**(Roll No. 9078 )**

Under the guidance of

**MR. ALOK VERMA**  
**ASSOCIATE PROFESSOR**

Department of Civil & Environmental Engineering  
Delhi College of Engineering  
University of Delhi, Delhi  
2009-2011

## **ACKNOWLEDGMENT**

It is a moment of great pleasure and immense satisfaction for me to express my sense of gratitude and indebtedness towards my guides Mr. Alok Verma Associate Professor of Department of Civil Engineering, Delhi College of Engineering, for their eminent guidance, keen interest and constant encouragement during the course of project. I am indebted to them for their supervision and guidance at all stages of work.

**Dated :**

**PREM SINGH**

**Department of Civil & Environmental Engineering  
Delhi College of Engineering, Delhi-110042**

**CERTIFICATE**

This is to certify that the Thesis work entitled "**SENSITIVITY ANALYSIS OF CONCRETE MIX DESIGN PROCEDURE**" being submitted by me, is a bonafide record of my own work carried by me under the guidance and supervision of Associate Professor Mr. Alok Verma in partial fulfillment of requirements for the award of the Degree of Master of Engineering (Structural Engineering) in Civil Engineering.

The matter embodied in this project has not been submitted for the award of any other degree.

PREM SINGH

Roll No: 9078

This is to certify that the above statement made by the candidate is correct to the best of our knowledge.

**Mr. Alok Verma.**

Associate Professor

Department of Civil & Environmental Engineering  
Delhi College of Engineering , Delhi-110042

## **1.0 ABSTRACT**

Design of concrete mixes is a very important step in the construction of RCC buildings. All the constituents of concrete are to be provided with correct quantities depending on various factors. Some of these factors may be dependent on environmental factors or conditions while some of them may be based on physical or chemical characteristics of various materials used in the mix. Quality of chemical admixtures such as superplasticizers may be important in the respect of workability provided by them. Due to variations in the workability of the mix, quantities of various constituents may vary.

Indian standard method of concrete design considers various factors for the design of concrete mix. In this project various such factors have been considered and effects of them has been studied on the design of plain concrete (PCC) mixes.

## 2.0 INTRODUCTION

Design of concrete mixes is a very important step in the construction of RCC buildings. All the constituents of concrete are to be provided with correct quantities depending on various factors. Some of these factors may be dependent on environmental factors or conditions while some of them may be based on physical or chemical characteristics of various materials used in the mix. Quality of chemical admixtures such as superplasticizers may be important in the respect of workability provided by them. Due to variations in the workability of the mix, quantities of various constituents may vary.

Indian standard method of concrete design considers various factors for the design of concrete mix. In this project various such factors have been considered and effects of them has been studied on the design of plain concrete (PCC) mixes.

### **3.0 OBJECTIVES OF THE PROJECT**

Following are the objectives of the project.

- To construct a facility to design a PCC mix.
- To study the effect of various factors on the design of concrete mixes of various grades.
- To study the effect of superplasticizers on the mix design of concrete.

## **4.0 LITERATURE REVIEW**

### **4.1 Factors in the Choice of Mix Design –**

Both IS : 456-1978 as well as IS : 1343-1980 envisage that design of concrete mix be based on the following factors:

- a) Grade designation,
- b) Type of cement,
- c) Maximum nominal size of aggregates,
- d) Minimum water-cement ratio,
- e) Workability, and
- f) Minimum cement content.

**a) GRADE DESIGNATION :**

The grade designation gives the characteristic strength requirement of concrete. Depending upon the level of quality control available at the site, the concrete mix has to be designed for a target mean strength somewhat higher than the characteristic strength.

**b ) TYPE OF CEMENT :**

The type of cement is important mainly through its influence on the rate of development of compressive strength of concrete as well as durability under aggressive environments. Where very high compressive strength is required, for example, in prestressed concrete railway sleepers, high strength ordinary Portland cement conforming to IS : 8112-1976 will be found suitable. Where an early strength development is required, rapid hardening Portland cement conforming to IS : 8041- 19786 is preferable. On the other hand in situations where heat of hydration has to be limited, for example, in mass concrete

constructions, low heat Portland cement conforming to IS : 269-1976' is preferable. Portland pozzolana cement and Portland slag cement are permitted for use in reinforced concrete constructions; while Portland slag cement is also permitted for prestressed concrete constructions. With such blended cements, the rate of development of early strength may be somewhat slower. On the other hand, these blended cements render greater durability to the concrete in sulphatic environment and sea water. The requirements of durability are achieved by limitations in terms of minimum cement content, the type of cement and the maximum water-cement ratio.

#### **c ) MAXIMUM NORMAL SIZES OF AGGREGATES :**

The maximum nominal size of aggregates to be used in concrete is governed by the size of the section and spacing of the reinforcement. Both IS : 456-19783 and IS : 1343-19804, specify that the nominal maximum size of coarse aggregate should not be greater than one-fourth of the minimum thickness of the member, and it should be restricted to 5 mm less than the minimum clear distance between the main bars or, 5 mm less than the minimum cover to the reinforcement and 5 mm less' than the spacing between the cables, strands or sheathing in' case of prestressed concrete. Within these limits, the nominal maximum size of coarse aggregates may be as large as possible. In general, it is found that larger the maximum size of aggregate, smaller is the cement requirement for a particular water-cement ratio . This arises mainly from the fact

that workability of concrete increases with increase in maximum size of aggregate. However, the maximum size of aggregates also influences the compressive strength of concrete in that, for a particular volume of aggregate, the compressive strength tends to increase with decrease in the size of coarse aggregate. This is due to the fact that smaller size aggregates present a larger surface area for bonding with the mortar matrix; it also results from the fact that the stress concentration in the mortar-aggregate interfaces increase with increase in the maximum 'size of aggregate'. Here is thus an interaction of the maximum size of aggregate as well as the grade of concrete which determine the 'strength efficiency' of the cement and, therefore, the requirement of cement for a particular compressive strength is to be specified. It is seen that for concrete with higher water-cement ratio, larger maximum size of aggregates may be beneficial whereas for high strength concretes 10 or 20 mm size of aggregates is preferable. It is because of such reasons that IS : 456-1978 and IS : 1343-1980, while recommending that nominal size of coarse aggregates be as large as possible, also suggest that for reinforced and prestressed concrete works, aggregates having a maximum nominal size of 20 mm or smaller are generally considered satisfactory.

#### D ) MINIMUM WATER CEMENT RATIO :

The compressive strength of concretes at a given age and under normal temperature, depends primarily on the water-cement ratio; lower the water-cement ratio, greater is the compressive strength and vice-versa. This was first enunciated by Abrams as:

$$S = \frac{K_1}{K_2}$$

where S is the compressive strength and w/c represents the water-cement ratio of a fully compacted concrete mix, and K<sub>1</sub> and K<sub>2</sub> are empirical constants.

In day to day practice, the constants K<sub>1</sub> and K<sub>2</sub> are not evaluated; instead the relationship between compressive strength and the water-cement ratio are adopted, which are supposed to be valid for a wide range of conditions.

e ) **WORKABILITY :**

From the stage of mixing till it is transported, placed in the formwork and compacted, fresh concrete should satisfy a number of requirements which may be summarized as follows:

- i) The mix should be stable, in that it should not segregate during transportation and placing. The tendency of bleeding should be minimized.
- ii) The mix should be cohesive and mobile enough to be placed in the form around the reinforcement and should be able to cast into the required shape.
- iii) The mix should be amenable to proper and thorough compaction as possible in the situation of placing and with the facilities of compaction.

iv) It should be possible to obtain a satisfactory surface finish.

The diverse requirements of -stability, mobility, compactability, placeability and finishability of fresh concrete mentioned above are collectively referred to as 'workability'. The workability of fresh concrete is thus a composite property. It is difficult to precisely define all the aspects in a single definition. IS : 6461 (Part VII)-1973' defines workability as 'that property of freshly mixed concrete or mortar which determines the ease and homogeneity with which it can be mixed, placed, compacted and finished . It is also clear that the optimum workability of concrete varies from situation to situation and concrete which can be termed as workable for pouring into large sections with minimum reinforcement may not be equally workable for pouring in thin sections with heavier concentration of reinforcement. A concrete may not be workable when compacted by hand but may be satisfactory' when mechanical vibration is used.

#### **f ) MINIMUM CEMENT CONTENT :**

The maximum limit of cement content in the concrete may also have to be specified. This is because concrete mixes having high cement content may give rise to shrinkage, cracking and creep of concrete also increases with the cement paste content. In thick concrete sections restrained against movements, high cement content may give rise to excessive cracking caused by differential thermal stresses due to hydration of cement in young concretes. For high strength concretes, increasing cement content beyond a certain value, of the order of 550 kg/m<sup>3</sup> or so, may not increase the compressive strength. From these considerations as well as those of overall economy, the maximum cement content in the concrete mixes was limited to 530 kg/m<sup>3</sup> for prestressed concrete structures (see IS : 1343-1980) and for reinforced concrete liquid retaining structures [see IS : 3370 (Part I)].

## **4.2 COMMON MIX DESIGN METHODS ::**

- (a) The ACI Mix Design Method,
- (b) The USBR Mix Design Practice,
- (c) The British Mix Design Method .and
- (d) The Mix Design Method according to Indian Standard Recommended Guidelines for Concrete Mix Design.

### **(a) The ACI Mix Design Method:**

The ACI method' gives mix design for normal and heavy weight concrete (air entrained and non-air-entrained) in the workability range of 25 to 100 mm slump, the maximum 28-day cylinder compressive strength being 450 kgf/cm<sup>2</sup>. There is a separate method\* for mix design of 'no slump' (slump being zero to 25 mm) concrete (air-entrained and non-air-entrained) having maximum 28-day cylinder compressive strength of 475 kgf/cm<sup>2</sup>. In the ACI method', the volume of coarse aggregate in the concrete mix is first determined depending on the maximum size of aggregate and the grading of fine aggregate. The ACI method also determines the proportions of dry-rodded coarse aggregate in the concrete mix, the rodding being done according to ASTM C 296 for unit weight of aggregate. It is based on the concept that in dry-rodded void content, the differences in the amount of mortar required for workability with different aggregates due to differences in particle shape and grading are automatically compensated for.

**(b) The USBR Mix Design Practice :**

In the USBR method5, mix proportioning is done only for air-entrained concrete, the maximum 28-day cylinder compressive strength being 455 kgf/cm<sup>2</sup>, when water reducing and set controlling admixtures are used. In **USBR method**, the proportion of dry rodded coarse aggregate is determined corresponding to the maximum size of aggregate, a fixed fineness modulus of sand and a fixed workability in terms of slump.

### **(c) The British Mix Design Method :**

The latest British mix design method does not consider the combined aggregate grading curves like those used in Reference 4 (for maximum sizes of aggregate of 40 mm and 20 mm) and those developed for 10 mm maximum size of aggregate . This implies admission to the use of aggregates of any grading as long as they are within the grading limits specified by the appropriate Codes/Specifications. In the British method, the proportion of fine aggregate is determined first depending on the maximum size of aggregate, the degree of workability, the grading of fine aggregate and the water-cement ratio of the concrete mix.

#### **(d) The Mix Design Method according to Indian Standard Recommended Guidelines for Concrete Mix Design:**

The 'Indian Standard recommended guidelines for mix design' includes design of normal concrete mixes '(non-air entrained)', both for medium and high strength concrete. In this method of mix design, the water content and proportion of SP : 23-1982 fine aggregate corresponding to a maximum size of aggregate are first determined for reference values of workability, water cement ratio and grading of fine aggregate. The water content and the proportion of fine aggregate are then adjusted for any difference in workability, water-cement ratio and grading of fine aggregate in any particular case from the reference values. The batch weight of materials per unit volume of concrete is finally calculated by the absolute volume method. The specific relationships (Figures and Tables) that are given in this method of mix design, have been arrived at by exhaustive tests at the Cement Research Institute of India as well as on the basis of data on concrete being designed and produced in the country". These guidelines, although based on data on concrete, majority of which were made with OPC, are also almost equally applicable to concretes made with PPC. The final mix proportions, selected after trial mixes, may entail some minor changes in each case; such variations may also be necessary in case of cements of one type (either

OPC or PPC) but from different sources, or aggregates varying in quality. In so far as selection of water-cement ratio for the target compressive strength at 28-day is concerned, Fig. 46 is applicable for both ordinary Portland and Portland pozzolana cements with comparable validity. However, if a more precise estimate is made with the help of Fig. 47 where cements are classified on the basis of their 28-day strengths, then use of OPC or PPC is not expected to make much difference. Experiences with fly-ash-cement concretes indicate that in such cases, for comparable workabilities, the water content can be reduced by about 3 to 5 percent and proportion of fine aggregates reduced by 2 to 4 percentage points. It is doubtful whether such generalization can be straightway extended in case of concretes made with PPC also, but any difference that would be necessary can be easily established by trials with the materials at hand.

### **4.3 Mix Design in Accordance with Indian Standard Recommended**

#### **Guidelines for Concrete Mix Designs –**

The following basic data are required to be specified for design of a concrete mix:

- a) Characteristic compressive strength (that is, below which only a specified proportion of test results are allowed to fall) at 28 days ( $f_{ck}$  )
- b) Degree of workability desired ;
- c) Limitations on the water-cement ratio and the minimum cement content to ensure Adequate durability for the type of exposure (see Tables 6 to 9);
- d) Type and maximum size of aggregate to be used;

e) Standard deviation (s) for compressive strength of concrete: The standard deviation has to be calculated from the results of tests. When, the results of sufficient number of tests under site conditions and for the grade of concrete are not available, the values of standard deviation for different degree of control as given in Table below may be adopted.

**TABLE : ASSUMED STANDARD DEVIATION**

| GRADE OF CONCRETE               | ASSUMED STANDARD DEVIATION (<br>N/mm <sup>2</sup> ) |
|---------------------------------|-----------------------------------------------------|
| M10<br>M15                      | 3.5                                                 |
| M20<br>M25                      | 4.0                                                 |
| M30<br>M35<br>M40<br>M45<br>M50 | 5.0                                                 |

#### 4.4 The step-by-step procedure of mix proportioning is as follows:

a) The target mean strength is first determined as follows:

$$f_t = f_{ck} + K.S. \quad (1)$$

where as

$f_t$  = target mean compressive strength at 28 days,

$f_{ck}$  = characteristic compressive strength at 28 days,

$S$  = standard deviation,

$K$  = a statistical value depending upon the accepted proportion of low results and the number of tests (see Table below).

NOTE - As per IS : 456 & 1978 the characteristic strength is defined as that value below which not more than 5 percent of the test results are expected to fall. In such case,  $K = 1.65$  in equation (1).

**TABLE : VALUES OF K**

| <b>PERCENTAGE OF RESULTS BELOW<br/>THE CHARACTERISTICS STRENGTH</b> | <b>K</b> |
|---------------------------------------------------------------------|----------|
| 50                                                                  | 0        |
| 16                                                                  | 1.00     |
| 10                                                                  | 1.28     |
| 5                                                                   | 1.65     |
| 2.5                                                                 | 1.96     |
| 1.0                                                                 | 2.33     |
| 0.5                                                                 | 2.58     |
| 0.0                                                                 | Infinity |

**(b) The water-cement ratio for the target mean strength is chosen from Fig. 1 .**

The water-cement ratio so chosen is checked against the limiting water cement ratio for the requirements of durability (Tables 6 to 9 ) and the lower of the two values adopted.

Fig. 1 is based on a large number of results under Indian conditions, but on a given situation, may need slight modifications depending upon then characteristics of cement available”. As such, it is used more as a guide and actual water-cement ratio is determined by means of trial mixes as described in Ref 8. A more precise estimate of the preliminary water-cement ratio corresponding to the target average strength may be made from the relationships shown in \*Fig. 2 , using the curves corresponding to the 28-day compressive strength of cement. It is to be noted that cements have been characterised by its 28-day strength in Fig. 2 rather than upon its 7-day strength because 28-day strength of concrete is found to be better related to the 28-day strength of cement rather than at earlier ages, more so for blended cements. The relationship in Fig. 1 is really a mean curve through Fig. 2 . However, such trials will need 28 days for determining the strength characteristics of cement and atleast

another 28 days for the trial mixes. In order to cut down the time required for trials, an alternative method has been suggested in Ref .In this method, the accelerated strength (boiling water method in accordance with IS : 9013 -1978 of a ‘reference’ concrete mix having water cement ratio 0.35 and workability of’ 0.80 compacting factor with the cement proposed

to be used is determined on 15 cm cube specimens. The nominal maximum size of aggregate of the 'reference' concrete should be 10 mm and fine aggregate should conform to Zone II of Table 4 of IS : 383-1970. Corresponding to this accelerated strength, the water-cement ratio is determined for the target mean strength. These curves are based on the relation between 28-day compressive strength of concrete having water-cement ratio of 0.35, which is found to be, on an average, 0.934 times that of 28-day strength of cement tested as per IS : 4031-1968, and correlation of accelerated and normal 28-day strength of concrete .

(c) The **air content (amount of entrapped air)** is estimated from Table 2 for the maximum size of aggregate used.

(d )The **water content and percentage of sand in total aggregate by absolute volume** are next selected from Tables 3 and 4 for medium and high strength concretes, respectively, for the following standard reference conditions:

i) Crushed (angular) coarse aggregate,

ii) Fine aggregate consisting of natural sand. conforming to grading zone II of Table 4, IS : 383-1970r3, in saturated surface dry condition,

iii) Water-cement ratio of 0.60 and 0.35 for medium and high strength concretes respectively, and

iv ) Workability corresponding to compacting factor of 0.80.

e) For other conditions of workability, water-cement ratio, grading of fine aggregate and for rounded aggregates, adjustments in water content and percentage of sand in total aggregate are made as per 5.

f) The cement content is calculated from the water-cement ratio and the final water content arrived after adjustment. The cement content so calculated is checked against' the minimum cement content from the requirements of durability (Tables 6 to 9) and the greater of the two values adopted.

g) With the quantities of water and cement per unit volume of concrete and the percentage of sand in the total aggregate already determined, the coarse and fine aggregates content per unit volume of concrete are calculated from the following equations:

$$V = \left[ W + \frac{C}{S_c} + \frac{1}{p} \cdot \frac{f_a}{S_{fa}} \right] \times \frac{1}{1000} \quad (2)$$

$$V = \left[ W + \frac{C}{S_c} + \frac{1}{1-p} \cdot \frac{C_a}{S_{ca}} \right] \times \frac{1}{1000} \quad (3) \text{ and}$$

Where as ,

$V$  = absolute volume of fresh concrete  
 = gross volume (1 m<sup>3</sup>) minus the volume of entrapped air,  
 $S_c$  = specific gravity of cement,

$W$  = mass of water (kg) per m<sup>3</sup> of concrete,

$C$  = mass of cement (kg) per m<sup>3</sup> of concrete,

$p$  = ratio of fine aggregate to total aggregate by absolute volume,

$f_a$  ,  $C_a$  = total masses of fine aggregate and coarse aggregate, (kg) per m<sup>3</sup> of concrete respectively, and

$S_{fa}$  ,  $S_{ca}$  = specific gravities of saturated surface dry fine aggregate and coarse aggregate respectively.

**TABLE 1 :DEGREE OF QUALITY CONTROL EXPECTED UNDER  
DIFFERENT SITE CONDITIONS**

| DEGREE OF CONTROL | CONDITIONS OF PRODUCTION                                                                                                                                                                                                                                                                      |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Very Good         | Fresh cement from single source and regular tests, weighbatching of all materials, aggregates supplied in single sizes, control of aggregate grading and moisture content, control of water added, frequent supervision, regular workability and strength tests, field laboratory facilities. |
| Good              | Carefully stored cement and periodic tests, weighbatching of all materials, controlled water, graded aggregate supplied, occasional grading and moisture tests, periodic check of workability and strength, intermittent supervision, experienced workers.                                    |
| Fair              | Proper storage of cement, volume batching of all aggregates allowing for bulking of sand, weighbatching of cement, water content controlled by inspection of mix, occasional supervision and tests.                                                                                           |

## **5.0 ANALYSIS PROGRAMME**

In the project a mix design programme was made and effect of changes in various parameters on the quantities of various mix constituents of concrete has been noticed. Graphs and data of the variations have been given in the project.

## 6.0 CONCLUSIONS

Following conclusions can be drawn from the study.

1. It has been seen that sensitivity of mix quantities as per the theoretical procedure of Indian standard should depend on the quality control of construction. The code provides guidelines for the choosing of water cement ratio based on the quality of construction control.
2. For rounded aggregates, sensitivity of mix quantities is from -5 to 10 percent for various constituents of the concrete mix as compared to the aggregates which are angular.
3. Sensitivity of mix quantities is seen to be dependent on the size of aggregates also. Sensitivity increases with an increase in the size of aggregates.
4. Quality of superplasticizer used in the concrete mix also affect the sensitivity of mix quantities of various constituents.
5. The quantity of mix constituents is also affected by the zone of fine aggregate used. For example, fine aggregate content is increased by 4% if the zone of fine aggregate is changed from zone 1 to 2.
