floods are the most frequent and often devastating (Alam & Muzzammil 2011). With the substantial changes in the global climate, growing urbanization, and land use, the dynamics of flooding are changing in ways that are complicated and unprecedented. Understanding river hydraulics is a crucial initial phase in the examination and management of floods. Determining flow discharge in rivers is a crucial aspect of designing river engineering projects (Azamathulla & Zahiri 2012). When assessing flood damages, it is essential to analyse the flow parameters in both the main channel and the floodplains (Pandey *et al.* 2022). By delving into these flow parameters, researchers and flood management authorities can gain a deeper understanding of the mechanisms at play, facilitating a more accurate assessment of the potential damages and aiding in the development of effective mitigation strategies.

Due to increased urbanization and changes in land use patterns, many natural watercourses differ from the uniform prismatic shape, although prismatic compound channels with uniform cross-sections have been the subject of several classic hydraulic research (Khatua *et al.* 2012; Proust *et al.* 2013). To handle these systems effectively, one must have a clearer understanding of their inherent non-prismatic complexity. The previous studies (Bousmar *et al.* 2004; Proust *et al.* 2006; Rezaei & Knight 2011; Yonesi *et al.* 2013; Das & Khatua 2018) reveal that flow parameters in compound channels with non-prismatic floodplains are considerably more complicated than that in prismatic channels. The investigation of flow in prismatic channels is a well-explored topic in current research. In the design phase, crucial parameters such as turbulent characteristics, conveyance capacity, mean flow pattern, distribution of depth-averaged velocity (DAV), secondary flow features, and boundary shear stress (BSS) play a significant role. Hydraulic engineers often rely on experimental research to gain insights into the complex flow parameters involved when examining turbulent flows in open channels. This complexity escalates when the floodplain is non-prismatic inducing mass transfer. The flow velocity decreases on spreading floodplains, while it increases on converging floodplains due to the convergence of channel shape, as observed in studies conducted by Rezaei (2006). Rezaei & Knight (2011) conducted experiments on compound channels with symmetrically narrowing floodplains, emphasizing the geometric transfer of momentum and the resulting additional head losses.

Many natural rivers display a two-stage geometry, and floodplains feature diverse roughness elements, including various sizes of gravel, vegetation, and combinations of these elements. Analysing the flow parameters becomes more challenging as the flow enters its floodplains.

Vegetation, including submerged, emergent, and floating types, significantly influences the flow characteristics within a channel. The introduction of vegetation elements adds complexity to the flow structure in non-prismatic compound channels. Brito *et al.* (2016) and Yang *et al.* (2007) conducted experimental studies to explore how vegetation impacts the three-dimensional flow properties. The presence of vegetation in floodplains not only alters the hydraulic capacity of compound channels but also impacts river ecosystems, influencing flow attributes like velocity distribution, turbulence patterns, vortices, and the exchange of mass and momentum between vegetated and non-vegetated zones (Nezu & Sanjou 2008; Uotani *et al.* 2014). Numerical simulations have been employed by numerous scholars, including Zhang *et al.* (2017) and Koftis & Prinos (2018) to investigate the characteristics of turbulent flow patterns within vegetated channels. Most of the research on vegetated floodplains has primarily concentrated on straight compound channels, while there is limited literature on compound channels with vegetation on diverging and converging floodplains (Mehrabani *et al.* 2020; Rahim *et al.* 2023). In previous studies, rigid vegetation models have been used by several researchers in their studies of compound channels (Rahim *et al.* 2022; Rao *et al.* 2022; Zhang & Hu 2023). However, it is important to note that in the natural river systems, flexible vegetation is prevalent. The fundamental distinction between rigid and flexible vegetation types can have significant implications for our understanding of how compound channels interact with their surrounding environments. It is crucial to investigate the impact and dynamics of flexible vegetation within compound channels. This article aims to bridge the gap between theoretical research and the actual conditions present in natural river ecosystems. Moreover, flexible artificial plants have been used to simulate floodplain vegetation in compound channels, and flume experiments have produced results similar to field observations (Huai *et al.* 2013; Liu *et al.* 2016). Previous studies have identified several unexplored aspects and gaps regarding vegetated floodplains in non-prismatic compound channels.

This article investigates the flow parameters in a converging compound channel with vegetative floodplains, the focus is on comprehending the flow physics under converging floodplains, considering flexible vegetation at various flow depths.

EXPERIMENTAL SET-UP

Experiments were conducted at the Hydraulics Laboratory of the Department of Civil Engineering, Delhi Technological University, using a symmetrical compound channel of dimensions 12 m long, 1 m wide, and 0.8 m deep. The cross-sectional width of the main channel (b) was 0.5 m and the depth (h) was 0.25 m. The converging segment of the channel had a convergence angle (θ) of 4°. The whole set-up was constructed with brick masonry and plastered with concrete to provide a smooth surface finish. The compound channel comprised a 6 m long prismatic section and a 3.6 m long non-prismatic section and a downstream portion as presented in Figure 1. To represent the flexible vegetation in the floodplains, the flume's bottom was covered with synthetic grass, with an average height of 8 cm as presented in Figure 2.

METHODOLOGY

The flume was operated at six different relative flow depths ($\beta = 0.20, 0.30, 0.35, 0.40, 0.45, 0.50$). The discharge in the channel varied with the relative depth.

$$\text{Relative depth } (\beta) = \frac{H - h}{H} \tag{1}$$

where H represents the water height at a specific section and h indicates the height of water in the main channel.

The relation between discharge (Q) and relative depth (β) is presented in Figure 3. Totally five sections termed Section 1, Section 2, Section 3, Section 4, and Section 5 were selected for the study as represented in Figure 1. Section 1 and Section 5 denote the start and end of channel convergence, while Section 2, Section 3, and Section 4, positioned equidistantly, serve as intermediate sections. The longitudinal distance between every section is constant. Velocity and shear stress were measured

at every non-prismatic section for each relative depth. Detailed information about measuring of velocity and shear stress is given in further sections.

FLOW CONDITIONS AND MEASUREMENTS

The water was drawn from an underneath sump and pumped to an overhead tank in the testing channel. A volumetric tank fitted with a v-notch was exercised for measuring the discharge from the experimental compound channel. The v-notch was calibrated for this specific purpose, and the water was subsequently returned to the sump located underneath. To control the water surface profile and enforce a particular depth of flow in the flume portion, a tailgate was installed at the downstream end of the flume.

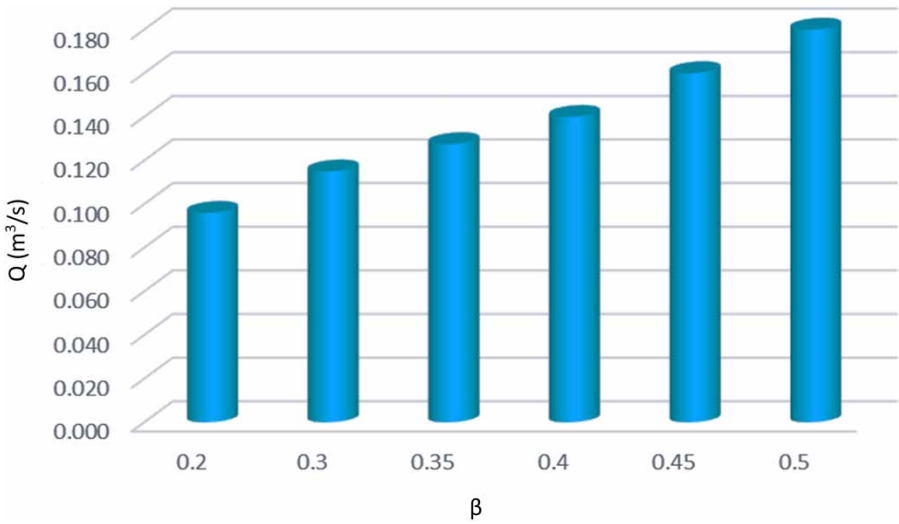

Figure 3 | Discharge vs. relative depth.

A point gauge with a precision of 0.10 mm was utilized to measure the water surface profile at distances of 1.0 and 0.30 m in the prismatic length and non-prismatic length of the compound channel, respectively. The point velocity at the pre-defined points along the wetted perimeter was determined using an acoustic Doppler velocimeter (ADV) at vertical intervals of 2.5 cm and horizontal intervals of 10 cm. The data obtained from the ADV underwent filtering using the ADV Horizon software.

The lateral variations in BSS were additionally gauged using a Preston tube featuring a 4.77 mm outer diameter at the identical sections where velocity distributions were assessed as in Figure 4. For measuring the pressure difference, a digital manometer was used, and Patel's (1965) calibration equations were used for calculating shear stress values.

Depth-averaged velocity

In this study, velocity measurements were performed using both Pitot tubes and a 16-MHz Micro-ADV. The ADV is unable to calculate velocity within 50 mm of the free surface and bed due to limitations of the instrument. To address this limitation, a standard Pitot tube with a 5 mm outer diameter was used in conjunction with a digital manometer to measure point velocity readings at specified locations within the upper and bottom 50 mm regions of the channel. Point velocities were measured at various points within pre-defined grids across the channel cross-sections to ensure comprehensive coverage of the entire flow area.

Uncorrected Proof

For every experimental configuration, velocity calculations were conducted at six different discharges, corresponding to six relative depths ($\beta = 0.20, 0.30, 0.35, 0.4, 0.45, 0.50$), at five different sections. The depth-averaged velocity (U_d) was computed using the following equation (Naghavi *et al.* 2023):

$$U_d = \frac{1}{H}\int_0^H u(z)dz \tag{2}$$

where U_d is the depth-averaged velocity; $u(z)$ denotes local velocity at z depth; and H is the flow depth.

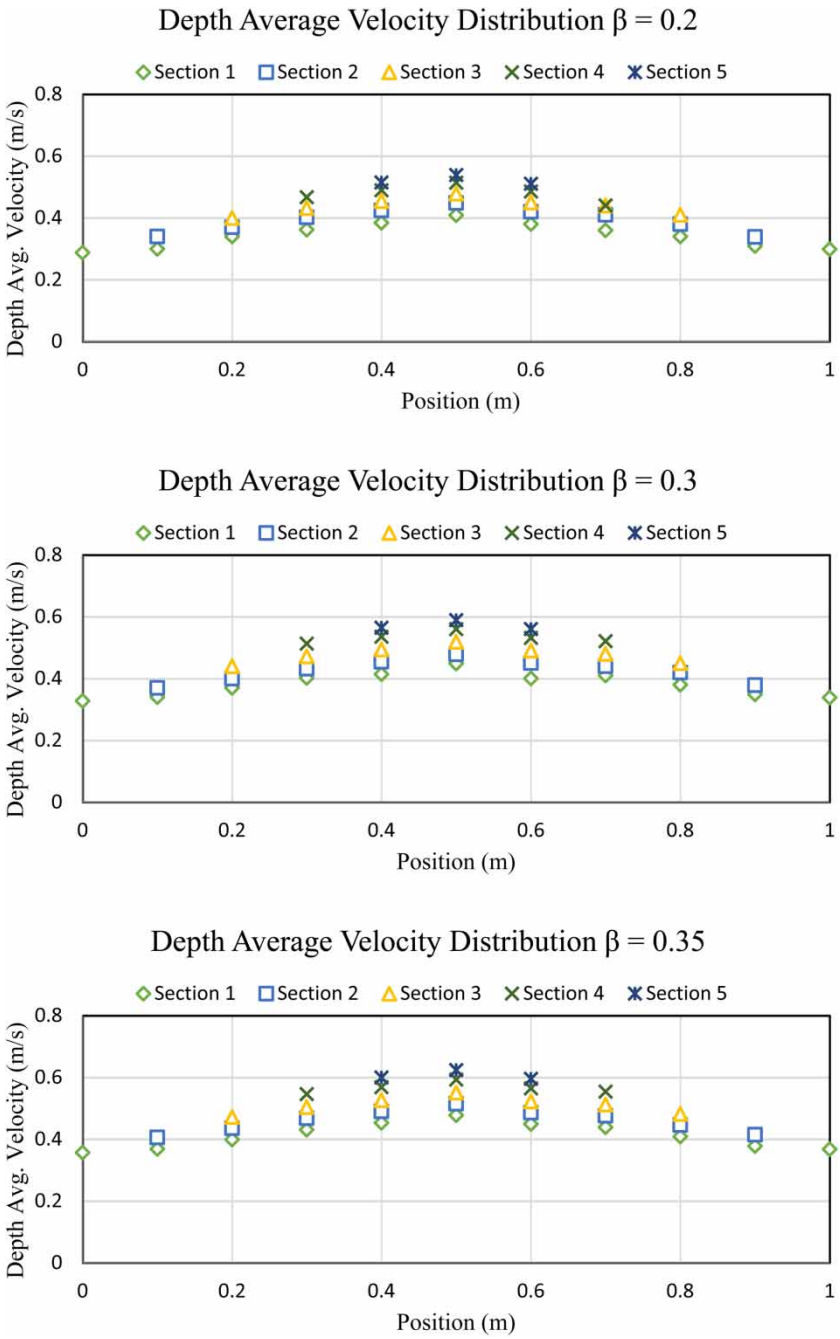

Figure 5 | DAV distribution at all six relative depths ($\beta = 0.2, 0.3, 0.35, 0.4, 0.45, 0.5$) without vegetation. (*continued.*).

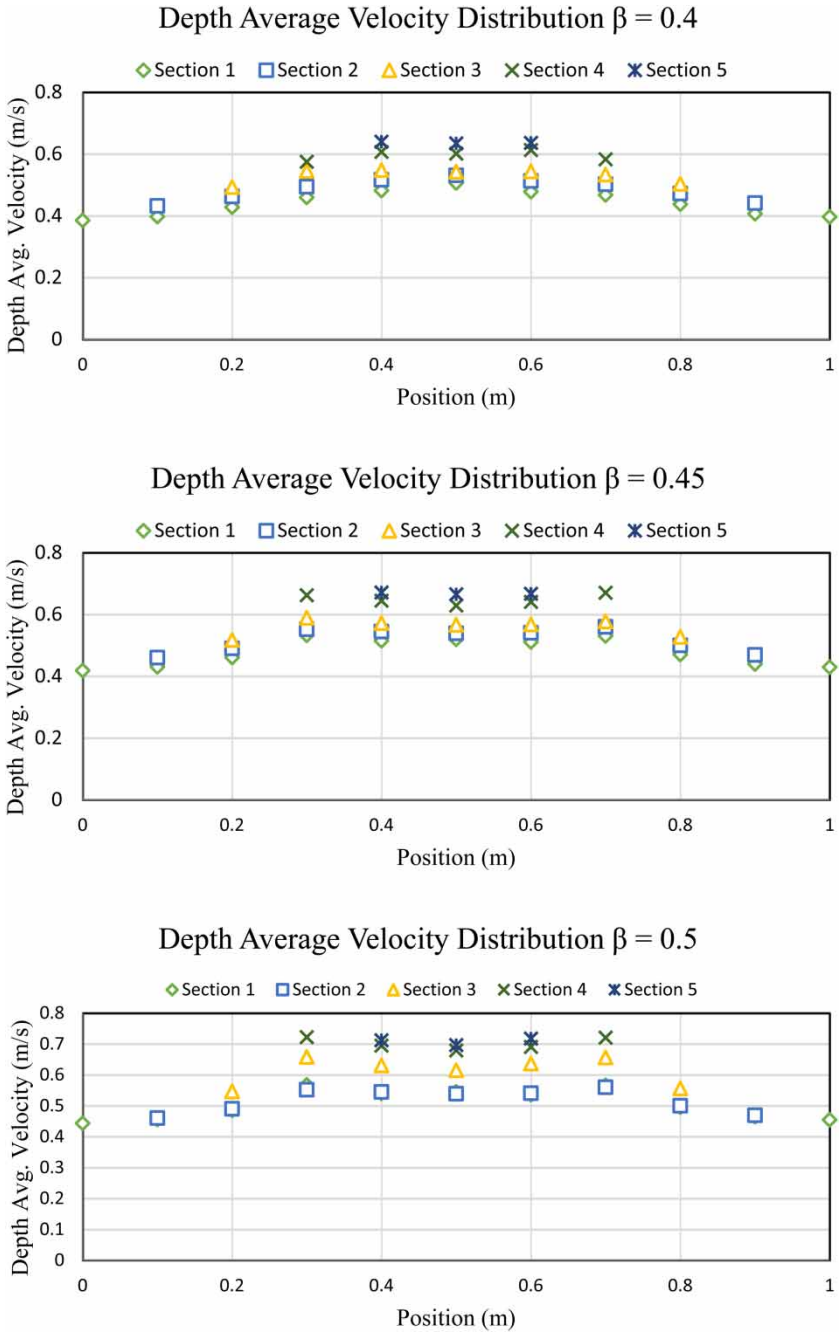

Figure 5 | Continued.

The parameter U_d is of crucial importance in compound channel flow studies. Accurate measurement of U_d and its distribution across the flow section is essential for understanding the behaviour of compound channels under varying relative depths.

Boundary shear stress

Explorations into shear stress within open channel flow carry extensive implications, impacting sediment transport, channel migration, calculation of energy losses, and momentum transfer. The Preston tube technique stands out as a widely employed indirect approach for gauging shear stress in measurements. In this study, local BSS measurements were conducted using Preston's technique (1954) in conjunction with Patel's (1965) calibration curves. The relation between BSS and differential

Uncorrected Proof

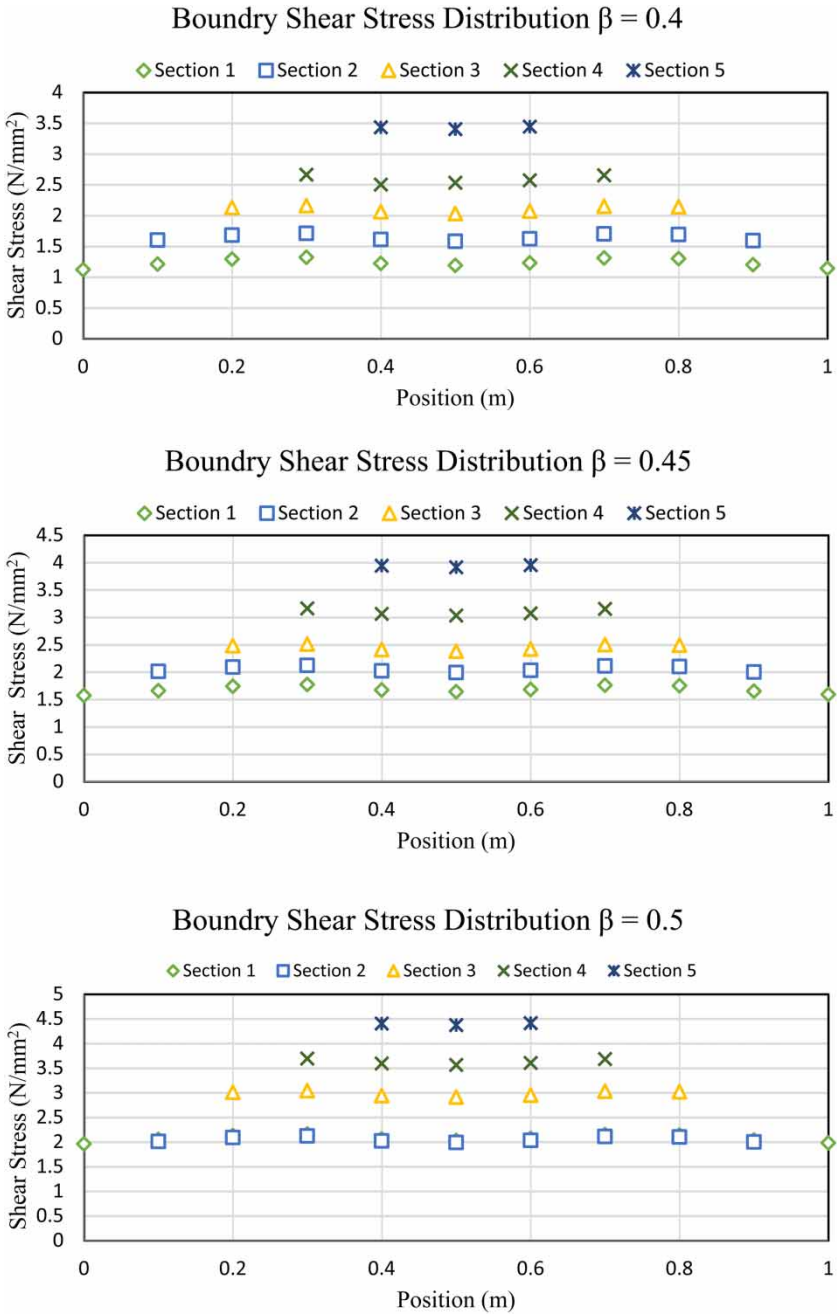

Figure 7 | Continued.

Shear stress assessments were carried out in each of the five sections of the channel. Pressure readings were obtained using a Preston tube positioned at previously defined grid points within the channel, oriented towards the flow. The differential pressure was measured using a digital manometer connected to the Preston tube.

RESULTS AND ANALYSIS

The flow is found to be non-uniform in the converging length of the channel. Subcritical flow conditions were attained under various conditions of the compound channel with a longitudinal bed slope of 0.001. The results of the DAV and BSS are discussed further in this section.

Depth-averaged velocity

The distribution of velocity across all cross-sections is illustrated in Figure 5 for all six relative depths ($\beta = 0.20$, 0.30, 0.35, 0.40, 0.45, 0.50). The observed rise in maximum average depth velocity across the channel coincides with the convergence of floodplains. There is a considerable increase in the velocity of the second half of the converging reach. The flow becomes increasingly restricted as a result of converging floodplains thus reducing the channel width, which results in momentum

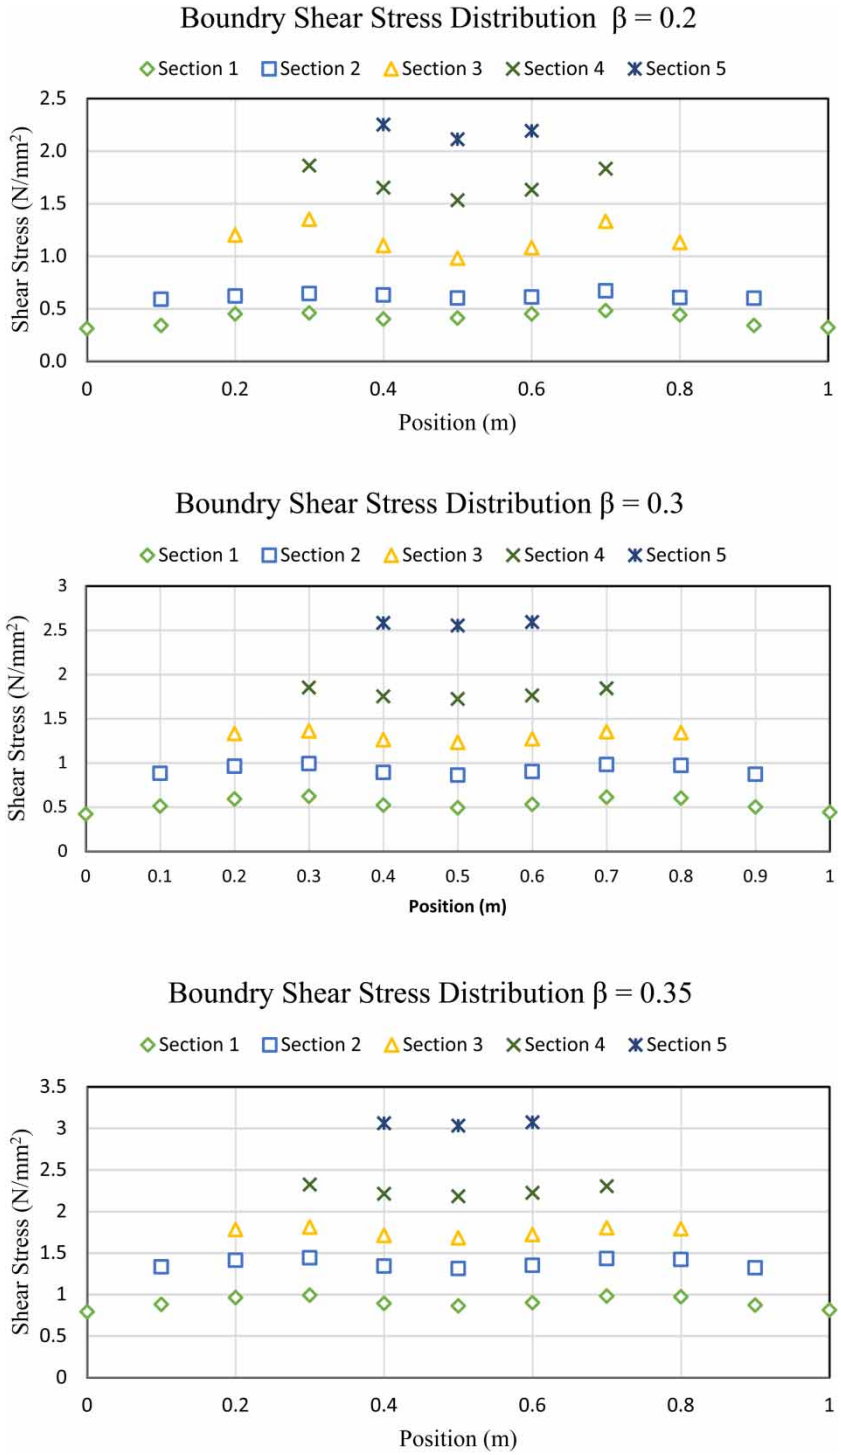

Figure 8 | BSS distribution at all six relative depths ($\beta = 0.2$, 0.3, 0.35, 0.4, 0.45, 0.5) with vegetation. (*continued.*).

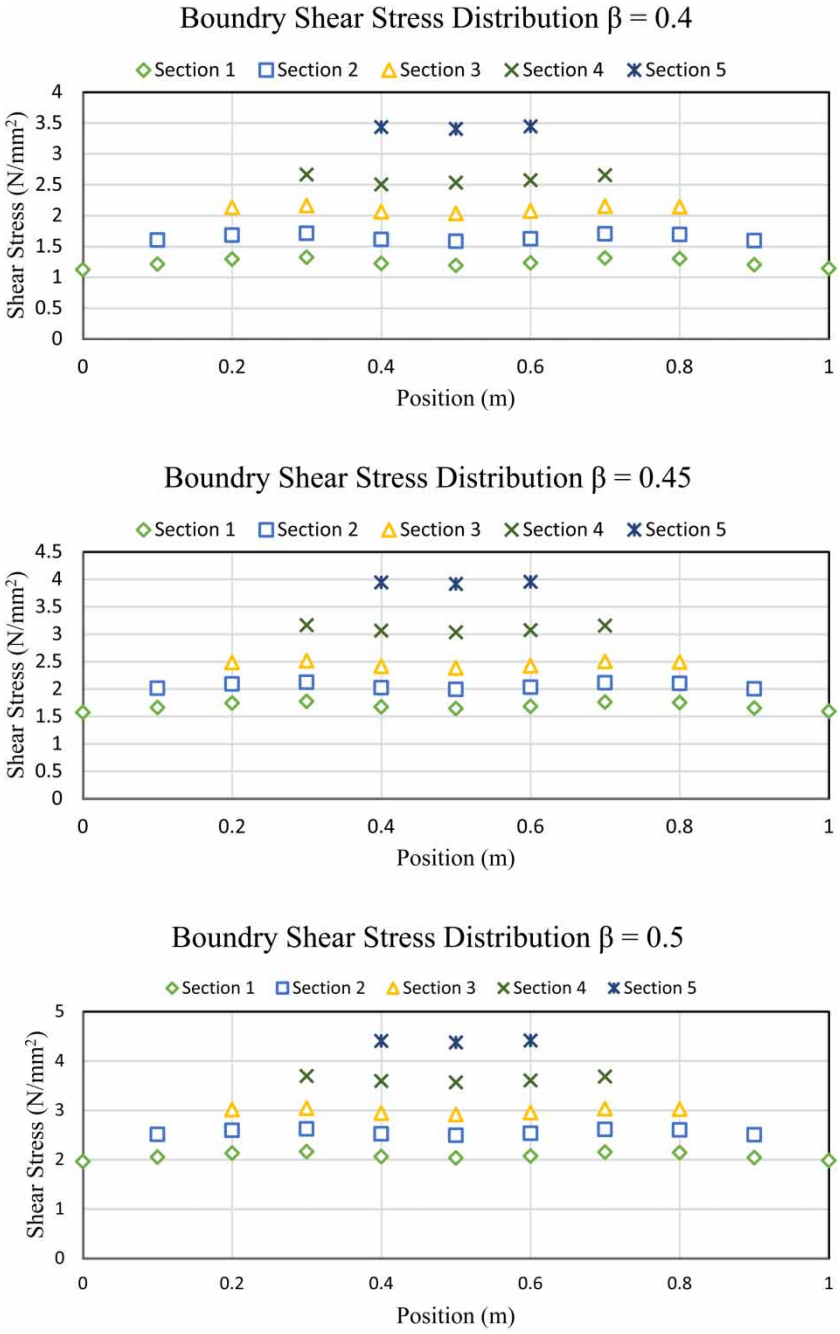

Figure 8 | Continued.

transfer. The increased velocity indicates the concentration of flow, resulting in a more efficient conveyance of water through the channel. Foreseeing the effect of channel geometry on overall velocity patterns and hydraulic efficiency in non-prismatic channels with converging floodplains becomes essential when understanding this phenomenon. Naik *et al.* (2018) conducted an experiment of overbank flow in a converging channel, exploring three convergent angles ($\theta = 5°$, $\theta = 9°$, and $\theta = 12.38°$). The study revealed that one of the results of the convergence on flow behaviour is an increase in velocity along the converging segment of the flume, aligning with the findings of the current research.

The observations of the study depicted in Figure 5 highlight that the highest velocity is typically concentrated in the central region of the main channel for the lower relative depths. The central concentration of maximum velocity in the main channel

by DELHI TECHNOLOGICAL UNIVERSITY (DTU) user

Uncorrected Proof

can be related to the fact that the highest flow velocities arise from diminished frictional resistance along this central axis. For higher relative depths, the maximum velocity shifts towards the floodplains.

Figure 6 illustrates how the flow velocity across the channel is significantly reduced when there is the presence of flexible vegetation irrespective of the relative depth in all cross-sections. It can be observed from Figure 6 that the maximum DAV in the main channel is in the centre for lower flow depths, whereas, when the flow depth increases, the maximum centre velocity shifts towards floodplains. Maximum DAV in the channel with a vegetated floodplain is lower compared with a scenario without vegetation due to the frictional resistance by the vegetation. Moreover, at higher flow depths, the decrease in flow velocity in the main channel and floodplains due to vegetation is less pronounced compared with lower flow depths. This effect of the floodplain vegetation at higher relative depths was never shown in previous studies.

Boundary shear stress

Figure 7 exhibits the experimental findings of the BSS distributions in all cross-sections without vegetation for the converging flood plain of angle 4° for all six relative depths ($\beta = 0.20$, 0.30, 0.35, 0.40, 0.45, and 0.50). The BSS distribution in all sections is logically symmetrical in these figures and progressively increases from $\beta = 0.2$ to $\beta = 0.5$. The minimum BSS is at the floodplains, whereas the maximum BSS is at the edge of the floodplain and main channel which is relatively higher than centreline shear stress along the channel as the floodplains converge. Notably, in the second half of the converging reach, there is a significant surge in BSS. This surge is attributed to the mass transfer from the floodplains into the main channel at the end of convergence.

Experimental results of the BSS distribution in all sections with vegetation for the converging flood plain of angle 4° for all relative depths 0.20, 0.30, 0.35, 0.40, 0.45, and 0.50, are presented in Figure 8. It shows similar distributions as without vegetation, but the flexible vegetation introduces additional roughness elements, causing an increase in flow resistance as water interacts with the vegetation. This increased resistance leads to higher BSS along the floodplains compared with the relatively smoother main channel.

CONCLUSIONS

The present research investigated the flow dynamics of a compound channel with converging floodplains, focusing on the impact of relative depth and flexible vegetation on flow parameters such as averaged depth velocity and BSS. The key findings of this study are as follows:

1. Converging floodplains cause a significant increase in the DAV because of channel convergence and momentum transfer which results in more concentrated flows.
2. The maximum DAV is significantly dependent on relative depth. As the relative depth increases, the DAV also increases.
3. The flexible vegetation in the floodplains causes resistance to flow which results in a significant drop in the DAV in the entire cross-section.
4. The reduced resistance of flexible vegetation at higher relative depths causes a lateral shift of the zone with maximum DAV towards the floodplains.
5. The BSS increases along the converging reach of the channel due to the convergence of the channel and momentum transfer.
6. In the presence of flexible vegetation, the BSS distribution remains similar to scenarios without vegetation. However, the introduction of flexible vegetation increases flow resistance due to additional roughness elements, resulting in higher BSS along floodplains compared with the smoother main channel.

Abstract

Background Several health insurance programmes have been launched in India to improve accessibility to healthcare services and safeguard people against health expenditure catastrophes.

Objective We studied the impact of health insurance enrolment towards accessibility, utilization of inpatient care, and safeguarding against financial risk across all states/union territories (UTs) of India.

Data and Methodology Data from the most recent round (75th round) of the nationally representative survey on health and morbidity, entitled "Social Consumption: Health," was employed in the study. The propensity score matching technique was used in the study to examine the accessibility and utilization of inpatient care, and financial risk protection in the context of health insurance across states/UTs of India.

Results The accessibility to inpatient care was statistically significantly higher among insured than uninsured in 21/32 states/UTs ($p < 0.05$). Hospitalization episodes more than once were also statistically significantly higher among insured than uninsured ($p < 0.05$). However, utilization pattern of inpatient care in terms of incidence of hospitalization with private healthcare providers and longer duration of hospital stay were not impacted much by the health insurance status. Furthermore, health insurance was statistically significantly effective in reducing both out-of-pocket health expenditure (OOPE) and catastrophic health expenditure (CHE) (at 10% threshold) for insured in a few states, namely, Assam, Uttar Pradesh, Karnataka, Maharashtra, Delhi, Punjab, Tamil Nadu, Kerala, Meghalaya, Andhra Pradesh, and Telangana ($p < 0.05$). On the other hand, in some states with good health insurance enrolment rates, including Rajasthan, Chandigarh, Goa, and Chhattisgarh, health insurance did not significantly reduce the OOPE and CHE incidence among insured in comparison to uninsured ($p > 0.05$).

Policy Implications Concerted efforts, such as increasing health insurance enrolment, raising awareness about the existing schemes and their eligibility criteria, and informing beneficiaries about the procedures to avail benefits, are required. There is also an urgent need to include outpatient services under the purview of health insurance to reduce the financial burden and make health insurance more viable. Furthermore, strengthening public healthcare facilities and regulating private healthcare providers are imperative in augmenting financial risk protection in India.

Keywords Health insurance · Inpatient care · Catastrophic health expenditure · Out-of-pocket health expenditure

Introduction

The reliance on out-of-pocket expenditure (OOPE) to finance healthcare is a common feature in many low and middle-income countries (WHO, 2014; Wagstaff et al., 2020). People lacking sufficient financial safeguards face the risk of incurring large unforeseen medical expenditures, which sometimes lead to a reduction in living standards, poverty, and indebtedness (WHO & World Bank, 2021; Rahman et al., 2022). Notably, OOPE pushes nearly 100 million people into poverty worldwide each year (WHO & World Bank, 2017).

In India, OOPE accounts for 50.6% of the total health expenditure (WHO, 2020a). Several health insurance programmes have been launched in India to improve accessibility to healthcare and safeguard people against associated financial catastrophes (Hooda, 2020). The government of India has initiated social health insurance programmes, such as Employees' State Health Insurance Scheme, 1952 (ESIS), and Central Government Health Scheme, 1954 (CGHS), to provide coverage to formal sector employees. Private health insurance is also available in India, which enables individuals to buy health insurance on their own based on their ability-to-pay premium (Hooda, 2020). Furthermore, government-sponsored health insurance (GSHI) schemes have received traction in India as a measure of risk-pooling and safeguarding against health shocks, mainly for poor and vulnerable populations (Hooda, 2020). Indian constitution has categorized health as a matter of state (Selvaraj et al., 2022); therefore, GSHI schemes are prevalent at both national (e.g., Rashtriya Swasthya Bima Yojsana (RSBY) 2008, Pradhan Mantri Jan Arogya Yojana (PM-JAY) 2018) and state levels (e.g., Rajiv Aarogyasri Health Insurance Scheme (2007) in Andhra Pradesh, Vajpayee Arogyasri Scheme (2009–2010) in Karnataka, Chief Minister's Comprehensive Health Insurance Scheme (2012) in Tamil Nadu) (Hooda, 2020).

In India, there is considerable variation in health insurance enrolment and schemes prevailing across different states (Hooda, 2020; Aashima & Sharma, 2023), highlighting the need to evaluate the impact of health insurance across all states. Previous studies were mainly limited to examining the impact of only GSHI schemes in a few states, namely, Chhattisgarh (Garg et al., 2020; Nandi et al., 2017), Haryana (Gupta et al., 2017; Prinja et al., 2019), Maharashtra (Rao et al., 2014; Rent & Ghosh, 2015; Sabharwal et al., 2014), Gujarat (Devadasan et al., 2013; Gupta et al., 2017; Prinja et al., 2019), Uttar Pradesh (Gupta et al., 2017; Prinja et al., 2019; Raza et al., 2016; Sabharwal et al., 2014), Andhra Pradesh (Garg et al., 2019; Rao et al., 2014), Karnataka (Aggarwal, 2010; Barnes et al., 2017; Garg et al., 2019; Sood et al., 2014), Bihar (Raza et al., 2016), Tamil Nadu (Garg et al., 2019), Kerela (Philip et al., 2016), Jharkhand (Sinha, 2018), and Odisha (Panda & Rout, 2018). A few studies analysed the impact of any health insurance scheme (Apyayee et al., 2021; Gupta, 2021; Mahapatro et al., 2018; Sahoo & Madheswaran, 2014) or any GSHI schemes at the national level only (Ranjan et al., 2018; Sriram & Khan, 2020). Therefore, a comprehensive examination of the impact of health insurance across all Indian states is missing. Also, previous studies were conducted in different years with different datasets, which limits the comparability between them. Furthermore, there is a dearth of studies examining the utilization pattern of inpatient care in the context of health insurance (Prinja et al., 2019; Garg et al., 2019, 2020; Sriram & Khan, 2020). Additionally, previous studies were mainly focused on specific cases (i.e., a particular state or insurance scheme) and lacked in providing a comprehensive examination of the impact of overall health insurance enrolment on accessibility, utilization pattern of inpatient care, and financial risk protection across all states and union territories (UTs) in India.

Against this backdrop, in this study, we first analysed the impact of health insurance in providing access to inpatient care. Second, we analysed the role of health insurance towards the utilization pattern of inpatient care (measured in terms of type of provider, duration of hospital stay, and number of times hospitalized). Third, we assessed the impact of health insurance in safeguarding against financial risk (OOPE, catastrophic health expenditure (CHE) at various thresholds, and impoverishment due to OOPE). The entire analysis was performed separately for each state/UT of India. Furthermore, we review and extensively discuss the findings of the previous literature that examined the impact of the health insurance schemes in providing financial protection in India. This comprehensive assessment of the impact of health insurance across all states/UTs is expected to serve as an informative guide to assess whether health insurance has met its objectives and to identify the states/UTs that require a greater policy attention.

Data and Methodology

Overview of Data Source

The most recent round (75th round) of the nationally representative survey on health and morbidity, entitled "Social Consumption: Health," was employed in the study. The survey was conducted by the National Sample Survey Organisation (NSSO) from July 2017 to June 2018, and covered 555,115 persons (325,883 in rural areas and 229,232 in urban areas) from 113,823 households (64,552 in rural areas and 49,271 in urban areas) in India. The survey collected extensive information about hospitalization, cost of care, nature of ailment, maternal and elderly health dimensions, and demographic and socio-economic characteristics of households and their members. A total of 91,445 hospitalization incidents were reported during the last 365 days. Information regarding the coverage of households under any health insurance scheme was also recorded and categorized into five groups: (i) government-sponsored (e.g., RSBY, Arogyasri), (ii) government employer (e.g., CGHS), (iii) employer-supported (other than government employer, for instance, ESIS), (iv) insurance arranged on their own (also known as private health insurance), and (v) others. Details about the prevalent health insurance programmes are elucidated in Supplementary File (pp 1).

Outcome Variables

The primary outcome variables analysed in the study were accessibility to inpatient care, utilization pattern of inpatient care, and financial risk due to inpatient care in the context

of health insurance. Access to inpatient care is determined by whether an individual has undergone hospitalization during the last 365 days preceding the survey. The utilization pattern of inpatient care was analysed in terms of the type of healthcare provider used (public or private), number of times hospitalized (one or more than once hospitalized), and the duration of hospital stay (short or long duration of hospital stay). The duration of hospital stay was considered "short" if it was up to 6 days and "long" if it exceeded 6 days. Six days was taken as the base because the mean duration of hospital stay in our data was recorded as 5.78 days. The financial protection was measured through OOPE, the incidence of CHE, and impoverishment. We computed OOPE by summing all hospitalization-related expenditures, including package component, doctors'/surgeons' fees, medicines, diagnostic tests, bed charges, other medical expenses, and transportation expenses, and then deducting any reimbursement received. The methodology provided by Wagstaff and Doorslaer (2003) was applied to estimate CHE incidence. The incidence of health expenditure was considered to be catastrophic if OOPE exceeded 10% (CHE-10), 25% (CHE-25), or 40% (CHE-40) of the total annual household consumption expenditure (Garg et al., 2019, 2020, 2022; Ranjan et al., 2018). Furthermore, impoverishment was said to be experienced by individuals whose annual per capita consumption expenditure was initially above the poverty line but later fell below it due to hospitalization-related OOPE (Sangar et al., 2019, 2022). For all outcomes, the impact of overall health insurance enrolment (i.e., enrolled in any health insurance programme) was analysed separately in each state/UT. We restricted our analysis to hospitalization cases only, as most health insurance schemes in India mainly cover inpatient care (La Forgia & Nagpal, 2012; Maurya, 2019).

Statistical Analysis

Propensity Score Matching

The study aims to compare the outcomes between insured and uninsured. However, a direct comparison of outcomes between the groups may lead to a biased estimate of the treatment effect (i.e., health insurance in our case) (Ali et al., 2019; Garrido et al., 2014; Zhao et al., 2021), because treatment groups may not be comparable in their pre-treatment characteristics (Ali et al., 2019; Garrido et al., 2014; Zhao et al., 2021). Therefore, in line with previous studies (Garg et al., 2020; Hou et al., 2022; John et al., 2024; Ranjan et al., 2018; Sabharwal et al., 2014; Sriram & Khan, 2020), we have employed the PSM technique to control for the confounding bias, thereby clearly demonstrating the treatment impact. We estimated the impact of health insurance on accessibility, utilization of inpatient care, and financial risk protection across states/UTs.

We estimated the average treatment effect on the treated (ATET), which measures the average difference in outcomes that the treatment group has obtained with health insurance coverage and the treatment group would have obtained without health insurance. ATET is measured through the following equation.

$$ATET = E(Y_1 - Y_0|(D = 1)) = E(Y_1|D = 1) - E(Y_0|D = 1)$$

In the above equation, ATET represents the change in outcome due to health insurance, Y_1 is the estimate of an outcome if treated (insured), Y_0 is the estimate of an outcome if not treated (not insured), $D=1$ is the participation status in the case of treatment, and $D=0$ is the participation status of the untreated. Variables, namely, age, gender, education, social class, sector (rural/urban), and economic quintiles, were used as matching variables for accessibility and utilization outcomes. Additionally, the type of healthcare provider and ailment category were also used as matching variables for financial protection outcomes. The model was run separately for each state/UTs for each outcome. All the data analysis was carried out using Stata software (version 14.1) (StataCorp, 2015).

Results

Health Insurance Enrolment Across States/UTs

In India, dismally low proportion of the population (15.53%) was enrolled under any health insurance programme, with a substantial variation across states/UTs (Fig. 1). In 22 out of 36 states/UTs, insurance enrolment was lower than the national average. Notably, in Mizoram (78.57%), Andhra Pradesh (72.79%), Chhattisgarh (64.29%), Telangana (61.09%), Dadra and Nagar Haveli (58.25%), and Meghalaya (53.9%), vast majority of the population was enrolled in any health insurance programme. By contrast, in Puducherry, Jammu and Kashmir, Sikkim, Manipur, Uttar Pradesh, Madhya Pradesh, Jharkhand, and Bihar, < 5% of the population was enrolled under any health insurance programme. Of all the health insurance programmes existing in India, the highest enrolment was observed under GSHI schemes (11.70%), followed by CGHS (1.37%) and private health insurance (1.28%) (Supplementary Table 1). In many states/UTs, enrolment was higher in GSHI schemes compared to any other health insurance, while in a few well-off states/UTs, such as Chandigarh (9.75%), Delhi (8.29%), Maharashtra (3.45%), and Haryana (2.42%), higher enrolment was reported under private health insurance. Nearly 5–15% of the population was enrolled under CGHS in a few states/UTs, such as Chandigarh, Mizoram, Lakshadweep, Andaman and Nicobar Islands, Delhi, Daman and Diu, Himachal Pradesh, and Meghalaya. However, enrolment

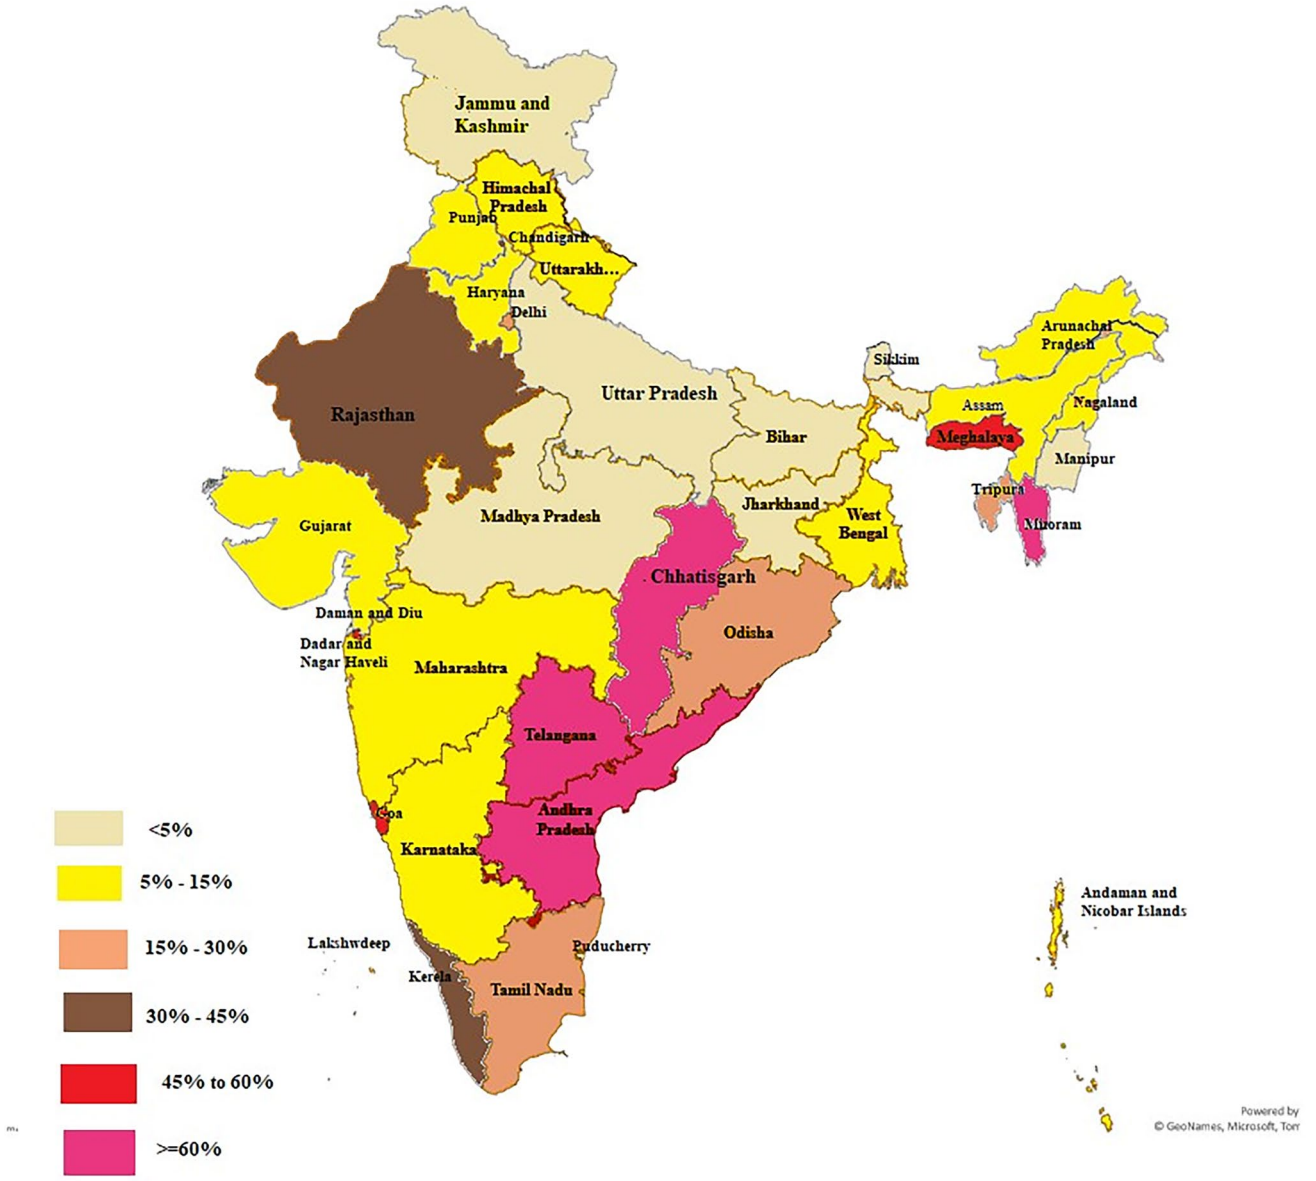

Fig. 1 Health insurance enrolment across states/UTs in India

under ESIS and other health insurance schemes was notably low across most states/UTs.

Impact of Health Insurance on Accessibility and Utilization Pattern of Inpatient Care Across States/UTs

Table 1 presents the impact of health insurance on accessibility and utilization pattern of hospitalization across states/UTs using PSM. Access to inpatient care was statistically significantly higher among insured than uninsured in 21/32 states/UTs ($p < 0.05$). In states/UTs, namely, Chandigarh, Uttarakhand, Tripura, Assam, Chhattisgarh, Dadar and Nagar Haveli, Andhra Pradesh, Goa, Tamil Nadu, Jammu and Kashmir, and Telangana, health insurance enrolment did not result in statistically significantly higher usage of inpatient care among insured than uninsured ($p > 0.05$).

Furthermore, among those who utilized the inpatient care, hospitalization episodes more than once were also statistically significantly higher among insured than uninsured across most states/UTs ($p < 0.05$). On the other hand, hospitalization episodes with private provider were marginally but statistically significantly higher among insured than uninsured in a few states/UTs, namely, Delhi, Karnataka, Maharashtra, West

Puducherry, Andaman and Nicobar Islands, Lakshadweep, and Daman and Diu union territories were dropped from the analysis due to the small sample size

ATET average treatment effect on treated

*$p < 0.05$; figures inside square brackets represent 95% confidence interval

Bengal, Sikkim, Tripura, Odisha, and Meghalaya ($p < 0.05$). In Kerala and Punjab, the hospitalization episodes with private provider were statistically significantly lower among insured than uninsured ($p < 0.05$). Similarly, the episodes of longer duration of hospital stay were statistically significantly higher among insured in only a few states, namely, Maharashtra, Himachal Pradesh, Punjab, Odisha, Uttar Pradesh, Manipur, and Sikkim ($p < 0.05$) (Table 1).

Impact of Health Insurance on Financial Risk Protection Across States/UTs

Table 2 presents the impact of health insurance on OOPE, CHE, and impoverishment. Health insurance enrolment statistically significantly reduced the OOPE for insured than uninsured in 12 states/UTs ($p < 0.05$). A substantial decrease in OOPE among insured was observed in Assam, Uttar Pradesh, Karnataka, Maharashtra, Delhi, and Punjab than uninsured ($p < 0.05$). The incidence of CHE-10 was statistically significantly lower among insured by more than 10% in Assam, Uttar Pradesh, Uttarakhand, Jammu and Kashmir, Maharashtra, Delhi, Punjab, Dadra and Nagar Haveli, and Andhra Pradesh ($p < 0.05$). In states, namely, Gujarat, Karnataka, Tamil Nadu, Kerala, Meghalaya, and Telangana, the reduction in CHE-10 among insured was between 5% and 10%. In all other states, health insurance was observed to be statistically ineffective in reducing the financial burden ($p > 0.05$). In some states with good health insurance enrolment rates, such as Rajasthan, Chandigarh, Goa, and Chhattisgarh, health insurance did not statistically significantly reduce the OOPE and CHE incidence among insured than uninsured ($p > 0.05$). Furthermore, CHE-25 was statistically significantly lower among insured in Delhi, Uttar Pradesh, Maharashtra, Andhra Pradesh, Kerala, and Telangana ($p < 0.05$). The CHE-40 incidence was statistically significantly lower in only Andhra Pradesh, Telangana, and Maharashtra ($p < 0.05$). Lastly, health insurance enrolment reduced the impoverishment incidence in a few states such as Punjab, Assam, Maharashtra, Kerala, and Telangana ($p < 0.05$). These findings suggest that health insurance enrolment has alleviated the financial burden among insured to some extent, albeit limited to certain states (Table 2).

Discussion

To the best of our knowledge, this is the first study that analysed the role of health insurance across several dimensions, namely, accessibility to inpatient care, utilization pattern of inpatient care, and financial risk protection across all states/UTs in India.

We observed a small but statistically significantly higher accessibility to inpatient care among insured than uninsured across most states/UTs of India. Previous studies have also found higher accessibility to inpatient care among insured (Mahapatro et al., 2018; Nandi et al., 2017; Prinja et al., 2017; Reshmi et al., 2021; Sriram & Khan, 2020). The hospitalization episodes more than once were also found to be higher among insured than uninsured. This observed trend could be attributed to a genuine decline in financial barriers to accessing care among insured, or due to moral hazard, or provider-induced demand (Dang et al., 2021; Prinja et al., 2017; Sengupta & Rooj, 2019; Sriram & Khan, 2020). Furthermore, we observed that the hospitalization episodes with private provider were only marginally higher among insured than uninsured in few states only. This may be attributed to the high OOPE in private health facilities irrespective of the health insurance status as highlighted by the previous studies (Nandi et al., 2017; Garg et al., 2019, 2020; Ranjan et al., 2018; Muraleedharan et al., 2020; Aashima & Sharma, 2024a). Also, the utilization of the type of provider depends upon the availability (Baru et al., 2010; Rout et al., 2021) and empanelment under different health insurance programmes (Smith et al., 2019). For instance, as per a policy brief, no private hospital was empanelled in aspirational districts[1] of nine states under the recently launched GSHI scheme, PM-JAY (Smith et al., 2019). Additionally, episodes of longer duration of hospital stay were also not statistically different among insured and uninsured across most states/UTs, which is in line with a previous study focused on poor individuals (Sriram & Khan, 2020), which argues that the length of hospital stay is primarily determined by the patient's health condition, and healthcare providers have little incentive to prolong stays due to low package rates in GSHI schemes (Sriram & Khan, 2020). Additionally, providers are often unaware of the patient's insurance status as this is typically handled by hospital administrative divisions (Sriram & Khan, 2020). By contrast, in Maharashtra, Himachal Pradesh, Punjab, Odisha, Uttar Pradesh, Manipur, and Sikkim, the episodes of longer duration of hospital stay were higher among insured than uninsured. Overall, this reflects that health insurance enrolment has increased the accessibility to inpatient care among insured; however, the utilization pattern of inpatient care (i.e., private provider usage and longer duration of hospital stay) was not impacted much by the health insurance status.

We found that health insurance was statistically significantly effective in reducing both OOPE and CHE (at 10% threshold) for insured in some states such as Assam, Uttar Pradesh, Karnataka, Maharashtra, Delhi, Punjab, Tamil Nadu, Kerala, Meghalaya, Andhra Pradesh, and Telangana. However, the incidence of CHE at 25% and 40% threshold and impoverishment were not statistically different among insured and uninsured across most states. Furthermore, in some states with good health insurance enrolment along with state's own GSHI schemes, such as Rajasthan, Goa, and Chhattisgarh, health insurance was not found to be effective in reducing the financial burden for the insured.

Previous literature reported the lack of effectiveness of GSHI schemes in providing the financial protection in states

[1] Aspirational districts are the most under-developed districts across the country, which are chosen to quickly and effectively transform under "Aspirational districts" programme.

such as Chhattisgarh, Gujarat, Haryana, Uttar Pradesh, Maharashtra, Karnataka, Andhra Pradesh, Tamil Nadu, and Jharkhand (Supplementary Table 2). On the other hand, few studies conducted in Bihar, Haryana, Karnataka, Uttar Pradesh, and Maharashtra reported the effectiveness of health insurance schemes in reducing the financial burden. It was observed that previous studies examining any health insurance scheme or any GSHI scheme at the national level also reported marginal effectiveness of health insurance in providing financial risk protection to the insured (Supplementary Table 2). The difference in results could be attributed to the differences in data, year, methodology, and scheme analysed (as most studies were restricted to analysing state-specific GSHI schemes). The prominent reasons highlighted by the previous literature for the limited effectiveness of GSHI schemes in reducing financial burden were (i) low awareness among beneficiaries regarding various facets of health insurance (such as information regarding stipulated benefits one is entitled to, the procedure to avail benefits, number of family members covered, list of empanelled hospitals, and ailments covered) (Ahlin et al., 2016; Devadasan et al., 2013; Rajasekhar et al., 2011; Rent & Ghosh, 2015; Sabharwal et al., 2014; Thakur, 2016) and (ii) continued spendings on medicines, diagnostics, and consumables (Ahlin et al., 2016; Devadasan et al., 2013;

Ecks, 2021; Kamath & Kamath, 2020; Nandi & Schneider, 2020; Rent & Ghosh, 2015; Sabharwal et al., 2014; Selvaraj & Karan, 2012). Studies have also reported malpractices by empanelled private hospitals, such as overbilling of insurance patients, persuading beneficiaries to utilize services that are not covered, performing unnecessary procedures on insured patients to claim insurance money, and lack of transparency in billing (Chakravarthi, 2018; Dehury et al., 2019; Selvaraj et al., 2022; Kamath & Kamath, 2020; Oxfam India, 2021). The inadequate monitoring of private healthcare providers is also a concerning issue (Chakravarthi, 2018; Dehury et al., 2019; Selvaraj et al., 2022; Oxfam India, 2021). Furthermore, problems with beneficiary card, long waiting time at empanelled hospitals, reimbursement issues, low package rates, and no coverage for outpatient care were other plausible reasons reported for less-than-optimal outcomes of health insurance in India (Ahlin et al., 2016; Devadasan et al., 2013; Kamath & Kamath, 2020; Rajasekhar et al., 2011; Sabharwal et al., 2014; Thakur, 2016).

There is a pressing need to strengthen the public health sector, improve regulations for healthcare providers, and address challenges encountered under health insurance schemes to augment financial risk protection in India. Also, it is important to increase public health expenditure in India. According to a WHO report (2020b), countries with higher public health expenditures can offer greater financial protection against catastrophic and impoverishing health spending. Furthermore, health insurance in India mainly provides coverage for the inpatient care, and outpatient care remains outside the ambit of health insurance. Even the recently launched central-level GSHI scheme, PM-JAY, which aims to cover the bottom 40% of the Indian population, does not provide coverage for outpatient services (Mukherjee & Chaudhuri, 2020), which puts a colossal financial burden of accessing healthcare in India (Gupta et al., 2016; Sangar et al., 2022; Nanda & Sharma, 2023a; Aashima & Sharma, 2024b). India is undergoing an epidemiological transition with an increasing burden of non-communicable diseases (Patel et al., 2011; Yadav & Arokiasamy, 2014), which requires frequent consultations, regular visits to a doctor, diagnostic tests, and long-term medication support to manage the disease progression (Nanda & Sharma, 2023b). Covering outpatient services can improve access to primary care and promote the viability of inpatient health insurance schemes (Taneja & Taneja, 2016). Evidence suggests that the composition of the benefit package has an impact on utilization and financial risk protection (Watson et al., 2021). For instance, in China, the New Rural Cooperative Medical System was reformed to include outpatient services, and as a result, the healthcare utilization by the poor has increased in the country (Watson et al., 2021).

Strengths and Limitations

The study leveraged the recent NSSO 2018 survey data, offering a notable improvement over earlier studies that were based upon previous NSSO rounds. Also, the study meticulously integrates insights from a wide array of existing literature. Furthermore, our study significantly contributes to the existing body of research by providing a comprehensive overview of the impact of health insurance on accessibility, utilization pattern of inpatient care, and financial risk across all states/UTs of India.

As with all studies, this study also has a few limitations. Survey information regarding hospitalization episodes involves a long recall period of 365 days, making it prone to recall bias (Yadav et al., 2024). The study relies on a cross-sectional survey that limits its use for causal inference and analyses of the extent of the economic strain and the disruption to living standards caused by health expenditures in the long term. Last, through this study, we couldn't estimate the impact of the recently launched PM-JAY scheme, which could be gauged in the coming years through future rounds of NSSO.

Conclusion and Policy Recommendations

We found that health insurance enrolment has increased accessibility to inpatient care among insured; however, the utilization pattern of inpatient care in terms of utilizing private healthcare provider and longer duration of hospital stay was not impacted much by the health insurance status across states/UTs. Also, health insurance was observed to be effective in providing financial protection to the insured in some states. Concerted efforts, such as increasing health insurance enrolment, raising awareness about prevalent schemes and their eligibility criteria, and informing beneficiaries about the procedures to avail benefits, are required. There is also an urgent need to include outpatient services under the purview of health insurance to reduce the financial burden and make health insurance more viable. Better monitoring, supervision, and regulation by state authorities are required to provide effective coverage under health insurance. Furthermore, strengthening public healthcare facilities, regulating private healthcare providers, and incentivizing the public healthcare sector to compete for better service provision are equally important in delivering quality and affordable healthcare services in India.

Abstract: In this paper, a detailed study of the Er/Yb/W tri-doped $BaBi_{2-x-y}Nb_{2-z}Er_xYb_yW_zO_9$ (BBN) system and a comparison of undoped, Er-doped, Er/Yb co-doped and Er/Yb/W tri-doped BBN systems are presented. All the BBN ceramics are prepared using the solid-state approach. The XRD spectra demonstrated that each BBN composition has an orthorhombic geometry. The UCL spectra are traced at 980 nm and exhibit two distinctive green bands and one red band at 535 nm, 556 nm, and 673 nm, respectively. The UCL intensity improves with W^{6+} concentration and reaches a maximum at (z = 0.02); after this concentration, the quenching effect occurs. The pump power variation on UCL spectra confirmed the involvement of two photons. The time-resolved fluorescence analysis was done for green and red emissions, and it was observed that the time decay increased for higher dopant concentrations, suggesting a non-radiative transition at higher dopant concentrations. The FIR technique measured the absolute sensitivity and had a value of 0.91% K^{-1} at 573 K. These improvements suggest that the prepared material may help develop advanced electronic equipment for multifunctional applications.

Keywords: Upconversion; time decay; sensitivity; BBN; ferroelectric; ceramic.

1. Introduction

Ferroelectric materials have gained prominence due to their multifunctional applications in optics, electrical engineering, bioimaging, sensing, energy storage, and many more [1-5]. They have high chemical and thermal stability, which is required to modify the host material by inserting foreign ions. Furthermore, the phonon energy of these materials is low, which is sufficient for the upconversion mechanism. The advances in electrical and optical applications have shown tremendous possibilities. Researchers have been inspired to explore multifunctional and hybrid materials due to the need for cost-effective and environmentally friendly materials capable of fulfilling several purposes [6-8]. The increasing recognition of layered bismuth structure ferroelectric (BLSF) materials may be attributed to their advantageous chemical and thermal durability, exceptional radiation tolerance, reduced phonon energy, and enhanced sensing capacity over a wide temperature range. BLSF provides a compelling alternative to lead-based ceramics due to their non-toxic nature and ecologically friendly characteristics, making them a preferable replacement choice. The BLSF comprise a distinct category of ferroelectric materials and are denoted by the formula $(Bi_2O_2)^{2+}$ $(A_{n-1}B_nO_{3n+1})^2$. The quasi-perovskite layer, $A_{n-1}B_nO_{3n+1}$, is enveloped by two layers of bismuth oxide $(Bi_2O_2)^{2+}$. Here, n is the number of octahedral layers that comprise the perovskite unit, A denotes mono, di, and tri valence ions, and B symbolizes higher valence ions (tetra, penta, hexa) [9-12].

The literature analysis revealed that incorporating rare earth (RE) ions into BLSF materials improved their electrical, optical, and sensing characteristics. In recent years, temperature sensing has attracted considerable interest due to breakthroughs in business and technology. Non-contact temperature sensors are needed in power plant electrical transformers in oil and coal factories, where traditional temperature monitoring equipment is prohibited. Developing high-temperature sensing materials with a substantial degree of sensitivity poses an immense challenge for contemporary researchers studying RE-doped materials. Luo et al., for instance, investigated the efficacy of Er^{3+}/Yb^{3+} co-doped $Ba_2NaNb_5O_{15}$ glass ceramics regarding UC luminescence, thermal sensing, and energy storage [13]. Additionally, a prior study employed co-doped tungsten tellurite glass doped with Er^{3+} and Yb^{3+} to fabricate a temperature sensor [14]. The sensor exhibited a respectable green emission luminescence and sensitivities of approximately 28.72×10^{-4} K^{-1} at 690 K. The luminescence intensity ratio of La_2TiO_7 ceramics doped with Yb^{3+}/Er^{3+} was investigated by Swami et al. [15]. At 498 K, the authors obtained a sensitivity of 0.29% K^{-1}. Furthermore, in $Bi_{0.5}Na_{0.5}TiO_3$: Yb^{3+}/Er^{3+}, approximate sensing of 0.49% K^{-1} at 363 K within an extensive temperature spectrum has been reported [16]. From the literature survey, it was found that to refine the luminous characteristics along with the electrical properties of lanthanide-doped materials, it is possible to alter the surroundings of the emission centers. The inclusion of some non-lanthanide elements has shown encouraging outcomes in effectively altering the nearby crystal field around the rare-earth ions. Several non-lanthanide elements, including Li^+, Mg^{2+}, Zn^{2+}, Mo^{3+}, Bi^{3+}, and W^{6+}, have been reported to have the ability to enhance the optical as well as electrical properties. For instance, the electrical and structural characteristics of Bi_3TiNbO_9 ferroelectric ceramic are improved by the incorporation of W^{6+} ions [17]. Hou.

et. al. reported the remanent polarization and d_{33} coefficient were increased in W^{6+} doped $CaBi_2Nb_2O_9$ [18]. In $Ho^{3+}/Yb^{3+}/Zn^{2+}$ tri-doped Y_2O_3 phosphor, the UCL emission is enhanced 11 times [19]. In $Bi_4Ti_3O_{12}$ ferroelectric ceramic, the upconversion luminescence and optical temperature sensitivity were improved by the introduction of W^{6+} ions along with Er^{3+} and Yb^{3+} ions [20].

The objective of this paper is to conduct a comprehensive investigation of the impact of singly doped Er^{3+} ions, co-doped Er^{3+}/Yb^{3+} ions, and tri-doped $Er^{3+}/Yb^{3+}/W^{6+}$ ions on the $BaBi_2Nb_2O_9$ ferroelectric ceramic. Enhanced green upconversion emission was observed in the ferroelectric ceramic $BaBi_2Nb_2O_9$ doped with Er^{3+} in our previous investigation. The highest upconversion luminescence (UCL) was noted at an Er^{3+} content of x = 0.04 [21]. Then, in another study, the Er^{3+} doped $BaBi_2Nb_2O_9$ ferroelectric ceramic is optimized and co-doped with Yb^{3+} ions. The highest green emission was observed at a Yb^{3+} (y = 0.10) concentration [22]. The impact of Er^{3+} and Yb^{3+} ions on electrical properties was also examined in a separate study [23]. These discoveries served as an incentive for us to further investigate the $BaBi_2Nb_2O_9$ system in order to enhance its properties by tri-doping it with $Er^{3+}/Yb^{3+}/W^{6+}$ for multifunctional applications. Therefore, in this paper, we conducted a systematic replacement of a B-site ion (Nb^{5+}) with a transition metal ion (W^{6+}) to investigate the optical and sensing properties of $BaBi_2Nb_2O_9$.

2. Synthesis and characterization description

The ceramic $BaBi_{2-x-y}Nb_{2-z}Er_xYb_yW_zO_9$ (BBN) is manufactured by a simple solid-state method. The Er^{3+} (x = 0.04) and Yb^{3+} (y = 0.10) were fixed at constant concentrations, and W^{6+} is varied during the process (z = 0.01 to 0.04). The selection of Er^{3+} (x = 0.04) and Yb^{3+} (y = 0.10) was based on the fact that this combination of dopant concentrations exhibited the highest green emission intensity peak in our previous work [21, 22]. The precursors used were $BaCO_3$, Bi_2O_3, Nb_2O_5, Er_2O_3, and Yb_2O_3, WO_3 having the highest purity (99.99%) from Sigma Aldrich. These initial substances were measured in stoichiometric proportions and homogenized using a mortar and pestle for 5 hours, using ethanol as the solvent. The automated high-temperature furnace is used for the calcination of the sample at 950°C with a hold time of 3 hours. Then, a binder PVA is mixed with calcined powder to prepare the pellets. The pellets were fabricated using a hydraulic press at a pressure of 5 MPa, having a diameter of 10 mm and a thickness of approximately 1 mm. These pellets were again put into the same furnace for sintering at 1050°C for 3 hours for the sample to harden. The schematic description of the preparation method via solid state route is given in Fig. 1.

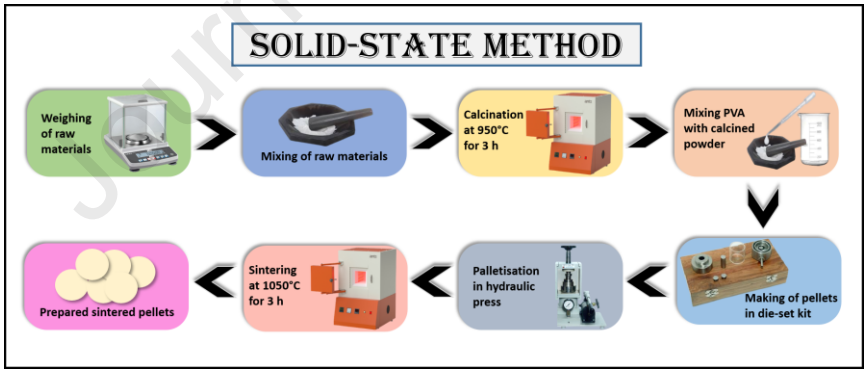

Fig. 1. Steps involved in solid-state method.

$BaBi_{1.86}Nb_{1.96}Er_{0.04}Yb_{0.10}W_{0.04}O_9$	BBNE4Y10W4	0.04	0.10	0.04

The investigation of the phase of the material was conducted through the analysis of XRD spectra utilizing Cu-Kα radiations by the use of a Bruker high-quality X-ray diffractometer. The refinement and lattice parameters are calculated by TOPAZ software. The HORIBA quanta master instrument was used to facilitate UCL spectra using laser source light at 980 nm. For the lifetime decay measurement, a pulsed laser was operated in modulation mode at its maximum power capability of 2W/cm^2 for 30 minutes. The synthesized

material was placed on the heaters to analyze the temperature-dependent UCL emission spectra while the temperature was measured with a thermocouple. A manually constructed heater equipped with a thermocouple, multimeter, and variable-voltage control was utilized to conduct the sensing, resolution, and stability analyses. The sample coding for all the prepared BBN ceramics is recorded in Table 1.

3. Results and discussion

3.1. XRD analysis

The spectra of XRD for undoped, Er^{3+} doped, Er^{3+}/Yb^{3+} co-doped, and $Er^{3+}/Yb^{3+}/W^{6+}$ tri-doped BBN ceramic is represented in Fig. 2. The X-ray diffraction (XRD) peaks exhibit a notable resemblance to the JCPDF file number 00-012-0403, which is associated with an orthorhombic crystal structure and is classified within the Fmmm phase group. The absence of secondary peaks in the XRD patterns provides evidence for an extensive incorporation of the dopant within the host lattice. The prominent XRD peak corresponds to the (115) plane, attributed to the BLSFs having n = 2. From the previous findings, it can be confirmed that the (112n+1) plane is associated with an intense XRD peak in the BLSF materials of the Aurivillius family. The density of the prepared sintered pellet is evaluated by the Archimedes method (Table 2). The measured density is comparable with the reported density in the JCPDS file with 95% accuracy. The A-site Bi^{3+} ions are replaced by Er^{3+} and Yb^{3+} ions at an optimized concentration, whereas W^{6+} ions systematically replace the B-site ion Nb^{5+}. The explanation for this replacement is based on the fact that they have equal charge valency and nearly comparable radii. The resulting change in lattice parameters is shown in Table 2, indicating a minor shift in the parameters, which implies the maintenance of electroneutrality inside the lattice, which prevents lattice deformation. Also, the increment in lattice cell volume can be explained by the lone pair character of Bi^{3+} ions. In the $BaBi_2Nb_2O_9$ structure, this phenomenon might be attributed to the restricted nature of the $6s^2$ lone pair of Bi^{3+} inside the host. This restricted lone pair in Bi^{3+} induces a little deformation in the surrounding lattice structure, resulting in an expansion of the unit cell volume [6, 15, 24].

3.2 Light upconversion luminescence spectra analysis

The upconversion luminescence (UCL) spectra of W^{6+} doped BBN compositions for different W^{6+} concentrations (z = 0.01, 0.02, 0.03, and 0.04) are shown in Fig. 3(a). The spectra were acquired using an irradiation of 980 nm excitation wavelength with a source density of 3.25 W/cm^2. At 535 nm and 546 nm, two distinct green emission bands were detected due to the transitions from $^4H_{11/2}$ to $^4I_{15/2}$ and $^4S_{3/2}$ to $^4I_{15/2}$,

respectively. The red band at 673 nm through the transition from $^4F_{9/2}$ to $^4I_{15/2}$ can be visible. The crystal field causes the $^4F_{9/2}$ energy level to be split into several sublevels via upconversion luminescence. Fig. 3(b) demonstrates that the emission intensity reaches its maximum value at a concentration of z = 0.02. Subsequently, the emission intensity decreases due to the occurrence of the concentration quenching effect. In this effect, the proximity of the dopant ions becomes sufficiently close, leading to their involvement in non-radiative transitions, hence causing a deterioration in the photoluminescence. The calculation of the interionic distance between dopant ions can be accomplished by the Blasse equation (1) [25]:

$$R_c \approx 2\left[\frac{3V}{4\pi X_c Z}\right]^{\frac{1}{3}} \quad (1)$$

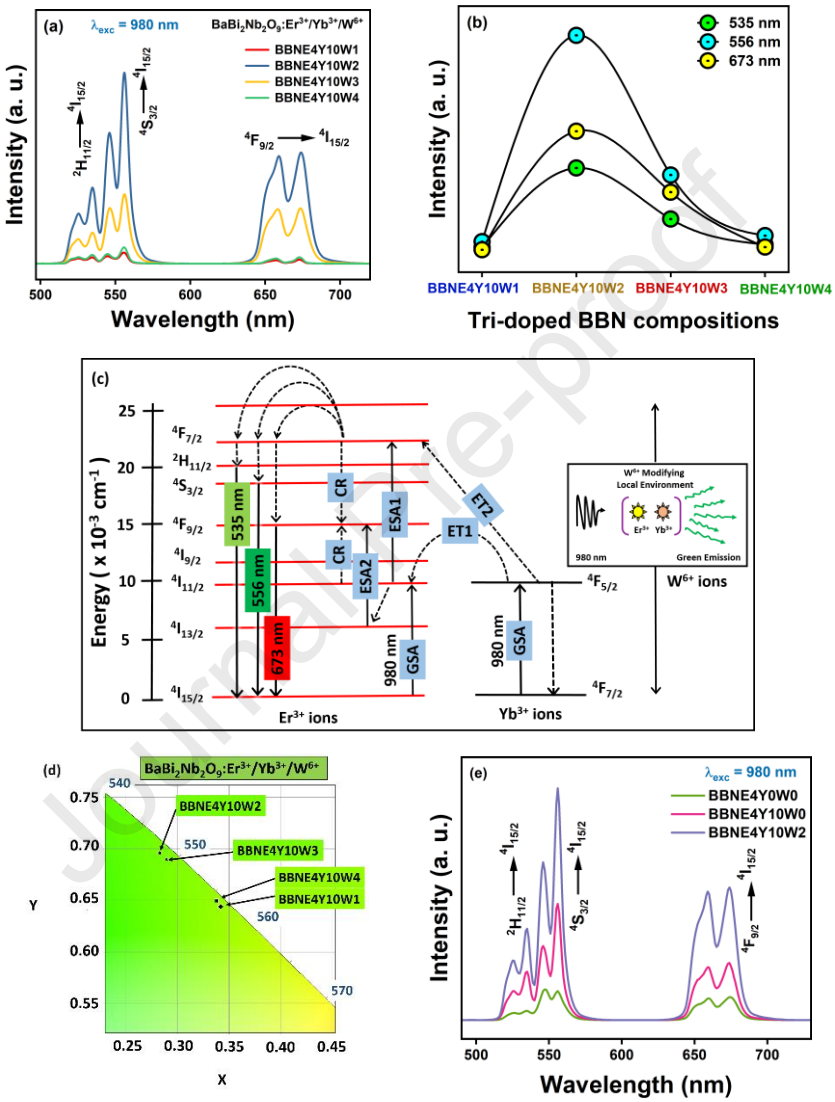

Fig. 3. (a) UCL spectra of all the compositions of tri-doped BBN ceramics (b) Variation of UCL intensity in the tri-doped system (c) Schematic depiction of energy levels of RE^{3+} ions (d) CIE (x, y) plot of tri-doped BBN ceramics (e) Comparison of UCL intensity of BBNE4Y0W0, BBNE4Y10W0, and BBNE4Y10W2 ceramic.

Here, V represents the volume of the unit cell, Z denotes the number of host cations, and X_c (x+y+z) refers to the optimal concentration at which quenching takes place. By substituting the given values into the equation mentioned above, the value of R_c may be determined as 13.34 Å. Fig. 3(c) depicts the energy level diagram illustrating the potential pathways for the up-conversion luminescence (UCL). The Yb^{3+} ions are subjected to illumination from a 980 nm laser, which results in energy absorption by ground state absorption (GSA). This energy is transferred to a higher energy level at $^4I_{11/2}$ through energy transfer 1 (ET1) and $^4F_{7/2}$ through energy transfer 2 (ET2). Photons may potentially be absorbed by Er^{3+} ions via GSA. Therefore, the level $^4I_{11/2}$ is produced by the ESA (excitation by stimulated emission) process to transition to a higher energy level, namely the $^4F_{7/2}$ level. Consequently, the level denoted as $^4F_{7/2}$ experiences an excessive population due to two distinct processes: energy transfer (ET) and excited state absorption (ESA). The ions undergo a non-radiative process known as multiphonon relaxation (MPR), resulting in their transition to energy levels $^2I_{11/2}$, $^4S_{3/2}$, and $^4F_{9/2}$.

Ions emit a single red band at 672 nm and two green bands at 535 and 556 nm due to their transition to the lower energy level $^4F_{15/2}$. The augmented red emission seen with a change in Yb^{3+} concentration may be attributed to an additional decay path facilitated via cross-relaxation channels CR1 and CR2. The CIE chromaticity coordinates (x, y) for different tri-doped BBN compositions were also calculated from the emission spectra. It has been observed that at z = 0.01 and 0.04, the spectra exhibit in the brighter green region, whereas for z = 0.02 and 0.03, they manifest in a deeper green region, as depicted in Fig. 3(d). Furthermore, the enhancement in UCL emission intensity by the incorporation of W^{6+} ions in the host lattice can be seen in Fig. 3(e). The local electric field surrounding the Er^{3+} ions changes, increasing the chance of electronic-dipole (ED) transitions, which causes this intensity spike. Consistent with earlier observations, the results show that changes in the crystal field influence the UC emissions of Er^{3+} ions linked to the intra-4f electronic dipole transitions [26].

3.3. Impact of changing pump power on the UCL emission spectra

To get a deeper understanding of the mechanisms behind upconversion luminescence, we investigated the transitions involving the levels $^2H_{11/2}$, $^4S_{3/2}$, and $^4F_{9/2}$ to level $^4I_{15/2}$ in the BBNE4Y10W2 composition system. The distinct pump powers range from 89 mW to 389 mW with an excitation source density of 5.79 W/cm^2 to 25.34 W/cm^2, as depicted in Fig. 4(a). It has been discovered that as the pump power increases, the UCL intensity also increases. Eq. (2) illustrates the correlation between pump power and UCL emission intensity [27, 28].

$$I_{UP} \propto P^n \tag{2}$$

Here, P represents the pump power, n signifies the low-energy photons necessary for the UCL, and I_{UP} denotes the UCL intensity. The curve of ln(intensity) against the ln(Power) is given in Fig. 4(b). The value of n (no. of photons involved in UC) can be obtained from the graph's slope. The n equals 1.33, 1.42, and 1.20 for emission bands at 535 nm, 556 nm, and 673 nm, respectively. The fact that n is greater than 1 means that more than one photon is involved in UCL. The disparity from n = 2 might be seen due to the impact of distinct UC mechanisms [26].

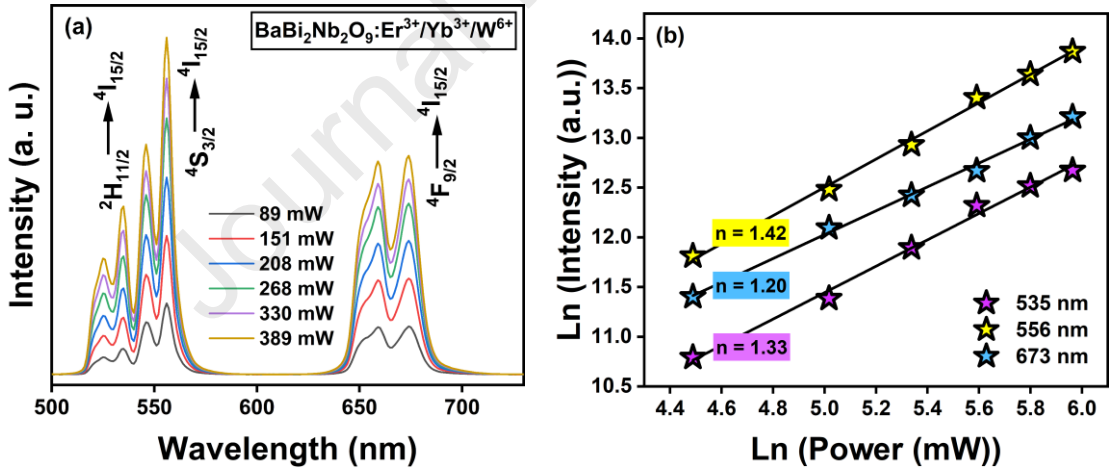

Fig. 4. (a) Dependency of varying pump power on UCL spectra (b) Ln(Intensity) versus Ln(Power).

3.4. Time-resolved photoluminescence analysis of green and red emission bands

In time-dependent dynamics of luminescence, the emission intensity gradually increases until it reaches its highest point as the excitation is prolonged. After the excitation source is removed, the emission intensity gradually decreases to zero, resulting in a comprehensive time-resolved curve. In general, the time required for an emission to decay to the 1/e value of the initial intensity is defined as the luminescence lifetime. In this study, the laser source in the modulation mode under the excitation of 980 nm wavelength is used for the time-resolved photoluminescence spectra of the green band and red band through transition $^4S_{3/2}$ to $^4I_{15/2}$ and $^4F_{9/2}$ to $^4I_{15/2}$ energy levels, respectively. The time decay profile of the green band at 556 nm for the Er^{3+} doped, Er^{3+}/Yb^{3+} co-doped, and $Er^{3+}/Yb^{3+}/W^{6+}$ tri-doped BBN system is given in Fig. 5(a-f). The curve is fitted using decay exponential fit given by Eq. (3):

$$I(t) = I_0 + \sum_i A_i \exp(-\frac{t}{\tau_i}) \ (i = 1, 2, 3) \tag{3}$$

where A_i (i = 1, 2, 3) is the fitting coefficient, τ_i (i = 1, 2, 3) is the decay time of luminescence, and I_0 is the intensity at the initial time. The mean lifetime is calculated using Eq. (4):

$$< \tau > = \sum_i \frac{A_i \tau_i^2}{A_i \tau_i} \text{ (i = 1, 2, 3)} \quad (4)$$

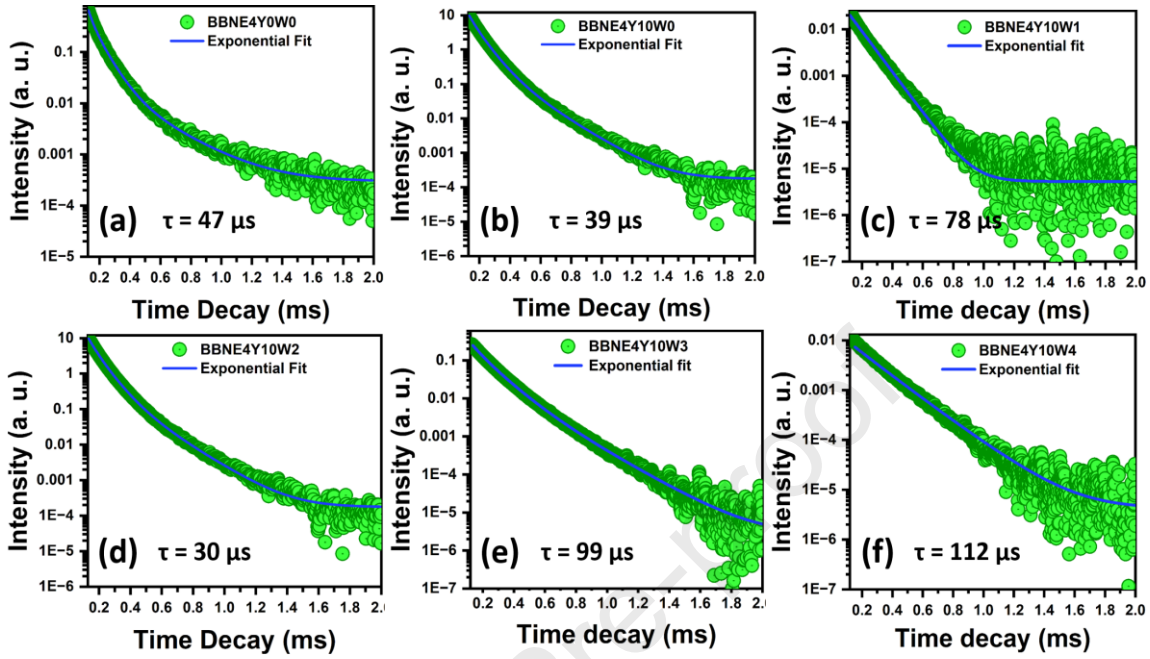

Fig. 5. Time decay curve of (a) BBNE4Y0W0 (b) BBNE4Y10W0 (c) BBNE4Y10W1 (d) BBNE4Y10W2 (e) BBNE4Y10W3 (f) BBNE4Y10W4 ceramics of green emission band at 556 nm.

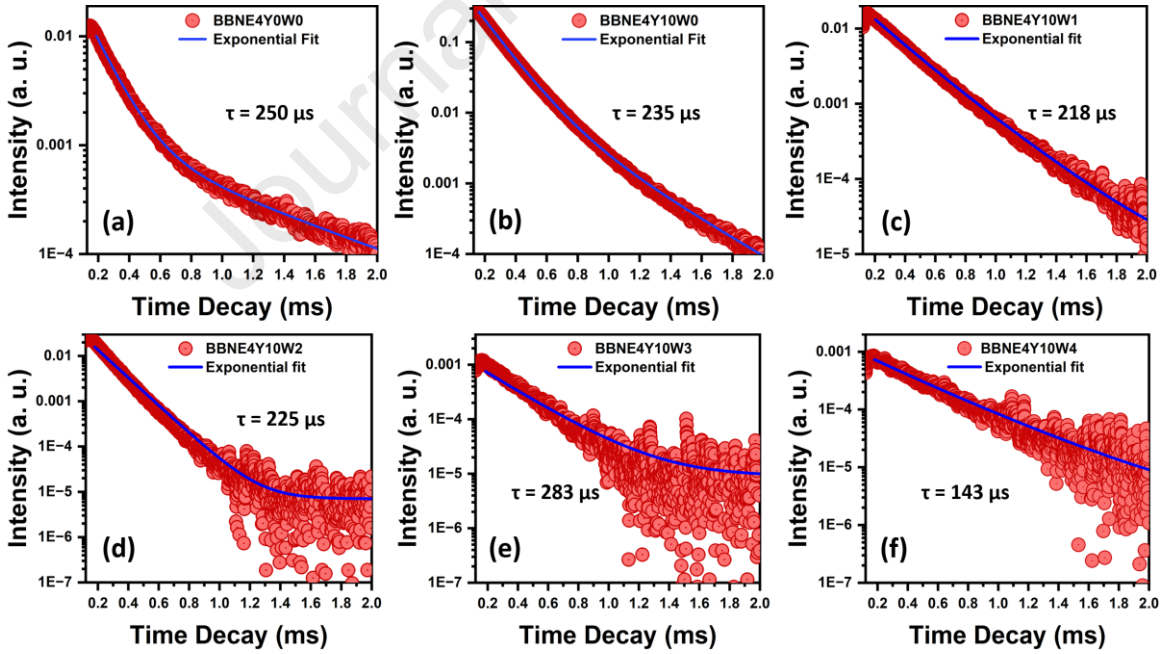

Fig. 6. Time decay curve of (a) BBNE4Y0W0 (b) BBNE4Y10W0 (c) BBNE4Y10W1 (d) BBNE4Y10W2 (e) BBNE4Y10W3 (f) BBNE4Y10W4 ceramics of red emission band at 673 nm.

The average lifetime for optimized (z = 0.02) BBNE4Y10W2 composition is 30 µs, which supports the high emission UCL intensity. After this, the average lifetime increases, possibly due to the non-radiative transitions at higher dopant concentrations. It has also been observed that the average lifetime of the green emission band at 556 nm is decreasing from single-doped BBN to tri-doped BBN, which prompts that the tri-doped system has a larger transition probability of the emitting level than the single-doped system [29]. Further, the time-resolved spectroscopy for the red emission band through a transition of ions from $^4F_{9/2}$ to $^4I_{15/2}$ is shown in Fig. 6(a-f). The average decay time for red emission is increasing with increasing W^{6+} concentration. The average

lifetime of the red emission band is also reduced in the co-doped and tri-doped systems due to the effective radiative transition probabilities in these BBN compositions. Also, the presence of Yb^{3+} ions prevents the clustering of Er^{3+} ions, thereby increasing the optical properties [30].

3.5. Contactless temperature sensitivity using FIR technique

The well-known method for contactless temperature sensitivity is the fluorescence intensity ratio (FIR) technique. This method is compatible with checking the capabilities of materials to be used as optical temperature sensors. We calculated the sensitivity of optimized W^{6+} content (z = 0.02) for the applicability of ceramic to be used as potential sensor material. The temperature-dependent UCL spectra are plotted in Fig. 7(a). In this method, the ratio of the integral intensity of green emission bands via transitions $^4H_{11/2}$ to $^4I_{15/2}$ and $^4S_{3/2}$ to $^4I_{15/2}$ is depicted in Fig. 7(b) and is calculated by Eq. (5) [26]:

$$FIR = \frac{I_H}{I_S} = C\exp\left(-\frac{\Delta E}{K_B T}\right) \quad (5)$$

where I_H and I_S are the symbolic representation for intensities via transitions $^4H_{11/2}$ to $^4I_{15/2}$ and $^4S_{3/2}$ to $^4I_{15/2}$, respectively; ΔE is the difference between thermally coupled energy levels, C is the coefficient of exponential, K_B is the Boltzmann constant, and T is the temperature at which spectra is traced. Eq. (5) can be re-written in linear form to ΔE and C and is given in Eq. (6) [26]:

$$Ln(FIR) = -\left(\frac{\Delta E}{K_B}\right)\left(\frac{1}{T}\right) + LnC \quad (6)$$

The Ln(FIR) slope against the temperature inverse gives us the values of $\Delta E/K_B$ and LnC to be 1158.53 and 2.97, respectively, provided in Fig. 7(c). These parameters determine the optical temperature sensitivity of the produced ceramic BBNE4Y10W2. Eq. (7) may determine a material's absolute sensitivity by plotting its changing FIR value against temperature. [26]:

$$S_a = \frac{d(FIR)}{dT} = \frac{d\left(C\exp\left(-\frac{\Delta E}{K_B T}\right)\right)}{dT} = C\exp\left(-\frac{\Delta E}{K_B T}\right)\left(\frac{\Delta E}{K_B T^2}\right) \quad (7)$$

To acquire the relative sensitivity (S_r) of the material, the absolute sensitivity (S_a) is divided by FIR as employed in Eq. (8) [26]:

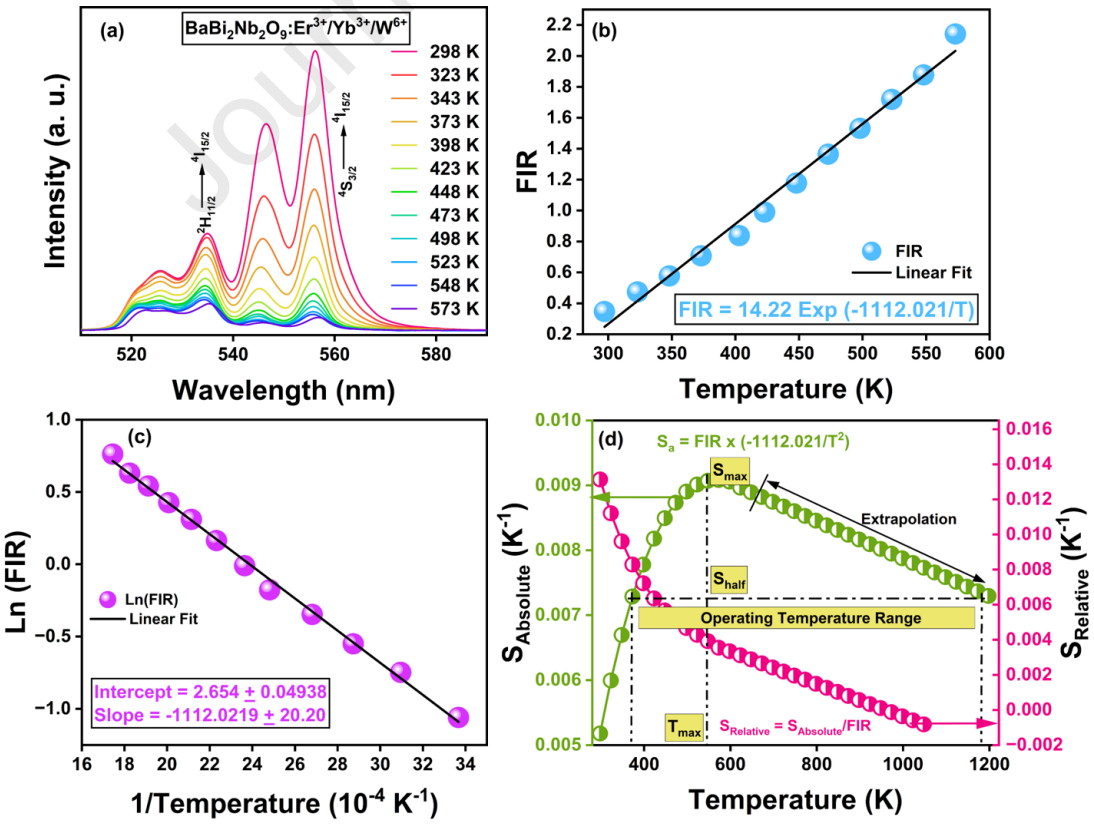

Fig. 7. (a) Emission pattern of BBNE4Y10W2 sample with varying temperature from 303-573 K (b) FIR versus temperature (c) Ln(FIR) against the inverse of temperature (d) Variation of S_a and S_r with temperature.

$$S_r = \frac{1}{FIR} * S_a = \left(\frac{\Delta E}{K_B T^2}\right) \quad (8)$$

The curve of S_r and S_a is shown in Fig. 7(d). The maximum S_a obtained at 573 K is 0.91% K^{-1}, whereas S_r is 1.32% K^{-1} at 297 K. The operational thermal range for sensors is represented by the shaded area in Fig. 9(d); S_a values are extrapolated up to S_{half} (S_a is more than half of the highest value) using Eq. 9. When the experimentally observed ΔE_{ex} and the theoretically calculated ΔE_{th} are nearly same, the material sensitivity is considered to be suitable. The ΔE_{ex} is calculated from the slope of Fig. 7(c), and the deconvoluted emission spectra give ΔE_{th} by the Viogt fit, as illustrated in Fig. 8. The inaccuracy is 2.8% calculated from Eq. (9) [24]:

$$\delta = \frac{|\Delta E_{th} - \Delta E_{ex}|}{\Delta E_{th}} * 100\% \quad (9)$$

The repeatability (R) and resolution (δT) of a sensing material are critical in determining its effectiveness. These parameters can be presented by Eqs. (10) and (11) [31]:

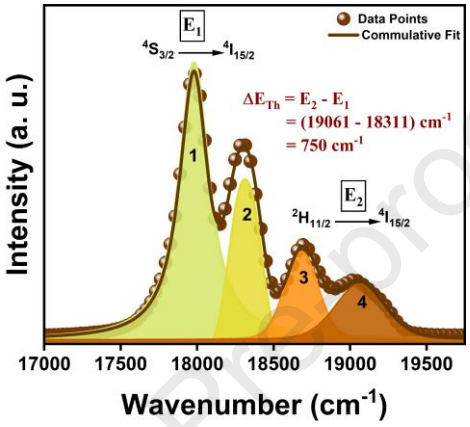

Fig. 8. Deconvoluted curve of BBNE4Y10W2 sample using Voigt fit for ΔE_{th} calculation.

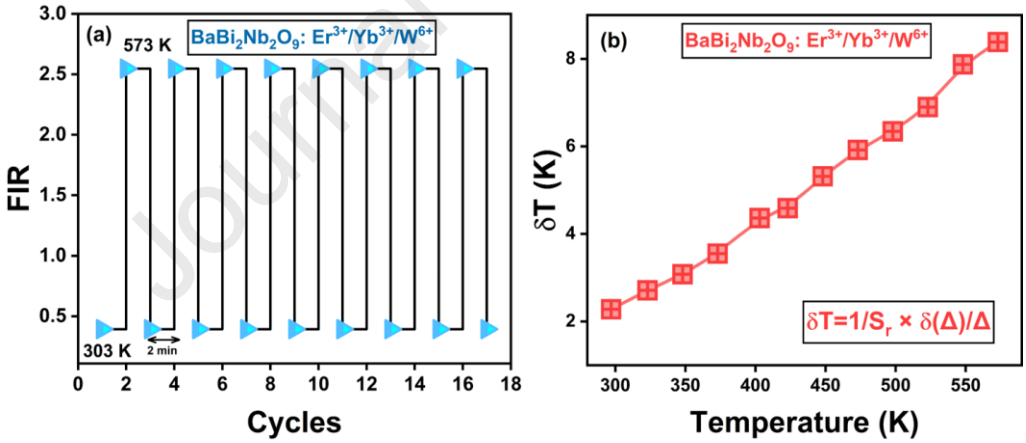

Fig. 9. (a) Repeatability test of BBNE4Y10W2 for 17 cycles with stabilization time of 2 minutes (b) Resolution of temperature from 303 K to 573 K.

$$R = 1 - \frac{\max(\Delta_{Av} - \Delta_{Sp})}{\Delta_{Av}} \quad (10)$$

$$\delta T = \frac{1}{S_r} \times \frac{\delta_\Delta}{\Delta} \quad (11)$$

where Δ_{Av} and Δ_{Sp} are FIR's mean and specific values in the temperature range 303-573 K for 17 cycles, and δ_Δ/Δ denotes the device's accuracy. Fig. 9(a) shows negligible change in the FIR values across the entire temperature range. The temperature resolution has improved from 2.67 K to 8.78 K, as depicted in Fig. 9(b). Table 3 compares the sensitivity of the Er^{3+} doped, Er^{3+}/Yb^{3+} doped, and $Er^{3+}/Yb^{3+}/W^{6+}$ doped BBN system with other RE-doped ferroelectric systems. Hence, it can be deduced that the prepared ceramic is a proficient material for sensing and has the potential to be extensively studied for its suitability in optical temperature sensor applications.

Table 3: Comparison of the sensitivity of various doped ferroelectric ceramics.

4. Conclusion

The solid-state method is used to produce the ferroelectric ceramic $BaBi_{2-x-y}Nb_{2-z}Er_xYb_yW_zO_9$ (BBN), which is doped with the transition metal ion, W^{6+} at a constant concentration of Er^{3+} and Yb^{3+}. The X-ray diffraction (XRD) spectra revealed the presence of a perovskite phase in each ceramic sample, which exhibited an orthorhombic crystal structure. The UCL spectrum displayed two distinct green bands and one red band. The UCL intensity exhibits enhancement with an increasing concentration of W^{6+} ions, peaking at (z = 0.02). Beyond this concentration, a quenching effect occurs. The presence of two photons was verified by observing the changes in UCL spectra caused by variations in pump power. The time-resolved fluorescence analysis examined the green and red light emission. The results indicated that the time decay increases as the dopant concentration increases, indicating the presence of non-radiative transitions at higher dopant concentrations. The FIR approach quantified the absolute sensitivity, yielding a result of 0.91% K^{-1} at a temperature of 573 K. These enhancements imply that the created material may be beneficial in developing sophisticated optoelectronic devices for versatile applications.

Journal Pre-proof

Highlights:

1. A detailed study of Er/Yb/W tri-doped $BaBi_{2-0.04-0.10}Nb_{2-z}Er_{0.04}Yb_{0.10}W_zO_9$ (BBN) system, and a comparison of undoped, Er-doped, Er/Yb co-doped and Er/Yb/W tri-doped BBN systems are presented.
2. The UCL spectra are traced at 980 nm and exhibit two distinctive green bands and one red band at 535 nm, 556 nm, and 673 nm, respectively.
3. The time-resolved fluorescence analysis was done for green and red emissions, and it was observed that the time decay increased for higher dopant concentrations.
4. The FIR technique measured the absolute sensitivity and had a value of 0.91% K^{-1} at 573 K.

***Abstract*—A Software Defined Networking is a modern offering against traditional network systems to make network control more efficient by reducing the dependency on the hardware side. With a logical control plane, it is essential to distinguish between benign and malicious data traffic. We explore the possibility of a hybrid neural network architecture for intrusion detection and traffic monitoring in an SDN environment. The suggested architecture stacks a Convolutional Neural Network (CNN) with Bidirectional Long Short Term Recurrent Neural Networks (BiLSTM) to provide a specialized architecture for distinguishing the incoming network traffic patterns in SDN. The results emphasize the hybrid architecture's effectiveness in detecting spatial and temporal features, contributing to improved network security in SDN environments.**

***Keywords*—Benign, Malicious, SDN, CNN, BiLSTM**

I. Introduction

Software Defined Networking is a modern approach that promises to change the network performance by splitting the network control from hardware devices like routers, switches, etc [1]. Unlike traditional approaches, SDN completely isolates the application tier from the control tier. Software defined networking reduces dependency on the hardware side by the logical centralisation of the control plane. However, it exposes the network to cyber threats. Despite available tools and techniques for enhancing security and detecting abnormal online behaviour, attackers persist in breaching confidentiality and compromising data. With more dependency on the software side, any intrusion into the control tier is a danger. So, there is a need for creating a robust solution for network traffic classification to boost accuracy and adaptability in network security. Machine learning based intrusion detection systems have gained importance for adapting to this evolving SDN network. Machine learning models automate real time threat detection by analysing extensive network data and traffic patterns.

Intrusion attacks involve penetrating the control tier that controls the entire network architecture. The main attacks might be ARP Spoofing, ARP Flooding Attacks, and Traffic Sniffing [2]. Attacks like SYN Flooding are also responsible for sending continuous requests to the network, causing it to flood with requests, ultimately disrupting the network functionality. In a malicious ARP request, the header of the data is tampered with in such as way that the data is received by the attacker instead of the genuine user for whom the data was originally intended. Once exploiters gain access to the control tier, they can easily manipulate the entire network, add their devices and steal valuable information from the user.

The primary motivation for this work is the understanding that traditional network security mechanisms often fall short in detecting network intrusion. The proposed approach uses the combination of CNN and BiLSTM to automatically extract and evaluate intricate elements in data packets, helping to achieve distinction of network traffic.

II. Background

A. Convolutinal Neural Networks

Operating under supervised learning, Convolutional Neural Network (CNN) is an essential model in computer vision. It makes good use of the weight sharing idea to solve the parameter explosion issue. A CNN architecture comprises of one or more convolutional layers, pooling layers, and fully connected layers. CNNs are widely employed in facial recognition and image processing applications. In the convolutional layer, linear operations are carried out by a filter that travels over the output of the previous layer [3]. The RELU activation function returns null for negative values in the feature map but returns the value for positive values. Multiple convolutional layers are used in CNNs, the first few layers extract simple characteristics like corners and edges, whereas the latter layers capture more intricate information. By shrinking the window size, the pooling layer lowers computation expenses. Given the wide deployment of CNN in various sub domains of deep

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:33:38 UTC from IEEE Xplore. Restrictions apply.

learning, it is worth analyzing if the inclusion of a CNN component can help enhance network intrusion detection [4].

B. Bidirectional Long Short Term Memory

While processing sequential data step by step, Recurrent Neural Networks (RNN) encounter obstacles such as exploding gradients. Problems in RNNs are addressed via memory units and gate mechanisms in LSTMs. Unlike LSTM, which processes input sequences in a unidirectional manner, Bidirectional Long Short-Term Memory (BiLSTM) consists of gates to allow information to flow in both directions, making it possible to efficiently capture contextual information. It uses two hidden states to store information about both the present and the future context.

In a BiLSTM architecture, the output of the first layer is the input to the second layer. The output of the second layer is the concatenation of the final unit outputs from both the forward and backward directions of the first layer [5]. Because BiLSTM can describe bidirectional connections in complicated sequential data, it is useful for tasks like natural language processing, gesture recognition, and time-series prediction [6]. So, they may prove useful in dealing with sequential network traffic data.

C. The proposed CNN-BiLSTM Hybrid Architecture

With the integration of both BiLSTM and CNN in a hybrid architecture, the suggested model improves traffic data feature extraction and pattern recognition in software-defined networking. The architecture starts with a CNN component. The convolutional layer applies a set of filters to the incoming network traffic to extract spatial data and look for local patterns within the traffic. CNNs excel when it comes to pattern recognition, so they can prove efficient in extracting malicious features from the network data packets. Because they are capable of detecting a pattern regardless of its position in the input sequence, CNNs can be the right choice for dealing with SDN network traffic data. Following the convolutional operation, the ReLU activation function is applied to introduce non-linearity into the network [7].

The dual bidirectional LSTM layers then capture both the forward and the backward temporal features. The first layer captures the immediate dependencies of the given source while the second layer looks for long-term dependencies within the source. Because BiLSTMs can handle sequences of variable length without the need for padding, they can be effective in dealing with network traffic data, which mostly come in variable length sequences. Furthermore, both LSTMs and BiLSTMs are known to be capable in learning from corrupted information, so they may be efficient in extracting meaningful representations from noisy input network traffic. This kind of special architecture may allow the model to effectively infer the sequential nature of the SDN traffic.

After the BiLSTM layers, a dense layer with 3 units along with a softmax activation function is introduced and finally, probabilities for each intrusion type is computed.

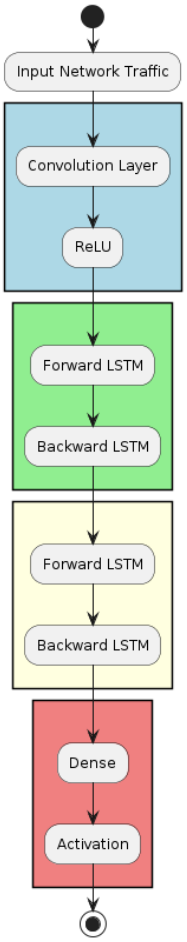

Fig. 1. Framework for the proposed architecture

The rest of the article proceeds as the following: Section III provides a brief summary of previous related works, Section IV lists out the methodology and the model workflow, Section V presents the experimental analysis and Section VI lays out the conclusions.

III. Literature Review

For the last few years, several studies have been conducted to improve intrusion detection in an SDN environment [8]. Given the growing need for SDN, it is essential to come up with ways to protect the network. Alzahrani and Alenazi first explored the potential of machine learning algorithms, such as Decision Tree, Random Forest, and XGBoost, for intrusion detection, avoidance, and traffic monitoring in Software Defined Networking [9]. The study primarily focused on detecting and classifying various types of common network attacks, like the Distributed Denial of Service (DDoS). The authors used the NSL-KDD dataset [10] for model training and achieved an impressive accuracy of approximately 95.95%.

In recent research conducted on intrusion detection in an SDN environment, deep learning techniques have been the most preferred choice, particularly CNN and LSTM models

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:33:38 UTC from IEEE Xplore. Restrictions apply.

[11]. These Deep learning models have been explored more as they have proven efficient in capturing temporal patterns as well as contextual information based on any sequence within the training dataset.

Tang, T. A., et al. implemented a model focused on detecting and identifying flow-based anomalies in an SDN environment [12]. Only six characteristics were focused out of all from the NSL-KDD dataset to reduce the overall computational cost. Comprising 12 neurons in the first layer, 6 neurons in the second layer, and 3 neurons in the final layer [13], the proposed three hidden layered Deep Neural Network model achieved an accuracy of about 75%. The score was considered too poor to be adopted for real-world scenarios. Thus for enhancement, the authors proposed a Gated Recurrent Unit (GRU), which increased the accuracy to about 89%.

Elsayed et al. proposed that having a memory understanding of the attack pattern could enhance intrusion detection. This could be done by utilizing the capability of long short-term memory with the understanding of a convolutional neural network [14]. This aggregation enabled the model to capture both temporal as well as spatial features effectively. To address overfitting, the authors employed the following regularization techniques: The L2 norm and Dropout. The authors tested the model's capability against the publicly available InSDN dataset [15]. The model gained an impressive accuracy of around 96%, which is greater than the accuracy of CNN and LSTM implemented individually.

Jiang et al. suggested a Deep Hybrid Intrusion Detection Technique, which used the combined capabilities of both convolutional neural networks and bidirectional long short-term memory networks [16]. To mitigate noise and establish a balanced dataset, the authors introduced One-Sided Selection (OSS). The model was tested against the following publicly available datasets: NSL-KDD, and UNSW-NB15. The results demonstrated promising performance, achieving an accuracy of around 83%.

Khan et al. introduced a Two-Stage Deep Learning Architecture to address the demand for efficient network intrusion detection [17]. The model comprises two decisional stages, the first differentiates the incoming network activity into normal and abnormal classes. For each instance, a score is assigned. This assigned score is then used in the latter decision stage, which distinguishes between normal network state and various attack classes. The proposed model was validated by conducting experiments with the KDD99 and the UNSW-NB15 datasets. While the model did achieve an impressive accuracy rate of around 99% for the KDD99 dataset and about 89% for the NSW-NB15 dataset, it is essential to highlight that networking-specific intrusion detection was not the focus point of the study.

ARP spoofing and flooding present significant security risks in network environments. ARP attacks, which include common attacks like DoS (Denial of Service), MITM (Man in the Middle), and host impersonation pose severe security risks to any network. Throughout the years, various diverse solutions have been proposed to detect and mitigate ARP attacks. Meghana, J. S. et al. highlighted the effectiveness of SDNs in reducing ARP attacks [18]. The authors proposed SDN-based techniques, employing buffer management, Bayes-based algorithms, and Network Flow Guard modules to enhance ARP attack detection. The study highlights the benefits of SDN features, such as centralized control and dynamic policy enforcement.

All these studies collectively underscore the efficiency and potential of deep neural networks in SDN security. So, it is worth studying if the proposed neural network architecture can give good results in SDN intrusion detection.

IV. Methodology

The workflow is as follows : Network traffic data simulated for the SDN environment is collected from Mendeley data [19], [20]. Preprocessing activities are carried out and the data is subjected to model training. Post training, performance metrics are calculated and results are compared with other neural network models.

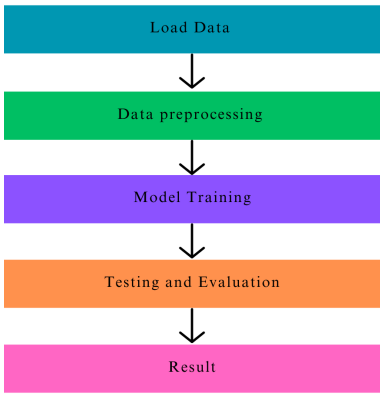

Fig. 2. Proposed workflow

A. Dataset

Many existing SDN datasets fail to provide diversity and relevance to current network conditions. The present research is limited to very few attacks and fails to cover ARP attacks. The datasets also lack genuine network traffic and consist of redundant and null values. To address this problem, the dataset chosen is generated using the mininet emulator, offering a realistic environment for experimental purposes. The simulated network consists of a Ryu controller, interconnected with 27 hosts and 12 switches, and uses a tree architecture with certain fan-out and depth parameters. The simulation examines network traffic that is both benign and malicious, focusing on ARP poison and ARP flood attacks.

The last column in the dataset acts as a class label, designating malicious (labeled 1 or 2) and legitimate (labeled 0) traffic. A total of 104,345 rows of data are gathered throughout a 250-minute simulation, and another 13,000 rows are obtained over a three-hour simulation. For model assessment, the used

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:33:38 UTC from IEEE Xplore. Restrictions apply.

dataset is subsequently divided into training and validation, where the former is used to train the model whereas the latter stage is essential for determining the model's ability to handle unknown input outside of its training set.

B. Data Preprocessing

Several data preprocessing techniques have been applied to ensure that the dataset chosen is clean and suitable for classification. Missing values are addressed by removing all the rows containing any missing values. Duplicate rows are eliminated to reduce redundancy and feature selection is performed by dropping columns that are irrelevant for model training. All these preprocessing activities enhance the quality of the chosen dataset for the subsequent model building.

Feature scaling is used to standardize the feature variables. Feature scaling provides a guarantee that all of the features are on a comparable scale, preventing some features from outperforming others throughout the training step. Because the network traffic is generated across an extended time period, there is a large scale in between certain features, such as the flow of packets. Thus, these features are normalised to have a range in between 0 to 1. The mathematical equation for the normalisation of the feature values is as follows :

$$f_{\text{normalised}} = \frac{f - \text{minimum}(f)}{\text{maximum}(f) - \text{minimum}(f)} \tag{1}$$

where $f_{\text{normalised}}$ is the normalised feature value, f is the original feature value, $\text{minimum}(f)$ is the minimum feature value in the dataset, and $\text{maximum}(f)$ is the maximum feature value in the dataset. Additionally, the categorical labels are transformed into binary vectors using one-hot encoding, thus enabling the model to learn from the categorical labels appropriately.

C. Model Training

To address issues like overfitting or underfitting and enhance overall model performance, it is essential to conduct hyperparameter adjustments. In this regard, a randomized search approach is employed to systematically define hyperparameters, aiming to optimize the model's accuracy and mitigate issues related to overfitting or underfitting. The hyperparameter configuration for the proposed model is as follows:

TABLE I
HYPERPARAMETER CONFIGURATION

Attributes	Values
Kernel Size	5
Filters	64
BiLSTM Layer	64, 128
Activation Function	ReLU
Kernel Regularization	L2 (0.01)
Loss Function	Categorical Cross Entropy
Optimizer	Adam
Dropout Rate	0.06

To evaluate the outcomes of the proposed model, the following neural network models are also trained on the same dataset: Vanilla RNN, BiLSTM, CNN, LSTM [21].

V. EXPERIMENTAL ANALYSIS

A. Evaluation Metrics

After training, to assess the performance of the model, the following evaluation metrics are computed:

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \tag{2}$$

$$Precision = \frac{TP}{TP + FP} \tag{3}$$

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{4}$$

The performance metrics shown in Equations (1), (2), and (3) above are derived from the four quadrants of the confusion matrix. The four quadrants are True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). A model correctly predicting a positive instance is known as a true positive. Similarly, when the model correctly predicts a negative instance, it is known as a true negative. When the model incorrectly predicts a positive outcome for a negative instance then it is known as false positive. Similarly, when the model incorrectly predicts a negative outcome for a positive instance it is known as false negative.

The Area Under the Receiver Operator Characteristics Curve (AUC-ROC) indicator measures the model's capability to differ across various categories. AUC, which is computed through the ROC curve, shows the sensitivity against the false positive rate. The classifier's effectiveness in distinguishing between network traffic being either benign or malicious can be enhanced with a higher AUC-ROC value, which should be positive and less than one.

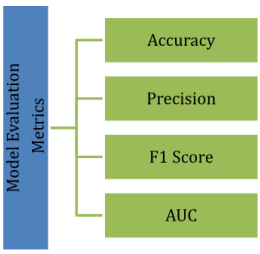

Fig. 3. Model evaluation metrics

Intrusion Detection Rate calculates the ratio of actual intrusions that are correctly identified by the model. For a particular class i, the intrusion detection rate can be calculated as the following:

$$IDR_i = \frac{TP_i}{\text{Z}i} \tag{5}$$

where IDR_i is the Intrusion Detection Rate for class i, TP_i is the total number of true positives for class i and Z is the total instances for the class i.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:33:38 UTC from IEEE Xplore. Restrictions apply.

B. Results and Discussion

The calculated evaluation metrics for the CNN-BiLSTM model, along with other neural network models are as follows:

TABLE II
EVALUATION SCORES

Model	Acc. (%)	Prec. (%)	F1-Score	AUC ROC
CNN	84.48	95.6	0.90	0.98
RNN	86.99	95.7	0.89	0.98
LSTM	87.57	95.8	0.90	0.98
BiLSTM	88.67	95.6	0.90	0.98
BiLSTM-CNN	**96.01**	**96.0**	**0.96**	**0.99**

With a high accuracy result, the model shows great promise in accurately classifying network traffic and distinguishing between normal and malicious data. The high precision score shows the model's effectiveness in minimizing false positives, which is crucial for mitigating operational disruptions and false alarms in SDN deployment. With a similar recall score, the model is able to identify a substantial number of true positive cases. Additionally, the high F1 score indicates that there is a perfect balance between precision and recall.

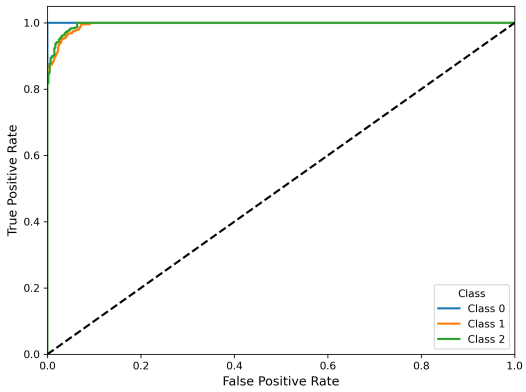

Fig. 4. Receiver Operating Characteristics (ROC) curve

Talking about other models, BiLSTM achieves a respectable accuracy of 88.67. Other traditional models also demonstrate competitive accuracies but lack the comprehensive ability of the hybrid model to encompass both local and global dependencies simultaneously. The ability of the combined architecture to extract both sequential and spatial feature extraction makes it a more suitable choice than the other baseline models.

TABLE III
INTRUSION DETECTION RATES

Class	Intrusion Detection Rate (%)
ARP Poison Traffic (Class 1)	92.44
ARP Flood Traffic (Class 2)	95.59

The Intrusion Detection Rate (IDR) measures the model's ability to correctly detect the instances of intrusion for each class. About 93 % of all the instances classified as ARP Poison Traffic were correctly identified. Similarly, around 96 % of all the instances classified as ARP Flood Traffic were correctly identified. These high detection rates further ascertain the architecture's effectiveness in identifying the instances of the corresponding intrusion classes.

While the model shows strong performance across the chosen evaluation metrics, there is still opportunity for further optimisation of the model. In the future, several strategies like fine tuning the hyper parameters, optimizing preprocessing activities and integrating ensemble learning techniques can be explored to enhance the precision. The proposed model's deviation from traditional architectures may be influenced by unique aspects of SDN traffic patterns, warranting further investigation into the dataset's intricacies.

VI. CONCLUSION

In this study, we proposed and evaluated a hybrid neural network architecture to classify ARP attack data in a software defined networking environment. To compare how well the model performs, other traditional neural network architectures were also trained on the same dataset. Each architecture's accuracy, precision, F1 score and AUC-ROC scores have been calculated and analyzed. The experimental analysis shows promising results for all the neural network architectures. But, on average of all performance metrics, the proposed BiLSTM-CNN hybrid model performed admirably, demonstrating significant promise and effectiveness. The model performed well in identifying occurrences, thanks to its comprehensive methodology, as demonstrated by the encouraging findings.

Identifying harmful incoming network traffic is crucial for delivering timely countermeasures against cyber threats. Future work will prioritize the development and implementation of a custom SDN infrastructure, enabling real-time data collection to assess and refine the model's functionality in practical scenarios. Comprehensive evaluations of the model's latency and throughput on live SDN networks will be conducted to gauge its real-world performance accurately. The performance of the model can also be assessed in other wider domains in the future [22]–[27].

Abstract: In modern wireless communication, achieving higher data rates, reliability, and spectral efficiency necessitates advanced transmission technologies. These technologies face challenges from unpredictable wireless propagation environments, particularly channel fading, which causes signal strength variations. Accurate channel estimation techniques are crucial for adapting transmission parameters to current channel conditions and optimizing performance. Orthogonal Frequency Division Multiplexing (OFDM) mitigates multipath propagation effects, and Multiple-Input Multiple-Output (MIMO) technology enhances capacity and reliability. The combined MIMO-OFDM framework relies on precise channel estimation, but traditional methods often fail in dynamic, complex channels. This research introduces a novel channel estimation technique, termed Modified M-estimator-I, which provides enhanced accuracy and resilience in estimating channel state information. Building on robust statistical estimation principles, the Modified M-estimator-I adapts to channel variations, offering more reliable performance across Rayleigh, Rician, and Nakagami fading environments. This innovative approach addresses the limitations of conventional estimators by incorporating advanced statistical methodologies to mitigate outliers and noise, thus optimizing the estimation process in diverse fading conditions.

Index: - Channel Estimation, M-estimator-I, Fading Channel, Pilot-symbol based Channel estimation

1. Introduction

In the realm of modern wireless communication, the quest for higher data rates, increased reliability, and enhanced spectral efficiency has driven significant advancements in transmission technologies. However, these advancements are continually challenged by the unpredictable and often adverse nature of wireless propagation environments. Channel fading, a phenomenon characterized by variations in signal strength over time and space, poses a formidable obstacle to the reliable transmission of data. To counteract these effects, accurate channel estimation techniques are indispensable, as they enable the adaptation of transmission parameters to the prevailing channel conditions, thereby optimizing performance.

Orthogonal Frequency Division Multiplexing (OFDM) has emerged as a cornerstone technology in contemporary wireless communication systems, renowned for its robustness against inter-symbol interference (ISI) and inter-carrier interference (ICI). By transmitting data across multiple orthogonal subcarriers, OFDM effectively mitigates the impact of multipath propagation. Transmitted symbols can be accurately recovered through effective channel estimation, which corrects the channel impulse response (CIR) and determines the channel's impact on the transmitted symbols. [1] MLE and MMSEE techniques for CIR estimation in OFDM systems was discussed. [2] The challenge of large CSI feedback in massive MIMO systems by proposing an efficient scheme using spatial correlation and compressed sensing (CS) techniques was discussed in [3]. Hence better reconstruction of transmitted symbols is required.

Complementing OFDM, Multiple-Input Multiple-Output (MIMO) technology leverages multiple transmitting and receiving antennas to enhance system capacity and reliability through spatial diversity and spatial multiplexing. The synergy between OFDM and MIMO, known as MIMO-OFDM, represents a powerful framework for high-performance wireless communication. Despite these technological advancements, the effectiveness of MIMO-OFDM systems is fundamentally dependent on precise channel estimation. Traditional channel estimation techniques, including pilot-based and blind estimation methods, have been widely studied and implemented. Various channel estimation techniques were studied for wireless communication system [4]. Least square channel estimation in MIMO-OFDM systems using block-type and comb-type pilot structures investigated in [5]. The estimation of channel parameters in OFDM and generalized frequency division multiplexing has been investigated in [6] and [7]. A combined approach of channel estimation and multi-user detection (MUD) in MIMO-OFDM systems to mitigate multi-access interference and reduce BER is proposed in [8]. LS and LMMSE-based channel techniques for channel parameters were compared in [9]. These conventional methods often fall short in addressing the dynamic and complex nature of wireless channels, particularly in the presence of severe fading. This necessitates the development of more sophisticated and adaptive estimation techniques. Robust multiuser detection using M-estimation in wireless communication systems was analysed in [10]. M-estimator-based approach compared with LS and MMSE approach in Rayleigh and Rician fading channel is done in [11]. Different channel estimation techniques are generally used for massive MIMO system, which are studied in [12].

In [13], a channel estimation technique for OFDM systems with fading channels is proposed. Rayleigh fading is commonly observed in environments with a high density of scatters, such as urban areas, where a direct line of sight between the transmitter and the receiver is absent. This results in a signal that is composed of numerous reflected and scattered paths, each with a different phase and amplitude. [14-15] proposes a method for analysing the performance of OFDM systems over Rayleigh fading channels, considering the effects of phase noise and carrier frequency offset. Rician fading, on the other hand, occurs in scenarios where there is a dominant line of sight path in addition to the scattered paths, leading to a more stable signal compared to Rayleigh fading. Nakagami fading provides a versatile model that can describe a wide range of fading conditions, from severe fading like Rayleigh to mild fading closer to Rician.

This research introduces a novel channel estimation technique, termed Modified M-estimator-I. The Modified M-estimator-I builds upon the principles of robust statistical estimation to provide enhanced accuracy and resilience in estimating channel state information. Unlike conventional estimators, which may be sensitive to outliers and noise, the Modified M-estimator-I incorporates advanced statistical methodologies to adapt to the variations in the channel conditions, offering a more reliable and robust performance across diverse fading environments.
In this paper, Section II outlines the system model. Section III explains the various channel estimation techniques and introduces the proposed Modified M-estimator-I. Section IV presents the simulation results, and Section V offers concluding remarks. The paper concludes with a list of references.

2. System MODEL

(A) OFDM and MIMO-OFDM System

Orthogonal Frequency Division Multiplexing (OFDM) is a wireless technology that transmits data on orthogonal subcarriers, allowing symbols to be closely packed without interference, thereby saving bandwidth. It uses Multi-Carrier Modulation to partition high-rate data into parallel bit streams, modulated by orthogonal subcarriers with IFFT and FFT for modulation and demodulation. Guard bands, cyclic prefixes, and pilot symbols are used to eliminate ISI, ICI, and assist in channel estimation. OFDM is robust against ISI, ICI, and fading, with enhanced performance when coupled with Multiple-Input Multiple-Output (MIMO) systems. MIMO employs multiple transmitting and receiving antennas to enhance system capacity and coverage through spatial multiplexing and diversity techniques. MIMO-OFDM improves link reliability and spectrum efficiency by increasing signal gain, reducing multi-path fading, and boosting channel capacity and SNR through spatial multiplexing and diversity coding.

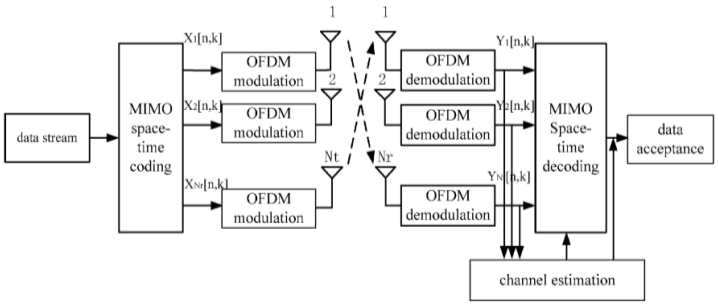

Fig. 1 Block diagram of MIMO-OFDM System

(B) Channel Estimation in Single Input Single Output (SISO) System

This analysis focuses on a single input, single output (SISO) system. Channels can affect different frequency signals in unique ways, making it essential to estimate the channel for each frequency channel. Due to the potentially large number of channels, this task can become complex and resource-intensive. Therefore, channel estimation is often performed on a subset of channels, with the estimates for the remaining channels being interpolated from these calculated values.

Consider selecting three frequencies, f_1, f_2 and f_3 from all the available frequencies. The corresponding reference or pilot signals will be $x(f_1)$, $x(f_2)$, and $x(f_3)$. These reference signals are complex, consisting of I/Q data. For the other frequency channels, we can interpolate the channel characteristics using the calculated ones. When these reference signals are received at the destination, they will include distortions and noise, represented by $y(f_1)$, $y(f_2)$, and $y(f_3)$. To express the received signals y(f) in terms of x(f), a channel function h(f) is required for the specific frequency. The relationship between the reference signal, the received signal, and the channel function can thus be represented by the correlation function.

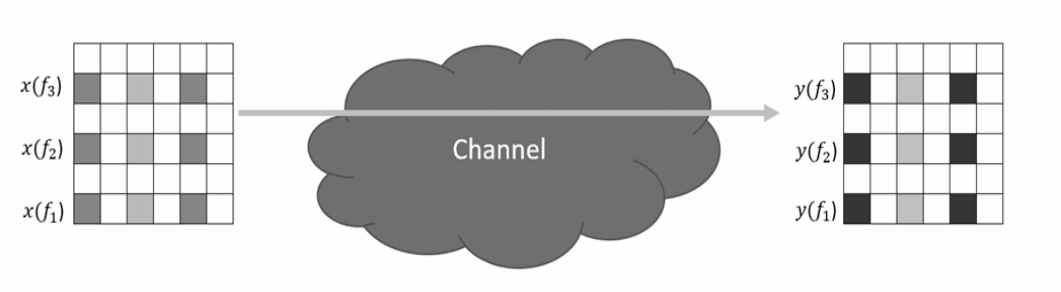

Fig. 2 Single Input Single Output System

Which can be written as

$y(f_1) = h(f_1) \cdot x(f_1)$
$y(f_2) = h(f_2) \cdot x(f_2)$
$y(f_3) = h(f_3) \cdot x(f_3)$
….(1)

from these equations, x(f) and y(f) are known thus h(f) can be calculated

$h(f_1) = y(f_1) \cdot x^H(f_1)$
$h(f_2) = y(f_2) \cdot x^H(f_2)$
$h(f_3) = y(f_3) \cdot x^H(f_3)$
….(2)

Here $x^H(f)$ is the Hermitian of $x(f)$.

Since only three frequencies have been considered and channel characteristics have been estimated for these frequencies, the properties for the remaining frequencies can be interpolated from the known characteristics. The channel function in these equations represents channel distortion. Additionally, noise is added to the distorted signals, so the actual equations of the received signal are as follows:

$y(f_1) = h(f_1) \cdot x(f_1) + n(f_1)$
$y(f_2) = h(f_2) \cdot x(f_2) + n(f_2)$
$y(f_3) = h(f_3) \cdot x(f_3) + n(f_3)$ ….(3)

Like how channel function was estimated, theoretically noise can also be estimated by using averaged channel estimate $\hbar(f)$.

$n(f_1) = y(f_1) - \hbar(f_1) \cdot x(f_1)$
$n(f_2) = y(f_2) - \hbar(f_2) \cdot x(f_2)$
$n(f_3) = y(f_3) - \hbar(f_3) \cdot x(f_3)$ ….(4)

However, absolute values of noise are not helpful for channel estimation due to the continuous variations in noise within a channel. What is beneficial is an estimated function of noise that accounts for and models these variations. Various algorithms and methods can achieve this. One such method, implemented in srsLTE (an open-source LTE implementation on SDR), involves subtracting the averaged channel estimate from the actual channel estimate.

$n(f_1) = h(f_1) - \hbar(f_1)$
$n(f_2) = h(f_2) - \hbar(f_2)$
$n(f_3) = h(f_3) - \hbar(f_3)$
….(5)

(C) Channel Estimation in Multiple Input Multiple Output (MIMO) System

In a multiple input multiple output (MIMO) system, there are multiple transmission endpoints and multiple reception endpoints.

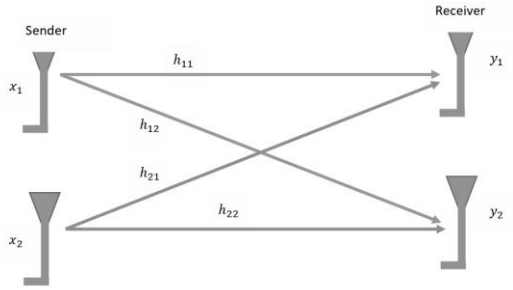

Fig. 3 A general 2x2 MIMO System

In a MIMO system, the channel estimation process is similar, but now there are two signals received from a single source. This indicates that two distinct paths in the medium were used, one for each signal. Therefore, to compute the final signal y(f) for each frequency, both received signals must be considered. This results in the formation of a matrix of received signals.

$$\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} n_1 \\ n_2 \end{bmatrix}$$

….(6)

Similar to a SISO system, in a MIMO system, the Hermitian of the input matrix x can be taken to estimate the channel matrix h. Similarly, the noise matrix n can also be calculated using matrix operations.

3. Channel Estimation

(A) Least Square (LS) Channel Estimation

Least squares (LS) channel estimation is a fundamental technique used in wireless communication systems to estimate channel state information (CSI). It is one of the simplest and most widely used methods due to its straightforward implementation and solid theoretical foundation. The LS channel estimation method aims to minimize the sum of the squared differences between the observed received signals and the predicted signals based on the estimated channel. This approach leads to a straightforward and intuitive solution, making it easy to implement.

LS channel estimation for 5G multicarrier wireless communications in Rayleigh, Rician and Nakagami fading channel is given by

$\hat{H}_{LS} = (X^H X)^{-1} X^H Y = X^{-1} Y$
….(7)

Where estimate of H is $\hat{H}$ and X^H is the Hermitian matrix of X.

(B) Minimum Mean Square Error (MMSE) Channel Estimation

Minimum Mean Square Error (MMSE) channel estimation is an advanced technique used in wireless communication systems to estimate channel state information (CSI) with improved accuracy and robustness compared to simpler methods like Least Squares (LS) estimation. MMSE channel estimation aims to minimize the mean square error between the actual and estimated channel responses by incorporating statistical knowledge

of the channel and noise. This method leverages both the received signal and prior information about the channel statistics to achieve a more accurate estimate.
MMSE channel estimation, the received signal y is modelled as
y = Hx + n,
where H is the channel matrix to be estimated, x is the transmitted signal, and n is the noise. The MMSE estimate $\hat{H}$ is given by:
$\hat{H}_{MMSE} = R_H X^T (X R_H X^T + \sigma^2 I)^{-1} y$
….(8)
Where R_H is the autocorrelation matrix of the channel, σ^2 is the noise variance, and I is the identity matrix.

(C) M-Estimator Channel Estimation

An M-estimator [16] is employed to enhance the robustness of channel estimation techniques in 5G wireless communication systems. The penalty, influence, and weight functions of the M-estimator for channel estimation in 5G multicarrier wireless communication over Rayleigh and Rician fading channels are provided by

$$\rho_{M-estimator}(x) = \begin{cases} \frac{x^2}{2} \ for\ |x| \le a \\ a^2 - a|x| \ for\ a < |x| \le b \\ \frac{-ab}{2} x\, exp\left(1 - \frac{x^2}{b^2}\right) + d \ for\ |x| > b \end{cases}$$

….(9)

$$\psi_{M-estimator}(x) = \begin{cases} x \ for\ |x| \le a \\ a\, sign(x)\ for\ a < |x| \le b \\ \frac{a}{b} x\, exp\left(1 - \frac{x^2}{b^2}\right) \ for\ |x| > b \end{cases}$$

….(10)

$$w_{M-estimator}(x) = \begin{cases} 1 \ for\ |x| \le a \\ \frac{a\, sgn(x)}{x} \ for\ a < |x| \le b \\ \frac{a}{b} exp\left(1 - \frac{x^2}{b^2}\right) \ for\ |x| > b \end{cases}$$

….(11)
Where d is a constant. The choice of the constants a(=kv^2) and b(=$2kv^2$) depends on the robustness measures derived from the influence function (k is also any constant). A robust estimator should possess a finite value of c. M- estimators reduce the outcome of outliers with $min \sum_i \rho(x_i)$, where ρ(x) is penalty function, influence function ψ(x) is the derivative of penalty function and $w_{Mestimator}(x)=\frac{\psi(x)}{x}$ is the weight function. The penalty function, influence function and weight function of M-estimator are shown in figures 4 – 6

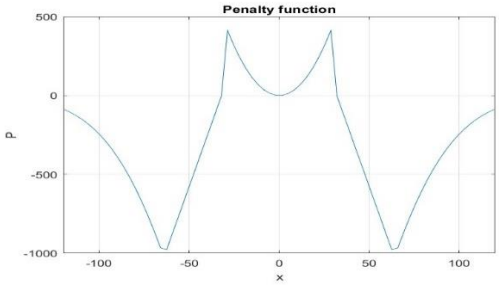

Fig. 4 Penalty Function of M-estimator

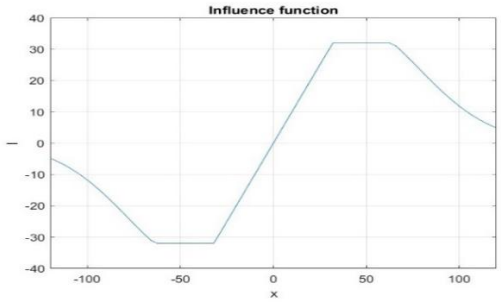

Fig. 5 Influence Function of M-estimator

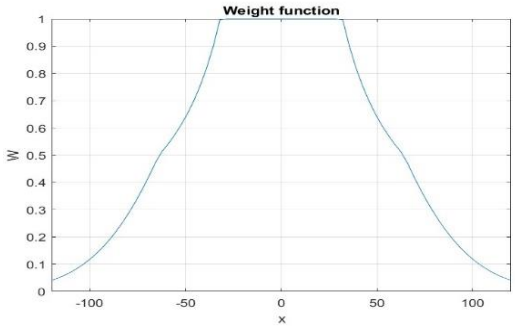

Fig. 6 Weight Function of M-estimator

M-estimator channel estimation for 5G multicarrier wireless communications in Rayleigh, Rician and Nakagami fading channel is given by

$$\hat{H}_{M-Estimator} = (X^H \psi(x) X)^{-1} X^H Y$$

….(12)

Where ψ(x) is influence function of the estimator described in above section. X is the transmitted signal in the channel. H is Hermitian transform matrix. Y represents the received signal in the channel.

(D) Modified M-estimator-I

From the statistics we know that the M-estimator is a statistical estimator used in robust statistics to estimate parameters of a statistical model. It is particularly useful when the data may contain outliers or other departures form the assumed model. In the context of wireless channel estimation, the M-estimator approach can be applied to estimate parameters such as the channel impulse response (CIR), the channel frequency response (CFR), or the channel matrix in MIMO systems. The previously proposed M-estimator based channel estimation algorithm uses the influence function of M-estimator. The modification proposed in M-estimator, which is named as Modified M-estimator-I uses ratio function instead of influence function.

The ratio function is described as the ratio of influence function to penalty function or object function. The ratio function is obtained as $R_{MODIFIED}(x) = \frac{\psi_{PROPOSED}(x)}{\rho_{PROPOSED}(x)}$. The proposed ratio function equation is described below

$$R_{MODIFIED}(x) = \begin{cases} \frac{2}{x} & for\ |x| \le a \\ \frac{sign(x)}{a-|x|} & for\ a < |x| \le b \\ \frac{\frac{a}{b}x\ exp\left(1-\frac{x^2}{b^2}\right)}{\frac{-ab}{2}x\ exp\left(1-\frac{x^2}{b^2}\right)+d} & for\ |x| > b \end{cases}$$

….(13)

The Modified M-estimator 2 based method finds the channels estimation parameters using the below equation

$$\hat{H}_{MODIFIED-I} = (X^H R(x) X)^{-1} X^H Y$$

….(14)

Where The R(x) is the ratio function described in above section. Ratio function is piecewise function, where the expression changes depending on the interval in which x lies. The X is the transmitted signal in the channel. H is Hermitian transpose matrix. Y represents the received signal in the channel. Figure… shows the ratio function of proposed Modified M-estimator-I.

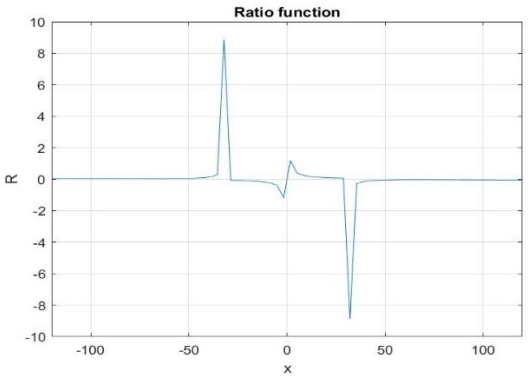

Fig. 7 Ratio Function of Proposed Modified M-estimator-I

4. Simulation Results

In simulations, channel estimation techniques based on LS (Least Squares), MMSE (Minimum Mean Square Error), M-estimator, and Modified M-estimator-I are compared. The performance evaluation of these techniques is conducted in terms of Mean Squared Error (MSE) and Signal-to-Noise Ratio (SNR). Figures 8 to 10 present the MSE and SNR results of these estimation techniques in Rayleigh fading, Rician fading, and Nakagami fading channels, respectively. It is evident across all these algorithms that MSE decreases as SNR increases, indicating better performance at higher SNR levels. Simulation results demonstrate that the Modified M-estimator-I outperforms LS, MMSE, and M-estimator techniques in channel estimation. All coding and simulations for channel estimation are implemented in MATLAB. The simulation parameters are detailed in the table below.

Table-1 Details of Simulation Parameters

Sr. No.	Parameters	Value(s)
1	Number of base station antennas	2
2	Number of UE antennas	2
3	Number of the resource block	6
4	Number of the resource bock per signal carrier	12
5	Number of transmitted symbols	2000
6	DFT size	Number of resource block X number of resource blocks per single carrier
7	FFT size	500
8	OFDM CP	Normal
9	Power delay profile	[1, 0.5, 0.25, 0.125]
10	Channel	Rayleigh fading channel, Rician fading channel, Nakagami fading channel
11	Channel estimation algorithms	LS, MMSE, M-estimator, Modified M-estimator

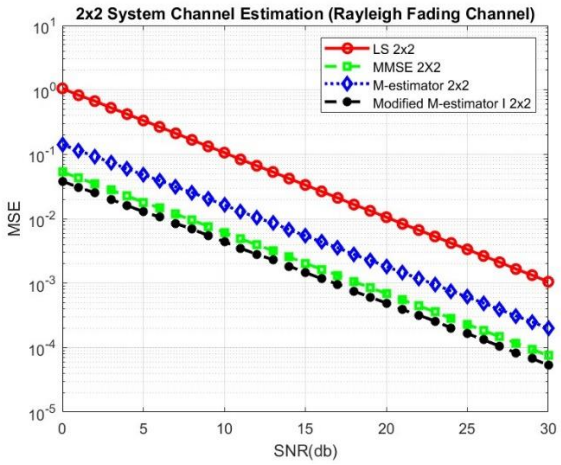

Fig. 8 BER vs SNR Performance of LS, MMSE, M-estimator and Proposed modified M-estimator-I in Rayleigh Fading channel.

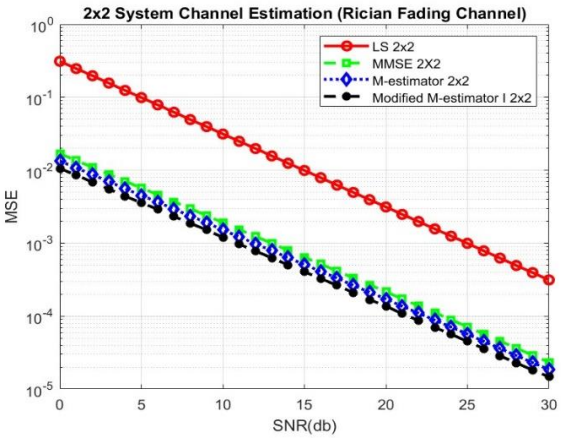

Fig. 9 BER vs SNR Performance of LS, MMSE, M-estimator and Proposed modified M-estimator-I in Rician Fading channel.

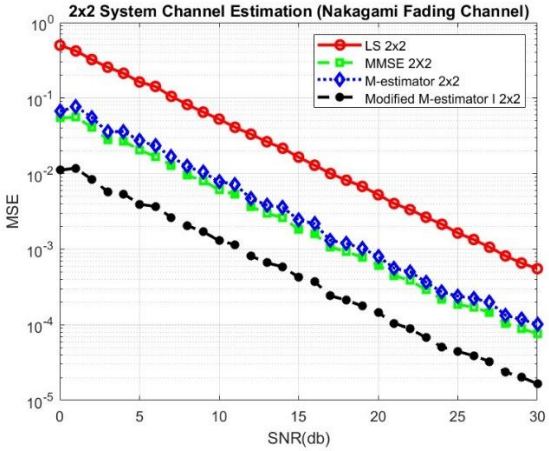

Fig. 10 BER vs SNR Performance of LS, MMSE, M-estimator and Proposed modified M-estimator I in Nakagami Fading channel.

5. Conclusion

In this paper, analysis of a Modified M-estimator-I based channel estimation technique for OFDM wireless communication systems in Rayleigh, Rician, and Nakagami fading channels is done. The newly proposed Modified M-estimator-I is employed to optimize the channel estimation process. To validate its effectiveness, we

provide simulation results that compare the performance of our proposed technique against the LS, MMSE, and M-estimator techniques. Based on these simulations, it is observed that the proposed Modified M-estimator-I based channel estimation technique demonstrates superior performance compared to LS, MMSE, and M-estimator techniques across Rayleigh, Rician, and Nakagami fading channels.

Integration of Deep Learning and Plant Biosecurity Toward Sustainable Agriculture: A SWOT Analysis

Abhilasha Sharma and Parul Sharma [a)]

Software Engineering Department, Delhi Technological University, Delhi, India

[a)] Corresponding author: sharma05oct@gmail.com

Abstract. Plant biosecurity holds immense significance for every nation as it plays a crucial role in protecting crops, ensuring food security, and safeguarding ecology and the livelihoods of individuals. In this regard, plant biosecurity constitutes a vital component of sustainable agriculture progress. Digitalization is the new go-to strategy to address agriculture's productivity, sustainability, and resilience challenges. Deep Learning and other digital technologies that have emerged in recent years are currently being applied in every agriculture practice. Researchers from multidisciplinary areas strive to use these technologies and propose novel solutions to expedite the in-field workflow. However, struggle to put their solutions into production, deliver tangible results and obtain favorable outcomes with limited in-field datasets. In this view, this paper reviews remarkable research integrating deep learning with plant biosecurity and provides a SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis to identify the strengths, weaknesses, opportunities, and threats inherent to deep learning-driven solutions as facilitators or barriers to plant biosecurity.

INTRODUCTION

Agriculture holds great importance in human civilization and is the cornerstone of modern society. Its profound connections to the global economy, biodiversity, and human history are undeniable [1]. As the most significant industry worldwide, it employs over 1.3 billion individuals and is valued at $5 trillion [2]. Agriculture enabled humans to cultivate their food, thus propelling the transition from a hunting society to a self-sustaining one. With the advent of digital technologies and the industrial revolution, the agriculture era has changed its paradigm from conventional to sustainable agriculture [3]. The agricultural transformation is represented in Fig. 1.

05 July 2024 06:08:08

Plant biosecurity is a critical use case of sustainable agriculture [4]. The pressures of population growth, environmental destruction, declining food security index, and climate change adversely impact agricultural sustainability [5]. Extreme climate change continues to raise the plant host's susceptibility to pests, diseases, and weeds, negatively affecting crop yields and quality. Pests, diseases, and weeds account for a massive loss in crop productivity and their nutritious values. Farmers invest a lot of money and time in preventing the abovementioned abnormalities; however, symptoms are hard to perceive through human sight, which may lead to total crop failure. Though conventional agriculture techniques provide some solutions, including applying chemicals and manual removal of weeds, these techniques are subjective to farmers' knowledge, time-consuming, and have adverse environmental effects. [6]. To this extent, smart agriculture, utilizing the techniques of Deep Learning (DL), has evolved to automate agricultural practices. DL algorithms empower plant biosecurity by automating diagnosis and decision-making [7-9].

However, many attempts at existing DL-based models and frameworks for plant biosecurity fail in natural field conditions. Despite the tremendous DL-based agricultural transformation in the last decade, NASSCOM estimates that only 2% of Indian farmers use technological solutions. Therefore, this paper aims to bridge the gap between recent developments and practices of DL in plant biosecurity. A comprehensive SWOT analysis, known as the Strengths, Weaknesses, Opportunities, and Threats, is conducted to accomplish this goal; it is worth mentioning here that this work is the first attempt to showcase a SWOT of this domain. This assessment examines the internal and external factors that influence the growth and potential of the area, encompassing both positive and negative aspects. The paper is further structured as follows: the next section describes the various terminologies constituting the research area. A brief overview of the SWOT matrix is presented in a further section. The consequent section explains the SWOT analysis of deep learning in plant biosecurity, followed by another section, which concludes the article.

1st International Conference on Recent Advancements in Computing Technologies & Engineering

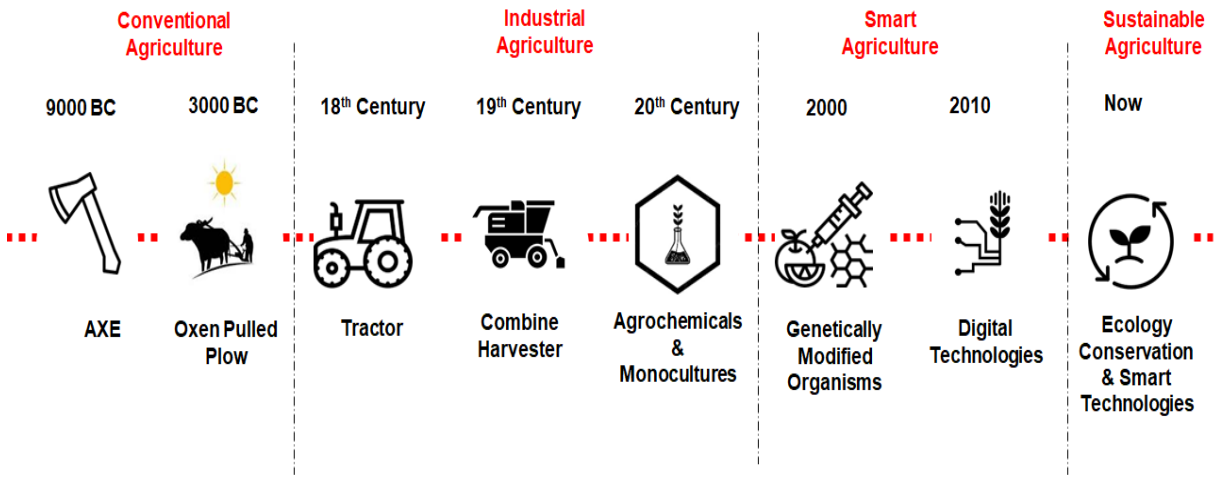

FIGURE 1. Evolution of Agriculture

TERMINOLOGIES

This section describes various terminologies that constitute the proposed research topic: Sustainable Agriculture, Plant Biosecurity, Smart Agriculture, and Deep Learning.

Sustainable Agriculture

Sustainability refers to fulfilling our current requirements without compromising future generations' needs. It enhances the quality of life, safeguards ecosystems, and preserves natural resources for the well-being of future generations. Given agriculture's profound ties to the global economy, human societies, and biodiversity, it is one of the most critical worldwide conservation domains. Hence sustainability in agricultural practices is the foremost need [10].

Sustainable agriculture involves employing environmentally friendly practices to meet the current demands for food and textiles while preserving resources for the coming generation. It encompasses farming methods that prioritize the protection of human and natural systems, ensuring the production of crops without causing harm to ecology. Sustainable agriculture rests on three essential pillars: environmental health, economic profitability, and social equity. Figure 2 presents the six primary components of sustainable agriculture: plant biosecurity, crop diversity, soil management, crop rotation, water management, and nutrient management [11].

Plant Biosecurity

Biosecurity implies implementing preventive measures to hinder the introduction and spread of harmful organisms such as viruses, bacteria, and other pathogens, aiming to minimize the risk of infectious disease transmission. The primary objective of biosecurity is to prevent, control, and manage risks associated with life and health, tailored to the specific sector of biosecurity. These measures safeguard crops against pests, invasive species, and other organisms threatening human and plant welfare. Plant biosecurity comprises a range of standards designed to shield crops from existing and exotic plant pests, diseases, and weeds at various levels, including national, regional, and individual farms [13].

Plant biosecurity is pivotal in ensuring food safety, food security, trade, market access, and development. It significantly influences the profitability and sustainability of plant industries [14]. Figure 3 illustrates the critical tasks involved in plant biosecurity, *Prevention* being the core focus to prevent the entry of exotic pests and diseases across boundaries. *Early Detection and Surveillance* indicates monitoring of pests, disease, and weeds to take prompt response against their growth; *Response and Management* imply the usage of various methods to mitigate the impacts

05 July 2024 06:08:08

and prevent further spread.; *Research and Innovation* suggest developing improved decision-making and risk analysis tools; *Collaboration and Cooperation* indicate communication and coordination among socio-economic drivers.

FIGURE 2. Elements of Sustainable Agriculture

Smart Agriculture

Smart agriculture refers to using digital technologies like the Internet of Things, sensors, location systems, robots, and artificial intelligence for automation and improving farm practices to increase crop quality & quantity while optimizing human labor. The penetration of the above-mentioned digital technologies brings many opportunities to enable a sustainable future in agriculture. These technologies play an essential role in achieving seven primary aspects of smart agriculture- digital soil analysis, intelligent irrigation, climate monitoring, agricultural robots, digital market intelligence, crop inspection, and crop protection [15,16]. The digital technologies that transformed agriculture as smart agriculture are represented in Fig 4.

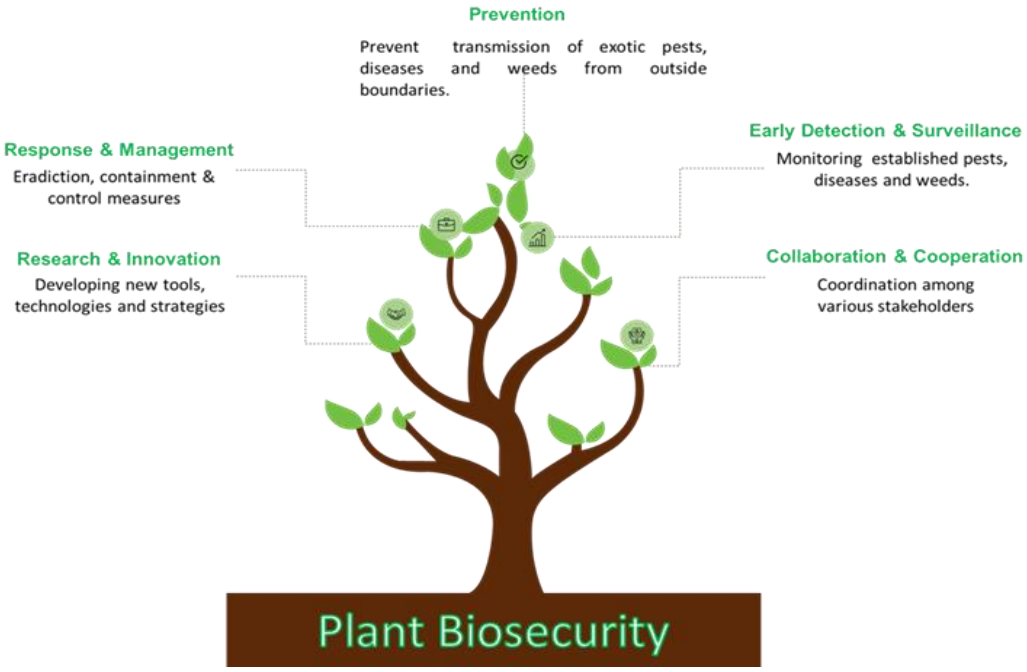

FIGURE 3. Elements of Plant Biosecurity Towards Safeguarding Plant Health

FIGURE 4. Key Technologies for Smart Agriculture

DL has recently emerged as a promising technology in intelligent agriculture, making a widespread digital impact. Deep learning refers to a class of artificial intelligence algorithms that utilize neural networks consisting of multiple layers to extract features from data and make predictions about new data. In artificial neural networks, learning involves adjusting the connection weights between neurons to improve network performance. Learning in artificial

05 July 2024 06:08:08

neural networks can be categorized into three main types: supervised, unsupervised, and reinforcement learning [17-19].

Supervised learning involves providing labeled input data to the model for training purposes and testing on unlabelled data. On the other hand, unsupervised learning focuses on identifying patterns and structures in unlabelled data, where only input data is provided to the model. Reinforcement learning enables an agent to learn in an interactive environment through trial and error, using feedback derived from its actions and experiences. Figure 5 depicts the relationship between Artificial Intelligence (AI), Machine Learning (ML), and Deep Learning (DL).

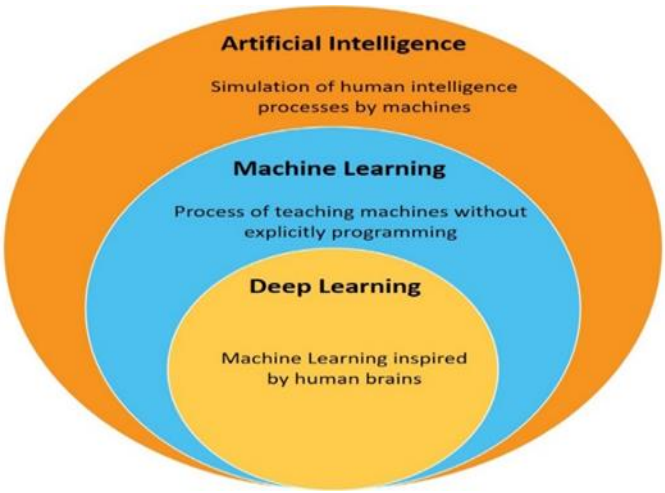

FIGURE 5. Cascading of Artificial Intelligence, Machine Learning, and Deep Learning

SWOT MATRIX- AN OVERVIEW

SWOT stands for Strengths, Weaknesses, Opportunities, and Threats. A SWOT matrix is a structured planning tool to assess an area's strengths, weaknesses, opportunities, and threats [20]. This analytical technique forms the basis for evaluating the internal capabilities and limitations, as well as the potential opportunities and threats stemming from the external environment. It considers all the positive and negative factors that impact the growth and scope of a particular field. The SWOT analysis encompasses the following scenarios: internal strengths & weaknesses and opportunities & threats in the external environment.

FIGURE 6. Generic SWOT Matrix

05 July 2024 06:08:08

SWOT ANALYSIS FOR THE INTEGRATION OF DEEP LEARNING & PLANT BIOSECURITY TO ACHIEVE AGRICULTURE SUSTAINABILITY

This section provides a structured SWOT analysis of DL-driven trends that can play an essential role in achieving plant biosecurity to strengthen agriculture sustainability. The SWOT matrix highlights the potential contributions, opportunities, weaknesses, and threats toward the applicability of DL in plant biosecurity. It provides recommendations to the researchers for an aligned use of DL for plant biosecurity. The following subsections expound on the details.

Strengths

Early Outbreak Warning

In recent years, the need for fast and accurate solutions for pests, diseases, and weeds management has been rising for better, reliable, and precise decision-making. Early-warning systems play a crucial role in plant protection, offering valuable tools that provide farmers with timely forecasts. Due to advances in computer vision and DL, the identification of crop disorders has shifted from conventional techniques to optical identification (use of digital images). DL-driven solutions provide accurate and swift detection methods and hold great potential that enables timely treatment. This, in turn, can significantly mitigate total crop loss failure, reducing financial setbacks and ensuring food security [21].

Improves Crop Yield and Lowers Production Costs

Agricultural production must rise by 70% by 2050 to meet the increasing global food demand. Managing pests, diseases, and weeds is paramount for food security. Plant disorders can significantly lower crop productivity. Traditionally, diagnosing crop abnormalities relied on human experts, which was expensive and time-consuming. Deep learning resolves the issues mentioned above and is employed to provide solutions for automated crop abnormalities detection without expert scouting. It improves productivity and lowers the cost incurred in traditional scouting techniques and blanket spraying of costly chemicals on plants [22].

Healthier Food Quality

Crop abnormalities affect crop yield and their nutritious value. The rise in plant diseases, pests, and weed outbreaks threatens food safety in various regions worldwide. Simultaneously, a global pandemic is endangering the health and well-being of millions of people on our planet. Further, this situation is worsened by farmers' blanket spraying of chemicals, pesticides, herbicides, and other chemicals without precise knowledge about these abnormalities. This has a significant impact on consumers' health and ecology. The DL-based automated solutions contribute towards maintaining nutritious food values by timely identifying phenotypic changes in plants and suggesting the exact abnormality and its possible solution [23].

Economic Benefits to Farmers, Consumers, and Country

Plant health has become a pressing global issue, impacting food crop production and nations' social and political stability. Agricultural productivity plays a vital role in the economic growth of every country. However, plant illnesses significantly affect agricultural production, resulting in substantial losses in the global economy. Monitoring plants' health and diagnosing disorders is crucial for promoting sustainable agriculture and enhancing trade. Automated DL-based early diagnosis solutions have emerged as valuable tools in disease control, aiding in selecting appropriate control techniques to improve productivity. Ultimately, this improvement benefits farmers, consumers, and the overall economy of nations [24].

Low Environmental Impacts

Agricultural practices and ecology are interconnected. Pests, diseases, and weeds are often controlled with artificial chemicals, which are harmful to producers, consumers, and ecology if not used in the correct amount. Hence to strengthen ecology, agricultural activities need to be redesigned. The introduction of DL in agricultural production is revolutionizing the farming sector. This advancement optimized inputs such as fertilizers, pesticides, herbicides, and other chemicals. By adopting DL-grounded solutions, farmers are motivated to reduce their environmental impact by adopting sustainable practices, resulting in a notable 21% reduction in greenhouse gas (GHG) emissions through the more efficient use of chemicals [26].

05 July 2024 06:08:08

Weaknesses

High Upfront Cost

DL has great potential to address the increasing food demand. However, the adoption of this technology in plant biosecurity has been relatively slow due to various factors. These include the high initial investment, limited technical expertise, and growing data privacy concerns. As DL applications tend to be computationally intensive, the requirement for substantial processing power is one of the major weaknesses. Additionally, DL-grounded solutions heavily rely on large amounts of data leading to significant costs associated with data processing. Overcoming these challenges is crucial for the widespread adoption of DL in plant health monitoring. By addressing the above-mentioned issues, plant biosecurity can fully leverage the potential of DL to meet the growing food demand effectively [26].

Low Awareness Among Farmers

Researchers are proposing automated solutions for plant abnormalities. However, low awareness among producers(farmers) about these tools and solutions is another hurdle. Easy comprehension, understanding, low access, and operational costs of radio broadcasts make them affordable for farmers seeking valuable insights regarding crop health. The automated DL solutions are being accessed by educated farmers only; less educated farmers are not exploiting these solutions because they need to gain basic knowledge about the usage of these solutions. Additionally, low-income farmers with small land areas have low interest in using these automated solutions [27].

Slow Adoption Rate in Developing Countries

Recently, DL has been addressing the management of pests, diseases, and weeds that hinder crop quality and quantity; however, only a few examples showcase positive impacts on rural livelihoods; these successes have yet to reach the expected scale. Inadequate infrastructure and resources, unreliable internet connections, and a need for more skilled professionals in the field are significant limitations. Overcoming these barriers is crucial for promoting the widespread adoption of DL in plant phenotyping. Efforts should focus on raising awareness, improving infrastructure, expanding resources, strengthening internet connectivity, and fostering the development of skilled professionals to maximize the potential benefits of DL for rural communities [27].

Non-Availability of In-Field Dataset

Most existing DL-based solutions to identify pests, diseases, and weeds are built using datasets captured in controlled conditions or considered only specific crops or diseases/pests/weeds. However, any technique used in practice must be prepared to deal with different environmental circumstances, diverse crops, pests, diseases, and weeds. Further, most self-collected datasets have yet to be released to be fully exploited for further research [7-9].

Heavy Models

DL-based solutions typically demand significant computational power and resources, making them less suitable to deploy on lightweight devices like mobiles and the Internet of Things (IoT). However, training these models can be exceedingly expensive due to the data models' complexity. Furthermore, the requirement for costly GPUs adds to the overall cost for developers and users. Additionally, efficient tuning of hyperparameters is necessary for optimizing the performance of these models [7-9].

Low Generalizability of Automated Solutions

As discussed above, most existing solutions are trained on laboratory-based datasets. Hence, their accuracy drops when these models are utilized for inference in field conditions. Further, researchers considered some specific crops or specific abnormalities, but in actual field conditions, varieties of crops and abnormalities exist. Hence a model/ solution developed for a particular crop is not generalizable to other crops.

05 July 2024 06:08:08

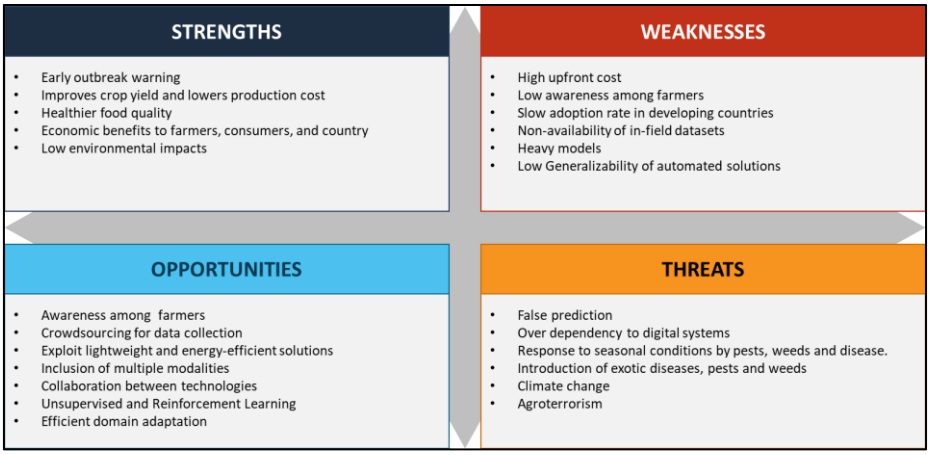

FIGURE 7. SWOT Matrix for Deep Learning in Plant Biosecurity

Opportunities

Awareness Among Farmers

To fully exploit the potential of DL for plant biosecurity, it would be beneficial if the government could circulate the various policies, websites, and apps for plant phenotyping through media. Digital literacy programs should be conducted for farmers. Farmers should also be encouraged to employ DL-based solutions to save their crops from pests, diseases, and weeds and make precise control decisions. Further, infrastructure (smartphones) should be made available to low-income farmers.

Crowdsourcing for Data Collection

A significant area for improvement in this field is the unavailability of standard datasets for DL. To make a model generalizable, it is required that researchers have datasets that are collected from diverse graphical conditions with varying weather conditions, illumination conditions, diversity of pests, diseases & weeds, and many more. Researchers alone cannot collect this data; hence crowdsourcing can generate many training data of good quality through social media or any other medium [28].

Exploit Lightweight and Energy-Efficient Solutions

As discussed above, heavy DL models cannot be deployed on embedded devices and mobile phones to be further utilized by farmers as a decision-making tool. Heavy models consume substantial energy resources that hinder the ecology facet. Considering these weaknesses, developing lightweight and energy-efficient models opens various opportunities for DL models to be fully utilized for plant biosecurity to improve agriculture sustainability [7-9].

Inclusion of Multiple Modalities

Multimodal learning is where models are trained to process and analyze multiple forms of input data, such as text, images, and audio. Most existing models primarily focus on visual information in embodiments for plant biosecurity, neglecting the potential insights from other modalities. However, incorporating multiple modalities holds immense potential for enhancing the monitoring of pests, diseases, and weeds [21-24]

Collaboration Between Technologies

To fully leverage the benefits of DL in plant biosecurity, collaboration among various technologies is essential. While DL has the potential to revolutionize this field, it is still evolving, and costs can be high. Therefore, ensuring widespread adoption will necessitate collaboration among different technologies. Integrating DL approaches with unmanned aerial vehicles (UAVs) and spectral data can facilitate the development of advanced intelligent solutions. Further, cloud computing can be integrated with DL to handle resource-intensive models, while edge computing can be combined with DL to reduce latency during inference. These are just a few examples of potential collaborations that can be explored to enhance the effectiveness and efficiency of plant biosecurity efforts [21-24].

Unsupervised and Reinforcement Learning

Existing DL solutions for plant biosecurity are based on supervised learning. However, the potential of unsupervised and reinforcement learning still needs to be addressed. To overcome the barriers of requiring large amounts of annotated data and building a heavy model for extensive labelled data can be addressed by exploring the solutions based on unsupervised and reinforcement learning [21-24].

Efficient Domain Adaptation

Domain adaptation is a computer vision field that aims to train a neural network on a source dataset and achieve high accuracy on a target dataset that significantly differs from the source dataset. The purpose of domain adaptation is to

05 July 2024 06:08:08

enable a pre-trained model to perform optimally on new data without retraining on a different dataset. Rather than starting from scratch with each new dataset, domain adaptation allows the adaptation of existing models to the target dataset, thereby saving time and resources. This approach facilitates the transfer of knowledge and learning from the source to the target dataset, enabling the model to perform well even in significantly different data domains. By leveraging domain adaptation, advancements can be made in strengthening plant biosecurity measures and addressing specific challenges related to detecting and preventing pests, diseases, and other threats to plant health [21-24].

Threats

False Prediction

A model trained on a poorly annotated dataset may lead to inaccurate predictions when tested in natural field conditions. However, farmers may adopt control measures per these false predictions, which may lead to complete crop loss failure and challenges to food security. Further, the inputs (pesticides, herbicides, fertilizers, and other chemicals) utilized as control measures will have poor impacts on ecology and causes economic loss.

Over-Dependency to Digital Systems

DL-based solutions can be employed with the help of digital devices only, like computers & smartphones; this increases farmers' dependency on these digital devices to make decisions. However, these digital gadgets may lead to GHG emissions, and the model deployed may cause high energy requirements.

Response to Weather Conditions by Pests, Weeds, And Diseases

A pest, disease, or weed may respond differently in different weather and geographic conditions. Considering all weather and geographic locations in a single dataset is almost impossible. This may cause a prediction bias and lead to poor results [29].

Introduction of Exotic Pests, Diseases, and Weeds

Exotic organisms refer to organisms introduced into an area beyond their natural range and become pests in the new environment. They are also known as alien, non-native, or introduced organisms. The entry of such exotic organisms poses a significant threat to plant security, as existing models may fail to recognize them, leading to wrong forecasts. This can result in financial losses, environmental damage, food production disruptions, and adverse effects on agriculture industries [30].

Climate Change

Climate change has complex and global impacts on agricultural ecosystems. It creates favorable conditions for the proliferation of pests and diseases, particularly in temperate zones. The effects of climate change have led to economically essential crop pests becoming more destructive, posing an increasing threat to food security and the environment. With the anticipated drastic changes in climate in the future, this situation may worsen [29].

Agroterrorism

Agroterrorism involves deliberate attacks on the food supply chain, targeting livestock and crops during various stages, including production, harvesting, storage, or transport. Agroterrorism poses a significant threat to achieving plant biosecurity and ultimately challenges the sustainability of agriculture. Terrorist actions to disrupt the food supply can have far-reaching consequences on economic stability and public health. These factors highlight the critical importance of addressing measures to counter agroterrorism to safeguard plant biosecurity and ensure the sustainability of agriculture [31].

CONCLUSION

The dependency of plant biosecurity over deep learning has increased remarkably in the last decade. Deep learning has automated pests, diseases, and weeds diagnosis & helps in decision-making for farmers and plant pathologists. Despite accelerated growth in this field, the agriculture industry still needs to catch up to the slow adoption of proposed solutions. In this view, to explore this area, a SWOT analysis is performed. The SWOT analysis of deep learning in plant biosecurity has identified several strengths, weaknesses, opportunities, and threats. Based on the SWOT analysis findings, the authors recommend that the researchers must focus on its strengths and opportunities to utilize the potential of DL better and take appropriate solutions to address its weaknesses and threats. Further, the government should run digital literacy programs, provide the necessary infrastructure to low-income farmers, and circulate various policies, websites, and apps for plant phenotyping. More importantly, a collaboration among DL and other digital technologies should be established; by doing so, deep learning can further strengthen plant biosecurity to achieve agriculture sustainability.

Abstract

An Improved Junctionless Nanowire Field Effect Transistor (I-JL-NWFET) device is proposed in this paper to address the limitations of conventional JL-NWFET. This research paper initially, comprehensively analyzes the impact of channel length (L) and channel thickness (t_{si}) scaling on the electrical, analog/RF, and linearity performance of I-JL-NWFET and JL-NWFET. The results suggest that the specific design features in I-JL-NWFET contribute to a more robust and less sensitive response to variations in scaling compared to its counterpart, JL-NWFET. Furthermore, an exploration into the impact of temperature on the electrical, analog/RF, and linearity performance is also conducted for both I-JL-NWFET and JL-NWFET. The electrical performance of I-JL-NWFET showcases a significantly reduced temperature sensitivity in parameters like drain current (I_D), Subthreshold Slope (SS) and Drain Induced Barrier Lowering (DIBL) compared to JL-NWFET. Subsequently, analyzing the analog/RF performance in the context of parameters such as transconductance (g_m), Transconductance Gain Factor (TGF), output conductance (g_d), early voltage (V_{EA}), total gate capacitance (C_{GG}), and cut-off frequency (f_T) under temperature variation, a lower degree of variability in I-JL-NWFET is observed compared to JL-NWFET. Furthermore, the linearity performance of I-JL-NWFET, assessed through parameters such as second and third-order transconductance (g_{m2}, g_{m3}), second and third-order input voltage intercept points (VIP2, VIP3), and third-order intermodulation distortion (IIP3 and IMD3) is improved at the higher temperature than that of JL-NWFET.

1. Introduction

The primary impetus behind the evolution of transistors towards miniaturization is to achieve higher density and enhanced performance for Integrated Circuit (IC) applications. However, this pursuit of miniaturization also introduces undesirable consequences in the form of adverse Short Channel Effects (SCEs) which impede technological progress [1]. To address these issues, the adoption of multi-gate transistors stands out as a promising solution for future technological advancements [2]. Nevertheless, the need for precise doping profiles at the metallurgical junctions and the necessity of a substantial thermal budget for dopant activation have become increasingly challenging as conventional Metal Oxide Semiconductor Field Effect Transistor (MOSFET) scaled down aggressively in size, which is also pertinent to future Complementary Metal Oxide Semiconductor (CMOS) technology [3].

Recently, Organic Thin-Film Transistors (OTFTs) have garnered significant attention for their commercial viability, primarily attributed to their mechanical flexibility, cost-effective fabrication, and semi-transparent characteristics [4]. Furthermore, leveraging the semiconductor properties of the organic materials used in their

© 2024 IOP Publishing Ltd

design, OTFTs find applications in diverse fields such as Organic Light Emitting Diode (OLED) [5, 6], digital inverters [7], organic solar cell [8], and more. Despite the widespread use of OTFT in various applications, there remains ample room for improvement in different aspects. The instability and degradation of organic materials stand out as primary concerns that need to be addressed for further advancements in these devices [9].

In response to these challenges, Junctionless Nanowire Field Effect Transistor (JL-NWFET) has been explored to replace the conventional MOSFET as well as OTFT. JL-NWFET provides an alternative approach by eliminating the necessity for p-n junctions at the source and drain ends, simplifying the manufacturing process and reducing the thermal budget [10]. However, to address issues such as the parasitic Bipolar Junction Transistor (BJT) phenomenon and insufficient volume depletion in JL-NWFET, the inclusion of an oppositely doped core in the channel region is explored [11, 12]. Furthermore, to overcome device degradation resulting from SCEs and parasitic BJT phenomena, as well as to enhance carrier transport efficiency, this paper introduces an Improved JL-NWFET (I-JL-NWFET) incorporating a Dual Material Gate (DMG) with a high-k material in the gate sidewall spacer region of the oppositely and equally doped core JL-NWFET.

The DMG structure employs two dissimilar gate work functions ensuring that the gate work function at the source side is higher than that at the drain side. This discrepancy in work function creates a potent electric field at the source, promoting the acceleration of electrons within the channel. Consequently, this enhanced acceleration increases drain current during the ON-state, thereby improving the current driving capability of the device. Moreover, the lower gate work function toward the drain reduces the magnitude of the drain-channel electric field experienced by electrons. As a result, the device is less susceptible to hot carrier-induced degradation and SCEs [13–15]. Additionally, the inclusion of the high-k material in the gate sidewall spacer region further alleviates the Lateral Band-to-Band Tunneling (L-BTBT) of electrons in the OFF-state [16, 17].

Recently, there has been a substantial increase in demand for portable electronic devices with high battery backup. To meet this heightened demand, it becomes imperative to increase transistor density and consequently scale the device's dimensions without compromising its performance. Moreover, elementary digital/analog circuits widely employed in sectors such as the military, automobile, nuclear, satellite communication, space, infrared detectors, and terrestrial systems are highly temperature-dependent [18]. The high-temperature reliability of a device ensures prolonged durability and stability. Additionally, linearity is a crucial requirement in all Radio Frequency (RF) systems, minimizing intermodulation and higher-order harmonics at the output. While there are system-level techniques for improving linearity, they often involve complex circuitry [19–21]. A transistor-level linearization is more suitable for power amplifiers in portable systems, necessitating an analysis of the linearity behavior at the device level. Therefore, it is crucial to investigate the impact of temperature variation on the device's RF, analog, and linearity performance for enhanced reliability. The investigation of temperature ranging from 200 K to 500 K is particularly relevant due to the diverse range of temperature-sensitive applications in electronics [22] and biomedicine [23]. Other reports are also available that have investigated the impact of temperature on similar ranges [24, 25].

In this paper, a detailed analysis of the scaling aspects of I-JL-NWFET and JL-NWFET is presented. Subsequently, an analysis of the electrical, analog/RF, and linearity performance is conducted, considering temperature variations ranging from 200 K to 500 K is also explored. The paper is structured into five sections, commencing with section 1 as the introduction. Section 2 outlines the device structure and characteristics, while section 3 delves into the impact of scaling on the electrical, analog/RF, and linearity performance of I-JL-NWFET and JL-NWFET. Additionally, section 4 scrutinizes the influence of temperature variations on the electrical, analog/RF, and linearity performance of I-JL-NWFET and JL-NWFET. The paper concludes with section 5, summarizing the findings and implications.

2. Device structures, specifications, and characteristics of JL-NWFET and I-JL-NWFET

For 3-D structure simulation of I-JL-NWFET and JL-NWFET, the SILVACO TCAD simulator is used [26]. Initially, to validate the simulation setup for conventional JL-NWFET, various physical models available in SILVACO, Technology Computer Aided Design (TCAD) has been employed and a combined transfer characteristics of simulation and experimental work [27] is plotted corresponding to $V_{DS} = 1$ V in figure 1. The Shockley-Read-Hall (SRH) recombination model is employed to address minority recombination, while the Bandgap Narrowing (BGN) model is utilized to factor in the impact of high doping in the channel. The inclusion of tunneling of electrons is achieved through the non-local BTBT model. The Lombardi mobility model (CVT), along with concentration and temperature-dependent and field mobility models, is also integrated. The convergence of results is facilitated by the numerical Newton method.

In figures 2(a) and (b), the 3-D and 2-D schematic diagrams of JL-NWFET are depicted, respectively. The structural parameters of JL-NWFET, including channel length (L), channel thickness (t_{si}), and gate oxide thickness (t_{ox}), adhere to the dimensions specified in the experimental paper [28], maintaining values of 60 nm,

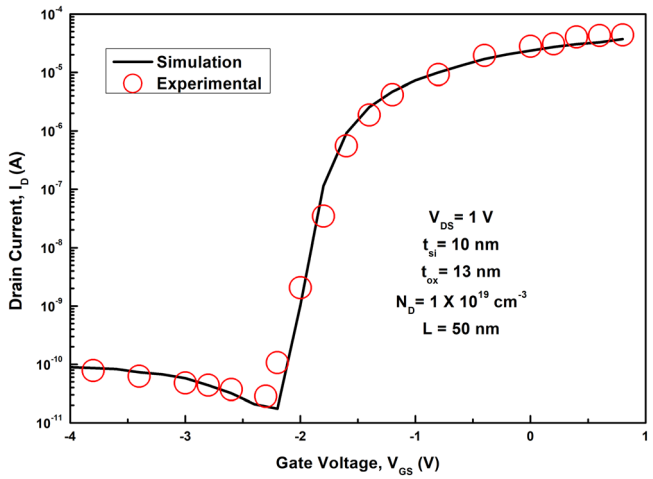

Figure 1. Combined plot of simulation and experimental results.

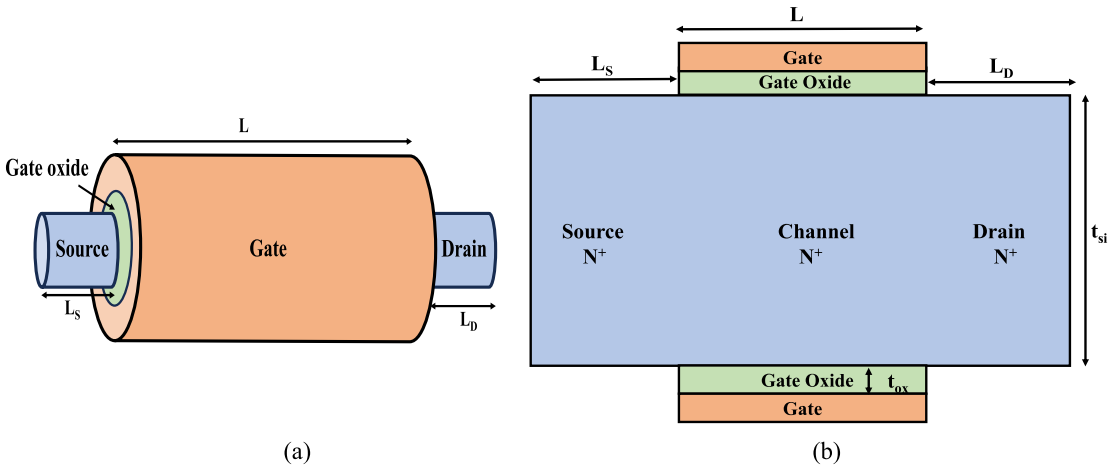

Figure 2. (a) 3-D and (b) 2-D cross-sectional view of JL-NWFET.

20 nm, and 1 nm, respectively. The length of source (L_S) and drain (L_D) is taken as 25 nm [11]. The SiO_2 is used as the gate oxide material. Subsequently, the consistent n-type doping concentration of 10^{19} cm^{-3} is utilized for defining the source, drain, and channel regions along with a high gate work function of 5.1 eV [11]. This heavy doping concentration also plays a pivotal role in ensuring the formation of Ohmic contacts at the metal-semiconductor interface [29]. By maintaining uniform doping levels at the source and drain regions, the possibility of Schottky contact formation can be mitigated.

Figures 3(a) and (b) showcase the 3-D and 2-D schematic depictions of I-JL-NWFET, respectively. I-JL-NWFET integrates a core that is equally and oppositely doped (p-doped), resulting in a reduced conduction layer referred to as the shell region (n-doped). The thickness of the core (t_{core}) and the shell (t_{shell}) contributes to t_{si} with $t_{si} = (2 \times t_{shell}) + t_{core}$. Furthermore, t_{core} is taken as 10 nm which is exactly half of t_{si}. The other structural parameters (L_G, t_{si}, t_{ox}, $L_{S/D}$) of the I-JL-NWFET mirror those of the JL-NWFET. The DMG structure in I-JL-NWFET comprises two gate metals (M_1 and M_2), each measuring 30 nm in length, with M_1 and M_2 having work functions of 5.1 eV (gold) and 4.6 eV (copper), respectively [30]. Additionally, HfO_2 is used as the gate sidewall spacer. Among the options explored, including air ($k = 1$), SiO_2 ($k = 3.9$), HfO_2 ($k = 22$) and Ta_2O_5 ($k = 26$), HfO_2 emerged as the most promising choice for enhancing device performance [12]. The device specifications of the JL-NWFET and I-JL-NWFET are outlined in table 1.

Figure 4 compares the transfer characteristics of JL-NWFET and I-JL-NWFET in linear and logarithm scales, respectively. The I-JL-NWFET demonstrates a remarkable enhancement in I_{ON}, surpassing that of the JL-NWFET by 23.1%. This improvement is credited to the emergence of an additional electric field at the interface of dissimilar gate metals within the DMG architecture of the I-JL-NWFET, thereby augmenting carrier velocity. Additionally, the incorporation of the high-k spacer proves instrumental in diminishing parasitic

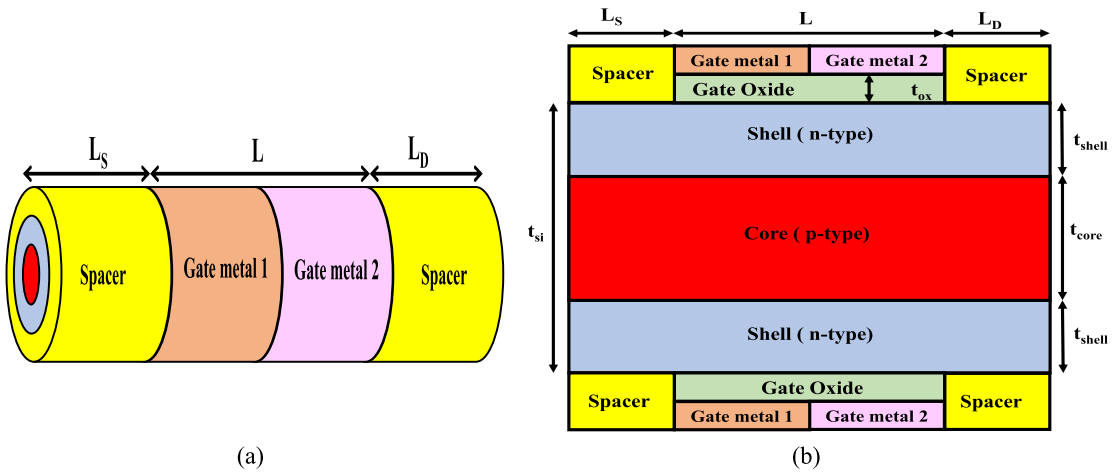

Figure 3. (a) 3-D and (b) 2-D cross-sectional view of I-JL-NWFET.

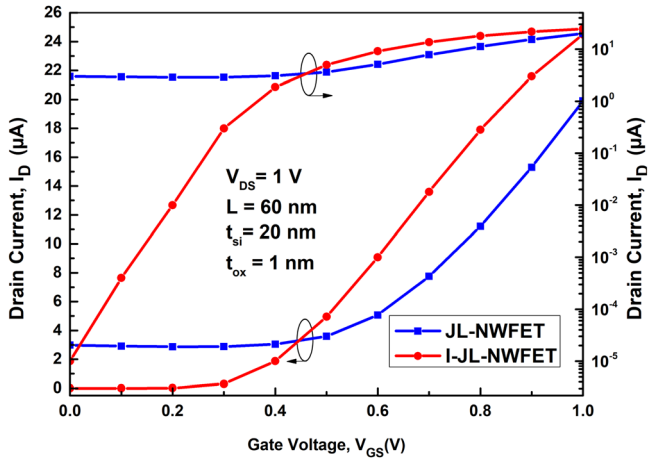

Figure 4. Plots of drain current of I-JL-NWFET and JL-NWFET in linear and log scale.

Table 1. Device specification for JL-NWFET and I-JL-NWFET.

Device parameter		JL-NWFET	I-JL-NWFET	
Channel	Material	Silicon	Silicon	
	Length, L (nm)	60	30 (L_{M1})	30 (L_{M2})
	Thickness, t_{si} (nm)	10	10	
	Doping, N_D (cm^{-3})	1×10^{19}	1×10^{19}	
Core	Material	—	Silicon	
	Thickness, t_{core}(nm)	—	10	
	Doping, N_A (cm^{-3})	—	1×10^{19}

	Length	—	25	

resistance beneath the spacer region, courtesy of the fringe field effect. The electrical performance of I-JL-NWFET is compared with JL-NWFET at the aforementioned structural parameters and results are succinctly presented in table 2.

Table 2. Performance comparison of JL-NWFET and I-JL-NWFET.

Parameter	V_T (V)	I_{ON} (μA)	I_{OFF} (μA)	I_{ON}/I_{OFF}	SS (mV/decade)
JL-NWFET	0.208	19.9	2.98	6.68	541.7
I-JL-NWFET	0.240	24.5	1.68×10^{-5}	1.81×10^{6}	64.8

Moreover, I_{OFF} is reduced by an order of 5 and accordingly, I_{ON}/I_{OFF} is improved by an order of 6 when compared to JL-NWFET. The integration of an oppositely doped core contributes to volume depletion, thereby mitigating I_{OFF}. The DMG architecture, in conjunction with the high-k spacer, widens the tunneling width and effectively suppresses the onset of the parasitic BJT phenomenon. Besides this, the Subthreshold Slope (SS) is improved by 88% in I-JL-NWFET as compared to JL-NWFET due to improved subthreshold characteristics exhibited by I-JL-NWFET. The most dominant parameters that contributes to the enhanced performance of I-JL-NWFET are the oppositely doped core and the DMG structure. As mentioned in the introduction section that conventional JL-NWFET suffers insufficient volume depletion and onset of parasitic BJT mechanism during OFF-state leading to high I_{OFF}. Moreover, JL-NWFET tends to experience reduced I_{ON} due to their heavily doped nature. The inclusion of an oppositely doped core facilitates hole recombination from the core and electrons in the channel, aiding in depletion during the OFF-state and consequently reducing I_{OFF}. However, it does not significantly affect I_{ON}. To address the need for increased I_{ON}, the DMG structure is introduced. This architecture amplifies the electric field at the source side by employing a higher gate work function at the source than at the drain, which accelerates electrons in the channel during the ON-state. This acceleration leads to enhanced I_D during the ON-state. The utilization of the high-k spacer, helps in reducing I_{OFF} by aiding in channel depletion beyond the gate region, is not as significant as the oppositely doped core and DMG structure in improving I-JL-NWFET performance.

3. Scaling impact on device performance

The device scaling represents a fundamental procedure within the semiconductor industry aimed at enhancing the transistor density on the chip. Therefore, it is imperative to assess how device scaling influences the performance of I-JL-NWFET. In this section, the impact of channel length (L) and channel thickness (t_{si}) scaling on the electrical, analog/RF and linearity parameters of I-JL-NWFET is analyzed. Furthermore, the results are also compared with that of conventional JL-NWFET.

3.1. Impact of channel length scaling on device performance

To observe the impact of channel length (L), an analysis is conducted on the electrical, analog/RF and linearity parameters of I-JL-NWFET and conventional JL-NWFET, with variations ranging from 70 nm to 20 nm keeping $t_{si} = 20$ nm, $L_{S/D} = 25$ nm, and $t_{ox} = 1$ nm as constant.

3.1.1. Impact of channel length scaling on electrical parameters

In this subsection, the impact of L on the electrical characteristics such as threshold voltage, drain current, OFF-state current, subthreshold slope and DIBL of I-JL-NWFET and JL-NWFET is analyzed.

Figure 5(a) illustrates the influence of L variation on the threshold voltage (V_T) and drain current (I_D) of I-JL-NWFET and JL-NWFET. The observed trend in figure 5(a) indicates a significant decrease in the V_T for conventional JL-NWFET when scaling down the L whereas I-JL-NWFET shows more consistent and lower variations in V_T. Notably, a sudden decline in V_T at an L of 20 nm suggests a loss of control of the gate voltage over the channel with a relatively large channel thickness. The drain current (I_D) for the scaled L is plotted in figure 5(a) at $V_{GS} = 1$ V. It corresponds to the maximum ON-state current of junctionless transistors as they are normally designed so that they operate in flat band condition in the ON-state [10].

The curve demonstrates that the I_D of both I-JL-NWFET and JL-NWFET increases with the scaling of L. The I_D of I-JL-NWFET surpasses that of JL-NWFET as the L is scaled down. Additionally, I-JL-NWFET shows enhancement of I_D due to the incorporation of DMG and high-k spacer implying better control over the flow of current through the channel.

The impact of L variation on the I_{OFF} and I_{ON}/I_{OFF} ratio of I-JL-NWFET and JL-NWFET is illustrated in figure 5(b). In the case of JL-NWFET, the I_{OFF} is higher than that of I-JL-NWFET as the L is scaled down. This is attributed to inadequate volume depletion in the large channel thickness and the initiation of parasitic BJT effects [31]. Typically, smaller L leads to higher I_{OFF}, which can be a concern for power efficiency and heat generation in integrated circuits. Conversely, I-JL-NWFET shows significantly better I_{OFF} variation at scaled L due to the presence of an opposite dope core which helps in volume depletion during OFF-state. Additionally,

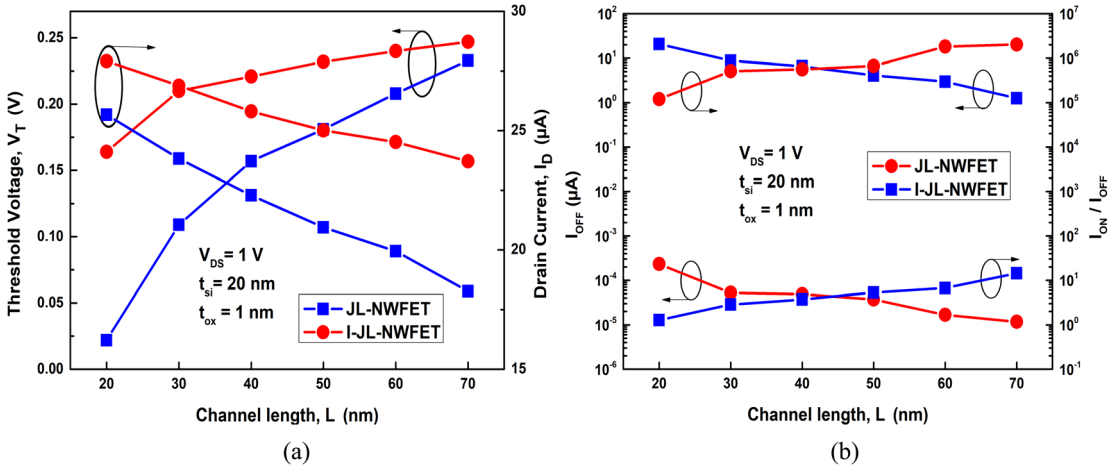

Figure 5. Plots of (a) threshold voltage and drain current (b) I_{OFF} and I_{ON}/I_{OFF} ratio of I-JL-NWFET and JL-NWFET for different channel lengths.

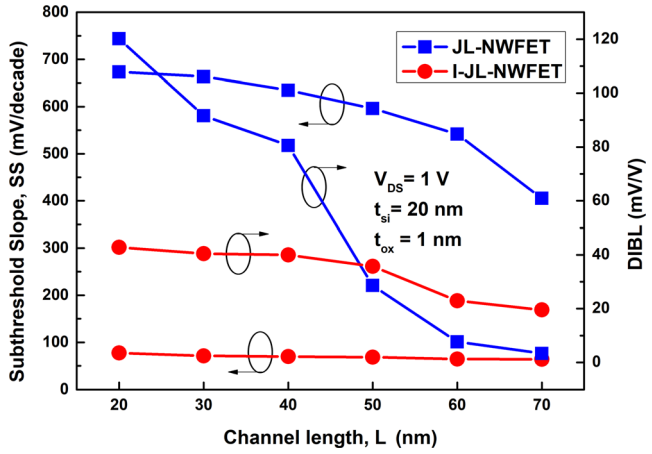

Figure 6. Plots of (a) SS and DIBL of I-JL-NWFET and JL-NWFET for different channel lengths.

DMG suppresses SCEs and Hot Carrier Effects (HCEs) more effectively and high-k material in the spacer region helps to deplete the channel beyond the gate edge. However, at a 20 nm channel length, there is a significant increase in the I_{OFF} of I-JL-NWFET, indicating poor electrostatic control of gate voltage. Consequently, the switching ratio (I_{ON}/I_{OFF}) of JL-NWFET and I-JL-NWFET decreases with decreasing L as portrayed in figure 5(b). Besides this, I-JL-NWFET depicts higher I_{ON}/I_{OFF} than JL-NWFET at scaled L. The I_{ON}/I_{OFF} ratio is determined by [10, 14]

$$\frac{I_{ON}}{I_{OFF}} = \frac{I_{DS}\,at\,V_{DS} = 1\ V\ and\ V_{GS} = 1\ V}{I_{DS}\ at\ V_{DS} = 1\ V\ and\ V_{GS} = 0\ V} \tag{1}$$

The Subthreshold Slope (SS) and Drain Induced Barrier Lowering (DIBL) are critical parameters when analyzing SCEs especially as L is scaled down. Figure 6 illustrates the influence of L variation on SS and DIBL. A lower SS is desirable to ensure efficient switching between the ON and OFF-states in the subthreshold region. SS is expressed as [10, 32]

$$SS = \frac{\partial V_{GS}}{\partial \log_{10}(I_D)} mV/decade \tag{2}$$

It can be noted from figure 6 that SS is lower for I-JL-NWFET than JL-NWFET. In JL-NWFET, the SS rises with the scaling of L because of an increase in I_{OFF}. This, in turn, leads to a reduction in the slope of the I_D-V_{GS} characteristics as the device transitions from the OFF-state to the ON-state. On the contrary, I-JL-NWFET shows less variation of SS at scaled L, implying improved subthreshold characteristics due to DMG and high-k spacer.

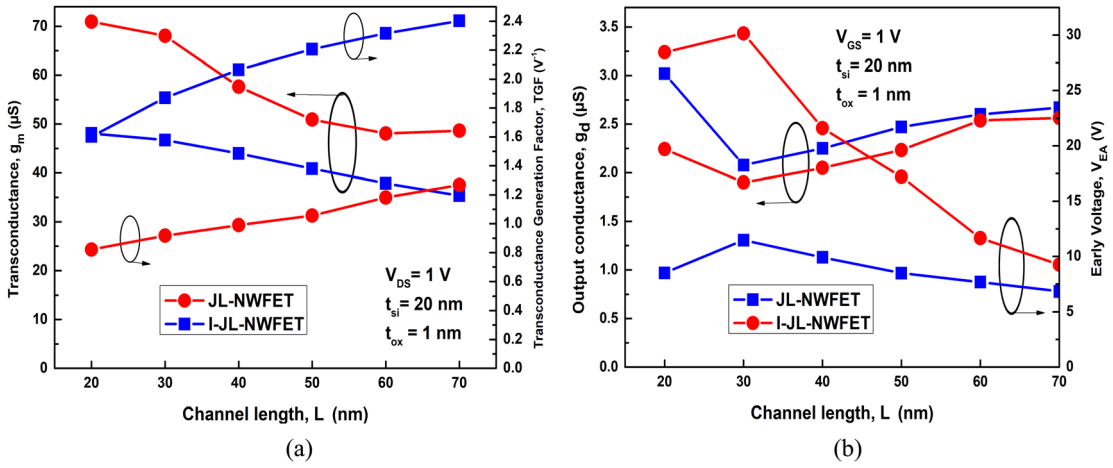

Figure 7. Plots of (a) transconductance and TGF (b) output conductance and early voltage of I-JL-NWFET and JL-NWFET for different channel lengths.

The DIBL refers to the reduction in the threshold voltage caused by an increase in the drain voltage and it is expressed as [33]

$$DIBL = \frac{V_T\ (V_{DS}\ = 0.05\ V) - V_T\ (V_{DS}\ = 1\ V)}{(V_{DS} = 1V) - (V_{DS} = 0.05V)} mV/V \tag{3}$$

The DIBL is quite severe in JL-NWFET as compared to I-JL-NWFET with scaling of L as demonstrated in figure 6. The reduction in DIBL effect in I-JL-NWFET is due to the presence of the oppositely doped core in the channel and DMG structure. The inclusion of an oppositely doped core decreased the active channel thickness of the I-JL-NWFET, improving gate control effectiveness and reducing the influence of drain voltage on the channel's electrostatics. As a result, the narrow conduction area led to a significant reduction in DIBL [34]. Additionally, the DMG structure aids in mitigating DIBL by providing a screening effect against drain voltage [33].

3.1.2. Impact of channel length scaling on analog/RF parameters

This subsection investigates the impact of L on the analog/RF parameters such as transconductance, Transconductance Generation Factor, output conductance, early voltage, total gate capacitance and cut-off frequency of the I-JL-NWFET and JL-NWFET.

The transconductance (g_m) stands out as a crucial analog metric in assessing devices, as it measures the relationship between the change in current and the variation in V_{GS}. A higher g_m signifies an inherent enhancement in amplification capacity. The Transconductance Generation Factor (TGF) holds significance in assessing the power needed to achieve high-speed concerning gate bias. TGF plays a pivotal role in determining how the current can be effectively utilized to attain a desired transconductance. The g_m and TGF are expressed as [17, 35]

$$g_m = \frac{\partial I_D}{\partial V_{GS}}\Big|_{V_{DS}=constant} \tag{4}$$

$$TGF = \frac{g_m}{I_D} \tag{5}$$

Figure 7(a) displays the influence of L variation on the g_m and TGF of I-JL-NWFET and JL-NWFET at $V_{GS} = 1$ V. With the scaling of L, the g_m of both I-JL-NWFET and JL-NWFET increases, with g_m of I-JL-NWFET exceeding that of JL-NWFET. This is attributed to the enhanced I_D in I-JL-NWFET than JL-NWFET as explained in figure 5(a). The TGF exhibits a greater decrease in I-JL-NWFET compared to JL-NWFET as L is scaled down.

The decrease in TGF is mainly attributed to the rising I_D as L decreases, which counteracts any potential improvement in g_m.

Generally, analog circuit devices are frequently operated in the saturation region. While I_D typically remains unaffected by V_{DS} in the saturation region, the impact of V_{DS} on channel electrostatics introduces variations in I_D, attributed to short-channel behavior. Hence, to understand the relationship between V_{DS} and I_D, output conductance (g_d) is evaluated. Additionally, the early voltage (V_{EA}) is crucial in the analysis and design of analog circuits, as it helps in determining the intrinsic gain of the device. The g_d and V_{EA} are formulated as follows [17]

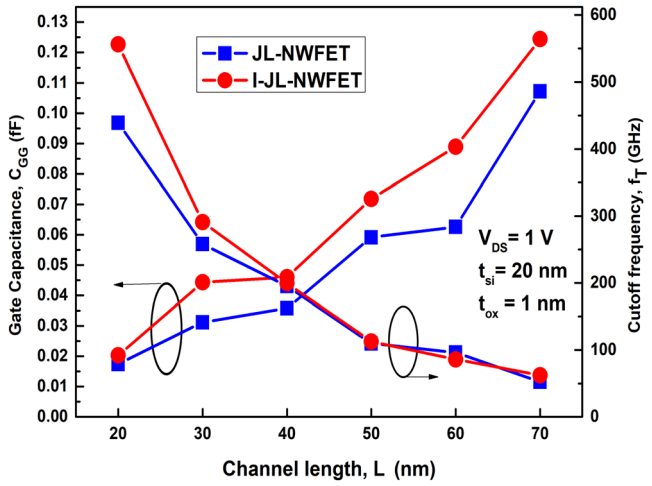

Figure 8. Plots of gate capacitance and cut-off frequency of I-JL-NWFET and JL-NWFET for different channel lengths.

$$g_d = \left.\frac{\partial I_D}{\partial V_{DS}}\right|_{V_{GS}=constant} \tag{6}$$

$$V_{EA} = \frac{I_D}{g_d} \tag{7}$$

The impact of L variation on the g_d and V_{EA} of I-JL-NWFET and JL-NWFET at $V_{DS} = 1$ V is portrayed in figure 7(b). The g_d of I-JL-NWFET reduces more than that of JL-NWFET as on scaling of L due to reduced DIBL in I-JL-NWFET than in JL-NWFET as observed in figure 6. Consequently, reduced g_d increases V_{EA} of I-JL-NWFET than that of JL-NWFET as on scaling of L. However, scaling of L below 30 nm may increase effect of drain bias leading to increase in g_d and decrease in V_{EA} in both I-JL-NWFET and JL-NWFET.

The total gate capacitance as parasitic capacitance (C_{GG}) and cut-off frequency (f_T) are important parameters for RF applications. C_{GG} in RF amplifiers may cause RF amplifiers to have low gain due to parasitic loss. The f_T is defined as the frequency at which the short circuit current gain drops to 0 dB. Mathematically, C_{GG} and f_T are formulated as [15]

$$C_{GG} = C_{GS} + C_{GD} \tag{8}$$

$$f_T = \frac{g_m}{2\pi C_{GG}} \tag{9}$$

where C_{GS} and C_{GD} are parasitic capacitances between gate-to-source and gate-to-drain terminals, respectively. Figure 8 shows the influence of varying L on the C_{GG} and f_T of I-JL-NWFET and JL-NWFET at $V_{GS} = 1$ V. The increase of C_{GG} of I-JL-NWFET exceeds that of JL-NWFET due to the presence of high-k spacer which increases capacitance at any given L. Moreover, the observed increase of f_T of I-JL-NWFET than that of JL-NWFET on scaling L is mainly due to increase in g_m as observed in figure 7(a).

3.1.3. Impact of channel length scaling on linearity parameters

The impact of scaling of L on linearity parameters of the I-JL-NWFET and JL-NWFET are analyzed in this subsection.

The fundamental parameters, g_{m2} and g_{m3}, are significantly influenced during high-frequency operation, leading to distortion and indicating nonlinearity. To enhance linearity performance, the peak values of g_{m2} and g_{m3} must be as low as possible. The g_{m2} and g_{m3} are expressed as [20]

$$g_{m2} = \frac{\partial^2 I_D}{\partial V_{GS}^2} \tag{10}$$

$$g_{m3} = \frac{\partial^3 I_D}{\partial V_{GS}^3} \tag{11}$$

Figure 9(a) depicts the influence of L variation on the peak value of g_{m2} and g_{m3} of I-JL-NWFET and JL-NWFET. The peak value of g_{m2} of I-JL-NWFET and JL-NWFET occurs at 0.6 V and 0.7 V, respectively while the peak value of g_{m3} of I-JL-NWFET and JL-NWFET occurs at 0.4 V and 0.5 V, respectively. The peak value of g_{m2} and g_{m3} increases on decreasing L due to less V_{GS} control on large channel thickness. Moreover, I-JL-NWFET

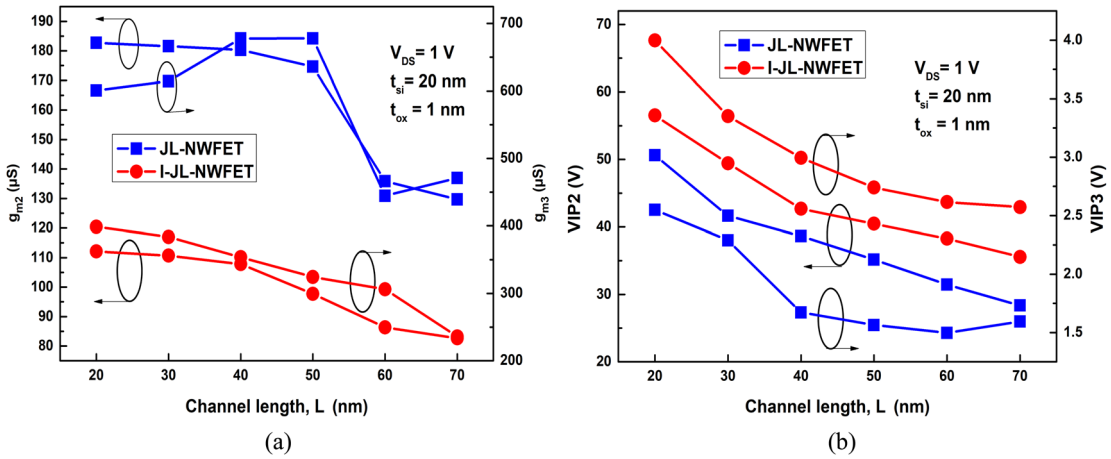

Figure 9. Plots of (a) g_{m2} and g_{m3} (b) VIP2 and VIP3 of I-JL-NWFET and JL-NWFET for different channel lengths.

exhibits low peak value of g_{m2} and g_{m3} than that of JL-NWFET at any given L, owing to inclusion of oppositely doped facilitating more effective V_{GS} control over channel region.

The set of metrics employed for evaluating distortion characteristics from DC parameters includes voltage intercept points (VIP2 and VIP3). The VIP2 signifies the extended input gate voltage where the voltage level of the fundamental signal equals that of the second-order harmonic signal. Beyond this crucial voltage, distortion is influenced by the amplitude of the first-order tone. The VIP3 represents the extrapolated input gate voltage at which the voltage levels of the fundamental and third-order harmonic signals become comparable. For high linearity performance and minimal distortion operation, a higher VIP2 and VIP3 is essential. These metrics can be expressed as follows [20]

$$VIP2 = 4 \times \frac{g_m}{g_{m2}} \tag{12}$$

$$VIP3 = \sqrt{24 \times \frac{g_m}{g_{m3}}} \tag{13}$$

Figure 9(b) illustrates the impact of L variation on the peak value of VIP2 and VIP3 of I-JL-NWFET and JL-NWFET. The peak value of VIP2 of I-JL-NWFET and JL-NWFET is observed at 0.7 V and 0.8 V, respectively while the peak value of VIP3 of I-JL-NWFET and JL-NWFET is observed at 0.6 V and 0.7 V, respectively. The peak value of VIP2 and VIP3 observed in I-JL-NWFET increases on decreasing L due enhancement in g_m that counteracts any increases in g_{m2} and g_{m3}.

The third-order input intercept point (IIP3) denotes the extrapolated input power level at which the powers of first and third-order harmonics become equal. IMD3, representing third-order intermodulation distortion, signifies the extrapolated intermodulation distortion power where the first and third-order intermodulation powers are equal. Equations (15) and (16) are employed to evaluate IIP3 and IMD3, respectively, with R_s assumed to be 50 Ω in analog and RF applications [20, 21]. Achieving a high IIP3 value and a low IMD3 value is desirable for enhancing linear characteristics.

$$IIP3 = \frac{2}{3} \times \frac{g_m}{g_{m3} \times R_S} \tag{14}$$

$$IMD3 = \left[\frac{9}{2} \times (VIP3)^2 \times g_{m3}\right]^2 \times R_S \tag{15}$$

Figure 10 demonstrates the impact of L variation on the peak value of IIP3 and IMD3 of I-JL-NWFET and JL-NWFET. The peak value of IIP3 of I-JL-NWFET and JL-NWFET is observed at 0.8 V and 0.9 V, respectively while the peak value of IMD3 of I-JL-NWFET and JL-NWFET is observed at 0.6 V and 0.7 V, respectively. Due to increasing g_m on decreasing L, the peak value of IIP3 in I-JL-NWFET increases than that in JL-NWFET. Furthermore, the peak value of IMD3 of I-JL-NWFET increases on decreasing L due to increasing g_{m3} and VIP3. I-JL-NWFET exhibits low peak value of IMD3 compared to JL-NWFET owing to low peak value of g_{m3} in I-JL-NWFET as observed in figure 9(a).

At 30 nm of L, I-JL-NWFET demonstrates optimal values for I_{OFF}, I_{ON}/I_{OFF}, and DIBL. Consequently, L of the I-JL-NWFET is fixed at 30 nm for further analysis in subsequent sections.

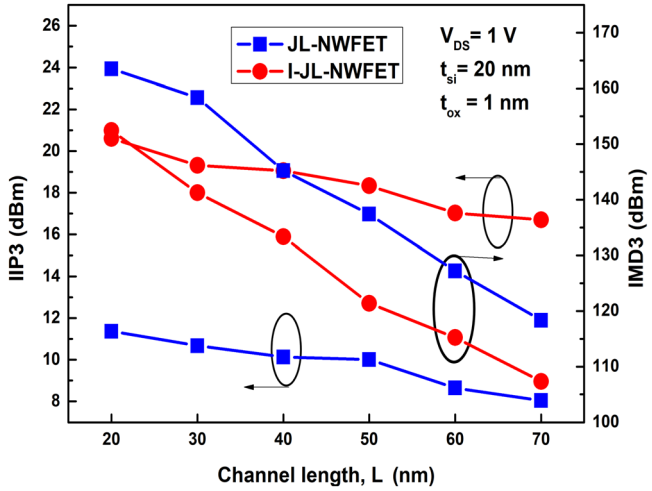

Figure 10. Plots of IIP3 and IMD3 of I-JL-NWFET and JL-NWFET for different channel lengths.

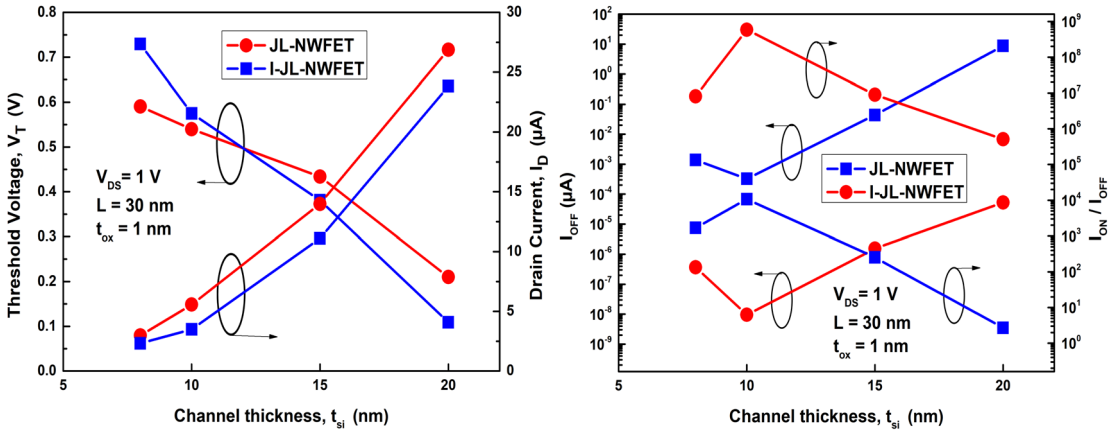

Figure 11. Plots of (a) threshold voltage and drain current (b) I_{OFF} and I_{ON}/I_{OFF} ratio of I-JL-NWFET and JL-NWFET for different channel thicknesses.

3.2. Impact of channel thickness scaling

The design of JL-NWFET is significantly influenced by the channel thickness (t_{si}), a crucial parameter essential for operation in various modes. Furthermore, the key concerns associated with JL-NWFET, namely insufficient volume depletion and leakage current, are strongly dependent on the t_{si} [27]. The impact of t_{si} on the electrical, analog/RF and linearity characteristics of both JL-NWFET and I-JL-NWFET is analyzed by varying it from 20 nm to 8 nm keeping $L = 30$ nm, $L_{S/D} = 25$ nm, and $t_{ox} = 1$ nm as constant. Moreover, t_{core} in I-JL-NWFET is varied as half of t_{si} during each scaling of t_{si}.

3.2.1. Impact of channel thickness scaling on electrical parameters

In this subsection, the analysis focuses on the impact of L on the electrical characteristics of I-JL-NWFET and JL-NWFET, including I_D, V_T, I_{OFF}, SS, and DIBL.

The impact of t_{si} scaling results in an increase in V_T for both JL-NWFET and I-JL-NWFET, as depicted in figure 11(a). In the case of large t_{si} of JL-NWFET, there is insufficient volume depletion, requiring less gate voltage to turn the transistor ON. I-JL-NWFET exhibits less variation in V_T as t_{si} is scaled, compared to JL-NWFET because of the presence of an opposite doped core that reduces active shell thickness for conduction.

Furthermore, as shown in figure 11(a), I_D decreases with a reduction in t_{si} for both JL-NWFET and I-JL-NWFET. In the case of JL-NWFET, where bulk conduction occurs, the decrease in cross-sectional area for current flow leads to a decrease in I_D. Conversely, in I-JL-NWFET, which features a DMG, the presence of dual materials enhances carrier mobility. This results in an increase in I_D compared to JL-NWFET, despite the

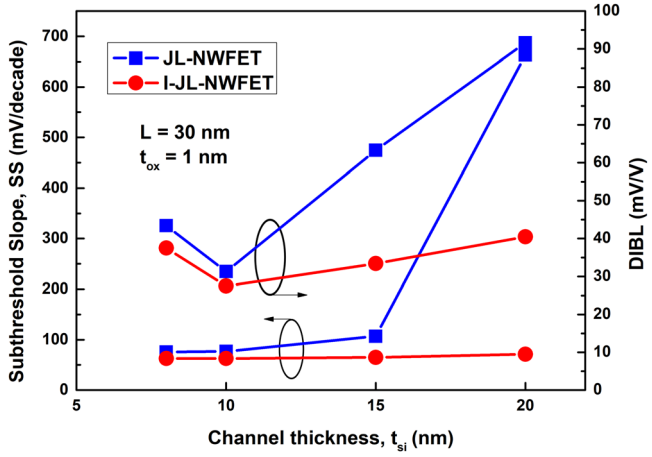

Figure 12. Plots of SS and DIBL of I-JL-NWFET and JL-NWFET for different channel thicknesses.

Table 3. Performance comparison of I-JL-NWFET with JL-NWFET and other reported devices.

Parameters	[10]	Re-S/D-JL-GAA MOSFET [36]	DPGAA MOSFET [37]	JL-NWFET	I-JL-NWFET
I_{OFF} (A)	1×10^{-15}	9.5×10^{-10}	5.34×10^{-13}	3.25×10^{-10}	9.55×10^{-15}
I_{ON}/I_{OFF}	1×10^{6}	1.2×10^{4}	2.14×10^{8}	1.07×10^{4}	5.83×10^{8}
SS (mV/decade)	64	73.63	69.96	76.83	62.75
DIBL (mV/V)	—	49.47	—	31.30	27.51

presence of the opposite doped core that reduces the active shell thickness for conduction. Figure 11(b) illustrate the influence of t_{si} variation on the I_{OFF} and I_{ON}/I_{OFF} ratio. The higher I_{OFF} in JL-NWFET with a t_{si} of 20 nm is attributed to insufficient volume depletion and the initiation of the parasitic BJT phenomenon. This effect diminishes with the scaling of t_{si}, allowing the gate voltage to more effectively control the channel. However, in I-JL-NWFET, the presence of an oppositely doped core aids in carrier depletion in the OFF-state. Additionally, the utilization of a DMG, including high-k material in the spacer region, further contributes to reducing I_{OFF} compared to JL-NWFET on the scaling of t_{si}. Both JL-NWFET and I-JL-NWFET experience an increase in I_{OFF} at a t_{si} of 8 nm due to a rise in SCEs. However, it is worth emphasizing that the I_{OFF} recorded for I-JL-NWFET at a t_{si} of 8 nm is comparatively lower than that observed in JL-NWFET under the same conditions. Consequently, I_{ON}/I_{OFF} ratio in I-JL-NWFET is higher than JL-NWFET.

The impact of varying t_{si} on SS and DIBL is shown in figure 12. The SS in JL-NWFET decreases drastically when t_{si} is scaled due to the significant reduction in the OFF-state current. Additionally, SS also increases since scaling of t_{si} beyond 10 nm increases I_{OFF} in JL-NWFET. However, SS in I-JL-NWFET shows less sensitivity towards scaled t_{si} due to improved I_{OFF} as discussed in figure 11(b). Furthermore, decreasing the nanowire t_{si} improves the efficacy of gate control, leading to a diminished impact of the drain voltage on the electrostatics in the channel region. Consequently, the effective gate control provided by the smaller t_{si} markedly reduces DIBL in JL-NWFET till 10 nm of t_{si} beyond which it increases due to reduced control of gate voltage over the channel region, as illustrated in figure 12. Nevertheless, in the case of I-JL-NWFET, DIBL exhibits less sensitivity on scaling t_{si}. This is attributed to the presence of the core with opposite doping, which effectively reduces the active channel region, and DMG, which improves gate control on the reduced active channel region.

Table 3 compares the electrical performance of I-JL-NWFET with JL-NWFET, experimental work [10], Recessed Source/Drain Junctionless Gate All Around (Re-S/D-JL-GAA) MOSFET [36] and Dielectric Pocket Gate All Around (DPGAA) MOSFET [37]. It can be observed that I-JL-NWFET showcases higher I_{ON}/I_{OFF}, and less value of I_{OFF}, SS and DIBL when compared to other published work. The superior electrical performance demonstrated by the I-JL-NWFET underscores its viability for various electronic applications.

3.2.2. Impact of channel thickness scaling on analog/RF parameters

The impact of scaling of t_{si} on analog/RF parameters such as g_m, TGF, g_d, V_{EA}, C_{GG} and f_T of the I-JL-NWFET and JL-NWFET are analyzed in this subsection.

Figure 13(a) illustrates the variation of t_{si} on g_m and TGF of I-JL-NWFET and JL-NWFET at $V_{GS} = 1$ V. The g_m of I-JL-NWFET and JL-NWFET decreases on scaling of t_{si} due to reduction of $I_{D.}$ Moreover, g_m of

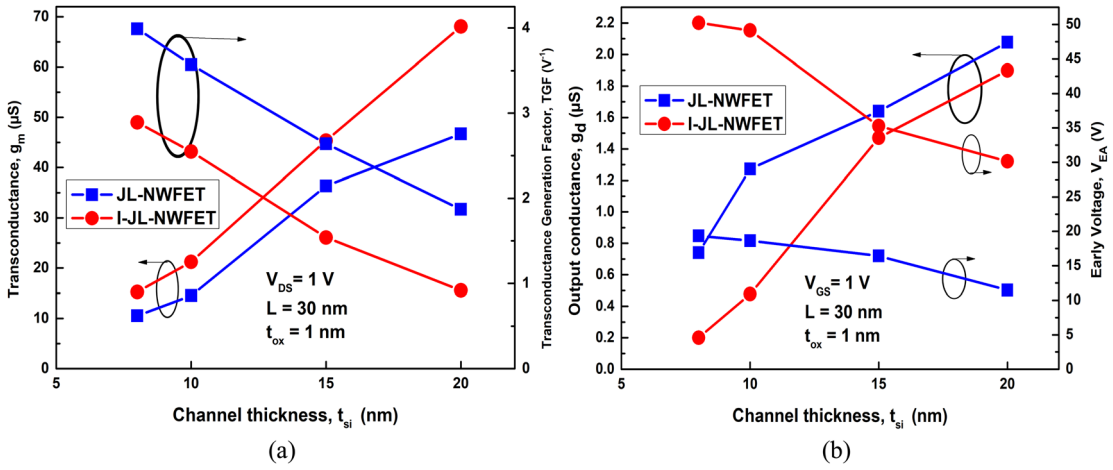

Figure 13. Plots of (a) transconductance and TGF (b) output conductance and early voltage of I-JL-NWFET and JL-NWFET for different channel thicknesses.

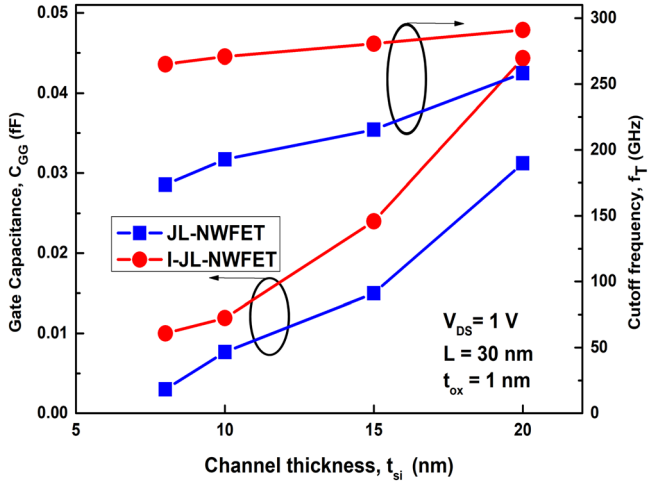

Figure 14. Plots of gate capacitance and cut-off frequency of I-JL-NWFET and JL-NWFET for different channel thicknesses.

I-JL-NWFET surpasses than that of JL-NWFET attributed to enhanced I_D at any given t_{si}, as exhibited in figure 11(a). Consequently, TGF of I-JL-NWFET and JL-NWFET increases as t_{si} is scaled down due to reduced I_D. Additionally, I-JL-NWFET exhibits higher TGF compared to JL-NWFET at any given t_{si}, due to DMG structure that increases carrier mobility in the channel.

Figure 13(b) illustrates g_d and V_{EA} of I-JL-NWFET and JL-NWFET at $V_{DS} = 1$ V on varying t_{si}. The g_d of I-JL-NWFET and JL-NWFET decreases on scaling of t_{si} due to reduction of I_D as observed in figure 11(a). Moreover, g_d of I-JL-NWFET is less compared to JL-NWFET at any given t_{si}, attributed due to the enhanced control of V_{GS} compared to V_{DS} on smaller channel thickness. Consequently, V_{EA} of I-JL-NWFET surpasses that of JL-NWFET due to lower g_d at any given t_{si}. It is also observed that there is marginal reduction of g_d below 10 nm of t_{si} leading to minimal change in V_{EA} of I-JL-NWFET.

Figure 14 depicts the impact of variation of t_{si} on C_{GG} and f_T of I-JL-NWFET and JL-NWFET at $V_{GS} = 1$ V. At any given t_{si}, I-JL-NWFET exhibit higher C_{GG} compared to JL-NWFET, primarily because of the inclusion of the high-k spacer, which enhances capacitance between gate to source and gate to drain. Furthermore, the noticeable enhancement in f_T of I-JL-NWFET compared to JL-NWFET on scaling t_{si} is predominantly attributed to the increase in g_m, as depicted in figure 13(a).

3.2.3. Impact of channel thickness scaling on linearity parameters

The analysis of this subsection focuses on the impact of variation of t_{si} on the linearity parameters of I-JL-NWFET and JL-NWFET, consisting g_{m2}, g_{m3}, VIP2, VIP3, IIP3 and IMD3.

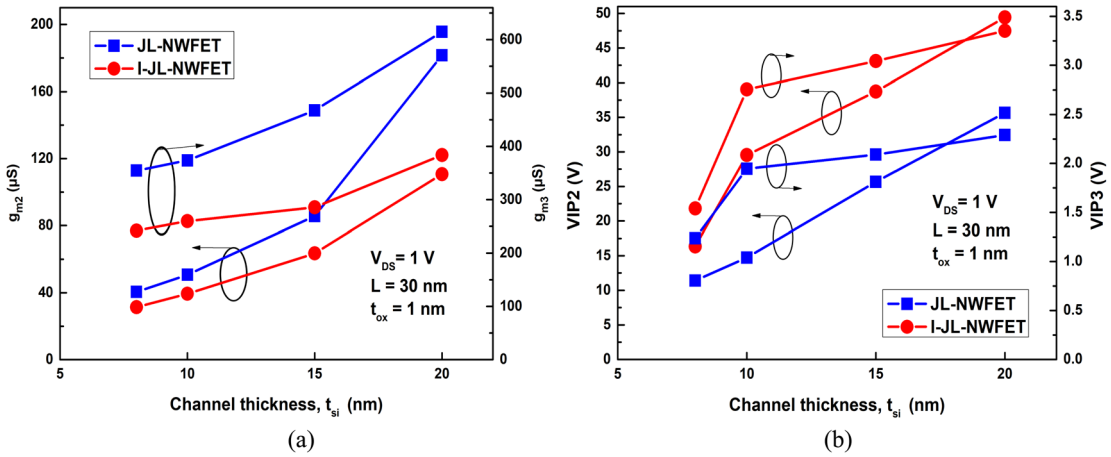

Figure 15. Plots of (a) g_{m2} and g_{m3} (b) VIP2 and VIP3 of I-JL-NWFET and JL-NWFET for different channel thicknesses.

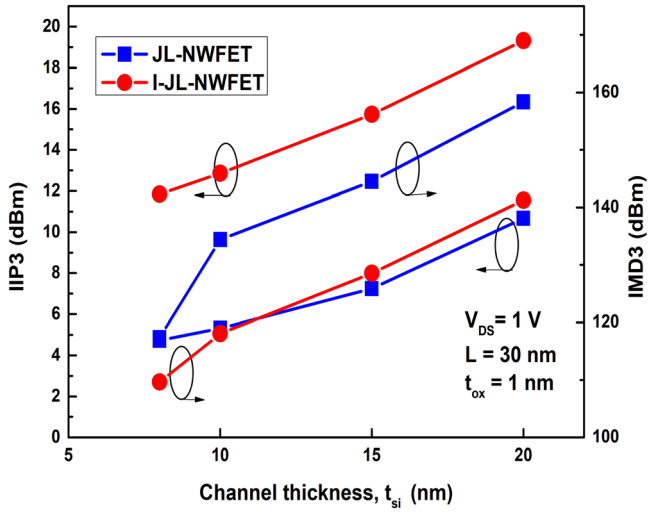

Figure 16. Plots of IIP3 and IMD3 of I-JL-NWFET and JL-NWFET for different channel thicknesses.

Figure 15(a) demonstrates the influence of t_{si} variation on the peak value of g_{m2} and g_{m3} of I-JL-NWFET and JL-NWFET. The peak value of g_{m2} of I-JL-NWFET and JL-NWFET occurs at 0.6 V and 0.7 V, respectively while the peak value of g_{m3} of I-JL-NWFET and JL-NWFET is observed at 0.4 V and 0.5 V, respectively. On decreasing t_{si}, I-JL-NWFET exhibits lower peak value of g_{m2} and g_{m3} compared to JL-NWFET due to enhanced V_{GS} control over smaller channel leading to reduced harmonic distortion [20].

Figure 15(b) shows the impact of varying t_{si} on the peak value of VIP2 and VIP3 of I-JL-NWFET and JL-NWFET. The peak value of VIP2 for I-JL-NWFET occurs at 0.7 V, whereas for JL-NWFET, it occurs at 0.8 V. Similarly, the peak value of VIP3 for I-JL-NWFET is observed at 0.6 V, while for JL-NWFET, it is observed at 0.7 V. I-JL-NWFET displays higher peak value of VIP2 and VIP3 compared to JL-NWFET due to lower peak value of g_{m2} and g_{m3}.

Figure 16 illustrates the impact of t_{si} variation on the peak value of IIP3 and IMD3 of I-JL-NWFET and JL-NWFET. The peak value of IIP3 of I-JL-NWFET and JL-NWFET is observed at 0.8 V and 0.9 V, respectively while the peak value of IMD3 of I-JL-NWFET and JL-NWFET is observed at 0.6 V and 0.7 V, respectively. Due to decreasing g_m on reducing t_{si}, the peak value of IIP3 in JL-NWFET reduces more than that in I-JL-NWFET. Furthermore, the peak value of IMD3 of I-JL-NWFET decreases on reducing t_{si} due to reducing VIP3. Notably, I-JL-NWFET demonstrates a lower peak value of IMD3 compared to JL-NWFET at any given t_{si}, owing to low peak value of g_{m3} in I-JL-NWFET as observed in figure 15(a).

I-JL-NWFET exhibits optimum value of I_{OFF}, I_{ON}/I_{OFF} and DIBL at 30 nm of L and 10 nm of t_{si}. Moreover, analog/RF and linearity parameters depend on electrical parameters. Therefore, the L and t_{si} of I-JL-NWFET are optimized at 30 nm and 10 nm, respectively for subsequent sections.

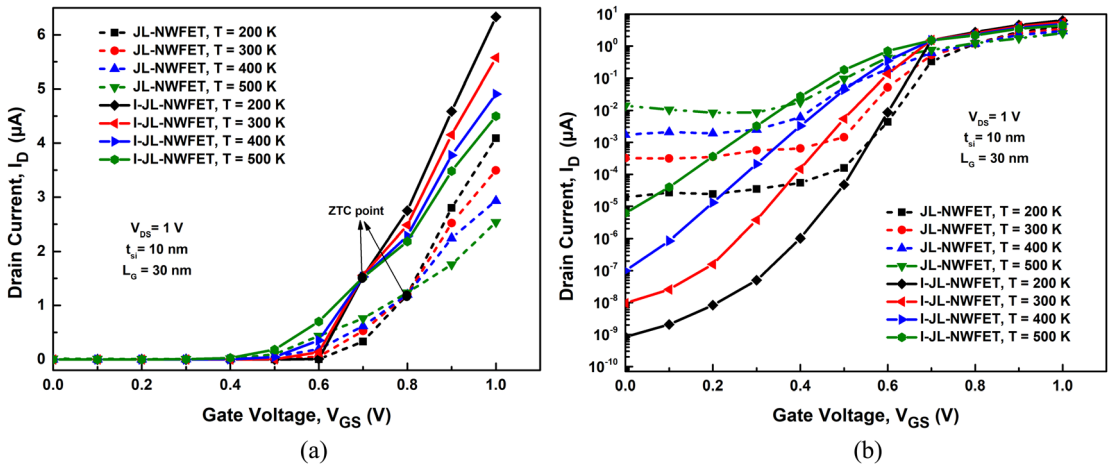

Figure 17. Transfer characteristics of I-JL-NWFET and JL-NWFET for different temperatures in (a) linear scale and (b) log scale.

4. Temperature impact on device performance

The temperature dependence analysis of nano-scale devices offers a more profound understanding of the intrinsic performance of the device, allowing for insights into its performance under varying temperature conditions. This section delves into exploring the impact of temperature on the characteristics of electrical, analog/RF, and linearity parameters in I-JL-NWFET and JL-NWFET.

4.1. Impact of temperature on electrical parameters

In this subsection, the impact of temperature on I-JL-NWFET and JL-NWFET is analyzed on the electrical characteristics such as drain current, threshold voltage, OFF-state current, subthreshold slope and DIBL by varying the temperature from 200 K to 500 K.

The dependence of temperature on transfer characteristics of I-JL-NWFET and JL-NWFET in linear and log scales are illustrated in figures 17(a) and (b), respectively. As the temperature rises, I_D initially rises at a specific V_{GS} and subsequently declines with further temperature increases. This point is called the Zero Temperature Coefficient (ZTC) at which I_D demonstrates almost no dependence on temperature [38]. Below the ZTC point, an increase in temperature leads to a decrease in V_T, causing an increase in I_D. Conversely, beyond the ZTC point, I_D decreases due to a decline in electron mobility with rising temperature. The ZTC of I-JL-NWFET and JL-NWFET are observed at 0.7 V and 0.8 V, respectively. In JL-NWFET, the primary degradation mechanism for electron mobility is phonon scattering, and this effect varies proportionally with $T^{-3/2}$ [38]. However, the I_D ($V_{GS} = 1$ V) of I-JL-NWFET is comparatively high in comparison to JL-NWFET attributed to the incorporation of DMG that enhances the current driving capability in the device as observed in figure 17(a). Moreover, it is found that the variation of I_D at $V_{GS} = 1$ V in I-JL-NWFET and JL-NWFET is 29% and 31.8%, respectively with an increase in temperature from 200 K to 500 K. This underscores the comparatively lower sensitivity of I-JL-NWFET to temperature variations when compared to JL-NWFET.

Additionally, I_{OFF} ($V_{GS} = 0$ V) increases in both I-JL-NWFET and JL-NWFET with an increase in temperature from 200 K to 500 K as depicted in figure 17(b). This is attributed to the increases in intrinsic carrier concentration (n_i) which is a dependent factor of temperature and expressed as [39]

$$n_i = \exp\left[\frac{-E_g}{2KT}\right] \tag{16}$$

where 'K' is the Boltzmann constant, E_g is bandgap of semiconductor, and 'T' is the absolute temperature. The I_{OFF} in I-JL-NWFET is comparable less in comparison to JL-NWFET due to an oppositely doped core which aids in depleting the channel during the OFF state.

The variation of Conduction Band (CB) energy and Valance Band (VB) energy along the device length of I-JL-NWFET and JL-NWFET for different temperatures at $V_{GS} = 0$ V is plotted in figure 18(a). As the band gap profile is analyzed below ZTC point of I-JL-NWFET and JL-NWFET, with an increase in temperature, band gap decreases that consequently increases I_D. Moreover, at any given temperature, JL-NWFET exhibits the smallest tunneling width from VB of channel to CB of drain region in comparison to I-JL-NWFET during OFF-state. This mechanism causes parasitic BJT and increases I_{OFF} in JL-NWFET [11]. However, the inclusion of an oppositely doped core widens this tunneling width and enhances source to channel barrier height that

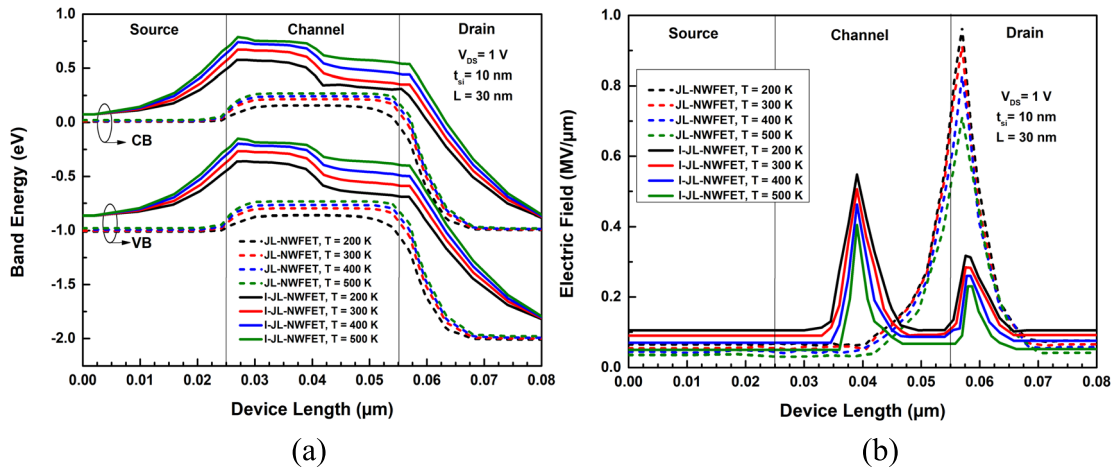

Figure 18. Plots of (a) energy band and (b) electric field of I-JL-NWFET and JL-NWFET for different temperatures.

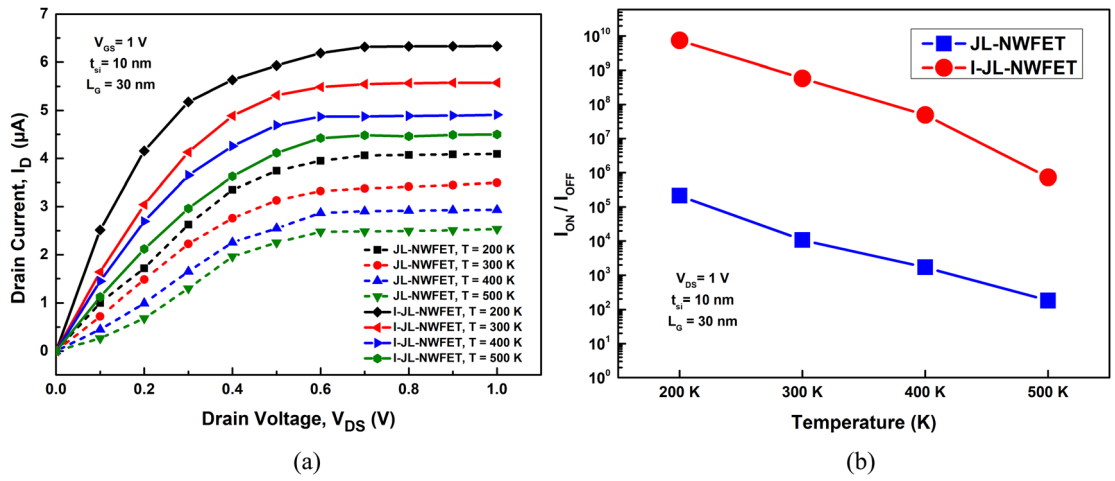

Figure 19. Plots of (a) output characteristics and (b) I_{ON}/I_{OFF} ratio of I-JL-NWFET and JL-NWFET for different temperatures.

cumulatively decreases I_{OFF} in I-JL-NWFET [11]. Additionally, the employment of two dissimilar gate work functions in the DMG structure results in an abrupt transition, further amplifying the tunneling width of I-JL-NWFET [13].

Figure 18(b) depicts the variation of the electric field along the device length of I-JL-NWFET and JL-NWFET for different temperatures at $V_{GS} = 1$ V. As the electric field is analyzed above ZTC point of I-JL-NWFET and JL-NWFET, with an increase in temperature, electric decreases, subsequently reducing I_D. At any particular temperature, I-JL-NWFET displays two electric field peaks leading to accelerating electrons in the channel, which consequently enhances I_D as compared to JL-NWFET in ON-state. Furthermore, the peak value of an electric field near drain region in I-JL-NWFET is reduced than that in JL-NWFET due to the lower work function of M_2. This characteristic enables better modulation of the V_{GS} over the channel rather than the V_{DS}, consequently mitigating SCE such as DIBL [14].

Figure 19(a) presents output characteristics variation of I-JL-NWFET and JL-NWFET with temperature at $V_{GS} = 1$ V. The I_D of I-JL-NWFET is observed to be higher than that of JL-NWFET. Analysis from figure 19(a) reveals that the ZTC for I-JL-NWFET and JL-NWFET occurs at 0.7 V and 0.8 V, respectively. Beyond this ZTC point, I_D decreases with increasing temperature. Consequently, as the output characteristics are plotted beyond their respective ZTC points, the I_D of both devices decreases as temperature rises. Moreover, for any given temperature, the I_D of I-JL-NWFET is observed to be higher than that of JL-NWFET as explained in figure 18(b).

The I_{ON}/I_{OFF} ratio of I-JL-NWFET and JL-NWFET at various temperatures is plotted in figure 19(b). As discussed in figure 17(b), an increase in temperature increases I_{OFF}, consequently decreasing I_{ON}/I_{OFF} ratio in both I-JL-NWFET and JL-NWFET. However, the I_{ON}/I_{OFF} ratio of I-JL-NWFET is notably higher compared to JL-NWFET. The reason behind this is the utilization of DMG architecture and oppositely doped core in

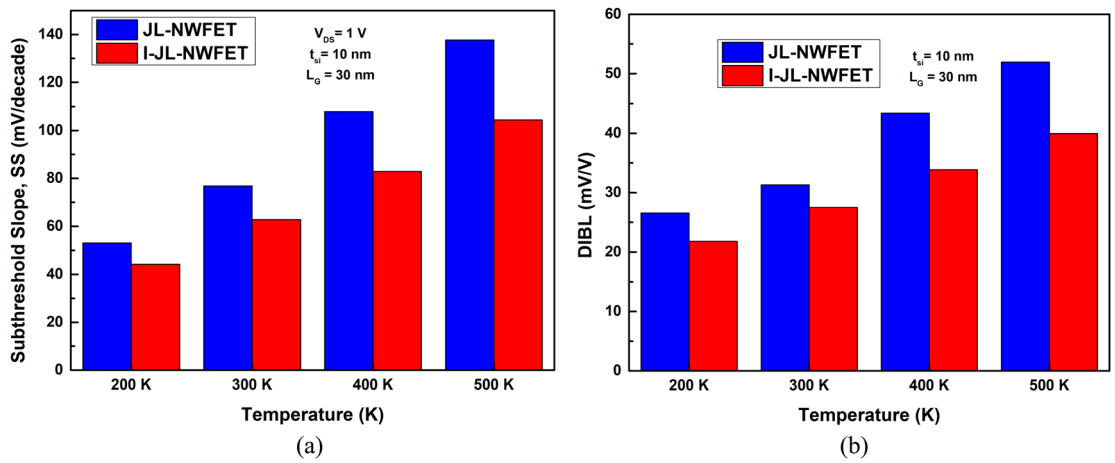

Figure 20. Plots of (a) SS and (b) DIBL of I-JL-NWFET and JL-NWFET for different temperatures.

Table 4. Effect of temperature on the electrical performance of JL-NWFET and I-JL-NWFET.

Parameters	Devices	200 K	300 K	400 K	500 K
I_{ON}/I_{OFF}	JL-NWFET	2.13×10^5	1.07×10^4	1.70×10^3	1.81×10^2
	I-JL-NWFET	7.40×10^9	5.83×10^8	4.93×10^7	7.37×10^5
SS (mV/decade)	JL-NWFET	53.14	76.83	107.85	137.68
	I-JL-NWFET	44.19	62.75	82.84	104.41
DIBL (mV/V)	JL-NWFET	26.54	31.30	43.40	51.95
	I-JL-NWFET	21.84	27.51	33.84	39.95

I-JL-NWFET, which work synergistically to increase I_{ON} and decrease I_{OFF}, respectively. The variation of SS and DIBL in I-JL-NWFET and JL-NWFET against increasing temperature is illustrated in figures 20(a) and (b), respectively. Notably, the observed variations in SS and DIBL are 29% and 28% less, respectively, in I-JL-NWFET compared to JL-NWFET when the temperature is increased from 200 K to 500 K. This indicates that I-JL-NWFET demonstrates a relatively lower sensitivity to temperature-induced changes in SS and DIBL compared to JL-NWFET over the specified temperature range.

The SS and DIBL in I-JL-NWFEET vary in a controlled manner with increasing temperature in comparison to JL-NWFET. At any given temperature, the reduced SS observed in I-JL-NWFET is credited to its high I_{ON}/I_{OFF} ratio, indicating superior switching speed compared to JL-NWFET. Furthermore, the DIBL of I-JL-NWFET is less than that of JL-NWFET at a specified temperature range attributed to the presence of the DMG architecture. As discussed in figure 18(b), the lower gate work function at the drain side than the source side results in a reduced electric field, allowing for greater control of the V_{GS} over the channel rather than the V_{DS}.

Table 4 provides a comprehensive comparison of the electrical performance of the I-JL-NWFET with that of JL-NWFET at various temperatures. Notably, the comparison demonstrates that parameters such as I_{ON}/I_{OFF} ratio, SS and DIBL are less susceptible to temperature fluctuations in the I-JL-NWFET when compared to the JL-NWFET.

4.2. Impact of temperature on analog/RF parameters

The analog/RF circuits are often sensitive to changes in temperature. An in-depth analysis of temperature variation is vital for ensuring the reliable and consistent performance of the device. This sub-section investigates the impact of temperature on the analog/RF parameters such as g_m, TGF, g_d, V_{EA}, C_{GG}, and f_T of the I-JL-NWFET and JL-NWFET.

Figures 21(a) and (b) exhibit the g_m and TGF variation with respect to V_{GS} at various temperatures, respectively. It is noted from figure 21(a) that the g_m of both I-JL-NWFET and JL-NWFET experiences an increase with temperature below ZTC. However, above the ZTC, the trends reverse, possibly attributed to an increase in the rate of scattering events with rising temperatures, as discussed in figure 17(a). Furthermore, for a given temperature, the g_m of I-JL-NWFET surpasses that of JL-NWFET owing to DMG architecture. Additionally, there is a decrease of 24.4% in g_m for I-JL-NWFET and 26.7% for JL-NWFET at $V_{GS} = 1$ V.

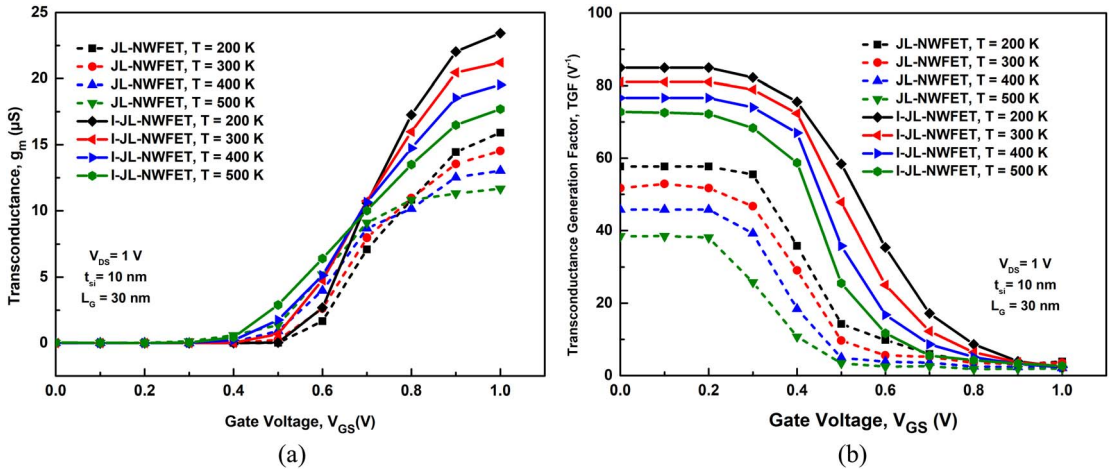

Figure 21. Plots of (a) transconductance and (b) TGF of I-JL-NWFET and JL-NWFET for different temperatures.

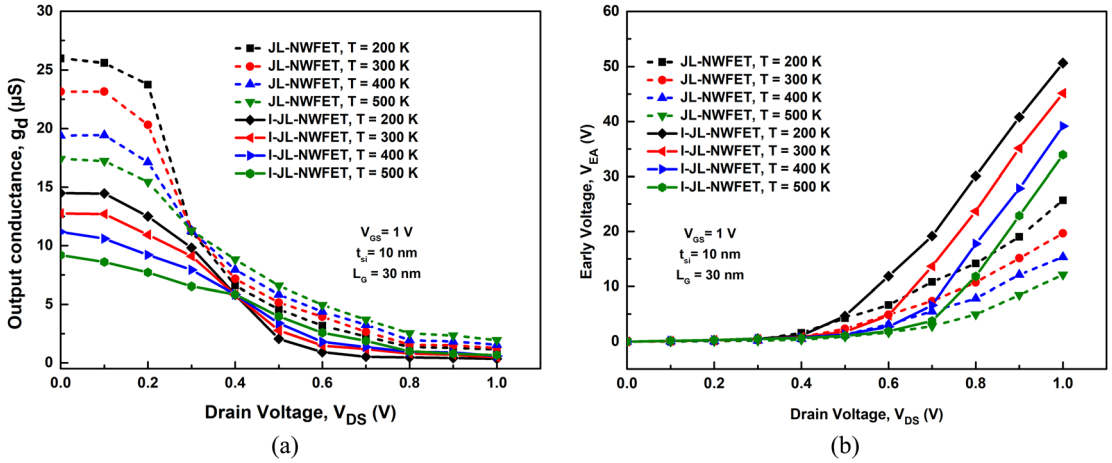

Figure 22. Plots of (a) output conductance and (b) early voltage of I-JL-NWFET and JL-NWFET for different temperatures.

Figure 21(b) reveals that in the subthreshold region, the TGF decreases by 14.32% in I-JL-NWFET and 33.40% in JL-NWFET, with an increase in temperature from 200 K to 500 K at $V_{GS} = 0$ V.

The impact of temperature on g_d and V_{EA} of I-JL-NWFET and JL-NWFET are portrayed in figures 22(a) and (b), respectively. At lower V_{DS}, the g_d is primarily influenced by Channel Length Modulation (CLM). Conversely, at higher V_{DS}, the g_d is governed DIBL [17]. CLM represents a SCE whereby the channel length is effectively shortened due to the application of drain bias. This phenomenon is particularly relevant because the output resistance of the device is directly proportional to the channel length. Consequently, when the channel length is shortened due to drain bias, it increases the output conductance.

As depicted in figure 22(a), it is evident that, at any given temperature, g_d in I-JL-NWFET is lower than JL-NWFET at higher V_{DS}. Additionally, a temperature increase at lower V_{DS} results in a reduction of g_d until a specific V_{DS}, beyond which g_d reverses its trend due to the occurrence of ZTC point and rise in DIBL with the temperature increment. Due to the lowest g_d of I-JL-NWFET at higher V_{DS} at any particular temperature, it attains a superior V_{EA} than that in JL-NWFET as illustrated in figure 22(b).

The enhanced V_{EA} contributes to an improved intrinsic gain of the device, particularly beneficial for analog amplifiers. Moreover, with the rise in temperature from 200 K to 500 K, V_{EA} decreases 32.9% in I-JL-NWFET and 52.72% in JL-NWFET.

Figures 23(a) and (b) depict the C_{GG} and f_T as a function of V_{GS} for temperatures ranging from 200 K to 500 K for I-JL-NWFET and JL-NWFET, respectively. From figure 23(a), it is perceived that, under low V_{GS}, C_{GG} is predominantly influenced by the depletion capacitance (C_{dep}) [38]. With the rising temperature, the surface potential diminishes, causing an enhancement in C_{dep}. Conversely, under high V_{GS} conditions, an increase in temperature leads to a reduction in C_{GG}. Notably, I-JL-NWFET exhibits a higher C_{GG} compared to JL-NWFET

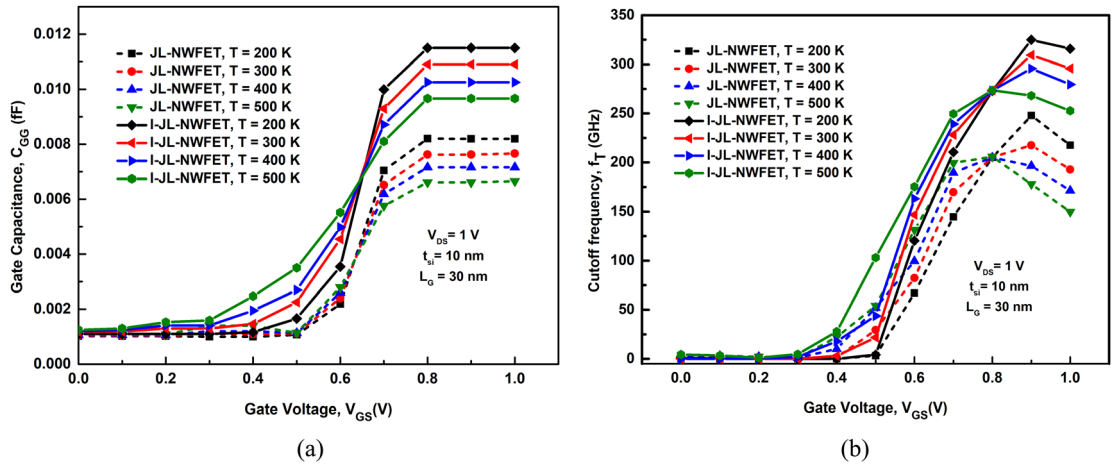

Figure 23. Plots of (a) gate capacitance and (b) cut-off frequency of I-JL-NWFET and JL-NWFET for different temperatures.

Table 5. Effect of temperature on the analog/RF performance of JL-NWFET and I-JL-NWFET.

Parameters	Devices	200 K	300 K	400 K	500 K
g_m (μS)	JL-NWFET	15.92	14.53	13.04	11.67
	I-JL-NWFET	23.43	21.21	19.53	17.70
TGF (V^{-1})	JL-NWFET	57.69	51.69	45.76	38.41
	I-JL-NWFET	84.91	80.98	76.61	72.75
g_d (μS)	JL-NWFET	1.16	1.27	1.56	1.95
	I-JL-NWFET	0.35	0.47	0.59	0.67
V_{EA} (V)	JL-NWFET	23.68	18.65	15.36	12.14
	I-JL-NWFET	55.63	49.14	39.14	33.94
C_{GG} (fF)	JL-NWFET	0.008	0.0070	0.0071	0.006
	I-JL-NWFET	0.011	0.0109	0.0102	0.009
f_T (GHz)	JL-NWFET	217.56	192.75	171.55	149.84
	I-JL-NWFET	315.80	295.80	279.54	252.73

at any given temperature, attributed to the increased outer fringe capacitance resulting from the utilization of the high-k spacer [17]. The behavior of f_T mirrors the trends observed in g_m and C_{GG}. It increases with a temperature rise at lower V_{GS} until a specific V_{GS}, after which it declines with further temperature increases, as demonstrated in figure 23(b). For the I-JL-NWFET, the decline in C_{GG} at higher V_{GS} is offset by an improvement in g_m, resulting in a superior f_T compared to the JL-NWFET. Notably, the reduction in f_T is 19.9% in I-JL-NWFET and 45.2% in JL-NWFET when the temperature is elevated from 200 K to 500 K.

The analog/RF parameters of JL-NWFET and I-JL-NWFET at different temperature are summarized in table 5. The analysis reveals that g_m, TGF, g_d, V_{EA}, C_{GG}, and f_T are less affected by temperature variations in I-JL-NWFET compared to JL-NWFET.

4.3. Impact of temperature on linearity parameters

In addition to achieving high speed, contemporary communication systems must ensure minimal signal distortion to assess the device's suitability for analog and RF applications. If a device fails to maintain linearity, the nonlinear components at the output may overwhelm the desired signal. To enhance the linearity of a system, the g_m must remain constant across the input voltage. In this subsection, the effect of temperature on the linearity performance of I-JL-NWFET is analyzed through metrics such as g_{m2}, g_{m3}, VIP2, VIP3, IMD3, and IIP3, and results are compared with JL-NWFET.

The effect of temperature on g_{m2} and g_{m3} against V_{GS} of I-JL-NWFET and JL-NWFET are portrayed in figures 24(a) and (b), respectively. The g_{m2} decreases as temperature increases in case of both I-JL-NWFET and JL-NWFET as exhibited in figure 24(a). Additionally, the peak value of g_{m2} of I-JL-NWFET is reduced by 2.53%, 5.45%, 10.74% and 11.67% as compared to JL-NWFET at 200 K, 300 K, 400 K and 500 K, respectively, indicating I-JL-NWFET is more linear than JL-NWFET at higher temperature. The linearity of the device is also associated with the flatness of the g_{m3} amplitude. The g_{m3} primarily contributes to the distortion of fundamental amplitude through signals in adjacent bands or intermodulation distortions. Moreover, the Zero-Crossover Point (ZCP) of

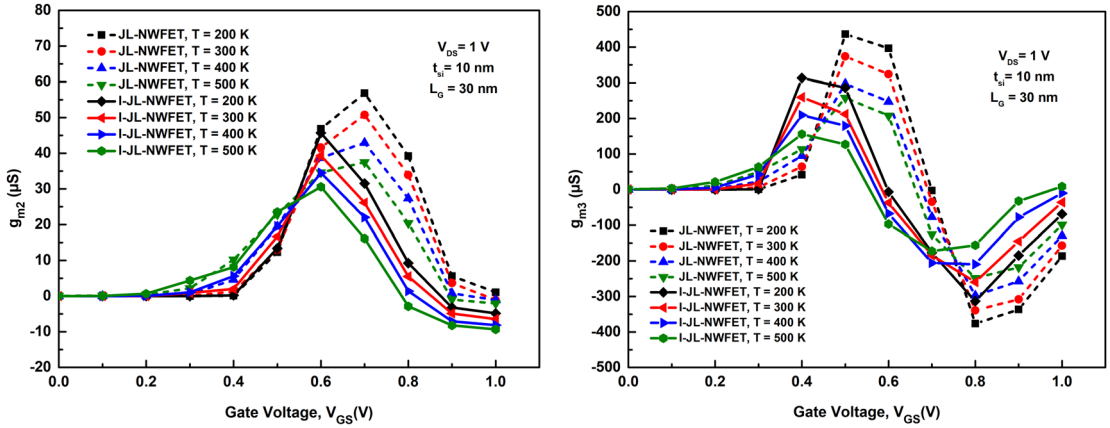

Figure 24. Plots of (a) g_{m2} and (b) g_{m3} of I-JL-NWFET and JL-NWFET for different temperatures.

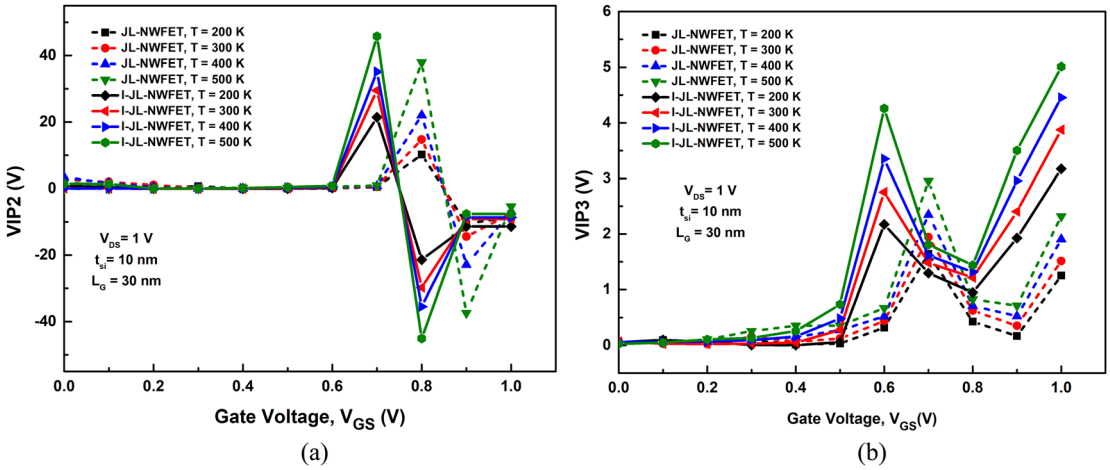

Figure 25. Plots of (a) VIP2 and (b) VIP3 of I-JL-NWFET and JL-NWFET for different temperatures.

g_{m3} should occur at a lower V_{GS} for improved linearity performance [20]. The V_{GS} value at which g_{m3} first crosses the zero axis is defined as ZCP and determines the DC bias point for optimal device operation. Furthermore, in I-JL-NWFET, ZCP is shifted towards lower V_{GS} compared to JL-NWFET at any given temperature. This shift is advantageous for achieving better linearity and lower distortion in device performance.

The influence of temperature on VIP2 and VIP3 of I-JL-NWFET and JL-NWFET are displayed in figures 25(a) and (b), respectively. It is observed in figure 25(a) that the peak value of VIP2 in I-JL-NWFET exhibits an increase by 2.09 times, 2.0 times, 1.59 times, and 1.20 times compared to that in JL-NWFET as the temperature escalates from 200 K to 500 K.

This augmentation is attributed to a reduction in the amplitude of g_{m2} with the rise of temperature. Furthermore, in figure 25(b), the peak value of VIP3 in I-JL-NWFET occurs when g_{m3} is zero and shows an increase by 32.3%, 41.7%, 43.1%, and 44% compared to that in JL-NWFET as the temperature increases from 200 K to 500 K.

Figures 26(a) and (b) depict the influence of temperature variation on IIP3 and IMD3 of I-JL-NWFET and JL-NWFET as functions of V_{GS}, respectively. The higher IIP3 peak observed in figure 26(a) of I-JL-NWFET than of JL-NWFET with rising temperature distinctly indicates enhanced linearity performance as the temperature increases. Additionally, IMD3 of I-JL-NWFET is found to be lower than that of JL-NWFET as depicted in figure 26(b). This observation ensures that in the I-JL-NWFET, HCEs have been mitigated, leading to a reduction in both power consumption and distortion of the device.

Table 6 summarized the less temperature variation of linearity parameter of I-JL-NWFET than that of JL-NWFET. Eventually, for increasing temperature (200 K - 500 K), I-JL-NWFET is reliable and useful in RF applications than JL-NWFET. Moreover, investigating alternative semiconductor materials with superior thermal stability could mitigate performance degradation at elevated temperatures. Material like silicon carbide (SiC) has

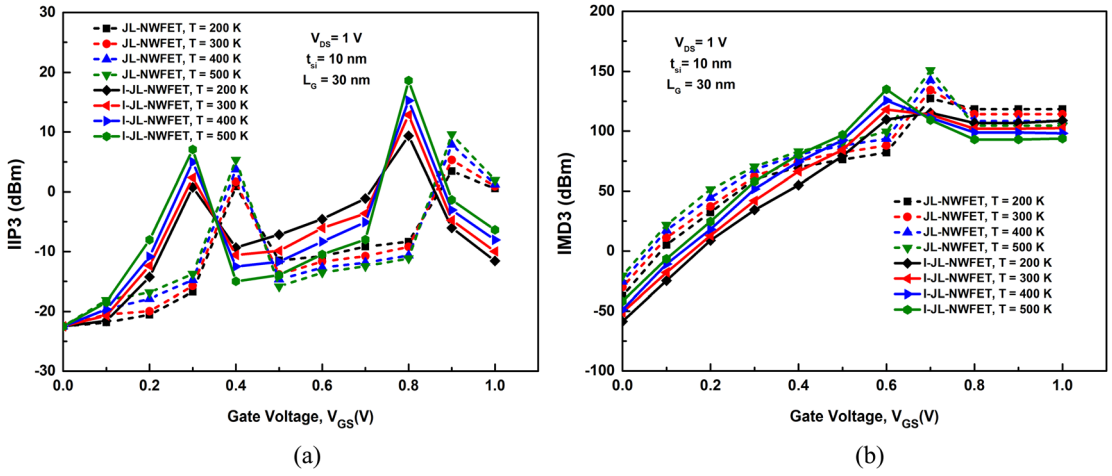

Figure 26. Plots of (a) IIP3 and (b) IMD3 of I-JL-NWFET and JL-NWFET for different temperatures.

Table 6. Effect of temperature on the linearity performance of JL-NWFET and I-JL-NWFET.

Parameters	Devices	200 K	300 K	400 K	500 K
Peak g_{m2} (μS)	JL-NWFET	56.82	50.75	42.89	37.47
	I-JL-NWFET	45.69	39.34	34.51	30.57
Peak g_{m3} (μS)	JL-NWFET	436.46	373.78	297.22	258.06
	I-JL-NWFET	313.35	259.73	209.30	155.98

exhibited notable potential in preserving electrical characteristics under at high temperatures [40]. It may serve as a potential future substitute for silicon material at high temperatures. Since this work has provided valuable insights through simulation analysis, forwarding to an experimental study may encounter challenges in fabricating a DMG in nanometer-scale technology. The fabrication process involves intricate steps such as contacting two gate materials, which introduces additional lithography complexity. Techniques like tilt angle deposition for different metal depositions further compound these challenges [41]. In response to this, the novel work function modulation method may be used which involves Molybdenum (Mo) as the gate material, allowing its work function to be adjusted by varying the nitrogen implantation in Mo [42]. This approach not only simplifies process integration but also opens avenues for enhancing device performance and scalability in future research efforts.

5. Conclusion

In this paper, a thorough investigation into the scaling of channel length and thickness for I-JL-NWFET is conducted and then the findings are compared with those of conventional JL-NWFET. The results demonstrate that the incorporation of an oppositely doped core, DMG, and high-k spacer in I-JL-NWFET leads to reduced sensitivity to the scaling of channel length and thickness compared to JL-NWFET. Furthermore, the effect of temperature on electrical, analog/RF, and linearity performance has been investigated for I-JL-NWFET and JL-NWFET. Notably, the electrical performance of I-JL-NWFET exhibits less variability than that of JL-NWFET. I_D experiences a reduction of 29% in I-JL-NWFET and 31.8% in JL-NWFET as the temperature changes from 200 K to 500 K. Moreover, variation in SS and DIBL of I-JL-NWFET are 29% and 28% less than in JL-NWFET. Analyzing the analog/RF performance of both I-JL-NWFET and JL-NWFET concerning parameters such as g_m, TGF, g_d, V_{EA}, C_{GG} and f_T based on temperature variation, it is observed that these parameter decreases with increase in temperature (200 K to 500 K). Besides this, due to rise in temperature from 200 K to 500 K, variation

of 24.4% (26.7%), 14.32% (33.40%), 32.9% (52.72%), and 19.9% (45.2%) in terms of g_m, TGF, V_{EA} and f_T for I-JL-NWFET (JL-NWFET) are observed. This indicates that I-JL-NWFET is less sensitive to temperature variations compared to JL-NWFET. Furthermore, the linearity performance of I-JL-NWFET, characterized by parameters such as g_{m2}, g_{m3}, VIP2, VIP3, IIP3 and IMD3 is improved at higher temperature than that of JL-NWFET. Therefore, temperature emerges as a significant factor affecting device characteristics, where an increase in temperature suppresses electrical and analog/RF performance while enhancing the linearity performance of I-JL-NWFET when compared to JL-NWFET.

Data availability statement

All data that support the findings of this study are included within the article (and any supplementary files).

Ethics approval

The manuscript is not submitted to anywhere else for the publication. The submitted work is an original work and have not been published elsewhere in any form or language. The authors do not have any conflict of interest. The research does not involve any human participant and/or animal thus, informed consent in not required.

Consent for publication

All the authors understand and give their consent for the publication of manuscript 'Investigating the Effect of Scaling and Temperature on the Performance of Improved Junctionless Nanowire FET through simulation Analysis' in 'Physica Scripta' Journal.

Competing interests

No, all the authors declare that they have no competing interests as defined by IOP Science, or other interests that might be perceived to influence the results and/or discussion reported in this paper. The authors have no conflicts of interest to declare that are relevant to the content of this article.

arXiv:2407.03498v1 [cs.CV] 3 Jul 2024

Biometric recognition technology has witnessed widespread integration into daily life due to the growing emphasis on information security. In this domain, multimodal biometrics, which combines multiple biometric traits, has overcome limitations found in unimodal systems like susceptibility to spoof attacks or failure to adapt to changes over time. This paper proposes a novel multimodal biometric recognition system that utilizes deep learning algorithms using iris and palmprint modalities. A pioneering approach is introduced, beginning with the implementation of the novel Modified Firefly Algorithm with Lévy Flights (MFALF) to optimize the Contrast Limited Adaptive Histogram Equalization (CLAHE) algorithm, thereby effectively enhancing image contrast. Subsequently, feature selection is carried out through a unique hybrid of ReliefF and Moth Flame Optimization (MFOR) to extract informative features. For classification, we employ a parallel approach, first introducing a novel Preactivated Inverted ResNet (PIR) architecture, and secondly, harnessing metaheuristics with hybrid of innovative Johnson Flower Pollination Algorithm and Rainfall Optimization Algorithm for fine tuning of the learning rate and dropout parameters of Transfer Learning based DenseNet architecture (JFPA-ROA). Finally, a score-level fusion strategy is implemented to combine the outputs of the two classifiers, providing a robust and accurate multimodal biometric recognition system. The system's performance is assessed based on accuracy, Detection Error Tradeoff (DET) Curve, Equal Error Rate (EER), and Total Training time. The proposed multimodal recognition architecture, tested across CASIA Palmprint, MMU, BMPD, and IIT datasets, achieves 100% recognition accuracy, outperforming unimodal iris and palmprint identification approaches.

***Index Terms*—Multimodal biometric Recognition, Metaheuristic Optimisation, Convolutional Neural Network, Feature Selection, Deep Learning, Transfer Learning**

I. Introduction

In today's digital landscape, traditional authentication systems relying on passwords and tokens are insufficient against modern cybersecurity threats like brute-force attacks and phishing exploits. These vulnerabilities leave sensitive data and systems at risk. The Biometric based recoginition system has emerged as a compelling solution to these shortcomings [1].

Biometrics involves identifying individuals based on their physiological or behavioral traits. This technology includes a diverse range of characteristics, from behavioral traits like signature dynamics, voice patterns, and gait analysis, to physiological traits such as fingerprints, iris patterns, and palmprints [2]. Biometric recognition systems automate this identification process, representing a fundamental shift in authentication methods.

Unimodal biometric systems rely on a single characteristic like iris patterrns or palmprints, for identification. These traits are particularly significant due to their permanence, uniqueness, and high resistance to forgery, which ensures high recognition accuracy and valuable security [3, 4]. However, unimodal systems face limitations. Factors like injuries, sensor noise, or temporary changes in appearance can affect their accuracy. Multimodal biometric authentication addresses these issues by combining multiple biometric modalities, thereby enhancing security against imposters who would need to replicate several unique identifiers [5].

Machine learning further enhances multimodal biometric systems by improving recognition accuracy and adapting to new data. This technology addresses the limitations of unimodal systems, making biometric recognition more reliable and secure.

Traditionally, biometrics researchers relied on machine learning algorithms for identification, which involved multiple steps: data cleaning, feature extraction, and classification. However, these methods have limitations, including unreliable feature extraction and difficulty with common image transformations. To overcome these limitations, many researchers have recently started using deep learning-based biometric systems. Deep learning significantly improves performance by automatically extracting features directly from raw biometric data, streamlining the process and enhancing robustness [6]. However, optimizing the fusion of multimodal features for accurate recognition remains complex. Metaheuristic algorithms play a crucial role in this context due to their efficiency in navigating complex search spaces and identifying optimal solutions. They offer a robust framework for effectively integrating multiple biometric modalities [7]. Leveraging sophisticated algorithms and pattern recognition techniques, biometric systems provide strong authentication by capturing and analyzing distinctive traits, ensuring secure access to sensitive information and safeguarding against unauthorized intrusion [8].

However, despite the advancements in biometric integration, a notable gap exists in the literature regarding the fusion of iris and palmprint recognition using deep learning methodologies. While metaheuristic algorithms offer promise in addressing these challenges, the direct fusion of iris and palmprint modal-

ities remains limited. Moreover, existing multimodal biometric systems employing deep learning often encounter limitations, including inadequate image preprocessing, feature selection, and classification techniques, which impede their effectiveness. Additionally, challenges such as rigid classification approaches susceptible to overfitting and scalability issues emphasize the critical need to bridge the gap between metaheuristic algorithms and deep learning methodologies to develop more robust and effective biometric recognition systems. [9, 10, 11].

This paper proposes a comprehensive approach to address the aforementioned limitations by integrating iris and palmprint modalities using deep learning and metaheuristic algorithms. Firstly, we enhance image contrast effectively by utilizing the Modified Firefly Algorithm with Lévy Flights (MFALF) to optimize the Contrast Limited Adaptive Histogram Equalization (CLAHE) algorithm. This optimization significantly improves the quality of input data. Secondly, we employ a unique hybrid of ReliefF and Moth Flame Optimization (MFOR) for feature selection. This approach ensures the extraction of informative features, enhancing the discriminative power of our system.

For classification, we adopt a parallel approach. Firstly, we introduce the innovative Preactivated Inverted ResNet (PIR) architecture to enhance classification performance. Secondly, we utilize metaheuristic algorithms, specifically a hybrid of the Johnson Flower Pollination Algorithm and Rainfall Optimization Algorithm, to fine-tune the learning rate and dropout parameters of the Transfer Learning-based DenseNet architecture (JFPA-ROA-DenseNet). This fine-tuning process optimizes model parameters, mitigating overfitting and improving generalization capability. Finally, we implement a score-level fusion strategy to combine the outputs of the two classifiers. This strategy ensures the development of a robust and accurate multimodal biometric recognition system by leveraging the strengths of both classifiers.

The key findings of this research are outlined below:

1) *We present a novel combination of Modified Firefly Algorithm with Lévy Flights (MFALF) to optimize the CLAHE algorithm for image contrast enhancement.*
2) *For enhancing feature selection, we introduce a unique hybrid of ReliefF and Moth Flame Optimization to extract informative features.*
3) *We present a parallel classification model encompassing transfer learning based novel Preactivated Inverted Resnet (PIR) architecture and an innovative hybrid metaheuristic optimized DenseNet architecture.*
4) *An innovative hybrid of Johnson Flower Pollination Algorithm and Rainfall Optimization Algorithm is proposed for fine-tuning parameters of Transfer Learning based DenseNet (TL-JFPA-ROA-DenseNet) for preventing overfitting.*

The rest of this paper is organized as follows: Section II provides an overview of previous studies. Section III presents the dataset description. Section IV outlines the proposed methodology, including preprocessing, classification, and score level fusion. Section V discusses the experimental setup and Implementation, while Section VI reports the obtained results. Section VII summarizes key findings and proposes future research directions, concluding the paper.

II. Literature Review

Numerous studies have presented multimodal biometric systems employing diverse recognition techniques. In this section, we review the existing literature related to multimodal biometric recognition, metaheuristic algorithms, and deep learning models.

A. Image Contrast Enhancement using CLAHE

Image enhancement plays a crucial role in various image processing applications. It improves the visual quality of images, making them easier to analyze for humans and facilitating further image processing tasks.

Image enhancement often faces challenges with uneven illumination, prompting the use of histogram equalization (HE). Yet, Salem et al. (2019) [12] noted limitations and explored alternatives. Their study evaluated HE alongside Contrast-Limited Adaptive Histogram Equalization (CLAHE), Cumulative Histogram Equalization (CHE), and Quadrant Dynamic Histogram Equalization (QDHE). They found CLAHE to outperform others, particularly in handling non-uniform intensity distribution.

CLAHE's success extends to diverse fields, notably biometric recognition, with studies by Nour et al. (2024) [13], Vidyarthi and Malik (2022) [14], and Lv et al. (2020) [15]. However, its manual parameter selection remains a time-consuming and inconsistent drawback.

Automatic parameter selection for CLAHE is an area of limited exploration in the literature. However Surya and Muthukumaravel (2023) [16] proposed an Adaptive Sailfish Optimization-Contrast Limited Adaptive Histogram Equalization (ASFO-CLAHE) method, which leverages an optimization algorithm to automatically determine the clip limit and number of tiles – key parameters in CLAHE. Similarly, Campos et al. (2019) [17] presented a supervised learning approach for parameter selection

These advancements in automatic parameter selection hold promise for enhancing the efficiency and effectiveness of CLAHE in various image processing applications.

B. Hybrid Feature Selection for Multimodal Biometric Recognition

Feature selection is pivotal in machine learning, targeting the identification of pertinent features to optimize model efficiency and performance. Agrawal et al. (2021) [18] offer an extensive review of feature selection employing metaheuristic algorithms from 2009 to 2019, categorizing approaches into filter, wrapper, and embedded methods. Filter methods assess feature relevance independently of the learning algorithm like information gain and ReliefF, while wrapper methods involve evaluating subsets of features based on model performance using metaheuristic algorithms like Moth-Flame Algorithm (MFA) and Genetic Algorithm (GA). Embedded methods integrate feature selection directly into the training process using regularization techniques.

Researchers have investigated diverse feature selection methods, like Trabelsi et al. (2022) [19] who utilized filter methods Fisher score and ReliefF algorithms. Gona et al. (2023) [20] introduced a wrapper method bio-optimization-based modified Lion optimization algorithm (MLOA) for optimizing feature selection by uncovering dependencies among biometrics.

Hsu et al. (2011) [21] suggested using a single filter or wrapper method for feature selection can lead to suboptimal results, as filters may miss feature interactions and wrappers are computationally expensive. Thus, a hybrid approach is needed to balance efficiency and accuracy. Dabba et al. (2021) [22] created a hybrid by merging Mutual Information Maximization and the Moth Flame Algorithm to assess gene relevance and redundancy, evolving subsets based on fitness functions. Similarly, Mafarja and Mirjalili (2017) [23] utilized a hybrid strategy combining Whale Optimization Algorithm with simulated annealing for feature selection.

These hybrid methods leverage the strengths of different approaches to achieve superior performance and accuracy in feature selection tasks.

C. Deep Learning for Biometric recognition

Deep learning models have revolutionized biometrics by providing advanced techniques for pattern recognition and classification tasks, resulting in high accuracy and robust performance.

Chollet (2018) [24] highlighted the reluctance to train deep learning models from scratch due to the time and extensive datasets involved. Instead, researchers prefer pre-trained models like Inception, VGGNet, AlexNet, and DenseNet, enabling faster development of deep learning-based biometric applications through fine-tuning and transfer learning.

Nguyen et al. (2017) [25] compared the effectiveness of five CNN pre-trained models—VGGNet, Inception, AlexNet, ResNet, and DenseNet—for iris recognition, with DenseNet yielding the highest accuracy. Meanwhile, Wang and Kumar (2019) [26] proposed an innovative approach utilizing ResNet with dilated convolutional kernels, resulting in substantial accuracy enhancements in iris recognition compared to traditional methods.

Zhang et al.(2018) [27] proposed a DCNN-based method for contactless palmprint and palmvein recognition using modified Inception_ResNet_v1 architecture for feature extraction, paired with an SVM classifier for identification.

While pre-trained models offer a good starting point, neglecting hyperparameter tuning can hinder the performance. Tuba et al. (2021) [28] emphasize its significance, particularly in adjusting the learning rate and implementing techniques to mitigate overfitting. Rosa et al. (2018) [29] explored dropout with meta-heuristic optimization to address overfitting in CNNs for biometric recognition.

Hence, Deep learning revolutionizes biometrics with precise recognition. However, selecting pre-trained models, new architectures, and hyperparameter tuning are critical for optimal performance.

D. Score level Fusion for multimodal Biometric Recognition

Lip and Ramli (2012) [30] highlight the significance of fusion strategies in multimodal biometrics, stressing the need to combine various modalities for improved authentication accuracy. They particularly emphasize three fusion levels: feature, score, and decision. Feature-level fusion combines features, score-level fusion merges model scores, and decision-level fusion integrates decisions from multiple models. Score-level fusion is preferred for its simplicity and effectiveness in distinguishing genuine from impostor scores.

Score-level fusion, noted for its simplicity and efficiency, has been extensively researched. Noh et al. (2020) [31] applied it to output scores from deep CNNs for finger-vein recognition, while He et al. (2010) [32] investigated sum rule and SVM-based fusion for fingerprint, face, and finger vein data. Additionally, Peng et al. (2014) [33] proposed a multimodal authentication approach combining various biometric scores using t-norms, offering reduced computational complexity without the need for learning or training.

Such fusion strategies enhance biometric system performance by leveraging the strengths of different modalities and reducing vulnerabilities inherent in single-modality approaches.

III. DATASET DESCRIPTION

The following section details the data collection process, describing the sources, methods, and protocols employed to gather the datasets used in this study.

Two distinct biometric traits, palmprint and iris, were utilized in our experiments.We have used MMU1 dataset [34] for collecting iris image & three datasets: CASIA-palmprint V1 (CASIA) [35], IIT Delhi Touchless Palmprint (IIT) [36], and Birjand University Mobile Palmprint (BIRJ) [37] were used for collecting palmprint images.The above mentioned unimodal datasets were selected due to their public availability, extensive use in numerous biometric research studies, and well-established status in the field.

A. Unimodal datasets

In the following points, we describe each unimodal dataset, separately.

- The MMU1[34] publicly avaiable iris dataset comprises 450 images, with 5 images each of left and right iris of 45 subjects. Training involves 8 images per subject, and testing uses 2 images per subject, maintaining an 80:20 train-to-test ratio.
- In the CASIA[35] palmprint dataset, there are 5,502 palmprint images of 312 subjects,and each palmprint image is an 8 bit gray-level JPEG file. To accommodate system limitations, 45 subjects were randomly chosen for evaluating our proposed methodology. The model is trained on both left and right palm print images, with a train-to-test ratio of 80:20 .
- The IIT[36] dataset encompasses 2,760 left and right palmprint images from 230 subjects acquired with a touchless setup, providing images in bitmap format with

variations in hand pose and scale. Our model has been trained over 1,380 left and right palmprint images of all 230 subjects. Testing involves 460 images, maintaining a train-to-test ratio of 75:25 . It is important to note that The PolyU palmprint database is widely used but relies on user-pegs to control variations in hand-pose and image scale, although inconvenient for users. This standardization is a key factor contributing to the notably high recognition accuracy, nearly 100%, achieved in version 2.0 of the database. In contrast, IIT Delhi's touchless palmprint database, aims for a user-friendly and reliable palmprint identification using completely touchless imaging setup.

- Regarding the Birjand[37] palm print images, the dataset comprises 1,640 images representing both left and right palm prints from 41 subjects, taken in two sessions two weeks apart. In the first session, six images of each palm were captured from a 20 cm distance, with no strict hand orientation control. In the second session, 16 images per palm were taken with increased hand rotation, promoting intraclass variability by having users close and open their hands between captures. Training and evaluation of the proposed model for all 41 subjects are conducted with an 80:20 train-to-test ratio.

B. Multimodal datasets

Due to the unavailability of multimodal biometric datasets, we have created three multimodal datasets for biometric evaluation:

- M-CAS: This dataset has been created by combining iris images from 45 subjects in the MMU Iris dataset with palmprint images from the same 45 subjects in the CASIA palmprint dataset, previously chosen for unimodal evaluation
- M-IIT: integrates palmprint and iris images by pairing 45 subjects from the MMU Iris dataset with randomly selected 45 subjects from the test dataset of the IIT palmprint dataset, which was originally used in Unimodal biometric recognition evaluation.
- M-BIRJ: Following a similar methodology as M-IIT, M-BIRJ dataset was developed comprising iris and palmprint images of 45 subjects.

The novel multimodal datasets discussed above enable comprehensive evaluation of multimodal biometric recognition systems, providing researchers and developers with valuable resources for testing and advancing biometric authentication technologies. Detailed description of our proposed approach is discussed in subsequent section.

IV. Methodology

In this section, we outline our proposed method for identifying individuals through a multimodal biometric recognition system utilizing both Iris and Palmprint data. The proposed methodology initiates by preprocessing the datasets. We aim to enhance image quality through Contrast Limited Adaptive Histogram Equalization (CLAHE), optimized using the novel Modified Firefly Algorithm with Lévy Flights (MFALF) for noise reduction and improved local contrast. Following this, we employ a unique blend of ReliefF and Moth Flame Optimization (MFOR) for feature selection to extract informative traits. The extracted features are then fed for classification in parallel. We introduce the innovative Preactivated Inverted ResNet (PIR) architecture and fine-tune the Transfer Learning based DenseNet by harnessing metaheuristics with hybrid of innovative Johnson Flower Pollination Algorithm and Rainfall Optimization Algorithm (JFPA-ROA-DenseNet). Finally, we merge classifier outputs through a score-level fusion strategy to deliver a robust and accurate multimodal biometric recognition system. The proposed model is illustrated in Fig. 1.

A. Contrast Limited Adaptive Histogram Equalization - Modified Firefly Algorithm with Lévy Flights (CLAHE-MFALF)

Inspired by Surya and Muthukumaravel (2023) [16], the proposed methodology exploits CLAHE preprocessing technique by optimizing it's clip limit parameter by novel MFALF algorithm. In CLAHE [38] the clip limit parameter sets the threshold for limiting the contrast enhancement in local image regions.

MFALF Algorithm

The Firefly Algorithm is a metaheuristic optimization technique inspired by the flashing behavior of fireflies. Firefly algorithm utilizes the behavior of fireflies in a search space, with attractiveness determined by fitness values. Brighter fireflies signal higher attractiveness, and through iterations, fireflies move towards brighter peers, influenced by distance and randomization.

For computing fitness function and attractiveness value of each "firefly" parameters like PSNR (Peak Signal-to-Noise Ratio), SSIM (Structural Similarity Index) are used emphasizing on quality and structural similarity of images. PSNR is the ratio of the maximum possible signal power to the power of the noise that affects the image. It quantifies image quality by measuring noise in optimized images.

$$\text{PSNR} = 10 \cdot \log_{10} \left(\frac{B_{Max}^2}{B_{MSE(i,j)}} \right), \tag{1}$$

Where, B_{Max} is the maximum brightness value in a target image (255 in an 8-bit grayscale image), B_{MSE} is the Mean Squared Error between the brightness values of the estimated (i) and high-resolution images (j).

SSIM is a metric that evaluates the structural similarity between the original and optimized images.

$$\text{SSIM}(x, y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \tag{2}$$

Where x and y are the original and optimized image respectively, μ_x is the mean of x, σ_x^2 is the variance of x, and σ_{xy} is the covariance of x and y. C_1 and C_2 are constants for stabilization.

Definition 1. ***Modified Attractiveness Parameter*** ***(β')***
It is a tuning parameter that governs the strength of attraction between fireflies. It is updated based on euclidean distance r.

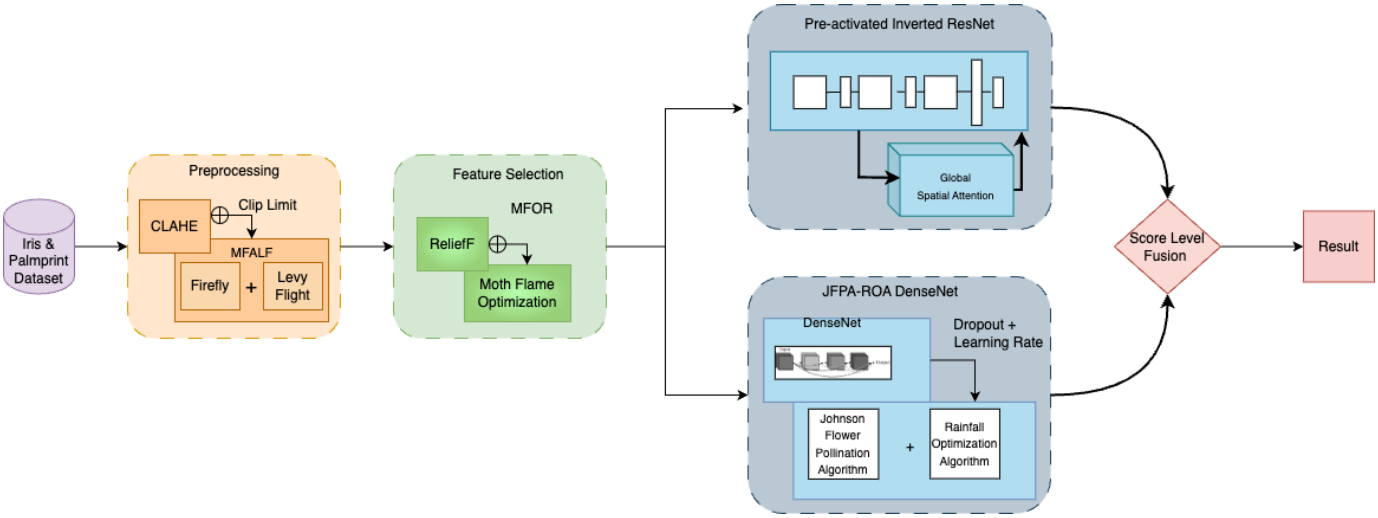

Fig. 1: Architecture of proposed model

$$r = \|\vec{X}_j - \vec{X}_i\| \tag{3}$$

$$\beta = \beta_0 \cdot e^{-\gamma \cdot \mathrm{r}^2} \tag{4}$$

Where, β_0 is a self tuned constant, γ is the absorption coefficient which controls the rate at which the β decreases and ranges between [0.1,1].

However this equation does not take into consideration the Weights of both the fire flies which is important according to the newton's law of attraction. Thus, We propose a modified equation for calculation of attraction :

$$\beta' = \beta_0 e^{\left(-\frac{\gamma r^2}{m_1 \cdot m_2}\right)} \tag{5}$$

Where m_1 and m_2 are decided by the fitness value of the firefly in population. We define the fitness function (F) and the firefly-attractiveness function (A) as :

$$F(\alpha) = \alpha \cdot \text{SSIM} + (1-\alpha) \cdot \text{PSNR} \tag{6}$$

$$A(i,j) = \beta e^{\left(-(F)^2\right)} \tag{7}$$

Here, α is a randomization parameter ranging [0,1] and β is attractiveness parameter ranging [0,1].

Definition 2. ***Levy Weighing Factor***

Levy Weighing Factor is a parameter which modulates the magnitude of random displacements in each iteration. It is proposed to introduce Levy flight, as an integral component of the Firefly Algorithm by modifying the equation 8 for new position of firefly as depicted in eq. 9.

$$x(i, i+1) = x(i,t) + A(i,j) \cdot F \tag{8}$$

$$x(i, i+1) = x(i,t) + A(i,j) \cdot F + W \cdot (rand() - 0.5) \tag{9}$$

Here, $x(i,j)$ denotes the firefly value at position (i,j) and W is the Levy Weighing Factor introduced in the model.

Levy flight's stochastic behavior reduces the likelihood of getting stuck in local optima and increases the algorithm's chances of finding a globally optimal solution.

Algorithm 1 describes the MFALF algorithm. Here, n is the population size, J is the search space, seed refers to the initial configuration of fireflies in the search space, $\alpha, \beta,$ andγ are the randomization, attractiveness and the absorption parameters respectively. Original and preprocessed images of palmprint and iris are shown in Fig 2 and Fig 3 respectively.

The preprocessed images are further passed in the model for extraction of relevant features such that dimensioality is reduced. The preprocessed images are then passed through the model to extract relevant features, effectively reducing dimensionality.

Algorithm 1 Modified Firefly Algorithm with Levy Flight

Require: $n, \alpha, \beta, \gamma,$ seed

Initialize fireflies $\vec{x}_1, \ldots, \vec{x}_n \in [\text{lb}, \text{ub}]$ with intensities $s_1, \ldots, s_n$ sampled from Population P

B. Moth Flame Optimization-ReliefF (MFOR)

Our proposed novel hybrid feature selection approach, termed MFOR, synergistically combines the robust feature ranking capabilities of filter method ReliefF with the efficient subset search strategy of Moth Flame Optimization (MFO) as a wrapper method. The hybrid can be categorized in 2 phases: *ReliefF* and *MFO*.

1) Phase I - ReliefF Phase

In the ReliefF phase, relevant features are selected based on their importance using ReliefF, and the corresponding subset is used for further optimization.

The original Relief algorithm [39] initially assigns equal weights to all features, then updates the feature scores ($W[f]$) for feature (f) as :

$$W[f] = \left(\frac{|x_i^{(A)} - x_i^{(M_j)}| - |x_i^{(A)} - x_i^{(H_j)}|}{\max(x_i) - \min(x_i)} \right) \tag{10}$$

Where $x_i^{(A)}$ is the value of the i-th feature for the instance being considered, $x_i^{(M_j)}$ and $x_i^{(H_j)}$ are the values of the i-th feature for the nearest instance of different ($Miss$) and same classes (Hit), respectively.

ReliefF [40] introduces key improvements: firstly, it incorporates a 'number of neighbors' parameter (k) for scoring updates, using k nearest hits and misses instead of just one, enhancing reliability, especially in noisy datasets. The ReliefF score for feature f is calculated as :

$$W[f] = \sum_{j=1}^{k} \frac{1}{k} \left(\frac{diff(x_i^{(A)}, x_i^{(M_j)})^2 - diff(x_i^{(A)}, x_i^{(H_j)})^2}{\max(x_i) - \min(x_i)} \right) \tag{11}$$

Where, k is the number of nearest neighbors and diff(a, b) computes the difference between a and b using Manhattan distance as defined below:

$$diff(\mathbf{x}_i^{(A)} - \mathbf{x}_j^{(M)}) = \sum_{k=1}^{n} |x_{i,k}^{(A)} - x_{j,k}^{(M)}| \tag{12}$$

This process is repeated for all instances, and the final feature scores are determined by averaging the accumulated weight updates across the dataset.

2) Phase II - MFO Phase

The Moth Flame Optimization phase refines the feature selection by applying MFO to the ReliefF-selected features.

Moth Flame Optimization (MFO) [41] is a nature-inspired optimization algorithm which mimics the moths flying around flames modelled by transverse orientation mechanism. Moths represent candidate feature subsets, while flames signify the fitness of corresponding subsets. Moths move towards flames using a logarithmic spiral function defined as :

$$X_i^{k+1} = \left\{ \begin{array}{l} \delta_i \cdot e^{bt} \cdot \cos(2\pi t) + Fm_i(k), i \leq n \\ \delta_i \cdot e^{bt} \cdot \cos(2\pi t) + Fm_n(k), i \geq n \end{array} \right\} \tag{13}$$

where, $\delta_i = \left| \vec{X}_i^k - \vec{F}_{m_i} \right|$ denotes how far a moth at position $\vec{X}_i$ is from its corresponding flame ($\vec{F}_{m_i}$) in iteration k, n is the number of flames, t denotes the phase of spiral motion, while b controls the scale of the spiral trajectory, influencing the movement of moths towards flames.

The value of t and n decreases linearly over the iterations, thereby balancing the exploration and exploitation. The mathematical equations for t and n are presented below:

$$r = Cur_{iter} \left(\frac{-1}{Max_{iter}} \right) - 1 \tag{14}$$

$$t = (r - 1) \times k + 1 \tag{15}$$

$$n = round \left(n_{Last\,iter} - Cur_{iter} \frac{(n_{Last\,iter} - 1)}{Max_{iter}} \right) \tag{16}$$

Where, Max_{iter} is the maximum number of iterations, Cur_{iter} is the current iteration, k denotes a random number ranged [0,1], r is the convergence parameter, and its value decreases linearly between [-2,-1].

The algorithm identifies and retains the most promising flames while disregarding the rest, iterating to optimize the feature selection process. These selected features are then utilized in the proposed classification models to ensure robust classification performance.

C. Classification

1) Preactivated Inverted Resnet (PIR)

The proposed classification method demonstrated in fig 4 introduces novel advancements including pre-activated weights in an Inverted-ResNet block with lightweight spatial attention utilizing C-pooling which are then stacked with global average pooling in the Final ResNet node, collectively aiming to improve efficiency and accuracy in image classification. The architecture initiates by integrating palmprint and iris modalities, each processed concurrently within separate branches

Algorithm 2 MFOR: Hybrid Feature Selection Algorithm

Initialize Dataset D, Number of features n, Number of nearest neighbors k, Maximum iterations Max_{iter}
Output: Selected feature subset S
ReliefF Phase:
for $i = 1$ to n **do**
    Compute ReliefF score $W[i]$ for feature i using Eq.(11)
end for
$S_{\text{ReliefF}} \leftarrow$ Features with top k ReliefF scores
MFO Phase:
Initialize n_{flames} moths with random feature subsets
for iter $= 1$ to Max_{iter} **do**
    Update t and n using Eqs. (14), (15), and (16)
    for each moth i **do**
        Compute δ_i
        if $i \leq n$ **then**
            Update X_i using Eq. (13) with $Fm_i = S_{\text{ReliefF}}[i]$
        else
            Update X_i using Eq. (13) with $Fm_n = S_{\text{ReliefF}}[i-n]$
        end if
    end for
    Update n_{flames} by selecting the top moths
end for
$S \leftarrow$ Features corresponding to top moths
return S

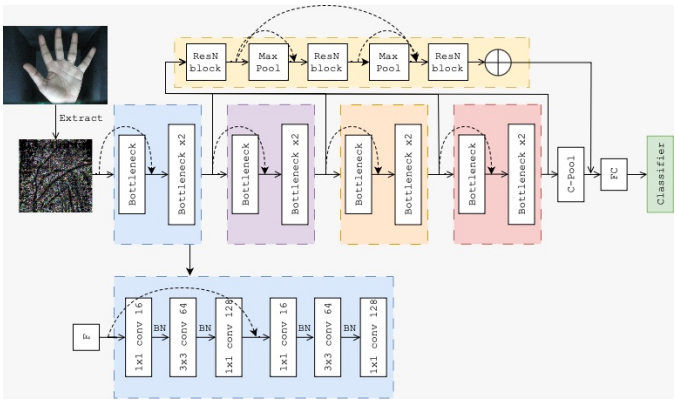

Fig. 4: PIR Architecture

of novel Preactivated Inverted Resnet blocks. The Inverted-ResNet block [42] with pre-activated weights modifies the traditional ResNet architecture by inverting the order of operations within a residual block. Inverted-ResNets with bottleneck connections allow for a highly reduced parameter count. Subsequently, Batch Normalization was used to optimize the high-dimensional network. Pre-activation involves applying activation functions before the skip connection, enhancing stability and convergence, with the leaky ReLU activation function used to prevent the vanishing gradient problem. The leaky Relu function can be defined as :

$$\text{LeakyReLU}(x) = \begin{cases} x, & \text{if } x > 0, \\ \alpha x, & \text{otherwise}, \end{cases} \tag{17}$$

Where α represents a small positive constant (usually around 0.01), which determines the slope of the function for negative input values x.

The output features from the initial ResNet units are split into two branches: the trunk branch and the soft mask branch. The trunk branch ($\mathcal{T}$) processes the features directly, while the soft mask branch generates an attention mask using bilinear interpolation ($\mathcal{F}$) with Resnet block outputs ($\mathcal{U}$).

$$o_{interp} = \mathcal{F}(o_{softmask}) \tag{18}$$

$$o'_{softmask} = \mathcal{U}(o_{interp}) \tag{19}$$

$$o = (1 + o'_{softmask}) \times \mathcal{T}(x) \tag{20}$$

The $o_{softmask}$ is created by downsampling the input tensor through max pooling, passing it through another residual block, and then upsampling back to the original dimensions. The attention mask is applied to the trunk branch output (20), modulating the features to highlight important regions. Finally, the modulated features pass through a final block, ensuring stable and efficient training by leveraging BatchNorm and leaky ReLU activations, and maintaining spatial information through global average pooling.

To facilitate the integration of information from the parallel branches, feature fusion layers are introduced. C-pooling layer is used within each block to combine the feature representations learned from each branch as described below.

$$C_{pooled} = \text{AvgPool}(I \times \text{Att}) \tag{21}$$

Where Att is the attention layer and I is the input. Global average pooling is used to aggregate spatial information across feature maps created by Preactivated Inverted Resnet blocks.

For measuring the model performance of the resnet, the cross-entropy loss function is employed. The cross-entropy function utilizes the softmax activations to generate an output within a probability distribution (p_i). The mathematical representation of cross-entropy loss is:

$$H(p, y) = -\sum_i y_i \log \left(\frac{e^{a_i}}{\sum_{k=1}^{N} e^{a_k}} \right), \tag{22}$$

where $i \in [1, N]$ and $e^{a_i} / \sum_{k=1}^{N} e^{a_k}$ represents the output class probabilities (p_i).

2) Johnson Flower Pollination Algorithm - Rainfall Optimization Algorithm - DenseNet (JFPA-ROA-DenseNet)

Parameter tuning plays a crucial role in the performance of deep learning models. Rosa et al.(2018)[29] highlighted the advantages of using metaheuristics for optimizing these parameters. In the parallel classification model, we propose a novel hybrid metaheuristic approach for optimizing DenseNet. The learning rate and dropout parameter of the DenseNet classifier are optimized through the hybrid of Novel JFPA-ROA. The dropout parameter controls regularization to mitigate overfitting, while the learning rate determines the step size for updating network weights during training.

Johnson Flower Pollination Algorithm (JFPA)

The Flower Pollination Algorithm (FPA) [43] is inspired by natural pollination in flowering plants, where global pollination resembles biotic cross-pollination and promote exploration using the Lévy distribution. A designated flower(pollinator) undergoes a Lévy flight. The updated position of the destination flower is represented as :

$$x_{i+1}^t = x_i^t + \gamma L(g^* - x_i^t) \tag{23}$$

$$L(x) = \begin{cases} 0, & \text{for } x < \mu \\ \sqrt{\frac{\pi}{c\alpha}} \left(\frac{1}{\alpha} \exp\left(-\frac{(\mu - x)^2}{c\alpha} \right) + \frac{1}{1-\alpha} \Gamma(1-\alpha, \frac{x-\mu}{c}) \right), & \text{for } x \geq \mu \end{cases} \tag{24}$$

Where, x_{i+1}^t is the updated solution of ith component at time t, $L(x)$ is the random step size chosen from the probability density function (PDF) of the Lévy distribution, g^* is the global best solution found so far and γ is the scaling parameter which indicates whether the update occurs between neighboring flowers ($\gamma = 1$) or not ($\gamma = 0$). $\Gamma(1-\alpha, \frac{x-\mu}{c})$ is the incomplete gamma function, $\mu(-\infty < \mu < \infty)$ is the location parameter which determines the center of the distribution, $c(c > 0)$ is the scale parameter controlling the spread of the distribution. and the stability parameter α ($0 < \alpha \leq 2$) defines the shape of the tails.

Use of levy distribution would not be able precisely capture the distinct peaks of multimodal biometric data and Its heavy-tailed nature would lead to premature convergence. To overcome these limitations we propose to modify the exploration in FPA by using Johnson distribution as it have 4 tailored parameters leading to broader range of distribution shapes making it more adept at representing the multimodal nature of biometric data.

Definition 3. ***Johnson based Exploration***

The Johnson distribution, a family of probability distributions derived through bijective transformation from the normal distribution, represents a versatile statistical toolset characterized by its probability density function. We incorporate Johnson distribution to update position while exploring the search space in FPA. The modified update position is defined as :

$$x_{i+1}^t = x_i^t + \gamma J(g^* - x_i^t) \tag{25}$$

$$J(x) = \frac{1}{x\sigma\sqrt{2\pi}} \frac{\Gamma \sqrt{\delta^2 + \lambda^2 \left(\frac{x-\xi}{\sigma} \right)}}{\Gamma\left(\sqrt{\delta^2 + \lambda^2} \right)} \tag{26}$$

Where, x_{i+1}^t is the updated solution of ith component at time t,$J(x)$ is the random step size chosen from the PDF of the Johnson distribution σ is the scale parameter, δ and λ are shape parameters and $\Gamma(\cdot)$ is the gamma function.

Local pollination, akin to auto-pollination, occurs probabilistically based on a variable P_c within [0, 1], representing the probability of change. The equation for updating x locally is as follows:

$$x_{i+1}^t = x_i^t + \epsilon \cdot \gamma \cdot (x_j^t - x_k^t) \tag{27}$$

Where, x_t^j and x_t^k represent two randomly selected solutions from the population at iteration t, ϵ is a constant that influences the step size during local pollination.

3) Rainfall Optimization Algorithm (ROA)

The Rainfall Optimization Algorithm (ROA) is a nature-inspired metaheuristic optimization algorithm motivated by the behavior of raindrops flowing down a terrain.

The algorithm initiates with a set of initial raindrops (P), representing a cloud of water droplets, each denoting a potential solution. Initially, all raindrops are considered "active," meaning they participate in the search process.

The algorithm generates neighbor raindrops(N) around the raindrop's current position. Fitness of all active raindrop is calculated as the accuracy of DenseNet classifier. The algorithm updates a raindrop's position to a significantly better neighboring raindrop (Dominant Neighbor), mirroring rain seeking lower elevations. The update equation is as follows:

$$x_i^{(t+1)} = Max_{j \in \{1,2,\ldots,n\}}(F(x_j^{(t)})) \tag{28}$$

Where $x_i^{(t)}$ is the position of raindrop i at iteration t and $j \in \{1, 2, ..., n\}$ represent the neighbor raindrops.

If no clear advantage is found, the "explosion process" generates random new neighbor raindrops, akin to rain dispersing upon hitting the ground, fostering exploration in diverse directions.

$$x_i^{(t+1)} = \begin{cases} x_i^{(t)} + E_p & \text{if } F(x_i^{(t)} + E_p) > F(x_i^{(t)}) \\ x_i^{(t)} & \text{otherwise} \end{cases} \tag{29}$$

Where, E_p is the explosion point calculated using johnson distribution.

After a predefined number (Ne) of unsuccessful explosion attempts, the raindrop is marked as "inactive." This prevents the algorithm from getting stuck in areas with low potential for improvement, similar to how stagnant water "evaporates". After processing all active raindrops, raindrops are ranked by fitness values. Low-ranking ones may be removed for diversity or high-ranking ones given more attempts. The loop continues until all raindrops are inactive or maximum iterations are reached, then raindrop with best fitness is selected.

4) JFP-ROA-DenseNet

JFPA's focus on global exploration may limit its effectiveness in exploiting local optima, potentially hindering its performance in complex multimodal image recognition tasks. Rainfall Optimization Algorithm excels in local search and can help FPA fine-tune its solutions by efficiently exploiting nearby regions. ROA may excel in local search but may not provide adequate global exploration. To address these limitations, our research proposes a hybrid approach that integrates ROA into JFPA for local pollination, targeting the optimization of DenseNet's dropout and learning rate and dropout parameters, thereby enabling enhancements in transfer learning-based DenseNet (TL-JFPA-ROA-DenseNet). This hybridization aims to strike a balance between global and local search, enhancing the algorithm's capabilities for improved performance.

Algorithm 3 illustrates the application of the TL-JFPA-ROA-DenseNet algorithm for optimizing the learning rate and dropout parameter within the DenseNet classifier.

Algorithm 3 TL-JFPA-ROA-DenseNet

Require: P: Population, Max_iter: Max iterations, P_c: Probabilty of change

for Each flower i in P **do**
  Evaluate the fitness of flower $F(i)$
  if $F(i) \geq F(f_{best})$ **then**
    $f_{best} \leftarrow i$
  end if
end for
for $t = 0$ in Max_iter **do**
  Generate random steps by *Johnson Distribution* eq(26)
  for Each flower i in P **do**
    Potential Flower $f_p \leftarrow i$
    Apply random steps to f_p *Global Pollination*
    if $P_{rand} > P_c$ **then**
      Use *ROA* for *Local Pollination*
    end if
    Calculate Fitness $F(i)$
    if $F(f_p) > F(i)$ **then**
      $i \leftarrow f_p$
      $F(i) \leftarrow F(f_p)$
      if $F(f_p) > F(f_{best})$ **then**
        $f_{best} \leftarrow f_p$
      end if
    end if
  end for
end for
return f_{best}

D. Fusion

For fusion of results from both the classification approaches Score-level fusion is adopted. To combine scores from M different modalities $(S_1, S_2, ..., S_M)$ into a single score vector S, a fusion function F is employed. The mathematical representation of the product rule of fusion used is as follows:

$$\begin{aligned} S &= F(S_{PIR}, S_{JFPA-ROA-DenseNet}) \\ &= \alpha * S_{PIR} + (1-\alpha) * S_{JFPA-ROA-DenseNet} \end{aligned} \tag{30}$$

The final score vector S is used to deduce results.

V. Experiment

In this section, we first outline the experimental setup essential for implementing our proposed methodologies. Following this, we provide a detailed explanation of implementing each proposed approach. This includes step-by-step descriptions from image preprocessing and feature selection to the implementation of our classifiers and their fusion. This approach ensures a comprehensive understanding of how each element contributes to our methodology.

A. Experimental Setup

The proposed methodolgy was put into implementation using Python 3 within the Google Colab environment that offers a convenient platform for running Python code with access to various hardware resources such as CPU, TPU (Tensor Processing Unit), or T4-GPU, depending on availability and requirements for speeding up computation of deep learning models and metaheuristic optimization techniques. Additionally, the system was equipped with 12.7 GB of RAM , providing sufficient memory for processing and storing data during the execution of the proposed methodology thus avoiding performance bottlenecks due to memory limitations. Overall, leveraging Python 3 on Google Colab, along with CPU, TPU, or T4-GPU runtimes, and supported by 12.7 GB of system RAM, ensured an optimal environment for implementing and executing the proposed methodology effectively and efficiently.

B. Implementation

In this subsection, we will outline the implementation of our proposed methodology. The process is detailed in the following points

- **Image Preprocessing**:
  The biometric image is initially enhanced using the CLAHE algorithm, with the determination of its Clip Limit parameter by using the novel MFALF algorithm.The image is initially resized to dimensions of 224 x 224 pixels utilizing OpenCV, converted to black and white, and subsequently forwarded to the CLAHE algorithm. In order to predict the Clip Limit, the search space for the CLAHE algorithm's Clip Limit parameter ranges from 0 to 60. The fireflies' population size is fixed at 10, with a total of 100 iterations set to find the optimal Clip Limit for image enhancement. For the CASIA Palmprint dataset, the optimal Clip Limit obtained was 18.67, while for MMU Iris image it is 20. In order To evaluate the performance of the proposed MFALF algorithm, we also applied well-known metaheuristic algorithms, including the Firefly Algorithm, Particle Swarm Optimization (PSO), Whale Optimization Algorithm (WOA), and Cat Swarm Optimization Algorithm (CSOA) for image enhancement in biometric recognition. The fitness function combines PSNR and SSIM, aiming to minimize it to extract useful features during image enhancement. As shown in Table I , the proposed MFALF algorithm achieves the lowest value (3.076) on CASIA palmprint image, outperforming the other metaheuristic algorithms in determining the most optimal Clip Limit for the CLAHE algorithm.

TABLE I: MFALF Performance Comparison

Algorithm	Clip Limit	Fitness Function
PSO	9.85	7.687
CSOA	2	7.617
WOA	60	5.264
Firefly	35.5	5.107
MFALF	**20**	**3.076**

- **Feature Selection**:
  After enhancing the contrast of the images, a novel hybrid methodology integrating ReliefF and Moth Flame Optimization (MFO) is introduced for the selection of informative features. This approach is structured into two distinct phases.

In the first phase, the initial set of 150,528 features undergoes processing via the ReliefF algorithm, which is a filter method that assesses the relevance of features independently of any specific learning algorithm. For this procedure, the number of neighbors is fixed at 100, which determines the number of neighbors considered when assigning feature importance scores; a higher number of neighbors leads to more accurate scores, albeit at the cost of increased computation time. The 'n_features_to_keep' parameter, which specifies the number of features to be retained post-ReliefF processing, is maintained as a variable to allow for adjustment based on specific requirements.

Subsequently, in the second phase, the features selected by the ReliefF algorithm are further refined using Moth Flame Optimization (MFO). MFO functions as a wrapper method, evaluating subsets of features based on the performance of a particular learning algorithm. In this phase, the maximum number of iterations is set to 10, and the population size is established at 20, representing the number of moths (candidate solutions) in the population. The parameter determining the final number of required features is maintained as a variable. An SVM classifier is employed to compute the fitness and accuracy of the feature subsets during this phase.The SVM classifier is preferred for its robustness in high-dimensional spaces and effectiveness with small to medium-sized datasets, making it ideal for the refined feature subsets in this methodology.

- **JFPROA Densenet**:
  We receive biometric image dataset with selected features through the feature selection process, which serves as the foundation for training and testing our novel model. Our approach focuses on optimizing the hyperparameters of a pre-trained DenseNet-121 model for biometric image classification. This optimization is achieved using a combined Johnson Flower Pollination Algorithm and Rainfall Optimization Algorithm (JFPA-ROA). We begin by refining the model's classifier with enhancements such as batch normalization, ReLU activations, and adaptive dropout layers. The process starts with a random initialization of a diverse set of hyperparameter configurations, including parameters like learning rate, & dropout rate. Key parameters such as population size (set to 2), maximum iterations (set to 2), and beta (set to 0.5) are predefined to balance exploration and exploitation within the algorithm. Specific ROA parameters (gamma = 2.0, delta = 3.0, epsilon = 0.01) shape the Johnson distribution used for random updates during exploration. Each configuration undergoes training to assess its performance based on validation accuracy. Through iterative refinement employing global pollination and explosion processes, the algorithm dynamically adjusts hyperparameters to optimize model performance. Learning rate & dropout parameter determined by the proposed JFPROA algorithm is 0.001 & 0.205 . Hence, in the pretrained Densenet121 CNN model, we set the Learning rate parameter to 0.001 and dropout rate parameter to 0.0205 and train out biometric images over the optimized model. This methodology not only highlights the efficacy of bio-inspired optimization techniques in deep learning but also facilitates the discovery of optimized model settings tailored for intricate image classification tasks
- **PIR**: We have designed a novel PIR architecture to function as a secondary classifier alongside the JFPROA DenseNet in a multimodal biometric recognition system. In this multimodal system, both classifiers operate simultaneously. For instance, if palmprint images are trained using the transfer learning-based JFPROA DenseNet, then iris images are trained and tested using the PIR architecture, and vice versa. The PIR Architecture uses a pre-activated inverted ResNet with a spatial attention mechanism. We optimize our approach over a residual convolutional neural network, leveraging the efficiency of existing inverted resnets (for eg. MobileNetv2), using a combination of lightweight stacked layers for spatial attention with C-pooling to improve the generalizability of models trained on small datasets. This setup enhances the network's focus on critical regions within an image and improves feature capture. By incorporating BatchNorm and pre-activation with leaky ReLU, we stabilize and accelerate the training process, leading to better gradient flow and reduced vanishing gradient problems. Our final architecture employs global average pooling to minimize parameters while maintaining spatial information, resulting in a robust, efficient, and scalable solution for biometric classification.

  PIR consists of multiple dense blocks where each layer is connected to every other layer in a feed-forward fashion. The preprocessed biometric images are then passed through the initial convolution and pooling layers of the network, which help in capturing basic features like edges and vein textures, and a lightweight stack of layers for spatial attention using C-pooling, enabling spatial feature extraction. The output features from the intial attention mechanism are subsequently fed into the inverted ResNet blocks with pre-activated weights. Each block contains several convolutional layers, where each layer benefits from pre-activation with leaky ReLU and BatchNorm, ensuring stable and efficient training.

  By using pre-activation, the activation functions are applied before the weights, which improves gradient flow and reduces the vanishing gradient problem. This allows the network to effectively train deeper architectures without degradation. Batch normalization further stabilizes the training process by normalizing the inputs to each layer, reducing internal covariate shift and ensuring consistent input distributions that prevent the model from overfitting to unique and complex patterns in the images. This combination of pre-activation, leaky ReLU, and BatchNorm leads to a more robust and efficient training process, which we note empirically in section VI.

  Each resnet block incorporates additional residual information provided by the attention block before passing on the normalized weights. We also find that incorporating an additional BatchNorm layer after the residual

operation further improves performance over the select datasets. The output from the final ResNet block is then passed through a global average pooling (C-pooling) layer, reducing the dimensions of the feature maps while maintaining spatial information. To further enhance the classifier, we find that including adaptive dropout layers (dropout rate $p = 0.2$) helps in regularizing the model and reducing the variability and noise in the datasets. Finally, the reduced feature maps are fed into a fully connected layer for classification into the specified number of classes. The PIR model was initialized with the desired number of output classes and trained using Adam optimization. The performance of the trained model was evaluated on separate validation and test sets to assess classification accuracy, convergence behavior, and computational efficiency. These enhancements and modifications enabled the development of a robust, efficient, and scalable framework tailored specifically for biometric recognition tasks.

- **Fusion**:
  To evaluate the multimodal biometrics dataset (palmprint & iris) results, we used a basic score level fusion approach to determine final scores. Using the final scores achieved, we assign the class with the highest score to the particular test image. We experimented to find the best alpha value in Eq 30 for every multimodal dataset M-BIRJ, M-IIT, M-CAS.

In the upcoming section VI, we will delve into an analysis of how effectively our proposed classifiers perform. This examination will cover various performance metrics and provide a comprehensive evaluation of their strengths and weaknesses.

VI. CLASSIFICATION RESULTS

In this section, we evaluate the performance of the proposed methodologies using key metrics, including Accuracy (ACC), Equal Error Rate (EER), False Acceptance Rate (FAR), False Rejection Rate (FRR), Total Training Time, Macro F1-Score, Detection Error Tradeoff (DET) Curve, and Receiver Operating Characteristic (ROC) Curve. These metrics collectively provide a robust framework for assessing the effectiveness of the novel approach for classification. This includes evaluating the impact of image preprocessing and feature selection, comparing the approach with other CNN architectures, comparing unimodal and multimodal biometric datasets,and assessing the overall versatility of the proposed approach alongside a comparison of the proposed classifiers. This comprehensive evaluation enhances understanding and guides future advancements in the field.

It is important to note that for evaluating the results of the unimodal datasets, IIT palmprint images are trained using Novel Preactivated Inverted Resnet architecture (PIR) , while MMU iris images, CASIA & BIRJAND palmprint images are trained using proposed Transfered Learning based JFP-ROA Densenet (JFPROA-Densenet) CNN Model.

A. Impact of Image Preprocessing

The impact of preprocessing on the performance of our proposed model is highlighted in Table II. This illustrates the impact of preprocessing on the performance metrics of the proposed model with the number of features selected in the range of 65k-75k. It is evident from Table II that preprocessed biometric images of all unimodal dataset (MMU, CASIA, BIRJAND, IIT) outperform unprocessed images across various metrics including Accuracy, FAR, FRR, and Macro F1 score, all achieved within a shorter total training time. This demonstrates the effectiveness of novel preprocessing approach in reducing the computational requirements & enhancing the performance of biometric recognition systems.

B. Impact of Feature Selection

Now let us understand the impact of feature selection on performance metrics of the proposed classifiers for various preprocessed unimodal biometric datasets. Table III showcases the performance of the proposed model for MMU , CASIA, BIRJ unimodal datasets, both without applying the MFOR algorithm and with the application of the MFOR algorithm for selecting the number of features within the ranges of 65k-75k and 35k-50k. It is evident that when the number of selected features falls within the range of 65k-75k, the model achieves maximum accuracy, Macro F1 score, and lower FAR and FRR values, all while reducing the total training time. This highlights the efficiency of our proposed MFOR algorithm for feature selection, which effectively selects relevant features, reduces computational complexity and risk of overfitting, while enhancing accuracy and other performance metrics of the proposed approach.

C. Performance of Preprocessed Unimodal Biometric Recognition using Different Models

As previously mentioned, for the results of unimodal datasets (as shown in Table II and Table III), such as the IIT Palmprint dataset, we utilized the proposed Preactivated Inverted Resnet (PIR) CNN architecture for training, while MMU Iris images, CASIA & BIRJAND Palmprint images were trained over the novel Transfer Learning based JFP-ROA Densenet Model.

To assess and compare the performance of the proposed classifiers, we accomplish training of MMU iris and IIT palmprint datasets over popular pre-trained CNN architectures like InceptionV3, Resnet50 as presented in Table IV and Table V. Analysis of Table IV reveals that our proposed models (JFP-ROA Densenet and PIR) for classification exhibit superior performance in terms of accuracy, train loss, and val loss achieved within a shorter duration of total training time for the MMU Iris dataset, demonstrating its practical deployment potential.

In the analysis of the IIT Palmprint dataset presented in Table V, the trends are similar to those observed in Table IV. However, when comparing the performance of our proposed JFP-ROA Densenet model and Resnet50, we notice that the train loss for the proposed Densenet (0.0021) is higher than that of Resnet50(0.0007). Nevertheless, the validation loss(Val Loss) of JFP-ROA Densenet (0.0082) is lower as compared to Resnet50 (0.0095), indicating that our proposed Densenet model avoids overfitting and achieves better accuracy within

TABLE II: Dataset Preprocessing Impact

Dataset	Preprocessing	Clip Limit	ACC	FAR	FRR	Macro F1 Score	Total Training Time

a much shorter duration (39 min) of total training time compared to Resnet50 (70 min).

Hence, We can conclude that our proposed models presents superior result as compared to other pretrained CNN architectures. And so the scores from the novel JFP-ROA Densenet architecture are fused with the scores of the proposed Preactivated Inverted Resnet (PIR) for evaluating the multimodal biometric results, as depicted in Table VIII.

We have evaluated the performance of our proposed classifier using different optimizers like Adam & RMSProp. Selecting the appropriate optimizer for a CNN model is imperative as it significantly impacts training speed, generalization, robustness, efficiency, hyperparameter sensitivity, and task-specific performance.Adam adapts learning rates per parameter, ideal for dynamic and noisy datasets, while RMSprop efficiently handles non-stationary objectives and converges faster on convex problems. Table VI presents the performance of our proposed model across various unimodal datasets with different optimizers. From the analysis of Table VI , it is evident that superior results are achieved when the Adam optimizer is used compared to the RMSPROP optimizer. Consequently, we have opted to use the Adam optimizer for our proposed classification models for training noisy biometric images.

We will now explore the rationale behind adopting a transfer learning approach for our model, as assessed in Table VII . This table presents a comparative analysis of test results with and without transfer learning across various unimodal datasets trained using our proposed methodology Transfer Learning based JFPROA Densenet. It underscores the substantial performance improvements and enhanced stability achieved through transfer learning in biometric recognition. By leveraging knowledge transfer from related tasks, transfer learning effectively enhances both the efficacy and computational efficiency of deep learning models, thereby revolutionizing their training paradigm.

D. Performance Comparision of Unimodal and Multimodal dataset

Now, let's compare the performance of our proposed classifiers on preprocessed unimodal datasets and preprocessed multimodal datasets, where the number of selected features ranges from 65k to 75k. Table VIII presents the comparison of performance of the M-CAS, M-BIRJ, M-IIT, and M-CAS2 multimodal datasets with the Unimodal dataset. In the M-CAS & M-IIT dataset, MMU Iris images are trained using the novel Transfer Learning based JFP-ROA-Densenet architecture, while CASIA & IIT palmprint images are trained using the proposed PIR CNN architecture. In contrast, for the M-BIRJ & M-CAS2 multimodal dataset, MMU Iris images are trained using the novel PIR, while BIRJ & CASIA palmprint images are trained using the proposed Transfer Learning based JFP-ROA Densenet model.

Analysis of Table VIII indicates that the accuracy of the M-CAS multimodal dataset is 1, which surpasses the accuracy achieved by the corresponding unimodal datasets: CASIA Palmprint (0.9334) and MMU Iris (0.9988). Similar trends are observed for other multimodal datasets such as M-BIRJ, M-IIT, and M-CAS2. The performance of multimodal datasets, as measured by other metrics like FAR, FRR, and F1-score, also exhibits superiority compared to the performance of unimodal datasets. This highlights the effectiveness of leveraging multiple modalities (palmprint and iris) in biometric recognition, leading to enhanced accuracy and performance across various metrics.

To assess the performance of the multimodal M-BIRJ dataset, we determine the final class prediction score by averaging the scores predicted by the Transfer Learning based JFP-ROA Densenet (for palmprint) and the PIR model (for iris). Subsequently, the test image is assigned to the class with the highest score. Through experimentation, we established that setting alpha to 0.5 yields optimal accuracy (1). Similarly, in the case of the M-IIT dataset, the peak accuracy(1) is attained when alpha equals 0.5. Conversely, for M-CAS multimodal

Fig. 5: Equal Error Rate Graphs

TABLE IV: Performance Metrics of Different Models On MMU with 74,413 selected features

Model	ACC	Train Loss	Val Loss	Total Training Time	Training Time per Epoch	Input Size
InceptionV3	0.7681	0.0001	0.0154	33 min	5.5 min	2,68,203
PIR	**0.9605**	**0.0001**	**0.0034**	**15 min**	**55 sec**	**1,50,528**
JFP-ROA Densenet	**0.9988**	**0.0001**	**0.0006**	**21 min 33 sec**	**2.08 min**	**1,50,528**
ResNet50	0.9464	0.0012	0.0078	26.4 min	2.4 min	1,50,528

dataset, accuracy reaches 1 when alpha is set to 0.6.

FAR (False Acceptance Rate) refers to mistakenly accepting an imposter as genuine, while FRR (False Rejection Rate) occurs when a genuine person is wrongly rejected. EER (Equal Error Rate) marks the point where the difference between FAR & FRR is minimum . At this threshold, decisions are made: scores below it are classified as imposters, and scores above it as genuine.Table IX indicates that the EER for multimodal datasets is significantly lower compared to unimodal datasets, demonstrating superior performance.

The FAR/FRR vs Threshold graph (Fig 5) helps in evaluating the EER and decision threshold. The performance of both unimodal and multimodal datasets were evaluated using the Detection Error Tradeoff(DET) curve, which is a graphical representation that illustrates the relationship between FAR and FRR. Fig 6 demonstrates that the FAR-FRR tradeoff for the M-BIRJ multimodal dataset is better than that of the unimodal MMU and BIRJAND dataset. Similar Graphs are observed for other multimodal datasets(M-CAS & M-IIT) as shown in Fig 6 . Receiver Operating Curve (ROC) depicts the tradeoff between True Positive Rate (TPR) and False Positive Rate(FPR) . Micro-Average ROC curves for CASIA & M-CAS datasets are shown in Fig 7. While ROC curves are commonly used, DET curves offer finer control over error rates, crucial for biometric recognition assessment. Hence, DET curves are often favored for comprehensive biometric performance analysis.

E. Comparison between the Proposed Classifiers & Versatility of our Proposed Approaches

Finally, we conduct a comprehensive comparison between our two novel CNN models, emphasizing their versatility to be trained on either modality. This showcases the adaptability and robustness of our models across different biometric data configurations.

As observed in Table IV & V, our proposed classifying models outperform other CNN classifiers. However, examining Table X, we notice that our proposed Transfer Learning based JFP-ROA Densenet model provides better accuracy for CASIA, MMU, and Birjand datasets compared to the proposed Preactivated Pre-trained Inverted ResNet. Nonetheless, it is essential to note that the Preactivated Pre-trained Inverted ResNet trains much faster. While the former algorithm offers superior results, it requires comparatively more training time. On the other hand, the preactivated inverted ResNet algorithm achieves good accuracy in significantly less training time. Therefore, the score-level fusion of both models helps enhance each other's performance, ultimately leading to the best performance for multimodal biometric recognition.

In Table VIII, comparing the results of M-CAS, where MMU iris dataset is trained using the Novel Transfer Learning based JFP-ROA Densenet model, and innovative PIR Model is used for training CASIA palmprint images, with M-CAS2 multimodal biometric dataset, where MMU iris images are trained using Novel PIR and CASIA images are trained using the proposed JFP-ROA Densenet model, both achieve

M-IIT	**PIR + JFPA-ROA-DenseNet**	**0**	**0**	**1**

an accuracy of 1. This demonstrates the versatility of our proposed classifiers, showing its effectiveness across different modalities to deliver the best multimodal results.

VII. Conclusion

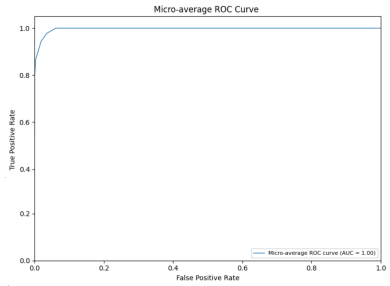
In this paper, we propose an innovative multimodal biometric recognition system leveraging deep learning techniques with iris and palmprint modalities. Our research introduces several novel methods to enhance efficiency and accuracy. Initially, the Modified Firefly Algorithm with Lévy Flights (MFALF) optimizes the Contrast Limited Adaptive Histogram Equalization (CLAHE) algorithm, enhancing image contrast. Following this, a unique hybrid of ReliefF and Moth Flame Optimization (MFOR) is employed for feature selection, extracting informative features.

For classification, a parallel approach is adopted. Firstly, a novel Preactivated Inverted ResNet (PIR) architecture is introduced. Secondly, metaheuristics are utilized, integrating Johnson Flower Pollination Algorithm with Rainfall Optimization Algorithm for fine tuning of the learning rate and dropout parameters of Transfer Learning based DenseNet architecture (JFPROA DenseNet). Finally, a score-level fusion strategy combines the outputs of the classifiers, ensuring robust and accurate multimodal biometric recognition.

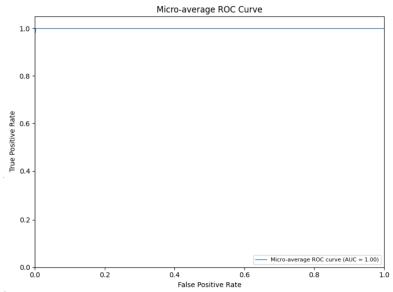
This multimodal approach achieves 100% recognition accuracy on various datasets, surpassing traditional unimodal iris and palmprint identification methods. It demonstrates high efficacy with a lower Equal Error Rate (EER), False Acceptance Rate (FAR), and False Rejection Rate (FRR). The Detection

TABLE X: Performance comparision between JFPROA Densenet & PIR

Dataset	Accuracy		Total Training Time (minutes)	
	JFPA-ROA Densenet	PIR	JFPA-ROA Densenet	PIR
CASIA	**0.9875**	0.9334	32	**19**
MMU	**0.9988**	0.9491	**21**	22
BIRJAND	**0.9938**	0.9875	231	**186**
IIT	0.9574	**0.9695**	73	**69**



(a) CASIA ROC Curve



(b) M-CAS ROC Curve

Fig. 7: ROC Graphs

Error Tradeoff (DET) curve further confirms the system's superiority over unimodal recognition. While highly scalable for a diverse dataset with a large number of individuals, the system's scalability is ultimately limited by computational resources and task complexity. Future improvements can focus on incorporating additional biometric traits like finger vein, palm vein, and facial features. This would further reduce the EER and enhance the overall recognition accuracy, creating an even more robust and secure multimodal biometric system

Abstract. This paper presents a thorough investigation into the mechanical characterization of Al6351 composites reinforced with TiC, B_4C, and WC particles. The primary objective is to assess how different proportions of reinforcements affect the mechanical properties and microstructure of the composites. The experimental approach involves the fabrication of composite specimens using the liquid route process, followed by comprehensive mechanical and microstructural analyses. The findings demonstrate that increasing the proportions of reinforcements significantly enhances the tensile strength, yield strength, hardness, and toughness of the composites. Microstructural analysis confirms the uniform dispersion of reinforcement particles throughout the matrix alloy, enabling effective load transfer and reinforcement mechanisms. In the hybrid metal matrix composite composed of 1.5 wt.% B_4C, 1.5 wt.% TiC, and 1.5 wt.% WC, the highest tensile strength of 140.7 MPa, and hardness of 76 HRC are observed. Conversely, the hybrid metal matrix composite with 0.5 wt.% of each reinforcement exhibits the maximum toughness of 28 Joules. These research findings offer valuable insights for the design and development of high-performance metal matrix composites with potential applications in industries such as aerospace, automotive, and manufacturing.

INTRODUCTION

Aluminum alloys encompass a category of metallic substances comprising mainly aluminum as the primary component, accompanied by the inclusion of other elements to augment their characteristics. These alloys present a multitude of benefits in diverse sectors. To begin with, aluminum alloys possess a lightweight quality, rendering them exceptionally suitable for implementations where minimizing weight is crucial, such as within the aerospace, automotive, and transportation fields[1]. Their low density allows for improved fuel efficiency, easier handling, and reduced transportation costs. Additionally, aluminum alloys exhibit excellent corrosion resistance, ensuring durability and longevity in challenging environments[2], [3]. This property eliminates the need for extensive protective coatings and reduces maintenance costs. Another advantage of aluminum alloys is their high formability, allowing for intricate shaping and complex designs through processes like casting, extrusion, and forging[4]. This versatility enables the production of customized components in industries such as construction, consumer goods, and electronics. Furthermore, aluminum alloys have good thermal and electrical conductivity, making them valuable for heat transfer applications and electrical conductivity requirements in industries ranging from heat exchangers to electrical transmission lines[5][6]. Lastly, aluminum alloys are highly recyclable, offering environmental benefits and contributing to the principles of sustainability and circular economy. With these advantages, aluminum alloys have become indispensable materials in numerous industrial sectors, providing a balance of performance, cost-effectiveness, and environmental sustainability[7][8][9].

In the realm of aluminum alloys, specifically Al6351, notable characteristics including formability, robust strength, and corrosion resistance have been identified [10]. However, researchers have sought to amplify its mechanical properties and broaden its range of potential applications by incorporating reinforcing elements,

particularly ceramic particles, into the alloy structure. Among the various ceramic reinforcements, TiC, B_4C, and WC hold great potential owing to their remarkable hardness, thermal stability, and resistance to wear[11], [12][13].

The research focuses on examining the mechanical characteristics of Al6351 when reinforced with varying ratios of TiC, B_4C, and WC is driven by the increasing interest in metal matrix composites. These composites have gotten a lot of attention because of their superior mechanical properties, which outperform those of traditional materials.[14]. Because of their lightweight nature and exceptional strength-to-weight ratio, aluminum-based composites have been extensively researched and used in industries such as defense, aviation, and automobile [15],[16],[17]. To optimize the material design and fabrication processes, it is critical to understand the effect of different reinforcement ratios on the mechanical properties of the composite[18]. By adjusting the proportion of ceramic reinforcements, a balance can be achieved between strength, hardness, and other mechanical properties, resulting in improved performance for specific applications[19].

The addition of reinforcing elements, namely TiB2 and ZrB2, to the Al6351 alloy, has notable impacts on its properties. These materials play a key role in improving the tensile strength and hardness of the matrix, Consequently, its overall mechanical performance improves. Furthermore, the inclusion of these reinforcements enhances the composite's resistance to wear, making it well-suited for applications involving abrasive contact or sliding[20][21][22]. The thermal stability of the alloy is also enhanced, as these reinforcing materials have high melting points and thermal stability. Moreover, certain reinforcements like Si3N4 and TiO2 can provide corrosion resistance, protecting the alloy from corrosive environments. Lastly, the electrical and thermal conductivity of the composite can be tailored based on the choice of reinforcing materials[23], [24], [25].

The application of agrowaste and industrial waste as a reinforcingagent to Aluminium based alloys offers significant advantages and diverse applications[26]. In the automotive sector, the incorporation of agrowaste and waste materials in metal matrix composites leads to lightweight components, improving fuel efficiency and reducing emissions. The utilization of agrowaste and industrial waste materials not only provides an eco-friendly solution but also enhances the thermal and electromechanical characteristics of the composites, making them attractive to various industries seeking sustainable and high-performance materials[27], [28].

The importance of this research lies in its contribution to existing knowledge about the mechanical behavior of Al6351 composites. Through a systematic investigation of varying proportions of TiC, B_4C, and WC, valuable insights can be gained into the structure-property relationships, deformation mechanisms, and overall performance of the composites. These findings will offer valuable guidance to materials engineers, researchers, and industries involved in the advancement and application of metal matrix composites.

The lightweight nature of these composites, coupled with their enhanced mechanical properties, can lead to improved fuel efficiency in the automotive sector, reduced structural weight in aerospace applications, and increased durability and wear resistance in defense applications. Additionally, the study contributes to sustainable materials development by utilizing aluminum alloys and ceramic reinforcements, which are abundant and recyclable.

Despite extensive research conducted on metal matrix composites (MMCs), there remains a gap in the literature regarding the mechanical characterization of Al6351 when reinforced with different ratios of TiC, B_4C, and WC. This research gap arises from the necessity to comprehend the precise influence of varying reinforcement compositions on the microstructuralstructure and mechanical properties of hybrid metal matrix composites. The study aims to contribute to the existing knowledge base and provide valuable insights for the advancement and application of advanced MMCs by bridging this research gap.

OBJECTIVES OF THE RESEARCH

The research aims to systematically study the influence of different wt.% proportions of TiC, B_4C, and WC on the mechanical characteristics of Al6351hybrid MMCs. The research endeavors to analyze and compare the outcomes obtained from various reinforcement compositions to determine the ideal proportion that leads to the paramountadvance in mechanical properties.

The research also aims to investigate the microstructure of the Al6351 composites at different reinforcement proportions. Optical microscopic examinations are performed to observe the distribution, size, and morphology of the reinforcing particles within the hybrid MMCs and identify any changes in the microstructure due to varying reinforcement proportions.

06 August 2024 04:48:46

MATERIALS AND PROPERTIES

Aluminium Metal Matrix

Al6351 belongs to the 6xxx series of aluminum alloys and is predominantly comprised of aluminum and magnesium. Widely utilized in engineering applications, Al6351 is a heat-treatable wrought alloy consisting primarily of aluminum (Al), with small additions of magnesium (Mg), silicon (Si), and trace elements. This alloy exhibits a favorable blend of tensile strength, hardness, impact strength, formability, and corrosion resistance, rendering it appropriate for a range of structural and mechanical applications. Its versatility is further enhanced by the ease with which it can be processed using various manufacturing techniques such as casting, extrusion, and rolling, enabling the production of intricate shapes and components.

Reinforcement Materials

Within the realm of hybrid MMCs, the incorporation of reinforcing materials holds significant importance in augmenting the mechanical properties and overall performance of the base metal. Among the various choices available, B_4C,TiC, andWC are extensively utilized as reinforcing materials due to their exceptional characteristics. The specific attributes of these reinforcement materials are elaborated below:

Titanium Carbide (TiC)

Titanium carbide is a refractory ceramic known for its exceptional hardness, outstanding surface scratching resistance, high melting point, and commendable chemical stability. It exhibits a remarkable level of hardness, comparable to that of diamond, thereby significantly enhancing the scratching resistance and tribological aspects of the MMCs and HMMCs. Moreover, TiC possesses a low density, contributing to the overall lightweight nature of the composite and preserving its inherent weight advantages.

Boron Carbide (B_4C)

B_4C is an extremely hard ceramic material known for its exceptional hardness, high melting point, and low density. It exhibits excellent wear resistance, making it suitable for applications where abrasive wear is a concern. is also characterized by its high strength, chemical stability, and neutron absorption capability, making it valuable in defense and nuclear industries.

Tungsten Carbide (WC)

WC is a hard and brittle ceramic material renowned for its exceptional hardness, high melting point, and excellent tribological properties. It exhibits remarkable strength, toughness, and thermal stability, making it suitable for applications requiring high-performance wear resistance. WC particles effectively reinforce the metal matrix composite and enhance its mechanical properties, particularly hardness and abrasion resistance.

TABLE 1. Physical Characteristics of Reinforcement

Reinforcement	Weight density(gram/cc)	Particle size (micron)	Color
Boron Carbide (B_4C)	2.52	80-120	Gray black
Tungsten Carbide (WC)	15.7	40-80	Gray
Titanium Carbide (TiC)	4.91	80-120	Silver gray

TABLE 2. Sample Nomenclature of AlGr hybrid MMCs

S.N	Al6351	B_4C	TiC	WC	Sample Code
1	100.00	0	0	0	ABTW01
2	98.5	0.50	0.50	0.50	ABTW02
3	97.0	1.00	1.00	1.00	ABTW03
4	95.5	1.50	1.50	1.50	ABTW04
5	94.0	2.00	2.00	2.00	ABTW05

TiC, B_4C, and WC are highly effective reinforcing materials used in metal matrix composites. Their exceptional scratching resistance, tribological properties, strength, and thermal stability contribute to the improved mechanical properties and performance of the composites, making them useful in a variety of industries including automotive, aerospace, defense, and manufacturing.

PREPARATION OF THE HYBRID MMC

The liquid routeprocess is exercised to fabricate MMCs with improved mechanical properties. Desired proportions of TiC, B_4C, and WC particles were selected based on the research objectives and reinforcement characteristics as shown in Table 1.

The process commenced by placing small pieces of Al6351 alloy into a crucible, which was then positioned inside a furnace at a temperature of 925°C, guaranteeing complete liquefaction of the metal. Throughout the melting process, a controlled atmosphere was maintained to prevent oxidation or contamination of the matrix alloy. Subsequently, the metal matrix was heated at 925°C for 30 minutes. Following this, the furnace temperature increased to 970°C. At this stage, preheated and pre-weighed particles of TiC, B_4C, and WC were introduced into the molten metal matrix. To ensure a uniform dispersion and spreading of the reinforcement within the matrix, the mixture underwent intense stirring using a mechanical stirrer. This stirring process played a critical role in breaking up any clumps or agglomerates, promoting effective bonding between the reinforcement and the matrix, and ultimately achieving a homogeneous composite mixture.

To ensure a thorough blending of the reinforcement particles with the molten alloy, the stirring process was continued for 30 minutes. Throughout this process, consistent stirring speed and direction were maintained to minimize the introduction of air bubbles or excessive shear forces that could compromise the integrity of the composite. After 30 minutes, the mixture was left in the furnace for an additional 20 minutes to allow it to settle down.

To prepare the molds, they were preheated at 410°C. This preheating step aimed to reduce the temperature gradient and prevent premature solidification of the molten composite mixture upon contact. The carefully controlled molten mixture of the composite was then poured into the molds, taking care to avoid splashing or introducing impurities. The molds were then allowed to cool down, resulting in the solidification of the molten mixture into a solid form. The solidification process took place in a still-air environment. Once the molds had cooled down completely, the fabricated hybrid MMCs were removed from the molds. Post-processing steps, including trimming excess material and removing surface defects, were carried out on the cast specimens.

This entire process was repeated for five different compositions to fabricate hybrid metal matrix composites. The resulting samples were labeled according to their composition, as indicated in Table 2.

EXPERIMENTATIONS

In the study centered on investigating the mechanical characteristics of Al6351 alloy reinforced with TiC, B_4C, and WC, a range of testing equipment and methodologies are utilized to assess the mechanical properties and analyze the microstructure of the composite specimens. The specific tests performed are elaborated upon below:

06 August 2024 04:48:46

Microstructural Analysis

Microstructural analysis techniques are used to examine the internal structure, distribution, and morphology of the reinforcement particles within the hybrid MMCs.The sample preparation procedure for scanning electron microscope testing involves several steps to ensure the proper examination of the material's microstructure. Firstly, a representative sample was selected from the material of interest. This sample was then cut into a smaller, manageable size using cutting tools or precision cutting machines. The next step was mounting, where the specimen was embedded in a mounting medium to provide support and stability. Grinding was performed using abrasive papers or grinding wheels to eliminate surface irregularities and scratches. Subsequently, polishing was conducted using progressively finer nylon cloth to achieve a smooth and mirror-like surface. For optical microscopy, the prepared samples were mounted on a microscope and the micrographs were taken using the embedded camera. Micrographs of the specimen were captured using microscopytechniques are shown in Figure 1.

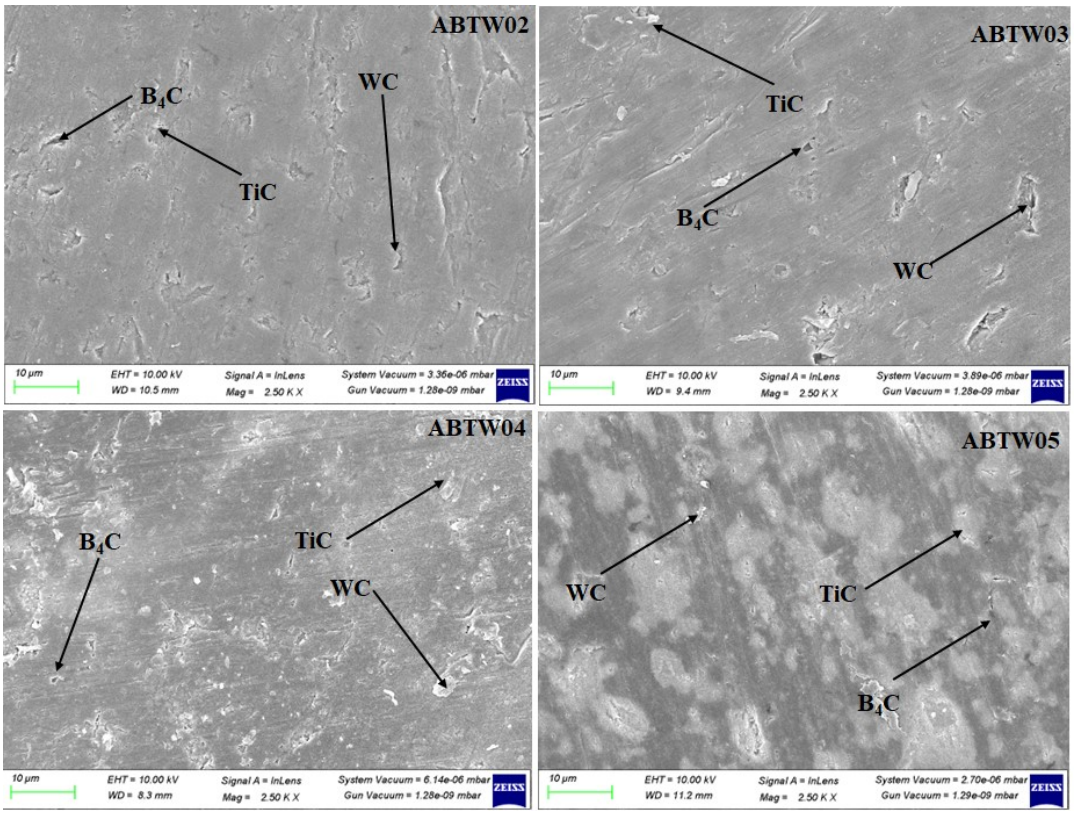

FIGURE 1: Optical Micrograph of Fabricated HMMCs

The manufactured hybrid metal matrix composite incorporates a small amount of lightweight reinforcing particles, which are uniformly dispersed within the metal matrix. This composite exhibits a consistent dispersion of the reinforcing particles and showcases robust intermetallic bonding.Sample ABTW02, AWTW03, and ABTW04 show a uniform dispersion of reinforced particles. However, when the weight percentage of reinforced particles surpasses 1.5%, clustering of the particles occurs, resulting in compromised intermetallic bonding. Sample ABTW05 with 2 wt.% of each reinforcement, shows huge clustering of the particles.

Mechanical Testing:

Hardness Testing:

Hardness tests are conducted to assess the hardness properties of the composite specimens, which provide insights into their resistance to localized deformation or indentation.Common hardness testing methods include

06 August 2024 04:48:46

Vickers, Rockwell, or Brinell hardness tests. A specimen of 10 x10 x 10 mm was fabricated to measure the Rockwell hardness of the specimen. Five hardness measurements were taken on each specimen. The hardness of Fabricated samples is shown graphically in Figure 2.

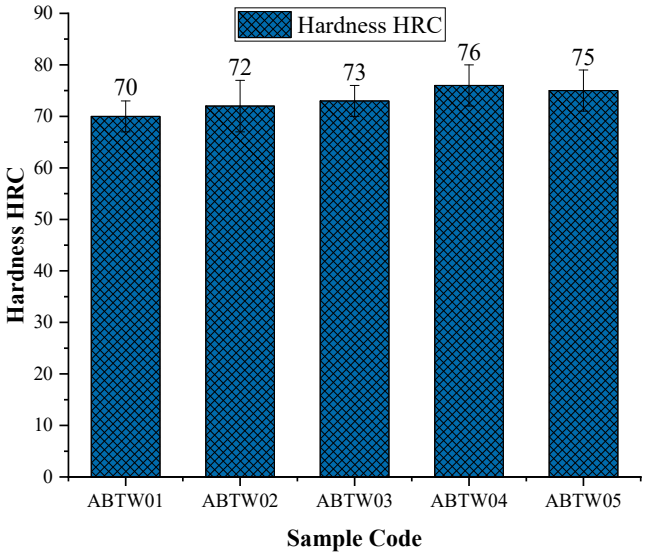

FIGURE 2: Hardness of Fabricated Specimen

Impact Testing

The impact test serves as a vital mechanical evaluation to assess the resilience and ability of a material to withstand abrupt loading. This test involves subjecting a standardized specimen to a rapid and high-velocity load, usually achieved by striking the specimen with a pendulum or hammer in a standardized manner. It provides valuable insights into the material's toughness and resistance to sudden loading. The impact test results provide valuable information about the toughness and fracture behavior of Al6351 alloy. It helps assess the material's ability to withstand sudden loading conditions, such as impact or collision, which is crucial in industries where the alloy is used for structural or safety-critical components.Fabricated specimens as per ASTM standards are shown in Figure 3.

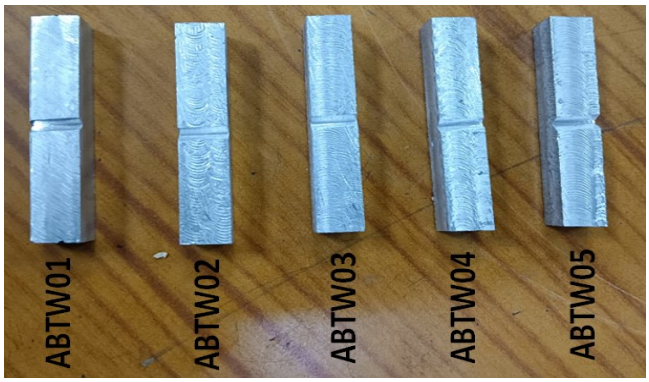

FIGURE 3: Charpy Test specimen

To perform the impact test, standardized Charpy specimens of hybrid MMCs were prepared using a slotter tool. The specimens were then placed in an impact testing machine as a simply supported beam. The machine delivered a high-velocity jolt to the sample, triggering it to crack. The amount of energy absorbed by the specimen was recorded from the scale. Three specimens of each composition were tested to obtain average impact strength. The average impact strength of each composition with experimental error is shown in Figure 4.

06 August 2024 04:48:46

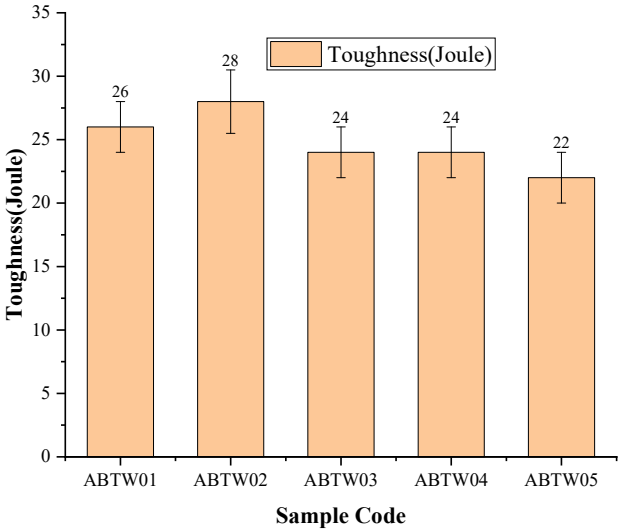

FIGURE 4: Toughness of Fabricated Specimen

Tensile Testing

After the post-processing of cast samples, three specimens for each composition were prepared for tensile testing. Tensile tests were conducted on a PC2000 tensiometer having a load capacity of 20kN. Testing samples were prepared as ASTM E8M standard. Figure 1 depicts tensiometer samples of Al6351 and hybrid MMCs.

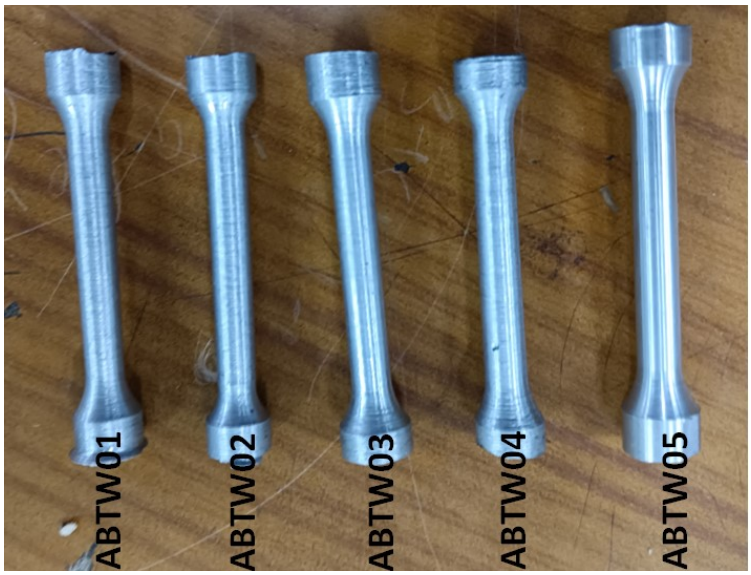

FIGURE 5: Tensiometer Specimen

The test report includes the measurements of Engineering UTS, True UTS, and elongation. The recorded results are presented in Table 3.

TABLE 3: Stress-Strain data of Hybrid Metal Matrix Composite

Sample	Eng UTS(MPa)	True UTS(MPa)	Break Displacement(mm)
ABTW01	100.2	136.7	3.92
ABTW02	117.5	141.8	2.93

06 August 2024 04:48:46

ABTW03	131.7	158.9	2.88
ABTW04	140.7	168.9	2.08
ABTW05	127.9	155.5	1.96

DISCUSSION

The microstructure of composites portrays a pivotal role in concluding mechanical properties. Uniform distribution of ceramic particles within the metal matrix facilitates consistent reinforcement and minimizing localized stress concentrations, effective load transfer, and enhances overall mechanical performance.

The bonding between the reinforcement particles and the matrix also plays animportant role. A strong and well-bonded interface enables efficient load transmission and improves the mechanical properties of the composite.

The microphotograph clearly shows that at lower reinforcement proportions, there is a uniform dispersion and distribution of the reinforcement particles, along with strong interfacial bonding. However, at higher reinforcement proportions, the distribution of reinforcement particles becomes non-uniform, leading to clustering and weak bonding between the reinforcement and the matrix metal.

Initially, the addition of B_4C, TiC, and WC reinforcing elements leads to an increase in hardness. This is because these materials typically have higher hardness than the Al6351 alloy. When incorporated into the matrix, they act as strengthening agents, hindering the movement of dislocations and impeding plastic deformation. As a result, the composite exhibits improved resistance to deformation, leading to higher hardness values.However, as the concentration of reinforcing elements increases beyond 1.5 wt.% each, the hardness start to decrease. This is attributed to the formation of clustering or agglomeration of the reinforcing particles, which create regions of stress concentration and lead to localized plastic deformation. These agglomerations act as initiation points for crack formation, reducing the overall hardness of the composite.

The inclusion of B_4C, TiC, and WC reinforcing elements in the composite leads to a slight improvement in impact strength. These reinforcing particles serve as obstacles, hindering crack propagation and dissipating energy during impact loading. The increased strength and hardness resulting from these reinforcements contribute to enhanced impact resistance. However, when the concentration of reinforcing elements exceeds 0.5 wt.% of each, the impact strength may diminish. Several factors contribute to the decrease in impact strength of the hybrid MMCs. One primary reason is the introduction of brittleness into the composite by adding reinforcement. Another reason is the potential formation of agglomerations or clusters of reinforcing particles, resulting in regions of stress concentration that initiate crack propagation. This clustering effect compromises the overall impact resistance of the composite. Furthermore, weak interfacial bonding between the reinforcing particles and the matrix material can hinder load transfer and impede energy absorption during impact loading. Insufficient interfacial bonding further contributes to the reduction in impact strength.

The mechanical testing results indicated a substantial enhancement in the tensile strength of the hybrid MMCs as the proportion of reinforcement increased. The hybrid MMCs with higher reinforcement proportions exhibited superior mechanical properties in comparison to the unreinforced Al6351 alloy. These improvements in mechanical properties can be ascribed to the strengthening effect caused by the reinforcement particles, which impede dislocation movement and enhance load transfer within the composites. The composite sample ABTW03, containing 1.5 wt.% B_4C, 1.5 wt.% TiC, and 1.5 wt.% WC demonstrated the highest engineering UTS among all the fabricated samples. However, further increasing the weight-wisepercentage of reinforcement led to a decrease in tensile strength. Table 3 indicates a continuous decrease in break displacement, indicating an increase in the brittleness of the hybrid metal matrix composite. Figure 6 graphically represents the Engineering UTS and True UTS.

The decrease in strength observed can be attributed to the agglomeration of reinforcement particles. Specimens with lower proportions of reinforcement exhibited a more uniform distribution and better bonding of reinforcement within the metal matrix. The results clearly indicated a correlation between the microstructure and mechanical properties. The presence of a uniform distribution of reinforcement particles and a strong interface between the particles and the matrix contributed to improved mechanical properties. However, when comparing these findings to previous studies, the addition of a third reinforcement instead of two did not demonstrate a significant impact on the tensile strength of the hybrid metal matrix composite[29].

06 August 2024 04:48:46

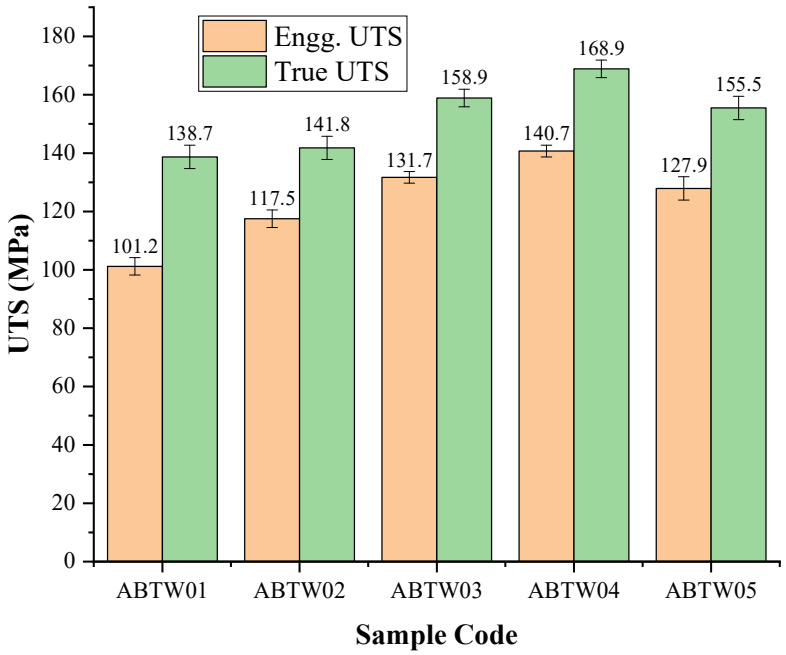

FIGURE6: Engg. UTS and True UTS of Fabricated Specimen

CONCLUSION

The research primarily focused on investigating the mechanical characteristics of Al6351 alloy reinforced with TiC, B_4C, and WC. The study yielded several noteworthy findings, including the following:

i. The microphotograph analysis confirmed the presence of a uniform distribution of reinforcement particles within the hybrid MMCs.
ii. The interface between the particles and the matrix demonstrated strong bonding, indicating effective load transfer between the reinforcement and matrix.
iii. The incorporation of TiC, B_4C, and WC reinforcement particles into the Al6351 alloy led to significant enhancements in mechanical properties.
iv. The ultimate tensile strength and hardness of the composite specimens showed a progressive increase with higher proportions of reinforcement.
v. The Hybrid MMC sample containing 1.5 wt. % of each reinforcement exhibited the utmostengineering UTS of 140.7 MPa and hardness of 76 HRC.Maximum toughness was observed in Hybrid MMC having 0.5 wt.% of each reinforcement as 28 Joule.
vi. However, beyond a certain reinforcement proportion, there was a diminishing return in the enhancement of properties, suggesting an optimal reinforcement range.

In brief, the research findings indicate that increasing the reinforcement proportions of TiC, B_4C, and WC in Al6351 alloy leads to improved mechanical properties and enhanced wear resistance. However, there is an optimal range of reinforcement proportions beyond which the benefits become less significant.

***Abstract*— Feature selection is a significant process in brain-computer interfaces (BCIs) that has the potential to significantly enhance system performance, especially if a large number of features are present. Feature selection can help decrease noisy data, overtraining effects, storage needs, and computational complexity thereby enhancing classifier performance. The various feature selection strategies have been reported to attain these objectives. In this work, a hybrid feature selection technique is suggested. It uses a wavelet packet decomposition technique to extract features and grey wolf optimization (GWO) technique to obtain the best subset of features. It is then evaluated with support vector machine (SVM) classifier and obtains maximum classification accuracy of 82.88% for the approximate entropy feature. Experimental findings reveal that the suggested approach outperforms the contemporary MI-BCI systems even with relatively small training data sets.**

Keywords*— Brain computer interfaces (BCIs), Feature extraction, Grey Wolf Optimization (GWO), Electroencephalography (EEG), Wavelet Packet Decomposition (WPD)

I. INTRODUCTION

The EEG, initially recorded for individuals by Hans Berger in 1929, provides information on neural activity in mind. It is a powerful approach for investigating the brain's thinking processes. [1]. Surface electroencephalography is a non-invasive approach that allows recording the biological electrical movement in individual brain, which is vital for various practical implications to improve life of a person suffering from locomotor difficulties [2]. EEG recordings are crucial in BCI applications for sensorimotor functions and established communication in patients with severe motor disabilities [3]. The applications of motor imagery BCI also extend to healthcare, navigation, military services, virtual gaming, robotics, communication and controls. Analysis of EEG signals is required for designing of BCI system. BCIs refer to the mutual interaction between human brains and computers, which can be examined via EEG-based motor imagery signals [4]. EEG-captured motor imagery (MI) signals are the most realistic foundation for BCI development and MI can affect neuronal activity in the subject brain. To control the device by BCI, it is essential to design an algorithm of channel selection, feature extraction, and selection associated to sensorimotor area of human brain [5]. Manual analysis of these processes by experts is time-consuming and costly. Nowadays, many techniques are appearing in literature to automate the analysis of EEG signals, and EEG-based MI BCI system provides a significant degree of mobility, which enables disable people to operate device. The sensorimotor region of individual brain-related feature selection and classification techniques significantly influences the success of the MI-BCI system [6]. Several intelligent and analytical methods based upon wavelet transform (WT), support vector machine (SVM), neural networks (NNs) [7] , evolutionary computation, principal component analysis (PCA), Genetic algorithms (GA) [8], correlation coefficient, grey wolf optimization (GWO), k-nearest neighbors (k-NN) and many more for analysis, classification, and implementation of a control system using MI signals are appearing in the literature [9] [10]. Although many intelligent methods appear in the literature for extracting knowledge and classification from EEG signals, still a lot of research work is needed to extract useful information from these signals to develop an effective BCI system that can help in improving human lives in terms of the design of perfect prosthetics for disabled subjects. A great challenge is to design an effective classification mechanism for EEG signals for different motor imagery activities for BCI systems. Although SVM is the most common classifier and offers numerous advantages, like noise tolerance and adaptivity, more research needs to be done to combine SVM with GWO for feature selection. The outcomes of the studies show that the proposed work effectively detects MI activity using EEG data. The proposed work can be used for seriously disabled people, mind reading, emotion finding and entertainment. The rest of paper is arranged as follows: Section 2 describes materials & methods. The findings and discussion are

explained in Section 3. The section 4 finally, presents the conclusion with future scope.

Contribution of the present work are summarized:

- Perform WPD up to the 8th level for the 8 to 32 Hz frequency range on the motor imagery electroencephalogram (MI-EEG) data.
- Mean, variance, standard deviation, and approximate entropy features are computed separately for 124 WPD nodes out of 256. These nodes are significantly associated with motor imager activities.
- GWO technique is used to selects optimal features for the MI signals.
- Benchmarked machine learning algorithm SVM is used for the classification process.

II. METRIAL AND METHODS USED

A. Dataset

The open-access "BCI Competition IV-dataset I" is employed in this work to analyse MI signals [11]. This dataset includes information from 7 participants and contains fifteen-nine channels sampled at 1000 Hz for motor imagery activities and participant chose two motor imagery activities out of three. To save computing work, 100 Hz down-sampled data was utilized in the present study, with each healthy person executing 200 trials. Participants visualized a single motor imagery activity in each trial for 4 seconds. In the timing scheme depicted [10], the subjects were given a stimulus from which the beginning and end times of an M.I. task could be precisely specified. Every participant provided a cue according to timing method, ensuring that the starting and end times for an MI activity were accurate. Table 1 shows the dataset description for proposed study.

TABLE I. DATASETS FOR FOUR HEALTHY SUBJECTS

Subjects	Data size	Motor imagery activities
a	$190549 \times 59\ int16$	Left hand and foot
b	$190549 \times 59\ int16$	Right and left hand
f	$190608 \times 59\ int16$	Left hand and foot
g	$190602 \times 59\ int16$	Right and left hand

III. FEATURE EXTRACTION TECHNIQUE

For EEG processing, feature extraction plays a vital role. Wavelet Transform (WT) is a generally employed for extracting features in time-frequency domain for BCIs. The wavelet packet decomposition (WPD) allows for a various-level time-frequency decomposition for input EEG signals [12]. Wavelet transform can represent any joint function as an endless sequence of wavelets. The suggested study uses WPD at the 8th level, generating 256 nodes. EEG data with frequencies ranging from 8 to 32 Hz include MI activities. For the 8-32 Hz frequency region, 124 out of 256 wavelet nodes of 14 channels are used to compute the mean, standard deviation, variance and approximate entropy (Table 2) feature vectors size 14×124 separately for sensorimotor related area of subject's brain. The Fig.1 depicts the WPD tree structure for the eighth-level decomposition and fig. 2 shows EEG signal and WPD nodes.

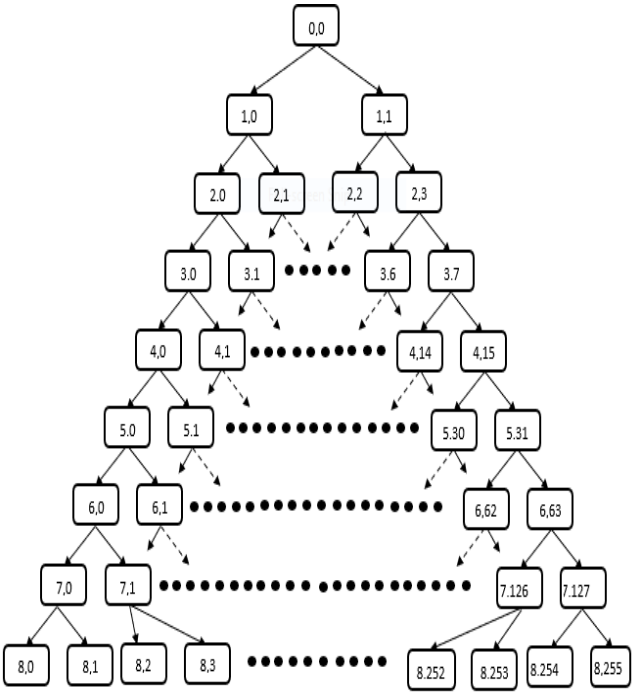

Fig. 1. WPD tree structure up to 8th level [12]

TABLE II. MATHEMATICAL EQUATIONS OF FEATURES EEG [12]

S. No.	Features	Equations
1	Mean (μ)	$\frac{1}{N}\sum_{n=1}^{N} f(n)$
2	Standard deviation (σ)	$\sqrt{\frac{1}{N-1}\sum_{n=1}^{N}(f(n)-\mu)^2}$
3	Variance (σ^2)	$\frac{1}{N-1}\sum_{n=1}^{N}(f(n)-\mu)^2$
4	Approximation Entropy (ApEn)	$(r)-\varphi^{m+1}(r)$ [13]

A. Grey Wolf Optimizer (GWO)

Mirjalili was motivated by grey wolves' social behaviour and hunting methods [14]. Grey wolves are generally into found in packs of five to twelve members. The population of GWO is divided generally into four groups**:** $alpha\ (\alpha), delta\ (\delta), beta\ (\beta)$ and $omega\ (\omega)$. The renowned leader of the pack, the alpha wolf, decides which individuals will move locations. As the second leader, the beta wolf helps the alpha decide which actions to take next and takes care of the pack if the alpha is sick or dead. The third-ranking wolf in pack is the delta wolf, responsible for controlling omega wolves. The best three most mathematically fit solutions in GWO are α, β, and δ. The hunting operation in GWO is led by α, β, and δ and ω follows them. The encircling behaviour of a chasing pack is generally denoted as:

$$\vec{P}(t+1) = \overrightarrow{P_p}(t) - \overrightarrow{F_1} \cdot \vec{D} \quad (1)$$

$$\vec{D} = \left|\overrightarrow{F_2} \cdot \overrightarrow{P_p}(t) - \vec{P}\,(t)\right| \quad (2)$$

Here, $\vec{P}$ is position of grey wolf, $\overrightarrow{P_p}$ is position of prey and distance vector between prey and grey wolf is represented by D. The $\overrightarrow{F_1}$ & $\overrightarrow{F_2}$ are coefficient vectors computed with following equation:

$$\overrightarrow{F_1} = 2\vec{a} \cdot \overrightarrow{r_1} - \vec{a} \quad (3)$$

$$\overrightarrow{F_2} = 2 \cdot \overrightarrow{r_2} \quad (4)$$

In this work, r_1 & r_2 are values chosen randomly from [0,1]. According to equation 5, the surrounding coefficient (a) decreases gradually from 2 to 0 over iterations [15] and z_1 and z_2 in fitness function are 0.99 and 0.01 respectively.

$$a = 2 - 2\left(\frac{t}{T}\right) \quad (5)$$

The wolf's new location is updated by equation (6) [16].

$$\vec{P}(t+1) = \frac{\overrightarrow{P_1}+\overrightarrow{P_2}+\overrightarrow{P_3}}{3} \quad (6)$$

Emary et al. [17] introduced GWO techniques to overcome feature selection difficulties.

B. Support Vector Machine (SVM)

SVM machine learning that was initially introduced for the classification of data. The aim is to find the hyperplane that separates training data based on expected risk [18] . SVM offers excellent accuracy for classification due to the maximum margin of hyperplanes [19] It is more flexible than standard neural networks because it includes multiple parameters to get better classification. SVM is seldom influenced by the well-known "curse of dimensionality." A optimal hyperplane obtained by solving the constrained optimisation problem [20]. Optimal hyperplane is achieved by linear SVMs by minimizing the cost function below with constraints.

$$\frac{1}{2}\|w\|^2 + C\sum_{i=1}^{n}\xi_i \quad (5)$$

$$y_i(w^T x_i + b) \geq 1 - \xi_i \quad (6)$$

Here, $\xi_i \geq 0$, $\|.\|^2$ represents euclidean norm, slack variables expressed by ξ_i, b is the bias, and C is a regularisation parameter. Selecting the correct C value is crucial for balancing complexity and non-separability. Table 3 depicts the parameters used in this proposed work.

TABLE III. PARAMETERS USED FOR SVM

Technique	Hyperparameter	min	max	Step size
SVM *rbf Kernel*	C is kernel coefficient gamma	0.01	0.1	1

IV. RESULTS AND DISCUSSION

The results of classifying motor imagery BCI data for all four participants in this research are present in Table 4 and Figure 4. Each channel is decomposed with WPD at the 8th level, obtaining 256 coefficients. The 124 wavelet packet coefficients representing the 8-32 Hz frequency range with M.I. activity are chosen for further processing. The mean, standard deviation, variance and approximate entropy features are calculated separately for selected nodes. The feature vector is generated for 14 channels (mentioned in section 3.1), spanning the brain's main motor imagery area [6]. The feature vectors have dimensions of 14×72=1008 obtained for four different features using GWO techniques. The suggested approach is tested using ten-fold cross-validation. The Proposed method obtained the maximum classification accuracy of 74.62%, 78.02%, 73.45% and 82.88% for mean, standard deviation, variance, and approximate entropy features respectively. Figure 3 shows proposed work flowchart. The Fig. 4 and Table 4 show classification findings for selected features.

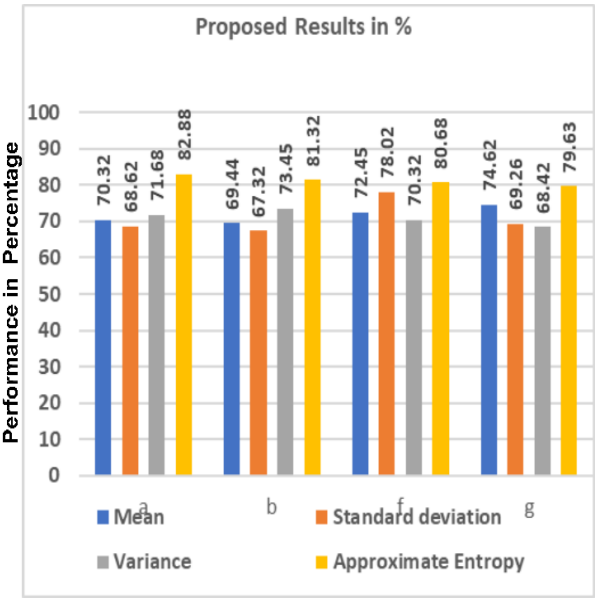

Fig. 4. Results for proposed work

TABLE IV. CLASSIFICATION RESULTS FOR PROPOSED WORK

S.No	Feature	Maximum Classification Accuracy (%)
1	Mean (μ)	74.62
2	Standard deviation (σ)	78.02
3	Variance (σ^2)	73.45

V. CONCLUSION WITH FUTURE SCOPE

The BCI permits injured patients to interact and operate equipment without relying on their peripheral muscles and nerves. The suggested technique is tested using data from four participants (a,b,f,g) in dataset I of BCI-Competition-IV. The suggested research used a WPD approach to extract features (mean, standard deviation, variance, and approximation entropy) and a grey wolf optimisation technique to identify the optimal subset features. It is then analysed using a support vector machine classifier, achieving an optimal classification accuracy of 82.88% for the approximate entropy feature. The method has been developed using MATLAB software. The future objectives involve reducing the dimensionality of feature vectors using different optimization techniques to improve classification accuracy for brain computer interface applications.

***Abstract*—Emotions, intricate mental states shaped by neurophysiological alterations influenced by cognitive processes, sensory inputs, behaviours, and diverse experiences, remain a compelling domain for exploration. The Electroencephalogram (EEG) is a potent tool that directly quantifies these emotional variations by capturing brain signals. Recent strides in emotion recognition have harnessed traditional machine learning classifiers to automate the identification of human emotions with remarkable success. This paper delves into the relatively underexplored Discrete Emotion Model, unveiling its capacity to achieve outstanding accuracy despite historical reservations regarding its effectiveness, using the ECSMP (Emotion, Cognition, Sleep, and Multi-model Physiological signals) dataset. It has two distinct environments, Video watching, and CANTAB-based cognitive assessment phases, enabling seamless data collection and analysis. This research effectively quantifies emotion for binary classification (classifies the type of emotion felt) and multiclass classification (classifies the intensity of emotion felt), elevating emotion recognition capabilities through the synergy of EEG technology. The exceptional performance of XGBoost, with a 96.5% accuracy rate in binary classification and 95% in multiclass emotion recognition, highlights its prowess compared to the other models tested.**

***Index Terms*—Emotion Recognition, Physiological signals**

I. Introduction

Emotions are states experienced by individuals that influence their behaviours and thoughts. They arise from both physical and physiological reactions to internal or external stimuli. Differentiating between emotions can be done through facial expressions, behaviours, and physiological responses. Physiological signals are precious in accurately reflecting a person's emotions in real-time. Monitoring these signals has become more accessible through wearable devices such as smartphones and smartwatches. However, improved emotional well-being necessitates developing techniques to extract emotional states from physiological measurements acquired via mobile devices. Electroencephalogram (EEG) is a widely employed and effective physiological signal for discerning emotions [1], [2]. This efficacy arises from its direct capture of signals emanating from the brain.

A. Emotion Model

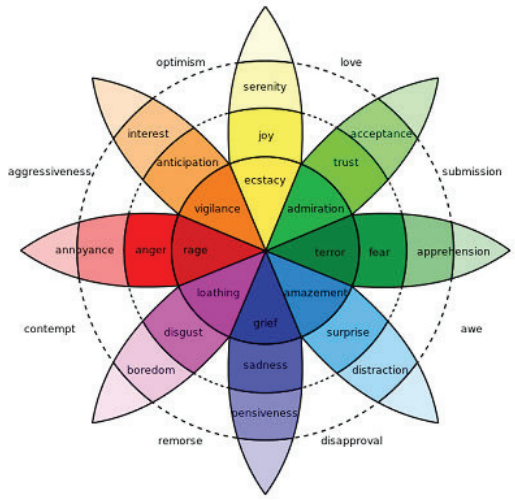

Fig. 1: Plutchik's Emotion Model [3]

Scholars and psychologists have proposed two prominent and widely accepted theories in studying emotions: the Discrete Emotion Model and the Dimensional Emotion Model [4], [5].

From a discrete perspective, influenced by Ekman's theory [15] and evolutionary insights from Darwin and Tomkins, six primary emotions emerge: happiness, sadness, anger, disgust, fear, and surprise. Additional feelings result from intricate combinations or variations of these core emotions. Plutchik [16] introduces a wheel model as shown in Fig. 1, classifying eight primary emotions by intensity. It is similar to mixing primary colors to create secondary hues. Izard [17]

identifies ten fundamental emotions, and Parrott [18] offers a comprehensive classification encompassing various emotional states.

In contrast, the dimensional model divides emotional space into two dimensions: Valence-Arousal (VA) or three dimensions with the Pleasure-Arousal-Dominance (PAD) framework. Valence encompasses pleasure or displeasure, spanning positive and negative aspects. Arousal signifies emotional alertness and physiological intensity, while Dominance denotes control or external influence.

The dimensional model assigns numerical values to represent emotions across the valence-arousal spectrum, even in complex cases. However, it faces challenges when similar feelings cluster closely on the valence-arousal plane, yielding distinct representations and behavioural reactions [19]. Researchers often categorize valence and arousal attributes in emotion recognition rather than pinpointing specific emotions. Emotions within the same category can vary in intensity, as with happiness from a sunset or academic success. Thus, while joy can have diverse valence and arousal levels, the reverse is not necessarily true.

B. Motivation

This work is motivated by the limited prior research in discrete model emotion recognition, noting that existing studies have not consistently demonstrated high precision, despite the potential superiority of the discrete model in handling complex emotions compared to the dimensional model. Addressing this knowledge gap and the opportunity to improve complex emotion recognition using the discrete model have been key drivers behind this research.

Table I illustrates the prevalent use of relatively small subject groups in previous studies. In contrast, this study is motivated to adopt a distinctive approach involving more subjects for a more comprehensive and in-depth analysis. The Dataset on Emotion, Cognition, Sleep, and Multi-model Physiological Signals (ECSMP) [20] serves as the basis for this exploration and has received limited prior attention.

Furthermore, the motivation also arises from the under-explored area of emotional intensity identification, often overlooked in previous research. This work aims to develop a comprehensive approach considering emotion recognition and nuanced emotional intensity measurement.

This study also aims to expand research by exploring various subjects and scenarios to assess the generalizability of findings and identify environments that favor effective emotion recognition. Context and conditions significantly impact recognition efficacy, further motivating this exploration. In particular, this study seeks to investigate two distinct environments within the ECSMP dataset [20]: 'CANTAB-Video' and 'Video-CANTAB.' By analyzing these environments, the goal is to determine which one demonstrates superior performance and applicability for emotion recognition tasks. This comparative analysis will contribute valuable insights into the suitability of different environments for such tasks, offering practical implications for future research and applications.

C. Related Work

Numerous studies have delved into the Valence-Arousal-Dominance (VAD) model of emotions, which has garnered significant attention in emotion recognition. However, there needs to be more research focusing on the Discrete Emotion Model. In Table I, a comprehensive summary of related works explicitly about the Discrete Emotion Model is provided, highlighting the limited existing research in this area. Notably, the best average accuracy achieved in previous works stands at 86% using KNN, as demonstrated by Muruguppan et al. [14], signifying room for improvement. This paper aims to advance the less-explored Discrete Emotion Model, addressing a research gap and boosting emotion recognition and classification accuracy.

In the domain of emotional classification, previous research primarily relied on stimuli to categorize participants' emotional states. However, this study illuminates the nuanced nature of human emotions, acknowledging that individual differences, cultural factors, and overall well-being can cause

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:29:10 UTC from IEEE Xplore. Restrictions apply.

emotional responses to vary, even when participants encounter identical stimuli. Babushkin et al. [21] explored this intricate variation in emotional intensity, achieving a 70% accuracy rate.

D. Contributions

- The study utilizes various ML models like XGBoost, ANN, LSTM, CNN, and KNN to fit the discrete emotion recognition model, fine-tuning them results in XGBoost outperforming every other model.
- Two types of environments were analyzed, namely, Cantab-Video and Video-Cantab. Cantab-Video gave significantly better results after training, underlining the importance of ambience, surroundings and temperament.

These findings advance the state-of-the-art in emotion recognition and open doors to more nuanced emotional intensity recognition, offering valuable contributions to fields such as psychology, healthcare, and human-computer interaction.

E. Roadmap

The paper comprises several sections. Section II presents the methodology of the proposed work, Section III focuses on the evaluation and discussion of results, and Section IV concludes the paper, providing insights into future research directions.

II. Methodology

The flowchart for the methodology being used in this study is shown in Fig. 2.

A. Dataset Description

The ECSMP [20] dataset comprises EEG data from 73 healthy individuals (26 males, 47 females; mean age: 23.53 ± 2.06 years) recorded during sleep, except for 7 participants who were registered post-experiment due to personal reasons.

During the experiment, participants completed cognitive tasks and watched emotion-inducing videos in a dim, quiet room. The order of the two studies was random. Before conducting both studies, the authors recorded a three-minute resting state with closed eyes followed by three minutes with open eyes to establish a baseline for unbiased recordings.

In the video-watching task, participants watched six 5-minute clips inducing emotions (neutral, fear, sad, happy, anger, disgust) with a 120-second break between each video. Post-viewing, the participants were required to fill out the Current Emotional Self-Assessment Form (CESAF) to describe their current emotion intensity level on a scale of 1-7 after watching videos for 30 seconds to assess arousal of each emotion, followed by a 90-second rest with eyes closed to recover from the previously induced feeling.

Participants' prefrontal and ear electrodes recorded scalp EEG. The dataset contains EEG records from 87 healthy students (31 males, 56 females; mean age: 23.59 ± 2.02 years) and responses from 88 subjects (31 males, 57 females; mean age: 23.69 ± 2.14 years) on Emotion Regulation Questionnaire (ERQ) , Self-rating Depression Scale (SDS) , Profile Of Mood States questionnaire (POMS) [6], Pittsburgh Sleep Quality Index (PSQI) scales.

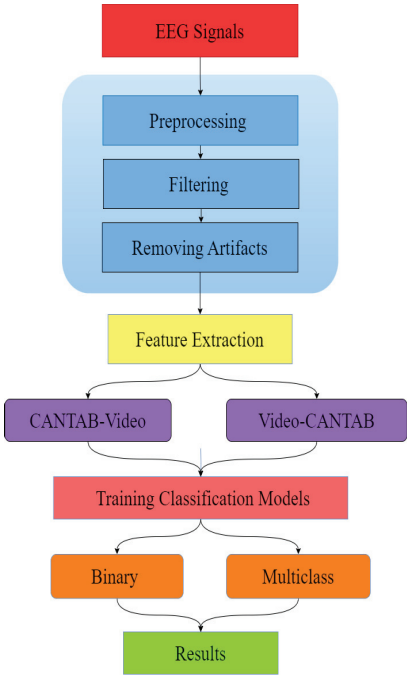

Fig. 2: Block Diagram for Proposed Methodology

B. Experimental Scenarios

Two different scenarios serve as the testing ground for the models. Users fall into two subsets, helping to delve into the nature and extent of emotional expression in humans:

1) In the first subset, the CANTAB experiment preceding the Video Watching task with 27 users.
2) In the second subset, the Video Watching task preceding the CANTAB Experiment, involving 42 users.

The difference between both subsets of user signals is because, several CANTAB-Video users are having a significant amount of noise in the signals after the pre-processing and signal cleaning phase. Hence, we removed it to maintain the integrity and quality of results of this study.

C. Pre Processing

The proposed study adopts the following steps to remove artifacts from the EEG signals, clip the data, and decompose the signal into IMFs for further classification.

1) **Artefact Removal:** Butterworth Bandpass filters achieve a smooth frequency response in the desired frequency range. It is a filter with an optimal magnitude response. This filtering approach ensured a consistent frequency response within the desired range (passband) while gradually reducing responses in the unfrequented range (known as stopband). The pace of this response varies directly with the filter's order. A filter of second order has a -12 dB decrease per octave, third order -18 dB, and so on. Our application implements a second-order filter with a low-cut frequency set at 1Hz and a high-cut frequency set at 40Hz.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:29:10 UTC from IEEE Xplore. Restrictions apply.

2) **Clipping:** The ECSMP [20] dataset includes EEG signal data from 89 users and demographic details like age, gender, Sleep Stats, and User ID. Initially stored in ".mat" format, the data is downsampled from 1000Hz to 250Hz and converted to ".csv." There are 250 rows per second for each user during the experiment.
The EEG data covers two tasks: cognitive assessment and video-watching. Since the order of these tasks is random for users, EEG signals recorded during cognitive assessments are excluded due to varying completion times, leading to different row counts in the CSV file. This research paper aims to develop models adept at figuring out the emotions of the users based on a "Video Stimulus", CANTAB shifts the user's active brain regions from Amygdala to the prefrontal Cortex, one handles emotions and the other cognitive ability and reasoning, Hence it swerves the user's brain as far as the scope of this paper goes, Although to include the CANTAB EEG Signals and analyze the changes from start to end could be a topic for another paper itself. The EEG device employs seven channels on the forehead: FP1, FZ, FP2, AF3, AF4, F7, and F8.
Preceding the experiment, a six-minute baseline EEG signal is recorded, constituting 90,000 rows. The baselines are extracted for each user and subtracted from the post-stimulus period of EEG Signals to ensure normalization throughout the user database. The investigation entails six videos, each lasting 5 minutes (75,000 rows), followed by participants filling out the CESAF form for 30 seconds and taking 90 seconds to transition to a neutral state before the following video. This cycle includes 120 seconds of rest (30,000 rows) between videos, requiring subsequent clipping. Therefore, this study removes the baseline EEG signals of 90,000 rows and the EEG signals comprising the rest between the videos (30000*6) rows.
3) **Empirical Mode Decomposition (EMD):** EMD, or Empirical Mode Decomposition [22], is an adaptable technique that dissects data and signals into meaningful components. Ideal for non-linear and non-stationary signals, EMD separates them into varying resolution components. It succinctly decomposes complex datasets into a comprehensive set of intrinsic mode functions (IMFs), offering an orthogonal basis for the original signal. The primary IMF usually captures high-frequency elements, enabling the removal of components like random noise. The recursive process of EMD extracts different resolutions directly from the data itself without resorting to fixed functions or filters. Empirical Mode Decomposition (EMD) extracts the clipped EEG signal's first intrinsic mode function (IMF), isolating the most prominent and relevant oscillatory patterns for further analysis and feature extraction.

D. Feature Extraction

This study extracts nine features from pre-processed EEG data across the seven channels, resulting in sixty-three features.

Time Domain Features: Consider the input signal as $x(t)$. This study calculates the time domain features as follows:

1) **Mean (Average):** The mean of the signal $x(t)$ can be computed as:
$$\mu = \frac{1}{N}\sum_{i=1}^{N} x(i) \tag{1}$$
2) **Standard Deviation:** The standard deviation of the signal $x(t)$ measures the extent of values around the mean.
$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x(i)-\mu)^2} \tag{2}$$
3) **Variance:** Variance is the square of the standard deviation, representing the average of squared deviations from the mean.
$$\text{Variance} = \frac{1}{N}\sum_{i=1}^{N}(x(i)-\mu)^2 \tag{3}$$
4) **Hjorth Mobility:** Hjorth's mobility assesses waveform dynamics by comparing variances between the first derivative and the signal.
$$\text{Mobility} = \frac{\sqrt{\text{Variance of the first derivative}}}{\sqrt{\text{Variance of the signal}}} \tag{4}$$
5) **Hjorth Complexity:** Hjorth's complexity measures waveform dynamics by comparing variances in the first and second derivatives.
$$\text{Complexity} = \frac{\text{Variance of the second derivative}}{\text{Variance of the first derivative}} \tag{5}$$

Frequency Domain Features: In the spectral domain, represented by X, these characteristics offer valuable insights into signal intricacy and irregularity through entropy-based measures:

1) **Spectral Entropy:** Measures the uncertainty in power distribution across frequency components.
$$\text{Spectral Entropy} = -\sum_{i=1}^{N} p_i \log_2 p_i \tag{6}$$
where p_i is the normalized power of the i-th frequency component.
2) **SVD Entropy:** Quantifies information in singular values obtained from signal spectrogram matrix.
$$\text{SVD Entropy} = -\sum_{i=1}^{N} \sigma_i^2 \log_2 \sigma_i^2 \tag{7}$$
where σ_i is the i-th singular value.

KNN	66.95	46.22	64.88	40.27	47.35	59.63

3) **Petrosian Fractal Dimension:** Evaluates signal self-similarity, considering its fractal intricacy.

$$\text{Petrosian FD} = \frac{\log(N)}{\log(N) + \log(N/\delta N)} \tag{8}$$

where N is signal length, and δN is sign change count in the first derivative.

4) **Katz Entropy:** Captures fluctuations' unevenness in signals, incorporating local and global aspects.

$$\text{Katz Entropy} = \frac{\log(L)}{\log(d/L) + \log(N)} \tag{9}$$

where L is the total path length, d is Euclidean distance between start and end points, and N represents signal length.

TABLE IV: Parameters used in various classifiers

Classifiers	Parameters
XGBoost	Booster: gbtree, Learning Rate: 0.3, Max Depth: 6, Min Child Weight: 1, Num Estimators: 100
CNN	Architecture: Conv1D (128, kernel=3, relu), MaxPooling1D (pool=2), Conv1D (128, kernel=3, relu), MaxPooling1D (pool=2), Conv1D (64, kernel=3, relu), MaxPooling1D (pool=2), Dense (64, tanh), Dropout (0.2), Dense (32, tanh), Dropout (0.2), Dense (16, relu), Dropout (0.2), Dense (num_classes, softmax) Training: Loss='sparse_categorical_crossentropy', Adam, Batch=256, Epochs=200, Early Stopping (0.005, patience=5, restore_best_weights=True), Validation=20%
KNN	Number of Neighbours: 11, Distance Metric: Euclidean, Nearest Neighbour Search Method: kdtree
ANN	Architecture: Dense (256, relu), Dense (128, relu), Dropout (0.25), Dense (64, relu), Dropout (0.5), Dense (32, relu), Dense (1, sigmoid) Training: Loss='binary_crossentropy', Adam, Batch=32, Epochs=5, Early Stopping (0.01, patience=5, restore_best_weights=True), Validation=20%
LSTM	Hidden Units: 10, Optimizer: Adam, Epochs: 10, State Activation: tanh, Gate Activation: sigmoid, Input Weights Initializer: glorot, Recurrent Weights Initializer: orthogonal, Bias Initializer: unit-forget-gate

E. Classification Method

This study performs two types of classification, as follows:

1) **Multiclass classification** aims to quantify the intensity of emotions on a scale of 1 to 7, with 1 being the lowest and 7 being the highest. The model learns to predict the power of the emotion based on the EEG signal. As we train the model on each emotion, the model only needs to learn about the trends of a specific feeling at a time. The loss function minimizes the error between the ratings provided by the users and the intensity predicted by the model.
2) **Binary Classification** is derived from MultiClass Classification employing putting a threshold value below which the output indicates a weak emotion and above which it shows a strong emotion. The proposed study uses a threshold value of 4 on a scale of 1 to 7 due to being in the middle of the intensity scale.

F. Classification Algorithms

After the feature extraction process, the study uses the input and output files to train the classification models. It distinguishes between 'CANTAB-Video' and 'Video-CANTAB' by testing various classifiers to suit the dataset.

For binary classification, the study uses Artificial Neural Networks (ANN), Long Short-Term Memory (LSTM) networks, XGBoost, and Convolutional Neural Network (CNN) models on the pre-processed dataset featuring EEG signal-derived features. For the multiclass classification, the study uses XGBoost, CNN, AdaBoost, and k-Nearest Neighbors (KNN) classifiers to predict the emotional intensity levels on a scale of 1 to 7.

The paper employs the following classification algorithms, along with their corresponding parameters described in Table IV, to train the dataset as elucidated below:

*1) **XGBoost**:* Its basis is the Gradient Boosting framework, an ensemble of decision trees that combine to derive complex relationships between data. This model includes L1 (Lasso) and L2 (Ridge) Normalization to prevent overfitting and bias of the data and enhance the overall.

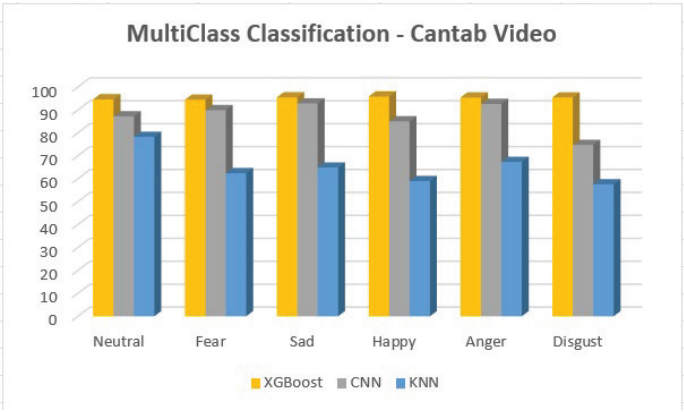
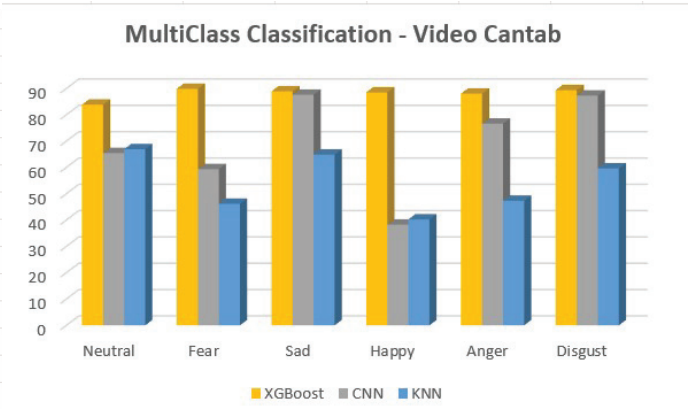
(b) Results for Video-CANTAB Binary Classification

Fig. 3: Binary Classification Results



(a) Results for CANTAB-Video MultiClass Classification



(b) Results for Video-CANTAB MultiClass Classification

Fig. 4: Multiclass Classification Results

*2) **AdaBoost**:* In multiclass EEG signal classification, 500 models (weak learners) are trained with a learning rate 0.1 using the AdaBoost ensemble learning boosting algorithm. The final step combines these models by calculating a weighted average of their predictions.

*3) **Convolutional Neural Networks (CNN)**:* 1D ConvNets extract relevant features from one-dimensional input using kernel-based convolution. We have implemented our custom CNN model, which has 106K trainable parameters.

*4) **K-Nearest Neighbours (KNN)**:* K-Nearest Neighbour (KNN) is a supervised machine learning algorithm using a lazy learning approach. It classifies new data points based on Euclidean distance from the training set data points, selecting the nearest neighbor (K=1) in multiclass EEG signal classification.

*5) **Artificial Neural Networks (ANN)**:* This architecture comprises interconnected artificial neurons and consists of three layers: Input, Hidden, and Output. Each layer processes the signal and passes it to the next layer. This work uses techniques like Dropout and Batch Normalization to foster neuron independence and enhance the model.

*6) **Long short-term memory (LSTM) network**:* LSTMs address RNNs' challenges with long-range dependencies. An LSTM consists of LSTM units with three gates: the input gate, the forget gate, and the output gate. The forget gate's crucial role is determining which information to retain before progressing to the next LSTM unit. Training involves Stochastic Gradient Descent and updates through backpropagation over time.

III. Results and Discussion

In the context of binary emotion classification tasks within the CANTAB-Video setting, the study evaluates five models—ANN, LSTM, CNN, KNN, and XGBoost—for their performance. These models exhibit remarkable accuracies, as depicted in both Fig. 3 and Table V. Notably, XGBoost surpasses all others, achieving an outstanding accuracy of 96.5%.

In transitioning to the Video-CANTAB scenario, the study employs the same five models for binary emotion classification tasks. Notably, there is a discernible difference in the results regarding average accuracies, as evident from Fig. 3 and Table

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:29:10 UTC from IEEE Xplore. Restrictions apply.

TABLE V: Binary Classification Results (Accuracy in %)

Environment	ANN	LSTM	CNN	KNN	XGBoost
CANTAB-Video	94.3	94.6	94.5	78.1	96.5
Video-CANTAB	85.0	84.7	90.5	68.4	88.5

TABLE VI: Multiclass Classification Results (Accuracy in %)

Environment	CNN	KNN	XGBoost
CANTAB-Video	87.0	64.9	95.0
Video-CANTAB	71.0	54.2	88.0

V. XGBoost stands out, achieving an accuracy of 88.5%, showcasing its superior performance compared to the other models.

In the context of multiclass emotion classification within the CANTAB-Video setting, the study assesses three models—XGBoost, CNN, and KNN—for their performance. These models achieve the following average accuracies, as shown in Fig.4 and Table VI. XGBoost achieves an impressive accuracy of 95.0%. CNN exhibits lower average accuracies, particularly for emotions like happiness and fear, with an accuracy of 87%. KNN achieves an accuracy of 64.9%.

As we transition to the Video-CANTAB scenario, we evaluate the same three models for multiclass classification. All models show a collective decrease in average multiclass accuracy compared to CANTAB-Video, as evident from Fig. 4 and TableVI. XGBoost outperforms the other models with an accuracy of 88%. CNN follows with an accuracy of 71%, while KNN achieves an accuracy of 54.2%. Once again, we highlight the impact of task sequencing on emotion classification performance through the collective decrease in average accuracies compared to CANTAB-Video.

IV. Conclusion

Emotions can manifest in individuals of all backgrounds, leading to variations in behaviour and physiological responses that may influence overall well-being. This study explores the Discrete Emotion Model's intricacies, achieving remarkable accuracy despite historical observations of lower rates. This paper also significantly contributes by accurately measuring the intensity of emotions using the multiclass scenario, thus advancing emotion recognition capabilities. XGBoost excels in this study's experiments, achieving 96.5% accuracy in binary and 95% in multiclass emotion recognition. By investigating two distinct environments, "CANTAB-Video" and "Video-CANTAB," this research reveals that the "CANTAB-Video" environment consistently offers superior outcomes for emotion recognition. These results underscore the importance of environment selection in refining recognition accuracy.

Future research in this domain should explore different feature combinations to enhance the system's classification accuracy. Moreover, this research can extend to exploring intricate interactions among emotion, cognition, and sleep using the ECSMP [20] dataset, resulting in a more comprehensive understanding of their impact on EEG signals and valuable insights for emotion recognition applications.

Abstract

Municipal organic solid waste in Palestine is causing several environmental and social problems. This paper studied management of this waste stream in the concept of urban mining and circular economy through composting and reuse the produced compost for different purposes as an indicator for the circular economy through the period extended from 2021 up to 2035. Two compost reuse scenarios are studied: use for agricultural purposes, and use as landfill cover materials. For agricultural purposes, compost can be used as an alternative fertilizer where nutrients in compost can replace the existing chemical fertilizers available in Palestine such as humic acid as a source of carbon, Ammonium Sulphate as a source of nitrogen, Triple Super Phosphate as a source of Phosphorus, and Potassium Phosphate source of Potassium. The estimated revenue from compost use in agriculture is USD 194.8 million in 2021 and USD 369.8 million in 2035. The estimated saving from using compost as landfill cover is USD 0.876 million annually, and USD 13.14 million during the 15 years' study period. Implementation of the circular economy principles in municipal solid waste management through composting can close the materials recycling loop, generating extra income, and adding net revenue to the national economy.

Introduction

Circular economy in waste management

The linear economic model "make-use-dispose" is the dominant global economy. It is considered as a challenge because it can generate waste, degrade the environment, cause price hike due to volatile resources and supply disruption, and cause supply risks for countries that depend

on imports. However, the circular economy is an alternative to the linear economy which can solve these challenges and promote environmental practices by returning the discarded products into the production cycle. The linear economy is the dominant consumption model in the developing world, while developed countries, such as the European Union (EU), are applying the principles of the circular economy in policy and action including the waste management sector [1]. In accordance with the EU plan, 65% of the municipal waste shall be recycled as a target [2] and food waste per capita shall be reduced on the retailer-consumer level to half by 2030 [3]. The principles of the circular economy include the preservation and enhancement of natural capital by controlling finite stocks and balancing renewable resource flows; optimization of resource yields by circulating materials at the highest utility at all times in both technical and biological cycles; and fostering system effectiveness by revealing and designing out negative externalities through reduced damage to systems (food, mobility, shelter, education, etc.) and managing externalities (land use, air, water, etc.) [4].

The aim of the circular economy is to use the products as longer as possible by reusing and repairing them to reduce waste production and use of more secondary raw materials in the production cycle [5]. Composting of municipal organic waste is an application of the use of secondary materials in the production cycle instead of depositing them at landfills. Following the model of the circular economy, previous studies highlighted the recycling of organic waste materials into various products. For example, grape skin and seeds along with stems can be recycled and converted into compost [6], and an organic fraction of municipal waste such as household food waste being transferred into compost [7]. The compost is rich in carbon, which in the soil, can resist soil erosion, improve soil water retention, improve soil fertility, and increase biodiversity due to the enumeration enrichment of bacteria, fungi, insects, and worms [8], which can support better soil health and plant growth, ultimately boosting its resilience to cope with harsh drought conditions.

Compost can support the food chain as well as food security by returning nutrients to the soil and enhancing its productivity and crop yield [4, 8]. In accordance with the European Compost Network (ECN), bio-waste through compost can contribute to the circular economy objectives via closing biological material cycles, and reducing the linear economy of landfilling of organic waste; rich in carbon and nutrients thus contributing to long-term soil fertility and C-sequestration through the production of quality soil amendments and organic fertilizers; producing bio-based products which can replace fossil-based products such as mineral fertilizers, peat, and fossil fuels [9].

Compost and urban mining

Composting is a technique for urban mining of organic waste to return it back to the material cycles as a form of circular economy. Through this process, the valuable materials are isolated/ extracted from the waste stream, recycled, and returned to the material cycle. It is widely defined in the literature. It is a process in which products, components of products, elements, and secondary raw materials from used products or elements from urban metabolisms are first discarded, and then recovered and reused as products or resources [10]. It is an effective way to recover resources from secondary mining, landfill mining, and hazardous waste deposits and includes hibernation mining, dissipation mining, and in-use mining [11]. Urban mining is, indirectly, the activity of reclaiming compounds, energy, and elements from products, buildings, and waste generated from urban catabolism [12, 13]. The terminology of urban mining was used for exploitation and extraction of secondary materials from landfills in the beginning, but nowadays it is widely used to include any sort of material recycling [5]. Using the terminology of urban mining that includes any sort of material recycling, extraction of organic waste toward its composting can be considered as compost of urban mining. Tejaswini et al. [14] reported the different types of urban mining (urban mined waste from electrical and electronic equipment -WEEE, urban mined construction and demolition (C&D) waste, urban mined plastic waste and urban mined organic waste) and mentioned that composting is an urban mining of solid waste. Moreover, it has been reported that the term "Urban Mining" is applicable to any type of waste stream [15, 16]. The term 'Urban Mining", "Landfill Mining", "Circular Economy" are contributors to waste management and have strong relationships. Since urban mining is extraction of reusable and recyclable material from the waste stream, and landfill mining is the extraction of such materials from old landfills, then these extracted materials are entered the material cycles through the circular economy concept and contribute to waste management.

The benefits of urban mining were widely reported in the literature. For example, mining of WEEE can reduce 80% of the raw materials required for production of new devices [17], source of job opportunities [18], reduce mining from ores and thus reduce environmental and social impacts [19], reduce the cost of material as identified by Zheng et al. [20] who found that the mean urban mining costs of copper and aluminum are less than the costs of virgin mining, urban mining and recycling of one ton of C&D waste reduce dependence on fossil fuel energy and have the potential for generating environmental benefits such as reduction in carbon emissions [21].

The composting process can be used to recover nutrients from the waste material [22], which can be used in agriculture to replace chemical fertilizers. Ddidba et al. [23] studied the circular economy approach for nutrient recovery from organic waste (fecal sludge, sewage sludge and solid waste) in the context of low- and middle-income countries using composting. Composting food waste is an effective method to valorize this waste stream into nutrient-rich biofertilizers [24]. This can achieve environmental and social benefits through reduction in emissions and nuisance, and reducing the energy and virgin raw materials used to produce chemical fertilizers simultaneously. Further, organic waste can be co-composted with other materials such as soybean crude residue and rice husk can enhance biodegradation [25] and return such materials to the material cycles and circular economy. Moreover, some degrading-resistant organic waste can be biochar amended during composting to enhance microbial activity and organic matter biotransformation into compost [26], thus enhancing the biochar material cycles. Previous studies reported that partial substitution of chemical fertilizers by organic matter can provide the soil with enough nutrient and increase yield [27], selenium-rich compost increase soil fertility and selenium content [28, 29] and replace inorganic selenium fertilizers, replacing 30% chemical fertilizers by organic one increase the quality and yield of cabbage plants [30], and replacement of chemical fertilizers by manure and biological fertilizers can achieve a qualitative and quantitative yield on saffron [31].

Potential for compost production in the study area

Organic fraction represents 46% of the total waste stream in the study area [32], which generates 1,200.0 tons of solid waste daily in average. This showed great potential for compost production from the urban mining of the organic fraction of the fresh waste collected on daily basis. The separation of this waste stream at the source can contribute to the production good quality compost and avoid potential contamination of heavy metals.

Another potential source of compost is the landfill mining, which is a type of urban mining, can result in the extraction of decomposed organic matter from the landfill to be reused. A previous study reported that solid waste buried in landfills for a long time can be excavated, extracted and used as compost for plants or can be reused as biocover for actively operating landfills [33], which can enhance methane oxidation by methanotrophic bacteria [34–36]. In the study area, there are 18 random dumpsites closed more than 9 years ago and contain large quantities of organic waste which can be extracted and used as compost. A study on landfill mining in Indonesia based on the garbage heap age found that the best percentage of compost can be attained after the garbage heap reaches the optimum age of 8–9 years [37]. In addition, the current regional landfill in operation in the study area, which contains more than 2.5 million tons of solid waste, is facing political and social constraints for expansion, which makes landfill mining one of the options to extend the service life of the landfills [33]. Moreover, the agricultural sector in Palestine is facing a severe shortage of chemical fertilizers due to the restrictions imposed by Israel on importing high-quality dual-use fertilizers, which makes the composting of organic waste one of the best options in hand.

However, special safety consideration and measures should be taken when planning to use compost produced from landfill mining in agriculture due to heavy metals contamination. Although some studies reported the suitability of soil-like material extracted from old landfills for soil amendment [38, 39], other studies pointed out high content of heavy metals [40–42] and, accordingly, such soil is not suitable for agricultural purposes. The effects of the heavy metals on the environment and human health owing to their toxicity and bioaccumulation were widely reported in the literature. For example, it is characterized by high toxicity and may be lethal to human [43], carcinogenic such as chromium [44], poisonous which causes intellectual abnormalities in children such as lead [45] and changes in synaptic transmission and neurotransmitter balance such as arsenic [46], and mercury causes kidneys' membranous nephropathy [47]. Therefore, the proper use of compost extracted from landfill mining shall be restricted to non-agricultural applications as recommended by Datta et al. [42] such as cover material for waste in active landfills.

Problems of solid waste management

Landfilling is the main waste disposal method currently in use, which poses environmental and health impacts due to the spread of flies and mosquitoes, odor release and greenhouse gas (GHG) emissions. The national reports showed that the emissions from the SW sector reaches 23% of the total emissions in Palestine [48], which is one of the main contributing sectors to the global warming and climate change as well. In accordance with the national strategies and plans, solid waste landfilling shall be reduced by 30% by 20,230 and 50% by 2040, and methane emissions shall be lowered by 30% by 2030 and 40% by 2040 [49]. Previous studies highlighted several negative impacts of landfills on the environment and human health in the surrounding communities. These were related to odor emissions, impacts on livestock and plants, hygienic impacts on nearby residents, leachate spills which causes pollution, impacts on aesthetic views and traffic, reduction in the value of the properties and nearby land, and health impacts related of the landfill of being a source of insects and rodents [50]. Moreover, landfill construction and expansion faces severe social and political

restrictions. A study conducted by Al-Khatib et al. [51] in the study area showed that more than half of the respondents were against landfill construction at 1 km from their houses. In the study area, in particular, urban mining of recyclables including metals, plastics, and wood is very limited and do not exceed 0.5% of the total waste stream while urban mining of organic waste and composting was initiated at pilot scale and stopped due to financial and technical constraints [49]. Therefore, proper management of the organic fraction of municipal solid waste is a pressing issue due to the large quantities of this waste stream and high environmental and social impacts.

Considering the problems of waste management and national plans mentioned above, it becomes imperative to devise ways that can help reduce the extent of the problem, minimize the environmental impacts, and promote sustainability without much of an economic burden. Utilizing the organic fraction of waste can significantly reduce the load over the waste management system and its composting can lead to the transformation of waste into wealth through a natural process. Apart from it, mining of compost from operational/ closed landfills can help create more space for waste landfilling. Since compost has nutrient value, its use can be promoted in agriculture, thereby completing the nutrient cycling and reducing the economic burden in terms of the impact of chemical synthetic fertilizers. Therefore, this study focuses only on the management of organic solid waste fraction separated at the source following the concept of urban mining and circular economy. Compost from landfill mining is not evaluated and not considered in this study due to the absence of reliable data on waste quantities and quality. The purpose of this study is to evaluate the role of composting in the circular economy through two scenarios: (1) the use of compost to replace chemical fertilizers in agriculture and (2) the use of compost as cover materials in the active landfill. The monetary savings can, thus, be a strong stimulus to policy to shift to sustainable ideas of material reuse and recycling.

Research gap

In Palestine, there is a research gap in the urban mining of compost and its potential contribution to the circular economy. Although many studies were conducted on compost production and uses, none of these studies evaluated the value chain of compost production and utilization to highlight its role in the circular economy and sustainability. This is the first study in Palestine that considers the current situations including the waste management and agricultural sectors' problems and highlight the importance of organic waste mining, composting, and its role in the circular economy and contribution to solve such problems. On the policy level, there are no guidelines regarding urban and landfill mining of solid waste in Palestine in general and in the study area in particular. Although there is a severe limitation on land use for landfills construction and expansion due to political reasons, there is no obligatory policy or legislative framework for waste reuse and recycling as well, and landfill mining has never been mentioned. Therefore, this study paves the way toward setting policy for urban mining of municipal SW to enhance circular economy in waste management.

Materials and methods

The study area

The study area is located in the southern part of the West Bank and consists of two governorates according to the governmental managerial system. These governorates are Hebron and Bethlehem, with a total population of 922,064 [52] and an annual growth rate of 2.8% [53].

Generation of solid waste

In accordance with the unpublished data obtained from the JSC-H&B, per capita waste generation was 0.69 kg/d and 0.79 kg/d in the Hebron and Bethlehem governorates respectively [32]. Currently, the study area is generating 925 tons daily as per the records of the JSC-H&B weighing bridge [54]. The waste characteristics are organics 46.0%, paper and cardboard 10.9%, plastic containers 18.3%, textile 6.1, metals 1.8%, glass 2.3%, and others 14.6% [32]. The highest fraction is organic which equals 425.5 tons per day.

Use of compost and chemical fertilizers in agriculture

The benefits of compost for agricultural purposes are widely reported in the literature. It can be used for soil bioremediation [55], control plant disease [56], weed control [57], improve soil biodiversity [58], improve soil fertility and water holding capacity [59], and substitute chemical fertilizers [60–62]. Palestinian farmers' acceptance of the use of compost in agriculture has been assessed at different locations. An assessment of the farmers' attitudes toward the use of compost in agriculture in Wadi Al-Far'ah Watershed in the north of the West Bank of Palestine [63] found that 84% of the farmers have the willingness to produce and use compost in agriculture. A study conducted in the Hebron district in the study area showed the farmers' attitudes toward the use of compost in agriculture are positive as 91.2% of the served farmers agree to use the compost [64].

The demand for compost in Palestine is increasing due to the shortage of chemical fertilizers in the market, because the Israeli occupation has restricted imports of dual-use fertilizers and chemicals [65]. These include fertilizers like

ammonium nitrate (NH_4NO_3), potassium nitrate (KNO_3), urea (CH_4N_2O), urea nitrate ($CH_4N_2ONO_3$), fertilizers containing nitrogen, phosphorus, and potassium (at percentages of 27-10-17 and 20-20-20) and any other fertilizer containing any ammonium nitrate, potassium nitrate, or urea [65, 66]. This has forced the Palestinian farmers to use alternative fertilizers with lower nutrient concentrations which is inappropriate and sometimes ineffective. The use of such low nutrient concentration fertilizers heavily burdened the farmers and incurred high costs due to the relatively large quantity of fertilizers they use to compensate for the low concentration, which in turn increases the soil salinity and deterioration of the agricultural productivity. It has been reported that the agricultural productivity declined in the range of 20–33% due to the use of N, P, K chemical fertilizers type 13-13-13 rating instead of 20-20-20 rating, and the farmers have borne extra costs of $29 million/year as well [66]. Under the current conditions of such severe restrictions on the import of chemical fertilizers, compost is the best alternative that can remediate the soil after the intensive use of inappropriate chemical fertilizers in relatively large quantities.

Use of compost as landfill cover

One of the uses of compost is replacing filling materials as landfill cover. This use is also widely reported in the literature [67–69]. Applying compost as cover materials over the waste at the landfills is considered an environmental benefit that can mitigate, the spread of odors, flies, mosquitoes, and reduce the release of methane. Methanotrophs in compost can oxidize methane gas and convert it into carbone dioxide, water, and biomass under aerobic conditions [34–36]. The introduction of compost as landfill cover could be one of the viable options to enhance methane reduction in landfills [70]. In addition, it can achieve financial benefits by reducing the preparation and transportation of filling materials to cover the landfill. A study on compost extracted from landfill mining [71] reported that the compost quality parameters exceed the quality limits of fertilizers, and accordingly, the extracted compost is suitable only for alternative landfill cover.

In the study area, the current cost of each ton of soil used as cover material is NIS 13 (USD 4.0/ton) [72]. Therefore, the diversion of organic waste from the SW stream and using it as cover materials after composting is a viable and sustainable option and supports the circular economy.

Methodology

A proposed model for waste management in the study area including the diversion of the organic fraction for recycling as an indicator for the circular economy is presented in Fig. 1. The saving will be revenues generated from the compost selling, saving the dumping fees that is normally paid for waste dumping at the landfill, saving from the methane emissions reduction, and saving from the reduction of the use of chemical fertilizers.

In Palestine, the landfill fee is USD 9.5/ton (NIS 30) which is usually paid by the local authority to the JSC-H&B for waste dumping. Methane emission reduction is paid through the Carbon Credit–Clean Development Mechanism (CDM) and equals USD 23.2/ton CO_{2eq} as per [73], although the CDM is not functioning in Palestine at the present. The solid waste management sector is contributing by 23% of the total emissions in Palestine [48]. The amount of methane gas emission saving that is supposed to be emitted from the waste diverted from the waste stream is calculated using the landfill gas emission model (LandGEM) version 3.03 designed by the United States Environmental Protection Agency. However, compost produced from organic waste is replacing synthetic fertilizers; therefore, the saving is the revenues generated from selling the compost and the saving from the replacement of the synthetic fertilizers.

The selling price of the compost as provided by a study conducted by the IFC on municipal organic waste composting in Palestine is USD 33/ton (NIS 100/ton) [32] considering the quality and promotion of the users. The saving in chemical fertilizers is estimated based on the nutrients which include carbon (C), Nitrogen (N), Potassium (K), and Phosphorus (P), which are available in chemical fertilizers and supplied to the plants. The commercial source of these nutrients is available in the form of Iperen Humic 12 + 3 liquid for C, Ammonium Sulphate for N, Triple Super phosphate (TSP) for P, and potassium sulphate (SOP) for K. The nutrient content in compost as reported by [74, 75] is 21.02% for C, 0.935% for N, 0.32% for K, and 0.235% for P, which will replace that available in the synthetic fertilizers when using the compost in agriculture. The nutrient content in the synthetic fertilizers and their prices are: Iperen Humic 12 + 3 liquid contains 7.3% C [76] with a price of USD 3,750.0/ton (NIS 12,000.0/ton), Ammonium Sulphate (AS) 21% N [77] with a price of USD 1,250.0/ton (NIS 4,000.0/ton), TSP contains 46% P [78] in the form of P_2O_5 with a price of USD 1,406.0/ton (NIS 4,500.0/ton), and SOP contains 50% K [79] with a price of USD 1,500.0/ton (NIS 4,800.0/ton). The prices of the fertilizers are provided by Sharabati Brothers Trading and Agricultural Company (SBTAC) [80].

The saving in the landfill volume is also considered depending on the construction cost of USD 2.64/m^3 space [81], and the waste density at the landfill after compaction which reached 0.93 [82]. Using the density in place, the space occupied by 1 ton of organic waste costs USD 2.84 (NIS 9.0/ton). The waste collection cost is excluded from the calculations, because the composting facilities is on the same site as the landfill, and in normal operation,

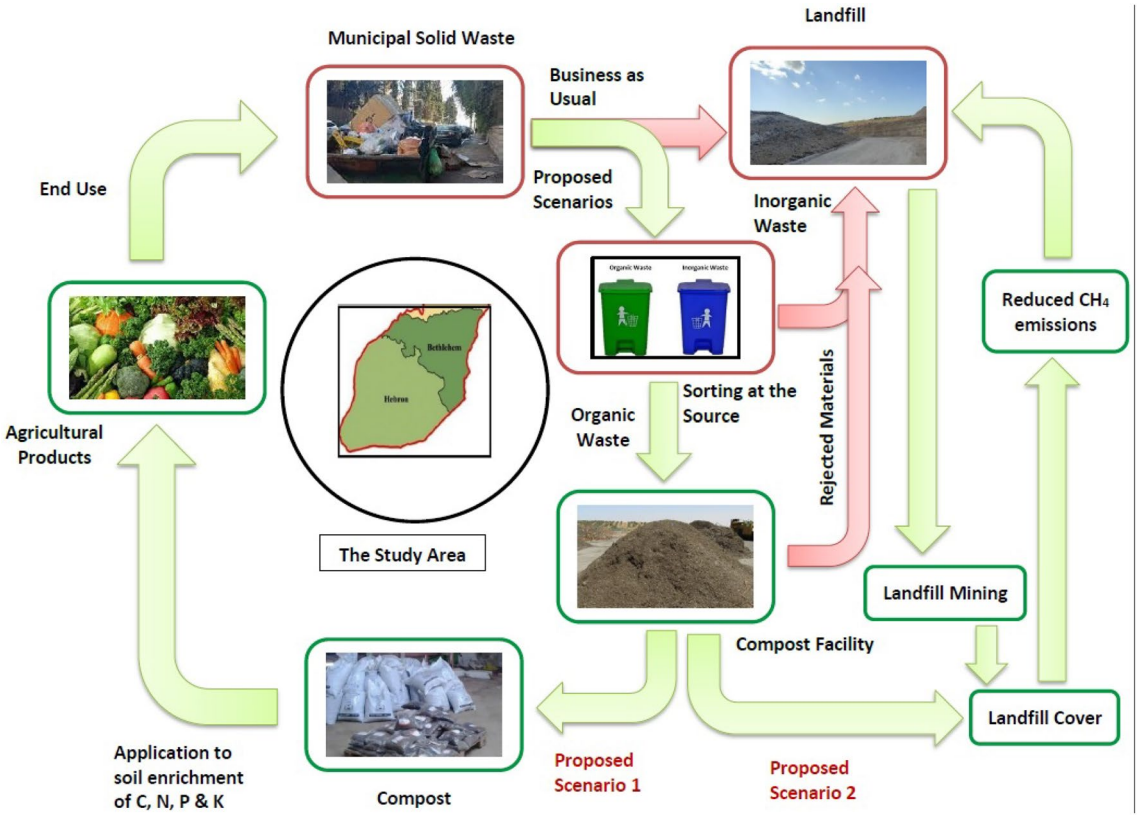

Fig. 1 Proposed waste management model for Hebron and Bethlehem governorates, Palestine

the waste is collected and brought to the site, so there is no difference in the waste collection cost between both scenarios, landfilling and composting.

The saving is calculated based on the following:

$$\mathrm{Rn} = \mathrm{Rg} - \mathrm{OM} \tag{1}$$

$$\mathrm{Rg} = \mathrm{D} + \mathrm{Cc} + \mathrm{C} + \mathrm{F} + \mathrm{Ls} \tag{2}$$

where Rn is the net revenue; Rg is the gross revenue; OM is the operation and maintenance cost of the composting plant; D is the dumping fee saving; Cc is the carbon credit value; C is the compost selling; F is the fertilizer savings; and Ls is the landfill space saving.

The trend is taken through the coming 15 years starting from 2021 to 2035. To calculate the waste generation projection, the population is projected using a 2.8% growth rate [53], and population baseline in accordance with the census in 2017 [52], and waste projection is calculated in accordance with Eq. 3 which is derived based on the actual SW quantities generated in 2015–2020.

$$\mathrm{WasteQuantity} = 850,744.61\ln(x) - 11,409,010.59 \tag{3}$$

where x is the number of population.

The organic compostable fraction is calculated based on the percentage of the organic waste fraction from the total waste stream based on the waste characterization which is 46%. It has been assumed that only 70% of the organic waste fraction is compostable [32] as a conservative figure taking into account that the waste separation at the source could be insufficient, which results in some rejected materials. The waste projection is shown in Fig. 2.

For compost yield, it has been assumed that 25% of organic waste is retrievable with 40% moisture content [74, 75].

This methodology can be used for other similar types of materials and wastes depending on the option of reuse, recyclability, or upscaling of refused material. The materials like paper, plastic, and metal have got fair scrap value recyclability in most of the countries [83] resulting in the generation of resource and revenue from the waste. Efforts are underway to effectively utilize the construction and Demolition waste [84] and agro-residues [85] to overcome the environmental effects and support circular economy. Since the present study integrates the waste utilization and economic growth while adopting nature-based solutions to overcome major issues related to environment and public health, it shall serve

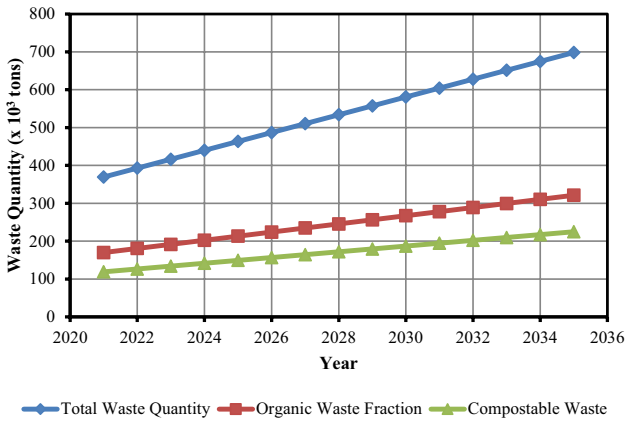

Fig. 2 Projection of waste generation in the study area from 2021 to 2035

as an important document for making rational decisions and framing policies.

Results and discussion

Based on the objectives of the present study, the results have been classified into two scenarios—the use of compost in agriculture, and the use of compost as landfill cover, as given below.

Scenario 1: use of compost in agriculture

Compost production and selling revenues

The organic waste generation is about 118,948.29 tons in 2021 and will reach 224,856.78 tons in 2035. It has been assumed that the organic waste generated will yield 25% compost, so the compost production is in the range of 29,737–56,214 tons for 2021–2035. The operation and maintenance (O&M) cost of the compost facility is assumed to be 60% of the compost sales considering the low prices of compost. Other researchers assumed the O&M cost to be 30% of the compost selling prices for operating and maintaining a compost facility [75]. However, the revenues generated from compost selling are in the range of USD 392,529–742,027 from 2021 to 2035. Table 1 presents the revenues for each year.

Potential replacement of chemical fertilizers and monetary saving

Compost can be used for agricultural purposes, and once it is produced and used, it enters the cycle of the circular economy. The available chemical fertilizers in Palestine and mostly used in agriculture are Ammonium Sulphate (AS), Triple Super Phosphate (TSP), and Potassium Phosphate (SOP). The calculations showed that 17,842 tons of compost can replace 794 tons of AS, 91 tons of TSP, and 29 tons of SOP in 2021, and 33,729 tons of compost can replace 1,502 tons of AS, 172 tons of TSP, and 54 tons of SOP in 2035, as shown in Fig. 3 and Table 2.

A study conducted in the Kingdom of Saudi Arabia (KSA) [75] using commercial fertilizers in the KSA found

Table 1 Compost production and revenues during the period 2021–2035

Year	Waste quantity (ton)	Compost (ton)	Selling value (USD)	O&M cost (USD)	Revenue (USD)
2021	118,948	29,737	981,323	588,794	392,529
2022	126,513	31,628	1,043,734	626,240	417,494
2023	134,078	33,520	1,106,144	663,687	442,457

DM: dry matter; compost contains 40% moisture content, 21.02% carbon, 0.935% N, 0.235% P, and 0.32% K. Alternative source of carbon such as humic acid used is "Iperen Humic 12 + 3 liquid" contains 7.3% carbon; ammonium Phosphate contains 21% N; TSP contains 46% P, and SOP contains 50% K

that 0.23 Mt of compost produced from organic food waste of Makkah city can replace 2.8, 0.7, and 0.9kt of Urea, diammonium phosphate (DAP), and sulphate of potash. This study showed that the same quantity of compost replaced AS, TSP, and SOP can enrich the soil with 3,750 tons of C which in turn can replace 51,376 tons of alternative fertilizers of humic acid (commercially used is Iperen Humic 12 + 3 liquid which contains 7.3% C) in 2021. The replacement increases with time as the compost quantity increases based on the waste generation. The projection of replacement showed that 33,729 tons of compost can enrich the soil with 7,090 tons of C which can replace 97,120 tons of "Iperen Humic 12 + 3 liquid" in 2035 as presented in Table 3. Previous research [66] found that 28.9 and 50.4 kt of C from compost quantities 0.23 and 0.40 Mt can replace 119.4 and 208.8 kt of humic acid in 2015 and 2030, respectively. Moreover, compost builds up organic matter which confers long-term nutrient release (approximately 6 years) [86], which is challenging to estimate. Taking this long-term effect of compost on the soil, the substitution value would be much higher during the subsequent years [87].

Table 3 Compost soil enrichment with C and replacement of alternative fertilizers

Year	Compost (ton)	Compost DM (ton)	C-enrichment (tons)	Alternative source (tons)
2021	29,737	17,842	3,750	51,376

2034	54,323	32,594	6,851	93,852
2035	56,214	33,729	7,090	97,120

Compost contains 40% moisture and 21.02% carbon, alternative source of carbon such as humic acid used is "Iperen Humic 12 + 3 liquid" which contains 7.3% carbon; ammonium Phosphate contains 21% N; TSP contains 46% P, and SOP contains 50% K

The monetary value of the saving from the replacement of the chemical fertilizers is depicted in Fig. 4. The estimated results show that the saving generated is USD 993,005.80, USD 128,157.73, and USD 42,821.38 from AS, TSP, and SOP, respectively, in 2021. The saving rises as the quantity of compost increased with time based on the population growth and reached USD 1,877,152.60 from AS USD 242,266.07 from TSP, and USD 80,948.44 from SOP in 2035. In addition, the estimated saving from replacing "Iperen Humic 12 + 3 liquid", the source of C, is USD 192.7 million in 2021 and USD 364.2 million in 2035. The total estimation of C, N, P, and K replacement savings of "Iperen Humic 12 + 3 liquid", AS, TSP, and SOP by compost is USD 193.8 million and USD 366.4 million in 2021 and 2035, respectively.

Reduction in methane emission and monetary saving

Reduction in methane emission is considered an environmental indicator of the circular economy. In the proposed scenario, organic waste will be composted and methane emissions will be prevented. The calculated results show that the methane emissions reduction is 165 tons, which is equal to 4,122 tons of CO_2 reduction in 2022, while the LGEM does not provide estimates in the first year (2021) and provides estimates next year from the start. By the year 2035, the methane emission reduction will reach 2,493 tons which is equivalent to 62,324 of CO_2 which is prevented from being released to the atmosphere, thus reducing the potential global warming and mitigating climate change. In a similar study, [66] found that composting of food waste can reduce CO_2eq emissions by 1.09 and 1.9 Mt in 2015 and 2030, respectively. The monetary value of this reduction according to the CDM is presented in Table 4.

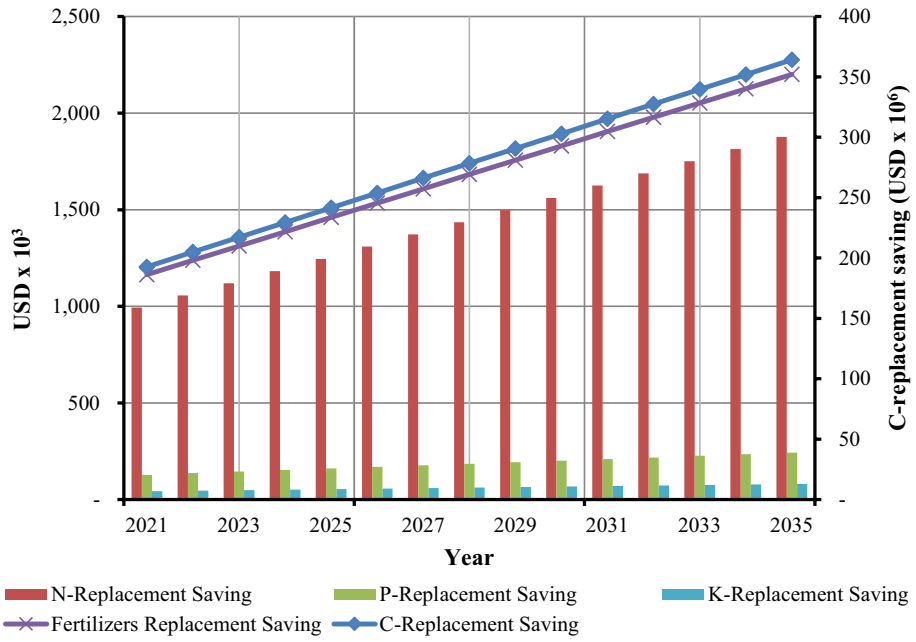

Fig. 4 Saving from replacement of chemical fertilizers by compost in Palestine

Table 4 Saving from CDM and dumping fees

Year	CH_4 (ton)	GWP CO_2 eq (tons)	Saving from CDM (USD)	Dumping fees (USD)	Total saving (USD)
2021	0	0	0	282,502	282,502
2022	165	4,122	95,640	300,469	396,109
2023	332	8,306	192,699	318,435	511,134
2024	502	12,548	291,106	336,402	627,508
2025	674	16,845	390,796	354,369	745,165
2026	848	21,194	491,708	372,335	864,043
2027	1,024	25,594	593,780	390,302	984,082
2028	1,202	30,041	696,956	408,269	1,105,225
2029	1,381	34,534	801,183	426,235	1,227,418
2030	1,563	39,069	906,410	444,202	1,350,612
2031	1,746	43,646	1,012,587	462,168	1,474,755
2032	1,931	48,262	1,119,668	480,135	1,599,803
2033	2,117	52,914	1,227,609	498,102	1,725,711
2034	2,304	57,602	1,336,369	516,068	1,852,437
2035	2,493	62,324	1,445,907	534,035	1,979,942

GWP of CH_4 = 25 CO_2; CO_2 saving price = USD 23.2/ton; dumping fees = USD 9.5/ton

Saving from dumping fees

The tipping fee for municipal waste at the regional landfill is USD 9.5/ton (NIS 30/ton). As the organic waste will be diverted from the waste stream, this fee will not be paid and is considered as saving. The calculations presented in Table 3 showed that the saving in 2021 from the dumping fees is USD 282,502. However, this saving will reach USD 534,035 in 2035. Similar to the present study, UCTAD [66] reported that composting food waste can achieve saving in the tipping fees of 524.25 and 914.19 million Saudi Riyal in 2015 and 2030, respectively.

Environmental saving

Saving achieved from the tipping fees and from the reduction of methane emissions in accordance with the CDM is considered *environmental saving,* and also is one of the indicators of the circular economy in organic waste management and composting. Through CDM, developing countries can implement projects to reduce carbon emissions, and this reduction can be sold to industrial countries to enable them to meet their targets according to Kyoto Protocol. Diversion of organic waste from the waste stream and composting of this waste will, definitely, reduce carbon emissions, where this reduction can be sold. The return generated from selling carbon is considered as an environmental saving. The calculations presented in Table 3 show that the environmental saving (total saving) is USD 282,502.19 and USD 1,979,941.67 in 2021 and 2035, respectively.

Landfill space saving

Diverting organic waste from the municipal solid waste stream causes a significant reduction in waste quantities and volumes that is currently sent to the landfill for disposal. This creates considerable savings in the landfill volume occupied by this waste stream. The landfill space saved from organic waste diversion can be used for other waste streams, thus increasing the life of the landfill and reducing the costs required for expanding the landfill or constructing a new landfill. As these costs are drawn from the budget, then saving the landfill space can reduce expenditure and support the treasury as well, which is considered an indicator of the circular economy. The landfill space construction cost USD 2.65/m^3 [81], which equals USD 2.84/ton of waste considering the density of the waste after compaction at the landfill 0.93 [82]. The calculation results of the landfill space saving are USD 337,813 in 2021 and USD 638,593 in 2035 as presented in Fig. 5.

Net revenues

The net revenue is calculated based on Eqs. 1 and 2 and presented in Fig. 6. It has been estimated that a sustainable composting system can add net revenue of USD 194.8 million to the national economy in 2021 and USD 369.8 million in 2035. Saving from the replacement of chemical fertilizers is relatively high, because the prices of chemical fertilizers in Palestine are very high compared to other countries where there is free access to fertilizers and the governments support the agricultural sector with fertilizers of viable prices. For example, the price of an alternative (C) source in Saudi

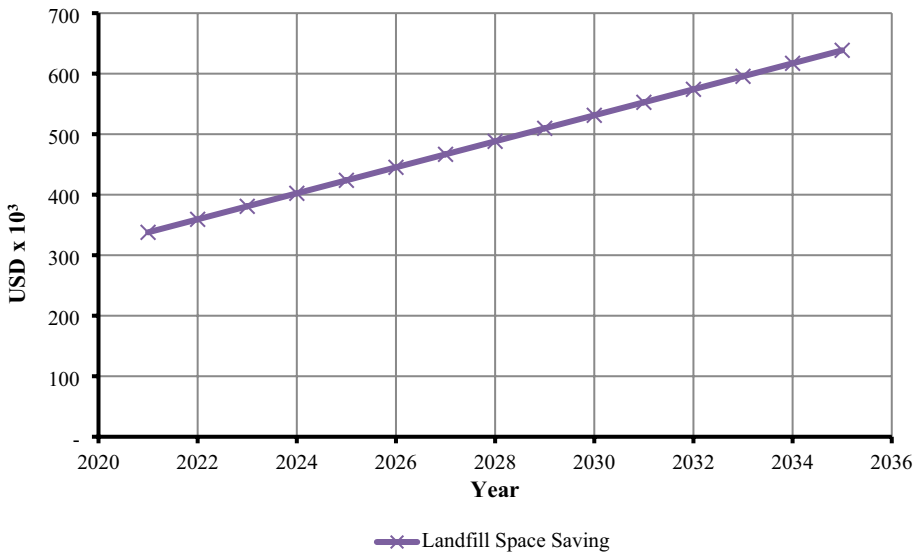

Fig. 5 Saving with respect to reduced space requirement for landfilling

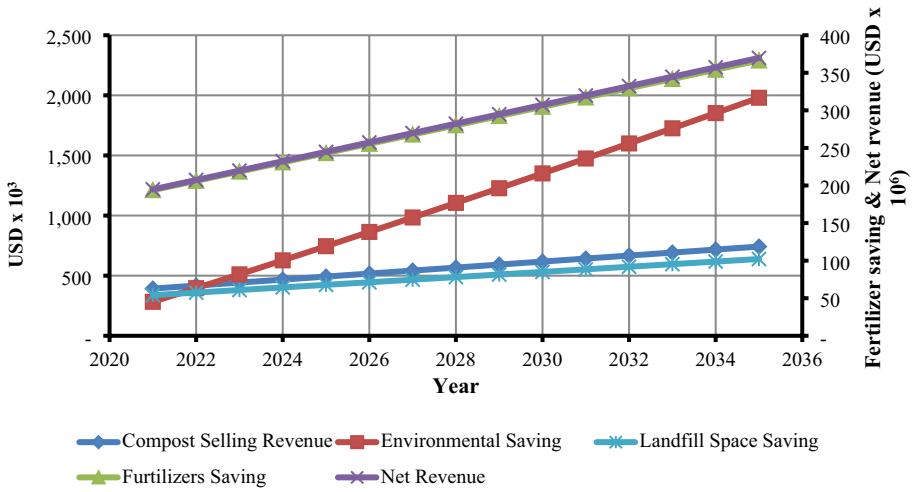

Fig. 6 Net revenues generated from compost selling, environmental saving, fertilizer replacement saving and landfill space saving

Arabia is 562.5 SAR/ton [75] which is equal to USD 150/ton. A study conducted in Kampala/Uganda on the recovery of fecal sludge, sewage sludge, and organic fraction of municipal solid waste, and found that the recovery through composting can generate USD 5.1 million [88].

Scenario 2: use of compost as landfill cover

Besides the agricultural uses of compost, it can also use as daily and intermediate landfill cover, thus saving the cost of the filling materials that are used on daily basis in the business-as-usual scenario. Landfill daily cover is essential, because it prevents the spread of flies, mosquitoes, and insects, and reduces odor emission. At the regional landfill in the study area, about 600 tons of filling materials consisted of crushed stone, marl, sand, and clay is used to cover the daily cell and working face. The price of the cover materials is USD 4.0 (NIS 13.0) per ton of cover material [72]. Accordingly, the cost of this quantity is USD 2,400.0/day. The landfill is open for 12 h per day and all days of the year. The annual estimated cost of the cover materials is USD 876,000.0 and USD 13.14 million during the 15 years starting from 2021 and up to 2035. These amounts can be saved if the compost is used as an alternative cover. Saving this amount is supporting the concept of the circular economy as the waste is recycled and returns to the material cycle and achieves financial profits. This scenario is less attractive compared with scenario 1 (use of compost in agriculture) based on the revenues generated. This agrees with Sardarmehni et al. [89] who modeled the use of compost as a soil amendment and alternative daily cover based on environmental impact and found that compost use as a soil amendment is preferable.

Impact on the long-term retention phase

The benefits of the organic waste composting increase on the long-term retention phase, and can contribute to sustainable waste management and agriculture. Given the restrictions on land use for landfill construction and expansion, and restricted access to chemical fertilizers in Palestine [65], composting can contribute to solving the current technical and financial problems of waste management and the agricultural sector, so it can reduce the demand for landfill space required for waste landfilling, thus, reducing the demand on the construction of new landfills or extension of the existing ones, and farmers will have access to compost to replace the low-quality chemical fertilizers currently in use [66]. In addition, it can reduce the demand for water for agriculture as compost can improve the water holding capacity and increase moisture retention time in the soil as well [59], knowing that water shortage is one of the biggest problems being faced in the agricultural sector in Palestine [90]. Therefore, compost can contribute to solving the problems related to fertilizers and water, thereby supporting food security in the country which suffers from political instability due to the Israeli–Palestinian conflict. However, agencies responsible for SWM can use the revenues as subsidies to cover part of the cost associated with SWM which in turn can improve the service. The environmental benefits are invaluable and are beneficial to humans, the climate, the soil, air quality and health, the water, and society, as well. It can support the sustainability pillars as well as contribute to achieving the sustainable development goals in Palestine at large.

However, a matter of concern is the reduction in the agricultural yield in the case of substitution of synthetic fertilizers by compost, because the quality of compost depends primarily on the raw materials. Therefore, the quantity of compost to be added depends on the nutrient available in the compost and the crop nutrient demand. Opinions about organic farming and inorganic farming are widely varied. Some studies consider organic farming is insufficient to meet the food demand [91], some see great potential of organic farming to secure food in an environmentally friendly manner [92], and others recommended the combined use of compost and chemical fertilizers [93, 94]. The later requires further studies considering the crop pattern to optimize the mixing ratio of compos and chemical fertilizers. However, sustainable agriculture takes into account the sustainability pillars: economic benefit, social acceptance, and environment protection. From sustainability point of view, the replacement of chemical fertilizers by compost in agriculture can reduce the crop yield [95], but ensures environmental protection and food safety.

Further, substitution of chemical fertilizers by compost depends on the country's internal situations and the global context. In Palestine, under the shortage of water for irrigation, restrictions on the import of good quality fertilizers as mentioned above, and a wide group of farmers depend on rain-fed agriculture, substitution of synthetic fertilizer by compost is a favorable option. Heydarzadeh et al. [96] recommended the substitution of chemical fertilizers by vermicompost and poultry manure in rain-fed agriculture. Moreover, the global market prices of synthetic fertilizers escalated by fourfold [97] due to Russia–Ukraine conflict, which makes the affordability of synthetic fertilizers under question especially in low- and middle-income countries.

Conclusion

The municipal SW in Palestine has the potential for recycling the organic fraction through composting and returns it to the material cycle as a resource for production as part of the circular economy. This study provides the economic and environmental benefits of compost use for agricultural purposes as well as cover materials in landfill. The estimated net revenue for the agricultural use of compost is USD 194.8 million in 2021 and USD 369.8 million in 2035 which supports the national economy and is a type of circular economy. However, using compost as landfill cover can achieve financial savings through a reduction in the use of the soil as cover materials, which is estimated annually at USD 0.876 million and USD 13.14 million throughout the study period. The results of this study can pave the way toward framing national policies and implementation of the circular economy in SWM in Palestine.

Novelty of the study

It is the first study in Palestine that focuses on nutrient recovery from organic municipal solid waste through a circular economy approach, which shed the light on recycling and could direct future studies to focus on other SW fractions following the same approach. Moreover, the study provides a solution for three major problems, including problems related to landfill construction and expansion, problems related to the restriction forced by the occupation on import of good quality fertilizers for agricultural purposes, and environmental problems related to improper waste management.

Limitations of the study

This study focused only on urban mining of the organic fraction of the municipal SW and its role in the circular economy through composting, which could open the door for future studies to follow the same circular economy approach and focus on other municipal SW fractions, such as metals,

plastics, WEEE, and glass. Although the study highlighted the potential of compost production from landfill mining, its use in agriculture and mineral recovery calculations was excluded from this study due to the absence of data on the quantities of the waste deposited in old landfills, in addition to high uncertainties of the quality due to potential heavy metals' contamination and safety concerns as well. The waste management model suggested waste separation at the source to avoid quality problems for using compost in agriculture, and use compost from landfill mining as a cover material for active landfill only.

Observational Constraints on the Parameters of Hořava–Lifshitz Gravity

*Himanshu Chaudhary, Ujjal Debnath, Shibesh Kumar Jas Pacif, Niyaz Uddin Molla, Ghulam Mustafa, and Sunil Kumar Maurya**

This study investigates the accelerated cosmic expansion within the Hořava–Lifshitz (HL) Model. To constrain the cosmological parameters of this model, 17 Baryon Acoustic Oscillation points, 31 Cosmic Chronometer points, 40 Type Ia Supernovae points, 24 quasar Hubble diagram points, and 162 Gamma Ray Bursts points, along with the latest Hubble constant measurement (R22) are incorporated. r_d is treated as a free parameter to extract H_0 and r_d using late-time datasets, aiming for optimal fitting values in each model. Treating r_d as free improves precision, reduces bias, and enhances dataset compatibility. The obtained values of H_0 and r_d are compared to the ΛCDM model, showing consistency with previous estimates from Planck and SDSS studies. The Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC) favor the Hořava–Lifshitz model, with the ΛCDM model having the lowest AIC. Additionally, ΔAIC and ΔBIC analyses are conducted to assess model preference. Validation using the reduced χ^2_{red} statistic indicates satisfactory fits for the Hořava–Lifshitz model, while recognizing ΛCDM as the preferred model. Extensions of the analysis warrant further investigation.

1. Introduction

Einstein's General theory of relativity (GR) remains the current gold standard for gravitational theories, consistently passing all tests to date.[1–3] Nevertheless, it is important to develop new theories to further test GR and to explore the potential for a theory of gravity beyond GR. Current research interests include finding a valid theory of quantum gravity and explaining cosmological phenomena such as dark energy and dark matter.[4–6] One challenge with GR is that it is not power-counting renormalizable. To address this, Hořava proposed a theory of gravity beyond GR that is both renormalizable and ultraviolet complete.[7] This theory, known as Hořava–Lifshitz (HL) gravity, breaks Lorentz invariance in the ultraviolet (UV) regime by introducing a Lifshitz-type anisotropic scaling between space and time.

In Einstein's gravitational theory, a prominent challenge arises from UV divergence, known as the UV completion problem. Stelle (1976) addressed this by proposing the incorporation of higher-order curvature invariants into gravitational theories.[8] However, this approach encountered difficulties due to the appearance of ghost degrees of freedom associated with higher-order derivatives. Horava (2009) effectively tackled this issue by introducing additional terms featuring higher-order spatial curvature components into the action, leading to what is now termed deformed HL gravity.[9] Under high-energy conditions, HL gravity is formulated by abandoning Lorentz symmetry through a Lifshitz-type rescaling process.[10] This rescaling involves altering the scaling properties of space and time coordinates, characterized by an exponent denoted as z, and d representing the space-time dimension. Lorentz symmetry is broken when $z \neq 1$ and restored only when $z = 1$. Modified HL gravity has garnered significant attention in scientific literature.[11–17] Researchers have explored various aspects, including cosmological implications, such as the Friedmann equation within the deformed HL gravity framework for the FLRW Universe,[18] novel approaches to dark energy like holographic dark energy (HDE),[19] and investigations into black hole properties such as quasi-normal modes.[20] Additionally, studies have delved into models involving ghost dark energy within the context of deformed HL gravity.[21] The HL gravity model has been extensively examined by numerous

researchers,[22–28] exploring its diverse implications and applications across cosmology and gravitational physics.

HL gravity represents a significant endeavor in theoretical physics, aiming to address the quantum gravity problem and rectify the lack of renormalizability inherent in standard general relativity. By providing a UV-complete theory, it seeks to offer a framework capable of describing gravitational interactions at both small quantum scales and large cosmological scales. Despite its ambitious goals, the theory has not been without challenges and criticisms. One major point of contention revolves around its viability as a quantum theory. Critics have raised concerns about the presence of ghost instabilities, which can lead to inconsistencies and unpredictability within the theory's predictions. These challenges have spurred ongoing debate within the scientific community regarding the feasibility and robustness of HL gravity as a fundamental theory of gravity. Nevertheless, researchers remain engaged in studying and refining the HL gravity framework, particularly in its implications for cosmology and black hole physics. Understanding the cosmological consequences of this theory is of particular interest, as it may offer insights into the nature of the universe at large scales. Investigations into black hole properties within this framework also hold promise for elucidating fundamental aspects of gravitational physics. It's important to recognize that the scientific community's understanding of HL gravity is dynamic and subject to change as further research and experimental data become available. Jawad et al.,[29] investigated the dynamical stability and cosmographic characteristics of some cosmic models under deformed HL gravity, matching their results with observational data. They studied cosmographic parameters and thermodynamics with regard to Einstein's gravity and deformed HL gravity associated with Kaniadakis HDE.[30] Additionally, they explored the cosmological consequences of Sharma–Mittal holographic dark energy (SMHDE), analyzing cosmological parameters and thermodynamics.[31] Further, constraining a model with observations is crucial for ensuring its physical relevance and predictive power. Observational constraints help in refining theoretical models by aligning them with empirical data, thus validating or refuting theoretical predictions. Following the theoretical formulation of HL gravity, various datasets were used by ref. [32] to constrain the corresponding cosmological scenarios. Additionally,[33] focused on the running parameter λ of HL gravity, which governs the flow between the UV and the Infra-Red. They found that λ is restricted to $|\lambda - 1| \lesssim 0.02$, with the best-fit value being $|\lambda_{\text{b.f.}} - 1| \approx 0.002$. This observational analysis confines the running parameter λ very close to its IR value of 1. It is important to note that basic versions of HL gravity may encounter perturbative instabilities, as highlighted in previous studies.[34,35] These instabilities pose challenges to the theory's robustness and reliability. Recognizing and addressing these issues is essential for advancing HL gravity and ensuring its consistency with empirical observations and theoretical expectations.

Motivated by the preceding discourse, this study explores into the realm of HL gravity, which emerges as a compelling alternative to Einstein's gravitational theory for several reasons. Both theories aim to describe the behavior of gravity, but they approach the challenge from different perspectives and with different goals in mind. One key motivation for considering HL gravity over Einstein gravity lies in addressing the UV completion problem, a significant challenge in theoretical physics. HL gravity offers a promising avenue for resolving UV divergences by introducing higher-order spatial curvature components into the action, thereby providing a UV-complete theory capable of describing gravitational interactions at both small quantum scales and large cosmological scales. Our primary objective is to meticulously evaluate the compatibility of HL model with observational data, thus deriving rigorous constraints on crucial cosmic parameters.

Harnessing recent measurements of the Hubble parameter, $H(z)$, extracted from cosmic chronometers, alongside a diverse array of datasets spanning Type Ia Supernovae, Gamma-Ray Bursts (GRB), Quasars, and uncorrelated Baryon Acoustic Oscillations (BAO), our analysis offers a comprehensive survey of the cosmic terrain. Additionally, we aim to probe the ongoing cosmological tensions such as H_0 and the sensitivity of r_d. The paper is structured as follows: In Section 2, we present the basic equations of HL Gravity. In Section 3, we focus on the methodology employed to constrain the crucial parameters of HL model. Our study's outcomes are detailed in Section 4, where we present the results obtained. Finally, in Section 5, we conclude the paper, offering discussions on the implications and significance of our findings.

2. Hořava–Lifshitz Gravity and Basic Equations

We assume the Arnowitt–Deser–Misner decomposition, which is provided as in the metric form:

$$ds^2 = g_{ij}\left(dx^i + N^i dt\right)\left(dx^j + N^j dt\right) - N^2 dt^2 \tag{1}$$

In the above equation, N is representing the lapse function, N_i is providing the shift vector, g_{ij} is denoting the spatial metric. For the present analysis, the scaling transformation in the framework of coordinates reads as $t \to l^3 t$ and $x^i \to l x^i$. The action of the HL gravity has two major components, namely, the potential term and the kinetic term. The HL gravity action within the scope of the potential term and the kinetic term is defined as:

$$S_g = S_v + S_k = \int dt d^3x \sqrt{g} N\left(L_v + L_k\right) \tag{2}$$

where, the kinetic term is defined as

$$S_k = \int dt d^3x \sqrt{g} N\left[\frac{2\left(K_{ij}K^{ij} - \lambda K^2\right)}{\kappa^2}\right] \tag{3}$$

where, The extrinsic curvature is provided as

$$K_{ij} = \frac{\dot{g}_{ij} - \Delta_i N_j - \Delta_j N_i}{2N} \tag{4}$$

The number of invariants, while working with the Lagrangian, L_v, can be reduced due to its symmetric property. This symmetry is referred to as detailed balance. By using this detailed balance, the action can be revised as

$$S_g = \int dtd^3x\sqrt{g}N\left[\frac{2\left(K_{ij}K^{ij}-\lambda K^2\right)}{\kappa^2}+\frac{\kappa^2 C_{ij}C^{ij}}{2\omega^4}-\frac{\kappa^2\mu\epsilon^{ijk}R_{i,j}\Delta_j R^l_k}{2\omega^2\sqrt{g}}+\frac{\kappa^2\mu^2 R_{ij}R^{ij}}{8}-\frac{\kappa^2\mu^2}{8(3\lambda-1)}\left\{\frac{(1-4\lambda)R^2}{4}+\Lambda R-3\Lambda^2\right\}\right] \quad (5)$$

$$\text{where} \quad C^{ij}=\frac{\epsilon^{ijk}\Delta_k\left(R^j_i-\frac{R}{4}\delta^j_i\right)}{\sqrt{g}} \quad (6)$$

is known as the Cotton tensor. Here the covariant derivatives can be determined by the spatial metric $g_{ij}\epsilon^{ijk}$, which is the antisymmetric unit tensor. Here, the parameter λ is the dimensionless constant, and the other parameters κ, ω, and μ are also the constants.

Horava obtained a gravitational action by considering the temporal dependency of the lapse function $N(t)$. For FRW metric with the assumptions $N=1$, $g_{ij}=a^2(t)\gamma_{ij}$, $N^i=0$ and

$$\gamma_{ij}dx^i dx^j=\frac{dr^2}{1-kr^2}+r^2d\Omega_2^2 \quad (7)$$

and by taking the variations of N and g_{ij}, we can obtain the two Field equations which are given below:

$$H^2=\frac{\kappa^2\rho_m}{6(3\lambda-1)}+\frac{\kappa^2}{6(3\lambda-1)}\left[\frac{3\kappa^2\mu^2k^2}{8(3\lambda-1)a^4}+\frac{3\kappa^2\mu^2\Lambda^2}{8(3\lambda-1)}\right]-\frac{\kappa^4\mu^2\Lambda k}{8(3\lambda-1)^2a^2} \quad (8)$$

$$\dot{H}+\frac{3H^2}{2}=-\frac{\kappa^2p_m}{4(3\lambda-1)}-\frac{\kappa^2}{4(3\lambda-1)}\left[\frac{3\kappa^2\mu^2k^2}{8(3\lambda-1)a^4}+\frac{3\kappa^2\mu^2\Lambda^2}{8(3\lambda-1)}\right]-\frac{\kappa^4\mu^2\Lambda k}{8(3\lambda-1)^2a^2} \quad (9)$$

where $k=0,\pm1$ represent the flat, closed, and open universe respectively. In the field equations mentioned above, the term proportional to $\frac{1}{a^4}$ is treated as the "Dark radiation" term and Λ denotes the cosmological constant. Also, $H=\frac{\dot{a}}{a}$ represents the Hubble parameter. Now we assume that the universe is filled with dark matter and we have not taken any external dark energy because the modified gravity can produce dark energy. So the conservation equation of the dark matter (DM) is given by

$$\dot{\rho}_m+3H(\rho_m+p_m)=0 \quad (10)$$

Since the dark matter has negligible pressure (i.e., $p_m\sim0$), so the Equation (10) yields $\rho_m=\rho_{m0}a^{-3}$. Using the dimensionless parameters $\Omega_{m0}\equiv\frac{\rho_{m0}}{3H_0^2}$, $\Omega_{k0}=-\frac{k}{H_0^2}$, $\Omega_{\Lambda0}=\frac{\Lambda}{2H_0^2}$, we obtain (choosing $\kappa^2=1$)

$$H^2(z)=\frac{2H_0^2\Omega_{m0}(1+z)^3}{3\lambda-1}+\frac{\mu^2H_0^2}{16(3\lambda-1)^2}\left[\Omega_{k0}(1+z)^2+3\Omega_{\Lambda0}\right]^2 \quad (11)$$

3. Data and Methodology

In the investigation, a specific set of recent Baryon Acoustic Oscillation (BAO) measurements extracted from multiple galaxy surveys was carefully picked, with a primary focus on data from the Sloan Digital Sky Survey (SDSS).[36–41] To enrich the dataset, it was augmented with valuable contributions from other surveys such as the Dark Energy Survey (DES),[42] the Dark Energy Camera Legacy Survey (DECaLS),[43] and 6dFGS BAO.[44] Recognizing the potential for interdependencies among the selected data points, this concern was diligently addressed. A subset was carefully curated to mitigate highly correlated points, fully appreciating the importance of managing possible correlations within the chosen dataset. To ensure a comprehensive assessment of systematic errors, mock datasets generated from N-body simulations were employed to precisely calculate covariance matrices. Obtaining accurate covariance matrices among measurements derived from diverse observational surveys presented a significant challenge. To address a significant challenge, covariance analysis was utilized as outlined in ref. [45]. Specifically, an approach was adopted where the diagonal elements of the covariance matrix, denoted as C_{ii}, was set equal to the square of the 1σ errors, σ_i^2. In order to introduce correlations among the selected subset of data, the covariance matrix was augmented by incorporating non-diagonal elements while preserving its symmetry. This was achieved by randomly pairing data points, resulting in a total of 12 pairs. For each pair, the non-diagonal elements were determined using the expression $C_{ij}=0.5\sigma_i\sigma_j$, where σ_i and σ_j represent the 1σ errors associated with data points i and j, respectively. Through this methodology, correlations within 56% of the BAO dataset under consideration were effectively stimulated. This approach enabled to capture the interdependence among data points, providing a more comprehensive representation of the underlying structure within the dataset. By incorporating these correlations, the aim was to enhance the accuracy and reliability of the analyses, thereby improving the understanding of the phenomenon under investigation. To constrain the cosmological model parameters, the dataset was expanded by including various additional measurements. First, 30 independent Hubble parameter measurements derived from cosmic chronometers (CC) detailed in refs. [46–49] were incorporated. Additionally, the study integrated recent Pantheon Type Ia Supernovae samples,[50] 24 binned quasar[51] distance modulus data, 162 Gamma-Ray Bursts (GRBs),[52] and the latest Hubble constant measurement (R22) as an additional prior.[53] To analyze these datasets, a nested sampling approach using the Polychord package was adopted,[54] enabling thorough exploration of parameter space for determining optimal fit values. Additionally, the GetDist package was utilized [55] to present the findings clearly and informatively, enhancing the interpretation and visualization of the analysis outcomes. This comprehensive methodology ensured a robust understanding of cosmological parameters while providing insights into the Universe's fundamental properties.

4. Results

Figure 1 shows the 68% and 95% confidence levels for important cosmological parameters in the HL Model. The best-fit values for these parameters are listed in **Table 1**. When we incorporate the

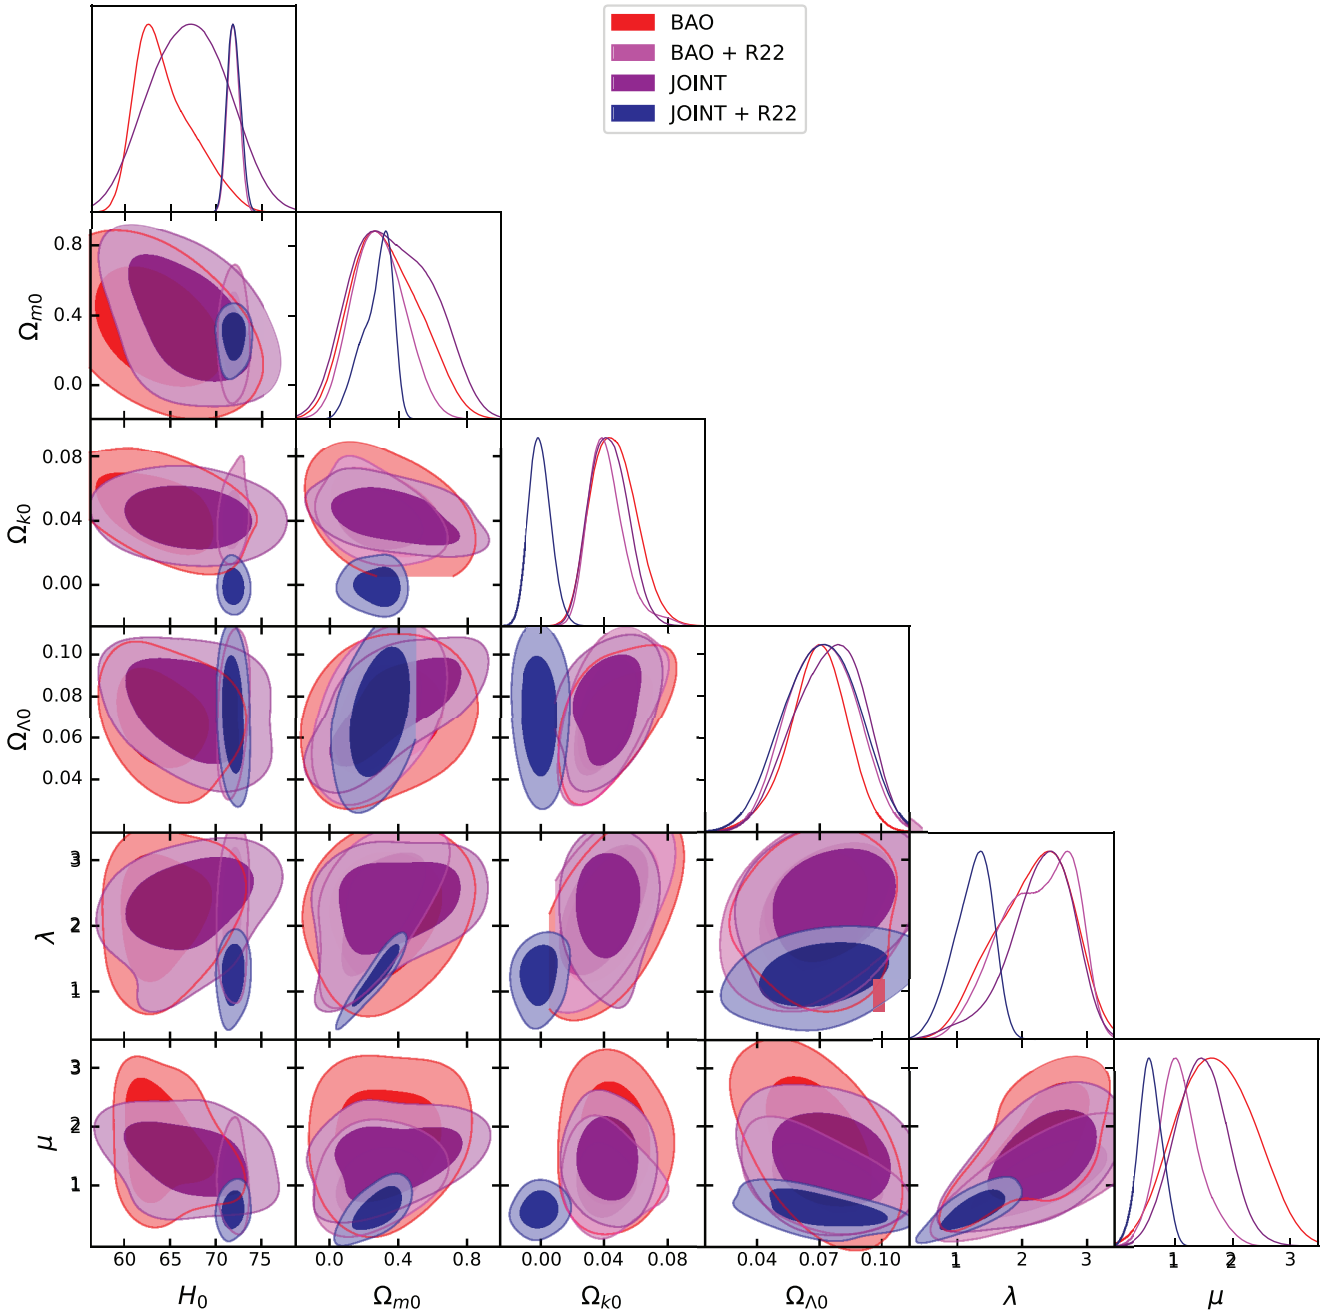

Figure 1. The figure illustrates the posterior distribution of various observational data measurements using the HL Model, highlighting the 1σ and 2σ regions.

R22 prior into the Joint dataset, the resulting value for H_0 deviates from the findings in ref. [56], but closely aligns with the SNIe sample in ref. [53]. Conversely, without the R22 priors and using the Joint dataset alone, the estimated value of H_0 aligns more closely with ref. [56]. These findings indicate that the inclusion of the R22 prior diverges from ref. [56] and aligns with ref. [53] showing the impact of prior choice on cosmological parameter estimation. The determined values for the matter density parameter (Ω_{m0}) and (Ω_{d0}) seem lower compared to those documented in ref. [56]. However, this observation aligns with findings from alternative studies.[57,58] One can observe that the running parameter λ, according to the Joint with R22 analysis, is constrained close to the expected value of 1. Now turning our attention to the Baryon Acoustic Oscillations (BAO) scale, which is a fundamental scale in cosmology derived from the cosmic microwave background, this scale originates from a significant event known as the drag epoch (z_d), marking a pivotal moment when baryons and photons transitioned into distinct entities. The BAO scale (r_d) is essentially a measure of the cosmic sound horizon at z_d, which reflects the separation distance between these baryons and

photons. To calculate r_d, we consider the integral of the ratio between the speed of sound (c_s) and the Hubble parameter (H) across a range of redshifts, starting from z_d and extending indefinitely. The speed of sound, c_s, is determined by the fluctuations in pressure (δp_γ) and density ($\delta\rho_B$ and $\delta\rho_\gamma$) within the photon and baryon components. Mathematically, this simplifies to $\frac{1}{\sqrt{3(1+R)}}$, where R represents the ratio of baryon density fluctuations to photon density fluctuations ($R \equiv \frac{\delta\rho_B}{\delta\rho_\gamma} = \frac{3\rho_B}{4\rho_\gamma}$). Observational data, as documented in ref. [56], has provided us with the precise redshift of the drag epoch, $z_d = 1059.94 \pm 0.30$. In the context of a ΛCDM model, the BAO scale r_d has been estimated to be 147.09 ± 0.26 megaparsecs (Mpc) based on measurements by ref. [56]. **Figure 2** shows the posterior distribution for the $r_d - H_0$ contour plane of the HL Model. In the HL model, the BAO scale derived solely from BAO datasets is 148.814 ± 10.558 Mpc. Upon including the R22 prior exclusively into the BAO dataset, the sound horizon at the drag epoch becomes 138.907 ± 2.129 Mpc. For the Joint dataset, the BAO scale is 145.843 ± 2.47 Mpc. Integrating the R22 prior into the full dataset yields $r_d = 142.742 \pm 1.658$ Mpc. The findings indicate that when incorporating the joint dataset, the obtained value of r_d in each dark energy model closely agrees with the values obtained in ref. [56]. However, when combining the R22 priors with the joint dataset, the obtained value of r_d aligns closely with refs. [59, 60] introduces an insightful perspective by employing binning and Gaussian methods to amalgamate measurements of 2D BAO and SNIa data. It's important to recognize that the outcomes we derive are closely tied to the initial range of priors we make about the BAO scale (r_d) and the Hubble constant (H_0). These priors significantly impact the values we estimate, particularly when considering the $r_d - H_0$ contour plot. An interesting observation emerges when we omit the R22 prior from our analysis: in such cases, the results for H_0 and r_d tend to better align with findings from the Planck and SDSS experiments.

When assessing various cosmological models, we employ both the Akaike Information Criterion (AIC)[57] and the Bayesian Information Criterion (BIC) for evaluation purposes. The AIC and BIC are statistical measures used to assess the goodness of fit of a model to a given dataset while penalizing for the number of parameters in the model. The AIC is calculated using the formula: $\mathrm{AIC} = -2\ln\left(\mathcal{L}_{\max}\right) + 2k + \frac{2k(2k+1)}{N_{\mathrm{tot}}-k-1}$. Here, $\mathcal{L}_{\max}$ represents the maximum likelihood of the data, N_{tot} is the total number of data points, and k is the number of parameters in the model. When the total number of data points (N_{tot}) is large, the expression simplifies to: $\mathrm{AIC} \simeq -2\ln\left(\mathcal{L}_{\max}\right) + 2k$ which is the conventional form of the AIC criterion. This criterion provides a trade-off between the goodness of fit and the complexity of the model. On the other hand, the BIC is defined as: $\mathrm{BIC} = -2\ln\left(\mathcal{L}_{\max}\right) + k\ln N_{\mathrm{tot}}$. The BIC also evaluates the goodness of fit while penalizing for the number of parameters, but it imposes a stronger penalty for additional parameters compared to the AIC, particularly for smaller sample sizes. To compare different models, we use the differences in AIC and BIC values, denoted as ΔAIC and ΔBIC, respectively: $\Delta\mathrm{AIC} = \mathrm{AIC}_{\mathrm{HL\ Model}} - \mathrm{AIC}_{\Lambda\mathrm{CDM\ Model}}$ and $\Delta\mathrm{BIC} = \mathrm{BIC}_{\mathrm{HL\ Model}} - \mathrm{BIC}_{\Lambda\mathrm{CDM\ Model}}$ These differences help to identify the relative performance of models, with lower values indicating a better fit relative to the reference model. The interpretation of ΔAIC and ΔBIC values is as follows: $-\Delta\mathrm{AIC}$ or $\Delta\mathrm{BIC} \leq 2$: Substantial evidence for the model. $-\Delta\mathrm{AIC}$ or ΔBIC between 4 and 7: Considerable evidence against the model. $-\Delta\mathrm{AIC}$ or $\Delta\mathrm{BIC} \geq 10$: Strong evidence against the model. When comparing the HL Model with the standard ΛCDM model, it's important to note that both proposed extensions encompass ΛCDM as a subset, differing only by 4 degrees of freedom. This aspect allows for the application of conventional statistical tests. Our evaluation primarily employs the reduced chi-square statistic, denoted as $\chi^2_{\mathrm{red}} = \chi^2/\mathrm{Dof}$, where "Dof" represents the degrees of freedom of the model and χ^2

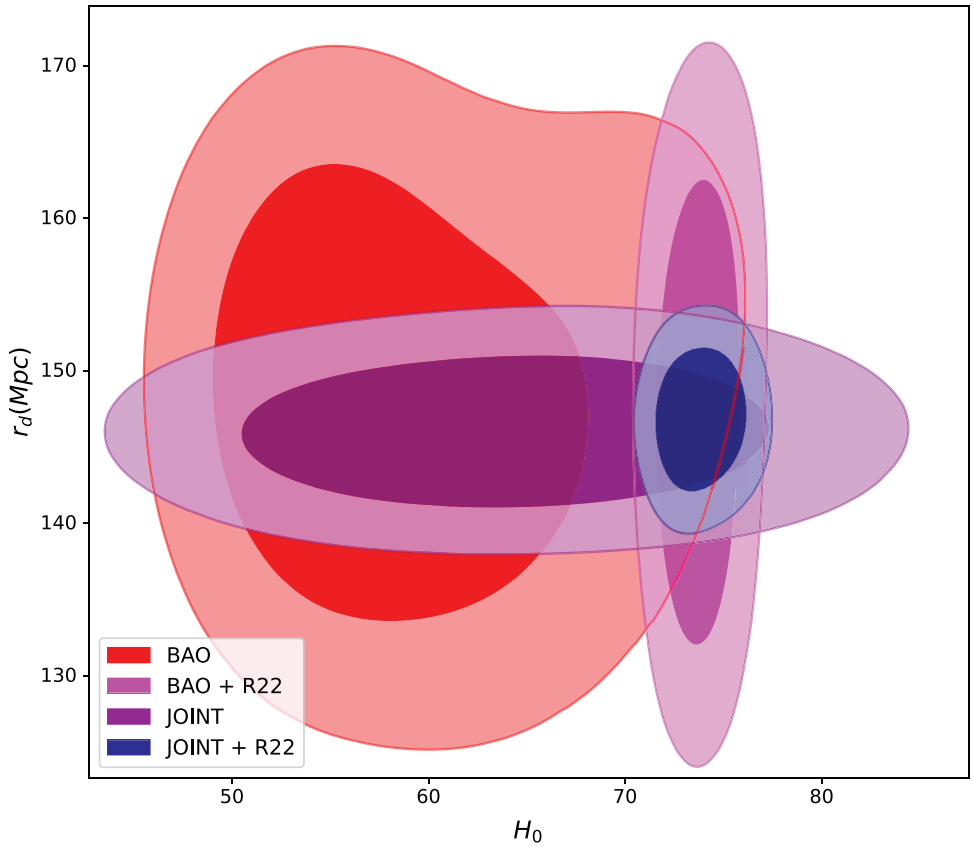

Figure 2. The figure illustrates the posterior distribution of various observational data measurements using the HL Model, highlighting the 1σ and 2σ regions.

signifies the weighted sum of squared deviations from the expected
values.

Based on the provided in **Table 2**, we can conduct a comparative study between the ΛCDM Model and HL Model using the metrics of reduced chi-square (χ^2_{red}), Akaike Information Criterion (AIC), ΔAIC, Bayesian Information Criterion (BIC), and ΔBIC. The reduced chi-square value is a measure of how well the model fits the data. A value closer to 1 indicates a better fit. Both models have χ^2_{red} values close to 1, suggesting that both models fit the data well. However, the ΛCDM Model has a slightly lower χ^2_{red} value, indicating a marginally better fit. In terms of the AIC, the ΛCDM Model scores 277.38, whereas the HL Model scores slightly higher at 279.13, resulting in a ΔAIC of 1.75. This indicates substantial evidence for the HL Model, though it is less favored compared to the ΛCDM Model. For the BIC, the ΛCDM Model has a score of 277.59, while the HL Model has a higher score of 280.51, leading to a ΔBIC of 2.92. This ΔBIC suggests positive evidence against the HL Model, indicating a stronger preference for the ΛCDM Model.

Table 2. Summary of χ^2_{red}, AIC, ΔAIC, BIC, and ΔBIC.

Model	χ^2_{red}	AIC	ΔAIC	BIC	ΔBIC
ΛCDM Model	0.949	277.38	0	277.59	0
Hořava–Lifshitz Model	0.961	279.13	1.75	280.51	2.92

5. Conclusion

In conclusion, our study focused on investigating the accelerated cosmic expansion in the late Universe within the context of the HL Model. This framework offers an alternative perspective to general relativity by incorporating anisotropic scaling at ultraviolet scales. We analyzed 24 Baryon Acoustic Oscillation (BAO) points, along with 31 uncorrelated data points obtained from Cosmic Chronometers methods. We also incorporated 40 points from Type Ia supernovae, 24 points from the Hubble diagram for quasars, and a substantial dataset consisting of 162 points sourced from Gamma Ray Bursts. Furthermore, our study included the latest measurement of the Hubble constant conducted by R22. Our primary objective was to determine the optimal fitting values for every cosmological parameter within each dark energy model. By treating the sound horizon r_d as a free parameter instead of relying on prior information from the Cosmic Microwave Background (CMB), we gain several benefits. First, it reduces bias by sidestepping potentially restrictive CMB priors, ensuring a more impartial estimation of r_d and other cosmological parameters. Second, it enhances precision by allowing late-time data, such as Baryon Acoustic Oscillations (BAO) or Type Ia Supernovae (SNIe), to directly inform the

measurement of r_d, leading to more accurate results. Moreover, this approach promotes compatibility between datasets from different cosmic epochs, facilitating a more holistic understanding of the Universe's evolution. We determined H_0 and r_d for the HL Model relative to the ΛCDM model as follows: In the ΛCDM model, our analysis yields $H_0 = 69.828145 \pm 1.009964$ km s^{-1} Mpc^{-1} and $r_d = 146.826212 \pm 2.201612$ Mpc. In the HL model, we obtain $H_0 = 69.966349 \pm 1.403864$ km s^{-1}Mpc^{-1} and $r_d = 145.843487 \pm 2.470309$ Mpc. Importantly, our findings underscore that the values of H_0 and r_d based on low-redshift measurements align with early Planck and SDSS estimations. While both the ΛCDM Model and the HL Model fit the data reasonably well, the ΛCDM Model is preferred based on the statistical criteria provided. The ΛCDM Model demonstrates a marginally better fit with a lower reduced chi-square value and is more strongly supported by both the AIC and BIC measures. The ΔAIC indicates substantial evidence for the HL Model, but it is still less favored compared to the ΛCDM Model. Additionally, the ΔBIC provides positive evidence against the HL Model, reinforcing the stronger preference for the ΛCDM Model for the given dataset. Therefore, the ΛCDM Model is favored over the HL Model. These findings underscore the importance of considering alternative cosmological models beyond the standard framework. While the ΛCDM model remains favored due to its simplicity and good fit, the extensions present viable candidates worthy of further investigation. To achieve a better understanding of the fundamental characteristics and development of the Universe, cosmological models must be continually examined and improved.

Abstract

This article proposes two different structures of fractional-order modified synchronous reference frame phase-locked loop (MSRF PLL) and discusses their performance under different grid abnormalities. Phase-locked loop (PLL) is a type of closed-loop feedback control system that ensures phase and frequency coherence between its input and output signals. The basic synchronous reference frame phase-locked loop (SRF-PLL) is a conventional synchronization technique that is frequently employed in grid-connected systems for power electronic converters. The SRF-PLL offers rapid and precise phase/frequency detection under ideal grid environments. However, its performance is severely hampered under unbalanced and distorted grid environments. This paper discusses two new configurations of fractional-order (FO) modified SRF (MSRF), one with fractional order only in additional low-pass filter of first order (FO-LP) and another fractional order in both first-order low-pass filter and PI (FO-LPFO-PI) of MSRF. These controllers are assembled using FOs "a" and "b" with limits as $0 < a < 2$ and $0 < b < 2$. The performance analysis of proposed FO MSRFs is done under grid abnormalities like voltage sag and swell, polluted grid supply, frequency change, phase change, and variables for dc offset. The outcomes of simulation are acquired using FO modeling and control (FOMCON) toolbox for MATLAB/SIMULINK, and the experimental results are validated with simulation results. A fair comparison among the MSRF-PLL, FO-LP MSRF-PLL, and FO-LPFO-PI MSRF-PLL is also depicted during grid abnormalities.

KEYWORDS

controller, fractional-order low-pass filter, phase-locked loop, SRF-PLL, synchronization

1 | INTRODUCTION

A vast majority of power electronic-based converter applications involving utility grid interconnections need precise estimation of utility information, particularly phase angle, frequency, and magnitude of the grid voltage.[1] The synchronization of power electronic converters with utility grid has become a crucial factor in managing the growing number of single-phase[2–4] grid-tied power conditioning systems. In general, SRF-PLL is a commonly utilized synchronization mechanism in three-phase grid connection due to its robustness. This technique offers rapid and precise phase/frequency detection and fairly satisfactory dynamic response under ideal grid circumstances. However, the performance

 © 2024 John Wiley & Sons Ltd.

of SRF-PLL deteriorates during adverse grid circumstances.[5] One method of improving the SRF-PLL performance issue is to add a low-pass filter to the control loop and decrease the bandwidth of the SRF PLL at the expense of dynamic performance.6 However, this approach is usually not preferred due to poor dynamic response.

Figure 1 shows the representation of the conventional SRF-PLL employed for single-phase systems, and it is designed comprising three basic parts: (i) a phase detector (PD), (ii) loop filter (LF) that is a PI controller, and (iii) voltage control oscillator (VCO) that monitors the grid voltage and synchronizes its output signal with an input reference signal in both frequency and phase.7,8 The performance of the grid-tied SRF-PLL using the traditional integer order is discussed in various research papers.[9–11] The traditional calculus based on integer order differentiation and integration is popular and convenient due to the absence of suitable and appropriate solution methods for fractional differential equations.[12]

Recently, there has been a lot of study done on fractional differential equations and their applications in different areas like control theory and electrical circuit theory. Many techniques have been used for approximating integrals and fractional derivatives.[13] Today, several applications in physics and engineering employ fractional controllers and employ fractional calculus. Electrical circuits using fractional capacitor (which is proportional to $s^a$where "a" is the arbitrary) are mentioned.[14]

The mathematics that deals with the study and use of integrals and derivatives of any order is defined as fractional calculus.[15]

Several approximations of fractional derivatives in different areas of control theory and PLL are discussed in different papers. It is argued by Stanislawski and Latawiec[16] that normalized finite fractional differences exist.[16] Tseng and some other authors have described numerical realization of differentiators or integrators of fractional variable order.[17,18] Nikhil and his co-authors have presented a cascaded control approach that includes a fractional-order PI (FO-PI) controller for controlling power flow in a renewable-energy-based microgrid connected to utility grid.[19] A servo control technique is suggested for tuning of fractional order PI (FO-PI) controllers with and without time delays.[20] In paper,[15] the authors have proposed a fractional-order analog phase-locked loop (FAPLL) model with fractional-order loop filter and voltage-controlled oscillator and compared the performance of FO-PLL to traditional integer order PLL in terms of capture and locking time response. In paper,[21] fractional-order low-pass filter and fractional-order VCO for FOPLL are used to compute the phase error, output phase, steady-state errors, and stability conditions of FOPLL. A novel fractional-order charge-pump PLL (FOCPLL) with the fractional-order loop filter (FO-LF) is proposed for the overall improvement of the system.[22] A novel PLL algorithm based on fractional-order proportional plus integral (FOPI) controller tuned through genetic algorithm is proposed in Pereira et al.[23] It overcomes the DSOGI PLL's phase peak response by producing a quadrature signal. In paper,[24] $(1 + \alpha)$ Butterworth filter with fractional-order α is presented to study the magnitude-frequency response. In the paper25 various types of "$1 + \alpha$" order Butterworth transfer functions are generated whose cutoff frequencies can be fully tuned. In another paper,26 higher-order fractional filters with fully controlled frequency characteristics are achieved after fitting the filter's magnitude response data with a minimum-phase state-space model. Paper[27] has discussed the design of the fractional-order analog filters and proved that the fractional-order domain adds more degrees of freedom to the filter design process. In paper,[28] fractional-order low pass, band pass, high pass, and all pass filters have been designed using fractional-order impedance in the complex

frequency range. It obtains the pole frequencies, half-power frequencies, right-phase frequencies, and quality factor expressions. Paper[29] focuses on developed fractional-order notch filter (FONF) control approach to estimate fundamental active component of current from the distorted load currents and utilizes it to obtain the gating pulses to operate the voltage source converter (VSC). The review of mentioned papers suggests that the use of fractional-order (FO) domain as a PLL for the estimation of frequency and phase angle is interesting and needs elaborate study. Keeping the gap in consideration, this article focuses on modified SRF PLL for single-phase system as well as two new FO SRF-PLL models. The novelty in this article is the introduction of the following:

i. Fractional order in the low-pass filter (FO-LP) of first order
ii. Fractional order in low-pass filter of first order as well as PI controller resulting in (FO-LPFO-PI) MSRF-PLL.

The performance analysis of these two newly developed MSRF-PLLs is studied under grid abnormalities like voltage swell and sag, phase angle change of 20°, frequency variation of + 5 Hz, dc offset, and polluted grid voltage. Thus, three PLLs, viz., (i) MSRF-PLL with low-pass filter having integral order, (ii) MSRF-PLL with low-pass filter having fractional-order (FO-LP), and (iii) MSRF-PLL with two FOs, that is, low-pass filter (FO-LP) and proportional plus integral (FO-PI) are designed and analyzed mathematically in fractional domain. The comparative performance analysis under grid abnormal conditions like 15% voltage swell and sag, phase change of 15°, frequency variation of + 5 Hz, 10% dc offset, and polluted input voltage are rigorously studied.

Theory of fractional calculus emerged with the introduction of regular (integer order) calculus by Leibniz and L'Hopitalin 1695 who proposed half-order derivatives. The idea of fractional calculus further developed in Europe.[30] The base of fractional calculus is the FO differentiations and integrations. It includes works based on Riemann–Liouville definition, the Caputo definition, the Grunwald–Letnikov definition, and the Cauchy integral formula definition and the Cauchy integral formula.[31] Fractional calculus is integrating and differentiating to a noninteger order fundamental operator ${}_{a}\mathrm{D}_{t}^{r'}$ where "a" and "t" are the limits of the operation. The continuous integral-differential operator is defined as

$$ {}_{a}D_{t}^{r'} = \begin{cases} d^{r'}/d^{r'} & R(r') > 0 \\ 1 & R(r') = 0 \\ \int_{0}^{t} d\tau^{-r'} & R(r') < 0 \end{cases} \tag{1} $$

where r' is the operation's order; often, $r' \in R$, but r' may also be a complex number.[19] The two most commonly used definitions in FO calculus are the Grunwald–Letnikov (GL) and the Riemann–Liouville (RL).[13] Letnikov (GL) is defined fractional order as

$$ {}_{a}D_{t}^{r'} f(t) = \lim_{h \to 0} h^{-r'} \sum_{j=0}^{\frac{t-a}{h}} (-1)^{j} \binom{r'}{j} f(t - jh) \tag{2} $$

where $\binom{r'}{j}$ denotes the binomial coefficients; subscripts to the left and right of "D" are the lower bounds and upper bounds in the integral. The value of "r'" can be positive or negative, corresponding to the differentiation and integration, and it is a noninteger. The FO integral according to RL[32] is expressed as

$$ {}_{a}D_{t}^{-r'} f(t) = \frac{1}{\Gamma(r')} \int_{a}^{t} (t - \tau)^{r'-1} f(t) d\tau \tag{3} $$

where $0 < r' < 0$ and "a" is initial value. For "a" $= 0$, the simpler integral notation is ${}_{a}D_{t}^{-r'} f(t)$. The FO differentiation according to RL[13] is expressed as

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4161 by Delhi Technological University, Wiley Online Library on [22/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$ {}_aD_t^{r/} f(t) = \frac{d^n}{dt^n}\left[{}_aD_t^{-(n-r/)} f(t)\right] = \frac{1}{\Gamma(n-r/)}\frac{d^n}{dt^n}\int_a^t \frac{f(\tau)}{(t-\tau)^{r/-n+1}}d\tau \tag{4} $$

where $(n-1 < r/ \le n)$. The Laplace transformation for the FO differentiation of the RL can be expressed as

$$ \int_0^\infty e^{-st}\,{}_0D_t^{r/} f(t)dt = s^{r/}F(s) - \sum_{k=0}^{n-1} s^k\,{}_0D_t^{r/-k-1} f(t)|_{t=0} \tag{5} $$

Fractional calculus helps to accurately develop models very close to real objects. Recently, its application is observed in many physical and engineering systems. Moreover, FO partial differential equations regulate numerous physical phenomena, including electricity, fluid dynamics, quantum physics, ecological systems, and many other models, within their respective domains of validity.[33] This paper discusses the use of fractional calculus for grid synchronization.

2 | SYSTEM DESCRIPTION

In this section, three mathematical models of modified PLLs are developed. The first model is the MSRF-PLL with integer order. The other two proposed PLLs are (i) FO MSRF-PLL with only one FO capacitor of order a at low-pass filter and (ii) FO MSRF-PLL that have two FO capacitors, both at low-pass filter of order a and FO PI controller of order b.

2.1 | Mathematical modeling of integer order MSRF-PLL

In this subsection, single-phase integer-order MSRF-PLL with low-pass filter of first order $\left(\frac{\omega_{cf}}{s+\omega_{cf}}\right)$ is developed as shown in Figure 2. This low-pass filter of first order is added in phase detection (PD) unit. MSRF-PLL works by introducing 90° phase change (delay of one-fourth of a cycle, T/4) into the input sinusoidal signal (or α signal) to generate the orthogonal signal (β signal) directly for Park transformation (conversion of stationary αβ axis to rotatory dq axis). The voltage referred to quadrature axis (v_q) is set to zero value so that output of MSRF-PLL locks into the grid utility voltage's phase angle (v_s*). The noise associated with v_q voltage traverses through the low-pass filter of first order that is further passed through filter of the loop (LF) and voltage-controlled oscillator (VCO) unit. The output of LF is the controlled frequency output (ω_c) that along with the nominal frequency ($\omega_{ff} = 2\pi f$) gives predicted frequency (ω_o) of grid voltage. The estimated phase angle θ_{out} of the input signal is derived through VCO by the integration of the calculated frequency (ω_o). All the control loops or the loop dynamics of MSRF-PLL are defined using integer-order transfer functions. The sinusoidal input grid voltage (v_s) is equivalent to v_α, and its $\frac{\pi}{2}$ time delay signal (v_β) is transformed into the dq voltage by the following equations where $T = 2\pi$.

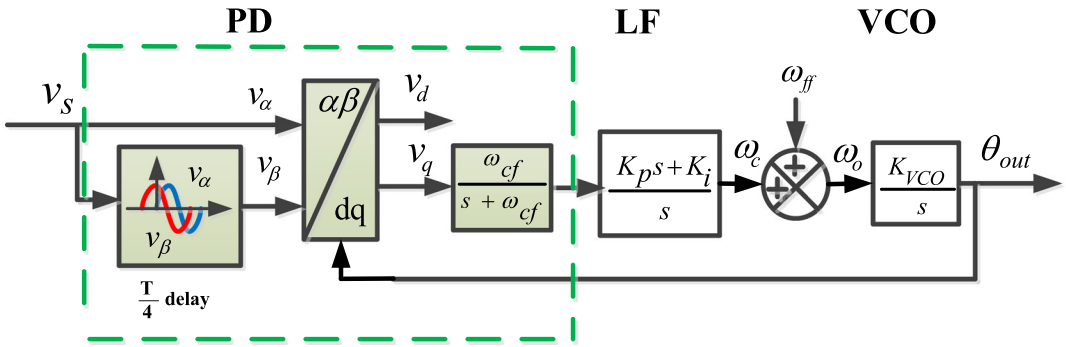

FIGURE 2 Block diagram of single phase MSRF-PLL in integral order domain.

$$\left.\begin{aligned} v_s &= V_s sin\omega_o t = V_s sin\theta_{out} \\ sin\left(\omega_o t + \frac{t}{4}\right) &= cos(\omega_o t) = cos\theta_{out} \\ v_{s\alpha} &= V_s sin\theta_{out} \\ v_{s\beta} &= V_s sin\left(\omega_o t + \frac{T}{4}\right) = V_s cos\theta_{out} \end{aligned}\right\} \tag{6}$$

Park transformation is applied to v_α and v_β from (6) to get v_d and v_q as given in (7) and (8).

$$\begin{bmatrix} v_{sd} \\ v_{sq} \end{bmatrix} = \begin{bmatrix} sin\theta & -cos\theta \\ cos\theta & sin\theta \end{bmatrix} \begin{bmatrix} v_{s\alpha} \\ v_{s\beta} \end{bmatrix} \tag{7}$$

$$\left.\begin{aligned} v_{sd} &= V_{s\alpha}\sin\theta - V_{s\beta}\cos\theta \\ v_{sq} &= V_{s\alpha}\cos\theta + V_{s\beta}\sin\theta \end{aligned}\right\} \tag{8}$$

where θ_{out} is the estimated angle in degree (°) given by transfer function $\theta_{out} = \frac{K_{VCO}V_c(s)}{s}$ which can be interpreted as the integral of control voltage; K_{VCO} is the VCO gain; V_c is the controlled voltage obtained as output from PI controller; $\omega_o = \omega_c + \omega_{ff}$ is the calculated frequency in Hz; v_s is input signal voltage in volts; and ω_{ff} is the nominally stated frequency; $\omega_{ff} = 100\pi$rad/s. The amplitude of v_s is calculated as $A_t = \sqrt{(v_{sd})^2 + (v_{sq})^2}$. The phase angle error, θ_{error}, of fundamental voltage, v_s, is computed from v_q at PCC of grid utility converters, and this v_q is passed through a low-pass filter (LPF) of first order to exclude high-amplitude steady-state oscillations in the calculated phase and frequency. The transfer function of LPF is expressed as

$$Tf_{LPF}(s) = \frac{\omega_{cf}}{s + \omega_{cf}} \tag{9}$$

where ω_{cf} is the cutoff frequency and the order of "s" is an integer. The PD output is a phase error passing through the loop filter (LF). The LF commonly designed for synchronization applications is a proportional and integral (PI) controller. The transfer function of PI controller is given as

$$Tf_{LF}(s) = \frac{K_p s + K_i}{s} \tag{10}$$

where K_p and K_i are the proportional and integral gains, respectively. A controlled voltage,V_c, that is proportional to controlled angular frequency, ω_c, is an output from PI controller that in summation with nominal frequency ω_{ff} is passed through VCO whose transfer function is given by

$$Tf_{VCO}(s) = \frac{K_{VCO}}{s} \tag{11}$$

which after integrating the estimated phase angle θ_{out} is obtained as the output from VCO. The transfer function of the open-loop system, also known as loop gain (LG) of the system, is shown in Figure 2 and expressed as

$$\begin{aligned} Tf_{LG}(s) &= [Tf_{PD}(s)]\,[Tf_{LF}(s)]\,[Tf_{VCO}(s)] \\ &= \left(\frac{K_{PD}\omega_{cf}}{s + \omega_{cf}}\right)\left(\frac{K_p s + K_i}{s}\right)\left(\frac{K_{VCO}}{s}\right) \\ &= \left(\frac{Ks + K^{/}}{s^3 + s^2\omega_{cf}}\right) \end{aligned} \tag{12}$$

where $K = K_{PD}K_{VCO}K_p\omega_{cf}$ and $K^{/} = K_{PD}K_{VCO}K_i\omega_{cf}$. The closed-loop transfer function for integer order MSRF-PLL is given by

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4161 by Delhi Technological University, Wiley Online Library on [22/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$H(s) = \frac{\theta_{output}}{\theta_{input}} = \frac{Tf_{LG}(s)}{1 + Tf_{LG}(s)} = \left(\frac{Ks + K^{/}}{s^3 + \omega_{cf} s^2 + Ks + K^{/}} \right) \tag{13}$$

The error response transfer function for MSRF-PLL is expressed as

$$E(s) = \frac{\theta_{error}}{\theta_{input}} = \frac{1}{1 + Tf_{LG}(s)} = \left(\frac{s^3 + \omega_{cf} s^2}{s^3 + \omega_{cf} s^2 + Ks + K^{/}} \right) \tag{14}$$

where $\theta_{input}, \theta_{error}, \theta_{output}$, are, respectively, the Laplace transformation for phase angle of input, error, and output signals.

2.2 | Mathematical modeling of FO MSRF-PLL

Two new configurations of FO MSRF-PLL are displayed in Figures 3 and 4, and their analysis is discussed in detail. The first configuration of FO MSRF-PLL algorithm is designed by utilizing a FO-LP filter of coefficient a as shown in Figure 3.

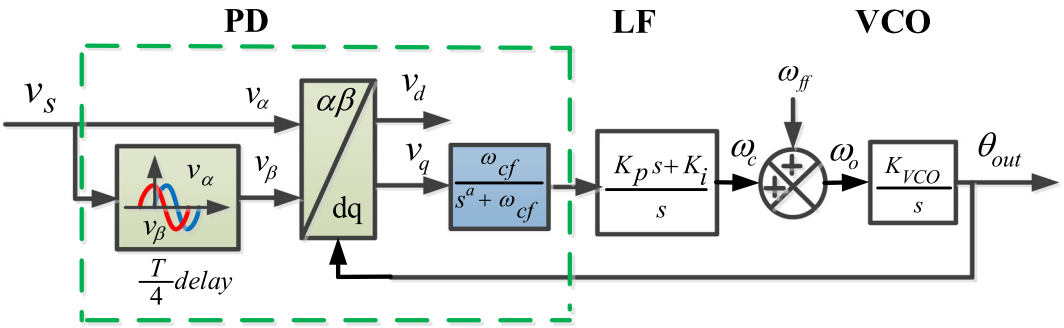

FIGURE 3 Diagram of MSRF-PLL with FO low-pass filter (FO-LP).

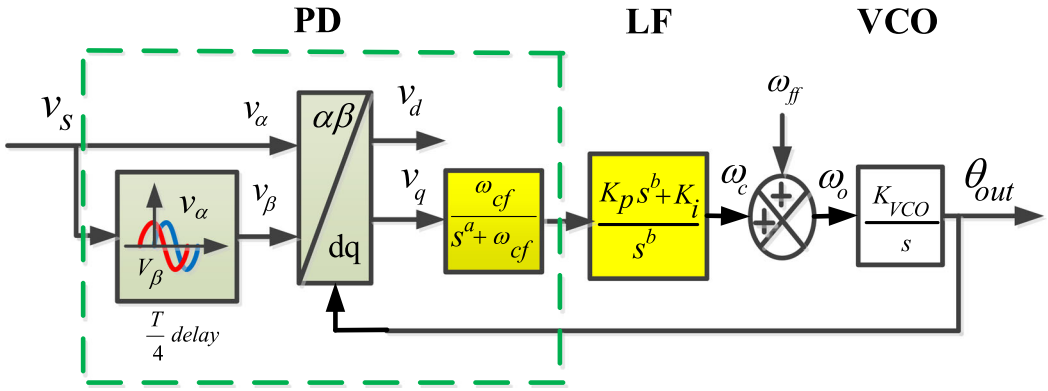

FIGURE 4 Block diagram of MSRF-PLL with fractional-order low-pass filter (FO-LP) and fractional-order proportional plus integrator (FO-PI).

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4161 by Delhi Technological University, Wiley Online Library on [22/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The second algorithm is designed considering FO MSRF-PLL which has both FO-LP filter of order a and FO-PI of fractional order b as shown in Figure 4. The FO MSRF-PLL is made fractional using FO capacitance and is given by $Z(s) = Cs^{\alpha} \Rightarrow Z(j\omega)$ in Laplace domain with $\alpha = -1$. The transfer functions of the two configurations designed in Figures 3 and 4 are discussed here in detail. The transfer functions of FO-LP filter having FO a $(0 < a < 2)$ and FO-PI having FO b $(0 < b < 2)$ can be expressed as

$$Tf_{FO-LP}(s) = \frac{\omega_{cf}}{s^a + \omega_{cf}} \tag{15}$$

$$Tf_{FO-PI}(s) = K_p + \frac{K_i}{s^b} \tag{16}$$

The transfer function of the VCO unit remains unchanged as given by Equation (11).

2.2.1 | Mathematical model of fractional-order MSRF-PLL with only fractional-order low-pass filter (FO-LP MSRF-PLL)

In this subsection, the mathematical model of various transfer functions for open loop, closed loop, and error response of the FO MSRF-PLL having only low-pass filter (FO-LP MSRF-PLL) is developed. The transfer function for open-loop gain FO-LP MSRF-PLL is expressed as

$$\begin{aligned} Tf_{FOLG}(s) &= K_{PD}[Tf_{FO-LP}(s)][Tf_{LF}(s)][Tf_{VCO}(s)] \\ &= \left(\frac{K_{PD}\omega_{cf}}{s^a + \omega_{cf}}\right)\left(\frac{K_p s + K_i}{s}\right)\left(\frac{K_{VCO}}{s}\right) \\ &= \left(\frac{K_{PD}K_P K_{VCO}\omega_{cf} s + K_{PD}K_i K_{VCO}\omega_{cf}}{s^{2+a} + \omega_{cf} s^2}\right) \\ &= \left(\frac{Ks + K^{/}}{s^{2+a} + \omega_{cf} s^2}\right) \end{aligned} \tag{17}$$

where $K = K_{PD}K_{VCO}K_p\omega_{cf}$ and $K^{/} = K_{PD}K_{VCO}K_i\omega_{cf}$. Closed-loop transfer function of FO-LP MSRF-PLL is expressed as

$$\begin{aligned} H_{FO-LP}(s) &= \left(\frac{\theta_{output}}{\theta_{input}}\right) = \left(\frac{Tf_{FOLG}(s)}{1 + Tf_{FOLG}(s)}\right) \\ &= \left(\frac{K_{PD}K_{VCO}K_p\omega_{cf} s + K_{PD}K_{VCO}K_i\omega_{cf}}{s^{2+a} + \omega_{cf} s^2 + K_{PD}K_{VCO}K_p\omega_{cf} s + K_{PD}K_{VCO}K_i\omega_{cf}}\right) \\ &= \left(\frac{Ks + K^{/}}{s^{2+a} + \omega_{cf} s^2 + Ks + K^{/}}\right) \end{aligned} \tag{18}$$

where $K = K_{PD}K_{VCO}K_p\omega_{cf}$ and $K^{/} = K_{PD}K_{VCO}K_i\omega_{cf}$.

The error response transfer function of the FO-LP MSRF-PLL is expressed as

$$\begin{aligned} E_{FO-LP}(s) &= \left(\frac{\theta_{error}}{\theta_{input}}\right) = \left(\frac{1}{1 + Tf_{FOLG}(s)}\right) \\ &= \left(\frac{s^{2+a} + \omega_{cf} s^2}{s^{2+a} + \omega_{cf} s^2 + Ks + K^{/}}\right) \end{aligned} \tag{19}$$

where $K = K_{PD}K_{VCO}K_p\omega_{cf}$, $K^{/} = K_{PD}K_{VCO}K_i\omega_{cf}$ and $\theta_{input}, \theta_{error}, \theta_{output}$, are, respectively, the Laplace transformation for phase angle of input signal, error signal, and output signal.

2.2.2 | Mathematical model of fractional-order MSRF-PLL with both fractional-order low-pass filter (FO-LP) and loop filter (FO-PI)

In this subsection, FO-LPFO-PI MSRF-PLL has been modeled considering both fractional low-pass filter and fractional loop filter, which is a PI controller. The open-loop gain transfer function of FO-LPFO-PI MSRF-PLL is expressed as

$$\begin{aligned} Tf_{LGFOLPFOPI}(s) &= K_{PD}(Tf_{FO-LP})(Tf_{FO-PI})(Tf_{VCO}) \\ &= \left(\frac{K_{PD}\omega_{cf}}{s^a+\omega_{cf}}\right)\left(\frac{K_p s^b + K_i}{s^b}\right)\left(\frac{K_{VCO}}{s}\right) \\ &= \left(\frac{K_{PD}K_PK_{VCO}\omega_{cf}s^b + K_{PD}K_{VCO}K_i\omega_{cf}}{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}}\right) \\ &= \left(\frac{Ks^b + K^/}{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}}\right) \end{aligned} \tag{20}$$

where $K = K_{PD}K_{VCO}K_P\omega_{cf}$ and $K^/ = K_{PD}K_{VCO}K_i\omega_{cf}$.

The closed-loop transfer function of FO-LPFO-PI MSRF-PLL is expressed as

$$\begin{aligned} H_{FOLPFOPI}(s) &= \left(\frac{\theta_{output}}{\theta_{input}}\right) = \left(\frac{Tf_{LGFOLPFOPI}(s)}{1+Tf_{LGFOLPFOPI}(s)}\right) \\ &= \left(\frac{K_{PD}K_pK_{VCO}\omega_{cf}s^b + K_{PD}K_iK_{VCO}\omega_{cf}}{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}+K_{PD}K_PK_{VCO}\omega_{cf}s^b + K_{PD}K_iK_{VCO}\omega_{cf}}\right) \\ &= \left(\frac{Ks^b + K^/}{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}+Ks^b + K^/}\right) \end{aligned} \tag{21}$$

where $K = K_{PD}K_PK_{VCO}\omega_{cf}$and $K^/ = K_{PD}K_iK_{VCO}\omega_{cf}$.

The transfer function for error response of FO-LPFO-PI MSRF-PLL is expressed as

$$\begin{aligned} E_{FOLPFOPI}(s) &= \left(\frac{\theta_{error}}{\theta_{input}}\right) = \left(\frac{1}{1+Tf_{LGFOLPFOPI}(s)}\right) \\ &= \left(\frac{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}}{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}+K_{PD}K_PK_{VCO}\omega_{cf}s^b + K_{PD}K_iK_{VCO}\omega_{cf}}\right) \\ &= \left(\frac{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}}{s^{(1+a+b)}+\omega_{cf}s^{(1+b)}+Ks^b + K^/}\right) \end{aligned} \tag{22}$$

where $K = K_{PD}K_PK_{VCO}\omega_{cf}$, $K^/ = K_{PD}K_iK_{VCO}\omega_{cf}$, and $\theta_{input}, \theta_{error}, \theta_{output}$, are, respectively, the phase-angle Laplace transformation for the signals of input, error, and output.

3 | ANALYSIS OF FRACTIONAL-ORDER MSRF-PLLS

This section focuses on the stability analysis of fractional MSRF-PLL using Bode plots. The open-loop and closed-loop transfer functions of FO-LP MSRF-PLL and FO-LPFO-PI MSRF-PLL are already described in Equations (17), (18), (20), and (21). It is well known that if the phase margin and gain margin are both positive, the FO system is considered stable.[13] The reciprocal of the frequency response amplitude in which the phase is -180° at crossover frequency (ω_{pc}) is the gain margin (Gm). It is measured in dB and expressed as

$$\mathrm{Gm} = -20\log\,|\,Tf_{LG}(j\omega_\pi)\,|\,\mathrm{dB}. \tag{23}$$

where $Tf_{LG}(j\omega_\pi)$ is the transfer function for the open-loop system. The frequency where either of the two $\pm 180^\circ$ axis crosses the open-loop locus is called as the phase crossover frequency (ω_{pc}).

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4161 by Delhi Technological University, Wiley Online Library on [22/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The phase margin is defined as the difference in phase between 180° and gain crossover and is measured in degrees. It is expressed as $\text{Pm} = \arg\,[Tf_{LG}(j\omega_{\pi})] + \pi$ (24)

The crossover frequency of the open-loop plot along 0-dB axis is termed as the gain crossover frequency (ω_{gc}).

The Bode diagrams (Figure 5 and Table 1) are analyzed to optimize the value of the fractional parameter a for stable FO-LP MSRF-PLL system. Figure 5A,B shows the Bode plots of open-loop and closed-loop transfer functions of FO-LP MSRF-PLL for various values of a ($0.2 \leq a \leq 1.7$) with step increment of 0.3 in a.

Table 1 gives the values of gain margins with its corresponding phase crossover frequencies and phase margins with its corresponding gain crossover frequencies for open-loop and closed-loop transfer functions of FO-LP MSRF-PLL for different values of a. From Table 1, it is evident that the phase margin is positive and almost constant for $a = 0.2$ to 1.7 for both open-loop and closed-loop system. However, for $a = 0.2$ to 0.8, the system is unstable as Gm is negative for open loop. The closed loop shows Gm is infinite with undefined phase crossover frequency. On varying a from 1.1 to 1.7, it is observed that the Gm is positive, but it decreases considering both open-loop and closed-loop systems. Hence, it can be concluded from Table 1 and Figure 5A,B that the designed FO-LP MSRF-PLL gives best performance with optimized value of a as 1.1.

The Bode diagrams (Figures 6 and 7 and Tables 2 and 3) are analyzed to optimize the values of the fractional order parameters a and b for FO-LPFO-PI MSRF-PLL system. Figure 6A,B gives the open-loop and closed-loop transfer function of FO-LPFO-PI MSRF-PLL for fixed $b = 1$ and variable a ($0.2 \leq a \leq 1.7$) having step change of 0.3. Table 2 gives information of the values of gain margin with corresponding phase crossover frequencies and phase margins with corresponding gain crossover frequencies. For $0.2 \leq a \leq 0.8$, the Gm is negative for open-loop and infinite for closed-loop system. From Table 2 and Bode diagram shown in Figure 6A,B, it is observed that for $a = 1.1$ to 1.7, the Gm

	At optimized value of $a = 1.1$ and $b = 0.1$	**88.10 dB**	**88.09 dB**
	Gm (dB)	**89.96°**	**179.958°**
	Pm (°)		

with gain crossover frequency (ω_{gc}) at 0.25 rad/s. The closed-loop analysis shows Gm of 88.09 dB with phase crossover frequency (ω_{pc}) at 1005.5 rad/s and Pm = 179.958°. The FO-LPFO-PI MSRF-PLL is found stable for the selected and optimized values of a and b as both phase and gain margin are positive.

Table 4 discusses the open-loop and closed-loop transfer functions of FO-LP MSRF-PLL with fractional parameter a as derived in Equations (17) and (18), and relevant Bode diagrams are presented in Figure 5. FO-LPFO-PI MSRF-PLL is designed with two fractional parameters a and b as per Equations (20) and (21) for its open- and closed-loop response. The Bode diagrams for FO-LPFO-PI MSRF-PLL are plotted in Figures 6 and 7 that show how parameters a and b can be optimized. The procedure followed for obtaining optimization of a and b involves fixing one fractional parameter while varying the other parameter. Figure 6 shows the Bode plots for FO-LPFO-PI MSRF-PLL with variable a and fixed $b = 1$. Figure 7 shows the Bode plot for variable b with fixed $a = 1$. The final open-loop and closed-loop transfer functions and Gm and Pm values are also indicated for the proposed FO-LPFO-PI MSRF-PLL (Table 5).

4 | SIMULATION AND EXPERIMENTAL RESULTS

The proposed FO-LP MSRF-PLL and FO-LPFO-PI MSRF-PLL are now tested using single-phase programmable grid voltage supply. The simulation is run with sampling time, Ts = 50e−6 s under grid abnormalities during disturbances introduced from time interval from 0.2 to 0.4 s. The voltage sag and swell condition causing amplitude variation may be due to voltage drop, change in load, relay malfunctioning, or transformer tap change in power system. Polluted supply is due to presence of nonlinear loads at the consumer end such as power electronic devices.

Various abnormal conditions of grid-tied supply voltage like voltage sag, voltage swell, polluted voltage, phase angle jump, frequency change, and dc offset are simulated, and the performance of the fractional PLLs for the proposed system is investigated. The fractional-order modeling and control (FOMCON) toolbox for MATLAB/Simulink is used for the performance analysis of the simulation results of the proposed system models. The experimental results of the proposed models are obtained from the laboratory setup consisting of a digital signal oscilloscope (DSO), Infinite Vision DSO-X-2014A, PC and real-time simulator.

4.1 | Dynamic performance under steady-state condition

The value of the parameters considered in the PLLs for simulation is given in Appendix A. Both the simulation and experimental performance analysis of the proposed system models are carried out with the real fractional parameter values for $a = 1.1$ and $b = 0.1$. The dynamic performance analysis of the proposed FO-LPMSRF-PLL and

TABLE 5 Comparative performance analysis of MSRF-PLL, FO-LP MSRF-PLL, and FO-PLFO-PI MSRF-PLL.

Testing conditions	MSRF-PLL	FO-LP MSRF-PLL	FO-LPFO-PI MSRF-PLL
Under 30% voltage sag			
Frequency overshoot	Larger peak overshoot of 51.782 Hz	Smaller peak overshoot of 50.99 Hz	Least peak overshoot of 50.28 Hz
Settling time	slow response (0.03 s)	Slower response (0.043 s)	fastest response (0.023 s)
Under 40% voltage swell			
Frequency overshoot	Larger peak overshoot of 53.42 Hz	Smaller with peak overshoot of 51.8 Hz	Smallest peak overshoot of 50.6 Hz
Settling time	Slow (0.04 s)	Sluggish (0.05 s)	Faster (0.02 s)
Under polluted grid supply			
Frequency overshoot	Largest peak overshoot of 2.95 Hz	Smaller peak overshoot of 1.305 Hz	Smallest peak overshoot of 0.44 Hz
Settling time	Slower (0.032 s)	Sluggish (0.033 s)	Faster (0.02 s)
Phase angle shift of 15°			
Frequency overshoot	Largest peak overshoot of 55.42 Hz	Smaller peak overshoot of 54 Hz	Smallest peak overshoot of 51.95 Hz
Settling time	Slow (0.051 s)	Sluggish (0.06 s)	Faster (0.05 s,)
+5 Hz Frequency change			
Frequency overshoot	Largest peak oscillation of 58 Hz	Smaller peak overshoot of 55.9 Hz	Smallest peak overshoot of 55.3 Hz
Settling time	Slower (0.049 s)	Faster (0.05 s)	Fastest (0.048 s)
Presence of dc offset			
Response in frequency	Large oscillations	Small oscillations	Minimum oscillations

FO-LPFO-PIMSRF-PLL is carried out by analyzing the grid parameters like input voltage supply (v_s) in volts, estimated frequency of the system in hertz), phase angle in degrees, and the amplitude (A_t) of source voltage at the point of common coupling of the system in volts, which is expressed as $A_t = \sqrt{v_{s\alpha}^2 + v_{s\beta}^2}$. Here, $v_{s\alpha}$ and $v_{s\beta}$ are the alpha and beta components of supply voltage.

The simulated and the experimental results of FO-LP MSRF-PLL for the dynamic performance analysis under various grid abnormalities are shown in Figure 9 (i) and (ii). Figure 9 (i) (a) gives the simulated dynamic performance at 30% input voltage sag ($v_s = 227.5$ V) during time interval of 0.2 to 0.4 s, and after 0.4 s, the normal condition is restored. The analysis is observed by studying "v_s" (V), estimated frequency (Hz), phase angle (°), and voltage amplitude A_t (V), and Figure 9 (ii) (a) validates its performance analysis experimentally. The estimated frequency is maintained at fundamental frequency while input voltage amplitude is decreased by 97.5 V (30% of v_s) during disturbance time interval. There is no change in the calculated phase angle. The value of the magnitude A_t diminishes during voltage sag conditions and is correctly estimated both in simulation and hardware results. Figure 9 (i) (b) gives the simulated dynamic performance under 40% input voltage swell ($v_s = 455$ V) during time interval of 0.2 to 0.4 s. Figure 9 (ii) (b) verifies the same case experimentally. From the analysis, small variations in estimating fundamental frequency can be observed with increased input voltage amplitude during swell condition. There is no change in the estimated phase angle, and this is verified from simulation and experimental results.

Figure 9 (i) (c) gives the simulated dynamic performance under polluted grid conditions when harmonic content is added to input signal during time interval of 0.2 to 0.4 s. The supply voltage v_s which is sinusoidal becomes distorted (nonsinusoidal) during the disturbed interval due to harmonic content. Magnitude A_t also shows some distortions in both simulation and experimental results. However, the frequency and phase angle are well tracked in Figure 9 (i) (c) which is verified experimentally by Figure 9 (ii) (c).

Figure 9 (i) (d) gives the simulated dynamic performance under 15° phase shift. The estimated frequency shows a peak overshoot of 54.32 Hz at 0.213 s. The overshoot in frequency settles down at 0.26 s. Figure 9 (ii) (d) verifies the simulated observation experimentally.

Figure 9 (i) (e) gives the simulated dynamic performance under +5 Hz change in frequency during time interval of 0.2 to 0.4 s. The frequency change leads to a peak oscillation of 55.92 Hz at 0.23 s and settles down at 0.25 s, and Figure 9 (ii) (e) upholds the simulation results experimentally. Thus, the developed FO-LP MSRF-PLL is able to track the frequency of 55 Hz within two cycles, and this result is validated by simulation as well asexperimental studies.

Figure 9 (i) (f) presents the simulated dynamic performance under 10% dc offset during time interval of 0.2 to 0.4 s. The presence of this offset is predicted in v_s and A_t. The distortion in frequency observed through phase angle is tracked faithfully. Figure 9 (ii) (e) proves the results experimentally under dc offset case.

The simulated and experimental dynamic performance of FO-LPFO-PI MSRF-PLL under various grid abnormal conditions like voltage sag, voltage swell, polluted voltage, phase jumps, step change of frequency, and dc offset are shown in Figure 10 (i) and (ii), respectively.

Figure 10 (i) (a) gives the simulated dynamic performance under 30% input voltage sag ($v_s = 227.5$ V) during time interval of 0.2 to 0.4 s. The analysis is performed by observing plots of v_s (V), estimated frequency (Hz), phase angle (°), and voltage amplitude A_t (V), while Figure 10 (ii) (a) confirms the performance analysis experimentally. The estimated frequency and phase angle remain unaffected though input voltage amplitude is decreased during disturbed time interval.

Figure 10 (i) (b) gives the simulated dynamic performance under 40% input voltage swell ($v_s = 455$ V) during interval of 0.2 to 0.4 s. The frequency is well tracked, while the input voltage amplitude is increased by 40% of the input supply voltage during disturbance period. There is no change in the estimated phase angle, and Figure 10 (ii) (b) validates this result experimentally.

Figure 10 (i) (c) gives the simulated dynamic performance under polluted input voltage supply during time interval of 0.2 to 0.4 s. The supply voltage is nonsinusoidal during 0.2–0.4 s owing to harmonic content. The computed input voltage magnitude A_t shows some oscillations, while frequency and phase angle are not affected. Figure 10 (ii) (c) predicts similar results experimentally.

Figure 10 (i) (d) gives the simulated dynamic performance under 15° phase shift. The estimated frequency shows a peak overshoot of 51.95 Hz at 0.22 s. The overshoot settles down at 0.25 s. Figure 10 (ii) (d) illustrates these results experimentally.

Figure 10 (i) (e) gives the simulated dynamic performance under + 5 Hz frequency change during time interval of 0.2 to 0.4 s. The frequency change leads to a peak oscillation of 55.3 Hz and settles down at 0.25 s. Figure 10 (ii) (e) verifies the results experimentally.

Figure 10 (i) (f) gives the simulated dynamic performance under 10% dc offset during time interval of 0.2 to 0.4 s. The presence of offset is seen in v_s and A_t, where slight distortion in frequency is observed. Phase angle remains unaffected. Figure 10 (ii) (e) verifies these results experimentally.

4.1.1 | Comparative analysis of simulation and experimental results

In this subsection, comparison of the simulated and experimental performance analysis under various grid abnormal conditions for MSRF-PLL and proposed FO-LP MSRF-PLL and FO-LPFO-PI MSRF-PLL is discussed.

Figure 11A performs the comparison of predicted frequencies for three developed PLLs, viz., MSRF-PLL, FO-LP MSRF-PLL, and FO-LPFO-PI MSRF-PLL under 30% voltage sag injected during 0.2 to 0.4 s. MSRF-PLL shows peak overshoot of 51.782 Hz at 0.201 s and settles down at 0.23 s while FO-LPFO-PI MSRF-PLL gives the smallest frequency overshoot of 50.28 Hz and the best performance.

Figure 11B performs the comparison of predicted frequencies under 40% voltage swell during 0.2 to 0.4 s. MSRF-PLL shows the highest frequency overshoot of 53.42 Hz at 0.232 s and settles down at 0.23 s while FO-LPFO-PI MSRF-PLL gives smallest frequency overshoot of 50.6 Hz at 0.203 s and its settling time is 0.22 s.

FO-LP MSRF-PLL has frequency overshoot of 51.8 Hz at 0.204 s settling at 0.25 s. Thus, it is observed that performance of FO-LPFO-PI MSRF-PLL surpasses that of FO-LP MSRF-PLL under swell condition.

Figure 11C predicts the comparison of frequencies under polluted input supply during 0.2 to 0.4 s. MSRF-PLL shows the largest oscillation in the tracked frequency among the three PLLs due to the presence of harmonics. The

FIGURE 10 (i) Simulated and (ii) experimental dynamic performance of FO-LPFO-PI MSRF-PLL under (a) 15% voltage sag, (b) 15% voltage swell, (c) polluted voltage, (d) 15° phase jump, (e) + 5 Hz frequency jump. And (f) 10% dc offset.

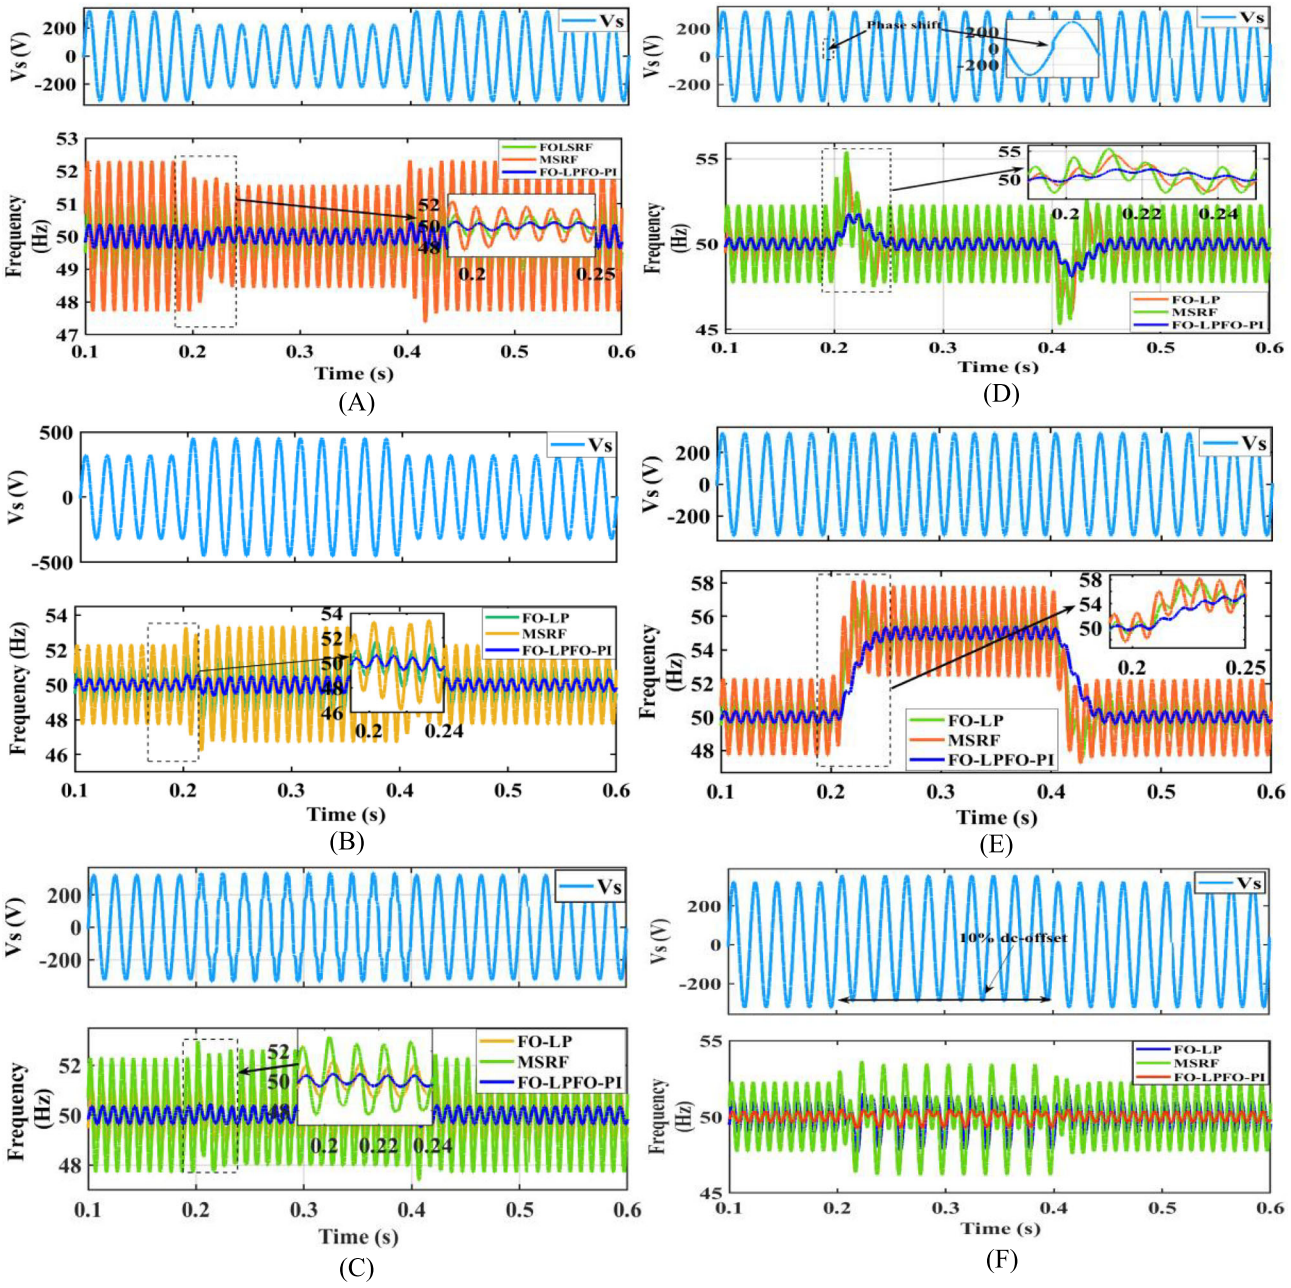

FIGURE 11 Simulated comparative analysis of MSRF-PLL, FO-LPMSRF-PLL, and FO-LPFO-PIMSRF PLL algorithms under (A) 15% voltage sag, (B) 15% voltage swell, (C) figure polluted voltage, (D) 15° phase jumps, (E) + 5 Hz frequency jump, and (F) 10% dc offset.

FO-LPFO-PI MSRF-PLL shows better performance with lower oscillations than FO-LP MSRF-PLL and MSRF-PLL under polluted grid.

Figure 11D predicts the comparison under 15° phase shift in input voltage at 0.2 s. MSRF-PLL shows the highest frequency overshoot of 55.42 Hz at 0.212 s which settles at 0.251 s while FO-LPFO-PI MSRF-PLL gives the smallest frequency overshoot of 51.95 Hz at 0.252 s, and the settling time is 0.22 s. FO-LP MSRF-PLL shows a frequency overshoot of 51.8 Hz at 0.204 s which settles at 0.26 s and shows moderate performance.

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4161 by Delhi Technological University, Wiley Online Library on [22/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 11E shows the comparison under + 5 Hz step frequency shift in input voltage at 0.2 s. MSRF-PLL shows the highest frequency overshoot of 58 Hz at 0.22 s which settles at 0.251 s, while FO-LPFO-PI MSRF-PLL gives the smallest frequency overshoot of 51.95 Hz at 0.252 s, and it settles down at 0.22 s. FO-LP MSRF-PLL shows lowest frequency overshoot of 51.8 Hz at 0.204 s, and it settles down at 0.26 s.

The transient performance is now tested experimentally under various abnormal grid conditions to validate the simulated performance analysis of MSRF-PLL and FO-LP MSRF-PLL. Figure 12 gives the comparison of experimental results under (a) 15% voltage sag, (b) 15% voltage swell, (c) polluted grid voltage, (d) 15° phase jump, (e) + 5 Hz frequency step change, and (f) 10% dc offset. The frequency errors of the integral model of MSRF-PLL, proposed FO-LP MSRF-PLL, and proposed FO-LPFO-PI MSRF-PLL are tracked for comparing performance under grid abnormalities. In all the conditions given in (a) to (f), it is observed that the proposed FO-LPFO-PI MSRF-PLL shows minimum frequency error oscillation which is much lower than that obtained with integer order MSRF-PLL and other proposed fractional FO-LP MSRF-PLL. Hence, the conclusive comparative performance analysis of the three PLLs is shown in Table 5. In this table, the frequency overshoot and settling time for integer order PLL and the proposed FO PLLs are indicated under different grid conditions.

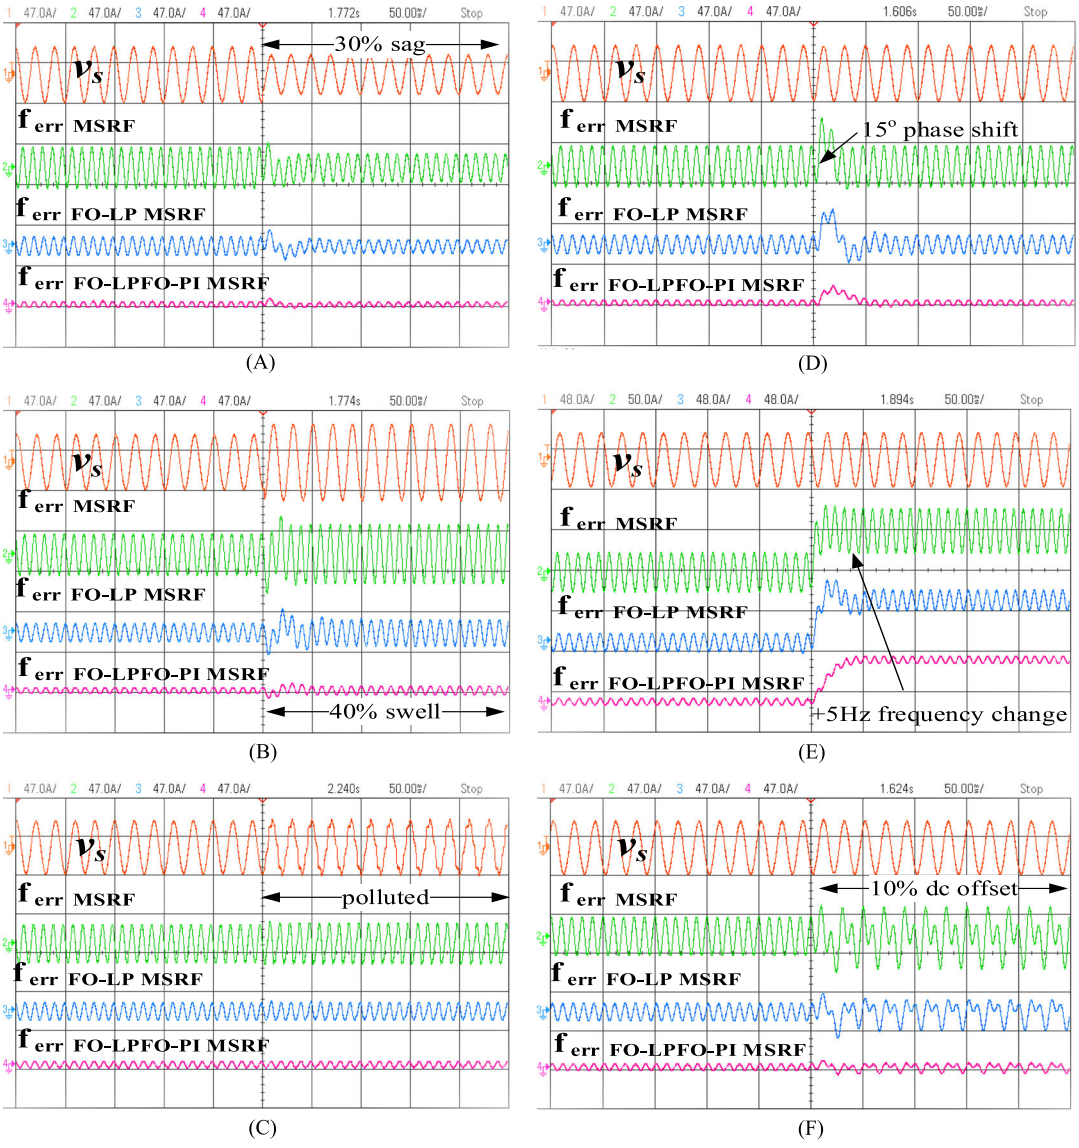

FIGURE 12 Experimental comparative analysis of MSRF-PLL, FO-LP MSRF-PLL, and FO-LPFO-PI MSRF-PLL under various abnormal grid conditions: (A) 15% voltage sag, (B) 15% voltage swell (C) polluted voltage, (D) 15° phase jump, (E) + 5 Hz frequency step change, and (F) 10% dc offset.

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4161 by Delhi Technological University, Wiley Online Library on [22/07/2024]. FIGURE 13 (A) Simulated and (B) experimental comparative analysis of MSRF-PLL, FO-LP MSRF-PLL, and FO- LPFO-PI MSRF-PLL under + 5 Hz frequency change.

Figure 13A,B shows the comparative simulation and experimental analysis of MSRF-PLL, FO-LP MSRF-PLL, and FO-LPFO-PI MSRF-PLL under + 5 Hz step change of grid frequency. Hence from Figure 13, it is clearly seen that FO-LP-FO-PI MSRF-PLL gives the best performance among the three PLLs with minimum overshoot and better settling time. The integer-order MSRF-PLL gives the highest overshoot among the three PLLs. The proposed fractional-order PLL (FO-LP MSRF-PLL) has lesser overshoot than MSRF-PLL but it is higher than that of FO-LPFO-PI MSRF-PLL.

5 | CONCLUSION

In the proposed article, the mathematical modeling of three PLLs, viz., integral order MSRF-PLL, fractional FO-LP MSRF-PLL with one FO capacitor a, and FO-LPFO-PI MSRF-PLL with two FO capacitors with both a and b coefficients is discussed. The three PLLs are designed and developed with their open-loop, closed-loop, and error-loop transfer functions. The open-loop and closed-loop Bode diagrams of FO-LP MSRF-PLL and FO-LPFO-PI MSRF-PLL are plotted to predict optimum values of a and b considering PLL stability. The Bode diagrams of FO-LPFO-PI MSRF-PLL are plotted for various values of a at fixed b as 1 along with various values of b for fixed a as 1. The Bode diagrams help to optimize the fractional parameters a and b. The selected optimized values of the real FO coefficients with $a = 1.1$ and $b = 0.1$ are chosen for the proposed FO-LP MSRF-PLL and FO-LPFO-PI MSRF-PLL.

The transient performance analysis for the conventional integral-order MSRF-PLL and proposed FO-LP MSRF-PLL and FO-LPFO-PI is performed under different grid abnormalities like voltage sag and swell, polluted voltage, phase shift, frequency change, and dc offset supply voltage. Both the simulated and experimental comparative analyses are performed rigorously. The comparative results predict that among the two proposed fractional PLLs, the FO-LPFO-PI MSRF-PLL with two FO parameters a and b gives the best performance results during grid abnormalities. Further, this PLL is more stable as compared with FO-LP MSRF-PLL after optimizing the values of a and b parameters.

Abstract This study investigated the growth of *Euphorbia tithymaloides* L. in soil contaminated with Cr (VI), focusing on plant development, Cr (VI) accumulation in the plant, and associated rhizosphere bacterial communities. Plants were cultivated in pots for a period of 123 days with varying Cr (VI) levels (0, 10, 20, 30, and 40 mg-kg^{-1}) in the soil. As Cr (VI) concentration increased, plant growth indicators such as fresh weight, dry weight, root length, and shoot length were observed to be decreasing. The Cr (VI) concentration peaked in plant tissues under the 40 mg-kg^{-1} treatment, with concentrations of 397.5 mg-kg^{-1}, 98.12 mg-kg^{-1}, and 62.32 mg-kg^{-1} in roots, stems, and leaves respectively. Whereas, the total Cr (VI) accumulation was maximum in the 30 mg-kg^{-1} treatment due to higher plant biomass. Further, the phytoremediation efficiency of the plant was evaluated through the bio-concentration factor (BCF) and translocation factor (TF). The BCF indicated soil-to-plant heavy metal uptake capacity exceeding 1, while the TF showed root-to-shoot translocation below 1 for all treatments, implying effective phytostabilisation potential. Metagenomic analysis of rhizospheric soil highlighted dominant bacterial phyla of Firmicutes, Proteobacteria, Bacteroidetes, Actinobacteria, and Acidobacteria. Many observed bacterial taxa are metal-tolerant and commonly found in heavy metal-contaminated soil, suggesting a potential contribution to mitigating metal toxicity and enhancing plant growth. However, a comprehensive investigation into microbial communities' roles during phytoremediation requires further in-depth research.

Keywords Phytoremediation · Chromium (VI) · Soil Contamination · Rhizosphere · Microbial Community · Metagenomic Analysis

Highlights
- The response of *E. tithymaloides* to different levels of Cr (VI) contamination in soil was evaluated through a pot experiment.
- Up to the Cr (VI) concentration of 30 mg-kg^{-1}, *E. tithymaloides* exhibited no significant toxicity to plant health.
- Cr (VI) uptake in plants increased with an increase in concentration.
- BCF was found to be > 1 under all treatments while TF remained < 1, indicating the phytostabilisation potential of the plant.
- Metagenomic analysis of rhizospheric soil highlighted dominant bacterial phyla of Firmicutes, Proteobacteria, Bacteroidetes, Actinobacteria, and Acidobacteria.

1 Introduction

Chromium (Cr) is one of the toxic heavy metals which has adverse effects on the environment and health. It enters the environment through various natural and

Published online: 10 July 2024

anthropogenic sources but the release of Cr from man-made activities remains a dominant source because of industrial and mining activities (Wu et al., 2016). Cr has found wide applicability in different industries, including chrome plating, petroleum refining, electroplating, leather tanning, textile manufacturing, wood preservation, production of paints and pigments, etc. (Ramana et al., 2015a, b). These activities inescapably contribute to environmental pollution through the discharge of industrial effluents into water bodies, the lack of management of solid wastes released during the mining process, and the emission of dust into the atmosphere (Karaca et al., 2018). Cr can exist in various oxidation states from 2 to+6 but Cr^{3+} and Cr^{6+} are generally found in the environment (Taneja et al., 2023). The dominantly present Cr (VI) is a strong epithelial irritant and has been categorised as a "group I" or "known" human carcinogen (IARC, 1990), and it is toxic to many plants, aquatic animals, and bacteria (U.S. EPA, 1984). Contrarily, Cr (III) is usually benign and even known to be an essential trace element and cofactor for many enzymes (Ashraf et al., 2019). Both the states are interconvertible in the environment under prevalent conditions, for example, in aerobic conditions Cr exists as Cr (VI) whereas under anaerobic conditions soil organic matter converts Cr (VI) into Cr (III) (Ashraf et al., 2019). Also, Cr (III) is found to be tightly bound with soil particles and forms precipitate with extremely low solubility, which hinders its leaching into groundwater or its absorption by plants, whereas Cr(VI) is highly active and soluble in soil solution (Xia et al., 2019). Therefore, restoration of Cr (VI)-contaminated soils has become very important, and considerable efforts have been made in the past for the development of suitable remediation techniques. Treatment of Cr-contaminated soil could be carried out using various conventional technologies such as soil replacement (Rajendran et al., 2022), immobilization (Vasarevicius et al., 2020), vitrification (ur Rehman et al., 2023), soil washing/flushing (Alaboudi et al., 2020), chemical leaching (Song et al., 2022), electrokinetic remediation (Taneja et al., 2022) and ion-exchange (Qayyum et al., 2020). However, these techniques are prohibitive with respect to time, cost, and production of secondary pollutants (Karaca et al., 2018).

Phytoremediation is an evolving technology that can be considered for the treatment of contaminated soils due to its advantages of being efficient, economical, eco-friendly, aesthetic, and sustainable in nature (Farooq et al., 2020; Zulkernain et al., 2023). This technique uses the remarkable ability of plants to uptake heavy metals from soil (Raj et al., 2020). Phytoremediation stands out as a better option for Cr remediation, particularly when compared to previous technologies. Unlike costly and impractical methods used in the past, phytoremediation offers a cost-effective, scalable solution suitable for larger contaminated areas. Its eco-friendly approach not only minimizes the risk of generating additional pollutants but also requires minimal maintenance and energy inputs once established. Additionally, it does not require the excavation of contaminated sites and offers an *in-situ* remediation. Further, unlike previous physicochemical technologies phytoremediation improves the soil characteristics, fertility, flora and fauna. Among all the processes in phytoremediation, phytoextraction, and phytostabilisation are the most acceptable for the removal of heavy metals from the contaminated soil. The main difference between the two is that phytoextraction uses hyperaccumulator plants to concentrate the contaminants from the soil into their shoots or aboveground biomass (Suman et al., 2018), whereas, in phytostabilisation, the plant reduces the mobility and bioavailability of contaminants (Awa & Hadibarata, 2020). Previously, many plant species have been used for phytoremediation but very few are termed hyperaccumulators as a smaller number of plants exhibited strong tolerance to pollutants along with the ability to transfer contaminants from roots to shoots (Huang et al., 2020). Hyperaccumulators have a 100-fold higher capacity to accumulate heavy metals than generally occurring plants. Additionally, these plants have a translocation factor (TF) greater than 1 (Rezapour et al., 2019). However, the applicability of hyperaccumulators is limited in practice due to their long growth period and low biomass (Farooq et al., 2020). On the other hand, ornamental plants offer an alternative proposition for the treatment of heavy metal-polluted soil due to their rapid growth, higher biomass, high metal tolerance, and non-edible nature (Sehrawat et al., 2021; Zeng et al., 2018). Additionally, these plants may provide economic benefits and improve the aesthetic values of the contaminated site (Mahmood-Ul-Hassan et al., 2020).

Many researchers have studied the feasibility of remediation of Cr-contaminated soils using ornamental plants such as *Polianthes tuberosa* L. (Ramana et al., 2012), *Mirabilis jalapa* L., *Impatiens balsamina* L. and *Tagetes erecta* L. (Miao & Yan, 2013),

Euphorbia mili (Ramana et al., 2015a, b) and *Vinca rosea* L. (Ehsan et al., 2016), etc. Most of the studies report ornamental plants which are seasonal with a short life cycle, therefore, representing lower overall removal efficiency compared to perennially growing ornamental plants. *Euphorbia tithymaloides* L. is an ornamental perennial plant. It is native to tropical and subtropical, North America and Central America, and some areas of South Asia. It is a shrub with zigzag branches and is generally used as an ornamental plant for fencing. It can remove metals from soil throughout the year and since its growth cycle is short, and it can be regularly harvested to export the accumulated 'Cr' out of the phytoremediation system. In addition, the plant is not being used as food for animals or humans, it overcomes the risk of subsequent contamination of food chain. Considering, these environmental benefits, *E. tithymaloides* could be a potential agent for the removal of Cr from contaminated soil.

The rhizospheric bacterial community is another important factor in promoting plant growth and facilitating nutrient availability (Li et al., 2022). The rhizosphere community includes microorganisms like root-associated free living as well as symbiotic rhizobacteria and mycorrhizal fungi. Plant–microbe interaction results in higher microbial diversity and microbial activity in the rhizosphere, even in heavy metal-contaminated soils (Glick, 2020). Previously, many microbes have been used for plant growth promotion and heavy metal immobilization (Chen et al., 2016, 2018). Plants are able to modify their root-associated microbiomes to their advantage even in heavy metal-stressed conditions and contribute significantly to the success of phytoremediation (Manoj et al., 2020). Therefore, the objective of this study was to investigate the phytoremediation of Cr (VI)-contaminated soil by *E. tithymaloides*, and to evaluate the composition of the rhizospheric bacterial community by the 16S rRNA metagenome sequencing method. It is expected that this study will provide information about the phytoremediation potential of *E. tithymaloides* as well as increase our understanding of the *E. tithymaloides*-chromium-soil microbial interactions.

The novelty of the study lies in its exploration of Cr (VI) phytoremediation using ornamental plants, a field that has seen limited attention compared to research focusing on food crops, grasses, and energy crops. Previous studies have primarily overlooked the potential of ornamental plants in remediating Cr-contaminated soil. Specifically, the utilization of *E. tithymaloides* for heavy metal remediation purposes is unprecedented in existing literature. So, this study is the first of its kind to investigate how well *E. tithymaloides* can clean up soil contaminated with Cr (VI).

2 Materials and Methods

2.1 Preparation of Soil and Plant Material

The experiments were carried out in the natural open environment in Delhi, India. The soil samples were collected from a depth of 0–15 cm from the horticulture plots located in the campus of Delhi Technological University, Delhi. Since the site is located in the outskirts of Delhi with minimum/negligible level of contamination of soil by any source. The same was confirmed by analysis of Cr in collected soil samples using atomic absorption spectroscopy (AAS) (Analytik Jena novAA 350 model). After air drying the soil and sieving through the 2 mm sieve, the samples were analyzed for various physicochemical parameters e.g., soil texture (ASTM, 2007), pH, electrical conductivity (EC), total dissolved solids (TDS) (ASTM, 2019), soil organic carbon (SOC) (ASTM, 2014), phosphorus (P) (Bray & Kurtz, 1945), total Kjeldahl nitrogen (TKN) (Blake, 1965), sodium (Na), potassium (K), calcium (Ca), lithium (Li) (APHA, 1992) and Cr (VI) (USEPA, 7196A) (Table 1).

The soil was spiked with a solution of analytical grade $K_2Cr_2O_7$ to prepare five Cr (VI) treatments of 0, 10, 20, 30, and 40 mg-kg^{-1} (T0-T4 treatments). Spiked soil was then allowed to equilibrate for one month with four wetting and drying cycles and intermittent mixing during each cycle. The spiked soil was filled into plastic pots (the bottom diameter: 14.5 cm, top diameter: 19 cm, and height: 17 cm) with 3 kg weight of soil per pot. After that, saplings of *E. tithymaloides* were transplanted into pots keeping three saplings in each pot, and tap water having inborn Cr concentration below the detectable limit (< 0.02 mg/l) was used for watering the plants to avoid any external addition of Cr (VI) during the experiments. In addition, soil spiked with a known concentration (10 mg-kg^{-1}) of Cr (VI) was filled into a pot and was used as a reference sample (without plant). At the end of the experimental period, 95% of Cr (VI) was recovered from the reference sample of soil. The experiment was performed under natural light, no fertilizer was added during the entire period, and tap water was

used for watering the plants @ 200 ml/pot/day. At the end of the analysis, the values of Cr (VI) obtained for soil were corrected against the percent recovery of the reference soil sample.

2.2 Determination of Chlorophyll Content, Growth Parameters, and Cr (VI) Content of Plant

Chlorophyll content in leaves was measured according to Arnon (1949). The weighed fresh leaves were ground well in 80% acetone, and the extract was centrifuged to get a clear solution. A UV–Vis spectrophotometer (LABTRONICS, Model LT-290) was used to determine the absorbance of extracts at wavelengths of 645 and 663 nm. The concentrations of chlorophyll a, chlorophyll b, and total chlorophyll were calculated using the formula suggested by Arnon (1949).

As the plants reached stability in terms of physical growth and completed almost a life-cycle (123 days), the plants were harvested for further investigation. Their roots were removed carefully from the soil and washed several times under running tap water followed by distilled water to remove all the dirt. The root and shoot lengths of all the plants were measured using a metric ruler. The plants were divided into roots, stems, and leaves and oven-dried at 80℃ for 72 h to get a constant weight. The fresh and dry weights of all parts of the plant were also measured and recorded before and after oven drying, respectively.

For extraction of Cr (VI), oven-dried plant samples were ground into a fine powder and thermally oxidised in a muffle furnace at 500℃ temperature for one hour. After that, samples were transferred into the conical flasks and mixed with water in a ratio of 1:10. The mixtures were shaken for two hours in an incubator shaker and then centrifuged at 5000 rpm for 5 min to get a clear extract. Finally, the extracts were analysed for Cr (VI) content in plants by the spectrophotometric method (USEPA, 7196 A). The diphenylcarbazide (DPC) in an acidic medium brings about the reduction of Cr (VI) to Cr3+, and DPC gets oxidised to diphenylcarbazone. The Cr3+-diphenylcarbazone complex formed in this process imparts reddish-violet colour to the solution. The absorbance of the colour solution was measured at 540 nm. The concentration of heavy metal in different plant parts was expressed as mg-kg-1 on a dry weight basis.

2.3 Estimation of Phytoremediation Efficiency

The phytoremediation efficiency of plants was estimated using the BCF, TF, translocation efficiency (TE%), and total heavy metal accumulation rate of plants. The Cr (VI)-tolerance of plant species was evaluated using the tolerance index (TI).

The BCF was described as (Deepika & Haritash, 2023a).

$$BCF = \frac{metal\ concentration\ in\ the\ plant\ (mg/kg)}{metal\ concentration\ in\ the\ soil\ (mg/kg)} \quad (1)$$

The TF showed the ability of plants to translocate heavy metals from the roots to the shoots and was calculated as (Deepika & Haritash, 2023a):

$$TF = \frac{metal\ concentration\ in\ the\ shoot\ (mg/kg)}{metal\ concentration\ in\ the\ root\ (mg/kg)} \quad (2)$$

TE (%) was estimated by using the formula suggested by Meers et al. (2004).

$$TE(\%) = \frac{metal\ content\ in\ the\ shoots\ (mg/kg)}{metal\ content\ in\ the\ whole\ plant\ (mg/kg)} \times 100 \quad (3)$$

The removal of Cr (%) by plant was determined by the formula given (Ramana et al., 2015a, b):

$$\%\ Cr\ removal = \frac{Total\ metal\ uptake\ by\ plant}{Total\ metal\ applied\ to\ the\ soil} \times 100 \quad (4)$$

The total heavy metal accumulation rate (µg g − 1 day^{-1} DW) of plant species can be calculated as follows:

$$Total\ metal\ accumulation\ rate = \frac{DW_s \times C_s + DW_r \times C_r + DW_l \times C_l}{DW_s + DW_r + DW_l \times days\ of\ harvest} \quad (5)$$

Where, DW (g) is dry weight, C ($\mu g/g$) is the concentration of Cr (VI) and the subscript of DW or C denotes the stem (s), root (r) and leaf (l).

TI of plant was calculated by the method adopted by Patra et al. (2020).

$$TI = \frac{Root\ biomass\ of\ treatment\ plants}{Root\ biomass\ of\ control\ plants} \quad (6)$$

2.4 Bacterial Community Analysis by 16S rRNA Metagenome Sequencing

After harvesting the plant, the rhizospheric soil samples were collected from control (T0 treatment) and spiked soil (T4 treatment) to establish the difference in microbial communities. Soil samples were analysed using 16S rRNA (V3-V4) metagenome sequencing method with bioinformatics analysis at Sandor Speciality Diagnostics Pvt. Ltd. Hyderabad, Telangana, India.

Microbial DNA was extracted from the Cr (VI) spiked soil (40 mg-kg^{-1}) and the control soil samples (0 mg-kg^{-1}) using Qiagen Kit Method. Extracted DNA from the samples was subjected to NanoDrop and Gel Check before being taken for PCR amplification. The NanoDrop readings of 260/280 at an approximate value of 1.8 to 2 are used to determine the quality of DNA. The V3-V4 region of 16S rRNA gene was amplified by the primers 16SF (AGAGTTTGATGMTGGCTCAG3') and 16SR (5' TTACCGCGGCMGCSGGCAC3'). The amplification process was carried out using 40 ng of extracted DNA along with 10 pM of each primer by the PCR program. The amplification process was as follows: initial denaturation at 95 ^{0}C, followed by 25 cycles of denaturation at 95 ^{0}C for 15 s, annealing at 60 ^{0}C for 15 s, elongation at 72 ^{0}C for 2 min, final extension at 72 ^{0}C for 10 min and hold at 4 ^{0}C. The raw PCR products were gel-purified and quantified using the Qubit dsDNA high-sensitivity assay kit. Sequencing was performed using Illumina Miseq with 2×300PE v3 sequencing kit.

2.5 Statistical Analysis

All the experiments were performed in triplicates and the data were statistically analysed in MS Excel using the single factor ANOVA and all statistical significance were set at the level of $p < 0.05$. The data presented are means ± standard deviation.

3 Results and Discussion

3.1 Plant Growth

One of the key characteristics of the ideal plant species to be used for the remediation of heavy metal-contaminated soil is its growth performance. In the present study, plant growth has been expressed in terms of biomass (fresh and dry weight) of different plant tissues (Fig. 1) and root and shoot length (Table 2). Higher biomass is a desired parameter for plants being used for phytoremediation, so plants can accumulate more amounts of heavy metals from soil (Cay et al., 2016). Results of this study showed that the application of Cr (VI) negatively affected plant growth compared to the control. The length and biomass of roots and shoots were significantly reduced under the T4 treatment in comparison to the T0 treatment and other treatments in which the concentration of Cr (VI) was low. This implied that up to T3 treatment plant was more adaptable for remediation of Cr (VI)-contaminated soil. The results indicated that Cr (VI) was more toxic to roots than leaves as under T4 treatment, Cr (VI) decreased the dry weight of roots by 92% and leaves by 62.9% over T0 treatment. In contrast to various other heavy metals, Cr exhibits limited mobility within plant roots. As a result, the concentration of Cr within the roots can be up to 100 times greater than in shoots. Within plant structures, Cr (VI) is transformed into Cr (III), which tends to attach to cell walls, preventing the subsequent movement of Cr within the plant's tissues (Sharma et al., 2020). Further, under T1 treatment, root, and shoot length were reduced by 0.91% and 3.1%, respectively, whereas, it was reduced by 37.7% and 41.07% under T4 treatment. Adverse effects of Cr application on plant growth have been previously confirmed by various researchers (Panda et al., 2020; Patra et al., 2020; Ramana et al., 2013, 2015b). Cr (VI) severely affects the membrane (because of high oxidation power), uptake of minerals, and carbon assimilation ability of the plant (Vazquez et al., 1987; Bonet et al., 1991). Prasad et al. (2001) also confirmed that root length was more affected by Cr than other heavy metals and the reason for limited root growth could be the inhibition of root cell division by Cr toxicity.

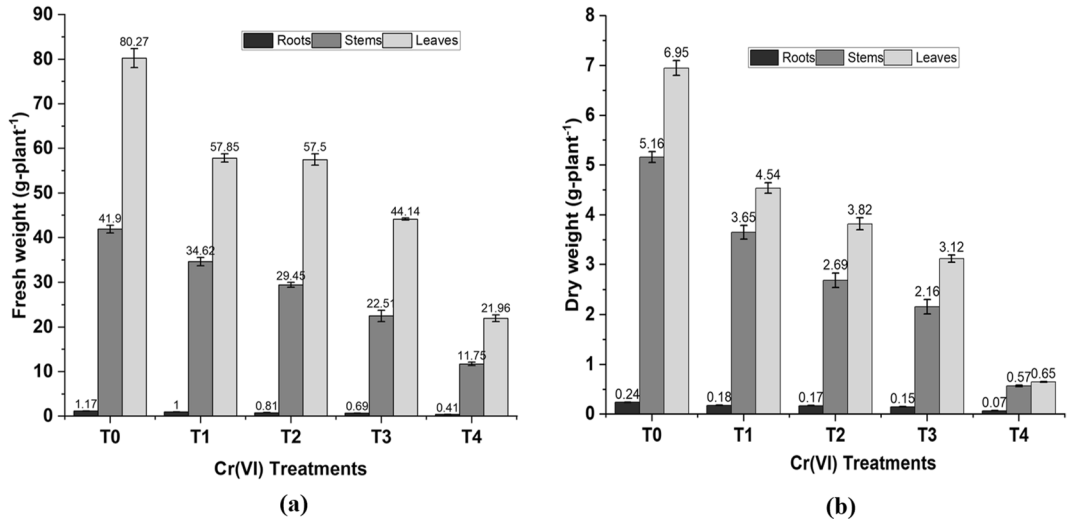

Fig. 1 Effect of Cr (VI) treatment on (**a**) fresh weight and (**b**) dry weight of plant. Mean values are given and error bars indicate standard deviation ($p < 0.05$)

Table 2 Effect of Cr (VI) treatment on root length, shoot length, and chlorophyll content

Soil Treatments	Root Length (cm-plant^{-1})	Shoot length (cm-plant^{-1})	Chl a (mg-g^{-1} FW)	Chl b (mg-g^{-1} FW)	Total Chl (mg-g^{-1} FW)
T0	8.8 ± 1.44	42.0 ± 4	0.99 ± 0.01	0.58 ± 0.05	1.6 ± 0.05
T1	8.8 ± 0.25	40.7 ± 3.21	0.98 ± 0.02	0.42 ± 0.06	1.4 ± 0.07
T2	7.9 ± 0.52	32.9 ± 3.85	0.96 ± 0.01	0.41 ± 0.01	1.4 ± 0.08
T3	7.1 ± 0.05	32.5 ± 2.5	0.95 ± 0.03	0.4 ± 0.02	1.4 ± 0.01
T4	5.5 ± 0.25	24.8 ± 1.15	0.89 ± 0.04	0.36 ± 0.03	1.3 ± 0.08

3.2 Chlorophyll Content

Photosynthesis is an important process for plant growth and biomass production, and the intensity of photosynthesis can be evaluated through the photosynthetic pigment in plant leaves (Liu et al., 2015). It was observed in the present study that a lower level of Cr (VI) did not produce any significant changes in the chlorophyll content of *E. tithymaloides,* but at a higher concentration of 40 mg-kg^{-1} (T4 treatment), the total chlorophyll content of the plant showed 20% reduction compared to T0 treatment (Table 2). A decrease in Chl a, b, and total chlorophyll is a well-documented effect of Cr-stress in plants (Afshan et al., 2015). Cr interferes with the synthesis of delta-aminolevulinic acid (ALA), which is the first step in the biosynthesis of tetrapyrrole leading to the synthesis of heme (Vajpayee et al., 2000). The biosynthesis of chlorophyll might be controlled not only by ALA synthesis, but also by delta-aminolevulinic acid dehydratase (ALAD) activity (Naito et al., 1980). Reduction of chlorophyll content due to altered ALAD activity has been reported in many terrestrial plants (Panda et al., 2020).

3.3 Partitioning of Cr (VI) and Estimation of Phytoremediation Efficiency

While assessing the capacity of plants to treat heavy metal-contaminated soil, it is important to determine the partitioning of heavy metals in the different plant tissues. The Cr (VI) concentration and total accumulation by *E. tithymaloides* are represented in Figs. 2 and 3, respectively. Generally, Cr (VI) concentration

increased in all tissues with an increase in Cr (VI) in soil, and the highest Cr (VI) concentration was found under T4 treatment in all three tissues *i.e.,* roots, stems, and leaves. The results on the partitioning of Cr (VI) showed that roots accumulated higher concentrations of Cr (VI) than stems and leaves indicating the poor translocation of heavy metal within the plant. One of the reasons for a higher concentration of Cr in the roots could be due to the immobilization of Cr in the vacuoles of root cells to render it non-toxic, which may be a natural response of plants (Shankar et al., 2004). Cr (VI) concentration in the roots was around 3 times higher than the stems and leaves together. The Cr (VI) in roots increased consistently from 211 mg-kg^{-1} in T1 treatment to 397.5 mg-kg^{-1} in T4 treatment. Similarly, the concentration of Cr (VI) in stems and leaves also increased uniformly with the increase of Cr (VI) concentration in soil (Fig. 2). These observations were in accord with the previous findings (Ramana et al., 2015a; Subhashini & Swamy, 2013). Lower transport of Cr to aboveground biomass has also been reported in tuberose and some other floriculture plant species such as chrysanthemum, Aster, Dahlia, and Calendula (Ramana et al., 2012, 2013). Further, the total accumulation of Cr (VI) in different tissues of plants was also calculated by multiplying the Cr (VI) concentration in the plant tissue with the respective dry weight and

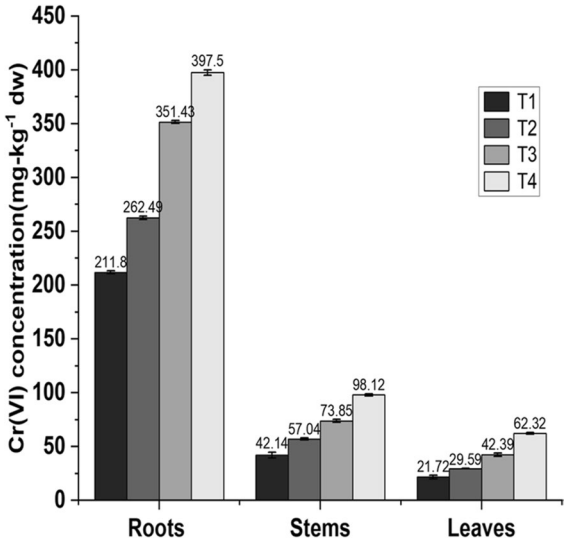

Fig. 2 Cr (VI) concentration in different tissues of *E. tithymaloides*

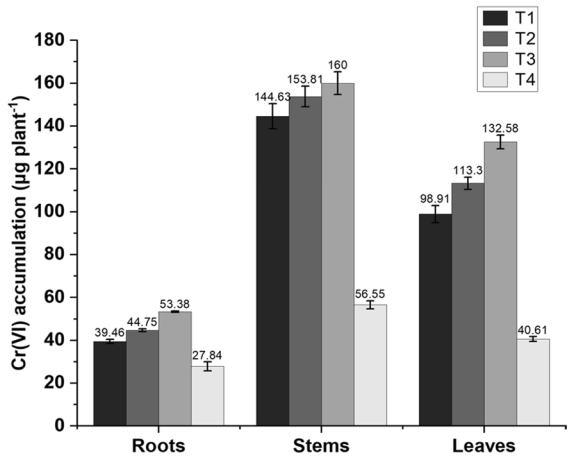

Fig. 3 Total Cr (VI) accumulation by *E. tithymaloides*

expressed as µg-plant^{-1}. The total accumulation of Cr (VI) by plant tissues was lowest under T4 treatment due to the significant reduction in plant biomass. Cr (VI) accumulation was found to be highest under T3 treatment reaching 53.38 µg-plant^{-1}, 160 µg-plant^{-1}, and 132.58 µg-plant^{-1} in roots, stems, and leaves, respectively. These results suggested that the concentration of Cr (VI) under T3 treatment was compliant with the remediation of soil by *E. tithymaloides.*

The phytoremediation efficiency of *E. tithymaloides* was evaluated through BCF, TF, TE, Cr removal (%) by plant, total heavy metal accumulation rate, and TI, which are given below (Table 3). The BCF and the TF are two essential indices for determining if a plant is suitable for phytoextraction or phytostabilization programs. BCF is an index of the ability of a plant to accumulate metal with respect to its concentration in soil and TF is an indication of the ability of a plant to translocate metal from roots to its aboveground tissues. Plants with both a high BCF and a high translocation factor (BCF and TF > 1) can be employed in phytoextraction. Additionally, plants with BCF greater than 1 but TF less than 1 (BCF > 1 and TF < 1) have the potential for phytostabilisation (Deepika & Haritash, 2023b). In the present study, data indicated that Cr accumulated by *E. tithymaloides* was largely retained in roots, as shown by TF < 1, whereas BCF was found to be > 1 across all the treatments. The BCF value was found to be 27.5 for T1 treatment and 13.9 for T4 treatment indicating the reduction in BCF values with an increase in Cr (VI) exposure concentration. Previous studies have also confirmed that BCF decreases with increasing

Table 3 Phytoremediation efficiency measures ($p < 0.05$)

Soil Treatments	BCF $_{(Whole\ plant)}$	TF	TE (%)	% Cr removal by plant	Total metal accumulation rate (μg g − 1 day^{-1} DW)	TI

soil heavy metal concentration (Budak et al., 2011; Farooq et al., 2020; Panda et al., 2020). However, the BCF value of *E. tithymaloides* is higher than the other reported studies for ornamental plants grown in Cr-contaminated soil. For example, the highest BCF value of *Euphorbia mili* was found to be 8.46 at 75 mg-kg^{-1} Cr concentration in soil (Ramana et al., 2015a). Similarly, the BCF of *Furcraea gigantea Vent.* was 5.83 for 100 mg-kg^{-1} of Cr in soil (Ramana et al., 2015b).

Further, the TF of *E. tithymaloides* was observed to be < 1, indicating the restricted movement of Cr (VI) to shoots from roots. However, a linear increase (0.3 in T1 treatment to 0.4 in T4 treatment) was observed in TF values in *E. tithymaloides.* Poor translocation of Cr from roots to shoots has been confirmed by other researchers also (Budak et al., 2011; Erenoglu et al., 2007; Patra et al., 2020). In addition, data on TE (%) (Table 3) also showed that the plant was not very efficient in translocating the Cr. Further, the fraction of Cr (VI) removed by *E. tithymaloides* was 7.7% under the T1 treatment and decreased to 0.60% in the T4 treatment. The fraction of Cr (VI) removal under T4 treatment is similar to *Euphorbia mili* (0.6%), a plant of the *Euphorbiaceae* family which has been used for phytoremediation of Cr-contaminated soil (Ramana et al., 2015a). The TI of Cr (VI), which was used to compare the endurance of plants under Cr (VI) stress conditions, gradually decreased with an increase in soil Cr (VI) concentration. Under T1 treatment, TI was 67.89% and then decreased to 54.16%, 44.03%, and 10.22% respectively, under T2, T3, and T4 treatment. A sharp decrease in the TI after T3 treatment implied that the plant could not grow well at higher Cr (VI) concentrations.

3.4 Rhizospheric Bacterial Community

Soil micro-organisms play an important role in the soil–plant system and can affect the phytoremediation of soil contaminants like heavy metals/metalloids by influencing the bioavailability of heavy metals (Nurzhanova et al., 2021). Microbes also help in plant growth and increase plant resistance to heavy metal stress (Tripathi et al., 2020). Compared to bulk soil microbes, rhizosphere microbes are directly involved in providing nutrient elements to plants and are influenced by the release of phytochemicals such as root exudates (Novo et al., 2018). Plants secrete organic compounds that support microbial activity, which tend to provide a beneficial effect on plants (Turner et al., 2013). The enrichment of a beneficial microbial community might be a strategy that enables the plant to survive in toxic environments such as mining-polluted areas (Lin et al., 2021). Therefore, to understand the behaviour of *E. tithymaloides* under a heavy metal-stressed condition, a detailed metagenomic analysis of the rhizosphere bacterial community has been done in the present study.

The 16S rRNA gene sequencing generated 732 valid sequences which could be clustered into 27 phyla, 51 classes, 109 orders, 169 families, and 340 genera. Of these phyla, 5 were considered to be the most dominant in both the soil samples (T0 and T4 treatment), as illustrated in Fig. 4. These phyla included Firmicutes, Proteobacteria, Bacteroidetes, Actinobacteria, and Acidobacteria, accounting for more than 95% of the classified sequences in the soil samples. In the present study, at the Cr (VI) spiking of 40 mg-kg-1 the order of dominant phyla remained the same. The above-mentioned dominant phyla have been reported in many other studies, however, the rank order might be different. For example, Proteobacteria (27.3%), Chloroflexi (25.9%), Actinobacteria (16.1%), Acidobacteria (13.1%), and Bacteroidetes (7.7%) were the dominant bacterial phyla in the rhizosphere of *Sedum alfredii* Hance grown in multiple heavy metal-contaminated soils (Hou et al., 2017). Similarly, Proteobacteria, Actinobacteria, and Bacteroidetes were found to be the predominant taxa,

when *Brassica juncea* was grown in heavy metal-contaminated mining soil. These taxa were reported to significantly enhance the metal bioavailability and mobilization in soil, therefore, enhancing the metal uptake in plant (Deng et al., 2021; Jeyasundar et al., 2021). Further, the relative proportion and abundance of microbial community is strongly related to the soil properties such as soil texture, pH, organic matter and heavy metal concentration (Xiao et al., 2022). A study by Jiang et al., (2019) confirmed that soils having clay percentage lower than 52% showed high abundance of Firmicutes (54.4%), followed by Proteobacteria (13.2%), and Chloroflexi (8%), whereas when clay percentage were higher than 52%, the dominant bacterial phyla were Actinobacteria (20.3%), Proteobacteria (18.6%), and Firmicutes (16.9%). Proteobacteria, Firmicutes, and Acidobacteria were the most influenced phyla by the soil texture, organic carbon and heavy metal contents in the aforementioned study.

In the present study, Firmicutes was the dominant phylum in both soil samples. The tolerance of Firmicutes to dry environmental conditions might be the reason for its abundance in the soil samples in the present study (Chodak et al., 2015). Also, the lower clay content of the soil (as discussed above) might be another reason for its abundance. Furthermore, the abundance of Firmicutes increased significantly in spiked soil (T4 treatment). These results are in accordance with many previous reports such as on an arsenic-contaminated region (Xiao et al., 2022), an abandoned mine site of rare earth elements (Wei et al., 2019), and an e-waste site in Nigeria (Jiang et al., 2019). Liu et al. (2018) confirmed that Firmicutes are found in abundance in heavy metal-contaminated soil and exhibit strong tolerance to heavy metals. In addition, studies reported that Firmicutes might be important for reducing heavy metal toxicity in soil (Burkhardt et al., 2011). Another phylum that showed a positive correlation with Cr (VI) was Actinobacteria. These results are in agreement with many previous reports which have indicated that Actinobacteria are frequently associated with heavy metal-contaminated environments, most probably due to their high metal tolerance (He et al., 2021; Jiang et al., 2016; Pires et al., 2017). These bacteria are able to promote plant growth by producing bioactive compounds (Alvarez et al., 2017). Some more beneficial features of Actinobacteria and other dominant phyla of the present study are listed in Table 4.

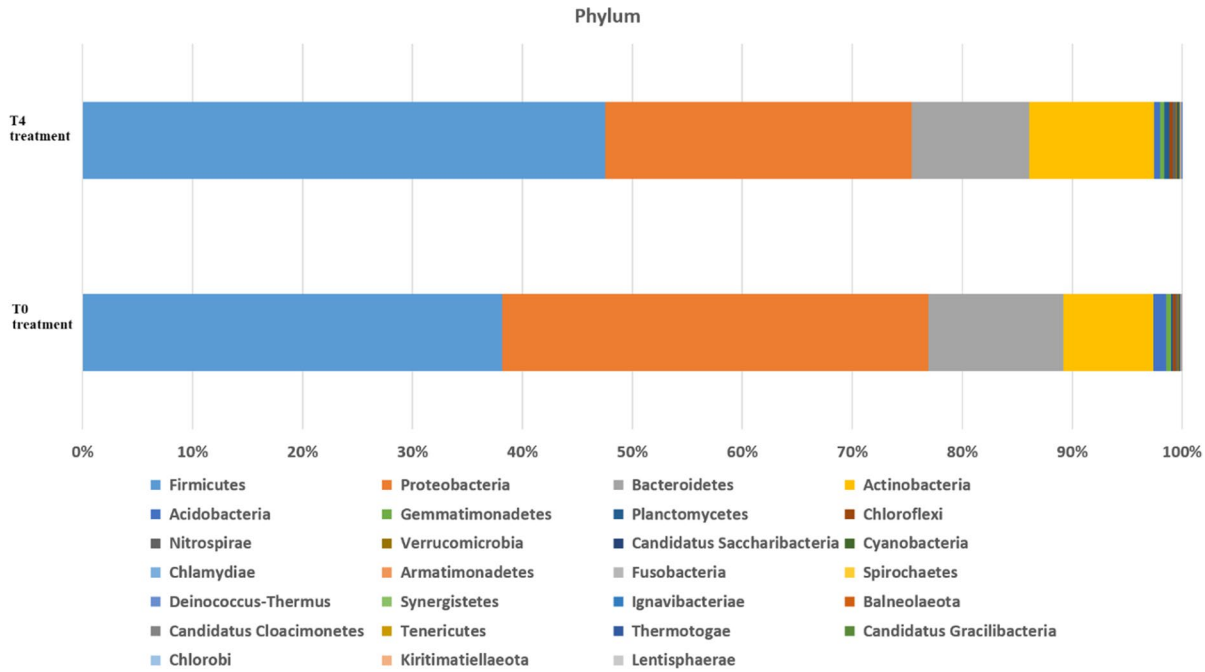

Fig. 4 Relative abundance of dominant bacterial phyla in T4 and T0 soil treatments

Phylum Proteobacteria is reported to be one of the most resistant phyla to heavy metal contamination such as cadmium (Cd), zinc (Zn), arsenic (As), copper (Cu), lead (Pb), and can be found in many mining areas (Chen et al., 2018; Ma et al., 2015; Narendrula-Kotha & Nkongolo, 2017; Yan et al., 2016). Likewise, Acidobacteria has been reported to be predominant in heavy metal-contaminated soil (Ward et al., 2009; Briceño et al., 2012). These are acidophilic in nature and ubiquitous in various ecosystems although these are reported to be abundant in high-nutrient soil (Wei et al., 2019). In the present study, it has been reported that Firmicutes, Proteobacteria, Bacteroidetes, and Acidobacteria are found relatively more (in the category of top 10 phylum); but Proteobacteria and Acidobacteria were slightly more in percentage compared to the spiked soil (40 mg-kg^{-1}), although the difference is very little. The difference may be ascribed to several factors (edaphic, biological, and chemical) which regulate bacterial diversity. Since there is no toxicity of Cr (VI) in control, a slightly higher fraction of Acidobacteria and Proteobacteria might be observed. Further, Bacteroidetes had no significant difference in both soil samples. Bacteroidetes have been found in heavy metal-polluted soil (Haller et al., 2011; Ma et al., 2015), and due to their presence at metal-contaminated and uncontaminated sites, researchers indicated that this phylum may possess metal-resistant properties (Ni et al., 2016). Wang et al. (2018) reported that Proteobacteria, Firmicutes, and Bacteroidetes are the important bacterial phyla that help in decreasing the toxicity of heavy metals.

At the genus level, a total of 340 genera were obtained in both the soil samples, and 228 genera were common to both soil samples, accounting for 67.1% of the total classified genera. The exclusive genera for soils with T4 treatment and T0 treatment were only 67 and 45, respectively. As shown in Fig. 5, the dominant genera were selected from each soil sample (accounting for approximately 80% of total classified genera) and their abundance was compared with each other. Among the dominant genera, the relative abundance of *Clostridium, Clostridioides, Bifidobacterium, Lactobacillus, Prevotella, Streptococcus, Megasphaera, Stenotrophomonas, Faecalitalea, Collinsella, Faecalibacterium, Weissella, Bacillus, pediococcus* and *Olsenella* was higher in soils with T4 treatment as compared to T0 treatment. However, the abundance of *Acinetobacter, Flavobacterium, Burkholderia, Sphingomonas,* and *Pseudomonas* was lower in the T4 treatment than T0 treatment. Additionally, *Janthinobacterium* was exclusively present in soil with T0 treatment. Many of

Table 4 Some beneficial features of dominant bacterial phyla of the present study

Phylum	Beneficial features
Firmicutes	-Weathering of minerals and nutrient cycling (Uroz et al., 2011) -Abundant in low-nutrient soil (Wei et al., 2019) -Participate in the degradation of macromolecular organic matter (Fan et al., 2016) -Important for ameliorating heavy metal toxicity (Burkhardt et al., 2011; Wang et al., 2018) -Inhibits soil-borne disease (Liu et al., 2018) -Resistant to drought and can survive in extreme environments (Chodak et al., 2015)
Proteobacteria	-Affect soil carbon and nitrogen cycling as well as enzymatic activities (Acosta-Martinez et al., 2010) -Most metal-tolerant and dominant bacterial groups in the mine tailings (Hamamura et al., 2013; Wei et al., 2019)
Bacteroidetes	-Indicator of soil health -Change physical and chemical characteristics of soil including soil pH and organic components in the rhizosphere (Gao et al., 2021; Wang et al., 2018) -Helps in the degradation of high-molecular-weight organic matter in the rhizosphere (Naumof & Dedysh, 2012)
Actinobacteria	-Influence pathogenic suppression and degradation of recalcitrant compounds - Heavy metal resistant due to their metabolic versatility and rapid colonization ability (Jeyasundar et al., 2021) -Promote plant growth by producing bioactive compounds (Wang et al., 2021) -Producer of many antibiotics and may enhance the plant immune system (Chen et al., 2018)
Acidobacteria	-Helps in the excretion of extracellular polymeric substances (EPS-polysaccharides and proteins) to detoxify Cr (Zhang et al., 2021) -Promotes plant hormone (indole-3-acetic acid) production and facilitates iron acquisition in the plant (Gong et al., 2021) -Disintegrators of organic matter and provides resilience in nutrient-deprived environments (Rawat et al., 2012)

the above-mentioned genus are reported to be associated with heavy metal-contaminated soil. For example, *Acinetobacter* have been frequently found in metal-polluted ecosystems (Brantner & Senko, 2014). Many strains of this genus are involved in mineral weathering, phosphate solubilization, iron chelation (Uroz et al., 2011) and degradation of contaminants (Simonsen et al., 2012). Many reports have highlighted the role of various bacterial genera in the phytoremediation of heavy metal-contaminated soil by enhancing the plant growth and metal uptake by plant. Previous reports on enhanced phytoremediation by some of the dominant genera of this study has been given in Table 5. Although, the role of some genera such as *Clostridium, Clostridioides, Bifidobacterium, Prevotella,* and *Blautia* is still unknown in the process of phytoremediation.

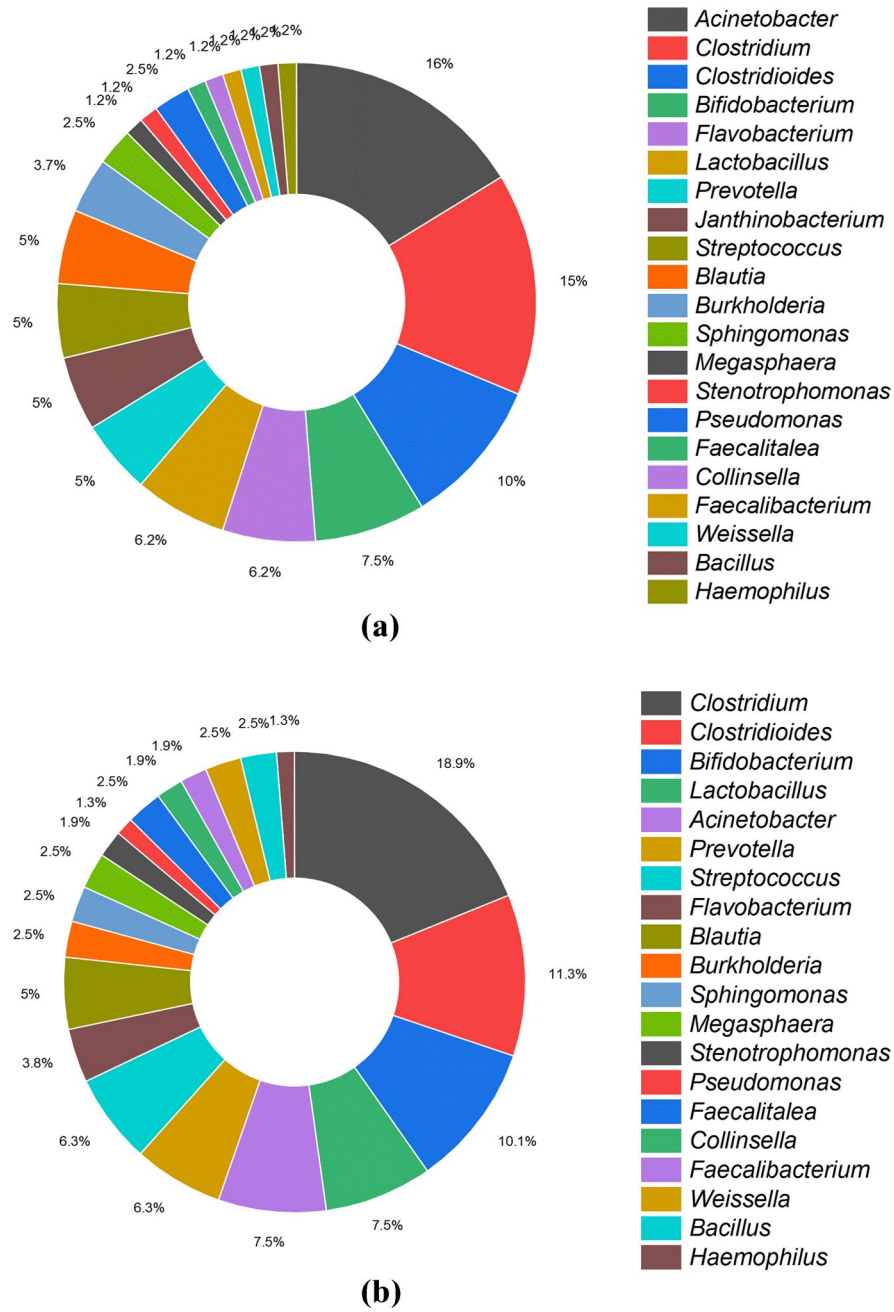

Fig. 5 Dominant genera of soils in (**a**) T0 treatment (control) and (**b**) T4 treatment (40 mg-kg-1)

Table 5 Previous reports on enhanced phytoremediation by some dominant genera of the present study

Genera	Associated plant (s)	Heavy Metal (s)	Beneficial features	Reference
Acinetobactor	*Catharanthus longifolius*	Cd	-Phosphate solubilization, ACCD activity, auxin, and siderophores production -Improved chlorophyll, soluble proteins, and sugar content -Higher metal uptake and translocation	(Yasin et al., 2019)
Flavobacterium	*Orychophragmus violaceus*	Zn	-Stimulated root elongation -Increased mobility and enhanced accumulation of Zn	(He et al., 2010)
Lactobacillus	*Brassica juncea* L	Cd & Zn	-decreased soil pH -enhanced plant growth and enzyme activity -enhanced phytoavailability of Cd and Zn	(Zhang et al., 2023)
Janthinobacterium	*Salix caprea* L	Zn, Pb & Cd	-IAA (indole acetic acid) production -showed resistant to high heavy metal concentration	(Kuffner et al., 2008)
Streptococcus	*Beta vulgaris* L	Cd, Zn & Cu	-Enhanced heavy metal tolerance and accumulation -Overproduction of GSH and phytochelatin	(Liu et al., 2015)
Burkholderia	*Catharanthus roseus* L	Cd	-Enhanced plant growth -Reduced production of MDA and H_2O_2 -ACCD activity, phosphate solubilization, auxin, and siderophore production -Enhanced the amount of water extractable Cd from soil	(Khan et al., 2018)

4 Conclusion

In conclusion, the findings of this study highlight the response of *E. tithymaloides* to different levels of Cr (VI) contamination. The results indicate that at concentration up to 30 mg-kg-1 (T3 treatment), *E. tithymaloides* exhibited significant growth, suggesting its adaptability for the remediation of Cr (VI)-contaminated soils. Phytoremediation efficiency assessment revealed that *E. tithymaloides* is not suited for phytoextraction, as it could not meet the criteria of TF value being more than 1. However, the observed BCF value exceeding 1 suggests that the plant is well-suited for phytostabilization. Further, metagenomic analysis of the rhizosphere revealed the prevalence of heavy metal-tolerant bacterial phyla, such as Firmicutes, Proteobacteria, Bacteroidetes, Actinobacteria, and Acidobacteria, in both T4 and T0 treatment soil samples. These bacterial taxa are recognized for their tolerance to heavy metals and their frequent association with metal-contaminated soils. This abundance of metal-tolerant bacterial phyla in the rhizosphere likely contributes to enhancing E. tithymaloides' tolerance under Cr (VI) stress.

Taken together, the outcomes of this study establish *E. tithymaloides* as a promising perennial ornamental plant suitable for phytostabilization of Cr (VI) contaminated soil ($\leq$30 mg-kg-1). Although several studies have reported efficient removal of Cr (VI) for concentrations up to 200 mg-kg^{-1} in contaminated soil using different species of ornamental plants, *E. tithymaloides* will be effective in Phytostabilisation of Cr (VI) up to a concentration of 30 mg-kg^{-1} without any effect on plant health. The coexistence of metal-tolerant bacterial phyla within the rhizosphere further underscores the plant's role in ameliorating metal toxicity in polluted soils. This research highlights the potential of using *E. tithymaloides* in ecological restoration efforts for Cr (VI)-contaminated environments, with implications for sustainable remediation strategies and environmental health.

Abstract
This work investigated a method for improving the efficiency of solar cells through the incorporation of carbon nanotubes (CNTs), which were used as the absorber layer of the solar cell. The CNTs were generated using plasma-enhanced chemical vapor deposition (PECVD). The use of the PECVD-generated CNTs in the absorber layer of the solar cell was found to increase the electrical conductivity due to the introduction of a large number of free charge carriers in the form of electrons and holes. We were thus able for the first time to estimate a relation between plasma variables and the efficiency of the proposed solar cell. The results showed that an increase in electron and ion density resulted in an increase in the efficiency of the solar cell, whereas an increase in electron and ion temperature led to a decrease in efficiency. We also studied the variation in efficiency in relation to the absorber layer of the proposed solar cell structure. The results obtained were consistent with those from previous studies based on solar cells.

Keywords Plasma-assisted carbon nanotubes · Solar cell efficiency · Fill factor · Quantum efficiency · Efficiency of the solar cell equipped with CNTs

Abbreviations

A	Effective area of the solar cell
R_s	Series resistance
S_e	Surface recombination velocity for electrons
N	Electron concentration
J	Current density
R_p	Recombination rate of holes
n_o	Ideality factor
R_{sh}	Shunt resistance in parallel
J_o	Reverse saturation current density
CNTs	Carbon nanotubes
R_n	Recombination rate of electrons
L	Length of CNT
R	Radius of CNT
PCE	Power conversion efficiency
T_{eo}	Electron temperature
T_{io}	Ion temperature
λ_D	Debye length
P_{in}	Solar irradiance
G_n	Generation rate of electrons
T	Absolute temperature
q	Electronic charge
n_{eo}	Electron density
S_h	Surface recombination velocity for holes
n_{io}	Ion density
N	No. of carbon nanotubes (CNTs)
η	Efficiency of solar cell
P_{out}	Power output
ITO	Indium tin oxide
V_{OC}	Open-circuit voltage
J_n	Electron current density
G_p	Generation rate of holes
AM	Air mass spectrum
J_{SC}	Photocurrent density
CB	Conduction band
K_B	Boltzmann constant
VB	Valence band
p	Hole concentration
φ	Metal work function
TCO	Transparent conductive oxide
J_p	Hole current density
QE	Quantum efficiency
V_S	Surface potential

1 Introduction

A solar cell is a photovoltaic device that converts light radiation into electrical energy [1]. It works the same way as a p–n-based photodetector. When sunlight is incident on the solar cell, the electrons in the conduction band (CB) jump to the valence band (VB), thus creating holes in the CB that facilitate the flow of current in the solar cell [2]. This electron- and hole-generated current is called photocurrent [3–7]. The photovoltaic conversion efficiency (PCE) of the solar cell has been reported up to 1–5% [1, 8], depending on the photocurrent density, fill factor (FF), input power irradiance (P_{in}), and open-circuit voltage (V_{OC}) [9]. There are various types of solar cells, including thin-film, perovskite, and dye-sensitized solar cells [2]. Perovskite-based solar cells have reported PCE up to 22.1% [10], but they are not stable under light illumination conditions. Researchers have reported that when carbon nanotubes (CNTs) are used in solar cells, an increase of 1.3% to as much as 30% in PCE has been achieved [9]. The structure of CNT-based solar cells is the same as the single p–n junction solar cell, where the CNTs can behave as both p- and n-type semiconductors [2, 10]. CNTs were first grown by the Japanese scientist Sumio Ijima in 1991 [11–13]. They are highly conductive—even higher than copper—with an extremely large surface area and high strength because of the covalent sp^2 bond between individual carbon atoms [14]. The bandgap of CNTs varies from 0.1 eV to 2 eV [14–17]. Their basic structure can be categorized into three types, i.e., armchair, zigzag, and chiral CNTs, with stability in the order armchair > zigzag > chiral [18–21]. Several kinds of solar cells with good photovoltaic properties have been developed using carbon nanotubes. We have used the plasma-enhanced chemical vapor deposition (PECVD) process for growing CNTs [22–26]. Although numerous works have investigated the use of CNTs in solar cells, no study has proposed a mathematical expression for calculating the efficiency of the solar cells based on plasma variables/parameters. In the present work, PECVD-grown CNTs were used in the absorber layer of the solar cell via simulation and a mathematical formula was devised for computing the solar cell efficiency as a function of plasma parameters including electron and ion temperature and density. With the use of CNTs, we observed an increase in the efficiency of ITO-/CdS-/CNT-based solar cells of up to 23–24%, which was similar to simulated and past research results [10]. For the simulation, we used SCAPS-1D software to construct the solar cell and calculate its efficiency. In the simulation setup, CNTs were used in the absorber layer, and the thickness of the absorber layer was varied from 100 to 1000 nm. Related variables including FF, V_{OC}, short-circuit current density (J_{SC}), PCE, and bandgap were determined. After simulation, we calculated the efficiency of the solar cell from our estimated expression, and the results were very close to the efficiency from the simulation, as shown in Fig. 11, and were also consistent with results from many previous studies [25–29, 54–70].

2 Simulation work and mathematical modeling proposed for ITO-, CdS-, and CNT-based solar cell structure

2.1 Work (1)

2.1.1 Simulation of ITO-, CdS-, and CNT-based solar cells

2.1.1.1 Solar cell simulation and incorporation of CNTs in solar cells Here, we used SCAPS-1D 3.3.10 software for the ITO-/CdS-/CNT-based solar cell simulations. In Fig. 1, CdS is illustrated in a schematic of the solar cell, acting as a buffer layer between the CNT absorber layer and the ITO window layer, with dimensions of 0.441 cm × 0.440 cm × (202 to 1102) nm, as given in Figs. 1 and 2. These fundamental components allow one to determine the electrical and photoelectric characteristics of a photovoltaic solar cell. In the proposed solar cell, the ITO and absorber layers are connected with Bi and Au material as electrical contacts [25–29].

SCAPS-1D software, which was developed by the University of Ghent, Belgium [30], can analyze the parameters of solar cells including current density, bandgap, layer thickness, quantum efficiency, fill factor, and dark saturation current. Figure 2 shows a schematic of the solar cell structure generated from SCAPS-1D, in which sunlight (incident

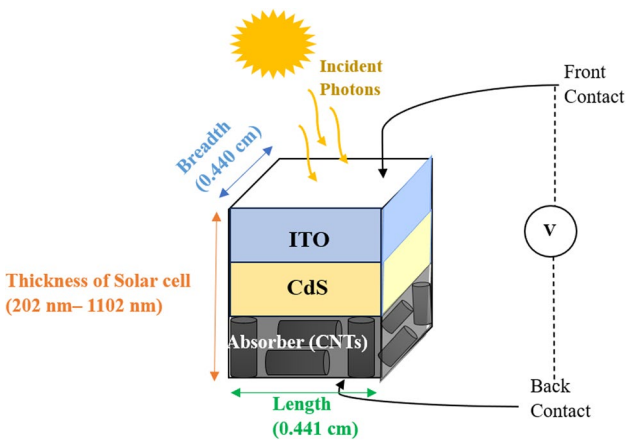

Fig. 1 Schematic diagram of ITO-/CdS-/CNT-based solar cell

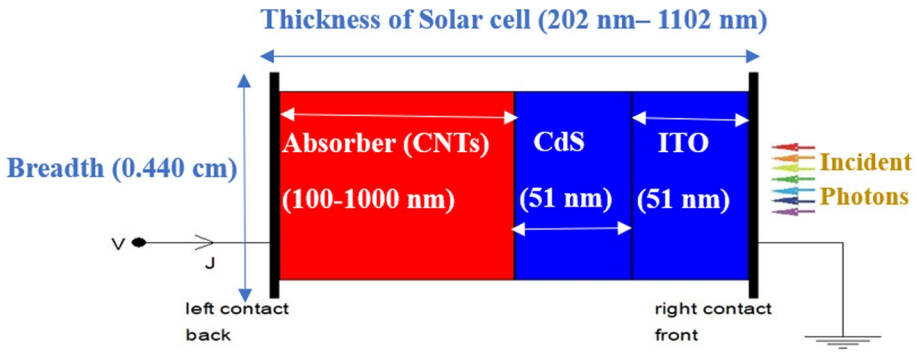

Fig. 2 Schematic diagram of solar cell constructed with SCAPS-1D software

photons) falls from the side of the right contact (front) (Bi) to the left contact (back) (Au).

SCAPS-1D uses basic concepts of physics and mathematics for semiconductor devices, as expressed in equations (a–c), as follows [25, 31]:

Poisson's equation:

$$\mathrm{div}(\varepsilon.\nabla\Psi) = -\rho \tag{1a}$$

The continuity equation for electron carriers:

$$\frac{\partial n}{\partial t} = \frac{1}{q}\mathrm{div}(J_n) + G_n - R_n \tag{2b}$$

The continuity equation for hole carriers:

$$\frac{\partial p}{\partial t} = \frac{1}{q}\mathrm{div}(J_p) + G_p - R_p \tag{2c}$$

In the SCAPS-1D simulation software, we have assumed air mass spectrum AM 1.5 radiation, working temperature of 300 K, and an ideal solar irradiance of 1 kW m^{-2}, using an applied voltage of 0.77 V. The values of the shunt and series resistance are 5.0×10^{10} Ω cm^2 and 0.44 Ω cm^2, respectively [9, 10]. The frequency of incident light is 1×10^6 Hz.

2.1.2 Simulation results and discussion

Tables 1, 2, and 3 present the data used in the SCAPS-1D simulations, with the results shown in Figs. 3, 4, 5, and 6.

2.1.2.1 Bandgap explanation Figure 3 presents an energy band diagram illustrating the energy levels of various layers of a solar cell derived from SCAPS-1D for analysis of the device performance. The absorber layer is made of CNTs, and we know that when we increase the radius of the CNTs, the energy bandgap will decrease, as clearly shown in Fig. 3 [52]. To understand this relation between the bandgap and radius of CNTs, we can refer to a basic concept of quantum mechanics called quantum confinement. Quantum confinement processes cause the bandgap of nanoparticles to increase with decreasing particle size. The continuous energy bands control the band structure and electronic characteristics of larger bulk materials. However, the bandgap increases when a material decreases to the nanoscale because separate energy levels are formed by the confinement of electrons and holes in a very small volume. This phenomenon is understood by the concept of quantum confinement, which results from the confinement of charge

Table 1 Simulation values for the proposed solar cell layers for SCAPS-1D software [25–29]

Parameters	ITO	CdS	Absorber
Layer thickness (μm)	0.051	0.051	0.1–1
Shallow uniform acceptor density NA (cm^{-3})	–	–	1.1×10^{17}
Electron mobility (cm^2 V s^{-1})	51	170	8.1×10^4
Layer electron affinities (eV)	4.5	4.2	4.28
Layer relative dielectric permittivity	8.8	8.72	3.5

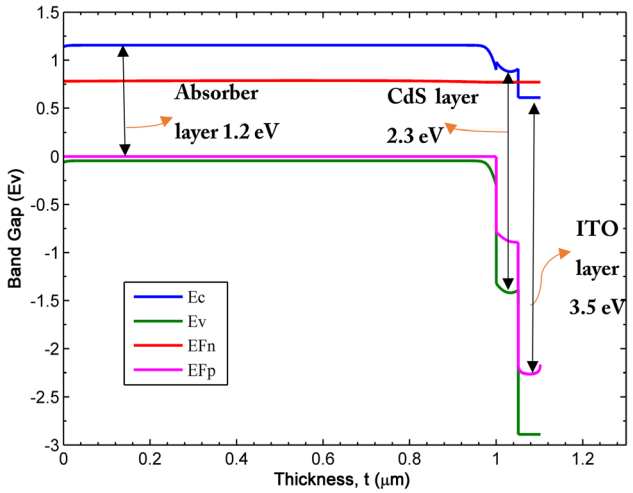

Fig. 3 Energy bandgap in relation to thickness of the absorber layer (t) of the proposed solar cell

carriers in a volume equal to their wavelength. Energy levels can be quantified when the spatial confinement of electrons and holes increases with decreasing nanoparticle size. The energy difference between the valence and conduction bands increases as a result of this quantization of energy levels.

2.1.2.2 Examination of QE curve, generated current density, and carrier generation and recombination When sunlight falls on a semiconductor, electron and hole generation and recombination take place inside the semiconductor [35–38, 38–51]. Since the absorber layer consists of CNTs which are electrically similar to semiconductors, the same phenomena of generation and recombination take place from this incident light process on the solar cell. The recombination and generation with respect to the absorption layer thickness (t) can be seen in Fig. 4a. This process facilitates the movement of charge carrier holes and electrons, which in turn causes the generation of current [35–38, 38–51], as can be seen in Fig. 4b. Similarly, we can see the quantum efficiency of the device with respect to various wavelengths of light in Fig. 4c; QE decreases with increasing wavelength because longer-wavelength photons have less energy, resulting in lower levels of carrier generation and recombination.

2.1.2.3 *J–V* characteristics of the solar cell with varied absorption layer thickness We know that for the solar cell, the power generated by the cell is $-(V\times I)$, and the power consumed by the cell is $+(V\times I)$. The photovoltaic process begins when the cell is exposed to the sun at AM 1.5. The absorption of light creates charge carriers, i.e., free electrons and holes in the absorption layer, which produces a continuous photocurrent [25]. Since CNTs have very high current flow and very low resistance, they also have many better electrical properties such as conductivity and mobility, which increase the current generation, thus enhancing the efficiency of the device. As shown in Fig. 5, increased absorption layer thickness enhances the photocurrent generated by the constructed solar cell, which indicates that as the power output of the cell increases, its efficiency will also increase. Here, we have taken the thickness of the absorber layer in the range from 100 to 1000 nm, which yields efficiency of 12–27%, consistent with the results of previous research [10, 33, 34].

2.1.2.4 SCAPS-1D-simulated solar cell with varied absorber layer thickness As shown in Fig. 6a, b, and d, in the simulated ITO/CdS/CNT solar cell, because the absorber layer is filled with a large number of CNTs, the rates of recombination and generation increase when the absorber layer thickness (t) increase, and the resulting increase in current generation leads to enhanced efficiency

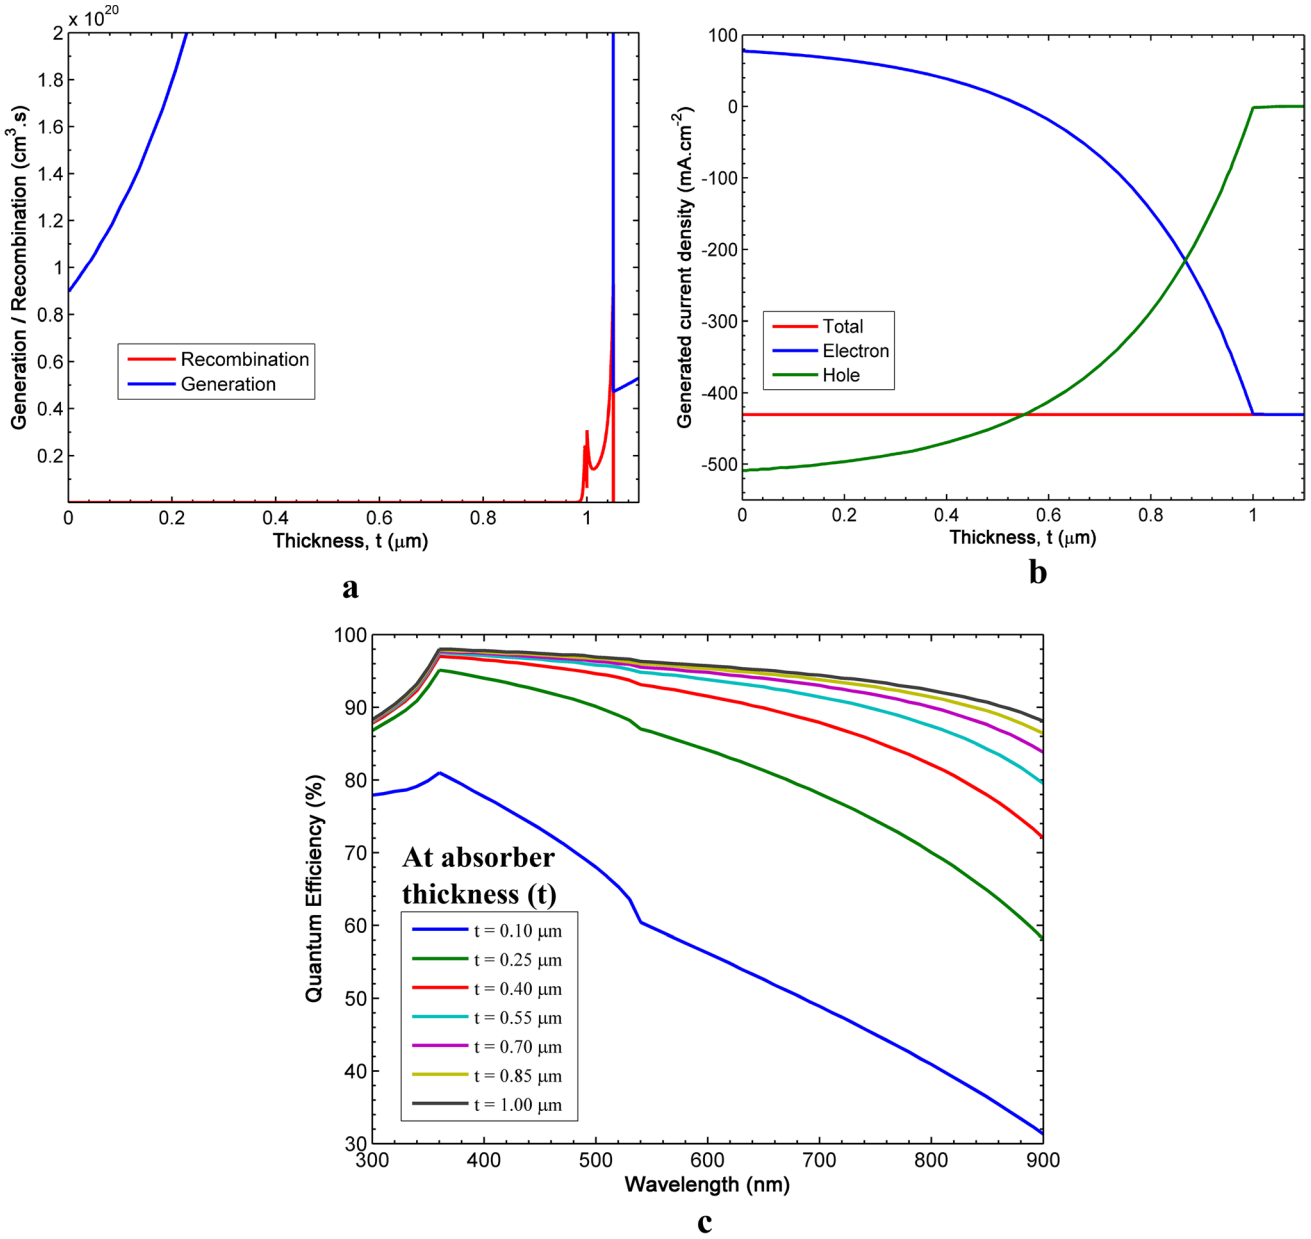

Fig. 4 Generation/recombination of carriers, generated current density, and QE of the SCAPS-1D-simulated solar cell. **a** Recombination and generation of carriers in relation to absorber layer thickness (*t*). **b** Generated current density with relation to *t*. **c** QE of the proposed simulated solar cell for incident photons with various wavelengths at varying values of *t*

of the constructed solar cell. In Fig. 6c, the parameter FF is found to decrease due to the increased generation and recombination of carriers, resulting in larger values of J_{SC} and V_{OC}. Because J_{SC} and V_{OC} are inversely proportional to FF [10], the FF value decreases. If we explain this phenomenon from a theoretical point of view, we know that a solar cell is a p–n junction device which works on a basic physics principle, namely the photovoltaic effect, where carriers are generated, which leads to the generation of electric current, and the special optical characteristics of CNTs allow the solar cell to absorb a wide range of light, including visible and near-infrared wavelengths. Increased absorption of sunlight by CNTs in the absorber layer results in increased creation of electron–hole pairs, also called excitons, since CNTs have high charge carrier mobility. In addition, the current loss decreases, which results in high J_{SC} and V_{OC} values and thus a decrease in the FF of the solar cell.

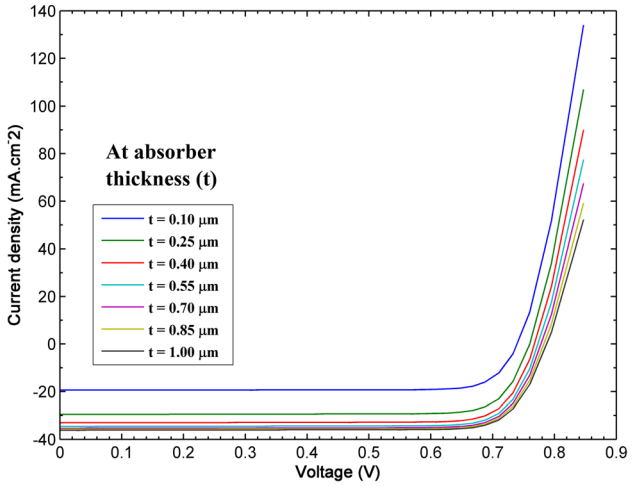

Fig. 5 Current–voltage (*J*–*V*) characteristic of the simulated solar cell with absorber layer thickness (*t*) ranging from 0.1 to 1.0 µm

2.1.3 Summary of results from SCAPS-1D simulation

The results obtained from the simulation are presented in Table 4.

2.2 Work (2)

2.2.1 Analytical modeling of ITO-, CdS-, and CNT-based solar cells

The efficiency of a solar cell can be expressed as follows [9, 10]:

$$\text{Efficiency of solar cell} = \frac{\text{Power output}\left(P_{\text{out}}\right)}{\text{Power input}\left(P_{\text{in}}\right)}$$

Solar cell efficiency (η) can be expressed mathematically as [9, 10]

$$\eta = \frac{\text{FF} \times V_{\text{OC}} \times J_{\text{SC}}}{P_{\text{in}}} \times 100 \tag{1}$$

The photocurrent density of the solar cell is defined as [10]

$$J_{\text{SC}} = J_{\text{O}}\left\{\exp\left(\frac{q\left(V_{\text{OC}} - \text{JAR}_{\text{S}}\right)}{n_{\text{o}}K_{\text{B}}T}\right) - 1\right\} + \left(\frac{V_{\text{OC}} - \text{JAR}_{\text{S}}}{\text{AR}_{\text{SH}}}\right) - J \tag{2}$$

Now, substituting the J_{SC} from Eq. (2) into Eq. (1), we obtain

$$\eta = \left(\frac{\text{FF} \times V_{\text{OC}}}{P_{\text{in}}}\right)\left[J_{\text{O}}\left\{\exp\left(\frac{q\left(V_{\text{OC}} - \text{JAR}_{\text{S}}\right)}{n_{\text{o}}K_{\text{B}}T}\right) - 1\right\} + \left(\frac{V_{\text{OC}} - \text{JAR}_{\text{S}}}{\text{AR}_{\text{SH}}}\right) - J\right] \times 100 \tag{3}$$

and power output will be

$$P_{\text{out}} = \left(\text{FF} \times V_{\text{OC}}\right)\left[J_{\text{O}}\left\{\exp\left(\frac{q\left(V_{\text{OC}} - \text{JAR}_{\text{S}}\right)}{n_{\text{o}}K_{\text{B}}T}\right) - 1\right\} + \left(\frac{V_{\text{OC}} - \text{JAR}_{\text{S}}}{\text{AR}_{\text{SH}}}\right) - J\right] \tag{4}$$

Here, we assume that the front face of the solar cell is a rectangular structure, as given in Fig. 1. Thus, the area of the proposed solar cell = side length × side width.

Therefore, the area of the solar cell can be expressed as

$$A = N \times (2R) \times L \tag{5}$$

where N is the available number of CNTs within the absorber layer, and the CNT radius and length are denoted by R and L, respectively.

Since we have used CNTs in the solar cell as the absorber layer, and the volume of this layer will vary with respect to CNT radius (R) and length (L) and the number of CNTs (N), the only quantity that will change is the number of CNTs when we alter that the value of t, maintaining the CNT length and radius constant. As indicated in Fig. 7, the absorber length and width are 0.440 and 0.441 cm, respectively, and its thickness (t) varies from 100 to 1000 nm.

For calculating the number of CNTs (N), we use the equal-volume concept, i.e., the volume of the absorber layer is equal to the available number of CNTs multiplied by the volume of a single CNT, as follows:

$$\text{Volume of absorber layer} = N \times \text{volume of single CNT}$$

Since CNTs are cylindrical, the volume of a single CNT will be $= (\pi \times \text{R}^2 \times \text{L})$

and the volume of the absorber layer will be expressed as Length × Breadth × Thickness of absorber layer

Thus,

$$N = \frac{\text{Volume of the absorber layer}}{\text{Volume of single CNT}} = \frac{\text{Length} \times \text{Breadth} \times \text{Thickness of the absorber layer}}{\pi \times R^2 \times L}$$

Now, from Eq. (5), substituting the value of A from Eqs. (3) and (4), we obtain

$$\eta = \left(\frac{\text{FF} \times V_{\text{OC}}}{P_{\text{in}}}\right)\left[J_{\text{O}}\left\{\exp\left(\frac{q\left(V_{\text{OC}} - \text{NL}(2R)\text{JR}_{\text{S}}\right)}{n_{\text{o}}K_{\text{B}}T}\right) - 1\right\} + \left(\frac{V_{\text{OC}} - \text{NL}(2R)\text{JR}_{\text{S}}}{\text{NL}(2R)R_{\text{SH}}}\right) - J\right] \times 100 \tag{6}$$

and power output will be

$$P_{\text{out}} = \left(\text{FF} \times V_{\text{OC}}\right)\left[J_{\text{O}}\left\{\exp\left(\frac{q\left(V_{\text{OC}} - \text{NL}(2R)\text{JR}_{\text{S}}\right)}{n_{\text{o}}K_{\text{B}}T}\right) - 1\right\} + \left(\frac{V_{\text{OC}} - \text{NL}(2R)\text{JR}_{\text{S}}}{\text{NL}(2R)R_{\text{SH}}}\right) - J\right] \tag{7}$$

The radius of the CNT can be expressed in terms of the plasma parameters [52, 53], or

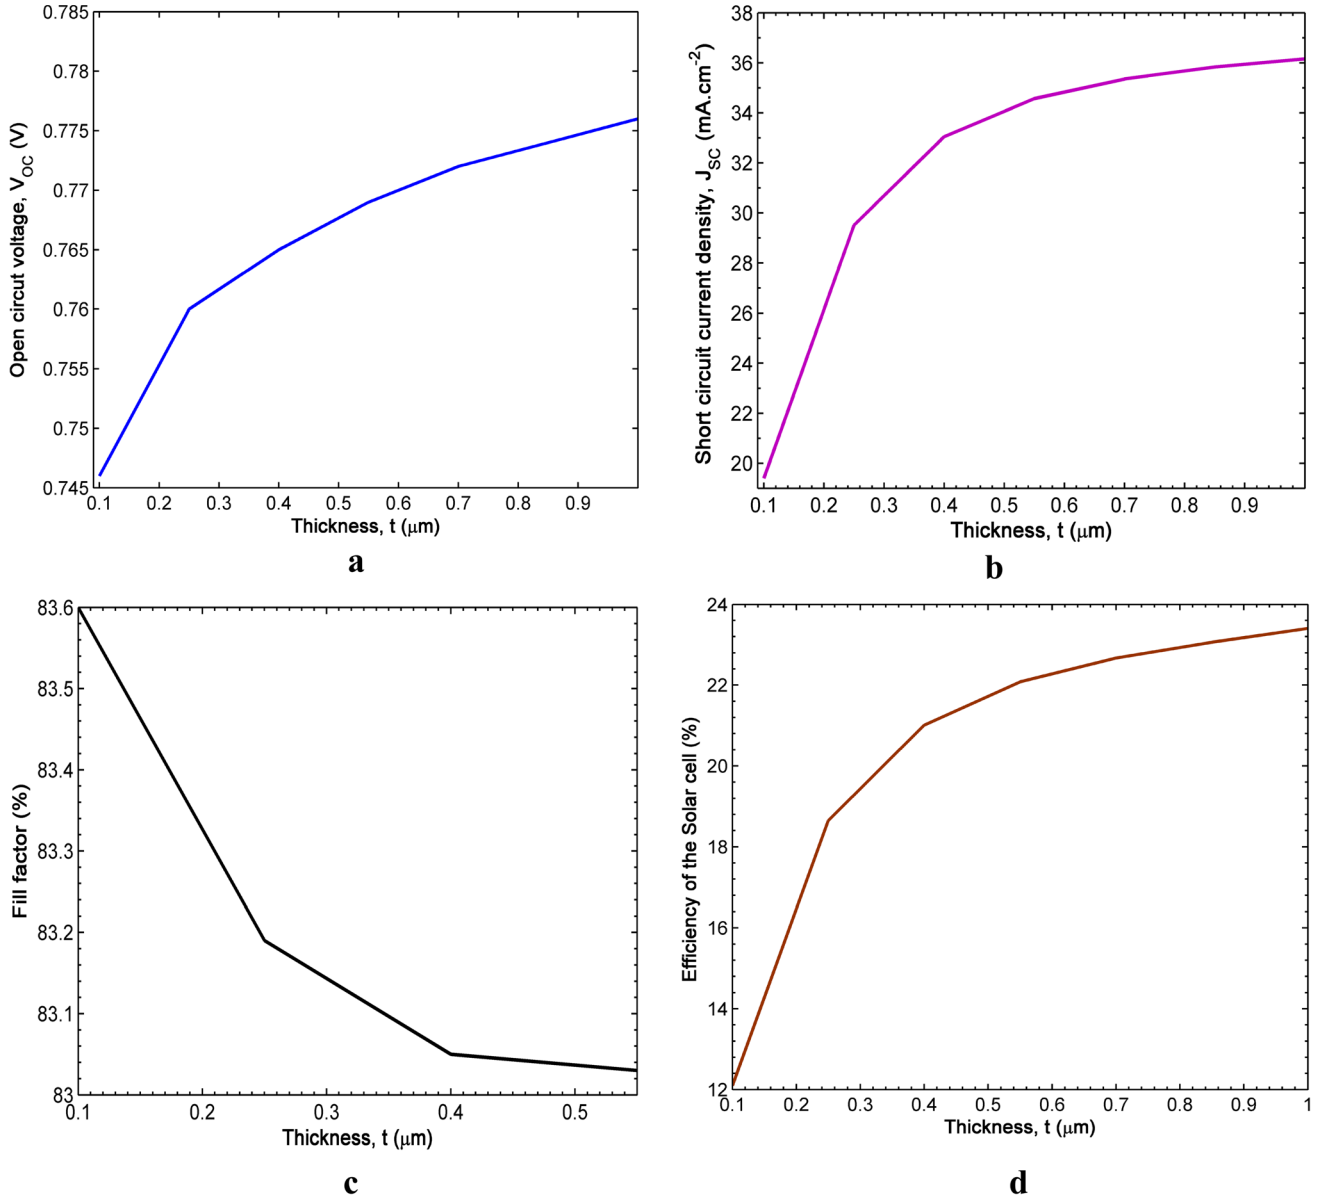

Fig. 6 Efficiency variables of the simulated structure of the solar cell in SCAPS-1D in relation to the thickness of the absorber layer (*t*). **a** V_{OC} in relation to *t*. **b** J_{SC} in relation to *t*. **c** FF in relation to *t*. **d** Efficiency in relation to *t*

Table 4 Summary of the results from SCAPS-1D simulation of the constructed solar cell

Thickness of absorber layer (*t*) (μm)	Volume of absorber layer (cm^3)	Total thickness of solar cell (μm)	FF (%)	V_{OC} (V)	J_{SC} (mA cm^{-2})	η (%)

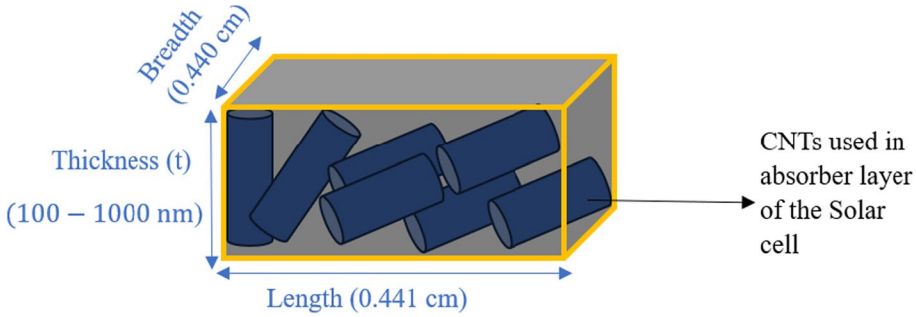

Fig. 7 CNTs utilized in solar cell absorber layer

$$R^2 = \exp\left(\frac{V_S L}{q}\right)\left[\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}} + \frac{n_{io}}{T_{io}}\right)}\right]$$

$$R = \exp\left(\frac{V_S L}{2q}\right)\left[\sqrt{\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}} + \frac{n_{io}}{T_{io}}\right)}}\right] \tag{8}$$

Now, substituting the value of R from Eq. (8) into Eqs. (6) and (7), we obtain

$$\eta = \left(\frac{\mathrm{FF}\times V_{OC}}{P_{in}}\right)\left[\begin{array}{c} J_O\left\{\exp\left(\frac{q\left(V_{OC}-2\mathrm{NL}\exp\left(\frac{V_S L}{2q}\right)\left[\sqrt{\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}}+\frac{n_{io}}{T_{io}}\right)}}\right]JR_S\right)}{n_o K_B T}\right)-1\right\}+ \\ \left(\frac{V_{OC}-2\mathrm{NL}\exp\left(\frac{V_S L}{2q}\right)\left[\sqrt{\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}}+\frac{n_{io}}{T_{io}}\right)}}\right]JR_S}{2\mathrm{NL}\exp\left(\frac{V_S L}{2q}\right)\left[\sqrt{\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}}+\frac{n_{io}}{T_{io}}\right)}}\right]R_{SH}}\right)-J \end{array}\right]\times 100 \tag{9}$$

and

$$P_{out} = (\mathrm{FF}\times V_{oc})\left[\begin{array}{c} J_O\left\{\exp\left(\frac{q\left(V_{OC}-2\mathrm{LN}\exp\left(\frac{V_S L}{2q}\right)\left[\sqrt{\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}}+\frac{n_{io}}{T_{io}}\right)}}\right]JR_S\right)}{n_o K_B T}\right)-1\right\}+ \\ \left(\frac{V_{OC}-2\mathrm{LN}\exp\left(\frac{V_S L}{2q}\right)\left[\sqrt{\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}}+\frac{n_{io}}{T_{io}}\right)}}\right]JR_S}{2\mathrm{NL}\exp\left(\frac{V_S L}{2q}\right)\left[\sqrt{\frac{1}{4\pi q^2\left(\frac{n_{eo}}{T_{eo}}+\frac{n_{io}}{T_{io}}\right)}}\right]R_{SH}}\right)-J \end{array}\right] \tag{10}$$

2.2.2 Analytical results

Our work was conducted in two parts: the first to fabricate CNTs using the PECVD method, and the second to use these CNTs in the solar cell absorber layer. For analytical calculation, we use the values of V_{OC}, J_{SC}, J_o, n_o, R_S, R_{SH}, and P_{in} at varied absorber layer thickness, which were obtained from the SCAPS-1D simulation, as summarized in Table 4. For mathematical calculation and results, we use constant values taken from the SCAPS 1-D simulation setup, which are given in Table 5.

2.2.2.1 Solar cell efficiency in relation to plasma parameters (n_{eo}, n_{io}, T_{eo}, and T_{io})

To analytically determine the effects of plasma parameters on solar cell efficiency, we take the required PECVD data from Table 5 and from the work (1) section in Table 6 [52, 53], which are essential for solving Eqs. (6), (7), and (9) to obtain the efficiency. When we put all the parameter values into Eqs. (9) and (10), we obtain the solar cell power output and efficiency, as shown in Table 6 in the work (2) section.

2.2.2.2 Influence of plasma parameters electron and ion density (n_{eo} and n_{io}) on solar cell efficiency

Figure 8 presents plots of the solar cell power output and efficiency in relation to electron and ion density (n_{eo} and n_{io}). In Fig. 8a–d, we see that when we increase the electron and ion density, the output power of the proposed solar cell increases. This is because, as we know, when we increase the plasma parameters n_{eo} and n_{io}, the radius of the CNTs will decrease, which leads to an increase in the voltage output of the device [52, 53], which in turn leads to an increase in the power output and efficiency of the solar cell. To understand this phenomenon, the increased electron density (n_{eo}) and ion density (n_{io}) parameters in the PECVD process typically result in a larger concentration of reactive species and energy in the plasma. The deposited CNTs and growth dynamics may be influenced by this higher energy and reactivity. Because higher plasma density and input power facilitate more rapid nucleation and growth of CNTs, the radius of the CNTs decreases

with increasing plasma parameters, thus producing thinner CNTs. In addition, the etching effect, in which reactive species in the plasma may degrade the CNT sidewalls during growth, can be improved by increasing the plasma parameter values. Thinner CNTs can be obtained by this etching action, which contributes to decreasing the CNT radius. At the interface between the CNTs and the active material (e.g., buffer layer and ITO), smaller-diameter CNTs can provide a stronger electric field. This results in higher voltage output, facilitating more effective separation of photogenerated electron–hole pairs. Moreover, smaller CNTs can provide a more direct route for charge carriers to reach the electrode, hence reducing recombination losses and increasing charge accumulation efficiency. This can result in higher current, which by Ohm's law can increase the voltage output because of changes induced by the plasma treatment, so the effective surface area of the CNTs can increase while the radius decreases. Because of

increase the electron and ion temperature, the output power of the solar cell decreases. This because, as we know, when T_{eo} and T_{io} are increased, the radius of the CNTs will increase, which decreases the voltage output of the device [52, 53], in turn leading to a decrease in the power output and efficiency of the solar cell. This phenomenon can be understood as follows: During synthesis procedures like PECVD, electron and ion temperature can affect CNT growth and stability. Faster growth rates and structural changes in the generated CNTs can be induced by higher temperature. However, the particular impact on the radius of CNTs can vary according to a number of variables, including the type of catalyst, the synthesis technique, the growth environment, and the kind of CNT (single-walled, multi-walled, etc.) generated. With higher electron and ion temperature in the PECVD process, CNTs can have larger diameters because of faster growth kinetics and enhanced carbon diffusion. At the interface between the CNTs and the active material (e.g., buffer layer and ITO), larger-diameter CNTs can provide a weaker electric field. This results in lower voltage output, which is less effective in inducing separation of photogenerated electron–hole pairs. This results in low current, which by Ohm's law is associated with decreased voltage output.

Because of changes induced by the plasma treatment, the effective surface area of the CNTs can decrease while the radius increases. This decrease in the active region available for charge generation and photon absorption results in lower current and voltage production.

2.2.2.4 The effect of absorber layer thickness (*t*) on the solar cell performance Figure 10 shows the variation in the solar cell efficiency with absorber layer thickness (t). It can be seen that when we increase the absorber layer thickness, the power output and efficiency of the solar cell increase. This is because an increase in the thickness of the absorber layer results in an increase in the number of CNTs, which leads to increased output voltage and thus an increase in the power output and efficiency of the solar cell [52, 53].

3 Comparisons of the efficiency of the simulated and analytical model of the proposed ITO-/CDS-/CNT-based solar cell

Figure 11 shows the efficiency of the constructed solar cell captured from simulation and analytical work. It can be seen that when we increase the value of t, the efficiency of the solar cell increases, and the slight difference between the analytical and simulation results may be the result of environmental effects such as differences in operating temperature and solar irradiance fluctuation.

4 Percentage error in solar cell efficiency between simulation and analytical work

The percentage error for the efficiency of the solar cell can be expressed as follows:

$$\text{Percentage error for the efficiency of the solar cell}(\%) = \left|\frac{\text{simulated value} - \text{analytical value}}{\text{simulated value}}\right| \times 100$$

Thus, the percentage error between simulation and analytical work is 1.71%. The results of calculations are shown in detail in Table 7.

5 Summary of results of the current work

A synopsis of the entire work is presented in Table 8.

6 Conclusion

In this work, PECVD was used to grow CNTs, which were incorporated into a solar cell as an absorber layer. Plasma parameters including electron and ion temperature and density as the result of PECVD treatment were then investigated with respect to their effects on the solar cell efficiency. Both simulation and theoretical modeling were carried out, and the results were very similar. This can be seen in the error calculation, which was about 1.7%. Here, we varied a number of plasma parameters that could impact solar cell efficiency. Since no previous studies have reported an expression that can directly relate plasma variables to solar cell efficiency, we solved this problem in the present work and successfully established a correlation between solar cell efficiency and plasma parameters. The results obtained from our work match very closely with those of recent research [25, 54–70]. The incorporation of CNTs and the efficiency achieved with respect to plasma parameters represents an important result and provides a foundation for further research. Here, we have used PECVD-grown CNTs in the absorber layer. For future work, CNTs can also be used in the hole transport layer (HTL), ITO-like layer, and electron transport layer (ETL), through which solar cell performance may be enhanced.

Abstract:

Cardiovascular disease is a very serious health issue. So, in order to prevent its spread, we need to understand the reason behind it's increase. Different factors like our lifestyle, our genes, the surroundings that we live in and so on all contribute to the risk of getting CVD. So, it is important to make positive changes in our day-to-day life which in the end will make us healthier. This research paper delves into understanding the importance behind such factors. We have used various classification models such as Logistic Regression, Decision Tree Algorithm, Random Forest, KNN, Support vector machine and Naïve Bayes to make predictions regarding cardiovascular disease patients. We have used data from UCI Repository that includes the features (predicator variables) such as age, BMI, gender, cholesterol, alcohol intake and so on to determine the presence of cardiovascular disease patients (response variable). Different models have been used to find out which model works best and we have done this by estimating various metrics that are essential for the assessment of model performance such as accuracy, precision, recall, etc. The Support Vector Machine model had the highest accuracy, Roc-Auc. So, this shows that the Support Vector Machine (SVM) so far is the best model for making predictions regarding CVD.

Keywords: Cardiovascular Diseases; Machine learning; Logistic Regression; SVM; KNN; Decision Tree; Random Forest; Naive Bayes; Roc-Auc.

Statement and Declaration:

Competing Interests and Funding:

We assert no competing interests concerning the research presented herein. The study was conducted independently and self-funded.

Author Contributions:

Aarushi Saini and Diya Malhotra played important roles in conducting this research including methodology, analysis, manuscript composition under the supervision of Prof. Anjana Gupta.

Ethical Approval:

This study was conducted in strict adherence and received approval from institution review board.

1.Introduction

The heart is a vital organ that is present in both human and animal bodies and is crucial for the survival. It circulates blood throughout the body via the circulatory/vascular system. Cardiovascular disease refers to a group of diseases that affect your heart and blood vessels. These diseases can impact your heart or blood vessels in one or more ways. A person might be symptomatic (feeling the disease physically) or asymptomatic (not feeling anything at all).

According to the World Health Organization (WHO) statistics, cardiovascular diseases (CVDs) were responsible for the highest number of deaths in 2019, representing 32% of all global deaths. The majority of the fatalities around 85% resulted from heart attacks and strokes.[1]. Populations that are growing older and becoming more numerous are making matters more complicated; in 2030, 22.2 million deaths from CVD are predicted [2]. Around 75% of cardiovascular fatalities happen in low and middle income nations. Heart disease is caused due to various risk factors, including physical inactivity, unhealthy diet, and the effective use of alcohol and tobacco. Most cardiovascular diseases can be averted by adopting a healthy daily lifestyle, which includes limiting salt in the diet, eating more vegetables and fruits, engaging in regular physical activity, and quitting smoking and excessive alcohol consumption [3]. Early detection of cardiovascular illness is crucial for the initial start of medication and counselling-based therapy.

Currently, computers are being used in various domains including medicine where they enhance decision-support system. Machine Learning (ML) is becoming more used in a variety of disciplines, including disease diagnosis in health care. Many researchers and healthcare professionals demonstrate the prospective of machine learning-based disease diagnostics (MLBDD), which is both affordable and time-efficient [4]. Health care data, such as pictures (X-ray, MRI) and tabular data (patient conditions, age, and gender), are utilised in developing MLBDD systems. ML is an instance of artificial intelligence (AI) that is becoming increasingly popular in the field of cardiovascular health. It is simply how computers process data and decide or classify tasks with or without human intervention. The ML conceptual framework is built on models that receive input data (e.g., images or text) and predict outcomes (e.g.,

favourable, unfavourable, or neutral) using a combination of mathematical optimization and statistical analysis. Several ML algorithms have been applied to everyday activities. Numerous causes of heart disease can complicate prediction.

With the help of machine learning techniques, heart disease can be identified. Various techniques are used to reliably and precisely predict heart disease. Feature selection methods such as Decision Tree (DT), Logistic Regression (LR), Random Forest (RF), Naive Bayes (NB), and Support Vector Machine (SVM) and many more have been developed to be equally effective in disease prediction. We aim to contribute to the development of more effective and efficient heart disease prediction models by investigating various methodologies.

The remaining section of this paper is organised as follows: Section II describes the approach in depth, including data collection, data preparation, and the use of logistic regression, random forest, decision tree, SVM, and Naïve Bayes classifiers. Section III compares the metrics of different classifiers using experimental results and performance evaluation indicators. Finally, Section IV summarises the important findings and their significance in the field of heart disease prediction.

2.Research Methodology

Data: The aim of the research paper is to predict the people suffering from cardiovascular disease. For that we have taken the dataset regarding cardiovascular disease from UCI Repository and it consists of 70000 records, each representing a patient's information. This dataset includes data on observable traits and risk factors related to heart attacks. Table 1 in the Appendix provides an overview of the dataset.

Data Preprocessing: After the data has been collected, Preprocessing was done that involves dealing with missing values, correcting incorrect records, inconsistencies and so on. We made use of some statistical methods such as mean to fill in any missing information and also removed duplicated values. This was done to ensure that our research is based on complete and accurate dataset.

Feature Selection: Refers to a process where the most important features are selected from the original dataset and neglecting irrelevant ones. This process helps in improving the performance of model as too many features may lead to overfitting, complexity and so on.

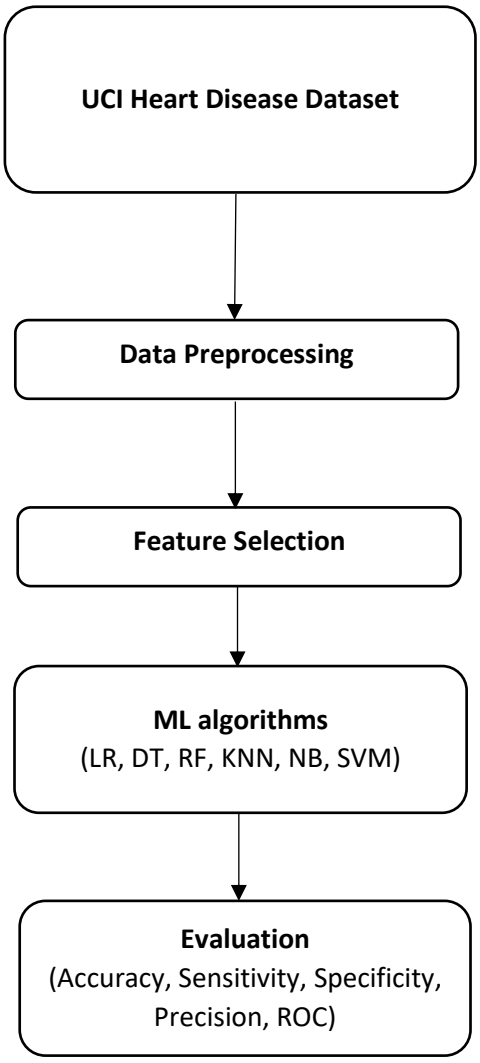

Figure 1. Research Methodology

2.1 Classification: Classification is the process of organizing a given dataset into distinct categories, a process which is applicable to both structured and unstructured data. The initial step in classification is predicting the category of the data points given. There are various methods in classification:

2.1.1 Logistic Regression: Logistic Regression (LR) is a supervised machine learning algorithm which aims at figuring out the chances of something happening based on different factors. It's like trying to predict if the person will have the cardiovascular disease or not. The LR technique is implemented in this study to classify heart disease. To boost performance, pre-processing of the data is performed, such as cleaning and detecting missing values. The most important part is feature selection, which improves algorithm accuracy and especially focuses on algorithm behaviour. Logistic regression's behaviour is that as training grows, so does prediction accuracy. The dependent variable in logistic regression is always binary. Logistic regression is mostly used for prediction and calculating the likelihood of success.

The sigmoid function is employed as a cost function to limit the logistic regression hypothesis between 0 and 1 (squashing), i.e., 0 h (x) 1 [5]. We classified and predicted the CVD patients in the machine learning LR using the function:

$$f(x) = \begin{cases} 1, & CVD\ present \\ 0, & CVD\ absent \end{cases}$$

In LR, the cost function is referred to as:

$$\log \frac{P(x)}{1 - P(x)} = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_P x_p \ldots .$$

2.1.2 Decision Tree: - The decision tree (DT) stands out as the most important predictive modelling and classification method within learning algorithms, extensively applied in practical approaches in supervised learning techniques [6, 7]. With the help of Decision Tree algorithm, a tree like structure is created which includes internal node (decisions made on the basis of features available), branches (outcomes of the decision) and leaf node (represents final decision).

While making predictions regarding cardiovascular disease through decision tree algorithm we first divided the dataset into training and testing datasets and then by calculating entropy which determines which feature to be used at various nodes. This process continues until a specific criterion is met i.e. all the decision nodes have been made.

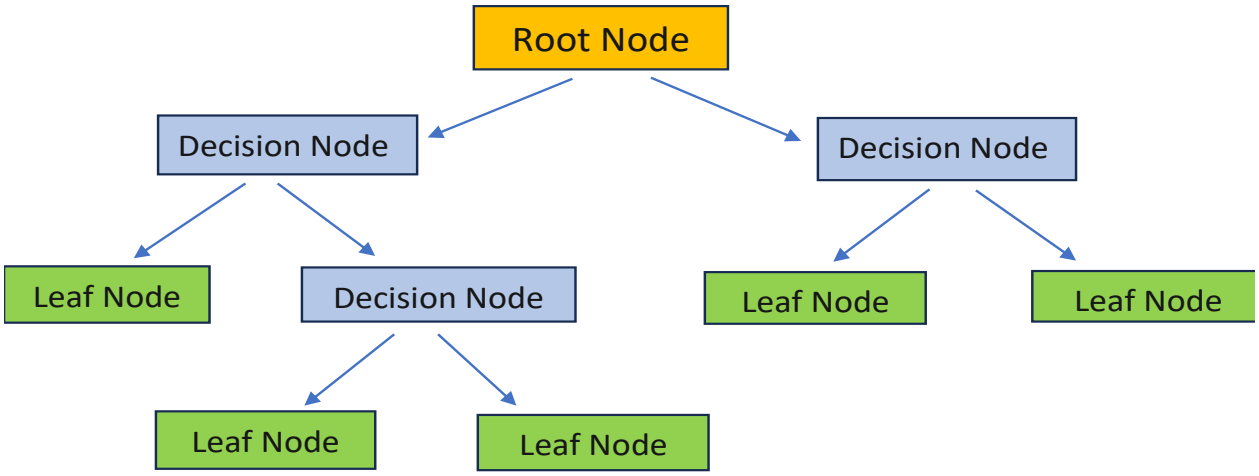

Figure 2: Decision Tree

2.1.3 Random Forest: The Random Forest (RF) is a supervised machine learning technique that uses decision trees to perform classification and prediction by averaging several independent base models [8]. The Random Forest creates a set of decision trees by randomly selecting a subset of the training set. It is essentially a set of decision trees (DT) drawn from a randomly chosen subset of the training set, and it then aggregates the votes from the many decision trees to determine the final prediction [9]. The greater the number of trees in the forest, the higher the accuracy and the lower the possibility of overfitting. The working of Random Forest algorithm is demonstrated in the below diagram [10]:

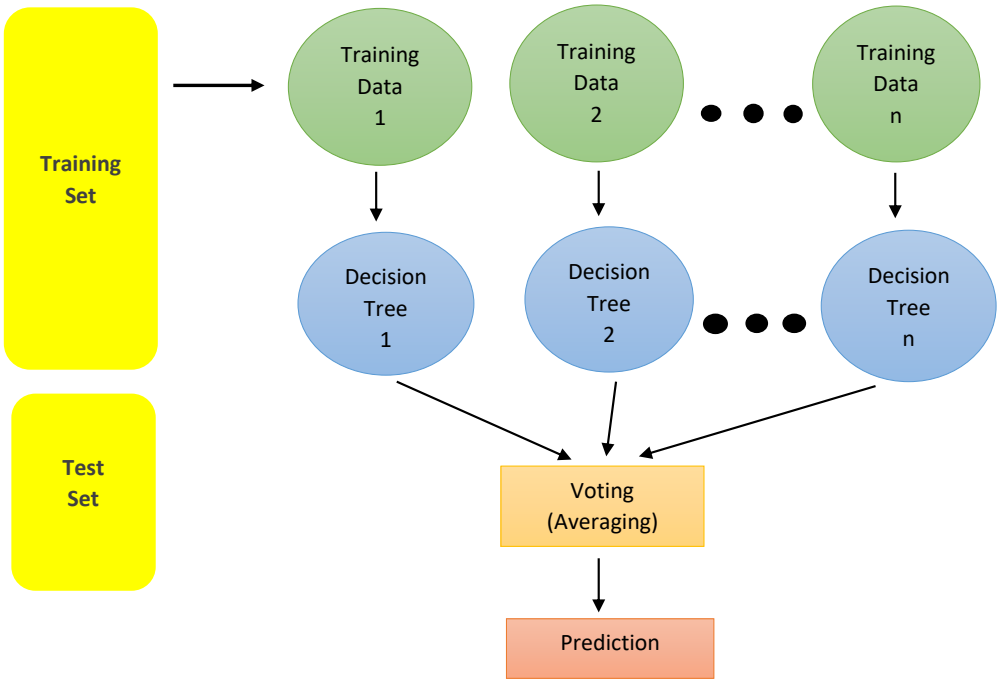

Figure 3: Random Forest algorithm

2.1.4 K-Nearest Neighbour (KNN): The K-Nearest Neighbours algorithm is a type of machine learning approach used for classification tasks. It works by determining the class of a given data point based on the distances between the point and the points in the training dataset. In KNN we need to find out the k neighbours in the space and then with the help of k neighbours we perform the classification i.e. KNN makes prediction on the basis of what majority of k neighbours indicate. For example, in case of predicting cardiovascular disease, if a lot of neighbours have the disease, then the new person also has the disease.

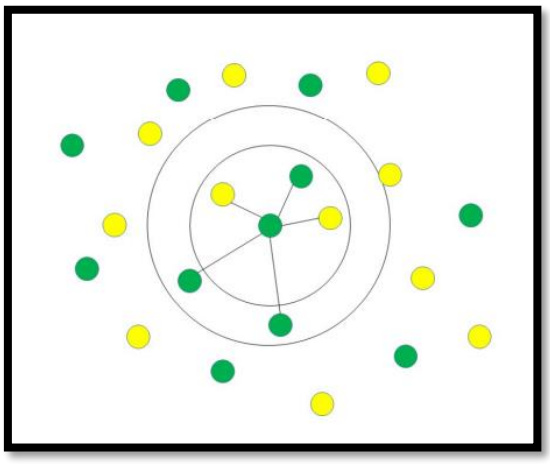

Figure 4: Demonstration of K-NN identifying unknown pattern by assigning a value to the K, where the nearest neighbour category of the K training sample is considered the same as the classification [11].

2.1.5 Support Vector Machine (SVM): SVM is commonly used for the purpose of classification. The aim of the SVM is to find a hyperplane that well separates the data points that belongs to different classes. SVM aims to maximize the margin which is the distance between the hyperplane and the nearest support vectors from each set. Larger the margin means there is gap between the classes and in turn we are able to draw the best possible line i.e. hyperplane that best separates the data as shown in the figure.

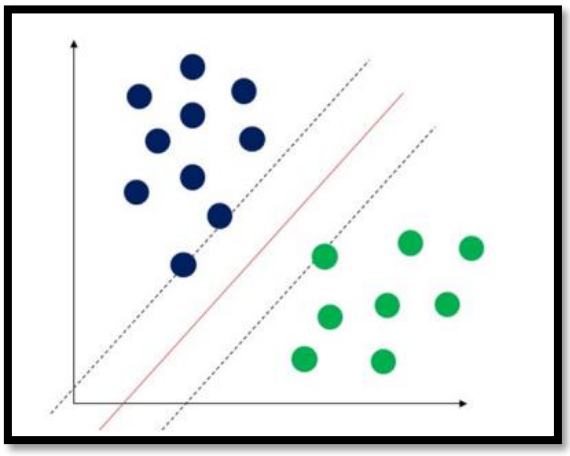

Figure 5: Demonstration of support vector machine. In the illustration, the solid red line represents the separating hyperplane, while the distance between two dotted lines depicts the maximum margin for separating distinct classes [12].

2.1.6 Naïve Bayes: The Naive Bayes algorithm is a supervised learning technique that uses the Bayes theorem with strong (Naïve) independence assumptions between features to solve problems regarding classification. It is a probabilistic classifier i.e. it predicts on the basis of an object's probability [13]. The Naïve Bayes classifier stands out as simple and efficient classification algorithm, hence making it a popular choice for quickly creating machine learning models making predictions swiftly.

Internal calculations will be performed to determine the probability of each value in relation to the feature. We take into consideration the value with the highest probability once we have computed the probability of each value of the output attributes [14,15]. Bayes algorithm is given by

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

where,

P(A|B) refers to Posterior probability: Probability of hypothesis A on the observed event B.

P(B|A) refers to Likelihood probability: Probability of the evidence given that the probability of a hypothesis is true.

P(A) refers to Prior Probability: Denoting the likelihood of hypothesis before considering the evidence.

P(B) refers to Marginal Probability: Probability of Evidence.

2.2 Assessment of model performance

To find out whether the model is performing successfully and making right predictions on the basis of new unseen data we use metrics which are used for almost all machine learning algorithms.

These are: -

1) Confusion Matrix:

	Actual Positive	Actual Negative
Predicted Positive	True Positive	False Positive
Predictive Negative	False Negative	True Negative

True positive are the outcomes that are correctly predicted as positive. For example, in case of Cardiovascular disease, True positive finds out that the person tested with cardiovascular disease actually have the disease whereas True Negative finds out that the person tested do not have the disease and indeed they do not have disease.

False Positive: Outcomes that are actually negative but incorrectly predicted as positive. For example, the test says person have the disease but actually they do not have and False Negative is opposite of False Positive.

2) Accuracy:

Accuracy is the ratio of sum of total number of true positives and true negatives to total number of instances.

i.e.

$$Accuracy = \frac{\text{Total number of true positives } + \text{ Total number of false positives}}{\text{Total number of instances}}$$

for example, in case of predicting cardiovascular disease, how well the machine learning model correctly identify patients with or without disease. The more the accuracy means the model is able to make correct predictions most of the time.

3) Precision and Recall:

Precision is the ratio of total number of true positives to the sum of total number of true positives and total number of false positives.

i.e.

$$Precision = \frac{\text{Total number of true positives}}{\text{Total number of true positives } + \text{ Total number of false positives}}$$

Precision measures the positive outcome, for example, in the dataset taken above regarding cardiovascular diseases, it measures whether the person has disease. The higher the precision means the model is accurate meaning if the model is predicting that a person has cardiovascular disease, it is likely to be true.

Recall also known as Sensitivity or True positive rate represents the proportion of true positives among all actual positives. It is the total number of true positives to the sum of total number of true positives and total number of false negatives.

i.e.

$$Recall = \frac{\text{Total number of true positives}}{\text{Total number of true positives } + \text{ Total number of false negatives}}$$

For example, Recall identifies the number of patients who actually have the cardiovascular disease. Higher the recall means our ML model is able to identify all the persons who actually have cardiovascular disease.

4) Specificity

Specificity also known as true negative rate is the ratio of total number of true negatives to the sum of total number of true negatives and total number of false positives.

i.e.

$$Specificity = \frac{\text{Total number of true negatives}}{\text{Total number of true negatives } + \text{ Total number of false positives}}$$

For example, in case of predicting whether the patients have cardiovascular disease or not, specificity helps in finding out how well the model is predicting the patients that do not have disease.

5) Receiver Operating Characteristic (ROC)

The ROC curve is a probability graph that illustrates how well a classification model performs at various threshold values. It plots the true positive rate (TPR) against the false positive rate (FPR) across various classification thresholds.

TPR or true positive rate also known as Recall, can be calculated as:

$$TPR = \frac{TP}{TP + FN}$$

FPR or False Positive Rate can be calculated as:

$$FPR = \frac{FP}{FP + TN}$$

where,

TP: True Positive; **FP**: False Positive; **TN**: True Negative; **FN**: False Negative

3. Results and Discussion

We have used various classification models such as Logistic Regression, Decision Tree Algorithm, Random Forest, KNN, Support vector machine and Naïve Bayes to make predictions regarding cardiovascular disease patients. First, we commence by initiating the data cleaning process that involves removing null values, removing duplicates and filtering out irrelevant information. The following is done to ensure that our research is based on complete and accurate dataset.

Python code

1) Data Understanding

```
data=pd.read_csv("/content/cardio_train.csv",sep=";")
data.head()
```

	id	age	gender	height	weight	ap_hi	ap_lo	cholesterol	gluc	smoke	alco	active	cardio
0	0	18393	2	168	62.0	110	80	1	1	0	0	1	0
1	1	20228	1	156	85.0	140	90	3	1	0	0	1	1
2	2	18857	1	165	64.0	130	70	3	1	0	0	0	1
3	3	17623	2	169	82.0	150	100	1	1	0	0	1	1
4	4	17474	1	156	56.0	100	60	1	1	0	0	0	0

2) Data Preprocessing

i) Age Transformation, BMI Calculation, Column Removal

```
data['age_in_years']=(data['age']//365).astype('int')
data.drop(['id','age'],axis=1,inplace=True)
data['bmi']=data['weight']/(data['height']/100)**2
data.drop(['height','weight'],axis=1,inplace=True)
data.head()
```

	gender	ap_hi	ap_lo	cholesterol	gluc	smoke	alco	active	cardio	age_in_years	bmi
0	2	110	80	1	1	0	0	1	0	50	21.967120
1	1	140	90	3	1	0	0	1	1	55	34.927679
2	1	130	70	3	1	0	0	0	1	51	23.507805
3	2	150	100	1	1	0	0	1	1	48	28.710479
4	1	100	60	1	1	0	0	0	0	47	23.011177

ii) Dealing with null values and duplicated values

```
print(data.isnull().sum())
print("{} rows are same".format(data.duplicated().sum()))
data.drop_duplicates(inplace=True)
print("{} rows are same".format(data.duplicated().sum()))
```

```
gender          0
Systolic_BP     0
Dialostic_BP    0
cholesterol     0
glucose         0
smoker          0
alcohol         0
active          0
cardio          0
age_in_years    0
bmi             0
dtype: int64
3210 rows are same
0 rows are same
```

3) Training and Testing Data

```
from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, stratify=Y, random_state=10)
print(X.shape, X_train.shape, X_test.shape, y_train.shape, y_test.shape)
```

```
(66790, 10) (53432, 10) (13358, 10) (53432,) (13358,)
```

i) Logistic Regression

```
# Logistic Regression
from sklearn.linear_model import LogisticRegression
log = LogisticRegression()
log.fit(X_train,y_train)
y_pred1 = log.predict(X_test)
```

ii) Decision Tree

```
[45] from sklearn import tree
     from sklearn.metrics import accuracy_score, precision_score, recall_score, f1_score, confusion_matrix, classification_report
     # Initialize Decision Tree classifier
     clf = tree.DecisionTreeClassifier(max_depth=3, criterion='entropy')
     # Fit the classifier on the training data
     clf.fit(X_train, y_train)
     # Predictions on the test set
     y_pred = clf.predict(X_test)
```

iii) Random Forest

```
7] from sklearn.ensemble import RandomForestClassifier
   from sklearn.metrics import confusion_matrix, accuracy_score, precision_score, recall_score, f1_score, classification_report
   # Initialize RandomForestClassifier
   rf = RandomForestClassifier()
   # Fit the classifier on the training data
   rf.fit(X_train, y_train)
   # Predictions on the test set
   y_pred1 = rf.predict(X_test)
```

iv) KNN

```
from sklearn.preprocessing import StandardScaler
from sklearn.neighbors import KNeighborsClassifier
from sklearn.metrics import confusion_matrix, accuracy_score, precision_score, recall_score, f1_score, classification_report
# Standardize the data
scaler = StandardScaler()
X_train_scaled = scaler.fit_transform(X_train)
X_test_scaled = scaler.transform(X_test)
# Initialize KNN classifier with 12 neighbors
knn = KNeighborsClassifier(n_neighbors=12)
# Fit the classifier on the training data
knn.fit(X_train_scaled, y_train)
```

```
KNeighborsClassifier
KNeighborsClassifier(n_neighbors=12)
```

v) Naïve Bayes

```
[51] from sklearn.naive_bayes import GaussianNB
     from sklearn.metrics import confusion_matrix, accuracy_score, precision_score, recall_score, f1_score, classification_report
     # Initialize Gaussian Naive Bayes classifier
     nb = GaussianNB()
     # Fit the classifier on the training data
     nb.fit(X_train, y_train)
     # Predictions on the test set
     y_pred1 = nb.predict(X_test)
```

vi) SVM

```
from sklearn.svm import SVC
from sklearn.metrics import accuracy_score, precision_score, recall_score, f1_score, confusion_matrix, classification_report
# Initialize Support Vector Machine (SVM) classifier
svm_classifier = SVC(random_state=50)
# Fit the classifier on the training data
svm_classifier.fit(X_train, y_train)
# Predictions on the test set
y_pred_svm = svm_classifier.predict(X_test)
```

We have also calculated various metrics that are essential for the assessment of model performance such as accuracy, precision, recall, etc. that can be seen from the figure below.

	Models	Accuracy	Precision	Recall	F1-score
0	Logistic Regression	65.990418	0.679325	0.635712	0.656795
1	Decision Tree	72.570744	0.753839	0.689237	0.720092
2	Random Forest	67.614912	0.678511	0.698157	0.688194
3	KNN	68.677946	0.722129	0.630886	0.673431
4	Naive Bayes	58.279683	0.735043	0.289266	0.415154
5	SVM	72.218895	0.770642	0.651068	0.705826

Figure 6: Assessment of model performance

From all the models we have found that the Decision Tree and Support Vector Machine have approximately same accuracy i.e. 72%. Higher Accuracy is important as it indicates the ability of model to make correct predictions. But accuracy alone might not be able to provide complete picture. Our main objective is to correctly identify the number of patients who actually have the cardiovascular disease.

So, sensitivity also known as recall is the metric that holds significant importance in the above context. Higher the sensitivity means our Machine Learning model is better at finding out larger proportion of persons who actually have the disease. We can also see the visualization of comparison of Model Metrics in Figure 7.

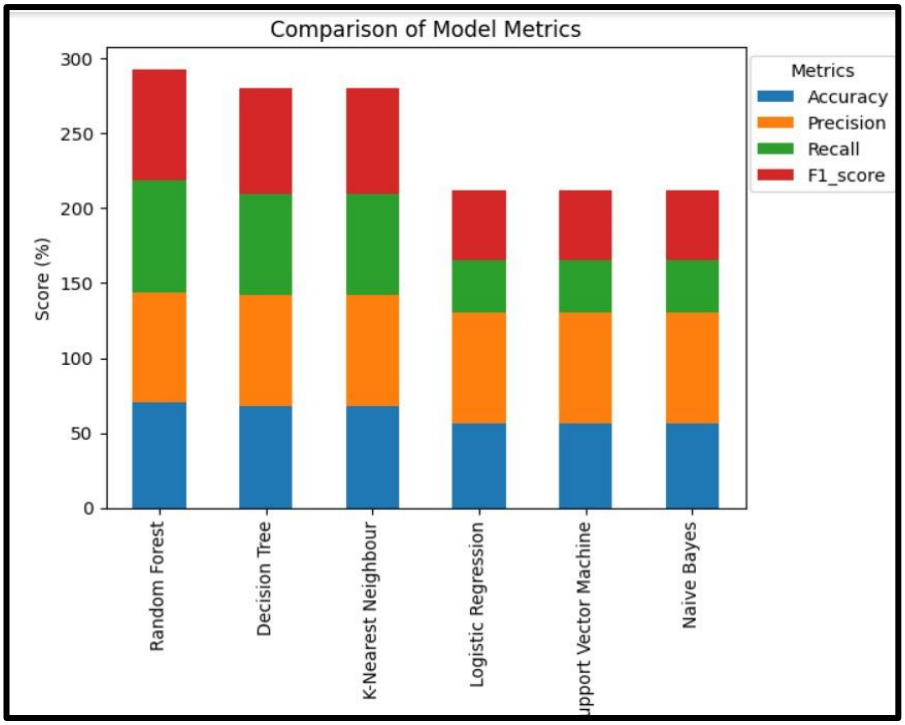

Figure 7: Visualization of metrics

Receiver operating characteristic (ROC) is also one of the important metrics that can be used to evaluate the performance of Machine Learning model i.e. ROC curve looks like a graph that can also show us what model is performing better. The Area under the curve (AUC) quantifies the overall effectiveness of the model, with a perfect classifier achieving an AUC of 1.0. Higher the score means that ROC-AUC is better at identifying the people who actually suffers from cardiovascular disease instead of making predictions that healthy people have the disease. In the analysis we have done, AUC (area under the curve) for Support Vector Machine (SVM) is highest i.e. at 79% value as illustrated in figure 8.

So, on the basis of our analysis, we have found that even though the Decision Tree model has slightly higher recall of 68% of class 1(with disease) whereas SVM achieves a slightly lower recall of 65% for the same class. But since our main objective is to correctly identify the number of patients who actually have the cardiovascular disease, it's important to consider the various performance metrics including ROC-AUC. Clearly from figure 8 we can see that SVM model outperforms all the machine learning models indicating that SVM is better at finding out larger proportion of persons who actually have the cardiovascular disease, making it a favourable choice for the data we have taken. Therefore, considering both accuracy and ROC-AUC, Support Vector Machine model appears to be more suitable for the dataset that we have taken.

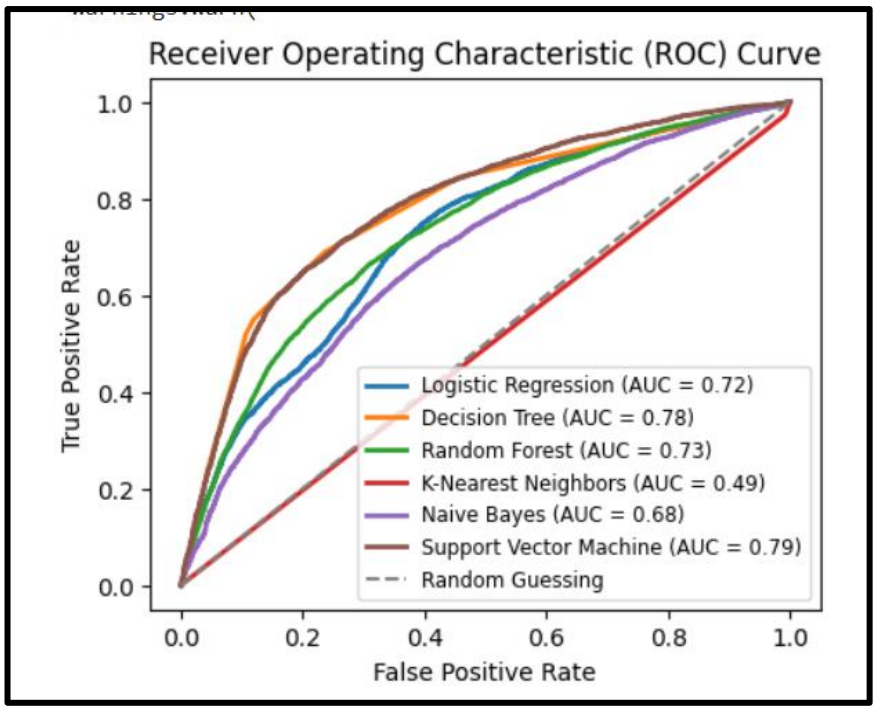

Figure 8: ROC-AUC

4. Conclusion

In medical data analysis, heart diseases are seen as a significant source of concern. Heart disease is a potentially fatal disease that affects millions of people worldwide each year (Asadi et al., 2021). As therefore, the early prediction of heart disease can benefit both patients and healthcare professionals by providing the statistical information required to avert deaths and expenditures. This research paper delves into the effectiveness of ML algorithms for predicting CVD patients. This research addressed the prediction problem of the UCI heart disease dataset including features such as age, BMI, gender, cholesterol, alcohol intake, and so on. The dataset consisted of labelled 70000 patients, it included both diagnosed heart disease patients and normal patients. To classify and predict CVD, six machine learning classification algorithms—DT, RF, LR, NB, KNN and SVM—were put into practice. It adhered to a suitable data science workflow, from data analysis and preparation to model creation, training, and evaluation. In order to identify the most appropriate machine learning algorithm within the model class, the performance of the selected ML method was estimated under a variety of conditions. The filter feature selection approach with the majority of features selected performed better than other methods in terms of the models Accuracy, Recall, Precision, and F-measures, according to the results.

The SVM algorithm had the highest accuracy of 72% for CVD. According to the above results, the SVM algorithm is the most suitable method for predicting cardiovascular disease patients for the dataset that we have considered. The ML algorithms used are restricted to research on heart disease prediction but we can use them for predicting a lot of other things. So, in general on the basis of our research we can see from ‘Figure 9’ that 56% of the people

are suffering from cardiovascular disease while 44% of the people are healthy according to the dataset that we have used.

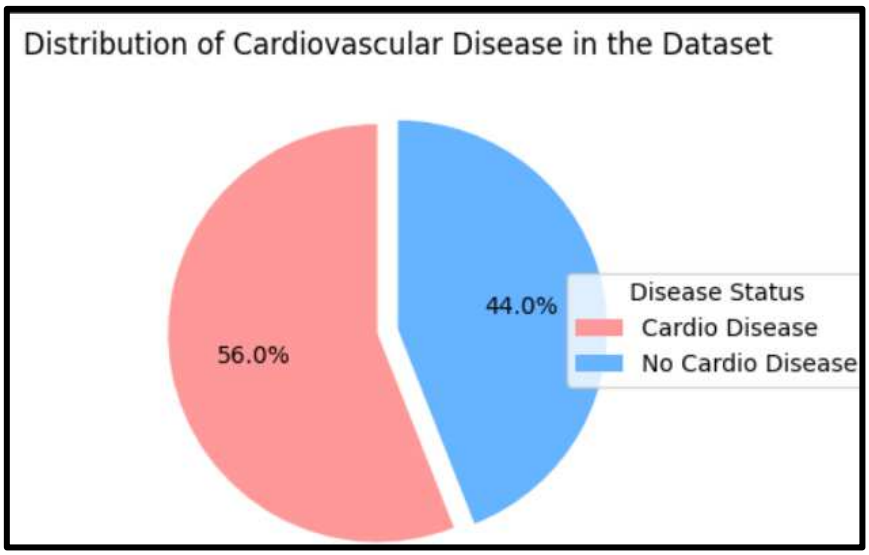

Figure 9: People having the disease and being healthy

Hence, we can conclude that machine learning has a significant role to play in our healthcare system. Historically, medical professionals used traditional processes and their intuition to diagnose diseases, which had drawbacks and resulted in higher expenses. However, with the use of machine learning models, diagnosis can be economically performed on large datasets.

Machine learning and HTLs

ABSTRACT

The commercial application of lead (Pb)-based Perovskite Solar Cells (PSCs) are restrained due to its toxicity. In this work, we have investigated potassium tin iodide ($KSnI_3$) which is a potential candidate for non-lead PSC. The SCAPS-1D simulation is employed to examine the effect of several Hole Transport Layers (HTLs) as follow: Spiro-OMeTAD, CuI, CuSCN, Cu_2O, PEDOT: PSS, CdTe, $MASnBr_3$, CFTS on the performance of $KSnI_3$-based PSCs. The impact of layer thickness, doping density (N_A) and defect density (N_t) has been analyzed. We have a trained Machine learning model to predict the performance matrices of PSCs. We have obtained a maximum efficiency of 23.08 % at the thickness of the $KSnI_3$ absorber layer of 550 nm and N_t of 10^{13} cm^{-3}. The ML model predicts the performance matrices of examined PSC with accuracy of ~ 89 %. Hence, the FTO/WS_2/$KSnI_3$/PEDOT: PSS/Au configuration is most suitable to manufacture highly efficient PV devices.

1. Introduction

Utilizing solar cells for solar energy harvesting presents a commendable approach mitigating concerns about global warming. The photovoltaic effect converts incident sunlight into electrical energy. In 2009, Perovskite solar cell (PSC) was reported with an efficiency of 3.8 % and has achieved maximum power conversion efficiency (PCE) of greater than 26 % till now [1]. It became popular among the scientific community due to its promising attributes such as tunable bandgap (E_g), high absorption coefficient, high carrier mobility, low manufacturing cost and high PCE or efficiency [2,3]. Perovskite material has an ABX_3 structure (where A is an organic or inorganic cation, B is an inorganic metal cation and X is halogen anion) [4]. Despite the high performance of lead (Pb) based PSC, its instability due to rapid oxidation of Pb cation and toxic nature restricted its commercialization [5]. There is a need for alternative perovskite materials that are both less toxic and environmentally friendly while also having the potential to deliver exhibit good photovoltaic (PV) outcomes [6]. Hence there have been various investigations to replace hazardous Pb ions with other alternatives such as Sn [7], Ge [8], Bi [9], Sb [10] and Ag [11]. The tin (Sn) is a suitable choice due to comparable ionic radii and the phenomenal semiconducting properties of $APbX_3$. The study comprises investigation of $KSnI_3$ as a perovskite material which is used as an absorber in a PSC. In past reported investigations there is very limited study on $KSnI_3$ PSC. Grishma et al. (2023) have reported efficiency of 9.77 % [12]. So there needs to be proper optimization to enhance the efficiency of PSC. Whereas, in this work we have obtained a maximum PCE of 23.08 %. The SCAPS enabled machine learning model is used to optimize and predict the best efficiency [13]. It has been exhibited that ML is helpful in forecasting the design and performance of PSCs [14]. Firstly, we have simulated $KSnI_3$-based PSC with several HTLs (Spiro-OMeTAD, CuI, CuSCN, Cu_2O, PEDOT: PSS, CdTe, $MASnBr_3$ and CFTS) and $KSnI_3$ is employed as a perovskite absorber layer. Secondly, we have optimized the effect of distinct performance parameters of PSCs such as absorber layer thickness, defect density (N_t) and doping density (N_A). Ultimately, we trained an ML model to predict the performance parameters of the PSCs with an accuracy of approximately 89 %. The present method serves as a sturdy foundation for subsequent research and investigations driven by artificial intelligence (AI). The efficient PSCs can be designed with application of ML modelling and SCAPS-1D assisted by previous studies.

2. Device architecture and methods

The PSC consists of $KSnI_3$ absorber material with layer architecture: FTO/ETL/Perovskite layer/HTL/Back-contact depicted in Fig. 1. All the input data used in SCAPS simulation obtained from experimental and theoretical work enclosed is in Table 1 for FTO/TiO_2/$KSnI_3$/Spiro-

2.1. SCAPS-1D

The data of different parameters are chosen from previous studies. The SCAPS-1D (version 3.3.10) has been employed for simulation. This software can be used for simulations at different input physical conditions. This tool calculation is dependent on Poisson's and continuity equations. It can calculate Quantum efficiency (QE), J-V curve and carrier lifetime for both electrons (e^-s) and holes (h^+s).

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{q}{\epsilon}[p(x) - n(x) + N_D - N_A + \rho_p - \rho_n = 0 \quad (1)$$

$$\frac{1}{q}\frac{dJ_p}{dx} = G_{op}(x) - R(x) \quad (2)$$

$$\frac{1}{q}\frac{dJ_n}{dx} = -G_{op}(x) + R(x) \quad (3)$$

The simulations were run at 300 K using a "air mass 1.5 global" spectrum and a light power of 1000 W/m^2. The work is dependent on change in thickness, N_t, and N_A at which simulation of the proposed PSC has been done. The outcome of the device has been reflected by the I–V characteristics which represent the following PV parameters: J_{SC}, FF, V_{OC}, and PCE. The simulation procedure is depicted in Fig. 2.

2.2. Machine learning

Python was chosen as the programming language for implementing machine learning (ML) due to its widespread use in AI applications [27–29]. To work with the dataset, Numpy and Pandas libraries were utilized. The dataset pertains to solar cell features and was thoroughly cleaned and preprocessed to make it compatible with ML algorithms. Initially, a simple Random Forest algorithm from Scikit-Learn (Sklearn) was employed to determine the significance of each feature for the final model. As a result of this phase, eleven features were selected for further analysis. For feature extraction related to composition of perovskites, Pymatgen and Matminer packages were utilized. The data was then split

into training and testing sets for model training. To find the best hyperparameters, two distinct approaches were taken. First a parameter grid (a Python dictionary) inclusive various values for each parameter was prepared. The RandomizedSearchCV and GridSearchCV tools from Scikit-Learn were employed to assess the optimal combination of hyperparameters from this grid. The RandomizedSearchCV randomly selected combinations from the grid and evaluated their performance using cross-validation, while the GridSearchCV evaluated every possible combination of the provided parameters. To ensure the model's performance and consistency, five-fold cross-validation was performed on the final model. Subsequently, a separate test set was used to assess the model's accuracy and overall performance. Random Forest's ability to aggregate the results of individual decision trees helped mitigate overfitting issues and improved the model's predictive performance [30]. Overfitting occurs when a model becomes too tailored to the training data, resulting in high variance and poor predictive performance on the test set. To mitigate overfitting, various techniques can be applied, such as comparing the prediction results between the training and test sets. Several approaches can be used, including increasing the number of decision trees and reducing their maximum depth. The prediction's coefficient of determination acted as the evaluation metric. According to the Sklearn, this metric exhibited as is defined as:

$R^2 = \left(1 - \frac{u}{v}\right)$ (4).u represent the residual sum of squares $((y_{pred} - y_{true})^2)$. Meanwhile, v stands for the total sum of squares $= ((y_{pred} - \text{mean}(y_{true}))^2$. It's worth noting that a constant model that solely predicts the anticipated y, irrespective of input, could obtain a score of R^2 equal to 0.0. The significance of a node j within a single decision tree, the calculation involved as follows [30]:

$$ni_j = w_j C_j - w_{left(j)} Cleft(j) - w_{right(j)} C_{right(j)} \quad (5)$$

where w_j denotes the weighted number of samples in node j as a fraction of the total weighted number of samples. C_j represents the impurity in node j and left (j) and right (j) corresponds to the child nodes associated with it. The following calculation is used to determine feature's importance [30]:

$$fi_i = \frac{\sum_{j:nodejsplitsonfeaturei} ni_j}{\sum_{j \in allnodes} ni_j} \quad (6)$$

Ultimately, the feature values were calculated as the mean of every particular decision tree.

3. Results and discussion

3.1. HTL

The HTL exhibits an important role in optimization of PSC performance via two ways such as it transports the light generated holes towards the back contact and HTL hampers the interaction between absorber layer and back contact. Despite the comprehensive application of Spiro-OMeTAD into PSC to increase PCE, low hole mobility (μ_p), and environment instability confined its commercial application. Consequently, various kinds of HTLs like CuI, CuSCN, Cu_2O, PEDOT: PSS, CdTe, $MASnBr_3$ and CFTS have been analyzed shown in Table 2. To begin the simulation, a PSC architecture of FTO/TiO_2/$KSnI_3$/Spiro-OMeTAD/Au was simulated to validate with previously reported results [8]. WS_2 opted as ETL due to its high electron mobility (μ_n), wide range of E_g, and high conductivity of $10^{-3}\ \Omega^{-1}\ cm^{-1}$ [31]. The validation of the simulated result shown below in Table 3. The highest occupied molecular orbital (HOMO) of HTL should be appropriately aligned with that of the perovskite layer. The proper optimization is required to select appropriate ETL and HTL to maximize the performance of the PSC. The energy bandgap diagram of ETL, absorber layer and various HTLs illustrated below in Fig. 3. The J-V and QE plots of PSC with various HTLs are shown below in Fig. 4. The plotted curve from simulations is well-fitted with the previously reported outcomes, which validates numerical simulations.

Table 3
Comparison with previously reported results.

Cell structure	V_{OC} (V)	J_{SC} (mA/cm^2)	FF (%)	PCE (%)
FTO/TiO_2/$KSnI_3$/Spiro-OMeTAD/W	1.70	15.85	36.13	9.77 [8]
FTO/C_{60}/$KSnI_3$/PTAA/C	0.76	17.44	80.80	10.83 [32]
FTO/TiO_2/$KSnI_3$/ Spiro-OMeTAD/Au	1.48	13.20	79.07	15.55 [This work]

To examine the impact of the several HTLs like Spiro-OMeTAD, CuI, CuSCN, Cu_2O, PEDOT: PSS, CdTe, $MASnBr_3$ and CFTS on the PV parameters of PSC. The thickness of HTLs was 50 nm throughout the simulation. The simulated results are demonstrated in Fig. 4. The PV parameters with several HTLs are presented below in Table 4.

The Spiro-OMeTAD and PEDOT: PSS both are organic materials. The E_g for Spiro-OMeTAD is 3 eV and for PEDOT: PSS is 2.2 eV depicted in table 1 and 2. The PEDOT: PSS has excellent properties such as high electrical conductivity, mechanical flexibility and suitable for thin film formation [33]. The simulation results demonstrated that $KSnI_3$-based PSC exhibited maximum PCE of 21.08 % (with V_{OC} of 1.59 V, J_{SC} of 15.08 mA/cm^2 and FF of 87.43 %) for WS_2 as ETL and PEDOT: PSS employed as HTL. The HOMO level of Spiro-OMeTAD and PEDOT: PSS has good band alignment with $KSnI_3$ therefore with PEDOT: PSS it has achieved maximum PCE but not for Spiro-OMeTAD. This can be attributed to lower hole mobility (μ_p) than PEDOT: PSS [34,35]. Hence, PEDOT: PSS is an appropriate HTL for achieving high PCE. Furthermore, the PEDOT: PSS exhibits good stability in air over Spiro-OMeTAD so that it has wide application in PSCs. Zuo et al. (2017) doped PEDOT: PSS with polymer electrolyte PSS-Na which results in high work function and good band alignment of modified PEDOT: PSS with the absorber layer. Hence, enhanced PCE has been obtained from 12.35 % to 15.56 % [36]. The small amount of 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4-TCNQ) added to PEDOT: PSS could improve the electrical conductivity and better band matching with the absorber layer. Therefore, the PCE enhanced from 13.30 % to 17.22 % [37,38].

3.2. Optimization of HTL

3.2.1. Impact of thickness

In the preceding section, Table 4 highlighted that PEDOT: PSS emerges as the most promising HTL for $KSnI_3$-based PSC. As the attributes of HTL, such as thickness, doping density (N_A), and defect density (N_t), exert a substantial influence on PSC performance and these parameters must be optimized. Notably, HTL thickness exhibits a vital role in facilitating efficacious carrier transport and controlling the recombination rate [39]. Consequently, the thickness of an HTL is optimized to get high PCE. Fig. 5a, b demonstrates the impact of PEDOT: PSS thickness on the J_{SC} and V_{OC} of PSCs. The findings reveal that increasing PEDOT: PSS thickness up to 250 nm enhances both J_{SC} and V_{OC}, beyond which they become constant. According to experimental surveys, thicker HTLs yields smoother film surfaces, reducing interfacial recombination and thus enhancing V_{OC}. The suitable HTL thickness is required to avoid series resistance (R_S) for thicker layers [40,41]. Firstly, a thinner HTL might not accumulate a sufficient number of holes. Secondly, the region among the absorber layer and a thin HTL might not be as potent as in thicker layers, leading to inadequate driving force for carrier partition. The study also indicates that when HTL thickness exceeds 250 nm both V_{OC} and J_{SC} tend to be constant. This is primarily due to carrier travel distance to reach the interface. Consequently, traps promote non-radiative Shockley–Read–Hall (SRH) recombination and enhanced trap-assisted recombination rate [42]. The influence of thickness on PV parameters is depicted in Fig. 5. The initial fall in the

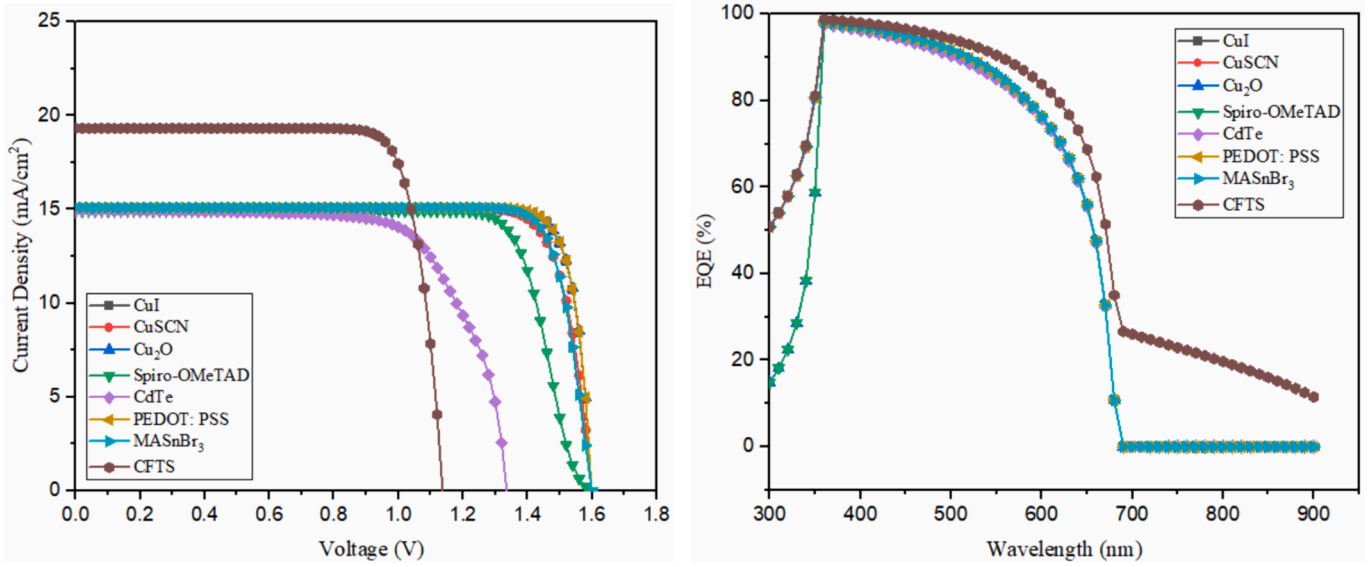

Fig. 4. (**a**) J-V and (**b**) QE plots of simulated PSCs with various HTLs.

Table 4
The PV parameters of $KSnI_3$-based PSC with distinct HTLs.

Cell structure	V_{OC} (V)	J_{SC} (mA/cm^2)	FF (%)	PCE (%)
FTO/WS_2/$KSnI_3$/CuI/Au	1.59	15.01	87.40	20.98
FTO/WS_2/$KSnI_3$/CuSCN/Au	1.59	15.01	84.48	20.27
FTO/WS_2/$KSnI_3$/Cu_2O/Au	1.59	14.96	87.63	20.96
FTO/WS_2/$KSnI_3$/Spiro-OMeTAD/Au	1.59	14.89	79.18	18.85
FTO/WS_2/$KSnI_3$/PEDOT: PSS/Au	1.59	15.08	87.43	21.08
FTO/WS_2/$KSnI_3$/CdTe/Au	1.33	14.93	71.06	14.18
FTO/WS_2/$KSnI_3$/$MASnBr_3$/Au	1.59	15.09	85.14	20.56
FTO/WS_2/$KSnI_3$/CFTS/Au	1.13	19.32	81.26	17.85

curve is a result of an increase in R_S. The optimized thickness of HTL is 250 nm, yielding a PCE of 21.30 % demonstrated in Fig. 5d.

3.2.2. *Impact of N_A*

The findings from previous studies have shown the significant impact of doping density (N_A) in the HTL vastly affects the PV parameters of PSCs, including conductivity, recombination rate and V_{OC} [6]. Hence, the solar cell parameters were simulated in the range of N_A values from 10^{14} to 10^{22} cm^{-3} at a thickness of 250 nm of HTL. As depicted in Fig. 6a, an enhancement in N_A leads to an increase in V_{OC}. In layered semiconductor architectures, the alignment of the fermi level at the same value results in an equilibrium state, causing band bending and built-in voltage (V_{bi}) [43]. This internal electric field drifts segregated photo-generated e$^-$s and h$^+$s towards the n and p regions respectively, where they gather. Under illumination and open-circuit conditions, the excited carriers induce the separation of quasi-Fermi-levels (EFn and EFp) for e$^-$s and h$^+$s, respectively, within the photoactive semiconductor material. This effectively nullifies V_{bi}, and forms a photo-voltage referred to as V_{OC} [44].

Raising the dopant concentration leads to reduction in the recombination rate, owing to an enhanced internal electric field and accelerated carrier segregation. Simultaneously, there's a slight decrease in J_{SC} within the N_A range of 10^{14} to 10^{18} cm^{-3}. Notably, a pronounced fall in the J_{SC} is observed at 10^{19} cm^{-3} due to generation of numerous deep Coulomb traps that reduce the μ_p [45]. The Fig. 6a shows that the maximum PCE of 21.32 % is obtained at N_A of 10^{20} cm^{-3}.

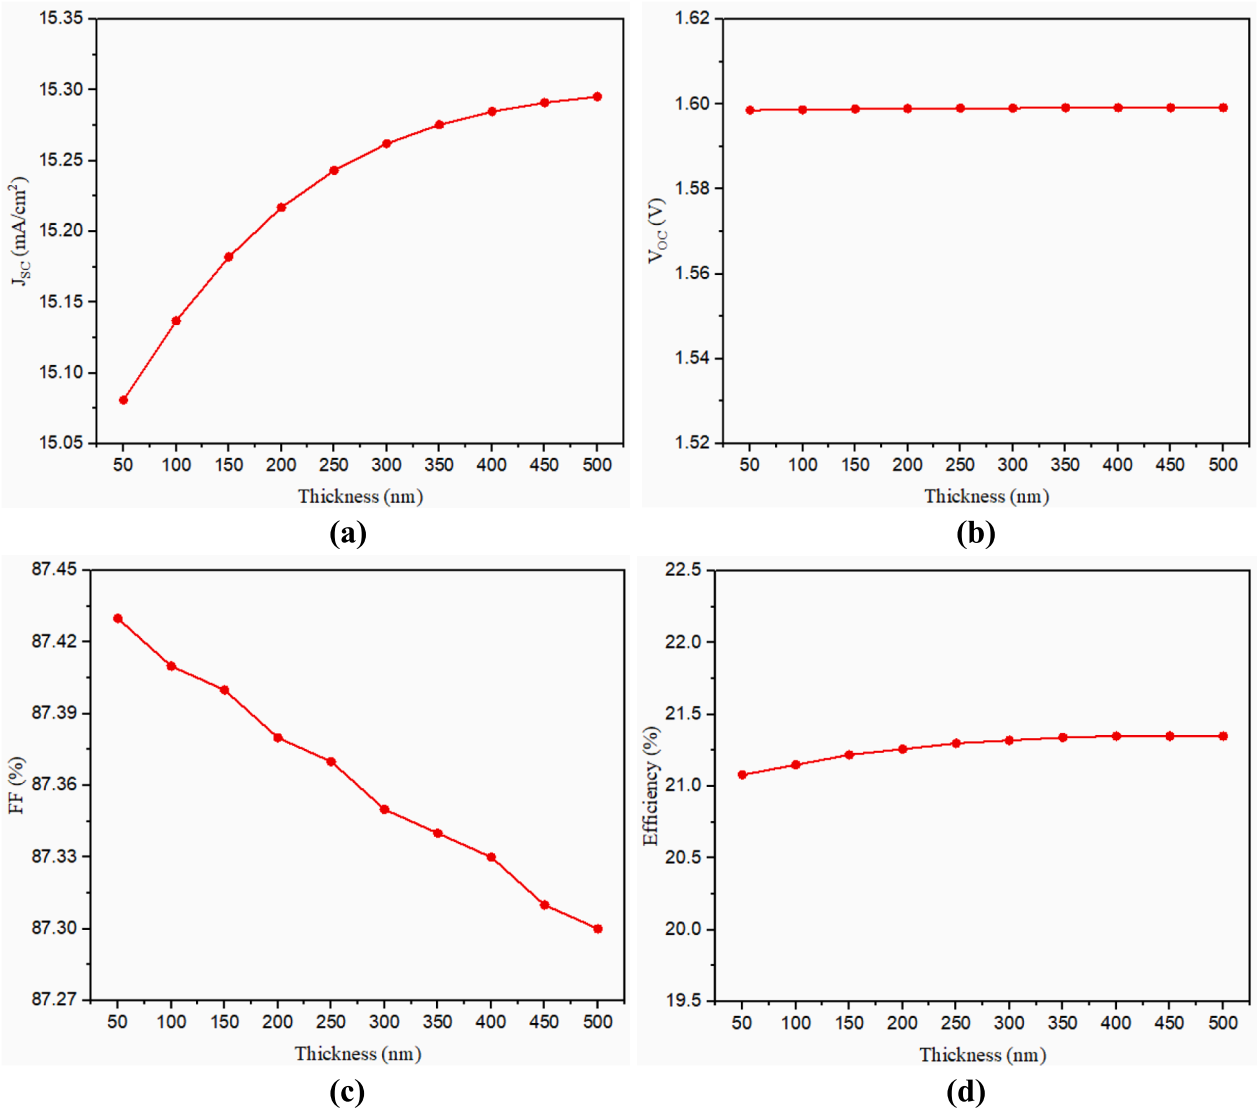

Fig. 5. Impact of the thickness of PEDOT: PSS layer on PV parameters of PSC.

3.2.3. *Impact of N_t*

In addition to the N_A, HTL defect density (Nt) affects the performance of PSCs. The impact on the PSC characteristics demonstrated in Fig. 7. The N_t of 10^{17} to 10^{22} cm^{-3}, Fig. 7a, b, c and d reveal no significant changes in PV parameters. However, a pronounced decline in V_{OC}, J_{SC} and PCE surface for change in N_t from 10^{14} cm^{-3} to 10^{17} cm^{-3}. This precipitous shift is primarily attributed to the rapid emergence of numerous recombination sites in the HTL and at interfaces [46]. A high value of N_t in HTL, arising from diverse sources like undesirable foreign atoms, and native defects, give rise to shallow or deep traps. These traps adversely impact cell performance. Fig. 7d shows that an increase in interface defects leads to reduced efficiency. Beyond a certain N_t, it becomes constant. These interface defects, primarily stemming from the lattice mismatch between absorber layer (AL) and HTL, yield deep traps at the interface. These traps function as SRH recombination centers. Consequently, PCE experiences a decline, reaching about 20.97 % at Nt $= 10^{22}$ cm^{-3}. In the beginning FF decline is attributed to the abundance of recombination centers and R_S resulting from a significant number of traps (Fig. 7c). Despite the superior outcomes at lower N_t, simulation results diverge from experimental findings. Hence, a value of 1×10^{14} cm^{-3} was selected.

3.3. *Optimization of $KSnI_3$ layer*

The above outcomes have shown that PEDOT: PSS is the most suitable HTL for $KSnI_3$-based PSC. The maximum PCE of beyond 21 % has been obtained at 250 nm of thickness of HTL, N_A of 10^{20} cm^{-3} and at N_t of 1×10^{14} cm^{-3}. Therefore, we have opted for this optimized value of thickness, N_A and N_t for the further simulation study to optimize the performance of $KSnI_3$-based PSC.

3.3.1. *Impact of thickness*

The characteristics parameters like J_{SC}, V_{OC}, FF and PCE of PSCs are significantly influenced by the thickness of the perovskite absorber layer. In our investigation, we explored the impact of thickness of the absorber layer on the performance of the architecture: FTO/WS_2(100 nm)/$KSnI_3$/PEDOT: PSS (250 nm)/Au. The thickness of the $KSnI_3$ layer has exhibited a straight relation with the evaluation of the outcomes of PSC through its effect on the charge carrier's diffusion length. It is known to us that as the thickness of the layer decreases, the absorption rate also lowers. This results in a decrement in photocurrent and therefore PCE of the PSC also reduces from 200 to 1000 nm. The change in PCE is depicted below in Fig. 8a. However, with the thickness increasing up to 550 nm, PCE gradually rises. This phenomenon can be attributed to the generation of large amounts of charge carriers by

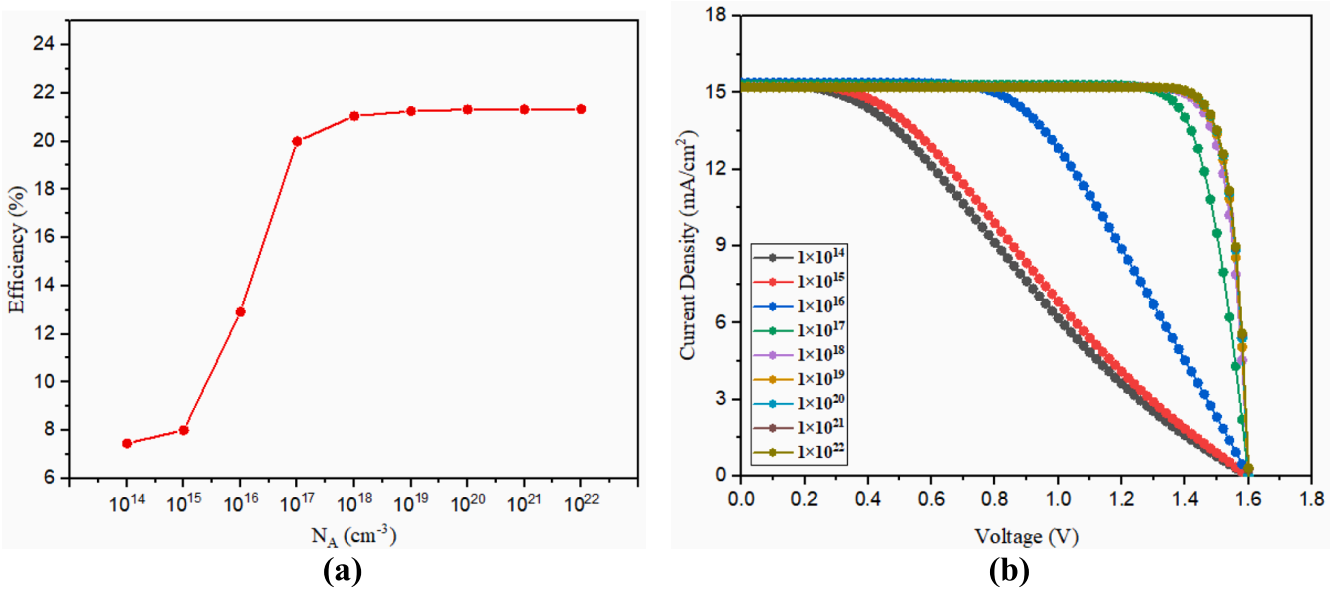

Fig. 6. (**a**) Efficiency versus N_A of the PEDOT: PSS. (**b**) J-V curves of HTL depending on its N_A. (**c**) Efficiency vs thickness of the HTL and (**d**) Effect of N_t on PCE.

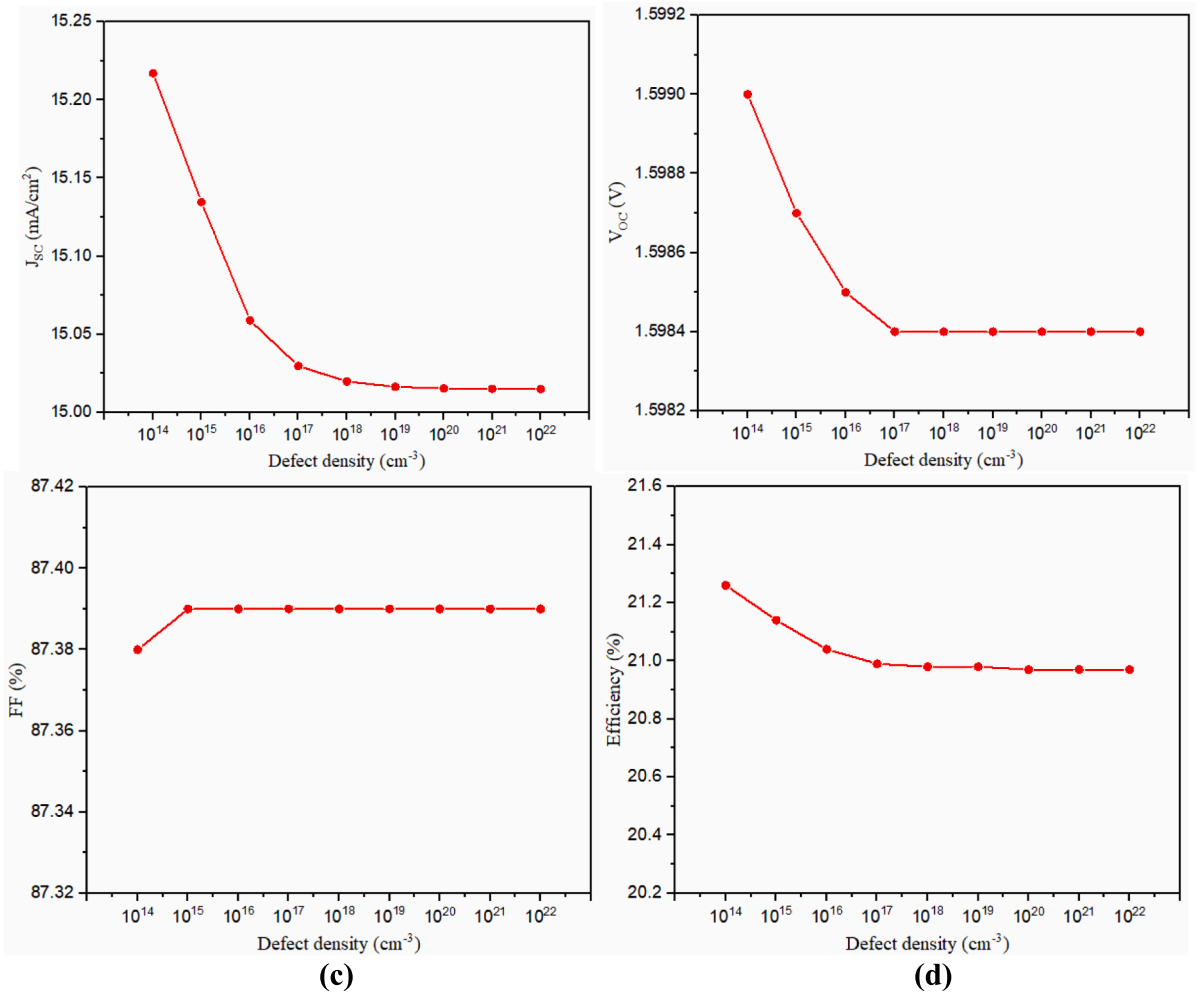

Fig. 7. Impact of N_t of the PEDOT: PSS on PV parameters of $KSnI_3$-based PSC.

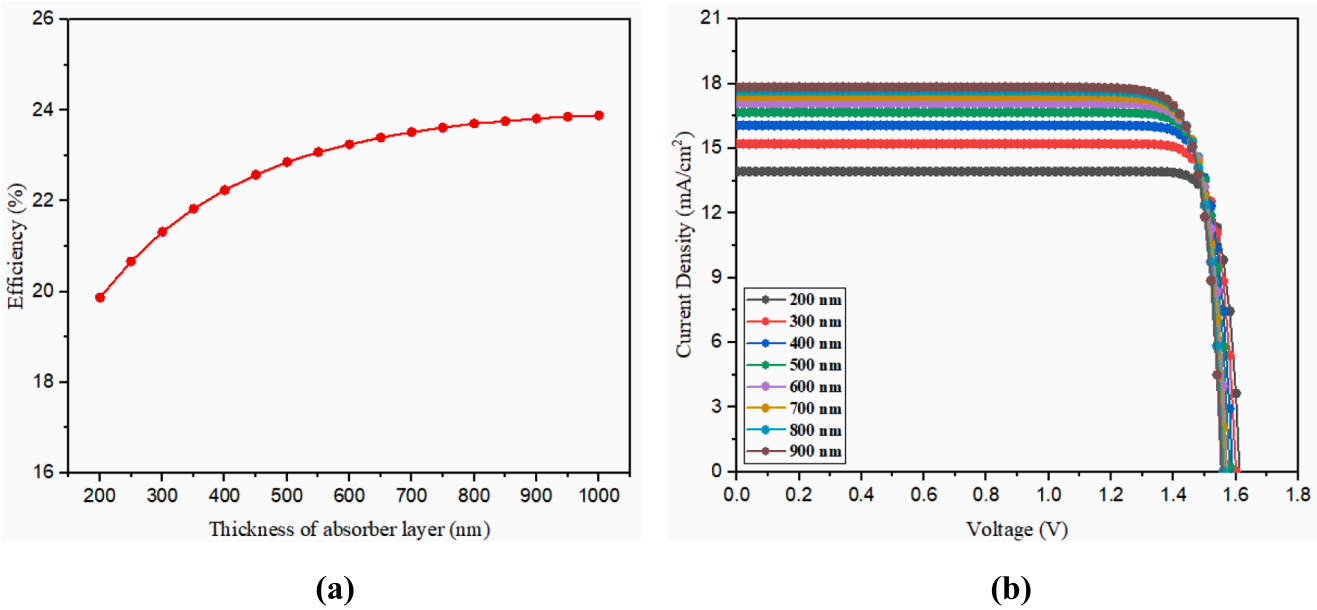

Fig. 8. (**a**) Efficiency vs thickness of the absorber layer. (**b**) J-V curves with function of absorber layer thickness.

absorbed photons, leading to higher EQE, J_{SC}, and overall improved performance [47]. This enhancement is also evident in the J-V curves (Fig. 8b). As the absorber layer thickness exceeds 550 nm, both V_{OC} and FF parameters decrease. Optimum thickness value for $KSnI_3$-based PSC is 550 nm. The maximum efficiency goes up to 23.08 % together with V_{OC} is 1.57 V, J_{SC} is 16.90 mA/cm^2 and FF is 86.59 % at a thickness of 550 nm.

3.3.2. *Impact of N_t*

Similarly, with the HTL influence, there is a lack of substantial change in the PV parameters until an N_t value of 10^{13} cm^{-3} is reached. These PV parameters exhibit a decline when a high defect concentration is present. A heightened defect concentration within a low-quality perovskite layer results in an increased number of non-radiative recombination centers, consequently deteriorating PV parameters of PSC. This degradation can be attributed to alterations in the diffusion length of charge carriers and their lifetime. While a low N_t value might contribute to high PCE in simulated PSCs, the elevated fabrication cost is a deterrent. Moreover, a low N_t value does not accurately reflect real-world conditions due to the instability of such perovskites under humid conditions, leading to partial degradation. Therefore, we propose N_t values ranging from 10^{13} to 10^{15} cm^{-3} for the building of high-performance PSCs with reasonable stability. The optimized N_t is 1×10^{13} cm^{-3} for $KSnI_3$ perovskite layer at which it has achieved the maximum PCE of 23.08 %, as demonstrated in Fig. 9a. The J-V plot of $KSnI_3$ PSCs based on the N_t of the absorber layer is simulated and demonstrated in Fig. 9b. For perovskite layers when N_t is increased, the undesirable recombination rate also rises, attributed to the formation of defects that act as dangling bonds, serving as trap state for the charge carriers. This enhancement in recombination leads to fall in J_{SC}, which is subsequently responsible for the decrement in FF of solar devices. The device PCE also decreased from 23.08 % to 7.85 %, when N_t was increased from 10^{13} to 10^{20} cm^{-3}. Such an increasing amount of recombination resulted in a sharp fall in PCE of PSC.

3.4. *Optimized device*

The optimized ETL and HTL are WS_2 and PEDOT: PSS respectively with the Au (gold) as metal back contact. The optimized parameters such as 1) Thickness: PEDOT: PSS (250 nm), $KSnI_3$ (550 nm), WS_2 (100 nm) and FTO (400 nm); 2) N_A: PEDOT: PSS (10^{20} cm^{-3}) and 3) N_t: PEDOT: PSS (1×10^{14} cm^{-3}), $KSnI_3$ (1×10^{13} cm^{-3}) and WS_2 (1×10^{13} cm^{-3}). The PSC structure and energy band diagram of the optimized device demonstrated in Fig. 10. The optimized PCE of 23.08 % with V_{OC} = 1.57 V, J_{SC} = 16.90 mA/cm^2, and FF of 86.59 % has been obtained. The JV and QE curves of optimized PSC are illustrated in Fig. 11(a-b).

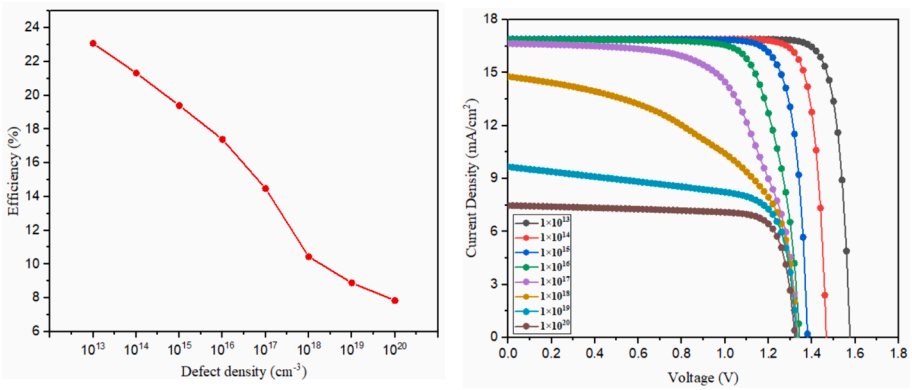

Fig. 9. (**a**) Efficiency vs N_t of the absorber layer and (**b**) Effects of N_t on the J-V characteristics of $KSnI_3$-based PSCs.

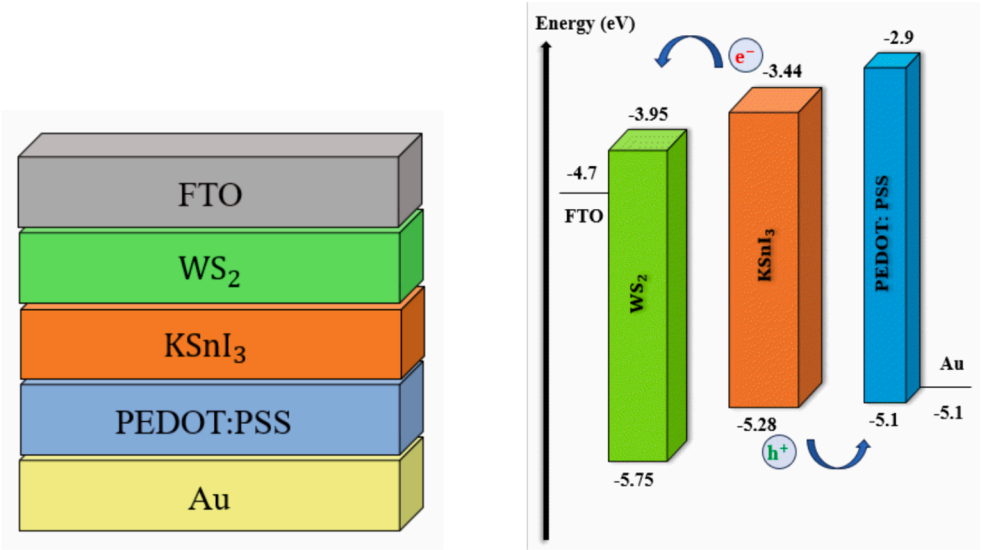

Fig. 10. Architecture and band alignment diagram of optimized PSC.

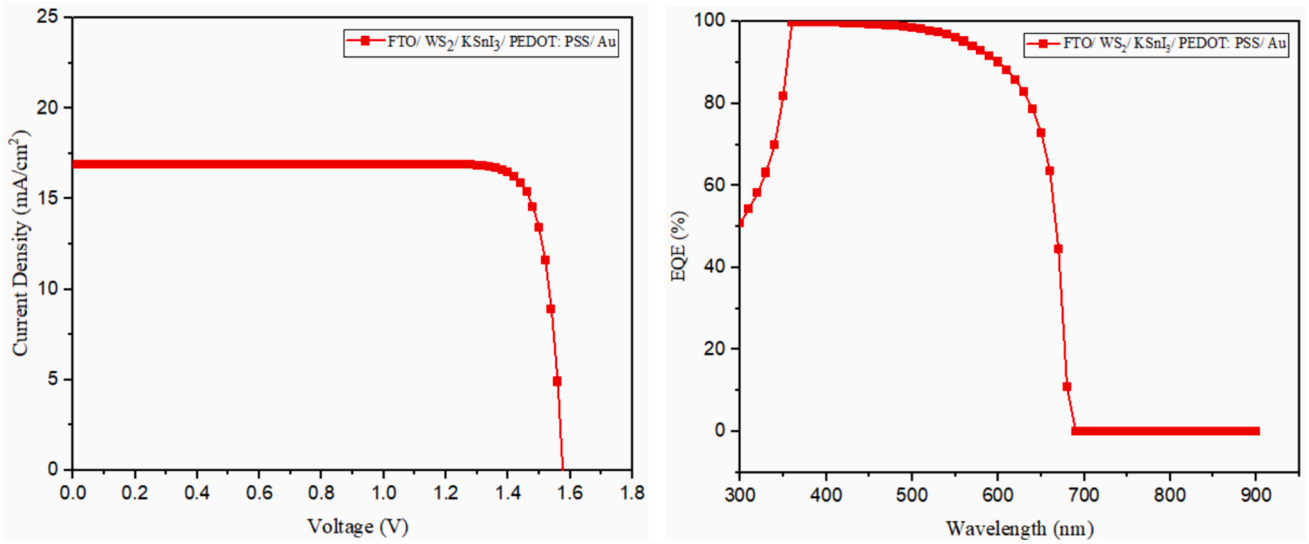

Fig. 11. (**a**) J-V and (**b**) QE plot of optimized device.

3.5. *Machine learning*

In this work, python is employed for the prediction of factors affecting the performance of the PSC. Due to its robustness to overfitting and optimal complexity, the Random Forest algorithm was used for the training and testing [48]. The researchers noted that more powerful rivals, like neural networks and deep neural networks, acquire needless complexity, leading to overfitting and reduced performance [49,50]. Considering the relatively small size of the dataset and its high complexity, compiling a larger set of records would be beneficial. The research focused on reducing the dataset's complexity to improve the model's accuracy. By employing Scikit-Learn, influence of every feature on the entire predictive performance of the ML model was observed. The eleven most important features were identified, and their relative importance was shown in Fig. 12. It has shown that the features such as thickness, N_t, N_A, of the HTL were found to be the most responsible in differentiating between the performance of two distinct PSCs. The outcomes guide for the design of new solar cells. Subsequently, a new model was built using the selected important features aiming to achieve a similar level of performance while reducing the model's size due to the

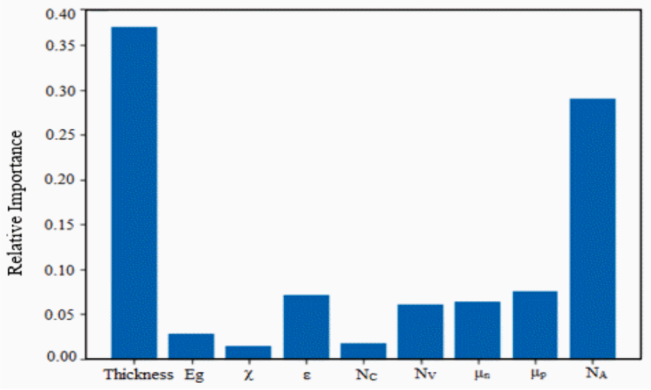

Fig. 12. Different features with relative importance in the ML model.

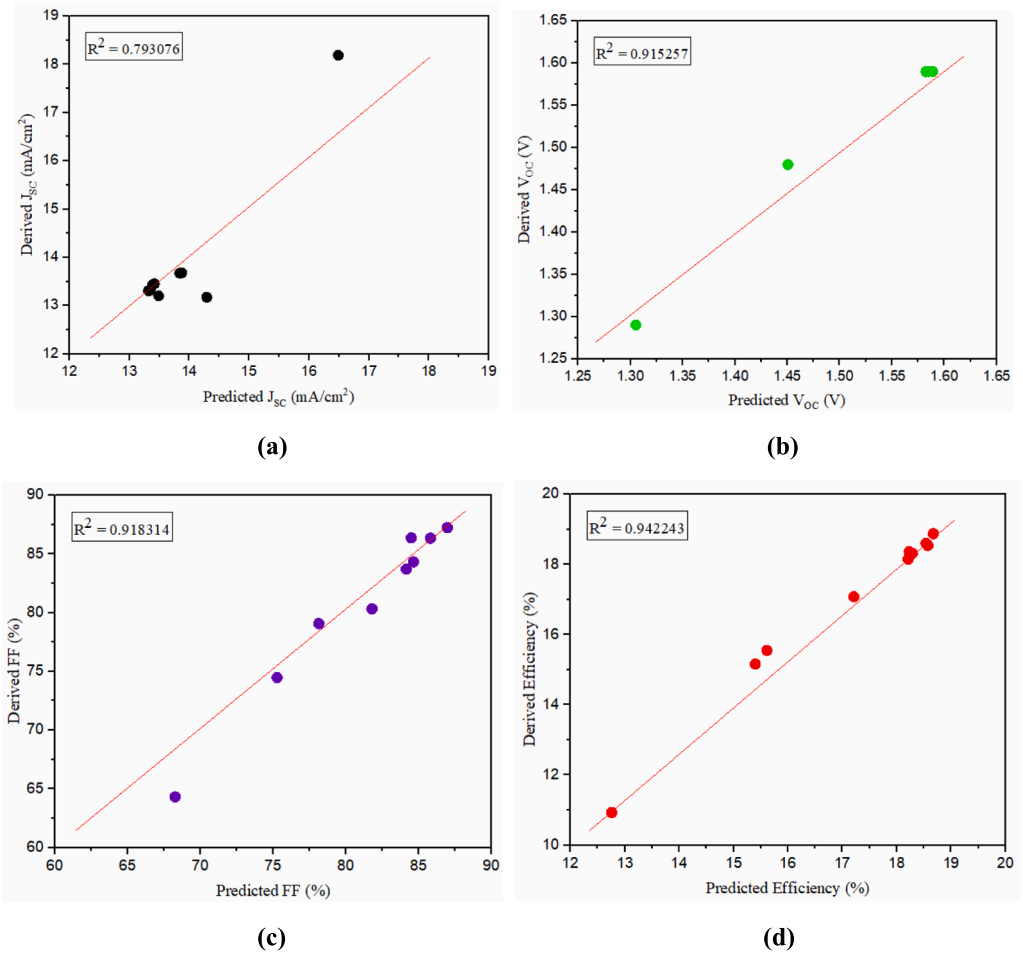

Fig. 13. Derived and predicted values of PV parameters.

fewer features used. The model results were measured and illustrated in Fig. 13 (a-d). Ideally, the slope of plots is near to 1, indicating accurate predictions. The ML model achieved a mean accuracy of 0.89 % and mean R^2 of 0.8921 between actual and predicted values for each target feature. While the accuracy might not be extremely high, the results are encouraging for further investigation and bridging the gap between artificial intelligence and materials science. The model trained for large input data which leads to highly efficient and realistic results.

4. Conclusions

This work comprises analysis of $KSnI_3$-based PSC with the various HTLs. The effect of distinct parameters, including thickness of perovskite absorber layer and HTL, as well as N_A and N_t have been examined using SCAPS-1D. The ML model was used to predict the performance of the PSCs. The study demonstrated PEDOT: PSS as a promising HTL that could replace the expensive and less-conductive Spiro-OMeTAD. The maximum PCE of 23.08 % was obtained for the configuration of FTO/WS_2/$KSnI_3$/PEDOT: PSS/Au. The SCAPS-1D outcomes, deduced that the optimized thickness of HTL was 200 nm, with N_t of 1×10^{14} cm^{-3} and a N_A of 1×10^{20} cm^{-3} results in maximum PCE. The optimized thickness of the $KSnI_3$ layer is 550 nm and at N_t of 1×10^{13} cm^{-3} for an efficient PSC. The incorporation of the ML approach provided enhanced insight into the critical factors involved in designing and fabricating solar cells. The ML model demonstrated an accuracy score of 89 % in predicting the performance metrics of PSCs. The device PCE improved beyond 23 % by optimizing parameters such as thickness of absorber layer and HTL, N_t and N_A. The study focused on proper optimization of perovskite absorber layer and HTL for advanced and efficient architecture of $KSnI_3$-based PSC. A precise and powerful model can be trained by providing a large number of inputs to ML. With the series of this study, we can study the lead free and other potential material to optimize the performance of PSCs using the ML model.

Primary Microplastics in the Ecosystem: Ecological Effects, Risks, and Comprehensive Perspectives on Toxicology and Detection Methods

Pooja Singh, Gunjan Varshney and Raminder Kaur

Discipline of Polymer Science and Chemical Technology, Department of Applied Chemistry, Delhi Technological University (Formerly Delhi College of Engineering), Delhi, India

ABSTRACT

Recent discoveries of microplastics in cities, suburbs, and even remote locations, far from microplastic source regions, have raised the possibility of long-distance transmission of microplastics in many ecosystems. A little is known scientifically about the threat that it posed to the environment by microplastics. The problem's apparent size necessitates the rapid development of reliable scientific advice regarding the ecological risks of microplastics. These concerns are brought on by the lack of consistent sample and identification techniques, as well as the limited physical analysis and understanding of microplastic pollution. This review provides insight regarding some unaddressed issues about the occurrence, fate, movement, and impact of microplastics, in general, with special emphasis on primary microplastics. The approaches taken in the earlier investigations have been analyzed and different recommendations for future research have been suggested.

KEYWORDS

Primary microplastics; ecological risk; identification techniques; bioaccumulation; microplastic toxicity

1. Introduction: general aspects of microplastics

Plastics, regarded as a miracle material, have freed humanity from the socioeconomic constraints brought on by a scarcity of natural resources. Globally, fossil fuel feedstock accounts for 97–99% of plastics while the remaining 1–3% are derived from bio (plant) based. In the last few decades, the amount of plastic manufactured annually around the world has dramatically expanded, rising from 2 million tonnes in 1950 – 381 million tonnes in 2015.[1] After 2000, more than 50% of the total amount of manufactured plastic was introduced into the market. It is anticipated that their production would rise, even more, hitting approximately 600 million tonnes in 2025 (Figure 1). About 42% of the plastic produced is consumed by the packaging business, with the construction and building sector using the remaining 19%. Numerous "essentials" in our daily lives, such as cling film, face masks, medical supplies, coffee mugs, and shopping bags are made of single-use plastic (SUP). The recent Covid-19 outbreak increased the usage of SUPs, particularly gloves, facemasks, and personal protective equipment (PPE) kits, which added 3.5% more to the world's solid waste percentage. The US, India, and China are the largest producers of SUP, respectively.[2]

Plastics are ubiquitous in the environment due to their high manufacturing rates and longevity. Initially, larger plastic trash drew the attention of scientists and the general public. Tiny plastic particles, however, were found in the marine environment as early as the 1970s.[3] Microplastics (MPs) in the environment have gained more attention over the past several years and are now a prominent field of study. MPs are typically characterized as plastic particles that are less than 5 mm in size and have a wide range of shapes (including fibers, spheres, and fragments), sizes, colors, and compositions. Further, MPs can be categorized into primary and secondary regardless of their sizes. For application, for instance, in medical equipment and in personal care items like cosmetics and soaps, primary

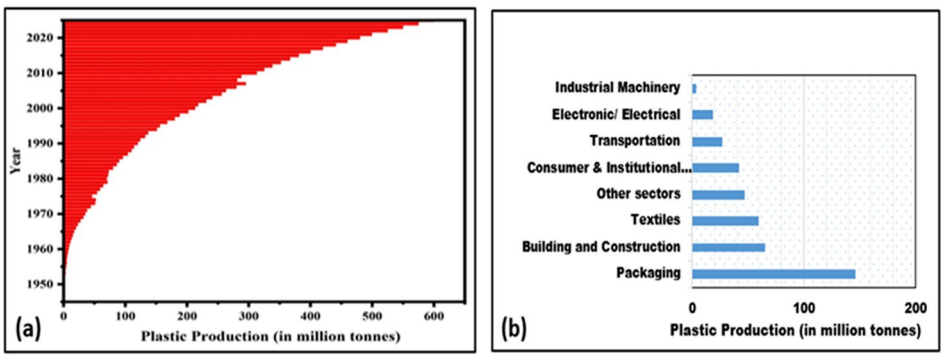

Figure 1. (a) Plastic production till 2025 and (b) primary plastic production by industrial sector, 2015.

MPs are found in microscopic sizes (fibers, microbeads).[4] Large plastic items, when in contact with the environment, physical, chemical, and biological factors cause the plastic to break down into tiny fragments, creating secondary MPs, including mulch breakage debris and tire-wear debris, among others. Terrestrial and aquatic ecosystems are found to contain enormous and diverse MPs. As MPs are difficult to degrade, they remain in the environment for a long time, which results in significant and harmful environmental pollution.[5]

This review addresses substantial knowledge gaps about the origin, destiny, migration, and effects of MPs, emphasising on primary MPs, which are becoming more widely acknowledged as a severe environmental threat. This study aims to provide a comprehensive understanding of the widespread presence of MPs in both terrestrial and aquatic ecosystems, their behavior, after entering the environment, as well as their potential negative effects on human and environmental health by integrating previous research findings. The goal of the review is to facilitate the development of evidence-based policies and interventions targeted at reducing the detrimental effects of MPs pollution by clarifying the sources, patterns of distribution, and ecological implications of primary MPs. Additionally, it offers guidelines for establishing effective risk management approaches for MPs by highlighting crucial areas for future research. This review seeks to give a thorough understanding of primary MPs and inspire the development of effective mitigation techniques, through a perspective, on which a relatively limited research is available.

2. Occurrence and distribution of MPs

Industrial, domestic and coastal activities are the prime anthropogenic actions that have resulted in the presence of these harmful plastic particles in the ecosystem (aquatic and terrestrial). In addition, the fragmentation of huge plastic garbage and residential runoff, comprising MPs fragments and microbeads (used in cosmetics and other consumer goods), are the major contributors to the entry of MPs into the aquatic ecosystem (Figure 2).[6] The air-blasted resin pellets and powders that are released by the plastic manufacturing sectors also end up contaminating the aquatic environment. MPs pollution in the marine ecosystem is also caused by coastal activities like aqua tourism, marine industries, and fishing.[7] MPs pollution in soils is mostly attributed to sewage irrigation, plastic trash, agricultural facilities (such as agricultural compost), surface runoff, fertilizer use and atmospheric deposition.[8] In addition, MPs are produced during the stacking, disposal, or burning of plastic trash. Other sources of MPs in the environment include clothes, industrial dust emissions, housing infrastructure, and other daily life activities. MPs can be suspended and transported

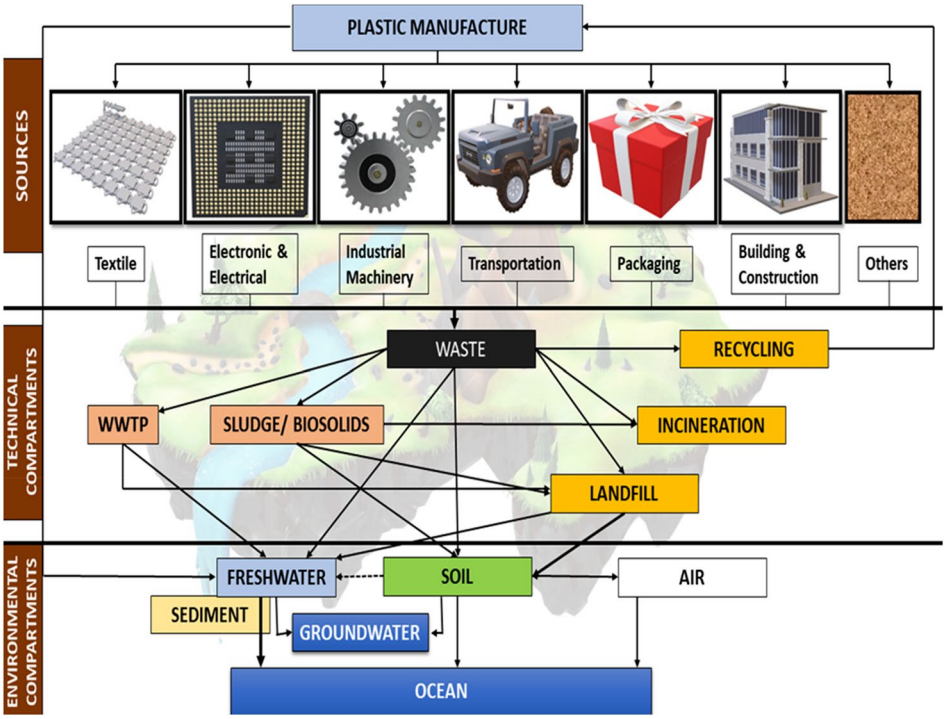

Figure 2. Occurrence and distribution of plastics into different environmental compartments.

by air in the atmosphere since they are naturally low in weight.[9] MPs temporal and spatial distribution across the soil, aquatic systems, and the atmosphere is controlled by the transit of those materials, as these can migrate between multiple ecological divisions. For instance, through human activity, wind erosion, and runoff, MPs in the soil can also be carried into neighboring environmental matrices including the water and air.[10] Their movement within the soil is influenced by a number of aspects, including soil texture, cracking, biotic transport (soil biodiversity and soil community composition), and aggregation.[11]

The vertical transportation of MPs in the soil is facilitated by agricultural methods, soil fissures, root growth, and soil pores. Organisms have also been observed to be involved in the mobility and distribution of MPs in soil.[8] Additionally, it's possible for MPs in the soil to get into groundwater. Pollution from MPs in the environment may end up in the oceans and on land. Numerous elements, including wind direction, wind speed, particle density, and rain, have an impact on the transportation of MPs and their fallout or deposition in the atmosphere.[12] While some MPs settle through dry and wet deposition processes, others remain suspended in the atmosphere or eventually settle into aquatic and terrestrial ecosystems.[13] Further, under intense and ongoing hydrodynamic events like waves,

rainstorms, ocean currents, monsoons, and tides, the aquatic environment is a dynamic region, and thus, MPs can travel between the marine environment and the land.[11] The fundamental characteristics of MPs, such as shape, density, color and size, can have significant impact on their transportation.[14]

3. Classification and sources of MPs

MPs are classified into two main types based on their origin and manufacturing processes: primary and secondary. Primary MPs are intentionally manufactured particles, such as microbeads in cosmetics, resin pellets used in plastic production, and fibers from textiles. MPs in the micro-meter size are specifically manufactured for use in industrial abrasives for sandblasting, such as polyester or acrylic beads, plastic pre-production pellets ('nurdles'), or personal care products like exfoliating agents in creams and cleansers comprising polyethylene 'microbeads'. Primary MPs particles are most likely to reach wastewater treatment streams, after being washed down by industrial or domestic drainage systems. In spite of the capability of a few sewage treatment works to evacuate up to 99.9% the absolute number of particles entering the system may still permit a noteworthy number to bypass filtration frameworks, and be discharged into the freshwater environment with wastes.[15]

Secondary MPs are created as a consequence of the fragmentation of the macro and meso-plastic litter, resulting from the degradation and disintegration of larger plastic items, such as bottles, bags, and packaging materials owed to environmental factors like UV radiations, mechanical abrasion, and microbial activity.[16] High temperatures and UV radiation can induce chemical changes in plastics, causing them to become brittle and therefore more prone to the fragmentation. Fragmentation allows greater surface area and particle count per unit mass. The contributing factors of fragmentation in marine waters are both wave action and sunlight. Plastic fragmentation is considered to occur readily on land, particularly at the soil surface, as a consequence of exposure to ultraviolet radiation from the sun, assisted also by temperature variations that are usually greater than those found in sea water. Despite the fact that microfibres are secondary particles, they will be released into the environment alongside primary MPs, via sewage effluents as well as sludge disposal. As a result, based on similar release routes, the fate and transfer of such fibers could be more closely linked with that of primary MPs. Understanding the distinction between the primary and the secondary sources is crucial for comprehensively assessing the impact of MPs on the environment and human health as depicted in Figure 3.

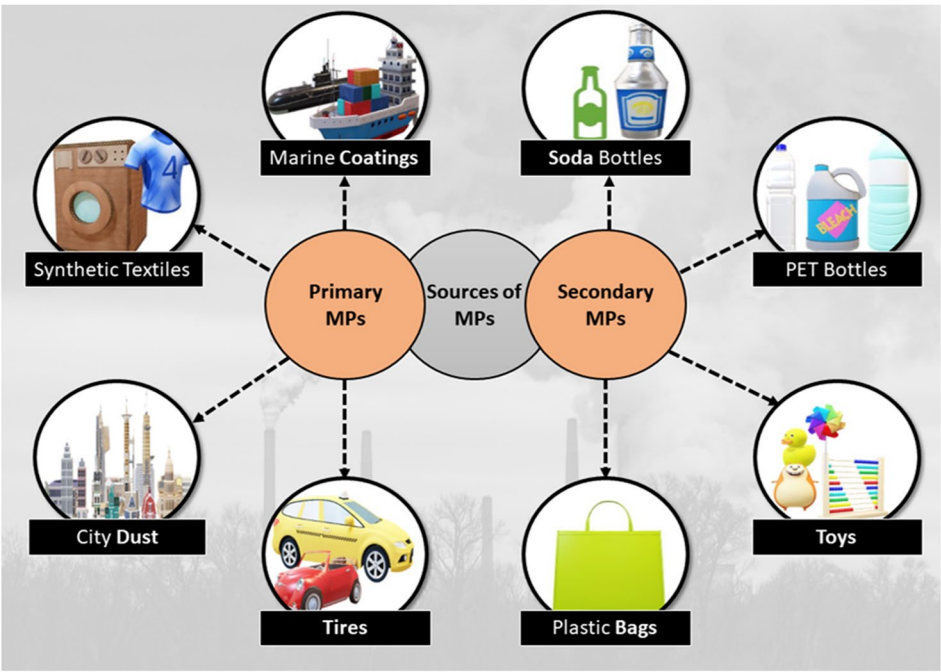

Figure 3. Primary and secondary sources of MPs in the environment.

3.1. Primary MPs

MPs particles are employed as exfoliants in some personal care product segments, such as hand cleaners, facial cleaners, and toothpastes.[17] Polyolefin particles exhibiting a size of 74-420 µm and an amorphous frame, with no sharp edges were characterized as suitable for use as exfoliants in a US patent for skin cleaners containing plastic microparticles.[18] Polyolefins used in them include polyethylene (PE), polypropylene (PP), and polystyrene (PS). Scrubs have been shown to contain PE microbeads in concentrations ranging from 0.4 to 10.6%, with sizes ranging from 40 to 1000 µm[17]. According to a Cosmetics Europe survey, PE accounted for 93% of the MPs used in skin cleaner products in these countries in 2012. MPs are also utilized in medical settings, such as in dental tooth polish and also as delivery systems for pharmaceutical active ingredients.[19] MPs from medical and personal care products can be released into the environment post used via wastewater. MPs are also used in industrial abrasives used for air-blasting the paint off the metal surfaces and cleaning various types of engines, as well as drilling fluids for oil and gas exploration.[20] MPs made of poly allyl diglycol carbonate, acrylic, PS, melamine, and polyester (PES) are among the materials found in industrial abrasives.[21] These may enter the environment if used in open systems or improperly disposed off. Another significant source of primary MPs is the raw material utilized to make plastic products (pre-production plastics), specifically plastic resin

flakes or pellets and fluff or plastic powder that can enter the environment as a result of improper handlings, such as through run-off from processing plants or accidental loss during transit. Furthermore, degranulate generated during the recycling of plastic and remnants from plastic processing factories can eventually reach the aquatic or terrestrial ecosystems.

Glitter, a form of MPs, comprised of tiny, flat, shiny particles, is commonly used in household items, cosmetics, and arts and crafts. It is typically made of Mylar^{TM}, a type of polyester film known as BoPET (biaxially-oriented polyethylene terephthalate), which has a melting point of 260 °C and a real density of 1.38 g/cm^3.[22] These particles are water-insoluble and often coated with metal to enhance the reflectivity. While plastic glitters come in a wide range of colors, shapes, and sizes; their environmental impact is a growing concern due to their potential to harm the ecosystems, as they can easily enter the environment and pose risks to life and human health. Though, some manufacturers have introduced biodegradable glitter alternatives made from plant-derived materials; despite this, the widespread use of plastic glitters continues, to raise the environmental and health concerns. Therefore, it is essential to address the ecological and health implications of glitter as a primary MPs, and to explore sustainable alternatives to mitigate its environmental impacts.[23]

3.2. Secondary MPs

Secondary MPs are produced when bigger plastic materials break down into smaller pieces. The four human activities responsible for the plastic entery into the environment are thought to be general littering, the dumping of plastic waste, loss from poorly managed landfill sites, and waste collection.[24] Additionally, waste from the recycling facilities is lost due to wind contributes significantly toward the MP polluton.[25] A huge portion of the plastics, that is produced and used for packaging of goods, with a limited shelf life is habitually dumped in the landfills and is often covered periodically with soil or synthetic material to prevent the trash from being blown away. During natural calamities like strong seas, tsunamis, and hurricanes, substantial amounts of these plastic particles may be released into the ocean.[25] Another significant source of MPs found in the environment is low-density polyethylene (LDPE) films, which are employed in enormous quantities to raise soil temperature, protect crops, suppress weeds, and hold irrigation water in the soil (a process known as "plastic mulching"). The particles from these thin plastic foils could wind up in the soil if they crumble. Additionaly, a significant culprit of MPs release in the fibers released after washing PES blankets, fleeces, and shirts in home washing machines. During a single wash, the tested PES fleece released over 1900 fibers in total. Also, synthetic textile fibers are discharged into the air during routine use or tumble

drying.[26] There are numerous other places from where MPs can enter the environment, such as car tyre abrasion and application of paints & protective coating. Abrasion from other plastic materials, such as household plastics, results in the release of MPs as well.[27] Material lost or discarded from fishing boats, aquaculture facilities, merchant ships, recreational boats, offshore oil or gas platforms, and during military operations are examples of ocean-based sources of marine litter. The dominant form in the environment is still unknown, but it is likely location-dependent; for example, the primary MPs may be more significant in areas close to wastewater discharge sources than secondary MPs, which may predominate in open waters. Table 1 provides the spatial and temporal pattern in the abundance of Primary MPs.

4. Characteristics of MPs

MPs pollution of the environment is now recognized as a risk to ecosystem and researchers have begun to address this field as an issue of importance in recent years, after recognizing the comparative lack of studies on MPs. The effects of MPs on soil ecosystems (both below and above ground) are almost unexplored. Furthermore, the effects of MPs on terrestrial systems vary depending on the type of MPs. It has been demonstrated that the physical and chemical characteristics of MPs influence their ability to bind pollutants.[51]

4.1. Physical properties of MPs

4.1.1. Size

The sampling and analytical techniques are frequently used to identify the sizes of micro/nano-plastics. While MPs come in a variety of sizes, the most prevalent range from 1 µm to 5 mm, nano-plastics (NPs) are approximately <100 nm in size.[52] The research on MPs size has gradually shrunk to less than 2000 µm, due to the progress made in the qualitative and quantitative approaches for MPs. The presence of smaller MPs in the atmosphere warrants additional investigation, as evidenced by the abundance of fluorescent non-fibrous particles <20 µm and smaller fibers that were found in the total atmospheric deposition in downtown London.[53] These investigations demonstrated that MPs, which can be inhaled and consumed, make up a non-negligible portion of the atmospheric particulate matter. Additionally, the research suggests that inhaling MPs could be harmful to human health.

4.1.2. Shape

The most frequent morphologies in atmospheric MPs are fragmented and fibrous. In addition, there are other shapes such as spheres, flakes, and

Table 1. Spatial and temporal pattern in the abundance of primary MPs.

S. No.	Country	Description	Ref.
1.	Mainland China	In 2015, one-sixth of the 737.29 Gg primary MPs waste from mainland China made its way out into the water. Tire dust and synthetic fiber accounted for the largest percentage of this trash, with 53.91 and 28.77% of the total, respectively.	28
2.	Netherlands	In STP effluent, the total estimated concentrations of primary MPs from consumer items are 0.2, 2.7, and 66 μ/L in three different scenarios. The three product categories under consideration, namely paint and coatings, cleaning agents, and cosmetics and personal care items, are all significant contributors.	29
3.	East Asia (marine medaka *Oryzias melastigma*.	Marine medaka embryos exposed to primary MPs experienced a variety of adverse outcomes, such as heart rate alterations, morphological irregularities, and various forms of deformity.	30
4.	Sweden	Major kind of detected MPs are fibers and fragments: Influent MPs concentration 15MP L^{-1} Effluent MPs concentration 8.3MP L^{-1} and Daily MPs discharge 3.6×10^{-4} MP d^{-1b}	31
5.	Finland (Baltic Sea)	Major kinds of detected MPs are synthetic particle and textile fiber: Influent MPs concentration 430, 180MP L^{-1} Effluent MPs concentration 9, 5MP L^{-1} and Daily MPs discharge 3.7×10^{9} MP d^{-1}	32
6.	Scotland (River Clyde, Glasgow)	Major type of detected MPs are fibers (polyamide, polyester, acrylic): Influent MPs concentration 16MP L^{-1} Effluent MPs concentration 0.3MP L^{-1} and Daily MPs discharge 6.5×10^{7} MP d^{-1}	33
7.	Germany (Lower Saxony)	Major type of detected MPs are fibers (polyethylene): Daily MPs discharge 4.2×10^{4}–1.2×10^{7} MP d^{-1}	34
8.	Australia (Sydney)	Major type of detected MPs are fibers (polyethylene): Influent MPs concentration 2MP L^{-1} Effluent MPs concentration 0.3,0.2MP L^{-1} and Daily MPs discharge 3.6×10^{6}–1×10^{7} MP d^{-1}	35
9.	Canada (Vancouver)	Major type of detected MPs are fibers and fragments: Influent MPs concentration 14MP L^{-1} Effluent MPs concentration 1MP L^{-1} and Daily MPs discharge 10.6×10^{9}–19.9×10^{9} MP d^{-1}	36
10.	Turkey (Seyhan and Yüreğir WWTP in Adana city)	Major type of detected MPs are fibers (polyester): Influent MPs concentration 4.8×10^{6} MP per day; 2.0×10^{6} MP per day Effluent MPs concentration 1.2×10^{6} MP per day; 0.35×10^{6} MP per day and Daily MPs discharge 2.2×10^{5}–1.5×10^{6} MP d^{-1}	37
11.	USA (Charleston Harbor, South Carolina)	Major type of detected MPs are fibers, microbeads: Daily MPs discharge 5×10^{8}–1×10^{9} MP d^{-1}	38
12.	China (WWTP located in Wuxi, Jiangsu Province, Eastern China)	Major type of detected MPs are fibers and fragments: Influent MPs concentration 4MP L^{-1} Effluent MPs concentration 0.1, 0.1MP L^{-1} and Daily MPs discharge 6.5×10^{6}–3.5×10^{6} MP d^{-1}	39
13.	Italy (Northern Italy)	Major type of detected MPs are fibers (polyamide and polyesters: Influent MPs concentration 3MP L^{-1} Effluent MPs concentration 0.4MP L^{-1} and Daily MPs discharge 10.6×10^{8} MP d^{-1}	40

(*Continued*)

Table 1. Continued.

S. No.	Country	Description	Ref.
14.	Netherlands (Dutch River Delta and Amsterdam Canals, Waste water treatment plant, North Sea Sediments and biota)	Major type of detected MPs are fibers: Influent MPs concentration 68–910MP L^{-1} Effluent MPs concentration 52MP L^{-1} and Daily MPs discharge 7.5×10^{8}–4.3×10^{10} MP d^{-1}	41
15.	Russia (Central WWTP of Vodokanal of St. Petersburg)	Major type of detected MPs are fibers, synthetic particles: Influent MPs concentration 467, 160MP L^{-1} Effluent MPs concentration 16, 7MP L^{-1}	42
16.	France (River Seine)	Major type of detected MPs are fibers: Influent MPs concentration 260–320MP L^{-1} Effluent MPs concentration 14–50MP L^{-1} and Daily MPs discharge 8.4×10^{9} MP d^{-1}	43
17.	South Korea (STF of M-city, Y-city, and S-city)	Major type of detected MPs are fibers and fragments: Influent MPs concentration 30, 17, 14MP L^{-1} Effluent MPs concentration 0.4, 0.1, 0.3MP L^{-1}	44
18.	Denmark (10 largest WWTP)	Major type of detected MPs are fibers and synthetic particles: Influent MPs concentration 7216MP L^{-1} Effluent MPs concentration 54MP L^{-1}	45
19.	Poland (Southern Poland)	Major type of detected MPs are fibers: Influent MPs concentration 19–552MP L^{-1} Effluent MPs concentration 0.028–0.96MP L^{-1}	46
20.	U.S. (Florida)	Prove that MPs have contaminated the tissues of intertidal marine predatory snails: 256 MPs were extracted from snails ($n=60$), of which 93% were microfibers and 7% were microfragments. Furthermore, 67 MPs (8.375 MP/L) of which 97% were microfibers and 3% were microfragments were extracted from 8 L of seawater.	47
21.	South Australia (Bellevue Heights, 5050)	MPs can be found in gardens as a result of using plastic landscaping fabrics in the mulch bed or by leaving plastic bubble wrap to be combined with mulches. They were initially quite huge, measuring more than 5 mm. However due to abrasion, weathering, or natural decay, MPs are freed from the garden after seven years.	48
22.	Rome, Italy (Ospedale Fatebenefratelli Isola Tiberina)	Detection of MPs in human breastmilk Major type of detected MPs are nitrocellulose, polyethylene, polyvinyl chloride, polypropylene, chlorinated polyethylene, polyvinyl alcohol. Breastfeeding moms may expose their infants to toxins from beverages, foods and personal care products, which could have a harmful impact.	49
23.	U.S.(Orontes River)	Major type of detected MPs are fibers and fragments: Influent MPs concentration 57.2MP L^{-1} Effluent MPs concentration 2.1MP L^{-1}[a]	50

[a]MP L^{-1}: Millions Particles per litre
[b]MP d^{-1}: Million Particles per day

films. MPs have distinct physical characteristics depending on their shape. Fibers are typically very thin, flakes are typically thick and asymmetrical, and films are typically thin and flexible. Overall, the primary MPs morphology at the time of manufacture, surface deterioration and erosion processes, and residence time in the environment all affect the form of MPs in the atmosphere.[54]

4.1.3. Color

One of the key aspects for the identification of plastic debris and potential contaminants during sample preparation is color. There have been reports of MPs/NPs in a variety of colors, including green, red, blue, orange, grey, yellow, white, brown, off-white, and tan. For the visual evaluation of MPs particles in the atmosphere, color is generally a helpful parameter. While low-density polyethylene (LDPE) has been given opaque colors, polypropylene has been clear and transparent. When reporting and interpreting results, it is important to take into account that MPs discoloration can happen during sample preparation (H_2O_2-oxidative digestion) and weathering.[55] Like natural foods, brightly colored NPs particles are frequently consumed by marine species. MPs in the colors black, blue, green, and red are primarily consumed by copepods, zooplankton, fish larvae, and euphausiid.[56]

4.1.4. Crystallinity

Plastics density, permeability, and swelling characteristics are affected by the organized structural links known as crystallinity.[57] As MPs/NPs spend more time in their surroundings, their crystallinity changes. The polymer's amorphous area breaking down encourages overall crystallinity and shrinks MPs/NPs size.[11] Crystallite materialization may change MPs/NPs from their counterparts and change their toxicity. It ultimately affects the surface area, particle shape, size, and chemical characteristics such as the adsorption of contaminants and additives, which in turn affects the ingestion rate.[58]

4.1.5. Surface properties

Surface chemistry and surface area are the two main components of surface property. Particles in the nanoscale have a significant impact because MPs/NPs surface area grows as particle size decreases.[58] The deterioration of the plastic surface by photo- and oxidative processes results in the formation of new functional groups when OH radicals, O and N oxides, and other photo-generated radicals are interacted with.[59] Due to the disruption of the plastic's surface area by these pathways—chemical leaching, creation of angular-shaped NPs from primary microbeads, and ingestion—microscopic particles are liberated.[57] Furthermore, because the microbial community uses the oxygenated binding sites, surface chemistry has a substantial impact on particle-biota interactions.[60]

4.2. Chemical properties of MPs

MPs comprise additives (plasticizers, antioxidants), polymers, dyes, and pollutants that get adsorbed on the surface. When plastics are produced, utilized, and deteriorate, these chemicals are easily discharged into the environment.[61,62]

4.2.1. Chemical additives

To increase the product's efficiency, additives are added during the production of plastic to achieve the desired color, and transparency. These additions increase the polymer's resistance to degradation by biological (bacteria and fungi), mechanical, physical (light radiation, ozone, and temperature) and electrical agents.[63] Additives include pigments, ultraviolet stabilizers, flame retardants, lubricants, and plasticizers as well as inert or reinforcing fillers. Additional ingredients include wood, clay or linen, graphite, cellulose pulp, glass fibers, jute, rock flour, cotton flakes and kaolin.[64] Low molecular weight additives embedded in the polymer matrix are brittle and can escape out into the neighboring water bodies (Polyethylene terephthalate (PET) oligomers from food trays and bottles; flame retardants from electronic items; nonylphenol from food contact materials; Lead (Pb) from un-plasticized PVC pipes; and Antimony (Sb) from PET water bottles).[59] The majority of MPs and NPs are additives and fundamental polymeric substances made from plastics and chemicals absorbed from the environment and are linked to plastic toxicity (i.e., monomers, plasticizers, solvents, additives-dyes, and catalysts).[60] These substances disturb the endocrine system, when ingested or inhaled, leading to metabolic diseases, hormonal imbalance, neuro-developmental abnormalities, reproductive issues and asthma. The impact of various additives in plastics on human health is given in Table 2.

4.2.2. Chemical structure

Higher sorption capacity may result from a chemical structure with a wide surface area or high porosity. For instance, PET had the highest sorption rate, while PE had the largest sorption capacity. The PE, with a higher sorption capacity, leads to more pollutant diffusion, due to its bigger surface area, wider space between polymer chains, and free volume.[67] As opposed to PE, PET has a smaller surface area and a glassy polymeric structure, which do not facilitate diffusion into the material and so have a faster sorption rate.

4.2.3. Chemical interactions

Pollutant affinity for MPs varies due to chemical interactions such as hydrogen bonding, electrostatic interaction, π–π interaction, hydrophobic interaction, or van der Waals force.[68] For example, because of the amide groups, hydrogen bonding between polyamide (PA) and antibiotics caused strong affinity.[69] The difference in the surface charges between amine-modified polystyrene (PS-NH_2) and carboxyl-functionalized polystyrene (PS-COOH), caused embryonic apoptosis, oxidative stress, cell death, and

5. Bioaccumulation of MPs

5.1. Transfer mode of MPs in human body

MPs enter the human body through three main routes: ingestion, inhalation and skin contact (Figure 4).[70] Due to their prevalence in the water supplies and food chain, MPs are easily consumed.[71] MPs are not able to penetrate the epidermal membrane being too thin, but they might still enter through hair follicles, wounds, or sweat glands. As they can easily enter the environment and pose risks to marine life and human health. The fact is that human body is exposed to MPs through all three channels, although environmental and seafood particles pose the highest danger of absolute exposure.

5.1.1. Gastric exposure

Recent investigations on MPs exposure and toxicity have shown that ingesting plastic particles is the main way that people are exposed to.[72] There are studies demonstrating that MPs are being consumed through food and drink, but there aren't any explicitly examining the toxicity of NPs in individuals.[73] Human feces samples were initially examined, and the results revealed that plastic particles were being ejected, supporting the theory that people are consuming these particles through water and food. These observations, along with studies on ingested uptake in environmental models, unequivocally demonstrate that MPs and NPs consumption by humans will be pervasive.[74] It would be vital to investigate their pathway

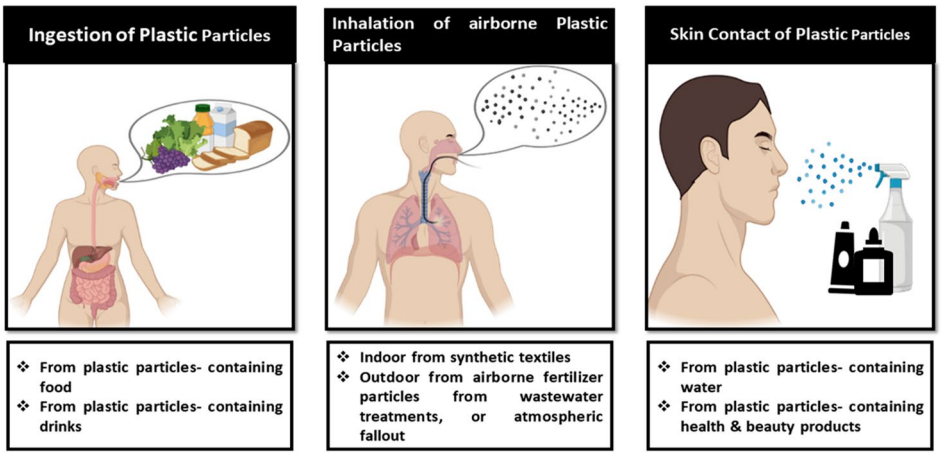

Figure 4. Three main routes by which plastic particles enter the body: Inhalation, ingestion, and skin contact.

via the GI tract and identify whether these particles translocate across the gut epithelia or persist in the gut lumen. MPs ability to penetrate at the paracellular level is uncertain since the pores at the tight junction channels i.e., relevant have a maximum functional size of about 1.5 nm. It is possible that they will enter via lymphatic tissue, and it is more likely that they enter through endocytosis or phagocytosis and invade the Peyer's patches' microfold (M) cells.[75]

5.1.2. Pulmonary exposure

Inhalation is the second most likely way for a human to come into contact with NPs. Indoor spaces have airborne plastic particles, mostly from synthetic textiles, which can cause occupational exposure or unintentional inhalation.[76] Exposure in outdoor areas may occur by inhaling contaminated aerosols from the ocean's waves or airborne fertilizer particles from dry wastewater treatment processes. The lung's alveolar surface area is substantial—about 150 m^2—and its tissue barrier is very thin—less than 1 μm. Nanoparticles can distribute throughout the entire human body because this barrier is permeable enough to pass through and into the capillary blood system.[72]

5.1.3. Dermal exposure

MPs/NPs are also commonly found in beauty and health products, especially in body and facial cleansers that are used directly on the skin.[77] Although there isn't enough evidence to draw firm conclusions on the impacts of nanocarriers, skin penetration depends heavily on the size of the particles and the health of the skin. Only one study describes that the synthetic textile causes the penetration of nanoparticles on the epidermal barrier at a very minute quantity. The stratum corneum, the skin's outermost layer, serves as a barrier to protect the skin from injury, microbial agents, and chemicals. Corneocytes comprise the stratum corneum, which is encased in lamellae of hydrophilic lipids which include long-chain free fatty acids, cholesterol, and ceramide. The skin could be exposed to plastic particles by contact with contaminated water or through the use of beauty and health products.[75] Plastic particles might enter the body through sweat glands, skin wounds, or hair follicles because MPs and NPs are hydrophobic, making it unlikely to pass through the stratum corneum and be absorbed.

5.2. Transfer in the bodies of animals (terrestrial and aquatic)

5.2.1. Terrestrial animals

MPs are ingested orally, where they enter the body, travel through the digestive system and is subsequently eliminated. However, a small number

of MPs can persist for days in the intestine of organsms.[78] Cells can absorb MPs in the intestine through endocytotic processes.[79] MPs that enter the intestines have also been demonstrated to induce inflammation and mechanical damage. Because of this damage to the intestinal epithelium, MPs can easily spread to other tissues and organs of organisms or enter their bloodstream through intestinal capillaries. Recently, it was shown that NPs can permeate the mucosa and muscularis layers of the intestine, pass beyond the gut epithelium, and then be transferred into other organs (such as the liver) by blood circulation.[80] This was done using an *ex vivo* salmon (*Salmo salmar*) gut sac exposure system.[81] Additionally, MPs can physically break up into smaller pieces as they go through the digestive system, which helps to facilitate their translocation.[82] An inhalation investigation in maternal rats also revealed that 20 nm NPs translocated to the fetal liver, brain, heart, kidney, and lungs by intratracheal instillation in addition to placenta, heart, and spleen during gestation.[83]

5.2.2. Aquatic animals

MPs in aquatic animals' gill canals could be directly injected, translocated to the gastrointestinal tract, or intercepted and then conveyed to the capillaries *via* the gill filaments.[84] Exposure to MPs caused several types of damage to fish gills, such as the lifting of epithelial, inner opercular membrane swelling, and aneurysms in secondary lamellae. Another potential pathway for MPs entrance into animal bodies is through the epidermis. By adhering to animals' damaged skin during the skin's healing phase, MPs can infiltrate muscle tissue. According to certain reports, some plastic that was wrapped around sea turtles eventually grew into their muscles.[85]

6. Fate of MPs

MPs appear to have no limits in the environment, and they are now pervasive throughout all ecosystems in the world (Figure 5). Plastic waste that has been released into the environment can be carried by the wind, swept from the land to surface waterways during rain, particularly with stormwater runoff, and transported in both freshwater and seawater. Large rivers are expected to transport a significant amount of micro- and macro-plastics into the oceans, although there aren't many studies to support this hypothesis. Over 50% of the world's population lives within 80 kilometers of the sea, thus, wind transport of macro-plastics to the oceans may be considerable. Very small MPs, which could be mobilized from open landfills, for example, may potentially be appropriate for airborne transport.

Depending on the density, plastics will either hover or submerge in water. Plastics having a density less than freshwater (about 1000 kg/m^3) or seawater (about 1030 kg/m^3) will be buoyant. The majority of consumer plastics, including PE, are buoyant in saltwater (Table 3). Plastics are typically colonized by a variety of species in aquatic environments. By increasing the density, this fouling can cause formerly buoyant objects to sink beneath the water's surface. The density of a plastic object may decrease if it becomes fouled by other species, causing it to resurface in the water. The specific density of MPs may also vary due to erosion, and wind-driven mixing of the upper water layer may cause previously buoyant MPs to sink. Depending on ocean currents, local winds, and shoreline geography, plastics can be transported over great distances. Beaches and oceanic gyres become overrun with buoyant plastic trash, and benthonic debris which occurs on the sea floor in the region with little circulation. Because smaller particles at the water's surface are less wind-exposed than larger ones, the mobility of MPs in surface waters may vary from that of macro-plastics.[87] Animals activity and aggregation of particles may also have an impact on the distribution of MPs. MPs can be covered by silt on beaches and in subtidal sediments, where they can be found at great depths. The movement of MPs throughout the terrestrial environment is still mostly unknown. It was established that the assimilation of micro- and macro-plastic particles into the soil is facilitated by terrestrial organisms like moles and earthworms. Plastic's photo-oxidative degradation is

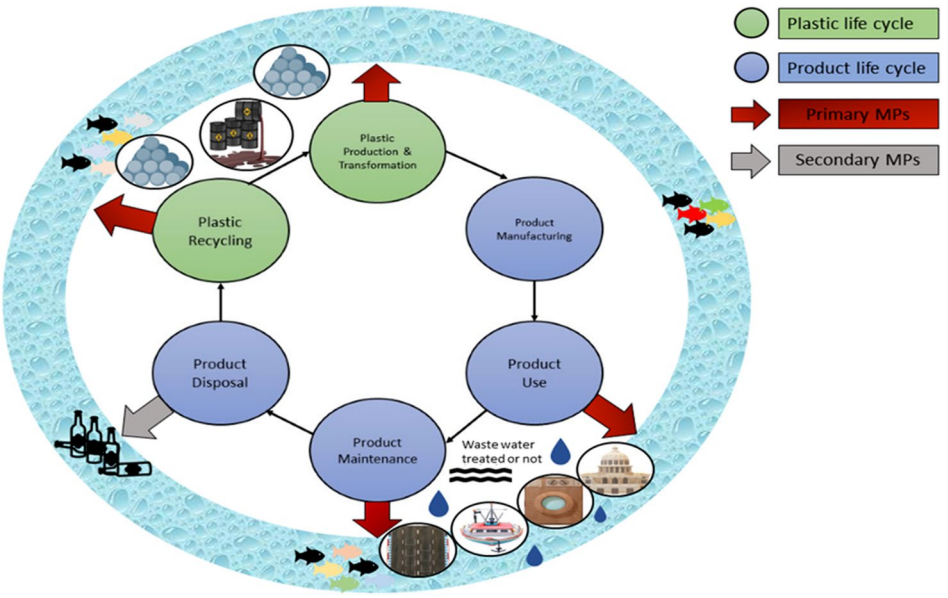

Figure 5. Plastic and plastic product lifecycle.

Table 3. Plastic material densities that are frequently observed in aquatic ecosystems.[86]

Abbreviation	Structure	Plastic class	Density (kg/m^3)
PTFE		Polytetrafluoroethylene	2100–2300
PES		Polyester	1240–2300
–		Alkyd	1240–2100
PU		Polyurethane	1200
PC		Polycarbonate	1200–1220
PVC		Polyvinylchloride	1160–1580
PMMA		Polymethyl methacrylate (acrylic)	1090–1200
PS		Polystyrene	1040–1100
PA		Polyamide (nylon)	1020–1160
PET		Polyethylene terephthalate	960–1450
PP		Polypropylene	830–920
HDPE	–	High-density polyethylene	940–980
LDPE	–	Low-density polyethylene	890–930
EPS	–	Expanded polystyrene (Styrofoam)	10–40

somewhat effective on a beach surface, but very slowly for plastics buried in soil or beach silt, or deep ocean.[88]

7. Ecological risks of MPs

7.1. Effects of MPs on the aquatic ecosystem

Atmospheric MPs penetrate the aquatic ecosystems by both dry and wet deposition. Thus, atmospheric deposition is a significant cause of the occurrence of MPs in the aquatic environment. Due to their longevity, MPs are persistent in aquatic conditions. Some MPs, might sink to the ocean floor as a consequence of having a higher density than sea water, whereas other MPs that are less dense than seawater frequently float on the water. Organisms in freshwater and the ocean may consume MPs.

7.1.1. Effects on aquatic animals

Diverse aquatic organisms, including invertebrates, mammals, fish, shellfish, and fish, consume MPs that enter the aquatic ecosystem. Both active ingestion of seawater and passive ingestion of prey can expose mammals to MPs.[89] Because of the chemicals involved, MPs can have an impact on the gut microbiome of aquatic animals.[90] They may build up in the gastrointestinal tracts of aquatic animals, preventing them from ingesting and properly digesting food.[91] Aquatic animals may become poisonous or even die as a result of this. Ingestion of modest dosages of MPs does not always result in the rapid death of organisms. MPs can have a major toxicological impact on fish, including the introduction of oxidative stress and inflammation in the gut. Non-aquatic animals like penguins and seagulls have been known to accidentally consume MPs that float on the water's surface. The MPs wafting on the water are susceptible to intentional or unintentional feeding by zooplankton because they resemble their food in size and colour.[92] Microfibres, mostly generated from synthetic textiles, seem to have a higher possibility than other fibers to infiltrate the food chain, as a consequence of ther size and shape. Ther size permit them to be promptly consumed by the aquatic organisms and are more susceptible to becoming entwined in large lumps inside the gut, instigating blockages.[93] In addition to having a deleterious impact on the flora and fauna directly, MPs can concentrate on living beings, reach the food chain, progress to various trophic levels, and potentially pose a risk to human health.

7.1.2. Effects on aquatic microorganisms

MPs increase the amount of inorganic and organic carbon in the aquatic environment, which increases microbial activity[94] and can cause additional

CO_2 to be released into the aquatic environment resulting from changes in the CH_4 cycle. The MPs invasion altered the structure and composition of the bacterial communities and reduced the diversity and richness of the biofilm.[95] Food webs and carbon metabolism in aquatic environments are impacted by changes in the aquatic microbiome. Microorganisms prefer using MPs as novel substrates because of their buoyancy, hydrophobic surface, and capacity for long-distance transmission.[96] The colonization of pathogenic microbes on the surface of MPs may impact the transfer of deadly microbes into the aqueous environment.[97]

7.1.3. Effects on hydrophytes

MPs that float on the water's surface inhibit phytoplankton from absorbing light, which prohibits them from offering oxygen and food to aquatic organisms.[98] The architecture of phytoplankton communities can be drastically altered by high MPs concentrations.[99] Food webs and ecological processes in the aquatic environment will be impacted by the modifications to phytoplankton colonies. MPs also impair chlorella's capacity for the process of photosynthesis through oxidative stress and physical deterioration.[100] Algae could become more prevalent in some areas of the phytoplankton habitat. Because they are generally denser than water, common MPs gravitate into aquatic habitats. Submerged plants will experience oxidative stress, antioxidant defenses, and chlorophyll fluorescence characteristics because of these MPs, which will result in decreased plant height.[101] Plants submerged in water may be exposed to MPs through their leaves or roots.[102] The presence of microfibrils in the cell wall provided evidence that MPs had penetrated the plant.

7.2. Effects of MPs on the terrestrial ecosystem

MPs are introduced into the terrestrial environment through littering and the dumping of sewer sludge to land. MPs have the capability to penetrate the terrestrial environment through atmospheric transport and deposition. Studies report that both dry and wet deposition are ways in which atmospheric MPs penetrate the terrestrial environment.[103] Tyre plastic may escape into the ground from the road.[104] MPs from the atmosphere that enter the terrestrial environment either linger in the soil for a long period or decay gradually. MPs build up significantly in the soil, potentially endangering terrestrial ecosystems.

7.2.1. Effects of MPs on the soil biophysical environment

The soil ecosystem is negatively impacted by MPs in a variety of ways depending on their type, size, and shape. Wearing clothing has also been

shown to cause textiles to emit MPs into the air, which are then deposited in soil.[105] When textile waste is dumped as litter or thrown away in landfills, it can disintegrate and cause fibers to leak into the ground. Examples include single-use face masks, ropes, tarpaulins, and misplaced clothing.[106] It is believed that organisms like earthworms have the ability to move considerable quantities of MPs from the soil surface to greater depths.[105] MPs, which resemble soil particles in size and form, have less of an effect on the soil's structure.[107] Since fibrous MPs have a very different form from soil non-linear particles, it is possible that they can coil around soil particles more effectively. MPs shapes have the power to change the biophysical characteristics of the soil. According to a study, MPs can alter the soil's structure and impair its bulk density and water-holding capacity.[108] Types of MPs have an impact on how MPs and soil pore space interact. As opposed to PES beads, polyacrylic beads and PE fragments did not significantly lessen soil bulk density.

7.2.2. Effects of MPs on soil organisms

MPs pollution changes the soil's physicochemical characteristics, which impacts soil hydrodynamics and microbiological activity.[109] Different soil microorganisms are affected by MPs in different ways. The microbial populations in the soil may unavoidably change as a result, having effects on the soil's flora and fauna. MPs affect the composition of the microbial community in the soil. It was discovered that PE considerably altered the composition of bacterial communities and had an impact on their succession.[110] By altering the soil environment, MPs have an impact on the evolution of soil microorganism.[111] MPs can provide nutrients and organic carbon to the soil, and bacteria that make use of this resource have a higher chance of surviving.

Moreover, MPs can be consumed by soil animals. Consumption of MPs may cause soil animals to receive insufficient nutrients, experience oxidative stress, and suffer intestine injury, which will impede their ability to develop and reproduce.[112] Lower concentrations of MPs had an impact on the mortality of soil animals in spite of the presence of tissue and immune system damage.[8] Future studies are required to determine whether the immune system and histopathology can assist as possible indications of sensitivity to ingested MPs. The effects of MPs on soil creatures might vary, depending on their size and concentration. Through experimentation, it was discovered that the presence of MPs could have a considerable impact on the diversity and abundance of nematode and microarthropod communities.

The soil food chain may be affected by the way soil fauna reacts to the addition of MPs. The presence of MPs can drastically alter the soil

fauna through extractable chemicals in MPs.[113] MPs from the atmosphere may contaminate soil and have an impact on plant growth as well as on the leaves of the plants through dry and wet deposition. MPs present in the air can cling to leaf surfaces and even enter plants through stomata. Because of the morphology of the leaf stomata, the majority of the MPs that attached to and entered the leaf were found to be fibrous.[114] Stomata in plant leaves take in NPs and send them downward to the roots. MPs foliar absorption may impact a plant's ability to photosynthesis.[115] Foliar MPs exposure can significantly slow growth by reducing the area of leaf, weight of dry crop and height of crop.[116]

7.3. Effects of MPs on the biogeochemical cycles of soil carbon and nitrogen

The carbon and nitrogen cycles, soil microorganisms, climate change, and greenhouse gases (GHGs) are all interconnected in significant ways. According to certain research, MPs deposited into the soil can change the makeup and operation of microbial communities, which in turn can influence the carbon and nitrogen cycles in the soil.[117] According to a study, MPs additions can considerably increase CO_2 emissions from soil.[58] This might accelerate global warming and lead to additional severe environmental issues. The addition of MPs had no impact on soil nitrogen emissions, though. The size of MPs has an impact on the type of dissolved organic carbon in soil. According to a study, PVC hindered sediment nitrification and denitrification, while PUF and PLA encouraged it. The soil's ability to hold nitrogen was diminished in MPs-treated soils, as MPs modify the porosity of the soil, which could further impact the nitrogen cycle.[117] MPs could affect the carbon, nitrogen, and phosphorus-related genes and enzymes in soil bacteria, which in turn could affect the soil nutrient cycle.[118]

7.4. Effect on human health

As per studies, humans are primarily in continuous contact with environmental MPs through inhalation, ingestion, and skin contact.

7.4.1. Inhalation by respiration

Gravity causes MPs to settle in different parts of the human respiratory system. The body's concentration of MPs can be decreased through the clearance mechanism. The clearance system may be slowed down by MPs particle toxicity brought on by cytotoxicity, excessive dust load, oxidative stress, and particulate matter translocation, thus impacting the overall human health.[119] Because only MPs having sizes less than 10 μm can be

ingested, an MPs size influences its respiratory potential. Since, MPs smaller than 10 µm were found both indoors and outdoors, they can also enter the human body though inhalation. Even though mucociliary clearance occurs for the majority of the coarse inhalable particles in the upper airway, some tiny particles can evade this system and settle deep inside the lungs.[120] As, fragments are mostly transmitted by air, 31 synthetic polymer particles and fibers, of which 87.5% fragmented and 12.5% were fibers, were found in the lung tissue of 13 of the 20 autopsies of the deceased, validating this theory. The upper respiratory tract retains the majority of the MPs that are inhaled. The duration and intensity of MPs exposure also have an impact on the impacts on human health. High levels of MPs in the environment could pose serious threats to people's health.[121] A mannequin could simulate inhaling 272 MPs within 24 h using a breathing thermal manikin.[120] When it comes to exposure to airborne MPs, young children are typically more at risk than adults.[122] Low concentrations of atmospheric MPs typically expose the general public. However, practitioners who are exposed to high levels of MPs on the job, run the risk of developing occupational illnesses.[123] The size and form of MPs have a significant impact on cytotoxicity.. Lung cells exposed to MPs experienced significant morphological alterations and a reduction in cell growth.[124] Human lung epithelial cells' internalization, cell viability, cell cycle, and apoptosis may be impacted by NPs.[125] It was shown that exposure to MPs caused inflammation, oxidative damage, and disruption of intercellular junctional proteins in normal human lung epithelial cells BEAS-2B.[126] Respiratory illnesses, both acute and chronic, may develop from this. Among other things, metals, possible PAH transporters, plastic additives, and airborne MPs were suspected of producing chemical toxicity.[75]

The inflammatory potential of MPs with additives was often higher than that of MPs without additives.[123] Ultrafine particles (UFPs) may be inhaled and diffused from the lungs into the bloodstream, or they may be ingested after airway mucociliary clearance. These inhaled or ingested particles may continue to travel in the bloodstream and become harmful to other organs after translocation, including the liver, embryo, brain, etc.[121]

7.4.2. Oral ingestion

MPs are typically found in the food and water consumed by humans. Additionally, a lot of MPs are present in commonly used tap water, bottled drinks, and alcohol. In tests of tap water and various brands of bottled water from around the world, MPs particles were found.[73] 95% of MPs particles having size in the range of 6–100 µm, or 80% of MP particles with a size of 5–20 µm, were found in bottled water. Moreover, alcohol, salt, and shellfish all contain human-caused MPs pollution. Some MPs that reach the

human digestive tract are expelled through feces[127] and some are still seen in human babies. The human body can develop abrasions, perforations, and even obstructions in the digestive tract as a result of MPs ingestion.[128] All plastic particles exhibited high resistance to artificial digestive juices, as demonstrated by the effects of artificial *in vitro* digestion on five types of MPs, and the primary stages of the human gastrointestinal tract do not break down particles.[129] PE could decrease cell functions and alter the composition of intestinal flora, which would be dangerous for human health, according to *in vitro* simulation studies on human cells Caco-2 and intestinal flora.[130] On the other hand, when PS of various sizes was utilized on Caco-2 cells, the particles did not harm or inflame the cells.[131] MPs at the ambient level are unlikely to provide a severe health concern to humans when consumed orally. Epidemiological studies, *in vivo* animal experiments, and *in vitro* cell, culture techniques are used in the majority of current investigations on MPs in the human digestive system. MPs present in the human body can accrue in the digestive system or go to other organs e.g., liver, kidney, by oral consumption.[132] Since MPs get decolorized in the digestive tract, the majority of MPs samples found in human digestion were clear laments.[133] It is thus far uncertain whether the MPs pigments stick around in people's bodies and harm them.

7.4.3. Skin contact and dermal absorption

Pollutants in the form of particles have been linked to skin ageing. Particles from traffic can worsen wrinkles in the nasolabial creases and freckles on the cheeks and forehead. Nevertheless, tiny particulate matter is frequently viewed as a significant environmental hazard that leads to skin illnesses. Skin illnesses can develop and worsen as a result of various air pollution particulates that cause oxidative stress by releasing pro-inflammatory cytokines and reactive oxygen species (ROS). Further study in this area is required because there is no direct indication that atmospheric MPs can enter the skin.

8. Identification methods in MPs analysis

Monitoring of MPs in a range of biotic and abiotic environmental matrices can give fundamental scientific data on their pollution status, concentration hotspots, historical trends, and the fate and exposure of organisms. MPs monitoring studies demand accurate and comparable sampling and analytical techniques. In addition, proper qualitative and/or quantitative analytical procedures for MPs are needed for laboratory accumulation, toxicity, and weathering research. However, because MPs research is a recently reemerging topic, analytical methodologies for MPs are still in the early stages of development. MPs in environmental samples can be analyzed

using extraction, isolation (or separation), identification, and quantification techniques (or classification).[134] Traditionally, preproduction resin pellets and other large MPs in the 1–5 mm size range have been identified by visual sorting with the naked eye.[135] However, in order to successfully perform an ecological risk assessment, quantification at the smallest scale is essential due to the ubiquitous environmental presence of MPs and their harmful biological consequences.

Researchers have been unable to create a uniform classification of MPs data due to the vast range of sizes of MPs and the complexity of their colors, shapes, and polymer kinds, which makes it more challenging to compare data. Using a single analytical technique, it is challenging to completely and accurately identify MPs of different sizes, shapes, and polymer types from complex environmental matrices. Therefore, it has become common practise to combine more than two analytical methodologies. MPs examination often involves two steps: physical evaluation of putative plastics (using a microscope, for example) and chemical characterization (using a spectrometer, for example) to confirm the presence of plastics. Each technique, as well as different combinations of them, has benefits and drawbacks.

8.1. Visual methods

Large MPs (1–5 mm) were commonly found on beaches and, to a lesser extent, in surface waters before the term "MPs" gained popularity. The size range of MPs is rather wide, hence sorting and identification was typically done side by side in a tray using forceps and the human eye. This visual method can be used to identify some small plastics, and colorful plastic pieces and pre-production resin pellets that vary in size from 2 to 5 mm and can be recognized by sight. There is a greater likelihood that small plastic particles will be missed by sorting in high strandline samples taken from beaches with high concentrations of interfering inorganic and organic materials, or in ambiguous plastics (approximately 1 mm in size) with colors similar to the interfering particles. However, for both specialists and nonprofessional volunteers who have undergone brief instruction, visual sorting and identification of big MPs offers an easy, straightforward, and quick procedure.[136]

8.2. Stereo (or dissecting) microscopy

A popular method for identifying MPs with sizes in the hundreds of micron range is stereo- (or dissecting) microscopy (e.g., neuston net samples).[137] Microscopy-enhanced photos give objects' surface textures and

structural details in great detail, which is crucial for recognizing confusing, plastic-like particles. Although most particles in this size range can typically be identified by microscopy, it can be challenging to confidently identify plastics in sub-micron-sized particles (<100 µm) that lack a characteristic color or shape.[138] The microscopic detection of MPs on filter paper can be hampered by sediment samples whose light sediment particles are poorly separated by density. Microscopic inspection is further complicated by biogenic elements from silt and neuston net samples that have not been entirely removed by chemical digestion. According to numerous field monitoring studies, the majority of the MPs in water, sediment, and biota were made up of fibres.[139] However, by using only a microscope, it was challenging to distinguish between fibers that were synthetic (like polyester) and natural (like colored cotton).

8.3. Scanning electron microscopy (SEM)

Images of plastic-like particles can be seen at extremely high magnification and clarity using scanning electron microscopy (SEM). The separation of MPs from organic particles is made easier by high-resolution pictures of the surface roughness of the particles. The elemental makeup of the same object is revealed by additional investigation using energy-dispersive X-ray spectroscopy (EDS). Carbon-dominant plastics can be distinguished from inorganic particles by looking at the elemental makeup of the particles. The number of samples that can be processed using SEM-EDS is constrained by its cost and the time and effort required for sample preparation and analysis. Plastic colors cannot be utilized in SEM as identifiers. The technique is advised for additional elemental analysis and surface characterization of particular plastic particles.[139]

In some instances, other cutting-edge microscopy methods have been utilized to identify plastic particles. In laboratory accumulation and toxicity investigations, polyethylene (PE) particles were successfully identified using polarized optical microscopy. Polarized light transmission can be affected by the crystal structure of plastics, and this transmission can then be measured.

8.4. Fourier transform infrared (FTIR) spectroscopy

A FTIR can be used for the identification to disclose the polymer composition as well as the abundance of MPs, which can assst in identifying identifying the source. The weathering status of MPs is also shown by the proportional content of oxygenated bonds (such as carbonyl groups) in the IR spectra. By using this technology, it is simple to identify

carbon-based polymers, and the distinctive spectra produced by various bond compositions, which allow the plastics to be distinguished from other organic and inorganic particles. A reliable polymer spectrum library permits the identification of particular polymer types in addition to the confirmation of plastics. Micro-FTIR (m-FTIR) is used to conduct microscopic observation of micro-sized plastic-like particles before spectroscopic identification on a single platform by shifting between the object lens and IR probe, which is necessary for small MPs. FTIR measurement for MPs is accessible in transmission, reflectance, and attenuated total reflectance (ATR) modes.[140] The sample preparation step is not necessary for thick and opaque MPs in the reflectance and ATR modes, in contrast to the transmission mode. Additionally, the ATR mode creates stable spectra from uneven MPs surfaces, whereas the reflectance mode creates unstable spectra. Theoretically, it is possible to detect MPs as small as the ATR probe's IR beam aperture (10 μm, for example). With the identification of plastic-like particles by microscopy and subsequent chemical confirmation by spectroscopy, m-ATR-FTIR now offers a promising way to identify MPs in environmental samples. However, it can be challenging to get distinct spectra for MPs with a maximum length of 50 μm, necessitating numerous attempts. Surface contact analysis is a type of measurement used in ATR-FTIR. MPs that are extremely worn or delicate may be damaged by the pressure from the ATR probe, and small plastic particles may be attracted to or pushed off the filter paper by electrostatic interaction with the probe tip. When used in contact analysis, remains of hard, sharp inorganic particles from sand samples can easily harm an ATR probe manufactured of germanium. By employing the IR spectra to identify each plastic-like particle, it is possible to limit the possibility of missing plastic particles and false-positive quantification of non-plastic particles. m-FTIR equipment is quite pricey. It takes a lot of time to use an ATR probe to identify each and every plastic-like particle. Samples may contain a large number of moderately or severely weathered MPs that are often formed of complicated and occasionally composite materials. Therefore, to acquire clear spectra and correctly interpret them, an expert operator is needed. A professional judgment based on a detailed examination of the spectrum is required when weathered plastics exhibit spectra of different polymers that have poor hitting potential in libraries. This may result in decisions that are made arbitrarily or based on statistical data and the criteria for meeting the percentage values. The human labor required in the FTIR process can be reduced by using pre-programmed, semi-automatic mapping without the requirement for microscopic pre-selection of particles for analysis.

It is uncommon to employ single FTIR mapping for routine examination of complicated field samples since it requires longer operating durations

and only covers a small region for the chosen wavenumbers of certain polymer types. When compared to single beam mapping, the shortcomings of the focal plane array (FPA)-based reflectance imaging method could be approved. This method could provide information for the identification of MPs (150-250 µm) on larger surface areas, more quickly, and without sacrificing spatial resolution. Although FTIR operation time is greatly reduced by semi-automatic mapping technology, it still takes at least 9 h to scan a single filter paper. To enable frequent use of this approach in MPs analysis, other challenges must be resolved, that include the potential for plastics to be aggregated and the potential for plastics with irregular shapes to cause refractive errors in the reflectance mode. Therefore, after the analysis, each location and spectrum must now be manually validated. Smaller plastics (e.g., <100 µm) need additional identification due to the reflectance mode's limits in producing clear spectra for tiny plastic particles. This needs more time for identification by ATR-FTIR or microscopy.

8.5. Raman spectroscopy

Micro-plastics have also been identified by using Raman spectroscopy. Each polymer has a distinct spectrum due to the molecular structure and atom composition that influence the backscattered light frequencies produced when a laser beam strikes an item. Raman analysis not only distinguishes between different types of plastics but also offers profiles of each sample's polymer makeup, much like FTIR. Raman spectroscopy is analogous to the FTIR method when it comes to the nondestructive chemical analysis and microscopy combination, including the need for pricey equipment. In difficult MPs identification, the various reactions and spectra from FTIR and Raman spectroscopy can conflict with one another. Raman spectroscopy, which uses a narrower laser beam than FTIR, can identify MPs as small as a few millimeters in size. The advantage of Raman spectroscopy's non-contact examination is that the MPs samples are preserved for potential future analysis. MPs in zooplankton samples can be found using confocal microscopy and Raman spectroscopy. Raman spectroscopy is sensitive to the addition and pigment compounds included in MPs, which makes it difficult to distinguish between different types of polymers.

8.6. SERS (surface-enhanced Raman spectroscopy)

SERS is a rapid, noninvasive spectroscopic analytical technique that uses distinct molecular vibrational fingerprints to identify analytes at the single-molecule level.[141] Most molecules in a typical Raman scattering process produce weak Raman signals due to their relatively lower Raman scattering

cross-section. Increasing the Raman signals to greater than or equal to the fifth order in SERS requires the use of plasmonic nanostructures composed of Ag, Au, Cu, and Al. The primary mechanism behind this amplification is the activation of localized surface plasmons, which came about as a result of incoming visible light interacting with noble metallic nanoparticles.[142] Specifically, light that corresponds with the electron oscillation frequency produces a localized surface plasmon resonance, which increases the electrical field at the particle surface.[143] Instead of being uniformly distributed across the plasmonic nanostructure, the produced electromagnetic field is typically limited to sharp edges and tiny interparticle gaps, creating plasmonic "hotspots." Moreover, the elevated electromagnetic field intensifies both excitation and emitted radiation, leading to the notable increase in SERS signals that are independent of analyte type. This phenomenon, known as electromagnetic SERS enhancement, is one of the two established theories for SERS signal amplification.[141] One of the challenges in SERS NPs detection might be optimizing the plasmonic hotspot for a strong SERS signal. It is commonly known that structures with sharp edges, are more effective at enhancing scattering strength. Therefore, employing optimally sized and shaped plasmonic nanoparticles to fabricate SERS substrates could be a great option.[144,145]

When utilizing SERS, it is essential to choose an appropriate laser power level. It is well known that, depending on the intensity of the laser, the temperature surrounding a hot spot can rise to much greater temperatures than 200 °C. This temperature is greater than most common polymers' glass transition temperature. To overcome these challenges, it is required to optimize the procedure by regulating the laser's power, analyte types, and excitation wavelength.[144]

8.7. AFM-IR

AFM-IR, or AFM with infrared spectroscopy, is a relatively new method in the sciences that examines events at the nanoscale. In AFM-IR, an AFM scans the surface of the material to provide an image with a high spatial resolution of as low as 50 nm, whereas infrared spectroscopy elucidates the mechanical and thermal properties of MPs. For the detection of PE, PET, and polycaprolactone with a particle size of less than 500 µm, this approach has shown noteworthy success. With spatial resolution below the traditional optical diffraction limits, it is utilized for compositional mapping and chemical analysis. With remarkable precision and detail, this approach provides physiochemical characteristics. It enables further MPs and NPs characterization, including hydrophobicity and conductivity. The

technique requires a sample pre-processing step to make presumed MPs accessible to AFM.

8.8. Mass spectroscopy

Using mass spectrometry in conjunction with gas and liquid chromatography, one can analyze MPs by examining the distinct products that are produced during the pyrolyzed or hydrolyzed of MPs. These mass approaches have considerable potential for MPs identification and quantification, especially NPs, due to their outstanding sensitivity.

8.8.1. Inductively coupled plasma mass spectroscopy

The development of isotope tagging technology resulted in the invention of single particle inductively coupled plasma mass spectroscopy (ICP-MS), a novel mass spectrometry method for measuring MPs. This innovative method has made it feasible to measure the size and quantity of nanoparticles. For metal-based nanoparticles in environmental materials, this technique is often employed.[146] For instance, at a comparatively low detection limit of 8.4×10^5 particles/L, ICP-MS has been used to evaluate the size and number concentration of the model Au-coated MPs (at submicrometer scale). Nevertheless, its utilization necessitated extensive sample preparation due to its reliance on an indirect evaluation of the Au coating.[147] It has been shown that ICP-MS can assess model MPs particle sizes and number concentrations by tracking 13 C during the process.[148]

8.8.2. Pyrolysis gas chromatography–mass spectrometry (Pyr-GC–MS)

Mass spectrometry-based destructive analysis following the pyrolysis of suspected polymers is becoming more and more popular. This technique employs the thermal degradation of MPs in an inert atmosphere to reveal the structural composition of a macromolecule. Sample preparation for this approach is minimal, and direct injection is a possibility based on the environmental matrix. This method overcomes the problem of potential plastic underestimation because it is employed regardless of particle size and provides information on the mass of polymers in the samples.[149]

When analyzing complex matrices, pretreatment procedures that include digestion or separation before injecting the material in the Pyr-GC-MS may be error-prone. As a result, the combination of pressurized liquid extraction (PLE) and other techniques has emerged as a potentially effective method to eradicate certain polymers (PVC, PMMA, PS, PE and PP) from intricate environmental samples. Because it can be difficult to prevent interference when working with environmental samples, double-shot pyrolysis in conjunction with PLE has also been employed.[150] In addition to polymer types,

Pyr-GC-MS may identify plastic additives in samples from the first shot, when low-temperature thermally desorbs the interference. But the second shot contains the real polymer identification and quantification. It can provide an estimate of the mass of polymers in each sample rather than a particle count. Pyr-GC-MS, like other methods without optical interrogation, does not reveal the physical form of plastic waste.[151]

8.8.3. Liquid chromatography–tandem mass spectrometry (LC–MS/MS)

Minimal quantities of polymers can be detected using LC-MS/MS. This a versatile instrument used in medicine, pharmacology and the assessment of environmental exposures to minute heat-labile, nonvolatile chemicals. Polycarbonate, PET and nylon-based MPs were successfully identified and quantitatively analyzed in sewage sludge using LC-MS/MS.[152,153] This method can be detrimental since it necessitates the depolymerization of macromolecules before examination. The mass and quantity of monomers produced during depolymerization are disclosed by the detection method; however, the size, number, color, and shape of the MPs remain unknown. The method can also yield information about the size profile distribution when combined with size fractionation. Additionally, this method necessitates a substantial financial investment, knowledgeable operators, and meticulous sample preparation—which is usually vulnerable to experimental contamination.[154]

8.8.4. Matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometry

MALDI-TOF is a mass spectrometry technique that uses an ion source of MALDI and a detector of TOF as the mass analyzer. MPs investigations may examine this technique, which has been utilized since 1996 to detect whole bacterial cells without pretreatment. The device has proven to be effective in differentiating between different types of polymers. In conjunction with imaging techniques, it can also make it easier to examine the shape, size, color, and composition of MPs. More specifically, MALDI-TOF is a crucial tool for complex polymer characterization. Recently, PS and PET in complex biological materials have been identified and quantified using this mass spectrometric approach.[155] Perhaps one of the preferred analytical techniques is this one due to its wide mass range of detection.[156]

8.9. Shrinking surface bubble deposition (SSBD)

The Shrinking Surface Bubble Deposition (SSBD) method is an innovative way to identify MPs in an array of environmental samples. The method concentrates the suspended particles in the water and deposits them on a substrate for observation and characterization by using plasmonic heating

of mixed silver NPs with ambient water samples to produce a bubble through laser excitation. This method enables the direct visualization and identification of NPs in a range of water samples.[157]

8.10. Flow cytometry

Flow cytometry is an extremely sensitive tool for detecting fluorescence signals and light scattering, which enables quick quantification of fluorescence-stained (NR, for example) MPs. It has been widely applied to the detection and analysis of MPs, such as molecules, cells, and microbes in liquid samples that are hydrodynamically concentrated into a stream so that they flow past incident light beams from one or more lasers one at a time. Sensitive photomultiplier tubes monitor parameters including light scatter and fluorescence, providing information about surface roughness/granularity (side scatter), size (forward scatter) and fluorescence from pigments or dye markers. A significant benefit of flow cytometry, aside from its sensitivity, is the elimination of human subjectivity because the method does not necessitate the visual interpretation of particles.[158,159]

8.11. Thermal analysis

Recently, the thermo-analytical method—which gauges changes in polymer physical and chemical characteristics based on their thermal stability—was put to the test for identifying MPs. The technique of differential scanning calorimetry (DSC) can be used to examine the thermal characteristics of polymeric materials. Each plastic product has unique DSC characteristics; hence the approach needs reference materials to distinguish between different polymer kinds. DSC can be helpful in locating particular principal MPs for which reference materials are accessible, like polyethylene microbeads. Polyvinyl chloride (PVC), polyamide (PA), polyester (PES), polyethylene terephthalate (PET), and polyurethane (PU) could not be detected by thermogravimetry (TGA) in combination with DSC because their phase transition signals overlaps. TGA combined the benefits of a larger sample size with TGA compared to pyrolysis (pyro)-GC-MS and higher resolution with GC-MS compared to DSC when paired with solid-phase extraction (SPE), which was then coupled with thermal desorption gas chromatography mass spectrometry (TDS-GC-MS). The TGA-SPE-TDS-GC-MS approach was used to quantitatively identify PE injected into soil and mussel samples. A polypropylene (PP), polystyrene (PS), and polymer combination were also examined using this method.[139]

Thermal analysis, however, is a destructive technique that precludes the further study of the MP sample. Although DSC analysis is quick and

relatively easy, it is not always successful in distinguishing MPs from other polymer products in environmental samples. Chemical additives in MPs can be simultaneously analyzed using thermal analysis and GC-MS. Bulk samples, and single particles, can be examined using GC-MS and thermal analysis, which gives weighted (w/w) concentration data for MPs. The bulk analysis does not, however, offer data on the quantity, size, and shape of the MPs that were analyzed. Contrary to FTIR and Raman spectroscopy, this method demands a skilled operator as well as significantly more time and effort for operating the instrument and data analysis. These techniques would be helpful for screening analyses of bulk samples or further corresponding investigations of MPs that have not yet been thoroughly characterized by spectroscopy, but it seems too soon to employ them for routine analysis of MPs from environmental samples.

8.12. Material-supported MPs/NPs detection

8.12.1. Nanopipettes

MPs have grown in importance during the previous 20 years, and numerous research have examined MPs/NPs in environmental sample data. Scientists have conducted extensive research on this subject and have developed a range of innovative analytical techniques for their detection.[160–162] It has recently been reported that the analytical community has several potential uses for nanopipettes, which are made by heating glass capillaries during the pull-out process. Nanopipettes became popular as a means of developing chemical and biological sensors and conducting ion transport investigations at the nanoscale.[163,164]

8.12.2. Microfluidic chips

To swiftly identify MPs in environmental samples, a unique analytical method still needs to be developed and optimised.[165–167] Micro-reservoirs leading to microfilters that are intended to capture all MPs particles in an ultra-compact region were used in the fabrication of the micro-optofluidic platform. To identify the type and nature of MPs present in this ultra-compact space, the researchers were able to successfully enable optical spectroscopy and imaging. Furthermore, passive size sorting was used to separate the MPs based on the size ranges in various reservoirs. The distributed sizes of the MPs samples were recovered using a reference technique that included flow cytometry; however, information regarding their chemical nature was lost in the process. In order to verify the possible use of this micro-optofluidic platform, model samples comprising standard MPs with varying sizes and chemical compositions were combined and effectively examined.[168]

9. Global initiatives and control measures by international organisations, regional unions, and associations

Globally, there is increasing concern about regulating MPs and NPs, and several nations have responded to this concern by enacting different laws and regulations. An outline of a few of these policies is provided below (Table 4). In an effort to lessen the negative effects that MPs and NPs have on the environment and human health, these policies combine voluntary actions, regulatory strategies, and international cooperation. The efficacy of these interventions varies and frequently necessitates continual evaluation and accounting in response to novel scientific findings and technological advances.

10. Recommendations for future research

The pollution of terrestrial and marine ecosystems by MPs is widespread worldwide. Research on a number of significant sources and release channels for MPs has been compiled in this review. Significant MPs loadings are anticipated across a wide range of environmental situations, which suggests a larger yearly discharge than the figure for the marine environment. After intensive literature survey it was found that there are various gaps in management of MPs which present numerous opportunities for future research. The distribution, movement, and destiny of MPs particles are predicted to be influenced by a variety of dynamic processes in terrestrial and freshwater systems because of their enormous complexity. A series of precise guidelines for further research have been identified by this review, as:

10.1. Harmonic progression of approaches and reporting, with improved quality assurance and control (QA/QC) techniques, to assure adequate data quality and enable accurateness between datasets

The vast range of methodological approaches used in the review for the investigations of the presence of MPs in terrestrial and marine ecosystems, including samples of biota, sediment and water is notable. This includes differences in the methods used for sampling, treating samples, using analytical procedures, and analyzing different particle size classes. Additionally, it is impossible to evaluate the quality of given data because many studies do not use a comparable set of QA/QC methods. Findings are frequently presented in a variety of ways, such as by using various measurement units or by publishing simply summary statistics that vary as well (such as minimum/maximum, mean, or median). The inability of diverse research to be compared is the pinnacle of this variability. In

Table 4. Different policy/strategies/initiatives adopted by the different national/international organisations, regional unions and associations.

National/ International	Policy	Goals/ Initiatives	Measures	Ref.
European Union (EU)	EU Plastics Strategy	Make all plastic packaging recyclable by 2030, reduce plastic waste, promote circular economy practices.	Bans on certain single-use plastics, mandatory recycled content in products, extended producer responsibility schemes, and incentives for innovation in plastic recycling technologies.	[169]
	REACH Regulation	Regulates chemicals and their safe use, including those that might contribute to MPs pollution.	Requires registration, evaluation, and restriction of substances, including additives in plastics that can degrade into MPs.	[170]
	(MSFD) Marine Strategy Framework Directive	EU maritime waterways must reach Good Environmental Status (GES) by 2020.	Member states must develop marine strategies including measures to reduce marine litter, monitor MPs levels, and assess the effectiveness of policies.	[171]
United States	Microbead-Free Waters Act of 2015	The production and distribution of rinse-off cosmetics with plastic microbeads are forbidden under federal legislation.		[172]
	NOAA Marine Debris Program	Addresses marine debris through prevention, removal, research, and outreach.	Funding for research on MPs, educational campaigns, and partnerships with local organizations for cleanup efforts.	[173]
Canada	Microbeads in Toiletries Regulations	Plastic microbeads in toiletries are prohibited nationwide from being developed, imported, or sold as of July 1, 2018.		[174]
	Canada-wide Strategy on Zero Plastic Waste	Eliminate plastic waste and reduce plastic pollution	Enhancing extended producer responsibility, improving waste management systems, and supporting innovation in plastic alternatives.	[175]
Japan	Act on Promotion of Resource Circulation for Plastics:	Comprehensive approach to plastic waste, promoting recycling and the use of biodegradable plastics	Encourages businesses to develop and use alternatives to traditional plastics and improve recycling infrastructure	[176]
	Law for the Promotion of Marine Litter Processing	Targets reduction of marine litter including MPs	Provides funding for local governments to clean up marine litter and improve waste management practices	[177]

(*Continued*)

Table 4. Continued.

National/ International	Policy	Goals/ Initiatives	Measures	Ref.
Australia	National Waste Policy	Reduce waste and improve recycling by 2030	Phasing out problematic and unnecessary plastics by 2025, promoting product stewardship, and enhancing waste management infrastructure.	[178]
China	Plastic Waste Management Policies	Limitations on microbeads in cosmetics and nationwide prohibitions on single-use plastics	Phased approach to banning and reducing single-use plastics, improving recycling rates, and promoting biodegradable alternatives	[179]
	Action Plan for Zero-Waste Cities	Pilot initiative aimed at creating sustainable waste management practices	Focus on reducing plastic pollution, enhancing waste segregation and recycling, and promoting public awareness	[180]
South Korea	Regulations on Microbeads	Ban on the manufacture, import, and sale of personal care products containing plastic microbeads, effective July 2017	–	[181]
	Marine Litter Management Plan	National strategy to reduce marine litter, including MPs	Regular cleanup activities, public awareness campaigns, and partnerships with fishing and shipping industries to reduce litter	[182]
International Initiatives	United Nations Environment Programme (UNEP)	Global initiatives to combat plastic pollution	The Clean Seas campaign, promoting policy changes, and supporting national and local initiatives to reduce plastic waste	[183]
	International Convention for the Prevention of Pollution from Ships (MARPOL)	Includes regulations to prevent pollution from ships, addressing both operational and accidental discharges of plastics	Amendments to MARPOL Annex V prohibit the discharge of all plastics from ships	[184]
	Global Partnership on Marine Litter (GPML)	A multi-stakeholder partnership to tackle marine litter	Facilitates international collaboration, shares best practices, and supports research and policy development to reduce marine litter, including MPs	[185]

addition to providing useful baselines that can monitor the influence of remediation or reduction measures, collaboration of analytical techniques and investigating formats and the publication of data in appropriate repositories will aid in reducing ambiguity in a comprehensive, global overview of the condition of contamination.

10.2. An exhaustive analysis of the fate, sources, and effects of MPs in agricultural environments

The confluence of numerous MPs particle sources and release channels can be seen in agricultural contexts. Although the extent and relevance of this are mostly unclear, particles may also be linked to greater chemical loads from plastic additives (mostly for reducing the photodegradation of mulching films) or sorbed contaminants (such as from wastewater treatment plants). It is challenging to evaluate the relative contributions of various sources under pertinent environmental conditions or the accumulation of particles over time because agricultural settings are relatively uncontaminated and the destiny of particles in agricultural soils is still poorly understood. The effects of MPs contamination in agricultural ecosystems have only recently been the subject of a tiny amount of research. To get a comprehensive understanding of the dangers presented by MPs over spatial and temporal domains, more research is necessary. This is especially crucial considering the possibility that any adverse consequences could affect the security of the food supply and the health of the land.

10.3. Assessment of road-associated MPs particles (RAMP) as a source of MP to the environment

There are significant awareness gaps regarding environmental loadings, transportation from the road to various matrices, and persistence in gully-pots and water treatment systems for MPs particles associated with the road. In order to precisely estimate the amount of these road-associated microparticles released into the environment, including the contributions from various road-related sources, more investigation is urgently required. This is relevant in view of the recent attention received by these road-associated microparticles in a number of analyses of the worldwide major sources of MPs in the environment. Through the use of a novel and improved method for analyzing these microparticles in environmental samples, quantification should be possible.

10.4. Measures and technologies to separate particles within waste water treatment plant system or to reduce MPs emissions to wastewater

The role of wastewater systems, including their plants and combined sewer overflows, as a release channel for MP particles into both terrestrial and marine environments, was underlined in this research. In order to lessen the load on these plants and restrict releases from untreated discharges like combined sewer overflows, attempts should be made to minimize the amount of MPs particles entering wastewater at the source. A large portion

of the wastewater produced worldwide is released untreated and is not connected to a WWTP. The environmental emission of MPs in so many nations would be constrained by improvements in wastewater treatment capacity worldwide. Many MPs forms have sewage sludge application on land recognized as a key release mechanism.

10.5. A Better perspective of the controls sustaining the preservation and transport of MPs particles in aquatic systems, including more accurate flux estimates to the marine environment

From their release to their final destination, MPs particles in freshwater systems are expected to travel over a complicated course. Several processes that obstruct downstream transit may be included in this. To establish thresholds and controls on MPs transport in freshwater environments, these dynamics need to be studied further. The bulk of particles is predicted to eventually end up in the marine environment, via fluvial systems. In order to incorporate the necessary complexity and pinpoint the effective constraints on MP's release to the marine environment, estimates for this flow must be based on process-based research. As well as identifying zones of MPs build-up in freshwater systems, further research on the dynamics of MPs movement and spatial patterns of contamination can also highlight the places most at risk from potential contamination-related negative effects. This will aid in concentrating efforts to safeguard freshwater environments.

10.6. Further study of the occurrence of MPs in terrestrial and aquatic organisms, with an explicit focus on particle types such as RAMP

The impact of MPs pollution on ecosystems and human health has prompted extensive ecotoxicological studies. However, there is a lack of evidence regarding the uptake of MPs in actual field settings. To address this, a more comprehensive analysis of particle absorption in actual environmental conditions is essential to provide a contextual understanding of ecotoxicological investigations and to enhance risk assessments. Exposure to MPs is a critical factor in evaluating risk, and their presence in the environment can have detrimental consequences for both ecosystems and human health. Furthermore, existing studies have primarily focused on the impact of individual materials, with limited consideration for mixtures of biodegradable MPs and MPs at concentration ratios that reflect real environmental circumstances. It is imperative for future studies to incorporate such mixtures to better understand the combined effects and interactions of different types of MPs. Moreover, the concentration of MPs used in many experiments exceeds those found in the actual environment.

Therefore, the concept of "environmentally relevant concentration" has become a significant consideration in toxicity experiments. Additionally, the duration of exposure is a crucial factor, as the continuous exposure to MPs in natural environmental conditions and the slower depuration process compared to other particles can significantly influence the outcomes of ecotoxicological studies.

10.7. Assessment of environment sinks for MPs particles at spatial and temporal scales

This analysis identified a number of potential locations that, in terrestrial and freshwater settings, could serve as transient, long-term, or even permanent sinks for MPs particles. Initial research has looked at the accumulation of some of these particles and their possible residence times. However, study is needed to determine the spatial and temporal scales on which these environments act as stores, as well as the possibility that they could later become sources of MPs contamination through reworking and remobilization. This is required to develop more appropriate and better-targeted remediation procedures rather than relying on quick solutions and acquire a better long-term perspective on environmental damage.

11. Comprehensive strategies for mitigating MPs pollution in textile lifecycles

11.1. The design and production pathway

One strategy for reducing microfibre shedding has been suggested: switching textile patterns to use more natural fibers. Besides this, the increased release of microfibres may be caused by the manufacturing procedures used to create synthetic fibers, yarns, textiles, and goods. Particularly, an essential component in the development of MPs is the use of abrasive friction during manufacture. Microfibre release while using a product could be decreased by employing alternate production techniques or textile construction techniques.

11.2. The use and caretaking pathway

The requirement that all washing machines have a specific microfiber filter by January 2025 was first introduced in France in 2020. Utilizing a washing machine filter can cut the emission of microfibres by as much as 80%. The release of microfibers is also impacted by the utilization of detergent and fabric softener. By designing non-aggressive, liquid detergents that are efficient at low temperatures and don't rinse off textile finishes,

some of which guard against fiber breaking, detergent producers can help reduce the shedding of microfibers. Powder detergents shouldn't be used on synthetic fabrics because they create friction and break fibers.

11.3. Change in consumer behavior

According to numerous studies, the first few washes of new clothing are when microfibre releases are particularly high. This indicates that fast fashion, in which clothes are worn briefly before being replaced frequently, is responsible for a significant portion of microfibre releases. Therefore, modifications in consumer purchasing habits are required, as well as understanding of the effect that new apparel has on MPs pollution. More regenerative business models, which encourage less consumption and longer use, could allow such a transformation. Reused items typically shed fewer microfibres when washed than new ones, which has the added benefit of reducing both the quantity of new purchases and trash generation. Moreover, preparing an old article for reuse requires fewer resources than the production of a new similar one, thus providing a further environmental benefit.

11.4. The disposal and end-of life processing pathway

In addition to promoting textile reuse and recycling, which would decrease MPs emissions during production and use, textile waste collection and end-of-life treatment can also reduce secondary MPs contamination by preventing littering, improperly managed waste, and textiles being blown by the wind from open landfills. Due to improper disposal, the dumping of trash from open landfills, or the washing of synthetic clothing in untreated waste water, there is a risk that microfibres will spread.

11.5. Increasing knowledge and awareness

To promote research aimed at filling these information gaps on the release, spread, and effects of NPs and MPs, continued public and corporate support is required. To solve the complex difficulties related to various primary MPs contamination from textiles, intensive interdisciplinary collaboration across technical, behavioral, and regulatory measures is required.

12. Conclusions

Concern over MPs in the environment has recently come under fire for being a distraction from other problems endangering the health of the

global environment. The impact of plastics on the environment is undoubtedly complex, and innovative approaches are needed to find answers. The fact is that, the outlaw or replacement of plastics is nearly imposible, because of their beneficial qualities and our growing reliance on them. The concern is that both their improper management and expansion into the natural environment are growing, as is their global utilization. Over time, these plastics will break down into MPs and NPs. The effects of these on toxicology or the ecosystem are not fully understood at this time. To comprehend how organic chemical partition coefficients to plastics are changed in the presence of sediment and soil, studies on the dynamic interactions between plastic particles, plasticizer additives, and environmental pollutants also need to be increased. In order to comprehend the mechanisms governing the bioaccumulation of plasticizers and co-transported compounds, studies of chemical dynamics within the guts of organisms are also required. Further investigation into MPs is required to determine their global distribution and potential human health exposure. This requires additional field sampling and the application of standardized analytical techniques.

ABSTRACT

In this paper, design and fabrication of a dual-band near-zero index metamaterial (MTM) structure using copper on an epoxy resin fiber (FR-4) dielectric substrate is reported for refractive index sensing applications. The primary objective is to achieve dual-band operation spanning a 1–15 GHz frequency range, with a specific focus on achieving a broad bandwidth in the C-band. The resonance of the MTM structure was ascribed to the coupling of plane electromagnetic waves with surface plasmon polaritons on the structure, resulting in a quadrupole plasmon resonance mode. Furthermore, transmission characteristics of the fabricated MTM structure were experimentally measured and found to align closely with the simulated results obtained through the finite element method in COMSOL Multiphysics. The designed MTM structure demonstrates negative and near-zero permittivity at resonance frequencies, enabling left-handed and near-zero index behavior in dual microwave frequency bands. Under room temperature conditions, the MTM sensor exhibited sensitivities of 1 GHz/RIU and 3 GHz/RIU at resonance frequencies of 2.7 and 7.3 GHz, respectively. Consequently, the MTM structure exhibits significant potential for diverse applications, serving as a valuable component in sensors, detectors, and optoelectronic devices operating in the GHz region.

I. INTRODUCTION

The S (2–4 GHz) band and the C (4–8 GHz) band hold significant importance across a spectrum of applications due to the unique electromagnetic characteristics of these frequency ranges. Modern optoelectronic devices developed for these bands are essential for various purposes, including wireless communications,[1] radar navigation,[2] remote sensing,[3] etc. However, effective utilization of the S and C bands often encounters challenges, primarily associated with the limitations of conventional materials and components in achieving the desired performance levels. These limitations can impede progress in the above-mentioned application and beyond. Metamaterials (MTMs) represent a groundbreaking solution that has revolutionized the world of electromagnetic engineering. These artificially engineered materials are engineered to manipulate electromagnetic waves in unconventional ways that were previously thought impossible.[4–6] One of the most remarkable feats achieved by metamaterials is the creation of a negative refractive index, allowing waves to bend in unconventional directions.[7] However, the evolution of metamaterials extends beyond this milestone, delving into the realm of zero-index materials—a cutting-edge development within the field. The zero-index metamaterials (ZIMs), a subset of metamaterials, present unique advantages that render them highly valuable for applications such as electromagnetic cloaking, tunneling, and beam splitting.[8] With a refractive index of zero, these materials exhibit remarkable properties that can significantly enhance the performance and efficiency of devices across various frequency ranges. These capabilities open new avenues for manipulating and controlling electromagnetic waves, promising a new range of advantages and applications that go beyond the capabilities of conventional materials.

MTMs can be classified according to their effective permittivity ($\varepsilon_{\text{eff.}}$) and effective permeability ($\mu_{\text{eff.}}$) parameters, resulting in categories such as single negative (SNG), double negative, and double positive metamaterials. Within the SNG metamaterials, there are two types known as ϵ-negative (ENG) and μ-negative (MNG) materials, depending on whether $\varepsilon_{\text{eff.}}$ or $\mu_{\text{eff.}}$ is negative.[9] Exploration of metamaterials in the GHz and THz frequency ranges has revealed their distinctive properties such as negative permeability (μ), negative permittivity (ε), and negative refractive index (η). As a result, these MTMs have found diverse applications in microwave and optical domains,[10] ranging from reconfigurable antennas,[11] satellites,[12] and dual-band sensors[13] to applications like invisibility cloaking,[14] tunable perfect reflectors,[15] filters,[16] self-adjustable smart metamaterial waveguides,[17] and super-lenses.[18,19] In recent investigations, there has been extensive exploration of sensors operating in several gigahertz ranges, leveraging MTMs. It has been shown that a relatively straightforward geometric structural design can yield impressive sensing capabilities across various applications. Enhanced sensitivity is crucial in sensing applications as it enables the detection of subtle changes in the surrounding environment. The MTM design has shown its great potential in sensing applications. The specific metamaterial belongs to the targeted sensing application as shown by Banerjee *et al.* SRR type of metasurface showed a sensitivity of 0.742 THz/RIU for ultrathin subwavelength films sensing through excitation of dark modes in the THz region.[20] Navaratna *et al.* showed all silicon topological waveguide cavity chips with a honeycomb lattice design operating in the THz range for biomolecule sensing applications.[21] Gupta and Singh[22] showed that a large Q/V meta-sensor emphasizing a high quality factor and a small mode volume with an I-shaped metasurface which resonates at 0.6 THz has a sensitivity of 18 GHz/RIU. Hyperbolic meta-sensors are known for their high-resolution sensing capabilities. Sreekanth *et al.* showed phase change materials based on low-loss visible frequency hyperbolic metamaterials for ultrasensitive label free biosensing applications.[23] Absorptive liquid meta-sensors are optimized for liquid environments of water methanol mixtures. Chen *et al.* showed high sensitivity due to multiple resonances, i.e., Fano resonance and dipole resonance, in the THz region metamaterial of highly absorptive water–methanol mixtures.[24] Microfluidic meta-sensors integrate fluidic channels for enhanced analyte interaction with dual torus (doughnut-shaped object) toroidal metasurfaces.[25] This designed structure is fabricated using single step lithography and shows a high sensitivity of 0.129 THz/RIU for 28 μm thick microfluidic layers of different mixed ethanol–water solutions. Lim *et al.* reviewed the high-Q planar Fano resonant metamaterial sensors that leverage interference effects to achieve high sensitivity toward futuristic technologies.[26] In this continuous development of metamaterial advancement in sensor applications, our study has shown that the MTM sensor utilizes quadrupole plasmon resonance to achieve high sensitivity in dual frequency bands in the GHz range of the S and C bands of microwave regions. This distinct mechanism not only provides high sensitivity but also ensures broad bandwidth coverage in the GHz range, which is a unique feature in the advancement of refractive index sensing. In 2017, Tian *et al.* developed an SRR configuration to create a refractive index sensor achieving a sensitivity of up to 1.69 GHz/RIU in the C-band.[54] Meanwhile, Hu and Liu[29] devised a microwave resonator measuring 18×18 mm^2 but failed to achieve significant sensitivity in the C-band. Additionally, Dadouche *et al.* obtained a corona-shaped metamaterial resonator for the S-band with low sensitivity in 2023.[55] Nevertheless, existing literature has identified constraints in these described MTM structures, underscoring the need for an enhanced dual-band MTM tunable sensor structure capable of achieving high sensitivities in both S- and C-bands.

Over the past several years, numerous MTM structures including V-shaped, modified H-shaped, oval-shaped, I-shaped, and Z-shaped designs have been developed to cater the increasing demands in antenna design for sensor, satellite, and radar communication applications.[30–34] The main goal has been aimed to improve the antenna's efficiency. Achieving compactness and miniaturization of MTMs relies on enhancing the bandwidth, which is a crucial factor in MTM research. In 2020, Rashedul Islam *et al.*[35] introduced an 8×8 mm^2 square enclosed circle split ring resonator (SRR) designed for satellite communications in the S, C, and X bands. This SRR had bandwidths of 0.11, 0.79, and 0.15 GHz in these respective bands. Similarly, Islam *et al.*[36] introduced an MTM structure designed to operate in the S, C, X, and Ku bands, exhibiting bandwidths of 0.19, 0.14, 1.3, and 0.6 GHz, respectively. Moniruzzaman *et al.*[37] suggested a symmetric resonator for the C, X, and Ku bands with bandwidths of 0.72, 1.55, and 0.24 GHz, respectively. Bellal Hossain *et al.*[38] presented a symmetric hexagonal split ring resonator MTM with dual-band operation and a wide bandwidth of 1.67 in the C-band for Wi-Fi applications. More recently, Hossain *et al.*[39] proposed an MTM structure with a bandwidth of 0.94 GHz in the C-band. However, the literature has shown limitations in these reported MTM structures, highlighting the necessity for an improved dual-band MTM structure with a wide bandwidth in the C-band.

In this current research, we have fabricated and examined a novel metamaterial (MTM) structure designed for dual-band operation, showcasing a broad bandwidth in the C-band for refractive index sensing applications. The MTM unit cell, also called meta-atom's scattering parameter, was studied using FEM based simulation, and the results were validated using experimentally measured results. Analysis of the proposed MTM structure reveals the presence of negative and near-zero effective refractive index (NZI) and epsilon near zero (ENZ) in the dual-band operation range, covering the S and C bands within the microwave region. The designed MTM structure demonstrates a high EMR of up to 6.93, which confirms the compactness of the proposed design. This study suggests that the MTM structure has the potential to significantly enhance the efficiency and compactness of devices and components used in wireless communication systems with its compact size, dual-band resonance, and wide bandwidth in the C band. Utilizing the proposed MTM as a refractive index sensor results in high sensitivity, specifically 1 and 3 GHz/RIU. To create high-performance multifunction sensors with exceptional sensing capabilities, this study presents a viable alternative technique. These sensors would be ideal for use in biochemical sensing, medical detection, and diagnostics.

II. FABRICATION AND MODELING OF THE DESIGNED MTM STRUCTURE

The schematic representation of the meta-atom of the designed MTM structure is demonstrated in Fig. 1(a), which is similarly used for simulation purposes. Figure 1(b) displays the fabricated prototype array of the same, periodically extended on all sides with a periodicity of 16×16 mm^2. The top view of the fabricated meta-atom (unit cell) structure is displayed in Fig. 1(c). The

FIG. 1. (a) The meta-atom or unit cell of the simulated MTM design from an orthogonal view. (b) The physical prototype array of the fabricated MTM design, (c) the top view of the meta-atom of the fabricated sample, and (d) flow chart representing the complete process of fabrication of the simulated MTM design.

designed MTM is composed of a copper (Cu) material resonating patch impinges on a 1.6 mm thick (t_s) epoxy resin fiber substrate. Fabrication of the unit cell of dimension $16 \times 16\ mm^2$ and a prototype array of 10×10 is achieved using a computer numerical control (CNC) machine, shown in Fig. 1(b). The fabrication process begins with creating a design layout using computer-aided design (CAD) or similar software, serving as the blueprint for the MTM structure. Next, the design is transferred onto a screener mask for subsequent printing. Material deposition onto the substrate follows using screen printing, a technique for depositing materials onto substrates. This step involves applying the desired material onto the substrate according to the design pattern. Etching is then performed to refine the geometry of the MTM structure by removing excess materials from the substrate. The final stages entail cleaning the fabricated MTM to eliminate any residues or contaminants remaining from the fabrication process. All the above fabrication processes are presented using a flow chart as shown in Fig. 1(d). All necessary physical parameters are listed in Table I.

TABLE I. The parameters of the fabricated and simulated designed unit cell MTM structure.

Parameter	Value (mm)	Description
l_m	15	Length of the material
G	1.5	Middle gap
l_s	16	Length of the substrate
w_r	1.5	Width of the resonator
t_s	1.6	Thickness of the substrate
t_m	0.35	Thickness of the resonator

The proposed structure is designed and simulated using the FEM based COMSOL Multiphysics simulation software, as

depicted in Fig. 1(a). The copper material patch in the design has a thickness (t_m) of 0.35 mm with an electrical conductivity (σ) of 5.99×10^7 S/m.[38] The dielectric substrate used in this study has a loss tangent (δ) of 0.025 radians and permittivity (ε) of 4.3.[36,38]

III. RESULTS AND DISCUSSION

A. Scattering parameter of the optimized metamaterial unit cell

Scattering parameters of the simulated design structure were computed using the Drude–Lorentz variables. A configuration with two waveguide ports was used, where port 1 acted as the signal transmitter, and port 2 served as the receiver [Fig. 2(a)]. The x axis was implemented with a perfect magnetic conductor (PMC), while the y axis had a perfect electric conductor (PEC) with periodic boundary conditions in x and y axes. The electromagnetic wave propagated vertically along the z axis. This setup allowed for precise simulations and analysis of the electromagnetic behavior of the proposed design.

The experimental configuration used for S_{21} measurement involves an antenna test setup illustrated in Fig. 2(b). This setup comprises connectors, RF cables, and calibration standards necessary for accurate measurements. A vector network analyzer (VNA-MS2028C) is employed for this purpose. The device under

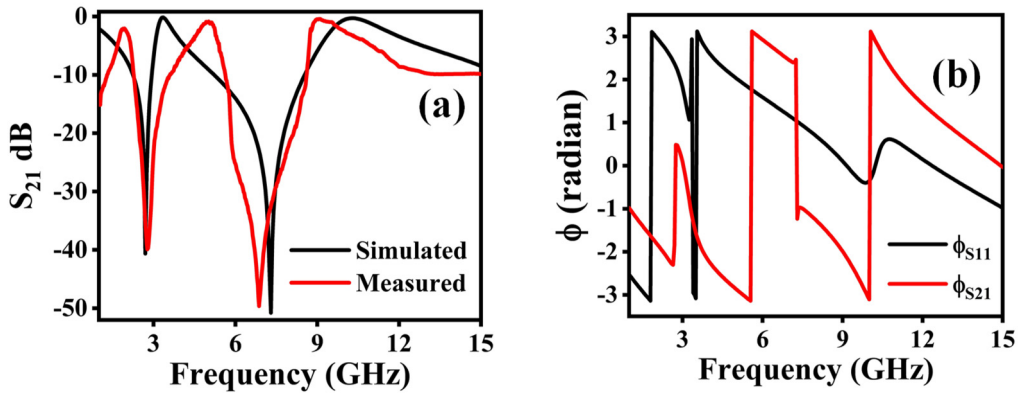

FIG. 3. (a) Transmission coefficient (S_{21}) for the simulated and measured response and (b) the phase plot of the scattering parameter at different incident wave frequencies of the unit cell structure.

test (DUT), a fabricated planar frequency selective surface (FSS), is positioned within the test setup. The VNA determines the transmitted signal (S_{21}) through the DUT. One port of the VNA connects to the transmitting horn antenna, while the other end is attached to the receiver horn antenna, with the DUT positioned between them. The entire antenna setup is placed in an anechoic chamber to minimize external interference and reflections. Calibration of the VNA is vital for obtaining precise measurements and involves the use of short-open-load-through (SOLT) calibration standards connected to the VNA's ports to establish accurate reference points. The VNA generates a swept RF signal transmitted through the DUT, and the transmitted signal is measured by the VNA in terms of magnitude and phase (expressed in dB). Detailed measurement processes are illustrated in a flow chart, as depicted in Fig. 2(c). Figure 3(a) depicts a comparative representation between the simulated and experimentally observed responses of the transmission coefficient (S_{21}) for the fabricated designed structure. Furthermore, the phase plot of the scattering parameters is shown in Fig. 3(b).

The experimental observations align well with the simulation results within the limits of the experimental setup. As depicted in Fig. 3(a), there is a very small and minor mismatch between the experimentally measured and simulated transmission coefficient (S_{21}) outcomes. This mismatch may be attributed due to factors like manufacturing variations, signal interference, reflection noise, and other similar effects. The experimental setup has certain limitations, wherein achieving the desired performance depends on the precise alignment of the two horn antennas. To ensure accurate experimental findings, it is crucial to calibrate the network analyzer properly. All these constraints contribute to a slight shift in resonance frequencies, as evident in the measurement results. Nevertheless, the simulated and experimentally measured data cover the S and C frequency bands. The study on the S_{21} parameter of the designed MTM unit cell indicates the presence of two resonance frequencies at specific points, namely, 2.7 and 7.3 GHz. These resonance frequencies fall within the microwave region, corresponding to the S-band and the C-band, which are commonly used in wireless communication applications. In contrast, Fig. 3(b) illustrates the phase plot of output scattering parameters (S_{11} and S_{21}), demonstrating variations from $-\pi$ to $+\pi$ values with a total phase change of 2π. The bandwidth of S_{21}, which is significant for wireless communication, is shown to be considerable in different frequency bands. For instance, it spans 0.44 GHz (2.42–2.86 GHz) and 1.98 GHz (6.10–8.08 GHz) for the S and C bands, respectively. Importantly, the proposed MTM unit cell has a relatively wider bandwidth for the C band as compared to previously published data,[35–39] as detailed in Table II. This makes it suitable for various wireless communication applications, including satellite and Wi-Fi technologies.[38]

B. Evaluation of effective electromagnetic parameters of the proposed MTM unit cell using the metamaterial extraction method

To observe the frequency-dependent behavior of the metamaterial, researchers have explored several models. Among these models, the Lorentz model is frequently employed for MTM characterization which involves the response of electrons to an electric field (E) by undergoing damped harmonic oscillations, resulting in a polarization field (P). The mathematical representation of the relationship between the polarization field (P) and the electric field (E) can be expressed as follows:[40]

$$\frac{d^2}{dt^2}P_i + \Gamma_L \frac{d}{dt}P_i + \omega_0^2 P_i = \varepsilon_0 \chi_L E_i. \tag{1}$$

In Eq. (1), the terms on the left side correspond to the acceleration of charges, damping coefficient (Γ_L), and the restoring force, which are represented by the first, second, and third terms, respectively. On the right-hand side, the excitation field, also known as the driving field, is present along with the coupling coefficient, χ_L. Employing Eq. (1), researchers assess the electric susceptibility $[\chi_{e,\text{Lorentz}}(\omega)]$, which can be expressed as follows:[40]

$$\chi_{e,\text{Lorentz}}(\omega) = \frac{P_i(\omega)}{\varepsilon_0 E_i(\omega)} = \frac{\chi_L}{-\omega^2 + j\Gamma_L\omega + \omega_0^2}. \tag{2}$$

By utilizing Eq. (2), researchers calculate the electric permittivity ($\varepsilon_{\text{Lorentz}}$)[40] of the Lentz model, which can be expressed as the following equation:

$$\varepsilon_{\text{Lorentz}}(\omega) = \varepsilon_0[1 + \chi_{e,\text{lorentz}}(\omega)]. \tag{3}$$

The Drude model is derived from the Lorentz model of electromagnetic characteristics by eliminating the restoring force from the left side of Eq. (1). Solving this modified equation results in an equation for the electric susceptibility $[\chi_{e,\text{Drude}}(\omega)]$ of the Drude model, which can be represented as follows:[40]

$$\chi_{e,\text{Drude}}(\omega) = \frac{\chi_D}{j\Gamma_D\omega + \omega_0^2}, \tag{4}$$

where Γ_D is the Drude damping coefficient.

Plasma frequency of the Drude model is determined using the following relationship:[40]

$$\chi_D = \omega_p^2. \tag{5}$$

The assessed plasma frequency can serve as an alternative to the coupling coefficient (χ_L) in the Lorentz model. For instance,

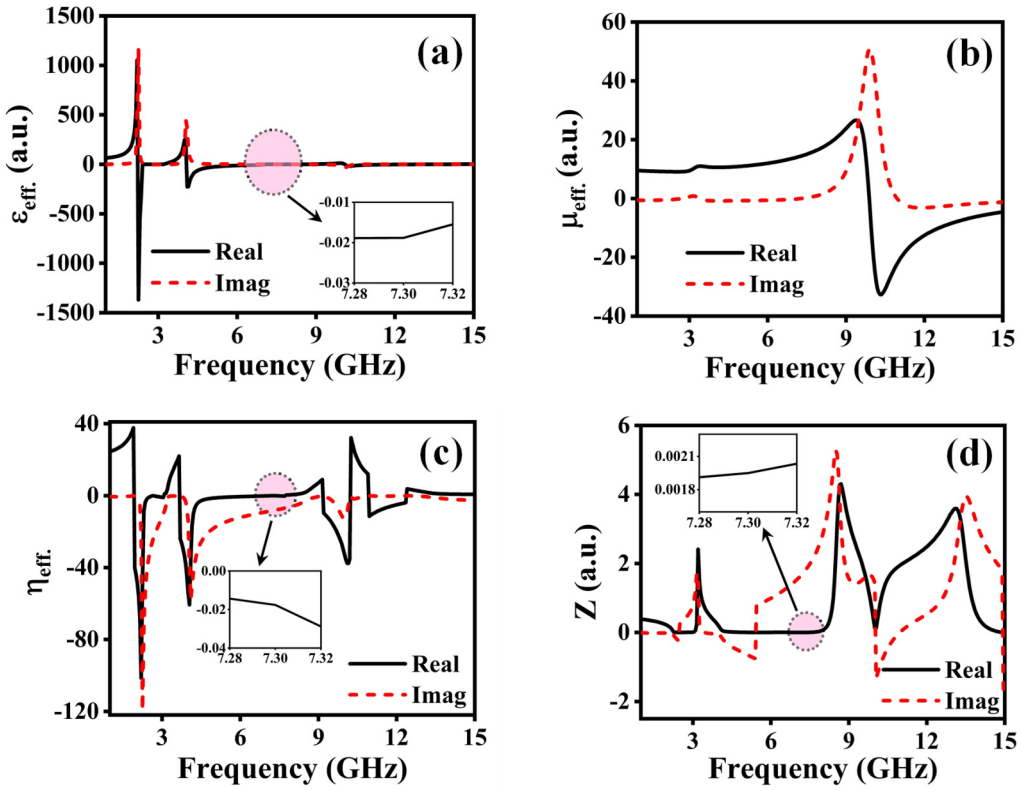

FIG. 4. (a)–(c) illustrate the graphical representations of real and imaginary $\mu_{\text{eff.}}$, $\varepsilon_{\text{eff.}}$, and $\eta_{\text{eff.}}$ for the proposed metamaterial unit cell structure.

TABLE III. Effective parameter property.

Parameters	Resonance Frequency (GHz)	Magnitude	Extracted property
Effective permittivity ($\varepsilon_{\text{eff.}}$)	2.7, 7.3	−0.085, −0.588	$\varepsilon_{\text{eff.}} < 0$ (ENG), $\varepsilon_{\text{eff.}} \sim 0$ (ENZ)
Effective permeability ($\mu_{\text{eff.}}$)	2.7, 7.3	9.118, 14.493	$\mu_{\text{eff.}} > 0$ (SNG)
Refractive index ($\eta_{\text{eff.}}$)	2.7, 7.3	−0.144, −0.017	$\eta_{\text{eff.}} < 0$ (LHM), $\eta_{\text{eff.}} \sim 0$ (NZI)
Impedance (Z)	2.7, 7.3	0.0030, 0.0019	$Z \sim 0$

when the coupling coefficient is positive, the Lorentz model exhibits a narrow band of negative real permittivity at frequencies beyond the resonance frequencies. On the other hand, the Drude model shows a wide spectral negative permittivity for frequencies below $\omega < \sqrt{\omega_p^2 - \Gamma_D^2}$. To analyze the metamaterial's scattering parameters, researchers utilized the Drude–Lorentz variables as parameters in numerical simulations. Ziolkowski *et al.* proposed a mathematical method to extract effective parameters such as $\varepsilon_{\text{eff.}}$, $\mu_{\text{eff.}}$, and $n_{\text{eff.}}$ using the NRW method, which is a widely used approach for effective parameter extraction. The NRW method employs transmission coefficient (S_{21}) and reflection coefficient (S_{11}) to derive the effective electromagnet parameters. The simplified equations used in this process are as follows:[41–44]

$$\varepsilon_{\text{eff.}} = \frac{2}{jk_0 d} \times \frac{(1 - V_1)}{(1 + V_1)} = \frac{c}{j\pi v d} \frac{(1 - S_{21} - S_{11})}{(1 + S_{21} + S_{11})}, \tag{6}$$

$$\mu_{\text{eff.}} = \frac{2}{jk_0 d} \times \frac{(1 - V_2)}{(1 + V_2)} = \frac{c}{j\pi v d} \frac{(1 - S_{21} + S_{11})}{(1 + S_{21} - S_{11})}, \tag{7}$$

$$n_{\text{eff.}} = \sqrt{\varepsilon_{\text{eff.}} \times \mu_{\text{eff.}}} = \frac{c}{j\pi v d} \sqrt{\left\{ \frac{(S_{21} - 1)^2 - (S_{11})^2}{(S_{21} + 1)^2 - (S_{11})^2} \right\}}. \tag{8}$$

In the given context, the parameters are defined as follows:

$$V_1 = |S_{21}| + |S_{11}|, \tag{9}$$

$$V_2 = |S_{21}| - |S_{11}|, \tag{10}$$

$$k_0 = \frac{2\pi v}{c}. \tag{11}$$

Here, d represents the metamaterial slab thickness and c represents the velocity of light.

The normalized impedance (Z) can be computed using the following formula:[45,46]

$$Z = \sqrt{\frac{(1 + S_{11})^2 - S_{21}^2}{(1 - S_{11})^2 - S_{21}^2}}. \tag{12}$$

According to the data presented in Figs. 4(a) and 4(b), it is evident that the effective permittivity ($\varepsilon_{\text{eff.}}$) of the proposed MTM structure is negative at resonance frequencies of 2.7 and 7.3 GHz, while it approaches near to zero (ENZ) at these frequencies as well [shown in the inset of Fig. 4(a)]. On the other hand, the effective permeability ($\mu_{\text{eff.}}$) remains positive across all resonance frequencies for the designed metamaterial structure, as shown in Fig. 4(b). Furthermore, Fig. 4(c) shows that the effective refractive index ($\eta_{\text{eff.}}$) exhibits negative and near-zero values at dual resonance frequencies, which correspond to the S and C bands [shown in the inset of Fig. 4(c)]. In Fig. 4(d), the normalized impedance (Z) demonstrates positive and near-zero real values across the resonance frequencies [represented in the inset of Fig. 4(d)]. Smaller values of normalized impedance at resonance frequencies indicate the passive nature (i.e., which have fixed properties determined by their structural design) of the designed metamaterial unit cell. Table III provides a summary of the overall parameter properties.

EMR plays a crucial role in metamaterial design and development as it contributes to the compactness of the structure. Effective medium theory (EMT) is employed in designing the metamaterial structure, and according to EMT, the unit cell dimension should be smaller than the operating wavelength.[47] In the case of the proposed structure, it is observed that the unit cell size is 16 mm, which is significantly smaller than the operating wavelength for all quad-frequency bands. As a result, the proposed structure meets the EMT condition, leading to the desired metamaterial (MTM) characteristics. The formula provided below can be used to calculate EMR,[47]

$$\text{EMR} = \frac{\text{Operating Wavelength for the unit cell}}{\text{length of the unit cell}}. \tag{13}$$

The proposed MTM unit cell exhibits a relatively high EMR and compact dimensions, enabling it to cover all dual frequency bands (S and C) commonly used in satellite and multi-band applications. The calculated EMR value for the designed metamaterial at its operating resonance frequency of 2.7 GHz is 6.93. The relatively high EMR value contributes to the improved compactness of the structure, making it a promising choice for various practical applications.

C. Optimization of the designed MTM geometry

The optimization process for the proposed MTM structure involves five design steps, as depicted in Fig. 5. Design 1 consists of four L-shaped metallic strips placed at the corners of the substrate, resulting in resonance frequencies at 11.65 GHz for the transmission scattering parameter (S_{21}), as shown in Fig. 6. Moving on to design 2, four horizontal metallic wires are added to the middle edges, leading to resonance frequencies at 7.6 GHz. Design 3 involves the addition of a central metallic strip incorporated into

© Author(s) 2024

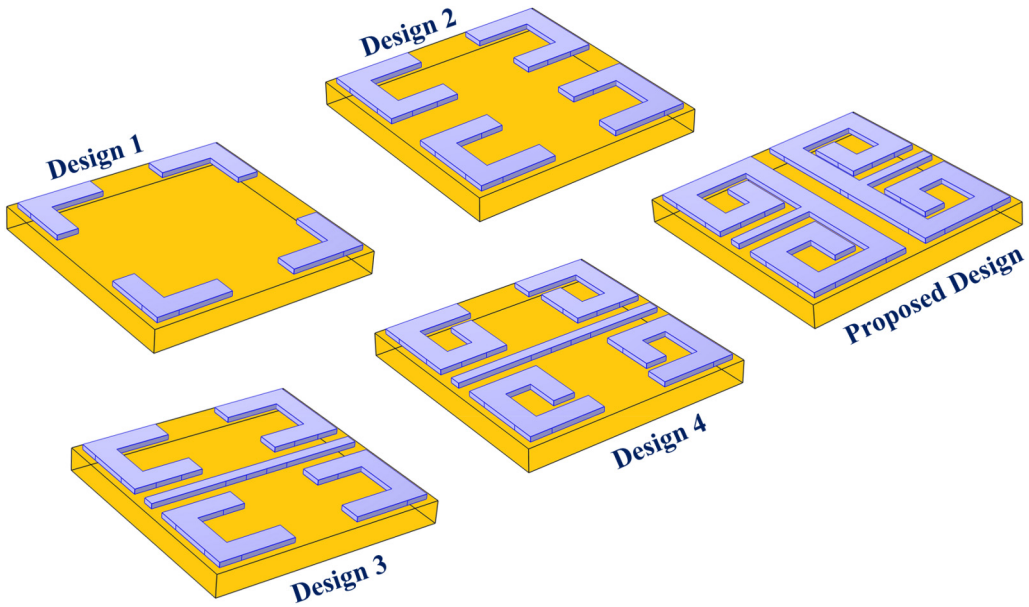

FIG. 5. The methodological approach employed in creating the MTM structure.

design 2, generating resonance frequencies at 7.45 GHz. All these designs resonate in single S bands.

Design 4 builds upon design 3 by adding four more vertical metallic strips, resulting in resonance frequencies at 6.25 and 14.6 GHz. But this design results in narrow band resonance frequencies although dual-band resonance occurs. Finally, in design 5, two vertical strips are joined at their ends in the center of design 4, forming an MTM with a mirror image shape. This design reflects dual-band operating resonance frequencies at 2.7 and 7.3 GHz in the S and C bands, respectively, within the microwave region, as depicted in Fig. 6. The resonance frequencies of the designed structure are due to the formation of a capacitor and an inductor for the gap region and metallic strips, respectively, which becomes an LC circuit like an LCR tank circuit.[48] The resonance frequency (f) can be found using the formula:[49]

$$f = \frac{1}{2\pi\sqrt{LC}}. \tag{14}$$

D. Electromagnetic field distribution of the designed metamaterial

The presence of induced current in the metallic component of metamaterials (MTMs) leads to the generation of a scattering field when a plane wave interacts with an MTM surface. Maxwell's equations provide a comprehensive explanation for how the electric field (E), surface current (J), and magnetic field (B) interact within an MTM. When a current flows through MTM conducting elements, it generates a magnetic field. However, any change in the magnetic field can induce an electromotive force. Consequently, Maxwell's formulation of Ampere's and Faraday's laws yields a set of four differential equations that establish connections between electric and magnetic fields, elucidating these phenomena.[50] The behavior of electromagnetic waves in a medium is influenced by several key factors, including permeability (μ), permittivity (ε), and

conductivity (σ) of that medium. These material properties, along with the boundary conditions of the medium, play a significant role in determining the electromagnetic characteristics.

Magnetic field distributions for two resonance frequencies, i.e., 2.7 and 7.3 GHz are shown in Figs. 7(a) and 7(b), respectively. Magnetic field and surface current density are correlated, as per Maxwell's equations. In Fig. 7(a), high magnetic field intensities are shown on the inner side of the structure, near the edges where a larger current density is observed. In Fig. 7(b), a magnetic field with low intensity is depicted, attributed to the low current intensity at this frequency. However, the field intensity remains low in other regions of the MTM structure.

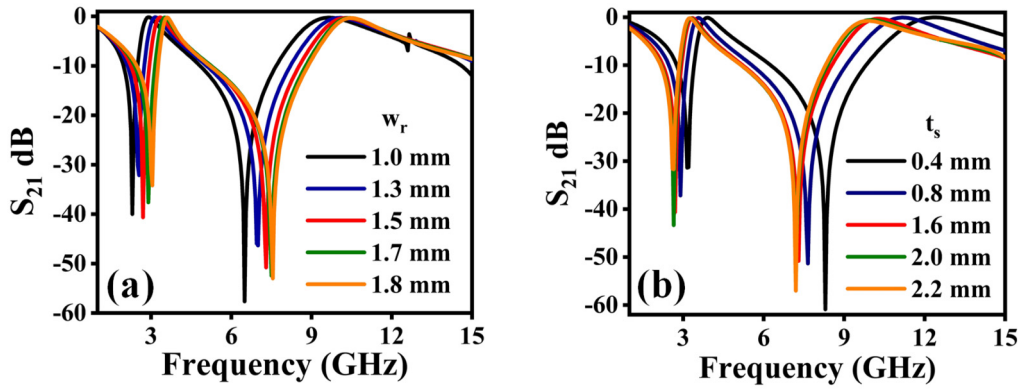

FIG. 9. The response of the scattering parameter (S_{21}) relating to (a) different resonator widths (w_r) and (b) different substrate thicknesses (t_s).

Figures 8(a) and 8(b) display the electric field distribution. It is evident that changes in the magnetic field affect the induced electric field. Intense electric fields are observed in areas where magnetic fields experience the most rapid rate of change, as illustrated by the comparison between Figs. 8(a) and 7(a). Due to the capacitive effect, a strong electric field is detected near the gap in the MTM structure. As a result, at 2.7 GHz, the outer and middle horizontal edges exhibit a stronger electric field than the remaining area. On the other end, in Fig. 8(b), at 7.3 GHz, a low electric field intensity is observed due to low electric current resulting in less magnetic field intensity. Furthermore, the electric field is neutralized when the magnetic field is constant in the resonator. Due to the interconnected nature of electromagnetic fields and currents, both play a vital role in the resonances at the frequencies mentioned above. In Figs. 8(c) and 8(d), the field distribution of the x-component of electric field (E_x) is presented which indicates the formation of electric quadrupole mode resonance at the metal–dielectric interface. The proposed structure's resonance is primarily caused by the excitation of surface plasmon polaritons (SPPs) due to electric quadrupole mode resonance, as indicated by the field distribution, which also shows the accumulation of positive and negative charges in the gap region of the resonator structure.[13,51–53]

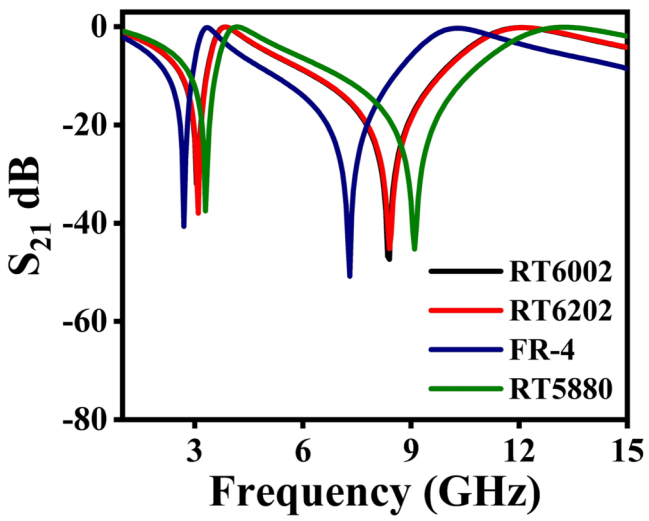

FIG. 10. The variation of the scattering parameter (S_{21}) with different materials as substrates.

E. Simulation-based parametric analysis of the proposed MTM unit cell structure

1. Effect of resonator width (w_r) on resonance frequency

Figure 9(a) demonstrates the relationship between the scattering parameter (S_{21}) and the resonator width (w_r). Altering the width has an impact on inductance, consequently leading to changes in the resonance frequency of the proposed MTM structure.[37,38] Notably, a significant blue shift is observed in the S_{21} parameter when w_r is increased from 1 to 1.8 mm leading to a rise in inductance, indicating an increase in the resonance frequency. The observed shift in resonance frequencies also imparts tunability characteristics of the designed MTM structure.

2. The impact of varying the thickness (t_s) of the FR-4 dielectric substrate

Substrate FR-4 thickness (t_s) is varied from 0.4 to 2.2 mm to analyze its influence on the scattering parameter (S_{21}), as shown in Fig. 9(b). Substrate thickness has less impact on resonance frequency, although this change is less observed at the lower-valued resonance frequency (in the S-band). However, at high values, particularly in the C band, the resonance frequency shift becomes more noticeable with increasing thickness of the FR-4 substrate. This is because the substrate functions as a dielectric medium, leading to the creation of capacitance between the two waveguide ports. As the substrate thickness increases, parallel capacitance also increases, causing a decrease in the resonance frequency.[38] Figure 9(b) illustrates that the MTM

TABLE IV. Various properties and S21 parameter results of different substrate materials.

S. No.	Substrate	Electric permittivity	Tangent loss	Resonance frequency of S_{21} (GHZ)	Frequency band	Magnitude of S_{21} (dB)
1.	Roger's RT6002	2.94	0.0012	3.1 and 8.4	S and X	−31.9 and −47.3
2.	Roger's RT6202	2.90	0.0015	3.1 and 8.4	S and X	−37.9 and −45.1
3.	Roger's RT5880	2.20	0.0009	3.3 and 9.1	S and X	−37.4 and −45.2
4.	FR−4	4.30	0.025	2.7 and 7.3	S and C	−40.6 and −50.7

unit cell achieves the required resonance frequencies in both S and C bands when the substrate thickness is set at 1.6 mm. Therefore, this variation of w_r and t_s shows the tunability characteristics of the designed structure with a shift in the resonance frequency.

3. Effect of different dielectric substrate materials

This study examines how changing the dielectric substrate material affects the performance of MTMs. When using Roger's versions instead of the FR-4 substrate, the frequency response of S21 shifts toward higher frequencies. This shift indicates that the choice of substrates significantly influences MTM performance, as depicted in Fig. 10. Each Roger's version demonstrates dual resonance frequencies in S and X bands with varying magnitudes, but not in C-bands. In contrast, the FR-4 substrate exhibits dual resonances at 2.7 and 7.3 GHz in S and C bands, with magnitudes of −40.6 and −50.7 dB, respectively. The discussion clarifies the significance of the FR-4 dielectric material as a suitable substrate for the proposed MTM structure. These above findings are summarized in Table IV.

F. MTM as a refractive index sensor

The transmission coefficient (S_{21}) change with respect to various refractive index (RI) values has been examined in the following section to evaluate RI sensitivity. The study of RI sensing properties involves altering the surrounding environment of the MTM to correspond with changes in its refractive index, consequently inducing a shift in the resonance frequency of the proposed MTM, as shown in Fig. 11(b). Sensitivity (S_R) serves as a crucial benchmark for evaluating sensing performance and is defined as follows:[27]

$$S_R = \frac{\Delta f}{\Delta n}. \tag{15}$$

Transmission coefficient spectra show a red shift as the refractive index of the surrounding environment changes from 1.00 to 1.20, as shown in Fig. 11(a). Figure 11(b) illustrates the correlation between the shift in resonance frequency shift (Δf) and the variations in refractive index (Δn) of the surrounding environment. Additionally, the resonance frequency of the proposed MTM exhibits a linear decrease with the rise in the refractive index of the surrounding environment. Moreover, it is clarified that sensitivities S_{R1} and S_{R2}, corresponding to the first and second resonance peaks in the S and C bands, are about 1 and 3 GHz/RIU, respectively. These sensitivities surpass those of the previously reported MTM sensors, as reported in Table V. Thus, it can be said that in the GHz band, the suggested MTM sensor has a high refractive index sensitivity.

G. Practical applications and commercialization of MTM sensors

The designed MTM structure is highly suitable for chemical and biological sensing applications, offering high sensitivity of 1 and 3 GHz/RIU at dual resonance frequencies. The MTM

This work	Metamaterial structure	Dual band (S and C bands)	$S_{R_1} = 1$ GHz/RIU $S_{R_2} = 3$ GHz/RIU

structure's dual-band operation within the GHz frequency range makes it a promising candidate for advanced optoelectronic devices. Its near-zero index and left-handed behavior are particularly advantageous for non-destructive testing and evaluation methods,[56] which are critical for material characterization and quality control in manufacturing industries.

This study has focused on developing technology that is both easy to fabricate and straightforward to implement within the GHz frequency range. This focus on simplicity and ease of production ensures that this technology can be readily adopted and scaled up for mass production. The level of accuracy achieved in the design process allows the technology to be classified within the microwave region of the electromagnetic spectrum, which spans from 1 to 15 GHz frequencies. This classification is important because a variety of applications, such as radar systems satellite and wireless telecommunications, depend on technology that operates in the microwave region. These technologies are very fascinating for commercial and industrial use due to their high-precision production capabilities and ease of fabrication. This easy manufacturing procedure lowers expenses and increases mass productivity, allowing for the large-scale production of these technologies. Therefore, this study's emphasis on easy-to-fabricate and implement technologies in the GHz region positions it well within the current technological landscape. This compatibility with mass production systems further boosts its potential for widespread adoption and integration into various applications that rely on microwave technology.

IV. CONCLUSION

The current study presents a novel design, fabrication, and simulation of an MTM structure capable of dual-band operation with a wide bandwidth in the C band and refractive index sensing application. The FEM-based high-frequency electromagnetic simulator in the frequency domain is used to design, simulate, and extract the MTM's scattering parameter. The experimental measurements were compared to the simulated results and found to be well-matched. The resonance frequencies showed minimal frequency shift, indicating that any differences between the simulated and measured values fell within the acceptable range. This study investigated the effective medium parameters of the designed MTM structure within the frequency range of 1–15 GHz using the NRW method. The analysis of the proposed mirror-shaped metamaterial revealed the presence of effective negative and near-zero refractive index (NZI) and effective negative and near-zero epsilon (ENZ) for dual-band operations. The electromagnetic field distributions were also plotted at the resonance frequencies. The EMR of the designed structure was measured to be 6.93, which confirms the compactness of the metamaterial and its applicability across all dual-frequency bands in the microwave region. Utilizing the suggested MTM as a refractive index sensor has the potential to attain significant sensitivity, specifically 1 GHz/RIU and 3 GHz/RIU. This research introduces a potential alternative approach for creating advanced multi-function sensors with exceptional sensing capabilities, making them suitable for applications in medical diagnostics, detection, and biochemical sensing.

Abstract

Quantum chemical calculations of 3-aminosalicylic acid (3ASA) (monomer and dimer forms) have been performed using DFT and TD-DFT theories with B3LYP/6–311 G(d,p) functional level in the ground and excited states. Using TD-DFT with IEF-PCM model, the electronic spectra of 3ASA in solvents were computed and correlated with the experimental data. The theoretically calculated absorption and emission maxima of 3ASA (monomer) are observed in the range of 343 - 347 nm ($S_0 \rightarrow S_1$ transition) and 429 – 448 nm ($S_1 \rightarrow S_0$ transition), respectively. The natural bond orbital (NBO) analysis shows that charge transfer interaction contributes significantly to stabilize the molecular system. In the case of dimer, hydrogen bonding plays a dominant role in stabilizing the molecular framework. Additionally, the obtained nonlinear optical (NLO) properties: polarizability (13.86×10^{-24} e.s.u for monomer and 29.46×10^{-24} e.s.u. for dimer), first-order hyperpolarizability (4.21×10^{-30} e.s.u for monomer and 0.18×10^{-30} e.s.u for dimer) and second-order hyperpolarizability (7.44×10^{-36} e.s.u. for monomer and 14.32×10^{-36} e.s.u. for dimer) were found to be larger than those of standard organic compounds suggesting that 3ASA has a significant NLO character for optoelectronic applications. The NLO properties of dimer may differ from monomer due to dimerization. Further, the radiative lifetime, light harvesting efficiency and band gap energy were calculated, and proposed that 3ASA may be useful in photovoltaics and wide bandgap power devices.

Highlights

- DFT and TD-DFT theories were employed to calculate structural and molecular properties of 3ASA (monomer and dimer) in ground and excited states.
- HOMO-LUMO study shows monomer and dimer of 3ASA are good reactive.
- NBO analysis reflects that charge transfer interactions stabilized the 3ASA molecule.
- Electronic absorption/emission spectra in solvents calculated by IEF-PCM/TD-DFT method correlate with experimental results.
- Calculated NLO parameters suggested that 3ASA is a potential candidate for NLO material.

Introduction

Salicylic acid (SA) is frequently used in the synthesis of organic compounds as well as in food preservation and plant hormones. It is extensively utilized in many skin care products to control hard skin, acne, corns, psoriasis, warts, and keratosis pilaris [1, 2]. It can even be used to treat headaches, arthritis pain, inflammation, and heart attack. It is an intermediate in the fabrications of agrochemicals, color products, and various dyes. Salicylic acid and its derivatives have drawn the interest of researchers due to their biological significance [1–5]. Moreover, 3-aminosalicylic acid is a

building block that can be utilized to synthesize antimycin A_3 [6].

Weller's crucial research on SA and its derivatives revealed that the photo-induced ESIPT (excited-state intramolecular proton transfer) reaction occurs between the nearby carboxylic group (COOH) and phenol group (OH) [7–9]. Based on computational and experimental examinations, it has been confirmed that ESIPT exists in salicylic acid derivatives in various solvents and polymers [7–15]. Jang et al. [16] have theoretically investigated the ESIPT mechanism for salicylic acid, 3-aminosalicylic acid (3ASA), 5-methoxy salicylic acid, and 5-aminosalicylic acid (5ASA) by potential energy curves calculated using the CIS (configuration interaction singles) and TD-DFT (time-dependent density functional theory) methods. Paul et al. [13–15] have studied the photophysics of various chloro-substituted salicylic acids (5-chlorosalicylic acid, 4-chlorosalicylic acid and 3,5,6-trichlorosalicylic acid) and explained the ESIPT process in various solvents. Joshi et al. [17] have studied the spectral and photophysical properties of substituted salicylic anions. Similar to the unsubstituted salicylic anion, the substituted anions show a large Stokes-shifted emission caused by ESIPT. Suyal et al. [18] have reported the photophysics of 4-aminosalicylic acid (4ASA) in polymer matrices of different polarity. These polymers displayed dual emission (shorter wavelength at 330 nm and longer wavelength at 410 nm in polyvinyl alcohol), with the bands at longer wavelengths being ascribed to ESIPT. Furthermore, Suresh et al. [1] have discussed the vibrational assignment, other quantum chemical properties and thermodynamic parameters of salicylic acid using Hartree Fock (HF) and DFT theories. Akkaya et al. [19] have reported the theoretical and experimental investigation of 4ASA and explored the modifications in the structure of dimers and various monomers. They also suggested that hydrogen bonding between carboxylic groups is accountable for dimerization. Singh et al. [20] have studied the experimental and theoretically calculated FT-IR/IR spectra of 3ASA, 4ASA, and 5ASA, which demonstrate different characteristics arising from low-frequency vibrational modes due to intramolecular motion. Moradi et al. [21] described the solubilization profile of 3ASA in the ethanol–water mixtures and it was observed that 3-ASA is preferentially solvated by water molecules in the intervals from neat water to the mixture x_1 (mole fraction of water) = 0.24 and from x_1 = 0.35 to neat ethanol. Nogueira et al. [22] have studied the intramolecular hydrogen bonding of 3-aminosalicylic acid on silver colloids using the surface-enhanced Raman (SER) spectra.

In recent years, computational calculations have been widely utilized to collect information regarding the molecular/electronic structures, orbital interactions, and other useful chemical properties of a molecule [23–39]. In quantum chemical computations, DFT and TD-DFT theories are very fruitful to predict the structural modifications, vibrational frequencies, and electronic spectra of a molecule [1, 3, 30, 34, 37]. DFT provides a good correlation between theoretical and experimental findings and facilitates prediction of molecular/electronic properties accurately [23–26, 35–38, 40]. These theories are also useful to obtain the kinetic stability, chemical reactivity, natural bond orbital (NBO) parameters and various thermodynamic parameters of a molecule [41–43]. Moreover, the NBO study of organic molecules is a comprehensive area for researchers to describe the numerous molecular properties such as bond type, bond order, occupancies and electron densities of donor–acceptor interactions, atomic charges, charge transfer or conjugative interactions as well as intramolecular and intermolecular interactions in a molecular system [1, 42, 44–47].

Additionally, it has been recognized that DFT is a straightforward and efficient approach to predict the nonlinear optical (NLO) properties of organic molecules such as polarizability, hyperpolarizability, and dipole moment [27, 28, 38, 39, 48–50]. The widespread use of NLO materials in photonics, telecommunications, frequency mixing, optical computing, electro-optical devices, molecular switches, dynamic holography, lasers, data storage, fast data transfer, medical diagnosis and other fields has made them an appealing and intriguing research topic. Because of their increased efficiency, greater molecule polarizability, and quick response time, organic NLO compounds offer several benefits over others [23, 51–53]. Moreover, the small HOMO (high occupied molecular orbital) – LUMO (lowest unoccupied molecular orbital) energy gap is essential for better NLO response. The HOMO–LUMO energy gap decreased by enhancing the conjugation. Structural modification is an effective approach to reduce the energy gap between the HOMO and LUMO [29, 30, 33, 34, 37–39].

This study focuses on the computational analysis of 3ASA, both as a monomer and a dimer, and examines its electronic and photophysical properties. Calculations include geometrical parameters, electronic absorption and emission spectra, HOMO–LUMO energy, energy gap, molecular electrostatic potential (MEP) map, and reactivity parameters. Additionally, NLO, NBO, and various thermodynamic parameters have been computed. Moreover, the spectral properties of 3ASA have been measured in solvents of varying polarity in order to compare the results with the theoretical calculations. Thus, the study could be valuable for applications in nonlinear optical materials and photovoltaics.

Computational and Experimental Details

The molecular structures of 3ASA were constructed using Gauss view 5.0 [54] and all the calculations were performed using the Gaussian 09 software [55]. The two conformers

(rotamer P and rotamer R) of 3ASA were constructed and optimized in the ground state in gas phase, by DFT/B3LYP/6-311G(d,p) method [24]. The B3LYP is a standard method, first developed to study vibrational absorption and circular dichroism, widely used and has a good compromise between computational cost, coverage, and accuracy of results [56]. Moreover, the higher basis set is more precise and more accurate for more complex molecular systems. 3-aminosalicylic acid is simple and thus, 6-311G(d,p) basis set is sufficient for the calculation. Frequency calculations were performed for the 3ASA (rotamer P and R) using the same method. This ensured that the molecular geometries were stable on the global minimum energy level because all frequencies are real (i.e. positive). The molecular structures of 3ASA (rotamer P and R) have also been optimized in the excited state. Further calculations such as HOMO–LUMO energy, MEP map, electronic transitions, NBO properties, NLO parameters, thermodynamic properties, and dimeric characteristics of 3ASA have also been performed for rotamer P. Moreover, TD-DFT theory [57] was employed to compute the electronic spectra (absorption/emission) of 3ASA in the gas phase. The effect of solvents on 3ASA has been studied using TD-DFT including the IEF-PCM (integral equation formalism of the polarizable continuum model) [58]. IEF-PCM is the current version of PCM useful in common quantum chemistry packages. One of the major challenges to PCM methods is that they are all derived assuming the solute charge density is entirely encapsulated in the cavity. This is often not the case, as the electron distributions frequently extend beyond the cavity. It has been demonstrated that IEF-PCM can effectively overcome this effect [59].

The NBO properties of 3ASA in the gas phase were calculated using NBO 3.1 program [24], which is incorporated in the Gaussian 09 software. The NLO parameters of 3ASA in the gas phase have been calculated by TD-DFT/B3LYP/6-311G(d,p) method. Furthermore, the thermodynamic properties of 3ASA at various temperatures were computed using the above mentioned theory in the gas phase. To study the dimeric nature of 3ASA, a molecular structure of a dimer of 3ASA was generated and optimized by DFT/B3LYP/6-311G(d,p) method in the ground and excited states and its properties viz. geometrical parameters, MEP, HOMO–LUMO energy and NBO parameters were obtained.

3ASA (purity: 97%) were purchased from Sigma-Aldrich and used as received. All the solvents used are of spectroscopic grade and de-ionized water/double distilled water was utilized whenever required. The absorption measurements were monitored using a UV/VIS/NIR spectrophotometer (Lambda-750, Perkin Elmer). The emission spectra were recorded with a Spectrofluorometer (Fluorolog-3 Horiba Jobin Yvon). A 450W xenon lamp was used as an excitation source. Transparent quartz cuvettes (path length: 1 cm) were used to measure the absorption and emission spectra.

Results and Discussion

Molecular Geometry Analysis

The molecular structures of 3ASA (rotamer P and R) were optimized using DFT and TD-DFT theories at B3LYP/6-311G(d,p) level in the ground and excited states, respectively. The optimized structures of 3ASA (rotamer P and R) are illustrated in Fig. 1 (a,b) including atomic numbering. The calculated energy of rotamer P is -551.57 a.u. in ground state and -551.45 a.u. in the excited state. For rotamer R, energy is -551.56 a.u. in the ground state and -551.44 a.u. in the excited state. The low energy values signify the stability of both the conformers. The comparative optimized geometrical parameters of 3ASA (for rotamer P & R) employing DFT/B3LYP/6-311G(d,p) are summarized in Tables 1 and 2. The optimized bond lengths and bond angles for 3ASA for both rotamers P and R are well matched with each other.

* The values of bond length for salicylic acid (SA) were taken from the literature [1]

The computed bond lengths and bond angles of 3ASA (rotamer P and R) were compared with the reported theoretical (by DFT/B3LYP/6–311 + + G(d,p)) results of SA [1]. It is noticed that the calculated bond lengths and bond angles of 3ASA are in near correlation with the theoretical results of SA [1]. The optimized values (bond lengths and bond angles) related to the carboxylic group (COOH) slightly deviate from the reported value (Tables 1 and 2), which may be possible due to the inherent basis set deficiency at the B3LYP level. These optimized geometrical parameters are also compared to the reported experimental data of SA [1]. The computed bond lengths C4-C5 (1.40 Å), C6-H9 (1.08 Å) and C10-O11 (1.23 Å) of 3ASA exactly matched with experimental values of the parent molecule, i.e. salicylic acid (SA). Moreover, calculated bond angles C3-C4-C5 and C1-C10-O12 obtained the minimum deviation of 0.1° and 0.2°, respectively, when compared with the experimental ones (Tables 1 and 2). The calculated parameters of 3ASA nearly match the experimentally reported values. The maximum deviation in the value of bond length (O14-H18) ~ 0.16 Å and bond angle (C2-O14-H18) ~ 4.1° was observed in rotamer P. These deviations may probably be associated with the inter- or intra-molecular interactions in the solid phase of SA [1].

The optimized parameters of rotamer P and R of 3ASA in excited state are also given in Tables 1 and 2. Because of the translocation of electronic charge density in the excited state, the structural properties may be changed [24]. For rotamer P, the bond length O12-H13 increases by 0.53 Å, and C10-O11 increases by 0.05 Å whereas the bond angles C3-N15-H16 and H16-N15-H17 increase by 6°and 6.1°, respectively.

Additionally, it is probable that 3ASA forms intermolecular hydrogen-bonded complex in the solid phase and stabilizes the molecular system. To study the intermolecular hydrogen bonded complex formation, a dimeric structure of 3ASA (constructed from rotamer P) was optimized in the ground state (gas phase) using DFT/B3LYP/6-311G(d,p) method. The optimized structure of the dimer is shown in Fig. 2 and some significant parameters are given in Table 1 and Table 2. The dimeric structure is more stable than the monomeric structure because the calculated energy (energy = -1103.16 a.u.) is approximately double in comparison to the monomer (rotamer P: energy = -551.57 a.u.). The stability of dimer may arise due to the formation of intermolecular hydrogen bonds between the atoms of the carboxylic group (between atoms O11 & H31, and O29 & H13) (Fig. 2) [19, 44]. The calculated bond lengths and bond angle values of the dimer are closer to that of rotamer P. The bond length

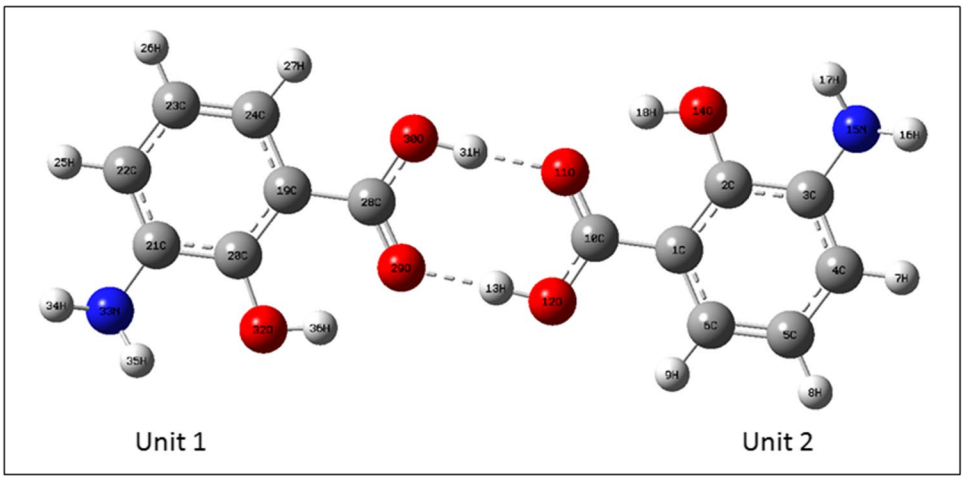

Fig. 2 Optimized molecular structure of dimeric form of 3ASA in gas phase with DFT/B3LYP/6-311G(d,p)

C10-O12 decreases by 0.3 Å and the bond length O12-H13 increases by 0.3 Å upon dimerization. These changes perhaps occurred due to the delocalization of the electronic charge densities on the electro-negative atom O12. The bond angle C10-O12-H13 increases by 4.1˚and the bond angle C1-C10-O11 reduces by 2.4˚ upon dimerization when compared with rotamer P. Thus, it can be inferred that intermolecular hydrogen bonding interactions are responsible for modifying the molecular structure of dimer and corresponding parameters [44]. Moreover, the cartesian coordinates of the geometric optimization for both the monomer and dimer forms of 3ASA were calculated. The cartesian coordinates for monomers P and R in the gas phase, in the ground and excited states, are detailed in Tables S1 and S2 of the supplementary information (SI). Furthermore, the Cartesian coordinates pertaining to the geometric optimization of the dimer in the gas phase, specifically in the ground state, have been compiled in Table S3 of the SI.

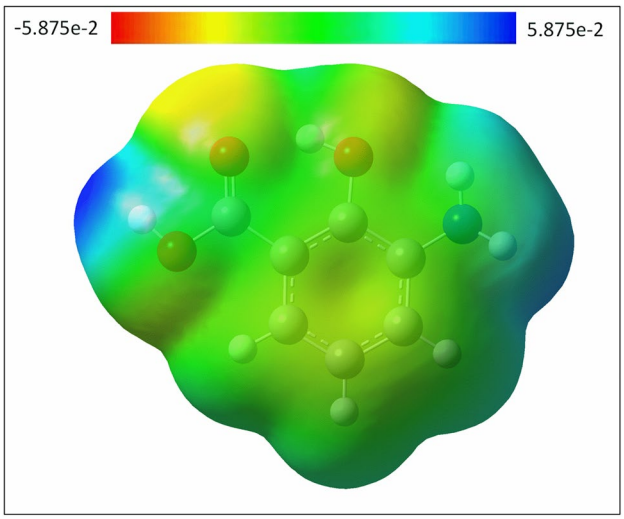

Fig. 3 MEP map of 3ASA (rotamer P) obtained using DFT/B3LYP/6-311G(d,p) in the gas phase

The association between the carboxylic groups of two monomers (i.e., rotamer P) results in stronger intermolecular hydrogen bonding (O11⋯⋯H31 (1.67 Å) and O29-H13 (1.67 Å)) in the dimer. These calculated bond lengths were estimated within the range of hydrogen bonding interactions (< 3.0 Å). Thus, the hydrogen bonding stabilizes the molecular system by pushing the two heteroatoms closer to one another [3].

Molecular Electrostatic Potential (MEP) Map

The MEP map of 3ASA (rotamer P) was generated using the DFT level and is shown in Fig. 3 with a color range of -5.875e-2 a.u. to 5.875e-2 a.u. The electrostatic potential is characterized by various colors, potential values in increasing order are arranged as red < yellow < green < blue. The portions of maximum and minimum potential are considered electron-rich and electron-deficient, respectively [3]. In Fig. 3, the maximum yellow color region (maximum negative electrostatic potential) mainly around the oxygen atom (O11) is electron-rich and it is a preferred region for an electrophilic attack [24, 44]. In the blue color region; positive electrostatic potential is mainly over the hydrogen atoms H13, H16, and H17, which are electron-deficient and provide the area for the attack of nucleophilic species. The region around H13 (Fig. 3) is the bluest and it is a predominant area of a nucleophilic attack [42, 60]. The MEP map is very convenient in the exploration of biological recognition mechanisms and intermolecular hydrogen bonding interactions [23, 61].

Figure 4 represents the MEP map for dimer within the color range from -4.463e-2 a.u. to 4.463e-2 a.u. The atoms

Table 3 Computed HOMO–LUMO energy, energy gap, and reactivity parameters of 3ASA (monomer and dimer) using DFT/B3LYP/6-311G(d,p)

Parameters	Monomer	dimer
E_{HOMO}	-5.58 (eV)	-5.62 (eV)
E_{LUMO}	-1.47 (eV)	-1.63 (eV)
$\Delta E = (E_{HOMO} - E_{LUMO})$	4.11 (eV)	3.99 (eV)
$I = -E_{HOMO}$	5.58 (eV)	5.62 (eV)
$A = -E_{LUMO}$	1.47 (eV)	1.63 (eV)
$\chi = (I + A)/2,$	3.53 (eV)	3.63 (eV)
$\mu = -(I + A)/2$	-3.53 (eV)	-3.63 (eV)
$\eta = (I - A)/2$	2.06 (eV)	2.00 (eV)
$S = 1/\eta$	0.49 (eV^{-1})	0.50 (eV^{-1})
$\omega = \mu^2/2\eta$	3.07 (eV)	3.29 (eV)
$\omega^+ = (I + 3A)^2/16(I - A)$	1.52 (eV)	1.73 (eV)
$\omega^- = (3I + A)^2/16(I - A)$	5.04 (eV)	5.36 (eV)

The reactivity parameter relations given in Table 3 used from the references [23, 24]

O11 and H13 (of monomer unit 1) strongly interact with the H31 and O29 atoms (of monomer unit 2), respectively, through intermolecular hydrogen bonding. Thus, the dimer is more stable than the monomer due to strong intermolecular hydrogen bonding [19, 44]. Due to dimer formation, now, the region around the atoms O11, H13, O29 and H311 is green, which signifies the zero electrostatic potential regions. The yellow color is located around the atoms O12, O14, O32 and O38, and these are the electrophilic regions, and the hydrogen atoms mainly associated with the amino groups are blue and are nucleophilic regions. Through MEP map analysis, it can be observed that the electrophilic and nucleophilic regions are different in monomer and dimer, and their molecular and electronic properties may also vary.

Frontier Molecular Orbitals (FMOs) and Chemical Reactivity Parameter Analysis

The FMOs provide information about chemical reactivity, kinetic stability, electronic spectra, electrical, and optical properties of the molecules [24, 60]. Figure 5 (a,b) illustrates the highest occupied and lowest unoccupied molecular orbitals (HOMO and LUMO) for 3ASA (rotamer P) monomer and dimer (in the gas phase obtained by DFT/B3LYP/6-311G(d,p)). The HOMO LUMO energy and its ΔE values are summarized in Table 3.

HOMO signifies electron donor and LUMO acts as an electron acceptor [60, 61]. In monomer and dimer, HOMO is positioned over amino and hydroxyl groups as well as the benzene ring, whereas LUMO is located over the whole 3ASA moiety. The value of energy gap ΔE is 4.11 eV (for monomer) is small, and is responsible for the charge transfer interactions within the molecular system [23, 61]. The value of ΔE is 3.99 eV for the dimer, which signifies that it is more reactive and stable than the monomer [62].

Additionally, various quantum chemical reactivity descriptors such as ionization potential (A), electron affinity (I), chemical potential (μ), electronegativity (χ), softness (S), hardness (η), and electrophilicity indices (ω), electron accepting/donating power (ω^+, ω^-) [23, 24, 61] were estimated using HOMO–LUMO energy for monomer and dimer in the gas phase and are listed in Table 3. The I and A values signify the electron donating and accepting power of a probe. The large value of I (5.58 eV) and ω^- (5.04 eV) indicate that 3ASA (monomer) has electron-donating nature. The positive value of A (1.47 eV) signifies the charge transfer character within the 3ASA molecule. The negative μ (-3.53 eV) value indicated that 3ASA is quite stable. The η and S are associated with the stability and reactivity of the molecule. The large η (2.06 eV) value shows that 3ASA is

Table 4 Electronic absorption and emission transitions and other corresponding parameters of 3ASA in gas/solvent phases obtained with TD-DFT/B3LYP/6-311G(d,p)

stable, and a moderate value of S (0.49 eV^{-1}) indicates that 3ASA is moderately reactive. The molecular structure, bonding interactions, reactivity, and stability of the molecule are described with ω value. The higher ω (3.07 eV) value shows that 3ASA is a good electrophile as $\omega > 1.5$ [24]. Furthermore, the greater μ, S and ω values propose that the dimeric structure of 3ASA is more reactive and stable as compared to the monomeric form [62].

Electronic Absorption and Emission Spectra

Electronic absorption and emission (fluorescence) spectra of a monomer (rotamer P of 3ASA) in the gas phase and different solvents were calculated using the TD-DFT/B3LYP method with a 6-311G(d,p) basis set. To investigate the influence of solvents on the 3ASA monomer, TD-DFT was combined with an IEF-PCM solvation model. A series of solvents of different polarities were selected, including non-polar, polar aprotic and polar protic solvents. This selection enables the investigation of the solvent effect on the photophysical properties of 3ASA, providing insights into

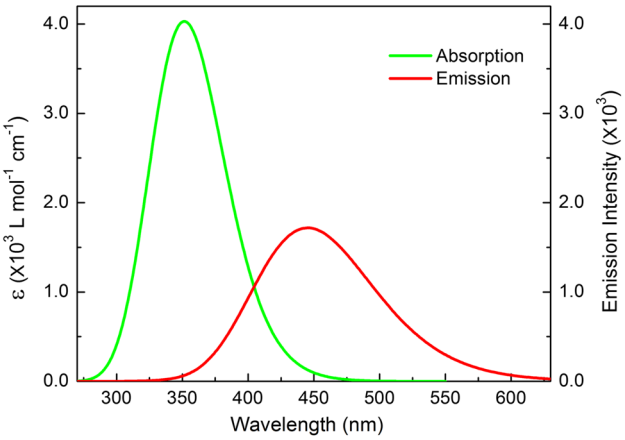

Fig. 7 Simulated absorption and emission spectra of dimer in the gas phase using TD-DFT/B3LYP/6-311G(d,p) method

how different solvent environments influence its behavior. The various parameters in the ground state such as excitation energy (E_{ex}), absorption wavelength λ_{abs} (nm), orbital assignment, CI value, and oscillator strength *(f)* of 3ASA

Table 5 Experimentally observed spectral parameters of 3ASA in solvents

Solvents	λ_{abs} (nm)	λ_{em} (nm)	ν_{abs} (cm^{-1})	ν_{em} (cm^{-1})	$\Delta\nu$ (cm^{-1})	f	τ_0 (ns)	LHE
DEE	342	411	29,240	24,331	4909	0.06	29.2	0.13

Water	302	407	33,113	24,570	8543	0.05	27.4	0.11

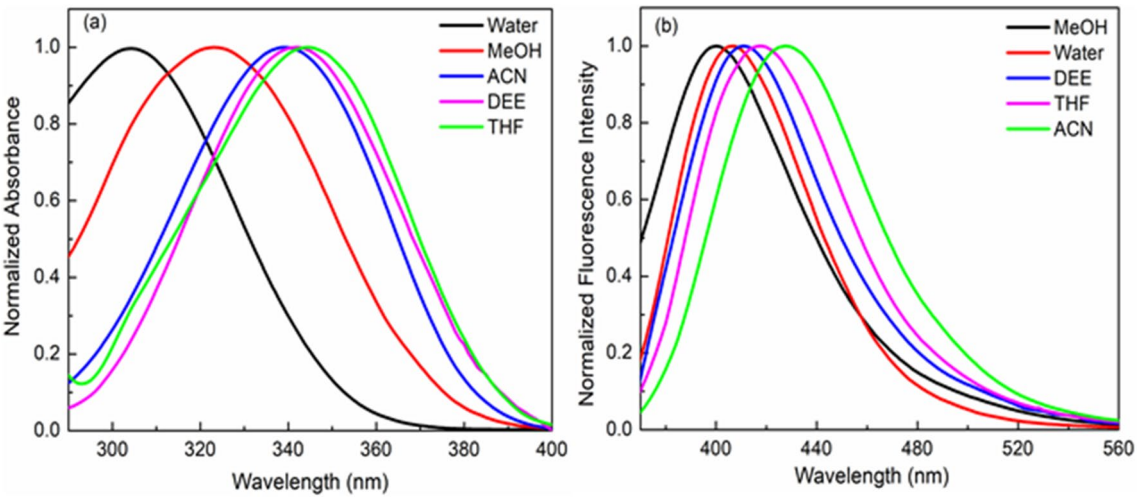

Fig. 8 Experimentally observed normalized (**a**) absorption and (**b**) emission spectra (excited at corresponding absorption wavelength) of 3ASA in different solvents

in the gas/solvent phases are listed in Table 4. The strong electronic absorption band of 3ASA was primarily obtained from the inclusion of HOMO → LUMO with a maximum contribution of 98% (CI value: 0.70). Thus, the main absorption band appeared in the range of 343–347 nm in the gas phase and different solvents. The calculated electronic absorption and emission spectra of 3ASA (monomer P) are shown in Fig. 6 (a,b) in gas/solvent phases. The absorption band of 3ASA was predicted around 343 nm in the gas phase, 347 nm in toluene (TOL), 346 nm in diethyl ether (DEE), 346 nm in tetrahydrofuran (THF), 345 nm in acetonitrile (ACN), 345 nm in methanol (MeOH), 346 nm in DMSO, and 345 nm in water with 98% contribution of HOMO → LUMO.

The emission spectra of 3ASA (Fig. 6 (b)) appeared around 429 nm in gas, 435 nm in TOL, 438 nm in DEE, 441 nm in THF, 444 nm in ACN, 444 nm in MeOH, 448 nm in DMSO and 445 nm in water. Thus, it can be noticed that absorption and emission spectra are red shifted in solvents as compared to the gas phase due to the solvent effect [50]. Moreover, the electronic spectra of the dimer were also calculated theoretically in the gas phase using the same method and shown in Fig. 7 (a,b). The computed absorption (λ_{abs} = 345 nm) and emission (λ_{em} = 445 nm) spectra of dimer are consistent with the theoretically observed spectra of the monomer (in water).

To authenticate the computed spectral properties, absorption/emission spectra of 3ASA (at 0.1 mM) were recorded experimentally in some solvents (Table 5). Figure 8 (a,b) shows the absorption spectra in the range of 290–400 nm and emission spectra of 3ASA in some solvents. It is important to state that the 3ASA is less soluble in non-polar solvents. Therefore, the absorption spectrum was not observed in TOL for the chosen concentration with the available instrument. The absorption spectra of 3ASA were appeared at 340 in ACN, 342 nm in DEE, 344 nm in THF, 322 nm in MeOH, and 302 nm in water. The emission maxima were observed at 411 nm in DEE, 418 nm in THF, 427 nm in ACN, 400 nm in MeOH, and 407 nm in water. Due to low solubility, the clear emission peak of 3ASA does not appear in TOL. Both spectra (absorption/emission) of 3ASA in water and MeOH are blue-shifted as compared to non-polar/polar protic solvents due to hydrogen bonding/anion formation (deprotonation of COOH) [23, 63, 64].

The absorption band maxima in DEE, THF, and ACN nearly correspond to the experimental ones. The absorption peak shows variations of 23 and 43 nm in MeOH and water, respectively, as compared to the theoretical values.

The difference in the theoretical and experimental values of emission maxima (in solvents) varies from 17 - 44 nm. The variations in experimental and theoretical results of absorption and emission spectra may be possible because experimental observations depend on various physical parameters such as the temperature of the surroundings, the concentration of solute and hydrogen bonding ability of solvents, etc., whereas in computational calculations solute–solvent interactions are not considered [65, 66].

The fluorophores that possess charge transfer characteristics are very useful in optoelectronic devices and are greatly influenced by the radiative (or excited state) lifetime. It is expected that fluorophores with considerably longer lifetimes will demonstrate effective electron injection and charge transfer [67]. The radiative lifetime of the fluorophore is calculated by Eq. 1.

$$\tau_0 = \frac{1.5}{f \times \nu_{abs}^2 (cm^{-1})} \tag{1}$$

where ν_{abs} is the absorption wavenumber. f is the oscillator strength [68] and can be calculated using Eq. 2,

$$f = 4.33 \times 10^{-9} \left[\int \epsilon_\nu d\nu\right]_{exp} \tag{2}$$

where ε_ν is the molar extinction coefficient at wavenumber (ν) measured from the absorption spectrum. $\left[\int \epsilon_\nu d\nu\right]_{exp}$ is the integrated area under the absorption spectrum.

The computed results (Table 5) show that 3ASA has large τ_0 values, resulting in greater photocurrent efficiency in photovoltaics, particularly dye-sensitized solar cells [67].

Light harvesting efficiency (LHE) predicts the ability of organic compounds to absorb photons and then inject photoexcited electrons into the conduction band of semiconductors [67]. LHE is estimated using the Eq. 3 and is given in Table 5.

$$LHE(\lambda) = 1 - 10^{-f} \tag{3}$$

The LHE values (experimentally estimated) of 3ASA have been found in the range of 0.11–0.17 in solvents which is close to the LHE value (0.21) of Red mulberry (H+) [69]. Moreover, the experimentally observed LHE values well matched with theoretically calculated LHE values (0.15–0.17) (Table 5). The result shows that 3ASA can act as a good candidate for light-harvesting materials which are significant for photoacclimation, photoprotection and photovoltaics [67, 69, 70].

Band gap energy (E_g) is an informative parameter to discuss the kinetic stability, chemical reactivity and optical polarizability [24, 71], and is calculated using Eq. 4

$$E_g = \frac{hc}{\lambda_{ae}} = \frac{1240}{\lambda_{ae}} \tag{4}$$

where λ_{ae} denotes the absorption edge wavelength (nm), h indicates Planck's constant and c is the speed of light.

The E_g value of 3ASA was calculated (experimentally) to be 3.18 eV in THF solvent. The calculated E_g value of 3ASA is close to the E_g values of wide bandgap power semiconductors such as gallium nitride (GaN: 3.39 eV) and 4H-silicon carbide (4H-SiC: 3.32 eV) and 6H-silicon carbide (6H-SiC: 2.9 eV) [72]. Wide bandgap power devices are integrated as replacements for silicon technology in multiple technological applications such as electric vehicle (EV) charging, motor drive applications, renewable energy systems, etc. [73].

Natural Bond Orbital (NBO) Analysis

The NBO calculations for 3ASA (rotamer P) were done by employing DFT/B3LYP/6-311G(d,p) method. The estimated hybridization and their corresponding characters of NBOs for 3ASA are tabulated in Table 6. The atoms O and N are considered to be highly electro-negative as the P_c (polarization coefficient square) value is large [23]. The other atoms connected with these O and N atoms have small electronegativity due to low P_c values. For example, the NBO σ(N15-H16) is established by the contribution of 68.47% of the electron density of the N15 and 31.53% of the H16 atom. This NBO is originated by the connection of $sp^{2.93}$ ($P_c = 0.83$ and p-character: 74.51%) of the N15 atom and $sp^{0.00}$ ($P_c = 0.56$ and p-character: 0.06%) of the H16 atom.

When the donor–acceptor interactions arise within the molecular framework, the occupancies and energies of donor orbitals reduce and charge transfer interactions occur [23, 44]. The charge transfer interactions between donor and acceptor NBO can be described by the stabilization energy ($E^{(2)}$) and corresponding relation given by Eq. 5.

$$E^{(2)} = \Delta E_{ij} = (q_i F^2(i,j)/(\epsilon_j - \epsilon_i)), \tag{5}$$

here, $E^{(2)}$ is the stabilization energy and is computed using the second-order perturbation theory. q_i is the orbital occupancy of the donor. $\in_i$ and $\in_j$ correspond to diagonal elements, and $F(i, j)$ signifies the off-diagonal NBO Fock matrix element.

A larger stabilization energy indicates stronger donor–acceptor interactions and a higher degree of conjugation throughout the entire molecular system [24]. Table 7 shows the stabilization energy for a few significant donor–acceptor interactions. The most significant NBOs are π(C1-C2)→π*(C10-O11), LP(2) O14→π*(C1-C2) and LP (2) O12→π*(2) (C10—O11) with higher $E^{(2)}$ values 29.54, 33.84 and 46.76 kcal/mole, respectively. The NBOs interactions probably arise because of the delocalization of π electrons from one NBO to another and hence charge transfer

interactions occur within the 3ASA molecule, which stabilizes the molecular framework.

The NBO study was performed in different solvents with the same method and related parameters are collected in Table 8. The $E^{(2)}$ values of various NBO differ may be due to the translocation of charge in a distinct degree due to solvent–solute interactions. The greater $E^{(2)}$ values of 47.96, 47.66 and 47.39 kcal/mol were estimated for the NBO LP(2)

Table 9 Stabilization energies for some significant donor–acceptor interactions of a dimer

Donor NBO (i)	Acceptor NBO (j)	E^2 (kcal/mol)	E(j)-E(i) (a.u.)	F(i,j) (a.u.)
Unit 1 → Unit 2				
LP(1) O11	σ*(O30-H31)	10.79	1.11	0.098
LP(2) O11	σ*(O30-H31)	15.86	0.70	0.096
Unit 2 → Unit 1				
LP(1) O29	σ*(O12-H13)	10.79	1.11	0.098
LP(2) O29	σ*(O12-H13)	15.86	0.70	0.096

O12 → π*(C10 – O11) in ACN, MeOH and water, respectively. The larger $E^{(2)}$ values of NBOs in solvents than in the gas phase reflect that the charge transfer interactions are stronger in solvents than in the gas phase due to solvent–solute interactions. Moreover, in dimer, the $E^{(2)}$ = 10.79 kcal/mole was found for the NBO LP(1) O11 → σ*(O30-H31) and LP(1)O29 → σ*(O12-H13) whereas the $E^{(2)}$ = 15.86 kcal/mole has been obtained for NBO LP(2) O11 → σ*(O30-H31) and LP(2) O29 → σ*(O12-H13) (Table 9). These larger values of $E^{(2)}$ suggest that intermolecular hydrogen bonding between carboxylic groups is responsible for dimerization [3, 44].

Non-Linear Optical (NLO) Analysis

The NLO properties: polarizability (α), first-order hyperpolarizability (β) and second-order hyperpolarizability (γ) of 3ASA were calculated using DFT/B3LYP/6-311G(d,p) method. The polarizability (α), first-order hyperpolarizability (β) and second-order hyperpolarizability (γ) values of 3ASA are calculated using the following Eqs. (6–11) [23, 24, 74].

$$\alpha_{total} = (\alpha_{xx} + \alpha_{yy} + \alpha_{zz})/3 \tag{6}$$

$$\beta_{total} = \left(\beta_x^2 + \beta_y^2 + \beta_z^2\right)^{1/2} \tag{7}$$

where,

$$\beta_x = \beta_{xxx} + \beta_{xyy} + \beta_{xzz} \tag{8}$$

$$\beta_y = \beta_{yyy} + \beta_{yzz} + \beta_{yxx} \tag{9}$$

$$\beta_z = \beta_{zzz} + \beta_{zxx} + \beta_{zyy} \tag{10}$$

$$\gamma_{total} = \frac{1}{5}\left[\left(\gamma_{xxxx} + \gamma_{yyyy} + \gamma_{zzzz}\right) + 2\left(\gamma_{xxyy} + \gamma_{xxzz} + \gamma_{yyzz}\right)\right] \tag{11}$$

where α is the polarizability tensor. The β and γ are the first-order and second-order tensors, respectively. Moreover, the first-order hyperpolarizability is represented as a 3 × 3 × 3 matrix and is a tensor of rank 3. According to Kleinman symmetry, the twenty-seven components of the 3 × 3 × 3 matrix can be diminished to ten components [24, 75]. The components of α (α_{xx}, α_{xy}, α_{yy}, α_{xz}, α_{zy}, and α_{zz}), β (β_{xxx}, β_{xxy}, β_{xyy}, β_{yyy}, β_{xxz}, β_{xyz}, β_{yyz}, β_{xzz}, β_{yzz} *and* β_{zzz}) and γ (γ_{xxxx}, γ_{xxyy}, γ_{yyyy}, γ_{xxzz}, γ_{yyzz}, γ_{zzzz}) have been obtained from Gaussian output.

The components of α and β for 3ASA (monomer and dimer) are summarized in Table 10 and the calculated α_{total} and β_{total} values are collected in Table 11 and compared with the reported data. The calculated values of α_{total} and β_{total} for 3ASA are 13.86×10^{-24} e.s.u. and 4.21×10^{-30} e.s.u., respectively. The α_{total} value of 3ASA is slightly small when compared to acetylsalicylic acid [51], 3,5-diaminobenzoic acid

Table 12 Second-order hyperpolarizability of monomer and dimer of 3ASA computed using DFT/6-311G(d,p) method in the gas phase

Second-order hyperpolarizability		
	monomer	dimer
γ_{xxxx} (a.u.)	38,949.40	93,698.9
γ_{xxyy} (a.u.)	3922.15	14,005.6
γ_{yyyy} (a.u.)	24,652.00	10,623.3
γ_{xxzz} (a.u.)	628.67	1408.82
γ_{yyzz} (a.u.)	423.34	1242.75
γ_{zzzz} (a.u.)	236.46	548.18
γ_{total} (a.u.)	14,682.48	27,636.92
γ_{total} (e.s.u.)	7.44×10^{-36}	14.32 ($\times10^{-36}$)

[23] and phenyl urea (Table 11) [52]. Moreover, the α_{total} value of 3ASA is significantly higher than the α_{total} values of the urea and thiourea [52]. Furthermore, the estimated value of β_{total} (4.21×10^{-30} e.s.u.) value of 3ASA is higher than the reported β_{total} values of salicylic acid [1], 5-iodosalicylic acid [76], 4-aminobenzoic acid [77] and acetylsalicylic acid [51] (Table 11). The β_{total} (4.21×10^{-30} e.s.u.) of 3ASA is very closed to β_{total} (4.25×10^{-30} e.s.u.) of 3,5-diaminobenzoic acid [23]. In NLO study, urea is generally used as a reference for comparison purposes. The β_{total} of 3ASA is ~ 11 times larger than the urea, ~ 5 times greater than thiourea and ~ 2 times more than phenyl urea [52] (Table 11). The larger value of polarizability and hyperpolarizability occur due to the charge transfer within the molecular system [24]. Thus, 3ASA may have substantial applications in NLO materials.

Furthermore, the polarizability (α) and first-order hyperpolarizability (β) for dimer were also computed using the same method (DFT/B3LYP/6-311G(d,p) method) in the gas phase and listed in Tables 10 and 11. The α_{total} and β_{total} values for dimer were found to be 29.46×10^{-24} e.s.u. and 0.18×10^{-30} e.s.u., respectively. The β_{total} value of the dimer is significantly smaller than the monomer. Moreover, the β_{total} value of dimer is smaller than the urea (0.37×10^{-30} e.s.u.) [52]. These changes in results may be obtained due to the formation of dimerization through hydrogen bonding.

Additionally, the second-order hyperpolarizability (γ) for both the monomer and dimer forms of 3ASA in the gas phase has been theoretically calculated using DFT/B3LYP level of theory with a 6-311G(d,p) basis set. The calculated values of γ for the monomer and dimer are provided in Table 12. Specifically, the γ_{total} value for the monomer was computed to be 7.44×10^{-36} e.s.u., while for the dimer, it was estimated to be 14.32×10^{-36} e.s.u. This indicates that the γ_{total} value is approximately twice as high for the dimer compared to the monomer, possibly attributed to dimer formation. These findings strongly suggest the potential of 3ASA for applications in nonlinear optical (NLO) fields.

Table 13 Thermodynamic parameters of 3ASA at 298.15 K along with global minimum energy using DFT/B3LYP/6-311G(d,p)

Thermodynamic parameters	Values
SCF energy (a.u.)	-551.57
Zero-point vibrational energy (kcal mol^{-1})	86.01
Total Thermal energy, E_{th} (kcal mol^{-1})	91.81

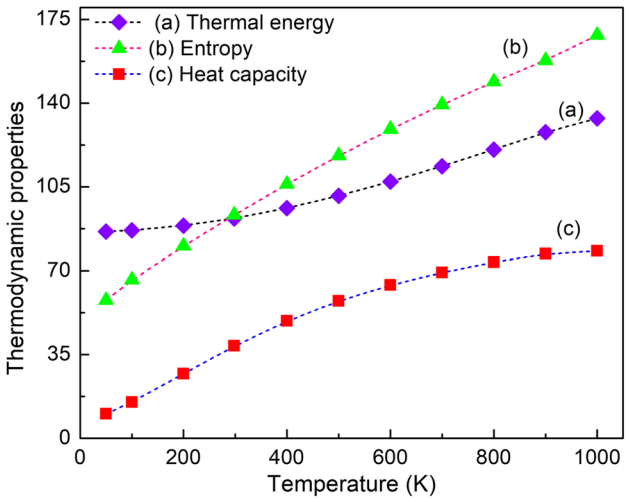

Fig. 9 Correlation graph of thermodynamic properties at different temperatures for 3ASA (rotamer P)

Thermodynamic Properties of 3ASA

The thermodynamic parameters such as zero-point vibrational energy, SCF energy, heat capacity at constant volume, thermal energy, dipole moment, and entropy, along with global minimum energy at temperature 298.15 K and pressure 1 atm have been computed employing DFT/B3LYP/6-311G(d,p) for 3ASA and are collected in Table 13.

Thermodynamics is considerably important in chemical engineering. It plays a significant role in the advance of the chemical industry, enabling design of new technologies, and avoiding challenging measurements [78]. In addition, the heat capacity is a fundamental thermodynamic parameter of a substance, and using the heat capacity information the associated thermodynamic functions such as enthalpy and entropy can be obtained using corresponding thermodynamic equations. These thermodynamic parameters are essential in examining phase change materials for energy storage applications [79].

To demonstrate the temperature dependency on the thermodynamic properties of 3ASA, heat capacity at constant pressure (C_p), total thermal energy (E_{th}) and entropy at different temperatures have been calculated by the same approach and are reported in Table 14. The temperature dependence of S, C_p and E_{th} for 3ASA is shown in Fig. 9 along with polynomial (quadratic) fitting.

From Fig. 9 and Table 14, it is noted that S, C_p, and E_{th} for 3ASA (monomer) increase on increasing the temperature from 50 to 1000 K because the molecular vibrational intensities increase with temperature [1]. Quadratic formulas were used for fitting the obtained thermodynamic parameters vs. temperature, and the resulting fitted regression parameters (R^2_{adj}) are all equal to 0.99. Therefore, the corresponding fitting equations for 3ASA are as follows,

$$S = 51.15 + 1.51 \times 10^{-2}T - 3.45 \times 10^{-5}T^2, R^2_{adj} = 0.99, \quad (12)$$

$$C_p = 2.16 + 1.41 \times 10^{-2}T - 6.66 \times 10^{-5}T^2, R^2_{adj} = 0.99, \text{and} \quad (13)$$

$$E_{th} = 84.57 + 1.72 \times 10^{-2}T + 3.33 \times 10^{-5}T^2, R^2_{adj} = 0.99 \quad (14)$$

These thermodynamic parameters for 3ASA are helpful to ascertain the direction of chemical reactions and to further estimate thermodynamic properties dealing with thermodynamic functions and the second law of thermodynamics [80].

Conclusion

The molecular structures of 3ASA (monomer and dimer) were optimized using DFT and TD-DFT theories in the ground and excited states and significant structural, molecular and thermodynamic parameters were obtained. The small energy gap suggests that both monomer and dimer are reactive. MEP map shows that the carbonyl oxygen is in a position of electrophilic attack in the monomer. Knowledge of MEP map is useful in understanding and foreseeing molecular interactions. Depending on the medium, the calculated absorption and emission maxima of 3ASA were observed in the range of 343—347 nm and 429 – 448 nm, respectively. The theoretical absorption and emission spectra in most of the solvents are closer to the experimental results. Moreover, the computed absorption and emission spectra of monomer and dimer are in correlation with each other. The radiative lifetime, light harvesting efficiency (LHE) and band gap energy show that 3ASA may be useful in photovoltaics and wide bandgap power devices. Moreover, the NBO analysis shows that charge transfer interactions contribute significantly in stabilizing the molecular system. In the case of dimer, H-bonding plays a dominant role in stabilizing the molecular framework. Furthermore, the calculated NLO parameters indicate that 3ASA can be used in NLO applications. The thermodynamic properties: entropy, total thermal energy and heat capacity at constant pressure increase with the increase in temperature as a result of rising molecular vibrational intensities. Thus, the thermodynamic study is important to predict the direction of chemical reactions and other thermodynamic parameters. Hence, the present study delivers detailed structural/molecular information of the 3ASA molecule.

***Abstract*— The development of quantum computing substantially threatens modern cryptographic functions in blockchains, making it unsafe to share sensitive details such as Electronic Medical Records (EMRs). To address this threat, the paper proposes a novel and secure architecture for EMR data sharing using permissioned blockchain and quantum-resistant cryptography. Blockchain technology is used to provide data immutability, transparency, and integrity. Hybrid encryption with CRYSTALS-Kyber, a post-quantum cryptographic algorithm for key encapsulation and AES-256 for symmetric data encryption is used to address the security concerns in conventional blockchains. The patient stores their access policies that control who can access their data. The data access is managed via the patient-controlled re-encryption mechanism through which the data requester may safely access the EMR. The paper presents a detailed analysis of the system's security, patient privacy, and data ownership control, offering a patient-centric solution for secure EMR sharing in the coming quantum age.**

Keywords*— *Blockchain, Post-Quantum, CRYSTALS-Kyber, Electronic Medical Record (EMR), Cryptography

I. INTRODUCTION

In modern healthcare facilities, Electronic Medical Records (EMRs) are electronic versions of a patient's medical data maintained by healthcare providers that contain their relevant medical information [1]. These are usually used to store patients' private data that can be useful in diagnosing, treating or researching. However, this data should be shared safely among authorized individuals, including lab technicians, doctors, and the patients themselves, so that they can receive the right medical care [1]. The traditional systems prevalent today make it difficult to balance between ease of access, data privacy and security. This, in turn, complicates the implementation of access control while ensuring data confidentiality as well as security since there are diverse parties affected by this problem. Moreover, there is a lack of accountability or confidence in the central authority leading to loss of data during storage and transmission among interested stakeholders [2], [3].

The secure sharing of EMRs while ensuring transparency, immutability and decentralization is possible through blockchain-based EMR systems. Being a decentralized approach, blockchain eliminates security concerns and unauthorized access to data. Its immutability ensures that data intractability and integrity [4]. Nonetheless, the threat of potential quantum computing attacks on prevailing cryptographic methods calls into question the long-term security of Blockchain-based EMR Systems. Quantum computers are equipped with certain properties such as superposition, entanglement and interference that enable them to resolve specific problems much faster than classical computers using specialized algorithms for those purposes [5]. Technological advancements necessitate the shift towards PQC approaches in securing the existing systems. The motivation lies in the need to build systems incorporating PQC algorithms.

A. Problem Statement

Quantum computing is a rapidly emerging field that utilizes quantum mechanics principles to perform information processing. This makes the industry very interesting for many sectors because quantum computing has well-established theoretical basis as well as experimental proof. However, if this new paradigm ever becomes a reality with sufficient qubits, it could spell doom for blockchain systems, which rely on pre-quantum cryptographic methods and are hence susceptible to attack from such computers. Shor's algorithm [6] among other quantum algorithms, can effectively break cryptographic problems at the heart of blockchain, like integer factorization, discrete logarithmic problems or elliptic curve intractability in polynomial time, which were computationally inefficient for classical computers. The Grover's Algorithm [7] in quantum computing can efficiently produce hashes and change any block without altering data integrity.

These advancements, especially the claim of achieving quantum supremacy, risk the confidentiality and integrity of traditional public key cryptosystems used in implementing blockchains. Hence, there is a pressing need for blockchain networks to be resistant to future quantum attacks. They need to be redesigned with the help of quantum-resistant cryptosystems, thus developing post-quantum blockchain cryptosystems. Lightweight and computational efficiency are required for such architectures [8]. More research is needed to overcome these vulnerabilities, specifically for sensitive medical data.

EMRs act as the centralized data source for a patient's sensitive medical data like demographics, medications, lab results, etc. This medical data is crucial for better healthcare quality, reduced costs and secure information sharing among authorized providers. Hence, to secure medical data in today's healthcare systems, blockchain-based EMR systems need to be secured and seamlessly incorporate efficient PQC algorithms into existing blockchain infrastructures.

B. Objectives and Contributions

The research aims to address the upcoming challenge of the necessity of quantum-resistant blockchain systems for EMRs and hence demonstrates the potential of utilizing PQC techniques to secure EMRs within a blockchain system for enhanced data security. The key objectives and contributions of the paper are as follows:

- To propose a novel blockchain-based architecture for secure medical data sharing among healthcare providers, patients, and authorized data requestors resistant to potential attacks from quantum computers.
- To utilize a hybrid encryption approach combining CRYSTALS-Kyber, a quantum-resistant key encapsulation mechanism, and AES-256, offering enhanced security for EMR data.
- The architecture is designed to prioritize patient control over data by allowing them to define access policies and facilitates secure data retrieval using re-encryption for authorized data requestors.

The organization of the paper is as follows. The related work summarizing the existing literature is discussed in Section 2. Section 3 overviews the technical background of blockchain and quantum-resistant cryptography. Section 4 proposes the novel quantum-resistant blockchain architecture and its components. The implementation, workflow, and algorithmic details are explained in Section 5. Section 6 discusses the security analysis and section 7 concludes the paper.

II. Related Works

In [2], a quantum blockchain approach for EMR privacy is proposed, which utilizes quantum communication, entanglement, and quantum key distribution protocols. Performance analysis shows that the proposed system can overcome intercept, entangle-measure, man-in-the-middle, intercept-resend, collective and coherent attacks. But it's difficult to determine the system's efficacy as no detailed implementation is given. In [9] a blockchain-based Electronic Health Records (EHR) system, implemented on Hyperledger Fabric, with user access control algorithms and quantum blind signatures for key distribution is presented. Although it enhances the security, it does not provide a detailed analysis of potential weaknesses and there are scalability challenges. [10] discusses the advantages of combining blockchain and quantum technologies in healthcare but does not give specific details of how quantum blockchain can be implemented in healthcare systems.

Apart from healthcare systems, research has also been done on other blockchain systems to make them quantum-resistant. In [11], a conceptual quantum-resistant blockchain system based on the Linux Foundation Hyperledger Fabric, for university credential verification is proposed. It utilizes Lattice-Based Cryptosystems along with Leighton-Micali Signature (LMS) (Hash-Based Signatures) and eXtended Merkle Signature Scheme (XMSS) for quantum-resistant public key cryptography and hashing respectively. Benchmark testing is needed to address performance uncertainties. [12] introduces a quantum-resistant e-voting protocol on blockchain combining code-based Niederreiter algorithm. Its security is based on the syndrome decoding problem of coding theory and a certificateless traceable ring signature algorithm. But it is efficient only for small-scale elections.

In [13] a quantum-resistant blockchain scheme is proposed using qTESLA, a digital signature based on lattice cipher for smart city applications. It stores public keys and signatures on the IPFS network to increase transaction speed and system performance. However, it doesn't allow parallel transactions. [14] explores PQC implementation in Federated Learning (FL) systems and proposes a hybrid approach combining Dilithium/Falcon with XMSS for security in blockchain-based FL systems. They utilized verifiable random functions to enhance security and performance. However, PQC schemes are still in the standardization phase creating concerns regarding their suitability for various applications and hardware systems.

[15] presents a blockchain voting system that utilizes Practical Byzantine Fault Tolerance for consensus, stateful hash-based signatures (LMS/XMSSMT/HSS), lattice-based and Super Singular Elliptic Curve Isogeny-based cryptic algorithms for public key encryption, but complete automation and device-level security are still concerns. In [16], a framework is introduced to secure the quantum-resistant cloud-based blockchain storage. It utilized a combination of Quantum key distribution (QKD) for key generation, CRYSTALS-Kyber for data encryption, and Zero-Knowledge Proof (ZKP) for user verification before giving access to decryption keys. However, further development is still needed to enhance its scalability and compatibility with existing blockchain systems.

In summary, there is previous research on quantum-resistant cryptography, but the work lacks focus on integrating PQC algorithms in blockchain-based EMR sharing or healthcare systems to enhance their security. The existing papers also lack post-quantum Key Encapsulation Mechanisms, and NIST-selected algorithms in their blockchain systems as they are relatively new. Recent research also failed to address the weaknesses in data sharing, storage, and access in these blockchain systems.

III. BACKGROUND

This section provides an introduction to Blockchain and PQC's technical background.

A. Blockchain

Blockchain is an immutable, decentralized, and shared ledger of transactions that can safely store asset information, eliminating the role of trusted intermediaries [17], [18]. Its base lies in cryptocurrency and its first appearance was when Satoshi Nakamoto introduced it as a peer-to-peer cash system [19]. A blockchain is formed by joining many blocks chronologically where each block is made up of a header and a body [20]. The header stores the previous block's hash, timestamps, and Merkle Root. In turn, the body contains the actual data that varies based on the type of blockchain. Consensus algorithms like Proof of Work (PoW) and Proof of Stake (PoS) are used to approve every transaction [21]. It determines which nodes in the network have the right to record requested transactions and allows them to validate them efficiently. Blockchain decentralization makes it tamper-proof and immune to any malicious alterations in

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:35:39 UTC from IEEE Xplore. Restrictions apply.

data. Blockchains use smart contracts to establish trust. They are predefined rules which are triggered automatically when certain terms and conditions, established beforehand, are satisfied. Hence, blockchain technology is the best solution for trustless environments like finance, voting systems, education systems, and healthcare systems [22].

B. Quantum Resistant Cryptography

The pre-quantum cryptography's security is based upon the hardness of mathematical problems like factorization of integers, discrete logarithm problems, and intractability of elliptic curves [23]. PQC is comprised of various algorithms that are built on different complex problems to withstand quantum attacks including cryptography that is code-based, hash-based, lattice-based and multi-variate polynomial cryptography. Lattice-based cryptography is based on hard problems defined on lattices such as the Shortest Vector Problem (SVP) or the Learning with Errors (LWE) problem [24]. Multivariate polynomial cryptography is based on the difficulty of solving systems of multivariate polynomial equations over a finite field [25]. Code-based cryptography is built on error-correcting codes like McEliece cryptosystems or Goppa codes [26], whereas Hash-based Cryptography uses special functions called cryptographic hash functions for digital signatures [27].

The threats of advanced quantum computers in 2016 made the National Institute of Standards and Technology (NIST) begin identifying and standardizing algorithms for PQC [28]. By 2017, it is stated that there were 82 algorithms submitted in total and only 69 candidates managed to be selected to represent the first round. The second-round evaluation was conducted in 2019 with 26 algorithms chosen by NIST and by the year 2020, seven finalists and eight alternates were shortlisted. In 2022, after several rounds of shortlisting and rigorous evaluation, 4 PQC algorithms were selected for standardization [29]. These are CRYSTALS-Kyber [30], a public key encapsulation mechanism along with three digital signature schemes: CRYSTALS-Dilithium [31], Falcon [32], and SPHINCS+ [33]. SPHINCS+ utilizes hash functions for security while the other three are based on lattice cryptography.

C. CRYSTALS-Kyber

CRYSTALS-Kyber is a member of CRYSTALS (Cryptographic Suite for Algebraic Lattices) standardized by NIST for PQC [34]. Kyber is an IND-CCA2 (Indistinguishability under adaptive Chosen Ciphertext Attack) secure KEM [30]. It is a cryptosystem that is lattice-based with security based upon the hardness of solving a variant of LWE problem over module lattices. The CRYSTALS-Kyber structure consists of two components KYBER.CCAKEM and KYBER.CPAPKE. The KYBER.CCAKEM is a KEM algorithm resistant to the most effective security assurance for public key encryption schemes like IND-CCA2 and KYBER.CPAPKE is an asymmetric encryption scheme that can withstand IND-CPA [35]. The KEM encapsulates bit strings (keys) which are randomly selected to produce a randomly chosen key and encapsulated key. This key can encrypt the data using symmetric encryption [32]. The key encapsulation mechanism involves three processes: key generation, encapsulation, and decapsulation [36]. Kyber-1024, Kyber-768, and Kyber-512 are three variants that differ in coefficient distribution and module dimensions and have security equivalent to AES-256, AES-192, and AES-128 respectively [36].

To create the Kyber key-pair after selecting system parameters, the private key is composed of small coefficient polynomials, while the public key is formed by matrix multiplication of a random matrix with the private key vector and the addition of a random error vector. This process is illustrated in Fig. 1. Kyber encapsulation then uses the public key and randomness via small coefficient polynomials to create a ciphertext that hides a secret shared key generated during the process. Kyber decapsulation uses the private key polynomials to remove the randomness embedded in the ciphertext using polynomial operations to recover the secret shared key. The randomness provides post-quantum security.

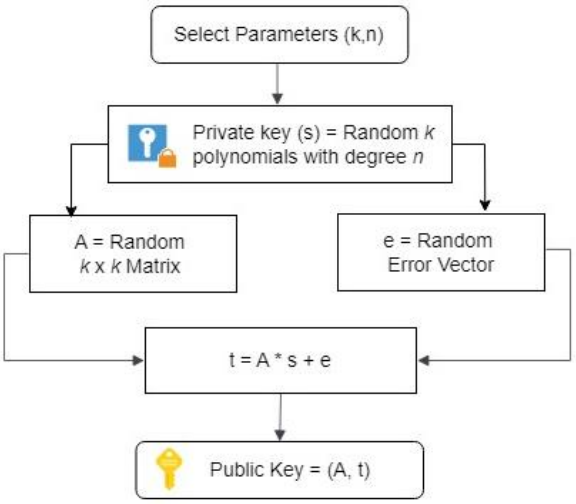

Fig. 1 Generation of Public and Private Key using CRYSTALS-Kyber

IV. PROPOSED MODEL

This section describes the system's overall components, the blockchain's detailed block structure, the hybrid data storage approach, and the cryptographic components used in the proposed quantum-resistant blockchain architecture.

A. System Components

The proposed architecture for secure sharing of EMR data among different stakeholders consists of the following system components:

- Users: These represent the different clients interacting with the system, like Patients, Healthcare Professionals, and Data Requestors.
- Certificate Authority: This supervising authority issues certificates to users after verifying their public keys and other identification documents.
- IPFS (Interplanetary File Storage): It is a decentralized, cost-effective and secure storage for encrypted EMRs.
- Blockchain Network: A permissioned blockchain network is used, as a digital ledger technology for secure data sharing and recording.

B. Blockchain Structure

A permissioned blockchain is used to ensure controlled access and authorization of participants. Each block consists

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:35:39 UTC from IEEE Xplore. Restrictions apply.

of a header and a body [37]. Fig. 2 represents the structure of a block and a transaction within this block. The block header contains essential data for maintaining blockchain integrity, including: a version of the blockchain protocol used, a hash of the current block, a hash of the previous block to link the blocks chronologically, a nonce that is used in proof-of-work mechanism to generate a valid hash of the block, a Merkle root representing all the transactions in the body to facilitate the verification of transaction data within the block and a timestamp. The body of the block stores the actual transaction data as a list of transactions authenticated with digital signatures.

Each transaction contains critical information about the EMR data being shared, including the transaction ID, patient ID, type of EMR data, reference ID of the EMR uploaded on IPFS, a hash of the encrypted EMR data to ensure data integrity, the patient's access policy specifying his access permissions to ensure authorized access, the quantum-resistant cipher key used for encryption, and other relevant metadata.

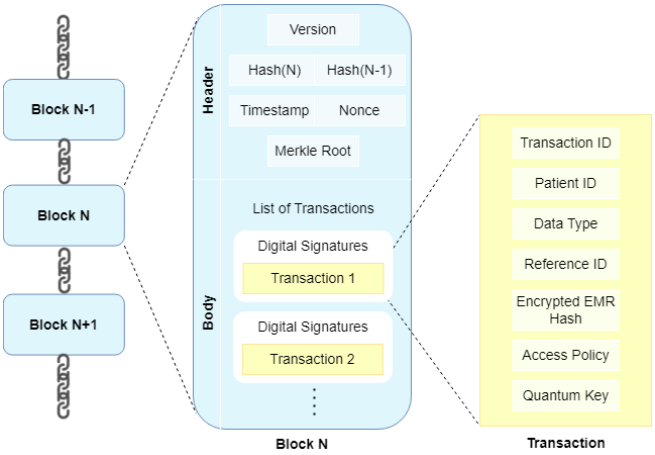

Fig. 2 Structure of a Block

C. Data Storage

A hybrid data storage mechanism is used that combines the strengths of blockchain and off-chain storage. The actual EMR data is encrypted with a quantum-resistant algorithm and stored securely in an off-chain decentralized database. The relevant metadata, such as the hash of the encrypted EMR, is stored on the blockchain. Since every node in the blockchain network has a copy of the ledger, this hybrid approach for data storage reduces storage costs, improves transaction processing speed and enhances the system's scalability.

IPFS (Interplanetary File Storage) [38] is used for the off-chain database. It is a decentralized storage designed to store encrypted data across multiple nodes when the size of the data is more than a threshold (size > 256KB), eliminating the role of a central server [39]. It stores the encrypted EMR and returns an IPFS Content Identifier for data retrieval. Due to its decentralized nature, IPFS is advantageous over the present cloud storage solutions. It eliminates a single point of failure, translates to high storage throughput, and improves data retrieval speeds [39].

D. Cryptographic Components

A hybrid encryption mechanism is used to securely encrypt the EMR, consisting of a post-quantum key encapsulation mechanism: CRYSTALS-Kyber and a symmetric encryption algorithm: AES-256. This is illustrated in Fig. 3. The key is encapsulated using the CRYSTALS-Kyber algorithm and the transaction data is encrypted using the AES-256 algorithm. AES is a block cipher that uses substitution, shifting, mixing, and key addition operations to achieve symmetric encryption [40]. AES-256 provides efficient encryption with a strong 256-bit key length, making it a suitable choice [41]. Combining asymmetric primitives for key establishment and symmetric cryptography for data encryption reduces the computational overhead [42].

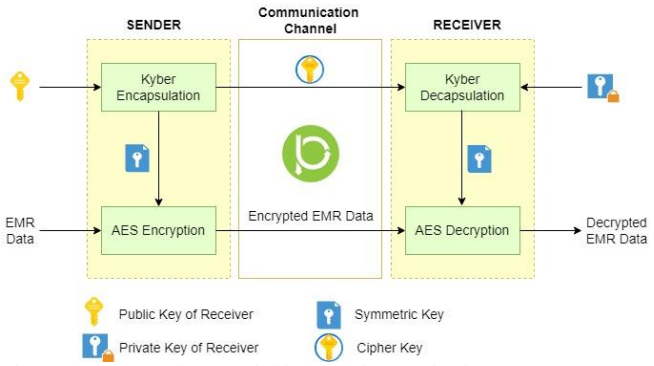

Fig. 3 Quantum-Resistant Hybrid Encryption Mechanism

First, Kyber encryption generates a key-pair comprising a symmetric and cipher key. The cipher key is the symmetric key encapsulated with the receiver's public key. The sender encrypts the EMR data with the symmetric key using AES-256 and transmits the encrypted EMR data and the cipher key to the receiver. The Kyber decryption algorithm decapsulates the cipher key into the symmetric key using the receiver's private key. The decapsulated symmetric key is finally used to decrypt and access the EMR data.

V. IMPLEMENTATION

This section demonstrates the novel blockchain-based architecture to securely share and access EMR with quantum-resistant cryptographic algorithms.

A. Interaction of System Components

The proposed architecture of the system is illustrated in Fig. 4 for blockchain-based EMR sharing using post-quantum cryptography. The sequence of actions is as follows:

1. User registers in the system, generates a cryptographic key pair – private and public key, and sends signed credentials to the Certificate Authority (CA).
2. CA issues a certificate on successful verification.
3. A Healthcare Professional (HP) creates an EMR and requests patient consent to upload patient data on the blockchain.
4. The patient may grant complete or partial consent or deny it. HP retrieves the patient's certificate and access policy if consent is granted.
5. HP encrypts the EMR data and uploads it on the IPFS network.
6. A reference to the uploaded EMR data is returned to the HP as Reference ID (RID).
7. HP signs a hash of the encrypted data, creates a transaction, and submits it to the blockchain.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:35:39 UTC from IEEE Xplore. Restrictions apply.

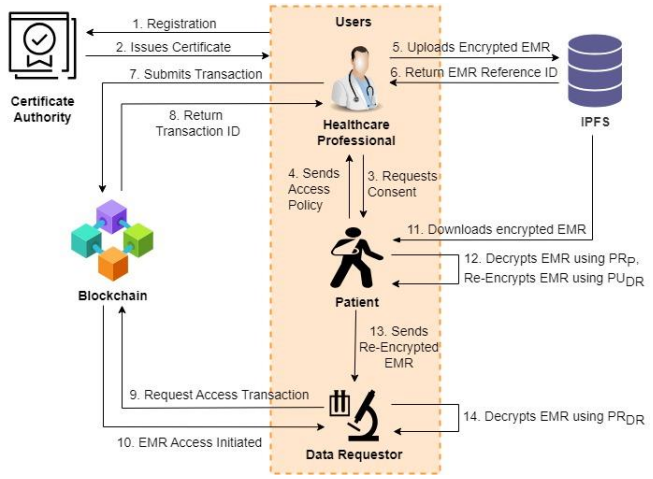

Fig. 4 Proposed Architecture

8. Once the transaction is validated after consensus, it is added to the blockchain and returns a transaction ID (TxID).
9. Data Requestor (DR) requests access to an EMR providing their certificate and TxID of the required EMR. The access request is verified based on the patient's access policy stored on the blockchain.
10. If the DR is authorized, the patient and the data requestor are notified.
11. Patient downloads the encrypted EMR data from IPFS using the RID stored in blockchain transaction.
12. Patient calculates the hash of the downloaded data and compares it with the signed hash stored in the transaction. If data integrity is verified, patient decrypts the EMR using his private key, generates a temporary key pair using DR's public key and then re-encrypts the decrypted EMR using the temporary symmetric key.
13. Patient sends the re-encrypted EMR data and the temporary cipher key to the DR.
14. DR uses their private key to decapsulate the temporary cipher key, which is used to decrypt the re-encrypted EMR data and gains access to the patient's medical record.

B. User Registration

Every user has to first register in the system. The user generates a quantum-resistant key pair composed of a public key (PU) and a private key (PR) using the Kyber algorithm. It is only executed once for every new user. Then, the user combines the public key (PU) and an identification document as his credentials and signs it with his private key. The user credentials and the signature are sent to the CA for verification. The CA issues a certificate encapsulating the user's public key and User ID (ID) after successful verification. The certificate is signed by the private key of the CA and sent to the user. If the verification fails, the CA rejects the registration request. Algorithm 1 illustrates the pseudocode for user registration.

C. Record Creation

HP generates a patient's EMR and requests the patient's permission to upload the EMR data to the blockchain. The patient reviews the request and may grant complete or partial consent or deny the permission to upload the EMR data. If consent is granted, the patient will provide his access policy and certificate containing his public key. HP uses a hybrid encryption approach to encrypt the EMR. First, a random symmetric key is generated and encapsulated with the patient's public key into a cipher key (encrypted symmetric key) using the Kyber algorithm. Then, the actual EMR is encrypted with the symmetric key using the AES-256. The encrypted EMR data is uploaded to the IPFS network, and the IPFS returns a reference ID (RID) of the encrypted EMR data. The hash of the encrypted data is calculated and HP signs it with his private key. A transaction is created that contains the signed hash, RID of the uploaded EMR on IPFS, cipher key, patient's access policy, and other relevant metadata (timestamp, data type, etc.) and submitted to the blockchain network. If the transaction details are validated and consensus is reached, it is recorded in the blockchain. This process is described in Algorithm 2.

Algorithm 1: Registration of a user Pseudocode (registerUser)
{PU, PR} ← generate_keypair()
credentials = {PU, ID}
S1 ← signData(PR, credentials)
Send {S1, credentials} to CA
IF verify(credentials, S1, PU) == **TRUE**
  Verification is successful
  certificate ← issueCertificate(PU , ID)
  S2 ← signData(PR_{CA}, certificate)
  RETURN {S2, certificate}
ELSE
  Display an error message

Algorithm 2: Creation of an EMR transaction on blockchain pseudocode (createEMR)
EMR ← generateRecord()
IF consentGranted(patientCertificate.ID) == **TRUE**
  patientPolicy ← getPatientPolicy(patientCertificate.ID)
  SK, EK ← kyberEncrypt(patientCertificate.PU)
  encryptedEMR ← AESEncrypt(EMR, SK)
  RID ← uploadToIPFS(encryptedEMR)
  h ← hash(encryptedEMR)
  s_h ← signData(PR_{HP}, h)
  transData ← createTransaction(s_h, h, RID, EK, patientPolicy)
  TxID ← submitTransaction(transData)
  RETURN TxID
ELSE
  Display error message

D. Access and Share Record

A Data Requestor (DR), such as a lab technician, medical researcher, or insurance company, identifies the data of interest and submits a request to access a patient's EMR. The system verifies the access request as per the patient's access policy stored in the blockchain transaction. If the data requestor is authorized, the patient and data requestor are notified to initiate the process. The patient retrieves the RID from the blockchain transaction. RID is used to locate and access the encrypted EMR data from the IPFS network. Then, the patient downloads the encrypted EMR from IPFS using the RID. The hash H(EMR) of the downloaded EMR data is calculated. The patient retrieves the signed hash H'(EMR) from the blockchain transaction and compares it with the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:35:39 UTC from IEEE Xplore. Restrictions apply.

computed hash. Data integrity is verified if H(EMR) matches H'(EMR). Now, patient retrieves encrypted symmetric key from the blockchain transaction. Kyber decryption is performed using the patient's private key to decapsulate encrypted symmetric key. The encrypted EMR is decrypted using the symmetric key to obtain the EMR data.

To share the EMR data with the data requestor, patient generates a temporary symmetric key (SK_t) and corresponding cipher key (EK_t) pair with the public key of data requestor using Kyber encrypt algorithm. The decrypted EMR data is re-encrypted with SK_t. Re-encrypted EMR data and EK_t are transmitted to the data requestor. The data requestor uses its private key to decapsulate EK_t into SK_t, and SK_t is used to decrypt the re-encrypted EMR to access the desired medical record. Algorithms 3 and 4 describe the process for requesting access to an EMR and secure sharing of the desired EMR respectively.

Algorithm 3: Request for access to EMR data Pseudocode (RequestAccessEMR)

```
TransactionData ← getTransactionData(TxID)
IF isAuthorised(DRCertificate.ID,
TransactionData.patientPolicy) == TRUE
   NotifyPatient(patientCertificate.ID, "Access granted")
   ReEncryptedEMR, EKt ← getRequestedEMR(TxID,
DRCertificate)
   SKt ← KyberDecrypt(PRDR, EKt)
   DecryptedEMR ← AESDecrypt(ReEncryptedEMR, SKt)
   RETURN DecryptedEMR
ELSE
   NotifyPatient(patientCertificate.ID, "Access denied to Data
Requestor")
```

Algorithm 4: Grant access to EMR data for Authorized requestor Pseudocode (getRequestedEMR)

```
TransactionData ← GetTransactionData(TxID)
RID = TransactionData.RID
DownloadedEMR ← DownloadFromIPFS(RID)
DownloadedHash ← hash(DownloadedEMR)
Hash = TransactionData.Hash
IF DownloadedHash == Hash, THEN
   EK = TransactionData.CipherKey
   SK ← KyberDecrypt(PRP, EK)
   DecryptedEMR ← AESDecrypt(DownloadedEMR, SK)
      SKt, EKt ← KyberEncrypt(DRCertificate.PU)
      ReEncryptedEMR ← AESEncrypt(DecryptedEMR, SKt)
      RETURN ReEncryptedEMR, EKt
ELSE
      Display data integrity error message
```

VI. DISCUSSION

This section will explore the proposed architecture's resistance to quantum attacks, data security and privacy, data integrity, and patients' ownership of data. Table 1 provides a comparison of the features of the proposed model with the traditional centralized approaches.

A. Quantum Attack Resistance

The proposed post-quantum blockchain is a secure technology that utilizes blockchain technology and quantum-resistant cryptography. It protects the architecture from classical attacks and ensures protection against known quantum attacks, such as Shor's and Grover's algorithms, ultimately improving security. The proposed architecture uses a lattice-based PQC algorithm for key encapsulation, CRYSTALS-Kyber. Lattice-based cryptosystems embrace lattices to address NP-hard problems which are confirmed to be safe for both classical and quantum computers [15]. The hybrid encryption technique of CRYSTALS-Kyber and AES-256 is rendered as a practical approach for medical data sharing, which offers secure protection.

B. Data Security and Privacy

The use of blockchain technology enhances data immutability, transparency, and tamper-proof auditing. With CRYSTALS-Kyber integrated, EMR data is secured against potential attacks from quantum computers and enhances the underlying cryptographic security levels relative to conventional methods. By storing the EMRs off-chain, on a decentralized storage network, the risks of a single point of access failure and unauthorized access is eliminated. The data retrieval-re-encryption process with temporary keys offers added layers of security and privacy during access from authorized requestors. Lastly, the system maintains data integrity by storing hashes of the encrypted EMR data on the blockchain, allowing patients to verify its authenticity before decrypting.

C. Data Ownership and Access Control

The architecture is designed for patients to explicitly grant consent before any EMR data is uploaded to the blockchain. They have the right to control the extent of data sharing. The system emphasizes patient control by enabling them to define their access policies for specific data elements within their EMRs to specify who can access their data. The paper proposes a patient-centric model where the patient's complete ownership of the medical data resides.

Table 1 Comparison of the proposed model with traditional architectures

Aspect	Centralized Traditional Architectures	Proposed Quantum-resistant Blockchain-based Architecture
Security	Vulnerable to quantum attacks (pre-quantum cryptography used)	Quantum-resistant cryptography (CRYSTALS-Kyber) is used for improved security.
Data Immutability	Data can be potentially altered or deleted.	Blockchain ensures tamper-proof and immutable data storage.
Data Privacy	Privacy breaches are possible due to centralized control.	Off-chain data storage with access control and re-encryption are used for enhanced privacy.
Data Ownership	Patients may have limited or no control over their data.	Patient-centric model with explicit consent and access policy management is proposed for data sharing.
Scalability	Struggles with large data volumes	Potential for scalability through hybrid data storage and permissioned blockchain

VII. CONCLUSION

With the dynamic development of quantum computing, sensitive data cannot be trusted with pre-quantum cryptography. The paper seeks to address the threat of a potential attack from a quantum computer by proposing a novel blockchain architecture integrated with quantum-resistant cryptography for secure EMR sharing. The tamper-proofing and transparency of blockchain technology assures data immutability. The hybrid encryption mechanism using

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 04:35:39 UTC from IEEE Xplore. Restrictions apply.

CRYSTALS-Kyber and AES-256 strengthens security against cryptographic security threats. Furthermore, the incorporation of PQC encapsulated within the hybrid encryption mechanism offers to protect sensitive EMR data against potential quantum attacks. Patient control of all data is also given priority to comply with data privacy. Patients will own their EMR completely and be able to determine the people they want to grant access to their data through access policy management. Authorized data requesters are granted access to desired EMRs through a secure re-encryption mechanism. Thus, the proposed architecture effectively deals with all the issues of ensuring data security, patient privacy, ownership control, and secure data sharing in the modern healthcare ecosystem.

However, quantum computing is rapidly developing, and even today's quantum-resistant encryption may become unsafe in the future. Therefore, it is necessary to develop rigorous security measures for both on-chain and off-chain data storage. There is a need to explore the regulatory and ethical implications of implementing quantum-resistant blockchain for EMR data sharing. Future research may include work on integrating the proposed architecture into existing healthcare systems and evaluating its performance by comparing it against existing solutions regarding scalability, efficiency and security. Altogether, the proposed architecture makes a significant contribution to EMR sharing securely and lays the foundation for a more secure healthcare data management system in the quantum computing era.

Abstract

This study aimed to explore the moderation effect of nonviolent work behavior on the relationship between workplace conflict and quiet quitting. The study is based on a longitudinal research design and uses AMOS to explore the results. Age and gender were used as control variables. The results suggest that the two dimensions of workplace conflict, that is, relationship and task conflicts, lead to the development of quiet quitting among Indian IT industry employees. The results also indicate that practicing nonviolent work behavior can reduce the development of quiet quitting arising out of workplace conflict. To the best of the authors' knowledge, this is one of the first studies that confirm the moderating role of nonviolent work behavior on the relationship between workplace conflict and quiet quitting, especially in India.

1 | INTRODUCTION

The workplace conflict arise among employees due to differences in perspectives, personalities, aspirations, cultural backgrounds, values, and communication styles (Cvenkel, 2020) and in some cases due to organizational and situational factors (Leiß & Rausch, 2022). Researcher argued "an inverted U shaped" graph of conflict and performance, wherein low level of conflict results in positive outcomes and conflict beyond a certain level produces undesirable outcomes (Pereira et al., 2023). The favorable results of workplace conflict include work engagement (Ter Hoeven & Van Zoonen, 2020), job satisfaction, better decision-making, and higher performance (Chakraborty et al., 2022; Pradhan & Jena, 2016), happier employees (Chen & Francesco, 2003), and better work-life balance (Bhende et al., 2020). Whereas, negative consequences include

 © 2024 Wiley Periodicals LLC.

lower career commitment (Deshpande & Chakraborty, 2023), mental health issues (Bansal et al., 2023), poor team collaboration (Donohue et al., 2023), turnover intentions (Badar et al., 2023), promote workplace deviant behavior (Atatsi et al., 2019), degraded work performance (J, 2014). One such deviant behavior is quiet quitting. Arnetz et al. (2018) suggest that some employees prefer responding to any conflict or violence with violence, resulting in a "tit-for-tat" situation, on the other hand, some employees may respond with a milder yet powerful withdrawal behavior known as quiet quitting (Ahmed et al., 2013). Quite quitting does not mean quietly quitting the present assignment and look for alternative jobs, it refers to significant reduction in the work efforts and limit oneself to only explicitly defined job profile. It is "sometimes conceptualized not as a way for employees to leave their current positions but to redistribute and re-prioritize how their time is spent" (Anand et al., 2023). It is a psychological withdrawal that generally precedes turnover (Hamouche et al., 2023). Previous studies have linked several factors as causes of quiet quitting, including COVID-19 (Hamouche et al., 2023), job burnout (Chakraborty et al., 2022; Cox et al., 2017), throat-cut competition (Xiong & Chen, 2018), and imbalanced work-life (Tapper, 2022). Further, quiet quitting results in various detrimental consequences ranging from employees becoming isolated to higher employee attrition and reduced overall productivity for the firm (Li et al., 2021). Current studies have shown that employees who tend to indulge in quiet quitting have faced actions such as being labeled as underperformers, demotions, and, in severe cases, termination from job (Serenko, 2023). Nevertheless, this concept is still new to researchers and requires further exploration, especially in the context of workplace conflict.

1.1 | Importance of studying quiet quitting

The research on quiet quitting is limited, especially on its relationship with workplace conflict. It is important to examine these initial and mild forms of employees response to conflict for three important reasons. First, early stage behaviors like quite quitting offer clear clues about latent workplace conflict which, if not addressed immediately, may blow up into full scale conflict (Serenko, 2023). Thus, organizations can take clues from these early signs to avoid future troubles. Secondly, quite quitting largely gets unnoticed as employees perform his/her assigned or explicitly defined duties. But they seriously dent individual and organizational performance as it kills organizational creativity and innovation, knowledge sharing, employee engagement, and committment (Anand et al., 2023; Lu et al., 2017). Last, although such behaviors evades organizational scrutiny, the gossip they generate motivates others to follow the suit causing serious ramifications for any organization. Therefore, this study aims to examine the influence of workplace conflict on quite quitting.

1.2 | Intervention suggested

The role of individual level intervention to counter the occurrences of the employee deviant behaviors needs to be explored (Biswas & Chakraborty, 2023). One such intervention is nonviolent work behaviors. Nonviolent work behavior does not mean mere absence of violence, rather, it includes trust, empathy, mutual respect, and forgiveness in mutual interactions, ensuring that even violent actions are responded in positive and constructive manner, defusing the conflicting situation with peace, love, and trust. Nonviolent work behavior interventions promote a strong positive organizational culture and are both preventive and cost-effective (Lata & Garg, 2023).

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

According to Sarkar and Palo (2019), nonviolence is "more than nonappearance of violence or non-harming. Rather, it is a condition of mental ablution and positive acts through body, mind, and speech." Bhalerao and Kumar (2015) offer a definition of nonviolence in the workplace as an individual's propensity to respond constructively to any provocation, which might include a violation of respect norms and justice in the organization. The authors further asserted that it includes nonviolence (not harming others) in one's thoughts, words, and deeds (Bhalerao & Kumar, 2015; Biswas & Chakraborty, 2023). However, being a new concept, not enough studies have adequately explored the affects of nonviolent work attitude on employee turnover, degraded work motivation, and quiet quitting. Hence, the present study examines the moderating role of nonviolent work behavior on the relationship between workplace conflict and quite quitting.

1.3 | Theory used

Based on Bandura's (1986) social cognitive theory (SCT), it is proposed that workplace conflict (environmental factors) leads to quiet quitting (behavioral factors). According to this theory, behavioral, personal, and environmental factors are in a loop, with each factor affecting others (Bandura, 1986). However, their nonviolent work attitudes (personal factors) can affect their choice of response. Hence, they may see that conflict may have occurred due to various factor like job stress, inability to cope with job related demand among other factor (Bhalerao & Kumar, 2015), thereby, people may not resort to quiet quitting. With this the study seeks to answer the following questions:

Does workplace conflict promotes quiet quitting among employees?
Does practicing nonviolent work behavior during workplace conflict reduce quiet quitting?

1.4 | Contributions

In light of the discussion presented in the preceding paragraphs, the current study has three important contributions. First, it explores one of the recent workplace phenomena of quite quitting. Second, it examines quite quitting in the larger organizational context, that is, workplace conflict. Third, this study suggests that nonviolent work behavior moderates the relationship between workplace conflict and quite quitting, which to the best of our knowledge, none of the previous studies have evaluated.

This paper is divided into three sections. The first section elaborates the theoretical framework of the study. The second section explains the methodology adopted to test the study's hypotheses. And lastly, results and implications along with limitations and scope for future studies are elaborated.

1.5 | Theoretical framework

1.5.1 | Workplace conflict and quiet quitting

Researchers suggest conflict is of two types: relationship and task. Relationship conflict is between people, and task conflict is any conflict related to a task being performed/planned

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. FIGURE 1 Proposed Relationship. *Source*: Bansal, S., Garg, N.

(Bhalerao & Kumar, 2015). Relationship conflict, one of the most common and widely occurring conflicts, can be triggered by various reasons, including poor communication, differences in belief systems, cultural differences, and the spreading of negative gossip in the workplace (Khan et al., 2021). Further, relationship conflict leads to an increase in the perceived job stress (Tu et al., 2022), for example, the team's work may require conflicting employees to work together, thus increasing their perceived job stress. This may further exacerbate workplace conflict and the development of employee deviant behaviors such as quiet quitting. Such behaviors can act as the early symptoms of latent conflict or severe consequences such as employee attrition and hence are required to be examined closely. It follows from the SCT that relationship conflict acts as one of the environmental factors that affect an individual's behavior, as a result of which they may tend to resort to quiet quitting (behavioral factor). Accordingly, following hypothesis and theoretical model (refer to Figure 1) are proposed.

H1. Relationship conflict positively relates to quiet quitting.

Similarly, task conflict is also one of the widely occurring conflicts in the workplace. According to Liao et al. (2022), task conflict can occur when employees are unclear about their responsibilities and authorities, and they are not sure about what is to be done and/or who will perform a specific task. Further, task conflict can be caused by the lack of proper communication, sudden change of goals, ambiguous information, change in requirements, or incomplete information (Shin et al., 2020). In such situations, if the concerned authority does not provide correct information, employees may perform only those tasks mentioned in their job description, thereby reducing their productivity. Serenko (2023) associates this situation with quiet quitting. Therefore, as per the SCT, individual's behavioral factors (quiet quitting) will be affected by their environmental factors (task conflict). Therefore, based on this theoretical premise, we propose the following hypothesis and theoretical model (see Figure 1).

H2. Task conflict positively relates to quiet quitting.

Although relationship conflict affects more severely than task conflict, researchers suggest that their combined effect is more detrimental to organizations and employees both. Hence, the need of the hour is to develop interventions to reduce their combined detrimental effect (Caesens et al., 2019). In other words, conflict and quiet quitting result in a phenomenon known as social death, that is, loss of social connectedness. Therefore the following moderation effect is proposed as an intervention.

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. FIGURE 2 Proposed moderation effect. *Source*: Bansal, S., Garg, N.

1.5.2 | The moderating effect of nonviolent work attitudes

Bhalerao and Kumar (2015) proposed four dimensions of nonviolent work behavior. NVT-Ignore behavior, employees consider acts of violence as non-worthy and respond by ignoring them. NVT-Stress, employees give the benefit of the doubt to the aggressor and do not respond violently considering the acts of violence as a result of stress on the aggressor. NVT-ability, any violence is labeled as incompetence and the inability of the aggressor against the given task, therefore, the victim does not respond. NVT-constructive, victim responds indirectly to the violence by bringing out changes in self, thereby responding pro-socially and defusing the spiral of violence. Hence, through these dimensions, it is clear that violence is a spiraling situation wherein the violence increases when the victim responds aggressively to the provocations.

The proposed moderating effect of nonviolent work attitude amidst the relationship between workplace conflict and quite quitting is theoretically premised in the SCT meaning that workplace experiences and personal attitude defines one's behavior. Bandura (1991) suggested that one's behavior is regulated by environmental circumstances and personal factors like attitude. Apart from individual effects, the interaction of these factors also influence one's behavior (Chakraborty & Biswas, 2021). Therefore, we propose that nonviolent work behaviors (personal factors) can help an individual understand the occurrence of the workplace conflict and prevent them from resorting to quiet quitting. Based on the theoretical premise, following conceptual model (refer to Figure 2) and hypothesis are proposed.

> **H3.** Nonviolent work attitude moderates the relationship between workplace conflict and quiet quitting.

2 | METHODOLOGY

Based on Sawyer et al. (2022) recommendations to conduct a longitudinal research design for better generalization of the results, this study explores the problem of quiet quitting arising from workplace conflict. It also explores the moderating effect of the nonviolent work behaviors on the proposed relationship.

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2.1 | Sample and data collection

This study uses the data was collected from the Indian IT professionals located in the Delhi NCR region. They were approached through their HR managers. The information technology industry (ITI) is a closely knit workplace, where employees from diverse backgrounds having diverse work opinions, ethics and believes are employed (Garg & Saini, 2023). Other than workforce diversity, factors such as continuous learning, collaboration, innovation and problem solving, and stressing work comprise the ITI work environment (D'Cruz et al., 2021). Researchers suggest that a fine balance exists among these factors, which maintains harmony in the work environment (Garg & Saini, 2023). However, considering the nature of the ITI's work environment, studying the effect of workplace conflict and quiet quitting is important, because they can cause a disbalance in the environment. For instance, Parayitam et al. (2020) highlights workplace conflict as one of the major factors leading to the development of the role ambiguity in the ITI employees. Also, quiet quitting hinders organizational culture which impacts the knowledge sharing and collaborative environment in the it is (Shah & Hashmi, 2019). Therefore, the Indian IT industry was considered as the best suited for this study.

A two-day seminar on work environment and toxicity was conducted. Every participant was given a unique ID. The data was collected using a structured questionnaire via Google forms was shared across groups created for the seminar. To qualify as the participant for our study, it was taken account that an employee pose at least 3 years of work experience and has worked at least on five projects to which they must have contributed significantly. It was found that off the 632 seminar attendees, only 593 qualified for our study. At time T1, demographic and workplace conflict information were collected. After 3 months (T2), information on nonviolent work behavior was captured. Finally, after another 3 months (T3), quiet quitting intentions were assessed. Only 519 participants out of 593 qualifying attendees participated in the first wave of the research, that is, T1. Subsequently, 428, and 395 working professionals responded at times T2 and T3, respectively. Cochran (1977) has recommended a sample size of 384 at a 0.05 significance level, thus the sample size of the present study seems appropriate. Table 1 reports the demographic information of the sample.

2.2 | Measures

2.2.1 | Workplace conflict

Meier et al.'s (2013) relationship and task conflict scale (RTCS) was used to measure perceived workplace conflict. The scale was initially developed by Jehn (1995) and was reworded by Meier et al. (2013) to have positive statements rather than questioning statements. This eight-item scale measures two dimensions of conflict- relationship conflict and task conflict—on a seven-point rating scale ranging from one (not at all) to seven (extremely) for relationship conflict and between one (never) and seven (always) for task conflict. A few items are "there is a friction among members of my organization" and "there are differences of opinions regarding work within my organization/institution."

2.2.2 | Nonviolent work attitude

The study used adopted version of nonviolence at workplace scale developed by Bhalerao and Kumar (2015). It is a 32-item scale that rates statements on a five-point rating scale ranging from one (strongly disagree) to five (strongly agree). A few items of the scale are "I inquire if the subordinate is upset due to some reason if he/she threatens me" and "I overlook impoliteness of co-workers."

2.2.3 | Quiet quitting scale

The scale has been taken from Anand et al.'s (2023) quiet quitting and quiet firing scales. The adopted scale is a unidimensional seven-item five-point rating scale ranging between one (completely disagree) and five (completely agree). The scale is used to measure the quiet quitting intentions of employees. A few items are "I am doing bare minimum work to avoid being fired" and "I feel I have a lack of meaningfulness at work."

2.3 | Reliability, validity, multicollinearity, and common method bias

The internal consistency reliability was assessed using Cronbach's alpha (CA), composite reliability (CR), and McDonald's omega (MO) values. The recommended values of these measures

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

TABLE 2 Descriptive statistics and discriminant validity.

Variables (study 2)	Mean	SD	CA	CR	MO	AVE	Discriminant validity RC	Discriminant validity TC
Relationship conflict	3.85	0.211	0.825	0.917	0.800	0.53	1 (0.53)	
Task conflict	4.45	0.153	0.839	0.942	0.817	0.55	0.362	1(0.55)
Workplace conflict	4.60	0.192	0.801	0.916	0.821	0.56		
Nonviolent work behavior	3.24	0.210	0.812	0.918	0.798	0.61		
Quiet quitting	4.80	0.351	0.807	0.911	0.811	0.59		

Source: primary data; RC–relationship conflict; TC–tack conflict.

are 0.70 and above (George & Mallery, 2003; Hayes & Coutts, 2020). Table 2 reports that CA, CR, and MO values for relationship conflict, task conflict, overall workplace conflict, nonviolent work behavior, and quite quitting are above 0.70, which established internal consistency reliability of the scales. The average value explained (AVE) values were used to ensure convergent validity of the scales. The accepted value of AVE is 0.50 and above. Table 2 states that the AVE values for relationship conflict, task conflict, overall workplace conflict, nonviolent work behavior, and quite quitting are 0.53, 0.55, 0.56, 0.61, and 0.59. The discriminant validity was assessed using the Fornell and Larcker (1981) testing system, which states that the squared correlation between the dimensions of the scales should be less than their AVE values. Again, Table 2 concluded the discriminant validity of the workplace conflict scale. Since there are two dimensions of workplace conflict, the multicollinearity was adjudged with the help of the variance inflation index (VIF) values, whose acceptable values are less than three. The VIF values for relationship conflict and task conflict are 1.24 and 2.67, which confirmed absence of significant multicollinearity. This study is based on the longitudinal research design, which is poised to negate common method bias. However, certain procedural and statistical methods are employed to minimize it. The methods like usage of pre-established scales, promise of anonymity and confidentiality, informed consent, and strict academic use of collected data reduce chances of common method bias (Podsakoff et al., 2003). Further, when all items of the study were subjected to factor analysis, more than one factors emerged. Also, single largest factor explains only 31.27% variance, which negates concluded absence of significant common method bias according to the Harman's one-factor method.

2.4 | Analysis of data

The study's explored the intricacies between workplace conflict, quiet quitting, and nonviolent work behavior using structural equation modeling (SEM) in IBM's AMOS 21. Two models- causal model and moderation model- were evaluated for model fitness.

3 | RESULTS

Table 3 reports the correlation coefficients of the variables used in the study. It reports significant positive correlations between the two dimensions of workplace conflict and quiet quitting

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. FIGURE 3 Model 1–proposed causal model. *Source*: Bansal, S., Garg, N.

($r_{\text{relationshipconflict}} = 0.467$, $p < 0.05$, and $r_{\text{taskconflict}} = 0.415$, $p < 0.05$). Thus, the results from correlation analysis suggest that workplace conflict positively affects quiet quitting, meaning workplace conflict can lead to higher quiet quitting intentions at the workplace. Further, the results of correlation analysis also suggest that nonviolent work attitude negatively correlates with the two dimensions of workplace conflict ($r_{\text{relationshipconflict}} = -0.271$, $p < 0.05$, and $r_{\text{taskconflict}} = -0.214$, $p < 0.05$) and quiet quitting ($r_{\text{quietquitting}} = -0.381$). These results are in line with previous studies, such as those conducted by Gürlek (2021), Sarkar and Garg (2020), and Guenter et al. (2016). Figure 1 represented a causal model that includes relationship conflict, task conflict, and quite quitting, which was evaluated using SEM in AMOS 21. As suggested by previous researchers, gender and age were controlled in the model. The threshold values of model fit indices are RMSEA <0.8, SRMR ≤0.05, GFI and TLI ≥0.95, and CFI ≥0.97 (Xia & Yang, 2018). Figure 3 represented SEM causal model. The model reports acceptable model fit values of RMSEA = 0.712, SRMR = 0.043, GFI = 0.972, TLI = 0.977, and

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

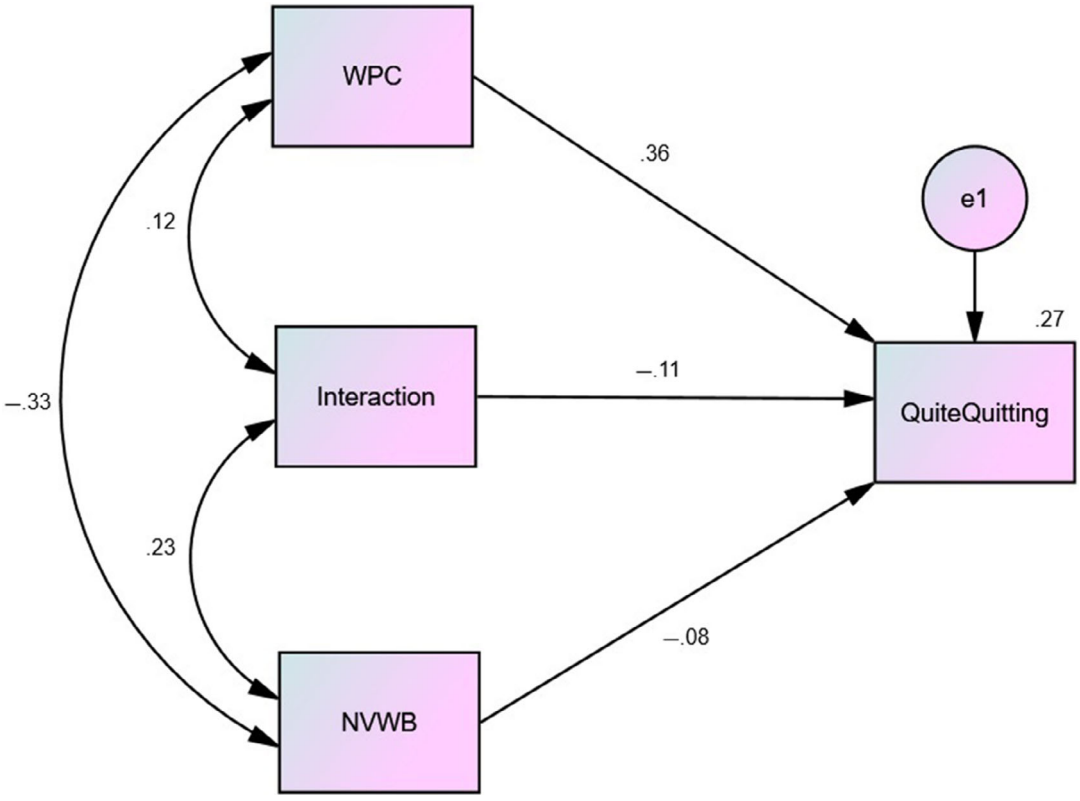

FIGURE 4 Model 2–Moderation analysis. *Source*: Bansal, S.; Garg, N.; WPC–workplace conflict, NVWB–nonviolent work behavior, interaction–WPC*NVWB.

CFI = 0.974. The model reported significant relationships between a) relationship conflict and quiet quitting ($\beta = 0.32$, $p < 0.05$, and b) task conflict and quiet quitting ($\beta = 0.28$, $p < 0.05$). Also, it stated insignificant effect of age and gender with regression weights of $\beta_{age} = 0.08$ and $\beta_{gender} = 0.02$. These results confirmed the acceptance of the first two hypotheses of the study. Figure 2 illustrates moderation model that examine the moderating effect of nonviolent work behavior amid the relationship between workplace conflict and quiet quitting. Figure 4 depicted moderation model in SEM, which reported a good fit overall with RMSEA = 0.561, SRMR = 0.036, GFI = 0.977, TLI = 0.986, and CFI = 0.989. It was interesting to note that the moderation model exhibited better model fit than the causal model, which suggest significant moderation effect of nonviolent work attitude. Workplace conflict and nonviolent work attitude were significantly related to quite quitting with βworkplaceconflict = 0.36 and βquitequitting = −0.08 at $p < 0.05$. The interaction effect of workplace conflict and nonviolent work attitude was also statistically significant with regression weight of −0.11 at $p < 0.05$. Hence, the moderation model is concluded to be statistically significant. Hence, H3 is also accepted. Figure 5 depicts diagrammatical representation of the moderation effect of nonviolent work behavior. It suggested that at higher levels of nonviolent work attitude the impact of workplace conflict on quite quitting is relatively less potent and effective.

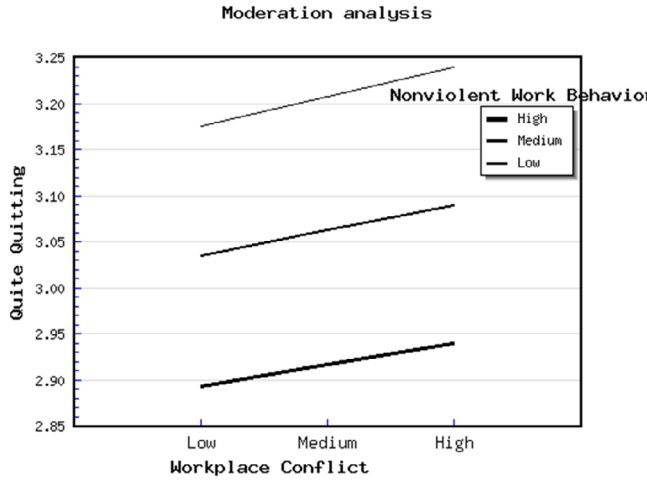

FIGURE 5 Moderation analysis. *Source*: primary data.

4 | DISCUSSION

4.1 | General discussion

The constant human-human interaction results in both positive or negative outcomes. Various social scientists and managers suggest that of these outcomes, conflict is one of the significant predictors of employee deviant behaviors (Sarkar & Garg, 2021). Researchers suggest that conflict is of two types: relationship and task (Bhalerao & Kumar, 2015), and can result in deviant behaviors ranging between mild to harsh deviant behaviors, such as lower productivity and absenteeism (Cong et al., 2015) to workplace bullying and harassment (Hamre et al., 2021). Though harsh deviant behaviors are of grave concern, studying mild deviant behaviors is a need of the hour because these mild deviant behaviors are the early warning signals of something of grave concern is happening or will occur in the near future. One such mild deviant behavior is quiet quitting (Serenko, 2023). As discussed in the earlier sections, quiet quitting can lead to the lower firm's productivity and can encourage higher employee absenteeism. Further, experts suggest when nonviolent behavior at the individual level are used for tackling such issues, they can benefits organizations and their employees because they are helpful in difusing the spiral of conflict without the need to intervene through punishments (Bhalerao & Kumar, 2015). Therefore, based on Bandura's (1986) SCT based interaction of personal, environmental, and behavioral factors, the study proposed that the two dimensions of workplace conflict significantly positively relate to quiet quitting intentions at work, and nonviolent work behavior can be used as a moderator with the proposed relationship. Moreover, based on the suggestions of various researchers, this study used a longitudinal research design. The data was collected in three waves. Further, the study used AMOS 21 to analyze the results of the data collected from the employees working in the Indian IT sector.

The proposed relationships between the two dimensions of workplace conflict, that is, relationship conflict, task conflict, and nonviolent work attitude, and quiet quitting were assessed using correlation analysis. The results suggested that relationship and task conflict have positive associations with quiet quitting, meaning, an employee can develop quiet quitting intentions if

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

relationship and task conflict occur. The results further indicate that nonviolent work attitude negatively correlates with the two dimensions of workplace conflict and quiet quitting, indicating that nonviolent work attitudes can be used during conflict to avoid quiet quitting. However, the results of the correlation analysis and model fit of the proposed relationship and moderation effect were further tested with a more robust testing method using structural equation modeling in AMOS 21. Age and gender were used as the control variables in Model 1 and they reported insignificant results. This means that quiet quitting is a natural phenomenon and an individual can resort to it despite of their age and gender. The results of Model 1 also report that the two dimensions of workplace conflict are positively associated with quiet quitting. The results of this study align with the SCT and suggest that relationship and task conflicts (environmental factors) can lead to quiet quitting (behavioral factor) among employees as conflict-coping strategies. As a result, they may decrease their performance to the bare minimum required levels to safeguard their jobs, arrive late in meetings, or avoid people even during informal meeting times like lunchtime. However, they are neither helping themselves or their organizations nor resolving conflict. Hence, the spiral of conflict is not diffused. The results of our study are inline with previous studies like the ones conducted by Dukhaykh (2023) and Gaiji et al. (2021). Dukhaykh (2023) suggested that workplace conflict is one of the major causes of emotional drain and emotionally drained employees find it hard to focus on their official tasks. Also, the study conducted by Gaji et al. (2021) indicated that employees may psychologically withdraw from their work as a result of their coping mechanism against workplace conflict, and such employees may show withdrawal behaviors by working only the bare minimum required.

The study also assessed the use of nonviolent work attitudes to diffuse the spiral of workplace conflict and quiet quitting. For this reason, the current study explored the moderation effect of nonviolent work behavior on the relationship between workplace conflict and quiet quitting using SEM in AMOS 21. The results of the moderation analysis (Model 2) emphasize the concept of reciprocal determinism of the SCT, where nonviolent work attitudes (personal factors) interact with workplace conflict (environmental factors) and affect the outcome of the environmental factors. For instance, the value of the interaction effect ($\beta = -0.11$) indicates that the nonviolent work behavior is one of the suitable moderators that can be used to diffuse the spiral of conflict. This interaction affects the third factor, behaviourial. In other words, when people exhibit nonviolent work attitudes, they can effectively adjust their responses to workplace conflict, leading to reduced impact of workplace conflict on quiet quitting intentions. Moreover, the results suggest that individuals with higher nonviolent work attitudes can quickly adjust their beliefs and approach conflict resolution more constructively and confidently. Hence, it is safe to say that practicing nonviolent work behavior during workplace conflict can cushion quiet quitting intentions arising due to workplace conflict. Consequently, the results of this study highlight the need to promote and reinforce nonviolent work attitudes and strategies in the Indian IT sector. Moreover, the results of the moderation analysis are inline with earlier studies like the one conducted by Mahipalan and Garg (2024), where the authors have suggested that practicing nonviolence can reduce the ill effects of workplace toxicity on employees psychological capital. Hence, it will be helpful to practice nonviolence during workplace conflict, which can reduce the occurrence of quiet quitting, especially among IT employees.

4.2 | Implications

The study presents exciting findings on workplace conflict, quiet quitting, and nonviolent work behavior. It also has the following implications.

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. 4.2.1 | Theoretical implications

The present study extends the literature on workplace conflict and quiet quitting. It suggests a gap that indicates that no previous study has explored quiet quitting arising out of workplace conflict. Therefore, the findings of this study fill this gap. The results suggest that relationship and task conflicts are positively associated with quiet quitting, indicating that relationship and task-related conflicts in the workplace can lead to employee(s) resorting to quiet quitting. The results further indicate that workplace conflict can also be associated with an antecedent of quiet quitting. Second, the study also extends the literature on nonviolent work behavior. The results of this study empirically prove that nonviolent work behavior can act as a cushion against quiet quitting arising out of workplace conflict. Therefore, an employee may use nonviolence as a tool to diffuse the spiral of workplace conflict and quiet quitting as they may perceive conflict as an inability of other employee to cope with stress or job related demands, or may try to bring out positive change in the self. Third, this study further extends the literature on SCT. The results of our study empirically explain triadic reciprocal causation between the environmental, behavioral, and personal factors. The results indicate that workplace conflict (environmental factor) leads to the development of quiet quitting (behavioral factor) and when an employee practices nonviolent work behavior (personal factor), such behavior reduces the quiet quitting arising out of workplace conflict.

4.2.2 | Practical implications

First, the results of our study shed light on the importance of tackling the rise of workplace conflict. The results will help managers, academicians, and policymakers to develop policies, programs, and regulations to create awareness about workplace conflict and its detrimental effects on people. Recently, we conducted a seminar on the importance of the nonviolence in colleges. On similar grounds, managers may conduct such seminars that highlight the importance of practicing nonviolence at the workplace. Also, such seminars may inculcate the methods and practices that employees can develop to practice nonviolent behavior during workplace conflict. Second, the results will help organizations and institutions combat the quiet quitting issue. Various policies can be developed to identify cases of quiet quitting. Also, these policies may mandate conducting workshops and seminars on quiet quitting, its nature, how it may arise, and how it affects an individual, organization, and families. Third, organizations operating in Indian culture need to be aware of the quiet quitting tendency of employees and should work on creating policies that promote a balance between collectivism and individual well-being while preserving organizational cultural values. Fourth, the results will help managers, policymakers, and academicians to incorporate an open-door policy wherein people can approach their managers and discuss the conflict situation and how they feel about it. Even if an employees has been detected resorting to quiet quitting, the open door policy may allow the mangers to investigate the reasons for it as such behavior are the results of numerous factors like workplace conflict and burnout (Biswas & Chakraborty, 2023). Fifth, the scales used in this study can be utilized to assess workplace conflict and quiet quitting proactively, and managers can devise corrective measures to identify and counter these issues. Further, recruitment policies may be amended to adopt the scale measuring the nonviolent work behavior to assess the nonviolent behavior among the potential candidates. Such behavior can indicate that a nonviolence preferring candidate would always try to look the cause of the conflict and act upon it,

15411508, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/crq.21444 by Delhi Technological University, Wiley Online Library on [17/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

thereby, diffusing the spiral of conflict. Last, the results of our study promote the use of nonviolent work behavior to counter or reduce quiet quitting arising out of workplace conflict. The use of Ahimsa may be promoted by developing and deploying plans, policies, and regulations because our results empirically support the use of Ahimsa to intervene in workplace conflict and quiet quitting. Hence, policies based on nonviolent work behavior shall be developed. For instance, based on the critical incident appraisal method, a new employee appraisal policy can be developed where every employee would be appraised on their use of nonviolent work behaviors, especially during conflict situations.

4.3 | Limitations and future research

Though this study presents unique and exciting findings, it has certain limitations. First, the study is the first of its kind and uses a sample representing the Indian population. Though not a limitation in itself, future researchers are encouraged to study the proposed relationship and moderation effect in the cross-cultural environment to produce more insightful results. Second, future researchers may use other variables, such as gratitude, psychological capital, karmic law, etcetera, to moderate the proposed relationship. Moreover, future researchers may analyze the results of the proposed relationship against big five personality types or use other demographic variables as the control variables. Third, the study uses a combined conflict scale while exploring the moderation analysis of nonviolent work behaviors on the proposed relationship. Future researchers may explore the moderation effect of NVWB separately on the two dimensions of workplace conflict to produce more robust results. Fourth, the study has used workplace conflict as one of the predictors of quiet quitting. The researchers are encouraged to use variables like workplace bullying, job stress, and burnout, as predictors of quiet quitting. Last, as previous studies have shown that modern day organizations are multi-generational organizations, it is imperative to add how generational differences impact the use of nonviolence in the organization and quiet quitting intentions.

4.4 | Conclusion

In a nutshell, the study proposed and confirmed that workplace conflict leads to the development of quiet quitting among employees. The study also confirmed that nonviolent work behavior moderates the relationship between workplace conflict and quiet quitting, indicating that when a person practice/show nonviolent work behavior during workplace conflict, they defuse the spiral of conflict, thereby limiting the occurrence of quiet quitting.

AUTHOR CONTRIBUTIONS

Suhans Bansal–Written original draft, conceptualization, data collection, analysis. Dr. Naval Garg–Supervision, conceptualization, revising the original draft.

ACKNOWLEDGMENTS

We would like to thank all the participants of this study for taking out time from their busy schedules and become a part of our study. Also, we would like to appreciate their patience for being part of this study in all the time frames. Lastly, we would like to express our gratitude to reviewers of this manuscript as your valuable inputs have made this manuscript more impactful for the literature and research community.

ORIGINAL PAPER

Real-time investigation of grid-interactive EV charger with two-stage bidirectional converter under wide voltage range scenarios

Gaurav Yadav[1] · **Mukhtiar Singh**[1]

Abstract
With the increasing popularity of electric vehicles, the grid-interactive electric vehicle chargers (GIEVC) are very vital in utilizing them for ancillary services to support grid through V2G mode of operation. Further, the front-end converter of charger may have to face several Power Quality (PQ) issues such as voltage sag, voltage swell, and grid distortions, which are very common in weak grid. Therefore, the proposed work is mainly focused on developing control algorithm for GIEVC in order to handle the PQ issues while providing seamless transition from G2V to V2G mode of operations. Since the proposed the charger is of Level 1 for domestic applications; the typical nonlinear domestic load is also compensated in order to avoid the exaggeration of weak grid issues. Here, the major challenge is in extracting the fundamental voltage component from non-ideal grid voltage for which a cascaded non-identical second-order generalized integrator has been utilized. The efficacy of these algorithms is studied in MATLAB/Simulink simulations and validated using the real-time hardware platform using OP4510 RTLAB provided by OPAL-rt.

Keywords Grid-interactive electric vehicle · Leaky least mean fourth · On-board bidirectional charger · Orthogonal signal generator · Wide voltage range

1 Introduction

In recent times, electric cars, or EVs, have become increasingly popular as an eco-friendly and high-performing substitute for conventional gasoline-powered automobiles. Due to developments in battery technology, an expanding infrastructure of charging stations, and rising consumer demand, EVs are now a practical choice for a large number of drivers worldwide. These vehicles, which utilize electric motors to drive the wheels and are propelled by electricity stored in a battery instead of gasoline, are revolutionizing the way we think about transportation [1, 2].

Furthermore, electric vehicles, which interact with the grid, are more prevalent in the global energy crisis and reduce greenhouse gases. But these grid-interactive electric vehicles have the challenges of keeping the power system overloaded when one or more EVs are connected to the grid at the same time [2–4]. In addition, these GIEV can transmit power from grid to vehicle (G2V), i.e., charging and when the load is not high, so they can deliver their surplus energy to the power grid [i.e., discharging via vehicle-to-grid (V2G)] [5, 6] during the peak hours (e.g., the evening in residential areas).

The previously described studies show that bidirectional chargers are practically feasible; yet, further research is required to understand how the grid interacts with chargers and loads linked at the point of common coupling (PCC) when there are various anomalies, such as sag and swell [7]. Furthermore, their duration may vary from several seconds to tens of milliseconds, contingent upon the dynamic properties of the electrical apparatuses linked to the network. A detailed network model is necessary in order to comprehend the impacts of GIEVC chargers on grid-connected systems and to put management mechanisms in place to lessen such effects. Because of this, a model of this kind should take switching dynamics into consideration. Small simulation time steps are necessary to account for the high switching frequency, which may reach up to 20 kHz, necessitating expensive and time-consuming calculations [8]. For grid-connected networks that use chargers and other different

types of equipment, this is not feasible. In power electronics, average modeling has been used to solve the aforementioned issue. By focusing on the behavior of the converter rather than the switching dynamics during a switching period, this modeling approach can improve simulation efficiency without compromising the ability to predict the steady-state and dynamic responses of the converter [9]. Therefore, it is a useful method for simulating EV chargers in grid-integrated systems. On the other hand, the dynamic response as discussed above comes into picture when there is increase or decrease in nonlinear load connected at the point of common coupling (PCC). Moreover, the grid side voltage disturbance at PCC is also a great issue and in anticipation to that the front end converter must be able to provide reactive power support (RPS). Therefore, maintaining requisite power quality standards at PCC within permissible limits is also one of the major challenges.

Therefore, PQ issues [10] mentioned above can be minimized by taking care of load current at the PCC. In addition, load current should be passed through the filters so as to result in the generation of the reference value for grid current [11]. An adaptive theory-based control utilizes a feedback mechanism and self-adjusts the internal parameters [12]. Some of the adaptive controls include LMS [13], VSSLMS [14], and RLS [15]. Regular shunt compensators had previously implemented LMS-based adaptive controllers because of their simplicity of implementation. Nevertheless, there is a greater steady-state inaccuracy and slower weight convergence with the traditional LMS. As a consequence, the LMS's performance is only passably good, and maybe better algorithms are needed. In this work, an LLMF control is presented. This approach is part of a novel family of stochastic gradient descent-based techniques and extracts the weight of load currents, which equates to the basic active component, and eliminates the mean fourth error. Through the reduction of detected current error, it offers a quick and precise method for estimating sinusoidal reference currents given distorted load currents. The application of this filter for shunt compensation is innovative and has not been reported in the literature [16]

In GIEV charger, the front-end converter (FEC) plays pivotal role in absorbing the grid side fluctuations while charging the battery and may provide ancillary services such as reactive power support and load harmonic compensation at PCC (as discussed above) if required [17]. Under normal grid conditions, there is no issue in FEC control. However, problem arises under non-ideal voltage conditions due to the presence of negative sequence and DC-offset components. To get rid of the negative sequence components in grid voltages, a Quadrature Signal Generator (QSG)-based two-channel method works well. Although QSG exhibits satisfactory performance in rejecting the negative sequence component as well as total harmonic distortion (THD) but have limitations in dealing with the DC-offset component [18]. Fourth-order QSGs (FO-QSGs) [19] provide complete dc-offset rejection and higher harmonics attenuation than second [20], third [21], and mixed (second and third) [22] QSGs. A SOSOGI [23] and a CSOGI [24] are two such FO-QSGs. Based on the system's settling time, the SOSOGI parameters are established. When choosing parameters, the fourth-order system in [25] is roughly equivalent to a lower-order system. Consequently, a sizable discrepancy exists between the predicted and actual settling periods for different combinations of damping factors and settling time. A CSOGI is created in [24] by cascading two SOGIs with comparable properties. Fourth-order harmonic attenuation is provided by the two cascaded SOGIs in CSOGI, while the first SOGI removes dc-offset from detected grid voltages. An over-damped cascaded SOGI might provide a more delayed reaction than a single SOGI, if the single SOGI-QSG damping factor is not adjusted correctly. This work proposes a CNISOGI filter to estimate the fundamental component (FC) from the polluted grid voltages to obtain improved compensation. Also, CNISOGI is the cascaded form of two SOGIs just like CSOGI, but differs in terms of having different or non-identical gains. Henceforth, it offers higher degree of freedom for achieving better settling time as compared to CSOGI [26]. Moreover, to achieve high reliability a real-time simulation of on-board bidirectional charger (OBBC), a CPU-FPGA-based real-time simulator, OP4510, from OPAL-RT Technologies is used.

The technical contributions involved in this microgrid are enumerated as follows.

- The complete equivalent model (CEM) simplifies OBBC by improving the simulation efficiency without compromising the accuracy of simulation performed [25].
- In order to compensate for imbalanced and distorted grid voltages, a CNISOGI filter is added for the first time to the OBBC. The grid voltages unit templates are generated by estimating the FC from the contaminated grid voltages. Therefore, even when the grid voltages exhibit anomalies, the grid currents obey a smooth, sinusoidal, and balanced pattern. It also computes the phase angle and frequency of the grid voltages. Thus, a smooth synchronization between the electrical grid and the OBBC is accomplished.
- Load compensation is achieved by using an LLMF adaptive filter, which calculates the fundamental active weight of load currents using a faster convergence rate with minimal weight oscillations. As a result, the supply current quality meets IEEE-519 requirements.

The structure of this document is as afterward. Section 1 provides a description of the literature review and recommended reading. The system description is discussed in Section 2. Controller design is discussed in Section 3.

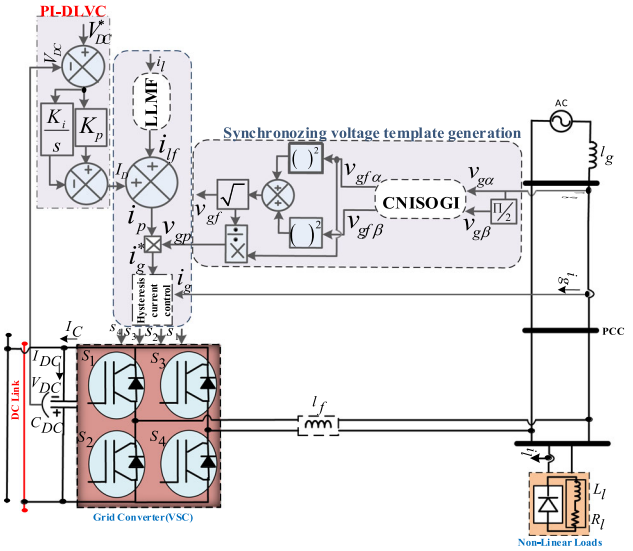

Fig. 1 Circuit Diagram of OBBC

Section 4 summarizes the suggested method. Section 5 summarizes about Results & discussion, & Section 6 about the conclusion.

2 System configuration

As shown in Fig. 1, the structure of OBBC under discussion consists of two conversion phases. The conversion of AC to DC is the responsibility of the first stage, and DC to DC is the domain of the second level. Additionally, the PCC has a nonlinear load linked. The first AC–DC converter in the recommended control configuration functions as a regulated rectifier, while the second phase uses a Bipolar Dual-Directional DC (BDDC) converter with two IGBT switches. After this setup, a mix of constant voltage (CV) and constant current (CC) methods are used to charge the lithium-ion battery. Source voltage (v_g), source inductance L_s, shunt R_l & L_l function as the load, and coupling inductance L_f are the different parameters and parts of the whole OBBC system. The switches (S_1, S_2, S_3, S_4) function as a bidirectional system due to the AC/DC inverter, particularly because of the DC link voltage's (V_{DC}) stiffness. DC/DC converter that performs buck-boost conversion, using Boost mode (S_6) for battery discharge and Buck mode (S_5) for charging batteries.

2.1 Modeling of single phase OBBC EV charger

Single phase OBBC EV chargers comprise of two stage AC/DC and DC/DC. In this section, firstly, the modeling of an AC/DC converter and secondly, a DC/DC converter are discussed.

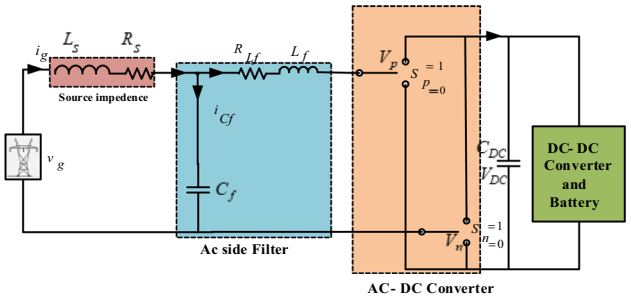

Fig. 2 Switching model of AC/DC converter

2.1.1 AC/DC converter

The switching architecture for a single-phase AC–DC converter is shown in Fig. 2. For each leg, a single pole double throw switch is used. The grid voltage as represented by v_g, the grid side inductor as L_s, the AC side filter inductance and capacitance as L_f and C_f, respectively, and the equivalent series resistance (ESR) of the filter inductance and capacitance as R_{Lf} and R_{Cf}. For switches S_1 and S_3, the on state is represented by $S_p = 1$ and $S_p = 0$, accordingly. where the on states of switches S_2 and S_4 are represented by the values $S_n = 1$ and $S_n = 0$, respectively. As a result, the grid current i_g becomes the DC side current I_{DC} and the variable V_{pn} equals V_{DC} when switches S_1 and S_4 are on and S_3 and S_2 are off.

$$v_{pn} = v_p - v_n \tag{1}$$

$$= S_p \times V_{DC} - S_n \times V_{DC} = (S_p - S_n)V_{DC} \tag{2}$$

$$= S_{pn} \times V_{DC} \tag{3}$$

where

$$S_{pn} = S_p - S_n$$

V_{DC}= Average DC link voltage.
And

$$I_{DC} = (S_p - S_n)i_{Lf} = S_{pn} \times i_{Lf} \tag{4}$$

Now applying KVL in outer loop and neglecting capacitor ESR,

$$v_g = v_{LS} + v_{Cf} \tag{5}$$

$$v_g = L_s \frac{di_g}{dt} + v_{Cf} \tag{6}$$

$$\frac{di_g}{dt} = \frac{v_g}{L_s} - \frac{v_{Cf}}{L_s} \tag{7}$$

Now applying KVL in the inner loop,

$$v_{Cf} = v_{Lf} + i_{Lf} \times R_{Lf} + v_{pn}$$

$$v_{\mathrm{Cf}} = L_{\mathrm{f}}\frac{\mathrm{d}i_{\mathrm{Lf}}}{\mathrm{d}t} + i_{\mathrm{Lf}} \times R_{\mathrm{Lf}} + v_{\mathrm{pn}} \tag{8}$$

$$\frac{\mathrm{d}i_{\mathrm{Lf}}}{\mathrm{d}t} = \frac{v_{\mathrm{Cf}}}{L_{\mathrm{f}}} - \frac{i_{\mathrm{Lf}} \times R_{\mathrm{Lf}}}{L_{\mathrm{f}}} - \frac{v_{\mathrm{pn}}}{L_{\mathrm{f}}} \tag{9}$$

where

v_{Lf}= AC side Inductor filter voltage.
i_{Lf}= AC side Inductor filter current.
R_{Lf}= Equivalent Series resistance of filter inductor.
L_{f}= AC side filter Inductance.
Now applying the KCL at the junction,

$$i_{\mathrm{g}} = i_{\mathrm{Lf}} + i_{\mathrm{Cf}}$$

$$i_{\mathrm{g}} = i_{\mathrm{Lf}} + C_{\mathrm{f}}\frac{\mathrm{d}v_{\mathrm{Cf}}}{\mathrm{d}t} \tag{10}$$

$$\frac{\mathrm{d}v_{Cf}}{\mathrm{d}t} = \frac{i_{\mathrm{g}}}{C_{\mathrm{f}}} - \frac{i_{\mathrm{Lf}}}{C_{\mathrm{f}}} \tag{11}$$

where

i_{g} = Grid Current.
i_{Lf} = AC side Inductor filter current.
i_{Cf} = AC side Capacitor filter current.
C_{f} = AC side filter Capacitance.

2.1.2 Average model

Using one switching period as the switching model, the averaging operator is used, the system average model is acquired. For a time-varying variable y, the averaging operator is illustrated as (12).

$$\tilde{y} = \frac{1}{T}\int_0^T y(\tau)\mathrm{d}\tau \tag{12}$$

where

$\tilde{y}$= Average Value.
$y(\tau)$ = Time-varying Variable.
T= Switching Period.
Applying the averaging operator to above derived state-space Eqns (5), (7), (9).

$$\frac{\mathrm{d}\tilde{i}_{\mathrm{g}}}{\mathrm{d}t} = \frac{\tilde{v}_{\mathrm{g}}}{L_{\mathrm{s}}} - \frac{\tilde{v}_{\mathrm{Cf}}}{L_{\mathrm{s}}} \tag{13}$$

$$\frac{\mathrm{d}\tilde{i}_{\mathrm{Lf}}}{\mathrm{d}t} = \frac{\tilde{v}_{\mathrm{Cf}}}{L_{\mathrm{f}}} - \frac{\tilde{i}_{\mathrm{Lf}} \times R_{\mathrm{Lf}}}{L_{\mathrm{Lf}}} - \frac{d_{\mathrm{pn}} \times V_{\mathrm{DC}}}{L_{\mathrm{f}}} \tag{14}$$

$$\frac{\mathrm{d}\tilde{v}_{Cf}}{\mathrm{d}t} = \frac{\tilde{i}_{\mathrm{g}}}{C_{\mathrm{f}}} - \frac{\tilde{i}_{\mathrm{Lf}}}{C_{\mathrm{f}}} \tag{15}$$

where

d_{pn} = The average value of S_{pn}

2.1.3 Small signal model

The steady-state values of the average model are combined with small AC changes that are overlaid to create the small signal model. The resulting Eqns 11, 12, and 14 for small signals are

$$\frac{\mathrm{d}\tilde{\tilde{i}}_{\mathrm{g}}}{\mathrm{d}t} = \frac{\tilde{\tilde{v}}_{\mathrm{g}}}{L_{\mathrm{s}}} - \frac{\tilde{\tilde{v}}_{\mathrm{Cf}}}{L_{\mathrm{s}}} \tag{16}$$

$$\frac{\mathrm{d}\tilde{\tilde{i}}_{Lf}}{\mathrm{d}t} = \frac{\tilde{\tilde{v}}_{\mathrm{Cf}}}{L_{\mathrm{f}}} - \frac{\tilde{\tilde{i}}_{\mathrm{Lf}} \times R_{\mathrm{Lf}}}{L_{\mathrm{Lf}}} - \frac{\tilde{d}_{\mathrm{pn}} \times V_{\mathrm{DC}}}{L_{\mathrm{f}}} \tag{17}$$

$$\frac{\mathrm{d}\tilde{\tilde{v}}_{\mathrm{Cf}}}{\mathrm{d}t} = \frac{\tilde{\tilde{i}}_{\mathrm{g}}}{C_{\mathrm{f}}} - \frac{\tilde{\tilde{i}}_{\mathrm{Lf}}}{C_{\mathrm{f}}} \tag{18}$$

Taking Laplace transform of Eqns 16-18,

$$\tilde{\tilde{i}}_{\mathrm{g}} = \frac{\tilde{\tilde{v}}_{\mathrm{g}}}{sL_{\mathrm{s}}} - \frac{\tilde{\tilde{v}}_{\mathrm{Cf}}}{sL_{\mathrm{s}}} \tag{19}$$

$$s\tilde{\tilde{i}}_{\mathrm{Lf}} = \frac{\tilde{\tilde{v}}_{\mathrm{Cf}}}{L_{\mathrm{f}}} - \frac{\tilde{\tilde{i}}_{\mathrm{Lf}} \times R_{\mathrm{Lf}}}{L_{\mathrm{f}}} - \frac{\tilde{d}_{\mathrm{pn}} \times V_{\mathrm{DC}}}{L_{\mathrm{f}}} \tag{20}$$

$$s\tilde{\tilde{v}}_{\mathrm{Cf}} = \frac{\tilde{\tilde{i}}_{\mathrm{g}}}{C_{\mathrm{f}}} - \frac{\tilde{\tilde{i}}_{\mathrm{Lf}}}{C_{\mathrm{f}}} \tag{21}$$

Putting Eqn (19) in Eqn (21)

$$S\tilde{\tilde{v}}_{\mathrm{Cf}} = \frac{1}{C_{\mathrm{f}}}\left(\frac{\tilde{\tilde{v}}_{\mathrm{g}}}{sL_{\mathrm{s}}} - \frac{\tilde{\tilde{v}}_{\mathrm{Cf}}}{sL_{\mathrm{s}}}\right) - \frac{\tilde{\tilde{i}}_{\mathrm{Lf}}}{C_{\mathrm{f}}} \tag{22}$$

$$\tilde{\tilde{v}}_{\mathrm{Cf}} = \frac{\tilde{\tilde{v}}_{\mathrm{g}}}{s^2L_{\mathrm{s}}C_{\mathrm{f}}+1} - \frac{\tilde{\tilde{i}}_{\mathrm{Lf}} \times sL_{\mathrm{s}}}{s^2L_{\mathrm{s}}C_{\mathrm{f}}+1} \tag{23}$$

Putting Eqn (23) in Eqn (20)

$$\tilde{\tilde{i}}_{\mathrm{Lf}} = \left(\frac{\tilde{\tilde{v}}_{\mathrm{g}}}{s^3L_{\mathrm{f}}L_{\mathrm{s}}C_{\mathrm{f}} + s^2L_{\mathrm{s}}C_{\mathrm{f}}R_{\mathrm{Lf}} + s(L_{\mathrm{f}}+L_{\mathrm{s}}) + R_{\mathrm{Lf}}}\right) - \left(\tilde{d}_{\mathrm{pn}} \times V_{\mathrm{DC}}\left(\frac{s^2L_sC_{\mathrm{f}}+1}{s^3L_{\mathrm{f}}L_{\mathrm{s}}C_{\mathrm{f}} + s^2L_{\mathrm{s}}C_{\mathrm{f}}R_{\mathrm{Lf}} + s(L_{\mathrm{f}}+L_{\mathrm{s}}) + R_{\mathrm{Lf}}}\right)\right) \tag{24}$$

Let us assume the ideal grid, then the final relation is as follows:

$$\tilde{\tilde{i}}_{\mathrm{Lf}} = -\tilde{d}_{\mathrm{pn}} \times V_{\mathrm{DC}} \times \left(\frac{s^2L_{\mathrm{s}}C_{\mathrm{f}}+1}{s^3L_{\mathrm{f}}L_{\mathrm{s}}C_{\mathrm{f}} + s^2L_{\mathrm{s}}C_{\mathrm{f}}R_{\mathrm{Lf}} + s\,(L_{\mathrm{f}}+L_{\mathrm{s}}) + R_{\mathrm{Lf}}}\right) \tag{25}$$

As it is known, at higher frequencies, the above equation results in (26).

$$\tilde{\tilde{i}}_{\mathrm{Lf}} = \frac{-\tilde{d}_{\mathrm{pn}} \times V_{\mathrm{DC}}}{sL_{\mathrm{f}} + R_{\mathrm{Lf}}} \tag{26}$$

From Eq. (26), it shows that $\tilde{d}_{\mathrm{pn}}$ increases with the decrement in $\tilde{\tilde{i}}_{\mathrm{Lf}}$ because of −ive sign. Therefore, the plant function is as follows in Fig. 6.

$$G_{P_{\mathrm{ac}}} = V_{\mathrm{DC}} \times \left(\frac{1}{sL_{\mathrm{f}} + R_{\mathrm{Lf}}}\right) \tag{27}$$

2.2 DC/DC converter

A pair of logical modes for the bidirectional buck-boost converter may be identified assuming complimentary switch control signals for S_5 and S_6 as shown in Fig. 10:

Topological mode 1 In this case, S_5 is ON and S_6 is OFF, yielding:

$$\frac{\mathrm{d}I_{L_{\mathrm{f}}}}{\mathrm{d}t} = \frac{1}{L_{\mathrm{f}}}V_{\mathrm{DC}} - \frac{1}{L_{\mathrm{f}}}V_b \tag{28}$$

$$\frac{\mathrm{d}V_{\mathrm{DC}}}{\mathrm{d}t} = \frac{1}{C_{\mathrm{DC}}}I_{\mathrm{DC}} - \frac{1}{C_{\mathrm{DC}}}I_{\mathrm{Lf}} \tag{29}$$

$$\frac{\mathrm{d}V_b}{\mathrm{d}t} = \frac{1}{C_{\mathrm{f}}}I_{\mathrm{Lf}} - \frac{1}{C_{\mathrm{f}}}I_b \tag{30}$$

Topological mode 2 In this case, S_5 is OFF and S_6 is ON, which leads to:

$$\frac{\mathrm{d}I_{L_{\mathrm{f}}}}{\mathrm{d}t} = -\frac{1}{L_{\mathrm{f}}}V_b \tag{31}$$

$$\frac{\mathrm{d}V_{\mathrm{DC}}}{\mathrm{d}t} = \frac{1}{C_{\mathrm{DC}}}I_{\mathrm{DC}} \tag{32}$$

$$\frac{\mathrm{d}V_b}{\mathrm{d}t} = \frac{1}{C_{\mathrm{f}}}I_{\mathrm{Lf}} - \frac{1}{C_{\mathrm{f}}}I_b \tag{33}$$

The following formulas may be obtained by averaging the first-order differential Eqs. (28–33) over a switching period; where D_S is the duty cycle for S_5 in Fig. 2:

$$\left.\frac{\mathrm{d}I_{L_{\mathrm{f}}}}{\mathrm{d}t}\right|_{\mathrm{av}} = D_{S_5}\left(\frac{1}{L_{\mathrm{f}}}V_{\mathrm{DC}} - \frac{1}{L_{\mathrm{f}}}V_b\right) + \left(1 - D_{S_5}\right)\left(-\frac{1}{L_{\mathrm{f}}}V_b\right) \tag{34}$$

$$= D_{S_5}\frac{V_{\mathrm{DC}}}{L_{\mathrm{f}}} - \frac{V_b}{L_{\mathrm{f}}} \tag{35}$$

$$\left.\frac{\mathrm{d}V_{\mathrm{DC}}}{\mathrm{d}t}\right|_{\mathrm{av}} = D_{S_5}\left(\frac{1}{C_{\mathrm{DC}}}I_{\mathrm{DC}} - \frac{1}{C_{\mathrm{DC}}}I_{L_{\mathrm{f}}}\right) + \left(1 - D_{S_5}\right)\left(\frac{1}{C_{\mathrm{DC}}}I_{\mathrm{DC}}\right) \tag{36}$$

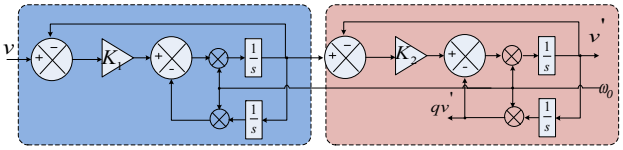

Fig. 3 Block diagram of suggested CNISOGI-QSG

$$= \frac{1}{C_{\mathrm{dc}}}I_{\mathrm{DC}} - D_{S_5}\left(-\frac{I_{L_{\mathrm{f}}}}{C_{\mathrm{DC}}}\right) \tag{37}$$

$$\left.\frac{\mathrm{d}V_b}{\mathrm{d}t}\right|_{\mathrm{av}} = \left(\frac{1}{C_{\mathrm{f}}}I_{L_{\mathrm{f}}} - \frac{1}{C_{\mathrm{f}}}I_b\right) \tag{38}$$

3 Control techniques

In context of control strategies, firstly, AC/DC converter control is discussed, followed by DC/DC control.

3.1 VSC switching strategy

Furthermore, Fig. 1 also states the switching strategy for VSC and the control steps are as follows:

3.1.1 Generation of unit templates

For the generation of the unit template of grid voltage (v_{g}) it is translated into $\alpha\beta$ -frame by simply taking grid voltage as $v_{g\alpha}$ and the same providing through transportation delay of 90° as $v_{\mathrm{g}\beta}$. In addition, it is processed through CNISOGI filter to remove the DC offset and harmonics components to get the fundamental $v_{\mathrm{g}f(\alpha\beta)}$.

The construction of a CNISOGI filter is given in Fig. 3. Additionally, the transfer function of the CNISOGI filter in-phase element (v') and quadrature-phase element (qv') to the input (v) is provided in (39) and (40) and may be derived in Fig. 3.

$$G_1(s) = \frac{v'(s)}{v(s)} = \left(\frac{K_1\omega_o s}{s^2 + K_1\omega_o s + \omega_o^2}\right)\left(\frac{K_2\omega_o s}{s^2 + K_2\omega_o s + \omega_o^2}\right) \tag{39}$$

$$H_1(s) = \frac{qv'(s)}{v(s)} = \left(\frac{K_1\omega_o s}{s^2 + K_1\omega_o s + \omega_o^2}\right)\left(\frac{K_2\omega_o^2 s}{s^2 + K_2\omega_o s + \omega_o^2}\right) \tag{40}$$

Figure 4 shows the pole-zero map of the CNISOGI filter. Furthermore, it can be seen that all poles lie on the left-hand side of the imaginary axis which states the stability of the system.

Figure 5 relates the Bode Diagrams of the in-phase com-

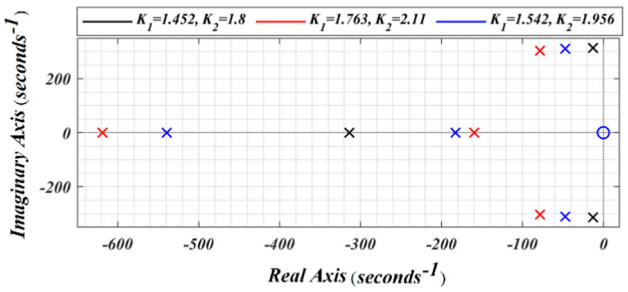

Fig. 4 Polar plot for CNISOGI

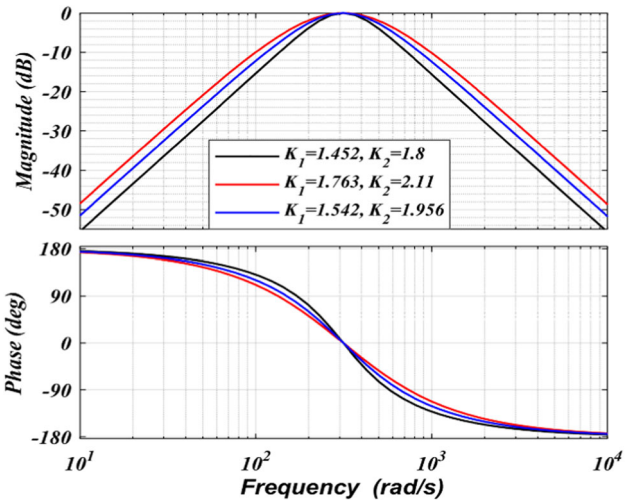

Fig. 5 Bode Diagram for CNISOGI

ponents of the CNISOGIs-QSG for the different values of K_1 & K_2. It is noticed that the CNISOGIs-QSG delivers stronger attenuation to harmonic components.

Furthermore, the $v_{gf\alpha}$ along with its phase-shifted quadrature component $v_{gf\beta}$ are conceded through a peak approximation block to calculate v_{gf}. Additionally, calculated v_{gf} is divided by $v_{gf\alpha}$ to obtain unit template v_{gp} as given in Eqs. (41), (42).

$$v_{gf} = \sqrt{\left(v_{gf\alpha}^2 + v_{gf\beta}^2\right)} \tag{41}$$

$$v_{gp} = \frac{\left(v_{gf\alpha}\right)}{((v_{gf\alpha})^2 + (v_{gf\beta})^2)^{0.5}} \tag{42}$$

Henceforth, to validate the effectiveness of the proposed method in extracting the in-phase and quadrature components out of a non-ideal voltage signal, an input supply comprising $5th$, $7th$, $11th$, and $13th$ harmonics and a dc offset, with an overall THD of 15%, has been considered, as shown in Fig. 6. The extracted values of in-phase and quadrature components utilizing and *CNISOGI* are shown in Fig. 7. On analyzing these waveforms, it can be observed

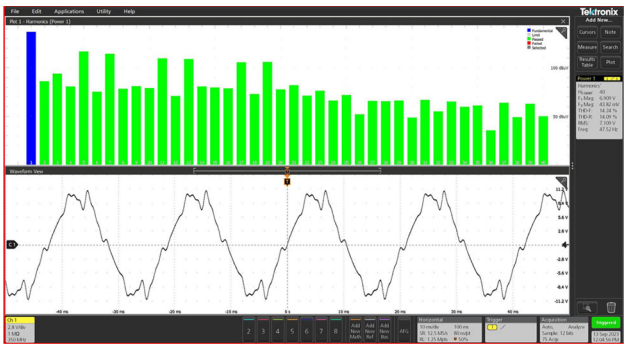

Fig. 6 Grid voltage comprising 5th, 7th, 11th, and 13th harmonics and a DC offset, with an overall THD of 15%

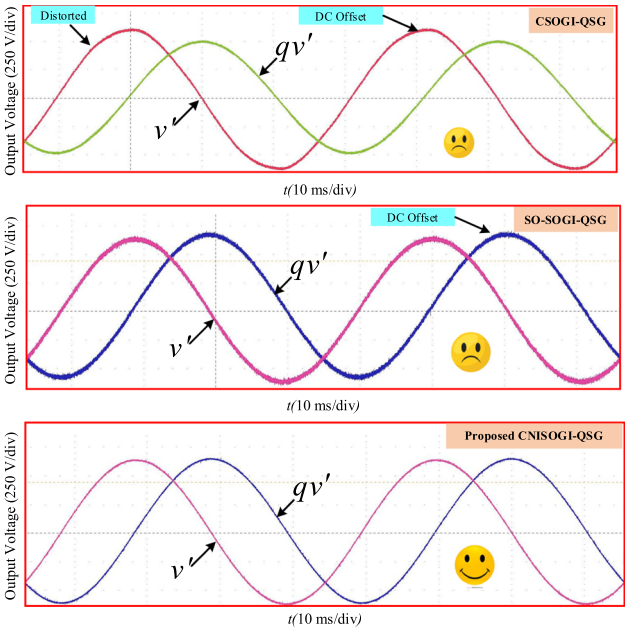

Fig. 7 Experimental output waveforms, spectrums of v' & spectrums of qv' for different *QSG* w.r.t output waveform

that *CSOGI* and *SO-SOGI* are not immune to grid side disturbances as they introduce DC-Offset and ripples in extracted components. However, the *CNISOGIs* approach tackles the grid side THDs effortlessly and extracts the fundamental component without any DC offset and ripples. Henceforth, comparison in terms of computational burden of proposed method (CNISOGI) with the other methods, i.e., CSOGI and SO-SOGI was performed on the real-time simulator using *d*-Space-1104 s. So, the proposed filter takes 3.7365E−05 while CSOGI takes 3.8489E−05 and SO-SOGI takes 3.94496E−05 turnaround time on the sample time of 5E−05. Therefore, it can be concluded that CNISOGI is 3.008% and 5.579% efficient than CSOGI and SO-SOGI, respectively.

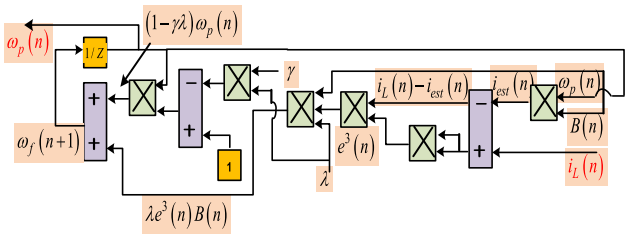

Fig. 8 Circuit Diagram of LLMF Control Architecture

3.1.2 Estimation of the active weight loss component of load current:

To calculate the switching loss within the shunt compensator V_{DC}^{*}, V_{DC} is passed via an LPF. Given the inaccuracy of the V_{DC} for feedback, a PI controller estimates the active component of DC-link voltage regulation and losses generated by the PI-DC link voltage controller (DLVC). A stable 400 V V_{DC} is maintained.

$$\omega_{\text{loss}}(n+1) = \omega_{\text{p}}(n) + [k_{\text{P}}\{V_{\text{dce}}(n+1) - V_{\text{dce}}(n)\} + k_{\text{i}}\{V_{\text{dce}}(n+1)\}] \tag{43}$$

where the constants for integral & proportional controller gains are represented by the letters k_{i} and k_{p}.

3.1.3 Generation of grid reference current & gating pulses:

About getting the pulse load current is fed to the LLMF filter as shown in Fig. 8 (for Eq. (59) explained in Section 5) which gives the $\omega_{\text{p}}(n) = i_{\text{lf}}$.

Furthermore, DC link loss component I_D and the fundamental load current component i_{lf} blend to prompt an overall active current reference (I_{p}) as given by Eq. (44).

$$I_{\text{p}} = I_D + I_{\text{lf}} \tag{44}$$

The active current reference I_{p} is multiplied with unit voltage template v_{gp} to provide the reference sinusoidal current corresponding to active power as given by Eq. (45).

$$i_{\text{g}}^{*} = I_{\text{p}} * v_{\text{gp}} \tag{45}$$

At last, these desired reference values are after comparison from actual grid current i_{g} is fed to Hysteresis current control (HCC) to compute gating signals GSC's (Grid side converter) IGBT switches.

Henceforth, Fig. 9 validates about the active fundamental weight (ω_{p}) and active current reference (I_{p}). As discussed earlier that ω_{p} is the filtered part of the load current generated by the LLMF.

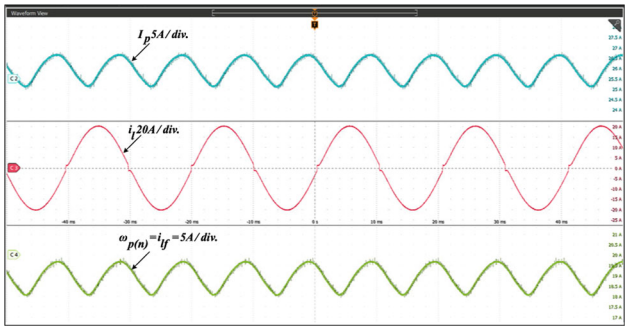

Fig. 9 Active fundamental weight (ω_p) and active current reference (I_p)

3.2 BDDC control in GCO

The primary goal of BDDC control is to continue charging or draining the battery in spite of grid-side interruptions. Here, the battery is charged using both constant voltage (CV) and constant current (CC). First, CC charging is used to manage battery charging. Once the battery voltage exceeds the allowed permissible voltage level, CV charging is introduced. This technique aids in quick battery charging without going over the charger's rated voltage and current limitations. The only thing left to do is build the battery reference current such that it includes CC/CV charging, as the DC-Link voltage is almost set at the rated voltage. Furthermore, since BDDC is a bidirectional system, its operation may be managed in both charging and discharging modes. Thus, in order to accomplish the intended goals, the controller must follow the reference current (I_b^{*}) for the battery, which may be developed based on the requirements. The BDDC's whole controller architecture is shown in Fig. 10.

4 Mathematical modeling of leaky least mean fourth algorithm

LLMF algorithm is a member of an entirely novel category of stochastic gradient descent-based algorithms that aims to reduce the mean fourth error, has become convex function for weight vector that is adaptable. Compared to the LMF method, the LLMF algorithm has a smaller steady-state error and quicker initial convergence, which is its main strength. As depicted in Fig. 11, N symbolizes the overall amount of matrix vectors.

The initial stages of interpolation involve identifying the interval index i that aligns with the input signal $t(n)$ and allocating the interpolation intervals, which are pivotal steps in the process. The control points for the look-up table (LUT) are given as follows:

$$A_N \in \Re^{Ax1} = [A_1 A_2 A_3 \ldots\ldots\ldots\ldots A_N]^T,$$

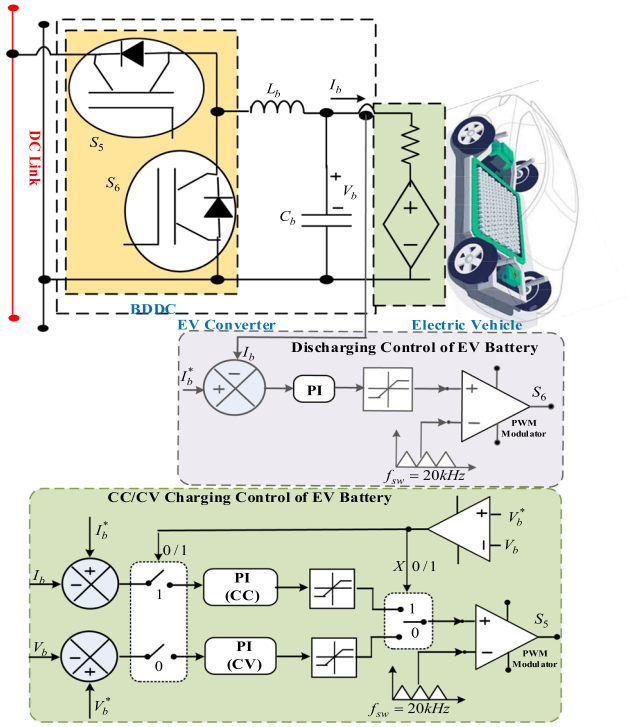

Fig. 10 BDDC control architecture

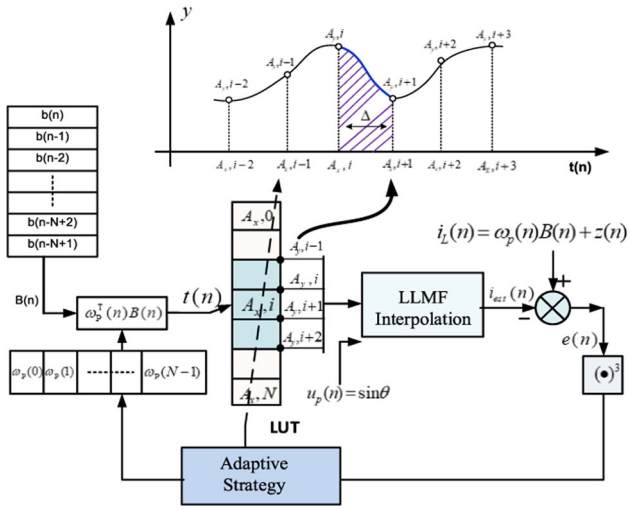

Fig. 11 Weight updating structure of LLMF adaptive algorithm

Where the ith control point denotes the A_i and $A_N \in \Re^{4x1} = A_{i-1}A_iA_{i+1}A_{i+2}]$ for the ith span. Additionally, by deducting the LLMF interpolation output out of the actual load current, $i_L(n)$, an error, $e(n)$, is derived. Once load dynamics are achieved, this adaptive progression is maintained until stable condition is attained.

Let us presume that the system receives the signal $B(n)$ together with a new weight coefficient vector.

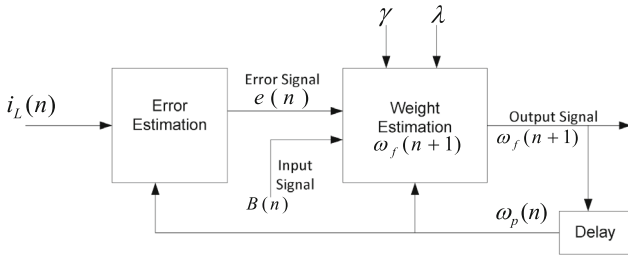

Fig. 12 Block diagram of LLMF control algorithm

$\omega_p(n) = \left[\omega_p(0)\omega_p(1)\omega_p(2)\ldots\omega_p(N-1)\right]^T$; and that the observed output signal $i_L(n)$ is given by (8)

$$i_L(n) = \omega_p(n) \times B(n) + z(n)$$

$$\mathrm{i}_L(n) = \omega_\mathrm{p}(n)B(n) + z(n) \text{ where}$$

$$B(n) = [b(n)b(n-1)....b(n-N+1)]^T$$

$z(n)$ represents the discovered noise, where is considered to be independent of $B(n)$, and shows the vector of the input signal $B(n)$

The objective is to use the input signal $B(n)$ & the measured output signal $i_L(n)$ to adaptively estimate the undefined channel coefficient vector $\omega_p(n)$. In Fig. 12, the LLMF block diagram is shown. Utilizing this block allows for the real-time estimation of the load current's basic weight and variations in weight. Comparing the LLMF control approach to the LMF method, it has been shown that the latter rapidly decreases error to zero.

In any AC system; the nonlinear load comprises the total of the fundamental and harmonic components, shown as;

$$i_L(t) = i_{L1}\sin(wt+\theta) + i_{L2}\sin(2\omega t+\theta) + \ldots\ldots\ldots\text{¥} \tag{46}$$

$$i_L(t) = i_{L1}\sin(wt+\theta) + \sum_{r=2}^{\text{¥}} i_{Lr}\sin(r\omega t+\theta_r) \tag{47}$$

where ω signifies the angular frequency of the fundamental harmonics, r indicates the order of harmonics, i_{L1} defines the fundamental harmonic, and i_{Lr} indicates the rth harmonics component of the current.

$$i_L(t) = i_{L1}[\sin wt\cos\theta + \sin\theta\cos\omega] + \sum_{r=2}^{\text{¥}} i_{Lr}[\sin r\omega\cos\theta_r + \cos r\omega t\sin\theta_r] \tag{48}$$

QUOTE $i_L(t) = i_{L1}[\sin\omega t\cos\theta + \sin\theta\cos\omega t] + \sum_{r=2}^{\infty} i_{Lr}[\sin r\omega t\cos\theta_r + \cos r\omega t\sin\theta_r]$

$i_{L1}\cos\theta$; $i_{L1}\sin\theta$; $i_{Lr}\cos\theta_r$; $i_{Lr}\sin\theta$ by $\omega_p(0)$; $\omega_p(1)$; $\omega_p(2)$; $\omega_p(3)$ and even harmonics are neglected

$$i_L(t) = \left[\omega_p(0)\sin\omega t + \omega_p(1)\cos\omega t\right] + \sum_{r=3,5\ldots}^{¥}\left[\omega_p(2)\sin r\omega t + \omega_p(3)\cos r\omega t\right] \quad (49)$$

In matrix form,

$$\left[\omega_p(0)\ \omega_p(1)\ \omega_p(2)\ \omega_p(3)\ ..\ ..\right]\begin{bmatrix}\sin\omega t\\ \cos\omega t\\ \sin 3\omega t\\ \cos 3\omega t\\ .\\ .\\ ¥\end{bmatrix} \quad (50)$$

where $B(n) = [sin\,\omega t cos\,\omega t sin3\,\omega t cos3\,\omega t.....\infty]^T$

$$\omega_p(n) = \left[\omega_p(0)\ \omega_p(1)\ \omega_p(2)\ \omega_p(3)\ ..\ ..\right] \quad (51)$$

Further, they used to calculate the load current presented as,

$$i_{\text{est}}(n) = \omega_p(n) \times B(n) \quad (52)$$

Let, Actual nonlinear load current and Rough current be $i_L(n)$ & $i_{est}(n)$, respectively, used to assess the error signal $e_p(n)$.

$$e(n) = i_L(n) - \omega_p(n) \times B(n) \quad (53)$$

With the LMF method, the cost function that has to be reduced is provided by

$$C_{\text{LMF}}(n) = 1/4 \times \left[e^4(n)\right] = 1/4 \times \left[\left\{i_L(n) - \omega_p(n)B(n)\right\}\right]^4 \quad (54)$$

The LLMF algorithm, together with the leakage parameter (γ), introduces the modified LMF cost function.

Consequently, the LLMF's minimal cost function is

$$C_{\text{LMF}}(n) = 1/4 \times \left[e^4(n)\right] + 2\gamma\left|\omega_p(n)\right|^2 \quad (55)$$

To get the partial derivative for cost function in relation to the weight vector is hence the definition of the gradient estimate.

$$\frac{\partial C(n)}{\partial \omega_p(n)} = \left[\left\{\gamma\omega_p(n) - e^3(n)B(n)\right\}\right] \quad (56)$$

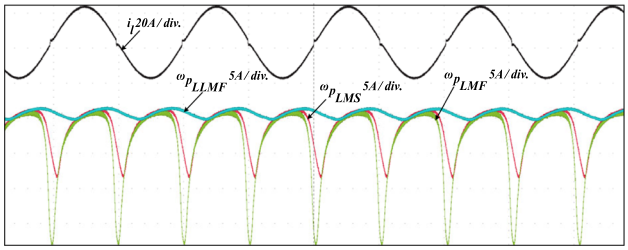

Fig. 13 Fundamental Active weight of load current

The gradient approach, sometimes referred to as the weight update equation of the LLMF, may be used iteratively to find the minimum of $C(n)$.

$$\omega_f(n+1) = \omega_p(n) - \lambda\frac{\partial C(n)}{\partial \omega_p(n)} \quad (57)$$

$$= \omega_p(n) - \lambda\left[\left\{\gamma\omega_p(n) - e^3(n)B(n)\right\}\right] \quad (58)$$

$$\omega_f(n+1) = \omega_p(n)(1-\lambda\gamma) + \lambda e^3(n)B(n) \quad (59)$$

where λ denotes the adaptation constant & γ is learning rate & its value ranges between 0 and 1.

Henceforth, preciseness of LLMF is shown in Fig. 13 where, for load current of 20A/div., active fundamental weight of different filter methods is compared and it can be observed among LMS and LMF, LLMF gives better result.

5 Result and discussion

5.1 Simulation validation

Using a variety of Simscape library components, the system is methodically designed and simulated in MATLAB/Simulink. A 230 v_{rms}, 50 Hz single-phase supply is used as the input for the OBBC FEC. Additionally, a nonlinear load that represents the normal home load has been linked to the PCC. Results from the simulation are available for two distinct periods. Figure 14 illustrates the controller's performance in the first phase while operating in the G2V and V2G modes. To enable UPF grid operation, the charger initially operates in G2V mode while meeting the reactive power needs of adjacent loads. The transition from G2V to V2G mode of operation occurs at 0.5 s. It is important to note that the transition between the two modes of operation is quite seamless. Furthermore, since the charger side is the sole source of reactive power, the grid always runs at UPF even when reactive power demand is at PCC. As the grid's present profile makes clear, the grid must only ever interact with active electricity. While the grid current operates in

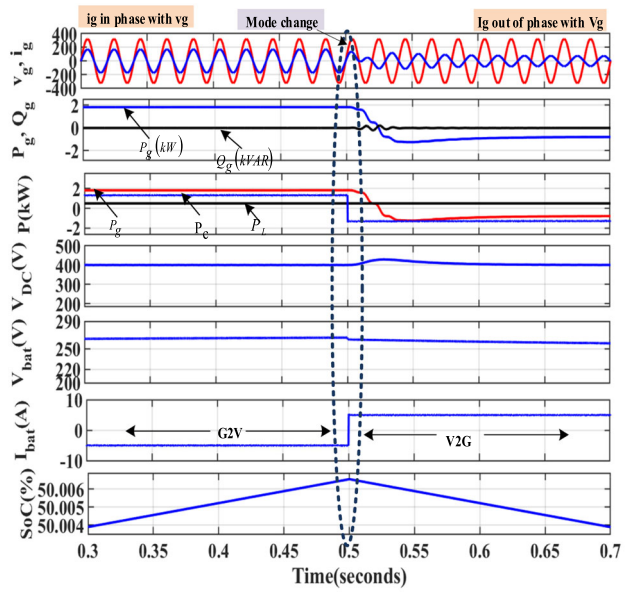

Fig. 14 Steady-state performance under normal operating conditions

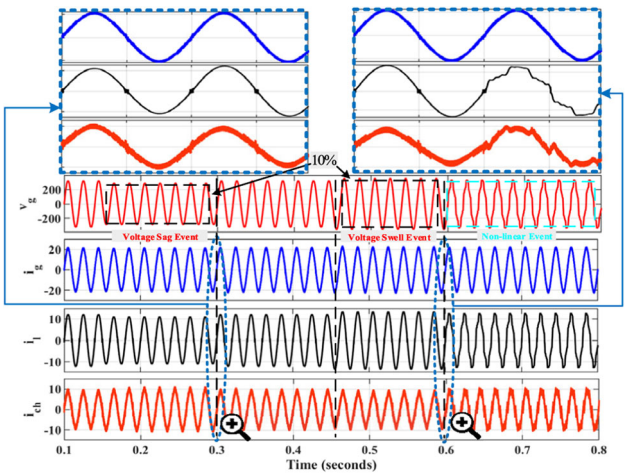

Fig. 15 Trace of Grid voltage (v_g), Grid current (i_g), load current (i_l), and FEC current (i_{ch})

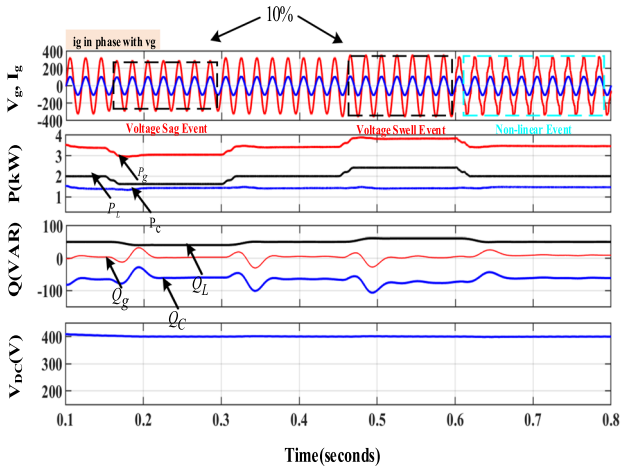

Fig. 16 Steady-state performance when harmonics are injected (weak grid operating condition)

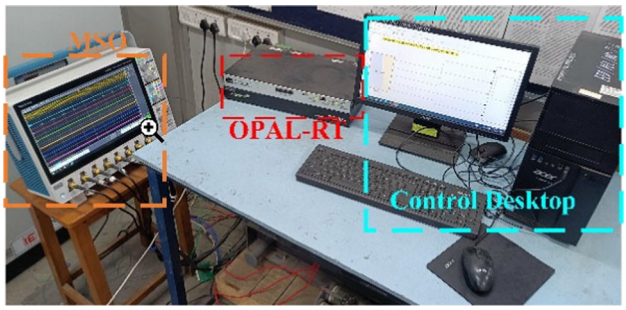

Fig. 17 Experimental Configuration

phase with the grid voltage in the G2V mode, it is out of phase with the grid voltage in the V2G mode.

During the second operating phase, various grid-side voltage disturbances are taken into consideration for system functioning. Here, as shown in Figs. 15 and 16, the voltage sag as well as swell of 10% with voltage THDs of 15% has been taken to examine the control performance of the charger. At first, as was previously said, the charger operates under typical grid circumstances. There is a voltage drop that occurs in 0.15–0.3 sec. The voltage returns to normal between 0.3 and 0.45. Finally, from 0.6 to 0.8, the nonlinear grid voltage with 15% THDs is taken into consideration. A voltage swell is inserted between 0.45 and 0.6. The waveforms for load current, FEC current, grid voltage, and grid current are shown in Fig. 15. Here, the FEC is set up to readily correct for both load harmonics and reactive power while concurrently charging the battery under various grid voltage disruptions. The grid voltage, current, active/reactive power of the FEC, load, and grid along the DC-Link voltage are all shown in Fig. 16, which further supports this claim. Here, grid voltage and grid current at UPF are always sinusoidal. This is further shown by the almost negligible reactive power on the grid side, which is a complement to the reactive power on the load from the charger.

5.2 Real-time HIL validation

The designed controller has been implemented into operation in real-time on a Hardware in Loop (C-HIL) configuration in order to fully evaluate its robustness and efficiency. The experimental setup, as shown graphically in Fig. 17, offers a thorough rundown of all the key parts that make up the HIL system. OPAL-RT ensures smooth integration and

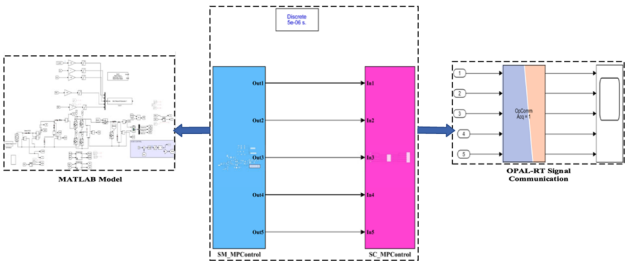

Fig. 18 OPAL-RT Simulator Model

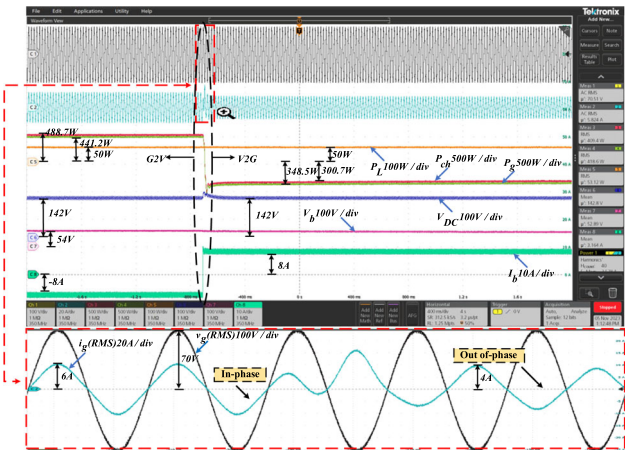

Fig. 19 Real-time *HIL* of Steady-state performance under normal operating conditions

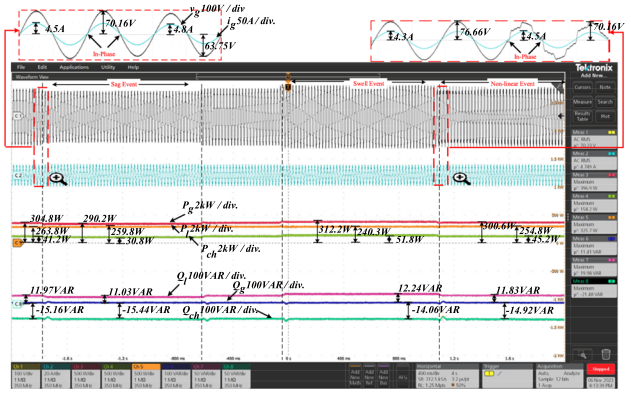

Fig. 20 Real-time validation of steady-state performance when harmonics are injected (weak grid operating condition)

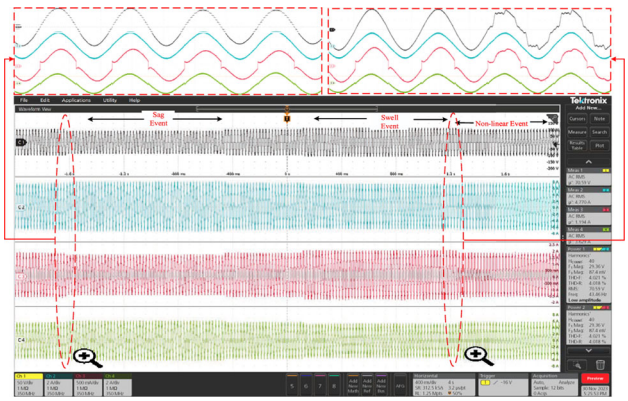

Fig. 21 Real-time *HIL* of Grid voltage (v_g), Grid current (i_g), load current (i_l), and FEC current (i_{ch})

accurate control by combining hardware and software synchronization options in a synergistic manner. In particular, the software synchronized mode is used for analysis in order to carefully assess the control method's effectiveness. The system performance is validated using MATLAB 2018a and the OP4510 model of RT-Lab 2019.2.3. Additionally, this part provides a comprehensive exhibition of the platform-obtained example test results depicted in Fig. 18, which serve to successfully reinforce the resilience and usefulness of the designed controller.

Figure 19 illustrates the Grid Voltage $v_g = 70\ v_{rms}$ at *100 V*/div. on Channel 1, and the real-time HIL results of the mode change from G2V to V2G. Channel 2 is devoted to Grid Current i_g. In charging mode (G2V), it draws a current of 6*A* (20*A*/div), and in discharging mode (G2V to V2G), it injects a current of 4A. The seamless transition from G2V to V2G with guaranteed UPF grid functioning while providing the load reactive demand from the FEC side alone is seen in the magnified version of v_g and i_g below. The power used by the load (50 W) and charger (440 W) in the presence of a nonlinear load connected at PCC may be determined to be provided by the grid (500 W) during G2V. After that, a reversal of power flow is seen as soon as the transition takes place. This is because the load (50 W) is receiving the required power from the charger (350 W), and the excess power (290 W) is being delivered into the grid, creating an out-of-phase grid current. Throughout all modes of operation, the DC-link voltage and battery voltage, which are 140 V at 100 V/div and 54 V at 100 V/div, respectively, are kept constant. Indicating the G2V and V2G modes of operation, the battery current may also follow the reference current change from − 8 to 8 A at 10 A/div.

Figs. 20, 21, and 22 show how the system might behave dynamically under non-ideal voltage settings. Initially, the optimal voltage is applied in this case. However, over time, voltage sag and swell of 10% and voltage THDs of 15% have been added to analyze the control performance. The charger is completely capable of responding to control instructions without being impacted by grid-side disruption, as can be shown by carefully examining the different waveforms. The battery current follows the reference current instruction with ease, the DC-link is almost always kept almost constant, and the FEC may concurrently charge and discharge the battery and correct for reactive power and load harmonics. The grid current at UPF consistently maintains a sinusoidal pattern

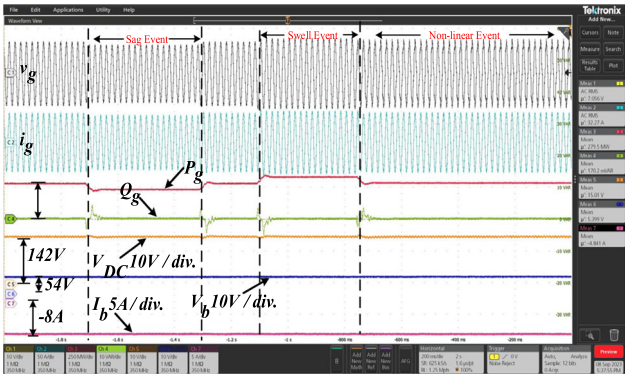

Fig. 22 Real-time validation of Steady-state performance when sag & swell in grid voltage

despite non-ideal voltage and nonlinear load at PCC, as can be seen from the magnified version of the grid voltage, grid current, load current, and FEC current shown in Fig. 21. Additionally, the reactive power profile of the grid, load, and FEC may be used to verify this fact. It shows that the UPF grid operates as shown in Figs. 20 and 22 when the FEC is able to fulfill the reactive power load requirement, keeping grid reactive power consistently around zero.

6 Conclusion

In this paper, a two-stage GIEVC charging system has been modeled, simulated, and validated through HIL in real-time. Furthermore, a fourth-order *CNISOGI* is realized and implemented. This unusual system effectively addresses irregularities in utility grid voltages by estimating synchronizing voltage template precisely. Moreover, it provides the sinusoidal nature of grid current although grid voltages are polluted. Also, LLMF filter approach is implemented for load compensation such as reactive power compensation and harmonics mitigation. The success of this technique is proven by *MATLAB/Simulink* simulations, specifically within the context of the V2G/G2V charging mode for *GIEVC* under voltage sag/swell and harmonics without affecting their normal operation. Also, to achieve high reliability, a real-time simulation of GIEVC, a real-time simulator, *OP4510*, from OPAL-RT Technologies is used. Additionally, the EV charger is easily able to compensate load harmonics while simultaneously regulating its output active and reactive power as per the set references.

Rheological Behaviour Analysis of Prepared Nano-Cutting Fluids from Al_2O_3 and Tio_2

Anurag Sharma[1],*, R. C. Singh[2], Ranganath M. Singari[2], S. L. Bhandarkar[3]

Abstract

In this research paper, an attempt has been made to characterize and analyse the rheological properties of two samples of nano-cutting fluids. Nanoparticles of Al_2O_3 and TiO_2 were characterized by SEM and EDS. The high peaks showed the respective presence of aluminium, oxygen for alumina and titanium and oxygen for titanium dioxide. The two samples of nano-cutting fluids were prepared. Alpha alumina, α-Al_2O_3 nanoparticles were used for the preparation of the sample of nano-cutting fluid in the ratio of 1% (w/w) with distilled water. TiO_2 nanoparticles were used for the preparation of nano-cutting fluid in the ratio of 1% (w/w) with distilled water. Conventional cutting fluid was made in the ratio of 1:20 (w/w) with distilled water. The three samples were analysed at room temperature 25°C and 65°C. It was found that viscosity of each sample was lower at higher temperature as compared to viscosity at 25°C. The thermal conductivity of each sample was increased at higher temperature by 10.91, 8.42 and 7.4% respectively as compared to low temperature.

Keywords: Nano-cutting fluids, nanoparticles, temperature, viscosity, SEM, TEM

INTRODUCTION

The researchers and scientists are meticulously working in reducing the values of machinability characteristics between the workpiece and cutting tool (i)surface roughness of the machined workpiece, (ii) cutting forces, (iii) coefficient of friction, (iv) tool wear, (v) cutting temperature etc. [1,2]. The attempts are made that coolant used during machining may not generate any effect harmful effects towards the operator and environment. Cryogenic cooling with liquid nitrogen has been used by researchers. This is environment friendly and does not produce any toxic effects on the operator [3, 4]. The conventional cutting fluids might produce fumes, itching to eyes skin etc. and various other types of human health issues problems during machining processes. The direct disposal of used one might not be environmentally friendly. The edible and non-edible oils have been used during machining processes. The health issue problems related to operator and pollution to the environment might have been improved [5-9]. Silver nanoparticles were mixed in conventional cutting fluid and it was found that surface roughness and tool wear reduced [10]. The nano boric powder was mixed in vegetable oil samples of coconut oil and soyabean oil and it was found that nanoparticles reduced the surface roughness and tool wear as compared to dry and wet machining with conventional cutting fluid [11-14]. The vegetable oil and compressed air mixed in a closed chamber are supplied at the interface of the workpiece and cutting tool. The minimum quantity lubrication prevented the excess flow of coolant and supplied the controlled amount of coolant [15]. Nanoparticles are very fine particles of the magnitude of 10^{-9}m. The lubrication, cooling and abrasive properties are dependent on the types of nanoparticles. The heat transfer and tribological

properties improved. The faster rate of heat transfer may keep the tool and workpiece at a lower temperature. This further might reduce the coefficient of friction and wear rate [16- 19]. Padmin et al. [20] made samples of nano MoS_2 with (0, 0.25, 0.5, and 0.75%) (w/w) in coconut oil and performed experiments on lathe machine and it was found that 0.5% of composition gave a better results as compared with other compositions. Uysal et al. [21] prepared a composition with MoS_2 1.0% (w/w) with vegetable oil with water emulsion during milling and found better surface finish than conventional cutting fluid. Kumar et al. [22] developed a nanofluid by using multi-walled nano carbon tubes in sunflower by 1% (w/w). The experimentation was performed on a tirbometer and grinder. It was found that tribological properties got improved as compared to a conventional cutting fluid. Amrita et al. [23] prepared various samples of nanofluids by using nanoboric acid, nano molybdenum disulphide with emulsion 0.3% (w/w). It was found that functionalised nano graphite showed good stability in oil emulsion. Sharma et al. [24] prepared different types of samples of nano-cutting fluids with Al_2O_3(0,0.25, 0.5,1.5,2.0 and 3 %) (v/v) with deionised water and found that with 1% composition gave a better performance during turning operations as compared with other compositions. Ramakrishanan et al. [25] found that marginal difference in surface roughness between experimentation performed on lathe machine during 0.5% and 1.0% (w/w) Al_2O_3 nanoparticles with inonized water as coolant. The tool wear was lower with 1.0% (w/w) nano-cuttig fluid as compared to dry and 0.5% (w/w) concentration of Al_2O_3. It was found that very limited literature work is available with the rheological property of nanocuting fluid.The novelty of this research work is that an attempt has been made to focus on characterization of nanoparticles, prepared nano-cutting fluid and the rheological property of nano-cutting fluid like viscosity has been analysed with time period of constant shear rate at two different temperatures like room temperature 25°C and 65°C and compared with conventional cutting fluid. The highly viscous cutting fluids may not be suitable for machining as they may not be able to reach properly at the interface of workpiece and cutting tool and very lean cutting fluid may not provide a good lubricating and cooling effect. The thermal conductivity of nano-cutting fluid was measured and compared with conventional cutting fluid. Therefore, nano-cutting fluids with Al_2O_3 and TiO_2 were prepared characterized and analysed for viscosities at a different temperature

Experimental Methodology

Two different types of nanoparticles like (α-Al_2O_3) alpha-alumina and titanium dioxide (TiO_2) were procured from the manufacturers M/S Plasma ChemGmbH, Berlin, Germany. The nanoparticles are water-soluble. The properties of nanoparticles are given in Table 1. The purity index of nanoparticles was very high in terms of percentage for both the selected nanoparticles.

Table 1. Properties of nanoparticles

S No.	Properties	Nano-Al_2O_3	Nano-TiO_2
1	Average grain size	40nm	8nm
2	Particle size full range	5-100nm	8-25nm
3	Purity	99.99%	99.98%
4	Specific surface	> 10 m^2/g	50±10 m^2/g

The composition was formed by considering the weight by weight ratio with base fluid. In present research work base fluid was distilled water. The empty beaker was weighted on weighing scale. Then scale reading was made zero. The beaker was filled with distilled water and weighed on a scale. Now, nanoparticles were weighed on micro-scale in proportionate to 1% weight of water and mix in beaker.

Nanoparticles of TiO_2 were weighed on micro digital balance with an accuracy of ±0.0001grams. A sample of nano-cutting fluid was made with distilled water in the proportion weight of 1% (weight by weight) of distilled water. Figure. 1 shows a magnetic stirrer for blending of nano-cutting fluid for 60 minutes at 520 rpm at 21°C and rest was given for half an hour. Rest was given for half an hour for checking the sedimentation. The process of magnetic stirring was repeated for 60 minutes. This process was repeated 4-5 times.

Figure 1. Magnetic stirrer for nano-cutting fluid with nanoparticles TiO_2

Ultrasonification was performed by a water bath ultrasonicator. It was operated with single-phase electric supply at 200-230Voltsat 50Hz as depicted in Figure. 2. One litre distilled water was used for filing the water bath container. 30k Hz utrasonfication waves were generated. Initially, ultrasonification was performed for 30minutes. The rest of five minutes was given. Then it was repeated for five times. Visual inspection did not show any sedimentation. Zeta potential test was conducted. The value was 32 which was in a stable range.

Nanoparticles of Al_2O_3 were weighed on micro digital balance with an accuracy of ±0.0001grams. A sample of nano-cutting fluid was made with distilled water in the proportion weight of 1% (weight by weight) of distilled water. Magnetic stirring was done for blending of nano-cutting fluid for 60 minutes at 520 rpm at 21°C and rest was given for half an hour. This was repeated 4-5 times and the rest was given overnight for checking any sedimentation. Most of the surfactant used by previous researchers was sodium-based. Tween-20 Biocompatible surfactant has been found, which is non-toxic. Initially, 0.25% was mixed with nano-cutting fluid. Further, it was increased to 1% (weight by weight) of prepared nano-cutting fluid. Magnetic stirring was done at 520rpm at 21°C for 60 minutes. Then ultrasonication was done for 30 minutes and repeated 4-5 times. Zeta potential test was done and value was 21 which was in the stability range.

The sample was prepared (w/w) in the ratio of 1:20. 1 part of conventional cutting oil and 20 parts of distilled water. This composition is used during machining processes like turning, milling, grinding, drilling etc.

The thermal conductivity of different cutting fluids was measured by hot wire (KD2 thermal properties analyse, Decagon devices, Inc. USA). The experiment of measuring thermal conductivity of every cutting fluid was repeated five times and an average was calculated for finding out the final value.

Each sample was kept by a dropper at the cup and hob of Rheometer in the enclosed chamber. The temperature was adjusted at room temperature at 25°C and readings were noted for viscosity at the shear rate of 100/second for the time period of 125 seconds. The cup and hob were cleaned by acetone soaked paper. After leaving for drying for some time place another sample of nao-cutting fluid was placed and the chamber was closed and temperature was adjusted to 25°C another sample. Similarly, the samples of nano cutting fluids of Al_2O_3 TiO_2 and conventional cutting fluid were placed and analysed at 65°C.

RESULTS AND DISCUSSION

The characterization of nanoparticles Al_2O_3 was done by SEM and EDS images as shown in Figure. 2(a) and (b) at 100µm.Fig. 2 (b) shows high peaks of aluminium and oxygen. It was found that the percentage oxygen was more. The percentage of oxygen and aluminium in weight was depicted as 52.673% and 47.327% respectively.

Figure 3. (a) SEM image and (b) EDS of nanoparticles Al_2O_3

The characterization of nanoparticles TiO_2 was done by SEM and EDS images as shown in Figure. 4 (a) and (b) respectively with high peaks of titanium and oxygen. It has been shown that percentage of titanium was more. Comparatively, oxygen was progressively lower. The percentage of titanium and oxygen in weight as 49.360% and 50.640%.

It has been shown in Figure. 7 that highest peak of Al_2O_3 was observed at 1100-1200 Raman shift /cm^{-1} for 380counts. This confirmed the presence of Al_2O_3. Another peak was observed at 2200-2300 Raman shift /cm^{-1} for 100counts.

Figure. 8 depicts that the highest peak was observed at 1200-1300 Raman shift /$cm^{-1}$for 980counts. This confirmed the presence of TiO_2 in the prepared nano-cutting fluid. Another high peak was observed at 3200-3300Raman shift /cm^{-1} for 450counts.

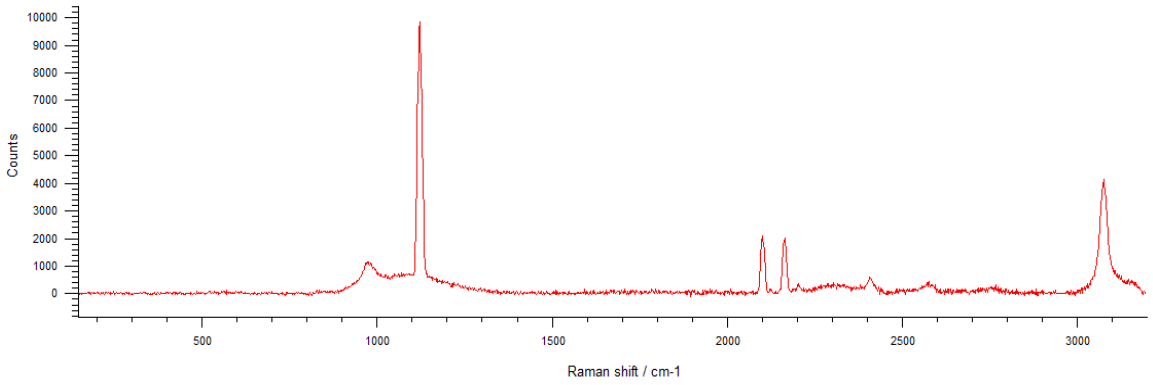

Figure. 8. Raman shift pattern for TiO_2 in prepared nano-cutting fluid

Figure. 8 depicts that the highest peak was observed at 1200-1300 Raman shift /$cm^{-1}$for 980counts. This confirmed the presence of TiO_2 in the prepared nano-cutting fluid. Another high peak was observed at 3200-3300Raman shift /cm^{-1} for 450counts.

It has been depicted in Figure. 9 that at the initial start of rheometer till first 20 seconds the viscosities of AA, TT and CC was higher than respective viscosities at the end of 125 seconds at the shear rate of 100/seconds at 25°C. On comparing the viscosity of nano-cutting fluids AA, TT with CC it was found that viscosity was declined by 91.92 and 90.81% respectively at the viscosity obtained at the end of 125 seconds. In Fig. 10, it was found that viscosities declined at the end of 125 seconds. On comparing the viscosity of nano-cutting fluids AA, TT with CC it was found that viscosity was declined by 94.02 and 86.19% respectively at the velocity obtained the end of 125 seconds at 65°C. On comparing both the Figures. 9 and 10 it was found that respective viscosity of nano-cuting fluids and cutting fluid were lower at higher temperature at 65°C due to weaker intermolecular forces.

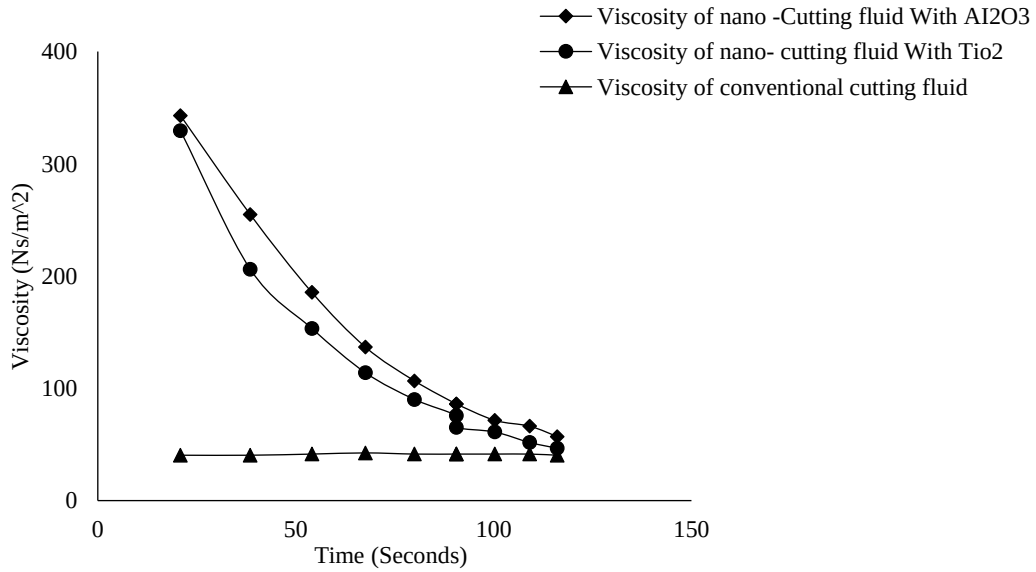

Figure 9. Visocity of cutting fluids with time at room temperature 25°C

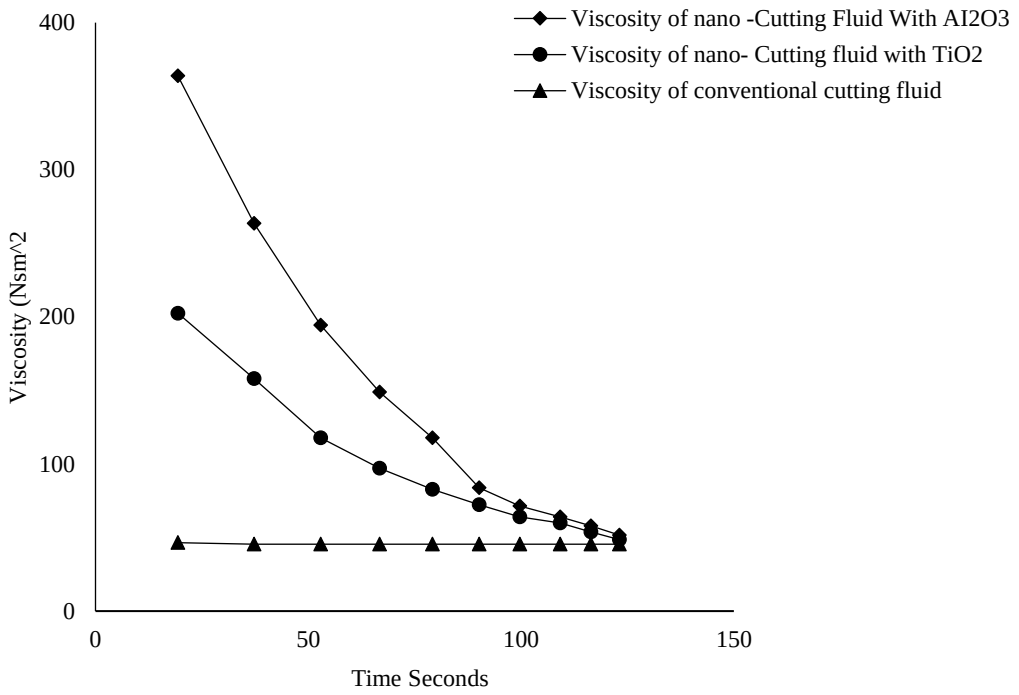

Figure 10. Viscosity of cutting fluids with time at 65°C

The thermal conductivity of cutting fluids was found to be more at higher temperature of 65°C on comparing with temperature of 25°C as depicted in Figure. 10. The thermal conductivity was enhanced by 7.42, 10.91 and 8.42 % respectively for CC, AA and TT at higher temperature of 65°C. The inclination in thermal conductivity was higher for nano-cutting fluid with Al_2O_3 due to the property of material.

CONCLUSIONS

The nano-cutting fluids were prepared from two distinct nanoparticles and after characterization the samples were testes for change in viscosities on a dedicated rheometer. The following conclusions were summarized.

1. Biocompatible surfactant was used during the preparation of nano-cutting fluid with Al_2O_3.
2. The temperature influenced the viscosity of prepared nano-cutting fluids.
3. The viscosity of nano-cutting fluids and conventional cutting fluids declined with the increasing time period at shear rate of 100/second.
4. The viscosity of nano-cutting fluids and cutting fluids declined with increasing temperature.
5. The nano-cutting fluid with Al_2O_3 depicted more stability in viscosity change.
6. The thermal conductivities increased during higher temperature.
7. The thermal conductivity of nano-cutting fluid with Al_2O_3 was higher than other cutting fluids.

Abstract

This article offers a novel flux controlled floating memristor emulator based on second-generation current conveyor (CCII). The floating memristor is designed using two CCIIs, one resistor, and one PMOS transistor. The presented memristor emulator does not need external capacitance. The proposed designed circuit exhibits pinch hysteresis loops in voltage–current plane up to 2 GHz frequency. The performance of the circuit under consideration is evaluated using 180 nm CMOS technology parameter by the SPICE simulator. The circuit requires a DC power supply of ±1.2 V and exhibits a power consumption of 0.766 mW. Furthermore, the resilience of the planned circuit is assessed by examining process corner fluctuation, supply voltage variation, temperature variation, and transistor size variations. In addition, a Schmitt trigger circuit and high order filters based on designed memristor are used to confirm the operation of the proposed design at high and low frequency, respectively.

KEYWORDS

memristor, non-volatile nature, pinch hysteresis loop, Schmitt trigger circuit, second-generation current conveyor (CCII)

1 | INTRODUCTION

Leon O. Chua introduces memristor as the fourth circuit element after the capacitor, inductor, and resistor in 1971.[1] The memristor is recognized as a nonlinear resistor with memory, serving as a crucial component that establishes a connection between flux and charge.[2] The memristor has desirable characteristics such as configurable resistance and memory functionality. Additionally, memristor has the ability to retain their prior state even in the absence of power, thereby exhibiting a non-volatile property.[2] A memristor may be used in cellular networks,[3] sensors,[4] chaotic circuit,[5,6] signal processing,[7–9] digital logic,[10] and neuromorphic systems.[11] Recently, various remarkable efforts have been undertaken to develop resilient memristor models for commercial applications, including spintronic memristors,[12] organic memristors,[13] carbon nanotube,[14] and amorphous silicon memristors.[15] However, these models are constrained by limits pertaining to cost, manufacturing, and performance. Hence, researchers put their effort to design a memristor emulator using active building block (ABB). The memristor developed by ABB has a comparatively low cost and easy to fabricate.

ABB-based memristor emulators have been described in a variety of research papers published in recent years.[16–43] Memristor circuits developed in previous studies[16,17] are based on programmable analog circuits. It consists of a digital potentiometer, a microprocessor, and an analog-to-digital converter (ADC). Despite this, performance is restricted due

 © 2024 John Wiley & Sons Ltd.

to the limiting resolution of the digital potentiometer. Fitch et al.[18] presented a memristor emulator circuit that was based on the light-dependent resistor (LDR). This circuit is made up of three operational amplifiers, 11 resistors, one LDR, one capacitor, and one diode. The performance of the memristor was hindered by LDR characteristics while operating at higher frequencies. By integrating four current feedback operational amplifiers (CFOA), two diodes, four resistors, and four capacitors, Abuelama'atti and Khalifa[19] were able to develop a memristor that was easy to use and had a wide range of applications. A voltage-controlled resistor (VCR) constructed with six resistors, two capacitors, two operation amplifiers (op-amps), and an NMOS transistor, together with a second-generation current conveyor (CCII), and an external capacitor are components that make up the memristor circuit that was developed by Hussein and Fouda.[20] An off-the-shelf floating memristor was proposed by Sozen and Cam,[21] and it is comprised of four CCIIs, three OTAs, one capacitor, and six resistors. It is necessary to use an additional voltage source in order to bias the current of one of the OTAs. Valsa et al.[22] designed a memristor employing five Op-amps, 14 resistors, one JFET, and one capacitor. To function properly, many memristor emulators[23–32] need additional circuits, like a multiplier circuit, in addition to both active and passive components. It is possible that the adoption of additional circuits will increase the complexity of the memristor circuit while simultaneously lowering the frequency at which it operates. The floating memristor described in this article[33] does not have any multiplier circuits; hence, it just has a single grounded capacitor and two OTAs. In spite of this, it is operated up to 400 kHz frequency. The voltage inverting metamutator (VIM) was developed by Arundeepakvel et al.[34] One VIM, one diode, two resistors, one capacitor, and one inductor make up its constituent parts. According to the literature, circuits that are based on passive inductors are both cumbersome and costly. The fact that the memristor emulators described in literature[35,36] make use of a variety of bias voltages makes it essential to have a layout of a high quality for their production.[33] To put this into perspective, the floating memristor emulator described in Vista and Ranjan[37] only requires one voltage difference transconductance amplifier (VDTA), one capacitor, and one resistor in order to operate up to 50 MHz. Further, Kumar et al. developed floating memristor[38] utilizing one dual-x current conveyor transconductance amplifier (DXCCTA), four resistors, and one grounded capacitor. It is able to operate up to 60 MHz. In addition, the floating memristor that is discussed in Ranjan et al.[39] has a maximum operating frequency of 10 MHz. There is one grounded capacitor, one current conveyor transconductance amplifier (CCTA), and three resistors utilized in the design of the emulator. A current-differencing transconductance amplifier (CDTA) and OTA were used in the construction of a floating memristor, which was described in Yadav et al.[40] It is possible to operate at a frequency of up to 1 MHz in incremental and decremental mode by making just minor adjustments to the design. A grounded memristor emulator may be found in the research literature.[41–43] The findings of the study indicate that grounded memristors are not desirable for use in complex circuits.[37,39]

It is observed from above literature that most of the reported memristor circuit employ parallel plate capacitor and additional circuit that leads to reduce in maximum operating frequency. There are a limited number of memristor emulators available that do not use analog multipliers and passive resistors. These emulators often include a hysteresis loop that is restricted to frequencies within the kilohertz range. Few memristors are designed for grounded mode of operation, which are not suitable for complex applications. This article aims to develop a capacitorless floating memristor emulator using two CCIIs, one resistor, and one PMOS transistor. The maximum operating frequency of the proposed memristor is 2 GHz. In addition, the proposed circuit is free from addition circuits like analog multiplier circuits, passive capacitor, diodes, LDR, passive inductor, and ADC, which is desirable in terms of the integration viewpoint. Further, memristor-based high-order high-pass filter circuit, memristor-based high-order low-pass filter circuit, and memristor-based Schmitt trigger circuit are implemented by the proposed memristor emulator. The subsequent sections of the article are structured in the following manner: Section 2 presents the circuit description of the proposed circuit. Simulation results of designed memristor emulators are presented in Section 3. Comparative study of the designed memristors with existing ABB based memristors is discussed in Section 4. Section 5 reports applications of the designed circuits. Finally, Section 6 contains the paper's conclusion.

2 | CIRCUIT DESCRIPTION

This section presents a basic overview of CCII. Following that, the proposed capacitorless floating memristor circuit is explained.

2.1 | Second generation current conveyor (CCII)

Second generation current conveyor (CCII) is a basic current-mode ABB. It provides wide dynamic range, high linearity, and high frequency performance as compared to performances of voltage mode ABB counterparts. Circuit symbol and CMOS structure of CCII are given in Figure 1A,B, respectively. Figure 1 shows that CCII has three ports, namely, X, Y, and Z. Port relations of the CCII are given as follows.

$$I_X = I_Z; V_X = V_Y; I_Y = 0 \tag{1}$$

It is observed from Equation (1) that the voltage at Y port is conveyed to X port while current fed into X port is conveyed to Z port.

2.2 | Proposed floating memristor emulator

Schematic of designed floating memristor is demonstrated in Figure 2. It consists of two CCIIs, one resistor and one PMOS transistor. The designed circuit utilizes parasitic capacitance (C_g) associated at gate terminal of M_P. CCIIs, resistor, and parasitic capacitance are the components of the feedback network. The memristor current passes through the transistor (M_P) is controlled by the feedback network.

In practice, CCIIs consist parasitic components at input and output terminals. Hence, the proposed floating memristor with parasitic components is depicted in Figure 3.

Figure 3 shows the parasitic components. R_{z1} and C_g are parasitic resistance at Z_1 terminal of CCII and capacitance associated at gate terminal of transistor M_P, respectively. The capacitance C_g is the equivalent capacitor of parasitic capacitances at the gate terminal of PMOS including C_{z1}, C_{gdP}, C_{gsP}, and C_{gbP}. Now, the maximum capacitance at gate terminal of M_P may be expressed as

$$C_g = C_{z1} + W_P L_P C_{OX} + C_{gsov} + C_{gdov} \tag{2}$$

where W_P, L_P, Cox, C_{gsov}, and C_{gdov} are channel width, channel length, oxide capacitance (per unit area), gate-source overlap capacitance, and gate-drain overlap capacitance, respectively. Now, using Sedra et al.,[44] we can derive the values for C_{gdP} and C_{gsP} as

$$C_{gsov} = C_{gdov} = W_P L_{OV} C_{OX} \tag{3}$$

Now, substitute Equation (3) into Equation (2), we obtain following expression of C_g as

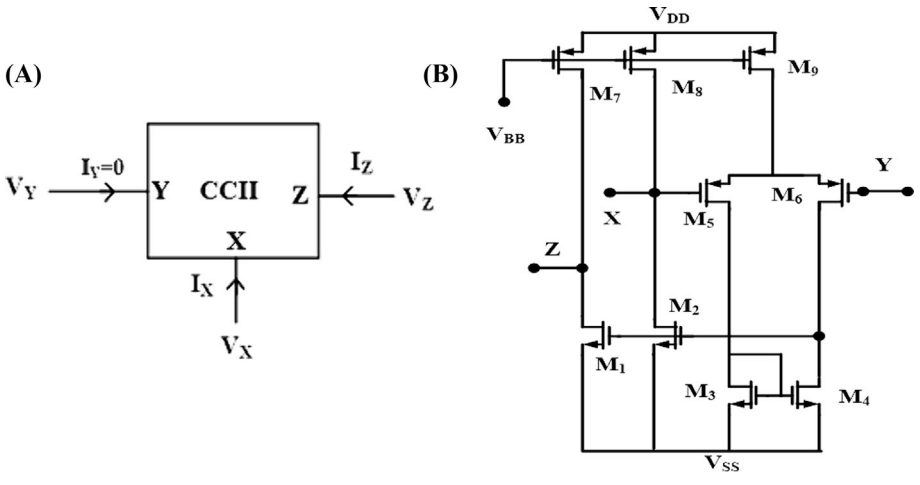

FIGURE 1 CCII circuit. (A) Symbol and (B) CMOS structure.

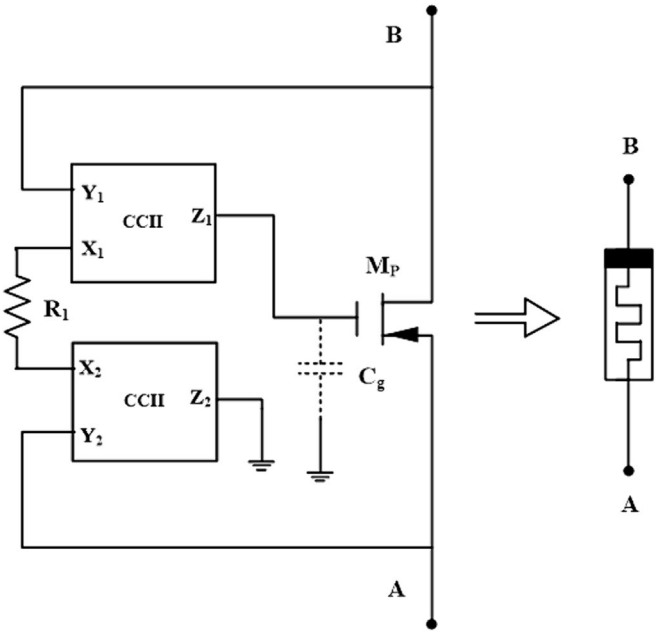

FIGURE 2 Proposed floating memristor circuit.

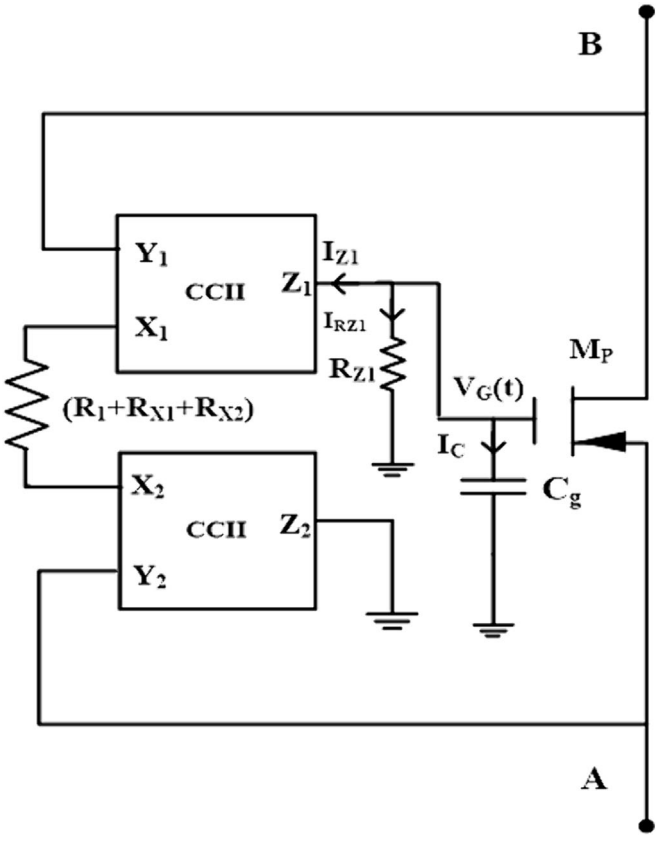

FIGURE 3 Proposed memristor circuit with parasitic components.

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4175 by Delhi Technological University, Wiley Online Library on [05/08/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$C_g \cong C_{z1} + W_P L_P C_{OX} + 2W_P L_{OV} C_{OX} \tag{4}$$

Substitute the value of $C_{OX} = \frac{\varepsilon_{ox}}{t_{ox}}$ in Equation (4); thus, expression of C_g may be expressed as

$$C_g = C_{z1} + W_P L_P \left(\frac{\varepsilon_{ox}}{t_{ox}}\right) + 2W_P L_{OV} \frac{\varepsilon_{ox}}{t_{ox}} \tag{5}$$

where t_{ox} and ε_{ox} are thickness of the oxide layer, and permittivity of the silicon oxide, respectively. Now, expression of $I_C(t)$ may be derived from from Figure 3 as

$$I_C(t) = -(I_{Z1} + I_{RZ1}) \tag{6}$$

The magnitude of current flows through I_{Z1} and I_{ZR1} of the proposed circuit may be expressed as follow.

$$I_{Z1} = \frac{V_{in}(t)}{(R_1 + R_{X1} + R_{X2})} \tag{7}$$

$$I_{ZR1} = \frac{V_G(t)}{R_{Z1}} \tag{8}$$

Substitute the values of I_{Z1} and I_{ZR1} in Equation (6), we get following expression of $I_C(t)$ as

$$I_C(t) = -\frac{V_{in}(t)}{(R_1 + R_{X1} + R_{X2)}} - \frac{V_G(t)}{R_{Z1}} \tag{9}$$

Substitute $I_C(t) = C_g \frac{dV_G(t)}{dt}$ in Equation (9), we get following expression as

$$\frac{dV_G(t)}{dt} = -\frac{V_{in}(t)}{C_g(R_1 + R_{X1} + R_{X2)}} - \frac{V_G(t)}{C_g R_{Z1}} \tag{10}$$

Rearrange the first-order differential equation as given in Equation (10) as

$$\frac{dV_G(t)}{dt} + \frac{V_G(t)}{C_g R_{Z1}} = -\frac{V_{in}(t)}{C_g(R_1 + R_{X1} + R_{X2)}} \tag{11}$$

Now, integrating factor (IF) may be obtained from Equation (11) as

$$IF = e^{\int \frac{1}{C_g R_{Z1}} dt} = e^{\left(\frac{t}{C_g R_{Z1}}\right)} \tag{12}$$

Now, solution of Equation (11) may be expressed as

$$V_G(t) e^{\left(\frac{t}{C_g R_{Z1}}\right)} = \left\{ -\frac{1}{C_g(R_1 + R_{X1} + R_{X2})} \int V_{in}(t) e^{\left(\frac{t}{C_g R_{Z1}}\right)} dt \right\} + c \tag{13}$$

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4175 by Delhi Technological University, Wiley Online Library on [05/08/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

where c is integration constant. Let $V_{in}(t) = V_m Sin\omega t$ where V_m represents the amplitude of the input voltage and ω represents the angular frequency; then, flux is $\varphi(t) = \int V_{in}(t)dt = -\frac{V_m Cos\omega t}{\omega}$, and $V_G(t)$ may be written as

$$V_G(t)e^{\left(\frac{t}{C_g R_{Z1}}\right)} = \left\{-\frac{V_m}{C_g(R_1 + R_{X1} + R_{X2})}\int Sin\omega t e^{\left(\frac{t}{C_g R_{Z1}}\right)}dt\right\} + c \tag{14}$$

Now, let $I = \int Sin\omega t e^{\left(\frac{t}{C_g R_{Z1}}\right)}dt$, then I can be found as

$$I = \int Sin\omega t e^{\left(\frac{t}{C_g R_{Z1}}\right)}dt = \frac{e^{\frac{t}{C_g R_{Z1}}}\left(C_g R_{Z1} Sin\omega t - \omega\left(C_g R_{Z1}\right)^2 Cos\omega t\right)}{1 + \omega^2\left(C_g R_{Z1}\right)^2} \tag{15}$$

Now, substitute the value of I in Equation (14), we get following expression of $V_G(t)$ as

$$V_G(t) = -\frac{V_m}{C_g(R_1 + R_{X1} + R_{X2})}\left\{\frac{C_g R_{Z1} Sin\omega t - \omega\left(C_g R_{Z1}\right)^2 Cos\omega t}{1 + \omega^2\left(C_g R_{Z1}\right)^2}\right\} + ce^{-\left(\frac{t}{C_g R_{Z1}}\right)} \tag{16}$$

If input angular frequency $\omega \gg \frac{1}{C_g R_{Z1}}$, then expression of $V_G(t)$ may be rewritten as

$$V_G(t) = \frac{V_m Cos\omega t}{\omega C_g(R_1 + R_{X1} + R_{X2})} + ce^{-\left(\frac{t}{C_g R_{Z1}}\right)} \tag{17}$$

Now, $\frac{V_m Cos\omega t}{\omega}$ is known as $-\varphi(t)$; thus, $V_G(t)$ may be expressed in terms of $\varphi(t)$ as

$$V_G(t) = -\frac{\varphi(t)}{C_g(R_1 + R_{X1} + R_{X2})} + ce^{-\left(\frac{t}{C_g R_{Z1}}\right)} \tag{18}$$

Since the value of $\frac{1}{C_g R_{Z1}}$ is high, $e^{-\left(\frac{t}{C_g R_{Z1}}\right)}$ term decays quickly towards zero; thus, Equation (18) may be rewritten as

$$V_G(t) \cong -\frac{\varphi(t)}{C_g(R_1 + R_{X1} + R_{X2})} \tag{19}$$

Since transistor M_P is used in the linear region, thus, current $i_D(t)$ of transistor M_P is written as follows:

$$i_D(t) = \mu_P C_{OX}\left(\frac{W}{L}\right)_P\left\{\left(v_{SGP} - \left|V_{Tp}\right|\right)v_{SDP} - \frac{V_{SDP}^2}{2}\right\} \tag{20}$$

By substituting $V_G(t) = -\frac{\varphi(t)}{C_g(R_1 + R_{X1} + R_{X2})}$, $V_A(t) = \frac{v_{in}(t)}{2}$, and $V_B(t) = -\frac{v_{in}(t)}{2}$ in Equation (20), expression for drain current may be obtained as follows:

$$i_D(t) = \mu_P C_{OX}\left(\frac{W}{L}\right)_P\left\{\left(\frac{V_{in}(t)}{2} + \frac{\varphi(t)}{C_g(R_1 + R_{X1} + R_{X2})} + V_{Tp}\right)V_{in}(t) - \frac{V_{in}^2(t)}{2}\right\} \tag{21}$$

The expression for the drain current, denoted as $i_D(t)$, of the constructed memristor emulator for small inputs $V_{in}(t)$ may be expressed in a simpler form as

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4175 by Delhi Technological University, Wiley Online Library on [05/08/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$i_D(t) = \mu_P C_{OX}\left(\frac{W}{L}\right)_P\left(\frac{\varphi(t)}{C_g(R_1+R_{X1}+R_{X2})}+V_{Tp}\right)V_{in}(t) \tag{22}$$

Thus, we may create the memductance $(w(\varphi(t)))$ of the designed circuit as

$$w(\varphi(t)) = \frac{i_D(t)}{V_{in}(t)} = \mu_P C_{OX}\left(\frac{W}{L}\right)_P\left(\frac{\varphi(t)}{C_g(R_1+R_{X1}+R_{X2})}+V_{Tp}\right) \tag{23}$$

More investigation into the frequency analysis of the suggested memristor emulator may be conducted recalling that $\varphi(t) = -\frac{V_m \text{Cos}\omega t}{\omega}$ and substituting into Equation (23) the memductance $w(\varphi(t))$ may be derived as

$$w(\varphi(t)) = \underbrace{\left\{\mu_P C_{OX}\left(\frac{W}{L}\right)_P V_{Tp}\right\}}_{\text{Linear time invarient part}} + \underbrace{\left\{\mu_P C_{OX}\left(\frac{W}{L}\right)_P \frac{V_m}{(R_1+R_{X1}+R_{X2})C_g\omega}\text{Cos}(\omega t-\pi)\right\}}_{\text{Linear time varient Part}} \tag{24}$$

Now, we may derive the ratio of amplitudes of linear time-variant part to linear time-invariant part as

$$\alpha = \frac{V_m}{V_{Tp}(R_1+R_{X1}+R_{X2})C_g\omega} \tag{25}$$

where α of the developed memristor depends upon amplitude of the input signal, threshold voltage of M_P, passive resistance, parasitic resistances, input angular frequency, and parasitic capacitance. From (25), it is obvious that for high frequencies of operation, α is decreased, and memductance value is dominated by the linear time-invariant part; thus, the hysteresis curve is converted to a simple straight line acting similar to a linear resistor.

3 | SIMULATION RESULTS AND DISCUSSIONS

A comprehensive examination of the designed capacitorless memristor is conducted by SPICE simulator, using 180 nm technology. The supply voltage is selected to be ±1.2 V. The aspect ratio of transistor M_1, M_2, M_3, M_4, M_5, M_6, M_7, M_8, M_9, and M_P is $\frac{2.4\,\mu m}{0.18\,\mu m}$, $\frac{2.4\,\mu m}{0.18\,\mu m}$, $\frac{0.65\,\mu m}{0.18\,\mu m}$, $\frac{0.65\,\mu m}{0.18\,\mu m}$, $\frac{0.35\,\mu m}{0.18\,\mu m}$, $\frac{0.35\,\mu m}{0.18\,\mu m}$, $\frac{2.4\,\mu m}{0.18\,\mu m}$, $\frac{2.4\,\mu m}{0.18\,\mu m}$, $\frac{2.4\,\mu m}{0.18\,\mu m}$, and $\frac{50\,\mu m}{0.18\,\mu m}$, respectively. The bias voltage (V_{BB}) is set at a value of 0.42 V. Current and voltage ratio of CCII are depicted in Figure 4. In order to design the memristor, passive component is selected as $R_1 = 10\ k\Omega$. Now, a device is considered to be a memristor if it possesses the following three fingerprints.[45] (1) "When driven by a bipolar periodic signal the device must exhibit a pinch

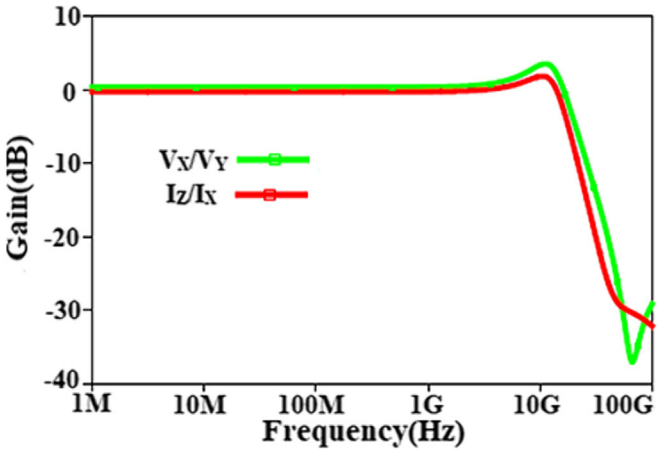

FIGURE 4 Frequency response of CCII.

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4175 by Delhi Technological University, Wiley Online Library on [05/08/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hysteresis loop in the voltage-current plane, assuming the response is periodic." (2) "Starting from critical frequency, hysteresis loop area should decrease monotonically as the exciting frequency increases." (3) "The pinch hysteresis loop should shrink to a single valued function when frequency tends to infinity." First fingerprint of the offered memristor is displayed in Figure 5A–H. It illustrates the progressive transformation of the pinch hysteresis loop (PHL) of the memristor under consideration, spanning the frequency range of 25 MHz to 2 GHz. Figure 5A–H is also depicting that the current passing across the memristor tends to approach zero as the input voltage is reduced to 0. The second and third fingerprints of the designed memristor are displayed in Figure 5E–H. Figure 5E–H shows that when the frequency of the applied signal increases from 200 MHz, there is a reduction in the area of the lobes seen in the PHL curve.

Given that the memristor is classified as a resistor, it can be inferred that the phase difference between the input current and input voltage is zero. The transient response of the memristor emulator under consideration, operating at a frequency of 200 MHz, is shown in Figure 6. The observation demonstrates that the magnitude of the input current is zero when the differential input voltage reaches zero.

The memristor circuit under consideration exhibits temperature-dependent variations in its current during practical implementation. Hence, the impact of temperature fluctuations ranging from −45°C to +90°C on the PHL of the

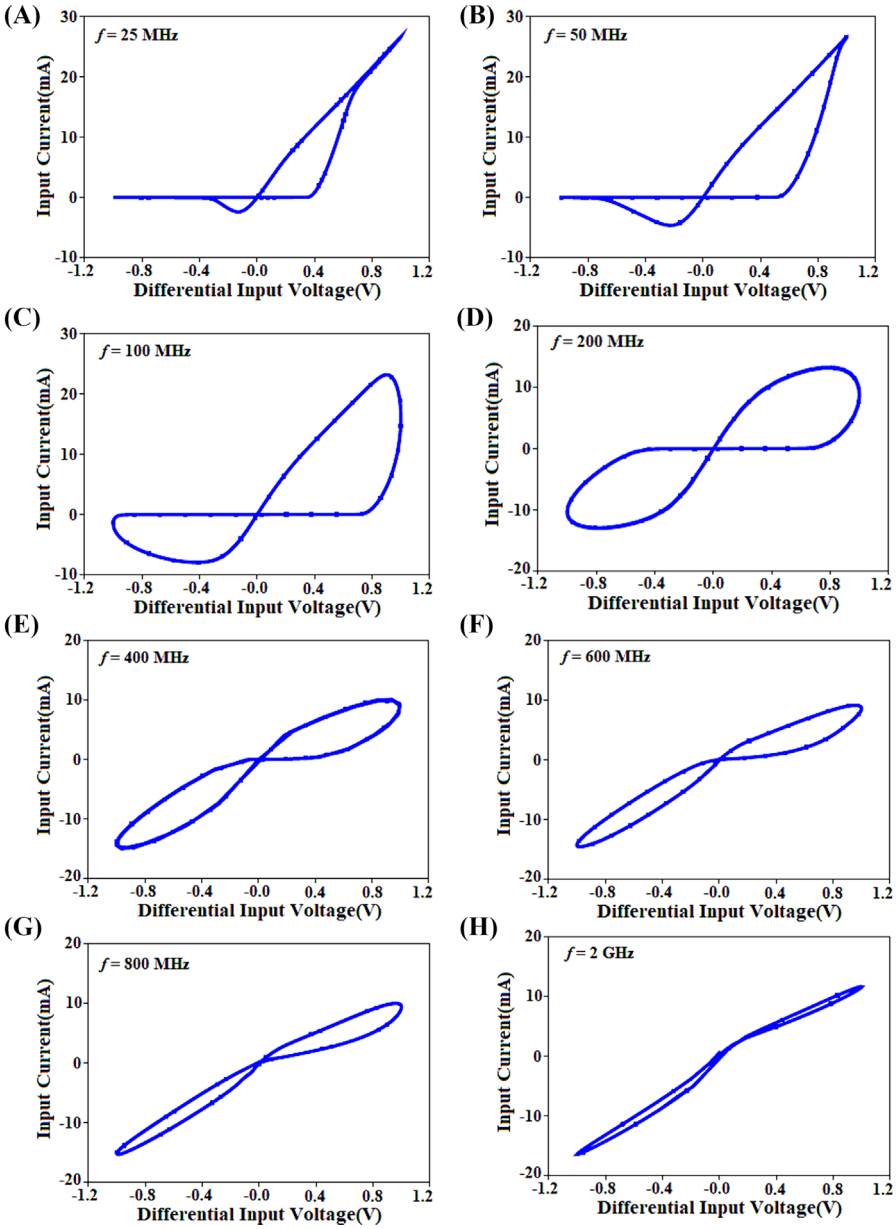

FIGURE 5 PHL for the frequency range 25 MHz to 2GHz.

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4175 by Delhi Technological University, Wiley Online Library on [05/08/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

memristor at a frequency of 200 MHz is shown in Figure 7. The observed phenomenon indicates that there is a drop in memristor current as temperatures rise, which may be attributed to a loss in carrier mobility. Further, Figure 8 shows the PHL of the proposed memristor at frequency of 200 MHz for various aspect ratios of the transistor M_P. It shows that the amount of current going through the memristor change from 6.15 to 25.96 mA as the aspect ratio of the transistor M_P goes up (30 μm/0.18 μm to 90 μm/0.18 μm).

The performance of the presented memristor emulator may be varied by the fluctuations in the bias voltage (V_{BB}) of CCII. Hence, Figure 9 shows the V-I characteristics of the developed memristor when the V_{BB} shifts from +0.35 to +0.45 V. Figure 9 is also depicting that increasing in the bias voltage from +0.35 to +0.45 V results change in input current between 13.3 and 15.4 mA.

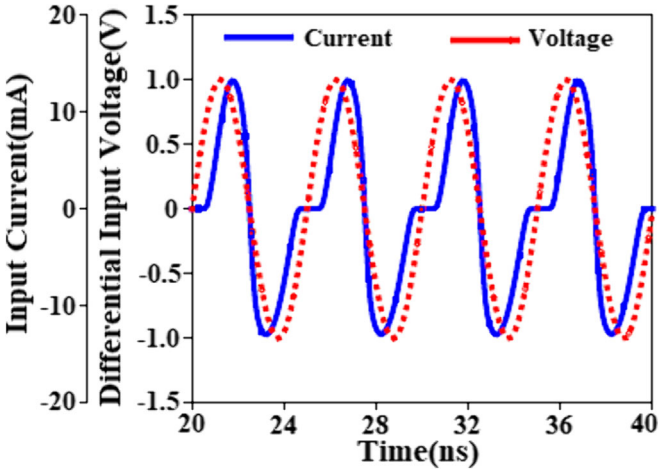

FIGURE 6 Transient response of the memristor at 200 MHz frequency.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The efficient operation of the planned memristor might be hampered due to fluctuations in the DC power supply. So, Figure 10 shows the suggested memristor's V-I characteristics curve when the supply voltage shifts from ±1.1 to ±1.3 V. Figure 10 displays that increasing in the supply voltage from ±1.1 to ±1.3 V results deviations in input current between 11.1 and 15.06 mA.

In monolithic integration, process corner has a major impact on how well the proposed circuit works. It has been meticulously examined in the slow slow (SS), fast fast (FF), and nominal nominal (NN) process corners. The PHL at different process corner of the presented circuit are depicted in Figure 11. The process, voltage, and temperature (PVT) variations are achieved by changing the supply voltage and temperature between (±1.1 to ±1.3 V) and (−45°C to

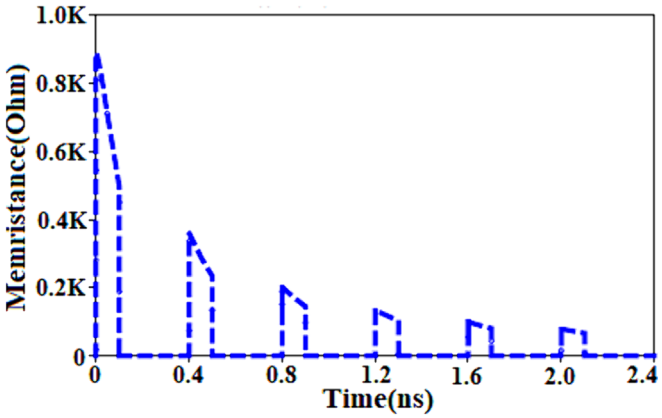

FIGURE 12 Memristance of the memristor.

+90°C) respectively. Figure 11 shows that the current through a memristor in SS mode is less than the current through the same device in FF mode. The proposed memristor exhibits a constricted PHL in each process corner, despite the fact that the hysteresis loop may exhibit some small-area fluctuation.

In addition to the PHL, the non-volatility of memristance is a distinguishing characteristic of the memristor emulator. The memristor has the potential to retain its programmed memristance value for a prolonged period even if no input signal is present. Figure 12 displays the memristance of the designed memristor circuit. This response is obtained by providing a pulse signal with amplitude of 1 V, having a pulse width of 100 ps, and time period of 400 ps has been applied at the input of the floating memristor. Figure 12 illustrates that a small amount of variation of memristance in ON period of pulse due to non-idealities associated with CCII.

4 | COMPARISON

Table 1 illustrates a comparative study between the performances of the designed memristor emulator and an existing memristor emulator. The comparison is conducted based on many factors, including the number of active blocks, the number of passive components, the technology node, power dissipation, supply voltage, need of passive capacitor, the mode of operation, and the maximum operating frequency.

There are following conclusion may be drawn from Table 1 as follows:

a. The memristor emulator reported in previous studies[18–43] utilizes parallel plate capacitor. In opposite, the proposed memristor uses parasitic capacitor.
b. The memristor emulator described in previous works[18,19,23–32,34] includes addition circuit such as diodes, LDR, inductor, and multiplier circuits, which may reduce the maximum operating frequency. However, the designed memristor emulator is free from additional circuits.
c. Power consumption in realization of memristor reported in literature[38,39,42,43] are 4, 7.5, 2.6, and 9.56 mW, respectively. However, the designed topology of memristor consumes 0.766 mW power.
d. The memristor emulator suggested in previous works[18,22,23,25–28,30–32,34,35,40–43] realize for grounded mode of operation. In opposite, the proposed circuit may be used in floating mode of operation.
e. Excessive active (more than 2) and passive components are utilized in the topology of memristor emulators presented in literature.[18–24,30,31] In contrast, the proposed memristor circuit employs two CCIIs and one floating resistor.
f. The memristor emulator presented in previous studies[21,26,28,29,32,35,36,38–41,43] requires OTA circuit. OTA restricts the operating frequency of the designed memristor at upper frequency range. However, the proposed circuit does not utilize OTA.
g. Maximum operating frequency achieved in literature[18–36,40,41] are within 10 MHz. In distinction, maximum operating frequency of the designed floating memristor circuit is 2 GHz.

5 | APPLICATIONS

The operation of the memristor emulators suggested in this study has been evaluated via several applications: (1) Schmitt trigger circuit using flux controlled memristor, (2) low pass filter using designed memristor, and (3) high pass filter using designed memristor.

5.1 | Schmitt trigger circuit using proposed flux controlled memristor

Schmitt trigger circuit is usually used to get rid of noise in digital circuits as part of signal shaping. It is also used for conversion of analog input signal to digital signal. Figure 13 illustrates a memristor-based Schmitt trigger circuit, serving as an exemplification of the intended memristor. The circuit configuration comprises a single operational amplifier, suggested memristor, and a floating resistor. Now, the higher and lower threshold voltages of a Schmitt trigger may be mathematically represented as:

$$V_{TH} = +V_{Sat}\frac{R_M}{R_2} \tag{26}$$

$$V_{LH} = -V_{Sat}\frac{R_M}{R_2} \tag{27}$$

where R_M is memristance of the developed memristor circuit. The dependence of the higher threshold voltage and lower threshold voltage of a memristor-based Schmitt trigger circuit on the supply voltage of the operational amplifier, memristance (R_M), and the feedback resistor (R_2) may be noticed from the preceding equations. The supply voltage for op-amp is chosen as ±15 V. The resistance values of R_1 and R_2 are selected as 10 kΩ. Amplitude and frequency of input sinusoidal voltage source are considered as 1 V and 200 MHz, respectively. Output and input voltage waveforms of the designed Schmitt Trigger circuit are presented in Figure 14. It may be noticed from Figure 14 that a sinusoidal signal is converted into to square wave signal by the designed circuit. In addition, hysteresis curve of the designed Schmitt trigger circuit is illustrated in Figure 15. Figure 15 illustrates transfer characteristics of the Schmitt trigger circuit. It is observed from Figure 15 that the upper threshold voltages are 367.40, 384.425, and 421.849 mV. Moreover, the lower threshold voltages are obtained as −183.68, −235.92, and −277.698 mV.

5.2 | Low pass filter using designed memristor

A low pass filter (LPF) using designed memristor is illustrated in Figure 16. The frequency response of the LPF is depicted in Figure 17. It is produced by applying a sinusoidal voltage source of 1 V with capacitance value $C_1 = C_2 = C_3 = C_4 = C = 1.85$ pF, and $R_{M1} = R_{M2} = R_{M3} = R_{M4} = R_M$ (using $R_1 = 200$ kΩ resulting in memristance value of approximately 230 MΩ at low frequencies). The transfer function of the given LPF may be expressed as

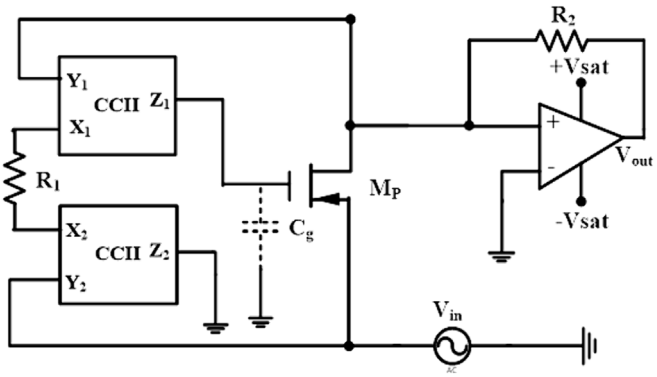

FIGURE 13 Schmitt trigger circuit using designed memristor.

$$\frac{V_{out}(s)}{V_{in}(s)} = \frac{1}{s^4R_M^4C^4 + 7s^3R_M^3C^3 + 15s^2R_M^2C^2 + 10sR_MC + 1} \tag{28}$$

It may be noticed from Figure 17 that the cut off frequency and roll-off rate are 22.12 Hz and −80 dB/decade, respectively. The result of the designed LPF exhibits the expected behavior that validates the applicability in biomedical fields. Monte Carlo analysis of frequency response of memristor-based low pass filter for 400 runs with 5% tolerance in passive components is shown in Figure 18. Figure 19 displays output noise of the memristor based LPF at 100 mHz and 1 MHz are −106.86 and −169.38 dB, respectively. Total power consumption of the designed filter is 3.06 mW.

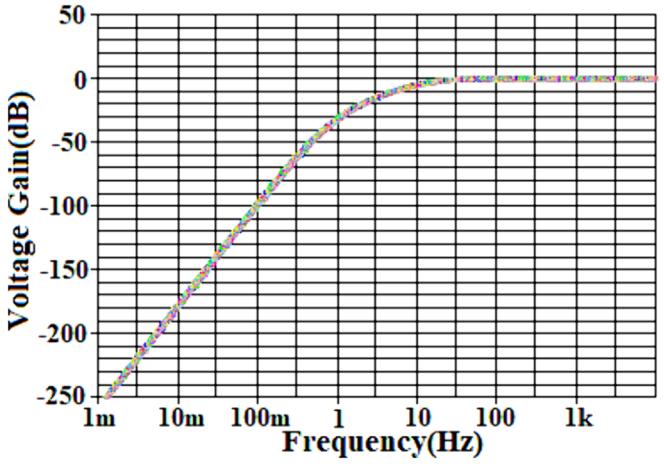

FIGURE 22 Monte Carlo analysis of frequency response of HPF.

5.3 | High pass filter using proposed memristor

The proposed floating memristor may be used as grounded memristor by providing $V_B(t) = 0$ V. A voltage mode high pass filter (HPF) using designed memristor is illustrated in Figure 20. The functionality of the HPF is tested using component values: $C_1 = C_2 = C_3 = C_4 = 200$ pF, and $R_{M1} = R_{M2} = R_{M3} = R_{M4} = R_M$ (using $R_1 = 200\,k\Omega$). The transfer function of the memristor based HPF may be derived as

1097007x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cta.4175 by Delhi Technological University, Wiley Online Library on [05/08/2024]. FIGURE 23 Output noise of HPF.

$$\frac{V_{out}(s)}{V_{in}(s)} = \frac{s^4 R_M^4 C^4}{s^4 R_M^4 C^4 + 10 s^3 R_M^3 C^3 + 15 s^2 R_M^2 C^2 + 7 s R_M C + 1} \tag{29}$$

Frequency response of HPF is illustrated in Figure 21. It may be noticed from Figure 21 that the cut off frequency and roll-off rate of the filter are 14.29 Hz and 80 dB/decade respectively. Monte Carlo analysis of frequency response of the HPF for 400 runs with 5% tolerance in passive components is shown in Figure 22. Figure 23 depicts output noise of the memristor based HPF at 100 mHz and 1 MHz are −112.89 and −191.077 dB, respectively. Total power consumption of the designed HPF is 3.06 mW.

6 | CONCLUSION

A capacitorless floating memristor emulator is designed in this manuscript. The reported emulator utilizes two CCIIs, one resistor and one PMOS transistor. Implementation of the proposed circuits does not include complex circuits like analog multiplier circuits, passive inductors, diodes, and ADC circuits. The developed memristor exhibits satisfying operation for changing the wide range of temperature. It shows a constricted PHL in each process corner, even though the pinch hysteresis loop may display some small-area fluctuation. Further, the PHL of the proposed memristor for various aspect ratios of the transistor (M_P) is also demonstrated. Since designed emulator excludes external capacitor, it exhibits PHL in V-I plane up to 2 GHz frequency. A Schmitt trigger circuit is constructed utilizing the suggested memristor to validate the workings of the created memristor at high frequency. It may be useful to get rid of noise in digital circuits at higher frequencies. In addition, high-order LPF and HPF circuits are also designed to illustrate the performances of the designed circuit at low frequencies. Results of the designed filters shows the expected behavior, which validates the applicability in biomedical fields. Thus, the proposed circuit exhibits the following advantages. (a) It is simple in structure. (b) It utilizes one passive component. (c) It is capacitorless. (d) The maximum operating frequency of the designed memristor emulator is 2 GHz. (e) The power consumption of the proposed memristor emulator is 0.766 mW. (f) It is suitable for complex applications. (g) It is free from additional circuit such as passive inductor, diodes, ADC, and analog multiplier. (h) It is suitable for monolithic integration. (i) It shows the applicability in biomedical fields.

***Abstract*—The paper "Sentiment Analysis of UPI Application Reviews using Machine Learning Algorithm" uses natural language processing (NLP) and machine learning to analyse user evaluations of Unified Payments Interface (UPI) applications for sentiments.The objective is to conduct a comparative analysis of different algorithms to better understand the user reviews of UPI applications and provide useful data for these digital platforms' strategic enhancements. Preprocessing is done on datasets, which includes text transformation with techniques like Word2Vec and Bag of Words. These techniques transform raw text into numerical vectors that are used by machine learning algorithms. Reviews are categorised into positive and negative sentiments using sentiment analysis algorithms. For sentiment classification, algorithms like C 4.5 (J48), Naive Bayes, and LSTM are used. Their effectiveness is assessed through comparative analysis. 90.02% was the highest accuracy recorded for sentiment classification of user reviews on Paytm. LSTM in conjunction with the word2vec skip-gram training model resulted in the attainment of this prediction. Results provide perceptions into user sentiments, facilitating purposeful enhancements in UPI applications that boost user contentment and adhere to changing digital payment requirements.**

***Keywords*—Sentiment Analysis, Natural Language Processing, Machine learning, Neural Networks, UPI, Word Embedding, Word2Vec, Naive Bayes, C4.5, LSTM**

I. Introduction

According to recent statistics, there has been a notable increase in UPI transactions in the recent past. These figures show a significant rise, with the UPI transaction volume showing an incredible 62% increase. In particular, the volume increased from 31.95 billion transactions in 2022's first half to a remarkable 51.91 billion transactions in 2023's same time[10]. User sentiments are crucial in determining the competitiveness and profitability of platforms in the dynamic world of mobile payment apps. To improve user experiences and effectively resolve problems, developers and stakeholders must have a sophisticated understanding of consumers' sentiments regarding particular applications. This study's detail makes it an invaluable addition to the ongoing efforts to enhance user experiences in the rapidly expanding field of digital payments.

Sentiment analysis, sometimes referred to as opinion mining, is the process by which machines accurately detect the emotions expressed in text, such as reviews or posts. Algorithms for sentiment analysis are essential for deriving insightful information from textual input. The analysis of feedback from users presents challenges since machines have difficulty identifying sarcasm. By using word2vec, this study aims to improve accuracy over existing sentiment analysis algorithms that have been used in the past.

This study uses various algorithms, including C 4.5, Naive Bayes, and the deep learning algorithm LSTM. To better align these digital payment platforms with user expectations and promote overall user satisfaction in the competitive world of mobile payment applications, the study's main goals are to conduct a comparative analysis to determine which one yields the highest accuracy in this particular situation and to offer insightful analysis that could direct future improvements. This work aims to investigate the potential applications of word embeddings produced by the word2vec algorithm for sentiment classification. The main idea is to use word embeddings to leverage sentiment-classifying features instead of manually constructing them.

This study's main contributions are as follows:

- A labelled dataset of reviews of Paytm applications that have been classified as either positive or negative.
- Building models with different algorithms designed

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:48:39 UTC from IEEE Xplore. Restrictions apply.

specifically for user review sentiment analysis.
- Determining the ideal Word2Vec parameters, including vector dimension, model architecture, and evaluation technique.

This paper's remaining sections are organised as follows:

Section 2 examines the existing literature of research on sentiment analysis, the Word2Vec method, and other noteworthy sentiment analysis models. The technique and the preprocessing- ing methods used on the dataset are described in Section 3-7. Section 8 presents the findings of the experiment. The paper is concluded in Section 9, where our results are summarised and compared to those of other experiments. Section 10 concludes by outlining possible directions for further research.

II. Literature Review

Baid, Gupta, and Chaplot's research [1] focuses on sentiment analysis applied to movie reviews using machine learning techniques. The research investigates the efficacy of different machine learning models in extracting sentiment from textual movie reviews.The research compares the KNN, Naive Bayes, and Random Forest algorithms for sentiment analysis of reviews. The paper's focus on sentiment analysis within the context of movie reviews is noteworthy, as it provides insights into the use of machine learning algorithms for sentiment classification. The study's significance is enhanced by the actual application of sentiment analysis in the context of movie reviews. However, as it mentions certain other algorithms also need to be tested.

Ngoc et al. in their paper [2] focus on emotional classification in English text, employing the C 4.5 algorithm. The paper investigates the effectiveness of C 4.5 in detecting emotional nuances in textual content. The dataset utilised in the study is fairly well documented and contains thousands of examples. However, the study lacks some critical preprocessing procedures that could improve the study's accuracy and efficiency. Each technique contributes to the detailed refinement of our dataset.

Vanaja and Belwal in their paper [3] present a method for aspect-level sentiment analysis, aiming to capture the intricacies of sentiment related to specific aspects of products or services. The study uses two machine learning approaches, Naive Bayes and Support Vector Machine, to address an important component of sentiment analysis in the realm of e-commerce data. It discusses the significance of evaluating e-commerce data for online retailers. The future work of the study focuses on using the C 4.5 algorithm and comparing it with others.

Saputra, Yulia, and Sholikha in their paper [4] investigate sentiment in Indonesian tweets related to e-money during the pandemic, employing both C 4.5 and Naive Bayes algorithms for comparison. They present statistics on the rise in e-money payment volume. They carried out a classification of negative and positive opinions related to e-money in Indonesia. The paper's contextual relevance is commendable, as it addresses sentiment analysis within the unusual conditions of a pandemic. However, sentiment analysis requires a high number of instances due to the sheer amount of words and phrases, and the dataset used in this classification study is not too vast.

In their research [5], Sholihat et al. use the Naive Bayes algorithm to analyse the sentiment of Twitter posts about illegal investments with the hashtags illegal investment and crazy rich. It was intended to address public concerns about illegal investments. According to the paper, their study performed more accurately than the prior studies.

Astuti, Wahyuni, Maulina, and Sidiq in their paper [6] explore sentiment analysis in the context of data leakage, employing the Naive Bayes based on machine learning approach.The research predicts sentiment patterns on public data leaks. The research addresses a crucial aspect of sentiment analysis in the domain of data security and leakage. The research clearly explains the methodology along with the algorithm used. However only Naive Bayes Algorithm was tested, it is required to test a few other algorithms as well.

Acosta et al. in their paper [7] explore the application of word2vec in sentiment analysis of Twitter messages. Drawing from existing literature, the study addresses challenges unique to analysing sentiments in tweets and evaluates the effectiveness of word2vec in capturing contextual information. By integrating word embeddings with Naive Bayes, Support Vector Machines and Logistical Regression machine learning algorithms, the paper contributes to advancing sentiment analysis techniques for social media data mining.

Rizka Putri Nawangsari et al. in their paper [8] explore the application of Word2Vec in the domain of sentiment analysis, particularly focusing on hotel reviews in the Indonesian language. They address the challenges associated with hand-crafted feature engineering, emphasising its labour-intensive nature and high cost. Instead, they propose Word2Vec as an alternative, leveraging its ability to generate vector representations of words, thereby facilitating the automation of feature extraction for sentiment analysis tasks. The study provides insights into achieving optimal accuracy in sentiment analysis of hotel reviews.

Putra Fissabil Muhammad et al. in their paper[9] explore sentiment analysis in Indonesian hotel reviews using Word2Vec and Long Short-Term Memory (LSTM) models. Online Travel Agents (OTAs) often include a review feature, enabling customers to provide feedback on their experiences with various services, including hotels. Sentiment analysis of these reviews aids both users in making informed decisions and service providers in evaluating customer satisfaction. The study employs LSTM, a type of Recurrent Neural Network (RNN) designed to retain information over long sequences. Results indicate that the Skip-gram architecture of Word2Vec outperforms CBOW.

III. Methodology

This paper presents a methodological framework for the systematic analysis of user reviews utilising machine learning algorithms. The research methodology employs a quantitative approach, progressing through distinct phases to extract valuable insights from user-generated content. To study the sentiment of user reviews, the experiments were conducted on a publicly available dataset (www.kaggle.com) of Google Play Store app reviews relating to users' experiences with the UPI payment application(Paytm). Subsequently, datasets undergo meticulous labelling procedures to enhance accuracy and relevance. Text preprocessing techniques are then applied to refine the textual data, optimising its utility for subsequent analysis. To make the datasets compatible with machine learning algorithms, they are preprocessed. This involves turning raw text into numerical vectors using methods like Bag of Words and Word2Vec. The main components of the methodology are the algorithms Naive Bayes, C 4.5, and Long Short-Term Memory (LSTM), which are intended to identify complex patterns and relationships in the dataset. Ultimately, extensive testing is carried out to assess the model's effectiveness and ensure the reliability of the findings. This methodological framework offers a systematic and thorough approach to user review analysis, combining advanced technological tools with analytical precision to derive robust conclusions.

Fig. 1. Methodology

IV. Data Collection

For this study, we used the open online platform Kaggle to gather useful data, with a focus on user reviews of well-known UPI payment services like Paytm. This large dataset serves as the foundation for our sentiment analysis study and allows us to gain insights into the opinions and experiences of users of these digital payment services. By using this strategy, we guarantee a thorough investigation of customer opinions regarding Paytm. Based on the review score, the gathered data is carefully labelled, with entries being classified as positive ($score > 3$) or negative ($score <= 3$)). The dataset has a set of attributes before it is labelled, which are described below and help with further analysis. The dataset used in this study had 68952 data points in total, 56520 of which had positive labels and 12432 of which had negative labels.

V. Data Preprocessing

Within the field of sentiment analysis, data preprocessing plays a crucial role as the foundational phase towards transforming unprocessed data into a format that is consistent and allows for insightful analysis. We carefully carried out several preprocessing procedures as part of our study, which

was centred on identifying sentiments in customer reviews of Paytm. Each step helped to refine our dataset subtly. This is a thorough examination of every preprocessing step:

A. Data cleaning and attribute selection

The first step involved clearing the data and eliminating any unnecessary attributes, including the review ID, username, user image, reply count, and review creation version. By concentrating the information down to its essential components—content/review and score, for example—we focused our research on the critical elements that significantly contribute to sentiment classification.

B. Handling missing values

We took the vital action of removing items without accompanying reviews to preserve the integrity of our dataset. This simplifies the data and improves the precision of the analyses that follow by eliminating instances that lack meaningful textual information.

C. Converting to Lowercase

To ensure consistency in analyses that follow, the text must be standardised by changing all of the characters to lowercase. To avoid any potential differences, this step ensures that words are handled consistently, regardless of their original case.

D. Removing Punctuations, Numbers, and Special Characters

Eliminating unnecessary components like punctuation, digits, and special characters is the next level of refining. By

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:48:39 UTC from IEEE Xplore. Restrictions apply.

concentrating on the key terms that support the meaning of sentiment, this method streamlines the text.

E. Removing URLs

Removing URLs from the text is essential to keep focus on the language used in reviews. If they are there, URLs could add noise to the dataset and cannot assist with sentiment expression.

F. Replacing Slang Words

Full forms of slang words were used in place of their informal, frequently shortened counterparts. By standardising the language, this transformation helps ensure that the sentiment analysis accurately captures the full range of user expressions.

G. Removing Stop Words

Stop words, which are frequently used terms with no semantic meaning, were omitted. This stage refines the dataset by removing terms such as ”the,” ”a,” ”an,” and ”in” that make no substantial contribution to sentiment expression.

H. Tokenization

Breaking down the text into distinct tokens, or words, is critical for future analysis. Tokenization lays the framework for interpreting sentences' semantic structure, allowing for a more detailed study of sentiments.

I. Stemming

The last phase is stemming, which involves reducing words to their base or root form. This ensures that different word variations—such as ”easy” and ”ease,” or ”running” and ”run”—are treated as the same thing, improving sentiment analysis algorithms' effectiveness.

VI. Text transformation

A key step in the advancement of our sentiment analysis study was applying the ”StringToWordVector” transformation to our textual data. This NLP approach converted strings of text into useful numerical representations known as word vectors. This transformation helps to prepare the data for later machine learning analysis. It simplifies the conversion of textual data into organised word vectors, setting the groundwork for more advanced analytics. Following the transformation, each document was represented as a numerical vector. Each member of the vector represents a specific word from the lexicon, and its value reflects the frequency or presence of that term in the document.

Furthermore, Word2Vec is a popular approach for creating word vectors. Word vectors are numerical representations of words that convey semantic meaning dependent on the context in which they appear. Word2Vec learns vector representations of words by training neural networks on massive text corpora. Using techniques such as Word2Vec, we may convert textual data into organised word vectors, setting the groundwork for advanced data analysis. Word2Vec helps capture the semantic meaning of words, allowing sentiment analysis models to better comprehend the context and sentiment expressed in the text.

In addition to its popularity, Word2Vec's Skip-gram design is noteworthy for its effectiveness in creating word vectors. Word2Vec uses two models: the Skip-gram architecture and the Continuous Bag of Words (CBOW). Unlike CBOW, which predicts the current word based on its context, Skip-gram predicts context words using the current word. This design is especially beneficial for capturing the contextual and semantic meaning of words in more detail. By taking the surrounding words as context, Skip-gram can effectively learn the links between words and their contexts, leading to richer and more advanced word embeddings. Skip-gram's ability to capture subtle semantic links between words helps improve understanding of sentiment represented in textual data, thereby increasing sentiment analysis model performance. Thus, introducing Skip-gram architecture into the Word2Vec training process enhances word embeddings with useful contextual information, allowing for more accurate sentiment analysis.

The vectors were then used to train various classifiers to determine which classifier produced the most accurate classifications. The findings were documented and explained further in the results section.

In this study, the Pandas library was used to load and manipulate the dataset, which included activities like removing extraneous columns, handling missing values, and preparing the data for analysis. NumPy also plays an important role in facilitating numerical computations and array operations during the data preprocessing stage. Matplotlib and Seaborn were used for data visualisation tasks, allowing for the production of useful plots and visualisations to investigate the distribution of sentiment categories in the dataset. Regular expressions from the re-library improved text processing by removing punctuation, special characters, and URLs. NLTK provided significant tools for natural language processing, including tokenization, stopword elimination, and lemmatization. Scikit-learn was used to divide the dataset into training and testing sets, while Keras was the major framework for developing and training deep learning models for sentiment analysis. Finally, Gensim was used to train word embedding models like Word2Vec, which helped convert textual data into numerical vectors while keeping semantic links between words.

VII. Classification

We examined the performance of three different classifiers: Naive Bayes, C4.5 decision trees, and Long Short-Term Memory (LSTM) neural networks. Each classifier was evaluated on its ability to identify sentiment in text data. Furthermore, the Skip-gram word embedding technique was integrated with the Word2Vec algorithm to improve the semantic representation of words. The dataset was divided into 80% training and 20% testing to properly evaluate the classifiers' performance. The next part describes the experimental results and evaluation criteria used to assess the classifiers' effectiveness in sentiment analysis tasks.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 06,2024 at 05:48:39 UTC from IEEE Xplore. Restrictions apply.

VIII. Results

Our study evaluates the accuracy of the Naive Bayes and C4.5 algorithms when applied to text data modified using a bag-of-words technique. We also trained the LSTM and prior classifiers using Skip-gram, which is integrated with the Word2Vec algorithm, as shown in Table 2.

TABLE II
ACCURACY PERCENTAGE BY CLASSIFIER AND TEXT TRANSFORMATION

Classifier	Text transformation	Accuracy
Naive Bayes	Bag of words	84.43%
Naive Bayes	Word2Vec (Skipgram architecture)	80.97%
C4.5	Bag of words	89.47%
C4.5	Word2Vec (Skipgram architecture)	87.46%
LSTM	Word2Vec (Pre-trained embedding)	88.04%
LSTM	Word2Vec (Custom trained embedding)	90.02%

Our results demonstrate that the Naive Bayes and C4.5 with bag of words text transformations have an accuracy of 84.43% and 89.47%, respectively. Also, according to the analysis, the C 4.5 approach takes much more time than the naive Bayes algorithm. Naive Bayes and C4.5, when employed with Word2Vec (Skip-gram), achieve an accuracy of 80.26% and 87.46%, respectively. Furthermore, the highest accuracy was found in LSTM using Word2Vec at 90.02% when the dropout value, learning rate, and vector size were 0.2, 0.001, and 100, respectively. When used with the LSTM classifier, Google's pre-trained Word2Vec embedding achieved an accuracy of 88.04%. In this use scenario, our custom-trained embedding outperformed the pre-trained word2vec embedding.

TABLE III
CLASSIFICATION REPORT (AVERAGE VALUES)

Algorithm	Precision	Recall	F-measure
Naive Bayes & Bag of words	0.84	0.85	0.84
Naive Bayes & Word2Vec	0.84	0.81	0.82
C4.5 & Bag of words	0.89	0.9	0.88
C4.5 & Word2Vec	0.87	0.88	0.87
LSTM & Word2Vec (Pre-trained)	0.89	0.97	0.93
LSTM & Word2Vec (Custom)	0.91	0.97	0.94

Determining the sentiment of reviews is important in many different contexts. It enables the creation of intelligent systems capable of providing customers with detailed reviews of UPI payment apps, products, and services. This removes the need for users to wade through individual evaluations, allowing them to make decisions based on the insights supplied by these intelligent systems.

IX. Conclusion

In conclusion, our study thoroughly analysed the performance of various machine learning algorithms in sentiment analysis of user reviews for the Unified Payments Interface (UPI) app (Paytm). This study tried to establish whether the Word2Vec technique, which generates word embeddings, might be used to classify sentiment. Using word embeddings would save the analysts from having to manually build stylometry-based features to appropriately classify data.

Our study found that using C4.5 and Na¨ıve Bayes algorithms with a bag-of-words text transformation approach resulted in higher accuracies (89.47% and 84.43%, respectively) compared to previous studies. Using Word2Vec embeddings, especially Skip-gram, with C4.5 and Na¨ıve Bayes achieved accuracy of 87.46% and 80.26%, respectively. Although the accuracy remained nearly equal, Bag of Words coupled with Naive Bayes and c4.5 outperformed Word2Vec paired with these algorithms. This could be attributed to the dataset's restricted contextual diversity. Notably, the LSTM model outperformed all other techniques, obtaining a maximum accuracy of 90.02% when combined with Word2Vec Skip-gram embeddings. Furthermore, we found that our custom-trained embedding outperformed pre-trained Word2Vec embeddings from Google.

Our findings highlight the importance of using advanced approaches like Word2Vec embeddings and LSTM models for sentiment analysis tasks since they provide important insights into user sentiments surrounding UPI applications. These findings can help digital platforms make strategic modifications to boost customer satisfaction and adapt to changing digital payment needs. Overall, our comparative analysis helps to gain a better knowledge of sentiment analysis approaches and their implications for improving user experiences in digital payment ecosystems.

X. Future scope

In future research on sentiment analysis for Unified Payments Interface (UPI) applications, incorporating transformer-based models such as BERT could greatly improve performance. Exploring alternatives such as FastText[11] embedding and hybrid techniques provides exciting opportunities for deeper insights and greater accuracy. FastText's subword information may improve sentiment representation, whilst hybrid techniques may address individual limitations. Integrating these improvements provides a complete strategy for refining sentiment analysis, which is critical for making informed decisions and improving user experiences in digital payment networks. Such initiatives pave the way for more effective sentiment analysis that is suited to the organisation's specific needs.

***Abstract*—Educational institutions are constantly striving to improve the services they provide; their goal is to have the best possible teaching staff, increase the quality of teaching, and improve their students' academic achievement. One of the initial steps taken by educational institutions was to establish Virtual Learning Environments (VLEs). This work uses a deep Explainable distillation model on a set of unique handcrafted variables collected from VLE clickstream data to forecast at-risk students and provide strategies for early intervention in such circumstances. Initially, the input data are gathered from publicly available source and pre-processing is done to enhance the quality of inputs using Missing Value Imputation. Then, in order to handle the unbalanced data, augmentation is performed by a new Improved Synthetic Minority Oversampling Technique (ISMOTE). After augmenting the data, the student's academic performance is predicted by proposing a novel Explainable Deep Learning based Knowledge Distillation Framework (EDL_KDF). Furthermore, the proposed model can be explained using Shapley Additive Explanations (SHAP)-based reasoning. Educational institutions can evaluate, audit, and validate explanations for such relevant features more easily than explanations from DL models. The proposed framework attained 99.6% % accuracy and 99.21% of precision over the Open University Learning Analytics Dataset (OULAD). Thus, the proposed study effectively predicts the students' performance compared to other existing models.**

Keywords—deep learning, student performance prediction, knowledge distillation, shapley additive explanation, improved SMOTE, OULAD dataset, resnet-101.

I. INTRODUCTION

Sudden advancements in enhanced technology-based learning platforms have provide a tremendous rise in online education related data for attaining plenteous educational repositories [1]. In recent years, it is noticed that e-learning systems have afford great flexibility and interactivity because which can easily use by the learners at any time in varied locations and devices [2]. Mainly, such systems are employed for blended and online universities by instructors to distribute, organize educational information to learners or students [3]. Nevertheless, the instructors in online platforms does not analyze academic performance and behavior of students. On the other hand, face-to-face instructors has the ability to attain the knowledge of student's behavior and easy to predict their academic performance [4]. Online instructors also can communicate with students in virtual manner but it face difficult to analyze the performance of each students [5].

Nowadays, educational institutions are becoming a large competitive environment because of enhancing people's interest in several courses [6]. Also, the need of assuring that the utilized resources is highly important because it can enhance the experience of student learning and increase esteem factors like student's performance and retention. Analyzing student performance is necessary as it aids in designing a student support strategy and enhance learning and teaching practice [7]. However, conducting a deep analysis of student academic efficacy is a challenging problem and some factors like social, economic, cultural, demographic and academic background may impacts the student's academic results. Developing an effective student academic performance factor demands a deep data analysis which can attain via Machine Learning (ML) and Deep Learning (DL) models [8]. Such models has the capability to attain more informative features from the input samples and can predicts the exact outcomes. Some of the preceding methods that used for analyzing student's academic performance are artificial neural network (ANN), deep neural networks (DNN), support vector machine (SVM) etc.

A. Motivation and Problem statement

Learning analytics based on Artificial Intelligence (AI) is one of the promising technology which highly support educators because which can collects, analyze and reports data regarding learners. However, predicting student's performance in online platforms is becoming a challenging issue because of the complex inputs, overfitting problems, reduced learning ability, etc. Recently, several studies have developed different models for making student's performance prediction. But, the performance is limited due to its inefficiency in prediction task. Nowadays, DL models have gained more attention in prediction and classification tasks due to its efficient characteristics. But, the complex structures of DL mechanisms impacts the network performance as well as it produced high computational complexity. Thus, to avoid this kind of issues, the proposed study plans to utilize an effective knowledge distillation-based DL models for enabling prediction process. The major objectives of the proposed work are,

- To enhance the quality of inputs by filling the missing values in the initial pre-processing step and thereby smoothening the further stages.
- To reduce the data imbalance issue by augmenting the data samples using a new Improved Synthetic Minority Oversampling Technique (ISMOTE).
- To propose a novel Explainable Deep Learning based Knowledge Distillation Framework (EDL_KDF) for predicting student's academic performance with less computational complexity and high accuracy.

The paper is structured as five different sections. Section 2 contained the review of the related works. Section 3

contained the detail explanation about the proposed methodology. Section 4 contained the result analysis and discussion and section consists of overall conclusion of the conference paper with future direction and references.

II. Related Works

Waheed et al. [9] have designed deep ANN for learning the predictive function of student's performance using features from the VLE. The simulation results shows that the developed model attains better classification accuracy as 84% to 93%. Giannakas et al. [10] have developed a DNN model for enabling predictions on academic team performance. Here, the utilized DNN model is trained by using varied activation functions and optimizers. For interpreting the developed framework, SHAP method is used. Also, the necessary features that involves positive and negative impacts on its resultant prediction process are extracted. DNN attained 86.57% and 80.76% for Adagrad and Adadelta optimizers correspondingly.

Asselman et al. [11] have used ML based ensembled algorithms for predicting students' performance. The study developed a performance factors analysis (PFA) method based on varied models like adaboost, XGBoost and random forest. The model attained 78.75% of accuracy over three different datasets. Rodríguez-Hernández et al. [12] have presented a systematic process for implementing ANN to analyze academic performance of students in their higher studies. This existing study used 162, 030 number of student data including males and females from the public and private universities in Colombia. The ANN model attained 82% of high accuracy. Kusumawardani et al. [13] suggested the DL based transformer encoder for student performance prediction using OULAD dataset. The encoder attained 83.17% of accuracy. From the analysis the existing model have several drawbacks such as less accuracy, high computational complexity, overfitting and dataset class imbalance issues occurred during the prediction.

III. Proposed Methodology

Predicting the academic performance of the student in the e-learning platform is more essential. In recent development of DL technology several methods are introduced but it have several limitation such as more computational complexity, overfitting problem etc. So that the proposed framework is developed to attain accurate student performance prediction with less computational complexity. Figure 1 shows the architecture of the proposed prediction model.

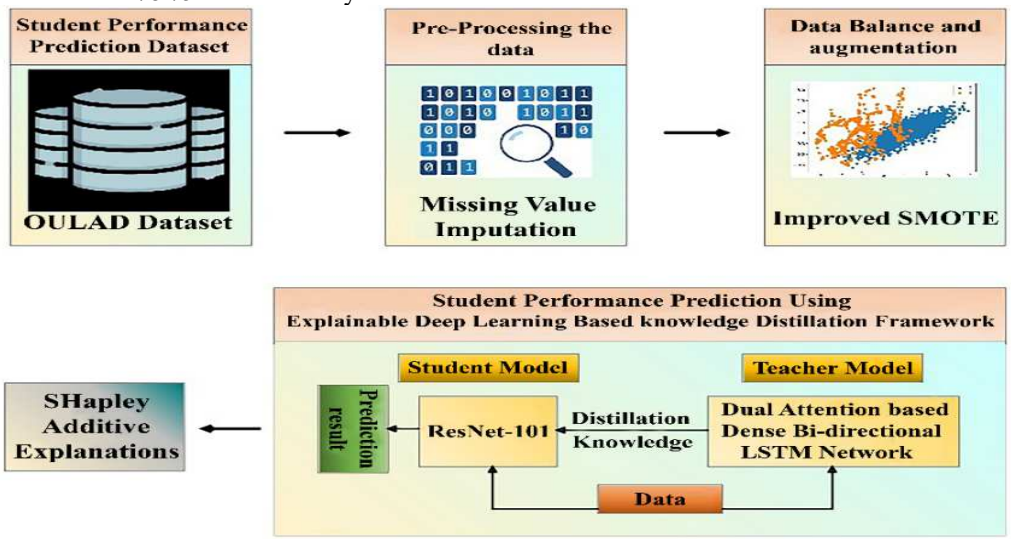

Fig. 1. Architecture of proposed framework

Initially, the input data is pre-processed using the Missing Value Imputation then data balance and data augmentation done using the ISMOTE that improve the quality of the dataset. After that, EDL_KDF is introduced for student performance prediction, which contained the DAbDBi-LSTM teacher model and ResNet-101 as the student model. Finally the predicted result is analyzed using SHAP to know the impact of each features presented in the dataset.

A. Pre-processing the input data using Missing value imputation

In general, due to some issues few values are missing in the dataset that can be replaced through the mean value of the neighboring non-missing values. The mean value is estimated by the equation (1).

$$V_i = \frac{V_{i-1}+V_{i+1}}{a} i \in C \quad (1)$$

Where, missing value is signified as V_i, previous value of the missing value is signified as V_{i-1} like that, the next value followed by the missing value is denoted as V_{i+1}. The natural number is represented as $C = 1,2,3,\ldots$. Through these techniques, the missed values in the dataset is effectively replaced, so that it enhanced the quality of the input data.

B. Data balance using Improved Synthetic Minority Oversampling Technique

ISMOTE intends to generate clear synthetic samples for the minority class of imbalanced dataset to data augmentation through SMOTE generalization in addition to accurately establishing the boundaries. Process of ISMOTE is explained as follow. Initially, synthetic instance is created through employing the SMOTE techniques that expressed in equation (2).

$$S = 2 * (u - v) + v \quad (2)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 06:56:58 UTC from IEEE Xplore. Restrictions apply.

Where, number of initial synthetic instance is represented as S, minority and majority class samples counts are denoted as v and u respectively. In second stage, remove the synthetic samples that are closer to the majority class compared to the minority, and the generated instances that are nearer the border created by SMOTE. The ISMOTE step by step process are given as below. Consider the new synthetic instance set as $\hat{y} = \{\hat{y}_1, \hat{y}_2, \dots, \hat{y}_S\}$ and $k - th$ attribute value of the $\hat{y}_l, k \in [1, C]$is denoted as $\hat{y}_l^{(k)}$, which are determine the accept or reject the instance created by SMOTE. Let set of majority and minority samples are denoted as $E_p = \{E_{p1}, E_{p2}, \dots, E_{pm}\}$ and $E_q = \{E_{q1}, E_{q2}, \dots, E_{qn}\}$respectively. To decide whether to accept or reject synthetic instance, the distance among the E_{pm} and $\hat{y}_l$ moreover distance among the$E_{qn}$and $\hat{y}_l$ are estimated in initial step using equation (3) and equation (4) respectively.

$$D_n(\hat{y}_l, E_{qn}) = \sum_{k=1}^{C} \sqrt{\left(\hat{y}_l^{(k)} - E_{qn}^{(k)}\right)^2}, n \in [1, v] \quad (3)$$

$$D_m(\hat{y}_l, E_{pm}) = \sum_{k=1}^{C} \sqrt{\left(\hat{y}_l^{(k)} - E_{pm}^{(k)}\right)^2}, \quad m \in [1, u] \quad (4)$$

Through the above expression, two different arrays was created through equation (5) and equation (6).

$$H\left(D_n(\hat{y}_l, E_{q1}), \dots, D_n(\hat{y}_l, E_{qn})\right)_{min} \quad (5)$$

$$H\left(D_m(\hat{y}_l, E_{p1}), \dots, D_m(\hat{y}_l, E_{pm})\right)_{max} \quad (6)$$

Then choose the minimum value off the minority and majority array, if the minority value is small than majority minimum value then synthetic sample is accepted or else it get rejected. That increase the speed of technique and increase performance. In next step, the noise is removed from the accepted synthetic instance$\hat{E} = \{\hat{E}_1, \hat{E}_2, \dots, E_z\}$.The equation (7) computed the distance among $\hat{E}_l$with all real minority E_q.

$$G_n(\hat{E}_l, E_q) = \sum_{j=1}^{v} \sum_{k=1}^{C} \sqrt{\left(\hat{E}_l^{(k)} - E_{qn}^{(k)}\right)^2} \quad (7)$$

Through the above expression the new Tsample set via eliminate the far away samples from the minority is created using equation (8).

$$T = \sum_{i=1}^{n} G_n(\hat{E}_l, E_q) \quad (8)$$

At the same method the distance among the synthetic instance and all majority samples are calculated then remove the minimum distance produced samples for attain high pure data. According to these methods, there are no noisy or borderline samples are augmented in the dataset.

C. Student Performance Prediction using Explainable Deep Learning based Knowledge Distillation Framework

The proposed work introduced the novel EDL_KDF framework for predicting thee student performance. The high accuracy can be attained complex DL model but it utilized more number of parameters thus produced high computational complexity. However, the KD can predicted the student performance with both less computational complexity and high accuracy. The KD produced the light-weight model by reduced the heavy-weight model without decrease the accuracy. Figure 2 shows the proposed framework structure.

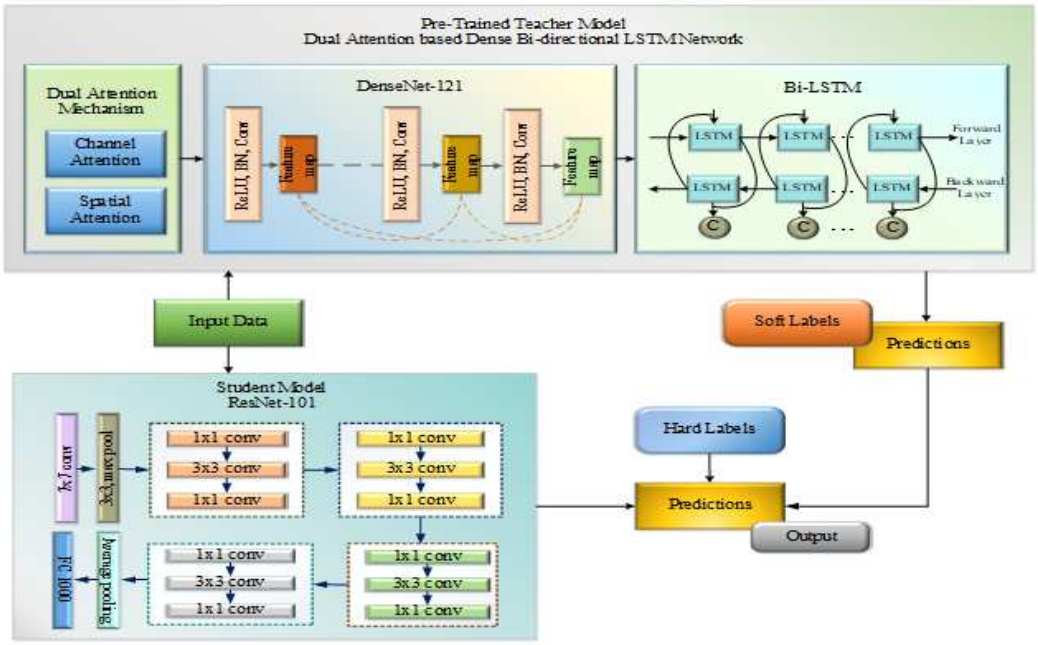

Fig. 2. Structure of EDL_KDF framework

KD employed the pre-trained teacher model (large model) that help to trained student model (small model) by applying the distilled knowledge. For student model training KD have two loss component. First reduces the variance among the predicted and actual labels (hard labels), however the latter reduces the teacher's predictions (soft labels). While distillation process, the probability value is attained using the temperature (T). Initially the logits is extracted from the student model for calculate the probability then it feed in the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 06:56:58 UTC from IEEE Xplore. Restrictions apply.

softmax function along with T. The equation (9) expressed the softened softmax function using with temperature.

$$Soft\,max(u_i) = \frac{e(u_i/T)}{\sum_{k=1}^{l} e(u_k/T)} \quad (9)$$

The input data is initially given to the both student and teacher model and receive the logits u_s and u_t. Student and teacher model's probability distribution calculated using equation (10) and equation (11).

$$Pp(T) = Soft\,max(u_t/T) \quad (10)$$

$$Pp(S) = Soft\,max(u_s/T) \quad (11)$$

The probability of teacher and student entropy are control by using the T. The distillation loss is calculated using equation (12).

$$L = \lambda * Lh(Pp(S), O) + (1-\lambda) * Ls(Pp(S), Pp(T)) \quad (12)$$

Where, O, λ, are denoted as actual label (hard label) and weight coefficient respectively. Lh and Ls are computed through the cross entropy. The student learns the appropriate probabilities of specific categories using the pretrained teacher model using an increasing entropy in $Pp(S)$ accordingly with T. The teacher model and student models are mentioned in the below sub-section.

1) Pre-trained Teacher Network using Dual Attention based Dense Bi-directional LSTM Network: DAbDBi-LSTM Network taken as the teacher model that comprises of Dual attention mechanism, DenseNet-121 and Bi-LSTM. The dual attention mechanism integrated the spatial attention and channel attention. The spatial data of feature maps is initially aggregated using average pooling with maximum pooling for channel attention that producing two separate spatial feature maps such as average pooling (C_{Ag}^{S})and max pooling (C_{Mx}^{S}).After that, an integrated network receives this feature map, producing the channel attention $H_S \in \Re^{S\times1\times1}$. The network have hidden layer and multilayer perceptron. By using the reduction ratio the hidden activation size is decreased as$\Re^{S/r\times1\times1}$for minimize the parameter overhead. Element summation is expressed in equation (13) and it employed to create a feature output vector for every feature map and channel attention.

$$H_S(C) = Sigmoid\big(MLP(C_{Ag}^{S}) + MLP(C_{Mx}^{S})\big) \quad (13)$$

The channel information of the feature map is combined using two pooling methods for spatial attention that producing two 2D feature maps such as average pooling ($C_{Ag}^{K} \in \Re^{1\times W\times H}$) and maximum pooling $C_{Mx}^{K} \in \Re^{1\times W\times H}$. Next, spatial attention map is create using equation (14) that joining the two feature maps onto a convolutional layer.

$$H_H(C) = Sigmoid\big(f^{7\times7}\big[C_{Ag}^{S}; C_{Mx}^{S}\big]\big) \quad (14)$$

Where, $f^{7\times7}$ denoted the convolution kernel with 7×7kernel operation. DenseNet-121 architecture contained the dense connection with 121 layers, which make connection among the all-following layers. In order to improve the efficiency of the network's training, each layer obtains significant features that have been learned by previous layers. It utilized less amount of parameter while training and it solve overfitting problem using dense connection. The dense block is the important part of the DenseNet that have Batch Normalization, ReLU and 3×3 Conv that can be expressed using equation (15).

$$D_i = W_i([D_0, D_1, \ldots D_{i-1}]) \quad (15)$$

Where, layers are denoted as $(0,1,\ldots i-1)$ the feature map conjunction generated by DenseNet-121 layers are represented as $[D_0, D_1, \ldots D_{i-1}]$. Operation done over $i-th$ layer is denoted as $W_i(.)$thus, the DenseNet effectively learn the feature map. To realize the deep features produced by the DenseNet-121, Bi-LSTM is introduced in the student model. The LSTM contained three gates such input (S_g), forget (T_g) and output (R_g) gates. For timestep$y$, the LSTM expression are derived in equation (16).

$$\widetilde{D} = tanh\big(K_g V_{xd} + F_{g-1} V_{hd} + Bs_g\big) \quad (16)$$

Where, Bs_g denoted as bias parameter, V_{xd} and V_{hd}represented as weight parameters. In LSTM, $S_g$note that new data get usingD_g. D_{g-1}contained old memory count is addressed by using T_g and by using the point wise multiplication the process is derived in equation (17).

$$D_g = T_g \otimes D_{g-1} + S_g \otimes \widetilde{D}_g \quad (17)$$

Using the output gate, the flow of information among hidden state and memory cell are controlled using equation (19).

$$T_g = R_g \otimes tanh(D_g) \quad (18)$$

The Bi-LSTM process based on the LSTM but it receive the input data in both direction. The Bi-LSTM at the timestep y is expressed in equation (19) and equation (20).

$$\begin{aligned} \vec{T}_y &= \phi\left(K_y V_{xy}^{(f)} + \vec{F}_{y-1} V_{hy}^{(f)} + Bs_y^{(f)}\right) \\ \overleftarrow{T}_y &= \phi\left(K_y V_{xy}^{(b)} + \overleftarrow{F}_{y-1} V_{hy}^{(b)} + Bs_y^{(b)}\right) \end{aligned} \quad (19)$$

By combining the backward and forward LSTM layer, the hidden state is obtain then it passed to the output layer that can be expressed as below.

$$R_g = K_g V_{hq} + Bs_q \quad (20)$$

Where, Bs_q is a bias parameter and V_{hq} is a weight parameters are the output layer's model parameters. Finally the softmax function predicted the student performance. Thus the model effectively learned the student performance data's presented in the dataset through the DAbDBi-LSTM Network.

2) Prediction make using ResNet-101 Student Network: Resnet-101 has an ability to optimize the residuals across input and targeted convolution features sets that contained

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 06:56:58 UTC from IEEE Xplore. Restrictions apply.

101 layers. So that target features are effectively attained effectively compare than other network. ResNet-101 greatly decrease the deeper network's parameter by applying the residual optimization, which also decrease the amount of layers in the network. Data that is not learned in the preceding layer of the ResNet architecture is applied from the old to its new layer through the ResBlock layer. The blocks of the Resnet architecture is ResBlock layer, which provide residual values into the subsequent layer. A two-layer activation includes a skip that provides value across the weight layers as well as the Relu activation code. This skip affects the system account. The equation (21) shows the nonlinear Relu function.

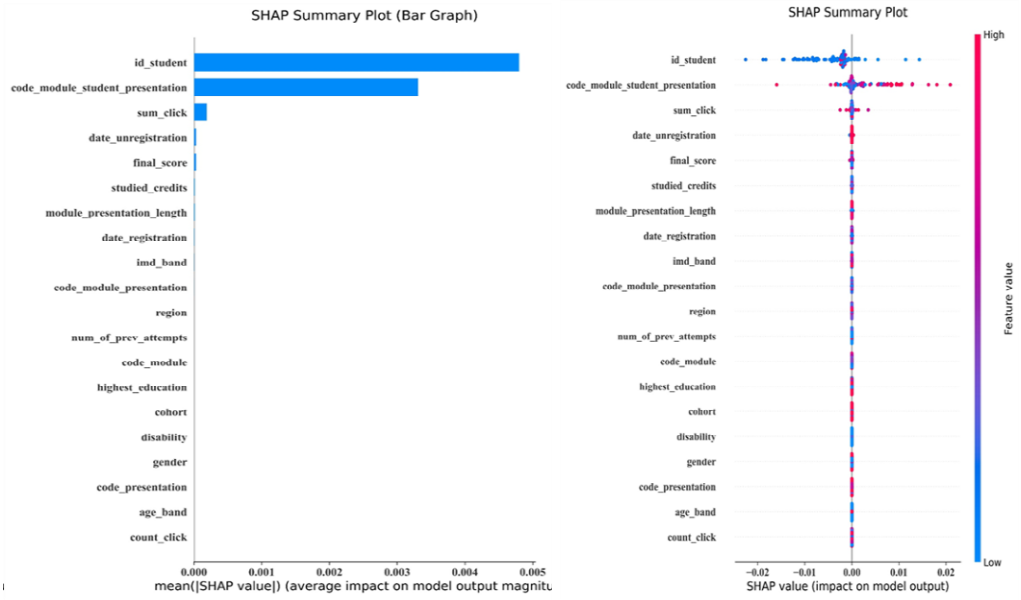
$$R = w_{2\sigma}(w_1 u) \tag{21}$$

Output is attained through equation (22) that concatenate the second Relu value.

$$O = R(u, \{w_i\}) + u \tag{22}$$

Where, u and O are represented the input and output vector respectively. At the end the softmax activation function predicted the student performance by using the ResNet-101 with the help of DAbDBi-LSTM teacher network.

3) SHapley Additive Explanations: SHAP is generally used for analyze the feature major contribution for the prediction output. A heatmap illustrates that how feature values are impact the prediction outcome. Figure 3 shows the model's features mean absolute Shapley value and magnitude outcome.



(a) (b)

Fig. 3. Analysis of (a) Mean absolute and (b) magnitude outcome of SHAP value

From the SHAP analysis, the feature id_student is observed that feature magnitude predicts the performance of the teams at approximately 0.005. Proposed prediction model received the positive and negative influence due to the low feature value from -0.02 till 0.014 for id_student feature. At the same time low feature value of code_module_student_presentation feature influence positive prediction from -0.006 to 0.02. This SHAP supports to determining the corresponding importance of several features as well as how these individuals affect the output of the EDL_KDF prediction model.

IV. Result And Discussion

In this section, the performance of the EDL_KDF framework is analyzed for proving the efficiency of the proposed work compared to other existing student performance prediction framework. The proposed EDL_KDF framework implemented through using the PYTHON tool.

A. Dataset description

Open University Learning Analytics Dataset (OULAD), which is a standardizing and benchmarking dataset. The dataset contained 32,593 students log data's like demographics, interaction data, registrations and assignments. The dataset is download using https://www.kaggle.com/datasets/anlgrbz/student-demographics-online-education -dataoulad link. The Open University consider social sciences and science, technology, engineering, and mathematics (STEM) courses for gathered the student activity. The student activity data's are recorded from 2013 to2014.

B. Analysis of result and comparison

The performance of the EDL_KDF framework is analyzed via several DL performance metrics such as accuracy, precision, recall, F1-Score and Receiver Operating Characteristic (ROC) Curve, these analysis graphs are given in Figure 4.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 06:56:58 UTC from IEEE Xplore. Restrictions apply.

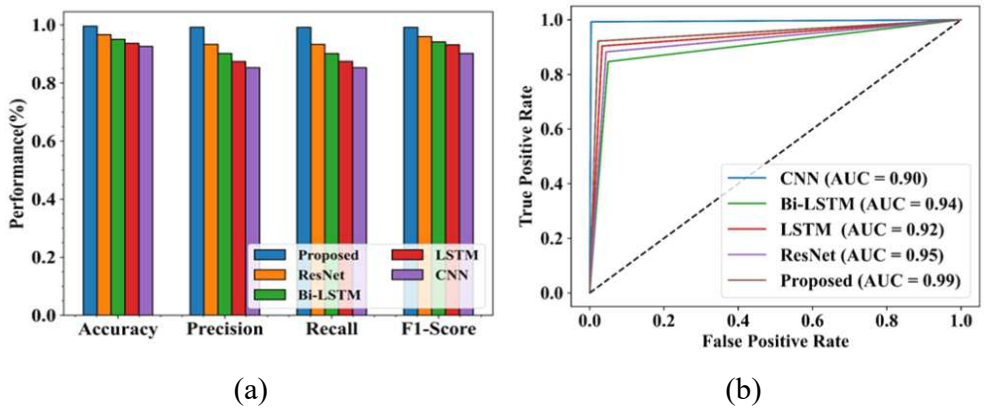


Fig. 4. Analysis of EDL_KDF framework using (a) various performance metrics (b) ROC curve

The DL performance metrics are commonly used to measure the effectiveness, robustness and efficiency of the prediction model. The high results in terms of F1-score, precision, recall and accuracy produced DL model outperform in the prediction. The EDL_KDF framework attained 99.6% of accuracy, 99.21% of precision, recall and F1-score. At the same time, the framework attained 0.99 Area under Curve (AUC) in ROC analysis. The obtained performance are shows better outcome compared to other DL model. Figure 5 shows the accuracy and loss curve analysis.

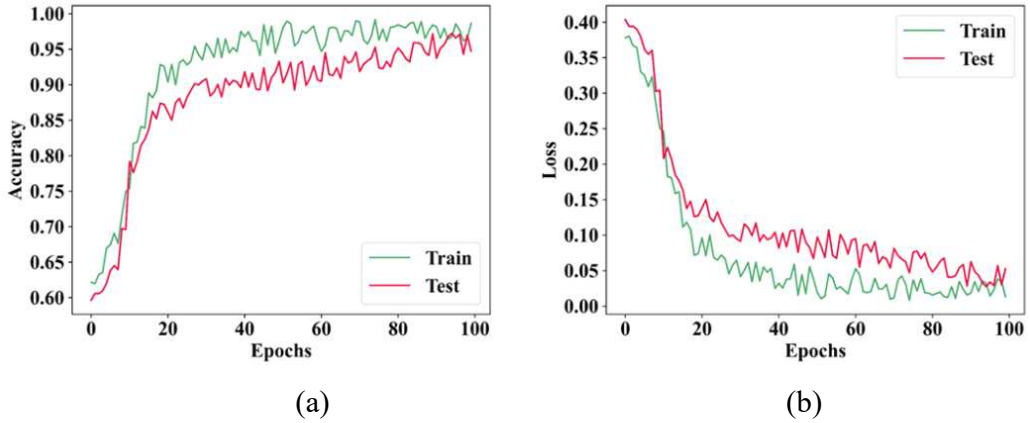

Fig. 5. Analysis of (a) Accuracy curve and (b) Loss curve

The EDL_KDF framework accuracy and loss are analyzed based on the 100 epochs in terms of both training and testing. After attaining the 40 epochs, the accuracy of the prediction is gradually increased as well as loss of the prediction model majorly decreased. Thus help to predict the student performance over the OULAD dataset. Figure 6 shows the analyzed the proposed framework performance regarding error metrics.

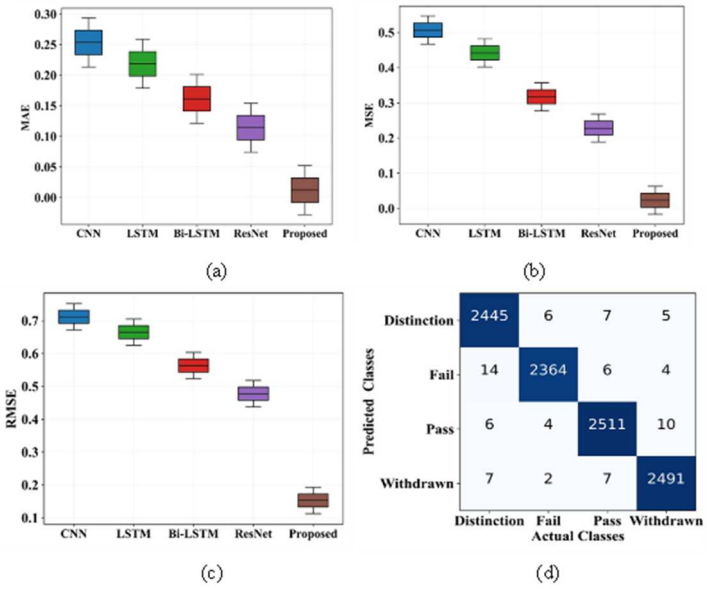

Fig. 6. Comparison and performance analysis based on (a) MAE (b) MSE (c) RMSE and (d) Confusion matrix

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 06:56:58 UTC from IEEE Xplore. Restrictions apply.

The MSE, MAE and RMSE are generally utilized for examine the error rate of the prediction model. The obtained value of the error metrics very low while the prediction model attained better performance. The EDL_KDF framework produced less error value such as 0.023% of MSE, 0.0122% of MAE and 0.1528% of RMSE. EDL_KDF framework accurately predicted into its corresponding classes. Less amount of prediction has been wrongly predicted into the other classes. From overall performance analysis, the EDL_KDF framework give the better performance over the student performance prediction.

C. Discussion

The performance of the EDL_KDF framework is discussed in this section. The existing student performance prediction model issues are effectively reduced by the proposed work. The overfitting problem [13, 16] was reduced by the DenseNet-121, which is utilized in the student model of the EDL_KDF framework. Dataset class imbalance problem [14] is overcome by the ISMOTE. Accuracy and computational complexity issues [15, 17] are solved by the novel EDL_KDF framework. The EDL_KDF framework make a prediction using the ResNet-101 network with the distillation knowledge of DAbDBi-LSTM network, thus effectively decrease the computational complexity without decreasing the prediction accuracy. Table 1 contained the comparison analysis with existing prediction model.

Through the analysis, proposed EDL_KDF framework effectively predicted the student performance with high accuracy, precision and recall with high computational complexity. Thus, the proposed work outperform compared to other existing prediction model.

V. CONCLUSION

In this paper, the proposed EDL_KDF framework effectively predicted the student performance over the OULAD dataset. The EDL_KDF framework initially increased the quality of the dataset at the pre-processing stage, thus improved the prediction accuracy. After that, novel EDL_KDF framework attained the accurate outcome in the student performance prediction through the KD model. The better accuracy was attained by the EDL_KDF framework with the help of both DAbDBi-LSTM network and ResNet-101. The DAbDBi-LSTM network was pre-trained in the EDL_KDF framework, which give the distillation knowledge to the ResNet-101 student model for predicting the output. Through the process, the less complex ResNet-101 model extracted the knowledge of complex DAbDBi-LSTM network, so that the computation

Complexity of the proposed student performance prediction was increased as well as it attain high accuracy in prediction. Finally the SHAP was introduced for analyses the every features in model that help to know the impact of the particular feature in the prediction. The EDL_KDF framework evaluated via several performance metrics and it achieved 99.6% and 99.21% of accuracy and precision over the OULAD dataset respectively. In future, the generalization loss of the KD model is focus the improvement student performance prediction performance for unknown data.

Abstract: Embracing hybrid energy systems (HES) to ensure access to clean, reliable, and cost-effective energy is necessary for nations that are striving for sustainable development. By leveraging precise meteorological data from forecasts, the HES can be rendered more accurate. Thus, firstly, the research presented here employed four machine learning approaches, such as Gaussian process regression (GPR), support vector regression, extreme gradient boosting, and decision trees, to carry out hourly forecasting of meteorological data over a year. The results obtained revealed that the GPR outperformed the other three forecasting models. For this reason, the forecasted meteorological data acquired from GPR is employed in the sizing of the HES. Tunicate swarm algorithm (TSA), a recently developed method, is applied to perform the size optimization of HES capable of meeting the energy necessities at remote sites in the Indian province of Uttar Pradesh. Following a comparative study of TSA, particle swarm optimization, and harmony search, TSA proved to yield a better outcome. Additionally, the simulation result showed a 0.33% cut in the per-unit cost of energy when forecasted data becomes the basis for the optimization of system size.

Keywords: Hybrid energy system; Forecasting; Tunicate swarm algorithm; Machine learning approaches

1. Introduction

The rise in greenhouse gases (GHG), involving methane, carbon dioxide, carbon monoxide, nitrous oxide, fluorinated gases, and others, has sparked concerns around the globe because it is directly indicative of climate change. The main root cause of GHG emissions, resulting in catastrophic consequences such as extreme weather, temperature rises, and ecological disruption, has been identified as the result of the burning of fossil fuels. The surge in energy consumption worldwide is also attributed to factors like urbanization, economic expansion, population growth, and a greater reliance on appliances and technology. To cope with these issues, efficient and environmentally conscious energy solutions ought to be devised with a view to complying with growing demand while limiting adverse environmental effects. The deployment of renewable energy is a crucial tactic to combat cutting-edge issues while paving the path for a resilient and cleaner future [1–4]. However, due to environmental conditions featuring fluctuating wind speed and sun irradiation, leaning solely on renewable energy sources ($R_E S$) seems to be less effective than conventional energy sources and grid-tied systems. The aforementioned factors may cause outages or cutbacks in generated energy at different instances of day. Hybrid energy system (HES) has been pitched as a pragmatic answer to this problem. HES blend a multitude $R_E S$ with energy storage or backup devices to improve reliability [5–7].

An essential aspect of the design of HES entails figuring out the optimal system size for a particular load demand. Researchers have come up with an assortment of optimization tactics, covering deterministic methods, metaheuristic algorithms, and software tools. For sizing HES, popular and effective software programs like hybrid

optimization model for multiple energy resources (HOMER), hybrid optimization by genetic algorithm (HOGA), RETscreen, and TRYNS, are often utilized. Specifically, HOMER is a potent tool for developing HES systems, finding the optimal size, and conducting economic evaluations as well [8, 9]. One of the primary downsides of the HOMER software is that users are unable to modify the modeling equation, sizing procedure, algorithms, or calculations. On the other hand, deterministic methods like graphical, probabilistic, analytical, iterative, and linear programming are more valuable than software tools since they have been applied in an extensive set of HES research. Conversely, deterministic approaches are limited to selecting a local optimal solution; they are incapable of stumping up a global optimal solution [10, 11]. In recent times, many meta-heuristic methods prompted by natural behavior have been applied with the aim of optimally sizing HES. A handful of these are the following ones: biogeography-based optimization (BBO), particle swarm optimization (PSO), grey wolf optimization (GWO), artificial bee colony (ABC), artificial bee swarm optimization (ABSO), simulated annealing (SA), ant colony optimization (ACO), harmony search (HS), bacterial foraging algorithm (BFA), mine blast algorithm (MBA), and others [12–21]. These algorithms can discover optimum solutions more precisely than deterministic techniques, avoiding the trapping of local optima [20]. Significant research has been done on the most effective ways to size HES, utilizing a range of optimization strategies. An overview of a handful of these investigations is provided in the subsequent paragraphs.

The most optimal HES of solar photovoltaic (S_{PV}), wind, diesel, and battery storage systems were found by employing the grasshopper optimization method [22]. The costs were maintained to a minimum by limiting the cost of energy (CE) while considering the probability of a power outage into consideration. The entire cost of HES, encompassing of a storage system, S_{PV} panels, diesel generator (DG), and wind turbine (WT), has been drove down with the aid of the PSO technique [23]. The whale optimization algorithm (WOA) and PSO approaches were applied in the design of a hybrid microgrid that included S_{PV}, fuel cells (FC), and biowaste [24]. The entire net present cost (NPC) was the fitness function in this design problem involving constraints relating to availability and loss of power supply probability (LPSP). A HES with a DG, WT, S_{PV}, and battery was suggested for the Dakhla area of Morocco. The goal of the research is to reduce investment expenses by utilizing the Equilibrium Optimizer (EO) while keeping into account multiple constraints such as renewable fraction, availability, and reliability. The computational outcomes were contrasted with those of optimization methods derived from Sooty Terns, GWO, Artificial Electric Fields (AEF), and harris hawks optimizer (HHO) [25]. In another instance, A HES for a microgrid in Egypt's Farafra region was developed using the improved archimedes optimization algorithm (IAOA). Slashing the NPC while attaining three critical constraints—renewable energy fraction, power supply reliability, and system availability—was the main objective. The outcomes of the simulation were contrasted with the outcomes of popular algorithms, especially, original archimedes optimization algorithm (AOA), AEF, EO, GWO, and hydrogen hydroxide optimizer. The results exhibit how effectively the IAOA copes with the design problem while showing how efficient it is in contrast to other algorithms [26].

A comprehensive assessment of HES with large-scale battery storage to enhance a smart city's sustainability was carried out by Nuvvula et al. Their work optimized the sizing of several R_ES within the system using mutation-enabled quadratic particle swarm optimization (QPSO). Limiting power supply losses, optimizing the net present value (NPV), and lowering energy expenses were the main goals [27]. A variation of the dragonfly algorithm termed the modified dragonfly algorithm (MDA) was employed in mathematical modeling with the intention of reducing the NPV of power systems over the course of their operational life. After weighing multiple possibilities, the model concluded that the best cost-effective way for bolstering dependability is to use the HES with grid interaction [28]. A methodology for the deterministic and probabilistic design of a S_{PV} module, biomass gasifier (B_M), and battery HES was proposed by Kumar and colleagues in a different study. In an effort to cut energy expenditures, they applied three optimization algorithms: the JAYA method, the aggrandized class topper optimization (ACTO), and the PSO [29]. Diab et al. [30] presented a simulation model for a HES microgrid along with battery storage. Their goal was to hone the HES's efficiency, dependability, and cost-effectiveness while figuring out the optimal system size. They employed revolutionary optimization methods such as the moth flame optimization (MFO), water cycle algorithm (WCA), and WOA. The simulation results showed that WOA performed more proficiently than the other algorithms. Tabak et al. [31] undertook research to optimize a HES comprising a B_M, WT, and S_{PV} module, components. They scaled the system to suit the energy needs of the faculty building by optimizing it by means of a genetic algorithm (GA). Unlike earlier research, they put more emphasis on reliability and optimized the system size by adopting GWO. They noticed that the GWO approach performed superiorly to the GA outcomes.

Divya et al. [32] used the black widow optimization (BWO) algorithm to optimize HES under uncertainty constraints. With rigorous modeling and realistic validation, it emphasizes combining S_{PV}, wind, and hydro

sources while retaining a balance between cost-effectiveness and reliability. BWO showcases its potential for sustainable energy solutions by optimizing fitness to cut annual operating costs while effectively complying with specified loads using MATLAB. Gupta et al. [33] proposed a novel spoonbill swarm optimizer (SSO) to identify the optimal hybrid renewable-energy microgrid (MG) system for an Indian community. Considering technological, financial, social, environmental, and reliability considerations, the selected model comprises S_{PV}, wind, B_M, battery, DG, and electric vehicle (EV) components. Results corroborate the optimized MG system's efficiency across multiple criteria, demonstrating the SSO's superiority over competing methods in reducing convergence time and iterations. With the intent of maximizing reliability, minimizing expenses, and maintaining a sufficient power supply, a hybrid approach termed light spectrum optimizer (LSO) and deep attention dilated residual convolutional neural network (DADRCNN), notably LSO-DADRCNN, is applied by Ramesh et al. [34] for optimizing the sizing of HES with EV. By employing DADRCNN for EV energy demand forecast and LSO for system sizing, the approach trumps previous approaches such as heap-based optimizer (HBO), wild horse optimizer (WHO), and PSO in the realm of accuracy and cost reduction, attaining 96% efficiency and saving $1.7. Messini et al. [35] examined S_{PV}-hydrogen-based HES integration in oil and gas sites, emphasizing efficiency and carbon reduction. By optimizing with Fick's law algorithm (FLA), it cuts down costs, eradicates power loss, and lowers carbon dioxide emissions by 80%, promoting S_{PV} -hydrogen-based HES for sustainable energy policies. In Kaele, Cameroon, Koholé et al. [36] investigated an off-grid HES involving S_{PV}, wind, batteries, and DG for household, multimedia, and healthcare centers. Four meta-heuristic algorithms, such as charged system search (CSS), colliding bodies' optimization (CBO), water evaporation optimization (WEO), and teaching–learning-based optimization (TLBO), were applied to optimize HES in view of NPC. Results revealed that TLBO outperforms the other approaches.

A major impediment to the design of HES is the problem of volatility in R_ES, which has led to the exploration of several solutions. A bibliographical evaluation was carried out by Lei et al., [37] who explored recent findings and breakthroughs in wind speed (WS) and power forecasts. A novel hybrid electrical engineering method for short-term wind forecasting via wavelet transform is presented by Catalao et al. [38]. The WS and GHI statistics from the past year often serve as the cornerstones of the optimization strategies outlined in the literature. It is acknowledged, therefore, that historic meteorological data diverge significantly from projections made now. With the goal of improving energy efficiency, a number of models involving uncertainties have been devised. In this vein, Hocaoglu et al. examined the influence of global horizontal irradiance (GHI) forecasting on optimal system design efficiency, whereas Tascikarao glu et al. and Khalid et al. [39–41] used wind power prediction for the development of HES. Zhang et al. [42] proposed a novel methodology that combines HS, SA, and chaotic search to figure out the ideal size of grid-connected HES. To augment the precision of the size-optimized design, weather and load forecasts were executed leveraging artificial neural networks. To forecast long-term weather conditions, Alfonso et al. [43] offer a sizing methodology that makes use of long-term memory cells. Maleki et al. [44] reported a study testing a HES employing iterative neural networks to predict meteorological data for fulfilling household water needs. The study involved HS and a mix of HS and chaotic search. Gupta et al. [45] suggested solar-wind forecasting using artificial neural networks and size optimization using the BBO technique. Using projected data instead of actual data, they emphasized the benefits of HES size optimization.

An extensive literature review underlines how crucial it is to thoroughly evaluate external, technical, and financial energy sources while setting up HES. Recently, intelligent techniques have gained a growing following due to their stunning outcomes. Much more research needs to focus on grid-tied HES adopting intelligent techniques, although simulation tools like the HOMER are frequently applied in studies dwelling on grid-connected scenarios. Researchers have paid scant attention to the generation of power from biogas and biomass, in spite of their immense potential—especially in rural zones. Further, it is pointed out that multiple investigations have demonstrated that intelligent techniques may solve optimization problems and often use data from a single day that has not undergone an intensive statistical investigation. Therefore, more specialized work in HES needs to be done to fill this research gap. Moreover, a lot of the size optimization methods that are currently in the literature rely on historical data for solar irradiance and wind speed. On the other hand, historical meteorological data shows notable differences from present values. It has also been noticed that previously published studies have rarely used machine learning (ML) techniques for forecasting solar, wind, and temperature data to size HES. More specialized work in HES needs to be done to fill this research gap. A significant research gap exists because previously published studies have rarely used ML techniques for forecasting solar, wind, and temperature data to size HES.

In order to address the aforementioned problems, the current study first uses ML techniques, specifically Gaussian process regression (GPR), extreme gradient boosting (XGBT), support vector regression (SVR), and decision tree (DT), to perform hourly forecasts of temperature and

GHI of selected site for a year. The most appropriate solution is subsequently determined. On top of that, the optimal HES has been developed using the predicted GHI and temperature data. Employing a recently developed method known as Tunicate swarm algorithm (TSA), the optimal sizing of HES is carried out both with and without the predicted data. Furthermore, a comparison of the TSA, HS, and PSO techniques has been done and identified the appropriate outcome. More precisely, the key findings of the present work are encapsulated as follows:

The research work addressed the problem of optimal component sizing in HES by utilizing the recently established TSA algorithm. An assessment of TSA's effectiveness has also been undertaken by comparing its outcomes with those of well-known approaches such as HS and PSO.

Researchers usually disregarded biogas and biomass-based power generation, despite understanding that they indicate substantial and likely advantageous resources, most notably in rural regions. By incorporating biogas and biomass generators into the enacted HES in tandem with the scheduling of their operation, this study bridges this research gap.

The optimization of HES component sizing is carried out through the use of forecasted data, an idiosyncratic facet rarely found in existing literature. This distinctive approach enhances the effectiveness of size optimization for HES components. To facilitate this, assorted ML algorithms have been deployed to forecast temperature and sun irradiation. On top of that, the outcomes obtained by forecasted and historical data are contrasted, and the most appropriate solution is found.

2. Tunicate Swarm Algorithm

The tunicate colonies—a species of marine animal that inhabits piers, rocks, or the underneath of ships and boats—serve as a metaphor for the TSA algorithm. Tunicates are discernible from a distance owing to their bright blue-green bioluminescence, which usually mimics tiny, colorful blobs. These creatures have two ends: an open end and a closed end. The open end generates jet propulsion by using atrial siphons. Tunicates boost themselves vertically in the water by putting out bursts of fluid along with an explosive force that is gauged in millimeters. Even though they are so small, tunicates have an amazing knack for detecting food sources in the water, regardless of whether they are cognizant of them. Tunicates' primary functions embrace jet propulsion and swarm intelligence, which facilitate their ability to figure out the best places to find food [46].

2.1. Mathematical Modeling of TSA Technique

The mathematical modeling of the initial course of action of the tunicates, specifically their jet propulsion, must satisfy three requirements. These standards are meant to avert disputes between tunicates, modify potential tunicate positions, and render closeness to the intended tunicate. However, in order to seek out the optimum and best-suited solution, swarm behavior entails keeping an eye on the existence of fellow seekers. The sections that proceed delve into more detail about how these behaviors are illustrated mathematically [46].

Step 1: Avoiding Search Agent Conflicts

To avert the conflicts among search agents (S_A), vector $\overrightarrow{M}$ is put to use in used to determine the new location of S_A.

$$\overrightarrow{M} = \frac{\overrightarrow{F_G}}{\overrightarrow{F_S}} \tag{1}$$

$$\overrightarrow{F_G} = R_2 + R_3 - \overrightarrow{A} \tag{2}$$

$$\overrightarrow{A} = 2.R_1 \tag{3}$$

where, $\overrightarrow{F}_G$ defines the gravity force; $\overrightarrow{A}$ signifies deep ocean advection;R_1, R_2, R_3 are indicative of the random values ranging from 0 to 1; The social forces among S_A are encapsulated by $\overrightarrow{F_S}$.

The subsequent equation has been applied for calculation of the vector $\overrightarrow{F_S}$:

$$\overrightarrow{F_S} = [N_{mn} + R_1(N_{mx} - N_{mn})] \tag{4}$$

where;N_{mn}, N_{mx} signifies initial and subservient speeds required for social interaction.

Step 2: Moving Ahead in the Path of Best Neighbor

After abstaining from neighbor contentions, the S_A moves ahead in following the path of best neighbor.

$$\overrightarrow{d} = | \overrightarrow{P_S} - R \cdot \overrightarrow{P_T}(i) | \tag{5}$$

where, $\overrightarrow{d}$ indicates the distance between food source and S_A; i is the present iteration. The position of optimal food source is encapsulated by $\overrightarrow{P_S}$; the tunicate position is denoted by $\overrightarrow{P_T}(i)$; and R signifies a random value in the range of 0 and 1.

Step 3: Converge towards the Best S_A.

e_A may preserve its position with regard to its optimal location, which happens to be close to a food source.

$$\overrightarrow{U_p}(i) = \overrightarrow{P_S} + \overrightarrow{M} \cdot \overrightarrow{d}, \quad \text{if} \quad R \geq 0.5 \tag{6}$$

$$\overrightarrow{U_p}(i) = \overrightarrow{P_S} - \overrightarrow{M} \cdot \overrightarrow{d}, \quad \text{if} \quad R < 0.5 \tag{7}$$

where; $\overrightarrow{U_p}(i)$ symbolizes the tunicate's updated position relative to the food source position $\overrightarrow{P_S}$.

Step 4: Behavior of Swarm

In order to mimic the swarm behavior of tunicates mathematically, the positions of the leftover S_A are updated in accordance with the optimal location of the first of the two optimal solutions, displacing the other S_A's position unalterable. The formula listed below can be applied to demonstrate the tunicate swarm behavior:

$$U_P\left(\overrightarrow{i}+1\right)=\frac{\overrightarrow{U_P}(i)+\overrightarrow{U_P}(i+1)}{(2+R_1)} \tag{8}$$

After satisfying the predetermined stopping criteria, the TSA algorithm successfully converges to the optimal design for the given problem as the swarm behavior iteratively modifies the positions of other S_A toward the best optimal solution. Because of its collective behavior, which enables adaptive and efficient adjustments to changes, TSA exhibits remarkable resilience in dealing with dynamic and uncertain environments. Further, the steps of the TSA algorithm are outlined below.

- **Step 1:** Initialization of tunicate population $\overrightarrow{U_P}$.
- **Step 2:** Select the maximum number of iterations as well as the initial parameters.
- **Step 3:** Compute the fitness value for each S_A.
- **Step 4:** Upon calculating the fitness value, the optimal search agent within the specified search space is investigated.
- **Step 5:** Update each S_A's position by applying Eq. 8.
- **Step 6:**In a specific search space, adjust the updated S_A that crosses the boundary.
- **Step 7:** Determine the current fitness value of the search agent. Update U_P if there is a better solution than the prior best option.
- **Step 8:** The algorithm comes to an end if the stopping criterion is met. If not, go back and do steps 5 through 8.
- **Step 9:** Provide the most optimal solution that has been found thus far.

3. Modeling of HES Components

The primary emphasis of this research is on development of the most optimal viable HES that integrates B_M, biogas generator (B_G), and S_{PV} energy sources. Formulating mathematical expressions for each component is essential to efficiently designing and figuring out the optimal size for the HES. Consequently, these mathematical expressions are given a thorough overview in the sections that follow.

3.1. S_{PV} Panels

A S_{PV} system's output power ($P_{SP_V}(t)$) can be affected by several factors, such as the panel's size, the amount of sunlight it receives each day, the cell temperature, and its placement. This relationship can be expressed using Eq. 9 [47]:

$$P_{SP_V}(t)=e_{SP_V}\times A_{SP_V}\times R_S(t)\ (1-0.005(T_{CL}-25)) \tag{9}$$

where the efficiency of the S_{PV} modules is encapsulated by e_{SP_V}, while A_{SP_V} symbolizes the surface area of these modules. Additionally, the solar radiation received by the S_{PV} panel is represented by $R_S(t)$, and T_{CL} stands for the cell temperature. The mathematical expression for computing the cell temperature is mentioned below:

$$T_{CL}=T_{AT}+T_{CO}-200.8*R_S(t) \tag{10}$$

where, T_{AT} and T_{CO} stands for the ambient temperature and nominal operating cell temperature are represented by respectively.

3.2. BM

The power output of the B_M at a given hour "t" symbolizes as "P_M (t)" is calculated using the following equation [48]:

$$P_M=\frac{c_M\times d_M\times e_M\times 1000}{365\times 860\times h_M} \tag{11}$$

Biomass's calorific value is encapsulated by "c_M", "d_M" represents the quantity of available biomass, "e_M" symbolizes the efficiency of the biomass conversion process, and "h_M" stands for the number of hours the B_M operates daily.

3.3. BG

The power output of the B_G at a specific time "t" denoted as "P_G (t)" is computed using the following formula [49]:

$$P_G=\frac{c_G\times d_G\times e_G}{h_G\times 860} \tag{12}$$

Here, "c_G" symbolizes for calorific value of biogas, the daily availability of biogas is encapsulated by "d_G"; "e_G" stands for the overall efficiency of the biogas-to-electricity conversion process, and the daily operational hours of the B_G is encapsulated by "h_G".

3.4. Battery

The method of operation for the battery can be charging or discharging, contingent upon the balance between energy production and consumption. When the hourly electrical

load requirement exceeds the amount of electricity generated by the $R_E S$, the excess energy is stored in the battery during the charging mode. On the other hand, in the discharging mode, the battery releases stored energy to fulfil the load demand when it surpasses the amount of electricity supplied by $R_E S$. Depending on whether the battery is in the charging or discharging condition, Eqs. 13 to 15 calculate the battery's capacity at hour "t".

In the state of charging, the energy stored in the battery is indicated in equation as follows:

$$E^{s}_{Bt}(t) = E^{s}_{Bt}(t-1) + \left[E^{EE}_{B_M}(t) + E^{EE}_{B_G}(t) + E^{EE}_{SP_V}(t)\right] \times e_C \tag{13}$$

In the above equation, the energy stored in the battery at hour "t" is encapsulated by "$E^{s}_{Bt}(t)$". The terms "$E^{EE}_{B_M}(t)$," "$E^{EE}_{B_G}(t)$" and "$E^{EE}_{SP_V}(t)$" define the surplus energy generated by B_M, B_G, and S_{PV} systems, respectively, after meeting the electrical load demand. The battery charging efficiency is encapsulated by "e_C".

$$E^{s}_{Bt}(t) = (1 - \cap) \times E^{s}_{Bt}(t-1) - E_{OD}(t) \tag{14}$$

$$E_{OD}(t) = \frac{E_{DE}(t)}{e_i \times e_D} \tag{15}$$

Here, '$\cap$' denotes the rate at which the battery self-discharges at a given hour 't.' '$E_{OD}(t)$' stands for the overall electrical energy demand. 'e_D' and 'e_i' symbolizes for the efficiency of discharging the battery and the efficiency of the inverter, respectively. The energy demand that is not fulfilled by $R_E S$ is encapsulated by '$E_{DE}(t)$'.

$$E_{DE}(t) = E_{ED} - [E_{B_M}(t) + E_{B_G}(t) + (E_{SP_V}(t) \times e_i)] \tag{16}$$

'E_{ED}' denotes the hourly electrical load demand. $E_{SP_V}(t)$, $E_{B_M}(t)$, and $E_{B_G}(t)$ denotes energy generated by $S_{PV}, B_M,$ and B_G system, respectively.

3.5. Utility Grid

In case of grid-tied HES, the grid can operates in two distinct ways. In the initial mode, it has the capability to supply more electricity to the HES if the combined output from $R_E S$ and the battery is not enough to cope with the energy demand. Equation (17) provides a mathematical expression for this scenario [50, 51].

$$E_{GP}(t) = E_{ED}(t) - [E_{B_M}(t) + E_{B_G}(t) + ((E_{SP_V}(t) + (E^{d}_{Bt}(t) - E_{Btn})) \times e_i)] \tag{17}$$

The grid-supplied energy is encapsulated by "$E_{GP}(t)$". "E_{Btn}" symbolizes the minimum required battery storage capacity.

The second mode involves returning the excess energy generates by HES to the utility grid, which is determined by the following equation:

$$E_{GS}(t) = [E_{B_M}(t) + E_{B_G}(t) + (E_{SP_V}(t) + (E_{Btx} - E^{d}_{Bt}(t)) \times e_i] - E_{ED}(t) \tag{18}$$

"$E_{GS}(t)$)" reflects the excess energy that must be returned to the grid. The battery storage system's maximum capacity is indicated by the symbol "E_{Btx}".

3.6. Objective Function

The main intent of this research is to attain cost minimization while designing and sizing of the HES. The objective function that has been selected for minimization is the NPC. As an economic metric, this function takes into account a number of factors, such as capital costs (C^{NV}_{CP}), replacement costs (C^{NV}_{RP}), operating and maintenance costs (C^{NV}_{OM}), fuel consumption costs (C^{NV}_{F}), costs associated with obtaining electricity from the utility grid (C^{G}_{P}), and other pertinent factors. Furthermore, the objective function takes into consideration the revenue obtained from the sale of electricity to the power grid at a predetermined price (C^{G}_{S}) and salvage value (C^{NV}_{SL}). The mathematical expression for these financial factors is as follows:

$$NPC = C^{NV}_{CP} + C^{NV}_{RP} + C^{NV}_{OM} - C^{NV}_{SL} + C^{NV}_{F} + C^{G}_{P} - C^{G}_{S} \tag{19}$$

3.7. Constraints

The present system's optimization is limited by practical and technical constraints that must be addressed so as to provide viable solutions.

3.7.1. HES Components Constraints

The sizing of multiple components, such as N_{SP_V}, N_{Bt}, P_G, and P_M is figure out based on the electrical load demand. Consequently, constraints are there by set forth by carving out minimum and maximum boundaries for these components, which are elucidated as follows:

$$N_{SP_V} = \text{Integer},\ N^{n}_{SP_V} \le N_{SP_V} \le N^{x}_{SP_V} \tag{20}$$

$$N_{Bt} = \text{Integer},\ N^{n}_{Bt} \le N_{Bt} \le N^{x}_{Bt} \tag{21}$$

$$P_G = \text{Integer},\ P^{n}_{G} \le P_G \le P^{x}_{G} \tag{22}$$

$$P_M = \text{Integer},\ P^{n}_{M} \le P_M \le P^{x}_{M} \tag{23}$$

3.7.2. Battery Storage Capacity Boundaries

To ensure the safe operation of battery energy storage systems, it is imperative to specify both lower and upper capacity boundaries for the battery. These boundaries are articulated as follows:

$$E_{Btn} \leq E_{Bt}(t) \leq E_{Btx}$$

3.7.3. Power Reliability Constraint

The investigation in hand covers the possibility of the loss of power supply while addressing power reliability. When a user's energy demand exceeds the readily available generation, they are not able to obtain energy. Consequently, the following formula can be used to determine LPSP [20]:

$$\text{LPSP} = \sum_{t=1}^{t=8760} \frac{\text{Unserved load for one year}}{\text{Total load for one year}} \quad (24)$$

4. Description of Study Area

A set of villages in Uttar Pradesh, India's Agra district, encompasses the selected area. NASA meteorological data is used to obtain the GHI and ambient temperature data for the chosen area [52]. It can be inferred from the wind resources that there isn't enough wind in this region to generate electricity. As a result, wind is not used when modeling H_ES. This region produces 395 tons of biomass annually from agricultural waste, and 739 m^3 of biogas is produced every day. The studied region receives, on average, 5.27 kWh/m2 of solar radiation per day. The study classifies the year into three distinct seasons, each lasting four months, pursuant to the belief that temperature variations have an immense impact on energy demand. The summer season (S_S) is outlined as April through July, the moderate season (S_M) as August through November, and the winter season (S_W) as December through March. The investigating geographical area estimated daily energy consumptions for S_S, S_M, and S_W seasons are 2985.66, 2341.72, and 1266.44 kWh/day, respectively. Further, Figs. 1, 2, and 3 provides the graphic representation of the hourly electrical load demand, solar irradiation, and ambient temperature at the designated area. Moreover, the scheduling of bio-generators during peak load hours in each season is carried out in the present work. During S_S and S_M, the B_G is scheduled from 1:00 AM to 5:00 AM, while the B_M will operate from 6:00 PM to 12:00 PM in S_S and 04.00–12.00 pm in S_M, respectively. In the case of S_W, the B_G will operate in the evening from 5:00 PM to 7:00 PM, and the BM will function from 8:00 PM to 10:00 PM, respectively.

5. Techno-Economic Indexes

In this preliminary investigation, the optimization outcomes were appraised based on various techno-economic indices specified in Table 1 [41]. Additionally, the annual rates of real interest, inflation, and escalation are pegged at 0.11, 0.075, and 0.05, respectively. Beyond that, for optimizing theobjective function, a number of parameters including search agents, maximum iterations, and trial runs for TSA, HS and PSO algorithms are set as 30, 150 and 30 respectively.

6. Results and Discussion

In the present study, at first, the goal is to generate hourly forecasts for GHI and temperature for a one-year span. For this purpose, a variety of ML techniques, notably SVR, GPR, XGBT, and DT, are applied. Further, the performance of these models is compared through statistical indicators, and the most effective solution is chosen. After that, the acquired forecasted data is employed to size the HES. The sizing process of HES is accomplished by applying a recently developed technique called TSA, both with as well as without the aid of forecasted data. Added to that, a comparison has been made between the TSA, HS and PSO approaches. These algorithms undergo implementation by way of MATLAB, which runs hourly simulations for selected grid-linked HES over a year. After that, the outcomes are contrasted according to how best to minimize NPC while retaining power supply reliability.

6.1. Forecasting of Meteorological Data

Hourly forecasting for GHI and temperature has been conducted over the course of one year period using various ML techniques, including SVR, GPR, XGBT, and DT models. To expansively appraise the accuracy of the forecasted models (FMs), a scrupulous training and testing approach was adopted. First, four years of historical data for temperature and GHI from 2016 to 2019 were used to train multiple FMs. In the aftermath of training, the FMs underwent a real prediction stage, referred to as the testing phase, where they were able to forecast temperature and GHI via 2020 data. Through comparing the predicted values with the actual data and using statistical parameters namely the root mean square error (E_{RMS}), mean absolute error (E_{MA}), and correlation coefficient (R^2), the precision of each FM was checked out. Further, the statistical parameters for GHI and temperature for both the training and testing stages using ML approaches are determined and demonstrated in Table 2.

Table 2 renders it explicit that, throughout each of the training and testing phases, including temperature and GHI, the GPR model has the smallest E_{RMS}, E_{MA}, and largest R^2. As a result, HES has been developed using the

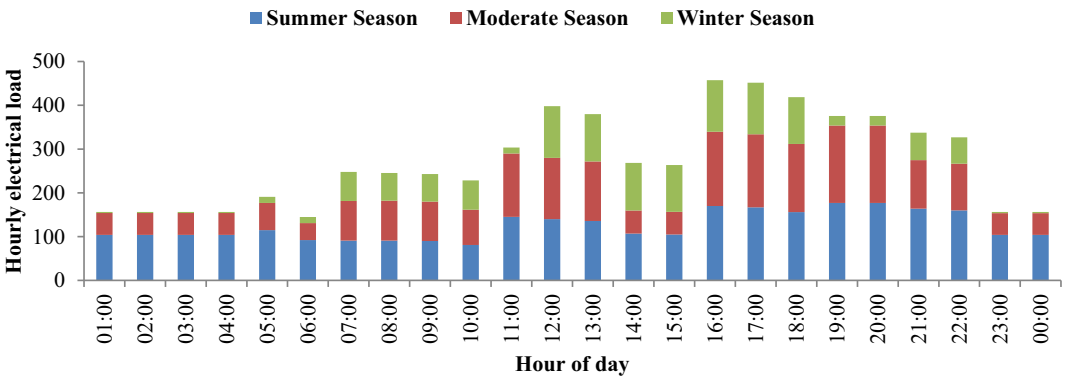

Fig. 1 Hourly electrical load demand of the designated area

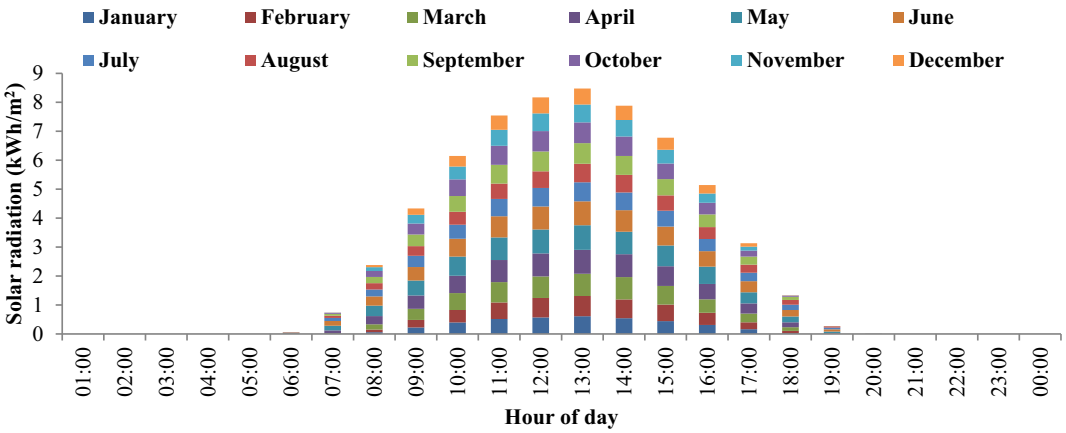

Fig. 2 Month wise solar radiation of given region

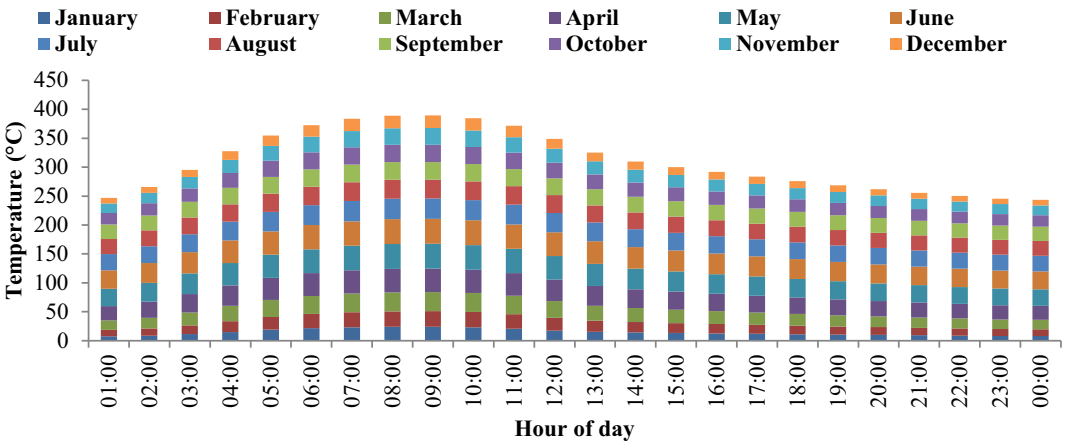

Fig. 3 Month wise temperature of given region

predicted GHI, and temperature data that were gathered through the GPR approach.

6.2. Optimization Results of Proposed HES

After acquiring the forecasted data for GHI and temperature for the chosen area, the optimal sizing of grid-linked HES, encompassing multiple R_ES, is practiced to accommodate the energy necessitates for the location at hand while utilizing the least amount of NPC and CE. TSA, a recently introduced optimization approach, was used to optimize the size of the intended HES. Likewise, to validate the findings, both the HS and PSO algorithms were applied for sizing. To facilitate this analysis, an hourly

simulation of selected HES was conducted in MATLAB for an entire year, with 150 iterations and 30 runs. Subsequently, a comparison of the different optimization outcomes derived through the use of these algorithms with and without forecasted data is shown in Table 3.

Upon analyzing the Table 3, it is clear that the TSA optimizer stands out as the most inexpensive option, with a minimal NPC of $519,340 and an enticing CE of 0.0606 kWh. These outcomes imply that the TSA prevails over the other selected approaches. A B_M of 85 kW, a B_G of 29 kW, a S_{PV} system of 234.7 kW (991 units), battery storage of 84 kWh (35 units), and a converter with a capacity of 100 kW are the optimal component sizes for this intended system. Additionally, some of the essential parameters incurred with the proposed grid-tied HES have also been looked at and addressed in the paragraphs that follow.

The fraction of $R_E S$ in the overall annual electricity generation facilitated by the implemented grid-tied HES is illustrated in Fig. 4. The data point out that S_{PV} panels, with an annual output of 439,410 kWh, are the predominant contributor to electricity generation. Next queued up were B_G and B_M generators that produced 45,907 kWh and 196,775 kWh annually, respectively.

Along with this, Table 4 lends a comprehensive analysis of the NPC by partitioning it into distinct categories that reflects revenue and cost components.

The data presented above reveals that the cost that stands out the most among all is the cost of hiring electricity. Under the given configuration, the total amount spent on grid purchases is $239,430, and the total amount

Table 3 Algorithms results for HES with and without forecasted data

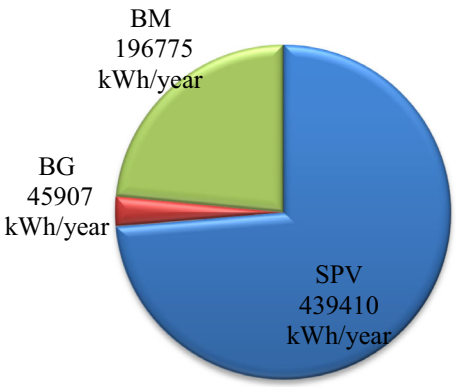

Fig. 4 Distribution of $R_E S$ in yearly electricity generation

Table 4 Cost wise distribution in NPC

S. no	Cost/revenue	Value ($)
1	C_{CP}^{NV}	137,430
2	C_{OM}^{NV}	130,520
3	C_{F}^{NV}	62,157
4	C_{SL}^{NV}	10,499
5	C_{P}^{G}	239,430
6	C_{S}^{G}	39,689

of earnings obtained from grid sales is $39,689. Further, Fig. 5 provides additional insight into the distribution of NPCs among HES components. Interestingly, B_M makes up 53% of the total, topping the shares held by S_{PV}, B_G, battery, and converter, which are 16%, 16%, 9%, and 6% of the total, respectively.

Additionally, information on the annual amount of electricity snapped up from and traded to the utility grid for each season is evaluated. It is measured that, for the S_S, 132,190 kWh were acquired from the grid, with 15,443 kWh sold back. Similarly, in the S_M, 67,567 kWh were purchased and 7240.2 kWh sold. In contrast, during the S_W, 27,358 kWh were bought and 18,603 kWh were sold to the grid. Overall, the annual energy sold and bought via the utility grid is 41,286 kWh and 229,900 kWh,

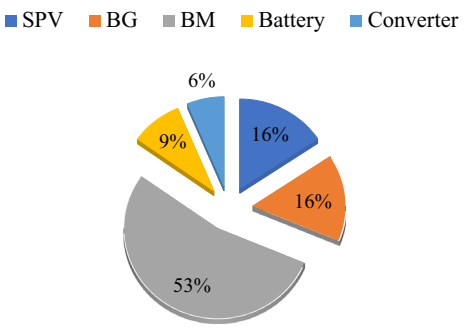

Fig. 5 NPC distribution among HES components

respectively. In response to heightened energy demand during the S_S, the HES yield a larger amount of energy in contrast to the S_M and S_W season. On the other hand, in S_W, sales and grid usage both turn down significantly, chiefly owing to lower energy demand during that time. Added to that, it is also assessed how battery input power (P_{BI}) and output power (P_{BO}) fluctuate cyclically. Specifically, P_{BO} for the S_S was the most substantial at 137,210 kWh in contrast to its P_{BI} of 22,817 kWh, indicating higher energy consumption than generation. Conversely, the S_M and S_W show higher P_{BI} values of 29,325 kWh and 39,571 kWh, respectively against their respective P_{BO} values of 80,254 kWh and 45,138 kWh, respectively, implying less energy demand. Interestingly enough, P_{BI} rises over S_W as opposed to S_S and S_M, indicating lower energy demand during this period.

7. Conclusion

This current investigation endeavors to optimize the size of HES in the far-flung territory of Agra district, India. A grid-tied system configuration was developed using forecasted data for GHI and temperature. Four ML methods—SVR, DT, GPR, and XGBT—were applied for forecasting, with GPR showcasing superior performance. As it turned out, data derived from GPR was used for sizing the HES. Further, size optimization of HES was then performed utilizing a recently developed approach, notably TSA. A comparison ensued between the TSA results and those obtained by HS and PSO. TSA encountered the optimal configuration of the HES, featuring a 234.7 kW S_{PV} system, a 29 kW B_G, an 85 kW B_M generator, and a 84 kWh battery bank with converter of 100 kW. The anticipated levelized CE and total NPC were set at $0.0606 per kWh and $519,340, respectively. The results of this research hold vitality for the development of HES in locales with reminiscent morphology. The implementation of these findings could lead to a consistent and reliable electricity supply, which would strengthen rural communities' quality of life. The result obtained from the proposed model is compared with the measured data to determine the level of uncertainty and accuracy. Since the proposed model has accuracy within the desired limit, therefore, the experimental and real-time models may be deployed at the selected site to provide electrical energy to consumers. Additionally, these research inferences line up with the aspirations of the Indian government, particularly in urging "power to all" diligence and striving to guarantee electricity supply 24 hours a day, seven days a week.

***Abstract*—This work introduces a Strategic Pseudo-Goal Perturbation (SPGP) technique, a novel approach to resolve deadlock situations in multi-agent navigation scenarios. Leveraging the robust framework of Safety Barrier Certificates, our method integrates a strategic perturbation mechanism that guides agents through social mini-games where deadlock and collision occur frequently. The method adopts a strategic calculation process where agents, upon encountering a deadlock select a pseudo goal within a predefined radius around the current position to resolve the deadlock among agents. The calculation is based on controlled strategic algorithm, ensuring that deviation towards pseudo-goal is both purposeful and effective in resolution of deadlock. Once the agent reaches the pseudo goal, it resumes the path towards the original goal, thereby enhancing navigational efficiency and safety. Experimental results demonstrates SPGP's efficacy in reducing deadlock instances and improving overall system throughput in variety of multi-agent navigation scenarios.**

***Index Terms*—Strategic Perturbation, Deadlock Avoidance, Multi-Agent Navigation, Social Mini-Games**

I. Introduction

In the domain of control and robotics, multi-agent navigation poses significant challenges, particularly when multiple autonomous agents operate within the same environment. These challenges are compounded in scenarios where agents must navigate social spaces and collisions among agents deemed to happen which are referred to as "social mini-games"—such as doorways, intersections, and L-corners. These environments necessitate not only collision avoidance but also efficient coordination among agents to prevent deadlock situations, where agents halt progress due to mutual obstruction [1]–[4].

Collision avoidance in multi-agent systems is a well-studied area, with numerous algorithms developed to enable autonomous agents to navigate without incidents [5]–[7]. But, the challenges of social mini-games introduces complex interaction dynamics which is not fully solved by the existing collision avoidance techniques. In these scenarios, agents often encounter deadlock due to the limited space for the agents to navigate and the symmetry found in the environment [8], [9]. Such deadlocks significantly restricts the flow of movement, leading to low efficiencies and performance.

Our method, Strategic Pseudo-Goal Perturbation (SPGP), addresses the challenge of deadlock in multi-agent navigation within social mini-games. SPGP innovates by combining Safety Barrier Certificates with a mechanism that, upon detecting a potential deadlock, strategically perturbs agents towards pseudo goals. These pseudo goals are generated based on a strategic algorithm that enforces efficient deviation from the agent's original path, facilitating the resolution of the deadlock. Once the agent reaches its pseudo goal, it recalculates its path towards the original goal, thus minimizing errors and increasing the efficiencies in this process. By concentrating on strategic perturbation rather than other techniques, SPGP offers solution to resolve deadlock in complex social navigation scenarios. This perturbation technique not only the efficiency of multi-agent navigation but also contributes to the improvement of autonomous agent coordination in constrained environments. Fig. 1 depicts the overview of SPGP method where navigation starts then deadlock ios detected and finally deadlock is resolved using the strategic perturbation.

This study lays contributions to the field of multi-agent navigation and deadlock avoidance in social mini-game scenarios. The key contributions are as follows:

- Introduced a Strategic Pseudo-Goal Perturbation (SPGP) method, a novel approach to generate deadlock-free situa-

tions in multi-agent navigation. This method strategically perturbs agents towards pseudo goals.
- Through iterative analysis, explored the variation of the perturbation radius and its effect on the effectiveness of deadlock resolution, providing insights into optimal perturbation strategies for varying environmental complexities and agent densities.
- Thoroughly tested the SPGP method across various complex social mini-games scenarios. These experiments depicts the flexibility and adaptability of our method, which shows its effectiveness in a wide range of common social navigation challenges.

II. Related Work

A. Safety Based Methods

The ORCA framework [10], along with its non-holonomic extension [11], shows provable safety in multi-agent navigation through single-integrator systems. This method efficiently generates optimal collision-free velocities by using linear programming to navigate constraints represented as half-planes in velocity space. While originally designed for holonomic systems, the framework's also been extended for non-holonomic constraints, aiming to impose minimal deviation from preferred velocities. However, the construction of half-planes in ORCA can lead to deadlocks, marking its primary limitation [12]. Ensuring safety in systems with double-integrator dynamics is more challenging, with safety largely influenced by the system's planning frequency. For instance, the NH-TTC framework [13] employs gradient descent to optimize a cost function that combines position with a time-to-collision component, which helps to prevent imminent collisions. NH-TTC's safety assurances improve as planning frequency increases towards infinity. Another set of methods uses the shortest path in the multi-agent network to reach the goal position in a complex environment [29], [30]. Similarly, the model predictive control (MPC) method [8] underscores safety as a function of both planning frequency and the extent of the time horizon. Further, Control Barrier Functions (CBFs) [15], [16] offer a method to design controllers ensuring safety by maintaining the forward invariance property in the set, ensuring that if an agent starts within a safety set, it remains within this set indefinitely, effectively preventing it to move away from the safe zone.

B. Learning Based Methods

The integration of conventional navigation techniques with machine learning represents a fast-evolving research space on learning-based motion planning. Among the various techniques, deep reinforcement learning (DRL) and trajectory prediction stand out for their success in multi-agent planning and navigation. DRL is applied to generate navigation policies through simulation, including for scenarios involving multiple robots in social mini-games. For instance, [17] describes a decentralized collision avoidance system for multi-robot scenarios using DRL and local sensory inputs. Another example is CADRL [18], which optimizes social robot navigation by employing a sparse reward system, with extensions like LSTM-based action selection in response to the proximity of other robots [19]. On the other hand, algorithms incorporating trajectory prediction focus on forecasting future robot positions to navigate dynamically among moving obstacles effectively.

Another avenue is Imitation Learning (IL) which is a machine learning strategy where an agent learns behaviors by mimicking expert demonstrations, typically faster than conventional optimization methods. These demonstrations often include state input pairs from expert policy executions. The main IL methodologies are Behavior Cloning (BC) [20], [21], which uses supervised learning to directly acquire an imitative policy; Inverse Reinforcement Learning (IRL) [22], which deduces a reward function from demonstrations to facilitate policy learning via Reinforcement Learning (RL) [23]; and approaches utilizing generative models [24]. Despite their efficiencies, IL approaches [25], [26] commonly face limitations in encoding state/safety and input constraints, presuming access to expert action data during demonstrations and struggling to adapt to scenarios beyond the expert demonstrations' distribution.

C. Deadlock Resolution Methods

Recent studies have explored structured perturbation strategies, such as the right-hand rule [27] and clockwise rotation [15], to enhance performance beyond random perturbation methods, even providing formal optimality guarantees. However, these approaches are constrained by a preset ordering, which restricts their applicability, often to scenarios with no more than three agents. Another different category of deadlock resolution techniques adopts priority and scheduling mechanisms which are generally found in managing intersection in autonomous agents research [28]. Notable among these protocols are First Come First Served (FCFS), reservation, and auction systems. Specifically, this method [29] prioritizes agents by their sequence of arrival at intersections. While straightforward to apply, this method may result in extended waiting periods and increased congestion when numerous vehicles converge on an intersection at the same time.

III. Preliminaries

In this section, we lay the basis for our contributions by discussing the foundational concepts of Control Barrier Functions (CBF), Safety Barrier Certificates (SBC) and Deadlock

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 10:26:38 UTC from IEEE Xplore. Restrictions apply.

conditions which form the basis for ensuring safety in multi-agent navigation.

A. Control Barrier Functions

Control Barrier Functions (CBFs) provides assurance of the forward invariance property of the safe set for the agents [15], [17].

$$\dot{x} = f(x) + g(x)u, \tag{1}$$

where $x \in \mathbb{R}^n$ represents the state and $u \in \mathbb{R}^m$ represents the control input, a set $\mathcal{C} \subseteq \mathbb{R}^n$ is said to be forward invariant if, for the initial condition $x(0) \in \mathcal{C}$, we have $x(t) \in \mathcal{C}$ for all $t \geq 0$. The set $\mathcal{C}$ is defined as the zero-superlevel set of a continuously differentiable function $h : \mathbb{R}^n \to \mathbb{R}$, such that

$$\mathcal{C} = \{x \in \mathbb{R}^n \mid h(x) \geq 0\}. \tag{2}$$

The time derivative of $h(x)$ around the trajectories of the agent's system is given by

$$\frac{dh(x)}{dt} = \frac{\partial h}{\partial x} \cdot \frac{dx}{dt} = \frac{\partial h}{\partial x} \cdot (f(x) + g(x)u), \tag{3}$$

or, using the Lie derivative form,

$$\frac{dh(x)}{dt} = L_f h(x) + L_g h(x)u. \tag{4}$$

A function $h(x)$ is a CBF for the set $\mathcal{C}$ if there exists an extended class-$\mathcal{K}$ function κ such that for all $x \in \mathbb{R}^n$,

$$\sup_{u \in \mathbb{R}^m} [L_f h(x) + L_g h(x)u + \kappa(h(x))] \geq 0, \tag{5}$$

where $L_f h(x)$ and $L_g h(x)$ denote the Lie derivatives of h along f and g, respectively. For $h(x)$ to serve as a CBF, it must satisfy the inequality

$$L_f h(x) + L_g h(x)u + \gamma h^3(x) \geq 0, \quad \forall x \in \mathbb{R}^n, \tag{6}$$

for some extended class-$\mathcal{K}$ function $\gamma h^3(x)$, assuring the system resides within the safe set $\mathcal{C}$ for every future timesteps. where γ represents the controlling parameter and $h(x)$ represents the barrier function.

B. Safety Barrier Certificates

Safety Barrier Certificates (SBCs) are designed for enforcing collision avoidance among various agents in a multi-agent system [15]. For agents i and j, with dynamics modeled as double integrator, the relative velocity and position vectors are denoted as Δp_{ij} and Δv_{ij} respectively. To ensure a safe distance D_s is maintained, the joint constraint for safety barrier of agents $i \neq j$ is expressed in equation 7:

$$A_{ij}u \leq b_{ij}, \tag{7}$$

where A_{ij} and b_{ij} are defined as follows:

- $A_{ij} = \begin{bmatrix} 0 \dots -\Delta p_{ij}^\top \dots \Delta p_{ij}^\top \dots 0 \end{bmatrix}$ with the corresponding states of agents i and j inserted in the matrix,
- $b_{ij} = \gamma h_{ij}^3 + \frac{\Delta v_{ij}^\top \Delta p_{ij}}{2(\alpha_i + \alpha_j)} - \frac{(\Delta v_{ij}^\top \Delta p_{ij})^2}{2\|\Delta p_{ij}\|^2} + \frac{\|\Delta v_{ij}\|^2}{2}$,
- $\gamma > 0$ is a controller parameter that regulates the approach to the safety boundary.

These constraints ensure that agent i's control input u_i and agent j's control input u_j avoid collisions by satisfying the safety barrier certificates, integrated within a quadratic programming (QP) framework for real-time applications.

Note: In the definition of b_{ij}, γ, h_{ij}, Δp_{ij}, and Δv_{ij} correspond to the controller parameter, the CBF function for agents i and j, relative position vector, and the relative velocity vectors among the two agents, respectively. The symbols α_i and α_j represent the acceleration constraints of agents i and j.

C. Deadlock Condition

Deadlock scenario in multi-agent navigation systems primarily arise due to the formation of symmetries in the environment that may lead to conflicts between agents. Such symmetries often manifest in scenarios where multiple agents, following identical or mirror-like navigation policies, encounter each other in narrow passages, intersections, or areas with restricted maneuverability. The mathematical expression for identifying a deadlock situation hinges on the actual control inputs u_i and the nominal control inputs $\hat{u}_i$. The nominal control inputs represent the intended direction and magnitude of movement in the absence of other agents in the given scenario. In contrast, the actual control inputs are adjusted based on the real-time navigation strategy, incorporating obstacle avoidance and agent-to-agent spacing requirements. Fig. 2 depicts the actual and nominal scenario along with the behaviour of controls which enforces deadlock to happen, equation 8 shows the condition for the deadlock to happen.

$$\text{Deadlock Condition:} \quad u_i = 0 \quad \text{and} \quad \hat{u}_i \neq 0 \tag{8}$$

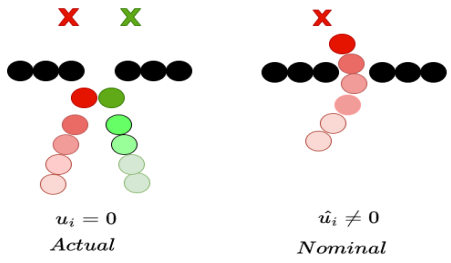

Fig. 2: Condition for deadlock among agents to occur

IV. Proposed Methodology

We introduce the Strategic Pseudo-Goal Perturbation (SPGP) framework, which is specifically designed to resolve deadlock in a centralized multi-agent environment through the use of pseudo goals. SPGP synthesizes strategic navigation with robust safety mechanisms to negotiate complex social interactions between agents.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 22,2024 at 10:26:38 UTC from IEEE Xplore. Restrictions apply.

A. Mathematical Formulation

In the Strategic Pseudo-Goal Perturbation (SPGP) framework, we analyse the problem with efficiently navigating a given set of autonomous agents $\mathcal{A} = \{1, 2, \ldots, N\}$ towards their respective targets within a given environment. Each agent i, starting from an initial position $\mathbf{p}_i(t)$, is tasked with reaching a designated goal $\mathbf{g}_i$. The SPGP framework aims to optimize the planned path so as to ensuring deadlock and collision avoidance and generating optimal path for the agents. This is achieved by generating the agent's trajectories using Safety Barrier Certificates (SBCs), which enforces a safety certificates using CBFs around each agent to prevent inter-agent collisions.

1) Safety Barrier Certificates: The SBCs are important in the SPGP's collision avoidance strategy, imposing constraints that dynamically adapt to the changing states and control of the agents. Given any two agents i and j, the safety constraints are formulated in the equation 9:

$$h_{ij}(t) = \|\mathbf{p}_i(t) - \mathbf{p}_j(t)\| - (r_i + r_j) \geq 0, \tag{9}$$

where $h_{ij}(t)$ denotes the euclidean distance between the two agents, and r_i and r_j represents their respective safety radius. This function ensures that the agents maintain a separation distance which should be greater than the sum of their respective safety radius, effectively establishing a collision-free path for the agents.

B. Pseudo-Goal Selection Strategy

When the agents actual controls are below a certain threshold ($\mathbf{u}_t$) then the deadlock occurs in the simulation. When deadlock occurs the pseudo-goal selection strategy plays an instrumental role in alleviating deadlock conditions that materialize when paths of agents intersect, leading to potential immobilization. This strategy ingeniously circumvents such predicaments by allocating an interim waypoint, designated as a pseudo-goal ($\mathbf{pg}_i$), towards which an agent can momentarily divert its course.

The framework develops the navigable region $\mathcal{B}(\mathbf{p}_i, \delta)$ as a circular section, the centre is positioned on the agent's existing position, with radius δ defining its extent. Within this area, a pseudo-goal is selected based on generating a random point x, y that aims to maximize the distance from surrounding agents, in alignment with the safety objectives for barrier certificates . The given procedure can be mathematically represented by the equation 10:

$$\mathbf{pg}_i = \mathbf{p}_i + \delta \times \begin{bmatrix} \cos(2\pi \times \mathrm{x}) \\ \sin(2\pi \times \mathrm{y}) \end{bmatrix}, \tag{10}$$

Fig. 3 depicts the strategic pseudo goal selection in a circle to resolve deadlock among the agents and enforce the maximum separation between agents.

Upon the identification of a feasible pseudo-goal, the agent updates its control inputs to navigate towards this new temporary target.The resulting trajectory is then a smooth, deadlock-free path that respects the dynamic constraints of the agent and is robust to uncertainties in the environment. As agents move towards their pseudo-goals, the path adjustment mechanism continuously updates the planned path to resolve the changing states of other agents and potential new obstacles in this process.

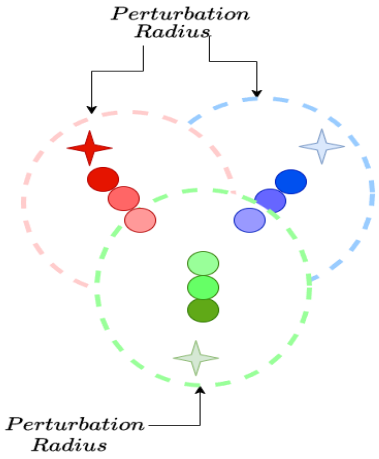

Fig. 3: Pseudo goal selection to resolve deadlock and enforce separation between agents

After reaching the pseudo-goal, agents resets their navigation systems back towards the primary target location. Algorithm 1 summarizes the Strategic Pseudo-Goal Perturbation (SPGP) algorithm and it's working to resolve the possible deadlocks.

C. Optimization Problem Formulation

The mathematical formulation of this optimization problem uses the core of Quadratic Programming (QP) expressed in equation 11. This approach tries to minimize the cost function $C(\mathbf{u})$, which serves as the main objective of our optimization. The objective function, represented in the equation 11, aims to reduce the squared deviation for the actual control inputs, $\mathbf{u}_i$, out of the nominal scenario, $\hat{\mathbf{u}}_i$. This minimization of cost function leads in achieving the scenario to mirror the nominal controller's trajectory, ensuring that each state remains as close to the intended path as feasibly possible, thus maximizing the accuracy and efficiency.

$$\begin{aligned} \mathbf{u}^* = \underset{\mathbf{u}\in\mathbb{R}^{2N}}{\operatorname{argmin}}\, C(\mathbf{u}) = \sum_{i=1}^{N} \|\mathbf{u}_i - \hat{\mathbf{u}}_i\|^2 \\ \text{s.t.} \\ A_{ij}\mathbf{u} \leq b_{ij}, \quad \forall i \neq j, \\ \|\mathbf{u}_i\|_2 \leq \alpha_i, \quad \forall i \in \mathcal{A}. \end{aligned} \tag{11}$$

This formulation considers the necessary constraints which includes $A_{ij}\mathbf{u} \leq b_{ij}$ condition that represents a safety barrier, which makes sure that each agent maintains a safe distance from its neighbouring agents, thereby reducing potential collisions. Furthermore, the condition $\|\mathbf{u}_i\|_2 \leq \alpha_i$ imposes a maximum limit on the magnitude of control inputs, confining all the agents within the practical and feasible values of dynamic capabilities .

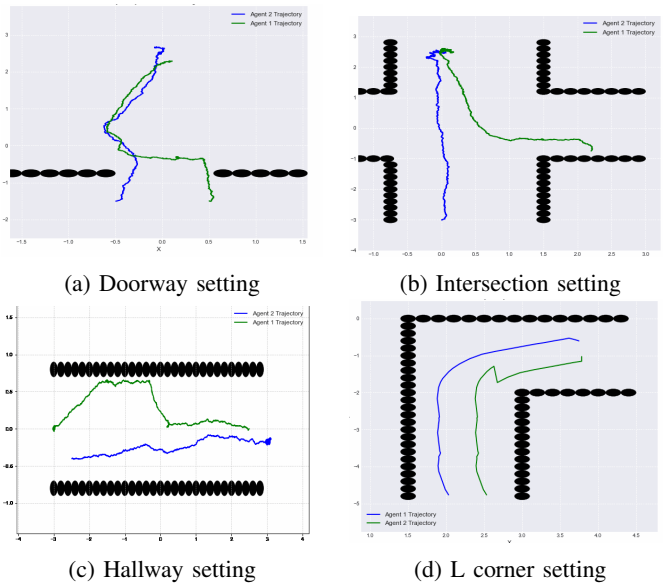
Run SBC Again

V. Results and Discussions

This section shows outcomes and comparative study of our Strategic Pseudo-Goal Perturbation (SPGP) framework against a suite of established methodologies within the multi-agent navigation domain. Central to our evaluation is the examination of Success rate (SR), average velocity change (ΔV) and path deviation across four challenging social mini-games scenarios. The optimization of agent trajectories, facilitated by Quadratic Programming (QP), seeks to minimize deviations from nominal controls, effectively mirroring the nominal controller's behavior.



(a) Doorway setting (b) Intersection setting

(c) Hallway setting (d) L corner setting

Fig. 4: Planned trajectories of two agent in social navigation settings using strategic perturbation

Table I shows the results for the SPGP and other baseline methods for Deadlock Resolution, Average change in velocity and Path difference. Due to random nature of our algorithm we carried out each scenario experiment 10 times and recorded the mean values and standard deviation values of the scores. The perturbation radius is taken as 1m and safety radius is taken as 0.2m for all agents. Our approach is meticulously benchmarked against counterparts such as SBC, ORCA and NH-TTC, Success rate measures the efficacy of reaching the goal position without and deadlock and collision, average change in velocity for each scenario is shown which should be minimal while navigation and path deviation is the difference in trajectory of actual and nominal case for the concerned scenario. It is measured by calculating the Hausdorff distance between actual and nominal trajectory. Notably, the SPGP framework depicts higher performance in achieving success as compared with different other methods, further SPGP also yields positive results in minimizing velocity changes and path deviations, thereby asserting its efficacy in ensuring smooth and efficient agent navigation. The trajectory for two agent scenario is depicted in Fig. 4. For doorway and intersection scenarios, the goal position for both agents were same. The SPGP successfully reaches the specified goal position without any collision and deadlock by enforcing the perturbation strategy. By ablation study, we concluded that SPGP is easily scalable upto 8 agents in the doorway setting, 10 agents in the intersection and hallway setting, and 5 agents in the L-corner setting however it was noted that on increasing the number of agents the time to goal for each agent increases which increases the simulation time and the maximum number of agent that each setting can handle vastly depends on the geometric properties of the social min-game scenarios.

Another experiment is performed to analyse the the effect on performance with variation of perturbation radius. In SPGP based on the perturbation radius the agent's perturbs from it's designated path to avoid deadlock and this effects the overall time in which the given agent's arrives at the goal position. To analyse this we measured the variation of makespan with different perturbation radius. The makespan value shows the time or timesteps required for the given agent to arrive at the goal position.

Fig 5 shows the change in makespan as the perturbation radius is varied. It is observed that on decreasing the perturbation radius the makepsan decreases, this happens because the agent's pseudo goal selection is confined to a circle of small radius. Also it was observed that after perturbation radius of

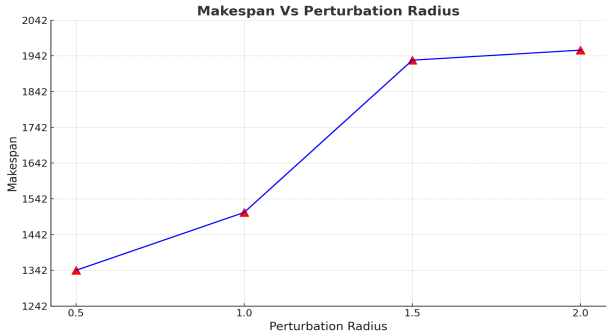

Fig. 5: Effect of different perturbation radius on the makespan of agent.

1.5m their is not much increase in makespan indicating that agent is not selecting too far away pseudo goal position so as to enforce distance between the deadlocked agents.

VI. Conclusion and Future Work

The study introduced a unique Strategic Pseudo-Goal Perturbation (SPGP) method, integrating Safety Barrier Certificates (SBCs) and a strategic pseudo-goal strategy to improve multi-agent navigation efficiency in complex social scenarios. Our findings, validated through diverse simulation scenarios, underscore SPGP's effectiveness in reducing makespan and enhancing path optimization. Future endeavors will focus on incorporating machine learning for predictive congestion management, extending the framework to heterogeneous agent systems for advanced coordination, and empirical validation in real-world settings to improve its application. Another extension of this work can be to integrate the SPGP framework with multi-agent reinforcement learning approaches and evaluate it on different social mini-game scenarios to check the method's efficacy for deadlock avoidance.

Abstract

This study investigates Electrostatic Ion Cyclotron (EIC) waves and their behaviour in weakly collisional plasmas, utilizing a proposed kinetic analytical model. The findings include alterations in EIC wave dispersion characteristics due to collisions, with parameters such as dust density, collision frequency, gyro-radius, magnetic field, density ratio, and electric field influencing wave growth rate and frequency. Temperature analysis reveals that higher electron-to-ion temperature ratios lead to increased frequency and critical drift velocity, while decreasing the growth rate. In addition, the critical drift velocity is studied for the unstable mode and it is observed that the relative density ratio increases with a reduction in critical drift velocity. Electron collisions destabilize EIC waves, while ion collisions stabilize them. Furthermore, the presence of dust particles decreases the growth rate of EIC waves as dust grain density increases. These results align with observations reported in previous literature.

1. Introduction

The widespread prevalence of plasma has made its exploration indispensable. Consequently, it's unsurprising that research on 'plasmas' [1–7] spans multiple domains, including various waves [8–14] and astrophysical phenomena [15–19]. Dusty plasmas are commonly utilized in semiconductor processing devices for various applications such as etching and deposition processes [20]. Dusty plasma is present in rocket exhaust, influencing the exhaust dynamics and interactions with the surrounding environment and the findings could be relevant for understanding and modelling the plasma phenomena in rocket exhaust plumes [21]. Dusty plasmas are employed in plasma processing reactors for material processing and surface treatments and the results from this work could be applied to improve the performance and control of these plasma processing reactors [20, 21]. EIC waves have been extensively studied using kinetic and fluid theories and their existence in laboratory plasmas has also been experimentally verified [22–25] [8, 9, 26–29]. These waves have been observed across diverse environments, spanning from fusion heating experiments [30–32], and space plasmas to laboratory experiments [33–38].

The initial experimental findings of EIC oscillations in laboratory plasmas driven by applying a positive potential to a small electrode immersed in a uniform magnetic field in a single-ended Q-machine were presented by D'Angelo and Motley [39]. The oscillations that were observed were identified to be current driven EIC instability which is theoretically anticipated by Drummond and Rosenbluth [40]. The fundamental characteristics of EIC waves lie in their propagation within magnetized plasmas, where ions and electrons oscillate perpendicular to the magnetic field due to their respective gyro-radii. The excitation mechanism of EIC waves involves the interaction between ions or electrons and the plasma waves, leading to the generation and propagation of EIC waves. EIC waves are often observed in a variety of plasma environments, including laboratory experiments, space plasmas, and astrophysical systems. In space, EIC waves have been detected in planetary magnetospheres, such as Earth's magnetosphere and the magnetospheres of Uranus [41].

Table 1. Detailing the species and their corresponding notations under consideration.

S. no.	Species	Equilibrium density	Drift Velocity	Velocity	Mass	Charge	Temperature	Collisional frequency
1.	Electrons	n_e^0	$u_{ed}\|\|\hat{z}$	v_e	m_e	$-e$	T_e	υ_e
2.	Ions	n_i^0	0	v_i	m_i	e	T_i	υ_i
3.	Dust Particles	n_d^0	0	v_d	m_d	Q_d^0	T_d	υ_d

Furthermore, EIC waves play a significant role in astrophysical environments such as in the Earth's magnetotail and in comets [42]. A well-known low-frequency field-aligned phenomenon which has received a lot of interest from the plasma physics field is the current-driven electrostatic ion cyclotron (EIC) instability [3, 43, 44]. In contrast to other current-driven instabilities, this one has a strikingly low threshold electron drift velocity [22].

The comprehension of the fundamental process that causes these ion-cyclotron instabilities in collisional plasma has been given by Chaturvedi and Kaw [45] using fluid treatment. D'Angelo [3] investigated in his studies the interaction between the plasma's charged dust particles and ion cyclotron waves. He showed that as the positive ion EIC mode's frequency gradually rises, the amount of negatively charged particles augments. In a Q-machine, the study on EIC wave was reported by Barkan *et al* [35] and it was observed that the growth rate of the wave was increased in the presence of a substantial amount of negatively charged dust particles. Chow and Rosenberg [46] concluded in their research using the kinetic theory, as the relative dust concentration augments, the critical drift velocity falls during the excitation of EIC waves.

Chaturvedi and Kaw [45] studied the collisional effects of EIC waves in a fully ionised collisional plasma and observed the stability of obliquely propagating EIC wave to current flow across the lines of the magnetic field via fluid theory. Satyanarayana *et al* [47] theoretically studied the collisional effects of EIC wave in bottomside ionosphere and it was discovered that electron collisions are unstable and are essential for causing the EIC instability to arise. Suszcynsky *et al* [38] conducted an experimental study on EIC waves in laboratory plasma in an auroral ionosphere regime and demonstrated the effects of collisions between neutral particles and waves in a Q-machine. Bharuthram *et al* [48] analyzed the impact of collisions on EIC waves in plasma using kinetic theory, resulting that the presence of collisions modifies the wave behaviour even in the absence of a transverse electric field.

In a magnetized plasma, Sharma *et al* [9] using fluid treatment examined the excitation of EIC waves. They found a strong relationship between the wave's frequency and growth rate in presence of an electric field, where the frequency rises as the growth rate lowers. The inclusion of a DC electric field can significantly affect the properties and behaviour of EIC waves, making it an important factor to consider in the analysis of these waves [49]. Koepke and Amatucci [8] studied the influence of transverse, localized, DC electric fields on the EIC instability in a Q machine. They have observed that the frequency increases with the magnetic field strength. Anshu *et al* [25] studied the EIC wave in a collisionless plasma via kinetic treatment. They observe that with an inclusion of an electric field, the dispersion relation modifies and it would further affect the frequency and growth rate of the wave.

A theoretical model has not been proposed, as far as the authors are aware to study the combined effect of collision, temperature and dust in the transverse DC electric field in a dusty magnetized plasma via kinetic theory. Therefore, the present study aims to extend the existing knowledge [9, 25] by investigating the collisional effects on the propagation of EIC waves in a magnetized dusty plasma with the inclusion of a DC electric field. This analysis is motivated by the need to understand the complex interplay between collisional processes, electric fields, and wave dynamics in such plasma environments.

This manuscript is structured as follows in the subsequent segments: section 2 presents an intricate examination of the electrostatic ion cyclotron wave, addressing the determination of growth rate, frequency, and critical drift. Section 3 involves a comparative analysis of our results with existing observational findings. Section 4 encapsulates the summary and conclusion.

2. Analytical modelling

We studied a magnetized dusty plasma consisting of multiple collisional species that is enclosed in a uniform and static magnetic field B oriented along the z-direction. The system under consideration comprises three distinct species: ions, electrons, and dust particles. A tabulated representation of their respective notations is presented in table 1.

An electrostatic ion cyclotron (EIC) wave exhibits a characteristic frequency ω and propagation vector k oriented in the y-z plane and its alignment is roughly perpendicular to the applied magnetic field. In addition, we

Table 2. Notations and their formulas.

S. no.	Notations	Terms	Formula
1.	ω_{ep}	Electron plasma frequency	$\sqrt{\frac{4\pi n_e^0 e^2}{m_e}}$
2.	ω_{ip}	Ion plasma frequency	$\sqrt{\frac{4\pi n_i^0 e^2}{m_i}}$
3.	ω_{dp}	Dust plasma frequency	$\sqrt{\frac{4\pi n_d^0 Q_d^2}{m_d}}$
4.	v_{et}	Electron thermal velocity	$\sqrt{\frac{2KT_e}{m_e}}$
5.	v_{it}	Ion thermal velocity	$\sqrt{\frac{2KT_i}{m_i}}$
6.	v_{dt}	Dust thermal velocity	$\sqrt{\frac{2KT_d}{m_d}}$

provide proposed system with a transverse dc electric field E in the direction of x. This introduction of an electric field induces $\vec{E} \times \vec{B}$ drift causing excitation of a wave and has a magnitude $v_E\left(=\frac{cE}{B}\right)$, oriented in the y-direction and c is the speed of light. We have also taken into consideration the appropriate drifting Maxwellian distribution function for the electrons which is as follows [43, 50]

$$f_e^0 = n_e^0\left(\frac{m_e}{2\pi KT_e}\right)^{3/2} \exp\left[\frac{-1}{2}\frac{m_e}{KT_e}\{v_x^2 + (v_y - v_E)^2 + (v_z - u_{ed})^2\}\right], \tag{1}$$

where $K =$ Boltzmann constant, $f_e^0 =$ Maxwellian distribution function at equilibrium, v_x, v_y and v_z represents the velocities in their respective directions.

On the other hand, by changing (n_e^0, m_e, T_e) with (n_d^0, m_d, T_d) and (n_i^0, m_i, T) and taking $u_{ed} = 0$ in equation (1), the dust (and ions) distribution function can be obtained.

In equilibrium, the quasi-neutrality condition says

$$en_i^0 = en_e^0 + Q_d^0 n_d^0 \tag{2}$$

For frequencies in the same range as the ion gyrofrequency, $\omega \approx \omega_{ic} \gg \omega_{dc}$, where $\omega_{ic}\left(=\frac{eB}{m_i c}\right)$ represents the ion cyclotron frequency and $\omega_{dc}\left(=\frac{Q_d^0 B}{m_d c}\right)$ is the dust cyclotron frequency. So, it is possible to consider the dust particles to be non-magnetized.

Applying the BGK collision model [23, 51] the following is the expression for the kinetic dispersion relation that governs the behaviour of electrostatic modes in a collisional dusty plasma with dust particles to be non-magnetized and is expressed as follows

$$\varepsilon(\omega, k) = 1 + \sum_\alpha \chi_\alpha = 0, \tag{3}$$

where χ are the susceptibilities and α refers to the electrons, ions and dust grains, respectively.

The electron, ion and dust grains susceptibilities are given as follows

$$\chi_e = \frac{2\omega_{ep}^2}{k^2 v_{et}^2}\left[1 + \frac{\omega_1 + i\upsilon_e}{k_z v_{et}}\sum_n \Gamma_n^e Z\left(\frac{\omega_1 + i\upsilon_e}{k_z v_{et}}\right)\right]\left[1 + \frac{i\upsilon_e}{k_z v_{et}}\sum_n \Gamma_n^e Z\left(\frac{\omega_1 + i\upsilon_e}{k_z v_{et}}\right)\right]^{-1}, \tag{4}$$

$$\chi_i = \frac{2\omega_{ip}^2}{k^2 v_{it}^2}\left[1 + \frac{\omega_2 + i\upsilon_i}{k_z v_{it}}\sum_n \Gamma_n^i Z\left(\frac{\omega_2 - n\omega_{ic} + i\upsilon_i}{k_z v_{it}}\right)\right]\left[1 + \frac{i\upsilon_i}{k_z v_{it}}\sum_n \Gamma_n^i Z\left(\frac{\omega_2 - n\omega_{ic} + i\upsilon_i}{k_z v_{it}}\right)\right]^{-1}, \tag{5}$$

$$\chi_d = \frac{2\omega_{dp}^2}{k^2 v_{dt}^2}\left[1 + \frac{\omega + i\upsilon_d}{k v_{dt}} Z\left(\frac{\omega + i\upsilon_d}{k v_{dt}}\right)\right]\left[1 + \frac{i\upsilon_d}{k v_{td}} Z\left(\frac{\omega + i\upsilon_d}{k v_{dt}}\right)\right]^{-1}, \tag{6}$$

where $\omega_1 = \omega - k_y v_E - k_z u_{ed}$ and $\omega_2 = \omega - k_y v_E$; k_y and k_z are the wave vector oriented along y and z-direction; $\Gamma_n^\alpha = I_n(\mu_\alpha)\exp(-\mu_\alpha)$, where $\mu_\alpha\left(=\frac{k_y^2\rho_\alpha^2}{2}\right)$, $\rho_\alpha\left(=\sqrt{\frac{v_{\alpha t}^2}{\omega_{\alpha c}^2}}\right)$ denotes the gyroradius, I_n represents the modified nth order Bessel function; Z depicts the plasma dispersion function [52] and other parameters are tabulated in table 2.

Analytical solutions of equation (3) are possible in some regimes by introducing some simplifying conditions. We are only concerned with the phase-velocity regime for the EIC waves. (Drummond and Rosenbluth) [40]

$$\frac{\omega_1 + i\upsilon_e}{k_z v_{et}} \ll 1, \tag{7}$$

$$\frac{\omega_2 - n\omega_{ic} + i\upsilon_i}{k_z v_{it}} \gg 1, \tag{8}$$

$$\frac{\omega + i\upsilon_d}{k v_{dt}} \gg 1 \tag{9}$$

Equation (4) can be simplified by assuming $\mu_e \ll 1$, and utilized only $n = 0$ term because $\Gamma_0^e = 1$ and $\Gamma_n^e = 0$ when $n \neq 0$. This presumption allows us to conveniently expand the plasma dispersive function $Z(\xi)$ within the framework of kinetic theory [53] as follows:

$$Z(\xi_\alpha) = -2\xi_\alpha + \frac{2}{3}\xi_\alpha^3 + ...+i\sqrt{\pi}e^{-\xi_\alpha^2}, \quad \text{if } \xi_\alpha \ll 1 \tag{10}$$

$$Z(\xi_\alpha) = -\frac{1}{\xi_\alpha} - \frac{1}{2\xi_\alpha^3} + ...+i\sqrt{\pi}e^{-\xi_\alpha^2}, \quad \text{if } \xi_\alpha \gg 1, \tag{11}$$

where $\xi_e = \frac{\omega_1 + i\upsilon_e}{k_z v_{et}}$, $\xi_i = \frac{\omega_2 - n\omega_{ic} + i\upsilon_i}{k_z v_{it}}$ and $\xi_d = \frac{\omega + i\upsilon_d}{k v_{dt}}$.

So, equation (4) can be rewritten after substituting equations (7) and (10)

$$\chi_e = \frac{2\omega_{ep}^2}{k^2 v_{et}^2}\left[1 + \frac{\sqrt{\pi}\upsilon_e}{k_z v_{et}} + i\sqrt{\pi}\frac{\omega_1}{k_z v_{et}}\left(1 + \frac{\sqrt{\pi}\upsilon_e}{k_z v_{et}}\right)\right]. \tag{12}$$

For the ions, we can approximate the equation (5) by retaining only n = 0 and n = 1 terms in the χ_i summation; including ions-neutral collisions and further assuming $\omega \approx \omega_{ci}$, $\frac{\upsilon_i}{\omega} \ll 1$ and $\frac{\upsilon_i}{\omega - \omega_{ic}} \ll 1$, the equation reduces to

$$\chi_i = \frac{2\omega_{ip}^2(\omega_2 + i\upsilon_i)\left(1 - \frac{1 - \Gamma_0^i}{\mu_i} - \Gamma_1^i\right) - \omega_{ic}(1 - \Gamma_0^i)}{k^2 v_{it}^2(\omega_2 - \omega_{ic}) - i\upsilon_i\left[\frac{\omega_2 - \omega_{ic}}{\omega_2}\Gamma_0^i - (1 - \Gamma_1^i)\right]}. \tag{13}$$

Equation (6) can be solved by substituting equations (9) and (11), here we have neglected the dust collision frequency because the mass of dust is very large and hence, this equation abridges to

$$\chi_d = -\frac{\omega_{dp}^2}{\omega^2}. \tag{14}$$

In this context, we can ignore this term $\frac{\omega_{dp}^2}{\omega^2} \ll 1$. Also, $\frac{\omega_{dp}^2}{\omega^2} \ll \chi_i$.

Substituting equations (12)–(14) in equation (3), we get

$$\begin{aligned}\varepsilon(\omega, k) = 1 &+ \frac{2\omega_{ep}^2}{k^2 v_{et}^2}\left[1 + \frac{\sqrt{\pi}\upsilon_e}{k_z v_{et}} + i\sqrt{\pi}\frac{\omega_1}{k_z v_{et}}\left(1 + \frac{\sqrt{\pi}\upsilon_e}{k_z v_{et}}\right)\right] \\ &+ \frac{2\omega_{ip}^2(\omega_2 + i\upsilon_i)\left(1 - \frac{1 - \Gamma_0^i}{\mu_i} - \Gamma_1^i\right) - \omega_{ic}(1 - \Gamma_0^i)}{k^2 v_{it}^2(\omega_2 - \omega_{ic}) - i\upsilon_i\left[\frac{\omega_2 - \omega_{ic}}{\omega_2}\Gamma_0^i - (1 - \Gamma_1^i)\right]}\end{aligned} \tag{15}$$

This results in the EIC waves' dispersion relation for collisional plasma.

The wave is either growing or damped, the dispersion relation is used to determine the solutions for the EIC waves. The following equations determine the real and imaginary components of the frequency

$$\varepsilon_r(\omega, k) = 0|_{\omega=\omega_r}, \tag{16}$$

where ε_r is the real part of equation (15)

The frequency imaginary part is defined by [54]

$$\gamma = \left.\frac{-\varepsilon_i(\omega, k)}{\frac{\partial\varepsilon_r(\omega, k)}{\partial\omega}}\right|_{\omega=\omega_r}, \tag{17}$$

where ε_i denotes the imaginary part of equation (15)

Determining the real and imaginary parts of the equations (16) and (17) and leading to

$$\omega_r = \omega_{ic}(1 + \Delta) + k_y v_E, \tag{18}$$

where

$$\Delta = \frac{\Gamma_1^i}{1 - \Gamma_1^i - \dfrac{1 - \Gamma_0^i}{\mu_i} + \dfrac{T_i}{T_e}\left(1 + \dfrac{k^2 T_e}{4\pi n_e e^2} + \dfrac{1}{1 + (P_e + P_i)}\right)},$$

where $P_e = \dfrac{\sqrt{\pi}\,\upsilon_e}{k_z v_{et}}$;

$$P_i = \upsilon_i \frac{\omega_2\left(1 - \dfrac{1 - \Gamma_0^i}{\mu_i} - \Gamma_1^i\right) - \omega_{ic}(1 - \Gamma_0^i)}{(\omega_2 - \omega_{ic})^2}.$$

$$\gamma = -\sqrt{\pi}\frac{(\omega_r - k_y v_E - \omega_{ic})^2}{\Gamma_1^i \omega_{ic}}\frac{T_i}{T_e}\left[\frac{(\omega_r - k_y v_E - k_z u_{ed})}{k_z v_{et}}\left(1 + \frac{\sqrt{\pi}\,\upsilon_e}{k_z v_{et}}\right)\right] - \upsilon_i[1 - \Gamma_1^i]. \tag{19}$$

The analytical expressions for the real frequency and growth rate are given in equations (18) and (19) of the EIC waves in the presence of a transverse dc electric field If $v_E \to 0$ and $\upsilon_i = \upsilon_e = 0$, these mathematical formulations are similar to the results that Chow and Rosenberg reported in their prior works [46, 55]. Moreover, we replicate the expressions of Anshu *et al* [25] in the absence of collisions.

The wave growth rate, given by equation (19), changes to equation (20), if we account for the dust component.

$$\gamma = -\sqrt{\pi}\left[\frac{\dfrac{2\omega_{ep}^2}{k^2 v_{et}^2}\dfrac{(\omega_r - k_y v_E - k_z u_{ed})}{k_z v_{et}}\left(1 + \dfrac{\sqrt{\pi}\,\upsilon_e}{k_z v_{et}}\right)}{\dfrac{2\omega_{ip}^2}{k^2 v_{it}^2}\Gamma_1^i\dfrac{\omega_{ic}}{(\omega_r - k_y v_E - \omega_{ic})^2} + \dfrac{2\omega_{dp}^2}{\omega_r^3}}\right] - \upsilon_i[1 - \Gamma_1^i]. \tag{20}$$

The criterion $\gamma = 0$, which pertains to the point of marginal stability, is referred to as the critical drift velocity, u_{ed}. The expression for u_{ed} is provided as follows

$$u_{ed} = \frac{1}{k_z}\left[(\omega_r - k_y v_E) + \frac{\omega_{ic}\Gamma_1^i \upsilon_i[1 - \Gamma_1^i]}{\sqrt{\pi}(\omega_r - k_y v_E - \omega_{ic})^2}\frac{T_e}{T_i}\frac{k_z v_{et}}{\left(1 + \dfrac{\sqrt{\pi}\,\upsilon_e}{k_z v_{et}}\right)}\right]. \tag{21}$$

3. Results and discussion

In this manuscript, an analytical model is formulated for a weakly ionized collisional magnetized plasma to investigate the excitation of the EIC wave in the presence of negatively charged dust grains, incorporating an electric field through kinetic theory. The proposed model aims to examine the interaction between various plasma parameters, including gyro-radius, temperature, density etc, and the impact of collisions to understand the behaviour of the wave. The equations governing the EIC wave in section 2 are utilized to determine the frequency, growth rate, and critical drift. MATLAB is employed to generate graphs, based on the analytical solutions for real frequency and growth rate. In the present analysis, typical dusty plasma parameters of the laboratory conditions have been used [8, 35, 46, 56] i.e., plasma density of ion $n_i^0 = 10^9$ cm^{-3}, plasma density of electron $n_e^0 = (1 \times 10^9 - 0.2 \times 10^9)$ cm^{-3}, density of the dust grains $n_d^0 = (1 - 5) \times 10^4$ cm^{-3}, magnetic field B = (0.1 − 4.5) kG, ion mass $m_i = 39 \times 1.67 \times 10^{-24}$ gm, the electron mass $m_e = 9.1 \times 10^{-28}$ gm, the electronic charge e = 4.8×10^{-10}*statcoul*, the speed of light c = 3×10^{10} cm s^{-1}, ion temperature $T_i = 0.2$ eV, electron temperature $T_e = 0.2$ eV [8, 35, 46]; the charge of the dust grain $Q_d^0 = (10^3 - 10^4)e$, dust grain mass $m_d = 10^{12} \times 1.67 \times 10^{-24}$ gm, K = 1.38×10^{-16} erg/Kel is the Boltzmann constant , $k_z = 0.1$ cm^{-1}, $k_y = 1$ cm^{-1} [25]; the relative density ratio varies from 1–10 [8], the gyro-radius parameter varies from 0 − 3.5 [8], Electric field E = 0.35 *stat V* cm^{-1} [25], an ion collisional frequency $\upsilon_i = 1 \times 10^3$ s^{-1} [38], an electron collisional frequency $\upsilon_e = 4 \times 10^5$ s^{-1} [38, 56], the critical electron drift velocity $u_{ed} = 6 \times 10^7$ cm s^{-1} [8].

Figure 1 portrays the plot of normalized growth rate as a function of the gyro-radius parameter for varying δ i.e., (a) $\delta = 0.4$, (b) $\delta = 1.4$, (c) $\delta = 3$, and (d) $\delta = 4$, respectively. From figure 1, observing the trend, it becomes apparent that as the gyro-radius parameter values increase, the growth rate of the instability initially increases, reaching a maximum value i.e., $\gamma = 2.19 \times 10^4$ s^{-1} for $\mu_i = 0.96$ at $\delta = 4$. Following this peak, the

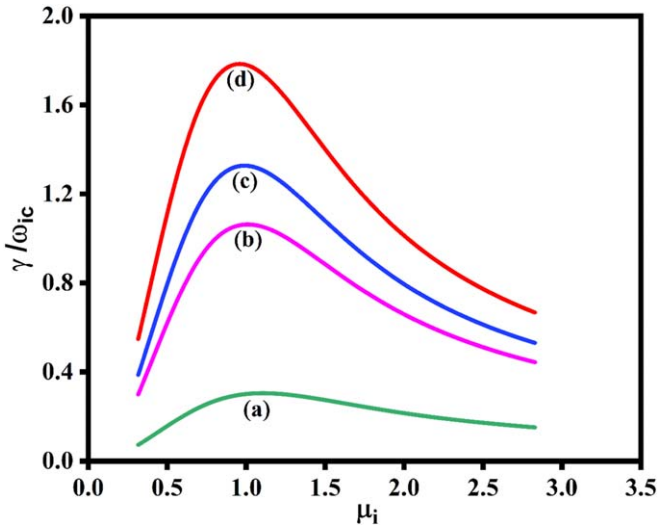

Figure 1. Variation in normalized growth rate γ/ω_{ic} with the finite gyro-radius parameter μ_i of EIC wave for varying δ i.e., (a) $\delta = 0.4$, (b) $\delta = 1.4$, (c) $\delta = 3$, and (d) $\delta = 4$..

growth rate of the instability subsequently decreases. It can also be inferred that with the increase in the relative density ratio, the growth rate of the unstable wave augments. When $\upsilon_e = \upsilon_i \rightarrow 0$ in equation (20), the growth rate increases and its corresponding value $\gamma = 2.5 \times 10^5$ s^{-1} for $\delta = 4$. This result follows the same trend as observed by the experimental observation of Chow and Rosenberg in the absence of collisions [46]. Moreover, it can also be observed that the maximum normalized growth rate of EIC wave for $\delta = 4$ is ~1.8 in the present model, whereas in our previous collisionless study, it was ~5 [25]. The reduction in the value of growth rate was observed after the inclusion of collisions can be ascribed to the increased complexity that is incorporated into the system. Because of these extra complexities, charged particles become less responsive to external perturbations, which results in a reduction in the overall growth rate.

The normalized real frequency variation corresponding to the gyro-radius parameter has been plotted in figures 2(a) and (b) for different sets of relative density ratios i.e., δ (a) $\delta = 0.4$, (b) $\delta = 1.4$, (c) $\delta = 3$, and (d) $\delta = 4$, in the presence and absence of electric field, respectively. From the plots, it can be noted that the frequency experiences an upward trend as the gyro-radius parameters increase until reaching their maximum point. Subsequently, there is a decline in magnitude for all relative density ratio values. Furthermore, an increase in the relative density ratio results in an augmentation of the real frequency. We can conclude that after the inclusion of the electric field, the real frequency follows a similar trend as in the case of the absence of the electric field despite the rise in their values. Hence, we can say that there is a significant increase in the real frequency by a factor of ~4 as the electric field included for $\delta = 4.0$ as compared with the real frequency without the electric field in the above-mentioned graphs. This is because of the reason that the Doppler effect is caused by $\vec{E} \times \vec{B}$ drift among particles, which is induced by the occurrence of an electric field. As a result, the waves' frequency grows when a dc transverse electric field is applied. The inset of figure 2(b) shows the result of $\upsilon_e = \upsilon_i \rightarrow 0$. We can say that the frequency, in collisionless case, is more as compared to collisional plasma because the charged particles can react more swiftly to an external perturbation than in collisional plasma. . Furthermore, the normalized real frequency in collisionless case ~1.46 for $\delta = 4.0$ as shown in inset of figure 2(b), which follows the same trend as observed in experimental results of Chow and Rosenberg where the value of normalized real frequency is ~1.47 [46]. Hence our result is in good agreement with the experimental observation of Chow and Rosenberg.

For the case $\delta = 1$ (no dust particles), figures 3(a) and (b) depict the impact of variation in electron collision frequency on the real frequency and growth rate, respectively. Observing the plotted data, it is evident that both frequency and growth rate values exhibit an upward trend as the gyro-radius parameter increases until they reach a maximum. Subsequently, there is a decrease in magnitude for both parameters. In both the graphs, the dash curve (a) corresponds to the collisionless case ($\upsilon_e = \upsilon_i \rightarrow 0$) and other solid curves corresponds to the collisional case for $\upsilon_i = 1 \times 10^3$ rad s^{-1} and varying υ_e i.e. (b) $\upsilon_e = 1 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (d) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (e) $\upsilon_e = 7 \times 10^5$ rad s^{-1}. It can be seen that the real frequency and growth rate (for curve (b)) for the chosen fixed plasma parameters is nearly equal to the collisionless case i.e., curve (a). This is because ion collisions have a stabilising effect whereas electron collisions have a destabilising effect [47]. For the limit, $\frac{\upsilon_e}{k_z v_{et}} \ll 1$, the ion collisions dominate electron collisions destabilising effects. As the υ_e increases to the higher value, the electron collisions start to dominate and an enhancement of the real frequency and rate of

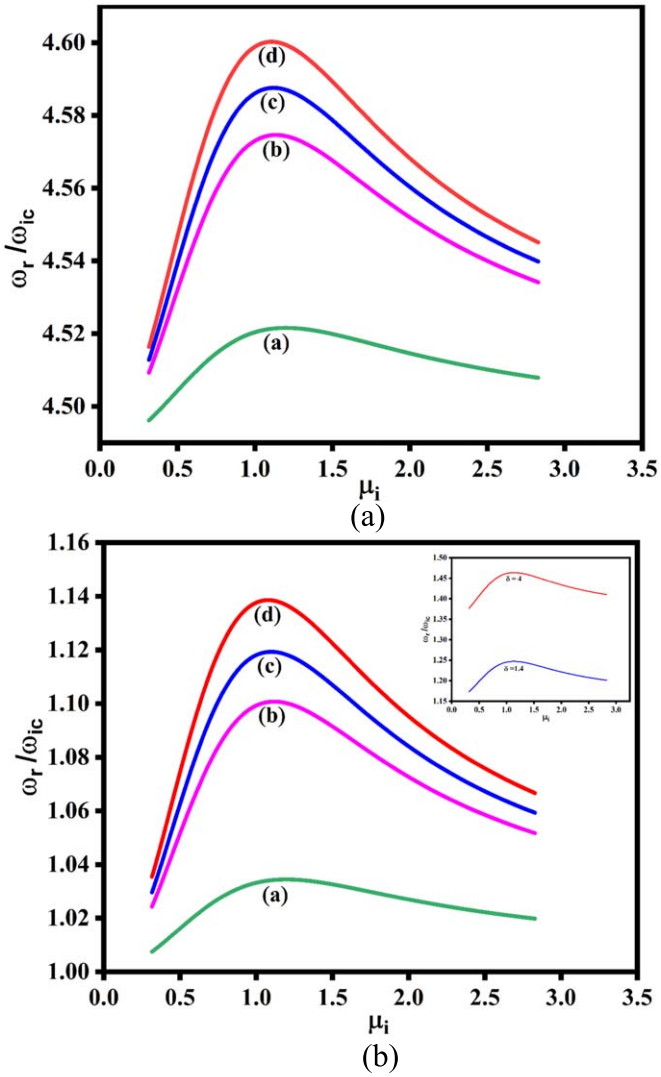

Figure 2. (a): The normalized real frequency ω_r/ω_{ic} graph with finite gyro-radius parameter μ_i of EIC wave with the electric field for varying δ i.e., (a) $\delta = 0.4$, (b) $\delta = 1.4$, (c) $\delta = 3$, and (d) $\delta = 4$. (b): Variation in normalized real frequency ω_r/ω_{ic} with the finite gyro-radius parameter μ_i without the electric field for varying δ with collisions and inset of figure 2(b) portrays the collisionless case.

growth is observed. We can infer that the wave's frequency has slightly increased while the growth rate has increased considerably when electron collision frequency augments. Our result is analogous to the Bharuthram *et al* [48] findings, where similar trend in real frequency and growth rate has been reported with an augment in the electron collisional frequencies.

The existence of negatively charged dust particles with $\delta = 3$ is the next aspect we take into account for $n_d^0 = 5 \times 10^4$ cm^{-3} in figures 4(a) and (b). Figures 4(a) and (b) depict the impact of variation of electron collision frequencies υ_e i.e. (b) $\upsilon_e = 1 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (d) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (e) $\upsilon_e = 7 \times 10^5$ rad s^{-1}. on real frequency and growth rate with gyro-radius parameter of the wave for $\upsilon_i = 1 \times 10^3$ rad s^{-1}. From the plots, it can be noted that it follows the same trend as in the above-mentioned graphs i.e., absence of dust particles with gyro-radius parameter and electron collision frequency. Moreover, we can conclude that after the addition of the dust grains in the plasma system, the growth rate and frequency for both the cases i.e., collisionless (figure 4 curve (a)) and collisional (figure 4 curve (b)–(e)) gets enhanced as compared to the previous graphs i.e., figures 3(a) and (b). Hence, we can say that after the inclusion of dust grains, growth rate upsurges by a factor of ~1.9 for $\upsilon_e = 0$ in the above-mentioned graphs. This is because the addition of the dust grains modifies the properties of the EIC wave and the collective effect of charged particles (electrons, ions and dust particles) becomes more intricate and their interaction leads to the augmentation in frequency and growth rate of the wave. Our findings matches with Chow and Rosenberg's [46] for a collisionless dusty plasma. Again, our results are in line with the findings of Bharuthram *et al* [48], because they also reported that the value of growth rate and real frequency increases after the inclusion of dust.

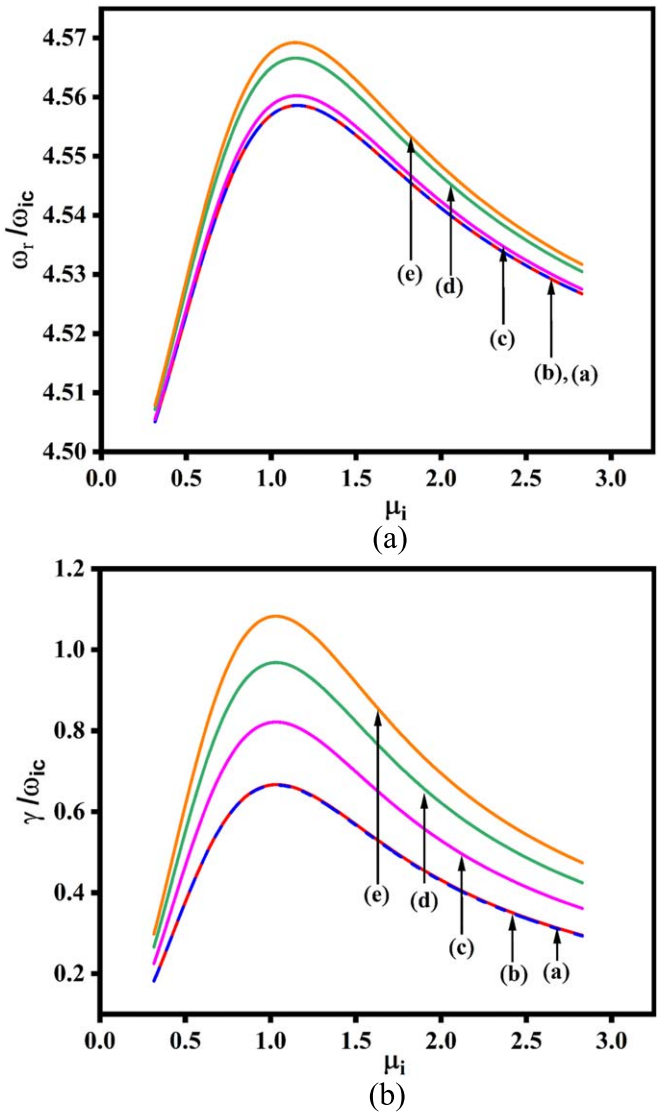

Figure 3. (a): The normalized real frequency ω_r/ω_{ic} variation for the case $\delta = 1$ corresponding to the finite gyro-radius parameter μ_i for different electron collisional frequencies υ_e i.e., (a) $\upsilon_e = 0$, (b) $\upsilon_e = 1 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (d) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (e) $\upsilon_e = 7 \times 10^5$ rad s^{-1}. (b): The normalized growth rate γ/ω_{ic} variation for the case $\delta = 1$ corresponding to the finite gyro-radius parameter μ_i for different electron collisional frequencies υ_e i.e., $\upsilon_e = 0$, (b) $\upsilon_e = 1 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (d) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (e) $\upsilon_e = 7 \times 10^5$ rad s^{-1}.

Figure 5(a) illustrates the impact of the relative density ratio on the normalized real frequency of the wave. We observed that the normalized real frequency is in a direct relationship with respect to the $\delta (=n_i^0/n_e^0)$, and it can be verified from our equation (18). Our outcome aligns with Chow and Rosenberg's theoretical conclusion [46] in the absence of an electric field and Anshu *et al* results in the absence of collisions [25].

Figure 5(b) illustrates the impact of normalized growth rate for varying υ_e i.e., (a) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (b) $\upsilon_e = 6 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 8 \times 10^5$ rad s^{-1} on the relative density ratio of the wave. As the relative density ratio increases in the plasma, the growth rate of the instability shows an augmentation. This phenomenon may be attributed to the concurrent decrease in the plasma density of electrons relative to the plasma density of ions. With an increase in the values of δ, the effective mass of ions $\mathrm{m_{ieff}}\left(=\frac{\mathrm{m_i}}{\delta}\right)$ becomes smaller than m_i, leading to enhanced mobility and, consequently, an increase in the growth rate of the instability. Figure 5(b) demonstrates unequivocally that, in accordance with the growth rate expression i.e., equation (19), the normalised growth rate increases linearly with an increase in υ_e. It is well known that electron collisions can cause the destabilization of EIC waves as shown by numerous studies [45, 47, 57]. Moreover, there is significant increase in growth rate by a factor of ~2.2 when δ changes from 1 to 4 for $\upsilon_e = 4 \times 10^5$ rad s^{-1}. Hence, our results qualitatively and quantitively both matches with the Sharma *et al* [56] findings and moreover, they have shown that, in their fluid analysis, the growth rate increases about ~2.1 when δ changes from 1 to 4 under similar conditions on the collisional EIC instability.

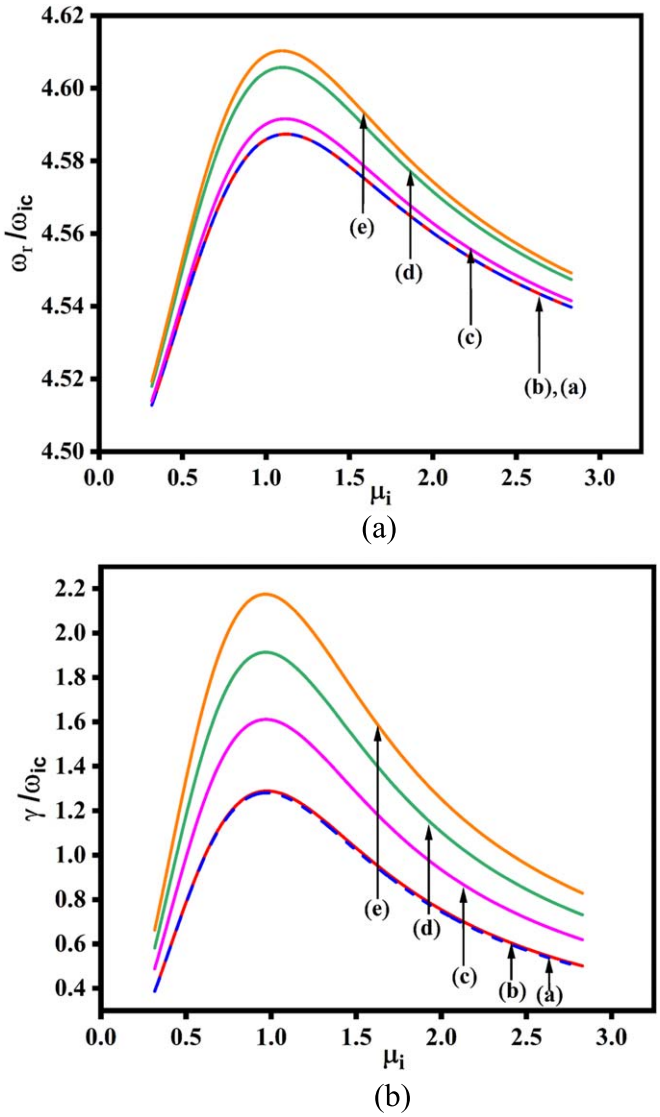

Figure 4. (a): The normalized real frequency ω_r/ω_{ic} variation for the case $\delta = 3$ corresponding to the finite gyro-radius parameter μ_i for different electron collisional frequencies i.e., (a) $\upsilon_e = 0$, (b) $\upsilon_e = 1 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (d) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (e) $\upsilon_e = 7 \times 10^5$ rad s^{-1}. (b): The normalized growth rate γ/ω_{ic} variation for the case $\delta = 3$ corresponding to the finite gyro-radius parameter μ_i for different electron collisional frequencies υ_e e.g., (a) $\upsilon_e = 0$, (b) $\upsilon_e = 1 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (d) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (e) $\upsilon_e = 7 \times 10^5$ rad s^{-1}.

For the case $\delta = 1$ (no dust particles), figures 6(a) and (b) depict the impact of variation in ion collision frequency on the real frequency and growth rate, respectively. From the graphical representations, there is an upward trend in both frequency and growth rate values as the gyro-radius parameters increase, reaching a maximum point. Subsequently, there is a reduction in magnitude for both parameters. In both the graphs, the curves correspond to the $\upsilon_e = 4 \times 10^5$ rad s^{-1} for varying υ_i i.e. (a) $\upsilon_i = 2 \times 10^3$ rad s^{-1}, (b) $\upsilon_i = 4 \times 10^3$ rad s^{-1}, (c) $\upsilon_i = 6 \times 10^3$ rad s^{-1}, (d) $\upsilon_i = 8 \times 10^3$ rad s^{-1}. It can be seen that the real frequency and growth rate reduce for increasing values of υ_i, the ion collision frequency. Further, for fixed υ_e, it is found that a rise in ion collision frequency results in the expected stabilising effect, which is also reported by Bharuthram *et al* [48]. This is because an increase in υ_i, leads to more frequent collisions between charged particles. These collisions will decrease the motion of ions reducing their ability to interact with the wave. When ions become less responsive to the wave due to increased collisions, the real frequency and growth rate of the wave decreases.

The relationship of normalized frequency and the growth rate are depicted in figures 7(a) and (b), respectively with the magnetic fields. The graphs demonstrate that the frequency and growth rate of the EIC wave correlate linearly to the magnetic field. As the magnetic field grows, so do the waves' frequency and growth rate. In the present work, the value of normalized real frequency and growth rate reaches up to ∼1.1 and ∼0.34, respectively, whereas in our previous work where collisions were not present, these values are 1.8 and 0.9, respectively [25]. It can be concluded that with the addition of collisions, the frequency and growth rate decrease

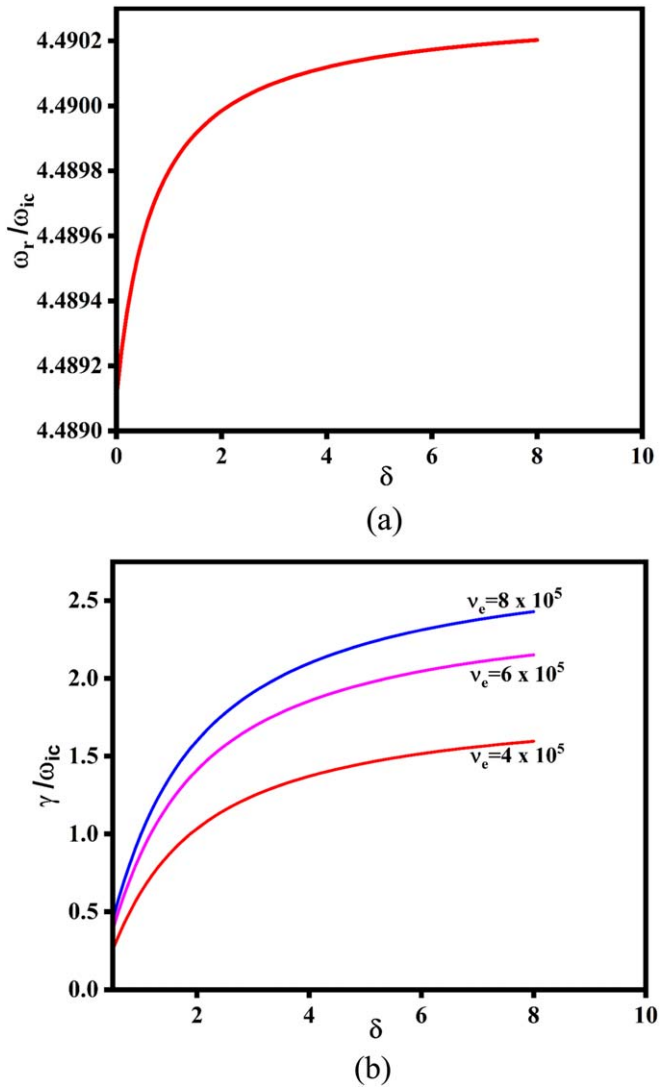

Figure 5. (a): The normalized real frequency ω_r/ω_{ic} versus relative density ratio $\delta(=n_i^0/n_e^0)$. (b): Variation in the normalized growth rate γ/ω_{ic} with relative density ratio $\delta(=n_i^0/n_e^0)$ for varying electron collisional frequencies υ_e i.e., (a) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (b) $\upsilon_e = 6 \times 10^5$ rad s^{-1} and (c) $\upsilon_e = 8 \times 10^5$ rad s^{-1}.

because the inclusion of collisions increases the complexity into the system as already discussed. The outcomes of Koepke and Amatucci [8] as well as Motley and D' Angelo [37] are comparable to this outcome without collisions. The kinetic theory yields better results than the fluid theory, according to the experimental evidence of Koepke and Amatucci [8].

In figure 8, we have displayed a normalized critical drift velocity u_{ed}/v_{et} curve with the relative density of the negatively charged dust grains. According to the graph and equation (21), the critical electron drift velocity u_{ed}/v_{et} reduces as the relative density ratio rises. Thus, as the amount of negatively charged dust particles rises, it stabilizes the EIC wave. The critical drift graph displays a trajectory that is consistent with the observed trend described in the observation done by Chow and Rosenberg [46].

As shown in figure 9, we have presented the normalized critical electron drift velocity graph for fixed $\upsilon_i = 1 \times 10^3$ rad s^{-1} for varying electron collision frequency υ_e i.e., (a) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (b) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 6 \times 10^5$ rad s^{-1}, and (d) $\upsilon_e = 8 \times 10^5$ rad s^{-1} in relation to the electron to ion temperature ratio. As we increase the T_e/T_i, critical drift rises, as seen in the graph and verified by equation (21). This is due to the fact that as the electron-to-ion temperature ratio increases, the electron temperature becomes more dominant in determining the electron mobility. With higher electron temperatures, electrons gain more kinetic energy, making them more responsive to external influences. As a result, the critical drift velocity increases as the electron-to-ion temperature ratio rises. Furthermore, with the augment in electron collision frequency, the critical drift of the EIC wave reduces [47]. This is due to the fact that numerous electron collisions might result in more effective energy dissipation and thermalization, changing the behaviour of the system as a whole and possibly stabilizing the system at lower critical electron drift velocities. We can conclude that higher

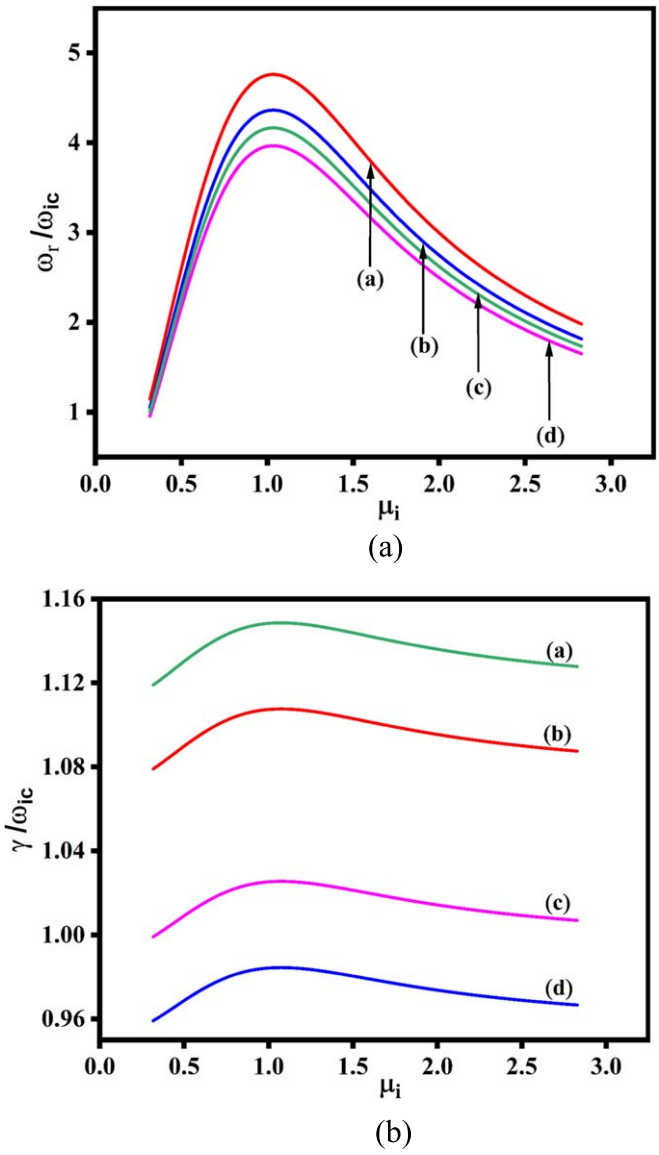

Figure 6. (a): The normalized real frequency ω_r/ω_{ic} variation for case $\delta = 1$ corresponding to the finite gyro-radius parameter μ_i for different ion collisional frequencies υ_i i.e. (a) $\upsilon_i = 2 \times 10^3$ rad s^{-1}, (b) $\upsilon_i = 4 \times 10^3$ rad s^{-1}, (c) $\upsilon_i = 6 \times 10^3$ rad s^{-1}, (d) $\upsilon_i = 8 \times 10^3$ rad s^{-1}. (b): The normalized growth rate γ/ω_{ic} variation for the case $\delta = 1$ corresponding to the finite gyro-radius parameter μ_i for different ion collisional frequencies υ_i i.e. (a) $\upsilon_i = 2 \times 10^3$ rad s^{-1}, (b) $\upsilon_i = 4 \times 10^3$ rad s^{-1}, (c) $\upsilon_i = 6 \times 10^3$ rad s^{-1}, (d) $\upsilon_i = 8 \times 10^3$ rad s^{-1}.

temperature further enhances the critical drift of the wave. Additionally, our result follows the same trend with the Levine and Kuckes [58] experimental observation in the absence of collisions.

In figure 10, the electron to ion temperature ratio in relation to the normalized growth rate graph is discussed for the EIC waves. It shows that the growth rate gradually lowers as the electron to ion temperature ratio rise and this conclusion is supported by equation (19). This is because as we have already discussed in our previous result that with increase in electron-to-ion temperature ratio, the electron mobility increases which will diminish the electron collisions there by decreasing the growth rate of the wave.

We have plotted the relationship between normalized real frequency and the electron to ion temperature ratio for varying υ_i i.e. (a) $\upsilon_i = 2 \times 10^3$ rad s^{-1}, (b) $\upsilon_i = 4 \times 10^3$ rad s^{-1}, (c) $\upsilon_i = 6 \times 10^3$ rad s^{-1}, (d) $\upsilon_i = 8 \times 10^3$ rad s^{-1} in figure 11. The normalized frequency of the wave augments with the rise in T_e/T_i. Using equation (18), it is clear that when T_e/T_i rises, Δ value rises which in turn increases the frequency. This outcome is consistent with the findings of Kindel and Kennel in the absence of collisions [23]. Moreover, higher ion collisional frequencies typically result in a reduction in EIC wave frequency.

The normalized growth rate graph versus δ for varying the values of dust number density i.e., (a) $n_d^0 = 2 \times 10^4$ cm^{-3}, (b) $n_d^0 = 4 \times 10^4$ cm^{-3}, (c) $n_d^0 = 6 \times 10^4$ cm^{-3}, and (d) $n_d^0 = 8 \times 10^4$ cm^{-3} is illustrated in figure 12. It is found that as the relative density ratio rises, the growth rate of the wave grows. According to the graphical analysis, the normalized growth rate and dust number density have an inverse

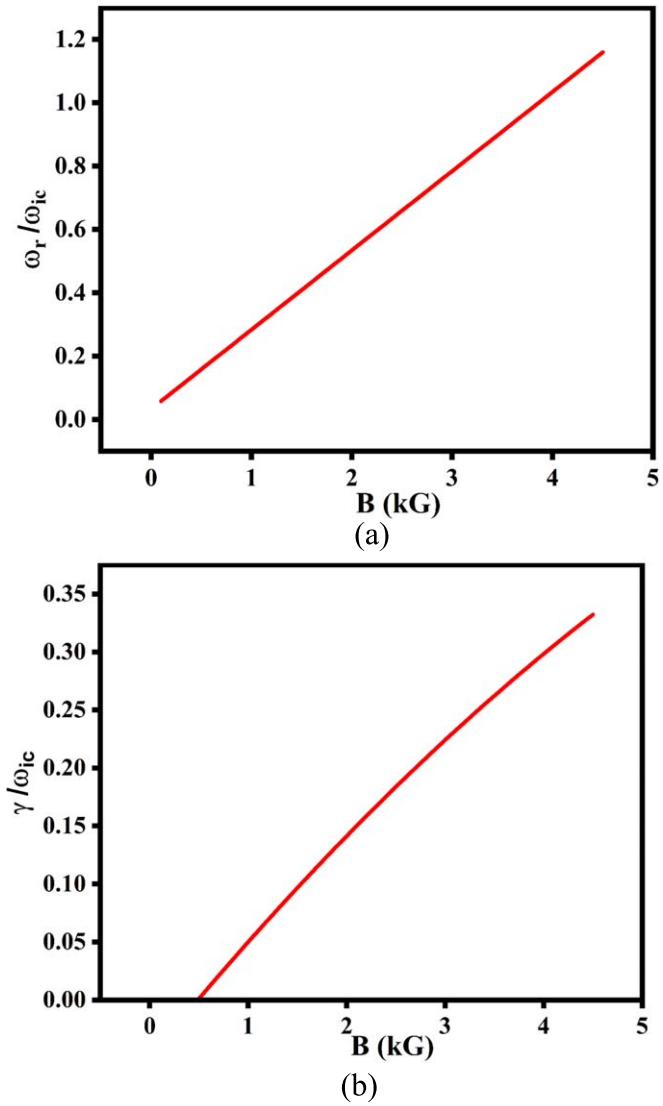

Figure 7. (a): The normalized real frequency ω_r/ω_{ic} versus magnetic field B(in kG) of EIC wave. (b): The normalized growth rate γ/ω_{ic} with respect to the magnetic field B(in kG) of the EIC wave.

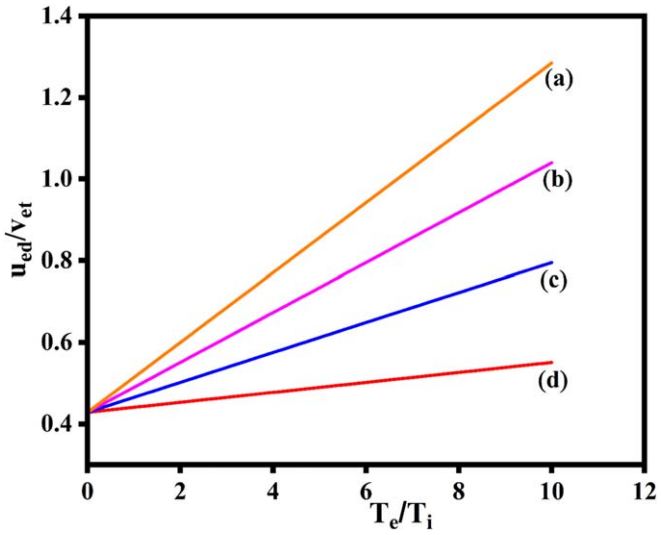

Figure 9. The normalized critical electron drift velocity u_{ed}/v_{et} for different electron collision frequencies υ_e i.e., (a) $\upsilon_e = 2 \times 10^5$ rad s^{-1}, (b) $\upsilon_e = 4 \times 10^5$ rad s^{-1}, (c) $\upsilon_e = 6 \times 10^5$ rad s^{-1}, and (d) $\upsilon_e = 8 \times 10^5$ rad s^{-1} as a function of temperature ratio (T_e/T_i).

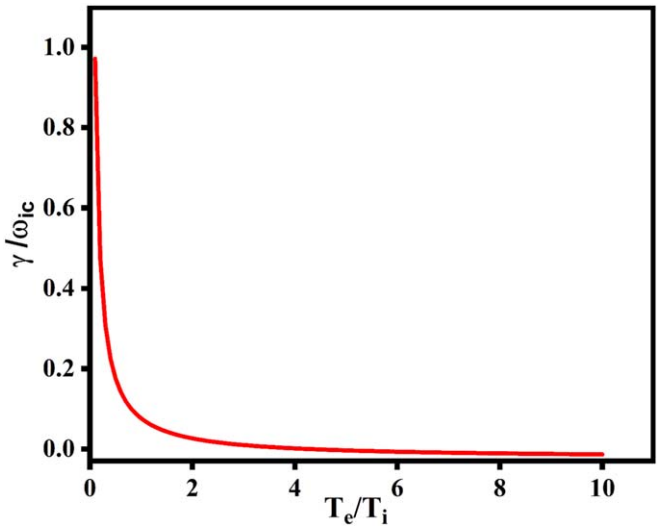

Figure 10. The normalized growth rate γ/ω_{ic} as a function of temperature ratio (T_e/T_i).

relationship, which is consistent with equation (20). This is because the rise in dust particles reduces the number of readily available electrons per dust grain. In turn, this leads to an increased need for electrons among the dust particles as a whole. This increased electron demand from the numerous dust particles leads to a fall in average dust grain charge Q_d^0, which, in turn, lowers the growth rate of the wave.

4. Conclusion

The EIC wave excitation in the weakly ionized collisional magnetized dusty plasma under the outcome of an electric field has been presented via kinetic theory. The exploration of collisional effects has been investigated across diverse plasma parameters, including growth rate, gyro-radius and frequency, among others. The wave's dispersive relationship has been deduced. The real frequency and growth rate augment with an augment in the relative density ratio. The influence of the gyro-radius parameter on both the frequency and growth rate of the wave was also assessed under varying electron and ion collision frequencies. It was observed that the frequency and growth rate initially increase with the augmentation of the gyroradius parameter before beginning to decrease as the gyroradius parameter further increases. Furthermore, it has been found that the effect of an electron collision destabilizes the mode whereas the effect of an ion collision stabilizes the mode and the growth

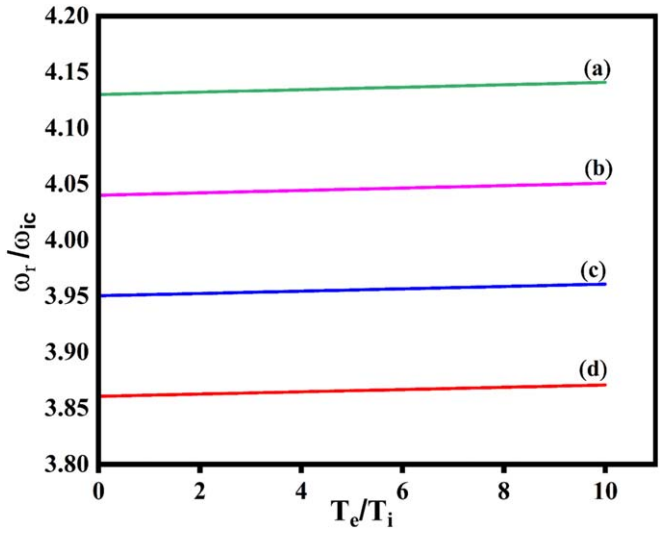

Figure 11. The normalized real frequency ω_r/ω_{ic} with varying ion collision frequency υ_i i.e. (a) $\upsilon_i = 2 \times 10^3$ rad s^{-1}, (b) $\upsilon_i = 4 \times 10^3$ rad s^{-1}, (c) $\upsilon_i = 6 \times 10^3$ rad s^{-1}, (d) $\upsilon_i = 8 \times 10^3$ rad s^{-1}. as a function of temperature ratio (T_e/T_i).

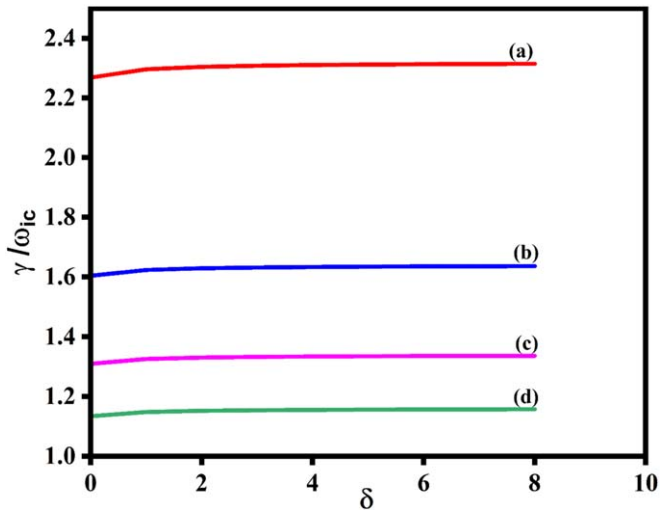

Figure 12. The normalized growth rate γ/ω_{ic} variation with $\delta(=n_i^0/n_e^0)$ for varying dust grain number density n_d^0(cm^{-3}) i.e., (a) $n_d^0 = 2 \times 10^4$ cm^{-3}, (b) $n_d^0 = 4 \times 10^4$ cm^{-3}, (c) $n_d^0 = 6 \times 10^4$ cm^{-3}, and (d) $n_d^0 = 8 \times 10^4$ cm^{-3} of the wave.

rate. The growth rate and frequency of the waves rise along with the magnetic field strength, emphasizing the stronger connection between the plasma particles and the magnetic fields. It was also discovered that as the relative density ratio rises, the critical drift reduces, which is essential for the mode's excitation. According to the study, the temperature analysis was also examined on the EIC wave and it was found that as the electron to ion temperature ratio rises, both the critical electron drift velocity and frequency rise. On the other hand, as the temperature ratio rises, the wave's growth rate reduces. It was also examined that with the increasing values of dust density, the growth rate of wave decreases. The acquired results were compared to the already existing observations [8, 23, 25, 48, 55] and are in good agreement.

The present work can be applied in laboratory plasma research [38]. This study improve our knowledge of plasma phenomena and have the potential to impact a variety of areas, including fusion energy research and could provide insights into the complex plasma dynamics in fusion devices and help in the development of more efficient and stable fusion reactors [21], tokamak and plasma heating [59, 60].

ABSTRACT

We propose a heuristic model of the universe as a growing quasicrystal projected from a higher-dimensional lattice. By extending the Schrödinger equation for a particle in a box with time-dependent boundaries, we derive an equation that resembles the Friedmann equation, addressing the Hubble tension. This model incorporates phonons and phasons, providing insights into cosmic-scale dynamics and the universe's expansion. We outline a pre-inflation tiling space phase with quantum error correction, a radiation phase dominated by quasiparticles, and a post-radiation phase with the emergence of matter. Our hypothesis, which posits that the universe is a growing quasicrystal, suggests that the necessity for an inflationary period may be obviated. Furthermore, phonon arising from this quasicrystalline structure could act as dark matter, influencing the dynamics of ordinary matter while remaining mostly undetectable by electromagnetic interactions. This hypothesis draws parallels with other crystalline matter at atomic scales that are fundamentally quantum in nature. We also explore how the notion of tiling space can support continuous symmetry atop a discrete structure, providing a novel framework for understanding the universe's expansion and underlying structure. Consequently, it is logical to start with quantum mechanics as the foundation of our model. Further development could enhance our understanding of cosmic expansion and the underlying structure of the universe.

1 Introduction

Recent developments in theoretical physics have propelled us toward a deeper understanding of spacetime and gravity. The field of emergent gravity [1] suggests that spacetime and gravity might be the byproducts of fundamental quantum mechanical processes. This paradigm shift is supported by theories such as loop quantum gravity and spin foam [2], as well as superstring theory and M theory [3], all of which propose a quantum-level discreteness underlying gravity.

A key focus since the advent of perturbative superstring theory has been the quest to unravel quantum gravity [4]. This endeavor involves comprehending the theory's foundational principles and extracting insights about Planck-scale physics [5]. Consequently, there is a growing trend to incorporate concepts from condensed matter or solid-state physics, such as viewing spacetime as a deformable solid or crystal [6]. More recently, quasicrystals have been investigated [7, 8].

Clues that our theories about reality are incomplete are emerging in various fields, from anomalies in particle physics experiments to unresolved problems in cosmology [9]. For instance, the discovery of neutrino oscillations challenged the Standard Model of particle physics, indicating that neutrinos have mass. Similarly, in cosmology, the Hubble tension [10] represents a profound discrepancy between measurements of the universe's expansion rate. On one side, observations of the Cosmic Microwave Background (CMB) by missions like the European Space Agency's Planck satellite suggest a slower expansion rate, based on the state of the universe shortly after the Big Bang and theoretical models of its evolution—around 67-68 km/s/Mpc. On the other, direct measurements of the current universe, notably from the Hubble Space Telescope and confirmed by the James Webb Space Telescope, indicate a significantly faster rate [11]—around 73-74 km/s/Mpc. This tension challenges our understanding of the cosmos and suggests that our theoretical models of the universe may be incomplete, indicating that new physics might be necessary to resolve the discrepancy. Despite the increased precision of observational instruments and techniques, this persistent tension highlights a crucial gap in our understanding of fundamental cosmic processes, making it a focal point for theoretical and observational cosmology alike.

Our research adopts a dual approach within this context. First, we start with conventional quantum mechanics. While the universe's expansion is typically addressed from a classical perspective on large scales, this expansion must also extend down to microscopic scales, as suggested by various approaches to quantum cosmology [12, 13]. Unlike conventional quantum cosmology, we analyze the wave function of a particle with mass m in a specific spatial domain using the Schrödinger equation, thereby focusing on intermediate scales. Crucially, we posit that the wavenumber, wavelength, and quantum amplitudes become functions of the dynamical size of the box and are subject to the Hubble law explicitly. Considerations about the dynamic boundary of the spatial domain lead us to a version of the Friedmann equation, crucial in cosmological models, thereby underscoring the emergence of classical spacetime from quantum mechanics.

Second, drawing inspiration from the concept of a deformable solid or crystal and quantum cosmology, which deals with discreteness, we propose modeling spacetime as a growing quasicrystal. Characterized by long-range order without periodicity, this structure reflects the aperiodic patterns found in condensed matter physics. Our principal finding suggests that the cosmological scale factor might be interpreted as an inherent scaling characteristic within a quasicrystal tiling space framework. We also consider the implications of this model for the Hubble tension, offering a fresh perspective on the general evolution of the universe and providing new insights into other issues in current cosmology models, such as dark matter and dark energy.

Our research adopts a dual approach that intersects at the idea of rescaling the underlying geometry, accompanied by emerging constraints pertinent to physics at varying scales. This approach aligns with our methodology of conceptualizing spacetime through the lens of a quasicrystalline structure. By integrating scale invariance into our framework, we aim to forge a connection between the microscale realms of quantum mechanics and the macroscale phenomena observed in cosmology. This synthesis offers a comprehensive and unified perspective, potentially enhancing our understanding of the universe's nature.

In the following sections, we will further elaborate on the mathematical foundations of our model, exploring how energy considerations translate into cosmological parameters. Moreover, we will delve into the concept of spacetime as a tiling space, drawing parallels with quasiperiodic structures in condensed matter physics to bolster our hypothesis of emergent spacetime and gravity.

2 From Schrödinger to Friedmann Equation

General relativity establishes a correspondence between the geometric aspects of spacetime and the distribution of matter and energy, as encapsulated by Einstein's local field equations,

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = \frac{8\pi G}{c^4} T_{\mu\nu}, \tag{1}$$

where $G_{\mu\nu}$ is the Einstein tensor representing the curvature of spacetime, $g_{\mu\nu}$ is the metric tensor describing the geometry of spacetime, $T_{\mu\nu}$ is the stress–energy tensor reflecting the distribution and flow of energy and momentum in spacetime, Λ is the cosmological constant, G is the Newtonian constant of gravitation, and c is the speed of light in vacuum. On the other hand, quantum mechanics introduces the principle of wave-particle duality, which manifests both wave-like and particle-like properties in matter and energy, as illustrated by the De Broglie relations and the Schrödinger equation-Equations 2, 3. In this sense, both equations of general relativity and quantum mechanics have matter on one side and something else on the other side of an equality. This "something else" being geometry-like or wave-like. In this discourse, we explore a simplified model within the context of cosmology, where the wave aspect of quantum mechanics is proportionally linked to the geometry of spacetime. This approach specifically considers the cosmological scale factor that characterizes the rescaling of spacetime within a homogeneous and isotropic universe described by a perfect fluid.

The Friedmann equations, which are central to our understanding of the universe's expansion, are primarily derived from general relativity and frameworks that integrates classical mechanics and thermodynamics. This exploration contemplates whether analogous dynamics might emerge from applying space rescaling concepts to a local particle quantum state. The conventional understanding posits that the universe expands on large scales, particularly in the vast regions between galaxies, while gravitational forces within galaxies maintain their structural cohesion. However, this view does not necessarily preclude the possibility of spacetime expansion within matter-dominated regions, which may be challenging to observe directly.

Given that matter fundamentally are quantum phenomena and acknowledging the absence of a unified quantum gravity theory, it is plausible to infer that the cosmological expansion observed at macroscopic scales originates from the spacetime fabric at the microscopic level, possibly extending down to the Planck scale. While general relativity provides a framework for understanding how matter influences spacetime curvature, the ability of classical gravity to keep matter bound at macroscopic scales, even amidst the potential expansion of the underlying spacetime, raises intriguing questions about the emergence of matter from fundamental quantum dynamics.

To explore these ideas further, our focus shifts to examining the behavior of an existing quantum state within the context of universal expansion. By investigating how quantum states respond to changes in the scale of spacetime, we may gain new insights into the interplay between quantum mechanics and cosmology, potentially shedding light on the origin of the observed cosmological expansion and its relationship to the microscopic structure of spacetime.

Consider the time-independent Schrödinger Equation for the wave function (energy eigenfunction) $\Psi(x)$, with x representing (x, y, z), of a particle with mass m under potential $V(x)$. The equation is given by:

$$\nabla^2 \Psi = -\frac{2m(E-V)}{\hbar^2}\Psi \quad , \tag{2}$$

with E, the energy eigenvalue for the stationary state $\Psi(x) = \Psi_E(x)$.

For a particle under a potential $V(x)$, the time-independent Schrödinger equation can yield different forms of solutions depending on the relationship between the energy E of the particle and the potential V. We consider the particle in a box situation with a finite potential inside and infinite outside. The box may be taken to be spherical with a given radius. Specifically, inside the box, for a constant potential, being zero, or when $E > V$, the solutions are of the form of plane waves. Conversely, for $E < V$, the solutions differ significantly. When these solutions are substituted back into the time-independent Schrödinger equation, we obtain:

$$k^2 = \frac{2m(E-V)}{\hbar^2}, \tag{3}$$

where k is the wavenumber.

This is a stationary state analysis. We now consider a scenario where spacetime itself begins to change, specifically, rescaling with a factor $a(t)$. Consequently, the volume of a given region $\eta(t_1)$ at time t_1 will relate to the volume $\eta(t_2)$ at time t_2 by

$$\eta(t_2) = \frac{a(t_2)^3}{a(t_1)^3}\eta(t_1), \tag{4}$$

ensuring that the ratio $\eta_0 = \frac{\eta(t)}{a(t)^3}$ remains constant. Thus, we can express $\eta(t)$ as $\eta_0 a(t)^3$.

Introducing time is essential to account for the rescaling effects. The problem now should be addressed by the time-dependent Schrödinger equation, as the potential depends on the dynamic radius or volume. This problem has been studied using various approaches [14] and references therein. In this context, the energies become dynamic, and a notion of energy density in quantum mechanics arises naturally [15]. Crucially, the wavenumber, wavelength, and quantum amplitudes become functions of the dynamical size of the box, and we posit that they are subject to the Hubble law explicitly. By connecting the geometry with the wave aspect of the particle-wave duality mentioned earlier, we aim to derive Friedmann-like equations.

Revisiting equation (3), we modify it by dividing both sides by the dynamical volume η, which confines the particle in space. Equation (3) encapsulates the wave-particle duality, highlighting that the matter wavelength, $\lambda = \frac{2\pi}{k}$, is a fundamental quantum mechanical attribute that determines the probability density of locating the particle within the configuration space. Notably, a particle's wavelength, inversely related to its momentum (and thus energy), serves as a bridge to cosmological dynamics. By invoking the Hubble law, expressed as $v = H\lambda$, where $H = \frac{\dot{a}}{a}$ is the time-dependent Hubble parameter, we correlate the particle's wavelength to the cosmic scale factor $a(t)$ while keeping the energy constant. This association suggests an emergent classical kinetic energy tied to the velocity v associated to the expansion. Consequently, equation (3) is transformed into

$$H^2 = \left(\frac{\dot{a}}{a}\right)^2 = \frac{K\eta}{\pi^2\hbar^2}\rho, \tag{5}$$

where $K = \frac{1}{2}mv^2$ is the kinetic energy, $\rho = E/\eta$ represents the energy density, and setting $V = 0$. Note that we are simplifying the concept of energy density here. The particle energy is time-dependent, and any particle would be subject to the same expansion that occurs everywhere. This brings a notion of a particle horizon and an energy density within each particle volume expansion. This equation bears a striking resemblance to the first Friedmann equation, suggesting that the dynamics of a quantum particle in a box with a time-dependent boundary may provide insights into the expansion of the universe. By establishing a connection between the particle's wave nature and the cosmic scale factor. To align with the usual first Friedmann equation's structure, the term $\frac{K\eta}{\pi^2\hbar^2}$ must remain constant

$$K\eta = \frac{8\pi^3\hbar^2 G}{3c^2} \tag{6}$$

with kinetic energy compensating for the changing volume and establishing a direct quantum mechanical analogy to cosmic expansion dynamics.

$$H^2 = \left(\frac{\dot{a}}{a}\right)^2 = \frac{8\pi G}{3c^2}\rho, \tag{7}$$

The analysis of a relativistic particle in a box with moving walls is similar to, but more complex than, the non-relativistic case. This complexity arises whether we consider a fermionic spin-1/2 particle described by the Dirac equation or a spin-0 particle described by the Klein-Gordon equation [16]. To gain insights into the relativistic case, we can apply the same analysis using the relativistic dispersion relation derived from the energy-momentum relation:

$$(\hbar kc)^2 = E^2 - (mc^2)^2. \tag{8}$$

To bridge the quantum and classical realms, we need to determine the energy density. This involves multiplying and dividing the equation by the dynamical volume η. In the non-relativistic case, we notice the appearance of a kinetic energy term linked to the expansion. This observation suggests that the dynamical energy E, for a unique particle, can transform into different forms during the expansion process. Specifically, in the case of photons, where, $mc^2 = 0$, we consider the energy density related to the photon's energy, which evolves with the expansion. Motivated by this observation, we apply the energy-balancing constraint:

$$C = E - K - V = 0, \tag{9}$$

where E is the total energy, K is the kinetic energy, and V is the potential energy, all associated with the dynamical expansion process. This constraint allows us to examine the system's properties across different scales, connecting the microscopic energy E to macroscopic scales potentially represented by K and V. Here, K and V can be viewed as effective parameters encapsulating average or microscopic system properties as the system expands.

The energy-balancing constraint in Equation 9 provides a framework for understanding how the total energy E is partitioned into kinetic and potential components during the expansion process. By considering the conservation

of energy and the interplay between these different forms of energy, we can gain insights into the dynamics of the system across various scales. In the context of the relativistic particle in a box with moving walls, the application of this constraint may lead to the emergence of terms analogous to the energy density ρ, pressure p, and possibly the cosmological constant Λ when deriving the relativistic Friedmann-like equation. By incorporating the energy-balancing constraint into the analysis, we can explore how the quantum mechanical properties of the system, such as the wave nature of the particle and the dynamical evolution of the wavefunction, relate to the classical cosmological parameters that describe the expansion of the universe.

Isolating K while keeping E and V independent, we obtain

$$E^2 = K(E + V + V^2/K). \tag{10}$$

Since the wave number is inversely proportional to the wavelength, we can apply the Hubble law as done before. Then, Equation 8 can be rewritten as:

$$H^2 = \beta^2 \frac{K\eta}{\pi^2\hbar^2}(\rho + p) + \frac{\beta^2}{\pi^2\hbar^2}V^2 - \frac{\beta^2}{\pi^2\hbar^2}(mc^2)^2 \tag{11}$$

with $\beta = v/c$, $\rho = E/\eta$ is the energy density, and $p = V/\eta$ is the pressure. Equation 11 is analog of the Friedmann equation for relativistic matter, derived from the quantum mechanical description of a particle in a box with moving walls. The first term on the right-hand side resembles the classical Friedmann equation. The second term, proportional to V^2, may be interpreted as related to the cosmological constant Λ as it does not explicitly depend on a.

To obtain the usual contribution to radiation, we set $mc^2 = 0$. Typically, radiation energy density enters the Friedmann equation as proportional to $1/a^4$, while non-relativistic matter is proportional to $1/a^3$. Here, we derive a notion of energy density for individual massive particles and photons subject to dynamical boundary conditions related to the expansion of space, and they share a similar form. The $1/a^4$ factor for radiation arises from considering the number density of photons, which scales like matter, times the photon energy, which scales with $1/a$ due to redshift as the photon wavelength expands. The redshift here is accounted for through the Hubble law applied to the wavelength.

The essential difference between non-relativistic matter and radiation is that in one case $H^2 \propto E$, and in the other, $H^2 \propto E^2$. To achieve the same notion of energy density, our approach introduces a new term for radiation. Essentially, we achieve the same result of having different phases: one in the short wavelength regime and the other at large wavelengths at later times.

Importantly, we note that different dispersion relations will lead to different dynamics for the scale parameter, and various relations may be considered. This is in line with the usual approach where different cosmological epochs have different evolutions due to varying energy densities. To motivate our quasicrystalline model presented in the next section, let us consider quantum excitations in lattice and quasicrystalline condensed matter systems. These systems are known for their phonon quasiparticles, which emerge due to the breaking of translational symmetry. Quasicrystals, however, also host phasons—a less understood type of quasiparticle. Phasons are particularly interesting because they are linked to a reduction in dimensions; this occurs as quasicrystals are formed, at least theoretically, from the projection of higher-dimensional lattices onto lower-dimensional spaces.

The dispersion relation for phonons in lattices is similar to the relativistic one in the regime of large wavelengths, but with the speed of light replaced by the speed of sound. In this regime, the phonon dispersion relation is nearly linear, and the crystal can be treated as a continuous elastic medium, with phonons behaving like classical sound waves. However, in the regime of short wavelengths, the dispersion relation becomes nonlinear, and the microscopic details of the lattice become important. In this case, phonons are sensitive to the discrete nature of the lattice, and the nonlinear dispersion relation can lead to phonon dispersion, where phonon packets with different wavelengths propagate at different speeds, causing distortion of the waveform. The transition between these two regimes occurs when the phonon wavelength becomes comparable to the interatomic spacing, with the specific wavevector or wavelength at which this transition happens depending on the details of the crystal structure and the interatomic forces.

In quasicrystals, the situation is more complicated because they do not have a simple primitive cell like periodic crystals but rather a complex, self-similar structure. As a result, the phonon dispersion relations in quasicrystals can exhibit intricate, fractal-like patterns. Despite these differences, the linear dispersion relation for phonons in quasicrystals shares similarities with the phonon branches in periodic crystals, particularly at low frequencies and long wavelengths. We will discuss more about phonons in the next section when discussing the quasicrystalline model, where they arise as candidates to contribute in both radiation (massless phonons) and dark matter regimes (massive phonons).

Phasons in quasicrystals also share similarities with those found in relativistic physics. However, a key difference is the presence of a dispersive imaginary term in the phason dispersion relation, which becomes prominent at very large wavelengths [17, 18]. This imaginary term is related to the diffusive behavior of phasons and is absent in the phonon dispersion relation.

The presence of both phonons and phasons in quasicrystals, along with their distinct dispersion relations, may have important implications for the dynamics of the scale parameter in the quasicrystalline model of the universe. The interplay between these two types of quasiparticles, their different regimes of behavior, and their potential connection to the emergence of cosmological equations could provide new insights into the relationship between quantum mechanics and cosmology.

Using $\omega = E/\hbar$, for phasons, we have

$$v^2k^2 = \frac{E^2}{\hbar^2} + i\gamma\frac{E}{\hbar} \tag{12}$$

where γ is the phason friction coefficient. The phason is a goldstone mode that arise under a symmetry breaking mechanism [17]. In the case of lattices, the energy states are defined in a Voronoi cell. For quasicrystals, there are more fundamental cells or tiles, but with one fixed, we can consider the expansion of that cell and, as before, apply the Hubble law to the wavelength. In addition, we can use Equation 10 and multiply by the volume on both sides of Equation 12, yielding

$$H^2 = \frac{K\eta}{4\pi^2\hbar^2}(\rho + p) + \frac{1}{4\pi^2\hbar^2}V^2 + i\gamma\frac{E}{4\pi^2\hbar} \tag{13}$$

where we considered the velocity associated to phasons equal to the one of the expansion. To deal with the imaginary part, this equation can be interpreted from the energy relation where in the regime of short wavelength the phason propagation dominates with $v^2k^2 = \frac{E^2}{\hbar^2}$ leading to a Friedmann like equation similar to Equation 11. In the regime of large wavelength we have $v^2k^2 = i\gamma\frac{E}{\hbar}$ which leads to diffusion and decoupling from expansion contribution. We will come back to these two regimes in context of the quasicrystalline model of the universe in next section.

To finish this analysis, we can add the acceleration equation from usual thermodynamics considerations when one derives the Friedmann equations from Newtonian physics. For this, one adds the continuity equation

$$\dot{\rho} + 3\frac{\dot{a}}{a}(\rho + p) = 0. \tag{14}$$

Taking the derivative in Equations (5), (11), and (13), with V constant and $\beta = 1$, we get for Equations (5) and (11):

$$2H\dot{H} = \alpha\dot{\rho}, \tag{15}$$

with $\alpha = K\eta/\pi^2\hbar^2$. For Equation (13), we have

$$2H\dot{H} = \alpha\dot{\rho} + i\gamma\frac{\dot{E}}{4\pi^2\hbar}. \tag{16}$$

Now, we can derive the acceleration term in both situations. For Equation (5), substituting the continuity equation into the derivative of the Friedmann-like equation yields (with the original potential equal to zero)

$$\frac{\ddot{a}}{a} = -\frac{\alpha}{2}(\rho + 3p). \tag{17}$$

This equation describes the acceleration of the scale factor in terms of the energy density and pressure, analogous to the second Friedmann equation in general relativity.

For Equations (11), with $m = 0$

$$\frac{\ddot{a}}{a} = -\frac{\alpha}{2}(\rho + p) + \Lambda \tag{18}$$

with $\Lambda = \frac{1}{\pi^2\hbar^2}V^2$.

For Equation (13), which includes the phason contribution, the acceleration equation becomes

$$\frac{\ddot{a}}{a} = -\frac{\alpha}{4}(\rho + p) + \frac{1}{4}\Lambda + \frac{i\gamma}{4\pi^2\hbar}(E + \frac{\dot{E}}{2H}) \tag{19}$$

The additional term involving the phason friction coefficient γ and the time derivative of the energy $\dot{E}$ modifies the acceleration of the scale factor. The imaginary nature of this term suggests that it may not significantly affect the expansion of the universe in the large wavelength regime.

These acceleration equations provide insights into the dynamics of the scale factor in the presence of matter, radiation, and phason contributions. They demonstrate how the quantum mechanical description of particles in a box with moving

walls can give rise to cosmological equations that resemble the Friedmann equations of general relativity. The inclusion of the phason term in Equation (13) highlights the potential role of quasicrystalline structures and their associated quasiparticles in the evolution of the universe.

Our analysis commenced with the time-independent Schrödinger equation for a particle confined within a potential well. We then introduced several crucial modifications to the system: a general energy-balancing constraint (Equation 9), a time-dependent boundary condition representing moving walls, and a dynamically evolving volume. These additions were aimed at establishing a connection between the quantum and classical regimes across different scales. By applying the Hubble law to the wavelength of the particle and relating it to the cosmic scale factor, we derived a Friedmann-like equation (Equation 5) from the quantum mechanical description of the system.

In the relativistic extension of our analysis, we employed the Klein-Gordon equation and the relativistic energy-momentum relation (Equation 8). This led to the emergence of a new term in the resulting Friedmann-like equation (Equation 11), which bears a resemblance to the cosmological constant term in the standard Friedmann equations of general relativity.

Furthermore, we explored the implications of different dispersion relations, particularly those associated with phonons and phasons in quasicrystalline structures. The presence of an imaginary term in the phason dispersion relation (Equation 12) led to a modified Friedmann-like equation (Equation 13) that includes a dissipative contribution arising from the phason friction coefficient. This can be interpreted as having different regimes contributions.

Bridging quantum mechanics and cosmology is complex and challenging. Our simplified model offers insights but may not capture all intricacies of this transition. A comprehensive framework incorporating quantum gravity, quantum field theory, and cosmological perturbation theory might be needed to fully understand the interplay between quantum phenomena and the universe's large-scale structure.

Nevertheless, our analysis demonstrates the potential for deriving cosmological equations from the quantum mechanical description of a particle in a box with time-dependent boundary conditions at intermediate scales. The derivation of Friedmann-like equations indicates a profound connection between the microscopic quantum world and the macroscopic evolution of the universe. This suggests that the local expansion, influenced by matter distributions, is analogous to the wave-like properties of quantum particles. The inclusion of phonon and phason contributions from quasicrystalline structures further emphasizes the potential role of condensed matter physics in understanding the nature of dark energy, dark matter, and the expansion of the universe.

3 The Universe Expansion from Quasicrystalline Tiling Spaces

Quasicrystals are characterized by several distinctive properties that make them a compelling model for the universe. These properties, as discussed in [19], include:

- **Uniformly Discrete:** For a certain radius $r > 0$, every sphere of radius r contains at most one point of the quasicrystal point set, $\triangle$.
- **Relatively Dense:** There exists a radius $R > 0$ such that each sphere of this radius encompasses at least one point of $\triangle$.
- **Locally Finite:** For any compact subset Λ in $\mathbb{R}^d$, the intersection $C = \Lambda \cap \triangle$, or cluster, is either finite or empty.
- **Finite Local Complexity (FLC):** The set $\{(t + \Lambda) \cap \triangle | t \in \mathbb{R}^d\}$, often represented by translations $\triangle - \triangle$, comprises only a finite number of clusters, modulo translations.
- **Uniform Distribution:** As proven in [19], the distribution of points within quasicrystals is uniform.

The first four properties align with a universe where matter is neither infinitely dense nor arbitrarily dispersed, and where the arrangement of matter is limited to a finite number of configurations. The fifth property, uniform distribution, supports the cosmological principle by suggesting large-scale homogeneity and isotropy in the universe, while allowing for small inhomogeneities.

A key aspect of quasicrystals with the aforementioned properties is their derivation from a specific projection from a higher-dimensional lattice. The so-called cut-and-project scheme (CPS) is defined as a 3-tuple $\mathcal{G} = (\mathbb{R}^d, G, \mathcal{L})$, where $\mathbb{R}^d$ represents a real Euclidean space, G is a locally compact abelian group (or any topological group), and $\mathcal{L}$ is a lattice in $\mathbb{R}^d \times G$. For our purposes, this scheme includes a natural projection $\pi : \mathbb{R}^d \times G \to \mathbb{R}^d$. In the context of an infinite quasicrystal, the projection typically involves restricting the points to a non-empty, relatively compact subset $K \subset G$, referred to as the window. However, in our study of a finite universe and finite quasicrystals, we project the entire mother lattice onto $\mathbb{R}^d$ part by part as explained below, thereby obviating the need to consider this window.

To illustrate our approach more concretely, let us consider the 4D Elser-Sloane quasicrystal (ESQC) derived from the E8 root lattice [20], which is the most studied 4D quasicrystal. We position a coordinate system on the E8 lattice, with the origin placed at an E8 vertex. The E8 lattice can then be visualized as concentric shells of points radiating from the origin. As noted in [21], the number of points on each E8 shell increases in a nonlinear fashion, described by the function

$$N_{E8}(n) = 240 \sum_{d|n} d^3 \tag{20}$$

where the right-hand side of the equation is the sum of the cubes of all divisors d of n, multiplied by 240. Projecting shell by shell, the E8 lattice to 4D using the ESQC CPS generates a growing 4D quasicrystal.

The projection of the initial shells of the E8 lattice, when visualized from a 3D slice perspective, reveals patterns that emerge under rescaling. See Image 1 for a visual representation.

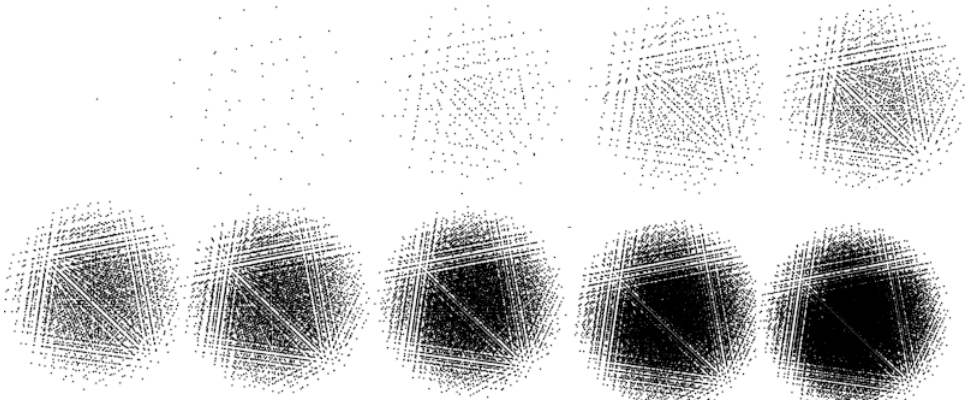

Figure 1: First 10 shells from E8 lattice to 4D ESQC to a 3D slice.

The notion of tiling spaces emerges from considering each possible tiling that can be built on a specific CPS as a point in an abstract space. In a quantum mechanical framework, each of these possible tilings can be defined as a state. However, rather than working with individual states, we employ the more comprehensive concept of Hilbert spaces, which encompass all possible states. This approach bridges the geometric nature of tilings with the probabilistic nature of quantum mechanics. Consequently, tiling spaces provide a robust framework for describing both the geometric structure and the quantum mechanical evolution of the universe during its expansion, offering a unified perspective on cosmic dynamics.

3.1 Universe as a Growing Quasicrystal Hypothesis

Our working hypothesis is that the universe is a growing quasicrystal. This is a simple heuristic model of the universe. Let us gather support for this idea and explore its consequences.

This model proposes an unconventional origin of the universe, diverging from the traditional Big Bang theory. It suggests that the universe began with the projection of a single point from a higher-dimensional lattice, such as the E8 root lattice. This initiated a sequence of point projections that sequentially constructed the universe's structure. This process, governed by a computational framework, unfolds step by step transitioning from one shell $N_{\text{E8}}(n)$ to the next $N_{\text{E8}}(n+1)$ and so forth. The number of points in each shell grows rapidly, with the first ten shells containing 240, 2160, 6720, 17520, 30240, 60480, 82560, 140400, 181680, 272160 points, respectively. The projection into a 4D quasicrystalline structure not only expands the universe but also intricately subdivides it internally, as points from newer shells intermingle with those from older shells, showcasing a complex process of growth and subdivision characteristic of the universe's early stages (see Figure 2 for a lower-dimensional illustration).

In this early stage, the universe consists of points, which are projections from the higher-dimensional root lattice. In the Lie algebra framework of modern gauge theories, these points represent fundamental particle states that form the Hilbert spaces of representations of the Lie algebra. At this stage, there is no scale or mass, and thus no distinction between particles, highlighting an analogy to the grand unification scale.

In condensed matter physics, a growing quasicrystal is associated with expanding Hilbert spaces. We can conjecture a similar process for the universe. As the universe grows, a burgeoning Hilbert space $\mathcal{H}_n$ emerges at each growth step n, reflecting the tiling spaces [22] of potential quasicrystalline configurations. To address the different tiling configurations

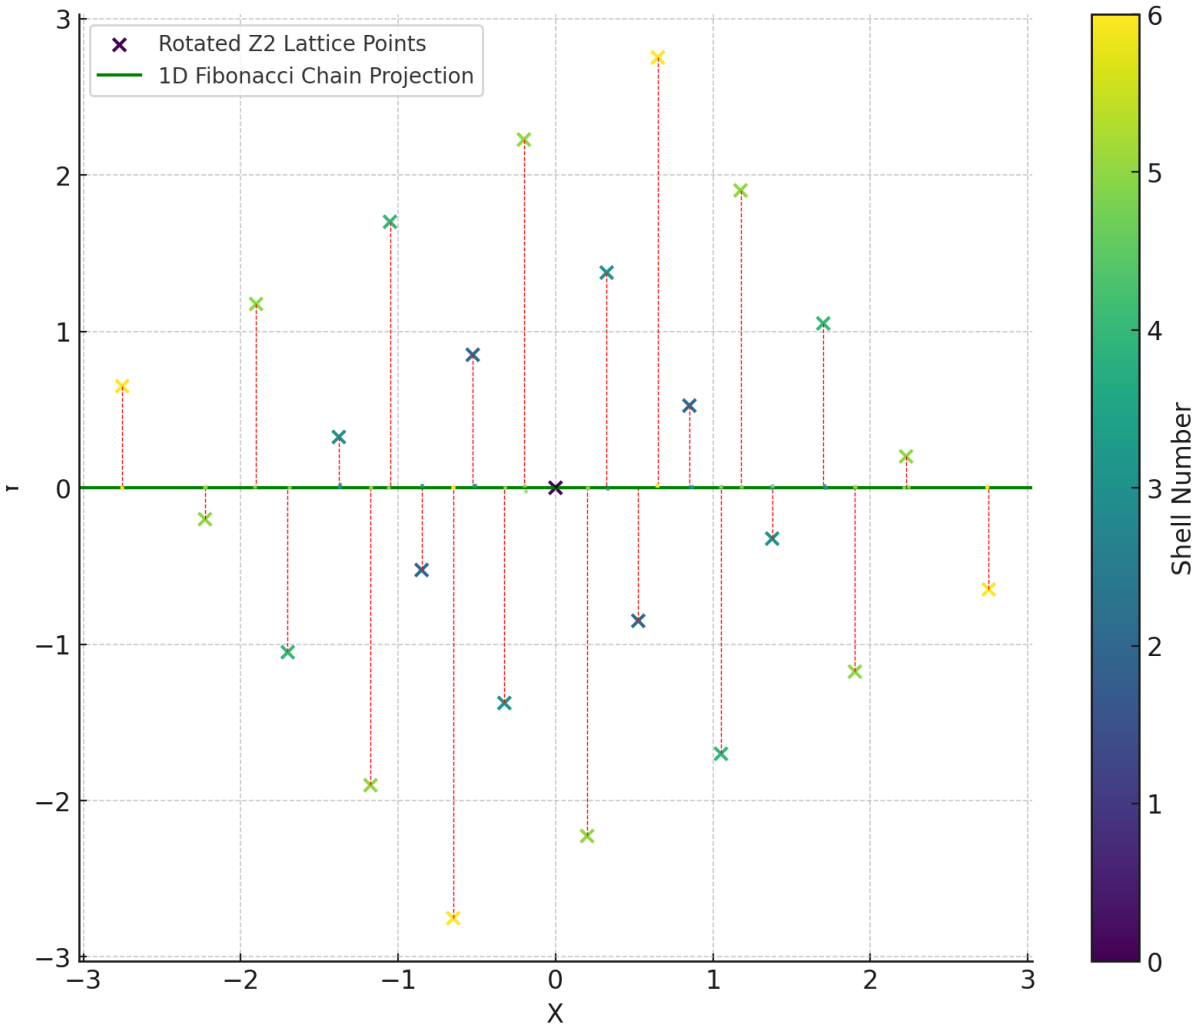

Figure 2: A rotated Z2 being projected shell by shell with the color tracking the ordering. As this one dimensional universe expands, it also get new points inside the already projected region.

of quasicrystals, it is standard to consider the associated C^*-algebra structures [23] and the notion of tiling spaces. This Hilbert space can be constructed as follows: Let $\mathcal{T}_n$ denote the set of all distinct tiling configurations at the n-th growth step, with each tiling configuration $T_n \in \mathcal{T}_n$ represented as a basis state $|T_n\rangle$ in $\mathcal{H}_n$. The growth process from step n to $n+1$ can be expressed as:

$$\mathcal{T}_n \to \mathcal{T}_{n+1}, \tag{21}$$
$$\mathcal{H}_n \to \mathcal{H}_{n+1}. \tag{22}$$

The wavefunction of the universe at the n-th growth step, $|\Psi_n\rangle \in \mathcal{H}_n$, can be written as a superposition of all possible tiling configurations:

$$|\Psi_n\rangle = \sum_{T_n \in \mathcal{T}_n} \alpha(T_n)|T_n\rangle, \tag{23}$$

where $\alpha(T_n)$ are complex coefficients determined by the specific growth rules of the quasicrystal. As the universe grows, the wavefunction evolves to incorporate the new tiling configurations that emerge at each step, $|\Psi_n\rangle \to |\Psi_{n+1}\rangle$.

This growing Hilbert space structure suggests that the early universe may be viewed as a form of a quasicrystalline topological quantum computer, with quantum error-correcting codes (QECCs) inherently embedded [24]. At each growth step, a subspace $\mathcal{C}_n \subset \mathcal{H}_n$ can be identified, spanned by a set of wavefunctions $|\Psi n, [T]\rangle$ that exhibit local

indistinguishability and recoverability properties [24]:

$$|\Psi_{n,[T]}\rangle = \sum_{g\in G_n} \beta(gT_n)|gT_n\rangle, \tag{24}$$

where $[T]$ denotes an equivalence class of tiling configurations related by the symmetry group G_n, and $\beta(gT_n)$ are complex coefficients. The subspace $\mathcal{C}_n = \text{span}(|\Psi_{n,[T]}\rangle)$ can be interpreted as the code space of a QECC at the n-th growth step, capable of correcting errors in any local region of the quasicrystal. As the universe grows, the QECC evolves, $\mathcal{C}_n \to \mathcal{C}_{n+1}$.

This growing QECC structure provides a framework for understanding how quantum information can be encoded and protected within the geometry of a quasicrystalline universe. Notably, the Hilbert spaces associated with certain quasicrystals are isomorphic to the fusion Hilbert spaces that appear in topological quantum computing systems [25]. This establishes a connection between QECCs and topological quantum computation within the context of our working hypothesis of the growing quasicrystalline universe.

The emergence of this quasicrystalline structure and its associated Hilbert spaces in the early universe may have profound implications for the evolution of spacetime, matter, and quantum information processing. As the universe continues to grow and evolve, the interplay between the quasicrystalline geometry, QECCs, and topological quantum computation may guide the formation of large-scale cosmic structures and the emergence of complex phenomena. This heuristic model offers a novel perspective on the origin and evolution of the universe, connecting ideas from condensed matter physics, quantum information theory, and cosmology.

As the quasicrystalline universe evolves, phonons and phasons should emerge naturally due to the intrinsic properties of growing quasicrystals, even those composed of 'spacetime atoms.' Phonons correspond to collective vibrational modes of the tiling configurations, while phasons are associated with the rearrangement of the quasicrystalline structure without changing the overall energy. The presence of these quasiparticles is significant, as their dispersion relations lead to a form of the Friedmann equation (Equation 13), implying the establishment of standard expansion.

To incorporate phonons and phasons into our quantum description of tiling spaces, we introduce creation and annihilation operators acting on the Hilbert space $\mathcal{H}_n$ at each growth step. Let $a^\dagger_{k,n}$ and $a_{k,n}$ denote the creation and annihilation operators for a phonon with wave vector k at the n-th growth step, satisfying the commutation relations:

$$[a_{k,n}, a^\dagger_{k',n}] = \delta_{k,k'}, \quad [a_{k,n}, a_{k',n}] = [a^\dagger_{k,n}, a^\dagger_{k',n}] = 0. \tag{25}$$

Similarly, let $b^\dagger_{q,n}$ and $b_{q,n}$ denote the creation and annihilation operators for a phason with wave vector q at the n-th growth step, satisfying similar commutation relations:

$$[b_{q,n}, b^\dagger_{q',n}] = \delta_{q,q'}, \quad [b_{q,n}, b_{q',n}] = [b^\dagger_{q,n}, b^\dagger_{q',n}] = 0. \tag{26}$$

The phonon and phason operators commute with each other:

$$[a_{k,n}, b_{q,n}] = [a_{k,n}, b^\dagger_{q,n}] = [a^\dagger_{k,n}, b_{q,n}] = [a^\dagger_{k,n}, b^\dagger_{q,n}] = 0. \tag{27}$$

Using these operators, we define phonon and phason excited states by acting on the tiling configuration states $|T_n\rangle$:

$$|T_n; \{k\}_m; \{q\}_l\rangle = a^\dagger_{k_1,n} \dots a^\dagger_{k_m,n} b^\dagger_{q_1,n} \dots b^\dagger_{q_l,n} |T_n\rangle, \tag{28}$$

where $\{k\}_m = \{k_1, \dots, k_m\}$ and $\{q\}_l = \{q_1, \dots, q_l\}$ characterize the m phonons and l phasons, respectively.

The growth of the quasicrystalline universe can be described in terms of the evolution of these excited states. As the universe grows from step n to step $n+1$, the phonon and phason creation and annihilation operators evolve:

$$a^\dagger_{k,n} \to a^\dagger_{k,n+1}, \quad a_{k,n} \to a_{k,n+1}, \tag{29}$$

$$b^\dagger_{q,n} \to b^\dagger_{q,n+1}, \quad b_{q,n} \to b_{q,n+1}. \tag{30}$$

The wavefunctions $|\Psi_n\rangle$ and $|\Psi_{n,[T]}\rangle$ can be expanded in terms of these excited states:

$$|\Psi_n\rangle = \sum_{T_n\in\mathcal{T}_n} \sum_{\{k\},\{q\}} \alpha(T_n; \{k\}, \{q\}) |T_n; \{k\}; \{q\}\rangle, \tag{31}$$

$$|\Psi_{n,[T]}\rangle = \sum_{g\in G_n} \sum_{\{k\},\{q\}} \beta(gT_n; \{k\}, \{q\}) |gT_n; \{k\}; \{q\}\rangle, \tag{32}$$

where the coefficients $\alpha(T_n; \{k\}, \{q\})$ and $\beta(gT_n; \{k\}, \{q\})$ depend on both the tiling configurations and the phonon and phason excitations.

The emergence of phonons and phasons in the growing quasicrystalline universe has important implications for the properties of the corresponding quantum error-correcting codes. The presence of these excitations introduces additional degrees of freedom that may affect the error correction capabilities of the code. As discussed in the previous section, the dispersion relations of phonons and phasons lead to Friedmann-like equations describing the expansion of the universe, contributing to the energy density and exhibiting different behaviors in various phases of cosmological evolution. In the spirit of [26], we propose that phonon and phason excitations can provide the seeds for composite matter formation. In this model, quasicrystal points act as point-particle excitations, forming composite particles such as hadrons. These excitations contribute to the radiation epoch spectrum, and as more composite matter emerges, the universe transitions to a matter-dominated epoch. As the universe expands, phonon excitations may continue to influence its evolution. In particular, the dispersion relation for phasons (Equation 12) includes an imaginary term that becomes significant at large wavelengths, leading to diffusive behavior, thereby excluding its contribution from the energy density.

3.1.1 Tiling Spaces: From Discrete to Continuous

While quantum field theory may be suitable for studying these transitions, most many-body systems, including quasicrystals and the universe, exist at finite temperatures. As a result, the equilibrium state of the system is described by a thermal density matrix, often involving mixed states. Consequently, conventional quantum field theory techniques may not be appropriate. The literature frequently employs effective field theory techniques to address these conditions. Here, we will describe tiling spaces using the probabilistic approach of [19]. Tiling spaces are defined by the continuous hull $X(\Lambda)$, which includes all translates of a point set Λ in $\mathbb{R}^d$. This framework is typically applied to infinite quasicrystals, but to understand regimes where dynamics occur at scales much larger than the underlying spacing (potentially at the Planck scale), we expect to recover invariance under continuous translations in the tiling space.

A characteristic property of a point set in $\mathbb{R}^d$ is the average number of points per unit volume, and we are interested in the relative frequency f^r of subsets or clusters of points, defined as the absolute frequency per unit volume over the density of the point set Λ. Various methods to compute this quantity can be found in the quasicrystal literature [19]. This will allow us to define a probabilistic measure in the tiling space.

These relative frequencies define an invariant probability measure on the set of tiling configurations $X_0(\Lambda)$, which consists of all tiling configurations with the origin as a point. For a non-empty finite cluster P, we define the cylinder set Z_P containing all configurations with P as a subcluster:

$$Z_P := \{\Lambda' \in X_0(\Lambda) \mid P \subset \Lambda'\}. \tag{33}$$

The measure of this cylinder set is given by the relative frequency:

$$\mu_0(Z_P) = f^r_\Lambda(P). \tag{34}$$

This measure extends to a positive measure on the entire tiling space $X(\Lambda)$ by standard arguments, using the σ-algebra generated by the cylinder sets. The invariant measureμ provides a robust framework to explore the statistical properties of quasicrystalline structures and their implications for cosmology. We can express the partition function as:

$$\begin{aligned} Z_X &= \sum_{\Lambda \in X(\Lambda)} \prod_{P \in \Lambda} f^r_\Lambda(P) = \sum_{\Lambda \in X(\Lambda)} \prod_{P \in \Lambda} \left(f^r_\Lambda\right)^{N f^r_\Lambda} \\ &= \sum_{\Lambda \in X(\Lambda)} e^{N \sum_P f^r_\Lambda(P) \ln(f^r_\Lambda(P))} = \sum_{\Lambda \in X(\Lambda)} e^{-N I_\Lambda}, \end{aligned} \tag{35}$$

where N is large, implying that the number of specific configurations P or clusters must approach its frequency. We introduce the information entropy of the tiling space as

$$I_\Lambda = -\sum_P f^r_\Lambda(P) \ln(f^r_\Lambda(P)). \tag{36}$$

To connect this framework with a notion of energy density, we start by calculating the emergent average energy $\langle E \rangle$ from the partition function Z:

$$\langle E \rangle = -\frac{\partial ln Z_X}{\partial \beta}, \tag{37}$$

where $\beta = N = \frac{1}{kT}$ is the inverse temperature. Note that N is playing the role of β. As the tiling space grows the temperature lowers.

Given the volume η, the energy density ρ is then:

$$\rho = \frac{\langle E \rangle}{\eta}. \tag{38}$$

This framework allows us to analyze the statistical properties of quasicrystalline structures and their implications for cosmology. The information entropy I_Λ plays a crucial role in understanding the distribution and frequency of clusters within the tiling space, and the derived energy density connects this microscopic structure to macroscopic physical properties at large scales. With matter distributions, there are associated dispersion relations, which can lead to dynamics as we pointed out earlier.

Another aspect to consider is the self-similarity of quasicrystals. Quasicrystal point sets and associated tilings, while not retaining the discrete translational symmetry of the lattice in the projected space, exhibit new discrete symmetries such as scaling symmetry (self-similarity). This implies that the frequencies in a growing quasicrystal are dynamic and may oscillate.

Let us consider some suggestive interpretations of our working hypothesis of the universe as a growing quasicrystal.

3.1.2 Growth Dynamics in a Quasicrystalline Universe and Dark Energy

This model incorporates two distinct types of growth, each playing a crucial role in the universe's evolution:

External Growth by Shell Projection: The first type of growth occurs through the projection of new points from a higher-dimensional lattice onto our observable universe. This process can be visualized as the universe growing outward, shell by shell, from a central point. Each new shell introduces additional points, expanding the universe's structure.

Internal Growth through Subdivision and Rescaling: The second type of growth is an internal process triggered by the introduction of matter, which naturally imposes a scale on the system. This scale can be aligned with the Planck scale, introducing minimum length and time scales. As new points are projected into the universe, they subdivide existing structures. To maintain consistency with the matter-imposed scale, the universe must undergo periodic rescaling.

To illustrate these growth processes, let's consider a simplified one-dimensional universe, the usual Fibonacci chain projected point by point:

Initial state: The universe begins with a single point and two tile lengths: short and long.

Second point: A new point arises. The original short tile becomes long, and a new short tile is introduced with the old long becoming a new long and a short.

Fourth point: With the addition of the fourth point, we now have three types of tiles. This illustrates the dynamic nature of the frequency distribution due to the asynchronicity between shell projections and the self-similarity requirements.

Fifth point: At this stage, we return to having two tile types, but at a different scale from the initial state.

If matter is defined based on the initial scale, the universe must rescale this new configuration to maintain consistency. The new long tile is rescaled to match the original long tile, and the same is done for the short tile. This rescaling process is crucial for maintaining the consistency of matter within the growing quasicrystal structure. It allows for the preservation of local minimum distances between points if the rescaling is precisely timed after a certain number of points is projected.

Matter and observers are ultimately composed of points that are continuously replaced by new points projected from a higher dimension. One analogy is the process in which a person's atoms are replaced many times throughout their life. This mechanism for dark energy can be modeled by assuming an energy constraint, leading to Λ in Equations 18 and 19.

The two distinct expansion processes may unfold differently in the early radiation-dominated epoch and the later matter-dominated epoch: Growth due to the construction of the quasicrystal shell by shell from projections from a higher dimension. Rescaling of internal subdivisions from points entering the quasicrystal from the projections, necessitated by matter fixing a scale. This dual growth mechanism qualitatively addresses the Hubble tension.

3.1.3 Phonons and Dark Matter

In our quasicrystalline universe model, we can extend the analogy with solid-state physics to propose a novel explanation for dark matter. This approach leverages the concept of phonons—quantized modes of vibrations in a quasicrystal structure—and applies it to the spacetime quasicrystal of our model.

In this framework, spacetime itself is viewed as a quasicrystal, and phonons represent vibrational modes within this spacetime quasicrystal. These phonons, particularly those with long wavelengths that persist to later times,

could potentially contribute to the dark matter component of the universe. This concept draws a parallel with how phonons interact with electrons in solid-state physics. In solid-state systems, phonons can scatter electrons, influencing phenomena such as electrical resistance and superconductivity. The interaction Hamiltonian in solid-state physics typically takes the form:

$$H_{\text{int}} = g \sum_{q,k} (a_q + a_q^\dagger) c_{k+q}^\dagger c_k, \tag{39}$$

where a_q and $a_q^\dagger$ are phonon annihilation and creation operators, respectively, and c_k and $c_{k+q}^\dagger$ are electron operators.

Extending this concept to our cosmological model, we can propose an interaction Lagrangian that couples spacetime phonons with ordinary matter (e.g., electrons):

$$\mathcal{L}_{\text{int}} = g_{ph} \sum_{q,k} (\phi_q + \phi_q^\dagger) \psi_{k+q}^\dagger \psi_k, \tag{40}$$

where ϕ_q and $\phi_q^\dagger$ are the phonon fields, and ψ_k and $\psi_{k+q}^\dagger$ are ordinary matter fields like electrons.

Dark Matter Candidate: These spacetime phonons, if weakly interacting, could serve as candidates for dark matter. They would influence the dynamics of ordinary matter while remaining largely undetectable through electromagnetic interactions. This is analogous to models where dark matter interacts with ordinary matter through new forces or mediators, modifying the dynamics of both dark matter and ordinary matter. For instance, similar to dark photon interactions in some models, phonons in the spacetime quasicrystal could potentially scatter off nuclei, producing recoil signals that might be detectable in experiments designed to look for Weakly Interacting Massive Particles (WIMPs). Furthermore, the decay or annihilation of these phonons might produce standard model particles that could be detected by telescopes or neutrino detectors. It's important to note that the quantitative details of this phonon-based dark matter model are still a work in progress. However, this approach offers a novel perspective on dark matter, grounded in the quasicrystalline structure of spacetime proposed by our model. This phonon-based dark matter hypothesis not only provides a potential explanation for the nature of dark matter but also further illustrates the deep connections between solid-state physics and cosmology suggested by our quasicrystalline universe model.

3.2 Implications of the Expanding Universe as a Growing Quasicrystal

The hypothesis that the expanding universe is a growing quasicrystal has several significant implications for our understanding of cosmology:

1. **Elimination of the Inflation Scenario:** The necessity for an inflationary period may be obviated. The large number of tiles or points, N, required for uniform distribution is achieved by construction through the imposition of a quasicrystalline structure. This uniformity, intrinsic to quasicrystals, provides a natural explanation for the observed large-scale homogeneity of the universe.

2. **Radiation Epoch:** Following the initial QECC construction phase, the universe enters a radiation-dominated epoch characterized by the emergence of phasons and phonons. These quasiparticles are analogous to relativistic matter and radiation, contributing to the early universe's dynamics. The presence of these quasiparticles can lead to unique dispersion relations influencing the energy density and expansion rate.

3. **Phason Contribution at Later Times:** At later times, as the number of points N increases, phasons do not significantly contribute to the energy density. This is due to the dominance of a diffusive imaginary term in their dispersion relation at large wavelengths, effectively damping their influence on the universe's expansion.

4. **Matter and Long Wavelength Phonons:** Matter, along with long-wavelength massive phonons, continues to play a critical role in the universe's evolution. These components contribute to the overall energy density and can interact with ordinary matter, potentially acting as candidates for dark matter.

5. **Accelerated Expansion:** The universe's accelerated expansion can be explained by the internal rescaling mechanism driven by a fixed matter scale. This rescaling process results from the continuous projection and replacement of points within the quasicrystalline structure, analogous to the cosmological constant or dark energy driving the observed acceleration in the universe's expansion.

6. **States and Symmetries:** It is, however, questionable whether one can find exactly invariant states in a discrete space-time setting [12]. In the context of our quasicrystalline model, this suggests that the emergent large-scale symmetry is an approximation resulting from the statistical mechanics framework applied to the tiling space microstates. This leads to a partition function and energy densities that, in turn, give rise to Friedmann-like equations by imposing the Hubble law on the wavelength in the dispersion relation of propagating degrees of freedom.

Overall, this model provides a novel framework for understanding the universe's structure and dynamics, integrating concepts from condensed matter physics and cosmology to offer fresh perspectives on longstanding issues such as the Hubble tension and the nature of dark matter and dark energy.

—

At this juncture, readers may question why projections occur, how the system determines which shells to project, and the nature of the computational framework underlying this higher dimensional lattice. They may also wonder if more lattices from higher dimensions are involved. These inquiries parallel conventional physics questions about the Big Bang, conservation laws, and the mechanisms underlying physical laws. Despite these profound questions, the hypothesis of a higher-dimensional framework introduces testable consequences for the cosmos—namely, the emergence of a quasicrystalline structure distinct from both continuous and traditional crystalline constructs.

If the cosmos possesses a quasicrystalline structure, this feature could potentially be identified using techniques similar to those employed in materials science for detecting crystalline arrangements. The structural nature of a material—whether crystalline, quasicrystalline, or amorphous—is revealed through distinctive diffraction patterns. In the lab, such patterns are commonly produced through electron diffraction, where an electron beam interacts with the material. The resultant diffraction pattern, which provides detailed information on atomic spacing and structure, is then recorded. The presence of definitive Bragg peaks within these patterns indicates constructive interference from regular atomic planes, revealing the material's symmetry and structure.

Applying this concept to a cosmic scale, one might consider the cosmic microwave background (CMB) radiation as a macroscopic "diffraction pattern" reflecting the universe's structure. The CMB, a relic radiation from the Big Bang, offers a primordial snapshot of the universe from 380,000 years after its inception, containing valuable structural and compositional data from that era. Detailed examination of temperature and polarization fluctuations within the CMB, as captured by observatories like the Planck satellite, allows researchers to piece together the universe's large-scale structure.

In a theoretical model positing quasicrystalline symmetry in the universe, this analysis would involve searching the CMB data for Bragg-like peaks—specific intensity points revealing an ordered pattern characteristic of quasicrystalline structures. Identifying such patterns would profoundly transform our understanding of the cosmic expanse and bridge celestial phenomena with quantum-scale observations in condensed matter physics.

4 Discussion

In this paper, we have expanded the interpretation of the wave function beyond its traditional role in estimating a particle's position probability. By exploring the Schrödinger equation for a particle in a box with time-dependent boundaries and introducing a constraint that bridges microscale and macroscale quantities, we have derived an equation that bears a structural resemblance to the Friedmann equation. This development could be instrumental in addressing pivotal cosmological challenges, such as the Hubble tension. This tension arises due to observed discrepancies in the measurement of the universe's expansion rate, as denoted by the Hubble constant H_0. Notably, H_0 shows differing values when measured in the early universe—particularly via the CMB, indicating a slower expansion rate—compared to measurements from the late universe using supernovae and Cepheid variables, which suggest a faster expansion rate. Such variations point to a potential gap in our current understanding of the universe's expansion trajectory.

Furthermore, we have hypothesized a novel heuristic model of the expanding universe conceptualized as a quasicrystalline projection from a higher-dimensional lattice. The inherent properties of quasicrystals, which resonate with cosmological principles, offer promising insights into the dynamics of the cosmic scale parameter. Our approach introduces a fresh perspective on comprehending the universe's structure and its expansion, with a specific focus on unraveling the Hubble tension, dark energy, and dark matter. In our model, the universe's scale parameter is envisioned as a function of both the non-linear increase in points from projections from a higher-dimensional lattice and the rescaling of spaces inside the matter content of the universe with new points coming to the projected tiling space. The model provides a phase pre-inflation with quantum error correction, bypassing the inflation phase, and transitioning to a phase dominated by propagating phasons, phonons, and radiation. Subsequently, it evolves to a phase characterized by the emergence of matter in the limit of very large number of tiles, culminating in a later phase with two kinds of expansion engines due to the projections. Long-wavelength massive phonons arise as candidates for dark matter.

A potential critique of this model could be the apparent contradiction between the continuous symmetry observed in the universe and the discrete nature of a quasicrystalline structure. This critique can be addressed by noting that quasicrystals give rise to tiling spaces that exhibit continuous symmetry on very large scales. We introduced a statistical mechanics framework to show how this can occur, using a probabilistic measure for tiling space microstates, which

leads to a partition function and energy densities. The Friedmann-like equations arise by imposing the Hubble law on the wavelength in the dispersion relation of propagating degrees of freedom.

To fully realize the potential of this approach, further detailed analysis is required. This will involve rigorously developing the quantitative model and enhancing its predictive power, thereby contributing significantly to our understanding of the universe's expansion and its underlying code structure.

Abstract
Multi-biometric authentication systems have been extensively investigated due to their merit over unimodal systems. Multi-biometric systems not only overcome various security and privacy concerns of unimodal systems but also enhance overall performance & reliability. However, optimal fusion of multi-biometrics to overcome environmental challenges remains an open-ended research problem that was limitedly addressed. To address this issue, optimal score level fusion is proposed for a multi-biometric authentication system which includes biometrics namely fingerprint, finger-vein, and iris. The proposed optimal score level fusion technique exploits the Whale Optimization Algorithm (WOA) to efficiently weight belief assignment of finger-vein, iris, and fingerprint classifiers. The key features of WOA namely encircling, exploration, and exploitation are exploited to obtain optimal solutions for the fusion of multi-biometrics. For this, belief assignment for the score obtained from three modalities is computed using the Denoeux model. Furthermore, belief assignments are fused using the combination rule of PCR-6 (Proportional Conflict Redistribution) to achieve adaptiveness of the system to environmental effects. The proposed multi-biometric system is evaluated over a benchmark dataset namely, VERA finger vein, FVC 2002 and FVC 2006 fingerprint, and IITD PolyU iris. The experimental evaluation shows that the proposed technique attains, on an average, accuracy of 99.33% & equal error rate (EER) of 0.27% and these results are compared with the state-of-the-art system.

1 Introduction

Biometric technologies are widely used in identifying and authenticating users. Biometric systems are very crucial for security requirements and access control. These systems utilized physical (face, iris, finger vein, fingerprint, etc.) or behavioral (voice, gait, signature, etc.) traits to recognize the authenticity of a person for verification or identification. Biometric traits cannot be used, stolen, or forged easily. Hence, biometric systems are considered more suitable as compared to the traditional security system. However, using a single biometric trait to establish the identity of a person suffers from many limitations, including noise, non-universality, intra-class variation, and spoof attacks. These limitations can be circumvented through the fusion of multiple biometric traits.

In multi-biometric systems, two or more physical or behavioral traits are combined to increase security, reliability, and resistance to spoof attacks. These integrated biometric systems provide an optimal value of equal error rate (EER) and hence improve system accuracy [1, 2]. In addition, researchers have developed many fusion techniques that can be used before or after the matching module to enhance the effectiveness of multi-biometric systems. These fusion approaches are difficult to apply due to variations in acquired biometric data and the size of derived feature vectors. Unless all modalities are related to the same kind of feature vectors that have been adjusted to a uniform proportion. Following the matching module, the fusion methods used are decision, rank, and score-level fusion. These techniques are commonly utilized in the field of multi-biometrics since they are independent of the characteristics of captured images or extracted features. Fusion is accomplished in all of these schemes only after individual modalities have been scored. Ranks are formed from the matching score in the rank-level fusion method. In decreasing order of confidence, these ranks represent a probable collection of matched identities. In the decision level fusion, only a decision from each matcher is required which is combined to produce the final decision. Due to this, a very limited amount of information is present during the fusion, which may result in false recognition. Score level fusion is used to produce similarity or dissimilarity scores for each biometric modality by comparing the traits of the probing subject to the traits of all enlisted subjects. Hence, score level fusion provides more information as compared to rank and decision level fusion to identify & authenticate the user [3, 4]. Multimodal biometric systems can be categorized into two distinct groups depending on the methods employed to collect various traits: (i) multiple traits collected using a single sensor and (ii) multiple traits collected using multiple sensors [5].

The constraints of unimodal biometric systems are effectively addressed by multimodal biometric systems. However, they can cause inconvenience for users during the enrolment and modalities acquisition process. Hence, from the perspective of the user, biometric features that are close to each other are chosen. The selection of biometric features frequently requires achieving a balance between system security and user comfort. Notably, modalities are integrated at different levels specifically at the feature level, score level, decision level, and rank level. Despite fusing several modalities at the score level is the easiest option to execute but achieving optimal fusion at the score level is still a challenge [6].

The proposed fusion model is robust against the spoofing attack as it is not possible to spoof three modalities at the same instance. Also, the fusion of multiple biometric traits is used to check the authenticity of the user in a multi-biometric system which makes it robust against spoof attacks. The proposed method is designed to provide expert discernment in distinguishing genuine subjects from impostors using an optimal score-level fusion approach. The fundamental fusion model acts as an intelligent agent with the utmost

decisiveness in identifying real users from imposters. The proposed score level-based fusion technique emphasizes optimizing the fusion of data derived from three complementing attributes: fingerprint, iris, and finger-vein. Furthermore, to make a final determination about user authentication, the proposed fusion process carefully considers the compatibility of the optimized source classifier. Below are the summarized key points of the proposed work:

- A novel adaptive approach for multi-biometric system using fingerprint, iris, and finger-vein
- Whale Optimization Algorithm (WOA) is exploited to cater to dynamic environmental challenges
- Conflicting beliefs among the classifiers are resolved using a score-level fusion model
- Outcome of the proposed system reveals low EER and high accuracy
- Proposed multi-biometric system is robust to security & spoofing attack

The paper comprises the following sections: An overview of related work and research gap has been highlighted in Section 2. Proposed fusion model core architecture, optimal score level fusion approach, classifier score computation, and performance optimization are discussed in Section 3. In Section 4, Implementation details and databases used for experimental simulations have been discussed. Also, the proposed system qualitative and quantitative performance is compared with the state-of-the-art techniques. Finally, Section 5 summarized our research findings and outlines future directions.

2 Related work and Research gap

To address the constraints associated with unimodal biometric systems, extensive research is currently focused on multi-biometric systems. It is believed that integrating similarity scores from numerous modalities is a pragmatic approach for combining different attributes. Details of recent research work for score-level fusion are summarized in Table 1, which depicts the comparison of score-level fusion across various modalities and a detailed analysis of experimental outcomes.

A multiple-instance score fusion strategy was suggested for the recognition of finger-knuckle prints [7]. In this work, the left index/middle finger and right index/middle finger of a person were combined at the score level. To generate fixed-length feature vectors from Finger-Knuckle Print (FKP) images, the combination of local binary pattern (LBP) encoding, Gabor filter convolution, and Bio-Hashing method was considered. The Bio-hashing approach provides separation between genuine and imposter. Likewise, the exploration of a score-based fusion for hand multi-biometrics was conducted in the study by Peng et al. [8]. Their research combined scores from finger shape, knuckle print, finger vein, and fingerprint attributes with binary operations. Frank, Yager, Hamanger, and Einstein product T-norms were used to normalize and combine the fused scores. The achievement of universality in biometric systems was not realized through these methods as they were constrained to a specific body part. Moreover, classifier performance optimization is not used in these fusion methodologies.

In 2014, Sim et al. [9] proposed a weight-based score-level fusion algorithm considering the non-ideal biometrics scenarios. The authors used a multimodal benchmark dataset (UTMIFM) for face and iris, UBIRIS version 2.0 for iris, and ORL for face. Additionally,

Shekhar et al. [10] explored a joint sparse representation approach within the context of a multi-biometric system. In this investigation, each modality was assigned a weight based on the quality assessment of the acquired data, and non-linearity was addressed through kernels. Despite incorporating the optimized classifier scores with quality measures, the optimal fusion of iris and fingerprint modalities was addressed partially.

Mukherjee et al. [11] proposed a multimodal biometric system based on differential evolution score-level fusion approach. In which adaptive weight and exponent-based function mapping combine matching scores from different biometric sources into a single score for classifier decision-making. Differential evolution algorithm was used to adjust tunable parameters and to minimize the overlap between the frequency distributions of genuine and imposter scores. The gaussian kernel density method is used to estimate the frequency distributions for greater accuracy.

Mezai and Hachouf [12] introduced a new technique instead of directly integrating classifier scores. They transformed individual classifier scores into belief masses by integrating measures from both facial and voice features. Particle Swarm Optimization (PSO) was used to compute confidence factors for individual classifiers. The Dempster-Shafer theory and proportional conflict redistribution (PCR-5) combination rules were used to determine user classes.

In 2016, Liang et al. [13] introduced a new technique in the context of a multimodal biometric system. In this, a probability-based score fusion algorithm known as an order-preserving tree, which is non-parametric, was presented. During the normalization stage, classifier scores were converted to posterior probabilities. These probabilities were merged to generate the final probability at the merge stage. In a dynamic environment, the effectiveness of most multimodal biometric systems is often compromised due to conflicting classifier scores, which in turn diminishes the system robustness and reliability. Addressing this challenge, Walia et al. [14] introduced a multi-biometric system that relies on an optimal score-level fusion approach. In their research, they achieved optimal integration of three complementary biometric traits and to enhance the performance of individual classifiers Backtracking Search Optimization Algorithm (BSA) was used. Further, any conflicting beliefs originating from these individual classifiers are efficiently resolved through the use of PCR-6 rules to improve template security and robustness in biometric systems.

Further, the authors have presented a multi-biometric system that combines multiple features such as face, iris, and ear [15]. The authors presented important components for creating cancellable biometric characteristics, and they used the cuckoo search optimization method to produce optimal belief masses for classifiers. Finally, the fusion of classifier beliefs is carried out using proportional conflict redistribution (PCR-6) rules. In 2019, Gupta et al. [16] presented a score level fusion approach to resolve the issue of score conflict between individual classifiers. They utilized a grasshopper optimization algorithm to optimize the score of individual classifiers and scores are fused using proportional conflict redistribution (PCR-6) rules to obtain a concurrent solution. The system shows high performance, reliability, and robustness against the dynamic environment. However, it utilized only two biometric modalities.

In 2020, Abderrahmane et al. [17] proposed score level fusion approach based on the weighted quasi-arithmetic mean (WQAM). The proposed approach contains the properties of both quasi-arithmetic mean and weighted mean. It was calculated using various trigonometric functions and there is no need for a learning process. The WQAM fusion technique outperforms earlier proposed score fusion algorithms that used transformation, classification, and density estimation approaches. In [18] Gupta et al. proposed an optimal score fusion model for multiple biometric sources viz. finger, face, and iris. This system

intelligently combines scores from individual classifiers to address the challenges associated with dynamic environments, spoofing attacks, noisy input images, and other limitations. In [19] Ramachandran and Sankar suggested a score-level fusion approach for multi-biometric biometric recognition using two biometric traits namely: iris and palmprint. For feature extraction, the authors used Log-Gabor transform, Local Binary Pattern, and Histogram of Oriented Gradients. Further, scores were generated using, Chi-Square distance, Euclidean distance, and Hamming distance measures, which were combined using a weighted sum score level fusion technique. They achieved a recognition accuracy of 92.23%.Further, Rane & Bhadade [20] have presented a multi-biometric system in which they utilized palmprint and face as two biometrics features. A t-norms-based score fusion method was used, which is a binary operation and provides the fusion result in the interval 0–1.

In 2021, Ahmad et al.[21] considered score-level fusion of multimodal biometrics as an optimization problem. To solve that optimization problem, the authors used a genetic algorithm (GA) based method. The genetic algorithm-based approach utilizes a weighted Spearman foot rule distance metric to determine the distance between two score lists. The proposed method outperforms as compared to the state-of-the-art score level and rank-level fusion methods and achieves an accuracy of 99.42%.In addition, Hammouche et al. [22] presented a novel and effective method for authentication, which involves score-level fusion of Minor and major dorsal finger knuckle patterns. They extracted reflectance and illumination information from these traits using the Adaptive Single-Scale Retinex (ASSR) technique. To extract normalized histogram features and facilitate the matching stage, the authors employed a binarized statistical image features (BSSF) approach along with the Cosine Mahalanobis distance.

A multi-biometric identification system has been presented by Shreya and Chatterjee [23] in which threshold and model-based techniques were discussed. The system used two biometric traits namely latent fingerprint and iris, which are fused using the score-level fusion approach. In the threshold-based approach identification rate achieved was 80%, while in the model-based approach, it was 87.3% which was better than the threshold-based approach. The accuracy rate achieved after the fusion was 91.15% and 86.63% for the sum and product rule respectively. Kazi et al. [24] have proposed a multi-biometric system in which biometric traits face, fingerprint, and signature were fused. The authors used similarity and dissimilarity measures to calculate the score, which are fused using the sum rule approach. Normalization is performed using z- normalization method. A high recognition rate of about 99.04% using the score-level fusion approach is obtained.

To prevent online image theft Fernandez & Pandian [25] have proposed a system in which iris and fingerprint features are used as the watermark. They used registration phase to generate the watermark from the features of iris and fingerprint, and verification phase was used when an ownership dispute emerged on the image. The authors used multimodal biometric watermarking, Lifting Wavelet Transform, and transformation-based score level fusion using triangular norms to achieve better accuracy and robustness against the various attacks. Furthermore, an exploration into enhancing the effectiveness of a score-based multi-biometric fusion model through the utilization of a quality index was conducted [26]. This approach involved evaluating the reliability of input sensors based on the quality of the input image. In this study, the authors introduced the concept of an uncertainty factor to quantify the level of reliability exhibited by the source classifiers.

In sum, the literature review shows that most of the research work is performed on genetic and swarm-based algorithms which are iteration-based and used to solve complex problems but genetic algorithms are relatively expensive and have a slow convergence

rate. Score-level fusion is used by most researchers and ideal integration of more than two modalities was mostly studied in a limited way. To resolve these issues, the proposed work utilized a whale optimization algorithm (WOA) which is a population-based meta-heuristic algorithm that solves high-dimensional problems. It is easy to use and known for its simplicity and fast convergence. WOA is a global optimizer as it includes exploration and exploitation to search the optimal positions. In addition, most biometric-based authentication work is limited to one or two biometric traits which leads to security concerns and spoofing attacks. This study aims to develop an appropriate fusion model for high-security applications.

The fundamental framework of the proposed approach is detailed in the next section. Feature extraction method and proposed score-level fusion approach are also discussed in detail.

3 Core design of proposed multi-biometric system

The proposed method utilizes a hybrid approach that uses a highly competitive meta-heuristic algorithm-Whale optimization algorithm (WOA) along with proportional conflict redistribution (PCR-6) rules for optimal score fusion. Figure 1 illustrates the comprehensive architecture of the proposed multi-biometric system. The proposed score-based fusion model comprises four stages: conversion of match score into belief mass, confidence factor estimation using WOA, optimal combination of belief mass using Dezert-Smarandache Theory (DSmT) based PCR-6 rule, and decision model.

As shown in Fig. 1, three biometric traits namely iris, fingerprint, and finger-vein are taken as input and corresponding feature vectors are extracted. Comparison of the extracted feature vectors is performed with their templates stored in the database to obtain match scores S_i, S_{fv}, and S_{fp} for iris, finger-vein, and fingerprint respectively. These scores are further processed using WOA and DsmT-based PCR-6 rules for optimal combination. Whale Optimization Algorithm (WOA) is used to calculate optimized confidence values

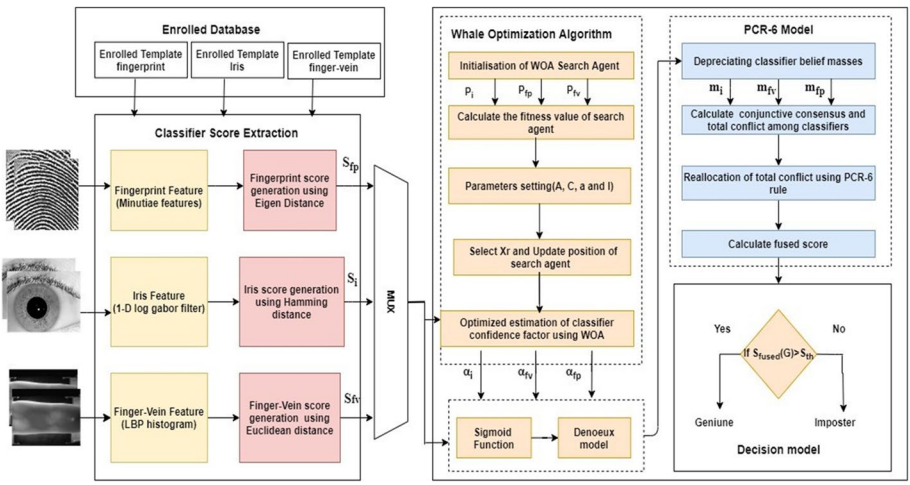

Fig. 1 Proposed Multi-biometric system using Whale Optimization Algorithm and PCR-6 based fusion rules

for individual classifiers [27]. These confidence values act as a confidence factor for the estimated match scores. The match scores are converted into the belief masses utilizing the Denoeux model. These belief masses are subjected to the DSmT-based PCR-6 rule model to resolve conflicts among individual classifier beliefs [28, 29]. Total conflict and conjunctive consensus are also determined for each classifier. The total conflict consisting of six partial conflicts is redistributed among the three classifiers and final belief mass is calculated for the entire system. Lastly, in the decision model, the final belief mass is compared with a predefined threshold value.

The proposed system demonstrates optimal performance across diverse scenarios. For example, in the case of concurrent classifiers, classifiers are boosted or suppressed. In the case of discordant classifiers, our proposed fusion model uses state-of-the-art conflict resolution. The following subsection presents the details of the proposed optimal fusion model along with the feature extraction methods.

3.1 Multi-biometric feature extraction

The three biometric features viz. fingerprint, finger-vein, and iris are selected based on their suitability and convenience of acquisition. Approaches used for the feature extraction of these modalities are as follows:

a) *Iris Feature Extraction*

Iris features are extracted using the approach by Monwar & Gavrilova [30]. Due to a precise localization of the iris region, this method has high accuracy. In this, the acquired iris image is initially processed to localize the region of interest, and after that rubber sheet model [31] is applied to the region of interest. Further, the obtained iris image undergoes convolution with 1-D log Gabor wavelets. The accuracy is ensured by filtering out the noise from the convolved pattern and the filtered pattern is transformed into phase-quantized bits. Further, the match score of the iris classifier S_i is computed by calculating the Hamming distance between the stored template and acquired phase-quantized bits using Eq. (1). The symbol $\odot$ used in Eq. (1) represents the convolved phase quantized bits of the iris.

$$S_i = \frac{\left| T_{ia} \odot T_{is} - HD_{s,a} \right|}{T_{ia} \odot T_{is}} \tag{1}$$

wherein, $HD_{s,a}$ indicate Hamming distance and is calculated using Eq. (2). T_{ia} and T_{is} indicate acquired and stored iris templates, respectively.

$$HD_{s,a} = T_{is} \oplus T_{ia} \tag{2}$$

b) *Finger-vein feature extraction*

Finger-vein features are extracted using the technique described by Peng et al. [8]. This approach achieves high accuracy because of the efficient filtering vein pattern. For this, the acquired image of a finger vein is normalized, and after that Gabor wavelet kernels are used to filter and create a map, which is known as the Gabor binary pattern map. Further, this map is divided into mutually exclusive rectangular blocks to create separate local binary pattern (LBP) histograms which are concatenated to obtain the final feature set. Further,

using Eq. (3) LBP histogram of the acquired vein image is compared against the stored templates to obtain the match score of the finger-vein classifier.

$$S_{fv} = \sum_{r} \frac{\sum_{u} \sum_{v} \min(h^{s}_{x,y,z}, h^{a}_{x,y,z})}{\sum_{u} \sum_{v} h^{s}_{x,y,z}} \tag{3}$$

where $h^{s}_{x,y,z}$ and $h^{a}_{x,y,z}$ represents the local binary pattern histogram of the stored feature set and the acquired image.

c) *Fingerprint feature extraction*

The feature extraction for fingerprint modality is attained via the minutiae extraction method presented by Ravi et al. [32]. The fuzzy rules-based approach [33] is used to filter out the false minutiae by estimating the threshold distance between terminations and the angle deviation across synchronized directions.

Further, to perform matching of legitimate minutiae pairs, ridge ending, and bifurcations are matched. The orientation of the fingerprint minutiae is considered throughout the matching process of the extracted characteristics The match score determines the similarity of two fingerprint features using Eq. (4).

$$S_{fp} = \frac{N^{2}_{match}}{N_{s} N_{a}} \tag{4}$$

where,

N_s represents the count of minutiae points in the stored template;
N_a denotes the count of matched minutiae points in the acquired template;
N_{match} represents the total number of matched minutiae pairs;

To achieve an optimal decision, the computed matched score or likelihood value of these classifiers, S_i, S_{fv}, and S_{fp} are fed into the proposed score level fusion model. The fundamental structure of the proposed model is elaborated in the next part.

3.2 Proposed score level fusion model

In a biometric system, multi-biometric fusion is essential for optimal decision-making. To integrate scores received from three biometric traits, this study provides a four-stage model of optimal fusion. In addition to performing concurrent classifier boosting and suppression, the proposed fusion model also successfully resolves conflicts between the discordant classifiers. The next subsection provides specifics of the suggested fusion model.

3.2.1 Conversion of match score into belief mass

Authentication step in a biometric system comprises a two-class problem. These classes are based on genuine and imposter users, here $\theta_{genuine}$, $\theta_{imposter}$ denoted as respectively. Therefore, based on Shafer's model the fusion problem is represented with the frame of discernment $\Theta = \{ \theta_{genuine}, \theta_{imposter} \}$. In step 1, the match scores S_y (y *i, fv, fp*) of each classifier are

transformed into belief masses m using the Denoeux model [34]. The computation of belief masses is given by

$$m_y(\theta_{genuine}) = \alpha_y * \psi(S_y) \tag{5}$$

$$m_y\left(\theta_{imposter}\right) = 1 - \alpha_y * \psi(S_y) \tag{6}$$

where $m_y(\theta_{genuine})$ and $m_y(\theta_{imposter})$ represent genuine and imposter class belief mass. α_y is the confidence factor, y$\in$iris, finger-vein, fingerprint, and ψ represent a sigmoid function or increasing function to map the scores in the range [0, 1].

The computation of the confidence factor (α_y) is performed by WOA in the next stage.

3.2.2 Confidence factor estimation using WOA

Whale Optimization Algorithm (WOA) is used for obtaining optimum values of confidence factors α_y (y$\in$*i, fv, fp*) for each classifier. WOA was proposed by Mirjalili et al. [27] which mimics the social behavior of humpback whales and is inspired by the bubble-net hunting strategy. The efficiency of WOA is evaluated by solving six structural and 29 mathematical optimization problems and, it outperforms compared to the other state-of-the-art methods. It is a nature-inspired meta-heuristic algorithm that utilizes randomly generated search agents or populations. The search for prey i.e. optimum value by search agent is divided into three phases: Encircling prey, Exploration, and Exploitation. These three phases are used for updating and improving the search agent position until the required optimum solution is not reached.

During the initialization phase, the position of the search agent is defined as P_{sa} (sa$\in$*i, fv, fp*) for each classifier. The position of each search agent is updated according to the current best position. Initially, the current best position of the search agent is defined. This newly defined best position helps other search agents to update their position towards the optimum solution. The updation of position is represented by Eq. (7) and (8)

$$\vec{D} = |\vec{C}.\overrightarrow{X^*}(t) - \vec{X}(t)| \tag{7}$$

$$\vec{X}(t+1) = \overrightarrow{X^*}(t) - \vec{A} \cdot \vec{D} \tag{8}$$

where, '$\vec{A}$' and '$\vec{C}$' denotes coefficient vectors, while 't' signifies the current iteration.

Furthermore, by allocating random values to A within the interval [-1, 1], the new position of a search agent is established between the initial position of the search agent and the position of the present best search agent. '.$\vec{X}^*$' stands for the new best position vector of the best solution acquired up to the present iteration, which is continually updated if a superior solution is found. ' X ' signifies the old best position vector, | | represents the absolute value, and '·' denotes element-wise multiplication. The vectors 'A' and 'C' are computed using Eqs. (9) and (10).

$$\vec{A} = 2\vec{a} \cdot \vec{r} - \vec{a} \tag{9}$$

$$\vec{C} = 2 \cdot \vec{r} \tag{10}$$

In this context, "a" progressively decreases from 2 to 0 throughout the iterations, while "r" represents a random vector within the range of [0,1].

Using the Spiral updating position technique, the distance between the search agent at (X, Y) and the prey/object at (X^*, $Y.^*$) is calculated and the position of the search agent in each iteration is updated using Eq. (11)

$$\vec{X}(t+1) = \overrightarrow{D'} \cdot e^{bl} \cdot \cos(2\pi l) + \overrightarrow{X^*}(t) \tag{11}$$

In this equation, $\overrightarrow{D'}$ signifies the distance, calculated as $|\vec{X}^*(t) - \vec{X}(t)|$, representing the separation between the old position of the search agent and the current best position or optimum solution. The parameter "b" remains constant while "l" takes on a random value within the interval of [-1, 1]. The symbol "·" denotes element-wise multiplication. Further in each iteration, the search agent element with the lowest fitness value is determined for each classifier. For this, Eq. (12) calculates the fitness value F_z to verify the optimality of the best position or solution obtained for each classifier. This value depends on the costs associated with false acceptance and rejection as well as the rates associated with each.

$$F_z = C_{fa} * FAR_z + C_{fr} * FRR_z \tag{12}$$

where, F_z denotes the fitness values of search agent position, C_{fa} and C_{fr} are the cost of false acceptance and false rejection respectively, FAR_Z and FRR_Z represent false acceptance and false rejection rate.

The lowest fitness values for each classifier act as the optimal values of confidence factor (α_y) which is used to convert individual classifier scores into belief masses by utilizing Eq. (5) and (6).

3.2.3 Optimal score level combination of belief mass

In the proposed work, the problem of multiple classifier fusion is described using Dempster Shafer's theory, with the frame of discernment $\Theta = \{ \theta_{genuine}, \theta_{imposter} \}$ stated over two focal elements. The belief masses for the frame of discernment are combined for multiple classifiers using DSmT-based PCR-6 rules [28, 29]. Proportional Conflict Redistribution(PCR-6) rule was developed by A. Martin and C. Osswald in 2006 as an alternative to the PCR-5 rule. PCR-6 is used when the number of sources or inputs to combine exceeds two. It is used to resolve the conflict among highly divergent evidence and comprises the estimation of conjunctive consensus, partial conflict, and total conflict. The proposed fusion model consists of three source (iris, fingerprint and finger-vein) system. In optimal combination of belief masses, the following steps are used:

a) Firstly, Conjunctive consensus among belief masses is calculated for the focal element $\theta_{genuine}$ as m_{cc} (θ_{genuine}) using Eq. (13).

$$m_{cc}(\theta_{\text{genuine}}) = \prod_{k=1}^{N} m_{s(k)}(\theta_{\text{genuine}}) \tag{13}$$

where N = 3 denotes the number of sources.

b) Secondly, the overall conflict among belief masses, m_{tc} ($\theta_{genuine} \cap \theta_{imposter}$) is calculated using Eq. (14), and it is composed of six partially conflicting masses.

$$m_{tc}\left(\theta_{\text{genuine}} \cap \theta_{\text{imposter}}\right) = \sum_{j=1}^{2} m_{s(1)}(Y_j) \sum \left\{ \begin{array}{l} c \bigcap_{n=2}^{3} Y(j) \cap Y_{S(n) \equiv \phi} \\ (Y_{(j)}, Y_{S(n) \in \Theta}) \end{array} \right. \prod_{k=2}^{3} m_{s(k)}(Y_{S(k)}) \tag{14}$$

These partially conflicting masses are redistributed using Eq. (15) in proportion to the mass of the focal elements that comprise the total conflict.

$$m_{rd}(\theta_{\text{genuine}}) = \sum_{\left\{ \begin{array}{l} ck = 1 \\ G \in \Theta \end{array} \right.}^{3} m_{S(k)}(\theta_{\text{genuine}})^2 \sum_{\left\{ \begin{array}{l} c \bigcap_{n=1}^{N-1} Y_{\sigma k(n) \cap \theta_{\text{genuine}} \equiv \phi} \\ Y_{\sigma k(1) \ldots\ldots Y_{\sigma k(N-1) \in \Theta}} \end{array} \right.} \left\{ cc \times \left[\frac{\prod_{j=1}^{2} m_{S(\sigma k(j))} \left(Y_{S(\sigma k(j))}\right)}{m_k(\theta_{\text{genuine}}) + \sum_{j=1}^{2} m_{S(\sigma(j))}(Y_{S(\sigma k(j))}} \right] \right. \tag{15}$$

where $m_k\left(\theta_{\text{genuine}}\right) + m_{S(\sigma k(j))}(Y_{S(\sigma K(j))}) \neq 0$ and the value of $\sigma_{k(j)}$ is calculated using Eq. (16)

$$\sigma_k(j) = \left\{ \begin{array}{l} j, if \;\; j < k \\ j+1, if \;\; j \geq k \end{array} \right. \tag{16}$$

c) Lastly, the overall belief mass is calculated for the genuine class using Eq. (17) by adding redistributed masses to conjunctive consensus.

$$S_{fused}(\theta_{genuine}) = m_{rd}(\theta_{genuine}) + m_{cc}(\theta_{genuine}) \tag{17}$$

3.2.4 Decision model

In this model, the ideal threshold S_{th} is compared with the final belief mass S_{fused} (G) to conclude. The estimation of the ideal threshold value is essential to achieve higher accuracy in a biometric system. Any variation from the ideal value can reduce the accuracy and durability of the biometric system. If the threshold value is lower than the optimal value, it may cause a large number of false acceptances (FAR). Choosing a higher threshold value rather than the optimal value results in a significant number of false rejection rate (FRR).

$$\text{Decision} = \left\{ \begin{array}{l} geniune; S_{fused}\left(\theta_{genuine}\right) \geq S_{th} \\ imposter; otherwise \end{array} \right. \tag{18}$$

Therefore, to reduce the risk of both excessive false acceptances and false rejections, the optimal threshold value of the system, denoted as S_{th}, is chosen to achieve an equal error rate. In the presented research, the experimentally validated optimal threshold value S_{th} is 0.53. Algorithm 1 outlines the pseudo-code for the proposed multi-biometric system. To validate this method, the experiment was conducted using benchmark datasets. The upcoming section provides comprehensive information about the datasets used and the implementation process for the proposed method.

Algorithm 1 Pseudo-code of proposed fusion approach

[Genuine, Imposter] = Optimal score fusion [$Image_i$, $Image_{fv}$, $Image_{fp}$]

1) Create feature vectors i.e. T_{ic}, $h^c{}_{x,y,z}$, N_c.
2) Utilizing Eqs. (1), (3), & (4), determine the S_i, S_{fv}, and S_{fp} similarity scores.
3) Stage I: Optimization of the classifier score
    a. Using Eq. (5), compute the belief masses [$m_i(\theta_{genuine})$, $m_{fv}(\theta_{genuine})$, $m_{fp}(\theta_{genuine})$].
    b. Initialize the position of the search agents
    c. Determine the fitness values [$F_z(i)$, $F_z(fv)$, $F_z(fp)$]
    d. Evaluate the fitness of each search agent
    e. Consider that search agent X* is the best.
    f. If current iteration< maximum number of iteration update a, A, C, l, and p.
    g. Adjust the current search agent position according to Eq. (7) for p<0.5 and |A|<1.
    h. If $|A| \geq 1$, Choose a random variable X_r and use eq (8) to update the position of the search agent.
    i. If $|p| \geq 1$, Choose a random variable X_r and use eq (11) to update the position of the search agent.
    j. Determine each search agent fitness and update the optimal position (X*) for an improved outcome
    k. Optimized estimation of the classifier confidence factor
4) Stage II:
    a. Discounting classifier belief masses
    b. Compute classifier conjunctive consensus and total conflict
    c. Redistribution of total conflict using PCR-6 rule
    d. Evaluate the fused score
5) Model of Determination:

    If ($S_{fused}(G) >= S_{th}$), Genuine

    Else Imposter

4 Database and experimental validation

This section contains a description of the benchmark datasets, experimental evaluation, and results obtained on the proposed fusion model. Also, to check the robustness and stability, the proposed system is compared with the currently used approaches.

4.1 Database

Different benchmark datasets are employed to create multimodal datasets that are used to validate the proposed technique. Specifically, four benchmark datasets: FVC 2006 fingerprint [35], FVC 2002 fingerprint [36], IITD PolyU Iris [37], and VERA finger vein [38] are used to create two chimeric datasets. These chimeric datasets are created by a unique combination of modalities (fingerprint, finger-vein and iris) obtained from four benchmark datasets.

These datasets are often used in the evaluation of biometric systems. Table 2 presents sample images from the selected datasets. The FVC2006 fingerprint dataset consists of fingerprint images from 140 subjects, with each subject having 12 images captured at different orientations. Each image is sized at 96×96 pixels. On the other hand, the FVC 2002 fingerprint database includes multiple images of each finger from different subjects, acquired at various orientations, and these images have dimensions of 328×356 pixels. The images acquired in indoor conditions employing a digital CMOS camera are included in the IITD

Table 2 Example images from benchmark datasets for experimental evaluation

Database	Example Imag
a) Fingerprint	 (i) (ii) (iii) (iv) FVC 2006 fingerprint dataset
b) Iris	 (i) (ii) (iii) (iv) IITD PolyU Iris dataset
c) Finger vein	 (i) (ii) (iii) (iv) VERA finger-vein datas

PolyU iris database. Within this dataset, there are five images available of each subject for both left and right eyes, with each image sized at 320×240 pixels. The VERA finger-vein dataset consists of 110 users and contains 6 images for the index, ring, and middle, fingers of both the right and left hands, encompassing a mix of indoor and outdoor environments. Each image within this database is sized at 665×250 pixels. In the experimental validation section, the proposed multimodal biometric system is utilized for reference and to validate its performance with the aid of two chimeric datasets: Dataset 1 and Dataset 2. Dataset 1 is composed of samples from 50 different subjects, drawing from FVC2006 fingerprint, IITD PolyU Iris, and VERA finger-vein datasets. Initially, 50 unique subjects were allocated from the iris dataset to 50 unique subjects from the finger vein dataset. Subsequently, 50 unique subjects were assigned from the fingerprint dataset to the subjects from the previously combined dataset. This process results in the creation of a virtual multimodal dataset comprising 50 unique subjects. Similar to Database 1, Database 2 is formed by selecting 40 distinct subjects from the IITD PolyU Iris, FVC2002 fingerprint, and VERA finger vein datasets. The subjects included in Database 1 are entirely separate and do not overlap with the subjects chosen for Database 2.

4.2 Experimental validation

The effectiveness and performance of the proposed multi-biometric system are developed and simulated on the MATLAB R2018 platform. The test platform (Intel i5 processor and

16 GB RAM) took 23 s to process dataset 50 identities over 25 algorithm runs. This shows that the system takes 25.01 ms on average, to authenticate each identity. The computational time for 50 identities is 25.01 ms, which is low compared to Particle Swarm Optimization (PSO), Sum Rule, and Backtracking Search Optimization Algorithm (BSA) methods. The experimental results are achieved through the fivefold cross-validation of the proposed fusion model. For this purpose, subject samples are separated into four enrolled samples and one test sample for each subject. The process is repeated five times, to ensure each sample is utilized as the test sample exactly once.The achievement of low computational demands can be primarily attributed to the optimization of classifier scores through the WOA. A chimeric multimodal dataset, which combines VERA finger vein, FVC 2002 fingerprint, FVC 2006 fingerprint, and IITD PolyU iris datasets, is used for evaluating the performance of the multi-biometric fusion model. The evaluation process is categorized into two parts: Quantitative evaluation and Qualitative evaluation. In qualitative evaluation, three biometric modalities fingerprint, iris, and finger-vein are fused to produce a final match score, which is then compared with the individual classifier match scores. Conversely, in quantitative evaluation, two performance metrics, decidability index (DI) and equal error rate (EER) are calculated and compared with other state-of-the-art techniques.

4.2.1 Qualitative evaluation

The qualitative evaluation of the proposed multimodal system is conducted through the utilization of a chimeric dataset. The optimal combination of three classifiers involves two significant stages in the proposed muti-biometric fusion scheme. The first significant stage involves determining the lowest fitness values for each classifier which in turn act as an optimized confidence factor (α_y). These confidence factors of respective classifiers are then converted into belief masses as discussed in Section 3.2. The larger belief masses are obtained for genuine subjects while smaller belief masses are for imposter subjects of each classifier. Further, these belief masses are combined/fused to obtain the fused mass. For this, Fig. 2a and b illustrate the process of resolving conflicts between belief masses from conflicting classifiers. When larger values of belief masses are obtained from divergent classifiers, they tend to result in larger values of fused masses, particularly in the case of genuine subjects. In simpler terms, substantial belief masses from individual classifiers validate a subject authenticity and consequently contribute to an increased overall belief mass.

As depicted in Fig. 2a, consider subject 8, the final fused mass surpasses the individual classifier belief masses due to concurrent agreement among the classifiers and hence illustrates a scenario of belief mass enhancement. Conversely, when all classifiers collectively indicate that the subject is unauthentic, the final fused mass is diminished, indicating belief mass suppression. Individual classifier belief masses, as depicted in Fig. 2b, are considerably smaller than the final fused mass. In situations where classifiers provide conflicting information, Eq. (14) is applied to assess the conflict among classifier masses, which is subsequently redistributed among the individual components based on their contribution to the conflict (Fig. 3).

The two-stage integration enhances the performance of individual classifiers and efficiently combines their belief masses. Consequently, this results in a more pronounced distinction between genuine and imposter score distributions. Figure 4, shows the score distributions of the individual classifiers and the proposed approach for Dataset 1 and Dataset 2. Figure 4a and b depict the score distribution for genuine and impostor subjects

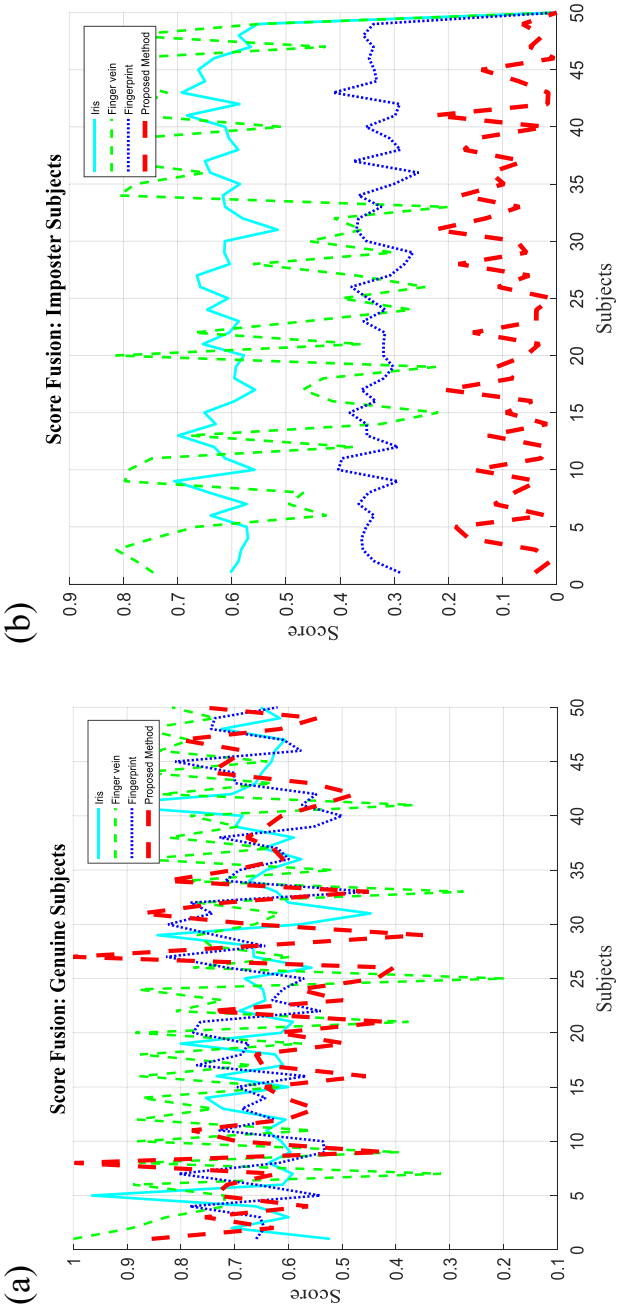

Fig. 2 Demonstration of Adaptive score fusion model vs Unimodal biometrics system for Dataset 1: (**a**) Genuine score fusion (**b**) Imposter score fusion

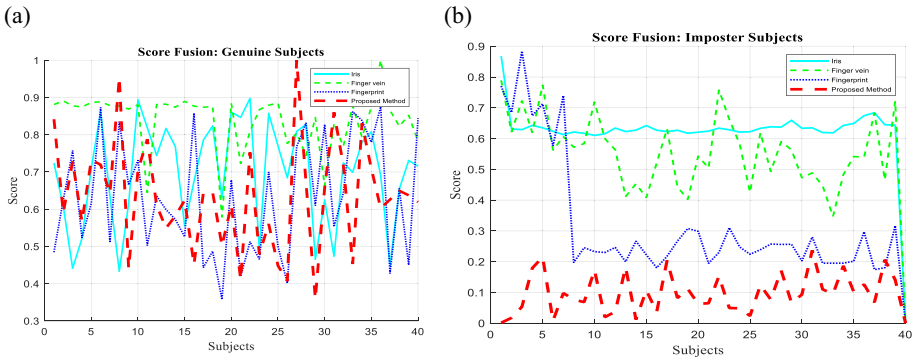

Fig. 3 Demonstration of Adaptive score fusion model vs Unimodal biometrics system for Dataset 2: (**a**) Genuine score fusion (**b**) Imposter score fusion

in the case of the fingerprint classifier, as observed in Dataset 1 and Dataset 2, respectively. Comparably, in Dataset 2, the captured fingerprint images suffer from a lack of

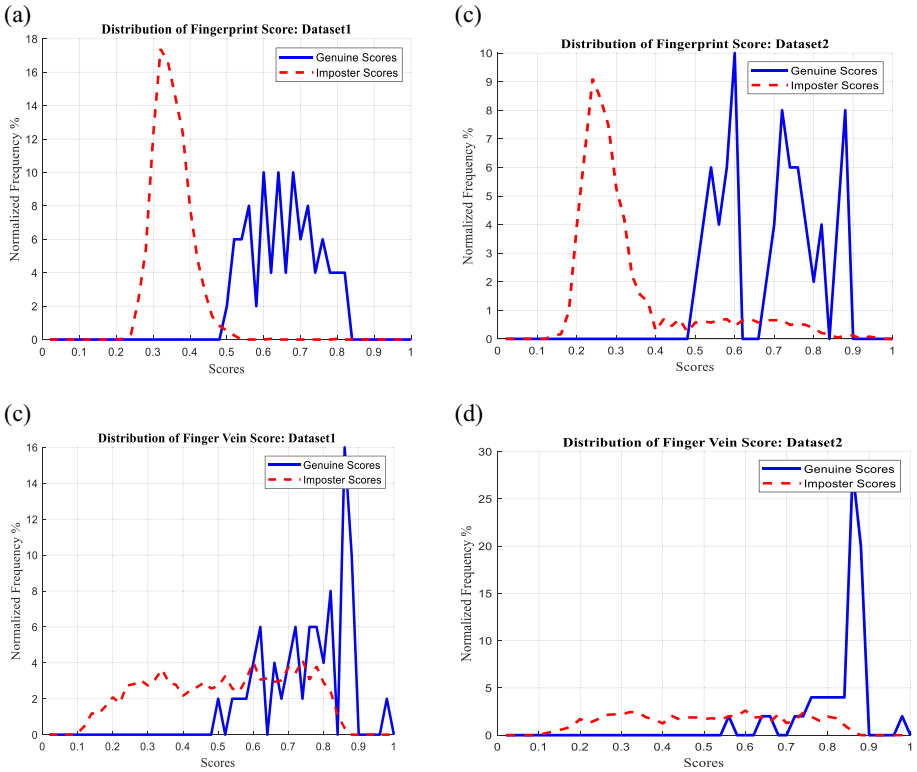

Fig. 4 Distribution of matching scores for the different classifier (**a**) fingerprint (dataset 1) and (**b**) fingerprint (dataset 2) (**c**) Finger vein (Dataset1) (**d**) Finger vein (Dataset 2) (**e**) Iris (Dataset 1) (**f**) Iris (Dataset 2) (**g**) Proposed optimal fusion model (Dataset 1) (**h**) Proposed optimal fusion model (Dataset2)

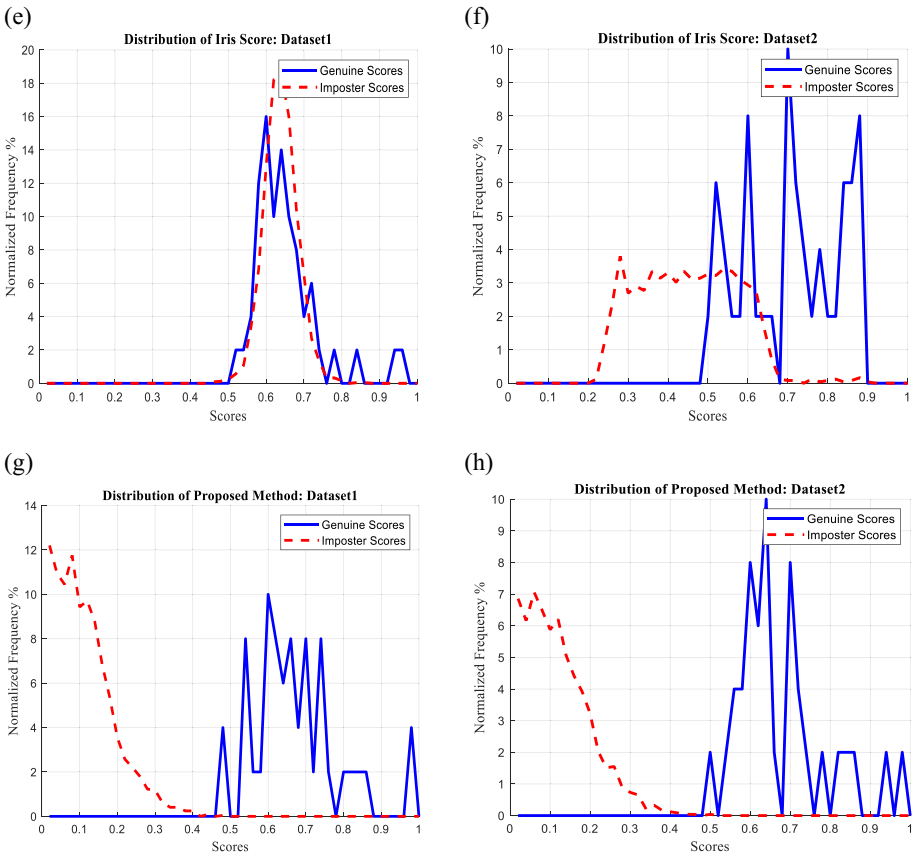

Fig. 4 (continued)

boundary information and are also affected by the surrounding environment. Consequently, this results in overlapping of score distribution for the genuine and impostor classes. Conversely, in Dataset 1, the fingerprint trait exhibits only a minor overlap between genuine and impostor scores, which can be attributed largely to the high-quality fingerprints of the subjects and the presence of distinct boundary information.

Likewise, Fig. 4c and d show the genuine and imposter score distribution for a finger-vein classifier. Even though vein patterns that are located underneath the skin are less susceptible to environmental factors, still, the distribution of imposter/ genuine scores is mainly attributed to the finger vein classifier employed for score estimation. Consequently, the false acceptance rate/ false rejection rate gets impaired and hence decreases the overall accuracy of the biometric authentication system. Genuine class and impostor class score distributions for the iris classifier for datasets 1 and dataset 2 respectively overlap with one another, as illustrated in Fig. 4e and f. Inconsistencies in iris shape, off-angle images, and blur are mostly responsible for this overlap between the score distribution of genuine and imposter classes. An increase in the false acceptance rate is caused by a small gap between the distributions of genuine and imposter class scores, which reduces the accuracy of the iris-based unimodal biometric system. However, score distributions for the genuine

Table 3 Decidability index for the individual classifier

Individual Classifiers	Decidability Index (DI)		
	Dataset 1	Dataset 2	Combined dataset (Dataset 1 and Dataset 2)
Fingerprint	4.814	6.048	5.121
Finger-vein	5.623	5.028	5.425
Iris	4.291	4.158	4.227

Table 4 Decidability index for different score-based fusion models

Score-based fusion approach	Decidability Index (DI)		
	Dataset 1	Dataset2	Combined dataset (Dataset 1 and Dataset 2)
PSO	8.901	12.632	10.420
Sum Rule	4.021	3.670	3.864
BSA	13.164	17.068	14.893
Proposed approach	4.6545	4.6351	4.643

and imposter classes of the proposed method are significantly distinct, which produces an optimal decision boundary for the two classes. Figure 4g and h, illustrate the separation of the score distribution for the proposed biometric system for dataset 1 and dataset 2, respectively. Further, the score distributions are enhanced by quantitative examination of the decidability index and equal error rate which is explained in the next section.

4.2.2 Quantitative evaluation

Biometric systems are quantitatively compared and characterized using equal error rates obtained from receiver operating characteristic (ROC) curves, as well as accuracy measures. High accuracy and low EER are desirable when aiming for the development of a high-performance biometric system. Equal error rate and decidability index are utilized to evaluate the performance of the proposed optimal fusion model. Decidability values for individual classifiers and different fusion models are shown in Tables 3 and 4. Also, the comparison of EER values of the proposed fusion model with various existing score fusion techniques namely: (i) Back-tracking Search Optimization Algorithm (BSA) [14] (ii)Particle Swarm Optimization (PSO) [39] and, (iii) Sum Rule [40] is shown in Table 5. Furthermore, the ROC curves plotted for different score fusion techniques and the proposed fusion model are shown in Fig. 5.

The proposed fusion model gives the lowest EER values, 0.3061 on dataset 1 and 0.2449 on dataset 2, as compared to the other existing fusion approaches, shown in Table 5.

Table 5 Comparison of EER values of score-based fusion models

Database	Proposed approach	BSA [14]	PSO [39]	Sum Rule [40]	Fingerprint	Finger Vein	Iris
Chimeric dataset1	0.3061	2.08	2.13	12.10	14.91	14.16	18.01
Chimeric dataset2	0.2449	0.98	1.29	4.35	10.03	13.20	16.28
Combined dataset (Dataset 1 and Dataset 2)	0.278	1.16	1.75	8.65	12.73	13.72	17.22

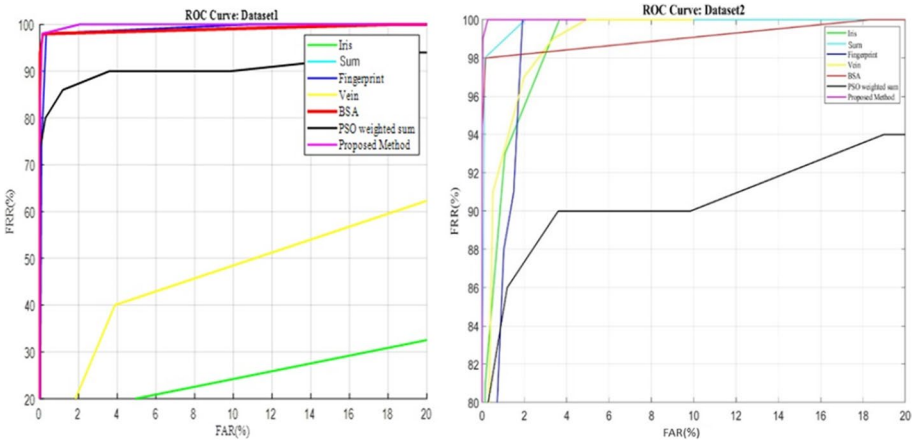

Fig. 5 Comparison of ROC curves of different fusion techniques with proposed fusion model for (**a**) Chimeric dataset1 and (**b**) Chimeric dataset2

Decidability index Decidability is a performance metric that is utilized to measure the separation between genuine and imposter score distributions. It is the difference between the means of genuine and impostor distributions relative to their variances and calculated using Eq. (19).

$$\mathrm{d} = \frac{|\mu_g - \mu_i|}{\sqrt{(\sigma_g^2 - \sigma_i^2)/2}} \tag{19}$$

where σ_i and σ_g represent standard deviations of imposter and genuine scores distribution respectively. μ_i and μ_g represent mean values of imposter and genuine scores distribution respectively.

With a high decidability value, a classifier can effectively distinguish between impostor and genuine subjects. To demonstrate, the low decidability index d of 4.814 for the fingerprint trait associated with Dataset 1 is mainly due to the inadequate subject boundary information. However, the high decidability index of d = 6.048 for dataset 2 is a result of the high quality of fingerprint images. In contrast, a uniform distribution of impostor scores leads to a low decidability index of 5.623 for Dataset 1 and 5.028 for Dataset 2 for

the finger vein classifier. Generally, the biometric systems that entrust simply on finger veins cannot distinguish between genuine and imposter subjects. Similarly, iris classifier has a low decidability index of 4.291 and 4.158 for Dataset 1 and Dataset 2, respectively, primarily attributed to the presence of off-angle images, blurriness, and inconsistencies in iris shape.

Table 4 presents a comparative analysis of the decidability index between the proposed fusion method and three other currently used fusion techniques namely: Particle Swarm Optimization (PSO), Sum Rule, and Backtracking Search Optimization Algorithm (BSA). The proposed fusion method achieved a decidability index of 4.6545 and 4.6351 for Dataset 1 and Dataset 2 respectively, which is better as compared to the Sum Rule approach.

Accuracy The accuracy measures the capacity of a system to correctly authenticate an enrolled user and is calculated using the following equation:

$$\text{Accuracy} = \frac{N_{gen}}{N_{imp} + N_{gen}} \tag{20}$$

where N_{gen} *and* N_{imp} represents the number of successful genuine and impostor attempts respectively.

Time complexity analysis Time complexity is a measure of how the execution time of an algorithm changes as the size of its input increases or the number of subjects increases. The computational efficiency of the proposed method is evaluated through the time complexity analysis of the score fusion process of different methods.

Equal error rate The Receiver Operating Characteristic (ROC) curve shown in Fig. 5, is plotted to determine the equal error rate. The curve is plotted between false rejection rate (FRR) and false acceptance rate (FAR) to compare different fusion techniques. The ROC curve for Dataset 1 in Fig. 5a demonstrates that the proposed technique requires a high FRR value for a given FAR value, resulting in high accuracy. Similarly, the ROC curve for Dataset 2 in Fig. 5b shows that the proposed technique requires a high FRR value for a given FAR value, resulting in high accuracy. The EER values for each examined fusion technique are summarized in Table 5.

The values presented for the proposed score-based fusion approach are average values acquired over 25 runs of the algorithm, which takes into account the random nature of WOA. Similarly, EER values for the PSO-weighted sum fusion approach are established as average values collected over 30 iterations of the fusion process. However, the Sum Rule fusion approach is deterministic hence, results were acquired after just one iteration of the fusion algorithm. As demonstrated in Table 5, the proposed method provides the lowest EER value for Datasets 1 and 2.

The fusion technique Sum Rule has high EER values mainly as a result of its deterministic fusion model and absence of classifier optimization. Though PSO-Weighted-Sum optimizes classifier score but conflicts between classifiers are not resolved, which leads to a high EER value. Similarly, BSA has a higher value EER as compared to the proposed approach due to the conflict between the classifiers. According to the quantitative study, individual classifiers are incapable of effectively discriminating between the genuine and imposter classes. This is mostly caused by the iris feature having an irregular shape and off-angle blur, as well as a lack of border information for finger vein and fingerprint features.

Table 6 Comparison of accuracy of different score-based fusion methods

Database	Proposed approach	Combined dataset	BSA	PSO	Sum Rule
Accuracy(%)	99.33	98.63	97.63	97.13	96.14

Table 7 Comparison of computational time for different fusion methods

Method	Proposed approach	BSA	PSO	Sum Rule
Time (milliseconds)	25.01	28.22	29.02	32.33

Therefore, to overcome these limitations the proposed optimal fusion model combines individual classifiers. Which, in turn, provides a high decidability index and low value of EER.

The key benefit of the proposed fusion model is that it can be utilized in critical applications demanding low computational time as well as ensuring varying level of security. WOA-PCR6-based fusion model performs efficiently because of the performance optimization, which is accomplished by resolving conflict among discordant classifier scores and boosting or suppressing concurrent classifiers (Tables 6 and 7).

5 Conclusion and future directions

Multi-biometric authentication systems have been extensively used due to their merit over unimodal biometric systems. Biometric modalities can be fused at feature, score, and decision level for the realization of the system however, score level fusion suffers due to the fusion of scores from different traits which are affected by dynamic environment. For this, in this manuscript, an optimal score-level fusion model has been proposed based on DSmT and WOA. The three complementary features namely fingerprint, iris, and finger-vein are considered for the realization of a multi-biometric system. The major contribution of this research work consists in evaluating the globally fit value of the confidence factor with the highly competitive nature inspired meta-heuristic algorithm WOA. Then, these factors transform the match score of three classifiers, respectively into belief mass. Individual classifier score is discounted using the Whale Optimization Algorithm and further fused using the PCR-6 Model to achieve adaptiveness to the dynamic environment. Concurrent classifier scores are booted and discordant classifier scores are suppressed leading high decidability index and hence performance optimization.

The proposed approach is evaluated on the chimeric dataset constituted from the benchmark dataset: VERA finger vein, FVC 2002, FVC 2006 fingerprint, and IITD PolyU iris of finger-vein, fingerprint, and iris respectively. The experimental result demonstrates qualitative and quantitative analysis that reveals the proposed approach surpasses other state-of-the-art fusion techniques for multimodal biometric systems. The proposed technique attains an average, accuracy of 99.33% & equal error rate (EER) of 0.27% in contrast to the current state-of-the-art system.

In the future, we will take into account the dynamic integration of uncertain information from different perspectives to provide a new paradigm for fusing scores of multiple classifiers or features of biometric traits. Also, a more efficient and effective method of integrating other factors such as the quality of biometric images, and reliability of biometric traits to improve the adaptive nature of fusion-based multimodal biometric systems.

Data availability All the details about data availability are mentioned within this manuscript. The datasets used are FVC 2006 fingerprint [28], FVC 2002 fingerprint [29], IITD PolyU Iris [30], and VERA finger vein [31].

Abstract
Lung cancer is the most fatal disease in recent times. Early detection of the same is very crucial and challenging task. Therefore, proper diagnostic and treatment strategies should be employed for the automatic detection of nodules from Computed Tomography (CT) images. In this direction this paper introduces a novel UDCT, a new and effective framework for detecting and classifying lung cancer based on CT images. The proposed framework exploits Modified U-Net architecture that utilizes the traditional U-Net architecture for multi-scale feature extraction with the DARTS (Differentiable Architecture Search) which utilizes the concept of continuous relaxation of the architecture representation with efficient gradient descent search for efficient classification of lung cancer. In addition to this, the proposed framework, incorporates Multilevel Otsu thresholding for image preprocessing and to further segment the lung nodule from the CT scan images. Furthermore, the modified U-Net is capable to detect and classify lung nodule effectively and efficiently. To evaluate the performance of the proposed UDCT framework, extensive experiments are conducted on LIDC-IDRI and IQ-OTH/NCCD CT image datasets that provided state-of-the-art results. The proposed UDCT framework provided an accuracy of 95.01% on LIDC-IDRI dataset and 96.82% on IQ-OTH/NCCD dataset. An ablation study is also conducted that validated the efficiency and efficacy of the proposed UDCT framework.

AUC & ROC	Area Under Curve & Receiver Operating Characteristics

Variables

N & A	Normal & Abnormal classes
X & L	Threshold value & Grayscale level
p	One pixel value
Pq_a^o	Distributional probability, where 'o' is component value and $'q_a^o\ '$ is histogram.
$H_0^o(X)$ and $H_1^o(X)$	Distributional Probabilities of classes 'N' & 'A' respectively.
μ & σ	Sum and Variance of the classes.
$Z^{(u,v)}$	Output of concatenation approach, where $v-th$ is the convolution in $u-th$ layer module.
M(•), D(•), S(•) and [•]	Cascaded operation, Down-sampling function, Up-sampling function, and Channel concatenation operation respectively.
$b^{(g,h)}$	Collection of operations including convolution and max pooling
$\gamma^{(g,h)}$	Vector Quantity

1 Introduction

Lung cancer, a highly lethal disease, is responsible for approximately one out of every five cancer-related deaths. It is characterized by the presence of solid masses of tissue known as pulmonary tumor that develop in and around the lungs [1–3]. Lung cancer is a major cause of mortality for males, females, and transgender individuals worldwide, claiming around five million lives annually. The WHO (World Health Organization) estimates indicate that lung cancer causes millions of deaths each year. Unfortunately, more than 80% of lung cancer patients face a poor prognosis due to the advanced stage of the disease, which often renders surgery ineffective at the time of diagnosis [1, 4].

Detecting lung cancer early is crucial for effective treatment and saving lives since symptoms typically appear only when the disease has progressed significantly [5, 6]. Manual interpretation of numerous medical images used for lung cancer diagnosis can be time-consuming, labour-intensive, and prone to inaccuracies. Different methods such as X-rays, CT scans, MRI, PET, and breath analysis can be employed for lung cancer treatment [7, 8]. MRI and PET have limitations in identifying and staging lung cancer, while CXR (Chest radiography) and CT imaging techniques are prone to radiation exposure. However, CT imaging has become the preferred method for diagnosing lung cancer due to its ability to provide detailed information about the location and size of nodules [9]. Low-dose CT screening has been effective in detecting early-stage cancer tumours. In the past, image-processing

techniques have been used for diagnosing lung cancer, and machine-learning algorithms have played a role in analyzing CT scans and classifying lung nodules [9]. Feature extraction is a critical step in implementing machine learning, but existing methods often rely on manually created features, leading to lower accuracy. This limitation hinders computer-aided detection (CAD) systems from achieving optimal performance [10]. To address this issue, researchers have proposed the use of Artificial Intelligence, particularly deep learning. Deep learning algorithms can automatically learn important features from observed data during training, eliminating the need for manual feature creation and enabling end-to-end detection in CAD systems [11]. Convolutional Neural Networks (CNN) have shown superior performance compared to other deep learning networks in this context [12, 13].

Deep learning methods have shown promising results in classification and segmentation. Deep learning approaches, however, still face numerous challenges in the identification of lung cancer. First, the robustness of the prediction model is a challenging task as these models rely on large sets of annotated medical pictures that are contributed by seasoned radiologists, to meet their training requirements. Furthermore, great interpretability is necessary for the clinical application of deep learning; however, the learnt features cannot be satisfactorily explained by existing deep learning algorithms. Additionally, the existing approaches are not very applicable in clinical practice, mainly due to the inexperience of non-medical investigators in choosing more pertinent clinical outcomes. Therefore, the primary objectives of this study are to improve performance, reduce diagnostic time, and identify the location and characteristics of lung nodules. The goal is to develop a deep learning architecture specifically for early diagnosis and classification of lung cancer using deep learning techniques. In this direction, this paper presents a novel UDCT structure that exploits the concept of DARTS and U-Net with multi-level Otsu thresholding for easy detection of lung nodules. A basic block diagram representation is depicted in Fig. 1. Further, the proposed UDCT can effectively classify lung cancer into benign or malignant nodules.

The main Contributions of this work are:

i. This paper presents a lung cancer detection and classification framework namely, UDCT that efficiently detects and classifies lung cancer from CT images.
ii. The proposed framework exploits Multi-level Otsu thresholding on pre-processed images to efficiently extract features from CT images. Further, the extracted features are utilized by the U-Net architecture for the segmentation of CT images.
iii. Further, the proposed U-Net architecture is fused with DARTS (Differentiable Architecture Search) that uses a simplified gradient descent search in conjunction with the concept of continuous relaxation to describe architecture for efficient classification of lung cancer.
iv. To confirm the efficacy of the suggested UDCT framework, extensive experiments are conducted on LIDC-IDRI and IQ-OTH/NCCD CT image datasets that provided state-of-the-art results.
v. Also, an ablation study is carried out to prove the efficiency and efficacy of the suggested framework.

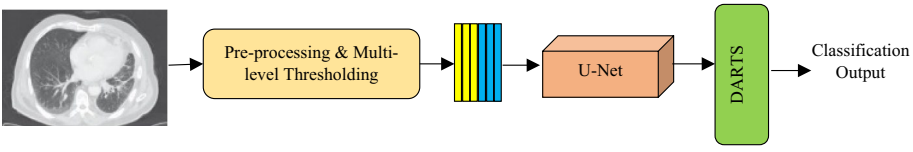

Fig. 1 Block Diagram for the proposed UDCT Framework

The organization of the rest of the paper is as follows: Section 2 presents the different state-of-the-art techniques for lung cancer detection, Section 3 presents the proposed methodology, Section 4 discusses the results obtained on the proposed UDCT framework. Finally, Section 5 concludes the work.

2 Related work

In [1], a thorough analysis was conducted on various CNN-based techniques and algorithms to analyse pulmonary nodules in medical images. The focus was on examining the methodologies employed, the datasets used for validation, and the detection outcomes of recently developed CNN-based systems for nodule classification. Three different architectures, each consisting of varying numbers of layers, were studied, leading to a fully connected layer and a SoftMax classifier. The LIDC-IDRI dataset was utilized for training and testing, as it yielded the best results in terms of accuracy and precision when combined with other architectures [8]. A state-of-the-art performance was achieved for both lung nodule identification and malignancy classification tasks using a cascade of 3D CNNs in a CADe & CADx system. However, if the CADe model fails to detect a malignant lesion, the subsequent CADx model is unable to classify that scan as malignant, resulting in a significant source of false negatives in the system [10].

To find pulmonary nodules in the lung's current CT pictures, a convolution neural network that has been genetically optimised is used [9] and also the detection rate and classification accuracy of pulmonary nodules can be effectively increased with the use of wavelet denoising on lung CT images. [13] You Only Look Once, Version 3 (YOLOv3), Single-Shot Detector (SSD), and Faster Region-Convolutional Neural Network (Faster-RCNN) are components of an automated deep learning system that is utilized for detection and Visual Geometry Group (VGG-16), Resnet 101, and Mobilenet for classifying lung nodules in CT scans. In this study, False Positive Rate (FPR) is reduced, and the accuracy is enhanced for classification and detection architectures. A hybrid approach that further aids in reducing the computational complexity of the classification is produced by combining Support Vector Machine with Feed-Forward Back Propagation Neural Network (FFBPNN) [14]. By using a hybrid classification algorithm, the classification accuracy is enhanced to 98.08%. To perhaps increase classification accuracy in the future, Deep Neural Network are used in contrast to FFBPNN. To identifying and categorizing lung cancer, a comprehensive framework is presented that includes a generative model designed to transform an unbalanced dataset which is smaller in size into a balanced one which is larger in size and ResNet50 which classifying CXR pictures into benign and malignant during the online phase by using a large balanced dataset [11]. In this, authors want to modify their system in the future to incorporate generative adversarial networks and other generative models. [30] Presents an optimization-driven technique for lung cancer classification. Lung cancer is classified using a Hierarchical Attention Network (HAN), Firefly Competitive Swarm Optimisation (FCSO), which combines the Firefly algorithm (FA) and Competitive Swarm Optimisation (CSO). The suggested FCSO-based HAN performs well, achieving a high accuracy rate of 91.3%, sensitivity of 88%, and specificity of 89.1%. The author addresses the convergence problems and computational overhead related to the multilevel thresholding process by utilizing the Levy flight and Gravitational Search Algorithm (LCGSA) based on Chaos theory. This technique is used to improve COVID-19 chest CT scan images

segmentation [31]. The author may also look into the future use of LCGSA in deep learning applications, such as CNNs, U-Nets, and LSTMs.

The authors of this paper addressed the scalability issue in architecture search by utilizing DARTS, a differential approach. This strategy depends on continuous or smooth relaxation, in contrast to traditional approaches that use evolutionary algorithms or reinforcement learning inside a discrete and non-smooth search space. The search was performed on multiple datasets including WikiText-2, CIFAR-10, Penn Treebank, and ImageNet. However, a limitation of this work is the potential discrepancies between the continuous architecture encoding and the resulting discrete architecture, which can impact the effectiveness of the current approach [15].

In another study, blood samples were taken from healthy individuals and those who had been diagnosed with breast cancer were subjected to metabolomics analysis using NMR spectroscopy and direct analysis in real time (DART)-MS. The new method introduced in this research improves the representation of disease classifications by allowing the expression of disease on a continuous scale rather than a binary scale, resulting in more accurate disease detection. However, DART-MS did not capture as much breast cancer-related variation [16]. In the same study, U-DARTS was employed to identify and categorize breast lesions in two datasets, achieving testing and validation accuracies of 91% and 98%, respectively. However, due to incomplete data, the study encountered low accuracy in one of the datasets [17].

Methods discussed above are mainly utilized for detecting and classifying lung cancer that may have certain limitations in a variety of areas, including accuracy, sensitivity, specificity, dataset availability, preprocessing techniques, and sometimes the classification models used. We present a novel UDCT framework with Multi-Level Otsu thresholding to address these issues and to improve image quality during preprocessing. Furthermore, to obtain higher accuracy, we combine U-NET and DARTS to improve lung cancer classification. Furthermore, different methods for the lung cancer detection are presented in Table 1.

3 Proposed methodology

This section describes the proposed UDCT framework (as depicted in Fig. 2) for the detection and classification of lung diseases. The proposed framework utilized a modified U-NET model which exploits DARTS architecture for efficient classification of lung cancer diseases. Initially, to improve the quality of the input images, an image enhancement technique is applied through pre-processing. The pre-processing step involves multilevel Otsu for better results. After pre-processing, the image is segmented using U-NET, and quantitative features are extracted. To enhance the classification accuracy, we fuse DARTS (Differentiable Architecture Search) with the U-NET model. The overall goal of this proposed work is to achieve improved results in the classification of lung diseases, particularly lung cancer.

3.1 Problem statement

In order to differentiate between benign and malignant nodules, computer-aided detection techniques for lung cancer require an examination of the visual properties of lung nodules on CT scans. Developing an automated detection method is becoming more and more crucial for early detection of lung cancer. It is incredibly challenging to build such a system using traditional approaches.

Table 1 Review based on some existing method for lung cancer detection

References	Approach	Evaluated Parameters
[1]	CNN-based techniques	–

Deep-learning-based architectures have been extensively researched and developed in the last few years with the goal of being used to the healthcare industry. Thus, the goal of this work was to develop a deep learning-based, reliable, and accurate framework for lung cancer detection and classification. Furthermore, the pseudocode for the proposed methodology is presented in Algorithm 1.

Algorithm 1 Pseudocode for the proposed UDCT Framework for Lung Cancer detection and classification for CT Images.

Input: $I_{CT}(xxy)$; Thermal image with x=no. of rows and y= no. of column

Output: I_{UDART}; Output Image

Procedure UDCT

Initialize the image $I_{CT}(xxy)$

Apply Otsu multilevel thresholding (OMLT) on I_{CT} to separate object pixels from background pixels.

$I_{CT-OMLT} \xleftarrow[OMLT]{} I_{CT}$

For Normal (N) & Abnormal (A) class calculate thresholding value X

$N \leftarrow p$ if $0 \leq p < X$,

$A \leftarrow p$ if $X \leq p < L\text{-}1$

Where p is one of pixels of the grayscale image that can be represented in L grayscale levels

Apply UNet segmentation on I_{CT} image.

while $(x < UNet_{\text{iterations}})$ do

for each patch do

Update the image patches obtained through segmentation using eq (14)

end for

end while

Update I_{CT}

for i = 1 to n (n= no. of column in image)

$U(I_{CT}) = U(I_{CT-OMLT})$

end for

Use DARTS for classification of abnormal and normal images.

return archive

end procedure

3.2 Multilevel Thresholding using Otsu method

Image thresholding is a method used to convert an image, whether it is in full-color or grayscale, into a binary image where pixels are either classified as foreground or background. Its main purpose is to separate object pixels from background pixels. The determination of an appropriate threshold value plays a critical role in the segmentation process. Here, threshold value X is calculated as:

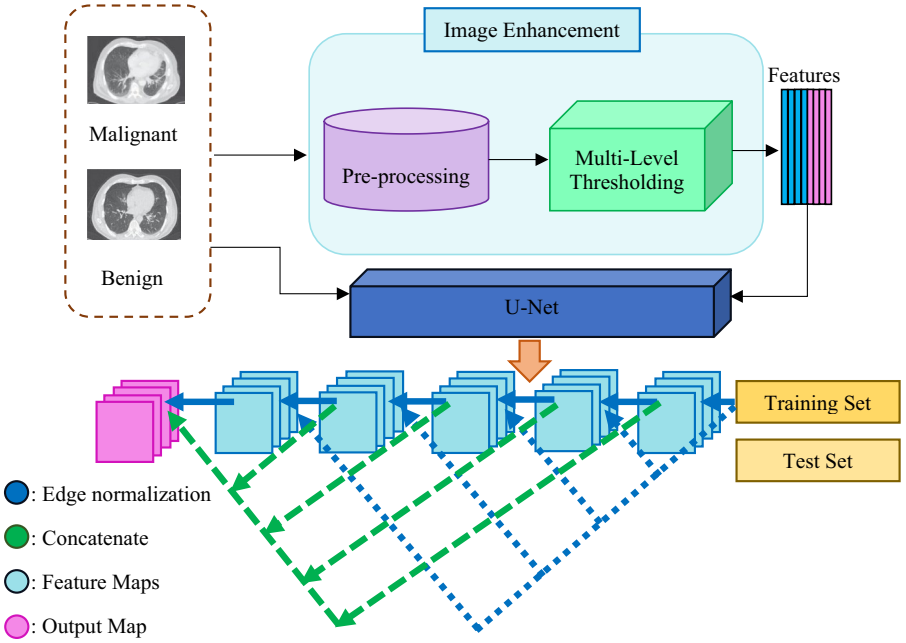

Fig. 2 Proposed UDCT Framework Methodology

$$\mathrm{N} \leftarrow \mathrm{p} \text{ if } 0 \leq \mathrm{p} < \mathrm{X}, \tag{1}$$

$$\mathrm{A} \leftarrow \mathrm{p} \text{ if } \mathrm{X} \leq \mathrm{p} < \mathrm{L} - 1$$

Where, N and A are the Normal & Abnormal classes when X is the threshold and p is one of pixels of the grayscale image that can be represented in L grayscale levels $L = \{0, 1, 2, \ldots, L-1\}$.

Equation (1) relate to the bi-level threshold and expanded to many sets like:

$$\mathrm{N} \leftarrow \mathrm{p} \text{ if } 0 \leq \mathrm{p} < X_1, \tag{2}$$

$$\mathrm{A} \leftarrow \mathrm{p} \text{ if } X_1 \leq \mathrm{p} < X_2,$$

$$N_n \leftarrow \mathrm{p} \text{ if } X_n \leq \mathrm{p} < X_{n+1},$$

$$A_m \leftarrow \mathrm{p} \text{ if } X_m \leq \mathrm{p} < \mathrm{L} - 1$$

In eq. 2, $\{X_1, X_2, \ldots.., X_n, X_{n+1}\}$ are different threshold levels. To determine the ideal threshold value, Otsu proposes various objective functions that must be maximised. For figuring out threshold values, Otsu is a well-known method. The Otsu method, which uses the greatest variance values of several classes as the only segmentation criterion in images, is preferred because of its ease of use and great efficacy. Applying the L designated intensity level for the grayscale image, the intensity value of image computation can be written as [18].

$$\mathrm{P}q_a^o = \frac{q_a^o}{P_{tot}}, \tag{3}$$

$$q_a^o \geq 0, \tag{4}$$

$$\sum_{a=0}^{P_{tot}} Pq_a^o = 1,$$

$$\mathrm{o} = \{1, \text{if Grayscale Image},$$

o = component, the value specified from I.

where,

$\mathrm{P}q_a^o$ = Distributional probability.

$\mathrm{P}_{\mathrm{tot}}$ = the total number of pixels in the image.

q_a^o =histogram (the number of pixels correlates to the intensity in o).

Now, Probability distributions for two classes (N and A) segmentation are given as [18]:

$$H_0^o(\mathrm{X}) = \sum_{a=0}^{X} Pq_a^o, H_1^o(\mathrm{X}) = \sum_{a=X+1}^{L} Pq_a^o \tag{5}$$

The mean and the variance is being calculated as representation mathematically in equation '6' and '9':

$$\mu_0^o = \sum_{a=0}^{X} \frac{aPq_a^o}{H_0^o(X)} \text{ and } \mu_1^o = \sum_{a=X+1}^{L} \frac{aPq_a^o}{H_1^o(X)} \tag{6}$$

$$\text{and } \mu_{tot}^o = H_0^o \mu_0^o + H_1^o \mu_1^o, \tag{7}$$

$$H_0^o + H_1^o = 1 \tag{8}$$

The total variation between the classes is computed after the calculation of the above values as,

$$\sigma^{2^o} = \sigma_1^o + \sigma_2^o \tag{9}$$

In the mathematical sense, number two does not represent exponent; it is a component of the Otsu variant operator in eq. (8). In the above, σ_1^o and σ_2^o are the variants of N and A which are obtained as:

$$\sigma_1^o = H_0^o\left(\mu_0^o + \mu_{tot}^o\right)^2 \& \sigma_2^o = H_1^o\left(\mu_1^o + \mu_{tot}^o\right)^2 \tag{10}$$

In (10), the value of $'\mu_{tot}^o{}'$ is find with the help of eq. (8).

For multilevel thresholding, the objective function can be defined by (9) because by the increase of number of thresholds there will be an exponential growth in processing time.

$$\theta(X) = \max\left(\left(\sigma^{2^o}(X)\right), 0 \leq \mathrm{X} \leq \mathrm{L} - 1\right. \tag{11}$$

Where, $\mathrm{X} = \{X_1, X_2, X_3 \ldots\ldots X_{k-1}\}$ there are multiple thresholds in the vector X. So, for various number of threshold values Variance, Probability Distribution and the Average values can be calculated by eqs. (11), (12) and (13) respectively.

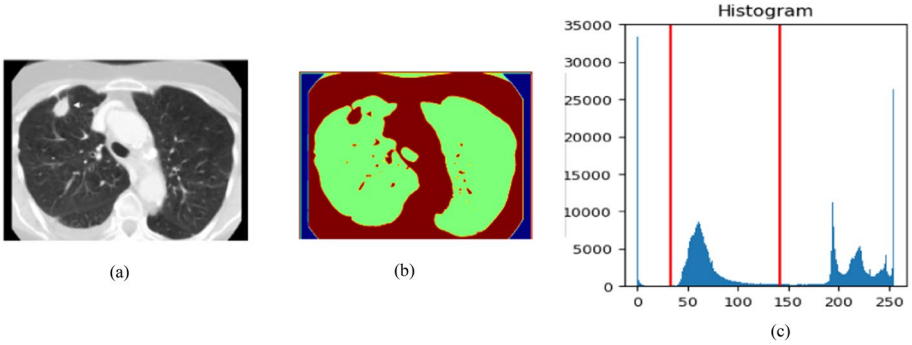

Fig. 3 Multilevel thresholding by using Otsu method, (**a**) Original lung image, (**b**) Result after Otsu thresholding, and (**c**) Equalized Histogram

$$\sigma^{2^o} = \sum_{c=0}^{k} H_c^o \left(\mu_c^o - \mu_{tot}^o\right) \tag{12}$$

$$H_0^o(X) = \sum_{c=1}^{X_1} Pq_c^o, H_{k-1}^o(X) = \sum_{c=X_{K+1}}^{L} Pq_c^o \tag{13}$$

$$\mu_0^o = \sum_{c=1}^{X_1} \frac{cPq_c^o}{H_0^o(X_1)}, H_{k-1}^o = \sum_{c=X_{k+1}}^{L} \frac{cPq_c^o}{H_1^o(X_k)} \tag{14}$$

Where, 'c' represents a class in the above equations.

Furthermore, the output obtained after multilevel thresholding on LIDC dataset is presented in Fig. 3. Multilevel thresholding is a technique that partitions an image containing various shades of gray into multiple distinct regions. This approach involves choosing multiple thresholds to separate the image into different brightness zones, representing various backgrounds and objects.

3.3 Image segmentation using U-net

The objective of segmentation is to separate individual elements from an entire image. Segmentation is a procedure that transforms original images into distinct regions or components. The accuracy of the resulting segmentation is used as a measure of how well the process was performed. The precision of the segmentation increases when the objects are recognized more accurately. In the field of biomedical imaging, the U-Net architecture is commonly utilized for image segmentation tasks. This architecture consists of two parts: a contracting side and an expanding side, which are symmetrical. The contracting side includes components such as dropout, pooling, convolutional, and Rectified Linear Unit (ReLU) layer. Each down sampling step in the process doubles the number of feature channels [19].

i. Down-sampling is performed in contracting path with the shallower, lower, and coarser grained characteristics are converted into the deeper, semantic, and finer grained features by this connection [20].
ii. The connection between contracting and expanding sides called skip connection enable the network to take in the required features from the relevant layer. Skip con-

nection bridges the shallower, lower, and coarse-grained features in the contracting path and the deeper, semantic, and fine-grained features in the expanding path.

iii. Up-sampling is performed in expanding path which transforms back Deeper, semantic, and fine-grained characteristics into shallower, lower, and coarse-grained features. At every section on the expanding side, the number of feature channels is cut in half [20].

Using the channel concatenation fusion approach, let $Z^{u,v}$ represent the $v-th$ convolution in the $u-th$ layer module. The output $z^{u,v}$ of $Z^{u,v}$can be calculated according to the following eq. [20]:

$$z^{u,v} = \begin{cases} \mathrm{M}\left(\mathrm{D}\left(z^{u-1,v}\right)\right) & \text{for u} > 0, \text{v} = 0 \\ \mathrm{M}\left(\left[\left[z^{u,l}\right]_{l=0}^{v-1}, \mathrm{S}\left(z^{u+1,v-1}\right)\right]\right) & \text{for u} = 0, \text{v} > 0 \\ \mathrm{M}\left(\left[\left[z^{u,l}\right]_{l=0}^{v-1}, \mathrm{S}\left(z^{u+1,v-1}\right), \mathrm{D}\left(z^{u-1,v}\right)\right]\right) & \text{for u} > 0, \text{v} > 0 \end{cases} \tag{15}$$

In the above equation, M(•) is a cascaded operation including convolution, ReLU activation function and batch normalization (BN), D(•) is a down- sampling function, S(•) is an up-sampling function, and [•] is the channel concatenation operation [20].

After multi-level thresholding, we have extracted following qualitative features with the following value: *Mean* = 1.925, *Standard Deviation* = 59.283, *Dissimilarity* = 0.6221, *Energy* = 24.171 *and Entropy* = 8.177 for LIDC-IDRI dataset. Furthermore, for IQ-OTH/NCCD dataset, *Mean* = 0.916, *Standard Deviation* = 50.302, *Dissimilarity* = 01.462, *Energy* = 23.059 *and Entropy* = 8.257 The different features shown with the help of Fig. 4. Along with the above network we explained DARTS (Differentiable Architecture Search) for searching the efficient architecture. Darts has had a significant impact on neural architecture search. The representation of DARTS is presented in Fig. 5. Earlier techniques relied on reinforcement learning and needed plenty of processing power. It required 3150 GPU days for evolution or 2000 Graphics Processing Unit (GPU) days for reinforcement learning [15].

We relax the search space to be continuous so that the architecture can be optimised via gradient descent with regard to the performance of the validation set. This allows us to search over a continuous universe of candidate architectures rather than a discrete set. This search is based on bilevel optimization and also relevant to recurrent structures as well as convolutional architectures. In the search space, a directed acyclic graph depicts the computation process for the proposed architecture as depicted in Fig. 5. A Directed acyclic graph with F nodes ($f_0, f_1, f_2 \ldots\ldots f_F$) arranged in an orderly manner.

In this work, we take B be a collection of operations which includes convolution and max pooling, where each operation denotes a function to be applied on $r(t)$ as $b(.)$. Here all possible operations are given by $b^{(g,h)}$ [15]:

$$b^{(g,h)}(r) = \sum\nolimits_{b \epsilon B} \frac{\exp\left(y_b^{(g,h)}\right)}{\sum_{b' \epsilon B} \exp\left(\gamma_{b'}^{(g,h)}\right)} r(t) \tag{16}$$

For a pair of nodes (g, h) a vector $\gamma^{(g,h)}$ of dimension $|B|$ is used as a parameter for the operation of mixing weights .After that, learning a set of continuous variables is all that

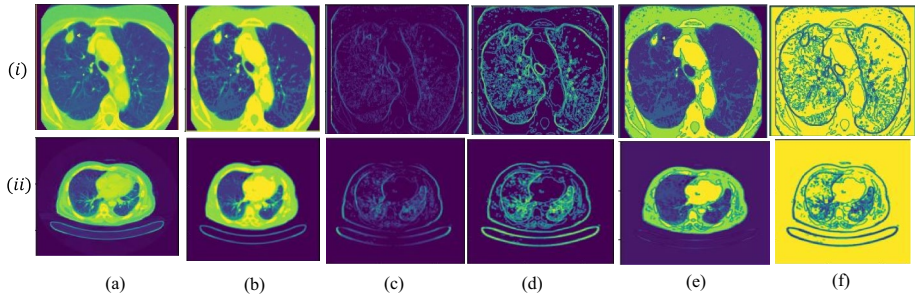

Fig. 4 Qualitative features extracted from the proposed U-NET approach for (*i*) LIDC-IDRI dataset, (*ii*) IQ-OTH/NCCD dataset. (**a**) Original source image from dataset, (**b**) mean value, (**c**) Dissimilarity, (**d**) Entropy, (**e**) Standard Deviation, and (**f**) Energy

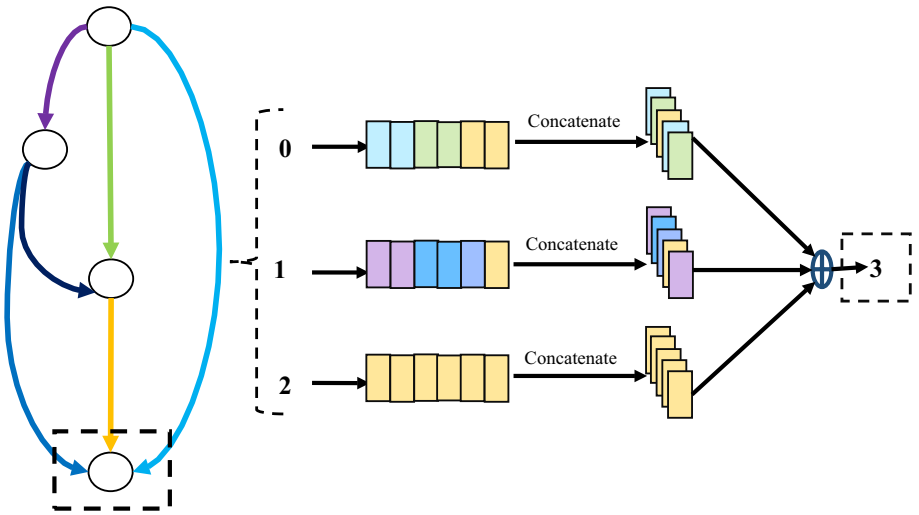

Fig. 5 Representation of DARTS

remains of the architectural search task $\gamma = (\gamma^{(g,h)})$ [17]. Based on each predecessor, each intermediate node is calculated by 'r(t)' mentioned in eq. 17 as follows:

$$\mathrm{r(t)} = \sum_{g<h} b^{(g,h)}(r(t)) \tag{17}$$

In this work, we have fused DARTS with UNET for getting better lung cancer classification results.

3.4 Dataset used

To assess the effectiveness of the proposed UDCT framework for the categorization of benign and malignant pulmonary nodules, the LIDC-IDRI public dataset of thoracic CT scans and IQ-OTH/NCCD dataset are used.

LIDC-IDRI stands for Lung Image Database Consortium and Image Database Resource Initiative. On a CT scan, lung nodules can be seen in several slices. Each case includes a clinical thoracic CT scan as well as the reports of four expert thoracic radiologists in an XML file [13]. Additionally, the XML files include semantic diagnostic elements that were noted by four qualified thoracic radiologists. The Lung Imaging Database Consortium (LIDC) initiative's goal is to assist a group of institutions in creating a database of spiral CT lung pictures and developing recommendations for a resource for spiral CT lung images. There are 1568 thoracic Computed Tomography (CT) scans with nodules in the dataset out of which 650 were malignant cases and 918 were benign cases [19]. There are three different types of nodules: ("nodule > or =3 mm," "nodule <3 mm," and "non-nodule > or =3 mm") [21].

The IQ-OTH/NCCD dataset, which stands for Iraq-Oncology Teaching Hospital/ National Center for Cancer Diseases, includes CT scans of both healthy persons and those with various stages of lung cancer diagnosis. It has 1190 images total, each of which shows slices from 110 CT scans. Three classes—normal, benign, and malignant—are used to group these situations. 40 cases are categorized as malignant, 15 as benign, and 55 as normal. DICOM is the original format used to store CT scan data.

4 Computational complexity

The computational complexity of the proposed UDCT framework algorithm is described in this subsection. The following describes the space and time complexity:

- **Time Complexity**

1. The implementation of UDCT algorithm desires $O(I_{CT}(x \times y))$ time where x and y represent the number of rows columns respectively in each image.
2. The OMLT calculation of each pixel requires

$$O\left(I_{CT}(OMLT \times x \times y)\right)$$

time.

3. The UNet calculations require

$$O\left(I_{CT}\left(U_{\text{iter}} \times OMLT \times x \times y\right)\right)$$

time where U_{iter} is the maximum number of iterations to simulate segmentation.

4. The algorithm requires $O(I_{UDART}) = O(I_{CT-DART}(O(I_{CT}(U_{\text{iter}} \times OMLT \times x \times y)))$ $I_{CT-DART}(O(I_{CT}(U_{\text{iter}} \times OMLT \times x \times y)))$ time to classify abnormal and abnormal type of cancer.

- **Space Complexity**

The UDCT algorithm's space complexity is determined at the initial stage, which at any given time requires space. Due to this, the UDCT algorithm's overall space complexity is $O(I_{CT}(x \times y))$.

5 Results and discussions

This section discusses the implementation details, and evaluation parameters with the experimental results obtained on LIDC-IDRI and IQ-OTH/NCCD CT image datasets.

5.1 Implementation details

We train our model from beginning to end in order to identify and extract image features from the lung images. The patch size is set to 9 and the batch size is set as 32. The input images are downsized to 124×124 resolution. A learning rate 0.0001 is used to train the entire model on the dataset. For the setup, there will be 100 epochs. Accuracy and loss curves are plotted to evaluate the effectiveness of the proposed model. Further, ThinkPad laptop that satisfies certain requirements is used for the experiment. It has an Intel Core i7 (11th generation) processor with integrated AMD Radeon Graphics, clock rates ranging from 1.90 GHz to 4.40 GHz, and 16 GB of RAM. The study's experiments were conducted on Windows 11 with Jupyter Notebook, Python 3.12.3, and the backend libraries for TensorFlow and Keras.

5.2 Evaluation parameters

Accuracy, Loss, Precision, Recall, Dice Coefficient, Specificity and F1-Score are the several parameters that are used to evaluate the proposed model's performance.

i) **Accuracy**: It is defined by the proportion of accurate predictions to all predictions [22]. Represented by

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{18}$$

ii) **Recall**: Ratio of the number of Positive samples that were correctly identified as Positive to all Positive samples. More positive samples are detected when the value of recall increases [22].

$$Recall = \frac{TP}{TP + FN} \tag{19}$$

iii) **Precision**: It shows the percentage of samples that were actually positive and those that were projected to be positive out of all the samples [22].

$$Precision = \frac{TP}{TP + FP} \tag{20}$$

iv) **Dice Coefficient**: It is calculated by dividing the combined pixels in the two images by the area of overlap, multiplied by 2.

$$DSC = \frac{2 * |D \cap E|}{|D| + |E|} \tag{21}$$

Where D is the expected set of pixels and E is the actual set of pixels.

xxii) Specificity: The ratio of real negative samples—both actual and predicted—to the total number of truly negative samples is used to compute specificity [22].

$$\text{Specificity} = \frac{TN}{TN + FP} \tag{22}$$

vi) F1-Score: The "F1-score" accounts for both false positives (FPs) and false negatives (FNs), striking a compromise between "precision" and "recall". Since each variable undermines the other, it penalizes extreme levels of "precision" and "recall" [22].

$$\text{F1} = \frac{2 * P * R}{P + R} \tag{23}$$

Where P and R represents Precision and Recall Respectively.

In the eqs. (18) to (22), *TP*, *TN*, *FN*, *and FP* represents true positive, true negative, false negative, and false positive, respectively.

5.3 Performance analysis on LIDC-IDRI and IQ-OTH/NCCD CT image datasets

The experimental findings for the proposed U-DARTS model are detailed in this section. The LIDC-IDRI dataset is used for the experiment. The sample contains a wide variety of lung nodules, which are separated into two groups: Benign (Unharmful) and Malignant (harmful). The experiment is done by using 80% training set and 20% testing set. Training and validation accuracy, as well as training and validation loss, are used to assess the proposed framework using the LIDC-IDRI dataset. Figures 6 and 7 shows training-validation loss and training-validation accuracy respectively for LIDC-IDRI and IQ-OTH/NCCD datasets. From these accuracy and loss curves it is evident that the as the number of epochs increases the accuracy increases whereas the loss decreases. Furthermore, the training and validation accuracy obtained for the proposed UDCT framework on LIDC-IDRI and IQ-OTH/NCCD is 93.5% and 95.01% and 94.8% 96.82% respectively. Furthermore, the training and validation losses attained are 0.32 and 0.28 for LIDC dataset and 0.38 and 0.25 respectively on IQ-OTH/NCCD.

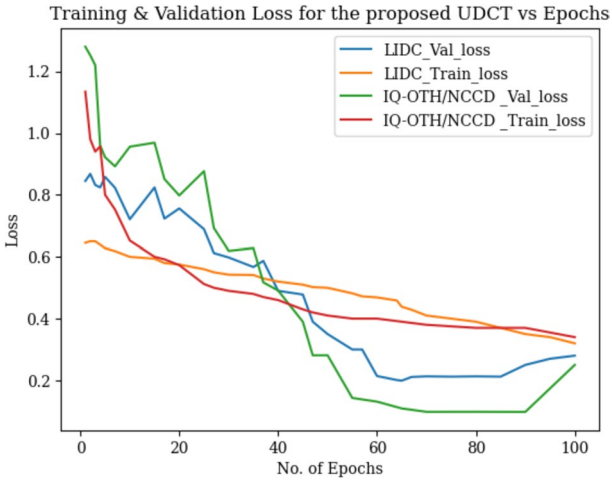

Fig. 6 Validation and Training Loss for the proposed UDCT Framework for LIDC and IQ-OTH Dataset

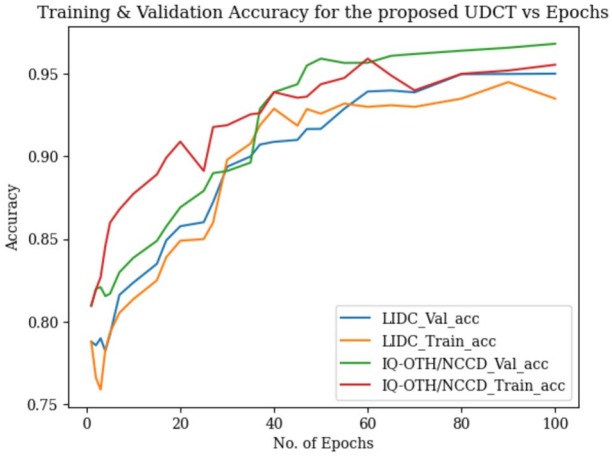

Fig. 7 Validation and Training Accuracy for the proposed UDCT Framework for LIDC and IQ-OTH Dataset

Tables 2 and 3 reports the comparison results obtained for the proposed UDCT framework with other state-of-the-art on LIDC-IDRI and IQ-OTH/NCCD CT image datasets for lung cancer detection and classification. The proposed work achieved an accuracy of 95.01%, Validation Loss of 0.28, Precision of 97.00%, Recall of 97.52%, Dice coefficient of 96.10%, Specificity of 99.09% and F1-Score of 96.01% on LIDC-IDRI Dataset. This proves that U-DARTS produces greater accuracy than the most effective approaches [24–29] presented in the Table 2. The proposed model offers relatively high accuracy when compared to the previous work because of these model adjustments, the usage of segmentation techniques, and the larger datasets as a result. Furthermore, a comparison for the proposed framework is made for the IQ-OTH/NCCD Dataset as reported in Table 3 which provided state-of-the-art results when compared with [33–38]. Also, Fig. 8(a) and (b) presents the confusion matrix for the proposed UDCT framework on LIDC and IQ-OOTH/NCCD datasets.

5.4 Ablation study

(i) An Ablation study is conducted to validate the performance of the proposed UDCT framework. In this section, we have performed three shuffles of the data, as depicted in Table 4, using fold 1, fold 2, and fold 3. This table illustrates how different evalu-

ation parameters vary across the different folds. The effectiveness of the method is demonstrated by employing a three-fold cross-validation approach in this study. Each fold of the cross-validation process allows us to assess the impact of the training samples on the accuracy, precision, recall, and Dice coefficient of the classification results by considering a specific fraction of the training data. Also, a comparison graph is depicted in Fig. 9 for three different folds with two classes each for one-fold.

(ii) An ablation is also conducted to study the influence batch size with optimizer utilized and learning rate. The results for the same are reported in Table 5. From these results we can infer that the best accuracy for 95.01% is obtained on Adam optimizer with a learning rate of 0.0001 for batch size of 32. Based on our results, we can say that the batch size and learning rate significantly affect the performance of the framework. Also, this experimental study aims at providing a better understanding of the batch size value which is 32 with the best suited optimizer and learning rate for the classification problems

6 Conclusion

This paper presents a novel framework, UDCT for automatic detection of nodules on CT images. The proposed framework utilizes Multilevel Otsu thresholding for accurate segmentation of lung tumours from CT scans. Multilevel Otsu thresholding helps to separate lung tissue from the CT scans. Further, the proposed model incorporates U-Net network with robust multi-scale feature extraction capabilities. Also, DARTS-based classifier is incorporated which utilizes the concept of continuous relaxation of the architecture representation with efficient gradient descent search for efficient classification of lung cancer.

The proposed framework combines the knowledge of DARTS and U-Net with aims to improve lung nodule classification into benign and malignant classes. The proposed technique was evaluated and validated on the publicly available LIDC-IDRI dataset and IQ-OOTH/NCCD dataset and provided state-of-the-art results. The results reported provided an accuracy of 95.01%, a dice coefficient of 96.10%, and a recall rate of 97.52% on LIDC-IDRI dataset. Also, accuracy of 96.82%, a dice coefficient of 96.40%, and a recall rate of 97.50% on IQ-OOTH/NCCD dataset. Further, an ablation study is also conducted to validate the efficiency and efficacy of the proposed model. In future, we can extend our experiment on large scale dataset. Also, weak supervised learning algorithm can be incorporated that utilizes large number of incomplete, inaccurate, and ambiguous annotation data in the existing medical records to achieve efficient model training. Furthermore, bringing prior clinical knowledge into model training should be encouraged so as the model provides the best possible classification output.

Funding No funding was received to assist with the preparation of this manuscript.

Data availability The datasets generated during and/or analyzed during the current study are available through an online web repository via https://wiki.cancerimagingarchive.net/display/Public/LIDC-IDRI and https://www.kaggle.com/datasets/adityamahimkar/iqothnccd-lung-cancer-dataset.

***Abstract*—In recent years, Artificial Intelligence (AI) has emerged as a powerful force, driving innovation across various industries. In the realm of healthcare, AI, particularly Natural Language Processing (NLP), is rapidly gaining prominence as a transformative tool with the potential to reshape patient care. Natural Language Processing, a subfield of AI, has proven to be a game changer in healthcare. It plays a pivotal role in improving patient care, empowering healthcare providers, and optimizing decision-making processes.In this research project, key focus is delving into the dynamic landscape of NLP for Clinical Text Mining, highlighting its profound impact on the healthcare industry. Multiple papers have already been written on this topic. These papers focus on a lot of different topics like cancer terminologies, EHR analysis for job extraction, drug attributes etc. These papers include different databases and mention the precision of all the results as well. NLP empowers healthcare providers in several ways. It discusses how NLP streamlines healthcare workflows, leading to more precise and timely diagnosis, personalized treatment plans, and cost-effective healthcare services.The potential of NLP in healthcare is boundless, promising a future where clinical text mining is integral to delivering superior patient care. This project aims to provide an in- depth analysis of NLP's transformative role, its current status and its evolving prospects within healthcare.**

***Index Terms*—Natural Language Processing, Clinical Text Mining, Clinical Text Analysis, Ensemble Learning, Information Extraction, and electronic health records.**

I. Introduction

A. Motivations and Contributions

The Electronic Health Records (EHRs) which are patients' health records stored in electronic have become a cornerstone in the advancement of healthcare delivery as through the aggregation and analysis of patient data, EHRs facilitate evidence-based decision-making, enabling personalised and timely medical interventions that significantly contribute to the improvement of healthcare quality and patient safety. Despite of this advancement, they are not being effectively being used by doctors due to their abundance and lack of time doctors have to read them.

An effective solution that one can think of is applying NLP to this problem and coming up with a solution that can help millions. However application of NLP to this problem is not easy due to several reasons: (1) records formats issue, (2) medical terminologies abbreviations, (3) clinical text exhibits fragmentation and employs shorthand terminology, (4) marked datasets are rare. Hence the paper has described a method which has huge and far reaching applications in the medical domain. Given medical records the models will give the terms that are relevant to the doctors. The applications include: (1) Early detection of health issues through Family Health (FH) records, (2) Pre-treatment identification of allergies to ensure safe administration of anaesthesia and other medical interventions, (3) Streamlining processes to optimise time efficiency for healthcare professionals.

There were several approaches for solving this problem through NLP. The paper focuses on testing out each one of them and finding out the results, improving the efficiency of the model one at a time. Datasets that have been used to train the models were very hard to find mainly due to the privacy issues in medical datasets. The pipeline used to come to the result includes pre-processing of the medical data (descriptions), since there were a lot of irrelevant terminologies that accompanies the informative ones. This process included performing stemming, tokenisation, TF-IDF etc.
Text similarity measures like Levenshtein distance, Cosine similarity and Jaro-Wrinkler distance were used to remove very similar terms. Thereafter several classifiers were used to figure out the result. These include one vs rest classifier, SGD (Stochastic Gradient Descent) classifier and Multilevel Neural Network. Inspired by the wisdom of the crowd principle, encapsulated ensemble technique was used to further take the advantages of each of the classifier and bring upon the result and observe their accuracies by assigning different weights to them. The best accuracy that was achieved by performing the above is = 83.205%. The paper also harnessed some tools to build graphs and word cloud based on the results.

B. Background and Previous Work

In a [1], João et Al's main objective is to enable medical practitioners to make prompt, well-informed decisions by identifying patterns that are hidden within the textual data. But the results highlight how difficult it is to obtain accurate diagnoses based just on keywords supplied by a Portuguese medical unit; the "K-Nearest Neighbor" algorithm is the only one that shows some effectiveness. In [2] James Mullenbach et Al's attempted to extract International Classification of Diseases (ICD) codes from clinical notes—a critical task for effective administration of healthcare.A brand-new method was put out that uses an attentional convolutional network

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 09:37:26 UTC from IEEE Xplore. Restrictions apply.

(CAML) to predict medical codes straight from clinical literature having a precision of 0.71 and a Micro-F1 score of 0.54 which surpasses previous works.

Ali et al [11] discusses supervised machine learning models that use high-dimensional omics data to predict drug response. The researchers also compared different machine learning models and omics measurements. The researchers find that feature selection techniques are necessary to identify the most predictive biomarkers. These researchers conclude that with more data machine learning models can be useful for drug response prediction. [12] explored the potential of NLP for automating the highlighting of new information in clinical notes, potentially improving healthcare efficiency and clinician decision-making using crucial updates in medical records. The authors argue that current methods are time-consuming and require significant human expertise.

In [3] Benicio et Al's offered a novel method for standardizing and retrieving patient data utilizing advanced Text Mining and Natural Language Processing (NLP) techniques from electronic patient records (EPRs). The research proves the usefulness of the strategy through thorough examination, including statistical comparisons between manually retrieved data and that processed using the proposed automated methodology. In [4] Shen F, Liu et Al's purpose were to create a common evaluation methodology for systems that extract FH data from clinical narratives. The task is divided into two smaller tasks: assigning living status, family side, and clinical observations to family members; and recognizing family member entities and clinical observations (diseases).The findings indicate that entity identification is not as challenging as relation extraction from FH.

Sezgin et al [13] explored the potential and feasibility of using NLP to extract medication and symptom information from unstructured patient data collected via a voice-interactive app. The analysis involved notes from 24 parents of children with special needs. The NLP pipeline used a zero-shot approach and achieved promising results (precision ¿ 0.65, recall ¿ 0.77, F1 ¿ 0.72) for medication and symptom extraction. Alfattni et al [14] evaluated the effectiveness of NLP and deep learning for extracting and linking drug information from clinical notes. The authors use 2018 n2c2 shared task data to propose an NLP system ("DrugEx") that utilizes various embedding techniques for drug entity recognition and relation extraction. Their findings suggest that deep learning with pre-trained word and character embeddings performs well, with additional insights on limitations of rule-based vs. context-aware LSTM methods for relation extraction.

In [5] Tal Baumel et Al's explored the complex process of assigning numerous diagnosis codes to patient records, which was difficult due to large number of codes.Utilizing the MIMIC II and III clinical datasets, the paper demonstrates HA-GRU's superior performance against SVM, CBOW, and CNN classification techniques, especially in identifying rolled-up ICD9 codes. In [6] Y. Wang et Al's goals were to investigate current studies on clinical IE applications. 263 pertinent publications were found after a comprehensive search across many databases was conducted between January 2009 and September 2016. This review provides information on this gap and suggests some ways to close it.

Rybinski et al [15] explored automated methods for extracting family history information from clinical notes using NLP. The authors present a system that combines transformers for disease mention detection and rule-based methods for family member identification. Their approach achieved an F1 score of 81.63% on a public dataset. Gholipour et al [16] investigated the use of NLP for automatically extracting cancer-related information from clinical notes. By analyzing previous research, authors found that rule-based NLP algorithms were most frequent, with a focus on accuracy and sensitivity. These researchers observed a preference for SNOMED-CT and UMLS terminologies for identifying cancer concepts. The authors suggest applying these methods to other diseases as well.

In [7] D. Antons et Al's describes the procedure, which uses techniques like tokenization and tf-idf measurements for content analysis and data preprocessing. Dictionary-based and algorithmic text mining techniques are distinguished, with examples including clustering and classification provided. It draws attention to the development of text mining algorithms and results as well as issues with reporting transparency. In [8] M. Oghbaie et Al highlighted how crucial information retrieval (IR) is to managing large amounts of data, as information extraction and pattern identification are aided by document classification and clustering.Vector Space Model (VSM) is presented, and other term weighting techniques such as tf-idf are addressed. The study suggests a novel similarity metric that improves text performance by taking into account both term weights and the total number of terms in documents.

Harrison et al [17] explored the use of NLP techniques for analyzing large text datasets using open-source software and freely available data of patient reviews for various drugs.While sentiment analysis skews towards particular drugs, unsupervised learning (LDA) identifies clusters of drugs based on review characteristics. Supervised machine learning models achieved moderate accuracy in predicting drug review ratings. Kersloot et al [18] analyzes 77 studies from a pool of 2355 and found a lack of consistent reporting, with over a quarter not evaluating their algorithms. Most studies relied on internal data and manual annotations. The authors propose 16 recommendations to improve future research, emphasizing standardized reporting, data use, evaluation, and generalizability.

In [9] N.Bhat et Al focuses on strategies for producing captions that can combine novel approaches to visual

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 09:37:26 UTC from IEEE Xplore. Restrictions apply.

attention and maximize current notions. The survey highlights computationally feasible and optimal techniques that can be supported on various platforms, including lightweight devices like smartphones, and emphasizes the significance of adaptability and effectiveness of existing research in real-life applications.In [10] E.Mahajan et Al's used Convolutional Neural Network (CNN), Bi-directional Long Short-Term Memory (BiLSTM), Bi-directional Gated Recurrent Unit (Bi-GRU), and Long Short-Term Memory (LSTM) approaches in their suggested model to improve overall performance. %.

Abhishek malik al [19] evaluated the performance of the suggested method against a number of state-of-the-art models that have recently been proposed, deep learning models, pre-trained Bidirectional Encoder Representations from Transformers (BERT) using transfer learning, and several standard Machine Learning baseline models. Four datasets from various areas are used to evaluate these models for both training and testing.Sanjay K et al [20] were following processing, the features are used to produce balanced, well-labeled datasets that are categorized according to predetermined time intervals. These datasets are then used to train several machine learning classifiers, which are subsequently combined in a weighted way to create a better recommendation system based on fusion.

II. Evaluation Metrics

Since the paper has adapted several approaches to solve the problem, several metrics had to be figured out on the basis of which it could figure out the best approach and in which direction to proceed to improve the results. Hence The paper adopted the standard metrics using which AI models are evaluated. These include Accuracy, Hamming Loss, Precision, Recall and F1- score. These metrics provide an insight on the performance of each of the approach. Accuracy quantifies the overall correct predictions among all cases, offering a snapshot of model performance.

$$\text{Accuracy} = \frac{\text{Number of Correct Predictions}}{\text{Total Number of Predictions}} = \frac{TP + TN}{TP + TN + FP + FN}$$

$$\text{Accuracy} = 1 - \text{Hamming Loss}$$

$$\text{Precision} = \frac{TP}{TP + FP}$$

$$\text{Recall} = \frac{TP}{TP + FN}$$

$$\text{F1 Score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} = \frac{2 \times TP}{2 \times TP + FP + FN}$$

Fig. 1. Evaluation Metrics Formulae

Hamming Loss measures the fraction of wrong labels to total labels, indicating label-specific errors in multi-label settings. Precision assesses the accuracy of positive predictions, showing how many selected items are relevant. Recall, or Sensitivity, evaluates the model's ability to capture all relevant instances. F1-Score harmonizes precision and recall into one metric, providing a balanced view of a model's precision and recall capabilities, especially useful in imbalanced datasets. The formulas are given in the Fig. 1. The terms have the following meaning TP = True Positive TN = True Negative FP = False Positive FN = False Negative

III. Dataset

The paper used mtsamples.com, a well-known large database of medical report transcriptions. Both aspiring and experienced medical transcriptionists can use these examples for their everyday transcribe requirements.

The data was quiet unstructured and it had the following parameters (1) Description: This column provided a summary of the medical transcription content, offering insight into the nature of the medical case or scenario documented within the transcription. (2) Medical Speciality: Each transcription is classified under a specific medical specialty This classification helps in organizing and filtering transcriptions based on the specialty they belong to. (4) Transcription: This is the heart of the dataset, this column contains the actual medical transcriptions in text format.These transcriptions detail the clinical encounters, patient histories, examination findings,etc. (3) Keywords : Extracted from the transcriptions, this column includes relevant keywords or phrases that capture essential concepts, conditions, procedures, or findings documented within each transcription.

The problem with the above dataset was it was highly unstructured so healthcare repository dataset was chosen which also had the same parameters but it was more structured and so it was easier to work with it,

IV. Methodology

A. Pre-Processing

Tokenisation : Tokenization is the process of breaking down a piece of text into smaller units called tokens. These tokens can be words, phrases, symbols, or other meaningful elements that serve as the basic building blocks of the text. It plays a fundamental role in various natural language processing tasks, such as text classification, sentiment analysis, and machine translation, by enabling efficient manipulation and understanding of textual data.

Pad_sequence: The pad_sequences function is used for padding sequences to ensure that they all have the same length. In NLP, when working with text data, it is common to have variable-length sequences of words. However, neural networks typically require fixed-length input sequences. The pad_sequences function is used to add padding (zeros) to shorter sequences or truncate longer sequences to achieve a consistent length. TfidfTransformer: It is commonly used in text processing to convert raw token counts into a numerical feature representation that takes into account the importance of terms in a document corpus.The paper used

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 09:37:26 UTC from IEEE Xplore. Restrictions apply.

TABLE I
EVALUATION METRICS FORMULAE

Clinical Dataset Details	Training Size	Testing Size	Tag Size
MedicalRecords 21' - MT Samples	1980	594	3007
Healthcare Insight Repository	1504	451	3898

this for transforming because it is light weight unlike the BERT Model. CountVectorizer: CountVectorizer is a feature extraction method that converts a collection of text documents to a matrix of token counts. Each row in the matrix represents a document, and each column represents a unique word in the corpus. The values in the matrix are the counts of each word in each document. It is commonly used as a preprocessing step in text classification tasks.

Stopwords Removal : Stopwords is a set of English stop words (common words that are often considered non-informative). The function iterates through the words in the text, and if a word is in the set of stop words, it is removed from the list of words. BadSymbolsRemoval: Remove the bad symbols which have no meaning in the context. In this context special symbols have no meaning so remove it.
To implement the preprocessing techniques keras and sklearn(python libraries) were used.Keras offers tokeniser and pad]sequences for tokenisation and pad_sequences respectively.For TfidfTransformation and CountVectorisation feature extraction library from sklearn module were used.

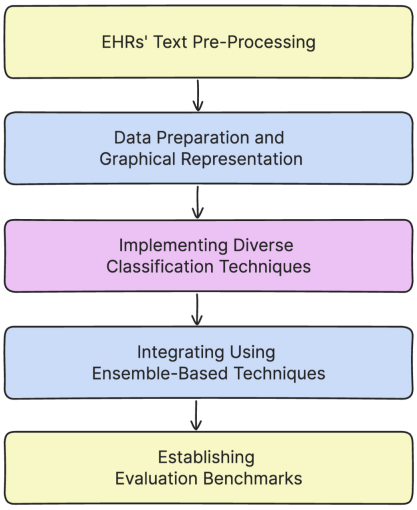

Fig. 2. Medical Term Extraction Visualization

B. Classifiers

1) One Vs Rest Classfier: The paper utilize the One-vs-Rest classifier in the study for its adept handling of multi-class classification challenges. Its strategic approach of breaking down intricate, multi-class tasks into several binary classification problems significantly streamlines both the training and prediction processes, making it an ideal choice for the research on extracting medically relevant terms from datasets.

The One-vs-Rest classifier operates by constructing a distinct binary classifier for each class, determining the membership of a given sample by comparing its prediction scores across these classifiers to select the class with the highest probability. The reduced accuracy observed with the One-vs-Rest classifier in the context may stem from the inherent imbalance in the dataset, where certain classes are underrepresented. This imbalance can lead to biased predictions towards more dominant classes, diminishing the model's ability to accurately classify minority class instances.

2) SGD Classifier: Next Up the paper focuses on an SGD classifier on the data. SGD classifier employs a stochastic approach, updating parameters using either single training examples or small batches, making it computationally efficient and suitable for large datasets. SGD is efficient as it uses small batch updates over dataset . It has high scalability and can easily handle high dimensional data .
It also allows us to apply various loss functions and regularization which makes it flexible with data. It Had a better accuracy then 1 vs rest classifier on the mtsamples dataset (70.43%). While applying SGD,be really careful with the input parameters as it is highly sensitive hence, careful pre-processing had to be done. Since it works in small batches so it is difficult for it to adapt to complex relationships. Also it is prone to over-fitting.

3) XGB Boost Classifier: The accuracy from SGD classifier was 70.43% so there was a huge room for improvement. So next up is to use XGB Boost classifier which is popular for its speed and performance in data tasks. It implements gradient boosting with enhancements like parallelized tree building and regularization techniques. The XGB classifier offers excellent in working on high dimensional data making it suitable for complex and diverse nature of clinical text. Also it has a very high ability to capture non linear relationships and interaction between features which allows for more accurate predictions and lastly it is scalable to large dataset. Got an accuracy of 73.2% which is more than both SGD and One Vs rest Classifiers.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 08,2024 at 09:37:26 UTC from IEEE Xplore. Restrictions apply.

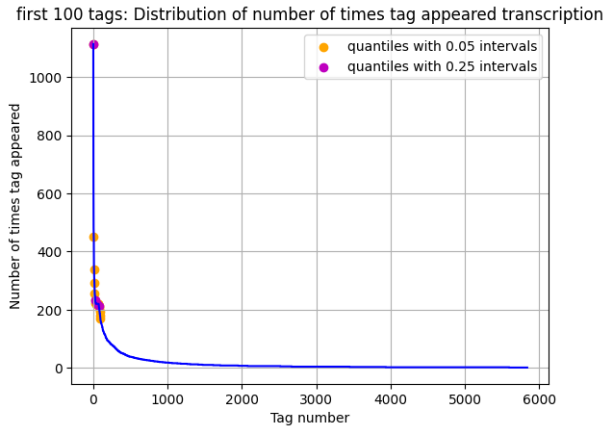

Fig. 3. Tag Frequency Distribution with Quantile Markers

Despite its strengths, XGBoost has its challenges when applied to clinical text data. One notable drawback is its difficulty in providing clear interpretations of its predictions, which can be crucial in complex medical scenarios where understanding the reasoning behind a prediction is essential. Additionally, fine-tuning XGBoost's parameters is a meticulous process, and improper tuning could result in models that either overfit or underfit the data, particularly when dealing with the nuanced and varied nature of clinical text.

4) MLP Classifier: Even after applying XGB Boost classifier the accuracy was still 73%, hence an MLP classifier which is an artificial neural network architecture renowned for its versatility in various machine learning tasks, including text classification was incorported. Their structure mimics the human brain, consisting of an input layer, one or more hidden layers with interconnected processing units (neurons), and an output layer. The major advantage of using MLP is its ability to model non-linear relationships between features and the target variables. This allows them to capture intricate patterns in data that linear models might miss.

However due to it's complex structure, it can lead to over fitting, especially with limited training data. Furthermore training MLPs often requires careful hyper-parameter tuning, which can be time-consuming and computationally expensive. Despite that, on the mtsamples dataset, MLP gives an accuracy of 82.69% which is way higher than other classifiers like SGD (70.43%), One Vs Rest (64.23%) and XGB (73.46%).

First the performance of the simple lone algorithms was analysed by performing tests on the same set of data in all of them. These include MLP, one vs rest ,SGD, XGB Boost Classifiers. However their performance was not upto the mark. Hence a different approach was taken to combine multiple classifiers and build upon their strengths to enhance

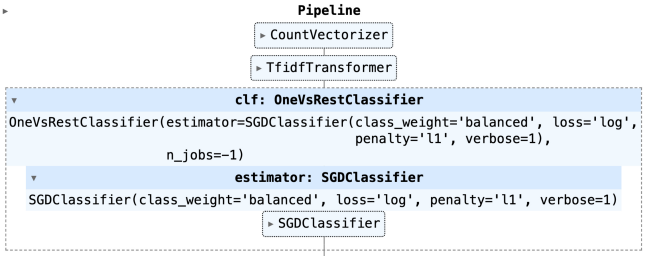

Fig. 4. Pipeline Visualization: Text Feature Extraction and Classification

the overall performance.

Various classification mechanisms can be utilised to enhance the performance of the model using the various python libraries like Sklearn and Keras. The models are inbuilt in into these libraries and the research paper has utilised these to come to results.

C. Ensemble Learning

Onto the final model, the paper used ensemble learning, it is a machine learning technique that combines the predictions from multiple base models to improve the overall performance and robustness of the final model. It operates under the principle that combining diverse perspectives from multiple models can lead to more accurate and reliable predictions. Types of Ensemble learning are as follows:

- Voting Classifier
- Stacking (Meta Learning)
- Bagging (Bootstrap Aggregating)
- Blending
- Boosting

The key benefit of using ensemble learning lies in its ability to reduce variance. By combining multiple models, it can average out the errors of individual models which can enhance robustness to overfitting. However, ensemble learning does come with certain drawbacks. The increased complexity of combining multiple models can lead to higher computational costs for training and prediction compared to simpler models. Furthermore, choosing the most appropriate base models and combining their predictions effectively requires careful consideration and experimentation.

The paper used Voting classifier for the model by using SGD, MLP and One vs Rest classifier as estimators. Some of the results obtained were: 78.2% (One vs Rest, SGD, MLP), 66.53% (One vs Rest, SGD), 82.17% (One vs Rest, MLP), 81.92% (MLP, XGB) and so on with weights equal to 1.

The paper also used different weights for different models to find the best model configurations. Out of all the tried configurations, found out that using MLP and SGD as estimators with weights 5 and 1 gives the best result of 83.21%.
The voting classifier has two types of voting's viz. Hard Voting and Soft voting. In Hard Voting what is done is predicting the

data into classification tasks. The final predicted value is taken as the majority votes among the classifiers. Hence the class with the maximum number of votes is the final output. In Soft voting, every base model provides a probability distribution over the possible outcomes rather than a single prediction. The final output is determined by averaging the predicted probabilities from all individual models. The class having the highest average probability across all the models is selected as the final prediction.

V. FINDINGS

After applying different models to the clinical dataset, the best results were obtained while working with a voting ensemble classifier which combines MLP Neural Networks and SGD classifier with weights set to 5 and 1 respectively. The maximum accuracy was 83.25%.

The research findings offer a detailed analysis of machine learning classifiers and ensemble methods applied to medical text classification tasks. It emphasises the importance of preprocessing techniques such as tokenisation, sequence padding, and feature extraction using TF-IDF and CountVectorizer to effectively prepare text data for analysis. Among the classifiers tested—including One-vs-Rest, SGD, XGBoost, and MLP—the MLP classifier emerged as the top performer with an accuracy of 82.69%, leveraging its ability to capture complex data patterns.

The study also explored ensemble learning techniques, demonstrating the effectiveness of a Voting ensemble approach that strategically combined MLP and SGD models to achieve an impressive accuracy of 83.21%. It also mentions the challenges associated with model interpretability and scalability, particularly with classifiers like XGBoost, underscoring the importance of balanced model selection for real-world medical text analysis. These insights provide valuable considerations for deploying machine learning solutions in healthcare applications.

VI. FUTURE WORK

The paper have successfully extracted the keywords from the clinical text, and Hence the symptoms can be extracted from the clinical text. Thus, using these symptoms the model should be able to figure out the disease with a viable accuracy. Further corresponding to the symptoms the the model will recommend medicines/prescriptions. Future work also includes development of an app that will store the prescriptions and medicines taken by the user.

This will require a local database that will be useful for future purposes for the doctor. Also, developing frameworks that ensure seamless integration with diverse electronic health record systems will be a potential useful feature as well.

Hyperparameter tuning for each individual classifier used as well as the ensemble classifier to boost the accuracy of the final model.Experimentation with different ensemble techniques such as stacking,blending or boosting can also give interesting results regarding the perfromance of the final model.

ACKNOWLEDGMENT

To express gratitude, the authors acknowledge the valuable tools and techniques that supported the research. The paper employed various machine learning tools including Stochastic Gradient Descent, One-vs-Rest, XGBoost, Multi-Layer Perceptron, and ensemble learning, which were trained on mtsamples dataset from kaggle. These diverse approaches enabled a comprehensive exploration of modeling techniques which lead to the successful extraction of relevant keywords with an accuracy of 83.205%.

Abstract
This research focuses on addressing the challenges of visual emotion analysis and emphasizes the need for improved comprehension and categorization of emotions by machines. The objective is to develop an efficient architecture for emotion classification in real-world scenarios encountered in multimedia retrieval tasks, considering factors like illumination, occlusion, pose variations, small face sizes, multimodal detection, and big data issues. The proposed Dense Blocked Network-based VEDANet architecture surpasses the state-of-the-art on benchmark datasets by leveraging pre-trained CNN architectures to recognize facial features and extract metadata. The exploration of 128 descriptors from a deep residual network further enhances the operations. Using the VEDANet framework, emotions are classified into seven categories with superior accuracy compared to conventional approaches. The study investigates the efficacy of an over-the-top optimization (OTO) layer to enhance emotion classification. The proposed model achieves impressive accuracy scores on diverse datasets, including AffectNet, Google FEC, Yale Face DB, and FER2013, with percentages of 87.30%, 92.75%, 95.07%, and 90.53% respectively. Real-time performance is achieved with exceptional accuracy of 93.46% on live frames, while minimizing turn-around time by optimizing network size and parameters. This research contributes to the advancement of visual emotion analysis, providing a comprehensive and efficient solution for AI-based emotion detection in various applications.

1 Introduction

Identification of a person's emotional state is crucial to several study fields, including political science, computer vision, psychology, and the sciences of medicine. Information reception, attitude development, and decision-making are all influenced by emotions. Sentiments exist on a deeper level of the human mind, whereas emotions at a given instant come from the subject's feeling for an item or person. Sentiments form part of a person's character and stay with them for a long time, whereas emotions are exhibited for a shorter time (typically instantaneously) as a result of an action or occurrence that triggers an emotional outburst.

Cognitive human emotion recognition and machine intelligence (AI), often known as human-computer interaction, are two subfields of emotion detection in academia. Facial landmarks, body language [1], and voice can reflect human emotions [2]. Mehrabian's 1967 research found 55% of emotional input was visual, 38% was aural, and 7% was spoken [3]. These findings still hold. Most research focus on facial expressions because they are the initial sign of emotional state transfer. The face displays emotions and intentions in social interactions and conflicts, which others see.

Advanced robotic and operational solutions will be based on face expressions. Human-based information extraction processed and classified into logical units will power robotic medical operations and sophisticated autonomous driving assistance technologies. Extracting features from one face compared to another to better categorisation is difficult and sensitive.

Ekman and Freisen were among the first scientists to examine face expression, establishing FACS (Facial Action Coding System) in 1978 to classify facial motions by AUs (Action Units). One or more face muscles are combined into 46 Action Units [4]. Geometric characteristics like Gabor wavelets [6], local binary patterns [5], and facial action units (FACs) [4] are already used to extract face features. However, categorising and identifying human emotions is difficult for a machine. Automatic Facial Emotion Detection is the most studied modality [7], but it's hard since everyone exhibits emotion differently. Researchers should consider the real-world challenges head position, brightness, backdrop, and occlusion. The current state-of-the-art, face landmark model [46] and face augmentation [47] approaches, addresses some of these difficulties but needs to be improved.

Corporate and academic interest in Deep Neural Networks (DNN) shows its efficacy. To comprehend human emotions, researchers are leveraging architectures such the deep convolutional neural network (DCNN), recurrent neural network (RNN), and attention networks, which enable automatic feature extraction and categorization [46]. CNN's key benefit over its forerunners is that it can recognise essential traits automatically, without human intervention and give better performance comparatively. Researchers have put forth a lot of effort to develop deep network architectures, going so far as to include blocks like the Squeeze-and Excitation Block to boost accuracy even more. Hu et al. (2018) used channel-wise attention with a squeeze and excitation network (SENet) across a deep residual network. The attention-module rearranges channels to teach the residual block quality features [8].

Liu et al. (2019) used Local Binary Pattern (LBP) and 2D-Gabor to extract feature discrimination using an ELM-SVM framework that achieved 85% accuracy on CK++ dataset [9]. Deeb et al. (2022) proposed the human emotion identification framework using HAAR, LDA, and IBH-based Extreme Learning Machine (ELM) classifier to detect the 7 fundamental emotions in real-time face emotion classification. The algorithm's accuracy on the

KDEF, CK+, and JAFFE (Japanese Female Facial Expression) public datasets reached 91.32, 97.62, and 97.78% respectively [10]. Appearance characteristics operate poorly with noisy facial images and are inconsistent with a number of facial changes (such as face size, head position, and face appearance) [40]. DenseNet methods achieved the highest results in terms of stability against noise perturbations in facial images [45]. Using findings from the most recent studies, we developed a framework that may be used in a variety of real-time applications in fields as diverse as teaching, autonomous vehicles, the entertainment industry, national security, and public safety.

In order to alleviate the burden of massive data training, it is prevalent to employ several well-known pre-trained CNN models, such as ResNet and VGGNet. So far, there has been no ground-breaking research into visual emotion identification that makes use of a pre-trained model to provide outcomes as similar to human emotions and thoughts as is practically possible. This is why in our system we employed ResNet as the underlying architecture for visual feature extraction. Features were retrieved by employing the transfer learning concept of computer vision by way of training deep CNNs on large data sets like ImageNet for VSA. During model training, there will be no need to start from scratch. We employed TL to minimise overfitting in our proposed study by bringing relevant information from one realm to another.

Previous research has focused on ideological input to the system. Our research provides an improved face value extraction approach based on integrating the most advanced pre-trained architectures in unity. Current researchers are attempting to achieve 100 percent efficiency; our study progresses towards this goal by delivering a more effective method to achieve a high rate of emotion recognition accuracy.

The primary contribution of the paper's proposed study is to provide a standard framework for detecting seven unique emotions—joyful, angry, disgusted, neutral, fearful, sad, and surprised—in face pictures and live broadcasts. The proposed work develops a pre-trained architecture for extracting visual face descriptors (FDs), which may be used for both face detection and recognition. Built on top of a modified Resnet (31layers) architecture, the model achieves good recognition accuracy owing to the inclusion of visual face descriptors (FD's), Bounding Boxes, and 68 Landmark points. The proposed work's main contribution is to explore the proposed framework on benchmark datasets and on real-time live frames, and present a novel VEDANet architecture (baseline: DenseNet-121) for Visual Emotion Detection and Analysis. The proposed architecture expanded by including an OTO Layer (Over the Top Optimization Layer) to boost the confidence score of the final result and speed up the precision with which emotions were identified.

In the final stage of the proposed work, the presented study contributed by providing the comparative analysis of the proposed model's (VEDANet) accuracy in emotion detection task with current SOTA and real-time live frames, demonstrating its competency to outperform. The investigation of proposed framework covered the interesting challenge of this field that is for balancing the accuracy over the emotion categories.

The paper is organized as follows. Section 1 serves as the introduction, providing an overview of the research and introducing the datasets used. In Section 2, we conduct a comprehensive review of existing approaches to emotion detection and analysis, focusing on their performance on standard benchmark datasets. Section 3 delves into the implementation process, including the data used, methodologies, and training hyperparameters. We also discuss the modifications made to enhance the performance of pre-existing models. The assessment metrics, results obtained from the experiments and their analysis are presented in Section 4. Finally, in Section 5, we draw conclusions based on the findings of the study.

1.1 Datasets used

1.1.1 Extended yale face database

This collection is made up of 16,128 facial pics that were all captured using the same light source. It has 28 unique subjects for 576 different viewing settings, including nine poses for each of the 64 different lighting conditions. Each facial image's actual dimensions are 320 x 243 pixels [11].

1.1.2 Google FEC database

700,000 triplets of distinct face crop photos made up the Google Facial Expression Comparison (FEC) [12] database. In each triplet, the most comparable pair of facial expressions are annotated [12] (Fig. 1).

1.1.3 Affectnet dataset

AffectNet [13], is actually the largest publicly accessible repository of face emotions which has ~ 440,000 in-the-wild face crop photos, each of which is manually tagged into one of eight categories of facial expression categories (Happy, Sad, Neutral, Surprise, Disgust, Fear, Contempt and Anger). In the presented work, to generalize the model seven emotion classes with annotations used except contempt emotion [13] (Fig. 2).

1.1.4 FER2013

The Face Emotion Recognition 2013 (FER-2013) dataset was developed by Pierre Luc Carrier and Aaron Courville for the facial expression recognition challenge of the ICML 2013 workshop [14]. The collection was created by crawling photographs that correspond to emotive keywords using the Google image search API [14] (Fig. 3).

1.1.5 Real-time wild dataset

We used a camera device (smartphones and webcam) to capture ongoing conversations and extracts ~350 frames from random instances. We exposed those frames to our proposed architecture to evaluate.

Fig. 1 Samples from google facial expression comparison dataset [12]

Fig. 2 Sample images from the AffectNet dataset (where 0,1,2,3,4,5,6,7 denoted emotion classes as neutral, happy, sad, surprise, fear, disgust, anger, contempt respectively) [13]

Fig. 3 Sample Images from FER2013 Dataset. (Having 35887 facial images= '8989 Happiness' + '6198 Neutral' + '6077 Sadness' + '5121 Fear' + '4953 Anger' + '4002 Surprise' + '547 Disgust') [14]

2 Background and related work

As per the recent past works in the field of emotion detection it was observed that CNNs are renowned for their ability to recognize and categorize images. A basic convolutional neural network typically comprises of neurons connected over several layers. These layers aggregate the incoming images and perform various processing layers on them.

Convolutional, pooling, and fully connected layers are the 3-types of layers that build up a basic CNN. The feature extraction process is carried out by the first two layers, which also introduce non-linearity and feature reduction to lessen overfitting. The last layer, referred to as a fully linked layer, aids in classifying data using attributes that were retrieved from earlier levels. The majority of the parameters are found in the fully linked (connected) layer. Certain architectures also aimed to reduce the number of parameters like in Inception V3 [15] the last layer of Global Mean (Average) Pooling operation is added. By averaging the feature map and turning it into a scalar vector, this layer shrinks the feature map. Modern CNN designs have demonstrated the utilization of residual modules [16] and depth wise-separable convolutions [17] to further minimize the parameters. The feature extraction task is split up and combined within the convolutional layer by the depth-wise-separable CNNs, which further reduces the parameters. A Mini-Xception CNN suggested by [18] that minimizes the number of parameters by using depth-wise separable dense blocks and eliminates fully connected layers. So, by taking motivation from [17, 18] research work, we additionally used depth-wise separable convolution layers rather than ordinary convolution layers that leads reduction in parameters.

Due to their built-in feature extraction method from images, Deep NNs (DNNs), mainly convolutional neural networks (CNNs), have gained attention in Facial Emotion Detection [19, 20]. In order to address the challenges with emotion detection, a few works have been reported with CNN [21–26]. The CNN's deeper model has been demonstrated to perform better at other image-processing tasks [27], however the Visual Emotion Detection methods now in use only take into account the first few layers of the CNN. The difficulties associated with the task of detecting emotions may be the facts underlying this. The first requirement for emotion recognition is a reasonably high-resolution image, which calls for working with high dimension data. Second, there are a tonne of hidden convolutional layers in a really deep CNN. It is difficult and unreliable to train the CNN with a large number of hidden layers. Additionally, the vanishing gradient issue means that just adding layers does not improve accuracy after a certain point [28]. The notion of skip-connection [29], which was first proposed in residual neural network (ResNet) [29], is one that stands out and is used by the majority of the later models. The fundamental concept behind a skip connection is to add a layer's input to the output after a few other layers. This gives the layer additional information and aids in resolving the vanishing gradient issue. There are already a few distinct ResNet models available, including ResNet-18 (17 convolutional layers), ResNet-34, ResNet-50, and ResNet-152.

According to DenseNet [30], which established extensive skip connections between layers, each layer now receives signals from its predecessors and uses their output to drive all succeeding layers. A single layer's input is blended with the channel concatenation of layers that came before it. DenseNet has [L (L + 1)/2] direct connections as opposed to the 'L' direct connections of conventional CNNs with 'L' layers. Because each layer has direct access to the layers above it, the network's information bottleneck is less severe. As a result, the model is substantially more compact and thinner, producing high computational efficiency. In addition to this, non-linearity on the kth layer is estimated using a non-linear function for this feature map and the concatenation of 0-to-(k -1) features. There are various variations of this model; the one we are interested in is the DenseNet-121, which uses activation functions and global level pooling to deploy 120- convolutional layers predominantly inside 4 blocks.

The deep CNN architectures have undergone a number of tweaks and training methods to improve accuracy [15, 31, 32]. VGG-16, Resnet-50, Resnet-152 [31], Inception-v3 [15], DenseNet121, and DenseNet-161 [32] are some of the often-used pre-trained DCNN models. But it takes a lot of data and powerful computing to train such a deep model.

So, we have picked some pitfalls from previous related work and tried to cover few challenges among them which are as follows: (i) Minimize error rate and increase accuracy for frontal face as well as side face images (ii) Use of Pre-trained architectures to minimize the pre-training computation time and cost. (iii) To provide a Real-time efficient and deployable Emotion Detection System. The proposed work discussed further in next section.

3 Proposed work strategy

The proposed stream-lined workflow represented in the block diagram as in Fig. 4. The pipelined steps involved in the workflow are as follows. (i) Input frame extracted from real-time device or external input source (datasets) (ii) Face Detection with pre-trained architectures (MobileNetV1- SSD, Tiny Yolo2) and Facial-Landmark model (with 68 view points) (ii) Visual Face Descriptors Extraction with VFDNet (Resnet- 31 layers) (iii) Visual

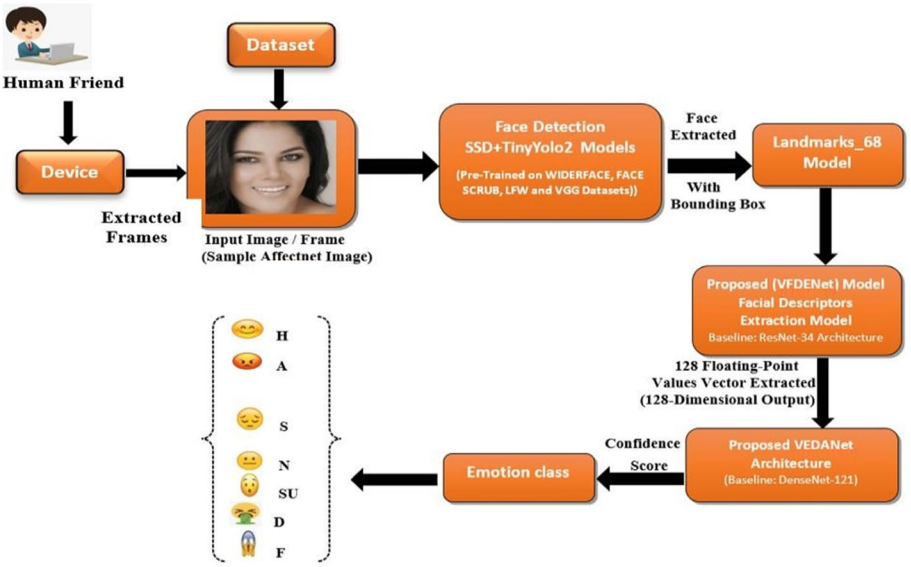

Fig. 4 Block diagram of proposed work for visual emotion detection and analysis

Emotion Detection and analysis with proposed VEDANet (baseline: Densenet-121) and extended the architecture by adding the OTO Layer in the end. The stepwise work progress is described below.

3.1 Face detection

MobileNetV1-SSD combines the depth-wise separable convolution from MobileNets with the Single Shot MultiBox Detector (SSD) framework, optimizing for speed and efficiency, ideal for mobile and real-time applications. Our face detection system utilizes the MobileNet SSD, a model optimized for efficient and speedy detection, integrated with the TensorFlow object detection API and refined using the extensive WIDERFACE dataset. This sophisticated network not only identifies the location of faces within an image by providing bounding box coordinates but also assesses the confidence level of each detection. Tiny Yolo2, a smaller and faster version of the YOLO (You Only Look Once) model, excels in real-time detection with reduced resource consumption. The synergy between these models arises from their complementary strengths: MobileNetV1-SSD's efficiency and accuracy in detecting larger faces, and Tiny Yolo2's capability to rapidly process images, albeit with slightly lower accuracy for small faces. This hybrid approach ensures robust face detection across various scenarios, balancing speed and precision.

Our face detection model has undergone training with a specialized dataset comprising approximately 14,000 images, each meticulously labeled with bounding boxes to ensure precise and accurate recognition capabilities. The enhanced model, trained to accurately predict bounding boxes that fully encapsulate facial feature points, delivers superior performance in landmark detection compared to using SSD MobileNet V1 alone. Leveraging the strengths of both the tiny face detector and SSD MobileNet, and augmented with a sophisticated landmark detection model, this approach ensures exhaustive facial feature coverage.

Such a comprehensive integration markedly boosts the system's efficiency under diverse conditions, guaranteeing precise and dependable face detection in various environments.

3.2 Visual facial features extraction

This stage of work implements a 68-point facial landmark detector that is lightweight, quick, and accurate. The standard pretrained model (face landmark-68 model) is just 351kb, while the tiny model (face landmark-68 tiny model) is only ~82kb. Both models make use of densely linked blocks and depth-wise separable convolutions. The models have been trained on a dataset of ~35k face images labelled with 68 facial-landmark points.

Deep convolutional neural networks have made a series of advancements in unconstrained face identification in current history, allowing us to deal with facial images with severe postures, lighting, and resolution changes. In the direction of further advancements to tackle these challenges, we have also designed VFDENet with 31 convolutional layers by considering ResNet as the baseline network shown in Fig. 5. It's a variant of the ResNet-34 network presented in Fig. 5, with three layers eliminated and the number of filters per layer halved to enhance operational efficiencies. This architecture is implemented to compute a face descriptor (a feature vector with 128 values) from any given face image, which is used to describe the characteristics of a person's face. The VFDENet architecture is shown in Fig. 5.

3.3 Visual emotion detection and analysis with proposed VEDANet architecture

After Face Detection and Facial Features Extraction (Landmark points and descriptors), this stage will evaluate the Emotion Classification based on proposed model VEDANet architecture (Table 1). Our proposed architecture exposed the exclusive outcomes comparative to SOTA due to the densely connected blocked network. The flow of working model is shown in Figs. 4 and 6. The Emotion Detection (ED) algorithm and Emotion Analysis (EA) algorithm is shown in Fig. 7.

Consider an input image x0 (128*128) that has been processed via the convolution layer. Proposed Architecture anatomy shown in Table 2, that takes the input image and turned half the size and doubled the filters and reduced number of parameters. The first convo block has 64 filters of 8*8 size and 2 strides. *Convo-layer is made up of feature maps and filters. Where feature maps are the outcome as per the weight applied to the filter and filters hold the input weights in accordance with that output value.* As in our architecture, 1st convo-layer is 8*8 and every dense block consists of two- convolutions with 1*1 and 3*3 sized kernels.

The Convolution layers are followed by 3*3 Max Pooling and 2 strides. The lth layer has $k0+k \times (l-1)$ input feature-maps, where k0 is the number of channels in the input

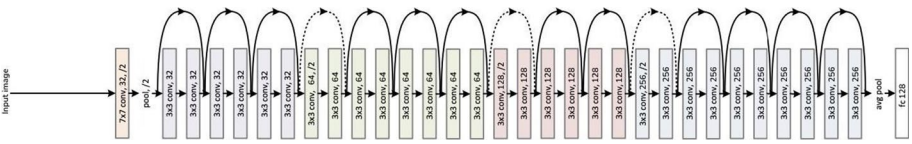

Fig. 5 Face descriptor extraction using the ResNet-31 layers' VFDENet architecture. The output is a vector of 128 floating-point values, and the dotted shortcuts add more dimensions

Table 1 VEDANet architecture: K = 32 represents the growth rate across the network

Layers	Output_Size	VEDANet Architecture (K=32)
Convolution	128*128	8 × 8 Convo_Layer (CL), Strides-2
Pooling	64*64	3 × 3 Max-Pool, Strides-2
Dense-Block (DB1)	64*64	$\begin{bmatrix} 1 * 1\text{conv} \\ 3 * 3\text{conv} \end{bmatrix} \times 6$

Fig. 7 Emotion detection (ED) algorithm and emotion analysis (EA) algorithm. In this algorithm, the keywords are described as follows: Xss (output from SSD for input), Xyo (output from YOLO), Lx is landmarks of input x, fo (Lmo) is function of landmark modal, Dface is Face Descriptors, Lx landmarks of x. X(us) is Output of our modal, X(ms) is output of Microsoft Cognitive Services (MCS), POP is post processing output of each modal. E1 is emotion of our modal, E2 is emotion of MCS, T is threshold, Conf is confidence score

layer. The convo layer and pooling layer together yield k feature-maps. k equals 32 in the current network design. The network growth rate is referred to as the hyper-parameter k. *To reduce sample feature detection in feature maps, pooling is necessary. By summing up the existence of features in feature map patches, pooling layers offer a technique for down sampling feature maps.* To facilitate down-sampling in our architecture, a batch normalization layer and 1×1 convolutional layer, followed by a 2×2 average pooling layer used at each transition layer. In our implementation work, we considered that each 1×1 convolution produce ~4k feature-maps.

The pooling operation draws attention to the characteristics that overlap with filters by swiping a 2-D filter across the 3-D feature-map. The result of the pooling will be (***(h - f+ 1)/ s * (w - f + 1) * c***), if a feature map with dimensions of w* h* c is provided. Here, the feature map's height and width are denoted by h and w, respectively. The channels shown in the feature map, the filter's size and stride length denoted by c, f and s respectively. Additionally, the convolutional layer's most noticeable feature is used by the layer in max-pooling to operate on the feature map. The sharpest features on the image are the best lower-level features of the image, which can be extracted with the use of max-pooling. In proposed architecture, before the first dense block operations, a 3*3 max pooling operation is deployed to extract the most prominent feature from the feature map.

When using average pooling, the layer chooses the mean values of the items present in the feature map patch. The entire feature map is basically down-sampled to the average value recorded by the feature map's region. Each Transition Layer in the design uses 2*2 Average Pooling to assess the average value recorded by the region of the feature map. So, the most apparent feature of any patch is thus revealed by max-pooling, whereas average pooling reveals the average of the covered region. Max and Average Pooling Operations represented as below in Fig. 8.

Table 2 Comparative Study of performance evaluation of proposed VEDANet Architecture with State-of-the arts

Datasets	Models	Accuracy (%)

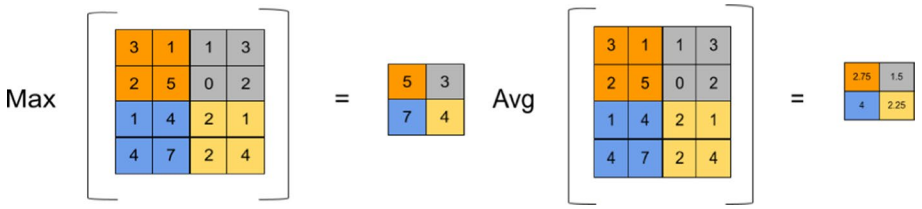

Fig. 8 Max pooling and average pooling operations

After receiving the input, each of the convo-block follow the further sequence as: Batch Normalization is followed by the ReLU activation function and the underlying Convo-2D layer.

Rectified Linear Unit (ReLU) activation is widely used in deep learning applications, and we adopted it for our work because of its many benefits. For newbies, the activation function f(x) is simply defined as the maximum value of the input x, making ReLU a computing juggernaut. Second, because it prevents saturation for high input values, ReLU eliminates the vanishing gradient problem that can hinder a network's ability to learn and effectively transmit gradients over several layers. In contrast, activation functions like the sigmoid or tanh could have to deal with this problem [48].

Additionally, deep networks benefit from ReLU's promotion of sparse representations. Keeping all negative activations at zero allows for just a subset of neurons to be active at once, which can help bring down the representation's complexity and simplify the model. The "dying ReLU" problem highlights a limitation of ReLU in which neurons might become locked in a "dead" state and fail to provide any output. To fix this, we first randomly sampled the weights from a normal distribution with mean 0 and standard deviation $\sqrt{\frac{2}{n {in} + n {out}}}$, where $n {in}$ and $n {out}$ are the input and output units for the layer.

Our architecture has four dense blocks, each has 2- convolutions with 1*1 and 3*3 sized kernels. Then, input is connected with the output tensor. And both of these convolutions will repeat for all the blocks (block-1:6times, block-2: 12times, Block-3: 24times and Block-4: 16times). Now, since the increasing number of channels can cause possible overfitting of the feature-map, we employ *Transition Layer* to cut-down the number of channels to half of the current channels. Then, we deployed the layer with 1*1 convolution and 2*2 Average Pooling Layer along with 2-Strides. Each of dense blocks are stacked with Transition Layers to make the model equably compact.

Later, till block-4, the output is structurally compact enough and hence, it is directly passed to classification layer as it's represented in Table 2 (VEDANet Architecture). In proposed architecture, at *Classification Layer,* the global average pooling layer averages each feature map and global max-pooling-layer extract maximum from each feature map then send the resulting vector (concatenation of both) direct into the softmax layer, *avoiding the possibility of overfitting*. Final output Layer as: FC Layer provides the emotion classification with respect to the input image X0 (128*128).

To further enhance our workflow for real-time live streams, we applied a hybrid approach to tap in potential of parallel processing, wherein we will parallelly assess our findings by taking advantage of another state-of-the-art cognitive service solution like, Microsoft Cognitive Services. In OTO layer we process the same input with Microsoft Cognitive Emotion Services and perform an attention-weighted average of the confidence scores to evaluate final confidence score (FCS). Further, we observed that if we tune the

threshold hyperparameter to be equal to 0.6 (i.e. T=0.6) the workflow achieves higher accuracy while classifying sub level classification predictions as inconclusive in turn decreasing the error rate at greater extent (~4-5%).

Finally, if the output of attention-weighted average is greater than the threshold (FCS >= T), we declare success. To assess the viability of our proposed model we also compared our model with SOTA benchmark datasets (AffectNet, FER2013, Yale, Google FEC) and Real- time live streaming.

3.3.1 Hardware GPU

The primary GPU used was NVIDIA RTX 4090 GPU with NVIDIA Ada Lovelace architecture and 24 GB of GDDR6X memory and a 384-bit memory interface. This configuration supports the 8-bit Float data type and contains Tensor Memory Accelerator (TMA) helpful for 8-bit matrix multiplication saving overhead of read/write indices.

4 Performance evaluation and comparative study

To evaluate the performance of the proposed architecture, the preferred evaluation matrices are Accuracy, Precision and F1-Score. Proposed Model proved the accuracy 87.30% on AffectNet dataset, 92.75% on Google FEC, 95.07% on Extended Yale Dataset and 90.53% on FER2013 dataset and 93.46 % on Real-Time Dataset respectively. The Confusion Matrix with respect to each benchmark datasets shown in Fig. 9. To measure how well a classification model does its job, statisticians create a Confusion matrix of size N by N, where N is the total number of classes being considered. The matrix evaluates the accuracy of the computational model's predictions vs the actual target values. Models with high TP and TN rates and low FP and FN rates are preferred.

Confusion matrices are the preferred metric for evaluating models when working with unbalanced datasets. The number of accurate and erroneous predictions produced by a classifier are summarized in a table called a confusion matrix. One uses it to evaluate how well a categorization model is doing its job.

Accuracy, precision, recall, and F1-score are just few of the performance indicators that may be calculated with this tool. Widespread use of confusion matrices can be attributed to their superiority over classification accuracy as a measure of a model's efficacy. For instance, in classification accuracy, we don't know how many cases were incorrectly labelled. Table 2 also shows a comparative study of the proposed working-model with current best practices. In this section, Table 3 represents the evaluated results of individual dataset's emotion classes with respect to the evaluation parameters accuracy, precision and F1-Score values.

From the Table 3, we can see that all emotion classes performed exceptionally well. If we look at the outcome of Fear and disgust, the performance of the model being a bit lower than other emotion classes, somehow, is related to the per instance physical ambiguity between the emotion classes. In human world, it is highly confusing to differentiate between the two emotions if one doesn't know the context of the dialogue resulting in those emotions. Nevertheless, in computational analysis this ambiguity is a result of low availability of defining state of the art datasets to train and improvise the model which in turn could possibly validate the contextual dependency to assess and segment these two emotions effectively.

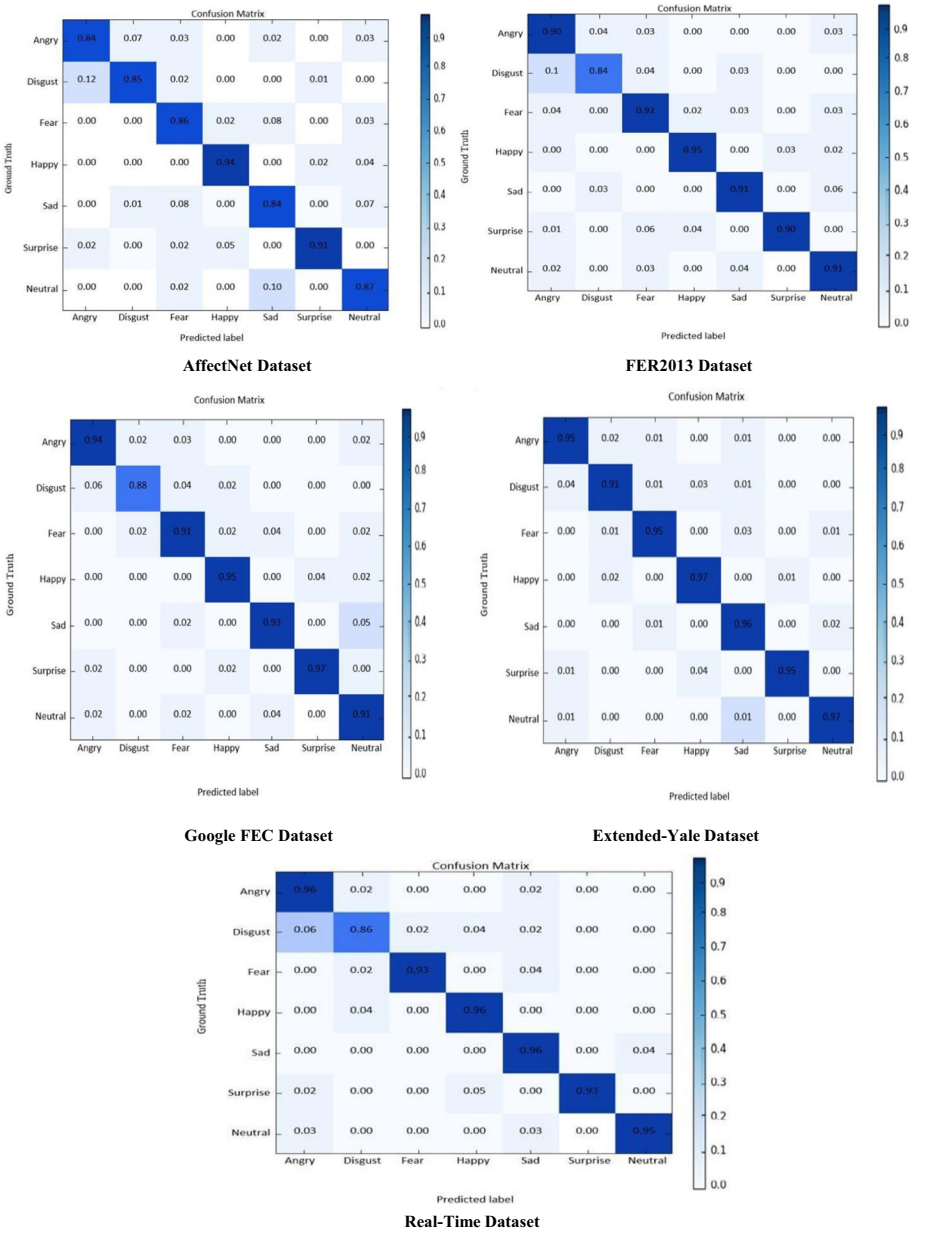

Fig. 9 Confusion matrices for affectnet, google FEC, extended yale, and real-time datasets

Accuracy is the classifier's prediction rate. The ratio of correct forecasts to total predictions. Unbalanced classes don't work with accuracy.

For unbalanced data, the model will predict that each point belongs to the majority class label, which is accurate but has drawbacks. The model is inaccurate. Achieving this level of accuracy is a hallmark of good prediction. For this reason, accuracy is

Table 3 Class wise (7 emotion classes) performance analysis of individual datasets (accuracy, precision and F1-score)

Emotion Classes (EC)		1	2	3	4	5	6	7	Overall
Datasets	Parameters	Anger	Disgust	Fear	Happy	Sad	Surprise	Neutral	Accuracy

	Recall	0.95	0.91	0.96	0.98	0.94	0.94	0.95	90.53%
	F1-Score	0.9	0.87	0.89	0.95	0.91	0.93	0.88	
	Accuracy	0.98	0.98	0.97	0.98	0.98	0.99	0.97	
Google FEC	Precision	0.92	0.95	0.89	0.95	0.93	0.97	0.88	92.75%
	Recall	0.97	0.93	0.95	0.97	0.96	0.98	0.95	
	F1-Score	0.93	0.91	0.9	0.95	0.93	0.97	0.89	
	Accuracy	0.98	0.98	0.99	0.99	0.99	0.99	0.99	
Yale-Face	Precision	0.94	0.93	0.96	0.94	0.94	0.99	0.96	95.07%
	Recall	0.98	0.95	0.96	0.99	0.98	0.97	98	
	F1-Score	0.95	0.92	0.95	0.96	0.95	0.97	0.96	
	Accuracy	0.98	0.97	0.99	0.98	0.98	0.99	0.99	
Real- Time	Precision	0.91	0.92	0.98	0.92	0.9	1	0.95	93.46%
	Recall	0.97	0.92	0.95	0.98	0.98	0.96	0.97	
	F1-Score	0.93	0.89	0.95	0.94	0.93	0.96	0.95	

a suitable criterion for assessing classification problems that do not involve an imbalance of classes. For classification issues when the classes are evenly distributed, such as when no class imbalance exists, accuracy is a suitable measure of performance that can be leveraged to the proposed work. Accuracy can be evaluated as follows:

$$\boldsymbol{Accuracy} = \frac{\boldsymbol{TP + TN}}{\boldsymbol{TP + TN + FP + FN}} = \frac{\boldsymbol{CorrectPredictions}}{\boldsymbol{TotalPredictions}}$$

Accurate prediction may be quantified by its degree of precision. In layman's terms, it informs us what fraction of all optimistic forecasts come true. Precision should be exceptionally good (ideally 1). For situations where avoiding false positives is more important than avoiding false negatives, precision might be a helpful statistic. Classifying genuine emotions requires a high degree of precision. Precision can be evaluated by using below equation:

$$\boldsymbol{Precision} = \frac{\boldsymbol{TP}}{\boldsymbol{TP + FP}} = \frac{\boldsymbol{ActuallyPositvePredictions}}{\boldsymbol{TotalPositivePredictions}}$$

When both the number of false-positive and false-negative results matter, utilise the F1-Score. To evaluate Uneven Data, the F1-Score is more appropriate which can be evaluated as follows (Figs. 10 and 11):

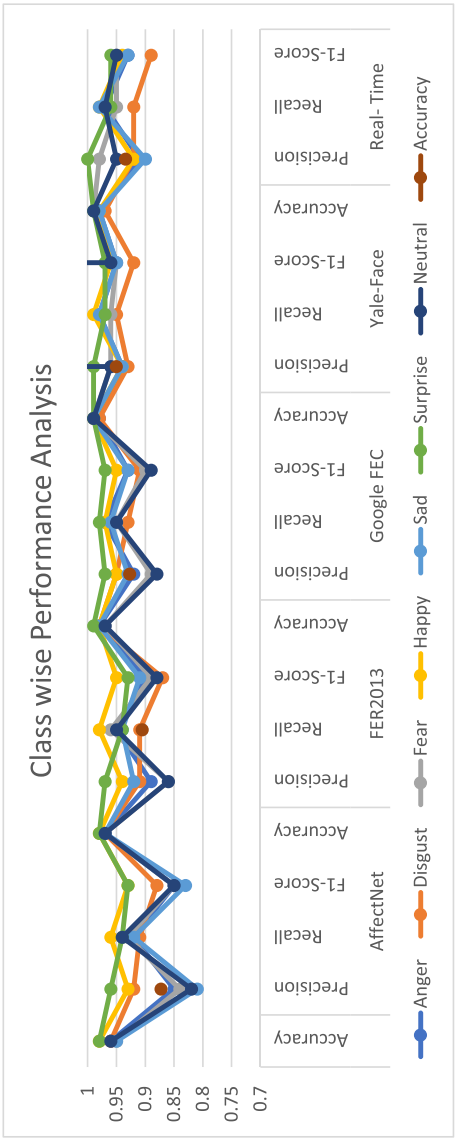

Fig. 10 Classwise emotion analysis of benchmark datasets

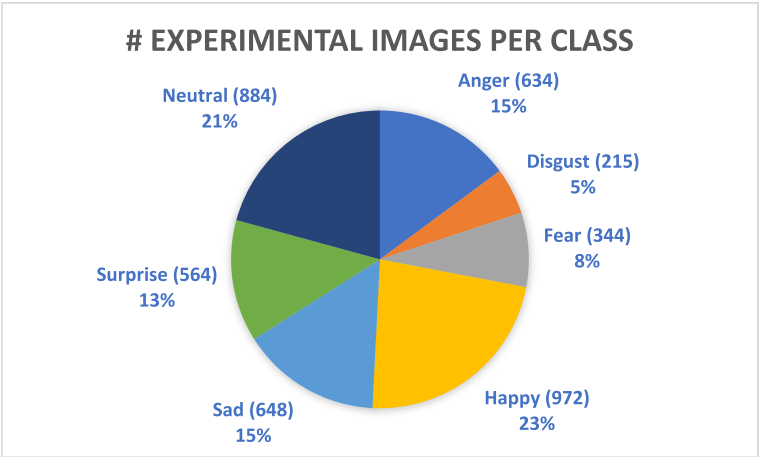

Fig. 11 Analysis of experimental images per emotion class

$$F1Score = 2 * \frac{Precision * Recall}{Precision + Recall}$$

5 Discussion

In this study, we introduced VEDANet, a novel deep learning architecture designed to significantly enhance visual emotion analysis. The core innovation of VEDANet lies in its One-To-Many (OTO) layer, a unique component that optimally maps single facial images to a spectrum of emotional states, acknowledging the complexity and subtlety of human emotions. This section delves into the methodology's effectiveness, the architectural novelties of VEDANet, its comparison with existing benchmarks, potential applications, limitations, and directions for future research.

5.1 Effectiveness of the methodology

VEDANet has demonstrated remarkable effectiveness in enhancing visual emotion analysis across various datasets, including both controlled and in-the-wild settings. The architecture's ability to learn deep, nuanced representations of facial emotions results in significantly improved accuracy rates in emotion detection tasks. The OTO layer, in particular, addresses the challenge of capturing the multiplicity of human emotions expressed even in a single instance, enabling a more refined and accurate emotion analysis.

5.2 Architectural innovations

The architectural innovations of VEDANet, especially the OTO layer, play a pivotal role in its success. This layer employs a sophisticated mechanism to disentangle the intricate

patterns of emotional expressions, allowing for a more precise classification of complex emotional states. It acts by expanding the conventional one-to-one mapping paradigm of emotion recognition into a more flexible one-to-many framework, thus capturing a broader range of emotional nuances from visual cues.

Comparative analysis with existing benchmarks indicates that VEDANet outperforms prior models in various aspects, particularly in terms of accuracy and robustness. While traditional models often struggle with the subtlety and variability of emotional expressions, especially in less controlled environments, VEDANet's architecture, leveraging the OTO layer, demonstrates superior performance. It effectively reduces the gap between controlled laboratory settings and real-world applications, a longstanding challenge in the field of emotion recognition.

5.3 Potential applications

The implications of VEDANet's advancements are vast, impacting several fields where emotion recognition is crucial. In healthcare, for example, VEDANet could enhance patient care by providing real-time emotional analysis, aiding in the diagnosis and treatment of psychological conditions. In the automotive industry, emotion recognition can improve safety by monitoring drivers' states and preventing accidents caused by drowsiness or stress. Moreover, in customer service, understanding customer emotions through visual cues can lead to more personalized and effective interactions.

5.4 Healthcare and mental health monitoring

As the work uses cognitive neural assessment of image sequences to determine human behavior [49]. Exploring another avenue is an interesting approach to analyze bosom malignancy by assessment of mammograms using machine learning [50]. Further [51] study proposes a game for development of emotional and social skills in differently abled autistic people. VEDANet can be employed to develop tools for psychologists and psychiatrists to monitor patients' emotional states, providing valuable insights into their mental health and progress over time. In telehealth platforms, it can assist therapists by offering an additional layer of emotional context during virtual sessions, enabling better assessment and treatment plans for conditions like depression or anxiety.

5.5 Education and e-learning

In the educational sector, VEDANet can be integrated into e-learning platforms to gauge students' emotional responses to different learning materials. This emotional feedback can help educators tailor content delivery, ensuring it resonates positively with students, thereby improving engagement and learning outcomes. Furthermore, it can assist in identifying students who may be struggling with stress or frustration, allowing for timely intervention.

5.6 Customer service and market research

VEDANet has the potential to revolutionize customer service by enabling more empathetic interactions between service agents and customers. By analyzing customers' emotional

states during service interactions, companies can adjust their communication strategies in real time, leading to improved customer satisfaction. In market research, VEDANet can analyze consumer reactions to products or advertisements, providing valuable insights into consumer preferences and behaviors.

5.7 Entertainment and media

In the entertainment industry, VEDANet can be used to test audiences' emotional responses to movies, TV shows, or video games, helping creators fine-tune their content for maximum emotional impact. Additionally, it could enhance interactive media experiences by adjusting content dynamically based on the user's emotional state, creating more immersive and personalized entertainment experiences.

5.8 Smart home and IoT devices

Smart home devices and IoT systems can leverage VEDANet to become more responsive to users' emotional and psychological needs. For example, a smart home system could adjust lighting, music, and temperature based on the occupants' mood, creating a more comfortable and supportive living environment.

5.9 Automotive industry

In the automotive sector, VEDANet can enhance driver safety by monitoring drivers' emotional states and alertness levels, providing warnings or taking corrective actions (like limiting the vehicle's speed) when necessary. It can also improve the overall driving experience by adapting vehicle settings and entertainment options according to the driver's mood.

5.10 Limitations and future research directions

While VEDANet introduces significant advancements in visual emotion analysis, it is not without limitations. One of the primary concerns is dataset biases, which can impact the model's ability to generalize across different demographics and cultural contexts. Additionally, while VEDANet excels in analyzing visual data, human emotions are complex and can be influenced by a multitude of factors beyond facial expressions.

Future research could explore integrating multimodal data (such as audio, textual, and physiological signals) with VEDANet to create a more comprehensive understanding of emotions. This could involve developing hybrid models that can analyze and interpret signals from multiple sources simultaneously. Another promising direction is exploring unsupervised or semi-supervised learning approaches to overcome the challenges of dataset biases and limited labeled data, potentially enabling VEDANet to learn from a broader range of emotional expressions and contexts.

By addressing these limitations and exploring these future research directions, VEDANet can evolve into an even more powerful tool for emotion recognition, with widespread applications across various domains where understanding human emotions is vital.

VEDANet represents a significant leap forward in the field of visual emotion analysis, offering innovative solutions to longstanding challenges. By emphasizing architectural innovations like the OTO layer, VEDANet not only achieves high accuracies across

varied datasets but also opens new avenues for real-world applications of emotion recognition technology. While acknowledging its current limitations, the proposed future research directions highlight the potential for further advancements, paving the way for more accurate, adaptable, and comprehensive emotion recognition systems.

6 Conclusion and Possible Future Directions

In this work, we introduce VEDANet, a robust and efficient architecture designed for the nuanced task of facial expression detection and analysis in both still images and video sequences. Leveraging the power of Transfer Learning, our approach excels in automatically extracting distinctive facial features, crucial for accurate emotion recognition. The integration of hybrid pre-trained Deep Convolutional Neural Network (DCNN) models significantly enhances our system's performance, as evidenced by our comprehensive experimental analysis across several esteemed datasets, including FER2013, AffectNet, Google FEC, and Yale emotion datasets.

The VEDANet architecture sets a new benchmark in emotion recognition accuracy, achieving an impressive 87.3% on AffectNet, 92.7% on Google FEC, 95.0% on Yale, 90.5% on FER2013, and 93.4% in real-time video analysis. These results are attained through the strategic application of the Top Optimization Layer (OTO-Layer), which meticulously fine-tunes the hyperparameters of each pre-trained model to focus on the salient facial features present in each image. This meticulous attention to detail ensures that VEDANet not only outperforms existing state-of-the-art techniques but also addresses some of the limitations observed in previous models, such as misclassifications under normal conditions and challenges in interpreting complex facial expressions.

The practical implications of our study extend far beyond the laboratory, offering valuable contributions to various commercial and industrial applications. For instance, the deployment of VEDANet in patient monitoring systems within healthcare facilities can provide caregivers with real-time, non-intrusive insights into patient emotional well-being, enhancing patient care and support. Similarly, in the realm of security and surveillance, VEDANet's ability to accurately analyze facial expressions in real-time can enhance threat detection and response mechanisms, ensuring safer public and private spaces.

Furthermore, the foundation laid by our study in facial emotion detection and analysis opens up exciting avenues for incorporating additional modalities, such as body language and auditory signals, to create a more holistic approach to emotion recognition. Such multimodal emotion detection systems could revolutionize a myriad of industries, from enhancing user experience in consumer electronics to providing deeper audience insights in marketing and entertainment.

In conclusion, VEDANet represents a significant advancement in the field of emotion recognition, combining high accuracy with real-world applicability. Our research not only sets new standards in facial expression analysis but also paves the way for future innovations in multimodal emotion detection, promising to unlock new dimensions in human-computer interaction.

Data availability The datasets generated during and/or analysed during the current study are available in the respective repositories as followed: 1. Affectnet [http://mohammadmahoor.com/affectnet/]. 2. FER2013 [https://www.kaggle.com/c/challenges-in-representation-learning-facial-expression-recognition-challenge/data] 3. VRFNet-ASLiT: Fused Deep CNN and Adaptive Super Resolution Transform Based Hand Gesture Recognition

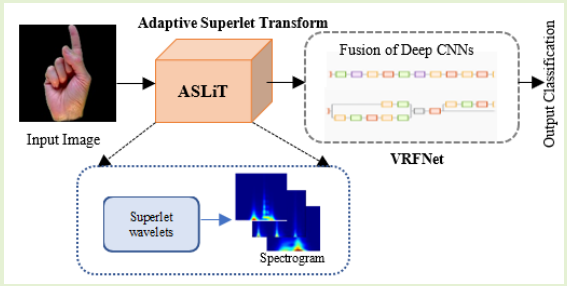
Roli Kushwaha, Manjeet Kumar*, Dinesh Kumar

***Abstract*— Hand gesture recognition plays a vital role in human-computer interaction, offering a natural and intuitive means of communication. However, vision-based hand gesture recognition is sensitive to variations in lighting conditions and may face challenges in accurately distinguishing between similar gestures or subtle variations in hand. To address this concern, a hybrid deep Convolutional Neural Network (CNN) model which is the fusion of VGG19 and ResNet50 ($VRFNet$) is proposed to encapsulate the intricacies of subtle variations or infrequent gestures. The proposed method incorporates the Adaptive Super Resolution Transform ($ASLiT$) technique to generate the high-resolution time-frequency representation of input images and $VRFNet$ effectively classify the different hand gestures. The proposed method is tested on LeapGestRecog dataset, Modified National Institute of Standards and Technology (MNIST) digits dataset and American Sign Language (ASL) digits and provides a recognition accuracy of 99.97%, 99.6% and 98.8%, respectively. In addition to the proposed $VRFNet$ model, the comparison of the performance with other two other models: AlexNet, VGG19 is also presented. The results reveal that $VRFNet$ model exhibits exceptional performance in hand gesture recognition tasks with improved precision of 99.83%, 99.64%, 99.05%, recall of 99.86%, 99.62%, 99.85% and F1 score of 98.85%, 99.63%, 98.96%, respectively, across the LeapGestRecog, MNIST, and ASL digits dataset. These results underscore the model's remarkable accuracy in recognizing hand gestures within diverse datasets. The proposed $VRFNet$ model is also competitively, comparable to other state-of-the-art hand gesture recognition techniques. Furthermore, an ablation study is conducted to analyze the impact of individual models for hand gesture recognition.**



***Index Terms*— Adaptive Superlet Transform, AlexNet, VGG19, ResNet50, Hand Gesture Recognition, Human Computer Interaction, Multiclass classification.**

I. Introduction

GESTURES play a crucial role in facilitating communication between humans and machines [1]. It allows users to convey commands, instructions, or intentions. The most used gestures of body for communication with machines is through intuitive hand gestures which enables a more natural and expressive form of communication with technology. Effective human-computer communication (HCI) can be achieved through various techniques such as machine learning [2], deep learning [3], reinforcement learning [4]. In comparison to other approaches, traditional machine learning relies on human feature engineering, limiting its ability to detect complex patterns in hand gesture images [2]. Reinforcement learning often relies on trial-and-error exploration, which is inefficient for high-dimensional tasks like image analysis [4]. Among these approaches, deep learning offers distinct advantage of automatically learn and extract complex patterns from data, making it an appropriate choice for the research. Convolutional Neural Networks (CNNs) are mostly used deep learning models particularly well-suited for image-based tasks, making them highly applicable for analyzing hand gesture images [5]. The recognition of hand gestures can be done using image-based analysis method or surface Electromyography signals (sEMG) based analysis method. The image-based analysis of hand gestures is preferred over employing sEMG due to the unique advantages of visual information, resistance to variability, natural representation, and the accessibility of large-scale datasets and provide a more thorough and robust method for hand gesture identification [6]. These advantages make image-based analysis a preferred choice over sEMG for many applications in human-computer interaction and gesture recognition.

Image-based analysis methods like deep learning have made it possible to extract significant features and patterns from images of hand gestures. In case of dynamic hand gestures, temporal variation plays a cruical role, thereby integrating image-based analysis with transform-based techniques to

examine the frequency characteristics of hand that enables the detection of temporal variations and dynamic nature of gestures [7]. Additionally, the time-frequency representation obtained through transform-based techniques [7]-[9] provides valuable insights into the temporal dynamics and rhythm of the gestures.

Existing transform-based techniques, such as Short-Time Fourier Transform (STFT) [7], which provides fixed time and frequency resolution, Adaptive Wavelet Transform (AWT) [9], adapting wavelet basis functions but potentially sacrificing resolution due to its susceptibility to noise and computational complexity, and Continuous Wavelet Transform (CWT) [8], offering superior time-frequency resolution through continuous wavelet scale variation but sacrificing frequency resolution due to variable scaling, often do not meet the high-resolution in both time and frequency simultaneously. To address this issue, a Super Resolution Transform (Superlet or SLT) was introduced by Moca et al. [10] [11] which provides high-resolution in both time-domain and frequency-domain. Thus, in order to obtain outstanding recognition accuracy of hand gestures, the proposed methodology incorporates hybrid deep CNN called $VRFNet$ including Adaptive Super Resolution Transform (ASLT) for hand gesture images called $ASLiT$ which offer valuable insights into the temporal dynamics and rhythm of the gestures.

The main contributions can be summarized as follows:

1) A hybrid hand gesture classification network $VRFNet$ is proposed. $VRFNet$ is a fusion of two deep CNN models namely ResNet50 and VGG19. The proposed hybrid model has the ability to extract high-level discriminative features from images which produces more precise predictions.
2) The proposed model leverages $ASLiT$ that transform input images into a time-frequency representation, enabling the model to achieve outperforming classification results of hand gestures.
3) Extensive experiments are conducted on multimodal dataset: LeapGestRecog (infrared images), MNIST digits (gray-scale images) and American Sign Language (ASL) digits (RGB images) to validate the efficiency and efficacy of the proposed model.
4) Further, an ablation study is also carried that justifies the performance effectiveness of the proposed methodology.

The organization of the rest of the paper is as follows: Section II discusses about the different state-of-the-art models for $ASLiT$ and hand-gesture recognition. Section III introduces proposed methodology including brief of $ASLiT$ and proposed $VRFNet$ deep CNN model-based recognition. The results of the simulations and discussion are presented in Section IV. Lastly, Section V presents the conclusions and future scope of this paper.

II. Related Works

This section provides the details of the previous works done for hand gesture recognition and ASLT in signal processing.

A. Hand Gesture Recognition

In this section, the related works that have focused on hand gesture recognition, specifically considering the utilization of deep CNN models are explained. Park et al. [12] employed a two-stage serial CNN model and a double parallel CNN model for the classification of hand gestures and two-dimensional fast Fourier transform for converting time-domain hand gestures to frequency-domain, resulting in a faster and more accurate model. Damaneh et al. [13], presented a CNN, Gabor filter, and Oriented Fast and Rotated Brief (ORB) feature descriptor based static hand gesture recognition network by merging extracted features into one feature vector resulting in enhanced resistance to uncertainties like rotation and ambiguity in hand gestures. In [14], researchers introduced HyFinet, a lightweight portable network with 2.3 million parameters, for hand gesture classification. It utilized multi-scale refined edge extraction and hybrid feature attention blocks, enhancing recognition accuracy with lower computational cost. Static hand gesture recognition, utilized EMG signals from three sensors by extracting time domain features and employing linear discriminant analysis is presented in [15]. For sEMG-based gesture recognition, a recursive neural network (RNN) architecture with six different types of images as an input and an attention-based CNN were discussed in [16]. Numerous studies also suggest gesture classification methods by converting sEMG signal to 2-D and then applying deep learning models for classification [17]-[19]. The majority of recent research on hand gesture recognition focuses on identifying static hand gestures. However, dynamic gestures are more natural and user-friendly for being employed as an alternative input modality in HCI applications. In [20], Tripathi et al. presented a dynamic hand gesture recognition model based on 2D CNN using EMG signals which are transformed into time–frequency representations using STFT and CWT. A multi-stream residual network was proposed by Yang et al. [21] for the classification of six dynamic gestures involving the complete hand movement based on sEMG data. Various researches are based on multimodal fusion for hand gesture recognition [22] [23]. In [22], gesture recognition based on Multimodal Fusion Hierarchical Self-Attention Network was employed that combines features from different modalities with skeleton features using self-attention blocks at multiple hierarchical levels. Rastgoo et al. [23], presented transformer based zero-shot dynamic hand gesture recognition by fusing deep features with skeleton based features extracted by 3D CNN.

B. Adaptive Superlet (ASLT) in Signal Processing

ASLT is widely used in different areas of signal processing; biosignals like Electrocardiogram (ECG) and Photoplethysmogram (PPG) in medical field [24]-[30], in industries like faults in bearings of motor in the form of vibration signals [31]-[34]. Tripathi et al. [24] utilized the ASLT to convert the 1-D ECG signal into a 2-D time-frequency spectrogram, which served as input to deep learning pre trained classifiers. In [25], heart rate (HR) monitoring was presented by Pankaj et al. using PPG signal by utilizing a multiorder super resolution transform (SLT) to separate motion artifacts from the acquired PPG signal resulting in detection of high-intensity lobes in the spectro-temporal representation of the SLT spectrogram. Bhatt et al. [26], introduced a method to identify Parkinson's disease by combining the Superlet Transform with Deep Neural Networks in order to get high-resolution time-frequency spectrogram. Tripathi et al. [27], presented a

technique for identifying seizure and non-seizure events using the superlet transform and a deep convolutional neural network. VGG-19. In [31], authors provided an ASLT methodology for fault by surpassing the s-transform in terms of both time and frequency resolution for fault identification in power systems. In [32], Mitra et al. introduced a fusion method incorporating the time-frequency characteristics of vibration signals using wavelets' super resolution property and a 2-D-CNN. Yi et al. [33], exhibited the novel method called High-order Synchrosqueezing Superlets Transform by demonstrating time frequency representation of vibration signals in mechanical transmission components under variable speed conditions.

Based on the notable performance of ASLT in signal processing domains, it provides a strong foundation for exploring its potential in image processing. Therefore, the proposed research incorporates the *ASLiT* in hand gesture recognition approach and aims to achieve higher recognition accuracy and performance.

III. Proposed Methodology

This section discusses the proposed methodology which utilizes *ASLiT* for images and an improved version of deep CNN. The proposed methodology aims to enhance the quality of images by using *ASLiT* and generating high-resolution spectrogram by effectively capturing fine-grained features. The classification of different gestures is performed by an improved version of CNN (*VRFNet*), thereby outperforming with existing hand gesture recognition system in terms of recognition accuracy.

A. Adaptive Superlet Transform for Images (ASLiT)

ASLiT is a modified version of Morlet transform, which provides high-resolution in localization of both time and frequency simultaneously unlike STFT [7], AWT [9] and CWT [8]. STFT segments signals for Fourier Transform, but fixed window sizes compromise capturing both high and low frequencies simultaneously, affecting frequency-temporal resolution. AWT adapts wavelet basis functions based on signal characteristics, offering flexibility but potentially sacrificing resolution due to its susceptibility to noise and computational complexity, making it less ideal for capturing rapidly changing features whereas CWT offers variable time-frequency resolution across frequencies, providing good temporal resolution at higher frequencies by compressing or dilating a mother wavelet based on frequency variations but sacrificing frequency resolution. To address this concern, SLT is introduced by Moca et al. [10] [11] to attain precise localization of both time and frequency concurrently. SLT utilizes a set of wavelets with increasingly constrained bandwidth. The use of multiple wavelets enables the localization of oscillations in time-frequency plane is improved than using single wavelet. SLT employs Morlet wavelet that is a complex-valued wavelet, derived from a Gaussian function modulated by a complex sine wave, thus making it well-suited for analysing non-stationary signals with time-varying frequencies.

The mathematical expression of mother wavelet in Morlet wavelet is shown in equation (1).

$$\psi_{fc,r}(t) = \frac{1}{T_r\sqrt{2\pi}} e^{-\frac{t^2}{2T_r{}^2}} e^{j2\pi f_c t} \quad (1)$$

where, fc is central frequency, T_r is time spread parameter (in seconds) and T_r which depends on number of base cycles r, standard deviation (SD) and fc as given by eq. 2. It determines the width of the time-domain representation of the wavelet. A larger T_r leads to a broader time-domain representation, which can capture lower-frequency components.

$$T_r = \frac{r}{SD \times f_c} \quad (2)$$

In addition to the 1D Morlet transform, there is also a 2D Morlet transform that extends the concept to analyze 2D signals such as images [12]. By convolving an image with the 2D Morlet wavelet at different scales and orientations, results in a time-frequency representation of the image. The expression of the 2D Morlet transform is shown:

$$\psi_{f_c,r}(x,y) = \frac{1}{T_r\sqrt{2\pi}} e^{\left(-\frac{x^2+y^2}{2T_r^2}\right)} e^{j2\pi f_c(x+y)} \quad (3)$$

where, $\psi_{f_c,r}(x,y)$ represents the 2D Morlet wavelet at spatial coordinates (x,y), fc is the central frequency of the wavelet in the x and y directions corresponding to the pixel positions, respectively, (x^2+y^2) shows how the pixel values of an image are affected by the Gaussian envelope and $(x+y)$ shows the spatial variation in the sinusoidal modulation across the image.

The Morlet wavelet's fixed shape and size limit its ability to capture diverse features in complex images, leading to less accurate localization and representation. It also struggles to effectively capture frequency content across image regions [14] [34], hindering precise time-frequency localization and fine-scale temporal variation capture. To overcome this limitation, SLT approach can be employed [13]. This approach involves using multiple Morlet wavelets with varying scales to analyze the image at different frequency resolutions. By adaptively selecting the appropriate scale for each image region, the spectrogram can better capture the frequency content and temporal variations across different scales, results in generating high-resolution spectrograms [11]. The mathematical expression of SLT based time-frequency analysis of images is:

$$SLiT_{f_c,M} = \{\psi_{f_c,r_x r_y} | r_x = r_1, r_2, \ldots r_M \; and \; r_y = r_1, r_2, \ldots r_M \quad (4)$$

where, $SLiT_{fc,M}$ represents the SLT that is obtained by set of 2D wavelets of images using order (number of wavelets) of M with varying the scale parameters (number of cycles for each wavelet) r_x and r_y within a range of $r_1, r_2, \ldots r_M$, $\psi_{fc,r_x r_y}$ represents the 2D wavelet at scale (r_x, r_y) and frequency f_c, r_x denotes the scale parameter in the x direction, while r_y denotes the scale parameter in the y direction, $r_1, r_2, \ldots r_M$ represent the range of scales (number of cycles) to be considered in both the x and y spatial coordinates.

$SLiT_{f_c,M}$ (SLiT) is also a measure that represents the geometric mean of the individual wavelet responses in the set defined by eq. (5). In other words, the SLiT combines the responses of multiple wavelets $R[SLiT_{fc,M}]$ at different scales using a geometric mean [11].

$$R\left[SLiT_{f_c,M}\right] = \sqrt[M]{\prod_{i=1}^{M} R[\psi_{f_c, r_{x_i}, r_{y_i}}]} \quad (5)$$

$R[\psi_{f_c, r_{x_i}, r_{y_i}}]$ is the response of i_{th} wavelet at frequency f_c and

This article has been accepted for publication in IEEE Sensors Journal. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/JSEN.2024.3424855

scale r_{x_i}, r_{y_i} is evaluated at the position (x_i, y_i) in the image I.

$$R\left[\psi_{fc,r_{x_i},r_{y_i}}\right] = \sqrt{2} \cdot I(x,y) * \psi_{fc,r_{x_i},r_{y_i}} \quad (6)$$

where $I(x,y)$ is an image and $*$ is the complex convolution operator. By calculating $R[SLiT_{fc,M}]$, a single value that represents the combined response of the SLiT across multiple scales and positions, summarizing the frequency content and spatial variations within the image at the specified frequency *fc* is obtained.

There are two ways to select number of cycles for each wavelet (r_{x_i}, r_{y_i}) explained in [13] viz. multiplicatively or additively where, $(r_{x_i}, r_{y_i}) = i \,.\, r_{x_1} r_{y_1}$ and $(r_{x_i}, r_{y_i}) = \{(r_{x_1} + i), (r_{y_1} + i)\} - 1$ for $i = 2, \ldots, M$) respectively. If the order of SLiT is fixed, then it can cause increase of wavelet bandwidth while increasing frequency. To recompense this issue, Adaptive SLiT ($ASLiT$) is designed which can adjust its order (M) to the central frequency (f_c). It works with low order for low frequencies and as frequency increases, it increases its order to provide enhanced time-frequency representations [11]. The process of increasing order is dependent on frequency as given by eq. (7).

$$ASLiT_{f_c} = SLiT_{f_c,M} | M = N(f_c) \quad (7)$$

where, $N(f_c)$ represents a function that increases in a consistent manner as the central frequency (f_c) increases. One straightforward approach is to select the order in a linear fashion, where the order increases proportionally with the central frequency given by eq. 8

$$N(f_c) = M_{min} + \left[(M_{max} - M_{min}).\frac{f_c - f_{c_{min}}}{f_{c_{max}} - f_{c_{min}}}\right] \quad (8)$$

where, M_{min}, M_{max} are the orders corresponding to smallest central frequency $f_{c_{min}}$ and largest central frequency $f_{c_{max}}$. $ASLiT$ generates high-resolution spectrogram for wide range of frequencies, thereby the proposed methodology utilizes the power of $ASLiT$ for hand gesture recognition.

B. Hand gesture Classification Network

The proposed methodology for hand gesture classification utilizes the power of $ASLiT$ that is employed to enhance the time-frequency representation of input images. This enhancement step plays a crucial role in mitigating the negative effects of low-resolution images on the accuracy of hand gesture recognition. Additionally, we incorporate an improved version of CNN into the proposed methodology which is hybrid model consisting of fusion of VGG19 and ResNet50. By concatenating the features learned by different models, the hybrid model can benefit from the strengths of each model and potentially achieve better overall performance. This enhanced CNN architecture is specifically designed to handle the high-resolution spectrogram generated by the $ASLiT$. The block diagram of the proposed methodology is shown in Fig. 1. The model inputs the infrared, gray-scale and RGB images from datasets named LeapGestRecog, MNIST digits and ASL digits dataset, respectively. The images are transformed into time-frequency representation using $ASLiT$ by taking the geometric mean of the responses of multiple wavelets as shown in eq. (5).

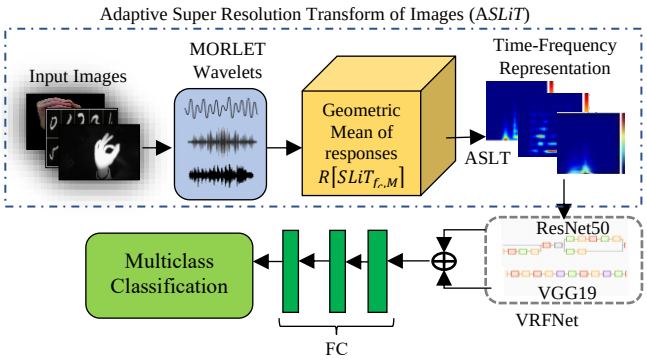

Fig. 1. Block diagram representation of the proposed $VRFNet$ based hand gesture recognition model.

The process of obtaining geometric mean results in generating high-resolution spectrograms.

The spectrograms of each dataset are saved which are further used to train the deep learning model $VRFNet$. The $VRFNet$ is the fusion of VGG19 and ResNet50 after concatenation of fully connected layers of both models. The output of the final max pooling layer of the VGG19 architecture is selected and the selected features are then fed into a new 1×1024 Fully Connected (FC) layer with ReLU activation function. Similarly, the output of the final average pooling layer of the ResNet50 architecture is taken and the features are fed into a separate 1×1024 FC layer with ReLU activation. To fuse the features generated from the VGG19 and ResNet50 architectures, a new 1×2048 FC layer is added. Additionally, a 1×512 FC layer is employed to extract more prominent features. Finally, the final classification task is performed using a 1×10 FC layer with SoftMax activation function as shown in Fig. 2.

Different hyperparameters selected for the proposed model are optimizer 'rmsprop', learning rate '0.00001', epochs '40', batch size '32', loss function 'categorical cross entropy', validation frequency '20'. The categorical cross entropy loss measures the losses for multiclass classification:

$$CEL = -\frac{1}{N_i}\sum_{n=1}^{N_i}\sum_{c=1}^{C_l}(T'_{nc}\, ln(I_{nc}) + (1 - T'_{nc})\, ln(1 - I_{nc})) \quad (9)$$

where N, T', I, and C_l represents number of observations, target input image set, number of observations and number of classes respectively. The categorical cross entropy loss function reduces training and testing loss. The algorithm for the proposed model for classification of different gestures using $ASLiT$ and $VRFNet$ is presented as Algorithm 1.

C. Datasets Used

Three different datasets are used for evaluating the performance of the proposed model. These datasets contain variety of images (multimodal); infrared, grayscale and RGB images.

The 'LeapGestRecog' dataset [35] [36] is a collection of 10 distinct hand gestures generated with 20,000 infrared images of 640×240 pixels, taken with the Leap Motion sensor. The different gestures include; Palm, Fist, Fist Moved, Thumb, Index, OK, Palm_moved, Down, C letter, and L letter constitute the hand motions in the collection. The MNIST digit dataset [37] [38] consists of 70,000 grayscale images of 28×28 pixels for handwritten digits, with 60,000 images for training and 10,000 images for testing for class 0 to 9.

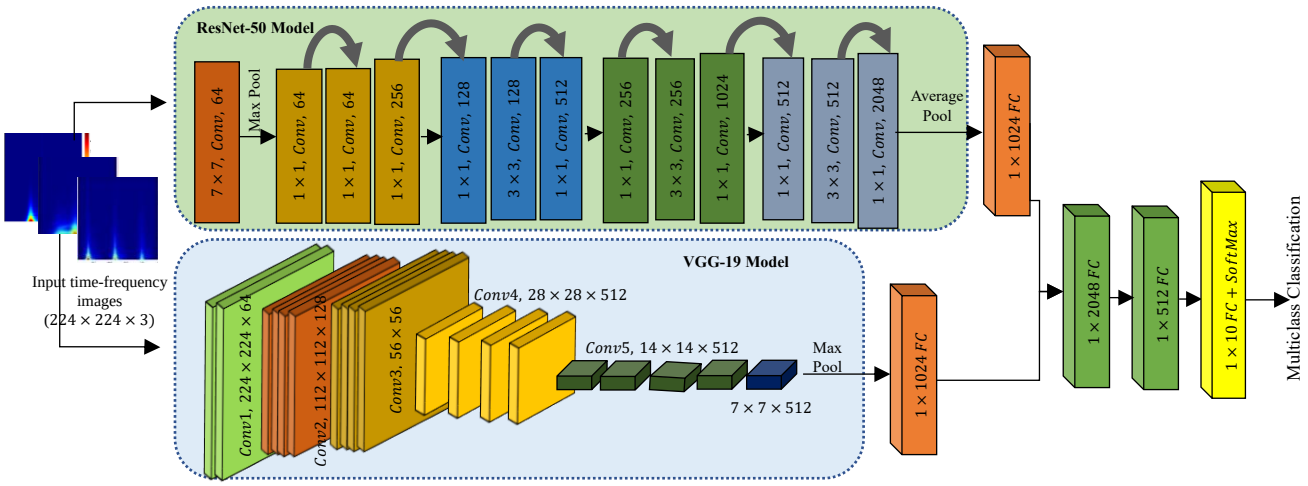

Fig. 2. Architecture of the proposed $VRFNet$ for hand gesture classification.

The ASL digit dataset [39] [40] is a collection of 5000 images of size 400 × 400 pixels that represent the numbers 0 to 9 in ASL. Some sample images of each dataset are shown in Fig. 3.

In order to visualize the datasets, t-SNE plots are presented in Fig. 4 (a), (b), and (c) for the three datasets. The t-SNE plots effectively capture the inherent structure and clustering of the datasets, enabling the observation of patterns and relationships among the data instances.

IV. Results and Discussions

In the proposed methodology, the utilization of the $ASLiT$ for generating high-resolution spectrogram followed by hybrid model $VRFNet$ for the classification of hand gesture. The high-resolution spectrograms of the datasets; LeapGestRecog, MNIST digits, and ASL digits datasets are shown in Fig. 5 (a), (b), (c), respectively.

The performance of the proposed methodology was evaluated by measuring the Accuracy (A_c), Precision (P_r) Recall (R_l) and F1 score (F_s) as shown in eqs. (10)-(13), respectively.

Algorithm 1 Proposed $ASLiT$ based hand gesture classification using $VRFNet$

Input: Images (Infrared, Gray, RGB), $I(x, y)$
Output: Classification of 10 classes (0-9 digits, 10 gestures), Accuracy (A_c), Precision (P_r), Recall (R_l), F1 score (F_s)

START

1. Convert input images into spectrograms using $ASLiT$:
2. Select mother wavelet:

$$\psi_{f_c,r}(x,y) = \frac{1}{T_r\sqrt{2\pi}} e^{\left(-\frac{x^2+y^2}{2T_r^2}\right)} e^{j2\pi f_c(x+y)}$$

3. Generation of spectrogram: $SLiT_{f_c,M} = \{\psi_{f_c,r_x r_y} | r_x = r_1, r_2, \ldots r_M \text{ and } r_y = r_1, r_2, \ldots r_M\}$
4. Multiplicative Spectrogram: $R\left[SLiT_{f_c,M}\right] = \sqrt[M]{\prod_{i=1}^{M} R[\psi_{f_c,r_{x_i},r_{y_i}}]}$

where, $R\left[\psi_{f_c,r_{x_i},r_{y_i}}\right] = \sqrt{2} \cdot I(x,y) * \psi_{f_c,r_{x_i},r_{y_i}}$

5. Apply $(ASLiT)$ with order (M) and central frequency (f_c) : $ASLiT_{f_c} = SLiT_{f_c,M} | M = N(f_c)$
6. Generated spectrogram by geometric mean of modified spectrogram of individual wavelets are used for training the $VRFNet$.
7. Prepare X_train, Y_train, X_test, Y_test
8. INITIALISE $VRFNet$
9. Train the $VRFNet$ by using X_train, Y_train
10. Compute the categorical cross-entropy loss (CEL) based on the predicted and true labels

$$CEL = -\frac{1}{N_i}\sum_{n=1}^{N_i}\sum_{c=1}^{C_l}(T'_{nc}\, ln(I_{nc}) + (1 - T'_{nc})\, ln(1 - I_{nc}))$$

11. Classification by X_test, Y_test.
12. Compute A_c, P_r, R_l, F_s

END

$$Accuracy\ (A_c) = \frac{(TP + TN)}{(TP + TN + FP + FN)} \times 100 \quad (10)$$

$$Precison\ (P_r) = \frac{TP}{TP+FP} \times 100 \quad (11)$$

$$Recall\ (R_l) = \frac{TP}{TP+FN} \times 100 \quad (12)$$

$$F1\ Score\ (F_s) = 2 * \frac{(Precision * Recall)}{(Precision + Recall)} \times 100 \quad (13)$$

where, TP denotes true positives, TN denotes true negatives, FP is false positive, FN is false negative outcomes.

The results revealed promising outcomes, with recognition accuracies of 99.97% with the LeapGestRecog, 99.6% using MNIST digits, and 98.8% with the ASL digits dataset as shown by the confusion matrix in Fig. 6 (a), (b), (c), respectively.

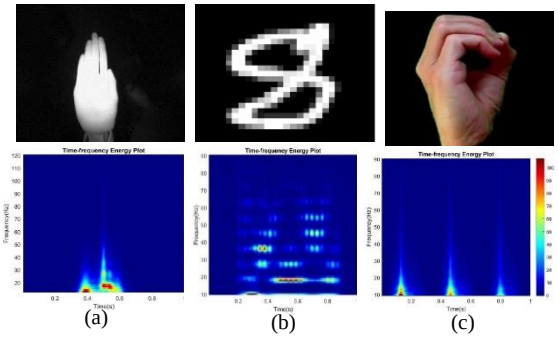

Fig. 5. Time-Frequency representation of some samples using $ASLiT$ of each dataset; (a) LeapGestRecog dataset, (b) MNIST digits dataset, and (c) ASL digits dataset for hand gesture recognition.

Furthermore, the three datasets are also tested with other deep learning models including AlexNet and VGG19. The accuracy of AlexNet was 95.29%, 93.9%, and 95.84% on the LeapGestRecog, MNIST digits, and ASL digits datasets, respectively. Meanwhile, VGG19 achieved accuracies of 96.83%, 96.41%, and 97.12% on the same datasets. The performance comparison of the proposed $VRFNet$ with AlexNet and VGG19 shows the outperforming results as reported in Table I.

The accuracies of different models at each epoch during training and testing process are shown by Box and Whisker plot to gain insights into their performance as depicted in Fig 7. It provides information about the distribution of accuracy per epoch (scaling factor of 1:4), central tendency, and variability of the accuracy scores. Also, the recognition accuracy and loss of the AlexNet, VGG19 and $VRFNet$ models using LeapGestRecog, MNIST digits, and ASL digits dataset are shown by Fig. 8 (a), (b) and (c), respectively.

TABLE I
COMPARISON OF THE PROPOSED MODEL $VRFNet$ WITH ALEXNET AND VGG19 USING DIFFERENT DATASETS FOR HAND GESTURE RECOGNITION

Dataset	Model	Evaluation Parameters (%)			
		A_c	P_r	R_l	F_S
LeapGestRecog	AlexNet	95.29	97.30	97.80	97.54
	VGG19	96.83	98.50	98.35	98.42
	VRFNet	**99.97**	**99.83**	**99.86**	**99.85**
MNIST digits	AlexNet	93.90	94.50	93.60	94.35
	VGG19	96.41	98.23	98.14	98.18
	VRFNet	**99.60**	**99.64**	**99.62**	**99.63**
ASL digits	AlexNet	95.84	96.90	96.20	96.54
	VGG19	97.12	98.04	99.01	98.52
	VRFNet	**98.80**	**99.05**	**98.85**	**98.96**

A. Comparative Study

The comprehensive comparison of the proposed methodology with state-of-the-art techniques that have been previously applied to the same datasets [35]-[46] as shown in Table II. Correspondingly, the comparison with existing methods using diverse dataset for hand gesture recognition [47]-[52] is given in Table III. The aim of this comparison is to evaluate the performance and effectiveness of the proposed approach vis-à-vis the state-of-the-art techniques applied for hand gesture recognition. From the comparison Table II, it is evident that the proposed methodology correctly distinguishes different hand gestures and provides a recognition accuracy of 99.97%, 99.6%

and 98.8% on the LeapGestRecog, MNIST digits and ASL digits datasets, respectively. From Table III, the exceptional performance of the $VRFNet$ architecture, leveraging the $ASLiT$ technique to improve recognition accuracy of hand gestures, is apparent. Additionally, the comparison of the proposed methodology employing AlexNet and $ASLiT$ with other wavelet transform based techniques CWT [53] and STFT [54] is presented in Table IV using LeapGestRecog dataset. The purpose of employing other wavelet transform based techniques is to assess the effect of $ASLiT$ on recognition accuracy compared to them. This comparison highlights the potential of $ASLiT$ in improving the accuracy of hand gesture recognition over CWT and STFT.

TABLE IV
COMPARISON OF THE PROPOSED *ASLiT* WITH OTHER WAVELET TRANSFORM-BASED TECHNIQUES FOR HAND GESTURE RECOGNITION USING LEAPGESTRECOG DATASET

Technique	Dataset	Classification Model	A_c (%)
CWT	LeapGestRecog	AlexNet	91.26
STFT		AlexNet	90.43
ASLiT		AlexNet	95.29

B. Ablation Study

To evaluate the impact of the proposed $VRFNet$ deep learning -based gesture classification model utilizing $ASLiT$ technique, an ablation study is conducted. Table V reports the progressive development of the $VRFNet$ model on different evaluation parameters. This analysis demonstrates the effect and contribution of the different models in enhancing the performance of the $VRFNet$ model. The study begins with model M1, that combines $ASLiT$ and AlexNet. This initial model, when compared to the Up-Down approach, lacks improved recognition accuracy of different classes. To enhance the M1, model M2 is introduced, incorporating a VGG19 in place of AlexNet. This upgraded model gives improved recognition accuracy but still model unable to distinguish between similar classes of some gestures.

M1, M2, M3, M4, M5, M6 represents model number, T_r is training time in hours, T_s is testing time in seconds.

To achieve better performance, model M3, M4 and M5 models are introduces which incorporates *ASLiT* with ResNet50, fusion of VGG19 and AlexNet, fusion of AlexNet and ResNet50 respectively. These approaches provide inferior evaluation parameters with respect to M1 and M2. Furthermore, model M6 which incorporates *ASLiT* with the fusion of VGG19 and ResNet50 provides outperforming results. In terms of evaluation parameters, improvement is observed in accuracy, precision, recall and F1 score with less training and testing time. This further emphasizes the benefits of employing model M6 in facilitating comprehensive and effective multimodal analysis of hand gesture recognition system.

V. CONCLUSION AND FUTURE SCOPE

The paper presents an Adaptive Superlet Transform for images which provides high-resolution in localization of both time and frequency simultaneously. To the best of our knowledge this is the first attempt that incorporates *ASLiT* for images. *ASLiT* is further incorporated with *VRFNet* that is a fusion of VGG19 and ResNet50 for the classification of hand gestures. Each model has learned different high-level features or captured different patterns, and combining them can provide a more comprehensive representation of the data. Extensive experiments are conducted on LeapGestRecog, MNIST digits, ASL digits datasets to validate the efficiency and efficacy of the proposed framework *VRFNet*. The proposed model provided a recognition accuracy of 99.97%, 99.6% and 98.8% LeapGestRecog, MNIST digits and ASL digits datasets, respectively. To evaluate the proficiency of the proposed methodology employing *ASLiT* in contrast to other transform-based techniques, the model is also assessed on the spectrograms generated by CWT and STFT, which yield subpar results. An ablation study is also carried out to support the experimental analysis. The findings highlight the importance of the *VRFNet* architecture and the utility of the *ASLiT* technique in improving recognition accuracy compared with several state-of-the-art techniques.

Future research may explore the applicability of the proposed framework to other modalities, such as video-based or depth-based hand gesture recognition, expanding to larger and more diverse datasets, could be a fruitful area of research.

The present study reviewed gratitude at work articles published in Scopus database using bibliometric analysis to examine growth in gratitude at work publications and citations, most cited publications, most influential authors, articles, publishers, universities and countries. The extracted data were analysed and visualised with the help of two analytical tools, that is, the Scopus analysis and VOSviewer (version 1.6.16). It identified 273 publications referring to gratitude at work in title, abstract, or keywords. The keyword co-occurrence highlighted four major clusters of workplace gratitude research: Psychological studies, Customer relationship management, Employees, and Ethics and spirituality.

KEYWORDS
bibliometric, trend analysis, Vos viewer, workplace gratitude

1 | INTRODUCTION

Modern workplaces are often characterised with a toxic environment that breeds egocentrism, deviance, incivility, harassments, office politics, glass ceiling, favouritism, and corruption (Fehr et al., 2017). The repercussions of such workplace toxicity could be seen at both levels: employee and organisational. At an individual level, it poorly affects employees' engagement, performance, self-esteem, psychological capital, work-life balance, physical and mental health, career progression, and stay in an organisational (Rasool et al., 2021). At the organisational level, it manifests as toxic culture which breeds toxic employees, toxic leaders, toxic processes and policies (Rasool et al., 2021). It creates a vicious circle wherein individual and organisational toxicity promotes each other. Luckily, organisations are trying out diverse means like promoting spirituality and gratitude to break this ominous cycle of toxicity. A few previous researchers have reported positive effects of gratitude at work. Gratitude improves life satisfaction (McCullough et al., 2002), reduces aggression (DeWall et al., 2012), motivates prosocial behaviour (Bartlett & DeSteno, 2006), supports work-family enrichment (Garg, 2020), creates positive relationships, social support, and workers' well-being (Di Fabio et al., 2017), enhances vitality and resilience (Garg et al., 2022a), promotes pro-social behaviour and organisational citizenship behaviour (Garg, 2017) and counters turnover and absenteeism (Garg et al., 2020). With the emergence of positive psychology, gratitude at work is increasingly advocated to promote workplace happiness, employee satisfaction, and humanity-based administration.

Although studies on gratitude have captured the attention of modern scientists in the last 34 years, exploration of gratitude at the workplace still remains a laggard (Fehr et al., 2017). There seems to be an interest in gratitude at work in the last couple of decades only. Nearly 55% of the organisational behaviour (OB) papers on gratitude have been published in the last 5 years (Locklear et al., 2022). There could be two possible reasons for ignoring gratitude at the workplace. Firstly, in the initial years, gratitude was a subject matter for philosophical and religious studies. The desirability of a secular and nonreligious workplace might have eluded the notion of grateful organisations from the mind of academicians, researchers and practitioners. Secondly, gratitude in work and non-work settings was not differentiated, thus, the findings of the studies conducted outside an organisation deem suitable and applicable on employees in professional settings too. But later on studies argued that one who is generally grateful in his/her personal life may not necessarily be so at work (Cain et al., 2019). Also, the diverse nature of challenges and aspiration at work offer different playing fields to gratitude. Given the benefits associated with practising gratitude at work and potential

 © 2024 John Wiley & Sons Ltd.

difference in experience of gratitude in work and non-work settings, it is imperative to have an in-depth understanding of various intricacies of gratitude at the workplace.

Accordingly, the present study attempts to review published manuscripts on gratitude at work using bibliometric analysis. Although there is a steep rise in the literature of gratitude at work research, there is no attempt to systematically identify the historical development and recent trends in workplace gratitude research. To the best of our knowledge and explorations, no previous researcher has reviewed and analysed the trends within the rapidly expanding domain of scientific knowledge of gratitude at work. There have been a few meta-analysis and systematic literature review articles on gratitude (see Boggiss et al., 2020; Davis et al., 2016), but bibliometric analysis are better than meta-analysis and systematic literature review studies in terms of its scope, coverage, utility, objectivity, and methodology (Donthu et al., 2021). As far as meta-analysis is concerned, it explains (1) the overall strength and direction of effects or relationships," and (2) "the across-study variance in the distribution of effect-size estimates and the factors that explain this variance" (Aguinis et al., 2011, p. 310). They are restricted to the examination of direction and strength of effects and relationships among two or more variables (Donthu et al., 2021). Further, systematic literature review uses systematic methodologies to acquire, arrange, and assess available manuscripts and articles. They are better suited for confined or niche research areas like domain-based reviews, methods-based reviews, or interventions-based reviews.

In contrast, bibliometric analysis studies are not restricted to any specific sub-theme, intervention, practice, or association between two variables. It is a scientifically developed mechanism introduced by Pritchard (1969) to logically examine historical developments, emerging trends, active research areas, and future directions in a particular field of interest. It has been defined as "the application of mathematical and statistical methods to articles and other means of communication" (Pritchard, 1969, p. 349). The bibliometric analysis is often advocated for its objectivity and ability to handle large data and files using mathematical and statistical methods (Donthu et al., 2021). It offers bibliometric and intellectual structure of available literature of the field of study through examining the social and structural relationships between different research constituents (e.g., authors, countries, institutions, and topics) (Donthu et al., 2021). The bibliometric analysis indicates rate, state, and direction of development of knowledge in a particular area. The present study offers an extensive understanding of publications, citations, journals, countries and authors in the domain of gratitude at work using bibliometric analysis. It highlights prominent/most contributing authors, institutions, and countries. It also captures whether the area of investigation is dominated by a few scholars, universities, or regions. It explains how gratitude at work research has developed and disseminated over the last few decades. It evaluates historical developments, emerging trends, and active research areas in the field of gratitude at work. The bibliometric analysis clearly delineates "what has already been examined," and "what has not been examined so far;" thus, it makes a researcher aware about development till date and the research gaps. Thereby, it acts as a guiding light for future researchers. "It enables us to unpack the evolutionary nuances of a specific field, while shedding light on the emerging areas in that field" (Donthu et al., 2021, p. 285). Accordingly, this study performs a bibliometric analysis of gratitude at work research to answer the following research questions. The present study utilised the stakeholders' perspective to explore the gratuitous behaviour of different stakeholders such as employees, customers, and suppliers. It is important to note that gratitude is contagion and one's gratuitous behaviour influences others to reciprocate in the similar fashion (Garg, 2024). Organisations put effort to elicit gratitude among its different players like leaders, employees, and consumers; thus, a study on gratitude at work needs to capture gratitude among stakeholders of a firm.

RQ1. What are the current publication and citation trends of gratitude at work research?

RQ2. Which are the most influential authors, articles, journals, publishers, and countries publishing extensively in the domain of gratitude at work?

RQ3. What are the different research areas that carry out research in the gratitude at work domain?

RQ4. Which themes of gratitude at work contemporary researchers are exploring, and also which topics have scope for future research?

2 | METHOD

2.1 | Data source, search strategy, and data retrieval

The Scopus database was used to extract data for bibliometric analysis. The Scopus is the largest database of peer-reviewed scientific literature including journals, books, and conference proceedings. Other databases like Google scholar, Pubmed, PsycInfo, and Web of Science (WoS) are also available but the Scopus database is used for its greater relevance in the present context. Google scholar does not provide a dataset in such a form suited for bibliometric analysis. The PubMed dataset predominantly comprises research in life sciences and biomedical topics. And the PsycInfo database consists of works in the field of psychology. However, studies on gratitude at work are distributed in psychology, marketing, human resource, economics, medical, etc. Also, Scopus is the largest database and it provides information about the most prominent authors, countries, affiliations, journals, and publication years both in tabular and graphic forms. Therefore, the Scopus database is preferred over all other available databases. The phrases "gratitude and work," "gratitude and workplace," "gratitude and organisations," "gratitude and company," "gratitude and worker," "gratitude and employee," "gratitude and profession," "gratitude and customer," "gratitude and consumer," and

14791854, 2024, 3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pa.2934 by Delhi Technological University, Wiley Online Library on [10/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

"gratitude and client," were searched on Scopus database in the title, abstract, or keywords of the publications as on 28th February 2023. Only documents of the article and review types were considered, and other document types like books, chapters, and letters were discarded. Articles published in journals are subjected to stringent review process conducted by editors, associate editors, and peer reviewers, which ensures the quality of the publication leading to greater acceptability of the results among academicians. On contrary, books and book chapters do not follow rigorous review process; thus they are excluded from the present study. Further, selection was restricted to "business, management, and accounting" category publications in English language only. Gratitude studies are widely spread across various disciplines such as psychology, sociology, ethics and spirituality, medicine, psychiatry, nursing, and philosophy. Since the present study intends to evaluate the gratitude at work; thus, the scope of the study was restricted to "business, management, and accounting." The search string resulted in 347 studies, which were manually screened through reading their abstract. Ultimately, 273 publications were selected from further analysis and deliberations.

2.2 | Data analysis and visualisation

The extracted data were analysed and visualised with the help of two analytical tools, that is, the Scopus analysis and VOSviewer (version 1.6.16). The Scopus database provides information about the most prominent authors, countries, affiliations, journals, and publication years. The VOSviewer provides visualisation facilities for country collaboration, co-authorship, and keyword co-occurrence. In this study, the number of publications and citations over years, most cited publications, and most influential authors, articles, publishers, universities, and countries are elicited as a part of performance analysis. Also, major research areas of gratitude research are also explored. Furthermore, collaboration among countries, keyword co-occurrence, and recent trends analysis are employed through science mapping. Donthu et al. (2021) recommended that performance analysis and co-citation analysis reveal the knowledge foundation (past knowledge) and keyword co-occurrence analysis reveals the knowledge production (present trend of knowledge development). Accordingly, this study employs both methods to deep dive into the ocean of knowledge of gratitude research.

3 | RESULTS

3.1 | Number of publications over years

Scopus database identified 273 publications referring to given keywords. It comprised 263 articles and 10 reviews. In the most recent article, published in *Journal of Service Marketing*, Qi et al. (2023) reported that the organisations' service climate leads to employee gratitude, which ultimately results in customer oriented behaviour by employees. In another recent article, Zhao et al. (2023) suggested a positive relationship between gratitude and employee well-being and organisational commitment. Although the first research article appeared in 1982, there has been an acute dearth of research until 2010. The scientific exploration of gratitude at the workplace gained momentum after 2010. The year 2010 witnessed only 1 publication and it rose to 44 publications by 2022. There have been 13 publications in the first 2 months of 2023. The last 12 years witnessed an exponential increase in publication with 229 publications and the last 4 years (2019 to Feb 2023) observed 129 publications. These trends clearly suggest a growing interest of academics and practitioners in developing gratuitous workplaces and experiences. Figure 1 provides the year-wise growth of publication referring to gratitude at the workplace

3.2 | Most cited publications

Table 1 reports the top 10 cited publications in the domain of gratitude at work. The most cited publication is "*The role of customer gratitude in relationship marketing*." It is published in the *Journal of Marketing* and has been cited 478 times since 2009. It also has the highest citation per year score of 31.87 citations per year. The study offers an important insight into how gratitude helps relationship marketing to achieve their intended performance outcomes. It reports that gratitude mediates the relationship between relationship marketing and purchase intentions, sales growth, and share of wallet. The second top cited publication is Morales's (2005) "*Giving firms an 'E' for effort: Consumer responses to high-effort firms*" published in the *Journal of Consumer Research* with 317 citations so far. The study reports that a firms' extra efforts in manufacturing, displaying, selling a product is rewarded by consumers' increasing their willingness to pay, store choice, and overall evaluations. Based on attribution theory, the findings of the study suggest that the proposed relationship is mediated by customers' feeling of gratitude. It is interesting to note that eight out of the ten top cited publications are in the domain of customer relationship management. One of the top cited articles beyond the scope of customer relationship is Fehr et al.'s (2017) "*The grateful workplace: A multilevel model of gratitude in organizations*" with 141 citations (20.14 citations per year). This article highlighted the scarcity of empirical studies on gratitude at the workplace and proposed a multilevel gratitude model for workplaces. It proposed a model consisting of episodic gratitude (at the event level), persistent gratitude (at the individual level), and collective gratitude (at the organisational level).

3.3 | Most prolific journal

There are 158 journals with at least one publication on gratitude at the workplace. Also, there are only seven journals with five or more publications and only 14 journals with four or more publications. The top three journals (in terms of number of publications) are *Journal of Business Research* (number of publications = 16, citation = 463, and

14791854, 2024, 3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pa.2934 by Delhi Technological University, Wiley Online Library on [10/07/2024]. FIGURE 1 Year-wise growth in publication of gratitude at work research. *Source*: Delineated from Scopus database.

TABLE 1 Top 10 most cited publications on gratitude at work.

S. No	Author	Title of publication	Journal	Citations	Citation per year
1	Palmatier et al. (2009)	The role of customer gratitude in relationship marketing	Journal of Marketing	478	31.87
2	Morales (2005)	Giving firms an "E" for effort: Consumer responses to high-effort firms	Journal of Consumer Research	317	16.68
3	Soscia (2007)	Gratitude, delight, or guilt: The role of consumers' emotions in predicting post consumption behaviours	Psychology and Marketing	216	12.71
4	Romani et al. (2013)	Explaining Consumer Reactions to Corporate Social Responsibility: The Role of Gratitude and Altruistic Values	Journal of Business Ethics	174	15.82
5	Xie et al. (2015)	The role of moral emotions and individual differences in consumer responses to corporate green and non-green actions	Journal of the Academy of Marketing Science	159	17.67
6	Fehr et al. (2017)	The grateful workplace: A multilevel model of gratitude in organisations	Academy of Management Review	141	20.14
7	Wetzel et al. (2014)	Gratitude versus entitlement: A dual process model of the profitability implications of customer prioritisation	Journal of Marketing	134	13.40
8	Simon and Tossan (2018)	Does brand-consumer social sharing matter? A relational framework of customer engagement to brand-hosted social media	Journal of Business Research	133	22.17
9	Van dierendonck and Patterson (2015)	Compassionate Love as a Cornerstone of Servant Leadership: An Integration of Previous Theorising and Research	Journal of Business Ethics	128	14.22
10	Steinhoff and Palmatier (2014)	Understanding loyalty program effectiveness: managing target and bystander effects	Journal of the Academy of Marketing Science	122	15.25

Source: Scopus database.

citation per year = 28.94), *Journal of Business Ethics* (number of publications = 10, citation = 545, and citation per year = 23.44), and *Journal of Service Marketing* (number of publications = 9, citation = 211, and citation per year = 23.44). Also, five out of top the 10 journals are directly related to marketing research. There are a few journals related to human resource and behaviour too. These journals are *Personnel Review*, *Journal of Organisational Behaviour*, and *Journal of Management, Spirituality, and Religion*. *Journal of Marketing* has highest number of citations (644) and citation per year (128.80). Table 2 reports 14 journals with four or more publications. Also, Figure 2 represents journal-wise trends in gratitude at work research publications, which suggests different clusters of journals. The earliest cluster shows publication in *Journal of Business Ethics* and *Journal of Management, Spirituality, and Religion*. Then a few clusters indicate prominence of marketing journals like *Journal of Service Marketing*, *Journal of Retailing and Consumer Services* and *Journal of Marketing*. And, the most recent cluster highlights publications in non-marketing journals like *Journal of Business Research*, *Personnel Review*, and *Journal of Organisational Behaviour*. These findings reveal a clear prominence of gratitude in marketing-related journals. However, recent trends suggest increasing publications in the domain of human resource and organisational behaviour. A few publications in 2023 reveal linkage between gratitude and employees' ability to take charge (Ren et al., 2023), workers' turnover intentions (Garg et al., 2022b),

workplace toxicity, employee well-being and organisational commitment (Zhao et al., 2023). It suggests gratitude practices are increasingly been used to solve organisational challenges in modern workplaces.

3.4 | Most prolific authors

Table 3 illustrates the list of authors with four or more publications on gratitude at work, along with their affiliation and country. There are three authors—Richard P. Bagozzi (University of Michigan, USA), Dora E. Bock (Auburn University, USA), and Judith Anne Garretson Folse (Louisiana State University, USA)—with a maximum eight publications on gratitude at work. It is interesting to note that five out of the top 10 authors are from the USA. Another notable contributor is Naval Garg (Delhi Technological University) with six publications. The author proposed gratitude as a construct of workplace spirituality and suggested institutionalisation of gratitude practices at the workplace (Saxena et al., 2020). In other papers, the authors reported positive association between gratitude and workplace happiness (Garg et al., 2022a), workplace toxicity (Sarkar et al., 2023), and technostress (Garg et al., 2022b). Two other top rated authors from Italy—Silvia Grappi and Simona Romani—have extensively examined the role of gratitude in customer relationship management.

3.5 | Most prolific countries

Table 4 reports the top 20 countries in terms of the number of research publications in the domain of gratitude at work. The USA tops the list with 124 publications, 3972 citations, and 32.023 citations per year. A few prominent authors of the USA are Richard P. Bagozzi, Dora E. Bock, Judith Anne Garretson Folse, Natalia Kolyesnikova, and Stephanie M. Mangus. The next top ranked country is India (26 publications, 110 citations, and 4.23 citations per year), followed by Australia and China with a similar number of publications (22 publications). Australia has a relatively higher number of citations of 436 (citation per year = 19.82) than China's 158 (citation per

14791854, 2024, 3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pa.2934 by Delhi Technological University, Wiley Online Library on [10/07/2024]. FIGURE 3 Recent country/territory-wise trends in gratitude at work publications. *Source*: Delineated by Vosviewer.

year = 7.18). Among these top 20 countries, the USA also has the highest number of citations (total number of citations = 3972), followed by Germany (total number of citations = 545) and Italy (total number of citations = 533). Norway (citations per document = 77.75), Netherlands (citations per document = 72.75), and Italy (citations per document = 59.22) are the three top most countries in terms of citation per documents. Interestingly, despite being in the top three countries (in terms of number of documents), India and China have relatively low citations per document with 4.23 and 7.18 citations per document. Figure 3 represents country/territory-wise trends in gratitude at work research work. It reports that earlier research was confined to the USA and European countries like UK, France, Germany, Norway, Italy, and Netherlands (highlighted in purple colour). Afterwards, scientific explorations of gratitude at work started in Australia, New Zealand and Asian countries like India, China, Hongkong, South Korea, and Turkey (highlighted in green colour). And recently, there is a growing interest in examining workplace gratitude in smaller countries like Pakistan, Malaysia, and Taiwan (highlighted in yellow colour). The figure suggests that gratitude at work research has spread over North America, Europe, Asia, and Australia continents; however South America and Africa are yet to contribute significantly in the domain of gratitude at the workplace research.

3.6 | Keywords co-occurrence

VosViewer was used to visualise keywords co-occurrence in the publications on gratitude at work. Figure 4 reports 10 keyword clusters, however four major clusters (with more than five items) are elaborated and considered for discussion. Further, Figure 5 reports most recent clusters or areas of workplace gratitude studies.

3.6.1 | Cluster-1: Gratitude and workplace well-being (red colour)

This cluster comprises 11 keywords like positive psychology, mindfulness, emotion, culture, psychological capital, and affect. A close examination of keywords hints toward two sub-themes. First, just like gratitude literature, gratitude at work has also been examined both as emotion and trait. Several publications including Schnall and Cannon (2012), and Liao et al. (2022) examined organisational benefits of gratitude as emotion. Other authors including Li et al. (2022), Zhoa et al. (2023), and Guzzo et al. (2020) explored trait gratitude at the workplace. Second, the cluster seems to capture the relationship between gratitude at work and workplace wellbeing. In a recent study, Sarkar et al. (2023) reported that employees' gratitude helps them counter workplace toxicity. They proposed that the negative relationship between gratitude and workplace toxicity is mediated by psychological capital. Based on the broaden-and-build theory, the authors stated that gratitude develops psychological capital (hope, resilience, self-efficacy, and optimism) among employees, which make them more competent to deal with workplace toxicity. Other psychological constructs like hope, loyalty, stress, burnout, trust, engagement, emotions, well-being, contentment, commitment, helping attitude, and happiness have also been examined in the light of gratitude. For instance, Zhoa et al. (2023) stated that gratitude positively influences individual (subjective well-being) and organisational (volunteer retention) outcomes through the mediating effects of prosocial motivation and

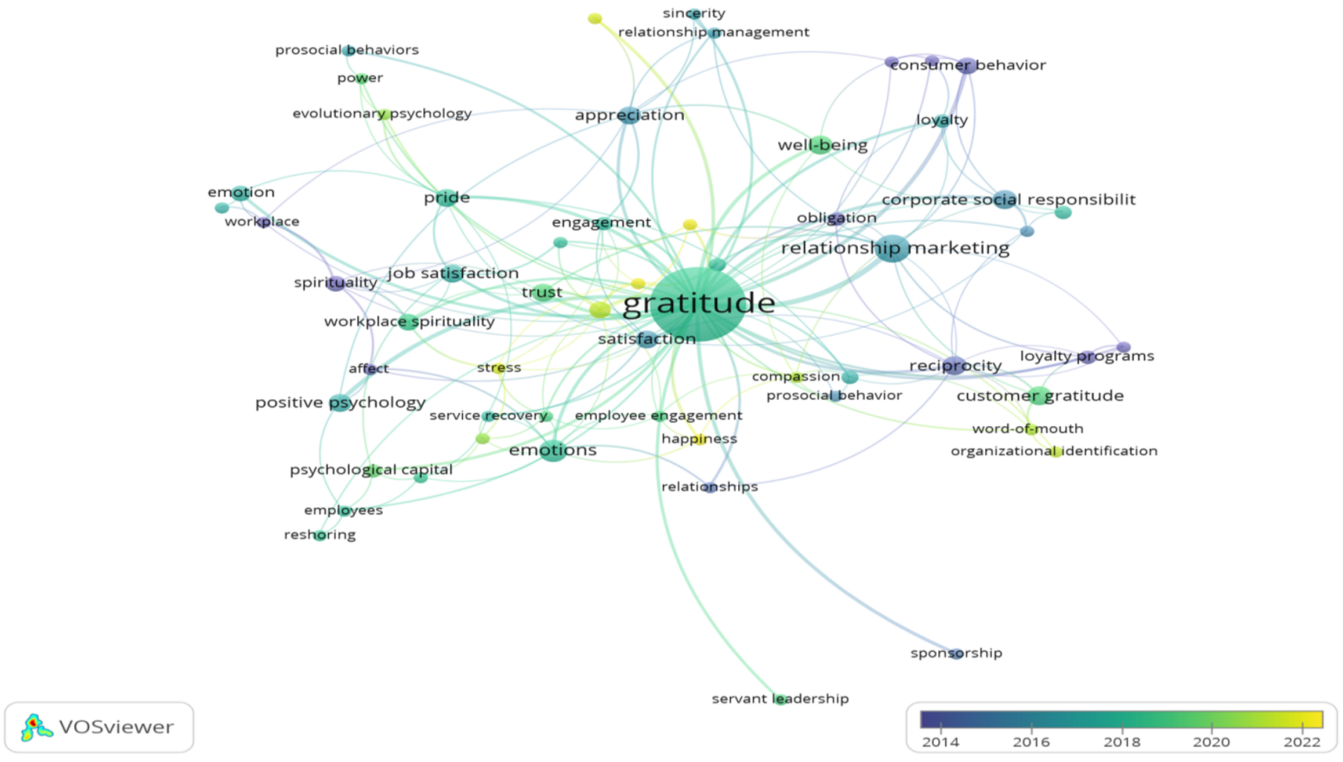

FIGURE 5 Recent clusters in gratitude at work literature. *Source*: Delineated by Vosviewer.

14791854, 2024, 3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pa.2934 by Delhi Technological University, Wiley Online Library on [10/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

volunteer engagement. Similarly, Li et al. (2022) reported that gratitude increases people's well-being through connecting them to nature. The authors argued that gratitude leads to positive emotion of transcendence, which results in deep oneness with nature leading to physical and mental wellbeing. Besides, Garg et al. (2022c) suggested that gratitude enhances employees' workplace happiness through augmenting their social and psychological capital. Ali et al. (2022) also concluded that gratitude and mindfulness are pivotal for one's well-being. They elaborated that gratitude increases hopefulness and optimism leading to enhanced levels of wellbeing. In a nutshell, gratitude seems to influence workplace wellbeing in two ways. First, it augments different individual psychological constructs such as self-efficacy, resilience, hope, and optimism that results in workplace well-being. Second, gratuitous behaviour leads to better social relations and affiliations with other stakeholders like colleagues, supervisors, subordinates, and consumers, which results in accumulation of social capital essential for workplace wellbeing.

3.6.2 | Cluster-2: Gratitude and customer relationship management (green colour)

The second cluster has eight keywords including relationship, relationship marketing, reciprocity, customer gratitude, customer relationship management, and loyalty program. It focuses primarily on customer gratitude and its implication on customer relationship management. Two types of studies were reported. The first type of studies examined the direct effect of customer gratitude and the second type of studies explored the mediating or moderating role of customer gratitude. The studies reported linkage between customer gratitude and cooperation and helping other consumers (Chou et al., 2023), marketing investment (preferential treatment and interpersonal communication investments) (Mittal & Maity, 2022), territorial behaviour of consumers (Chou et al., 2023), customer loyalty (Mittal & Maity, 2022), relationship quality between salesperson and customer (Mangus et al., 2022), consumer intentions to spread electronic word-of-mouth (Septianto et al., 2020), individuals' sustainable product choice (Liang & Guo, 2021), and customer trust (Huang, 2015). Customer gratitude is reported to mediate the association between functional value and pay for price premium (Liu et al., 2022), brand likeability and brand love (Suetrong & Pires, 2021), consumer responses and marketing communications (Bridger & Wood, 2017), corporate philanthropy and consumer loyalty (Park et al., 2016), and human resource management attributions and employees general work stress (Hameed & Khwaja, 2022).

3.6.3 | Cluster-3: Gratitude at work and individual-level outcomes (blue colour)

The third cluster consists of eight keywords including employee performance, leader-member exchange, obligation, stress, engagement, and organisational commitment. This cluster seems to highlight various gratitude-driven individual outcomes in professional settings. While, the first cluster enumerates studies depicting association between gratitude and workplace wellbeing, this cluster encompasses studies highlighting other employees-related outcomes such as job satisfaction, team building, vitality, and proactive workplace behaviours. Again, two sub-themes were reported. In the first sub-theme, direct relationships were established between gratitude and employee-related variables. Various studies highlighted positive linkage between job satisfaction (Effendi et al., 2021), organisational commitment (Zhoa et al., 2023), take charge (Ren et al., 2023), work-to-family conflict (Zhan et al., 2022), employee performance during crisis (Ni et al., 2022), organisational citizenship behaviours (Li et al., 2022), work-family enrichment (Garg, 2020), psychological availability (Li et al., 2022), interpersonal helping behaviour (Kersten et al., 2021), turnover intentions (Garg et al., 2021), burnout, and stress (Saxena et al., 2020), and exhaustion and disengagement (Kersten et al., 2021). Another set of studies concluded a mediating or moderating effect of employee gratitude among the relationship between leaders' favourable feedback and employees' withdrawal behaviour (Jiang & Qu, 2022), workplace toxicity and turnover intentions (Garg et al., 2023), and corporate social responsibility and job satisfaction (Akram et al., 2023).

3.6.4 | Cluster-4: Gratitude at work, ethics, and spirituality (yellow colour)

The fourth cluster comprises seven keywords including spirituality, ethics, workplace spirituality, corporate social responsibility, and trust. Two sub-themes of studies were reported in this cluster. The first sort of studies examines the interrelationships between gratitude and workplace spirituality. Several studies have considered gratitude as a construct of workplace spirituality (Saxena et al., 2020). They argued that the Eastern conceptualisation of gratitude is incomplete without incorporation of gratitude. Besides, they elaborated that measurement of workplace spirituality is incomplete without inclusion of gratitude. Similarly, Loi and Ng (2021) also recommended that gratitude leads to enhanced experience of spirituality and meaningfulness. Büssing et al. (2021) supported and recommended gratitude as an experiential aspect of spirituality. The other sub-theme highlights different interfaces of gratitude and business ethics. Badrinarayanan et al. (2021) concluded that gratitude toward the manager moderates the relationship between ethical leadership and salespersons' emulation. In another study, Lee et al. (2022), gratitude reduces materialistic values by decreasing entitlement and perceived resource scarcity. They elaborated that gratitude-driven marketing drives reduce materialistic values and purchases and promote experiential consumption. Thus, consumers may prefer non-materialistic products and services are more effective during gratitude-related holidays (e.g., Thanksgiving, Mother's Day) Romani et al. (2013) also reported that gratitude mediates the linkage between perceived corporate social responsibility (CSR) and consumer reactions. They elaborated that firms' indulgence in CSR activities generate gratitude among beneficiary and customers leading to favourable consumer's reactions.

4 | CONCLUSION

Employing the bibliometric analysis methods, this study offers a deeper understanding of the articles on gratitude at the workplace that has been published in Scopus-indexed journals over a period of time. Bibliometric studies help one evaluate and understand development of a field, research impact, research productivity, research trends, and future directions. Accordingly, 273 publications on gratitude at work are subjected to bibliometric analysis in the study. It revealed that publications in the field have increased steadily since 2010 and 47.25% (129 articles) have been published in the last 4 years (2018 to Feb, 2023). It suggests the growing importance and acceptance of gratitude in professional settings. Studies have suggested that gratitude is beneficial for benefactor, beneficiary, and bystander, as it develops a sense of connection and desire to reciprocate the good deeds. A good number of studies have tried to elicit gratitude among customers to reap multiple benefits like customer satisfaction, retention and loyalty, sales maximisation, and service customisation. Other studies have examined the individual and organisational impact of employees' gratitude. Individual benefits include employee well-being, commitment and engagement, psychological capital, conducive work environment, life satisfaction, trust, and compassion.

Further, the list of most influential journals is dominated by marketing journals followed by a few human resource, organisational behaviour, ethics, and spirituality journals. These results suggest that workplace gratitude studies are not confined to the domain of organisational behaviour; rather they are widely spread across diverse professional domains such as marketing, human resource, ethics, and workplace spirituality, which recommends the validity of the stakeholders' perspective of gratitude. The overlay visualisation suggests a clear preference to work upon employees' gratitude level to bring out desired results and changes in the professional settings, which is marred by workplace toxicity and a blind pursuit of materialism and success (Mehta et al., 2023). The trend is definitely toward creating organisations that offer a luxury to remain human with limitations and endless possibilities of love, trust, faith, and mutual support. Gratitude interventions like gratitude journaling, introspection, and gratitude letters help one to understand the interdependence and mutual coexistence among employees and their organisations (Bansal et al., 2023).

The country-wise analysis reports the USA as top contributor followed distantly by India, Australia, and China. It is quite understandable as the majority of major contributors of gratitude research like Roberts A Emmons, Philip Watkins, Todd B Kashdan, Sonja Lyubomirsky, Sara B Alogoe, and M E McCullough are from the USA. Also, the American researchers contributed to the early growth and development of scientific exploration of gratitude in the first decade of the twenty-first century. Now, it seems that the same trend continues in gratitude at work research with major contributions coming from the USA. The findings also report a paucity of studies by African and South American scholars. Also, studies conducted by Asian and European scholars are confined to a few countries only. It raises an immediate need of gratitude studies in different geographical and cultural settings. Such studies are poised to bring to light unexplored dimensions and effects of workplace gratitude to forefront.

The keyword co-occurrence suggests four major research areas—workplace wellbeing, customer relationship management, individual-level outcomes, and ethics and spirituality. It reflects that current focus of workplace gratitude studies are majorly confined to these four areas with emphasis on reaping its benefits. The recent studies hint toward social exchange, leader-member exchange, and HRM attribution theory. It indicates a probable amalgamation of gratitude in HR practices and policies of the companies. The social exchange states that the relationship between employer and employee is based on social exchange, wherein employees tend to respond positively to any pro-employee and empathetic move of the employer. Based on social exchange theory, it is argued that a grateful disposition by employers is going to create a positive ripple effect which will be beneficial for all stakeholders including employee, employer and the overall organisation. Similarly, leadership-exchange theory also highlights the importance of exchange/interactions between leader and follower. Garg (2020) suggested gratitude as an essential trait of an effective leader. These academic developments advocate a strong case of institutionalisation of gratitude-based interventions and practices at the workplace. Such changes have started at the college and University levels. For inference, a few universities in India have started a course on 'The art and science of gratitude' to prepare aspiring managers for future corporate journeys (Garg, 2024).

It offers several insights to future researchers to investigate numerous unexplored facets of gratitude at work. First, the current literature an acute shortage of workplace gratitude scale with majorly studies using the GQ-6, GRAT-16, or other gratitude scale (not developed in workplace contexts). Researchers have argued that workplace offers different contextual and behavioural factors to gratitude than non-professional settings. Thus, it requires scales to gauge into professionals outlook and manifestation of gratitude. Second, currently workplace gratitude studies mainly examine individual level effects with group and organisational-level effects are yet to be explored extensively. Future scholars might be interested in examining role of gratitude in facilitating group dynamics such as trust, cooperation, organisational citizenship behaviour, and pro-social activities. Similarly, gratitude could be explored in the context of organisational performance, brand image of a firm, organisational culture and climate, and organisational structures and processes. Third, existential gratitude is yet to find a place in workplace gratitude studies. Positive psychology 2.0 strongly suggests reapplication of different organisational constructs in challenging and difficult times. Thus, future studies are encourage to observe the effect of gratitude when employee or organisational are passing through turbulent time.

Despite a meticulous examination of the existing publication on gratitude at the workplace, this study has two major limitations. First, this bibliometric analysis is based on data retrieved and downloaded from the Scopus database. Although previous studies have advocated for and utilised the Scopus database, there are significant possibilities of missing articles on gratitude at work that are not indexed in the

14791854, 2024, 3, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/pa.2934 by Delhi Technological University, Wiley Online Library on [10/07/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Scopus database. There could be publications in other databases like WoS or PsycInfo but not indexed in the Scopus database. Future researchers are advised to integrate data from different databases (after avoiding duplication of articles). It might represent a more comprehensive picture of gratitude at work research. Also, researchers could use other databases like WoS to either refute or support the findings of the present study. Second, this study is based on a relatively large sample size of 273 publications; thus, the study could not analyse the underpinning theories, dimensions, constructs, scales, interventions, and methodologies of the articles reviewed. Future researchers may conduct systematic literature review or meta-analysis studies or theme-based reviews to focus on evaluating theories, dimensions, scales or methodologies in the domain of gratitude at work. In a nutshell, the present study provides a wide-ranging encapsulation of gratitude at work research using bibliometric analysis. It offers a wide range of information on publication and citations over the years, most cited articles, most prolific authors, journals, and countries, and important research areas. Most importantly, trend analysis suggests four clusters of research works, which not only throws light on the current status of gratitude research but also foresights future directions too.
