have been conducted on the Horava-Lifshitz gravity model [35].

In modern theoretical physics, the main goal is to explain how the universe behaves and understand its mysterious components differently. In the last 30 years, observations have indicated that the universe is extending at an accelerated rate, and standard FRW cosmology with ordinary matter fields (cold dark matter, radiation) is not to describe this. The introduction of a cosmological constant Λ in the classical Hilbert action of general relativity (GR) can explain this accelerated expansion. However, its value cannot be calculated theoretically and must be adjusted by hand to match observations. Attempts have been made to relate the cosmological constant to the vacuum energy of quantum fields, but the calculated value deviates from the value suggested by observations. The causality for the accelerated expansion is called "dark energy," although we know very little about it. Several modified gravity theories have been offered as nominees to explain theoretically the observations, usually by modifying the Hilbert action in a Riemannian framework. Finsler Geometry is a hopeful approach to unraveling the secrets of gravity more comprehensively. Instead of using pseudo-Riemannian geometry to describe the gravitational interaction, Finsler space-time geometry offers a viable method for a geometric explanation of the dark matter and dark energy phenomena [36–40]. Within the context of Finsler geometry, various mathematical expressions can be studied, e.g., cosmological implications of scalar-tensor theories were studied in Ref. [41]. These theories were obtained, in effect, from the Lorentz fiber bundle of a Finsler-like geometry. In recent studies, some researchers have investigated dark energy models and used the Finsler geometry as their framework of choice. Finsler and Finsler-like theories take a different approach because they change the geometry instead of the action. Generally, metrical extensions of Riemann geometry can be equipped with a Finsler geometrical structure in a manifold that leads to generalized gravitational field theories. They are drawing inspiration from the osculating Barthel–Kropina geometry [42, 43], Barthel–Randers geometry [44], Finsler–Randers geometry [45, 46] in their investigation. During these years, applications of Finsler geometry, especially the Finsler-Randers (F-R) model, have developed rapidly, mainly in general relativity, astrophysics, and cosmology. The F-R field equations supply a Hubble parameter that contains an extra geometrical term that can be utilized as a probable nominee for dark energy [47].

On the other hand, recent observations of the cosmic microwave background (CMB) by experimentations like the Planck satellite have demonstrated potential anomalies and deviations from statistical isotropy on large angular scales [48, 49]. Noteworthy studies have been executed on the observable anisotropies of the universe [50–53]. These are associated with the very early state of the universe and related to the estimates of the Wiener-filtered map of the cosmic microwave background (CMB), the anisotropic pressure, or the composition of a primordial vector field (instance magnetic field) to the metrical spatial structure of the universe [54–56]. In this case, the form of the scale factor can be impacted by the preliminary field. Lately, anisotropies also have been discussed by the Royal Society, and there is a compelling case that there are anomalies in data [57]. These anomalies, including the well-known low multipole alignments, cold spot, hemispherical asymmetry, and parity asymmetry, have sparked expansive discussions within the cosmology community about their origins and implications. While these anomalies could be mere statistical flukes within the standard Λ-CDM model, they have also been interpreted as potential signatures of new physics or extensions to the standard cosmological framework. One fascinating possibility is that these anomalies might

be related to the primordial anisotropies' existence or preferred directions in the early universe. Such anisotropies could derive from various sources, such as anisotropic inflationary models, vector or tensor fields, or even more exotic scenarios like cosmic birefringence or violations of fundamental symmetries. Probing the effects of such anisotropies on the evolution of the universe and the formation of large-scale structures is an active area of research with potential importance for our understanding of the early universe and the nature of dark energy.

A geometry that possibly connects the Riemannian metric structure of space-time to physical vector fields is a class of the Finsler-Randers variousness of spaces. In these spaces, an electromagnetic field, a magnetic field, or a gauge vector field may derive from the universe's physical source and can be contained in the geometry and create an anisotropic structure [58–62]. As a generalization of Riemannian geometry, Finsler geometry [63, 64] is the most general geometry where the line element depends on space-time coordinates (x) and tangent vectors (y). This y-dependence essentially describes the Finsler field and is merged with the concept of anisotropy, which creates deviations from Riemannian geometry [65]. Therefore, internal variables generate these geometrical anisotropies. With these conditions, Finsler geometry can be regarded as a physical geometry on which the matter dynamics occur, while Riemann geometry is the gravitational geometry [66–68].

II. GRAVITATIONAL FIELD EQUATIONS FOR FINSLER-RANDERS METRIC

The F-R cosmic scenario is established on the Finalerian geometry, which expands the Riemannian geometry. It is worth noticing that Riemannian geometry is also the particular case of the Finslerian geometry. Here, we examine only the main characteristics of the theory (see [63, 68, 69]). Generally, a Finsler space is derived from a generating function F(x, y) on the tangent bundle TM of a manifold M. The generating function F is differentiable on $\widehat{TM} = TM \setminus \{0\}$. The function F is also positively homogeneous of degree one in y. The $n \times n$ Hessian matrix is positive definite at every point of $\widehat{TM}$ that as the following form,

$$g_{ij} = \frac{\partial^2(\frac{1}{2}F^2)}{\partial y^\mu \partial y^\nu} = \frac{1}{2}\dot{\partial}_\mu \dot{\partial}_\nu F^2, \tag{1}$$

In other words, pair (M, F) is called Finsler space-time. In the F-R space-time, we have

$$F = \alpha(x, y) + \beta(x, y), \tag{2}$$

where

$$\alpha(x, y) = \sqrt{a_{ij} y^i y^j}, \qquad \beta(x, y) = \mathfrak{u}_i y^i, \tag{3}$$

$a_{ij}(x)$ is the FRW metric defined as a tensor corresponding to the Riemannian metric,

$$a_{ij}(x) = diag\left(1, -\frac{a^2(t)}{1-\kappa r^2}, -a^2(t)r^2, -a^2(t)r^2 \sin^2\theta\right), \tag{4}$$

and $\kappa = 0, \pm 1$ for a flat, closed and hyperbolic geometry respectively. Consequently, the geometrical structure of Finsler-Randers space is a generalization of Riemannian geometry. Here, the spatial coordinates are comoving the time coordinate defines the proper time investigated by the comoving observer. The vector $y^i = \frac{dx^i}{d\tau}$ expresses the four tangent vectors that depict the velocity of a comoving observer towards an appropriate family of world lines, namely fluid flow pathways, in a locally anisotropic universe. The arclength τ is the proper time. So we have $y^i = (1, 0, 0, 0)$. $\mathfrak{u}_i$ expresses a weak primordial vector field with $|\mathfrak{u}_i| \ll 1$ and $\mathfrak{u}_i = (\mathfrak{u}_0, 0, 0, 0)$, where $\mathfrak{u}_0 = \mathfrak{u}_0(t)$. Here, β is an 1-form. Now, using Eq. (1), the metric for the Finslerian space-time can be defined as follows [47, 70]:

$$g_{ij} = \mathfrak{g}_{ij} + \frac{1}{4\alpha}\left(\mathfrak{u}_i y_j + \mathfrak{u}_j y_i\right) - \frac{\beta}{\alpha^3} y_i y_j + \mathfrak{u}_i \mathfrak{u}_j, \tag{5}$$

where

$$\mathfrak{g}_{ij} = \frac{F}{\alpha}(x, y) a_{ij}(x). \tag{6}$$

Cartan tensor can be easily defined in full expression as follows [71]

$$C_{ijk}=\frac{1}{2}\left[\frac{1}{\alpha}\mathfrak{S}_{(ijk)}(a_{ij}\mathfrak{u}_k)-\frac{1}{\alpha^3}\mathfrak{S}_{(ijk)}(y_iy_j\mathfrak{u}_k)-\frac{\beta}{\alpha^3}\mathfrak{S}_{(ijk)}(a_{ij}y_k)+\frac{3\beta}{\alpha^5}y_iy_jy_k\right], \tag{7}$$

where $\mathfrak{S}_{(ijk)}$ expresses the sum over the cyclic permutation of the indices. It has been found that $C_{000}=\frac{\mathfrak{u}_0}{2}$ [47]. The Finsler–Randers field equations are the following form,

$$L_{ij}=\frac{8\pi G}{c^4}\left(T_{ij}-\frac{1}{2}T\mathfrak{g}_{ij}\right), \tag{8}$$

where

- T_{ij} are the energy-momentum tensor components for describing Finslerian anisotropic matter

$$T_{ij}(x,y(x))=(\rho+P)y_i(x)y_j(x)-P\mathfrak{g}_{ij}(x,y(x)), \tag{9}$$

  and T is the trace of them. Thus we have

$$T_{00}=\rho,\quad T_{11}=-P\mathfrak{g}_{11},\quad T_{22}=-P\mathfrak{g}_{22},\quad T_{33}=-P\mathfrak{g}_{33},\quad T=\rho\frac{\alpha}{F}-3P, \tag{10}$$

  where $\frac{F}{\alpha}\approx 1$ at the weak field limit.

- $L_{ij}=L^k_{ikj}$ is Ricci tensor and by inflicting the conditions $\ddot{\mathfrak{u}}_0,\dot{\mathfrak{u}}_0^2\approx 0$, its non-zero components as the following form [72],

$$L_{00}=-3\left(\frac{\ddot{a}}{a}+\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0\right), \tag{11}$$

$$L_{11}=\frac{a\ddot{a}+2\dot{a}^2+2\kappa+4a\dot{a}\dot{\mathfrak{u}}_0}{1-\kappa r^2}, \tag{12}$$

$$L_{22}=\left(a\ddot{a}+2\dot{a}^2+2\kappa+4a\dot{a}\dot{\mathfrak{u}}_0\right)r^2, \tag{13}$$

$$L_{33}=\left(a\ddot{a}+2\dot{a}^2+2\kappa+4a\dot{a}\dot{\mathfrak{u}}_0\right)r^2\sin^2\theta. \tag{14}$$

Now by imposing $c=1$ and $\kappa=0$ we have

$$\frac{\ddot{a}}{a}+2\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0=\frac{-4\pi G}{3}(\rho+3P), \tag{15}$$

$$\frac{\ddot{a}}{a}+2\frac{\dot{a}^2}{a^2}+4\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0=4\pi G(\rho-P), \tag{16}$$

where the symbol dot denotes the derivative with respect to t and $\dot{\mathfrak{u}}_0<0$ [73]. By using Eqs. (15) and (16) we obtain the Friedmann equation

$$\frac{\dot{a}^2}{a^2}+\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0=\frac{8\pi G}{3}\rho, \tag{17}$$

and

$$-2\frac{\ddot{a}}{a}-\frac{\dot{a}^2}{a^2}-5\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0=8\pi GP. \tag{18}$$

Eq. (17) is similar to the Friedmann equation in the Riemannian framework, apart from the extra term $\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0$. We associate this extra term with the present universe's anisotropy. By using Eqs. (17) and (18) we obtain deformed parameters as following form

$$\tilde{H}^2=\frac{\dot{a}^2}{a^2}+\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0,\quad\xrightarrow{\dot{\mathfrak{u}}_0^2\approx 0}\quad\tilde{H}=\left(\frac{\dot{a}}{a}+\frac{\dot{\mathfrak{u}}_0}{2}\right),$$

$$\tilde{q}=-\left(\frac{\ddot{a}}{a}+\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0\right)\tilde{H}^{-2},$$

Parameter	Classification
$\omega_{\mathfrak{de}} = -1$	cosmological constant
$\omega_{\mathfrak{de}} =$ Constant$\neq -1$	cosmic strings, domain walls, etc.
$\omega_{\mathfrak{de}} \neq$Constant	scalar fields (quintessence, k-essence etc.), braneworlds, Dirac-Born-Infeld (DBI) action, Chaplygin gas etc.
$\omega_{\mathfrak{de}} < -1$	phantom models

TABLE I: Classification of ω_{de} parameter.

where $\tilde{H}$ and $\tilde{q}$ are Hubble parameter and deceleration parameter, respectively. Conservation of energy-momentum results from Eqs. (17) and (18) as follows,

$$8\pi G\dot{\rho} + 24\pi G(\rho + P)H + 6H^2\dot{\mathfrak{u}}_0 + 12\pi G(\rho + P)\dot{\mathfrak{u}}_0 = 0. \tag{19}$$

The continuity Eq (19) plays an essential role in evolution because it deals with matter and its interactions. In current cosmology, two types of dark energy models are generally debated. Dark energy interaction models (taking into account the interaction between cold dark matter and dark energy) [74] and non-interaction models of dark energy, where matters are authorized to evolve individually [75]. Up to date, there are no known interactions other than gravity between the matter and dark energy. The present study only refers to non-interacting models. The system of equations is non-linear ordinary differential equations, and finding exact solutions is difficult. In the past, many attempts have been made to find exact and numerical solutions for EFEs. In the next section, solving techniques from the above system of equations will be discussed in detail.

III. EINSTEIN FIELD EQUATIONS FOR FINSLER-RANDERS METRIC WITH DARK ENERGY

The nature of dark energy and its candidature are not yet known, and its expression as a source term in Einstein's field equations is speculative. However, DE is assumed to be homogeneous, permeating all over the space, and the energy-momentum tensor can be expressed as a perfect fluid $T^{\mathfrak{de}}_{ij}$. In this case, its equation of state is in the form $P_{\mathfrak{de}} = \omega_{\mathfrak{de}}\rho_{\mathfrak{de}}$ where $\omega_{\mathfrak{de}}$ is the equation of state (EoS) parameter and is a function of time. Generally, it holds for the inequality $\omega_{\mathfrak{de}} < 0$. The appropriate value of $\omega_{\mathfrak{de}}$ is hotly debated, and analysis of some observational data suggests that its value is -1.018 ± 0.031 (Planck 2018 or SNe IA^a) [76]. Different values of $\omega_{\mathfrak{de}}$ in particular ranges produce different candidates, and they can be generally classified as seen in Table I, See [77, 78] (and Refs. therein) for a more extensive list of dark energy models. In each of them, fascinating cases exist that are associated with problems. For example, the cosmological constant is the most consistent model for dark energy that explains the observations but faces fine-tuning issues. Similarly, phantom models are fascinating, where the weak energy condition ($\rho > 0$, $P + \rho > 0$) with finite time singularity property is violated. In general relativity, dark energy can be introduced by adding the energy-momentum tensor $T^{\mathfrak{de}}$ as a perfect fluid together with the matter source $T^{\mathfrak{m}}$ into the Einstein field equations $G_{ij} = 8\pi G T_{ij}$ as following form,

$$T^{\mathfrak{tot}} = T^{\mathfrak{de}} + T^{\mathfrak{m}}, \tag{20}$$

$\rho_{\mathfrak{tot}} = \sum \rho + \rho_{\mathfrak{de}}$ and $P_{\mathfrak{tot}} = \sum P + P_{\mathfrak{de}}$ denote total energy densities and the total pressure corresponding to all kinds of matter (baryonic matter, dark matter, and radiation) and dark energy, respectively. According to Eq. (20), we can rewrite Eqs. (17), (18), and (19) as follows,

$$\frac{\dot{a}^2}{a^2} + \frac{\dot{a}}{a}\dot{\mathfrak{u}}_0 = \frac{8\pi G}{3}\rho_{\mathfrak{tot}}, \tag{21}$$

$$-2\frac{\ddot{a}}{a} - \frac{\dot{a}^2}{a^2} - 5\frac{\dot{a}}{a}\dot{\mathfrak{u}}_0 = 8\pi G P_{\mathfrak{tot}}, \tag{22}$$

$$8\pi G\dot{\rho}_{\mathfrak{tot}} + 24\pi G(\rho_{\mathfrak{tot}} + P_{\mathfrak{tot}})H + 6H^2\dot{\mathfrak{u}}_0 + 12\pi G(\rho_{\mathfrak{tot}} + P_{\mathfrak{tot}})\dot{\mathfrak{u}}_0 = 0. \tag{23}$$

The system of the above equations has only two independent equations with five unknowns a, ρ, P, $\rho_{\mathfrak{de}}$, $P_{\mathfrak{de}}$ (or $\omega_{\mathfrak{de}}$). The universe's large-scale homogeneous distribution of matter requires the barotropic equation of state to be considered $P = \omega\rho$, $\omega \in [0, 1]$. The equation of state expresses various kinds of matter sources in the universe depending on the discrete or dynamical values of the equation of state parameter as follows: baryonic matter ($\omega_{\mathfrak{bm}} = 0$), dark matter ($\omega_{\mathfrak{dm}} = 0$), radiation ($\omega_{\mathfrak{r}} = \frac{1}{3}$), stiff matter ($\omega_{\mathfrak{s}} = 1$), quintessence ($-1 < \omega_{\mathfrak{q}} < -\frac{1}{3}$), etc.

This extra equation represents the third restriction equation. Another restriction equation can be the regard of the EoS of dark energy ($\omega_{\mathfrak{de}}$ = constant or a function of time t or function of the scale factor or redshift), which is well known as a parametrization of dark energy EoS. These four equations can describe the cosmological dynamics of the universe where all the geometrical or physical parameters such as Hubble parameter (H), deceleration parameter (q), jerk parameter (j), densities (ρ , $\rho_{\mathfrak{de}}$), pressures (P, $P_{\mathfrak{de}}$), EoS parameter ($\omega_{\mathfrak{de}}$), density parameter (Ω_i), etc. are signified as functions of either scale factor or the redshift $z = \frac{a_0}{a} - 1$ (a_0 is the current value of the scale factor, usually normalized to $a_0 = 1$). But, we still need another equation to solve the system. The time evolution of the scale factor a is not yet known. Various schemes exist for parametrizing the scale factor and its higher-order derivatives (H, q, j, etc.). They provide the complete solution of EFEs, i.e., the explicit forms of the cosmic parameters as a function of t. An essential analysis of the solution methods of EFEs in general relativity theory or modified theories has two parts: One is the parametrization of geometrical parameters, and another is the parametrization of the physical parameters. The first type of parameterization scheme (geometric parameterization) is considered to find exact solutions that discuss the expansion dynamics of the universe and provide the time evolution of the physical parameters. This method is generally known as an independent model for cosmological models or cosmological parameterization [79–81]. It does not affect the background theory and provides solutions for EFEs. As well as it has the advantage of reconstructing the cosmological history of the universe and describing some of the phenomena of the universe. The goal is to achieve the exact solution of the Einstein field equations in standard general relativity with a simple parametrization of the Hubble parameter under the Finsler-Randers structure.

IV. PARAMETRIZATION OF HUBBLE PARAMETER IN FINSLER-RANDERS MODEL

Cosmological investigations provide clues to explore the evolution of the observable universe in a model-independent way in terms of kinematic variables [82]. Furthermore, the cosmological parameters analysis helps to study dark energy without any assumptions of any particular cosmological model other than the cosmological principle. In this paper, we intend to use a simple parametrization of the Hubble parameter, which is an explicit function of the cosmic time "t" as following form [81],

$$H(t) = \frac{k_2 t^{\mathfrak{m}}}{(t^{\mathfrak{n}} + k_1)^{\mathfrak{p}}}, \tag{24}$$

where $\mathfrak{m}, \mathfrak{n}, \mathfrak{p} \in \mathbb{R}$, k_1, $k_2 \neq 0$, and both have the dimensions of time. Some special values of the parameters $\mathfrak{m}$, $\mathfrak{n}$, and $\mathfrak{p}$ present some distinct models [81]. The parameterization (24) generalizes several well-known models, e.g., ΛCDM model, power law model, hybrid expansion model, jump model, linear variable deceleration parameter model, etc. As we know, $|\mathfrak{u}_i| \ll 1$ for parametrization Hubble parameter in Finsler structure we take $\mathfrak{u}_0 = \exp(-t)$. Table II can describe cosmic phase transition phenomena for negative values of k_1, and k_2 in two models. In studying late-time

Models	$H(t)$	$\tilde{H}(t)$	$a(t)$	$\tilde{a}(t)$
Model 1	$\frac{k_2}{t(k_1-t)}$	$\frac{k_2}{t(k_1-t)} - \frac{1}{2}e^{-t}$	$\beta\left(\frac{t}{k_1-t}\right)^{\frac{k_2}{k_1}}$	$\beta\left(\frac{t}{k_1-t}\right)^{\frac{k_2}{k_1}} e^{\frac{1}{2}e^{-t}}$
Model 2	$\frac{k_2}{t(k_1-t^2)}$	$\frac{k_2}{t(k_1-t^2)} - \frac{1}{2}e^{-t}$	$\beta\left(\frac{t^2}{k_1-t^2}\right)^{\frac{k_2}{2k_1}}$	$\beta\left(\frac{t^2}{k_1-t^2}\right)^{\frac{k_2}{2k_1}} e^{\frac{1}{2}e^{-t}}$

TABLE II: The Models

universe and observational studies, expressing all the cosmological parameters as functions of redshift z is convenient. It is well known that the Hubble parameter ($H = \frac{\dot{a}}{a}$) directly probes the universe's expansion history where $\dot{a}$ is the rate of change of the universe's scale factor. The Hubble parameter is also related to the differential redshift $H(z) = \frac{1}{z+1}\frac{dz}{dt}$, where dz is obtained from spectroscopic surveys. Table III shows the t-z relations, that $\alpha = \frac{k_1}{k_2}$ and parameters α and β are sufficient to describe these models.

Models	$t(z)$	$\tilde{H}(z)$
Model 1	$\frac{k_1}{1+[\beta(1+z)]^{\alpha}}$	$\frac{H_0(1+[\beta(1+z)]^{\alpha})^2}{(1+\beta^{\alpha})^2(1+z)^{\alpha}} - \frac{1}{2}e^{-\frac{(1+\beta^{\alpha})^2}{\alpha H_0 \beta^{\alpha}(1+[\beta(1+z)]^{\alpha})}}$
Model 2	$\frac{\sqrt{k_1}}{\sqrt{1+[\beta(1+z)]^{2\alpha}}}$	$\frac{H_0\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{3}{2}}}{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}(1+z)^{2\alpha}} - \frac{1}{2}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0 \beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}$

TABLE III: Hubble parameter vs. z in two models.

V. METHODOLOGY

In cosmology, parameter estimation often employs the Bayesian framework, which entails calculating the posterior distribution of parameters θ given the observed data D. This relationship is represented as:

$$P(\theta \mid D) = \frac{\mathcal{L}(D \mid \theta)P(\theta)}{P(D)}, \tag{25}$$

where $\mathcal{L}(D \mid \theta)$ is the likelihood function, $P(\theta)$ denotes the prior distribution of the parameters, and $P(D)$ is the marginal likelihood. The posterior distribution is explored across the parameter space θ, typically using algorithms such as Metropolis-Hastings. This algorithm directs a random walker through the parameter space, favoring areas with higher likelihood values. Parameter estimation involves determining the mean and uncertainty of the parameter distribution by examining the locations where the walker frequently visits and the extent of its deviations within the parameter space. To approximate the shape of the posterior distribution, the walker needs to take a sufficiently large number of steps. In Bayesian model selection, the evidence for each model is computed individually and then compared. This task usually demands substantial computational resources and often utilizes nested sampling methods. However, simpler tools like information criteria can offer reliable insights into model preferences when the posterior distributions closely resemble a Gaussian distribution. Our study investigates Dark Energy Models within Finsler geometry and Riemannian geometry frameworks. We aim to determine the optimal parameter values for these models and estimate the present-day Hubble constant (H_0). We employ Markov Chain Monte Carlo (MCMC) analysis using the Polychord package to explore the parameter space and obtain reliable estimates efficiently. This approach ensures robust exploration of the parameter space and accurate parameter estimation.

A. Cosmological Data Sets

1. *Cosmic Chronometers (CC)*

Cosmic chronometers are reliable probes for studying cosmic expansion, providing a model-independent method to measure the Hubble constant and the expansion rate. By analyzing the age and metallicity of nearby passive galaxies, we can estimate the expansion rate $H_{\rm CC}(z)$ at a given redshift $z_{\rm CC}$. This estimation is based on the observation that the expansion rate can be approximated by the ratio of the redshift difference to the time difference, adjusted by the redshift itself: $H_{\rm CC}(z) \approx -(\Delta z_{\rm CC}/\Delta t)/(1+z_{\rm CC})$. We have gathered cosmic chronometer data from various sources [83–86] covering a redshift range of approximately $0.07 \lesssim z \lesssim 1.97$. These data provide direct constraints on the universe's expansion history. To evaluate the consistency between theoretical predictions and cosmic chronometer measurements across different redshifts, we calculate the chi-squared distance $\chi^2_{\rm CC}$:

$$\chi^2_{\rm CC} = \sum_{i=1}^{31} \left(\frac{H(z_{\rm CC}) - H_{\rm CC}(z_{\rm CC})}{\sigma_{\rm CC}(z_{\rm CC})} \right)^2. \tag{26}$$

In this equation, $H_{\rm CC}(z_{\rm CC}) \pm \sigma_{\rm CC}(z_{\rm CC})$ represents the cosmic chronometer measurements of the expansion rate at redshift $z_{\rm CC}$, along with their uncertainties. We assume that the cosmic chronometer observations are uncorrelated.

2. *Type Ia Supernova (SNIa)*

One of the most renowned and commonly utilized cosmological tools is the study of distant Type Ia Supernovae. These supernova explosions are exceptionally luminous, often rivaling the brightness of their host galaxies [87]. Their

observed light curves typically exhibit peak brightness levels that remain relatively unaffected by distance, making them invaluable as standard candles. A key metric used to constrain cosmological models is the observed distance modulus, denoted as $\mu_{\rm obs}$. For our analysis, we use the most recent dataset available, the binned Pantheon dataset described in [87]. The likelihood function for the Type Ia Supernovae data, $L_{\rm SNIa}(Y;M)$, is expressed as:

$$L_{\rm SNIa}(Y;M) \propto \exp\left(-\frac{1}{2}\sum_{i=1}^{40} m_i C_{\rm cov}^{-1}\,{\rm cov}_m^{\dagger}\, i\right). \tag{27}$$

In this context, Y represents the vector of free parameters of the cosmological model. The term m_i is defined as the difference between the observed distance modulus $\mu_{{\rm obs},i}$ and the theoretical distance modulus $\mu_{\rm theor}(z_i)$, adjusted by M. The theoretical distance modulus $\mu_{\rm theor}$ is calculated using the standard luminosity distance formula:

$$\mu_{\rm theor} = 5\log\left(\frac{D_L}{1\,{\rm Mpc}}\right) + 25, \tag{28}$$

where D_L represents the luminosity distance, given by $D_L = c(1+z)\int_0^z \frac{dz'}{H(z')}$. This formula is applicable in a flat Friedmann-Robertson-Walker (FRW) space-time, irrespective of the underlying cosmology. Finally, $C_{\rm cov}$ denotes the covariance matrix associated with the binned Pantheon dataset. The parameter M is an intrinsic free parameter within the Pantheon dataset, capturing various observational uncertainties, including those related to host galaxy properties. To broaden our observational spectrum, we include 24 binned quasar distance modulus data from [88], a sample of 162 Gamma-Ray Bursts (GRBs) as described in [89]

3. *Baryon Acoustic Oscillations (BAO)*

For our analysis, we utilize a comprehensive list of BAO data points, including effective redshifts ($z_{\rm eff}$), observables, measurements, and associated errors, as provided in [90]. The BAO feature in the transverse direction offers a measurement of $\frac{D_H(z)}{r_d} = \frac{c}{H(z)r_d}$, where $D_H(z)$ is the Hubble distance at redshift z, and r_d is the sound horizon at the drag epoch. In a flat Universe, the comoving angular diameter distance is given by $D_M = \frac{c}{H_0}\int_0^z \frac{dz'}{E(z')},$. where $E(z)$ is the dimensionless Hubble parameter. The angular diameter distance D_A is defined as $D_A = \frac{D_M}{1+z}$, and the volume-averaged distance $D_V(z)/r_d$ contains information about the BAO peak coordinates. The volume-averaged distance is given by$D_V(z) = \left[zD_H(z)D_M^2(z)\right]^{1/3},$. with r_d being the sound horizon at the drag epoch, measured as 147.1 Mpc [91]. To compare theoretical predictions with observational BAO data, we calculate the distance function $\chi^2_{\rm BAO}$ as follows:

$$\chi^2_{\rm BAO} = \sum_{i=1}^{17}\left(\frac{H(z_{\rm BAO}) - H_{\rm BAO}(z_{\rm BAO})}{\sigma_{\rm BAO}(z_{\rm BAO})}\right)^2, \tag{29}$$

where $H_{\rm BAO}(z_{\rm BAO}) \pm \sigma_{\rm BAO}(z_{\rm BAO})$ represents the BAO-derived measurements of the expansion rate at redshift $z_{\rm BAO}$, scaled by the sound horizon radius. In our analysis, we have employed a nested sampler, implemented within the open-source package Polychord [92], in conjunction with the GetDist package [93] for presenting the results. Figs 1 and 2 depict the 68% and 95% confidence levels for key cosmological parameters in both the Riemannian and Finslerian dark energy models. Table IV presents the best-fit values of the model parameters α and β, along with the current Hubble constant H_0.

VI. OBSERVATIONAL AND THEORETICAL COMPARISONS OF THE HUBBLE PARAMETER, HUBBLE DIFFERENCE, AND APPARENT MAGNITUDE

After obtaining the best-fit values for both dark energy parametrizations in Riemannian and Finslerian models, it is necessary to compare these models with real observational datasets and the standard ΛCDM paradigm. To conduct a comprehensive comparative study, we will plot the Hubble function for all three scenarios: the Riemannian model, the Finslerian model, and the ΛCDM model. We will use the 31 Cosmic Chronometer (CC) datasets using their corresponding error bars for this analysis. Additionally, we will plot the difference between the Hubble functions of the Riemannian and Finslerian models relative to the ΛCDM model, denoted as $H_{\rm Model}(z) - H_{\Lambda{\rm CDM}}(z)$, against the CC datasets. Furthermore, we will plot the apparent magnitude in each mode and compare these with each other

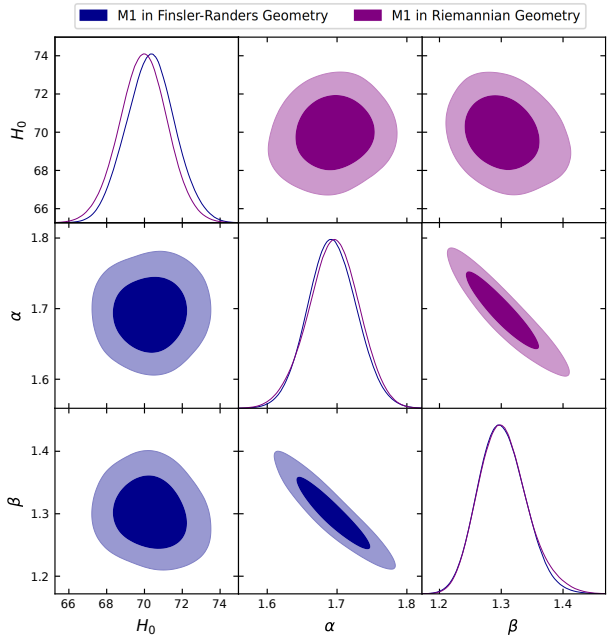

FIG. 1: MCMC confidence contours at 1σ and 2σ for Model 1.

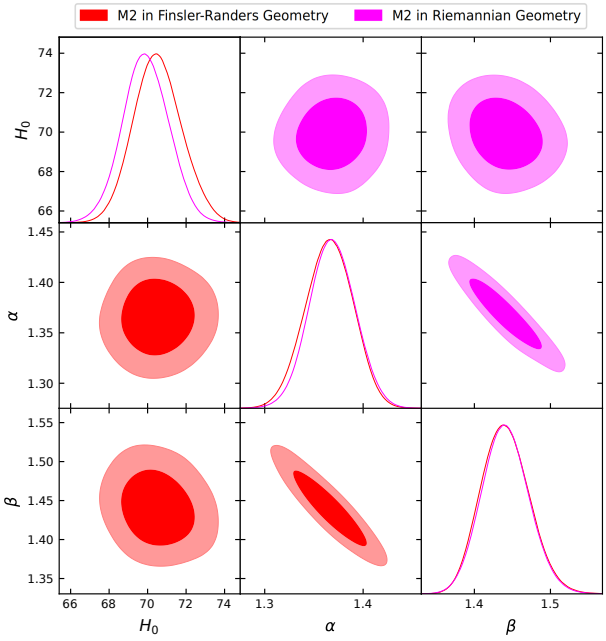

FIG. 2: MCMC confidence contours at 1σ and 2σ for Model 2.

MCMC Results					
Finslerian Geometry	Parameters	Best-fit Value	Riemannian Geometry	Parameters	Best-fit Value
Model 1	H_0	$70.326621^{\pm 2.380077}_{\pm 1.381923}$	Model 1	H_0	$69.946236^{\pm 2.522770}_{\pm 1.203929}$
	α	$1.693215^{\pm 0.066342}_{\pm 0.033153}$		α	$1.695306^{\pm 0.073840}_{\pm 0.033177}$
	β	$1.300786^{\pm 0.068124}_{\pm 0.037316}$		β	$1.302990^{\pm 0.069706}_{\pm 0.040574}$

	α	$1.365617^{\pm 0.046564}_{\pm 0.024308}$		α	$1.368668^{\pm 0.043644}_{\pm 0.022250}$
	β	$1.440327^{\pm 0.055222}_{\pm 0.031578}$		β	$1.440785^{\pm 0.058645}_{\pm 0.029173}$

TABLE IV: Summary of MCMC Results.

and with actual observational data. This comparison is essential for assessing the viability and accuracy of both dark energy parametrizations in explaining the Universe's accelerated expansion. Analyzing the Hubble function allows us to directly examine the rate of expansion over time while comparing $H_{\rm Model}(z) - H_{\Lambda{\rm CDM}}(z)$ helps us understand deviations from the standard model. The apparent magnitude comparison provides insights into the models' predictions of luminosity distance, which is crucial for understanding cosmological distances and the scale of the Universe.

A. Hubble Parameter $H(z)$

Figs. 3 and 4 illustrate the evolution of the Hubble parameters as a function of redshift for both the Riemannian and Finslerian models, with the ΛCDM model (black line) included for comparison, using cosmological parameters $\Omega_{\rm m0} = 0.3$ and $\Omega_\Lambda = 0.7$. In Fig. 3 for model M1, a deviation between the Riemannian (purple line) and Finslerian

(blue line) models and the ΛCDM model is evident at $z > 0.6$. However, all three models exhibit close agreement at $z < 0.6$. Similarly, in Fig. 4 for model M2, a deviation between the Riemannian (magenta line) and Finslerian (red line) models and the ΛCDM model is observed at $z > 1.2$ and close agreement at $z < 1.2$.

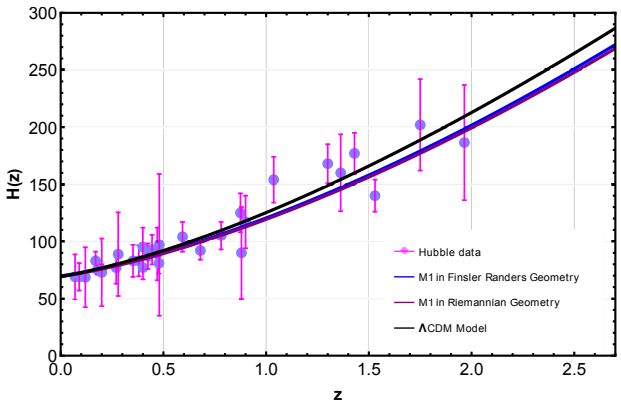

FIG. 3: Evolution of the Hubble Parameter as a function of redshift in Riemannian and Finslerian Modes

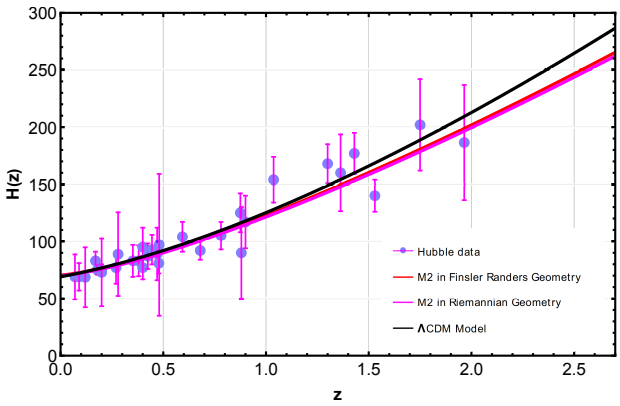

FIG. 4: Evolution of the Hubble Parameter as a function of redshift in Riemannian and Finslerian Modes

B. Hubble Difference $\Delta H(z)$

Figs. 5 and 6 illustrate the evolution of the difference between the Hubble parameter H predicted by specific cosmological models, Riemannian and Finslerian in our case and the Hubble parameter H predicted by the ΛCDM model, both evaluated at a given redshift z. Fig. 5 shows $\Delta H(z) = H_{\mathrm{M1}}(z) - H_{\Lambda\mathrm{CDM}}(z)$. It can be observed that $\Delta H(z)$ is significant at $z > 0.6$ for both the Riemannian (purple line) and Finslerian (blue line) models compared to the ΛCDM model. However, at $z < 0.6$, $\Delta H(z)$ becomes negligible. Fig. 6 for model M2 shows $\Delta H(z)$. A significant difference between the Riemannian (magenta line) and Finslerian (red line) models and the ΛCDM model is observed at $z > 1$. However, $\Delta H(z)$ becomes negligible at $z < 1$.

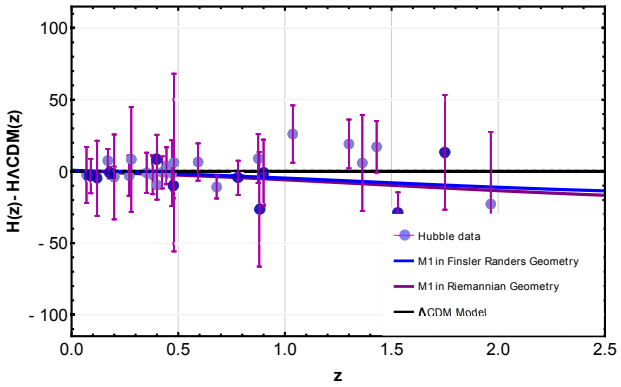

FIG. 5: Evolution of the Hubble Difference in Riemannian and Finslerian Models

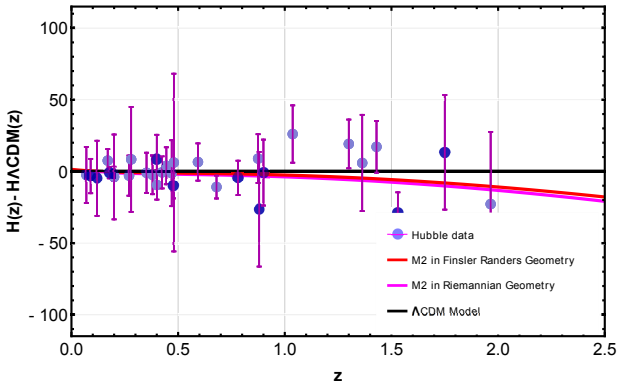

FIG. 6: Evolution of the Hubble Difference in Riemannian and Finslerian Models.

C. Distance Modulus $\mu(z)$

Figs. 7 and 8 depict the evolution of the distance modulus $\mu(z)$ for a Type Ia supernova (SINa), Gamma Ray Burst (GRB), and Quasar (Q). The distance modulus is an astronomical measure used to quantify the apparent brightness of celestial objects based on their redshift z, which indicates how much the Universe has expanded since the object's

light was emitted. It is related to the luminosity distance D_L by the formula: $\mu = 5\log_{10}(D_L) + 25$, where μ is the distance modulus and D_L is the luminosity distance in megaparsecs (Mpc). In the standard cosmological model, the luminosity distance is calculated as: $D_L = (1+z) \cdot D_C(z)$. Here, z is the redshift, and $D_C(z)$ is the comoving distance, which represents the spatial distance between the observer and the object, accounting for the expansion of the Universe. The comoving distance $D_C(z)$ is given by an integral involving the inverse of the Hubble parameter $H(z)$: $D_C(z) = \int_0^z \frac{c\,dz'}{H(z')}$, where c is the speed of light and $H(z)$ is the Hubble parameter at redshift z. Fig. 7 illustrates a close agreement between the Riemannian (purple line) and Finslerian (blue line) modes with ΛCDM model and SNIa dataset at low redshift. However, differences become evident at high redshifts when considering the SNIa dataset. Fig. 8 exhibits a similar trend in model M2, where both Riemannian (magenta line) and Finslerian (red line) modes closely resemble the ΛCDM model.

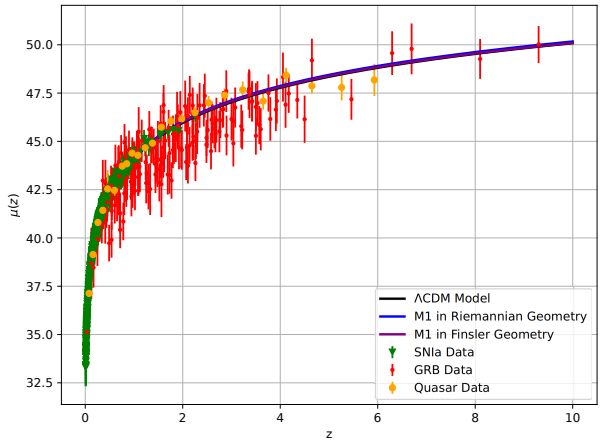

FIG. 7: The evolution of Distance Modulus in Riemannian and Finslerian modes.

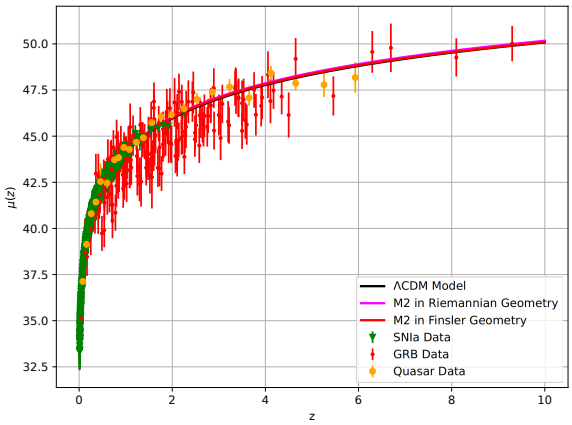

FIG. 8: The evolution of Distance Modulus in Riemannian and Finslerian modes.

VII. COSMOGRAPHIC PARAMETER

A. Deceleration Parameter

The deceleration parameter (DP), q, is a dimensionless measure in cosmology that describes the rate of change of the universe's expansion. It is defined as $q = -\frac{\ddot{a}a}{\dot{a}^2}$, where a is the scale factor of the universe, $\dot{a}$ is its first derivative with respect to time (the expansion rate), and $\ddot{a}$ is its second derivative (the acceleration of the expansion). A positive q indicates a decelerating expansion, while a negative q indicates an accelerating expansion. Understanding q is crucial for studying the dynamics of the universe, including the transition from a decelerated to an accelerated phase, which is associated with the influence of dark energy. In the case of Finslerian Geometry, the expression of the deceleration parameter in terms of redshift z for Models 1 and 2 is provided in Table V. Figs 9 and 10 show the evolution of the deceleration parameter for Models 1 and 2 in both Riemannian and Finslerian geometries, compared with the ΛCDM model.

B. Jerk and Snap Parameters

As we know, $q(t)$ represents the deceleration parameter, which measures the Universe's acceleration. Now, we are going to introduce other parameters such as $j(t) = \frac{\dddot{a}}{aH^3}$ (jerk parameter), and $s(t) = \frac{a^{(4)}}{aH^4}$ (snap parameter). These parameters play significant roles in the cosmographic analysis of the Universe, specifically in understanding the

VIII. STATEFINDER DIAGNOSTIC

Statefinder diagnostics [94–97] is generally utilized to denote various dark energy models and compare their behavior using the higher-order derivatives of the scale factor. The parameters are $\mathfrak{s}$ and r are computed by using the following relations:

$$r = j = \frac{\dddot{a}}{aH^3}, \qquad \mathfrak{s} = \frac{r-1}{3\left(q-\frac{1}{2}\right)}.$$

The statefinder diagnostics pairs are made as s, r and q, r wherein various trajectories in the $\mathfrak{s}-r$ and $q-r$ planes scheme to see the temporal evolutions of various dark energy models. The fixed points in this context are generally considered as $\{\mathfrak{s}, r\} = \{0, 1\}$ for the ΛCDM model and $\{\mathfrak{s}, r\} = \{1, 1\}$ for the SCDM (standard cold dark matter) model in FLRW background and the departures of any dark energy model from these fixed points are examined. The other diagnostic pair is $\{q, r\}$ and the fixed points considered are $\{q, r\} = \{-1, 1\}$ for the ΛCDM model and $\{q, r\} = \{0.5, 1\}$ for SCDM model.The statefinder parameters for the considered Model 1 and Model 2 are computed as follows

Model 1

$$\tilde{r} = \tilde{j}, \qquad \tilde{\mathfrak{s}} = \frac{8\alpha\triangle_1}{27\triangle_2}, \tag{30}$$

where

$$\begin{aligned}
\triangle_1 \;=\; & -\Bigg[\left(\frac{3}{2}\,\alpha+\frac{27}{8}\right)(\beta\,(1+z))^{2\,\alpha}+\left(\frac{5}{4}\,\alpha+\frac{15}{8}\right)(\beta\,(1+z))^{3\,\alpha}+\left(\frac{5}{4}\,\alpha-\frac{15}{8}\right)(\beta\,(1+z))^{4\,\alpha}\\
& +\;\left(\frac{5}{4}\,\alpha-\frac{27}{8}\right)(\beta\,(1+z))^{5\,\alpha}+\left(\alpha-\frac{15}{8}\right)(\beta\,(1+z))^{6\,\alpha}+\left(\frac{\alpha}{4}-\frac{3}{8}\right)(\beta\,(1+z))^{7\,\alpha}\\
& +\;\left(\alpha+\frac{15}{8}\right)(\beta\,(1+z))^{\alpha}+\frac{\alpha}{4}+\frac{3}{8}\Bigg]H_0^2\mathrm{e}^{\frac{2\,\beta^{-\alpha}+4+2\,\beta^{\alpha}}{\alpha\,H_0\,(1+(\beta\,(1+z))^{\alpha})}}+\Bigg[\left(\frac{\alpha}{2}+\frac{9}{4}\right)(\beta\,(1+z))^{2\,\alpha}\\
& +\;\left(\frac{\alpha}{2}-\frac{9}{4}\right)(\beta\,(1+z))^{3\,\alpha}+\left(\alpha-\frac{27}{8}\right)(\beta\,(1+z))^{4\,\alpha}+\left(\frac{\alpha}{2}-\frac{9}{8}\right)(\beta\,(1+z))^{5\,\alpha}\\
& +\;\left(\alpha+\frac{27}{8}\right)(\beta\,(1+z))^{\alpha}+\frac{\alpha}{2}+\frac{9}{8}\Bigg](1+z)^{\alpha}\,H_0\left(\frac{1}{2}\,\beta^{2\,\alpha}+\beta^{\alpha}+\frac{1}{2}\right)\mathrm{e}^{\frac{\beta^{-\alpha}+2+\beta^{\alpha}}{\alpha\,H_0\,(1+(\beta\,(1+z))^{\alpha})}}\\
& -\;\frac{3}{4}\,(1+z)^{2\,\alpha}\left(\beta^{\alpha}+\frac{3}{2}\,\beta^{2\,\alpha}+\beta^{3\,\alpha}+\frac{1}{4}\,\beta^{4\,\alpha}+\frac{1}{4}\right)\Bigg((\beta\,(1+z))^{\alpha}-(\beta\,(1+z))^{2\,\alpha}\\
& -\;(\beta\,(1+z))^{3\,\alpha}+1\Bigg),
\end{aligned}$$

$$\begin{aligned}
\triangle_2 \;=\; & \Bigg[-H_0\left(\left(\frac{-\alpha}{3}+\frac{1}{2}\right)(\beta\,(1+z))^{2\,\alpha}+(\beta\,(1+z))^{\alpha}+\frac{\alpha}{3}+\frac{1}{2}\right)\mathrm{e}^{\frac{\beta^{-\alpha}+2+\beta^{\alpha}}{\alpha\,H_0\,(1+(\beta\,(1+z))^{\alpha})}}\\
& +\;(1+z)^{\alpha}\left(\frac{1}{2}\,\beta^{2\,\alpha}+\beta^{\alpha}+\frac{1}{2}\right)\Bigg]\Bigg[-\frac{2}{3}\,H_0\left((\beta\,(1+z))^{\alpha}+\frac{1}{2}\,(\beta\,(1+z))^{2\,\alpha}+\frac{1}{2}\right)\\
& .\;\;\mathrm{e}^{\frac{\beta^{-\alpha}+2+\beta^{\alpha}}{\alpha\,H_0\,(1+(\beta\,(1+z))^{\alpha})}}+(1+z)^{\alpha}\left(\frac{1}{2}\,\beta^{2\,\alpha}+\beta^{\alpha}+\frac{1}{2}\right)\Bigg]\left(1+(\beta\,(1+z))^{\alpha}\right)^3.
\end{aligned}$$

Model 2

$$\tilde{r}=\tilde{j},\qquad \tilde{\mathfrak{s}}=\frac{-3\alpha\triangle_3}{2\triangle_4},\tag{31}$$

$$\begin{aligned}
\triangle_3 \;=\; & -\frac{28\,{H_0}^2\left(1+(\beta\,(1+z))^{2\,\alpha}\right)^{\frac{3}{2}}}{9}\Bigg[\left(\alpha+\frac{15}{14}\right)(\beta\,(1+z))^{2\,\alpha}+\left(\frac{3}{7}\,\alpha+\frac{9}{14}\right)(\beta\,(1+z))^{4\,\alpha}\\
& +\;\left(\frac{\alpha}{7}-\frac{3}{14}\right)(\beta\,(1+z))^{6\,\alpha}+\left(\frac{\alpha}{7}-\frac{3}{14}\right)(\beta\,(1+z))^{8\,\alpha}+\frac{4}{7}\,\alpha+\frac{3}{7}\Bigg]{H_0}^2\mathrm{e}^{2\,\frac{\left(1+\beta^{2\,\alpha}\right)^{\frac{3}{2}}\beta^{-2\,\alpha}}{\alpha\,H_0\,\sqrt{1+(\beta\,(1+z))^{2\,\alpha}}}}\\
& +\;\frac{28\left(1+\beta^{2\,\alpha}\right)^{\frac{3}{2}}(1+z)^{2\,\alpha}}{9}\Bigg[\left(\alpha+\frac{45}{28}\right)(\beta\,(1+z))^{2\,\alpha}+\left(\frac{3}{7}\,\alpha+\frac{27}{28}\right)(\beta\,(1+z))^{4\,\alpha}\\
& +\;\left(\frac{\alpha}{7}-\frac{9}{28}\right)(\beta\,(1+z))^{6\,\alpha}+\left(\frac{\alpha}{7}-\frac{9}{28}\right)(\beta\,(1+z))^{8\,\alpha}+\frac{4}{7}\,\alpha+\frac{9}{14}\Bigg]H_0\,\mathrm{e}^{\frac{\left(1+\beta^{2\,\alpha}\right)^{\frac{3}{2}}\beta^{-2\,\alpha}}{\alpha\,H_0\,\sqrt{1+(\beta\,(1+z))^{2\,\alpha}}}}\\
& +\;\left((\beta\,(1+z))^{2\,\alpha}-2\right)\left(1+(\beta\,(1+z))^{2\,\alpha}\right)^{\frac{3}{2}}(1+z)^{4\,\alpha}\left(\beta^{2\,\alpha}+\beta^{4\,\alpha}+\frac{1}{3}\,\beta^{6\,\alpha}+\frac{1}{3}\right),
\end{aligned}$$

$$\begin{aligned}
\triangle_4 \;=\; & \left(1+(\beta\,(1+z))^{2\,\alpha}\right)^{\frac{5}{2}}\Bigg[\left(1+(\beta\,(1+z))^{2\,\alpha}\right)^{\frac{3}{2}}H_0\,\mathrm{e}^{\frac{\left(1+\beta^{2\,\alpha}\right)^{\frac{3}{2}}\beta^{-2\,\alpha}}{\alpha\,H_0\,\sqrt{1+(\beta\,(1+z))^{2\,\alpha}}}}-\frac{3}{2}\left(1+\beta^{2\,\alpha}\right)^{\frac{3}{2}}\\
& .\;\;(1+z)^{2\,\alpha}\Bigg]\Bigg[\left(\left(\alpha-\frac{3}{2}\right)(\beta\,(1+z))^{2\,\alpha}-2\,\alpha-\frac{3}{2}\right)\sqrt{1+(\beta\,(1+z))^{2\,\alpha}}H_0\\
& .\;\;\mathrm{e}^{\frac{\left(1+\beta^{2\,\alpha}\right)^{\frac{3}{2}}\beta^{-2\,\alpha}}{\alpha\,H_0\,\sqrt{1+(\beta\,(1+z))^{2\,\alpha}}}}+\frac{3}{2}\left(1+\beta^{2\,\alpha}\right)^{\frac{3}{2}}(1+z)^{2\,\alpha}\Bigg].
\end{aligned}$$

IX. $Om(z)$ DIAGNOSTIC

Om diagnostic is another instrument defined in [98–101] that uses the Hubble parameter and provides a null test of the ΛCDM model. Similar to the statefinder diagnostic, the $\tilde{O}m$ diagnostic is also a productive method to distinguish different DE models from the ΛCDM model according to the slope variation of $\tilde{O}m(z)$. The positive slope of the diagnostic indicates a quintessence nature ($\omega > -1$), the Negative slope of the diagnostic indicates a phantom nature ($\omega < -1$), and the constant slope with respect to redshift reveals the nature of dark energy coincides with the cosmological constant ($\omega = -1$). The $\tilde{O}m(z)$ for a flat universe is defined as follows:

$$\tilde{Om}(z)=\frac{\left(\frac{\tilde{H}(z)}{H_0}\right)^2-1}{(1+z)^3-1},$$

Model 1

$$\tilde{Om}(z)=\frac{\left(\frac{(1+[\beta(1+z)]^{\alpha})^4}{(1+\beta^{\alpha})^4(1+z)^{2\alpha}}-\frac{(1+[\beta(1+z)]^{\alpha})^2}{H_0(1+\beta^{\alpha})^2(1+z)^{2\alpha}}e^{-\frac{(1+\beta^{\alpha})^2}{\alpha H_0\beta^{\alpha}(1+[\beta(1+z)]^{\alpha})}}\right)-1}{(1+z)^3-1},$$

Model 2

$$\tilde{Om}(z)=\frac{\left(\frac{\left(1+[\beta(1+z)]^{2\alpha}\right)^3}{(1+\beta^{2\alpha})^3(1+z)^{4\alpha}}-\frac{\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{3}{2}}}{H_0(1+\beta^{2\alpha})^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}\right)-1}{(1+z)^3-1}.$$

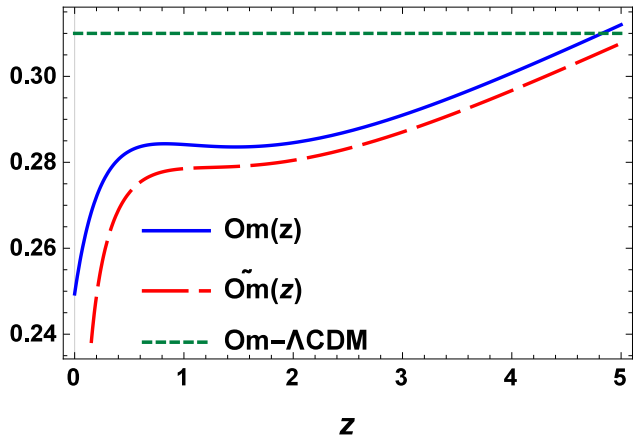

FIG. 19: $Om(z)$ vs. z in Riemannian and Finslerian modes.

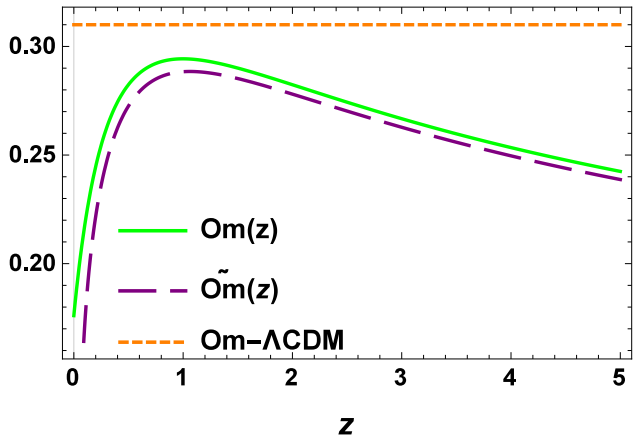

FIG. 20: $Om(z)$ vs. z in Riemannian and Finslerian modes.

X. PHYSICAL PARAMETERS

Here, we consider a two-fluid model, cold dark matter and dark energy, since the radiation contribution at present is negligible. The matter pressure is $P_{\mathfrak{m}}=0$ for cold dark matter, the equation of state is $P_{\mathfrak{de}}=\omega_{\mathfrak{de}}\rho_{\mathfrak{de}}$ for dark energy, and $M_{pl}=(8\pi G)^{-\frac{1}{2}}$. By utilizing Eqs (21) and (22), we derive expressions for critical physical parameters. These expressions allow us to interpret the physical behavior of matter and dark energy densities and pressures. Graphical representations further elucidate these behaviors for both Model 1 and Model 2, providing insights into their respective dynamics within the cosmological framework.

Model 1:

$$\frac{\tilde{P}_{\mathfrak{de}}}{M_{pl}^2H_0^2}=\frac{(-3+2\alpha)\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^4-4\alpha\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^3}{\left(1+\beta^{\alpha}\right)^4(1+z)^{2\alpha}}+5\frac{\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^2}{H_0\left(1+\beta^{\alpha}\right)^2(1+z)^{\alpha}}$$
$$\cdot\ e^{\frac{-(1+\beta^{\alpha})^2}{\alpha H_0\beta^{\alpha}(1+[\beta(1+z)]^{\alpha})}},\qquad(32)$$

$$\frac{\tilde{\rho}_{\mathfrak{de}}}{M_{pl}^2H_0^2} = \frac{1}{\omega_{\mathfrak{de}}}\Bigg\{\frac{(-3+2\alpha)\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^4-4\alpha\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^3}{\left(1+\beta^{\alpha}\right)^4(1+z)^{2\alpha}}+5\frac{\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^2}{H_0\left(1+\beta^{\alpha}\right)^2(1+z)^{\alpha}} . \ \mathrm{e}^{\frac{-(1+\beta^{\alpha})^2}{\alpha \mathrm{H}_0\beta^{\alpha}(1+[\beta(1+z)]^{\alpha})}}\Bigg\}, \tag{33}$$

$$\frac{\tilde{\rho}_{\mathfrak{m}}}{M_{pl}^2H_0^2} = \left(3\frac{\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^4}{\left(1+\beta^{\alpha}\right)^4(1+z)^{2\alpha}}-\frac{1}{\omega_{\mathfrak{de}}}\frac{(-3+2\alpha)\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^4-4\alpha\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^3}{\left(1+\beta^{\alpha}\right)^4(1+z)^{2\alpha}}\right) - (3+\frac{5}{\omega_{\mathfrak{de}}})\frac{\left(1+\beta^{\alpha}(1+z)^{\alpha}\right)^2}{H_0\left(1+\beta^{\alpha}\right)^2(1+z)^{\alpha}}\mathrm{e}^{\frac{-(1+\beta^{\alpha})^2}{\alpha \mathrm{H}_0\beta^{\alpha}(1+[\beta(1+z)]^{\alpha})}}. \tag{34}$$

Model 2:

$$\frac{\tilde{P}_{\mathfrak{de}}}{M_{pl}^2H_0^2} = \frac{(-3+2\alpha)\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3-6\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^2}{\left(1+\beta^{2\alpha}\right)^3(1+z)^{4\alpha}}+5\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^{\frac{3}{2}}}{H_0\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}(1+z)^{2\alpha}} . \ \mathrm{e}^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha \mathrm{H}_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}, \tag{35}$$

$$\frac{\tilde{\rho}_{\mathfrak{de}}}{M_{pl}^2H_0^2} = \frac{1}{\omega_{\mathfrak{de}}}\Bigg\{\frac{(-3+2\alpha)\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3-6\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^2}{\left(1+\beta^{2\alpha}\right)^3(1+z)^{4\alpha}}+5\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^{\frac{3}{2}}}{H_0\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}(1+z)^{2\alpha}} . \ \mathrm{e}^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha \mathrm{H}_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}\Bigg\}, \tag{36}$$

$$\frac{\tilde{\rho}_{\mathfrak{m}}}{M_{pl}^2H_0^2} = \left(3\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3}{\left(1+\beta^{2\alpha}\right)^3(1+z)^{4\alpha}}-\frac{1}{\omega\mathfrak{de}}\frac{(-3+2\alpha)\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3-6\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^2}{\left(1+\beta^{2\alpha}\right)^3(1+z)^{4\alpha}}\right) - (3+\frac{5}{\omega_{\mathfrak{de}}})\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^{\frac{3}{2}}}{H_0\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}. \tag{37}$$

When the candidate of dark energy is considered as cosmological constant, we have $\rho_{\mathfrak{de}} = \rho_{\Lambda}$ and $\omega_{\mathfrak{de}} = -1$, then the evolution of the physical parameters can be illustrated as shown in the following figures: **Scalar Field** Since the equation of state for the cosmological constant is non-dynamical, the observations favor the dynamical equation of state. This feature makes another suitable candidate for depicting dark energy, such as the general scalar field. For a general scalar field ϕ, the action can be denoted as

$$S = \frac{1}{16\pi}\int d^4x\sqrt{-g}\left\{\frac{M_{pl}^2}{2}R-\frac{1}{2}\partial_{\nu}\partial^{\nu}\phi-V(\phi)+{}^{Matter}\mathcal{L}\right\}.$$

In 2018, S. I. Vacaru [102] derived respective energy-momentum tensors for Lagrange-Finsler. Due to this

$$S = {}^{g}S+{}^{\phi}S+{}^{Matter}S, \quad T_{\alpha\beta} = {}^{g}T_{\alpha\beta}+{}^{\phi}T_{\alpha\beta}.$$

In GR, the Lagrange density for gravitational fields is postulated in the form

$${}^{g}\mathcal{L}(g_{ij},\nabla) = \frac{M_{pl}^2}{2}R,$$

where R is the Ricci scalar and the Planck mass M_{pl} is determined by the Newton constant G. $R_{ij} = \frac{8\pi G}{c^4}\left({}^{g}T_{ij}-\frac{1}{2}g_{ij}{}^{g}T\right)$. The Lagrange density for scalar fields is defined in the following form

$${}^{\phi}\mathcal{L} = \frac{1}{2}\dot{\phi}^2-V(\phi),$$

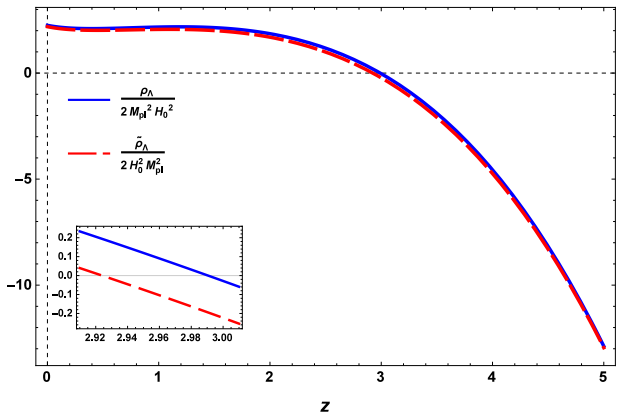

FIG. 21: Model 1: The evolution of the energy densities of the cosmological constant ($\rho_{\mathfrak{de}} = \rho_\Lambda$ and $\omega_{\mathfrak{de}} = -1$) in Riemannian and Finslerian modes.

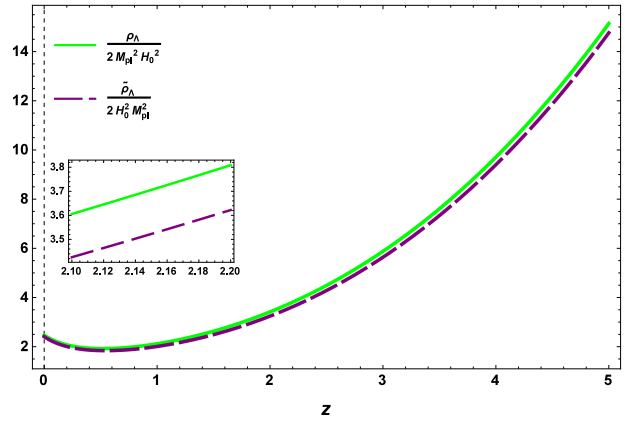

FIG. 22: Model 2: The evolution of the energy densities of the cosmological constant ($\rho_{\mathfrak{de}} = \rho_\Lambda$ and $\omega_{\mathfrak{de}} = -1$) in Riemannian and Finslerian modes.

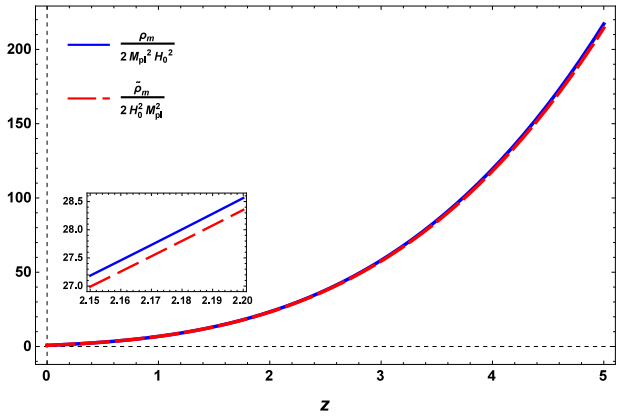

FIG. 23: Model 1: The evolution of the matter energy densities (ρ_m) in Riemannian and Finslerian modes.

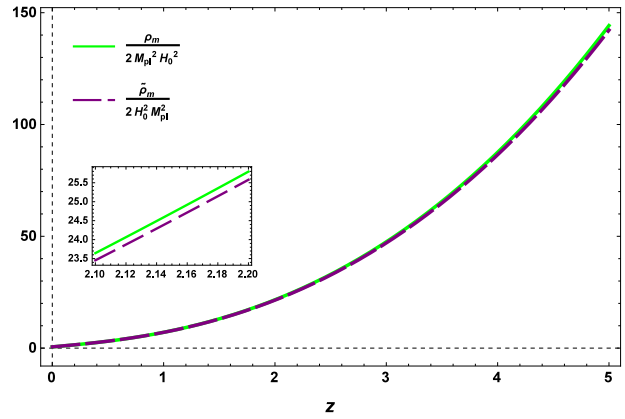

FIG. 24: Model 2: The evolution of the matter energy densities (ρ_m) in Riemannian and Finslerian modes.

where ${}^{\phi}T_{\alpha\beta} = \frac{-2}{\sqrt{|g_{\alpha\beta}|}}\frac{\delta(\sqrt{|g_{\mu\nu}|}{}^{\phi}\mathcal{L})}{\delta g^{\alpha\beta}}$. Therefore, similar to the Riemannian state, we have

$$\tilde{\rho}_\phi = {}^{\phi}T_{00} = \frac{1}{2}\dot{\phi}^2 + V(\phi).$$

For a two-component universe, scalar field and cold dark matter with minimal interaction between them (i.e., $\rho_{\mathfrak{tot}} = \rho_\phi + \rho_{\mathfrak{m}}, \rho_{\mathfrak{m}} = ca^{-3} = c(1+z)^3$, c is a constant of integration), then the solutions obtained from Eqs. (21) and (22) are

Model 1:

$$\begin{aligned}\frac{\tilde{\rho}_\phi}{M_{pl}^2H_0^2} &= \frac{c(1+z)^3}{M_{pl}^2H_0^2} - \left(\frac{2\alpha\left(1+\beta^\alpha(1+z)^\alpha\right)^4 - 4\alpha\left(1+\beta^\alpha(1+z)^\alpha\right)^3}{\left(1+\beta^\alpha\right)^4(1+z)^{2\alpha}}\right)\\ &- 2\frac{\left(1+\beta^\alpha(1+z)^\alpha\right)^2}{H_0\left(1+\beta^\alpha\right)^2(1+z)^\alpha}\mathrm{e}^{\frac{-(1+\beta^\alpha)^2}{\alpha H_0\beta^\alpha(1+[\beta(1+z)]^\alpha)}},\end{aligned} \tag{38}$$

$$\frac{\tilde{V}(\phi)}{M_{pl}^2H_0^2} = \frac{c(1+z)^3}{2M_{pl}^2H_0^2} - \left(\frac{(\frac{-3}{2}+2\alpha)\left(1+\beta^\alpha(1+z)^\alpha\right)^4 - 4\alpha\left(1+\beta^\alpha(1+z)^\alpha\right)^3}{(1+\beta^\alpha)^4(1+z)^{2\alpha}}\right) - \frac{7}{2}\frac{(1+\beta^\alpha(1+z)^\alpha)^2}{H_0(1+\beta^\alpha)^2(1+z)^\alpha}e^{\frac{-(1+\beta^\alpha)^2}{\alpha H_0\beta^\alpha(1+[\beta(1+z)]^\alpha)}}. \quad (39)$$

Model 2:

$$\frac{\tilde{\rho}_\phi}{M_{pl}^2H_0^2} = \frac{c(1+z)^3}{M_{pl}^2H_0^2} - \left(\frac{2\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3 - 6\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^2}{(1+\beta^{2\alpha})^3(1+z)^{4\alpha}}\right) - 2\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^{\frac{3}{2}}}{H_0(1+\beta^{2\alpha})^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}, \quad (40)$$

$$\frac{\tilde{V}(\phi)}{M_{pl}^2H_0^2} = \frac{c(1+z)^3}{2M_{pl}^2H_0^2} - \left(\frac{(\frac{-3}{2}+2\alpha)\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3 - 6\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^2}{(1+\beta^{2\alpha})^3(1+z)^{4\alpha}}\right) - \frac{7}{2}\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^{\frac{3}{2}}}{H_0(1+\beta^{2\alpha})^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}. \quad (41)$$

As we know, the total density parameters is written as follows,

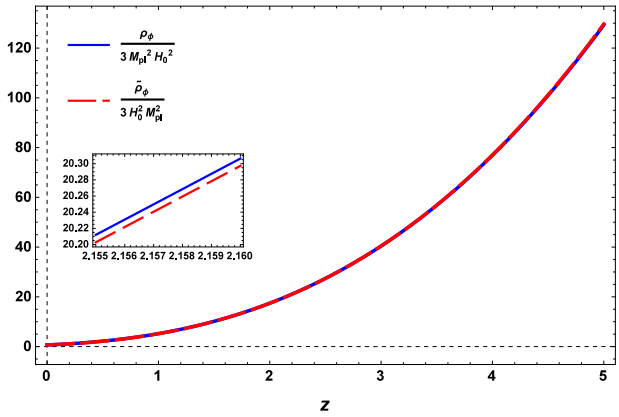

FIG. 25: Model 1: The evolution of the scalar field energy density (ρ_ϕ) in Riemannian and Finslerian modes.

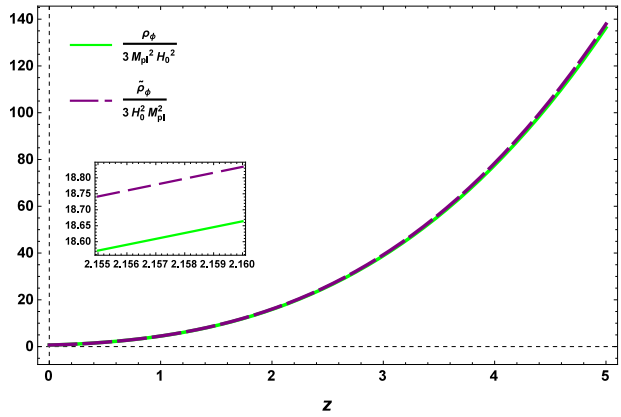

FIG. 26: Model 2: The evolution of the scalar field energy density (ρ_ϕ) in Riemannian and Finslerian modes.

$$1 = \tilde{\Omega} = \tilde{\Omega}_\phi + \tilde{\Omega}_{\mathrm{m}} \quad (42)$$

where $\tilde{\Omega}_\phi = \frac{\tilde{\rho}_\phi}{3M_{pl}^2H^2}$ and $\tilde{\Omega}_{\mathrm{m}} = \frac{\tilde{\rho}_{\mathrm{m}}}{3M_{pl}^2H^2}$ are density parameter for the scalar field and density parameter for the matter, respectively. They can be computed for two models as,

Model 1:

$$\tilde{\Omega}_\phi = \frac{\frac{c(1+z)^3}{M_{pl}^2H_0^2} - \left(\frac{2\alpha(1+\beta^\alpha(1+z)^\alpha)^4 - 4\alpha(1+\beta^\alpha(1+z)^\alpha)^3}{(1+\beta^\alpha)^4(1+z)^{2\alpha}}\right) - 2\frac{(1+\beta^\alpha(1+z)^\alpha)^2}{H_0(1+\beta^\alpha)^2(1+z)^\alpha}e^{\frac{-(1+\beta^\alpha)^2}{\alpha H_0\beta^\alpha(1+[\beta(1+z)]^\alpha)}}}{3\left(\frac{(1+[\beta(1+z)]^\alpha)^4}{(1+\beta^\alpha)^4(1+z)^{2\alpha}} - \frac{(1+[\beta(1+z)]^\alpha)^2}{H_0(1+\beta^\alpha)^2(1+z)^{2\alpha}}e^{-\frac{(1+\beta^\alpha)^2}{\alpha H_0\beta^\alpha(1+[\beta(1+z)]^\alpha)}}\right)}, \quad (43)$$

from Eqs. (42) and (43), we obtain

$$\frac{c}{M_{pl}^2H_0^2} = 3(1-\Omega_{\mathrm{m}_0})(1-\frac{1}{H_0}e^{\frac{-(1+\beta^\alpha)}{\alpha H_0\beta^\alpha}}) + (2\alpha - \frac{4\alpha}{1+\beta^\alpha}) + \frac{2}{\mathrm{H}_0}e^{\frac{-(1+\beta^\alpha)}{\alpha H_0\beta^\alpha}} = \mathcal{A}, \quad (44)$$

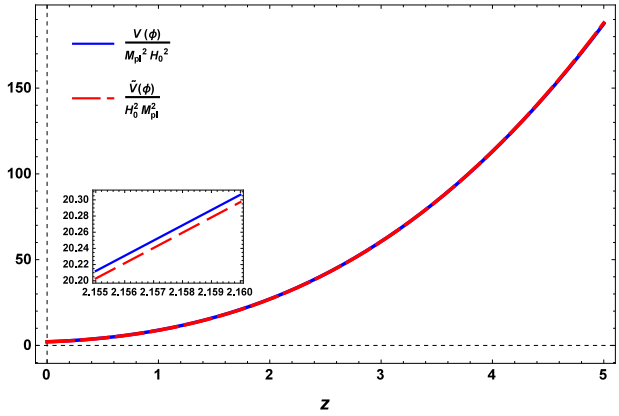

FIG. 27: Model 1: The evolution of the scalar field potential ($V(\phi)$) in Riemannian and Finslerian modes.

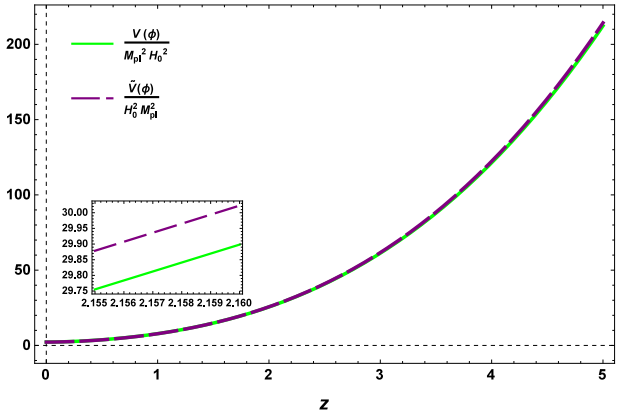

FIG. 28: Model 2: The evolution of the scalar field potential ($V(\phi)$) in Riemannian and Finslerian modes.

the equations of state parameter ($\tilde{\omega}_\phi = \frac{\tilde{P}_\phi}{\tilde{\rho}_\phi}$) are given by

$$\tilde{\omega}_\phi = \frac{\frac{(-3+2\alpha)(1+\beta^\alpha(1+z)^\alpha)^4-4\alpha(1+\beta^\alpha(1+z)^\alpha)^3}{(1+\beta^\alpha)^4(1+z)^{2\alpha}} + 5\frac{(1+\beta^\alpha(1+z)^\alpha)^2}{H_0(1+\beta^\alpha)^2(1+z)^\alpha}e^{\frac{-(1+\beta^\alpha)^2}{\alpha H_0\beta^\alpha(1+[\beta(1+z)]^\alpha)}}}{\mathcal{A}(1+z)^3 - \left(\frac{2\alpha(1+\beta^\alpha(1+z)^\alpha)^4-4\alpha(1+\beta^\alpha(1+z)^\alpha)^3}{(1+\beta^\alpha)^4(1+z)^{2\alpha}}\right) - 2\frac{(1+\beta^\alpha(1+z)^\alpha)^2}{H_0(1+\beta^\alpha)^2(1+z)^\alpha}e^{\frac{-(1+\beta^\alpha)^2}{\alpha H_0\beta^\alpha(1+[\beta(1+z)]^\alpha)}}}. \tag{45}$$

Model 2:

$$\tilde{\Omega}_\phi = \frac{\frac{c(1+z)^3}{M_{pl}^2H_0^2} - \left(\frac{2\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3-6\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^2}{(1+\beta^{2\alpha})^3(1+z)^{4\alpha}}\right) - 2\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^{\frac{3}{2}}}{H_0(1+\beta^{2\alpha})^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}}{3\left(\frac{\left(1+[\beta(1+z)]^{2\alpha}\right)^3}{(1+\beta^{2\alpha})^3(1+z)^{4\alpha}} - \frac{\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{3}{2}}}{H_0(1+\beta^{2\alpha})^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}\right)}, \tag{46}$$

from Eqs. (42) and (46), we obtain

$$\frac{c}{M_{pl}^2H_0^2} = 3(1-\Omega_{\mathfrak{m}_0})(1-\frac{1}{H_0}e^{\frac{-(1+\beta^{2\alpha})}{\alpha H_0\beta^{2\alpha}}}) + (2\alpha - \frac{6\alpha}{1+\beta^{2\alpha}}) + \frac{2}{H_0}e^{\frac{-(1+\beta^{2\alpha})}{\alpha H_0\beta^{2\alpha}}} = \mathcal{A}, \tag{47}$$

the equations of state parameter ($\tilde{\omega}_\phi = \frac{\tilde{P}_\phi}{\tilde{\rho}_\phi}$) are given by

$$\tilde{\omega}_\phi = \frac{\frac{(-3+2\alpha)\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^3-6\alpha\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^2}{(1+\beta^{2\alpha})^3(1+z)^{4\alpha}} + 5\frac{\left(1+\beta^{2\alpha}(1+z)^{2\alpha}\right)^{\frac{3}{2}}}{H_0(1+\beta^{2\alpha})^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{\left(1+\beta^{2\alpha}\right)^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}\left(1+[\beta(1+z)]^{2\alpha}\right)^{\frac{1}{2}}}}}{\mathcal{A}(1+z)^3 - \left(\frac{2\alpha(1+\beta^{2\alpha}(1+z)^{2\alpha})^3-6\alpha(1+\beta^{2\alpha}(1+z)^{2\alpha})^2}{(1+\beta^{2\alpha})^3(1+z)^{4\alpha}}\right) - 2\frac{(1+\beta^{2\alpha}(1+z)^{2\alpha})^{\frac{3}{2}}}{H_0(1+\beta^{2\alpha})^{\frac{3}{2}}(1+z)^{2\alpha}}e^{-\frac{(1+\beta^{2\alpha})^{\frac{3}{2}}}{\alpha H_0\beta^{2\alpha}(1+[\beta(1+z)]^{2\alpha})^{\frac{1}{2}}}}}. \tag{48}$$

XI. STATISTICAL ANALYSIS

When comparing the dark energy models in both Riemannian and Finslerian modes with the ΛCDM model, it's important to recognize that the ΛCDM model is encompassed within both dark energy models. This nesting property allows for the application of standard statistical tests. We compute these tests using the complete dataset. Consequently, one can define the reduced chi-square statistic as $\chi^2_{\rm red} = \frac{\chi^2}{\rm DoF}$, where DoF represents the degrees of

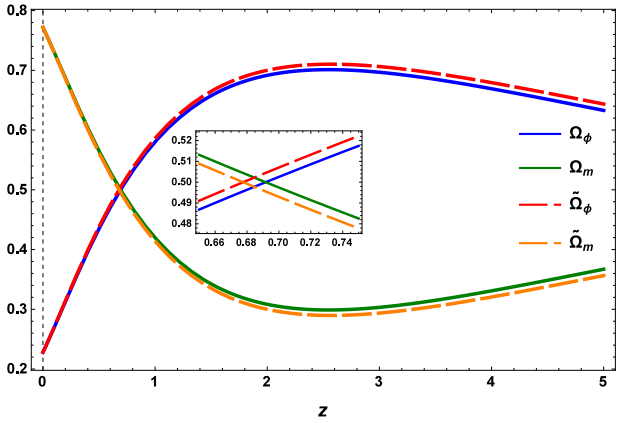

FIG. 29: Model 1: The evolution of the density parameters Ω_ϕ and Ω_m in Riemannian and Finslerian modes.

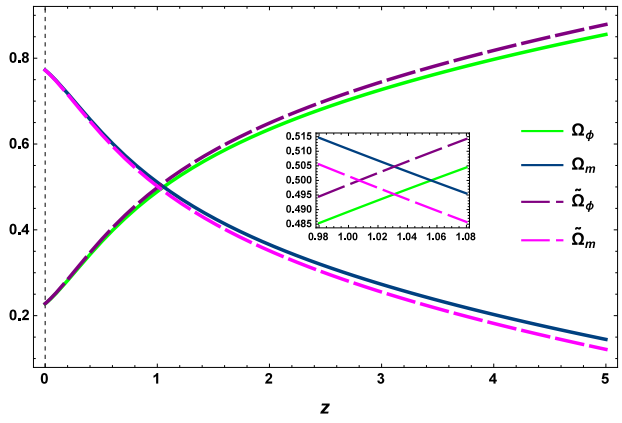

FIG. 30: Model 2: The evolution of the density parameters Ω_ϕ and Ω_m in Riemannian and Finslerian modes.

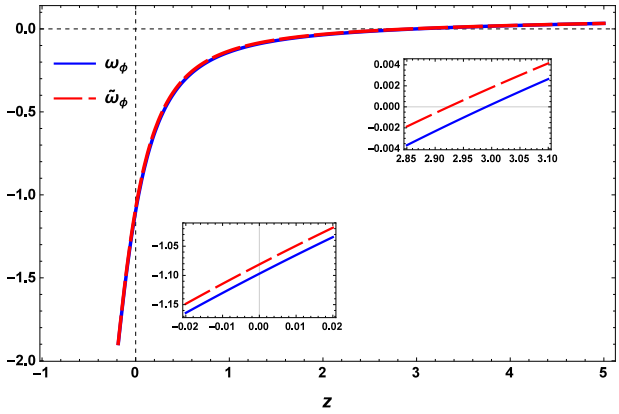

FIG. 31: Model 1: The evolution of equation of state parameter ω_ϕ in Riemannian and Finslerian modes.

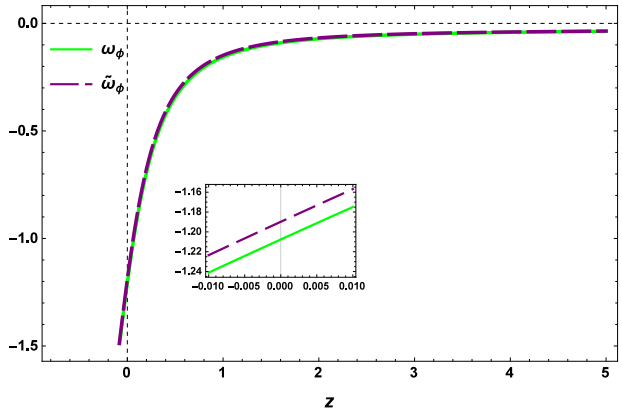

FIG. 32: Model 2: The evolution of equation of state parameter ω_ϕ in Riemannian and Finslerian modes.

freedom of the model, and χ^2 denotes the weighted sum of squared deviations. This calculation is performed under the constraint of the same number of runs. Certainly, here's an addition to the text that includes the P test [103–105]: The Akaike information criterion (AIC) [106, 107] provides a means of comparing different models, considering a large dataset (in our case $N = 273$). It is defined as follows: $\mathrm{AIC} = -2\ln(\mathcal{L}_{\max}) + 2k$. We utilize the Akaike information criterion (AIC) and the Bayesian information criterion (BIC) to evaluate our cosmological models. Specifically, the AIC is defined as:

$$\mathrm{AIC} = -2\ln(\mathcal{L}_{\max}) + 2k + \frac{2k(2k+1)}{N_{\mathrm{tot}} - k - 1}, \tag{49}$$

where $\mathcal{L}_{\max}$ represents the maximum likelihood of the considered data, N_{tot} is the total number of data points, and k denotes the number of parameters. For large N_{tot}, the expression simplifies to:

$$\mathrm{AIC} \approx -2\ln(\mathcal{L}_{\max}) + 2k, \tag{50}$$

which is the standard form of the AIC criterion. Conversely, the Bayesian information criterion is defined as:

$$\mathrm{BIC} = -2\ln(\mathcal{L}_{\max}) + k\ln N_{\mathrm{tot}}. \tag{51}$$

In addition to AIC and BIC, we can also consider the P-test, which evaluates the significance of the difference between the two models. This test quantifies whether the improvement in fit provided by a more complex model (compared to a simpler one) is statistically significant. It is commonly used in model selection to determine whether additional parameters introduced in a more intricate model are justified by improved fit. The P-test complements AIC and BIC in providing model performance and complexity with a comprehensive assessment.

Model	$\mathcal{L}_{\max}$	χ^2_{red}	AIC	BIC	P-Value
ΛCDM Model	254.53	0.9497	264.53	264.76	0.7127
Model 1 Finslerian Geometry	253.32	0.9452	263.32	263.55	0.7307
Model 1 Riemannian Geometry	253.60	0.9462	263.60	263.82	0.7267
Model 2 Finslerian Geometry	250.75	0.9356	260.68	260.90	0.7675
Model 2 Riemannian Geometry	250.68	0.9353	260.75	260.98	0.7686

TABLE VII: Summary of the $\mathcal{L}_{\max}$, χ^2_{red}, AIC, BIC and P-Value

XII. RESULTS AND DISCUSSION

a. Deceleration parameter Figs. 9 and 10 illustrate the evolution of the deceleration parameter (q) in terms of redshift for both Model 1 and Model 2, in both Riemannian and Finslerian geometries, compared to the standard ΛCDM model. In Fig. 9, one can observe that in the distant past ($z \to \infty$), Model 1 predicts values of approximately 0.6932 in Finslerian geometry and 0.6921 in Riemannian geometry. In contrast, the ΛCDM model predicts a value around 0.449. This behavior suggests that in the early Universe, both Model 1 variants exhibit higher deceleration compared to the ΛCDM model. As the redshift approaches zero ($z \to 0$), the present-day deceleration parameter (q_0) is approximately -0.6238 in Finslerian geometry and -0.6227 in Riemannian geometry. In contrast, the ΛCDM model predicts a value around -0.5506. This indicates that, in the current epoch, both geometrical models (Finslerian and Riemannian) predict a slightly higher Universe acceleration compared to the ΛCDM model. The phase transition redshift (z_{tr}) is 0.6958 in Finslerian geometry, 0.7066 in Riemannian geometry, and 0.6824 in the ΛCDM model. The phase transition redshift marks the point at which the Universe transitions from decelerated to accelerated expansion. In Finslerian and Riemannian geometries, this transition occurs slightly later than in the ΛCDM model. Fig. 10 illustrates the behavior of Model 2 in Finslerian geometry, contrasting it with the ΛCDM model. In the distant past ($z \to \infty$), Model 2 predicts deceleration parameter values of approximately 0.3656 in Finslerian geometry and 0.3643 in Riemannian geometry, compared to the ΛCDM model's 0.4490, indicating higher deceleration in both geometrical models. At present ($z \to 0$), the deceleration parameter (q_0) is approximately -0.7352 in Finslerian geometry and -0.7323 in Riemannian geometry. While the ΛCDM model predicts -0.5506, suggesting a slightly higher current acceleration in both geometrical models. The phase transition redshift (z_{tr}), marking the shift from decelerated to accelerated expansion, is 0.6072 in Finslerian geometry, 0.6176 in Riemannian geometry, and 0.6824 in the ΛCDM model, indicating a slightly later transition in the alternative geometries. In each case, the Universe initially experiences a smooth deceleration phase, indicating that no inflationary phase exists included in these models. As redshift decreases, the Universe transitions from this decelerating expansion to an accelerating expansion phase. It can be observed in the figures that the phase transition occurs earlier in the Finslerian mode compared to the Riemannian mode.

b. Jerk parameter Figs. 11 and 12 illustrate the evolution of the jerk parameter (j) in terms of redshift. At high redshifts, Model 1 and Model 2, in both Riemannian and Finslerian geometries, exhibit deviations from the ΛCDM model. This deviation is evident as the jerk parameter value of the ΛCDM model remains constant at $j = 1$ across all redshifts. At redshift z_0, for Model 1 in Finslerian geometry, the jerk parameter value is 1.5465 times that predicted by the ΛCDM model. Similarly, in Riemannian geometry, the jerk parameter value for Model 1 is also 1.5247 times that predicted by the ΛCDM model. For Model 2, in Finslerian geometry, the predicted value j_0 is 2.5956 times that of the ΛCDM model, while in Riemannian geometry, j_0 is 2.557 times the value predicted by the ΛCDM model. The deviation of jerk parameter values from the ΛCDM model suggests that both Model 1 and Model 2 exhibit different evolutionary behaviors, particularly at high redshifts. The higher values of the jerk parameter at z_0 compared to the ΛCDM model imply that these alternative models may incorporate additional factors or mechanisms influencing cosmic acceleration, indicating potential differences in the underlying dynamics of cosmic expansion.

c. Snap parameter Figs. 13 and 14 illustrate the evolution of the snap parameter (s) with respect to redshift. At high redshifts, Model 1 and Model 2, under both Riemannian and Finslerian geometries, deviate from the ΛCDM model. Specifically, Model 1 and Model 2 predict negative snap values, whereas the ΛCDM model predicts positive values of snap. At redshift z_0, for Model 1 in both the Finslerian and Riemannian modes, the predicted values are 2.4039 and 2.3807, respectively. In the case of Model 2, in both the Finslerian and Riemannian modes, the predicted values are 7.7836 and 7.6217, respectively, while the ΛCDM model predicts 0.3573. The negative values of the snap

parameter predicted by Model 1 and Model 2 suggest that these models exhibit behaviors not captured by the ΛCDM model, particularly at high redshifts. Additionally, the significantly higher values of snap at present (z_0) in both models compared to the ΛCDM model indicate that these alternative models may involve additional physical effects or cosmological components that contribute to the observed cosmic dynamics.

d. Statefinder diagnostic In Figs. 15 and 16, one can see the divergence evolutions of Model 1 and Model 2 in the $\mathfrak{s} - r$ planes. Both models show distinct characteristics as compared to the other standard models. One can observe that at early times, Model 1 presumes values in the range $r > 1$ and $\mathfrak{s} < 0$ denoting Chaplygin gas type DE model and evolutes to the quintessence region and again retreats to Chapligyn gas region at late times by crossing the intermediate ΛCDM fixed point $\{0, 1\}$ during evolution. But, Model 2 is different, and evolutes from the quintessence region in the past and moves to the Chaplygin gas region intermediating, the ΛCDM fixed point $\{0, 1\}$ while evolving for all cases. Figs. 17 and 18 represent the temporal evolution of Model 1 and Model 2 in the $\{q, r\}$ plane and provide additional information about both models wherein the dashed lines describe the evolution of the ΛCDM model below which quintessence region and the upper one is Chaplygin gas region are shown. The evolution of Model 1 and Model 2 are observed. Both models deviates from de Sitter point $(-1, 1)$.

e. $Om(z)$ diagnostic Figs. 19 and 20 show the evolution of the $Om(z)$ diagnostic parameter in terms of redshift z for Model 1 and Model 2 in both Riemannian and Finslerian geometries. For Model 1, $Om(z)$ consistently decreases (negative slope) across all redshifts, indicating quintessence-like dynamics. In contrast, for Model 2, $Om(z)$ initially increases (positive slope) for $z > 1$, suggesting a phantom-like evolution, and then decreases (negative slope) at lower redshifts, indicating a return to quintessence-like dynamics.

f. Energy Density & Pressure of DE The cosmological evolution of the energy density of dark energy, indicated by $\rho_{\mathfrak{de}}$, and the dark energy pressure $P_{\mathfrak{de}}$ for our models, Model 1 and Model 2 supply valuable perspicuity into the behavior and effects of dark energy in a cosmological context. In the above plotted figures: Figs. 21, 22, 23, and 24, we have shown the evolution of the dark energy densities and the matter-energy densities when the cosmological constant is considered as a candidate of dark energy. They show almost similar behaviors in the standard mode in both the Riemannian and Finslerian modes for Model 1 and Model 2. Similarly, when a scalar field is considered to be a candidate of dark energy, the evolution of the physical parameters such as the time-dependent dark energy densities, pressures, energy density of cold dark matter, the potential $V(\phi)$ and the equation of state parameter ω_ϕ together with the density parameters Ω_ϕ are shown in the above figures: Figs. 25, 26, 27, 28, 29, 30, 31, and 32 depicting the physical evolution of the Universe for both the models with the solid and dash lines representing the Riemannian and Finslerian modes, respectively. Since we are more concerned about the late Universe, we have kept the redshift range as (0,5) only in most of these figures. We can also predict the values of these physical parameters at redshift $z = 0$. For example, In the case of Model 1, as redshift approaches zero ($z \to 0$), the present-day energy density (ρ_ϕ) is approximately 0.6746 in Finslerian geometry and (ρ_ϕ) assumes value 0.6842 in Riemannian geometry. And, in the case of Model 2, as $z \to 0$, ρ_ϕ is approximately 0.6746 in Finslerian geometry and 0.6830 in Riemannian geometry. As the redshift approaches zero ($z \to 0$), the present-day EoS parameter ω_ϕ is approximately -1.0812 in Finslerian geometry and -1.0971 in Riemannian geometry for Model 1 and for Model 2, ω_ϕ is approximately -1.18981 in Finslerian geometry and -1.2077 in Riemannian geometry. Similarly, we can see the evolution of the other physical parameters as shown in the figures.

g. Statistical analysis Based on the information provided in Table VII, let's conduct a comparative study: The highest likelihood is obtained for the ΛCDM model, followed closely by both Model 1 and Model 2 in both Finslerian and Riemannian geometries. This indicates that all models provide reasonable fits to the data, with slight variations in their maximum likelihood values. The reduced chi-square values are close to 1 for all models, indicating that the models adequately describe the data within the uncertainties. Again, no significant differences are observed between the models in terms of their goodness of fit. Lower values of AIC indicate better model performance. The ΛCDM model has the lowest AIC suggesting that it provides the best balance between goodness of fit and model complexity. However, the differences in AIC between the ΛCDM model and the Finslerian and Riemannian models are relatively small. Similarly, lower BIC values indicate better model performance. Again, the ΛCDM model has the lowest BIC, indicating its preference over the alternative models. However, similar to AIC, the differences in BIC between the ΛCDM model and the Finslerian and Riemannian models are not substantial. The P-values for all models are relatively high, ranging from 0.7127 to 0.7686. These values indicate that the models are statistically consistent

with the observed data, with no strong evidence against them. Overall, while the ΛCDM model performs slightly better according to AIC and BIC, the differences between the Finslerian and Riemannian models and the ΛCDM model are marginal. However, if we consider simplicity and theoretical elegance, Finslerian geometry may be favored over Riemannian geometry. Finslerian geometry offers additional flexibility and generality compared to Riemannian geometry, allowing for a more comprehensive description of the underlying physics, which could lead to a better overall understanding of the universe's dynamics.

XIII. CONCLUSION

In this paper, with the aim of whether the space-time of our universe could be a Finsler-Randers manifold instead of a Riemannian one, we have initiated studying an FRW model with a weak vector field embedded in the metric structure of space-time. The metric structure supplies us with the extended Friedmann equation like 17. The contribution of the variation of anisotropy is described by the extra parameter $\dot{\mathfrak{u}}_0$ yielded by the Finslerian space-time. Specifically, as it is obvious from equation $2\dot{C}_{000} = \dot{\mathfrak{u}}_0$, $\dot{\mathfrak{u}}_0$ directly depends on the Cartan torsion component C_{000}. We considered the Finsler-Randers space-time to offer a novel perspective on cosmic dynamics, departing from the constraints of general relativity. We proposed two dark energy models resulting from the parametrization of H within this geometric framework. We have derived the field equations governing the universe's evolution within the Finsler-Randers formalism, incorporating the presence of dark energy. Through this, we explored its implications on cosmological phenomena, including cosmic expansion, late-time behavior of the universe, cosmological phase transition, and a few more. The comparative analysis of Model 1 and Model 2 in Riemannian and Finslerian geometries against the standard ΛCDM model yields substantial insights into the dynamics of the universe's expansion and the behavior of dark energy. The examination of the Hubble parameter $H(z)$, Hubble difference $\Delta H(z)$, and distance modulus $\mu(z)$ reveals that deviations from the ΛCDM model become significant at higher redshifts. Model 1 shows noticeable deviations for $z > 0.6$, whereas Model 2 exhibits deviations for $z > 1.2$. At lower redshifts, all models demonstrate close agreement, particularly with observational data, underscoring the alignment of the alternative geometries with the ΛCDM model during recent epochs. This close agreement at lower redshifts, where dark energy dominates the expansion dynamics, highlights the robustness of the Riemannian and Finslerian formulations in capturing the late-time evolution of the universe. The analysis of the deceleration parameter (q) indicates that both models predict higher deceleration in the early universe and slightly higher acceleration in the current epoch compared to the ΛCDM model. Additionally, the phase transition redshift (z_{tr}) occurs slightly later in both alternative geometries. The jerk parameter (j) shows that both models predict significantly higher present-day values than the ΛCDM model, suggesting different evolutionary behaviors and potential additional mechanisms influencing cosmic acceleration. The snap parameter (s) also deviates from the ΛCDM model, with both alternative models predicting higher present-day values and negative values at high redshifts, indicating the presence of additional physical effects or cosmological components. The Statefinder diagnostic further distinguishes the evolutionary paths of Model 1 and Model 2 in the $\mathfrak{s} - r$ and $\{q, r\}$ planes, showing transitions through various regions associated with different dark energy models and highlighting their differences from the ΛCDM model. The $Om(z)$ diagnostic suggests that $Om(z)$ decreases for Model 1, indicating quintessence. Model 2 exhibits a more complex behavior with an initial increase (phantom-like) at $z > 1$ followed by a decrease (quintessence-like) at lower redshifts. Statistical analysis using likelihood, reduced chi-square, AIC, and BIC values reveals that while the ΛCDM model performs slightly better overall, the differences between it and the alternative models are marginal. The high P-values indicate that all models are statistically consistent with the observed data. This statistical consistency underscores the viability of the Finslerian and Riemannian models as alternatives to the ΛCDM framework. In conclusion, the ΛCDM model remains slightly preferable based on statistical metrics; however, the Finslerian and Riemannian models offer comparable fits and provide additional flexibility and generality. Finslerian geometry, in particular, may offer a more comprehensive framework for understanding the Universe's dynamics, potentially leading to new insights and a deeper understanding of cosmic evolution. The subtle differences in the evolution of physical parameters between Riemannian and Finslerian geometries, especially at higher redshifts, highlight the potential of Finslerian geometry to accommodate a broader range of cosmological phenomena, making it a promising candidate for future explorations in cosmology.

Received 26 February 2024; accepted 22 May 2024

This study is focused on the synthesis of a hydrogel based film for food packaging applications. Xanthan gum (XG) and hydroxypropyl guar gum (HPGG) based hydrogel films have been synthesized using citric acid (CA) as crosslinker, loaded with zinc oxide (ZnO) nanoparticles (NPs) and curcumin (Cur). The structural characteristics of hydrogel films is analysed by FTIR and XRD. Thermal analysis is conducted using TGA and morphological examination is done using SEM. Rheological analysis is performed to determine the viscoelastic behaviour of the hydrogel films. Anti-microbial assay, anti-oxidant assay and SRB assay are conducted to analyse the anti-bacterial, scavenging and cytotoxicity activity of the hydrogel films. The film shows biodegradability under compost environment in 30 days. Fruit shelf-life enhancer capabilities are also assessed by using an edible coating of strawberry. The results so obtained showed that the synthesized XG-HPGG-CA-ZnO-Cur Film has potential application in edible food packaging.

Keywords: Curcumin, Citric acid, Hydroxypropyl guar gum, Xanthan gum, ZnO

Introduction

Food packaging materials ensure that the quality of food is maintained throughout its shelf life. Hydrogel is a beneficial approach for food packaging systems, especially in managing moisture, which can be a barrier to the longevity of food[1]. The primary purpose is to extend the life span of processed food products and maintain freshness, instead of being subjected to intricate and lengthy storage methods[2]. Due to their affordability and ability to withstand water exposure, plastic polymers have become a convenient and cost-effective choice for packaging. However, plastic films are not fully recyclable or biodegradable, leading environmentalists to look for materials derived from renewable resources[3].

Researchers have developed ecologically friendly packaging options, such as biopolymers, as a promising replacement for non-biodegradable plastics in food packaging[4]. Research is being conducted to enhance the performance of polymers by investigating superabsorbent hydrogel that can absorb water and other water-compatible fluids up to 100% of their dry weight[5]. Given the health risks associated with synthetic polymers and the surge in plastic waste, active packaging materials made from natural antimicrobial ingredients are gaining interest. Proteins, polysaccharides, and lipids are some diverse food-grade polymers being investigated for this purpose. Bio-based antimicrobial packaging can prevent undesired changes in food quality and ecological waste while carrying nutrients. These biodegradable polymers can be used as films or applied in the form of coatings to the food[6].

Bio-derived polymeric hydrogels offer an effective alternative for addressing the challenge of plastic packaging disposal in the context of food applications. Plasticused in food packaging, tends to be non-biodegradable, which poses an imminent threat to the environment. For the development of environmentally friendly packaging materials, a variety of renewable biopolymers, such as proteins, lipids, and their composites generated from plant and animal sources, have been studied as substitutes for their non-biodegradable petrochemical-based counterparts. In this study, a hydrogel-based film containing natural biopolymers is prepared to be used as a food packaging material. It also covers changes to the film's properties induced by biodegradation.

Xanthan gum (XG) is a high molecular weight acidic biopolymer obtained from (*Xanthomonas campestris)* during aerobic fermentation using corn or sugar cane derivatives. Its primary function is to thicken food and cosmetics due to its 2:2:1 molar ratio of d-glucosyl, d-mannosyl, and d-glucuronyl acid

residues along with varying amounts of pyruvyl groups[7]. XG exhibits hydrocolloid nature, making it highly functional in difficult settings such as high shear stress, high salt and acidic conditions. XG can also be used in small amounts to achieve zero-order release kinetics[8].

Another biopolymer with significant characteristics in food packaging is guar gum (GG), which is also a high molecular weight polysaccharide, obtained from *Cyamopsis tetragonolobus* embryos of the Leguminosae family. GG is composed of a polysaccharide chain consisting of mannose as the linear backbone and has a side chain made up of a [2:1] ratio of mannose to galactose[9]. Hydroxypropyl guar gum (HPGG), a derivative of GG, is created by reacting GG with propylene oxide. HPGG produces highly viscous and biodegradable solutions. HPGG is considered a better option in food packaging applications due to its greater thermal stability and solubility in comparison to GG[10].

Combining two biopolymers to synthesize hydrogels, increases their stability and usefulness[11]. Cross-linkers can enhance the mechanical properties of biopolymers, making them suitable for food packaging. Chemical crosslinking is the most effective method, particularly for biopolymers. Various crosslinking agents, such as Ca^{2+} ions, citric acid, glutaraldehyde and boric acid can be used[4]. Covalent bonds, hydrogen bonds, ionic interactions, hydrophobic and dipole-dipole interactions can all crosslink polymer chains, resulting in hydrogels with various shapes such as films, coatings and sheets[11]. XG and HPGG crosslinked with CA forms a film which is useful in the application of food preservation.

Further, zinc oxide (ZnO) nanoparticles (NPs) possess antioxidant activity and properties of food preservation. Along with ZnO NPs, curcumin (Cur) show antioxidant and antimicrobial properties. Both ZnO NPs and Cur can enhance the property of the XG-HPGG based film.

The aim of this research is to develop a novel hydrogel-based film of XG and HPGG cross-linked with CA and loaded with ZnO NPs and Cur for food packaging applications. Moreover, thermal analysis (TGA), structural characteristics (FTIR and XRD), morphology (SEM), rheological measurement (viscosity, amplitude and frequency sweep) mechanical strength, fruit preservation, anti-microbial activity, anti-oxidant activity and cytotoxicity assay were analysed for the hydrogel-based films.

Experimental Section

Materials

XG was purchased from local market, HPGG was procured from Hindustan pvt. Ltd. Bhiwadi, India, as a gifted sample, CA was purchased from CDH, New Delhi, Cur from SD fine chemical, Mumbai and ZnO NPs were purchased from sigma Aldrich, USA. Glycerol was purchased from Fisher chemicals, UK. Milli Q water was used for all the experimental work.

Synthesis of XG-HPGG-CA-ZnO-Cur hydrogel-based film

The food grade XG and HPGG were used for fabricating packaging hydrogel-based films. XG and HPGG being hydrophilic polymers easily dissolve in water. The ratio of [Gums: CA] was taken to be [1:1.5]. The required amount of XG and HPGG are dissolved in distilled water at a fixed interval of time. CA as a cross-linker was added to the homogenous solution of XG and HPGG. Glycerol was added as plasticizer to the homogenized solution. A fixed and same composition of [ZnO: Cur] was added to the hydrogel preparation with constant stirring for 3 h. Afterwards, sonication was done to remove entrapped air, then poured into Petri dish and left for drying in the oven at 45°C for 24 h. Subsequently, hydrogel-based films were made and then used for further characterization analysis. A control film i.e., XG-HPGG-CA was synthesized by same method without ZnO NPs and Cur.

Characterization of hydrogel-based film

The Perkin-Elmer model 2000 FT-IR was used to perform analysis of functional groups in XG, HPGG, XG-HPGG-CA film, and XG-HPGG-CA-ZnO-Cur film. The data was collected in the range of 4000-400 cm^{-1} by taking 32 scans at 4 cm^{-1} resolution. X-ray diffraction was conducted using a wide-angle X-ray diffractometer. Bruker D8 Advance was used with Cu-Kα radiations of λ = 1.5406 Å, a scanning range of 2θ (5°–80°), and a scan rate of 1°/min at 20 kV and a current of 10 mA. The SEM (JEOL JSM-6610LV) was utilized to examine the surface morphology of the samples at 500, 1000, and 2500X magnifications under an accelerating voltage of 20 kV. To determine the thermal stability of the samples, TGA (TGA 4000) was used. The samples were heated from 25°C to 800°C at a heating rate of 10°C/min in N_2 atmosphere. Using Anton Paar Modular Compact Rheometer 302 (MCR), the rheological properties of XG-HPGG-CA solution and XG-HPGG-CA-ZnO-Cur solutions were determined at room temperature. The tests were conducted using a 40 mm parallel plate.

The mechanical properties of XG-HPGG-CA-ZnO-Cur Film were analysed by a Universal Testing Machine (UTM), LLOYD LR 5K. Load range was 1-50 N with a 1000 mm extension range and 5 mm gauge length. The test and approach speed were 500 mm/min with no preload. A strip of 15 mm width and 150 mm length was cut from each film for mechanical testing. Under air conditions, three readings were taken for each sample and the average result was evaluated for mechanical properties of the film.

To evaluate the antimicrobial activity of the films, the agar disk diffusion method was used against *Escherichia coli* and *Staphylococcus aureus*, representing Gram-negative and Gram-positive bacterial strains respectively. Bacterial cultures were prepared in nutrient broth and inoculated onto agar plates. Disks were cut from each film and put on the plates. The fully formed zones (ffz) were measured using a digital calliper after incubating the plates for 14-16 h at 37°C. The films used in the experiment were 0.7 cm in diameter. In order to conduct a comparative study regarding the rate of food spoilage, fresh strawberries were taken. One strawberry was coated with synthesized hydrogel and the other was used in uncoated form and stored in glass petri plates. Samples were tested at regular intervals of 24 h for 1 week. All studies were conducted in natural lighting at a constant temperature of 25℃. The UV-visible spectrophotometer was used to evaluate the antioxidant activity of hydrogel solution by DPPH free-radical scavenging[12]. A modified method based on a previous study was used to determine the photochemical stability, in which varying amounts of hydrogel solution (3 mg, 5 mg, 7 mg, 20 mg, and 50 mg) of XG-HPGG-CA-ZnO-Cur solution were dissolved in 50 mL ethanol solution at 37°C[13]. Eq. (1) was used to determine the percentage of DPPH scavenging activity after mixing 1 mL of the solution with 3 mL of ethanol solution containing DPPH (1 mg/20 mL) and incubating it in the dark at room temperature for 30 min. The absorbance was measured at 517 nm.

$$\text{Scavenging activity of DPPH (\%)} = \left(1 - \frac{A_{sample}}{A_{control}}\right) x\ 100 \quad \ldots(1)$$

The value of $A_{control}$ indicates the absorbance of 1 mL ethanol and 3 mL ethanol solution of DPPH, while A_{sample} refers to the absorbance of 1 mL XG-HPGG-CA-ZnO-Cur solution and 3 mL DPPH solution, as stated in prior research[14].

The degradation tests were performed on XG-HPGG-CA-ZnO-Cur Film by the method of burring the film in standard soil (ISO 17556 standard soil) for 30 days at room temperature and moisture-controlled conditions. The film was buried 2 cm under the soil. The buried film was removed from the soil, gently brushed and washed with distilled water, dried and analysed for weight loss after every 5 days. The weight loss was observed through TGA. As a fragment of film was studied for weight loss and compared it with the freshly prepared film. The percentage weight loss was calculated as by Eq. (2),

$$\text{Percentage weight loss} = \left(\frac{w_i - w_f}{wi_i}\right) \text{x } 100 \quad \ldots(2)$$

Where w_i is the initial weight of the film and w_f is the weight after 5 days interval.

The cytotoxicity of the films using Hep-G2 cell line was determined using the SRB assay[15]. In the initial stage, cells were cultured in a 96-well plate with DMEM medium supplemented with 10% FBS and 1% antibiotic solution, at a density of 8000 cells/well, and incubated at 37°C with 5% CO_2. Following 24 h, the cells were exposed to varying concentrations of the dose (ranging from 0.05-1.25%), prepared in an incomplete medium. After an additional 24 h of incubation, each well was treated with 100 µL of 10% trichloro acetic acid (TCA) and incubated for 1 h. The plate was then washed with DM water and allowed to air dry at room temperature, followed by the addition of a final concentration of 0.04% SRB solution to each well, and incubated for 1 h. Once incubation was complete, the plate was rinsed with 1% (v/v) acetic acid to eliminate any unbound dye and left to air-dry at room temperature. To solubilize the protein-bound dye, a Tris base solution (pH=10.5) was introduced to each well and agitated for 10 min using an orbital shaker. Finally, the plate was examined in an ELISA plate reader (iMark, Biorad, USA) at 510 nm.

Results and Discussion

FTIR

FTIR was carried out on XG, HPGG, XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film to determine their functional groups in the range of 4000-400 cm^{-1} as shown in Fig. 1. XG showed characteristic peaks at 3325 cm^{-1} for O-H stretching and 1608 cm^{-1} for C=C stretching vibrations[16]. HPGG showed characteristic peaks at 2912 cm^{-1} for C-H stretching, 3342 cm^{-1} for N-H stretching and

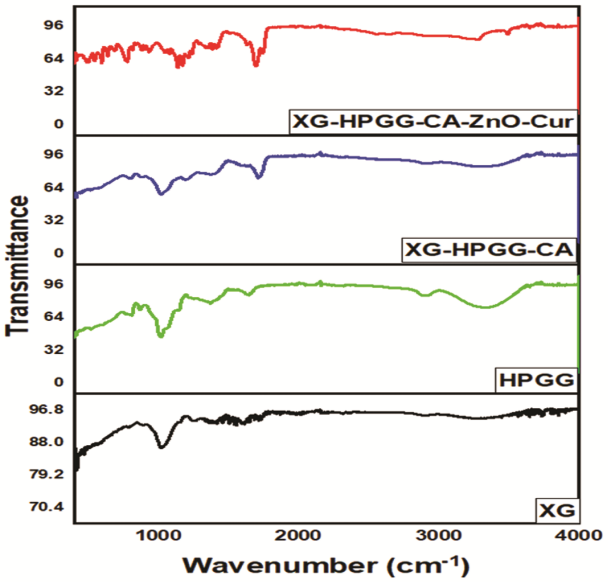

Fig. 1 — FTIR spectra of XG, HPGG, XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film

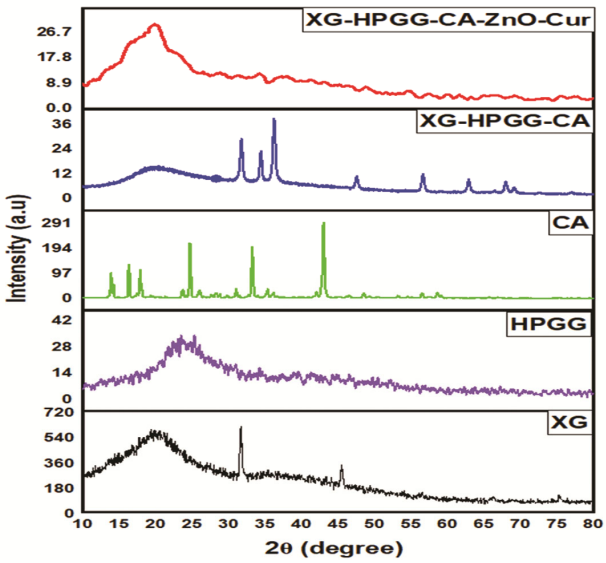

Fig. 2 — X-ray diffractogram of XG, HPGG, CA, XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film

1635 cm^{-1} for C=O stretching vibrations[17]. The FTIR spectra of XG-HPGG-CA showed a significant shift in peak from XG and HPGG at 3360 cm^{-1}, 2921 cm^{-1} and 1722 cm^{-1} due to crosslinking with CA. The FTIR spectra of XG-HPGG-CA-ZnO-Cur film showed a significant peak at 3273 cm^{-1}, corresponding to the -OH stretching vibrations, and 1697 cm^{-1}, due to carbonyl (C=O) stretching vibrations[18]. These shifts are majorly due to esterification with CA and incorporation of ZnO and Cur, which are essential in various applications, including food packaging[11].

XRD

The x-ray diffractogram of XG, HPGG, CA,XG-HPGG-CA film and XG-HPGG-CA-Cur-ZnO film are shown in Fig. 2. HPGG and XG exhibited broad peaks at 23.8° and 20.4°, respectively. CA showed peaks at 14º, 16º, 17º, 24.7º, 33º and 43º. XG-HPGG-CA film displayed a similar peak at 18.64° due to cross-linking of the two gums with CA. The shift of peaks was observed in XG-HPGG-CA-Cur-ZnO Film at 19.92º due to esterification. XRD patterns of XG, HPGG, XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film showed amorphous structure with low overall crystallinity. The crystalline regions of XG and HPGG were due to hydroxyl groups at18.86°and 19.96°, respectively. The stability of XG and HPGG was maintained by hydrogen bonds, which when broken, led to a decrease of crystallinity in XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film[19-22].

SEM

SEM images of XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film are shown in Fig. 3 at 500X and 1000X magnifications. SEM has been demonstrated to be quite useful for determining and verifying morphological traits[23,24]. The interior structure of the film was heterogeneous and inter-linked, which can result in significant swelling and permeability as well as facilitate cellular growth. Crosslinking of XG and HPGG with CA was responsible for homogeneous covering of XG-HPGG-CA film in Fig. 3c. On adding ZnO and Cur to the XG-HPGG-CA film, the morphology of the film changed from smooth surfaces to rough and hollow-follicular, as shown in Fig. 3(a,b). This shift in morphology after cross linking is due to the presence of ZnO and Cur constituents and the irregular pore network structure in XG-HPGG-CA-ZnO-Cur film is responsible for the heterogeneity in the polymeric hydrogel[25]. These structural characteristics provide additional evidence that cross-linked hydrogel networks were formed during the polymerization phase[26]. The surface morphology of polymers can provide valuable information regarding their specific pore size distribution or specific areas of the polymer matrix[14]. The structure of XG-HPGG-CA-ZnO-Cur film, as revealed by the surface morphology shows that this biopolymer is well suited to be used as a food packaging material[27].

TGA

TGA of XG, HPGG, CA, XG-HPGG-CA film, and XG-HPGG-CA-ZnO-Cur film is shown in Fig. 4. In

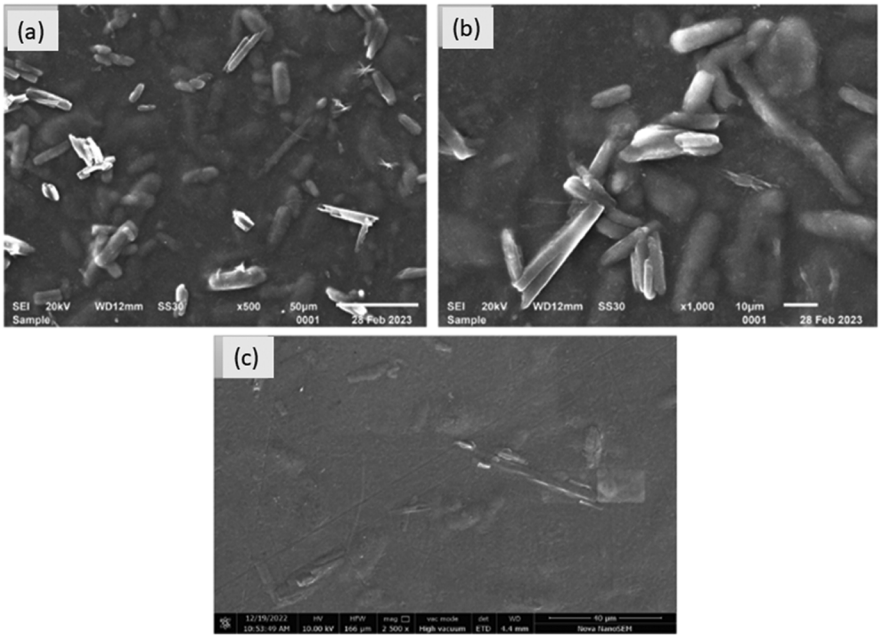

Fig. 3 — SEM micrographs at different magnifications of (a, b) XG-HPGG-CA-ZnO-Cur film at 500 and 1000X magnifications, respectively and (c) XG-HPGG-CA film at 2500X magnifications

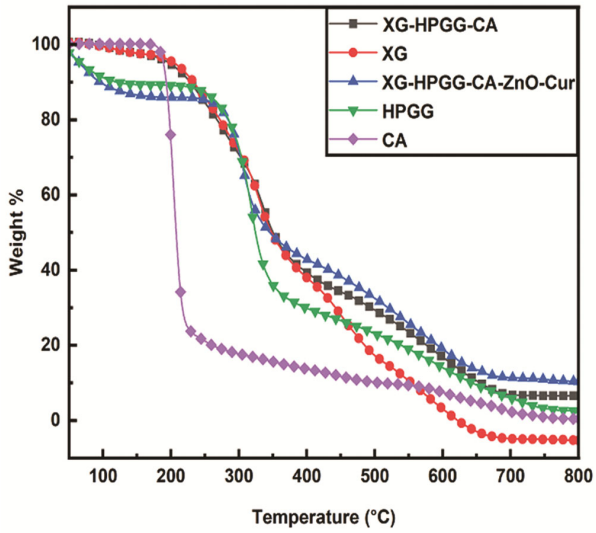

Fig. 4 — TGA of CA, HPGG, XG, XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film

each instance, the initial decomposition temperature (IDT) was employed to adjust for any loss of weight. For XG, an IDT of 13.66% was observed at (29°C to 222.27°C), while HPGG showed an IDT of 8.94% at (45.26°C to 183.92°C). IDT for CA was observed to be 83.772% at (163.68°C to 332.63°C). The crosslinked polymers, XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film, showed a weight loss of 3.239% and 2.268%, respectively, within almost the same temperature range. This demonstrates the added stability of XG-HPGG-CA-ZnO-Cur film was due to the presence of ZnO and Cur. T_{max} is the temperature at which the maximum rate of weight loss occurs[1], was observed in the range of (222.27°C to 418.32°C), (183.92°C to 392.92°C), (17.089°C to 388.9°C), and (151.2°C to 461.7°C) for XG, HPGG, XG-HPGG-CA film, and XG-HPGG-CA-ZnO-Cur film, respectively. These observations indicate that the thermal stability of gums, such as XG and HPGG, decreases during the stages of decomposition, but the polymerization and formation of films of XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film, showed an increased degree of stability due to the less percentage of weight loss compared to XG and HPGG[28].

Viscosity

Rheology is the scientific study of the deformation and flow of matter, which elucidates the relationship between force, time and deformation. It is the experimental method employed to assess the rheological characteristics of materials[29]. Shear rheological testing was conducted by varying the shear rate from 10 s^{-1} to 100 s^{-1}. Throughout the shear rate range, it was observed that XG-HPGG-CA-ZnO-Cur solution exhibited a stronger shear thinning behaviour than XG-HPGG-CA solution as shown in Fig. 5a. The significant shear-thinning characteristics were attributed to the incorporation of ZnO and Cur in

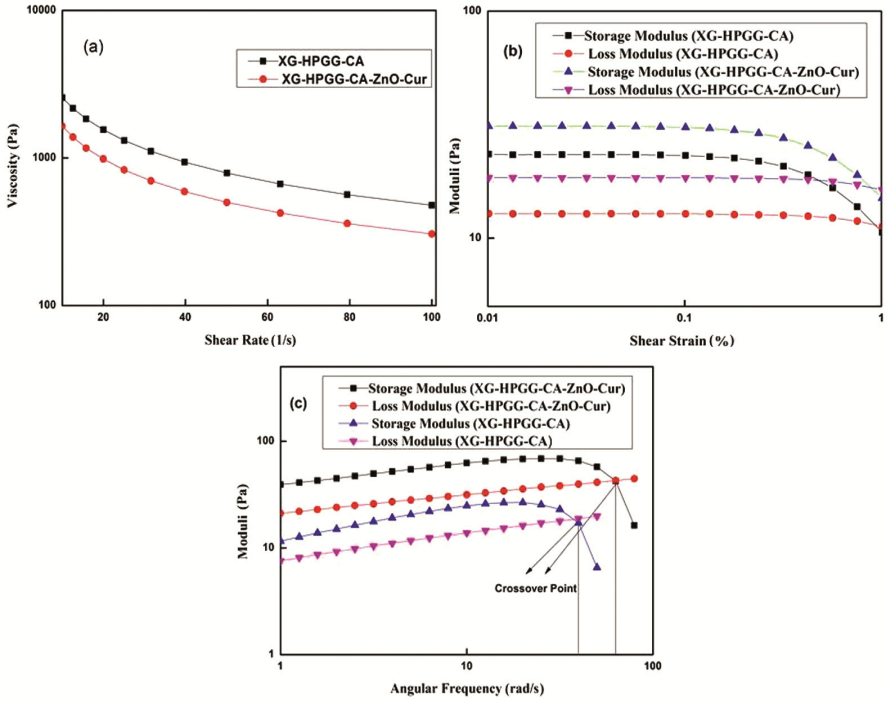

Fig. 5 — (a) Shear viscosity profile (b) amplitude sweep and (c) frequency sweep of XG-HPGG-CA solution and XG-HPGG-CA-ZnO-Cur solution

the XG-HPGG-CA-ZnO-Cur solution composition. In both cases, a considerable reduction in viscosity was observed due to the shear-induced alignment of XG-HPGG-CA solution and XG-HPGG-CA-ZnO-Cur solution in the flow direction[30].

Amplitude sweep

The amplitude sweep was conducted to determine the upper and lower limits of the linear viscoelastic (LVE) range and to assess the hydrogel's structural and mechanical stability[31]. Fig. 5b illustrates the plotted results of the storage modulus G' and loss modulus G" against shear strain percentage. The LVE range was characterized by a constant G' at low deformation, indicating that the sample structure remained intact[32]. At lower strain, both XG-HPGG-CA-ZnO-Cur solution and XG-HPGG-CA solution behaved as viscoelastic solids, while at higher strain, they behaved as viscoelastic fluids due to the disturbance of the structure, indicating the end of the LVE-region. The sample's rigidity at rest is characterized by the plateau value G′ within the LVE region. The LVE range for XG-HPGG-CA-ZnO-Cur solution was found to be G′=29.8 Pa, and for XG-HPGG-CA solution, G′=22.9 Pa, due to the addition of Cur and ZnO. When the sample reaches its most solid state, the LVR typically ends. The shear modulus at this point was observed to recover around 80% of its initial value[33]. The solution with ZnO and Cur showed a lower critical value (γc) of 18.6% compared to the solution with XG-HPGG-CA (γc) of 13%.

Frequency sweep

The frequency sweep test is used to assess the viscoelastic properties of a material by comparing the values of G' and G" over a range of frequencies[34]. Ajovalasit *et* al. conducted a study to investigate the effects on G' and G" within a frequency range by adding additives and concluded that all hydrogels showed the viscoelastic nature and found that both G' and G" showed positive slopes with the loss modulus increasing more rapidly compared to the storage modulus[35]. Throughout the test, the shear strain percentage was kept constant in the LVE region and frequency varied from 1 to 100 rad/s. The results in Fig. 5c show that for both XG-HPGG-CA solution and XG-HPGG-CA-ZnO-Cur solution solutions, G" dominates at high frequency while G' dominates at low frequency, indicating a viscoelastic solid behaviour and the Moduli of XG-HPGG-CA-ZnO-Cur solution is higher than XG-HPGG-CA hydrogel solution at all frequencies which proves extra stability due to ZnO and Cur.

Table 1 — Mechanical properties

Film	Maximum force (N)	Tensile strength (MPa)	Elongation at break (%)
XG-HPGG-CA film	49.5 ± 0.54	28.4 ± 0.10	8.9 ± 0.24
XG-HPGG-CA-ZnO-Cur film	54.6 ± 0.42	29.7 ± 0.15	7.88± 0.54

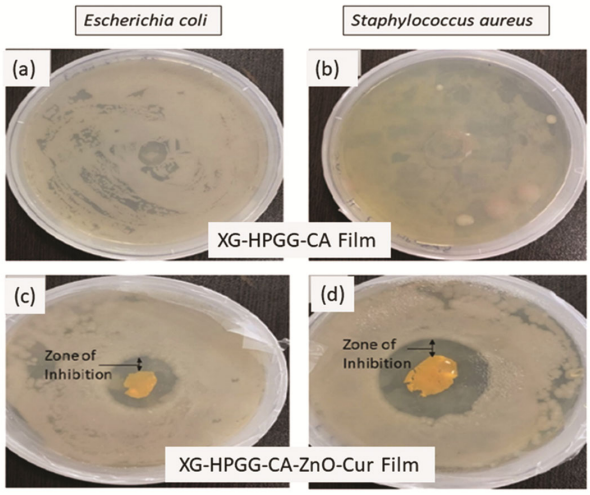

Fig. 6 — Disk diffusion test against *Escherichia coli* (a and c) and *Staphylococcus aureus* (b and d) for XG-HPGG-CA Film (a ,b) and XG-HPGG-CA-ZnO-Cur Film (c, d).

Mechanical Properties

The tensile properties of XG-HPGG-CA and XG-HPGG-CA-ZnO-Cur films were studied. The results for thickness (mm), width (mm), maximum load (N), elongation at break (%) and tensile strength (MPa) of the film are shown in the Table 1.

The XG-HPGG-CA-ZnO-Cur film showed an elongation at break % of 7.88 ± 0.54 which indicated its ability to withstand stretching and deformation before breaking. It has a high tensile strength of 29.7 ± 0.15 MPa which was indicative of its ability to withstand tension and resist breaking under force. These properties have made this film suitable for biomedical applications such as food packaging material.

***In Vitro* Test**

Disk Diffusion test

Active food packaging technology, involving incorporation of antimicrobial agents in the packaging to prevent microbial growth and prolong the shelf life of food, is becoming popular[36]. Fig. 6 shows the results of testing the antimicrobial activity of XG-HPGG-CA film and XG-HPGG-CA-ZnO-Cur film composites against two bacterial pathogen strains, *Escherichia coli* and *Staphylococcus aureus* using the disk diffusion method. In Fig. 6(a,b), XG-HPGG-CA film did not exhibit any antibacterial activity against either *E. coli* or *S. aureus* and it could not penetrate the bacterial cell. However, XG-HPGG-CA-ZnO-Cur film, (Fig. 6 (c, d) demonstrated a clear zone of inhibition of 87 mm and 102 mm, respectively, against both *E. coli*. and *S. aureus*. The results imply that XG-HPGG-CA-ZnO-Cur film exhibits significant antibacterial properties against both Gram-negative and Gram-positive bacteria, indicating that it has a broad-spectrum antibacterial activity.

The presence of an inhibition zone in the XG-HPGG-CA-ZnO-Cur film nanocomposite suggests that the biocidal action of ZnO NPs involves disrupting the membrane by generating surface oxygen species rapidly, ultimately leading to the death of pathogens[37]. This demonstrates the potential of XG-HPGG-CA-ZnO-Cur film composites as an effective active food packaging technology for inhibiting microbial growth and extending the shelf life of food products.

Food sampling test

After conducting antimicrobial tests using the disk diffusion method, the films were evaluated as a potential food packaging material for a food sample coated with hydrogel and a comparison was made with non-coated food material. To create a protective layer over the surface, the strawberries were directly immersed in the XG-HPGG-CA-ZnO-Cur solution and left to air dry[38]. Although strawberries have high antioxidant properties, their susceptibility to mechanical damage can lead to infectious symptoms, and their postharvest life is limited to about five days at 4°C[39]. The study aimed to enhance the shelf life of strawberries by coating them with an effective solution of prepared hydrogel.

Fig. 7 depicts one strawberry coated with the XG-HPGG-CA-ZnO-Cur solution while the other remains uncoated. The XG-HPGG-CA-ZnO-Cur solution coated strawberry showed slower deterioration compared to the uncoated sample. Day-1, showed no microbial growth on either of the fruit samples. Day 3, showed microbial growth on the non-coated fruit sample, and the fruit was shown to be deteriorated by Day 7. On the other hand, no microbial growth is observed on the strawberries coated with XG-HPGG-CA-ZnO-Cur solution coating till day 7. All these results confirm XG-HPGG-ZnO-Cur solution as a potential food packaging material with antimicrobial characteristics and Cur and ZnO as effective ingredients in active packaging films. Fruits and

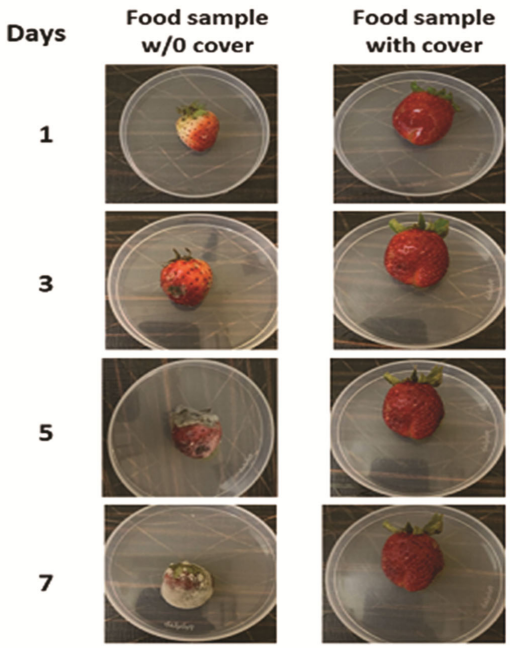

Fig. 7 — Food sample testing using strawberry without coating and with coating of XG-HPGG-CA-ZnO-Cur solution

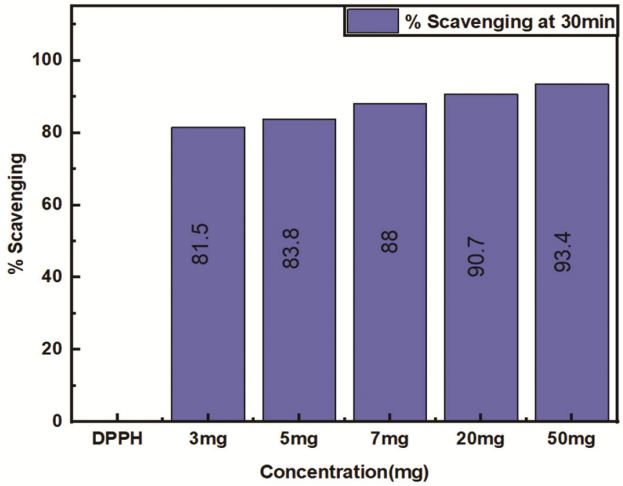

Fig. 8 — Scavenging of $DPPH^+$ radical by XG-HPGG-CA-ZnO-Cur film

vegetables with a high respiration rate can also be packaged using biopolymer sheets with a water permeability function[40].

Antioxidant activity

Although the conjugated diene moiety found in Cur accounts for the majority of its activities, the nearby phenolic groups have also been implicated in its antioxidant properties in Fig. 8. The results of the $DPPH^+$ Assay demonstrated that Cur facilitated hydrogen atom transfer, leading to conversion of a

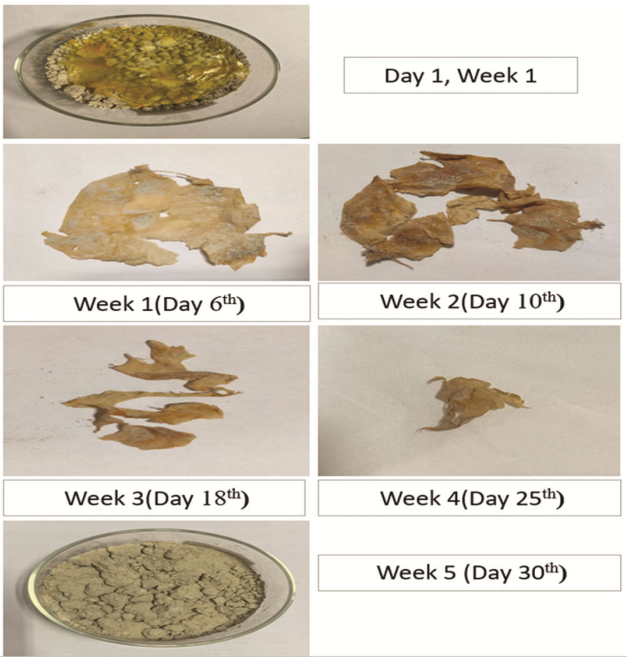

Figure. 9 — Biodegradation of XG-HPGG-CA-ZnO-Cur film

Table 2 — Biodegradability assay: XG-HPGG-CA-ZnO-Cur film weight loss

Day	Initial weight (g)	Final weight (g)	Percentage weight loss
5	0.472	0.337	28.6%
10	0.315	0.194	38.4%
15	0.194	0.093	52%
20	0.093	0.039	58%
25	0.039	0.085	78.2%
30	0.085	0.000	100%

stable radical called 2,2-diphenyl-1-picryl hydrazyl into 2,2-dipheny-l-picryl hydrazine (diamagnetic, non-radical)[41]. The assay showed a trend of increasing antioxidant activity. The combination of ZnO nanoparticles and Cur exhibited significant antioxidant activity against $DPPH^+$ free radicals[42]. The antioxidant activity was evaluated by incubating the solutions of varying concentrations (3 mg, 5 mg, 7 mg, 20 mg, 50 mg) with $DPPH^+$ solution for 30 min, resulting in an increase in antioxidant activity of 81.5%, 83.8%, 88%, 90.7% and 93.4%, respectively. The antioxidant activity of food packaging film can positively impact the packaging process by regulating the production of reactive oxygen species[43].

Biodegradability test using soil burial method

The results of the biodegradability test using soil burial method have been shown in the Fig. 9 and degradation was calculated at the interval of every 5 days that was shown in Table 2. It has been

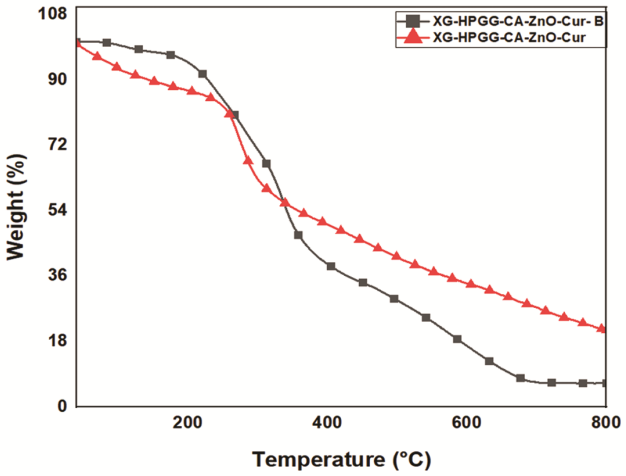

Fig. 10 — TGA graph of initial XG-HPGG-CA-ZnO-Cur film and the same film upon biodegradation (XG-HPGG-CA-ZnO-Cur –B)

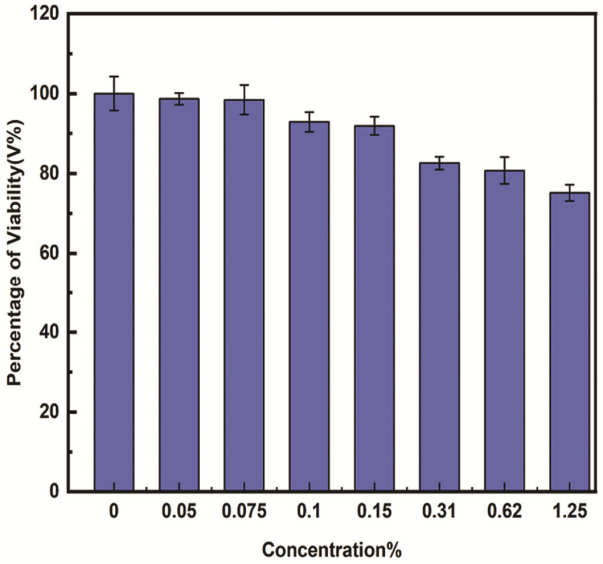

Fig. 11 — The viability percentage of Hep-G2 cells, for XG-HPGG-CA-ZnO-Cur film

observed that longer the burial time, higher will be the degradation of the film, which proved the environmentally friendly properties of the film[44]. The film gradually started to break down into small fragments around day-6 of first week after burial. Deterioration of film was seen on the surface as the film became fragile further in week 2. Cracks were observed on the surface of the sample all along the coming weeks of week 3 and week 4 as the film broke down in further smaller fragments. Soil degradation influenced macrostructural changes. Most of the film was degraded by the end of week 4 and only a small section of the film could be seen. The film was seen to be completely degraded around day 30th in week 5.

The film was weighed to calculate the weight loss over the period of degradation of 5 days. On around 5th day in week 1, the film was dusted and washed with distilled water to perform thermal degradation analysis. The results were then compared with an initial bioactive film as shown in Fig. 10. Shifts in peaks of both the films and amount of residual content was observed which further led to the observation that components of the biodegraded film broke down due to natural decomposition of the film upon microbial action in the soil. The biodegraded film showed wt. loss at a much faster rate than the XG-HPGG-CA-ZnO-Cur Film. Hence, it could be concluded that XG-HPGG-CA-ZnO-Cur Film is biodegradable film, which is an important aspect in packaging applications.

Cytotoxicity evaluation by SRB Essay

The cytocompatibility of XG-HPGG-CA-ZnO-Cur films was assessed using human hepatic cell lines (Hep-G2) as model cell lines. The results of the cytotoxicity test for different concentrations are presented in Fig. 11. The experiment with Hep-G2 cell culture demonstrated that the cells were able to attach to the surfaces of the films, proliferate, and disseminate[15]. After the incubation period, the cells on the XG-HPGG-CA-ZnO-Cur films exhibited normal morphology. The viability values of all film samples at different concentrations as shown in Fig. 11 were above 80%, indicating that the films were biocompatible with Hep-G2 cells.

Conclusion

This study demonstrated the successful fabrication of XG-HPGG-CA-ZnO-Cur films with antimicrobial properties and a strong zone of inhibition, making them suitable for use as edible food packaging material. The addition of glycerol also improved their thermal and mechanical stability compared to XG-HPGG-CA-ZnO-Cur. The characterization of the samples using various analytical techniques, such as FTIR, XRD, SEM, TGA, rheology, *in-vitro* tests revealed that XG-HPGG-CA-ZnO-Cur films promoted cell growth and differentiation, indicating their potential as a food packaging material. The films have antimicrobial, antioxidant properties and show biodegradable properties. These findings suggest that the use of harmful plastics in food packaging could potentially be reduced by utilizing these edible and affordable options. Overall, XG-HPGG-CA-ZnO-Cur films show promise as a sustainable and biocompatible alternative for food packaging applications.

Acknowledgements

The authors would like to thank Dr. Swarmita Dixit (Aakaar Biotechnologies Pvt. Ltd., Jankipuram Extension, Lucknow, India) for carrying out SRB test for the synthesized XG-HPGG-CA-ZnO-Cur Film. The authors are also thankful to UFlex Pvt. Ltd. Noida, India, for mechanical strength testing. Furthermore, the authors acknowledge the Vice Chancellor of DTU, for supporting the project with research facilities and financial aid.

Abstract: This paper presents the design and theoretical analysis of a photonic crystal fiber (PCF) based chemical sensor model. To evaluate the efficiency of this model, various optical parameters are analysed using finite element method based COMSOL Multiphysics Software. Different analytes namely methanol (1.317), water (1.330), ethanol (1.354) and benzene (1.366) have been considered for the sensing purpose in this study. The core region is infiltrated with different analytes separately. The model is simulated in THz regime (0.5–1.5 THz) to evaluate optical properties. The proposed structure design exhibits a high relative sensitivity of 96.85%, 97.32%, 97.99% and 98.33% for methanol, water, ethanol, and benzene, respectively at an operating frequency of 1.3 THz. The proposed model demonstrates exceptionally low confinement loss values which are 2.22×10^{-12} dB/m for methanol, 1.16×10^{-11} dB/m for water, 1.34×10^{-11} dB/m for ethanol and is 1.30×10^{-12} dB/m for benzene. Additionally, the effective material loss for the designed PCF also comes out to be very low for all the analytes, 0.0044 cm^{-1} for methanol, 0.0040 cm^{-1} water, 0.0034 cm^{-1} for ethanol and 0.0032 cm^{-1}, for benzene. Furthermore, the PCF shows large effective mode area and numerical aperture (NA) within the mentioned range, at 1.3 THz. The NA values obtained at 1.3 THz are 0.32 for methanol, 0.40 for water, 0.32 for ethanol, and 0.32 for benzene. The obtained Effective mode Area (EMA) values are 1.46×10^5 μm^2 for methanol, 1.45×10^5 μm^2 for water, 1.44×10^5 μm^2 for ethanol and 1.43×10^5 μm^2, for benzene. Subsequently, the optimal profile provides birefringence values of 0.0009 for methanol, 0.0010 for water, and 0.0011 for both ethanol and benzene. The practical implementation of the proposed PCF structure is possible using subsisting modern fabrication techniques. Consequently, the proposed PCF design should be helpful in industrial areas for chemical research, food and biomedical sensing.

Keywords: Photonic crystal fiber; Terahertz; Relative sensitivity; Confinement loss; Chemical sensing

1. Introduction

Analysing and exploring unidentified substances is an intriguing subject in the field of science, essential for the well-being of human health. For this purpose, researchers are working diligently to develop and design different kinds of sensors which can aid in detecting unknown chemicals. Substances like alcohol and water are the most common chemicals that are used as primary components in many compound solutions. So, an effective method should be accessible for chemical sensing. Sensors based on PCFs are expected to be beneficial in industrial sectors, particularly for applications in chemical research, as well as in the fields of food and biomedical sensing [1]. In this paper, we have explored the application of chemical sensing in the terahertz regime. In the past decade, photonic crystal fibers (PCFs) operating in the terahertz region have gained tremendous popularity. Terahertz frequency belongs to the sect of electromagnetic radiation that lies in the range of microwave and infrared frequency. Terahertz radiation frequency region ranges from 0.1 to 10 THz [2]. A major setback that hindered the comprehensive study of the THz band earlier was the transmission loss due to the atmospheric moisture during propagation [3]. To address this problem in THz communications, THz optical photonic crystal fibers (PCFs) have been utilized as waveguides across a range of applications, encompassing THz antennas [4] and polarization-maintaining THz systems [5]. PCFs operating in THz regime showcase numerous promising traits and advantages; THz sensors are bigger than the sensors operating in the mid-infrared region, in terms of

core area and diameter of the fiber, thus demonstrating better analyte sensing [6].

The two key important guiding attributes for sensing and chemical sensing are confinement loss and relative sensitivity. The refractive index significantly impacts the Relative Sensitivity; a higher refractive index contrast between the core and cladding ensures the improved light confinement, resulting in increased sensitivity to changes in the surrounding environment. Birefringence of PCF is another remarkable factor taken into consideration, high value of birefringence is inherently preferred. Besides the mentioned characteristics, effective mode area (EMA), numerical aperture (NA), and effective material loss (EML) are also examined to evaluate the efficiency of the sensor.

Due to its unique geometrical structure, PCF-based devices hold an advantage over the ones based on conventional fiber. One can easily elevate the sensing of a PCF by controlling its various design parameters. The design flexibilities make PCF favourable over conventional fibers [7]. By altering the diameter and pitch of holes in the cladding and core region, we can enhance the field interaction with the analyte in the core region of the fiber. The hollow core has a prominent core volume which provides significantly better sensing than the porous-core photonic crystal fibers [8]. A greater core area enhances the interaction of light and the analyte in the core, thus helping in the sensing application.

A variety of distinct biosensors have been introduced in the last two decades for chemical sensing. The innovations have paved a way for design of PCF-based sensors operating in different wavelength regimes. Designs with different core-structure such as porous-core octagonal PCF [9], quasi-PCF [10, 11], and dual-diamond ring PCF [12] was proposed for chemical sensing in terahertz and infrared spectrum. Chemical sensors based on Surface plasmon resonance is another effective way to obtain the sensitivity for a broad range of unknown analytes. Phase matching is a vital condition necessary for SPR, when the frequencies of light photons and electron of the plasmonic material match we observe a sharp loss peak, the fluctuation in the peak is used to identify analytes [13]. A dual-core refractive index fiber is also used for sensing application, the resonant coupling is observed between the two cores, the transmittance of the fiber changes significantly with variations in the refractive index of the surrounding medium [14].

In the past few years, different materials such as Topas [15], Zeonex [16], Teflon [17] and Silicon [18] have been used as background material for PCF based sensors. Material selection is an important aspect, and we chose it based on its distinctive properties which fits the criteria of our study. Topas and Zeonex exhibits similar properties such as constant refractive index (RI) of approximately 1.53 within THz range [19], low material loss, low dispersion, high transparency window, high transition temperatures etc. In our proposed design, we have chosen Zeonex as the bulk material. Zeonex is chosen as the background material over TOPAS and silicon due to its low absorption loss in terahertz regime (0.1–10 THz). The bulk material loss of Zeonex is 0.2 cm^{-1} [20] and the refractive index remains almost constant in the THz range. Zeonex also displays comparatively greater chemical resistivity and higher glass transition temperatures which is an essential factor for the fabrication of fiber [21].

In the past several years, many studies were conducted for the development of PCF based chemical sensors in THz frequency band. In 2023, Hossain et al. suggested a decagonal shaped PCF-based chemical sensor with hexahedron core, using Topas as the bulk material. The relative sensitivity for ethanol, benzene, and water turned out to be 92.55%, 94.65%, 90.30%, respectively. The confinement loss was measure to be 5.81×10^{-08} dB/m for ethanol, 6.01×10^{-08} dB/m for benzene, and 5.84×10^{-08} dB/m for water [6]. In the same year, Hossen et al. [22] proposed another hexahedron-shaped core, with Zeonex as the bulk material for sensing three distinct alcohols. Relative sensitivity and confinement loss for ethanol was reported as 89.50% and 5.45×10^{-08} dB/m, respectively. Ferdous et al. [23] presented an octagonal structure with a square-core. On simulation relative sensitivity for three substance water, ethanol and benzene were 90.65%, 91.93%, and 93.06%, at 1.3 THz. The confinement loss for the same substance were 2.12×10^{-13} dB/m, 2.00×10^{-13} dB/m, and 1.88×10^{-13} dB/m, respectively. In 2021, Sen et al. [24] designed a decagonal PCF with rotated-hexa core and by using Zeonex as the background material. For ethanol, water, benzene the fiber obtained values 78.56%, 79.76% and 77.51% for relative sensitivity, and for confinement loss values were 5.80×10^{-08} dB/m, 6.02×10^{-08} dB/m, and 5.74×10^{-08} dB/m, respectively. In 2020, Iqbal et al. [25] suggested a hexagonal geometry PCF using rectangular air holes for the classification and detection of alcohols. At a monitoring frequency of 2 THz, relative sensitivity for methanol was 88%, for ethanol was 91%, for propanol 92.30%, and for water it was 90.03%. Confinement loss at the optimum frequency for methanol, ethanol, propanol, and water was 0 cm^{-1}, 1.515×10^{-14} cm^{-1}, 5.935×10^{-15} cm^{-1}, and 4.045×10^{-15} cm^{-1}, respectively. In 2019, Sen et al. [26] proposed a circular design with a hexagonal core and used Silicon as the background material. The design was evaluated for ethanol, benzene, and water. At 1 THz, relative sensitivity for ethanol, benzene, and water were 76.44%, 77.16% and 73.20%, respectively. Additionally, confinement loss for the chemicals were 2.33×10^{-03} dB/m, 3.07×10^{-06} dB/m, and 2.84×10^{-02} dB/m. Recently, Kundu et al. proposed a

terahertz PCF sensor for chemical identification and achieved 95.21% for benzene and 94.67% for ethanol and the corresponding confinement loss for benzene and ethanol are 4.674 × 10^{-3} dB/m and 1.378 × 10^{-2} dB/m [27].

The following paper presents a rectangular shaped air hole based PCF chemical sensor model. The effectiveness of the design is assessed on various optical parameters. The optical parameters are calculated for four different analytes- methanol, ethanol, benzene, and water. The model is simulated in the THz range from 0.5 THz to 1.5 THz for evaluation.

2. Design methodology and fabrication possibilities

To study the performance of the proposed PCF sensor, the PCF model is designed using COMSOL Multiphysics software. Figure 1 represents the transverse section view of the proposed sensor model. We have considered methanol, water, ethanol, and benzene as our analytes which are to be infiltrated in the core for sensing purposes. Figure 2 represents the electric field distribution of the propagating fundamental mode in the core region at 1.3 THz. The hollow core photonic crystal fiber offers low effective material loss (EML) and provides higher sensitivity. In this model, the purple-coloured central rectangular hole acts as the core of the fiber in which different analytes are to be filled and the cladding region consists of 16 rectangular air holes which help in guiding the light to propagate through the core region. The total fiber diameter is 2.50 mm and the cladding region is adjoined with a cylindrical layer called perfectly matched layer (PML) to avoid the effect of back reflections into the study area by absorbing the outgoing waves. Generally, the thickness of PML is kept between 2 and 10% of the total fiber diameter [28]. In our simulation, we considered the thickness of PML to be 9% of the fiber

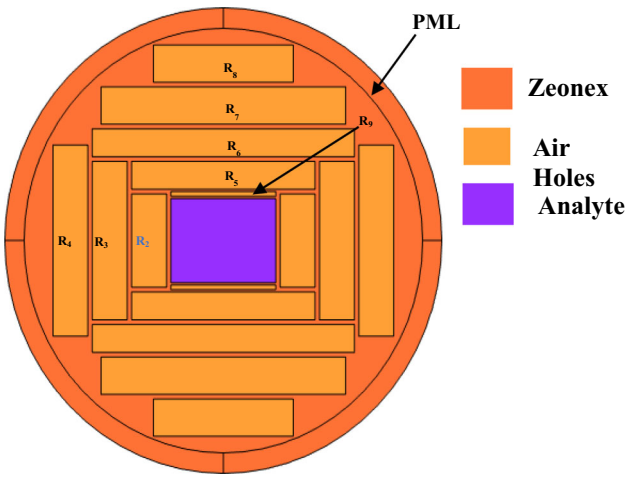

Fig. 1 Proposed structure design

diameter which ensures convergence of the result. The FEM method is executed by using physics-controlled mesh. To get better simulation results we have chosen finer mesh elements having 8742 triangular elements with 1438 edge elements and 76 vertex elements. The height and width of the core are 600 μm and 450 μm, respectively. In cladding region, six rectangles are positioned on left and right sides of the core with the same width but different heights. Identical rectangles are denoted by the same variables. In that way, the nearest rectangles to the core are denoted by R2 with height and width of 500 μm and 200 μm respectively. Similarly, the next nearest rectangles are denoted as R3 and R4 with height and width of 850 μm and 200 μm for R3 and 1025 μm and 200 μm for R4. In the vertical direction, the rectangles above the core region namely R5, R6, R7 and R8 have heights and widths of 150 μm and 1050 μm, 150 μm and 1500 μm, 200 μm and 1400 μm, 200 μm and 800 μm respectively. The pitch in the horizontal direction and vertical direction is kept constant to be 25 μm. Two similar rectangular air holes are also arranged just above and below the core to confine the propagating electric field more effectively in the core region by creating the index contrast. They are denoted as R9 and have height and width of 25 μm and 600 μm. The dimensions of the core must be kept as large as possible to get higher values of core power fraction. But keeping in mind the feasibility and fabrication complexities, we cannot choose the dimensions as per free will. In our proposed model, while simulation we have kept the width and height of the rectangular holes to be the same and varied the dimensions of the rectangular core region by 2% to experience the change in sensing performance of the model. After that, we stated the height and width of the core region as optimum (OPT). In recent times, various PCF fabrication techniques and methods have been used to fabricate different PCF geometry structures. For the fabrication of circular air holes, stacking and sol–gel methods are widely used [29–31]. Furthermore, for the fabrication of asymmetric PCF structure extrusion method and 3-D printing techniques [32, 33] are used. Using the extrusion method rectangular and spider-web-shaped PCFs have already been realized which opens up the possibility of fabrication of the proposed design structure [32]. Hence, the fabrication of the proposed PCF structure is attainable by the subsisting modern fabrication techniques.

3. Numerical analysis

The following study is conducted for four different analytes methanol, ethanol, benzene, and water. To assess the performance of the proposed chemical sensor, different analytes are separately injected into the rectangular core

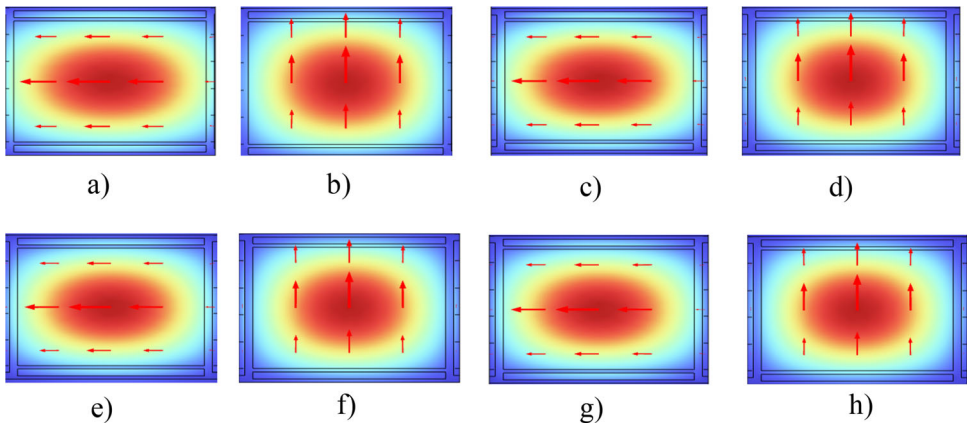

Fig. 2 Mode field distribution of fundamental mode for (**a**) Methanol, x-pol (**b**) Methanol, y-pol (**c**) Water, x-pol (**d**) Water, y-pol (**e**) Ethanol, x-pol (**f**) Ethanol, y-pol (**g**) Benzene, x-pol (**h**) Benzene, y-pol

and are studied. The effectiveness of the sensor depends on various optical parameters which include, Relative sensitivity, Power fraction, Confinement loss, Effective mode area, Effective material loss, Numerical Aperture, Birefringence etc.

When light propagates through a fiber it experiences an average refractive index which is determined by the design of the PCF. This mean refractive index is referred to as the effective refractive index.

The key element for analysing the performance of a sensor is the Relative Sensitivity (RS), which is calculated by the following equation [34]:

$$RS = \frac{n_a}{n_{eff}} \times P \tag{1}$$

where n_a represents the refractive index of the analytes which is 1.317 for Methanol, 1.354 for ethanol, 1.330 for water, and 1.366 for benzene, n_{eff} stands for effective-mode index and P for power fraction.

In PCF-based chemical sensors, power fraction can be defined as the amount of propagating light that interacts with the analyte present within the core region. Power fraction (PF) is calculated using the equation given below [35]:

$$P = \frac{sample \int R\left(E_x H_y - E_y H_x\right) dxdy}{whole \int R\left(E_x H_y - E_y H_x\right) dxdy} \tag{2}$$

In the above equation, we perform integration to calculate the light propagated within a particular analyte concerning the cross section of the fiber. Here, Ex, Ey represents the electric field components and Hx, Hy represents the magnetic field components.

Another important optical parameter which helps in the analysis of a PCF-based sensor is Confinement Loss. Confinement loss (CL) is the propagation loss due to leakage which determines the light confining ability of any PCF. The lower the confinement loss, better will be the confining ability which is a pre-requisite for any PCF based

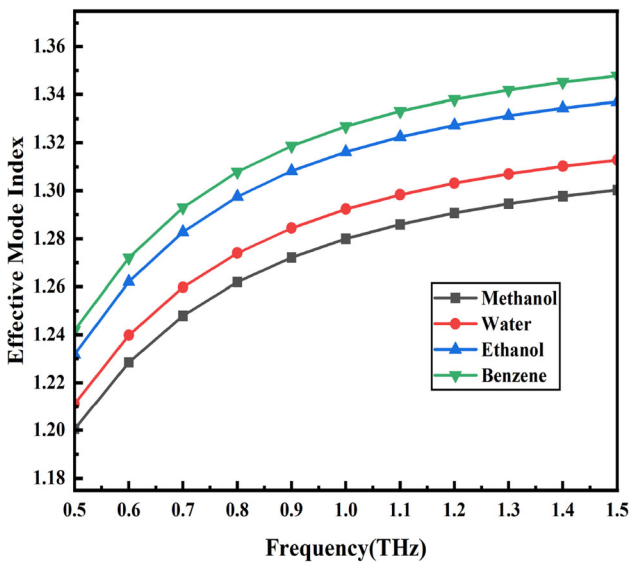

Fig. 3 Effective mode index variation (x-pol)

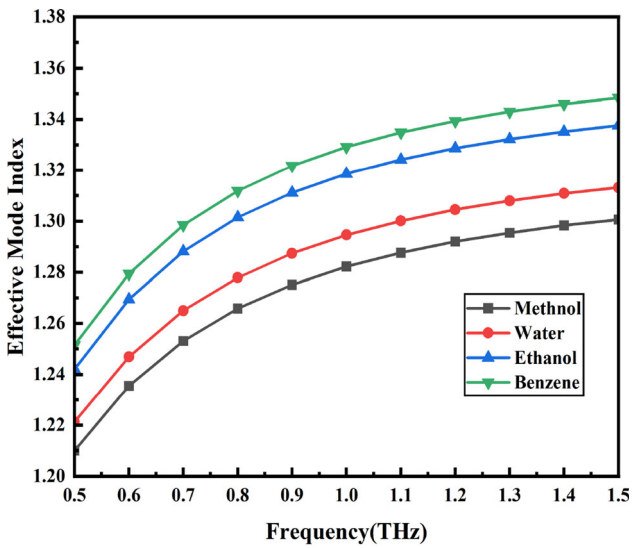

Fig. 4 Effective mode index variation (y-pol)

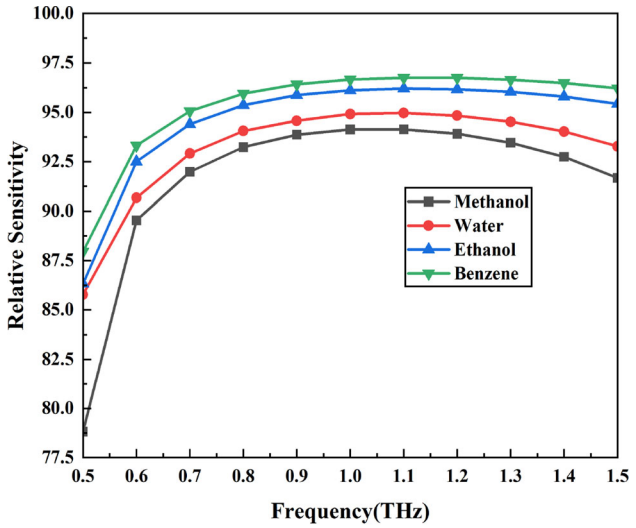

Fig. 5 Relative Sensitivity for OPT-2% profile (x-pol)

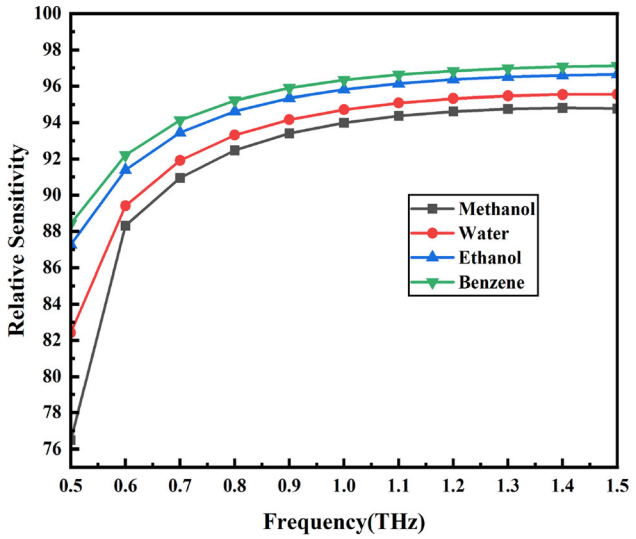

Fig. 6 Relative Sensitivity for OPT-2% profile (y-pol)

sensor model. CL depends on the imaginary part of effective mode index and is given as [24]:

$$C.L = 8.868 \times k_o I_m\left(n_{eff}\right) dB/m \tag{3}$$

Here, k_o is the propagation constant and $I_m\left(n_{eff}\right)$ is the imaginary part of the effective refractive index of fundamental mode.

Effective mode area (EMA) is also an important optical parameter in any PCF. PCFs with low effective mode area can be useful in non-linear optics and PCFs with large effective mode area can find potential applications in laser communications as well as in optical and electronic devices. It gives the idea about the amount of light propagating in the cladding region of the fiber and in the core region where the analyte is to be filled. In a PCF-based sensor

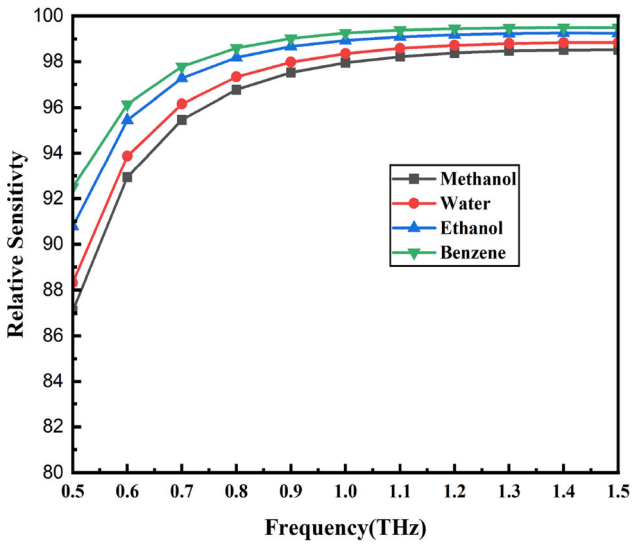

Fig. 7 Relative Sensitivity for OPT+2%profile (x-pol)

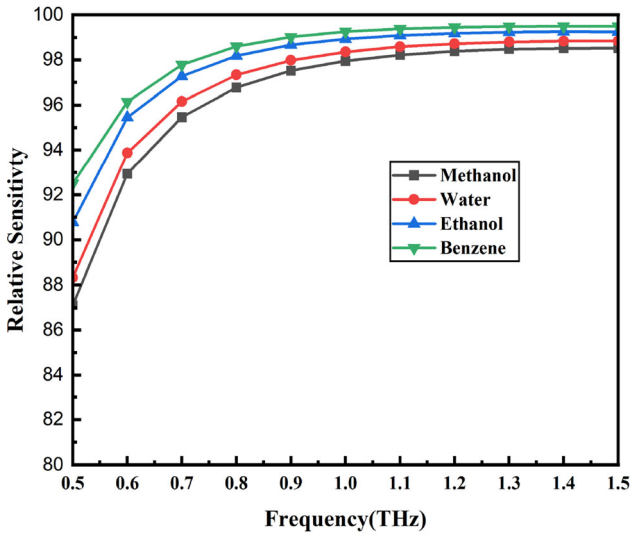

Fig. 8 Relative Sensitivity for OPT+2% profile (y-pol)

model, the high effective mode area indicates high relative sensitivity and low confinement loss. EMA which is usually referred as A_{eff} is calculated using the equation given below [36]:

$$A_{eff} = \frac{\left(\iint |E|^2 dxdy\right)^2}{\iint |E|^4 dxdy} \tag{4}$$

Here, |E| represents the electric field distribution of the suggested fiber sensor.

Effective material loss (EML) is another loss which comes into play during the propagation of light due to absorption by the material of the fiber. EML can be calculated as [35]:

Table 1 Comparative study of relative sensitivity of all four analytes for y polarization mode

Analyte	Profile	Operating frequency (THz)	R.S (%)
Methanol	OPT − 2%	1.3	94.75
	OPT	1.3	96.85
	OPT + 2%	1.3	98.35
Water	OPT − 2%	1.3	95.46
	OPT	1.3	97.32
	OPT + 2%	1.3	98.66
Ethanol	OPT − 2%	1.3	96.50
	OPT	1.3	97.99
	OPT + 2%	1.3	99.14
Benzene	OPT − 2%	1.3	96.97
	OPT	1.3	98.33
	OPT + 2%	1.3	99.32

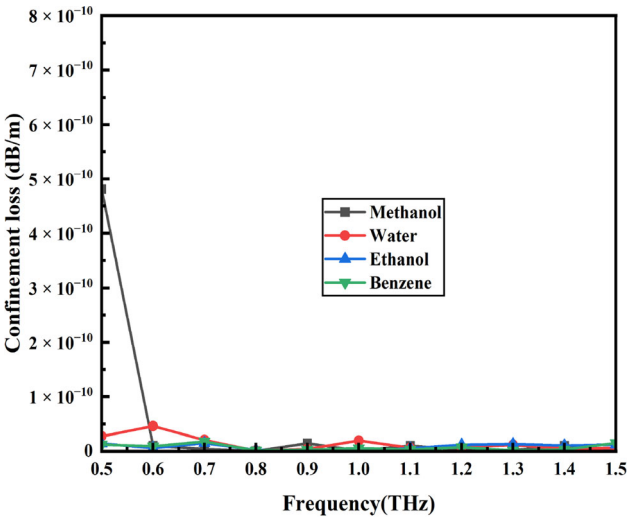

Fig. 10 Confinement loss as a function of frequency

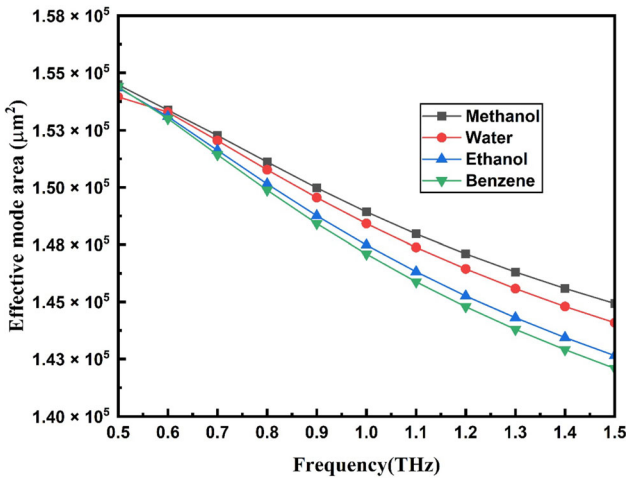

Fig. 9 Effective mode area as a function of frequency

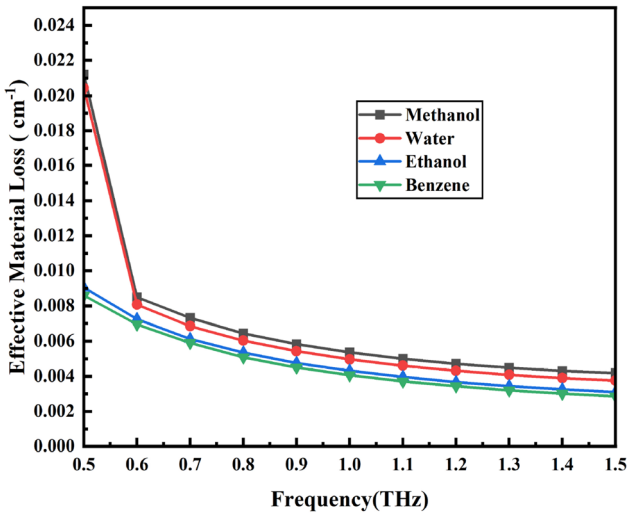

Fig. 11 Effective material loss as a function of frequency

$$\alpha_{eff} = \sqrt{\frac{\varepsilon_o}{\mu_o}}\left(\frac{\int n_{mat}|E|^2\alpha_{mat}dA}{|\int P_z dA|}\right) \quad (5)$$

In the above equation, ε_o is the permittivity in free space and μ_o is the permeability in the free space. n_{mat} represents the refractive index and αmat represents the bulk absorption loss of the Zeonex. P_z represents the Poynting vector in the z direction.

Numerical Aperture is another important characteristic which is significant to check the efficiency of any PCF-based sensor model. Generally, a large numerical aperture is preferred for better sensing results as the higher the NA of the fiber higher the light-gathering capacity which further improves the field interaction with the analyte [37].

$$NA = \left(1 + \frac{\pi A_{eff} f^2}{c^2}\right)^{-\frac{1}{2}} \quad (6)$$

In terahertz communication systems and sensing applications, it is necessary to maintain a high polarization state. Birefringence is the property which helps in maintaining the polarization state of a fiber. Birefringence is defined as the difference in effective refractive indices of the fundamental mode of the fiber in x and y polarizations. It can be calculated by [35]:

$$B = |n_x - n_y| \quad (7)$$

n_x and n_y here represent the effective mode indices of *x*-polarization and *y*-polarization, respectively.

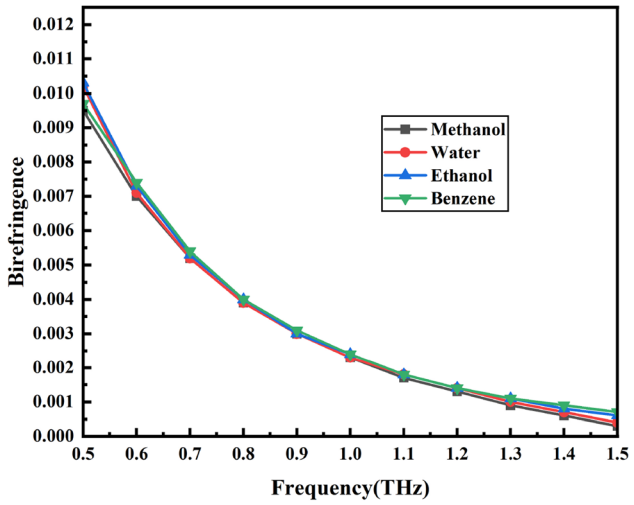

Fig. 12 Birefringence as a function of frequency

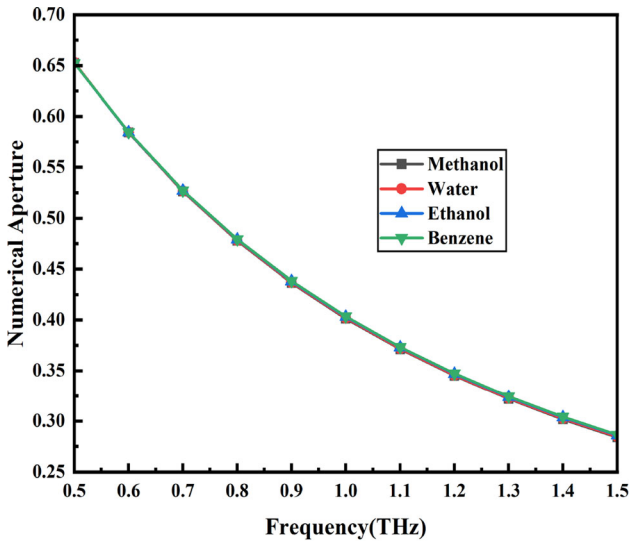

Fig. 13 Numerical aperture as a function of frequency

4. Results and discussion

The proposed sensor model is simulated using COMSOL Multiphysics software and all the optical characteristics are calculated using the same tool. We get the results in the frequency range of 0.5–1.5 THz, and the declared optimum frequency is 1.3 THz. We have calculated the Relative Sensitivity (for both *x* and *y*- polarization modes), PF, CL, A_{eff}, EML, NA and birefringence.

We have first analysed the effect of frequency of the effective-mode-index of the propagating mode for all the analytes for the both polarization and shown in Figs. 3 and 4 respectively. As expected, an increase in the effective mode index with frequency is observed for all analytes for both polarizations. As the refractive index of benzene is highest among ethanol, water and methanol hence the effective-mode-index of benzene is highest followed by ethanol, water and methanol at a particular frequency.

As mentioned earlier, we have considered three different core design parameters (OPT −2%, OPT, OPT + 2%). The relative sensitivities of methanol, water, ethanol and benzene as a function of frequency are shown graphically in Figs. 5, 6, 7 and 8. In these figures, one can observe that RS increases with frequency. Confinement of the modal field increases with frequency and hence increases in the power fraction, *P*, thus increasing relative sensitivity. The relative sensitivity also depends proportionally on the RI of the analyte being used, as with high-index, the confinement of light is high. As a result, the relative sensitivity for benzene is highest among all analytes. Initially, the values of relative sensitivities for x polarization mode is greater than that of y polarization mode as the area of the proposed structure's core is higher in x-direction but after 1.2 THz the y polarization mode has higher relative sensitivities as light confinement becomes effective due to the presence of two nearly arranged holes in the y-direction. For OPT-2% profile, the relative sensitivities of methanol, water, ethanol and benzene are 93.46%, 94.52%, 96.03%, and 96.66% in x-polarization mode and are 94.75%, 95.46%, 96.50%, and 96.97%, respectively in y- polarization mode. For OPT profile the relative sensitivities for methanol, water, ethanol, and benzene are 96.57%, 97.15%, 97.96%, and 98.35% in x-polarization mode and are 96.85%, 97.32%, 97.99%, and 98.33% in y-polarization mode at operating frequency of 1.3 THz. For OPT + 2% profile case, the calculated relative sensitivity for benzene reaches 99.34% but as we increase the length and width of the core by 2%, the chances during fabrication that the core and cladding holes get merged increase, therefore we chose the OPT profile case as a compromise. The comparative study of the relative sensitivity of all four analytes for the y-polarization mode is shown in Table 1.

Figure 9 shows the variation of Effective mode area as a function of frequency. It can be observed that the EMA of the OPT profile decreases with the increase in frequency. High operation frequency causes tight confinement of light in the core region, thus reduces the mode area of the propagating mode. At operating frequency of 1.3 THz, the values of effective mode area are 1.46×10^5 μm^2 for methanol, 1.45×10^5 μm^2 for water, 1.44×10^5 μm^2 for ethanol and 1.43×10^5 μm^2, for benzene.

Confinement loss for the OPT. profile is shown graphically as a function of frequencies in Fig. 10. As the frequency increases the value of confinement loss decreases because of the effective confinement of light at larger frequencies. Confinement loss for benzene is lowest among all other analytes as the R.I of the benzene is highest,

Table 2 Comparative study of optical parameters among previous works and proposed work

reason being the same that light gets more confined with analytes having greater refractive indices. As observed from the graph the values below 10^{-11} dB/m are unstable reason being the values are too small and are comparable to the numerical errors introduced during the simulations [3]. The values of confinement loss at 1.3 THz are is 2.22×10^{-12} dB/m for methanol, 1.16×10^{-11} dB/m for water, 1.34×10^{-11} dB/m for ethanol and, 1.30×10^{-12} dB/m for benzene.

Effective material loss is shown graphically as a function of frequencies in Fig. 11. For a PCF based sensor low EML is preferred as high values of material loss limits the sensor performance. At operating frequency region of 1.3 THz, the proposed sensor offers low values of EML which are 0.0044 cm^{-1} for methanol, 0.0040 cm^{-1} water, 0.0034 cm^{-1} for ethanol and 0.0032 cm^{-1}, for benzene.

Figure 12 illustrates the birefringence as a function of frequency. Due to the asymmetry between the core and cladding air holes of the fiber, birefringence will also be present in our designed structure. Birefringence decreases as the frequency increases because the difference between the effective indices of x and y polarizations decreases with the increase in frequency. The optimum profile offers birefringence around 0.0009 for methanol, 0.0010 for water, 0.0011 for ethanol and 0.0011, for benzene at operating frequency of 1.3 THz.

Figure 13 illustrates the variation of numerical aperture as a function of frequencies. As it is logical that NA decreases with the increase in frequency which is verified by the graph in Fig. 13. The obtained values of NA at 1.3 THz are 0.32 for methanol, 0.40 for water, 0.32 for ethanol and 0.32 for benzene. To get an overall idea about the performance of proposed PCF based chemical sensor model, the comparative result of the sensing properties are tabulated and represented in Table 2.

5. Conclusion

In conclusion, a PCF based chemical sensor with rectangular-core model is presented for its sensing application in THz region. Using Zeonex as the background material, various optical parameters of the proposed sensor model have been examined over the range of 0.5–1.5 THz. All the numerical calculations are performed by PML boundary condition using FEM based COMSOL Multiphysics software. The optimum profile of the proposed sensor model exhibits high relative sensitivities of 96.85%, 97.32%, 97.99%, 98.33%, and low values of confinement loss as 2.22×10^{-12} dB/m, 1.16×10^{-11} dB/m, 1.34×10^{-11} dB/m, 1.30×10^{-12} dB/m for methanol (1.317), water (1.33), ethanol (1.354) and benzene (1.366) respectively at 1.3

THz operating frequency. Further, effective material loss for the model also comes out to be very low which makes our proposed sensor model worthy of proficient sensing. So, the proposed PCF sensor model should be helpful in industrial areas for chemical sensing, food and biosesning applications. Furthermore, with the advancement in modern fabrication techniques, the fabrication of the proposed PCF is attainable.

***Abstract*— Retrieving relevant medical data promptly is essential for both improving patient care and scientific discoveries. To compare the performance of Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), Deep Neural Networks (DNNs), and a unique fusion approach called Random Multimodel Deep Learning (RMDL), this study addresses the application of deep learning models in medical document retrieval. The findings of this research emphasize the value of RMDL's multi-model fusion and imply that integrating several learning modalities can have positive effects in the medical field. improved document retrieval systems have the potential to provide medical personnel with faster access to pertinent information, which could result in more precise diagnoses, more focused treatment regimens, and ultimately improved patient outcomes. Improved retrieval also makes it easier to collect information for medical research in an efficient manner, which speeds up breakthroughs across a range of domains and aids in the creation of individualized medicine strategies. Ultimately, the most effective model is assessed using performance evaluation parameters.**

Keywords- Medical data, CNN, RNN, DNN, RMDL fusion

I. INTRODUCTION

Retrieving document information is the process of comparing a group of free-text records to a user-specified query. Any kind of primarily unstructured material, including newspaper articles, real estate records, and manual paragraphs, could be included in these records. User queries might be as short as a few words or as long as many sentences that fully describe what information is needed. Sometimes, Document Information Retrieval (DIR) is referred to as text retrieval, or as a subset of it. Within the field of information retrieval, text retrieval deals with information that is predominantly stored as text. Since text retrieval is the foundation of all Internet search engines, it is an important field of study today.

The use of neural network architectures such as CNNs, RNNs, and transformers in the analysis and extraction of data from text documents is part of Document Information Retrieval (DIR) with Deep Learning [1]. These models are learning how to interpret the content of documents in a sophisticated way to improve tasks like document classification, grouping, and relevance ranking. By analyzing the semantic meaning and context of documents, deep neural networks can improve document retrieval systems' accuracy and efficiency.

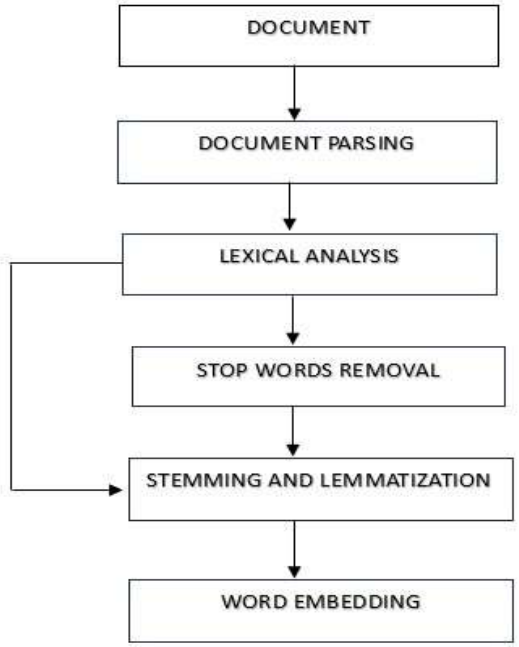

Fig. 1. Document Information Retrieval

A CORD 19 [2] dataset with 1,00,000 records is first collected. Importing necessary libraries such as NumPy, Pandas, and Matplotlib allows for the manipulation and analysis of data, the support of multi-dimensional arrays and mathematical functions by NumPy, and data visualization by Matplotlib. After loading the dataset into a Pandas data frame, actions for data cleaning are performed to address missing, null, and duplicate values as well as to eliminate superfluous symbols like commas, question marks, and punctuation.

During the pre-processing phase, the document is divided into discrete parts using document parsing. Subsequently, the significant pieces are tokenized and transmitted for Parts of Speech Tagging through lexical analysis. By eliminating affixes and locating roots, the stemming and lemmatization processes improve words. Last but not least, Word Embedding converts every document into a fixed-length vector that represents the frequency of words.

Using Principal Component Analysis, or PCA, dimensionality reduction is carried out. The technique known as *"dimensionality reduction"* essentially aids in improving

our understanding of our facts on a macro level. Our dataset's features are reduced to just the most crucial elements by doing this. A powerful yet straightforward method for reducing dimensionality is principal component analysis or PCA. It allows to immediately reduce the number of feature variables, focusing on the most crucial aspects and reducing the number of computations required. The Doc2Vec [3] approach is then used to extract the data. Regardless of a document's length, doc2vec aims to generate a numerical representation of it. A generalization of the word2vec method, Doc2vec is an NLP tool for expressing documents as a vector.

The K-means algorithm [4], a widely used method for exploratory data analysis, is used to cluster data. It seeks to locate subsets in the data where data points in one cluster are comparable to each other but data points in other clusters are not. By reducing the squared distance between data points and cluster centroids, K-means divides the dataset into pre-defined clusters and encourages both intra- and inter-cluster dissimilarity.

The organization of this paper is as follows: Section II elaborates on the literature review for Document Retrieval using various NLP algorithms. Section III depicts, in a nutshell, the various deep learning models used in this research paper for document retrieval purposes. Section IV describes the dataset and various parameters based on which describes the dataset and various parameters based on which the best model will be evaluated. Section V gives the conclusion and suggests topics for further research.

II. LITERATURE SURVEY

The technique for creating deep sentence embeddings using long short-term memory (LSTM) networks is presented by Palangi, H., Deng, L.[5]. By calculating the semantic similarity between queries and documents, these embeddings are used to improve information retrieval. Results from experiments show how well LSTM-based embeddings work to increase retrieval relevance and accuracy in NLP tasks.

Neural information retrieval (IR) strategies are reviewed in detail by Zhang, Y., Rahman.[6] The study looks at different neural network models and architectures used for information retrieval tasks like query comprehension and document ranking. In using neural networks to improve information retrieval systems, the article outlines developments, obstacles, and potential paths forward.

The performance of deep learning algorithms for biomedical document classification is assessed in this research by Behera, B., Kumaravelan.[7] The classification of biomedical documents was evaluated using several deep learning models at the 11th International Conference on Advanced Computing, 2019. The study adds to our understanding of how well deep learning methods work for classifying and organizing biological material.

III. DEEP LEARNING MODELS

Progressive outcomes have been attained by deep learning models in NLP application domains. Basic structured deep learning models and Ensemble deep learning models can be used to group all deep learning models for document information retrieval.

The term "Basic Structure DL models" refers to deep learning models with their own basic deep learning structure, such as CNN, DNN, and RNN. Ensemble Deep Learning models are those types of deep learning models that are constructed by integrating fundamental deep learning models, such as RMDL. The following is a brief explanation of those DL methods.

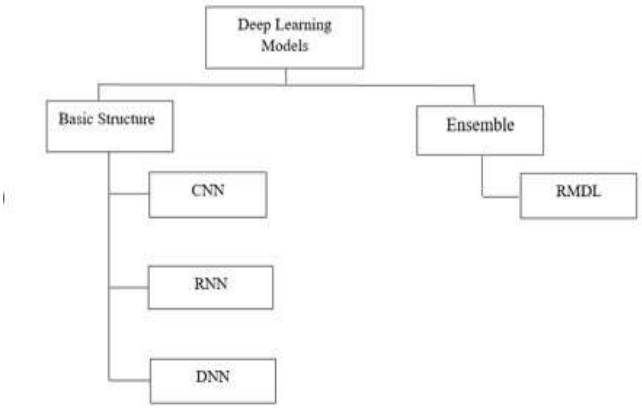

Fig. 2. Segmentation of Deep Learning Models

A. Deep Neural Network

In contrast to MLP, DNN [8] has a large number of hidden layers. Following that, the neural network is trained by the conventional backpropagation process. Nodes in the input layer are equal to the number of characteristics that were extracted. For multiclass classification, SoftMax is employed as the activation function in the output layer and sigmoid and Re-LU are utilized in the hidden layers. The prediction model is employed in the output layer. The number of nodes in the output layer corresponds to the number of classes in the dataset.

B. Convolutional Neural Network

With its several layers, including embedding, convolutional, and pooling layers, CNN [9] offers the best feature extraction techniques. As the input layer, the embedding layer transforms each word from the pre-processed texts into an embedding vector with an embedding dimension. The dimension of the Convolution layer is decreased by the Pooling Layer. After receiving two-dimensional representations of words or features, the Flatten Layer transforms them into vector form that the Fully Connected Layer can use. One or more neural layers that employ activation functions and dropout rates to learn the model are referred to as the fully connected layer or dense layer. Model prediction is done using the Output Layer, whose activation function is SoftMax and whose nodes are equal to the number of classes in the dataset.

C. Recurrent Neural Network

Better semantic analysis of the dataset is made possible by the RNN's [10] recurrent structure, which conveniently takes into account the information from earlier nodes. Every word in the pre-processed texts is transformed into embedding vectors with an embedding dimension by the embedding layer of the RNN model, which functions as the input layer. To learn the model, RNN architectures like GRU or LSTM are employed in conjunction with the dense layer. Nodes equal to the number of classes in the dataset are present in the output layer, which employs SoftMax as its activation function.

D. Random Multimodel Deep Learning

By using ensembles of different underlying deep learning architectures, such as DNN, RNN, and CNN, RMDL [7,11] improves accuracy while simultaneously solving the problem of identifying the simplest deep learning structure and design

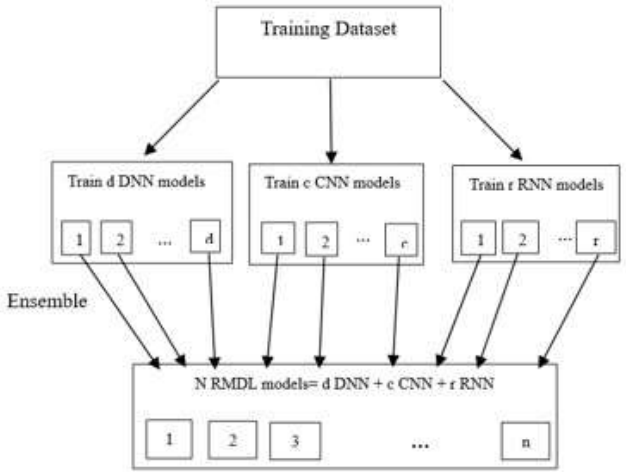

Fig. 3. RMDL Model Overview

A training dataset is given to each of the component DL models, such as DNN, CNN, and RNN, to construct the RMDL model. With the help of the Python-based sk-learn library's TfidfVectorizer [12], the DNN models preprocess the training dataset. Similar to this, Glove pre-trained word embedding and Keras tokenizer are used by the CNN and RNN models to preprocess the training dataset. Create d, c, and r numbers of CNN, RNN, and DNN models from the training dataset during the training phase. Thus, the sum of d, c, and r represents the total number of models in RMDL. After the testing data is loaded into the final neural model, the recovered documents will be evaluated for ranking and relevancy, and any additional features that are needed will be improved or integrated.

IV. RESULTS AND DISCUSSIONS

A. Dataset

The COVID-19 Open Scientific Dataset (CORD-19) [2] was created in reaction to the epidemic by the White House and a partnership of eminent scientific organizations. CORD-19 is a collection of more than 200,000 academic publications about COVID-19, SARS-CoV-2, and similar coronaviruses, of which more than 100,000 are available in full text.

B. Performance Metrics

Four features—true positive, true negative, false positive, and false negative—are used to establish performance measures like accuracy, precision, recall, and F1-score. Performance metrics including accuracy, weighted-average-based precision, recall, and F1-score are utilized in this experiment to assess the classifier's effectiveness. Here is a definition of the performance measures
which more than 100,000 are available in full text.

1. Precision is the percentage of all affirmative cases that were accurately identified.

Precision = True Positives / (True Positives + False Positives) (1)

2. The percentage of accurately recognized positive instances relative to all real positive cases is recall

Recall = True Positives / (True Positives + False Negatives (2)

3. An impartial indicator of model performance is the F1-score, which is the harmonic mean of precision and recall.

F1 Score = 2 * (Precision * Recall) / (Precision + Recall) (3)

C. Results

The results of a comprehensive experiment on various Deep Learning (DL) algorithms, including DNN, RNN, CNN, and RMDL, for the COVID-19 medical dataset CORD 19, are examined in this part. In this work, we integrated the DNN, RNN, and CNN models after using 200,000 words for the embedding layer. 30,000 of the 200,000 queries were utilized for testing the model and 30,000 for training.

TABLE I. Performance of DL Models

PERFORMANCE MEASURES	*DNN*	*RNN*	*CNN*	*RMDL*
Accuracy	87.43	82.65	98.84	98.96
Precision	86.2	83.4	97.1	98.24
Recall	87.12	85.7	98.3	98.31
F1-Score	86.3	84.5	97.7	98.26

We examined the effectiveness of several deep learning models for the CORD 19 dataset in this study. Convolutional Neural Networks (CNNs) had the highest accuracy (98.84%) among the individual models, followed by Recurrent Neural Networks (RNNs, 82.65%), Deep Neural Networks (DNNs, 87.43%), and Random Multimodel Deep Learning (RMDL) models (98.96%). While reaching equivalent accuracy to CNN, RMDL surpassed both DNN and RNN across all evaluation criteria (precision, recall, F1 score). Notably, RMDL outperformed CNN in terms of accuracy (0.13%) and F1 score (0.56%), indicating that it may be able to increase performance in situations where individual models may not be at their best.

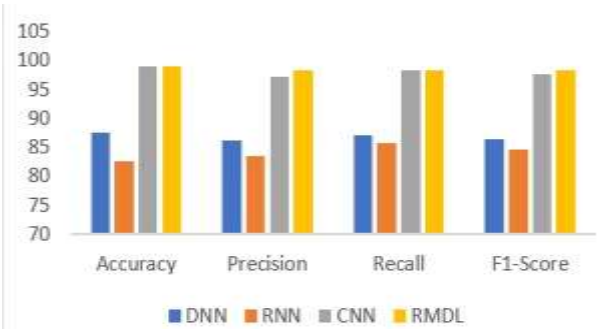

Fig. 4. Comparison of Performance Metrics

V.CONCLUSION

Important insights from our investigation into deep learning models for medical document retrieval are obtained. The new Random Multimodel Deep Learning (RMDL) method proved to be a powerful rival, even if individual CNNs achieved the best standalone accuracy. RMDL drove

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 19,2024 at 05:54:24 UTC from IEEE Xplore. Restrictions apply.

both DNNs and RNNs in crucial parameters such as precision, recall, and F1 score, even though CNNs and RMDLs exhibited comparably high accuracy. Indeed, RMDL exceeded CNNs in terms of accuracy and F1 score, indicating the potential for outperforming individual models under certain conditions. These outcomes highlight the way RMDL performs in the retrieval of medical documents and opens up new avenues for study. Further research into the distinct design and hyperparameter tuning of RMDL is necessary to completely understand its benefits and drawbacks in a variety of medical subdomains and retrieval activities. Furthermore, adding interpretability strategies to RMDL may improve its clinical relevance by providing insightful information about how it makes decisions.

Abstract

For sentiment analysis, lexicons are among the important resources. Existing sentiment lexicons have a generic polarity for each word. In fact, many words have different polarities when they are used in different domain. For the first time, in this work automation of a domain-specific sentiment lexicon named "*DoSLex*" has been proposed. In *DoSLex*, all the words are represented in a circle where the centre stands for the domain, and the *x* and *y* axis for the strength and the orientation of the sentiment, respectively. In the circle, the radius is the contextual similarity between the domain and term calculated using MuRIL embeddings, and the angle is the prior sentiment score taken from various knowledge bases. The proposed approach is language-independent and can be applied to any domain. The extensive experiments were conducted on three low-resource languages: Hindi, Tamil, and Bangla. The experimental studies discuss the performance of the combinations of different word embeddings (FastText, M-Bert and MuRIL) with several sources of prior sentiment knowledge bases on various domains. The performance of *DoSLex* has also been compared with three sentiment lexicons, and the results demonstrating a significant improvement in sentiment analysis.

1 Introduction

India is a multi-lingual country and Indians feel comfortable to express their feelings in their native/local language. The number of Indian language internet users across India has reached around 500 million in 2021.[1] This implies that Indians prefer their local languages over English to read, write and converse with each other as they feel more connected and heard. With the ease of internet access, Indian languages such as Hindi, Tamil, Telugu, Bengali, Kannada, and Marathi (to name just a few of the country's 22 official languages) have entered the digital space in a big way. Now it is possible for Indian users to create and consume content in their local language and there is a remarkable rise in content in local languages. Many multi-national companies are also investing in research and resource development for local languages (AL-Husan et al., 2021). The Indian government is also promoting the study and work on regional languages. Despite of the available large amount of content and encouragement, there is a lack of resources in Indian languages (Mohanty, 2008). Developing resources for local/regional languages will usher in an era where there will be an economic boost to the Indian economy. Sentiment analysis can turn out to be beneficial to companies who want to improve the quality of their product or service. Analyzing opinions in the native language can be useful for the Indian government in determining whether the public is satisfied with new policies. Applications of sentiment analysis of social media content can further be seen in entertainment, educational fields, stock market, disaster alerts, management etc.. Sentiment analysis is a natural language processing (NLP) technique that involves determining and extracting sentiments expressed in a piece of text. The primary goal is to understand the subjective information conveyed in the text and categorize it as positive and negative (Joshi et al., 2010).

In the relevant literature there are two widely used approaches for sentiment analysis (a) Lexicon-based and (b) Machine learning based. Machine learning based methods require substantial training data that is representative of the specific domain in which they are applied. They might not perform as well in new or specialized domains without retraining. Whereas Lexicon-based methods can be more domain-independent since they use predefined lists of words with associated sentiments. (Taboada et al., 2011). The proposed work emphasis creating lexicons for sentiment analysis within the framework of lexicon-based methods.

A sentiment lexicon is an important resource composed of sentiment words with polarity and sentiment score (sentimental strength) (Cambria et al., 2015; Esuli & Sebastiani, 2007; Thelwall, 2017). Instances for sentiment lexicons are SentiwordNet (Esuli & Sebastiani, 2007), SenticNet (Cambria et al., 2015), Sentistrength (Thelwall, 2017) etc. HindiSentiWordNet (Joshi et al., 2010) is a sentiment lexicon for the Hindi language. The main notion behind this is that the sentiment of a term is not static, as in traditional lexicon-based approaches, but rather depends on the context or domain in which the term is used, i.e., its contextual semantics. Table 1. illustrates five

[1] https://www.statista.com/statistics/718420/internet-user-base-by-language-india/.

Table 1 Sample sentences having words with different polarity in different domains (with transliteration and English translation of each sentence)

	Domain	Sentence	Word with different polarity	Polarity
1	Movie	फिल्म अनावश्यक रूप से लंबी है *philma anāvashyaka rūpa se laṁbī hai* (The film is unnecessarily long)	लंबा *laṁba* (long)	Negative
	Product (Shampoo)	यह शैम्पू लगाने से बाल लंबे हो जाते है *yaha shaimpū lagāne se bāla laṁbe ho jāte hai* (Applying this shampoo makes the hair long.)		Positive
2	Kitchen(Utensils)	इस बर्तन मे तांबे की मिलावट है *isa bartana me tāṁbe kī milāvaṭa hai* (There is a mixture of copper in this vessel)	तांबे *tāṁbe* (copper)	Neutral
	Jewelry	इस हार मे तांबे की मिलावट है *isa hāra me tāṁbe kī milāvaṭa hai* (There is copper adulteration in this necklace)		Negative
3	Restaurant	रेस्टोरेंट का खाना **ठंडा** था *reṣtoreṁṭa kā khānā ṭhaṁḍā thā* (The food at the restaurant was cold.)	ठंडा *ṭhaṁḍā* (cold)	Negative
	Product (Air Conditioner)	एर कंडीशनर अच्छे से **ठंडा** कर रहा है *era kaṁḍīshanara achchhe se ṭhaṁḍā kara rahā hai* (The air conditioner is cooling well.)		Positive
4	Electronics	फोन **आसानी से** चार्ज हो रहा है *phona āsānī se chārja ho rahā hai* (Phone is charging easily)	आसानी से *āsānī se* (easily)	Positive
	Movie	फिल्म मे आगे क्या होगा **आसानी से** अनुमान लगा**ई** जा सकता था *philma me āge kyā hogā āsānī se anumāna lagāī jā sakatā thā* (What will happen next in the film could have been easily predicted.)		Negative
5	Toy	दोनो कंपनी की कारे **एक जेसी** थी *dono kaṁpanī kī kāre eka jesī thī* (The cars of both the companies were the same.)	एक जेसी *eka jesī* (same)	Neutral

Table 1 (continued)

Domain	Sentence	Word with different polarity	Polarity
Vehicle	दोनो कंपनी की कारे **एक जेसी** थी *dono kaṅpanī kī kāre eka jesī thī* (The cars of both the companies were the same.)		Negative

instances where the polarity of words changes according to the domain. First word is "लंबा" (*laṃbā, length*) which has negative polarity in the movie domain but positive polarity in the domain of product, specifically shampoo or hair treatment products. Similarly, the word "तांबे" (*tāṃbe*, *copper*) has neutral polarity in the case of utensils; on the other hand, it has a strongly negative polarity in the domain of jewellery. From Table 1, it is clearly observable that assigning static polarity to words can degrade the performance of lexicon-based sentiment analysis methods.

In this work, we propose a method that creates a domain-specific lexicon for sentiment analysis. In the proposed approach, the polarity of words is updated by adding contextual semantics of words with the domain. In the proposed *DoSLex*, the lexicon is represented in a geometric 2D circle to identify words' polarity and their sentiment score. The circle's centre is the domain name, and all the terms contextually associated with the domain are plotted in different circle quadrants. Words are classified into four categories, namely positive (words in the first quadrant),

very positive (words in the second quadrant), negative (words in the third quadrant), and very negative (words in the fourth quadrant). The radius in the circle is calculated using FastText, MBert and MuRIL embeddings, and the angle is taken from various knowledge bases. To apply and evaluate proposed *DoSLex*, we also proposed a lexicon-based sentiment analysis method.

The main contributions of this article are listed below:

1. In this research work for efficient sentiment analysis, a semantically rich domain-specific lexicon "*DoSLex*" is proposed.
2. This is the first language independent work for sentiment analysis lexicon generation.
3. The proposed lexicon is evaluated for various domains viz. movie, politics, tourism, books, and news and satisfactory results are obtained with 0.837 F-measure. The proposed approach can be applied to any domain to generate domain-specific lexicon.
4. Unlike state of art sentiment lexicons, the proposed lexicon has been made semantically rich using FastText, M-Bert and MuRIL embeddings

The rest of the article organizes as follows. Section 2 describes the existing state of the art for lexicon generation and sentiment classification methods. The proposed lexicon generation and sentiment classification method is presented in Sect. 3. In Sect. 4, this research shows the experimental results and analysis of the proposed approach. Lastly, Sect. 5 concludes the article with the future direction of lexicon generation research.

2 Related work

Today, after the introduction of UTF-8 encoding style, Hindi content on web is increasing very quickly. Now, it has become easy to type in Hindi, with the help of new keyboards and transliteration resources such as Quillpad (VB et al., 2010)

and Google transliteration. Although there is a lot of content available in the Hindi language, yet the amount of research done in the field of sentiment analysis for Hindi is low. This section discusses the existing literature for lexicons available for both generic or domain-specific sentiment analysis developed for the Hindi language. In the literature, there are different methods for lexicon creation such as manual construction, dictionary-based or corpus- based approaches (Taboada et al., 2011). Manual construction involves human experts creating a sentiment lexicon, who assign sentiment labels (positive, negative, neutral) to words or phrases based on their understanding of the language and context. This method is generally less adopted by researchers because it is time-consuming and it's tough to get sufficient experts (Das & Bandyopadhyay, 2010). Dictionary-based methods utilize a pre-existing small set of seed words with assigned sentiment scores. This list is then extended iteratively by using different approaches (Garg, 2020).

Corpus-based methods involve analyzing large collections of texts (corpora) to identify words and their sentiment scores based on the surrounding context. Machine learning techniques may be employed to extract sentiment information (Medhat et al., 2014). Lexicons are required to contain this type of information to get the polarity of words. Hindi has the Hindi Senti-WordNet (HSWN) (Das & Bandyopadhyay, 2010). HSWN was created manually by IIT Bombay and this resource was developed using English SentiWordNet and linking English-Hindi WordNet. Hindi SentiWordNet consists of synsets that are labelled with positive, negative and neutral sentiment scores attached to their senses. HindiSentiWordNet is a base for many other advances in Hindi sentiment analysis. Next authors automatically and semi-automatically generated a sentiment lexicon using SentiWordNet (Joshi et al., 2010). This lexicon was created for Hindi, Bangla and Telugu languages. A lexicon for adjectives and adverbs was developed by Bakliwal et al. (2012) using Hindi WordNet and they named it HSL (Hindi subjectivity lexicon). Authors used Breadth-first search (BFS) and Hindi WordNet to build HSL. A method to increase the coverage of Hindi Senti WordNet by adding more subjective words was proposed by Mittal et al. (2013). This method also handled negation during the sentiment classification task. The experimental dataset is taken from domain movies only. Next, Arora et al. constructed a sentiment lexicon using the graph theory approach (Arora et al., 2012). A graph is created using WordNet, where nodes are the words and edges are the relations, especially synonymy and antonymy between words taken from WordNet (Arora et al., 2012). This work utilized a pre- annotated small seed list in the beginning. Next Sharma et al. (2014) proposed a bootstrap approach to create the Hindi SentiLexicon that covers Nouns, Adjectives, verbs and adverbs. They developed a multi-module, rule-based, sentiment analysis system. To construct the Hindi SentiLexicon, one positive and one negative seed word are selected. For each keyword from the list, all senses are extracted, and if any of these words have an opposite polarity, the sense is discarded; otherwise, it is added to the lexicon with its polarity. A method by Jha et al. (2016) implemented both lexicon-based classification and machine learning techniques on a Hindi movie reviews dataset. Authors extracted only adjectives and used them as

polarity words for classification. They also used negation handling to improve the accuracy of their methodology. In Mishra et al., (2016) Mishra et al. have built a CSPL (context-specific polarity lexicon) resource for hotel and movie domain in Hindi. They also compared it with standard Hindi SentiWordNet and suggested the inclusion of antonyms, larger datasets, and more. Modi et al. proposed a part-of-speech tagging method using a rule-based approach. For known words, authors used corpus matching and for unknown words, grammar rules were used. This work is for the Hindi language (Modi & Nain, 2016). Jha et al. (2018) developed a sentiment-aware dictionary to handle multiple-domain sentiment classification. The proposed dictionary consists of nouns, adverbs, adjectives and verbs and is aimed to classify amazon product reviews. Hussaini et al. (2018) implemented a score-based sentiment analysis technique with word sense disambiguation handling. They considered book reviews for experimentation. An algorithm for lexicon-based SA is proposed by Yakshi Sharma et al. (2015) and applied to Hindi tweets of "JAI HIND" and "World Cup 2015" topics. A subjectivity lexicon named HSAS (Hindi subjectivity analysis system) was proposed by Jha et al. (2015). It investigates two different strategies for building subjectivity lexicons utilising English language resources, as well as their comparative evaluation in executing the task of subjectivity analysis at the sentence level. The first method makes use of the Opinion-Finder subjectivity lexicon in the English language. The second method starts with a small seed word list in Hindi and develops it to create a subjective lexicon. This second method used PMI (Pointwise mutual information) score and thus expanded 60 seed words to around 4500 polarity words. The PMI (Shapiro et al., 2020) score gives the confidence score of how much is a particular word is associated with a sentiment. Garg et al. (2020) utilized lexicon-based method to perform sentiment analysis of the tweets related to the topic "Mann ki Baat by prime minister Mr. Narendra Modi". Authors used a generic Hindi SentiWordNet lexicon in this approach. Rich Sharma et al. (2014) created a sentiment-oriented system for movie reviews in the Hindi language, they also handled negation in text and achieved 65% accuracy. Authors also compared machine learning and domain-specific-lexicon approach for sentiment analysis (Gupta et al., 2021). Table 2 compares various research works on lexicon-based sentiment analysis and sentiment lexicon generation. The table explains the purpose of the work, the language, the domain used and the accuracy obtained. The accuracy mentioned in fifth column of Table 2 has been taken from the experimentation section of associated research papers.

3 Proposed methodology for generation of *DoSLex* and lexicon-based sentiment analysis

This section introduces the framework for the generation of the domain-specific sentiment lexicon "*DoSLex*". The same steps can be applied to any language for lexicon generation. *DoSLex* aims to represent word sentiment polarity (positive, very positive, negative and very negative) with its associated sentiment score using contextual

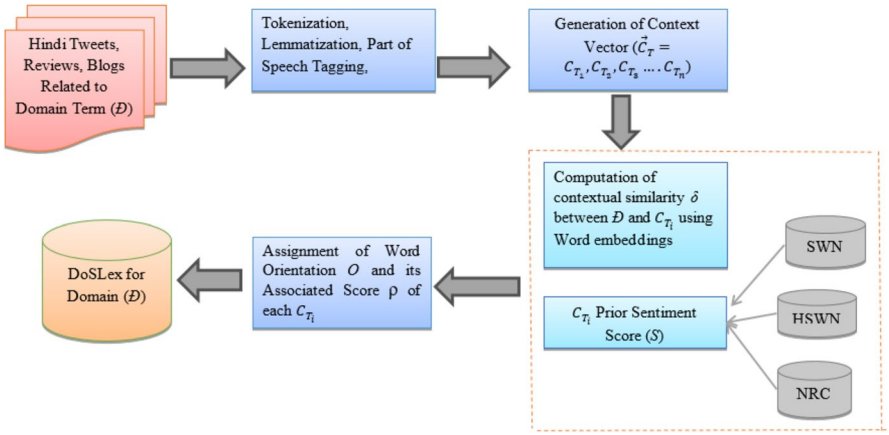

Fig. 1 Overall Framework for Hindi *DoSLex* Generation

semantic analysis and word embeddings. After the *DoSLex* generation, a lexicon-based sentiment analysis was conducted to evaluate the lexicon's performance. This lexicon generation framework considers the six main steps that are shown in Fig. 1. For the better understanding and ease of explanation of the proposed methodology, the illustrations are given for Hindi language.

3.1 Data collection and pre-processing

The proposed approach for lexicon building can be applied to any domain but in this paper to make it feasible, we have selected five Hindi domains, one Tamil and one Bangla namely movie, restaurant, politics, books and tourism, Tamil movie and Bangla news. Sentences related to these domains are extracted from various sources including Twitter,[2] News websites,[3,4,5,6] IIT Bombay site. After extraction, the first pre-processing step is the lemmatization and tag extraction of data according to suitable part of speech. For lemmatization, we have used pyspark from John snow labs[7] and for part of speech tagging NLTK POS tagger is used.

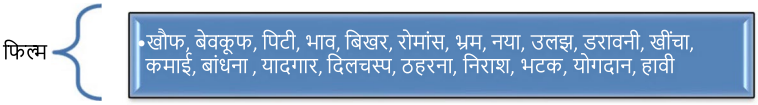
Algorithm 1 Domain Specific Lexicon (*DoSLex*) Generation

Input: Dataset related to domain ($Đ$) from various sources for language L
Output: Domain-Specific Lexicon *DoSLex* comprising polarity and sentiment score for each word. (classification of words in four polarity: positive, Very positive, Negative and Very Negative)
Initialize POS^{+} List, $VPOS^{++}$ List, NEG^{-} List, $VNEG^{--}$ List to empty
for each sentence in dataset
Perform Lemmatization and Tokenization
for each token do
Part-of-Speech tagging (POS)
if POS= nouns||adjectives|| adverbs || verbs || Unknown then
Add token in to context vector $\overrightarrow{(C_T} = C_{T_1}, C_{T_2}, C_{T_3} \ldots . C_{T_n})$
for each context term $C_{T_i} \in \vec{C}_T$
Calculate $\delta\,(Đ, C_{T_i})$ // δ is semantic relation between domain term and context term
Calculate $S(C_{T_i})$ // S is prior sentiment of context term
Plot in 2D circle
$A_i = \delta\,(Đ, C_{T_i})$ // radius $0 \leq A_i \leq 1$
$\emptyset_i = S(C_{T_i}) * \pi$ //angle
Coordinates for each context term
$X_i = A_i \sin \emptyset_i$ // polarity score of context term
$Y_i = A_i \cos \emptyset_i$ // polarity of context term
if (X_i, Y_i) lies in first quadrant
Add C_{T_i} in POS^{+} List
Elseif (X_i, Y_i) lies in Second quadrant
Add C_{T_i} in $VPOS^{++}$ List
Elseif (X_i, Y_i) lies in Third quadrant
Add C_{T_i} in $VNeg^{--}$List
Elseif (X_i, Y_i) lies in Fourth quadrant
Add C_{T_i} in Neg^{-} List
Return *DoSLex*, POS^{+} List, $VPOS^{++}$ List, NEG^{-} List, $VNEG^{--}$ List

3.2 Generation of context vector ($\vec{C}_T$)

A context vector is denoted as $(\vec{C}_T = C_{T_1}, C_{T_2}, C_{T_3} \ldots C_{T_n})$ where, $C_{T_i} \in \vec{C}_T$ and C_{T_i} denotes a context term. Context terms are words, related to the domain $Đ$ whose polarity we are going to assign using proposed approach. This work considers all terms that occur in the same context to generate a lexicon for each domain $Đ$. Let's say if domain $Đ$ is "फिल्म" (*Filma, Movie*), then all the sentences related to the domain are extracted from different platforms (in the previous step). This implies that acontext vector comprises contextual terms of domain. For domain "फिल्म" (*Filma, Movie*) a sample context vector is shown in following figure.



3.3 Computation of semantic relation (δ) between $Đ$ and C_{T_i} using word embeddings

To compute semantic relation (**δ**) between domain $Đ$ and *CTi*, we have utilized the word embedding method. A word embedding is a term used for the vector representation of words and phrases with similar words and phrases having similar word representation in a predefined vector space (Gaikwad & Haribhakta, 2020). FastText is one of the effective word embeddings for the Hindi language (Kumar et al., 2020). FastText is an open-source, free, lightweight library that allows users to learn text representations and text classifiers. FastText (essentially an extension of the word2vec model) treats each word as if it is composed of character n-grams. That means that the vector for a word is made up of the sum of its character n-grams. For the work discussed here, we initially applied FastText embeddings. However, since the results were not satisfying, we shifted to M-Bert (Multilingual BERT) and then finally to the latest embedding method for Indian languages MuRIL (Multilingual Representations for Indian Languages) (For results, please refer to Sect. 4.2). Multilingual Bidirectional Encoder Representations from Transformers (M-Bert) is a pre-trained language model developed using the 104-language Wikipedia corpus (Pathak et al., 2021). The main accomplishment of this model is its ability to transfer across languages with different vocabularies, such as English and Devanagari Hindi, even though it was trained on distinct 104 monolingual corpora beforehand. Additionally, empirical evidence suggests that M-Bert is able to detect semantic relationships between words. Another model built on Bert that is pre-trained in Indian languages is MuRIL (Khanuja et al., 2103). It is a recently released BERT model that has been pre-trained on 17 Indian languages, including Hindi and English, as well as their transliterated equivalents. It is a modified version of M-Bert for Indian languages with limited resources because pairs of translated and transliterated texts have been used for its training.

3.4 Prior generic sentiment score (*S*)

In this step, each context word $C_{T_i} \in \overrightarrow{C}_T$ is assigned an initial score from external sentiment lexicons. Here sentiment scores for each Hindi context word are taken from the Hindi SentiWordNet lexicon (Joshi et al., 2010), NRC-Emotion lexicon (Bose et al., 2019; Mohammad & Turney, 2013) and English SentiWordNet. For a maximum coverage of words, more than one lexicon has been considered. The words that were not listed the Hindi Senti WordNet and NRC emotion lexicon were translated to English and checked in the English Senti WordNet. For Bangla and Tamil languages, Bengali SentiWordNet and Tamil SentiWordNet are utilized.

3.5 Computation of word orientation *O* and its associated sentiment score ρ of each C_{T_i}

Each domain $Đ$ and its context term $C_{T_i} \in \overrightarrow{C}_T$ are represented in a geometric 2D circle. This circular representation is beneficial as it allows us to use trigonometric

identities to estimate the sentiment orientation and strength of the various context terms. *DoSLex* is based on contextual semantic relations within a domain *Đ*. In this geometric circle, domain *Đ* is the centre of the circle and the terms in domain *Đ* are points found around it. The position of a context term C_{T_i} is defined jointly using word embeddings and prior sentiment scores. Mathematically, a 2D circle polar coordinate system is represented with the following equation:

$$\mathrm{A}^2 - 2\mathrm{A}\mathrm{A}_0 \cos(\emptyset - \theta) + \mathrm{A}_0^2 = \mathrm{R}^2 \tag{1}$$

where *R* denotes the radius of the circle, the polar coordinate of a domain term *Đ* that situated in centre of the circle as (A_0, θ) and the polar coordinate of a context term C_{T_i} as (A, $\varnothing$). This study considers context wordC_{T_i}, radius A_i, angle $\varnothing_i$ to build *DoSLex* of *Đ*, Prior of sentiment score *S* and word embedding semantic relationship score δ (Arora et al., 2012) of word C_{T_i}. The Eqs. (2) and (3) help build the 2D circle for *DoSLex*.

$$\mathrm{A}_i = \delta(Đ, C_{T_i}) \tag{2}$$

$$\emptyset_i = S(C_{T_i}) * \pi \tag{3}$$

The radius of all terms in a 2D circle is considered a scale between 0 and 1, and the circle's radius R is 1. All angle values are computed in radians.

3.6 Generation of *DoSLex*

DoSLex uses the Cartesian coordinate system from the polar coordinate system by applying the sineand cosine trigonometric functions to compute the coordinates of term C_{T_i}.

$$X_\mathrm{i} = \mathrm{A}_i \sin\emptyset_i$$

$$\mathrm{Y}_\mathrm{i} = \mathrm{A}_i \cos\emptyset_i$$

The Y-axis of the Cartesian coordinate system denotes sentiment orientation (positive, very positive, negative and very negative) of term C_{T_i} and the X-axis denotes the degree (score) of the C_{T_i} term in the context of the domain. A positive Y value stands for positive sentiments and negative Y value for negative sentiments. A small X value denotes strong sentiment as shown in Fig. 2.

Figure 3 represents a sample 2D circle representation of *DoSLex* of domain movie, tourism, books and news for the Hindi language. Translation and Transliterations of each illustration are provided in Appendix 1. In this figure, terms present in the first and second quadrant are positive terms with respect to domain and terms in the third and fourth quadrant are negative terms. This domain-specific lexicon is a very significant resource for research in sentiment analysis. It provides context words strongly related to the domain with polarity and ignores context words that

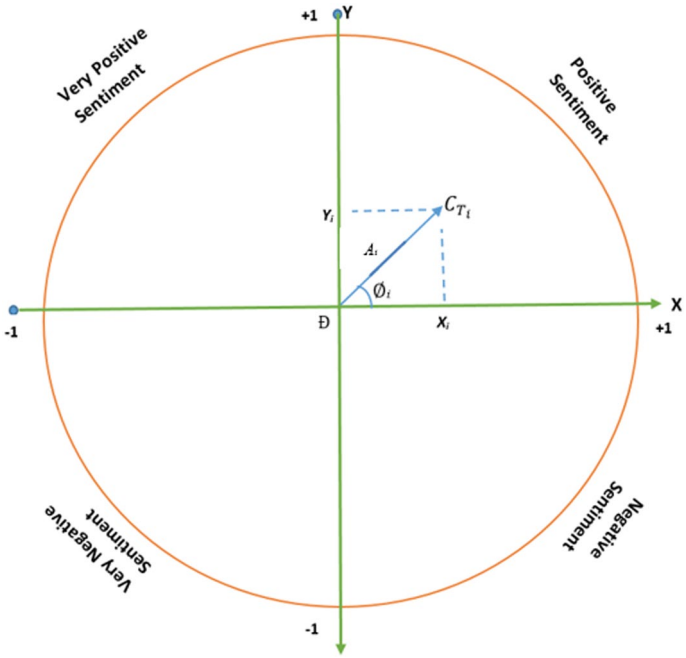


Fig. 2. 2D circle representation for *DoSLex* with Four Polarity quadrants

contribute low polarity scores in the particular domain. In Fig. 3, the 2D circles for "किताब" (Kitāba, book) and "समाचार" (samāchāra, news) share the term "शांति" (Shāanti, Peace) but with varying polarities. In the 2D circle for "किताब" (Kitāba, book), "शांति" (Shāanti, Peace) has a positive polarity, while in the circle for "समाचार" (samāchāra, news), it has a very positive polarity. Number of homonyms or the terms having different polarities in dataset is approx. three hundred forty-five terms.

3.7 Lexicon-based sentiment analysis using *DoSLex*

In this section, we discussed a methodology for lexicon-based sentiment analysis using *DoSLex* for Hindi language. Figure 4. presents the overall workflow diagram for the sentiment analysis task. Regarding the computation of sentiment score, the first step is to pre-process the extracted text T. Input text can be taken from any source such as reviews, tweets etc. Pre-processing includes removal of URLs, abbreviations, punctuations and symbols. Next step is the identification of the domain using topic modeling LDA (Latent Dirichlet Algorithm) (Jelodar et al., 2019). LDA is a generative probabilistic model used for topic modeling (Jelodar et al., 2019). LDA is an unsupervised learning algorithm, it doesn't require labeled training data and it can be applied to a variety of textual data, such as articles, books, or social media posts (Jelodar et al., 2019). The identified domain is then searched in

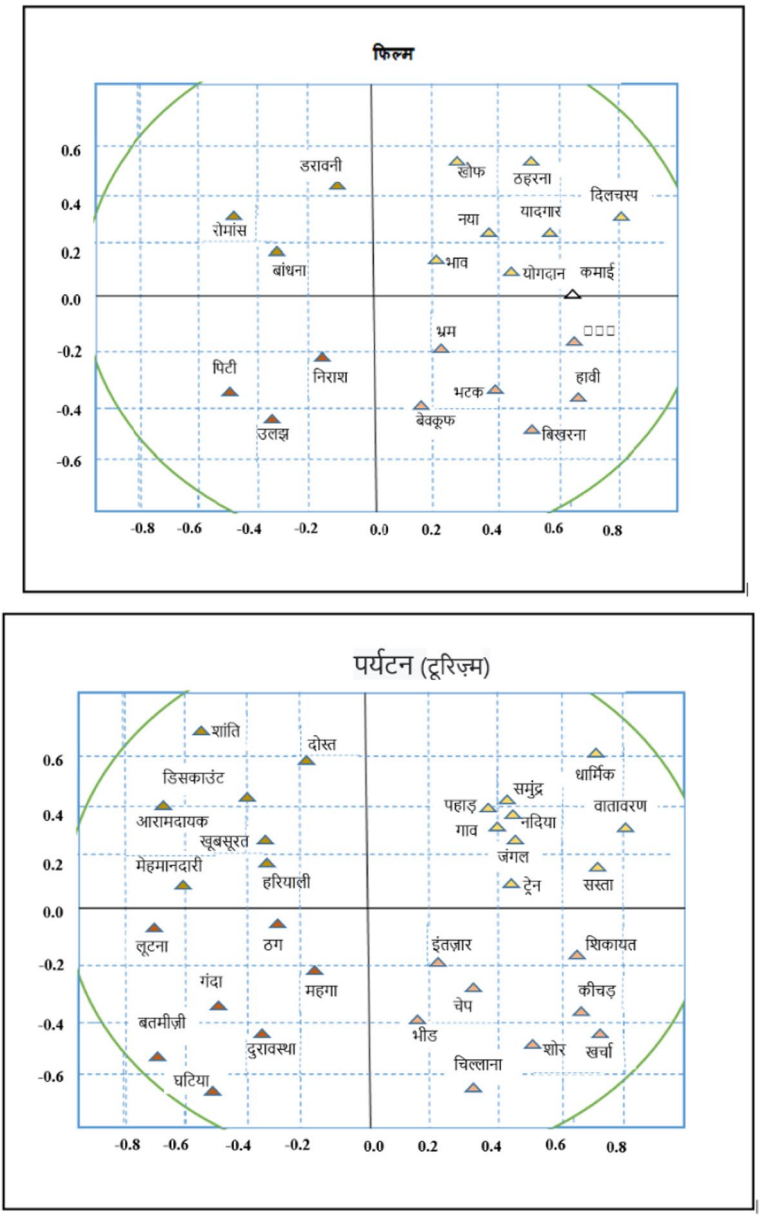

Fig. 3 *DoSLex* 2D circle representation for domains फिल्म (movie), पर्यटन (Tourism), किताब (book) and समाचार (news) in Hindi

to proposed list of lexicons (for instance in this proposed we have created lexicons for movies, tourism, news, politics, books domain). In case of non-availability of domain, system checks it's synonym in *DoSLex*. And if neither a synonymy is available, then algorithm 1 is applied to generate the required lexicon. After getting the

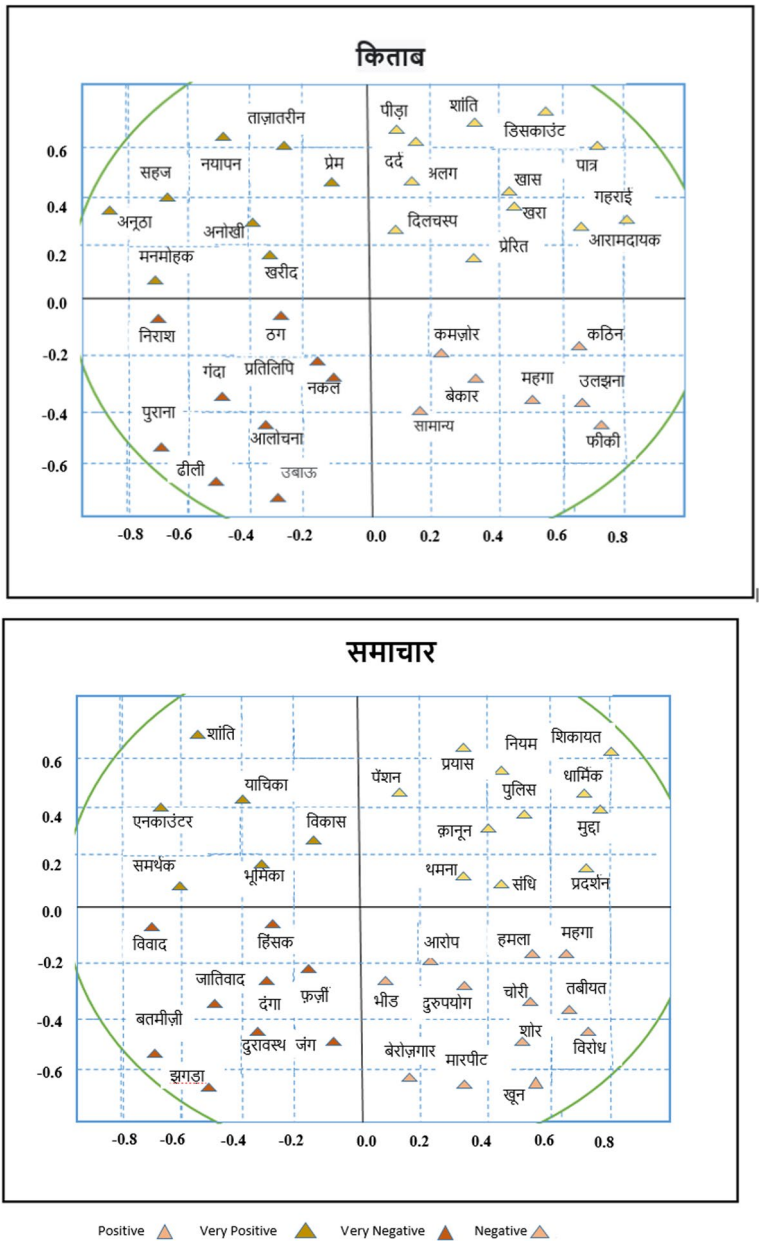

Fig. 3 (continued)

relevant domain specific lexicon,the text is split to sentences ($T = S_1, S_2, S_3, \ldots S_p$) where T is the text and $S_i \epsilon T$ is the sentence of text. Each sentence is then tokenized and each token tagged according to appropriate part of speech. For each noun,

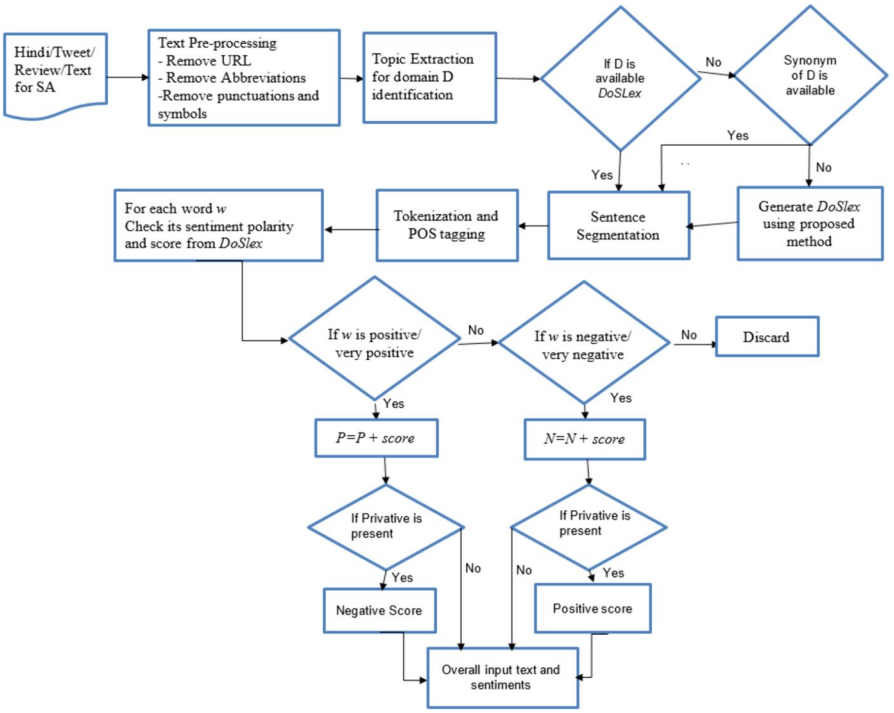

Fig. 4 Overall flowchart for lexicon-based sentiment analyses approach using *DoSLex*

adverb, adjective and verbs tag we check the sentiment polarity and strength in *DoSLex*. So now, there are two categories of sentiment score: one is positive and other is negative. In case negation/privative is present in the sentence, its polarity will be reversed. This step normalizes the impact of negations in a sentence. For example, in the sentence "I am not satisfied with the product," the presence of "not" (negation) alters the polarity of the sentence from positive to negative. In last step all the sentiment scores are aggregated and an overall positive score/negative score of sentence is obtained.

4 Experimental results and discussion

This section the efficiency of the proposed method is tested with several experiments. To this end, evaluation matrices, datasets description and experiment details with results are presented and discussed. This research utilizes Quad core Intel Core i7 Skylake system with16GB of RAM. The model is implemented in Keras and TensorFlow (TensorFlow 2018).

4.1 Dataset description and evaluation matrices

Obtaining annotated datasets for low-resource languages is a challenging task. Although the proposed approach can be applied to any language, yet for ease and understandability, three Indian languages Hindi, Tamil and Bangla are used. This section discusses the dataset for Hindi, Bangla and Tamil languages. Hindi Dataset by IIT Bombay: Annotated dataset for domain tourism and movie in Hindi language is taken from IIT B site. The movie domain consists of 252 positive and negative labelled reviews (Joshi et al., 2010). The tourism domain has 200 positive and negative reviews (Balamurali et al., 2012).

Twitter Dataset: The dataset for evolution of proposed methodology has been fetched from twitter using the tweepy API. The 2467 tweets have been extracted for "राजनीति" (politics) domain from twitter by selecting language Hindi in the search filter. Out of these tweets, we removed tweets with English words written in Hindi, non-Hindi tweets and tweets without subjectivity. Tweets without subjectivity in annotation are tweets presenting factual information without expressing personal feelings or opinions. They are typically neutral and do not convey sentiment.

Example: "The smartphone has a 6-inch display and a 12-megapixel camera." The proposed work is handling positive/very positive, negative/very negative sentiments After elimination 1534 subjective tweets were left. These tweets were given to three annotators for manual labelling. The annotators were graduate students and native speakers of Hindi language. They have been asked to label each tweet with the lables "positive" or "negative" according to their understanding. Now, different annotators may have different perceptions of meaning convey through context.

Cohen's Kappa was used to measure inter-annotator agreement. This is a statistical measure used to assess the inter-annotator agreement or reliability between two or more annotators when labelling categorical items. It accounts for the agreement occurring by chance. This measure is widely used in various fields, including natural language processing (NLP), to measure agreement on categorical annotations.

Disagreement Handling: In case of disagreement, the examples at stake were excluded from the corpus.

We also used Gwet's AC1 which is designed to address limitations of Cohen's Kappa.

Finally, a dataset of 1534 tweets belonging to domain "politics" were extracted; of them 654 tweets were assigned the label "positive" and 880 the label "negative".

Amazon Product review dataset: It is a benchmark dataset which is widely used for sentiment analysis task. All the reviews are collected from amazon.com. There are 1000 positive and 1000 negative reviews for each product. We collected for domain "किताब" (*Kitabh*, books) and translated them using Google translator.

News Comment Dataset for Bangla: This dataset is collected from two popular Bangla newspapers, BBC Bangla and Prothom Alo. It contains 5205 positive comments and 5600 negative tagged comments (Taher et al., 2018).

Tamil Movie Reviews: This dataset consists of 200 positive and 200 negative comments reviews from Movie dataset (Film: Baahubali) (Sivasankar et al., 2021b). Table 3 shows a detailed description of annotated dataset of all domains.

Table 3 Annotated Dataset Description

Language	Domain	Positive Annotated dataset	Negative Annotated dataset
Hindi	Books	1000 Reviews	1000 Reviews
	Movies	127 Reviews	125 Reviews
	Tourism	100 Reviews	100 Reviews
	politics	654 Tweets	880 Tweets
Bangla	News	5205 Comments	5600 Comments
Tamil	Movie	200 Reviews	200 Reviews

The evaluation matrices considered in this research are precision (P_R), recall (R_E) and F-measure score (F_M). These matrices will assess the performance of the proposed Domain-Specific lexicon. The P_R is the fraction of correctly classified sentences of a sentiment (Positive or negative) among number of sentences classified by the relevant sentiment. The R_E is fraction of correctly classified sentence count among the total number of sentences of that sentiment. The R_E and P_R helps to understand the degree of relevance. The F score is the harmonic mean of the P_R and R_E.

4.2 Results analysis of the proposed *DoSLex* on various datasets

This section describes in detail the experimental results that will help to comprehend how the proposed Domain-Specific lexicon performed well in sentiment classification tasks. For evaluation, the lexicon-based approach discussed in Sect. 3.7 has been applied to different domains. We conducted experiments using HSWN, followed by NRC, SWN, and *DosLex*, as outlined in Table 4. The performance of *DosLex* on the dataset is notably superior because these lexicons offer generic polarity for each term without considering the specific domain in which the term appears. For example, the word 'long' has a generic positive polarity in SentiWordNet, but *DosLex*, provides polarity scores based on the domain context (negative in the case of a movie like 'long movie' and positive in the case of a product like 'long hair' shampoo). In many instances, HSWN, NRC, and SWN yield inaccurate results. We compute the performance of *DoSLex* with different sources of prior sentiment knowledge bases. First is *DoSLex* with HSWN only. Second is *DoSLex* with HSWN + NRC and the last one is *DoSLex* with HSWN + NRC + ESWN. Table 5 presents the evaluation of all the cases. It can be noticed from the table that *DoSLex* with HSWN achieves maximum F-measure of only 0.306 in domain of Hindi movies. The performance of *DoSLex* with HSWN is very low due to narrow coverage of polarity words in Hindi SentiWordNet related to the domain HSWN has very limited polarity words in the lexicon. Out of this polarity some words are wrongly labelled for example word "हिंसा" (*hinsa,* Violence) is marked with neutral polarity instead of negative polarity. However, *DoSLex* with HSWN + NRC gives maximum F-measure of 0.542 due to increase in polarity word coverage and reconsideration of neutral words. Out of these three cases, *DoSLex* with HSWN + NRC + ESWN (FastText)

Table 4 Performance evaluation results of proposed *DoSLex* with different existing sentiment bases

Dataset	Domain	HSWN			NRC			SWN			Proposed lexicon		
		P_R	R_E	F_M	P_R	R_E	F_M	P_R	R_E	F_M	P_R	R_E	F_M

achieves a better F-measure of maximum 0.683 in domain movie. This performance depends on prior sentiment values and can be improved further with a more accurate and large size of sentiment lexicon. The proposed approach is also reliant on the performance of word embeddings including FastText. M-Bert and MuRIL. Tables 5, 6 and 7 provides the results of all combinations with three word embeddings. Figure 5 represents the f-measure comparison of FastText, M-Bert and MuRIL embeddings on different domain datasets. Figures shows M-Bert performs better than FastText because in FastText each word has fixed representation regardless of context and M-Bert is a contextual based word embedding. MuRIL performs best out of

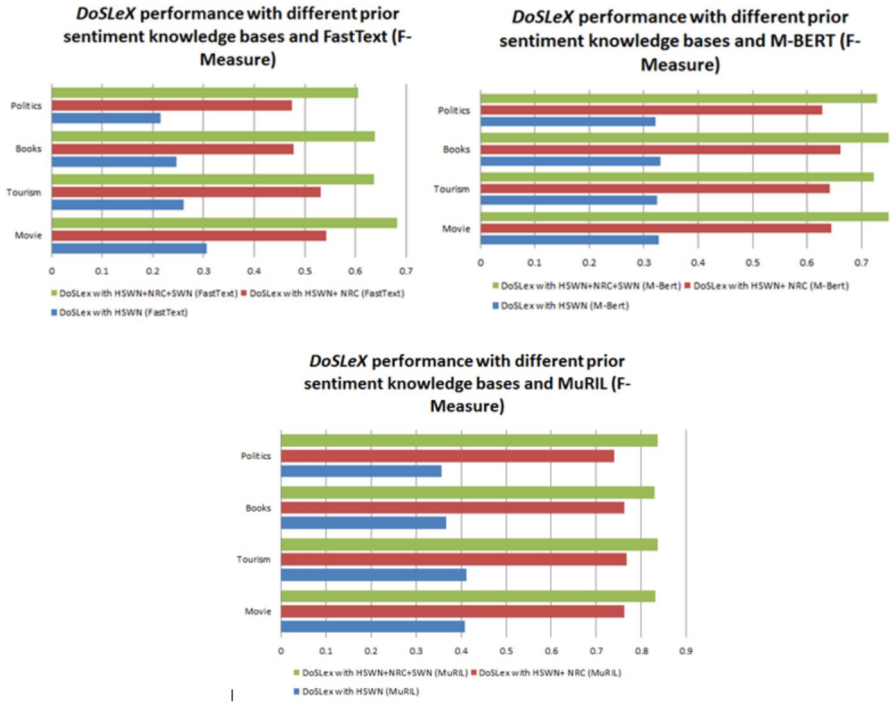

Fig. 5 Graphical representation for the performance of *DoSLex* with different prior sentiment knowledge bases and embeddings (F-measure)

Table 8 Performance evaluation of *DoSLex* for Bangla and Tamil low-resource languages

Domain and Language	Model Combinations	P_R	R_E	F_M
Bangla News	*DoSLex* + BSWN + FastText	0.323	0.337	0.329
	DoSLex + BSWN + M-Bert	0.572	0.563	0.567
	DoSLex + BSWN + MuRIL	0.685	0.677	0.680
Tamil Movie	*DoSLex* + TSWN + FastText	0.381	0.372	0.376
	DoSLex + TSWN + M-Bert	0.591	0.601	0.595
	DoSLex + TSWN + MuRIL	0.721	0.703	0.711

these three embedding techniques. MuRIL has similar training strategy as M-Bert with few modifications Maximum F-measure is 0.837 given by *DoSLex* + HSWN + NRC + SWN with MuRIL embedding. Tables 5, 6 and 7 show the result for Hindi language.

Next experiments are done for Bangla and Tamil languages for news and movie domain. Table 8 shows results with different combinations. For Bangla news domain *DoSLex* + BSWN + MuRIL combination provided best performance with 0.68 F-measure. And for Tamil movie domain *DoSLex* + TSWN + MuRIL gives best

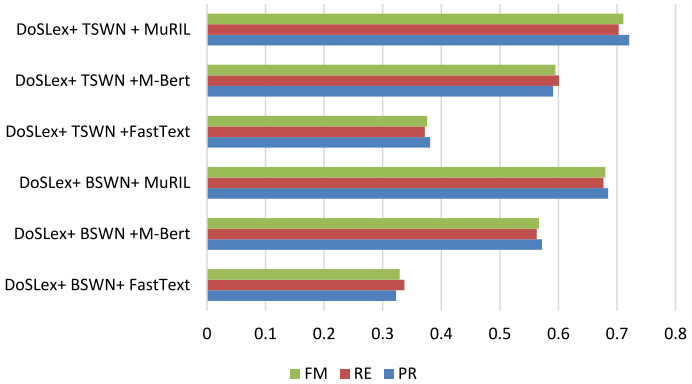

Fig. 6 Graphical representation for performance of DoSLex for Bangla and Tamil language

Table 9 Performance evaluation results of proposed *DoSLex* with Indic_SWN on various datasets

Dataset	Domain	*DoSLex* (Proposed)			Indic_SWN (HSWN, BSWN, TSWN)		
		P_R	R_E	F_M	P_R	R_E	F_M
IIT B	Movie	0.829	0.836	0.832	0.160	0.181	0.169
	Tourisms	0.833	0.843	0.837	0.158	0.140	0.149
Amazon	Books	0.824	0.835	0.829	0.176	0.174	0.175
Twitter	Politics	0.842	0.831	0.836	0.147	0.125	0.135
	Bangla News	0.685	0.677	0.680	0.120	0.131	0.125
	Tamil Movie	0.721	0.703	0.711	0.061	0.134	0.083

results of 0.711 f-measure. BSWN and TSWN are Bangla SentiWordNet and Tamil SentiWordNet respectively. The results are shown in graphs in Fig. 6. The standard/classic Indic_sentiwordNet (SentiWordNets for Indian languages such as Hindi, Bangla, Tamil) are compared with proposed *DoSLex*. The comparison with existing popular generic-lexicons is performed on different domains to show the performance of proposed *DoSLex* over existing lexicons. For experimentation, same sentiment classification method explained in Sect. 3.7 is applied to all datasets. Table 9 and Fig. 7. shows the evaluation results and from the table it can be noticed that proposed *DoSLex* performs much better with maximum F-measure of 0.837, 0.680, 0.711 in Hindi, Bangla and Tamil languages respectively. The major reason of very low performance of generic lexicons is non consideration of topic or domain of the text. For instance, "small" is assigned negative in SentiWordNet but it is positive in many domains such as mobile "small and handy". Moreover, the proposed lexicon is extendable to any number of polarity words depending on prior knowledge and word similarity and *DoSLex* is language independent. *DoSLex* is also fully scalable and adaptable to any domain. Figures 5, 6 and 7 show the graphical representation of whole experimental results. Indic_SWNs, encompassing Hindi WordNet, Bangla WordNet, and Tamil WordNet, cannot be deemed reliable due to a notably low

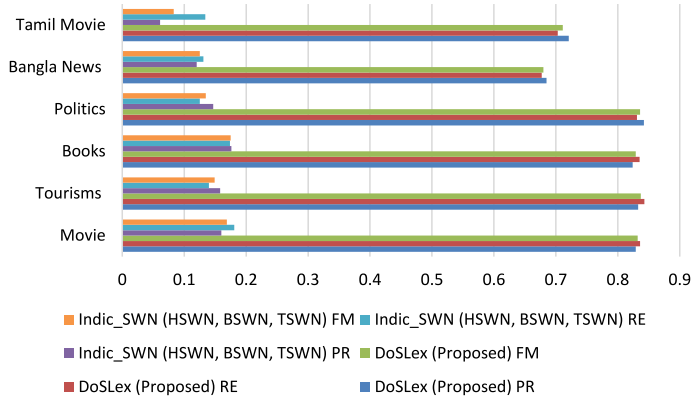

Fig. 7 Graphical representation for comparative results of proposed *DoSLex* with indic_sentiwordnets on various datasets

F-measure, falling below 0.2. However, the proposed lexicon, when amalgamated with these Indic_SWNs, yields satisfactory results with an F-measure of 0.83.

5 Conclusion and future work

In this paper, the authors describe the lexical resource *DoSLex which is* a domain-specific sentiment lexicon. The methodology leverages domain-related corpora, word embeddings and prior sentiment knowledge bases. In this work, it has been found that representing lexicons in the 2D geometric circle is helpful as it allows to use trigonometric formulas to calculate sentiment orientation and strength of words in a given context. The proposed method is applied to three low-resource languages Hindi, Bangla and Tamil and can be applied on any other languages such as Sanskrit, Marathi etc. It can also be extended effortlessly to any number of domains. The experimentation section revealed that the proposed method performs well in different domains (Movie, Books, Politics, Tourism, Tamil movie, Bangla News). The method is validated for three languages and it is found that *DoSLex* performs much better than traditional generic sentiment lexicons. A key advantage of the proposed method is its language independence, making it applicable for generating lexicons in any domain. Following the similar approach, lexicons can also be generated for agriculture, healthcare incorporating depression detection, hate speech detection, pandemic support, pharmacy, disease detection & treatment, and vaccine performance evaluation, which do not exist right now. It would be interesting to see the implementation and performance of *DoSLex* for lexicon generation in these specific areas. In the future, it would be interesting to work on lexicon generation for low-resource code mixed languages such as Hindi-English, Punjabi-English etc. One drawback of the proposed approach is that it doesn't account for the influence of modifiers and adjectives on the polarity of a term. An interesting future research direction may be the investigation of modifiers. adjectives, slang terms, metaphors and sarcasm in the

text to assign word polarity more accurately. Handling word sense disambiguation in languages is another area that can be done in future for better performance.

Abstract :

Vidyapati (1360-1470 AD) is considered as one of the greatest writers of Mithilanchal, Bihar. He composed songs in such a manner that they became enshrined in the hearts of the natives of Mithila region. He wrote in Sanskrit and Maithili. Still, many of his Maithili songs are sung as folksongs. The present study revealed that his Maithili songs are abundant with the description of the ecological elements. His style contains the aura of the deities through the establishment of their relation with the environment. In his songs, both Gods and human beings are affected by nature. The physical environment acts as a stimulus to their behaviour. The relationship between the compositions of Vidyapati and the environment has been analysed with an ecocritical perspective in this research.

Keywords :

Ecocriticism, Maithili, Environment, Folksongs, Mithila

Introduction :

Vidyapati (1380-1460 AD) was born into an affluent and intellectual family. Also called as *Maithil Kokil* (The cuckoo bird of Mithila), his creative abode is highly related to the folk life of Mithila. The writer created several Maithili compositions, including devotional songs on Hindu deities like Vishnu and Shiva. The simple fact that Shiva is the sole Hindu god whose love and worship have endured over time is why he created so many songs dedicated to him. They have been approved by the straits for any man and woman, regardless of caste or gender. Music dedicated to Shiva were the only devotional songs that could connect with ordinary men and women, regardless of caste or sex, for whom Vidypati penned the songs. *Kirtipataka, Purusparikshа*, *Goraksavijaya* and *Bhuparikrama* are some of his compositions. His compositions were an amalgamation of folk life and Hindu mythology. Maithili folksongs are often not anonymous. Vidyapati composed Maithili songs that are still sung as folksongs. Most commonly, the last line of the lyrics mentions the name of its composer too. Maithili folksongs are abundant with the mention of ecological elements. Vidyapati

(1350-1450) composed songs enriched with the inclusion of flora and fauna of Bihar. According to Pankaj Jha (2018) Vidyapati has been interestingly memorialised and mythologized throughout the course of the previous six centuries or more. His followers believe that he has received supernatural favours and worked miracles in ways that would be outside the scope of a "rational" approach that is fact-focused. The most widely accepted mythology among them states that Lord Œiva was so inspired by the poet's piety that he assumed the identity of a poor man and called himself Ugna in order to serve as the poet's personal attendant. This "episode" in Vidyapati's life is recounted in almost every one of his numerous biographies. Any discussion about him with a Maithil, the author claims, must mention the story.

Discussion :

The anthology *Vidyapati Rachnavali* by Dubey (1981) contains various verses of the Maithili poet Vidyapati. Dubey has categorized these in six categories. The categories are *upeksha geet* (songs of hope), *milan-gopan geet* (songs of love), *har gouri geet* (songs of Shiva and Gouri), *vandana geet* (Songs of devotion), *ritu geet* (Seasonal songs) and *samanya geet* (simple songs). These songs reflect on the cultural, environmental, philosophical and sociological aspects of the people who are singing and their surroundings. In 1971, Ramanath Jha wrote about Maithili:

> The State of Maithili publications in 1970 was as depressing as during the previous years. There has been no change in the apathetic attitude of the Government of Bihar towards Maithili but much more depressing is the apathy of the people speaking the language. Even the educated among the speakers of this language do not purchase Maithili books and Maithili publication, therefore, is commercially a losing concern (Ramanath Jha, 1971, p. 86).

Those were the times when the folk languages started depleting. Though the Indian government takes several initiatives in contemporary times to save the folk languages, but their extinction seems inevitable. The eminence of this language before could be seen in the writings of Vidyapati. According to Mishra (1966), his songs are embodied with a touch of Mithila folk life. He further comments :

Armed with a thorough knowledge of Sanskrit poetics, he does not hesitate to bring together the sacred Shastras and the profane elements of the Maithili folklore, like the myth of the twin rivers Ganges and Jamuna. Some Folk-songs of Mithila can be easily traced in the Pada vali: The lonely, melancholy girl, separated from her lover, pleads with the Kokila bird :

'The moon spits fire,

lotuses droop and loaded with fragrance mingle in sad love.

Kokila, bird of spring, why do you torture me?

Why do you sing your love-provoking song?' (Mishra, 1966, p.136)

This song of Vidyapati, quoted by Mishra, is full of nature imagery. The inclusion of words such as "lotuses," "*kokila,*" and "spring" all coalesce together to offer the readers synaesthesia.

In one of the compositions, Vidyapati depicts the pang of a wife whose husband has gone to another region:

Mor Piya sakhi gel door des
Jouvan daye gel saal sanes
Maas asadh unat nav megh

(Vidyapati, 2018, p. 271)

O friend, my husband has gone to a distant land

My youth has given me a message this year

The season is rainy, and new year's heavy rain is there.

The ongoing of season has been equated with the conditions of the woman who is full of sorrow as her husband is not with her. Heavy rain is symbolic of the tears that the woman is shedding. This description points to the innate nature of human beings to see their psyche in the various happenings of their natural environment.

Vidyapati applies vivid imagery in a consistent manner. There are several instances in the creative expression of Vidyapati that hint at the essence of nature and glorify the ecosystem along with its flora and fauna. One of the folksong runs as follows:

Lata taruvar mandap dia, nirmal sasdhar bhiti dhablih

Parun naaal aipan bhal bhel, raat Pallav nav pahiran del

Gabah mai he mangal aaye, basant-bibah kanan thali jaye

Madhukar-ramani mangal gab, dujbar kokil mantra padhab

Karu makrand hathodal neer, bidhu bariyati dheer Sameer

Kanau keaasuti toran tool, lava bithrak belik fool

Kesu kusum karu siddur daan, joutuk paol maanini maan

*(*Vidyapati, 2018, p.176)

The tree embellished with climbers got venerated for the wedding, the pious moon cleaned its walls.

The lotus lot added to the beauty, the new tender leaves clothed the night

O maids, sing an auspicious song together, and witness the wedding of Spring

Bumblebee sings joyful song, the brahmin birds are making the cuckoo recite mantras.

The male voice acted as promising pious water, slow wind turned groom's side group

Plumeria and banana turned decorative strings; the scattered jasmine flowers became auspicious grains

Flame of the forest put vermillion, and the groom acquired respect as brides' gift.

There is a recurrent inclusion of the seasonal changes of nature in the compositions of Vidyapati. In these texts, the reflection of the seasons includes a plethora of personification and symbolism. One of his texts read as following:

Magh maas siri Panchami ganjaili, navam maaa pancham haruaai hey

Ati ghan peera dukh bar paaol, banaspati bheli dhai hey

Subh khan bera sukul pakkh hey, Dinkar udit samai he

Sorah sampun batis lakhne sah, janam lel riturai hey

Nachaye jubitjana harkhit man, janmal baal madhai hey

Madhur maharas mangal gaabaye, manini maan urai hey

Bah malyanil ot uchit hey, nav ghan bhau ujiaara

(Vidyapati, 2018, p.172)

(The weather is again about to beget a son, those nine months were painful

She was full of sadness, so all the herbs came together like her midwife

In pious timing, spring was born, complete with abundant virtues

On this occasion of baby spring's birth, all young ladies danced

Egoistic women shed their egos and started singing

The Malaya Mountain breeze touched the baby by bringing rain

The spring flowers were mesmerising, so they were used in making a cradle)

This folk utterance of Vidyapati is connotative of the effects that nature has on its inhabitants. When the poet says that all women had an impact of Spring on them, it exhibits the effect that nature could have on our minds. In the past, several established authors such as William Wordsworth, John Keats, Percy Bysshe Shelley, and Henry David Thoreau have asserted the force that nature has on driving our emotions. Pankaj Jha puts forth :

> A literary device that helped Vidyapati accomplish this was the tradition of 'subhāsita' in Sanskrit literature. In fact, the whole text of Purucaparīksā, and occasionally even Likhanāvalī, is liberally sprinkled with independent couplets of (un) identifiable origin. These were drawn from the free-floating reserve of an ever-growing śloka tradition, called subhāsita, literally, 'well said' a 'witty saying' or an aphorism. As such subhāsita belonged both to the folk as well as to the classical tradition, and very often, to a classical rendering of folk traditions (Pankaj Jha, 2018, p. 176).

Through the utilization of such proper tropes, Vidyapati enhanced folksongs and brought them from the rustic sphere to the zone of intellectuals.

Conclusion :

There lies a great inclusion of various environmental elements in the Maithili songs of Vidyapati. The reassertion of Indian folk values could lead to a better future in terms of the environment. By reclaiming the past lineage of folk beliefs and its positive outlook towards the ecosystem, we can guide ourselves on how to conserve biodiversity and do less harm to the ecosystem. The folk songs of Vidyapati acts as a successful medium in judging the psyche of human beings when they connect themselves with the environment and knowingly or unknowingly disrupt nature. Equating the connection between human beings and the environment with the reflections in the compositions of Vidyapati, this research intends to offer a newer perspective on understanding the human-nature relationship. Through such examination of mindset, researchers could develop sensitivity and raise the oneness of the native with the ecosystem in which they live.

ABSTRACT

The shortage of potable water is a vital issue for isolated communities in some countries. Utilizing solar still (SS) has proven to be an effective and economical method for producing potable water, but it suffers from low productivity. Among the multiple innovative techniques employed to enhance the performance, employing phase change materials (PCMs) ensures enhanced incessant production of potable water during the night, thus bridging the gap between supply and demand. Further, as an emerging field, the application of nano-enhanced PCMs (NePCMs) has been found promising in augmenting the thermal conductivity of PCMs. In this manuscript, a review of the recent studies on the performance enhancement of solar stills incorporated with PCMs, nano-enhanced PCMs, hybrid PCMs, bioactive PCMs, etc., has been carried out. The novel approaches have demonstrated the enhancement of yield in the range of 31–100 % and 49.5–132 % by incorporating PCMs and NePCMs, respectively, using passive solar stills, while reaching a maximum of ~140 % and ~ 244 % with active solar stills. Bioactive NePCM has shown enhanced yield by ~124.2 % compared to conventional solar still. The use of hybrid PCMs and NePCMs is found attractive and enhances the yield further by ~9 % compared to single PCM. It is further revealed that adding sensible heat storage materials with basin water as a hybrid approach with PCMs/NePCMs loaded solar stills is promising, along with augmenting the performance using magnetic field and UV plasmon resonance. This review also emphasizes the opportunity and future research and would form a road map for the researchers to explore appropriate hybrid combinations to compete with the other technologies.

1. Introduction

Potable water is one of the basic human needs and faces global challenges due to its increasing scarcity and non-sustainable supply in different regions globally. Around one billion people suffer from freshwater scarcity, which will continue to increase due to population and industrial growth [1]. A freshwater scarcity of~40–80 % has been reported in China, India, and the United States [2]. The water scarcity score and the daily available solar energy in some countries are depicted in Fig. 1. Around 17 nations in the Middle East, North Africa, and Sub-Saharan Africa are severely water-stressed. The report published in the year 2018 has mentioned the top five countries facing water scarcity based on their population, i.e., India (163.1 million), Ethiopia (60.5 million), Nigeria (59.4 million), China (57.4 million), and the Democratic Republic of Congo (46.87 million) [3]. Moreover, most water-scarce countries have ample solar energy potential, which can be effectively used for desalting saline/impure water and assist countries in reaching carbon neutrality targets, reducing carbon emission levels to 50–60 % by 2050 [4,5]. Diverse solar desalination methods include multiple-effect humidification (MEH), multi-stage flash distillation (MSF), multiple-effect distillation (MED), multiple-effect boiling (MEB), humidification–dehumidification (HDH), and solar stills. Numerous studies have been carried out to ensure access to potable water, but these are challenging because of the increased expenses associated with purification, transportation, and storage [6]. The deployment of solar still in the duopoly market would address the scarcity of drinking water in an eco-friendly manner and at an affordable cost, especially for underserved populations in rural and island regions, and hence, would produce more welfare to the community than monopoly technologies and can be an effective solution [7,8]. Nevertheless, low productivity from conventional solar stills is the biggest flaw, which hinders its commercialization, and it is crucial to incorporate modifications to improve its productivity and efficiency [9,10].

Several design modifications have been accomplished to improve the productivity, efficiency, and economic viability of solar stills, which have been historically documented since the 1970s, classifying them as passive and active solar stills. To enhance the productivity of solar stills,

Nomenclature

A_b	area of basin (m^2)
A_g	area of condensing cover (m^2)
B	Boltzman constant (1.381×10^{-23} J/K)
C_w	specific heat capacity (J/kgK)
d_{np}	diameter of nanoparticle (m)
h_{bp}	overall h.t.c. from basin to PCM (W/m^2K)
h_{bw}	convective h.t.c. from absorber to basin fluid (W/m^2K)
h_{1w}	total internal h.t.c. (W/m^2K)
h_{kg}	h.t.c. of inner glass covers (W/m^2K)
ho	top h.t.c. from glass surface (W/m^2K)
h_{go}	overall top h.t.c. from outer surface (W/m^2K)
$I_s(t)$	radiations (W/m^2)
K_b	basin's thermal conductivity (W/mK)
K_{pcm}	basin's thermal conductivity (W/mK)
l_b	thickness of basin (m)
lg	thickness of glass (m)
l_{inc}	thickness of insulation (m)
l_{pcm}	PCM thickness (m)
M_w	water mass (kg)
M_{pcm}	mass of PCM (kg)
Pr	Prandtl number
Gr	Grashof number
Q_{char}	heat flux during charging (W/m^2)
Q_{dis}	heat flux during discharging (W/m^2)
t	time (s)
T	temperature (°C)
∂t	incremental temperature rise (°C)
U_{ins}	overall heat loss coefficient from PCM (W/m^2K)
V_a	speed of wind (m/s)
$h.t.c.$	heat transfer coefficient

Greek symbols

$\propto'$	absorptivity
$\varnothing$	fractional nanomaterial
μ	viscosity (NS/m^2)
ϵ	correction factor in the brownian motion term

Subscripts

g	glass
b	basin
w	water
i	initial
ins	insulation
equ	equivalent
s	solid
l	liquid
m	melting
np	nanoparticle

various initiatives, such as enhancing the solar collection, increasing basin water temperature, reducing heat losses, and re-utilization wastage heat, can be implemented [11]. The various modified designs and new enhanced techniques, such as the use of insulation [12], optimum cover tilt [13], external condensers [14,15], solar collectors/concentrated parabolic reflectors [16–18], V-groove basin [19–21], waste heat recovery of PV/T system [22,23], photothermal absorbers [24], glass cover cooling [25–28], thermoelectric cooling [25,29], wind ventilators [30], reflectors [10], domed cover designs [31,32], prismatic absorber basin [6], pulsating heat pipe [33,34], heat storage materials [35,36], biomaterials [37], porous materials [38–40], Sensible heat storage materials [41] nanomaterials [42–45] and nano-enhanced PCM [32,46], and their hybrid applications [47] have been researched. At optimal operating conditions, an optimal yield of 3.10 kg/m^2 from a dual slope SS, while 5.0 kg/m^2 from a single slope SS were reported [48,49]. The mean energy efficiency of ~30 % has been reported using CSS, reaching up to ~60 % under idealistic conditions [50]. Moreover, integrating the evacuated tube heat pipe and external condenser with solar still has enhanced the daily yield by 2.13 times [51]. A detailed overview has been presented for the solar stills integrated with heat pipes and pulsating heat pipes, concluding the lowest production cost of distillate when coupled with an evacuated heat pipe [52].

Thermal energy storage systems (TES) have been the emerging waste/excess heat recovery methods, potentially boosting energy resilience by storing thermal energy. The TES are classified as sensible heat storage, latent heat storage, and thermochemical energy storage systems, which have been extensively reviewed [53]. Spherical rock salt balls (0.50, 1.0, 1.50, and 2.0 cm diameter) as a low-cost sensible energy storage material has been investigated on hemispherical solar still and found promising [41]. They have reported enhanced daily productivity

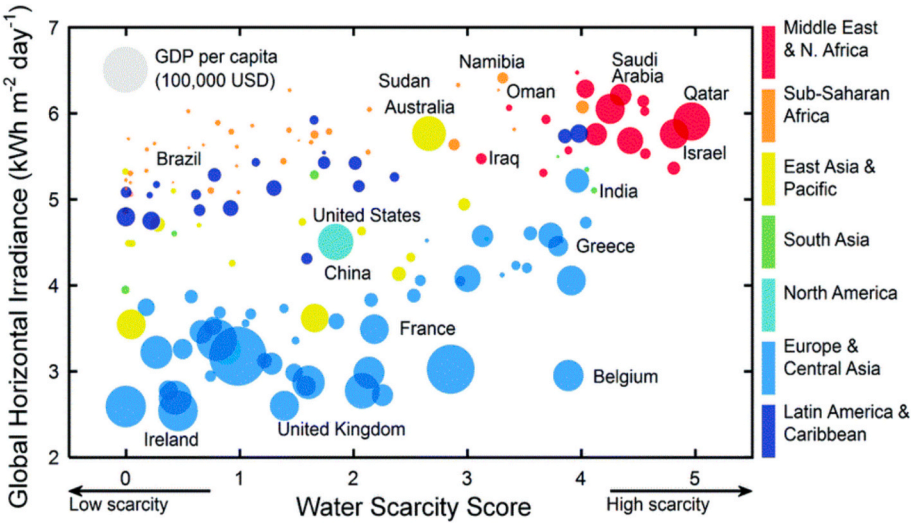

Fig. 1. Water scarcity score and availability of daily solar radiation [4].

of hemispheric solar still, reaching 6.77, 6.25, 5.92, and 5.67 kg/ m^2 by incorporating ball sizes of 2.0, 1.50, 1.0, and 0.50 cm, respectively, compared to 4.65 kg/m^2 yielded by the reference solar still. Moreover, using the spherical salt balls of respective sizes decreased the yield by 8.83 %, 23.47 %, 19.73 %, and 16.84 % compared to reference solar still. From the summarized study, it has been explored that much research has been carried out on improving the performance of the solar still using different wicked materials such as jute, linen, cotton wicks and PCMs and NePCMs as well as combinations to ameliorate the productivity of solar still. Incorporating PCMs can be beneficial for storing the excess heat, enabling the system to operate beyond daylight and thus increase the system reliability and enhanced yield by 49 % was reported using paraffin compared to conventional solar still [54]. Radhwan [55] has fabricated five stepped basins solar still for heating and humidification of agricultural greenhouse. Each basin was placed on a PCM-filled slab (paraffin 0.01–0.03 m thick), insulated from the bottom using a foam of 0.02 m thickness. The re-circulated air from the greenhouse enters the still from the bottom, flows between the basins and glass cover, and after heating and humidification it flows back into the greenhouse. The total yield of 4.6 kg/m^2 with 57 % energy efficiency with PCM, while 4.9 kg/m^2 with 61 % efficiency without PCM has been obtained, maintaining 0.015 m water depth and 0.001 kg/s airflow rate. Furthermore, a single slope solar still of GI basin (1 m^2), insulated with 0.05 m thick foam, and v-corrugated basin with Cu absorber (0.002 m thick) and incorporated with 18 kg paraffin wax beneath was tested with and without the PCM. The glass cover was 0.003 m thick and inclined at 30°. Thirteen copper tubes of diameter 0.01 m were inserted through the PCM to counter the problem of the increasing volume of wax upon melting. Adding wicks over the corrugated absorber with PCM was also investigated and found an increase in daily yield by 12 % and 11.7 % using PCM and PCM/wicks arrangement, respectively, compared to the still without PCM for 25 kg basin water [56]. Using PCM, day yield was decreased by 7.4 %, while night yield increased by 72.7 %. Moreover, the cost of distillate production has been estimated as 0.08369, 0.09558, and 0.07182 $/kg using PCM, PCM with wicks, and without PCM solar still, respectively. Kabeel and Abdelgaied [57] studied the effect of PW on single slope solar still made of 0.0015 m thick GI sheet of 0.072 m^2 basin area, insulated by 0.005 m thick fiber glass. The glass cover was 0.003 m thick and inclined at 30°. The daily yields of 7.54 kg/m^2 and 4.51 kg/m^2 were obtained from the solar still with PCM and without PCM. The production cost of distillate using PCM was found to be lower using PCM (0.03 $/kg) compared to still without PCM (0.032$/kg), due higher productivity. In addition to experimental analysis, numerical studies including thermal modeling and computational fluid dynamics (CFD) simulations have also been carried out to study the behavior of energy storage materials. El-Sebaii et al. [58] have developed a mathematical model to study the impact of PCMs using stearic acid in conventional solar still and found a higher yield by 80 %. The effect of PW on a dual pass solar air heater–coupled conventional solar still with hot air injection has shown an enhanced yield of 9.36 kg/m^2, which is ~108 % higher than the yield obtained from conventional solar still (4.5 kg/m^2) [59]. Khalilmoghadam et al. [60] have reported daily yield and production cost of distillate as 6.3 kg/m^2 and 0.0093 $/kg, respectively, using acetone as PCM on pulsating heat pipe solar still. Pulsating heat pipes (PHPs) were used in the thermal storage system as heat transfer devices between PCM and basin water due to their high conductivity. To prevent heat transfer from the basin to the PCM during daytime, the basin was placed in the center of the chamber and away from the PCM to avoid direct contact with it. A numerical study has been conducted on organic and inorganic PCMs to investigate productivity, retention time, and economics, and found that CSS incorporated with A-48 PCM yielded maximum with lower production cost and was recommended for use from the environmental aspects [61]. Hafs et al. [62] have carried out a numerical simulation of passive and parabolic trough collector integrated active solar still with corrugated absorber surface (rectangular, triangular and spherical ripples) embedded with PCM. The results have shown that the passive solar still with rectangular ripples yields higher than other configurations with increased productivity by 109 % and 42 % than the conventional solar still and PCM-loaded CSS, respectively. Moreover, PTC integrated solar still with rectangular ripples has improved the yield by 549.36 % compared to passive mode of operation. Research initiatives incorporating PCMs have inferred higher productivity from the solar stills. Moreover, PCMs are associated with the discrepancy of low thermal conductivity [63].

To overcome the discrepancy of low thermal conductivity, the surface area of PCMs/water can be enhanced by using extended surfaces, dispersing nanoparticles, or both [64,65]. Karthikeyan et al. [66] tested solar stills containing pebbles, pebbles with color dye, gravels, gravels with color dye, a glass ball, a glass ball with color dye, and Al_2O_3 nanoparticles and found maximum productivity of 6.3 kg/m^2 using Al_2O_3 nanoparticles. The thermal conductivity of paraffin wax (PW) has been improved by four times by mixing alumina nanoparticles (5–10 wt %), which was enhanced further to 35–40 % by adding carbon nanotubes (1–2 %) [67,68]. Moreover, mixing alumina and graphite nanoparticles into myristic acid (PCM) enhanced the thermal conductivity by 125 % [69]. Incorporating copper nano-composite with PW enhanced the yield by ~125 % [70], decreased melting point by 15 % using CuO+ PW blend [71], and enhanced energy storage capacity with graphite-based PW [72] have been reported. The thermal conductivity of the PCM has been increased by over 200 % by the hybridization of Al_2O_3-CuO in the ratio of 3:1 [1]. A comparative experimental study of the stepped still using two types of basin liners (curved and corrugated), cloth wicks, CuO/PW, and vapor suction has revealed that the use of corrugated liner with wick, with wick + CuO/PW, and with wick + CuO/PW + vapor suction improved the yield by 95 %, 127 %, and 170 %, respectively, compared to conventional solar still [73]. Implementing the stepped absorber of multi-conical trays with fountain feed seawater supply enhanced the absorption surface area. A dome-shaped solar distiller with a stepped conical absorbent basin with multi-trays was tested by incorporating a blend of PCM/CuO nanoparticles (NePCM) with a fountain feed supply and found significant enhancement in yield (7.21 kg/m^2) [32]. Saeed et al. [74] designed a corrugated drum solar still, combining PCM with silver nanomaterial and nano-painting in the basin. The effect of rotating the drum at various speeds (0.05, 0.2, 0.3, 0.5, 0.7 rpm) was also studied. The result revealed an increased yield of 318 % at 0.1 rpm compared to conventional solar still. The numerical study on NePCMs loaded solar still inferred that the TiO_2 + PW blend is the most suitable and has stable thermophysical properties during sunshine hours, improving the daily yield to 6.6 kg/m^2 [75]. Numerical studies using PW and Al_2O_3 + PW have been carried out on COMSOL 5.3 software to optimize the performance of CSS, and results show that 3 vol % of Al_2O_3 nanoparticles with 1 kg of PW improve the daily yield by 20 %. [76]. Moreno et al. [77] explored RT70 HC as an improved PCM, predicting a day/night yield of 4.14/1.28 kg/m^2 for 0.01 m water depth. Shoeibi et al. [78] numerically investigated the use of hybrid Al2O3/TiO2 water nanofluid to cool the condensing cover of solar still, predicting increased yield by 11.09 %. Jamil et al. [79] have reviewed the application of advanced energy-stored materials in direct solar desalination and reported a significant enhancement in the performance of their applications. Recently, Hemmatian et al. [80] positioned the wax within the thermosyphon/pulsating heat pipe evacuated tube at 50 % and 100 % filling ratios and found enhanced daily yield and energy efficiency by 40.7 and 42.9 %, respectively, but simultaneously the production cost of distillate was increased by 19.5 % compared to CSS. Elsheikh et al. [6] have identified artificial neural network methods (ANNMs) as a tool for simulation for better decisions and found underexplored forecasting opportunities for the operational production of solar distillation technologies, which can provide timely feedback to decision-makers.

Conventional passive solar still has not yet been commercialized because of its lower productivity. To solve the issue of low productivity, applications of PCMs and NePCMs are emerging, including hybrid

nanomaterials and bioactive-driven materials for the justified deployment for commercialization [7]. Fig. 2 depicts the trend of publications in the field of solar still focusing on the application of PCM and NePCM, and shows an increment during the last five years. This trend signifies a continuous research interest globally in the field (data searched as keywords on Web of Science).

This work aims to review the incorporation of novel materials in recent studies that can improve potable water productivity by solar stills. Therefore, this article focuses on the impact of varied energy-stored materials and methods that can be deemed effective for enhancing the performance of solar stills due to their modified melting points and thermal conductivities, such as applications of hybrid PCMs, diversified NePCMs, and their hybrid combinations. The present work has a novelty that is reflected by the comprehensive coverage of enhanced configurations of solar stills such as dome-shaped with fountain feed, hybrid PV/T, and simultaneously incorporation of different energy storage materials such as bioactive nanomaterials, rehashed edible oils, hybrid NePCM, and influence of magnetic field being done in recent time, which were not included before according to the knowledge of the authors. This updated review provides a unique study for the future researchers, exploring new materials/combinations to investigate diverse novel configurations of solar stills to improve the performance. This review will facilitate a better understanding of the progress and serve as a road map for the commercialization of solar still. Additionally, the future possible works in this area are presented.

The article is categorized and structured under different sections. Section 2 describes the energy storage materials, Section 3 explains the thermal analysis for each element of the solar still and PCM during phase transformation mode, Section 4 details the studies on PCM incorporated solar stills along with the combinations of sensible heat storage, Section 5 comprises of research configuration concerning to solar stills incorporated with NePCMs, hybrid NePCMs, bioactive nanomaterials, hybrid PCMs, and their combinations, and finally, in Section 6, conclusions and future direction of research and applications are presented.

2. Energy storage materials

The energy storage materials have been categorized as sensible and latent heat storage materials. Sensible heat storage materials have two benefits, namely availability and compatibility. Latent heat storage materials are preferred over sensible heat storage materials due to their larger storage capacity/m3 and energy retaining time [81]. PCMs are classified according to their nature, as shown in Fig. 3. The organics are

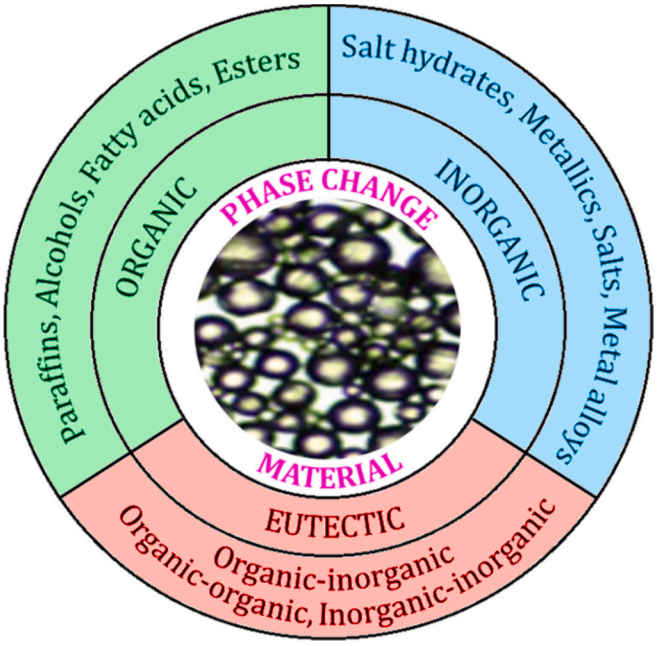

Fig. 3. Classification of PCM.

paraffin or non-paraffins, while inorganic PCMs cover mainly salt hydrates. The melting point of most organic compounds is <80 °C. Eutectics are a mixture of PCMs, and many blends have been investigated to suit the desired applications. Organic PCMs are inexpensive, stable, recyclable, non-corrosive, and possess high latent heat of fusion. However, their main drawbacks are low thermal conductivity, flammability, volatility, and comparatively lower phase change energy [82]. Inorganic salt hydrates are highly conductive than organic PCMs and cheaper but lead to phase segregation, supercooling difficulties, low latent heat, and environmental hazards. The eutectics are the mixture of two or more PCMs, each solidifying and melting concurrently to serve a specific purpose. Eutectic PCMs possess higher heat conductivity and density but are associated with lower specific and latent heat capacity when compared to paraffin/salt hydrates; however, their melting point can be adjusted depending on the mixing ratio [83]. The use of thermochemical energy storage is under the research and development stage.

The appropriate selection of PCM is influenced by phase change

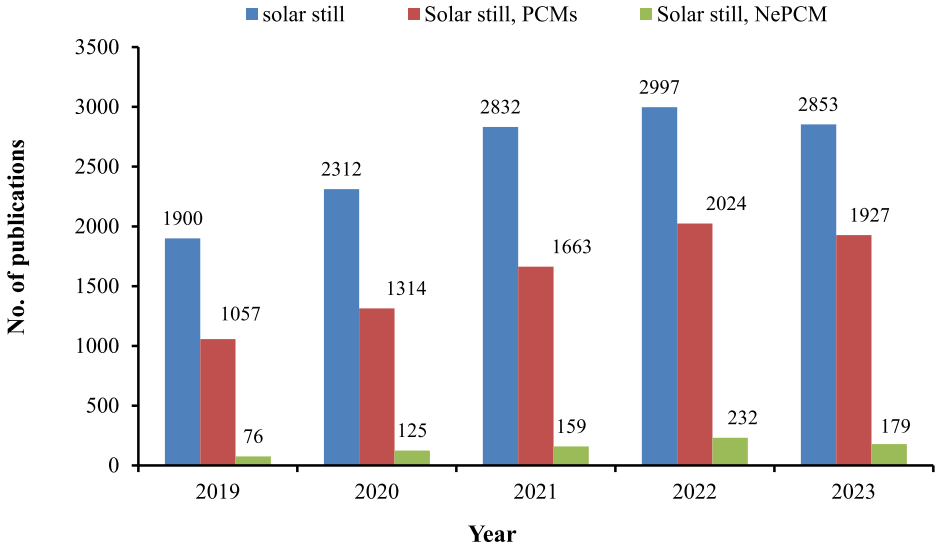

Fig. 2. Publication details with keywords as solar still, solar still with PCM, NePCM.

temperature, latent and specific heat, and their thermal conductivity, and the most suited melting temperature range of PCMs is 40 to 80 °C for solar heating applications [84]. For the passive stills, Su et al. [85] have reported the selection of PCMs of a low melting point range of ~30-45 °C, with preferred materials being paraffin and acetamide. Mousa and Gujarathi [54] have found that PCMs with a melting point range of 40-50 °C are favorable in solar still and yield higher than the PCMs with a melting point below 40 °C. The effect of inorganic PCMs (potassium dichromate, sodium sulfate, and sodium acetate) on the yield of solar still was investigated [86], and sodium sulfate was found promising and economical, however, due to corrosiveness, it requires a stainless steel container [87]. The course of PCM during charging and discharging is shown in Fig. 4. As the radiations increase, PCM temperature increases from point 'a' and reaches the melting point 'b'. At this point, PCM starts melting at constant temperature till point 'c'. After complete melting, upon further heating, the temperature rises to a peak 'd' and further drops back around sunset to point 'e' till it completely solidifies (point f) with the discharge of storage energy and finally reaches near the initial condition during the night (point g).

Nowadays, bio-based PCMs are derived from eco-friendly renewable resources, such as palm kernel oil, palm oil, coconut oil, soybean oil, etc. The wide range of melting points, high latent heat, stability, availability, non-toxicity, and less flammability make bio-based PCMs more attractive than paraffin [84]. The study on various fatty acids has revealed that stearic acid posses maximum heat storage capacity and minimum with capric acid among palmitic, myristic, stearic, capric, and lauric acids. To overcome the possible leakage and diffusion of less viscous PCMs on melting, macro-encapsulation and microencapsulation have been carried out, which also improve the heat storage capacity [88]. Microencapsulation increases the attainment of PCMs by enhancing the thermal transfer area and avoiding leakage issues after melting. In comparison, microencapsulation contains PCM-filled capsules made of silica/organic polymers of size ranging from 1 to 300 μm and reduces toxicity upon mixing liquid and solid PCMs [89]. Zhang et al. [90] have investigated PCM microcapsules with Ti_4O_7 nanomaterial for solar thermal energy storage and found absorptivity up to 88.3 % and photothermal storage efficiency up to 85.36 % using PCMs and SiO_2/Ti_4O_7 compared to pure PCM (24.14 %). The encapsulation makes the PCMs compatible with containers and overcomes their main disadvantages, especially salt hydrates [91]. The selection of PCM for specific applications is based on its latent heat, thermal conductivity, sensible heat, melting point, and chemical and kinetic characteristics.

3. Thermal analysis of solar still loaded with PCM

Fig. 5 shows a diagrammatical presentation of single slope solar still incorporated with PCM. The radiations are passed through the condensing cover and water and further get absorbed by the basin liner.

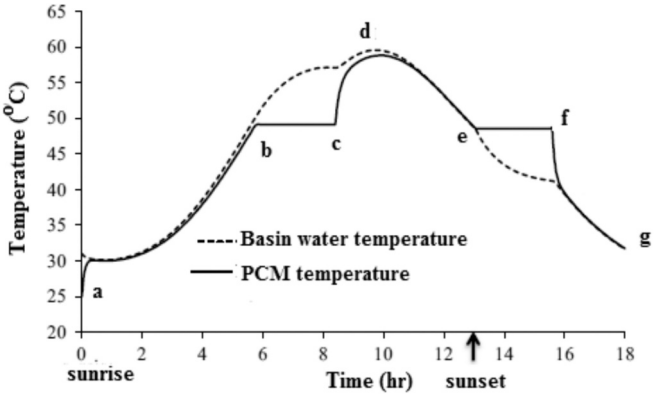

Fig. 4. PCM behavior during charging/discharging.

After absorption, the absorber plate gets heated and transferred heat partially into basin water, while remaining to PCM layer through the bottom. The charging of PCM occurs during radiation availability and decreases the bottom losses. On heating, water evaporates, condenses under the top cover, and trickles down in the channel fabricated with the still body at the lower end. During low/off sunshine hours, the basin liner temperature starts decreasing. As a result, liquid PCM starts discharging heat by transferring it back to the basin absorber and basin water until complete solidification is reached. Thus, the still yields continuously at night, even at lower water depths, because of the increased temperature difference between water and condensing cover.

The energy balance for each component has been formulated using the assumptions presented [92,93].

3.1. Solar still loaded with PCM (charging period)

The energy balance at various components of the system can be expressed as [58,94];

3.1.1. Lower surface of condensing cover

$$\alpha_g' I_s(t) A_g + h_{1w} A_b (T_w - T_{gi}) = h_{kg} A_g (T_{gi} - T_{go}) \tag{1}$$

3.1.2. Outer surface of condensing cover

$$h_{kg} A_g (T_{gi} - T_{go}) = h_o A_g (T_{go} - T_a) \tag{2}$$

3.1.3. Basin liner

$$\alpha_b' I_s(t) A_b = h_{bw} A_b (T_b - T_w) + h_{bp} A_b (T_b - T_{pcm}) + m_b c_b \frac{dT_b}{dt} \tag{3}$$

3.1.4. Energy balance for water mass

$$\alpha_w' I_s(t) A_b + h_{bw} A_b (T_b - T_w) = h_{1w} A_b (T_w - T_{gi}) + M_w C_w \frac{dT_w}{dt} \tag{4}$$

3.1.5. Energy balance at PCM

The energy balance during charging at PCM can be represented as;

$$h_{bp} A_b (T_b - T_{pcm}) = U_{ins} A_b (T_{pcm} - T_a) + M_{equ} \frac{dT_{pcm}}{dt} \tag{5}$$

where M_{equ} is the PCM's equivalent heat capacity and may be evaluated as follow [58];

$$M_{equ} = M_{pcm} C_{s,pcm}, \text{ if } T_b < T_m \tag{6a}$$

$$M_{equ} = M_{pcm} L_{pcm}, \text{ if } T_b = T_m + \partial T \tag{6b}$$

$$M_{equ} = M_{pcm} C_{l,pcm}, \text{ if } T_b > T_m \tag{6c}$$

Solving Eqs. (1–5), and assuming negligible mass/stored energy in basin liner, the following expressions can be obtained;

$$T_{gi} = \frac{\alpha_g' I_s(t) A_g + h_{1w} A_b T_w + h_{go} A_g T_a}{h_{1w} A_b + h_{go} A_g} \tag{7a}$$

$$T_{go} = \frac{h_{kg} T_{gi} + h_o T_a}{h_{kg} + h_o} \tag{7b}$$

$$T_b = \frac{\alpha_b' I_s(t) + h_{bw} T_w + h_{bp} T_{pcm}}{h_{bw} + h_{bp}} \tag{7c}$$

where, $h_{kg} = \frac{K_g}{l_g}, h_{bp} = \frac{K_b}{l_b}$, $U_{ins} = \left[\frac{l_{ins}}{K_{ins}} + \frac{1}{2.8+3V_a}\right]^{-1}, h_o = 5.7 + 3.8V_a$

$h_{go} = \left[\frac{1}{h_{kg}} + \frac{1}{h_o}\right]^{-1}, h_{bw} = \frac{K_w}{l_b}\left[C(GrPr)^{1/n}\right]$

Following [93], the value of C and $1/n$ is reported as 0.54 and 0.25

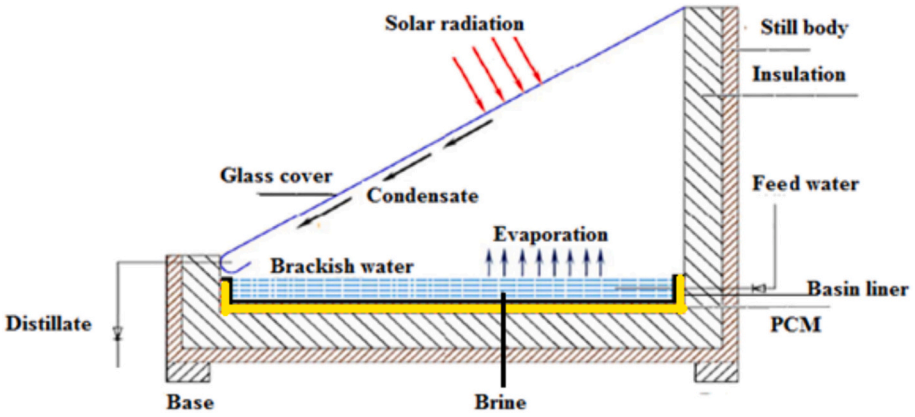

Fig. 5. Diagram of PCM incorporated solar still.

for passive solar still. The heat transfer coefficients can be estimated using the correlations proposed [22]. After rearranging various terms, the water and PCM temperatures can be estimated after time interval 0-t as follows [58,93];

$$T_w = \frac{\overline{f_1(t)}}{a}(1-e^{-at}) + T_{wi}e^{-at} \tag{8}$$

$$T_{pcm} = \frac{\overline{f_2(t)}}{b}(1-e^{-bt}) + T_{pcm,i}e^{-bt} \tag{9}$$

where

$$a = A_b \frac{\left[\frac{h_{bp}h_{bw}}{(h_{bp}+h_{bw})}\right] + \left[\frac{h_{1w}h_o}{(h_{1w}+h_o)}\right]}{M_w C_w}$$

$$b = A_b \frac{\left[\frac{h_{bp}h_{bw}}{(h_{bp}+h_{bw})}\right] + U_{ins}}{M_{equ}}$$

$$f_1(t) = \left(\alpha_w^{'} + \alpha_b^{'}\frac{h_{bw}}{(h_{bp}+h_{bw})}\right) I_s(t)A_b + \frac{\left[\alpha_g^{'} I_s(t)h_{1w}A_g + h_{1w}h_o T_a A_g + h_{bp}h_{bw}T_{pcm}A_b\right]}{(h_{1w}+h_o)}$$

$$f_2(t) = \left(\alpha_{b_}^{'} I_s(t) + h_{bw}T_w\right)\frac{h_{bp}A_b}{(h_{bp}+h_{bw})} + U_{ins}T_a A_b$$

3.2. Discharging mode of PCM

The energy balance equations during low/off sunshine period of solar still when PCM discharges are detailed as under;

3.2.1. Energy balance for PCM during time interval of 'dt' can be written as;

$$M_{equ}\frac{dT_{pcm}}{dt} = \left[h_b^{'}(T_{pcm}-T_b) + U_{ins}(T_{pcm}-T_a)\right]A_b \tag{10}$$

where, $h_b^{'} = \frac{K_{pcm}}{l_{pcm}}$.

3.2.2. Energy balance at basin liner

$$h_b^{'}(T_{pcm}-T_b) = h_{bw}(T_b - T_w) \tag{11}$$

3.2.3. Energy balance at basin water

$$h_{bw}(T_b - T_w)A_b = h_{1w}(T_w - T_{gi})A_b + M_w C_w \frac{dT_w}{dt} \tag{12}$$

Following [58,94], the water and PCM temperatures during discharging mode can be estimated by solving eqns. (11–15).

$$T_w = \frac{\overline{f_3(t)}}{c}(1-e^{-ct}) + T_{wdi}e^{-ct} \tag{13}$$

$$T_{pcm} = \frac{\overline{f_4(t)}}{d}(1-e^{-dt}) + T_{pcmdi}e^{-dt} \tag{14}$$

where

$$c = \frac{\left[\frac{h_{bw}h_b^{'}}{h_b^{'}+h_{bw}}\right] + \left[\frac{h_{1w}h_o}{(h_{1w}+h_o)}\right]}{M_w C_w}A_b$$

$$d = \frac{(h_b^{'}+U_{ins})}{M_{equ}}A_b$$

$$f_3(t) = \left(\frac{h_{1w}h_o}{(h_{1w}+h_o)}\right)T_a A_b + \frac{\left[h_b^{'}h_{bw}T_{pcm}A_b\right]}{(h_{bw}+h_b^{'})}$$

$$f_4(t) = \left[h_b^{'}T_b + U_{ins}T_a\right]A_b$$

The detailed procedure for energy balance equations for the system without PCM can be followed from [93] to estimate temperatures, yield, and efficiency. The hourly yield per unit area may be estimated as;

$$\dot{m}_{ew} = \frac{h_{ew}\,(T_w - T_{gi}) \times 3600}{L} \tag{15}$$

4. Performance augmentation using PCMs

This section encompasses a broad range of subject areas, highlighting the significant diversity of PCMs and solar still configurations explored

in the literature. The results of incorporating PCMs on various configurations of solar still are analyzed, and findings are presented to provide insights using various energy storage materials, including combination with sensible heat storage/dispersed nanomaterials.

4.1. Passive solar stills

To estimate the effect of stearic acid on the performance of a solar still, El-Sebaii et al. [58] formulated heat balance equations for a solar still using stearic acid in a crevice beneath the basin liner and numerically solved. The basin was 1 m^2, fabricated using a black painted galvanized iron sheet of 0.002 m thickness, leaving a crevice beneath for PCM. The bottom and sides of the solar still were insulated using sawdust layer of 0.03 m thickness housed in a 0.01 m thick wooden frame. The condensing cover was made of 0.003 m thick window glass, inclined at an angle of 22.76°, equal to the latitude of the place. An increase in PCM mass has significantly improved overnight and daily yield. Moreover, the daytime yield has decreased due to the enhanced heat storage during sunny periods. For 0.033 m depth (30 kg) of PCM beneath the basin liner, the evaporative heat transfer coefficient was increased by 27 %, with an enhanced daily yield of ~9.0 kg/m^2 and thermal efficiency of 85.3 %. The increase in yield was 80.1 % higher than the solar still operating without PCM (~5.0 kg/m^2). However, PCMs were found to be more effective for low water mass during the winter, further observing that for a deep basin solar still (water mass > 100 kg), the incorporation of 15 kg of stearic acid yields maximum during the night due to considerable storage of sensible heat in basin water during daytime. To explore the irreversibility during PCM's storage/discharge period, Asbik et al. [95] conducted an exergetic assessment of single slope solar still. Using paraffin wax (PCM), higher irreversibility occurred during daytime compared to night, which is crucial in the basin liner and PCM during the energy storage phase, and its variation depends on PCM depth beneath the basin liner. Maximum exergetic efficiency can reach >30 % by varying PCM depth (0.005 to 0.05 m) and wind velocity, excluding the heat storage period. The exergy efficiency of passive solar still was found to be comparatively lower using PCMs because a large part of latent heat remains unutilized during discharging mode. The effect of PW mass of 18 kg (0.02 m thick) on weir-type cascade solar still was experimentally investigated [96]. The absorber of solar still consisted of 15 steps (0.6 × 0.05 × 0.03 m dimension) with the absorber and evaporation surface of 0.72 and 0.45 m^2, respectively. The absorber plate was painted black with a weir of 0.02 m height and placed into an aluminum frame with a glass cover tilt of 30°. The feed water was injected continuously with a 0.07 kg/min flow rate. They found a higher daily yield of 6.7 kg/m^2, which was ~31 % higher than the yield obtained from a system without PCM, which yielded 5.1 kg/m^2. The overall energy efficiency of the still with PCM and without PCM was estimated as 64 % and 47 %, respectively.

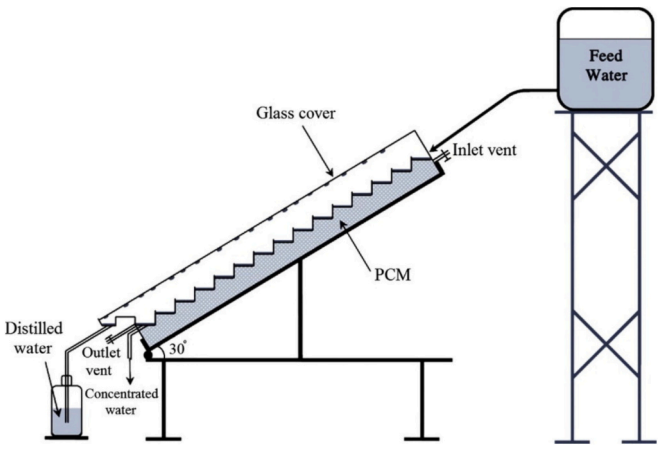

Fig. 6. Diagrammatic representation of weir type solar still [94]. Adapted with permission from Elsevier.

Further, Kumar et al. [97] tested weir-type cascade solar still of 0.20 m^2 basin area incorporating PCMs, namely bee wax, stearic acid, and palmitic acid, having melting points of 61.0, 55.0, and 54.3 °C, respectively. Area of each weir was 0.01 m^2, glass tilt of 30°, and flow rate of inlet water was maintained as 2.9 ml/s. The yield and energy efficiency of the solar still incorporated with palmitic acid has been found to be 2.35 kg/m^2 and 24.58 %, respectively, due to its low melting point of palmitic acid, and found higher by 33.69 % and 35.46 %, respectively, than the solar still without PCM. Energy efficiencies using bee wax and stearic acid were 21.7 and 20.6 %, respectively. In continuation, a theoretical assessment of the same solar still using 18 kg PW under sunny and semi-cloudy was carried out for the system, as shown in Fig. 6 [94]. The solar still incorporated with PCM yielded 4.94 kg/m^2 with energy and exergy efficiency as 76.69 % and 8.59 %, respectively. While yield, energy and exergy efficiency from solar still were found to be 3.84 kg/m^2, 74.35 %, and 6.53 %, respectively, without using PCM. Solar still without PCM yields higher during daytime than still with PCM because absorbed solar energy is utilized to increase PCM temperature, leading to low evaporative heat transfer between water and glass cover. The PW-loaded system performed better during partial cloudy conditions because evaporative exergy in the still without PCM is lower than still with PCM during low solar radiation intensity. The absorber plate has the highest irreversibility rate, accounting for ~78.8 and 83.1 % of the total irreversibility for the system with PW (semi-cloudy) and without PW (sunny day), respectively.

Pyramid-shaped solar still yields higher than conventional solar still. Keeping in view, the effect of using PCM (PW) on a GI sheet (0.0015 m thick) fabricated pyramid-shaped solar still of 0.64 m^2 basin area with side height 0.15 m and a v-grooved absorber plate was studied [98]. The side walls were insulated with fiberglass (0.05 m), which was placed within the wooden box of 0.03 m thickness. The PCM (44 kg) was filled between a square basin made from 0.001 m thick copper material and a v-grooved absorber. The glass cover of 0.003 m thickness was tilted at 30.47°. For 0.02 m basin water depth, the total yield obtained from the PCM-loaded solar still was 6.6 kg/m^2, higher by 87.4 % than the yield obtained from the pyramid-shaped solar still without PCM (3.5 kg/m^2). Furthermore, Kabeel et al. [61] theoretically examined the influence of various PCMs such as stearic acid, capric-palmitic acid, calcium chloride hexahydrate, A-48, etc. on conventional SS. The results revealed an increase in yield by 92 % and 100 % by incorporating 0.04 m thick organic A 48 and inorganic capric-palmitic PCM, respectively, as solar still without PCM. In addition, no remarkable effect on productivity has been observed with PCM thickness, so a small thickness is recommended to reduce the cost. The capric-palmatic acid has a low melting temperature of 22.5 °C, but its low thermal conductivity with high latent and specific heats enables it to give high storage energy compared to A48. The payback estimated from the solar still incorporated with various PCMs is depicted in Fig. 7. However, A-48 was recommended because of its eco-friendly nature and minimal effect of PCM thickness on the performance. A 43.3 % increase in yield was reported using PW-stabilized material on pyramid solar stills [44].

To investigate the results of basin materials and PCM, Vigneswaran et al. [99] used two materials to fabricate single slope solar still and study the effect of bottom and side losses, i.e., still made of galvanized iron (TSS), incorporated with PW (TPSS) and another made of acrylic with PW (APSS). The PW was filled in the annulus of 21 GI tubes (0.286 kg in each tube) and placed over the basin liner in basin water. It was inferred that the usage of acrylic as basin material reduced the charging time of the PCM but also delayed the discharging time of the PCM, resulting in enhanced yield. The daily yields of 4.36, 3.9, and 3.66 kg/m^2 with exergy efficiencies of 3.56, 2.99, and 3.46 % were obtained from APSS, TPSS, and TSS systems, respectively. The production cost of distillate from APSS (Rs. 1.23) was higher than the distillate cost produced by TSS (Rs. 0.67) and TPSS (Rs.1.09) due to higher fabrication

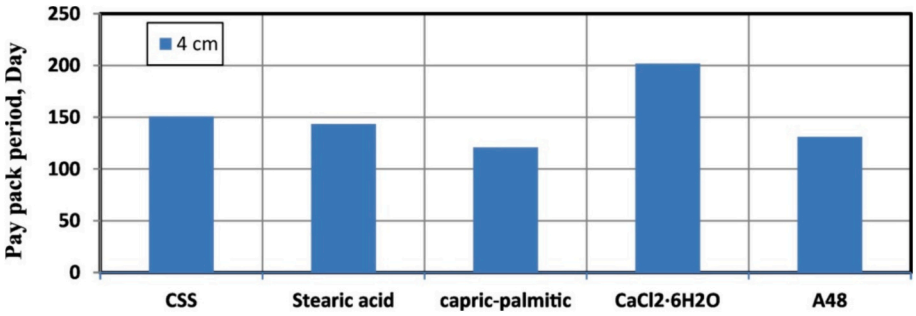

Fig. 7. Payback time using various PCMs in solar still [61]. Adapted with permission from Elsevier.

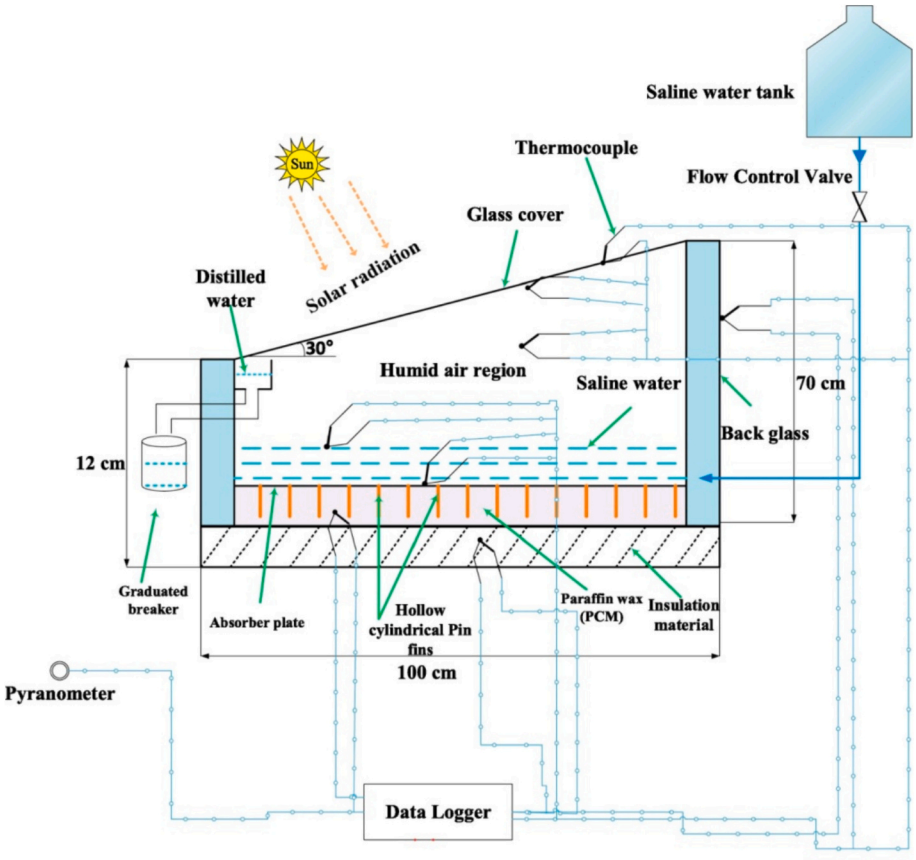

Fig. 8. Schematic of PCM with fin configuration in solar still [100]. Adapted with permission from Elsevier.

costs using acrylic. It was recommended that wicking material be placed on the water surface to overcome the low yield from TPSS and APSS during sunshine hours compared to TSS.

To study the combined effect of latent and sensible heat storage materials, the performance of conventional solar still was investigated using various arrangements such as (a) conventional (case-1), (b) PCM loaded (17 kg paraffin) (case-2), (c) with hollow cylindrical pin fins attached to PCM (case −3), and (d) PCM along with steel wool fiber in the basin (case-4), as shown in Fig. 8 [100]. The basin liner thickness of 0.004 m is painted black to capture maximum radiation, and armaflex insulation prevents heat dissipation from the basin liner to the ambient. The top cover and lateral walls were fabricated from a transparent glass of 0.005 m thick. PCM's reservoir made of a GI sheet of 0.026 m was placed beneath the basin liner and employed with 17 kg of PW to enlarge the heat exchange contact with the liner. The hollow cylindrical pin fins occupy a smaller volume compared to PCM and also enhance the heat transfer between the fins and PCM by maximizing the projected surface area, resulting in augmentation of the rate of heat storage and retrieving energy/exergy transfer from and to the saline water. The system under case-3 yielded higher by 17.0 % and 7.0 % compared to the solar still under case-1 and case-2, respectively. Solar still under case-2 has enhanced the yield by 7 % during the day and 400 % during the night, compared to the solar still under case-1. The solar still under case-4, has enhanced the daytime yield by 14 % compared to the case-2. This is due to the enhanced heat transfer within basin water, which is attributed to increased internal convective and evaporative heat transfer coefficients. However, in this arrangement, less energy is available during the day for the PCM to store, resulting in a decrease in night yield by 80 % compared to case −2. The production cost of distillate was found to be 0.427, 0.51, 0.54, and 0.50 $/kg for cases 1 to 4, respectively [Fig. 9]. The energy efficiency of solar still under case-2, 3, 4, and 5 enhanced by 9.4, 18, 16 and 28 % compared to case-1, while the exergy efficiency using case 4 increased by 10, 50, and 68 % compared to case-1, 2, and 3, respectively. Placing steel wool fiber in the basin significantly enhances the daytime

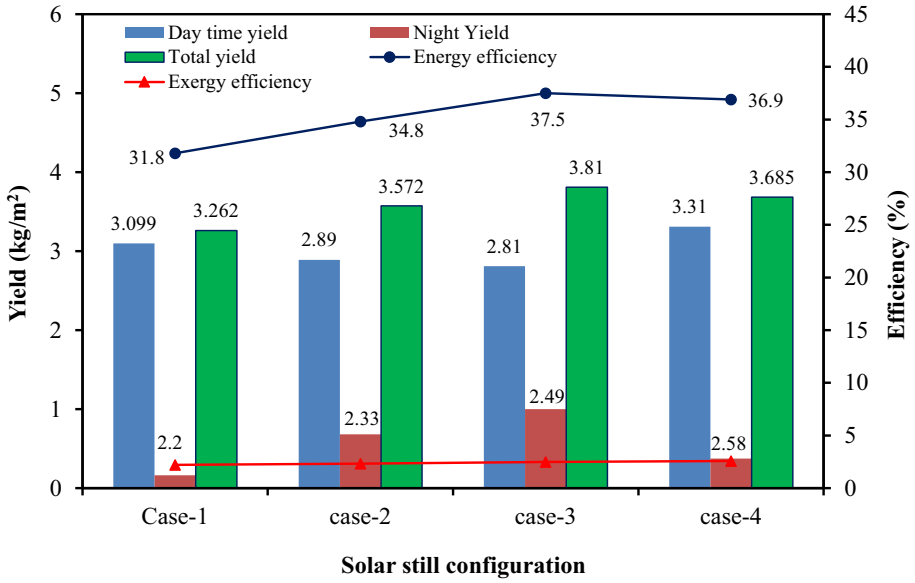

Fig. 9. Comparative overall performance of PCM and sensible heat storage material on solar still.

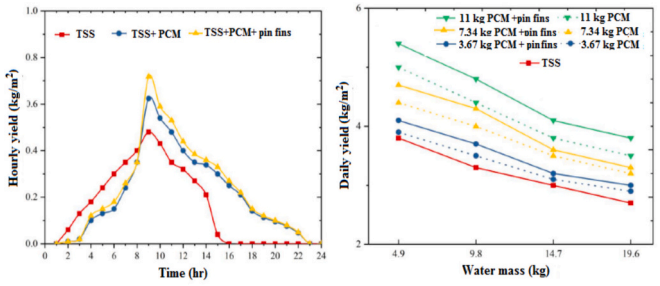

Fig. 10. Effect of palmitic acid and basin water on the productivity [101]. Adapted with permission from Elsevier.

energy and exergy efficiencies, however, considerably reducing these values at night. The steel wool fiber compensates for the evaporation loss during the daytime (due to heat transfer from basin to PCM) owing to the increased effective convective and radiative energy transfer area.

Further, Kateshia et al. [101] investigated the effects of different organic fatty acids such as lauric acid, palmitic acid and stearic acid along with high-conductive aluminum pin fins which were inserted in the PCM storage to enhance the rate of heat conduction. The solar stills were fabricated with a 0.002 m thick GI sheet of 0.49 m^2, painted black, and insulated using 0.005 m thick glass wool. A 0.004 m thick glass cover, tilted at 23° was placed as a condensing cover. The yields from the solar still with pin fins embedded PCM and solar still with PCM were higher by 30 % and 24 %, respectively, compared to solar still without PCM and pin fins. The yields obtained during low/off sunshine hours are depicted in Figs. 10–11. The yield, energy efficiency, and exergy efficiency were observed maximum as 4.43 kg/m^2, 47.9 % and 2.23 % using lauric acid and pin fins in winter. While maximum using stearic acid and pin fins in summer as 5.74 k/m^2, 56.2 % and 2.96 % with production cost 0.016 $/L and 72 days payback time, respectively. The application of Al_2O_3 dispersed water and PW underneath the absorber has also been reported using SS of 1 m^2 of absorber plate made of 0.0015 m aluminum sheet, insulated by 0.002 m thick plywood and 0.004 m thick glass cover inclined at 26° over the still [102]. Al_2O_3 dispersed water with PCM enhanced the daily from 5.1 to 5.47 kg/m^2 compared to PCM loaded solar still alone. Higher yield using Al_2O_3 dispersed water and PCM system is due to an increase in heat transfer coefficient with the basin water during sunshine hours and higher water temperature during night

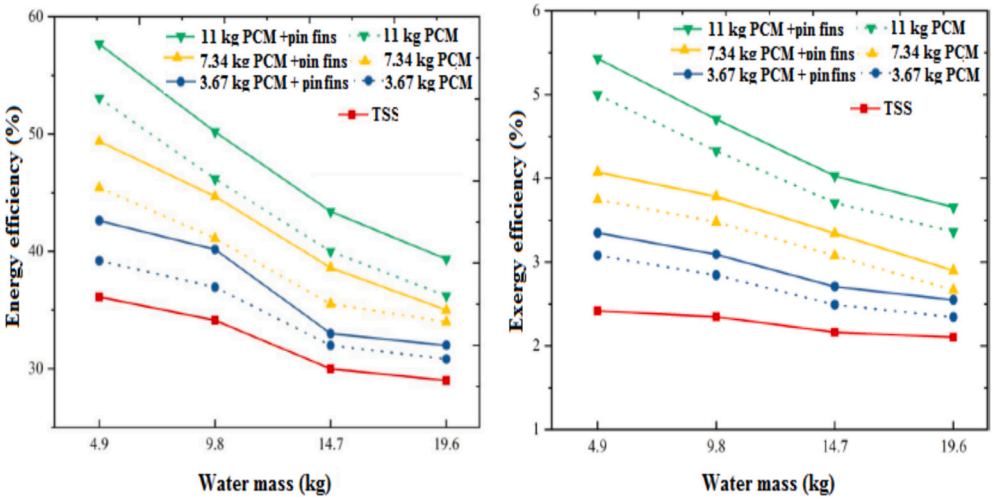

Fig. 11. Effect of palmitic acid and water mass on energy and exergy efficiency [101]. Adapted with permission from Elsevier.

(during discharge of PCM), resulting in the increased convective and evaporative heat transfer coefficients from water to glass cover. Furthermore, the effect of micro-flakes of graphite and CuO with different concentrations (0.125–2 %), different water depths (0.0025–0.05 m), and film cooling flow rates (1 and 12 kg/h) investigated by Sharshir et al. [103]. The still was made of 0.0015 m thick iron sheet of 0.25 m^2 basin area and insulated using 0.05 m thick fiberglass. The thickness of glass cover was 0.0035 m and tilted 30°, equal to the latitude of the place. The yield enhancement by 53.95 % and 44.19 % using graphite and CuO micro-flakes, respectively, which enhanced further to 57.6 % and 47.8 %, respectively, with glass cover cooling. Based on the particle size, 1 wt% has been obtained as the optimal concentration, beyond which no marked benefit was obtained. At the water nanofluid depth of 0.0025 m, the lower yield is obtained due to the creation of dry spots, while yield increases for 0.005 to 0.01 m water depth due to faster evaporation and condensation. The study was further extended using paraffin wax, mixing the graphite flakes with basin water and with glass cover cooling, and with basin water, and the yield improved by 73.8 % compared with the conventional still [104].

To test the effect of PCM and nanofluid combination, a hemispherical solar still was fabricated using 0.001 m thick galvanized steel of 0.34 m diameter and 0.04 m height, placed in a circular wooden container of 0.38 m diameter and coated with black silicone rubber, maintaining 0.02 m gap between bottom and side for PCM [47]. A 0.003 m thick hemispherical plastic cover was placed over the basin. Four stills, namely conventional hemisphere, hemisphere with PW (2 kg), hemisphere with 0.3 wt% CuO/water nanofluid, and hemisphere with PW + 0.3 wt% CuO/water nanofluid were tested, as shown in Fig. 12. Maintaining basin water depth of 0.01 m, the yield has been enhanced by 60.41 % and 29.17 % from the solar still loaded with nanofluid and PCM, respectively, compared to conventional hemisphere solar still. A hybrid combination of PCM and CuO/water nanofluid further enhanced the yield by 80.20 % and reduced the production cost by 75 %. The energy efficiency of respective hemisphere solar stills has been estimated as 35.52 %, 45.45 %, 56.46 %, and 63.61 %, respectively.

The enhancement of yield by employing various PCMs on various configurations of passive design of solar stills compared to solar still without PCM under different geographical locations is shown in Fig. 13. A considerable enhancement in yield has been found using PCMs, depending on their selection, position, and system configuration. An increased yield in the order of capric-palmitic (100 %) > A-48 (92 %) > stearic acid (68 %) was reported [61]. The capric-palmitic has high latent and specific heats, low melting point (22.5 °C), and improves energy storage, response time, and heat transfer, with reduced heat losses compared to other PCMs. However, A-48 PCM is preferred due to its less environmental impact and cost less compared to capric-palmitic. Using stearic acid as a PCM, the productivity has been enhanced by ~80 % compared to the CSS without PCM. While PW enhanced yield by ~87 %, using pyramid-shaped solar still has been reported, possibly due to the high latent heat of fusion and thermal conductivity of PW compared to stearic acid. However, the choice between stearic acid and PW depends on the desired temperature range, thermal conductivity, cost, and availability. The study has further revealed that most of the studies used organic PCMs such as paraffin wax, and more work is needed on other types of PCM in the specific field. Fabricating materials also play an essential role in enhancing the performance of solar stills. The acrylic sheet made solar still with PW yielded higher by ~11.0 % compared to the solar still made of GI sheet with PW, possibly due to the transfer of more radiations to the basin water [99]. The variations in the performance using the same PCM for similar solar stills may be due to the variable operating and climatic parameters, including designs of solar stills tested. The hybrid operations of solar still using PCM and nanofluids/steel weir mesh have been found beneficial. The PCM acts as a heat source during night to augment the night yield, while CuO nanoparticles work as a thermal enhancer for harvesting solar energy by the saline water due to the higher thermodynamic stability and thermal conductivity.

4.2. Active solar stills loaded with PCMs

To enhance the productivity, solar stills are fed by preheated water to operate at high temperatures. To investigate the effect of PCM on high-temperature desalination, Arunkumar et al. [111] incorporated 1.2 mm thick black-painted paraffin wax-filled copper balls in a hemispherical solar still integrated with a concentrator (Fig. 14). On a typical sunny day, the system loaded with PCM yields 4.46 kg/m^2, about 26 % higher than the system operating without PCM (3.52 kg/m^2). The metallic balls act as sensible heat storage for the increase in yield during the day.

The impact of PCM on solar still coupled with oil serpentine loop from a cylindrical parabolic concentrator and loaded with PW beneath the basin was investigated by Kabeel and Abdelgaied [112]. A CSS fabricated using a 0.0015 m thick GI sheet of basin area 0.72 m^2 was insulated with fiberglass (0.05 m thick). A commercial glass cover, with a thickness of 0.003 m, was positioned at the top of the body at 30.47^o. The absorber vessel made from a copper sheet (0.0004 m thick) was placed inside the basin, and the gap was filled with a PCM of 0.03 m thickness. The oil heat exchanger consists of a black-coated single copper tube with inside diameter of 0.0125 m, 12 passes 8.4 m long, and immersed in the basin water. The concentrator has a 1.2 m wide and 2 m long dimension, an aluminum reflector with a receiver of copper tube 2 m long and 0.019 m diameter covered by an evacuated tube of 0.038 m diameter. The enhanced daily yield from ~4.48 to 10.77 kg/m^2 was obtained using the modification [Fig. 15]. The yield enhanced by ~140.4 % with a decreased production cost from 0.0177 to 0.0174 $/kg

than the conventional solar still. However, the overall daily efficiency was found to be reduced by ~44 % due to the increase in solar collection area.

Further, Faegh and Shafii [113] incorporated two different mechanisms for the system consisting of two evacuated tube collectors, a saline water basin, a tank and paraffin wax, a fan, and also twenty

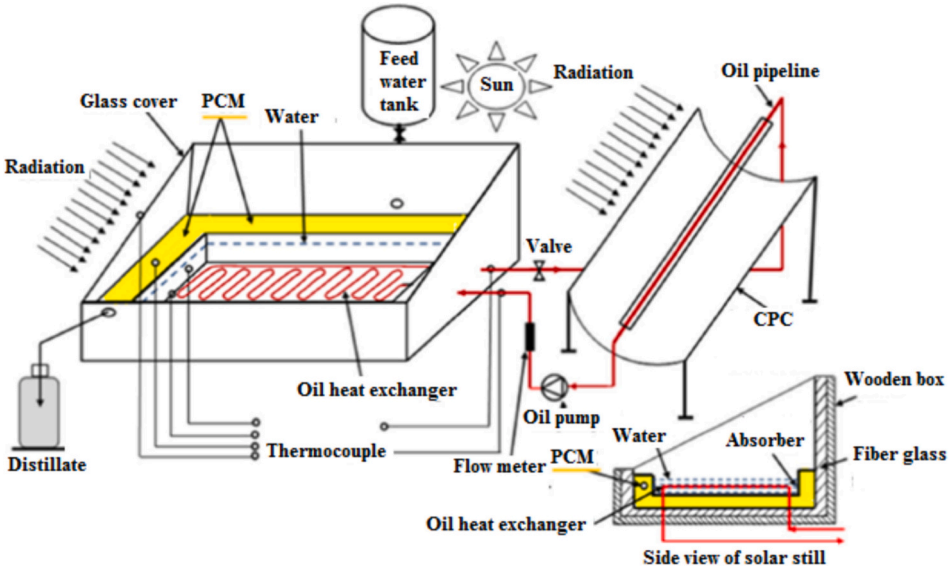

Fig. 15. Solar still integrated with CPC and loaded with PW [112]. Adapted with permission from Elsevier.

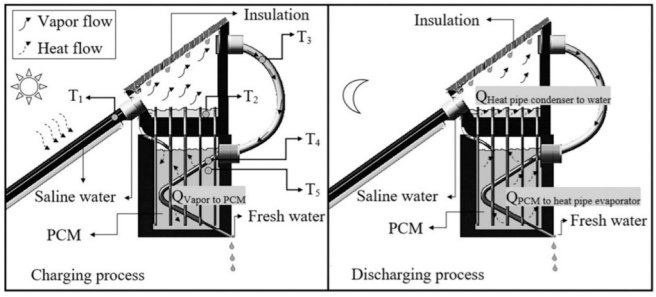

Fig. 16. Diagram of ETC integrated solar still with PCM loaded external condenser [113]. Adapted with permission from Elsevier.

thermosiphon heat pipes as depicted in Fig. 16. A fan conducts the vapor from the basin through the PCM by suitable connecting tube, insulated by polyurethane of thickness 0.03 m. PW-charged the external condenser and discharged heat to heat pipes. The evaporative section of the heat pipes lies inside the PCM, and its condenser section was placed inside the basin water. The daily yields of 3.53, 3.73, 5.49, and 6.55 kg/m^2 were obtained from the respective case as shown in Fig. 17. Daily yield increases by 86 % from the system modified under case 4. Energy efficiency of 24.0 %, 25.43 %, 41.86 %, and 50.0 % have been estimated for cases 1 to 4, respectively, with the distillate production costs of 0.021, 0.027, 0.138, and 0.015 $/kg from the respective system. From the results, it can be concluded that PCM incorporated solar stills yield more effectively once incorporated with other external modifications such as condensers. In another arrangement, ETC-integrated solar still incorporated with PW and found maximum yield, energy efficiency, and

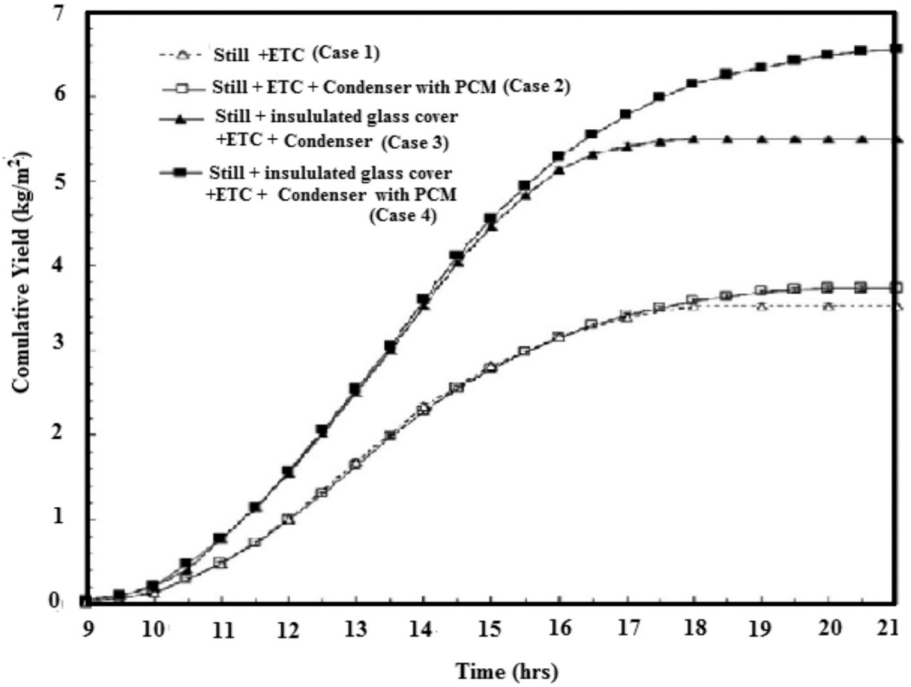

Fig. 17. Cumulative yields in various combinations [113]. Adapted with permission from Elsevier.

distillate production as 6.55 kg/m^2 with 50 % energy efficiency and a distillate production rate of 0.015 $/kg.

Al-harahsheh et al. [114] investigated the effect of inorganic sodium thiosulfate pentahydrate (STP) on active solar still. A solar still of 1 m^2 basin area has a double glass cover at 0.01 m apart. The cooling of the lower glass cover increases condensation due to enhanced driving force. A heat exchanger consisting of an aluminum coil of 0.01 m diameter was connected to a flat plate collector of 2.5 m^2 consisting of 10 copper tubes of 0.008 m diameter. A stainless steel box tub contains 15 plastic tubes and attached to the bottom of the solar still and filled with PCM. This inorganic sodium thiosulfate pentahydrate (STP) is considered due to its high latent heat of fusion, small volume change upon melting, ease of availability, and low cost compared to other competitive PCMs. A significant enhancement in yield during the night (40 % of accumulated yield) was obtained. The increase in flow rate through the collector from 2 to 30 ml/s enhanced the yield three times and found to be more effective at lower water mass in the basin due to the increased heat removal rate by the water flowing in the FPC tubes with an increased flow rate. The influence of inorganic PCM (sodium thiosulfate pentahydrate) to water ratio on the performance of glass cover cooled solar still integrated with PV/T flat plat collector has been studied as depicted in Fig. 18. The increase in PCM to water ratio from 10 to 100 % decreases the yield by ~30 % due to more storage of PCM energy, resulting in a decrease in the basin water temperature during solar time and less daytime productivity. The increased flow rate of cooling water from 0.01 to 0.1 kg/s increased the yield by 37 % due to an increase in the temperature difference between water and glass cover, resulting in an increase in the evaporative heat transfer coefficient. Furthermore, at low depths of basin water, PCMs have been more effective, and yield was doubled by decreasing the depth from 0.1 to 0.05 m. Mehdiabadi et al. [115] studied the double slope solar still integrated with a single PV/T collector and incorporated with PW. Increased yield and exergy efficiency by 10.6 % and 27 %, respectively, were found with an increase in the water circulation rate (0.001 to 0.01 kg/s) during summer. As shown in Fig. 19, the exergetic efficiency increases linearly with the increase of PCM and basin water mass. Furthermore, the effect of the water/PCM ratio has been investigated using PW, stearic acid, and lauric acid filled in the annulus of 6 copper cylinders placed in basin water [116]. The drop in water temperature by 9.2, 17.6, and 21.5 % have been reported using PW, stearic acid, and lauric acid, respectively, with the rise in water depth from 0.01 to 0.05 m with a maximum increase yield 1.2 kg/

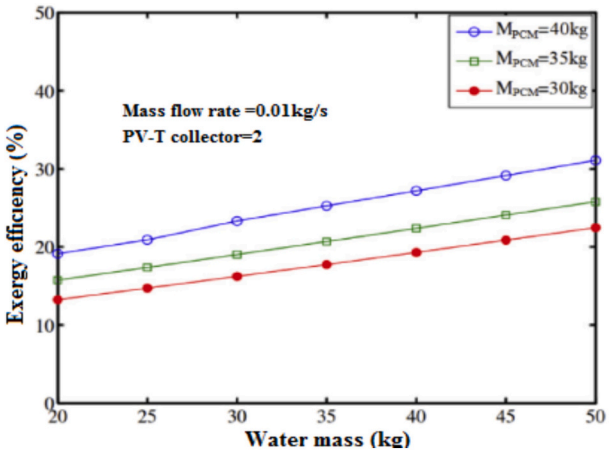

Fig. 19. Impact of water mass and PCM on exergetic efficiency of PV-T integrated dual slope still [115]. Adapted with permission from Elsevier.

m^2 due to paraffin wax, flowed by 1.0152 kg/m^2 (stearic acid) and 0.932 kg/m^2 due to lauric acid. This is due to the lower melting point of lauric acid (42–46 °C) as compared to paraffin wax (58–60 °C) and stearic acid (52–56 °C).

Mazraeh et al. [117] integrated single slope solar still with PV module, evacuated tube collectors, and PCMs (PW, Gallium, PWRT44HC) to evaluate the effect of PCM-PV modules, water depth, and number of collector tubes on the performance. ETC collector with an efficiency of 0.536 consists of concentric tubes with inner and outer diameters of 0.044 m and 0.047 m, respectively, and a length of 1.4 m and operates in natural mode as shown in Fig. 20. The incorporation of PCM has improved the thermal efficiency with negligible effect on exergy efficiency. The use of PW for 0.03 m water depth and 30 ETC tubes yields 4.5 kg/m^2, significantly higher (20.32 %) than the system without PCM (2.3 kg/m^2). The maximum energy and exergy efficiencies were estimated at 17.93 % and 6.95 %, respectively, using PW with ten tubes. When the PV was placed, only fractions of radiation entered the basin directly, which had a negligible effect on increased heat storage within the PCM during sunshine hours.

Abed et al. [118] have extended the investigation with various combinations such as conventional design (case-1), conventional with

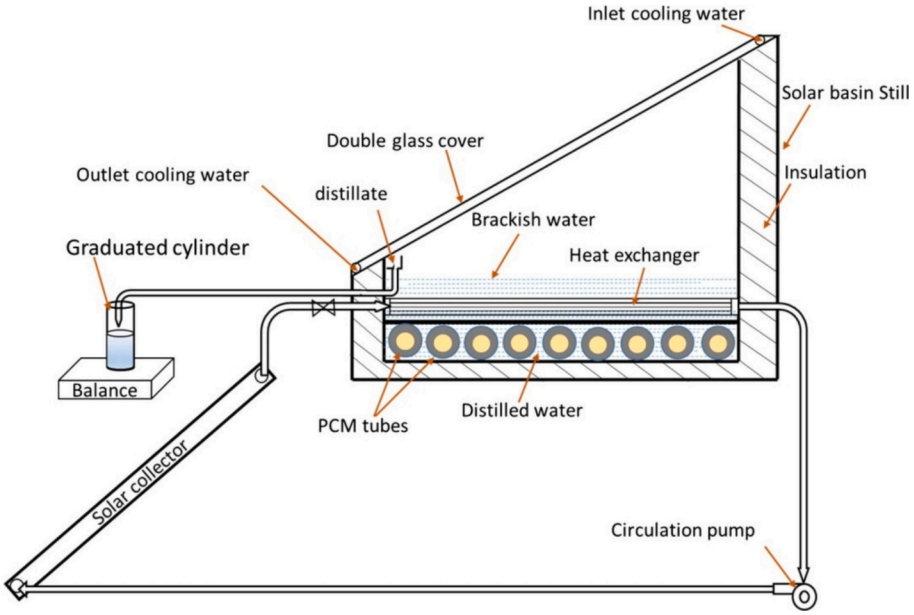

Fig. 18. FPC coupled solar still incorporated with PCM and glass cooling [114]. Adapted with permission from Elsevier.

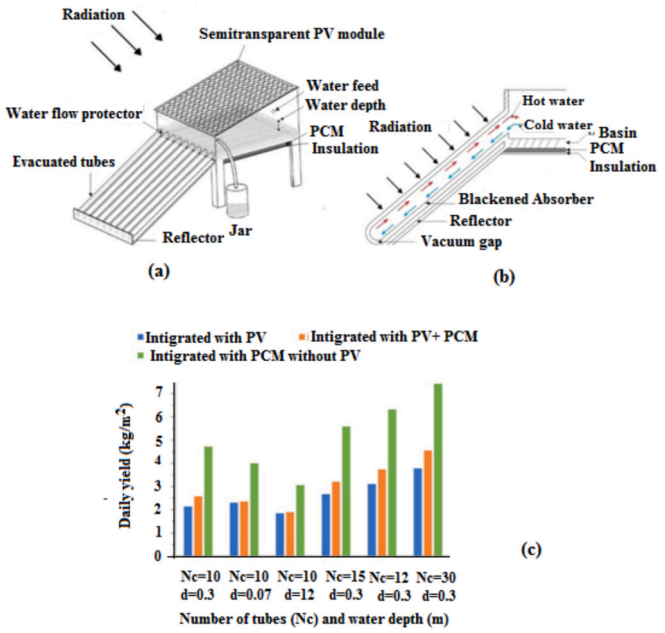

Fig. 20. Schematic of (a) solar still (b) evacuated tube, and (c) PCM effect [117]. Adapted with permission from Elsevier.

cylindrical paraffin capsules (case-2), conventional with cylindrical paraffin capsules and coupled with the collector (case-3), conventional with cylindrical paraffin capsules and coupled with collector and UV vaporizer (case-4), with the arrangement shown in Fig. 21. The rectangular solar still was fabricated with a wooden area of 0.5 m^2 and 0.004 m thick glass cover fixed at an angle of 35° on the top. The basin was fabricated from 0.0015 m thick GS, and the bottom and side walls were insulated externally using plywood with a thickness of 0.01 m. 20 PW cylindrical capsules of 0.025 m diameter and 1 m length were positioned inside the basin water. The solar collector was a rectangle lope in which the water flowed via the 1.5 m tube. On a typical summer day, the increased daily yield with PCM (case-2) was reported to be 30.6 % higher than case-1, while the solar still with case-3 yielded 244 % and 163 % higher compared to case-1 and case-2, respectively. However, including all combinations (case-4), 7.255 kg/m^2 yield was reported, which was 415 %, 340 %, and 49.9 % higher compared to cases 1, 2, and 3, respectively, with a deviation in maximum productivity time. The energy efficiency obtained in each case is shown in Fig. 22. The production cost associated with each case is estimated as 0.037, 0.056, 0.40, and 0.028$/kg, respectively, accounting for 270 clear days.

The stepped solar still fitted with an external condenser was fabricated to study the impact of PCM and condenser on yield [15]. The modified solar still consisted of 7 steps of 0.8 × 0.08 × 0.035 m size, made of 0.0015 m thick iron sheet and 0.003 m thick glass cover inclined at an angle of 36.26^o, equal to the latitude of the place. Basin and the bottom of the steps were insulated with 0.002 m thick elastomeric material. Water vapor from the solar still was transferred to the condenser by a fan, creating negative pressure inside the comber of the solar still. The 0.001 m diameter of the copper tube with length of 2 m rolled inside the water cooled external condenser (Fig. 23). Using 2.5 kg stearic acid (PCM) beneath the steps and maintaining 0.003 m steps water, the enhancement of daily yield by 26 % (0.8 kg), 43 % (0.91 kg), and 104 % (1.3 kg) has been obtained using system incorporated with the external condenser, with PCM alone, and condenser + PCM, respectively, compared to the conventional stepped solar (0.635 kg). The results have revealed a significant contribution of PCM and external condenser on the performance of stepped solar still.

Fig. 24 represents the comparative enhancement in accumulated yield using various PCMs and active designs of solar stills, which have

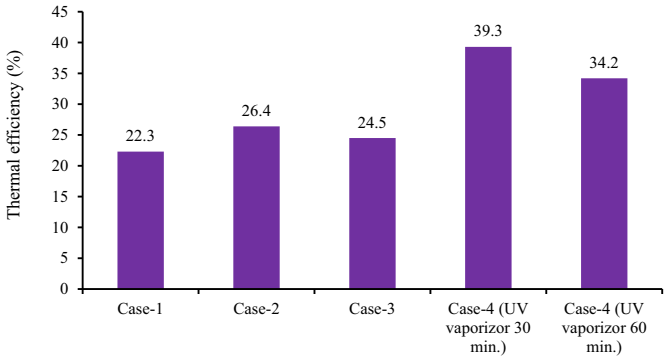

Fig. 22. Energy efficiency of solar still with various combinations, derived from [118].

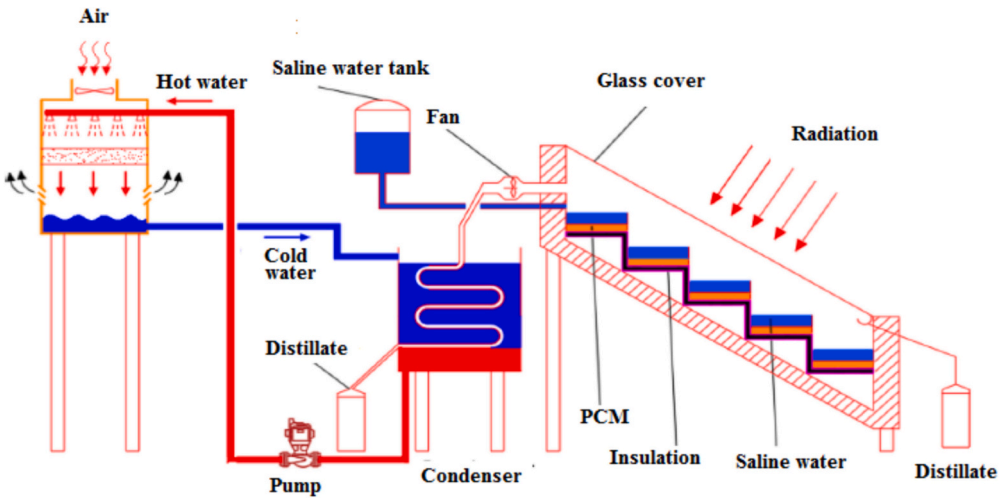

Fig. 23. Schematic of stepped solar still with PCM [15]. Adapted with permission from Elsevier.

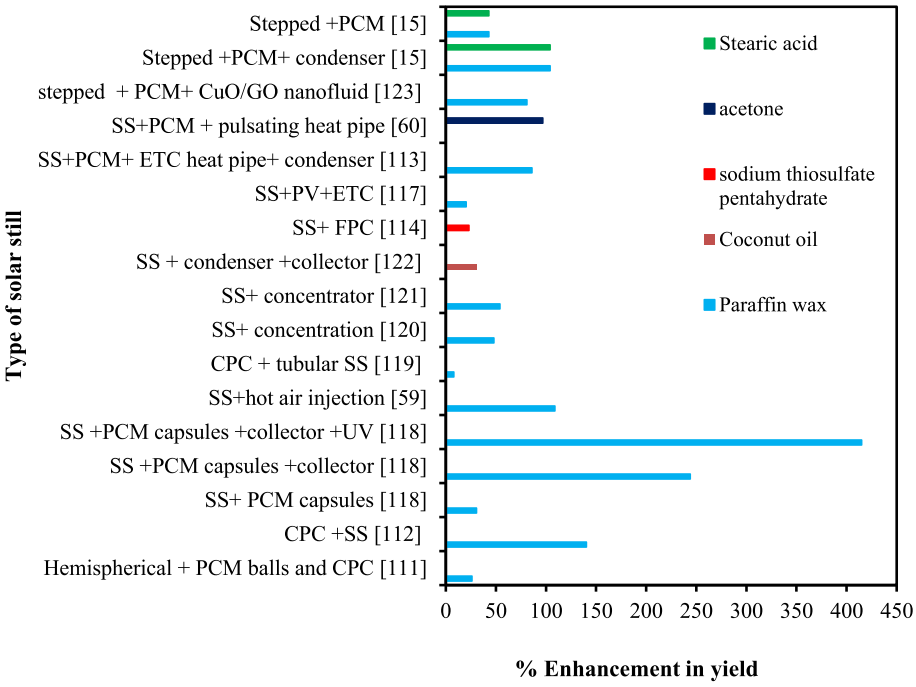

Fig. 24. Comparative enhancement in yield using PCM in active solar stills (%) [15,59,60,111–114,117–123].

been found to be more effective than passive solar stills for greater yields, subject to the type of combination employed. A significant improvement in the yield can be noticed by incorporating PCMs and collectors together, and the use of stearic acid and PW appears to be a more effective PCM for the systems researched. Incorporating PW, PW + FPC, and PW + FPC + UV systems enhanced the productivity by 30.6, 244, and 415 %, respectively, compared to the CSS. The inclusion of UV vibrator can agitate the water surface, breaking the surface tension and promoting more rapid evaporation. However, the higher operating time of the UV system adversely affects the yield due to disruption in the temperature gradient within the still, affecting the vaporization and condensation rates. Coconut oil is a green PCM and has some potential for thermal energy storage. However, its performance in solar still may be limited due to factors such as phase change temperature range, heat transfer properties, stability, etc.

5. Incorporation of NePCM in solar stills

Nanoparticles are heat carriers, improving the thermal conductivity of base fluids upon mixing. Prasad et al. [124] have achieved a maximum efficiency of 49 % from a solar still loaded with silica gel and filled with graphite nanofluid. Thermal conductivity has been reported to be improved using CNTs and CNFs compared to the use of metal or their oxides as nanoparticles alone [125]. Mehrali et al. [126] reported the enhancement in the thermal conductivity of PW to 0.9 W/mK upon mixing graphene oxide (GO). Mixing multiwall carbon nanofluid with particle sizes over 10 nm has reported a higher enhancement in the thermal conductivity of paraffin [127]. Modi et al. [128] have reported an increased yield from double slope solar still by 58.25 % and 26.6 %, maintaining 0.02 m basin water and adding 0.1 wt% of CuO and Al_2O_3 nanoparticles, respectively. Further, a decrease in water depth to 0.01 m leads to an increase in yield by 56.31 % and 26.60 %, respectively.

Al-Kayiem and Lin [129] employed PW with Cu nanoparticles (1.0

wt%) using a flat plat collector and found the system efficiency of 51.1 %, 52.0 %, and 47.6 % utilizing PCM, NePCM, and without PCM, respectively. Bait and Si-Ameur [130] provided a complete analysis of the applications of nano-enhanced solar distillation. Following [29,131], the thermophysical parameters of a micro PCM blend can be estimated as follows;

Density,

$$\rho_{nPCM} = \varnothing\rho_{np} + (1-\varnothing)\rho_{PCM} \tag{16}$$

Specific heat,

$$L_{nPCM} = \frac{(1-\varnothing)(\rho L)_{PCM}}{\rho_{nPCM}} \tag{17}$$

Latent heat,

$$L_{nPCM} = \frac{(1-\varnothing)(\rho L)_{PCM}}{\rho_{nPCM}} \tag{18}$$

Dynamic viscosity,

$$\mu_{nPCM} = 0.983e^{12.959\varnothing}\mu_{PCM} \tag{19}$$

Thermal conductivity;

$$K_{nPCM} = \frac{K_{np} + 2K_{PCM} - 2(K_{PCM} - K_{np})\varnothing}{K_{np} + 2K_{PCM} + 2(K_{PCM} - K_{np})\varnothing} + 5\times10^4\beta_k\epsilon\varphi(\rho c_p)_{PCM}\sqrt{\frac{BT}{\rho_{np}d_{np}}}f(T\times\varnothing) \tag{20}$$

where $B = 1.38\times10^{-23}$ and $\beta_k = 8.4407\times(100\varnothing)^{-1.07304}$

$$f(T\times\varnothing) = \left(2.8217\times10^{-2}\varnothing + 3.917\times10^{-3}\right)\frac{T}{T_{ref}} - \left(3.0669\times10^{-2}\varnothing + 3.91123\times10^{-3}\right)$$

5.1. Passive solar stills incorporated with NePCM

Chaichana and Kazem [132] explored the effect of nanofluid on single slope solar still and found an enhancement in yield by 10.38 % with PW, while 60.53 % using Al_2O_3-PW. This is due to the decreased melting point and increased thermal conductivity of PCM on mixing with Al_2O_3 [133]. Elfasakhany [68] fabricated 3 single slope solar stills i.e., (a) without PCM, (b) using PW (2.2 kg), and (c) PW with copper nanoparticles (40 g of 20 nm size) for the arrangement shown in Fig. 25. The rectangular basin was made of iron, insulated by a wooden plate of 0.001 m thickness with a gap of 0.02 m in between, and filled with glass wool. Another still was modified by adding a copper tube heat exchanger filled with PW, while the third still incorporated Cu/PW nano-composite in the tube heat exchanger instead of PW. The

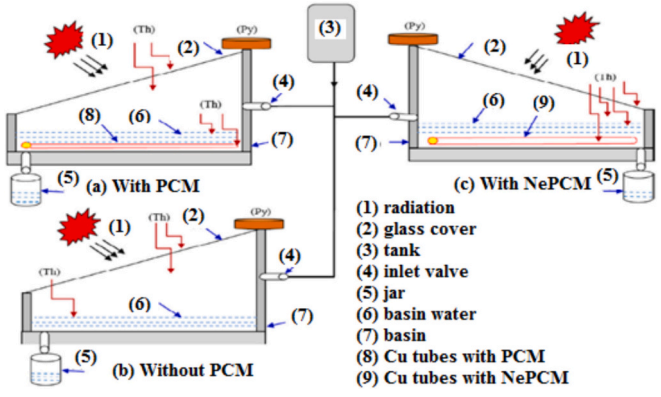

Fig. 25. A schematic of still with different concentration of nanoparticle [68]. Adapted with permission from Elsevier.

significantly enhanced yield of 119 % and 125 % with PW and PW/Cu nanofluid, respectively, has been obtained compared to still without PW. Further, during the increased radiation period, the still without PW yielded higher than those with PCM and NePCM by 9 % and 12 % due to the storage effect in PCM/NePCM. The difference in yield obtained from various arrangements has been insignificant between 12 and 14 pm, i.e., during PCM's phase transformation time.

Rufuss et al. [64] reported that solar still with NePCM (Cuo + PW) yields 35 % higher (5.28 kg/m^2) than using PW alone. Further, the effect of dispersion of various nanoparticles (TiO_2, CuO, and GO) with PW was investigated [134]. They found a significant increase in productivity by dispersing CuO, which was higher than the CSS incorporated with PW (3.92 kg/m^2), and the results are depicted in Fig. 26.

Rajasekhar and Eswaramoorthy [135] investigated the effect of Al_2O_3 mixed paraffin (NePCM) placed underneath the base plate. They observed an energy efficiency of 25, 45, and 66 % using CSS, CSS + PCM, and CSS + NePCM, respectively. The above unit was further tested for the 2 and 4 % nano concentrations [136]. The increased nano concentration has shown better energy and exergy efficiency and was found optimal at 4 % concentration with increased energy and exergy efficiency of 14 % and 11 %, respectively (Fig. 27). The combined effect of adding hybrid material with PCMs has been examined by [137,138]. The yield was reported to be enhanced by 37.55 %, while energy and exergy efficiency increased by ~37 % by using PW+ carbon gravel compared to the solar still with an inside reflector. The increase in yield using hybrid material has been investigated as 8.52 kg/m^2 by mixing 20 % graphite concentration, which was significantly higher than the yield obtained from CSS (4.38 kg/m^2). The yield and efficiency were also improved by 94.52 and 65 %, respectively, significantly higher than the unmodified stills. The efficiency of modified and unmodified solar still has been estimated as 62.38 % and 32.3 %, respectively. The effects of adding Cu chips and PW + CuO on a dual-slope solar still have been experimentally studied [139]. They reported an increased yield, energy, and exergy efficiency by 113, 112, and 190 %, respectively.

Chamkha et al. [140] investigated single-slope solar stills employing a blend of paraffin and carbon nanotubes (CNTs) to boost energy storage and thermal conductivity. The thermal conductivity increased by 26 % due to the CNT-doped paraffin compared to SS without CNT. The daily yields obtained from solar stills loaded with NePCM, PCM, and without PCM were found to be 5.8, 3.4, and 2.5 kg/m^2, respectively, with payback periods of 2.3, 2.7, and 3.0 years. The increase in PCM temperature with the addition of CNT nanomaterial is shown in Fig. 28 and found to be higher by 1.0–9.0 % on an average basis compared to the paraffin-loaded solar still alone.

The effect of NePCM on cascade-stepped solar still has been experimented on, as depicted in Fig. 29 [133]. The PW and GO mixture in varying concentrations (0.2 to 0.6 wt%) was encapsulated between the water tray and bottom absorber plate. The increase in yield by 25 % was obtained using the NePCM. The work was further extended for varying the shape of still's absorber plates (i.e., semicircular, triangular, and rectangular), incorporated with PW, and a mixture of PW and GO in the concentrations of 0.1, 0.3, and 0.5 wt% [141]. A better performance was observed using NePCM at 0.5 wt% GO with a semicircular basin, as illustrated in Fig. 30. The system with a semicircular basin yielded 20 % more than the rectangular basin. Moreover, the rectangular basin yielded 10 % higher than the triangular basin using NePCM.

The effect of the internal reflector, black paint, CuO nanoparticles, and CuO + PW nanofluid on tray-type solar still has been explored, as shown in Fig. 31 [142]. The enhancement in yield was found to be improved by 14.0, 57.0, 70.7, and 108.0 % in the order of CuO with paint< reflectors < reflectors + nanoparticles coating < reflectors+ nano-coating+ NePCM, compared to the conventional design. The daily yield obtained by incorporating all the modifications has been reported to be 5.0 times (~12 kg/m^2) higher than the conventional design (2.4 kg/m^2), with an energy efficiency of 51.5 %. CuO paint enhances the thermal conductivity of the basin liner, while the internal reflector

decreases the heat loss from the side walls and adds radiation to the basin and trays.

The effect of loading PW and NePCM (GO+PW) on tubular solar still (TSS) has been investigated, and rise in a water temperature by ~17.1 % was obtained using NePCM for 0.01 m basin water depth, as represented schematically in Fig. 32 [143]. The NePCM and PCM loaded stills yielded 83.7 % (7.9 kg) and 39.5 % (6.0 kg) higher than the CSS (4.3 kg), with the respective energy efficiencies of 59, 46, and 31 %, while exergy efficiencies were evaluated to be 3.75, 2.2, and 1.67 % from the respective system. Additionally, under the geographical conditions of Chennai (India), TSS loaded with PCM and NePCM has been studied [144]. Upon the addition of GO with a concentration below 0.3 wt%, the conductivity of NePCM was enhanced by 52 % compared to the system loaded with PCM. The daily yields obtained from solar still loaded with NePCM, PCM, and CSS have been explored as 5.62, 3.35, and 2.59 kg, respectively, with the respective energy efficiencies of 50.85, 30.31, and 23.48 % (an increment of 116.5 %).

The effect of adding CuO and Al_2O_3 nano-enhanced PW on single-slope solar still has been investigated [145]. Additionally, CuO was dispersed in the black paint (10 wt%) to enhance the thermal conductivity and coated on the surface of the copper pipe block positioned over the porous material (anthracite) in the basin. The daily yield obtained by various arrangements is shown in Fig. 33. The productivity of solar still has been increased by 55.8 % using CuO-enhanced PW and by 49.5 % using Al_2O_3 enhanced PW at 0.3 wt% concentrations in combination with nano-coated tubes, respectively. Further, a decrease in the melting point of PCM to 2.7 °C and 2.3 °C was reported with the mixing of CuO and Al_2O_3 nanoparticles at 0.3 wt%, respectively. The CuO nanoparticles have been found to be more effective compared to Al_2O_3. Moreover, nano-coating has increased water production costs by about 5.7 %. Selimefendigil et al. [146] have experimented with different single slope solar stills incorporated with paraffin, NePCM (Paraffin+CuO), and NePCM + matt black paint liner, and found productivity enhancement by ~26.8 % using above combined modification. The thermal and exergy efficiency increase was reported by ~4.0 % and 0.75 %, respectively.

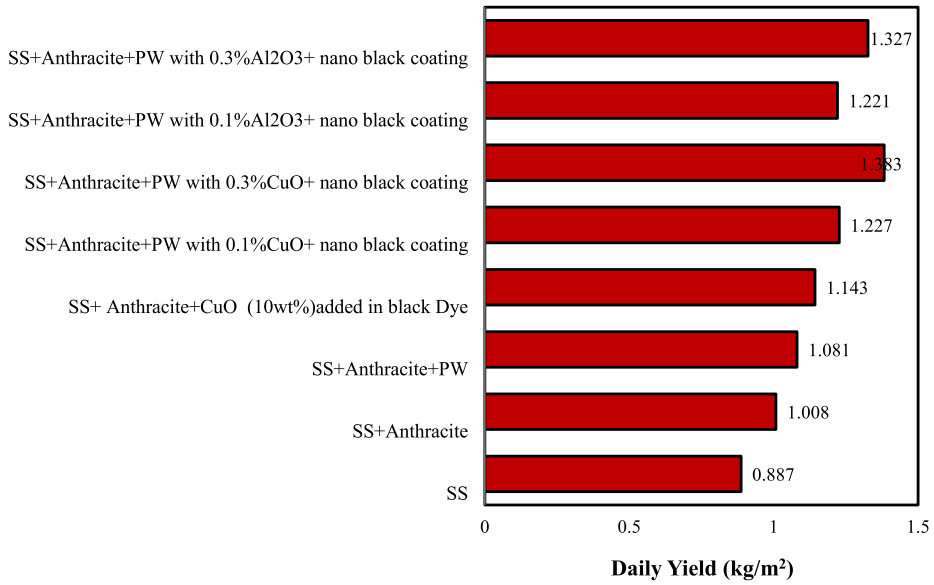

Fig. 33. Variation of yield in double slope solar still incorporated with modifications, derived from [145].

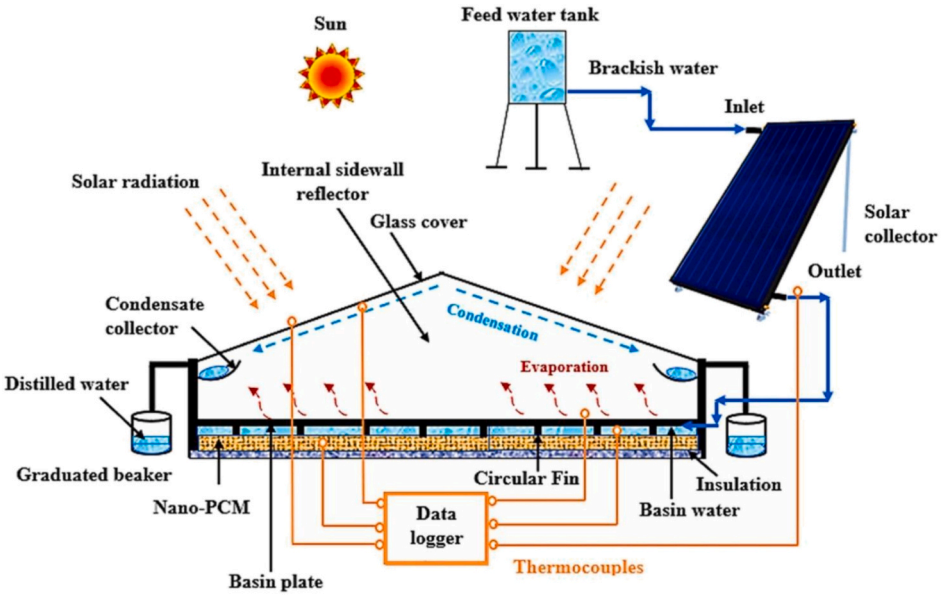

Fig. 34. Modified dual slope still with internal reflector and NePCM [147]. Adapted with permission from Elsevier.

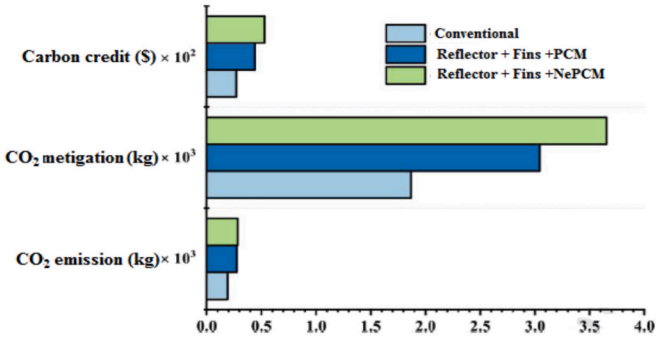

Fig. 35. Comparative environmental effect of adding PCM and NePCM [147].

5.2. *Active solar stills incorporated with NePCM*

Integrating solar stills with collectors, heat pipes, and pulsating heat pipes has been widely used to enhance the yield. However, the performance can be boosted further by incorporating energy storage materials. Dual slope solar still coupled with the collector, internal reflectors, circular fins (hollow), PW, and Al_2O_3 nanoparticles has been experimented as shown in Fig. 34 [147]. The investigation revealed a 51.8 % increase in yield by incorporating the reflector, fins, and PCM combination. The additional increase in yield by 21.5 % has been obtained using NePCM, with an enhancement of thermal and exergy efficiency by 20.1 and 25.0 %, respectively. The distillate production cost decreased by 2 % using NePCM and has been evaluated as 0.020 $/kg with a modified combination, with CO_2 mitigation of 3.65 tons, as depicted in Fig. 35.

Further, the performance of PTC-integrated tubular solar still incorporated with PW-filled aluminum tubes (12 in number) has been investigated using novel PCM-tube geometry, as depicted in Fig. 36

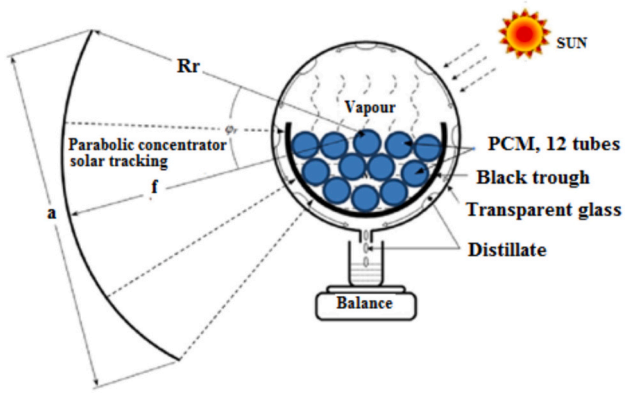

Fig. 36. CPC integrated TSS loaded with NePCM [148]. Adapted with permission from Elsevier.

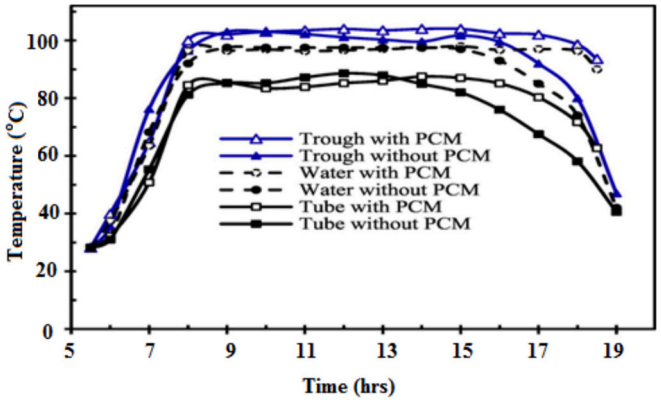

Fig. 37. Temperature profile attainable in various components of solar still during day [148]. Adapted with permission from Elsevier.

[148]. Sun tracking PTC was used to activate the tubular solar still, which consists of 12 aluminum tubes for PCM. The enhancement in productivity by ~40.5 % and energy efficiency by 38.3 % has been estimated. The modified solar still yielded 5.55 kg/m^2 with an energy efficiency of 44.1 % and a production cost of 0.00782 $/kg. The results obtained were higher compared to the yield (3.95 kg/m^2), efficiency (31.9 %), and cost of distillate (0.0163 $/kg) obtained from solar still without PCM. The higher surface temperatures of PCM-filled tubes between 13:00–18:30 h were estimated due to enhanced heat transfer conditions of heterogeneous geometry with large contact surface area with saline water during the low sunshine period (Fig. 37).

Recently, Hammad et al. [32] fabricated a novel design of dome shaped solar still with a stepped conical multi-trays absorbent basin and fountain feeding of saline water. The domed solar distiller has a large surface area compared to a single inclined solar still, and offers enhanced exposure to the ambient leading to reduced condensing cover temperature and improved condensation. The multi-tray stepped conical basin offers a larger area for radiation and increases the vaporization area for water, while fountain feeding minimizes the water thickness in basin trays. The schematic of three techniques used by fabricating the solar still is shown in Fig. 38. The basin was constructed by 0.001 m thick copper sheet of 0.7 m diameter, insulated by 0.004 m thick foam. A mixture of PW with CuO (1 wt%) was stored in one of the still within the conical basin. The findings indicate that daily yield, energy efficiency, and exergy efficiency from NePCM modified solar still were 7.21 kg/m^2, 62.42 %, and 4.16 %, respectively, while the modified solar still without PCM yielded 6.84 kg/m^2 with energy and exergy efficiency of 60.40 % and 3.59 %, respectively. Production cost from the modified solar still with NePCM and without NePCM decreased by 18.48 % and 16.13 %, respectively, compared to the reference solar still without fountain feed (yielded 4.44 kg/m^2). Further, this indicates an augmentation in energy efficiency of 59.61 % and 53.56 %, while exergy efficiency of 123.66 % and 98.39 %, respectively, over the reference solar still.

A summary of studies reported by various investigators related to NePCM-based active solar stills is summarized in Table 1. The use of nanomaterial with PCM has shown a considerable increase in yield and efficiency due to the augmentation of heat transfer coefficient of the composite mixture and a decrease in heat losses from the solar still.

5.3. Miscellaneous NePCM loaded solar stills

5.3.1. Bioactive NePCM loaded solar still

The recent advancements in solar still technology have witnessed a surge in research focusing on nanomaterial integration and novel design configurations. To capture the excess heat and reduce the heat losses to the ambient from the bottom and side walls of SS, a mixture of ricinus communion leaves doped with Ag nanoparticles and paraffin wax was applied in the cavity all around the basin enclosure between the basin and insulation, as shown in Fig. 39 [151]. Solar still was fabricated using a 0.0015 m thick GI sheet of 1 m^2, insulated using plywood and glass wool, and covered from outside by 0.004 m thick transparent glass, allowing for better daytime absorption. The mixture was also employed inside the basin of one of the solar stills. Doping with leaf extract enhances the thermal conductivity and specific heat of the blend. The enhancement of yield/thermal efficiency of three solar stills incorporated with a blend of PW (P) with leaves extract (RC), Ag nanoparticle with leaves extract (ARC), and NePCM with leaves extract (RC) has been found to be 28.5 %/38.3 %, 66 %/44 %, and 96.5 %/48.5 %, respectively, compared to the CSS. The highest yield and thermal efficiency

Various studies of 10 years on the effect of NePCM on various configurations of solar stills.

Ref.	Solar still	Country	PCM	Nano-material	Daily yield (kg/m^2)	Outcome
[135]	SS + NePCM	India	PW	Al_2O_3	4.84	• energy efficiency of 66 %.
	SS + PCM		PW	–	4.19	• energy efficiency of 45 %.
[64]	SS + NePCM *Sodium dodeecycl-benzene surfonate	India	SDBS*	Cu	5.28	• yields 35 % higher than PCM alone.
[132]	SS + PCM	Iraq	PW	–	2.64	• yields 10.38 % higher than CCS.
	SS + NePCM		PW	Al_2O_3	3.70	• yields 60.53 % higher than SS+ PCM.
[134]	SS + NePCM	India	PW	TiO_2	4.94	• yields 26 % higher than SS with PW (3.92 kg/m^2)
			PW	CuO	5.28	• yields 34 % higher than SS with PW.
[133]	Stepped + NePCM	Iran	PW	GO	6.25	• yields 25 % higher then still without NePCM.
[137]	SS + NePCM+ reflector	Egypt	PW	Black gravel	3.27	• yields 37.55 % higher than SS with PCM. • Increase in energy and exergy efficiencies by ~37 %.
[138]	SS + NePCM	Egypt	PW	Graphite	8.52	• yields 7.12, 7.47, 7.94, 8.25, and 8.52 kg/m^2 using 0–20 wt% graphite.
[39]	Trays type + NePCM + reflector + nano black paint	Egypt	PW	CuO	12.00	• increased yield and energy efficiency higher by 108 % and 47 %, respectively, than the CSS.
[144]	Tubular +PCM+ GO	Egypt	Polyethylene glycol	GO	5.62	• yields higher by 116.5 % than CSS and 52 % higher than PCM loaded. • energy efficiencies 50.85 %
[140]	SS + NePCM	Iraq	PW	CNTs	5.80	• payback period of 2.3 years • yields 132 % higher than CSS.
	SS + PCM		PW	–	3.50	• payback period of 2.7 years • yields 40 % higher than CSS.
[143]	Tubular + NePCM	India	PW	GO	7.90	• yields 83.7 % higher than CSS.
	tubular +PCM		PW	–	6.00	• yields 39.5 % higher than CSS.
[148]	Tubular + PTC+ aluminum tubes with PCM	Saudi Arabia	PW	*Al* tubes	5.55	• yields 40.5 % higher and energy efficiency by 38.3 % than still without PCM.
	tubular + PTC		–	–	3.95	
[145]	SS + NePCM + nano coating	Iran	PW	Al_2O_3	1.32	• yields 49.5 % higher than CSS.
			PW	CuO	1.38	• yields 55.8 % higher than CSS.
[139]	Dual slope+ NePCM +nanofluid+ Cu chips	Egypt	PW	CuO	6.52	• Efficiency 68 % and CPL 0.011$/kg. • yield, energy, and exergy efficiency enhanced by 113, 112, and 190 %.
[149]	SS + PCM + ferrite material	India	PW	–	5.50	• yields 62 % higher than CSS.
[146]	SS + PCM	Turkey	PW	–	4.10	• nanoparticle increases the yield by 26.77 % than CSS.
	SS + NePCM		PW	CuO	4.53	
	SS + NePCM + black nanopaint		PW	CuO	4.83	
[147]	Dual slope + NePCM +reflector +hollow circular fins +FPC	India	PW	Al_2O_3	3.37	• yield, energy and exergy efficiency higher by 84, 121 and 111 %, respectively. • additional increase in yield by 21.5 % using NePCM than PCM.
[150]	SS + hybrid nano PCM + glass cooling	Iran	PW	Al_2O_3/TiO_2	–	• yield and efficiency increased by 11.09 % and 28.21 %, respectively.
[151]	SS + bioactive PCM	India	PW + RC leaf	–	2.80	• yield and efficiency increased by 28.5 % and 38.3 % than SS.
	SS + bioactive nano		–	Ag + RC leaf	2.98	• yield and efficiency increased 66 % and 44 % higher than SS.
	SS + bioactive NePCM		PW	Ag + RC leaves	3.46	• yield and efficiency increased by 96.5 % and 48.5 % than SS.
[156]	SS + PCM+ hybrid nano material + Magnetic field	Iran	PW	Fe_3O_4 + GO	1.79	• yields 98 % higher than CSS.
	SS + PCM+ hybrid nano material		PW	Fe_3O_4 + GO	1.58	• yields 75 % higher than CSS.
	SS + PCM		PW	–	1.24	• yields 37 % higher than CSS.
[154]	wick SS+ bioactive NePCM	India	PW	TiO_2 + PC leaf	8.70	• yield and efficiency enhanced by 42.74 and 48 %, respectively, than the CSS.
[32]	Domed SS+ stepped conical multi-trays+ fountain	Egypt	PW	CuO	7.21	• Yield improved by 62.38 % than the reference domed still.

increase has been estimated to be enhanced by 124.2 % and 52.0 % using solar still incorporated with all modifications under typical conditions.

Recently, a nano-composite consisting of a mixture of green-sourced *petroselinum crispum* (P) leaf extract blended with TiO_2 nanoparticles (T) and paraffin wax (P) was applied in wick-type solar still [152]. Solar still was made of GI of sloped surface area 1 m^2 and insulated using glass wool. The slope of the surface was 16°, which is equal to the latitude of the place. The inner surface was painted with matt black and contains 3 g of PTP, and a glass cover of 0.004 m thickness was used. The composite samples were applied in the solar still to induce surface plasmon resonance around 450 nm across the absorber plate (Fig. 40). *Petroselinum crispum* leaf offers the benefits of thermal regulation and moisture retention and acts as a reducing and stabilizing agent when mixed with NePCM. The matt-black paint as a nano-composite was applied on the inner surface. The pellets of PTP were placed on the basin surface. The excitation of PTP composition led to significant heat release, attributing to an increased water temperature. The effect of composite concentration shows an optimal yield of 6.721 kg/m^2 during summer and 6.044 kg/m^2 in winter at 30 % concentration, whereas the conventional solar still yielded 2.85 kg/m^2 and 3.160 kg/m^2 in summer and winter, respectively. The night yields of 1.958 kg/m^2 and 1.892 kg/m^2 have been obtained from the modified solar still in summer and winter, respectively. Moreover, conventional solar still yields 0.950 kg/m2 and 0.851 kg/m^2 in summer and winter, respectively. On investigation, it has been revealed that incorporating 30 % nano-composite enhanced

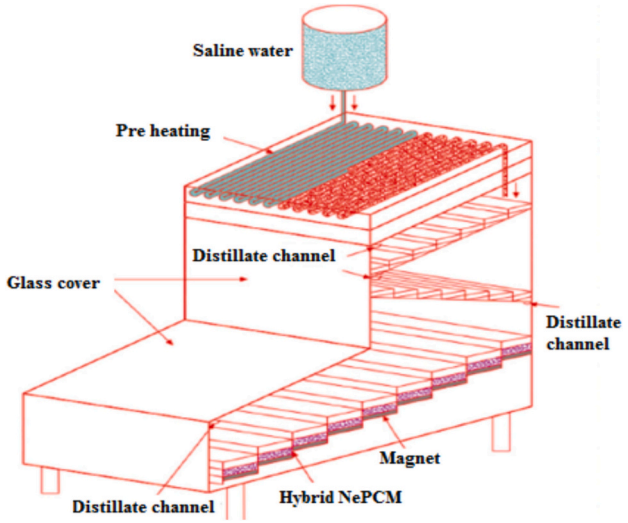

Fig. 41. Modified stepped solar still with hybrid NePCM and magnet [156]. Adapted with permission from Elsevier.

the daily yield extremely (8.70 kg/m^2), including 1.95 kg/m^2 at night on a typical day, resulting in an efficiency of 42.74 %, higher by 48 % than the conventional still.

More recently, Ganeshan [153] used rehashed corn oil as a phase change material to enhance the performance of hybrid PV/T active solar still and found an enhanced PV electrical and thermal efficiency of integrated solar still at 11.7 % and 18.01 %, respectively. The modified solar still produced a daily yield of 7.04 kg/m^2, and corn oil was more effective than coconut, sesame, and peanut oils.

5.3.2. *Hybrid nano materials with PCM and magnetic field*

To study the effect of magnetization in solar still, a mixture of paraffin wax and ferrite material has been incorporated [149]. The total daily yield was found to be enhanced by 62 %, increasing it from 3.4 to 5.5 kg/m^2. The magnetic field breaks the Van der Waals force between the water molecules and soluble salts, increasing the diffusion coefficient and evaporation process. Dhivagar et al. [154] used black iron oxide magnetic powder as an energy storage material to enhance the performance of solar still. The increased daily yield, energy, and exergy efficiency were obtained as 31.2, 18.9, and 19.04 %, respectively. In addition, the still was coupled with the district heating system, and using black powder-coated crushed granite stone significantly improved the distillate yield and was found to be independent of basin water depth [155]. Compared to non-integrated solar still, the enhanced daily yield of 105, 135, and 182 % has been found at 0.01, 0.02, and 0.03 m water depths.

Further, Toosi et al. [156] utilized the effect of the magnetic field in stepped solar still incorporated with a mixture of PW and hybrid nanoparticles (Fe_3O_4 + GO) (Fig. 41). 28 steps were divided into 3 stepped surfaces and made of 0.002 m thick iron sheet. The glass cover thickness was 0.003 m and tilled at 36.26°. Water was preheated using 4 collectors. The magnetic sheets were used under each step of the solar still. Graphene oxide has favorable characteristics and was synthesized and mixed with Fe_3O_4 and PW. The daily yields obtained from solar still

without PCM, solar still with PCM, hybrid NePCM, hybrid NePCM with magnetic field are 0.90 kg, 1.235 kg, 1.577 kg, and 1.79 kg, respectively. The daily yield from solar still incorporated with PCM, hybrid NePCM, and NePCM with the magnetic field have been enhanced by 37, 75, and 98 %, respectively, compared to conventional stepped solar still. The Fe_3O_4 is highly reactive to the magnetic field, which increases the thermal conductivity of NePCM. This is due to the formation of particle chains inside the magnetic nanofluid along the direction of the temperature gradient, lowering the thermal resistance.

5.3.3. Hybrid PCMs loaded solar still

In order to prolong the discharging time of PCMs, a study has been carried out using a hybrid of two PCMs, each having a different melting temperature range [157]. The melting temperature of the PCMs selected has been in the range of 58.03 °C–64.5 °C and 53.05 °C–62 °C, keeping in view that both PCMs should have the same latent heat capacity. However, to increase the discharge time, one PCM in the blend was so selected that it should start discharging once another PCM has almost discharged. An appreciable enhancement yield during daytime/nighttime (2.78/1.62 kg/m^2) has been reported using a solar still incorporated with hybrid PCM compared to the CSS (3.68/00 kg/m^2) and CSS with single PCM (2.72/1.3 kg/m^2). The total accumulated yield (4.40 kg/m^2), energy efficiency (46.29 %), and exergy efficiency (3.52 %) have been found to be higher by ~9 % than the solar still using single PCM.

The use of single organic PCM has many limitations, and to meet the objectives, binary PCMs (eutectic) for energy storage have been developed. The use of eutectic PCMs has shown a significant impact on enhancing the yield of solar stills without increasing the production cost of distillate. Using eutectic PCM (palmitic and stearic acids mixture) and steel wool fiber increased productivity by 35 % while energy efficiency by 37 % [158]. Further, the effect of eutectic PCM (mixture of palmitic/stearic acids, 64/36 wt%) was investigated on dual slope solar still [159]. The eleven copper tubes and six cylinders containing 0.002 kg and 0.009 kg PCM were filled, respectively [Fig. 42]. The energy efficiency was increased by ~37.0 % compared to the conventional design (22.21 %) using binary eutectic PCM.

5.3.4. Hybrid-nanoparticles with PCM

The inclusion of nanofluid boosted the yield of the SS because of the enhanced heat transmission properties of nanoparticles. Recently, a combination of different nanoparticles, such as Al_2O_3/Cu, TiO_2/Ag, TiO_2/Cu, Fe_3O_4/carbon, and CuO/graphene oxide (GO), has been tested to enhance the heat transfer characteristic of thermal systems [123]. The appropriate mixing of hybrid Al_2O_3 + CuO in the ratio of 3:1 with PCM enhanced the thermal conductivity by over 200 % compared to the system operating with pure PCM [56]. Shoeibi et al. [150] explored that combining $Al_2O_3/TiO_2/H_2O$ with an optimal fraction of 0.45 wt% increased the yield and efficiency of solar still by 11.09 % and 28.21 %, respectively. The hybrid Fe_2O_3 and multi-walled carbon nanofluid significantly enhances the base fluid's thermal conductivity and system's energy efficiency [1].

6. Conclusions and future work

6.1. Conclusions

The conventional solar stills are easy to use and inexpensive, but their poor productivity makes them unsuitable for commercial use. An enhanced, consistent productivity can be obtained by incorporating PCMs and NePCMs, reducing production costs and payback time. However, the percentage enhancement depends on various parameters such as the design of solar still, type of PCM, nanoparticle, auxiliary combinations, operational and environmental conditions, etc. The research on various low-cost and eco-friendly PCMs and nanomaterials, including their hybridization, is futuristic. The following are emerging from the review.

a. The theoretical enhancement of yield and energy efficiency for the passive solar still incorporated with stearic acid/basin water ratio of 3:5 have been explored as 80.1 % and 85.3 %, respectively, for typical conditions. Further, incorporating PW in V grooved pyramid-shaped solar still enhanced the yield by 87.4 %. The results revealed that the application of PW is more effective than stearic acid. By incorporating PW, the daytime and nighttime yield enhanced by 7 % and 400 %, respectively, on a typical day.
b. The use of hybrid capric-palmitic acid is better than other PCMs in the order of yield as 100 % > A-48 (92 %) > stearic acid (68 %). However, A-48 PCM is recommended due to its lower cost and environmental benefits.
c. Operating the solar still incorporated with PCM in combination with sensible heat material improves the yield further. CuO-dispersed PW (NePCM) yields 35 % higher than using PW alone. Adding Cu chips in basin water increased the yield, energy, and exergy efficiency by 113, 112, and 190 %, respectively.
d. The productivity enhancement by 30.6, 244, and 415 % has been reported by using CSS+ PW, active design (CSS + PW + FPC), and

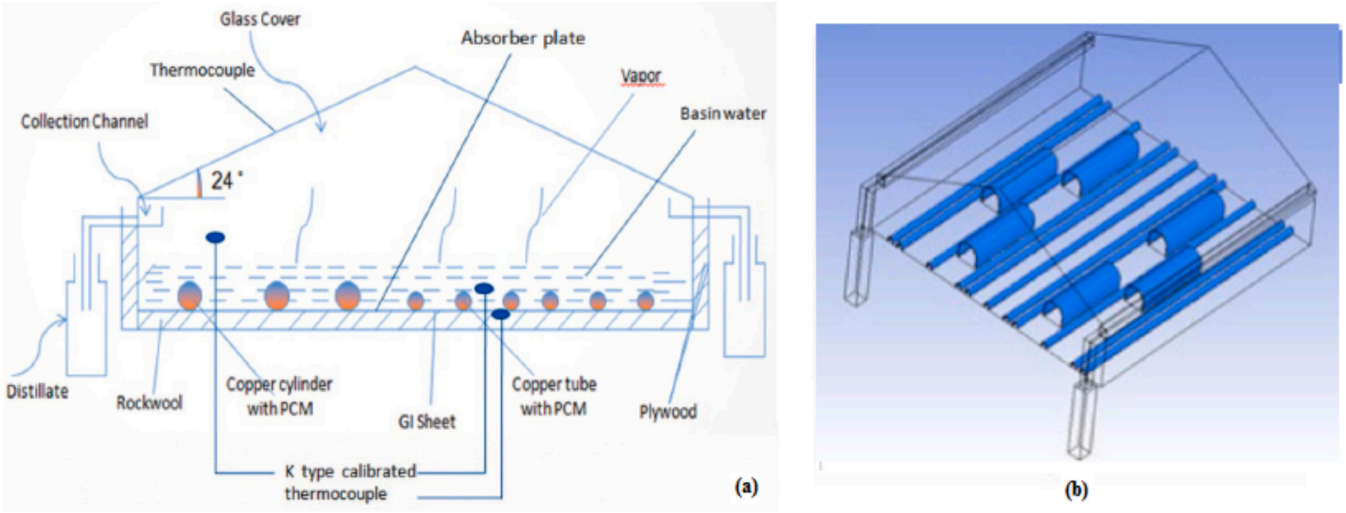

Fig. 42. Schematic of (a) dual slope still with eutectic PCM, (b) PCM tubes and cylinder arrangement [158,159]. Adapted with permission from Elsevier.

CSS+ PW + FPC + UV plasmon resonance solar stills, respectively, compared to the CSS.

e. Dome shaped solar still with stepped conical multi-tray absorbent basin and fountain feed enhanced the performance remarkably, which further enhanced using NePCM.
f. The mixing of nanoparticles has a significant potential for enhancing the thermal conductivity. A mixture of hybrid nanomaterial (Al_2O_3 + CuO) in the ratio of 3:1 enhanced the thermal conductivity of PW by over 200 %, favouring the hybridization with low cost nanomaterial.
g. Rehashed corn oil as PCM in hybrid PV/T active solar still has enhanced electrical and thermal efficiency of integrated solar still by 11.7 % and 18.01 %, respectively, and found to be more effective than coconut, sesame, and peanut oils, with the yield of 7.04 kg/m^2.
h. The daily yield obtained by incorporating internal reflectors+ nano-coating+ NePCM (CuO + PW) enhanced by 5.0 times (~12 kg/m^2) than the CSS (2.4 kg/m^2), with an energy efficiency of 51.5 %.
i. The carbon nanotubes (CNTs) are the most effective nanomaterial, followed by GO, CuO, and Al_2O_3 among the materials under study. The incorporation of NePCM such as CNTs+ PW, GO + PW, CuO+ PW, Al_2O_3+ PW has enhanced the yield by 132 %, 83.7 %, 55.85, and 49.5 %, respectively, than the CSS.
j. Incorporation of bioactive NePCM (Ag + PW+ RC leaves) enhanced the maximum yield and efficiency by 124.2 % and 52.0 %, respectively, compared to the system without PCM.

6.2. Scope for future research

The current review shows that most of the studies have been carried out using paraffin wax as PCM. Moreover, limited studies are available on bioactive NePCM, bio-based PCM, hybrid PCMs, and hybrid NePCMs. The further recommendations are;

(i) Wicked prismatic-shaped basin solar still and dome-shaped spherical solar still (stepped conical multi-trays absorbent basin and fountain feed) have the potential. Further investigations should be carried out incorporating various low cost NePCMs and feeding of preheated high temperature saline water using collectors/concentrators to compete with the existing configurations of solar stills.
(ii) The optimization of NePCM loaded solar stills in combination with other sensible heat storage materials can be the subject of future studies from the viewpoint of thermal management.
(iii) Synthesizing of various nanomaterials with different PCMs to investigate the impact of their utilization on the performance.
(iv) Future investigations are suggested to study the performance using plasmon resonance and magnetic field, which has the potential in combination with NePCMs.
(v) Explore the potential of advanced machine learning algorithms for forecasting the performance of various configurations of solar stills under various geographical locations.

REGULAR PAPER

Efficient hashing technique for malicious profile detection at hypervisor environment

Abstract

Attack detection in cyber security systems is one of the complex tasks which require domain specific knowledge and cognitive intelligence to detect novel and unknown attacks from large scale network data. This research explores how the network operations and network security affects the detection of unknown attacks in network systems. A hash based profile matching technique is presented in this paper for attack detection. The main objective of this work is to detect unknown attacks using a profile matching approach in Hypervisors. Hypervisors are characterized by their versatile nature since they allow the utilization of available system resources. The virtual machines (VMs) in the hypervisors are not dependent on the host hardware and as a result, hypervisors are considered advantageous. In addition, hypervisors have direct access to the hardware resources such as memory, storage and processors. However, hypervisors are more susceptible to the security threats which attack each and every VM. A SHA3-512 hashing algorithm used for generating hash values in hypervisor and the proposed model is used to verify whether the profile is malicious or benign. The performance of the hashbased profile matching technique is compared with traditional hash techniques namely SHA-256 and MD5 algorithm. Results show that the proposed SHA3-512 algorithm achieves a phenomenal performance in terms of phenomenal accuracy and zero false positive rates. Simulation results also show that the computation time required by Sha3-512 algorithm is lower compared to SHA-256 and MD5 algorithms. The performance analysis validates that the hash based approach achieves reliable performance for attack detection. The effectiveness of the hashing technique was determined using three different evaluation metrics namely attack DR, FPR, and computational time. Simulation results show that the existing SHA3- 512 algorithm detection rate of 97.24% with zero false positive rate and faster computational time compared to SHA 256 and MD5 algorithms.

Keywords Attack detection · Hash-based profile matching · Cryptographic hash algorithms · Sha3-512 hashing algorithm · Detection accuracy · False positive rate

1 Introduction

Cyber security and security of network systems are the fastest growing paradigms in recent times. Injection of cyber-attacks is an attempt to disrupt the operations of network systems and make them unavailable to the users [4]. Most of the time, the attacks are novel and it is highly challenging to detect and defend such attacks because of its unknown nature [15]. Though several techniques are available for defending unknown attacks in the systems, these attacks keep evolving and transforming themselves which makes it complicated to detect them [16, 25]. With the evolution of advanced network systems and technological enhancements, the attackers are finding different ways to introduce unknown attacks into the network system. In general, there are two forms of attacks, one that disrupts the network operation and another one that crashes the system completely.

Conventional attack detection techniques such as signature based systems [9] and intrusion detection systems [3] have been used extensively in several approaches. However, these attacks are limited to the detection of known or predefined attacks. Few researchers have also suggested the application of cryptography based encryption techniques along with intrusion detection techniques [5, 10, 26]. Cryptography based techniques have yielded superior results in terms of protecting the security of network data [18, 28]. Cryptographic hashing is another technique which has gained huge popularity in recent times for attack detection [7, 22]. Cryptographic hashing is different from conventional cryptography based data encryption techniques. Encryption defends passive attacks, while cryptographic hashing algorithms are used for creating a digital fingerprint of the data which helps in preventing active attacks in the network. Each digital fingerprint is unique and hence it can prevent falsification of attacks and thereby enable secure authentication of data [17].

Hence, Secure Hashing Algorithms (SHAs) are employed for ensuring the security and privacy of network systems [29]. Hashing algorithms are considered to be more appropriate for securing the network applications which contain sensitive and confidential information. One of the prominent features of SHAs is that even a smaller variation in the input results in the significant variation in the output [14, 24]. According to NIST, the SHA algorithms are categorized into different hash algorithms namely SHA- 0, SHA-1, SHA- 2, and SHA- 3. The SHA- 0 algorithms was the initial version of the 160- bit hashing algorithm which was introduced in 1993. As a result of the continuous transformation of SHA, the improved version of SHA-1 was developed. The SHA- 1 algorithm consists of a 160- bit function and is similar to the fundamental MD 5 algorithm. The SHA -1 algorithm was designed to be an integral part of the Digital Signature Algorithms (DSA) [17]. Most of the limitations of cryptographic methods were observed after the implementation of SHA- 1 algorithm and hence this algorithm was restricted from being implemented after 2010, for securing the network information. The drawbacks of SHA- 1 algorithm were resolved in another version of

SHA algorithm namely SHA- 2, which is the integrated form of peer hash functions such as SHA- 256 and SHA- 512 which has varying block sizes.

Few other modified versions of the SHA are introduced with different specifications as shown in Table 1 [20, 30]. The SHA-2 hash functions are one of the widely used hashing techniques compared to other algorithms. However, the development of SHA- 3 hash function has improved the attributes of SHA- 2 algorithms [8].

The variants of SHA3 are discussed in Table 1. This research aims to address these challenges by presenting an efficient hash-based profile matching technique for detecting unknown attacks, utilizing the SHA-3-512 algorithm. This algorithm generates unique hashes for each profile, enhancing the detection of malicious activities in network systems. The novel SHA-3 can be employed in various tasks that require robust security such as banking, and financial applications, biometric techniques for authentication etc.

The contributions of this research are as follows:

This paper presents an efficient hash-based profile matching technique for detecting unknown attacks in hypervisors.
A Sha3- 512 hashing algorithm is implemented in this work, which generates a unique hash for each and every profile.
The proposed hash-based profile matching model is provided with new inputs to verify whether the profile is benign or malicious.
The proposed model works based on the profile length and profile data for detecting the attacks. The efficacy of the profile matching model is evaluated based on the detection ratio (DR) and false positive rate (FPR).
A comparative analysis is conducted wherein the potentiality of the Sha3- 512 algorithm is validated with respect to SHA-256 and MD5 algorithms.

The article is further structured as follows: Sect. 2 discusses the existing works related to cryptography based attack detection. Section 3 discusses the hash-based profile matching technique for detection of unknown attacks and how the proposed system is developed. Section 4 outlines the results of the proposed methodology and Sect. 5 presents the conclusion.

Table 1 The variants of SHA3 algorithm and its specification

SHA 3 Variant	Output size (bits)	Block size (bit rate r) (bits)	Capacity c (bits)	Security
SHA3 -224	224	1152	448	112
SHA3 -256	256	1088	512	128
SHA3 -384	384	832	768	192
SHA3 -512	512	576	1024	256

2 Related work

Various literary works have been published for identifying security attacks in cyber network systems [6, 11, 13]. A hash based contextual signature is used for detecting unauthorized intrusions in the network [21]. The proposed approach intends to overcome the drawbacks of conventional IDSs using hash based contextual signature which integrates the intrusion detection signatures with hash functions. The contextual signatures are used to strengthen the security of the contextual information and its ability to filter out redundant alarms. The performance of the IDS was tested considering the probability of selecting relevant hash functions and its adaptability in a real time network environment. Results of the experimental analysis show that the proposed approach is highly effective in minimizing the non-critical alarms. Sharma [27] reviewed different encryption techniques. The significance of cryptography in information security is proposed by [12]. The study validates that cryptography based techniques are highly efficient in protecting confidential data from unauthorized users. The security of data is ensured using encryption and decryption which also ensures that the privacy of communication is maintained. This research states that without cryptographic techniques the sensitive information can be easily accessed by the intruders and cryptographic methods encrypt the data into an unreadable format and thereby ensures that the data is not accessible to unverified users. This research also discusses recent advancements in the field of cryptography, state of art of cryptographic techniques and different types of cryptography. Although cryptography ensures high level security of confidential information, it cannot be ensured that the data is completely protected from unauthorized access. To overcome this, the cryptography techniques are improvised by using hashing algorithms. The work presented by Maetouq et al. [19] compared different hash function algorithms for attack detection. Different hashing algorithms are studied to assure authentication and privacy of the information using MD5, SHA and RIPEMD. Different algorithms are analyzed and their limitations are discussed. This work suggests that the performance of the existing hash algorithms is computationally intensive.

3 Proposed research methodology

A Sha3-512 hashing algorithm is adopted in this paper. The proposed approach is based on profile matching and in this hashing technique, the hash values which are in the form of strings are converted into hash structure with a key value. The data structure of the hash map is directly mapped into the relevant data using a given key for classifying the attacks. If no matching key is found, the hash table is updated with the newly generated key and the updated table is mapped to each location. This process is continued on a regular basis until all the matching keys are identified. The stages involved in the implementation of the Sha3-512 hashing technique are described in Fig. 1.

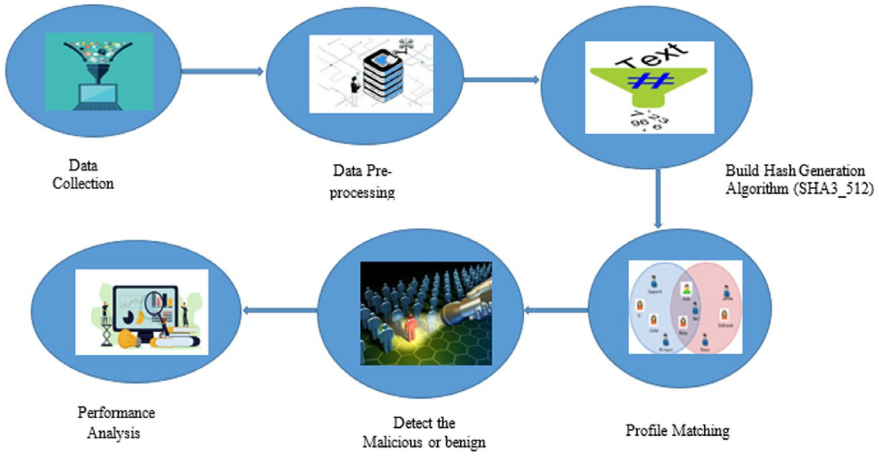

Fig. 1 Workflow of the proposed approach

3.1 Data collection and preparation

The data for the experimental analysis is collected from the HYPERVISORS. A hypervisor is software which creates and executes virtual machines (VMs). It distinguishes the hypervisor operating systems with VMs and thereby allows the creation and execution of VMs. Hypervisors when used as physical hardware are called hosts and the VMs that employ the resources of hosts are defined as guests. The hypervisor software treats different elements of computer systems such as memory, processing units and storage units as a pool which can be shifted from one VM to another.

The data collected from the Hypervisor cloud dataset [1] consists of three different network traffic scenarios namely, internal, external, and local network traffic. The external data flow is between the outside machine and the virtual machine. Meanwhile, the internal traffic is defined as the data flow between one hypervisor to another (this traffic is known as hypervisor traffic). On the other hand, the local traffic happens between two instances on the same hypervisor and this traffic is called instance-instance traffic. In this research, two types of data are collected from the network traffic: (i) network traffic data without any payload on the instances and the hypervisor (ii) complete network traffic focused only on the hypervisors. The dataset consists of both malicious and benign network data packets. The total numbers of data packets in the datasets are 22,372,418, out of which 22,356,769 packets are benign and 15,649 are malicious [2].

3.2 Data pre-processing

Data pre-processing is the primary and most important step in most of the attack detection tasks. It is highly significant in enhancing the accuracy of attack detection techniques. In general, the data is pre-processed to eliminate redundant data from the input data. Pre-processing is carried out to remove the external noise, to

prevent the influence of uncertainties, removal of null values, and filtering of missing data. The cyber security dataset includes attack related features which are used for the classification of unknown attacks. From the available set of attributes, only the relevant features are considered for the detection process based on the respective correlation.

3.3 Hash generation

In the proposed research, a hash value is generated for each profile. As discussed previously, a Sha3- 512 hashing is used for hash generation. The hash generation process is executed using different input features such as (i) source Ip, (ii) dest Ip, (iii) mac_address_sourceIp (iv) mac_address_dest Ip, (v) seq Number (vi) ack Number. Further, the inputs are given to the Sha3- 512 hashing, based on which the algorithm generates a unique hash value for each and every profile.

The process of hashing involves the application of hash functions to the data items using a hashing key to generate a hash value. Hashing algorithms use values of larger range defining all possible data strings. These values are mapped to the smaller set of values such as an18-bit number. There are two important applications involved in the hashing process i.e., improving the speed of data retrieval and validation of data. Hashing algorithms make use of hash values to perform complex calculations and generate an output with a fixed length string. The main intention behind using a hashing algorithm in this research is its non-reversible nature. In general, hash values cannot be reversed and obtaining the result of hash value of a file from the hashing algorithms does not ensure the reconstruction of file's information. However, the hash values can be used to determine whether the profile of two files are identical or not without even analyzing the information of the files. Hence, the concept of utilizing hashing algorithms for profile matching is unique and is applicable to the entire hash functions. If two files can generate the same information then this process is termed as collision and in such cases, it is not possible to use the hash values for matching the profiles. To avoid collision, this research intends to use SHA3- 512 hashing algorithm.

3.4 Proposed secure hash algorithm (SHA3- 512)

As discussed previously, hashing algorithms suffer from collision attacks which affect the performance of the algorithms. In this case, the SHA- 3 hashing is regarded as the advanced algorithm. Cryptographic hash secures the data by generating a unique hash value for each data sample. For comparing two or more data samples, it is suggested to perform hashing first. Even the slightest change in the algorithm will generate different hash values. This attribute makes the SHA algorithms more suitable for verifying the integrity of any information along with other technologies such as digital signatures and anti-tampering. The process involved in the SHA3-512 technique is illustrated in Fig. 2.

A cryptographic hash function known as the SHA3-512 algorithm generates a fixed-size output of 512 bits from an input message of arbitrary length. The

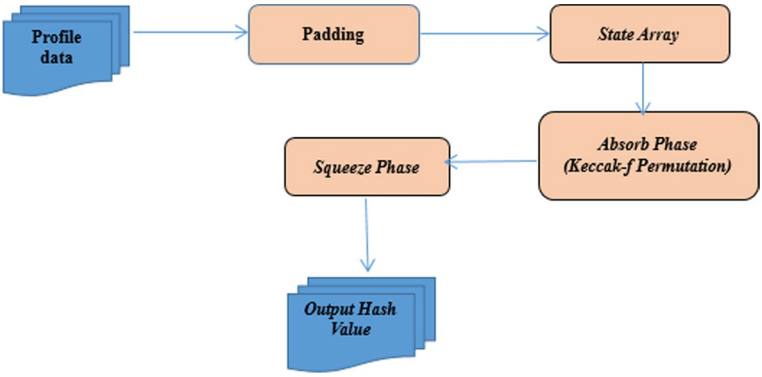

Fig. 2 Process of the SHA3-512 algorithm

algorithm is based on the Keccak sponge function, which is a type of hash function that can be used to create hash functions with arbitrary output lengths. When using the SHA3-512 algorithm, the input message is first padded to make it a multiple of the block size, which is 72 bytes in this case. After that, each block of the padded message has been divided up and processed by the Keccak sponge function.

3.4.1 Keccak sponge function

The KECCAK is the final version of the SHA-3 algorithm. The sponge function used in this research is designed using two stages namely the absorbing stage and the squeezing stage. This is responsible for mixing and transforming the internal state of the hash function during the computation of the hash value. The permutation operates on a state array, which consists of a grid of lanes. The structure of the permutation is characterized by a few key features:

3.4.1.1 Padding The input message is padded in the first unit to make sure it is the right length. The padding phase creates padded messages that are length multiples of the bitrate r in order to strengthen and enhance Keccak's defenses from length extension attacks. The padding process involves adding a series of bits to the end of the input message to bring it up to the required block size. The first step in the padding procedure is to finish the message with a single "1" bit. When the message length is one bit short than a multiple of the block size, a string of "0" bits are appended in succession. Using a fixed-length encoding scheme, the original message's length is then added to the end of each padded message. The goal of the padding procedure is to guarantee that the input message meets the Keccak sponge function's requirement that it be a multiple of the block size.

3.4.1.2 State array The state is made up of a matrix of 5×5 64-bit words. Blocks of the padded message that are individually the same size as the state array are then created. For SHA-3–512, each block is 72 bytes (576 bits).The state 'S' is considered as

a 3-D array with x, y, and z as three coordinates. The 3-D state is represented as 1-D array state which is denoted by 'A' and is determined as shown in Eq. 1:

$$A[x, y, z] = S[w(5y + x) + z] \text{ Where } 0 \leq x \leq 4,\ 0 \leq y \leq 4, \text{ and } 0 \leq z \leq (w - 1) \tag{1}$$

Here 'w' is a parameter representing the width of the state array, which is related to the number of bits in each lane.The array state in this research incorporates lanes of dimension 5×5 with each lane consisting of 64 bits.In other words, the array state consists of 64 segments wherein each segment is made up of 25 bits. For the proposed SHA3- 512 algorithm, $w = 64$ and the bit rate is equal to 1600. In the initial process, the hash function converts the input information with an arbitrary length of fixed size.

3.4.1.3 Absorbing phase Every message block gets XOR-ed with the initial r bits of the state during the absorption phase, which is followed by the implementation of the permutation f. The Keccak permutation, a series of mathematical processes intended to offer a maximum level of security, is used in SHA-3-512. The state array is mixed and altered iteratively using the Keccak permutation. Up untill all message blocks have been handled, this procedure is continued.

3.4.1.4 Squeezing phase After the absorbing phase is complete, the state array contains a fixed amount of information derived from the input data. In the squeezing phase, this information is extracted to produce the final hash value. The squeezing phase may involve multiple iterations of the Keccak permutation to obtain the desired hash length of 512 bits.The first r bits of the state are returned as (part of) the output at each iteration, and the current state is then subjected to the permutation*f*.

Figure 3 depicts the block diagram of the sponge construction. Keccak-based hash functions, i.e., SHA-3, use a sponge construction. This means they absorb input data into the state array and then squeeze out the hash value. An input called state is given to the algorithm as a matrix. The state is made up of a three-dimensional 5×5

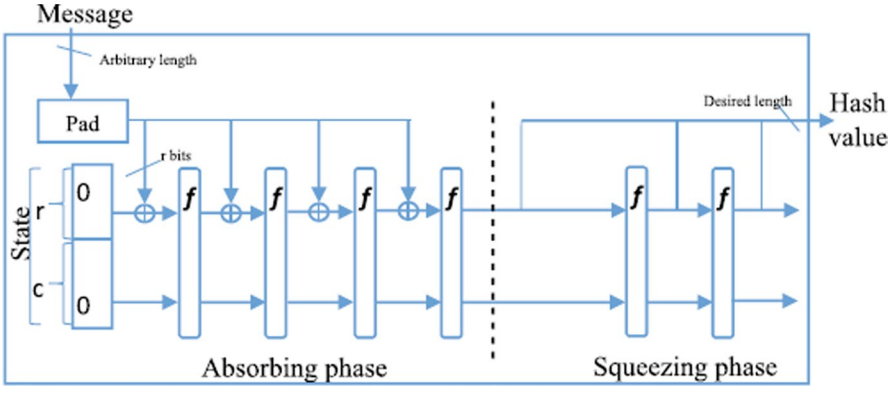

Fig. 3 Keccak sponge function

word-size table with a length of 1600 bits, where word-size $\in \{1, 2, 4, 8, 16, 32, 64\}$. Two parameters are used by the method to form the sponge, based on the required output length. The two input parameters that affect the security level that can be achieved are the bit rate with r bits as well as the capacity with c bits. The input message has been padding and split into r-bit blocks. The primary processing phase, function f, has 24 cycles with processes. A state with width is affected by the function f, whereby r denotes the outer state and c the inner state. The Keccak permutation operates in round functions, and each round applies a series of bitwise operations to the state array. For SHA-3-512, the Keccak-f permutation operates for 24 rounds. These operations include:

The Keccack function KECCACK-f (1600) contains 24 permutation rounds, and each round is made up of five successive phases designated in the state matrix A as theta, rho, pi, chi, and iota, denoted as θ, ρ, π, χ, τ respectively. The algorithm receives the state matrix A as well as the round constant as inputs in every iteration Round[b] (A, RC), producing a hash code output of size b for the following round. The following formulas illustrate the information flow through these five KECCACK-f phases (Fig. 4).

Step theta (θ)

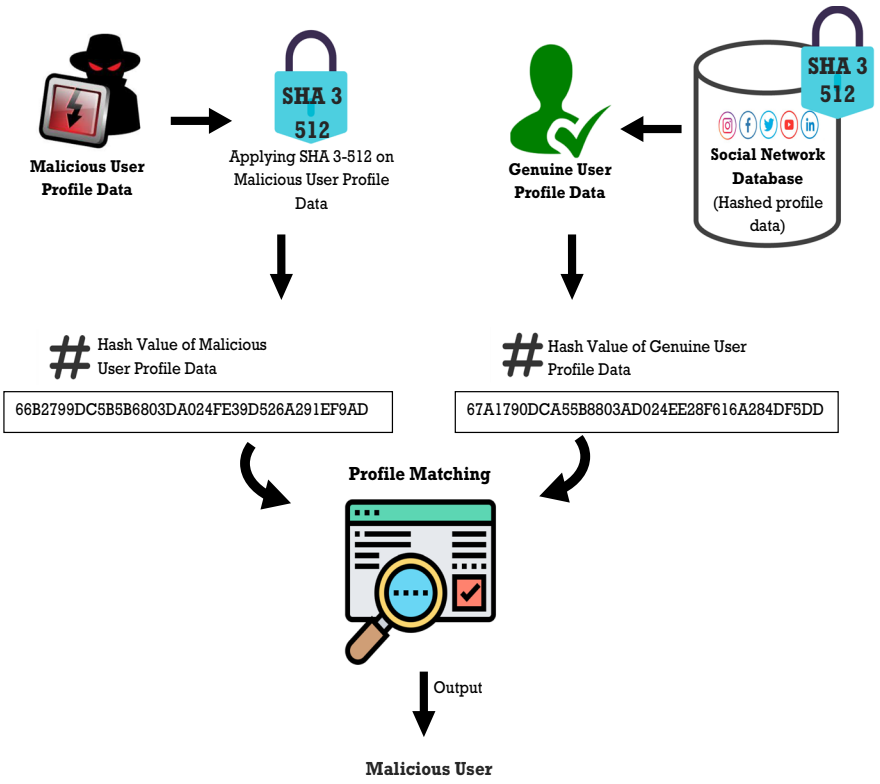

Fig. 4 Profile matching model

Equation (2) demonstrates that theta is composed of a bitwise XOR, a rotation of one position, and a parity calculation.

$$\begin{aligned} C[x] &= A[x,0] \oplus A[x,1] \oplus A[x,2] \oplus A[x,3] \oplus A[x,4] \quad 0 \le x \le 4 \\ D[x] &= C[x-1] \oplus Rot([x+1],1) \quad 0 \le x \le 4 \\ A[x,y] &= A[x,y] \oplus D[x] \quad 0 \le x,y \le 4 \end{aligned} \tag{2}$$

Step Rho (ρ) and pi (π)

In Eq. (3), pi is a permutation, and Rho is a rotation with an offset that is dependent upon the word position.

$$B[y, 2x+3y] = Rot(A[x,y], r[x,y]),\ 0 \le x,y \le 4 \tag{3}$$

Step Chi (ρ)

Equation (4)'s Chi is made up of bitwise XOR, NOT, and AND gates.

$$A[x,y] = B[x,y] \oplus ((NOT\, B[x+1,y])\, AND\, (B[x+2y]) \qquad 0 \le x,y \le 4 \tag{4}$$

Step iota (τ)

Iota in Eq. (5) is a constant round addition, to sum things up.

$$A[0,0] = A[0,0] \oplus RC[i] \tag{5}$$

Here, *RC[i]* represents the round constant for round i. A round is finished once these five steps are finished. The bits that must be processed are completed by the Padding function. B[x, y], C[x], and D[x] are the intermediary variables.Rot () denotes the binary cyclic shift operation. Once the hash generation process is completed, the model is tested for performance evaluation. During testing, the new inputs to the hash based profile matching model are generated and based on the new inputs; the model will check whether the profile is benign or malicious (Fig. 5).

3.5 Profile matching

After hash generation, the hashed profile data is stored in the database. When a new input profile is obtained, same hashing function is performed on the new input using SHA 3-512 algorithm. This model compares the hash value of each new input with the hash value of each stored input in the database. The user is referred to as "Benign" if both the hash values of the stored input and new input match, otherwise the user is referred to as "Malicious" if they both differ with each other. If both the hash values of stored input and new input match, then the user is “Benign” user, otherwise the user is referred to as "Malicious" as if both the hash values differ with each other.

The steps involved in SHA3-512 Hashing algorithm are explained as follows:

Step 1 Obtain the user profile data from the social network database.

Step 2 Perform hash function on the obtained user profile data using the SHA-3–512 hashing algorithm.

Step 3 Store the hashed profile data of the user in the database, associating it with the user's profile features (e.g., user ID).

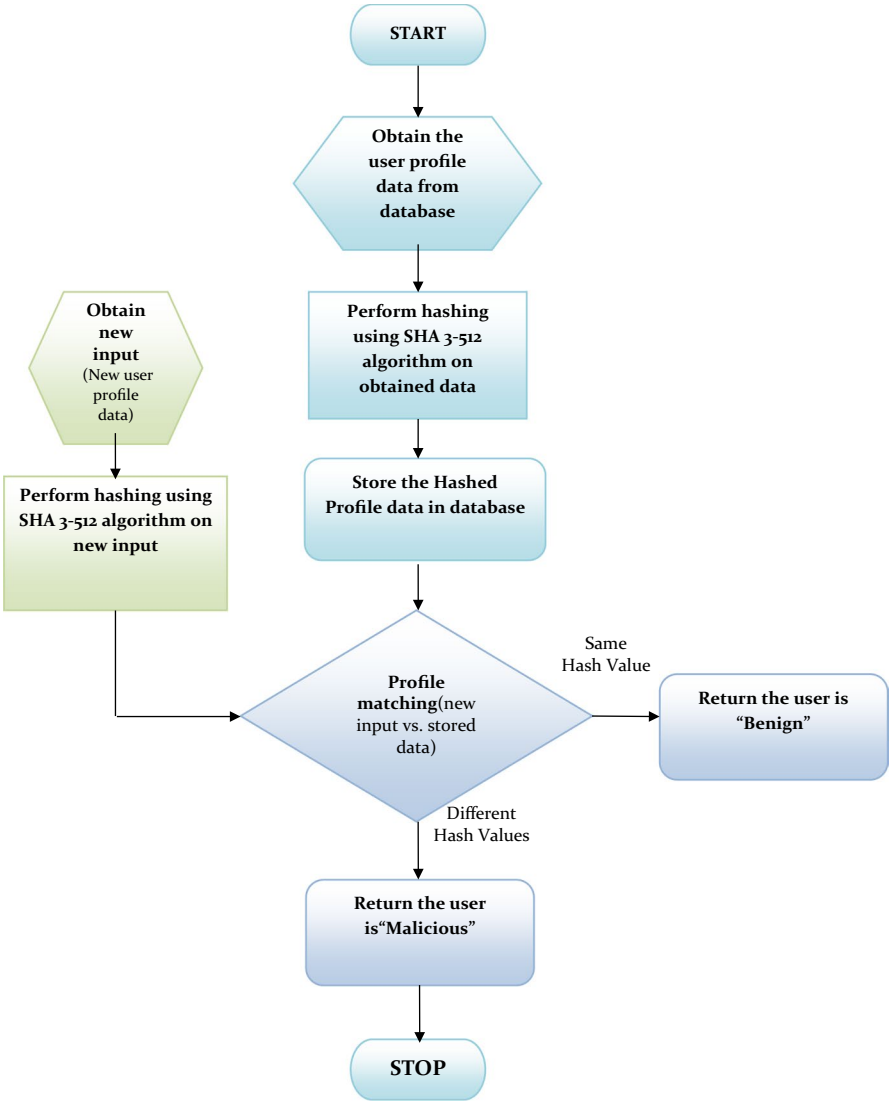

Fig. 5 Flowchart of proposed methodology

Step 4 Get new user input profile data to verify whether the user is malicious or benign.

Step 5 Repeat Step 2 for the new input data and hash it using the same SHA-3–512 hashing algorithm.

Step 6 Execute profile matching to verify the user's status:

(i) Compare the hash value of the new input with the hash value of the stored input in the database.

(ii) If the hash values match, return "Benign" (indicating the user is benign).
(iii) If the hash values do not match, return "Malicious" (indicating the user is malicious).

Step 7 Return whether the user is “malicious” or “benign”The overall flow of the proposed work is represented as below;

Once the testing of the hashing process is completed, the performance is evaluated based on the DR and FPR. The outcome of the simulation analysis is discussed in the next section.

4 Experimental results

A brief overview of the simulation of the SHA3- 512 hashing algorithm and its attack detection ability in terms of three performance evaluation metrics namely DR, FPR and computational time. Two simulations were performed using the same executable file without employing any optimization levels. The performance of SHA3- 512 algorithm was also analyzed without using any compiler optimization. In general compiler optimizations are employed for improving the performance of simulated models and several researchers have determined the influence of code optimization on different aspects of simulation such as reliability of the model and energy consumption. In addition, it was observed from the simulation analysis that the optimization of the compiler minimizes excess consumption of system energy by minimizing the number of instructions of the machine required for executing any operation [23]. Furthermore, the minimization of the number of computations affects the execution of software programs and thereby reduces the hardware errors. It was also inferred from the simulation analysis that the compiler optimizations have a negligible effect on the error sensitivity of different hashing algorithms.

4.1 Performance evaluation

The performance of the hashing technique was determined in terms of DR, FPR, and computational time. The results of the simulation analysis are compared with other two conventional hashing algorithms namely SHA 256 and MD5 (Message Digest) algorithm and other models such as Snort (ET rule set), Snort (Custom rule set) and a hypervisor based IDS.

The SHA 256 is one of the cryptographic hash functions which is used to compare two sets of data. The SHA 256 algorithms can identify even small variations in the data and it generates a different hash value which indicates the difference in the data. The algorithm generates a unique, and fixed size 256-bit (32-byte) hash which makes it appropriate for validating the integrity of the data by identifying the tampering of the digital signatures. On the other hand MD5 algorithm is a one-way hash function which makes it practically impossible to retrieve the original data from its hash value. The MD5 algorithm generates a unique 128-bit hash value for each input. However, MD5 is not used extensively in cryptographic applications because

Table 2 Comparative analysis

Algorithms	Detection rate (DR)	False positive Rate (FPR)	Computational time (Sec)
SHA3 -512	97.240	0.0	30.261
SHA 256	76.155	0.063	29.038
MD5	87.934	0.536	25.141
Snort (ET rule set)	10.5	0.002	26.380
Snort(Custom rule set)	41.23	0.0065	24.754
Hypervisor-based IDS	96.11	7.3	27.148

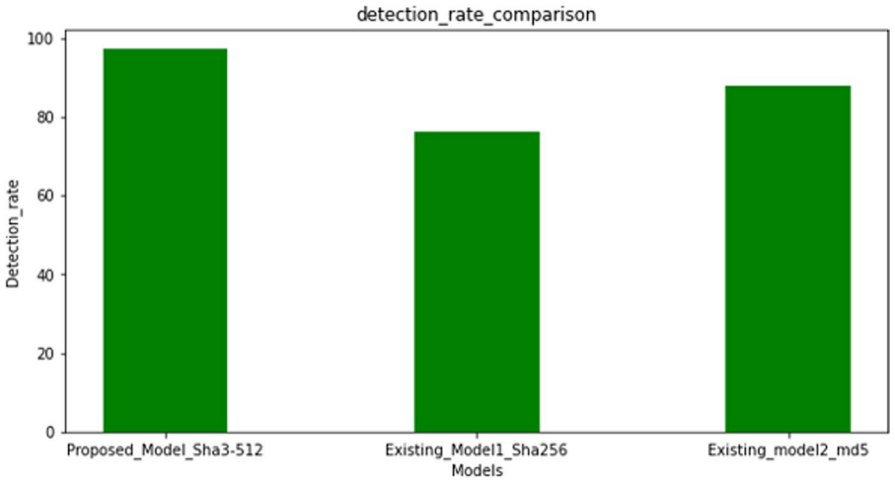

Fig. 6 Detection rate of different hashing models

of its vulnerabilities and SHA-256 is mostly preferred as an alternative. Snort is one of the widely used open source IDS which provides network traffic information in real time. One of the main functionality of Snort emerging threats rule set (Snort (ET rule set)) is its updated set of rules which improves the intrusion detection capability of Snort. The Snort(Custom rule set) helps the researchers to customize the IDS based on their requirements. This enables the model to detect threats precisely and respond to the threat. The custom rule set provides proactive security measures and strengthens the security of the organization in terms of addressing their concerns. A hypervisor-based IDS operates at the hypervisor level by exploiting the advantages of the virtualization technology for monitoring and detecting malicious activities in the virtualized environments. It is mainly designed to provide a comprehensive analysis of the security threats and protect VMs running on hypervisors.The outcome of the comparative analysis is tabulated in Table 2.

The graphs depicting the DR, FPR and computational time are discussed in the following Figs. 6, 7, 8.

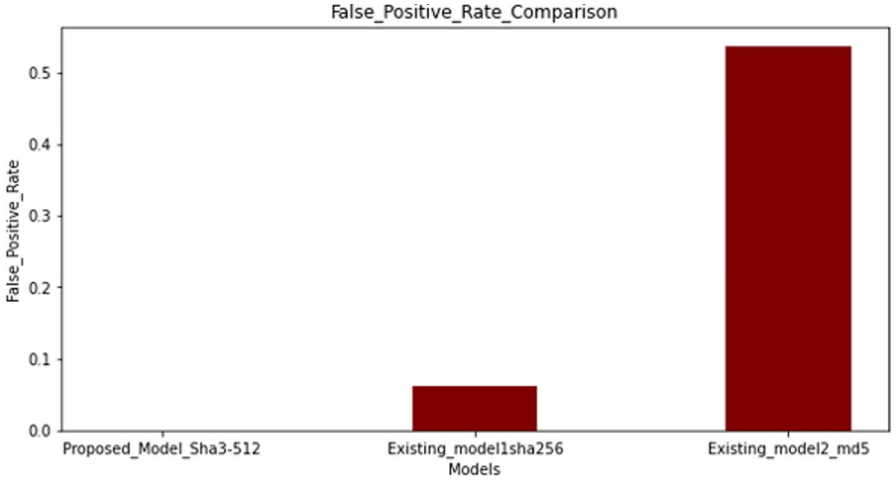

Fig. 7 FPR of different hashing models

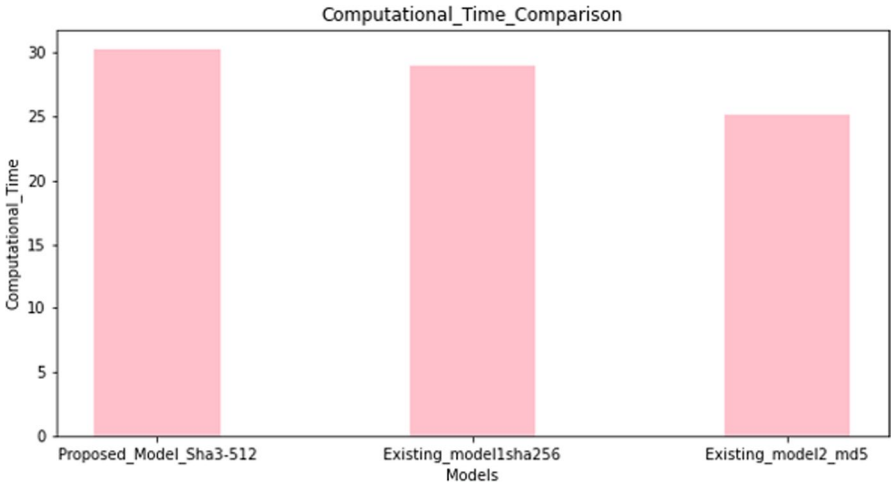

Fig. 8 Computational time taken by of different hashing models

It can be inferred from the results of the comparative analysis that the proposed SHA3- 512 hashing algorithm achieves a DR of 97.24% with zero FPR and faster computational time. The model takes only 30.26 s for executing the hashing process. On the other hand, the MD5 algorithm performs better compared to SHA 256 algorithms by achieving an attack detection rate of 87. 93% with a FPR of 0.53. However, the performance of SHA 256 algorithm is better with respect to FPR. It achieves a FPR of 0.06 which is very less compared to SHA 256 hashing algorithm. In terms of hierarchy, it can be inferred that the performance of the existing SHA3- 512 hashing algorithm is better compared to the other two algorithms.

The SHA-3-512 algorithm is inherently more computationally efficient. This cryptographic hashing method simplifies the detection process, reducing the computational time and resources needed. Our evaluation has demonstrated that the SHA-3-512 algorithm not only achieves superior detection rates and lower false positive rates but also completes the hashing process in a much shorter time frame, specifically in 30.26 s. The performance of the proposed approach is also compared in terms of detection accuracy and the obtained results are tabulated in Table 3. The existing results mentioned in Aldribi et al. [2].

The detection comparison is schematically in Fig. 6.

Correspondingly, the global detection results that define the performance of the existing hypervisor presented in Aldribi et al. [2] and proposed hypervisors are tabulated in Table 4.

As inferred from the results tabulated in Table 4, the proposed hypervisor based on the profile matching technique achieves excellent results compared to existing hypervisors (Fig. 9).

5 Conclusion

This paper presents an SHA3- 512 hashing based profile matching approach for detecting unknown attacks. The proposed model works based on the profile length and profile data. As observed from existing literary works, there are several types of hashing algorithms employed for ensuring the confidentiality and authentication of the information. Few hashing algorithms such as variants of SHA have proven their ability to provide security to the information. However, this research implemented SHA3- 512 algorithm to avoid the effect of collision. A comprehensive review of existing algorithms was conducted and it was observed that most of the existing algorithms are computationally intensive. In addition, the paper also reviews other hashing techniques such as AES, DES, which were discussed in the existing literary works. Based on the observations, this study concludes that the hash function is highly efficient and is capable of satisfying the requirements for attack detection such as data confidentiality, and authenticity. The effectiveness of the hashing technique was determined using three different evaluation metrics namely attack DR, FPR, and computational time. Simulation results show that the existing SHA3- 512 algorithm detection rate of 97.24% with zero false positive rate and faster computational time compared to SHA 256 and MD5 algorithms. Results validate the efficacy of the SHA3- 512 algorithms in terms of detecting unknown attacks compared to existing hypervisors and Snort techniques. While this study demonstrates the efficacy of the SHA3-512 hashing based profile matching approach for detecting unknown attacks in static environments, several limitations and opportunities for future work are identified. One notable limitation is the current focus on static environments, which may not fully capture the dynamic nature of modern networks, such as IoT environments where devices and threats evolve rapidly. To address this, future research could extend the SHA3-512 approach to dynamically adapting environments by developing algorithms that can effectively handle changing network conditions and evolving attack vectors in real-time. However, the evaluation primarily

Optimization

ABSTRACT

In lignocellulosic biomass, reducing structural recalcitrance and enhancing hydrolysis efficiency are crucial factors for increasing fermentable sugars and the production of valuable products. This biomass substrate comprises lignin, hemicellulose, and cellulose. In this study, response surface methodology was employed to optimise alkaline pre-treatment followed by enzymatic hydrolysis, aiming to enhance the saccharification of *Pistia stratiotes*. The NaOH concentration during pre-treatment significantly influenced the delignification process, resulting in increased cellulose content. The highest cellulose content was achieved with 2.47% NaOH at 120 °C for 60 min, leading to enhanced cell porosity and facilitating greater enzyme saccharification accessibility. Under these optimized conditions, the sample exhibited a 51.66% cellulose content. The physicochemical characteristics of the cellulose obtained after pre-treatment were analysed using SEM, FTIR, and TGA. After enzymatic hydrolysis of the cellulose with a commercially available cellulase enzyme, 31.06 g/L of reduced sugar was produced after 72 h. This study demonstrates that alkaline pre-treatment of *Pistia stratiotes* significantly increased its cellulose content, leading to a higher sugar yield during enzymatic hydrolysis.

1. Introduction

The primary issue facing the ecological niche that negatively affects aquatic and terrestrial life systems is environmental pollution. Fossil fuel consumption is the primary source of this pollution. The majority of environmental contaminants are hydrophobic so that they dissolve slowly in the water, which restrict microorganisms to utilize them as carbon source.(Gu, 2016).

The need for energy has grown significantly in recent years, placing additional strain on the use of fossil fuels, a resource that is running out quickly. In order to meet the demands of the world's expanding population, significant production and resource extraction will continue to accelerate due to the rising consumption of natural resources, particularly the non-renewable ones, which power most countries' economies today (Gu, 2020). Many scientists are employed worldwide in the field of waste-based renewable energy production By using greener and more innovative methods, renewable energy sources are displacing fossil fuels. Biofuel is a form of renewable energy obtained from sources such as agricultural waste, food waste, algae and municipal waste (Wannapokin et al., 2018). One likely way to achieve the Sustainable Development Goals (SDGs) is through the production of biofuels from lignocellulosic biomass (LCBs) (Nazari et al., 2021). LCBs contain secondary cell wall enriched with sugars that are feasible, sustainable and economically directed to the production of valuable products such as biofuels, polymers and biochemicals (Culaba et al., 2022). Currently United States and Brazil are front runners in bioethanol production using corn as a substrate, thereby creating the deficiency of food crops (Tse et al., 2021). Both on land and in water, a variety of invasive species can be used as a substrate for the long-term, sustainable production of valuable products. These lignocellulosic invasive weed species serve as an alternative to food crops in the same capacity. A lot of work has gone into using terrestrial lignocellulosic substrates to produce reduced sugars that microbes can use to produce biofuels and biogas (Moerman, 1996). The inability of lignocellulosic biomass to grow quickly due to a lack of agricultural resources and land presents a barrier to the industrial production of bioenergy (Chen et al., 2015). Aquatic biomass could be utilised as a substrate for the synthesis of biofuel to address the aforementioned issue. The advantage of aquatic weed over terrestrial lignocellulosic biomass is its lower lignin content and faster growth rate. Because of their components, a variety of aquatic plants have the

potential to produce bioethanol.

Pistia stratiotes (water lettuce) is a monocotyledonous weed found in fresh water. It can obstruct the water channel due to its dense growth connected with the root nodules. This weed's primary drawback is that it can deteriorate the quality of the water, which is why it's considered an invasive weed. When used as a substrate for the production of bioethanol, this weed's drawback can be turned into a useful resource for financial gain (Jayanth, 2000). Early in the 1990s, *Pistia stratiotes* was discovered to be a valuable carbon source for the creation of products like biogas. In addition to the weed's anaerobic digestion, which yields biogas, continuous fermentation also forms an alternative by producing bioethanol. (Yang et al., 2022). Harvesting the aquatic weeds is the first stage in turning them into biofuels. Compared to alternative strategies, mechanically more efficient methods can be used to remove these weeds (Alam et al., 2021).

Lignocellulosic substrates are highly recalcitrant as a consequence of lignin along with cellulose and hemicellulose in the cell wall of plants. For the saccharifying enzymes to access the substrate, this is a significant barrier. Pre-treatment is necessary to get rid of lignin and hemicellulose and make cellulose more accessible to hydrolysing enzymes in order to improve the saccharification from lignocellulosic biomass (Fillat et al., 2017). Pre-treatment raises the biomass porosity by eliminating lignin and hemicellulose (Asghar et al., 2015). Pre-treatment can be categorized as biological (fungi) like white-rot fungus (Saha et al., 2016), physical (milling, extrusion, microwave heating), chemical (alkali, acidic, ionic, and with organic solvents) and physiological (CO_2 explosion and wet oxidation)(Aguilar-Reynosa et al., 2017). However, none of these meet the requirements in terms of inherent advantages and drawbacks. Thus, to improve the effectiveness of the conversion process, a valuable pre-treatment procedure is evaluative. When fungi are co-cultivated during a biological pre-treatment, their combined growth can sometimes inhibit the growth of the individual fungi, but it also has a synergistic effect on lignin degradation and the expression of lignolytic enzymes (Meehnian et al., 2017).

Alkaline pre-treatment is a more intently studied technique and has many advantages, such as effective lignin solubilization in contrast to other pre-treatments. Alkaline pre-treatment is used for delignification with minimal loss of reduced sugar and unescorted by inhibitory compound formation (Alvira et al., 2010). Saphonication and solvation are the causes of swelling in alkaline pre-treatment. The lignin and hemicellulose eater bonds break down as a result of the saponification reaction. The surface area of cellulose increases as the polymerization and crystallinity decrease as a result of the swelling of the biomass. Alkaline concentration, reaction temperature, and reaction time are some of the parameters that need to be optimized in order to get the most out of the alkaline pre-treatment (Kim and Han, 2012).

Response surface methodology (RSM), a statistical tool, is used for the optimization process, which involves combining the results of each experiment to optimise multiple variables under various experimental conditions (Ali et al., 2015; Manmai et al., 2020). It is a statistical tool that draws on scientific techniques such as analytical and classical methods, producing responses that are influenced by a variety of variables and that ultimately relate to optimization. Numerous lignocellulosic biomass, including rice straw grass, switchgrass, and corncob, are optimized using RSM (Başar et al., 2021; Gundupalli et al., 2022; Selvakumar et al., 2022). The most popular and frequently utilised RSM design is the central composite design (CCD). Enzymatic hydrolysis requires cellulase enzyme for conversion of cellulose into reduced sugar. The source of carbon has the lowest concentration limit at which the balance between newly produced and dead cells keeps the amount of living cells relatively constant (Gao and Gu, 2021).

Therefore, the main goal of this investigation was to optimise the alkaline pre-treatment of *P. stratiotes* starting from raw material to enzymatic hydrolysis. To our knowledge, no pretreatment study on *P. stratiotes* has been reported. The content of cellulose is affected by three distinct factors: temperature, time, and alkali concentration. Central composite design (CCD) and factorial design were used to optimise the pre-treatment process. Fourier transform infrared spectra (FTIR), thermogravimetric analysis (TGA), and scanning electron microscopy (SEM) were used to further characterise the recovered cellulose fraction following the pre-treatment. The commercially available cellulase enzyme was used to hydrolyse the recovered solid fraction (cellulose). The estimation of reduced sugar was computed after hydrolysis. It is possible to conclude from the study's observations that this is the first study to optimise the alkaline pre-treatment of Pistia stratiotes using RSM, resulting in a higher cellulosic content.

2. Materials and methods

2.1. Collection and preparation of sample

Pistia stratiotes, commonly known as water lettuce, were harvested in August 2022 from a local pond in Delhi, India's Hauz Rani City Forest (28.51590 N, 77.21110 E). The harvested material included all plant parts: roots, stems, and leaves, with an average plant size of 35 cm. Subsequent to collection, the sample underwent a dual cleansing process with tap water to eliminate any impurities. Following this, it was allowed to air-dry for 48 h at room temperature. The air-dried sample was further dehydrated in an oven at 45 °C overnight and subsequently ground using a grinder. The resulting finely ground sample was stored in an airtight polybag for future use.

2.2. Sample composition analysis

2.2.1. Quantification of cellulose

To estimate cellulose content, the Updegraff method was employed. Initially, for washing 70 mg sample was incubated in 1.5 ml of 70 % ethanol at 70 °C for 1 h and then removed out ethanol by an aspirator twice. After that 1 ml of acetone was added for 2 min and then aspirated out and put the sample in a fume hood for 3–4 h, keep the sample in the oven at 37 °C overnight, resulting in what is known as alcohol-insoluble residue (AIR). This sample was stored at room temperature for further use. This AIR was then subjected to a 30-min treatment at 100 °C in a water bath using 3 ml Acetic nitric reagent (80% glacial acetic acid: 10 % nitric acid: 20 % Milli-Q). Following this treatment, the sample underwent rinsing with ethanol and water until cellulose became apparent. After that 4 ml acetone was added to the sample and evaporated in a fume hood. The resulting residue was subsequently placed in an oven overnight at 37 °C. Subsequently, 1 ml of 67 % H_2SO_4 was added to the sample, and the mixture was placed in a shaker for thorough mixing. After the cellulose was effectively mixed with the acidic solution then glucose standards were made from 100 mg/ml stock solution. Anthrone reagent was prepared by mixing 0.3 % anthrone in H_2SO_4. For testing 500 μl sample and blank take out in the Eppendorf and add 1 ml anthrone reagent in each, now boil each for 5 min and take the OD at 620 nm. The anthrone test was employed to estimate the amount of glucose present in the cellulose (Kumar and Turner, 2015).

2.2.2. Hemicellulose and lignin

The fibre analysis method was used to estimate hemicellulose. This methodology starts with the estimation of neutral detergent fibre (NDF), moves on to the calculation of acid detergent fibre (ADF), and subtracts ADF from NDF to find the concentration of hemicellulose (Holtzapple, 2003). National Renewable Energy Laboratory (NREL) protocols are followed for the lignin estimation. The first step in this process was the extraction of the sample with the help of milli Q water using probe sonicator (Branson Sonifier W450 Digital, tip size 6.5 mm) (Zhou et al., 2017). The resulting extracted sample was treated with 72 % H_2SO_4 in the water bath for 1 h. It was then diluted with 4 % milli Q and autoclaved for 1 h at 121 °C and 15 psi. After that, the sample was filtered using a vacuum filtration unit in a crucible that had been preheated. After being dried at 105 °C for 4 h, the residue was weighed and

designated as acid-insoluble residue (AIR). Then the crucible was transferred into muffle furnace at 575 °C for 24 h and weighed once more. The outcome obtained after burning the sample in the muffle furnace gives % of ash in filter (Xia et al., 2022). Acid-soluble lignin was calculated by measuring absorbance at 280 nm (Nomanbhay et al., 2013). All the calculations were performed using the formulas mentioned below Eqs. (A.1, A.2 and A.3).

Eq.(A) was used to calculate the lignin.

$$\%\ AIR = \frac{(Crucible\ plus\ AIR\ weight - Crucible\ weight)}{Sample\ loading\ in\ Crucible} \times 100$$

$$\%\ Ash\ in\ filter = \frac{(Crucible\ plus\ ash\ weight - Crucible\ weight)}{Sample\ weight} \times 100$$

$$\%\ Acid\ insoluble\ lignin = \%\ AIR - \%\ Ash\ in\ filter \quad \text{Eq.(A.1)}$$

$$\%\ Acid\ soluble\ lignin = \frac{UV_{absorbance\ (280nm)} \times Voulme\ of\ filtrate \times dilution}{Absorptivity \times dry\ weight \times pathlength} \quad \text{Eq. (A.2)}$$

$$\%\ Lignin = \%\ Acid\ insoluble\ lignin + \%\ Acid\ soluble\ lignin \quad \text{Eq. (A.3)}$$

2.3. Sample characterization

2.3.1. Fourier-transform infrared (FTIR) spectroscopy

The changes in functional groups after alkaline pre-treatment were determined through the use of FTIR spectroscopy (PerkinElmer 400 FTIR/FTIR). With the control sample, the spectra span the frequency range of 4000 cm^{-1} to 400 cm^{-1}. Pellet preparation involved the use of potassium bromide (KBr), and scanning was done at a resolution of 4 cm^{-1} (Kataria et al., 2018a).

2.3.2. Thermogravimetric analysis (TGA)

The TGA of raw and alkaline pre-treated samples was performed by PerkinElmer TGA 4000. The samples were heated using a nitrogen flow rate of 10 mL/min and a heating range of 10 °C min^{-1} from room temperature to 600 °C (Kataria et al., 2018b; Umesh et al., 2022)

2.3.3. Scanning electron microscopy (SEM)

The changes in surface and fibre morphology of pre-treated sample were examined using Scanning Electron Microscopy (SEM) (Model: EV018 Zeiss, Germany) with 5 kV voltage at 10,000× magnification. SEM analysis was used to identify the structural alterations following cell wall breakdown (Umesh et al., 2022).

2.4. Optimization of pre-treatment using RSM

RSM is a multivariant statistical tool that provides a new approach for determining the ideal pre-treatment state. Design Expert software assisted in the development of a central composite design, which was used to determine the effects of various independent variables on cellulose extraction. Temperature (60, 90, and 120 °C), time (30, 45, and 60 min), and NaOH concentration (0.5, 1.75, and 3 %), were the variables. RSM was responsible for determining the results. The variables in this model were represented by codes, which were represented by the numbers −1,0, and 1. The neighbouring distance from the value of the central point determines how variables are coded. The experiment's independent variables, such as the temperature, time, and NaOH concentration, were transformed into code variables Xi (Eq. (B.1))

$$Xi = 2\left(\frac{OV - V}{\Delta}\right) \quad \text{Eq. (B.1)}$$

Equation 2 comprises the following terms:

Δ (difference between largest and smallest values (range)), OV (original variable), and V (average of the largest and smallest values of variables or mid value). Three independent variables with lower and higher levels are mentioned in Table (A.1).

2.4.1. Statistical analysis and model fitting

The statistical tool known as Analysis of variance (ANOVA) was employed for divination of the statistical factors required in the assessment of the RSM model between the independent variables and response of parameters. Utilising the software Design Expert, regression analysis of trial data was employed to generate the contour plot, pareto chart, and optimized condition. The influence of independent variables on the cellulose concentration is shown by the contour plot and pareto chart. The outcome of the model predicted statistically significant values by F test and p value. If the value was less than 0.05, then the model was stated as statistically significant with lack of fit test that is insignificant in the same model. Independent factors significantly impacting the response were determined by p test value less than 0.05 with confidence level above 95 %. Significance of the model was accessed by R^2 predicted and R^2 adjusted value (Ramaraj and Unpaprom, 2019). To determine the ideal condition divided into linear, quadratic, and interactive components, the effects of independent variables on the dependent variable (response) were estimated using a polynomial equation. Eq. (C.1) displayed the entire cellulose concentration estimation.

$$Y = \beta_o + \sum_{i=1}^{k} \beta_i X_i + \sum_{i=1}^{k} \beta_{ii} X_i^2 + \sum_{i<j}^{k} \beta_{ij} X_i X_j + \epsilon \quad \text{Eq. (C.1)}$$

where Y is the predicted response (cellulose concentration); β_o the intercept; β_i the linear constant; β_{ii} the quadratic coefficients; β_{ij} the interaction effect of coefficients; X_i and X_j the coded values used for variable parameters; and ϵ is the random error (Dahunsi et al., 2019).

2.5. Enzymatic hydrolysis

After pre-treatment, 10 ml of citrate buffer (0.05M, pH 4.8) was added to 150 ml test tubes containing 0.5 g of both pre- and untreated samples for enzymatic hydrolysis. The commercially available cellulase enzyme (40000 U/g) was sourced from IndiaMart, and the Filter Paper Unit (FPU) was calculated following NREL protocols. The cellulose loading was adjusted to 25, 50, and 75 FPU/g of dry biomass.

The hydrolysis was carried out in an incubator shaker (New Brunswick Innova 44 series, Germany) with a rotation speed of 150 rpm for 96 h at 50 °C. Samples were withdrawn at 24, 46, 72, and 96 h. The reducing sugar was quantified using the DNSA method as described by Liu et al. (2021). After enzymatic hydrolysis, the sugar yield was determined using Eq. (D.1), and each experiment was conducted in triplicate.

$$Sugar\ yield\ (\%) = \frac{0.9\ X\ reducing\ sugar\ \left(\frac{g}{L}\right) X\ volume\ (L)}{solid\ cellulose\ fibre\ wt.\ (g)}\ X\ 100 \quad \text{Eq. (D.1)}$$

2.6. Reducing sugar extraction

The 3, 5-Dinitrosalicylic acid (DNSA) method was used to estimate the total amount of reducing sugar (Miller, 1959). After preparation of DNSA reagent (10 g 3,5 DNS, 0.5 g sodium sulphate, 182 g sodium potassium tartrate, 10 g sodium hydroxide and 2 g phenol in 1 L), it was kept in an amber bottle for storage. For the standard curve, a stock solution of glucose standard was prepared. Initially, 1 ml DNSA reagent was added to the sample, glucose standards and a blank and put in the water bath and left for 15 min. Then the samples were removed from the water bath and 5 ml milli Q was added for dilution to take the OD of each sample to quantify reduced sugars, the optical density of the samples was measured at 540 nm using a glucose standard.

3. Results

3.1. Composition analysis of the sample

P. stratiotes can be used as a good carbon source for the production of value-added products. In the raw sample, the estimated contents of cellulose, hemicellulose, and lignin were 25.90 %, 18.44 % and 25.25 % respectively. The composition analysis proves that in this weed, a high amount of cellulose content was found compared to hemicellulose and lignin. After the chemical pre-treatment, the composition analysis showed that it might be a useful carbon source for the production of bioethanol. By applying the alkali pre-treatment to remove the lignin content from the raw sample, the cellulose content could be increased.

3.2. Optimization of alkali pre-treatment and validation

After pre-treating *P. stratiotes* with alkali (NaOH), which had an impact on the raw material's depolymerization, cellulose was the final product, with lignin removed. The reduced sugar obtained from the hydrolysis of cellulose can be used to further produce ethanol. The best conditions were achieved by optimising biomass using RSM, which is 2.47 (w/v) NaOH at 120 °C for 60 min after autoclaving. The optimal condition gives the result of 51.66 % cellulose. The result of the alkali pre-treatment under various conditions is cellulose, which is shown in Table (A.2).

The factors that affect the expected changes in the mean response when the factors change from a lower to a higher level, which also establishes the coded coefficients. The alkali concentration shows major positive impact so that this parameter has an effect on increased response (cellulose concentration) proceeding from 0.5 % to 3 %. If the alkali concentration is higher, then the cellulose concentration will also be enhanced. However other factors like time, temperature, alkali conc. *alkali conc. And alkali conc.*time, shows the negative sign which successively impacts on reducing the response.

Table (B) illustrates an ANOVA statistical model for cellulose estimation from CCD. ANOVA and the lack of fit test are used to analyse the model's fitness. When the experimental data fits the model, significant regression and non-significant lack of fit are displayed. This model's statistical advantage was evaluated and attributed to the interactions between the model's factors and p-value. Table (B) shows that the model's p-value for cellulose concentration is 0.000, which is less than 0.050 and suggests that the response to the model is substantial and meaningful. The model is considered highly significant when the p-value is less than 0.001. A p-value greater than 0.1 indicates that the model is not significant. However, because of the large f value (53.79), the model result has a significant impact on the response. This f-value is probably going to demonstrate the significance of the model. There is only a 0.01 % chance in the statistical model that a large f value could arise from (Pashaei et al., 2020).

3.2.1. Model summary

The adjusted R^2 of 96.15 % and the predicted R^2 value of 92.48 % agree rationally, indicating a difference of less than 4 %. This result demonstrates that this model can accurately represent the percentage of cellulose extraction from *P. stratiotes* and can be shown as coded variables, as shown in Eq. (E.1).

3.2.2. Regression equation in Uncoded units

Cellulose = 64.90 + 12.18 Alkali conc. - 0.986 Time - 0.697 Temp.

−2.409 Alkali conc.*Alkali conc.+ 0.00465 Time × Time +0.001267 Temp.*Temp.

−0.1395 Alkali conc.*Time +0.0675 Alkali conc.*Temp. +0.01109 Time × Temp. Eq.(E.1)

3.2.3. Contour plot

The contour plot describes the impact of different variables on the response, and change in cellulose content depending on the temperature and time). The effects of temperature and time on cellulose are interpreted in Fig. (A.1). A notable increase in cellulose is seen as a result of the temperature rising over time. A rise in cellulose content of more than 50% was noted after 55–60 min at 110–120 °C. Conversely, after pre-treatment, a higher amount of cellulose content is obtained by raising the temperature and alkali concentration. The maximum cellulose content, or >50%, is achieved at 120 °C and >2.5 % alkali content, as Fig. (A.2) illustrates.

3.2.4. Pareto chart

The Pareto chart was used to clearly illustrate the significance and magnitude of the impact of independent variables on response. The complete values of the regulated effects, arranged from highest effect to lowest effect, are shown in the Pareto chart. The chart's reference line indicates statistical significance for the effect. The statistical significance is shown by the bar that crosses the reference line. The cellulose Pareto chart is shown in Fig. (A.3). This chart indicates that the parameters are statistically significant because of time × temperature (BC), alkali conc.* time (AB), alkali conc.* temp. (AC), alkali conc. (A), alkali conc.* alkali conc. (AA), temp. (C), and time (B) cross the reference line.

3.2.5. Response (cellulose) optimization

The response observed in the complete process was cellulose. After statistical analysis of the optimization model, the target cellulose content was 50.87 %, and the objective was to maximise the cellulose outcome with a lower cellulose content of 21.17 %. The ideal condition was discovered at 2.4 % alkali concentration with 60 min at 120 °C temperature after multiple responses. Post the optimization experiment the cellulose fit was 51.65 % with 1 % composite desirability.

3.2.6. Response outcome

RSM was used to determine the response (cellulose content) outcome, and it fit 51.66 % of the cellulose content with a standard error of 1.06. With a prediction interval ranging from 47.92 to 55.39 %, the confidence interval fell between the range of 49.92–54.01 % cellulose content.

3.2.7. Multiple response prediction

The optimized condition was discovered through multiple response prediction after carrying out a series of experiments. All variables were then fixed, and after 60 min at 120 °C, the maximum cellulose content was discovered at 2.46 % alkali content.

3.2.8. Optimization plot

Optimization of alkaline pre-treatment was performed, optimized condition considered at 2.47 % NaOH, 120 °C with 60 min. This optimized condition was performed separately to check the reliability. After performing the optimized condition, 51.67 % cellulose was found in the hydrolysate which shows the reliability of the model. A model created by Minitab software in which independent variables are adjoined to estimate the target response. Combined desirability ranges from 0 to 1 are helpful for the calculation of optimization. Cellulose has an independent desirability outcome of 1.0 as a predicted outcome of 51.65 %. The separate desirability of 1.0 is an excellent score which shows that response is immediate to their absolute setting. The optimization of response (cellulose) gives an ideal desirability score as cellulose was an absolute setting that is included in the justifiable range. The optimized condition established after the RSM model is represented in Fig. (A.4).

3.3. Effect of cellulase loading on enzymatic hydrolysis

A comparison of the pre-treated and raw samples' enzymatic hydrolysis shows promising results following pre-treatment. 25 FPU, 50 FPU, and 75 FPU cellulase loadings are used to hydrolyse the raw and pre-treated samples in a shaker at 150 rpm and 50 °C. The sample that was pre-treated and hydrolyzed by 50 FPU of cellulase, displayed a maximum concentration of 25 g/L of sugar reduction (fig. (B.2). With an enzymatic activity of 75 FPU, the pre-treated sample's maximum reduced sugar of 33.62 g/L was formed in 72 h. After 72 h, the pre-treated sample's maximum sugar yield was discovered, with 75 FPU enzymatic activity of 60.53% (Fig. (B.2). In contrast, under the same conditions, the raw sample yields 6.68 g/L of reducing sugar with 50 FPU in 72 h following hydrolysis. With 75 FPU, the maximum reduced sugar of 11.56 g/L was formed in 96 h. After 96 h, the raw sample's maximum sugar yield of 20.80 % was formed, with an enzymatic activity of 75 FPU Fig. (B.1). It demonstrates how successful the pre-treatment is when hydrolysis occurs. Mass balance of the complete study was determined by the total product formation from the substrate (Njoku et al., 2013). The mass balance is shown in Fig. (C).

3.4. Improvisation of the raw and treated sample

3.4.1. Phonological modulation in raw material (SEM analysis)

The sample's initially smooth surface transforms into a rough texture under the influence of elevated temperatures and alkaline conditions, causing the breakdown of cellulose and hemicellulose bonds upon lignin removal. This alteration increases the surface area of the biomass, enhancing its accessibility to enzymes, as demonstrated by Kataria et al. (2017). Post-alkaline treatment, noticeable structural changes in the untreated sample are evident, as depicted in Fig. (D). Comparative analysis with the untreated raw material reveals a more pronounced disruption in the sample following alkaline pre-treatment. In Figure (D.2), the most significant disruption is observed after alkaline pre-treatment. Notably, severe conditions (3 % NaOH concentration) also exhibit substantial disruptions, as illustrated in Fig. (D.4) In contrast, mild pre-treatment conditions (0.5 % NaOH concentration) are shown in Fig. (D.3).

3.4.2. FTIR spectrum of the untreated and treated sample

The functional group and its properties are specifically revealed by the FTIR spectrum. The treated sample's FTIR spectra (Fig. E.1) showed a broad, highly intense peak spanning 3500–3200 cm^{-1} that indicated N–H stretching of primary amines, an increase in free O–H bonds as a result of extractives being removed, and the presence of cellulose (Lu and Hsieh, 2010). When the sample is left untreated, an ester bond-related band at 1740 cm^{-1} indicates that the polymer within is mutually interconnected; however, when the sample is treated with alkali, xylose solubilization takes place and the band vanishes (Sills and Gossett, 2012). The treated sample exhibits more intense peaks at 1430 cm^{-1} and 1320 cm^{-1}, which correspond to C–H_2 and C–H bending, respectively, in relation to cellulose (Sombatpraiwan et al., 2019). The hemicellulose acetyl ester's stretching vibration is reduced in the treated sample, indicating the removal of the xyloglucan acetyl group with the COOH group from the lignin hemicellulose matrix. This is represented by the peak at 1231 cm^{-1} (Trevorah and Othman, 2015) 2015. The peak at 1024 cm^{-1} represents polysaccharides. The treated sample has high intensity at this region because of C–O, C═C, and C–C–O stretching for polysaccharides, which correlate with hemicellulose decomposition (Bano and Irfan, 2019). The aromatic band ranges from 950 to 700 cm^{-1}, which corresponds to the β-glycosidic linkage in cellulose and hemicellulose units (Gusain and Suthar, 2017). Due to C–O–C stretching in the β-glycosidic linkage in cellulose and hemicellulose, which makes cellulose accessible to enzymes, the intensity of the peak at 880 cm^{-1} increases in the treated sample (Deng et al., 2019).

3.4.3. Thermogravimetric analysis (TGA) and differential thermogravimetric analysis (DTG)

Fig. (E.2) shows the thermogravimetric analysis of the untreated sample (raw), mild (0.5 % NaOH conc., 30 min and 60 °C), harsh (3 % NaOH Conc., 60 min and 120 °C), and optimized pre-treated condition (2.47 % NaOH conc., 60 min and 120 °C) to determine their degradation characteristics at 0–600 °C. During the TGA analysis shown in Fig. E.2, four distinct types of weight reduction were observed in *Pistia stratiotes*: moisture, cellulose, hemicellulose, and lignin reduction. Water evaporation causes weight loss to begin at 100 °C. At 200–300 °C, hemicellulose depolymerizes and breaks down its cellulosic glycosidic bonds. Water loss causes a mild, raw sample to lose 10–12 % of its weight between 100 and 200 °C. Unexpected weight loss of approximately 50 % was noted in all samples between 250 and 350 °C as a result of hemicellulose, cellulose, and lignin degradation. Lignin breaks down between 200 and 500 °C. The primary thermal degradation region was observed to be between ~325 and 345 °C, indicating the degradation of cellulose and lignin in the sample. (Basak et al., 1993). The range of 200–500 °C was where the optimized condition's 55 % weight loss occurred. This indicates the sample's delignification and is the result of the alkaline pre-treatment. The optimized sample's DTG curves show a peak at 345 °C, respectively, with the hydrolyzed sample showing the strongest signal because of its higher cellulose content. The raw material's maximum thermal stability, which corresponds to its non-cellulosic content, was measured at 325 °C. Fig. (E.3) illustrates the optimized sample's high thermal stability, with the DTG curve indicating a maximum stability temperature of 345 °C. The optimized sample's degradation temperature is higher than that of other lignocellulosic materials that have been reported, such as Napier grass (300 °C) (Reddy et al., 2018), roselle fibres (326 °C)(Kian et al., 2017) and kans grass (340 °C) (Baruah et al., 2020).

4. Discussion

Biofuels can be produced from biomass, which is an environmentally friendly way to mitigate the energy crisis. The sustainable development goal is aided by the bioconversion of lignocellulosic biomass into biogas and biofuel, which lessens the carbon footprints. Lignocellulosic biomasses are composed of lignin, hemicellulose, and crystalline cellulose. Unlike the first generation, which used sugar directly, intrinsic biomass recalcitrance significantly hinders lignocellulose's bioconversion by protecting carbohydrates from degradation. The recalcitrance of wrapped cellulose significantly hinders the recovery of fermentable sugar from it. These types of biomass degrade slowly, so effective pre-treatment and enzyme dosage are necessary (Hu et al., 2023a). Pre-treatment is a crucial stage in the bioprocess technology process as a whole. In modern biorefineries, various pre-treatments such as physical, chemical, and biological are used to overcome the recalcitration of lignocellulosic biomass (Mankar et al., 2021). Physical pretreatment is used to reduce the size of particles and increase the surface area of lignocellulosic biomass by disrupting of structure of cellulose, hemicellulose and lignin for accessibility of enzymes e.g. grinding (Ji et al., 2017) Chemical pretreatment is more effective for increasing the hydrolysis and it is a simple procedure with high efficiency. Different chemicals are used in this process like acids, alkali, organic solvents and ionic liquids, all of these can break down the lignocellulosic biomass. Acidic pretreatment is specific for lignin degradation by using different concentrations of acid, reaction time and temperature. The disadvantage of this pretreatment is its ineffectiveness in the lignin removal and stopping its hindrance effect on cellulose (Rodrigues Gurgel da Silva et al., 2019). Alkali pretreatment is helpful for lignin and hemicellulose removal and increases the accessibility to the enzymes for hydrolysis with a high reduced sugar yield. The expensive neutralization and secondary contamination are its drawbacks (Malik et al., 2020) Ionic liquids are advantageous over acids with non-flammability, thermal stability and chemical adjustability (Abushammala and Mao, 2020).

Biological methods use fungi and bacteria, its advantage over other methods is the low cost of the downstream process, simple procedure, and low energy consumption. The drawback is its low-efficiency limit and time-consuming process (Rezania et al., 2020)(Li et al., 2022). Lignocellulosic biomass includes corn stover, which undergoes enzymatic hydrolysis and pre-treatment before being transformed into a value-added product (Li et al., 2017). One abundant and renewable feedstock for making biofuels is grass. Its growth cycle is short, with low lignin content, and its crystallinity is also less. However, getting a high yield of biofuels from grass is difficult due to the stiff cellulose-hemicellulose-lignin network that resists enzyme attack. Consequently, various pre-treatment methods have been applied to different types of grass in order to boost the yield of biofuels (Jin et al., 2015). Due to their low lignin content, aquatic weeds are classified in the same category as grasses. Numerous aquatic weeds, such as *Eichhornia* sp., *Pistia stratiotes*, *Lemna minor*, and *Lemna gibba*, can serve as good carbon sources for the synthesis of biofuel (Gusain and Suthar, 2017). Each of these weeds has a different composition. According to a previous study, duckweed (*Lemna minor*) contains cellulose 55.2%, hemicellulose 32.6 %, and lignin 12.2% (Yadav et al., 2017). The composition of water hyacinth before pre-treatment showed 1.77% acid-soluble lignin, 6.33% acid-insoluble lignin, 32.84% cellulose, and 24.7% hemicellulose. The results of the thermal pre-treatment were different: by using the autoclave technique, 1.58% acid-soluble lignin, 8.35 % acid-insoluble lignin, 27.8% hemicellulose, 29.26% cellulose were formed (Barua and Kalamdhad, 2017). Organic waste also includes rice straw that is used to optimise the alkali pre-treatment process. The temperature, time, NaOH concentration, and solid loading were the independent variables. The sugar reached its peak at 121 °C, 40 min, 2% w/v NaOH concentration, and 5% loading. With 50.5 g/L of glucose, 13.5 g/L of xylose, and 1.3 g/L of arabinose, the maximum sugar content was 65.3 g/L(Valles et al., 2021). A comparative investigation of diverse chemical pretreatment was performed on sorghum straw. Six different pretreatment were applied to it, namely, 2 % (w/v) NaOH, 2 % H_2SO_4, 2 % (w/v) Na_2CO_3, 2 % (w/v) oxalic acid, 2.15 % (w/v) H_2O_2 and 95% (v/v) glycerol pretreatment. In this study, 2 % NaOH pretreatment was most effective for lignin removal and enzyme-mediated hydrolysis process (Bhati and Sharma, 2023). Another optimization of alkaline pretreatment by central composite design with enzymatic hydrolysis study was performed on the cocoa pod husk. The optimal condition was 5%(w/v) NaOH for 30 min at 120 °C increased the content of cellulose from 27.68 (untreated) to 57 % and then enzymatic hydrolysis was performed resulting in 66.80 g/L reducing sugar yield up to 98.75 % (Hernández-Mendoza et al., 2021) which is high from our study. When alkaline pretreatment was done on the *Brassica juncea* with a low concentration of NaOH (0.5 M) at 160 °C for 30 min with 10 % loading. The delignification occurred in the sample and then enzymatic hydrolysis was done by the mixture of cellulase obtained from *A. niger* MTCC284, *T. harzianum*MTCC8230 and *F. incarnatum*KU377454. Then 62.35 mg/ml reduced sugar was formed after hydrolysis in 48 h at 50 °C with 15 % loading (Pant et al., 2021). Optimization of alkali pretreatment was performed with the help of response surface methodology and maximum cellulose content was formed by 2 % NaOH i.e. 62.7 % and highest 78.3 g/L glucose was obtained at 20 g/L enzyme loading with 50 °C for 72 h (Punia and Singh, 2024). Another study on *C. oleifera* fruit shell and its seed cake used as a substrate for enzymatic hydrolysis after oxalic acid pretreatment. SSF (Solid state fermentation) performance of *A. niger* with 50 °C at 200 rpm for 24 h gives 20.58 g/L reduced sugar which is less than our study (Dessie et al., 2024). *Pistia stratiotes* contains 49.4 % carbohydrates, 17.8 % fibres, and 16.5 % protein with 23.8 % ash content (Pantawong R., Chuanchai A., Thipbunrat P., Unpaprom Y., 2015). The cellulose content of *Pistia stratiotes* was extracted in a previous study under various conditions using bleaching agents. Four distinct conditions were used to optimise the pre-treatment: (1) 2% sodium chlorite + 2% glacial acetic acid; (2) 4% sodium hypochlorite; (3) 4% hydrogen peroxide + 4% sodium hydroxide; and (4) 4% soapnut solution. The results of all the conditions in the form of cellulose yield as a percentage were 38.92, 25.70, 10.7 and none in the fourth condition (Umesh et al., 2022). In another study, 1% alkali (NaOH) and 1% H_2O_2 were used to treat *Pistia stratiotes* and water hyacinth. Following this treatment, the cellulose results in water hyacinth increased from 19.7 to 34.2% and in *Pistia* from 16.5 to 28.4% (Mishima et al., 2008). After the Pre-treatment, besides ethanol, other solid-liquid products are also produced like foliar fertilisers, jet fuels and catalysts from the *Pistia stratiotes* (Yang et al., 2022). The optimization of pre-treatment was done on water hyacinth. Different acids like HCL/H_2SO_4/HCOOH (2% v/v) with varied concentrations were used such as 1%,2%,3% and 4% v/v to obtain a high amount of reduced sugar. Also, 3% v/v NaOH was used for alkali pre-treatment. The observed results gave maximum reduced sugar at 37.89 mg/100 ml filtrate with 4 % H_2SO_4 (dilute acid pre-treatment). With the alkali pre-treatment, 3% NaOH gave 17.185 mg/100 ml sugar concentration (Awasthi et al., 2013). In contrast, the highest amount of reduced sugar detected in our study was 33.62 g/L following 72 h of enzymatic hydrolysis. The pre-treatment of lignocellulosic biomass with enzymatic hydrolysis is crucial. The saccharification of cellulosic biomass or the low degradation of lignocellulosic biomass for the production of valuable products is the bottleneck in this field, necessitating the use of economically used enzymes that are effective in the saccharification process. Enzymes ought to be less expensive to produce at the industrial scale. The cost of using sugars from the lignocellulosic biomass reaches 25–30% of the total cost of producing biofuel (Hu et al., 2023b). Either commercially available or in-house-produced cellulase enzymes can be used for enzymatic hydrolysis. The primary source of fermentable sugars is plant cell walls. Certain bacteria possess the ability to break down cellulose, hemicellulose, and lignin. For example, the bacterium, *Trabulsiella* sp. is capable of efficiently breaking down the lignin model compound, guaiacylglycerol-β-guaiacyl ether (Suman et al., 2016). *Clostridium thermocellum* is an isolated bacteria which is capable for degradation of the cellulose and used for saccharification process. It is isolated by the goat rumen and is a thermophilic bacteria that is active at temperature of 50–70 °C and works on the agro-industrial waste (Hamann et al., 2015). Apart from bacteria, the fungus is also used for the production of enzymes. Different types of fungus used for the production of cellulase enzymes like *Aspergillus* sp. A1C2-06, *Talaromyces verruculosus* A1C2-05 (Fontes et al., 2023), *Aspergillus niger* (Sulyman et al., 2020) and *Trichoderma resei* (Wu et al., 2019). In the previous study, the *A.niger* produced enzymes by using the waste of *C. oleifera* as a substrate and the conditions were 50 °C at 200 rpm for 24 h and produced 20.58 g/L sugar (Dessie et al., 2024). Another study shows that using the same fungus stain and conditions were different than was at 50 °C at 150 rpm for 48 h on the wheat straw after thermal pretreatment produced 32.90 g/L sugar (Infanzón-Rodríguez et al., 2022) Commercially available cellulase enzymes suitable for the saccharification process are also reasonably priced. We employed the inexpensive, readily available commercial cellulase enzyme in our investigation to achieve successful saccharification results.

5. Conclusions

Alkali pretreatment of biomass is a crucial step for lignocellulosic biomass delignification. This lignin removal process results in the exposure of cellulose and the liberation of sugars. Depending on the type of plant biomass, pretreatment process need to be employed. In the present study, alkaline pretreatment was optimized for *Pistia stratiotes* biomass and 51.66 % cellulose was formed. The biomass characterization of pretreated biomass also revealed the delignification. The enzymatic hydrolysis was done after pretreatment by a commercially available enzyme which gives a maximum of 31.06 g/L reduced sugar with 75 FPU in 72 h. Hence, this renewable sugar obtained by hydrolysis may be employed for various microbial metabolites production such as ethanol, bioplastics, organic acids and different metabolites. This makes it a sustainable and cost-effective process.

Abstract

This study introduces a novel approach to enhance the durability and strength of concrete by integrating abrasion and cement slurry treatments on surface-treated recycled coarse aggregates (STRCA). Initial abrasion treatment removes aged mortar from the recycled coarse aggregate (RCA) surface, while subsequent cement slurry modification provides a fresh surface, reinforcing the bond with the concrete matrix. Through detailed material analyses including x-ray diffraction, scanning electron microscopy, and energy-dispersive x-ray, microstructural changes are evaluated alongside compressive strength, drying shrinkage, electrical resistivity, and chloride ion penetration of STRCA-based concrete. Results indicate significant improvements in mechanical properties and durability as the treatments eliminate mortar and enhance the interfacial connection with cement paste. Notably, a substantial 29.37% strength enhancement is observed at 25% replacement (STRCA 25), demonstrating treatment efficacy. While a reduction of 11.58% occurs at 100% replacement (STRCA 100), up to 75% replacement shows minimal strength loss, with optimal enhancements at 50% replacement. Additionally, STRCA concrete exhibits lower drying shrinkage (11%–20% reduction) and increased electrical resistivity (28%–36% rise), indicating improved durability at 100% replacement. Enhanced resistance to chloride ion penetration is also evident, with a 22%–28% increase at 100% replacement compared to conventional RCA. Overall, this study highlights the effectiveness of dual treatments for enhancing concrete properties using STRCA.

KEYWORDS

abrasion treatment, cement slurry treatment, concrete durability, microstructural characteristics, surface-treated recycled coarse aggregates

1 | INTRODUCTION

The confluence of economic expansion and urbanization has emerged as a driving force behind environmental degradation,[1] posing a formidable threat to sustainability.[2] The escalating demand for natural resources, particularly within the construction sector, has given rise to a significant volume of construction waste, often inadequately managed in landfills.[3,4] This pervasive waste, spanning diverse sectors, presents complex environmental

challenges.[5] Recycling emerges as a pivotal solution, offering a multitude of benefits such as resource conservation, diminished CO_2 emissions, and bolstered economic competitiveness.[6–8] The concrete industry, notably cement, is highlighted as having a significant contribution to environmental harm and carbon emissions.[9–11] Recycling construction materials not only addresses environmental concerns but also bestows economic advantages by extracting value from waste, reducing environmental protection costs, and curbing waste transportation expenses.[12–15] In addressing environmental considerations, numerous studies have been conducted to advocate for the integration of recycled aggregates in the construction of concrete.[16–20] Many studies have examined the mechanical properties and durability of concretes containing recycled coarse aggregate (RCA), focusing on aspects like water permeability, chloride ion permeability, corrosion resistance, and resistance to carbonation.[21–24] Nevertheless, apprehensions have arisen regarding diminished mechanical strength and durability, attributed to factors like reduced density, increased water absorption, and the presence of mortar adhering to recycled particles.[25–29]

Numerous studies have been undertaken to enhance the performance of RCA, employing a diverse array of methods. These methods include the removal of old mortar using acid solutions[30–32] and abrasion machines,[33–35] as well as fortifying the old mortar through processes such as CO_2 treatment,[36–38] cement-based slurries,[39,40] nanomaterials,[41–43] sodium silicate,[44] and bacteria,[45] among others. While these approaches have shown promise in improving RCA performance, they are not without challenges. The use of acid solutions presents environmental risks, and the abrasion method requires additional energy, contributing to CO_2 emissions. Moreover, CO_2 and bacteria treatments often involve extended durations. Addressing these concerns, enhancing the old mortar of RCA through a solution (slurry) emerges as a promising alternative. Innovative mixing techniques, such as early incorporation of cement and recycled aggregates, show promise in enhancing compressive strength over time.[46,47] Even with the use of recycled aggregates, performance comparable to conventional concrete can be achieved by adjusting the water-to-cement ratio.[48–51] Novel mixing methods, involving the pre-treatment of recycled aggregates with specific substances, hold potential for preserving the modulus of elasticity.[52,53] Variables such as replacement content, mixing techniques, aggregate type, and porosity significantly influence the mechanical properties of recycled aggregate concrete (RAC).[54,55] Durability emerges as a critical aspect, and various tests, including electrical resistivity tests, can provide estimates in this regard.[56,57] In general, RAC exhibits lower electrical resistance than regular concrete, with variations dependent on factors such as concrete composition, environmental conditions, and exposure to aggressive agents.[58–60]

This research aims to address critical challenges and bridge knowledge gaps related to the integration of recycled aggregates in concrete manufacturing. Despite the positive environmental impact of recycled aggregates, obstacles such as impurities, mechanical vulnerabilities, and bonding difficulties pose challenges to concrete durability.[61–63] In response, various researchers have explored different treatment techniques, including cement slurry coating, abrasion treatment, chemical treatment, carbonation treatment, and various combinations of these methods, to modify the surface of recycled aggregates and enhance the bond between aggregates and the cement matrix.[64–67] Out of the different treatment solutions and slurries available, cement-based slurry stands out as a commonly employed choice due to its economic feasibility and ready availability. Importantly, the impact of applying abrasion treatment followed by cement slurry treatment on both strength and durability has not been previously studied. This study introduces a novel approach that utilizes abrasion and cement slurry treatments to improve the connection between recycled materials and the concrete matrix. The expectation is that implementing this technique will significantly enhance the durability of RAC, aligning with the principles of the circular economy. While existing studies primarily focus on mechanical properties, there is a noticeable gap in research dedicated explicitly to concrete durability. This study, however, focuses on surface-treated recycled coarse aggregates (STRCA), delving into parameters such as drying shrinkage, electrical resistivity, and chloride ion penetration. The objective is to elucidate the mechanical and physical characteristics of STRCA, quantify the bond strength with cement paste, and scrutinize the durability of concrete containing these modified aggregates. By systematically addressing these aspects, this study introduces an innovative perspective to concrete technology, providing a comprehensive framework for the effective and sustainable utilization of recycled aggregates in concrete production.

2 | EXPERIMENTAL PROGRAMS

2.1 | Materials

Ordinary Portland cement of grade 43 that complies with IS 269-2015[68] standards, served as the primary binder in this investigation for concrete. The natural fine aggregates (NFA) comprised natural sand, complying with IS

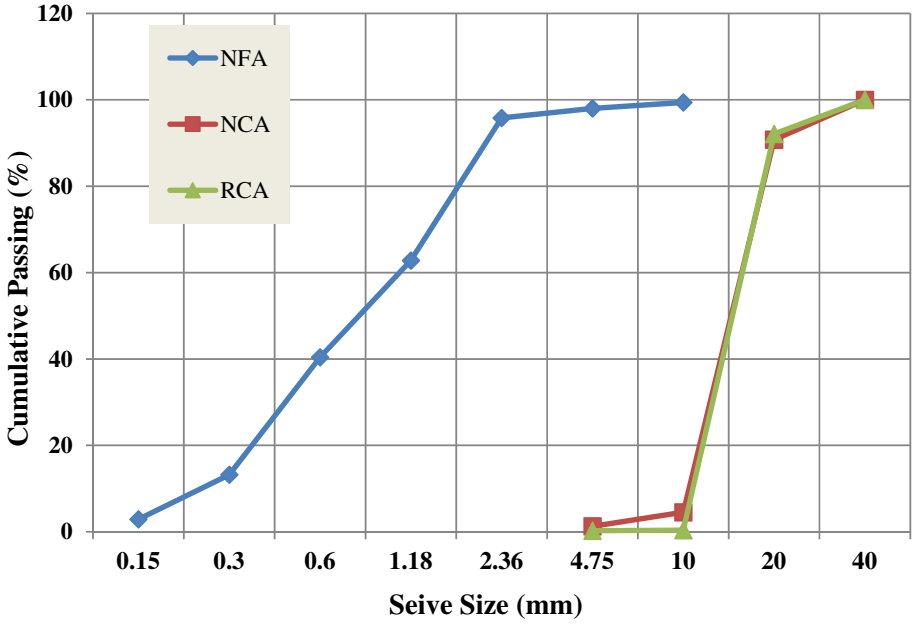

FIGURE 1 Particle size distribution curves. NCA, natural coarse aggregates; NFA, natural fine aggregates; RCA, recycled coarse aggregate.

TABLE 1 Different characteristic of aggregates.

Property	NFA	NCA	RCA	STRCA	Standard limits
Bulk density (kg/m^3)	1625	1740	1660	1704	1200–1750 (IS 2386 Part 3)[70]
Specific gravity	2.675	2.754	2.681	2.607	2.30–2.90 (IS 2386 Part 3)[70]
Water absorption (%)	0.51	1.12	5.35	5.51	≤2.0 (IS 2386 Part 3)[70]
Abrasion loss (%)	15.52	25.43	28.76	27.46	<30 (IS 2386 Part 4)[71]
Crushing value (%)	16.12	26.42	27.17	26.63	< 30 (IS 2386 Part 4)[71]
Impact value (%)	15.13	17.41	20.86	15.62	<30 (IS 2386 Part 4)[71]

Abbreviations: NCA, natural coarse aggregates, NFA, natural fine aggregates; RCA, recycled coarse aggregate; STRCA, surface-treated recycled coarse aggregates.

383-2016[69] standards, while the natural coarse aggregates (NCA) were sourced from crushed stone following the mix proportion guidelines outlined in IS 383-2016.[69] Waste from building and demolition was used to create RCA, which was processed with an impact crusher to meet specified dimensions. The distribution of aggregate particle sizes is illustrated in Figure 1. Table 1 provides a detailed presentation of the thorough physical and mechanical analyses conducted on the utilization of RCAs in concrete. A notable bonding challenge stems from the presence of residual old cement mortar on aggregate surfaces, resulting in a strength reduction. To overcome this, an integrated approach combining abrasion and cement slurry treatments is applied. Abrasion treatment yields a coarse surface, and cement slurry treatment produces a smooth one. These STRCA are commonly termed STRCA.

Aggregate specific gravity and water absorption were tested in accordance with IS 2386 Part 3.[70] The specific gravity values for NFA, NCA, and RCA are 2.675, 2.754, and 2.681, respectively, conforming to the standard limits of 2.30–2.90, indicating compliance with the specified requirements for specific gravity. In terms of water absorption, NFA exhibits the lowest absorption at 0.51%, followed by NCA at 1.12%. In contrast, RCA displays a higher water absorption of 5.35%. According to IS 9103–1999,[72] a chemical admixture—specifically, superplasticizer (C-MAX)—was used as an additive at a rate of 1% by cement weight. Mixing and curing of the materials were conducted using potable water available within the laboratory.

2.2 | Surface treatments of RCA

In the pursuit of mitigating the substantial strength reduction observed in RAC due to insufficient bonding with the cement matrix, a novel approach involving abrasion and cement slurry treatments was implemented. The aim was to enhance the surfaces of RCA, addressing the bonding challenges attributed to aged mortar residues. The comprehensive process, depicted in Figure 2,

represents a strategic approach to improve the properties and overall performance of RAC, with a particular focus on enhancing compressive strength. The treated recycled aggregates, termed STRCA, were then incorporated into concrete preparations. This innovative surface modification technique contributes to closing the existing gap in addressing durability challenges in RAC. In the abrasion treatment, a Los Angeles abrasion machine was employed, rotating at 25 revolutions per minute for 5 min to dislodge the attached mortar, following Panghal and Kumar's methodology.[64] The outcomes of the physical performance of RCA treated by abrasion are documented in Table 2.

This apparatus streamlines the process of efficiently removing mortar from the surface of the RCA. As the drum undergoes rotation, the individual aggregate particles interact with each other, initiating mechanical actions that effectively eliminate any adhered mortar. This abrasion mechanism, wherein particles rub against each other, guarantees a comprehensive cleaning of the RCA surface, rendering it free from excess mortar. Figure 2 illustrates the treatment applied to RCAs.

Subsequently, the weakened mortar adhering to the RCA surface underwent a cement slurry treatment, involving immersion in a formulated cement paste followed by drying, which aligns with Panghal and Kumar's earlier methodology.[65] To prepare the cement paste, cement is combined with water at a 10% cement-to-water ratio, ensuring an effective coating of aggregate surfaces by the paste. The mixture undergoes thorough agitation for 10–15 min to achieve homogeneity. Once the cement paste reaches readiness, abrasion-treated RCA is immersed in the slurry for 24 h, allowing the paste to be fully absorbed by the porous surfaces of the RCA. Subsequently, the coated aggregates are dried in an oven to optimize the penetration of cement particles into the aggregate structure. This controlled drying process eliminates excess moisture from the aggregates, leaving behind cement particles that have effectively permeated the porous surface. Through this meticulous combination of abrasion and cement slurry treatments, the RCA undergoes a transformative process, enhancing the mechanical strength of the aggregates and establishing a robust interfacial connection between the surrounding concrete matrix and the treated aggregates.

2.3 | Mix proportioning

To assess the efficacy of surface-treated Recycled Coarse Aggregates (RCA), six concrete mixtures (Table 3) were meticulously prepared with target strength of 25MPa.[73] The first reference mixture is (RC1) produced by utilizing natural aggregates, whereas second reference mixture is produced with substituted NCA with untreated RCA (RC 2), whereas the experimental mixtures (STRCA 25 to STRCA 100) substituted NCA with surface-treated RCA. Accurate weight batching, following IS 10262-2019,[74] ensured a consistent water-to-cement ratio of 0.50 for every combination. This methodical approach ensures uniformity in experimental conditions, allowing for a comprehensive investigation into the influence of STRCA on the characteristics of the final concrete mixes (Table 3).

2.4 | Testing methodology

A thorough examination of structural concrete encompassed a diverse array of tests (depicted in Figure 3), incorporating the analysis of microstructural features through x-ray diffraction (XRD), scanning electron microscopy (SEM), and energy-dispersive x-ray (EDX). Mechanical properties, including compressive strength, were assessed by averaging results from three specimens per mix. Long-term performance evaluations involved tests for drying shrinkage strain, electrical resistivity, and rapid chloride ion penetration.

2.4.1 | Material characterization

Prior to incorporating a diverse array of materials into the concrete mix, a crucial and meticulous step involves evaluating their compatibility through comprehensive microstructural analyses. This examination entails an in-depth scrutiny of the chemical elements, mineralogical properties, and microstructure of the materials. Employing EDX, XRD, and SEM analyses enables a discerning analysis of the constitution and structure of the materials, ensuring their suitability for concrete applications.

x-Ray diffraction

XRD is utilized for analyzing phase features and conducting mineralogical evaluations of crystalline minerals in various materials. Samples are scanned across an angular range of 3°–70° at a speed of 2 degrees per minute, with a sampling interval of 0.005 degrees at a 2° angle, using the Bruker D-8 advanced diffractometer system. Using Jade 7 XRD software, the study visualizes intensity on the y-axis during scans across the x-axis range from 0° to 70° by visually depicting peak intensities versus $2\theta°$.

Scanning electron microscopy analysis

Different materials used in the study undergo detailed characterization through SEM analysis. This involves a meticulous analysis of the surface morphology and microstructure of material samples from various

combinations, conducted at 30 kV using the JSM 6610V scanning electron microscope at the University Science Instrumentation Centre (USIC) in Delhi. This rigorous analysis provides a comprehensive understanding of the intricate details of various materials, offering insightful knowledge on the overall composition and structure of materials.

Energy-dispersive x-ray analysis

The chemical composition of different materials is subjected to a complex statistical examination through EDX analysis, conducted using the SEM integrated with the Amatek EDS detector. Materials underwent detailed characterization at 30 kV using the JSM 6610 V scanning electron microscope at the USIC in Delhi. Because SEM utilizes vacuum conditions and an electron beam to form an image, special sample preparations are required. Samples are mounted on carbon tape, with a maximum size of 1 × 1 cm. All water must be removed to prevent vaporization in the vacuum. Electrically conductive samples require no further preparation, but non-conductive samples must be made conductive by coating them with a thin layer of Au using a sputter coater. This application adds a level of accuracy to the characterization process by analyzing the presence of distinct constituents in different materials using both qualitative and quantitative evaluations. Collectively, these analyses contribute to a comprehensive assessment of material suitability, ensuring the effective integration of components in the various materials.

2.4.2 | Compressive strength

Thirty meticulously crafted specimens, contained within steel cube molds measuring 150 × 150 × 150 mm, underwent meticulous preparation, curing, and subsequent compressive strength testing. Utilizing compression testing equipment with a capacity of 2000 kN, the average compressive strength values for each combination were calculated based on data from three specimens. These comprehensive assessments conducted over both 7 and 28 days offer a profound understanding of the strength properties exhibited by diverse concrete mixes at different points in time.

2.4.3 | Drying shrinkage

The evaluation of drying shrinkage in concrete mixes adhered to a systematic observation of length changes over time, following the IS 516 (Part 6) 2020[75] standards. For each of the five mixtures, three specimens measuring 75 × 75 × 285 mm were stored for a duration of 28 days. Initial measurements were meticulously recorded with a precision of 0.005 mm. Subsequent readings at 28, 56, and 90 days were obtained using dial gages. The alteration in length for each specimen was calculated by assessing the disparity between the final and initial values, providing a comprehensive understanding of the drying shrinkage characteristics over an extended duration.

2.4.4 | Electrical resistivity

The assessment of concrete electrical resistivity plays a vital role in comprehending potential corrosion risks to embedded steel reinforcement bars. This method entails measuring the surface resistivity of fresh concrete using a four-electrode setup and a Resipod Resistivity Meter. The samples meet RILEM TC 154-EMC[76] requirements and are made in 100 mm diameter by 200 mm height cylindrical molds. Evaluations conducted at 28 and 56 days

17517648, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/suco.202400387 by Delhi Technological University, Wiley Online Library on [22/07/2024]. FIGURE 3 Evaluations of (a) compressive strength, (b) drying shrinkage, (c) electrical resistivity, and (d) rapid chloride penetration test setup.

provide comprehensive insights into the evolution of concrete electrical resistivity over time, contributing to a thorough analysis of corrosion susceptibility.

2.4.5 | Rapid chloride penetration

Conforming to the American Society for Testing and Materials (ASTM) C1202[77] standards, the mold of the rapid chloride penetration test (RCPT) apparatus has a 100 mm diameter and a 50 mm height. Thirty specimens were meticulously prepared for this study. The unit incorporates two sealed chambers containing sodium chloride (NaCl) at 0.24 M and sodium hydroxide (NaOH) at 0.3 M. A 60 V current source connects to the NaCl and NaOH cells, with readings recorded at 30-min intervals for up to 6 h. Tests conducted at 28 and 56 days measure the charge passed, providing a crucial indicator of concrete's resistance to chloride ion penetration.

3 | RESULTS AND DISCUSSION

3.1 | Materials characterization

The examination of material microstructure, such as cement and aggregates, with concrete involves a crucial preliminary step of microstructural analysis before

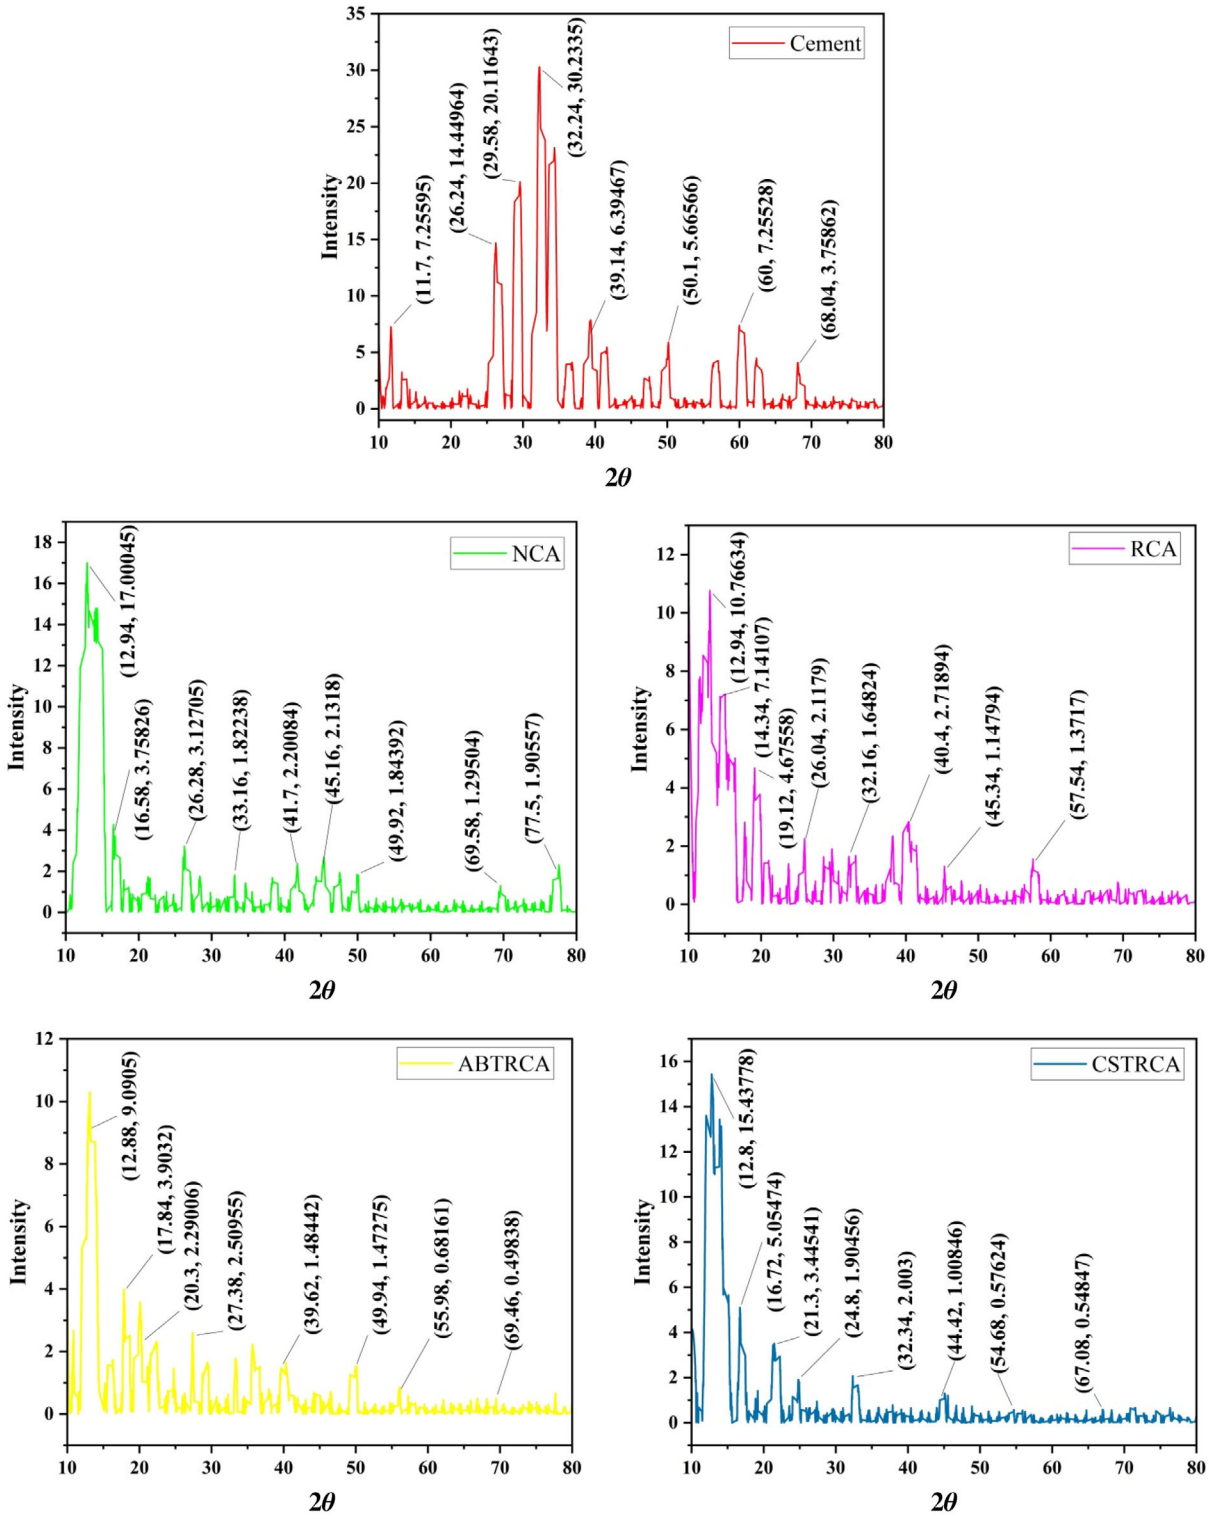

FIGURE 4 x-Ray diffraction data comparison of cement, natural coarse aggregates (NCA), recycled coarse aggregate (RCA), abrasion-treated recycled coarse aggregates (ABTRCA), and cement slurry-treated recycled coarse aggregates (CSTRCA).

incorporation. To comprehensively evaluate the chemical elements, mineralogical properties, and microstructure of these materials, an in-depth analysis was conducted using XRD, SEM, and EDX. These analytical methods provide thorough insights into the structure and composition of the materials, establishing a foundational understanding of their suitability in concrete applications. The ensuing discussion will delve into the implications of these findings on the overall performance and durability of the concrete mixtures.

Abbreviations: ABTRCA, abrasion-treated recycled coarse aggregates; CSTRCA, cement slurry-treated recycled coarse aggregates; NCA, natural coarse aggregates, RCA, recycled coarse aggregate.

3.1.1 | XRD analysis of materials

In Figure 4, the XRD results for cement reveal distinct peaks corresponding to calcium silicate, tricalcium aluminate, and silica phases. Table 4 provides comprehensive details regarding XRD peaks, including their positions, intensities, chemical nomenclature, chemical formulas, and crystal systems for all materials. Moving

17517648, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/suco.202400387 by Delhi Technological University, Wiley Online Library on [22/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

on to NCA in Figure 4, the XRD analysis focuses on selected chemical elements, including calcium (Ca), oxygen (O), silicon (Si), aluminum (Al), iron (Fe), potassium (K), sodium (Na), and magnesium (Mg). The subsequent XRD analysis of RCA (Figure 4) unveils its mineralogical properties, showcasing peaks corresponding to quartz, hornblende, albite, and anorthite. Notably, the nature of RCA appears crystalline prior to surface modification treatment, indicating that the aggregate surface has ancient cement mortar adhered to it, potentially leading to weak bonding with the cement matrix. The unmodified RCA particles exhibit insufficient bonding, prompting the need for their removal to establish robust bonding with the cement matrix. To address this, abrasion and cement slurry treatments are applied for surface modification. The XRD analysis of STRCA, following abrasion and cement slurry treatments, presents mineralogical properties in Figure 4.

Notably, a significant peak indicates the prevalence of quartz in the majority of the treated material. Abrasion and cement slurry treatments induce observable changes in the XRD patterns of RCAs. These changes include discernible alterations in peak intensities, indicating the dissolution of minerals present on the aggregates' surface. The emergence of new peaks suggests the potential formation of novel compounds previously obscured by impurities. Amorphization, reflected in broader peaks, indicates a shift from crystalline to amorphous structures. Crystal structure modifications and shifts in peak positions signify alterations in specific mineral phases. The abrasion treatment may also result in mineral depletion, removing some minerals entirely from the surface. These variations collectively enhance our understanding of how abrasion treatment influences the mineralogical composition of RCAs, as discerned through XRD analysis. These results highlight how well the surface treatments work to improve the mineralogical features of RCA, thereby contributing to improved bonding with the cement matrix. A comparable observation is also noted by Kazemian et al.,[59] as indicated by the reported findings. The ensuing discussion will delve into the implications of these mineralogical variations for the overall performance and durability of the concrete mixtures. The STRCA exhibits a rougher surface, closely resembling the characteristics of NCA. This distinction suggests that STRCA is more conducive to forming a robust bond with the cement matrix, thereby enhancing the mechanical characteristics of RAC.

3.1.2 | SEM analysis of materials

SEM was employed for the characterization of various materials, including cement, NCA, RCA, abrasion-treated recycled coarse aggregates (ABTRCA), cement slurry-treated recycled coarse aggregates (CSTRCA). This analytical instrument allows for the examination of the surface morphology and particle microstructure of these materials. As depicted in Figure 5, SEM images provide insights into the surfaces of NCA, RCA, and STRCA samples. The SEM image of the NCA sample reveals a dense, uniform surface, relatively free of impurities except for minor dust resulting from the manufacturing crushing process. In contrast, the unmodified RCA sample exhibits a more porous surface covered with fine particles and loose cement mortar, a consequence of the crushing process, as observed in the figure. A similar observation is reported by Ismail and Ramli.[30,58] SEM images of the surface of CSTRCA samples depict the covering with cement particles. The abrasion treatment effectively attacked the RCA surface, dissolving the adhered mortar and creating new pores, as seen in SEM images of ABTRCA. These surface modifications, attributed to the cement slurry treatment, contribute to increased bonding with cement paste and enhance the overall strength of the mixture. ABTRCA and CSTRCA exhibit a cleaner, denser, and more uniform surface compared to the unmodified RCA, as visually represented in Figure 7.

3.1.3 | EDX analysis of materials

Thorough analysis using EDX was conducted to identify the crystalline constituents within both cement powder and coarse aggregates, following the stringent guidelines outlined by ASTM. Figure 6 presents the outcomes of the EDX analysis for various materials, including cement, NCA, RCA, ABTRCA, and CSTRCA. The comprehensive EDX analysis distinctly illustrates the presence of all chemical elements in each material, forming a foundational understanding of their elemental composition. The ensuing discussion will delve into the implications of these findings for the structural and chemical properties of the concrete mixtures. The figures clearly illustrate a noticeable rise in Si percentages following surface modification. This uptick signifies the enhanced distribution of calcium silicate minerals on the surface of RCAs, characterized by the presence of Si, O, and Ca. The higher percentage of this distribution has a major role in the enhanced cement paste-aggregate bond. Thus, the material's mechanical characteristics have increased, and this reinforced link is to blame. Kessal et al.[51] also make a comparable observation, according to the reported findings.

3.2 | Compressive strength

The results presented in Table 5 and Figure 7 elucidate the percentage variation in compressive strength among

17517648, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/suco.202400387 by Delhi Technological University, Wiley Online Library on [22/07/2024]. FIGURE 5 Scanning electron microscopy analysis results for natural coarse aggregates (NCA), recycled coarse aggregate (RCA), abrasion-treated recycled coarse aggregates (ABTRCA), and cement slurry-treated recycled coarse aggregates (CSTRCA).

various concrete mixtures at 7 and 28 days, referencing the control mix (RC 1), all characterized by medium workability (50–100 mm). Concrete mixes incorporating increasing amounts of STRCA exhibit lower compressive strength than the reference mix RC 1, and strength levels ascend with the curing age. Notably, among the evaluated surface modifications, a 50% replacement emerges as the optimal choice. This implies that substituting 25% of regular aggregate with STRCA yields the highest strength after 28 days. This enhancement stems from the utilization of recycled aggregate, effectively eliminating outdated mortar and resulting in a mix denoted as STRCA 25, which offers maximum strength with reduced voids and higher particle density. Compressive strength serves as a pivotal parameter in evaluating concrete performance, and variations in strength offer insights into the efficacy of incorporating supplementary materials. The control mix RC 1 demonstrated a compressive strength of 23.01 MPa at 7 days and 33.91 MPa at 28 days. In comparison, the control mix RC 2 demonstrated a compressive strength of 16.31 MPa at 7 days and 22.91 MPa at 28 days. Subsequent mixtures integrated STRCA at different replacement levels—25%, 50%, 75%, and 100%.

At 7 days, the STRCA 25 mixture showcased a noteworthy increase in compressive strength, reaching 29.95 MPa, representing a positive variation of 30.16% compared to the RC 1 mix. This suggests that the inclusion of 25% recycled concrete aggregate positively influenced early-age strength development. Similarly, STRCA 50 and STRCA 75 mixtures displayed positive variations of 18.99% and 1.59%, respectively, indicating continued enhancement in compressive strength compared to the control mix (RC 1) at 7 days. However, STRCA 100 exhibited a decrease in strength, registering 19.18 MPa and a negative variation of 16.64%, indicating that a complete replacement of natural aggregates with recycled material adversely impacted early-age compressive strength. As the curing period extended to 28 days, the trends in compressive strength variations persisted with some modifications. STRCA 25, STRCA 50, and STRCA 75 maintained positive variations of 29.37%, 17.13%, and 1.59%, respectively, compared to the control mix (RC 1). These results indicate that the positive influence of recycled concrete aggregate on compressive strength was sustained over the curing period. However, STRCA 100 continued to exhibit a decrease in strength with a negative variation of 11.58%, suggesting a long-term

17517648, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/suco.202400387 by Delhi Technological University, Wiley Online Library on [22/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

adverse effect on compressive strength when natural aggregates are entirely replaced with recycled material. According to the study findings, STRCA 25 demonstrates the highest compressive strength at 43.87 MPa, while STRCA 100 exhibits the lowest at 29.98 MPa. The results in Table 5 show that all mixtures produced with integrated STRCA at various replacement levels (25%, 50%, 75%, and 100%) performed significantly better than the control mix RC 2, which was produced with untreated RCA substituted for NCA at a 100% replacement level.

To gain a thorough and comprehensive understanding of the results obtained from our compressive strength tests, it is crucial to closely analyze the combined aspects of the loading rate and the force–displacement curve. The loading rate, which refers to the speed at which the load is applied to the test specimen, significantly influences the material's response under stress. Simultaneously, the force–displacement curve provides a detailed graphical representation of how the material deforms under various loads, showcasing the relationship between the applied force and the resulting displacement. By examining this aspect, we can gain valuable insights into the material's behavior under compression, identify any potential weaknesses, and better understand its mechanical properties. Figure 8 provides a detailed illustration of these parameters, offering a visual aid to support the analysis and interpretation of the test results. This figure is essential for grasping the nuances of the material's performance and for making informed decisions based on the test outcomes. These results align with those reported

by Kessal et al.[51] Additionally, Wagih et al.[78] observed a notable reduction in compressive strength by 20%–34% at 7 days and 18%–28% at 28 days when using RCA in concrete mixes. However, after applying surface treatment, the decrease was limited to only 04%–17% at 7 days and 02%–12% at 28 days, even with 100% replacement of RCA. Similar positive outcomes were noted in an earlier study conducted by Wang et al.[32] and Kazemian et al.[59] In summary, the variations in compressive strength for different mixtures indicate that the inclusion of recycled concrete aggregate at lower replacement levels positively influences both early-age and long-term strength, while complete replacement may result in a decline in compressive strength. These findings bear significant implications for the sustainable use of recycled materials in concrete production, emphasizing the necessity for careful consideration of replacement levels to optimize both short-term and long-term performance.

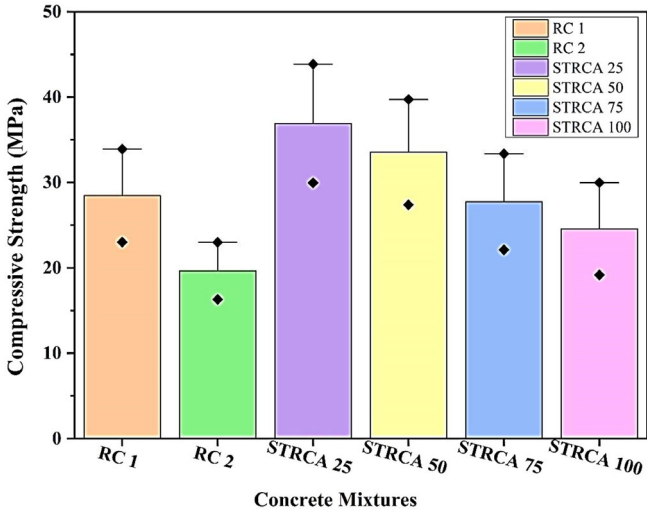

FIGURE 7 Variations in compressive strength across different concrete mixtures. STRCA, surface-treated recycled coarse aggregates.

3.3 | Drying shrinkage

Drying shrinkage assessment is crucial for understanding structural concrete performance. Table 6 and Figure 9 depict percentage variations in drying shrinkage for different concrete mixtures at 28, 56, and 90 days, referencing the control mix (RC 1). This parameter is vital for evaluating cracking and deformations. Results show that all mixtures align with Indian standards, implying that incorporating STRCA is viable within defined limits. The drying shrinkage curve transitions from steep to flat with prolonged drying time, indicating a diminishing rate of change. Higher STRCA replacement increases drying shrinkage, but it also positively influences and mitigates it compared to untreated RCA. This emphasizes the strategic use of STRCA to balance sustainability without compromising concrete performance. The control mix RC 1 exhibited drying shrinkage values of 348×10^{-6} at 28 days, 431×10^{-6} at 56 days, and 474×10^{-6} at 90 days. In contrast, the control mix RC 2 exhibited

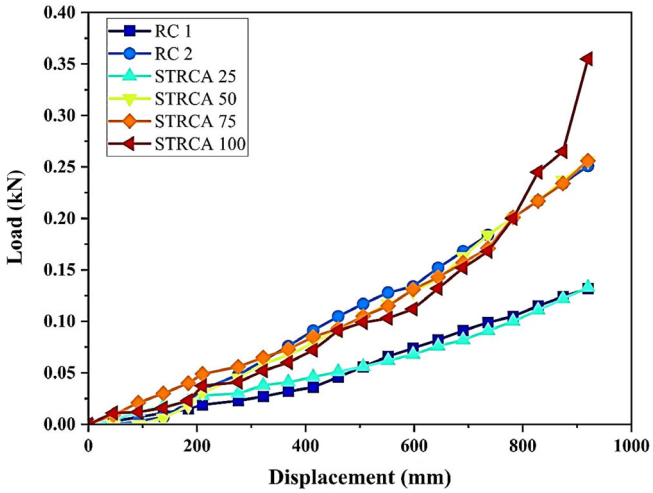

FIGURE 8 Load–displacement curve for different mixtures.

drying shrinkage values of 499×10^{-6} at 28 days, 624×10^{-6} at 56 days, and 641×10^{-6} at 90 days. Subsequent mixtures incorporated STRCA at various replacement levels (25%, 50%, 75%, and 100%). At 28 days, STRCA 25 showed a slight increase in drying shrinkage (354×10^{-6}), representing a positive variation of 01.72% compared to the RC 1 mix, indicating minimal impact at this early stage. However, as the percentage of STRCA increased, drying shrinkage also rose, with positive variations of 10.91%, 25.86%, and 38.79% for STRCA 50, STRCA 75, and STRCA 100, respectively, at 28 days.

At 56 days, STRCA 25, STRCA 50, STRCA 75, and STRCA 100 exhibited percentage variations of +02.32%, +10.90%, +26.68%, and +40.60%, respectively, at 56 days. These results indicate a sustained influence of STRCA on increasing drying shrinkage over time, with higher replacement levels contributing to more significant variations. Moving to 90 days, STRCA 25, STRCA 50, STRCA 75, and STRCA 100 showed percentage variations of +02.32%, +10.97%, +22.15%, and +31.85%, respectively, at 90 days. The results in Table 6 show that all mixtures produced with integrated STRCA at various replacement levels (25%, 50%, 75%, and 100%) have lower drying shrinkage values than the control mix RC 2, which was produced with untreated RCA substituted for NCA at a 100% replacement level. The positive variations observed in drying shrinkage imply that the inclusion of STRCA, especially at higher replacement levels, contributes to an increase in the potential for cracking and deformations in the concrete. This information is crucial for structural engineers and concrete designers as they consider the long-term durability and performance of concrete structures. Furthermore, STRCA proves advantageous in minimizing drying shrinkage compared to unmodified RCA, attributed to the efficacy of the surface modification process applied to RCAs. This process substantially diminishes mortar presence on the aggregate surface, a pivotal factor in augmented water absorption and ensuing drying shrinkage. Consequently, the removal of attached mortar through surface modification results in significantly reduced drying shrinkage compared to unmodified RCA, underscoring the crucial role of surface modification in enhancing the performance of STRCA.

The study concludes that at 100% replacement, STRCA exhibits an 11%–20% reduction in shrinkage strain compared to unmodified RCA. This finding aligns with research conducted by Ismail and Ramli,[30] exploring how treated recycled aggregates influence the drying shrinkage of concrete. Prior research by Kioumarsi et al.[79] indicated a higher drying shrinkage strain with unmodified RCAs, consistent with observations by Wang et al.,[32] suggesting a systematic increase in shrinkage with a higher proportion of unmodified aggregates. In summary, the results presented in Figure 8 indicate that the drying shrinkage of concrete increases with higher replacement levels of STRCA. While lower levels (STRCA 25) show minimal impact, significant positive variations in drying shrinkage are observed at higher replacement levels (STRCA 50, STRCA 75, and STRCA 100). These findings underscore the importance of carefully balancing the use of recycled materials in concrete mixtures to mitigate the risk of increased drying shrinkage and its potential consequences on the long-term performance of concrete structures.

3.4 | Electrical resistivity

The connectivity of the porous network within cement mortar directly influences electrical conductivity,

providing a precise measure of ionic transport resistance. Consequently, electrical resistivity serves as a crucial metric for assessing concrete quality. Table 7 and Figure 10 illustrate the percentage variations in electrical resistivity for diverse concrete mixtures at 28 and 56 days, using the control mix (RC 1) as a reference. The outcomes reveal a substantial improvement in the electrical resistance of cement mortar following surface modification. In this study, the primary factor contributing to decreased electrical conductivity appears to be the integrated surface modification approach applied to the cement mortar. This modification is presumed to play a pivotal role in altering the pore network, enhancing electrical resistance. At 28 days, RC 1 exhibited an electrical resistivity of 47.45 kΩ. Mixtures with STRCA at varying replacement levels showed diverse effects on electrical resistivity. STRCA 25 displayed a positive variation of +03.41%, indicating a slight increase, while STRCA 50 showed a marginal rise of +01.26%. However, STRCA 75 and STRCA 100 exhibited negative variations of −15.44% and −26.25%, suggesting decreased electrical resistivity. As the curing period extended to 56 days, the trends in electrical resistivity variations continued. The control mix, RC 1, had an electrical resistivity of 58.91 kΩ. STRCA 25 and STRCA 50 displayed positive variations of +00.88% and +01.74%, respectively, indicating slight increases compared to the control mix. However, STRCA 75 and STRCA 100 showed negative variations of −12.47% and −22.23%, respectively, signifying a notable decrease in electrical resistivity. The control mix RC 2 exhibited electrical resistivity values of 16.01 kΩ at 28 days and 26.29 kΩ at 56 days. The results in Table 7 show that all mixtures produced with integrated STRCA at various replacement levels (25%, 50%, 75%, and 100%) have higher electrical resistivity values

than the control mix RC 2, which was produced with untreated RCA substituted for NCA at a 100% replacement level.

In summary, STRCA inclusion had varied effects on electrical resistivity, with lower replacements showing marginal increases or maintenance, while higher replacements led to significant decreases. The results underscore the need to carefully evaluate electrical properties when incorporating recycled materials, which are crucial for concrete durability and corrosion resistance. In the context of these findings, the incorporation of STRCA significantly influences the electrical resistivity of cement mortar. The observed variations suggest that STRCA surface modification effectively alters the concrete's porous network, contributing to enhanced resistance to ionic transport. The study concludes that at 100% replacement, STRCA exhibits a 28%–36% increment in electrical resistance compared to unmodified RCA. These findings align with studies by Sasanipour and Aslani,[52] investigating the electrical resistivity of concrete with pre-treated RCA. Similarly, research by Zhan et al.[36] exploring treated recycled aggregates aligns with our study, suggesting that concrete with STRCA poses a low risk of corrosion to steel bars. These results highlight the potential of STRCA as a beneficial component in concrete mixtures, particularly for applications requiring improved electrical resistivity. Consequently, concrete with up to 100% RCA replacement carries a low risk of corrosion.

3.5 | Rapid chloride penetration

The evaluation of concrete's chloride resistance relies on the total charge measured by the RCPT, offering insights into chloride ion transport characteristics. Table 8 and Figure 11 illustrate the percentage variations in passed charge for diverse concrete mixtures at 28 and 56 days, using the control mix (RC 1) as a baseline. Passed charge is a crucial parameter in appraising the electrical performance of concrete, providing indications of its ability to conduct electrical current. Remarkably, the outcomes suggest that surface modification positively influences chloride ion penetration resistance. The inclusion of STRCA contributes to establishing a robust bond between aggregates and cement paste, fostering the formation of strong interfacial transition zones (ITZs). These enhanced ITZs play a pivotal role in impeding chloride ion penetration, owing to the cleaner, denser, and more uniformly shaped STRCA acting as a barrier against chloride ion ingress. This signifies a substantial enhancement in concrete's ability to withstand the deleterious effects of chloride exposure, highlighting the positive influence of surface modification on chloride resistance. At 28 days, the control mix, RC 1, recorded a passed charge of 704 C. Subsequent mixtures with STRCA at various replacement levels displayed variations. STRCA 25 showed a slight decrease of −00.56%, indicating a marginal reduction. In contrast, STRCA 50 exhibited a positive variation of +04.54%, suggesting an increase. Notably, STRCA 75 and STRCA 100 demonstrated significant positive variations of +11.78% and +22.72%, respectively, indicating substantial increases in passed charge at 28 days. As the curing period extended to 56 days, the trends persisted. RC 1 had a passed charge of 683 C. STRCA 25 exhibited a marginal decrease of −00.43%, while STRCA 50 and STRCA 75 showed further positive variations of +05.85% and +16.54%, respectively. STRCA 100 displayed the highest positive variation of +28.69%, indicating a significant increase in passed charge at 56 days. The control mix RC 2 demonstrated a passed charge of 1053 C at 28 days and 1050 C at 56 days. As illustrated in Table 8, all mixtures incorporating STRCA at varying replacement levels (25%, 50%, 75%, and 100%) exhibited lower passed charges, indicating higher resistance values compared to

TABLE 8 Percentage variations in passed charge for different mixtures.

Concrete mix	Charge passed (C)					
	28 Days	% Variation with respect to RC 1	% Variation with respect to RC 2	56 Days	% Variation with respect to RC 1	% Variation with respect to RC 2
RC 1	704	-	-	683	-	-
RC 2	1053	+49.57	-	1050	+53.73	-

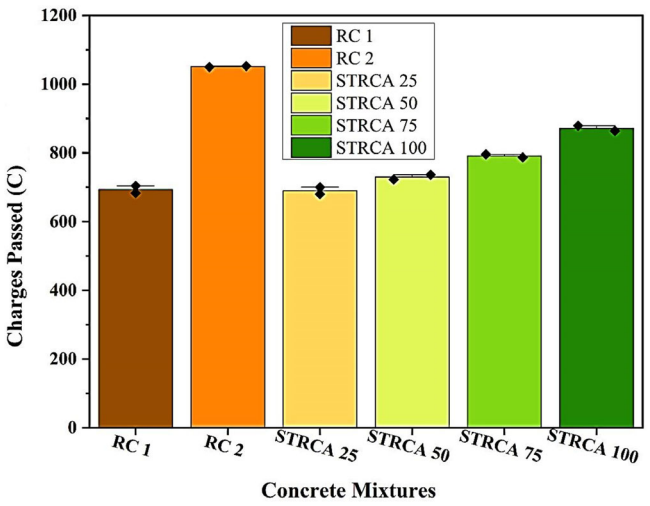

FIGURE 11 Variations in the amount of charges passed for different concrete mixtures. STRCA, surface-treated recycled coarse aggregates.

the control mix RC 2. The control mix RC 2 was produced using untreated RCA entirely substituted for NCA at a 100% replacement level.

In summary, the results indicate varied effects of STRCA on passed charge, with lower replacement levels (STRCA 25) showing marginal reductions and higher levels (STRCA 50, STRCA 75, and STRCA 100) leading to substantial increases. These findings suggest that surface modification crucially influences the chloride ion transport properties of concrete, with potential positive or negative impacts depending on the percentage of STRCA incorporated. Specifically, at a 100% replacement level, STRCA demonstrates a substantial 22%–28% reduction in chloride ion penetration compared to unmodified RCA. This aligns with prior research by Sasanipour and Aslani,[52] highlighting increased resistance with a higher water-cement ratio, and correlates with Zhan et al.'s[36] study on the impact of treated recycled aggregates on chloride permeability. The observed variations underscore the complex relationship between chloride ion transport and surface-modified recycled concrete aggregate, emphasizing the necessity for meticulous consideration of STRCA proportions in concrete mixtures. Despite diverse effects, the study indicates the potential for surface modification to be a valuable tool in tailoring concrete chloride resistance for specific applications. However, further research and optimization efforts are needed to precisely define optimal incorporation levels for desired chloride resistance properties. These findings underscore the importance of carefully considering the electrical properties of concrete when incorporating recycled materials, impacting the conductivity and overall electrical performance of concrete structures.

3.6 | Discussion

The abrasion treatment proved to be highly effective in addressing the surface of RCA, where it successfully dissolved the adhered mortar and introduced new pores, as evident in the SEM images (Figure 5) of ABTRCA. These alterations on the surface, credited to the cement slurry treatment, lead to the formation of a robust layer on the RCA surface. Notably, the utilization of cement slurry in treating RCA results in the filling of pores and cracks, consequently augmenting the strength of the treated RCA and yielding a smoother surface, as depicted in the SEM image (Figure 5) of CSTRCA. These modifications contribute significantly to the enhanced bonding with cement paste, thereby elevating the overall strength of the mixture. Despite these positive outcomes, the presence of capillary pores remains observable, and the hydrophilic nature of the hardened layer implies that water absorption does not decrease but may even experience a slight increase. When the STRCA is incorporated into RAC, there is a marked improvement in compressive strength and durability, attributed to the heightened strength and altered surface properties of the RCA. However, it is noteworthy that the water absorption of RAC is not noticeably affected, and the ITZ in RAC becomes more intricate. In cases where abrasion and cement slurry treatments are employed in conjunction, the comprehensive performance of STRCA sees further enhancement. This encompasses improvements in both strength and water absorption, ultimately leading to an augmented strength and durability of concrete incorporating STRCA.

4 | CONCLUSIONS

The study's conclusions propose that STRCA presents a viable and sustainable alternative for concrete production. Effective surface modification techniques mitigate the negative effects of contaminants on the surfaces of reinforced concrete, resulting in enhanced mechanical properties and increased durability. Upon conducting an in-depth analysis, a multitude of pivotal findings surfaces:

- Abrasion and cement slurry treatment efficiently enhance RCA by removing mortar and improving recycled aggregates, strengthening the interfacial connection with cement paste. Material characterization using XRD, SEM, and EDX reveals superior chemical properties in STRCA, showcasing positive enhancements in compound composition, intensity, and microstructure compared to conventional and unmodified counterparts.

- Compared to the RC 1 mixture, STRCA 25 shows a significant 29.37% improvement in compressive strength at 25% replacement, but STRCA 100 experiences an 11.58% reduction at 100% replacement. STRCA can substitute up to 75% of coarse aggregates without a substantial loss in compressive strength. While improvements are seen up to a 50% replacement ratio, performance declines at 100% replacement.
- The drying shrinkage values of various concrete mixtures incorporating STRCA were notably lower than those of the reference concrete. At 100% replacement, STRCA demonstrates a reduction in shrinkage strain ranging from 11% to 20% compared to unmodified RCA.
- Surface modification techniques enhanced electrical resistivity, attributable to the dense microstructure of STRCA particles. At a 100% replacement level, STRCA demonstrates a 28%–36% increase in electrical resistance compared to unmodified RCA.
- STRCA concrete exhibits enhanced resistance to chloride ion penetration, classifying it as having low penetrability and a low risk of corrosion. At a 100% replacement level, STRCA demonstrates a significant 22%–28% reduction in chloride ion penetration compared to unmodified RCA.
- All STRCA integrated mixtures produced at various replacement levels (25%, 50%, 75%, and 100%) significantly outperformed the control mix RC 2, which was produced with untreated RCA substituted for NCA at a 100% replacement level.

This research affirms that the integrated surface modification of RCA, as demonstrated by the STRCA series, effectively enhances concrete durability. The applied surface modification techniques exhibit notable efficacy, resulting in concrete with improved durability characteristics. This strategy not only addresses challenges linked to recycled aggregates but also contributes to an overall advancement in concrete performance. The positive outcomes underscore the significance of the STRCA series as a promising avenue for improving concrete durability through innovative surface modification of recycled aggregates, making a valuable contribution to concrete technology.

5 | FUTURE SCOPE AND RECOMMENDATIONS

The positive outcomes of the STRCA series underscore its potential for concrete durability enhancement. Future research should focus on optimizing surface modification techniques, exploring alternative methods, and conducting in-depth microstructural analyses. Long-term durability studies, performance under varied environmental conditions, and scalability considerations are crucial for practical application. Integration with emerging technologies and a comprehensive life cycle assessment will further validate the sustainability of STRCA. Continued exploration of these aspects will contribute to advancing recycled aggregates in construction, promoting sustainable practices, and innovative solutions for the industry.

Abstract

The integration of large language models (LLMs) with vision-language (VL) tasks has been a transformative development in the realm of artificial intelligence, highlighting the potential of LLMs as a versatile general-purpose chatbot. However, the current trend in this evolution focuses on the integration of vision and language to create models that can operate in more diverse and real-world contexts. We present a novel approach, termed Bottleneck Adapter, specifically crafted for enhancing the multimodal functionalities of these complex models, enabling joint optimization of the entire multimodal LLM framework through a process known as Multimodal Model Tuning (MMT). Our approach utilizes lightweight adapters to connect the image encoder and LLM without the need for large, complex neural networks. Unlike the conventional modular training schemes, our approach adopts an end-to-end optimization regime, which, when combined with the adapters, facilitates the joint optimization using a significantly smaller parameter set. Our method exhibits robust performance with 90.12% accuracy, outperforming both human-level performance (88.4%) and LaVIN-7B (89.41%).

Keywords: NLP, MLLM, Adapter

1 Introduction

In the landscape of modern computational linguistics, large language models (LLMs)[1–4] have been at the forefront, consistently expanding the boundaries of what machines understand about human language. This expansion has been largely driven by increases in the models' complexity, measured by the number of parameters, and

the breadth of pre-training data. One notable advancement in this domain is the concept of instruction tuning[1, 5–7], which has significantly enhanced the ability of LLMs to mimic human conversational patterns and effectively perform a variety of natural language processing (NLP) tasks, inching closer to the elusive goal of artificial general intelligence, as exemplified by models like GPT-3.5 [1]. The current trend in this evolution aims to imbue LLMs with multimodal understanding, particularly the integration of vision and language, to create models that can operate in more diverse and real-world contexts. This ambition has been partly realized in recent advancements like GPT-4 [8], which represents a leap forward by incorporating a substantial vision-language dataset directly into the training of a multimodal generative pre-trained transformer.

In the expansive domain of artificial intelligence, the integration of large language models (LLMs) with vision-language (VL) tasks has been a transformative development. However, this integration often comes with considerable computational and storage demands. Traditional parameter-efficient transfer learning (PETL) [9–13] methods, designed to reduce these demands by fine-tuning a minimal number of parameters, have not fully met the efficiency and performance needs, particularly for multimodal LLMs. Existing approaches also show a gap in performance compared to full model fine-tuning and exhibit significant redundancy when combining LLMs with vision models for tasks like image captioning[14] or text-to-image generation[15]. Moreover, modular training strategies, although beneficial, involve expensive VL pre-training and often necessitate extensive updating of LLM parameters, hindering quick and efficient model adaptation.

In light of these challenges, our model introduces an innovative approach that stands out from the current landscape. By not freezing the LLM and vision encoder and implementing these layers in a quantized format, our model significantly slashes the memory footprint. It's designed to support not just image-text but also text-only instructions, addressing a major limitation in models like BLIP2[16] and miniGPT4[17].

Our approach utilizes lightweight adapters to connect the image encoder and LLM, enabling joint optimization of image and language models without the need for large, complex neural networks. This framework allows for seamless shifting between single and multi-modal instructions without compromising natural language understanding capabilities. Unlike the conventional modular training schemes, our model adopts an end-to-end optimization regime, which, when combined with the lightweight adapters, facilitates the joint optimization of the entire multimodal LLM using a significantly smaller parameter set. This leads to an impressive reduction in storage overhead, outclassing existing solutions by a considerable margin.

Our method's ability to process both image-text and text-only instructions, along with its quantized form, ensures that it can be swiftly trained on a single GPU, marking a substantial leap in training efficiency. In summary, our key contributions are as follows:

- We present a novel method that bypasses the need for costly training while preserving the LLM's NLP capabilities, addressing a critical gap in current multimodal LLMs.

- Through rigorous experimentation, we demonstrate that not only does our model excel in efficiency, but also delivers competitive performance compared to existing multimodal LLMs, highlighting its potential as a versatile general-purpose chatbot.

2 Related Work

Parameter-Efficient Fine-Tuning (PEFT) techniques, in contrast to complete fine-tuning strategies, keep most of the parameters of pretrained models fixed while achieving similar performance on subsequent tasks. In the realm of PEFT, several methods have been investigated. These include prompt tuning[18–21], Low-Rank Adaptation (LoRA)[12], and adapters[9, 22, 23]. Prompt tuning entails adding trainable prompt tokens to pre-trained large models, either in input embeddings exclusively or throughout all intermediate layers. LoRA integrates trainable rank decomposition matrices into network weights, demonstrating promising fine-tuning capabilities, particularly in large generative models. Adapters incorporate lightweight adaptation modules into each layer of pre-trained transformers, providing flexibility across various domains. These PEFT approaches aim to find a middle ground between efficiency and effectiveness in fine-tuning pre-trained models for a variety of downstream tasks. LAVIN [24] examines the incorporation of lightweight adapters into transformer blocks. They propose the idea of Mixture-of-Modality Adaptation (MMA) to connect Language and Vision tasks (LLMs) with Vision-Language (VL) tasks, allowing for the concurrent improvement of image and language models. MMA utilizes a routing algorithm to facilitate the smooth transition of LLMs between single- and multi-modal instructions while maintaining their expertise in natural language understanding. However, this study argues that dynamic adapters such as MMA may not be essential for achieving similar levels of accuracy, which could streamline both time and space requirements.

3 Method

Our research introduces a distinctive approach, termed Bottleneck Adapter (BA), specifically crafted for enhancing large language models (LLMs) with vision-language capabilities. The Bottleneck Adapter seamlessly integrates into LLMs, bestowing them with multimodal functionalities. It adeptly navigates between single- and multi-modal instructions while allowing for a unified optimization of the entire multimodal LLM framework through a process known as Multi Model Tuning (MMT). This methodology is particularly noteworthy for its efficiency, significantly reducing both the computational resources and storage needed during training.

3.1 Bottleneck Adapter Structure

At the heart of our methodology lies the Bottleneck Adapter(BA). Traditional visual adapters typically include a non-linear function to bolster adaptation for NLP tasks. Our research, however, unveils that omitting this non-linearity does not detract from the Adapter's performance in visual tasks. As a result, we redefine the adapter function

$g(Z)$ as:

$$g(Z) = Z + \psi_u(\psi_d(Z)) \tag{1}$$

Here, ψ_u and ψ_d signify the dense projections that are standard in typical adapters. Observing that sparse transformations are fundamental in numerous vision modules, our design introduces a dense-to-sparse architecture for the Bottleneck Adapter. We articulate the transformation ψ_u as a group-wise operation:

$$\psi_u(Z) = [Z^{'}_{p0}W_{p0}, ..., Z^{'}_{pk}W_{pk}] + b \tag{2}$$

In this formulation, $Z_i \in \mathbb{R}^{nx\frac{c}{k}}$ represents the subset of features extracted from $Z \in \mathbb{R}^{mxc}$, with p denoting the total number of groups. $W_i \in \mathbb{R}^{\frac{c}{k}\times\frac{d}{k}}$ is the projection weight matrix, and $b \in \mathbb{R}^d$ is the bias term. This design, pivoting on sparse transformations, considerably trims the BA's complexity, rendering it more streamlined than the typical visual adapters.

3.2 Bottleneck Adapter Placement

Recognizing the profound disparities between visual and linguistic models, we meticulously consider the placement of adapters within the model architecture. Inspired by the LAVIN adapter placement strategy, we select to situate each adapter prior to the Transformer block. This strategic positioning is not limited to Multi-Head Attention (MHA), but is also extended to the Feed-Forward Network (FFN) within the Vision Transformer (ViT). Such a deliberate placement strategy ensures that our adapters are optimally positioned to promote effective and efficient integration and learning within the multimodal LLMs.

In essence, our Adapter-based methodology marks a significant step forward in the realm of vision language adaptation for LLMs, presenting a lightweight, resource-efficient, yet highly effective solution to augmenting the multimodal functionalities of these complex models.

3.3 Model

In our model architecture, we integrate the Bottleneck Adapter into a large language model (LLM), specifically LLaMA-2[25], and pair it with the diht-ViT[26] as the image encoder. For processing an input image $I \in \mathbb{R}^{h\times w\times 3}$, we extract the visual features from the [cls] tokens at every fourth layer of the ViT, represented as $V \in \mathbb{R}^{n\times d}$. In the image encoder architecture, adapters are strategically positioned before each multi-head attention module.

For text instructions, we utilize word embeddings, denoted as $T \in \mathbb{R}^{l\times c}$. To align the visual features with the LLM's dimensionality, we employ a visual adapter, which transforms V as follows:

$$V' = \rho(VW_v + b_v)W_t + b_t \tag{3}$$

Here, $W_v \in \mathbb{R}^{d\times d_v}$ and $W_t \in \mathbb{R}^{d_v\times c}$ are the transformation weight matrices, while $b_v \in \mathbb{R}^{d_v}$ and $b_t \in \mathbb{R}^c$ serve as bias terms. The activation function ρ is chosen as the SwiGLU[27] function for its efficiency. Importantly, the dimension d_v is selected to be considerably smaller than both d and c, optimizing resource usage.

The input to the LLM is defined as:

$$Z = \begin{cases} [u_m, V', T] & \text{for text-image input,} \\ [u_m, T] & \text{for text-only input.} \end{cases} \tag{4}$$

In this equation, $[\cdot]$ symbolizes concatenation. The LLM then predicts the next token in a step-by-step manner based on this multimodal input, which can be mathematically represented as:

$$p_t = \prod_{s=1}^{S+1} p(Q_s | Z, Q_{0:s-1}; \theta_m, \theta_r) \tag{5}$$

Here, $p_t \in \mathbb{R}^m$ indicates the probabilities of the predicted word, with m being the length of the word embeddings. The parameters θ_m and θ_r correspond to those of the LLM and adaptation modules, respectively.

This architecture offers a significant simplification and reduction in complexity compared to previous models such as LLaVA[28]. For instance, the visual neck of our model is six times smaller than that of LLaVA, yet the performance between the two models remains comparable, demonstrating the efficiency and effectiveness of our design.

4 Experiments

In Section 4.1, we detail our approach's multimodal performance on the ScienceQA benchmark. An ablation study conducted on the ScienceQA validation set is presented in Section 4.2.

4.1 Experiment Setup

Datasets and tasks.

Models. In our approach, we utilize the Vision Transformer Large/14 (ViT-L/14-336PX)[29], pre-trained using the DIHT framework[26], to serve as the image encoding mechanism. This process involves the extraction of visual features through six [cls] tokens, each derived from every fourth layer within the ViT-L/14-336PX structure. For the language model component, we incorporate the LLaMA-2-7B variant. The visual processing section, referred to as the visual neck, is configured with a dimension of 128. Meanwhile, the Adapter is specified to have a dimension of 16, with the temperature settings adjusted to 10 for 7B.

Baselines. We compare our method with the recent parameter-efficient fine-tuning methods and adapters where a new adapter structure with down-projection, up-projection and non-linear function are inserted into the transformer (both vision and NLP) and only the parameters of this new module are updated. Our baseline mmodels for comparison include the LaVIN-7B lite-clip[24], the LaVIN-13B - clip[24], the LLaMA adapter[30], LLaVA[28], Chameleon[31], the MM-CoTLarge[32], InstructBLIP (FlanT5XXL)[33] and BLIP-2 (FlanT5XXL)[16].

Implementation details. We process the image by directly resizing to 224×224 without any augmentation. The AdamW[34] optimization algorithm is employed to

fine-tune our model, which undergoes a training regimen spanning 20 epochs, guided by an absolute learning rate. The training process is characterized by a batch size of 1, a learning rate of 0.009, and a weight decay factor of 0.02.

During the text generation phase, a top-p sampling strategy is adopted, utilizing a temperature setting of 0.1 and a top-p threshold of 0.75.

4.2 Results and Analysis

Table 1 Accuracy on ScienceQA test set.

	Subject			Context Modality			Grade		Average
Method	NAT	SOC	LAN	TXT	IMG	NO	G1-6	G7-12	
Human	90.23	84.97	87.48	89.60	87.50	88.10	91.59	82.42	88.40
LaVIN-7B	89.25	94.94	85.24	88.51	87.46	88.08	90.16	88.07	89.41
LaVIN-13B	90.32	94.38	87.73	89.44	87.65	90.31	91.19	89.26	90.50
BLIP-2	-	-	-	-	-	-	-	-	89.5
InstructBLIP	-	-	-	-	-	-	-	-	90.7
MM-CoT-Base	87.52	77.17	85.82	87.88	82.90	86.83	84.65	85.37	84.91
MM-CoT-Large	95.91	82	90.82	95.26	88.8	92.89	92.44	90.31	91.68
LLaVA	90.36	95.95	88	89.49	88	90.66	90.93	90.9	90.92
Chameleon	89.83	74.13	89.82	88.27	77.64	92.13	88.03	83.72	86.54
LLaMA-Adapter	84.37	88.3	84.36	83.72	80.32	86.9	85.83	85.83	85.19
7B-lite-diht-BA(ours)	90.28	92.46	87.91	89.25	87.01	90.38	90.68	89.12	**90.12**

Our 7B-lite-diht-BA demonstrates competitive or superior performance, especially in the SOC and NO context categories. It signifies the model's balanced capability across different subjects and contexts, affirming the effectiveness of our proposed adaptations and optimizations. The human benchmark is 88. 40% average accuracy, highlighting the challenging nature of the ScienceQA dataset and the impressive capability of AI models such as LaVIN-13B, MM-CoTLarge, and our LaVIN-7B-lite-diht in approaching human-level performance on complex and multimodal scientific question answering.

Despite the higher performance of the MM-CoT-Large model, it is important to consider the advantages of our model's lighter and smaller architecture. The MM-CoT-Large model outperformed the 7B-lite-dith-BA (ours) model, likely due to a larger parameter space, sophisticated chain-of-thought reasoning capabilities, and potentially more effective multimodal integration. In social sciences, our method achieves 92.46% accuracy, surpassing LaVIN-7B (94.34%) but falling short of LaVIN-13B (94.38%) and LLAVa (95.95%). This indicates a strong performance, albeit with room for improvement in comparison to the top-performing methods. Our method's accuracy in language-related questions stands at 87.91%, which is competitive against LaVIN-7B (85.24%) but not as high as LaVIN-13B (87.73%) or LLAVa (88%). Our method gave an accuracy of 89.25% in text modality, which is comparably better than LaVIN-7B (88.51%) and closely aligned with the human benchmark (89.60%). With 87.01% accuracy in image-based questions, our method outshines LaVIN-7B (87.46%) but

is marginally outperformed by human accuracy (87.50%). The 7B-lite-diht-BA(ours) achieves an average accuracy of 90.12% across all categories. This is a remarkable result that closely mirrors human performance (88.40%) and surpasses LaVIN-7B (89.41%) by a narrow margin.

Table 2 This table presents the performance of each configuration across various accuracy metrics, demonstrating how changes in the adapter's dimension and group settings affect model performance in different contexts.

Adapter Dim	Groups	Overall Acc
8	2	87.88
16	2	90.12
4	2	86.49
32	2	84.15
16	4	89.74

Table 2 compares performance across various metrics for each configuration. The adapter dimension of 16 with 2 groups stands out as the most effective, achieving the highest overall accuracy and performing well across most individual metrics. Interestingly, increasing the adapter dimension to 32 with 2 groups resulted in lower performance, highlighting the potential for overfitting or inefficient parameter use at higher dimensions.

Table 3 This table presents the performance of various adapters and backbones, demonstrating how changes in the adapter and backbones affect model performance.

S No	Model	Backbone	Adapter	Overall Acc
1	7B-lite-clip	LLaMA	Router	88.35
2	7B-lite-clip	LLaMA-2	Router	88.78
3	7B-lite-alip	LLaMA-2	Router	87.97
4	7B-lite-diht	LLaMA-2	Router	88.68
5	7B-lite-diht	LLaMA-2	Concat Router	87.62
6	7B-lite-diht	LLaMA-2	Concat Router	86.88
7	7B-lite-diht-loha-1	LLaMA-2	loha	63.10
8	7B-lite-diht-loha-2	LLaMA-2	loha	55.10
9	7B-lite-diht-loha-3	LLaMA-2	loha	49.68
10	7B-lite-diht-lora-rep	LLaMA-2	lora-repAdapter hybrid	85.81
11	7B-lite-diht	LLaMA-2	bottleneck with weight scales	84.01

From table 3, if we look at the impact of the change in the backbone (different version of LLAMA), it can be seen that LLAMA-2 gives a slight edge in overall accuracy. With LLAMA[2] and Rep-Adapter[24, 35] we obtained an accuracy of 88.35%, while simply changing the backbone to LLAMA-2[25] we got an accuracy of 88.78 %. The vision backbone used here was CLIP[36]. With this result in mind, consecutive experiments were done using LLAMA-2 as a LLM backbone.

Motivated by CSPNet[37], we did concatenation of features in adapter. We look at the experiments 5 and 6 in which concatenation in adapter was used, it can be

found that concatenation didn't increase the accuracy. For concatenation equation 1 was modified to concatenate the features as: $[\psi_1(Z), \psi_2(Z)]$. The idea was to preserve the features with each blocks.

Experiment 7,8 and 9 were done using LoHa[38] as adapter. In the first one, we didn't use any down scaling convolution. We just used two LoHa conv_1d. While adding these two convolutions we used dynamic weight factors same as in LAVIN[24]. This is formulated as follows:

$$adapter(Z) = \hat{w}_1 \cdot f(Z, W_1) + \hat{w}_2 \cdot f(Z, W_2) \tag{6}$$

where, $\hat{w}_1$ and $\hat{w}_2$ are the routing weights and W_1 and W_2 are the Hadamard product of two low-rank inner matrices, $W := (X_1 Y_1^T) \odot (X_2 Y_2^T)$. In the second experiment, we simply replaced conv_1d in LAVIN with LoHa conv_1d. In the third expeitment, we added silu activation function without any weight factors which can be formulated as follows:

$$g(Z) = \phi_{L1}(Silu(\phi_{L2}(Z))) + Z \tag{7}$$

where, ϕ_{L1} and ϕ_{L2} are the LoHa convolution 1D operators.

Lower accuracy with LoHa can be linked with higher number of trainable parameter added in the adapter. Since, other adapters are using very less number of trainable parameters, they achieve higher accuracy with less data.

In the next experiment (11), we tried an hybrid of LORA and Rep-Adapter. In this LORA was used in LLM backbone (LLAMA-2) and Rep-Adapter was used in the vision backbone (CLIP). The reason of this experiment was to see the relation between dynamic Rep-Adapter with the vision. But the accuracy was not able to surpass the baseline.

In the final experiment we tried our mainline adapter with dynamic weight factors, but the results were not promising. Which allowed us to come to the conclusion that dynamic weight factors are not helpful for multi-modal fine tuning.

While selecting vision backbone we did experiment with CLIP[36], ALIP[39] and DIHT[26]. With CLIP we got an accuracy of 88.78% and with ALIP we got an accuracy of 87.98% and with DIHT we got an accuracy of 88.68%. While CLIP and ALIP used an image size of 224x224, DIHT uses an image of 336x336. With this in mind we used DIHT as our vision backbone even though CLIP had a slight edge over DIHT.

5 Conclusion

In this paper, we introduced a novel approach to enhance large language models (LLMs) with multimodal capabilities, addressing the critical challenge of computational and storage demands in integrating vision-language tasks. Our method leverages lightweight adapters and quantized encoding layers to significantly reduce the memory footprint, facilitating swift training on a single GPU without compromising the model's natural language processing capabilities. By eschewing conventional modular training strategies for an end-to-end optimization regime, we achieved notable efficiency and performance improvements over existing solutions.

ABSTRACT

At present, diesel engines are confronted with the formidable task of reconciling aggressive emission regulations with the preservation of intended engine performance. In order to tackle this concern, India can implement a comprehensive strategy that includes waste reduction, recycling programs, and the innovative use of waste-to-energy technologies. The potential synergistic effects of combining fuel mixtures with cerium oxide nanoparticles in CRDI diesel engines remain unexplored. This study employs response surface methodology and MLP regression to investigate these effects. This study explores the experimental design includes variation in blend ratios of karanja biodiesel (upto 20 %), compression ratios (18–22), and injection pressure (400–1200 bar), as well as CeO_2 nanoparticle concentrations (50–150 ppm) using 10 % biobutanol. A combination of response surface methodology (RSM) and artificial neural network (ANN) techniques is used to assess and optimise the influence of diverse process parameters on engine responses. The machine learning processor (MLP) regressor model is more capable of forecasting engine responses than RSM modelling, as it has lower MAE, RMSE, and higher R^2 values. According to the study, the best blend ratio, CR, Injection Pressure, and CeO_2 concentration for the best performance and lowest emissions are 9.97 % biodiesel blend, CR of 20, an injection pressure of 797.4 bar, and CeO_2 nanoparticle concentration of 100.1 ppm. The MAE value of the MLP regressor-based model ranged from 0.0011 to 0.0119. In terms of RMSE, MLP regressor-based model outputs are within reasonable boundaries. This study highlights the optimization of engine operating parameters and the application of nanotechnology in biodiesel blends. These findings can lead to the development of durable and eco-friendly fuel alternatives for internal combustion engines, promoting sustainable transportation.

1. Introduction

In the 21st century, there is a big issue regarding living organisms due to hazardous pollution. This harmful emission from vehicles and the automobile sector plays an important role in this problem of pollution. These problems have a significant impact on the very existence of human beings, and so must be addressed with the utmost care and caution [1]. In order to combat this problem, the Indian government has implemented various initiatives to reduce emissions from vehicles and to encourage the use of cleaner fuels. Additionally, the government has also implemented stricter emission standards for all vehicles, and stricter regulations for the use of conventional fuels like diesel, gasoline, etc. [2–5].

To achieve the aforementioned conditions, biodiesel has emerged as a viable alternative fuel, notably in India, which has a broad spectrum of flora and fauna [6]. However, due to the underpayment of workers

involved in agriculture, a significant portion of the population remains impoverished. Researchers have conducted extensive investigations and concluded that India has the potential to meet its biodiesel production needs by carefully examining and exploring the plant species available in the country [7–10]. Non-edible oil crops such as Jatropha, Jojoba, Mahua, Polanga, Karanja, Simarouba, and others are gaining popularity as a technique of creating biodiesel without jeopardising food supply, which could lead to malnutrition, famine, and shortages. It is important to exercise caution in the production of biodiesel to ensure that it does not negatively impact food security [11,12]. Biodiesel is seen as more secure than diesel due to its higher flash and fire points. Because of its high oxygen content, its combustion produces less carbon monoxide and hydrocarbons (CO and HC), but it also increases emissions of NOx, one of the most harmful characteristics that can lead to acid rain and smog and thus ecological degradation. There is growing interest in undertaking further research to determine the best acceptable fuel option for contemporary diesel engines [13,14] in light of the existing energy catastrophes dependency on imported fossil fuels, and global warming. Ö. Cihan [15] discovered that biodiesel blends had lower levels of CO, particulate matter (PM), and UHC emissions. Higher biodiesel concentrations did, however, result in a modest rise in NOx emissions in comparison to diesel. According to Ho Young Kim et al. [16] the greater cetane number and oxygen percentage of biodiesel blends led to enhanced combustion efficiency. This resulted in decreased fuel consumption and improved thermal efficiency when weighed against pure diesel fuel. K Viswanathan et al. [17] investigated curry leaf biodiesel and discovered that biodiesel blends dramatically reduced CO, NOx, and total hydrocarbons (THC) emissions when compared to diesel. This demonstrates that biodiesel may serve as an environmentally preferable alternative to diesel fuel.Because of its low volatility and high viscosity, utilising pure biodiesel in diesel blends can lead to inadequate atomization and unfinished combustion, and it also creates carbon deposits [18].

Despite biodiesel's many benefits, there are some drawbacks to using it in internal combustion engines. Some biodiesel's much higher viscosity compared to diesel leads to issues including a smaller injection spray angle, deeper in-cylinder immersion of the fuel spritz, greater strain on fuel pump components, narrower poor vaporisation, huge droplet formation, and poor fuel atomization. In addition, biodiesel's mass-based gross energy density is roughly 12 % lower than diesel's, resulting in slower engine speed and less efficient operation. The increment of NOx emission is also a big issue with biodiesel [19–21]. The addition of nanoparticles to biodiesel and fitting with diesel, on the other hand, can relieve all of the difficulties connected with the direct use of biodiesel in internal combustion engines because it prevents significant engine alterations such as replacing the fuel line arrangement. Furthermore, the scientists suggest that a diesel–biodiesel combination with nanoparticles improves efficiency. In studies on emissions from this combination, researchers found low levels of CO and HC, as well as low levels of NOx and CO_2. As a result, it is prudent to investigate

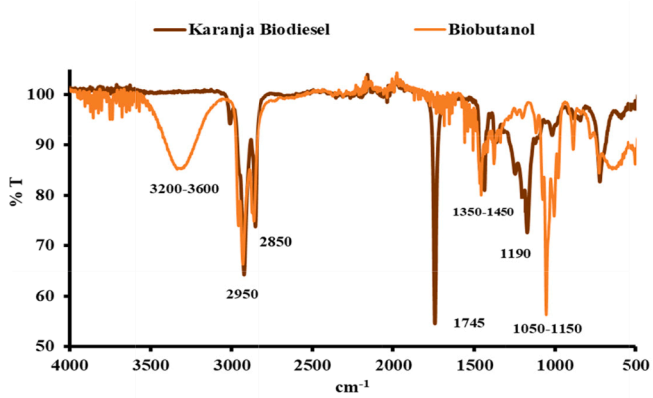

Fig. 2. FTIR of Karanja Biodiesel and Biobutanol.

nano-additives that can increase performance, reduce harmful emissions, and encourage greater fuel economy. There have been sevral studies [22–25] that looked at the potential benefits of using metal nanoparticle-based additives in biodiesel and its blends to boost engine performance. Metal oxides such as aluminium (Al_2O_3), titanium (TiO_2), copper (CuO), cerium oxide (CeO_2), carbon nanotubes (CNT), and more are known to help in the catalytic combustion of hydrocarbon fuels. As a consequence, introducing such ingredients to biodiesel fuels may enhance fuel properties including radiative mass transfer, ignition delay reduction, and self-ignition settings within the combustion zone [25–27]. Yusuf et al. [28] studied the effects of adding CeO_2 nanoparticles to biodiesel-diesel blends and discovered that all blends ofnanofuels enhance HRR, reduce CO and UHC emissions, and increase NOx emissions from 2.78 % to 19.01 %. Shengbo Ge et al. [29] revealed that TiO_2 nanoparticles at 50 ppm applied to blends (diesel + microalgae) enhance BTE by 5 %, reduce BSFC, raise HRR and cylinder pressure, and improve the combustion process. As a result, lower HC, CO, and CO_2, while increasing NOx.Cerium oxide (CeO_2) is utilised as an ingredient with diesel and biodiesel blends in this study to investigate its effect on the performance and emission aspects of CRDI engines. Due to its long-term viability, low cost, and simplicity of usage, the synthesis of CeO_2 has recently attracted a lot of attention. Therefore, CeO_2 was chosen as the preferred nano-additive for this study project. The oxygenated content of cerium oxide, which can enhance engine characteristics, is another factor in its selection as the chosen nano-additive for this investigation. Also, the addition of cerium oxide nanoparticles to biodiesel fuel enhanced its flash point and kinematic viscosity [30].

Numerous experts have undertaken comprehensive tests on diesel engines fueled with mixed diesel fuels, revealing a complex interplay of factors that influence engine performance. Singh et al. [31] delved into the impact of butanol blends on unmodified CI engines, noting a nuanced trade-off between engine power and brake thermal efficiency.

Meanwhile, Ge et. al.[32] shed light on the perplexing dynamics of particulate matter and emissions, highlighting the role of oxygen availability in mitigating pollutants while observing slight increases in certain emissions. Singh et. al. [33] contributed to the discourse by uncovering the surprising influence of oxygen on cold start combustion uncertainties, challenging conventional notions of fuel properties' importance. Yan et al. [34] explored the burstiness of optimal operational conditions in compression ignition engines with butanol diesel blends, emphasizing the significance of injection pressure thresholds. Parvesh et. al. [35] provided valuable insights into the burstiness of injection timing's effects, revealing a complex relationship between timing adjustments, emissions, and engine efficiency. Finally, Praveen et al. and Cai et al. [36,37] documented burstiness in brake thermal efficiency with varying oxygenate content, while also unveiling perplexing trends regarding ethanol's impact on emissions profiles. Together, these studies underscore the intricate nature of diesel fuel blends and their effects on engine performance, highlighting the importance of considering burstiness and perplexity in optimizing combustion processes.

The researchers had to undertake multiple trials to determine the optimal blend of elements for achieving the target results. As a result, researchers in numerous fields have begun to employ optimisation techniques to cut time consumption and forecast unknown combinations of parameters. The response surface method (RSM) is a mathematical tool for planning experiments and optimising variable effects [38]. The fundamental purpose of using RSM in experiment design is to maximise a response outcome (the contingent factor) that is influenced by controlled factors (the independent variables). The RSM optimisation

approach can also be utilised to improve the mixture ratio for binaries or ternary fuel in regard to engine performance, emissions, and nanoparticle concentration [39,40].

Unfortunately, several experimental research in the field of engineering necessitate large time and financial commitments. As a result, academics have focused their efforts on reducing the number of experimental trials [41]. The critical aspect in these endeavours is anticipating the experimental results. Tosunet et al. [42], predicted CO, NOx, and CO_2 emissions from a diesel and nanoparticle-blended CI engine. To forecast emissions, the scientists used ANFIS, regression analysis, and ANN algorithms in their study. According to their findings, the most successful model for estimating emissions in this investigation was ANFIS, subsequent to ANN and regression analysis. Machine learning models can complement complex physical models and optimize engine performance, emissions, and lifespan [43]. Meanwhile, Jafarmader et al. [44] used a wavelet neural network and a stochastic gradient technique to predict engine performance and emission attributes. During the algorithm's training phase, the authors took into account engine speed and nanoparticle percentages. They demonstrated unequivocally that the wavelet neural network was a fairly precise and efficient method for forecasting the nonlinear reactions of CI engines. A random forest machine learning tool, trained on experimental engine data, effectively predicts IMEP, reducing the need for extensive testing and aiding in engine design and optimization [45]. In another study, Saraee et al. [46] studied the impact of incorporating CeO_2 nanoparticles into a diesel engine on both performance and emission parameters. For projecting these traits, the authors also used the ANN algorithm. The results demonstrated that when forecasting CI engine reactions, ANN generated very pleasing results. Machine learning improves mixing models in high-Ka turbulent combustion by accurately specifying key parameters, significantly enhancing performance over empirical models with minimal sensitivity to input uncertainties [47].

As a result, researchers have demonstrated the capability of making very accurate predictions about experimental results. This innovation

NOx	0 – 5000 ppm	±10 ppm	Chemiluminescence Detection (CLD)

not only saves time and money [48,49] but also demonstrates the possibility for significant efficiency gains in the engineering area.

This study developed machine learning models to relate engine control variables to efficiency and emissions. The artificial neural network outperformed the random forest in accuracy for predicting combustion processes [50]. ANN outperformed other algorithms in accuracy, effectively removing noise and revealing that a higher compression ratio and near-stoichiometric equivalence ratio improve engine power without requiring compression ratio modifications [51].

The preceding research shows that fuel with nanoparticles is an excellent combination for enhancing engine performance and reducing emissions. The impacts of various process parameters, including applied load, engine speed (RPM), compression ratio, injection timing, injection pressure, fuel blends, additives, and nanoparticles, have been documented in the literature review [52,53]. Among these, fuel blends, injection pressure, doping of nanoparticles, and compression ratio have been identified as particularly significant for engine performance, especially in CRDI engines. Controlling of these parameters simultaneously makes polynomial response equations (parameters) almost difficult to address optimum response. So, new machine learning techniques like MLP regressor of ANN add novel dimensions to find the optimum solution with the help of RSM and, at the same time, CRDI engines with the provision of variable compression ratio and variable injection pressure provide unique response outcomes for transport engines. Specifically, the proper selection and optimization of parameters can substantially enhance engine performance without engine modifications.

Furthermore, it has been observed that other machine learning methods, such as the multilayer perceptron (MLP) regressor of ANN, are extensively used in a variety of technical domains. To the best of the Authors' knowledge, no previous work has used multilayer perceptron (MLP) regressor algorithms to forecast engine emission and performance parameters. To fill this void, the current work will apply this method to the emission and performance features of a diesel engine fueled by cerium oxide nanoparticles biodiesel-diesel blends.

1.1. Novelty

Previous research are concentrated on either biodiesel feedstocks or alcohols, but this study investigates the combination of biodiesels generated from Karanja and Biobutanol to improve fuel qualities and engine performance. The synergistic effects of combining fuel blends (karanja biodiesel, diesel and 10 % biobutanol) with cerium oxide nanoparticles are investigated in this work, which is largely unexplored in the context of CRDI diesel engines. Another distinctive feature of this study is the utilisation of the response surface approach and MLP regressor. RSM allows for the simultaneous optimisation of input variables while taking into account their interactions and nonlinear effects. RSM is utilize to determine the appropriate blending ratios of Karanja biodiesel, nanoparticle concentrations with variations of compression ratio and injection pressure. It resulted the best balance between engine performance (BSEC and BTE) and emissions characteristics (CO, NOx and HC). This study coupled with multilayer perceptron (MLP) regressor algorithms in ANN approch to forecast engine emissions and performance. The evaluation is based on two key metrics: MAE and RMSE. The findings should contribute to the optimisation of alternative fuels and nanotechnology in CRDI diesel engines, paving the way for more sustainable and efficient transportation systems.

2. Materials and methods

2.1. Preparation of fuel

2.1.1. Biodiesel

Transesterification is a common method for manufacturing biodiesel from plant-based or fats from livestock. Step-by-step procedure for the transesterification process, which was developed specifically for manufacturing Karanja biodiesel: Karanja seeds are procured from botanical gardens of Delhi Technological University, and oil has been extracted through mechanical extraction processes. Oil has been refined through mechanical processes and is free from contaminants such as water, particles, and other pollutants. To begin, heat 100 ml of raw oil at 100 °C to remove water traces from the oil. Meanwhile, a sample of methoxide (Methanol and KOH in a 6:1 ratio) is created in a beaker. The raw oil is now being cooled to roughly 60 °C. The methanol-KOH combination was then progressively added to the heated Karanja oil in the reactor while stirring constantly to encourage excellent mixing and contact between the reactants. For about an hour, the reaction is kept at a temperature of 50–60 °C as shown in the Fig. 1. The catalyst promotes the conversion of triglycerides to methyl esters (biodiesel) by facilitating the interaction between Karanja oil and methanol. Allow the mixture to settle for a sufficient amount of time after the reaction to separate the glycerin phase (bottom layer) from the biodiesel (top layer). This settling stage could continue many hours or overnight. When the separation is complete, carefully drain the glycerin layer from the bottom of the reactor. The biodiesel was then properly cleansed with clean water to remove any remaining catalyst, soap, or impurities. Allow enough settling time after each wash and gently agitate the mixture while washing. The biodiesel was dried after washing to eliminate any leftover water. For purity of biodiesel Fourier Transform InfraRed (FTIR) of the karanja biodiesel is shown in Fig. 2, peak at 1745 cm^{-1} indicates the presence of ester carbonyl group, confirming the fatty acid methyl esters. The peak at 2850–2950 cm^{-1} corresponds to C–H methylene and methyl group in the fatty acid chains, whereas the peak at 1190 cm^{-1} is due to C-O stretching vibration confirming the ester linkage in biodiesel molecules.

2.1.2. Biobutanol

Fermentation of biomass source (sugar cane) is chosen to make Biobutanol of bio-origin. Biomass is introduced to clostridium acetobutylicum for the consumption of sugar and produces Biobutanol and byproducts like acetone and ethanol. After fermentation the mixture is separated using distillation, as Biobutanol has higher boiling point compared to ethanol and acetone. The crude Biobutanol is treated for solvent extraction for further refining to meet specific quality standards. For purity of biobutanol Fourier Transform InfraRed (FTIR) of the obtained biobutanol is shown in Fig. 2, a broad peak at 3200–3600 cm^{-1} indicates the O–H stretching vibrations, characteristics of alcohols. The peak at 2850–2950 cm^{-1} corresponds to C–H stretching in the alkyl group, whereas the peak in the range of 1350–1450 cm^{-1} indicates O–H bending vibrations, which further confirms presence of alcohol. Peaks around 1050–1150 cm^{-1} is due to C-O stretching vibration confirming the presence of alcohol functional group.

2.1.3. Cerium oxide nanoparticles

CeO_2 nanoparticles were purchased from an authorised vendor of Sigma Aldrich. Characterisation of the nanoparticles is shown in the Fig. 3. In Fig. 3 (a), the Scanning Electron Microscopy depicts that the average particle size of 25–30 nm and spherical structure of the particles. X-Ray Diffraction is illustrated in Fig. 3 (b) and detection of cerium oxide element in the nanoparticle confirming the purity of the nanoparticles.

2.2. Preparation of fuel samples

The test fuels were prepared by amalgamating karanja biodiesel, Biobutanol, and diesel alongside CeO_2 nanoparticles. The ratios of karanja biodiesel were varied up to 20 %, accompanied by 10 % Biobutanol, and CeO_2 nanoparticles ranging from 50 to 150 ppm within the fuel blends. These blends underwent ultrasonication at 40 Hz for a duration of half an hour. Following this procedure, it was noted that the samples remained steadfast for over 72 h without necessitating any surfactants.

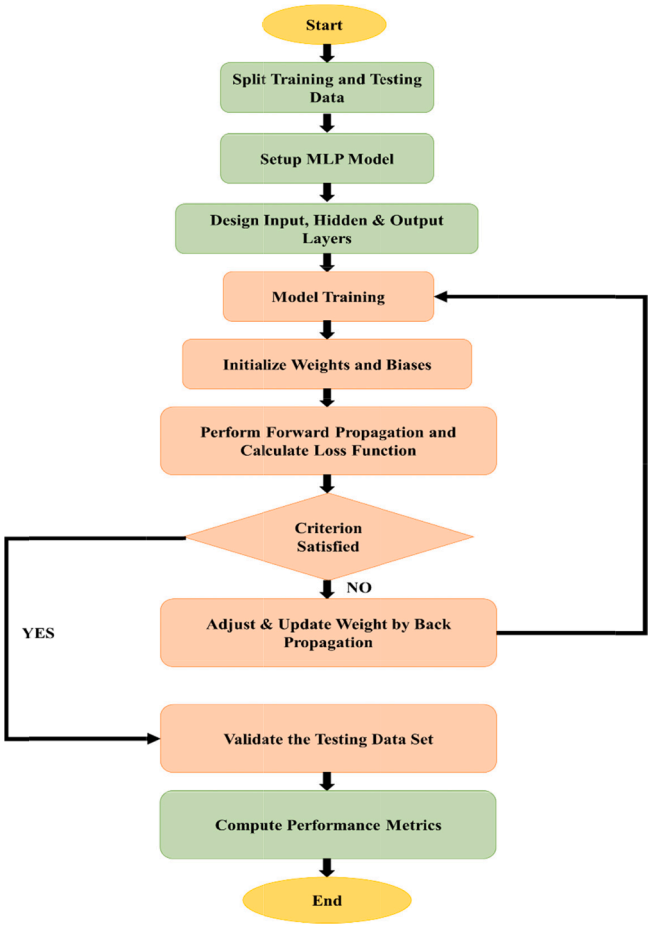

Fig. 6. Flow Chart of MLP algorithm.

Table 1 shows the test fuel samples of 100 ml in each bottle blended with diesel, Karanja biodiesel and biobutanol. The biobutanol ratio is kept constant at 10 %, and Karanja biodiesel is varied from 0 to 20 % v/v. where D refers to diesel, KB means Karanja Biodiesel and BB is Biobutanol. The term D85KB05BB10 means a blend of 85 % diesel, 5 % karanja biodiesel and 10 % biobutanol.

The physico-chemical properties of Karanja biodiesel and Biobutanol are measured and mentioned in Table 2 with ASTM standards.

Biobutanol, biodiesel-diesel blend, CeO_2 nanoparticles, and diesel biodiesel fuels had been employed as experimental fuels in this experiment. For the experiment, CeO_2 nanoparticles with a particle size range of 10 to 25 nm were utilised. The CeO_2 nanoparticles were mixed with diesel fuel at concentrations of 50, 75, 100, 125, and 150 ppm in fuel samples. The process used to disperse nanoparticles in the test fuel by using ultrasound reduces the possibility of nanoparticle aggregation for around 30 min.

2.3. Engine setup and procedure

All the testing has been done on partial full loading (i.e. 80 % load) with a corresponding torque of 24 Nm at an engine speed of 1500 rpm at around 4.8 bar of BMEP, on a single-cylinder 4-strokes, CRDI diesel engine of 661 cc with water cooling has been employed to conduct this experiment. Fig. 4 displays diagrammatic representations of the test rig and engine parameters. The engine's compression ratio can be adjusted by manipulating the position of the auxiliary piston using the screw rod and hand wheel assembly. The calibrated scale is provided on the screw rod assembly to enable exact positioning of the auxiliary piston to a different compression ratio (CR). The test engine was subjected to a load-through by utilising an eddy current dynamometer. The rotary encoders and piezoelectric pressure sensors were utilised to measure the combustion chamber pressure and crank angle. The weight loss of fuel in the fuel tank was determined by using a load cell, which allowed for the calculation of the rate of fuel flow. An airflow measurement was conducted using a manometer equipped with an aperture. The proximity sensor was utilised to determine the speed of the engine. Performance

parameters were evaluated subsequent to the collection and analysis of test parameters using the computerised engine analysis software "EngiSoft". The emissions of NOx, HC, and CO from the engine were monitored and analysed using an AVL gas analyzer. The specification of the engine setup and AVL Gas Analyser are given in Table 3 and Table 4.

2.4. Uncertainty analysis

Analysis of uncertainty is a crucial part of both engineering studies and scientific research. It entails evaluating and quantifying the degree of uncertainty around observations, computations, and model projections. Researchers can assess the correctness and dependability of their findings, pinpoint the causes of inaccuracy, and give a degree of confidence in their conclusions by doing an uncertainty analysis. Nevertheless, the uncertainty or error ratio is influenced by various factors, including the selection and calibration of the equipment, measurement methodologies, weather conditions, and experimental design. The Guide to the Expression of Uncertainity in Measurements (GUM) technique was used in this analysis to obtain the uncertainty, which is detailed below:

Total Uncertainty $= \pm \sqrt{\{}$(uncertainty of Speed sensor)^2 + (uncertainty of pressure sensor)^2 + (uncertainty of temperature sensor)^2 + (uncertainty of load cell)^2 + (uncertainty of Manometer)^2 + (uncertainty of fuel flow)^2 + (uncertainty of stop watch)^2 + (uncertainty of CO)^2 + (uncertainty of HC)^2 + (uncertainty of NOx)^2}.

$= \pm \sqrt{\{(0.1)^2 + (0.1)^2 + (0.15)^2 + (0.2)^2 + (1)^2 + (1)^2 + (0.2)^2 + (0.2)^2 + (0.2)^2 + (0.2)^2\}}$.

$= \pm 1.49$ %.

3. Optimization and Machine learning

3.1. Response surface methodology

Response Surface Methodology (RSM) is a statistical method for analysing and optimising systems or processes. Understanding the relationship between the input factors and the output factors of interest necessitates the use of mathematical models, specifically polynomial quadratic equations. RSM reduces the number of experiments needed and improves a response that is affected by several input variables. Fuel blends, CR, CeO_2 nanoparticle concentration, and injection pressure were all investigated in this study as input factors. Based on the prior research by Kumar et al. [52] and Pali et al.[54], the ranges for optimizing parameters have been determined, which were further refined through the conduction of pilot tests. BTE, BP, CO, HC, and NOx are a few examples of output reactions that these factors could affect. In this study a full factorial CCD is used which gives 30 runs in the design of experiments with 16 factorial points, 8 axial points and 6 center points. Flow chart of RSM is shown in Fig. 5. The input parameters and their levels are shown in Table 5.

The total number of experimental runs necessary to build the response surface when there are four variables with five levels each varies on the experimental design that is used. The Central Composite Design (CCD), which comprises factorial points, axial points, and centre points, is one often used design.The overall number of trials for a four-factor CCD with five levels is as follows:

Total number of experiments $=.2^p + 2p + c$

Where, 2^p is the factorial point, 2p is the axial point and c is the central point runs (i.e. 6), p is the number of input factor i.e. 4.

Total number of experiments $=2^4 + 2*4 + 6 = 30$ runs.

The 30 experiment runs were performed on the CRDI engine and their result were shown in Table 6.

3.2. RSM modelling and ANOVA analysis

The statistical metrics, such as R^2, Adjusted R^2, Predicted R^2, the F-value, and p-value, were calculated using ANOVA after conducting trials according to the design matrix. P-values below 0.05 are considered statistically significant when the F-value rises and the P-value drops, indicating greater significance. Table 7 presents the results of the engine performance, combustion, and emission reaction R^2, corrected R^2, and anticipated R^2. The second-order response surface models for brake thermal efficiency (BTE), brake specific energy consumption (BSEC), carbon monoxide (CO), hydrocarbons (HC), and nitrogen oxides (NOx) were constructed in Design Expert 13 using the experimental response data acquired from the central composite design (CCD) matrix. The BTE, BSFC, CO, HC, and NOx values are calculated using the equations provided in Tables 7 and 8. Table 9 presents the results of the engine performance and emission response, including the R^2, corrected R^2, and anticipated R^2 values.

3.3. Machine learning algorithms

Machine Learning (ML) is a common subset of Artificial Intelligence (AI) techniques. Because of its outstanding precision and efficacy, AI has received substantial attention and popularity due to its varied applications [46,48,49]. AI not only has an intrinsic attraction, but it also has an inherent potential to explore new realms and forecast uncharted scenarios. Without a doubt, the efficacy of ML algorithms is inextricably tied to user characteristics and the degree of success in their training. The performance of ML algorithms demonstrates their potential, which is moulded by user skill and the success of their training procedures. In the context of the current study, an in-depth examination of Multi-layer Perceptron Regressor (MLPR) algorithms was carried out. This algorithm was thoroughly explored, providing light on their unique traits, capabilities, and applications. A MLP regressor is preferred over other machine learning models due to its ability to capture complicated, nonlinear relationships in data, making it highly adaptable for a variety of regression applications. MLPs are capable of managing high-dimensional data and learning from detailed patterns, ensuring robustness against noisy data. Given a sufficient number of neurons in the hidden layers, they may approximate any continuous function, allowing for flexibility and power in a variety of regression applications. Furthermore, MLPs may be easily customized to different sorts of issues by modifying their architecture, which includes the number of layers and neurons, activation functions, and training procedures. MLPs also function easily with modern machine learning frameworks and can supplement other models in ensemble techniques, expanding their utility in a variety of applications.This analysis yielded a more detailed knowledge of the this algorithm, laying the groundwork for informed decision-making in their actual implementation. Fig. 6 give the flow diagram of MLP regressor.

Using MLPR algorithms to model engine responses, the study focuses on forecasting engine performance metrics (brake power and brake thermal efficiency) and emission characteristics (nitrogen oxides (NOx), carbon monoxide (CO), and hydrocarbons(HC). The algorithm uses four important input elements during the training phase: injection pressure (ranging from 400 to 1200 bar in 200 bar increments), biodiesel blend percentage (ranging from 0 to 20 %), CeO_2 nanoparticle concentration (ranging from 50 to 150 ppm), and compression ratio (18 to 22).A dataset of 30 data points is used to facilitate this investigation. The dataset is partitioned using a random shuffled sample strategy to maintain robustness. Notably, 70 % of the data points are set aside for algorithm training, with the remaining 30 % set aside for testing. The machine learning algorithm used in this study requires additional development. It uses complex quantitative methods to establish connections between the factors mentioned above and the engine's outputs (such as performance and emissions). Using this computational approach, we are able to comprehend the interplay between these numerous properties, which will lead to improvements in engine design and optimisation.

3.4. Multi-layer perceptron regressor (MLPR)

For many machine learning regression tasks, the multilayer perceptron (MLP) regressor is the ANN of preference. It is a feed forward neural network that can be trained to figure out intricate nonlinear connections between inputs and outputs, thanks to its many layers of artificial neurons (often called perceptrons).

To sklearn with a neural network. Scikit-learn's MLP Regressor represents an MLP regressor, a type of multi-layer perceptron. With its ability to do regression tasks, MLP is a sort of ANN. It may be trained to recognise non-linear associations between input and output.

Table 10
Metric equation, outline, and assessment.

Metrics	Equation	Description	Performance Criteria
MAE	$\mathbf{MAE} = \frac{\sum_{i=1}^{n}\left(\mathbf{Y_i^{predicted}} - \mathbf{Y_i^{experimental}}\right)^2}{\mathbf{n}}$	The MAE is a widely used indicator that provides useful insights into prediction models' prospective performance potential. Its widespread application emphasizes its importance in measuring predictive model efficacy over long time periods. MAE provides practitioners with a full grasp of a model's ability to maintain consistent accuracy across varied settings by quantifying the equilibrium between mistakes.	The lower value of MAE is a solid indicator that the used prediction model performs well. In fact, an MAE score of zero is the ideal circumstance, indicating a perfect match between forecasts and actual results.
RMSE	$RMSE = \sqrt{\frac{\sum_{i=1}^{n}\left(Y_i^{predicted} - Y_i^{experimental}\right)^2}{n}}$ Where, n = number of training data points; Y=values.	The RMSE is a valuable indicator of the prediction models' immediate efficacy. It is critical in determining how well these models correspond to real-world outcomes. RMSE provides insight into the accuracy and precision of forecasts by quantifying the difference between projected and observed values. This metric allows us to understand not only the existence of deviations, but also their amount, allowing us to conduct a thorough evaluation of the model's efficacy.	The RMSE is a measure that is constantly positive and should be as close to zero as possible. A lower RMSE suggests that a predictive model is more accurate in estimating values. In practice, an RMSE near to zero may indicate a significant alignment between anticipated and actual values, emphasizing the model's efficacy in minimizing prediction mistakes.
R^2	$R^2 = 1 - \frac{\sum_{i=1}^{N}(X_i - Y_i)}{\sum_{i=1}^{N}(X_i - Y_k)}$ Where, $Y_k = \frac{\sum_{i=1}^{N} Y_i}{N}$ N=No training data X_i = Experimental data Y_i = Model anticipated data Y_k = Model average anticipated data	The coefficient of determination is a fundamental measure utilised to evaluate the quality of fit of a regression model.	Although the coefficient of determination offers valuable insights into the accuracy of a regression model, it is important to analyse it alongside other metrics and factors to make accurate inferences regarding the interaction between variables.

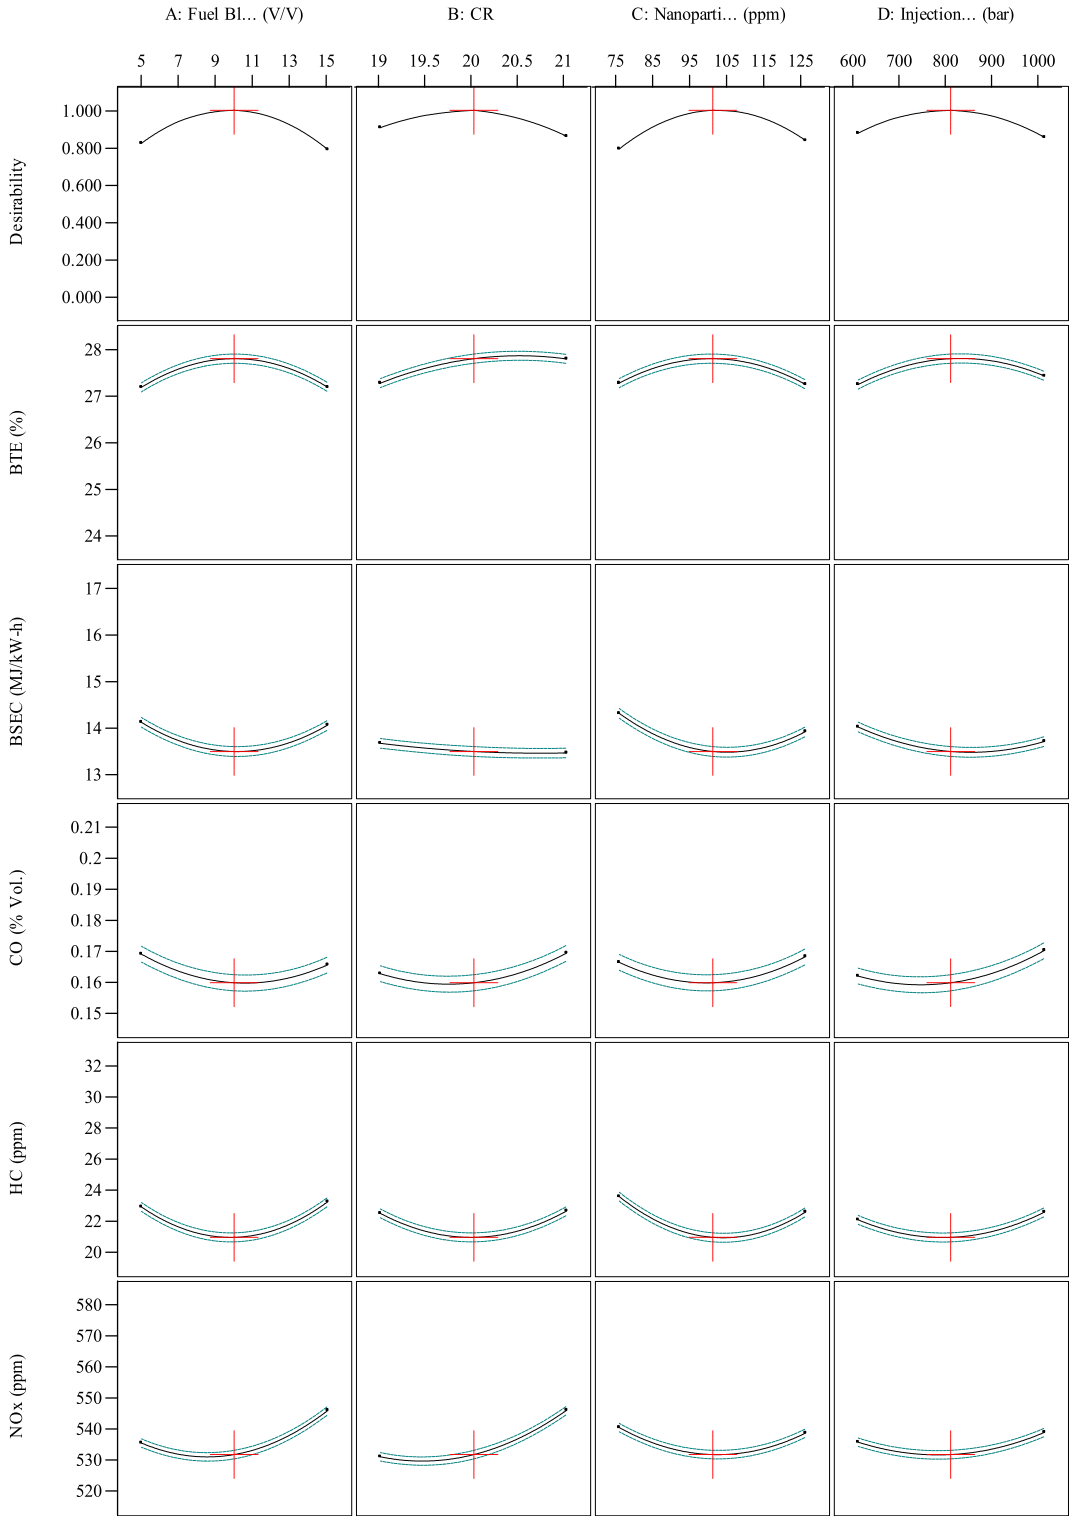

Fig. 10. Optimization plot.

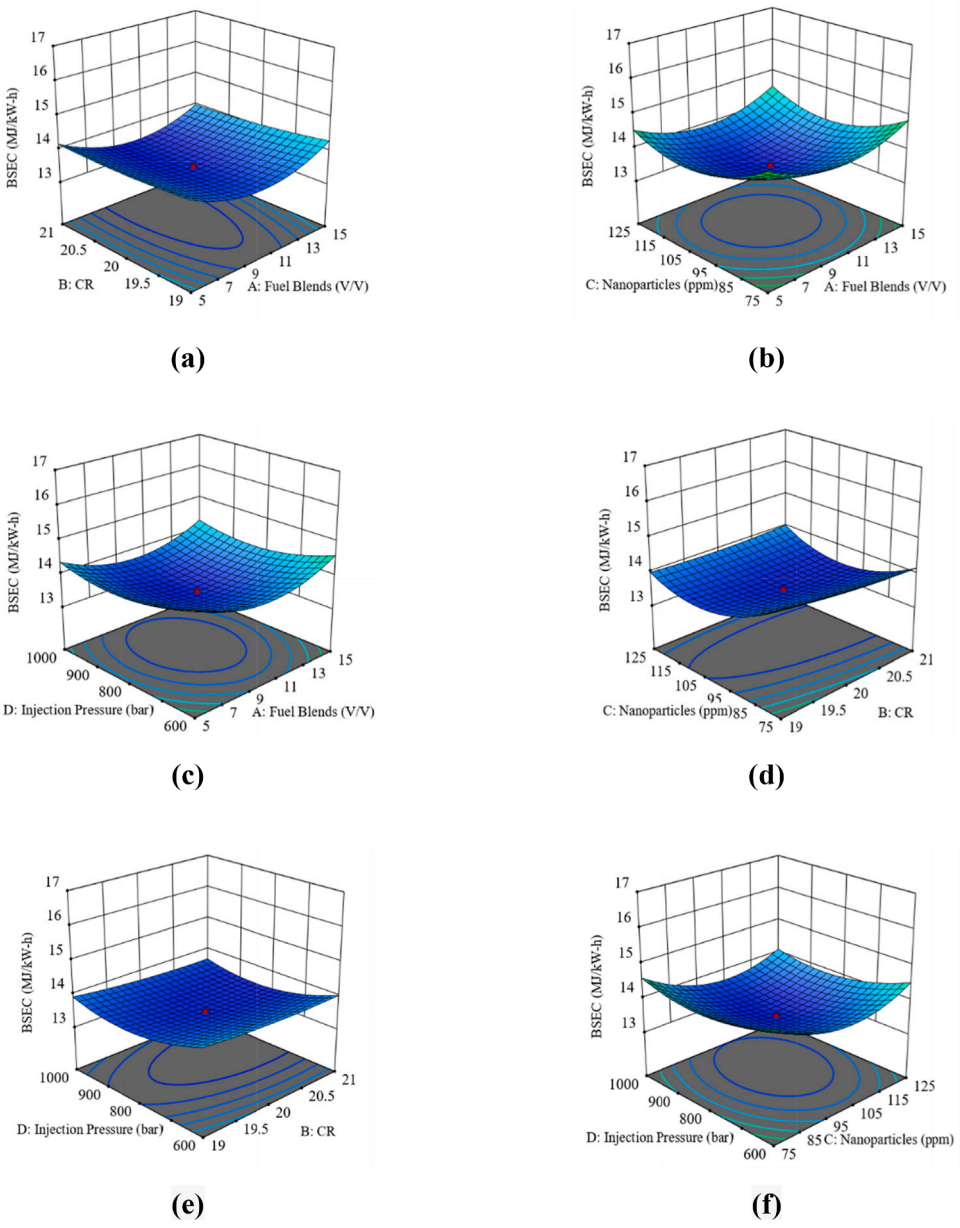

Fig. 11. Variation of BSEC against CR, fuel blend, injection pressure, and CeO_2 nanoparticles.

Throughout several industries, including finance, engineering, and healthcare, MLP regressors are used to address regression problems. Intricate relationships between inputs and outputs can be captured, and they can also be used to approximate complex nonlinear functions. To obtain optimal performance and avoid overfitting or underfitting, the number of hidden layers, the number of neurons in each layer, the activation functions, and the optimisation technique must be carefully chosen. An MLP regressor's architecture consists of three types of layers. The input layer gets four input characteristics (fuel mixes, CR, nanoparticles, and injection pressure), and each neuron represents a particular feature. The hidden layers, which sit between the input and output layers, are made up of many neurons that alter input data to learn complicated patterns. The output layer contains a single neuron that represents the projected output value (BTE, BSEC, CO, HC, NOx), and it generates the final predicted output.

The network architecture typically comprises of an input layer, 50 hidden layers, and an output layer when employing an MLP regressor for 4 inputs and 5 outputs. Each layer is made up of neurons, and the connections between them are represented by weights. Here's a full breakdown of the parts and stages needed in training an MLP regressor with four inputs and multiple outputs. The architecture of MLP regressor model is shown in Fig. 7. To bring nonlinearity into the network, activation functions are introduced to the output of each neuron in the hidden layers and the output layer. ReLU (Rectified Linear Unit), sigmoid, and hyperbolic tangent are examples of frequently employed activation functions. The activation function of MLP regressor model used in present work is shown in Fig. 8. The activation function in a MLP regressor model is an important component that affects the model's capacity to learn and predict. Activation functions add nonlinearity to the network, allowing it to learn from errors and create complicated mappings between inputs and outputs. Weight initialization is crucial to avoid the network being stuck in local optima during training. Before training, weights are generated randomly. During training, forward and backward propagation is performed on batches of training data and the weights are adjusted to minimize the loss function. The limited-memory Broyden-Fletcher-Goldfarb-Shanno (lbfgs) optimization method can be

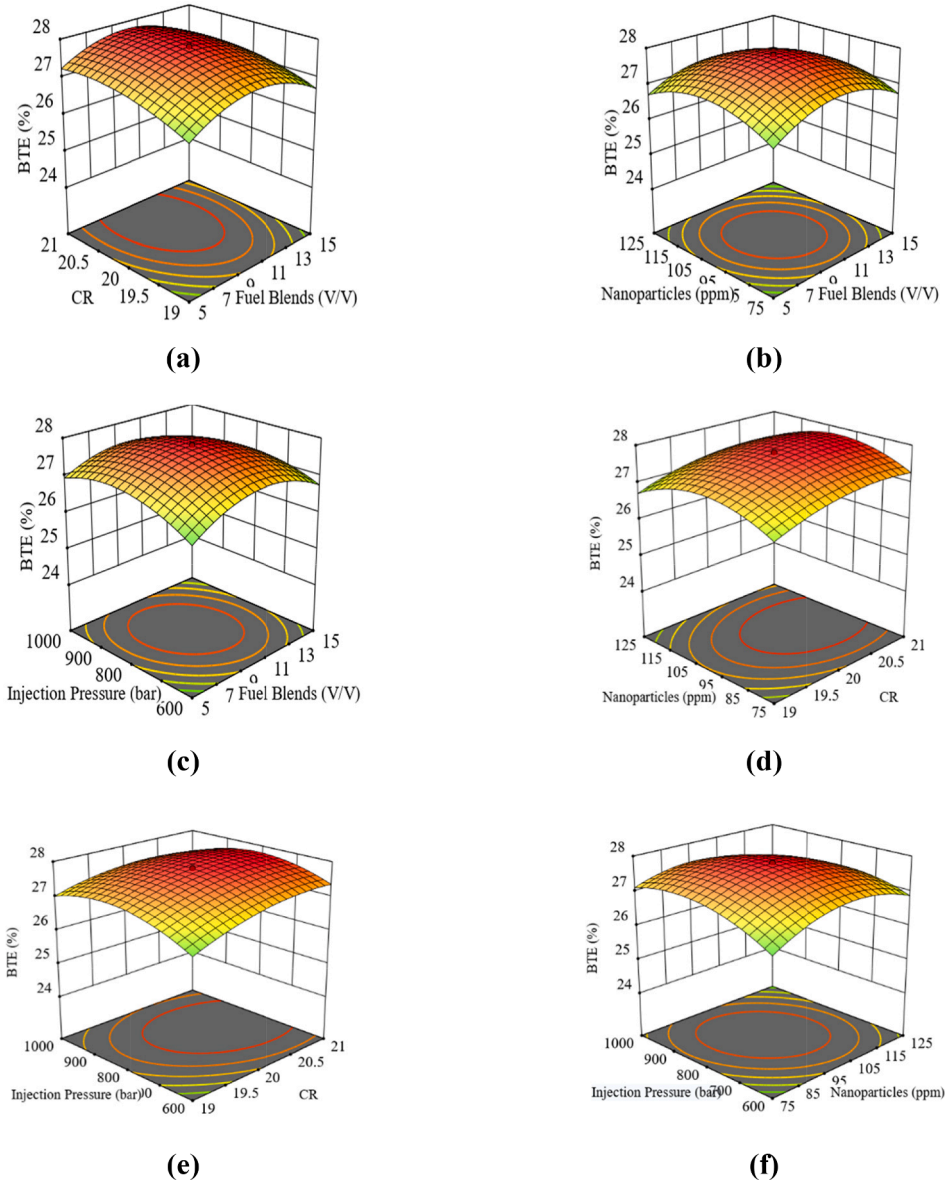

Fig. 12. Variation of BTE against CR, fuel blend, injection pressure, and CeO_2 nanoparticles.

used to adjust the weights during training. This optimizer belongs to the quasi-Newton method family and adjusts the learning rate and momentum to optimize the network's convergence.

3.5. Validation and Testing

Following training, the MLP regressor's performance is assessed on different validation and testing datasets. The regression metrics mean squared error (MSE), mean absolute error (MAE), and R-squared (R^2) are produced to assess the model's accuracy and generalisation ability. The Fig. 9 depicts a series of Python code executed in a Jupyter Notebook environment for the purpose of data processing and machine learning tasks. The starting code block includes the necessary libraries, such as pandas and numpy for data manipulation, sklearn for machine learning models and preprocessing, and matplotlib.pyplot for data visualisation. Subsequently, the code establishes a connection to Google Drive in order to get external files, emphasising the incorporation of cloud storage for data access. The dataset is imported from an Excel file, with certain columns chosen as inputs and outputs, indicating a setup suitable for regression analysis. The last code sample demonstrates data normalisation using the Min Max Scaler from the sklearn library. This process scales the characteristics of the data to a designated range in order to prepare it for modelling. This configuration exemplifies a standard machine learning procedure designed to train models using preprocessed data. The offered code presents a transparent and replicable approach for researchers to preprocess data, specifically by using cloud storage for data retrieval and implementing normalisation algorithms.

A variety of statistical criteria have been devised in the existing body of literature to analyse the performance of prediction models accurately. We used two widely recognized measures that are commonly used in this domain in the context of our study: MAE and RMSE. We hope to completely evaluate our models' prediction capability by incorporating these well-regarded indicators. RMSE provides a full grasp of the dispersion between anticipated values and actual observations, whereas MAE provides insights into the overall bias demonstrated by the model's predictions. Table 10 exhaustively documents the mathematical formulations of these indicators, as well as extensive descriptions and criteria for evaluating their efficacy. This detailed presentation ensures that everyone understands how these indicators contribute to the

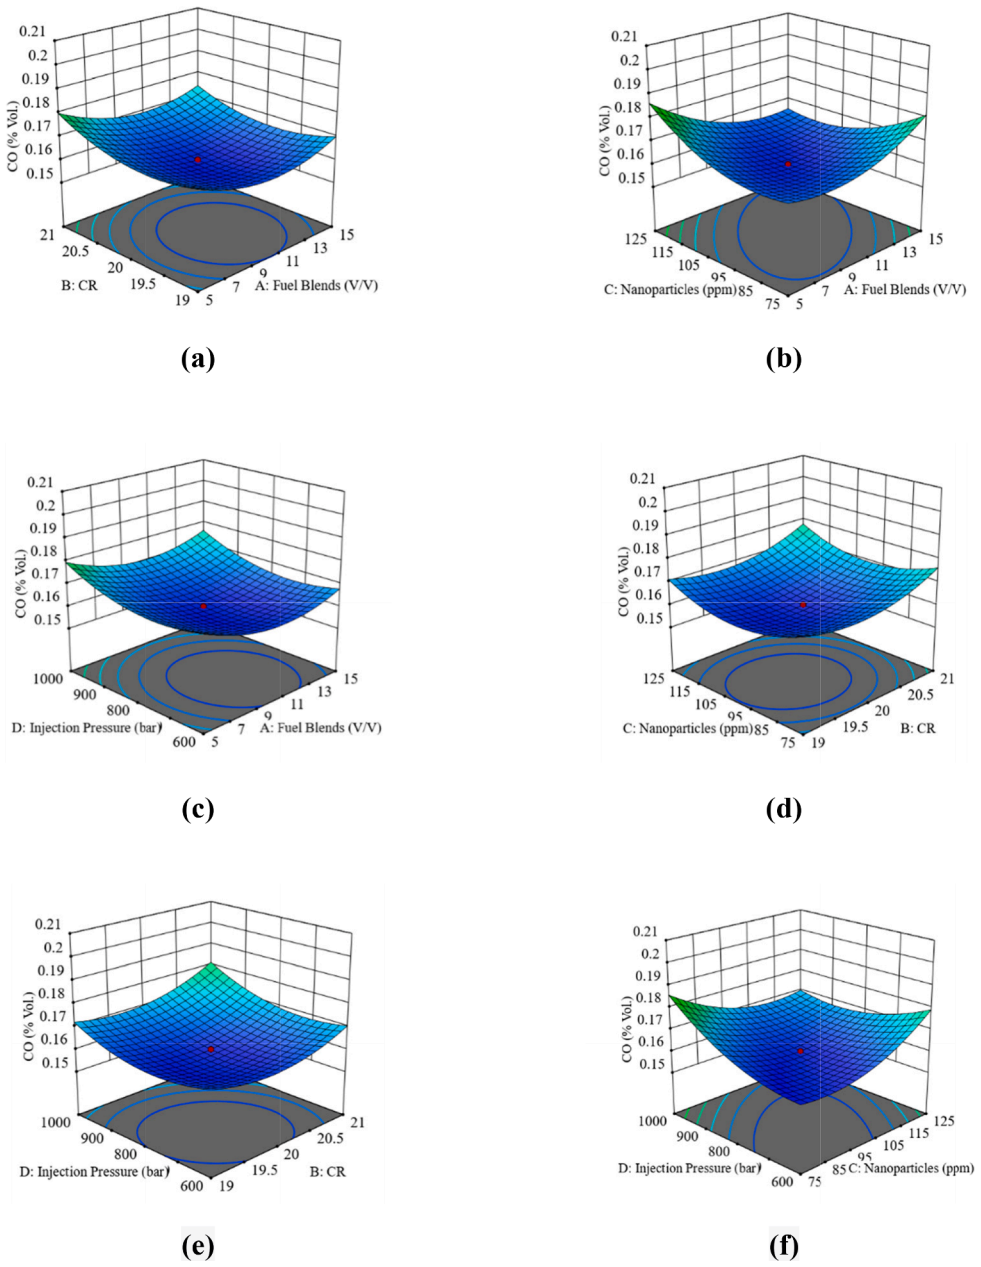

Fig. 13. Variation of CO emission against CR, fuel blend, injection pressure, and CeO_2 nanoparticles.

evaluation of our prediction models and helps us make relevant conclusions from our research.

4. Result and discussion

4.1. Results obtained from RSM

This section focuses on the effect of diesel engine input factors on five engine output responses. During surface plotting, the four-engine input variables (CR, Fuel Blend, CeO_2 concentration, and Injection Pressure) cannot be changed concurrently. Fig. 10 demonstrates the optimizer, and the optimised result for process parameters were obtained as fuel blend of 9.91 %, CR of 20.018, CeO_2 concentration of 10.696 ppm and injection pressure of 793.109 bar. At the optimal engine conditions are BTE of 27.8 %, BSEC of 13.5 MJ/kW-h, CO as 0.16 vol%, HC of 20.981 ppm, and NOx of 531.986 ppm. The obtained desirability of the sytem was found as 0.95.

4.1.1. Effect of control factors on brake-specific energy consumption

BSEC is an important metric for evaluating the efficiency of internal combustion engines. Lower BSEC values indicate greater energy efficiency, meaning the engine or powertrain is able to convert more of the fuel energy into useful work with minimal losses. Fig. 11 demonstrate the combined effect of CR, fuel blend, injection pressure and CeO_2 nanoparticles on BSEC while keeping the other values at hold. Fig. 11(a) illustrate the effect of fuel blends and CR on BSEC. There is a marginal change in BSEC concerning to CR, it was observed as the fuel blends increases the BSEC reduces to 13.49 MJ/kW-h at 10.4 % V/V and it increases further for higher values as the blends increases to 15 % V/V. Sayin et al. [55] also observed a similar pattern of increase in BSEC with fuel blend. Fig. 11(b) demonstrate that optimized value of BSEC is obtained at the range of nanoparticle concentration in between 90.23 ppm to 118.15 ppm while having the fuel blends concentration in range of 6.67 to 11.58 % v/v. Fig. 11(c) illustrate the minimum value of BSEC of 13.5 MJ/kW-h in the fuel blends range of 6.58 to 12.01 v/v with the injection pressure of 791.94 bar. Fig. 11(d) depicts the variation of BSEC

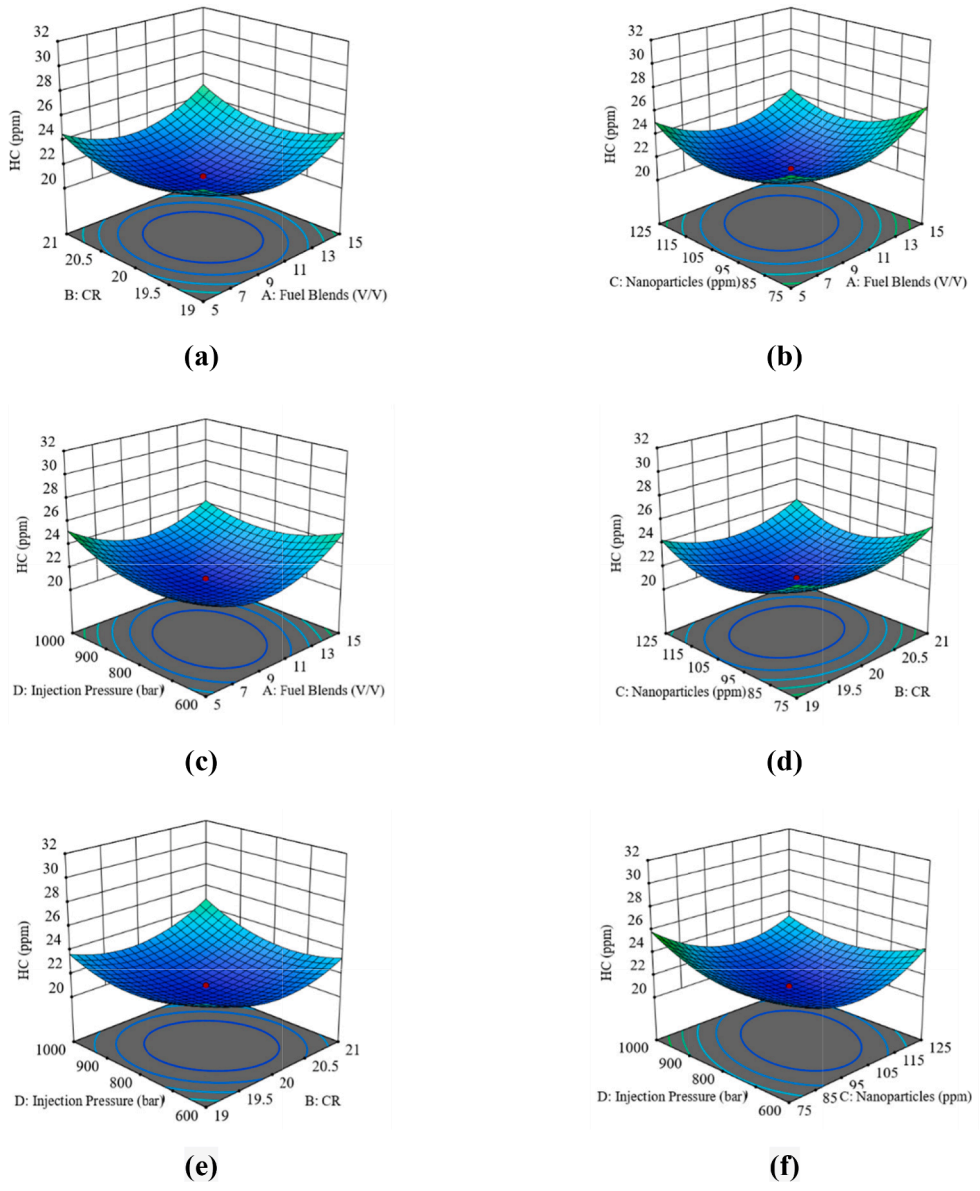

Fig. 14. Variation of HC emission against CR, fuel blend, injection pressure, and CeO_2 nanoparticles.

with nanoparticles range and compression ratio. The optimum value were found in the range of nanoparticles in 90.6 to115.4 ppm, whereas a minimal variation of BSEC were found of 13.6 MJ/kW-h at CR of 19 to 13.4 MJ/kW-h at CR 21. Fig. 11(e) shows the variation of injction pressure of 734.67 bar to 923.86 for the optimum value of BSEC for the range of minimalist compression ratio. The range of injection pressure with variation in nanoparticle is shown in Fig. 11(f). It depicts the optimum value of BSEC is found at the injection pressure of 102.9 bar with the concentration of nanoparticles of 802.14 ppm.

4.1.2. Effect of control factors on brake thermal efficiency

The efficiency with which an engine transfers the energy content of fuel into usable work is referred to as brake thermal efficiency (BTE). The influence of input parameters on BTE with hold values is depicted in Fig. 12. Fig. 12(a) shows the cumulative effect of fuel blend % and CR on BTE. It was found that there is a slight variation in BTE due to the fuel blend % since it is 9.9 % in actual concentration. The biodiesel has a higher CV than butanol, therefore it is marginally increased with blend %. Furthermore, BTE improves with increasing CR up to 20.7, after which it begins to decline. This might be because, with greater compression ratio, the engine may face greater heat losses and pumping losses, resulting in a lower BTE. When changing the load to the different fuel blend ratios, O D Onukwuli et al. [56] discovered an analogous set of findings. Fig. 12(b) depicts the interaction effect of CeO_2 nanoparticles and fuel blend on BTE. The addition of nanoparticles to the test fuel raises the BTE, as illustrated. Because of their huge surface area and catalytic impact, nanoparticles increase BTE, resulting in more fuel oxidizer contact and rate of reaction, which enhances combustion efficiency. The optimum value of BTE is observed within the range of nanoparticles in 85.4 to 114.9 with the variation of fuel blends of 7.17 to 12.8 % v/v. Fig. 12(c) depicts the variation of injection pressure and fuel blend on BTE, it shows optimum range of injection pressure within 688.5 bar to 947.7 bar for range of fuel blends within 7.07 to 12.5 % v/v. Fig. 12(d) illustrate that optimum value of BTE is observed at CR higher than 19.6 for the range of nanoparticles in 86.2 to 113.34 ppm. Furthermore, higher BTE is associated with higher compression ratios. A higher CR raises the temperature and pressure of the air in the combustion chamber, enabling better fuel atomizing and blending. This results in more consistent and efficient combustion, which improves BTE [57]. Fig. 12(e) depicts the impact of CR and injection pressre on the BTE

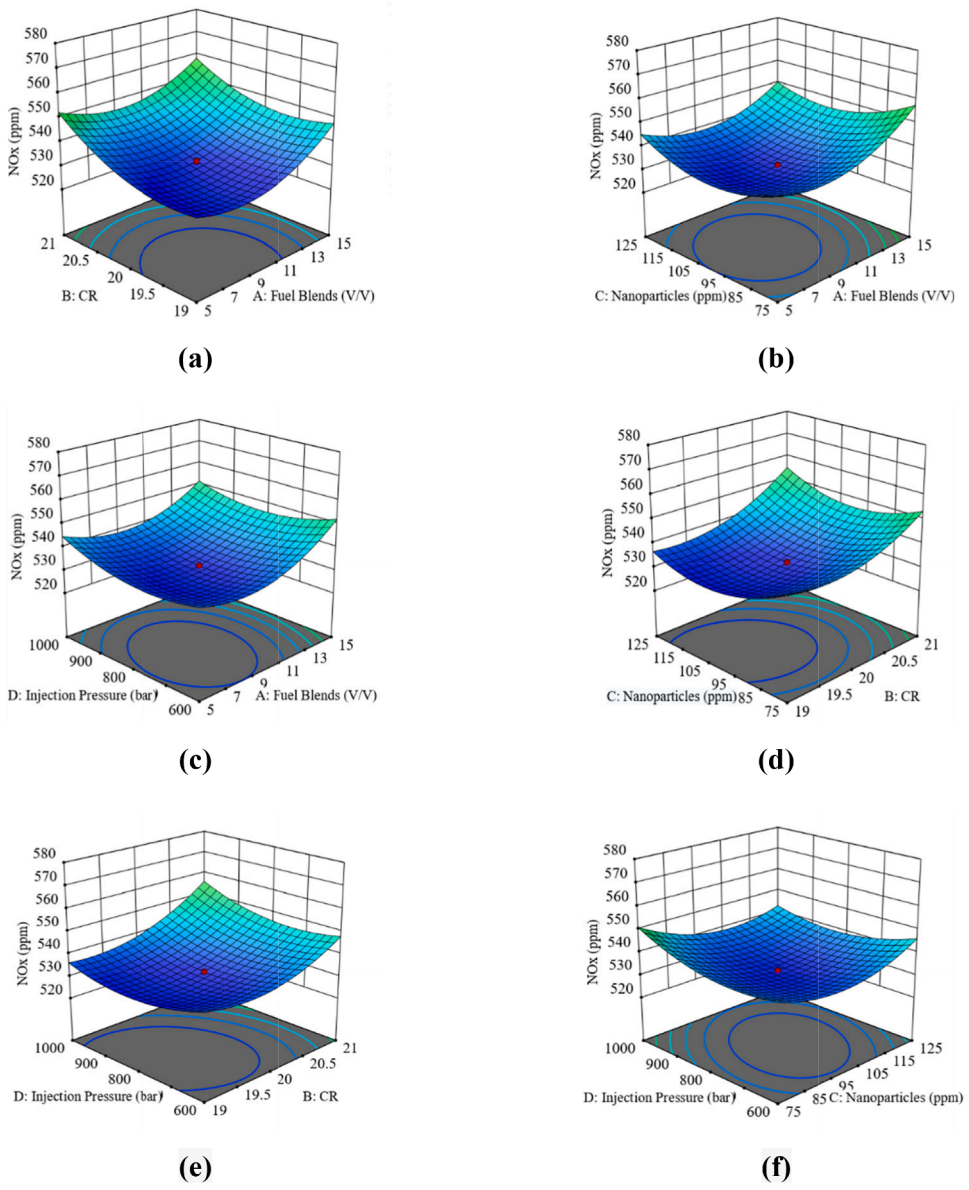

Fig. 15. Variation of NOx emission against CR, fuel blend, injection pressure, and CeO_2 nanoparticles.

of the CRDI engine, which showed that CR above 19.6 improves the BTE since higher CR allows for more efficient combustion of the air–fuel mixture. The range of injection pressure is observed within 682.9 to 923.9 bar. The effect of CeO_2 NP and the injection presure was reported in Fig. 12(f), there is a drastic increase in BTE due to nanoparticle since the engine can operate closer to its optimal operating point, resulting in higher BTE. For the nanoparticle variation of 83.5 to 111.34 for injection pressure variation in between 693.8 bar to 935.47 bar optimized value of BTE is obtained.

4.1.3. Effect of controlling parameters on carbon monoxide

The main factors influencing the generation of carbon monoxide (CO) emissions include a lack of sufficient oxygen for complete combustion, inadequate mixing of air and fuel, areas with higher fuel concentration, and moderate combustion temperatures. Fig. 13 depicts the influence of input parameters on CO, alongside the hold values. Fig. 13 (a) demonstrates that when the blend ratio is increased, the response CO decreases and the load increases until it reaches a minimum at blend 10.16 % for a CR of 20.04. This might result from the combustion process being less effective at a high compression ratio, increasing CO emissions. Fig. 13(b) displays the effect of CeO_2 NP and fuel blend on CO emission while maintaining other parameters at hold. It was discovered that the inclusion of CeO_2 nanoparticles reduced CO emissions. The minimum value of CO emission is found at a concentration of 98.17 ppm of nanoparticles. This can be attributed to enhanced fuel–air blending, accelerated combustion due to catalytic activity, and reduced ignition delays, all of which contribute to more efficient combustion and lower CO emissions. Fig. 13(c) shows the range of 600 to 875.44 for the variation of injection pressure for obtaining the optimised value of CO for the fuel blend in variation of 7.45 to 13.6 % v/v. Fig. 13(d) depicts the variation of nanoparticles and compression ratio on the CO. Minimized value of CO is observed for the range of CR in 19.08 to 20.44 for concentration of nanoparticles in range of 82.6 to 113.9 ppm. This is because compressing the air–fuel combination to a smaller volume before ignition promotes greater atomization and mixing of the fuel with air. Also, a higher compression ratio leads to a lesser amount of CO emission as shown in the surface plot. This can result in more complete combustion, minimising the amount of unburned fuel and, as a result, CO emissions. Earlier studies by C Srinidhi et al. [58] had similar findings. Fig. 13(e) and 13(f) showed the cumulative effect of injection

pressure and compression ratio, injection pressure and nanoparticle, respectively, on CO emission. The CO emission becomes lesser by enhancing the NP concentration to 101.9 ppm and CR range of 19.1 to 20.5. The air–fuel ratio inside the combustion chamber is affected by the CR. A greater CR can cause the air–fuel mixture to have a higher air-to-fuel ratio. Leaner mixes with more air and less fuel tend to emit less CO.

4.1.4. Effectof control factors on hydrocarbon

Fig. 14 depicts the surface plots of the Hc emission. There is a marginal change in Fig. 14(a) owing to fluctuation in the fuel blend ratio since it is 10.13 % in concentration. However, the quantity of HC emissions produced by a CRDI diesel engine rises as the compression ratio increases to 20.5. Higher compression ratio need more fuel to be fed into the combustion chamber, which can result in incomplete combustion and the generation of HC emissions. Fig. 14(b) demonstrated the iterative effect of CeO_2 NP and fuel blend on the emission of HC while holding the other value. It shows that minimum value of 21 ppm HC is obtained at 99.4 ppm concentarion of nanoparticles and 9.95 % of fuel blend having the optimized range of 86.8 to 116.4 ppm and 6.9 to 12.6 % v/v of CeO_2 NP concentration and fuel blend respectively. Fig. 14(c) shows the varitation of injection pressure and fuel blend ratio on HC emissions the optimal range of injection pressure is observed in the range of 642.8 bar to 906.24 bar for the range of blend percentage in 6.8 % to 12.67 %. Considering biodiesel's substantial amount of oxygen minimises nearby affluent mixture regions and a higher compression ratio lowers the temperature where it fires up, it should emit fewer hydrocarbons. Increasing the CR reduces hydrocarbon emissions, as seen in Fig. 14(d). The concentration of CeO_2 nanoparticles increases to more than 117.3 ppm, the emission of HC also increases. This is because nanoparticles have a higher catalytic efficiency and a significant surface-to-volume ratio, which improves fuel fragmentation and burning, resulting in reduced levels of hydrocarbon (HC) emissions.The acquired results were more consistent with those of Gavhane et al. [59]. The cumulative effect of injection pressure and compression ratio, injection pressure and nanoparticle depicted in Fig. 14 (e) and (f) on the variation in the emission of HC. CeO_2 nanoparticles are thought to have catalytic capabilities that can improve combustion efficiency and minimise HC emissions. These nanoparticles may increase fuel atomization, air–fuel mixing, and combustion efficiency, resulting in fewer unburned hydrocarbons in the exhaust.

4.1.5. Effect of control factors on NOx

Fig. 15 depicts the combined impacts of CR, fuel blend ratio, injection pressure, and CeO_2 nanoparticles concentration on NOx emission with hold values. Fig. 15(a) showed the effect of fuel blend % and CR on the variation of NOx emission while the hold values were CeO_2 NP 100 ppm and Injection pressure at 800 bar. Minimised value of NOx were found for the blend ratio of less than 11.8 % v/v and the CR below 20.07. There is a slight variation in the NOx emission due to a change in the fuel blend ratio. It was also discovered that NOx emissions rise with compression ratio. This is because heavier CR necessitates more fuel burning, resulting in higher temperatures and more nitrogen oxide (NOx) generation. At higher CR, the combustion process is more vigorous, which might encourage the production of NOx particles. Fig. 15(b) showed that raising the NP concentration with fuel blend causes an increase in NOx production. The effect of nanoparticles on NOx emissions varies from 81.15 ppm to 117.7 ppm, depending on the nanoparticles utilised and their characteristics. In some situations, nanoparticles can operate as catalysts, promoting more complete combustion and lowering NOx emissions. Fig. 15(c) depicts the variation of injection pressure and fuel blend % on the emission of NOx and its show the optimum value in the range of injection pressure in between 611.41 bar to 916.34 bar for the range of fuel blend in 5.3 % to 11.4 % v/v. Fig. 15(d) illustrate the variation of NOx for the range of nanoparticle concentration in between 87.3 ppm to 120.8 ppm, whereas keeping the CR below 20.2. In internal combustion engines, higher compression ratios tend to increase NOx emissions. This is owing to the increased temperatures and pressures encountered during the combustion process. Higher peak temperatures arise from increased compression ratios, which can aid in the generation of thermal NOx [60]. The cumulative effect of of injection pressure and compression ratio, injection pressure and nanoparticle depicted in Fig. 15(e) and (f) on the variation in the emission NOx. As the compression ratio rises, the NOx emission value rises as well. The inclusion of additional oxygen particles in biodiesel raises the oxygen level within the combustion chamber, boosting NOx output.

4.2. Comparative analysis of experimental and predicted value of engine emissions and performance responses

The comparative analysis of engine emission and performance is depicted in Figs. 16 to 20, utilising RSM and MLP regressor models.

Fig. 16 depicts the variations in the expected and observed values of BSEC. It is worth noting that both the RSM and MLP regressor models show a drop in performance, particularly in the experimental data range of 5–10. Interestingly, when analysing the coefficient of determination (R^2), the MLP regressor models have the greatest R^2 value as compared

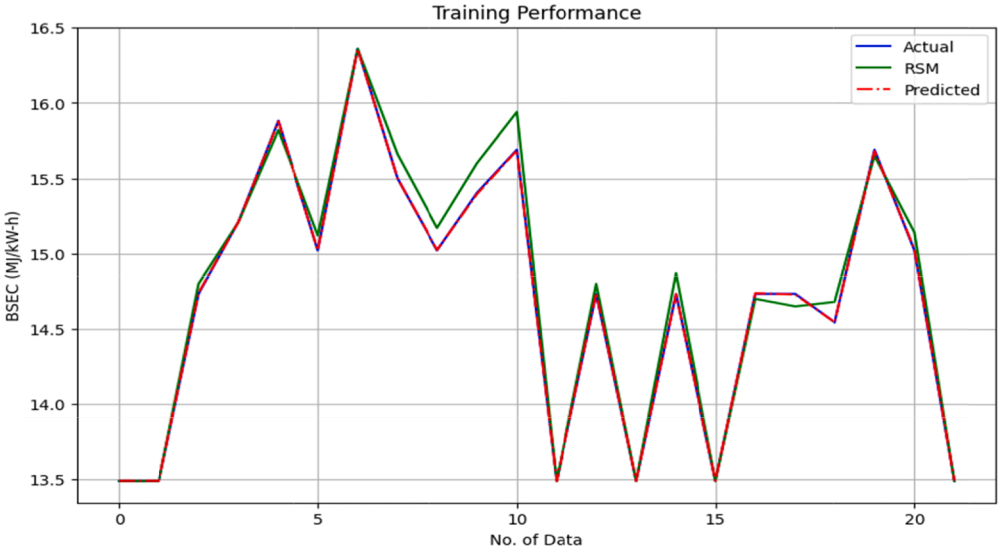

Fig. 16. Comparison of experimental, RSM, and MLP regressor models for BSEC.

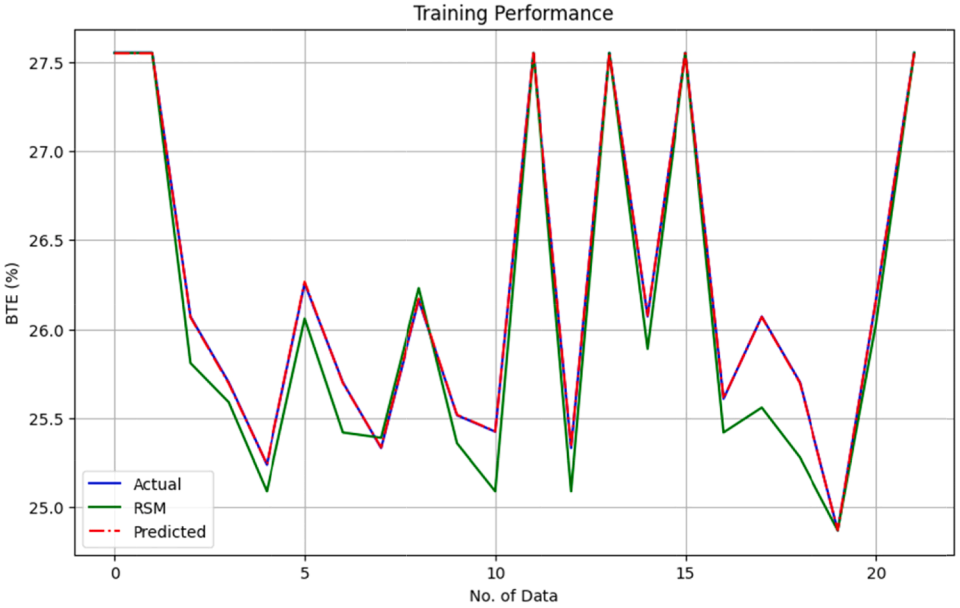

Fig. 17. Comparison of experimental, RSM, and MLP regressor models for BTE.

to RSM model. This gap could be traced to the RSM model's poor performance, as evidenced by the 5th and 10th sets of experimental data.

Fig. 17 compares the BTE forecasting results to the RSM and MLP regressor models, offering a comparison of their performance. Table 12 elaborates on these findings, showing that the R^2 values ranged between 0.9967 and 0.9998 across the models. Notably, the MLP regressor model has the greatest R^2value, at an amazing 0.9998. According to evaluation standards, prediction outcomes are considered "excellent" when the RMSE value is low or close to zero [42,44]. According to the extant research, both models produced impressive outcomes. Furthermore, the MLP regressor-based model distinguishes itself by producing "outstanding" results, highlighting its superiority in forecasting accuracy.

Fig. 18 shows the differences between the projected CO values of the RSM and MLP regressor models and the actual experimental results. A careful examination of Fig. 17 reveals the effectiveness of both predictive models in anticipating CO levels. The findings given in Table 12 provide more evidence of its effectiveness. Notably, in terms of CO prediction, the MLP regressor model has the highest R^2 value, indicating higher performance. Nonetheless, the RSM model's R^2 values are very similar to those of the MLP regressor model, demonstrating its comparative performance.

Fig. 19 shows the differences in projected HC values between the RSM and MLP regressor models as compared to experimental values. Fig. 16 shows that the RSM model performed poorly when predicting HC. Notably, its predictions differed significantly from those produced by the MLP regressor model, particularly for data ranging from 2 to 10. This deficiency is further supported by statistical analyses, which highlight the RSM model's shortcomings in this area. Furthermore, the mismatch underlines the need for improvement or other methodologies in predictive modelling to achieve correct HC estimates.

Fig. 20 compares the NOx values projected by the RSM and MLP regressor models to the experimental data. Notably, the predictive models' NOx predictions are quite accurate, as shown in the image. Table 12 contains further information about the performance of these models, including significant statistical measurements. The R^2 value for

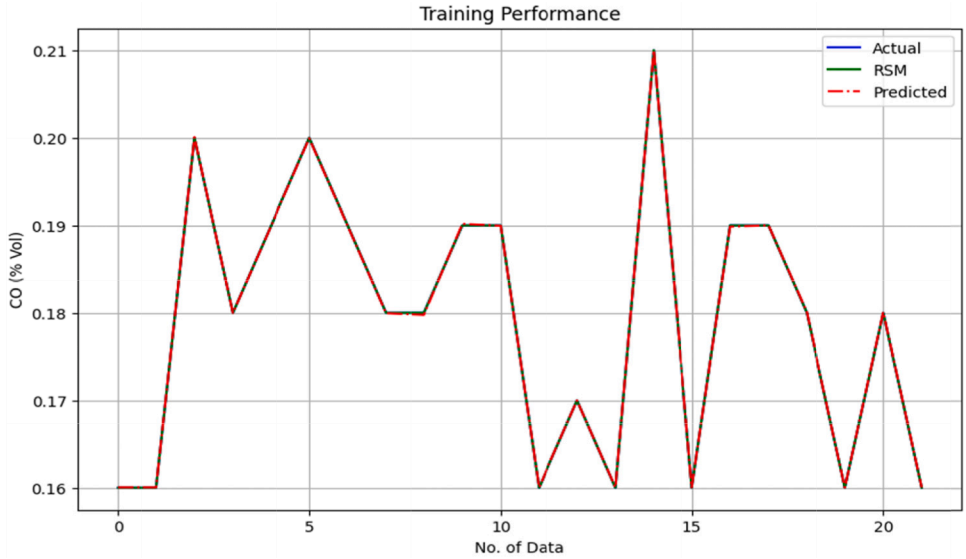

Fig. 18. Comparison of experimental, RSM, and MLP regressor models for CO(%).

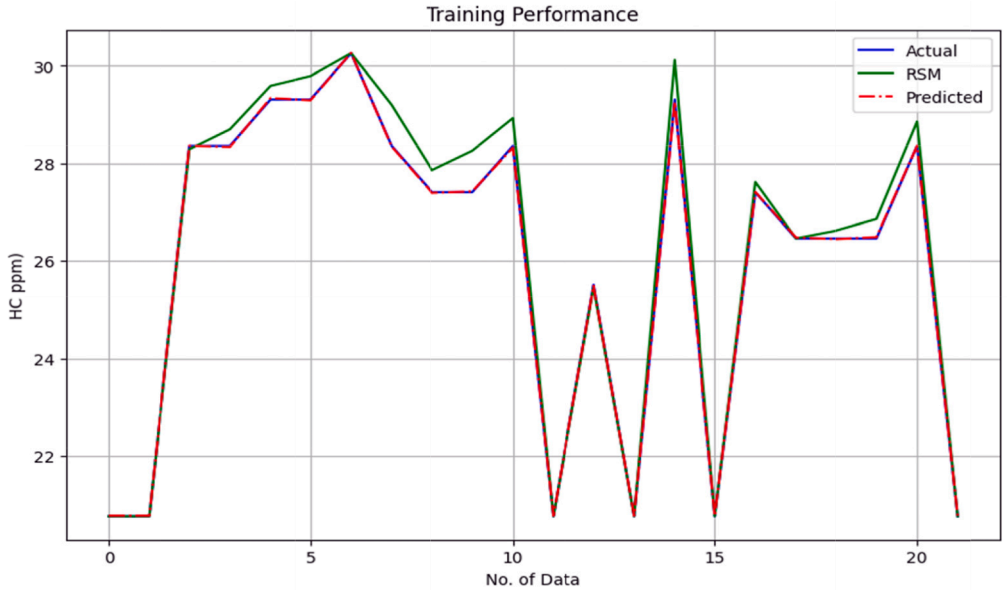

Fig. 19. Comparison of experimental, RSM, and MLP regressor models for HC.

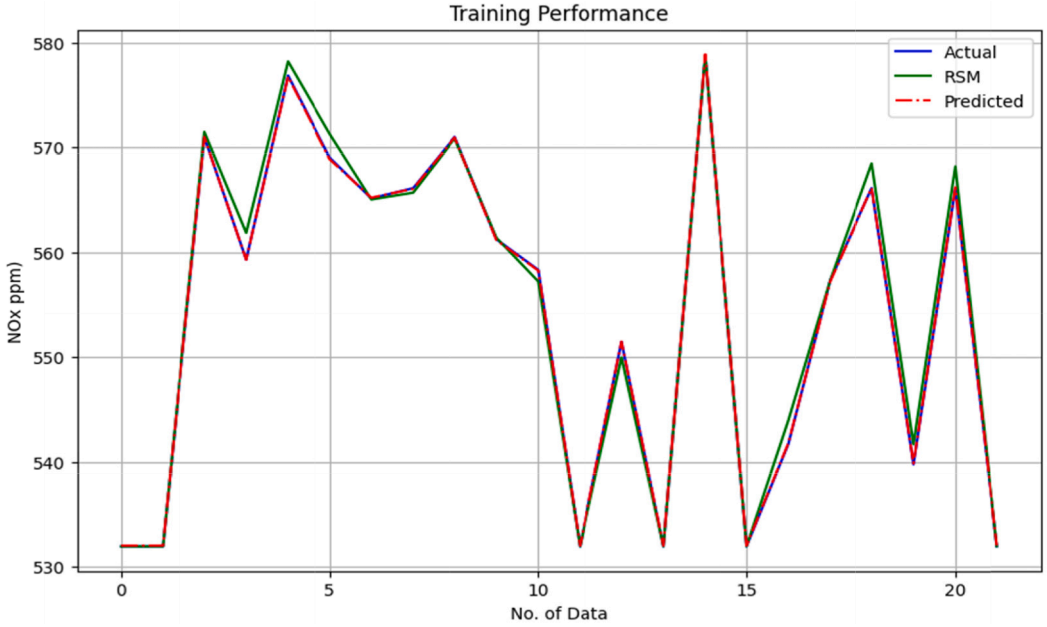

Fig. 20. Comparison of experimental, RSM, and MLP regressor models for NOx.

NOx prediction using the MLP regressor was an astounding 0.9998, above that of the RSM model at 0.8998. However, it is worth noting that, despite having a higher R^2 value, the MLP regressor model produced much worse predictions than the RSM model, as seen in observations 3, 4, and 5. This difference is further explained by statistical analysis.

The comparative analysis of engine emission and performance is depicted in Figs. 16 to 20, utilising RSM and MLP regressor models. The graphical representations clearly demonstrate that the MLP regressor model consistently exhibits superior accuracy in predicting values compared to the RSM-based models. This observable pattern leads to the

Table 11
Validation and experimental confirmation tests for input factor.

Response	Experimental responses on optimised process parameters	Predicted responses by RSM	Predicted responses by MLP	% Error with respect to RSM	% Error with respect to MLP
BSEC (MJ/kW-h)	13.9	13.5	13.47	2.87	3.09
BTE (%)	28.7	27.8	27.55	3.13	4.00
CO (%vol.)	0.17	0.16	0.16	3.85	3.85
HC (ppm)	21.44	20.996	20.685	2.14	3.52
NOx (ppm)	551.77	531.989	531.823	3.58	3.61

Table 12
Statistical indicators estimated values.

Factors	Statistical Matrices	Predictive models	
		RSM	MLP
BSEC	MAE	0.0815	0.0650
	R^2	0.8987	0.9987
	RMSE	0.0141	0.0015
BTE	MAE	0.0085	0.0640
	R^2	0.9887	0.9998
	RMSE	0.0376	0.0017
CO	MAE	0.0103	0.0598
	R^2	0.8987	0.9967
	RMSE	0.0444	0.0016
HC	MAE	0.0157	0.0681
	R^2	0.8897	0.9977
	RMSE	0.0560	0.0023
NOx	MAE	0.0193	0.0716
	R^2	0.8998	0.9998
	RMSE	0.1365	0.0167

conclusion that the MLP regressor model surpasses the RSM-based models in accurately predicting engine emission and performance. Consequently, this finding emphasises the effectiveness of the MLP regressor approach in achieving more precise predictions within this specific context.

4.3. Confirmation of the result

To assess the correctness of the findings achieved by optimisation and MLP regressor, a validation test was done in combination with optimisation; for verification, a test was performed using the optimal engine settings obtained during optimisation. Due to experimental limitation, optimised process parameters are considered in the absolute fixation such as 9.97 % fuel blend is taken as 10 %, injection pressure is taken as 800 bar, and CR is taken as 20. Table 11 displays the results of the optimal and test validations and the degree of error across them. The recorded discrepancy is approximately 5 %, which is deemed within an acceptable range.

4.4. Phase of prophecy

Table 12 summarises the numerical data derived from the statistical indicators employed to all of the study's anticipated data. Table 10 illustrates that the MLP regressor's RMSE values generate good results. Furthermore, the MAE values of the forecasts are typically close to zero. As a result, the algorithm-generated parameter averages are typically lower than the actual observed data averages. Notably, when the RMSE values are compared, the MLP regressor predictions exhibit lower RMSE values than the RSM-based models. When compared to RSM models, these findings show the efficacy of MLP regressors in providing accurate predictions with higher statistical performance.

5. Conclusions

The results of this study showed the possibility of combining the blend ratio of Karanja biodiesel and diesel with 10 % Biobutanol, CR, IP, and CeO_2 nanoparticle concentration in a CRDI engine were explored in the present investigation. The following finding were obtained from the current study.

- The optimal process parameters are achieved a biodiesel blend ratio of 9.96 %, CR of 20, IP 797.4 bar, and a CeO_2 nanoparticle concentration of 100.3 ppm through CCFD model of RSM.
- After optimization the responses were BSEC of 13.49 MJ/kW-h, BTE of 27.8 %, and emitted 0.16 % CO, 20.9 ppm HC, and 531.9 ppm NOx.
- The high R^2 values for each response variable (99.98 % for BTE, 99.97 % for BSEC, 99.67 % for CO, 99.77 % for HC, and 99.98 % for NOx) suggest a significant connection between the input parameters and the response variables.
- The MAE value of the MLP regressor-based model ranged from 0.0011 to 0.0119. In terms of RMSE, MLP regressor-based model outputs are within reasonable boundaries.
- The most detrimental RMSE findings were reported in NOx anticipate for both. Only RSM-based models exceed 10 % in NOx emissions.
- The accuracy of the results obtained by optimisation and MLP regression; a validation test was conducted to confirm; the reported disparity is around 5 %, which is considered within acceptable limits.

This study suggests that sustainable and efficient engine technology can be achieved by methodically investigating parameter space and determining optimal operating conditions. It also highlights the potential benefits of using a combination of Karanja biodiesel and Biobutanol with diesel, along with CeO_2 nanoparticles, to improve the performance and emissions characteristics of CRDI engines.

RESEARCH PAPER

Evaluation of the role of process parameters of CMT welding and their statistical behaviour on the tensile properties of weld joint of novel aluminium hybrid composite

Abstract
The present study investigates the cold metal transfer (CMT) welding of a novel hybrid aluminium composite (AA6061-T6/ 2wt.% TiB_2/ 0.5wt.% La_2O_3) fabricated via stir casting. It analyzes the effect of welding parameters, i.e. current, travel speed, and gas flow rate, on the tensile strength of the composite's weld joint using response surface methodology (RSM). Also, a dedicated study of the microstructure and mechanical properties of weld joints at optimal parameters has been conducted. Results indicate that current significantly affects tensile strength, followed by travel speed and gas flow rate. The optimal parameters identified are 142 A current, 9 mm/s travel speed, and 14 L/min gas flow rate for maximizing tensile strength. Welds at optimal parameters displayed no solidification cracking and minimum porosity. The microstructural analysis confirmed the presence of reinforcements in the composite with the formation of finer grains in the fusion zone (FZ) compared to the heat-affected zone (HAZ). Microhardness tests showed the highest values in the FZ and the lowest in the HAZ, while tensile tests showed reduced strength at HAZ compared to the FZ and base composite, with dominant brittle behaviour. Post-weld heat treatment improved ductility, as indicated by deeper dimples and tear ridges with fewer cleavage facets in fracture analysis.

1 Introduction

In the current context of globalization, the demand for materials with advanced properties and the capability to be used in state-of-the-art process technologies is increasing at an exponential rate. Metal matrix composite (MMC) can satisfy these needs as it is an engineered material known to have metal as the matrix and one or more reinforcements with different forms like particles, fibres, and whiskers. MMC has replaced a large number of traditional monolithic materials from various industries like aerospace, automobile, and defence as monolithic materials do not offer the advantage of tailoring the properties of materials as MMC has the capacity of displaying excellent properties like high strength, lesser weight, enhanced fatigue properties, better modulus of elasticity, and good wear resistance. These properties can be controlled by the proper choice of reinforcement, their size and type, and their bonding pattern with the matrix materials [1, 2]. Aluminium, the thirteenth element of the periodic table, has emerged as one of the highly favoured choices from researchers worldwide for selecting the matrix of MMC. Aluminium and its alloys find a special place in automobile and aircraft industries as it helps in reducing its overall weight subsequently cutting down fuel consumption and resulting in lesser carbon footprints. Imparting aluminium alloys with reinforcement particles aids in further enhancing its strength [3]. Generally, hard ceramic materials like Al_2O_3, TiO_2, ZrO_2, SiC, B_4C, ZrB_2,

TiB_2, TiN, and BN are injected into an aluminium alloy to reinforce its various mechanical properties [4]. From all the above ceramics available, titanium diboride (TiB_2) stands out as one of the predominant choices as it imparts advanced phase strengthening of aluminium alloys since it portrays exceptional characteristics like a high melting point of 2900 °C, less density of 4.52 g/cm^3, enhanced corrosion resistance behaviour, and minimum wear rate [5]. Also, from earlier research work [6], it is widely acknowledged that the addition of rare earth elements (REE) like Er, Sc, Sr, Yb, La, Zr, and Ce or their oxides like CeO_2 or La_2O_3 can significantly modify or enhance the mechanical properties of various aluminium alloys through grain refinement, improving dispersion of other ceramic particles, control of dynamic recrystallisation etc. Furthermore, the addition of rare earth oxide (REO) also helps in expanding various alloying possibilities. However, the utilization of REE or REO has been limited because of their soaring market cost [6, 7]. Different methods known for fabricating MMC include stir casting, squeeze casting, friction stir casting, centrifugal casting, and a range of in situ methods [8]. Nowadays, various state-of-the-art techniques, such as wire arc additive manufacturing, are also gaining attention for fabricating composites [9]. But among these, conventional stir casting stands out as one of the most widely employed techniques because of its simplicity, cost-effectiveness, and versatility.

The limited compatibility of MMCs with conventional welding methods has been a significant barrier to their widespread application, since research on fusion welding techniques for MMCs, including laser welding, electron beam (EB) welding, metal inert gas (MIG) welding, and tungsten inert gas (TIG) welding, remains limited [10]. The following literature highlights some of the research. Garcia et al. [11] performed a comparative study using direct and indirect electric arc MIG welding on Al-1010/TiC/50p composite. Results showed that indirect arc showed better weld uniformity, less TiC dissolution, lessened heat-affected zone, and consistent mechanical strength (182–186 MPa), which concluded that indirect arc is preferable for welding these composites, even with high reinforcement content. Kun et al. [12] conducted an EB welding of TiB_2/ZL101 composite, resulting in defect-free welding seams with a homogeneous dispersion of TiB_2 particles. Welding has improved the mechanical properties of the base alloy. Tensile tests reveal that fractures occur in the base metal, and the elastic modulus of the welded specimens is relatively greater compared to the pre-welded base alloy. Also, under proper parameters, EB welding successfully prevented porosity and deepened the narrow cross-section of the weld. A study conducted by Ureña et al. [13] involved TIG arc-welding of thick sheets of aluminium alloy (AA) 2014/SiC composite, with varying SiC volume fractions of 6%, 13%, and 20%. The research aimed to explore the impact of interfacial reactions between the matrix and reinforcement on the fracture performance of the composite during welding. Tensile results consistently indicated that failure predominantly occurred within the weld metal, exhibiting its lower tensile strength compared to base alloy due to the formation of Al_4C_3, which weakened the interface between reinforcement and matrix and limited the propagation of cracks within the composite particles. Yue et al. [14] fabricated a composite sheet of AA2124/25(vol)% SiC (3 μm) with 3.5 mm thickness and utilized pulsed Nd-YAG laser welding to join the sheets. Results showed that the presence of brittle carbides in the centre of the fusion zone, which is mainly impacted by laser intensity and pulse duration, and by optimizing these parameters, excessive carbide formation, which can be detrimental to mechanical properties, could be mitigated. Welding MMCs using conventional fusion welding techniques like MIG or TIG presents several challenges. These include the segregation of strengthening agents, chemical interactions between reinforcement and matrix, and the appearance of various interfacial phases. Also, the occurrence of porosity in the liquified state or at higher solidification temperature and liquation cracks can develop between the reinforcements and the matrix. These problems are worsened by the high heat input required in the melt pool, leading to the degradation of the MMC's properties [10, 15]. Therefore, solid-state processes are often preferred for the welding of MMCs, among which friction stir welding (FSW) and friction welding (FWs) are mainly significant. Devanathan et al. [16] utilized FSW to join B_4C-reinforced AA5083 MMC, employing tools coated with titanium nitride, aluminium chromium nitride, and diamond-like carbon with varying friction coefficients and the flower pollination algorithm (FPA) was employed for optimization. Results showed that the coating significantly influenced tensile strength, microstructure, and tool condition. Ali et al. [17] performed a study to examine the impact of process parameters on the properties of friction stir welded MMCs comprising AA6061 with various weight percentages of SiC and B_4C particles. Outcomes revealed that the highest tensile strength, reaching 174 MPa, was achieved with composites containing 10% SiC and 3% B_4C. Moreover, the elongation percentage rose with increasing B_4C content but declined with decreasing SiC content. As a development of FSW, the friction stir vibration process, denoted as FSVP, uses controlled vibrations to improve the weld quality on alloys and composites. Abbasi et al. [18] fabricated a surface composite using an Al5052 alloy sheet and SiC nanoparticles via friction stir processing (FSP). A comparative study of the microstructure and mechanical properties between FSP and FSVP, where the workpiece is vibrated perpendicular to the processing line, was conducted. The results indicated that FSVP refined the grain in the stir zone and improved the homogeneity of particle distribution. Also, FSVP specimens

demonstrated better strength, hardness, and ductility than FSP specimens, which increases on increasing the vibration frequency. Barati et al. [19] used FSP and FSVP to AA5052 to fabricate a surface composite with SiC nanoparticles and compared their effects. The results revealed that FSVP significantly improves the microstructure and mechanical properties compared to FSP as it reduces the stir zone's grain size and attains a more homogeneous distribution of SiO_2 particles, resulting in greater strength, ductility, and wear resistance. The literature above highlights FSW as among the most preferred methods for welding MMCs, yet they are disadvantaged by their exposure to defects like cracking, splattering, extreme generation of heat during rotation, creating a turbulent flow of base metal, a lengthy welding procedure, less flexible to fusion welding, fast and extreme wear of the tool, contamination of the joint by remains from the tool, the sizeable downward force required for clamping weld plates, non-preferrable for mass production, inferior efficiency in comparison to fusion welding, demands a high early investment cost, higher energy consumption, rigid process control conditions, or probable material damage from excessive vibrations [20, 21]. Hence, traditionally available welding methods may not always meet the demands of joining MMCs, requiring exploring alternative approaches such as cold metal transfer (CMT) welding. With its precise control over heat input and metal transfer, the CMT technique may present a promising solution for welding MMCs. CMT, a modified and colder version of conventional MIG, can potentially knock off the above-mentioned issues by providing the advantages of 1/3rd heat input, spatter-free material transfer, penetration control to get a proper dilution ratio in bead, and an option to control arc length during welding in comparison to other fusion processes [22, 23]. CMT is an emergent technology that involves dip transfer technology and uses a three-phase welding cycle as follows: (1) In peak current, this phase occurs within a constant voltage environment with high current. The high current is necessary to establish an arc between the filler wire and the base metal, subsequently heating the filler wire for melting. (2) In background current, this phase involves a reduction in the current value to inhibit the transfer of filler metal droplets in the form of globules, promoting a short-circuit transfer between the molten pool and the tip of the filler wire and (3) in short circuit, in this phase, the short-circuit current is further reduced to a lower current level while simultaneously sending a signal to retract the wire from the wire feeder. This action prompts a backward drawing force within the wire feeder, causing the droplet to detach from the filler wire and transfer into the molten weld pool [23]. The above three-step cycle then repeats. By carefully optimizing different process parameters influencing the CMT technique, MMCs can be efficiently joined while minimizing defects such as porosity, solidification cracking, and distortion. Isitan et al. [24] casted two distinct composites using the liquid metallurgy vortex-route process with AA6013 as matrix and nano-Al_2O_3 as reinforcement (0.5% wt. and 1% wt.) and joined via butt welding at two current (110A and 120A) and using welding methods, i.e. CMT and pulse multi-control (PMC). Results showed that nanocomposites with nano-sized reinforcement reduce grain size and improve mechanical properties with a composite having nano-Al_2O_3 reinforcement (0.5%wt) welded at 120 A using the CMT process, achieving the highest tensile strength value. Further, the CMT process allows for better control over the formation of intermetallic compounds at the interface between the matrix and reinforcement, which can significantly influence the different properties of the welded joints. Overall, utilizing the CMT technique for welding MMCs can have excellent potential for different industries, like aerospace, automotive, defence, sports, and marine applications, where welding of lightweight, high-strength materials is in demand [25]. From the above literature, it is evident that though CMT welding has been extensively used in traditional aluminium alloys [26], its use in the welding of MMCs composed of these alloys remains relatively unexplored, representing a significant research gap. Furthermore, fusion welding, specifically CMT welding, of hybrid composites comprising a novel combination of hard ceramic and rare earth oxide reinforcements into the AA-6061 T6 matrix still needs to be explored.

In the present work, a novel hybrid composite has been fabricated by incorporating micro-sized TiB_2 particles and nano-sized REO La_2O_3 particles as reinforcements within an AA6061-T6 matrix using conventional stir casting. The CMT technique is then employed to weld two similar plates of fabricated composites. Response surface methodology (RSM) using central composite design (CCD) is utilized to model and optimize the tensile strength of CMT weld joints in composite plates by considering three critical process parameters: current, travel speed, and gas flow rate. Subsequently, the accuracy of the developed model is validated through experimental verification. Lastly, an in-depth investigation of the microstructural evolution and mechanical properties of the CMT weld joints of fabricated composite has been performed to provide an overall better understanding of the welding process and its effects.

2 Experimental methods

2.1 Materials

In this research, the matrix material employed for the preparation of the composite is AA6061-T6 (Fig. 1a), with its elemental composition shown in Table 1. Hard ceramic TiB_2 powder (Fig. 1b) with 14 µm particle size and 2 wt.% and REO La_2O_3 powder (Fig. 1c) with a particle size ranging

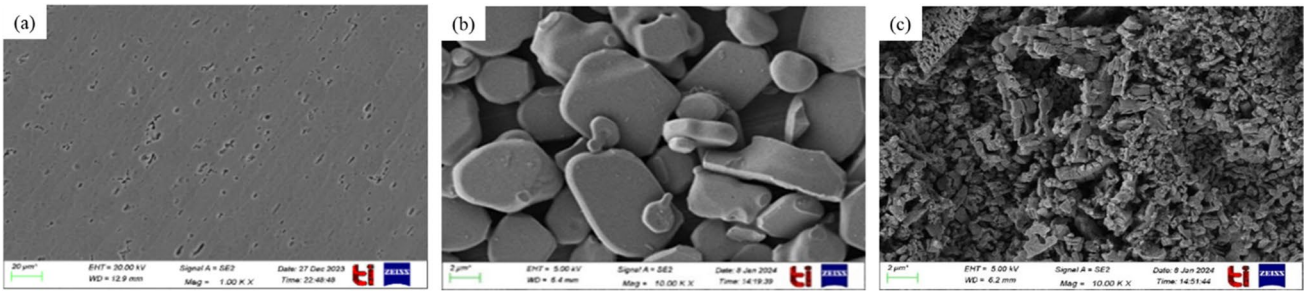

Fig. 1 FESEM image of **a** AA6061-T6, **b** TiB_2 powder (size 14 µm), and **c** La_2O_3 powder (size 40–50 nm)

from 40 to 50 nm and a 0.5 wt.% are selected as reinforcements. Figure 2 displays the XRD peaks of each powder and matrix involved in the fabrication of the hybrid composite.

2.2 Composite plate fabrication

The preparation of the composite follows the methodology outlined in established literature [8, 27]. A solid cylindrical bar of AA6061-T6 weighing 1 kg is utilized as the matrix for preparing the composite. Micro-sized TiB_2 ceramic powder with 2 wt.% and nano-sized La_2O_3 powder with 0.5 wt.% are selected as reinforcements. Figure 3a illustrates the complete methodology involved in fabricating the composite plates. Initially, the AA6061-T6 cylindrical bar is heated within the furnace of stir casting setup, achieving temperatures ranging from 700 to 800 °C for approximately 1 h, transforming it into a molten state. Simultaneously, both reinforcements are preheated at 300 °C in a muffle furnace to remove any possibility of impurities, moisture, or dust. Once the alloy gets melted, a stirrer is inserted into the melt, up to a depth of 1/3rd of the molten surface, to create a vortex. Following the formation of a vortex, both reinforcements are introduced via a feeder positioned at its centre, with TiB_2 powder being added first, followed by La_2O_3 powder. The stirrer is continued at 600 rpm for the next 10 min to assist in the mixing of reinforcement particles and arrest any possibility of agglomeration of particles within the molten matrix. As soon as mixing is achieved, the hot molten mixture is poured into a cuboidal mould (Fig. 3b) and kept untouched for cooling and solidification to achieve a casted composite, as shown in Fig. 3c. Wire EDM process is performed on each fabricated cuboidal composite to get the plates of the required dimension displayed in Fig. 3d.

2.3 CMT welding

Composite plates with dimensions of 110 mm × 60 mm × 3.2 mm have been used for the welding purpose. CMT welding has been carried out using ER5356 filler wire (1.2 mm Dia) with the elemental composition mentioned in Table 1, keeping the torch angle at 90° , CTWD to 13 mm and using pure Argon as a shielding gas. As shown in Fig. 4, pure argon was used as the shielding gas during CMT welding. TransPuls Synergic Advanced Cold Metal Transfer Welding (400TPSi) machine setup shown in Fig. 4 and supplied by Fronius, Austria, has been used for welding. Plates are cleaned with acetone to prepare them for welding and are joined in a square-butt configuration through a single pass, as shown in Fig. 5a.

Process parameters that need to be investigated depend upon the response parameter. After an in-depth review of the literature, it has been determined that the major factors influencing the response, i.e. tensile strength of the weld joint, are current, travel speed, and gas flow rate. To initiate the welding process, a few welding trials were conducted with a range of values for the above-mentioned factors. These values were chosen based on a few previous literatures [28–31] and the constraints associated with parameter selection in the Fronius CMT welding machine setup due to the choice of ER5356 filler wire. Considering these factors, the ranges on which experiments were done are as follows: current (A): 110, 115, 120, 125, 130, 135, 140, 145, and 150; travel speed (mm/s): 6, 8, 10, 12, 14, and 16; and gas flow rate (L/min): 12, 14, 16, 18, 20, and 22. After welding with various parameter combinations, each weld bead was inspected based on specific visible

criteria, including spatter amount, penetration depth, base plate distortion, arc stability, and surface porosity, as shown in Fig. 5b. Following inspection, the optimal levels for each control factor were finalized, as detailed in Table 2.

2.4 Development of design matrix for CMT welding

RSM is a multivariable statistical tool used to improve outcomes by developing, analyzing, and optimizing the model. It establishes a relationship between multiple input process variables and desired results. It is one of the most popular and fittest optimization tools as it helps achieve the experimental goal with a minimum number of runs compared to other tools. This method significantly improves processes by examining the effects of different input factors and their interactions on the response variable. Its main advantage

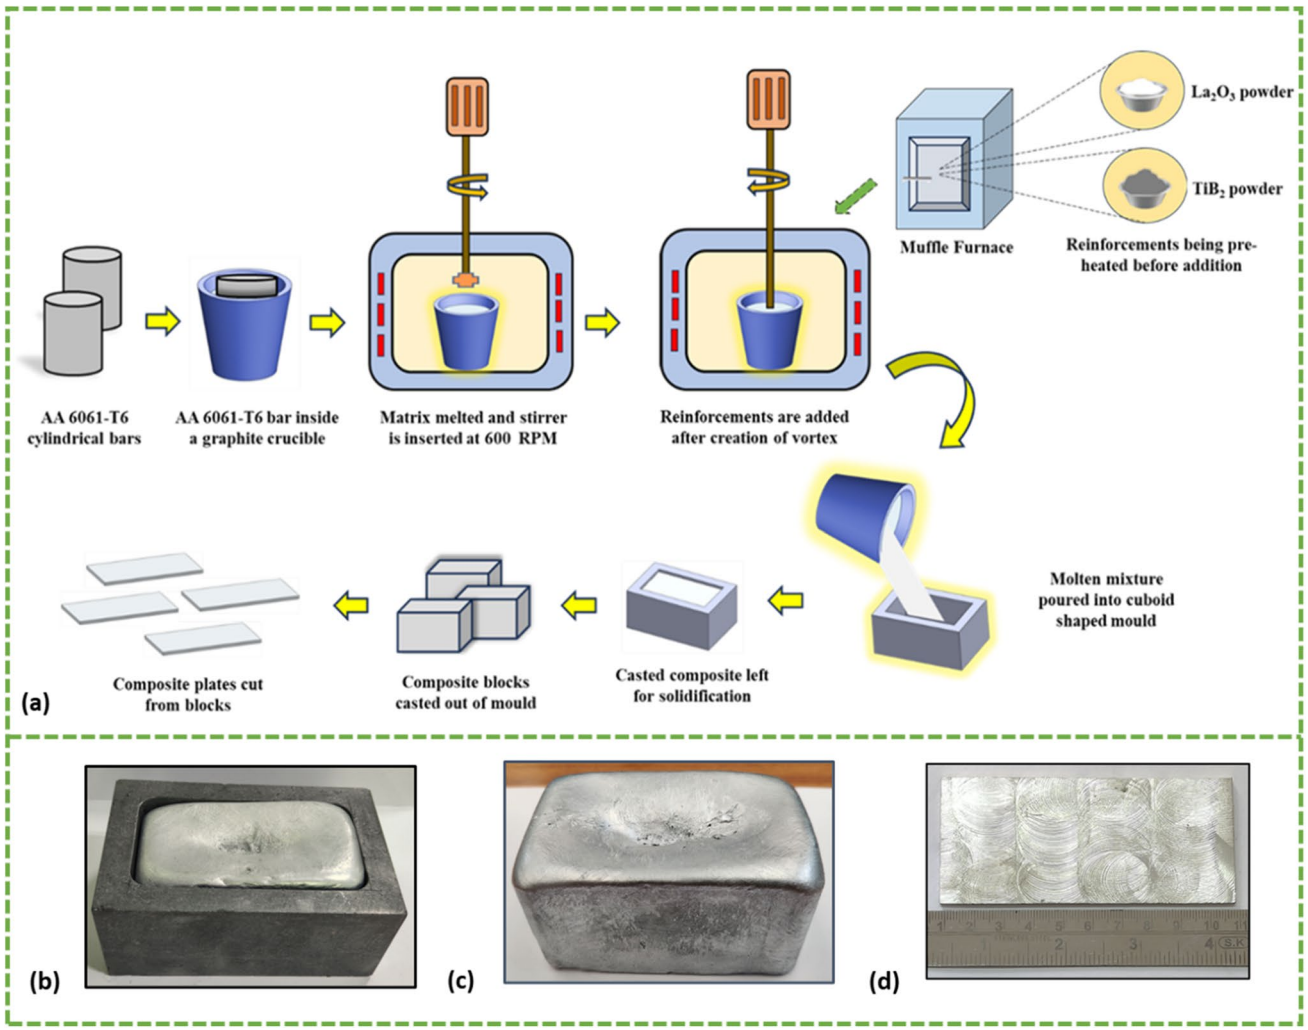

Fig. 3 **a** Steps involved in the fabrication of composite plates. **b** Casted composite solidifying in the graphite mould. **c** Fabricated composite. **d** Composite plate cut from the casting

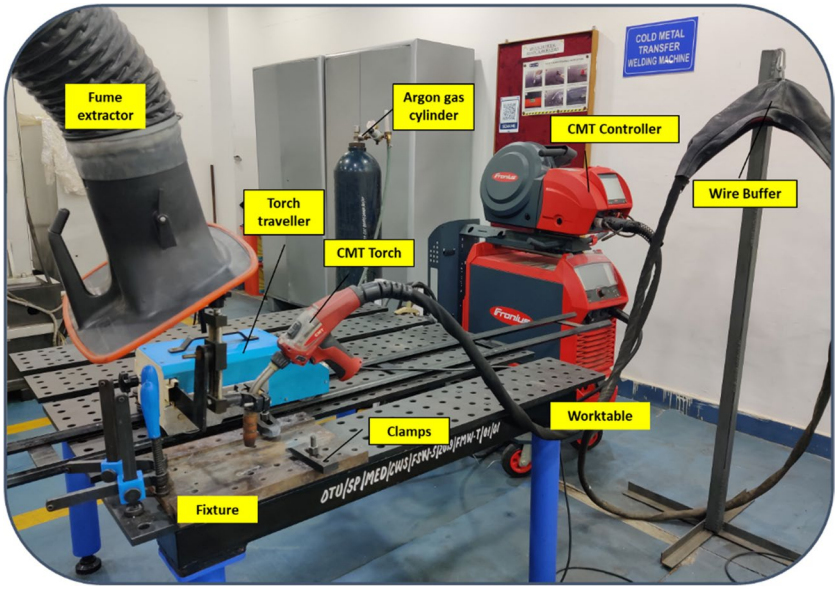

Fig. 4 Lab setup of CMT machine

is identifying optimal process parameters while minimizing experimental runs. By minimizing the number of runs, RSM reduces the resources, time, and costs related to the experimental phase of process optimization, making it specifically helpful in various engineering and industrial fields like mechanical, chemical, medical, or manufacturing, where experimental costs can be high [32, 33]. Here, response surfaces are graphically represented to interpret the interactions between control factors and their resulting outputs. Generally, two types of RSM design are available, central composite designs (CCD) and Box-Behnken designs (BBD), among which CCD is one the popular and favoured designs developed by Box and Wilson in 1951 since it is suitable to fit a quadratic model and is of great use in the successive investigation as it provides to the development of previous factorial trails by additional axial and centre points [34, 35]. In this work, the rotatable design of CCD (shown in Fig. 6) has been selected as it contributes to consistently predictable variance at every point which is at an equal distance from the centre of the design matrix, thereby providing a quality prediction. The flowchart employed for optimization using the RSM is displayed in Fig. 7. Design Expert software has been used to design the CCD matrix having three control factors with five levels, each with $-\alpha, -1, 0, +1$, and $+\alpha$. A total of 20 runs is conducted in CCD, which is calculated using the formula: Total runs $= 2^p + 2*p + N$ centre points (p = input variables, N = no of repetition of centre value) using $\alpha = 2$.

Quadratic response surface models are constructed to analyze tensile strength based on experimental data and ANOVA. The resulting response function is represented by Eq. (1), where Y = tensile strength.

$$Y = \varphi(current, travel\ speed, gas\ flow\ rate) \tag{1}$$

The second-order response, incorporating the K factor-surface model equation, is defined in Eq. (2) as follows [35]:

$$Y = \alpha_0 + \sum_{i=1}^{K} \alpha_i X_i + \sum_{i=1}^{K} \alpha_{ii} X_i^2 + \sum_{i<j} \sum_{j=2}^{K} \alpha_{ij} X_i X_j + \epsilon \tag{2}$$

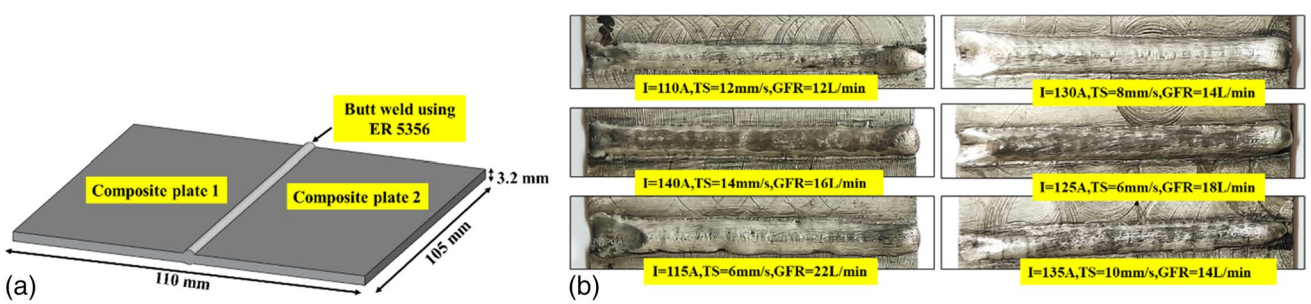

Fig. 5 **a** Schematic diagram of square butt weld joint of composite plates. **b** Trial weld beads of composite plates

Table 2 Process parameters and their levels selected for CMT welding of composite plates

Process parameters	Unit	Level				
		−2	−1	0	+1	+2
Current	A	125	130	135	140	145
Travel speed	mm/s	8	10	12	14	16
Gas flow rate (GFR)	L/min	12	14	16	18	20

Here, Y denotes the output response, X_i represents the linear terms, X_i^2 defines the quadratic terms, X_iX_j signifies the interaction terms, a_0, a_i, a_{ii}, and a_{ij} are constants associated with the input parameters, and ϵ represents the fitting error. Figure 8a shows a total of 20 runs for CMT welding with square butt joint configurations, which is performed as per the process parameters outlined in Table 3. Once all composite plates are welded, each plate is subjected to a wire EDM process to get the required specimen for different tests, as illustrated in Fig. 8b.

2.5 Porosity and dilution

Porosity always stands out as a prevailing defect during welding, resulting in a decreased strength of the welded joint by weakening atomic bonds within the material. This defect is marked by the existence of gases or voids within the melted weld pool. In the present study, the calculation of porosity percentage at two distinct locations across the fusion zone has been conducted using a digital camera and an inverted metallurgical microscope. The microscope employs a specific formula (Eq. 3) to analyze the percentage of porosity within the weld bead [28]

$$Porosity\ percentage = \left\{ \frac{(Total\ feature\ area\ X\ 100)}{Total\ area} \right\} \quad (3)$$

In fusion welding, dilution denotes the ratio of filler wire present in the weld pool relative to the parent material. This ratio is the proportion of the penetration area (Ap) to the total area (Ap + Ar) resulting from a single bead deposit, generally expressed as a percentage [36].

2.6 Microstructural characterization

After CMT welding, the plate is cut using the wire-EDM technique to get different sizes of specimens for various microstructural and mechanical tests. The specimen has been cold moulded using the epoxy-hardener combination for the optical microscope. After mounting, the specimen is subjected to various dry and wet polishing to get a mirror-like polish on the surface. Finally, it is subjected to Keller's reagent for etching. Weld microstructure has been observed using an OLYMPUS optical microscope and ZEISS Gemini 1 Sigma-500 field emission scanning electron microscopy (FESEM) setup equipped with an energy-dispersive spectrometer (EDS). Electron backscatter diffraction (EBSD) analysis is performed on the weld specimen after it is electropolished using methanol (70%) and nitric acid (30%) at a voltage of 13 V for a time of 13 s to get an insight into the grain size. X-ray powder diffractometer (XRD) BRUKER D8 Advance machine has been employed to identify different chemical compounds formed during the welding. Post tensile test, the fracture surface is analyzed using a JEOL JSM-6610 LV scanning electron microscope (SEM) provided with EDS.

2.7 Mechanical test

The microhardness test is achieved using a Duramin-40 M1 machine, set to a hardness scale of 0.5 HV with a dwell time of 10 s between consecutive indentations. Specimen for the test has been prepared as per ASTM E384 standards with indentions taken along a linear line of the weld bead at a space of 1 mm each. The Tinius

Olsen H50KS universal testing machine has been used to conduct tensile tests on two samples prepared from each welded specimen according to ASTM E8 standards, as shown in Fig. 8c. The average value of these tests is then used for further evaluation.

3 Results and discussion

3.1 Statistical analysis

Twenty welded specimens are prepared by joining composite plates in square butt joints, and tensile tests are performed on each of them. Table 3 displays the tensile strength of all weld specimens. ANOVA assesses process parameters' significance and model adequacy. The lists of the sum of squares (SS), degrees of freedom (DOF), *F*-value, and *P*-value are mentioned in Table 4. *F*-statistic is only a ratio of two variances-variation between factors to variation within the factors with higher values denoting greater significance of that particular input parameter. The *P*-value symbolizes and demonstrates the probability at a confidence level of 95%, such that a *P*-value < 0.05 denotes the significance of the model term. In contrast, a *P*-value exceeding 0.1 indicates insignificance [37, 38]. Model adequacy is assessed based on R^2, adjusted R^2, and predicted R^2 values. Table 4 shows that the model displayed an *F*-value of 283.94 and a *P*-value < 0.005, indicating its significance. Consequently, the lack-of-fit *F*-value of 0.63 suggested that most residual variations originated from pure errors rather than a lack of fit. The significant regression and non-significant lack of fit affirmed the model fitted with the experimental data. Notably, terms such as A, B, C, A^2, B^2, C^2, and AB are significant, whereas AC and BC are insignificant. Additionally, the R^2 value of 0.9961 and adjusted R^2 value of 0.9926, both nearing 1.0, indicated a strong fit with the experimental data. The predicted R^2 value of 0.9872, differing by less than 0.2 from the adjusted R^2 value, implied the model's suitableness for

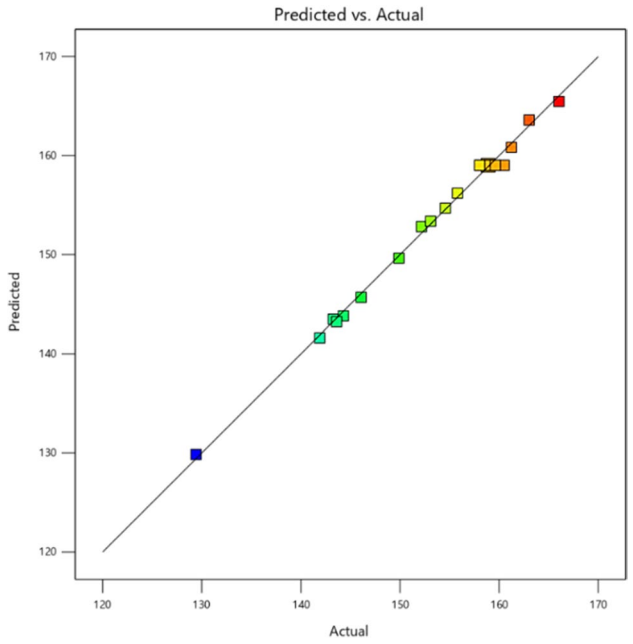

Fig. 9 Predicted vs. actual graph for tensile strength of CMT joint

further predictions. The adequate precision, exceeding 65.1709 (> 4), indicated an adequate signal, affirming the tensile strength model's significance and precision.

Once the adequacy and reliability of the models are confirmed, insignificant terms are eliminated without compromising the accuracy of the models. Through regression analysis, the quadratic equation for predicting tensile strength is derived and is represented by Eq. 4:

$$\begin{aligned} \textit{Tensile Strength} &= 159.03 + 7.74A - 3.24B - 0.9369C \\ &\quad - 2.14A * B - 3.42A^2 - 2.33B^2 - 1.88C^2 \end{aligned} \tag{4}$$

Here, A, B, and C represent current, travel speed, and gas flow rate, respectively. A positive sign preceding the terms denotes that the term works to create a better response, whereas a negative sign indicates that the term works against and reduces the overall outcome [39]. The quality of the developed model is estimated using the correlation coefficient value. Figure 9 illustrates the predicted vs actual graph in which actual and predicted responses clustered closely around the $y = x$ line, affirming the significance of the regression equation model. Consequently, the ANOVA outcome is considered reliable. Figure 10a and b illustrate 2D and 3D graphical representations of the regression equation, showing the relationship between tensile strength, current, and travel speed while maintaining a constant shielding GFR of 16 L/min.

3.2 Effect of process parameters on response

3.2.1 Single effect of current

The welding current influences the weld bead's metallurgical and mechanical properties as changes in current can result in transformations of the structure of the weld zone at the micro level, affecting its mechanical properties. It is

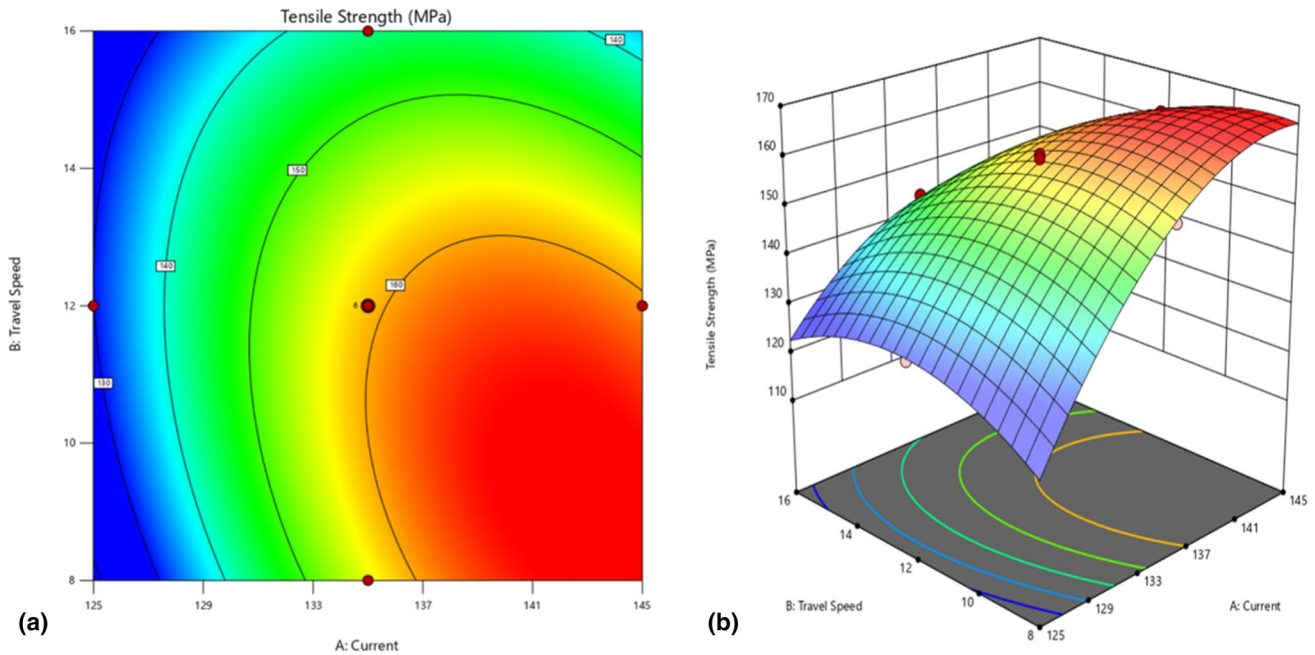

Fig. 10 Interaction between current and travel speed. **a** 2D contour plot, **b** 3D response surface plot

evident that change in the current tends to modify the tensile strength of the weld sample by directly influencing heat input into the weld pool. When the current is lower, there is lessened heat input, as confirmed by Eq. 5 [40].

$$Q = k\frac{VI}{v} J/mm \tag{5}$$

where Q is the heat input (J/mm), k is the thermal efficiency, V is the arc voltage (V), I is the current (A), and v is the travel speed (mm/s). Therefore, due to the decreased heat input, the filler wire melts less. This results in inadequate penetration, particularly with ER5356 filler wire, which has lower silicon (Si) content. This lower Si content reduces the wire's fluidity, which might contribute to the formation of pores when the filler wire is introduced into the weld. Thus, the welded joint exhibits lower tensile strength [41]. As the heat input increases, the filler wire melts more, as indicated by Eq. 5, and therefore, the weld bead's geometry, i.e. width and penetration, generally increase. This increase in bead geometry can also be justified by Eq. 6 [42], which relates arc force (F) and current:

$$F = \frac{K}{2} I^2 \tag{6}$$

where K is a coefficient, and I defines the current. According to Eq. 6, as the current increases, the heat input and the value of F also increase. Typically, an increase in F facilitates greater arc penetration, enhancing weld penetration. Therefore, increasing the welding current leads to the opposite effect, resulting in an upward trend in tensile strength. The temperature also rises with increasing heat input due to higher current in CMT welding. This increase in temperature influences the absorption of hydrogen. Generally, as temperature increases, the solubility of hydrogen in the aluminium matrix also increases, following Sievert's Law [43], according to which the total volume of hydrogen in the liquid metal ([H]) is proportional to the partial pressure of hydrogen in the arc (P_{H2}), represented as $[H] = K\sqrt{P_{H2}}$. At high temperatures, the favourable distribution of hydrogen atoms into the aluminium lattice happens due to increased kinetic energy, facilitating the increased dissolving of hydrogen atoms into the aluminium matrix. This increased porosity can reduce the tensile strength of the bead at a higher current [44].

3.2.2 Single effect of travel speed

The speed at which the welding torch travels is crucial in determining the tensile strength of weld specimens, as it directly impacts the weld bead geometry and, consequently, the mechanical properties of the weld joint. Decreasing the speed may result in excessive heat being applied per unit length to the base material, as indicated by Eq. 5, which shows an inverse relationship between travel speed and heat input. This excessive heat also causes the excessive melt of filler material and possibly results in the collapse of the weld bead and the formation of defects through more penetration. On the other hand, increasing the speed can lead to incomplete fusion, as less heat will be shared with the base material per unit length, resulting in reduced penetration and weakening of the weld joints [45].

3.2.3 Single effect of GFR

A suitable amount of shielding gas is significant to keep the weld pool stable, prevent excessive splattering, and regulate the heat during welding. Results have shown that when the GFR is too low, it fails to adequately protect the weld area, resulting in defects like porosity that can weaken the weld's tensile strength. As GFR increases and reaches an optimum value, it leads to a reduction in porosity, ensuring consistent deposition of filler material, uniform heat distribution, and less spatter, therefore providing better tensile strength comparatively. However, further increasing the GFR beyond the optimum level can actually be detrimental in shielding a weld pool and contribute to porosity, as excessive gas flow can create turbulence around the weld pool. This disrupts the smooth flow of shielding gas and allows atmospheric air to mix in, which is readily absorbed by the molten weld metal. Upon solidification, these gases are released and form porosity, leading to less tensile strength [46, 47].

3.2.4 Interaction effect of current and travel speed

Current and travel speed play an interactive role in influencing the tensile strength of the CMT weld joint of composite plates. Increasing current generally leads to increased heat input into the weld zone, as per Eq. 5. More heat allows for deeper penetration and better fusion between the base material and filler metal, potentially increasing strength. However, excessive current has negative consequences, such as too much heat can cause excessive melting of the filler wire and base material, leading to the collapse of the weld bead. Travel speed is inversely related to heat input as per Eq. 5. A slower travel speed allows for more heat input as the torch dwells on the joint for a longer duration, whereas a faster travel speed does the opposite. Materials might require higher currents and slower travel speeds for proper penetration. It is observed that the tensile strength maximizes around higher current values and lower travel speed [40–42, 45].

3.3 Optimal parameters

Design Expert Software provides numerical optimization options to determine an optimal combination of variables

Table 5 Maximum and minimum limit of process parameters

Factors	Units	Goal	Min limit	Max limit
Current	A	In range	125	145
Travel speed	mm/s	In range	8	16
GFR	L/min	In range	12	20
Tensile strength	MPa	Maximize	129.42	166.04

that satisfy defined requirements. The primary objective of this optimization is to achieve the maximum response while ensuring that all variable properties are satisfied simultaneously. The software employs five goal options to create desirability indices: maximize, minimize, target, in range, and equal to. Table 5 displays the criteria of optimal parameters used in the experiment. This experiment used numerical optimization to optimize the response variable, i.e. tensile strength. The single optimization results indicated that the maximum tensile strength of CMT welded joints could be achieved when the current is set at 141.637 A, the travel speed is set at 8.6 mm/s, and the gas flow rate is 13.75 L/min. The maximum value of tensile strength achieved at these values comes out to be 166.247 MPa, as displayed in Fig. 11. However, due to the constraints of the CMT machine setup, these values are rounded to the nearest whole numbers, i.e. a current of 142 A, a travel speed of 9 mm/s, and a gas flow rate of 14 L/min.

3.4 Confirmation test

Confirmation is performed using a single combination of optimal parameters to validate the empirical equation related to current, travel speed, and GFR. If the average observation falls within this prediction interval, it confirms the model's accuracy. Three confirmatory runs were carried out during the welding process to validate the model, and the resulting averages were recorded, as shown in Table 6. The validity test results show that confirmation results closely match the predicted values, revealing that the designed model is accurate.

3.5 Microstructure characterization of welded specimen at optimum process parameters

3.5.1 Porosity and dilution

Figure 12a represents a good-quality bead, showing no sign of solidification cracking and minimal presence of pores. The challenge of solidification cracking has commonly been prominent in fusion welding of MMC, but CMT welding at its optimal setting has effectively addressed this issue, resulting in fewer defects. The porosity in the fusion zone of the weld bead is calculated at two locations, as displayed in Fig. 12b, using the formula mentioned in Eq. 3. The total porosity percentage for both locations is determined to be 1.82% and 1.76%, resulting in an average value of approximately 1.79%. During welding, the affinity of hydrogen gas towards liquid aluminium matrix increases, which might result in pores formation within the fusion zone of the CMT welding [44]. The dilution of the welded joint of composite plates comes out to be 61.26% using the dimensions shown in Fig. 13a and b. This shows a complete penetration of the filler wire and is a balance between excessive and insufficient dilution since excessive dilution can lead to issues

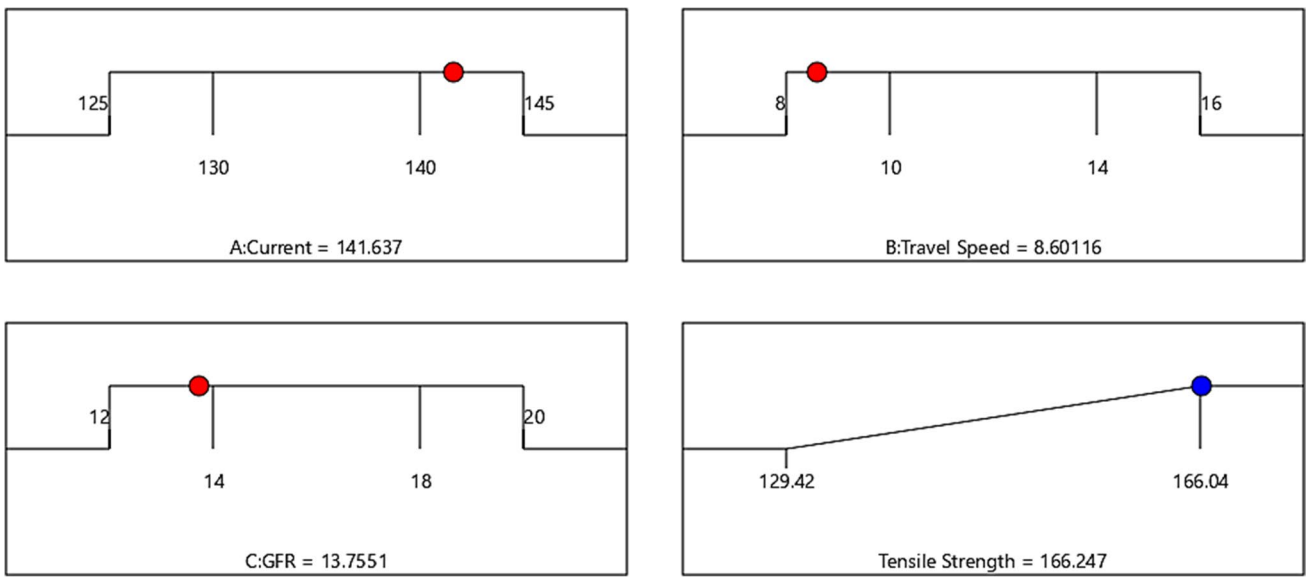

Fig. 11 Ramp function graph showing the optimal value of each process parameters

Table 6 Predicted and experimental values at optimum parameters

Run no	Current (A)	Travel speed (mm/s)	GFR (L/min)	Tensile strength (MPa)		
				Predicted	Experimental	Error %
1	142	9	14	166.247	165.04	0.726
2	142	9	14	166.247	165.73	0.310
3	142	9	14	166.247	166.81	0.338

such as reduced mechanical strength, changes in chemical composition, and the formation of undesirable microstructures, while insufficient dilution may result in inadequate fusion between the base plate, leading to defects such as lack of penetration or incomplete joint formation [28, 41].

3.5.2 Optical and FESEM analysis

Figures 14 and 15 show the optical and FESEM images of three zones formed during CMT welding of composite plates, i.e. fusion zone (FZ), heat-affected zone (HAZ), and base material (BM), which is a fabricated composite in this study. FZ shows finer and equiaxed dendrites formed at a high current value of 142A. At a high current value, a faster solidification rate occurs, thereby promoting the formation of smaller grains [48]. However, these dendrites are distributed non-uniformly throughout the zone. At HAZ, coarse columnar crystals are visible. In any welding system, the solidification structure mainly depends on the ratio of the thermal gradient of the liquid–solid line (G) and the solidification growth rate (R). The value of this ratio increases from the centre of the FZ toward the solid–liquid boundary. Now, at a higher current value, the heat input in the weld zone increases, leading to a higher thermal gradient near the fusion line. However, the growth rate will be minimal, resulting in a lower cooling rate; hence, grain growth will be slow, and coarser grain will be formed in HAZ [48, 49]. BM shows the non-uniform distribution of both reinforcements within the volume of AA6061-T6, which substantially impacts the composites' properties, such as mechanical and fracture behaviour. The grayscale contrast discovered in the FESEM images corresponds to the α-Al phase, while the darker areas reveal the presence of secondary phases such as Mg_2Si, $Al_{12}Mg_{17}$, and reinforcement TiB_2. Also, a few accumulations of micro TiB_2, along with a few precipitates, are visible along the boundary. During solidification, the microstructures of composites include a solid solution of aluminium and an inter-dendritic structure of eutectic aluminium–silicon [50]. The reinforcement particles are constrained toward refined α-Al grains as the composites solidify. Due to this, more refinement of α-Al grains occurs, and the TiB_2 and La_2O_3 particles serve as nuclei on which the α-Al grains solidify, providing resistance against the increasing α-Al phase during the solidification process of casting [50]. Figure 16 displays the EDS analysis at the fusion line, in which different peaks conform to the presence of various elements. The presence of titanium (Ti) and lanthanum (La) suggests the incorporation of reinforcement materials within the matrix of the fabricated composite, accompanied by lesser peaks signifying the presence of magnesium (Mg) and silicon (Si).

3.5.3 Electron backscatter diffraction (EBSD)

The inverse pole fig (IPF) map shown in Fig. 17a illustrates different zones in the CMT-welded composite, specifically focusing on the region near the fusion line of the weld bead.

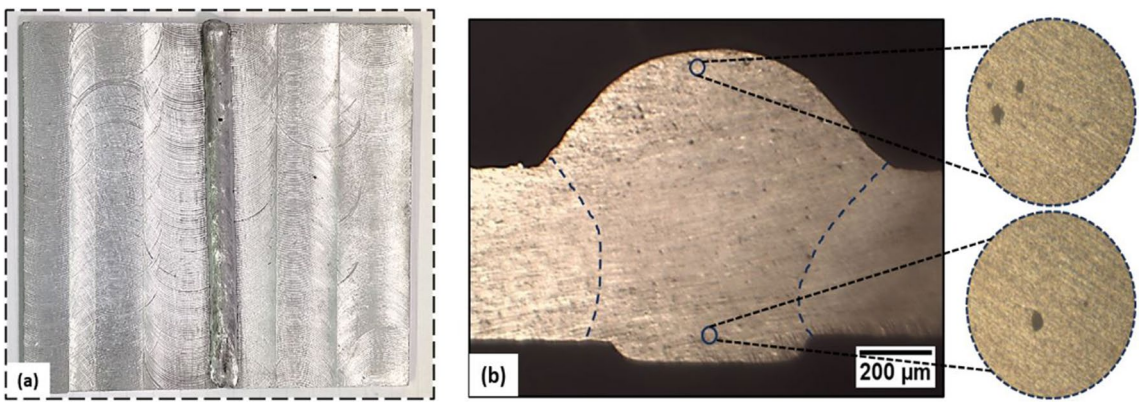

Fig. 12 **a** Top view of CMT weld bead at optimum welding parameters. **b** Location for porosity measurement

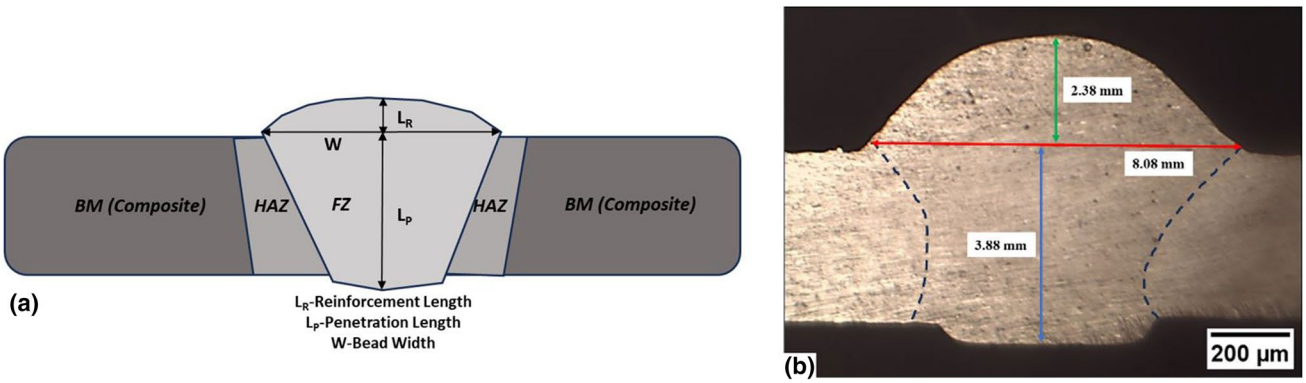

Fig. 13 **a** Geometry of CMT weld bead, **b** Dilution of weld bead

On the left side of the fusion line, a cluster of finer grains ranging in size from approximately 3 to 9 µm is observed. In contrast, the right side of the fusion line exhibits comparatively larger grains with a size range of approximately 12 to 76 µm. Moving towards the base material further increases the grain size, ranging from ~ 95 to 237 µm in comparison to the fusion zone. Figure 17b displays the boundary map where sub-grain boundaries, low-angle grain boundaries (LAGB), and high-angle grain boundaries (HAGB) are represented with red, green, and blue lines, respectively. The observation reveals a higher prevalence of sub-grain boundaries (< 5°) in comparison to LAGB (5–15°), while HAGB (> 15°) has the highest density among all. The microstructural variations during the welding process with ER5356 filler wire are apparent in Fig. 18a. Also, as per Fig. 17a, the presence and distribution of reinforcement particles within the aluminium matrix are visible, with some TiB_2 particles located at grain boundaries near the

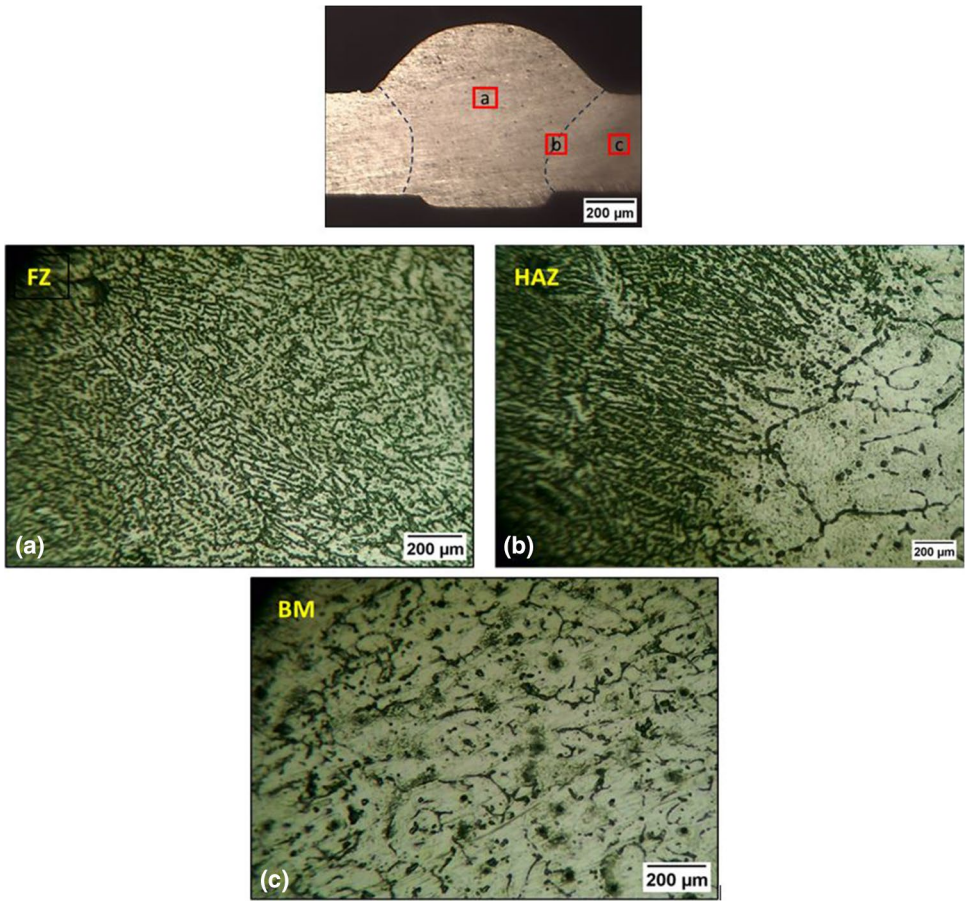

Fig. 14 Optical images of **a** FZ, **b** HAZ, and **c** BM

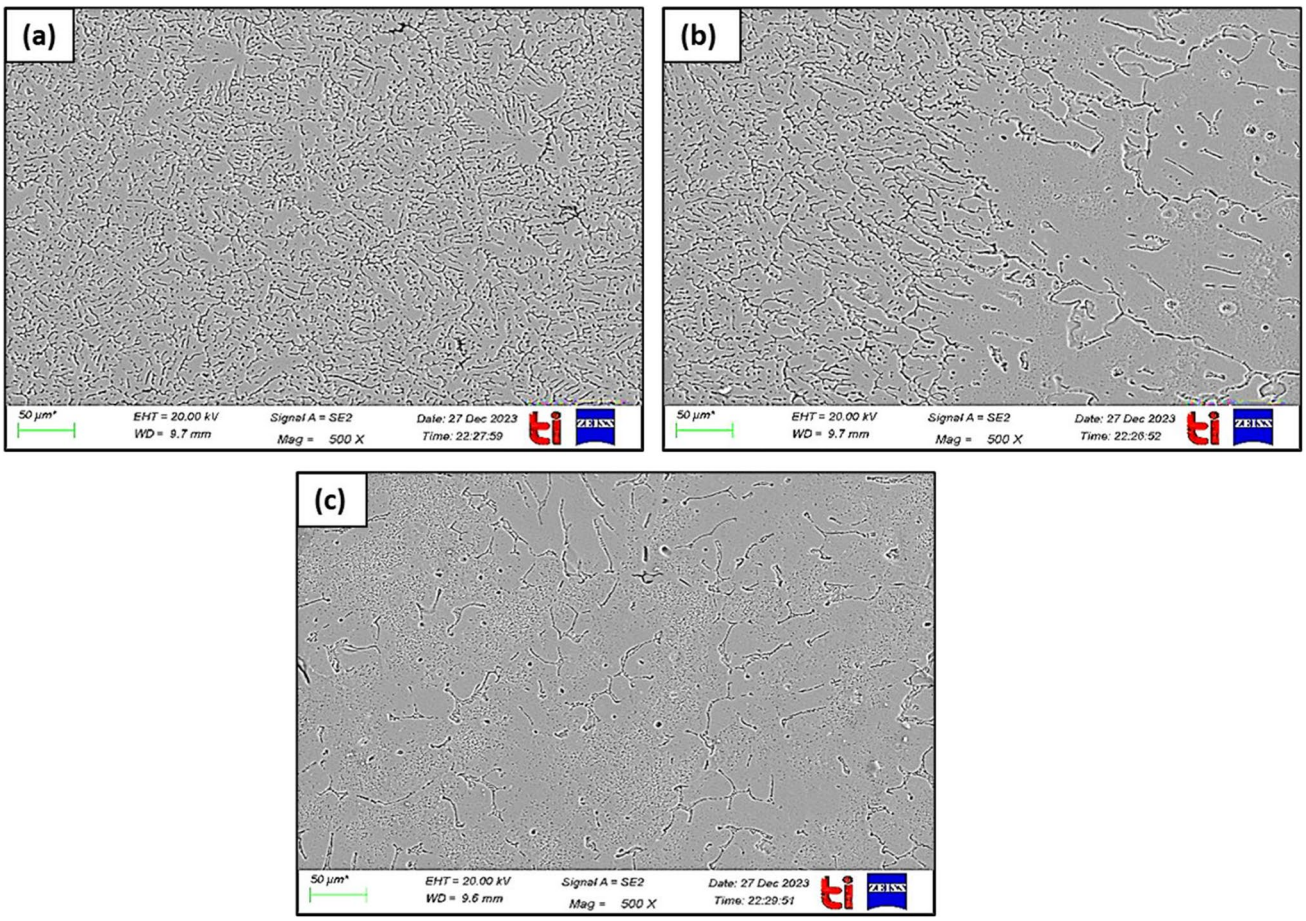

Fig. 15 FESEM images of **a** FZ, **b** HAZ, and **c** BM

HAZ region. This type of distribution is called necklace-type, as shown in Fig. 18b, and is a characteristic of MMCs produced via stir casting, which induces weak interface bonding between reinforcement particles and matrix in particle-segregated zones [51]. This is confirmed by the research of Sun et al. [52], which showed that a distinctive necklace-type distribution is shown when SiC particles are imparted into AZ91D composites.

3.5.4 XRD analysis

In Fig. 19, XRD peaks detected in the fusion zone of the welding reveal the existence of reinforcement materials such as TiB_2 and La_2O_3 within the aluminium matrix, with aluminium exhibiting the most evident peak intensity. Additionally, XRD analysis identified several intermetallic compounds in the weld zone. These compounds form during CMT welding due to the interaction between the filler metal and the dilution of the composite. Major compounds observed include $Al_{3.21}Si_{0.47}$, $Al_{12}Mg_{17}$, Mg_2Si, TiO_2, Al_3Ti, and $Al_{2.12}La_{0.88}$. The rationale behind the formation

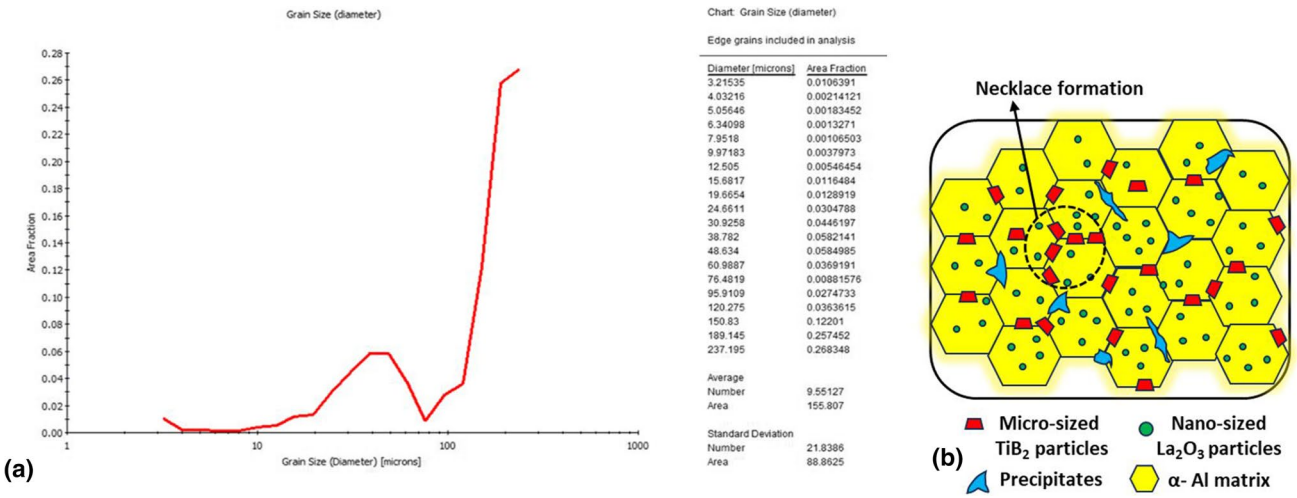

Fig. 18 **a** Distribution of grain size. **b** The schematic diagram illustrates the formation of microstructure in a composite

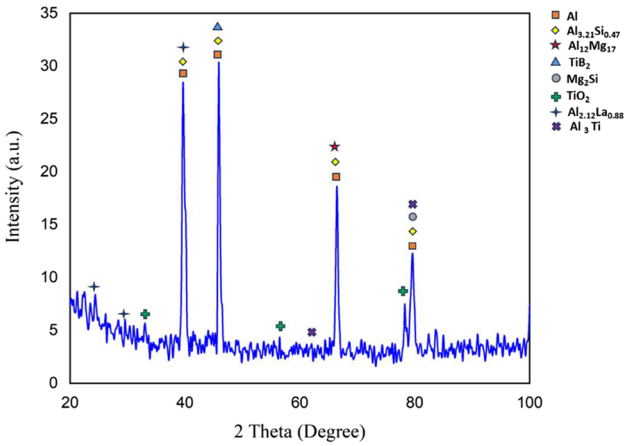

Fig. 19 XRD analysis at the fusion zone

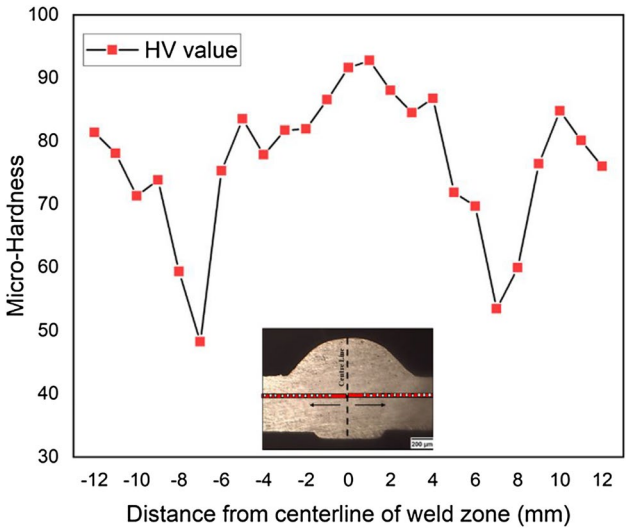

Fig. 20 Average hardness distribution across the weld joint

of intermetallic compounds, $Al_{12}Mg_{17}$, lies in the fact that magnesium (Mg) and aluminium (Al) exhibit complete mutual solubility in the molten state. During the solidification process, a eutectic reaction occurs, leading to precipitation ($Al_{12}Mg_{17}$), which possesses brittle and hard properties. Moreover, during the solidification process of molten Mg-Si within the weld bead region, the presence of silicon (Si) is attributed to diffusion and recrystallization between Si and Mg elements, leading to the formation of Mg_2Si, which is recognized for its favourable mechanical properties, including high hardness, lower density, and a high melting temperature [53]. These findings are consistent with the study conducted by Lakshminarayanan et al. [54], who examined the effect of welding methods (MIG, TIG and FS) on the mechanical properties of AA6061 aluminium alloy and discussed the impact of alloying elements. The appearance of hard and brittle-natured intermetallic compounds such as Al_3Ti and TiO_2 improves the composite's mechanical properties. But at the same time, they pose a challenge in CMT welding due to their tendency to weaken the HAZ [55].

3.6 Microhardness

Figure 20 illustrates the average microhardness results measured at 12 positions across the cross-section of the welded specimen, in which it is observed that the weld joint exhibits the highest microhardness, approximately 92.7HV in FZ. This microhardness is notably greater than the HAZ (48.25HV) and the BM (84.76HV). XRD results indicated the formation and presence of intermetallic compounds such as Mg_2Si and $Al_{12}Mg_{17}$. These intermetallic, along with reinforcement particles, provide additional nucleation sites. The increased number of nucleation sites leads to the formation of more grains and grain boundaries, creating a finer grain structure. These additional grain boundaries inhibit dislocation movement, thereby enhancing the hardness of the weld zone compared to the base composite. EBSD results also confirm this refinement of grains in the FZ. Also, the refinement of grains helps in improving the hardness of the weld zone further comparatively, as confirmed by the Hall–Petch relationship [56] $HV = HV_0 + K_H . d^{1/2}$, where HV_0 and K_H are the constants associated with the hardness measurement and the material, and d is the grain size. HAZ display the lowest hardness, which is mainly attributed to microstructural alterations, such as grain coarsening and recrystallization phenomena, along with the formation of combined precipitates resulting from the thermal fluctuations induced by the welding process [57]. Compared to the HAZ, composites show much higher hardness due to hard ceramic TiB_2 particles [58]. Additionally, the introduction of TiB_2 and La_2O_3 particles enhances the dislocation density around these reinforcement particles during solidification through the Orowan strengthening mechanism [58]. This high dislocation density increases the resistance to dislocation motion, thereby inhibiting plastic deformation. Furthermore, the presence of nano-sized La_2O_3 particles decreases voids within the base alloy [59]. Moreover, an effective bond between the reinforcement and the matrix facilitates the transfer of applied loads from the soft AA6061-T6 matrix to the strong TiB_2 reinforcement, consequently improving the composite's resistance to indentation. Pazhouhanfar et al. [60] validated an increase in the microhardness of the Al6061 matrix as the volume fraction of TiB_2 reinforcement increased. Similarly, Sharma et al. [6] indicated a 33.80% increase in the hardness of the Al6061 with the addition of 2.5 wt.% of REO cerium oxide. Furthermore, the formation of the hard and brittle Al_3Ti and TiO_2 intermetallic compound, as evident from XRD peaks, is another contributing factor to the enhanced hardness of hybrid composites.

3.7 Tensile strength

The tensile test demonstrated that the welded specimen's ultimate tensile strength at optimum parameters is 166.81 MPa, marking a decrease of 25.9% compared to the unwelded hybrid composite's tensile strength of 225.18 MPa. Figure 21a shows that the specimen is broken from the HAZ, indicating that the FZ and BM are stronger than the HAZ under uniaxial tensile loading. The mechanical characteristics of CMT-welded joints primarily depend on defects and metallurgical changes occurring during the welding process. The reason FZ has more strength than HAZ is evident from EBSD, which shows its finer microstructures compared to HAZ, leading to an increase in its strength as per the Hall–Petch effect [60]. It is well-accepted that the increased tensile strength of base materials, i.e. composite, has been brought about by imparting two reinforcements (TiB_2 and La_2O_3) in the matrix, which is responsible for showing various effects within the base matrix to enhance its strength and reducing its ductility like Orowan strengthing, the difference in coefficient of thermal expansion, and the shift of load from matrix to reinforcing agents accompanied by grain refinement. So, in general, the distribution of both the strengthening agents is crucial to increase the strength of the composite [6, 58, 60, 61].

Figure 21b displayed the fracture morphology of the welded specimen after tensile testing, and Fig. 22 demonstrates the mechanism involved in the fracture of CMT-welded joints in composite plates. The fracture region of the specimen is in the HAZ, which is also identified as the weakest area in the hardness test. The fracture displayed a combination of ductile and brittle failures, as both dimples and trans-granular cleavage facets are visible, with brittle failure being the dominant one. The presence of round and elliptical dimples suggests a ductile failure that has elongated in the loading direction, whereas cleavage planes indicate a brittle failure [62]. EDS analysis of the fracture surface, shown in Fig. 23, also confirms the presence and involvement of TiB_2 and La_2O_3 during the fracture of the welded specimen. The fractography of HAZ shows the brittle failure occurred due to the presence of two reinforcements within the composite. However, during welding, HAZ is subjected to a thermal cycle, which leads to modifications in the microstructure, such as grain growth, recrystallization or dissolution, or coarsening of strengthening Mg_2Si precipitates [60]. These changes often lead to coarser and less favourable microstructure compared to the BM and FZ, making the HAZ comparatively weaker. Also, the occurrence of voids or pores during welding initiates cracks that propagate and may result in failure during the tensile test [40].

3.7.1 Post-weld heat treatment (PWHT) of tensile specimen

PWHT is a controlled process involving reheating a welded material to a specific temperature, maintaining it for a set duration, and gradually cooling it down. PWHT is widely recognized for reducing residual stress and enhancing ductility and toughness. When a combination of ductile and brittle failure occurs, with brittle failure predominating, it becomes essential to shift towards a mode of failure where ductility is dominant, as ductile failure is often preferred in structural applications where early warning signs before complete failure are necessary, as it provides better resilience and is less susceptible to abrupt catastrophic failure. In contrast, brittle failure leads to sudden and unexpected fracturing once the material reaches its ultimate tensile strength, which is less desirable [63].

PWHT can enhance ductility, thereby shifting the failure mode from brittle to ductile during tensile testing of welded specimens. In this study, post-welding, composite

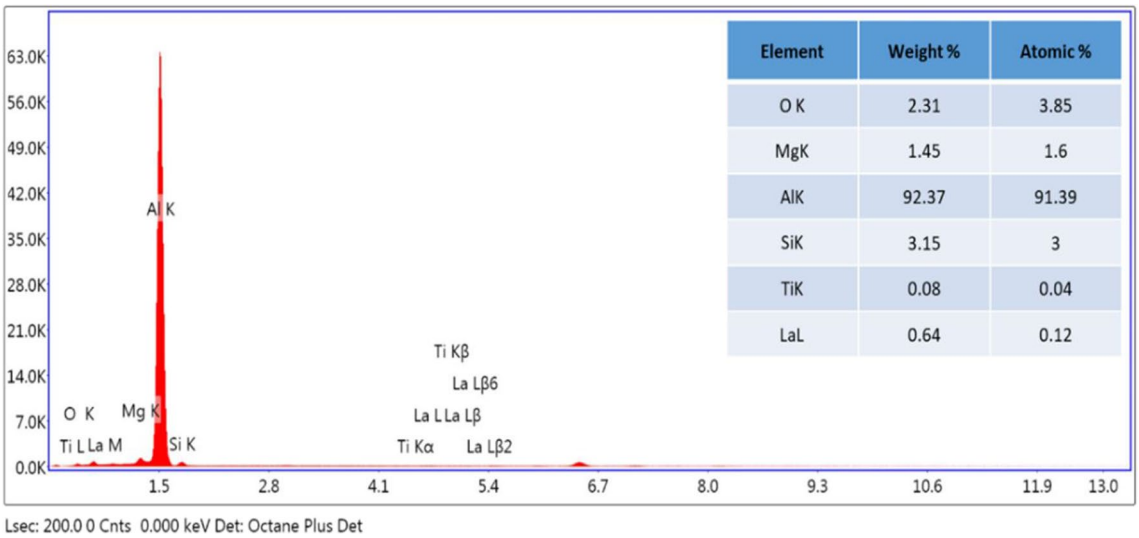
plates underwent T6 heat treatment to induce significant microstructural changes. Initially, the specimens underwent solution heat treatment at 520 °C for 2 h in an industrial muffle furnace, followed by quick quenching in water. After that, ageing is conducted at 180 °C for 5 h, followed by cooling in atmospheric air-cooling. Following this, heat-treated welded specimens are subjected to uniaxial tensile testing. Results displayed in Fig. 24a indicate that following T6 heat treatment, the plasticity of the welded composite specimen increased, leading to improved ductility and elongation. Specifically, the elongation increased by 17.80% compared to the non-heat-treated weld specimen, accompanied by a slight increase in strength of 4.13%. Also, fractographic analysis of the heat-treated specimens in Fig. 24b showed that the elongated dimple density increases, with few transgranular



Element	Weight %	Atomic %
O K	2.31	3.85
MgK	1.45	1.6
AlK	92.37	91.39
SiK	3.15	3
TiK	0.08	0.04
LaL	0.64	0.12

Fig. 23 EDS analysis of fractured tensile specimen

cleavages, observed due to the presence of hard reinforcement (TiB_2) within the matrix. The T6 heat treatment process may help facilitate the diffusion of alloy elements and enhance the uniformity of microstructures [64, 65]. Overall, the dominant failure mode shifted from brittle to ductile with the application of heat treatment. Li et al. [66] reached a comparable conclusion when applying a T6 heat treatment to an Al/Si/Cu/Mg aluminium alloy containing 1.5 wt.% SiC particles as reinforcement. The composite displayed increased tensile strength and elongation compared to the base alloy.

4 Conclusions

In this study, the process parameters of CMT weld joints of a novel AA6061-T6/2 wt.% TiB_2/0.5 wt.% La_2O_3 hybrid composite fabricated through stir casting are optimized to achieve maximum tensile strength. Quadratic statistical models are formulated to analyze the effect of current, travel speed, and gas flow rate on the tensile strength. Also, the study thoroughly evaluates the influence of these process parameters on weld formation quality. The key conclusions from the experiment are:

- CMT welding of the hybrid composite with an AA6061-T6 matrix and 2 wt.% TiB_2 and 0.5 wt.% La_2O_3 as reinforcements, fabricated via conventional stir casting, was successful, with all experimental runs producing continuous, uniform bead profiles with negligibly detectable visual defects.
- ANOVA indicates that current has the most significant influence on the tensile strength of CMT welds (61.31%), followed by travel speed (10.78%) and gas flow rate (0.89%). Using the desirability function, the optimal input parameters for maximizing tensile strength are current at 142 A, travel speed at 9 mm/s, and gas flow rate at 14 L/min.
- EBSD analysis, along with optical and FESEM imaging, indicates grain refinement in the fusion zone (FZ) compared to the heat-affected zone (HAZ) and base material (BM), where the HAZ exhibits columnar dendritic grains. EDS and XRD analyses confirm the presence of TiB_2 and La_2O_3 within the matrix, along with several intermetallic compounds such as $Al_{3.21}Si_{0.47}$, $Al_{12}Mg_{17}$, Mg_2Si, TiO_2, Al_3Ti, and $Al_{2.12}La_{0.88}$.
- Vickers's microhardness indicates that the FZ exhibits the highest hardness, while the tensile test of weld specimens reveals a 25.9% decrease in strength compared to the unwelded BM (composite), with the HAZ identified as the weakest region.
- The tensile specimens exhibit a primarily brittle behaviour, characterized by cleavage facets and few shallow dimples and tear ridges. Post-weld heat treatment results showed increased ductility indicated by more pronounced dimples and tear ridges and fewer cleavage facets in the fracture analysis.

Given the advantageous characteristics of the CMT welding sources, this technology may emerge as a promising method for welding MMCs, deserving further research and exploration.

Abstract: The Stirling cryocoolers are widely used in the military and aerospace fields due to advantages such as high efficiency and compact structure. The pistons of these coolers with very small clearances operate at high speed and without lubrication. Piston failure in the coolers has often affected the operational life of the cooler. The objective of the study was to find a solution to piston failure by providing a surface coat to the pistons, carrying out their tribological evaluation, and analyse cooler thermal performance to identify the better of two coatings for field applications. In the present experimental study, a Stirling cooler developed with a cooling capacity of 0.5 W @80 K with Helium as the working fluid was integrated with surface-coated pistons and tested for its mechanical and thermal performance. On testing, DLC coating exhibits better wear resistance than TiN coating and therefore is a more suitable coating for cryocooler pistons. The present study clearly shows that DLC-coated pistons reduce power consumption and increase the number of operational hours of miniature Stirling cryocoolers.

Keywords: Stirling; Cryocooler; Titanium nitride (TiN); Diamond-like Carbon (DLC); Infrared

1. Introduction

Research on miniature mechanical cryocoolers with investigation of different types of refrigeration cycles for small cryocoolers has continued since the earliest interest in infrared sensors cooling in thermal cameras, space exploration, earth observation, and medicines (MRI). Stirling cryocoolers are particularly attractive for miniature units because of their compact configuration, low weight, and high efficiency in terms of power input per unit of refrigeration produced. They are designed to be unlubricated and wear-free, to meet the requirements of high reliability, high efficiency, and long maintenance-free life.

All dynamic machines are expected to meet the requirement of good mechanical as well as tribological performance over a wide and changing set of environmental conditions. Surface coating continues to be the most prevalent and cost-effective method in reducing the tribological issues related to friction and wear. The compressor piston in a cryocooler reciprocates at around 75 Hz (stroke of 2 mm) inside the cylinder in a Helium atmosphere. It compresses Helium to around 30 bars with a pressure ratio of around 1.2. The working of the piston under high pressure at very high speed with very small clearances increases wear possibility. This makes the cooler susceptible to early failure as both cylinder and piston are of the same material and hardness, and are also ground. To overcome this, the piston needs to have sufficient hardness at the surface and a low coefficient of friction between the piston-cylinder assembly. To fulfill this requirement, the piston is coated with harder surface coatings in comparison to the cylinder. In addition, the dimensional aspects of the piston are maintained with low coating temperature and submicron thickness uniformity. Ceramic and carbon coatings such as titanium nitride (TiN)

and diamond-like carbon (DLC) coatings possess good mechanical properties and chemical inertia. Various conventional binary coatings such as TiN, CrN, TiC, etc., are used for improving tribological behaviour between moving and contacting surfaces like piston cylinder liner assembly, bearings, workpieces, and tools.

In the present case, Titanium Nitride and Diamond Like coating are the most suitable candidates as they are harder than hardenable steels. Titanium nitride (TiN) is a metal nitride hard ceramic coating having remarkable tribo-mechanical properties like high hardness, low rate of wear and corrosion [1–5] with a broad range of tribological applications in machine elements, turbine bearings, aerospace, automotive, and cutting tools. Extensive research on the areas of application of TiN coatings, their characterization, and deposition technique has been carried out to highlight the advantages of TiN coatings over uncoated surfaces of the mechanical components and tools.

Aytacet et al. [6] studied the wear of TiN-coated AISI 3343 steel used extensively in the moulding sector and Ghani et al. [7] investigated the wear mechanism of TiN-coated carbide and uncoated cermet's tools for end milling of AISI H13 tool steel by varying combinations of feed rate, depth of cut, and speed of cutting. Koeskiet et al. [8] compared CVD- and PVD-deposited TiN coatings for their cutting performance and wear properties during the continuous cutting of Ni-based super alloys. In a study by Xian et al. [9], TiN coating was deposited on three different tool materials i.e., high-speed steel, cemented carbide, and TiCN-based cermet using arc evaporation. The effect of tool materials on the microstructure, composition, hardness, adhesion, and tribological properties of the coatings was investigated to explore the relationship between the substrate material and the microstructure and mechanical properties of the coating. Hsu et al. [10] evaluated the performance of titanium nitride (TiN) coated Fiber Bragg grating (FBG) sensors in cryogenic temperature environments. Single metal-coated and bare FBG sensors were placed in an aluminium alloy mould, packaged in a thermally insulated, and used as cryogenic temperature sensors. TiN coating on FBG sensors changed nonlinear characteristics of the thermo-optic and thermal expansion coefficients resulting in accurate cryogenic temperature measurements. In addition to TiN coatings, Diamond-like carbon (DLC) coating is also widely used because of its good tribological characteristics and aesthetic value. DLC coating on machine parts allows them to operate under heavy loads, high temperatures ($\sim$ 500 °C), and corrosive environments. Diamond-like carbon (DLC) coatings are also relatively popular due to their superior properties like high hardness and lower coefficient of friction.

Li et al., [11] carry out a progress review and discuss various coatings, such as Cr-Al_2O_3 coating prepared by a process of electroplating, CrN and DLC coatings prepared by physical vapor deposition (PVD), and Mo-based and C-based coatings prepared by the thermal spraying process. In addition, development trends of commonly used piston rings are summarised and the pros and cons of commonly used piston ring coatings are also discussed.

DLC coatings find extensive application in the automotive industry [12–14] and are also applied to sliding gasoline engine parts. DLC coatings effectively reduce friction under an electrohydrodynamic lubrication (EHL) region [15] and are thus used to coat piston rings and valve lifters. Various studies have also been done on other DLC-coated mechanical components such as bearings [16], gears [17], and cutting and forming tools [18, 19]. Hanzelka et al. [20] proposed a DLC layer as an anti-seizing coating for their cryogenic apparatus and carried out measurements of thermal radiative properties such as thermal emissivity and absorptivity in the range of cryogenic and room temperature.

In certain applications of cryogenic cooling, a temperature down to 80 K is required, and cooling power varies from milli-watt to a few Watts. One such defence application is the cooling of infrared (IR) sensors to cryogenic temperature to minimise background 'noise' and get a sharp thermal image [21]. A reliable refrigeration system is necessary for cooling the detector to low temperatures and thus reducing the noise. In this application, isolating the sensor from mechanical shock, vibration, and electromagnetic interference is also important. In addition to the Joule Thomson (JT) cryocooler, a miniature cryocooler working with the reversed Stirling cycle principle is a solution for cooling such detectors. Miniature Stirling cryocoolers are widely used in an infrared detector assembly for maintaining cryogenic temperature. For optimum performance, the life of the Stirling cryocooler is a critical parameter. Several investigations [22, 23] have been carried out to address the cryocooler modelling, optimization of the design parameters [24, 25], and regenerator design of the Stirling cycle cryocooler [26–29]. However, limited literature is available on the cryocooler compressor piston design [30] and no studies are available on the effect of coatings on the thermal performance and operability of the cryocooler with a coated piston.

Stirling cryocooler compressor pistons with small clearances function under high pressure and speeds in the absence of lubrication increasing the wear possibility. Piston seizure and failure were identified to be one of the key reasons for cooler failure in field operations. The motivation for carrying out this study was to eliminate the possibility of cooler failure due to failure of piston by providing a hard coat and increasing the operational life of the coolers in field applications.

In the present investigation, the effect of TiN and DLC coating on the thermal performance and operational life of the Stirling cooler has been studied with two primary objectives. The first objective is to determine a suitable surface coating method and material for miniature Stirling cryocooler pistons, while the second objective of the present work is to carry out mechanical testing and thermal performance testing of a miniature Stirling cryocooler integrated with coated pistons on an in-house created experimental test setup. In this regard, the tribological performance of pistons with TiN and DLC coating was evaluated.

2. Experimental Study

2.1. Coating Methodology

A semi-industrial sputtering system was used for the deposition of TiN coatings. The effective plasma volume of the sputtering system was 0.005832 m^3. The sputtering system mainly consists of a cylindrical double-walled water-cooled vacuum chamber with several ports, which act as the sputtering chamber. It houses the magnetron cathodes, the substrate holder, feed-throughs, etc. A high vacuum pumping system with a turbomolecular pump is used to create a vacuum in the chamber of the order of 5.6×10^{-6} mbar. The coatings were deposited at a substrate temperature in the range of 250–325 °C. DLC coating was added to the piston surface by the Plasma-assisted Chemical Vapour Deposition (PACVD) method by magnetron sputtering techniques. The processing temperature (< 250 °C) at which the material properties of the parent material remain unaffected. The general coating parameters for deposition of TiN and DLC coatings on the pistons are listed in Table 1.

A piston cylinder is shown in Fig. 1. The required thickness of the coating on the piston is within 2–3 µm and the uniformity of thickness within 1 µm is a crucial requirement for the maintenance of the part geometry. The parent material before the coating is M42 alloy steel, hardened and ground to a hardness of 55–60 HRC with a surface roughness value of Ra ~ 0.20 µm. After coating, the piston-cylinder pair is lapped and polished to the surface finishes of the order of 0.05 µm Ra. TiN-coated and DLC-coated piston samples are shown in Fig. 2.

Table 1 General parameters for TiN and DLC coating

Parameters	TiN Coating	DLC Coating
Coating technique	PVD	PACVD
Colour of coating	Golden Brown	Black
Coating temperature (°C)	250–325	< 250
Friction coefficient	0.4	0.1
Micro hardness HV 0.5	691	1173
Thermal conductivity (W/mK)	19.2	500

2.2. Characterization of the Coating

The SEM and EDS results of the coated samples are shown in Fig. 3. While the SEM micrographs reveal the morphology of the coatings, the chemical composition of the coating was evaluated using EDS. The energy spectrum as presented alongside the micrographs, clearly reveals the peaks of titanium in the coated sample and the peak of carbon in the DLC-coated sample are visible in the test results. The elemental concentration of TiN and DLC coating were identified by a scanning microscope coupled with energy-dispersive X-ray spectroscopy (EDS). EDS

analysis with the elemental concentration corresponding to each coating is shown in Tables 2 and 3.

The microhardness measurements of the samples were performed using the DURAMIN-40 A2 testing machine. The testing method was VICKERS on HV 0.5 scale and the dwell time was 15 s. The surface hardness on the TiN and DLC-coated samples is given in Table 4. The readings are taken at four different points to consider the repeatability.

Steady-state power input	< 10 Watt
Room temperature	25 ± 2 °C

Figure 4 shows the indentation imprints by diamond indenter on the samples after 500 gf normal load was applied during the hardness test. The shape of the indentation marks reveals a pile-up in TiN-coated samples, while in the case of DLC-coated samples, no such pile-up was observed. The reason for the same is the softer coating.

Further, GIXRD measurements were also carried out on the samples. The pattern developed in DLC and TiN-coated

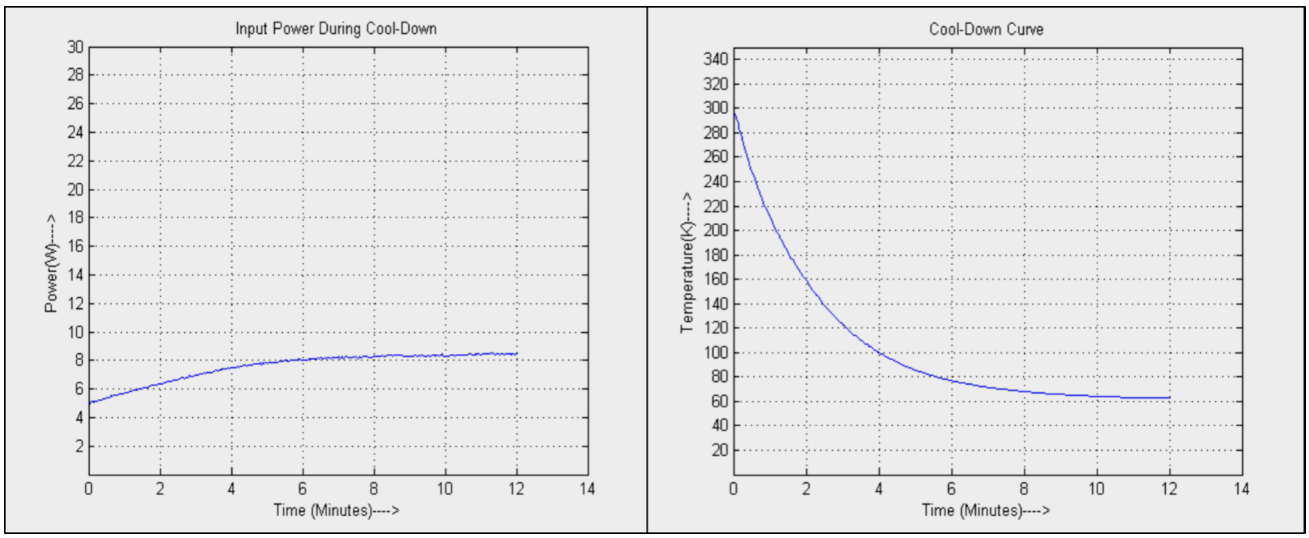

Fig. 8 Screen shot of data acquisition system of a typical performance run

samples is shown in Fig. 5a, b respectively. Phase analysis of the coated samples reveals that the most intense diffraction peaks originate mainly due to the Ti microparticles on the coating surface. On the other hand, the DLC-coated sample shows the presence of the graphite phase.

2.3. Testing of the Coated System

The cryocooler is tested on a dedicated experimental rig where the output parameters are continuously monitored through a dedicated data acquisition system. The data acquisition system generates an automated report at the end of every experiment containing the experimental results and system configuration. The cryocooler is charged and purged several times (10–12 times) to eliminate contaminations in the working medium like moisture, dirt, grease, etc. For the purging process, the cryocooler is coupled with a rotary vacuum pump. This process is carried out at room temperature and the cryocooler is not in operative mode. The helium gas charging line also includes a cryogenic trap in which the coil is immersed in liquid nitrogen to the filling station and a filter to remove the moisture/contaminations present in the gas. After the repetitive purging process, finally, the cryocooler is refilled with pure (purity 99.99%) and fresh Helium gas at 26–28 bar charge pressure.

After the final assembly, the prototype cryocooler is to be tested for its mechanical and thermal performance as shown in Fig. 6. In the mechanical testing, the dry run without the charging gas is carried out for several hours to monitor the abnormal sound, vibration, and power characteristics. The prototype undergoes thermal testing with helium gas charged if it passes through the dry run test. In thermal testing, the cryocooler is sealed through various stages and finally with a charging screw placed to ensure any type of gas leakage. A helium leak detector in sniffer mode is used to check the gas leakage from the outer casing of the main body of the cryocooler. The permissible value of the rate of cooler filling gas leakage is less than 4×10^{-8} atm cc/sec. After successfully passing this test, a RTD (Pt-100) temperature sensor is mounted at the cold end of the test Dewar to monitor the temperature available at the cold end. In the thermal performance, the cooldown time, the temperature, and the power input to the cooler are monitored. Continuous data logging is performed by a dedicated data acquisition system. The cold-finger region, on which the RTD is mounted, is maintained in a vacuum of the order of 10^{-7} mbar with the help of a turbo vacuum pump (Pfeiffer HiCube 80), to prevent any formation of frost due to cryogenic temperatures, which eventually may cause damage or may result in measurement variations. A programmable DC power supply (Tektronix PWS4305, 0–30 V) is used to supply and record the input electrical parameters like current, voltage, etc. A multimeter (Fluke 8845A) is used to monitor the temperature parameters and a Line valve (Nupro make), and a Pressure gauge (Wika make Range 0–40 kg/cm^2) are other components of the setup.

The complete lab setup to test the cryocooler prototype is shown in Fig. 7. Initially, the power input to the cooler is high until the system has cooled to its operating temperature (80 K) which is about 4–6 min. After achieving that condition, the first few hours of operation may see some further reduction in the input power in terms of a reduced motor supply voltage and hence machine speed. During the thermal test, if there is a flaw in desired performance parameters, the cooler undergoes extensive fault diagnosis

for a series of temperature and power checks at various levels.

3. Results and Discussions

To investigate the effect of TiN and DLC coating on cryocoolers, four-piston samples (two each) have been tested with a cryocooler. Initially, two coolers were sealed and assembled with TiN-coated pistons after charging the refrigerant (He) gas. A dummy dewar was used to create a vacuum in the range of 10^{-7} mbar around the cold tip of the cryocooler with a Turbo molecular pump (TMP). A calibrated RTD (PT-100) was used for cold tip temperature measurement. A data acquisition system was put in place for monitoring and logging the data. The testing requirement criteria are given in Table 5 for these experiments.

Results of a prototype cryocooler that met the performance criteria in a typical test run were obtained with the help of a dedicated data acquisition system. The results in terms of power characteristics and cold tip temperature of the cryocooler are shown in Fig. 8.

The cryocooler parameters maintained for testing the piston and cylinder assembly in the different prototype cryocoolers are given in Table 6. The Experimental test results in terms of run hours, cold tip temperature, cool down time & power drawn by the coolers are shown in Table 7.

The results obtained in terms of power characteristics and cold tip temperature are shown in Fig. 9. The four plots (cool down temperature & power vs time) are shown for two sets of each piston coating TiN and followed by DLC

Table 6 Cryocooler parameters during the experiment

Nominal speed	4200 RPM
Charging medium	Helium gas
Charging pressure	28 bar

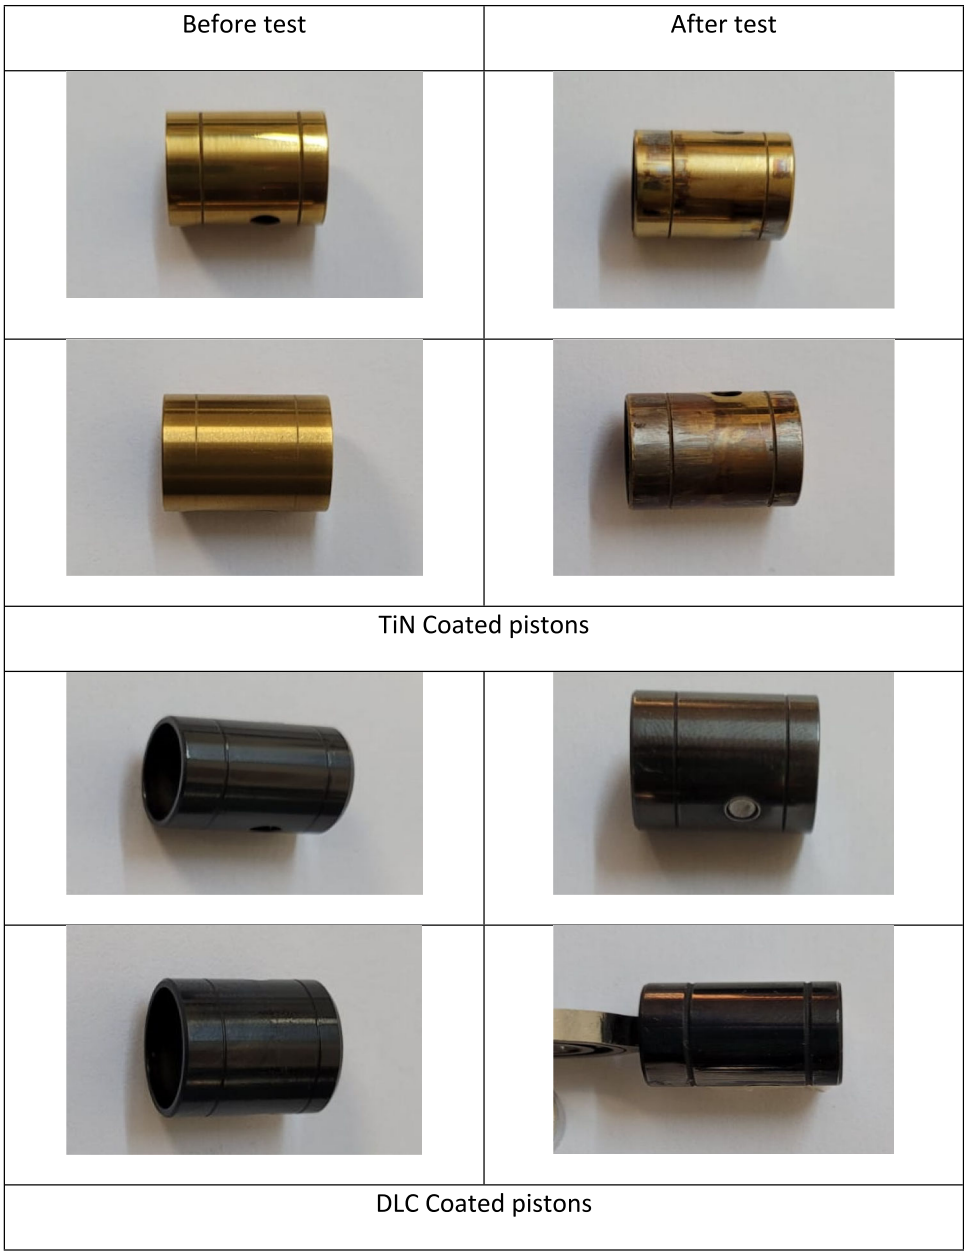

Fig. 10 TiN & DLC coated pistons before and after the cooler operation

coated with the parameters shown in the table at two prototype cryocoolers.

The other parameters of the test results such as time duration of the test run, cold tip temperature during the test, cool down time & power drawn by the coolers are tabulated in Table 7 below:

The cooler-1 was clocked around 30 h continuously. Initially, for the first few hours, it operated without an increase in power. The temperature during this period was also around 77 K, less than the set value of 80 K. The audible noise observed during this period was also negligible (permissible level < 35 dB). However, after a few hours, the power gradually rose till 30 h of run and its peak value went up to more than 20 Watts along with a substantial increase in audible sound levels. A cyclic rise and fall in power levels were seen and once power reached a certain high level, a high audible sound from the cooler was observed. Due to the continuous high power being drawn and a very high audible sound from the cooler the testing had to be discontinued. A similar pattern was observed for cooler 2, during 37 h of continuous run. Figure 9b–d shows the power vs time and Fig. 9a–c shows the cold tip temperatures vs time logged on the data acquisition system. Both the coolers failed to meet the required thermal test specifications. The cooler was disassembled to see the reasons for failure, especially for the power rise. The following were the main observations:

a) A brown powder-like substance could be seen on the components such as the piston & cylinder, crankcase, displacer assembly, etc. Brownish color powder could also be seen on the inner side of the main body
b) Several rubbing marks on the piston and sleeve assembly were seen and this hindered optimal operation since clearance space was filled with powder/debris.
c) The rest of the components showed no changes.

The images of the piston before and after assembly are shown in Fig. 10. There were visible rubbing and scratch marks on the piston/cylinder showed some signs of drawing a high current. This is looking to be the most probable cause of this failure as the coating comes out in the form of brown powder. Both the coolers were opened and reassembled with fresh DLC-coated pistons. Cooler-1 operated continuously for 83 h and cooler-2 operated for 101 h without any sign of a mechanical seizure, abnormal sound, vibration, or any surge in current/power during the period of testing. The power drawn and cold tip temperature measured during the experiment are shown in Fig. 9e–h. All the specified thermal test specifications were met successfully. The testing was stopped and similar tests were carried out after regular periods of intervals with satisfactory results.

4. Conclusion

In this study, a Stirling cryocooler with titanium nitride (TiN) and Diamond-like coating (DLC) pistons has been investigated experimentally for its thermal and operational performance involving measurement of its cooling, power characteristics, and the number of operational hours. The following major conclusions can be drawn from experimentations:

(i) The TiN-coated pistons showed less adhesion and more abrasion during cooler operation. The primary cause of brown powder observed in most components was the wear of coating between the piston (compressor) and the sleeve. DLC coating exhibited minimum or no visual transference of wear debris from the DLC coating during testing.
(ii) The TiN-coated piston samples could not hold for more than 40 h cycle whereas DLC-coated piston samples sustained more than 100 h cycles of cryocooler operation without any changes in the surface or size variations of the wear zones. This inferred that DLC-coated piston coolers can be easily operated at least for twice the operation hrs in comparison to TiN-coated piston coolers as given in Table 7. Also, the power drawn by the cryocooler was approximately half in comparison to the cryocooler with a coated piston.

The major outcome based on tribological evaluation and cooling performance assessment of hard-coated stirling cooler pistons is that DLC coating exhibited better wear resistance than TiN. The DLC-coated pistons cryocooler gave a satisfactory cooling performance for even more than 300 hrs of continuous cycle tests without any wear on the piston surface. DLC surface coating emerged as a more suitable coating on cryocooler pistons for the increased operational life of the Stirling cryocooler in field operation.

Abstract: An alloyof AA7475 sheets and plates is currently being used for high-performance aircraft applicationsbut the main hurdle for such applications is its proper joining technique because AA7475 alloy is hard to weld. This investigation is done to characterize the microstructural and mechanical properties of a weld created by GMAW on AA7475 alloy in T7351 temper conditions. The tensile strength (TS) yields strength (YS), and percentage elongation was analysed and observed that theweld metal (WM) has a % elongation of 3% which is slightly less than 3.2% of heat affected zone (HAZ) and significantly less than 7.2% of the base metal (BM). Hardness tests were also performed and it was observed that the weld metal carried lower hardness values.For microstructural analysis, the micrograph and corresponding Energy Dispersive X-ray analysis were done at base metal, HAZ and weld metal. The compositions at the top, centre and root of the weld were discussed through EDX analysis. The fractography of WM ofthe fractured tensile samplewasalso studiedand reported.

Keywords: GMAW, Aerospace material, Aluminium Alloy, SEM, EDX.

INTRODUCTION

The applications of lightweight material in weight-sensitiveapplications like aircraft, automobiles, and marine life are growing day by day. It is also observed that weight reduction is directly related to the reduction in fuel consumption and the economy of the products [1]. Initially, these applications are fulfilled by using wood, iron, and their derivatives which have high weight orless corrosion resistant as well as expensive. To replace these heavy and bulky parts and components, a material is required that can replace these materials with reasonable qualities. After rigorous research, it was found that aluminium and its alloy can replace these materials because it isinexpensive, lightweight has high resistance to corrosion, is easily recyclable,also heat treatable to a major level of strength [2]. As the research advances, highly tailored high-strength aluminium alloys are being created to fulfil the industry requirements [3]. As a result, different series of aluminium alloys were developed to fulfil the time-to-time requirements. In this regard,different series of aluminium alloys like 2000, 4000, 5000, 6000, and 7000 were developed to fulfil the demand of the industry. The addition of 2% of copper along withZn and Mg, is able tosignificantly increase the strength of AA7xxx series alloys [4]. The new AA7000 series alloy like AA7050 offers excellent corrosion resistance, improved fatigue, strength and toughness. The alloy AA7075 was introduced by changing its Si and iron content as well as by changing its quenching/ageing conditions, enhancing the fatigue strength and fracture toughness. In the AA7075 alloy, the total iron content is 0.90 % and by decreasing its iron content by 0.22 per cent a new aluminium alloy, AA7475 is formed with excellent corrosion resistance and high fatigue strength [5]. The AA7475-T7351 has greater fracture toughness but comparatively lower yield strength and significantly improved ductility than the AA7075-T651 [6]. In the low-stress region, the alloy AA7475-T7351 outperforms in comparison to other 7000 series aluminium alloys. Due to its superior properties nowadays, alloy AA7475 is frequentlyused as a sheet and plate in high-performance aerospace applications and for components working in a hostile environment. With these facts and properties, the heat-treated AA7475 alloy will surely and safely be able to reduce the weight of the spacecraft structure and simultaneously improve fuel economy [7].

It is observed that as material improves, to form a structure,improved joining methods are required. Welding is generally used as a connecting method to form a structure of aluminium, and GMAW isa generally usedmethod for joining Al-alloy parts and components in automotive, marine, and aerospace applications [8].The GMAW process shows high welding efficiency, and less time consumption, has a simple setup and is ultimately cheap in the fabrication process [9,10]. Despite many advantages, the base metal's mechanical and microstructural properties were changed during welding due tothe melting of base metal with a highly heated

arcand if not controlled, provide poor weld joint properties. To fulfil the requirements of high strength and high corrosion-resistant material in different applications the joining of 5000 and 6000 series aluminium alloys was necessitated [11]. An AA6061 is welded by the GMAW process and concluded that the fracture takes place at the WM [12]. Defects have a significant effect on weld quality as well as joint efficiency. In this regard, different welding techniques have been tried to form an efficient weld with improved mechanical properties for different grades of Al-alloy and they are TIG, MIG, LBW, FSW, and GMAW. GMAW is a commonly used method for joining Al-alloy parts and components in the UK and also in Europe [13].Likedifficult-to-weld,all AA7000 series alloys as an age-hard-enable alloy,the aluminium alloy 7475 is also found very difficult to weld, by common fusion welding processes or by FSW [14].The GMAW process is cheaper and more flexible for joining thick sections compared to other welding processes [15]. The deeper penetration and high deposition rate were ensured by the GMAW process due to its continuous wire-feeding system and as a result, it produces high-strength weldments [16].

So, due to its distinct benefits over other welding processes,the GMAW welding process is considered the optimum solution to weld a such hard-to-weld, age-hard-enable Al-alloy 7475. In this investigation, the alloy of AA7475 in T7351 temper was welded by using the GMAW process, and the mechanical and microstructural properties were analysed tocheck the potential of the GMAW process for hard-to-weld, age-hard-enable Alalloy.

MATERIALS AND METHODS

Base Metal and Filler Material

An aluminium 7475 in T7351 temper condition sheet of thickness 3mm is taken as the base material. Coupons were cut and put in but joint configuration and are spaced at 1 mm.By using the protocol of ASTM-E-1251-17, the base material and filler compositions are reported in Table 1. Table 2 represents the mechanical properties of base Al-alloy. As per the ASTM E-8-16a Protocol,the mechanical propertiesof the AA7475-T7351 plate as BMare shown in Table 3.Table 4, represents the welding parameters that are used for the best weld bead after a set of pre-experiments. The oxide layers were removed before the weld with the help an emery paperand acetone.The argon as a shielding gas was used with a purity of 99.9% and fed with a 13.8 l/min flow rate, 3 seconds before the arc was struck.

EXPERIMENTAL SET-UP AND PROCEDURE

GMAW set-up and process-

A semi-automatic GMAW welding setup carrying a TPS 320i GMAW welding power source which has an inbuilt wire feeder, a welding torch, an air cleaner for an air gun, which is operated by an air compressor, a welding table equipped with anadjustable demonstration wall is shown in Figure 1. A spool of UNI-ER 4043 ($AlSi_5$) welding wire of diameter 1 mm is used as filler material. A number of pre-experiments were performed to optimize the welding parameters for the best weld bead.

FIGURE 1. Schematic of the Semi-automatic complete GMAW welding setup

Microstructural Observations:

A microstructural study is performed by extracting a specimen from a weld cross-section as shown in Figure 2. The specimen was etched in Keller solutionfor 35 seconds. BMI-101 A, an optical microscope was used to studythe microstructure of the joint, andby using aLEO EVO-40XVP, an SEM,the micrographs were taken and analysed. The fractured surface wasanalysedwith an SEM equipped with EDX to evaluate the compositions of a weld after performing tensile tests. BM, and WM, as well as HAZ, are analysed from SEM micrographs and corresponding phase composition with EDX.

06 August 2024 04:46:25

2.3 Mechanical Characteristics of the joint

2.3.1 Mechanical properties of the joints:

A non-destructive test was done and was followed by visual observation to identify the flaw left with the weld surface. A liquid penetrant test (LPU) was performed and itwas observed that there were no significant welding flaws available on the weld surface. A Vickers Hardness Tester (VH-1000B), was used to evaluate the microhardness of the transverse portion of the welded specimen by using ASTM E-384:11, ASME Sec-IX-2019 protocol. The tensile test samplesaremade as per the ASTME E-16a protocol. Thetensile strength, yield strength as well and % elongation was assessed on tensile test specimens, also the corresponding tensile samples andweld plateare shown in Figure 2(a, b).

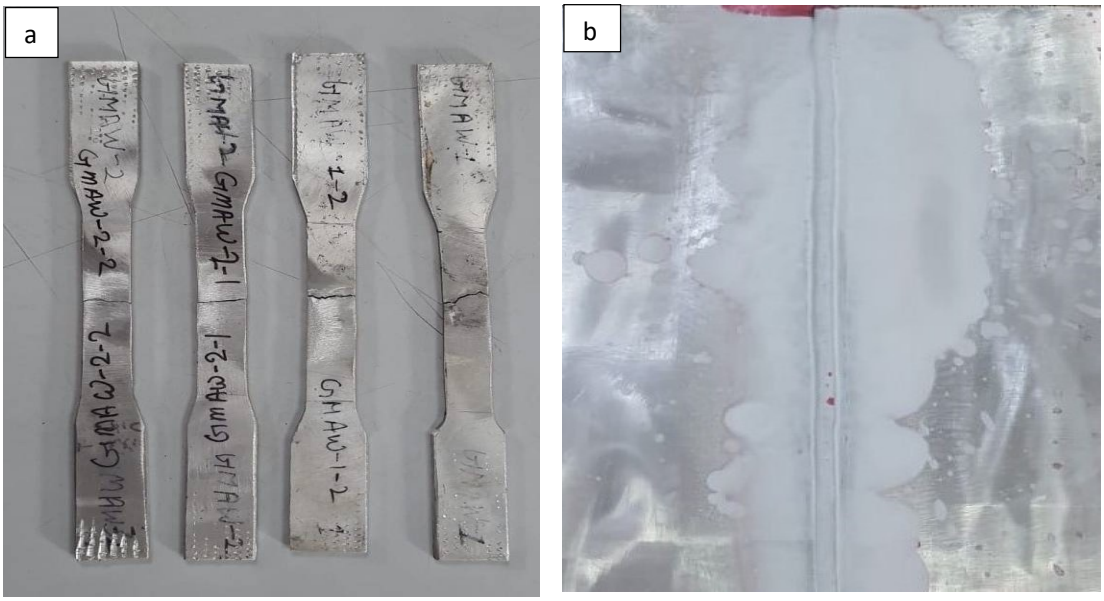

FIGURE 2. Shows the (a) welded samples for tensile testand (b) welded plate.

RESULT AND DISCUSSION

Weld Defect-

After visual inspection and liquid penetrant test, it is observed that there is no measure defect or other imperfections on the weld surface. From the macro-structure of the weld at 10X, some porosities are visible at the weld surface but they are few in number and have negligible effects on weld quality. There are no blow holes, hot cracks, orother harmful defects on the weld as per the test results as shown in Table 5.

Weld Structure Test:

Table 5. WM Test as per the Protocol of ASME S-9, ASTM E-381, ASM V-IX.

Parameters:

1.	3.251 mm	6.258mm	Not Observed at theWM

Macrostructures of weld sample

Figure 3, shows that there is no connection between the fusion area and the HAZ at even low magnification. There is a little difference in compositions between the weld metal and base metal except a minor concentration of Si elements on the weld metal, that may be due to the filler material.

06 August 2024 04:46:25

FIGURE 3. Macrostructures of welded specimen at a Magnification of - 10X**.**

Tensile properties of BM, WM, and HAZ

To examine the weld performance, a tensile test was performed at the BM, HAZ, and WM. The TS, and YS, as well as % elongation, was measured and the values are presented in Figure 4.Among all, the best tensile curvesarechosen and compared. In terms of % elongation, the BM shows 7.5% in comparison to 3% of WM and 3.2% of HAZ. It observed that the weld metal does not experience plastic deformation as compared to BM and HAZ and as a result, the WM shows lowest elongation. Due to this, there is a loss of strength, an increase in flexibility and significant softening. GMAW welded AA6061 joint [17] confirms that the weld metal showed lower tensile strength than BM and HAZ also showed lower plastic deformation.The tensile strength of BM is 435 MPa, much greater than 220 MPa of HAZ and 218 MPa of WM. Similar patterns are observed in the case of YS. All the specimen fails at the weld metal. The TS and YSvalues of HAZ are less than that of the BM but more than that of the WM, this may be due to the coarsening that takes place inside the HAZ. HAZ works as a heat sink probably due to the faster cooling rate that takes place at the weld metal and HAZ appears to be coarser than weld metal [18]. It was found that for the stress value 0 to 435 MPa of the base metal the load-displacement curve is linear and during that, the specimenexhibitsa pattern of elastic deformations. After that,the sample shows a homogeneous plastic deformation with an increase in stresses till the fracture takes place. Figure 4 (a-c) shows the load-displacement curve of the base metal, HAZ and weld metal. HAZ load-displacement curve is drastically different as compared to BM as shown in Figure 4b. As the load increase, the material starts yielding rapidly and get distorted followed by eventual breaking due to plastic slip deformation experienced by the material [19]. The WMengineering displacement curve is shown in Figure 4c. In this, it is observed that the WM shows a significantly lower value of percentage elongation than the HAZ and base metal, this is due to plastic deformation that takes place till the breaking point. Table 6 shows the average values of TS and % elongation for the WM and heat-affected zone.WM has a % elongation of 3% which is slightly less than HAZ and significantly less than BM.So, it is concluded that in terms of % elongation, TS, and YS, the WM is the weakest link of the weldments formed and all the samples failed at the weld metal.

Table 6. TS and % Elongation Values of the WM and HAZby following the protocol ofASTM E-8-16-a.

Microhardness and Microstructure of Base Metal, HAZ, Weld Metal

The weld characteristics were studied for theAA7475-T7351 alloy welded joint, a harness test was conducted by using the protocol of ASTM E-384-11, ASME Sec-IX-2019 and a micrograph was taken from the BM, HAZ, and WM of the specimen. Table 7, illustrates the weld metal and HAZ microhardness test results. The WM shows the lowest hardness which is 57.64 percent of the BM. The recorded hardness value of 170 HV was observed at BM which is significantly larger than that of the 98 HV of WM. The WM is primarily made with the filler metal and shows a heterogeneous structure this may be the cause of the lower hardness value as compared to BM. Al5.5Zn2.5Mg2.2Cu welded joints, have observed similar outcomes where the weld metalis observed as the weak link and carrying hardness only 56 % of BM. This may be due to movements of alloy constituents towards the grain boundaries and softening of the WM at the time of solidification [20]. This may be due to the softer filler wire material than BM.Columnar grain is the outcome of a joint made by ER4043 wire whereas ER5356 provides fine equiaxed grains. Fine equiaxed grains result in improved mechanical properties [21].Stainless steel and copper are successfully welded by the GMAW process and microhardness results reveal that the reduction in microhardness was observed at HAZ and WZ as compared to the base metal on both sides [22].The hardness value of HAZ is 136 HV which is 80% of the BM.This is due to the fact that, the HAZ is made with the help of semi-molten base metal.

A typical metallographic image was takenfrom the BM, HAZ as well and WM by using ASME Sec-9, ASTM E-381, and ASM V-9 Protocol and aredisplayed in Figure 5(a-c).The base metal shows elongated grains at 400X. The dendritic structure was reported due to melting and solidification in the weld metal during GMAW welding which shows elongated grains [23].Figure 5a depicts the microstructure of the HAZ at 100X and 200X. The General Microstructure shows ununiformly dendritic structure observed throughout the matrix.At the weld

06 August 2024 04:46:25

interface, a dendritic microstructure was observed that is due to the high cooling rate and less heat input. [24,25].Due to thermal cycling, the columnar crystallization takes place at the molten pooland shows typical eutectic crystallization behaviour. Figure 5 shows the weld metals metallographic image at a magnification of 100X and 200X. The structure shows a fine and dendritic grain and is observed as full penetration welding in the BM.The metallograph in Figure 5c at 400X shows the HAZ and WMmicrostructures which havea non-uniform and uniform dendritic grain structure respectively. A faster cooling rate refined the grain size because of no time of grain growth and shorter grains are formed [26].The HAZ shows a larger and coarser grain structure compared to weld metal which may be due to the high cooling rate [17].

FIGURE 5. Metallography of GMAW Weld, (a) BM (b) HAZ (c) HAZ and WM, at different magnifications.

Microstructural composition analysis of weld

The above hardness values and the tensile test resultshow that in comparison to the HAZ and BM, the WM is the weakest link. So, for the detailed analysis of the weld EDX analysis is done with a corresponding SEM micrograph taken from the top middle and root of the weld fractured surface are shown in Figure 6 (a-c). EDX result in Figure 6a shows that the constituent Mg, Fe, Cu, Zn and other elements were migrated from the BM towards the WM during the welding process. The results of EDX from the top portion of the weld reveal 47.47% Al, 25.99% Cu,2.16% Zn, and 8.04% O elements, indicating that the solution is an Al-Cu-based solid solution. In Figure 6-b which is from the weld centre of the weld the EDX result shows an increment in Al elements up to 65.43% and a decrease in the Cu and O elements by 15.02% and 4.23 % respectively. This indicates that the centre of the weld is not fully made up of an Al-based solid solution. In this, there is a diffusion of some other elements like Mg, Fe and Zn from base metal to WZ enhanced. The composition from the root of the weld shows pure Al-based solid solution with Al-80.97%, O element 4.51 % and an increase in the Zn and Mg content was observed. The diffusion of Cu content was not found in this region and is shown in Figure 6c. Similar outcomes are observed and explained in the solidification theory that at the solid-liquid interface an accumulation layer was formed by varying amounts in the welding pool [27]. Based on particular research, the particle phase of the Al/Cu reaction was primarily made up of Cu_2Mg. As a result, it can be explained that at the top and centre of the fusion zone, there may be some brittle inter-metallic compounds dispersed that are the cause of the fracture[28].Similar outcomes werefound for all the analysed welded samples.

Fracture Analysis of Weld

The fracture behaviour of the weld surface after the tensile test was analysed using SEM. For this, the SEM fractographywas taken from the top, centre, and root (bottom) of the weld after failure under tensile loading and presented in Figures7(a-c).It is observed that there were no visible defects over the weld surface although the fracture took place at WM. Fractography shown in Figure 7a taken from the weld top portion reveals a fracture with a large number of dimples that are equiaxed and uniformly distributed. Also, the fractography from the middle of the weld shows, that the dimples are nearly identical with varying numbers of fine dimples on the fractured surface of the weld shown in Figure 7b. Through the fractography from the top and centre of the fractured weld surface, it can be concluded that the major portion of failure is ductile in nature and that is due to the predomination of the dimples on the fractured surface. The flat surfaces represent the brittle fracture and the ductile fractures are represented by dimples. Also, some flat surfaces and dimple mixtures shows both ductile

and brittle fracture [29]. This conclusion is also supported by [30], in his findings he explained that the samples withheat-treated by solution have a sufficientquantityof fine dimples as compared to samples without heat-treated. Figure 7c shows the fractography taken from the rootof the fractured weld surface. It is observed that when the material goes under tensile test, voids emerge in the ductile material prior to necking and as a result, the cleavage failure pattern was the outcome. The coarse and elongated grain was observed at the root of the weld due to the early start of necking which resulted in much more evidence of void development. This outcome is supported by the pulsed wave GMAW joint created in PWHT samples and observed prolonged and coarse dimples [31]. At the weld root section, the metal consolation was generally inadequate this may be due to the poor weld quality and lack of penetration are the cause of brittle fracture that takes place in the root potion [32].

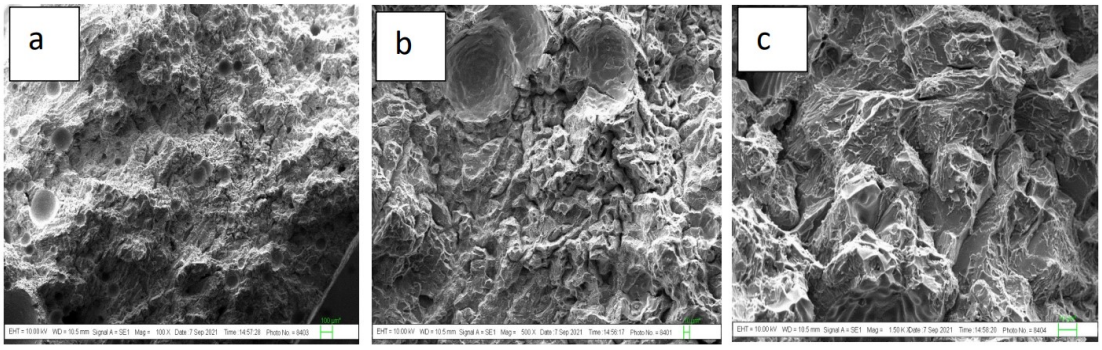

FIGURE 9. The SEM fractography oftensile tested weld sample; from (a) top; (b) centre and (c) root.

At the centre of the weld fracture surface the dimple appears wider and deeper in comparison to the sample from the top of the weld, as a result,it was concluded that the top portion of the weld is more ductile. The toughness fracturing mode is observed at the middle and root of the weld [33].Small and deep dimples represent the high ductility of the fractured tensile samples and the distance between the grain is the measure of ductility of the weld [34]. Cleavage failure patterns were discovered at the root of the weld.

06 August 2024 04:46:25

CONCLUSIONS

The main conclusions are summarized as follows:

1. WM has a % elongation of 3% which is slightly less than 3.2% of HAZ and significantly less than 7.2% of the BM. It is found that in terms of % elongation, TS, and YS, the weld metal is the weakest link of the weldments formed and all the samples failed in the WM.
2. The BM is the hardest portion with a harness of 170 HV, much greater than the HAZ and WM, and the lowest harness 98 HV, was recorded at the WM, which is only 57.64 % of the BM.
3. A metallographic image taken from BM shows that it is made up of elongated grains whereas an ununiform dendritic structure was observed in the HAZ throughout the matrix. The general microstructure of WMshows full penetration welding in the base structure. The structure consists of fine and uniform dendritic grain structure.
4. From EDX analysis it was found that during the welding process, the elements Mg, Zn, and Cu migrate from the BM towards the WM. The results from the top of the weld show a pure Al-Cu-based solid solution, at the weld centre, indicating that this location had not yet been made up of an Al-based solid solution, however, the diffusion of other elements like Zn, Mg, and Fe from BM to WM had enhanced. The EDX results from the root of the weld show a pure Al-based solid solution.
5. Fractography from the top of the weld depicts a fracture with a large number of equiaxed dimples which are uniformly distributed. The dimples here on the centre of the weld's fracture surface are wider and deeper than the dimples on the fracture surface of the top of the weld, showing that the top region of the weld is more ductile than the centre and root of the weld. Cleavage failure patterns were observed at the root of the weld.

***Abstract*—Explainable AI (XAI) has gained significant attention globally due to its capability to provide transparency and understanding of complex machine learning models.We explore the potential benefits of XAI and integrate them into the domain of disease detection. Our objective is to leverage the power of large language models coupled with advanced explainability algorithms to enhance the accuracy and interpretability of disease predictions based on input symptoms. By doing so, we aim to not only achieve precise disease identification but also offer clear and comprehensible explanations for the predictions made. This approach holds the promise of bridging the gap between the intricate nature of AI-driven disease detection systems and the need for transparency and trustworthiness in medical diagnoses.**

***Index Terms*—SHAP, explainable AI,Large language models, Neural networks,shapley scores,Prompt development,Acceptance Score, Agreement Score, Weightage**

I. Introduction

The integration of Artificial Intelligence (AI) in healthcare has transformed disease detection and diagnosis. However, the adoption of complex machine learning models presents challenges in terms of transparency and explainability. Decision-makers, including medical professionals and patients, demand clarity and comprehensibility in AI-driven medical predictions to trust these systems.

The importance of "Explainable AI" (XAI) is highlighted by recent regulations, such as the proposed EU legislation mandating a "right to an explanation" for algorithmic decisions. Historically, Expert Systems researchers have developed explanation methods, and AI systems have garnered attention in the popular press, prompting discussions on AI's implications for social justice and fairness.

This research aims to develop an AI-based disease detection system using machine learning algorithms, promising higher accuracy and efficiency compared to conventional methods. We also plan to employ Feature Mapping and Natural Language Processing to provide clear, text-based explanations for the system's predictions. Given AI's capabilities in processing complex healthcare data, the system can offer accurate diagnoses promptly, potentially saving lives by enabling timely treatments

A. EXPLAINABLE AI

Explainable Artificial Intelligence (XAI) encompasses processes and methodologies that enable human users to understand and trust the outcomes produced by machine learning models. Unlike interpretable AI [1], which focuses on making the model's decisions understandable, XAI goes further by providing explicit explanations for its predictions and actions, ensuring a deeper level of transparency and clarity for users.

B. FOCUS AREAS

We will be focusing on the following:

- Develop an Artificial Intelligence based Disease detection system which can act as a virtual doctor but more efficiently and with a consistent level of accuracy. Developing a medical diagnosis system based on machine learning (ML) algorithms for prediction of any disease can help in a more accurate diagnosis than the conventional method.
- Explaining the result of the Disease Detection system using the Feature Mapping methods and Natural language processing to have a text-based system that can generate the explanation considering the model parameters and understanding.

C. SHAP

SHAP, or SHapley Additive exPlanations, is a prominent method in machine learning designed to enhance model interpretability and facilitate the understanding of model predictions. Its foundation lies in cooperative game theory, particularly Shapley values, which are used to attribute contributions fairly among a group of contributors based on their marginal impacts in all possible combinations. The primary goal of SHAP is to assign each feature's contribution to the prediction of a specific instance [2], thereby providing insights into the factors influencing model output.

The term "additive" in SHAP underscores the property that the explanation for a specific prediction is the sum of individual feature contributions. This additive nature allows the decomposition of model predictions into the impact of each feature, offering a clearer understanding of the model's decision-making process. By adopting Shapley additive explanations, SHAP values provide a unified and comprehensive

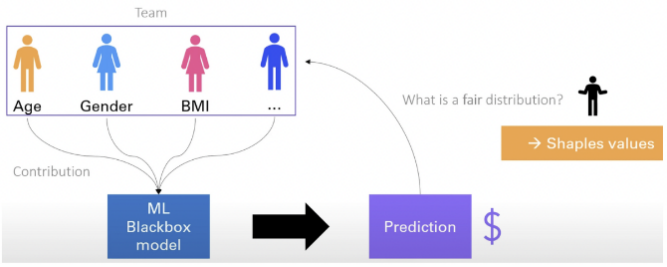

Fig. 1. Shapley Explanation - A Visual Representation of working of Shapley algorithm

measure of feature importance, making it a versatile tool applicable to various machine learning models.

II. Related Work

Numerous studies have explored the use of artificial intelligence techniques for disease detection. Machine learning algorithms have been employed to diagnose various diseases, achieving high levels of accuracy. Similarly, deep learning models have been utilized for the early detection of specific diseases, demonstrating promising results. However, the lack of transparency and interpretability in these models often limits their applicability in clinical settings.

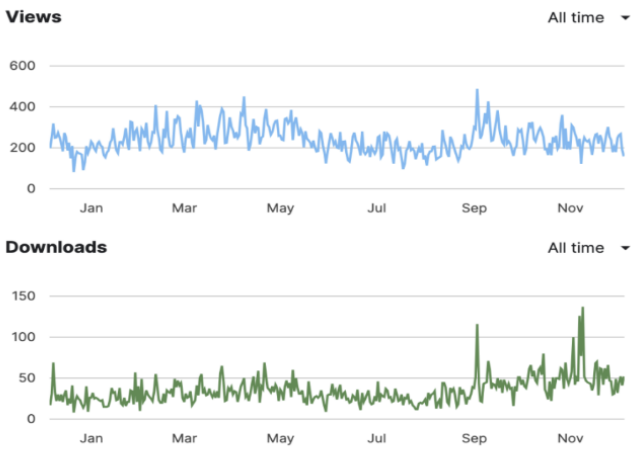
Explainable AI has emerged as a crucial area of research in healthcare to address the interpretability issue of AI models. SHAP (SHapley Additive exPlanations) scores have been utilized to provide interpretable explanations for the predictions made by disease detection models. Another approach involves the use of Large Language Models (LLMs) [3] to generate human-readable explanations, enhancing the transparency of AI-based diagnostic systems.

Another interesting development in XAI is the use of prompting techniques like chain of thought (COT) [4] prompting. Here, the model is prompted to not only generate a prediction but also explain its reasoning process step-by-step. This can provide a more granular understanding of how the model arrives at its conclusions.

III. Methodology

A. DATASET

The dataset is taken from the kaggle named Disease Prediction Using Machine Learning. This dataset provides valuable insights for applying existing knowledge to disease prediction in the medical field. Dataset is in one-hot encoding format which is extracted from the diseases and their respected symptoms showed in different patients. This resulted in 132 unique symptoms. With 132 parameters, the dataset allows for the development of models that can predict 42 different types of diseases. This has the potential to improve physician efficiency and patient care. The dataset consists of two CSV files, one for training and one for testing machine learning models. Each CSV file contains 133 columns.132 of these columns represent various patient symptoms, while the final column indicates the corresponding disease diagnosis. This structure allows models to learn relationships between symptoms and diseases, enabling the classification of 42 different disease types based on a set of symptoms. There are various disease classes included in the dataset like hepatitis, common cold, pneumonia, Tuberculosis, Aids, Migraine, vertigo, Heart Attack, etc. The symptoms include itching, skin rash, red spots, chest pain, bloody stool, joint pains, chills, high fever,stomach pain, dark urine, fluid overload, etc.



The Views and Downloads of the Dataset on kaggle over time.

Fig. 2. Dataset - Views and Downloads

B. NEURAL NETWORK

In our search for the best model architecture to predict the diseases from the symptoms we have tried different machine learning techniques. In our project we have used the custom neural model using the nn module in PyTorch which provides a set of high-level abstractions for building and training neural networks. The F module in PyTorch stands for the functional module, and it provides a set of functions that perform operations without maintaining internal states. PyTorch tensors are the fundamental building blocks for constructing and training neural networks. These are multi-dimensional arrays similar to NumPy arrays but designed to work efficiently on GPUs, allowing for accelerated computation.

In our study we have created this custom neural model in order to predict the disease from 42 predefined classes using the 132 possible symptoms. This model includes two hidden neurons layers, where the first one is double the size of input neurons and the second one is of 300 neurons. We have tried few different layer configurations also and selected this out of all to enhance it's capacity to learn complex patterns in the data and dropped few neurons to prevent over-fitting. The activation function used in each layer is ReLU and there is a final softmax layer to ensure that the output is a valid probability distribution, where each value represents the probability of belonging to a particular class. We have used manual seed 41

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:32:20 UTC from IEEE Xplore. Restrictions apply.

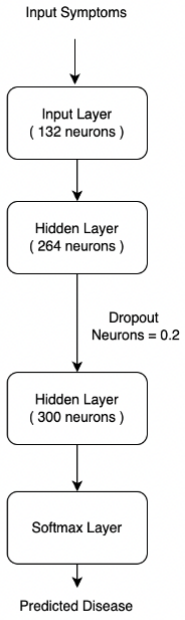


Fig. 3. Flowchart For Custom Neural Network for predicting the disease using symptoms

to ensure result generation is consistent across different runs. In this custom neural network, we have used a cross entropy loss function for multi-class classification. We have used Adam optimizer for our neural network model. Adam is a popular optimization algorithm that adapts the learning rates for each parameter individually. We have trained our custom prediction model up to 100 epochs

C. SHAPLEY VALUES

We have used the SHAP module of python in order to calculate the shapley values associated with the features, which use the game theoretic approach to explain the result of a machine learning model [5].

A set of 500 reference data points were passed to create the kernel explainer object. The explainer object used this subset of training data to estimate how each feature in a new datapoint contributes to the model's prediction. A wrapper was created in order to handle different data type requirements of model and SHAP explainer.

Explainer gives a 2-D vector of size equal to the number of classes to be predicted multiplied by the number of features. In our case it was 41*132. For visualisation we have used the force plot function provided by the shap library itself, which requires the expected values and actual values calculated. Figure (needs to be added) shows one of the generated results.

D. PROMPT DEVELOPMENT

We used an iterative process which is known as prompt engineering [6] in order to create our input to the large language model. During this process, we experimented with several different types of prompts. In each round of prompt engineering, we evaluated the result with BioMistral-7B and ChatGpt-3.5, and selected the most optimum prompt from all. The selected prompt style consisted of 5 parts including context, task, symptoms along with their shapley scores, predicted disease from the custom neural, and line stating the reason explanation from where the explanation would start.

An example is shown below (in figure number 5)

E. REASONING MODEL

In our quest to develop a disease classification system, which can help in providing a better reasoning than the traditional approaches with LLMs, we tried different text generated LLMs available, which can provide reasoning based on the informative prompt we have designed. We first chose the BioMistral language model which is a part of Mistral models family and tailored for the biomedical domain, utilizing the Mistral as its foundation model and further pre-trained on PubMed Central. The model is only available as a research tool and not meant for direct real world application and clinical prediction.

We have used the HuggingFace transformer library to load the BioMistral directly through the pipeline function. Huggingface also has support for loading models directly, which requires to initialise the token and model separately and input needs to be passed through tokenizer in order to generate result from the model. Our pipeline was setted to the text generation task option, so that we can generate the reasoning from the prompt. Prompt and the maximum number of new tokens to be generated were passed for the result generation.

We have also used ChatGpt 3.5 for better result analysis by using prompts we have created along with the Persona Prompting Technique. In this, we have asked Gpt-3.5 to act like a Medical Expert [7] in order to confine its boundary and make it more specific towards Healthcare. Then we have passed the information regarding the input format and their significance into the reasoning so that Gpt can grasp the essence of information in prompt.

We have used two methods to compare the reasoning of BioMistral and GPT-3.5. Method 1 includes the passing of Symptoms along with their shapley values generated from the Shapley explainer and predicted disease given by the custom neural model. The top four symptoms based on the Shapley values were passed for reasoning along with the weights assigned by the Shapley explainer. Method 2 includes the passing of Symptoms with the Predicted Disease by custom neural model.

IV. RESULTS

In our work we have used our custom neural network to predict the disease. The shapley algorithm is used over this model to generate and shapley values for symptoms in each new datapoint. Since the dataset was in one hot encoding, it was easy for neural machines to learn the symptoms - disease relationship and perform the same. The predicted result had a loss of 0.004689. Here is the f1-score results changes for the prediction over 100 epochs.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:32:20 UTC from IEEE Xplore. Restrictions apply.

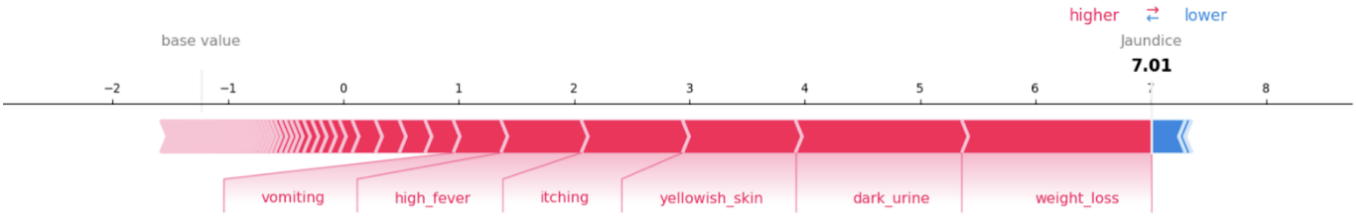

Fig. 4. Shapley Visualization - Example of Visual representation for numeric contribution of each symptoms towards the predicted disease

Context: A disease is predicted based on symptoms and amount of their contribution is represented by scores along with them

Symptoms
1. extra_marital_contacts: 2.6
2. patches_in_throat: 2.49
3. high_fever: 0.94
4. fatigue: 0.22

Predicted Disease: AIDS

Task: Explain the predicted disease in a paragraph considering all symptoms below
Reason Explaination:

Fig. 5. Prompting for Reasoning using LLMs

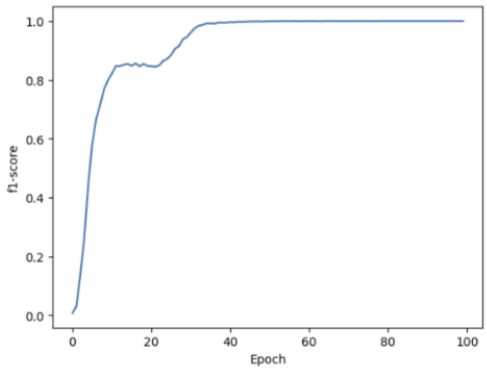

Fig. 6. Change in f1-score over the 100 epochs during training for custom neural prediction

In this study, for the reasoning part we have analyzed the result produced by both the LLM including BioMistral using Hugginface transformer library and ChatGPT-3.5 for Prompt Engineering support.

In the case of BioMistral, the results produced seem to be more satisfactory regarding method 1, which include the Shapley values. Model was able to slightly grab the weightage of symptoms and was able to produce the reason over symptoms having the greater score whereas in case of Method 2, models were mostly mapping the symptoms along with the predicted disease stating that this is the symptoms of predicted disease. Although the overall results were not stable due to the limitation of Model regarding the generation capability and prompt tuning. Due to this the model was not able to generate the complete reasoning including just stating symptoms might be a possible reason.

ChatGpt-3.5 has shown better results over reasoning as it is an advanced LLM with great ability of reasoning generation. We have tried the reasoning generation using both methods. Since the ChatGPT-3.5 is highly developed LLM, it was able to slightly manage without score results too. Using our scoring prompting method, ChatGpt was able to give better weightage to the symptoms that were contributing to the predicted disease. This reasoning includes the identifying specific and non-specific symptoms towards the predicted disease. Giving reason why these symptoms drive the result instead of just mapping the internal cause of symptoms. In this study, we have analyzed a dataset consisting of 50 data samples that were independently reviewed by five different reviewers. The goal was to assess the level of agreement among the reviewers in evaluating the data samples. After careful analysis, we found the agreement score(Fleiss Kappa) among the reviewers to be 50

TABLE I
SURVEY RESULT

Choice	P1	P2	P3	P4	P5	Total
Yes	74%	72%	66%	62%	64%	67.6%
No	26%	28%	34%	38%	36%	32.4%

During our survey, we found an acceptance score of about 70% for our model indicating that most of the reviewers felt positive and confident about this new model of disease detection and explanation.

V. Conclusion

In this research, we pioneered a novel approach to disease detection by leveraging text-based inputs, a shift from the conventional image-based systems. Our emphasis on Explainable AI (XAI) addresses the critical issues of transparency and trust in AI-driven diagnoses, making the decision-making process of the model more understandable and reliable for clinicians and patients alike. By employing a comprehensive and diverse dataset, our model demonstrates real-world applicability across a wide range of health conditions, underscoring its adaptability to complex medical scenarios.

Through meticulous data preprocessing and the implementation of a feed-forward neural network, we achieved commend-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:32:20 UTC from IEEE Xplore. Restrictions apply.

able accuracy in disease prediction. Our study reaffirms that deep learning, particularly when coupled with XAI techniques, offers a promising avenue for enhancing the accuracy and interpretability of disease detection systems. The transition from the inherent opacity of traditional AI to the clarity of XAI transforms the diagnostic process from a 'black box' to a 'white box', offering insights into the model's decision-making process. This not only enhances the credibility of AI-based diagnostic systems but also paves the way for their wider acceptance and integration into mainstream healthcare practices. Our findings highlight the potential of XAI in revolutionizing disease detection, offering a more transparent, trustworthy, and effective alternative to existing AI applications in the medical domain.

VI. Future Work

One promising direction for future research is the integration of multimodal data, such as medical images, patient history, and laboratory test results, along with textual symptom descriptions. Incorporating such diverse data types could provide a more holistic view of the patient's condition, thereby improving the accuracy and reliability of disease classification. Advanced techniques such as multi-modal learning and attention mechanisms can be employed to effectively fuse and utilize these different data sources.

Moving beyond disease classification, future research can focus on developing a more comprehensive AI system that not only identifies diseases based on symptoms but also provides personalized treatment recommendations [8]. The AI systems should not only try to map to symptoms with cause, but should also have knowledge of which symptoms are deriving the result and hold how much weightage. This can be achieved by integrating the AI model with the algorithms which can explain the model results such as lime and shap as we do but in a much more efficient way and use medical knowledge bases, drug databases, and treatment guidelines. By considering individual patient characteristics such as age, gender, medical history, and genetic information, the AI system can generate tailored treatment plans and recommendations. Reinforcement Learning techniques can be employed to continuously learn and adapt the treatment recommendations based on the patient's response and feedback.

Lastly, as AI technologies continue to advance and become increasingly integrated into healthcare systems, it is crucial to address the ethical and regulatory challenges associated with their implementation. Future research should focus on developing robust frameworks and guidelines to ensure the responsible and ethical use of AI in healthcare. This includes addressing issues related to data privacy and security, transparency, interpretability and explainability of AI algorithms, and the potential biases and limitations inherent in AI-based diagnostic systems. Collaborative efforts involving healthcare professionals, ethicists, policymakers, and technologists are essential to establish a comprehensive regulatory framework that promotes the safe, equitable, and effective use of AI in healthcare while maintaining patient trust and confidence in the healthcare system.

Abstract

The outermost layer of a fire proximity suit needs to conform to a strict requirement of radiant protection performance (RPP) ≥ 20s, which is indicative of its ability of offering a protection for at least 20s duration from second degree burn upon radiant heat exposure (84 kW/m^2). Typically, this layer is fabricated by laminating a single-side metallized PET (SMPET) layer with glass fabric. However, upon erosion of the deposited metal, this laminate is rendered unsuitable due to loss of reflectivity. Here, we explore the possibility of replacing the SMPET with its dual-metallized analogue (DMPET) and determine the effect of increasing the optical density (OD) on the adherence and protection level. Metallized films with OD varying from 2.2 to 4.8 were laminated with glass fabrics of twill, satin and plain weave pattern using a silicone adhesive. The peel adhesion strength of laminates prepared using DMPET was found to be higher (1.01 ± 0.03 N/mm), as compared to SMPET (0.63 ± 0.03 N/mm) and the resulting films did not undergo delamination during flexing. Laminates prepared from satin woven glass fabric exhibited lowest flexural rigidity followed by twill and plain woven glass fabric. Protection offered by the laminate from convective heat was quantified in terms of the thermal protective performance (TPP), and the abraded laminate prepared using DMPET (OD-4.8) was found to meet all the mandatory requirements of proximity clothing, offering an RPP of 27 s and a TPP of 62 cal/cm^2 s. In comparison, SMPET laminates exhibited lower level of adhesion and offered an RPP of only 7.5 s.

fire proximity, laminate, reflective layer, thermal stability

1 | INTRODUCTION

Depending upon the fire scenario, fire-fighting operations are primarily categorized into three different categories namely structural, wildland and proximity.[1–4] Amongst these, proximity fire-fighting is a specialized operation which involves activities associated with the highest level of conductive, convective and radiative heat exposure.[5] Fire protective clothing is required to be worn by the fire-fighters to guarantee requisite level of thermal protection to the personnel involved in these operations. A proximity firefighter clothing is assembled out of several layers, each having its own specific role to play as per its placement in the configuration (Figure S1). Since very high level of radiant heat exposure is expected during proximity operations, the outer shell is expected to reflect at least 90% of the radiant heat.[4] This is quantified in terms of radiant protective performance (RPP), where in the layer is initially abraded and subsequently subjected to extremely high levels of radiant heat flux as observed under flash fire conditions (84 kW/m^2). Conventionally, the reflective layer is

 © 2024 John Wiley & Sons Ltd.

prepared by laminating an aluminized polyester film over an underlying fabric.[5,6] Unfortunately, a significant fraction of the topmost metal coating gets eroded during abrasion; therefore, the requisite level of radiant protection is not achieved. In addition, the layer is expected to maintain its integrity by not undergoing any damage in terms of cracking or delamination during flexing cycles, even under wet conditions. This essentially implies that there should be excellent adhesion of the deposited aluminium with the PET film as well as that of the resulting metallized film with the base fabric.

Aluminized fabric laminates have been reported to reflect 80% to 90%[7,8] of radiant heat, which is quantified in terms of percentage reflectance and radiant protection levels. Earlier, aluminium foil was used for preparing aluminized fabric laminates; however, the tear resistance of the foil is rather low.[9] With technological advancements, metallized PET films have become more common, as they offer better mechanical properties at reduced costs. In the wake of these developments, metallized PET has practically replaced aluminium foil not only in the field of food packaging but also in firefighter clothing as well.[10]

Recently, the preparation of reflective aramid fabric laminate with both double- and single-sided aluminized films has been reported by Jin et al.[7] The entire assembly comprising of the developed reflective layer, moisture barrier layer and thermal barrier layer was subjected to a radiative flux of 40 kW/m^2, and the configuration containing dual-metallized films was found to offer high radiant protection ($RHTI_{24}$ > 100s); however, it was not sufficient to meet the criteria mandated in EN 1486 ($RHTI_{24}$ > 120s).[11] Furthermore, the effect of higher radiant flux (84 kW/m^2 as mandated in NFPA 1971) on the protection level offered by the laminate was not studied.[12]

Liu et.al. have reported the use of pigment coating technique for the preparation of aluminized fabric, where aluminium pigment was formulated with intumescent flame-retardant system in thermoplastic polyurethane solution for coating aramid fabric.[8] The commercial aluminized fabric laminate was found to display excellent thermal insulation performance and exposures to heat fluxes (21 kW/m^2) did not result in first or second degree burns even after duration of 30 s.

In our recent study, we employed a single-sided aluminized PET film for the fabrication of a reflective laminate meant for fire proximity operations. However, to achieve the radiant performance requirements, the adhesive was formulated with aluminium powder,[13] which led to reduced flexibility.

We hypothesize that by increasing the optical density (OD) of the metallized PET, it is possible to meet the stringent requirements of radiant protection mandated by NFPA 1971.[12] Furthermore, by replacing the single-metallized PET film with its dual-metallized analogue, it is possible to overcome the damage caused by abrasion. In the present work, we prepare laminates of single- and dual-metallized PET films with glass substrates of different weave patterns. Of particular interest was to explore the effect of increasing the OD of the dual-metallized PET films on various properties of the laminate, like adhesion, protection level against convective and radiative exposures as well as flexibility under both dry and wet conditions, for establishing its candidature as a material as an outer layer of fire proximity suits.

2 | EXPERIMENTAL

2.1 | Materials

Metallized biaxially oriented PET film (single side aluminized and double side aluminized) were obtained from SRF, Indore. Glass fabrics of three different weaves (satin weave, plain weave and twill weave, 390 gsm, thickness ~ 0.41 mm) were obtained from Montex glassfiber industries. A poly(siloxane)-based resin (SE 9152 HT) was procured from Dow and used as a laminating adhesive. Neoprene-coated glass fabric (120 gsm) was obtained from Raksha Polycoat, Needle-punched Oxidized PAN fabric (200 gsm) was obtained from Welspun, and a twill woven fabric (165 gsm, 50:50 FR Viscose- m-aramid fabric) was obtained from Shingora Textiles, Ludhiana for use as an ensemble for TPP testing.

2.2 | Metallization

The metallization of PET was performed on a vacuum metallizer unit (General Vacuum Equipment). In brief, the metal to be deposited (aluminium) was heated to its melting point in a vacuum chamber and subsequently condensed over biaxially oriented polyester films (BOPET, 14 μ). For improving the adhesion, the surface of BOPET was coated with a thin layer of amorphous copolyester. A representative schematic is presented in Figure S2. The stretched film was forced to travel at high speeds over the aluminium evaporators, where it received both the radiated heat and the latent heat from the condensing aluminium. The required OD was achieved by controlling the speed of the moving web. The metallic vapour condenses over the film, as it proceeds to the cooling roll, following which it is rewound and removed as a reel. For preparing dual-side coated films, the operation was performed twice, once on each side. The sample designations of the films are presented in Table 1.

2.3 | Preparation of reflective laminates

A moisture curable poly(siloxane) adhesive was used to laminate the metallized BOPET film with the underlying glass substrate, using a hand layup technique, while maintaining an adhesive thickness of ~0.04–0.08 mm. The laminates were left undisturbed under room temperature conditions for 24 h to ensure complete curing. The designation and grammage of the laminates prepared have been presented in Table S1.

2.3.1 | Characterization technique

Water vapour transmission rate

The water vapour transmission rate (WVTR) of the metallized BOPET films was determined according to procedure B (upright cup method) of ASTM E 96.[14] Circular specimen (6 no's, 5 cm diameter) was cut

TABLE 1 Details of the metallized films and their sample designation.

Sample designation	Metallization	Optical density	Grammage (gsm)	Metal bond strength (kg/25 mm)
SMPET-2.2	Single side	2.2 ± 0.1	17.0	>1.3
DMPET-3.1	Both sides	3.1 ± 0.1	17.0	>1.3
DMPET-4.8	Both sides	4.8 ± 0.4	17.1	>1.3

and placed on aluminium cup (155 mL capacity), filled with 100 mL of distilled water. The cup was clamped to position by covering with a gasket, and the assembly was placed under controlled temperature and humidity conditions (23 ± 1°C, 50 ± 2 % RH). The weight of each cup was recorded at regular intervals, and the WVTR (gh/m^2) was quantified as follows:

$$\mathrm{WVTR} = \frac{G}{t \times A} \quad (1)$$

where G refers to mass change (g), t being the time associated with the mass loss (h), and A refers to the test area (m^2). The data have been reported in g/24 h/m^2 along with the standard deviation.

Fourier transform infrared spectroscopy (FTIR)

The structural characterization of poly(siloxane) was performed using Thermoscientific FTIR (NICOLET 8700) analyser with an attenuated total reflectance (ATR) crystal accessory in the wavelength range 400–4000 cm^{-1}.

Thermo-gravimetric analysis

The thermal decomposition behaviour was analysed using Perkin Elmer Diamond STG-DTA over the temperature range 50–600°C.

Contact angle studies

The contact angle and surface free energy of the metallized BOPET sample were determined using a Drop Shape Analyser (DSA100E) from KRÜSS Scientific. For contact angle measurements, distilled water was used as the probing liquid, and for surface energy measurements, contact angle measurements were performed with two probing liquids (water and N, N-DMF).

Waterproofness

The degree of waterproofness offered by the metallized film was quantified using Hydrostatic Head Tester as per ISO 811. In brief, one of the face of the specimen was subjected to a steadily increasing hydrostatic pressure (10 mbar/min) till penetration was observed at three different sites on the opposite face.

2.3.2 | Characterization of laminate

Dimensional stability

In view of the targeted application of the laminate, the dimensional stability of the fabric in terms of resistance to thermal shrinkage was determined as per ASTM F2894[15] at a temperature of 260°C. For this purpose, a sample of standard dimensions (381 × 381 mm^2) was suspended through a metal hook at a temperature of 260 ± 3°C for 5 min and examined for evidence of ignition, melting, dripping or separation and resultant dimensional change was recorded.

Physical properties of fabrics

The stiffness of fabric was determined as per ASTM D1388[16] using a Shirley stiffness tester (Figure S3). Prior to the tests, the samples were preconditioned at 25°C and 65% relative humidity (RH) for 24 h. Five replicates were tested in both warp and weft directions. The bending rigidity was calculated as follows:

$$G = W \times c^3 \quad (2)$$

where G is the fabric's bending rigidity (mg cm), W is the weight per unit area (mg/cm^2), and the bending length c is half the length of the overhang (L, cm). The overall bending rigidity was determined as follows:

$$G_0 = \sqrt{G_w \times G_f} \quad (3)$$

where G_o is the fabric's overall bending rigidity (mg cm), and G_w and G_f refer to the bending rigidity (mg cm) in the warp and weft directions, respectively.

Dynamic mechanical properties

The dynamic mechanical analysis (DMA) was conducted on rectangular samples (10 × 4 × 0.8 mm^3) at a fixed frequency of 1 Hz, temperature range of 20–180°C at a heating rate of 10°C/min and in strain sweep mode using a dynamic mechanical analyzer (Netzsch, Artemis-242E) and tensile fixture.

Rheology

Anton Paar Rheometer MCR-102 has been used to study the rheology associated with the curing of the siloxane resin. All the experiments were performed using a parallel plate accessory (diameter: 25 mm) with a gap of thickness 0.5 mm. Temperature-sweep experiments were performed in oscillatory mode over the temperature range 30–200°C at 5°C/min. A constant strain of 0.5% and constant angular frequency of 10 rad/s was maintained during each interval.

Peel adhesion strength

The peel adhesion strength (N/mm) was established as per ASTM D1876[17] as both the substrates were flexible. For this purpose,

10991018, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/fam.3229 by Delhi Technological University, Wiley Online Library on [08/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

laminates (317 mm × 25 mm) were cut, where 241mm of the region was kept bonded, with the remaining 76 mm being non-bonded. The non-bonded region was fixed within the grips of a tensile testing equipment and subjected to a strain rate of 10 mm/min. The peel adhesion strength (N/mm) was determined over at least a length of 200 mm of the bond line after the initial peak was observed. A total of six replicates were tested, and the average of the adhesion strength values with standard deviation has been reported.

Wet flex test

For this purpose, the samples were cut into 20 cm × 10 cm rectangular-shaped specimens in warp direction, which were then placed in a beaker (1000 mL) at 60 ± 2.8°C for 15 min. Blotted dry samples were flexed at a rate of 45 cycles per minute, using a motion that repeatedly twists the film. The samples were subjected to 1000 full flex cycles on the Flex Tester in accordance with standard test method as per NFPA 1971.[12]

Vertical flammability tests

Vertical flame resistance test was conducted on a flammability tester (Prolific Engineers, India), as per ASTM D6413-99.[18] In brief, the sample of requisite dimensions (5 cm × 25 cm) was exposed to a propane flame of 36 mm height for a period of 12 s and the flame time (time for which the material continues to burn after flame removal), after glow time (time associated with the material glow post-flame extinguishment) and char length (length of the area damaged) were recorded.

Heat resistance and thermal shrinkage

The dimensional stability of the laminate in terms of resistance to heat and thermal shrinkage was determined as per ASTM F2894[15] at a temperature of 260°C. For this purpose, sample of standard dimensions (381 × 381 mm^2) was suspended by a metal hook in an oven maintained at the mentioned temperature for 5 min and examined for evidence of ignition, melting, dripping or separation and resultant dimensional change.

Scanning electron microscopy (SEM)

ZEISS EVO 50 series instrument, operating at 10 kV acceleration voltage, was used to study the char observed in the reflective layer after the testing of thermal protective performance (TPP). In addition, the satin weave pattern of the glass fabric utilized in the present study was analysed. Aluminization on both sides of the aluminized polyester film was confirmed by EDAX mapping. For the investigation, the specimens were mounted on the aluminium sample stub using double sided carbon tape and were subjected to gold coating prior to the analysis.

Heat transmission on exposure to radiant heat

For this study, a bench-top RPP tester was used, which utilizes a bank of 9 quartz lamps to deliver a total radiant heat flux of 84 kW/m^2 (as specified in NFPA 1971)[12] on the reflective surface of the developed laminates. A schematic of the experimental setup used is shown in Figure S3. Specimens (3 inches × 10 inches) were cut and abraded using an oscillatory cylindrical abrasion tester. In brief, the specimens were mounted on the oscillating drum of the apparatus, where a hard textured cotton duck abradant was employed to impart 300 cycles of abrasion under a load of 1.36 kg (3 lb). The abraded samples were then placed in the sample holder of the RPP tester, which was positioned in front of the quartz tubes and blocked by a shutter. A copper calorimeter was placed behind the sample for recording the temperature rise as a function of time.

Heat transmission on exposure to flame

For these studies, the developed reflective laminate, vapour barrier (neoprene-coated glass fabric), a thermal barrier based on spun lace OPAN followed by an inner liner (50:50 FR Viscose- m-aramid fabric), with dimensions 6 inches × 6 inches was assembled and subjected to a predetermined heat flux as per ASTM D 4108.[19] The flow rates of propane and air were adjusted to generate a heat flux of 84 kW/m^2, and a copper calorimeter was placed at the back of the multilayer component assembly. The temperature rise as a function of time was plotted alongside the Stoll curve (second degree), to arrive at the time associated with second degree burn which in turn was used to determine the TPP as the product of the incident heat flux with the intersect time recorded.

3 | RESULTS AND DISCUSSION

The present work aims at improving the performance of the reflective outermost layer of fire proximity clothing by replacing the single-metallized BOPET-glass laminate with its dual-metallized analogue. The effect of increasing the OD of the MPET film on the radiant protection level has also been studied.

3.1 | Metallized BOPET

Metal-PET adhesion is an extremely important parameter for the present application as the layer needs to maintain its reflectivity and integrity even under extreme conditions, especially high temperatures and high radiant flux. It is to be noted that the adhesion of metal with the substrate is governed by several factors, particularly the nature of the surface and its interaction with the incoming metal vapours. The adhesion of metal with PET can be improved by either introducing functionalities on the underlying substrate, commonly known as chemical bonding, or by increasing the mechanical interlocking between the two. In the present work, PET was first coated with an amorphous aliphatic copolyester to increase the degree of mechanical interlocking.[20] By varying the coating thickness, which was in turn controlled by altering the speed of the PET film over the evaporator unit, different optical densities could be obtained. Characteristic physical properties of the metallized BOPET films are presented in Table 2.

In line with previous studies, the metallized films exhibited excellent resistance to the transfer of water vapour, which reflected in

terms of extremely low WVTR values. Additionally, the films also possess high degree of waterproofness, due to which they find application in food packaging.[21] As expected, dual metallization led to a significant increase in OD, which is indicative of the light blocking ability of the film.

In the past, extensive studies have been performed on the Al-PET interface to understand the underlying pathway behind the metallization process. Most of these studies are based on X-ray photo-electron spectroscopy (XPS) which are aimed towards identification of the chemical bonds at the interface.[22–24] A general schematic of the metallization process is presented in Figure 1. The chemical structure of the PET has also been included in the figure for the ease of visualization. It can be seen that the repeat unit has 10 C, 4 O and 8 H atoms, which have been labelled in the figure to distinguish between the different sites (Figure 1A). The chemical species identified through XPS and a simplistic model of Al-PET surface is also included in the Figure 1C. As the Al atoms strike the polymer surface, they tend to lose their energy, thereby penetrating into the amorphous regions of the polymer resulting in 'Mechanical locking'. In addition, chelation occurs between the surface functionalities and the metal, a phenomenon referred to as 'Chemical locking' (Figure 1B). It is the interplay of both these phenomenon, which define the overall adhesion levels observed in the metallized film. XPS studies suggest that the incoming Al interacts with the C=O and C–O groups on the PET surface to form an oxy–carbide complex, Al–O–C, in which the Al is bonded to both C and O (Figure 1C).[25] Al has been reported to form bonds with three fourths of the C=O groups and to half of the C–O groups

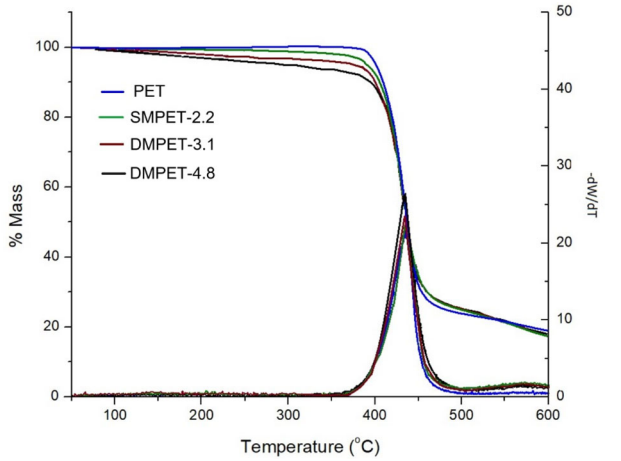

FIGURE 3 TG-DTG trace of PET and metallized PET.

present on the surface. Carbide-like bonds (Al–C) have also been observed in the interface, the presence of which has been attributed to the reaction of Al with the surface phenyl moieties, resulting in the loss of their aromaticity and thus in the disappearance of the C(1s) $\prod$–$\prod^*$ transition peak.[23] However, it is to be noted that there is still ambiguity in this structure, as the valency of the Al remains uncertain, and further studies are required for proper elucidation. A simplistic model of the Al-PET interface as suggested by Sandrin et.al[24] is also included in Figure 2D. The metal atoms continue to grow layer by layer into a continuous film, initially following the Frank-van der Merwe growth mode.[26] However, after formation of a few monolayers the growth pattern shifts to a mixed mode (Stranski-Krastonov).[27] Detailed studies have revealed that the increased mechanical penetration of the metal into the amorphous copolyester is the primary reason behind the high adhesion levels in the coated film as the chemical nature of the copolyester and PET is rather similar. According to TEM analysis of metallized chemically coated PET film, the depth of penetration is ~50–60Å in comparison with ~30–40Å for uncoated film.[23,28]

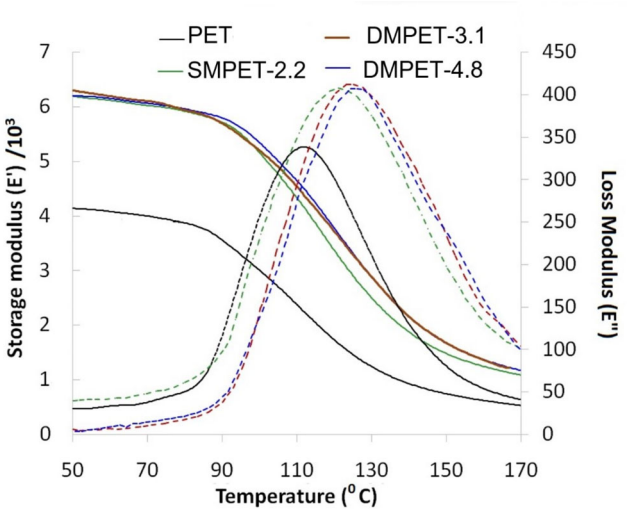

FIGURE 4 Variation of storage modulus (solid lines) and loss modulus (dashed lines) with temperature.

3.2 | Thermal properties

The DSC traces associated with PET and MPET are presented in Figure 2. Neat PET exhibits a glass transition temperature of ~80°C, followed by crystallization at ~136°C, and final melting at ~254°C. Metallization was not found to affect these properties appreciably, which remained within a range of ±1°C.

The TG-DTG traces of PET, single- and dual-metallized PET of different optical densities are presented in Figure 3. A single-step decomposition was evidenced in all the traces. It is interesting to note a slightly larger mass loss in the initial periods of heating in the metallized films, which is reflected in terms of lower T5% (Table S1). However, the temperature associated with the subsequent major mass loss step (T_{max}) remained unaffected. The mass loss in the initial stages can be attributed to the presence of the amorphous copolyester with which the PET film is coated in order to improve its adhesion level with the metal. The copolyester being amorphous permits the mechanical penetration of the incoming aluminium into the film (mechanical locking), thereby increasing the adhesion levels. The copolyester exhibits relatively lower thermal stability than the underlying PET and therefore accounts for the higher mass loss in the coated samples. Furthermore, the coating had to be performed on single and both sides of the film for preparing SMPET and DMPET, respectively, which accounts for the lower T5% in the dual-metallized films.

3.3 | Dynamic mechanical properties

Variation of characteristic properties namely storage modulus and loss modulus of BOPET as well as MPET films due to increasing temperature is presented in Figure 4. As expected, the storage modulus 'E' decreases with temperature due to softening of the polymer, which is particularly pronounced in the region ~90–150°C, where the glass transition phenomenon was evident. This region is also associated

10991018, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/fam.3229 by Delhi Technological University, Wiley Online Library on [08/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

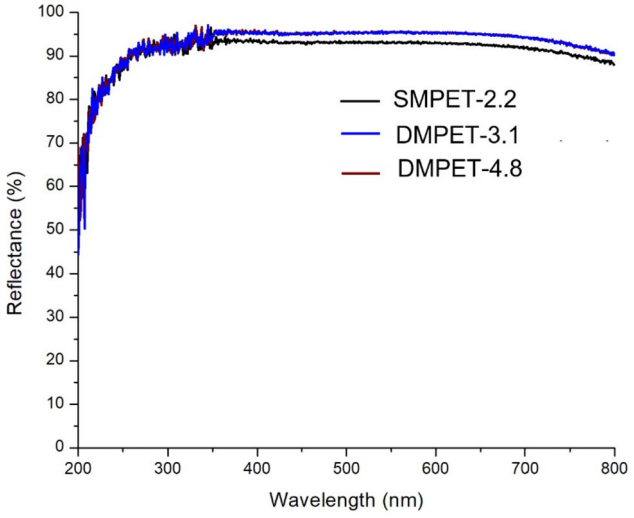

FIGURE 5 Reflectance of metallized film as a function of wavelength.

with a characteristic peak in the loss modulus trace. In line with previous studies, the storage modulus of MPET is relatively higher than the neat films.[28] This can be attributed to the deposition of the metal on the polymer, which restricts the free motion of main chain in various directions, resulting in higher stiffness. In addition, metallization brings a slight shift in the temperature associated with the glass transition phenomenon. The T_g as determined from the peak of the tan δ trace was found to be 124°C for neat BOPET film, which increased to ~138°C for MPET (single metallized), 139°C for MPET (low-OD dual metallized) and 140°C for high-OD dual-metallized films.

3.4 | Reflectivity

The reflectance spectra of both types of MPET over the wavelength region 200–800 nm are presented in Figure 5. It can be seen that the reflectance exceeded 95% over this entire region and as expected the dual-metallized PET films exhibited higher reflectance as compared to the single-metallized films. In comparison, previous studies reveal that coloured textiles are capable of reflecting only ~10% of the radiation.[4] In this direction, Quintiere et al.[29] studied a variety of textile samples for thermal protection from fires, including cotton, nylon and aromatic polyamides of different colour (white, yellow, black and silver). It was noted that the colour of the textile samples had an insignificant influence on reducing the radiative heat load, and more interestingly, the influence of colour was negated post-wetting. Subsequent studies have revealed that construction of aluminized fabrics via pigment coating method are highly effective in reducing the radiative heat load on the textile sample, and this has been attributed to the increase in spectral reflectance due to aluminium coating.[30] Furthermore, studies have also been performed on aluminium foil laminated basalt and glass fabrics. Due to the differences in the yarn parameters and weave structures, their spectral reflectance was found to differ significantly.[31] As expected, the TPP of aluminized fabrics was found to be better than those of the substrate fabrics.

3.5 | Contact angle measurements

The contact angle and the surface energy of the metallized and non-metallized face of the film are presented in Figure S5. Due to the polar nature of the glass fabric substrate, it was not possible to determine the contact angle as they completely absorbed the water and DMF droplets. The contact angle associated with the non-metallized face of the single-metallized PET film was 79 ± 0.11°. Post metallization, a decrease in the contact angle was observed, with both the faces of the dual-metallized film exhibiting contact angles of the same order (57 ± 0.11°) with a surface energy of 43 ± 0.82°, indicative of the relatively higher hydrophilicity of the film.

3.6 | Rheology

For all practical applications, the adhesive resin is coated on the fabric, prior to lamination with the MPET film. For obtaining a uniform coating, the viscosity of the formulation should be in the range of ~2–4 Pa.s, and additionally, sufficient time also must be ensured (15–20 min) for curing.[32] Therefore, it is essential to study the rheological changes to establish a suitable 'processing window'. During any polymerization reaction such as the curing of poly(siloxane) at a given temperature, the storage and loss moduli evolve over time, providing useful information about the polymerization kinetics and the viscosity of the system.[33] The follow-up of their evolution as a function of time is referred to as rheo-kinetics. Figure 6 shows the evolution of storage and loss moduli as a function of time at different temperatures (30–60°C), which was used to arrive at the activation energy associated with curing. During the initial stages, the poly(siloxane) resin is a liquid with viscosity ~10.7 Pa.s and storage modulus ~25Pa. Due to moisture curing, an increase in viscosity and storage modulus was observed. The time associated with the crossover of storage and loss modulus is referred to as the 'gel time', which basically gives an indication of the time available for processing.[31]

The variation of gelation time with temperature was used to arrive at the activation energy associated with the curing process. The variation of t_{gel} as a function of absolute temperature and the derived activation energy is presented in Figure S6. The activation energy was determined to be 43.53 kJ/mol, which appears to be suitable for commercially viable adhesive formulations.[34]

3.7 | Laminate of glass fabric with dual-metallized PET

Previously, different adhesives have been explored for lamination, for example, fluorinated elastomers, polyurethane adhesives and rubber-based adhesives. Silicone-based elastomers exhibit high

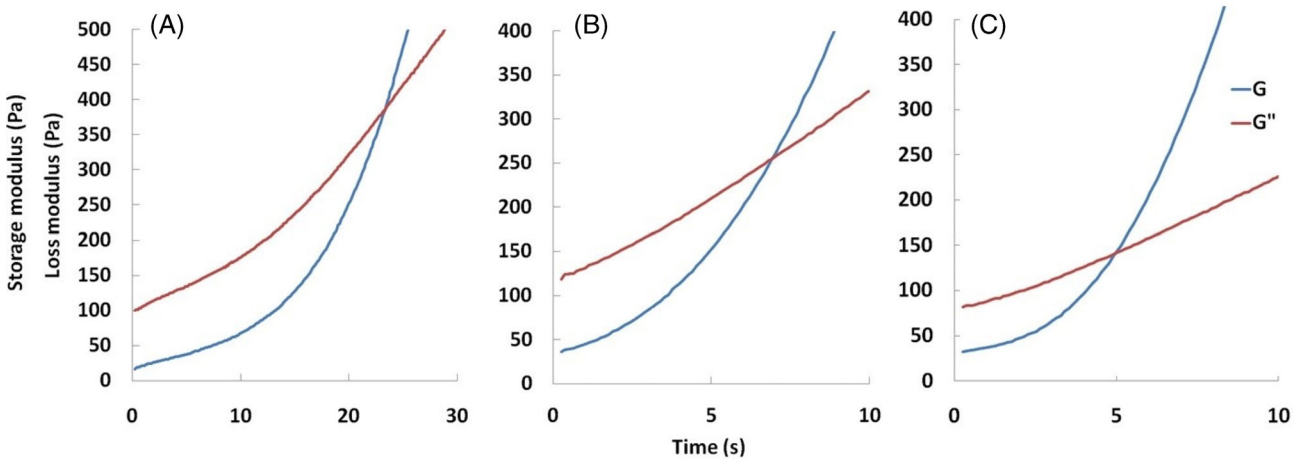

FIGURE 6 Evolution of storage and loss moduli as a function of time at different temperatures (A) 30°C, (B) 45°C and (C) 60°C.

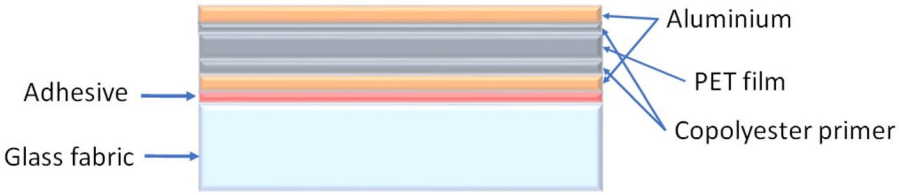

FIGURE 7 A schematic illustration of the laminate components.

thermal stability and high flexibility[35]; therefore, the same was chosen as the adhesive for the said laminate. In our previous work, we have reported an epoxy-based adhesive to laminate a single-side metallized PET (SMPET) with glass fabric. The laminate met all the requirements; however, it was relatively inflexible in view of the nature of the epoxy-based adhesive used for lamination purposes.[13] To address this issue, a poly(siloxane) resin has been employed in the present work. The moisture curable resin contains alkoxy or acetoxy groups, which undergoes hydrolysis in the presence of the atmospheric water vapour, thereby forming silanol (Si–OH) functionalities. These in turn undergo condensation to form a cross linked network, thereby releasing water molecules, as depicted in a representative reaction in Figure S7.

The DSC curve of the cured resin is presented in Figure S8. A glass transition temperature of −49°C was observed, which is responsible for its flexible nature.[36] The poly(siloxane) films exhibited the requisite level of flame retardancy as confirmed through vertical flammability tests. The FTIR of the cured poly(siloxane) is presented in Figure S9. Characteristic absorption peaks were evidenced in the region 1000–1130 cm^{-1}, which can be attributed to Si-O-Si stretching. Absorption peaks associated with $(CH_3)_2SiO$ groups were evidenced at 802 and 1258 cm^{-1}. The peaks at 2962 $cm^{-1}$are associated with methyl CH_3 stretching.[33]

Both types of MPET films were laminated with the glass fabrics using hand layup technique and all the laminates were found to exhibit a grammage of 490 ± 5 gsm, with a thickness 0.4 mm ± 0.05. The final configuration of the laminate prepared using dual-metallized PET is presented in Figure 7.

3.8 | Stiffness

In view of the final targeted application in the field of clothing, it is important to be cognizant about the flexibility of the laminate, which has been quantified in terms of the bending rigidity in both warp and weft directions. The bending length in both the directions and the overall flexural rigidity is presented in Table 3. The thermal shrinkage in all the laminates was found to be <1% at 260°C. In line with previous studies, the order of bending rigidity of the laminates prepared using woven fabrics followed the order satin < twill < plain.[36] Our studies indicate that of the three weave patterns, laminates prepared using satin fabrics are the most flexible and exhibit excellent potential to be used as outer layer of fire proximity clothing.

3.9 | Adhesion strength of laminates

In view of the flexible nature of both the substrates, the peel adhesion strength was determined as per ASTM D1876. The load-displacement plots associated with the peel test performed on representative laminates are presented as Figure 8. It can be observed that peel adhesion strength for the laminates prepared using dual-metallized PET films (irrespective of the OD) was found to be relatively higher (1.01 ± 0.03 N/mm), than that of single-metallized PET (0.63 ± 0.03 N/mm). This can be attributed to the stronger interaction of the poly(siloxane) adhesive with aluminium as compared to that with the polyester film. All the specimens fabricated displayed uniform peeling during the test. A photograph depicting the same is also included in the figure.

3.10 | Flexing under wet conditions

Fire proximity suits are prone to folding and puncturing; therefore, it is important to understand the effect of flexing on the properties of the laminate.[37] Amongst the several methods that have been used to simulate the mechanical stresses that laminates encounter during usage, the most widely used is Flex Testing, which is designed to evaluate the performance of laminates upon being subjected to reproducible mechanical stresses. The advantage of this stress simulation test is to reduce the cost and time associated with practical field tests. Flexing leads to the initiation of pinholes and stress cracks that could subsequently lead to a loss in barrier properties.[10] As observed during the T-peel tests, the laminates prepared using single-sided metallized PET films underwent significantly more damage during the wet flexing test as well. The photographs of the laminate prepared using both single- and dual-metallized PET after wet flex test is presented in Figure S10. It can be seen that the extent of damage was even more pronounced than in the dry state. The laminates prepared using single-sided metallized PET underwent delamination after ~500 cycles of flexing, while the dual-metallized PET layer adhered strongly after 1000 cycles even under wet conditions.

3.11 | Vertical flammability

One of the most important requirement of any material to find utility in fire protective clothing is its fire retardancy, which was established through vertical flammability testing. A photograph of a

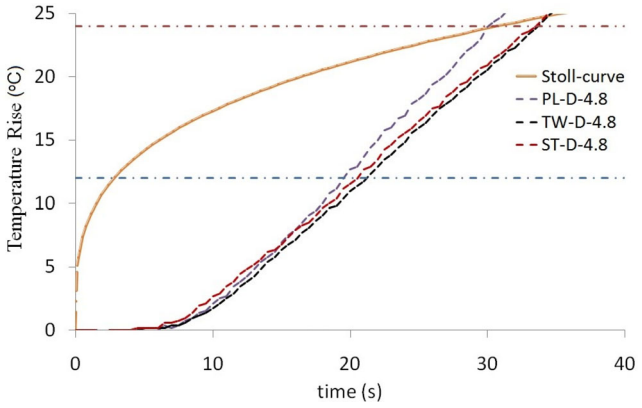

FIGURE 12 Response of ensemble in terms of temperature rise upon exposure to heat flux.

representative laminate post-testing is presented in Figure S11. It is to be noted that the MPET film when subjected to a vertical flame was totally engulfed in fire. However, post lamination, the laminates do not exhibit any after-flame or afterglow and there is no reportable char length. As per EN 1486,[11] for the outermost layer of the fire proximity clothing, the after-flame, after-glow and the char length requirement is ≤2.0 s, ≤2.0 s and ≤10 cm, respectively. In addition, melting or dripping of the sample is also not acceptable. Our studies reveal that all the laminates prepared meet the standard requirements.

3.12 | Radiant protection

The radiant protection is undoubtedly the most important criteria to be met by the laminate for possible use in the context of fire proximity clothing. For all practical purposes, the laminate needs to retain its reflectivity even after being subjected to a fixed number of abrasion cycles as mentioned in the standard. However, in the case of single side metallized film, this wearing process leads to a significant loss of the coating, which allows the radiative heat flux to be transferred. The effect of abrasion on these films was captured through digital imaging, the results of which are presented in Figure S12. It can be seen that significant erosion occurs in single-metallized films, which could be reduced substantially by dual metallization.

The effect of dual side metallization and increasing OD on the performance of the laminate upon exposure to fixed radiative heat flux (84 ± 2 kW/m^2) in terms of temperature rise as a function of increasing time duration is presented in Figure 9. It can be seen that the satin glass fabric is a rather poor shield against radiative heat, and it intersects the Stoll curve at 2.5 s. When laminated with a single-metallized PET film, the radiant performance of abraded film improved

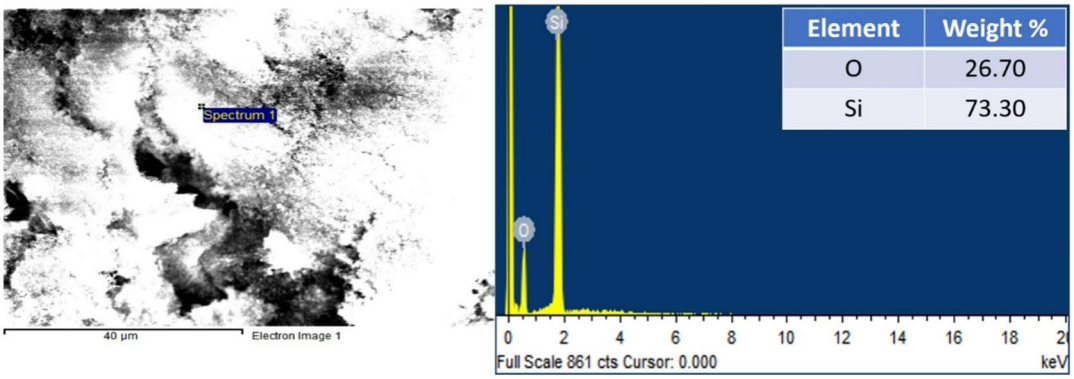

FIGURE 13 Elemental composition of the char formed as a result of convective exposure.

to 7.5 s; however, the requirement is not met. With dual metallization, the time to second degree burn increases further (t_{2nd} = 11 s), but only films with OD 4.8 were able to meet the requirements mandated by the standard (t_{2nd} > 20s).

3.13 | Effect of weave pattern on radiative exposure

Post confirming the ability of the high OD dual-metallized PET-glass laminate in meeting the standard requirements, it was considered prudent to investigate the effect of the weave pattern of the underlying substrate on the level of radiant protection offered. Previous studies have revealed that the surface roughness of the base fabric plays a crucial role in defining the level of protection offered against radiant heat. In this context, amongst the different aramid fabric structures studied, laminated non-woven fabrics were found to exhibit the highest RPP; however, they were unable to meet the requirement of mechanical strength mandated in the standards.[7] We hypothesized that smoother surfaces of satin and twill woven glass fabrics should offer higher level of radiant protection and the results of our studies are presented in Figure 10. Interestingly, both twill and satin woven fabrics were found to offer slightly higher protection against radiant heat flux as compared to plain weave configuration. Similar results have been previously obtained by Talukdar et al.[38]

It is to be noted that no visual damage was observed after 30 s of exposure in any of the laminate; however, the damage was evident in the SEM images (Figure 11). The SEM image clearly revealed the smooth surface of the laminated satin fabric.

3.14 | Thermal protective performance (TPP)

The TPP rating gives a quantitative estimate of the protection offered to the wearer upon exposure to heat flux.[39] The test was performed on the entire assembly of layers, which are used to fabricate the proximity suit. The photograph of the layers post-TPP testing is presented in Figure S13. Although the metallized PET reflective was completely destroyed due to exposure to convective heat, the underlying glass substrate remained intact, and so were the underlying substrate. It is interesting to note that upon exposure to radiant heat of similar heat flux for the same duration, the dual-metallized layer does not undergo any kind of damage which is visible to the naked eye; however, convective exposure leads to its complete destruction. It can be concluded that the role of the thermal barrier layer is more important in this type of exposure. The response in terms of temperature rise as a function of time is presented in Figure 12. It can be seen that irrespective of the weave pattern, all the ensembles exhibited tolerance time to second degree burn > 17.5 s (TPP = 35 cal/cm^2 s), which is a requirement of EN 1486. As observed in the case of radiant exposure, the laminate based on twill and satin woven fabric offer higher protection (tolerance time = 31 s, TPP= 62 cal/cm^2 s) as compared to plain woven fabric (tolerance time = 29 s, TPP = 58 cal/cm^2 s).

The SEM image and EDAX analysis of the char formed due to convective exposure is presented in Figure 13. As expected, the char formed comprised primarily of silicon and oxygen. The fluffy nature of the char could be considered responsible for preventing the transfer of heat to the underlying layers. Since laminate fabric prepared using satin fabric was observed to be more flexible than the twill and plain woven analogues, the former is considered to be the most suitable for application as the outermost layer in fire proximity suit.

4 | CONCLUSIONS

In the present work, the effect of dual side metallization and increasing OD of metallized PET films on its performance as the outermost reflective layer of fire proximity clothing was established. For any laminate to qualify the requirements of the outermost layer of fire proximity clothing, it should exhibit high level of reflectance as well as high degree of adhesive strength in addition to being flexible in both dry and wet conditions. Our studies reveal that a substantial fraction of the metal coating erodes during the abrasion cycle, which renders the laminate prepared using SMPET unsuitable for application as proximity outer layer. The abraded single-sided PET laminated on glass fabric (OD 2.1) is able to grant a

radiant protection from second degree burns for a period of ~7.5 s ($t_{2nd\ degree}$) upon exposure to radiant heat flux of 84 kW/m^2. In the dual-metallized analogue (OD 3.1), the metal coating present on the opposite face is able to effectively block the transfer of radiant heat, thereby increasing the protection level to ~11 s ($t_{2nd\ degree}$). By increasing the OD further to 4.8, the protection level could be increased to ~27 s, which is sufficient to meet the standard requirements. Furthermore, laminates prepared using single-sided metallized PET underwent delamination during the wet flexing tests and therefore were not suitable for fire proximity clothing applications. The weave pattern of underlying glass fabric was found to have a pronounced effect on the flexibility as confirmed by stiffness testing. Satin woven substrate was found to exhibit the lowest flexural rigidity followed by twill and plain weave substrates. Our studies lead us to conclude that for all practical purposes, dual-metallized PET film of high OD (4.8) laminated with both satin and twill woven glass fabric is the most suitable candidate for fire proximity clothing applications.

ACKNOWLEDGEMENTS

Abstract. The wear behavior of Al6351-Gr composites reinforced with B_4C, WC, and TiC were investigated in this study. Wear resistance is a critical factor in determining the functionality and durability of materials in different industrial relevance. Hybrid composites were created using a liquid metallurgy technique. The samples were subjected to wear tests using a pin-on-disk apparatus under controlled experimental conditions. Wear performance, friction coefficient, and wear processes were evaluated and compared between the composite materials. According to the result, the addition of B4C, TiC, and WC to the Al6351-Gr composite significantly improved its wear resistance. The examination of the worn surfaces through scanning electron microscopy (SEM) unveiled a diverse range of wear mechanisms, encompassing both adhesive wear and abrasive wear. The reinforced composite samples exhibited reduced wear severity and extent compared to the unreinforced material, confirming the improvement in their wear resistance.

INTRODUCTION

Composite materials are specifically designed materials comprising two or more constituent substances possessing distinct physical or chemical characteristics. These materials are designed to take advantage of the unique properties of each constituent material to achieve specific performance characteristics that cannot be obtained with any single material alone. The constituent materials of composites are typically classified as either matrix materials or reinforcement materials.

In composite materials, the matrix material acts as a continuous phase, enveloping and providing support to the reinforcement material, which, in turn, imparts strength and rigidity to the composite structure. The reinforcement material can manifest in various forms, such as fibers, particles, or flakes.

Composite materials possess the advantageous characteristic of combining multiple desirable properties, including but not limited to exceptional strength, lightweight nature, resistance to corrosion, and thermal stability. As a result, they find extensive utilization across various industries, such as aerospace, automotive, construction, and sporting goods, due to their versatility and broad range of applications.

Silicon carbide is an effective ceramic material that enhances the wear properties of hybrid MMC. When combined with Graphite, which possesses excellent self-lubricating properties, the addition of Graphite, along with other ceramics, further enhances the wear characteristics of the hybrid MMC. Moreover, the inclusion of Silicon carbide helps maintain the desired hardness properties of the hybrid MMC [1][2][3].

Bhowmik et al. conducted a study on the wear properties of Al7075 by incorporating various proportions of SiC through the stir-casting process. During the stirring process, XRD analysis revealed the presence of silicon carbide particles well dispersed within the aluminum matrix. The wear rate was observed to increase, while the coefficient of friction (COF) decreased with higher sliding speeds, primarily due to intense friction between the pin and disc. Examination of the worn surface of the pin indicated that the Al7075 reinforced with 9% SiC composite exhibited the least material removal [4]. Furthermore, it should be noted that not only the presence of SiC but also its particle size, significantly influences the wear characteristics[5]. Other studies focusing on SiC reinforcement have also demonstrated promising improvements in wear properties in aluminum alloys[6].

Naseem et al. conducted a study on the wear properties of Al6351 by incorporating a combination of Al_2O_3 and Carbon. The worn surface was analyzed using a scanning electron microscope, which revealed that the pure Al matrix exhibited deep grooves, higher debris accumulation, and a rough surface compared to the composites with a

higher percentage of reinforcement. Interestingly, as the percentage of reinforcements increased, the wear rate of the hybrid composite decreased [7]. Adding SiC or TiO_2along with Al_2O_3 and graphite shows further enhancement in wear attributes of hybrid MMCs[8][9], [10][11].

Mohanavel et al. developed a composite by incorporating varying proportions of Si_3N_4 into Al6351 and investigated its wear characteristics. The inclusion of Si_3N_4 particles had a significant impact on the hardness of the original material, leading to a reduction in the material's wear rate. Furthermore, the strong bond between the Al6351 matrix and the Si_3N_4 ceramic reinforcement particles prevented the detachment of Si_3N_4 material during sliding. Consequently, the Al6351 composite reinforced with 3 wt.% Si_3N_4 exhibited the lowest wear rate compared to the unmodified alloy [12]. The inclusion of TiB_2 and ZrB_2 in aluminum-based alloys significantly enhances both the wear resistance and mechanical properties of the alloys. [13][14].

Numerous research studies have examined the wear characteristics of composites reinforced with graphene nanoplatelets (GNPs). These investigations have consistently shown that the inclusion of GNPs significantly enhances the wear endurance of the composites. This improvement can be attributed to the exceptional properties of graphene, including its high strength and low friction [15][16][17].

Rice husk ash and eggshells, which are considered waste materials, are commonly employed to improve the mechanical properties and wear characteristics of aluminum-based hybrid composites. The addition of these reinforcements not only yields beneficial results but also provides the advantage of cost-effectiveness [18][19].

This study aims to explore the effects of incorporating B_4C, TiC, and WC as reinforcements in an Al6351-Gr composite on its wear characteristics. While previous studies predominantly focused on investigating high proportions of reinforcement, this study specifically aims to explore the effects of a lower proportion of reinforcement.

RESEARCH OBJECTIVES

The primary goal of this research is to stir cast Al6351&Graphite composite reinforced with B4C, TiC, and WC. The specific goal of this research is:

1. To assess the wear functionality of the prepared hybrid MMC using a pin-on-disk wear testing machine.
2. To analyze the microphotograph of worn surfaces.
3. To propose potential applications for hybrid composite alloy matrix hybrid composites based on their performance characteristics.

06 August 2024 04:50:07

MATERIALS AND METHODS

Materials

To fabricate a hybrid metal matrix, aluminum ingots with a were utilized as the matrix metal. Graphite, B_4C, TiC, and WCwere used as reinforcement materials. Graphite is a lightweight and strong structure material with excellent thermal conductivity[20].

B_4C is a low-density ceramic with exceptional hardness and high wear resistance. Its high hardness makes it effective in reducing abrasive wear by acting as a protective barrier against contacting surfaces. B_4C has a low coefficient of friction, which can help reduce frictional wear between surfaces. It can form a self-lubricating film during wear, reducing the tendency for adhesive wear.

TiC is a ceramic material known for its exceptional hardness, strength, and resistance to wear. It provides high wear resistance due to its hardness, effectively reducing abrasive wear. TiC has a high melting point, making it suitable for applications involving high temperatures or frictional heat generation. It can improve the load-bearing capacity and endurance of composites by reinforcing the metal matrix.

WC is a hard compound composed of tungsten and carbon atoms, known for its extreme hardness and wear resistance. It possesses excellent resistance to abrasive wear, making it suitable for applications involving harsh conditions. WC particles can reinforce the composite matrix, improving its strength, toughness, and wear resistance.

Table 1 displays the physical properties of Graphite, B4C, WC, and TiC.

TABLE 1. Physical Characteristics of Reinforcement

Reinforcement	Weight density(gram/cc)	Particle size (micron)	Color

Graphite (Gr)	1.35	40-80	Gray black
Boron Carbide (B4C)	2.52	80-120	Grayblack
Tungsten Carbide (WC)	15.7	40-80	Gray
Titanium Carbide (TiC)	4.91	80-120	Silver gray

The terminology and composition of the fabricated hybrid MMCs are shown in Table 2.

Table 2. Sample Nomenclature of AlGr hybrid MMCs

S.N	Al6351 (wt. %)	Reinforcement (wt. %)	Sample Code
1	100.00	0 wt %	AlGr
2	98.0	1.00 wt % Gr + 1.00 wt % B4C	AlGrB
3	98.0	1.00 wt % Gr + 1.00 wt % TiC	AlGrT
4	98.0	1.00 wt % Gr + 1.00 wt % WC	AlGrW

Fabrication Technique

The fabrication of the Al6351 & Graphite composite reinforced with B4C, TiC, and WC using the stir casting process involves the following steps:

In the very beginning, the materials were prepared according to the composition shown in Table 2. AA6351 was cut into small pieces and according to the weight of Al6351, the reinforcement proportion was measured. Melting of the Al6351 aluminum alloy was carried out in a temperature-controlled muffle furnace at 930°C.Reinforcements as per proportions were heated in another horizontal muffle furnace to remove moisture content. After Approx 40 minutes, the temperature of the vertical furnace was increased to 960°C and the molten mixture was stirred for five minutes to get uniformity. Then after, gradually reinforcement particles are introduced into the molten matrix material. The Stirring of the mixture was carried out continuously using a mechanical stirrer to ensure uniform distribution of the particles throughout the molten matrix. A degassing agent was used to remove any trapped gases or air bubbles from the molten mixture.The stirred molten composite mixture was poured into the preheated mold and allowed molten composite to cool and solidify inside the mold. The solidification process was carried out in natural air cooling.Once the composite solidified and reached sufficient strength, it was removed from the mold carefully, and postprocessing finishing processes such as machining, grinding, and polishing were carried out to achieve the desired shape, dimensions, and surface finish. A similar process was repeated for fabricating other hybrid composites.

The stir-casting process allows for the incorporation of reinforcement particles into the matrix material, resulting in a homogeneous distribution of the particles within the composite. The process offers flexibility in controlling the composition, particle size, and volume fraction of the reinforcement materials. It is a widely used and cost-effective method for fabricating metal matrix composites.

EXPERIMENTATION

After solidification, samples were gone through various machining processes. Samples were prepared for mechanical and wear tests. Then after the samples go through the various tests.

Mechanical Testing

The fabricated samples underwent various tests to evaluate their mechanical properties. Tensile strength was measured using a PC2000 Kundle tensiometer, hardness was determined using a hardness testing machine, and the impact strength of the hybrid composite was assessed through a Charpy test. The specimen preparation followed the

06 August 2024 04:50:07

guidelines outlined in ASTM standards. The results obtained from the tensile test, hardness test, and impact test are consolidated in the table below.

TABLE 3. Mechanical characterization of fabricated samples

Sample	Engg. UTS (MPa)	Hardness (HRC)	Toughness (Joules)
AlGr	100	69	26
AlGrB	134	82	32
AlGrW	154	76	25
AlGrT	206	85	33

Sample AlGrT shows the best mechanical characteristics among all the fabricated samples due to uniform proper mixing and lower defects.

WEAR TEST

The wear behavior of the fabricated hybrid MMCs was evaluated using a pin-on-disk wear testing machine. The wear testing of the Al6351 & Graphite composite reinforced with B4C, TiC, and WC involves the use of an experimental setup designed to simulate the wear conditions and measure the wear behavior of the composite material. The wear testing was performed using a pin-on-disk apparatus, which consists of a rotating disk and a stationary pin. The composite sample, in the form of a pin, was brought into contact with the rotating disk under controlled conditions. Below explained parameters and test conditions were considered for wear experiments:

- Applied Load: The load or force applied to the composite material during wear testing is an important parameter. Load in the range of 10 to 40 N varied with equal intervals of 10 to simulate different levels of contact pressure and determine the load-bearing capacity and wear resistance of the composite.
- Sliding Speed: The sliding speed or rotational speed of the test setup is another critical parameter. It represents the relative motion between the composite sample and the counterface material. Sliding speeds can range from low-speed conditions to higher speeds, depending on the intended application.The tests were performed with a consistent track diameter of 65 mm on the disc. The disc's speed varied at 295 RPM during the experiments to get a linear relative velocity of 1m/s.
- Sliding Distance: The sliding distance represents the cumulative distance traveled by the sliding contact. It is an essential parameter for assessing the wear resistance and durability of the composite. The workpieces were subjected to a sliding distance of 1000 m to achieve a noticeable weight loss in the specimens.
- Counterface Material: The choice of counterface material, which encounters the composite sample, is crucial. It should represent the intended application or the typical wear conditions that the composite will encounter. Based on the recommendation of ASTM, EN31 steel was selected due to its hardness and compatibility with the composite material.

Experimental Procedure

To conduct a wear test on the fabricated hybrid MMCs, the following steps were implemented. Firstly, the experimental setup was prepared by meticulously cleaning the specimen pin and eliminating any burns on the circumference using fine-grade emery paper. The disc was also thoroughly cleansed with a solvent and allowed to dry to assess wear on the disc surface. The weight of the specimen was then accurately measured using a highly precise weighing machine. Subsequently, the sample pin was securely clamped to the loading lever tip using hardened jaws of appropriate size. To establish a wear radius of 65 mm, the sliding plate was adjusted by unscrewing and shifting it to the desired position, aligning it with the graduated scale, and then securing it in place with the clamp screw. The machine operated at a speed of 295 RPM, and the process continued for the remaining duration while monitoring for any fluctuations.

sliding velocity and sliding distance were calculated by using below equation:

$$\text{Sliding speed in m/sec} = \frac{\pi DN}{60000}$$

06 August 2024 04:50:07

$$\text{Sliding distance in meters} = \frac{\pi DNT}{60000}$$

Where D is the diameter of the wear track in mm, N is the disc speed in rpm and T is the test duration in seconds.

After setting the rotation of the machine, the normal load was applied slowly withoutshaking. The experiment was conducted for all the specimens, and the data was observed.During and after experimentation weight loss and coefficient of friction data were collected to analyze the wear behavior of the hybrid MMCs.

Wear Experimental Result and Analysis

The specimens were subjected to a wear testing machine to assess their performance. Initially, a low load of 10N was applied to each specimen. After traveling a distance of 1000 m, the weight losses and coefficients of friction were measured. Subsequently, the load was incrementally increased to 20N, 30N, and 40N, and the corresponding weight losses and coefficients of friction were recorded and presented in the table. The wear rate data is summarized in Table 4, and its graphical representation is depicted in Fig. 1.

40	0.4321	0.387854	0.4121	0.374286

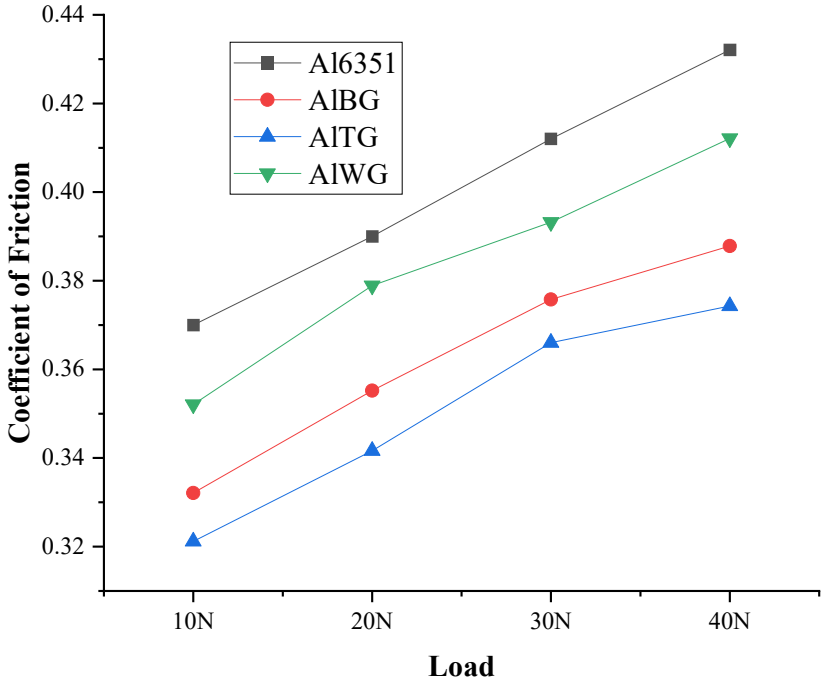

FIGURE 2. Variation of friction with load

In accordance with Archard's equation, the wear resistance of a material is inversely related to its hardness. By increasing the hardness of composite material, its ability to withstand sliding wear is improved. The addition of reinforcement particles, which are inherently hard, reduces the effective contact area between Al6351 and the disc. This redistribution of contact area, where some of it is occupied by the ceramics particles, enhances the wear resistance of the composite. Furthermore, the strong bond between the matrix and the ceramics particles prevents their separation during sliding, further enhancing the wear resistance of the hybrid MMC compared to the monolithic alloy. Figure 1and Fig. 2 illustrate the impact of load on the wear rate of the unreinforced Al alloy and Hybrid MMCs. Notably, the Al6351 matrix reinforced with 1 wt% TiC and 1 wt.% consistently exhibits a lower wear rate under all load conditions.

Worn Surface Analysis

Following the experimentation, the worn surfaces were studied using a high-resolution microscope (SEM). These detailed images serve as a valuable tool for identifying wear mechanisms, observing wear tracks, and analyzing wear debris.Fig. 3 showcases the impact of reinforcement content on the worn microstructure of the composites under a normal load of 40 N. The worn surface microstructure of the Al6351 alloy displays noticeable plastic deformation.Heat is generated between the specimen to be tested and the countersurface due to their relative motion and friction between them. The wear mechanism is predominantly adhesive. In Fig. 3(b, c, d), the worn surface micrographs of the composites display narrower grooves and a smaller number of pits. The presence of reinforcement particles reduces the depth of the grooves and minimizes plastic deformation along the groove edges. The wear mechanism in this case is primarily abrasive.

06 August 2024 04:50:07

In Fig. 3(a), the observed microstructure reveals several grooves and scratches that are oriented along the sliding direction. This observation provides significant insights into the predominant wear characteristics, which are primarily attributed to adhesion and delamination.

The presence of multiple grooves suggests the occurrence of adhesive wear, where the contact surfaces experience strong forces leading to material transfer and subsequent formation of grooves. This phenomenon is often associated with the intimate contact and bonding between the mating surfaces, resulting in material removal and the formation of wear debris.

Additionally, the presence of scratches further indicates the involvement of delamination wear. Delamination occurs when layers of material separate or peel off from the surface due to shear forces during sliding. These scratches can be considered evidence of localized material detachment and failure, which contributes to the overall wear process.

Figures 3(b), 3(c), and 3(d) showcase the impact of adding reinforcement particles on the worn surface characteristics. These figures reveal that adding the reinforcement particle restricts plastic deformation and minimizes the formation of grooves on the worn surface. Notably, the movement of metal on the worn surfaces of the hybrid Metal Matrix Composites (MMCs) is substantially reduced compared to the unreinforced Al6351 alloy.

Among the different hybrid MMC compositions investigated, the hybrid MMC with a 1wt% reinforcement particle content exhibits the least number of debris and a smoother worn surface when compared to the other hybrid MMC variants. This indicates that a 1wt% reinforcement particle content effectively mitigates wear and results in improved surface quality.

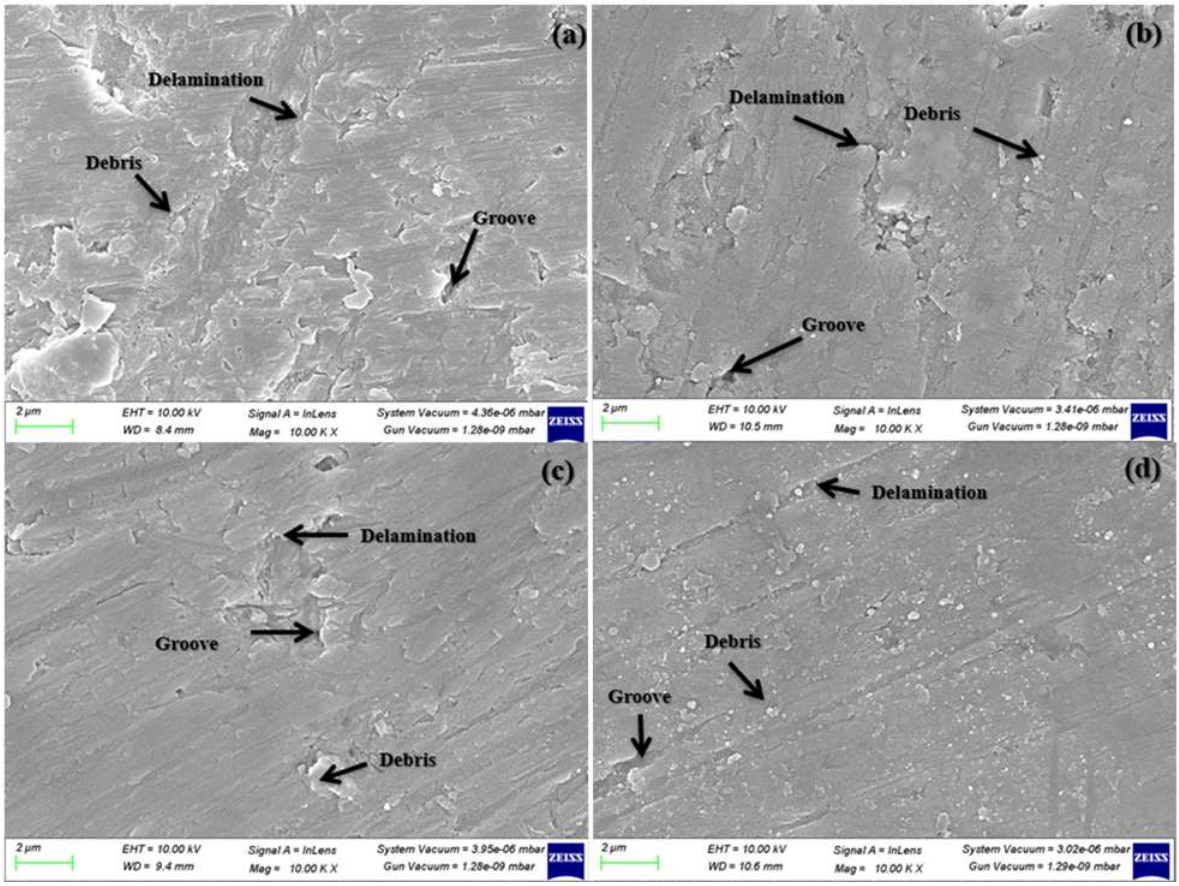

FIGURE 3.SEM of Worn Surfaces

Based on the improved corrosion and wear resistance of the Gr-TiC-Al6351 alloy matrix hybrid composites, potential applications include marine and aerospace industries, where corrosion and wear resistance are critical. Composites can also be used in automotive and mechanical engineering applications, where improved performance is desired.

06 August 2024 04:50:07

CONCLUSION

The present study explored the wear performance of Al6351-Gr reinforced with B4C, WC, and TiC. The hybrid MMCs were fabricated using a stir-casting process. The wear test revealed a consistent improvement in the wear performance of the fabricated HMMCs in comparison tothe base Al6351 alloy. The highest wear rate was observed in Al6351 as 0.007621 mm^3/m and the lowest in AlGrT (1 wt.% Gr& 1 wt.% TiC) as 0.00592 mm^3/m. The coefficient of friction shows an increasing pattern with increasing load. The lowest friction was observed for sample AlGrT at 40 N as 0.374286.

In microphotograph, Al6351 shows a large number of debris and plowing. The addition of reinforcement shows a reduction of debris. Sample AlGrT shows the least number of debris and plowing.

Urban ultrafine particles

ABSTRACT

The study measured and analysed the particle number concentration of particles ranging from 10 to 800 nm in urban and background sites. The aim of the study is to estimate the role of anthropogenic sources in urban regions in terms of number concentration. The study finds that the particle number concentration in an urban site is ~8 times higher than in the background sites. In the urban site, the Aitken and Nucleation modes contributed more to the total particle concentration, while in the background site, it was Aitken and Accumulation modes. The annual average concentration in the urban and background sites was 2.5×10^4, 2.9×10^3 cm^{-3} respectively. Aitken-mode particles dominated both in the urban and background sites, having the lowest concentrations in summer (6.4×10^2 cm^{-3}) and monsoon period (1.09×10^2 cm^{-3}), respectively. The diurnal concentration depicts the role of transportation emissions in the urban site and the natural process of particle condensation in the background site. The long-range transportation of sources shows that during winter and autumn seasons, the westerly and north westerly wind brings biomass burning emissions smoke to urban region and it was seen less in the background conditions.

1. Introduction

Atmospheric aerosols persist in solid or liquid form (Kompalli et al., 2018; Sebastian et al., 2021), determine region's air quality, and contribute to climate change and human health (Ambade and Kurwadkar, 2021; Hussain et al., 2023; Trechera et al., 2023). These are known for its increased toxicity due to their higher surface area and volume. The aerosol concentration is quantified in terms of particle number concentration (PNC) per unit volume of air (particle number or # per cm^3) (Damayanti et al., 2023; Damayanti and Harrison, 2022). Recent research studies worldwide show that particle number concentration in urban and background regions is dominated by particles with size ranges <100 nm, i.e., often referred to as ultrafine particles, which attain peak concentration when the solar radiation increases (Van De Beek et al., 2021).

The most recent studies in Asian regions show that air quality in many Asian cities is deteriorating alarmingly and poses a major

threat to human health (Ambade, 2021; Ambade et al., 2020).

Delhi, being one of the megacities in the Asian continent, is not an exemption (Mohan et al., 2024; Rajagopal et al., 2023, 2024; Yadav et al., 2021, 2022b). Various measures have been taken, such as closing 1300 industries due to hazardous emissions, banning vehicles older than 15 years, and introducing compressed natural gas fuel-based vehicles to curb air pollution in Delhi. All the mitigation measures help to reduce the sulfur concentration to 50 ppm (Mishra et al., 2019; Pandey et al., 2022; Yadav et al., 2022a). A city like Delhi, where the $PM_{2.5}$ concentration increases steadily, consequently involves a significant increase in the particle number concentration from different sectors, such as automobile and industrial sectors (Ambade et al., 2022; Gani et al., 2021; Zheng et al., 2021). Around 80% of the population who reside in urban areas are exposed to levels of air pollution that exceed WHO recommendations (WHO, 2022), as is the case of the particles larger than 10 nm (1000 cm^{-3}/24-h mean and 20,000 cm^{-3}/1-h) (Su et al., 2021). Ultrafine particles are considered as a universal carrier of a wide variety of toxic chemicals to humans. The deposition of particles in the human respiratory system varies based on the size of the particles, such as nucleation, Aitken, and accumulation. Also, the concentration of these particles signifies the emissions sources in a particular region. These can enter the deeper regions of the respiratory system, such as alveoli, and can be translocated to the circulatory system and enter any organ of the body (Ambade, 2016; Austin et al., 2021; Gani et al., 2021; Pirhadi et al., 2020; Zhao et al., 2020).

This study analyzes the particle number size distribution (PNSD) and the variations of total and modal (nucleation, Aitken and accumulation) concentrations in two geographical locations, an urban and a background site, during different seasons. The concentration of pollutants in the urban and background sites is distinct due to the different types of sources present. Various studies presented the characteristics of these particles in different environmental conditions, but this study compares these two regions in the Indian domain. The main objectives of this work are to (i) investigate the variability of aerosol number size distributions in an urban and a background site and their modal particle number concentration, (ii) examine the diurnal variation of the modal particle number concentration and (iii) investigate the role of meteorological parameters in determining the concentration of these aerosols.

2. Methodology

2.1. Sampling sites

Two different regions were selected as sampling sites for this study. One is located in a highly urbanized area with a complex mixture of different sources, and the other is a background site where the anthropogenic sources are found in lesser concentration (Fig. 1 & Table. 1).

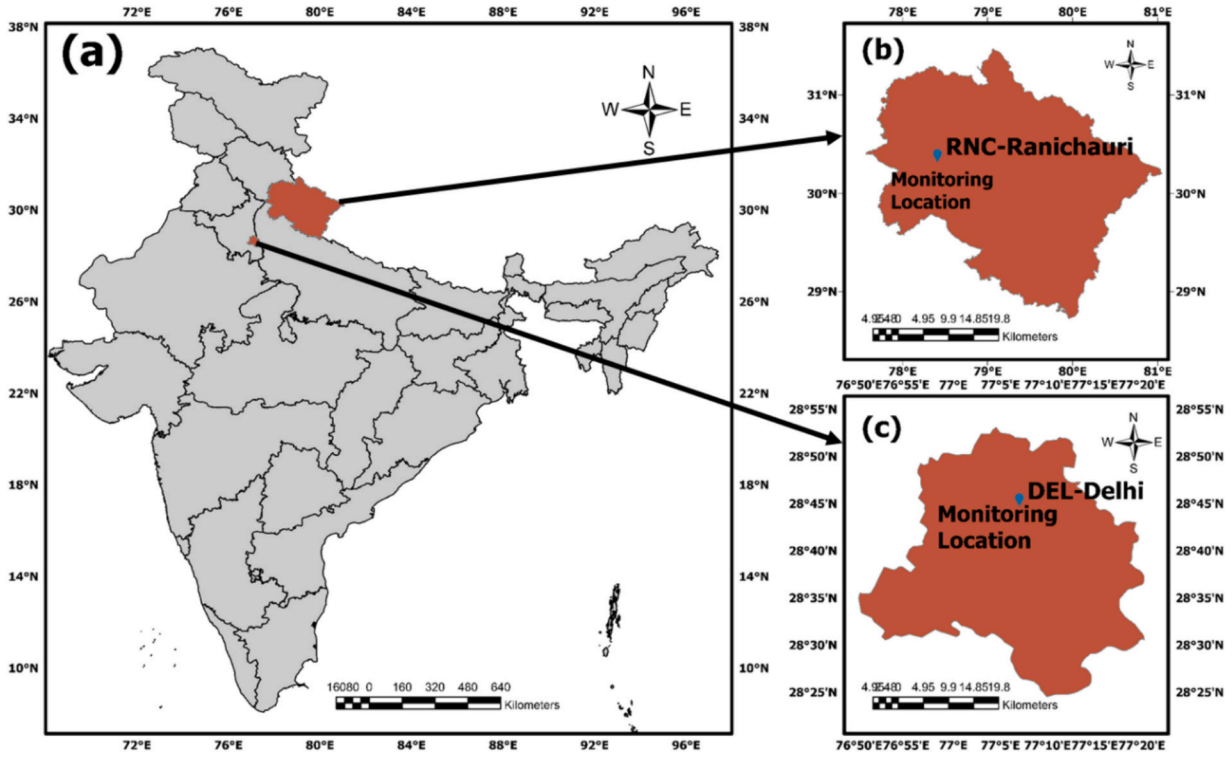

Fig. 1. (a) India Map, (b) Ranichauri (RNC) with a blue mark indicating the location of background site, and (c) Delhi (DEL) with a blue mark indicating the location of urban site. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

2.1.1. Urban site (Delhi)

The urban region observatory was in the northwest part of Delhi (28.75°N, 77.12°E). It is located inside the campus of Delhi Technological University, which is ~223 m above the mean sea level (amsl) and 8 m from the roadside. The region is highly populated, with commercial, residential, and industrial zones surrounding the sampling site. The sampling location is on the Bawana road connecting Delhi and Haryana, with a dense vehicular population of ~1300 vehicles per hour. During the sampling period, the meteorological conditions in the study area were temperature (25.89 ± 8.35 °C), wind speed (1.35 ± 0.83 m/s), and relative humidity (59.52 ± 18.73%), respectively.

2.1.2. Background site (Ranichauri)

The background observatory is in Ranichauri, Tehri Garhwal district in Uttarakhand state (30.25°N, 78.08°E). It is on the western Himalaya's southern slope, ~1930 m amsl. The nearest city from the background location is Rishikesh, which is 70 km away, and all other cities on different sides are above 100 km. Different types of lands, such as forest and agricultural activities, surround the study area. The meteorological condition in the study area during the sampling period is temperature (18.49 ± 7.02 °C), wind speed (2.39 ± 1.42 m/s) and relative humidity (58.67 ± 22.97%), respectively.

2.2. Instrumentation and campaign

Aerosol number size distributions were measured based on particle electrical mobility in an urban and a background site to compare them in terms of sources and meteorology (temperature, wind speed, wind direction, relative humidity). A GRIMM Inc. scanning mobility particle sizer model no. 5.403 measured particles from 10 to 1090 nm with a time interval of about ~7 min between each scan at the urban site. It comprises a long differential mobility analyser (LDMA) and a butanol vapor condensation particle counter. A β-radioactive source (Ni-63) was employed to bring the particles to an equilibrium charge distribution before they entered the classifier system. In the background location, a custom-built differential mobility particle sizer (DMPS) with a size range of 10 to 800 nm (30-size bins) is used for measurement. The Instrument is TSI make model no. 3772. It consists of a Vienna-type differential mobility analyser (DMA) that classifies charged particles based on their electrical mobility. The time interval between each scan in this instrument is ~10 min with a flow rate of 1 LPM and a sheath air flow rate of 5 LPM. The campaign was conducted in 2017 at the background site and 2022 at the urban site. The particles were then analysed using a scanning mobility particle sizer (SMPS) and a condensation particle counter (CPC). The data were analysed using R statistical software version 2023.12.1.

The meteorological parameters such as relative humidity, temperature, wind speed, and wind direction are also collected along with the particle number concentration in both locations to determine the role of meteorological parameters in different regions. The meteorological parameters are measured at a frequency of about 5 min. The accuracy of all the meteorological instruments follows the standards of the World Meteorological Organization. Accuracies of meteorological sensors are ±0.05 °C for temperature, ± 0.1 hPa for atmospheric pressure, ± 0.5 m/s, and ± 1° for wind speed and direction.

2.3. HYSPLIT trajectory

The long-range transportation of the pollutants analysis is done using the Hybrid Single Particle Lagrangian Integrated Trajectory (HYSPLIT) open-source model developed by the Air Resource Laboratory (ARL), NOAA (National Oceanic and Atmospheric Administration). The seasonal average trajectories are plotted for 3 days (−72 h) back trajectory for every day (24 h, starting at 00 h) and the clustering is done for each season. The season has been considered for winter (December to March), summer (April to June), monsoon (July to September), and post-monsoon (October to November) for the years 2022 and 2017 of urban and background sites. The input of the models is taken from REANALYSIS data at a height of 1000 agl (above ground level) for both urban and background sites for analysing back trajectory in MeteoInfoMap.

2.4. Limitations of the study

The study measured particle number concentration of particles ranging from 10 to 800 nm in urban and background regions to compare the concentration of sources and type of particles present. Due to the limitations of the resources, the measurements are not done parallelly in both locations. Due to constraints in the instruments, two different instruments that work on the same principle are used for the measurements. These two are considered limitations of the present study, and still, the data used for analysis are checked for quality checks, and necessary statistical analysis was done to ensure the quality of the data. The significance of the data is tested using the Levene test and F test, and found the p-value <0.05, so the null hypothesis is rejected.

Table 1

2.	Ranichauri	RNC	30.25°N	78.08°E	Background (BG)

3. Result and discussion

3.1. Variation of modal particle number concentration in an urban and a background site

The modal particle number concentration, Nucleation (N_{nuc}, 10 to 30 nm), Aitken (N_{atk}, 30 to 100 nm), Accumulation (N_{acc}, 100 to 800 nm), and total particle number concentration (N_{tot}, < 800 nm) were compared between the two different sites (urban and background). The analysis shows N_{tot} concentration in the urban and background sites were found to be 2.5×10^4 cm^{-3} and 2.9×10^3 cm^{-3}, respectively (Table. 2). Trechera et al., 2023 reported 6 cities in Europe country showed higher PNC ranging from 1.35×10^4 to 1.05×10^4 # cm^{-3} near the traffic-related site whereas, cities from Italy showed lower concentrations in regional background ranges from 7.4×10^3 to 4.5×10^3 # cm^{-3}. Similar studies showed that the concentration in the urban site is higher compared with the background site (Rose et al., 2021; Trechera et al., 2023). The number concentration analysis reveals that in urban regions, the N_{atk} concentration was found to be higher than N_{nuc}, and followed by $N_{acc,}$ but in the background site, N_{atk} was higher than N_{acc}, followed by N_{nuc}, respectively. In urban regions, the higher concentration of N_{atk} and N_{nuc} is due to transport-related anthropogenic emissions, with an average of 5.7×10^2 cm^{-3}, 8.3×10^2 cm^{-3}, and 4.3×10^2 cm^{-3} for N_{nuc}, N_{atk}, and N_{acc}, similarly for the background site it was 0.4×10^2 cm^{-3}, 1.6×10^2 cm^{-3} and 0.9×10^2 cm^{-3}. On average, the difference in N_{tot} between the urban and background sites showed that N_{tot} was ~8 times higher in the urban site compared to the background one (Chatain et al., 2021).

The modal particle number concentration variations showed different patterns based on the characteristics and intensity of the sources in each study area. In both sites, N_{atk} showed a higher concentration than other modes, possibly due to the short-lived nature of N_{nuc} associated with the coagulation and condensation processes in the atmosphere (Chen et al., 2022; Sun et al., 2019). In the winter season, the maximum N_{tot} was observed, 1.0×10^3 cm^{-3} in the urban site and 2.3×10^2 cm^{-3} in background one (Şahin et al., 2022; Sun et al., 2019) (Fig. 2). The lowest concentration was observed for N_{atk} during the summer (6.4×10^2 cm^{-3}) in the urban site, while in background one was observed in the monsoon period 1.09×10^2 cm^{-3} (Table. 3). In summer is usual to find lesser concentration compared to winter due to the meteorology (Kalkavouras et al., 2020). The seasonal average for N_{tot} varies from one site to another. In the urban site, N_{tot} was higher in post-monsoon (3.0×10^4 cm^{-3}), followed by winter (2.9×10^4 cm^{-3}), monsoon (2.2×10^4 cm^{-3}), and summer (2.0×10^4 cm^{-3}) (Table. 3).

In the urban site, N_{nuc} and N_{atk} were similar during the summer and monsoon, but in the background site, the modal particle number concentration was as follows: $N_{atk} > N_{acc} > N_{nuc}$ for all seasons. The variations for N_{tot} between the urban and background sites were highest during the monsoon, which was ~13 times higher in urban regions, followed by post-monsoon ~12 times, winter ~7, and summer ~6.

3.2. Particle size distribution in an urban and a background site

Aerosol particle number size distribution was used as a tool to identify the sources of the particles. The size distribution pattern varies from the background to the urban site. The size distribution of the particles in urban site showed a single clear peak concentration between 80 and 90 nm, which typically refers to engine exhaust emissions (Chen et al., 2022; Kontkanen et al., 2020) (Fig. 3). In the background site, particle size distribution ranged gradually increase from 20 to 100 nm due to particle growth, a common phenomenon in this type of sites.

In the urban site, the PNC contribution from the transportation sector is more dominant than other sources (Chen et al., 2022; Gani et al., 2021). The highest concentration was obtained during winter, around 4×10^4 cm^{-3}, while the concentration ranged between 1-2×10^4 cm^{-3} in the rest of the seasons. Global studies showed similar behaviour during winter (Gani et al., 2021; Şahin et al., 2022). In the background site, the highest concentration was in winter, followed by summer, post-monsoon and monsoon.

In almost all the seasons, the gradual growth of the particles was observed. The size distribution pattern of the urban site showed that during all the seasons, the concentration of the particles emitted also lies in the range of 1 to 2×10^4 cm^{-3}, which is the result of direct emission from anthropogenic sources. In the background site, the sub-10 nm particles showed the particle concentration gradually reducing around 10 nm and increasing after 10 nm due to the change of particle phases from gaseous to solid due to the particle formation process. Consequently, the concentration of the size distribution varies from season to season. However, the emission profile remains similar in all the seasons, whereas in the urban site, the size distribution and emission profile change from season to season due to the influence of sources meteorology and the intensity of the sources.

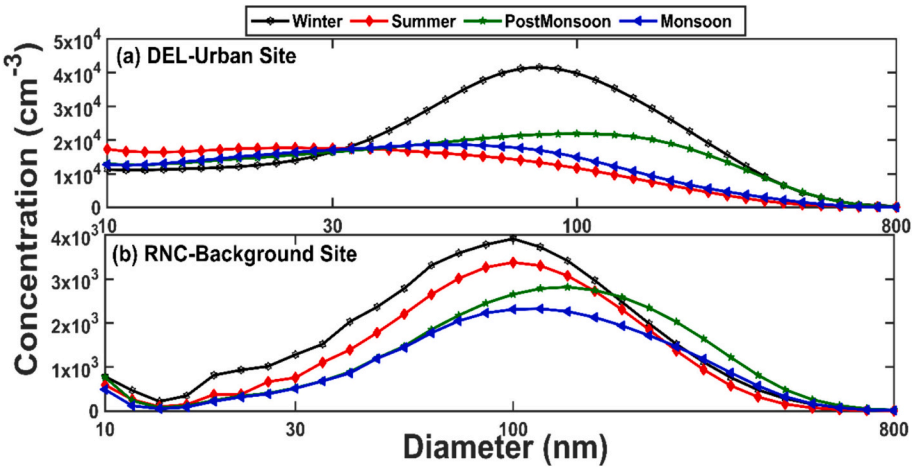

Fig. 3. Particle number size distribution of particles in (a) an urban and (b) a background site during different seasons.

3.3. Diurnal variations of modal particle number concentration in the urban and background sites

The diurnal variation of modal particle number concentration in the urban and background sites indicates how the concentration of the particles varies in terms of source during the different seasons.

In the urban site, N_{nuc} peaked from 8 to 12 h in the morning due to the fresh engine exhaust emissions, while in the background site during the winter and spring seasons, this peak was shifted (12 to 20 h) (Chen et al., 2022; Zhu et al., 2002, 2004). This was due to the increase in the formation of new particles into the atmosphere by gas-to-particle conversion induced by photochemistry and their subsequent growth. N_{atk} in the urban site showed a clear double hump model during the morning (8 to 11 h) and evening peak hours (16 to 20 h) which was associated with the transport of emissions from urban areas. Globally, this pattern signifies the role of pollution transportation in determining the particle concentration in the urban site (Fig. 4). The N_{acc} mode in the urban site followed a similar pattern to that of N_{atk}.

In the urban site, the N_{nuc} varied from 2.5×10^2 cm^{-3} to 1.5×10^3 cm^{-3}, while in the background site, it lies $<1 \times 10^3$ cm^{-3}, the evening peak higher due to the N_{acc} accumulation throughout the day. The N_{nuc} in monsoons was seen more during the morning hours due to the wet removal of the pre-existing larger particles, which promoted an increase in particles fresh from exhaust emission (1.5×10^3 cm^{-3}). The N_{atk} and N_{acc} mode particles showed higher concentration during the winter and post-monsoon periods. In the background site, the concentration of the three particle modes was higher during winter and summer, followed by post-monsoon and monsoon seasons.

3.4. Diurnal variation of meteorological conditions

The existing meteorological conditions influence particle number size distributions, mainly relative humidity and temperature. Thus, the relative humidity played a crucial role in inducing the particle to undergo condensation and coagulation processes (Mohan et al., 2024).

In the urban site, the lowest mean temperature was registered during winter (18 °C) and the highest during summer (33 °C), reaching a maximum of ~46 °C, while in the background site, it was only 38 °C (Fig. 5 & Table. 4). The relative humidity in the study sites was directly proportional to the particle concentration in the accumulation mode. The humidity >50% increased the possibility of

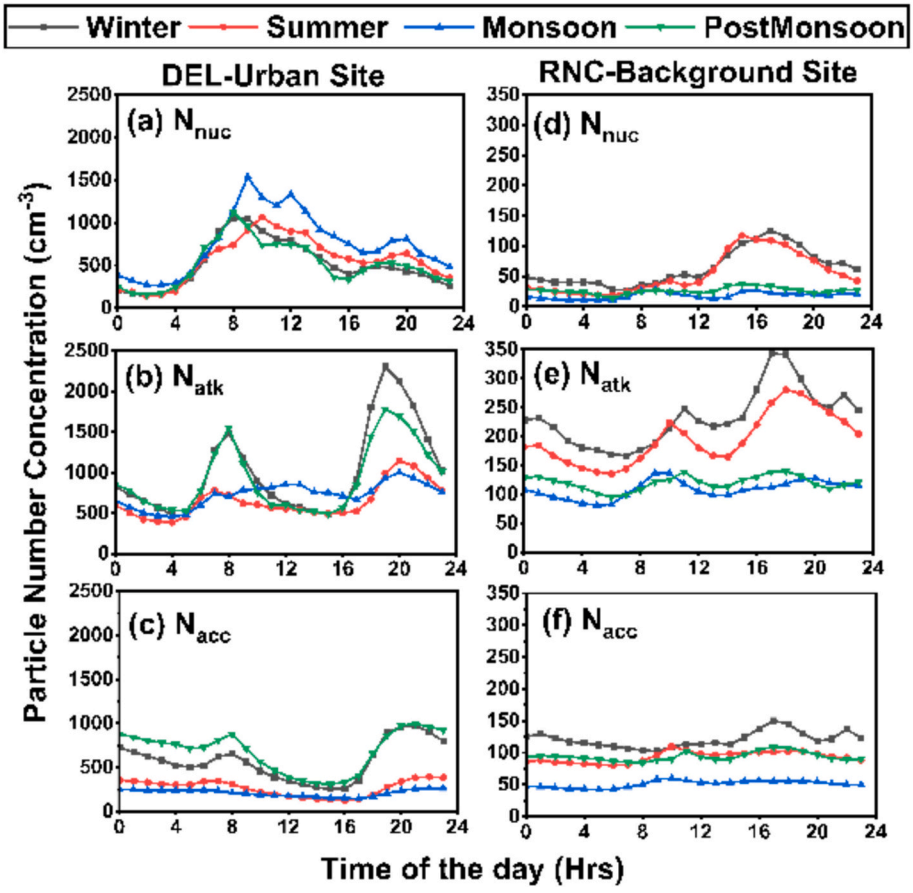

Fig. 4. Diurnal variation of modal particles number concentration in an urban and a background site during the different seasons.

	SD	15.7	5.4	0.6	12.8	4.9	0.8

coagulation and condensation of the lower-size particles (N_{nuc} and N_{atk}) into accumulation mode particles, especially in the urban background. However, the geographical characteristics in the background promoted the arrival of air masses with a higher humidity than in the urban site, particle coagulation and condensation processes were inhibited by their low concentration. In the urban site, even >70% humidity increased the particle condensation and coagulation; consequently, the accumulation-mode particles also increased (Mohan et al., 2024; Zhu et al., 2006).

3.5. Role of wind speed and direction on particle dispersion

The wind speed and direction determine the pollutant's dispersion and rate from the sources to receptors. The urban site is surrounded by various buildings, which creates a shielding effect. Thus, the average wind speed was <2 m/s in all seasons, except for the post-monsoon season, with a similar wind direction in almost all seasons. In the post-monsoon season, the urban region receives an average wind speed throughout the season, ranging from 6 to 8 m/s. Similarly, the wind speed reached up to 10 m/s in the background site, but changes were found seasonally in the wind direction. Thus, particle dispersion occurs at a larger rate in this site during higher

wind speeds, and the particle concentration lies between 1.2 and 1.4 $\times$ 10^3 cm^{-3}.

The wind speed comparison between the urban and background sites showed a higher particle concentration in the background site, identifying an average wind speed of 2 to 3 m/s, while in the urban site, it was 1 to 2 m/s. The season-average wind speed was not >2 m/s in any season.

The mean N_{tot} may also increase based on the dispersion of pollutants from one region to another region due to the wind speed and direction. Calm winds (< 2 m/s) led to less particle dispersion, oppositely with winds >4 m/s (Fig. 6), being pollutants transported to the leeward side from the windward side. Other authors have also stated similar kind of findings in their study (Mohan and Mishra, 2022; Şahin et al., 2022).

3.6. Long-range dispersion pattern in urban and background site

The trajectory plot shows that the pollutants are not only generated from the local sources but also transported from long-range transportation. To analyse the impact of long-range transportation of pollutants from different faraway regions, the back trajectories were analysed for 2022 and 2017 in urban and background regions (Fig. 7&8). In the urban region of Delhi, the back trajectory shows that for most of the seasons, the winds are blown from the western side of the study location (Sharma et al., 2022). During the onset of winter, and post-monsoon season (October to March), most of the wind comes from the neighbouring states, namely Punjab and Haryana (~60 to 80%). This period is known for the crop residue burning period, where burning the remaining crop wastes brings large amounts of smoke particles to Delhi and causes smog formation. Severe air pollution events are attributed to the downwind movement of aerosols from biomass burning (Kanawade et al., 2020). In our study, the concentration of ultrafine particles was higher during the mentioned period. Around 82% of the winds come from the same direction possible, causing long-range transportation of aerosols apart from the local sources. Similarly, during summer, the winds are from Rajasthan, i.e., the westerly and north-westerly direction brings a significant amount of dust from the Thar desert that contributed to concentrations during the summer period (Banoo et al., 2022; Singh et al., 2020). However, from July to September, the wind pattern in the urban regions changes and the winds travel from the Arabian Sea or Bay of Bengal, i.e., from the southwestern coast. These winds are responsible for the precipitation in both the study regions, bringing many marine aerosols to the study location. The shift in the dispersion of wind patterns could attributed to the dominant monsoon winds from the Indian Ocean. In the background region, the wind pattern is more or less similar to the urban regions. The fascinating thing about the background region is that the hilly terrain restricts long-range transportation. At the same time, the regional wind sources contribute to around 50% of the wind in almost all the seasons in the background conditions (Fig. 8). This analysis shows that the concentration of ultrafine particles is based on the long-range transportation of the winds and associated pollutants. Also, it varies from one geographical domain to another geographical condition, such as urban and background conditions.

4. Conclusions

This study analysed the variation in aerosol particle number concentration in urban and background conditions. The annual

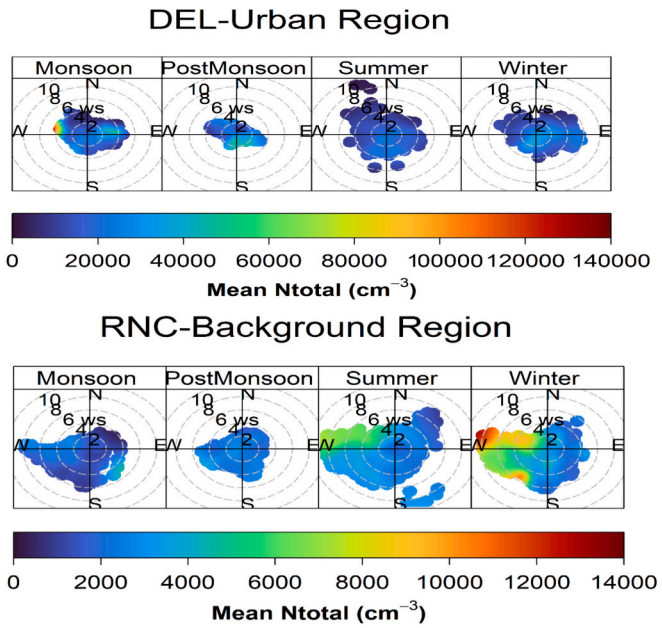

Fig. 6. Polar cluster analysis of seasonal total particle concentration in the urban and background sites during different seasons.

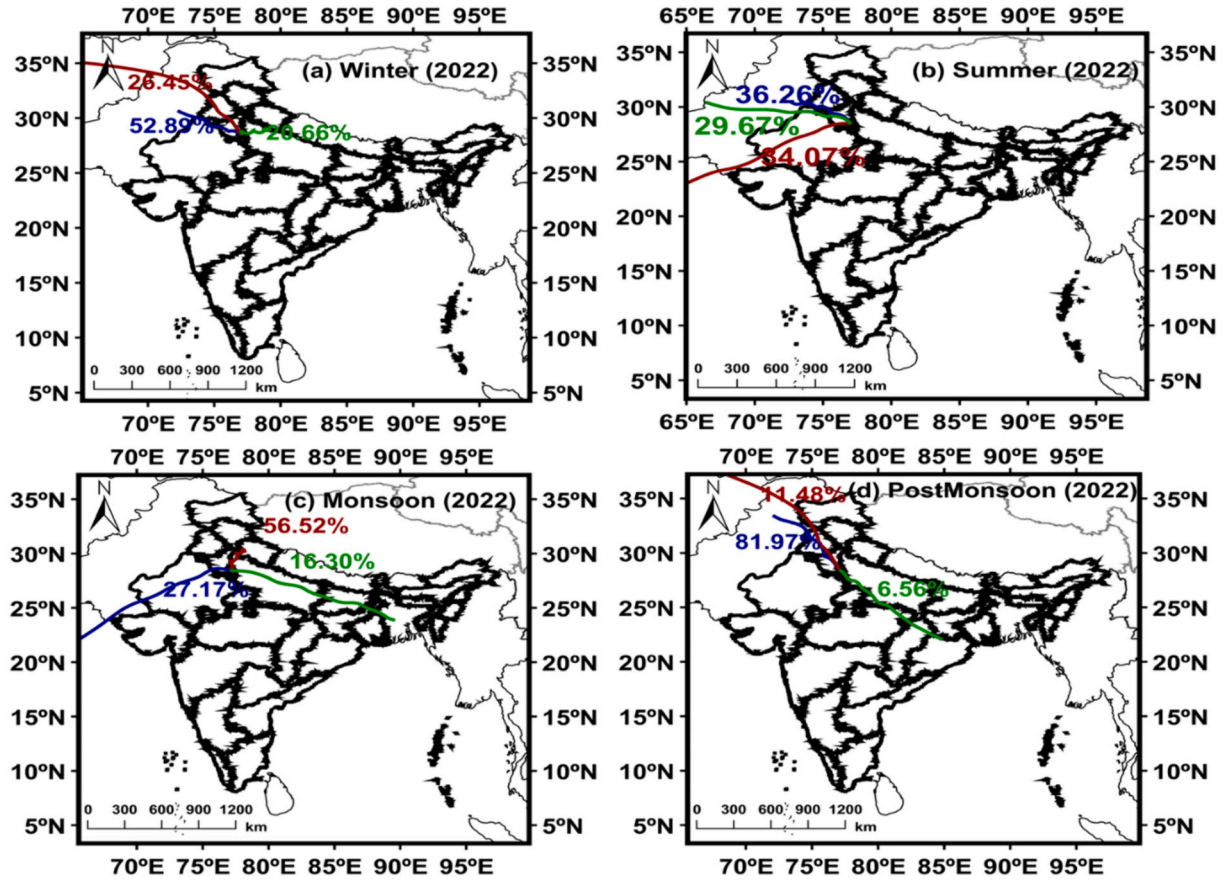

Fig. 7. Back trajectory plots in urban site for the different seasons.

average N_{tot} in the urban site was 2.5×10^4 cm^{-3}, and the concentration in the background site was 2.9×10^3 cm^{-3}. Particle number concentration in the urban site was higher for N_{atk} followed by N_{nuc} and N_{acc}, whereas, in the background site, it was for N_{atk} followed by N_{nuc} and N_{acc}. In both urban and background locations, the concentration of N_{atk} was found more in urban and background regions. The lowest concentration (6.4×10^2 cm^{-3}) for N_{atk} in the urban site was observed during the summer, and in the background site during the monsoon season (1.09×10^2 cm^{-3}). The urban regions with more anthropogenic emissions, especially the transportation sources, exhibit a peak around 80 to 90 nm. Similarly, in the background site, the size distribution changes gradually from lower to higher sizes due to the particle growth.

The diurnal variation of the particles in the urban site and background regions shows the impact of anthropogenic sources, where transport emissions are higher during morning and evening peak hours. In the background site, particle concentration was high during the evening hour due to their accumulation from the morning emissions to the evening in the study area. The meteorological conditions promoted the secondary formation of aerosol, which was observed when the RH was >70% in the urban site and > 50% in the background site. The annual wind speed in the urban site was <2 m/s and ranged from 6 to 10 m/s in the background site. The back-trajectory analysis shows that in both the study sites, during different seasons, wind pattern changes, especially the global wind direction, which contributed to different types of particles originating from various sources such as burning, sand dust and marine aerosols. The comparative study in urban and background sites provides a detailed assessment of the role of anthropogenic emission in determining the particle number concentration in the study regions.

The study helps to identify the role of different sources, meteorology and geographical condition in determining the concentration, size distribution, influence of other factors which are crucial to understand the dynamics of the ultrafine particles in different environmental conditions. Further similar studies can be conducted in different environmental condition to examine the sources, concentration and potential health impacts caused due to these UFP's. Urban regions pose a serious threat to exposure to these particles. The deposition potential of the particles in the respiratory system is based on the concentration and properties of the particles, which increases toxicity. The present study may be useful to estimate the long-term and short-term seasonal exposure. The measured concentration can be further used for simulating health impacts such as pulmonary deposition. The study also emphasizes the need to initiate mitigation measures to improve air quality and policy-driven action measures to attain sustainability.

Abstract:

This work proposes a Penrose-based photonic quasi-crystal fiber (PQF) composed of Arsenic-free, non-toxic chalcogenide glass for Supercontinuum (SC) generation consisting of quasi-crystal lattice of air holes having eight-fold rotational symmetry. Following optimising the structural parameters, the proposed PQF offers zero dispersion wavelength (ZDW) at around 3.8 μm, an effective mode area of 30 μm^2, and a respective high nonlinearity of 824 $W^{-1}Km^{-1}$ at 2 μm wavelength. By injecting a secant hyperbolic optical pulse having a central wavelength of 4 μm with 20kW peak power and pulse width of 50 fs, a broadband SC of 2-21 μm is generated, which mostly covers the transparency range of the proposed material as well as Mid-IR regime. To the best of our understanding, this particular type of PQF for broadband SC generation has been proposed for the first time, serving as the novelty factor. Apart from novelty, the wide-band SC assists the proposed PQF in becoming a better counterpart for applications like optical coherence tomography (OCT), frequency metrology, and other Mid-IR applications.

1. Introduction:

Supercontinuum generation (SCG) is the phenomenon in which a short, high-intensity optical pulse transforms into a broadband spectrum having a range of wavelengths when it travels down through a nonlinear optical medium such as optical fibers. The transformation takes place due to the interaction of optical pulse with the nonlinear and dispersive effects such as stimulated Brillouin scattering (SBS) [1], Stimulated Raman Scattering (SRS) [1, 2], self-steepening, four-wave mixing (FWM) [2, 3], self-phase and cross-phase modulation (SPM-XPM) [4, 5], and many more. The variation in the effect of nonlinearities depends on the structural and material composition of the utilized medium for SC generation. Micro-structured holey fibers (MOFs) are superior candidates over conventional fibers due to certain advantages like endless single-mode operation, high power delivery, high birefringence and better dispersion adjustment [6-12]. MOFs like photonic crystal fiber (PCF) [13, 14], photonic bandgap fibers (PBGF) [15], photonic quasi-crystal fibers (PQF) [16, 17], and micro-porous core fibers (M-PCF) [18] are successful candidates for enhancing the nonlinear and dispersive outcomes and, more importantly, for the highly broadband SC generation. The phenomenon of supercontinuum was demonstrated by Alfano and Shapiro for the first time in 1970 [19]. In 2000, Ranka et al. were the first to generate SC spectra in PCF [20]. Afterward, works related to SCG in PCF continued to flourish [21-25]. Various notable works about SC generation in PCF have recently come to light. In 2024, Wen et al. generated a highly coherent SC spectrum spanning from 1300-2800 nm at low peak power of 1000 W [26]. In the same year, Nguyen

Thi et al. achieved a Supercontinuum spectrum spanning from 0.843 μm to 2.517 μm at the pumping of 1.57 μm with a peak power of 350 W [27].

Apart from PCF, PQFs have started to grab attention by emphasizing their features like ultra-flattened dispersion [28, 29], large modal area [30], endless single-mode operation due to the large magnitude of the cut-off ratio, and many more. The air holes do not exhibit any recurring translational pattern but attain two different types of lattice units, which repeat themselves by maintaining the rotational symmetry across the cross-section of the fiber. These characteristics allow PQFs to have greater structural degrees of freedom and distinctive cladding configurations that provide greater guiding feature tuning flexibility [31]. In the field of SCG, PQF also stands out as a competitive candidate that can deliver broadband SC spectrum at comparable peak powers and a short length of fiber. In 2016, Ahmad et al. proposed a circular lattice As_2Se_3-based PCF, which can be christened as sunflower-type PQF, has the ability to display a wide band of SC, i.e., 1.2-9.3 μm at only 0.5 cm of length [32]. Vallliammai et al. designed a circular PQF the following year and generated an SC spanning 2-15 μm with a very low confinement loss [33]. In the same year, Zhao et al. extracted an SC band of 1-12.5 μm by numerically simulating a twin bow-type PQF at the pumping of 2.94 μm operating wavelength [34]. Other than SCG, In 2014, Su et al. introduced twin-bow type PQF for high birefringence offering high magnitude (~2.43×10-3) [16]. In the same year, an octagonal penrose-based double cladding PQF was proposed by Liu et al., which delivers a very low loss profile, and ultra-flattened dispersion [17]. From the past literature discussion, it is clear that Penrose-based PQF has already been proposed for EMA and dispersion engineering calculations. Therefore, to upscale the research focussing on Penrose-based PQF, We have selected that specific PQF design for the Supercontinuum generation, which is proposed for the first time in the field of SCG applications and introduces a difference between the past works and our presented work.

Higher energy in the near-IR (and visible) regions excites overtone/harmonic and combination bands, whereas lower energy mid-IR radiation excites the fundamental vibration bands. These fundamental vibrations are more powerful than the overtone and combination bands that occur from the fundamental vibrations because they originate from the molecule's most basic vibrational states. This leads to significantly cleaner spectra originating from fundamental vibrations, which produce a distinct fingerprint for the material that may be utilized for identification. This respective reason increases the importance of mid-IR spectroscopy. Silica-based fibers can only offer SC band in the near-IR region since beyond 2.5 μm, high material absorption comes into play, which disrupts the respective SC band. Chalcogenide glasses and their various compositions inherit transparency beyond the near-IR region and wrap the mid-IR region [35], which qualifies them as the perfect choice for PCF fabrication. Along with a large span of transparency, chalcogenide glasses inherit a high magnitude of linear and nonlinear refractive indices. Tellurium (Te)-based chalcogenides can offer a transparency range beyond 25 μm. $Ge_{20}Se_{70}Te_{10}$ is a representative of Ge-Se-Te (GST) glass, which acquires high nonlinearity of order of 10^{-18} $W^{-1}km^{-1}$ along with a transmission range of 2-25 μm [40]. Apart from these qualities, GST glass has also been proven to be non-toxic due to the absence of Arsenic in molecular compositions [36]. The past works prove that the particular glass composition was readily used for designing and fabricating PCF structures for SCG applications due to its numerous advantages. In 2019, Lemiere et al. fabricated a step-index GST-based fiber and successfully generated an SC spectrum of 2-14 μm [37]. In 2021, a

broadband SC band of 1.7 to 18 μm was achieved by simulating a GST-based step-index fiber with the input of 200 kW peak power pulse centered at 8.15 μm wavelength [38]. Since $Ge_{20}Se_{70}Te_{10}$ has several advantages, we have chosen this glass to design our PQF structure.

In this paper, we propose a novel penrose-type PQF structure that consists of $Ge_{20}Se_{70}Te_{10}$ as background material and is surrounded by air holes. The air holes are located in such a manner that they do not exhibit translational symmetry but exhibit an eight-fold rotational symmetry. The proposed fiber is employed for generating SC spectra, which deliver a wide-band SC of 2-21 μm at the input of 4 μm pump wavelength with a peak power of 20 kW and respective fiber length of 4 mm. Apart from wide-band SC, the devised fiber has the capability to offer high nonlinearity of 824 $W^{-1}Km^{-1}$ at 2 μm wavelength. Due to high nonlinearity and wide transmission window, the PQF proves its potential to become a better counterpart for delivering mid-IR broad SC spectra, which opens new application gateways in optical coherence tomography and other mid-IR applications.

2. Proposed PQF Design

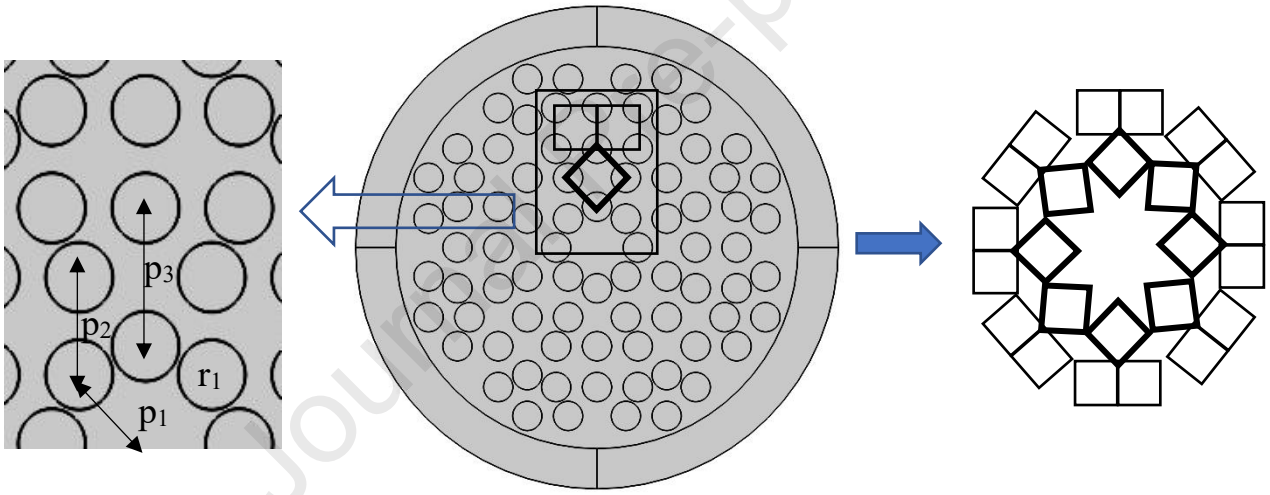

Fig. 1. Proposed Penrose-type PQF Structure

A Penrose-type PQF is designed with a circular core adjoining by cladding layers of air holes. The central core is specifically composed of Te-based $Ge_{20}Se_{70}Te_{10}$ chalcogenide glass. The radius of air holes is kept constant throughout the cladding of the proposed PQF structure, denoted by r_1. The respective air holes are located at two different lattice units, which satisfy eight-fold rotational symmetry without a translational symmetric nature. The two lattice units are one rhombus and one rectangle (divided into two squares) stacked over the other. We have defined three different types of pitch. p_1 is the first pitch parameter that defines the distance of the air hole of the first cladding layer from the centre of the PQF. Following p_1, p_2 and p_3 served as two distinct pitches which defines the centre-to-centre interspace of air holes of first and second layer of cladding and centre-to-centre stretch of air holes of first and third layer of cladding respectively. To eliminate the back reflection effect, a perfectly matched layer (PML) is applied as a layer surrounding the PQF structure. The Penrose-type PQF is proposed for the first time for SCG applications, which arises as a novelty factor for using this certain design.

The proposed PQF was successful in delivering a flat near zero dispersion and respective zero dispersion wavelength at 3.8 μm.

3. Linear and nonlinear characteristics

The GST based-$Ge_{20}Se_{70}Te_{10}$ is the chalcogenide glass implied in the PQF structure as the core material. The refractive index of the mentioned GST glass is defined as a wavelength-dependent Sellmeier equation, and the same is mentioned below with all the numerical parameters [39]

$$n^2(\lambda)=1+\frac{\left(5.225\times\lambda^2\right)}{\lambda^2\text{-}0.298^2}+\frac{\left(0.202\times\lambda^2\right)}{\left(\lambda^2\text{-}21.606^2\right)} \tag{1}$$

The spectral components of input optical pulse traverse at different phase velocities in PCF or PQF structures. The group velocity dispersion (GVD) parameter determines the limit at which the intervals between the phase velocities are created. The GVD parameter is totally dependent on the variation of the real part of the effective mode index.

$$D(\lambda)= -\frac{\lambda}{c}\frac{d^2n_{eff}}{d\lambda^2} \tag{2}$$

Equation (2) comprises the effect of both material and waveguide dispersion. The *β(ω)* parameter is also evolved with the dispersion calculation. The term *β(ω)* contains a discrete set of parameters obtained by expanding Taylor's series. Every term of *β(ω)* describes a characteristic of the optical wave. The effective mode index is well defined by the first term. The second term denotes the group velocity, and the third describes the GVD parameters. We have taken 9th-order consideration for the *β(ω)* parameter.

$$\beta(\omega) = \beta(\omega_o) + \beta_1(\omega_o)(\omega - \omega_o) + \frac{1}{2!}\beta_2(\omega_o)(\omega - \omega_o)^2 + \frac{1}{3!}\beta_2(\omega_o)(\omega - \omega_o)^2 \ldots \tag{3}$$

For generating broadband spectra, our ultimate aim should be the adoption of PCF parameters such that the magnitude of the effective mode area must exhibit a low magnitude such that it can successfully sustain modal fields at larger wavelengths and enhance the respective nonlinearity towards higher magnitude (in the order of 100 $W^{-1}km^{-1}$). Therefore, the effective mode area must be calculated using the following formula.

$$A_{eff} = \frac{\left(\iint_{-\infty}^{\infty}|E|^2dxdy\right)}{\left(\iint_{-\infty}^{\infty}|E|^4dxdy\right)} \tag{4}$$

The nonlinearity term comprises the effect of all the nonlinearities that participated in the fiber, like SPM, XPM, SRS, SBS, and many more. The overall quantification of nonlinearities is done by calculating the value of γ by the given formula.

$$\gamma = \frac{2\pi n_2}{\lambda A_{eff}} \tag{5}$$

Equation (5) shows the direct relationship of γ with the nonlinear refractive index and the inverse relationship with effective mode area and wavelength. The nonlinear refractive index of the proposed material $Ge_{20}Se_{70}Te_{10}$ is 8×10^{-18} $W^{-1}km^{-1}$ [39, 40].

4. Theoretical Model of Supercontinuum generation

For the simulation of SC in PQF, a generalized nonlinear Schrodinger equation (GNLSE) is formulated which comprises all the effects of linear and nonlinear characteristics of the proposed model. The GNLSE is solved using the split-step Fourier method (SSFM) and the same equation is described below [41].

$$\frac{dA}{dz}+\frac{\alpha}{2}A-\left(\sum_{n\geq 2}\beta_n\frac{i^{n+1}}{n!}\frac{\partial^n A}{\partial t^n}\right)=i\gamma\left(1+\frac{i}{\omega_o}\frac{\partial}{\partial t}\right)A(z,t)\int_{-\infty}^{\infty}R(t')\left|A(z,t-t')\right|^2dt' \quad (6)$$

The above equation denotes the optical field envelope as *A(z, t)* and fiber losses as *α*. The term *β(ω)* and its parameters are already discussed in the above section. *R(t)* represents the instantaneous functional form of the electronic and Raman contributions and the same can be written as [41]

$$R(t') = (1 - f_r)\delta(t) + f_r h_r(t') \quad (7)$$

In equation (7), fractional participation is denoted as fr=0.115 [42], which was responsible for the delayed response of Raman contributions to nonlinear polarization. $h_R(t)$ is represented as the Raman response function, which consists of the Raman period and lifetime denoted as τ_1 and τ_2, consists of values 23.1 fs and 195 fs, respectively [42], and the corresponding quantified function is described below [41]

$$h_r = \frac{\tau_1^2 + \tau_2^2}{\tau_1\tau_2^2}\exp\left(-\frac{t'}{\tau_2}\right)\sin\left(\frac{t'}{\tau_1}\right) \quad (8)$$

Relative coherence between the consecutive spectral evolutions of the SC is used to quantify changes in spectral phase over the Supercontinuum band. The following equation measures the first-order relative coherence [41]:

$$\left|g_{12}^{(1)}(\lambda, t_1 - t_2)\right| = \left|\frac{< E_1^*(\lambda, t_1)E_2(\lambda, t_1) >}{\sqrt{< |E_1(\lambda, t_1)|^2 >< |E_2(\lambda, t_2)|^2 >}}\right| \quad (9)$$

The degree of coherency of the produced SC spectra at optimal parameters is verified by the numerical magnitude for coherence, which should be closest to unity. The average coherency must be close to one to strongly agree with generated SC spectra.

5. Numerical Simulations and Observations

This section is divided into three segments which describe the dispersion characteristics of the proposed fiber and help in optimizing the parameters like r_1, p_1, p_2, p_3. A deep understanding of effective mode area and nonlinearity is also realized from this section. Numerical simulations for SC and corresponding observations are reported in the concluding segment.

5.1.Evaluation of Dispersion Characteristics

The normal and anomalous region's realization is obtained from the respective PQF's dispersion characteristics, which was displayed in fig. 2. The respective characteristics also give an understanding of the operating wavelength to be used for further SC simulations. Our eventual goal is to extract a flat-top near zero dispersion by optimization of the fiber parameters. For the sake of optimizing the parameters, we have kept all the pitch parameters like p_1, p_2, and p_3 constant at 6.6 μm, 6.7 μm, and 9.5 μm, respectively, and changed the magnitude of r_1 by

0.1 µm from 2.3 µm to 2.5 µm at the initial study. It is reported in fig. 2(a) that zero dispersion wavelength (ZDW) is shifted towards lower wavelength (blue-shifted) on the increment of r_1 by 0.1 µm. At 2.3 µm, the ZDW falls at 3870 nm, but when we increase the parameter r_1 by 0.1 µm, the ZDW begins decreasing by 50 nm. Therefore, it is concluded that influencing the magnitude of r_1 can vary the dispersion to a larger extent. In the second stage of the study, shown in fig. 2(b), we influenced the parameter p_1 by keeping constant magnitudes for r_1, p_2 and p_3 as 2.4 µm, 6.6 µm and 9.5 µm. The observation shows that on increasing the p_1 by 0.2 µm, from 6.4 µm to 6.8 µm, the ZDW is red-shifted from 3740 nm to 3910 nm. The same

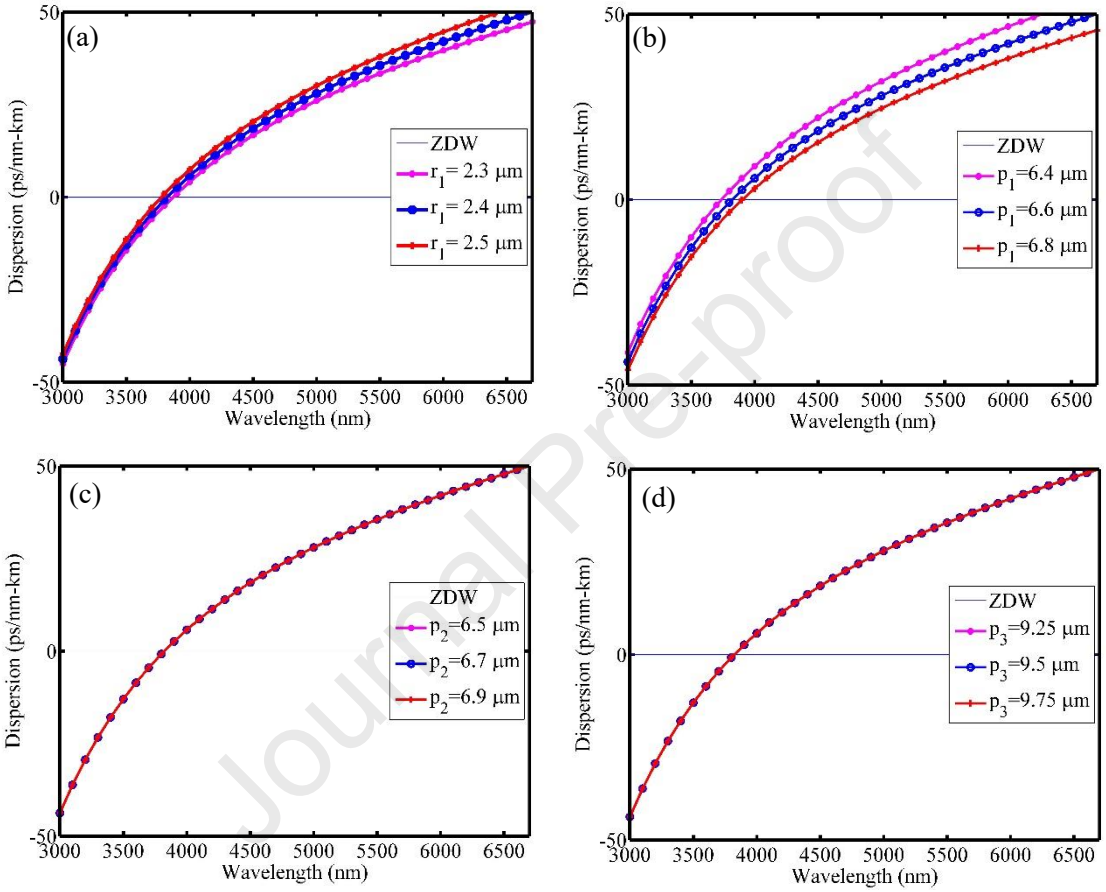

Fig. 2. Dispersion Characteristics on influencing (a) r_1 (b) p_1 (c) p_2 (d) p_3

statement concludes that affecting the p_1 can also influence the ZDW at a higher rate. Now, we set the parameters like r_1, p_1, and p_3 constant at 2.4 µm, 6.6 µm, and 9.5 µm and changed the measure of the second pitch parameter p_2 by 0.2 µm from 6.5 µm to 6.9 µm shown in fig. 2(c). The observation displays no change in ZDW on influencing the value of p_2. Similarly, we have extracted dispersion data by changing the value of p_3 from 9.25 µm to 9.75 µm at the span of 0.25 µm by keeping other parameters constant. The observation is identical to the former observation and offers no change in the magnitude of ZDW displayed in fig. 2(d). This signifies that p_2 and p_3 have no influence over dispersion. Therefore, by maintaining the balance between the best dispersion argument and fabrication possibility, we have optimized our parameters, and the same is tabulated in Table I. Furthermore, from the fabrication point of view, we have influenced the optimum parameters by ± 2% and extracted the dispersion manner illustrated in fig. 3. It is noticed that only ± 30 nm (~ 0.8 %) change (with respect to optimum ZDW, i.e., 3820 nm) is observed in ZDW respectively, which does not influence our ZDW highly. Our

resultant SC data will also be unaffected by this minor change. In the accordance to our calculated ZDW value, we have chosen our central wavelength as 4 μm, which lies in the anomalous region having a small magnitude of dispersion i.e., 6.5 ps/nm-km. A mode-locked thulium-based femtosecond laser operating at 4 μm can be used for this simulation [43]

Table I
Optimized PQF Parameters

	Radius of air holes (r_1)	1st Pitch (p_1)	2nd Pitch (p_2)	3rd Pitch (p_3)
PQF Parameters	2.4 μm	6.6 μm	6.7 μm	9.5 μm

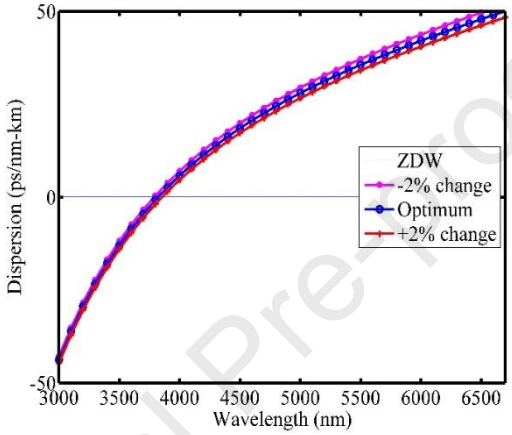

Fig. 3. Tolerance study of parameters at ±2% deviation

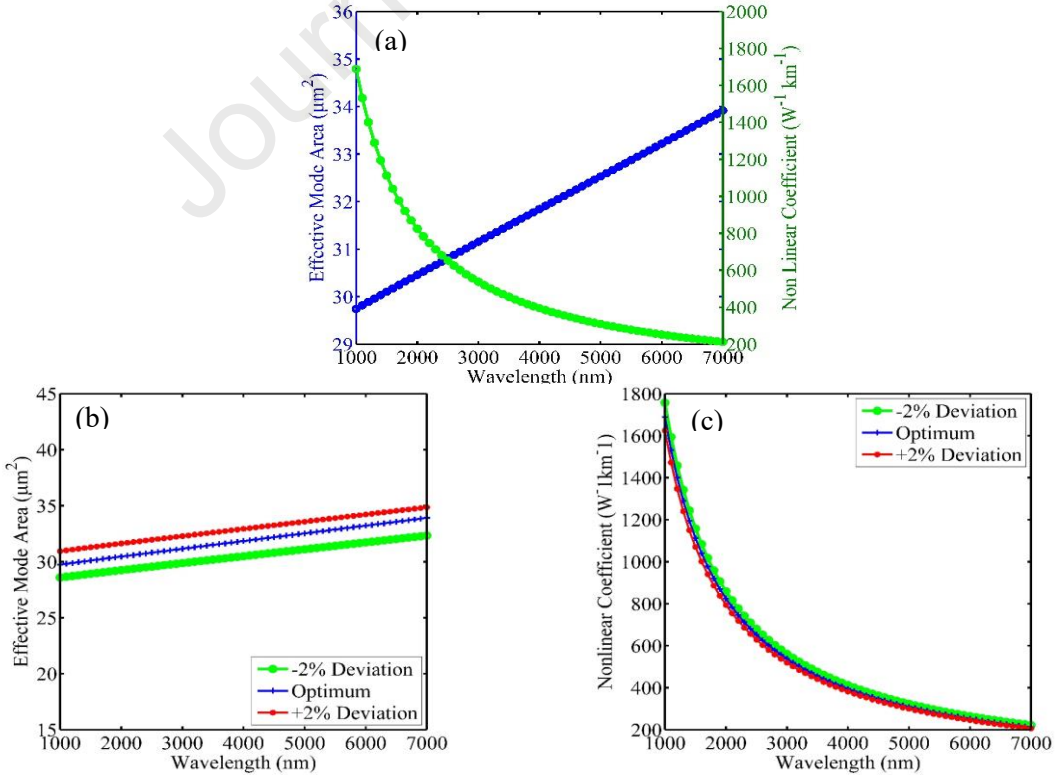

Fig. 4(a) Study of Effective Mode Area (EMA) and Nonlinearity at optimized parameters with the change of wavelength
(b, c) tolerance study of EMA and nonlinearity at ±2% deviations

Journal Pre-proof

5.2.Evaluation of Effective Mode Area and Nonlinearity

The estimation of effective mode area (EMA) and respective nonlinearity is displayed in Fig. 4(a). The figure concludes that EMA keeps increasing with the increment of wavelength, and the corresponding nonlinearity decreases as the wavelength increases. At 3.8 μm (ZDW at optimized parameters), the magnitude of EMA is 31.7 μm^2, and nonlinearity attains a larger value of 417 $W^{-1}km^{-1}$. The tolerance study is also done by variating the parameters by ± 2% and the same is displayed in fig 4(b, c). It is observed that ~3 % change is observed in the effective mode area (with respect to EMA at optimized parameters, i.e., 31.7 μm^2) and the respective nonlinearity observed the change of ~3% with respect to nonlinearity at optimum parameters. The same PQF may be fabricated by method of extrusion or drilling in future times [44, 45]. Compared to silica glass, the extrusion method allows for more flexibility in the creation of PCFs/PQFs derived from chalcogenide glasses and can withstand high dopant concentrations. This allows for easier modifications to the mechanical and optical properties of the material.

5.3.Evaluation of Supercontinuum Generation

For the generation of wide-band SC, a secant hyperbolic pulse is considered as the input pulse, and the corresponding pulse is expressed as:

$$U(z=0,t)=\sqrt{P_0}sech\frac{T}{T_0} \tag{10}$$

The numerical investigations were done by solving the GNLSE using the split-step Fourier method. The input pulse evolution in the PQF suffered a symmetric type broadening at the initial stage due to the participation of phase-matched conditions like SPM, dispersive effects, and other nonlinearities. At the later stage, the pulse broadening is the outcome of higher-order solitons generated in the PQF due to anomalous-region pumping. The appropriate action of the nonlinearities is clarified by calculated values of the distinct time scales tabulated in Table II, such as nonlinear length, dispersion length, soliton fission length, and order of solitons.

Table II
Length scales and other nonlinear parameters

Length Scale/ Parameter	Formula	Calculated Value
Peak Power	P_0	20 kW
Pulse Width	T_{FWHM}	50 fs
Pulse Duration	$T_0=\frac{T_{FWHM}}{1.763}$	28.3 fs
Group Velocity Dispersion	β_2	4.7359×10^{-2} ps^2/m
Nonlinear Length	$L_{NL}=\frac{1}{\gamma P_0}$	0.127 mm
Dispersion Length	$L_D=\frac{T_0^2}{\lvert\beta_2\rvert}$	16.91 mm

Soliton Order	$N = \sqrt{\frac{L_D}{L_{NL}}}$	≈12
Soliton Fission Length	$L_{fs} = \frac{L_D}{N}$	1.41 mm

From Table II, clear conclusions are drawn that after the propagation for 0.127 mm, nonlinear effects begin to act on the input pulse propagate over the proposed PQF, and dispersive effects get the participation at a fiber length of 16.91 mm. Since we are working on an anomalous region, the soliton fission length is also calculated, and the magnitude arrived at 1.41 mm, which gives a clear understanding of the position at which soliton fission will begin. The respective order of solitons is also calculated. Therefore, we begin our investigations by changing the fiber length beginning from 1 mm, and the same is displayed in Fig 5.

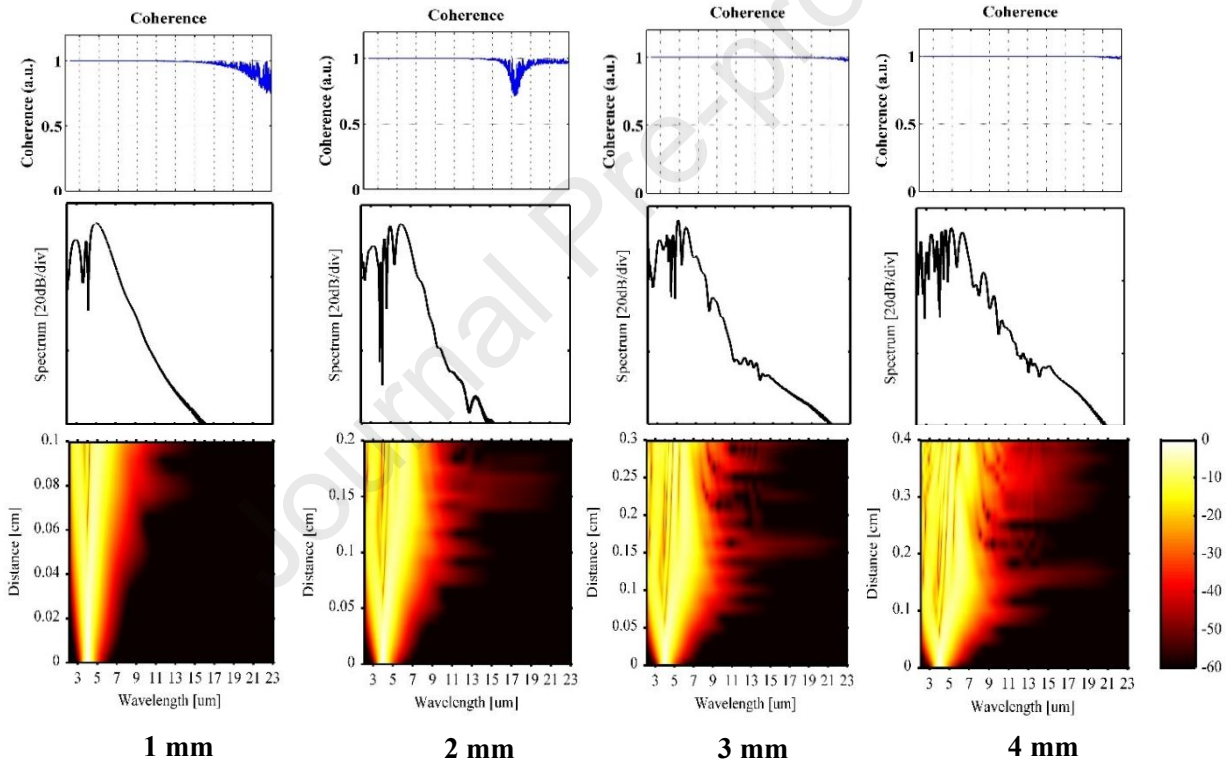

Fig.5. Numerically Simulated SC spectra at different fiber lengths at 4 μm pumping
(Top-Bottom) Coherence, Line Plot, Spectral Plot

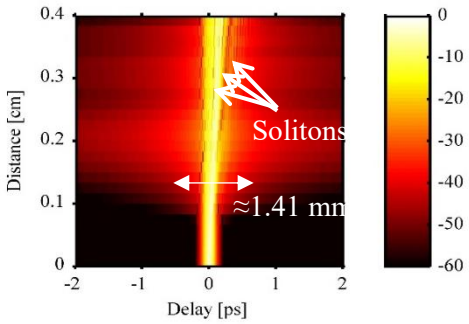

Fig. 6. Generation of solitons and soliton fission after traversing soliton fission length

It has been noticed that the SC spectra are broadened with the increment of fiber length. Till 4 mm, it kept on broadening with a highly coherent nature. Since 4 mm is greater than our calculated nonlinear length, nonlinear effects have started to act and ultimately broaden the band. Self-phase modulation is the reason behind such widening, which is due to the domination of SPM over dispersive effects, as the fiber length is smaller than the calculated dispersion length.

After propagating 1.41 mm (soliton fission length), the higher-order solitons started to break down into fundamental solitons displayed in fig. 6. The corresponding solitons suffered from a red shift due to the action of Raman-self frequency transfer. At the final stage of all the nonlinear actions, our SC spectrum is generated having the range of 2-21 μm (at 60 dB power level) devised with a highly coherent nature.

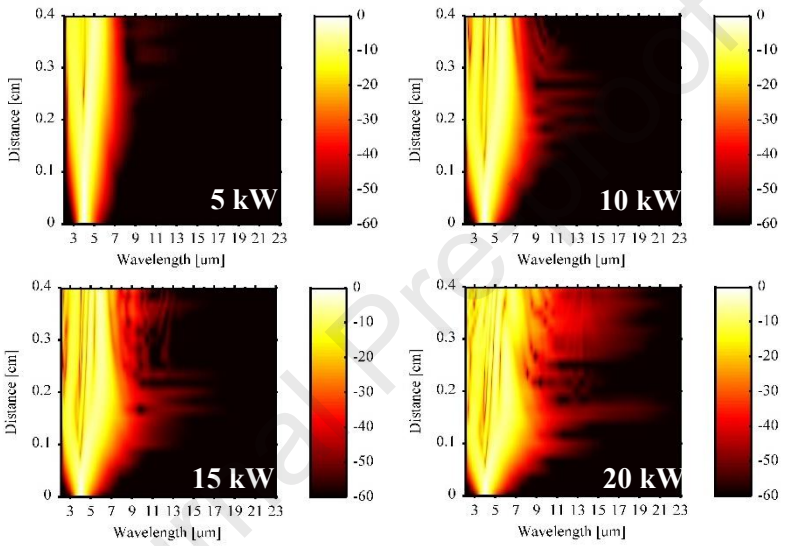

Fig. 7. Numerically Simulated SC spectra at different peak powers at 4 mm length of fiber

In the following study, we have influenced the peak power of the input pulse with a constant fiber length of 4 mm and pulse width of 50 fs. The results are exhibited in Fig. 7. Since nonlinear length is inversely proportional to the peak power, the subsequent increment in peak power results in a decrement in the nonlinear length and correspondingly increases the bandwidth of SC in a very short fiber length. Therefore, on increasing the peak power up to 20kW, the spectra keep on broadening. However, after 20 kW, the resulting spectra turn out to be noisy and disrupt the coherency. Therefore, we have taken peak power 20kW as our ideal operating peak power. Since dispersion length is directly proportional to pulse width,

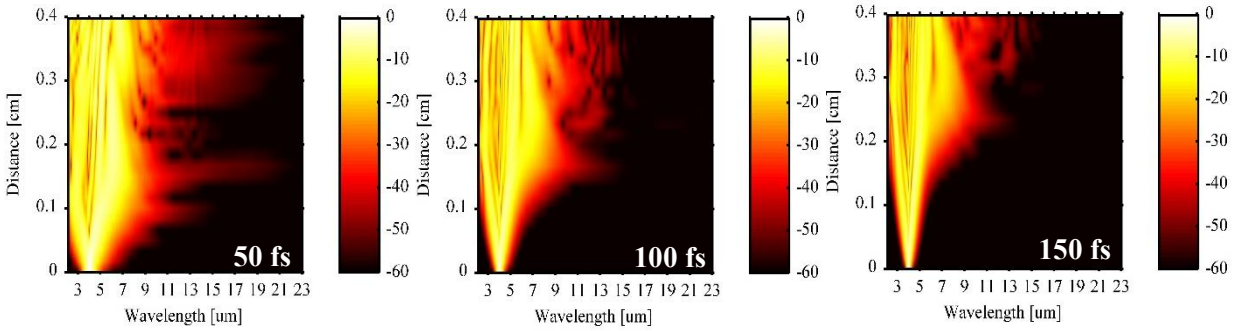

Fig.8. Numerically Simulated SC spectra at different pulse width at 4 mm length of fiber with peak power of 20 kW

escalating the magnitude of pulse width automatically increases the dispersive length, which ceases the wide-band SC at a smaller fiber length shown in fig. 8. Nonlinear length is independent of pulse width. The time-delayed components are clearly observable at FROG

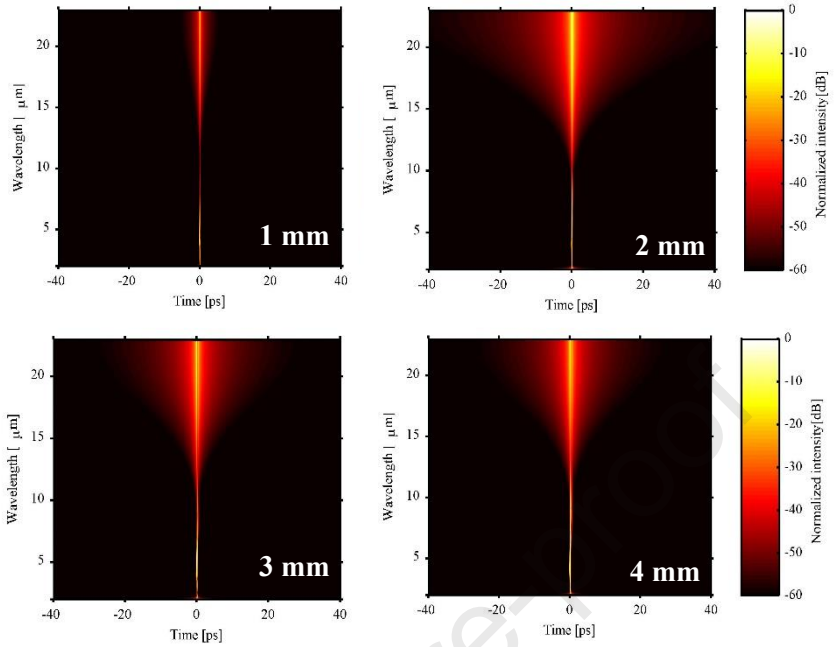

Fig. 9. Time-Wavelength FROG spectrogram

spectrograms manifested in fig. 9. The information about pulse shape, variation in optical pulse, and frequency chirp can be gathered from FROG spectrograms.

After performing all the studies, the conclusion can be drawn that at the input of femtosecond laser having a wavelength of 4 μm, a wide band spectra of 2-21 μm is extracted at 20kW peak power and 50fs pulse width in the fiber length of 4 mm. Due to the small fiber length and moderate peak power, the proposed Penrose-based PQF can be a perfect candidate for performing SCG and a better counterpart for applications like optical metrology (OM), OCT, etc.

Table III
Comparison of extracted results with previously done works

Sr. No.	Material & Fiber type	SCG spectra	Broadening	Peakpower & Fiber Length	Ref.

6. Conclusion

In this proposed work, we have designed a Penrose-based PQF containing air holes of the same magnitude. The distribution of air holes does not inherit any translational symmetry among them but exhibits eight-fold rotational symmetry. We have calculated the dispersion characteristics of our proposed PQF, which delivers a flat-top dispersion model inheriting ZDW at 3.8 μm. Furthermore, we have also calculated the effective mode area having a magnitude of 31.7 μm^2 and respective nonlinearity having a magnitude of 417 $W^{-1}km^{-1}$ at extracted ZDW. We have adopted 4 μm as our pump wavelength, which falls in the anomalous region, and successfully demonstrated wide-band spectra of 2-21 μm at a peak power of 20kW and pulse width of 50 fs, which wraps the transparency range of the proposed material and Mid-IR range very efficiently. The same observation is generated at the very small length of fiber, i.e., 4 mm, which is the key highlight of our work. Apart from these demonstrations, we have also done the tolerance study by changing the measurement of parameters by ±2%, which is a very important aspect from the fabrication point of view. The generated wide-band SC opens the doors for the Penrose-based PQF for the Mid-IR applications such as optical metrology, optical coherence tomography, etc., and can be exploited to become a perfect candidate for nonlinear applications.

Journal Pre-proof

Highlights

- The Penrose-based Photonic Quasi Crystal Fiber is proposed for the first time for Supercontinuum (SC) Generation.
- The GST based-$Ge_{20}Se_{70}Te_{10}$, a non-toxic, Arsenic-free highly nonlinear chalcogenide glass is used for the PCF composition.
- A wide band of SC (2-21 μm) is generated at moderate peak power (~20 kW), which is very less as compared to previous Te-based chalcogenide PCF which had utilized 200 kW of peak power.
- The broadband extracted SC is able to wrap the proposed material's transparency range (2-25 μm) and also covers the Mid-IR range simultaneously.

***Abstract*—In recent times, both social media platforms and researchers have been working to identify hateful language using large language models. However, none of these efforts have focused on using instruction-based fine-tuning with explanations and additional context information in the detection process. This research study has conducted experiments with LaMini and Google Flan-T5 models to analyze the impact of CoT prompts and explanations in zero shot and few shot settings to enhance model interpretability. The analysis reveals that on average including target information in pipeline significantly improves model performance. There is also a considerable effect of adding the explanations into the pipeline, boosting accuracy. The research findings highlight the importance of context and structured prompts in improving model accuracy, highlighting the need for responsible development and deployment of hate speech detection systems in online environments.**

***Index Terms*—Hate Speech Detection, Contextual Information, Large Language Models, Lamini Model, Google Flan-T5, Prompts**

I. Introduction

The prevalence of hate speech on modern online social media platforms has become a significant concern. More and more individuals are falling victim to online harassment, abuse, and cyberbullying, causing substantial trauma and psychological distress [1] Language has a powerful ability to spread social prejudices and stereotypes, which are frequently hidden under layers of implicit meaning rather than being explicitly stated [2] [3]. To address this troubling trend, social media platforms have implemented moderation policies to limit the spread of hate speech and abusive content. A crucial aspect of content moderation involves identifying and filtering out abusive language.

Typically, this is done by training language models on human-annotated data for classification. However, this approach comes with challenges, including the significant resources required in terms of labour and expertise to annotate such hateful content. Moreover, the process of annotation exposes individuals to disturbing material, which can take a toll on their psychological well-being. As a result, recent efforts have explored the potential of Large Language Models (LLMs) for detecting hate speech [4]. Interestingly, studies on intersection of hate speech detection and LLMs have not yet deeply examined the role of additional contextual information as input or output to LLMs. For LLM systems, attempting to negotiate the complex web of social relationships, the identification and understanding of hate biases are critical needs because a lack of these can lead to the deployment of harmful technologies [3]. This suggests a potential avenue for further research in enhancing the effectiveness of LLMs in combating hate speech online.

This research focuses on hate speech detection—an effort to identify (online) language that manifests biases and stereotypes in harmful ways. This task commonly requires generating a comprehensive full-text explanation alongside a classification for human content moderators to review.

Remarkably, this explanation-seeking is consistent with current advances in the field of LLMs [5] [6]. Typically, task-specific instructions and/or demonstration examples are used to urge these models during their evaluation in the zero-shot or few-shot scenario. The few-shot prompting technique takes advantage of in-context learning, in which models ”learn” to improve their decision-making in response to the context that they are given. Although this approach has shown results, a current research line along similar lines suggests that adding explanations to the prompting process can further improve these models' in-context performance [7].

Explanations give information structure and logic, which helps the models analyse data more logically and enable better decision-making. Pre-answer chain-of-thought (CoT) reasoning and post-answer explanations are the two main approaches to integrating explanations. The former has demonstrated potential in challenging tasks requiring iterative reasoning, such as arithmetic and logical reasoning [8]. It generates intermediate reasoning steps prior to the final predictions. On the other hand, the latter produces answers ahead of the explanations that go along with them. This has been shown to improve few-shot learning in LLMs by creating a

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:37:23 UTC from IEEE Xplore. Restrictions apply.

more abstract reasoning process, which positively alters task inference [5].

Considering this, we pose the following research question: Can we prompt LLMs to reason about a potentially hateful post and subsequently produce a prediction or vice versa? In light of this, we explore whether an inductive (i.e. post-answer explanations) or deductive (i.e. CoT) approach leads to better performance on hate speech datasets with full-text annotations. To answer these questions, we use the SocialBiasFrames dataset **[3]** as our primary data source. We include both distilled versions of larger models and a full-size non-distilled model in our analysis.

II. Related Work

A. Explainable Hate Speech Detection

Hate speech detection (HSD) has attracted significant attention in recent years, with early research primarily focusing on binary classification of hateful, abusive, or toxic language [9] [10]. However, the importance of not only classifying but also understanding the model's reasoning behind HSD has become increasingly relevant, as it could enable automatic flagging or AI-augmented writing interfaces to analyse potentially harmful content with detailed explanations for users or moderators to verify [3].

The HateExplain dataset, presented by [11] includes span annotations at the word and phrase levels that record human reasoning behind labelling. They noticed that models with high performance metrics and bias scores, such BERT [12], have trouble with measures related to plausibility and explainability. Using the SocialBiasFrames dataset, [3] trained models based on OpenAI's GPT and GPT2 [13] [14] to produce implicit power dynamics in textual form and categorize a post's offensiveness. These models were effective in categorizing speech patterns that conveyed unwanted social bias, but they struggled to provide comprehensive explanations.

The LatentHatred dataset [4] [15] used ChatGPT to categorize samples and produce explanations that matched. With an accuracy of 80%, ChatGPT was highly likely to be accepted by laypeople, even in circumstances where there was 20% disagreement. The algorithm produced high-quality annotations for implicit hate speech that were on par with those provided by human annotators. This allowed users to verify the implicit hatefulness of tweets more quickly with the use of more detailed visuals. However, [16] hypothesized that the prompting approach may have a significant impact on ChatGPT's performance on HSD tasks.

B. Instruction Based Fine-Tuning

A variety of methods for training and refining models have been studied in the past [17] [18]. These methods include starting from scratch and fine-tuning them to provide intermediate reasoning stages. The use of language models to predict intermediate computational results line-by-line for Python programs was first introduced by [19], outperforming direct final output prediction in terms of performance. Following the emergence of many-shot prompting strategies as recommended in [20], [5] demonstrated the effectiveness of including explanations in addition to examples in a few-shot prompt, improving language model performance on Big-Bench assessment tasks. Notably, they highlighted the effectiveness of explanations tuned using a validation set, showcasing improvements even with untuned explanations that outperformed meticulously matched control conditions. [21] critically evaluate the cross-domain performance of fine-tuned LLMs for hate speech detection, emphasizing the importance of model fine-tuning for nuanced understanding. In another study, [22] explore zero-shot learning with LLMs for detecting hate speech, showcasing the potential of prompt-based approaches in low-resource settings.

By using few-shot chain-of-thought (CoT) prompting, [23] investigated the natural growth of reasoning abilities inside suitably large language models. Results from their research showed significant improvements in arithmetic, commonsense, and symbolic reasoning performance. Furthermore, the effectiveness of CoT prompting was examined by [7] within the framework of the Big-Bench-Hard assessment suite, which is a subset of especially difficult tasks where model performances frequently fall short of human evaluations. As seen by the Codex model code-davinci-002 [24] outperforming average human-rater performance on 17 out of 23 evaluation tasks, their results demonstrated the superiority of CoT prompting. Furthermore, these developments highlight how important instruction-based fine-tuning approaches are for enhancing the logic and performance of models.

C. Models

LaMini [25]is a set of compact, effective language models, distilled from ChatGPT and trained on a sizable dataset consisting of 2.58 million instructions. Instructions from previous datasets, including self-instruct [26], P3 [27], FLAN [28], and Alpaca are compiled into this dataset. [25] employed ChatGPT (GPT-3.5-turbo) to produce additional instructions in order to augment the dataset. The focus was on diversifying these instructions while maintaining existing human-written instructions in the prompt. After that, GPT-3.5-turbo was used to produce answers for every instruction. Following the creation of the dataset, the authors improved a number of smaller language models on the instruction-response pairs, ranging in size from 61 million to 1.5 billion, and using different architectures (encoder-decoder and decoder-decoder). The T5 [29], Flan-T5 [30], CerebrasGPT [31], GPT-2 [14], and GPT-Neo [32] sources were the five sources used to initialize these models. The proposed models achieved comparable performance to Alpaca-7B while being significantly smaller, ranging from 4.5 to 10 times fewer parameters.

III. Methodology

A. Pre-processing

For our analysis, we utilise the test split of the SocialBiasFrames dataset, originally comprising 12,578 entries. . All columns other than "post" and "offensiveYN," which contain the textual post and the associated offensiveness ratings as

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:37:23 UTC from IEEE Xplore. Restrictions apply.

annotated by a human, are removed during the first pre-processing step. We then manually aggregate posts and remove examples with empty labels. This phase involves averaging the offensiveYN scores (which range from 0 to 1) that each human annotator assigned to the post. A score of 0.5 or above indicates that the post is offensive; otherwise, it is classified as non-offensive and indicated with a ”no.” The posts are then made uniform by changing all Unicode characters to ASCII. In the end, 4691 posts are found, of which 2710 are marked as ”yes” and 1981 as ”no.”

B. Experimental Setup

Utilizing the LaMini models [25] on the resulting subset of the SocialBiasFrames dataset, we ran several tests. We also incorporated a non-distilled model—specifically, Google’s Flan-T5 variant—into our research so that our findings can be validated more broadly [30].

Four different experiments are included in our study to evaluate the performance of the models. First, we used a simple bare-bones zero-shot prompt to set the starting point for each model’s performance on the HSD task. Secondly, we investigated if using a zero-shot CoT prompt enhances the models’ performance. Thirdly, we used a few-shot prompt with post-answer explanations to examine if the models could learn from several examples. Lastly, by reversing the explanation and prediction’s sequence, we investigated the differences between the deductive and inductive approaches. We only used 4 shots for the latter two prompts because any more would have filled some models’ context windows.

The perplexity score, a gauge of how ”surprised” a model is to receive a particular input, affects how successful a prompt is [33]. We developed a “seed prompt” for the HSD task in accordance with [33] which was utilized to prompt the gpt-3.5-turbo model to produce potential variants. The prompt with the lowest perplexity was chosen as the first ”Question” in our prompts after the perplexities of each version and the seeds themselves were computed. We used beam search with a beam size of three for decoding. In order to prevent repetitive outputs, we also disabled early halting and made sure the output didn’t contain the same bigram twice. Owing to computational limitations, the explanation that the model produced could only contain a maximum of 100 tokens. The test was conducted through multiple iterations to train the model on context with the assistance of prompts, including instruction-based fine-tuning. The total computation time for all models exceeded 200 GPU hours.

C. Instruction Tuning through Prompts

The prompts we employed for each of the four strategies are displayed below in **Fig.1 - 4**. The post to evaluate is used in place of {post} at runtime.

D. Evaluation

The advantages of post-answer explanations were emphasized by [5] since they do not interfere with the evaluation pipeline. This is so that we may save computational resources

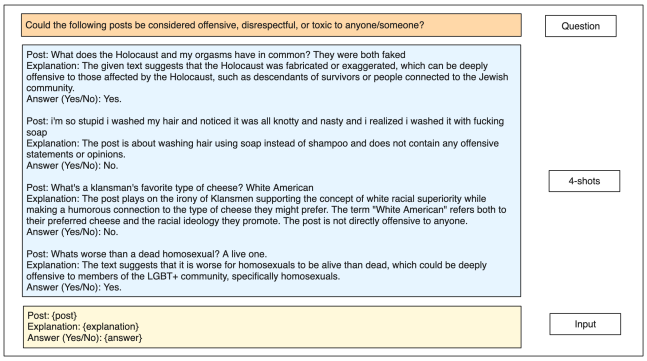

Fig. 1. default_4shot_cot_expl_first Prompt

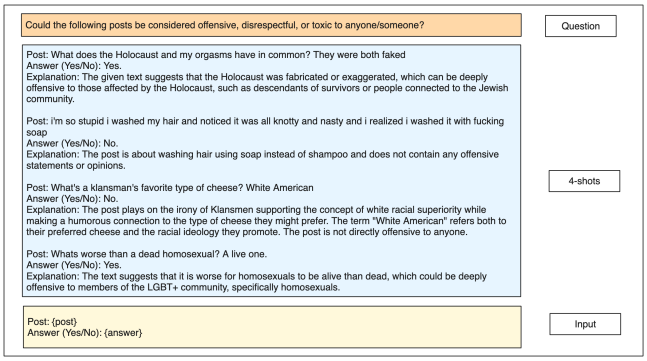

Fig. 2. default_4shot_cot_ans_first Prompt

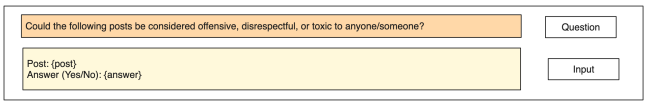

Fig. 3. default_0shot_no_cot Prompt

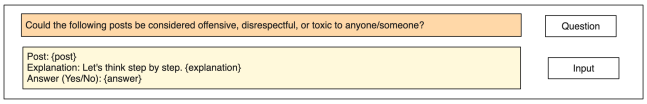

Fig. 4. default_0shot_cot_expl_first Prompt

by stopping computation after the first token is generated. In contrast, pre-answer reasoning chains need the assessment function to extract the solution from the model’s output, which adds complexity to the evaluation process. We use the two-step prompting approach suggested by [8] to handle this. We first entered the prompts into the model for each chain-of-thought prompting approach up until the {explanation} marker. Then, to produce a ”yes” or ”no” prediction, we replace {explanation} with the entire generated content of the model and enter the prompt up to {answer} again into the model. We basically employ the “reasoning” prompt as a tool to extract a comprehensive explanation from a language model. Subsequently, the “answer” prompt is utilised to extract the final response as shown in Fig. 5 Prompt pipeline. Using a SoftMax function, the output logits for the positive and negative classes were normalized and compared during the evaluation process. The language tokens for the positive class were [”Yes,” ”yes,” and [”No,” ”no”]. The tokens for the negative class were [”No,” ”no.” The label ”yes” was applied if the likelihood of the affirmative class was more than 0.5; if

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:37:23 UTC from IEEE Xplore. Restrictions apply.

not, the label ”no” was applied.

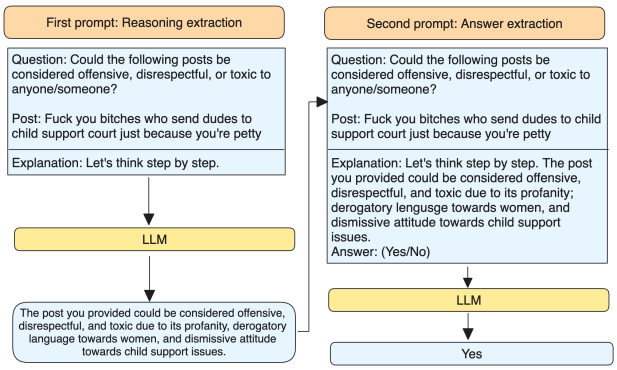

Fig. 5. Prompt Pipeline

By undergoing multiple runs on the LLM, we ensured a rich contextual understanding, crucial for accurate response generation. Furthermore, prompts served as navigational cues, aiding the model in focusing on relevant details and improving hate speech detection. This iterative refinement of prompts significantly boosted the model's performance, ensuring a deeper comprehension of the input data and improving its ability to identify and classify instances of hate speech accurately. Moreover, we calculated the average of the top three accuracies from these runs to conduct a thorough analysis of the model's effectiveness in hate speech detection tasks.

IV. Result and Analysis

Tables I - VI present the performance metrics of various LaMini and Google Flan-T5 models on the Hate Speech Detection (HSD) task across different prompting strategies and shot settings.

Starting with the 0-shot baseline, we observe that most models demonstrate improved performance compared to a ”constant” model that always outputs the same class. Notably, LaMini-Cerebras-256M and LaMini-Neo-125M consistently exhibit high accuracies across all prompting strategies, with a increase of 16.1% and 6.45%, respectively, when utilizing CoT compared to the baseline. Google Flan-T5-base model witnesses a notable 8.6% accuracy increase when incorporating CoT, highlighting the impact of contextual prompts in improving model performance.

Transitioning to the 4-shot settings, LaMini-Cerebras-256M and LaMini-Neo-125M continue to demonstrate strong performance, with both models experiencing moderate accuracy improvements of 24.1% and 22.5%, respectively, when employing the explain-first prompting strategy. LaMini-Flan-T5-248M and LaMini-T5-223M models display substantial accuracy boosts of 37.03% and 42.3%, respectively, with the post-answer explanation strategy, underscoring the efficacy of this approach in enhancing hate speech detection capabilities.

Moreover, the graphical representation of these results in Fig. 12. visually emphasizes the impact of different prompting strategies on hate speech detection accuracy across various LLM models. The trends depicted in the graph further reinforce the significant improvements observed from baseline models, particularly with the adoption of CoT and structured prompting strategies.

The CoT prompts improve methodical thought and, therefore, improved accuracy, interpretation, and increased trust with transparency in the decision-making taken from the model predictions. It helps explain why post-hoc remains largely relevant for improving model performance while still supporting learning and decision quality in sensitive domains, among others, such as hate speech detection.

However, a few points will need some further investigation for optimization, for instance, poor quality of the dataset and computational limits. This will further be improved as even more sophisticated prompting approaches, including dynamic prompts from domain-specific data, and finer tuning with larger and more diverse datasets, will be used. The continuous learning approaches are also useful in the ongoing applicability and efficacy of the identification of hate speech.

V. Conclusion

This research study has analyzed the efficacy of Large Language Models (LLMs) in hate speech detection, exploring various prompting strategies and shot settings across LaMini and Google Flan-T5 models. The findings revealed insightful patterns in accuracy variations, highlighting the significant impact of contextual prompts and post hoc explanations on model performance. Analysing the patterns across different models and prompting strategies, we observe that contextual information, particularly when provided through CoT prompts, significantly enhances hate speech detection accuracy across different LLM models. Moreover, post hoc explanations emerged as a valuable tool for improving model interpretability and guiding the decision-making process, leading to substantial accuracy improvements in certain configurations.

ABSTRACT

Floodplains in natural rivers are curved and narrow, rather than following a straight path and the presence of vegetation and varying depth of flow affects the flow parameters of the channels. The purpose of this study is to investigate the effects of the convergence of the channel and relative depth of flow on the depth-averaged velocity (DAV) and boundary shear stress (BSS) of a converging compound channel. The effect of vegetation on DAV and BSS was also deliberated. To examine the effect of vegetation, synthetic grass 8 cm in height was used as a flexible vegetation to depict the natural conditions of the rivers. The DAV was calculated using an acoustic Doppler velocimeter (ADV) and the measurement of BSS was done using the Preston tube technique. After analysing the data, it was revealed that as the convergence of floodplains increases, maximum DAV increases. The presence of vegetation reduces the velocity specifically at lower flow depths. BSS increases with the convergence as well as vegetation. This research provides valuable data and results which will be helpful in better flood management, river restoration, and designing effective hydraulic structures.

Key words: boundary shear stress, compound channel, convergence, depth-averaged velocity, flexible vegetation, relative depth

HIGHLIGHTS

- The study examines the influence of channel convergence across various flow depths on depth-averaged velocity and boundary shear stress within a compound channel.
- Synthetic grass (flexible vegetation) is utilized to mimic natural vegetation, offering insights into vegetation's influence on flow parameters.
- The study's findings provide valuable insights for enhancing flood management, river restoration, and hydraulic structure design.
