Step 8: In the output layer, the prediction is computed as $\hat{Y}(x) =$ *Num / Denom*.
Step 9: The accuracy of prediction is measured by computing MSE.
Step 10: Steps 3 to 9 are repeated for the 10 folds of data.
Step 11: Average MSE for 10-FCV is computed and reported.

The architecture of GRNN++ is the same as the traditional GRNN except for the presence of the clusters (obtained through K-means||) occupying the pattern layer in place of the patterns themselves (see Fig. 1). The third and fourth layer of GRNN++ are identical to that of GRNN.

5 Experimental Setup

The system configuration for carrying out experimental work consists of standalone Spark cluster 2.2.0 as the computational framework on top of HDFS which is the distributed storage system. The program development environment used is Apache

Table 1 System configuration description

Central processing unit	Intel® Core™ i7-6700 CPU @ 3.40 GHz
No. of cores	4 Physical cores or 8 logical cores
Primary memory	32 GB
OS	Ubuntu 16.04 LTS

Table 2 Details of resource allocation in the cluster and coding environment

Allocated resource details	Node type	
	Master	Worker
Memory allocated for driver process	14 GB	–
Count of worker daemons	2	4
Memory allocated to worker daemon	7 GB	7 GB
Number of executors per node	2	4
Memory allocated to each executor	7 GB	7 GB
Cores allocated per executor	2	2
Memory allocated to all executors	14 GB	28 GB
Total memory utilized (out of 32 GB)	28 GB	28 GB
Framework for computation	Apache Spark 2.2.0	
Distributed storage system	HDFS (Hadoop 2.7.3)	
Coding interface	Apache Zeppelin 0.7.3	
Programming language	Scala 2.11.8	

Zeppelin 0.7.3 with Scala 2.11.8 as the coding environment. The Spark cluster consists of a system as a master node and seven systems as worker nodes. The driver program resides in the master node along with two instances of worker daemons. Each of the worker nodes executes four instances of worker daemons. All the seven systems have a similar configuration (refer to Table 1). In a standalone cluster system, each worker daemon has one executor. The details of resources allocated to worker daemon or executor, driver process, and programming environment details are presented in Table 2.

The GRNN++ was implemented with the above cluster configuration and programming environment. We found the best execution time by adjustment of the amount of memory allocation to the executors along with the optimum data partitions.

Table 3 Attribute details of ethylene–CO gas sensor array dataset

Attribute name	Attribute details
Time (s)	Time measured in seconds for the sensor readings
CO conc. (ppm)	The concentration of CO measured in ppm
Ethylene conc. (ppm)	The concentration of ethylene measured in ppm
Sensor readings (16 channels)	Readings from 16 chemical sensors forming the data comprising 16 columns

6 Dataset Description

The current work has analyzed the data from an array of gas sensors involving different gas mixtures. The dataset [38] was collected from UCI ML repository [39]. The dataset contains the readings gathered from 16 sensors exposed to varying concentrations of gas mixtures. The original dataset contains readings of two different mixtures of gas in air, namely, ethylene with methane, and ethylene with CO. We have analyzed only the ethylene and CO mixture in air dataset for prediction of ethylene and CO concentration in air. The sensor readings were the data from 16-sensor array signals gathered uninterruptedly for about 12 h.

The ethylene and CO mixture in air dataset, which is analyzed in the current work, presents 19 features. Here, the first feature represents the time of sensor reading; the second feature represents CO concentration in ppm; and the third feature represents the ethylene concentration in ppm. The next 16 features represent the sensor readings from 16 chemical sensors (see Table 3). The dataset contains 4.2 million samples. The dataset is of 643 MB.

For our regression work, we have dropped the first feature being the time series values. Out of the second and third feature, one is selected as the dependent variable. We have selected the features from the fourth to the last as independent variables for our experimentation.

7 Results and Discussion

The research work conducted comprises the analysis of the dataset mentioned above with the proposed approach. The results of the carried out work cannot be compared with any other technique as we could not find any work carried out in the same domain and using such hybrid architectural techniques.

The experiment was carried out with ten-fold cross-validation (10-FCV) of the min–max normalized dataset. The K-means‖ was carried out with k value ranging from 2 to 10 and then the Dunn-like Index was taken into account for cluster validity for finding out the optimal cluster centers. Then, with the selected cluster centers GRNN++ was carried out with sigma (σ) value ranging from 0.001 to 1.0

Table 4 Mean MSE for 10-FCV

	Ethylene concentration prediction from ethylene to CO dataset	CO concentration prediction from ethylene to CO dataset
Gaussian activation function	0.075	0.076

with an increment of 0.001. The error is calculated as MSE. Table 4 presents the average MSE of 10-FCV.

The activation function used in GRNN++ is the Gaussian function which captures the features of a test data and correspondingly presents the prediction value.

8 Conclusion and Future Directions

The GRNN++, a parallel and distributed version of GRNN, is proposed in Apache Spark, where HDFS takes care of the distributed data storage. The GRNN++ is implemented in Scala programming language. The GRNN++ could achieve big data regression in a single pass and by yielding a very low mean squared error of 10-FCV. The hallmark of the proposed method is the invocation of the parallel distributed K-means++ aka K-means‖ into the architecture of the traditional GRNN. GRNN being the non-parametric estimation provides better accuracy.

The innovation of the proposed method resulted in a drastic reduction in the count of neurons in the pattern layer of GRNN. This feature has made the system overcome the major shortcoming of GRNN which is computational overhead.

The effectiveness of GRNN++ is tested on a static dataset, but it can be modified to suit online streaming data mining by invoking parallel evolving clustering method (PECM) [28] in place of the K-means‖. Thus, it can be extended to handle real-time or quasi-real-time prediction from streaming data. Further, the logistic activation function can also be considered in place of the Gaussian in the pattern layer.

An Entropy-Based Technique for Conferences Ranking

Fiaz Majeed and Rana Azhar Ul Haq

Abstract Ranking of conferences is carried out to guide the researchers so as to publish their work in top-level venues. Existing works are needed to be improved in regard to accuracy. In this paper, we have proposed a ranking technique of conference papers named as influence language model (InLM). It uses entropy to calculate score for the purpose of ranking. It identifies level of the paper as well as level of the conference based on entropy score. Experiments have been performed on bigger dataset. The results reflect better position in comparison to the existing systems.

Keywords Conference ranking · Language model · Influence language model · Entropy · Scientific research

1 Introduction

The ranking of the conferences is an important area of research to assess quality of research work. Such a ranking provides recommendations to the researchers to publish their valuable work in reputed conferences. Several measures have been developed to rank the conferences [3].

This paper solves the problem of ranking the conference papers so that relevant papers of top ranked conferences are placed at first places in the retrieved results. The quality of paper is measured based on its frequency of citations. The main purpose of this research is the semantic ranking of conference papers using influ-

ence language model (InLM). In conference paper ranking, we utilize search and ranking technique that use query string to rank the conference papers. To evaluate the InLM technique, a dataset containing 32,000 papers and 50 user queries is built. We have performed comparative analysis of InLM with the existing methods.

The motivation of this research work is that quality researchers need to search the quality conference papers. As conferences have no standardized impact factor system similar to journals, this research work provides them quality conference papers (which is measured based on citations of the particular paper). The relevant documents are then ranked based on calculation of entropy that uses citations of the paper.

The key contributions of this paper are summarized as follows:

- We have proposed a conference papers ranking technique named as InLM.
- We have presented a ranking algorithm based on entropy to rank the conference papers.

The paper has been organized as follows: The review of related works is comprehensively described in Sect. 2. Later, the proposed solution is presented in Sect. 3, and experimental evaluation is provided in Sect. 4. Finally, conclusion and future work is given in Sect. 5.

2 Related Works

Existing methods on conferences ranking have achieved less accuracy in comparison to the journals ranking. A review of those methods is provided to justify further improvement in this domain: the ranking of authors and conferences based on citations is performed by adding time factor. It is the extension of PagRank for yearly conferences ranking. The DBLP dataset is used for experiments and top 10 authors and conferences have been provided [7]. In another work, conferences are ranked based on publication of their extended papers in top journals. For this purpose, acknowledgment information of finance journals is taken and analyzed. The dataset comprised footnotes of 3000 journal articles and 9000 conference articles. Based on this, 47 conferences have been ranked [4].

Currently, two citation analysis systems only exist for journals ranking, which are CiteSeer and Institute for Scientific Information (ISI). The ranking system for the conferences is equally important. Thus, Scientific Collection Evaluator by using Advanced Scoring (SCEAS) system is developed that considers age of the conference. Using DBLP dataset, a web-based application is built [6].

In computer science (CS) domain, few ranking methods exist. Thus, ranking of CS conferences is performed using RsIT technique. It uses a set of conferences, relatedness measure and baseline method to rank the top CS conferences. The Microsoft Academic dataset is used for experiments. The comparison is carried out with the existing CCF rating list. This method provides better results in comparison

to the CCF list [2]. An analysis of the criteria of existing measures for CS conferences is performed. The conference ranking is compared using bibliometric indicators and acceptance rate. The experiments are carried out on three datasets: RankX, Perfil-CC and ERA2010 [3]. The health of conferences related to the software engineering is checked by defining a suite of metrics. The comparison of conferences by parameters like author, PC candidates and scientific prestige is used. Based on the results, 11 top conferences are selected for the interval of 10 years [8]. A technique to rank the CS conferences is proposed with the extension of existing metrics. It generates self-organizing maps for the purpose of ranking. This method is evaluated in correlation to ERA using Microsoft Academic Search dataset including 3442 conferences [1].

The extension of h-index is presented for the journals and conferences ranking. For this purpose, yearly h-index and normalized yearly h-index have been proposed. The DBLP dataset is used with 2024 conferences [5].

In the existence of above conferences ranking methods, no system could be used as standard similar to the ISI. This is due to the fact that current methods do not achieve the required level of accuracy. It is still required to work on achieving the accuracy. This work is build based on this idea.

3 Proposed Solution

The architecture of the InLM is shown in Fig. 1. The input query is processed on the pre-processed dataset. Further, the retrieved results are ranked based on the proposed InLM-based ranking algorithm.

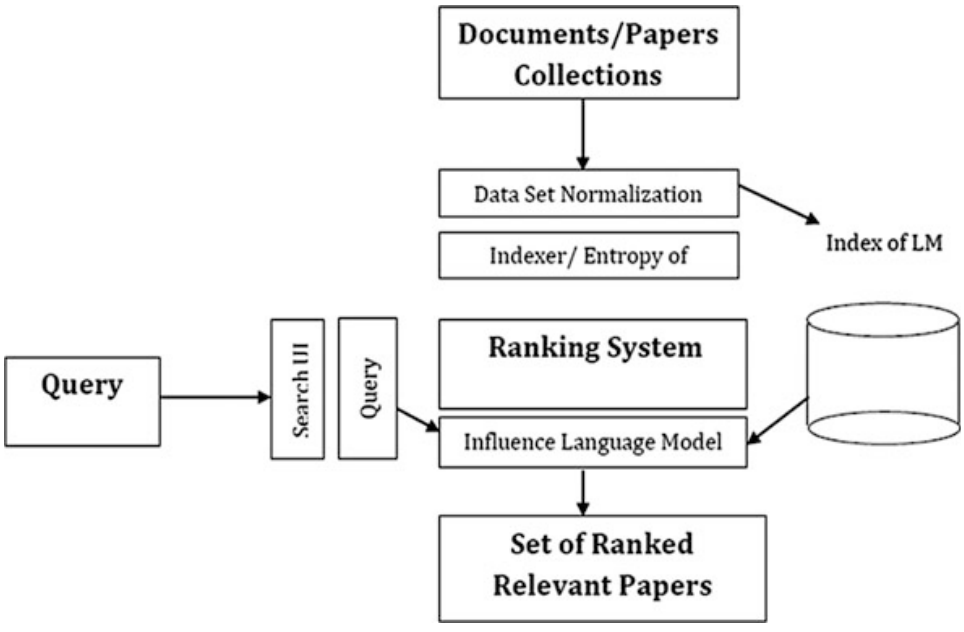

Fig. 1 InLM ranking system

3.1 Entropy Score

As shown in Eq. (1), the entropy of the conferences can be calculated as:

$$\mathrm{Ent}(v) = -\sum_{i=1}^{m} w_i \log_2(w_i) \tag{1}$$

where word_i has the probability w_i at venue v. Individually, all publications of each conference can be used for computation of the probability for input query.

The entropy of papers is calculated as given in Eq. (2):

$$\mathrm{Ent}(p) = \sum_{i=1}^{m} w_i \log_2(w_i) \tag{2}$$

In a paper (p), w_i provides the probability of word_i.

3.2 Calculation of Citations

In comparison to the DBLP, it was tricky to develop a crawler for the Google Scholar. The procedure was to input the query in the search box of Google Scholar and then find out the relevant paper from retrieved results after pressing the search button. Google Scholar provides the citation count for each paper. This process was required to be automated. Initially, the papers were searched manually for analysis. The URL of the relevant results was changed programmatically in such a way that half part of URL was updated to route the citations in our database. The search page of Google Scholar was explored by using the PHP's html document object model for required data, thus put all the citations in Wamp Server and updated the database. For the improved language model, citations of each ranked paper were measured.

3.3 Influence Language Model

This method measures the worth of a paper, whether it is published in low- or high-level conference. The entropy of the conference is calculated to check the level of a conference. The publication of a paper in certain level of conference is proportional to the number of citations. For instance, a paper published in high-level conference will have increased citations, whereas low citations will be received for the paper published in a low-level conference. The InLM increases the score for high-level conference having low entropy, whereas for the low-level conference with high entropy, the method decreases the score.

Two thresholds of entropy 1.8 and 1.85 have been defined and taken as limiting values. The conference or venue is considered as high level in case the entropy value remains below 1.8. Further, in case the entropy value reaches above 1.85, the venue is considered as low level. In influence language model, the probability of a query over document $P(q|d)$ and the resulted value with the entropy result is multiplied. The entropy of the high-level venue is multiplied to increase the score as high-level venue gain smaller value of entropy then multiply the resulted entropy value with $P(q|d)$ (Eq. 3). The entropy is first divided with 3 for decreasing its value for low-level venues and then $P(q|d)$ is multiplied with the resulted entropy value (Eq. 4). We simply multiply $P(q|d)$ with entropy for the venues whose value of entropy is between the range 1.8 and 1.85. The proposed composite model does not consider venues influence.

$$\begin{aligned} &\text{If ent } < 1.8 \\ &\text{ent_value} = \text{ent} \times 3 \\ &\quad \text{Elseif ent } > 1.85 \end{aligned} \tag{3}$$

$$\text{ent_value} = \text{ent}/3 \tag{4}$$

The values of language model are multiplied with entropy values. So the main Eq. (5) of InLM is as follows:

$$\text{InLM} = \text{LM} \times \text{ent_value} \tag{5}$$

In Eq. (5), the entropy value of each conference paper is multiplied with each paper of language model result.

It is necessary to prepare the data before input to the machine learning algorithm, so the pre-processing procedure is given in Algorithm 1.

Algorithm 1

1. Extract all the titles from html pages.
   - Read the html file in java.
   - Patternpt2 = Pattern.compile(“b>.*?</b”);
2. Remove stop words from extracted data.
   - Give input of the raw file.
   - By using the string tokenizer, string is matched. The stop words are removed if those are matched.
   - Then line-by-line matching of each token is performed.
   - StringTokenizer stnz = new StringTokenizer(“*+<>,&-:;.()[]$#@!/\\’\”` ~ ^? ”);
   - By using the above code, each token is matched one by one.

3. Conversion in lower case
   - The search becomes much easier by converting these letters in lowercase. Lowercase function is used for this purpose.
   - Token = token.toLowerCase ();.
4. Frequency Removal
   In the research paper titles, there are many words which are used frequently by many researchers. If a word is matched more than thrice, then it will be removed from the data.
5. Normalize the whole data.

3.4 Application of the InLM

For instance, three papers say P1, P2 and P3 are chosen from the dataset. According to the existing language models, all have the same score because of having equal p (q|d). Let according to previous models,

$$\begin{aligned} P(q|d) \text{ for } \quad & P1 = 0.85 \\ P(q|d) \text{ for } \quad & P2 = 0.85 \\ P(q|d) \text{ for } \quad & P3 = 0.85 \end{aligned}$$

These papers should not have the same scores as they contain the same length of query and published in different conferences, as well as have same number of query terms.

The venue's entropy can be calculated as:

Let

doc 1 entropy = 1.87 (P1 belongs to low-level conference)
doc 2 entropy = 1.69 (P2 belongs to high-level conference)
doc 3 entropy = 1.95 (P3 belongs to low-level conference)

The following result is achieved when the results of previous language models are divided with entropies of conference.

Doc 1 = 0.85 * (1.87/3) = 0.52 (P1 is also low-level conference)
Doc 2 = 0.85 * (1.69/3) = 4.30 (P2 is of high-level conference)
Doc 3 = 0.85 * (1.95/3) = 0.55 (P3 is of low-level conference)

According to the values, the level of conference is being decided.

4 Experimental Evaluations

The experimental evaluation is performed on big dataset. In this respect, the details of the dataset are given below.

4.1 Dataset

Conferences data:

- Data of 100 conferences
- Around 32,000 papers
- Collection of all the title of publications

Query set:

We have developed a query set for experimental purpose. Few of the queries are given below:

- Machine language
- Data mining
- Formal languages
- Group theory
- Information retrieval
- Computer networks
- Semantic web
- Analysis of algorithm
- Natural language processing
- Databases

These queries are used to find the best conference papers from the conferences data. In other words, quality papers of the authors in the relevant field are ranked by the proposed InLM. The dataset is made up of different CS conferences and more than 32,000 research papers of these conferences. The searching technique used for this purpose is content-based ranking. Specifically, there are 100 CS conferences that are extracted from the DBLP. The research papers are taken in the duration of 2003–2007 (5 years).

The support vector machine (SVM) algorithm has been used for the classification of the data and the results are measured using precision, recall and F-measure.

4.2 Pre-processing

Initially, the whole data are pre-processed. In Fig. 2, raw data in html pages are shown, which contain conference information, that is, author's name, title of the paper and name of the conference where the paper has been published.

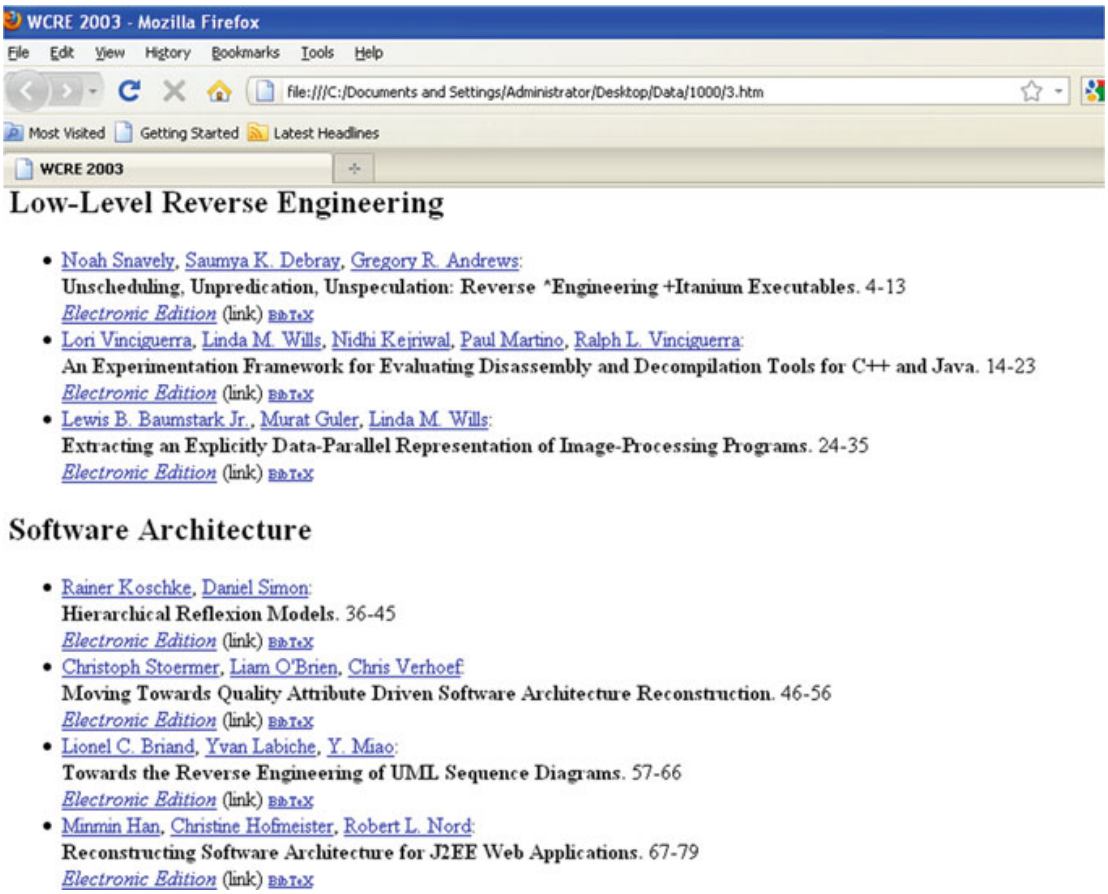

Fig. 2 html pages including raw data

4.3 Results

In this section, we produce the ranking result of our language model and some key terms are used for showing the results of both language models. These terms include Name (title of research paper), Cit (citations), LM (language model) and InLM. The results about one of the query from the query set are given in Table 1.

These are the average results of given base queries using the InLM, including the citations and entropy of the papers for particular input query strings.

In Table 2, the comparison of two models has been taken under consideration, one is previously implemented LM for average of 10 queries and showed the value

Table 1 Top 2 conferences against "data mining" query

S#	Name	Cit	InLM	Name	Cit	LM
1	Region restricted clustering geographic data mining	6	1.875	Data mining track editorial	0	0.675
2	Measuring effectiveness agile methodologies data mining knowledge discovery	4	1.627	Optimization of language data mining	0	0.607

Table 2 Average citations results of top 10 queries

Models	Average citations for 10 queries
LM (VSM)	184.92
InLM	457.36

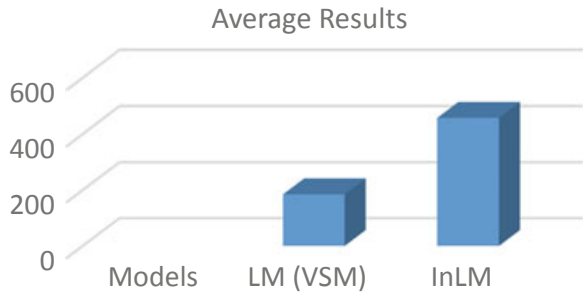

Fig. 3 Graphical representation

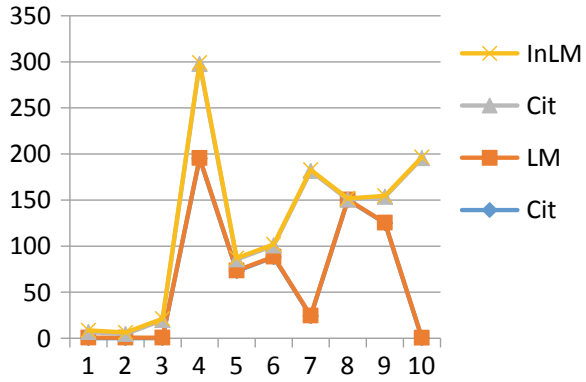

Fig. 4 Comparison of results for data mining query

of 184.92 after setting parameters. On the contrary, the proposed model InLM with the same parameters has given a value of 457.36 with more accuracy and precision for average value of 10 queries.

Figure 3 shows the models along the horizontal axis and number of citations along the vertical axis. The graph clearly mentions that the model InLM has better average results, including entropy results, in more than 400 citations than the LM which is less than 200 citations.

In Fig. 4, the result of InLM is better than LM for "data mining" query.

In Fig. 5, graph depicts score comparison of LM and our proposed model InLM, which shows much better results than LM and has a better ranking for the conference papers.

In Fig. 6, line chart shows ranking result of LM and Fig. 7 shows the result for the InLM.

It has been clearly seen that InLM clearly shows better ranking including entropy of the paper for query. In addition, classification results are shown in Table 3.

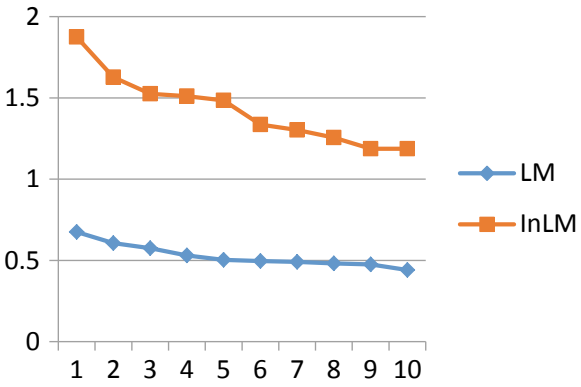

Fig. 5 Comparison of language models results for data mining query

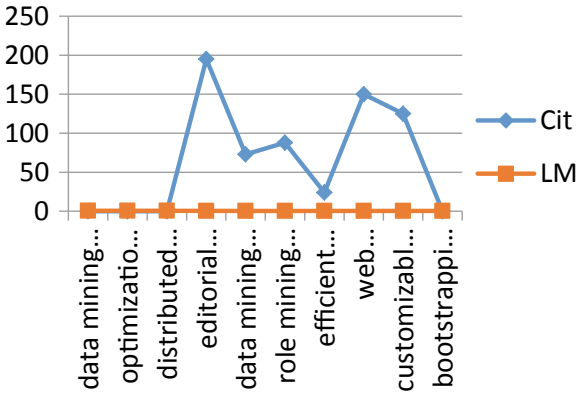

Fig. 6 Language model results of ranked conference papers

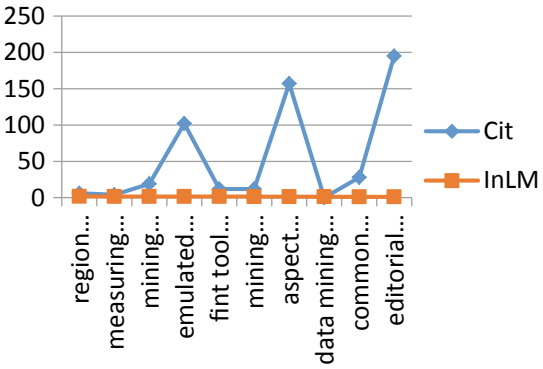

Fig. 7 Language model results of ranked conference papers

Table 3 Classification results

Precision	Recall	Measure-F
82%	79%	81%

5 Conclusions

In this work, the ranking of the conferences is performed using the entropy measure. The InLM system computes entropy of the conferences to generate a ranking list. Further, a comparative analysis is performed with LM. The InLM shows better results in comparison to LM. Furthermore, time factor and names of authors' papers can also be incorporated to improve the ranking.

MapReduce mRMR: Random Forests-Based Email Spam Classification in Distributed Environment

V. Sri Vinitha and D. Karthika Renuka

Abstract The furthermost standard message transfer system used on the internet for communication is email. These days spam is a serious concern that causes major problems in today's internet. Spam emails are uninhibited messages that are sent to a large number of beneficiaries arbitrarily. Owing to an overgrowing rise in reputation, the number of unsolicited data has also increased promptly and has led to many security concerns. Although the sufficient number of spam filtering techniques exists, nowadays spammers start discovering innovative practices to escape data that are filtered using the spam filters. Spammers use this communication source for spreading the malware in the name of an executable file. These spam emails waste user's system memory, computing power, and bandwidth of the network. Spam emails have been initiated to progressively damage the integrity of email and destroy the online experience. The research revealed that if the classification algorithms are used with feature selection then that will return the exact results than the standard classification. In this paper, feature selection is done through minimum redundancy and maximum relevance (mRMR) and the classification is done by means of Random Forests in the MapReduce environment. The performance is compared using various measures, namely sensitivity, correctness, and accuracy with the Random Forests in the distributed environment using Spambase dataset.

1 Introduction

Nowadays, the internet has been mostly used for the purpose of exchanging information. Email has started rising on the internet because of its simplicity, cost-effectiveness, and commercial tool for exchanging information and business communication, and so on [1]. It is exposed to many threats because of its easiness. One among them is email hazard which becomes a big trouble over the internet. Spam email is sent to an enormous amount of users since it charges very less amount for transferring data between the different users. When the user receives the wide range of spam emails then it becomes extremely tough to predict whether the received emails are spam or ham, as it consumes more bandwidth on the internet, wasting user's time and memory. Gradually, spam emails are directed through "zombie systems", or through worm-contaminated PCs around the world. Advanced worms permit spammers to access the user's PC indirectly for malicious purposes. At present, there are some important work-related emails in the spam folder. Globally, the amount of users using email is increased from over 88.6 million in 2014 to over 200.3 million in 2018. Today, various types of spam email exist, and certain things include making money through advertisement and so on. [2]. The sender of a spam email looks like real mail that is not judged by some of the existing filtering techniques. The unwanted spam emails getting into user's inbox should be avoided and to increase the accuracy of email classifiers on the user side, spam filtering techniques are used.

2 Related Works

Nowadays, most people have the habit of using the internet for browsing data, communication purpose, business promotion, and an innovation, providing business services and sharing knowledge with others. Henceforth, the internet has started developing promptly. One of the common threats is spam. Spam message is sent to massive number of recipients for the purpose of advertising, marketing products, job offers, and so on with large incomes for spammers. It also wastes user's time and occupies more memory. These days most of the emails received are spam. Therefore, Bassiouni et al. [3] proposed a technique for classifying spam emails with better performance using ten classification algorithms. The ten different classifiers such as logistic regression, decision tree, Bayes net, support vector machine, naïve Bayes, k-nearest neighbors, Random Forests, artificial neural network, random tree, and radial basis function are used for classification. The ten classification algorithm provides accuracy such as 92.4, 90.3, 89.8, 91.8, 89.8, 90.7, 95.4, 92.4, 91.5, and 82.6. The experimental result shows that the system achieves a correctness of about 95.45% by using Random Forest's approach for Spambase UCI datasets.

Email is the most active and fastest method of correspondence to trade data over the web. It is so popular for its cost-effectiveness, easiness, and fastest mode of communication. Since there is an expansion in the number of users using the diverse social sites, there is a massive increase in unwanted messages. Spam can cause the severe financial disaster, loss of data transmission, and wastage of memory. Spam emails have been created to progressively damage the integrity of email and destroy online experience. The problem of spam mail getting into user's inbox is resolved by using spam filtration approach. In this paper, Kaur et al. [4] suggested the N-gram technique for feature selection and improved multilayer perceptron for spam classification. The result comparison is performed on emails collected from Enron dataset shows that the proposed N-gram-based K-enhanced MLP demonstrated higher performance than existing MLP along with low error rate. Future work uses optimization techniques and some other feature selection techniques for selecting the best features for numerical data, text data, and image corpus.

Currently, the internet has turn out to be an essential one in everyone's life. With this increased use, the number of email users is also enlarged nowadays. It is predicted that 90% of the emails sent are spam. This leads to a problem initiated by spontaneous bulk email stated as spam. It is expected that 90% of emails are sent every day with the intention of advertising any product or spreading any kind of malware to the user PCs without any notification. Spam email is sending unwanted communications to different email users. This spam email causes severe harms for internet users such as the delay in sending legitimate messages, wastage of network bandwidth, storage, and computation power. To avoid this problem, various spam filtering techniques exist. Vijayasekara et al. [5] propose machine learning algorithm naives Bayesian with three-layer structure for classifying spam in bulk emails. The feature selection method is used to select the best attributes and categorize spam emails using naïve Bayesian algorithm which helps to increase the correctness of the system.

To select the best attributes from the high-dimensional data, it uses feature selection techniques. The methodologies used for feature selection should be efficient to manipulate multivariate historical data. To elucidate this problem, Radovic et al. [6] recommend the significant and repeated data with some modification for the assessment process. The features can be discrete as well as continuous. F-statistics can be considered for significant data and Pearson correlation or mutual information for assessing repeated data. The recommended technique is measured using gene expression temporal datasets and provides high performance compared to other systems. Forthcoming work will be applied to various algorithms with feature selection approach that chooses the slightest repetition and more importance.

At present, electronic mail has become the popular mode of communication on the internet which is used to exchange information to a large number of beneficiaries. It is used for getting and transferring data among different users. Because of its fastest delivery, less time, and low cost for sending emails to make people use it for advertising products, sending fraudulent mails and phishing mails resulted in

unwanted spam emails. Spam is the unsolicited, unwanted mail that sends messages to a large number of recipients. It also wastes user's time, transmission capacity, and user's system space. Spam filtering approaches categorize the spam email based on the information it contains and sends the spam mails into spam folder. Easwaramoorthy et al. [7] proposed the system consisting of the training and testing phase. In the preliminary phase, the hybrid Firefly GSO algorithm takes the input mails to choose the best attributes from the huge dataset. Then the selected features are classified using three classification algorithms, namely decision tree, neural networks, and naïve Bayes algorithm. Then the result is evaluated using UCI repository Spambase dataset through various metrics.

3 Proposed Methodology

The process of the proposed email spam classification technique as in Fig. 1 can be described in the succeeding phases:

- Prepare the UCI repository Spambase dataset for the proposed system
- In the MapReduce framework, do the feature selection and classify the spam emails

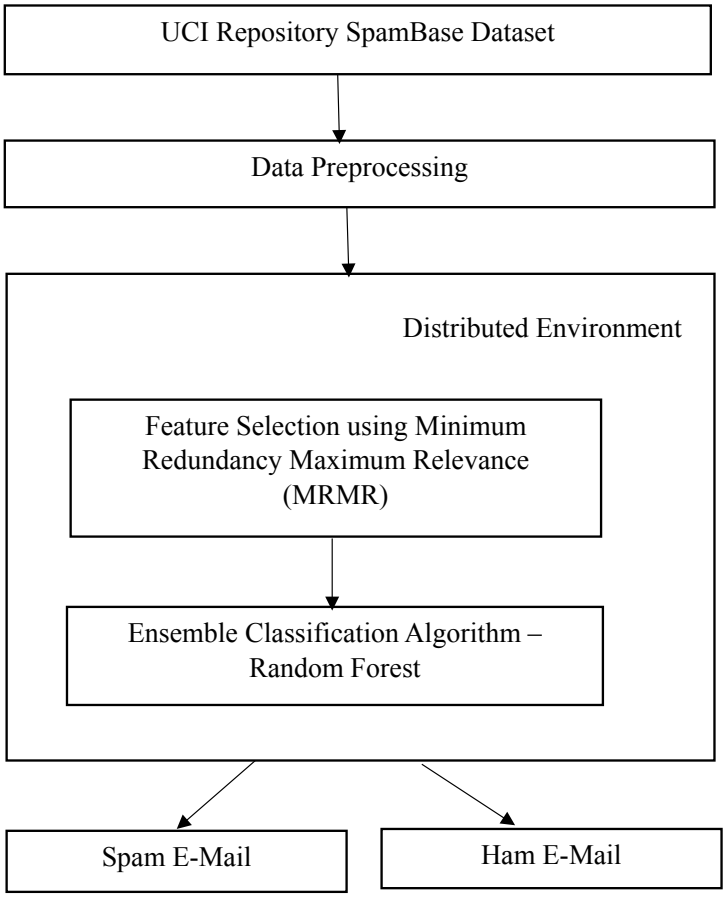

Fig. 1 Framework of the proposed spam email classification

- Feature selection is done by using minimum redundancy and maximum relevance technique to select the best attributes from Spambase dataset
- Then the selected attributes are classified by using Random Forest classification algorithm
- Finally, compare the proposed framework with Random Forest classification in a distributed environment.

3.1 Dataset

In this paper, UCI repository Spambase dataset has been taken for email spam classification. Totally, there are 4601 emails in the Spambase. In this 39.4%, that is, 1813 emails are spam and remaining 60.6%, that is, 2788 are ham emails [8]. There are 58 features in UCI repository Spambase dataset out of which 57 attributes are continuous and one with class label (d). The description of the attributes is given in Table 1 as.

3.2 Data Preprocessing

In real world, Spambase dataset contains some missing values, and this missing data may lead to incorrect or even misleading statistics. Data preprocessing procedure is used to remove noise, inconsistent, and incomplete data in order to obtain a quality result. It is the initial step which makes sure that data is prepared to be analyzed [9]. There are various preprocessing steps available, and here data normalization is done in order the make the dataset suitable for further processing.

Data discretization: Discretization states the method of converting continuous attributes into discretized variables. It transforms data from numeric into nominal data type. The generic representation of Spambase dataset is given by:

$$\text{Spambase Dataset} = d_k; \quad 1 \leq k \leq p \tag{1}$$

Table 1 Description of Spambase dataset

Attribute number	Type of attribute
1–48	word_freq_WORD
49–54	char_freq_CHAR
55	capital_run_length_average
56	capital_run_length_longest
57	capital_run_length_total
58	Class attribute

The Spambase dataset is given to the discretization function to transfer the input data into discretized one. Discretization converts the data into specific range. The highest and smallest value of every attribute is identified and the I interval is followed by taking the proportion between the differed value and the I value.

- For example, at-first, the deviation is calculated for every k value

$$\mathrm{Dev}(k) = \frac{\mathrm{Max}(d_k) - \mathrm{Min}(d_k)}{2} \tag{2}$$

- After calculating deviation values for each row, values are converted to the following condition:

$$\left.\begin{array}{ll} 0, & \mathrm{input} < 1(\mathrm{Dev}(k)) \\ 1, & \mathrm{input} < 2(\mathrm{Dev}(k)) \\ 2, & \mathrm{input} < 3(\mathrm{Dev}(k)) \\ 4, & \mathrm{input} < 4(\mathrm{Dev}(k)) \end{array}\right\} \tag{3}$$

Then, the value which comes under particular range is substituted by interval value in order to convert the input data into discretized data. After discretization function, the training dataset is converted to above conversion Eq. (3) and then each value is converted into 8421 binary conversions as discretized format.

3.3 MapReduce

MapReduce is a framework of Hadoop system designed to examine large dimensions of files in a parallel mode on commodity machines. Its objective is to get used to the available computational resources and process data in a massively scalable way in two processing phases, that is, map and reduce phase.

The entire process of MapReduce can be illustrated using the following notation [10]:

$$\mathrm{Map}{:}(k1, v1) \rightarrow \mathrm{list}\ \{k2, v2\} \tag{4}$$

$$\mathrm{Shuffle}\ \&\ \mathrm{Sort}{:}\ \mathrm{list}\{\mathrm{k2},\ \mathrm{v2}\} \rightarrow (\mathrm{k2}, \mathrm{list}\{\mathrm{v2}\}) \tag{5}$$

$$\mathrm{Reduce}{:}(\mathrm{k2},\ \mathrm{list}\{\mathrm{v2}\}) \rightarrow \mathrm{list}\{\mathrm{k3}, \mathrm{v3}\} \tag{6}$$

In the Map step, Spambase dataset after preprocessing into discretized data is loaded once into a mapper function as in Eq. (4). Then the feature selection is done by using minimum redundancy maximum relevance and the features are delivered by means of a list of key-value objects. The output of mapper will be the sequence of new objects with maximum relevance features without any repetition.

In the Reduce step, the input of a reducer is the intermediate object as in Eq. (5), which shares the same features that will be collected together. The features are classified by means of Random Forest algorithm and the output is obtained by the majority voting of the classification trees that have been formed. The final output will be produced as in Eq. (6).

3.3.1 Minimum Redundancy Maximum Relevance (mRMR)

The process used for obtaining the subset of relevant attributes is a feature selection process, that is, the dimensionality reduction method [11]. Its objective is to attain a better result with the minimum number of features. The filter method used in this paper selects the feature with minimal repetition and maximal importance. mRMR depends on two metrics: the least repetition among the attributes that have chosen and the greatest significance among candidate features and target class. In the Mapper step, the Spambase dataset D is given as input with N samples (4601 instances) and M features (57 attributes) $X = \{x_1, x_2, x_3, \ldots. x_m\}$ and the target classification variable c. The feature selection technique finds the subset of m attributes, R^m from the M-dimensional data, R^M.

Maximal relevance is selecting the features from the Spambase dataset with the maximum significance to the target class c. Either correlation or mutual information may be the measure used to define dependency of variables. Max-relevance is an average of all collective information values among individual attribute x_i in the Spambase dataset and class c as in Eq. (7).

$$max\, D(S, c), D = \frac{1}{|S|} \sum_{x_i \in S} I(X_i, c) \tag{7}$$

The subsets that are identified by the maximum relevance often contain relevant repeated data. mRMR challenges to provide the solution to this problem by eliminating those repeated subsets. The minimal redundancy property is included to choose mutually exclusive features from the Spambase dataset as in Eq. (8).

$$\min\, R(s) = \frac{1}{|S|^2} \sum_{X_i X_j \in S} I\left(X_j, X_j\right) \tag{8}$$

Minimum redundancy maximum relevance is combined to select the features that have the high association with the criterion without any repeated data that can be denoted as in Eq. (9). This gives the subset of features S^* selected using mRMR, which is the output of Map step.

$$S^* = \arg\max_{S \subseteq F}[\max D(S, c) - \min R(s)] \tag{9}$$

mRMR Algorithm

```
INPUT: Data, Features
// Data – Spambase Dataset
// Features - 57 features in Spambase Dataset
OUTPUT: SubsetofFeatures // Set of features selected from Spambase dataset.
for features fi in SpambaseDataset do
        rel = mutualInfomation(fi, classlabel);
        redundant = 0;
        for features fj in SpambaseDataset do
                redundant += mutualInformation(fi, fj);
        end for
        mRMRData[fi] = rel - redundant;
end for
SubsetofFeatures = sort(mRMRData). take(Features);
```

The algorithm for minimum redundancy maximum relevance is given above [11]. In the mRMR system, the core problem is associated with the calculation of the mutual information among two components: either exists as a couple of input features or feature by means of the class. This task is figured among every single pair of features; some of the pairs of features are still unrelated for the final outcome, which is insignificant in high-dimensional problems.

3.3.2 Random Forests

Random Forest is an ensemble learning technique that works best for high-dimensional data and was developed by Leo Breimanand Adel for classification and regression not pruned trees. The bagging technique uses a decision tree for selecting arbitrary features to improve classification performance by combining the results of different classifiers. It uses randomized node optimization. Based on the arbitrary choice of data and variables, the progress of the trees can be determined.

The selected feature S^* from mapper phase is given as input to the reducer phase. With the selected feature, it builds an m number of decision trees and forms a forest. Then the new object which is necessary to be classified is placed under each of the

decision trees for classification. The mail is categorized as ham or junk mail based on each trees decision by voting as in Fig. 2. The prediction of the spam emails is attained by majority voting of the decision trees that have been formed, which will be the results of the reducer phase.

Every tree is developed as follows [12]:

1. Spambase dataset after feature selection contains S^* features; the training set will be sample M cases from the subset of features S^*.
2. Choose the best split between the M features.
3. Develop each one of the trees to the biggest possible level without pruning.
4. The spam emails are estimated by grouping the predictions of m trees by majority voting technique.

Certain features of the Random Forest algorithm are given as follows:

1. It provides better accuracy and also lighter compared to other ensemble algorithms.
2. It does not overfit the data because it does not have any insignificant data.
3. It is sturdy to noise and outliers and can also handle uneven datasets.

Pseudocode for Random Forests Algorithm

```
Begin RandomForests
      Input:   N:number of nodes
               F: Spambase Dataset with the subset of features S*
               T: Total amount of trees to be created
      Output: MV : the class label spam or ham with majority voting
       While ending condition is incorrect do
            The underneath phases are used to build the tree from the training data:
            1)  Select the features f arbitrarily from F; where f ≪ F
            2) For node t, compute the best split point between the f features
            3) Based on the best split, divide the node into two child nodes
            4) Iterate the steps 1, 2 and 2 up to n amount of nodes has been reached
         Construct the forest by iterating steps from 1–4 for T periods
       End While
         Display all the created trees
         The new sample is applied to all the created trees beginning from the initial node
         Allocate the new object to the external node with the resultant class label.
         Aggregate the votes of all the nodes in the trees.
         Display the final output MV, with the highest vote.
End RandomForests
```

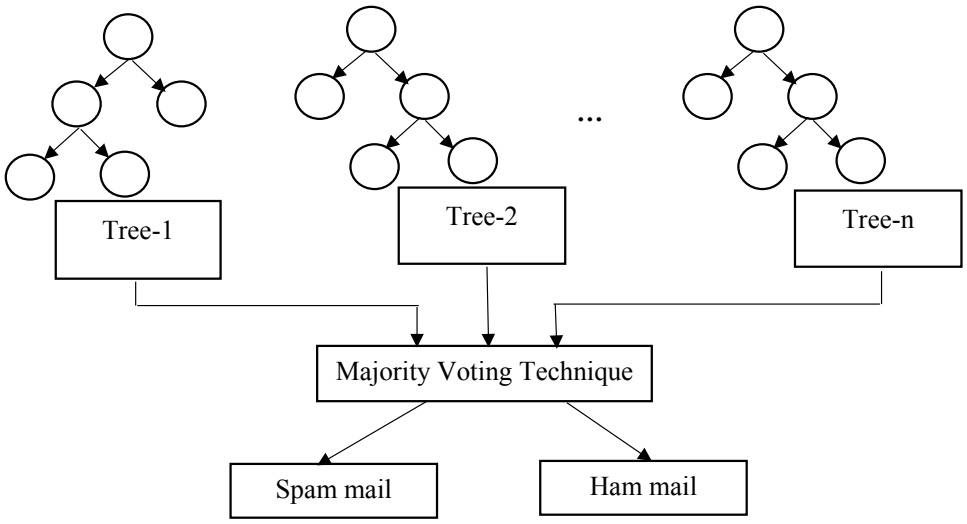

Fig. 2 Random Forests algorithm

4 Performance Analysis

Table 2 shows the performance comparison for Spambase dataset using Random Forests in the distributed environment, and MapReduce minimum relevance maximum redundancy (mRMR) feature selection with Random Forests algorithm. The different assessment metrics have been used for investigating the performance.

Table 2 Comparison of precision, recall and accuracy

Model	Precision	Recall	Accuracy
Random Forests in distributed environment	0.837624	0.846754	0.840721
MapReduce mRMR feature selection with Random Forests	0.852746	0.864657	0.860824

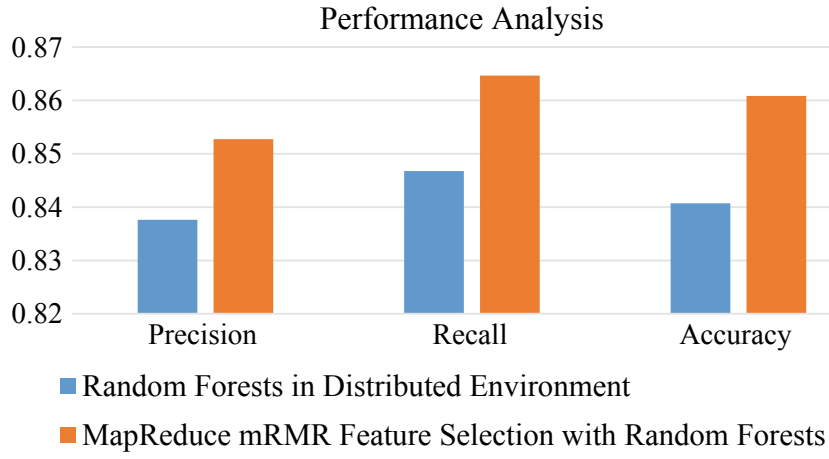

Fig. 3 Performance analysis

By analyzing the plotted graph in Fig. 3, the performance of the proposed email spam classification is significantly improved by selecting the best features using minimum redundancy maximum relevance (mRMR) in MapReduce environment, and the classification is done using the Random Forest.

5 Evaluation Metrics

The efficiency of the recommended methodology for discovering spam emails has been estimated by means of some metrics such as precision, recall, and accuracy. The assessment metrics can be defined as [13]:

Precision

It is the fraction of spam emails that are correctly categorized as spam from the given input emails. Precision illustrates the exact correctness and can be represented using Eq. (10) as:

$$\text{Precision} = \frac{\text{Spam emails correctly classified}}{\text{Spam emails correctly classified} + \text{Ham emails wrongly classified}} \tag{10}$$

Recall

It is the fraction of spam emails that are categorized as spam from the given input emails. Recall illustrates the completeness and is represented using Eq. (11) as:

$$\text{Recall} = \frac{\text{Spam emails correctly classified}}{\text{Spam emails correctly classified} + \text{Spam emails wrongly classified}} \tag{11}$$

Accuracy

It is determined as the percentage of addition of all true positives and true negatives to the entire amount of emails. Accuracy can be denoted by means of Eq. (12) as:

$$\text{Accuracy} = \frac{\text{Spam emails correctly classified} + \text{Ham emails correctly classified}}{\textit{Total emails}} \tag{12}$$

6 Conclusion

Email is an efficient, fastest, and cost-effective communication system in today's world. In the email, spam is the common problem, which sends data to the large number of recipients for distributing malware, advertising products, phishing, and so on. Spam emails take excess time in deleting junk mails, surplus disk space, and network bandwidth. Therefore, the filter is needed with great precision to filter the unsolicited emails. To filter the spam emails, here feature selection is done using MapReduce minimum redundancy maximum relevance (mRMR) to select the best features for classification. The selected features are classified by using the Random Forests algorithm. In the Random Forests, by means of voting technique, it classifies the junk mails and ham emails. The comparison indicates that the proposed email spam classification gives better accuracy than classification using Random Forests in the distributed environment.

The Impact of Sustainable Development Report Disclosure on Tax Planning in Thailand

Sathaya Thanjunpong and Thatphong Awirothananon

Abstract This paper aims to examine the impact of sustainable development report disclosure (hereafter called SDRD) on the tax planning (hereafter called TP) of listed companies, which exclude the financial sector, in the Stock Exchange of Thailand. The data of this paper is based only on the year 2016 and the sample size consists of 337 companies from seven industries. The questionnaires from Global Report Initiative are used for evaluation of SDRD. The TP is also measured by the ratio of total tax expenses to total assets. Overall, this paper finds that the SDRD had a statistically negative effect on the TP. This indicates that companies with good SDRD practices could have a higher level of TP. Regarding control variables, financial leverage and capital intensity had a statistically positive effect on the TP, while profitability and family control had a statistically negative effect on the TP. This paper further divides the sample into family and non-family companies to examine whether there is any different effect of SDRD on the TP. The results further indicated that the relationship between SDRD and TP was significantly negative for the family companies. The relationship was, thus, weak and insignificant for the non-family companies. The results are useful to market regulators since they could make some decisions about adjusting some rules and regulations or give some incentives to encourage the Thai listed companies to perform better sustainable development practices.

1 Introduction

Corporate social responsibility (hereafter called CSR), as a consequence of corporate governance (hereafter called CG), in Thailand particularly seems to have become more important. The Corporate Governance Center is established in the year 2002 by the Stock Exchange of Thailand (hereafter called SET) to support the listed companies in developing their CG system by complying with the international assessment regarding the improvement of CG [8]. As a result, the voluntary CG rating was subsequently introduced in the year 2008. The SET was set up [31] to continue the long-term sustainable growth of the capital market in the year 2007 and launched the "Thailand Sustainability Investment" scheme in the fourth quarter of 2015 by applying three criteria, which are economic, social, and governance criteria, respectively. The Thai listed companies and related organisations consequently become more involved with CSR. This is supported by the additional sections on the disclosure reports and the annual report; however, it is not officially required to disclose the CSR section. There is also a significant increase in the number of activities and projects of listed companies. Sustainable development report disclosure (hereafter called SDRD) is also a report published by companies about the practice of measuring, disclosing, and being accountable for their performance from their everyday activities, while they try to operate their business towards the sustainable development. This report could provide balanced and reasonable representations of sustainability performance, including both positive and negative contributions. It could also be considered as non-financial reporting, or triple bottom line reporting, or CSR reporting. The quality of SDRD is expected to increase the overall value creation, which is the increase in the performance of organisation.

The tax planning (hereafter called TP) is also along the continuum depending upon how aggressive the activity is in reducing total tax expenses. The tax avoidance (hereafter called TA) is some activities that reduce companies' cash-effective tax rate within the legal framework of tax regulations over a long period of time [12, 29]. These activities take some advantages of the loopholes in the tax regulations in order to reduce companies' tax liabilities [19, 34]. Companies, for example, could choose some advantageous methods in the financial reporting and could reduce their tax liabilities; consequently, the TA for this paper is a part of TP, although in some prior studies, including Chen et al. [6], Lestari and Wardhani [24], Zhang et al. [39], and Ying et al. [38], the effective tax rate is popularly used as the TP measurement. This paper, therefore, has developed a new measurement of TP. It is measured by the ratio of total tax expenses to total assets. This measurement is popularly used as the TP measure in Thailand [35, 36]. Under the assumption of corporation with the same profitability we should have the same total tax expenses at any condition, as well as an earning management of the statement of financial position is more difficult than that of the income statement. This leads to

the conclusion that companies with CSR should have the total tax expenses as well. The companies with higher SDRD practices would, therefore, have higher total tax expenses, which indicate the lower TP. The SDRD quality is also expected to improve the overall value creation, which is the reduction in TP.

Many previous papers show that SDRD has a significant impact on the increasing TP [5, 9, 22, 28]. In developed countries, the authors of [22] investigated a legitimacy theory during the 2001–2006 period in the Australian corporations by comparing the CSR disclosures of tax aggressive corporations with those of non-tax aggressive corporations. Their results show that CSR has a statistically and positively significant effect on the TA. Davis et al. [9] further investigated the relationship between CSR and corporate tax payment in the US-listed companies during the year 2002–2011. Their results show that CSR has a significantly positive effect on the TP. Preuss and Preuss [28] also found that CSR and corporate tax payments act as substitutes in the European public companies. In the developing region, Chen [5] found that the CSR disclosure significantly strengthens the possibility of TP in the Chinese-listed companies from 2008 to 2014. However, many prior studies show that SDRD has a significant impact on the decreasing TP. In the developed countries, Hoi et al. [18] found a statistically negative relationship between irresponsible CSR and TA in the US public companies during the 2003–2009 period. Lanis and Richardson [23] further showed that companies with the higher level of CSR disclosure could have the lower level of corporate TA for the 2008–2009 financial year. The CSR disclosure, therefore, has a significant negative effect on the TA in the Australian listed companies. In the Asia region, Sari and Tjen [30] recently revealed that the CSR disclosure has a significantly negative effect toward the TA in the Indonesian-listed companies during the 2009–2012 period.

Some earlier papers, including Laguir et al. [20], Nadiah et al. [27], and [33], further showed that SDRD is not significant or cannot summarise the relationship between CSR and TA. In the developed region, Laguir et al. [20] revealed that the relationship between various CSR dimensions and TA is either positive or negative in the French companies during the 2003–2011 period. In the developing countries, Nadiah et al. [27] further found the relationship between CSR disclosure and corporate TA is either positive or negative in Malaysia in the year 2014. Susanti [33] also investigated the effect of CSR on the TA for manufacturing listed companies in the Indonesia Stock Exchange in the year 2012–2014. These results show that CSR does not have any influence on the TA. On the other hand, SDRD is not associated with the TA. Recent empirical studies find a mixed evidence of the impact of SDRD on the TP. This paper, therefore, aims to search the benefit of SDRD implementation to the TP.

2 Research Methodology

The population of this paper are listed companies, which are excluded financial sectors (58 companies), in the Stock Exchange of Thailand (hereafter called SET) in the year 2016. The purposive sampling method is used for sample selection. The selection is done in accordance with two criteria as follows:

(a) Companies that publish financial statements, annual report, and Form 56-1 in their website and from the SETSMART database with completed period of 2016.
(b) Companies that have the sustainable development report during the study period and their necessary data of TP is available.

According to the above two criteria, the sample consists of 337 companies in this paper. These companies are categorised into seven industries according to SET categorisation. It comprises (1) 35 agro and food industry companies, (2) 28 consumer products companies, (3) 64 industrial companies, (4) 74 property and construction companies, (5) 24 resources companies, (6) 81 services companies, and (7) 31 technology companies, respectively.

The dependent variable is the TP, which is calculated as the total tax expenses for the year divided by the total assets. The most important independent variable is SDRD, which is measured by the Global Report Initiative (hereafter called GRI) index score. This index score is calculated from 18 separate criteria to quantify the overall GRI principles from the Global Sustainability Standards Board [14]. The scorecard criteria span three dimensions of the GRI principles, which are economic dimension that has five criteria, environmental dimension that has nine criteria, and social dimension that has four criteria, respectively, as shown in Table 1.

This paper acquires SDRD index scores from Form 56-1, SETSMART database, and annual reports for the year 2016. These index scores are also adjusted to consider the subtleties of Thai laws and regulations. The inclusion of each attribute is scored on a binary basis as “yes” (included) or “no” (not included). Each “yes” answer is equal to the value of one point, while “no” is equal to the value of zero point. This paper also includes some control variables that have been shown to have a statistically significant impact on the TP [36]. This paper uses firm size (hereafter called SIZE), which is measured by the natural logarithm of total assets. The financial leverage variable (hereafter called LEV) is also included in this paper. The LEV variable, which is a proxy of the differences in the financial structure of companies, is computed as the percentage of total debt to total assets. This paper also includes the return on equity (hereafter called ROE) by dividing the net profit to total equity, as an indicator of companies’ financial performance. In addition, this paper uses the capital intensity variable (hereafter called CAP) by dividing the property, plant, and equipment to total assets, as a proxy of companies’ working capital management.

Table 1 SDRD index score

Dimensions	Details
Economy dimension	1. The results on economic growth as net profit of companies were shown
	2. The results on a growth of community economy as nearby community incomes created partly by companies were demonstrated
	3. The results on a partly growth of national economy as corporate income tax and others related to business operation were exhibited
	4. The results on a circular flow of capital among those diverse stockholders in different business companies were presented
	5. The results on corporate information related to policy and campaign against corruption inside their business organisations were proven
Environment dimension	1. Companies that affected human life and exiting organism were demonstrated
	2. Companies that affected ecosystem and quality of water, soil, and air were exhibited, respectively
	3. Companies that affected our natural resources were shown
	4. Companies that affected input factors, namely, energy, and water were demonstrated, respectively
	5. Companies that followed relevant laws and environmental regulations were provided
	6. A disclosure of costs of environmental disposal
	7. Companies that dealt with waste and garbage disposal were provided
	8. Companies that are concerned with their productions and environmental-friendly logistics were demonstrated
	9. Companies that handled with diversified activities like campaign, public relation events, publications, and donation against environmental damage were exhibited, respectively
Society dimension	1. Companies that are concerned with labour forces and employment were demonstrated
	2. Companies that are concerned with human rights were provided
	3. Companies that are concerned with their public accountability were shown
	4. Companies that are concerned with their productions were described

Source Improved from the Global Sustainability Standards (14)

There is a large number of Thai-listed companies that are still family-owned companies, where the family members being the owners have substantial control over both ownership and management [7, 32]. This paper, therefore, uses family control (hereafter called FAM) to separate between family and non-family companies as some previous papers, including Tantiyavarong [35], Chen et al. [4], Landry et al. [21], and Landry et al. [36], show that family companies have a significant impact on the TP. In the developed countries, Chen et al. [4] and Landry

et al. [21] revealed that the relationship between family companies are less TA than their non-family companies because family companies being more concerned with the reputation damage and potential penalty. Bauweraerts and Vandernoot [1] and Martinez and Ramalho [25], however, found that the family companies are more TA than non-family. Recently, Gaaya et al. [13] revealed that the family ownership has a positive effect on corporate TA in Tunisian-listed companies during 2008 and 2013.

In the Asian region, Tantiyavarong [35] found that family companies have positive effects on the TP during the 2001–2007 period. In addition, Thanjunpong and Bangmek [36] further showed that the relationship between family companies is more tax planning than their non-family companies in Thailand during the 2012–2014. Masripah et al. [26], however, found that the entrenchment effect of controlling shareholder has negative effect on the TA in manufacturing industries on the Indonesia Stock Exchange companies during the 2010–2013 period. Furthermore, Bousaidi and Hamed [3] found that the concentration ownership exhibits a negative association with the effective tax rate, which indicates there is a higher TP in Tunisian-listed companies during the 2006–2012 period. Therefore, the FAM variable, which is a dummy variable, has a value of one for the family companies and zero otherwise for non-family companies. The family companies are defined as when a stake of 25% or above of companies' outstanding shares belongs to the major family shareholders.

3 Research Methods

This paper uses the multiple regression analysis technique to determine the relationship between SDRD and TP. According to the objective of this paper, the multiple regression on the full sample model will be utilised as follows:

$$\text{Model 1}: \ \text{TP}_i = \beta_0 + \beta_1 \text{SDRD}_i + \beta_2 \text{SIZE}_i + \beta_3 \text{LEV}_i + \beta_4 \text{ROE}_i + \beta_5 \text{CAP}_i + \beta_6 \text{FAM}_i + \sum_{j=7}^{12} \beta_j \text{IND}_j$$

In addition, this paper separates the full data to two sub-groups (family and non-family companies) to examine whether there is any different effect of SDRD on the TP among the family companies (Model 2.1) and the non-family companies (Model 2.2) as follows:

$$\text{Model 2}: \ \text{TP}_i = \beta_0 + \beta_1 \text{SDRD}_i + \beta_2 \text{SIZE}_i + \beta_3 \text{LEV}_i + \beta_4 \text{ROE}_i + \beta_5 \text{CAP}_i + \sum_{j=6}^{11} \beta_j \text{IND}_j$$

4 Results and Discussion

The descriptive statistics for the full and separate sub-samples for family and non-family companies in the SET for the year 2016 are reported in Table 2. It also presents the mean values and the *t*-statistics that test for the mean differences of all variables between family and non-family companies. The results show that the average value of TP for the full sample was 0.011%, which was a low level (representing the TP was a high level), while the values for both family and non-family companies were 0.011 and 0.009%, respectively. The results also reveal that the TP value shows statistically significant difference between family and non-family companies at the 0.10 level. The results show that the family companies had a lower TP than the non-family companies. This implies that the family companies had higher level of TP than the non-family companies.

The values of descriptive statistics in Table 2 show that the mean value of SDRD for the full sample was 11.580. It also shows that the mean value of SDRD for the family companies was 11.730, which is higher when compared with the non-family companies, 11.110. However, the *t*-statistics for the mean difference of SDRD between family and non-family companies was not statistically significant. This indicates that both family and non-family companies had the same level of SDRD implementation. Additionally, the average value of SIZE for the full sample was 22.606, while the mean values for both family and non-family companies were 22.700 and 22.330, respectively. The results indicated that the mean value of SIZE for the family companies was greater than that for the non-family companies, since the *t*-statistics of the mean differences were statistically significant at the 0.05 level. Moreover, the average value of LEV for the full sample was 0.438. The mean value for the family companies, which was 0.437, was also higher than that for the non-family companies (0.442). However, the results indicated that the non-family companies had the same LEV value on the average as the family companies, since

Table 2 Descriptive statistics

Variables	Full sample (n = 337)		Family companies (n = 254)		Non-family companies (n = 83)		*t*-statistics of mean difference
	Mean	SD	Mean	SD	Mean	SD	
TP	0.011	0.013	0.011	0.014	0.009	0.010	1.865*
SDRD	11.580	3.048	11.730	3.118	11.110	2.789	1.612
SIZE	22.606	1.513	22.700	1.578	22.330	1.263	2.154**
LEV	0.438	0.252	0.437	0.258	0.442	0.237	− 0.168
ROE	0.070	0.776	0.077	0.256	0.046	1.505	0.189
CAP	0.340	0.237	0.343	0.235	0.330	0.244	0.422
FAM	0.754	0.431					

Note One, two, and three asterisks indicate statistical significance at the 0.10, 0.05, and 0.01 levels, respectively

the *t*-statistics for the mean differences were not statistically significant. Furthermore, the mean value of ROE for the full sample was 0.070, while the values for both family and non-family companies were 0.077 and 0.046, respectively. Furthermore, the average value of CAP for the full sample was 0.034, while the mean values for both family and non-family companies were 0.343 and 0.330, respectively. Nevertheless, both family and non-family companies had the same level of CAP as the *t*-statistics for the mean difference was not statistically significant. The mean value of FAM for the full sample was 0.754.

The Pearson's product-moment correlation, as shown in Table 3, is computed to examine the correlation among all variables of this paper. The correlation between SDRD and TP, for example, was −0.121, which was statistically and negatively significant. It indicated that higher SDRD practices could lower the TP, representing the TP of companies is at a high level. The correlations among explanatory variables were between −0.025 and 0.369. For instance, the correlations between CAP and other explanatory variables were not statistically significant. The correlations of FAM and ROE variables with others were also not statistically significant. Overall, the correlation among independent variables was also moderately low (below ± 0.7), indicating that there is no any multicollinearity problem [17]. This paper further considers whether data has the normal distribution or not. According to Berenson et al.'s [2] statement, the sampling distribution becomes almost normal, regardless of the shape of population since the sample size is large enough (which is greater than 30 observations). The data of this paper, therefore, has the normal distribution.

As previously mentioned, this paper uses the multiple regression analysis technique for analysing data and tests for the heteroscedasticity problem. According to the White's [37] test, all models, including the full sample and both family and non-family companies, did not have the problem of heteroscedasticity. The problem of autocorrelation also does not exist in all the models, as the Durbin–Watson [10, 11] statistics are between 1.50 and 2.50 [16]. The values of variance inflation factor (hereafter called VIF) in Table 4 for all models are further less than 10, indicating that the multicollinearity does not exist [15]. Overall, the results in Table 4 show

Table 3 Pearson correlation matrix

Adjusted R^2	0.066			0.204			0.121		

Note One, two, and three asterisks indicate statistical significance at the 0.10, 0.05, and 0.01 levels, respectively

that the coefficient for SDRD and TP was statistically significant at the 0.05 level. It indicated that companies with good SDRD practices could decrease the TP, representing the TP of companies is at a high level. These findings are consistent with prior studies, including Hoi et al. [18], Sari and Tjen [30], and Chen [5]. When dividing the data into family and non-family companies, the result indicated that there was no significant relationship between SDRD and TP for the non-family companies. On the other hand, the relationship between SDRD and TP for the family companies was negatively and statistically significant at the 0.10 level. This finding is consistent with previous papers, including Chen et al. [4], Landry et al. [21], and Thanjunpong and Bangmek [36]. Moreover, sustainable development is related to higher disclosure and transparency, higher accounting quality, and audit quality. Therefore, high SDRD companies might be able to decrease their TP, resulting in the TP of companies at a high level.

For the control variables, the relationship between SIZE and TP was not significant for full sample, as presented in Table 4. When dividing full sample into two sub-groups (family and non-family companies), the results show that the relationship between SIZE and TP was positively and statistically significant at the 0.05 level for the family companies, while the relationship was negatively and statistically significant at the 0.01 level for the non-family companies. Similarly, the effects of LEV on the TP for the full sample and the non-family companies were positively and statistically significant at the 0.01 level. Moreover, the effects of ROE on the TP for the full sample and the family companies were negatively significant at the 0.01 level. In addition, the effects of CAP on the TP for the full sample and the family companies were positively and statistically significant, while the effect of CAP on the TP for the non-family companies was not statistically significant. Finally, the relationship between FAM and TP was negatively statistically significant at the 0.10 level. This relationship is consistent with prior studies, including Chen et al. [4], Landry et al. [21], and Thanjunpong and Bangmek [36]. The relationship between IND and TP, however, was not statistically significant for the full sample.

This paper further does an additional analysis by excluding the industry variable, which is a dummy variable, for a robustness investigation. All models are also tested for the problems of autocorrelation and multicollinearity. The results in Table 5 show that the Durbin–Watson [10, 11] statistics are between 1.50 and 2.50, resulting that the autocorrelation problem does not exist [16]. Each variable of all models also has the VIF value less than 10, indicating that the problem of multicollinearity does not exist [15]. The results in Table 5 show that the coefficient for SDRD and TP was negatively and statistically significant at the 0.05 level. It indicates that the TP could be reduced, when companies have a good SDRD implementation. This implies that companies have a high level of TP. These findings are consistent with previous papers, including Hoi et al. [18], Sari and Tjen [30], and Chen [5]. Once dividing the full sample into family and non-family companies, the result indicated that relationship between SDRD and TP for the non-family companies was not statistically significant. However, the relationship between SDRD and TP for the family companies was negatively and statistically

Durbin–Watson	1.780			2.005			2.016		
F-statistics	4.883***			13.303***			3.412***		
R^2	0.082			0.211			0.181		
Adjusted R^2	0.065			0.196			0.128		

Note One, two, and three asterisks indicate statistical significance at the 0.10, 0.05, and 0.01 levels, respectively

significant at the 0.05 level. These results were similar to the above results, which were reported in Table 4, and prior studies. Consequently, sustainable development is associated with higher disclosure and transparency, higher accounting quality, and audit quality. As a result, high SDRD companies might be able to decrease their TP, representing the TP of companies is at a high level.

5 Conclusion

This paper investigates the effect of SDRD on the TP of listed companies, excluding financial sectors, in the SET. The sample size consists of 337 companies, based only on the data for the year 2016. The questionnaires of GRI are used for evaluation of SDRD. The TP is also measured by the ratio of total tax expenses to total assets. Overall, this paper finds that the SDRD had a significant and negative effect on the TP. This indicates that companies could have a higher level of TP, when they have higher SDRD implementation. Regarding some control variables, the financial leverage and capital intensity variables had a positive effect on the TP. However, the profitability and family control variables had a significantly negative impact on the TP. In addition, the relationship between SDRD and TP was significantly negative for the family companies. The relationship was, however, weakly insignificant for the non-family companies. As a result, the results are useful to tax officers for making a decision of initial audit. They, for instance, should pay attention on companies that have low SDRD implementation. Moreover, the results are useful to the SET and Securities and Exchange Commission (hereafter called SEC). They could further make some decisions about adjusting some rules and regulations or give some incentives to encourage the Thai-listed companies to perform better SDRD practices. For example, market regulators, including SET and SEC, should focus on family companies and encourage them to improve their SDRD implementation by giving them some incentives, and the results indicate that the relationship between SDRD and TP for the family companies is negatively significant.

Clustering and Labeling Auction Fraud Data

Ahmad Alzahrani and Samira Sadaoui

Abstract Although shill bidding is a common fraud in online auctions, it is however very tough to detect because there is no obvious evidence of it happening. There are limited studies on SB classification because training data are difficult to produce. In this study, we build a high-quality labeled shill bidding dataset based on recently scraped auctions from eBay. Labeling shill biding instances with multidimensional features is a tedious task but critical for developing efficient classification models. For this purpose, we introduce a new approach to effectively label shill bidding data with the help of the robust hierarchical clustering technique CURE. As illustrated in the experiments, our approach returns remarkable results.

Keywords Auction fraud · Shill bidding · Hierarchical clustering · CURE · Silhouette · Data labeling

1 Introduction

In the last three decades, we witnessed a significant increase in exchanging goods and services over the Web. According to the World Trade Organization, the worldwide merchandise during the period 1995–2015 was over 18 billion.[1] Online auctions are a very profitable e-commerce application. For instance, in 2017, eBay claimed that the net revenue attained 9.7 billion US dollars, and the number of active users hits 170 million.[2] Regardless of their popularity, e-auctions remain very vulnerable to cybercrimes. The high anonymity of users, low fees of auction services, and flexibility

of bidding make auctions a great incubator for fraudulent activities. The Internet Crime Complain Center announced that auction fraud is one of the top cybercrimes [2]. As an example, the complaints about auction fraud in only three states, California, Florida, and New York, reached 7,448 in 2016 [2]. Malicious moneymakers can commit three types of fraud, which are pre-auction fraud, such as auctioning of black market merchandise, in-auction fraud that occurs during the bidding time, such as Shill Bidding (SB), and post-auction fraud, such as fees stacking. Our primary focus is on the SB fraud whose goal is to increase the profits of sellers by placing many bids through fake accounts and colluding with other users. SB does not leave any obvious evidence, unlike the two other auction fraud. Indeed, buyers are not even aware that they have been overcharged.

Identifying relevant SB strategies, determining robust SB metrics, crawling and preprocessing commercial auction data, and evaluating the SB metrics against the extracted data make the study of SB fraud very challenging as demonstrated in our previous technical paper [1]. In addition, labeling SB instances with multidimensional features is a critical phase for the classification models. In the literature, labeling training data is usually done manually by the domain experts, which is quite a laborious task and prone to errors. Due to the lack of labeled SB training datasets, the prime contribution of this paper is to produce high-quality labeled SB data based on commercial auction transactions that we extracted from eBay and preprocessed [1]. As illustrated in Fig. 1, we introduce a new approach to effectively label SB data with the help of data clustering. First, we split the SB dataset into several subsets according to the different bidding durations of the extracted auctions. Second, we efficiently partition each SB subset into clusters of users with similar bidding behavior. Last, we apply a systematic labeling method to each cluster to classify bidders into normal or suspicious.

Hierarchical clustering is significantly preferable over partitioning clustering because it provides clusters with a higher quality [10]. This type of data clustering has been utilized successfully in numerous fraud studies [8, 10]. In fact, we employ the Clustering Using REpresentatives (CURE) technique to produce the best differentiation between normal and suspicious activities. CURE [11] has proved over the years to be a highly efficient clustering method in terms of eliminating outliers and producing high-quality clusters, especially for large-scale training datasets. The

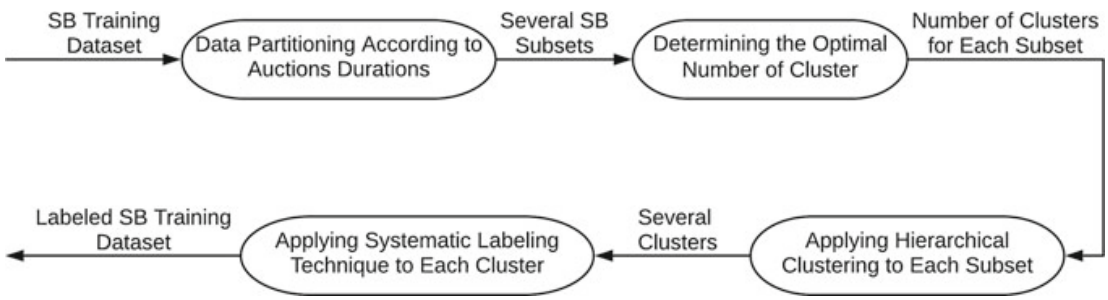

Fig. 1 The labeling process of shill bidding training data

labeled SB dataset that we produced can be utilized by the state-of-the-art supervised classification methods. Furthermore, the accuracy of new predictive models can also be tested using our SB training dataset.

The rest of the paper is organized as follows. Section 2 discusses related work on data clustering in the context of online auctions. Section 3 describes the SB patterns used in this research as well as the SB data produced from the commercial website eBay. Section 4 explains how to apply the hierarchical clustering CURE according to different bidding durations. Section 5 exposes a new approach to label the clusters of bidders. Finally, Sect. 6 summarizes the results of this study and highlights important research directions as well.

2 Related Work

Many researchers utilized data clustering to examine auctions from different angles, such as studying the dynamics of auction prices and bidder behavior. For instance, [13] introduced an approach to model and analyze the price formation as well as its dynamics to characterize the heterogeneity of the price formation process. The proposed functional objects represent the price process by accommodating the structure format of bidding data on eBay. Then, the curve clustering is used to partition auctions by grouping similar price profiles. Finally, differential equations are used to specify the price of each group.

Another work [7] measured the similarity of bidder behavior using specific attributes, such as bidder feedback rating, average increment difference, and number of bids. Then, a centroid-based hierarchical clustering approach is presented to group similar bidders. Each produced cluster is then labeled manually according to the overall bidder behavior in that cluster.

The study [14] suggested an SB detection model utilizing k-mean clustering technique. The latter groups similar buyers in one class to differentiate between general buyers and shill bidders. There are four features that represent a buyer: "how long the buyer has been in the auction," "the times of buyer bids," "the average response time of the buyer," and "the absolute average discrepancy of buyer bids." Based on these features, k-mean classifies bidders into one of the two clusters: general buyers and shill bidders. However, we believe the second and third features do not really reflect SB since a buyer might be very interested in winning the auction. Besides, there are stronger patterns that highly identify SB. Since SB behavior is somehow similar to real bidding [5], there is a possibility that some SB samples fell in the normal class.

In [4], the authors proposed a two-step clustering model to recognize bidding strategies. The hierarchical clustering is the first step to produce a dendrogram and an agglomeration schedule table to find the best number of clusters. The next step employs k-mean clustering to provide more details about the bidders' strategies in each cluster. The experiment was operated on an outdated data (2003) collected

from Taobao.com. According to the agglomeration coefficients, the optimal number of clusters is three: "early bidding strategy", "snipe bidding strategy," and the third one groups bidders that enter the auction early and remain for a long time. The first cluster has shown low values for the given features, which indicates that the bidders' strategy is to enter and exit auctions early and participate infrequently. The second cluster has displayed high values for some features and low values for others. This illustrates that bidders enter and exit auctions late and rarely participate. The final cluster has administered the bidders' strategy where bidders enter early and stay for a long time and highly participate in the auctions.

Zhang et al. [20] proposed a model based on hedonic regression and Fuzzy Logic Expert System (FLES) to analyze bidder behavior. The hedonic regression is used to select key variables that are passed to FLES to produce a knowledge base about the relationships between variables, like auction characteristics. Since the examined data have no relational information, k-mean is employed to obtain the minimum squared-error clusters. So, each training sample is classified to low, medium, or high membership degree. The issue here is that the study is based on an outdated dataset (2004). Also, there is a potential for fabricating feedback ratings conducted between shill bidders and fraudulent bidder rings [7].

More recently, [12] applied k-mean clustering to categorize bidders' habits. The observations are obtained by the k-mean and then passed to the Baum–Welch algorithm and Hidden Markov model. Three main clusters were suggested according to the values of the given features, which are low, medium, and high cluster values. A bidder habit with values beyond these clusters values is considered as a fraudster. The experiment showed that only two simple features were given to identify the clusters: the number of auctions that a bidder participated in and the number of submitted bids by that bidder. Thus, if more features were considered to define the clusters, then the samples' distribution on each cluster might be changed. As a result, this may influence the outcomes of the detection model. Also, the clustering is based on a dataset that is not adequately described, and only ten samples were used for explaining the results.

Lastly, [10] applied a hierarchical clustering to group users with similar bidding behavior. The centroid linkage is used as the similarity measure. The described SB patterns were computed for all the bidders of each of the generated clusters. Then, the authors introduced a semi-automatic approach to label each cluster according to the general behavior of users in that cluster and the weights of the fraud patterns.

3 Shill Bidding Overview

SB is a well-known auction fraud, and yet it is the most difficult to detect since it behaves similarly to normal bidding [5, 8]. The aim of this fraud is to increase the price or desirability of the auctioned product through imitation accounts and collusion

with other users. In other words, shill bidders do not tend to win the auction but to increase the revenue of the seller. SB leads buyers to overpay for the items, and for high priced items, buyers will lose a substantial amount of money. As mentioned in [5], excessive SB could lead to market failure. Thus, e-auctions may lose their credibility [5]. In fact, several sellers and their accomplices have been prosecuted due to SB activities, including

- In 2007, a jewelery seller was accused of conducting SB fraud on eBay and had to pay $400,000 for a settlement. Also, he and his employees were prevented from engaging in any online auctioning activities for 4 years.[3]
- In 2010, a seller faced a £50,000 fine after being found outbidding himself on eBay. He claimed that "*eBay let me open up the second account and I gave all my personal details and home address to do so.*"[4]
- In 2012, the online auction Trade Me had to pay $70,000 for each victim after the investigation discovered SB fraud conducted by a motor vehicle trader in Auckland. The fraud was carried out for 1 year and caused a significant loss for the victims. Trade Me blocked this trader from using their site, and referred the case to the Commerce Commission for a further investigation.[5]
- In 2014, a lawsuit was filled against Auction.com by VRG in California claiming that the website allowed SB. The bid of $5.4 million should have secured the property as the plaintiff declared, and yet the winning price was 2 million more. Auction.com was accused of helping the property loan holder, which is not fair for genuine bidders. The California state passed a law on July 1, 2015, which requests the property auctioneers to reveal bids they submit on a seller's behalf.[6] The spokeswoman for the California Association of Realtors said "*To the best of our knowledge, we are the only state to pass this sort of legislation, even though we believe shill bidding to be prevalent all over the country.*"

By examining throughly the literature on the SB strategies [6, 8, 17], we compiled in Table 1, the most relevant SB patterns. Each pattern, which is a training feature, represents a unique aspect of the bidding behavior in auctions. The feature uniqueness will lead to an improved predictive performance.

Table 1 SB patterns and their characteristics

Name	Definition	Category	Source	Weight
Bidder tendency (BT)	Engages exclusively with few sellers instead of a diversified lot	Bidder	User history	0.5
Bidding ratio (BR)	Participates more frequently to raise the auction price	Bid	Bidding period	0.7
Successive outbidding (SO)	Successively outbids himself even though he is the current winner	Bid	Bidding period	0.7
Last bidding (LB)	Becomes inactive at the last stage to avoid winning	Bid	Last bidding stage	0.5
Early bidding (EB)	Tends to bid pretty early in the auction to get users attention	Bid	Early bidding stage	0.3
Winning ratio (WR)	Participates a lot in many auctions but rarely wins any auctions	Bidder	Bidder history	0.7
Auction bids (AB)	Tends to have a much higher number of bids than the average of bids in auctions selling the same product	Auction	Auction history	0.3
Auction starting price (ASP)	Offers a small starting price to attract genuine bidders	Auction	Auction history	0.3

4 Production of Shill Bidding Data from Online Auctions

4.1 Auction Data Extraction and Preprocessing

To obtain a reliable SB training dataset, it must be built from actual auction data. Nevertheless, producing high-quality auction data is itself a burdensome operation due to the difficulty of collecting data from auction sites on one hand, and the challenging task of preprocessing the raw data on the other hand. The latter consumes a significant time and effort, around 60–80% of the entire workload [15]. In our technical study [1], we employed the professional scraper Octoparse[7] to collect a large number of auctions for one of the most popular products on eBay. The extracted dataset contains all the information related to auctions, bids and bidders. We crawled completed auctions of the iPhone 7 for 3 months (March to June 2017). We chose iPhone 7 because it may have attracted malicious moneymakers due to the following facts:

- Its auctions attracted a large number of bids and bidders.
- It has a good price range with the average of $578.64 (US currency). Indeed, there is a direct relationship between SB fraud and the auction price [5].
- The bidding duration varies between 1 (20.57%), 3 (23.2%), 5 (16.23%), 7 (38.3%), and 10 (1.7%) days. In long duration, a dishonest bidder may easily mimic usual bidding behavior [5]. However, as claimed in [3], fraudulent sellers may receive a positive rating in short duration. Thus, we considered both durations.

[7] https://www.octoparse.com.

Table 2 Preprocessed auctions of iPhone 7

No. of auctions	807
No. of records	15145
No. of bidder IDs	1054
No. of seller IDs	647
Avg. winning price	$578.64
Avg. bidding duration	7
No. of attributes	12

Table 2 presents the statistics after preprocessing the scraped auction data. This operation was very time consuming as it required several manual operations [1]: (1) removing redundant and inconsistent records, and also records with missing bidder IDs; (2) merging several attributes into a single one; (3) converting the format of several attributes into a proper one; (4) assigning an ID to the auctions. For example, the two attributes date and time in each auction are converted into seconds; as an example, 1-day and 10-day durations are converted into 86,400 and 864,000 seconds, respectively.

4.2 SB Data Production

The algorithms to measure the SB patterns are presented in [1, 17]. Each metric is scaled to the range of [0, 1]; a high value indicates a suspicious bidding behavior. We evaluated each metric against each bidder in each of the 807 auctions [1]. Therefore, we obtained a SB training dataset with a total of 6321 samples. A sample is described as a vector of 10 elements: the eight SB features along with Auction, and Bidder identification numbers. Once labeled, an instance will denote the conduct (normal or suspicious) of a bidder in a certain auction.

5 Hierarchical Clustering of Shill Bidding Data

Since the produced SB data are not labeled, data clustering, an unsupervised learning method, can be utilized to facilitate the labeling operation. Clustering is the process of isolating instances into K groups w.r.t. their similarities. The clustering techniques fall into one of the following categories: (1) Partitioning-based, such as K-medoids and K-means; (2) Hierarchical-based, such as BIRCH, GRIDCLUST and CURE; (3) Density-based, such as DBSCAN and DBCLASD; (4) Grid-based, such as STING and CLIQUE. In our work, we select agglomerative (bottom-top) hierarchical clustering where instances are arranged in the form of a tree structure using a proximity matrix.

5.1 CURE Overview

Among the hierarchical clustering methods, we choose CURE because it is highly performant in handling large-scale multidimensional datasets, determines non-spherical shapes of the clusters, and efficiently eliminates outliers [11]. Random sampling and partitioning techniques are utilized to handle the large-scale problem and to speed up the clustering operation. Each instance is first considered as an individual cluster, and then the cluster with the closest distance/similarity is merged into it in order to form a new cluster [11]. Two novel strategies have been introduced in CURE:

- **Representative Points (RPs)**, which are selected data points that define the cluster boundary. Instead of using a centroid, clusters are identified by a fixed number of RPs that are well dispersed. Clusters with the closest RPs are merged into one cluster. The multiplicity of RPs allows CURE to obtain arbitrary clustering shapes.
- **Constant shrinking factor** (α), which is utilized to shrink the distance of RPs toward the centroid of the cluster. This factor reduces noise and outliers.

The worst-case computational complexity of CURE is estimated to $O(N^2 \log N)$, which is high when N is large (N is the number of instances) [18]. Since the SB data clustering is an offline operation, so the running time is not an issue. The only disadvantage of CURE is that the two parameters RP and α have to be set up by users.

To run the experiments, we utilize the Anaconda Navigator environment for running Python 3, and incorporate the CURE program developed by Freddy Stein and Zach Levonian. CURE code (in Python) is available at GitHub.com.[8]

5.2 SB Data Preparation

Since the bidding duration is used as a denominator for the two patterns Early Bidding and Last Bidding, the large gap between different durations greatly affects the computation results. The computed value of the fraud pattern for 10 days is far smaller than for 1 day. So, before applying CURE, we first partition the SB dataset into five subsets according to the five durations (1, 3, 5, 7, and 10 days) as presented in Table 3.

5.3 Optimal Number of Clusters

It is always difficult to decide about the optimal number of clusters of a training dataset. Besides, normal and shill bidder behavior is somehow similar. Thus, deter-

[8] https://github.com/levoniaz/python-cure-implementation/blob/master/cure.py.

Table 3 SB dataset partitioning according to bidding durations

Subset	1 Day	3 Days	5 Days	7 Days	10 Days
No. of auctions	166	187	131	309	14
No. of Instances	1289	1408	1060	2427	137

mining the best number of clusters is an essential step to achieve a better interpretation for classifying similar SB instances [19]. There are several methods to address this problem, such as Elbow, Dendrogram, the Rule of Thumb and Silhouette. In our study, we employ the Silhouette method where each group is represented as a silhouette based on the separation between instances and the cluster's tightness [16]. The construction of a silhouette requires the clustering technique to generate the partitions and also to collect all approximates between instances [16]. K-mean clustering algorithm has been successfully utilized for this task due to its simplicity and effectiveness [19]. Consequently, we apply K-mean to estimate the number of clusters for each of the five SB subsets.

Next, for each subset, we examine the silhouette scores of 19 clusters (2–20 clusters), and choose the best number based on the best silhouette score. We have noticed that once the peek (denoting the optimal number) of the silhouette score is reached on a certain number of clusters, the silhouette score gradually decreases with the increasing of the number of clusters. In Fig. 2, we give an example for the 7-day bidding duration for which the optimal number of clusters is eight since the highest silhouette score (0.4669) is obtained on that number. In Table 4, we expose the best number of clusters for each of the five SB subsets. The total number of produced clusters is 29.

5.4 Cluster Generation

CURE has three parameters that need to be setup: representative points (RPs), shrinking factor (α) and an optimal number of clusters. Based on the results of silhouette, we have obtained the optimal number of clusters for each of the five SB subsets. The two parameters RPs and α are defined by selecting the configuration that provides the best instance distribution among the specified clusters. Thus, CURE is applied with different values of RPs and α starting from the default values (5 for RPs and 0.1 for α). We throughly conducted trial-and-error experiments for all the clusters (29 clusters in total) of the five SB subsets to determine the best values of the parameters (Table 4). The best parameters' values are selected based on the best distribution of a subset population between the defined clusters. As an example, in Table 5, we present the results for the eight clusters that we have generated previously for the 7-day bidding duration subset. The best value configuration is shown in bold. Each

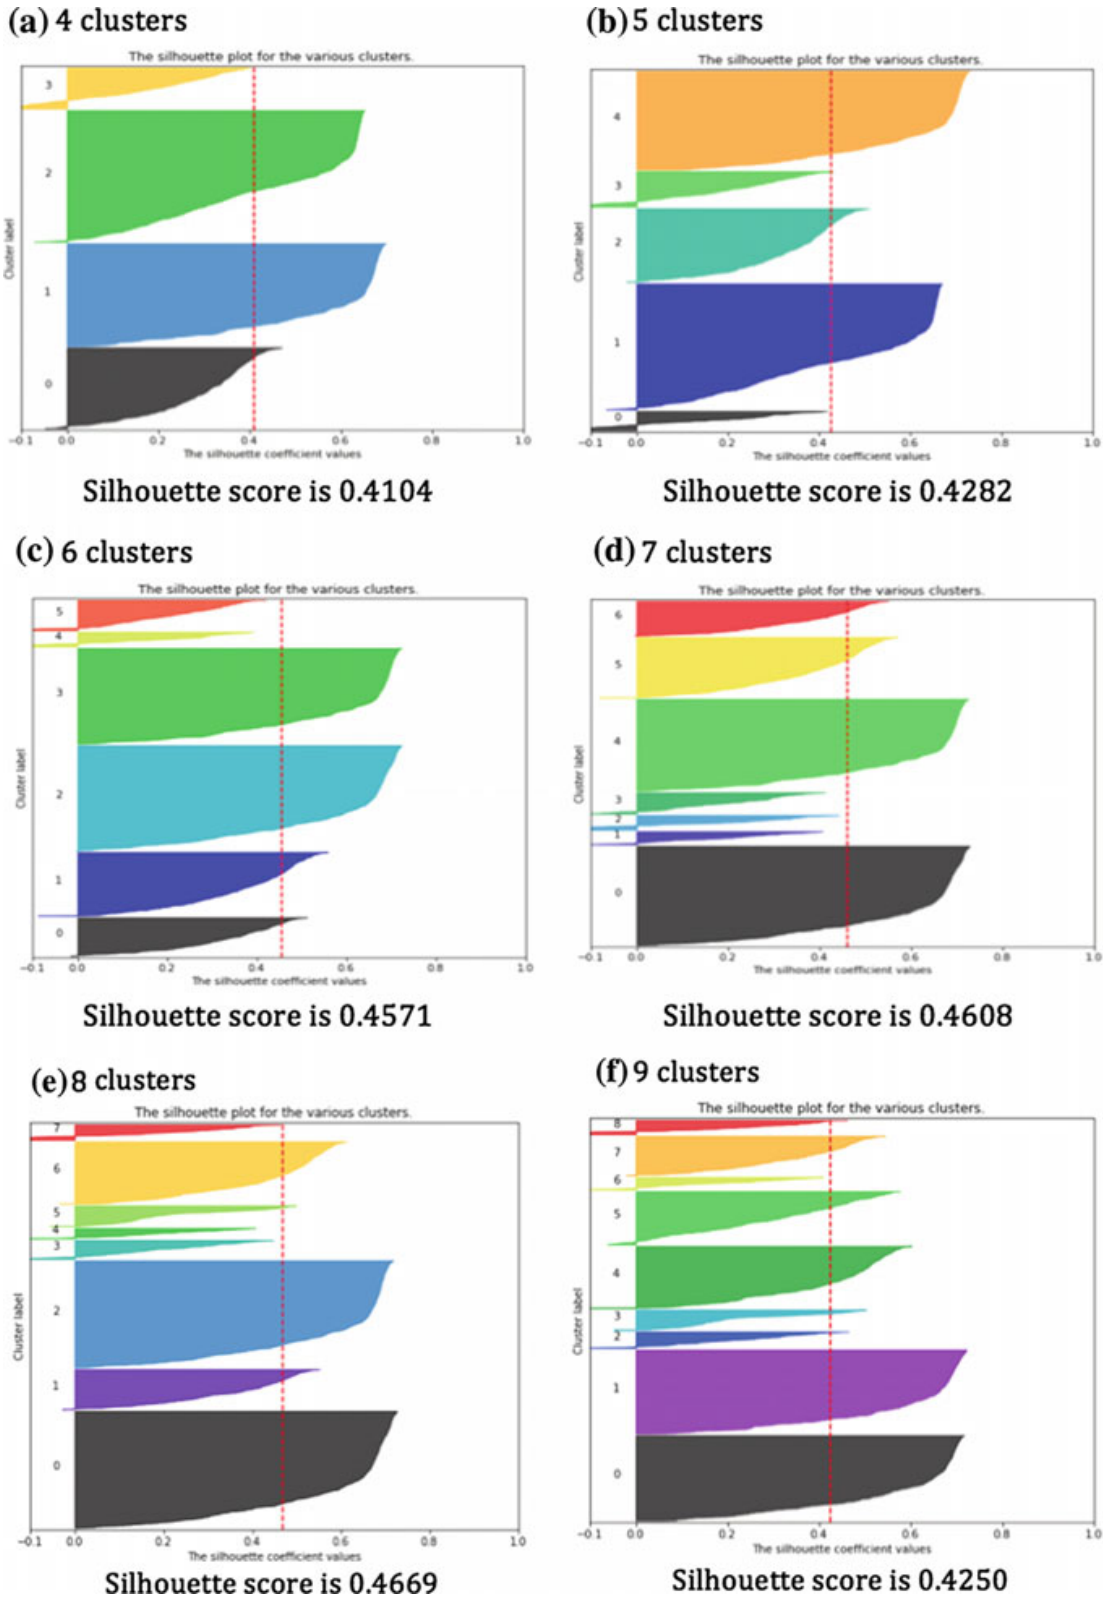

Fig. 2 Optimal number of clusters for 7-day bidding duration. Silhouette score is examined 19 times. We show the top Silhouette scores

Table 4 Optimal number of clusters and optimal CURE parameters

SB subset	No. of samples	No. of clusters	Silhouette score	RPs	α
1 Day	1289	7	0.4597	5	0.05
3 Days	1408	7	0.4672	5	0.01
5 Days	1060	5	0.4758	5	0.05
7 Days	2427	8	0.4669	10	0.001
10 Days	137	2	0.5549	5	0.1

Table 5 CURE clustering for 7-day bidding duration (8 clusters)

RP	α	Cl. # 1	Cl. # 2	Cl. # 3	Cl. # 4	Cl. # 5	Cl. # 6	Cl. # 7	Cl. # 8
5	0.1	136	1438	1	2	657	190	2	1
5	0.05	657	328	2	1408	1	28	2	1
5	0.01	1438	640	1	1	17	1	1	328
5	0.001	21	166	2	1	2	25	2209	1
10	0.1	2	1	657	1410	22	8	137	190
10	0.05	2	133	2	1	2	31	2066	190
10	0.01	1	1	1	1	135	31	2067	190
10	**0.001**	**189**	**654**	**1410**	**3**	**137**	**31**	**1**	**2**

cluster consists of users with similar bidding behavior. As we can see, the clusters 4, 7, and 8 have very few bidders, which are most probably outliers i.e., suspicious.

6 Labeling Shill Bidding Data

In Algorithm 1, we show the steps to label the bidders of a given cluster. A cluster belongs to a certain SB subset. As shown in Table 6, for each subset, we first compute the mean and STandard Deviation (STD) of each fraud pattern for all the instances in that subset. Then, we compute the average of the means (Avg. Means) and average of the STDs (Avg. STDs) of all the patterns for that subset. We consider the value of $(Avg.Means + \frac{1}{2}Avg.STDs)$ since it produces the best decision line that separates between normal and suspicious instances as depicted in Fig. 3. Then, we calculate the average of the means of all the patterns for the cluster. So, if the average mean of the cluster is greater than the decision line of the subset, then instances are labeled as suspicious (1) in that cluster, otherwise, they are labeled normal (0).

Table 6 Characteristics of SB subsets

Subset	1 Day	3 Days	5 Days	7 Days	10 Days
Mean of each pattern per subset

Algorithm 1 : Labeling Bidders in a Cluster

Require: AvgMeans and AvgSTDs of the corresponding SB subset
1: Compute $MeanCluster$
2: **if** $(MeanCluster \geq (AvgMeans + \frac{AvgSTDs}{2}))$ **then**
3: **for** x=1 to $NumberBiddersCluster$ **do**
4: $LabelBidder_x$ = 1 (Suspicious)
5: **end for**
6: **else**
7: **for** x=1 to $NumberBiddersCluster$ **do**
8: $LabelBidder_x$ = 0 (Normal)
9: **end for**
10: **end if**

To validate our approach, we choose randomly 5 auctions among the 7-day duration auctions (in total 309) and select randomly one bidder in each auction (Table 7). As we can observe from this table, the shill bidding instances were successfully labeled by our approach. For example, bidder "g***r" has four fraud patterns with very high values; among them, two have a high weight and one a medium weight. Therefore, the activity of this bidder in auction ID # 2370 is suspicious. On the other

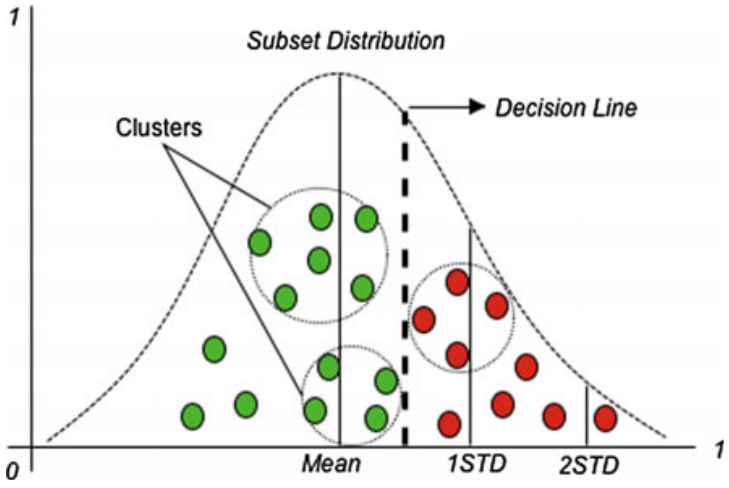

Fig. 3 Decision line of a subset and its labeled clusters

Table 8 Final results of instance labeling

SB subset	1 Day	3 Days	5 Days	7 Days	10 Days	Total
No. of normal instances	1135	1303	975	2098	135	5646
No. of suspicious instances	154	105	85	329	2	675

hand, the bidder "k***a" has all his fraud patterns with very low values; this indicates that this bidder behaved normally in the auction ID # 900. All these results are consistent with the labels produced by our approach.

Table 8 provides all the final results of the labeling task of our SB training dataset. There are 5646 instances categorized as normal and 675 instances as suspicious.

7 Conclusion and Future Work

There are limited classification studies on the SB fraud due to the difficulty of producing training data on one hand and labeling multidimensional instances on the other hand. Our aim in this paper is to effectively label SB instances based on the hierarchical clustering CURE that showed a remarkable capability for partitioning the online behavior of bidders. First, we divide the SB dataset into several subsets according to the different bidding durations of the auctions that we scraped from eBay. Then, we efficiently partition each SB subset into clusters of users with similar bidding behavior. At last, we apply a systematic labeling approach to each cluster to classify bidders into normal or suspicious.

In the following, we highlight two important research directions:

- The generated SB dataset is highly imbalanced, which will negatively impact the performance of classifiers as demonstrated in numerous studies such as [9]. The decision boundary of the fraud classifiers will be biased toward the normal class, which means suspicious bidders will be poorly detected. Handling the class imbalance problem is a continuous area of study [21]. In our research, we will investigate this problem by testing different types of techniques, such as data sampling and cost-sensitive learning, to determine the most suitable technique for our SB dataset.
- Ensemble learning has produced a reliable performance for many practical applications. The goals defined by ensemble learning are lowering the model's error ratio, avoiding the overfitting problem, and reducing the bias and variance errors. The most common ensemble methods are Boosting and Bootstrap Aggregation (Bagging). Thus, we will employ ensemble learning to develop a robust SB detection model, and examine the most fitting ensemble strategy for our SB dataset.

Big Data Security Challenges and Preventive Solutions

Nirmal Kumar Gupta and Mukesh Kumar Rohil

Abstract Big data has opened the possibility of making great advancements in many scientific disciplines and has become a very interesting topic in academic world and in industry. It has also given contributions to innovation, improvements in productivity and competitiveness. However, at present, there are various security risks involved in the process of collection, storage and use. The leakage of privacy caused by big data poses serious problems for the users; also the incorrect or false big data may lead to wrong or invalid analysis of results. The presented work analyzes the technical challenges of implementing big data security and privacy protection, and describes some key solutions to address the issues related with big data security and privacy.

Keywords Big data · Big data analysis · Big data security · Privacy protection

1 Introduction

In today's world, a large number of people share their social information and behavior using the internet and it has led to the explosion of data generated. The constant advance of technologies has allowed an "explosive" growth in the amount of data generated from different sources, for example social networks, mobile devices, sensors, X-ray machines, telescopes, space probes, applications logs, climate predictions, geo-positioning systems and, in general terms, everything that can be classified within the definitions of the internet of things [1]. According to

statistics, an average of 40,000 search queries occur every second; in other words, it can be said that over 3.5 billion searches are processed per day by Google search [2]. At the same time, various monitoring and sensing equipment are also generating data continuously. There is also a large amount of data in various fields such as scientific computing, healthcare, finance and retail. This phenomenon has aroused widespread concern.

The generation of this big data makes data analysis and application more complicated and difficult to manage. According to statistics, the amount of data generated globally over the past 3 years is more than the previous 400 years of data, which include documents, pictures, videos, web pages, e-mail, microblogging, and other types, which include mostly unstructured data as compared to structured data [3]. Gartner had forecasted that 4.9 billion connected objects to be in use by 2015, up 30% from 2014 and will reach 25 billion by 2020 [4]. At present, big data has become another information industry growth point in the field of information technology after cloud computing.

Like other current information systems, big data also involves security risks in the process of storage, processing, transmission and similarly it needs the data and privacy to be protected. The services like storage and management of data are provided in big data and cloud computing by the service providers themselves. But, the problem with big data as compared to cloud computing is that in case of cloud computing the user still has some control over their data to some extent; for example, through the use of cryptographic methods and through the other trusted computational methods. However, in the context of big data the businesses like Facebook not only produce the data but also provide the services like storage and management of data themselves. Therefore, it is extremely difficult to restrict the use of user information by means of technology and to protect the privacy of users' data [5].

At present, many organizations are aware of the big data security issues, and actively take action to focus on big data security issues. This paper focuses on the security challenges brought by the current big data technology and elaborates on the key technologies used for big data security and privacy protection. It should be pointed out that while introducing new security issues and challenges, big data also brings new opportunities in the field of information security. That is, big data-based technologies for information security can be used in turn for big data security and privacy protection.

2 Big Data Research Overview

2.1 Big Data Sources and Characteristics

Big data may have various sources from where it may be generated. Based upon the source of generation of big data, it can be divided into following categories [6]:

1. From the people: all kinds of data generated by people in the process of performing activities over the internet. The generated data can be in the form of text, images, videos or of any other type.
2. From the machines: This includes the data which is generated by different computers and information processing units which may be in the form of files, databases, multimedia, and so on, and also includes automatically generated information such as logs.
3. From the devices: data collected by various types of digital devices, such as the digital signals continuously generated by the camera; the different data related to human beings generated through various medical devices; the large amount of data which is generated by the astronomical telescopes.

2.2 Big Data Analysis Goal

At present, big data analysis is applied to various diversified areas such as science, medicine and commerce. Overall, the goals of big data analytics fall into the following categories:

(1) *Gain knowledge through extensive analysis*

People have a long history of data analysis. There may be various reasons. The first and most important reason for analyzing the data is to get knowledge from it. Since there is a large amount of unprocessed real sample information, it can effectively abandon individual differences and help people through the mining, and more accurately grasp the common purpose behind the things. Depending on the knowledge they have discovered, one can predict more accurately the nature or social phenomena that will occur. Typical examples include the ability to retrieve information about the flu through Google's search using data mining [7]; predicting stock quotes based on Twitter information [8]; and so on.

(2) *Grasp individual laws through long-term analysis*

Individual activities have distinct personal characteristics while satisfying certain common characteristics. Through long-term multi-dimensional data accumulation and gaining information through that data, various companies get the insights of users' behavior and this may help them to accurately describe the individual user's profiles. In this way, it helps them to provide more accurate products and services according to users' individual needs. It also helps companies to accurately provide recommendations related to advertisements.

For example, Google analyzes users' habits and hobbies through its big data products, helping advertisers to evaluate the efficiency of their advertising campaigns, and it is estimated that there may be hundreds of billions of dollars in the market in the future [9].

(3) *Control epidemic through analysis*

Many times the timely information obtained through the analysis of big data can provide more valuable information regarding spread of epidemics, than by disease-prevention centers. For example, during the 2009 flu pandemic, big data analysis was performed by Google to get the timely information. Generally, patients do not go to the doctor immediately just after getting infected, but their search and discussion trends can be analyzed to get information about most influenced geographical areas.

2.3 Big Data Technology Framework

Big data processing involves data collection, management, analysis and display. Figure 1 is a schematic view of the relevant technology, including four stages.

1. Data acquisition and preparation

The data sources of big data are diversified, including all kinds of structured, unstructured and semi-structured data such as databases, texts, pictures, videos and web pages. Therefore, the first step in big data processing is to gather data from the data source and pre-process it to provide a consistent, high-quality data set for subsequent processes.

Since there exist various sources of big data, therefore, there may be different models for its description and these may even contradict. Therefore, it becomes important to clean the data during the data integration process so that similar, repetitive or inconsistent data can be removed. In the literature, data cleaning and

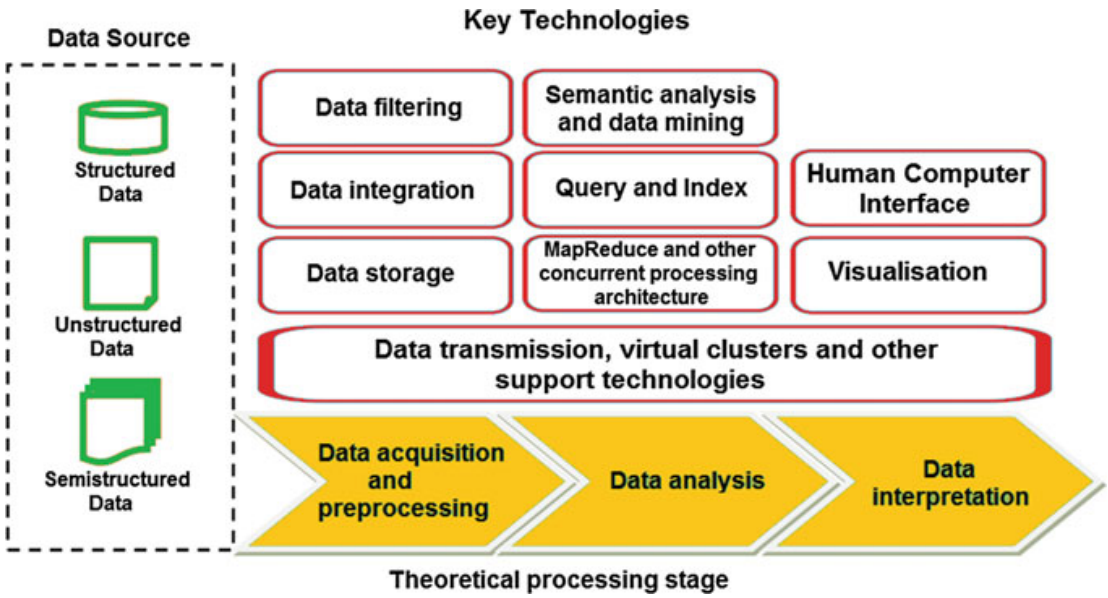

Fig. 1 Big data technology architecture

integration technology is aimed at the characteristics of big data, and proposes the cleaning of unstructured or semi-structured data and the integration of very large-scale data [9].

Data storage and big data applications are closely related. Real-time applications using big data require strong computational ability so that large amount of data could be processed in less amount of time. Therefore, big data processing system for real-time systems should quickly respond to the requests generated. This requires robust computing power for big data. Stream processing mode is more suitable for such applications. Most of the other applications need storage for subsequent deeper data analysis process. This may increase the storage cost. Usually big data uses distributed architecture to increase data throughput and reduce storage cost. Representative studies include file system GFS, HDFS and Haystack; NoSQL database Mongodb, CouchDB, HBase, Redis, Neo4j and so on [10].

2. Data analytics

Traditional data analysis may not work for big data as it was devised for structural data sources, but big data mostly consists of semi-structured or unstructured data. This presents a big challenge to big data analysis, but it is also the core process of big data applications. Based on the different levels, it can be broadly divided into three categories: computing architecture, queries and indexes, and data analysis and processing.

In terms of computing architecture, MapReduce [11] is a widely used big data set computing model and framework. In order to adapt to some analysis requirements that require high task completion time, work in [12] optimizes its performance. In [13], a data flow analysis solution based on MapReduce architecture, MARISSA, was proposed to support real-time analysis task. Dede et al. [14] proposed Mastiff, a big data analysis program based on time. Chandramouli et al. [15] proposed a TiMR framework based on MapReduce to deal with the real-time streaming for applications with high real-time demand such as advertisement push.

In query and indexing, traditional relational database query and indexing techniques are limited due to the large amount of unstructured or semi-structured data contained in big data, and NoSQL database technology received more attention. For example, Chandramouli et al. [16] proposed a hybrid data access architecture, HyDB, as well as a method of concurrent data query and optimization. Wang et al. [17] optimizes the query of key-value type database.

In data analysis and processing, the main technologies involved include semantic analysis and data mining. Owing to the diversification of data in big data environment, it is difficult to unify the terms to mine information when semantic analysis of data is concerned. In [18], for the big data environment, a high-efficiency terminology standardization method for solving the term variation problem is proposed. Keteta et al. [19] studied the heterogeneity of semantic ontology in semantic analysis. Traditional data mining technology is mainly aimed at structured data, so it is very important to study unstructured or semi-structured

data mining technology. Kang et al. [20] proposed a mining technique for image files, and Kang et al. [21] proposed a large-scale TEXT file retrieval and mining technology.

3. Data interpretation

The purpose of data interpretation is to represent data analysis results in a way which can serve the user's purpose. The major technologies which make it possible are visualization and human–computer interaction. There have been some visualization studies for large-scale data [22], which solve the display problem of large-scale data through data projection, dimension degradation or display wall. As human visual sensitivity limits the effectiveness of larger screens, a human-centric human–computer interaction design will also be an important technique to address the display of big data analytics results.

4. Other support technologies (data transmission and virtual cluster)

Although big data applications emphasize data-centric computing and push calculations to data execution, data transmission is still essential throughout the process, such as the transmission of some scientific observations from observation points to data centers. In [23] the authors study efficient transmission architectures and protocols for big data features.

In addition, because virtual clusters have the advantages of low cost, flexible construction and easy management, people can choose more convenient virtual clusters to complete the various processing tasks during big data analysis. Therefore, virtual machine cluster optimization research for big data applications is needed [24].

3 Big Data Security Challenges

Big data provides a great technology which has its significance in various fields and the security requirements in these fields are also changing. During the various activities performed over data during its collection, refinement and mining, many security threats are also associated. During this process the data may be destroyed, leaked, tampered, which can put the user privacy or corporate secrets to be compromised. In general, the security related to big data has the following characteristics and challenges.

3.1 Technical Challenge

The technical challenges of big data applications are mainly in the following three aspects:

First, as we all know, the application of big data is based on the possession of massive data. This involves the challenges of data storage technology and the technical challenges for data processing and analysis, including the data processing capabilities of computer hardware and supercomputer algorithm technology. The report learned from interviews with technical experts indicates that they are not optimistic about the recent overcoming of the technical challenges described above. Second, in the educational application of big data, data collection and problem-solving analysis are the core links, and application developers have to face the challenges of data acquisition technology and problem-solving analysis technology. The third aspect is the data compatibility challenge, the inconsistency of data encoding and format in different data storage systems, resulting in data sharing difficulties between different systems. The main reason for this problem is the lack of unified planning for the construction and purchase of various systems which results in inability to form unified data platform.

3.2 Mobile Data Security Challenge

In the world of today, various new applications related to social media have been emerged; besides this it is not uncommon for e-commerce portals and mobile applications to generate enormous amount of data. Analyzing such large amount of data in addition to data generated through internet of things network is a big challenge for companies. It also put responsibilities over the companies as the demand for data security capabilities on enterprises also increases greatly. In addition, the increase in data secrecy results in more sensitive analysis of data which is being transferred between mobile devices. Personal information may also be compromised because of the malware which may track user location or steals the confidential information. It requires increasing the safety related to user's privacy and data. Since the mobile devices have grown rapidly in recent years, it has created a challenge for big data security that how the samples of malware could be tracked which may enable analyzing these malware samples and finding the relationship between them.

3.3 Easy Target for Attackers

The various resources and personalized services are being provided through the network access in a flexible manner. In such a large networked society, the voluminous data attract the hackers because of the potential value associated with it. Such big data is large and has interrelated information stored, and due to this an attacker finds it easy to get more information by successfully attacking once, which further reduces the attacking cost and increases their profit value. A good example of such situation is when hackers use information in big data and take control of

important systems to take advantage from it for the time being. Hackers can also deploy AI technologies to take full control of the system by slowly penetrating it over time. Such strategy may work, as it would perform minor changes and such changes would appear natural. Thus, its detection could be avoided.

3.4 User Privacy Protection Challenge

Worldwide people use different kinds of web services and while using such services they need to access the network which stores their credentials like name, username, password, contact information, address and so on. It also includes their other personal information, behavior, habit, political or religious inclination and location; this has increased the risk of user privacy and data disclosure. Through the use of various data mining approaches such data can be easily recorded. If these data are found to be useful, then companies in the relevant areas of customer's need and habit can target to the specific users to achieve greater benefits. The traditional approach of privacy protection is based on anonymity of user data which is publicly available. But in reality, the user privacy protection cannot be achieved only through data protection through anonymity. There exist many other requirements and characteristics for user privacy. But the problem is that most of the existing privacy protection models and algorithms are only for traditional relational data, and cannot be directly applied to big data applications.

3.5 Safe Storage of Massive Data Challenge

The quantity of big data has increased tremendously, which includes structured and unstructured data. It has increased to such a level that the previous storage systems are not capable to meet the needs of big data applications. The current disk technology has some limitations and this limit is around 4 terabytes per disk. So for such a massive data of exabyte levels, this limitation creates a problem, because just to store 1 exabyte requires around 25,000 disks. It will really create the hardware issue of how to attach such large number of disks to a single computer, even if the computer is capable of processing that much of data.

To satisfy the demands of data storage of such large amount, various new storage technologies have been developed. Storage technologies such as direct attached storage (DAS), network attached storage (NAS) and SAN (storage area network) are being used to solve the data storage-related issues. Another technology called NoSQL storage technology is also used to capture, manage and process big data. Using NoSQL data storage can be extended and performance also can be improved, but still some issues exist. These issues include access control and

privacy control issues, issues related to technical vulnerabilities, security issues for authorization and verification, data management and confidentiality issues, and so on.

3.6 Challenge of Analysis

With the increase of storage capabilities, prior selection of data became insignificant. This can be seen as a real chance, allowing to keep focus on the potential future uses and which are not always fully defined at the time of their acquisition. In particular, many issues that were considered nonexistent later become accessible before the use of their potential of significant advantage (competitive advantage for example). It should be kept in mind, however, that more data is not always better data. It depends on whether or not they are heterogeneous, and whether they are representative of what is being sought. In addition, as the number of parameters increases, the number of erroneous correlations also increases. The analysis part will have to take into account these essential aspects.

Heterogeneous (structured, unstructured) data or incomplete or uncertain data for which specific treatments are needed will also be stored. Moreover, in this regard specific treatments are already required for the more standard data, even if some old methods remain effective for the volume of the existing data, which may cause theoretical and practical difficulties, unknown in advance. Thus, the simple statistical tests [25] become inoperative for large sample sizes. We can also mention the difficulty of multi-dimensional analysis on large sets of data, which arises during their interpretation. The visualization is considered until now as an extremely powerful tool, but it risks becoming inoperative by simple graphic saturation effect. In addition, real-time analysis of continuous flow of data from different sources also poses specific challenges. All these problems involve the development of new statistics for big data, for example, requiring a review of basic calculations such as statistical tests and correlations [26]. Of course, these technical analysis tools cannot be isolated from the computer tools and techniques dedicated to big data, for example, NoSQL, Hadoop, MapReduce or Spark.

3.7 Big Data Security Trust Challenge

Although big data has provided various opportunities to its users, but still it lacks the complete trust of the people using it. The visibility of social profiles generated by users varies across different types of networks and these are crawled by the search engines and therefore they become visible by the other users whether they have account or not. Therefore, here a trust issue arises from the user that how safe their data privacy is. This requires trust measures to be integrated with big data. These trust measures should not be treated as a static measure. That means, as the

data evolves the trust measures should also be updated accordingly. Yin and Tan [27] in their research have put the fact that semi-supervised learning methods that start with ground truth data are able to provide higher accuracy and trust on the source data. Another fact is that the different people have different personal opinions regarding various factors affecting their life and when there exist differences with statistics it leads to the market doubts about statistics.

4 Key Technologies for Big Data Security and Privacy Protection

At present, it is urgent to carry out research on key technologies of big data security in view of security challenges such as user privacy protection, data content credibility and access control faced by the big data. This section introduces some related key research areas for this.

4.1 Data Anonymity Protection Technology

For structured or unstructured data in big data, the core key technologies and basic means for data protection to achieve its privacy protection are still in the stage of development and improvement. Take the typical k anonymity scheme as an example. The early schemes [28] and their optimization schemes [29] group quasi-identifiers by data processing such as tuple generalization and suppression. The quasi-identifiers in each packet are the same and contain at least k tuples, so each tuple is at least indistinguishable from $k - 1$ other tuples. Since the k-anonymous model is for all attribute collections, it is not defined for a specific attribute, and it is prone to insufficient anonymity of a certain attribute. If the value of a sensitive attribute in an equivalence class is the same, the attacker can effectively determine the value of the attribute. This research is for static, one-time release. In reality, data publishing often faces scenarios in which data is continuously and repeatedly released. It is necessary to prevent an attacker from analyzing the data associations that are published multiple times, and destroying the original anonymity of the data [30].

In big data scenarios, data anonymity protection is more complicated: an attacker can get data from multiple sources, not just the same source. For example, in the Netflix application, people [31] found that an attacker could identify the target's Netflix account by comparing the data to the publicly available imdb. According to this, the user's political inclinations and religious beliefs are obtained (obtained through the user's viewing history and comments and scoring analysis of certain movies). Such issues are subject to further research.

4.2 Social Network Anonymity Protection Technology

The data generated by social networks is one of the important sources of big data, and it contains a large amount of user privacy data. Because social networks have the characteristics of graph structure, their anonymous protection technology is very different from structured data.

The social networks also require anonymity protection. Here, some typical requirements are user anonymity and attribute anonymity. While using social networks the user identity and attribute information is also required to be hidden while publishing these. The related data of different users should not disclose their relationship and anonymity between users is required. It is also known as edge anonymity. Hide the relationship between users when publishing. The attacker tries to use the various attributes of the node (degrees, tags, some specific connection information, etc.) to re-identify the identity information.

The current side-anonymity schemes are mostly based on additions and deletions of edges. The method of randomly adding and deleting exchange edges can effectively implement edge anonymity. Among them, Ying et al. [32] keep the eigenvalues of the adjacency matrix and the corresponding second eigenvalues of the Laplacian matrix in the anonymity process. Zhang et al. [33] group according to the degree of the nodes, and select the nodes with the same degree. The problem with this type of method is that the randomly added randomness is too scattered and sparse, and there is a problem of insufficient protection of the anonymous side.

4.3 Data Watermarking

Digital watermarking refers to a method in which identification information is embedded in a data carrier in an imperceptible manner without affecting its use, and is more commonly found in multimedia data copyright protection. There are also some watermarking schemes for databases and text files.

The method of adding watermarks in databases and documents is very different from the multimedia carrier, which is determined by the characteristics of data disorder and dynamics. The basic method is that there can be redundant information in the data or it can bear certain precision errors. For example, Agrawal et al. [34] have an error tolerance range based on numerical data in the database, embedding a small amount of watermark information into the least significant bits randomly selected from these data. Sion et al. [35] proposed a scheme based on statistical features of data sets, embedding one-bit watermark information in a set of attribute data to prevent attackers from destroying the watermark. In addition, by embedding database fingerprint information in the watermark [36], the owner of the information and the object being distributed can be identified, which is beneficial for tracking the leak in a distributed environment. Watermarking based on text content [37] depends on modifying the content of the document, such as adding spaces,

modifying punctuation, natural language-based watermarking [38] and so on, through the understanding of semantics to achieve changes, such as word substitution or sentence changes.

4.4 Data Traceability Technology

Owing to the diversified sources of data, it is necessary to record the source of the data and its distribution to provide support for later mining and decision-making. Data provenance technique has been extensively studied in the database field long before the big data concept emerged. The basic purpose is to help people determine the source of each data in the data warehouse, for example, which data items in tables are computed, so that it is convenient to check the correctness of the results at a very small cost. The basic method of data tracing is notation, such as marking the data in the data warehouse in [39] to record the query and propagation history of the data in the data warehouse. Data traceability techniques can also be used for traceability and recovery of files. For example, the work in [40] created a prototype system of data origin storage systems by extending the Linux kernel and file system, which can automatically collect origin data.

Further data traceability technologies can play an important role in the field of information security. However, data traceability technology also faces the following challenges in the protection of big data security and privacy:

1. *The balance between data traceability and privacy protection.* Using traceability to provide big data security protection requires first to obtain big data source using analysis of big data. Then the next step becomes to define the security policy and provide the required security mechanism. Often, the source of big data is privacy-sensitive and users are not interested that data to be accessed by the analysts also. Therefore, the problem is how to balance these two requirements simultaneously so that data traceability and privacy protection of the data both can be achieved.
2. *Security protection of data security technology itself.* The data tracing techniques currently employed are unable to handle the security issues correctly. The problem is that how to determine whether the tag associated with the data is itself correct or not. The other problem is that the tag information itself may not be securely bound with the data content and there may be other similar issues. Also in case of big data, since it is implemented on such a large scale, high speed and diverse characteristics such problems become more important.

5 Conclusion

The arrival of the era of big data has opened great opportunities. Big data not only has impact on everyone's social and economic behavior but also has influenced their way of living and thinking. Although big data is an important solution to various problems, it has also brought new security issues into existence. From the perspective of privacy protection, trust and access control of big data, this paper analyzes various security features and problems in the big data environment, namely, mobile data security, attack targets, user privacy protection challenges and security, storage issues, data security evolution, trust security issues and so on, and also discusses the preventive solutions for them. However, generally speaking, the current research on the protection of big data security and privacy is not sufficient. Only through the combination of technical means and relevant policies and regulations combined can better solve the big data security and privacy protection issues.

Role and Challenges of Unstructured Big Data in Healthcare

Kiran Adnan, Rehan Akbar, Siak Wang Khor and Adnan Bin Amanat Ali

Abstract Unprecedented growth in the volume of unstructured healthcare data has immense potential in valuable insight extraction, improved healthcare services, quality patient care, and secure data management. However, technological advancements are required to achieve the potential benefits from unstructured data in healthcare according to the growth rate. The heterogeneity, diversity of sources, quality of data and various representations of unstructured data in healthcare increases the number of challenges as compared to structured data. This systematic review of the literature identifies the challenges and problems of data-driven healthcare due to the unstructured nature of data. The systematic review was carried out using five major scientific databases: ACM, Springer, ScienceDirect, PubMed, and IEEE Xplore. The inclusion of articles in review at the initial stage was based on English language and publication date from 2010 to 2018. A total of 103 articles were selected according to the inclusion criteria. Based on the review, various types of healthcare unstructured data have been discussed from different domains of healthcare. Also, potential challenges associated with unstructured big data have been identified in healthcare for future research directions in the technological advancement of healthcare services and quality patient care.

1 Introduction

Rapid advancement in healthcare systems from disease-centric systems to patient-centric systems involves patient health records, integration of data from various health and social sources, advancement in mhealth, smart health and tele-health devices. Advanced Healthcare systems are required to support clinical decision support system, personalized and precision medicine, diagnostics systems, health and wellness monitoring, patient care and predictive analytics. This data-driven healthcare support leads to orchestrate data preprocessing, analytics, interpretation, management and curation techniques for improved healthcare services. Most of the healthcare data are unstructured such as medical prescriptions (hand-written, free-text), clinical notes, Electronic Health Records (EHR), Electronic Medical Records (EMR), Patient Health Record (PHR), Medical Imaging (Magnetic Resource Imaging, MRI, Photoacoustic imaging, Fluoroscopy, Positron emission tomography), discussion forums, social media, sensor data, medical sounds and video data, genomics, and in many other transactional, biometric and application data. By definitional perspective of unstructured data, it has no schema or predefined model, attitudinal and behavioral, and without specified format. This heterogeneity, variability, and diversity of unstructured data make it difficult to get valuable insights from unstructured data that if analyzed in a controlled manner, can improve healthcare analytics and extraction of more real values. In past years, the unstructured data growth rate is increasing exponentially. 90% of digital universe data are unstructured. 57% of all healthcare data will be useful if it is properly tagged and analyzed whereas only 3.1% of healthcare data are providing the highest value. It is a challenging and daunting task to find a needle in a haystack [1, 2].

The role of multifaceted unstructured big data in healthcare is very challenging and gaining popularity because it contains more rich information that is helpful to provide novel insights as well as improve technological capabilities in healthcare systems. Unstructured data in healthcare have great potential but a lot of challenges remain to be addressed. Several techniques have been proposed in the literature regarding big data management, analysis, and representation of data but very less number of articles dealt with the unstructured data in healthcare. The literature about unstructured big healthcare data emphasizes technological advancement need to be more focused. The main objective of this literature review is to highlight the most affected areas of healthcare big data solutions from unstructured data. This review is an attempt to answer the following question about unstructured data in healthcare, i.e., which domains of healthcare are suffering from the complexity of unstructured data, what challenges are being created by unstructured data, and what is the role of unstructured data in inefficient and poor results in analytics and data-driven decision-making in healthcare. The review discusses the types of unstructured big data in healthcare and the challenges associated with unstructured big healthcare data since 2010. A systematic literature review has been conducted in

this regard to fulfill the objectives of the study. The review of existing literature on the challenges associated with unstructured big healthcare data will help to improve usability and quality of unstructured data in various fields of healthcare. It will highlight the major challenges of unstructured data in healthcare that need advancement in tools and technologies.

The rest of the paper is organized in the following manner: Sect. 2 discusses the methodology used and the results of the systematic literature review. Challenges associated with unstructured big healthcare data in technological advancement have been elaborated in Sect. 3. Next Sect. 4 includes the findings of the review. Finally, Sect. 5 presents the conclusions.

2 Methodology

A systematic literature review has been used to conduct an effective review to highlight the potential challenges in healthcare domain due to unstructured data. The objectives of this research were to discuss the types of unstructured big data in healthcare and to explore the challenges associated with unstructured big healthcare data. This review has comprised of three phases: planning the review, conducting the review and reporting. In the planning phase, the fundamental search has been performed using specific keywords. The second phase involves the searching keywords on specific sources to conduct the review and results are obtained. In the third and last phase, results are presented.

2.1 Searching the Literature

According to the objectives of the study, the best suitable keywords were identified to organize more effective review. “Unstructured data” and “healthcare” were the queries formed from the keywords. This search query was used on some of the popular academic databases: IEEE Xplore, Springer, ScienceDirect, ACM digital library, and PubMed.

2.2 Inclusion Criteria

Articles deal with unstructured data in the healthcare domain, published between 2010 and 2018, using the English language was the inclusion criteria to capture the literature. According to the results of databases and inclusion criteria, a total number of articles (n) selected for review were 1522. Articles were filtered by title reading and the total number of articles reduced to (n) = 566. After that, abstracts

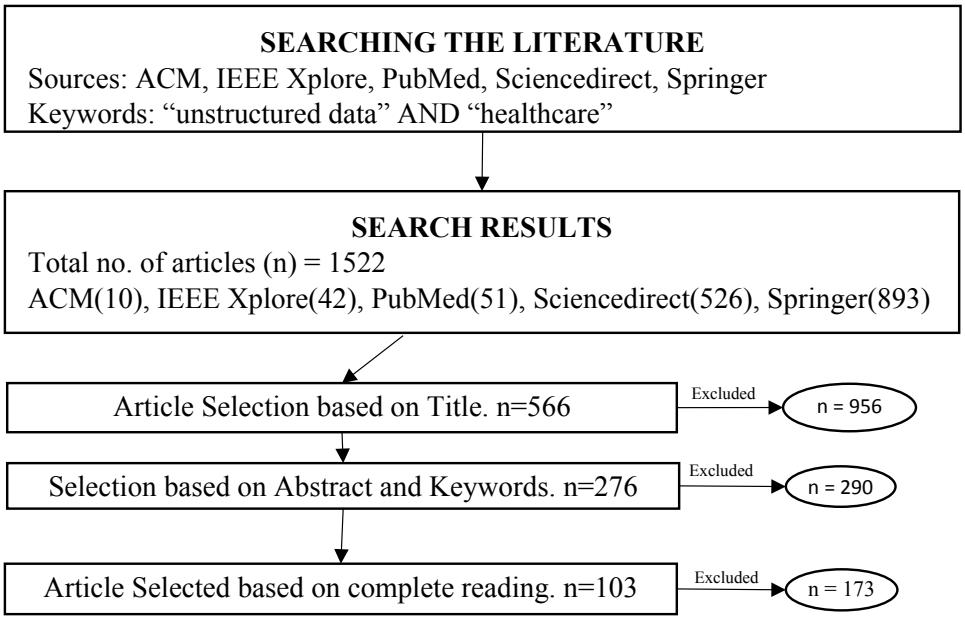

Fig. 1 Literature review process

and keywords were carefully studied and n decreased to 276. Based on the complete article study, 103 articles were selected for the study. Type of healthcare technology, type of unstructured data used, the domain of work and identified challenges are the records kept from each selected paper. Following Fig. 1 describes the whole research process in detail.

2.3 Results

This review was conducted to analyze the challenges in technological advancement due to the huge volume of unstructured healthcare data. The following Fig. 2 shows the research trend of selected articles for this review according to the year of publication. The figure shows the number of publications in each year that deals with unstructured data. An exponential rise can be seen in the following diagram that reflects the importance of unstructured data in the healthcare industry.

The results witness several types of healthcare advancement in four major categories: healthcare analytics (51% of selected articles), decision support systems (12%), health and wellness monitoring (18%), precision and personalized medicine (6%). In selected articles, several types of unstructured data have been used in various domains of healthcare such as disease identification from EHR, pharmacovigilance, drug effects identification, phenotyping, genotyping, and medical recommendation systems. Unstructured data are found in EHR, EMR, PHR, medical imaging, discussion forums, social media, sensor data, medical sounds and video data, genomics, and in many other transactional, biometric and application data. A major portion of selected research articles in this literature review was

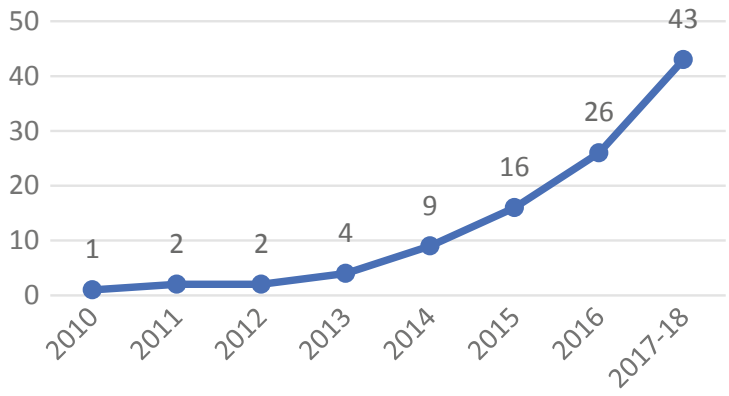

Fig. 2 Research trend of publications

related to the clinical hand-written notes, free-text in EHR, and text from social media. The main purpose of this literature review was to identify the most affected areas due to unstructured data in healthcare where technological advancement is required in order to improve the patient care. In the following section, challenges identified from the literature have been described in each category along with the requirements.

3 Challenges

This section describes the challenges of unstructured big data in healthcare identified in the literature. Selected articles are divided into five major categories with respect to their relevancy. The major categories of challenges are preprocessing, interoperability, Information Extraction (IE), analytics and result interpretation, and some other issues related to data exfiltration, standardization, and data curation. The following subsections describe the challenges associated with unstructured big healthcare data in detail.

3.1 Data Preprocessing

The variety of data is available in healthcare but these data are not fully usable for analysis and other processing due to noise, errors, missing values, and other quality issues. Preprocessing is a step that can reduce the inefficiency of unstructured data. As, 95% of healthcare data are unstructured data, available in various formats and facing more complexity, quality, usability and dimensionality issues. It arises the importance of preprocessing to improve the efficiency and accuracy of healthcare systems. Clinical decision support systems, health and wellness monitoring, disease identification, precision medicine, and analytics are important areas where unstructured data preprocessing techniques are required. Data preprocessing and

data cleaning are required for improved results in predictive analytics from social media text [3], complaint management in health information systems [4], decision support system from medical text and images [5], disease identification from health and wellness monitoring EHR data [6], in analytics and management of unstructured data [7, 8].

Data aggregation prepares the data in the required format as data is coming from various sources with different formats, frequencies, and representations such as structured EHR, semi-structured logs and unstructured images, audio and video data. The volume of unstructured data is far higher than the structured data. Hence, unstructured data aggregation and acquisition are more challenging. Free-text doctors' notes, handwritten clinical notes, patient care data, transactional, biometric and application data, EMR, and many other types of unstructured data are coming from various sources. Collection of these data found in a variety of formats is more challenging to handle [9]. Transformation engines clean, split, translate, merge, validate and sort unstructured data and make data prepared for analysis. Transformation techniques are required to transform the representation of data from unstructured to structured data in healthcare analytics, drug safety surveillance and clinical decision support systems [10–13]. Healthcare domains like identification of drug safety issues, disease identification systems need an automatic conversion of unstructured documents to structured data to increase the availability and usability of data analytics and databases [14–16]. But context-aware transformation based on user requirement and finding the relationships between the data items is still an open issue in healthcare. Personalized medicine, disease identification, adverse drug events identification, and medical knowledge base are the fields of healthcare where aggregation of structured and unstructured data is found critical. Integration of structured and unstructured data [17], improvement in predictive performance by combining structured and unstructured data [18], combining structured and unstructured data for comprehensive representation in predictive analytics [19], advanced analytical techniques [20], mapping of unstructured data to normalized content [21], complexities arise when outcomes of diverse sources need to be combined [22], and classification of combined data [23] are the challenges found in the literature.

Unstructured data require more advanced techniques than structured data because it has no schema, no predefined model, and no formal representation. Advancement is required to prepare unstructured healthcare data with more efficient data preprocessing methods. New big data technologies are emerging with adapted preprocessing. Apache Spark [24], Hadoop [25], and Flink [26] are performing better in processing big data. Apache Spark is making effort particularly in preprocessing and implemented MLlib to bridge the gap. It is highly desirable to develop new preprocessing techniques for data cleaning, discretization, feature selection, and data profiling using these advanced big data processing tools in healthcare.

3.2 Interoperability

Interoperability is another challenge to advance healthcare systems where two or more systems share and use data. Integration of data from different systems without any middleware and exchange of data poses more challenges to healthcare analytics (Table 1).

It requires common interfaces of healthcare systems, standardization of processes and data, and share common characteristics of a variety of data. Lack of uniform coding system across vendors is a challenge to interoperability that needs to be solved in order to manage patient information across hospitals and different applications with considering the ethical and privacy issues of patients' personal data. Following are the challenges identified in this literature review regarding interoperability in healthcare with a variety of healthcare data:

- Integration (Late or Early) of heterogeneous data and common type system for a variety of data types are the common challenges in predictive analytics in precision medicine and clinical diagnostics.
- Conventional databases are not adequate to handle this diversity of data types. Consolidated view of patient-related data using distributed storage is required for advanced information systems.
- Lack of harmonization between structured and unstructured data, evolving interoperability standards and integration of EHRs are creating challenges in analytics, data-driven medicine, precision and personalized medicine, and decision support system.
- All stakeholders need to work together in order to achieve interoperability [46]. Semantic and syntactic interoperability is important and essential for context awareness. Shared use of heterogeneous data, common representation of combined data, and deep understanding of unstructured data is an open issue. However, technical solutions are required for interoperability and integration.

3.3 Information Extraction

Disease diagnosis and its complications, communicable and non-communicable diseases' identification, drug surveillance, surgery details, and patient history are some examples of healthcare data where data are stored in the form of natural language text. Information extraction is a technique to extract structured information from these clinical texts with the help of natural language processing and machine learning. These information extraction techniques are helpful in predictive, prescriptive analytics, clinical care, clinical decision support system, disease identification from clinical notes, and precision medicine. Information extraction challenges due to unstructured healthcare data (i.e., free-text and handwritten clinical notes, EHR and EMR) found in the literature are described in Table 2.

Table 1 Related literature regarding interoperability and integration

Healthcare category	Data type used	Domain	Description of challenges
Analytics	Physician's and pharmacy notes, medical images	Systemic Lupus Erythematosus	Integration of various data formats, interoperability, evolving standards are the main challenges for which Common Type System is required for Clinical Natural Language Processing. The accuracy of predictive analytics can be improved using the advancement of these techniques [21, 27–31]
Analytics	EMR Clinical Free Text	Phenotyping	
Predictive Analytics	EHR Text	Clinical Diagnostics	
Analytics	Genomic Data	Evidence-based precision medicine	
Analytics	Omics data	Health data Spectrum	
Distributed Storage	Medical Images and associative text data	Radiology Information System	Conventional databases are not able to handle the complexity of a variety of data in healthcare. Consolidated View of Patient-relevant data from heterogeneous and disperse systems [32, 33]
Distributed Storage	Free-text, images and Proprietary formats	Medical Information Systems	
Data-driven Medicine	Text and medical images	Epilepsy	Lack of harmonization between structured and unstructured data, evolving interoperability standards, and integration of EHRs are the potential challenges and need solutions for efficient and effective curation [24, 25, 34–40]
Healthcare Systems	Genome and Medical images	European Single Market for health	
Data Analysis, Representation	EHR	Health Information Systems	
Precision and Personalized Medicine	Omics data	Molecular characterization of diseases	
Decision Support system	Behavior data and EHR	Medical Recommendations for Diabetes	
Information Management	Clinical Text	Common type of system development	Deep semantic understanding required structured data [41]. Semantic interoperability and data sharing are required to make computers context-aware [42, 43]. Shared use of heterogeneous data sources [44]. Interoperability, standardization, and integration of data sources are open issues [45]
Smart Healthcare	PHR	IohT	
Decision Support system	Structured and unstructured text	Pharmaceutical IE and Integration	
Medical Image Processing	Medical and diagnostic images	Medical diagnosis	
Decision Support system	Text and images of clinical data	Dental Clinics	

Table 2 Related literature regarding information extraction

Healthcare category	Data type used	Domain	Description of challenges
Analytics	Clinical documents	Open sources IE software	Extracting quality insights from healthcare data sources [47]
Analytics	Social Media streams	Drug and its effects detection	IE regarding drug and its effects from social media text streams is challenging due to ambiguous information [48]
Predictive Analytics	Clinical discharge summaries	Prediction of readmission from discharge summaries	Gaining information regarding readmission from unstructured clinical discharge summaries [49]
Analytics	Clinical Text data	Physiotherapy treatment	IE from unstructured EHR clinical notes [50]
Clinical Care	EHR	Phenotyping	Phenotype extraction from unstructured EHRs [51]
Personalized medicine	EHR and biomedical text literature	Genotype and phenotype extraction for cancer	Finding actionable granularity in disease identification and risk score [52]
Adaptive Analytics	Clinical Text trails of EMR and EHR	Cancer Clinical trials	Subject extraction [53]
Analytics	Unstructured medical notes	Disease identification	Semantically informed IE [54]
Sentiment Analysis	Discussion forums	Medical forum Discourse	Semantic extraction [55]
Exploratory Analytics	Physician and Biomedical data	Dashboard for querying heterogeneous data	Standardization, data formats, and their aggregation will improve semantic data processing [56]
Information retrieval and extraction	Clinical text documents	Software implementation in hospital	Finding relevant data [57]
Analytics and Representation	Imaging, Genetic and healthcare data		Multifaceted proprietary, open-source, and community developments [58]
Decision Support system	Medical and clinical references and publication text	Medical Recommendation System for Mental health	Predefined schema, large manually crafted dictionaries and ontologies are required to extract information from medical domain publications [59]
Clinical Decision Support System	EMR, Unstructured Clinical Notes	Automatic diagnosis prediction	Unstructured data combined with structured and semi-structured data will show good results [60]

(continued)

Table 2 (continued)

Healthcare category	Data type used	Domain	Description of challenges
Disease identification	Emergency dept. text notes	Automated identification of Pediatric Appendicitis Score	Unstructured data processing is challenging to extract useful information [61]
Bio surveillance	Clinical Free text	Detailed clinical and epidemiological variable extraction	Temporal IE and its integration for more elaborative and comprehensive representation of information [62]
Precision Medicine	EHR text	Prescreening and automated identification of HFpEF patients	The immense need for automatic data extraction system for the transformation of unstructured data into structured representation [63]
Data Management	Social Network text	Health data mining	Extracting information and associative features from unstructured text (associative analysis) [64]
Database Analytics		Data linkage and administrative databases	Metadata Management and IE [65]

Entities, relations, events, terms, and other important information can be extracted from text data in healthcare. These subtasks of information extraction are valuable to identify important terms and its associative relations in the medical domain. In healthcare analytics, decision support systems, medicine, and data management area, information extraction deal with several challenges due to unstructured big data. This review identifies those challenges to highlight the potential areas that need solutions for improved healthcare. Following is the summary of challenges:

- Extracting quality insights from EHR clinical notes, documents, clinical discharge summaries, and social media streams for healthcare analytics in treatment and medicine.
- Phenotype and genotype information extraction for disease identification from EHR and biomedical text up to actionable granularity and identify risk score.
- Semantic information extraction from various types of analytics to identify the disease from medical data and advanced intelligent IE systems are required to extract semantic information from multifaceted, open, and diverse unstructured health data.
- Automated extraction of various types of information from EHR clinical notes, EMR, medical and clinical publication text for medical recommendation system and automatic disease prediction is an immense need to represent data into the more elaborative structured form.

- Information extraction from healthcare unstructured data and metadata management can facilitate data linkage and databases. Traditional knowledge-based decision support systems deal with the data that have clear structure [66]. Lack of knowledge-based systems for unstructured data requires advance automatic IE system to build knowledge bases.

3.4 Data Analysis and Representation

Healthcare analytics is comprised of automated computer-based processes and workflows to transform raw health data into meaningful information for effective healthcare decision-making and wellness monitoring. Healthcare analytics is not only facilitating patients but also physicians, clinicians, nursing and other administrative staff. This review explores the challenges of unstructured big data to healthcare where analysis of data needs more accuracy because it is directly related to human life. According to the review, healthcare analytics has been identified as the most critical and most prominent research field and most affected by the heterogeneity and diversity of unstructured data. Table 3 briefly describes the related research.

Application of big data analytics techniques on disease diagnosis, pharmacovigilance, intelligent patient care, phenotyping, disease prediction, and patient health and wellness monitoring is helpful for preventive interventions and treatments. Technological development in healthcare is producing huge volume of different types of data. Patient demographic data, laboratory results, patient history, genomic data, EHR, EMR, PHR, and many other types of data are being produced every day. These data can be structured, semi-structured or unstructured. Due to the heterogeneity, different data formats, no predefined schema or model, and diversity of data sources adding more challenges to unstructured big data analytics in healthcare. This section identifies the potential challenges of unstructured data analytics to predictive, prescriptive, descriptive and diagnostic analytics. According to the literature review, the following is a brief description of the area where unstructured data are critical for analytics and data representation. The challenges of each area are also described categorically.

3.4.1 Smart Healthcare

Most of the data generating by sensors in smart healthcare are unstructured. Sensor-based health and wellness monitoring are generating a huge amount of unstructured data which could not be handled and interpreted manually. This huge amount of unstructured data is generating a gap between its potential and usability. The huge amount of streaming data from sensors is not usable due to heterogeneity and dimensionality of unstructured data. The data analytics pipeline for smart

Table 3 Related Literature regarding Healthcare Analytics and Representation of data

Healthcare category	Data type used	Domain	Description of challenges
Smart Healthcare	Sensor data	Patient Monitoring	Data discovery in heaps of unstructured data where streams of data are coming at very high speed, advanced smart health, and management to automate the curation process and improve the infrastructure for context-aware analytics [67–69]
	Heterogenous dataset text, images, sound	Healthcare Analytics pipeline	
		Analysis of healthcare systems	
Data Representation and Predictive Modeling	Clinical text events	Pharmacovigilance	Summarization and representation of data are facing difficulties due to lack of standardization such as abbreviations. Aggregated data from multiple sources contain diversity, sparsity, and multidimensionality due to data formats and representations. These different representations of EHR data making context-aware analytics challenging [70–73]
Data representation	Clinical Text documents	Phenotyping: Cancer Care	
Data representation	Clinical Notes and EMRs	Congestive heart failure	
Decision Support system	EHR text and Genetic data	Phenotyping using HER	
Healthcare System		Israel Health Policy Research	Due to data quality issues and heterogeneity, unstructured data are considered useless for clean analytics. Missing data and acronyms decreases the efficiency of analytics. Social media data have poor quality and noise, so the analysis of social media data is critical. Hashtag words can be used to improve analytical process but still, it needs health, media, and computer literacy for efficient results [74–79]
Predictive Analytics	EHR clinical narratives	Framingham risk factors identification of Coronary artery disease	
Twitter Analytics	Twitter text	Common disease identification	
eHealth	All	Implementation of eHealth platform	
Healthcare big data		Review of healthcare big data	
Twitter Analytics	Twitter hashtag words	Identification of top diseases	
Text Analytics	EHR Text	Russian language medical data of acute coronary syndrome	The gap between semantic and syntactic structure creating challenges for context understanding of the unstructured text. Although context understanding can improve the results of Analytics. But privacy and security of patient data is also an issue. While extracting maximum information from unstructured data, security issues should also be considered [80–85]
Text Analytics	Clinical Notes	Medical Research	
Privacy and Security	EHR text	Conceptual design of healthcare system	
Visual Analytics	Structured and unstructured text	Visual content correlation analysis	
Predictive Analytics	EHR Text	Eczema Disease identification	
Predictive Analytics	EMR-free clinical text	Coronary Artery Disease identification	

(continued)

Table 3 (continued)

Healthcare category	Data type used	Domain	Description of challenges
Advanced analytics	EMR	Intelligent patient care	Efficient Unstructured Data Analytical techniques are required for technological development which can be achieved using integrative and combined approaches that can handle a variety of data [86–90]
Content Analysis	Medical images, sound, video, text	Big data Analytics Capabilities	
Text Analytics	Biomedical and clinical datasets	Pharmacovigilance: drug safety surveillance	
Text Analytics	Free clinical text	Patient safety event (PSE) reports	
Unstructured Data Analytics	Medical Imaging data	Deep learning	

healthcare applications deals with data discovery and curation, analysis, and result of interpretation phases similar to the traditional analytical process. But in healthcare, good data discovery, data processing, and data management need sound considerations for further development [67, 68]. Good data discovery means right data at the right time for the right context. In order to improve the context awareness in healthcare applications, there is a need to remove the gap between multiple disciplines such as computer science and medical science [69]. Hence to deal with good data discovery, data curation is more helpful to improve understanding of patient physiological and psychological care.

3.4.2 Data Interpretation

Combining structured and unstructured EHR data can improve the performance of predictive analytics. Clinical events in EHR data can be extracted and semantic space classification of similar words can be performed. This combination of structured and unstructured data by concatenating their representation using semantic space for each category of clinical events is more efficient than shared semantic space. Diverse distributed representations of clinical text from EHR using semantic spaces showed pretty notable results for predictive performance [70]. But semantic classification based on similar words can reduce the efficiency for different datasets because there is no standardization for words, and acronym, abbreviations which add more challenges to the semantic classification of data. Pharmacovigilance, phenotyping, and disease identification from health records are examples where different types of information can be extracted for different purposes from the data. EHR, EMR, PHR, and omics data contain rich information for various medical fields but there is a need to explore the ways to leverage these data

for healthcare advancement. In this regard, clinical data and genomic data have been integrated for deep phenotyping of cancer, and the proposed model was evaluated using interviews with domain experts [71]. Since the research has some limitation, that is, nor the representation standard was defined neither the evaluation of the proposed model was on real-time dataset. A comprehensive knowledge-base and precise data modeling can be helpful to leverage unstructured clinical notes of diverse formats across different facilities [72]. Extracting useful data from various types of health records is not sufficient for efficient unstructured data analytics but the interpretation or representation of data is also important for improved unstructured data analytics [73].

3.4.3 Data Quality

Several quality factors have been identified in the literature to improve and asses the quality of big data such as accuracy, completeness, consistency, timeliness, objectivity, interpretability, and accessibility [91, 92]. Unstructured data are adding more challenges to this task due to heterogeneity, lack of structure, noise, no schema, and no predefined model [74, 75, 77, 78]. Social media analytics are helpful for analyzing the psychological issues of the patient or most common diseases of society. Social media analytics is suffering from quality issues more than any other field because social media posts, reviews or comments cannot be standardized. Abbreviations, acronym, short words, and other language ambiguities generate problems for clean analytics [76]. In this regard, hashtag words can improve the efficiency of analytics but still, it needs health, media, and computer literacy to improve healthcare social media analytics [79]. Lack of structure and data heterogeneity and other quality issues can be reduced by continuous data acquisition and data cleaning for efficient healthcare analytics.

3.4.4 Context-Aware Analytics

Understanding the clinical notes in the right context is one of the challenges for unstructured data analytics. Information in the medical domain is coming from various health examiners, each examiner examines in his own way. Hence, understanding the right context is difficult due to non-standardized approaches for unstructured data while aggregation [81]. The structure is one of the important dimensions for unstructured data in terms of quality and context understanding. But the gap between semantic and syntactic structure leads to inefficient results in unstructured data analytics [80]. In this regard, the time-based topic-oriented visualization technique has been designed to find a correlation between unstructured and structured data fields for context-aware analysis [83]. But the study deals with limited text fields, whereas unstructured data in the medical field come in different formats. Also, the study steps to the initial phase of context understanding

by finding the context of written notes using words correlation. More advanced techniques with improved efficiency are required to extract useful information from unstructured clinical notes and other types of data without sacrificing the privacy of the patient [82]. Feature extraction, feature selection, and dimensionality reduction are important areas where advancement for a variety of medical data can significantly improve information extraction and analytics [85]. Anonymization and de-identification can hide the identity of the patient but still revealing or extracting maximum information from an unstructured text can be harmful to the privacy and security of data. Hence, the advancement of approaches is required to shift from data analytics to context-aware analytics by considering the ethical and privacy issues of patient data.

Efficient unstructured data analytical techniques are immense need for technological development which can be achieved using integrative and combined approaches that can handle a variety of data in healthcare [87, 88]. It means data aggregation and unstructured data analytics are important for improved analytics. Cognitive computing where computers and humans can interact in a natural way to predict, analyze, and diagnose using human cognition. Problem-oriented summary of patient EMR with IBM Watson has been proposed and generated a problem list with the help of NLP and ML. Data summarization and semantic search capability are two important factors in cognitive computing [86]. Patient safety event system has been designed where patient safety reports (containing structured and free-text unstructured data) are summarized and search approach was applied to find the most common events [89]. Unstructured healthcare data do not exist only in text form but also MRI, X-ray, and other types of visual data. Using deep learning, these data can be analyzed by several techniques of machine learning [90] but the selection of classification technique(s) for improved accuracy is critical.

3.5 Other Issues

There were some other issues discussed in the literature regarding unstructured data in healthcare.

- The healthcare systems are inadequate to handle data exfiltration due to unstructured data and its constantly evolving nature [93]. Patient data are personal and sensitive data which cannot be shared. But sharing is important to integrate and advanced processing of unstructured data [94]. De-identification and anonymization are used to cure privacy issues, but the deep analysis is required to identify the issues of unstructured big healthcare data and their solutions in technological advancement. Privacy protection of patient data, secure accessibility, extensive query frameworks, and unstructured data management are the challenges that cause inefficiency and inaccuracy of results with a variety of unstructured data in healthcare [95–98]

- Standardization of processes are required to deal with unstructured data quality and care, especially in integration, accessibility, and data extraction [99–103]
- Data curation is more critical for unstructured data than structured data due to several factors such as data quality, usability, heterogeneity, and high dimensionality issues of unstructured data. Automatic data labeling for disease severity in health and wellness monitoring for heterogeneous data [104, 105], semantic data enrichment [106], immense data cleaning of unstructured data for analytics [107], evaluated advanced data curation framework and data fusion techniques for unstructured data [108] are some of the main challenges that need to be considered.

4 Findings

This systematic literature review assessed the potential challenges associated with unstructured data in healthcare. Several literature reviews are available on big data analytics in healthcare, but this literature review is specific to unstructured data in healthcare and explore the challenges being created by unstructured data in healthcare. Best available literature has been identified about the healthcare systems, sources of various types of healthcare unstructured data, domains of healthcare affected by unstructured data, and problems generated by these data. Figure 3 depicts the categorization of unstructured data challenges found in the literature.

The results revealed that unstructured data are critical for healthcare analytics, preprocessing, information extraction, and interoperability, but healthcare analytics is most affected by the unstructured data. These areas need to be addressed to improve healthcare systems. This literature reveals that unstructured data are the most critical challenge for the advancement of healthcare systems because it is affecting almost all areas of healthcare. Following are the main findings of the review:

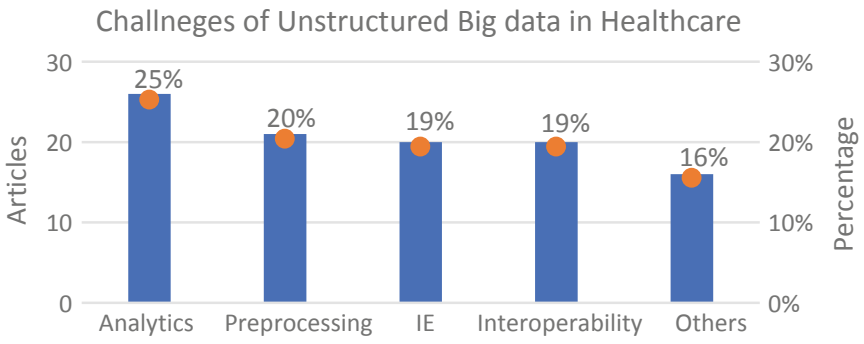

Fig. 3 Challenges of unstructured healthcare data

- Advanced techniques for data preprocessing emerged with big data processing tools are the ultimate requirement for improved healthcare systems. Efficient transformations of unstructured data, semantic data enrichment, profiling, feature selection, cleaning and other activities of preprocessing are to be assessed for multifaceted unstructured data in healthcare. Sequence of preprocessing activities, combining structured and unstructured data, mapping of content, selection of tools are some open issues to develop preprocessing tools in healthcare.
- Semantic and syntactic interoperability is important and essential for context awareness, shared use of heterogeneous data, common representation of combined data, and deep understanding of unstructured data. Standardization of processes and data can reduce the lack of uniform system but privacy and security of patient data should also be considered while achieving interoperability in healthcare systems
- Semantic information extraction in healthcare is a critical challenge to extract disease information from text. It requires a higher accuracy level. Automatic information extraction systems with improved accuracy for unstructured healthcare data with actionable granularity are required to improve the quality of healthcare systems
- Unstructured data analytic techniques are an ultimate requirement of the healthcare industry to improve the quality of care, effective and uninterrupted healthcare services, and diagnostic and decision support tools. Efficient data discovery, context-aware analytics by integrating structured and unstructured data, improving the quality of unstructured data for analysis, and effective interpretation are the ultimate challenges in unstructured data analytics that need to be addressed in future.

Unstructured data exploitation is an important task that can help to reduce the number of technical challenges in healthcare. But the quality, usability, heterogeneity, multidimensionality, scalability, and complexity of unstructured data are making healthcare analytics more challenging. Healthcare systems are unable to achieve higher accuracy and quality in service without considering the importance of unstructured data exploitation.

5 Conclusion

The exponential growth of unstructured data in healthcare forces to adopt more advanced computational systems with more innovative solutions to process the huge volume of unstructured data. Unstructured big healthcare data are rich in content and context as well which will play a pivot role in the development of more advanced and efficient technologies in future healthcare. This review explores the influence of healthcare unstructured data on analytics, clinical decision support systems, health and wellness monitoring, medicine, and smart healthcare.

Various types of unstructured healthcare data such as clinical notes, free-text EHR, handwritten prescriptions, EMR, medical imaging, X-ray, MRI, genomic sequencing, audio, and video medical data are generating challenges in all fields of technology in healthcare. Here, these challenges have been identified and discussed. The results of the literature review have shown that most of the technical challenges of healthcare unstructured data include healthcare analytics, interoperability and integration, preprocessing, and information extraction. Unstructured data have quality and standardization issues which require advanced data cleaning and semantic data enrichment in terms of preprocessing of data. Integration of health data from diverse sources, combining data from various systems to centralize the patient record is future of healthcare which can be achieved using the precise interpretation of data, secure data management, and intelligent healthcare systems. Unstructured data processing and management is an important task in order to improve context-aware analytics and semantic information extraction. The exploitation of unstructured data will maximize the efficiency of healthcare analytics and services.

Zip Zap Data—A Framework for 'Personal Data Preservation'

K. Arunkumar and A. Devendran

Abstract In the era of Mobile devices, a huge volume of mobile applications produces vast and variety of data in their own formats. There is every chance that most of these data will be lost or gone forever. Let us explain how, technically any digital data becomes irretrievable if there is a change of data format or a change in application interpreting it or a change in platform feature used by the application and your app did not change to accommodate it. In simple terms, if you try to upgrade your mobile—there are a lot of possibilities that data from your previous mobile could be lost forever. Reason for loss could be your newer device comes with some obsolete platform features and hence some of your applications no longer run in the new device as developer decided to discontinue that app. Even more pressing issue is there is no way to transfer application data from old to a new device and this is very common with mobile apps. The root cause for this is the lack of backup and retrieval mechanisms in devices and applications. We studied various approaches and research works related to this problem and proposed 'Zip Zap Data', a framework for effective backup and recovery of personal digital data.

Keywords Personal data longevity · Personal data preservation

1 Introduction

We are seeing a huge increase in the smartphone adoption across the globe. This is the main reason we see millions of mobile applications in different mobile platform (Android, iPhone, and Windows). These applications were developed by enormous developers/companies across the globe. Most of the applications produce a lot of

N. Sharma et al. (eds.), *Data Management, Analytics and Innovation*, Advances in Intelligent Systems and Computing 1042, https://doi.org/10.1007/978-981-32-9949-8_23

data related to users, which can be of value to the user or not. Some of them could be really confidential and private. Since there is no standard or protocol in restricting the data representation inside the application, every developer is storing data in their own tool and formats. What it means is even if you get the raw application data file from the device somehow, one cannot make use of it easily. It is only their application code which can access the data and deserialize it properly. The schema of data representation and security of accessing it are the reasons. This part closely ties data with apps on smartphones.

So what is the problem? One fine day when the app developer decides to stop supporting his app in play store, all data of that app is almost gone or at least locked with that current device. There is no way you can get it out meaningfully.

Practical problem: Moving/Upgrading to a new smartphone.

Many of my friends including me have faced the below-stated problem when upgrading to a new model of smartphone. Google, Mac, and device manufacture helps to migrate your contacts, gallery, and platform apps data. But there is no easy way you can get all your apps, especially with data. For example, for the popular messaging app 'WhatsApp' you have to configure your backup option and do the backup functionality regularly. Alternatively, there is an option for exporting data to your pc and later you can import back in the new device. If this is a way for migrating data to a famous app with $\sim$ 00 million active users, consider the case of others (especially free ones) out there in the market. Hundreds and thousands of apps out there in play store are left orphans for different reasons.

Security of apps data: Most of the mobile platforms runs every app in a sandbox to ensure the safety of system resources and data. Following diagrams (Fig. 1) shows the sandboxing in iPhone. Every application needs users permission to access additional system resources like using storage, camera, internet(wifi, mobile data), bluetooth, etc. Also, data from platform apps like SMS, Gallery, Calendar, etc.

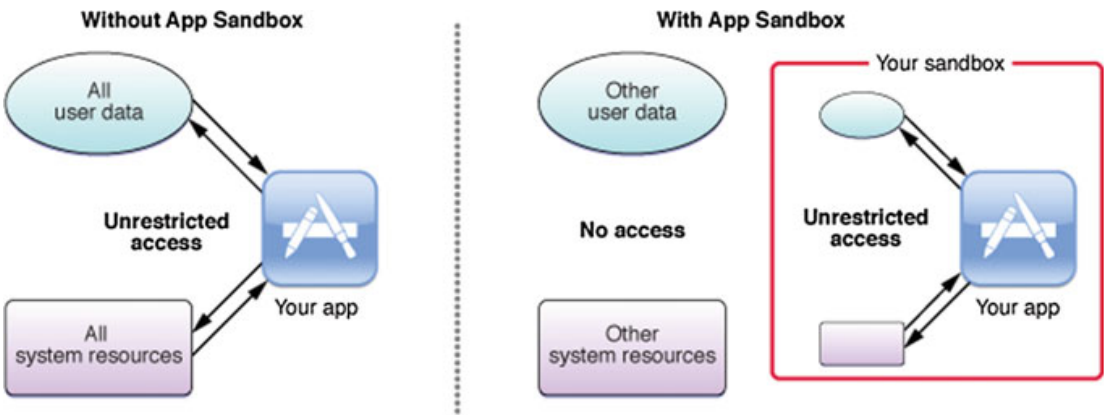

Fig. 1 iPhone App Sandbox model for data security

1.1 Digital Data Preservation

Having said the problem in accessing and interpreting mobile data, can solution to the well know problem of digital realm 'Digital data preservation' help us here?

What is digital preservation? In the definition medium from American Library Association(ALA) => 'The goal of digital preservation is the accurate rendering of authenticated content over time.'

In other words, Digital preservation is the mean of ensuring access of digital data across time (10s, 100s or even 1000s of years). Clearly, this impacts the future of 'history of events', the future of knowledge, culture, evidence, etc.

Couple of statements to understand the seriousness of 'Data Preservation'

1. In his interview on BBC @ 13 February 2015—Vint Cerf, one of 'the fathers of the Internet', expressed his concern that today's digital content might be lost forever. His talk mainly points on the fact that—if technology continues to outpace preservation tactics, future citizens could be locked out of accessing today's digital content enter a 'digital dark age'.
2. "Digital data lasts forever or 5 years, whichever comes first". This is from a Scientific American journal released back in 1995 written by Jeff Rothenberg [10].

Discussing in detail about digital longevity is out of scope.

Fundamental problem with digital data: A sequence of bits is meaningless if it cannot be decoded and transformed to some meaningful representation and viewability. Example: consider documents created with 'WordStar' (a 1980s software for data handling), are unreadable today as there is no software to interpret this data.

Another important question is what to preserve? Clearly, we need to preserve digital data for our future generation. Should all details available in the digital realm be preserved? If not, what should be preserved? Who will define the archival selection—what and whose story gets told, and whose do not. Again discussion on this direction is out of the scope of our work.

The main concern here is the data is being generated by a wide range of electronic devices and the quantities of data being generated are really huge. Now, digital data comes from personal computers, smartphones, game devices, digital cameras, digital recorders, digital TVs, and so on. The main cause for this exploded data quantity is the increase in dependency of our modern society on digital information and devices. Without proper strategies and technology support for preservation of all these data are under huge risk of being lost.

2 Core Problem

In digital preservation paradigm, one of the most difficult challenges is to maintain the interpretability of data across changing technologies. As the sequence of bits is meaningless if it cannot be decoded and transformed into some meaningful representation.

2.1 Internet Era Data Problem

Most of the modern world data be it books, images, videos, music exist as digital data. All these are represented and stored in different formats. Some of these data formats are standard and others are proprietary (purely dependent on software generating them). In the internet-connected world, anyone with proper privileges can access them instantly. The data generated can be static (created and stored once) or dynamic (generated on every time a request for access comes).

The irony is even though most of the content which could be static is often dynamically generated(i.e., through execution of code to create content at runtime).

The challenge is how do we preserve these data over time? It is no longer the three static object or collection of static objects to be preserved. It is the entire stack of technology that is serving content along with its data needs to be frozen and preserved., i.e., We need to freeze and precisely reproduce the execution that dynamically produces the content.

What is the problem there? Preservation and reproduction of software execution are one of the most complex problems. Because this involves perfect alignment of many moving parts to make it work, like OS support for older system libraries, dlls, implementation specific libraries, and hardware and firmware. Preserving this alignment over time is difficult. Many things can change hardware, operating system, linked libraries, configuration and user preferences, geographic location, execution timing, and so on. Even a single change may completely break execution.

2.2 Mobile Devices Data Problem

Across the globe, 52.3% of internet traffic comes from mobile devices and it has been increasing year by year. The study and inference on the mobile device adoption and usage show it [12]. And for data generation, even a greater percentage of the share goes to mobile. Mobile data can be generated by native apps or mobile web apps running in a browser. Recently, we see a shift towards PWA (progressive web app) from native apps, coz of its lightness and features or maybe google is

batting for it. Technically speaking, PWA is more of an optimized mobile web application with a shortcut in app screen.

In general, we can group apps under 2 categories, from data generation point. Both brings its own complexity.

- Native mobile apps (running in sandbox)
- PWA or Web apps (running in browser sandbox)

2.3 Personal Data Preservation

Digital data preservation is a long and still open research area. There are various solutions proposed and implemented till date. All the solutions can be broadly classified into 2 categories (migration and emulation), based on the strategy to ensure longevity [11]. We restricted our focus on 'Personal data preservation' [14] using the emulation approach and proposed a framework for preserving personal data from modern devices especially smartphones.

2.4 Data Privacy—Huge Concern

Data privacy is a huge concern these days. Every big corporate with personally identifiable information or other sensitive information about users is investing lots in ensuring the data privacy of its data. When you should worry—You are collecting, storing, using above mentioned user data – in digital form or otherwise. Consider your healthcare records, financial transactions, biological traits, such as genetic material, residence and geographic records in wrong hands. The challenge of data privacy is to utilize data while protecting individual's privacy preferences and their personally identifiable information.

2.5 Secured Documents Problem

The simplest way to achieve secrecy and longevity is to store the secret in a distributed way on many servers and put a constraint that a minimum number of shares be required to reconstruct the secret. From a long term archival point of view, any retrieval of such secured document needs some piece of software along with the data for the construction of secret key from k or more pieces. There a is lot of research work happening in this area.

3 Related Works

3.1 Parity Cloud Service: A Privacy Protected Personal Data Recovery Service

Here the authors mainly talk about the privacy protection of data in the cloud, an important problem in providing personal data recovery as a service. They proposed a novel mechanism 'data recovery service framework' built on cloud infrastructure. PCS (Parity Cloud Service) can be easily set up on any cloud provider. The main differentiating factor in the proposed framework is that zero user-specific data to be uploaded/saved to the server for data recovery.

3.2 Algorithm for Backup and Recovery of Data Stored on Cloud Along with Authentication of the User

Authors of this work propose a scheme of storing data on the cloud server along with a copy in the remote server. They propose the process of taking a backup copy in remote server regularly. If the main file is lost, it can be recovered from the remote server. To make backup and recovery more secure, user authentication based on attributes, secret keys are used. Every transaction in the system is authenticated per above scheme for security.

3.3 Securing BIG Storage: Present and Future

In this work, the authors reviewed existing works in cloud computing technologies and security threats of BIG DATA storage in cloud environments. Also, existing solutions that address security threats. They also discussed Internet of Things (IOT) and its influence in BIG DATA and propose solution to various threats identified.

3.4 A Framework for Aggregating Private and Public Web Archives

Here the authors talk about the problem of existing public web archive systems and HTTP memento RFC-7089 [13]. The problem with users personalized web pages (Facebook like), feeds and even instance of a private web application (banking like) in existing archiving systems and ways to mitigate them. They worked on amending existing Memento and Timestamp syntaxes of HTTP archiving to accommodate the private data.

3.5 Syncing Mobile Applications with Cloud Storage Services

The authors analyzed various cloud providers APIs and in the context of mobile application data sync. Their experiments show various options for mobile app developers to choose among the providers to sync their app data across multiple devices.

3.6 Commercial Products

Most of the commercial applications doing entire app backup and restore with data need a rooted device for accessing the data specific to the application.

Following list of applications fall in this category:

Helium, MyBackup Pro, **Titanium Backup, Ibackup**, etc.

Google Backup & Restore—is a recent feature from google, which will allow the user to store some of users app data like calendar, Browser, Contacts, Gmail, Photos, and Music to his google drive account and retrieve it when needed. However, this is not a complete solution for the backup/restore.

3.7 Limitation of Existing Backup/Restore Apps

1. They need a rooted device (so that root permission can be granted to the backup app)
2. Google vendor lock and not a complete backup and restore for everything
3. Some of them only backup apps (not the data generated by them) and common user data like contacts, photos, videos, downloads, etc.

4 Our Contribution

The fundamental problem with the existing backup and restore system is closely tied with the security model of android applications. All the files created in an app are stored by default in app's own sandbox, which is not visible to any other app running in the device. Unless you have an app running with root privilege, nothing can see the data created by it.

4.1 Core Idea

The novelty comes in bringing the backup/restore action to the app level and breaking the security barrier of the android system. Also, another important part of the idea is storing data in end user cloud storage and not in any app developer or company cloud storage, which opens doors for privacy vulnerabilities.

To put it simple Zip Zap Data

1. Store user data in the user's cloud space and retrieve it when needed.
2. Store app data along with the app and its metadata like device model, OS, etc.
3. All the data is compressed and encrypted before storing and applied in reverse order @ retrieval time.

4.2 Zip Zap Data Framework

Application specific data:

Most of the useful mobile application has some data starting from user preferences, game scores, to do notes to complex databases. As an app developer, depending on the use case one can store data in a mobile device or some external cloud storage. Some apps were built to operate 100% online and store all its data in the cloud. Even those apps started storing part or some data in a mobile device to provide offline support.

This offline feature in most applications gives seamless behavior to users and crucial for their user engagement in developed/developing countries. The point we try to make here is—every modern app being developed have a lot of application-specific data. It is this data residing in the device needs to be backed up and restored properly to give seamless transition when upgraded.

Synchronize data across multiple device:

These days, it is very normal for a user to have more than one device and very likely that he/she uses the same application in all of them. As an end user—I expect the app should be intelligent to be in the same state across all my devices. This use case brings its own complexity to app developers to write special mechanism to synchronize data across multiple devices of the same user. Even though our work focused on the data backup/retrieval part, a properly implemented system could achieve synchronization across devices with our framework.

4.3 Data in Mobile Application

Almost all the apps even the ones storing data in cloud stores data in device memory (for storing user preferences or to give offline capability). Let us get into

implementation details. As an app developer, storing data in a mobile device can be done in three ways.

- Shared preferences: This is a key, value store provided by android SDK. It is straight forward to use. There are ways in which you can make this data visible outside application sandbox. One has to set 'Context. MODE_WORLD_READABLE' or 'Context.MODE_WORLD_WRITABLE' on the preference for this to work.
- Local files: Any mobile application can create/update/delete raw files (text or any binary files) with standard file system calls. The files created are completely inside the sandbox of application and no other application can see this. These files cannot survive multiple installations even on the same device.
- Local Databases: From a technical point of view, this is very similar to local file case. All the raw files of DB are stored within the sandbox of app.

5 SDK for Backup & Recovery

As developing backup/retrieve capabilities require a considerable time and additional skills on the part of developers. If an easy to use and off the shelf utility is available for this purpose, developers would be too happy to adapt it. Hence, we developed an open-source SDK for this purpose. Zip Zap Data Framework allows developer separate interfaces to handle these three cases of app data stored in devices mentioned above in Sect. 4.3. This SDK solves the fundamental backup/recovery problem along with other benefits listed below.

Solving—Data preservation problem:

As we are storing 'app metadata' along with the data, we are ensuring the retrieval of the data stored any time in future, i.e., the data is readable 'simply…forever'. The fundamental philosophy is to recreate the original environment [11] for the app and its data @ the time of retrieval. Worst cases might involve making a new application or providing dependencies to a lost/obsolete library component.

Solving—App data sync problem:

Integrate app data sync feature into your android, iOS and web apps with just a few lines of code without any server setup or cost. Enable your users to have a seamless experience across device usage. Allow him to move to new devices without any issue of data loss.

Unlike existing cloud provider solutions like parse or azure or others, which require payment from developers for the sync feature, the proposed solution won't require any cost from the developer. This is possible as we are going to use end user's cloud storage (like dropbox, Google Drive, iCloud, SkyDrive, etc.) for storage part and also the data privacy part is taken care.

Avoiding cloud vendor lock in problem:

The key thing in our proposal is to store user's data in user's own cloud space (like dropbox, Google Drive, iCloud, SkyDrive, etc.), which avoids any vendor locking for server-side implementation for giving sync mechanism. As we are storing data in compressed and encrypted form, concerns on the privacy of user data and security are addressed.

5.1 How It Works?

1. The cloud storage of the user is configured in that app once for every device.
2. The SDK part running in every application identifies and send application data be it local files or shared preferences or sqllite DB to the backup and restore app regularly.
3. For optimized data transfer from device to cloud storage, we have version based files maintained across all apps using SDK.
4. The delta of the data to or from the cloud is identified as mentioned above and transfer is done when the user goes online.

5.2 Zip Zap Data Sync Backup and Restore

Zip Zap Data Sync is the open-source app that backups & restores apps and app data. This app needs no rooted devices to backup and restores user app-specific data. It gets the data from the app through SDK and uses it for backup/restore.

Along with the app data, user can get the entire list of installed apps in the device. There is a provision to maintain and retrieve multiple versions of apps something like marking a checkpoint and retrieve from that stable point.

6 Integration and Results

6.1 Integration Steps

SDK is available as an archive file (source code for the same is available in github). Integration can be done in a few steps after configuring the file, shared preference or DB details. It can be done in below four steps.

1. Import the 'Zip Zap SDK.aar' file as a new module
2. Add a dependency in the application gradle file 'compile project(':zipzapsdk')'
3. For restoring data or fetching data from cloud storage use '**sync**.getZipZapData();'
4. For data backup or store data to cloud storage use '**sync**.putZipZapData();'

6.2 Open-Source Integrations

We have integrated our SDK with some open-source android application and made them available in git after our integration [9]. Now, these apps have Backup/Restore feature along with seamless data sync across multiple devices of the same user.

Application	Local data	Usage
AndroFish	Shared Preference	A simple game, where user can guide fish to eat the other fish and grow bigger
Android-PreferencesManager	Shared Preference	Preferences Manager is an open-source application that allows you to seamlessly edit application's preferences
Android-pedometer	Local File	App for Android phones that counts your steps
Simple-Draw	Local File	A canvas you can draw on with different colors
LeeCo	Local File	LeeCo is an awesome app for (including unlock) problems, solutions, discuss(from leetcode) and comments
todo.txt-android	Local File	Official Todo.txt Android app for managing your todo.txt file stored in Dropbox

(continued)

(continued)

Application	Local data	Usage
Design game-pegboard	Local File	A simple design game with pins—to demonstrate the usage of ZipZapData SDK
OpenSudoku	Local DB	open-source Sudoku game for Android
CoCoin	Local DB	CoCoin, Multiview Accounting Application
Runnerup	Local DB	An open-source run tracker for Android
Simple-Notes	Local DB	A simple textfield for adding quick notes without ads

7 Conclusion

The main idea of the proposal is moving the responsibility of backup/restore data of an application to application itself rather than a separate stand-alone app on its own. This is working well and addresses the fundamental security model. This works well for real time app sync across the devices. With our integration on 10 + open-source applications, we observed backup/restore functionality can be added with few lines of code. App sync is a bit tricky as put Zip Zap Data () and get Zip Zap Data () needs to be called in proper life cycle of the corresponding activities. But we have seen it working well in 'OpenSudoku' game.

The current implementation of android app 'Zip Zap Data Sync', giving the feature of synchronize of device files and user's cloud storage is more like the – 'One click to Backup all' feature most user will like to have. Also, the storage choice of users cloud in encrypted form adds great value to the system by addressing the data privacy concerns.

We are planning to integrate more android apps with our SDK both open-source and commercial apps. Our development of SDK for iOS and Windows platform is in progress and will be available in github shortly. Another addition will be the flexibility of user to create multiple checkpoints for user data being preserved similar to memento work, which will let the user replay various instances of data with the application at any point of time.

A Systematic Mapping Study of Cloud Large-Scale Foundation—Big Data, IoT, and Real-Time Analytics

Isaac Odun-Ayo, Rowland Goddy-Worlu, Temidayo Abayomi-Zannu and Emanuel Grant

Abstract Cloud computing is a unique concept which makes analysis and data easy to manipulate using large-scale infrastructure available to Cloud service providers. However, it is sometimes rigorous to determine a topic for research in terms of Cloud. A systematic map allows the categorization of study in a particular field using an exclusive scheme enabling the identification of gaps for further research. In addition, a systematic mapping study can provide insight into the level of the research that is being conducted in any area of interest. The results generated from such a study are presented using a map. The method utilized in this study involved analysis using three categories which are research, topic, and contribution facets. Topics were obtained from the primary studies, while the research type such as evaluation and the contribution type such as tool were utilized in the analysis. The objective of this paper was to achieve a systematic mapping study of the Cloud large-scale foundation. This provided an insight into the frequency of work which has been carried out in this area of study. The results indicated that the highest publications were on IoT as it relates to model with 12.26%; there were more publications on data analytics as is relates to metric with 2.83%, more articles on big data in terms of tool, with 11.32%, method with 9.43% and more research carried out on data management in terms of process with 6.6%. This outcome will be valuable to the Cloud research community, service providers, and users alike.

Keywords Big data · Cloud computing · Internet of Things · Real-time analytics · Systematic mapping

1 Introduction

Cloud is popularly known as a distributed and parallel computing system which comprises a multitude of virtualized and interconnected computers which are provisioned dynamically and shown as at least, one unified computing resource established through negotiations among the service providers and clients which is in the form of a service level agreements (SLAs) [1]. Cloud computing provides storage and compute resources that appear inexhaustible. This is essential to the utilization of Cloud's broad-scale foundation for real-time analytics, IoT (Internet of Things), and big data. Several Cloud service types are known but three main ones standout, namely Software-as-a-Service (SaaS) which offers customized apps to its users across the Internet and the CSP (Cloud Service Provider) which takes the burden of installation and license from the user. Platform-as-a-Service (PaaS) enables the users to deploy and develop various apps on the CSP's infrastructure, while Infrastructure-as-a-Service (IaaS) allows the Cloud users to have control of some of the Cloud service provider's infrastructure and the consumer benefits from the massive compute and storage capacity available to the CSP. Cloud computing is turning out to be very valuable and the services being offered are continuously being improved on a day–to-day premise due to the strong indispensable applications and infrastructure [2, 3]. Cloud computing also has four deployment models and these are private, public, community, and hybrid Cloud. The private Cloud is hosted on-premises in an organization and could either be run by a third party or the organization itself, but in-house staff is utilized. Public Cloud are hosted by major Cloud service providers that possess the resources to build large data centers across various geographical locations. Community Cloud are usually hosted by institutions and organizations having common interests. Hybrid Cloud are used to take advantage of the different Cloud types. Organizations may want to retain core operations on-premises on a private Cloud at the same time, a lesser amount of essential data and services are migrated to the public Cloud. That being said, because of the multitenancy and virtualization procedure in Cloud, a lot of security issues have begun to surface [4, 5].

Big data deals with large volumes of data, IoT involves data transfers between "things", while real-time analytics relates to the processing of data in real time. The common denominator here is usually the processing of a large amount of data and based on the models and service types, Cloud computing has the infrastructure to support the processing and storage of large volumes of information. The big data paradigm often points to a vast and convoluted datasets which conventional processing does not have the capacity to capture, store, and analyze [6]. The essence is to obtain intelligence from such complex big data, which also requires more computing and storage power which could be administered by the Cloud [6].

The growing interest in IoT and big data requires an understanding of their definitions, challenges, and potentials [7]. Big data analytics is needed in the advancement in IoT services and processes due to the ever-increasing amount of data being generated daily [7]. The pace at which current data is being generated is astonishing and at this rate, it has surpassed the available capability to create the appropriate Cloud computing platform for the analysis of data which is a major challenge for researchers [8]. Again, one may be wondering about the connection between all these and the Cloud. This is simply summarized by Amazon Web Services (AWS). Analyzing a huge set of data requires a powerful compute capacity which can change in size depending on the volume of input data and the type of analyses [9]. Despite the fact that Cloud service providers are striving to offer reliable and efficient services on the Cloud, there is a major problem of trust [10]. The data workloads characteristics are impeccably appropriate to the pay-as-you-go model of the Cloud, whereby applications can easily be scaled down or up depending on the demand [9].

In embarking on a research or writing an article, a technical interest area must be considered by the researcher. This includes understanding the topic by reviewing relevant studies relating to that particular topic. It generally involves reviewing multiple journals, conference proceedings, books, etc. In addition, determining an area of interest may also require a lot of search on digital libraries, attending workshops, seminars, and conferences. Researchers can often stumble onto new and often unanticipated research ideas through long hours spent reviewing other people's research and through the process of conducting research as well. Also, researchers may become interested in particular research in a specific observed phenomenon serving as motivation to carry out a large-scale research in all fields and areas of study. To summarize, the researcher's curiosity about an observed phenomenon can usually provide a satisfactory impetus for selecting a research topic. Clearly, the way toward deciding a research topic is sometimes usually complicated. In the area of Cloud large-scale foundation, a large number of research have been undertaken especially as it relates to IoT, big data, and real-time analytics, hence it has become imperative to sum-up and provide an analysis of some of the work that has been done in this field. A systematic mapping study is the process of categorizing research by utilizing a structure and scheme and reporting the result using a map [11].

In this paper, a systematic mapping study presenting the frequency of studies of Cloud large-scale foundation is presented. Such information allows further insight into research carried out so far and areas requiring further attention. The systematic map was obtained by using three facets because of the areas being investigated and these three facets are as follows: the research facet which focuses on the types of research conducted and result within such areas; the contribution facet that deals with the mode of research, in terms of method and tool; and, the topic facets which extracts core topics in Cloud large-scale foundation. The purpose of this paper is to conduct a systematic mapping study of Cloud large-scale foundation for IoT, big data, and real-time analytics. The remaining paper is organized as follows:

Sect. 2 examines related work. Section 3 discusses the systematic mapping process. Section 4 presents the results and discussion. Section 5 is the conclusion with a suggestion for future work.

2 Related Work

In [12], the planning stage of a systematic mapping study was analyzed and it identified the software patterns as evident all through the requirement engineering phase of multiple projects, seeking for a better understanding of the parts being carried out by these patterns which is usually dependent on the fundamental parameters needed in the development procedure. A protocol was created for the study with the fundamental steps to replicate such a work in the research community in order to ascertain the validity of the research. The digital libraries that were utilized in their work were IEEExplore, ACM DL, Web of Science, and Scopus. The guidelines laid down in [11] were followed for this study.

In [13], they dwelled on the protocol's depiction for a systematic mapping study as it relates to DSL (domain-specific languages). Their study is diverted toward a better understanding of the domain-specific language research area with an emphasis on future directions and research trend. This study encompasses between July 2013 to October 2014, and it takes advantage of three rules for carrying out a systematic review which are conducting the review, planning, and reporting such.

In [14], the systematic mapping study is dependent on the examination of the utilization of idea maps within Computer Science and their study conveys the result which was centered on the evaluation and collection of previous research on concept maps within Computer Science. For this study, five different electronic databases were utilized. Manual approaches and backward snowballing were utilized in the search procedure. This study also showed a rich investigation and massive interest in concept maps because of teaching and learning support toward that path or area. The search strings of this study were applied on ScienceDirect, Scopus, ACM DL, Compedex, and IEEExplore.

Within the research work of [15], systematic mapping to inquire how game-related methods have been utilized in software engineering education and how these methods bolster explicit software engineering knowledge domains with the future directions and research gaps recognized. The essential investigations of the work tie down on the assessment of games, their factors, and use on software engineering education. Based on publications from 1974 to 2016, a sum of 156 essential investigations was recognized in this research and the mapping procedure was carried out in tandem with [11].

The research in [16] carried out a power system model mapping centered upon the overview of the power system models and applications being utilized by organizations in Europe, and identification and analysis of both their modeling gaps and features. 228 surveys were sent to power experts for information elicitation,

and 82 questionnaires were completed and the knowledge mapping was done accordingly.

In [17], a domain-specific languages systematic mapping was carried out with an essential enthusiasm for the kind of research, the type of contribution, and the focus area. The work features an inquiry from legitimate sources between 2006 to 2012 with the systematic mapping carried out dependent on highlighting the research questions, data extraction, search, classifying, and conducting the screening. The materials utilized in this research are experience papers, opinion papers, solution proposal, conceptual or philosophical papers, and validation of the research materials.

A systematic mapping was conducted in [18] on legal core ontologies and was based on [19] concepts. The work based its search more on both "legal concepts and theory". The studies selected were classified based on the contribution as reflected in tool, language, model, and method. Other steps include the identification of focus with a clear recommendation to use the two ontologies, identification of the used legal theories in legal core ontologies building process, and the analysis of every chosen research for cogent deductions about ontological and legal research.

In [11], a systematic mapping study in software engineering was conducted and is a foundation for many systematic mapping studies. It provides guidelines for the conduct of systematic mapping studies. In addition, a comparison of systematic reviews and systematic maps was also carried out. The work revealed that systematic maps and reviews are not the same in terms of goals, breadth, validity measures, and implications, because they employ different analysis methods.

The work in [20] provides an observational research in software Cloud-based testing based on systematic mapping. The procedure involves building a categorization scheme making use of both functional and nonfunctional testing methods, which were examined closely alongside the applications of their methods and peculiarities. They made use of 69 main analyses as discovered in 75 publications and just a small amount of the examination unites exact factual investigation with quantitative outcomes. Many of the analyses made use of a singular experiment for the assessment of their proposed solution and there has not been any research focused on systematic mapping of Cloud large-scale foundation for IoT, real-time analytics, and big data from the literature.

3 The Systematic Mapping Process

A systematic study provides an overview of a field of interest by depicting article frequencies in that area. This research was carried out by utilizing the formal steps on systematic mapping research in [11] and [19]. A systematic mapping research is a replicable process of eliciting and translating the available materials associated with a research objective [21]. There are definite procedures for designing a systematic map [11]. Usually, where the scope of the review is developed, the definition of

research questions is the initial step. An inquiry is normally conducted on each and every paper accessible in the proposed area of study and after the search, such papers are examined to discover those important and relevant to the study. Next is the classification scheme based on the use of keywording that is applied to the abstracts of the searched papers. Finally, there is a process of data extraction that prompts the making of the systematic map and each step is utilized in the making of the systematic map of Cloud large-scale foundations for IoT, big data, and real-time analytics. In the perspective of the paper choice criteria in terms of the requirements and research question, a sum of 112 publications were appropriate for inclusion based on the initial 1,716 papers from 2011 to 2018 and the list of selected main research papers are in the Appendix.

3.1 Definition Research Question

The significance of a systematic map is to offer a better understanding of the frequencies and types of research that has been done in an area under consideration. It might likewise be important to find out where such research articles were distributed. These issues determine the focus of the inquiries that are utilized for the research. In this particular paper, the research questions are

- RQ 1: What and how many articles cover the different areas in Cloud large-scale foundation for real-time analytics, IoT, and big data and how are they addressed?
- RQ 2: What evaluation and novelty do they constitute in particular, and what papers are being published in this field/area?

3.2 Conduct of Research for Primary Studies

The strategy of inquiry of primary studies is mostly accomplished by examining unique digital libraries. This is done through searches carried out on conferences and journal publications. To acquire the necessary papers needed for this systematic mapping paper, a search was performed on some scientific digital libraries that are accessible online and information from printed materials and books were not focused on in the search. The search was conducted on journal and conference

Table 1 Digital libraries used for the systematic mapping study

Digital libraries	Uniform resource locator
ACM	http://dl.acm.org/
IEEE	http://ieeexplore.ieee.org/xplore
Science direct	http://www.seciencedirect.com/
Springer	http://www.springerlink.com/

publications in four major digital libraries due to the high-impact factors of their articles. Table 1 shows the URL and the databases used in this research.

The outcome, population, comparison, and intervention in the focus of study influenced the design of the search string. The keywords utilized in the search string were gotten from every aspect structure of the title for this research on large-scale foundations for real-time analytics, big data, and IoT. The search string being utilized on major digital libraries are

(TITLE(Cloud) AND (TITLE("Large scale") OR KEY("Large scale")) ((TITLE ("Big Data") OR KEY(Big Data") OR (TITLE(IOT) OR TITLE ("Internet of things") OR KEY("Internet of things")) OR TITLE("Real time analysis"))) AND (ALIMIT-TO(BUBJAREA, "COMP").

The searches were carried out by making use of the above-customized search string on document metadata in order to make sure that the important articles were not omitted and appropriate databases significant to Computer Science and the Cloud were considered.

3.3 Screening of the Papers for Inclusion and Exclusion

The essence of a selection process is to discover and include each and every publication important to the review being carried out. It is a normal procedure to use exclusion and inclusion criteria to remove articles which are not important to real-time analytics, IoT, and big data in Cloud computing. The exclusion and inclusion criteria are also utilized to eliminate publications which are not important to the research questions. A few abstracts tend to point out the main focus without any further details, hence such abstracts were not considered in the review process. This study excluded papers on panel discussions, tutorials, summaries, and prefaces because they do not contain abstracts. Articles that discussed the main focus of the paper and some measure of secondary aspects were considered. The list of included papers is in the Appendix. The primary focus of this research is on big data, IoT, and real-time analytics, therefore, the exclusion and inclusion procedure was carried out as shown in Table 2.

Table 2 Inclusion and exclusion criteria

Inclusion criteria	Exclusion criteria
The abstract explicitly mentions real-time analytics, big data, and IoT as it relates to Cloud computing. Furthermore, the abstracts has a secondary focus on large-scale foundation to a certain extent	The paper lies beyond the area of Cloud computing notably as it related to big data, IoT, and real-time analytics

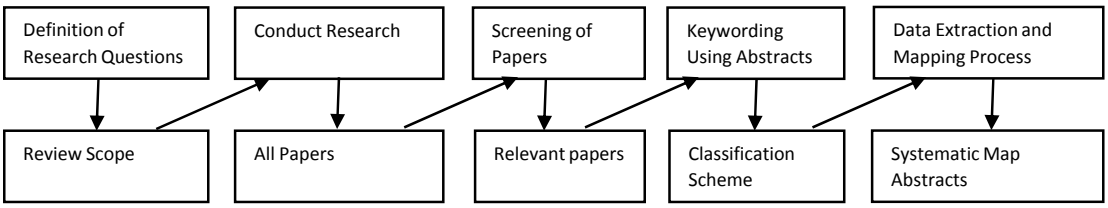

Fig. 1 The systematic mapping process [11]

3.4 Keywording of Abstracts

The keywording of abstracts is the process that leads to the design of a classification scheme. The systematic mapping process shown in Fig. 1 involves the entities listed below [11].

- Abstract
- Keywording
  - Article
  - Sort article into scheme
  - Update scheme
- Systematic map

Keywording is obviously required to lower the time needed to create a systematic map for real-time analytics, big data, and IoT in the Cloud. Also, keywording guarantees that the classification pattern covers every important study and the process includes examining the abstracts in order to extract ideas and keywords from different articles on the focus of study. Keywords from different articles are usually combined to provide a better understanding of the contribution and type of research. Subsequently, this was used in order to better comprehend the set of classifications needed for the study, but it was also crucial in some cases to also examine the introduction and conclusion of some publications so as to ensure reliable keywording. A cluster of keywords was used in order to know the types of facets to be used for creating the systematic map for this study and three main facets were eventually utilized for creating the map. The first facet is the topics category that utilizes the keywords that were directly related to the topic of study. Hence, the topic facet used keywords such as real-time, big data, IoT, orthogonal, and data analytics. The second facet focused on the type of contribution available in a research type. It considered the research contribution in terms of metric, model, method, tool, and process as it relates to the field of study under consideration. The third facet sees to the nature of study carried out.

3.5 Research Type Facet with Category and Description

The essence of the third facet is to determine what types of research were conducted and the applicability to the area of study. The style of the categorization of research approaches by [22] was utilized in this facet and has the following categories and description:

- Evaluation Research: Techniques adopted here have been implemented and evaluated. The outcome of such implementation also considered advantage and disadvantages.
- Validation Research: Processes utilized are novel, though are still to be applied.
- Solution Proposal: Research provides a unique answer to an issue and the advantages plus application of such solutions can be verified.
- Philosophical Papers: The method introduces a new way of examining a challenge with the use of concepts and frameworks.
- Opinion Papers: This kind of study does not adopt any known research methodology; it naturally expresses the researcher's opinion.
- Experience Papers: Relate the researcher's unique experience and explain the way things can be accomplished.

These categories were thought to be adequate and suitable for their utilization in this research. The papers included in this research were reviewed on this basis of the categories of research discussed above.

3.6 Data Extraction and Mapping of Study

During the keywording process, pertinent articles were arranged using a classification design. The following step was to extract data from the relevant publications and this procedure determines the nature of the classification scheme. During this process, new categories could be added, some categories could be eliminated, while some categories could be merged. The data extraction process for this study was done using Microsoft Excel tables which contain frequencies of publication based on different research types and contributions. The frequencies of publication are determined by combining either the contribution or topic tables or the research or topic type tables. The analysis focused on presenting the rates of publication as obtained from the Excel tables which help to identify which areas of the study were emphasized more. Furthermore, it facilitates the identification gaps in the publications that could stimulate further research.

By using the results of the Excel tables, bubble plots were created for the purpose of visual presentation of the frequencies of publications and the systematic map was produced using a two x–y scatter plot with bubbles to indicate the number of articles based on the classes under consideration. There were two quadrants in the systematic map that was created in this study as a result of the three facets

employed. Every quadrant presents a visual map which is usually centered at the junctions of either the research types or topics facet with the contribution category. This makes it uncomplicated to visualize multiple facets at the same time. Furthermore, summary statistics were entered into the bubbles to further enhance understanding of the systematic map and provide a quick summary of the study in the area of big data, IoT. and real-time analytics.

4 Results and Discussion

The primary objective of this research on a large-scale foundation for real-time analytics, big data, and IoT is to have a thematic analysis, carry out classification, and possibly identify the areas where the articles were published. From the analysis, gaps were noticeable from the map, thus identifying which topic areas and research types were lacking in papers. On the contrary, the results also point to areas that are sufficiently covered in terms of publications. Within this research, high-level classifications were utilized in order to access the papers mentioned, hence the reliable readings are obtained and used for developing the map.

4.1 The Contribution Category

The systematic map created from this study is in Fig. 2. On the x-axis of the left quadrant of Fig. 2 is the result of the contribution facet. The contribution facet indicates the type of inputs in the focus of study. The result showed that publications that discussed model in relation to big data, IoT and real-time analytics was 35.85% out of 106 papers examined in this category. Also, tool had 20.75%, metric had 5.66%, method had 25.47%, and process had 12.26%.

4.2 The Research Type Category

On the x-axis of the right quadrant of Fig. 2 is the type of research conducted on the Cloud that is related to big data, IoT and, real-time analytics. The result showed that publications that discussed solution research in relation to big data, IoT, and real-time analytics was 43.75% out of the 112 papers reviewed. Also, evaluation research had 33.93%, validation research had 4.46%, philosophical research had 7.14%, and experience research had 10.71%.

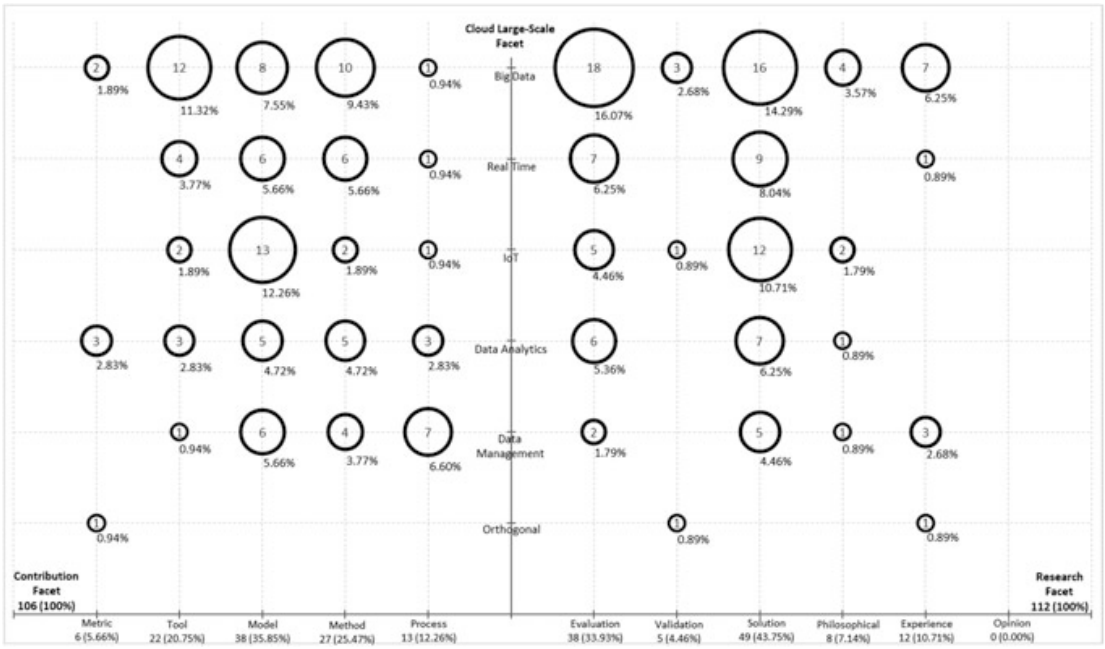

Fig. 2 Systematic map for real-time analytics, big data, and IoT on the Cloud

4.3 Topics and Contribution Facet

The topics used were extracted from the abstracts which related directly to the title of this research work. They are

1. Big data
2. Real-time analytics
3. IoT
4. Data Analytics
5. Data Management
6. Orthogonal

The left quadrant of Fig. 2 displays the relationship between the topics extracted and the contribution facet. Models contributed 38.85% of the papers reviewed, however, a breakdown showed that 7.55% was on big data, 5.66% was on real-time analytics, 12.26% was on IoT, and 4.72% was on data management and no orthogonal contribution. Other aspects of the contribution category as it relates to topics are shown in Fig. 2.

4.4 Topic and Research Facet

The right quadrant of Fig. 2 displays the relationship among the topics and research category and, for example, 33.93% of the papers reviewed in real-time analytics, big data, and IoT in the Cloud were related to evaluation research. The breakdown

indicated 16.07% was on big data, 6.25% was on real-time analytics, 4.4% was on IoT, 5.36% was on data analytics, and 1.79% was on data management. Other aspects of the topics category as it relates to research types are shown in Fig. 2.

4.5 Systematic Map for Big Data, Internet of Things, and Real-Time Analytics

The systematic map for real-time analytics, IoT, and big-data on the Cloud is shown in Fig. 2. The first quadrant is a two x–y scatter plot with bubbles at the intersection of the topic and contribution facet, while the left quadrant is the systematic map depicting a two x–y scatter plot showing the node of the topic and research facet. As discussed earlier, the results made it possible to identify which category of the study had more emphasis in terms of publications. It can be identified from the left quadrant of Fig. 2 that the highest publication was on IoT as it relates to model with 12.26%; there were more publications on data analytics as it relates to metric, (2.83%), more articles on big data in terms of tool, (11.32%), and method (9.43%). Furthermore, there were more research carried out on data management in terms of process with 6.6%. Similarly, on the right quadrant, the highest publication was on big data in terms of evaluation research. More articles also dealt with big data with respect to validation research (2.68%), solution research had 14.29%, philosophical research had 3.57%, and experience research had 6.25%.

On the other hand, to the best of our understanding, there were no any articles on metric in relation to real-time analytics, IoT, and data management on the left quadrant and there were no publications on validation research as it relates to real-time, data analytics and data management on the right quadrant. In addition, there were no publications on experience research in relation to IoT and data analytics. Furthermore, there were no articles on opinion research. Also, the least number of articles were in the study of model and process in the contribution category, while the lowest publications were on validation research, philosophical research, and experience research, in the research category. The visual appeal of the systematic map has been used to summarize the categories of publication making results available to researchers. The essence was to generate interest in the gaps, based on shortages in publications identified and then encourage further research. The value of a systematic map even without a consecutive systematic review cannot be overemphasized. Research gaps could be identified with ease, based on a shortage of publications as shown in frequencies of articles published. This research has created a systematic map that points to the areas lacking in studies in terms of Cloud large-scale foundation. The primary purpose of this study is that analysts at all levels and venture professionals can utilize this as a beginning stage to direct further investigations. This investigation created six classes, namely big data, real-time analytics, IoT, data analytics, data management, and orthogonal in connection to the focus of study. What's more, the six classes of study can be talked

about either regarding the instrument, method, model, process, and metric or in terms of validation, evaluation, philosophical, solution, and opinion research. These fields among others are consequently prescribed for future research. The rundown of included references will likewise help expecting researchers. The significant lessons learnt in this research is that research work is inexhaustible and continuing.

5 Conclusion

Cloud computing is a model that is becoming more relevant by the day. The Cloud enhances the operations of IoT and the processing of big data. Despite the volume of studies, it was identified from the results that so much is happening in terms of big data and IoT compared to real-time analytics. Systematic mapping is a veritable tool in helping to summarize and visually depict the frequencies of publications in an area of research. The mapping process was applied to big data, IoT, and real-time analytics with the attendant results displayed on the systematic map. The results from this research are based on the gaps identified in terms of model, tool, metric, method, and process in relation to real-time analytics, big data, and IoT. This research also identifies some gaps in the area of validation, evaluation, solution, opinion, and philosophical research on real-time analytics, IoT, and big data. To the best of the authors' understanding, there were no articles on metric in relation to real-time analytics, IoT, and data management. In addition, there were no publications on validation research as it relates to data analytics, and data management. Also, there were no publications on experience research in relation to IoT and data analytics. There were no articles on opinion research. Furthermore, the least number of articles were in the study of model and process in the contribution category, while the lowest publications were on validation research, philosophical research, and experience research, in the research category. It is normal that this outcome will fill in as a wide guide into topics that can be looked into on the region of real-time analytics, big data, and IoT. Further research could likewise be completed to approve this investigation or resolve conflicting issues.

Studies on Radar Imageries of Thundercloud by Image Processing Technique

Sonia Bhattacharya and Himadri Bhattacharyya Chakrabarty

Abstract Severe atmospheric event can cause huge damage to civilization. Severe thunderstorm is one of those weather events. Analysis of cloud imageries can be used to forecast severe thunderstorm. Convective clouds are one of the main reasons for the formation of severe thunderstorm. Analysis of such cloud imageries by image processing can be used to predict severe thunderstorm. Analysis of RGB values of pixel of cloud imageries can be used to show the formation of severe thunderstorm. Histogram analysis of such cloud imageries can also be used to predict severe thunderstorm. In this study analysis of RGB values of pixels and histograms of cloud imageries has been used to now cast severe thunderstorm with a lead time of 6 to 8 h. This lead time is necessary to save life and property from huge damages.

1 Introduction

Convective clouds are formed vertically upwards as the result of the instability of atmosphere. In India, the coastal areas (like the west coast, Orissa, Andhra Pradesh, and West Bengal) as well as north east have been affected many times by thunderstorms and heavy rainfall. Natural calamities are unpreventable and incur huge losses both in terms of life and property. Analysis of convective cloud imageries can give correct prediction of such severe weather event. During the last decade, new classes of cloud resolution mesoscale models have been hurriedly developed. They are able to simulate the life cycle of each convective clouds [1]. Some papers [2–4] concerned the propagation and regeneration of cells within a multi cell storm. The three months of March–April–May (MAM) are pre-monsoon season in India. Severe thunderstorms occur mostly in this time period. Four months of June–July–August–September are identified as monsoon time in India. Cyclonic weather features are evolved generally at the post-monsoon season due to formation of convective cloud during October-November months. The observations showed that the mesoscale phenomenon is the beginning of a severe convection before the monsoon and its effect on the climate, [15]. It is often apparent on satellite photos that convective conditions are occurring simultaneously over extensive areas and are the result of the vertical structure of an air mass and the characteristics of the actual dominant large-scale weather systems, [5]. A large number of research works have been done to analyze clouds based on satellite images [5]. Since the number of droplets of cloudy liquid and ice crystals increases in the cloud, reflectivity value increases, this has a direct relation with the rain [6]. Color is an important feature for image representation [5]. Color moments, color histogram and coherent color vector are the important components of the extraction of color characteristics [7]. Any satellite picture of convective cloud fields has a great variety of cloud patterns and cloud sizes, [8]. The size distribution of convective clouds might give hints of the precipitation observed at ground stations [8]. The main aim of this research work is to study color density of the pixel which changes with formation of cloud. Red color in cloud imagery represents water content of the cloud. This study will reveal that color density of pixel increases from image to image as the cloud devolved with respect to time. In this work the imageries of a thunder cloud have been studied stage by stage such as developing stage/Cumulus stage, mature stage, and Dissipating stage.

2 Data

Here in this study ten images of a thundercloud having different stages from time to time are considered for analysis. All these images are taken over Kolkata (22.3°N/88.3°E) on April 10, 2005 from 07:12:04 to 14:12:04. The cloud imageries were obtained from the observations through Doppler Radar of Regional Meteorological Center, India Meteorological Dept., Kolkata.

3 Methodology

Image Processing

Here in this study ten GIF images have been considered for weather forecast. All these imageries are TRUE color image. Here each pixel has a particular color; that color being described by the amount of red, green and blue in it. Since the total number of bits needed for each pixel is 24, these images are also called bit color images. An image of this type can be considered as a stack of three matrices; representing the values of red, green, and blue for each pixel. This means that for each pixel there are three values [14]. Here in this study impixel (I) function has been used which returns the value of pixels in image I. The pixel values of two consecutive images have been obtained using impixel function which gives two three columnar matrices. A comparison has been done between these two matrices of two consecutive imageries which revealed that there is a noticeable increase between their values. There are a total of nine comparisons between these ten images.

4 Observations on Cloud Imageries

As the first three images showed that formation of convective cloud, in which mainly three types of colors are observed, these are Blue, Red and Yellow. Red color represents the water content of the cloud. In the first image there is no cloud activity is observed, in the second image cloud has been formed over Bankura and Purulia and became denser in the third image moving towards Kolkata (Figs. 1, 2, 3, 4, 5 and 6).

In the fourth, fifth and sixth images it can be observed that density of red color pixels has been increased noticeably and the cloud has been moved more towards Kolkata. It can be observed that from seventh image the density of red colored pixels were decreasing as it moves over Kolkata. Since red colored pixel denotes water content of the cloud, reduction of red color pixel density indicates towards the precipitation (Figs. 7 and 8).

It can be clearly observed that in ninth and tenth image red colored pixel were noticeably reduced leaving yellow colored pixels, this signifies that precipitation has been done (Figs. 9 and 10).

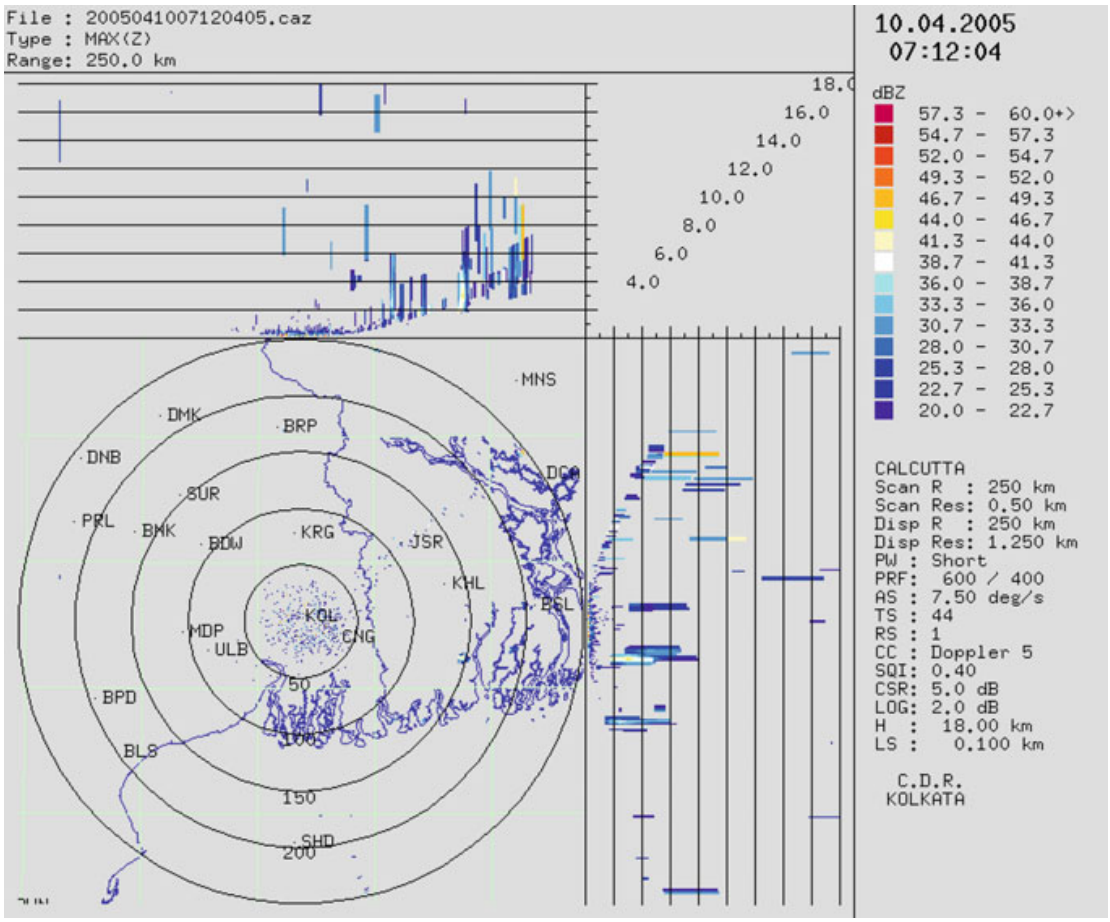

Fig. 1 First image of cloud formation

5 Result

Using impixel function RGB value of each pixel has been obtained and a comparison between the RGB values of the pixels of two consecutive images yield the following result:

Table 1 show that the density of RGB values increases from image to image and has maximized between sixth and seventh images. We have already observed that red color pixel density were most in seventh image. These values are reducing for the next remaining images, though values increase slightly in the last image. Comparing the last two images, it has been found that a few more red colored pixels are present in the tenth image.

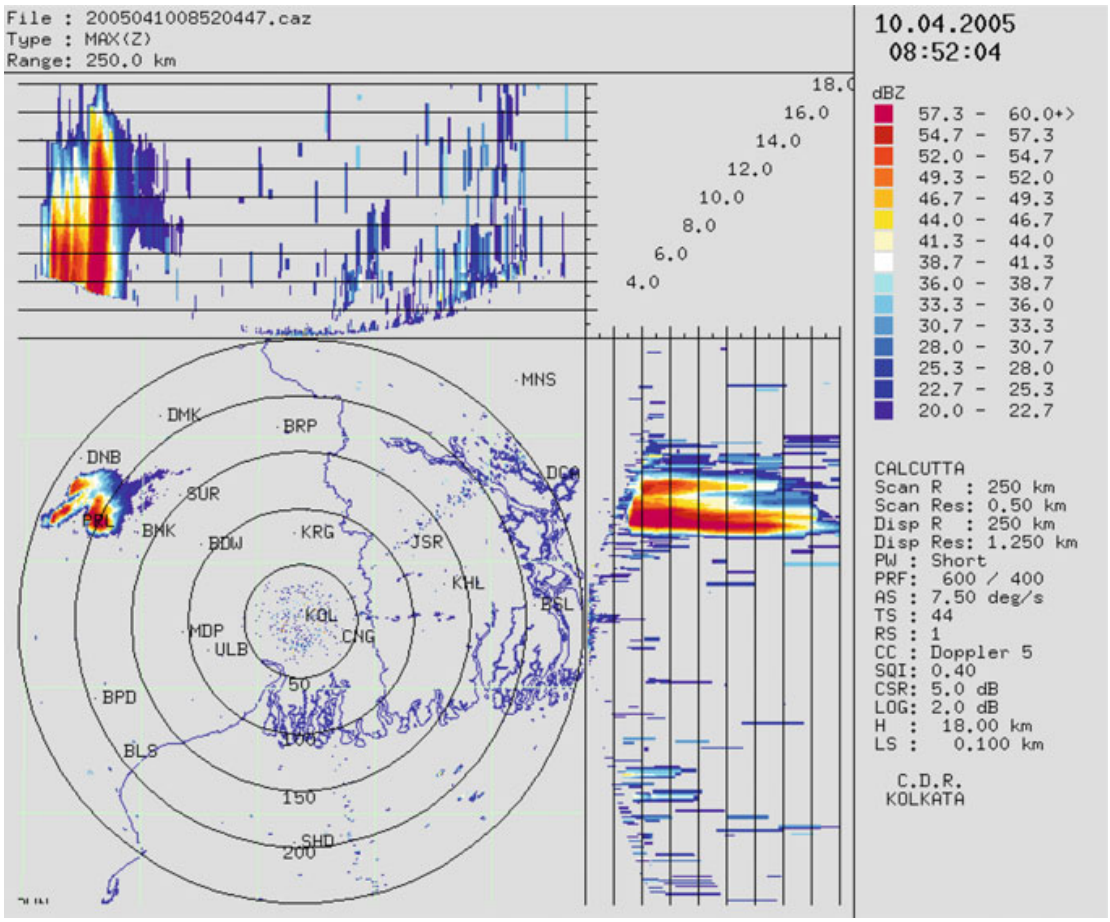

Fig. 2 Second image of cloud formation

6 Analysis of Histograms

It can be further observed that the histograms of these images show that the intensity has increased with formation of the cloud. The imhist(I) function displays plot of the histogram. The histogram shows the distribution of pixel values. The study reveals that frequency of pixels has been increased from one image to next consecutive image. It has been reached most in the seventh image. The seventh image shows maximum presence of red colored pixels indicating towards the intensification of cloud. Precipitation is indicated by increase of yellow colored pixels in image the effect of which can be seen from eighth imagery. The distribution of pixel values has been increased from image to image as cloud has developed with respect to time (Figs. 11, 12, 13, 14, 15, 16, 17, 18, 19 and 20).

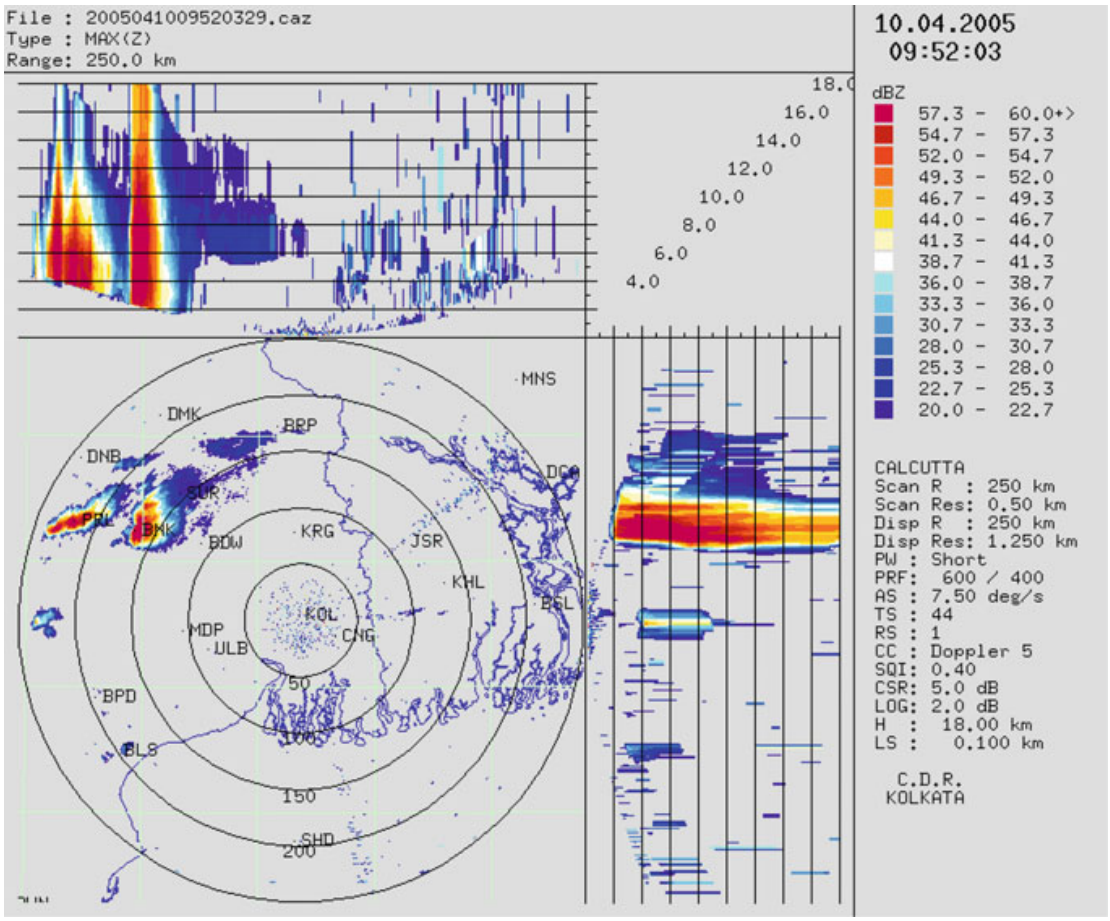

Fig. 3 Third image of cloud formation

7 Discussion

The pixel comparison of clear sky images is used for the determination of colors [9]. It is very important to monitor the analysis of clouds images to forecast when the thunderstorm along with the precipitation occurs. It can also be analyzed how much precipitation can occur by studying cloud images and its duration of rainfall. One can guess the severity of the natural disaster tentatively 6 h before by this type of cloud analysis. People can become alert with a lead time of 6 to 8 h. There are several meteorological satellites that provides large-scale observation of clouds through the day [10, 11, 12]. The patterns of image pixels are used for the classification of images [13].

Artificial Intelligence and Data Analysis

PURAN: Word Prediction System for Punjabi Language News

Gurjot Singh Mahi and Amandeep Verma

Abstract This paper presents an outline of the PURAN: A state-of-the-art word prediction system for Punjabi language news. Word prediction systems are used to increase the user text composition rate while typing the text. Brief background of the various approaches utilized in the development of word prediction systems, while discussing the various factors affecting the development of such systems is provided. This paper also elaborates the word prediction system architecture in detail. The system performance was tested on Keystroke saving, Hit ratio, Average rank and Average keystrokes benchmark metrics. The paper demonstrates that the PURAN has achieved highest Hit ratio in Regional news genre followed by National news genre by making lowest average keystrokes in the said categories of news. The results show that system has achieved 88.38% Average Hit ratio with 51.42% Average keystroke saving for $N = 10$.

Keywords Word completion · Word prediction · Punjabi text composition

1 Introduction

Word prediction system enables the user to complete the partially entered string known as the prefix, by providing the selection among list of possible words. The word prediction system populates the list of possible words from the provided database for the given prefix. The word prediction systems instinctually help the user with automatic completion of the word. Thus word prediction system in turns helps to increase the text composition rate. Several software applications like PROFET [1], FASTY [2], PAL [24] were proposed to predict the word in English and other European languages. Text composition in Indian languages is relatively

more tedious as compared to other languages due to numerous concerns. Large character database, different vowels symbols, and complex language syntax makes text composition difficult in Indian context [4]. The studies like hIndiA [4] and [29] were performed for other Indian languages—Hindi and Bengali.

This paper intends to present a word prediction system—PURAN, designed to predict the words in News items for Punjabi language. PURAN was designed to increase the text composition rate for Punjabi news composition for 5 news genres namely Business, International, National, Regional, and Sports. PURAN system architecture is divided into two phases—Corpus creation and statistical inference phase and word prediction phase. The PURAN system has performed well on all benchmark metrics when tested in simulated environment.

The paper is distributed into eight sections. Section 2 provides the background about the state of art in word prediction systems and various factors affecting its performance. Section 3 presents the proposed system architecture used to design PURAN word predictor. System architecture is elaborated using a working example in Sect. 4. Performance metrics used to test the system architecture are discussed in Sect. 5. Testing dataset and system configuration is given in Sect. 6. Explored results and discussion is mentioned in Sect. 7. Section 8 concludes the study.

2 Background

Many studies [1–5] have been carried out to develop specialized software applications known as word prediction systems to increase the users' text composition rate. The idea of the development of a word prediction system was started way back in 1968 when [9] published the technique to reduce the keystrokes for completing a word [10]. Most of the word prediction systems were developed to help the people with motor and speech disabilities to overcome the communication problems [11]. Garay-Vitoria and Abascal [11] also states that word selection based text-input interfaces helps the people having poor control over the limbs to communicate in regular conversations. The success of word prediction system depends on various factors, i.e., prediction methodology, prediction speed, dictionary structure, user interface used for demonstrating the results, number of suggestions in user interface, etc. Some of the main factors affecting word prediction are discussed as follows.

2.1 Methodology

The success of word prediction system heavily depends on the methodology used for the design of the system. Although, diverse strategies are used for designing prediction systems, but collectively predictors methodology can be divided into two main categories, (1) Statistical Predictor and (2) Syntactic Predictor [4].

Statistical Predictor. The statistical predictors rely on the n-gram language model for language information in statistical word prediction system [4]. Most of the word prediction systems designed were based on frequency calculation, where distinctive word unigram occurrences were taken into account. Garay-Vitoria and Abascal [12] suggested the method of using the frequencies for word prediction, in which a dictionary-based approach is used. Dictionary is composed of words (unique unigrams) with respective frequencies. Each time a word is accepted from the proposed list of words the frequency of the respective word is updated in the frequency. Similar frequency-based approach was used by [13–16] for the development of word prediction system.

Frequency-based completion system concentrates on the unigram language model for prediction of the word. Fazly [17] gave the predictor which was trained on very large English language corpus using unigram and bigram language model. Unigram language model only concentrate on the current word being typed and bigram model approximated the probability of one word in the past for word prediction. Also, trigram (which takes the two previous words into account for prediction) is the baseline language model used for the word prediction systems [4, 18]. The main disadvantage of trigram model is that it requires large training data and demand huge memory space to store the processed corpus [11]. The present study used the frequency distribution method for the development of PURAN word prediction system.

Syntactic Predictor. Rule based syntactic structures of a natural language are followed for the design of syntactic word prediction systems. Frequency remains an important factor in addition to the other approaches during design of syntactic word prediction system, like [2] used the frequency table of words with syntactic knowledge i.e. Part-of-Speech (PoS) for more precision to design the prediction system—FASTY, for people suffering from motor and speech disability, enabling them to type 4 European languages, i.e., German, French, Dutch, and Swedish more precisely. Syntactic predictors like FASTY takes the probability of the grammatically correct Part-of-Speech (PoS) information into account for making any natural language word prediction. Another prediction system named New Profet [1] used lexicons for word completion for individuals suffering from linguistic impairments. [1] developed an efficient lexicon development algorithm, which helped in the creation of word lexicons from Stockholm-Umeå Corpus.[1] Furthermore, this algorithm facilitates the creation of new lexica from untagged or PoS tagged corpus.

In addition to the lexicon- and PoS-based syntactic word predictors, [19] developed a morphologically based word predictor for the Swedish language. An algorithm developed by the [19] allows users to select words by providing the base form of the word in a two-step process. Another syntactic prediction system like [20] and [21] provides a word completion or prediction system for Inflected languages. Syntactic predictors make the prediction using semantic knowledge about the natural language for which the word prediction system is being designed.

2.2 Dictionary

An arrangement of the words with their frequencies or probability values requires a data structure for enhanced and firm results. Garay-Vitoria and Abascal [11, 22, 23] provide a detailed architecture about importance and usage of dictionaries in the word prediction systems. Dictionary is a general concept that is used to manage the keys and its values in an efficient manner. Keys in a dictionary data structure are implied as words and values are referred as words frequencies or probabilities. Word predictors designed using bigram or trigram language model require large storage capacity, which results in large dictionary size and complexity [22]. A single dictionary structure used for lexicon makes the access easy, but with the increase in number of dictionaries the problem complexity and access time for lexicon also increases [11, 22]. The lexicons are usually stored in the tree data structure, which helps in faster search but also have a complex organization structure.

Garay-Vitoria and Abascal [11] states that adapting dictionaries is an important factor while considering the natural language word prediction system. A single dictionary containing words and their respective frequencies are easy to maintain and update, as these frequencies can be easily updated in accordance to their usage in the real time.

2.3 User Interface

Newell et al. [24] gave detailed arguments about the importance of user interface in the selection of word from the suggestion list. The user interface provides an interactive space for a list of suggestions to appear from which user selects the most appropriate word that matches the user-specified prefix. Cognitive cost and suggestions demonstration are one of the factors related to the user interface. Point-of-gaze[2] plays an important role in increasing the production rate of a word predictor, as ease to locate the needed word in the list directly affects the hit ratio of the word prediction [24]. The design of user interface unswervingly affects the eye and hand movement during the selection of a word from suggestion list [4, 11, 24, 25]. Minimum eye and hand movement should be supported by the user interface [4]. Newell et al. [24], Swiffin et al. [15] suggests that vertical list of suggestions require less effort to select the word from the suggestion list. Swiffin et al. [15] argues that keeping the user interface immediately below the given prefix help in keeping minimum head and eye movement. Garay-Vitoria and Abascal [22], Koester and Levine [26] suggests that user interface suggestions can be listed in alphabetical order for better results. Garay-vitoria and Abascal [22] also mentions that triangular matrix provides the best average case access time to select the word

[2]"Eye tracking", https://en.wikipedia.org/wiki/Eye_tracking.

from the suggestion list, but difficult screen presentation makes them hard to use. Due to the extensive importance of word prediction system, user interface perspective is the uttermost important factor to look into.

2.4 Number of Suggestions

Another significant factor affecting the deliverance of words prediction system is the number of suggestions appearing for the user to select from. With the use of more suggestions in the suggestion list, a predictor can avail higher hit ratio, but will also increase the cognitive load on the user [11]. Garay et al. [21] points that suggestion list with ten suggestions provide stability between keystrokes and cognitive cost.

3 System Architecture

To perform the prediction of the word - ω, the system architecture is distributed into two phases, (1) Corpus creation and statistical inference phase and (2) word prediction phase. The phase of corpus creation and statistical calculation is performed only once whereas, phase 2 is initiated whenever the user enters any new prefix or update the prefix with a new set of characters.

3.1 Corpus Creation and Statistical Inference

The initial phase of the system architecture is divided into four diverse steps, (1) Extraction of Punjabi news corpus, (2) Preprocessing of the corpus, (3) Calculation of frequency distribution and (4) Formation of words Trie and frequency dictionary. Figure 1 illustrates the Corpus creation and statistical inference phase of system architecture.

Extraction of Punjabi news corpus. Corpora or Corpus[3] or Text corpus is referred to as a structured set of text, which is used to formulate some hypothesis about language features or perform statistical analysis on the language data. India is country of 1,324,171,354 people.[4] Such a large population is usually seen as a huge potential reader base by Indian news industry. In 2013–14, 99660 registered newspapers and periodicals were in circulation in India [6] with the reader base of 450586 [7] in various Indian languages. The findings by [8] suggest that there are more than 300

[3]"Text corpus", https://en.wikipedia.org/wiki/Text_corpus.

[4]World Population Prospects: The 2017 Revision". United Nations Department of Economic and Social Affairs, Population Division.

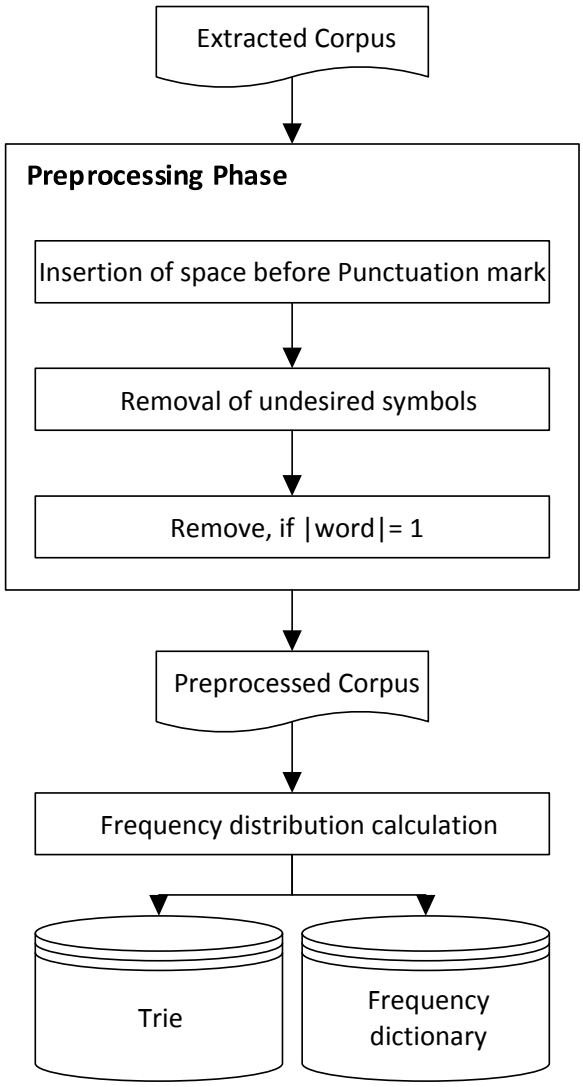

Fig. 1 Corpus creation and statistical inference

million internet users across India. Advancement of technology and low data rates has widely increased the viewership of e-paper and online newspapers across readers in India. Indian newspapers have also reinvented themselves to stay relevant in changing time and have started publishing news online in local Indian languages. One of the most popular Indian languages is Punjabi[5] language. Punjabi (ਪੰਜਾਬੀ [pañjābī]) is an Indo-Aryan language with more than 100 million speakers across the world. Punjabi is widely spoken in Punjab state of India and Pakistan, with speakers distributed across the world and is written using two distinct scripts—*Gurmukhi* and *Shahmukhi*. 1212 Newspapers and periodicals are published in Punjabi language (specifically using Gurmukhi script) in India [6] with enormous reader's base.

The Punjabi language news content extracted from Ajit,[6] a prominent Punjabi news website was used for developing the news corpus. The extracted corpus contains five genres of news, i.e., Business, International, National, Regional, and

[6]"Ajit", https://www.ajitjalandhar.com/.

Table 1 Summary of extracted corpus statistics

Statistics	Before preprocessing	After preprocessing
Total words	1408041	1357443
Total characters	8795714	7075784
Average length of words	4.252	4.212
Unique words	65551	48521
Mode of words	4	4

Sports. This extracted corpus is further sent to preprocessing step for additional refinement.

Preprocessing of the corpus. The extracted corpus contains many undesired symbols and words, which does not hold any semantic meaning in the word prediction system. This makes the corpus to be preprocessed before any statistical inference could be obtained from the corpus. The preprocessing phase is divided into three stages, (1) Insertion of Space before a punctuation mark, (2) Removal of undesired symbols, and (3) Removal of words with length equal to one.

Insertion of Space before a punctuation mark. The preprocessing is instigated by inserting a space before Punjabi language punctuation mark—"।" [ɖan̪ ɖɑː]. In the extracted corpus, many sentences are ended by joining "।" [ɖan̪ ɖɑː] with no space before the preceding word, which create an ambiguousness in the corpus. This makes many words a diverse entity, even if similar words are present in the corpus. For example, in ਮੇਰੀ ਮਾਂ ਬੋਲੀ ਪੰਜਾਬੀ ਹੈ। [meːriː mɑːŋ boːliː pañjābī hɛːɖan̪ ɖɑː], punctuation mark "।" [ɖan̪ ɖɑː] is joined with the word "ਹੈ" [hɛː], which make a word "ਹੈ।" [hɛːɖan̪ ɖɑː] incorrect in accordance to the Punjabi language semantics, as "ਹੈ" [hɛː] is acknowledged as a complete word. Inserting one-character space before punctuation mark makes the words recognizable and accessible for processing in the later stage of statistical inference. For example, in the sentence—ਮੇਰੀ ਮਾਂ ਬੋਲੀ ਪੰਜਾਬੀ ਹੈ । [meːriː mɑːŋ boːliː pañjābī hɛː ɖan̪ ɖɑː], in which "ਹੈ" [hɛː] is now renewed into an individual word in the corpus and is available for further processing.

Removal of undesired symbols. Another stage in the preprocessing step comprises of the elimination of undesired symbols like @,!,(,), etc., as such symbols do not hold any semantic value during the statistical inference stage. After removal of undesired symbols, the processed corpus is sent to stage 3 for final processing.

Removal of words with length equal to one. All single length words were removed from the list, as such words are merely characters and do not hold any significant value in the corpus.

After completing all the stages of preprocessing on the extracted corpus, the remaining corpus is stated as the preprocessed corpus. Statistical analysis was conducted on preprocessed corpus and summary of the calculated statistics is shown in Table 1.

This preliminary preprocessing step can be stated more formally as,

Let c denotes the extracted corpus, i.e., unprocessed Bag of Words (BoW). The preprocessing phase on c can be stated as

$$\text{Preprocess(c)} = \acute{c} \tag{1}$$

where $\acute{c}$ is the processed corpus with N variables. This processed corpus ć is forwarded to step 2 to make statistical inference.

Calculating frequency distribution. Subsequently, after the preprocessing step, another significant step in the system architecture is to make the statistical inference. For this Frequency distribution is calculated from the preprocessed corpus ($\acute{c}$). The frequency distribution is an instantaneous description of the dataset which states the frequency of the discrete variables in the processed corpus. This step can be stated as,

Let n denotes the number of discrete variables x in processed corpus $\acute{c}$. Then $\text{VAR}_{\acute{c}}$ is denoted as the set of discrete variables as

$$\text{VAR}_{\acute{c}} = \{x_0, x_1, x_2, \ldots, x_n\} \tag{2}$$

The frequency of ith discrete variable in the corpus $\acute{c}$ can be given by

$$f_0 + f_1 + f_2 + \ldots + f_n = N \tag{3}$$

which furthermore can be given in form of a frequency set $\text{FREQ}_{\acute{c}}$,

$$\text{FREQ}_{\acute{c}} = \{f_0, f_1, f_2, \ldots, f_n\} \tag{4}$$

where, f_i is the frequency for *ith* discrete variable for $i = 0, 1, 2, \ldots, n$ in $\text{VAR}_{\acute{c}}$.

Set $\text{VAR}_{\acute{c}}$ and $\text{FREQ}_{\acute{c}}$ are further utilized in step 3 of a system architecture for the generation of word Trie and Frequency dictionary.

Formation of words Trie and frequency dictionary. Set $\text{VAR}_{\acute{c}}$ and $\text{FREQ}_{\acute{c}}$ are utilized in the final step for the formation of word Trie and frequency dictionary. Frequency dictionary named DICT_{PUN} is modeled in form of "<word>": <frequency>, in which <word> corresponds to the distinct variable or word in the set $\text{VAR}_{\acute{c}}$ and <frequency> corresponds to its relative frequencies which is extracted from set $\text{FREQ}_{\acute{c}}$. DICT_{PUN} is utilized to extract the frequencies of distinct words in O(1) time. Extracted distinct variables in a set $\text{VAR}_{\acute{c}}$ are further saved in the form of word Trie data structure named $(\text{TRIE}_{\text{PUN}})$ for an efficient words organization and extraction. The algorithm given in [27] is applied for the development of words Trie data structure $(\text{TRIE}_{\text{PUN}})$. The TRIE_{PUN} and DICT_{PUN} are further utilized in phase 2 of system architecture for generation of suggestion list and ranking of words.

3.2 Word Prediction

After phase 1 of system architecture, another phase is to predict the user intended word starting with specified prefix, i.e., string of character/s. This phase is termed as Phase 2. This phase is divided into three steps, (1) Initialization of prefix,

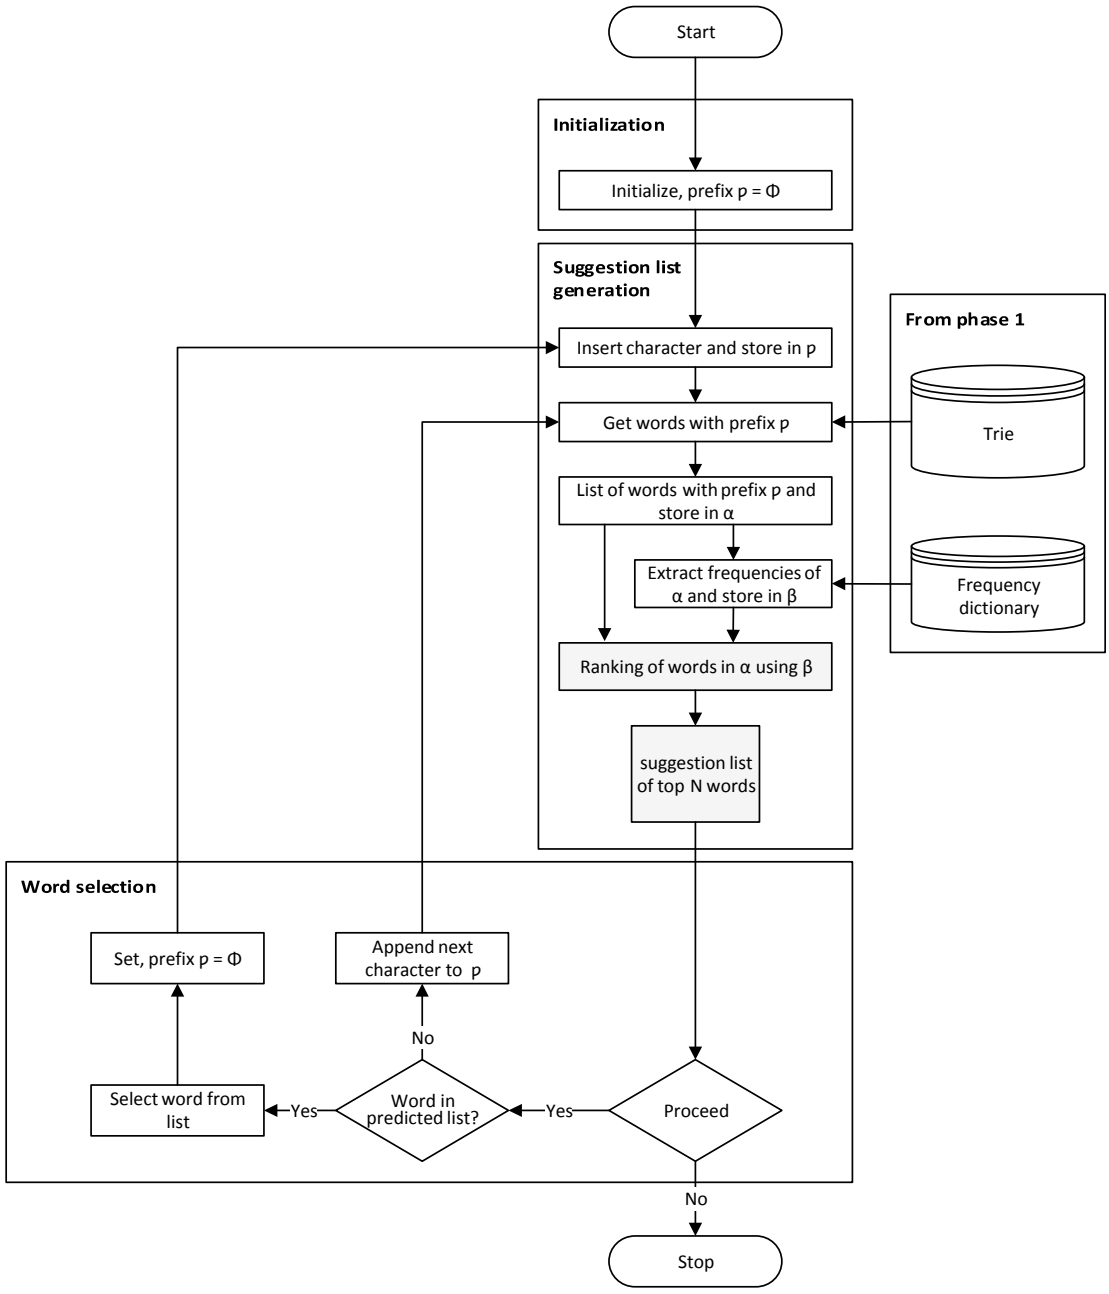

Fig. 2 Word prediction

(2) Suggestion list generation, and (3) Word selection. Figure 2 illustrates the final word prediction phase of system architecture.

Initialization of prefix. The initial phase in this step starts by initializing the prefix with null. If p denotes the user entered prefix, then this step can be stated as,

$$p = \Phi \tag{5}$$

This prefix (p) is further utilized in step 2 of the word prediction phase.

Suggestion list generation. TRIE_{PUN} and DICT_{PUN} generated in step 4 of phase 1 is utilized in this step. Subsequently, user-intended first character is stored in prefix $-p$ and is used to extract all the similar words in list $-\alpha$, from TRIE_{PUN}, which more formally is known as set $\text{VAR}_{\acute{c}}$ in Eq. 2. Furthermore, list of words in α are used to extract frequencies in another list $-\beta$, using frequency dictionary DICT_{PUN}, which more formally is stated as set $\text{FREQ}_{\acute{c}}$ in Eq. 4. The words in α are ranked against the extracted frequencies in β using the Heap Sort algorithm [27], from higher frequency to lower frequency. Algorithm 1 is used to accomplish this task. This α list of top N suggestions is listed for user selection. This system architecture was tested for 3, 5, 10, 15, 20, and 25 values of N in Sect. 7 of this article.

ALGORITHM 1: List Generation Algorithm

INPUT: Prefix(p) of the word to be predicted and dictionary (punjabi_dict) of Punjabi words as keys corresponding to their frequencies as values

OUTPUT: Returns the list of predicted words(α) to be generated

1. α = TRIE(p) // List of all the words to be generated with prefix p
2. β = [] // Empty list for frequencies
3. **for** each $\tilde{\omega} \in \alpha$ **do**
   β.append(punjabi_dict[$\tilde{\omega}$]) // extract frequency β for corresponding word $\tilde{\omega}$
4. HEAPSORT(α,β) // Perform heapsort on α on the basis of β
5. Return α // Return the words in order form of frequencies

The problem of suggestion list generalized more formally by [10] as follows, Let $L_{\text{PRED}}(p)$ denotes the set of extracted words from TRIE_{PUN} such that

$$L_{\text{PRED}}(p) \in \text{VAR}_{\acute{c}} \tag{6}$$

$L_{\text{PRED}}(p)$ is seen as a set of k suggestions from set $\text{VAR}_{\acute{c}}$. The foremost job of said system architecture is to rank the predicted suggestions in set $L_{\text{PRED}}(p)$ to set $R_{\text{PRED}}(p)$ from higher to lower, such that $|R_{\text{PRED}}(p)| = N$, where $\text{N} > 0$, represents the top suggestions of set $L_{\text{PRED}}(p)$ to be included in set $R_{\text{PRED}}(p)$, for which cost function $\text{COST}(R_{\text{PRED}}(p))$ for ranking set $R_{\text{PRED}}(p)$ is formulated as

$$\text{COST}(R_{\text{PRED}}(p)) = \sum_{\omega \epsilon R_{\text{PRED}}(p) \subset L_{\text{PRED}}(p)} \text{cost}(\omega) \tag{7}$$

where $\text{cost}(\omega)$ represent the cost of suggesting ω.

The purpose of step 2 of word prediction phase is to rank the words extracted in set $L_{\text{PRED}}(p)$ with minimum rank in the set $R_{\text{PRED}}(p)$ which is purposely known as the cost of selecting the word $-\omega$.

Word selection. After step 2, the last step is to select the user intended word $-\omega$ from N words in the list α. If the intended word $-\omega$ is found the list, the word is

selected from the list and prefix is again initialized to null, i.e., $p = \Phi$. If user intended word is not found in the list, next character is appended to prefix $-p$.

Step 2 and 3 of phase 2 is iterated till user intended word $-\omega$ is not found for the updated value of p or till system does not exit. The maximum number of iterations made for predicting single word depends upon the length of word needed to be predicted, i.e., if $|\omega| = l$, then the number of iterations needed would be l.

4 Working Example

The intended system functioning is described using Table 2. It is assumed that the proposed system wants to predict the user intended word (ω)"ਸੋਨਾ" [so:nɑ:]. The system initiate by entering initial prefix p_0 to be "ਸ" [s]. The system extracts the words list (α_0) starting with p_0 from $TRIE_{PUN}$ as ['ਸਿੰਘ', 'ਸੀ', 'ਸਰਕਾਰ', 'ਸ਼ੁਰੀ', 'ਸਨ'] and list of corresponding list of frequencies β_0 from $DICT_{PUN}$ as [54442, 7132, 5418, 5100, 3982] from higher to lower. For every extracted word x_i in α_0, the corresponding frequency f_i is extracted in β_0 for every $i = 0, 1, 2, \ldots, n$. This initial process is termed as iteration 0.

Table 2 System architecture working example

User intended word (ω)		ਸੋਨਾ
Total characters in ω		4
Iteration 0	Prefix (p_0)	ਸ
	Total characters (c_0)	1
	Extracted words from $TRIE_{PUN}(\alpha_0)$	['ਸਿੰਘ', 'ਸੀ', 'ਸਰਕਾਰ', 'ਸ਼ੁਰੀ', 'ਸਨ']
	IPA Format (ipa_0)	['sɪn̪g^h', 'si:', 'sarkɑ:r', 'ʂ^{r}i:', 'sn']
	Extracted frequencies from $DICT_{PUN}(\beta_0)$	[54442, 7132, 5418, 5100, 3982]
Iteration 1	Prefix (p_1)	ਸੋ
	Total characters (c_1)	2
	Extracted words from $TRIE_{PUN}(\alpha_1)$	['ਸੋਢੀ', 'ਸੋਚ', 'ਸੋਨੂੰ', 'ਸੋਧ', 'ਸੋਨੀ']
	IPA format (ipa_1)	['so:ɖ^{h}i:', 'so:c', 'so:nu:̃', 'so:d^h', 'so:ni:']
	Extracted frequencies from $DICT_{PUN}(\beta_1)$	[198, 126, 116, 112, 112]
Iteration 2	Prefix (p_2)	ਸੋਨ
	Total characters (c_2)	3
	Extracted words from $TRIE_{PUN}(\alpha_2)$	['ਸੋਨੂੰ', 'ਸੋਨੀ', 'ਸੋਨੀਆ', 'ਸੋਨੇ', 'ਸੋਨਾ']
	IPA format (ipa_2)	['so:nu:̃', 'so:ni:', 'so:ni:ɑ:', 'so:ne:', 'so:nɑ:']
	Extracted frequencies from $DICT_{PUN}(\beta_2)$	[116, 112, 76, 48, 44]

If the intended word "ਸੋਨਾ" [soːnɑː] is not found in α_0, next character is appended to the prefix p_0 and is termed as p_1. Again system process is repeated for p_1, the said process is termed to be iteration 1. In iteration 1, α_1 and β_1 is extracted as ['ਸੋਢੀ', 'ਸੋਚ', 'ਸੋਨੂੰ', 'ਸੋਧ', 'ਸੋਨੀ'] and [198, 126, 116, 112, 112]. Again system process is repeated as the intended word is not found in α_1. Iteration 2 is performed by appending next characters to p_1 and terming it as p_2. The predicted system is again tested to extract the user intended word using three characters in the prefix p_2. α_2 and β_2 list is extracted to be, ['ਸੋਨੂੰ', 'ਸੋਨੀ', 'ਸੋਨੀਆ', 'ਸੋਨੇ', 'ਸੋਨਾ'] and [116, 112, 76, 48, 44] for iteration 2.

In iteration 2 the user-intended word is found at rank 5 in list α_2 by making three keystrokes. One keystroke is saved using the described system architecture in Sect. 3.

5 Performance Metrics

For the assessment of proposed system architecture, testing metrics proposed by [11] are used. The metrics used for the assessment are discussed as follows:

Hit ratio. It is a metric that is used to describe the reliability of the word prediction system. Higher the hit ratio, higher will be the credibility of the prediction system to predict the correct word. It is defined by formula 8,

$$\text{Hit ratio} = \frac{\text{number of times words is predicted}}{\text{total number of written words}} \tag{8}$$

in which, number of times words are predicted is the calculation of the words prediction before the length actual word.

Keystroke saving. Hit ratio is not only enough to measure the actual saving of keystrokes as the predictor can guess words after entering all the characters. So, to measure the keystroke saving, the following formula 9 is used,

$$\text{Keystroke saving} = 1 - \frac{\text{number of keystrokes made}}{\text{total length of word}} \tag{9}$$

which is defined as the number of keystrokes saved during the course of prediction of the word. It can be defined as follows if the word comprises of n characters, and predictor predicts the word by making m strokes, the number of keystrokes saved can be defined as 1—(m/n). It is depicted using the following Fig. 3.

If total keystrokes m is equal to n, then the resulting response would be 0, as no keystrokes are saved, as the resultant word is completed by making n strokes only.

Average rank. As the vertical list is used to demonstrate the predicted for user selection. The Average rank calculation mechanism is utilized to compute the average rank of the predicted words in the vertical list of suggestions. This helps in

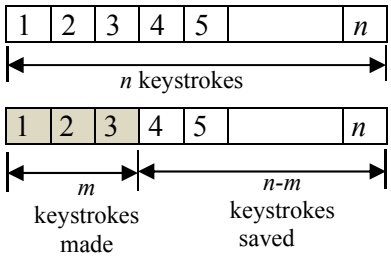

Fig. 3 Keystroke saving mechanism

calculating at which rank the selected word appears in the list. Formula 10 is used for calculation of average rank,

$$\text{Average rank} = \frac{\text{ranks total}}{\text{number of words}} \tag{10}$$

If during the prediction of the word is not found in the list, rank is set to be 0.

Average keystrokes. The average keystroke calculation mechanism is utilized to recognize the average number of keystrokes entered for each word during the prediction testing. Formula 11 is used for the calculation of average keystrokes,

$$\text{Average keystroke} = \frac{\text{total keystrokes made}}{\text{number of words}} \tag{11}$$

6 Testing Dataset and System Configuration

One of the prominent newspaper of Punjabi–Jagbani[7] was selected to test the performance of system architecture. Jagbani News crawler[8] was developed to extract the Punjabi news in accordance to the news genres. As the training corpus consists of five major genres of news, i.e. Business, International, National, Regional, and Sports, similar genres of news were extracted from Jagbani website to test the performance of the system. The statistics of the news items in each genre are given in Table 3.

The system architecture was implemented on the Windows 10 Operating system, Intel Core i5-6200U CPU 2.40 GHz with 8 GB RAM. The system is designed using Python programming language. NLTK and URLLIB packages are used for the implementation of said system and design of Web crawlers. The screenshot of the designed system is shown in Fig. 4.

Table 3 Classification of news in testing corpus

Genre	News items
Business	22
International	65
National	48
Regional	115
Sports	31

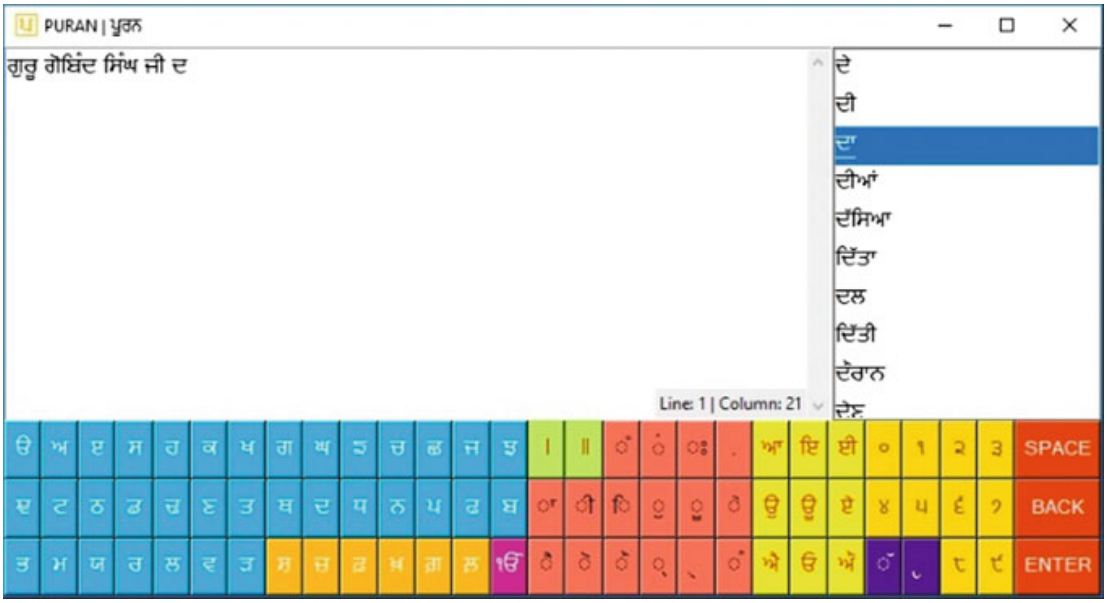

Fig. 4 Punjabi news words prediction system—PURAN

7 Results and Discussion

The performance of PURAN system was rigorously tested in the simulated environment on the basis of metrics mentioned from Eqs. (8) to (11). The extracted news items were passed to the PURAN news words prediction system for evaluation in accordance with the genres. The resultant system is observed by setting the number of words in suggestion list, i.e., N to be 3, 5, 10, 15, 20, and 25. The value of N shows the number of predicted words in accordance to their ranks, to choose from during performance analysis. Table 4 demonstrates the calculated metrics values for the proposed system architecture.

The observed scores are plotted using a line chart. Figure 5 shows PURAN performance for different genres of news in a simulated environment. Figure 5a, depicts the Hit ratio for different Genres of news, Fig. 5b illustrated the Average Rank for different genres of news, Fig. 5c depicts the Keystroke saving for different genres of news and Fig. 5d depicts the Average Keystrokes for different genres of news in a simulated environment.

Table 4 Calculated metrics for proposed system architecture

Metric	Genre	Words in the suggestion list					
		3	5	10	15	20	25
Hit ratio	Business	0.770	0.832	0.881	0.887	0.893	0.897
	International	0.781	0.847	0.878	0.887	0.891	0.895
	National	**0.805**	**0.868**	**0.901**	**0.907**	**0.912**	**0.916**
	Regional	**0.829**	**0.890**	**0.924**	**0.932**	**0.938**	**0.940**
	Sports	0.727	0.792	0.835	0.846	0.854	0.858
Average rank	Business	**1.459**	**2.125**	3.475	4.498	5.856	7.097
	International	1.464	2.151	**3.315**	**4.394**	**5.358**	**6.349**
	National	1.519	2.238	3.456	4.554	5.821	6.869
	Regional	1.544	2.207	3.481	4.649	5.811	6.788
	Sports	**1.373**	**2.027**	**3.290**	**4.342**	**5.480**	**6.238**
Keystroke saving	Business	0.386	0.444	0.503	0.528	0.550	0.565
	International	0.398	0.458	0.510	0.535	0.551	0.563
	National	**0.410**	**0.471**	**0.524**	**0.549**	**0.570**	**0.583**
	Regional	**0.429**	**0.487**	**0.541**	**0.569**	**0.588**	**0.600**
	Sports	0.381	0.440	0.493	0.518	0.538	0.547
Average keystrokes	Business	2.606	2.360	2.112	2.006	1.911	1.848
	International	2.577	2.319	2.099	1.990	1.923	1.870
	National	**2.569**	**2.301**	**2.072**	**1.959**	**1.871**	**1.814**
	Regional	**2.423**	**2.177**	**1.945**	**1.829**	**1.750**	**1.698**
	Sports	2.582	2.336	2.113	2.008	1.928	1.888

The bold text highlight the top values in the particular range

As the above results clearly demonstrate that the PURAN word predictor has performed very well on all the benchmark metrics. From Fig. 5a and d, it can be clearly derived that, PURAN has achieved highest Hit ratio in Regional news genre followed by National news genre by making lowest average keystrokes for predicting the words. These results clearly demonstrate that words can be easily predicted using PURAN words predictor for several mentioned news genres with high hit ratio and low keystrokes in Regional and National news genres. Figure 5c demonstrates that PURAN has given outstanding results for keystroke saving for Regional news genre and trailed by National genre, which is above the benchmark of 49.1%, 47%, and 40.5% keystroke saving given by [1, 16, 28], when N is taken as 10, 15, 20, and 25. Subsequently, it can be clearly stated that with the increase in the number of words in suggestion list the average keystroke saving also increases. Figure 5b states that with the increase in a number of suggestions in a vertical list of predicted words the average rank also increases.

8 Conclusion

Most the word prediction systems earlier designed were for the English and other European languages. This work is an effort to accomplish Punjabi Language with its first prediction system, particularly in News category. This paper presents the reader with the word prediction background with various factors affecting the word predictor accuracy, i.e., predicting methodology, a number of suggestions, user interface, and other features. The overall applied architecture used for suggesting the user the most appropriate word based on the prefix provided by the user was demonstrated. The system performance is tested on the various benchmark metrics like *Keystroke saving*, *Hit ratio*, *Average rank,* and *Average keystrokes* for rigorous review of the proposed system to examine its credibility in Punjabi news category.

PURAN prediction system works well in the categories of Regional and National news genres followed by International, Business, and Sports genres.

Garay et al. [21] states that no more than 10 suggestions must be presented to the user in suggestion list considering more physical movement, i.e., more hand and eye movement during the selection of the desired word. The authors also endorse the idea of [21] and take only 10 words for Final system architecture. The system has achieved 88.38% Average Hit ratio with 51.42% Average keystroke saving for $N = 10$. It is meaningful to mention while concluding that PURAN word predictor can be easily used to write articles for the Punjabi newspapers with an ease and also with high hit ratio and keystroke saving.

Acknowledgements The Authors would like to acknowledge the contribution of Arvinder Singh Kang from UrbanLogiq for providing the Punjabi news corpus for this research. We thank Varun Manchanda, Faculty, RGNIYD Regional Centre, Chandigarh for proofreading the draft.

Implementation of hDE-HTS Optimized T2FPID Controller in Solar-Thermal System

Binod Shaw, Jyoti Ranjan Nayak and Rajkumar Sahu

Abstract In this paper, a fair approach is interpreted to validate the novelty of Type-2 Fuzzy PID (T2FPID) controller over Type-1 or conventional Fuzzy PID (FPID) and PI controller as secondary frequency controller and Heat Transfer Search (HTS) algorithm is adopted to extract the optimum gains of the controllers. T2FPID controller has a beautiful property to handle large uncertainties of the system with extra degree of freedom. T2FPID controller is implemented in a two area interconnected thermal-PV power system to enhance the system performance. ITAE is adopted as objective function of the system to lessen the undershoot, overshoot, and settling time of frequency and tie-line power deviation. A novel hDE-HTS algorithm is adopted to enhance the system performance by searching the relevant pair of gains of controller. This analysis is executed by implementing a step signal (load disturbance) of magnitude 0.1 in area-2 to study the transiency of the system. The novelty of this work is to implement hDE-HTS optimized T2FPID controller to enhance the Solar-thermal system responses (Frequency and tie-line power deviations).

1 Introduction

In recent power system, interconnection of areas is an eminent approach to share the load demand along with to maintain stability and reliability of the system. This helps to supply reliable, stable, and economical power to the consumers. In interconnected power system, load deviation in one area causes frequency and power deviations in all interconnected areas. The small deviations are diminished by primary controller of generators. But for large deviations, secondary controller is highly essential to diminish the deviations [1]. Proportional (P), Integral (I), Derivative (D), PID, fuzzy, etc., are used as secondary controller to enhance the capability to handle the load fluctuations in the power system. The elementary purposes of the AGC are to

i. Settle the frequency deviation as soon as possible (i.e., $\Delta f = 0$).
ii. Settle the tie-line power deviation to its scheduled value (i.e., $\Delta P_{\text{tie}} = 0$).
iii. Minimize settling time, undershoot, and overshoot and of the system after any load fluctuation.

Renewable energy is an imperative alternative to fulfill the enormous expanding load demand. Solar system is the most preferable energy system due to its simple implementation. The combination of renewable energy systems enhances the complexity of the power system. In complex power system, intelligent controllers with enormous competence to handle uncertainties should prefer.

AGC is the most important strategy in the power system which concerns the reliable and stable power generation. Various secondary controllers have been implemented as AGC to enhance the system capability to handle the load fluctuation. Ibrahim et al. [2] have portrayed a review of AGC with different schemes to analyze the novelity of controllers. Abraham et al. [3] have implemented superconducting magnetic energy storage (SMES) to portray the effect of storage device on AGC in a two area interconnected hydro-thermal system. Singh and Sen [4] have successfully designed an interconnected power system with thermal units by using PID controller optimized by GA. Dash et al. [5] has introduced cascade controller titled as PI-PD controller optimized by FPA in four area interconnected reheat thermal power plants. Many researchers have enhanced the PID controller by reconstruct the PID controllers entitled as 2DOF PID, 3DOF PID, cascade PD-PID, etc. in [6–8] respectively. Even for better performance the fractional order PID controller is enforced as AGC in [9] and [12]. From last few decades, fuzzy logic controller is generally preferred for various applications. Fuzzy logic controller (FLC) has convinced as a very robust and intelligent controller used as AGC in [13, 14]. The robustness of FPID controller is enhanced with the assemblage of advantages from both PID and FLC controller. FPID controller optimized by different powerful algorithms have depicted in [15–19]. The degree of freedom of FLC is enhanced by providing Foot Of Uncertainty (FOU) entitled as T2FLC [20]. T2FPID controller is adopted to enhance the AGC performance in [21].

In present work, grid connected PV system is enforced in area-1 and reheat thermal plant is enforced in area-2. From last few decades, FPID controller has dominated over conventional controllers. T2FPID controller is an adequate controller over FPID controller to handle nonlinear and uncertain system. HTS algorithm is adopted to extract the controller gains. The superiority of hDE-HTS algorithm is validated over HTS to tune T2FPID controller.

2 System Investigated

In this work, two area interconnected power system is implemented. In area-1 PV system and in area-2 reheat thermal system are resided in the power system network as illustrated in Fig. 1 [10, 11]. The power system parameters are portrayed in Appendix 1. To verify the transiency of the system a 10% load change is enforced in area-2 which propagates an error in each area entitled as Area Control Error (ACE). The basic objective of AGC is to lessen the ACE which concedes deviations in tie-line power and frequency deviation as characterized in Eq. (1).

$$\text{ACE} = B\Delta f + \Delta P_{\text{tie}} \tag{1}$$

where B_1, and B_2 are the bias factors of frequency. The deviations of frequency with respect to nominal value in area-1 and area-2 are Δf_1 and Δf_2 respectively. The deviation of power in tie-line is ΔP_{tie} and is characterized in Eq. (2).

$$\Delta P_{\text{tie}} = \frac{2\pi T_{12}}{s}(\Delta f_1 - \Delta f_2) \tag{2}$$

PI, FPID, and T2FPID controllers are executed in both the areas individually to scrutinize the controller potency to enhance the system performance. Intelligent T2FPID controller is observed as superior controller over other conventional controllers due to its capability to handle nonlinear and uncertainties. The structure of T2FPID controller is as portrayed in Fig. 2. The objective function for this system by considering tie-line power deviation and frequency deviation is characterized in Eq. (3)

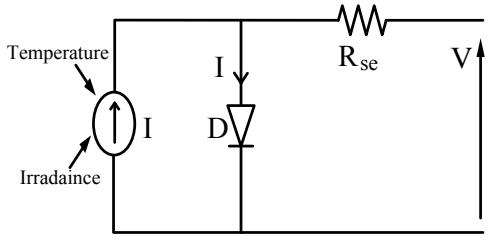

Fig. 1 Equivalent circuit solar system [11]

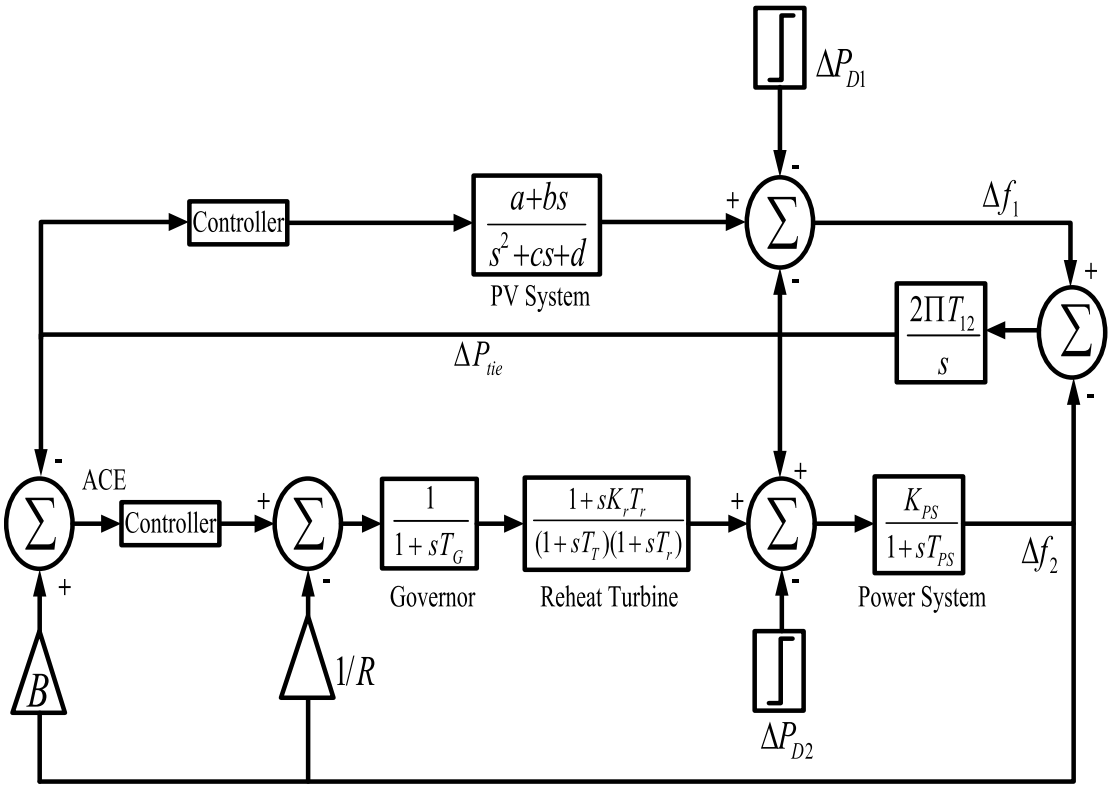

Fig. 2 Transfer function model of solar-reheat thermal power system [10] and [11]

$$J = \text{ITAE} = \int_0^T t(\Delta f_1 + \Delta f_2 + \Delta P_{\text{tie}}) \tag{3}$$

Subject to:

$$-2 \le K_i \le 2 \quad \text{i} = 1, 2, \ldots, \text{n}$$

PV System

The PV system is basically depends upon two important factors, i.e., irradiance and temperature. The PV system can be represented with a current source, diode and series resistance as portrayed in Fig. 1.

In present work, PV system is adopted with constant irradiance (1000 w/m^2) and temperature (27 °C). The transfer functions by concerning MPPT, inverter, and filter as characterized in Eq. (4).

$$G_{\text{PV}} = \frac{-18s + 900}{s^2 + 100s + 50} \tag{4}$$

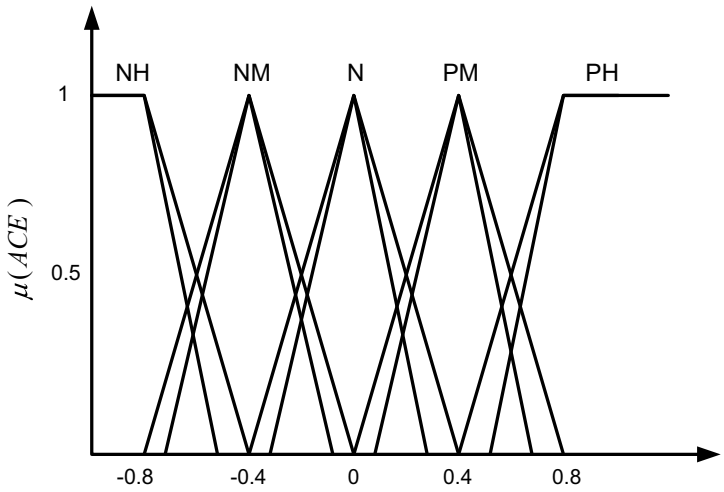

Fig. 3 MFs of Type-2 FLC

3 Type-2 Fuzzy PID Controller

Design of intelligent controllers is an imperative approach to provide reliable and stable power in a highly complex power system. T1FPID controller has substantiated as a better controller over classical controllers. In this work, T2FPID controller is adopted to contribute the supremacy of T2FPID controller over FPID and PID controller. The framework of T2FPID controller is portrayed in Fig. 5. The supremacy of T2FLC is better than T1FLC because of the FOU provided by the controller. FOU is the boundary provided by the two type-1 membership function (MF) entitled as Lower mf (LMF) and Upper mf (UMF) as portrayed in Fig. 4 [20]. The degree of freedom is enhanced by this FOU and also enhances the capability to handle the uncertain information. The MF adopted for T2FPID controller is illustrated in Fig. 3. In this work, five interval type-2 MFs are adopted entitled as negative huge (NH), negative mild (NM), Null (N), positive mild (PM), and positive huge (PH). The rule base is tabulated in Table 1.

4 hDE-HTS Algorithm

The basic purpose of using optimization technique is to design optimum controller which is best-suited for the system. In this work, a novel algorithm entitled as HTS is adopted to contribute highly convenient gain parameters within specified band to minimize "*J*" as illustrated in Eq. (3). Patel et al. [22] have introduced HTS algorithm stimulated from the law of thermodynamics and heat transfer. HTS algorithm is derived from the movement of molecules during three modes of heat transfer, i.e., conduction, convection, and radiation. HTS is a population-based iterative computational technique. The molecules, temperature and energy level are proportionate to the population, design variables and solution respectively. DE algorithm is very influential to enhance the diversity factor of the algorithm with a possibility to trap into local optima [23]. The combination of benefits of both algorithms is proficient enough as compare to individual one. The steps for hDE-HTS algorithm are as:

1. Initialize random population, i.e., $[X]_{\mathrm{NP}\times D}$.
2. Evaluate the fitness of the population, i.e., $f(X)$.
3. Initialize the conduction factor (CEF), convection factor (COF) and radiation factor (RF).
4. Donor vector (V_i) is defined as in Eq. (5).

$$V_i = X_{i,r_1} + F(X_{i,r_2} - X_{i,r_3}) \tag{5}$$

where X_{i,r_1}, X_{i,r_1} and X_{i,r_1} are three randomly taken vectors from X_i.

5. Offspring vector (U_i) used for crossover operation is characterized as in Eq. (6).

$$\begin{array}{ll} U_i = V_i & \text{If rand} \leq \text{cr} \\ = X_i & \text{Otherwise} \end{array} \tag{6}$$

6. Selection of target vector is defined as in Eq. (7).

$$\begin{array}{ll} X_i = U_i & \text{If } f(U_i) \leq f(X_i) \\ = X_i & \text{Otherwise} \end{array} \tag{7}$$

7. The solution of DE algorithm is considered as initial vector for HTS algorithm.
8. Initialize a random value R [0 1].
9. Conduction phase (if $R \leq 0.33333$)
   Update the particle position as characterized in Eqs. (8) and (9).

$$X_i^{g+1} = \begin{cases} X_k + (-R^2 * X_k), & \text{if } f(X_i^g) > f\left(X_k^g\right) \\ X_i + (-R^2 * X_i), & \text{if } f(X_i^g) < f\left(X_k^g\right) \end{cases} \quad \text{if } f(X_i^g) \leq f\left(X_{\text{best}}^g\right)/\text{CEF} \tag{8}$$

$$X_i^{g+1} = \begin{cases} X_k + (-r * X_k), & \text{if } f(X_i^g) > f\left(X_k^g\right) \\ X_i + (-r * X_i), & \text{if } f(X_i^g) < f\left(X_k^g\right) \end{cases} \quad \text{if } f(X_i^g) \geq f\left(X_{\text{best}}^g\right)/\text{CEF} \tag{9}$$

   where r, g and k are the random number, generation and random solution.
10. Convection phase (if $0.3333 \leq R \leq 0.6666$)
    Update the particle position as characterized in Eq. (10).

$$X_i^{g+1} = X_i^g + R * (X_{\text{best}} - TCF * X_i) \tag{10}$$

    Where TCF is the temperature change factor.

$$TCF = \begin{cases} abs(R - r), \text{if } f(X_i^g) \leq f\left(X_{\text{best}}^g\right)/COF \\ round(1 + r), \text{if } f(X_i^g) \leq f\left(X_{\text{best}}^g\right)/COF \end{cases}$$

11. Radiation phase ($R \geq 0.6666$)
    Update the particle position as characterized in Eqs. (11) and (12).

$$X_i^{g+1} = \begin{cases} X_i^g + R(X_k - X_i), \text{if } f(X_i^g) > f\left(X_k^g\right) \\ X_i^g + R(X_i - X_k), \text{if } f(X_i^g) < f\left(X_k^g\right) \end{cases}, if\, f(X_i^g) \leq f\left(X_{\text{best}}^g\right)/RF \tag{11}$$

$$X_i^{g+1} = \begin{cases} X_i^g + r(X_k - X_i), \text{if } f(X_i^g) > f\left(X_k^g\right) \\ X_i^g + r(X_i - X_k), \text{if } f(X_i^g) < f\left(X_k^g\right) \end{cases}, if\, f(X_i^g) \geq f\left(X_{\text{best}}^g\right)/RF \tag{12}$$

12. The best fitness particles updated for next generation by replacing the worst particles.
13. Repeat steps 4–12 until the termination criteria satisfied.
14. Evaluate the optimum solution.

The parameters of hDE-HTS algorithm are illustrated in Appendix 2.

5 Result and Discussion

HTS algorithm is adopted to design optimum PID, FPID, and T2FPID controller. K_1, K_2, K_3 and K_4 are the design variables to be tuned by HTS. A novel hDE-HTS algorithm is opted to tune T2FPID controller to validate the superiority of the hybrid controller. Both HTS and hDE-HTS algorithm are executed individually for different controllers. Each controller is optimized with 50 numbers of population and 100 generations. The basic purpose of execution of HTS algorithm is to lessen ITAE (Integral Time Absolute Error) as cited in Eq. (3). The optimal gain values of all controllers extracted by using both algorithms are tabulated in Table 2.

HTS algorithm optimized PI is validated as better controller than FA optimized PI controller [11]. In the same fashion, supremacy of HTS optimized FPID controller is substantiated by contrasting with ICA-optimized FPID controller [10].

The response parameters by conceding the settling time, undershoot and overshoot of both frequency and tie-line power deviation are tabulated in Table 3. In Table 3, a fair observation is illustrated to demonstrate the supremacy of T2FPID controller and hDE-HTS algorithm. The response parameters and ITAE of the T2FPID controller are minimum.

The deviations in frequency of both areas and tie-line power are portrayed in Figs. 6, 7, and 8 respectively.

Figures 6, 7, 8 and Table 3 precisely represent the superiority of the T2FPID controller. T2FPID controller minimizes the transiency (undershoot, overshoot and settling time) of the system as correlate to PI and FPID controllers.

6 Conclusion

In this work, the interconnected power system integrated with PV system with constant irradiance and temperature is simulated with various controllers. The purpose to contribute an intelligent control of frequency and power is achieved by employing PI, FPID, and T2FPID controllers. T2FPID controller yields better response over other controllers due to its capability to handle nonlinear and uncertain information. HTS and hDE-HTS algorithms are employed to extract the relevant gain parameters of controller to enhance the potential of the controller. An effort to validate the excellency of T2FPID controller and hDE-HTS algorithm is portrayed clearly through this paper.

Design of Sigma-Delta Converter Using 65 nm CMOS Technology for Nerves Organization in Brain Machine Interface

Anil Kumar Sahu, G. R. Sinha and Sapna Soni

Abstract In this paper, an overview of the present related works in the field of neuroscience is determined. The parts of the neural interface using sigma-delta converter are examined the overall ADC is driven with low voltage to improve the control utilization in the nerves organization. In this work, a basic parts of nervous system is demonstrated which is conquer to solve the problem by delivering power and transmitting data in a minimized manner. For these the above signal is first transmitted to the brain using the help of electrode into the central nervous system of the brain where the signal is diagnosed using brain computer interface by analyzing the data from analog-digital converter. Sigma-delta converter is used for visualizing low frequency signal. Major advantage of this converter is that firstly, clocking circuit need not be design and secondly, it provides good accuracy. Actually, there is no role of digital to analog converter (D/A) connected wirelessly in proposed design. A new topology based on A/D converter, which plays a wide role to minimum supply voltage, and an inactive integrator to decrease control utilization is exhibited, for empowering an in-channel advanced converter plot in a large-scale neural recording implant.

1 Introduction

In this work, a basic parts of nervous system is demonstrated which is conquer to solve the problem by delivering power and transmitting data in a minimized manner. For these the above signal is first transmitted to the brain using the help of electrode into the central nervous system of the brain where the signal is diagnosed using brain computer interface by analyzing the data from analog-digital converter. Sigma-delta converter is used in this paper for visualizing low frequency signal; a comparator based sigma-delta converter has designed in order to change over a few input nerves path into an advanced representation with low obstruction. Sigma-delta A/D converter has been successfully designed so that a couple of info nerves way into an upgraded model with low barrier. In this type of converters clocking circuit is avoided that is why accuracy is better to maintained from low frequency signal into high resolution digital value. Right when the need is to restrict control utilization, an in-channel execution one A/D per channel can provoke huge change. The input signal is determined by utilizing an analog to digital converter by considers as an outsourcing the benefit and control of converter part on the outer collector side when joined with radio transmitter, which have a successful part for nerves organization implementation.

A new topology based on simple to advance converter that play a wide role to minimum supply voltage and an inactive integrator to decrease control utilization is exhibited, for empowering an in-channel advanced converter plot in a large-scale neural recording implant.

2 Literature Review

This section identifies and formalizes the problem faced while implementing the references. Noteworthy contributions in the proposed area have been summarized in previous section. However, some significant contributions are reported here as noteworthy contribution.

Sigma-delta converter has been used in channel medium for digitalizing small amplification of brain signal for large-scale implantation of neural implants because dynamic range of sigma-delta modulator is still less in [1]. Dynamic range will be improved depends on design parameter of operational amplifier comparator circuit and switch capacitor used in the design specification. 3-D neural chronicle micro-system has been created in [2] to drives the signify number of neural channels that can be recorded over a trans-conductions for remote connection. Some places front-end processor for multichannel neuronal narrative is depicted in [3]. It gets 12 differential-input channels of embedded account cathodes.

Low power consistent time sigma-delta modulators circuit has been used to configuration subtle elements in [4]. Lithographically portrayed microelectrode clusters currently allow high-thickness recording for recreation in the cerebrum and

are empowering new bits of information into the affiliation limit of the focal sensory system in [5]. In [6] exhibited a coordinated circuit for remote neural incitement, alongside bench top and in vivo trial comes about. The chip can drive 100 individual incitement terminals with consistent current heartbeats of shifting adequacy, span, interphase deferral, and redundancy rate. In [7] presented a multichip structure accumulated with a therapeutic survey treated steel microelectrode group expected for neural records from different channels. Transmission limit diminishing is capable through movement potential disclosure and finish catch of simulation by strategies for on chip data buffering in [8].

The SAR ADC has been utilized to controlled 32 bit channel remote incorporated in system on-a-chip (SoC). The estimated control utilization of each chronicle channel; consume less power in [9]. Ultra-low-power 32-channel neural-recording coordinated circuit chip comprises of eight neural account modules in [10] where every module contains neural recorder unit, multiplexer(MUX) unit, an A/D converter, and a serial programming interface unit. Introduced a third request incremental sigma-delta converter (ADC) for time-multiplexed signals. Incremental sigma-delta modulation has been used to convey medium to high assurance necessities of multichannel applications, while a third demand steady time execution be inspected as a possibility for low-control plans in [11]. Inside neural interface IC for neural activity dynamic figure of A/D is key factor for electronic control modules and power organization circuits in [12]. The sigma-delta is used to control the voltage controlled oscillator circuit used in neural prosthetic [13]. Different sigma-delta modulator has been proposed to diminish control utilization and size in implantable bio-interfacing frameworks in [14].

Bidirectional neural interfacing applications with filter information rates: higher rates are required for recording of uplink signals compare to downlink signals in [15]. In [16] Exhibited a mind development in vivo requires gathering bioelectrical signals from a couple of microelectrodes in the meantime in demand to get neuron associations. Brain machine interface setup for neural implants is shown in Fig. 1.

The fundamental problem are examined and reported in following:

- The basic neural-recording implants using sigma-delta converter is designed for storage purpose, in this design the area of the chip is less but the power dissipation and delay is quite high.
- In order to reduce the area, power and delay of the chip, the basic chip is designed using sigma-delta converter with different technologies and with using switch capacitor.
- The four bit sigma-delta converter has been designed and their performance is compared, in result we observed that only power is reduced, there is not much affect in area.
- We also noticed that in designing of many CMOS circuits the use of switch capacitor is very important, which plays a major impact on designing the chip by achieving a great resolution.

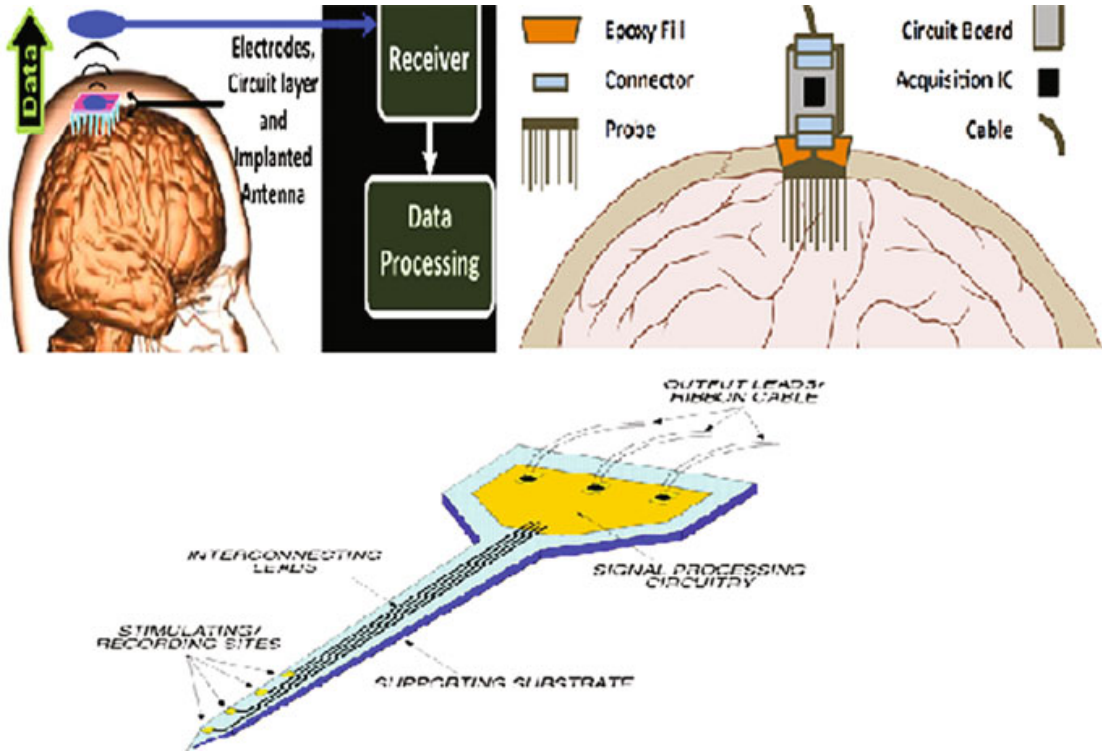

Fig. 1 Brain machine interface setup for neural implants

3 Methodology

In this part, we will examine about first neuron cell, neural action, and neural chronicle interface, second stage portray the execution of four info comparator circuit for neural account and the proposed circuit usage of the sigma-delta converter. In this postulation, proposed approach is outlined and recreated by utilizing Tanner EDA at CMOS BSIM4 innovation. To start with area clarifies the neural chronicle inserts, next segment clarifies the sigma-delta converter and last segment clarifies the proposed technique utilizing BSIM4 innovation.

The objectives of this proposed work are

(1) To design and characterize sigma-delta modulator based on comparator circuit using Quad input.
(2) To improved performance of sigma-delta modulator data converter.

Figure 2 shows the design flow chart of sigma-delta converter.

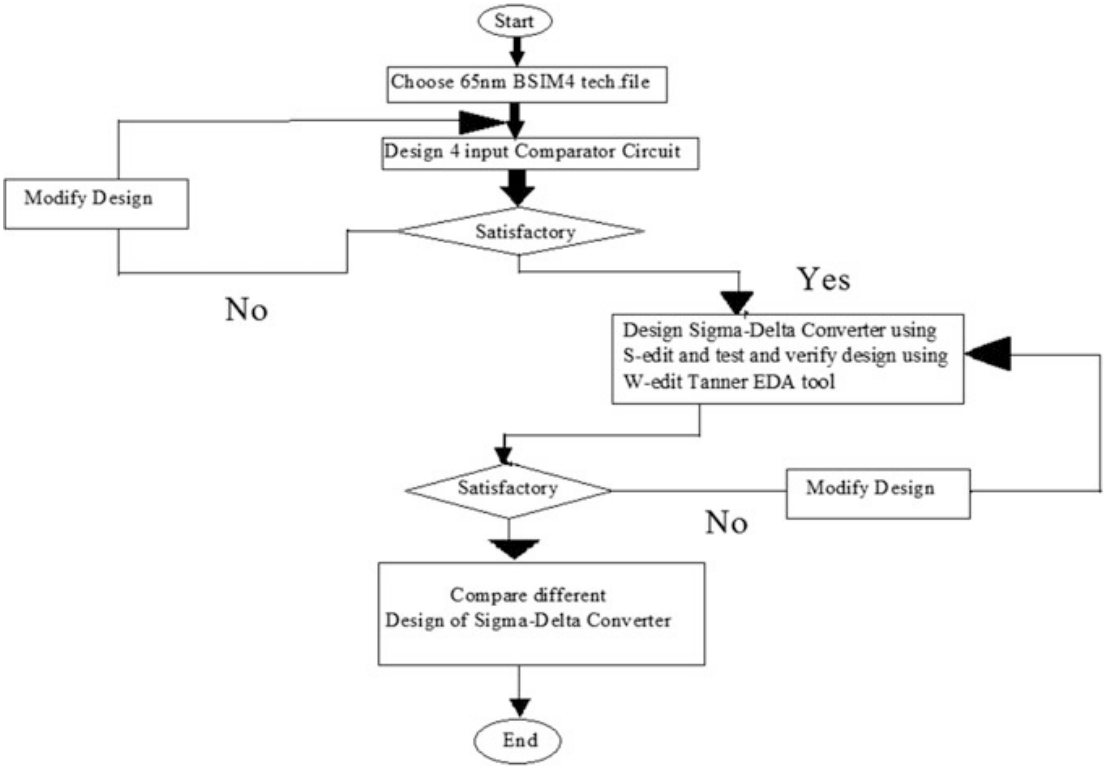

Fig. 2 Flow chart of sigma-delta converter

3.1 Design of Comparator

From Fig. 3 it can be seen that Comparator is design using 12 transistor such as M1, M2, M3, M4, M5, M6, M7, M8, M9, M10, M11, M12 and Two Inverter connected as output. It is simply differential amplifier with two input fw- and fw+. Depend on clack signal $\varphi 1$ Comparator will compare the input and produce output.

From Fig. 4, it can seen that comparator circuit using four input is implemented in tanner using 65 nm technology. Figure 5 shown top view of sigma-delta converter using four-input comparator circuit used in Nerves Organization system shown in Fig. 6. It can be seen that the nerves signal read by the terminal hold little a motivation in solitude. Warm noise from the cathode and the tissue interface and natural commotion from the neighboring neurons are accessible. These signs ought to be adjusted and arranged before the information they contain can be considered. This is where the neural interface accepts a critical part (Figs. 7 and 8).

Table 1 Performance comparisons

Performance parameter	Ref. [3]	Ref. [1]	This work
Technology (nm)	180	180	65
Topology	DT-∑Δ	DT-∑Δ	DT-∑Δ
BW (KHz)	5	10	10
SNDR (dB)	105	55.2	50.2
ENOB (bits)	17.15	8.88	7.58
OSR	–	50	–
Power (μW)	280	0.11	0.4
FOM	190	11	45

4 Results and Discussion

The proposed circuit has been made in a TSMC 65-nm CMOS circuit. In this paper the input in the above circuit is feeded into the central nervous system where the flexible power coil is implanted using implantable flexible board in which the array of electrode is fully distributed inside the cerebellum by the help of four-input comparator circuit and the output driven signal of the above comparator circuit is used to drive the sigma-delta converter which holds a great impact of driving low frequency signal with low power consumption is determined in this paper, The power utilizes in the above circuit is above 0.4 μW that include only two non-covering clock generator. In this paper, the circuit utilizes real time user interface, which holds a great impact of determining damage nerves inside the brain to cure various chronic disease, brain tumor, various trauma inside the cerebellum (Table 1).

5 Conclusion

In this paper, we presented outline of a novel sigma-delta converter that can be used for high-thickness neural record and biotelemetry applications. A FOM has been relate and figured for a couple of determined diagrams, and the implemented circuit poses great impact with relative data converters. The over all circuit inside a multichannel recording neural testing activity is implemented successfully.

Analyzing of data on recorded. To fulfill the predetermined unique fluctuate, in any case utilization of low consumption of control power. Here the style investigations, circuit execution and stream of digital signal determination whole power utilization of the modulator is 0.4 μW that compares to a FOM of 45 fJ/change step. The focused circuits details make this style a good possibility for building high accuracy neurosensory. Highlights drawback is to control the input relate to sigma-delta converter using comparator circuit as shown above. The proposed arrangement includes speed frequency range of 1 kHz of 10 kHz, and gives 7.58

bits value of precise division by using another feed forward topology, while including minimum number of additional portions and switches. A four-channel straightforward front-end has been executed in this proposed structure and made in a CMOS 65-nm innovation.

The major limitation of our proposed methodology is to operate switch capacitor and overall circuit design is quite complex and increases the chip size. Here the overall power delay of the entire circuit may be vary when operated with different technology. In future, this sigma-delta A/D design approach using comparator circuit can be designed for n number of bits, which results in low power and lower delay. It is beneficial for larger circuits, in order to reduce the delay.

Performance Comparison of Machine Learning Techniques for Epilepsy Classification and Detection in EEG Signal

Rekh Ram Janghel, Archana Verma and Yogesh Kumar Rathore

Abstract Epilepsy is a neurological affliction that in impact around 1% of humankind. Around 10% of the United States populace involvement with minimum a solitary convulsion in their activity. Epilepsy has recognized respectively tendency of the cerebrum outcomes unforeseen blasts of weird electrical action which disturbs the typical working of the mind. Since spasms by and large happen once in a while and are unforeseeable, seizure identification frameworks are proposed for seizure discovery amid long haul electroencephalography (EEG). In this exploration, we utilize DWT for highlight extraction and do correlation for all kind of Machine learning order like SVM, Nearest Neighbor Classifiers, Logistic relapse, Ensemble classifiers and so on. In this examination classification accuracy of Fine Gaussian SVM recorded as 100% and it has better as compare to other existing machine learning approaches.

Keywords Decision tree · Ensemble classifier · Electroencephalogram (EEG) · Epileptic seizure · *k*-Nearest neighbor · Support vector machine

1 Introduction

Epilepsy problem is a bunch of typical neurological conditions of the mind distinguished by recurrent unprovoked convulsions which are consequence of sudden bursts of abnormal electrical discharges in the brain [1–3]. According to a report by WHO [4] around 50 million people are in effected by epilepsy worldwide [5–8].

N. Sharma et al. (eds.), *Data Management, Analytics and Innovation*, Advances in Intelligent Systems and Computing 1042, https://doi.org/10.1007/978-981-32-9949-8_29

Nearly one in every 100 persons effected by a convulsion in their lifespan [8], generally 2.4 million new instances of epilepsy accounted for consistently internationally [6, 9]. Until now, the manifestation of an epileptic is eccentric and its course of process has been less understood [10], Epileptic patients experience varying symptoms depending on the section and the expanse of the brain affected, Epileptic seizures can induce dull physical, social consequences and psychological, which include loss of consciousness, injury and abrupt death. Epilepsy is of two samples which are depending upon the degree of involvement of the brain tissue, which is, generalized seizures and, partial involves closely to the complete brain, partial seizures create in a specific area of the mind and stay constrained to that segment [8]. Electroencephalogram (EEG) distinguished by the electrophysiological technique to appreciate the problematic activity of the human brain [11]. EEG exactly gauges and registers the electrical action of the mind. Natural EEG signals have classifieds into many rhythms based on their frequencies, which are a band (3–4 Hz); band (4–8 Hz); band (8–13 Hz); band (13–30 Hz) [12, 13]. An EEG is particularly helpful on occasion when the cerebrum is in danger by giving a delicate sign of cerebral working. Such interim is as a rule of long time ranges, thus a broadened EEG recording required early investigations have demonstrated proof of this unusual movement to be an advantageous guide in the identification of epilepsy and cerebral tumors. These days EEG signals are utilized to get data significant to the determination, visualization, and cure of these anomalous case. EEG can be register using electrodes arranged on the head and have tiny amplitudes in the range of 20 V [14, 15, 16]. The anodes are put according to the 10–20 international system which is shown in the Fig. 1.

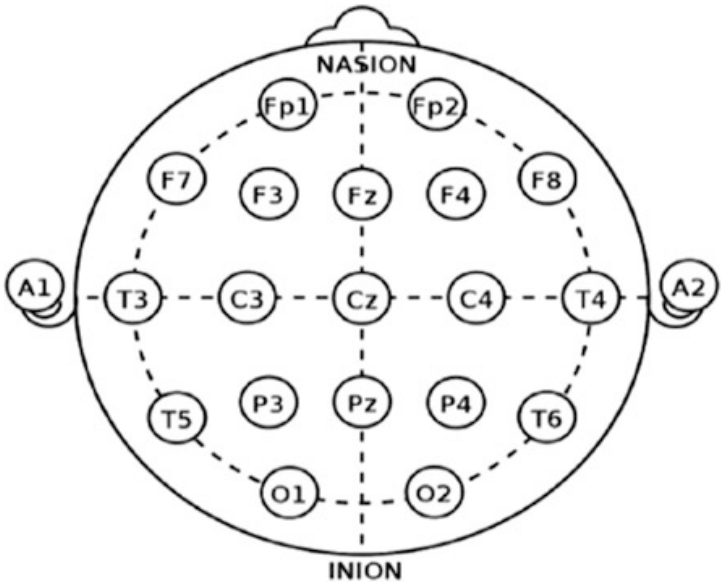

Fig. 1 Standardized electrode placement scheme

2 Proposed Work

SVM algorithm is used to a classification of healthy and seizures in 17 full term dataset of newborns baby with seizure by the author [17]. Using PCA with help of decomposing WPD getting an accuracy of 99% with a less computational cost for extracting features on Bonn University data set [18]. Using Novel wavelet-base and SVM for repeated seizure detection and getting sensitivity is 94.46% and specificity is 95.26% [19]. Using the Expectation–Maximization algorithm used for learning the Mixture of experts network structure getting an accuracy of 93.17% for classification seizure and non-seizure [20]. Fuzzy c-mean algorithm and MLP sub-network are used for ECG beat classification in this MIT/BIH dataset are used and enhance their performance [21, 22].

2.1 Dataset

The data elucidated by Andrzejak et al. [8] was employed for the current research. The total data set is comprised of five subsets, (denoted as Z, O, N, F, S) every each subset having 100 single-channel EEG fragments each being on 23:6 s time span sampled at 173:6 Hz. The fragments were chosen and hand-picked from regular continue multi-channel EEG recordings after ocular examination for artifacts for e.g., eye movements or muscle action etc. shown in Fig. 2.

2.2 Discrete Wavelet Transforms

DWT is best for DE noising and it think about signs and pictures as it helps indicates numerous regular happening signs and pictures with the assistance of fewer coefficients this empower a sparser introduction base scale in dwt is organized by you can get diverse scales by raising.

$$2^j, \quad \text{where } (j = 1, 2, 3, 4 \ldots)$$

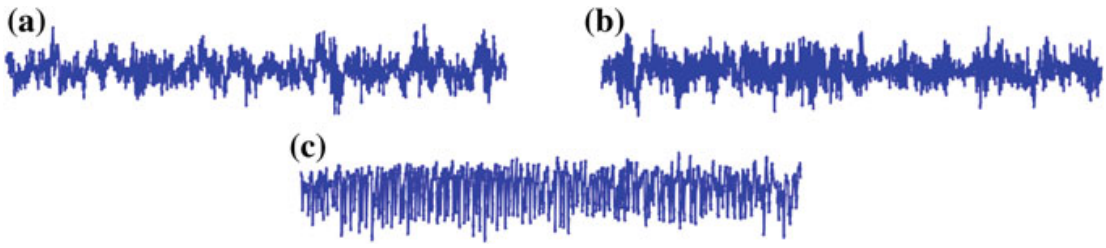

Fig. 2 Raw EEG data belonging to each of subsets **a** Z, **b** O and **c** S

Base scale to integer value shows in below

$$2^j m, \quad \text{where } (m = 1, 2, 3, 4\ldots)$$

The interpretation comes at whole numbers numerous speaks to in this condition this procedure is frequently alluded to as power scaling and moving this sort of inspecting wipes out repetition in coefficients. The output of the change yields the same number of coefficients from the length of the discrete wavelet transform process is proportional to contrasting a signal with discrete multi-rate filter banks conceptually.

The discrete wavelet change is a flexible flag handling device that searches many building and logical functions. One zone in which the DWT has been especially fruitful is the epileptic seizure identification since it catches transient highlights and restricts them in both time and recurrence content precisely. Different data sets are shown in Fig. 3.

After applying Discrete Wavelet transform we apply multiple methods have been put forward for epileptic seizure detection and compare their accuracy with help of confusion matrix. Dataset divided in the 10-k fold for training and testing. Multiple classifications we use for comparing data accuracy of various algorithms.

2.3 Different Machine Learning Techniques

A Detailed flowchart of the proposed approach is shown in Fig. 4.

2.3.1 Support Vector Machine

SVM is a supervised learning Model. It associated learning algorithms analyzing data used for classification and also regression analysis [23]. In this paper we use 2-class. Linear SVM, Quadratic SVM, Cubic SVM, Fine Gaussian SVM, Medium Gaussian SVM, and Coarse Gaussian SVM is prediction speed is fast in binary input and easy interpretability. It uses medium memory usage shown in Fig. 4.

2.3.2 KNN

The *k*-closest neighbor's calculating (*k*-NN) is a non-parametric approach utilized for characterization and relapse [24]. In the two cases, the data comprises of the *k* nearest preparing cases in the element space shown in Fig. 5. In this paper, we use Fine KNN, Cubic KNN, Coarse KNN, Weighted KNN, Medium KNN, Cosine KNN and calculate accuracy and compare each other (Fig. 6).

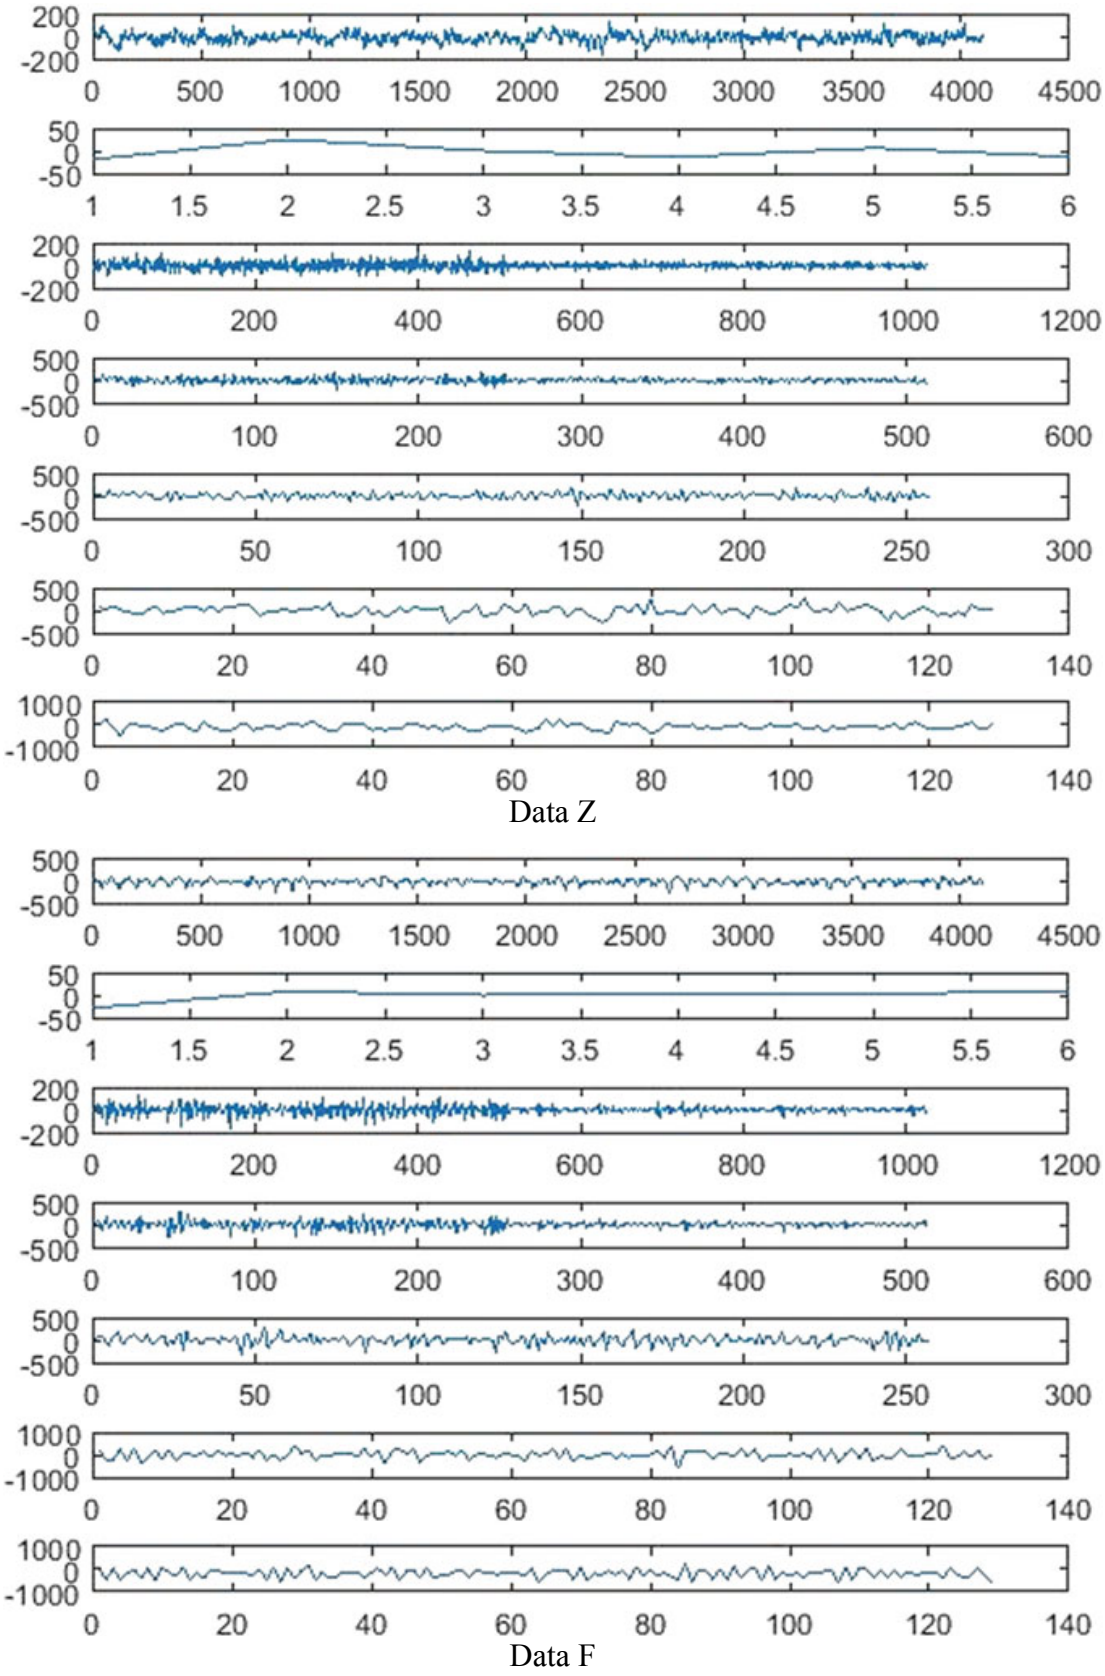

Fig. 3 Decompose dataset by using DWT

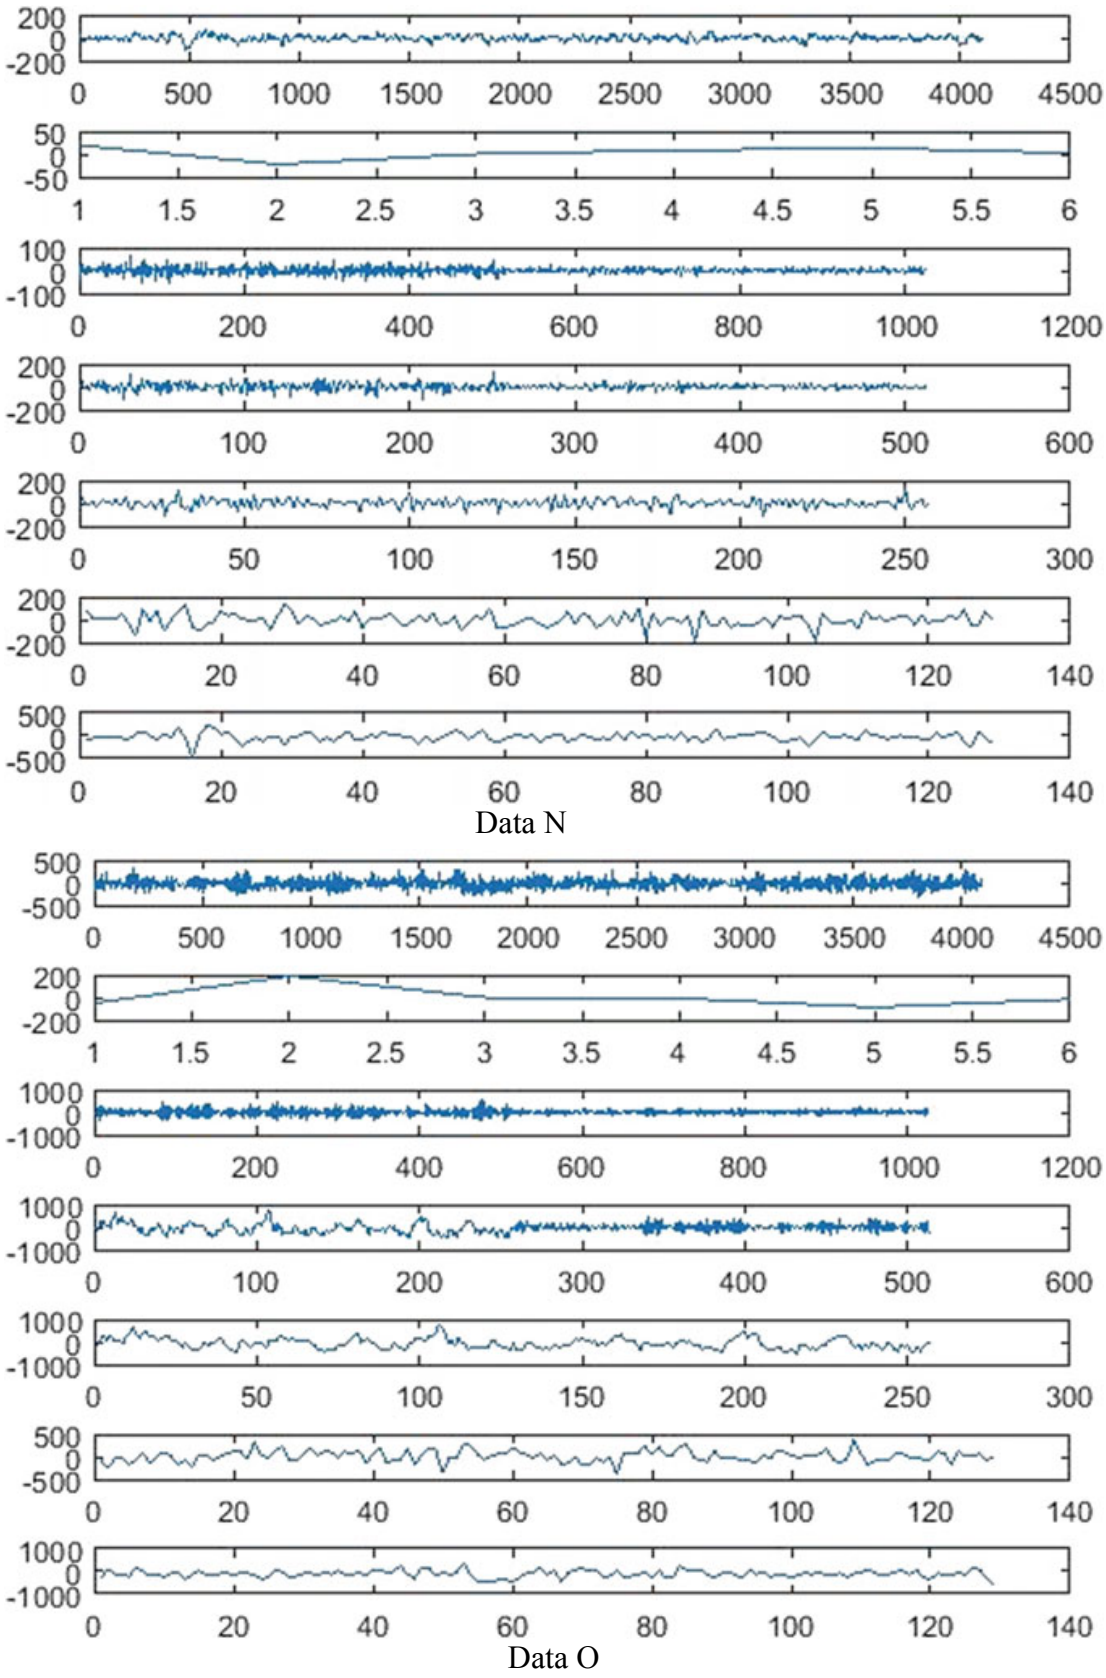

Fig. 3 (continued)

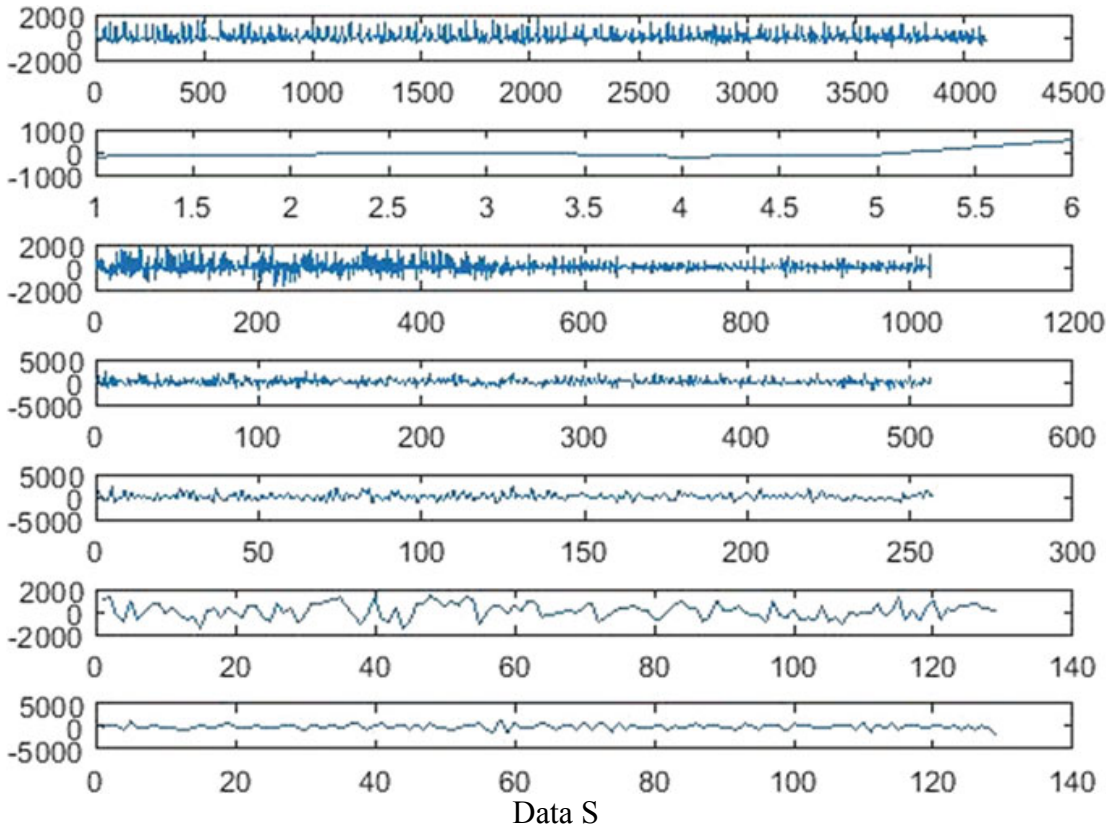

Fig. 3 (continued)

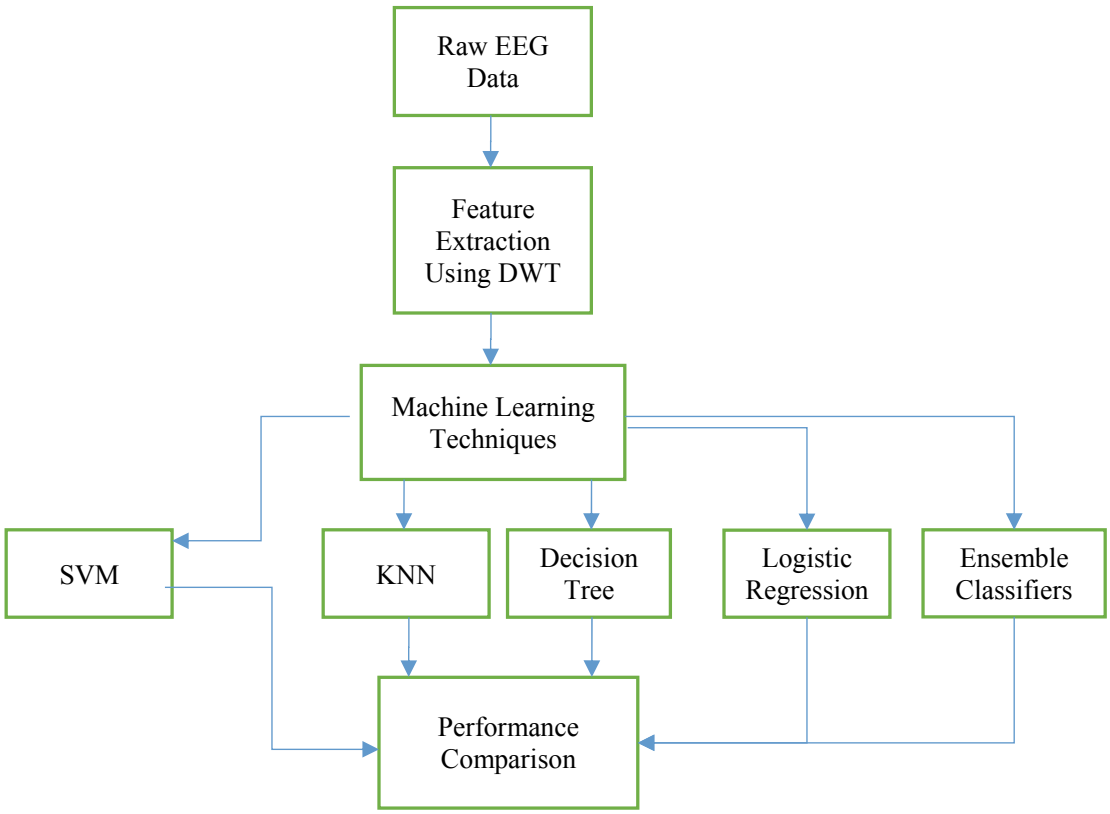

Fig. 4 Flowchart of Proposed Approach

Fig. 5 SVM Classifier [6]

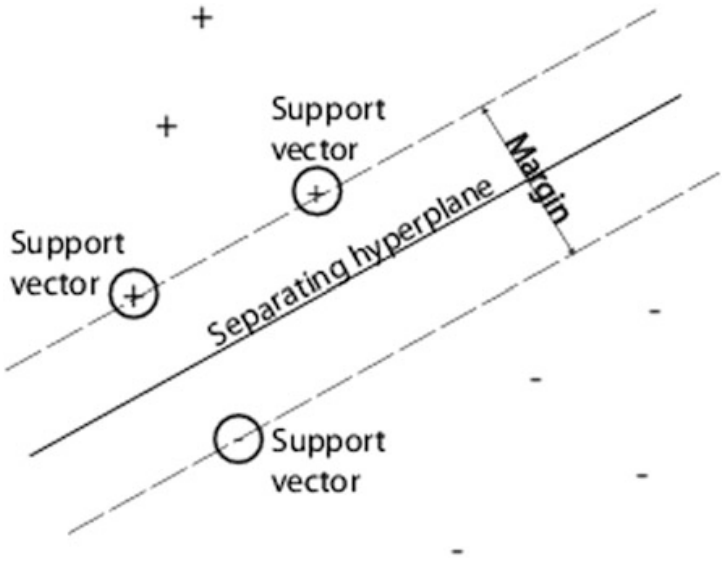

Fig. 6 KNN Classifier [10]

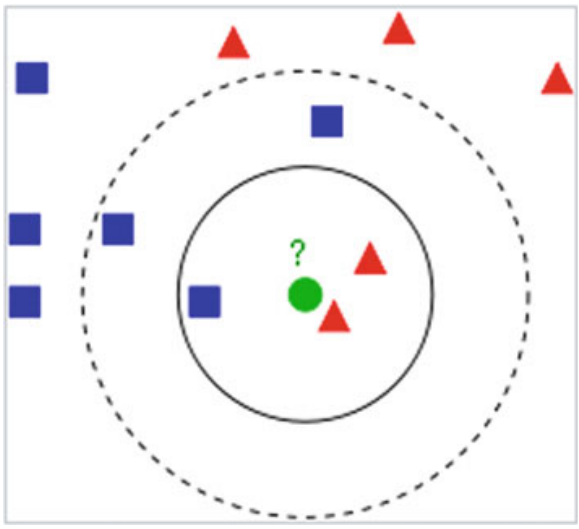

2.3.3 Logistic Regression

Logistic regression is a generally utilized factual displaying procedure in which the probability, $P1$, of dichotomist result occasion is identified with an arrangement of illustrative factors in the shape

$$\begin{aligned} \text{logit}(P1) &= \text{In}\left(\frac{p1}{1-p1}\right)\beta_0 + \beta_1 X_1 + \cdots + \beta_n X_n \\ &= \beta_0 + \sum_{i=0}^{n} \beta_i X_i \end{aligned} \tag{1}$$

In Eq. (1), β_0 is the intercept and $\beta_1, \beta_2, \ldots, \beta_n$ are the coefficients combine with the analytical variable $X_1, X_2, \ldots, X_n$. These info factors are the norm of the wavelet coefficients (D3—D5 and A5) of four-channel EEG signals [25]. A dichotomous variable is confined to two qualities, for example, yes/no, on/off, survive/bite the dust or 1/0, for the most part speaking to the event or non-event of some occasion (for instance, epileptic seizure/not). The illustrative (free) factors might be consistent, dichotomous, and discrete or blend. The utilization of common straight relapse (OLR) in light of slightest squares strategy with a dichotomous result.

2.3.4 Decision Tree

Decision tree learning is a standout amongst the usually broadly utilized and practical strategies for inductive inference. It is a technique for estimation of discrete-valued function that is hearty to uproarious information and fit for learning disjunctive expression [26].

Decision tree study is a route for looking like discrete-valued function, in which the prepared function is spoken to by a decision tree. Decision trees can likewise be spoken to an asset or it at that point guidelines to enhance human intelligibility. Decision tree study is an analytic, one-advance look forward (slope climbing), non-backtracking seek through the space of all conceivable Decision trees.

2.3.5 Ensemble Classifier

It is used for multiple learning algorithms to enhance better predictive performance. It can do increments with the number of training or splitting model flexibility. It's prediction better and memory usage is average. Here, we work on Boosted Tree, Bagged Tree, Subspace Discriminant, Subspace KNN, and RUSBoost tree ensemble classifiers.

3 Experimental Results and Analysis

From the Table 1, we can see that italic value shows the highest performance of a classifier whereas bold value shows the best classification result for a particular feature. On below graphs (Figs. 7, 8, 9, 10) and tables (Table 1 and 2) comparison of classifiers on the basis of accuracy is shown.

Table 1 Results of the implementation

4 Conclusion and Future Work

In this work Bonn University dataset which consist of five sub samples is individually subjected to all machine learning techniques i.e. SVM, KNN, Decision Tree, Logistic Regression and Ensemble classifiers. For feature extraction to increase performance we have used DWT. Our experimental result shows highest accuracy on using Fine Gaussian SVM machine learning technique on this data set.

Table 2 Compare research for detection of normal and epileptic classes

Author	Classifier	Accuracy (%)
Inan and Elif [27]	SVM	99.28
Varun and Ram [28]	Bandwidth features (BAM and BF M) and the LS-SVM	99.50
Abdulhamit [29]	Discrete wavelet transform (DWT), mixture of expert model	95.00
Kamal and Salih [30]	FFT-decision tree classifier	98.72
Yuan and Qi [31]	Nonlinear features + ELM	96.5
Our work	Fine Gaussian Support Vector Machine (SVM)	100.00

Here, we achieved highest accuracy with 100% for seizure classification and detection. Since the proposed framework was designed for limited number of EEG signals and machine learning modalities, it can also be applied and executed for a large data set and different machine learning or deep learning architectures.

Novel Approach for Plant Disease Detection Based on Textural Feature Analysis

Varinderjit Kaur and Ashish Oberoi

Abstract The image processing is the technique which can propose the information stored in the form of pixels. The plant disease detection is the technique which can detect the disease from the leaf. The plant disease detection algorithms have various steps like preprocessing, feature extraction, segmentation, and classification. The KNN classifier technique is applied which can classify input data into certain classes. The performance of KNN classifier is compared with the existing techniques and it is analyzed that KNN classifier has high accuracy, less fault detection as compared to other techniques. This paper presents methods that use digital image processing techniques to detect, quantify, and classify plant diseases from digital images in the visible spectrum. In plant leaf classification leaf is classified based on its different morphological features. Some of the classification techniques used are neural network, genetic algorithm, support vector machine, and principal component analysis. In this paper results are compared between KNN classifier and SVM classifier.

Keywords GLCM · KNN · K-means · WDDIP-KNN · Plant disease detection

1 Introduction

Agriculture helps to create wealth, improvise farmer's livelihood and decrease the rate of hunger and poverty especially in the remote areas. Agriculture plays an important role to improve the food and life security. But nowadays farming is suffering from various diseases, parasites, shortage of irrigation facilities and lack of best-suited fertilizers. Diseases are not the only reason for the downfall of farm marketing but unhygienic and improper sanitation at farms are also the major issues

for the diseases to human. Various methods are used for the detection of plant diseases in which a vast image processing techniques are used. The plant diseases can be analyzed by the texture, color, and structure of the leaf [1]. The information regarding the diseases and species of any plant or crop is given by the leaves, by studying the structure of a leaf researcher can generalize about the diseases of any crop. Since there are huge impacts of plant disease detection on the quality and quantity of the agricultural products, there is a need to study this field and present improvements such that the issues that are being faced can be eliminated. Agriculture is the field on which around 70% of the population of India relies. Appropriate fruit and vegetable crops to be grown can be chosen by the farmers from diverse choices available. However, the technicality level with which these crops are cultivated such that optimum yield and quality product can be produced, is very high. Technical support is highly useful in fulfilling these requirements. There is a need to monitor the fruit crops very closely so that they can be managed efficiently such that no diseases affect their productivity. Depending upon the high resolution multispectral and stereo images, the leaf diseases are to be detected and classified automatically and to do so several researchers have proposed various techniques. Providing a direct economical optimization of the agricultural products is not the only requirement here [2]. There is a need to ensure that the living beings or the environment is not harmed due to them. The crop production particularly needs to reduce the level at which the water, soil, and food resources are being contaminated due to the pesticides. Further, the proposed methods also need to have higher speed and accuracy to provide efficient results as per the technology advancements. The plant disease detection process includes some basic steps which are

a. *Input image* Capturing a sample image using a digital camera is the initial step of this process. Further, the features are extracted from the image to perform operations. The important features are stored initially within the database and the further processing will be performed in the next steps.
b. *Image database* In the next step, an image database is generated that includes all the images which will further be used to train and test the extracted data. The application is clearly the most important factor on which the image database is constructed. The efficiency of the classifier is responsible to decide the robustness of an algorithm and it completely relies on the image database.
c. *Image preprocessing* The operations that are performed on the images at the lowest level of abstraction are collectively known as image preprocessing. The image data is improved and the distortions that are unnecessarily present are suppressed within this process [3]. The processing and task analysis are performed with the help of image features which can be improved through this process. The information content on the image is not increased due to this process. Sufficient amount of redundancy is provided in the images with the help of this method. The brightness value, of neighboring pixels that belong to

the same real object, is also same. In the form of an average value of the neighboring pixels, it is possible to restore a pixel that has been distorted within an image. The image that has been stored within the image database is captured with the help of image preprocessing techniques as well.

d. *Feature extraction* The features that help in determining the meaning of a given sample are used for the identification and extraction of features from it. Color, shape and texture features are mainly included as image features in case of image processing.
e. *Recognition* and *classification* Training and classification are the two broader phases in which the complete recognition process is divided. The numerical characteristics of several image features are analyzed using image classification. Further, the data is categorized in an organized way through this process [4]. Training and testing are the two phases that are used by classification algorithms. The isolation of properties of basic image features is done within the initial training process. Further, a training class is introduced with the help of these isolated features, which has a unique description for each classification category. The image features are classified within the further testing phase with the help of these feature-space divisions created here.

A nonlinear classifier that is used to solve several pattern recognition issues is known as Support Vector Machine (SVM). For achieving better performance of classification, mapping of nonlinear input data is done to the linearly separated data within certain high dimensional space in SVM. The marginal distance present among various classes is increased through SVM [5]. Various kernels are used to divide the classes. Only two classes are used by SVM and to partition them, a hyper plane is defined by it. To do so, the margin that exists between the hyper plane and the two classes is maximized. Support vectors are known as the samples that are nearest to the margin and were chosen such that the hyper place could be determined.

2 Literature Review

Mattihalli et al. [9] proposed a novel approach for detecting the diseases from leaves. Here, the leaf images are taken such that few important features can be extracted which can further be used in this proposed work. A device named as Beagle bone black is used in this work which also consists of a web camera that helps in identifying diseases from the leaf samples. The device includes a database in which there are few pre-stored leaves images. This paper compares the pre-stored images with the images captures from the Beagle bone black device. GSM is used to transmit the information related to detect the diseases and operate the valves. As per the simulation results, it is seen that the proposed approach provides very low cost, user friendly and highly efficient results.

Tichkule and Gawali [10] reviewed various techniques through which plants diseases can be detected. Image processing technique is used for the detection and identification of diseases caused by bacteria, fungi, virus, and excessive use of insecticides. Therefore, this method is used to classify the diseases caused in agricultural field. The authors accurately detected and classified diseases on various plants using all above techniques. K-Means Clustering method is used to detect infected plants and Neural Networks provides the accuracy in detection and classification of diseases. So, these methods have ability to be used in Agrobot system.

Tlhobogang and Wannous [11] proposed the study that investigated the problems related to unavailability, irrelevant, and less accurate farming information. The main objective was to deal with infected plants and to diagnose them. Image analysis, convolutional neural networks and the knowledge of machine learning offer a stable and movable solution. A Science Research Methodology was used in framing the prototype. Proper and systematic studies on farmers' agricultural techniques and effect of recently on-going projects are used to understand the benefits of mobile based agricultural services. The contribution of ICT in agricultural fields, collecting, storing, and disseminating the development are required by the farmers to increase their market value.

Gandhi et al. [12] presents an image-related classification which identifies the plant diseases. As, there are many datasets used in other countries but none of them are connected to India. So, there is a need to develop a local dataset for the benefits of Indian farmers. Generative Adversarial Networks (GANs) are used to limit the number of local available images. A Convolutional Neural Networks (CNN) is employed on the smart mobile applications. This application can be easily installed in any smart phone and the farmer needs to move through the field and capture the images. This could capture the several images which can be further send to the server through which the model runs and gives the classification.

Khan et al. [13] presented multilevel segmentation method in which initial segmentation is performed using expectation maximization algorithm. In this method, there is a very few chances of information loss. Finally, a region is taken out from the quantized image by empowering the binary partitioned tree which is further used in principle Eigen vector. Post processing methods are used to eradicate the useless fragments and to resolve the image labeling problem. When the salient region of the image belongs to single class this technique is mostly used. The new cascaded design in primary color segmentation with the confirmation of infected regions extractions gives the experimental analysis.

3 Research Methodology

This research work is based on the detection of plant disease. To detect plant disease with the proposed technique following steps are followed

1. *Preprocessing* The image is taken as input on which disease need to detect. The image is converted to the grayscale for the feature extraction.
2. *Feature extraction* In the second phase the algorithm of GLCM is applied which can extract features of the input image and store in the database. A tabular description which shows the number of times various combinations of pixel brightness values occur within an image is known as Gray-Level Co-occurrence Matrix. The locations of pixel that has alike gray level values are presented by GLCM [7]. The pairs of gray level values are provided as input from GLCM calculation units. When the original and predictive images are compared, the deviation present in them is presented here. The relationship among two neighboring pixels is considered within GLCM. The initial pixel is called the reference pixel whereas the neighbor pixel is known to be the second one. A two dimensional array in which a set of possible image values are presented in rows and columns is known as a co-occurrence matrix.
3. *Segmentation* The k-mean segmentation algorithm is applied which can segment input image into certain parts. K-means is the data clustering algorithm in which the numbers of clusters within the data are pre-specified is known as k-means algorithm. A trial-and-error method in which appropriate numbers of clusters for particular data set are identified has made it difficult to define correct clustering method [8]. Through the selection of K value, the performance of a clustering algorithm is affected. Thus, there is a need to adopt a set of values instead of using a single predefined K. For reflecting the special properties of data sets, the consideration of large number of values is important. Further, in comparison to the number of objects present in the data sets, there need to be less number of selected values.
4. *Classification* The classification detects the name of the disease with which plant is affected. The system is training with the number of images and test set is given as input after extracting image features. The Proposed Model (WDDIP-KNN) classifier is applied to detect the disease name and flow chart is blow. A classifier, that performs classification through the recognition of neighbors that are closest to the query examples, is known as k-Nearest Neighbor. The class of query is determined with the help of these identified neighbors. In this algorithm, on the basis of the least distance present between the given point and other points is calculated which is then used to perform classification that helps in determining the class within which a particular point belongs [6]. There is no training process involved within this classifier. Since, the robustness to noisy data for this classifier is zero it is not applied within very large number of training examples. The calculation of Euclidean distance between the test and training samples is done which is further used within plant leaf classification. Thus, similar measures are identified in this manner which further helps in identifying the class for test samples as well (Fig. 1).

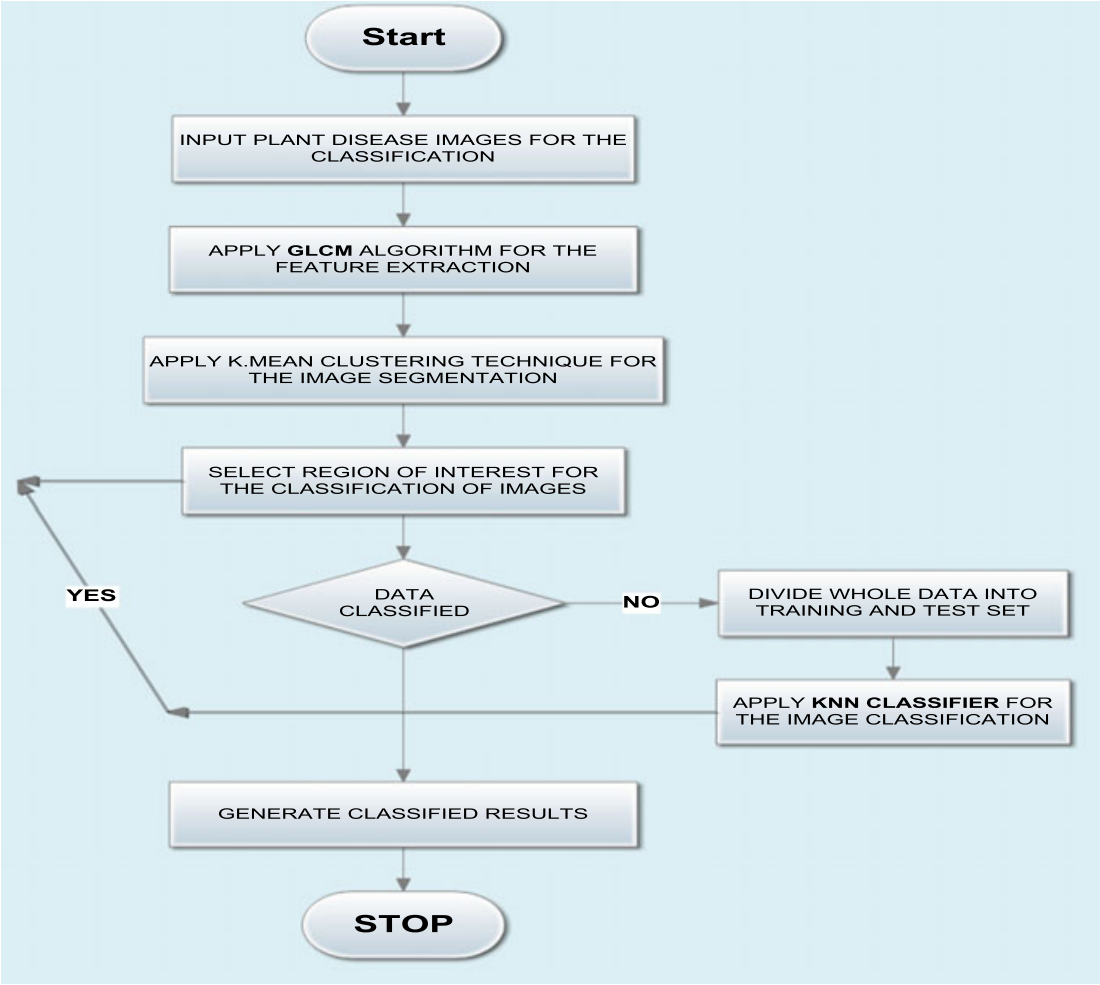

Fig. 1 Proposed model (WDDIP-KNN) control flow

4 Results and Discussion

The technique is proposed for the plant disease detection based on feature detection and classification. The GLCM algorithm is applied for the feature extraction. The k-mean clustering is applied for the image segmentation and KNN algorithm is applied for the disease classification. The Data set of about 25 images is taken as input to prepare the training set. The results are analyzed in terms of certain parameters which are described below.

As shown in Fig. 2, the fault of the proposed and existing algorithm is compared for the performance analysis. It is analyzed that proposed KNN technique has less faults as compared to existing technique SVM (Table 1).

$$\text{Fault Detection Rate} = 100 - \text{accuracy}$$

5 Conclusion

In this work, it is concluded that plant disease detection is the technique (WDDIP-KNN) which is applied to detect disease from the plants. The technique of plant disease detection has various steps like feature extraction, segmentation, and classification. In this paper, novel technique(WDDIP-KNN) is proposed based on the GLCM algorithm for the feature extraction, K-mean segmentation is applied for the image segmentation and KNN classification technique is applied for the disease classification. The performance of proposed algorithm is compared with the existing algorithm in terms of accuracy and fault rate. It is analyzed that KNN classifier has high accuracy and less fault rate as compared to existing technique.

Novel Approach for Brain Tumor Detection Based on Naïve Bayes Classification

Gurkarandesh Kaur and Ashish Oberoi

Abstract The brain tumor detection is the approach which can detect the tumor portion from the MRI image. To detect tumor from the image various techniques has been proposed in the previous times. The technique which is adapted in research work is based upon morphological scanning, clustering, and Naïve Bayes classification. The morphological scanning will scan the input image and clustering will cluster similar and dissimilar patches from image then Naïve Bayes classifier spot the tumor portion from magnetic resonance imaging. The advance algorithm is implemented in MATLAB and results are analyzed in terms of PSNR, MSE accuracy, and fault detection and also calculate overlapping area with dice coef. The proposed method has been tested on data set with more than 25 slide scanned images. This proposed method achieved accuracy with 86% best cell detection.

Keywords Brain tumor · Clustering · MRI · Morphological scanning · Naïve Bayes NBC-BTD model

1 Introduction

Several lives have been affected because of a common brain disease known as brain tumor. The patients suffering from this disease have not survived in most of the cases. For fighting this disease, several techniques have been proposed such that the knowledge related to medicine can be expanded and one can understand calculations in a better manner such that the tumor can be detected. Due to the high complexity of brain images and the fact that only expert physicians can analyze the tumors, brain tumor detection is a challenging task within medical image processing [1]. To detect brain tumor from various images, the two most common tests that are

applied are Magnetic Resonance Image (MRI) and Computer Tomography (CT) scan of brain. Further, to perform various treatments, the location of tumor is also identified through this technique. To heal brain tumor, several treatment techniques are proposed today such as radiation therapy, chemotherapy as well as surgery. On the basis of size, type of tumor as well as its grade, the treatment type is chosen. To check whether other parts are being affected by this tumor or not, it is also important to perform certain analysis. When the appropriate treatment method has to be chosen by the doctor, there are certain factors that are to be considered. The possible side effects of a treatment, consideration of complete health and checking whether the central nervous system is affected due to the tumor or not, are few of these factors. Radio imaging is the most commonly applied technique within MRI due to its dynamicity and flexibility [2]. Various pulse sequences and modification in imaging parameters that are based on Longitudinal Relaxation Time (LRT/T1) and Transverse Relaxation Time (TRT/T2) are used to perform acquisition of variable image contrast. Particular tissue properties are provided in relevance to signal intensities provided on the weighted images T1 and T2. On the basis of pulse sequence parameters, the contrast on MR images is provided. For knowing the details of structures of various organs of the body such as liver, chest, and brain, MRI imaging of the body is done. The treatment can be monitored in the patient efficiently with the help of this approach. There are certain steps performed in order to identify the tumor in the patient's body [3]. Preprocessing, segmentation, feature extraction as well as classification are the commonly applied steps. The MRI samples are gathered at the initial stage.

a. Preprocessing and Enhancement: The chances that a suspicious region can be detected can be improved through this initial step being performed in image processing. From the image, the noise is eliminated and finer details are extracted. The accuracy of an image is minimized when noise is present within the MRI image. The noise is removed by applying different filters on the image. The filters are also applied to sharpen the image. Since the detection of boundary of tumor can be done more effectively and easily, it is important to sharpen the image with the help of various low pass filters once the noise has been completely eliminated from the images.
b. Segmentation methods: The procedure where the image is broken down to smaller parts and segments is known as image segmentation. The analysis can be performed in easy manner through this step. Several image segmentation methods have been developed over the time. The approach in which the object boundaries are assumed to be defined by the detected edges and which further helps in recognizing these objects is known as edge-based segmentation approach [4]. There is a need to achieve very distinct and closed boundaries to perform direct segmentation which can be done through this approach. False edge detection can occur many times and the partial edges can be joined within an object boundary through edge linking process. The approach in which the bordering pixels present in one area assume to have similar values is known as region based approach. Instead of identifying the edges, the identification of

object region is more important in this case. The pixels are compared with the neighboring pixels. The pixels is said to belong to the cluster in the form of one or more of its neighbors in case when the congruence criteria is satisfied.

c. Feature Extraction: To detect brain tumor from images, the extraction of exact tumor image is very important since the structure of brain is very complex [5]. In order to extract certain features, it is important to consider few parameters. The tumor can easily be classified with the help of results achieved from feature extraction process.

2 Literature Review

Kaur et al. [11] analyze technique of Magnetic Resonance Image (MRI) for brain tumor detection. It shows difficult structure of brain cells with thin network. It also considers solid growth. If we want to study the growth we need to study the fragmentation process, which is a huge disadvantage. This disadvantage can be solved by clustering technique. For this extraction of segmented brain tumor from its area a sobel edge detection is used. In clustering technique, the no of clusters is counted by computing them on the peak of histogram. The size and location can be analyzed by the segmented part of the binary image. The final fragmented part is then use to analyze size and perimeter of the tumor. It concludes that. The brain tumor can be detected using MRI and clustering techniques. So, it is used on the nature of image and the number of peaks, the clusters can be computed.

Hazra et al. [12] reviewed detection and localization of tumor region present in the brain by using patient's MRI. It contain three levels namely, preprocessing, segmentation, and edge detection. Preprocessing converts the original image into grayscale image and eradicates noise if any which further followed by the edge detection using Sober and Canny algorithms with technique of image enhancement. The segmentation is applied to display the tumor affected region. Lastly, the clustering algorithm is used for the image clusters. It results identification of the brain tumor is done efficiently using MRI and K-means algorithms. In order to detect the tumor more accurately the algorithms can be improvised.

Chauhan et al. [13] proposed preprocessed median filtering MRI brain images. In order to separate the area from image- and color-based segmentation and edge detection is done. Histogram of oriented gradients and gray level co-occurrence matrix is used to represent the images. The respected extracted features are stored in the transactional database to classify the tumor into normal benign. The classified accuracy is being calculated 86/6%. This summarized that the proposed system help to know about the type of brain tumor and its further treatment. This system has been successfully tested on the large-sized brain scanned images of brain tumor.

Reema Mathew et al. analysed that the Magnetic Resonance Image (MRI) is effective technique of the brain tumor detection and classification. This classification is done in various steps like preprocessing, filtration of sound, feature

extraction, and segmentation. These methods preprocessed the MRI brain image using anisotropic diffusion filters. The discrete wavelet transforms are extracted in the feature extracted step. These features are further given as the input to the segmentation step. A support Vector Machine was used segmentation and tumor classification. Hence, it concludes that the accuracy of proposed system is 86%. The validation of this method with the recent results can be used in the future proposals.

3 Research Methodology

This research work is relies on brain tumor detection.

The technique to detect tumor are based on following steps:

Step 1: Morphological Operations:

The process through which the structure or shape of an object can be deformed or reconstructed is known as morphology. For the representation of shape of an object, the operations that are applied on binary images are known as morphological operations. While performing pre or post processing, these operations are applied such that the shape of objects or areas can be known in more appropriate way. Following are few of the most commonly used morphological operations:

a. Erosion: The operation with the help of which the boundaries of areas of front-end pixels are eroded from the binary images is known as erosion. In terms of size and holes present within it, the regions of foreground pixels are shrunk. There are two inputs given here [6]. The image is eroded within the initial input and the structuring element is given as the second input. The structuring element place upward of given image such that the erosion of binary image can be calculated. Thus, the origin of structuring element and input pixel coincide with each other.
b. Dilation: The approach through which the holes are filled by adding the pixels to the boundaries of objects present within the image is known as dilation. Two pieces of data are taken as input in this operator. Image is dilated in the initial one and elements are structured in the second one. On the input image, the structuring element is placed for every background pixel such that the given image pixel position and structuring element coincide [7]. Increase the area of foreground pixels is the basic effect of dilation on the binary image. There is a complete closing up of the operation however, in this operation which is its only demerit. There are several classifiers used in the process of detection brain tumor from images. A data structure in the form of a tree is created within a decision tree classifier. On the basis of one particular feature, each interior node that includes decision criteria is based. The entropy reduction that presents the purity of samples is used to calculate the features that are in relevance to classification [8]. The classifier through which two classes are separated using a hyper plane is known as Support Vector Machine (SVM). From the empirical data, an optical

function can be calculated in case when the classes are separated by hyper plane. A basic feed forward based artificial neural network classifier was introduced known as multi-layer perceptron classifier. For performing simple functions, a single hidden layer is used here at first. Further, to improve the classification performance, two hidden layers were included here. For every data set, different hidden units were selected. Across a number of trails, the numbers of hidden neurons were identified. Back propagation algorithm was used to train the neural network.

c. Clustering: In image processing is basically defined as the technique in which groups of identical image primitive are identified. Clustering is a method in which objects are unified into groups based on their characteristics. A cluster is basically an assembly of objects which are similar between them and are not similar to the objects fitting to additional clusters. C-mean clustering is mainly assigning points to cluster or class. In this clusters are mainly indentified by similarity measure, in terms of distance, connectivity and intensity. Moreover, in this technique, each data point belongs to more than one cluster.

Step 2: Naïve Bayes Classifier: Naive Bayes algorithm is effective method of text classification. It works on large training sample set and gives an accurate result. It is a probabilistic classifier based on Bayes theorem with independent assumption which assumes the presence of particular features of a class is unrelated to presence of other features.

Naive Bayes classifier is a simple probabilistic classifier based on applying Bayes' theorem (from Bayesian statistics) with strong (naive) independence assumptions. A more descriptive term for the underlying probability model would be "independent feature model". In simple terms, a naive Bayes classifier assumes that the presence (or absence) of a particular feature of a class is unrelated to the presence (or absence) of any other feature. The morphological scanning technique will scan the image and technique of Naïve Bayes is applied which mark the tumor in the image. The classifier that includes all independent attributes when the value of class variable is given is known as Naïve Bayes classifier. Conditional independence is another name for this classifier and it is known to be the easiest form of Bayesian network [9]. Here, the Bayes' theorem is applied along with the naïve assumption that shows the independence among every pair of features within the set of supervised learning algorithms. Following relationship is stated by the Bayes' theorem:

$$P(y|x_1,\ldots,x_n) = \frac{P(y)P(x_1,\ldots,x_n|y)}{P(x_1,\ldots,x_n)} \tag{1}$$

Here, y is a class of variable and from x_1 to x_n a dependent feature vector is included.

PSNR and MSE: The PSNR signal is used to measure the quality of loss and lossless compression (e.g., for image compression). The peek signal used original data. The noise is the error introduced by compression. When comparing

compression codecs, PSNR is an approximation to human perception of reconstruction quality. Although a higher PSNR generally indicates that the reconstruction is of higher quality. When PSNR signal is maximum, the MSE signal is minimum (Fig. 1).

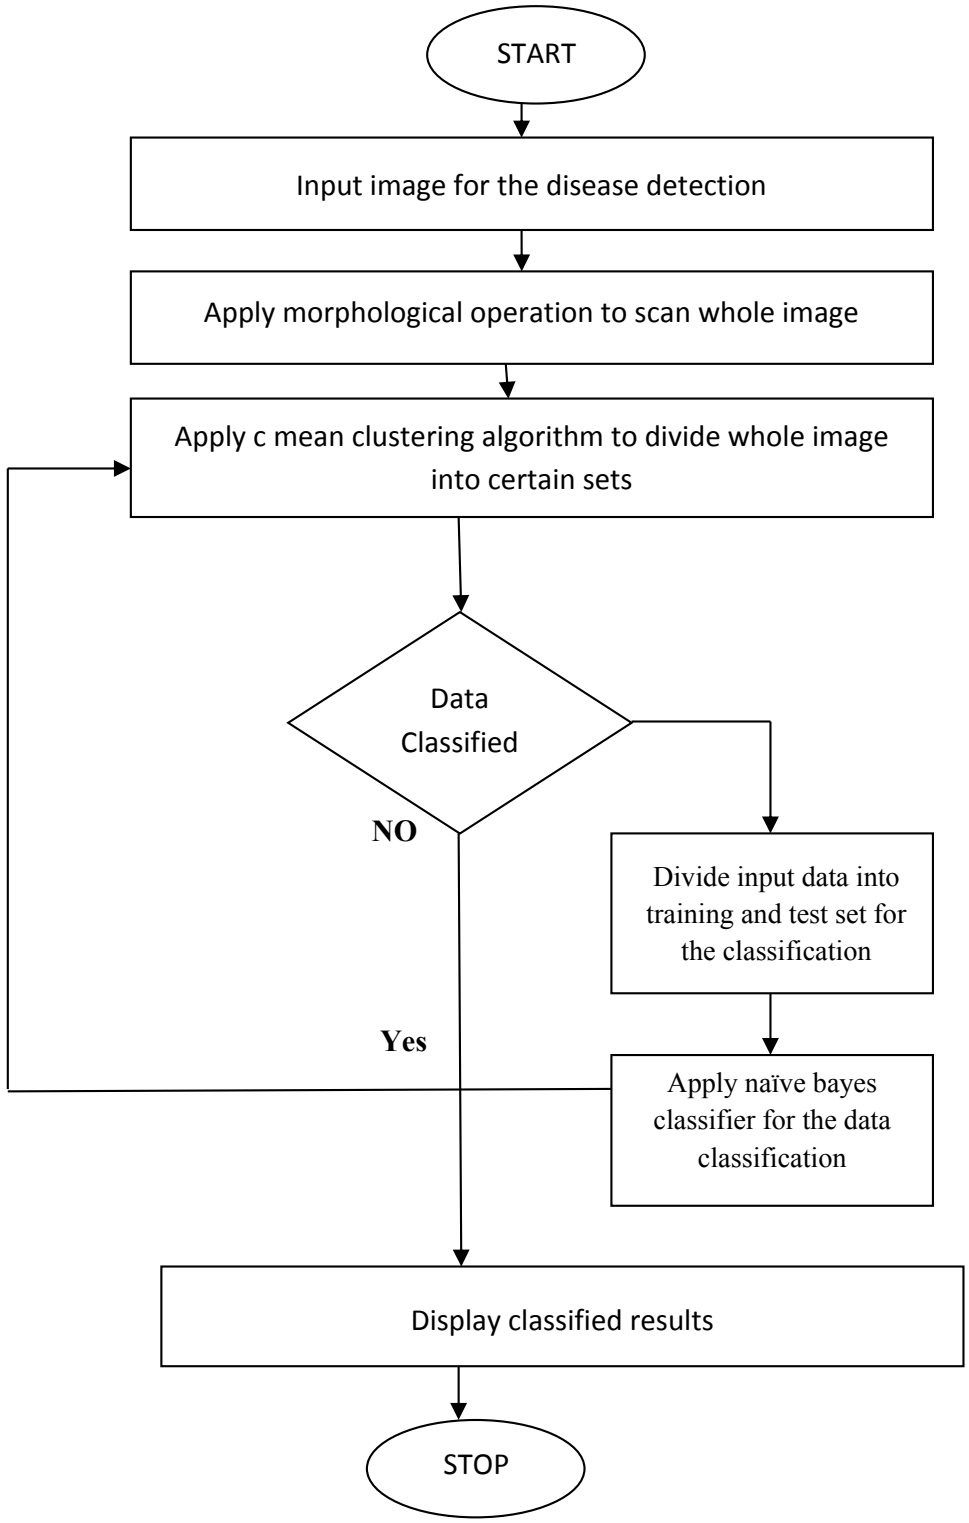

Fig. 1 Proposed flowchart NBC-BTD (brain tumor detection)

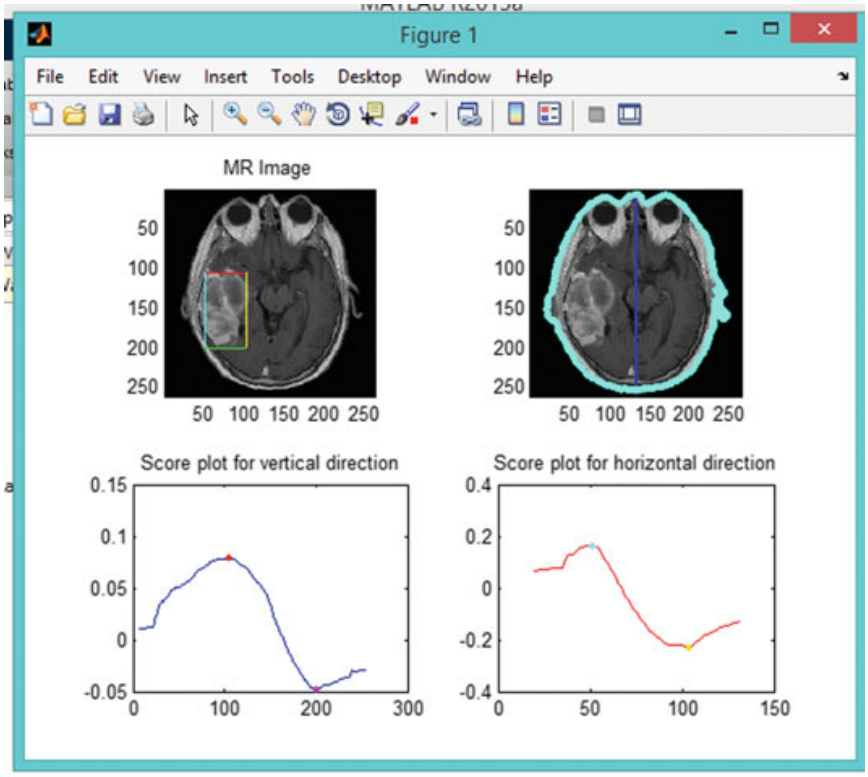

Fig. 2 Naïve Bayes classifier

Result and Discussion: This research work was based on the brain tumor detection; the 20 images taken from data respiratory set. To detect tumor from the MRI images technique of classification was applied. Input the test data for tumor detection, applied in the morphological operations; divided input class into training set; then classified the data. The technique of Naïve Bayes classifier NBC-BTD model marks the tumor portion in the image with horizontal and vertical plot with segmented tumor area. The tumor region grew which segmented tumor would portion from non-tumor region. That gave false positive and negative rate.

As shown in Fig. 2, the technique of Naïve Bayes classifier was applied which marked the tumor portion on the image. The vertical and horizontal position was also calculated from the input MRI Image (Fig. 3; Table 1).

The PSNR value of the Advance and previous research algorithm has compared for the performance analysis. It has analyzed that PSNR value of advance algorithm was high as that to previous research algorithm (Fig. 4; Table 2).

The MSE value of advance and previous research algorithm is compared for the performance analysis. It is analyzed that MSE value of advance algorithm is less as compared to previous research algorithm (Fig. 5; Table 3).

The accuracy value of the advance and previous research algorithm was compared for the performance analysis. It was analyzed that proposed algorithm has high accuracy as compared to previous research algorithm (Fig. 6; Table 4).

The fault detection rate value of the present and previous research algorithm was compared for the performance analysis. It was analyzed that present algorithm has high fault detection as compared to previous research algorithm.

4 Conclusion

In this work, it is concluded that image processing is the technique which can process information stored in the form of pixels. The brain tumor detection is the technology which can detect tumor portion from the MRI image of brain. In this research work, novel technique is proposed which is based on the morphological operation and Naïve Bayes classifier and clustering techniques. The performance of present algorithm is collate with past and it is analyzed that present algorithm performs well in terms of PSNR, MSE, and accuracy and fault detection with 86% ratio.

Automatic Classification of Carnatic Music Instruments Using MFCC and LPC

Surendra Shetty and Sarika Hegde

Abstract With a large collection of digital music in recent days, the challenge is to organize and access the music efficiently. Research in the field of Music Information Retrieval (MIR) focuses on these challenges. In this paper, we develop a system which automatically identifies the instrument in a given Carnatic music on ten different types of instruments. We extract the well-known features namely, MFCC and LPC, and analyze the capability of these features in distinguishing different instruments. Then, we apply, the classification techniques like, Artificial Neural Network, Support Vector Machine, and Bayesian classifiers on those features. We compare the performances of those algorithms along with different features for Carnatic music instruments identification.

Keywords Audio data mining · Carnatic music · Instrument classification · MIR

1 Introduction

Music Information Retrieval (MIR) research explores the different applications involving the retrieval of contents or information from a given music which can be useful for categorizing and indexing music. Due to rapid increase in digital media collections, organization and accessing of the music from large collection has become one of the challenges. Usually, metadata is used to label and segment the songs and is used to search and access a particular music. But this process needs lot of manual intervention for preparing metadata and labeling process which is not so

efficient. Hence, this process can be automated using Machine Learning techniques including both labeling and searching. The digital music may be labeled based on instrument type, singer, genre of music, etc.

Lot of research has been done in this area on western music for content-based information retrieval. However, research on Indian music started very recently with mainly Raga identification as focused application. Instruments like Harmonium, Tabla, etc., are integral part of Indian music. The instrumental music is very melodic and pleasant, played in important Indian occasions like, marriage, festivals, funeral. The Indian instruments can be divided into three types, rhythmic instruments, wind instruments and string instruments. In our paper, we have selected the wind and string types of instruments and applied machine learning technique for automatic identification of instrument. The basic steps include preprocessing and feature extraction from audio, visualizing the features and applying classification algorithms. The set of standard audio features namely, Mel-frequency cepstral coefficient (MFCC) and Linear Predictive Coefficient (LPC) are used. We compare the capability of these features in representing an instrument. The research work in this paper explores the following objectives,

1. Extraction of MFCC and LPC features
2. Analysis of suitability of features through visualization
3. Classification of audio features using Artificial Neural Network (ANN), Bayesian classifiers, and Support Vector Machine (SVM)
4. Comparison of classifiers performance based on classification accuracy.

The content discussed in this paper is organized in five sections. We briefly discuss the literature works on MIR in second section. The methodology and the techniques used in our work are described in third section. The method of experiments and the corresponding results is covered in fourth section which is followed by conclusions in fifth section.

2 Background

Martin and Kim [13] have applied statistical pattern recognition technique for instrument identification. They have demonstrated the usefulness of organizing the musical instruments hierarchically for identification and illustrated the usefulness of timbre feature for this application. An automated system for signer identification from western music is proposed by Kim and Brian [12]. The music is first analyzed to extract the vocal segments and then the singer is identified using GMM and SVM algorithms. Similar work is proposed in Zhang [25] using a statistical model with 80% accuracy. MFCC feature with 32 coefficients is used to characterize the voice of singer and further classified using Neural network in Mesaros and Astola [15]. SVM algorithm along with LPC feature is used by Chetry and Sandier [4] for classifying six instruments successfully. Benetos et al. [3] have performed

instrument identification experiments on large dataset with 20 instruments using variety of classifiers and have reported accuracy ranging between 88.7 and 95.3%. Usefulness of MFCC coefficients for identification of instruments in monophonic signals is investigated in Sturn et al. [21]. A new nonlinear method involving the fractal theory is proposed by Zlatintsi and Maragos [26] for instrument identification. Polyphonic signals are considered in Giannoulis and Klapuri [7] using local features and missing features for instrument identification. Gaussian mixture model based semi supervised learning algorithm is applied on instrument identification by Diment et al. [5].

A continuous polyphonic music is analyzed to perform two tasks namely, automatic music transcription and instrument assignment by Giannoulis et al. [8]. Factorial Gaussian Mixture-HMM (F-GM-HMM) algorithm is used by Hg and Sreenivas [11] for solving the problem instrument detection in a given polyphonic music. Uhlich et al. [24] have used deep neural network for extracting instrument from music. Isolated Instruments identification from noisy clips has been proposed by Mukherjee et al. [16] using the statistical feature LPCC-S which is computed well-known method, Linear Predictive Cepstral Coefficient. Banerjee et al. [2] have proposed a novel approach for string instrument identification using frequency and wavelet domain analysis and the classification algorithms namely, k-NN and random forest method. A very detailed review on Music Information retrieval, its applications and the related work is described in Murthy and Koolagudi [17].

3 Methodology and Techniques

The instrument classification problem can be solved using Machine Learning algorithms. The input is an instrumental audio and the output is the label corresponding to the identified instrument. Before giving the input to Machine Learning algorithm, the input needs to be processed using Digital signal processing technique for extracting the features. In this section, we discuss briefly about the considered dataset, the feature extraction techniques and classification algorithms used in our experiment.

3.1 Dataset

There is no standard benchmark dataset for Indian instrumental music recordings. We collected few CD's consisting of music. From these songs, we extracted the first portion with duration in the range of 2 s–3 min based on the availability. The collection of recordings prepared in this manner consists of instruments namely, *Flute, Harmonium, Mandolin, Nagaswara, Santoor, Saxophone, Sitar, Shehnai, Veena and Violin.* We collected up to 15 audio clips of each instrument category with total number of audios as 150.

3.2 Audio Data Preprocessing and Feature Extraction

To extract useful information from audio which is a non-stationary data, we apply "framing". It is a mechanism of dividing the audio into smaller chunks of duration of 10–30 ms along with overlapping and windowing. Overlapping is done to ensure continuity in the data and windowing is done for smoothening the data at the edges. Each frame is then processed to extract the audio features namely, Mel-Frequency Cepstral Coefficient (MFCC), Linear Predictive Coefficients (LPC). We get a features vector of size "*d*" after applying feature extraction technique. The feature for each frame may be denoted as $\mathrm{FV} = \{\mathrm{fv}_1, \mathrm{fv}_2, \ldots, \mathrm{fv}_d\}$. The set of features extracted from all the recording is further used as input for Machine Learning algorithms.

a. *Mel Frequency Cepstral Coefficients (MFCC)*

It is a well-known feature used in the areas of speech recognition, MIR applications [9, 20]. This feature simulates the behavior of human ear where the time domain signal is first converted into frequency domain signal using discrete Fourier algorithm. The computed power spectrum from DFT coefficients are filtered using a set of triangular filters with mel-scale spacing. In the last step, inverse Fourier transform is applied by computing DCT from logarithm of Mel-spectrum given as

$$C_i = \sum_{k=1}^{K} (\log S_k) \cdot \cos\left(\frac{i\pi}{K}\left(k - \frac{1}{2}\right)\right) \quad i = 1, 2, \ldots, K \tag{1}$$

Here, the value C_i is the ith MFCC coefficient computed, S_k is the output from kth filterbank channel and K is the number of filterbanks used in the set of triangular filters [19].

Using this technique, 12 MFCC coefficients and its first/second derivative can be computed. The number of coefficients to be used is not fixed. Depending on the requirements of application, number of MFCC can be changed. Most of the time 12 MFCC's are used. Less number of MFCC makes the model simple. Aucouturier and Pachet [1] in their work have used *eight* MFCC coefficients. In our work, we have experimented with less than eight. The MFCC feature is computed using Auditory Toolbox [20]. Out of the 12 coefficients computed, we consider first *six* coefficients.

b. *Linear Predictive Coefficients (LPC)*

The time domain signal of a given audio can be analyzed using Linear predictive analysis tool to extract features from it. This tool is found to be very useful in signal processing applications. In this technique, each sample is defined with the weighted sum of previous "*d*" samples. The weights assigned to each previous sample are termed as LPC coefficient which is unknown term. The predicted value for a sample is given as [18]

$$\widehat{s(k)} = \sum_{i=1}^{d} a_i s(k-i) \tag{2}$$

Here, the $\widehat{s(k)}$ is a predicted value for kth sample, $s(k-i)$ is the sample value at index $(k-i)$. The coefficient a_i is an unknown term. We get such equations with linear combinations for all the samples in the frame where a_i's are unknown and to be computed. The constraint for computing a_i's is that the difference between the actual sample $s(k)$ and the predicted sample value $\widehat{s(k)}$ termed as Mean Squared Error (MSE) must be as minimum as possible. This is a least square problem which can be solved using normal equations.

Using this mechanism, we get "d" LPC coefficients which are equal to 13 by default. To keep the number of MFCC's and LPC's same, we consider only first *six* LPC coefficients. For a given frame f_i, the set of six LPC coefficients is represented as, $\mathrm{LP} = (\mathrm{lp}_1, \mathrm{lp}_2, \mathrm{lp}_3, \mathrm{lp}_4, \mathrm{lp}_5, \mathrm{lp}_6)$. This LP is used as the feature vector (FV) for discriminating different classes of audio signal in further experiments.

3.3 Machine Learning Algorithms

Classification is a task under Machine Learning algorithm with an objective to assign a given feature vector to one of the known class labels [6]. In our system, the given input is a feature extracted from audio and the label assigned is one to ten corresponding to the ten instruments. The dataset is first divided into training and testing set. The training set is used to construct ML model and the testing set is used to evaluate the performance of ML model. We use three algorithms, namely, Artificial Neural Network, Support Vector Machine, and Bayesian classifier which is discussed in his section.

a. *Artificial Neural Network (ANN) Classifier*

Artificial Neural Network is one of the popular Machine Learning algorithms mimics the behavior of human brain. It is a network of computing elements known as Neurons. The working of single neuron has two components, summation and activation function given as,

$$y = \frac{1}{1 + e^{-(\sum_{j=1}^{p} w_j x_j)}} \tag{3}$$

where x is an of "p" dimension and w is the weight corresponding to each input. The neurons can be arranged in layers. The three types of layers in ANN are, input layer, hidden layer, and output layer [6]. The number of hidden layers may be zero or more. The number of neurons in input layer is same as the number of feature (p) and in output layer is same number of class labels (10). The number of hidden

layers and number of neurons in hidden layer need to be decided through trial and error. In our work, we have one hidden layer with same "p" neurons. The following algorithm shows the usage of ANN in our work.

```
ALGORITHM 3.1: Training and Testing steps using ANN
// The algorithm takes dataset of feature vectors as input and generates the accuracy of classification using ANN
algorithm
//Input: D is a dataset (features vector along with target label)
//Output: m (Confusion matrix)
dataset=D;
[training_set   testing_set]=hold_out(dataset);
//Training the ANN
x=Store all the set of feature vectors of training set
y=Sequence of class labels in training set
c=no_of_class
//Each row in T represents the binary pattern of the corresponding value of y
For each row in y
    Initialize the T(i) to 'c' number of zeros
    Set the value of T(y(i))=1
End
network=trainANN(x,T);
//Testing the ANN
For each row from testing set
        FV=feature vector
        output_array=testANN(network, FV); / / list of values from Output neuron
        pos=index of maximum value in output_array
        predicted_target_label=pos;
        m(actual_target_label, predicted_target_label)= m(actual_target_label, predicted_target_label)+1
end
```

b. *Support Vector Machine (SVM)*

This is a supervised machine learning algorithm which constructs a hyperplane that can separate the feature vector of one class with feature vectors of all other classes. Out of the different possibilities of hyperplane, the one with widest margin is selected as classifier called Maximal Margin Classifier [23]. Let us consider a set of training observations, given as $(\boldsymbol{x_i}, y_i)$ $(i = 1, 2, \ldots, k)$ where $\boldsymbol{x_i} = \left(x_{i1}, x_{i2}, \ldots, x_{ip}\right)^{\mathrm{T}}$ corresponds to the feature vector (MFCC or LPC) for the ith input observation and $y_i \in \{-1, 1\}$ denote its class label. SVM is a two-class classifier which constructs a hyperplane separating the observations from two class. In our paper, *ten* hyperplanes will be constructed. For each instrument, a constructed hyperplane will separate the observations of that instrument from all other instruments [10]. The decision boundary (hyperplane) can be defined as follows,

$$\boldsymbol{w} \cdot \boldsymbol{x} + b = 0$$

The parameters **w** and b need to be estimated in training phase for a given dataset. Since the hyperplane need to maximal, the constraint and objective function to be minimized for computing the parameters is given as,

$$\begin{aligned} \boldsymbol{w} \cdot \boldsymbol{x} + b \geq 1 \quad \text{if } y_i = 1 \\ \boldsymbol{w} \cdot \boldsymbol{x} + b \leq -1 \quad \text{if } y_i = -1 \\ f(w) = \frac{\|\boldsymbol{w}\|^2}{2} \end{aligned} \tag{4}$$

The following algorithm illustrates the steps followed for using SVM algorithm in our work.

ALGORITHM 3.2: Pseudo code for SVM algorithm

```
// The algorithm takes dataset of feature vectors as input and computes the accuracy of classification
using SVM algorithm
//Input: D is dataset (feature vector along with target label)
//Output: m (Confusion matrix)
dataset=D;
[training_set   testing_set]=hold_out(dataset);
//Training the SVM
x=Store all the set of feature vectors of training set
y=Sequence of class labels in training set
c=no_of_class
Apply Gaussian kernel function to x
[xsupport, w, b]=trainSVM(x,y);
//Testing the SVM
For each row from testing set
        FV=feature vector
        predicted_target_label =testSVM(FV, xsupport,w,b);
        m(actual_target_label, predicted_target_label)= m(actual_target_label,
predicted_target_label)+1
end
```

c. *Bayesian Classifier*

Bayesian classifier works based on conditional probability. Posterior probability using Bayes theorem is computed for an feature vector x given as,

$$p(c_j|x) = \frac{p(c_j)p(x|c_j)}{p(x)} \tag{5}$$

where

$$p(x) = \sum_{j=1}^{c} p(w_j)p(x|w_j) \tag{6}$$

The posterior probability $p(c_j|x)$ indicates the probability that feature vector x belongs to jth class where $j = 1, 2, \ldots, 10$ in our work. To compute the class label for a given x, all the 10 posterior probabilities are evaluated and the class corresponding to the highest probability is chosen [22]. The prior probability for class j, i.e., $p(c_j)$, represents the initial degree of belief that a given set of feature vector is a

data from jth class. The class-conditional probability $p(x|c_j)$ is also called as class-conditional probability representing the probability distribution of the features for each class [14].

4 Experimental Results and Discussion

Each audio from the collected dataset is retrieved and processed to extract MFCC and LPC features. The feature vector corresponding to each frame is considered as an observation (an input) for the next stage. Total number of observations for each class is equivalent to number of audios of that class multiplied by number of frames in the audio. We get up to 600–1000 observations for each class. We have considered four different frame size, 512, 1024, 2048, and 4096 for the experiment. For the final classification, we selected the best frame size among this.

In this section, we discuss three types of experiments and the corresponding results. The first one is visualization of features, second is to select the best frame size, and the third one is the classification of instruments. For visualization on 3-D plot, we select the first three coefficients $(fv_{i1}, fv_{i2}, fv_{i3})$ of MFCC and LPC. Randomly selected 25 observations are plotted on 3-D graph with different color/symbols for different instruments. Figures 1 and 2 show the plot for MFCC and LPC features respectively. It can be clearly observed that the instruments of same type are grouped together in both the plots. We can also observe that similar types of instruments like *Saxophone(inverted triangle)* and *Nagaswara(circle)* groups are nearer to each other.

This result of this experiments just gives a brief idea about the potentiality of a feature to distinguish the various instruments and the similarity among some instruments. As per the results, both MFCC and LPC features capable to that. Such experiments are useful in Machine learning applications as a preprocessing step to

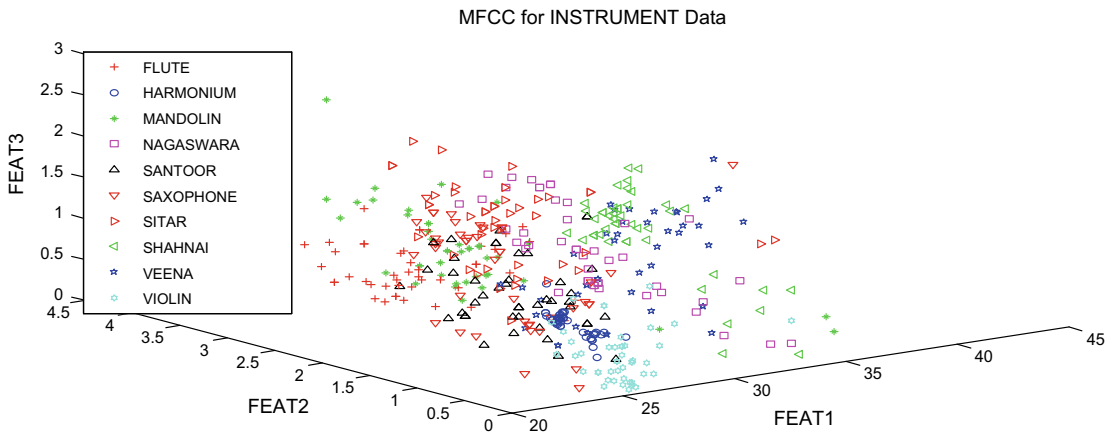

Fig. 1 Visualization of MFCC feature for Instrument data

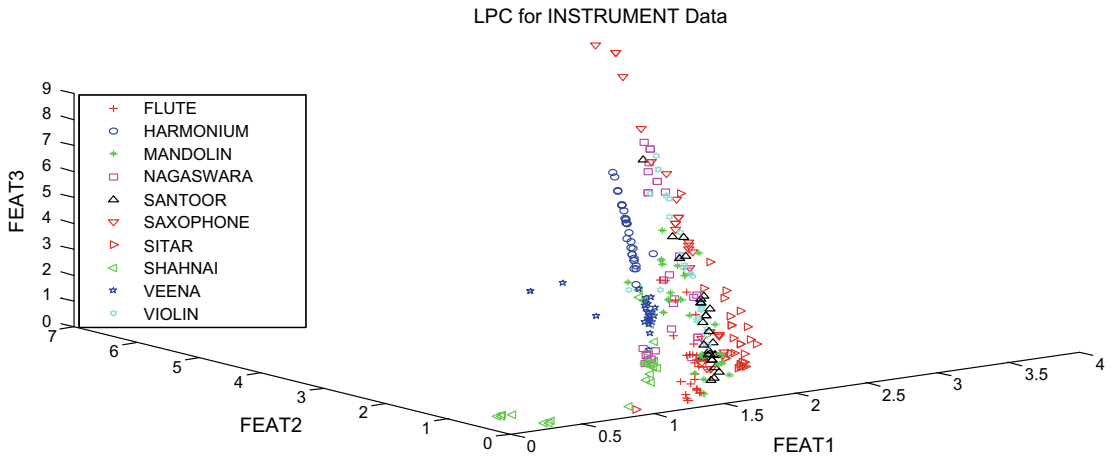

Fig. 2 Visualization of LPC feature for Instrument data

understand the features at preliminary level. The discrimination of instruments through MFCC is slightly clearer than LPC features.

The next experiment done is to select the best frame size suitable for instruments classification. For this experiment, we randomly retrieve *50* observations from each class and apply all the classification techniques using twofold cross-validation evaluation method. Various frame sizes considered are *512, 1024, 2048 and 4096* sample per frame. The features extracted with various frame size are stored as separate datasets. The frame size which gives the highest classification accuracy is selected and considered for further evaluation of classification experiments. Table 1 shows the results of varying frame size across *two* features and the different classification algorithms for the instrument dataset.

We can observe from the table that the performance of classification is better for the dataset constructed with the frame size of *2048* sample observations. For the further analysis, we consider the dataset which is constructed with the frame size 2048.

The last experiment is classification of ten instruments using, ANN, SVM, and Bayesian classifier. For this, we retrieve *500* observations from each class of instruments, totally constituting *5000* observations from *ten* classes. The dataset is divided into two sets, set1 and set2 in the ratio of *50:50* randomly. In the first iteration, set1 is used as training set and set2 is used as the testing set and the

Table 1 Comparison of class accuracy for different frame sizes for Instrument data

Classifier		512	1024	2048	4096
ANN	MFCC	56%	31%	72%	55%
	LPC	25%	61%	61%	66%
SVM	MFCC	88%	82%	86%	85%
	LPC	75%	77%	76%	70%

Table 2 Comparison of classification accuracy for Instrument data

Classifier/feature	ANN (%)	SVM (%)	Bayesian (%)
1. MFCC	**83.07**	69.13	67.12
2. LPC	81.81	67.91	51.25

accuracy of classification is calculated for the test set. Same thing is repeated in the second iteration where set2 is used as the training set and set1 is used as the testing set. Finally, the average accuracy of classification of the two iterations is calculated. Classifiers are evaluated by repeating each of the experiments for *fifteen* times and the average accuracy of classification is taken as the final accuracy of classification. Table 2, shows the accuracy of classification for the dataset of *5000* observations with MFCC and LPC features and the ANN, SVM and Bayesian classifier algorithms. We can observe from the results that MFCC feature is better representative for instrument data and the ANN algorithm classification is better compared to other algorithms. But LPC feature is also useful in representing the instrument data.

The highest accuracy rate for 500 observations is 83.07% with MFCC feature and ANN classifier and Fig. 3 shows the graphical view of the result. The *x* axis gives the name of the instrument (actual target class) and the *y* axis gives the number of observations considered. In visualization, we claimed that MFCC discriminates instrument data better than LPC. This is found to be same in classification also. Even though there is not much difference in the accuracy, MFCC has shown slightly better performance than LPC in all the cases.

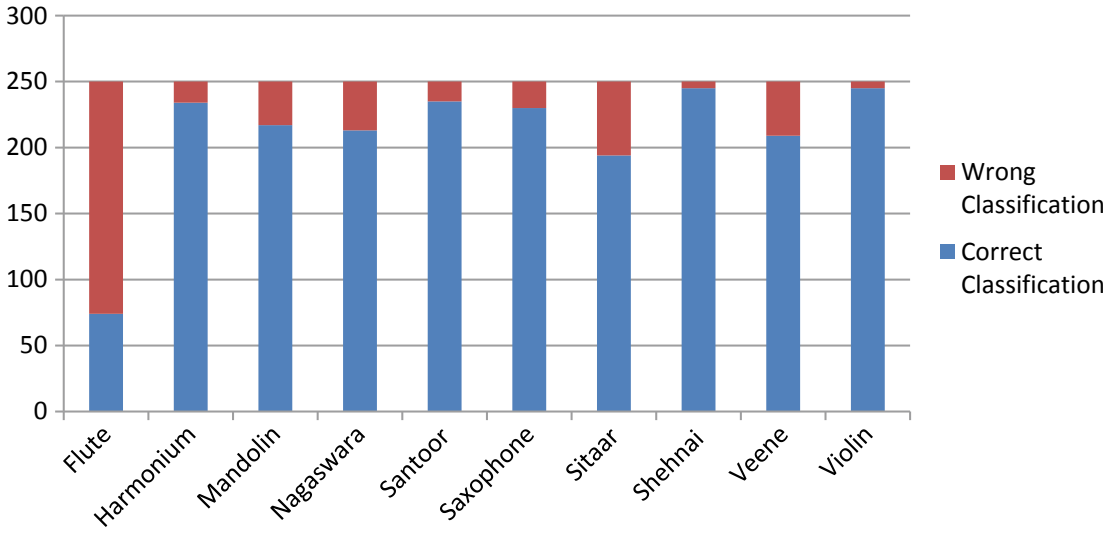

Fig. 3 Graphical representation of confusion matrix for Instrument data classification with ANN and MFCC feature

5 Conclusions

Even though, lot of research is carried for western music, the research in Indian music has lot of scope due to versatile nature of Indian music. Instruments are integral part of Indian music. The automatic identification of instruments from Carnatic music can ease the process of indexing and retrieval. We have developed a system for instrument identification using MCC and LPC features. The visualization helped in understanding the capability of MFCC and LPC features in distinguishing the various instruments. The training dataset and test dataset are selected randomly in each of the iteration and it is found that MFCC feature is shown to be more discriminative than other features. The highest rate of classification accuracy for *10* classes of instrument data is 83% with ANN classifier. More variety of instruments may be considered in future to develop an instrument identification system using deep neural network.

Semiautomated Ontology Learning to Provide Domain-Specific Knowledge Search in Marathi Language

Neelam Chandolikar, Pushkar Joglekar, Shivjeet Bhosale, Dipali Peddawad, Rajesh Jalnekar and Swati Shilaskar

Abstract In this research work, our goal is to build a self-sustainable, reproducible, and extensive domain-specific ontology for the purposes of creating a knowledge search engine. We have used online data as the primary information store using which we construct ontology by identifying concepts (nodes) and relationships between concepts. The project encompasses preestablished ideas gathered from successful NLP trials and presents a new variation to the task of ontology creation. The system, for which the ontology is being created, is a knowledge search engine in Marathi. This aims at building semiautomated ontology whose target demographic is primary school children and the selected domain is science domain. This project proposes a method to build semiautomated ontology. We use a combination of natural language processing method and machine learning method to automate the ontology learning task. Automatically learned ontology is further modified by language and domain experts to enrich the contents of ontology. Unlike, standard search engines, our knowledge search engine attempts to provide learned resources directly to the user rather than website links. This approach enables the user to directly get information without having to spend time on browsing indexed links.

Keywords Knowledge search engine · Natural language processing (NLP) · Ontology · Resource description framework (RDF) · Semantic search

1 Introduction

Knowledge sources are rarely available in Marathi language on World Wide Web. This paper proposes to provide domain-specific search facility in Marathi. It also aims at converting the extracted data into knowledge and provides output in more semantically coherent form. The proposed knowledge search in Marathi would be based on semiautomated ontology-based framework.

1.1 Ontology

Ontology has the ability to capture the structure of a domain. Ontology has a knowledge base which contains structures that are defined by the allowed constructs of ontology [1, 2]. Ontologies are building blocks of semantic web-based systems [3]. Creating ontologies is an intricate process [4, 5]. Ontology defines a common vocabulary for researchers who need to share information in a specific domain. Ontology of any domain is a specification of a conceptualization of that specific domain. Ontologies are concerned with the meaning of terms. Ontology typically consists of concepts and relationship between those concepts. It includes definitions of basic concepts in the specific domain and relations among them. Ontologies are used to represent domain knowledge in a digital form. Ontologies can be automated or semiautomated. Semiautomated ontology is created automatically and edited manually.

1.2 Knowledge Search Engine

Knowledge search engine [6–8] provides semantically correlated information to the input keyword. Knowledge search engine is somewhat similar to semantic search engine. A semantic search engine interprets the meaning of a given keyword and provides information either in the form of relevant links or in the form of summarized information. Ontologies allow smart linking of knowledge resources. This gives a computer the potential to use intelligent agents to access knowledge and deliver good quality information to the user. Agents also have the ability to use the ontology semantics [9, 10] to communicate with other agents and thus making computer communications smarter.

1.3 Resource Description Framework (RDF) and Web Ontologies

Ontologies are stored in RDF format [11]. RDF is the widely accepted standard framework for representing information about a certain system. RFD is built around the concept of uniform resource identifier (URI) which is used to describe website metadata. A typical RDF graph consists of RDF triples (subject, predicate, and object) which is displayed as a graph. Web ontology complements the RDF and RDF Schema by giving it an ability to express reasoning and convey logical structure.

2 Related Work

In 2007, author Horacio Saggion et al. proposed the system on ontology-based information extraction for business intelligence in which they used information from business graphics and tabular data and they applied OCR analysis of images and then output of the OCR analysis was corrected by the exploitation of collateral information found around the graphics [12]. In 1992, author Marti A. Hearst described a method for the automatic acquisition of the hyponymy lexical relation from large text corpora first they identified a set of lexico-syntactic patterns and then described a method for discovering these patterns [13]. In 2006, author Patrick Pantel et al. proposed a weakly-supervised, general-purpose algorithm, called Espresso, for harvesting binary semantic relations from raw text. In which they have extracted several standard and specific semantic relations like is a, part of, succession, reaction, and production [14].

In 2004, author Patrick Pantel et al. used top-down approach for labeling semantic classes. They used co-occurrence statistics of semantic classes discovered by algorithms like CBC to label concepts. In this paper, they proposed an algorithm for automatically inducing names for semantic classes and for finding instance/concept (is-a) relationships [15]. In 2013, author Tomas Mikolov proposed two novel model architectures for computing continuous vector representations of words from very large datasets. The author worked on distributed representations of words learned by neural networks in which they proposed two models Continuous Bag-of-Words Model and Continuous Skip-gram Model [16]. Natural language processing methods [17– 20] of pos tagging and chunking is widely used by many researchers for identification of concepts for domain-specific ontology. Machine learning techniques like classification [21–24] is used widely for relationship classification.

3 Proposed Methodology

In the proposed methodology, we have focused on creating ontology for a science domain which includes science subject terms and concepts understandable to primary school-going children of Marathi medium. However, proposed methodology can be applied to any domain. In the proposed methodology we at first define ontology structure followed by this ontology learning method is proposed and finally we provide knowledge search through knowledge search engine.

3.1 Defining Structure of Ontology

For building ontology and its nodes, we have initially defined ontology structure as per the requirement of project. Ontology ideally has terms and relationships. In this research work for every term, one ontology node is created. Structure of ontology node which is used is as follows:

1. Keyword in English.
2. Definition in English.
3. Automated Translated Marathi keyword.
4. Marathi definition by domain and language expert.
5. Image link.

Once this ontology node structure is defined, all the terms (concepts) are stored using the same node structure.

3.2 Methodology to Create Semiautomated Ontology

We have presented a combined approach to natural language processing and machine learning classification for ontology learning. Ontology learning has six individual modules, namely, seed word resolution, data scraping, pos tagging and chunking, predicate classification for identification of relationship, ontology writer and graph intelligence, and text simplification. Figure 1 shows the block diagram of ontology creation. The detailed explanation of the ontology creation are as follows.

3.2.1 Seed Word Resolution

The semantic search engine takes an input seed word for learning ontology. The search engine operates on one seed word at a time so as to limit the divergence of

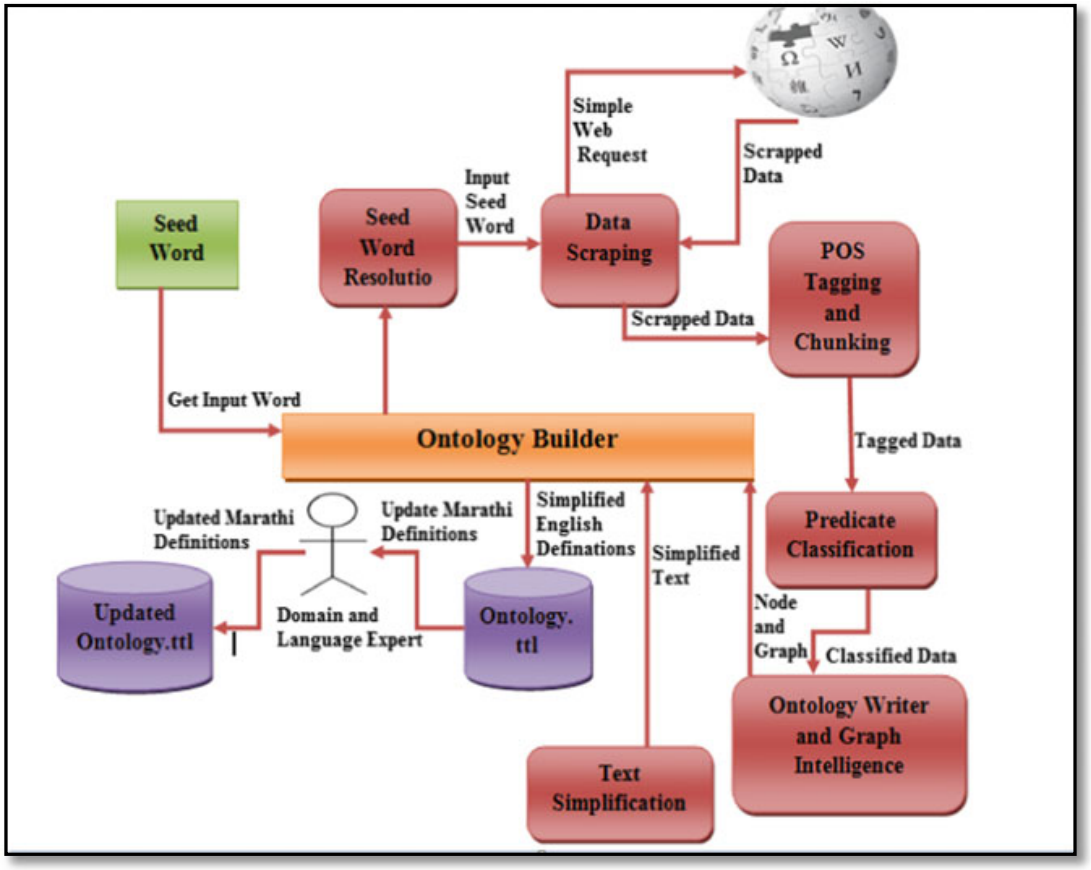

Fig. 1 Block diagram of ontology builder

the data that is gathered. Traditional encyclopedias such as Wikipedia or Britannica are replete with example of entries with topics that can be interpreted in a much broader sense. Our algorithm, in order to avoid this problem, gets additional five words that are semantically similar to the seed word. This is done using Word2vec. Word2Vec is a vector embedding space that encodes semantically similar words in an N-dimensional vector space such that their cosine similarity is minimum. We used Google's dataset which is trained on roughly 100 billion words with a vocabulary of 3 million words. The top five words similar to the seed word make sure that the algorithm will always have relevant information when displaying to the user. However, to be able to know the meaning of millions of words there is no practical classifier that will give us good description of any word. A dictionary can be used instead but it does not capture the linking between two or more terms. To be able to do this, our algorithm treats Word2vec model as the classifier for the word. This is the prime reason behind the extraction of top five similar words. They act as an index as to what words will point wherein the ontology.

3.2.2 Web Data Scraping

Web Data Scraping is a computer science application, where a programmer automates the process of retrieval of information from websites by the use of intelligent scripts. Every website typically has an HTML format which tells the browser how the raw data must look to the user. Now, say a user wants to analyze product prices on a web store, manual extraction is impractical. In such cases, a simple script can be written to talk to the website's server and retrieve the required data directly into user-defined data structures. Our search engine relies heavily on web scraping to eliminate the need for storing data offline. The top five similar words to the seed word will be the basis of getting raw text data. The algorithm will first scrape data for each word from https://simple.wikipedia.org/, which is a simplified version of Wikipedia. At this stage, the algorithm has all the relevant data for each wiki pages for each of the five words and the seed word. The scraper will extract definitions, images, (links) and other paragraphs from each web page. The scraped data objects will be provided to a module that performs a series of operations to further refine the data.

3.2.3 Part of Speech (POS) Tagging

Every word used in a sentence is assigned a specific part of speech. There are several parts of speech and the most important and commonly recognized ones are nouns, verbs, and adjectives. We have to dive a little deeper into the grammar of English language to understand the importance of this module.

A sentence in English falls into three categories, namely, simple, compound, and complex. A machine, however, does not understand these categories. To allow the computer to understand this, we exploit the patterns that the POS tags that appear in all three kinds of sentences. We use NLTK's inbuilt POS tagger for this purpose.

NLTK's POS tagger works on a saved per-trained POS tagging machine learning models. The NLTK POS tagger recognizes the various types of POS tags.

3.2.4 Chunker

The next phase that comes is chunking. Chunking is the process of converting a POS tagged sentence into a list of tree structures that recognizes a certain user-defined grammar. The root of all trees are defined by the letter 'S' and in the absence of grammar, all the words are leaves of this tree. The chunking process, allows us to recognize the subject, predicate, and the object of the sentence. NTLK's Chunker is a regular expression-based function that parses the sentences into the tree from the user-defined grammar. Our algorithm attempts to recognize

the subject, predicate, and object of every sentence. To do this, we defined our own grammar rules to recognize the subject, predicate, and object in a sentence. The grammar used is as follows.

```
“”””
        NP :    {<PRP|PRP$>?<DT>?<JJ>*<NN.*>+}
                {<JJ>?}
                {<PRP|PRP$>}
        REL : {<V.*><TO>?}
                {<DT>?<JJ>*<NN.*>+}
                }<VBZ|VBP>{
        REL_BOOL : {<RB|RBR|RBS>?<VBZ|VBP*>?<RB.>?<TO>?<IN>?}
                Commas : {<,><NP>}
                NPlist : {<NP><Commas>*<CC>?<NP>}
        SVO: {<NP|NPlist><MD>?<REL_BOOL>+<REL>*<IN>*<CD>*<NP|NPlist>}
        Prep : {<IN>+<N.|VBG|PRP.>}
        Simple: {<SVO><Prep>*}
        tag :   {<CC><Simple>}
        Compound: {<Simple><tag>+}
“”””
```

In the above-defined grammar, “NP” is the grammar used to chunk noun phrases, “REL” and “REL_BOOL” are used to chunk verb phrases from sentences. When the chunker spots the grammar defined by “SVO” tag, it will indicate that the algorithm has now safely found an SPO triple. This triple will be further analyzed to generate the ontology.

3.2.5 Concept Identification

After POS tagging and chunking phase, subjects and objects are identified as concept (term) of ontology. After identification of terms, for every term following details are stored in the node of ontology: keyword in English, definition in English, automated translated Marathi keyword, and Marathi definition by domain and language expert and Image link for term.

3.2.6 Predicate Classification

As humans, understanding the meaning of any sentence is very easy. When trying to replicate the same task for computers, the biggest challenge is where to start in order to solve this problem. Ideally one would think that there is no problem in storing the relationship directly as it would make any difference when it is presented to the user. However, the opposite is true for machines. Machines have not been taught to recognize the relationship between two or more entities. When dealing with computers, ultimately, it comes down to etching strict borders to these abstract tasks that humans perform. Ideally, a human will be able to understand if two entities are related, but to know how they are related is quite a huge and complicated task. For instance, a human can easily declare that the word "dog" and the word "golden retriever" are related. As humans, we can relate "dog" and "golden retriever" as class and instance of the class, respectively. However, it is important to note that we can do this without the presence of a predicate. Humans can also express more than one relation between the two entities. This is unique only to humans.

In order to replicate the same result in machine, we first need to define how the relationships are to be specified. This is where the ontology comes into the view. As we discussed in the initial section of this paper, ontology is a specification for conceptualization. The exact syntax and rules that are specified in RDF will form the basis for recording the knowledge in the ontology. For our purposes, we have tested four classifiers, namely, Decision Tree, SVM, Naïve Bayesian, and Maximum Entropy.

In this paper, we propose the use of maximum entropy techniques for ontology building for knowledge search. Experimental results show that max entropy gives more accurate result. Maximum entropy is a method used for a natural language processing task like text segmentation. The first step for constructing model using max entropy is to collect a large number of training data which consists of samples represented in the following format: (x_i, y_i) where the x_i includes the contextual information of the document (the sparse array) and y_i its class. The second step is to summarize the training sample in terms of its empirical probability distribution:

$$\breve{p}(x, y) = \frac{1}{N} \times T$$

where T is the number of times that (x, y) occurs in the sample and N is the size of the training dataset.

3.2.7 Graph Intelligence

Simply storing the data in the ontology is not very useful if the user has to link the data using their own intelligence. Our graph intelligence module generates a graph that records all the knowledge in terms of subject, predicate, and object represented

as the nodes. The graph intelligence automatically integrates definitions and images for the nodes from the ontology.

After the machine has recognized the word, the next step of the algorithm is to describe the word. To describe a word, we as humans have a brain wiring that allows us to record the features of the word. For example, we can say that to describe a dog, we humans will recall the image of the dog and then describe the features of the dog that we imagine. A particular node in the ontology is the feature of that word that the algorithm has learned and stored by analyzing all the raw text data. Over time all these nodes automatically form connections and which the algorithm can describe. The algorithm allows the user to traverse along the edges of the ontology nodes thus simulating a primitive thought process. This graph is well connected to the other related entities but with a few erroneous relationships. The graph currently traverses two levels deep. The graph can be visualized as follows (Fig. 2).

3.2.8 Text Simplification

Text simplification [25] is a technique in natural language processing which is used to modify text in such a way, that the grammar and structure of the given text is

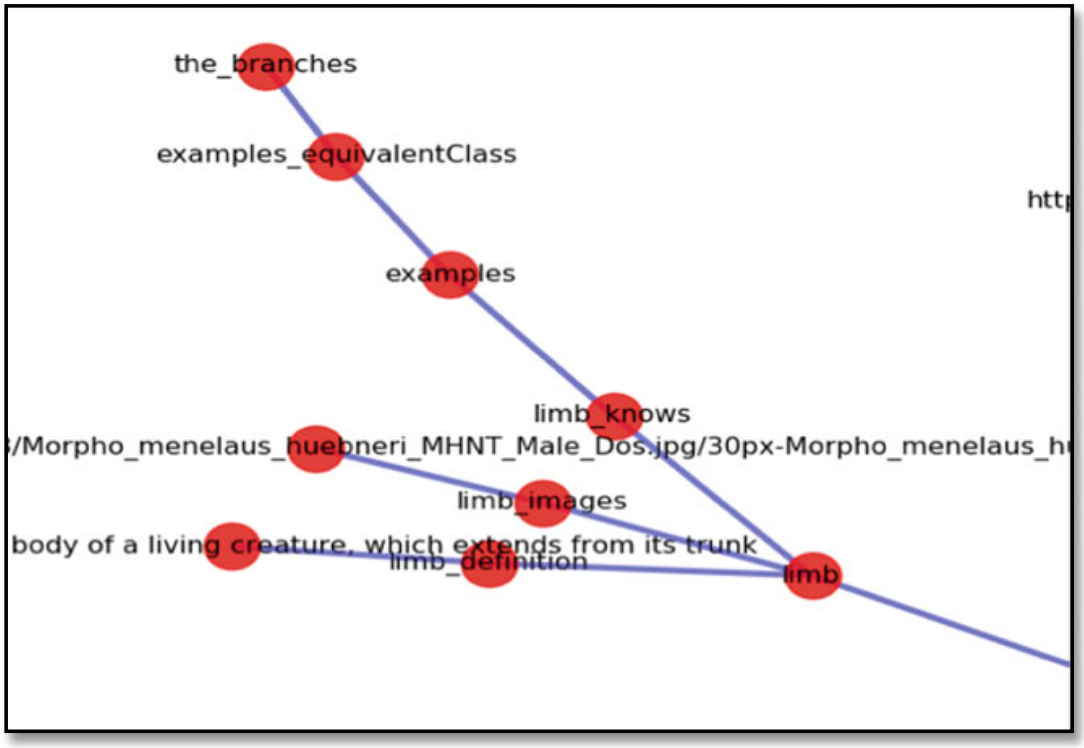

Fig. 2 A part of the subgraph, partly describing the node "limb"

greatly simplified, while the meaning and information remain the same. The target demographic of the knowledge search engine is school-going children so; it is necessary to create definitions which will be understandable by children. In-text simplification we converted complex words to easily understandable words and complex sentences to simple sentences. In this work English definition which is retrieved from World Wide Web and stored in ontology node are further simplified, so that it becomes understandable to target demographics. Further, Marathi definitions are added by domain and Marathi language expert, to complete ontology node as per defined structure.

3.3 Knowledge Search Engine

In the second part, we created a web application using Django framework. This application will help student to search the science terms. This application will give direct results to the students instead of giving a link as a result. So, it will help student to get the result without wasting time on indexed link. Figure 3 shows a block diagram for ontology search.

We will enter a science keyword in Marathi as input. Then that Marathi word is converted to English word then semantic search engine will search that keyword in updated ontology file and will return output definitions and images.

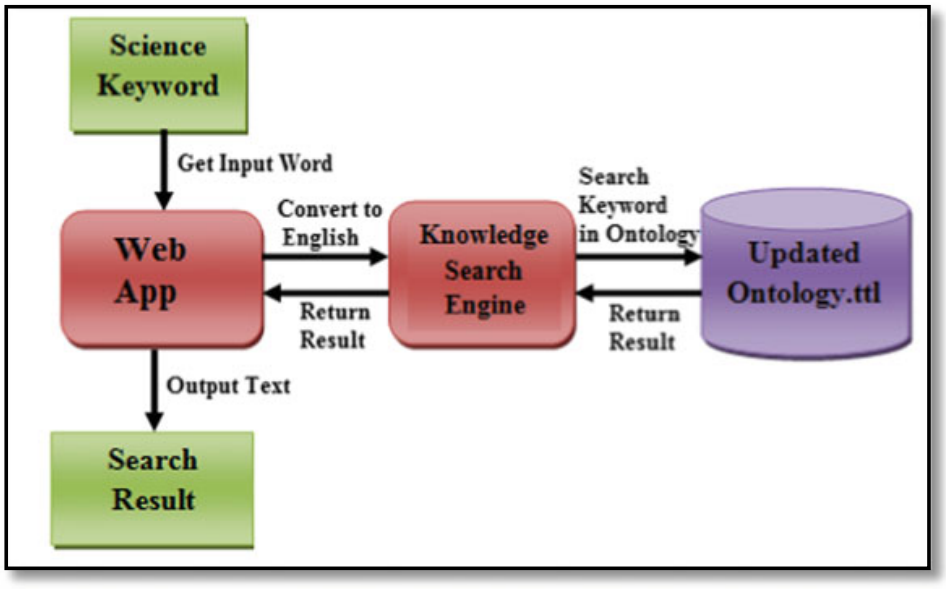

Fig. 3 Block diagram of ontology search

4 Experimental Result

During the course of the project, it has been found out that to generate good quality ontology; the most significant task identifies relevant triples. A relevant triple is a triple in which the subject, predicate, and object talk about the seed word. Current chunking methods perform fairly well for simple and complex sentences.

4.1 Comparative Analysis of Classifiers

The initial approach was to use the Naive Bayes classifier to classify the predicate. In later comparative analysis of the dataset, the following were the accuracies for each classifier (Table 1).

4.2 Classification of Predicate

The predicate classification task requires a huge amount of data along with good labels. The predicate classification works fairly well on maximum entropy classifier with an average accuracy of 76%. The feature of the predicate can be a dictionary of POS tags as the keys and the corresponding word in the predicate as the value of the dictionary.

Maximum entropy classifier gives the highest accuracy. Therefore, this method is used for building ontology nodes and relationships. Relationships are mainly classified into subclass, equivalent, object property, and irrelevant. The relationships that are classified as irrelevant are of varying nature. They do not directly fall into subclass, equivalent, or object property relations but they usually are not completely useless. They are stored as a friendly relation.

Table 1 Comparative analysis of classifiers on our dataset

Classifier	Accuracy (avg of 20 shuffled iterations) (%)
Naive Bayes classifier	72.42
Maximum entropy classifier	76.39
Support vector machine (SVM)	75.15
Decision tree	73.18

4.3 Created Ontology

The proposed method provides a good mechanism to generate domain-specific ontology. Given a seed word, relevant terms are added into ontology. Created ontology has terms and relationships. For every term one ontology node is created. Following examples illustrates ontology node and ontology structure.

(a) Example of ontology nodes

1. Keyword in English:- "Sunlight".
2. Definition in English (simplified definition):- "It is the light of the sun. Sunlight, also called sunshine. What we experience as sunlight is actually solar radiation. It is the radiation and heat from the Sun in the form of waves. The atmosphere affects the amount of solar radiation received. When solar radiation travels through the atmosphere, some of it is soaked up by the atmosphere (16%)".
3. Marathi definition (provided by language and domain expert):- "सूर्यप्रकाश म्हणजे सूर्याचा प्रकाश. आपण जो सूर्यप्रकाश अनुभवतो, ती खरे म्हणजे सौर प्रारणे आहेत. सूर्यापासून नघिालेली सौर प्रारणे आर्णि उष्णता तरंगांच्या रूपात असतात. सौर प्रारणांमुळे वातावरणावर परणिाम होतो. सौर प्रारणे जेव्हा वातावरणातून जातात तेव्हा त्यातील काही प्रारणे (सुमारे 16%) वातावरणात शोषली जातात".

3. Image link: https://upload.wikimedia.org/wikipedia/commons/thumb/7/71/Antelopecanyonjh1.jpg/220px-Antelope_canyon_jh1.jpg.

5 Conclusion

In the context of the current project, we are planning to use the ontology for knowledge search engine where users are school-going children. The semantic search engine is mainly focused on science keywords which will provide a Marathi definition of a keyword as output. Creating ontologies is not an easy task and there is no unique correct ontology for any subject. So, in this project, we used a combined approach to natural language processing and machine learning method for creating ontology. The predicate classification task requires a huge amount of data along with good labels. The predicate classification works fairly well on maximum entropy classifier with an average accuracy of 76%. The maximum entropy classifier is the most suitable for our ontology creation. This paper proposes the building of ontology which provides knowledge search in Marathi, which takes a keyword as an input and uses ontology to provide semantically coherent information and present summarized information in the structured form.

Identifying Influential Users on Social Network: An Insight

Ragini Krishna and C. M. Prashanth

Abstract The advancement in the speed of the internet connection on handheld devices has led to an increase in the usage of social media. This drew the attention of advertisers to use social media as a platform to promote their products thus leading to an increase in the sales of their product, increasing the brand awareness. To increase the rate of information dissemination within a short period of time, influential users on social media were targeted, who would act as the word-of-mouth advertisers of the product. However, there are various parameters on which the influence of a user has to be determined. The parameters can be (1) the connectivity of the user in the network (2) knowledge/interest of the user on a particular topic/product/content (3) activity of the user on the social media. This survey focuses on the various methods and models for identifying influential nodes and also the effect of compliance, where a user falsely agrees to the content of another influential user by retweeting, just to gain status or reputation and thus increasing his influential score. Thus, the list of influential nodes of a social network can be faked upon, due to this issue.

1 Introduction

It is an era of automation and people's digital presence is increasing and finding the influence of the user based on their digital presence is the talk of the time. The digital presence of the user on various social media like facebook, twitter, linkedln, google+, etc., are used to find the influence of the user on the digital social networks.

With the vast usage of the social network [1] to connect to friends and pass information across the network of friends, the social networks are being targeted for the use of business. Thus, social media is used for promoting a product or for passing on information or news. To speed up the process of the spread of information, people target the influential users.

It is already proven and now it is a fact that social media marketing affects the brand awareness and the purchase intentions [2] but the author "Romy Sassine" [1], also discusses that the effect of influencers for a brand marketing is decreasing due to the overuse of the social media.

The reasons for such a trend can be the overuse or wrong placement of the hashtags in a particular message or it may be due to the competition among the influencers to get more brands contract instead getting connected to the audience.

According to [3], the advertizing done using the word-of-mouth strategy increased the sales of the product by twice and the customers gained from this method had a higher retention rate of 37%. The author also states that just having a large number of followers does not indicate an influence, moreover to determine the influence of a person, his credibility towards the topic and strength of the relationship with followers along with the total numbers of followers should be considered.

To determine the influential users in the social network is one of the most trending research areas. There have been many research work carried to find the influential users in a social network. In this paper, Sect. 2 introduces the methods used to find the centrality of the nodes in a network. In Sect. 3, the various methods used to find the influence on social media is discussed. Section 4 lists out the various shortcomings of the methods and in Sect. 5, we discuss the prospect into the future of identifying the influence on social media.

2 Background

A large number of methods have been proposed to find the influential users on the social network so far. Initially, researchers proposed methods which were based on the centrality [4, 5] of the nodes in the network, such as degree centrality, betweenness centrality, closeness centrality, eigenvector centrality, these methods mostly assumed that the network was static, as they never considered the interactions among the nodes of the network. Thus, to consider the dynamicity of the network various researchers started considering the interactions among nodes in the network [6, 7], such as α-centrality and β-centrality. Thus, link strength was determined based on the level of interactions among the nodes in the network to consider the dynamicity of the network. The link strength indicates the ratio of interaction with the concerned node as compared to the interaction with other nodes, which gives the weightage to the concerned link. The link strength between nodes u and v is the ratio of interaction between u and v to the sum of total interactions of u and total interactions of v.

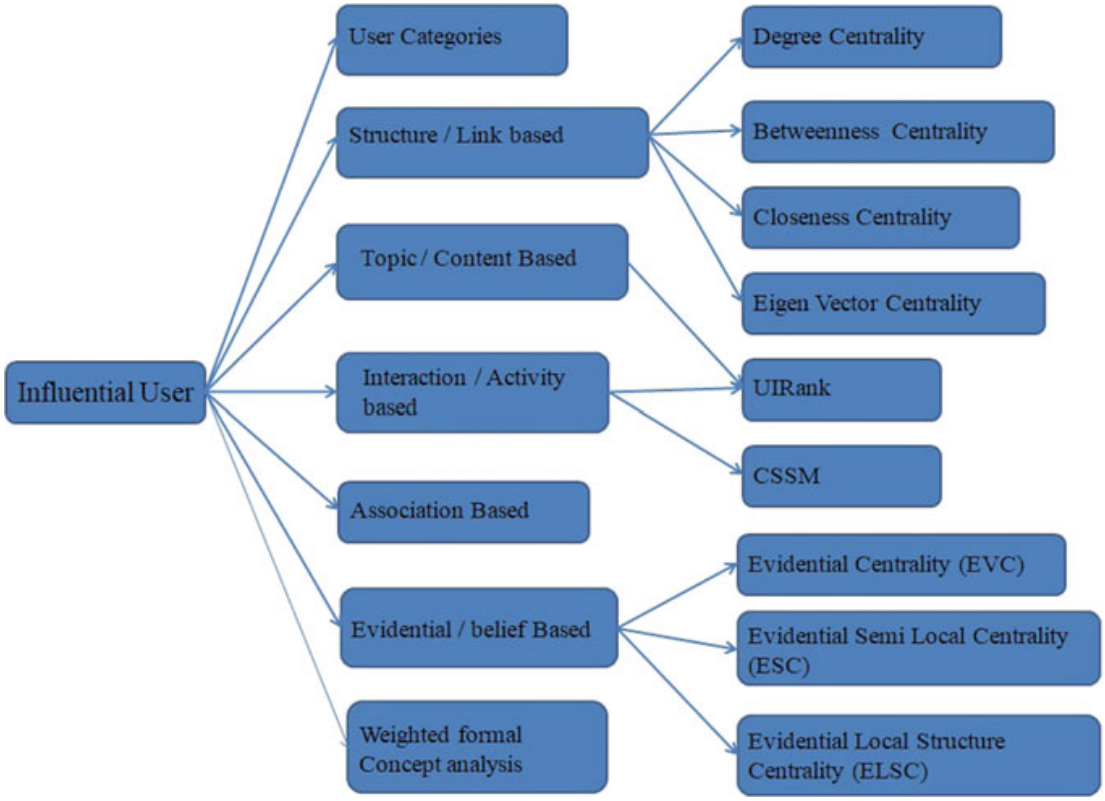

Fig. 1 Categorization of the various methods to find influential users in social networks

The influence of a node in the network can be determined based mainly on its link strength, its interest in the topic of discussion or its activity in the network. Figure 1 shows the categorization of the various methods which determine influential users on the social network.

3 Methods for Finding Influence on Social Network

In this section, we will discuss methods (Fig. 1) to find the influential users based on various parameters like the level of interaction among the nodes, interest of the user in the topics, etc.

3.1 Structure or Link Based Influence

These methods used the connectivity of the nodes in the network to find the influential nodes. However, with the increasing usage of the social media, the connectivity among the nodes kept changing at a frequent interval, thus making them more dynamic, which was not addressed in the link-based methods of finding influence [4, 5, 7].

3.2 User Categories Based Method to Optimize the Popularity of Twitter Messages

There are number of users on twitter who generate a million of content everyday however many of the contents go unnoticed or unread which can reduce the popularity of the applications among the users. This may happen because different categories of people will be interested in different topics/content. To detect the effect of the content in the tweet, on its popularity, the tweets were categorized on topics like brands, celebrities, community, entertainment, media, sport, places, and society [8]. The activities of the users were monitored for all these categories. The data was collected and five features-(1) number of mentions, (2) number of hashtags, (3) number of URLs, (4) the number of pictures, and (5) the sentiment of the tweet were collected, where the first four were directly derived from the twitter API but the fifth feature, the sentiment of the tweet, was extracted from the tweet using labMT word list. The sentimental analysis was done on the tweets and then segregated into neutral and positive or negative, 0 being neutral and 1 being extreme either positive or negative.

1. Analyzing the Influence of the content on the popularity of the user's tweets:
   The popularity of the user's tweets was determined based on the features of the content and how the popularity differs for a tweet of different user categories. Each feature of the content was ranked based on its importance for the popularity of each and every user categories.
   To minimize the sum of squared error in the prediction for finding the most popular content, LASSO (least absolute shrinkage and selection operation) [9] was used.
   From the results in [8], it was observed that the sentiment feature plays a very insignificant role towards the popularity of the tweets for every user categories, whereas when considering retweets and favorites, the feature-mentions were ranked high for favorite but had lower ranking for retweets.
   When considering the user categories for the most number of retweets, the feature -picture was ranked highest for communities and brands, whereas the feature-URLs was ranked highest for media and places.
2. Predicting the popularity of the tweets
   This work predicts the popularity of a tweet given its features. A prediction model was built using a regression model consisting of 50% of the tweets for the training and 25% to validate and another 25% for evaluating the model.
   There were three ways in which the prediction was done, Generic model, the category-specific model, and the smoothed model. In the generic model, the training was done on all the data, whereas in the category-specific model, the training was done based on the segregation of the categories of the tweets.
   The Generic model gave high prediction errors for different categories of users. In the category-specific model, the category to which, the tweet in the test set,

belongs was found out and then it was used in the prediction model. According to the arrived results [8], the category-specific model showed improvement in the prediction of the number of retweets, however, it did not outperform the generic model in many other cases, the reason for this may be because the test set considered was very small.

Thus, to get the best from both the models, the best elements of both the models were combined to get the smoothed model. This was achieved by considering the weighted average of both the generic model and the category-specific model. The smoothed model proved to be giving better results as compared to generic or category-specific model.

3.3 *Interaction or Activity Based*

1. Time slice-based interaction:

To calculate the level of interaction of nodes in the network, methods like indegree and outdegree centrality were used. High indegree of a node represented an inactive user as he/she consumes the information but does not help in the information dissipation.

The steps involved to calculate the influence of a user based on its interaction with its neighbors are [10]:

- Indegree and outdegree centrality
- Link strength
- Clustering value based on indegree and outdegree
- Calculating the influence

Let's take an example to illustrate it:

Step 1: The indegree for the nodes of the network from Fig. 2 at $t1$ are:

$A = 0,\ B = 2, C = 1,\ D = 2$ and $E = 2$

Thus, the outdegree for the nodes at time $t1$ are:

$A = 1,\ B = 1,\ C = 2,\ D = 1$ and $E = 1$

Thus, if there are users with high indegree and zero or low outdegree, it represents a very low activity.

Step 2: To find the influence of the nodes among friends of a node, the strength of the link that the nodes share across the network is calculated. If the link between nodes is found to be strong, then they can be influenced by their friends with a very little effort from the influencer. Thus, the link strength between the two friends 'a' and 'b' can be calculated by:

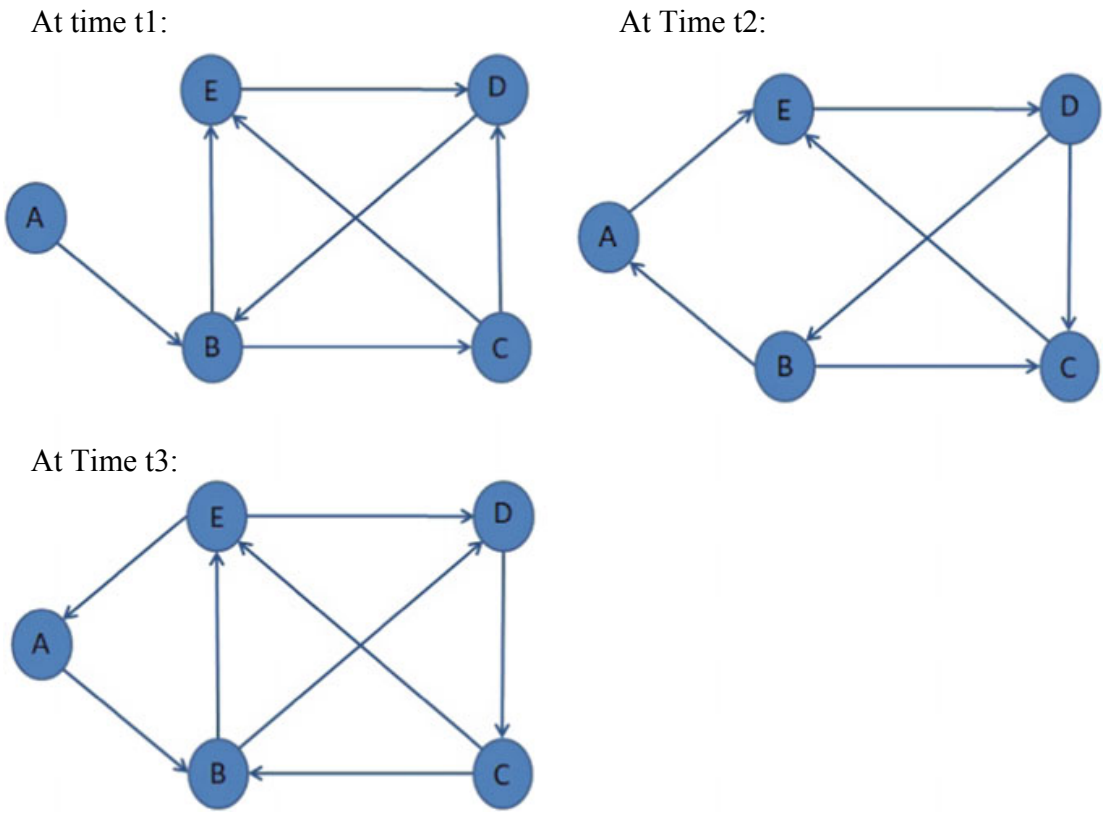

Fig. 2 Representation of nodes interaction in a network at the time slots t1, t2, and t3

$$L(b,a) = \frac{|\bar{\epsilon}(b,a)| + |\bar{\epsilon}(a,b)|}{d_o(b) + d_o(a)} \tag{1}$$

In the example that has been taken, there are three time periods that are considered as the time of interactions between the various nodes in the network.

Thus, the indegree and outdegree for the nodes across all the three-time slots are:

Indegree centrality:

$d_i(A) = 2$ $d_i(B) = 4$ $d_i(C) = 4$

$d_i(D) = 5$ $d_i(E) = 6$

Outdegree centrality:

$d_o(A) = 3$ $d_o(B) = 4$ $d_o(C) = 5$

$d_o(D) = 4$ $d_o(E) = 3$

Thus the link strength is calculated and the values are as follows:

Link strength between node A and B:

L(B,A) = 0.428

Link strength between Node A and E:

L(E,A) = 0.333

In a similar way, the link strength between various nodes is calculated. Thus it is inferred that the link strength between the node A and B and the nodes D and E, with the strength value of 0.428, seems to be stronger as compared to the other nodes.

Step 3: clustering value based on indegree and outdegree:

The connectivity of the node within a group of nodes is represented by the cluster value. The higher the cluster value of the node, the more connected it is, to a number of clusters and thus has more reachability to pass on the information to more number of people in the network.

The high indegree clustering value indicates that a number of messages are being transmitted from the neighboring nodes to the node in question, which implicitly means that the concerned node is involved in more number of discussions and thus there will be a high chance of him/her adopting other's behavior. The indegree clustering value is given by:

$$C_i(a) = \frac{\sum_{b \in S} d_i(b)}{d_i(a) * (d_i(a) - 1)} \tag{2}$$

From Eq. (7), the indegree clustering value for node A is 5, node B is 1.75, node C is 1.25, node D is 0.7, and node E is 1.25. It is evident that node A has high indegree clustering value and thus is connected to more number of clusters.

The number of messages transmitted from the concerned node to its neighboring nodes is indicated by outdegree clustering value. Thus a node with high outdegree clustering value has a high chance of being influential. The outdegree clustering value for a node is given by:

$$C_o(a) = \frac{\sum_{b \in S} d_0(b)}{d_o(a) * (d_o a - 1)} \tag{3}$$

After calculating the outdegree clustering values of the nodes in the network, A has a value of 1.167, B has 1.25, C has 0.55, D has 1, and E has 1.167. This clearly shows that the nodes A and E can be influencers in the network. Any node in the network with a high outdegree but a zero indegree value can be a spammer.

Step 4: Thus to find the influencers in a network, the values of the indegree centrality, outdegree centrality and indegree – outdegree clustering values will be used. Thus, from the above discussions, it is quite clear that the user who has high outdegree centrality with high outdegree clustering value will be influential. But the weightage of these parameters depends on the case. For example, maybe the user does not have high outdegree cluster value but he generates a lot of content which make him quite active and thus the interaction of the user with it neighbor will go high, which may make him influential. Thus, to normalize these parameters, two normalizing factors, α_1 and α_2 are introduced. The influencer of the network can be calculated by:

$$Infr(a) = [\tanh(d_0(a))] * (\alpha_1 d_0(a) + \alpha_2 C_0(a)) * \sum_{t\varepsilon S} L(b,a) \tag{4}$$

After calculating the influencer values for the nodes, it is found that the node B is most influential with an influencer value of 3.690 after assuming the value for both α_1 and α_2 as 0.5.

The users with high indegree centrality and high indegree cluster value are the users who can be influenced by its neighbors. Thus, they should not be mistaken for inactive users. To remove the inactive users in finding the influencer or the influenced user, the hyperbolic tangent is used to translate the outdegree value of the concerned node '*a*' to either zero or one.

The influenced value of a node is:

$$Infd(a) = [\tanh(d_0(a))] * (\alpha_3 d_i(a) + \alpha_4 C_i(a)) * \sum_{t\epsilon S} L(b,a) \tag{5}$$

Furthermore, the influenced value for each node in the above example is calculated and thus node B has the highest value with 4.087 with the assumption of α_3 and α_4 as 0.5. Thus, from the example network, it can be inferred that the node B creates influence on its neighboring nodes and it is influenced too by its neighbors.

The authors [10] have worked towards finding the influence of users using interaction among them in the network, which clearly avoids the problem of spammers or inactive users in the network.

2. Discovering influence using community scale-sensitive maxdegree (CSSM)

The community in a network is detected based on the interaction among the nodes in the network which represent similarity among the nodes present in the same community. The communities can be identified using various clustering algorithms.

Influence of a node depends on the parameters like the centrality based on the degree of the node, sum of neighbor's degree, and the attributes of the node [11].

The outdegree centrality (ODC) of the node is given by:

$$\mathrm{ODC}(x) = \frac{o(x)}{m-1} \tag{6}$$

where $o(x)$ is the number of neighbors adjacent to x and m is the total number of nodes in the network.

The sum of neighbor's degree (SND) is given by:

$$\mathrm{SND}(x) = \sum_{i=1}^{o(x)} o(y_i) \tag{7}$$

where y_i is the ith neighbor node of x. The value represented by SND denotes the number of followers of the node x at level 2.

The results obtained from ODC and SND are summed together for each community and they are finally given as the most influential nodes in the network.

The above method considers only the interaction among the nodes in the network, however, the interaction can be using a negative tweet, which will give an inaccurate result in identifying influence. This issue is rectified by considering the content of the interaction.

3.4 Content Based User Influence Rank (UIRank)

The influence of user on a microblogging site is calculated by a method called UIRank where the node's information disseminating ability (connectivity) and the contribution of the user's tweet (content) is considered [12].

The content generated by the user, that is, the tweet, retweet, and the comment is considered and the influence of the tweet is calculated by considering the retweet and comments on that tweet and is given by:

$$sp(u) = \sum_{t \in \text{Tweets}(u)} Rr(t) + Cr(t) \tag{8}$$

where $sp(u)$ is the probability that the user's u tweet propagates from user u to the neighbors of the fans of user u, $Rr(t)$ is the retweet to the read ratio of the tweet t and $Cr(t)$ is the comment to the read ratio of the tweet t.

The user's influence in the network is found out by finding the connectivity of the user in the follower relationship network. The connectivity of the user will decide the rate of diffusion of the user's tweet in his network and then his follower's network and so on until it reaches all the nodes in the connection. The rate at which the user's tweet is spread depends on the connectivity of the user in his follower relationship and then his fans influence their respective neighbor's network

The centrality of the node gives the importance of the node in the relationship network. The centrality of the node can be measured by degree centrality, betweenness or closeness centrality.

$Sa(u)$ is defined to measure the network influence of a node in the network and it is represented by:

$$sa(u) = C_d(u) + C_b(u) + C_c(u) \tag{9}$$

where $C_d(u)$, $C_b(u)$, and $C_c(u)$ are the degree centrality, betweenness centrality, and the closeness centrality of the user respectively.

The nodes disseminating ability is given by:

$$\pi_{uv} = \begin{cases} \frac{sp(u) + sa(u)}{u_{\text{out}}} & \text{if } u \text{ follows } v \\ 0 & \text{otherwise} \end{cases} \tag{10}$$

Thus, all the nodes disseminating ability is calculated and put in the form of a transition matrix. Using a random walk method and the page rank algorithm, the UIRank is defined as:

$$IR(u) = \alpha \sum_{v \in \text{followers}(u)} (IR(v) * \pi_{uv}) + (1 - \alpha) \tag{11}$$

where α is a delay factor.

The performance of UIRank is compared to the other four influence finding methods like retweet Rank, outdegree rank, tunk Tank, and fans Rank. The results derived show that UIRank performs best on precision, recall, and F measure, as compared to the other four.

Further, the work can be improved by considering the topic of the tweet posted by the user to find the influence of the user on that topic and also finding the trust factor of the tweet posted by the user.

3.5 Based on Evidence Theory or Belief Based

Evidence theory or Dempster–Shafer theory (DST) works on the principle of reasoning with uncertainty. The theory combines, evidence from many sources and then arrive at a belief.

The evidential centrality (EVC) uses the nodes degree and the weight strength of each node in the network to find the influential nodes in the network [13]. However, EVC assumed a uniform distribution regarding the connectivity of the nodes, however, in the complex networks, the interconnectivity of the nodes in the network is unpredictable, and thus it may not be suitable for the complex weighted network. Thus, to overcome the assumptions of the EVC method, semi local structure centrality (ELSC) along with modified EVC [14] was used to find out the influential nodes in weighted networks.

The most common relationships in the twitter social network are follow, mention, and retweet. The belief function is used [15, 16] to overcome the data imperfection in the twitter dataset due to the limitation on the data extraction from twitter. It considers the strength of the link between the direct neighbors, information exchange, and propagation between the users and the assumption that if the user is connected to an influential node, becomes influential. Thus, the influence calculation has been taken up in two sections, the first section where the influence of the node on the directly connected nodes are calculated and the section calculates the influence of the user's neighbors in their respective network. The results of this

method show that it fetches better seed sets of influential users as compared to the previous methods.

3.6 Formal Weighted Concept Analysis

Formal concept analysis (FCA) [17] uses binary objects and attributes relationships to build the knowledge hierarchy which very well represents the relationship between the objects and attributes. A social network can be represented in terms of the formal context by representing the connectivity of the network where nodes indicate the objects and the attributes whereas the edges indicate the binary relationship between them.

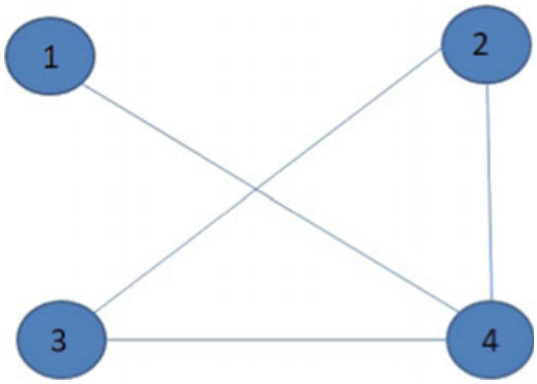
To calculate the important nodes using FCA includes three steps. First, the concepts are computed from the adjacency matrix of the formal concepts. Then, the weight of each node is calculated based on the concepts. Thus, to rank the nodes in the network based on its importance, the weighted formal concept Analysis (WFCA) [18] is used, where the hierarchical tree is generated from the cluster of nodes and then the concepts of the network are computed.

The adjacency matrix in Fig. 3b of the graph from Fig. 3a is considered as the formal concept where a row represents an object and a column represents an attribute. Thus, the weight of each node is calculated and then ranked according to this weight, given by

$$w_i = \sum_{k=1}^{n} \frac{O_{ik}}{A_{ik}} \tag{12}$$

where O_{ik} is the object number of the concept C_{ik} and A_{ik} is the attribute number of the concept C_{ik}

(a)



(b)

	1#	2#	3#	4#
1	0	0	0	1
2	0	0	1	1
3	0	1	0	1
4	1	1	1	0

Fig. 3 An example network **a** Graph G for the network. **b** Formal context of the network G

Once the weights of the nodes are calculated, they are ranked depending on their weights.

The adjacency matrix for the network in Fig. 3a is constructed and shown in Fig. 3b. The entries in the adjacency matrix are either 1 or 0 representing the presence of an edge between the nodes or absence of it, respectively.

Figure 4 represents the Hasse Diagram which contains all the concepts of the formal context. The weights, $W_{i,}$ of all the nodes are calculated using the equation 17 to find the rank of the nodes. From the example network of Fig. 3a, the weight of the node 1 is calculated by using the value of its attributes and objects as follows:

({4}, {1#}), ({4}, {1#, 2#}), ({4}, {1#, 3#}), ({4}, {1#, 2#, 3#,}). Thus, according to the equation 17, the weight of the node 1, W_1, is: $\frac{1}{1} + \frac{1}{2} + \frac{1}{2} + \frac{1}{3} = 2.33$. Similarly, the weight of node 4 is: $\frac{3}{1} + \frac{1}{2} + \frac{1}{2} = 4$.

After calculating the weights of each node in the network, they are ranked. So from the above example, using WFCA, node 4 is considered to be most influential among other nodes in the network.

4 Outcome of the Review

- Since the social network's size is increasing exponentially, thus to find an influential node, a sample of dataset representing the social network is

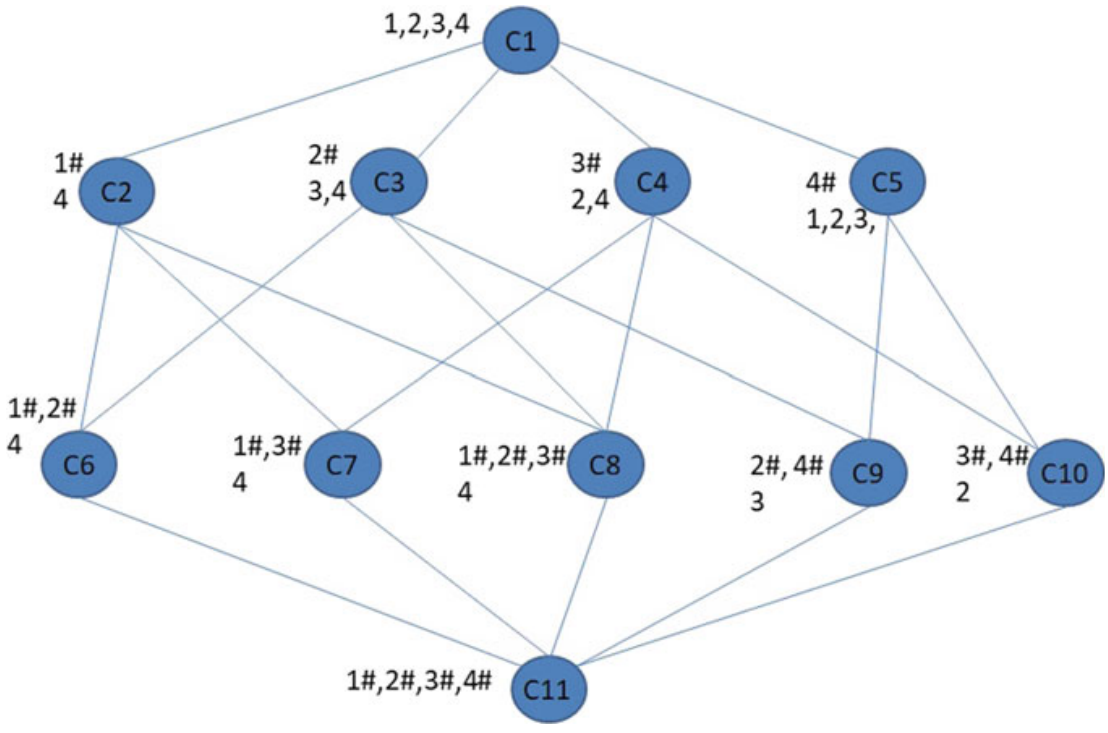


Fig. 4 Concept lattice (Hasse diagram) for the graph in Fig. 3a

considered. Thus, the accuracy may suffer as the result depends on the sample set that is chosen.

- The user's interest can be determined based on the activity of the user, like tweet or retweet. However, if a particular topic is not of a user's interest, he/she may not react to it at all or may give a negative comment. Thus for any business model trying to use influence on social media to promote their business, can't blindly use the user (influential) without knowing their sentiment regarding the product. For example, a user is a well-known wrestler who has won a gold medal at Olympics (thus influential), if an artificially flavored juice product is given to him to promote among his followers, he may not react to it at all.
- Influence of web users is determined by (1) connectivity of the nodes [4–6, 19, 20], (2) through user categories [8], (3) interaction-based [10, 21, 13], and (4) based on the content of the tweet as well as the connectivity [14]. It is observed that the two methods, the content of the tweet and the connectivity is considered, yields a better accuracy, thus there is a need to find the influence based on a method which considered all the above parameters and thus accuracy of the result will be improved.

5 Conclusion

The determination of influential users in the network can be done in many ways; however, the result of finding the influence by combing two or more methods is better as compared to determining by just one method as shown in [12, 14, 15]. Thus, to obtain an accurate and improved result, it is advisable to combine two or more appropriate methods. The study also reveals that one can create a fake influence by retweeting/commenting/following the already established, highly influential user on social media, without being actually influential. The author proposes to explore this issue in future work. A method to detect such fake influencers may be devised so that such users are excluded from the list of the influential user.

Factex: A Practical Approach to Crime Detection

Rachna Jain, Anand Nayyar and Shivam Bachhety

Abstract The crime on roads is a major problem faced today by all the modern cities. Road Transport is the most common escape route for many criminals. Thefts and many other crimes remain unregistered and unsolved due to lack of evidence. Effective tracking of vehicles and criminals is still a big problem and involves plenty of resources. To evade such a condition, we have proposed a machine learning-based practical crime detection system using the text and face recognition techniques. Such systems will be proved useful in parking lots, toll stations, airports, border crossings, etc. In the proposed system, the text recognition involves extracting the characters present in the Indian number plates and the predicted output will be compared with the registered vehicle database. Simultaneously, Face recognition feature constitutes identifying criminal faces based on certain face regions and then mapping the respected coordinates with the criminal database. The proposed system presented in this research paper targets to deliver improvised outcomes considering the time constraints and accuracy with more than 85% successful recognitions in normal working conditions with the goal to accomplish the successful detection of crime using machine learning algorithms such as KNN, SVM, and face detection classifiers to present a practical real time detection.

1 Introduction

The recent works in computer vision and machine learning, text recognition, and face recognition can be visualized as effective measures against rising criminal activities. Using video surveillance, license plate recognition has been an effective approach utilized in the past for traffic management and crime detection. With the integration of text recognition from number plate, an added feature of face recognition can prove to be a boon to the overall system. These techniques involve certain considerations of subjects, posture, emotions, and light for its smooth implementation. Text recognition [1] involves the basic steps of extraction, recognition, and identification of characters, whereas Face recognition [2] involves detecting faces, matching the input face images based on pre-stored face data points and its coordinates and then identifying it. The implemented method with a limited dataset can be seen as a milestone for better surveillance if extended to actual case databases [3]. In the proposed system, KNN is used as text recognition technique and HAAR Faces Classifier and SVM technique for the performing face recognition.

In India, the problems related to traffic are increasing day by day. A typical number plate in India has black foreground color and white background color for private cars. The number on the license plate consists of the two-digit letter showing "state code" followed by two numeral digits, followed by a single letter and then the last four digits. The system consists of the identification of number plate present in the car and then segmentation of all the characters on the number plate. The identification task is interesting because of the nature of the light. Noise in the image background and other environmental factors can result in low accuracy of output. In the proposed system, the edge detection method and mid-filtering are used for noise removal. The next aspect of face recognition consists of mining some significant features of the image and then transforming them for classification. It mainly involves geometric computation of facial features as regions. The face recognition process consists of making a database of faces with numerous facial images for each person. Next, is to detect faces present in the database and then train the face classifier. The last step is testing the classifier to recognize faces it was trained for.

This paper highlights a novel approach to recognize the license plate and criminal face in real time and then matches the output in the vehicle registration database and criminal record face database respectively. The output result produces an email alert to the respective concerned authorities with the license plate number and recognized face details from the database.

1.1 Organization of Paper

Section 2 elaborates the related works highlighting the contributions by several other authors in the corresponding domain. Section 3 highlights the proposed

system, methodology as well as the algorithm used for the live implementation of the proposed system. Section 4 gives a detailed overview of the results produced by the system. Section 5 concludes the paper with future scope.

2 Related Works

Various techniques are proposed and implemented in the past few years regarding license plate detection using visual image processing. Vuong et al. [4] focus on license plate detection based on features like color feature, edge detection, equilibrium, and other operators. Gou et al. [5], proposed license plate detection system in which the structure is regarded as a crucial factor to verify characters from number plate and extraction is done via projected segmentation. For most of the algorithms, Sobel as edge detection operator is frequently used and marked as the best method to transmit from grayscale image to gradient image. Ahmad Radmanesh [6] focused chiefly on the vertical edge detection via the Sobel detection, in comparison to the horizontal edge density of background objects. The template matching and neural networks proved to be an effective technique for character segmentation and recognition as used by Zhu Wei-gang et al. [7] but template matching feature has many limitations when compared to neural networks. After segmentation, the neural network method is expected to be the template match one.

The first approach established for proficiently demonstrating faces was using PCA. The aim of this method was to present a human face as a coordinate system. The vectors setup on the coordinate system were known as eigenfaces vector. Later, Turk and Pentland used this to develop an eigenface-based algorithm for face recognition [2]. SVMs as linear classifiers were first used by Osuna et al. [8] to feature the border between the resulting hyperplane and the training set examples. The ultimate goal of optimal hyperplane was to minimize the error in the classification of the unseen test patterns. Schneiderman and Kanade [9] labeled an object recognition algorithm and projected the results via Bayesian classifier. The result lies in computing the probability of a face to be present in the image based on the count of the frequency of occurrence of a series of patterns over the training images. Saraswathi et al. [10] proposed face recognition authentication process via feature extraction technique, i.e., Linear Discriminant Analysis (LDA). It generates facial regions and then classifies using Euclidean Distance. The experimental results were as high as about 93.7% using the LDA feature set. Extending the PCA to GPU power, Bhumika Agrawal et al. [11] with the help of NVIDIA CUDA performed computations for faster processing of face recognition on Principal Component Analysis algorithm. In the later phase, the work is compared to varied CPU implementations. Jian Yang et al. [12] used the one-dimensional, pixel-based error model based on regression analysis to characterize two-dimensional error image matrix, namely nuclear norm-based matrix regression (NMR) and the alternating direction method of multipliers (ADMM) to estimate the regression coefficients.

3 Proposed System

The present system is mostly based on license plate number recognition using video surveillance, but it has several limitations. The systems based on OCR are highly time-consuming lacks any facial identification for crime detection. The system proposed in this research paper is highlighted in Fig. 1 for observing and supervising real time traffic in the parking lots of private and public organizations, airports, toll booths, and border crossings. Apart from identifying any stolen vehicles, it is highly proficient to track escaping criminals. With minimal processor units and cameras, the system can be installed with much ease. A 24/7 all-time working solution can eliminate human dependency and prevent any crime in the case of negligence also. It can also help keep evidence of crime by capturing images and be used in future investigations. Other benefits of the proposed system include fake number plate detection, tracking criminal activities and better surveillance.

The proposed system has certain limitations in terms of light illumination, masked face identity or makeup, predicting accuracy, facial emotions, and expressions.

3.1 Methodology: Algorithms and Implementation

3.1.1 Text Recognition

K-Nearest Neighbors (KNN) Algorithm

KNN is used for classification of characters present on the number plate. In classification, the class of an object is calculated using the class of its neighbors as

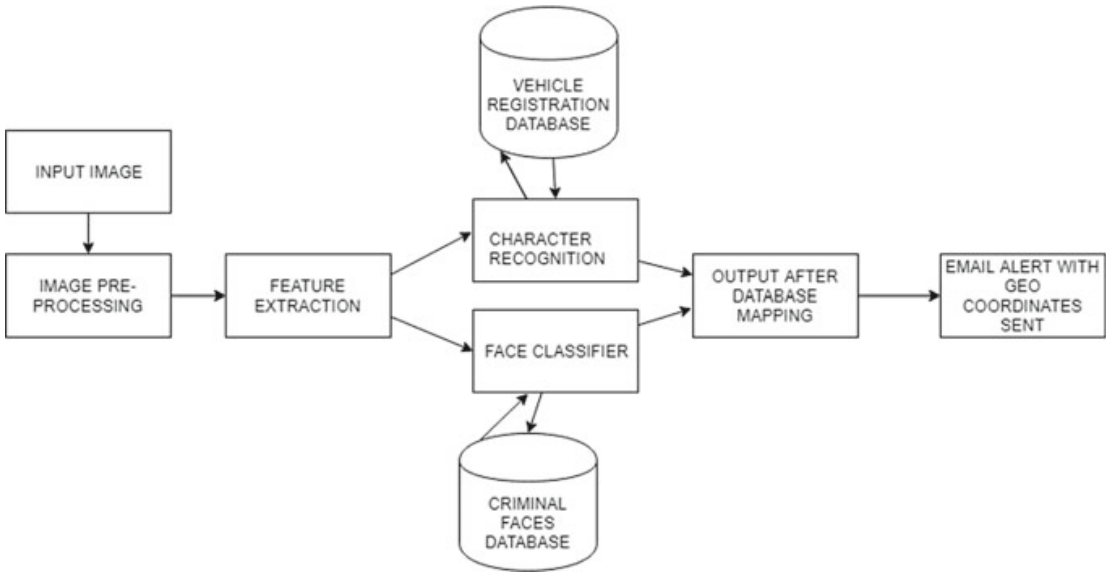

Fig. 1 Proposed method working flow diagram

shown in Fig. 3. It involves two main steps: 1. Character Segmentation [13] and 2. Character Recognition [14]. Characters including alphabets and digits are trained and then recognized by extracting features from the image. The characters are segmented first and then recognized by the algorithm as shown in Fig. 2 (Table 1).

Number Plate Recognition: Steps

Text extracted from the number plate comprises of various steps:

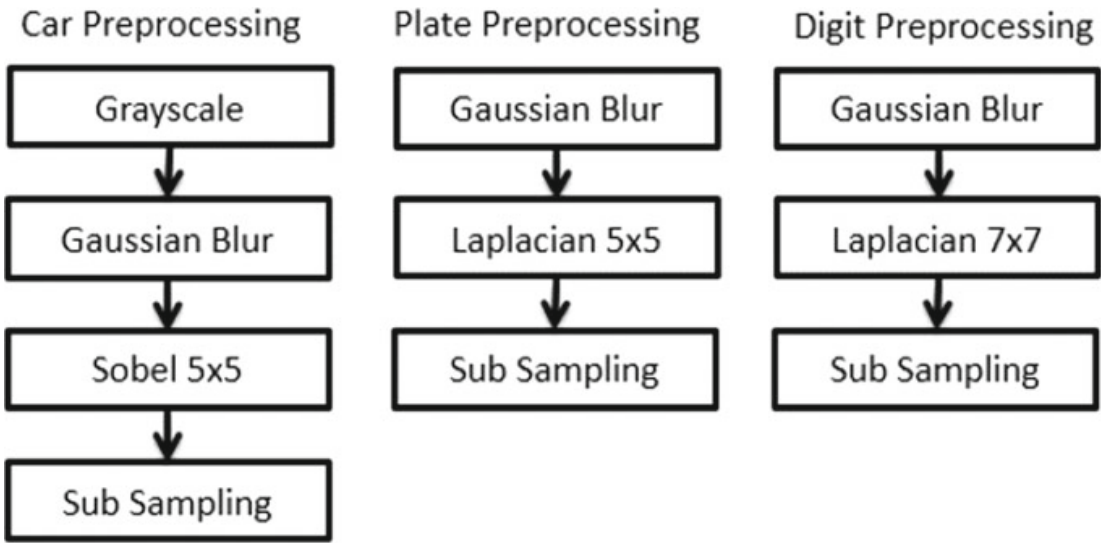

Fig. 2 KNN algorithm flowchart of steps in text recognition

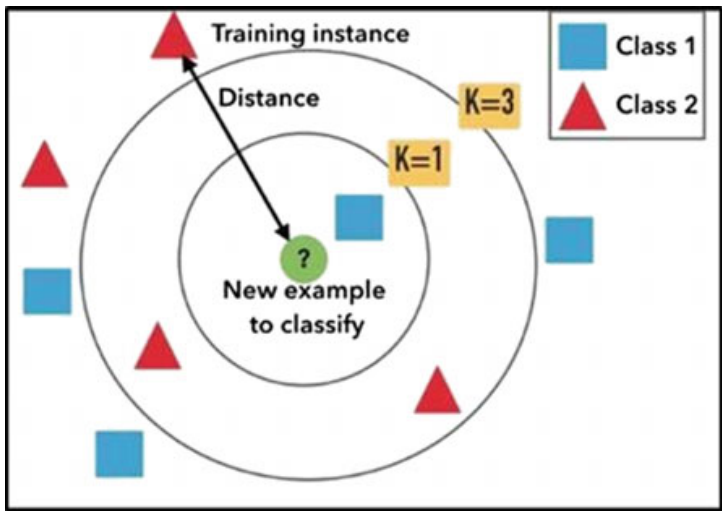

Fig. 3 Green circle is the sample for which classification has to be performed. It has to be assigned either of the two classes, i.e., either class 1 of blue squares or class 2 of red triangles. With $k = 1$, class 1 is assigned to it as its 1 nearest neighbor is a blue square. Now when $k = 3$, class 2 is assigned to the sample because there are 2 triangles in comparison to only 1 square inside the inner circle. *Source* https://cdn-images-1.medium.com/max/800/0*Sk18h9op6uK9EpT8

Table 1 k-NN Algorithm comparison

Pros	Cons
Output is not affected by those sets that are outside the selected boundary	Storing all the training data makes this algorithm computationally expensive
Assumptions are not made by KNN	More memory is required
One of the simplest algorithms	If the value of k is high, then output may be slow
Accuracy is high but not as high as some of the other better supervised learning algorithms	Output is affected by unrelated features and noise

- *Step 1* Capturing the image from a camera.
- *Step 2* Converting an original image to a grayscale [15] image.
- *Step 3* Converting the grayscale image to binary image and applying morphological transforms using OpenCV library for the ease of detection of a license plate from the image.
- *Step 4* Applying Gaussian blur filter [16] to smoothen the image.
- *Step 5* Listing all contours in the image to remove the boundary of the image that has the same color of intensity.
- *Step 6* Applying KNN algorithm to list all matching characters [17] in the image.
- *Step 7* Listing all possible plates that can be found in the image.
- *Step 8* Selecting the highest probability [18] license plate that is matched from the standard license plate measurement and extracting it.
- *Step 9* Reapplying/Repeating steps 2 to 8 to the number plate after extracting it so as to recognize the characters in the number plate. Recognition [19, 20] is done with the help of the KNN algorithm with the training data set. Recognized characters with KNN results in the output [6].

Face Recognition

For face recognition [21], dlib and OpenCV are used to spot all facial landmarks. Relevant regions of the face are represented by facial landmarks [22]. These regions are:

- Eyes
- Nose
- Jaw
- Mouth
- Eyebrows.

Detection of Facial landmarks is a subset problem of the shape prediction problem. In shape prediction problem, the aim is to identify and localize important points of interest.

In the problem of face recognition, facial landmarks are localized by identifying key points in the face. With problems such as face alignment, head pose estimation, face swapping, blink detection, etc., facial landmarks have been effectively used.

For detecting facial landmarks, the following two steps are used:

- *Step 1* In the image face is identified and localized.
- *Step 2* Key facial structures are detected in the face.

Step 1 Different ways of performing Face detection (Step 1):

- OpenCV's built-in Haar cascades.
- Pre-trained HOG + Linear SVM object detector.
- Deep learning-based algorithms designed for face localization.

Irrespective of the algorithm used, our main aim in this step is to find a closed bounding box around the detected face. This is achieved by finding the set of (x, y) coordinates that bound the face.

Step 2 No matter which face landmark detector is used the basic thing they all do is localizing key facial regions. These regions include:

- Right eyebrow
- Left eyebrow
- Right eye
- Left eye
- Mouth
- Nose
- Jaw

- In this method, images in which facial landmarks are manually labeled are used as training images. These specify (*x*–*y*) coordinates of regions surrounding each facial structure.
- Without feature extraction [23], from pixel intensities, the facial landmark positions are projected and a group of regression trees is trained.
- All this results in creating a detector that can detect facial landmarks in real time with good efficiency.

dlib's facial landmark detector.

In the proposed system, the dlib's facial landmark detector is used. It estimates the location of 68 points that locates various facial structures in the human face.

Figure 4 demonstrates the indexes of the 68 coordinates of the human face.

3.1.2 Face Recognition: HAAR Faces Classifier and SVM

Considering face recognition, the complete process can be divided into three main steps:

1. The first step involves finding a decent database of faces which contain several images of each person.

Fig. 4 Picturing the 68 facial landmark coordinates. *Source* https://content.iospress.com/articles/journal-of-intelligent-and-fuzzy-systems/ifs169436

2. The second step is to find faces in the database images and make use of them to get face recognizer trained.
3. The last step is to check face recognizer whether it identifies faces it was trained for or not.

Database

The database is created using webcam capturing images of an individual (Fig. 5).

Face Detection Classifiers

A classifier [24] is a computer program that finds out whether an image is a positive image (face image) or negative image (non- face image). We are using OpenCV [25] for this purpose.

Every file starts with the name of the classifier, it belongs to. For example, a Haar cascade classifier starts off as *haarcascade_frontalface_alt.xml.*

Haar Classifier

The Haar Classifier [4, 5] is an algorithm made by Paul Viola and Michael Jones which uses a machine learning-based approach.

It gets started by digging out Haar features [5] from each image as shown in Fig. 6.

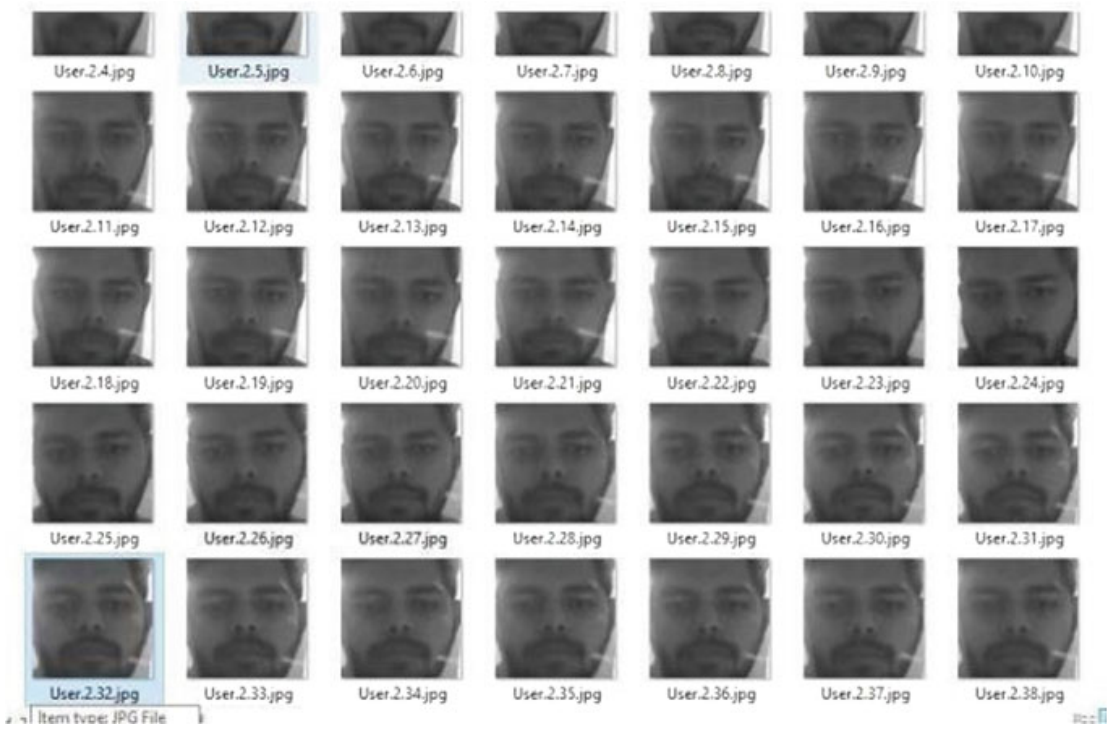

Fig. 5 Image database consisting of 50 images of individual people. Each image has an altered facial expression [JPG]

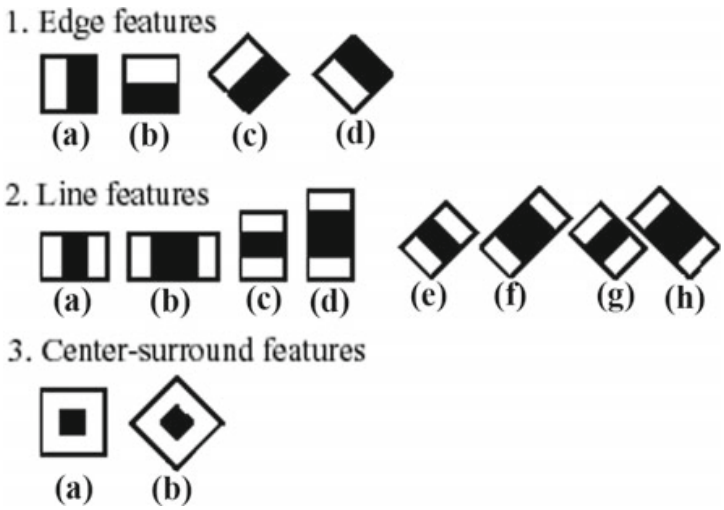

Fig. 6 A couple Haar-like edge, line and center-surround features. *Source* https://docs.opencv.org/2.4/_images/haarfeatures.png

A particular feature is determined by placing each window on the picture. This feature is denoted by a single value which is calculated by subtracting the sum of pixels below the white part of the window from the sum of pixels below the black part of the window [26, 27].

Now, plenty of features are determined by placing all possible sizes of each window on all possible locations of each image. In the end, generally the fact which is considered by the algorithm is non-face region [28, 29] covers most of the area in an image:

- Step 1: Adjusting Tolerance/Sensitivity [30].
- It is done with the tolerance parameter [31]. The default tolerance value is 0.6 and lower the numbers, stricter become face comparisons.
- Step 2: All the faces in an image are automatically found.
- Step 3: The facial features of a person in an image automatically located.
- Step 4: Faces in images are recognized and identified who they are.

4 Result Analysis

The following results were produced using Python programming language. Every detailed step from grayscale conversion to possible vector contours for number plate recognition is shown in the Fig. 9 for the number plate highlighted Fig. 7. Figure 8 shows the predicted output produced on the screen. The result of face recognition is shown in Fig. 10 with the identified faces marked with red squares and the respective names under it. The screen displays Unknown in case the name is not present in the database. The results are much accurate compared to real time objects when tested with different images.

Fig. 7 Actual image of number plate

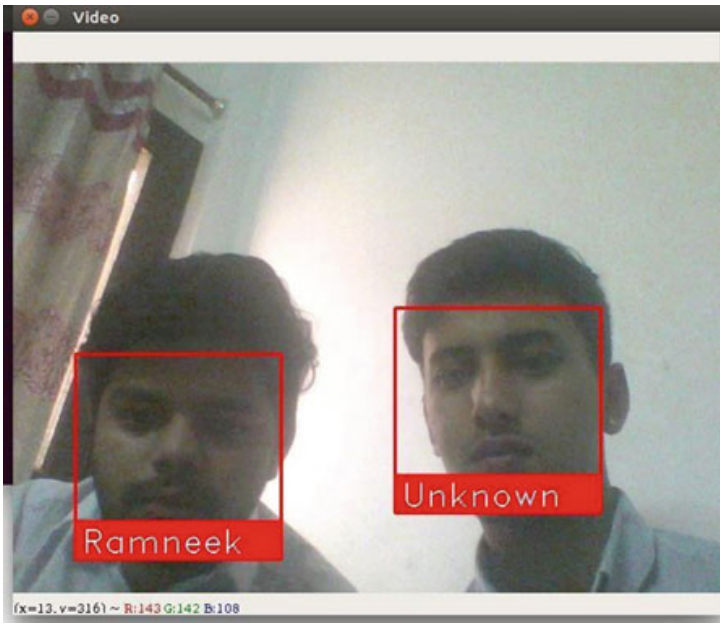

Fig. 10 Final output window of real time face recognition based on image dataset

5 Conclusion

The system for crime detected is improved with much more accurate results and higher efficiency. This system is complete and sophisticated in terms of crime detection. It uses the features of both text and face recognition. Segmenting the characters of the license plate and the English letters and numerals are trained as per the requirement of Indian number plate. Using Gaussian Blur filter in KNN algorithm makes it efficient to deal with all types of images for number plate detection irrespective of noise, intensity, and other factors. It generates multiple plate combinations and chooses one with the highest probability. Similarly, for face recognition, the self-built database is predicting much accurate results in terms of lighting conditions and the movement of persons. The localized facial features based on sensitivity and tolerance parameter in Haar Classifier can also be changed as per requirements. Also, the present values are fit enough to predict well in almost all conditions. The final implementation involves an effective tracking module in the form of a Python Email Script that sends an alert message to the concerned authorities and the nearby police stations and geo-coordinates of the place where the criminal activity took place including the number plate and criminal name detected after matching with their respective databases. The proposed system working with an accuracy of more than 85% successful detections in ambient light conditions.

6 Future Scope

For higher precision and accurate model, certain new features and techniques need to be incorporated to identify faces in all possible conditions of light, barriers in front of the face and aging of facial features with time. An additional phase of the exploration involves, developing a generic model to be installed at all traffic lights in the cities for operating it in dynamic moving traffic.

Analysis of Classification Algorithms for Breast Cancer Prediction

S. P. Rajamohana, K. Umamaheswari, K. Karunya and R. Deepika

Abstract According to global statistics, breast cancer is the second of all the fatal diseases that cause death. It will cause an adverse effect when left unnoticed for a long time. However, its early diagnosis provides significant treatment, thus improving the prognosis and the chance of survival. Therefore, accurate classification of the benign tumor is necessary in order to improve the living of the people. Thus, precision in the diagnosis of breast cancer has been a significant topic of research. Even though several new methodologies and techniques are proposed machine learning algorithms and artificial intelligence concepts lead to accurate diagnosis, consequently improving the survival rate of women. The major intent of this research work is to summarize various researches done on predicting breast cancer and classifying them using data mining techniques.

Keywords Breast cancer prediction · Classification · Decision tree · Feature selection · K-NN · Random forest · SVM

1 Introduction

A malignant tumor developed from breast cells is termed as breast cancer, and it is the most commonly observed type of tumor in women. Almost 70% of deaths due to cancer arise in poverty-stricken and developing countries. Breast cancer affects about

10% of women at some point during their lives. As of late, the death rate continues to expand, with 88% of survival following 5 years from determination and 80% following 120 months from conclusion. There exists a popular method, called knowledge discovery in databases (KDD) which is used by medical researchers to predict the disease outcome by discovering patterns and relationships among the various number of variables stored in the database as historical data. In order to maintain the natural working mechanism of the body, a balance must be maintained between the growth and death rate of cells. But sometimes there is an abnormal and rapid growth of cells which can lead to cancer. Among numerous types of cancer, breast cancer is the major cause for the death of the women worldwide [1]. It is proved that there is a reduction of 38–48% in the mortality rate. There might be several reasons for breast cancer, including age, bosom density, obesity, and changing food habits like alcohol, causing undesirable effects. It is evident from the recent statistics tha, currently the scenario has become worse. The major symptom is a lump observed underarm or in the mammary gland that continues to exist even after the menstrual cycle of a woman. Out of the lump formed, most of them are painless, some may give prickly sensation. The other common symptoms are redness, swollen lymph nodes, or thickening or puckering off the skin. Milk secreting and duct cells are the main cells that cause tumors by draining the milk into the nipple from lobules. A proportion of growth developed from fibrous or fatty tissue can lead to breast cancer. This kind of gene mutation related to cancer is very popular among woman. The treatment for breast cancer includes chemotherapy, hormonal therapy, and radiation therapy. The efficiency result of treatment is comparatively low and requires more attention for preventive measures and control in the current research world. Many breast cancer charities are organizing campaigns such as National Breast Cancer Awareness Month (NBCAM) on the eighth month of every year to bring about awareness of breast cancer in society. This annual international health campaign assists in raising funds for research in breast cancer.

Breast Cancer is categorized as follows:

(i) **Benign (Noncancerous)** The benign cases are those which are noncancerous and non-life threatening. But they could turn into cancerous cells easily. However, these cells could be easily separated.
(ii) **Malignant (Cancerous)** Malignant case leads to abnormal cell growth invading nearby tissues. It is life-threatening in most cases.

Many researchers proposed various data mining algorithms that are deployed for the diagnosis of breast cancer. Among which, feature extraction and classification algorithms employed in it lead to the design of an efficient system. These techniques provide a significant process for extracting the key features which can lead to a proper diagnosis. It is experimentally proven that machine learning and deep learning algorithms are efficient when compared to conventional approaches [2].

2 Breast Cancer Overview

The twentieth century is also called as the cancer century because hundreds of cancer types were discovered in this century. After decades of hard work in analyzing various types of cancers, doctors are now able to identify the causes of these diseases, preventive measures to adopt, and type of treatment to be given. Among all types of cancers existing, breast cancer is rampant among women, very rarely in men. Heredity is a major factor among multiple factors that can cause breast cancer. Nearly 15–20% of women identified with breast cancer has had a recorded occurrence of the same through their generations. In extremely rare cases, a gene called p53 is responsible for breast cancer. The severity of breast cancer was 16 times more than average in families having this type of gene. The number of families with this gene is about 100 all over the world. Researchers have noticed the double risk of breast cancer in individuals producing wet wax of ear glands than in those producing dry wax. Some of the most common symptoms and types are listed in Tables 1 and 2.

Table 1 Breast cancer factors with symptoms

Breast cancer risk factors	Symptoms
Age	• Redness • Swollen lymph nodes • Thickening or puckering of the skin • Scaling of nipple
Family history	
Genetics	
Breast cancer history	• Dimpled skin • Change in the texture of the skin • Breast or nipple pain
Exposed to radiation in the chest or face below the age of 30	
Race/ethnicity	
Being overweight	
Menstrual history	
Drinking alcohol	

Table 2 Breast cancer types

Types of breast cancer	Description
Metastatic breast cancer	Cancer cells break and spread from the original tumor to other parts by means of the lymphatic system or through the blood
Phyllodes tumors of the breast	These are rare case tumors which require surgery to reduce the risk as they can grow rapidly fast. Phyllodes tumors are malignant and borderline benign
Lobular carcinoma in situ	In this type, the growth of cells in milk producing glands is abnormal and increases the person's risk of developing invasive breast cancer
Inflammatory breast cancer	Instead of lump, this type of cancer is found with swelling and reddening in the area of the breast and spreads rapidly to other areas with symptoms worsening
Invasive lobular carcinoma	Also known as infiltrating lobular carcinoma. It starts in duct cells of milk carrying area and spreads beyond it

3 Related Works

There are several studies on breast cancer prediction based on machine learning algorithms.

A. A Novel Approach for Breast Cancer Detection Using Data Mining Techniques [2014]

Chaurasia and Pal [3] compared the performance of the supervised learning classifiers like Naive Bayes, decision tree, and SVM-RBF kernel and simple CART. The dataset that is used for classification is the Wisconsin breast cancer dataset that comprises 11 attributes. The attributes include sample code number, clump thickness, uniformity of cell size, cell shape, and marginal adhesion. The experiment's results proved that the SVM-RBF kernel has the maximum accuracy of about 96.84.

B. Artificial Neural Networks Applied to Survival Prediction in Breast Cancer [2000]

Lundin et al. [4] constructed the classification model using neural network and statistical analysis. The dataset that is used consists of the attributes like age, primary tumor size, axillary nodal status, mitotic count, and tumor necrosis. The dataset contains the details of 951 breast cancer patients, predicted 5-, 10-, and 15-year breast cancer by using ANN and logistic regression models. The accuracy obtained from the constructed model is about 94.35% which is a considerable accuracy.

C. Hybrid Bayesian Network Model for Predicting Breast Cancer Prognosis [2009]

Choi et al. [5] constructed the classification model using artificial Bayesian network. The dataset that is used consists of the attributes such as age at diagnosis, a clinical extension of the tumor, and the number of primary tumors. The dataset consists of the details of 2, 94,275 breast cancer patients. This dataset uses 15 attributes of which seven are primary attributes, seven derived, and one target attribute. The accuracy obtained from the constructed model using the artificial Bayesian network is 88.8%.

D. Predicting Breast Cancer Survivability: A Comparison of Three Data Mining Methods [2004]

Delen et al. [6] refined a prediction model with the help of ANN, decision tree, and logistic regression to envision breast cancer and to determine the survival rate by analyzing the SEER cancer incidence database. The SEER breast cancer dataset consists of 4, 33,272 records and 72 variables. The accuracy obtained from the model is 89.2%.

E. Using Three Machine Learning Techniques for Predicting Breast Cancer Recurrence [2013]

Ahmed et al. [7] analyzed the use of decision trees, SVM, and artificial neural network on breast cancer prediction. The dataset used contains population characteristics and includes 22 input variables. The sample dataset is the data collected from 1189 women. The experimental results found that the SVM produced the least error rate with greater accuracy of 95.7%.

F. Breast Cancer Prediction Using DT-SVM Hybrid Model [2015]

Sivakami [8] developed a model for the breast cancer prediction which uses the Wisconsin breast cancer dataset. The dataset encompasses 699 records, containing 458 belonging to the benign class and the remaining to malignant class. The data is collected from the needle extracts of patients' breasts. Before the prediction process, preprocessing must be done. Preprocessing fills up missing values with attribute's mean value in the dataset. The nine traits of the dataset include uniformity in size of the cell, the shape of cell, and thickness of clump. The implemented algorithm in this work is based on SVM and decision tree. The accuracy obtained from the classification model is 91%, and the error rate is 2.58. The number of precisely classified instances is 459 and imprecisely classified instances are 240.

G. Combining Bagging and Boosting [2007]

Kotsiant et al. [9] worked on various ensemble approaches such as bagging, boosting, and combination of both with a variety of base learners. They are C4.5, Naïve Bayes, OneR, and decision stump. These algorithms used datasets from the UCI repository dataset. The accuracy obtained is about 93.47%.

H. Prediction of Breast Cancer Using Support Vector Machine and K-Nearest Neighbors [2017]

Islam et al. [10] used the most common dataset, Wisconsin breast cancer (WBC) dataset obtained from the repository of UCI machine learning. This dataset consists of 699 instances, where the cases are labeled as either benign or malignant. Classification is performed using SVM and K-NN. The accuracy obtained from the model using SVM and K-NN is 98.57% and 97.14%, respectively.

I. Heterogeneous Classifiers Fusion for Dynamic Breast Cancer Diagnosis Using Weighted Vote-Based Ensemble [2014]

This work proposed an ensemble approach by combining various classifiers including decision tree with Gini index and information gain, Naïve Bayes, SVMn and memory based learner. The classification is decided on the basis of weighted voting. Different datasets are collected from the public repository. Classification accuracy is enhanced using different preprocessing techniques and feature selections. The experimental results conclude that proposed approach contributed to major improvement than other existing classifiers. The accuracy obtained from the ensemble model is about 97.2%, the precision is 100%, and the recall value is 98.60%.

4 Proposed Methodology

4.1 Data Source

The publicly available breast cancer database is used. The database [11] constitutes about 570 records. The dataset consists of numeric attributes. Most of the research papers referred to the 32 attributes present in the dataset for breast cancer prediction.

4.2 Data Preprocessing

The dataset applied in the proposed work is a clinical dataset which may contain many inconsistent, incomplete, or missing data. Such data reduces the accuracy of the model. Hence, preprocessing is an important step that needs to be carried out. To remove the inconsistencies in the dataset, several preprocessing techniques were applied. Also, normalization techniques were applied to handle the missing data. Thus, preprocessing techniques tend to increase the accuracy of the model constructed. The workflow of the proposed model is shown in Fig. 1.

4.3 Random Forest

For the classification of malignant and benign types of cancer, random forest algorithm can be employed. Based on various types of randomization, random forest has

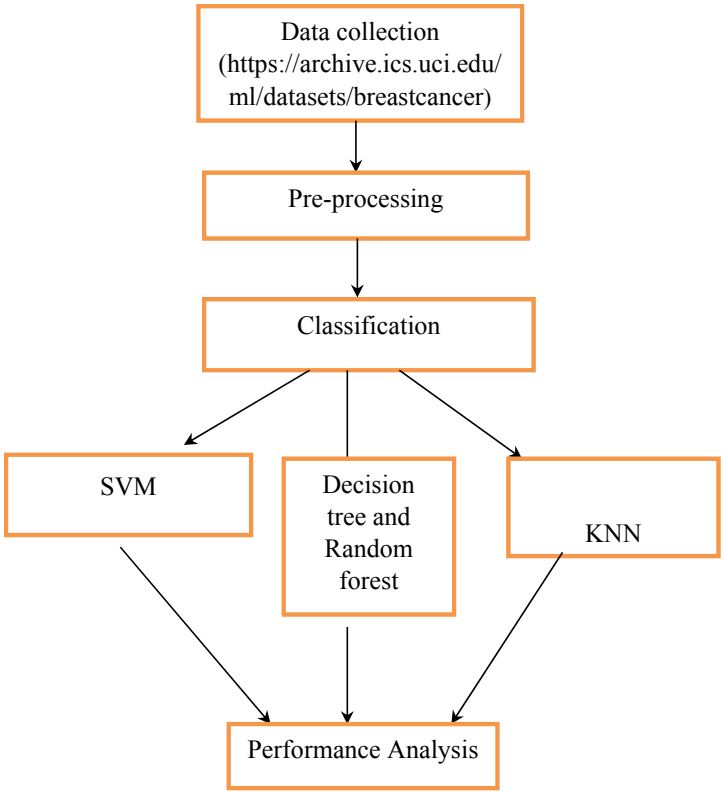

Fig. 1 Workflow of the proposed model

been built as it is an ensemble of decision trees. As the random forests are very flexible rather it is widely used [12]. This supervised learning algorithm creates forests using many trees. The accuracy depends on the number of trees. One of the major advantages with random forest is that it could be functioned as both regression and classification. It can also handle the missing values and it will not overfit in case of a greater number of trees [13]. The random forest takes the test features and predicts the outcome of the randomly created trees based on rules and then stores the result. The votes for each predicted target is calculated, since each tree results in different prediction. Finally, the target receiving high vote will be considered as the final prediction. The random forest processes a huge amount of data at very high speed. The random forest has each tree in binary structure form, which is created based on top-down approach. Generally, the convergence in the random forest algorithm is very fast. The most important parameters are the depth and number of trees. Increasing depth led to an increase in the performance [14]. Thus, random forest is considered as the best classification algorithm on the basis of the processing time and accuracy. This algorithm is implemented on the dataset and the accuracy obtained is 97.34%. The overall view of the random forest algorithm is laid out in Fig. 2.

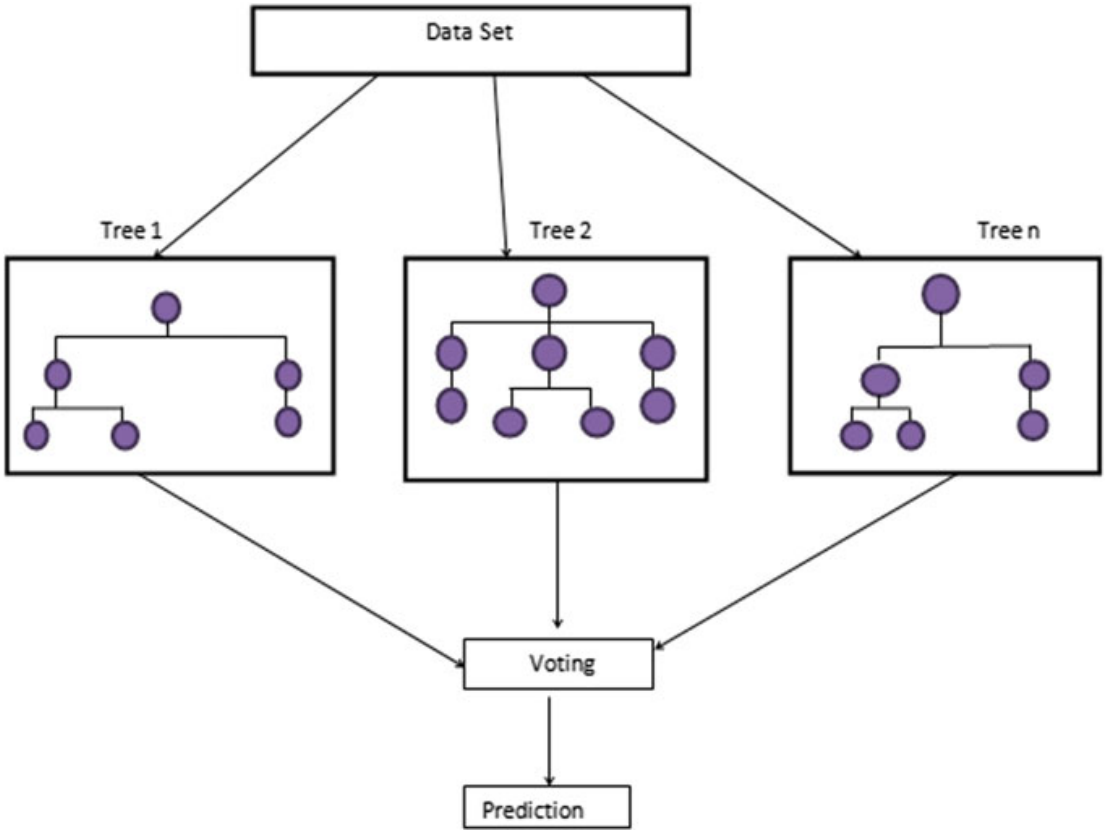

Fig. 2 Random forest

4.4 Support Vector Machine (SVM)

Another powerful supervised learning model is the support vector machine that examines the data for classification and regression analysis using the support of associated learning algorithms. SVM has been specialized for a certain range of problems and gained success in the field of pattern recognition specifically in bioinformatics and cancer diagnosis. In support vector machine, all the data points are drafted in an N-dimensional space [15]. SVM performs linear classification. In addition to this, it also performs nonlinear classification by mapping the inputs implicitly at the range of high-dimensional feature space. The main advantage of SVM is considered to be a unique technique called kernel trick, where lower dimensional space is converted to higher dimensional space and classified. In other words, a hyperplane or set of hyperplanes can be constructed with support vector machine constructs in a high- or infinite-dimensional space for the purpose of classification, regression, or outlier detection [16]. In general, the hyperplane with the largest functional margin achieves good separation as it lowers the generalization error of the classifier. Support vector machine gives an accuracy of 97% when employed on the dataset. The hyperplane used for classification is illustrated in Fig. 3.

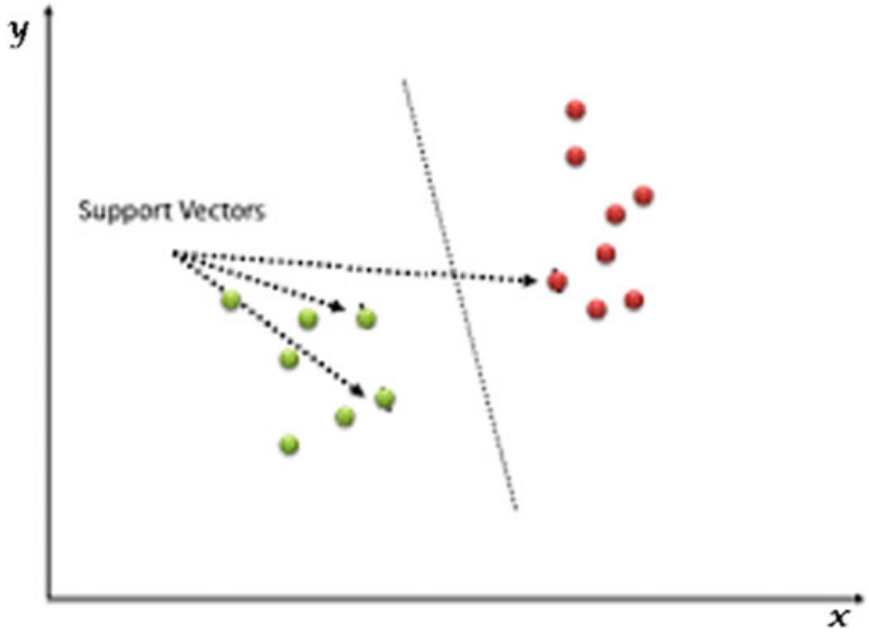

Fig. 3 Support vector machine

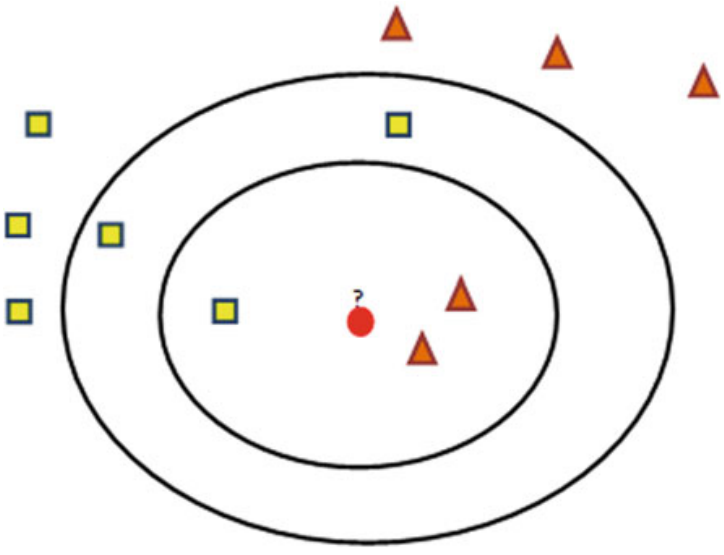
4.5 K-Nearest Neighbor

A nonparametric method, K-nearest neighbors algorithm (K-NN) is another algorithm to be utilized for various purposes like regression and classification. The output of the classification from k-NN is a class label which describes to which class or group it belongs to [17]. In K-NN, the membership is assigned based on the majority vote by the neighbors which is decided by the K value. In other words, each object has been assigned to one class that is most common among the neighbors. For example, if $K = 2$, then the query point is assigned to the class where two nearest neighbors belong to. Being the simplest machine learning algorithm, the explicit training step is not essential. In the training step, neighbors are chosen from the set of objects for which their corresponding classes are known. The algorithm is very sensitive to the local data [18]. Euclidean distance for continuous variables and Hamming distance for discrete variables are most widely used. However, the accuracy can be improved by using specialized algorithms like Large Margin Nearest Neighbor or Neighborhood Components Analysis. The K value is chosen based on the data. Choosing an appropriate K value is significant because that decides if the data is classified correctly. Heuristic techniques like hyperparameter optimization are used because the larger K value reduces the effect of noise but makes less distinct boundaries between classes [19]. The performance gets degraded as the noise in the data increases. The level of accuracy achieved from K-NN is about 95% with an appropriate K value. K-NN is shown in Fig. 4.

4.6 Decision Trees

These are classification algorithms where the attributes in the dataset are recursively partitioned. Decision trees contain many branches and leaf nodes. All the branches tell the conjunction of the attributes that leads to the target class or class labels [20].

Fig. 4 K-nearest neighbor



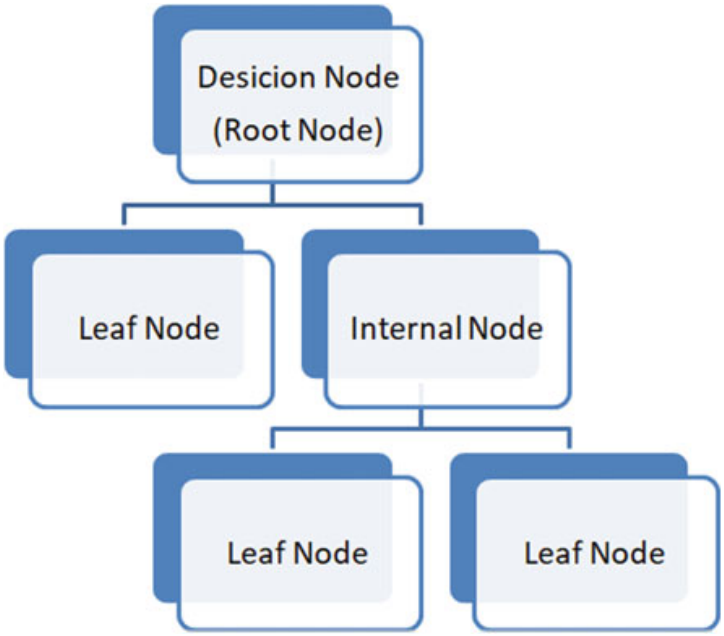


Fig. 5 Decision tree

The leaf nodes contain class labels or the target class that tells to which class tuple it belongs to [21]. There are various decision tree algorithms which can be used for classification of the data. Some algorithms include C4.5, C5, CHAID, ID3, J48, and CART [11, 22].

The Decision Tree can be built as

- The attribute splits decide the attribute to be selected.
- The decisions whether to continue for splitting or to represent as a terminal node is made.
- The assignment of the terminal node to a class.

Information gain, gain ratio, Gini index, etc. are the impurity measures to decide attribute splits done on the tree. After pruning, the tree is checked against noise and overfitting. As a result, the tree becomes an optimized tree. The main advantage of having a tree structure is that it is very easy to understand and interpret. The algorithm is also very robust to the outliers also. The structure of the decision tree is shown in Fig. 5.

5 Experimental Results

Initially, the entire dataset was preprocessed and normalized to handle all the missing values. The mandatory features are extracted using statistical methods. Similar to the experimental results shown in the table above, for the breast cancer prediction, random forests can give a better result that helps the people to get a systematic way of treatment and save their life and hence decreasing the mortality rate. Support vector machines are also equally good with an accuracy of about 91%.

Table 3 Performance analysis of various machine learning algorithms

Algorithm	Accuracy (%)	Precision (%)	Recall (%)
Support vector machine	91	82	81
Decision trees	90.6	83	79
K-nearest neighbor	87	78	76.8
Random forests	93.34	89	86.3

The decision tree and K-NN also give us a good result in predicting breast cancer with an accuracy of 90.6% and 87%, respectively. Hence, a good and accurate model can be built using the algorithms mentioned above. In conclusion, random forest has proven that it is very efficient for breast cancer prediction with an accuracy of 93.34% for diagnosis is exhibited in Table 3. It achieves the finest performance with respect to precision and recall.

6 Conclusion

Most of the Indian women die due to breast cancer [23]. Proper diagnosis of breast cancer is very important in the medical domain. Many models are built using machine learning and data mining methodologies to analyze huge voluminous data. But the challenge with the model is its accuracy and precision for the medical industry. The key for proper treatment and cure is significantly dependent on detecting breast cancer at its early stages [24]. This paper describes how several machine learning algorithms like random forests, decision trees, K-NN, and SVM are employed to model the exact diagnosis of breast cancer for an organized treatment which can save lots of life. The experimental results show the effectiveness of various machine learning algorithms and it proves to be efficient in breast cancer classification thus providing a major breakthrough in clinical diagnosis and treatment of the same. As mentioned earlier, the SVM, K-NN, decision tree, and random forest have their own advantages. Hence, the careful usage of the above will definitely lead to better results. Thus, the appropriate use of a proper algorithm eliminates the risk of death and alleviates the survival rate in women.

Real-Time Footfall Prediction Using Weather Data: A Case on Retail Analytics

Garima Makkar

Abstract Be it a retailer, producer, or supplier, the weather has a substantial effect on each one of them. Climate variability and weather patterns have become critical success factors in retail these days. As a matter of fact, weather forecasting has become a $3 billion business now. One of the main reason behind this surge is the capability of the forecasters to sell weather-related information to businesses who then strategize their various decisions regarding inventory, marketing, advertising, etc. accordingly. Hence only those retailers who stay "ahead of the game" will be able to enjoy huge sales while others who do not would face the consequences. Various studies regarding change in consumer behavior occurring due to the change in weather conditions have shown that even a degree change in temperature affects the store's traffic and reflect the growing importance of predictive analytics in this domain. However, these studies incorporate only the historical weather statistics into account. In this paper, we will propose our methodology for footfall analytics to see how the changes in weather conditions will impact the retail store's traffic and thereby retailing value chain, using real-time weather forecasts and footfall data. This analysis provides a platform for retailers to make evidence-driven decisions and strategize their business plan which would help them to deepen the customer involvement and to get efficiency in the planning process.

Keywords Footfall · Retail · Retailers · Real time · Weather

1 Introduction

Climate decides what shall we eat and wear, where shall we spend our holiday, how shall we commute, and even what shall we do every single day. All in all, weather affects four basic purchasing decisions: where, when, what, and in what quantity to purchase [1]. Be it a producer, supplier, or retailer, the weather has a substantial

N. Sharma et al. (eds.), *Data Management, Analytics and Innovation*, Advances in Intelligent Systems and Computing 1042, https://doi.org/10.1007/978-981-32-9949-8_37

effect on each one of them. From the availability of products and logistics to purchaser demand patterns and sudden spikes, the groundwork for and mitigating the consequences of weather is a real trouble in all aspects of retail sector. Weather conditions affect whether customer would visit brick and mortar outlets or would shop online, making this another important reason for retailers to regulate their operations in order to avoid retail risks associated with different climate patterns. Hence, for retail success, meteorology is as important as geography is. All this have led to the growing importance of weather variability in the retail domain.

Traditionally, it was believed that the retail sector does not get affected much by climate, but a series of recent studies have concluded that retail sector is a weather-sensitive sector. In other words, weather plays an important role in sales of many product categories, store's footfall and store types. Many store managers often blame climate for poor store traffic/sales, but only some of them are able to manage the weather-related risk given that most of the suppliers offer diversified products thus alleviating the effect of weather on store's traffic. Incorporating the effect of weather on consumer behavior demand was considered as a real challenge in the past. For a long time, retailers have been aware of the fact that weather affects the footfall in the stores, but until now, nothing much was being done by most of the retailers to manage such weather-related risks. The rising variability in weather these days have stimulated new interest in studying the relationship between footfall and weather.

Footfall, being a bread and butter for any retail store manager, is directly linked to drive retail sales and improve conversion rates—the more people who come to the store, the more chance they will buy something. While the conditions like heavy rainfall, snowstorm coming, heat and dry conditions, etc., keep the tendency to impact the footfall drastically. So it becomes important to know the footfall peaks and troughs which could help retail managers to optimize in-store operations and manage their resources effectively. Thus we propose a methodology for predicting the footfall of customers in different retail stores given real-time weather forecasts and historical footfall data using a supervised analytical methodology. This paper allows retailers to find the threshold probabilities that will trigger warning and require necessary decisions to decrease inventory waste. Also, this methodology would predict favorable climatic conditions which could be taken care of before-hand in order to achieve retailer's motive of maximizing sale/footfall in real time. Thus, this analysis can be used by retailers to make evidence-driven decisions and strategize their business plan which would help them to deepen the customer involvement and to get efficiency in the planning process.

This paper is divided into the following sections: Sect. 2 highlights the literature survey and critical research gaps. Section 3 defines our problem statement. In Sect. 4, the methodology followed has been proposed. The results are highlighted in Sects. 5 and 6. The conclusion is explained in Sect. 7.

2 Literature Review

This section gives a brief about some of the works that have been done related to retail and weather so far. Generally speaking, these researches can be divided into two groups: (1) theories about the nature of the impact and (2) theories about the magnitude of the impact. Here, impact refers to the impact of weather on consumer activities in a retail store. So the former group explains why and how the change in climate brings the change in retail shopping behavior while the latter explains the extent of the weather change on activities such as consumer spending. The following is the description of some of these theories explaining the consequences which retail sector faces because of the change in the climatic conditions. First, we explain the theoretical work linking weather stimuli to shopper's behavior. Second, we review some of the empirical studies done in this context. Lastly, we review the analytical models predicting the footfall for retail firms during different climatic conditions.

2.1 Theoretical Work

There are different ways by which meteorological factors can affect both psychology and physiology of consumers. Overall, these researches have confirmed that weather has the tendency to influence an individual's mood. For instance, Sanders and Brizzolara [3], studied the effects of various climatic factors such as temperature, biometric pressure, relative humidity, precipitation, and wind speed on a one-dimensional mood rating scale. They concluded that sunshine and biometric pressure together have the strongest impact on mood. Following the same methodology but different mood scales, other researchers like Persinger and Levesque [2], Howarth and Hoffman [4] and Miranda-Moreno and Lahti [5], etc. have reported that rain tends to decrease the sense of comfort of pedestrians impacting consumer's behavior negatively. Similarly, studies by Cunningham [6] and Parrott and Sabini [7] have suggested that sunshine affects customer's mood to visit a retail outlet in a positive way. Experimenters like Sherman et al. [8] and Keller et al. [9], etc., have found that two major factors responsible for moderating psychological effects of weather are the season and the amount of time spent outside and thus pointing toward a positive association between mood and shopping intentions. Robert and John [10] and Gardner and Hill [11] etc., are some of the other contributors of theoretical work done in this context.

2.2 Empirical Studies

All these behavioral instances which are explained in above subsection generally comes from investigational and fieldwork. However, there is also empirical evidence demonstrating the impact of weather on different aspects of retail sector, but the number of works is limited. For example, Steele [12], has presented a paper about weather effects on sales of a departmental store and found that factors like snow, rain, and extreme temperature are responsible for making shopping at store less attractive and thus, affects sales and store traffic negatively. Agnew and Thornes [13], conducted a survey study on the weather sensitivity of food and beverages sector and concluded that in terms of number of customers, the bad weather affects the hypermarkets located in urban areas more adversely as compared to small retail stores located in rural stores. Kirk [1], concluded that about 35% of inquiries in his study would avoid shopping at low temperatures, 37% would avoid going shopping when it is raining, and 30% would not go shopping in excessive heat. Murray et al. [14], further investigated that high temperature is correlated positively to emotions as well as to greater propensity to consume.

2.3 Analytical Work

Various studies regarding change in consumer behavior occurring due to the change in weather conditions have shown that even a degree change in temperature affects the store's traffic, reflecting the growing importance of predictive analytics in this domain. Most of the work on footfall analytics based on weather data has been done using multiple regression analysis. Agnew and Palutikof [15], implemented separate regression models for each month of the year to examine the impact of temperature, precipitation, and sunlight on the total U.K. retail sales and sales of some products categories. Their approach concluded that the sign of the effects of weather variables and percentage of sales volatility is fluctuating between months and product categories. Another regression analysis by Starr [16], concentrating on effect of temperature on the U.K. retail sector, showed that temperature has dual effects, i.e., current and lagged effect in retail. They concluded that weather effect depends on sales assortment and thus, is not same for all retail types. After a year, Parsons [17], examined the correlation between shopping store attendance and weather on a daily basis using a multiple regression model. It was seen that temperature and rainfall are the most tangible weather variables having negative impact on number of visitors while variables like humidity, sunshine hours, etc., show insignificant effect on the store's traffic. However, this analysis was being done for the colder half of the year only. Also, Bahng and Kincade [18] carried out a simple regression analysis to uncover the associations between temperature and apparel retail sales in the U.S. and concluded that weather defines the start and the end of a

season, with summer and winter selling season lasting up to 20 weeks. And any unusual change in weather can delay the beginning of each of these selling seasons.

Thus all in all various researches have been conducted to give prominent result for the effect of weather change on a retail store but all of them links retail and consumer activities to historical weather events. And none of them forecast this relationship in real time. While this paper tends to analyze the correlation between weather and retail shopping behavior (i.e., footfall) in real time and in unique manner.

3 Problem Statement

Weather, being an unmanageable factor, tends to influence shopper's purchasing decisions and causes the revenue to move in any direction. In order to manage the considerable revenue swings caused by fluctuating weather patterns, retail distribution needs to understand the relationship between weather patterns and customer activity. Basically, there are two types of risk which can affect retail performance and retailer's abilities to fulfill customer demands: the risk of understocking and the risk of overstocking. If they miscalculate these, retailers end up losing millions through disappointed customers and incorrect stock levels. Thus, impacting the costs and efficiencies of whole retail business.

It is in this context that the present analysis aims to examine, quantify, and predict the impact of weather factors on retail traffic across various stores located at different regions of the U.S. The aim here is to create an early warning decision-making system relating the retail sector to real-time weather events, preparing both retailers and customers against any weather-related risk. It should be noted that this experiment focuses on weather as an important factor affecting footfall of these retail stores.

4 Analytical Methodology to Predict Footfall

Our experimentation contributes to the field of retail distribution system by giving significant instance of association between meteorological phenomena and retail business. This section provides a recommendation on how to make weather information useful to retailers, through expected footfall levels. The first subsection gives a detailed description about our dataset. Followed by data preparation and experiment analysis.

4.1 Data

For our analysis, the data has been taken from two different sources: (1) OpenWeatherMap, which is a global geographical platform providing various types of earth observation data. 2) Kaggle, also known as "Home for Data Science", is a stage for analytics and predictive modeling competitions. To carry out our experiment we are considering three datasets namely, Footfall/Store data, Key dataset, and Real-time weather API data. The following is the description of each of these datasets:

(a) *Footfall data:* This is a customer's footfall data for 44 hypermarkets (all located in the United States) where footfall may be affected by the change in weather conditions. The footfall dataset provides us detailed information about each hypermarket/store, which can be used to find some interesting facts. For example, The column "station_nbr" corresponds to an id for one of the 10 weather stations covering these 44 locations. It should be noted that some of the stores are nearby and hence share the same weather station. Also, another column called "X3 h" measures the amount of rainfall (in inches) that occurred near each store on a daily basis. Similarly, there are other columns like "temp", "snowfall", "pressure", etc. describing the type of weather conditions near each store location.
(b) *Key data:* The key dataset comprises mainly of two columns: (1) "station_nbr" representing weather stations and (2) "store_nbr", which is an id showing one of the store locations. These columns are then mapped together in such a way that stores nearby would come under the same weather station.
(c) *Real-time weather API data:* This dataset gives us the 5-day weather forecast, i.e., how the weather conditions would be in the coming 5 days. Using an API key, the required dataset would be generated in JSON file format. And for our analysis, we converted this extracted dataset into csv format. The weather API data tells upcoming climate conditions helping retailers to plan their inventory stock accordingly. It should be noted that this data includes weather-related information every 3 h.

The entire dataset captures information about footfalls happening each day in each store for the complete 2 years. And with the count of shoppers, the retailers can easily find out the sales taking place in each store at the time of different climatic conditions. Retailers use various metrics to maximize their sales, with thinking behind making a purchase massively influencing where items are kept in a store, availability of customer's background data and shopper's every move observed as they move around stores. Amid all these factors, the most important factor from the perspective of retailers is "Footfall", which is the count of shoppers who has visited a hypermarket during a given period of time. Thus, using the above-mentioned datasets, we applied real-time footfall analytics to forecast the number of people visiting each store at the time of different climatic conditions.

4.2 Data Exploration and Preparation

In today's world, data comes from various industries, varied sources, and in various formats. The industries can be telecom, insurance, etc. while data sources can be open-source data providing sites, sensor data, social media data, etc. and formats can be .csv, .xls, .txt, etc. Each of these datasets would be having its own set of challenges and thus would be requiring a different series of steps for data preprocessing. Some of the problems which various analysts face while dealing with data include the presence of missing data, outliers, or operational challenges while capturing data and various such other challenges. Due to all these difficulties, it is believed that data preprocessing usually takes 70% of the total time devoted for building the entire model. Since it is the quality of inputs that decide the quality of output so once the hypothesis is built, it is recommended to spend a lot of time and effort performing this step (i.e., exploration, cleaning, and preparation of data).

Keeping this in mind, the second step we did is exploration and analyzing the data chosen for our analysis. Following are the steps performed for understanding, cleaning, and preparing the final dataset which was then used for building our predictive model:

(a) *Variable Identification*: Under this, the first step is to identify independent (Input) and target (Output) variables and then identify the category and datatype of all the variables. The following Fig. 1 shows this variable identification for our dataset:

(b) *Missing Value Treatment*: Missing value/data is defined as the value that is not present for the variable under interest. Being a symbol of messiness in the data, if missing values are not handled properly then it could lead to invalid conclusions about the data. The absence of data can cause several problems like

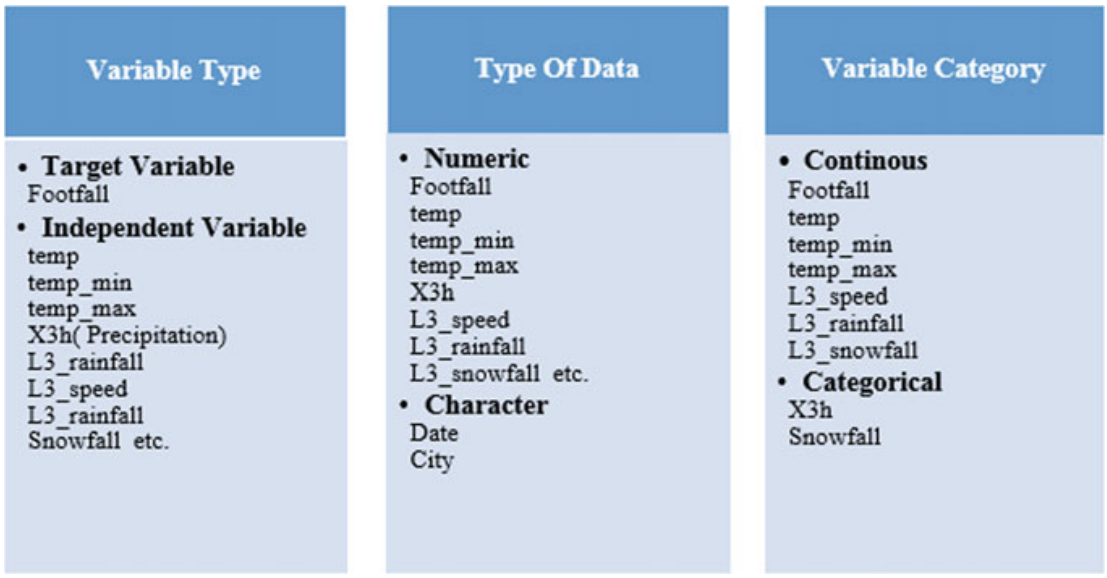

Fig. 1 Example of variable identification (modified and appended from Analytics Vidhya blog [19])

reduction in statistical power of the study, producing biased estimates, complicating the analysis of the study, etc. Thus in order to avoid these distortions, the treatment of missing values is considered as a necessary step in analyzing the data. The dataset which we considered also contained missing values for some of the columns like, "temp_max", "temp_min", "X3 h", "pressure", "snowfall", etc. But different treatments were being done for each of them. For example, missing data in column "snowfall" was handled by the sum of snowfall happened in past 3 days. Similarly, the maximum temperature in the past 3 days was used to replace the missing values present in the column "temp_max."

Hence, by following different treatment methods for each of the above-mentioned columns, we removed all the missing values from our dataset.

(c) *Bivariate Analysis*: This analysis helps to understand the hidden insights present in the dataset. Basically, bivariate analysis is a way of finding the relationship between two or more variables present in the underlying dataset. And since visualization makes understanding of data easier so we used stacked bar charts for the demonstration purpose. The following figures (Figs. 2, 3, 4) show few relationships existed among variables in our dataset:

Due to the presence of detailed information about each store, the footfall data thus can be used to extract numerous useful statistics as shown above.

(d) *Feature Engineering*: The art of extracting more statistics from existing data is known as feature engineering. So it is like making already existing data more useful from analysis point of view. For instance, consider the case of predicting

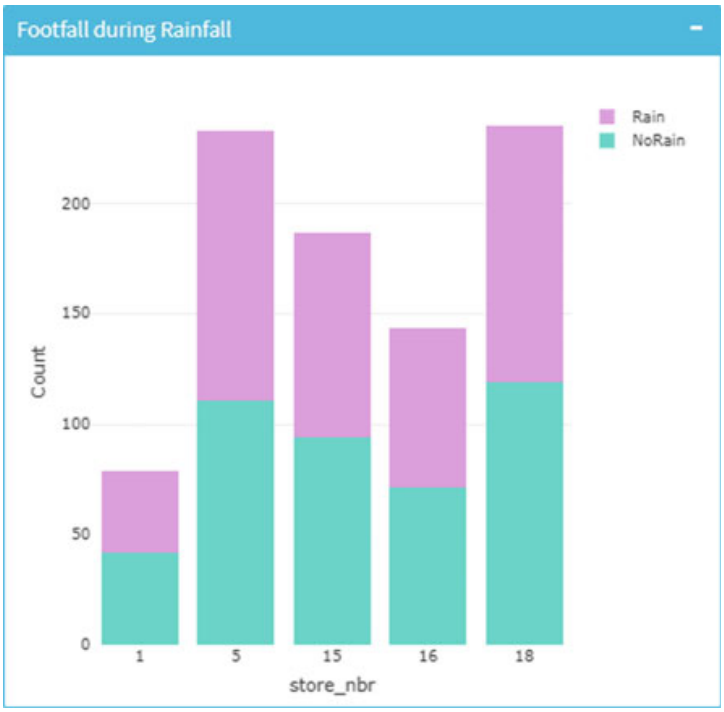

Fig. 2 Footfall during rain and no rain

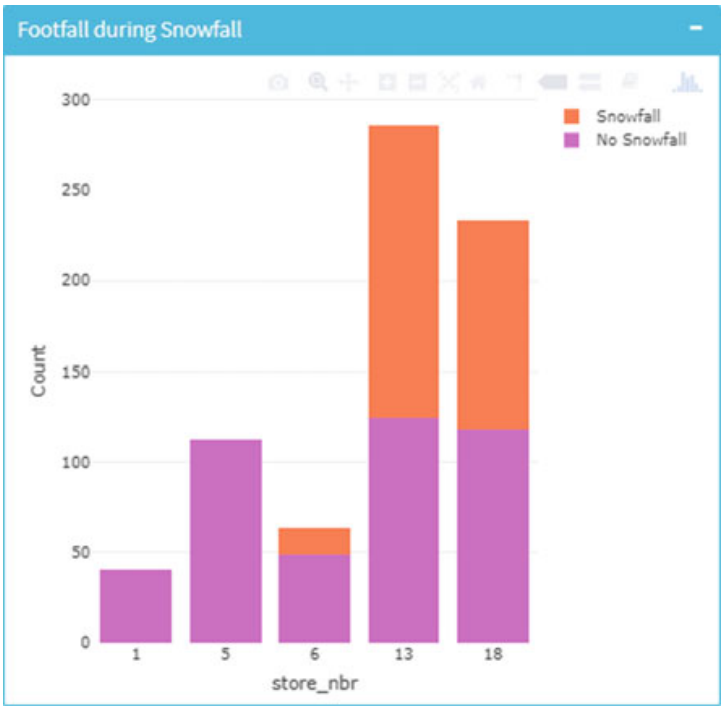

Fig. 3 Footfall during snow and no snow

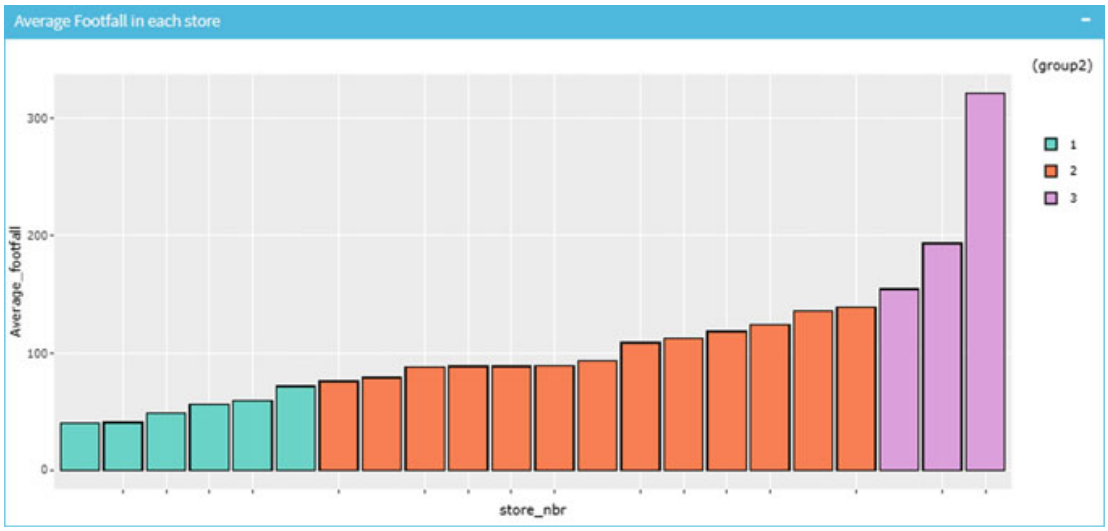

Fig. 4 Average footfall in each store

footfall in a shopping mart on the basis of dates. Here, using dates directly may not yield useful statistics from the data under consideration. This is because count of people visiting a shopping mart is likely to get less affected by the day of the month than the day of the week. And the latter information is present implicitly in the data which needs to be taken out for achieving reliable results. Thus, this activity of taking out information from data is known as "feature Engineering." This step contains two substeps: (1) Variable Transformation and

(2) Feature Creation. In our analysis, we created some new variables from already existing variables. For example, "Date" variable was split into three other new variables—"Day", "Month", and "Year." Also from input variables "temp_max" and "temp_min", new columns called "L3_temp_max" and "L3_temp_min" were being generated. This step was being done thinking that these newly formed variables may have better relationship with the dependent variable and thus could impact the power of prediction remarkably.

In the next section, we will discuss how these steps are combined together so as to predict the footfall based on real-time weather API and store dataset.

4.3 Random Forest as a Supervised Detection Technique

With limited information about climate variability and weather patterns, we solve our problem statement using a supervised machine learning algorithm called random forest. Being a part of ensemble learning algorithm, random forest works by generating multiple models over training dataset where the output of each model is then combined to produce a stronger model.

In the present analysis, this algorithm is applied for regression purpose helping us to map both linear as well as nonlinear relationships existing between the variables. The concept here is to decorrelate the various trees that are produced from separate bootstrapped training data samples. After which, the mean of output of all the trees is used to reduce the overall variance which eventually would help to avoid overfitting. It should be noted that the tree-based algorithms are famous for building models with high stability, accuracy, and easy interpretability.

4.4 Footfall Prediction Based on Weather with Random Forest Technique

In the current study, random forest algorithm has been applied to forecast footfall in different hypermarkets during different climatic conditions. Because of continuous nature of our target variable, regression analysis was being done using random forest. Machine learning algorithms like Support Vector Machine (SVM) etc., could have also been used to solve this problem statement. But the reason for choosing random forest over these techniques is the ease with which it tells the important variables contributing toward regression (and classification) analysis and the relative importance of each of them based on their depth of location in the tree. The following steps explain how random forest for regression works in predicting store's traffic given the weather data:

Each tree is generated as follows:

(i) Random Sample Selection: Divide dataset into train and test. Using around 2/3rd of the training dataset, each tree is trained. This 2/3rd selection is done randomly with replacement and is the training set for that particular tree.
(ii) Random Variable Selection: Each tree is trained using some number of predictor variables (say *m*) which are chosen randomly out of all the independent variables present in the dataset. For regression, the default value of *m* is total number of predictors divided by 3.
(iii) Splitting of node and Parameter Tuning: Each split is done by examining all the variables one by one and then the best split is picked using methods like Gini Index, Chi-square, or Information Gain, etc. Also to get better accuracy important parameters like "mtry", "ntree", etc. are tuned accordingly.
(iv) Calculation of "Out of bag" (OOB) error rate: Calculate the error rate of remaining 1/3rd data for each tree. Aggregate the errors for all the trees to get overall OOB error rate.
(v) Averaging the dependent variable: On the remaining data, each tree is generated giving output equal to some value of dependent variable. Then the average of all these values is taken as the predicted probability.

In the next section, we have leveraged aforesaid approach to showcase some footfall prediction scenarios. There is lot of potentials to extend our methodology to different sectors, different scenarios related to weather and technical approaches.

5 Result and Experimentation

After preprocessing the raw data as explained in Sect. 4.2, we have our dataset ready which could now be used for building the model. With "footfall" as a target variable, we applied random forest algorithm steps (as explained in Sect. 4.4) to carry out regression analysis for the underlying problem statement. It should be noted that the optimal value of parameters such as "mtry" and "ntree" has been found using fivefold cross-validation technique. Following results are obtained from the application of random forest for prediction of footfall in a retail firm:

(i) *Variable Importance Plot*: One of the advantage of random forest technique over other machine learning algorithms is that it tells which input parameters are important for predicting the target variable. Figure 5 shows the top five important parameters for predicting footfall in our model. This plot, called variable importance plot, tells which independent variables contribute more for the variation of target variable. Such information is used to choose the right set of features so as to make target predictions more accurate. It is important to note that these variables does not tell whether there would be more or less

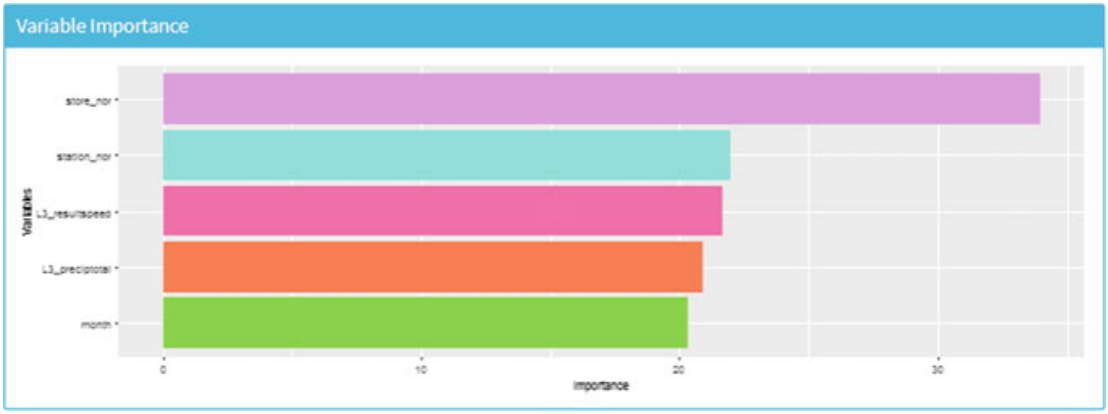

Fig. 5 Variable importance plot

footfall, but tell which all variables are important from prediction perspective. It can be seen that apart from store type, the weather variables such as precipitation and wind speed appear to be the most important parameters in our model.

(ii) *Root Mean Square Error*: The Root Mean Square Error (RMSE) is a performance metric measuring the difference between actual and predicted values of the model. This measure tells us how well our model is able to predict the test outcomes. For our model, RMSE is equal to 11% indicating the good fit of our model, given the spread of our dataset.

Using these two performance metrics, we were able to predict the expected footfall given the weather conditions for all 44 retail stores for the test dataset.

6 Live Demo Model

The above section explains our study for predicting the footfall given the weather conditions near every 44 retail stores. It should be noted that this procedure is based on historical weather data of the U.S. Now to carry out the same experiment in real time, we will make use of 5-day weather forecast data obtained using an API key. Thus, by integrating this new information we are able to predict the expected number of people in each store for the upcoming 5 days over a google map. This live demo model showcase two things: (1) current weather conditions of all the 44 stores present at different locations in the U.S. on a google map and (2) expected footfall curve for the 5 days using which retailers can strategize their activities accordingly. Figure 6 shows this dashboard which we have built using RShiny. It should be noted that the output from this model would keep on changing as the inputs are subjected to real-time factors.

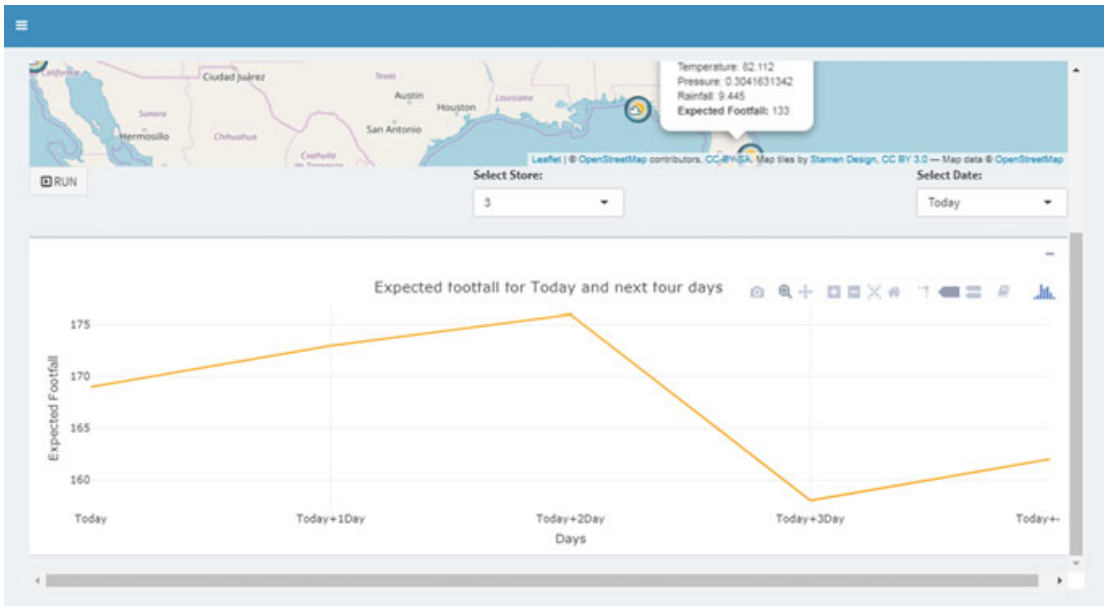

Fig. 6 Real-time demo model

7 Conclusion

The effect of climate variability and weather patterns on retail store's traffic using a supervised machine learning algorithm has been investigated in this paper. Most of the retailers are unaware of the weather consequences on footfall or believe that climate exposure is unmanageable. But, even though weather cannot be managed, the revenue strategies can easily be managed which will secure retailers against any adverse weather conditions. Keeping this in mind, we developed an early warning decision-making system associating retail sector with changing weather events, preparing retailers as well as shoppers against any weather-related risk in this sector. Our methodology put weather in a business context and provides actionable insight into customer behavior, which results in increased footfall levels and improved profitability. Thus, this experimentation is applicable universally and enables comprehensive scenarios of daily footfall traffic to be explored using real-time weather API data, allowing retail strategies to be targeted and implemented effectively.

The major implications of this analysis are as follows:

1. This analysis provides a platform to researchers, practitioners, and decision-makers for sharing and examining how non-catastrophic weather events affect the retail's footfall and the impact it will have in the future(real time).
2. It uses disaggregated data at a large scale and unlike past studies, the lagging effect of weather variables on store's traffic has also been taken into account while building our predictive model.

3. Apart from providing valuable insights about the drivers of footfall, this application can be used as a tool for evaluating how successful the previous events in each of these stores were after taking account of various weather factors.
4. Also, measuring customer's foot traffic and engagement would enable retailers to ensure the right number of staffs as well as products that are required during the impetus of global climate variation.

Normal Pressure Hydrocephalus Detection Using Active Contour Coupled Ensemble Based Classifier

Pallavi Saha, Sankhadeep Chatterjee, Santanu Roy and Soumya Sen

Abstract The Brain plays an imperative role in the life of human being as it manages the communication between sensory organs and muscles. Consequently, any disease related to brain should be detected at an early stage. Abundant accumulation of cerebrospinal fluid in the ventricle results to a brain disorder termed as normal pressure hydrocephalus (NPH). The current study aims to segment the ventricular part from CT brain scans and then perform classification to differentiate between the normal brain and affected brain having NPH. In the proposed method, firstly few preprocessing steps have been carried out to enhance the quality of the input CT brain image and ventricle region is cropped out. Then active contour model is employed to perform segmentation of the ventricle. Features are extracted from the segmented region and Ensemble classifier is used to classify CT brain scan into two classes namely, normal and NPH. More than hundreds of CT brain scans were analyzed during this study; area of ventricle has been used as a measure of feature extraction. Experimental results disclosed a significant improvement in case of ensemble classifier in comparison to Support Vector Machine in terms of its performance.

1 Introduction

Recent studies have revealed biomedical image processing as an application in the detection of a wide range of diseases. It has a great contribution which allows physicians to perform an accurate diagnosis. The human brain is composed of cerebrum, brainstem, and cerebellum. Apart from these parts, there is a part called ventricle which is stuffed with a vivid and colorless fluid regarded as cerebrospinal fluid (CSF). Shape and size of the ventricle depend on the amount of CSF present in the ventricle. Accumulation of excessive amount of CSF in ventricle gives rise to a brain disorder known as NPH. This paper focuses on the detection of NPH brain disease by segmentation [4–6] of ventricle using ACM [2] and then estimates the area of ventricle which is then sent as input to the Ensemble classifier. Ensemble classifier performs classification of the CT brain scan and predicts as either normal brain or affected brain having NPH. This classifier comprises of three weak learners viz. Discriminant, Decision tree, and *K*-th nearest neighbor (KNN). The performance of Ensemble classifier is then compared with SVM and the best classifier is traced out. Features form the principal element in the training stage as well as in the testing stage. The efficiency of a classifier vastly depends on the extraction of features. At times, the best classifier fails to produce proper results if weak features are employed. In the field of image processing, a vast amount of work has already been undertaken by various researchers in the past and brought remarkable changes in the medical history. Classification of brain diseases has been achieved through several methods like Support Vector Machine (SVM), Random Forest, Artificial Neural Network skilled with Genetic Algorithm (GA) termed as ANN-GA, and ANN trained with particle swarm optimization (ANN-PSO). Ensemble classifier has also been applied in the detection of brain disease. Clangphukhieo et al. [1] designed an algorithm for the segmentation of the ventricular part from CT brain image. Initially, CT brain image is normalized and region of interest is estimated by applying gray level profile analysis followed by the Bayesian segmentation. This segmentation enables us to demarcate among the three intensities viz. white matter, gray matter, and CSF and at last the area of CSF is determined. Experimental results disclosed a minimum error of 3.14% and a standard deviation of 1.41 has been achieved by the proposed algorithm. Butman et al. [3] introduced an algorithm to calculate the size of the ventricle in the brain MRI examinations. This has been attained by firstly integrating the different serial images in order to enhance the SNR. Active Contour Model and fast marching techniques were applied to perform segmentation and later deformable registration was used to propagate the segmentation. Zhukov et al. [7] put forward a method based on the concept of a decision tree to estimate the credibility of power systems. Ensemble classifier is used for the classification of the system to determine whether it is in a safe state or not and aggregation is done based on boosting model and random forest model. Shenbagarajan et al. [12] proposed an efficient method to classify an MRI brain image into three types viz. normal, noncancerous, and cancerous. This method involves four phases namely preprocessing steps, segmentation, feature extraction

followed by the classification. Active Contour Model (ACM) is engaged for segmentation and then Artificial Neural Network (ANN) trained with Levenberg–Marquardt (LM) algorithm is used for classification. An enormous amount of research work has been performed in the past in the field of biomedical image processing. Still, it is difficult to meet the growing requirements. In the current study KNN, Decision tree, and Discriminant forming together the Ensemble classifier is implemented to perform classification between a normal brain and affected brain having NPH. The current paper is arranged as follows. Section 2 describes the contrast adjustment, segmentation, and classification model. Section 3 represents the proposed system laid out for the classification of the brain between a normal brain and affected brain having NPH. Section 4 reflects the depiction of experimental results in terms of its performance calculated from the confusion matrix.

2 Methodology

2.1 Image Enhancement and Cropping

Image enhancement forms one of the preprocessing steps that are extensively employed in image processing [15]. The main purpose behind image enhancement is to improve the intelligibility of data in images for viewers. Contrast is an essential factor in the calculation of the quality of an image.

In the current study, the contrast has been adjusted by adjusting the intensity values accordingly in the input CT brain scans to retrieve information efficiently from it. This, in turn, brightens up the image and then the ventricular part is cropped out from the input image.

2.2 Active Contour Models

Active Contour Model (ACM) also termed as snakes is well known in the field of computer vision and is widely applied in applications such as segmentation, edge detection, etc. ACM is classified into two types namely: Edge-based ACM and Region-based ACM [2, 16]. In order to hold back the contour during development for recognizing the boundary of the foreground object, edge-based model makes use of the gradient of the image.

The region-based model utilizes mathematical information regarding the regions lying both inside as well as outside the curve for contour development. In the proposed method, region-based model has been implemented for segmentation which focuses to encourage the curves to arrive at the boundaries of the input CT brain scans.

2.3 Region-Based ACM for CT Brain Segmentation

The region-based model has undertaken with the consideration that the pixel regions of the input image are mathematically similar. It works well on noisy, hazy images, and images having disconnected regions, etc. In the analysis of CT brain scans, region-based model believes the global properties like the length of contour and CT scan image pixel regions are opposite to the local properties like a gradient. The energy minimizing function can be written as:

$$\ln P(I_s|p) = \iint_A {}^0 I_S(x, y)\mathrm{d}A$$

$I_S(x, y)$ represents the intensity value at the pixel location (x, y) in the CT brain image and integral provides the sum total of area A confined by the curve p.

2.4 Feature Extraction Based on Area

The selection of the feature extraction technique plays a leading role in the performance of a classifier [8–11, 17]. In both the training and testing phase, the feature is the crucial element. In the current study, the area of the ventricle in the segmented region forms the measure of feature extraction. Extracted features become the dataset and thereafter enable us to classify between the normal and affected NPH brains.

2.5 Ensemble Classifier

Support Vector Machine (SVM) is a model that is widely applied for classification and regression analysis. The application of SVM in the field of image processing is an example of linear discrimination. The basic working principle of this model is that it divides the space into which the CT scan brain images are assigned into two classes by identifying a separating hyper plane. In 2D space, a line defines the boundary and hyperplane in higher-dimensional space. The inclination towards the application of SVM is that it employs the basis of fundamental risk reduction, which focuses to locate a hyperplane that decreases the area between training classes. The pixels that are nearest to the separating boundary describes the optimal separating hyperplane (OSH) produced by an SVM.

The SVM classifier is trained with the color features extracted from the pixels of several CT scan brain images to differentiate between two regions (classes) namely CSF and non CSF. In the testing phase, an unseen CT scan brain image is selected, then each and every pixel of the testing image is sent as input to the trained SVM

classifier and it assigns a class or a region to each of the pixels in the image as a response. This model is an age-old model and various researchers have adopted this classifier in the field of biomedical image processing to dig out some new innovations, here we have adopted this model and performed a comparison with the proposed model to determine the best classification model in terms of its performance.

2.6 Ensemble Classifier

The foundation of machine learning is the ensemble methods. The amount of diversification among the different learners that exists in the ensemble affects the efficiency of the ensemble to a huge extent. Ensemble learning employs various classification models together to achieve superior predictive performance during testing whereas this level of performance is never achieved by any classification model alone. This model works by integrating many poor learners namely Discriminant, Decision Tree, and KNN. Figure 1 describes the common workflow of ensemble classifier. Once the outcome from each of the weak learners is attained, an aggregation method such as AdaboostM1, Gentleboost, Logitboost, etc., is applied to forecast the final result for the test data.

3 Proposed System

Experiments have been carried out on more than 100 slices of CT brain scans that were gathered from the Apex Hospital situated at Kolkata in West Bengal. Initially, the contrast of the input CT brain image [13, 14] was enhanced and a part of the image was cropped out for later processing steps. Then segmentation of the ventricular part from CT brain scan was employed by using ACM. Features were extracted from the segmented region based on the area of that particular region. These extracted values of area for different CT brain scans together formed the dataset. These dataset were utilized in both the training and testing phase.

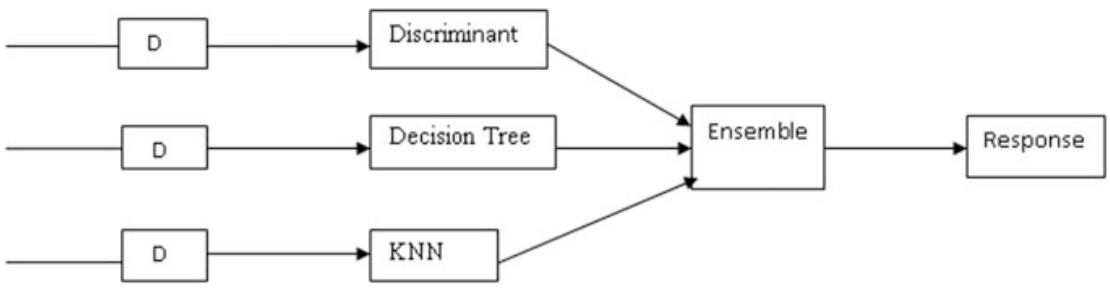

Fig. 1 Represents the workflow of Ensemble classifier

Further on, the extracted dataset is divided into two parts; former part is used for training the classification model and the later part is used during the training stage, depending on the value of data it is classified into either of the two classes namely: normal brain and affected brain having NPH.

In the present study, depending on the training data three weak learners such as Discriminant, Decision Tree, and KNN were trained and the predictions of each model were combined together by using few methods namely; AdaboostM1, Gentleboost, etc. Simultaneously, the training data is also sent to SVM model to train the model and prediction for the test data is noted. In the testing phase, test data was fed as an input to the three classification models and results are recorded and the efficiency of the ensemble classifier is determined and compared with SVM in terms of its performance. The different performance metrics which has been determined from the confusion metrics are as follows (Fig. 2).

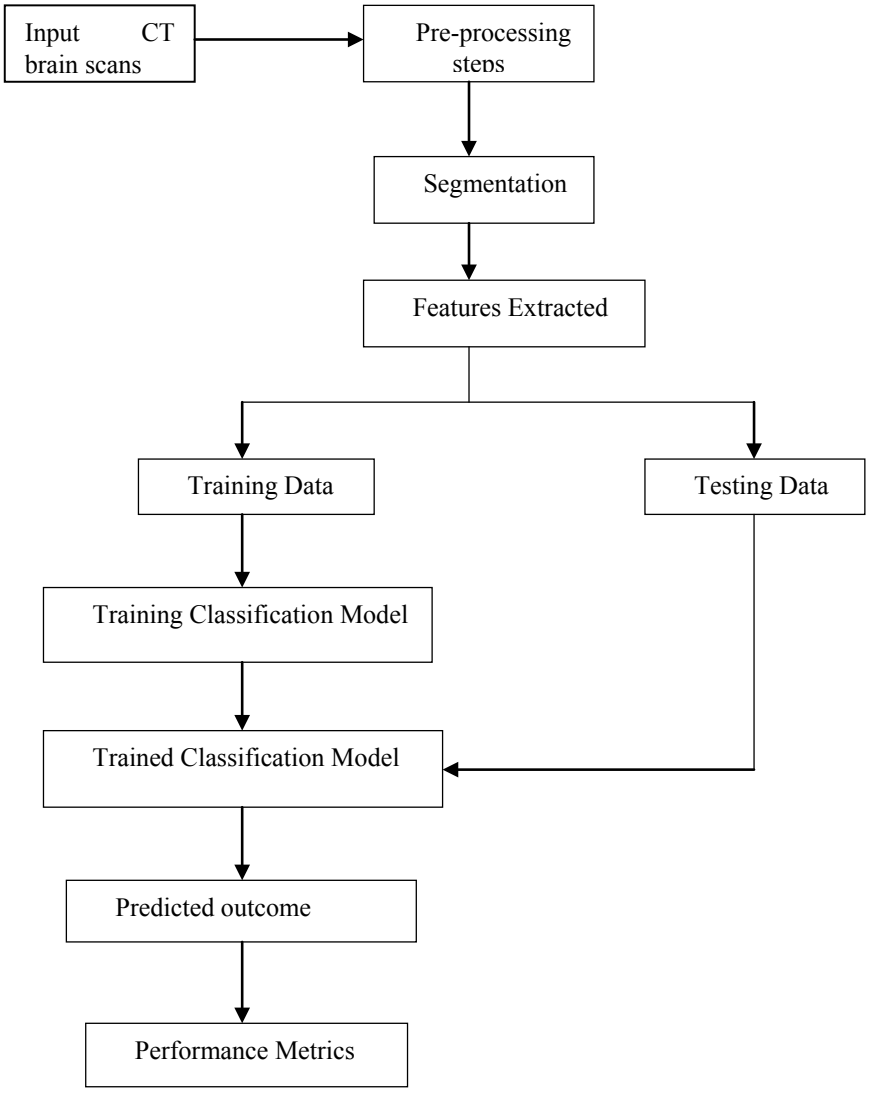

Fig. 2 Depicts the flowchart of the proposed system

$$\text{Accuracy} = \frac{\text{tp} + \text{tn}}{\text{tp} + \text{fp} + \text{fn} + \text{tn}}$$

$$\text{Precision} = \frac{\text{tp}}{\text{tp} + \text{fp}}$$

$$\text{Recall} = \frac{\text{tp}}{\text{tp} + \text{fn}}$$

$$F\text{-measure} = 2 * \frac{\text{Recall} * \text{Precision}}{\text{Recall} + \text{Precision}}$$

In the above equations, tp represents true positive, tn represents true negative, fp represents false positive and fn represents false negative for testing the efficiency of the classification model.

4 Experimental Results and Discussion

The simulations were carried out on more than 100 CT brain scans by using the proposed method. The resolution of each brain scan is 512 × 512. The dataset comprises of 100 instances among which 60 are normal brain and 40 are affected brain having NPH.

Figures 3a and 4a depicts the input CT brain image, Figs. 3b and 4b represent the enhanced images of the input image. Figures 3c and 4c reflect the cropped part of the input enhanced image, Figs. 3d and 4d depict the segmented ventricle portion from the input CT brain image. Since CSF is stuffed in the ventricle, area of the ventricle can be used to determine the amount of CSF present in the brain which in turn helps to diagnose the condition of the patient. On further calculation, it has been found that the area of the ventricle in Fig. 3d to be around 268.687 mm and Fig. 4d to be 7764.5 mm. Radiologists have also manually calculated the area of ventricle for Fig. 3a which was 268.254 mm.

Moreover, Radiologists have also informed that the CT brain scan to be the healthy and normal brain. The estimated area of the ventricle in a CT brain scan of Fig. 4a is quite greater than the normal brain henceforth it is considered to be affected brain having NPH. Moreover, Radiologist has also determined manually the area of the ventricle in Fig. 4a to be 7764.21 mm. In addition, Radiologist has also intimated that the corresponding CT brain scan to be affected brain having NPH. Table 1 epitomizes the performance of Ensemble and SVM classifier in terms of accuracy, precision, recall, and *F*-measure.

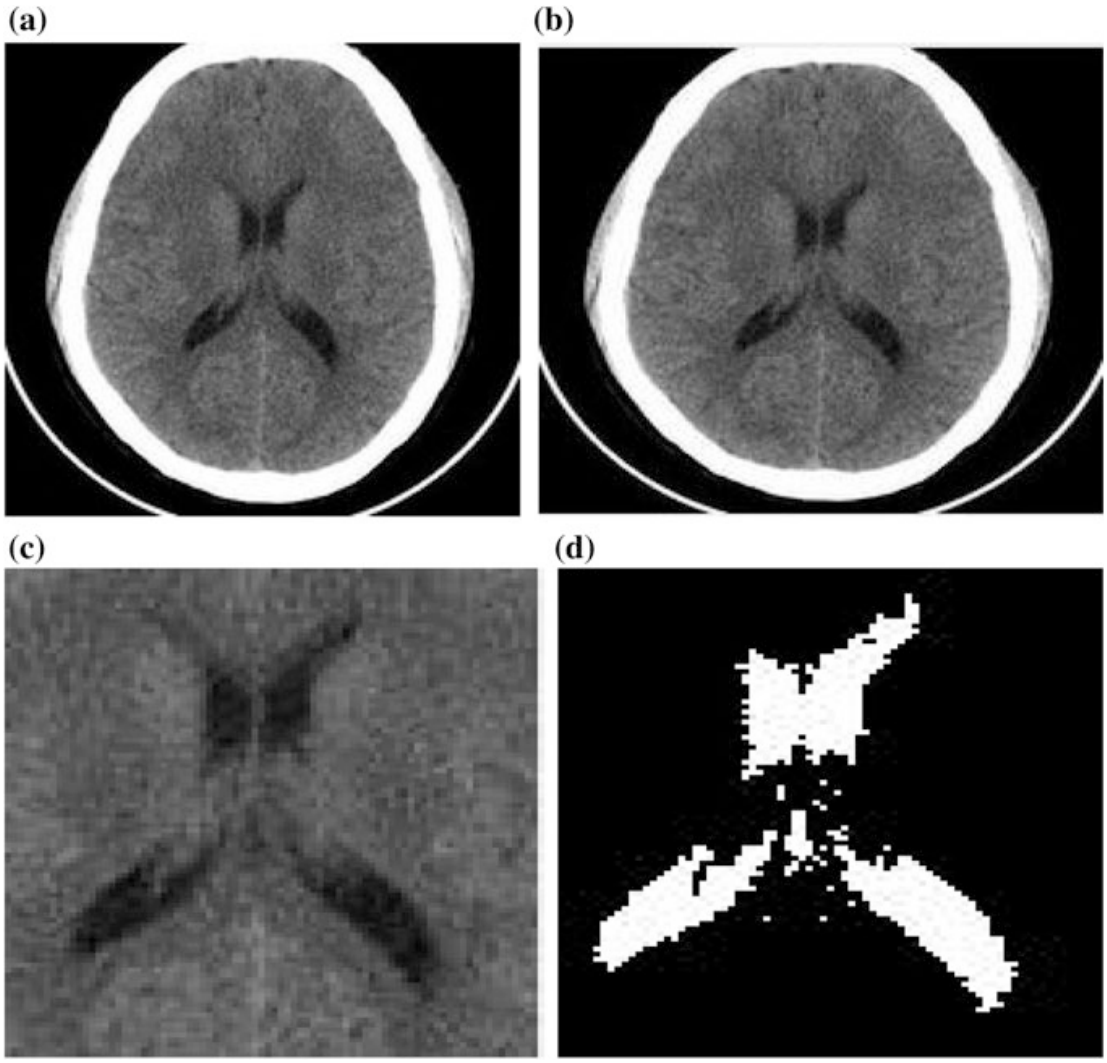

Fig. 3 **a** Source image. **b** Contrast adjustment. **c** Cropped image. **d** Segmented image

Table 1 reports that the accuracy obtained by the ensemble classifier is 93.06% in our proposed method while it achieves precision of 95.65%, recall of 94.28%, and *F*-measure of 94.96%. It has been observed that the performance of SVM is poor in comparison to the Ensemble classifier, achieved an accuracy of 87.12, precision of 88.40, recall of 91.42, and *F*-measure of 89.88.

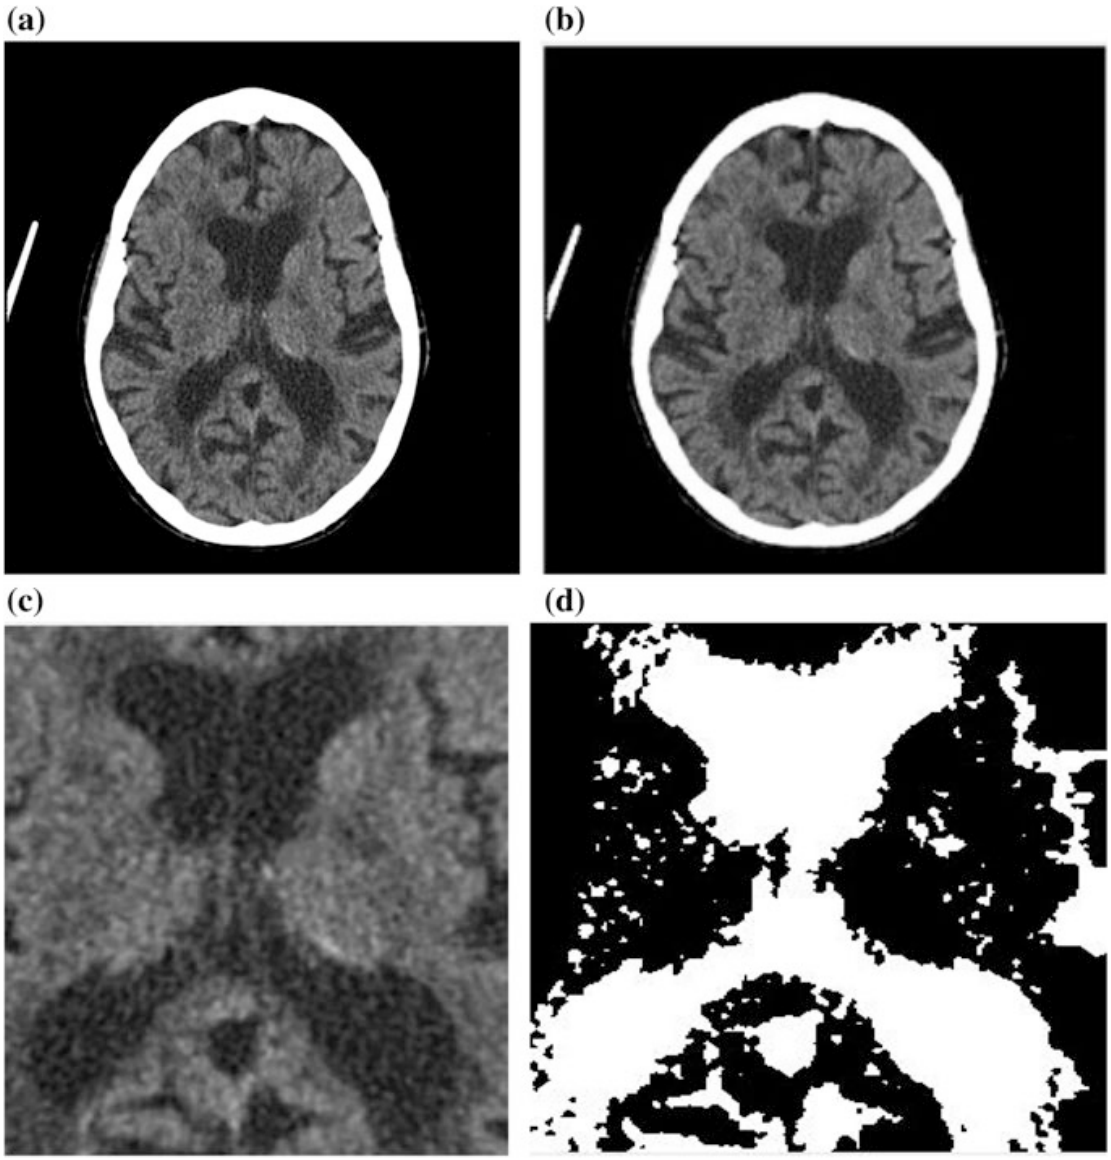

Fig. 4 **a** Source image. **b** Contrast adjustment. **c** Cropped image. **d** Segmented image

Table 1 Performance of the Ensemble classifier (in %)

Metrics	Ensemble	SVM
Accuracy	93.06	87.12
Precision	95.65	88.40
Recall	94.28	91.42
F-measure	94.96	89.88

5 Conclusion

Since the human brain controls many other parts of our body, hence proper functioning of the brain should be ensured primarily. Human brain forms the central organ of the nervous system, so any diseases related to the brain should be diagnosed at an early stage. In the current work, a powerful technique has been put forward for the detection of NPH in the CT brain scans. Experimental results disclosed that ensemble classifier produces better and satisfactory results in comparison to SVM by achieving an accuracy of 93.06%, precision of 95.65%, recall of 94.28%, and *F*-measure of 94.96%.

Question–Answer System on Episodic Data Using Recurrent Neural Networks (RNN)

Vineet Yadav, Vishnu Bharadwaj, Alok Bhatt and Ayush Rawal

Abstract Data comprehension is one of the key applications of question-answer systems. This involves a closed-domain answering system where a system can answer questions based on the given data. Previously people have used methods such as part of speech tagging and named entity recognition for such problems but those methods have struggled to produce accurate results since they have no information retention mechanisms. Deep learning and specifically recurrent neural networks based methods such as long short-term memory have been shown to be successful in creating accurate answering systems. This paper focuses on episodic memory where certain facts are aggregated in the form of a story and a question is asked related to a certain object in the story and a single fact present is given as answer. The paper compares the performance of these algorithms on benchmark dataset and provides guidelines on parameter tuning to obtain maximum accuracy. High accuracy (80% and above) was achieved on three tasks out of four.

1 Introduction

Question answering is a complex NLP task which involves understanding of the meaning of text and after understanding, ability to reason about important facts [1]. This becomes tricky as computer does not infer like humans given text data and a set of questions to answer. The problem is very specific and involves answering factual questions, for example, given a paragraph on the US Administration and being asked: "Who is Donald Trump?".

A lot of interest is being shown by organizations in creating question–answer systems that can accurately answer simple questions without the use of a lot of training data. The focus is on obtaining the best possible approach to certain problems in the benchmark bAbI dataset using LSTM.

The bAbI dataset consists of total 20 tasks. These tasks are related to support facts about a question for which an algorithm should provide an answer. These supporting facts are single supporting fact, e.g., Mary traveled to office. Where is Mary? Two or three supporting facts, e.g., "John is in the playground" and "John picked up the football". Where is the football?

This problem involves learning from a large data which is in episodic form and has facts which are related to the asked question. An attempt has been made to solve this using a modern neural network architecture which uses the facts to train and is able to produce the specific answer.

2 Related Work

We have seen the emergence of QA-based strategies in the field of language understanding. QA is easy to evaluate, especially for those questions which have true/false or yes/no answers. These questions should be unambiguous which a human can understand and answer. Memory network proposed by Weston et al. [2] is a new network architecture called memory network which consists of a memory component m and four components I [Input feature map], G [Generalization component], O [Output feature map], and R [Response component] which are potentially learned.

Another work on Large-scale Simple Question Answering with Memory Networks by Bordes et al. [3] proves that question answering systems can handle millions of data points very well and that training on two related datasets enhances overall accuracy. It involves the process of generating the most similar candidates through n-gram matching and getting the best candidate through finding cosine similarity.

A work on end-to-end memory network by Sainbayar Sukhbaatar et al. [4] which can be seen as an extension of RNN search having multiple computational steps known as hops per output symbol. This model can be considered as a

continuous form of memory network which can be trained end-to-end with less supervision on an input–output pair. It also performs well on various tasks from question–answer task to language modeling.

3 Scope of the Work

Four tasks are selected and are mentioned below to build question–answer models. The selection was done with the objective of having unique unrelated contexts.

Task1: Single supporting fact
Task4: Two logical arguments
Task7: Counting
Task17: Positional Reasoning

The detailed description of these tasks is provided alongside model results. We have also conducted error analysis on Task 1 to study the algorithm in depth.

4 Our Approach

A deep learning Recurrent Neural Networks (RNN) architecture is designed which uses the concept of LSTM. The data used to train the models is the bAbI 10,000 sample dataset.

RNN is the preferred architecture for sequential information. In a standard neural network, there is an assumption that all inputs and outputs are independent of each other. Practically this assumption may not always hold true. To predict the next word in a sentence it would help to know the words appearing previously. RNN are known as recurrent neural networks because they perform the same task on every element of a sequence, where output dependents on computations of previous steps. RNN has memory which captures information about the computations of previous steps. In theory, RNN has the potential to use information present in long sequences, but practically it is only applicable for looking back at few steps (Fig. 1).

LSTM belongs to RNN family which has the capability of persisting information in longer sequence, which RNN lacks in implementation [5]. Key element of LSTM is known as cell state. This cell state keeps track of long-term sequential information [6]. LSTM neuron has three gates input, output, and forget. These gates regulate the interaction of information with RNN data flow (Fig. 2).

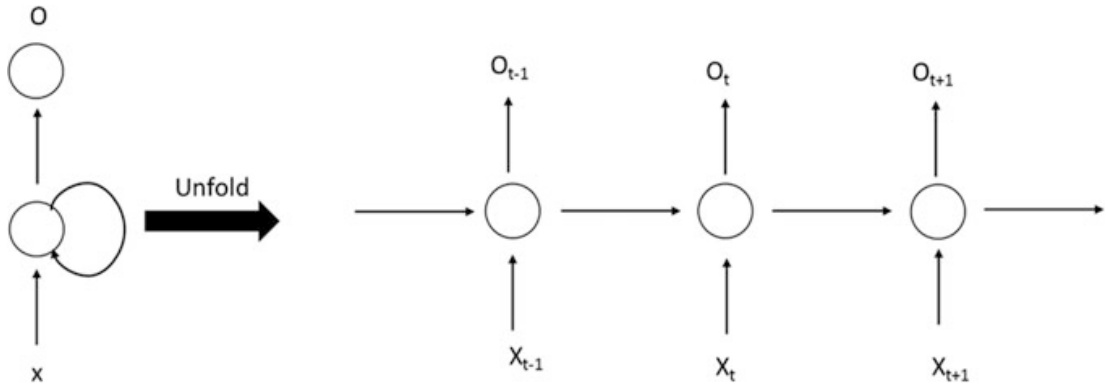

Fig. 1 Recurrent neural network architecture after unfolding the loop

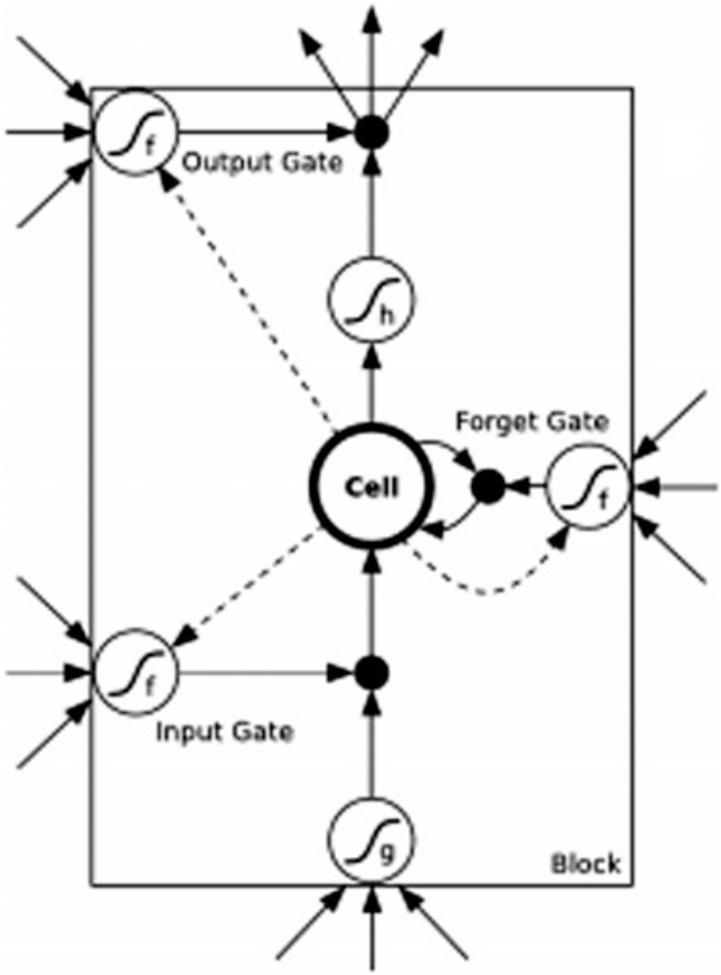

Fig. 2 LSTM cell with input, output, and forget gate which helps in passing specific information to the next level

4.1 Solution Architecture

The solution architecture used incorporates the memory network and has certain connections that help to emphasize the most appropriate words to pick the answer.

This consists of mainly four layers:

1. Embedding layer: It converts each word of dictionary to a vector.
2. LSTM: This is a type of RNN which is used for sequence data and overcomes short-term memory of regular RNN. Memory network is being used in this layer.
3. Dropout layer: It will shut off few neurons from a layer based on user-defined criterion and thus prevents model overfitting.
4. Dense layer: It is a layer with softmax activation [7], which will produce answer for a specific question by choosing the option with highest probability (Fig. 3).

First each question and story gets converted to embedding. After this, allow the network to follow the question based on story and give attention to certain most relevant words in the question; dot product between both the embedding was taken [8].

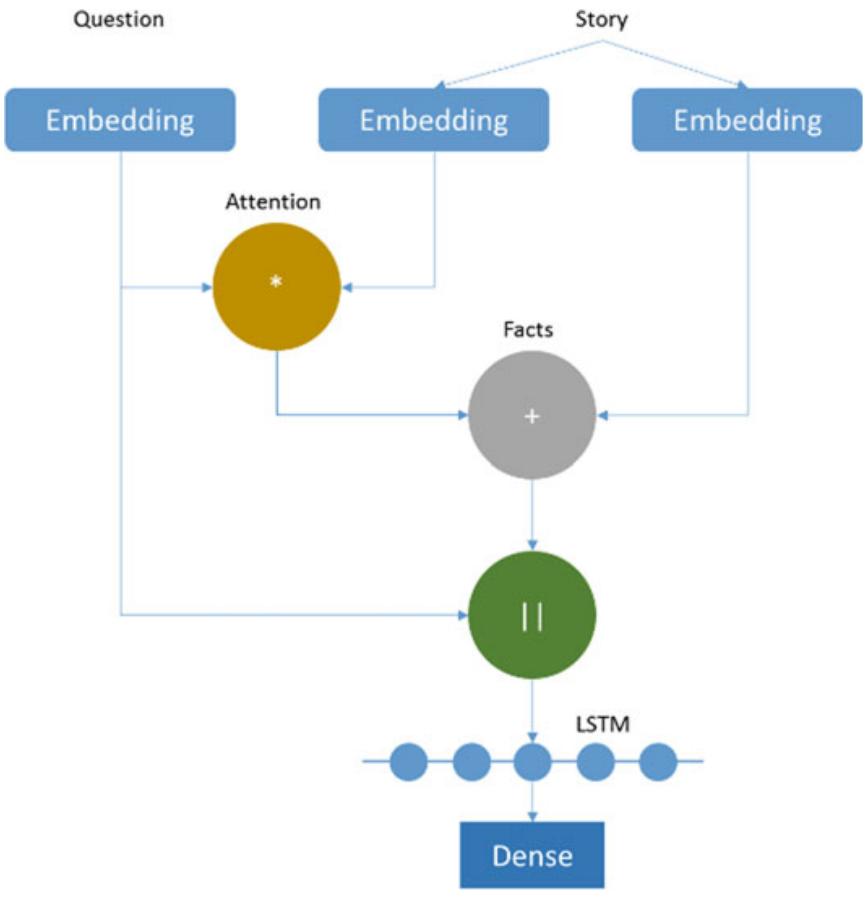

Fig. 3 Solution architecture involving embedding layers to dense layer that produces answer for a question given a story

This produces a vector which will have more weights to the words which are more relevant based on story and questions. This forms the network memory. This attention gets combined with the story embedding to find out facts about the question. These facts are then combined with questions and this information is fed into LSTM network to produce answer for a question.

4.2 *Memory Network*

This is the key component of the solution architecture and it controls information flow using gates. Memory networks [9] architecture enables them to store all the state from a given input, which means that queries can be asked and the memory is able to go many steps back to find the most suitable portions that need to be given greater "attention" as illustrated in the figure below (Fig. 4).

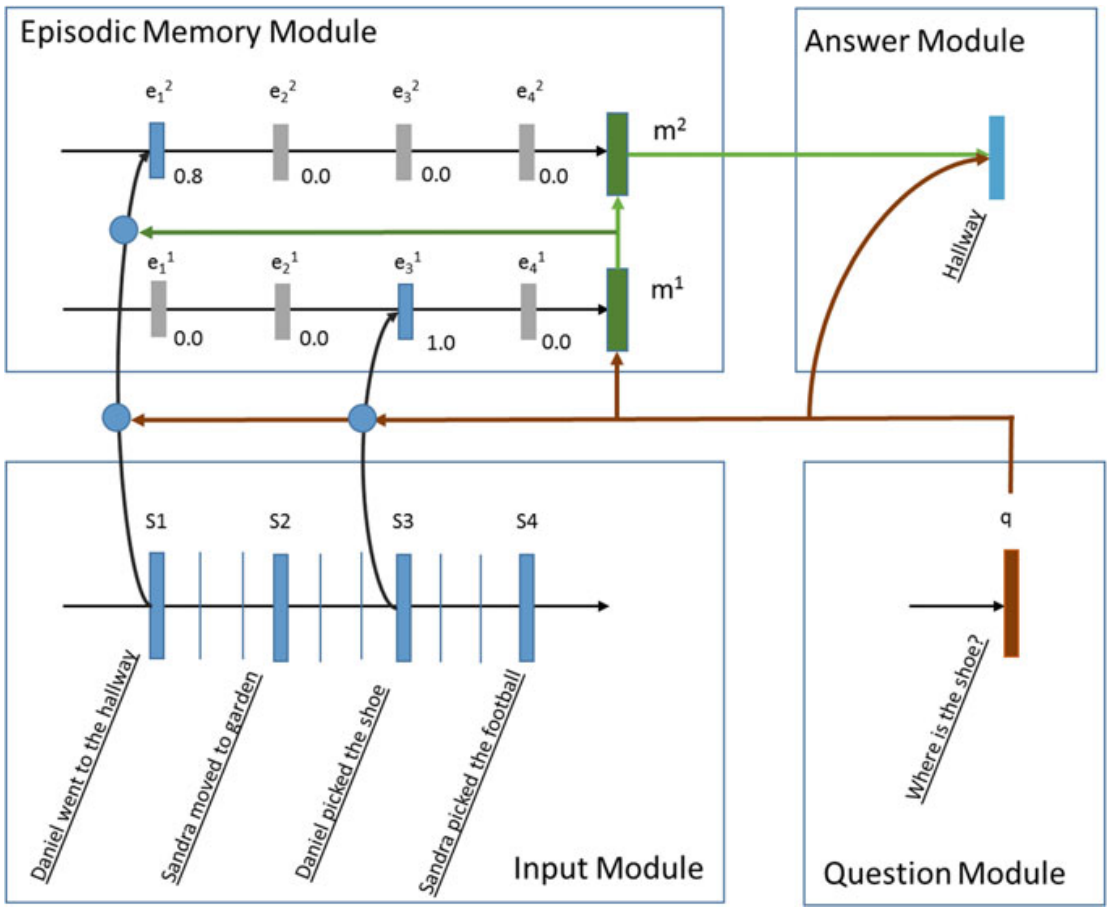

Fig. 4 Illustration showing memory network showing how relevant portions are being given more attention

4.3 Task Description and Model Results

This memory network was trained using different tuning parameters such as embedding size and LSTM size described below.

Embedding Size: This is the size of the Word2vec—word convert to a numerical vector.
Latent Size: Number of neurons in the LSTM layer.
Batch Size: Number of inputs processed together.
Epochs: Number of passes of forward and backward propagation in the deep network.

Changing dropout rate did not have any significant impact on model accuracy. Below are descriptions of each task and the results for different combinations and with 30% dropout for every model.

Task 1: This task consists of a story where answer is based on single supporting fact. For example,
Story: Dan went to the bedroom. Sunny moved to the bathroom. Q: Where is Dan? A: bedroom.
Results for the task (Fig. 5, Table 1).

Epochs were not contributing to increased accuracy in a significant manner. Small latent size with less number of epochs is producing the best accuracy.
Task 4: Answer for this task will depend upon understanding two logical arguments. For example,

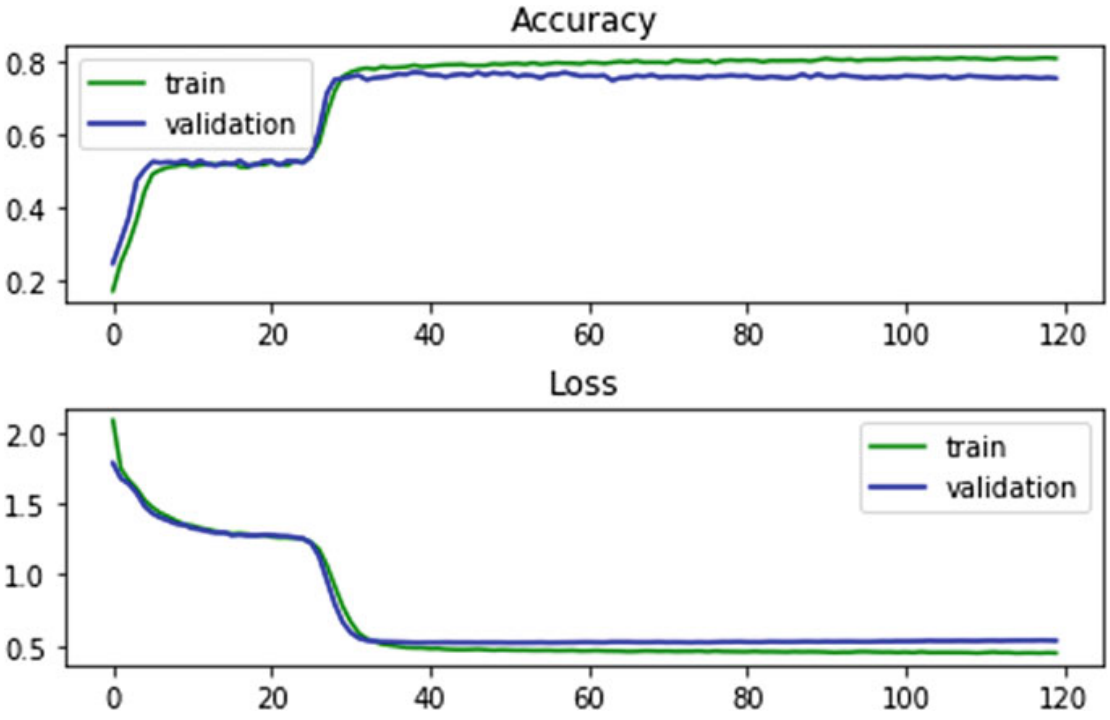

Fig. 5 Accuracy and loss for train and validation set w.r.t. epochs for Task 1

Table 1 Combinations of different parameters for Task 1 which shows changing architecture is having little impact on validation accuracy

Embedding size	Latent size	Batch size	Epochs	Validation accuracy (%)
32	32	64	120	77.98
32	64	64	300	74.83
32	128	64	120	76.2

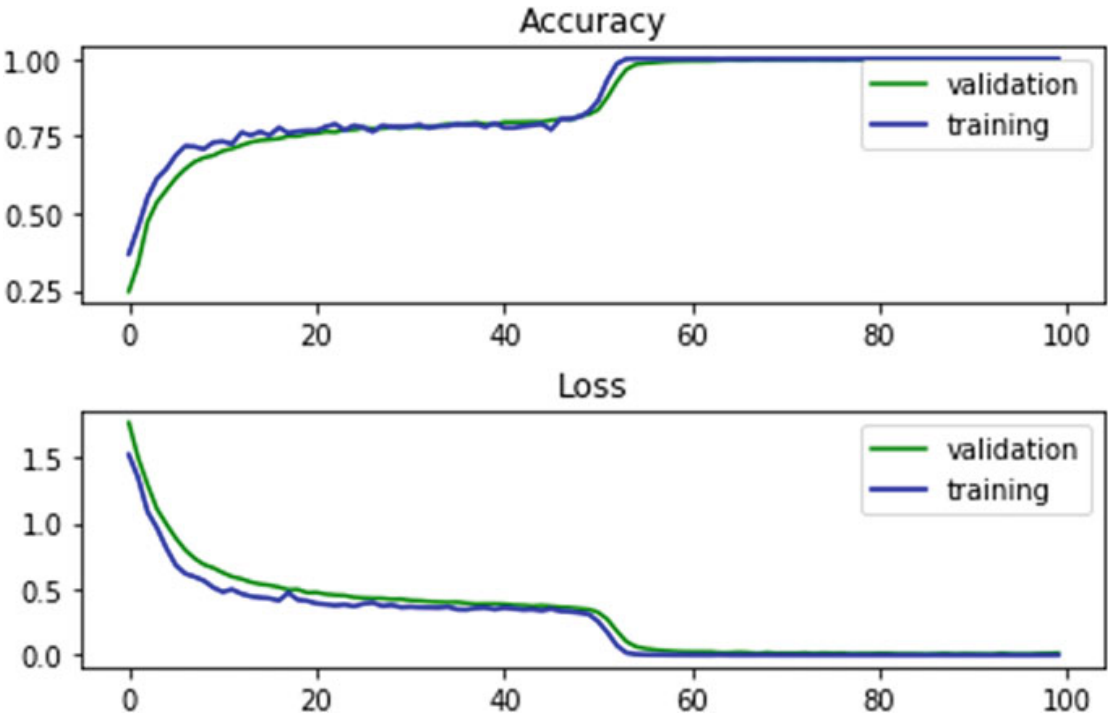

Fig. 6 Accuracy and loss for train and validation set w.r.t. epochs for Task 4

Table 2 Combinations of different parameters for Task 4

Embedding size	Latent size	Batch size	Epochs	Validation accuracy (%)
16	16	32	100	85.24
32	32	32	100	97.01
48	48	48	100	99.64

Story: The bathroom is west of the bedroom. The study room is east of the bedroom.
Q: Bedroom is west of what? A: study room.
Results for the task (Fig. 6, Table 2).

Increasing the embedding size is the key to obtain more accuracy on this task. Embedding is capturing more semantic relationship between words so increasing it is making model more robust. Even simple models give high accuracy on this task.

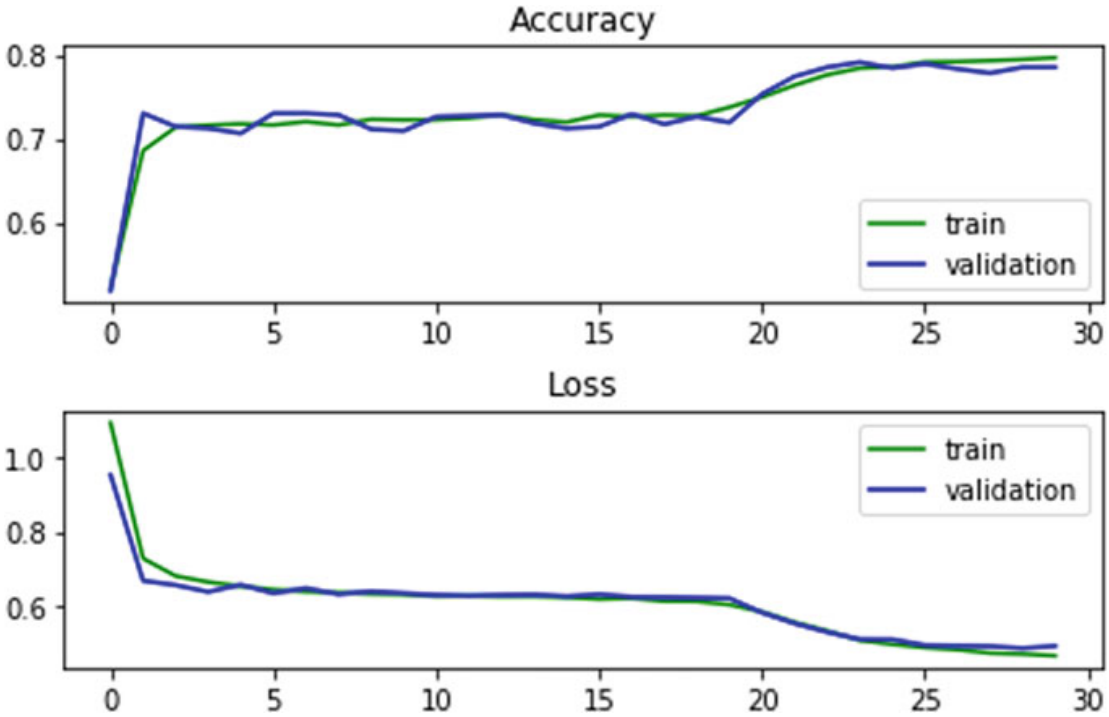

Fig. 7 Accuracy and loss for train and validation set w.r.t. epochs for Task 7

Table 3 Combinations of different parameters for Task 7

Embedding size	Latent size	Batch size	Epochs	Validation accuracy (%)
64	32	64	30	79.35
64	48	64	50	78.00
64	64	96	100	79.26

Task 7: This is a counting task, where counting of objects is to be done based on understanding the statements. For example,
Story: Jonny went to the garden. Daniel went to the bedroom. Sam picked up the apple there. Jonny got the milk there.
Q: Sandra is carrying how many objects? A: one.
Results for the task (Fig. 7, Table 3).

Other tests showed that embedding size was not contributing much to accuracy so the focus was on latent size and batch size. Overall we observe that models with low hyperparameter values are performing as well as those with high values.

Task 17: This is a task where the question relates to the position of an object based on given statements. For example,
Story: The red triangle is to the left of the yellow rectangle. The red triangle is below the pink square.
Q: Is the pink square to the right of the yellow rectangle? A: no
Q: Is the yellow rectangle to the right of the pink square? A: yes
Results for the task (Fig. 8, Table 4).

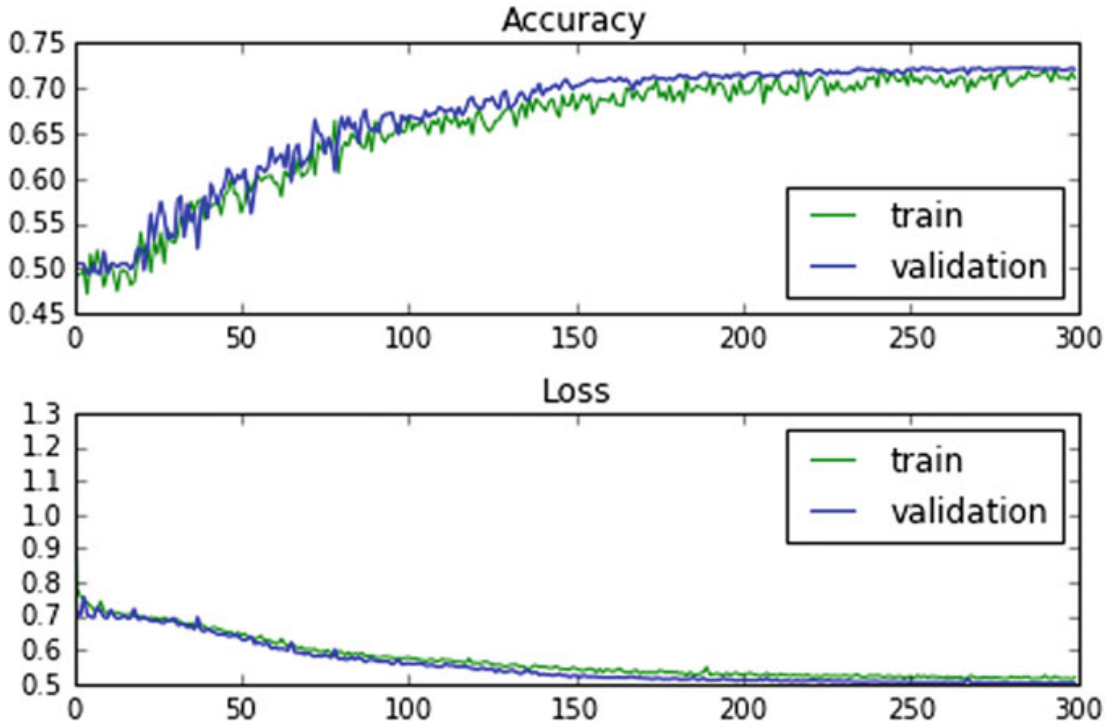

Fig. 8 Accuracy and loss for train and validation set w.r.t. epochs for Task 17

Table 4 Combinations of different parameters for Task 17 which shows increasing epochs and latent size does not improve accuracy much

Embedding size	Latent size	Batch size	Epochs	Validation accuracy (%)
32	64	64	300	70.70
32	128	64	300	72.10
32	300	64	300	72.30

Using different combinations of hyperparameters did not improve the accuracy of this task much with maximum accuracy of 72.3%. This is because in this task it becomes very hard for the memory network to exactly pinpoint the exact lines from which the solution gets extracted as there are several objects present in several positions.

5 Error Analysis

In this section, we analyze output on the basis of different criteria. This would help us in limitation and scope planning of output. The shortcomings which we have identified post-process will also help us to improve training models and algorithms.

Table 5 Accuracy rates by distance of relevant sentence

Distance	Accuracy (%)
1	100
2	100
4	65
5	55
7	20

Currently, this has only been done on the single supporting fact case. The following are a list of few experiments.

5.1 Position of Relevant Sentence from Answer

Our assumption is, if relevant sentence far from the question, then the algorithm has to disambiguate between lots of sentences (Table 5).

For example, in the case below, we see the question present at distance of 1 and 5, respectively, and therefore see a difference in accuracy.

Sandra went to the office
Daniel went to the hallway
Where is Daniel? *Prediction:* ***Hallway*** *Answer:* ***Hallway***
Daniel went to the office
John moved to the hallway
Where is Sandra? *Prediction:* ***Hallway*** *Answer:* ***Office***

We see that by the time the distance becomes seven sentences the accuracy reduces significantly since the question answering system has to look at much longer distances.

5.2 POS (Part of Speech) Tagging Cleanup

POS tagging will help in identification of content word which contains noun, verb, adverb, and adjectives. Also, it would help in ignoring the functional word and stop word like preposition and determiner (a, an, the, etc.). It would help in data cleanup process. The following sentences show input sentence and clean sentence. These extra words may increase the noise and reduce the discriminative power of the model.

Example: Daniel journeyed to the hallway gets converted to Daniel journeyed Hallway after excluding prepositions and determiners.

With POS tagging for 10 separate bootstrap tests, on an average the accuracy was **77.8%** with a while with ignoring unnecessary POS tagged keywords, we got average **82.8%** accuracy on test.

5.3 Number of Nearest Relevant Statement/Answer

In Babl dataset, the question is followed by two answers or statement. There are three different conditions.

(a) Relevant sentence is not present in the previous two sentences.

John moved to the garden
Sandra moved to the bedroom
Where is **Mary**?

Here Mary word is not present in previous two relevant statements before the question "Where is Mary?".

(b) One relevant sentence is present in two different sentences.

Mary went to the bedroom
Daniel went to the garden
Where is **Mary**?

Here Mary is present only once in previous two statements before the question "Where is Mary?"

(c) Two relevant sentences are present in the previous two sentences.

John moved to the bedroom
John journeyed to the hallway
Where is John?

Here John word is present in both previous two statements before the question, "Where is John?".

Here, in Case a, algorithm has to look at relevant statement which is at longer distance from the question, so accuracy would be low.

In Case b, the algorithm has just identified answer from one relevant statement so this would give more accurate results.

Table 6 Accuracy rates for the three possible cases

Number of nearest relevant statement/answer	Accuracy
0	0.64
1	0.8
2	0.6

In Case c, the algorithm has to disambiguate probable answer from two relevant statements. So accuracy is expected to be lesser (Table 6).

6 Conclusion

In this paper, we have utilized recurrent neural network for typical question answering system. Generally, the question answering system explores feature engineering tasks like parsing, pos tagging, and tasking. We have explored how features like token sequences are important for question answering system. We have changed deep learning parameters like epoch, embedding size, latent size, and batch size and identified batch combination to generate the highest accuracy. We also have performed error analysis, where we identified how salient features like (1) presence of stop words, (2) number of relevant statement/answers for different questions, and (3) distance between relevant statement and questions can improve the algorithm in identification of current answers for respective question.

It has been shown that each task will have its own specific architecture with different parameters driving accuracy improvements in each context. So a one size fits all approach which cannot be used in the question and answering systems if we use this framework. Three of the four tasks described have good accuracy (75% plus) which shows we can create very accurate systems. Further steps would involve trying a radically different architecture on the tasks or performing NLP modifications on the inputs where accuracy obtained is low.

Convoluted Cosmos: Classifying Galaxy Images Using Deep Learning

Diganta Misra, Sachi Nandan Mohanty, Mohit Agarwal and Suneet K. Gupta

Abstract In this paper, a deep learning-based approach has been developed to classify the images of galaxies into three major categories, namely, elliptical, spiral, and irregular. The classifier successfully classified the images with an accuracy of 97.3958%, which outperformed conventional classifiers like Support Vector Machine and Naive Bayes. The convolutional neural network architecture involves one input convolution layer having 16 filters, followed by 4 hidden layers, 1 penultimate dense layer, and an output Softmax layer. The model was trained on 4614 images for 200 epochs using NVIDIA-DGX-1 Tesla-V100 Supercomputer machine and was subsequently tested on new images to evaluate its robustness and accuracy.

Keywords Convolution neural network (CNN) · Softmax · Dropout · Galaxy type

1 Background and Introduction

The galaxy classification problem was given initially by Edwin P. Hubble in 1926 [1] and later extended by the scientist: de Vaucouleurs [2]. galaxy classification is a major task involved with all domains of analytical astronomy with major space research agencies relying on automatic classification of galaxies into their corresponding correct classes to further understand the properties and possibilities. Galaxy shapes form the basis of classification of galaxies. Three major shapes of galaxies are noticed

by scientists: elliptical, spiral, and irregular. As we know, the orbits of planets are elliptical due to gravitational force [3]. Similarly, galaxies which are a group of stars also form shapes similar to symmetric curves due to mutual gravitation between stars. Stars are in constant motion with respect to each other due to gravitational pull which causes galaxies to rotate [4]. Irregular galaxies are an exception from above circular shapes and do not have any symmetric shape. This is due to a lot of elemental hydrogen or dust in these galaxies. As we also see on earth dust particles do not form any regular shape, thus the reason behind the shape of irregular galaxies.

Generally, there are three major classes of galaxy, which is described as follows.

1.1 Elliptical Galaxies

A galaxy which has the ellipsoidal shape and a smooth nearly featureless image [5]. Moreover, the spherical form in $3D$ appears to us as a circular shape in $2D$. These are classified into $E0$ which are perfectly circular to $E7$, which are most flattened. Such type of galaxy is the brightest at center and brightness diminishes moving away from the center [6] (Fig. 1).

1.2 Spiral Galaxies

These have three major components: bulge, disk, and halo. Bulge is the central portion which consists of old stars [7]. Arm is the linear portion of stars which are in circular motion around bulge and is made of dust and younger stars. Halo is the spherical part around bulge and covers some part of the disk. Arms emerge directly from bulge (ordinary spiral) or from a bar of material around bulge (barred spiral) [8]. They are also further classified into lower case letters: a, b, c., on how tightly the arms are bound to bulge. The category has most tightly bound arms (Fig. 2).

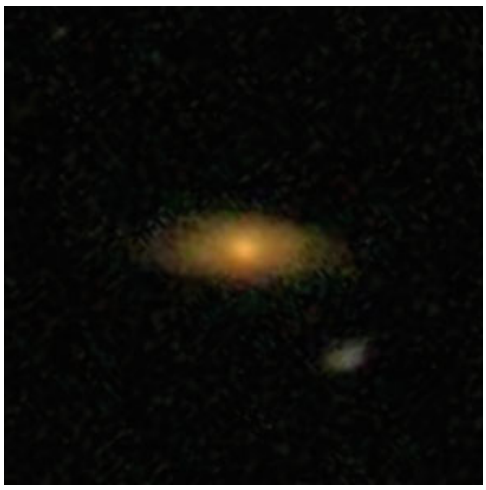

Fig. 1 Sample elliptical galaxy image

Fig. 2 Sample spiral galaxy image

1.3 Irregular Galaxies

These are classified into Irregular I or Irregular II [9]. First category has a lot of elemental hydrogen and young stars. Irregular II has a lot of dust that makes the distinct stars not clearly visible [8] (Fig. 3).

We have made an effort to use deep learning and train the system using some existing labeled images. After this, if the machine is fed with new galaxy images, it will classify the new image into the correct type of galaxy with some degree of accuracy.

In this paper, we approached the problem of galaxy classification based on galaxy images into its three major classes elliptical, irregular, and spiral by applying a Deep Convolution Neural Network (CNN) Architecture. We applied the deep CNN comprising of four hidden layers, one flatten layer, and another dense layer using a Softmax Activation function. The network architecture used max pooling and dropouts wherever required and Tanh activation function was applied in every layer. The model was trained for 200 epochs on the dataset and then was subsequently tested on real-life images in batches of 64 for all the 3 categories. The model was

Fig. 3 Sample irregular galaxy image

highly accurate in its predictions and outperformed existing models and conventional machine learning models in this regard. The rest of the paper is organized in the following chronological order.

In Sect. 2, literature survey of related past work in this domain of galaxy classification is discussed. Followed by Sect. 3 which extensively elaborates about the proposed work and is divided into three corresponding subsections which are introduction to CNN, dataset description, and proposed architecture. Section 4 embeds the experimental setup and results obtained in forms of interactive visualizations and graphs. Concluding, Sect. 5 summarizes the whole paper and provides the conclusion of the research.

2 Related Work

Kormendy and Bender [10] explained about $S0$ galaxies which are intermediate between $E7$ (elliptical) and Sa (true spiral). They have a bulge and a disk, but no spiral so differs from both elliptical and spiral galaxies and are called lenticular galaxies. Authors make a parallel classification of $S0$ galaxies to Sa, Sb, Sc and give them names $S0a$, $S0b$, $S0c$. This classification is done based on B/T ratio, i.e., bulge divided by total light. This value decreases from a to c for both spiral and lenticular galaxies. Buta et al. [11] proposed a new classification of galaxies by the name Comprehensive de Vaucouleurs revised Hubble-Sandage (CVHRS). In this, authors classified galaxies in notations of the form: Sab-A Sab galaxy that is closer to Sa than to Sb, Sab-A Sab galaxy that is closer to Sb than to Sa and so on for other galaxies. Shamir described the automatic classification of galaxy images into elliptical, spiral, or edge-on galaxies [12]. For the experimental purpose, authors used manually classified images to extract image features and discussed the Fisher score. Moreover, test images are classified using nearest weighted neighbor using the Fisher score as an important parameter. The author found automatic classification into elliptical, spiral, or edge with 90% accuracy [12].

In 2013, M. Martin et al. cite9 have proposed galaxy classification algorithm based on Naive Bayes and random forest. The achieved accuracy was about 91% for the Naive Bayes and 79% for random forest classifier. In [13], authors have proposed a classification method based on supervised machine learning with non-negative matrix factorization for images of galaxies in the Zsolt Frei Catalog [14] and achieved the accuracy about 93%. In 2017 [15], authors proposed a new automated machine supervised learning astronomical classification scheme based on the non-negative matrix factorization algorithm with the accuracy of about 92%. Kim and Brunner [16] describe that most star-galaxy classifiers use reduced information from catalogs, this requires careful feature extraction and selection. With the latest advances in machine learning which use deep CNN allows the machine to automatically learn the features directly from the images and minimizes the need for human input. Authors present a star-galaxy classification framework using (ConvNets) directly on galaxy images pixel values.

In contrast to above mentioned approaches, we have used the deep convolution network to improve the accuracy. The details about the proposed model are discussed in the following sections.

3 Proposed Work

3.1 Dataset

In this research project, we classified galaxy Image data into its three corresponding major classes—elliptical type, spiral type, and irregular type using a Deep Convolutional Neural Network (CNN) architecture. The dataset containing the galaxy Images were downloaded from Kaggle [17] and NASA Hubble-Space Gallery Websites [18]. The dataset was categorized into three classes with images kept in two main folders: training and validation. The training folder is further subdivided into three subfolders for three classes: spiral, elliptical, and irregular. The validation folder is also similarly having three subfolders with same names as the classes. The number of images in these folders is listed in Table 1.

Initially, we had only 11 images for the Irregular class. So, we used the Augmentor Package of Python to perform Image Augmentation on those 11 images and generated 1615 augmented images.

Convolution Neural Network (CNN)—A deep learning framework used mostly for object detection and image classification.
Softmax—An activation function used for multiclass categorization.
Dropout—A regularization technique in neural networks to reduce overfitting.
Deep Learning—Deep learning (also known as deep structured learning or hierarchical learning) is part of a broader family of machine learning methods based on learning data representations, as opposed to task-specific algorithms.
Galaxy—A cosmological cluster of stars systems and planets.

3.2 Brief Discussion About Convolutional Neural Network

Convolution Neural Networks (CNN) [19] is the state-of-the-art deep learning model for object recognition, image segmentation, classification, and analysis; but are not only restricted to this scope of problems and fare very well in many other aspects

Table 1 Different classes with the number of images for training, validation, and testing

Classes	Total images	Training set	Validation set	Testing set
Spiral	1464	1000	400	64
Elliptical	1464	1000	400	64
Irregular	1686	1232	390	64

including generating new images as used in Generative Adversarial Networks (GAN) [20]. CNNs are very robust and are very efficient in understanding the features in an image by applying simple convolution formula on the input features using random initialized weights.

The pictorial representation of the architecture of the convolutional neural network is given in Fig. 4.

We built our Convolutional Neural Network (CNN) model in Python using the Keras framework. The CNN architecture comprised of one Input Convolution $2D$ layer followed by four hidden layers, one penultimate dense layer, and finally one output layer. We used a filter size of 3×3 in each layer. All the images were resized

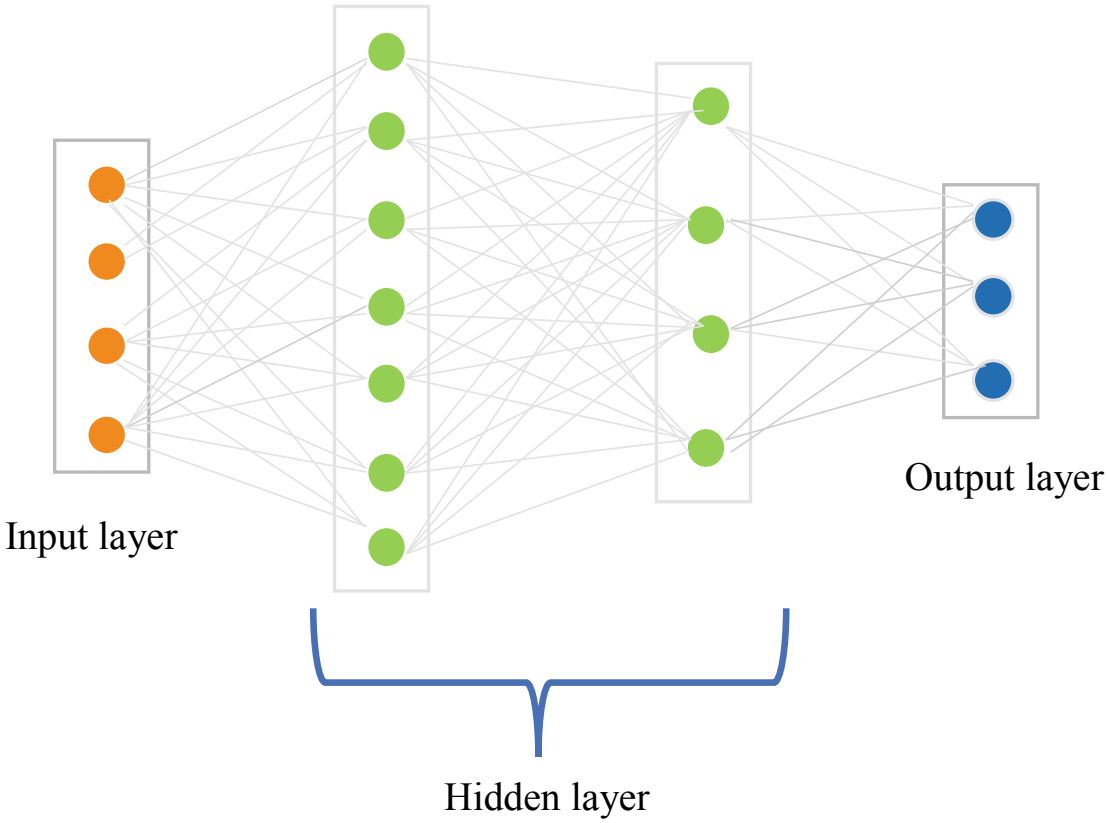

Fig. 4 CNN architecture Layman's visualization

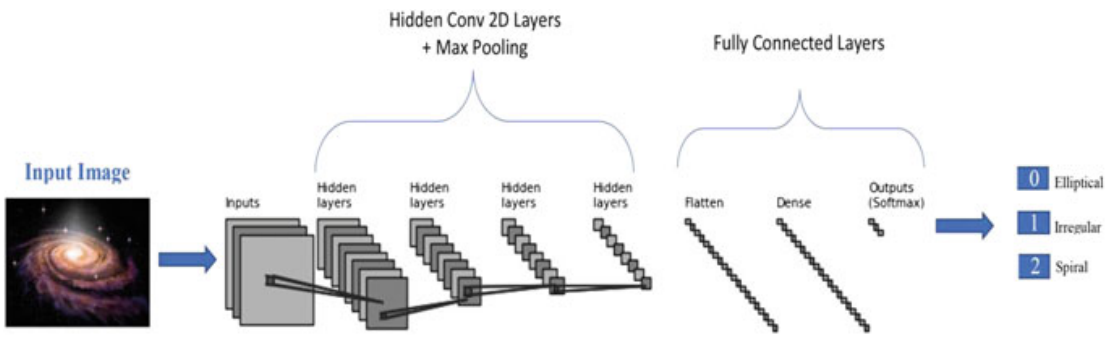

Fig. 5 The architecture of convolution neural network for galaxy classification

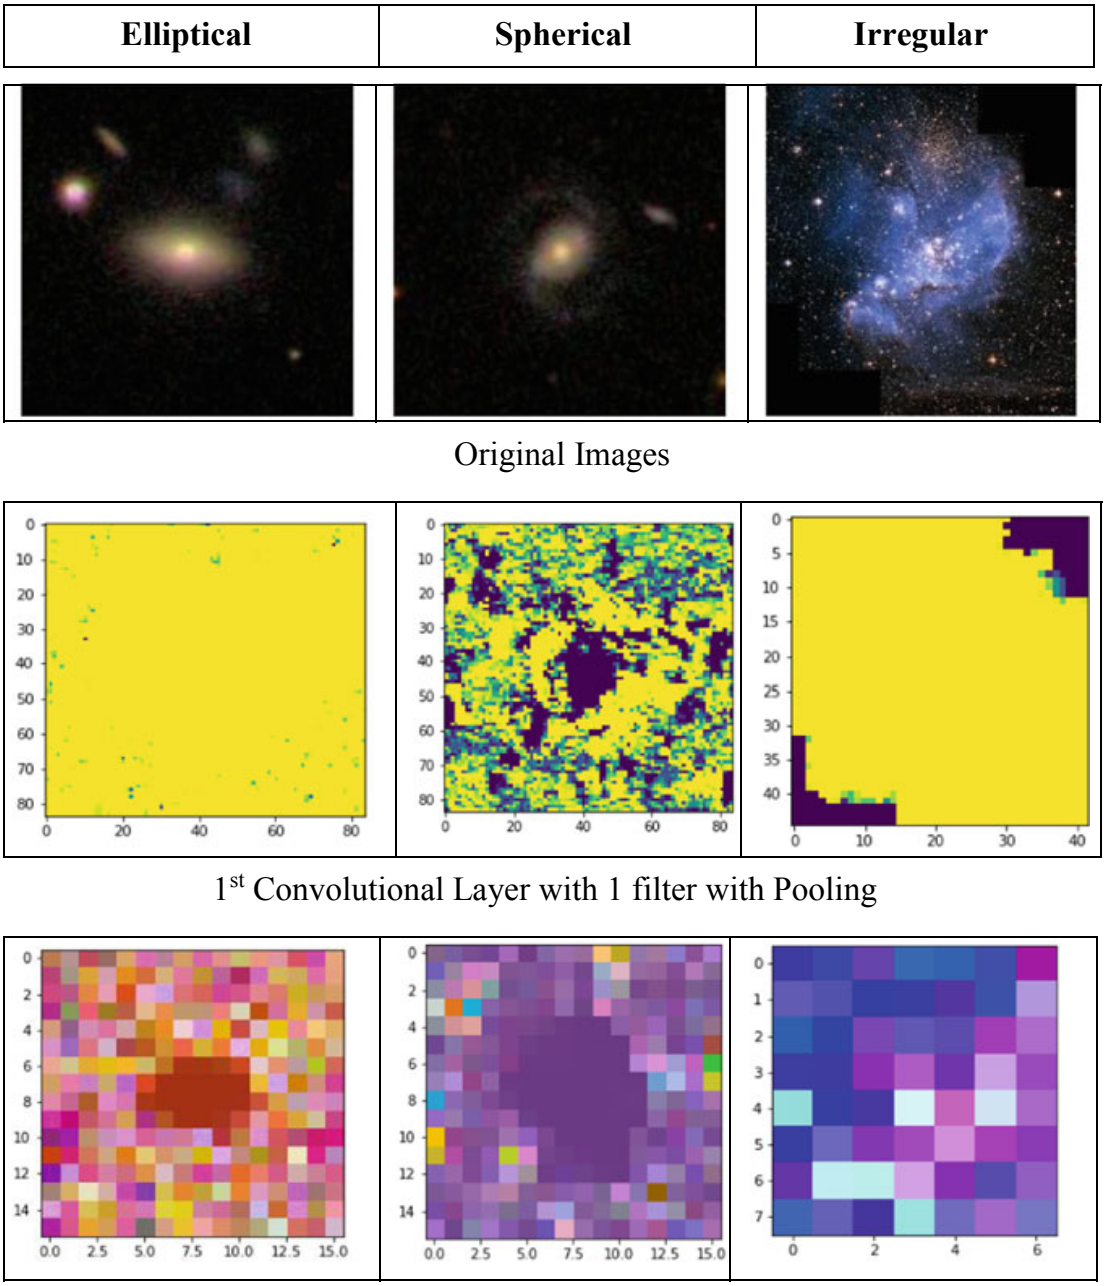

Fig. 6 Intermediate feature map representation with and without pooling

to 256 × 256 pixels. The batch size used was 64 and was trained for 200 epochs with 10 timestamps per epoch. We used dropout regularization after the hidden layers and before the output layer. The detailed architecture diagram is shown in Fig. 5.

After training the CNN model, we saved the weights of the model in weights .h5 file as we could now perform testing easily as many times we needed using the already trained model weights. This step was also performed as training took nearly 1.5 h to complete and it was not feasible to train the model every-time for testing. Thus, this time was saved by making the weights .h5 file for testing. The output images after the execution of intermediate operation of CNN is depicted in Fig. 6.

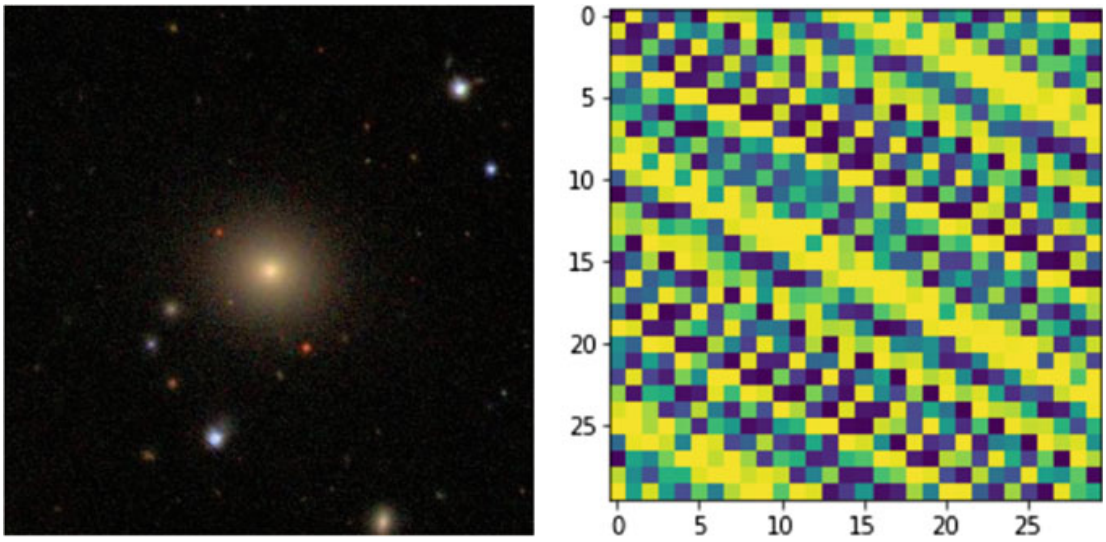

Fig. 7 Feature map representation of hidden layer for an elliptical galaxy image

The hidden layer feature map representation for a sample elliptical galaxy image from the training data is shown in Fig. 7.

4 Experimental Setup

We also trained the model on the Nvidia-DGX-1 (8X Tesla V100) Supercomputer servers having 5120 Nvidia Tensor Cores and a computing power of 960 TeraFlops. The python code was written on Spyder 3.0.0, Jupyter 1.0.0, and Python 3.5.2. using Keras 2.1.3 framework.

After 200 epochs, we obtained a training accuracy of 99.20% and a validation accuracy of 98.45%. After training and saving the model weights, we tested the model and obtained a test accuracy of 97.3958%. The model accuracy and loss curve are depicted in Figs. 8 and 9, respectively.

Upon testing, the results were obtained in the form of a list with each image having labels as 0, 1 and 2 where 0 stands for elliptical type, 1 stands for irregular type and 2 stands for spiral type. The sample output for 64 elliptical images is shown below:

array([0, 0, 0,

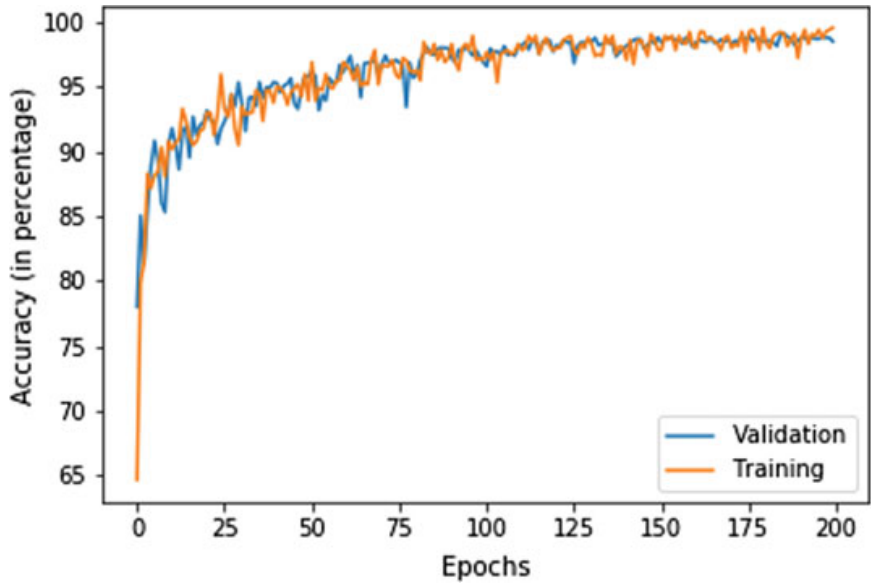

Fig. 8 Graphical representation of accuracy versus epochs

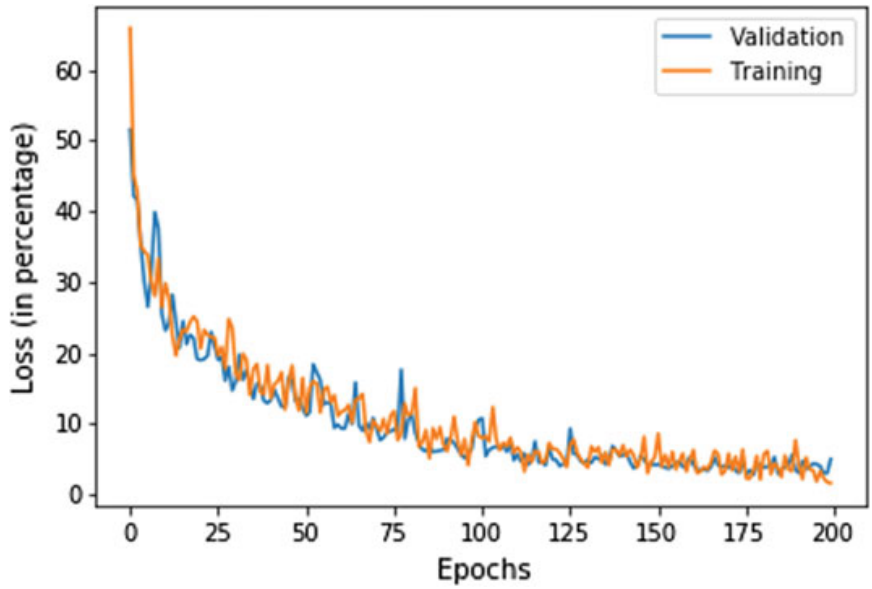

Fig. 9 Model loss curve

Elliptical 100%
Spiral 100%
Irregular 92.187%.

The testing accuracy of images of the various galaxy types is represented in the following Fig. 10 using bar chart representation.

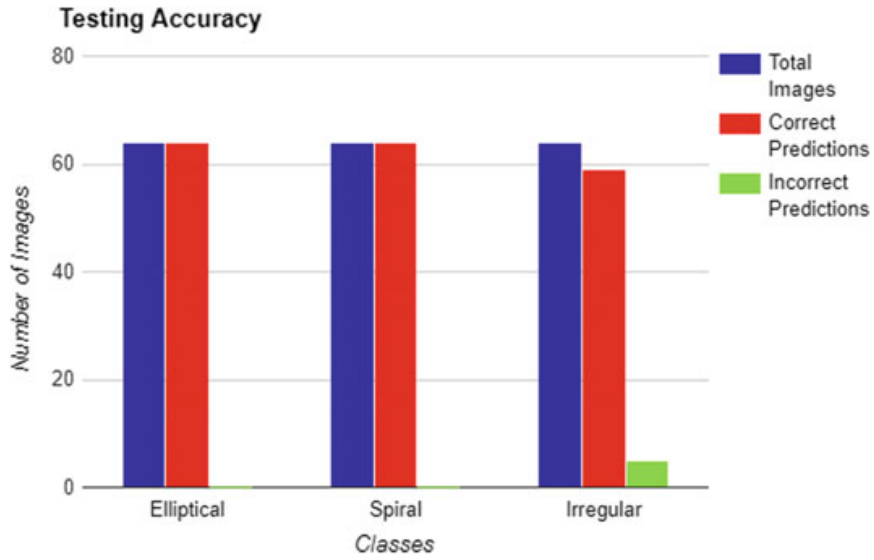

Fig. 10 The representation of testing accuracy using bar chart

5 Conclusion

In this research article, a galaxy classification algorithm has been proposed. The algorithm is based on deep convolution neural network with four hidden layers, max pooling layers after every convolution layer and one dense layer. The proposed research will be helpful for astronomical scientists and cosmologists. It will help to classify huge collection of galaxy images without manual effort of viewing each image individually. Research can be fine-tuned for further classification of galaxies into their subclasses as explained in the previous sections. The testing time was reduced to few seconds by saving the CNN weights file and thus it will be working on real time scenarios also.

Advances in Network Technologies

Energy-Based Improved MPR Selection in OLSR Routing Protocol

Rachna Jain and Indu Kashyap

Abstract Wireless Ad hoc networks are consisting of wireless nodes that communicate over wireless medium without any centralized controller, fixed infrastructure, base station, or access point. The networks should be established in a distributed and decentralized way. Performance of mobile Ad hoc network depends on the routing scheme chosen. Extensive research has been taken place in recent years to suggest many proactive and reactive protocols to make them energy efficient. In this work, table-driven routing protocol, i.e., optimized link-state routing protocol (OLSR) is tried to make more energy efficient which also helps in prolonging the network lifetime. OLSR is a proactive routing protocol in Mobile Ad hoc Networks (MANETS) which is driven by hop-by-hop routing. The conventional OLSR is hybrid multipath routing, in which link-state information is forwarded only by Multi-Point Relays (MPRs) selected among one-hop and two-hop neighbor sets of host. In this work, a novel mechanism is introduced to select MPR among nodes neighbor set to make it more energy efficient by considering willingness of node. Proposed energy-aware MPR selection in MDOLSR is compared with conventional OLSR. Extensive simulations were performed using NS-2 simulator, and simulation results show improved network parameters such as higher throughput, more Packet Delivery Ratio (PDR) and lesser end-to-end delay as simulation time progresses.

1 Introduction

Mobile Ad hoc Networks (MANETS) are general-purpose multi-hopping Ad hoc networks [1]. In these networks, mobile nodes can freely roam within the communication range. These nodes have limited battery capacity [2]. Due to the mobility of nodes topology of the network can change at any time. Routing of data, conservation of energy and bandwidth, and security of information have become major challenges in these battery operated nodes. Despite all these challenges, ad hoc networks have become popular especially in military applications, search and rescue operations, and vehicular communications. Based on network topology routing protocols are broadly categorized as proactive, reactive, hybrid as well as cluster based. In proactive routing protocols, each node maintains a routing table to carry forward the data, whereas in reactive routing route is searched on demand. Hybrid routing protocol combines the advantages of both. Figure 1 shows a scenario of mobile Ad hoc networks.

Although many protocols have been suggested for energy-efficient routing in MANETS but selecting a single path results in quick depletion of energy among nodes. Multipath routing ensures better utilization of the network through load balancing. Routing protocols depending on network topology can be divided into proactive, reactive, and hybrid routing protocol. In proactive routing protocol, every node maintains a routing table. Destination Sequence Distance Vector (DSDV) and Optimized Link-State Routing (OLSR) [3] come under this category. In case of reactive protocols, route is searched on demand. Ad hoc Distance Vector Routing (AODV) and Dynamic Source Routing (DSR) come under this category. Hybrid routing combines the advantages of both proactive and reactive routing.

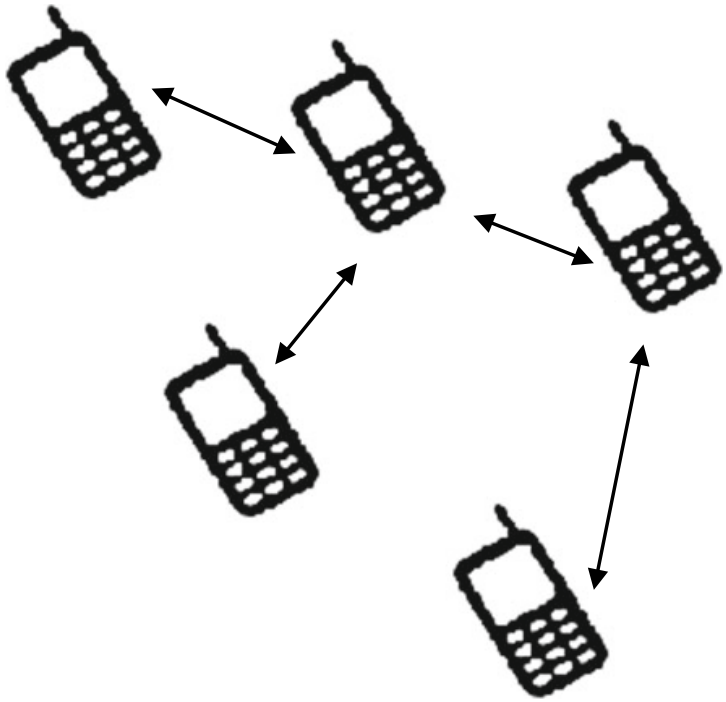

Fig. 1 Mobile Ad hoc networks

Zone Routing protocol (ZRP) comes under this category. This paper is organized as follows: Sect. 2 discusses related work, Sect. 3 discusses OLSR routing protocol in detail, Sect. 4 discusses the concept of energy willingness in detail. Section 5 tells about performance parameters studied and Sect. 6 shows the simulation scenario and results obtained. In last, Sect. 7 discusses the conclusion and future work.

2 Related Work

A detailed literature survey of energy-efficient MANET routing protocols especially focusing on OLSR routing protocol is discussed in this section.

In [4] authors have proposed a modified OLSRM protocol which is based on conventional OLSR. Energy-aware metric used in this protocol is the number of nodes alive against varying simulation time of nodes. Authors have framed an analytical model to compute the correct behavior of the network.

In [5] authors have proposed EEOLSR energy-efficient routing protocol in MANETS which extends network lifetime without losing other Quality of Service (QoS) parameters. Multi-point Relay selection is done on the basis of node willingness to become MPR. This process of MPR selection is discussed in detail in Sect. 3.

In [6] a different approach is used to make energy-efficient OLSR with Autoregressive Integrated Moving Average timeseries model (ARIMA). In this method per interval energy consumption is computed. Composite energy cost model is developed with the help of the calculation of residual energy of the node and consumed transmission power of the node. Sakthivel et al. [7] gave a different metric for MPR selection using energy accuracy metric. Since MPR node is selected from one-hop neighbor set of the host which covers its two-hop neighbors also. Modified MPR is selected from an ordered set based on the value of highest residual energy along with considering timestamp values.

Jabbar et al. [8] gave a new metric, i.e., Multi-Criteria Node Rank metric (MCNR) metric comprising residual battery energy along with node speed to propose a new energy and mobility aware (EMA-OLSR) scheme for selection of MPR in OLSR. Jabbar et al. [9] have proposed Multipath Battery Aware OLSR (MBA-OLSR) which is based on OLSRv2 and its multipath links between source and destination. In this work, the author has considered remaining battery power of nodes to calculate the initial cost of links between sender and destination. Simulations are done using EXata simulator and results show better network lifetime.

Natarajan and Rajendran [10] proposed AOLSR which is hybrid advanced OLSR by modifying Dijakstra's algorithm to compute multiple paths in both dense and sparse networks from source to destination. Whereas Dhanalakshmi [11] proposed Energy Conserving Advanced Optimized Link-State Routing (ECAO) model by calculating energy costs of all nodes and compared results with OLSR and

AOLSR. The author has also implemented modified Dijakstra's algorithm to compute multipath and also checked for link failure for further analysis.

Moussaoui [12] devised stability of nodes (SND) and fidelity of nodes (FND) parameters to elect Multi-Point Relays (MPR) in case of OLSR. The author has proved via simulation that his selected method provides better Quality of Service (QOS) parameters than the traditional method in OLSR for MPR selection which considers Expected Transmission Time metric (ETX). The limitation of using ETX is overestimating link delivery ratio when packet size is too large.

Rango [13] gave a unique routing protocol which considered both link-stability and energy-aware parameters by proposing Link-stability and Energy-aware Routing protocols (LAER). The author has considered link stability along with minimum drain rate energy consumption. Same author Rango [14] has extended Dynamic Source Routing (DSR) protocol packet format to make it energy efficient. Modified DSR header packet included cost function both in route request and route reply packet. Both DSR and OLSR routing protocols have been thoroughly studied from an energetic point of view. The path according to minimum cost function is organized from best to worst path. Many node disjoint paths have been found, out of which most energy-efficient path is chosen. Since node disjoint provides higher fault tolerance. In non-disjoint routes link or node failure causes many routes to fail. Whereas in node or link disjoint routes link failure will cause only a single route to fail.

Another approach to improve routing efficiency is to use multipath in comparison with a single path. More than one path is used to increase routing efficiency. Multiple paths can be linked disjoint or node disjoint. In link disjoint paths, there is no common link, whereas in node disjoint path there is no common node. In link, disjoint paths goal is to reduce delay and increase efficiency. Multipath AODV or Multipath OLSR is proposed to prove it.

3 Optimized Link-State Routing Protocol

Routing algorithm for Ad hoc networks can be classified as routers obtain routing information along with the type of information used to calculate routing path. According to the way routers get information, protocols are classified as proactive, reactive, or hybrid as shown in Fig. 2. According to the type of information proactive protocols are further subdivided as distance-vector-based or link-state-based. Distance-vector protocol uses distance information to obtain path up to destination, whereas link-state-based protocols use topological information to obtain path up to the destination. Link-state algorithms are less inclined to routing loop formation as changes in network topology are known by nodes as compared to distance vector routing protocols. But link-state protocols are more expensive for implementation since they require more CPU power.

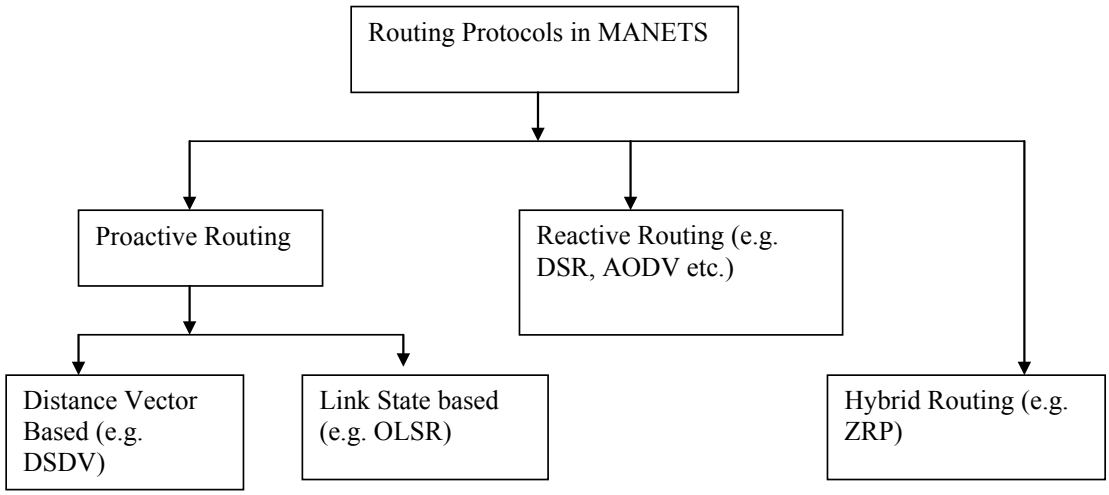

Fig. 2 Classification of routing protocols

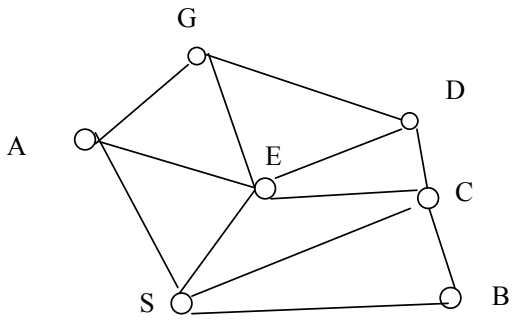
Optimized link-state routing protocol (OLSR) is a proactive, table-driven routing protocol which works on the concept of link sensing. Being a proactive routing protocol, routes are always available. But, if there is any change in network topology due to the mobility of nodes then the information should be flooded through the entire network. To control this flooding, Multi-Point Relays (MPR) are selected from one-hop neighbor set and two-hop neighbor set from the source node. Only selected MPR nodes are now responsible for the flooding of information, hence conserving the bandwidth by avoiding unnecessary flooding. Selecting the minimum number of one-hop neighbors which covers all two-hop neighbors is the goal of MPR selection. There are two types of control messages in OLSR.

(i) HELLO Messages
(ii) Topological Control Messages (TC Messages).

HELLO messages are periodically broadcasted to the neighbors that are only one-hop away. Hello messages obtain information about local links and its neighbors. Since links can be unidirectional or bidirectional, the host should know about all its neighbors. Links are subdivided as symmetric (bidirectional), asymmetric (unidirectional), or heard.

HELLO messages are periodically broadcasted after HELLO refresh time period and received by all one-hop neighbors. Each node attaches a list of its own neighbors to obtain the information about two-hop neighbors as shown by Fig. 3. Once the node has information about its one-hop and two-hop neighbors, it can select Multi-Point Relays (MPRs) which covers all two-hop neighbors as explained by Fig. 4.

Each node periodically broadcasts its HELLO messages to obtain the information about its neighbors and their link status. HELLO message contains a list of



Source Node	1-hop Neighbors	2-hop neighbors	Multipoint Relay
S	A,E,C,B	G,D	E

Fig. 3 Network example for MPR selection

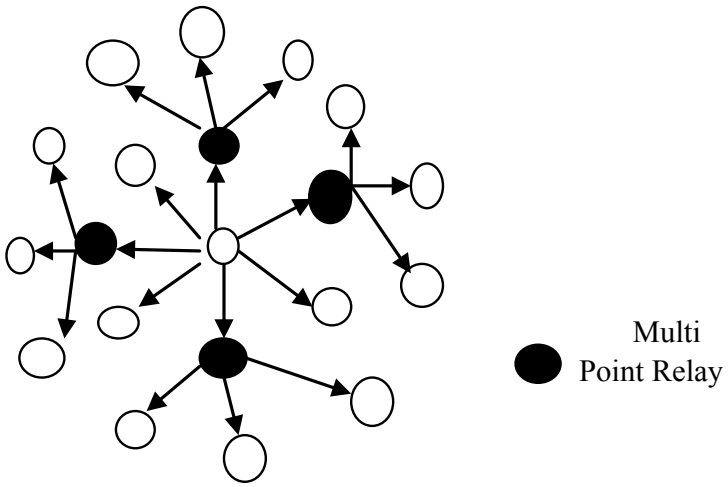


Fig. 4 Diffusion of broadcast message using MPR

addresses of neighbors to which valid bidirectional (symmetric) link exists. It also has a list of addresses of neighbors which have heard HELLO messages but the link is not bidirectional (asymmetric). Format of HELLO message is shown in Fig. 5.

Message Type	Vtime	Message Size	
Originator Address			
Time to Live	Hop Count	Message Sequence Number	
Reserved		Htime	Willingness
Link Code	Reserved	Link Message Size	
Neighbor Interface Address			
Neighbor Interface Address			

Fig. 5 HELLO message format in OLSR

Destination Address	Destination's MPR	MPR selector sequence number	Holding time

Fig. 6 TC message format in OLSR

HELLO message helps in link sensing as link code has the information about link type (Symmetric or Asymmetric) and neighbor type. Each node has knowledge about its two-hop neighbors so it helps in neighbor detection also. On the basis of this information, each node selects its MPR's which is responsible for the forwarding of control packets. On reception of HELLO message, each node constructs its MPR selector table. Multi-point relays are declared in the transmitted HELLO messages. If there is any change in the neighborhood up to two-hop neighbors, then multi-point relay set is recalculated.

Each node maintains a topology table on the basis of Topology Control (TC) messages. Routing tables are calculated on the basis of topology table. Format of TC message is shown in Fig. 6.

If there is entry to the same destination node with higher sequence number then the TC message is ignored. New topology entry is recorded if there is any entry with lower sequence number to the same destination node. Holding time of entry is refreshed in case entry is same as in TC message. New entry is recorded in case there is no corresponding entry.

Each node maintains a routing table to all known destinations in the network on the basis of topology table and neighbor table. Routing table is recalculated after a change in topology table. Destination address, next-hop address, and distance to every node are stored in the routing table.

4 Concept of EA: Willingness in OLSR

4.1 Energy Consumption Model

All the nodes in wireless networks are equipped with IEEE 802.11 g Network Interface Card. Energy required to transfer a packet p from any node is

$$E = i * v * tp \tag{2}$$

where i = Current (in Ampere), v = Voltage (in Volts), tp = Time taken to transmit the packet p (in Seconds)

Transmission time tp is given by

$$tp = (ph/6.10^6 + pd/54.10^6) \tag{3}$$

where ph = Packet Header in bits, pd = Size of payload

Assuming that energy consumption caused by packet overhearing is same as energy consumed in actually receiving a packet.

$$E(p, na) = Etx(p, na) + Erx(p, nb) + (N - 1)\{Eo(p, ni)\} \tag{4}$$

where $Etx(p, na)$ = Amount of energy spent in transmitting packet from node na, $Erx(p, nb)$ = Amount of energy spent in receiving a packet by node nb, $Eo(p, ni)$ = Amount of energy spent by overhearing nodes, N = Average number of neighboring nodes affected by transmission, $E(p, na)$ = Total energy spent in transmitting packet from node na to node nb.

From Eq. 4 it can be concluded that if the network is denser then overhearing causes much energy consumption. Modification is introduced in OLSR to include node willingness to be chosen as Multi-point Relay (MPR). In OLSR routing protocol, each node declares its willingness to be selected as MPR by default. In the proposed work, willingness is decided on the basis of remaining battery capacity of the node along with its lifetime which is dependent on drain rate.

4.2 Passive Hearing by Neighboring Nodes

As simulation time progresses, we can see from simulation results that energy of nodes that are not actively participating in routing is also becoming low. This is due to overhearing by neighboring nodes. Overhearing can be avoided by turning off device/node when unicast message is exchanged among neighboring nodes. It can be obtained by sending signaling messages (RTS/CTS) at MAC layer.

5 Performance Metrics

Performance parameters considered in this work are throughput, end-to-end delay, Packet Delivery Ratio (PDR), and energy required for transmission.

Throughput: It is the measure of rate of successful data transfer over the network. It is measured in bits per second (bps).

End-to-end delay: It is the total time taken in data transfer from source node to destination node. Latency in route discovery, delay in retransmissions at MAC, propagation delay as well as transfer time all contributes to end-to-end delay.

Packet Delivery Ratio (PDR): It is defined as a ratio of packet received by the destination node to the packets sent by source node. Higher the PDR, better is efficiency of routing protocol.

Consumed Energy: It is the sum of total energy spent by all the nodes.

Residual Energy: It is the initial energy minus consumed energy of the node.

Energy Cost per packet: It is the ratio of total consumed energy over number of successfully received packets at the destination.

6 Simulation Results

In this work, MDOLSR is built over UM-OLSR [19]. Simulation parameters are listed in Table 1.

Figure 7 shows that HELLO packet transmission is taking place while the simulation is in progress.

In this work, different performance parameters of modified OLSR, (MDOLSR) such as throughput of the network, packet delivery ratio, energy cost per packet are

Table 1 Network parameters

In this work following initial parameters are taken.	
Channel type	Wireless Channel
Radio propagation model	Two Ray Ground
Mobility Model	Random Way Point
MAC type	IEEE 802.11 a
Interface queue type	Drop Tail
Antenna model	Omni Antenna
Agent	UDP (User Data Protocol)
Application	CBR (Constant Bit Rate)
MANET topology	Dynamic
Speed of nodes	1 m/s…10 m/s
Max packet in ifq	50
Number of mobile nodes	20
Simulation area (*X*)	870
Simulation area (*Y*)	870
Simulation time	30 s….400 s
Pause time of nodes	50 s ….250 s
Initial energy	100 J per node

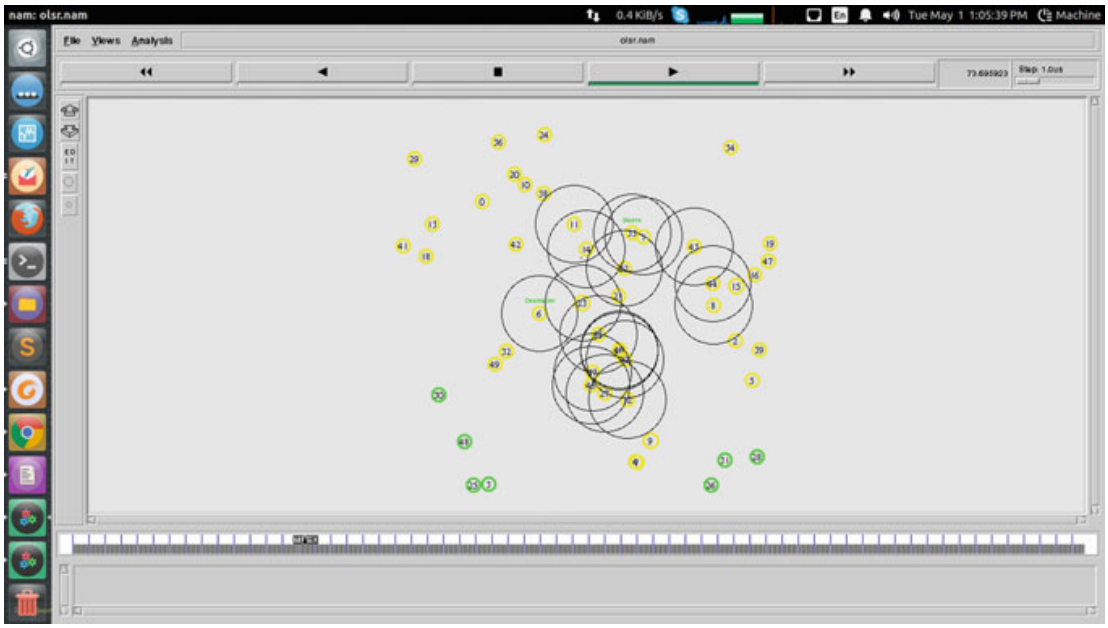

Fig. 7 Network scenario when the nodes have medium energy level

studied according to varying network conditions such as different values of pause times of nodes, varying node speed, and different values of simulation times (Table 2).

Simulation results obtained from modified OLSR are compared with conventional OLSR as shown in Fig. 8 which shows better results for PDR in case of MDOLSR, whereas Fig. 9 justifies the lesser time taken to search the route as the speed of node increases.

Now pause time of nodes is varied from 50 to 250 s and different performance parameters have been studied (Table 3).

The above results obtained are compared with conventional OLSR for same network parameters as depicted in the following graphs. Figure 10 shows there is a significant improvement in PDR of MDOLSR in comparison to traditional OLSR.

Now simulation time of nodes has been varied, and different performance parameters are captured. Table 4 clearly shows that as simulation time progresses residual energies of nodes deplete sharply.

Figure 11 shows the improvement in the throughput of the network of proposed MDOLSR in comparison to OLSR.

Table 2 Node's speed versus QoS parameters

Speed of node (m/s)	Total initial energy (J)	Consumed energy (J)	Residual energy (J)	Energy cost per packet (mWh)	Average energy (J)	Throughput (bytes/s)	PDR (%)	End-to-end delay (s)

7 Conclusion and Future Work

Extensive simulations of OLSR routing protocol are chosen over other proactive protocols as it instantly knows about the status of the link and Quality of Service (QoS) information can be provided immediately. Another reason for considering OLSR is that reactive routing protocols result in large overhead as nodes are highly mobile but overhead in OLSR is independent of traffic as there is a fixed upper bound limit for overhead. This routing protocol is suitable for the large and dense network. Proposed methodology in modified MDOLSR results in better QoS parameters such as higher values of throughput and PDR whereas lesser values of energy cost per packet along with a smaller end-to-end delay. In future work energy-efficient OLSR can be further optimized using meta-heuristic techniques such as ant colony optimization, etc.

Table 4 Simulation time versus QoS parameters

A Novel Approach for Better QoS in Cognitive Radio Ad Hoc Networks Using Cat Optimization

Lolita Singh and Nitul Dutta

Abstract Cognitive Radio is a Wi-Fi verbal exchange methodology that allows the user to engage except having a fixed preassigned radio spectrum. Cognitive Radio Networks (CRNs) are having the routing hassle that is one of the serious constraints. Ad hoc networks are non-centralized Wi-Fi networks that can be constructed and there is no need for any preexisting infrastructure for these networks. Here every point can work as a router. In this paper, the authors have explained the Cognitive Radio Networks (CRN) that are obtaining so a whole lot of recognition where the principal focus is on the dynamic undertaking of channels to wireless devices. In this paper, cognitive radio networks are primarily focused. Nowadays, almost all the networks rely on fixed allocated networks in an approved or unapproved frequency group. In this paper literature evaluates associated to CRN and an optimization algorithm to enhance the overall performance of TE under CRN has been discussed. Swarm intelligence technique is used in the paper. Swarm approach is clearly the combination of the decentralized attribute to gain excellent viable solutions. The motivation regularly creates from nature, more often than non natural outlines. One of the effective approachs known as Cat swarm has been used to acquire high price of accuracy and much low error rates which improves the lifespan of the network. The results are carried out by the use of CSO (Cat Swarm Optimization) algorithm and parameters like energy consumption, congestion, overhead consumption, and number of routing rules are used to analyze the overall performance of the algorithm.

1 Introduction

Cognitive Radio is developed by popular person Joe Mitola in 1999 [1]. They allow wireless communication to come into a new method. The CR science provides a flexible result for the trouble of spectrum shortage by means of potential of dynamic spectrum allocation for community communication. It permits the coexistence of CR successful devices with licensed band customers [2] and allows the later to use the licensed spectrum opportunistically. The CR units can correctly feel on hand idle spectrum, reconfigure parameters to get admission to the quickly unused spectrum, and produce unbearable interference to licensed users, which make them successfully network among themselves [1].

Routing in traffic engineering using cognitive radio networks is one of the major topics. The routing hassle is one of those recent research topics which shows up in Cognitive Radio Networks (CRNs). The CRN has confirmed itself as a network to improve spectrum strength via self-organization and dynamic reconfiguration and thus, the Cognitive Radio Ad Hoc Network (CRAHN) [3] is introduced as a promising conversation technology. But, CR users need to stop their conversation or lower their transmission power to keep away from disturbances to authorized licensed customers (called Primary Users (PUs)). Because PUs are the owners of the channel, and the CR units (also referred to as Secondary Users (SUs)) opportunistically use the channel when PUs have no statistics to transmit [4]. That is why the unused spectrum (called spectrum hole) needs to be used successfully to make CRN successful. Besides that, if transmissions of CUs do no longer purpose dangerous interferences with PU transmissions, then CUs can communicate among themselves. CU and SU actually mean the same. From overall discussion CU, SU, and CR are the terms used interchangeably for a cognitive node (Fig. 1).

Network investigation is succeeding in all areas nowadays. Rare greatest capable expertise like 4G [1], facts-centric communication, and software-defined interaction [4] are receiving substantial importance. However additional idea named green

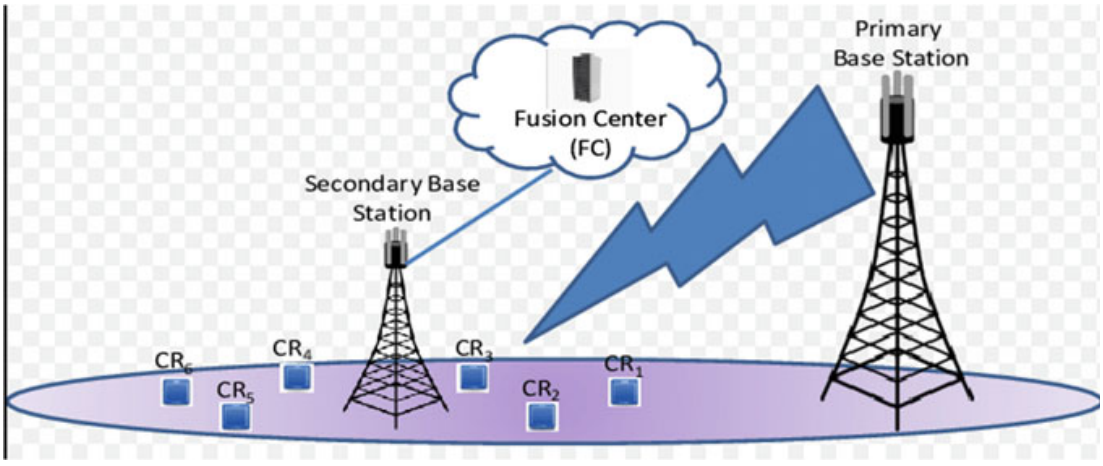

Fig. 1 CRN (cognitive radio network)

mobile computing is also attaining attention. In this, the procedures are intended to reduce power intake thus carbon emanation is minimized throughout the calculation. A review of such green computing constructed routing is established. Biology impressed algorithms are a unit extra step to green computing. Time serving packet forwarding and routing in Delay Tolerant Network (DTN) [9] is alternative space wherever several analysis work is established. These embrace transport network primarily based DTN and transport detector network. The routing in MANET with QoS improvement acquires an equivalent position in several analyses. Though, of these systems declared on top of depends on statically allotted channels either in authorized or unaccredited band. Such fixed channel job construct ends up in spectrum congestion and thus spectrum insufficiency in today's thickly inhabited situation. That's why, a replacement technology psychological feature i.e. Cognitive Radio Networks (CRN) attaining quality that works on vibrant task of channels to wireless devices.

2 Literature Review on CRN

Author	Description
Cacciapuoti et al. (2010)	Presented a routine procedure known as CRN On-demand Distance Vector or CAODV. This suggested technique designed for MANET is an adjunct of Ad Hoc On-demand Distance Vector routing protocol. Like AODV, this procedure also makes a path once there is a route for a package to send. Numerous manage packages of AODV, e.g., path appeal; neighbor discovery packets are moreover castoff in CAODV
Karim Habak et al. (2013)	Proposed a technique of routing known as LAUNCH. This procedure has certain features like effective usage of the frequent manage network, negligible path arrangement postponement. However, this procedure doesn't warranty the steadiness of the mounted path for the duration of conversation [6]
Sun et al. (2014)	Introduced a CRN-based totally vehicular network routing protocol. As mentioned in the paper, the protocol is appropriate for conditions like herbal disasters which cause extreme damage to communication infrastructure. Additionally, such herbal disasters are accompanied through sharp spikes in the utilization of commercially licensed spectrum. In such case, if pretentious victims try to transfer facts with excessive bandwidth requirement, wireless network, then the proposed protocol can suitably be used in CRN [11]
Ian F. Akyildiz et al. (2009)	Introduced CRAHNs current challenges and intrinsic features. The Software-Defined Networking (SDN) has been introduced and proposed. CRN deployments interference is managed by using the advantages of cloud computing and SDN in case of residual areas [5]
Anatolij Zubow et al. (2015)	A new CR SDN based structure has been introduced in which Spectrum Broker (SB), centralized controller primarily related cloud and it takes over spectrum task to CR Base Stations (CR-BS). The Wi-Fi information are combined to the SB beneath CR-BSs

3 CSO (Cat Swarm Optimization)

The Swarm Intelligence (SI) algorithms are optimization algorithms that were formulated for copying the intelligent behavior and nature of animals. In these technologies, a population of living things such as ants, bees, birds, and fish is communicating with each other and with their place via sharing information that results in the use of their place and things. Cat Swarm Optimization (CSO) algorithm is one of the more recent SI-based algorithms in which the nature of cats is simulated. The CSO algorithm is developed by Chu and Tsai (2007), and its things have been implemented for different optimization problems.

3.1 Natural Process of the Cat Swarm Optimization Algorithm

High alertness and curiosity about the environment is the nature of cats. They cannot spend most of their time resting; moving objects in their surroundings are their normal things. By this behavior, cats can cheat and seek their food. They spend very less time chasing prey to consume their energy as compared to the time dedicated to their resting. Chu and Tsai (2007) really got inspired by this behavior of cats and introduced CSO which is called as Cat Swarm Optimization. CSO has two modes: "seeking mode" it is the mode when cats are having rest and "tracing mode" it is the mode when cats are seeking their prey or food. CSO algorithm does the same thing. In CSO, a population of cats is first formulated and assigned in the M-dimensional solution space. Here each cat is representing a result. Then further two subgroups are made by the population. In the first group, the cats are rest mode and are very alert about their surroundings (i.e., seeking mode), while in the second group, the cats are trying to chase their preys (i.e., tracing mode). The hybridization of these two groups helps CSO to get the global solution in the M-dimensional solution space. The tracing subgroup should be small because the cats do not spend much time in the tracing model. The Mixture Ratio (MR) is defined for this which has a small value. New positions and fitness functions can be obtained after sorting the cats into these two modes. After this, the cat with an optimistic solution is

selected and saved in the memory. These steps have to be repeated until the stopping criteria are satisfied (Fig. 2).

The steps of CSO are given below:

Step 1: Initial population of cats has to be created and make them into the M-dimensional solution space (Xi,d) and provide each cat a velocity in the range of the maximum velocity value (ti,d). Then further two subgroups are made by the population. In the first group, the cats are in rest mode and are very alert about their surroundings (i.e., seeking mode), while in the second group, the cats are trying to chase their preys (i.e., tracing mode).

Step 2: Give every cat a flag to arrange them into the tracing mode process or seeking mode process. This depends on the value of MR. The tracing subgroup should be small because the cats do not spend much time in the tracing model. The Mixture Ratio (MR) is defined for this which has a small value.

Step 3: Calculate the fitness value of every cat and the cat with the best fitness function has to be selected. The position of the best cat tells the best solution so far. Xbest is the position of the best cat.

Step 4: The cats are applied to the seeking or tracing mode process and is based on their flags. New positions and fitness functions can be obtained after sorting the cats into these two modes. After this, the cat with an optimistic solution is selected and saved in the memory.

Step 5: If the termination process is accepted, end the process. Otherwise, repeat steps 2–5.

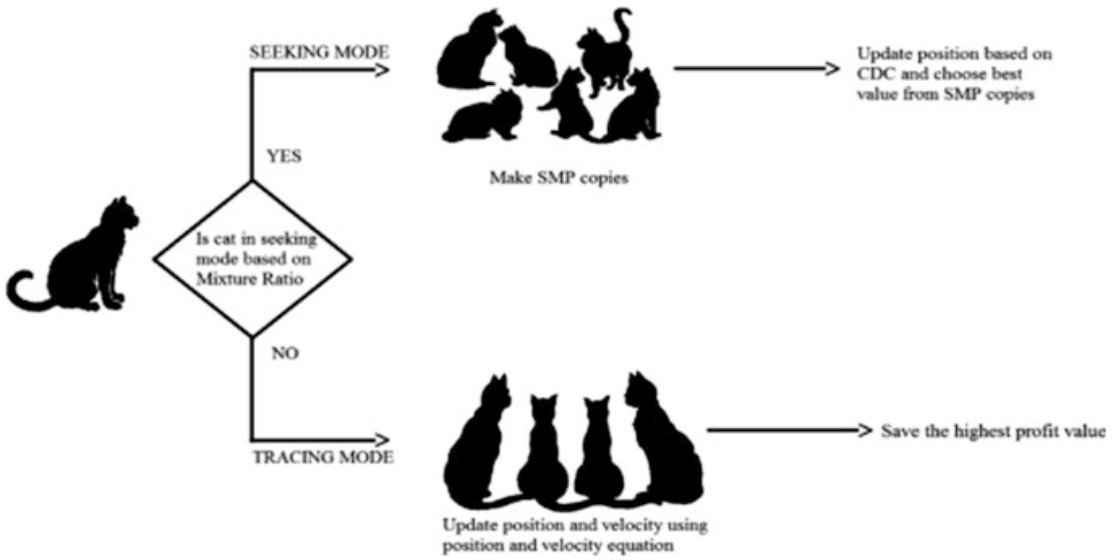

Fig. 2 Cat swarm optimization

3.2 CSO Algorithm

Algorithm for Cat swarm Optimization is given below:

Begin
Input parameters of the algorithm and the initial data
Initialize the cat population Xi (i = 1, 2. n), υ and w
While (the stop criterion is not satisfied or I < I max)
Calculate the fitness function values for all cats and sort them
Xg = cat with the best solution
For i = l: N
If w = l
Start seeking mode
Else
Start tracing mode
End if
End for i
End while
Post-processing the results and visualization
End

CSO algorithm normally uses the behavior of the cats and main focus is on two modes, i.e., "seeking mode" it is the mode when cats are having rest and "tracing mode" it is the mode when cats are seeking their prey or food.

4 Problem Formulations

Cognitive radio networks in routing in traffic engineering are one of the serious topics. The routing problem is one of those recent research topics which occur in Cognitive Radio Networks (CRNs). There is no need for preexisting infrastructure for Ad hoc networks (CRN). These are non-centralized wireless networks that can be easily formulated. An optimization algorithm is used to solve the problems in routing in traffic engineering using cognitive radio networks. Optimization algorithms are those that help in obtaining the best optimistic results. The optimization can be done using (CSO) Cat Swarm Optimization to optimize link utilization for the routing. Cat swarm is one of the effective approaches to get such optimize solutions to achieve a high rate of accuracy and fewer error rates which increase the lifespan of the network. The cat with an optimistic solution is selected and saved in the memory. The optimistic result would be the greatest and best position which is nothing but one of the cats to keep the best solution till it spreads the end of repetitions.

Objectives:

- To implement optimization algorithm called as CSO (Cat Swarm Optimization)
- To analyze the performance of the CSO for less overhead, congestion, and energy consumption to achieve a high quality of service.

The parameters are

- Energy consumption
- Congestion
- Overhead
- Variation of the routing rule.

Swarm intelligence approach has been used because it is a metaheuristic approach which is globally applied to any file to achieve high-end results according to the designed objective to achieve the best solution from the number of solutions.

5 Results and Discussions

The swarm intelligence approach is simply the combination of the decentralized characteristic to obtain the best optimistic results. The idea is utilized in an efficient method at computerized cognitive.

Swarm intelligence frameworks include regularly of a population of direct particles known as swarms interfacing with each other for the solution. The motivation frequently formulates from nature, mainly organic outlines. Cat Swarm optimization is used in this paper. The main aim of selecting this algorithm in the paper is to get optimistic solutions. In Cat Swarm Optimization, high alertness and curiosity about the environment is the nature of cats. They cannot spend most of their time resting; moving objects in their surroundings are their normal things. By this behavior, cats can cheat and seek their food. They spend very less time chasing prey to consume their energy as compared to the time dedicated to their resting. Chu and Tsai (2007) really got inspired by this behavior of cats and introduced CSO which is called as Cat Swarm Optimization. CSO has two modes: "seeking mode" it is the mode when cats are having rest and "tracing mode" it is the mode when cats are seeking their prey or food. CSO algorithm does the same thing. In CSO, a population of cats is first formulated and assigned in the M-dimensional solution space. Here each cat is representing a result. Then further two subgroups are made by the population. In the first group, the cats are rest mode and are very alert about their surroundings (i.e., seeking mode), while in the second group, the cats are trying to chase their preys (i.e., tracing mode). The hybridization of these two groups helps CSO to get the global solution in the M-dimensional solution space. The tracing subgroup should be small because the cats do not spend much time in the tracing model. The Mixture Ratio (MR) is defined for this which has a small value. New positions and fitness functions can be obtained after sorting the cats into these two modes. After this, the

cat with an optimistic solution is selected and saved in the memory. These steps have to be repeated until the stopping criteria are satisfied.

6 Result Explanation

The results are shown in the form of graphs and table.

Figure 3 shows the initialization of the network and shows that the cognitive radios are deployed and primary users are shown for the traffic communication and for the services and the common receiver is deployed to receive the packets and act as the destination.

Figure 4 shows the overhead consumption in which the overhead consumption is decreasing rapidly and is the desired output which is done using Cat swarm optimization approach and is able to achieve fewer collisions and intelligent transmissions (Fig. 5).

As we can see from the above figure that the energy consumption is decreasing in an efficient manner which is one of the main constraints in traffic engineering using the processing elements. The energy consumption is decreasing as the mobility increases which is also one of the desired outputs of the cognitive radios.

Figure 6 shows the congestion in the network which is one of the important parameters in the cognitive-based traffic engineering and shows that the congestion also increases as the mobility increases which increases the lifespan of the cognitive network (Fig. 7).

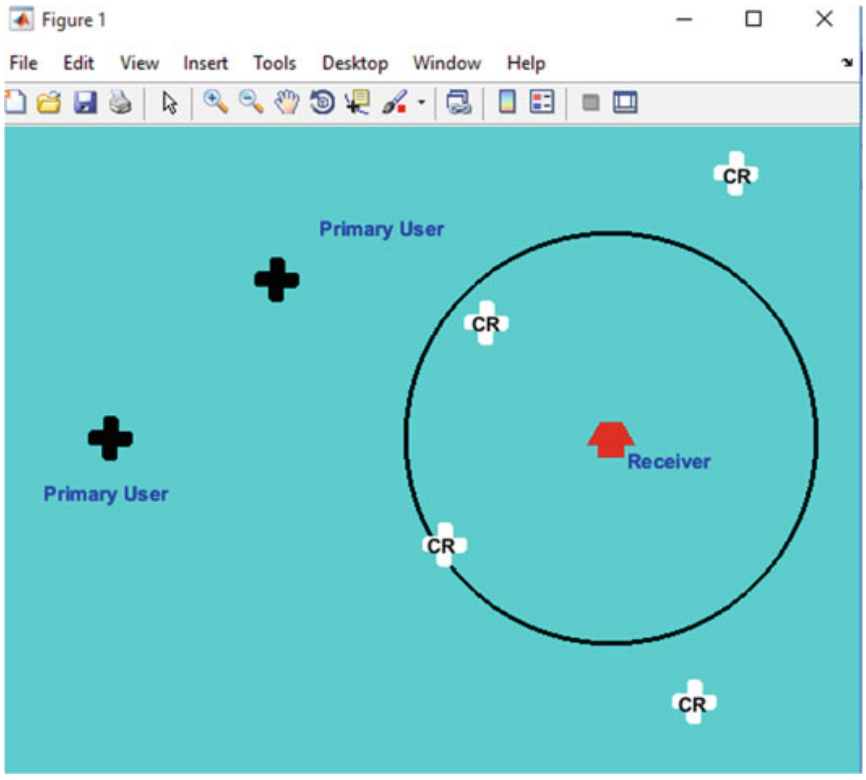

Fig. 3 Network initialization

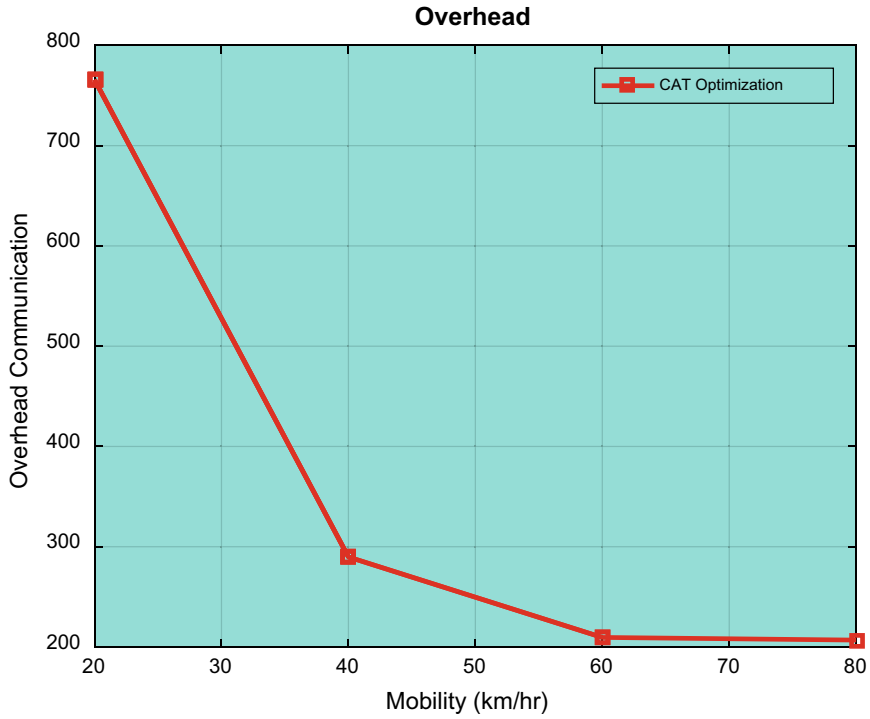

Fig. 4 Overhead consumption

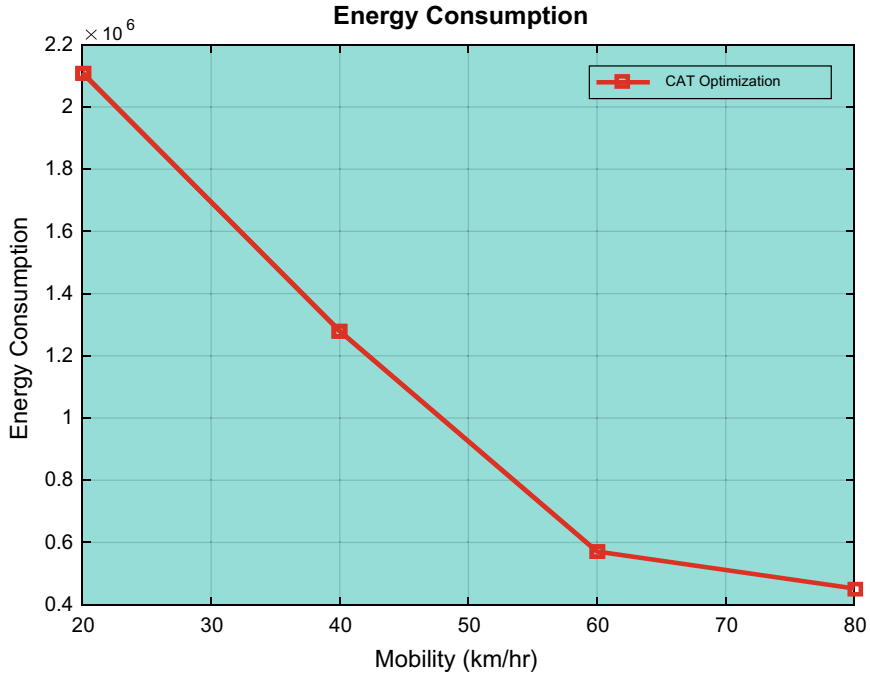

Fig. 5 Energy consumption

In the above figure, we can see the performance in terms of the routing rule which increase with an increase in the dynamic change in the topology using cognitive networks. Route rule is one of the significant parameters which divides

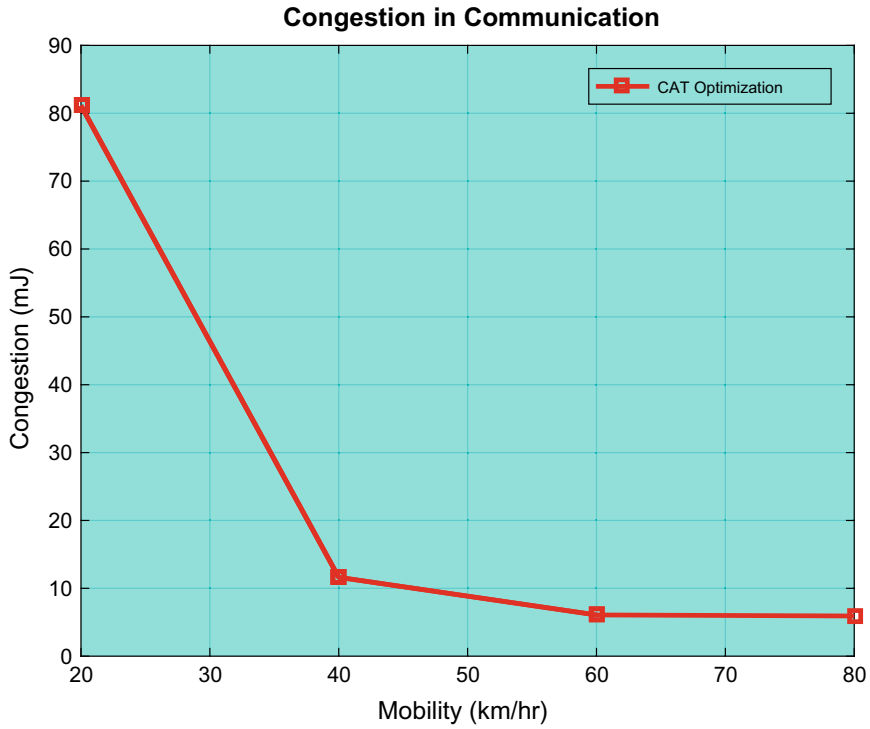

Fig. 6 Congestion

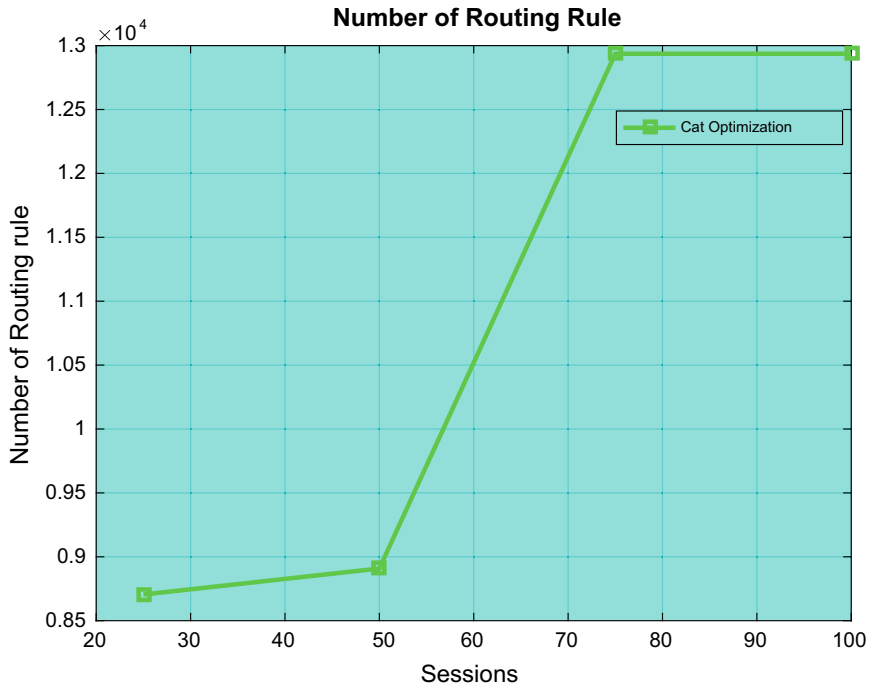

Fig. 7 Number of routing rule

the number of workflows into various threads and provides high hierarchy to the cognitive-based networks and is must be high.

Table 1 Performance analysis using CAT swarm optimization

Parameters	Proposed approach
Energy consumption	0.5×10^2 mJ
Congestion	5 mJ
Overhead consumption	200
Number of routing rules	1.3×10^4

Table 1 shows the performance analysis of CRN using Cat swarm optimization.

7 Conclusion and Future Scope

This paper explained the unique technique called Cognitive Radio Networks (CRN) that is becoming so much popular where the main aim is on active consignment of networks to wireless expedients. The routing in MANET with QoS improvement acquires an equivalent position in several analyses. Though, of these systems declared on top of depends on statically allotted channels either in authorized or unaccredited band. This static channel assignment proved spectrum congestion and thus spectrum shortage in a thickly occupied situation. Cognitive radio networks are introduced and a literature review related to CRN is discussed in the paper. An optimization algorithm to improve the performance of TE under CRN has been discussed. Swarm intelligence approach is used in the paper. Swarm approach is simply the combined part of the decentralized characteristic to obtain optimistic possible results. One of the optimistic approaches called Cat swarm has used to get a high rate of accuracy and fewer error rates which improves the lifespan of the network. The results are obtained using CSO (Cat Swarm Optimization) algorithm and parameters like energy consumption, congestion, overhead consumption, and number of routing rules are used to analyze the performance of the algorithm.

In future work, another Swarm optimization algorithm (BAT swarm) will be implemented to reduce congestion and overhead consumption. After getting results from BAT swarm hybrid model i.e. Cat Swarm +Bat Optimization will be achieved to get better results and comparison of this hybrid model will be done with the individual optimization techniques.

(T-ToCODE): A Framework for Trendy Topic Detection and Community Detection for Information Diffusion in Social Network

Reena Pagare, Akhil Khare and Shankar Chaudhary

Abstract The increased use of social network generates a huge amount of data. Extracting useful information from this huge data available is the need of today. Study and analysis of this data generated provide insight into the behavior of the customers or users and thus will be beneficial to increase the sales of products or understand customers. To achieve the same, we propose a novel framework which will extract trendy topics, identify communities related to these trendy, topics, and also identify influential or seed nodes in communities. The framework intends to find the list of topics which are popular, second, find trend-driven communities, and from these trend-driven communities find nodes which act as seed nodes and thus dominate the spread of information in the community. Analysis of real-world data is done and results are compared with baseline approaches.

Keywords Community detection · Information diffusion · Topic detection · Trend topics · Social network

1 Introduction

Over the past few decades, we can see rapid change in technology and the way technology is used by the world. Social network has become an inseparable part of every person's life today. As the number of user increases day by day there lies great potential in analyzing the social network for the kind of relationships and the actors in the network. The study of social network is not only limited to the behavior of people, but it can be a relationship between people, organization, cells, genes, etc.

Social network application expands over a vast horizon from psychology, sociology, marketing, communication, and political science.

Formally a social network can be defined as a network which is a collection of objects in which some pairs of these objects are connected by links. When the structure of the network is considered, it is more in terms of "who is connected to whom" and the other connection at the "level of behavior", one person can be friend of other, or he may be follower of the person, or he must have retweeted on a post or commented on a post, etc. This means that in addition to the language for discussing the structure of networks, there is also a need of a framework for reasoning the behavior and interaction in the network context.

Much research effort has been put into analyzing information diffusion, with most studies investigating which factors affect information diffusion, which information diffuses most quickly, and how information is disseminated. These questions are answered using information diffusion models and other methods, which play an important role in understanding the diffusion phenomenon. Information diffusion is about understanding who the important users are and which factors are influencing the information diffusion process. A good performance model is very important for understanding how to predict and influence information diffusion and has significant reference value to various applications, e.g., rumor controlling, behavior analysis, gaging public opinion, the study of psychological phenomena, and for resource allocation in public health care systems.

The social influence in a network can be identified through tracking communities and studying the behavior in the community. Social influence was studied in the context of influence maximization where the method was proposed to find the nodes in the network which will increase the spread of information in the community and hence in the network [1, 2]. Their work highlights the social diffusion model and marketing strategies for various applications [3, 4]. The work of [5] relates to the study of how one person influences the other person for buying of products. The author suggests a method to increase this influence to increase the spread of information in the network. Social influence is defined as the force exerted on a person due to her influencer and homophily is considered as the tendency that the other inactive node or person will follow the active node or influencer [6, 7, 8].

The work done in the above methods only exploit the topology of the network, and ignore other important properties, such as nodes' features and the way they process information. Most of the users in social network are in passive mode, based on this observation, researchers [9] suggested an approach similar to HITS algorithm which is a graph-based approach. The method assigns to every node in the network a value based on the influence and the rate at which the information is forwarded in the network. The users who work as a catalyst in spreading of information are called the seed nodes. These seed nodes are specific to a community. Therefore, Pal and Counts [10] develop a non-graph-based, topic sensitive method. The method uses structural as well as social attributes of the network to identify the most influential nodes. The set of identified users are clustered by using probabilistic technique and

therefore could find a list of nodes which are more in the network related to the topic. In paper [1], the author uses independent cascade and linear threshold model for influence maximization. The influence maximization problem asks for a parameter "k", to find a k-node set of maximum influence in the network. Depending on the basis of number of nodes activated at the end of information cascade, the influence of a given set of nodes is identified. The author uses a greedy hill-climbing strategy for the optimization problem and provides appropriate solutions.

A **Social network** can be defined as a graph in which vertices represent people or groups of people and edges represent some kind of social relationship or social interaction between vertices. These social graphs can further be defined as the ones in which direction to the links or edges may or may not be known as directed or undirected graphs like Twitter and Facebook, respectively [11].

A **community** in the social network is a set of nodes or users which can be potentially grouped and examined together such that the interactions or the ties between the communities are quite dense [1]. In terms of the graph, we can say it is a giant connected component that is very dense. The users in social network exhibit a behavior where users ignore the information available with themselves and are influenced by the behavior of the neighbor's. This decision taken is transferred in the form of information to all the connected users in the networks. This phenomenon is known as **information diffusion** in social networks.

Information diffusion is a process in the social networks in which the information is transferred from one user to the other, who are connected with each other via social network relationship. Information diffusion includes (a) Detection of popular topics (2) Community Detection (b) Identification of Influential spreaders (Fig. 1).

Even though the framework associated with social networks can change with time, communities stay fairly steady. The primary problem is how one can identify individual's communities which have higher influence inside a social network, and several techniques are suggested for this; some techniques use links between users and some use network attributes. Information diffusion is a hot topic within social networks investigation recently. Even though there has been numerous revolutionary research in this area, there are still some less explored areas.

The remaining paper is arranged as follows: second part is related to state of art; third part describes our framework; fourth section presents result and experimentation; last section presents conclusion and future work.

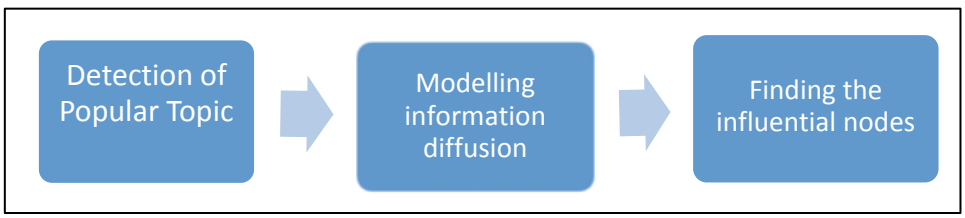

Fig. 1 Processes involved in information diffusion

2 Related Work

2.1 Information Diffusion

In paper [12], theauthor explores connections as well as designs developed by the aggregated interactions within Facebook webpages throughout catastrophe reactions. Evaluates social roles as well as crucial gamers utilizing social network evaluation. Research suggests measures to enhance information diffusion by considering social as well as network attributes. In Paper [13], theauthor suggests a differential equation model associated with information within thenetwork. The model is associated with temporal–spatial information diffusion. This model is set up prior to the topological framework associated with the network, semantic content material as well as interactive actions associated with users within thenetwork. Experimental calculations display the feasibility from the suggested model, conformity along with network topology with potential users associated with scalability with regard to big networks. The authors in paper [14] suggest parameters which evaluate topical importance as well as social. The work suggests that to study the information diffusion, it is important to study the behavior of user by taking into account different parameters like retweet count, followers information. In [15], through mixing users social as well as picture information, the model forecasts the actual diffusion route of the image much more precisely when compared with alternative baselines, which possibly encode just picture or even social functions, or even absence storage. Through mapping person users to person prototypes, the model generalizes for new users. The models are able to produce diffusion trees and shrubs, as well as display how the produced trees and shrubs carefully look like ground-truth trees and shrubs. Paper [16] detects communities based on not only structure properties of the network but also used ground-truth information. The author studied a collection of 180 real-world social, effort, and data networks exactly where nodes clearly condition their own community subscriptions. The suggested technique accomplishes 30% relative enhancement more than present nearby clustering techniques. In [17], the author proposes a CID model with regard to damaging information diffusion within competitors towards an optimistic information circulation. The model is an aggressive information diffusion model or even CID with regard to brief. This is the first model which talks about negative as well as positive information flow in the network and propagation of the same. The authors [18] proposes a grading opinion diffusion model. The opinion leaders play an important role in information diffusion in microblogs. The model is combined with communication power. The opinion leaders influence people who are unsteady concerning specific event. The work demonstrates how the brand new suggested models tend to be sensible as well as efficient for information spread within microblog information diffusion. The actual Information Systems (IS) community is constantly on the help to make inroads to improve using systems to aid catastrophe administration [19]. The actual community is constantly on the determine as well as lengthen the actual appropriate hypotheses, and also to create brand new paradigms

that may be delivered to keep about the ownership as well as diffusion associated with information techniques with regard to catastrophe administration. Research by authors in [20] handles the problem of advertising data diffusion, the degree to that data spreads, upon social media systems. This specific A–B–C framework (1) examines the textual options that come with Internet record articles making use of linguistic issue as well as phrase rely, (2) does apply the prior results in creating information suggestions, as well as (3) suppliers verified training supplies based on information tips to promote information diffusion among Internet record site visitors. The author suggests an evolutionary game theoretic framework [21] to model diffusion procedure within social networks. The framework is analyzed for degree and nonuniform degree network. Present social networks tend to be of very large scale producing huge data moves for each and every second. Exactly how data diffuses more than social networks offers has attracted a lot of interest. Author obtains diffusion characteristics within just complete networks, typical degree, without homogeneous degree networks, with identify connected with two distinctive networks. The authors in their work [22] depicted a person's behavior of online social networks opens new alternatives to systematically realize the data diffusion process after social networks. Random Recursive Tree (RRT) is used to help model with this advancement associated with Cascade trees. The use of stochastic sensitive look at forwards eliminated model to help demonstrate the particular potent individual behavior including producing, seeing, forwarding, and overlooking the information for the furnished social network.

The authors argued Twitter data is very loud [23] every twitter is brief, unstructured and along with casual vocabulary, challenging with regard to present subject modeling. About the additional hand, Twitter posts tend to be associated with additional data, for example, authorship, hashtags and the user-follower network. Taking advantage of this information, the author suggests the Twitter-Network (TN) subject model collectively model the written text and the social network inside a complete Bayesian nonparametric method. The TN subject model utilizes the hierarchical Poisson–Dirichlet Procedures (PDP) with regard to textual content modeling and the Gaussian procedure Random function model with regard to social network modeling. The author implies that the TN subject model considerably outperforms a number of current nonparametric models because of its versatility. Furthermore, the TN subject model allows extra educational inference, for example, authors' interests, hashtag evaluation, in addition to resulting in additional programs, for example, author suggestion, automated subject marking, and hashtag recommendation. Be aware the common inference framework may easily be reproduced to additional subject models along with inlaid PDP nodes. Another work [24] uses Louvain community detection algorithm and Girvan algorithm to find communities and centrality measure to find the nodes in the communities which help in the diffusion process. The author also uses the shortest path algorithm to find the communities formed using the seed nodes. The work considers the network attributes for community detection. The communities formed are not dense and are formed on the basis of only structure of the network. Does not consider the content in the network. As per study, in [25], twitter comprises a good obtainable system with

regard to learning and tinkering with the character of data dissemination. The author uses hashtag to find topics which disseminate most in the network. As per [26], it is vital to find out, monitor, review, as well as forecast well-liked subjects and occasions happening within the social networking within the space–time framework. Simultaneously, it's very helpful which a number of "what if" situations could be created to estimation the meme diffusion. The author has made use of location and time attribute to study the diffusion. The work [27] represents impact maximization issue in attempting to recognize some ``K'' nodes through that distribute associated with impact, illnesses, or even data is maximized. The author suggests a ``Greedy ad Community-Based'' formula.

2.2 Topic Detection

The paper [28] proposed LDA model which is the most popular and efficient model for topic modeling. But it does not consider the correlation among topics. It works only on content and is a probabilistic model that considers the distribution of words for identifying popular topics. An online LDA model is proposed [29], it considers the document in batches. Thus the memory requirement is reduced. It does not consider the social attributes of the network. Considers the distribution of word for topic definition. Takes only content into consideration while modeling. The authors [30] propose a model using wavelet analysis, detects event inferred using LDA gives a better description of the event and uses hashtag for topic inference. Topic popularity is found by using only content, the network attributes too can be considered to improve the accuracy of the model. In his work [8], the author proposes a model for unbounded topics. The hierarchical structure can help to identify popular topics. The model does not work for definite and bounded topics. A topic model based on time [31] is implemented, the model accuracy can be improved by consideration of other attributes of the network like retweet count and followers count. A parallel algorithm for topic modeling [32] gives a good speed up as compared to the sequential approach, but the resource requirement is huge. The model can be implemented on a small scale for less number of processor and it is important to study the behavior of the algorithm.

Most of the work done, find trendy topics irrespective of the social attributes and take content only into consideration, some works find communities and then find topics which are discussed mostly in these communities. In our proposed work, we make an attempt to identify trendy topics based communities that have played an important role in making the topic trendy. Given this real-time scenario, our objective is to (1) extract trendy topics (2) find communities related to these trending topics (3) identify the influential node in this topic-driven community.

To the best of our knowledge, our work is the first attempt toward presenting a framework which will identify trendy topics, find trend-driven communities, and then find the most influential nodes in the community. The topic-driven communities identified can be used to spread message or information related to the event or these set of users can be used for the marketing of products or to increase sales of

products. The work finds application in many areas related to identifying users for marketing, identifying users who spread wrong information in a closed network, or terrorist network. In order to detect communities related to trending topics, we focus on twitter, the widely used micro-blogging platform. The activity of twitter is depicted by tweets, retweets, comment, likes, and its structure of follower and followed unidirectional relationships.

To spread information in the network, it is needed that the users have information related to the topic. This information can be received by connecting with users having similar topic information. Thus forming of groups or communities of similar interest, users will be effective for spreading of information in the network. Accordingly, we present a method to identify these communities of topic-dependent users who created the post related to the topic Uc. Another important parameter of our work is followers users U_f information of these users Uc. These U_f users will be responsible for the spread of information in the network.

To summarize, given a trending topic, the objective is to detect community of users who (1) are related to the trending topic (2) are related to the same topic (3) are connected to each other (follow) (4) can be identified as U_c or U_f.

3 Proposed Work

3.1 Problem Formulation

Definition 1

Let $T = \{t_1, t_2, \ldots t_m.\}$ *be the set of tweets collected during a particular period.*

Each tweet $t_i = \{w_1, w_2, w_3, \ldots w_i \ldots w_n\}$ *where* w_i *represents the sets of word in the tweet* t_i.

Analyzing these tweets T for the word occurrences in each tweet and document as whole and finding which words w_j *are maximum talked about is topic detection.*

Where w_j *is subset of* w_i, $w_j \in w_i$
These w_j *words are the set of Trendy topics,* Tr.

The first goal is to identify this Tr set

Definition 2

Let $\mathrm{Tr} = \{\mathrm{Tr}_0, \mathrm{Tr}_1, \mathrm{Tr}_2 \ldots \mathrm{Tr}_9\}$ *be the set of trendy topics. Here we assume that we identify top 10 topics only. For each topic* Tr_i *belonging to* Tr *(a) find set of users U who have tweeted, retweeted about the topic* Tr_i *(b) Generate a graph G, of these users* u_i *from U where* u_i *belongs to U. The graph G formed represents a community* Ctr_i *which is related to topic* Tr_i. *Each vertex in community* Ctr_i *is related to user* u_i *who in turn is related to topic* Tr_i. *There exists an edge between* u_i *and* u_j, *where* $(u_i, u_j) \in U$ *iff* u_j *is in followers list of* u_i *or vice versa or* u_i *retweeted on* u_j *The users* $u_{z \in U,}$ *who are not a part of the connected graph are discarded.*

The second goal is to generate graph G (V, E) of users related to topics. This graph represents a set of users who will play an important role in identification of communities in next phase.

Definition 3
For the graph G generated for topic Tr_i *we run community detection algorithm to identify community. The community detection algorithm will identify communities associated with topic* tr_i*, which will be used to identify node with highest degree,* $u_{i \in U}$

A degree here means the node which will have the highest number of connections. The node having the highest connection is the one who will spread maximum information in the community.

To summarize, our contributions

(a) A model to find trend-driven communities and influential nodes.
(b) A unique framework which combines topic detection and topic-driven community detection.

3.2 Overview

We propose a novel framework where both topic modeling and community detection are collaborated to study the information diffusion in the network. The topic modeling module is the first module which takes as input tweets dataset and identifies topics which are trendy. This module can also be called as trendy topic detection. The second submodule is related to forming communities which are related to a particular topic. The communities formed are called as topic-driven communities. We name them so because the communities identified are related to the topic. After identification of communities, the nodes with highest degree centrality are identified since these are the nodes which influence the propagation of information in the network. Thus the framework will not only detect trendy topics but will also help to identify users and communities which play a substantial role in spreading of information (Fig. 2).

3.2.1 Data Collection

The Twitter dataset is used as input to the system. The twitter data is extracted using twitter API and stored in CSV form. The tweets collected have fields like retweet count, comment count, user who tweeted or retweeted about post, followers. We also store separate information about the users or owner (the user who first posted the tweet) of the tweet. We maintain separate information about the user—follower relationship.

The twitter data was collected from March 2018 to August 2018. Due to restriction by twitter, only 15 lacs of tweets were collected. The data collected included fields like user id, username, tweet, retweet count, mention count, followers of users, and followers count. Figure 3 shows the distribution of messages over different domains. The diagram below shows that floods, health, and politics topics were mostly covered in the tweets captured.

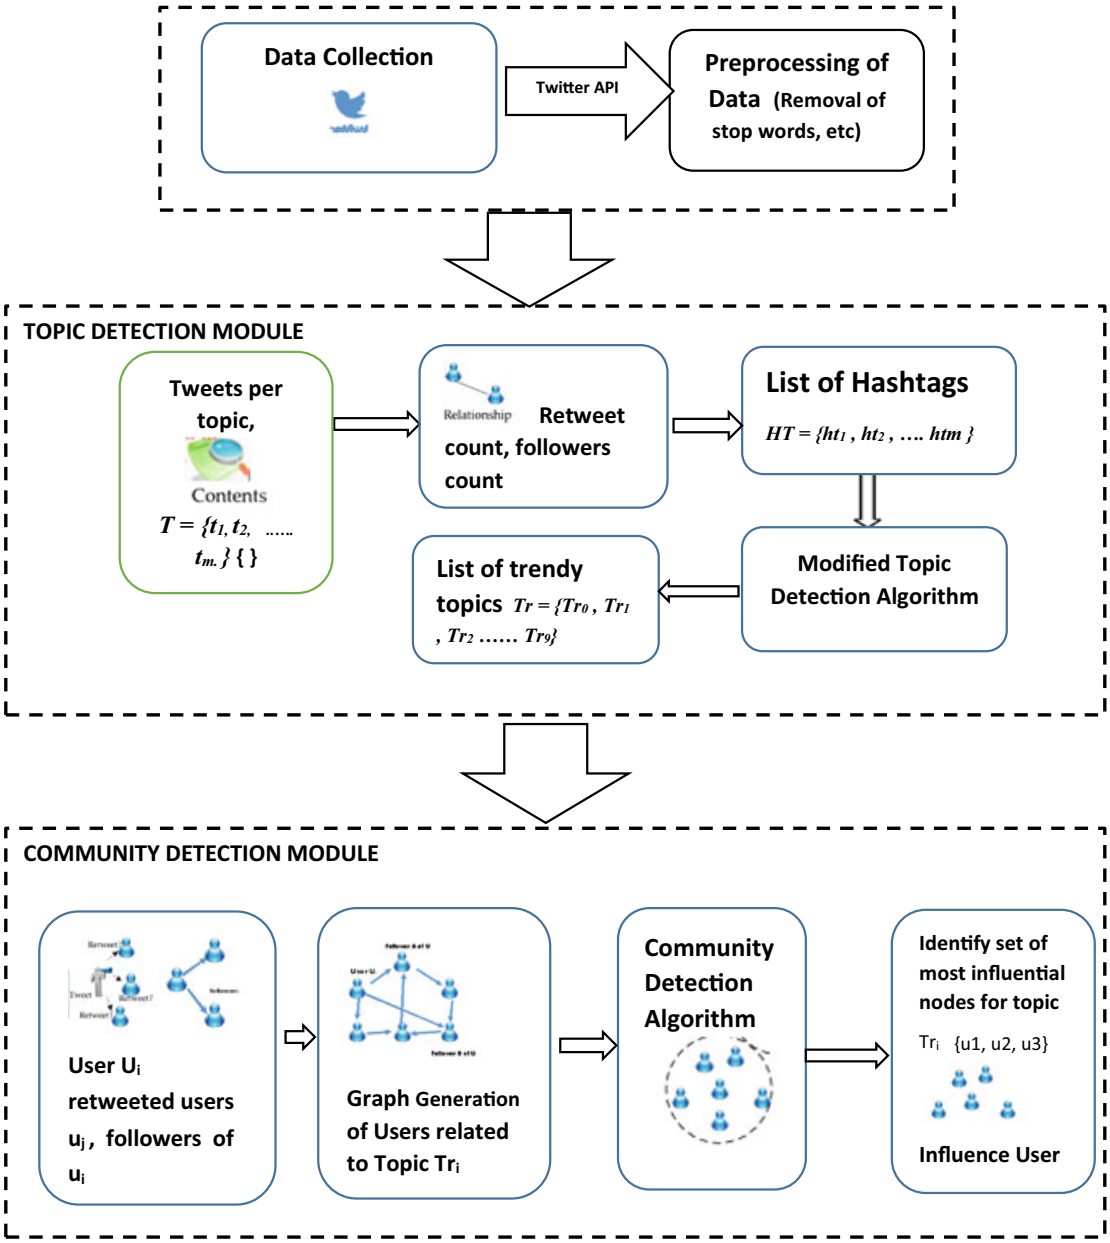

Fig. 2 Collaborative framework design

3.2.2 Data Preprocessing

In this step, the noise in the data is removed. The preprocessing deals with stop word removal, repeated data removal, filling of missing data by taking a mean of the values.

The next section provides details of our approach named T-ToCODE (**T**rendy **T**opic detection and trendy **CO**mmunity **DE**etection) which is able to detect hot topics and second the communities associated with every popular topic.

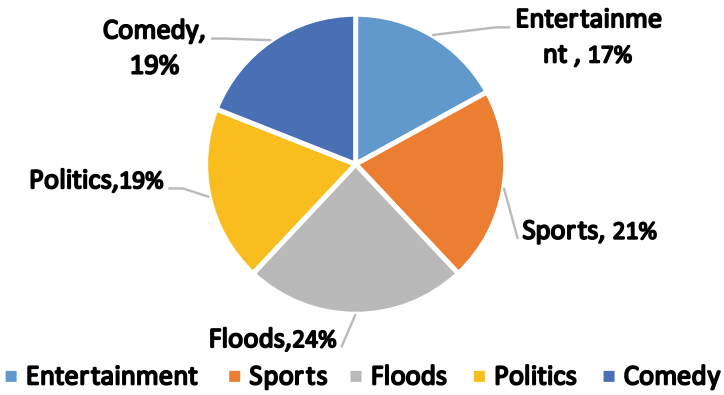

Fig. 3 Distribution of messages in the dataset over different domain

3.2.3 Trendy Topic Detection

Latent Dirichlet Allocation (LDA) is a classic model for topic modeling of documents. LDA detect underlying topics in text documents. LDA is based on the assumption that documents with similar topics will use similar groups of words. Documents are probability distributions over latent topics. Topics are probability distribution over words. Thus LDA is an unsupervised, probabilistic model. We propose a novel approach for finding trendy topics, where we consider the hashtag, comment count, retweet count, and likes for a particular post to identify if the topic is trendy or not. We compare our modified Multiparameter LDA (MP-LDA) with Twitter LDA and baseline LDA.

The proposed algorithm is mentioned below.

Generative Process for MP-LDA:

1. Initialize: Time distribution value of L_w, vector δM , δV.
   // word distribution for topic t
2. For each topic t = 1,2, …… T
   a. Draw $\emptyset\, t \sim dir(\beta)$
   End for
3. For each user u = 1,2, ….. U
   a. Draw $\theta u \sim \text{dir}(\alpha)$ *// topic distribution of user u*
   b. For each document/tweet s = 1,2,…….N_u
      i. Draw $Z_{u,s} \sim \text{Multi}(\theta u)$ *// Topic selection based on users topic distribution*
      ii. Draw $V_{n,s} \sim \text{dir}(\alpha)$
      End for
   c. For each word n = 1, 2,….. $N_{u,s}$ *// words are selected one by one based on value of P*
      i. compute P = Pw || Pd according to Lw
         if P = 0 then
            draw $Y_{u,s,n} \sim \text{Multi}(\vartheta g, u)$
         draw $W_{u,s,n} \sim \text{Multi}(\Phi z, Y_{u,s,n})$
      if P = 1 then
         draw $Y_{u,s,n} \sim \text{Multi}(\vartheta h, m)$
         draw $W_{u,s,n} \sim \text{Multi}(\Phi_{y,u,s}, \delta m, nu)$
      end if
   end for
end for

Let $\emptyset t$ be word distribution for topic t. P parameter is used to decide word belongs to a general topic or hot topic. The hashtag in the model is associated with a topic and word. δM is the hashtag associated with documents and δV is hashtag associated with word. The values that vectors can take is either 0 or occurrence count over the entire dataset. Latent variable learning is done by using Gibbs sampling. The MP-LDA is applied after preprocessing step to only those tweets which are above the threshold value of popularity count, comment count, and retweet count. All the tweets with parameter values below the threshold are not considered. Tweets with lesser retweet count or likes will not be popular and thus processing of these tweets for identifying popular topics is not required. The selection of threshold for retweet count, comment count and likes is based on the empirical analysis. It is seen from the statistics that most of the messages have less than 50 retweet and comment count. As the count reaches 1000 the distribution in number of messages is almost constant. Therefore we choose the threshold as 1000. After the application of MP-LDA to the dataset, we were able to find the topics which were most popular in the dataset. The topics like yoga for health, women's health, Asian games, US open championship and Kerala floods, Japan floods were found to be the trendiest topics.

3.2.4 Topic-Driven Community Detection

The steps involved in this submodule are given below.

Input: Topic Tr_i
STEP A: Identification of posts $P_t = \{P_1, P_2, P_3 \ldots P_l\}$ which are related to topic Tr_i
STEP B: Identification of user sets U_o who created the post, related to popular topic Tr_i
STEP C: Identification of user sets U_r who retweeted. The set identified in STEP B and STEP A together will be merged to form a set U_{rcl} where $U_{rcl} = U_r + U_o$
STEP D: Identification of followers of users U_f who created the post P_l. The followers play a crucial role in the propagation of information and thus follower's information will be useful.
STEP E: Graph creation based on user- follower data, user—U_{rcl} data
STEP F: Detection of communities related to a topic
Output: Community Ctr_i

STEP A:

Given a set of tweets $t = \{t_1, t_2, t_3, \ldots, t_m\}$ related to a topic. Identify tweets ti which are related to popular topic Tr_i. The data set of tweets will be searched and it will retry tweets related to these popular terms.

The output of this step will be a set of tweets $T_{Tr} = \{t_1, t_2, t_3, \ldots . t_j\}$ where $j < m$ and $t_j \in t$

STEP B:

From stepA all the tweets from set TTr are parsed to identify the tweets or post which are source post. The tweets are parsed to get the user id of the users who have

tweeted about a topic and is the origin of the post. This step will give output a set of users.

$U_o = \{U_{o1}, U_{o2}, ..U_k\}$ such that $U_{oi} \in U$ and U_{oi} is the owner of the post and $r < m$

STEP C:

Given a set of tweets T_{Tr}. Identify users who retweeted Ur on post in T_{Tr}, This third step gives a set of users who have retweeted a post.

At the end of step C, we get a set of users $U_{rcl} = \{U_o, U_r\}$ who may play an important role in the formation of communities

STEP D:

The belief that followers will play a substantial role in spreading message, the followers list is identified. Given a set of users Uo, find the follower of Uo and store it in the form (user id, user id follower[]). The set is identified as U_f

Also, a separate data related to User—U_{rcl} user data is stored. It contains those users who commented, retweeted a post by user.

STEP E:

Graph Generation:

Step D gives the vertices of the graph G. The set U_f (User - Follower) and the set U_m (user—U_{rcl}) will form the vertices of the graph.

Vertex set $\mathbf{V} = \mathbf{U_f} \cup \mathbf{U_m}$; union of set U_f and set U_m

The edge between a set of vertices can be of two types. The edge set is represented by E. User u1 and user u2 there exists link between u1, u2 if and only if

Type 1: User u2 retweet on user u1 post

$$R = \{\text{retweet}(u1, u2) = \text{TRUE}; u1, u2 \in U_m\}$$

Type 2: User u2 is follower of user u1

$$F = \{\text{follow}(u1, u2) = \text{TRUE}; u1, u2 \in U_f\}$$

The set of edges $\mathbf{E} = \mathbf{R} \cup \mathbf{F}$

On the basis of links and vertices a graph is formed. The belief that users who retweet or are followers of a particular user say u1 has more probability of spreading message which is posted by user u1 is used while formation of the graph G(V,E).

STEP F:

On the graph generated in step E, we apply Louvain community detection algorithm [33].

The decision of applying community detection algorithm was done because it can handle in a very short time a huge network. Also, the algorithm reveals hierarchical structure which can be useful in understanding the overall functioning of the network.

The Algorithms working is explained below

1. A greedy assignment of nodes to communities, favoring local optimizations of modularity.
2. New—coarse-grained network in terms of communities found in the first step.

The above two steps are repeated until no further modularity increasing reassignments of communities are possible.

3.2.5 Identification of Influential Nodes

Once the communities are identified finding nodes which are having a higher degree in the community is obviously the node which is going to be more responsible for spreading of information in the network. Average degree is used to find nodes which are most influential in the network.

The list of influential users is given by $U_{\text{In}} = \{U_1, U_2, \ldots U_x\}$ where $U_i \in$ to U

4 Experimentation

4.1 Topic Detection

4.1.1 Dataset

We use twitter dataset for experimentation. It consists of 132,009 posts/re-posts as well as 73,257 person nodes. Table 1 gives statistics of dataset. The data collection is as mentioned in Sect. 3.2.1

4.2 Analysis

Table 2 gives the list of hot topics and top words in each topic. When the result was compared to LDA and T-LDA it was observed that the top words in MP-LDA were more accurate as compared to T-LDA and LDA. For example, the first topic has words like Japan under topic FLOOD, but LDA and T-LDA did not return this word as a top word in the list. If we consider the result and compare with trending topic during the period, there are tweets related to floods in Japan during the same time as in India in Kerala.

Table 1 Statistics of dataset

Total tweet	Original tweets	Retweet	Users
1,32,009	9600	1,22,409	73,257

Table 2 Top topics with top words

Topic id	Top words
0	Flood rescue stressed relief Kerala donation Japan Gordon
1	Sports Asian Games, Indians US open, football Cleveland baseman, Serena
2	Health, women's health, Rohingya, yoga, mental health, medicine, organic, weight loss

Table 3 Coverage rate

	Top 10	Top 20	Top 30
MP-LDA	0.66	0.75	0.78
T-LDA	0.45	0.50	0.53
LDA	0.23	0.35	0.40

We also compared the coverage rate of T-ToCoDE with the baseline LDA method and Twitter LDA. It was observed that the result obtained by our method which considered social attributes gave better accuracy as compared to traditional methods.

$$\textbf{Coverage rate} = (\textbf{Extracted Hot Topics}/\textbf{Actual Hot Topics}) * \textbf{100}$$

The comparison was done for the top 10 topics, consecutively for 20, and then 30 topics. The proposed method showed consistent improvement in accuracy (Table 3; Fig. 4).

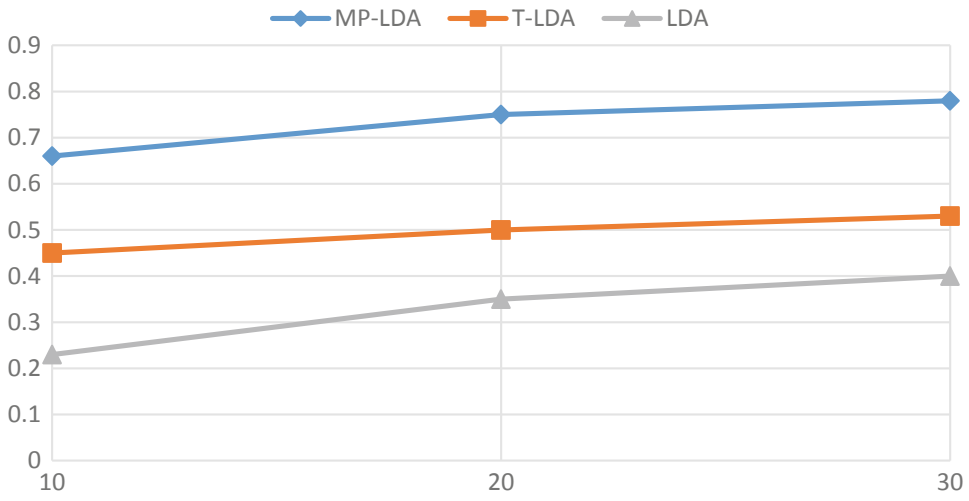

Fig. 4 Coverage rate versus no of topics for twitter data

4.3 Community Detection

4.3.1 Dataset

The trendy topic is given as input to the community detection module. The first topic which was trendy as per the topic detection was related to hashtag flood. First, we collected all tweets which were related to hashtag flood. This gave a list of 30,000 tweets related to floods. The captured tweets were then separated for the original tweet and retweet. It was found there were 2930 original tweets and remaining were retweets for flood dataset. From this set of original tweets identified, we considered only those users original tweets which had retweet count more than the threshold. After applying the threshold, we were left with 670 users who were original tweet users for flood dataset. We extracted the followers of these original tweet users. To this collected data then was Louvain Community detection method applied to find the communities related to Topic FLOOD.

The communities formed are evaluated on the basis of disconnected users, cohesiveness among users, and clustering coefficient. We compared our work in three different scenarios.

Scenario 1 (M1): The entire network is considered irrespective of tweet and retweet and an attempt was made to identify the communities. No threshold was applied for the selection of users. The graph was constructed on the basis of the followers and the followee network. Dataset considered for this method had all the 23,257 users included.

Scenario 2 (M2): The graph was constructed on the basis of retweet count and the retweet relationship and threshold considered was 1000. For the tweets collected for hashtag flood, out of 30,000 tweets, there were 2930 original tweet users, 7640 retweet users, and the remaining were duplicate users. There were a total of 10,570 users. When the threshold was applied to the original set of users, only 670 original users were considered for graph construction. The edge was considered between two users if user u1 retweets about the post by user u2 and vice versa.

Scenario 3 (T-ToCODE): The graph was constructed as per the proposed method in the framework. After the threshold applied, there were 670 users. For these 670 users, the followers list was considered and the graph was constructed on the basis of retweet as well as followers information. Due to the restriction by twitter, we could retrieve followers list for only 200 users and the total user were 41,235.

4.3.2 Metrics

Disconnected Users: This metrics will help to find users who are not part of the community

$$\text{ratio of disconnected users} = \frac{\text{users who are not connected to any other user}}{\text{total no of users}}$$

Cohesiveness among users: The second metric used is cohesion among users, this metrics allows to evaluate the quality of connection among users by using standard metrics such as modularity, the ratio between no. of communities and number of users, and density.

The ratio between the no. of community and no. of users allows to evaluate the ability of the approach to group the individual users into communities.

Lower the value, the better communities are formed, it signifies that communities are less in number with more number of users in each community.

The density is the ratio between the numbers of edges per node to the number of possible edges.

Clustering Coefficient: Clustering Coefficient quantifies the extent to which nodes in the graph tend to cluster together.

4.3.3 Analysis

Analysis of Disconnected Users

The result showed that 80% of users took part in the topic with our approach as compared to 76% with scenario 2 as compared to 72% of scenario 1. These results demonstrate that our graph construction approach includes more no of users.

Our approach considers the followers also thus increasing the number of users who can contribute toward spreading of information. In scenario 2, the graph is constructed using only retweet users thus leaving out a good percentage of users who may contribute toward information spread. Though in scenerio1 there are more numbers of users, due to consideration of the entire network a large number of users are disconnected users.

Analysis of Cohesiveness Among Users

Density is influenced by the fact that T-ToCODE framework share retweet, followers link and therefore has higher density compared to approach in scenario 2. The average number of communities found in Scenario 2 is 0.28 per user that exceeds the amount of community in T-ToCODE (Table 4).

Table 4 Cohesiveness among the users

Method	Modularity	Ratio of communities per node	Density
Scenario 1	0.420	0.321	0.010
Scenario 2	0.530	0.278	0.020
T-ToCODE	0.780	0.173	0.029

Table 5 Analysis of the structure of community (average)

Method	% of Post creators	% of followers	Clustering coefficient
Scenario 2	4.14	6.87	0.088
T-ToCODE	5.20	8.23	0.078

Analysis of Community Structure

The percentage of users who are the owners of post is more in scenario 3 (Proposed method) as compared to scenario 2 where only retweet relationship is considered. The increase in scenario 3 is obvious since we consider the retweet relationship along with follower's relationship. T-ToCODE creates communities on the basis of retweet relationship and followers relationship; therefore, the followers percentage is observed more as compared to scenario 2. Since the communities formed are related to a topic and the communities are dense thus the clustering coefficient is also improved in T-ToCODE method (Table 5).

After identification of communities, the nodes with the highest degree were found in the network. For finding these nodes, we used GEPHI visualization tool. It was observed that the nodes which had the highest degree on an average were the nodes which were the most influential nodes in the network. The entire community could be reached through the users who were having a higher degree.

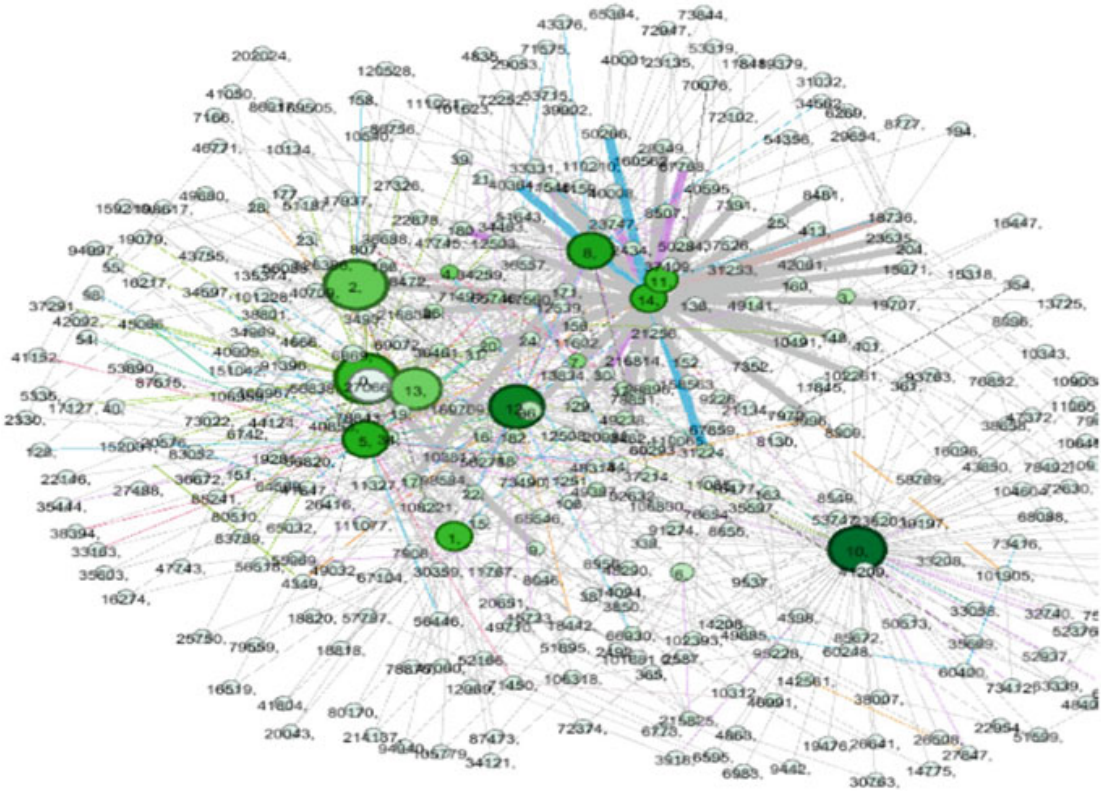

Fig. 5 Influential nodes for topic FLOOD: Scenario 3

The fig. 5 shows the influential nodes in the network ;nodes 8 , 11 and 13 are more dominant in the network. The edge thickness represents the ties among the nodes. From the graph, it can be observed that the nodes 8, 11, and 13 are the influential nodes in the community, along with a few other nodes in the network. There are communities identified for topic FLOOD, and there are nine influential nodes identified, the nodes which have the highest degree. The nodes at the center of each community are the node with the highest degree and thus they are the influential nodes in the network.

5 Conclusion

The novel framework proposed allows to identify hot topics and the communities which are influential in making those topics trendy. The analysis did prove that communities formed with relation to topics have more strength and lesser communities with more no of nodes are formed. The communities formed are denser and less overlapping. The topic detection model performs better as compared to the traditional model. The accuracy of topics identified is increased due to the inclusion of social attributes like retweet count, comment count and hashtag. Consideration of behavior of users in the network gives better results is proved.

5.1 Future Scope

The framework can be extended by considering the spatial and temporal attributes of the data. Thus adding these attributes can give a more personalized analysis, which can be used by an individual as well as businesses to target the customers.

ns-3 Implementation of Network Mobility Basic Support (NEMO-BS) Protocol for Intelligent Transportation Systems

Prasanta Mandal, Manoj Kumar Rana, Punyasha Chatterjee and Arpita Debnath

Abstract In an Intelligent Transportation System for a Smart City, seamless connectivity is essential for each user during mobility for efficient data communication. For a group of mobile users in a vehicle (bus/train/flight), due to high mobility, implementing a protocol in order to manage handoffs smoothly is a challenging task. Network Mobility Basic Support (NEMO-BS) protocol was proposed to comply with this requirement. It is an extended version of Mobile IPv6 (MIPv6). But, the MIPv6 implementation in ns-3, which is the most widely used open-source simulator, is still not extended so far, to support network mobility. In this work, we have implemented the functionality of the NEMO-BS protocol in ns-3.25 by modifying the existing MIPv6 module to enrich the ns-3 library.

Keywords Intelligent Transportation Systems · Mobile IPv6 · Network · Mobility · Smart City

1 Introduction

In the era of Smart City and Internet of Things (IoT), each and every user needs to be connected to the Internet seamlessly. Intelligent Transportation Systems is one of the main aspects of the Smart City. In case of group mobility, i.e., when a group of

users is moving in a vehicle (bus/train/flight), due to the mobility of the vehicle [1], the wireless interface of it sometimes switches the on-road access points. This event is called the IP handoff. This results in severe service degradation of the vehicular users. To handle it, the Internet Engineering Task Force (IETF) standardizes the Network Mobility Basic Support (NEMO-BS) protocol by extending the base Mobile IPv6 (MIPv6) scheme [2]. The objective of this is to provide uninterrupted Internet connectivity to the vehicular mobile users by maintaining ongoing sessions during handoff. UMIP (Usagi Patched MIPv6 stack) is an open-source implementation of MIPv6 and NEMO-BS protocols for Linux and can be used for network simulator ns-3. But it is only executed on ns-3 Direct Code Execution with the Linux native stack and that is why if any changes may be proposed in NEMO, then the users must have to trace the Linux stack. But, it is quite complicated to the naïve users to do any changes in Linux stack.

To fix the above issue, we have implemented the NEMO-BS protocol [3–6], using the ns-3 stack, by modifying the existing MIPv6 module [7, 8] in ns-3, that may be added to the ns-3 library which may help the ns-3 users a lot.

The paper is arranged as: Sect. 2 describes the Literature Survey, Sect. 3 describes the working principle of the protocol, Sect. 4 gives the description of the Class Diagram Implementation, Simulation and Results are given in Sect. 5 and finally, Concluding remarks emerge in Sect. 6.

2 Literature Survey

In [1], they proposed a group-based network mobility controlling technique to diminish the signaling problem. Besides this, they reduce the handover latency as well. But they did not investigate the finest mode for vehicles to be clustered together or they did not employ the neighboring association among the vehicles when alliance them.

In [8], they introduced a NEMO support protocol for Intelligent Transportation Systems that support mobility management as well as handover. But they did not support the guaranteed seamless connectivity during a handover.

Hager et al. [9], illustrate MINT- a Mobile Internet Router having enough computational capability to execute all essential communication protocol operations while enabling connections for the nodes. Transparency of the communication software is provided by the MINT router, and there is no requirement of any modifications with the basic software of mobility support while connecting via such a router to the Internet.

In the Request for Comments [10] which was on IP mobility support, clearly specifies the fact of using a Mobile Router for the mobile network.

By considering all the limitations of the above-related study, we try to implement NEMO-BS protocol using ns-3 network simulator that ensures the seamless network connectivity as well as the IP handoff management.

3 Working Principle of NEMO-BS Protocol

The working principle of the protocol is depicted in Fig. 1. The network entities for the handoff operation includes a Mobile Network Node (MNN), Mobile Router (MR), Home Agent of the MR (MR-HA), and Correspondent Node (CN).

Step 1: When MNN enters into a vehicle, it connects with the MR as MR is the default Internet Service Provider for the MNN inside a vehicle and acquires a Care-Of-Address (CoA), configured from the MRs prefix.
Step 2: As MNNs home prefix differs from that prefix, it binds the CoA with its HA (MNN-HA) through a Binding Update (BU) process.
Step 3: When the MR changes access point, it performs the BU process with the MR-HA. The BU processes result in two tunnels between entities (MR and MR-HA, MNN and MNN-HA).

A packet from CN to MNN follows the route: CN → MNN – HA → MR – HA → MR → MNN. It is encapsulated first by the MNN-HA such that it could reach the MR's home. Reaching MR's home, the packet is automatically redirected toward the MR-HA as the corresponding HA contains MR's home links. MR-HA has the binding of the MR's advertised prefixes to the MR's current CoA. So, the MR-HA encapsulates the packet, setting MR's CoA as the destination. The tunnel headers are decapsulated in the reverse order, i.e., in the MR first and then, in the MNN.

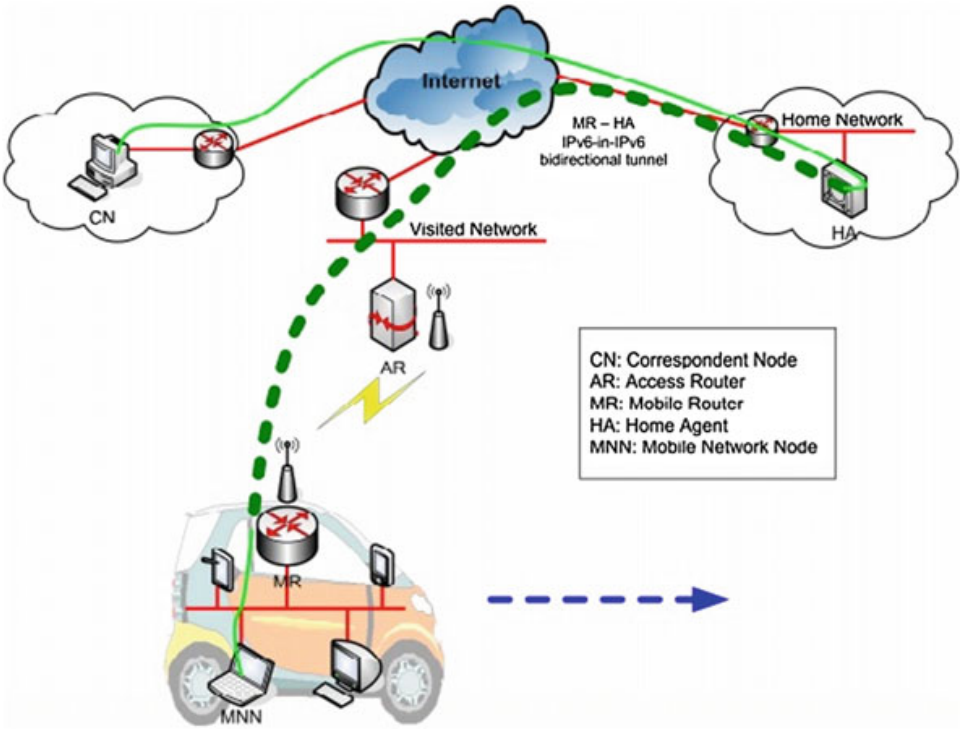

Fig. 1 NEMO-BS operation [4]

The working process of the NEMO-BS differs from the MIPv6 in the following two ways:

- The MR registers all its prefixes (which it advertises to the MNNs) during its BU process, instead of only the home address.
- Unlike MIPv6, the MR-HA must have to advertise all those MR's prefixes to its neighbors such that the MR-HA can receive all the packets, destined to the MNNs CoAs, configured from those prefixes.

Here, we will describe the Binding Update (BU) process and data packet processing in NEMO-BS in detail.

3.1 Binding Update (BU) Process of NEMO-BS

In MIPv6, when a mobile host configures a new address in its interface, it sends single BU to its HA. But in NEMO-BS instead of sending single BU, each MH in the mobile network sends BU to its corresponding HA through MR when they configure a new address in the mobile network. In the same way, when MR configures a new IPv6 address in a new subnet from a new access router advertised prefixes, it also sends a BU to its HA. When a node configures an address on an interface, immediately Duplicate Address Detection (DAD) method is started to verify the delicacy of that address. After the time-out session of DAD, it calls the SetState() which is defined in ns3 core.

3.2 Packet Processing of NEMO-BS

After the successful completion of Binding Update process, a bidirectional tunnel is established between MR and MR-HA and another tunnel is established between mobile network MN and MNHA (Fig. 2). That is why when a mobile host in the

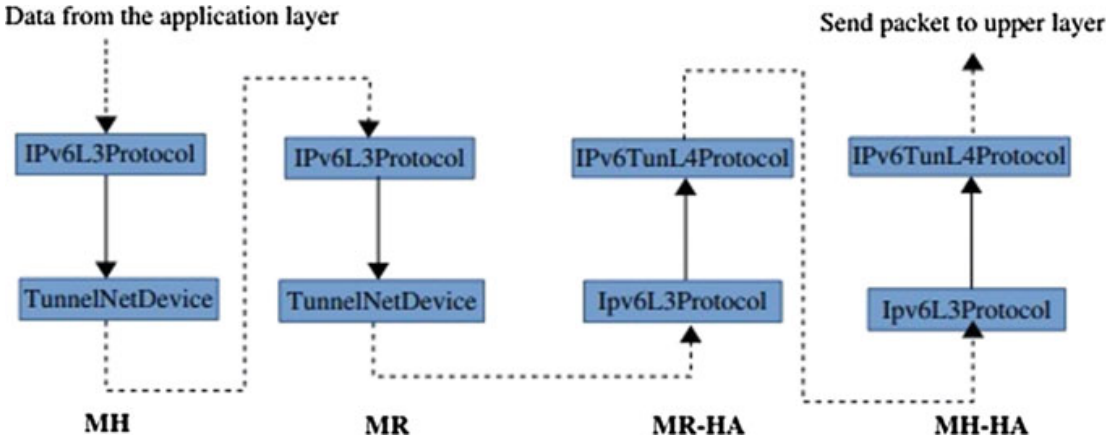

Fig. 2 Data packet processing from MH to MHHA

mobile network sends a data packet to a Correspondent Node (CN), the first level encapsulation is done by the tunnel between in MH and MHHA, and then is sent to MR. After that, second-level encapsulation is performed by MR because of the tunnel between MR and MR-HA. When the two-level encapsulated packet reaches the MR-HA, it decapsulates the outer encapsulation and forwards the remaining packet to the MHHA. When this packet reaches MHHA, it decapsulates the first level of encapsulation and sends it to the right destination that is the correspondent node. Besides this, the data packets are processed in reverse direction from the CN to MH.

4 Class Diagram Implementation

The existing classes of the implemented MIPv6 module [7] are modified to support the NEMO-BS functionalities as shown in the class diagram in Fig. 3. We divide our NEMO-BS classes into mainly four modules:

- Header
- Internet stack
- Net device
- Helper.

The important operations and functionalities of each module are detailed as follows:

4.1 Header

We have implemented the NEMO-BS functionality in ns3, by modifying some of the existing MIPv6 headers message formats in ns3 as defined in RFC3963. All the headers are inherited from the base class Header in ns3 system. In Fig. 3, we have depicted the main data members of NEMO-BS headers and relationship among them as defined in RFC3963. For NEMO-BS in ns3, we have added m flagR data field in Binding Update (BU) and Binding Acknowledgement (BA) header to denote the mobile node's status. If this flag value is set in BU, then HA assumes that MIPv6 mobile node acts as a NEMO-BS MR otherwise it considers it as MIPv6 Mobile Host (MH). A new mobility option header named as Mobile Network Prefix Option Header is added with existing headers shown in Fig. 3, which is also inherited from MIPv6OptionHeader class. It carries the one or more prefix information (128 bit or more) from MR to its HA within BU message and these prefixes are advertised by MR-HA to receive the packet correctly for the mobile host in the mobile network.

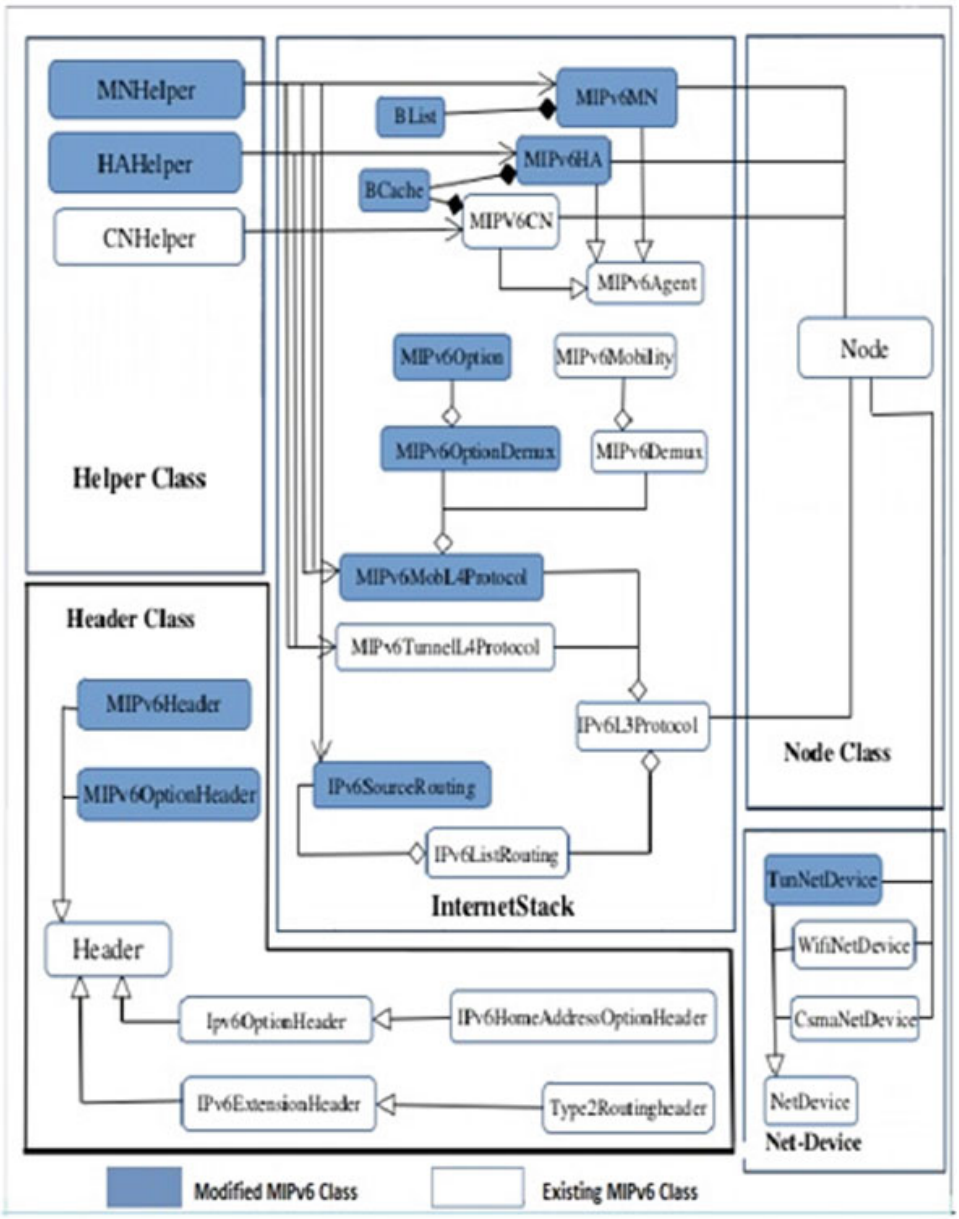

Fig. 3 NEMO-BS classes and their functional relationships

4.2 InternetStack

NEMO-BS implementation contains the two types of Demux classes named as MIPv6Demux and MIPv6OptionDemux. Details of the functionality of Demux classes are described in paper [7]. For NEMO-BS, a new mobility option is added to the MIPv6Option class. The MIPv6MobL4Protocol deals with mobility messages necessary for communication, whereas the MIPv6TunL4Protocol deals with data packets in the time of communication. When from lower layer, a packet is recognized by IPv6L3 Protocol and then sends it to the MIPv6-layer. The summarized data packet or a mobility message contains the MH type value in its header

which is dissimilar from normal data packet. The MH Type field value is checked by IPv6L3Protocol class, and depending on this value, appropriate upper layer L4 protocol class is called. If the packet is received by Receive() function of MIPv6TunL4Protocol class, then its Receive() function checks the summarized packet tunnel line which may use to de-capsulate the packet. It drops the packet if there is no matching tunnel interface found. The MIPv6TunL4Protocol class may be added, removed, or modified a tunnel.

4.3 NetDevice

A tunnel is made for virtual MAC layer by the TunNetDevice class. The TunNetDevice class reimplements the base class Send() function. After the reception of a packet from the upper layer, the Send() function accomplishes IPv6inIPv6 encapsulation by making a new IPv6 header. The main functionality of the MIPv6TunL4Protocol class is TunNetDevice class.

4.4 Helper

This is in the top of the above all implemented classes. When a user wants to use the NEMO-BS protocol, they don't have to bother about the complex internal structure rather they only call the Install() function of MIPv6Helper class to install the functionality on a particular node.

5 Simulation and Results

The simulation framework is shown in Fig. 4. We have used ns-3.25 for simulation. The MR has two interfaces.

- It connects with the Access Router (AR) through Wi-MAX interface and
- With the MNNs through Wi-Fi interface.

Simulation setup: The simulation snapshot is shown in Fig. 5. The Mobile Host (MH) and Correspondent Node (CN) perform as a host and remaining all others as a router. A middle router R1 connects the AR1 and AR2 connects with CSMA interface to MR-HA, another middle router R2 connects the CN and MHHA through CSMA interface to R1. The MR has two interfaces, it connects with access router through Wi-Fi interface, and connects with the mobile host in the mobile network through Wi-Max interface. IEEE 802.11 radio is used over here in AR1 and AR2. Beacons are generated in every 100 ms. Here, the data rate is set at

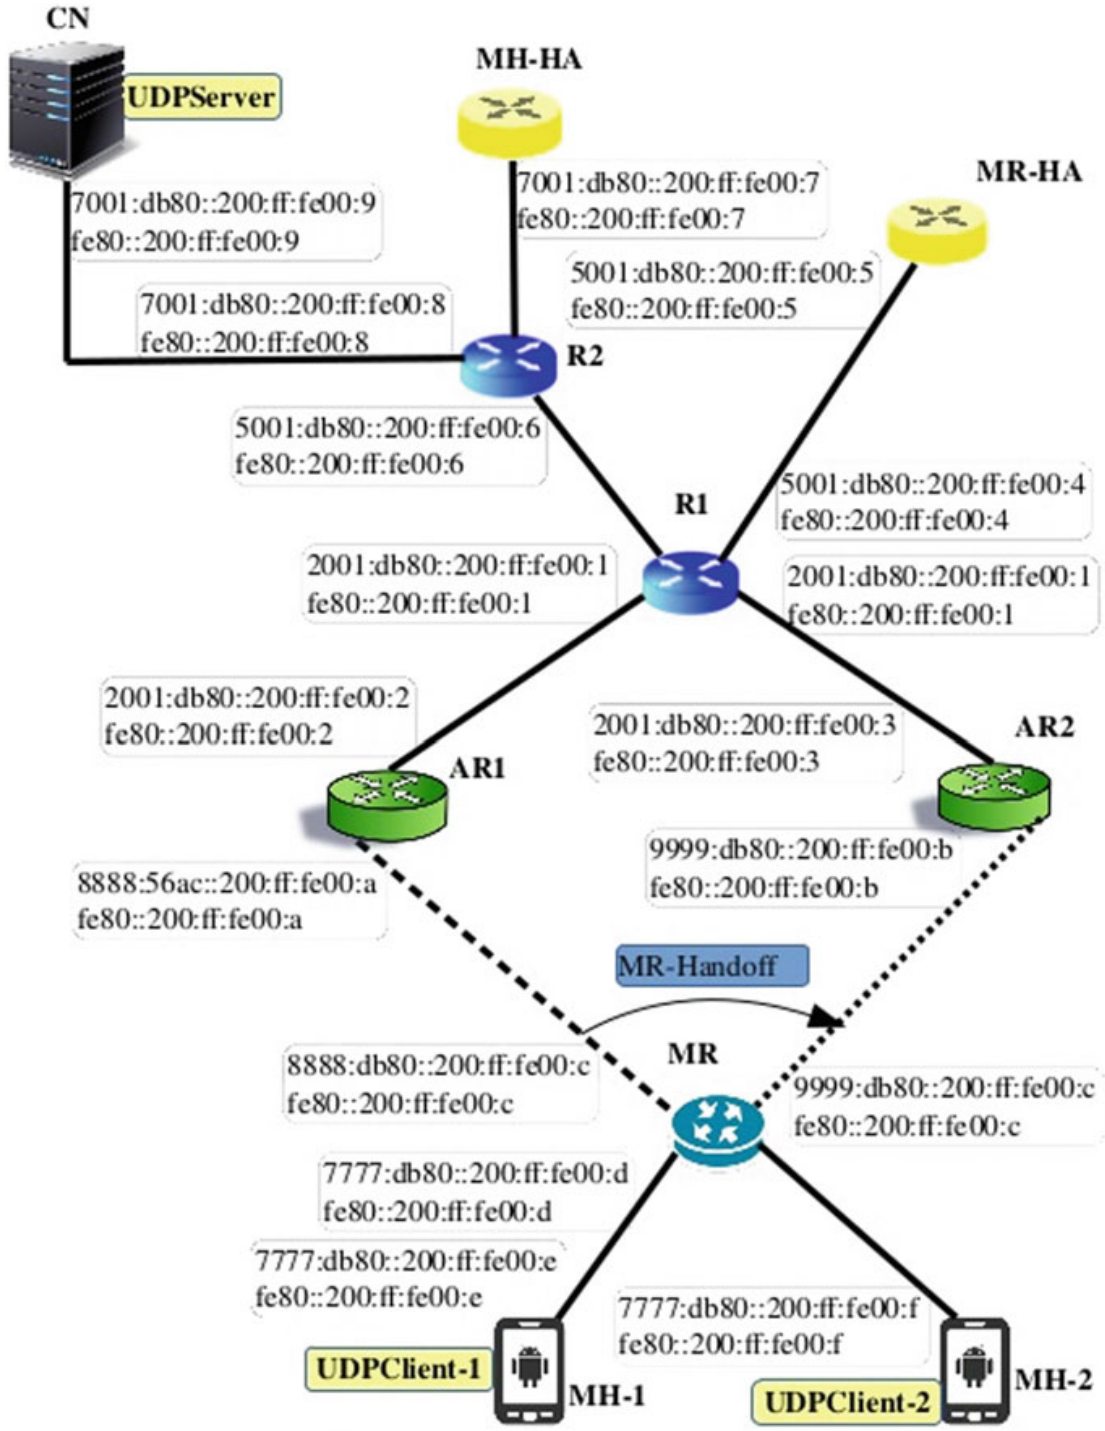

Fig. 4 Simulation Framework

2 Mbps and the link delay at 1.0 ms. On mobile hosts (MH1 and MH2), a UDP echo-server application is installed. On the CN, an echo-client application is running with 1024 packet size and maximum 100,000 packets. Here, the MR home network prefix is 5001:db80:/64, and MR's HoA of MR is expressed from this.

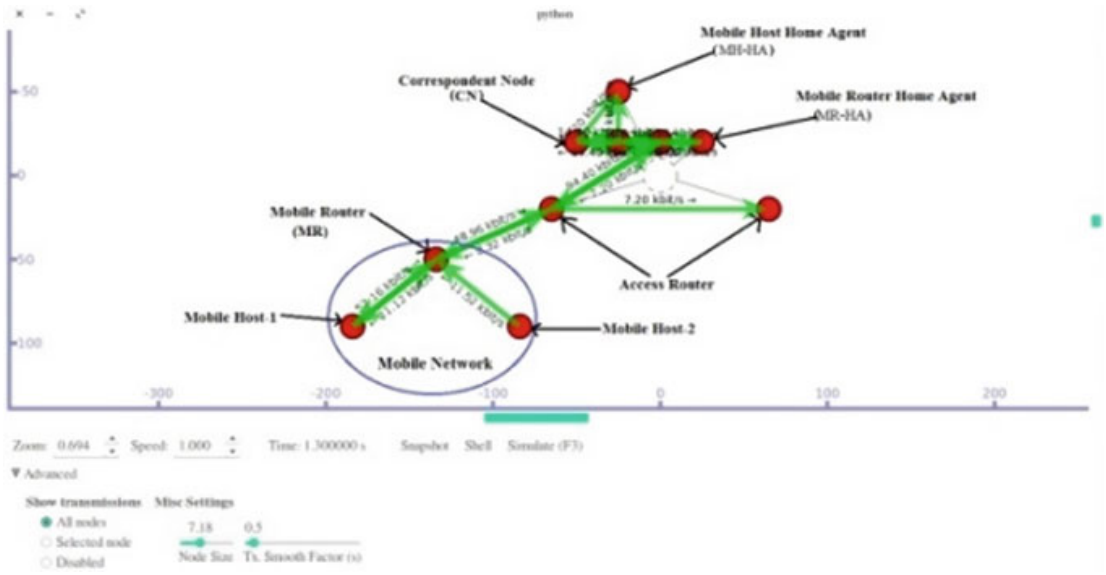

Fig. 5 Simulation snapshot of implemented NEMO-BS in NS3

The constant velocity model (20 m/s) is used for all the MR and moves from left to right fashion.

The simulation parameters are given below:

- Both the AR1 and the AR2 generate beacons in every 100 ms.
- All CSMA links use 2 Mbps data rate and 1.0 ms link delay.
- A UDP echo-server is fixed on the MNNs (MNN is called as MH) (MNN-1 and MNN-2) (say at port 9).
- The MR with all the MNNs in the mobile network uses the constant velocity mobility and travels from the left to right with 20 m/s velocity.

From the packet capture (PCAP) files, we can calculate the delay experienced by MNN1 in the mobile network due to the handoff of MR from AR1 to AR2. At t = 7.240 s, the MNN1 successfully receives the preceding packet from the CN. After that MR changes the point of attachment and after successful completion of the handoff of MR, MNN1 again successfully receives the next packet at t = 12.245 s. So, the delay experienced by MNN1 = (12.245–7.240) s = 5.005 s.

6 Conclusion

NEMO-BS protocol provides seamless Internet connectivity by providing smooth and fast hand-off for a group of users moving from one place to another. In this paper, we have implemented this protocol as an extension of MIPv6 in ns3 environment, so that it can be appended as a new library file in ns-3 in future, which will help the naive users. The above implementation complies with the standard, defined by the IETF. But, a few future works are also required to make it fully usable by the

research community. As the open-source simulator like ns-3 presently mandates validation for any new implemented module, our implementation must be validated against some of the strong existing implementations. Above all, integrating NEMO into LTE would be very interesting as recent research trends mostly rely on LTE communication.

Modified DFA Minimization with Artificial Bee Colony Optimization in Vehicular Routing Problem with Time Windows

G. Niranjani and K. Umamaheswari

Abstract A NP-hard problem, vehicular routing is a combinatorial optimization problem. Vehicular routing problem with time windows indicates vehicular routing with specified start and end time. There will be "n" number of vehicles starting from the depot to cater to the needs of "m" customers. In this paper, Gehring and Homberger benchmark problems are considered wherein the size of customers is taken to be 1000. Artificial Bee Colony Optimization algorithm is executed on these 60 datasets and the number of vehicles along with total distance covered is recorded. The modified version of Deterministic Finite Automata is applied along with the Artificial Bee Colony Optimization and the results produce 25.55% efficient routes and 15.42% efficient distance compared to simple Artificial Bee Colony Optimization algorithm.

Keywords Artificial Bee Colony Optimization · Minimization · Number of routes · Total distance

1 Introduction

Vehicular routing problem with time windows is a NP-hard problem. It is a combinatorial optimization mechanism. Vehicular routing problem is similar to travelling salesman problem. In the travelling salesman problem, a sales person has to start from one city, travel to all the other cities only once and then return to the original city with the minimum cost possible. In VRPTW, the number of customers and the number of vehicles are specified. These vehicles start from the depot that is also specified in the problem, go to different customers that are distributed across

and then return to the depot. The customers are specified as x and y coordinates of the point. When a customer is reached, the next customer is selected which has the minimum distance from the current point among all the points that are not yet visited. This paper considers the 60 datasets pertaining to Gehring and Homberger benchmark problems that service 1000 customers.

In the real world, these vehicle routing problems are being used in distribution and transportation logistics [1] and also specific applications such as solid waste, beverage, food, diary and newspaper industries [2].

The dataset, in general, contains the following details: vehicle count and the capacity of each vehicle. For each vehicle, the following details are specified: (1) Customer number: for depot, the customer number is zero. All the other vehicles have natural numbers sequentially. (2) x-coordinate of the customer. (3) y-coordinate of the customer. (4) Demand: this denotes the priority. (5) Start time: the customer needs to be serviced after the start time. (6) End time: the customer needs to be serviced before the end time. (7) Service time: the time taken to perform service for this particular customer. The Gehring and Homberger benchmark problems have six sets of problems: C1 type, C2 type, R1 type, R2 type, RC1 type and RC2 type. Each type has 10 problems. The types vary in terms of vehicle count and the capacity of each vehicle.

1.1 Reason for Considering the Gehring and Homberger's Problem for the Experiments

1. Solomon's benchmark problems have been considered in many algorithms associated with vehicular routing problem with time windows. In these problems, the maximum number of customers in a single instance is 100. Gehring and Homberger benchmark problems are a variation of Solomon's benchmark problems with more number of customers for each instance.
2. The number of customers represented in each of the instances is 1000. To demonstrate that the algorithm can handle a huge amount of customers comparative to the other algorithms such as branch and price, Tabu search, firefly algorithms and even some variations of ABC [Tournament selection, Vector Evaluated Technique and Roulette Wheel Selection technique], these problems are selected.

2 Artificial Bee Colony Optimization

Karaboga [3] started the Artificial Bee Colony algorithms after observing the behaviour of honey bees and applied them to real-time problems. He along with Karaboga and Basturk [4] further extended the usage of the algorithm for solving

various optimization problems. Karaboga and Basturk [4] and Singh [5] propose a solution that shows the better performance of bee colony algorithms in comparison with particle swam optimization and genetic algorithms, particle swarm optimization [6, 7], Tabu search and ACO algorithms, respectively.

2.1 Working of Honey Bees

Artificial Bee Colony Optimization algorithms are based on the working of real-world honey bees. These algorithms come under swarm intelligence—wherein problems are solved based on the collective behaviour of social insect colonies and other animals. In this paper, the honey bees are considered. There are three types of honey bees: (1) Scout bees: these are used to search for new food sources randomly. (2) Onlookers: the onlooker bees calculate the nectar amounts available in the food sources. (3) Employed bees: these determine the nectar amount and the probability value with which the food source can be reached from the bee hive.

2.2 Essential Components of Forage Selection

(1) Food sources: a particular food source is selected based on its proximity to the hive, richness/concentration and the ease of extracting energy. (2) Employed forager: it carries information about the food source, how much distance it is from the hive and the direction of the food source from the hive, profitability and it shares information with a certain probability. (3) Unemployed forager: the scout bees and the onlooker bees come under this category.

2.3 Modes of Behaviour

There are two important modes of behaviour of the honey bees with respect to the food sources. (1) Recruitment of the food source, (2) Leaving behind the food source. The honey bees exchange information about the food sources among themselves by means of the “waggle dance”.

2.4 Basic Self-Organization Properties

(1) Positive feedback: when the nectar in the food source is high, the number of onlooker bees is high. (2) Negative feedback: when the nectar in the food source is poor, there are no bees nearer. (3) Fluctuations: probability value of the nectar in the

food source in comparison with others [8]. (4) Multiple Interactions: Communication between different types of bees with regard to the food source. Many tasks are performed at the same time leading to the division of labour [3].

2.5 Algorithm

The general Artificial Bee Colony Optimization algorithm proposed by Dervis Karaboga [4] is as follows:

Send the scout bees onto the initial food sources

REPEAT

Send the employed bees and find the nectar amounts in the food sources
The onlooker bees decide the selection of food source based on its probability value
They go to the respective food source and determine the nectar amount
The food source selected by the bees are exploited
Again, send the scout bees to search for new food sources
Remember the food sources exploited so far.

UNTIL (constraints are satisfied).

2.6 Parameter Setting for the ABC Algorithm

1. All the vehicles start from the depot.
2. It is assumed that the vehicles are not affected by traffic conditions.
3. All the customers will be serviced only after the start time but before their end time.
4. A particular vehicle should be available to service a customer within the service time of that particular customer.

3 VRPTW

The study of vehicular routing started in 1959 when G. B. Dantzig and J. H. Ramser [9] proposed the truck dispatching problem applicable to the delivery of gasoline to service stations. It was followed by Clarke [10] to provide an iterative procedure to select the optimum or near-optimum route in a better way. A lot of algorithms [11] have been proposed and some implemented to this problem which provide both exact and approximate solutions.

The vehicular routing problem with time windows has been solved by many algorithms. Some of the well known algorithms are presented in Table 1.

3.1 Objectives

The following are the objectives of the VRPTW:

1. Minimization of Total routes:
   The total number of routes refers to the total number of vehicles needed to solve a particular problem. The number of vehicles varies depending on the placement of customers. If the customers are nearer, a single vehicle is enough to service all those customers, provided that particular vehicle is available within the start time and the end time of that customer. The algorithm is designed such that the total number of routes is minimized [12].
2. Minimization of the total distance travelled:
   Distance of a single vehicle is measured as the sum of the distance between the depot and the first customer that the vehicle is servicing and the distance between the first and the second customer and then the second and the third and so on till the last customer. The distance between the last customer and the depot is added along with these values. The total distance of a particular customer is calculated as the summation of distances of individual vehicles. This algorithm takes care of the fact that the total distance is reduced.
3. Minimization of the total time taken:
   Time taken for a single vehicle is calculated as the summation of the start time of the first customer and its service time and then subsequent service time of the corresponding customers. Total time is calculated as the summation of the time taken by individual vehicles which is to be reduced by the proposed algorithms.

   It has to be taken care that the capacity constraints are not violated [13].

3.2 Procedure

There are different variations for solving VRPTW using Artificial Bee Colony Optimization algorithm. Some are presented in Table 2.

The vehicle count, the capacity of vehicles and the depot details—customer number: 0, x-coordinate and y-coordinate of the depot, demand, start time, end time and unload time—are got from the input dataset along with the details of the 1000 customers. The number of routes is initialized to 0.

The following procedures are executed until all the customers are serviced:

1. MemorizeBestSource (): This function is used to select the customer with the least start time and also that has not been serviced yet.

Table 1 Existing solutions for VRPTW

Author and year	Title	Strategy	Parameter	Dataset	Methodology	Benefits	Limitations
Bulhões and Uchoa [16]	A branch-and-price algorithm for the Minimum Latency Problem	Minimum Latency Problem	Minimize the sum of waiting time of customers	40 TSP Library instances with up to 200 vertices	In branch-and-price method, the arcs are considered instead of specific nodes	Roberti and Mingozzi (2014) did not solve nine instances. This method solved them. Also, branch-and-price could solve larger instances of size 159, 175, 180 and 195	When the vertices are greater than 150, it is difficult to solve
Michael Schneider, September 2015 [17]	The vehicle-routing problem with time windows and driver-specific times	Tabu search	Minimize travelling distance and working duration	Solomon's 100 customer instances	Relocation, Exchange of data and 2-Opt methods	10 runs are executed and the optimal ones are considered	Meta-heuristic method can be improved by means of splitting methods for solutions of higher quality
Huang et al. [18]	Multi-agent ACO for VRP with soft time windows and road condition	A mathematical model of VRP with soft time windows [penalty for lateness] and road factor	Transport cost, fuel consumption and customer satisfaction achieved by the arrival time of vehicles and the expecting time of customers	40 customer problem	Adaptive pheromone trail, state transition rule and pheromone updating, 3-opt solution	Multiagent ant colony optimization is considered better than ACO and AGA	For larger instances, yet to be verified

Matthopoulos and Sofianopoulou [19]	A firefly Algorithm for the Heterogeneous Fixed Fleet VRP	HFVRP is a variation of VRPTW wherein the customers have different capacities and costs for goods distribution	Relative brightness, Degrees of attraction, Distance between fireflies	Augerat et al. (1995)	Relative brightness, Degrees of attraction, Distance between fireflies, Position update and Parameters values selection	Produces the best known solution for small datasets—up to 39 nodes	The next node is determined by means of a random walk of the firefly and hence, it is not much effective

Table 2 Existing solutions for ABC in VRPTW

Author and year	Title	Strategy	Parameter	Dataset	Methodology	Benefits	Limitations
Shi et al. [20]	A modified ABC algorithm for vehicle routing problems with time windows	Tournament selection	Minimize the total distance	Solomon's R102 problem	Fitness points are calculated between pairs of points and at the end, the one with the larger fitness value is selected	Travelled distance is better than the ant colony algorithm, iterated local search and genetic algorithms	Only one instance of 100 customer problem was considered
Nahum et al. [21]	Multi-Objective VRPTW: a Vector-Evaluated ABC Approach	Vector-Evaluated Technique	Count of vehicles and the total cost	Solomon's 25, 50 and 100 customer problem	(1) Minimize the number of vehicles, (2) The total path length is optimized based on the results calculated beforehand	Optimal solution can be obtained by running the algorithm again and again	The end result is based on previous runs. So, it takes lots of time for computation
Bhagade and Puranik [12]	Artificial Bee Colony (ABC) Algorithm for Vehicle Routing Optimization Problem	Effective path planning	Tour length and bee travel time	Results are simulated	Control parameters are set which help in determining the next node using the nearest neighbour method	Optimal distance is obtained by greedy selection strategy	Very few parameters are considered
Alzaqebah et al. [22]	Modified Artificial Bee Colony for the vehicle routing problems with time windows	Roulette wheel selection	Convergence speed increased	Solomon's 100 customer problem	The bees select the best node based on the random selection of nodes for the count of maximum trials	67% of the results are better than simple- ABC	The results need to be increased

2. SendEmployedBees (): This function is used to execute the work of the employed bees. The customer selected by the MemorizeBestSource () is to be processed. This function selects the route that this customer is to be placed in. A group of routes is selected based on the following conditions:

   - The distance from the depot should be greater than the distance from the routes latest point to this customer.
   - The time taken by the route until the latest point should be less than the customer's end time.

3. CalculateProbabilities (): This function selects the route with the minimum distance among the set of routes selected in the SendEmployedBees () function.
4. SendOnlookerBees(): If no such routes are selected by the CalculateProbabilities () function, a new route is created with the following conditions:

   - The vehicle count of the new route is set to 1.
   - The customer is marked as serviced.
   - A new route is created with the present customer as the first vehicle.
   - Route time is equal to the sum of the starting time of a particular customer and the time taken to unload.
   - Distance of the route is calculated as the distance from the depot to the present customer.
   - The number of routes is incremented by 1.

When a sample route is selected to fit in this customer, the following procedures are carried out:

- The customer is marked as serviced.
- The present customer is added with the selected route as the last one.
- The number of vehicles processed by the current route is incremented by 1.
- If the start time of the present customer is before the route time, the route time is calculated as the sum of route time and the unload time for this particular customer. Else, the route time is calculated as the sum of the starting time of the present customer with its unload time.
- Distance of the route is calculated as the sum of the previous distance and the distance between the previous point and the present customer.
- The present customer is made as that particular route's last point.

All the distances are measured using the Euclidean distance—The distance between two points (x_1, y_1) and (x_2, y_2) is

$$\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$$

5. SendScoutBees (): The scout bees manage the customers that can be selected in the next iteration.
   The route number, the number of vehicles, specific distance, number of customers serviced and time taken is displayed for each route. In the end, the total

number of routes, total distance—the summation of the distance of individual routes and the total number of serviced customers—are displayed. The number of vehicles and the total distance travelled is recorded to be compared.

4 Minimization of Deterministic Finite Automata

Deterministic Finite Automata refers to a machine that has a countable number of states and each input state has exactly one output state on a given input. The deterministic finite automata is indicated as $(Q, \sum, \delta, q0, F)$ wherein Q refers to the set of states, $\sum$ refers to the input alphabet, δ refers to the transition equation which contains the input state, input alphabet and the output state, $q0$ refers to the initial state and F refers to the set of final states [14].

For minimizing a DFA, initially, the final states are considered as one component and all the other states are considered as another component. Each component is checked whether they all give the states belonging to the same component for each alphabet. If so, they are retained in the same component. Else, the component is split and the same procedure is followed again until there is no change. In the end, the states belonging to the same component are considered as one state and the Deterministic Finite Automata is reconstructed [15].

4.1 Algorithm for Modified DFA on ABC

On applying modified DFA minimization, the ABC algorithm changes as follows:

Send the scout bees onto the initial food sources
Group the food sources based on the distance between them
REPEAT

Send the employed bees and find the nectar amounts in the food sources
The onlooker bees decide the selection of food source based on their probability value
They go to the respective food source and determine the nectar amount
The food source selected by bees are exploited.

For each food source that is available in the group of the current food source

If the food source is currently available and is not yet exploited, it is exploited by the bees

Again, send the scout bees to search for new food sources
Remember the food sources exploited so far

UNTIL (constraints are satisfied).

4.2 Parameter Setting for Modified DFA on ABC

In addition to the above-mentioned parameters, a few are added to the modified DFA with the ABC algorithm:

1. The customers in a single group will be serviced by a single vehicle only when the start time and the end time coincide with the free time of the vehicle. Otherwise, different vehicles will be assigned to vehicles in a single group.

5 Modified DFA Minimization with Artificial Bee Colony Optimization in Vehicular Routing Problem with Time Windows

5.1 Changes to Artificial Bee Colony Optimization in VRPTW

In normal DFA minimization, the states that are grouped as a single component are considered as a single state. Here, it is modified such that the customers are grouped such that they belong to the same route if the capacity does not exceed. If the capacity exceeds the specified limit, the group can be split into different customers belonging to different routes.

The customers are considered in pairs having a minimum distance between them and they are grouped based on the following conditions:

- When both the customers are not in any groups, and they have a minimum distance between themselves compared to others; those two customers are combined together to form a new group.
- When any one customer of the pair is grouped and the other one is not paired, the customer not paired belongs to the group of the paired customer.
- When both the customers are paired, then two conditions are checked: (1) When they both belong to the same group, they are left as such. (2) When they both belong to different groups, any one of the customer groups is discarded and the customers belonging to the discarded group is added to the group of the other customer.

The functions of the Artificial Bee Colony Optimization for vehicular routing problem are executed as such except the functions:

- SendOnlookerBees (): In this function, a small change is done. When a customer belonging to a group is selected to be attached to a route, the customers belonging to the same group are given a preference to be selected in the same route, provided the constraint pertaining to the capacity of the vehicle is not violated.

- SendScoutBees (): This function is used to service the customers belonging to the group of the last serviced customer whose start time is less than the route time of the present route.

The route number, the number of vehicles, specific distance, number of customers serviced and time taken are again displayed for each route. In the end, the total number of routes, total distance—the summation of the distance of individual routes, the total number of serviced customers—are displayed. The number of routes and the total distance travelled is recorded to be compared with the previous one.

6 Results and Discussion

6.1 Comparison of Routes

The routes obtained from the Artificial Bee Colony algorithm is compared with the routes obtained in the Minimized DFA combined with ABC algorithm for the VRPTW. The comparison is done for each problem type separately.

C1_Type: Ten problems with count of vehicles: 200 and capacity: 250. There are 1000 customers in these problems each with service time of 90. The modified DFA with ABC algorithm gave better results for 90% of problems than the ABC algorithm as indicated in Fig. 1. The number of routes using minimized DFA is found to be 7.10% better than ordinary Artificial Bee Colony Optimization algorithm.

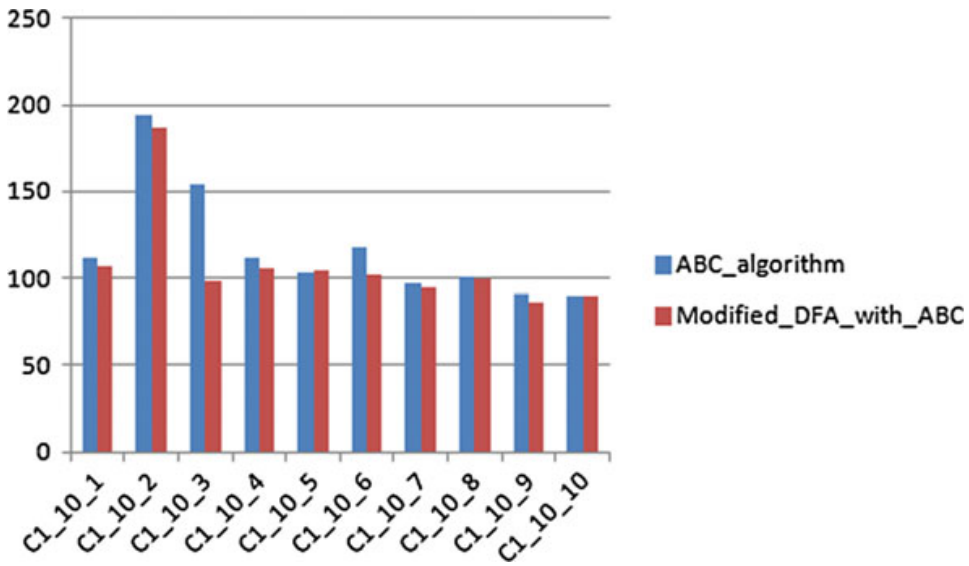

Fig. 1 Comparison of the number of routes for the ABC algorithm with the Modified DFA with ABC algorithm for C1 type problem

C2_Type: Ten problems with count of vehicles: 700 and capacity: 250. There are 1000 customers in these problems each with service time of 90. The modified DFA with ABC algorithm gave better results for 80% problems than the ABC algorithm as indicated in Fig. 2. The efficiency when minimized DFA is applied improves by 16.8% in terms of the number of routes.

R1_Type: Ten problems with count of vehicles: 200 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The modified DFA with ABC algorithm gave better results for 90% problems than the ABC algorithm as indicated in Fig. 3. The number of routes is found to be 24.38% more efficient when minimized DFA is applied.

R2_Type: Ten problems with count of vehicles: 1000 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The modified DFA with ABC algorithm gave better results for 100% problems than the ABC algorithm as indicated in Fig. 4. When minimized DFA is applied over Artificial Bee Colony Optimization, the results obtained are found to be 40.59% more efficient in terms of the number of routes.

RC1_Type: Ten problems with count of vehicles: 200 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The starting time of customers in this data-set is far less compared to the previous problems. The modified DFA with ABC algorithm gave better results for 90% problems than the ABC algorithm as indicated in Fig. 5. These instances are found to be 10.43% more efficient when minimized DFA is applied for calculating the number of routes.

RC2_Type: Ten problems with count of vehicles: 1000 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The starting time of customers in this dataset is far less compared to the R1, R2, C1 and C2 type problems. The modified DFA with ABC algorithm gave better results for 100%

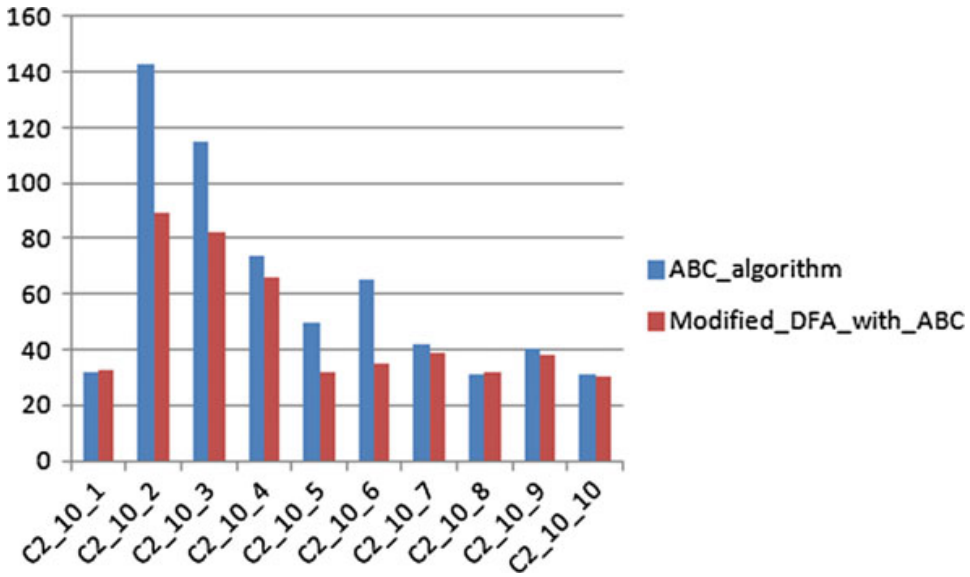

Fig. 2 Comparison of the number of routes for the ABC algorithm with the Modified DFA with ABC algorithm for C2 type problem

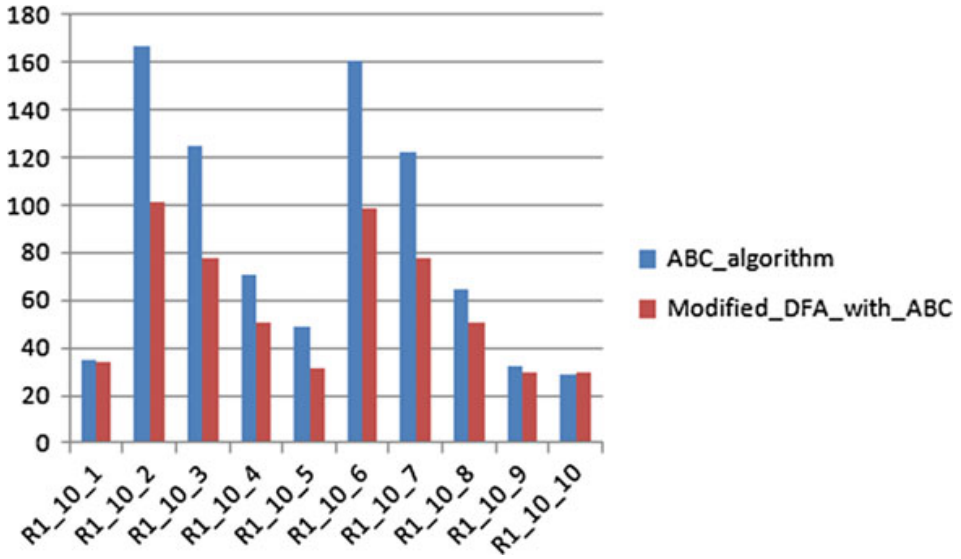

Fig. 3 Comparison of the number of routes for the ABC algorithm with the Modified DFA with ABC algorithm for R1 type problem

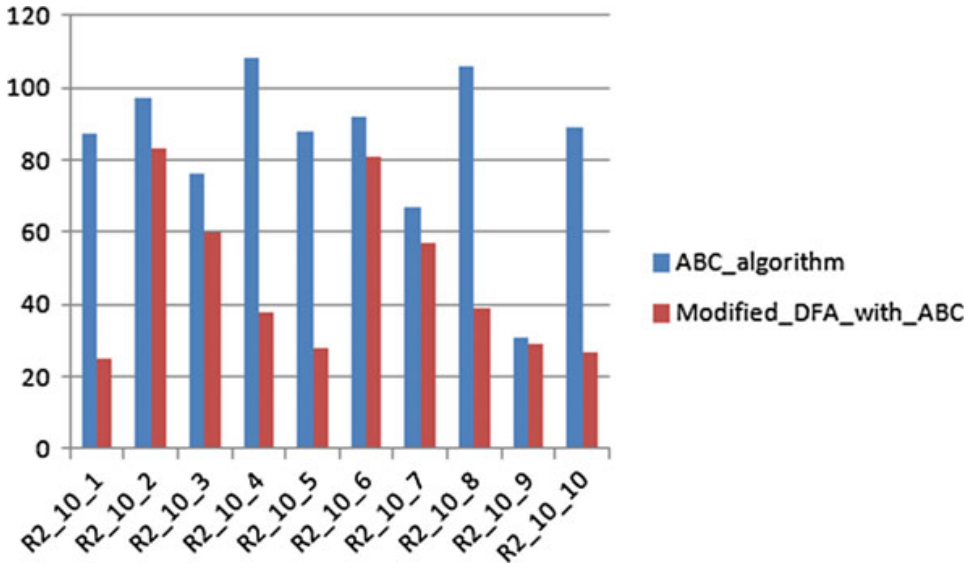

Fig. 4 Comparison of the number of routes for the ABC algorithm with the Modified DFA with ABC algorithm for R2 type problem

problems than the ABC algorithm as indicated in Fig. 6. 53.97% more efficiency is achieved for the RC2 type problems when minimized DFA is applied compared to Artificial Bee Colony Optimization algorithms for finding the number of routes.

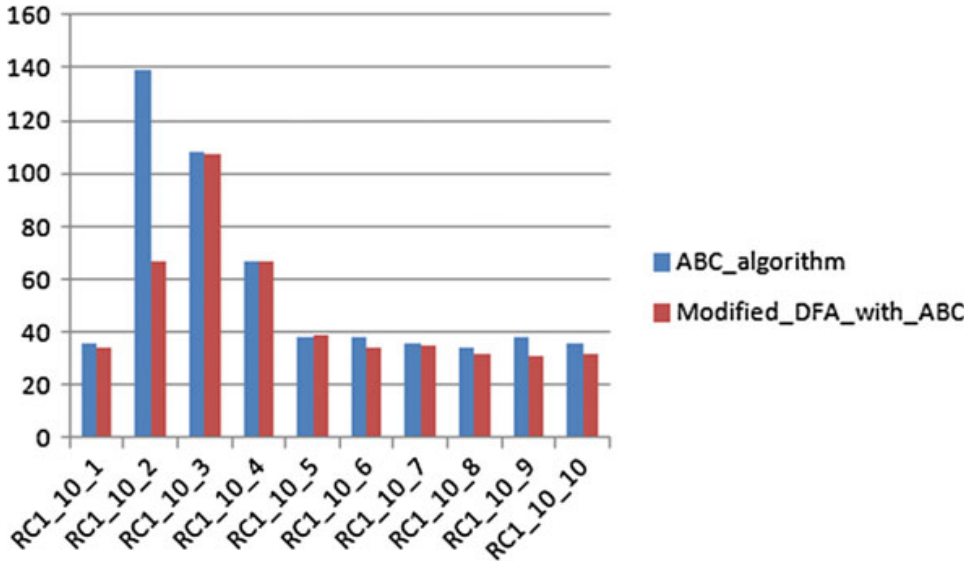

Fig. 5 Comparison of the number of routes for the ABC algorithm with the Modified DFA with ABC algorithm for RC1 type problem

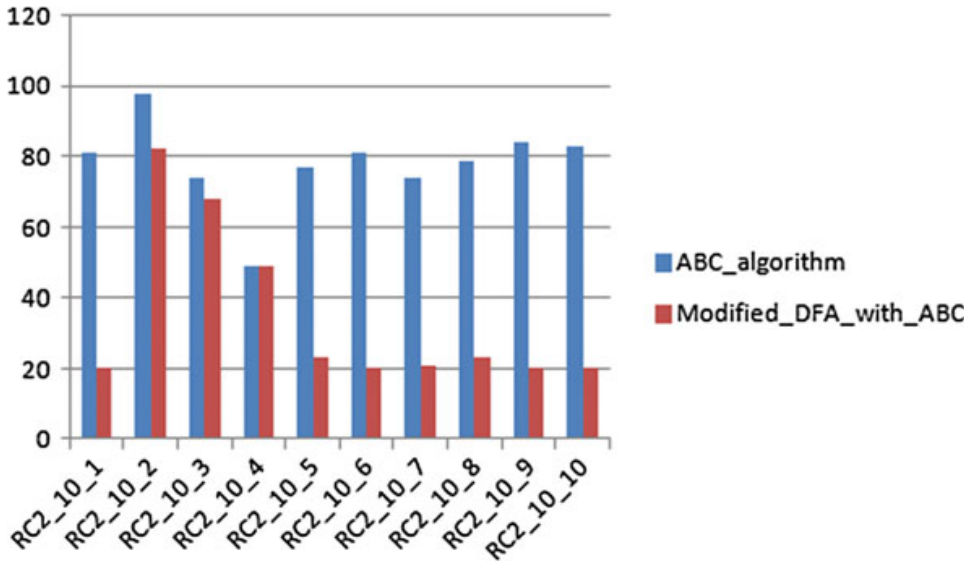

Fig. 6 Comparison of the number of routes for the ABC algorithm with the Modified DFA with ABC algorithm for RC2 type problem

6.2 Comparison of Distances

C1_Type: Ten problems with count of vehicles: 200 and capacity: 250. There are 1000 customers in these problems each with service time of 90. The modified DFA with ABC algorithm gave better results for 100% problems than the ABC algorithm as indicated in Fig. 7. The instances are found to be 7.29% more efficient when minimized DFA is applied on top of Artificial Bee Colony Optimization algorithms.

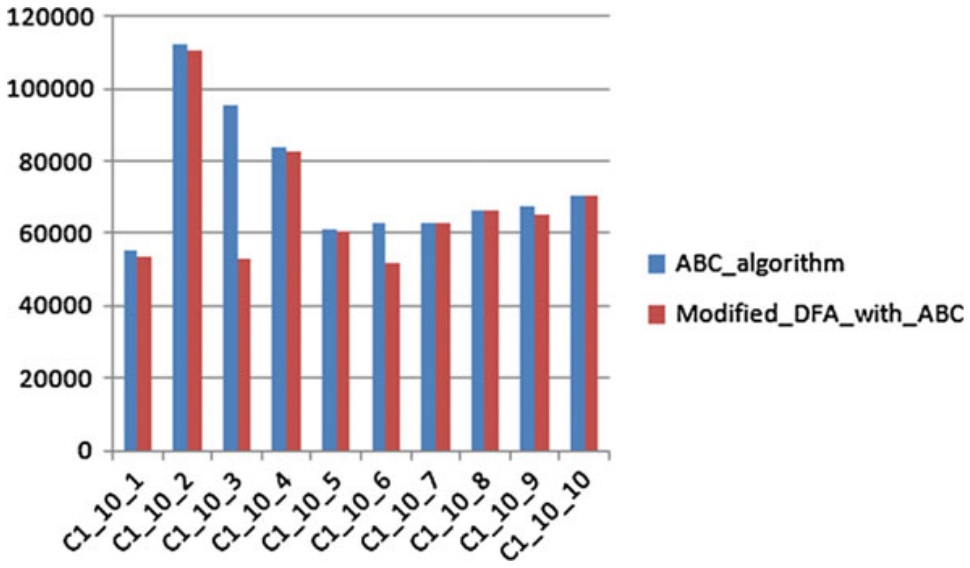

Fig. 7 Comparison of the total distance for the ABC algorithm with the Modified DFA with ABC algorithm for C1 type problem

C2_Type: Ten problems with count of vehicles: 700 and capacity: 250. There are 1000 customers in these problems each with service time of 90. The modified DFA with ABC algorithm gave better results for 90% problems than the ABC algorithm as indicated in Fig. 8. The efficiency when minimized DFA is applied improves by 18.02% in terms of the total distance.

R1_Type: Ten problems with count of vehicles: 200 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The modified DFA with ABC algorithm gave better results for 80% problems than the ABC

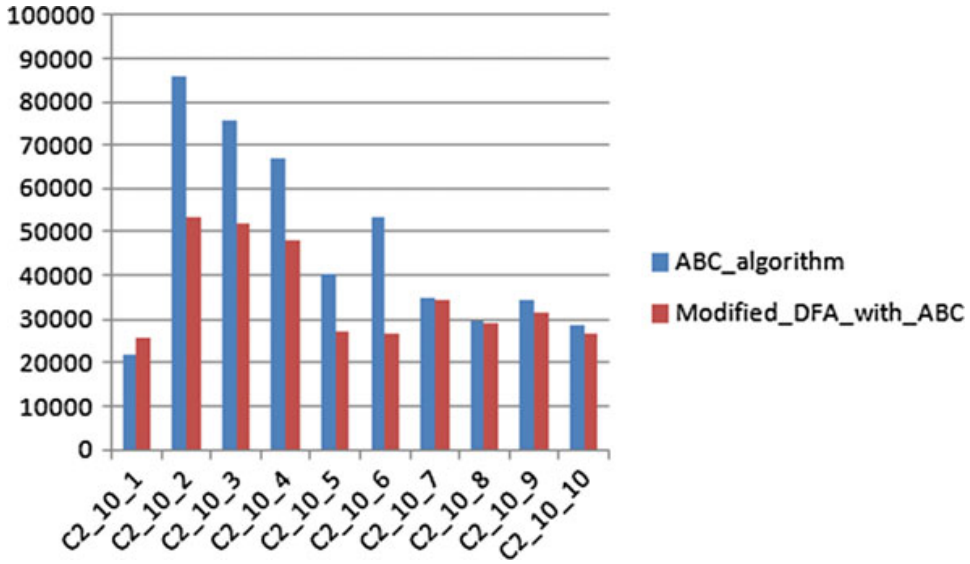

Fig. 8 Comparison of the total distance for the ABC algorithm with the Modified DFA with ABC algorithm for C2 type problem

algorithm as indicated in Fig. 9. The total distance is found to be 8.44% more efficient when minimized DFA is applied.

R2_Type: Ten problems with count of vehicles: 1000 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The modified DFA with ABC algorithm gave better results for 100% problems than the ABC algorithm as indicated in Fig. 10. When minimized DFA is applied over Artificial Bee Colony Optimization, the results obtained are found to be 31.72% more efficient in terms of the total distance.

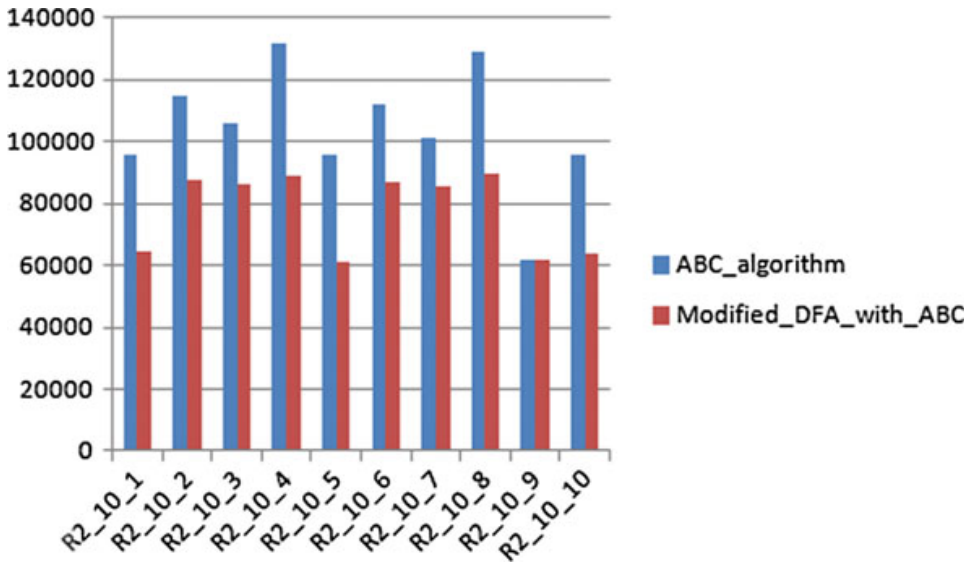

Fig. 10 Comparison of the total distance for the ABC algorithm with the Modified DFA with ABC algorithm for R2 type problem

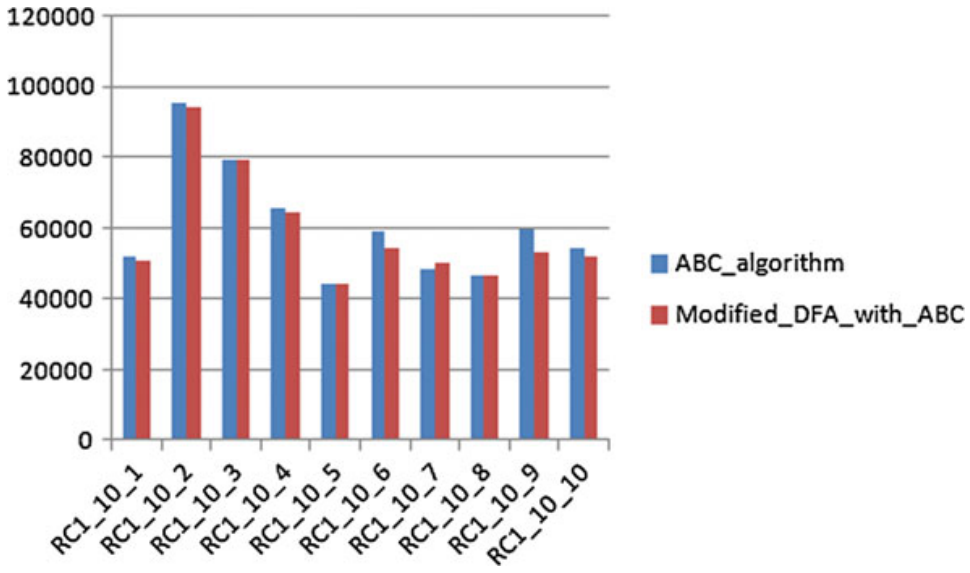

Fig. 11 Comparison of the total distance for the ABC algorithm with the Modified DFA with ABC algorithm for RC1 type problem

RC1_Type: Ten problems with count of vehicles: 200 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The starting time of customers in this dataset is far less compared to the previous problems. The modified DFA with ABC algorithm gave better results for 90% problems than the ABC algorithm as indicated in Fig. 11. These instances are found to be 2.47% more efficient when minimized DFA is applied for calculating the total distance.

RC2_Type: Ten problems with count of vehicles: 1000 and capacity: 250. There are 1000 customers in these problems each with service time of 10. The starting

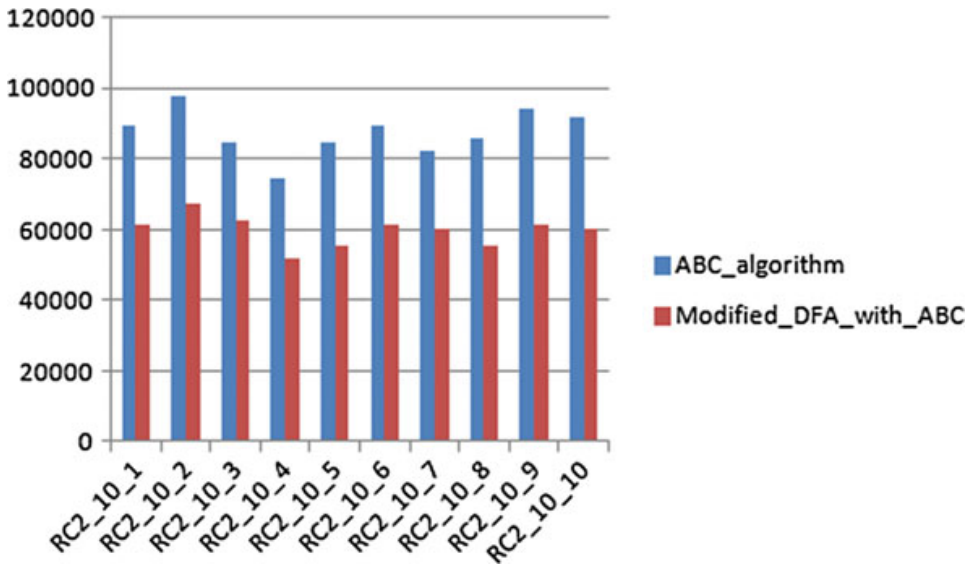

Fig. 12 Comparison of the total distance for the ABC algorithm with the Modified DFA with ABC algorithm for RC2 type problem

time of customers in this dataset is far less compared to the R1, R2, C1 and C2 type problems. The modified DFA with ABC algorithm gave better results for 100% problems than the ABC algorithm as indicated in Fig. 12. 53.97% more efficiency is achieved for the RC2 type problems when minimized DFA is applied compared to Artificial Bee Colony Optimization algorithms for finding the number of routes.

7 Conclusion and Future Work

The Modified DFA with Artificial Bee Colony algorithm has a higher performance when compared to the Artificial Bee Colony Optimization algorithm when applied to vehicular routing problem with time windows. Overall performance: 91.67% problems got better results, i.e. 25.55% more efficient in terms of the number of routes and 93.33% of the problems got better results, i.e. 15.42% more efficient for the total distance travelled by all the vehicles as a whole for the vehicular routing problem with time windows. The total time taken can also be added as a parameter along with these values. Even other algorithms such as genetic algorithms, particle swarm optimization and ant colony optimization can be optimized by applying DFA minimization along with those concepts for the VRPTW.

Coverage-Aware Recharge Scheduling Scheme for Wireless Charging Vehicles in the Wireless Rechargeable Sensor Networks

Govind P. Gupta and Vrajesh Kumar Chawra

Abstract Recent advancement in the wireless power transfer technology has motivated the development of a wireless rechargeable sensor network (*WRSN*). In WRSNs, the formation of an optimal recharging schedule for each wireless charger vehicle is a well known NP-complete problem. To determine the optimal recharging schedule for each wireless charger vehicle, this paper presents a coverage-aware recharge scheduling scheme (*CRS*) where *ACO*-based metaheuristic algorithm is employed. In order to provide fast recharging in WRSN, the proposed scheme employs multiple wireless charger vehicles to perform the charging task. Performance analysis of the proposed scheme confirms its superiority in terms of charging latency.

Keywords Recharging scheduling · Wireless rechargeable sensor networks · ACO-based metaheuristic

1 Introduction

In *WSRNs*, a set of rechargeable sensor nodes are deployed over an area of interest where each sensor node carry a wireless rechargeable battery and one or more wireless charging vehicle (*WCV*) are deployed for efficient recharging task [1, 2]. Recharging of the sensor nodes before their battery power vanishes by using multiple *WCVs* is a very critical task. Hence, optimal scheduling of the WCV is a fundamental research issue in WSRNs [1–5].

In WRSNs, the formation of an optimal recharging schedule for each mobile recharger is a well known NP-complete problem [2–7]. There are many solutions

proposed in the literature for designing the recharge schedule for *WCV*. Most of the solutions consider only single *WCV* for completing the recharging task. However, these techniques suffer from charging latency problem [3–6].

In order to enhance charging efficiency and reducing the charging latency, this paper proposes a coverage-aware recharge scheduling (*CRS*) scheme. In the proposed scheme, *ACO*-based metaheuristic algorithm is used for deriving the optimal recharge schedule for each *WCV*. In *CRS*, multiple *WCVs* are used for delay efficient recharging of the deployed sensor nodes. The proposed scheme contains mainly two phases: task assignment process for the *WCV* and derivation of the optimal recharge schedule for each *WCV*. To ensure the coverage of *WCVs*, proposed scheme divides the monitoring area into a set of logical grids and a subset of grids are allocated to each *WCV* for power transfer task. In order to schedule the traversal path of each *WCV*, an *ACO*-based metaheuristic algorithm is used for deriving the recharge schedule for each *WCVs*.

The remaining parts of the paper are structured as follows. A brief overview of the related work on recharge scheduling methods for the *WCV* is described in Sect. 2. Section 3 presents the network model and various assumptions used in this work. Section 4 discussed the proposed coverage-aware recharge scheduling scheme for wireless charging vehicles. In Sect. 5, simulation result analysis and a detailed performance comparison of the proposed scheme with the existing scheme are discussed. Finally in Sect. 6, the paper is concluded.

2 Related Work

In the literature, several research works have been proposed for deriving the recharge schedule for wireless charging vehicles. In [3], the authors have described a mobile charging method where the first clustering algorithm is employed to cluster the nodes based on their energy consumption rate. After the formation of the cluster, a set of nested *TSP* tours are formed for traversing the nodes that require energy. In [4], authors have presented two different charging algorithms, keeping an objective to minimize charging time as well as travel distance.

In [5], Wang et al. have discussed a node deployment scheme where a data gathering vehicle and multiple charging vehicles are employed to balance the energy resources and maximize the network lifetime of the network. In this scheme, only a single mobile charger is used for recharging task. The authors in [6] have presented a multimode wireless charging method where the mobile charger can charge multiple nodes at a time. In this scheme, the network area is partitioned into hexagonal cells. In this scheme, it is assumed that charging point is always at the center of the cell.

In [7], the authors have considered charging problem as two subproblems such as tour formation and assignment problem. In this scheme, a greedy technique-based heuristic algorithm is proposed for solving these problems. In [8], Jia et al. have discussed an integrated solution for charging and routing problem in

WRSNs. In this scheme, a heuristic algorithm is employed to derive optimal charging tour using a predetermined routing tree. This scheme employed a *GA*-based metaheuristic optimizing technique for optimizing charging and the routing tasks. This scheme considered only a single mobile vehicle for charging and data gathering task. Thus it suffers from charging latency problem.

The authors in [9] have proposed a collaborative scheme for solving the recharging problem in *WRSNs*. In this scheme, the network area is divided into a set of concentric circles and authors have tried to optimize the number of charging vehicles required for completing the charging task. In the literature, there are many solutions proposed by different researchers to solve the recharge schedule problem in *WRSNs*. Most of the scheme only utilized a single mobile charger vehicle for completing the recharging task. Thus, suffers from charging latency problem. In this paper, multiple *WCVs* are employed for reducing the charging latency and enhancing total charging efficiency. In addition, the proposed work also considers the coverage issue of recharging so that all required sensor nodes are recharged by the dispatched *WCVs*.

3 Network Model and Assumptions

These research works consider a wireless rechargeable sensor network where network area is logically divided into a set of equal size grids. Each grid can contain a set of sensor nodes and one of the them is selected as cluster head node which collects the sensed data from its cluster members and handovers to mobile sink during its data collection process [11–13]. In this work, we assume that all sensor nodes are homogeneous and haveequal sensing and communication range [13–16]. Figure 1 illustrates the network model used in this paper.

4 Coverage-Aware Recharge Scheduling Scheme for Wireless Charging Vehicles

This section presents a detail explanation of the working of the proposed coverage-aware recharge scheduling scheme (*CRS*). In the proposed scheme, ACO-based metaheuristic algorithm is used for deriving the optimal recharge schedule for each wireless charging vehicle (*WCV*). In CRS, multiple *WCVs* are used for delay efficient recharging of the deployed sensor nodes. The proposed scheme contains mainly two phases: task assignment process for the *WCV* and derivation of the optimal recharge schedule for each *WCV*.

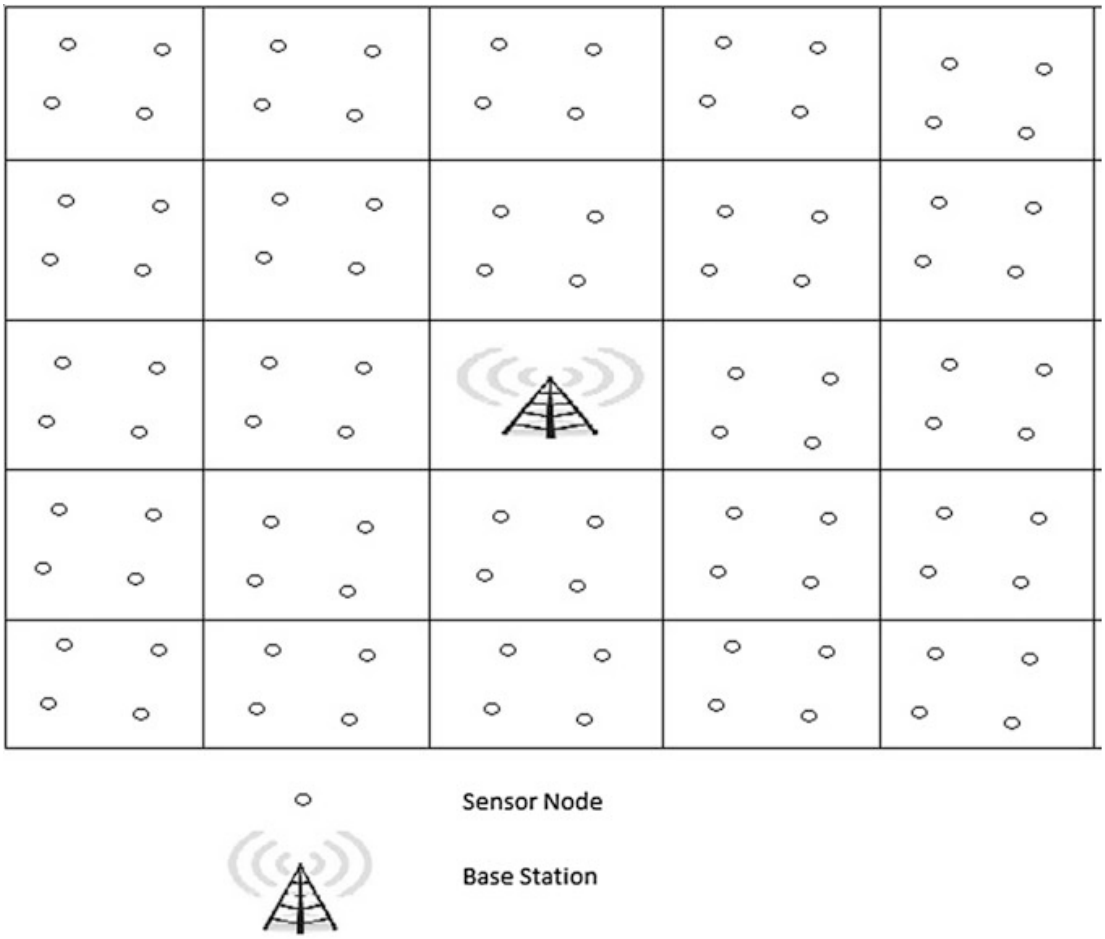

Fig. 1 Network model used in the proposed scheme

4.1 Task Assignment Process for the WCV

In order to assign the recharging task to each involved *WCV*, available area of interest is logically divided into equal size grids and a subset of grids is assigned to each *WCV* for traversing and recharging the sensor nodes located in that grid. In the experiments, the proposed scheme has taken 25 × 25 dimensions for each grid. In order to ensure coverage of recharging task by the *WCs*, the monitoring area is divided into logical grids. For scheduling the traversal path for each *WCV,* an *ACO*-based metaheuristic algorithm is used which is described in Sect. 4.2.

4.2 *Derivation of the optimal recharge schedule for each* WCV

For the derivation of the optimal recharge schedule for each deployed *WCV,* the proposed scheme employed an *ACO*-based metaheuristic algorithm. The working of the *ACO*-based optimal recharge scheduling algorithm is described as follows:

(i) **Initialization** In this phase, the proposed scheme selects a set of location points where *WCV* stay for a fixed charging time to wirelessly transmit power to recharge all sensor nodes located in the grid. Since each *WCV* stays at a particular point of each grid, a population set is randomly generated by selecting a random location point from each grid. Let a *WCV* needs to visit a set of *M* grid so a set of M stay points are randomly selected and need to devise a optimal visiting schedule for traversing theses stay point such that total traveling cost of *WCV* will be minimum. Each *WCV* is dispatched from the base station to visit each grid and recharge all sensor nodes located in each grid. Base station (BS) and a set of stay points (S_i) form a connected graph *G* where source node *BS* connects all destination points S_i. Each link between (BS, S_i) is initialized with a variable called pheromone trail ($\tau_{ij} = \tau_0$). The value of the pheromone trail can be read and updated by ants.

(ii) **Selection of visiting schedule for optimal recharging** In this phase, probability of each link (i, j) of the graph is calculated by using the following formula as given in [17, 18]. Here, N_i is set of neighboring stay points of the points i.

$$p_{ij} = \begin{cases} \frac{1}{d_{ij}} \times \frac{\tau_{ij}}{\sum_{j \in N_i} \tau_{ij}} & \text{if } j \in N_i \\ 0 & \text{otherwise} \end{cases} \tag{1}$$

After calculation of probability (p_{ij}) of each link, a sequence of stay points is selected based on their computed probability value. This sequence of stay points considers as a recharge schedule which starts from the base station and ends at the base station. After getting the recharge schedule, calculate its cost (C_s) by calculating total traveling distance by *WCV*.

(iii) **Pheromone Update** In this phase, after calculation of cost of the derived schedule, the value of pheromone trail (τ_{ij}) for each link is updated using the following formula which is given in [17, 18].

$$\tau_{ij}(t+1) = \rho \times \tau_{ij}(t) + \frac{q}{C_s(t)} \tag{2}$$

Here ρ is the evaporation rate whose value is between 0 and 1. Q is a constant and $C_s(t)$ is the cost of the derived schedule in t iteration. After updating the value of pheromone trail, Step (ii) and (iii) are repeated until we get an optimal cost schedule for *WCV*.

5 Result Analysis

This section presents the result analysis of the proposed scheme and compares its performance with the single *WCV-based* scheme. Implementation of the proposed scheme and the existing scheme are done using *MATLAB R2014*. In the experiments, this paper considers four *WCVs* for recharging tasks. Figure 2 illustrates traversing of each *WCV* for recharging the sensor nodes of each grid.

Figure 3 illustrates the result analysis of the proposed scheme (*CRS*) and compares its performance with the single *WCV*-based scheme in terms of charging latency by varying the speed of the *WCV*. It can be depicted from Fig. 3 that charging latency for the proposed scheme is significantly much lower than the existing scheme. This is due to the use of multiple WCV and derivation of optimal recharging schedule in the proposed scheme.

Figure 4 illustrates the result analysis of the proposed scheme (*CRS*) and its comparison with the single *WCV*-based scheme in terms of charging latency by varying the grid size from (10 × 10) to (60 × 60) within the network. It can be observed from Fig. 4 that charging latency for the proposed scheme is significantly much lower than the existing scheme. This is due to the use of multiple *WCV* and derivation of optimal recharging schedule in the proposed scheme.

Figure 5 illustrates the result analysis of the proposed scheme (*CRS*) and its comparison with the single *WCV*-based scheme in terms of charging latency by varying the number of stay points from 9 to 400 within the network. It can be

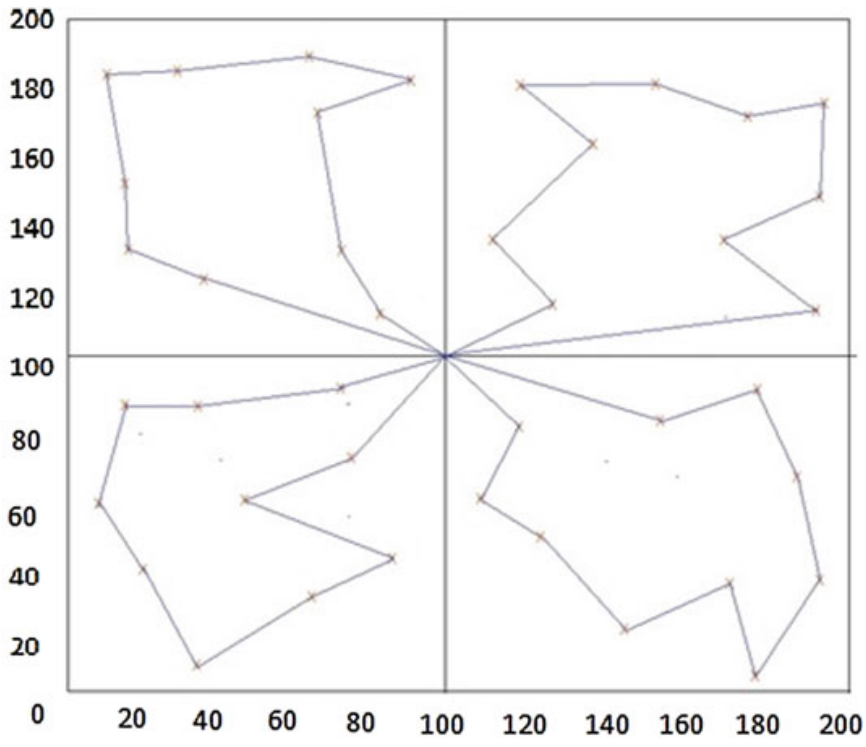

Fig. 2 Illustration of the traversal path of each *WCV* for recharging tasks

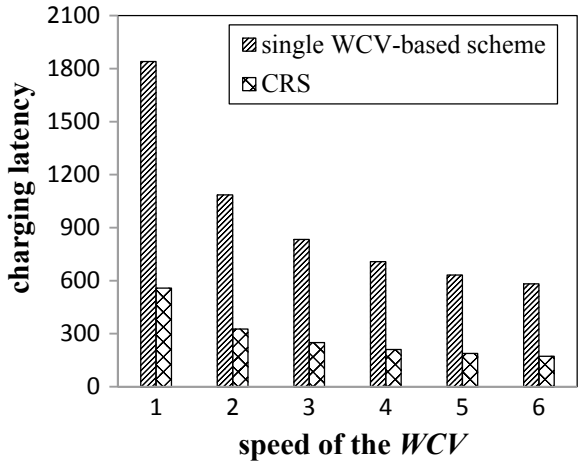

Fig. 3 Speed versus charging latency

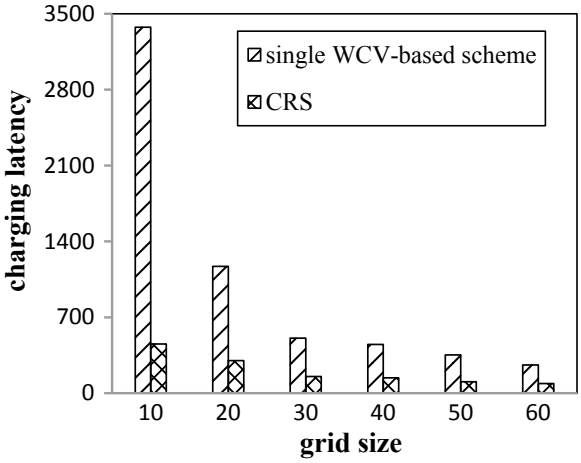

Fig. 4 Grid size versus charging latency

observed from Fig. 5 that as the number of stay points increases, the charging latency also increases. Charging latency for the proposed scheme is significantly much lower than the existing scheme. This is due to the use of multiple *WCV* and derivation of optimal recharging schedule in the proposed scheme.

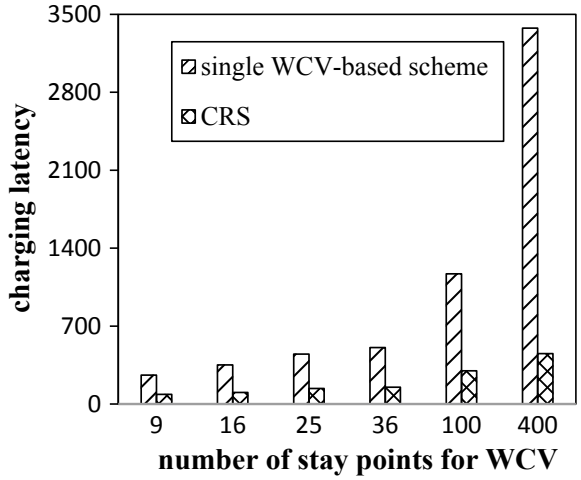

Fig. 5 Number of stay points versus charging latency

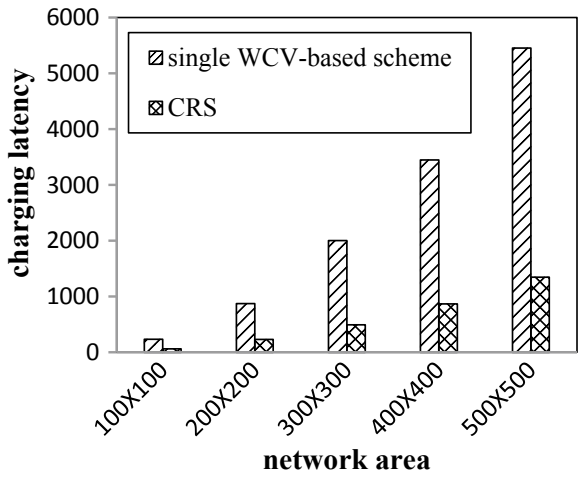

Fig. 6 Network area versus charging latency

Figure 6 illustrates the result analysis of the proposed scheme (*CRS*) and its comparison with the single *WCV*-based scheme in terms of charging latency by varying the size of the network area (100 × 100) to (500 × 500). It can be observed from Fig. 6 that as the size of the network area increases from (100 × 100) to (500 × 500), charging latency also increases. This is due to the fact that the total number of grids visited by a *WCV* also increases. Charging latency for the proposed scheme is significantly much lower than the existing scheme. This is due to the use of multiple WCV and derivation of optimal recharging schedule in the proposed scheme.

6 Conclusion

This paper proposed a coverage-aware recharge scheduling scheme for wireless charging vehicle where ACO-based metaheuristic algorithm is employed to determine the optimal schedule for each wireless charging vehicle. In order to reduce charging latency, the proposed scheme employs multiple charging vehicles that are dispatched by the base station concurrently. Simulation results and its analysis confirm that the proposed scheme performs significantly better than the existing scheme in terms of charging latency.

A Transition Model from Web of Things to Speech of Intelligent Things in a Smart Education System

Ambrose A. Azeta, Victor I. Azeta, Sanjay Misra and M. Ananya

Abstract Several terms have been used to describe Internet of Things; Web of Things (WoT) is a term which can be used interchangeability and it is referred to as the capability of devices to interconnect to the World Wide Web and sharing the information and data to one another. WoT has been mentioned in the literature to improve interconnection between devices at all times. In WoT, two different modes of communication which are generally mentioned in previous studies include person-to-thing (or thing-to-person) and thing-to-thing. This paper presents an architecture for transiting from WoT to speech-enabled WoT known as Speech of Intelligent Things (SoIT). The system employs a combination of technologies such as system design, server-side scripting, speech-based system tools, and data management in developing the SoIT prototype system as a third mode of communication. This paper illustrates a scenario whereby remote monitoring and controlling of WoT devices within the university campus might be difficult to manage by only using the modes discussed in the literature. An evolution of WoT to SoIT was realized using speech technology to provide a prototype system. Technical implications involve using a telephone by connecting an object telephone number (OTN) and dial WoT objects and establish a control mechanism. The research limitation is mainly the cost of dialing an OTN number. The contribution of this paper is to favor and encourage the use of speech technology to enhance the convenience of communication between WoT devices within the school campus.

Keywords e-Campus · OTN · Speech interface · SoIT · WoT

1 Introduction

Among the web technologies that are presently gaining attention in the research community is the Web of Things (WoT). Web of Things transforms the connection between millions of devices and smart devices and interactions with humans and one another. In WoT, sending and receiving of information exists between cloud and one another, with the possible aim of collection and analysis of huge amount of data accurately [1] suggesting that distinct approaches exist across a variety of technologies such as vehicles which are able to sense fatigue of the user and execute maintenance which is self-scheduled and provide dynamic analysis, execute, and inform the forecasted time of arrival of waiting passengers.

The literature has failed to discover that the concepts of WoT have been applied to e-Learning and school environment to enhance teaching and learning results thereby providing greater achievements than in other fields. In other words, educational institutions are a good place in which WoT can be researched [2].

There are two different modes of the interface in WoT usually discussed in the studies. Thing-to-person or person-to-thing in which there is an interaction between people and things and thing-to-thing in which day-to-day objects communicate with each other. In this research, it is envisaged that control and monitoring of WoT objects remotely might be burdensome with the use of two modes only. Some uncertainties do exist on how the WoT will be controlled and monitored. Some years ago, Internet Protocol Version 6 (IPv6) was developed to facilitate a high number of systems with a distinct IP address that aided the transmission and receiving of information [3]. The entire world seems to approach a global village where the exchange and sensing of data are done through the connection to different types of networks (private and public). Data is collected, processed, and used from time to time from the connected device to provide more information about the devices. This process provides intelligent data for control, plan, management, and decision-making.

A method has been proposed on how to control the WoT objects involving mobile telephony. This method involves dialing the Object Telephone Number (OTN) through the use of a mobile device and connection to any of the WoT objects, which will begin this mechanism. In this environment, different SoIT devices are assigned a value for OTN which is used instead of an IP address for communication among the devices. The communication occurs when an OTN value is dialed via a mobile device. A lot of objects and entities such as traditional office systems, educational programmes, vehicles, mobile devices, and students and staff residents can be replaced by an SoIT-based campus. When universities are compared to this system, universities consist of, accommodations, clinics, athletic facilities, health institutions, hospitals, offices, parking areas, classrooms, restaurants, and libraries [4].

With Speech of Internet Things (SoIT), wearable computer can be used by students to explore the points of the university transportation which can be done by dialing an OTN number, attend their classes online, perform online bank transactions, be up-to-date with the library transactions, in other words, check the availability of a book, be aware of the prices of food items in canteens, and order items in the storage. In an educational environment, a large portion of information needs is shared by students and staffs which include information regarding classrooms, schedules, locations, seminars, lab equipment, student residences, assignments, presentations, sports events, etc. This information is highly relevant and related to people and objects found in the institutional environment. When wireless technology such as WLAN (Wireless Local Area Network) is implemented in conjunction with SoIT platform, technologies, and smart devices, it helps to detect devices or places, thereby making this feasible for fulfilling information needed by the individuals in a typical learning atmosphere in an efficient and effective way [5].

A discussion is made regarding the provision of accommodation for students and staffs of the higher institution in Nigeria whereas higher educational institutions which can provide this facility have not yet implemented the required technology in various other units such as transportation, storage, commercial institutions, cafeterias, classrooms, hospitals and clinics, dormitories, library, etc. In other words, manual processing of transactions is still done in many units. Supervision of a human is needed to control objects such as electrical appliances used in homes and offices. Devices have no interconnection and remote manipulation between them. Mostly, learning takes place 40% online and 60% involves the presence of an individual and this illustrates that ICT and the Internet are not being used with their full capabilities for administration, management, learning, and teaching.

Institutions which have been able to provide adequate accommodation for the staff and students still have the problem of providing exact locations of students to the facility as well as the visiting parents. There are several students' engagement activities on campus. Students can be found in places within the campus such as the library for the borrowing of books, storage, cafeterias, banks, and lecture halls for lectures. They sometimes tend to go home for personal reasons. The availability of transportation services for students and staffs not fully on ground. The wide use of SoIT devices should be encouraged for different systems of the campus to work together for successful management and easy access for everyone by an electronic device (remote control) and manipulation of OTN devices. A framework of SoIT based on the above is proposed in [27]. In this paper, we are extending the SoIT framework by developing a real system with a prototype and implementing it on a system.

This paper has six sections. In Sect. 2, the related work is provided. Section three presents the SoIT framework. The fourth section discusses the potential advantages and disadvantages of using WoT/SoIT. In section five, the SoIT prototype and evaluation is presented while section six concludes the paper.

2 Related Work

A research was carried out in [6] which gives a summary of the difficulties faced in the areas such as reliability, security, mobility, and connectivity of WoT with the use of IPv6 to achieve Internet of Everything (IoE). The main challenges and solutions of IPv6 were also addressed. Some of the future works which discuss the emergence of IoE to make applications mobile, distributed, secure, and powerful. An example of such application is smarte cities which were also highlighted. The study in [7] discussed the necessity of business organizations to develop WoT and show the power of digitalization to entities for the creation of more business opportunities. The design and evaluation of the model are presented that will give researchers and industrialists to record, see, and analyze the current and future commercial areas in WoT.

An attempt is made by studies to give an account of the architecture of WoT. The research that was carried out in [8] introduces key enablers of WoT and gives details of the main components of WoT such as the concept of machine-to-machine (M2M), portability and mobility of devices, protocols for communication that are appropriate for the WoT environment. It also discussed the difficulties faced in WoT. A prototype of navigation-based solutions for WoT and an architectural framework of WoT were also mentioned. In [9], an architecture and cloud-centric vision are given for WoT implementation. This study presented major technological development and applications which will make research in WoT feasible in the future. The authors in [10] showed the perception of the future by Rambus. As the number of devices is increasing dramatically and connection to the Internet is possible, the world is deviating from a PC-based model and going toward interconnected systems.

3 The SoIT Architecture

The SoIT system signifies a vision by which the Internet interconnects on a daily basis using OTN. Physical entities are now connected to the virtual world which can serve as access points to Internet service and can be managed from a distance by phone calls. SoIT is a ubiquitous computing platform with a lot of possibilities for the advancement in society. Despite the numerous benefits, there are a lot of technical challenges and risks. SoIT can only continue to grow if the technological advances in the information and communication area are seen in the upcoming years. Due to the creation of smaller versions of technological devices, reduction in energy consumption and price devices can easily be adapted to daily lives. Smart devices play an important role in SoIT because information and communication technology are causing radical changes in the world [11].

According to authors of [12], smart campus comprises other smart components such as smart technology, lecturers, students, and environment. The framework by Abuelyaman needs a smart campus to contain a smart cafe, smart storage, smart residential areas, smart commercial banks, smart lecture rooms, smart hospitals and clinics, smart transportation, smart devices such as smartphones, tablets, laptops, etc. In SoIT, sensors interact with one another automatically and provide real-time response rather than interacting with humans only. Local area networks (LAN) will be used to mitigate physical devices. In WoT, each device will possess a unique IP address in IPv6 format only whereas in SoIT in addition to the IP address, the device will also have the OTN address.

The phone of the user would keep track of the physical and mental requirements of states through the interconnection of the components which contains the main system. Similarly, the complete set used at the higher institution may make efficient use of resources by sharing and distributing the resources with other components [13]. For example, during the arrival and departure from home, an automation system can control the front porch light according to the needs of the user [14]. Figure 1 shows the SoIT framework for a smart campus. Objects have been placed in a circular manner from 1 to N. Every object has a sensor attached and all of them (sensors) are interconnected to each other by wireless sensor network (WSN). This will aim to detect the transmission signals from the neighboring sensors which form the network. WSN which works for information and communication is also called revolutionary collection method. These sensors enhance the effectiveness and improve the efficiency of the architecture for a smart campus [15].

In SoIT, all the objects have an OTN value on every node in the network. Message transmission between users can be connected simply by calling an OTN for a particular system, for example, staff can call the OTN of a commercial bank to

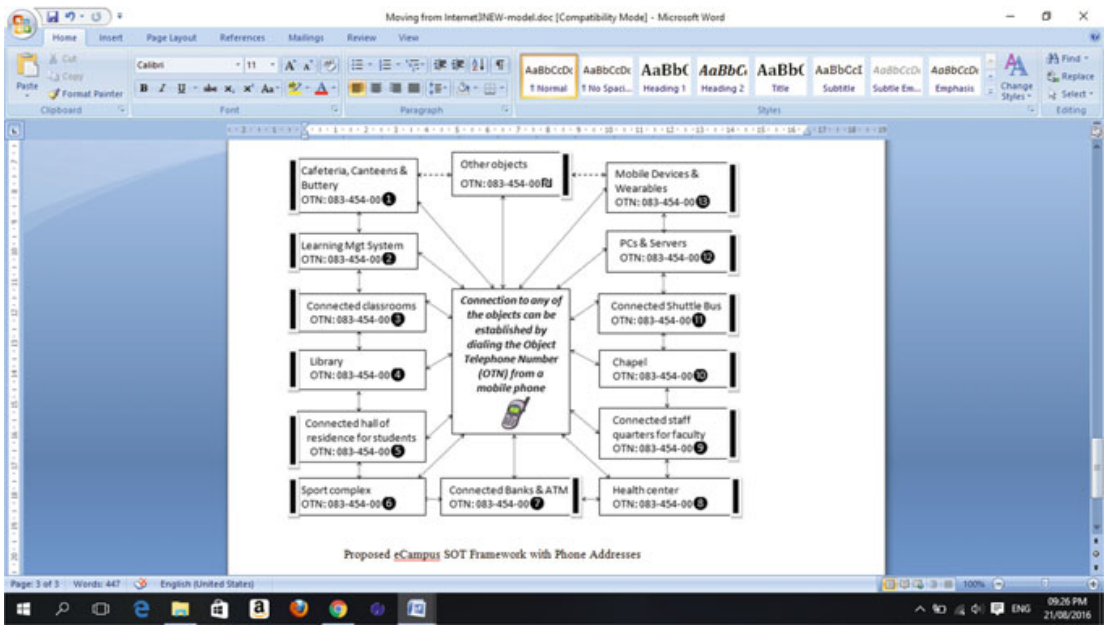

Fig. 1 The SoIT framework for smart campus

perform certain transactions such as checking the bank balance of the account. The student may want to check resources in the library or lecturers might want to connect with the students for giving lectures, answer questions, or make discussions on a particular topic. All these activities can be made possible when objects are interconnected to each other using the SoIT framework.

4 SoIT Prototype and Evaluation

In order to understand the SoIT concept, a simple prototype speech-based application was developed and deployed using VoiceXML [21] for speech interface, PHP for server side, and MySQL for the database. A database with a field named power status was created and assigned the value 1 to put off the computer system, and 0 to restart the computer system. This system allows a user to dial a phone number as an OTN address that is mapped to an object. The system responds through speech interface by saying say 1 to put off or 0 to restart the computer system. Once a 1 is selected, the computer will shut down. The web interface uses an auto-refresh command that constantly checks for the value in the database field of the power status button. The web interface of the system is shown in Fig. 2.

When OTN is dialed from a mobile phone, the system will say "Welcome to shutdown utility", and request for authentication information from the user. After successful authentication, the user responds to the system request by saying 1 or 0. A 1 will shut down the system, and a 0 will restart the system. In experimenting

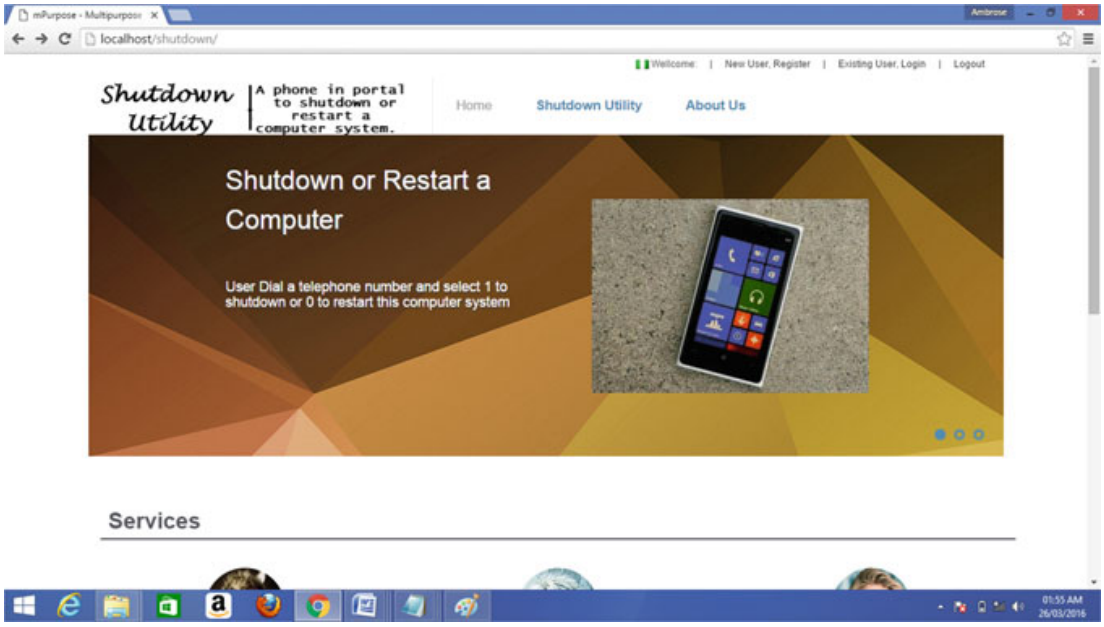

Fig. 2 The web interface. *Source* The researchers

with SoIT with respect to architectural considerations, hardware, software, and deployment requirements, the design and implementation testbed in [22] may be considered.

Typical Scenario

The call sequence in Fig. 3 exemplifies the interaction of the user with the system.

A prototype for an application called VoiceXML (speech user interface) is developed for the web application on a Voxeo voice server and can be retrieved from a mobile phone and as well as in fixed phone-line connections by adopting the following structure: <source country int. dial out #><destination country code><destination area code><generated voice network 7 digit #> [23].

A cognitive method called Cognitive Walkthrough Strategy was developed by Rieman and Redmiles [24]. Cognitive Walkthrough Strategy [24] makes use of one or a group of evaluators which are responsible for checking the user interface by following a certain number of tasks, making learning easy, and accessing the system's understandability.

A questionnaire was developed and used as a survey instrument. Twenty questionnaires were distributed to the users and we got responses from 16. The received responses were analyzed and reported, and the results were presented. We use a five-point Likert scale for our study and analysis (1 = strongly disagree and 5 = strongly agree). The findings show good usability of 4 as the mean rating on a 1–5 scale.

User : Dial OTN address 083-454-0012 to access a computer
System: Wellcome to Shutdown Utility.
What is your userid?
User : My userid is kane.
System: What is your pin?
User : My pin is 4109
(System search the database to authenticate the userid and pin)
System: Say 1 to Shutdown your PC, or
Say 0 to Restart your PC.
User : 1
(System process the input value 1 and initiates a shutdown process)
System: Please save your work and shutdown, the system will go off in 1 minute!!

5 Advantages and Disadvantages of Using SoIT and WoT

WoT and SoIT have numerous unlimited benefits. WoT systems can make our lives better by conservation of resources, the creation of new opportunities, innovation, and improvement of knowledge [16]. In [17], the authors have explained that WoT is developed to improve connections among devices by using WSN everywhere at a given time. WoT is presently being used positively by some business organizations. Users of business organizations can utilize the services of WoT for data analytics to generate more revenue, monitor the activities and assets, modify new business models, and develop an operational performance for innovation [18].

However, among several obstacles and hindrances of WoT security is one of the areas that prevents WoT from gaining its actual potential. The connection of hundreds of billions of devices gives a serious concern regarding the issue of security. Business owners and stakeholders need to take this issue into consideration for WoT to develop and overcome these obstacles [19]. Other major discoveries in [20] regarding WoT are given below.

- The connection between Secure Socket Layer (SSL) connections with cloud in 19% of mobile applications which are used for the control of WoT devices
- No provision of authentication between client and server in the devices
- Some devices lacked strong password and enforcement strategies
- Some WoT cloud interfaces were not compatible with two-factor authentication (2FA)
- Lack of lock-out or delaying measures against brute-force attacks in some WoT services which hindered the protection of user accounts
- Some devices were not protected from account harvesting mechanism
- Many WoT cloud platforms such as web applications were exposed
- No provision of encrypted firmware updates by majorly all WoT services
- Shortage of IP addresses.

SoIT and WoT and Smart Campus

The basic idea of IoT is the pervasive presence around us of a variety of things or objects connected via enabling technologies such as Radio-Frequency IDentification (RFID) tags, sensors, actuators, and mobile phones, which through unique addressing schemes, can interact with each other and cooperate with their neighbors to reach common goals [33]. WoT includes the interconnection of devices and smart campus includes different smaller systems to interact with other systems to make the bigger system work.

Spoken dialog system has become very popular in the industry with the advent of continuous speaker-independent speech recognition technology over the last few years [28–30]. Speech technology is now combined with human spoken language capabilities to boost learning in students and to make communication between human and computers easier [31, 32]. This incorporation between spoken language and speech technology will make it possible for machines to take over the trivial tasks performed by humans. Intelligent things, on the other hand, will be able to

perform communication among humans and devices and choose the appropriate decision for any situation. Since smart campus consists of smart devices, addition of speech technology will make the device smarter. Current research claims that SoIT and WoT are being seen to work together for a better communication environment.

6 Conclusion

In this paper, a review of WoT and the ability to develop SoIT in a school environment was presented. The office or home appliances, and SoIT devices may be developed which will respond by calling on an OTN address when called by any telephone, cell phone, or mobile. This study has contributed to the area of transiting from WoT to SoIT. WoT is an emerging area of research and scientists are working worldwide by utilizing speech for monitoring systems in the WoT environment which will sharpen the technology and realize the expectation of a smart academic institution system.

With SoIT, students are able to dial an OTN address of a cafeteria and order for food, dial an OTN address of a classroom and receive lecture remotely while in the dormitory. Lecturers and students are able to dial the OTN address of any bank within the school premises and check balance, and also transfer money online. Campus shuttle bus service can be called by dialing the corresponding OTN number. The university library service and health centre can be linked by dialing the corresponding OTN address to ascertain the availability of a certain book and pharmaceutical drugs, respectively. In the case of home appliances, a user may forget to power off a television, fridge, or electric bulbs or any electrical home appliances when leaving home for work; all he needs do is dial the OTN address of the object and say shutdown to power off the system.

Dramatically, changes in information and communication technology also affected the style of education and the choice of students. Thus, a smart campus can be realized by making all the facilities in its jurisdiction smart. Educational institutions are some of the key centers in a smart city, which play an important role in preparing students for tomorrow [25]. In a smart academic environment, worldwide educational resources are shared to all faculty and students, and this will make the academic life of students and staffs easier, comfortable, and attractive. These potentials will be fully realized when IP for everyone in the case of IoT [26] changes to OTN for everyone in the case of SoIT.

Intrusion Detection and Prevention Systems: An Updated Review

Nureni Ayofe Azeez, Taiwo Mayowa Bada, Sanjay Misra, Adewole Adewumi, Charles Van der Vyver and Ravin Ahuja

Abstract The evolution of Information Technology (IT), cutting across several divides in our daily endeavors allows us to interact with all forms of data at different OSI model layers from application to physical. These data are susceptible to intrusion, aimed at compromising its integrity; thus, the need to protect these data, maintain its integrity, confidentiality, and availability cannot be overemphasized. Intrusion Detection and Prevention System (IDPS) is a device or software application designed to monitor a network or system. It detects vulnerabilities, reports malicious activities, and enacts preventive measures to keep up with the advancement of computer-related crimes using several response techniques. This paper presents an updated review on IDPSs given the fact that the most recent review found on the subject was done in 2016. It will also discuss the use of IDPSs to identify vulnerabilities in various channels through which data is accessed on a network or system and prevention mechanisms applied to mitigate against intrusion.

1 Introduction

During 1984 and 1986, more research on intrusion detection system was done by several researchers. James P. Anderson's [1] presented a research on Intrusion Detection System (IDS). In the mid-1990s, IDS products were first commercialized by two companies, Internet Security System Inc (ISS) and Wheelgroup. They designed a network-based IDS called RealSecure and Netranger, respectively. ISS Inc. released the first version of RealSecure 1.0 for Windows NT 4.0. RealSecure used a knowledge base by matching signatures, however, it was ineffective for new attacks which became a major setback. Wheelgroup's Netranger was a known network-based IDS back in 1995; it functioned by scanning network traffic. Wheelgroup was acquired in by Cisco in February 1998; today, it forms an intrinsic part of Cisco's security.

Many researchers identified the setback in using the knowledge-based technique of matching signatures because it required continuous update of the database to recognize new attacks; more so, network and packet switching began to rise to a high speed from megabits to gigabits per sec. This was a major challenge as it became more difficult to scan through, analyze traffic, and detect attacks in real-time; thus, researchers were burdened with designing an IDS fit for high-speed networks. This led to the invention of host-based IDS, for example, TCP Wrappers, Tripwire, and Snort which provided analysis of system logs in real time. Snort is a free IDS tool, known for its multi-functionality as a network-based and host-based IDS. It was first released by Marty Roesch on December 22,1998 for UNIX systems; later in 1999, a version of Snort (version 1.5) was released; it was effective in analyzing and logging packets in real-time; it was later modified for Windows system by Michael Davis in the year 2000 [2].

Today, as the functionality of IDS advances, attackers now explore means of detecting, bypassing, and disabling IDS before penetrating the infrastructure, resulting in denial of service (DoS). Security experts aim to curb these attacks by using Intrusion Detection and Prevention System (IDPS) architectures which are not visible to attackers by restricting communication permitted among various security components on a network. Due to the gradually increasing number of vulnerabilities, the identification of attack is essential. To this end, a number of reviews have been done on IDPSs in the literature [3] with the most recent one being [4] which was conducted in 2016. A lot has happened since that period that is worthy of reporting. For instance, it was in 2016 that the biggest DDoS attacks powered by a Botnet [5] were recorded. An example is Mirai, a Botnet primarily composed of infected routers and security cameras, low-powered and poorly secured devices which caused a lot of major DDoS attacks [6].

Internet attacks thus must be defined to measure security. Also, in recent times, infrastructure has evolved from a network of systems, private cloud infrastructure to the Internet of Things (IoT) offering several cloud-based services and solutions. While this has provided limitless opportunities on the choice of where to store data, the risk that accompanies these opportunities is also considered enormous because

these data can be compromised via several intrusion methods irrespective of the platform on which the data is stored [7].

2 Motivation

Intrusion is a criminal act committed against an information system, e.g., computer system, network or web infrastructure, such that security on the system is breached or compromised thereby putting it in an insecure state which allows for unauthorized access to the data being hosted by the system. This is done either by bypassing, disabling or exploring vulnerabilities on the system, typically leaving traces which can be discovered by the intrusion detection system.

The most recent review [4] focused majorly on network intrusion detection systems. The elements of security here are basically availability, accuracy, access control, confidentiality, integrity, and identification [8]. Intrusive attacks can be classified into passive [9] and active [5] attacks. An attack is classified as active when data is being altered with the intent to corrupt, destroy the data or the entire network hosting the data [5, 10]. An example of an active attack is interruption. This can include Denial of Service (DoS) [9], Distributed Denial of Service (DDoS) [6], SQL Injection [11], fabrication, replay attack [9], masquerading [12], and modification [5]. Some examples of passive attacks include traffic analysis [9], sniffing [5], and keyloggers [13]. The drawback of the study includes the fact that it mentioned but did not show the classification of intrusion detection systems. Also, network IDPS are known to identify abnormal behavior in network nodes only after the damage has been done to network resources [14]. Furthermore, with the increasing growth of the Web—a global network—network intrusion detection systems are limited in capacity at detecting anomalies on the web.

Newer models comprising a combination of machine learning techniques are being applied to combat attacks on the Web [15]. Some of the models also respond to security threats by detecting various malware intrusions and protocol authentication based on human behavior.

In addition, IDPSs are also being developed for cloud-based environments/systems; hence, the deployment of distributed IDPSs in cloud systems raises many challenges due to the diversity of its services and the complexity of its infrastructure.

3 Intrusion Detection and Prevention Systems

Security systems are designed in practice, to detect, identify and respond to malicious attacks against, a computing system, network or in general, information systems. These attacks are aimed at undermining the integrity of these systems,

steal information and in some cases cause damage to the systems thereby making the system unavailable.

IDS is either a software or hardware that automates intrusion detection, monitors network traffic for suspicious activities, and sends notifications to an administrator [7]. Intrusion Prevention System (IPS) is a software or hardware that prevents an intruder from gaining access to a network, let alone attack a network [16].

Today, security experts are trending with security appliance combining both intrusion detection and prevention capabilities which identify, log possible incidents, prevent attack, and send report to an administrator [16, 17]. Intrusion Detection and Prevention Systems (IDPS) ensures that the protection, availability, integrity, and confidentiality of information systems are guaranteed.

IDPS has become important when putting the security of information systems into context, preserving data, protecting data from unauthorized access or theft, and ensuring continuous availability of services that these information systems provide. Until recently, attackers' focus was on bank customers, where accounts were raided through fraudulent acquisition of personal details either by sending phishing emails or keyloggers, and credit cards were stolen [18].

3.1 Classification of Intrusion Detection and Prevention Systems

IDPS can be classified based on the following criteria [19]:

1. **Type of Intruder**: This is either external or internal. An external intruder is one who does not have any form of access to a network or service, while an internal extruder is one who has authorized access to a network but has restricted permissions on the network.
2. **Type of Intrusion**: There are various types of intrusions which are discussed in chapter two.
3. **Detection Technique**: Three different types of techniques are normally adopted for intrusion detection, misuse detection, anomaly detection, and stateful protocol analysis [20].

    - **Misuse Detection**: It is a signature-based detection method which matches intruder attack patterns, represented by signatures against a knowledge base of known exploit on software and system vulnerabilities. Signature-based detection analyzes and identifies specific patterns of events or behavior that portray an attack using either static, dynamic or hybrid approach. The static approach in misuse detection analyzes intrusion activities against a program and its code before execution. Dynamic approach analyzes attack patterns during or after the execution of a program while hybrid combines both static and dynamic approach to detect malicious attacks [21].

- **Anomaly-Based Detection**: It is a behaviur-based detection technique which gets its input from audit logs generated from the operating system. This type of technique looks for variations in behavior which might indicate masquerading. Anomaly-based detection uses profiles created through monitoring the behavior of typical activity or models of intended behavior of users and applications over a period. It analyzes malicious attacks by using these profiles which represent the normal behavior of users, hosts, network connections, or applications against profiles of monitored activities; any deviation from the norm is triggered via an alert system [21].
- **Stateful Protocol Analysis**: Stateful [22] protocol analysis detects changes of protocol state. Unlike the anomaly detection method, this adopts predetermined universal profiles created based on accepted definitions of protocol behavior created by vendors and industry leaders [23].
- **Rule-based**: This involves making decisions based on rule sets which are defined by domain experts. They can detect known attacks but are incapable of detecting novel attacks. Also, with increase in network traffic, finding and coding rule sets is both difficult and time-consuming.
- **Supervised Machine Learning (ML)**: It does not require model building as in the case of anomaly-based detection. Rather it is able to learn complex malicious and normal models.
- **Unsupervised Machine Learning**: An example is clustering-based IDPS. This approach to intrusion detection involves building models with unlabeled data; however, their performance is not as good as the supervised models (Table 1).

3.2 Types of Intrusion Detection and Prevention Systems (IDPS)

IDPS will be discussed based on the way they are deployed and the type of activities they monitor [16].

- Network-Based Intrusion Detection and Prevention System (NIDPS)
- Wireless Intrusion Detection and Prevention System (WIDPS)
- Network Behavior Analysis (NBA)
- Host-Based Intrusion Detection and Prevention System (HIDPS)

3.2.1 Network-Based IDPS

Network-Based IDPS (NIDPS) technology is designed to analyze packets at the network, transport, and application layer of the Open System Interconnection (OSI) model. NIDPS is most efficient when deployed within a network

Table 1 Advantages and disadvantages of intrusion detection techniques

Detection techniques	Advantages	Disadvantages
Signature-based detection	Effective and simple method of detecting known attacks since it uses signatures of known attacks	Cannot track unknown attacks and variants of known attacks
	Analyzes and identifies attacks by matching malicious signatures against known knowledge base	Attackers can make adjustment to attacks to avoid matching known attack signature
	Detection accuracy for known attacks is high	Requires continuous update of signatures or patterns
	Low computational cost	Newer attack signatures may not be in the signature database
	Rate of false alarm is very low	Detect only the attacks for which they are configured
Anomaly-based detection	Ability to detect and reduce the false alarm rate of unknown attacks	Detection accuracy is based on the amount of collected behavior or features
	Can detect new and unforeseen vulnerabilities	Well-known attacks may not be detected if they fit established a profile
	Dependency on the operating system is minimal and it is able to detect privilege abuse	Intruder can change profile slowly over a period
	Uses statistical test on collected behavior to identify intrusion	Configuring profiles is time-consuming
	No need for priori knowledge of security flaws	Less effective in the dynamic environment due to constant changes in monitored events
	System can also detect attacks from inside a network	
Stateful analysis	Adds stateful characteristics to regular protocol analysis	Resource intensive for protocol state tracing and analysis
	Distinguishes unexpected sequences of commands	Cannot detect attacks that do not violate the characteristics of generally accepted protocol behavior
	Identifies unexpected sequences of commands	
Rule-based	Can easily detect known attacks	Unable to detect unknown attacks
		Finding and coding rule sets is both difficult and time wasting
Supervised ML	Ability to learn complex and malicious models	They are hardly ever used in a real-world scenario owing to the fact that they require sufficient supply of labeled branding data
		Training data is labeled by domain experts which is both costly and time-consuming
Unsupervised ML	Works with unlabeled data on domain specialist may not be required	Performance is not as good as supervised ML

infrastructure with a specific design where it is able to monitor and analyze real-time packets for intrusion and take a decision on any suspicious activity. While NIDPS is effective in analyzing and detecting suspicious network packets in real time, it cannot analyze encrypted traffic, traffic over Virtual Private Network connection (VPN), SSH or HTTPS sessions, and traffic on mobile computing networks [17].

NIDPS has broad intrusion detection capabilities. An example of an NIDPS is KEMP Loadmaster which can detect intrusion and prevent intrusion by shutting down the device.

3.2.2 Wireless IDPS

WIDPS is a variant of NIDPS which monitors and analyzes packets and protocols on a wireless network. Despite its ability to analyze network traffic, WIDPS cannot detect abnormal activities within an application [17].

Advantages

- It is effective for monitoring and analyzing intrusion on a wireless network.
- WIDPS can identify various problematic issues like policy violations and mis-configurations at the WLAN protocol level.

Disadvantages

- It is vulnerable to DoS attacks.
- It cannot monitor and analyze packets on transport layer, network layer, and application layer.
- It is susceptible to evasion technique when an intruder attacks channels that are not currently monitored.

3.2.3 Network Behavior Analysis (NBA)

NBA is also a variant of NIDPS with the ability to monitor and analyze network traffic to detect unusual activities that may emanate from violation of policy, DDoS attacks or malware intrusion [17].

Advantages

- It is effective in detecting DoS attacks.
- It is effective for monitoring packets on transport, network application TCP/IP layer, etc.
- It can monitor and detect threats caused by malware, policy violation, and DDoS.

Disadvantages

- Packets are analyzed in batches, thus delaying the rate of intrusion detection.

3.2.4 Host-Based IDPS

Host-Based IDPS technology is designed for Application level and Operating System intrusion detection and prevention by monitoring the events on a single host on which it is installed. Aside from having the capability of monitoring and analyzing network traffic, HIDPS can analyze system-specific settings such as software calls, local security policy, and audits logs within the host for suspicious activities. HIDPS functionality can be divided into four categories [17]:

- **File System Monitoring**: Every system has a file system to detect and prevent intrusion; HIDPS monitors file systems regularly by checking variations in files size and file content against a known knowledge base. Whenever a system or user file shows a significant deviation, an alert is triggered which sends a notification to an administrator, indicating the detected intrusion and the action taken to prevent access or damage to the file [23].
- **Log File Analysis**: System events are generally logged in a file. These files (event logs) are analyzed constantly by HIDPS for changes or abnormal activities; a typical event log changes in the login information.
- **Connection Analysis**: HIDPS monitors and analyzes network packets (TCP/IP) for suspicious activities such as the ratio or sequence of TCP/IP connections on the host on which it is installed [24].
- **Kernel-Based HIDPS**: The kernel is provided with extra security capability which allows it to identify and prevent intruder activities itself.

Advantages

- It can detect intrusions on host applications, operating system, and network layer traffic.
- It can monitor and analyze suspicious activity on encrypted communication.
- It can detect intrusion on host systems by monitoring its file system, file access, system calls, etc.
- It does not require additional hardware since it is deployed on the host system.
- It can detect misuse of profile because it interacts with the user, as well as server installed application.
- It can prevent intrusion at the system level and detect attacks which NIDPS cannot detect.

Disadvantages

- It does not use a predefined database, therefore, detection accuracy is limited.
- Its uses more host resources, therefore, impacting on the system host performance.
- It must be deployed on each host which is expected to monitor.
- Its monitoring is restricted to the host on which it is deployed.
- There is a possibility of conflict with preexisting security configuration.

4 IDPS, Design, and Architecture

Information systems today have become a target for hackers whose only aim is to undermine the integrity, availability, and confidentiality of data. Therefore, proper design consideration must be put in place when designing an IDPS to increase its capacity to detect a threat and prevent it from gaining access to an information system. In designing an IDPS, the following must be considered [25].

4.1 Speed and Accuracy

These are highly desirable features. The sensitivity of an IDPS in terms of its speed and accuracy determines the rate of false negatives and false positives reported by the system. If the sensitivity of an IDPS is too low, it will have a high rate of false negative where intrusive activities are not detected, thus, no alert is triggered. Whereas if the sensitivity of an IDPS is too high, there is a high tendency of reporting false positives where an alarm is triggered for nonintrusive activities. False negatives and false positives can be triggered by several factors discussed below [26].

Causes of False-Negative Alerts:

- Improper spanning of switch ports which can cause network traffic to overwhelm the switch which can contribute to events with false-negative triggers.
- Flaws in the design of encrypted traffic which are usually not clear to the IDPS.
- A poorly written signature which does not have the capacity to detect an attack even though the attack is known.
- Improper communication of change management on network and server infrastructure to the information security team.
- Intrusive attacks caused by unpublicized or new attacks thus making it invisible to existing signatures.

Causes of False-Positive Alerts:

- A reactionary traffic alarm caused by equipment failure can trigger a false positive alert. For example, an ICMP flood caused by unreachable destination can trigger a false positive alert.
- An equipment-related alarm, e.g., a load balancer can trigger an alert generated from unrecognized packets from the equipment itself.
- A poorly written client software can trigger alerts of policy violation, e.g., alerts triggered by software bugs.
- Alerts triggered by unmalicious events.

4.2 Logging Capabilities

The logging capability of an IDPS is also very important because it facilitates its ability, identifies, detects, and reports malicious activities. The following are the logging capabilities to consider when designing an IDPS:

- IDPS must be able to log time stamps which include the date and time the malicious activity occurred.
- IDPS must be able to log connection ID, usually a unique number assigned to a session or a TCP connection.
- IDPS must effectively log an alarm type, set its severity rating, impact, and the priority of attack.
- IDPS must have the capacity to analyze protocols like TCP, UDP, ICMP at the network, application, and transport layer.
- IDPS must be able to identify the source and destination IP of connections and determine the number of bytes transmitted over the connection.
- IDPS must effectively understand the characteristics of application request and responses.

4.3 Information Gathering Capabilities

For an IDPS to be effective in detecting and preventing malicious activities on an information system, it must be able to gather information about the system upon which it is deployed.

- IDPS must be able to gather information on host profiles which include host IP and their corresponding MAC address.
- Ability to determine the OS version to enable it to determine the type of vulnerability it is susceptible to.
- Ability to identify network characteristic by gathering information on changes in network configuration.

4.4 Architecture of IDPS

Depending on the expected outcome, IDPS can be deployed using the following architecture [20]:

- Centralized: This architecture collects data centrally, sends it to a single location for analysis. Data collection is either from a single host or from several hosts.

- Hierarchical: This architecture collects data from several hosts which are analyzed according to the layers of the deployed IDPS.
- Distributed: This architecture collects data host by host and it is analyzed.

5 Conclusion

Security threats and incidents have evolved and pose a great challenge to information systems; thus, the importance of deploying an IDPS cannot be overemphasized and efforts to create more security techniques must continue to ensure that the integrity, originality, and confidentiality of information systems is guaranteed, thus making it accessible to everyone when the need arises.

IDPS in its various forms according to Chap. 3 is essentially beneficial in that it has the capacity to identify and detect vulnerabilities and prevent all forms of intrusion discussed in Chap. 2. However, consideration must be given to the type of deployment method to get the best of IDPS.

Furthermore, IDPS has extensive logging capacity which makes it effective in intrusion detection, most especially against signatures of various attacks against network systems; this has made a necessity for enterprise environment to protect data, as data sharing of all sorts has evolved to a global trend.

Lastly, when multiple IDPS technologies are combined into a single protection solution, it reduces management costs considerably because IDPS engages several techniques in intrusion detection and prevention; thus when developing a security strategy, it is important that it is comprehensive to stay ahead of the next threat.

Simulation-Based Performance Analysis of Location-Based Opportunistic Routing Protocols in Underwater Sensor Networks Having Communication Voids

Sonali John, Varun G. Menon and Anand Nayyar

Abstract Recently, Underwater Wireless Sensor Networks (UWSNs) have emerged as a prominent research area in the networking domain due to their wide range of applications in submarine tracking, disaster detection, oceanographic data collection, pollution detection, and underwater surveillance. With its unique characteristics like continuous movement of sensor nodes, limitations in bandwidth and high utilization of energy, efficient routing and data transfer in UWSNs have remained a challenging task for researchers. Almost all the protocols proposed for terrestrial sensor networks are inefficient and do not perform well in an underwater environment. Recently Location-Based Opportunistic Routing Protocols have been observed to perform well in UWSN environments. But it is also observed that these protocols suffer from performance degradation in UWSN networks with communication voids. The objective of this research paper is to discuss the working of major Location-Based Opportunistic Routing Protocols in UWSNs with communication voids and to highlight their issues and drawbacks. We analyzed the Quality of Service parameters, packet delivery ratio, end-to-nd delay, throughput, and energy efficiency of two major Location-Based Opportunistic Routing Protocols, i.e., Vector-Based Forwarding (VBF) and Hop-by-Hop VBF (HH-VBF) in UWSNs with communication voids using NS-2 simulator with Aqua-Sim extension. Simulation results state that both VBF and HH-VBF protocols suffered from performance degradations in UWSNs with communication voids. In addition to this, the paper also highlights open issues for UWSN to assist researchers in designing efficient routing protocols for UWSNs having multiple communication voids.

1 Introduction

Recently, Underwater Wireless Sensor Networks (UWSNs) [1, 2] have emerged as a prominent research area in the networking domain. The increasing interest in applying sensor networks into the underwater environment has found numerous applications in civilian and military fields such as coastline surveillance, pollution detection, and underwater surveillance. In UWSNs, a group of sensors is placed at different depths in the ocean to gather information. This collected information is then forwarded to the target devices positioned at the surface via a network of intermediate nodes. The data is then stored, processed, and passed to different applications for appropriate utilization. As radio signals have many limitations due to its mediocre propagation through water, the acoustic medium is used between the sensor nodes in UWSNs [3]. Most of the applications are highly sensitive and their success relies on the accuracy of the collected data. Many recent applications of underwater sensor network ranging from aquaculture to the oil industry, instrument monitoring, climate recording, natural disturbances prediction, and study of marine culture depend heavily on the accuracy of the collected data. Thus, efficient routing and data transfer among the nodes is vital in UWSNs.

Routing and data transfer from the sender to the sink stations, through the network, have been a tough task for researchers. Incessant movement of the nodes placed in the water due to the difference in the ocean environment and ocean currents is a major challenge. Limitations in bandwidth, frequent link interruptions, increased delay of data transfer, interference caused by marine mammals, etc., are some of the other elements influencing the efficiency of routing in UWSNs [4, 5]. Due to these unique characteristics, almost all the protocols drafted for conventional sensor networks do not perform well in UWSNs [6]. Recently, Opportunistic Routing Protocols (ORPs) [7–10] have found to give better performance in data transfer in UWSNs. The major advantage of this routing strategy is that it dynamically selects one best forwarder device from a group of candidate devices. This selection is based on the present scenario of the network, which leads to better performance of this latest category of protocols. Many ORPs have been designed for ad hoc, terrestrial sensor, and UWSNs [11–16]. Among all categories in opportunistic routing, Location-Based Opportunistic Routing Protocols (LBORPs) has found to give better performance. LBORPs make use of the knowledge on the present location of the devices to dynamically route message packets from the sender to the target. A few Location-Based ORPs have been efficiently used for data forwarding in UWSNs [17–23].

Communication holes or voids have been a major problem in most of the dynamic sensor networks. Often defined as the unreachability problem, the source node suffers from lack of adequate forwarder nodes in its transmission range. Frequent movement of sensor nodes in underwater increases this problem further. Limited research has been performed to determine the working and performance of LBORPs in UWSNs with communication voids [24–27]. In large UWSNs with a limited number of sensors, it is very significant to have a protocol that can handle

communication voids efficiently. In this article, we analyze the working and performance of two major LBORPs in UWSNs with communication holes. Vector-Based Forwarding (VBF) [21] and Hop-by-Hop VBF (HH-VBF) [20, 28] have been used by many applications for data transfer in UWSNs. VBF is an LBORP that constructs a virtual vector pipe between the sender and the sink node for routing. Only the devices within the virtual vector are selected for forwarding the data packet. Extending the VBF protocol, the HH-VBF protocol makes use of different virtual pipes for each node and the direction of the virtual pipe changes during the entire time of transmission.

Objectives of this research paper are

- To study the functioning of major LBORPs designed for UWSNs and to determine their issues and drawbacks.
- To analyze the simulation-based performance comparison of VBF and HH-VBF protocols in UWSNs with communication voids on parameters—PDR, throughput, end-to-end delay, and energy efficiency.
- And, to discuss the issues, challenges, and future directions in UWSNs routing research.

This research article is structured as follows. Functioning of the major Location-Based ORPs in UWSNs is discussed in detail in Sect. 2. The section also discusses the issues and drawbacks with these protocols. Section 3 describes the working of VBF and HH-VBF in a comprehensive manner. Section 4 presents the simulation-based analysis of VBF and HH-VBF protocols in UWSNs having communication voids using NS2 + Aqua-Sim simulator. Section 5 enlists open issues and challenges of existing ORPs in UWSNs. The paper concludes in Sect. 6 with future research directions.

2 Literature Survey

This section examines the functioning of some of the major LBORPs proposed for UWSNs. One of the most accepted protocols in UWSNs is Vector-Based Forwarding (VBF) [21]. VBF uses the details on the present position of the sensor devices for routing the information packets. In VBF, within a fixed virtual pipe the information packets are forwarded between the source and destination devices. These information packets are then transmitted along the redundant paths and thereby remain stable against packet loss. The major limitation with VBF is that the construction of a solitary virtual pipe will decrease the performance of routing in various node density areas and the productivity drops with communication holes.

Hop-by-Hop Vector-Based Forwarding (HH-VBF) [20] is a variant of the VBF protocol that uses virtual pipes from every intermediate device to the target device. Every device then dynamically makes packet forwarding choices with reference to its present location in the network.

Directional Flood Based Routing (DFR) [29] is a receiver-based, stateless, and LBORP in which each and every node is informed about the position of the destination device and one-hop neighbors. DFR utilizes a limited flooding method, in which every node passes its location details to all the other nodes and achieves more reliability in data transmission in the network. The flooding mechanism results in duplicate transmissions and energy loss. DFR also failed to address the void problem.

One of the earliest protocols that functions with reference to the pressure information proposed for UWSNs was Depth-Based Routing (DBR) [18]. DBR utilizes the knowledge on the depth of devices placed underwater to decide whether to transmit the packets or not. When a packet is received, each node will forward the packet to a smaller depth than that stored in the packet. Otherwise, the packet is discarded. Both communication holes and node mobility are the major problems influencing the limited performance of DBR.

GEographic and opportunistic routing with Depth Adjustment-based topology control for communication Recovery over void regions (GEDAR) [30] is another location-based anycast ORP that sends information packets from intermediate nodes to different target nodes. The protocol uses periodic beaconing to get the position information of every node in the network. The protocol suffers from increased duplicate message transmissions.

Hydraulic Pressure-Based Anycast Routing (HydroCast) [31] also utilizes the knowledge on the depth of the deployed device to choose the candidates for routing from the nearest nodes. HydroCast elects a subgroup of neighboring devices with the largest greedy progress to the target node. The performance of the protocol is not satisfactory with voids.

Multi-Path Routing (MPR) [32] helps to solve the data concussion issue at the sink nodes. The data collision is prevented at the receiving packets by creating a route that consists of various sub-paths between the sender and the sink. Geographic Partial Network Coding (GPNC) [33] is another geographic, partial network coding-based protocol proposed for UWSNs. Void is a major concern for this protocol too.

Focused Beam Routing (FBR) [34] was designed to minimize energy drainage during the routing process by controlled flooding of the packets. Although a preventive void handling technique was used, high delay was incurred. Void-Aware Pressure Routing (VAPR) [33] uses an opportunistic data forwarding technique coupled with information on the pressure of the deployed devices. VAPR selects a subgroup of candidate devices with the greatest progress to target. The holding time details of two-hop neighboring nodes helps to deal with the void areas but imposes a high overhead on the system. In Relative Distance-Based Forwarding (RDBF) [35], the packets are sent via the nodes that are nearest to the target node. RDBF uses a fitness value as an upper limit to supervise the number of transmitting devices to the sink. Moreover, the performance of RDBF also comes down with the presence of communication holes in the network.

In the next two sections, we discuss the working of the two LBORPs, VBF, and HH-VBF, used in UWSNs. VBF and HH-VBF utilize the knowledge of the location

of nodes in the network for routing. These protocols use greedy forwarding mechanism that chooses the node nearer to the target as the next forwarder for every data packet. We analyze the performances of these two protocols in UWSNs having multiple communication voids. We have selected these two protocols for the analysis because they are the two popular protocols used by various applications in UWSNs. Further, the design of these protocols is less complex and also incurs less overhead compared to other protocols.

3 Location-Based Opportunistic Protocols

3.1 Vector-Based Forwarding (VBF)

VBF [21, 36] was proposed to addresses the problem of energy limitation and efficient packet delivery. VBF utilize the knowledge of the location of nodes in the network for routing. Each data packet in VBF contains the three position fields named as OP1, TP1, and FP1. This represents the coordinates of the source, the sink, and the forwarder node. The RANGE field in the packet deals with node mobility. As soon as the information packet advances to the region marked by its TPI, it is flooded in that region controlled by the RANGE field. The virtual routing vector from the source to the sink describes the transmitting path. The RADIUS field inside the packet is a precomputed value that is utilized by intermediate devices to check whether they are near to the vector pipe and suitable for packet transmission. In order to limit the number of intermediate transmitting devices and to conserve energy in the network, VBF makes use of a self-adaptive algorithm. Upon getting a data packet, each node first computes whether it is inside the virtual vector and whether it can act as a potential forwarder to the next node. Each potential member device awaits a limited period of time to check its desirability value in the pipe. It describes the closeness of the current node to the past forwarder node, and the virtual pipe between the sender and the sink. The waiting time depends on the desirability factor. If a node is more desirable, then it waits for less time. During this time, the device pays attention to the channel to observe the number of devices that are transmitting the same information packet as the present device. When the period expires, the node will transmit its packet if and only if the reduced desirability value of the other nodes is less than a precomputed level (Fig. 1).

3.2 Hop-by-Hop Vector-Based Forwarding (HH-VBF)

Hop-by-Hop Vector-Based Forwarding (HH-VBF) [20] is a variant of VBF that constructs virtual routing pipes from each hop in the network as packets travel from

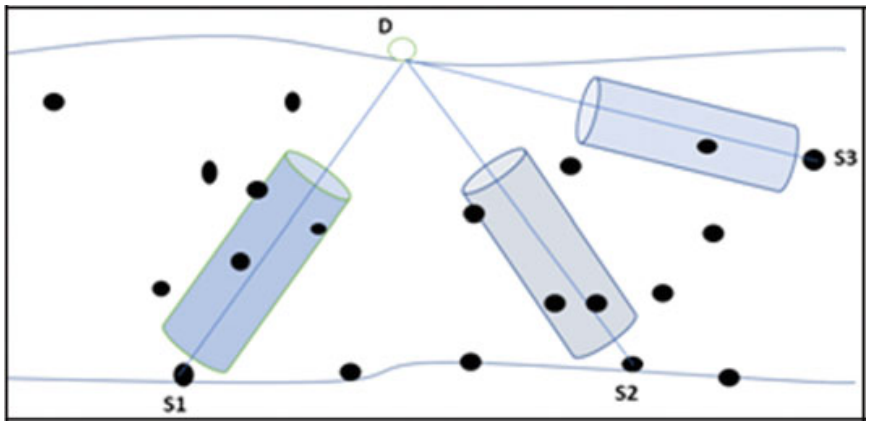

Fig. 1 Virtual vector pipe from sender to receiver node in VBF

the sender device to the receiver. This protocol creates a virtual routing pipe from each hop to the target device. Many studies have discussed the better working of HH-VBF in comparison with VBF. The pipeline radius is similar to the transmission count of the node. The protocol improves the direction of the transmitting pipe hop by hop, in the entire life period and in this way, all transmitting devices can generate a routing choice based on the present local topology details. By changing the direction of flooding pipeline dynamically, the performance can be enhanced. When a stable routing vector radius is set, the protocol shows a reduced performance in the sparse network compared with VBF. However, both the protocols are exposed to interferences caused by marine mammals as the data forwarding happens only inside the pipe. Here, the transmission can be interrupted when marine mammals block the pipe. There is an increased choice of finding a more acceptable forwarder within the hop-by-hop vector pipeline; HH-VBF gives better Packet Delivery Ratio (PDR). However, both the protocols do not succeed to yield energy fairness within the network. Also, they fail to effectively handle the communication hole problem.

The working of HH-VBF is described in Fig. 2. The sender node S2 wants to transmit an information packet to the destination device D2. Here S2 creates a virtual pipe to the destination D2. Once the packet reaches the intermediate sensor node M, it creates a virtual pipe to the destination. Now there are more nodes (N and P) included for sending the data packet to the target location. HH-VBF uses this forwarding strategy until the data reaches the target location. HH-VBF improves the performance in the network by dynamically moving the direction of the flooding pipe. Figure 3 illustrates the communication void problem in UWSNs. We can see that the source node S1 and S2 are trying to forward data packets to the destination D by creating virtual pipes. Data from S2 reaches the destination node located at the surface, but data from source S1 is unable to proceed due to the communication void near to the surface. Table 1 highlights the technical comparison of both the routing protocols.

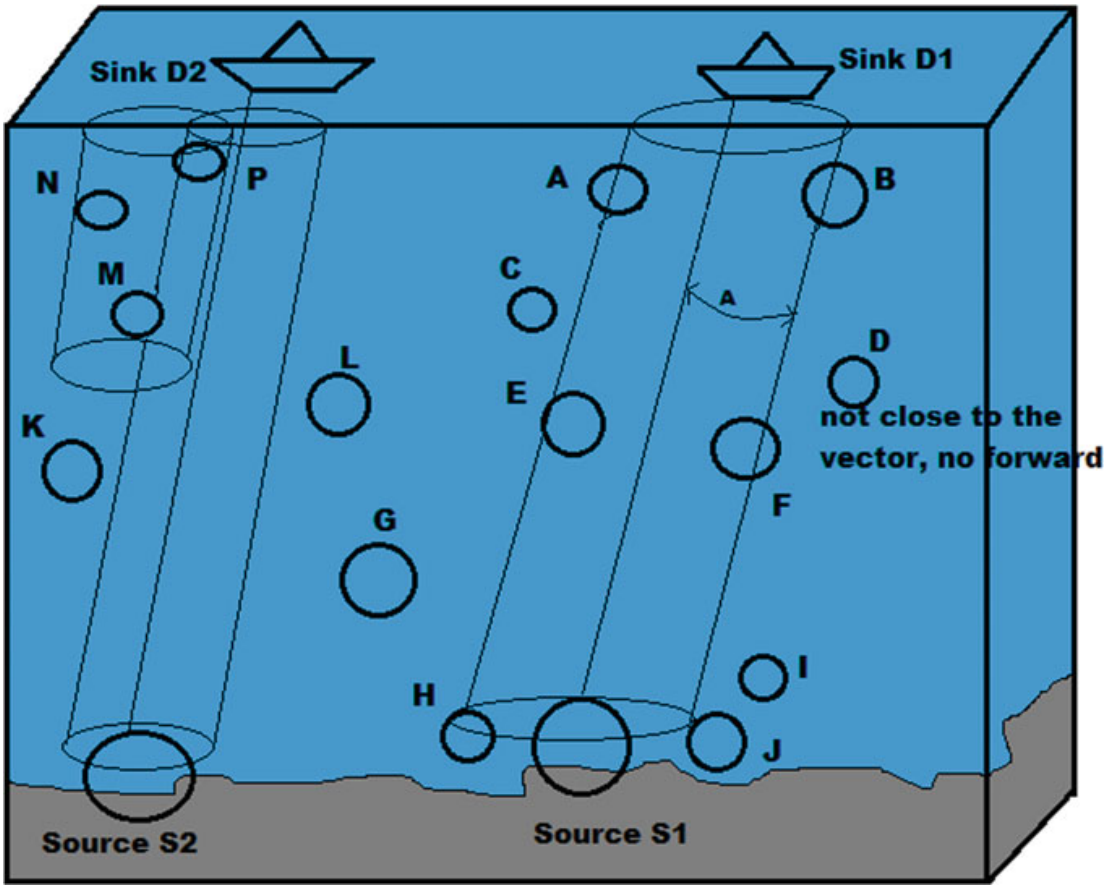

Fig. 2 Illustration of the functioning of VBF and HH-VBF

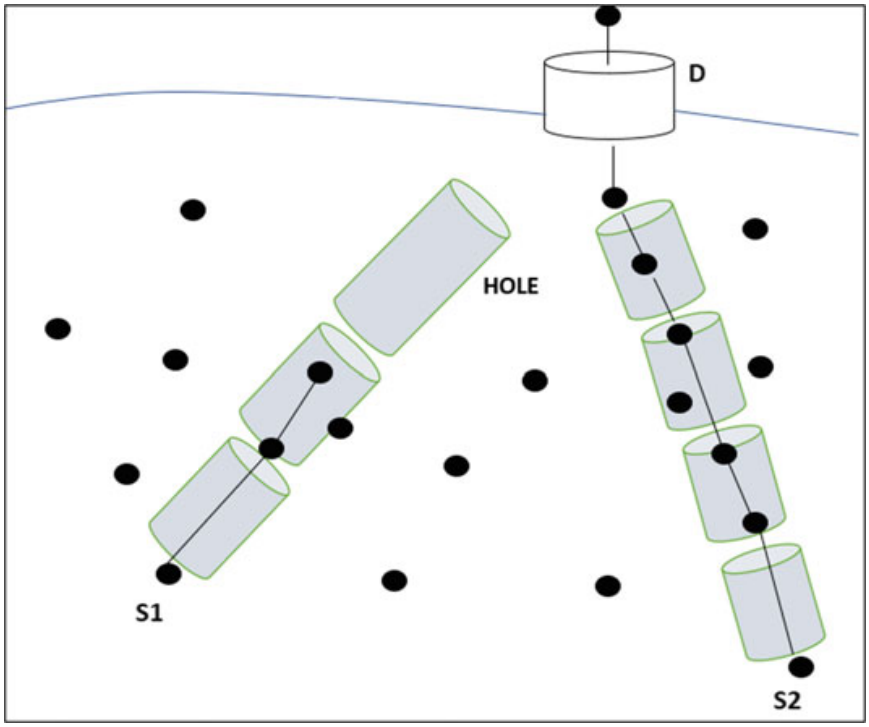

Fig. 3 Communication void problem with VBF

Table 1 Comparison of VBF and HH-VBF

Parameter	VBF	HHVBF
Metric used	Node location	Node location
Candidate coordination	Timer based	Timer based
Void handling	No	No
Routing	Single virtual pipe from the sender to the destination	Individual virtual pipes from each transmitting device to the target device
Advantages	Simple and flexible	Simple and flexible
Limitations	Duplicate messages performance degrades with communication holes	Performance degrades with communication holes

4 Simulation and Performance Analysis

4.1 Simulation Parameters

Performance of VBF and HH-VBF routing protocols are analyzed using simulations in Aqua-Sim [37]. Aqua-Sim is an extended version of NS-2 that efficiently simulates collision behaviors in large delay acoustic networks and also attenuation of underwater sensor networks. Aqua-Sim uses OTcl to model the protocol parameters implemented through C++ algorithms. The simulator creates a 3D environment of packet transmission in the network, which shows that the efficiency of both the protocols comes down with communication holes. Communication voids are created between the source and sink devices to measure QoS parameters in the overall network. Table 2 highlights the Simulation Parameters used to test the performance of the protocols in Aqua-Sim.

Table 2 Simulation parameters

Parameter name	Values
Simulator name	NS 2.35 + Aqua-Sim
Dimension of topology	1500 × 1500 × 1500 m
Transmission range	250 m
Antenna type	Omnidirectional
Data rate	50 kbps
Packet size	25–125 bytes
Number of nodes	100–600
Simulation time	300 s
Number of simulation runs	10
Protocols	VBF, HH-VBF

4.2 Performance Analysis

The performances of VBF and HH-VBF protocols were analyzed in a normal network scenario and in networks with communication void. Figure 4 shows the values of various parameters used in simulations. Four different QoS parameters were measured in the network.

- **Packet Delivery Ratio (PDR)**: PDR is the ratio of the overall packets arrived at the target device to the number of transmitted packets. Figure 4 shows the PDR in UWSN network scenario with varying number of nodes for the two protocols in normal network conditions and also with communication voids. Table 3 highlights the data values of VBF, VBF-Void, HH-VBF, and HH-VBF-Void. From the analysis, it is observed that both VBF and HH-VBF protocols give better performances in networks without communication voids. This proves that communication voids degrade the performance of even the latest LBORPs in UWSNs.
- **Average End-to-End Delay**: It is the time incurred by the information packet in reaching the target device from the sender device. Figure 5 highlights the average delay incurred by VBF, HH-VBF protocols in transferring data packets across the network with varying number of devices in normal and void environments. Table 4 highlights the data analysis of delay observed by routing protocols with void and under normal operating conditions. the data values, it is

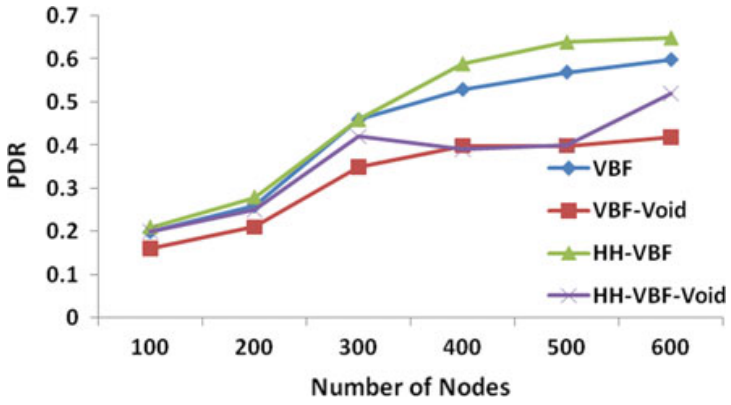

Fig. 4 PDR versus nodes

Table 3 PDR

No. of nodes	VBF	VBF-void	HH-VBF	HH-VBF-void
100	0.2	0.16	0.21	0.2
200	0.26	0.21	0.28	0.25
300	0.46	0.35	0.46	0.42
400	0.53	0.4	0.59	0.39
500	0.57	0.4	0.64	0.4
600	0.599	0.42	0.65	0.52

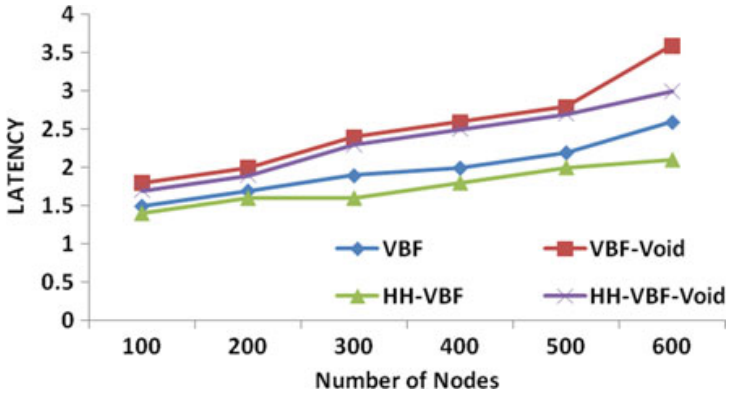

Fig. 5 Latency/End-To-End Delay versus nodes

Table 4 Average end-to-end delay

No. of nodes	VBF	VBF-Void	HH-VBF	HH-VBF-void
100	1.5	1.8	1.4	1.7
200	1.7	2	1.6	1.9
300	1.9	2.4	1.6	2.3
400	2	2.6	1.8	2.5
500	2.2	2.8	2	2.7
600	2.6	3.6	2.1	3

evident that the delay is less VBF and HH-VBF in normal environments as compared to networks with voids.

- **Throughput**: It is the rate or amount of data that is effectively transferred from the sender device to the target in a given time period. Figure 6 highlights the throughput of both VBF and HH-VBF protocols in normal and void environments. Table 5 enlists the data values of throughput. It is observed that HH-VBF protocol has the highest throughput compared to other routing protocols. Both the protocols suffer from degradation in throughput with voids in the network.
- **Energy Consumption**: In order to test the validity of the performance of the routing protocols, energy consumption is regarded as a significant parameter. Energy consumption is regarded as how much energy is consumed by

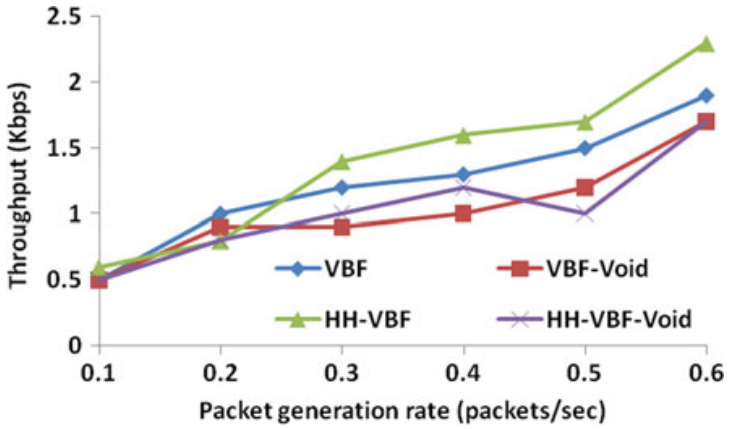

Fig. 6 Throughput versus packet generation rate

Table 5 Throughput

Packet generation rate	VBF	VBF-void	HH-VBF	HH-VBF-void
0.1	0.5	0.5	0.6	0.5
0.2	1	0.9	0.8	0.8
0.3	1.2	0.9	1.4	1
0.4	1.3	1	1.6	1.2
0.5	1.5	1.2	1.7	1
0.6	1.9	1.7	2.3	1.7

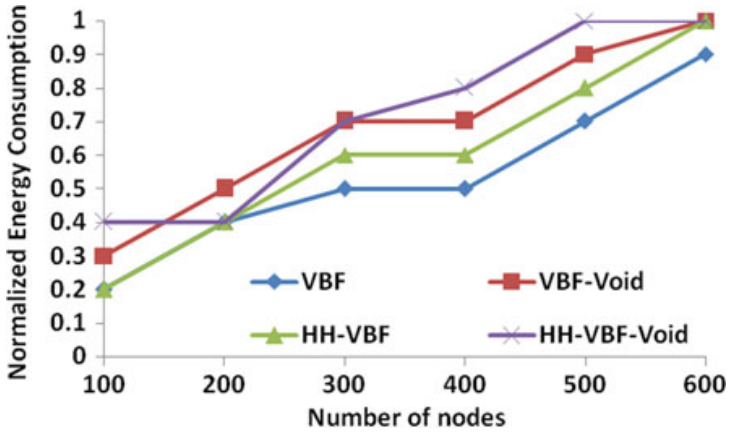

Fig. 7 Normalized energy consumption versus no. of nodes

Table 6 Normalized energy consumption

No. of nodes	VBF	VBF-void	HH-VBF	HH-VBF-void
100	0.2	0.3	0.2	0.4
200	0.4	0.5	0.4	0.4
300	0.5	0.7	0.6	0.7

600	0.9	1	1	1

transmitting nodes and intermediary nodes to make sure that the packet reaches the destination. Figure 7 elaborates the graphical analysis of the energy consumption of energy nodes in different protocols under UWSN operating scenarios. Table 6 also highlights the data values of protocols and it is observed that both protocols consume more energy in void scenarios.

5 Open Research Areas and Recommendations

In this section, open research problems generated by communications holes in UWSNs are discussed. Researchers designing routing protocols need to address the following issues to come up with optimal routing solutions for UWSN scenarios.

- Quality of Service (QoS): Communication voids drastically degrade the QoS offered by the routing protocols in UWSNs. The data delivery rate is reduced with increased data loss due to communication holes and void nodes. Delay in data transmission increases with frequent loss of data packets.
- Reliability: Reliable data delivery is a vital factor in the success of any routing protocol. Void nodes are often unable to find the next forwarder node in the network and are forced to drop the data packet. Thus, reliability is a big concern in UWSNs with communication voids.
- Scalability: In many UWSNs, the problems of communication holes occur when the network size is increased. With a reduced number of sensor nodes in a large geographical area, the chances are high for the occurrence of communication holes. Solutions to avoid communication voids with a minimum number of sensor nodes are to be found out.
- Mobility: Frequent mobility of sensor nodes is another reason for the communication voids. Good protocols should handle the mobility of nodes effectively for better performance.
- Energy: Loss of energy due to communication voids is another area of concern. With constrained battery and inability in frequent recharges, underwater sensor nodes need to be protected from unwanted drainage of energy.

6 Conclusion and Future Work

Underwater Sensor Networks have come out as a prominent research area in the networking domain with a wide range of aquatic applications. Routing in UWSNs is an area of major concern due to its unique features such as continuous node mobility, frequent disruption of links, and interference caused by other underwater acoustic systems such as marine mammals. Recently in UWSNs, opportunistic routing has been accepted as an efficient routing approach. The paper discussed the functioning of various Location-Based Opportunistic Routing Protocols proposed for UWSNs and evaluated the performance of two major protocols, VBF and HH-VBF using simulations in Aqua-Sim. The performances of these protocols are evaluated in normal network scenarios and also in networks with communication voids. We could observe that the performance of these protocols comes down with communication voids in the network. Insights from this article would enable researchers to work toward designing more effective protocols for underwater environments having voids. In the near future, a novel routing protocol, especially

designed for UWSN operating scenarios would be proposed and compared with existing routing protocols in terms of PDR, Energy, Delay, and Throughput and above all will give good performance in networks with communication voids and that are highly secure from all sorts of intruders and man-in-middle attacks.

A Hybrid Optimization Algorithm for Pathfinding in Grid Environment

B. Booba, A. Prema and R. Renugadevi

Abstract Grid computing has been highly effective in the area of life sciences, financial analysis, research collaboration, and engineering. This paper is a study of existing algorithms like Swarm Intelligence (SI) algorithms such as Ant Colony Optimization (ACO), Particle Swarm Optimization (PSO), Artificial Bee Colony (ABC–PSO), and Parallel Particle Swarm Optimization (PPSO) to opt for the optimal path in a grid computing environment. These algorithms were used to solve the complex optimization problems in finding the path between source node to destination node effectively. Nature computing techniques based on the study of the collective behavior of ants, particle swarms, and bees are used to find the optimal path, improve the optimization methods and scalability in a set of representative problems. The hybridization of a grid computing environment and nature-inspired computing algorithms such as ACO, PSO, ABC–PSO, and PPSO has resulted in a class of solutions that differ in structure and design from the peer-to-peer network algorithms and the evaluated results showed the effectiveness of the pathfinding problem. ACO is implemented on a dynamic grid computing environment to demonstrate scalability and a solution for pathfinding. A class of four algorithms is used to find an optimal path and improve the optimization methods and shorten the computational time in a grid computing environment.

1 Introduction

1.1 Overview of Grid Computing

Grid computing is a platform for solving computational problems in science, engineering, commerce, and other fields. Numerous solutions to grid computing are being developed. Grid computing has been proven to be highly effective in the area of life sciences, financial analysis, research collaboration, and engineering [1].

Grid computing is the accumulation of computer resources to achieve a common goal. The grid provides location-transparent scheduling that is a measure of registering resources required at a determined time interval for computation. Grid capacity has to make more cost-effective utilization of a given measure of computer resources as an approach to tackle problems that cannot be approached without a huge measure of computing power. The fact that it utilizes the resources of numerous workstations might be helpful synergistically to harness and manage as cooperation to a typical destination [2].

1.2 Problem Definition

The objectives are to find the grid computing based-pathfinding, identifying the position of the obstacles being developed on the grid computing environment and comparing, analyzing the performance results of the class of four algorithms in nature-inspired computing. This paper focuses on motion planning for "pathfinding". It addresses the optimal pathfinding problem in a grid computing environment [3]. This paper focuses on the use of SI algorithms such as ACO, PSO, PPSO, and hybrid ABC–PSO to find the optimization problems for selecting the shortest path in a grid computing environment. These algorithms utilize the swarm intelligence in grid environment to obtain an optimal solution over an iterative process. The optimal solutions are evaluated using different kinds of aspects, the hybrid ABC–PSO has been evaluated against other SI algorithms. A conclusion has been shown that the hybrid ABC–PSO algorithm performs better in terms of intensification and diversification concepts. This paper is to demonstrate robustness, scalability of the nature-inspired pathfinding algorithms in a customized grid computing environment.

1.3 Proposed Work

The pathfinding algorithms are analyzed to stumble on the shortest path in grid computing milieu from source node to destination node even if there are any

obstacles. This paper focuses on the use of ACO, ABC–PSO, and PPSO for selecting the shortest path in a grid computing environment [4].

The following approaches are used in the proposed work:

- Election of shortest path using ACO algorithm.
- Selection of shortest path by means of Parallel Particle Swarm Optimization (PPSO) algorithm.

The above mentioned approaches were used to solve the complex optimization problem in pathfinding between source nodes to destination node effectively.

2 Related Works

ACO methods are useful in reducing the problems of finding paths to a goal state. I showed the behavior of real ants, and to provide heuristic solutions for optimization problem. Cellular-DPSABC algorithm is able to apply dynamic optimization problems. The principle of this algorithm was implemented in PSO to fitness value population in Artificial Bee Colony Algorithm (ABC). This projected algorithm can be applied for solving optimization problems. The new algorithm is simple and flexible swarm-based one. It is also robust, it was established on a limited set of test problems [5].

An abstraction mechanism which maintains memory competence using a large-scale grid. It is also effective in reducing planning costs. This mechanism called a Minimal-Memory (MM) abstraction distinguishes the abstraction representation of the techniques which use the abstraction for pathfinding. Memory-efficient way of precomputing subgoals reduces the main obstacle in applying real time search systems in video games. Bee Colony Optimization (BCO) algorithm is focused on obstacle prevention and shortest safe path from the source to the target. Field D* can be used to approximate a distance find on the nodes of a complex, and the distance field can be used to weight the complex [6].

3 Contribution of the Paper

3.1 Design of ACO Algorithm for Pathfinding

ACO is a streamlining algorithm in light of the activities of strategies which are to diminishing the issues of finding the paths to a goal state. ACO basically is an artificial system that takes motivation from the conduct of genuine states. It locates the most efficient routes from their nests to food sources [7]. The attribute of ACO algorithms is the permutation of the structure of a solution. ACO algorithms are

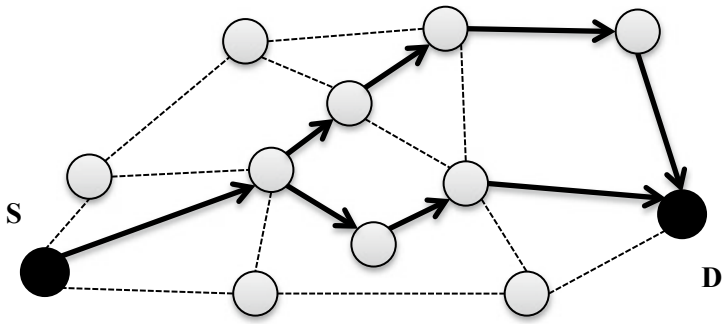

Fig. 1 Grid pathfinding

capable of solving minimum cost path problems on more complicated graphs as shown in Fig. 1.

ACO is capable of solving the large computational problem in gird computing [8]. When all the jobs are assigned, the resources are allocated by the pheromone trails. The pheromone trail can be proposed from the source node while traveling through several nodes to the target node.

The trails are updated by

$$\tau_{ab} \leftarrow (1-p)\tau_{ab} + \sum_{m} \Delta_{\tau_{ab}}^{m} \tag{1}$$

Equation (1) is the amount of pheromone deposited for a state transition, *ab* is the pheromone evaporation coefficient and τ_{ab} is the amount of pheromone deposited by *m*th system [9].

3.2 Design of ABC–PSO Algorithm

The benefit of ABC over other swarm intelligence approaches is that in the ABC algorithm the imaginable solutions indicate food sources. A total number of employed bees are identical to the number of nourishment sources, with each working honey bee speaking to a sustenance source [10]. Nourishment source signifies an answer for the issue that is fundamental to be upgraded. Every sustenance source is produced as pursues

$$X_{ij} = X_{\min j} + \text{rand}[0,1]\left(X_{\min j} - X_{\min j}\right) \tag{2}$$

ABC–PSO, two algorithms' components smoothly with the end goal to pick up profit by their specific qualities Fig. 2. The incorporating PSO with ABC is to build goal of the pbests of the particles. The algorithm with segments from both ABC and PSO is shaped with the end goal to have a calculation that easily tackles distinguishable issues as while having iteratively invariant conduct as PSO in the meantime [11].

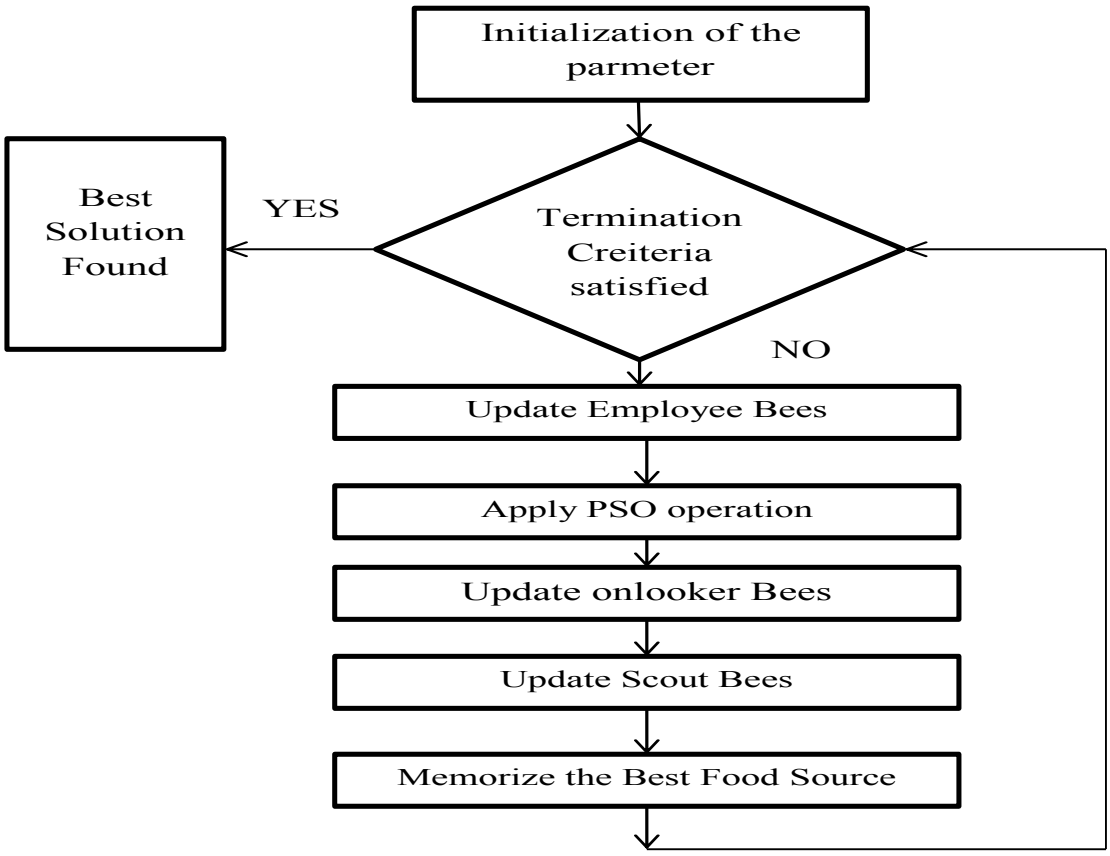

Fig. 2 ABC–PSO algorithm

For every molecule i in the swarm, the ABC calculation method refresh condition is down to business to the individual best $pbest_i$. This is done after iteratively choosing another molecule k, arbitrary issue variable j, hence c$pbest_i$ is refreshed as pursues

$$pbest_{ij} = pbest_{ij} + \phi_{ij}\, X\left(pbest_{ij} - pbest_{kj}\right) \tag{3}$$

3.3 Design of PPSO Algorithm

Parallel processing is to generate the same results and feasibly uses multiple processors to reduce the run time. Each time, all particles are independent it can be easily analyzed in parallel [12]. The PPSO algorithm solves complex functional optimization problems. The particles in PPSO algorithm are attracted to the best locations in the search space [13]. The process of PPSO group is shown in Fig. 3.

The above technique gives the worldwide best and the neighborhood best arrangements [14]. It builds the shot of particles to find a superior arrangement and to expand the nearby ideal arrangements.

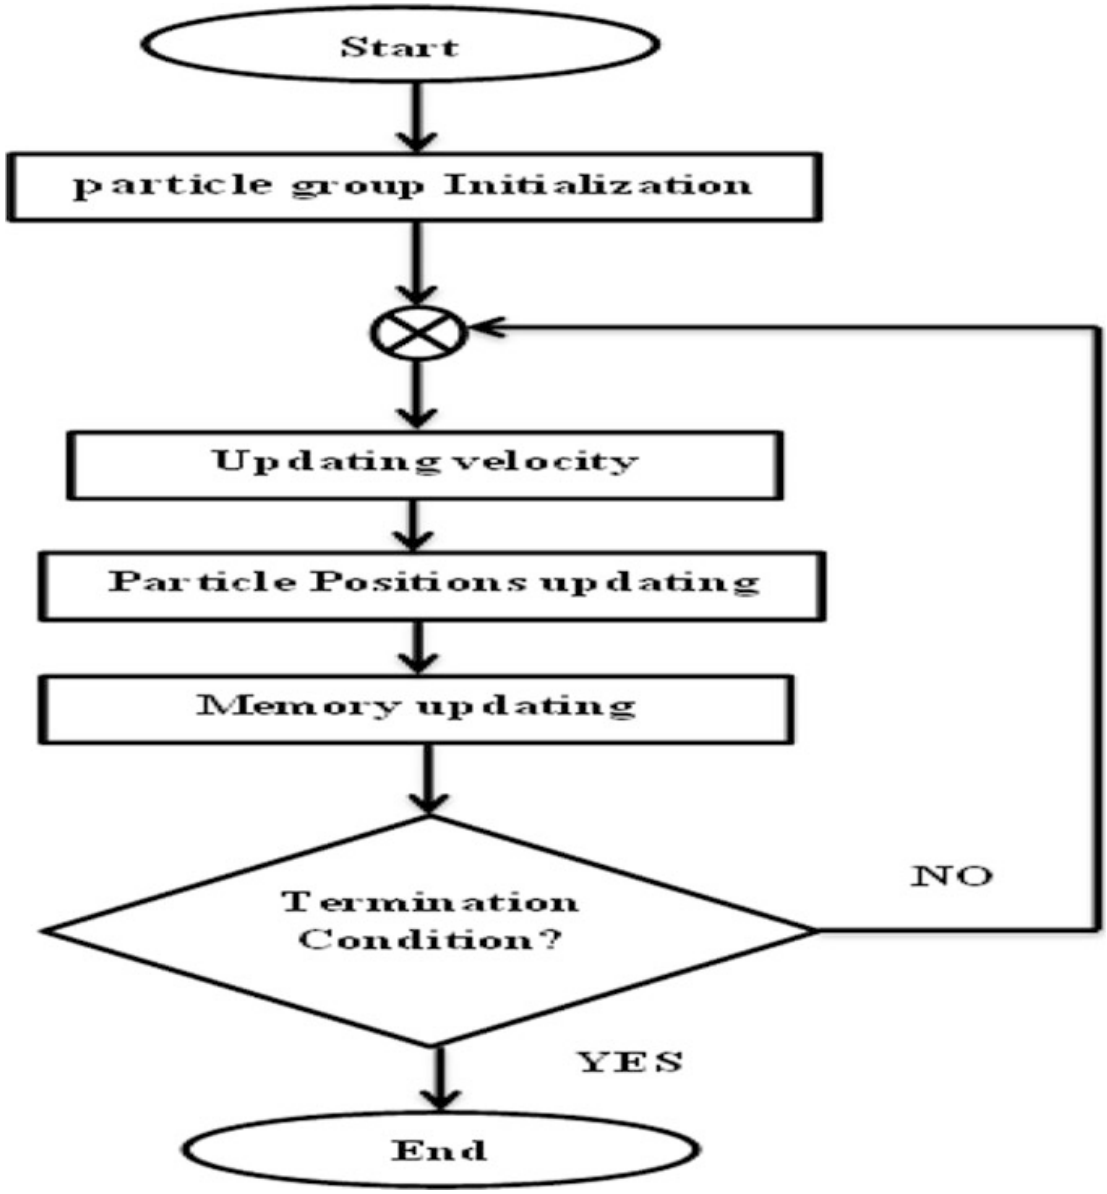

Fig. 3 The process of parallel particle swarm optimization/group

4 Simulation Results

In this work, MATLAB tool is used to build the simulation environment and the proposed techniques are simulated to evaluate the performance of Make span and to find an optimal path [15].

$$\text{Make span} = \text{Completion time of last job} - \text{Starting time of first job}$$

To evaluate the effectiveness of these algorithms, the average deviation of the present best result from the optimum in all iterations is determined. The yield of the dynamic condition gives the premise on which most limited ways can be figured between any two hubs utilizing pheromone esteems at every one of their neighbor hubs [16, 17]. The system show utilized in unique is made out of the hubs and connections that are viewed as bidirectional. It very well may be finished by dissecting the likelihood make length esteems [18].

5 Performance Analysis

The Proposed technique is replicated for various combinations of grid sizes such as 128 × 8, 256 × 16, 512 × 32, and 1024 × 64. The results are shown in Table 1. It demonstrates the performance of the ACO, PSO, ABC–PSO, and PPSO algorithms. This performance measure produces a fast rate of better optimization make span [19].

Figure 4 defines a method to find the solution for the problem of resource with total execution times which equal to the make span. According to this, the optimal solution for each algorithm is found based on the global pheromone.

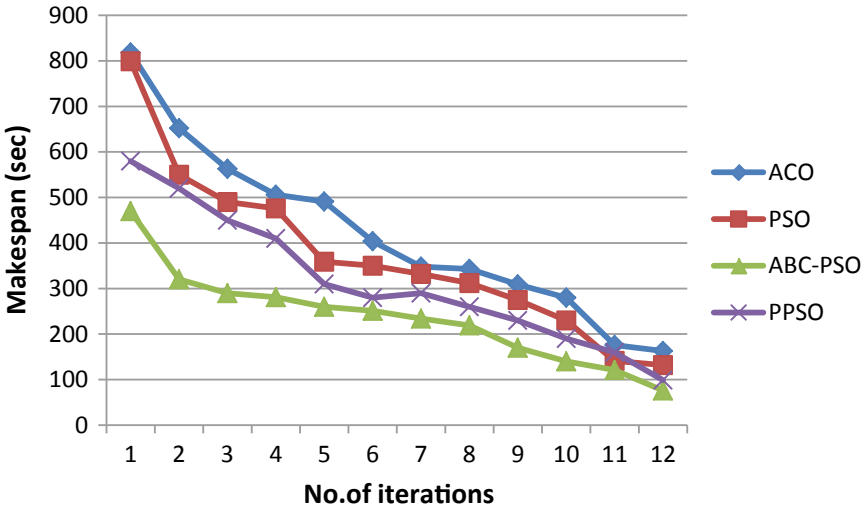

Fig. 4 ACO, PSO, ABC–PSO, and PPSO performance

6 Conclusion

This work reports the application of ACO for pathfinding in a simulated grid computing environment which is suitable for comparison with PSO, ABC–PSO, and PPSO algorithms. The hybridization of grid computing environment and swarm intelligence algorithms such as ACO, PSO, ABC–PSO, and PPSO has resulted in a class of solutions that differ in structure and design from the peer-to-peer network algorithms. The distinction between ant colony and bee colony is also studied through simulation studies in MATLAB. ACO is implemented on a dynamic grid computing environment to demonstrate the scalability of the proposed solution for pathfinding. For the future, this can be implemented in a cloud environment to avoid obstacles freely and improve the scalability.

Dynamic Hashtag Interactions and Recommendations: An Implementation Using Apache Spark Streaming and GraphX

Sonam Sharma

Abstract Hashtag, started with Twitter is a keyword with prefix "#" and now being used mostly for all communication on social media. It has been identified as very powerful and effective in organizing communications according to the topic and trend. Hashtag can further help on various analysis, as it links users with their topic of interests. Hashtag aids in building communities of similar interests. With hashtags, we can follow current trend and interest on twitter which can help us in analyzing multiple factors, e.g., sensitivity of the ongoing trend, its spread, people getting affected, its effect on business and so on. Traditionally available approaches help us in analyzing batch data and finding interests and trends on it. Now with the advancements in the field of technology helps us in analyzing a large amount of online data within seconds. In this paper, we will be exploring dynamic hashtag interactions to find correlations among them and propose a methodology which can successfully find relevant hashtags based on the interest in focus. We will propose our methodology of analyzing and exploring tweets in real time with the extent of converting information; we are getting from twitter to knowledge.

Keywords Co-occurrence graph · Community networks · Hashtags · Graph mining · Real-time analytics · Streaming graph · Social media

1 Introduction

GRAPH structures have many application areas named cybersecurity, social network, e-commerce websites, etc. With the abundant data getting generated in wide variety, with different sets of volumes and rates. The increased usage and connectedness of social media have given rise to trends and interests which can be triggered for various reasons. Analyzing social media data whether in batch or in real time with this freely available interesting public information could yield

interesting results. People on social media have been expressing their feelings freely, which makes Twitter an ideal source for accumulating wide amount of data for real-time on-time analysis on the vast amount of opinions and on a wide range of topics. Although this information can be easily collected, getting the information from it and representing it in good form has its challenges. These challenges withstand even with the advancement of tools and technologies. Additionally, analyzing twitter data is indeed a challenging problem due to the nature, diversity, and volume of the data.

Whenever we talk about social media, the combination of graphical data and big data is inevitable and is the reason it is popularly known as Social Network Analysis (SNA). There are various types of graph structures that are possible where the most popular ones are user-followers graph, user-mentions graph, etc. But here we are basically building and analyzing the graphs based on hashtags for a particular trend,which can further help us in analyzing the trending hashtags and other related hashtags. We are focusing on open-source software technologies named Spark which provides a graphical layer on top of it.

Data Streams have gain popularity in data mining techniques, where time is the most relevant factor since such data helps in providing *on-time* analysis and focus on *now*. But it is a very challenging task in various aspects [1]:

1. Dynamic nature of the data streams can cause data distribution changes with time (called concept drift) [2]
2. It not feasible to store the data since the data is in infinite volume
3. The analysis of data streams must happen as quickly as possible so as to get quick insights and operate in real time.

We can also see that when it comes to real-time analytics, many canonical analytics approaches may not be suitable for handling real-time data and providing *on-time* analytics. Here, we require a knowledge-based system for social network analysis which can handle streamed data and find interesting patterns on it and deliver the results within seconds [3, 4].

It is expected that the new approaches developed for extracting insights from real-time data will help in advancing the development of more sophisticated analytics allows better decision-making. This will help in gaining insights from your data as you receive with improved decision-making. This will help customers in quick and immediate decisions based on the scenario that is happening now, not what happened weeks, or months ago. Most of the big data that we receive are in real time and it is most valuable at the time of arrival (Fig. 1).

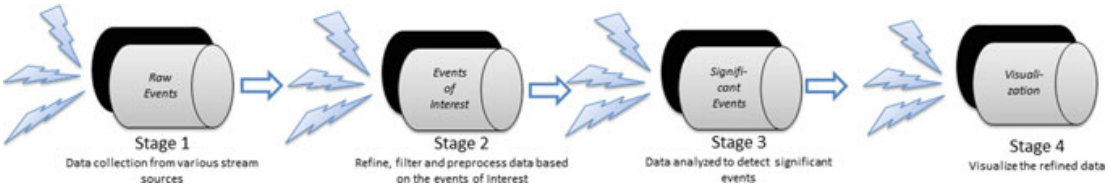

Fig. 1 A canonical real-time event processing pipeline

In any canonical real-time event processing pipeline at every stage, we polish for further step and at every stage we try to refine the data in a way to get new insights from it which can further help end users for decision-making. This streaming data can help in building final products which provide *actionable on-time insights*. The initial stage is to collect data from the various stream sources which is the first stage of any data processing pipeline. The main challenge with stream data preprocessing is that new data continuously arrives and we need to apply fully automated preprocessing methods. Also, we need to be able to update the methods with evolving data and optimize model parameters to deal with rapidly changing data. Streaming data needs to be fully automated with the required preprocessed methods.

In this paper, we present various methodologies on a linguistic process for building knowledge-based social media framework based on hashtag interactions. The framework works seamless with upcoming big data technologies and software. The state-of-the-art methodologies in the data analytic techniques on social media data are provided.

This paper is divided into the following sections: Sect. 2 discusses literature review and critical research gaps highlighted in this paper. In Sect. 3, the detailed problem statement for our analysis is defined. The proposed methodology is stated in Sect. 4. The results and conclusions are explained in Sects. 5 and 6 [5].

2 Literature Review

Activity on social media platform has become a part of daily activity of users because of which it has become one of the most powerful mediums for many researchers and enterprises to perform extensive analysis and derive interesting results. In this section a detailed study about various techniques on knowledge discovery using hashtags on social media. Although the problem of knowledge mining from twitter has been studied extensively during recent years and some we discuss below. Wei Wu designed a system for automatically generating personalized annotation tags to label Twitter user's interests and concerns [6]. However, user-level tags have its limitations as it only focuses on the particular user and their content and Twitter being a very large community, where we can focus on communities or on a large set of people which can help us in building strong knowledge-based system. Other such kinds of implementations have been performed on key-phrase extraction which determines important phrases from single documents or an entire collection of text documents [7, 8]. These approaches are not immediately applicable on Twitter because even if Twitter offers textual information but canonical NLP techniques cannot work on it as people on twitter tend not to follow basic norms of grammar on which we can do language processing. Apart from this, if we focus on single tweet for analysis we will most of the information which is being generated on Twitter.

However, current explorations being dined on social media are more matured than ever before and still it is one of the most chosen topics for researchers because

of its freely available data and whenever there is twitter, hashtag plays the most significant role in tweets and now people have started to understand this and follow it across various social media platforms. It has been identified that hashtag inclusion in the posts are increasing nowadays, because of which hashtags act as the fundamental information facet associated with social network messages [9]. Made a significant contribution by observing that hashtag recommendations aim to encourage the user to use hashtags more often and it is better to use appropriate hashtags and also avoiding synonymous in hashtags. All these observations indicate that the hashtag recommendation is not only interesting but an important problem statement.

Also, most of these existing solutions suffer from certain limitations. One problem is that the majority of approaches are limited to centralized environments. The proposed techniques are very time-consuming and take many computational resources. Most of the available solutions are neither sufficient nor suitable for building total knowledge analytics system on Twitter, since there is a huge mismatch between their processing capabilities and when we get the output from them, we lose the value (the fifth V of big data) of the data since that is not o*n-time.*

Thus, in all, it can be stated that they are solving the purpose of providing knowledge to the user but all the knowledge that is provided is either insufficient for the business users to go with or not on-time. Most of the methodologies that are developed on Twitter are on batch data. With the advent of the technologies, we can modify or build these methods on the top of stream data to help the business in providing on-time and social media presence using this.

3 Problem Statement

(a) *Proliferation of trends on social media*

Trends in social networks are elements of communication which helps in analyzing the popularity of a particular event (news) on social media. The more popular the event is, the more the occurrence of interactions on social media is. On trending events, people express their opinions which further helps them to build community and helps in the spread or proliferate the trend.

Most often hashtags help in the spread of trend and there are various combinations of hashtags which help people in expressing their thoughts clearly and be able to connect to the like-minded people. Sometimes trends can be misleading and biased too as it is basically the opinions which people are expressing what they feel and their personal thoughts. Understanding the dynamics of trend spreading could be of the great value of information for social media research areas.

(b) *Objective*

The objective of this paper is to propose a methodology to analyze hashtag interactions dynamically and graphically detect current ongoing trends on Twitter by building real-time hashtag co-occurrence graph on the top of real-time streaming engine. Real-time co-occurrence graph can help in analyzing popular hashtags. For this study, we have used big data technologies like *Spark Streaming* and *GraphX*. Graph visualization libraries like *graphstream* are used to visualize the graph in real time. Only the activities of Twitter after the connection are made. We analyze the streaming pipeline for each sliding window and perform the analysis. Under such circumstances, it becomes essential to understand each and every aspect of the data beforehand and constantly update the algorithm so as to deal with a future discrepancy.

4 Analytical Methodology for *On-Time* Twitter Analysis Hashtag Recommendations

How should we decide on managing data across an enterprise or an organization which is streamed from multiple sources like various kind of sensors, security data in the form of video from webcam, data from IDS/IPS, telematics data, and so on. Apart from management of data which is getting generated in real time, the other most important task is to analyze and find insights from it the moment it gets generated. Properly managing the data what is the best possible way to find insights from it as soon as it gets generated, so that there is no loss of data value and take necessary "*on-time*" actions on it [10].

Whenever a tweet is being twitted on twitter which contains keyword that starts with '#' called hashtags. Hashtags mostly contain current trends or hot topics in discussion. A single hashtag has the capability to describe the whole tweet. And if there are multiple hashtags available in the same tweet it can help in analyzing and getting interesting results. Multiple hashtags can further help us in analyzing user of the tweet. Multiple hashtags are getting created on Twitter and Trending Hashtags getting retweeted which helps in spread of the news faster not just on Twitter platform, but people use these hashtags on other social media sites to increase awareness. Hashtags refer to specific topics related to particular ongoing event or trend, but only a few of them become too exclusive and popular. People use hashtags to show their interest in a particular topic. Hence, a hashtag can provide valuable information about the topic, its evolution, and what user community of the analyzed hashtag is interested in through time.

Experiments and their results with real-time twitter data and analysis being done here provide real-time recommendations on what hashtag to follow next based on the topics which can help in building the related hashtags network and organization of trend. Finally, we discuss techniques that can describe the way hashtags, related to the same event, evolve through time and what are the most recommended

Table 1 Sample keywords to be crawled from twitter

Tradewar	Tradewars	Trump	trade

Table 2 Combination of hashtags considered

US AND trade	US AND China	Trump AND tradewar	China AND tradewar

hashtags. Keeping this in mind, we now explain the procedure which we followed for our experiment.

(A) *Data*

Tables 1 and 2 have listed the keywords used to crawl the data from Twitter. Where Table 1 shows specific keyword whereas Table 2 shows combination of these keywords to further enhance our analysis.

We have built our analysis from July 16 to Sept 12 2018. And we will be showcasing the results for the 6-min window in spark streaming. We have decided this window based on the amount of data and cluster size so that we can get seamless and fruitful results. These hashtags will be the *Focus Point* for our analysis and will further be enhanced by building the real-time graph and getting related Hash-tags on it.

(B) *Real-time Tweet Statistical Analysis and Data-set Preparation*

The next steps we perform will further provide ongoing real-time analysis on the data. Since our analysis majorly focused on hashtags, so we have filtered hashtags and build our analysis on top of it with some other information like users who have used this hashtag and number of tweets, this hashtag has been used shown in Fig. 2, which gives us an understanding that how important the analyzed topic used by the

Fig. 2 A *Map()* collection displaying the Hashtag -> (#unique tweets, #unique users) for some specific window

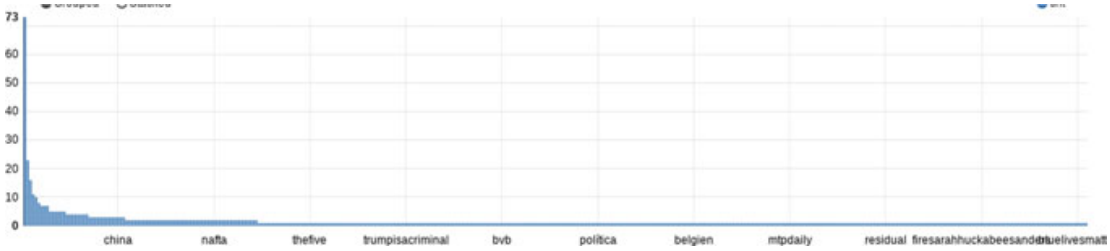

Fig. 3 Bar chart representation of hashtag distribution on some *window()* in Spark Streaming

Fig. 4 Classes of hashtags at a particular time window

hashtag is for this particular window of stream. In this section, our main goal is to get an aware of the streaming twitter data from different angles to get the full view (Figs. 3, 4).

For further analysis, we have to focus on major top hashtags and their co-occurrences on tweet. And for this analysis, we have filtered the tweets which contain no hashtags even when they can help us in analyzing the content more but these tweets do not fit our use case.

5 Hashtag Interaction and Recommendation

Here, we will look at the major top hashtags and their co-occurrences. For this analysis, we have filtered the tweets which have no hashtags available with them (Fig. 5) [11, 12].

While analyzing the tweets for multiple *window(),* we have identified that some hashtags which are particularly in trend and popularly occur together or individually for a specific period of time. This makes them most relevant among all. We have also added pairs count in the Edge property of the graph for its use in further analysis.

6 Architecture Flow of the Analysis

The streaming data we have used for our analysis and provided use case is taken from Twitter using Twitter Streaming API. Figure 6 shows the components we have used for this analysis. Specific to this use case the architecture is kept understandable with least and default configurations. The graph visualization uses *graphstream* library, which is both easy to integrate and visualize the graph in Spark and can help in streaming too if we will be using bigger batched in spark streaming window, and the graph which is getting visualized is small enough to fit the window. With multiple tweaks between the window sizes in *graphstream,* we were able to successfully visualize the graph [13, 14].

Kafka which is a distributed stream processing engine helps us in getting the streaming data and can also act as buffering the data for specified configuration and all the analyses of the data have been done on *Spark Streaming*.

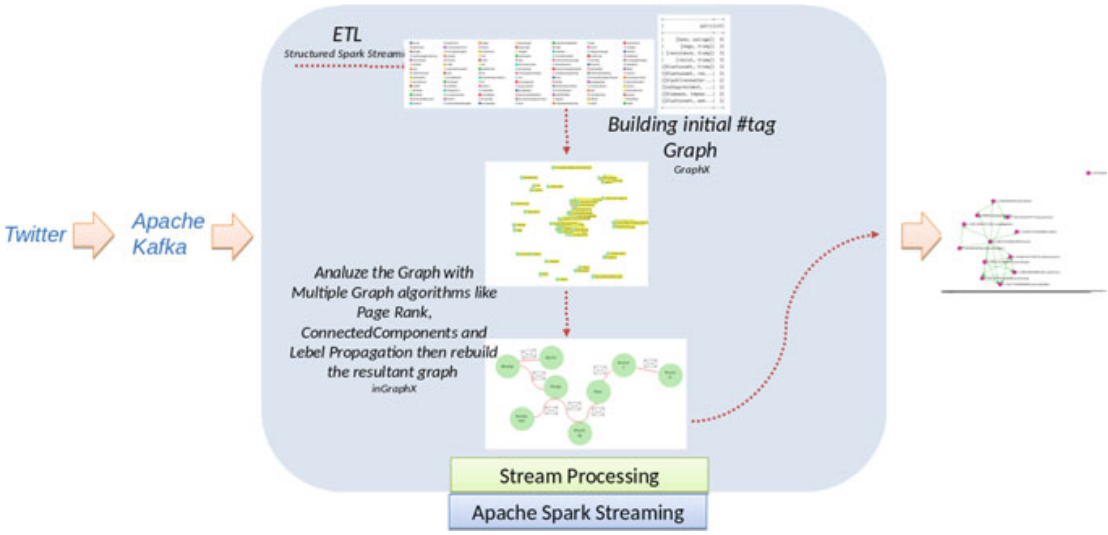

Fig. 6 Architecture defining the flow of analysis

7 Algorithms and Results

In this section, we describe the graph algorithms that we have used to build final hashtag co-occurrence graph for the specific batch window in Spark Streaming.

(a) ***Preliminaries***

(i) For any graph to be built, we have to preprocess and make dataset ready in the desired format for GraphX. For GraphX vertices, we will find *#unique* hashtags and provide them the *id* with *Long* datatype, since GraphX only understands long as a datatype for ID. For this, we have encoded the hashtag string using *MD5 hashing* algorithm so that we get unique id for each hashtag string. We also have to verify that if all hashtags have got different ids since no hashing algorithm can perfectly encode all the strings uniquely. This will make out Vertex RDD in the form of

$$\texttt{vertexRDD} : \texttt{RDD}[(\texttt{Long}, (\texttt{String}))]$$

(ii) Another preliminary component to build a graph is edges. For this, we will create hashtag *combinations* for each tweet and filter out empty tweets. After creating the *combinations,* we will *flatMap* them and create edge RDD by encoding the hashtags in a similar manner as vertices.

$$\texttt{edgeRDD} : \texttt{RDD}[\texttt{Edge}[\texttt{Int}]]$$

With above vertex and edge RDD's, we will build a graph (Fig. 7)

$$\texttt{Graph}[(\texttt{String}), \texttt{Int}]$$

(b) ***Applying Algorithms***

After building the graph we will perform the following analysis to get the final hashtag co-occurrence graph.

(i) To understand structural property of a graph we apply GraphX *Graph* class provides a number of methods to explore the graph.

(a) **Connected Components**

This is the method which can help us in understanding the graph on its connectedness. To describe this, we can say that a graph is called connected when any vertex in that graph can reach another vertex by following a sequence of edges from one vertex to another. If not so, then a graph can have multiple connected components which can act as a connected subgraph (Fig. 8).

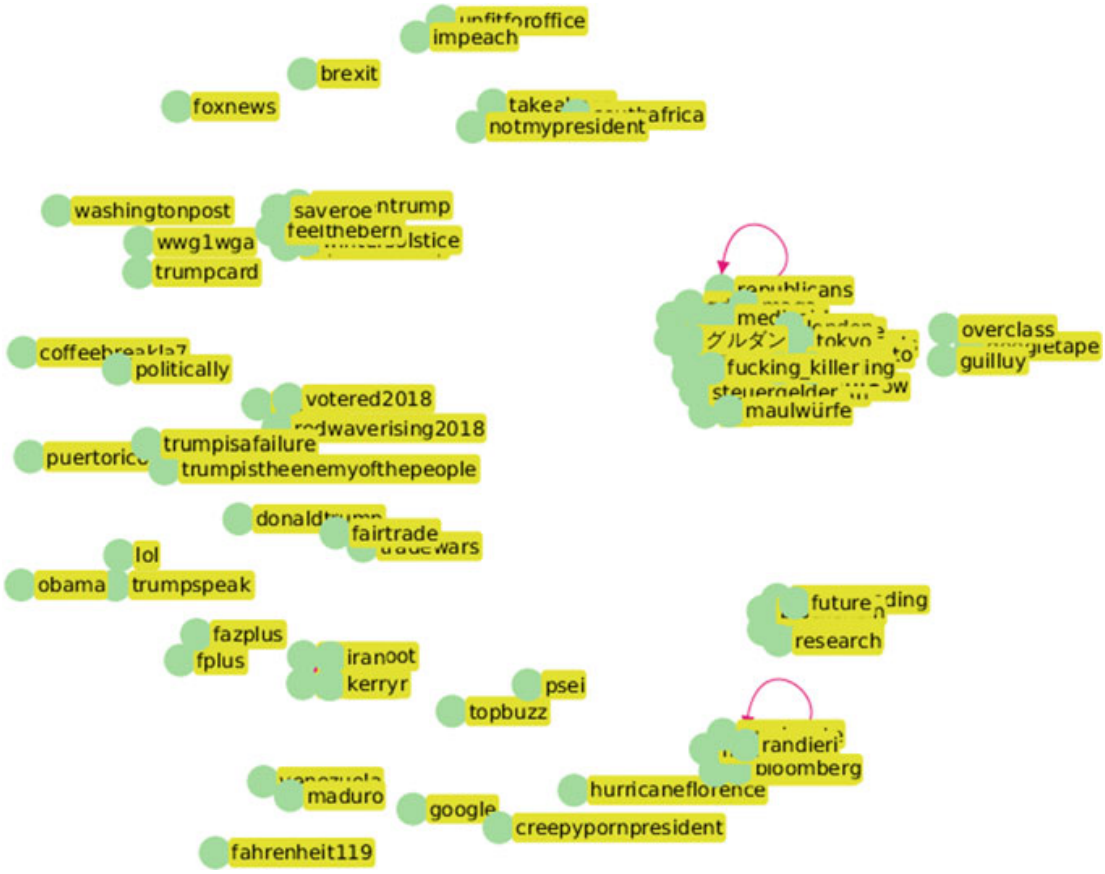

Fig. 7 Result of initial graph created and displayed using graphstream in real-time sliding window

(b) Degree Distribution

A connected graph can have many different structures. For example, there can be one vertex that is connecting the whole graph. Eliminating the total graph becomes disconnected. So, for all these types of insights degree distribution that is *degree* of each vertex, where degree is defined as a number of edges connected to the vertex (Fig. 9).

(c) Community Detection in GraphX

Community detection algorithms usually focus on determining the graph which can either be overlapping or non-overlapping communities. When the communities are disjoint, there are no common elements we find between the communities. But when communities are overlapping or non-disjoint the elements among the nodes have common elements which they share. In this paper, we are focusing on one of the algorithms available on GraphX, i.e., Label Propagation and we are trying to visualize these using graphstream library (Fig. 10).

How Label Detection works is that it propagates the labels of node throughout the network which helps it to form the communities. The propagation of label is called as label flooding. In label flooding at a point of time single label becomes

Fig. 8 Result of realtime connected components in a GraphX. -9181200170680562787 is the most connected component with a node count of 23. We have identified that #trump helps in building the component with maximum node count

dominant when it is inside the densely populated community which is very well connected where we say that labels are trapped inside. Labels are supposed to be trapped inside whenever it is inside the densely populated network. Labels of each node are treated as opinion. Whenever the opinion is same, therefore the community is same.

In our case whenever the hashtags and their co-occurrence are closely related to trump the form of a community. Apart from trump, there is very less number of communities that are formed which are subsequent across windows of the given timeframe. So for our analysis, we will consider the community containing trump as the most important community and choosing other hashtags connected to it we will move to PageRank which further helps us in ranking the nodes in the graph and within the community.

In the community detection Label propagation algorithm using pregel in spark GraphX we have used a 5 step algorithm since waiting till convergence can hamper the streaming flow of the engine. And we have identified 5 to be the most optimal choice among all.

Fig. 9 Result of degree distribution for a streaming graph. Hashtags *trump* and *maga* are among the highest degree vertices subsequently among various stream windows

(d) **PageRank**

Though the original PageRank algorithm was originally developed by Larry Page to rank Google search results. It can be applied majorly to all graphs where we are required to find the influence of the vertices in any graph.

Similarly for our problem statement, we have a graph where we have hashtags as vertices and an edge between the hashtag if two hashtags co-occur together in a tweet. So, our main motive here to apply the PageRank algorithm is to build the subgraph by removing all irrelevant nodes.

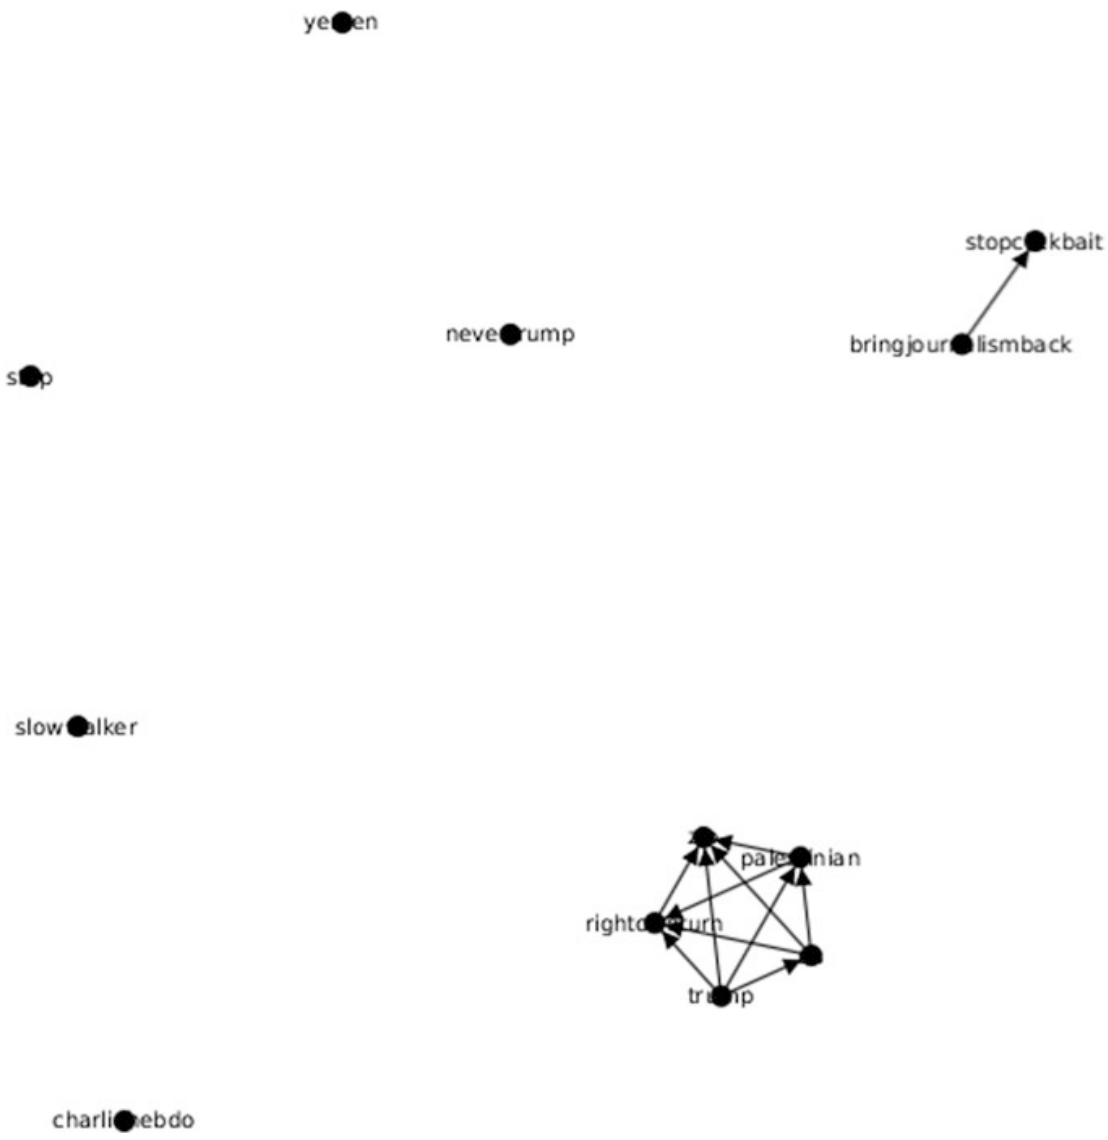

Fig. 10 Result of communities generated by the graph in one of the stream time window. Here, we can see various communities getting created with #trump is the largest community of in a particular sliding window

GraphX property graphs are directed multigraphs, which mean each edge in the graph specifies a unidirectional relationship, i.e., if there is an edge between two vertices in hashtag co-occurrence graph then hashtag1 and hashtag2 occur together in a similar fashion than hashtag2 and hashtag1. So we need to have two directions among two nodes for the PageRank to work correctly. *GraphX* offers static and dynamic implementations of PageRank where static PageRank runs for fixed no. of iterations and dynamic PageRank runs until convergence.

For our analysis, we will be using dynamic PageRank algorithm with a tolerance value of 0.01. We have done our analysis of multiple tolerance values like 0.01,

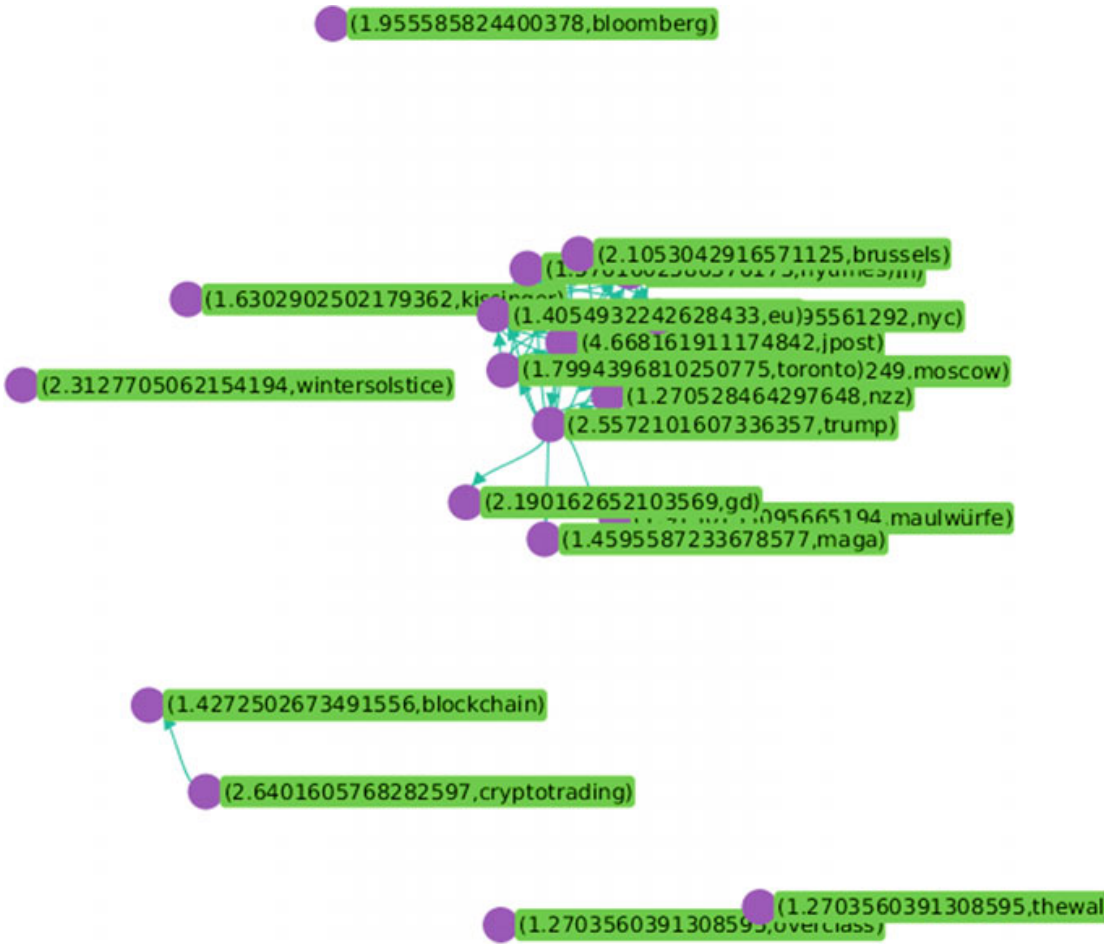

Fig. 11 Final graph visualization using graphstream. A result after community detection and PageRank in spark

0.0001, and 0.001, and found 0.01 to be the best. Since we are using real-time Spark Streaming and other tolerance values have taken longer than expected to converge and which might hamper our results for other subsequent windows of analysis in Spark Streaming [3, 15].

After we have got the PageRank, we will find top 20% of nodes in the graph and discard all irrelevant nodes. A node is called irrelevant. if it is not in topmost 20% of ranks in PageRank and create the new subgraph from this. This final graph will be our output graph for graphstream to visualize (Fig. 11).

> PageRank helps in ranking across the communities in the graph. And after fetching the top 20% of the nodes for every community of Hashtag we can see that PageRank can help us in getting the most important hashtags that can be recommended to the user for further analysis.

8 Conclusion

The practicality of building real-time graphs using Spark Streaming and identifying the related hashtags which help in hashtag recommendation is being investigated in this paper. Twitter analytics has considered to the top priority for most to get public opinions and views and hashtags helps us in understanding it in a better way. From the real-time hashtag co-occurrence graphs, we have seen the relevance of hashtag pairs and how to be so important for a specific period and how their importance fade with time. But some always remain relevant for a specified long period which played an important role in our analysis. Also, we have seen that we can seamlessly build real-time engine with graph functionality on top of it.

This can be proved to be a crucial tool for both social media and real-time applications. In this paper, we have also identified that if we will be able to combine the generated communities by Label Propagation with the PageRank algorithm, we get better results than waiting for both the algorithms to converge since in real-time analytics the one more thing followed is that how soon we are generating the results.

Further steps are required to improvise this.

Work on enhancing PageRank and community detection algorithm and improvement in tolerance of PageRank for better convergence this can further help us in recommending the graphs better.

Improvement in graph creation is required and to enhance we will build the graph by saving previous window data on creating a bigger and better graph which can help in giving better results.

Also, instead of using hashtags we will focus on creating graph with additional properties from the data.

ABSTRACT

In today's competitive environment components having high dimensional accuracy and better functional performance are highly demanded. Abrasive Flow Machining is one of the vital non-conventional techniques used for the finishing of complex geometries which is not easy with other conventional processes. It provides finishing up to nano level. During the finishing, parameters affecting the system efficiency are very important to identify to improve the productivity of the system. This paper discusses a newly developed technique i.e spark assisted Abrasive Flow machining, which uses the spark energy to improve the material removal and providing better surface finish and also parameters such as rotational speed of the electrode, duty cycle and current were optimized for the better surface finish using Taguchi L_9 OA.

KEYWORDS: Finishing, Spark, Hybrid, Current, Duty Cycle & Rotation

Original Article

INTRODUCTION

Abrasive Flow Machining (AFM) is a nonconventional technique used for the finishing of complicated shapes which cannot be obtained by conventional techniques. However, in recent past, many traditional processes such as honing, lapping and broaching were used for finishing. But these processes cannot provide nano level finishing. AFM is a technique that uses a non-Newtonian media (combination of polymer, gel and abrasive) and is forced to flow through the restrictive path at a huge pressure. The advantage of using this media is that it can flow to any unreachable area which is not possible using traditional techniques [1, 2]. This process can be used to finish the burrs, edges, recast layers [3]. The disadvantage of this process is low material removal. So various researchers hybridize this process with other techniques to get better material removal. Kenda et al. [4] used AFM process for finishing the profile of plastic gear and found an increase in the life cycle of the gear with a significant decrease in the finishing cost. Subramanian et al. [5] finished hip joint of Co-Cr alloy using AFM process in the biomedical area and found minimum surface roughness of 39 nm. Sidpara et al. [6] studied the rheological behavior of the MR fluid in the presence of a magnetic field. Sambharia and Mali [7-9] developed a new media based on polymer abrasive gel and identified the effect of parameters such as abrasive concentration, abrasive mesh size, media temperature, an additive percentage on the viscosity of media. Judal and Yadava [10] combined ECM process with Magnetic assisted AFM to finish non-magnetic stainless steel and analyze the effect of parameters such as magnetic flux density, rotational speed and current on the material removal and surface roughness.

METHODS

Although Abrasive Flow Machining process provides a good level of finishing it has a constraint of low material removal. Many researchers have hybridized this process with other nonconventional techniques to improve its material removal. This paper discusses a newly developed technique which uses the spark energy to melt the surface material so that the abrasives can easily take away the softened material. This process uses a power supply system which converts the AC supply to the pulsed DC supply. The positive supply was given to the workpiece while negative supply was given to the electrode inside the hollow cavity. When the supply is given to both the poles electrons start generating between both the poles and start moving to the opposite polarity. This movement of ions can be seen as a spark which melted the surface material. The experimental setup of the developed hybrid process is shown in figure 1.

Figure 1: Experimental Setup of Developed Hybrid Abrasive Flow Machining Process

The experimental setup included a fixture for holding the workpiece and guiding the media from one media cylinder to the other, power supply system, gears for the rotation of electrode to maintain the uniformity of surface, bearings. The rotation of either workpiece or electrode is necessary to maintain the uniformity of the surface otherwise spark will melt the surface at a particular spot and damages the surface integrity of the surface.

PERCENTAGE IMPROVEMENT IN SURFACE ROUGHNESS

To analyze the effect of variable parameters on the response i.e percentage improvement in surface roughness, experiments were planned and analyzed using Taguchi L_9 Orthogonal array. Percentage improvement in surface roughness can be calculated by the equation given below-

% improvement in R_a = (Initial Roughness - Final Roughness)/(Initial Roughness) * 100

The present L_9 OA has three parameters with three levels of each. It has 8 degrees of freedom. Brass was taken as the workpiece having a hollow cylindrical shape of an outer diameter of 10 mm and an inner diameter of 8 mm with a length of 16 mm. The variable parameters with their levels affecting the performance of the system are noted in Table 1.

Table 1: Process Parameters and their Values at Different Levels

Symbol	Parameters	Unit	L_1	L_2	L_3
S	Rotational speed	RPM	150	200	250
D	Duty Cycle	Fraction	0.68	0.73	0.78
I	Current	Ampere	3	6	9
Polymer to Gel Ratio: 1:1, **Workpiece Material:** Brass, **Abrasive Type:** Al_2O_3, **Initial Surface Roughness:** 1.1 - 2.85 microns					

Experiments were performed according to the L_9 OA. A number of 9 experiments were performed with three times each, which means a total 27 experiments were performed to analyze the behavior of the parameters as given in Table 1. The initial surface roughness of the workpiece was in the range of 1.1-2.85 micron. For every sample operation and its replications, % ΔR_a was measured and recorded in Table 2.

Table 2: Experimental Results of Percentage Improvement in Surface Roughness as per TAGUCHI L_9 OA

E.N	Run Order	% Improvement in Ra			S/N Ratio
		R_1	R_2	R_3	
1	1	7.25	8.34	8.79	18.11
2	4	16.1	17.1	19.24	24.78

Total		**143.39**	**155.56**	**161.275**	
		T ΔRa = Overall mean of ΔRa=17.04%			

RESULTS AND DISCUSSIONS

Surface roughness was measured through the Taylor Hobson precision machine having the resolution of 0.01 micrometer. The percentage improved R_a value for each trial condition is shown in Table 2. Higher the better quality characteristic was taken for the response and for calculating the S/N ratio as given in equation 1.

$$(S/N)_{HB} = -10 \log[\frac{1}{n} \sum_{j=1}^{R} \frac{1}{Y_j^2}] \quad (1)$$

Figure 2 shows, on increasing the rotational speed percentage improvement in surface finish increased up to 200 rpm and further decreased on increasing the rotational speed. As the rotational speed was increased it forced the abrasive particles towards the surface with a larger force due to the developed centrifugal force which corresponded more material removal and greater surface finish, but further increasing the rotational speed increased the media temperature and caused restriction during the media flow. This reduced the media viscosity which corresponded decrease in viscosity of media due to which abrasive particles did not participate in the abrasion process which reduced the percentage improvement in the surface roughness.

Figure 3 shows surface finish got better on increasing the duty cycle up to 0.73 but decreased after a further increase in duty cycle. Duty cycle means the frequency of spark in the gap. As duty cycle increases, the discharge energy will be available for a larger duration which developed high temperature on the surface and abrasive particles easily took away the melted material. However, on further increasing the duty cycle produced a larger crater on the surface and

degrades the surface quality.

Figure 4 shows the effect of current on the surface finish of the product. As the value of current was increased larger discharge energy was available for melting the surface material, which made easy for the abrasive particles to take away the softened material and corresponded better surface finish.

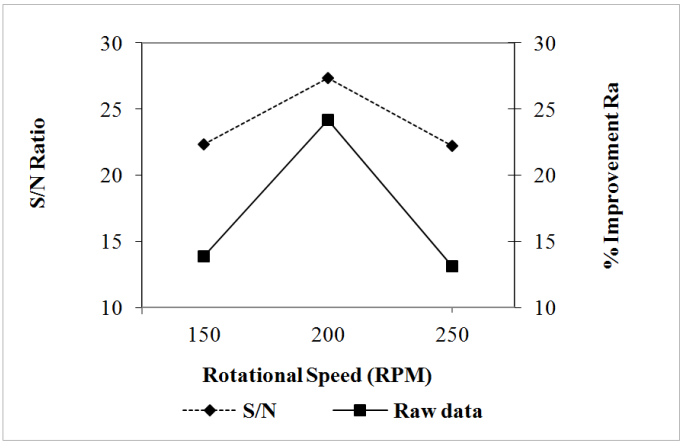

Figure 2: Effect of Rotational Speed on the S/N Ratio and % ΔR_a

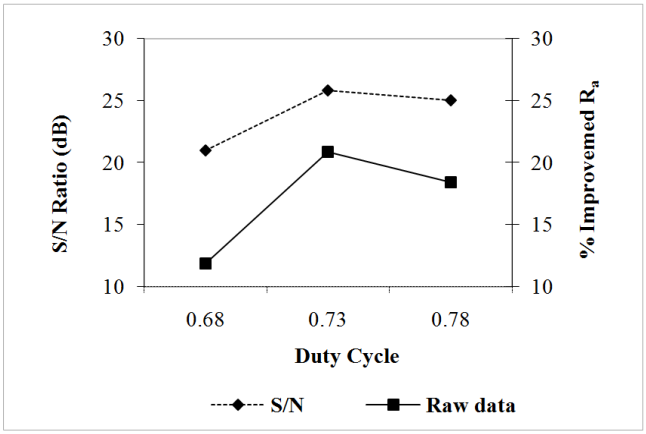

Figure 3: Effect of Duty Cycle on the S/N Ratio and % ΔRa

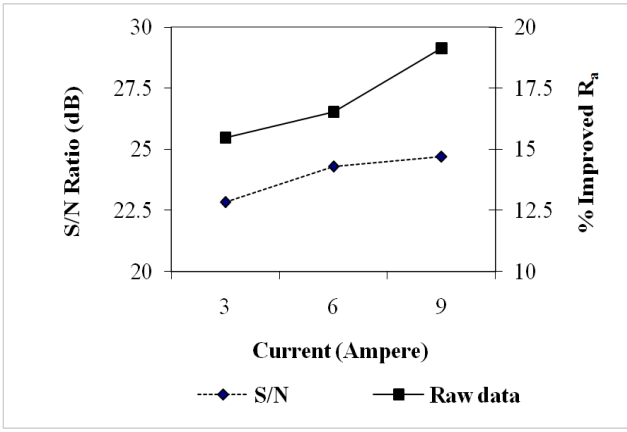

Figure 4: Effect of Current on the S/N Ratio and % ΔR_a

Table 3 shows the average value and main effect for the % Δ R_a.

Table 3: Main Effects of % Δ R_a

Process Parameter	Level	Rotational Speed (S)		Duty Cycle (D)		Current (I)	
Type of Data		Raw Data	S/N Ratio	Raw Data	S/N Ratio	Raw Data	S/N Ratio
Average Values(%Ra)	L_1	13.86	22.31	11.89	21.01	15.48	22.84
	L_2	24.17	27.33	20.85	25.83	16.52	24.3
	L_3	13.09	22.2	18.39	25	19.12	24.7
Main Effects(%Ra)	L_2-L_1	10.31	5.02	8.96	4.81	1.04	1.45
	L_3-L_2	-11.08	-5.13	-2.46	-0.83	2.59	0.4
Difference (L_3-L_2)–(L_2-L_1)		-21.39	-10.15	-11.42	-5.65	1.55	-1.05
L_1, L_2, L_3 shows levels of parameters.							

In this analysis, ANOVA technique was used to analyze the effect of variables on the response, i.e % ΔR_a. Table 4 and Table 5 represent the ANOVA for the raw data and S/N data. It can be observed from the Tables that the parameters affect the mean and variability in the R_a value.

Table 4: Pooled value of ANOVA for Raw Data (ΔR_a)

Source	SS	DOF	V	F-Ratio	SS'	P%
Rotational Speed	689.3	2	344.65	97.11	682.2	56.99
Duty Cycle	386.04	2	193.02	54.38	378.94	31.91
Current	63.11	2	31.55	8.89	56.01	5.21
E	70.98	20	3.54	------	92.27	5.86
Total (T)	**1209.44**	**26**	*	-------	**1209.44**	**100**
Fcritical =3.4928 (Tabulated Value)						

Table 5: Pooled ANOVA (S/N Data)(ΔR_a)

Source	SS	DOF	V	F-Ratio	SS'	P%
Rotational Speed	51.56	2	25.78	207.87	51.31	52.97
Duty Cycle	39.77	2	19.88	160.33	39.52	40.86
Current	5.74	2	2.87	23.17	5.50	5.90
e	0.24	2	0.12	------	0.99	0.25
Total (T)	**97.33**	**8**	--------	-------	**97.33**	**100**
F critical = 19(Tabulated Value)						

The optimum %ΔR_a was determined and related confidence intervals were predicted.

For the mean of %ΔR_a, optimum condition for the response is estimated as:

$\mu = \bar{S}_2 + \bar{D}_2 + \bar{I}_3 - 2\bar{T}$ (1)

$\bar{T}$ = overall mean of the R_a obtained = 17.04 %

$\bar{S}_2$ = Average value of % age improvement in R_a at the 2nd level of rotational speed = 24.17%

$\bar{D}_2$ = Average value of % age improvement in R_a at the 2nd level of duty cycle = 20.85 %

$\bar{I}_3$ = Average value of % age improvement in R_a at the 3rd level of Current =19.12 %

Substituting these values, % improvement in R_a = 30.06 %

(CL_{CE}) and (CL_{POP}) can be calculated by using the equations (2) & (3):

$$CI_{CE} = \sqrt{F_a\,(1, f_e)\, V_e \left[\frac{1}{n_{eff}} + \frac{1}{R}\right]} \quad (2)$$

$$CI_{POP} = \sqrt{[F_a(1, f_e)\, V_e]/ [n_{eff}]} \quad (3)$$

Where CI_{CE} = Confidence interval for confirmation experiments

CI_{POP} = Confidence interval for population

$F_\alpha(1, f_e)$ = The F- ratio having confidence level of (1-α)

f_e =3.49 (Value Tabulated)

f_e = Error Degree Of Freedom = 20

N= Total number of experiments =27

R = Size of Sample = 3

V_e = Error variance = 3.55

By using equation no. (4), one may achieve

n_{eff} = 3.86

So, $CI_{CE} = \pm 2.70$

and $CI_{POP} = \pm 1.79$

The Confirmation interval for predicted response is:

27.36< %age improvement in ΔR_a <32.76

The 95% confirmation interval of predicted mean is

28.27<%age improvement in ΔR_a <31.85

The optimum level of the parameters for percentage $\%\Delta R_a$ is $S_2D_2I_3$.

S_2 = Rotational speed at second level =200 RPM

D_2 = Duty Cycle at second level = 0.73

I_3 = Current at Third level =9 Ampere

The results are presented in Table 6 for % improved R_a.

Percentage improved R_a from the confirmation experiments are inside the specified range.

The mean values of percentage improved R_a and S/N ratio for every parameter at all the levels was calculated and given in Table 6.

Table 6: Values Obtained from Confirmation Experiments

Response	Optimum Condition	Predicted Response	Confidence Intervals 95%	Real Value
%Improvement ΔR_a	$S_2D_2I_3$	30.06 %	CI_{CE}:27.36<%ΔR_a<32.76 CI_{POP}:28.27<%ΔR_a<31.85	27.75 %

SEM ANALYSIS

As the power supply is provided between both poles, a spark is generated in the gap. This developed high temperature on the surface and caused oxide layer formation on the surface. The surface materials started melting and became soft. The melting of the surface can be easily studied by figure 5, which clearly shows the spots developed by the spark on the surface.

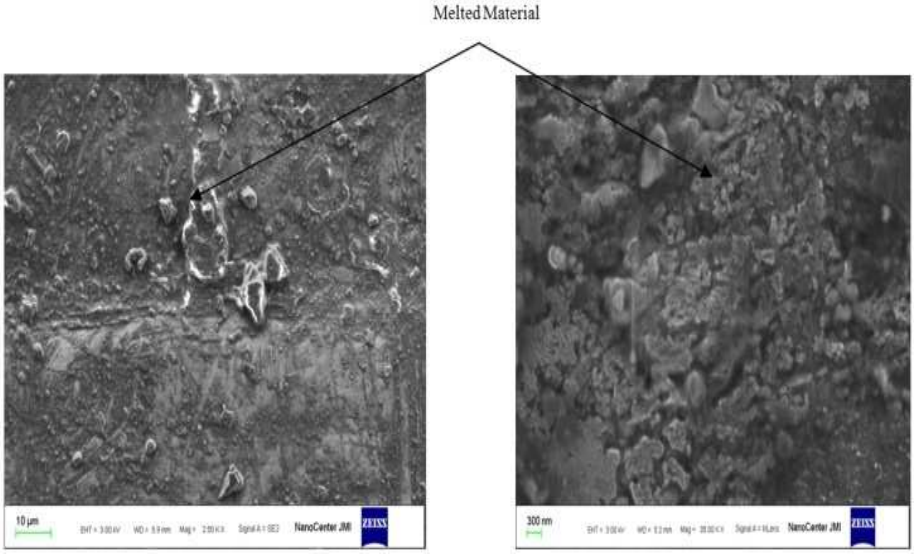

Figure 5: SEM Images of Surface During Finishing

XRD ANALYSIS

X- ray diffraction technique for the finished surface was analyzed by using "X' Pert High Score" software. XRD of the brass workpiece after finishing can be observed from figure 6. The figure confirms the formation of Copper vanadium fluoride oxide at the plane (004) for a diffraction angle of 49.48 degrees [Ref- 00-043-0082], and formation of Copper magnesium oxide at the plane (4400) for a diffraction angle of 43.418 degrees [Ref- 01-074-1921]. Copper Praseodymium oxide was formed at a plane (105) with a diffraction angle of 43.47 degrees [Ref- 00-049-1891].

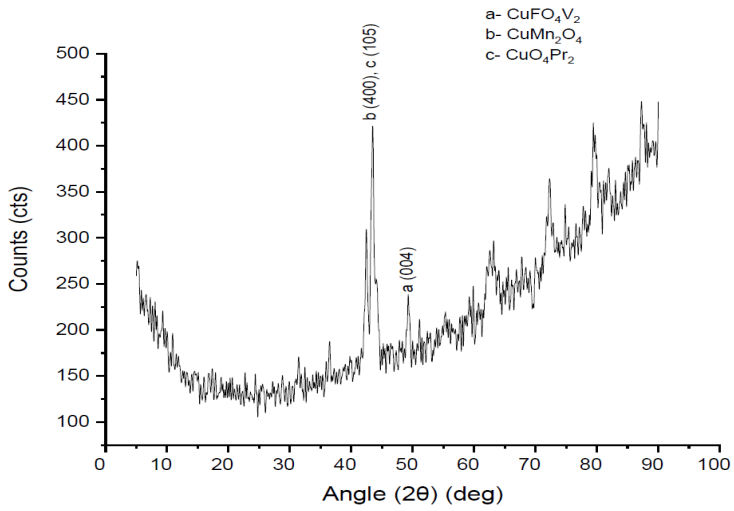

Figure 6: XRD Graph of the Finished Brass Workpiece

CONCLUSIONS

The following conclusions can be drawn on the basis of the above experimental study-

- The experimental results show that rotational speed is contributing 56.99 %, a duty cycle is contributing 31.91% and current is contributing 5.21 % towards percentage improvement in surface roughness.
- The 95% confidence interval of the % ΔR_a is $27.36 < \%\Delta R_a < 32.76$.
- The experimental results show optimum result at the second level of rotation speed (200 rpm), a second level of the duty cycle (0.73) and third level of current (9 Ampere).
- Melted material observed by the SEM image shows less requirement of abrasion force for removing the material.
- The XRD results confirm the oxide formation on the surface of the materials.

Abstract: Fused deposition modelling (FDM) is the one among various additive manufacturing techniques which can fabricate component of multi material. However, the tensile strength of FDM component is naturally low and hence it is difficult to use for the engineering application. For enhancing the mechanical properties, this study explores a novel methodology by adding the high strength material in between matrix material as reinforcement in the additive structure. In this study, ABS and PLA based reinforced composites are prepared. ABS and PLA are used as matrix material whereas PETG is used for the reinforcement. Unidirectional tensile test is performed to check the effect of reinforcement on tensile strength of the fabricated component. Experimental results depict that addition of PETG reinforcement material improves the tensile strength of ABS by about 70% and tensile strength of PLA material is improved by about 8%. Computational analysis is also performed under similar boundary condition to physical model. It is observed that computational results are close approximation to the experimental results. The methodology proposed in this study could be very useful for the fabrication of high strength component by using low cost FDM technology.

Keywords: Multi materials; reinforced additive manufacturing; mechanical properties; computational analysis; fused deposition modelling

1. Introduction

Over the past few years, industrial demand of biodegradable materials has suddenly increased due to the biodegradability, renewability of the base materials and less greenhouse gas emissions and recycling [1)]. ABS, PLA and PETG have been extensively used in the medical industry, packaging industry, automobile industry, aerospace industry etc due to its biodegradability[2)]. However, poor mechanical, thermal properties and higher cost limit to use in large scale in the industry. Therefore many researchers have made effort to improve the mechanical properties of ABS and PLA material by varying the process parameters like raster angle, orientation, infill pattern, infill density, layer thickness, shell thickness etc. Some studies were carried out to improve the mechanical properties by mixing the reinforcement fiber into the extruding wire. Significant improvement in the mechanical properties was found due to the addition of reinforcement fiber in the matrix material.

Panes et al.[3)] have performed an experiment to characterize the tensile strength of ABS and PLA part printed by FDM process. The process parameters used in this study were layer thickness, infill density and orientation. Pruska i3 printer was used for the fabrication of test samples and HAYTOM HM-D was used for the tensile test. Mansour et al. [4)] have conducted a series of experiments to find out the dynamic and mechanical behavior of 3-D printed material. Reinforced carbon fibers PETG material was used for the fabrication of specimen. The reinforcement direction of the fibers was 0° and 90°. It was observed that due to addition of carbon fibers, modulus of elasticity and hardness increased by 30% whereas compressive strain increased by 66%. Masood et al.[5)] have performed an experiment to investigate the effect of FDM process parameter orientation on tensile strength and surface roughness of PLA material. Along y-axis uneven surface roughness was observed and tensile strength of material was more along x-axis as compared to y-axis. At an angle of 45°, tensile elongation was nearly same for all the three orientation.

Wu et al.[6)] have highlighted the influence of layer thickness and raster angle on the mechanical properties of 3-D printed component. It was found that for higher layer thickness, tensile strength of ABS and PETG material tends to maximum at 0° degree and 90° orientation. Lanzotti et al.[7)] have highlighted the impact

of process parameters such as infill orientation, layer thickness and number of shell on tensile strength of PLA component fabricated through FDM process. Results shows that on increase of orientation, ultimate tensile strength of the material was found to be decreased. On increasing the number of shell from 2 to 6, ultimate tensile strength was increased from 42 MPa to 52 MPa. Whereas when the layer thickness increased from 0.10 mm to 0.20 mm, minute changes were observed in the ultimate tensile strength of material.

Sugavaneswaran et al.[8] have conducted experimental and analytical investigation for the effect of reinforcement and its orientation on elastic modulus of structures manufactured by polyjet 3D printing technique. Vero black "ABS like" material was used as reinforcement and darus white as matrix material. Instron machine was used for tensile testing and rom equation was used to find out analytical results. The results shows that due to presence of reinforcement, elastic modulus increased by 6.79% in transverse direction (90°), 21.9% along the longitudinal direction at (0°) and 14.88% along inclined direction at (45°). There was good correlation between experimental and analytical results. Afrose et al.[9] have carried out experimental study to investigate the impact of orientation on tensile properties of the PLA thermoplastic material FDM AM technique. The specimens were printed at three orientations namely X, Y and 45°. The shape of the specimen was used similar to dog bone. Result shows that maximum tensile strength was found along the X orientation. Summary of some other research work related to FDM technology is reported in table 1.

Recent development in the field of additive manufacturing is to fabricate heterogeneous material by using multi material. In present work, an attempt was made to investigate the effect of unidirectional reinforcement of PETG material on mechanical properties of ABS (material) and PLA (material). Significant improvement in the tensile strength was found due to the reinforcement of PETG material.

2. Materials and Method

The present study focuses on development of reinforced composite material by using multi material. In additive manufacturing softer material is referred as matrix material and harder material is referred as reinforcement material [17]. Development of AM for the fabrication of multi material had improved the mechanical properties, specific functional requirement and design feature for the new product design. In this work, effect of unidirectional reinforcement of PETG material on mechanical properties of ABS and PLA material was investigated. The next sub section will provide the details of matrix and reinforcement material used in this investigation.

2.1 Matrix and reinforcement material

In this work, two separate cases were considered for selection of matrix material. In first case, ABS was considered as matrix material and PETG was used as reinforcement material. In second case, PLA filament was used as matrix material and PETG was considered as reinforcement material. Three different reinforcement percentages were used for the preparation of test samples viz., 15%, 25% and 35%. ABS was the weakest material and PETZ was the stronger material among all the three material. The schematics arrangement of matrix and reinforcement material is shown in Fig.1. The characteristics of ABS, PLA and PETG materials are shown in table 2.

Table 1 Summary of the characterization of mechanical properties in FDM technology

Investigator Name	Material	Raster angle	Other process parameters	Mechanical properties
Durgun et al. [10]	ABS	0°, 30°, 45°, 60°,90°	Orientation (horizontal, vertical and perpendicular)	Tensile strength
Ravari et al.[11]	PLA	Constant	-	Compressive strength, collapse stress
Onwubolu et al.[12]	ABS	Constant	Layer thickness, part orientation, raster angle, raster width, and air gap	
Dawoud et al.[13]	ABS	0/−90, 15/−75, 30/−60, 45/−45	Raster gap	Tension, bending, impact
Espin et al.[14]	PC	constant	orientation	Young's modulus, ultimate strength, elastic constant, poission's ratio, shear modulus
Chacon et al.[15]	PLA	constant	Build orientation, layer thickness and feed rate	Tensile strength and bending strength
Mohamed et al. [16]	PC-ABS	0°, 45°and 90°	Slice height, air gap, part print direction, bead width and number of shells	Creep displacement (μm)

2.2 Selection of specimen geometry and 3D modeling

American society for testing and materials (ASTM) has fixed some standards for testing of materials under different tests [18)-23)]. The D638 series corresponds for tensile testing of plastic and polymers. ASTM D638 specifies methods for testing the tensile strength of plastics and other resin materials and for calculating their mechanical properties [24)]. Fig. 2 show the ASTM D638 Type-IV specimen which was fabricated through FDM printer. ASTM D638 specimen has the dog bone like structure [25)]. Specimen has shoulders at the both ends, which are wider than other portion of the structure. In this work, Autodesk Fusion @360 was used for the 3D modelling of the specimens shown in Fig. 2. 3D CAD model of specimen is shown in Fig. 3. The next section will give the fabrication method of test specimens.

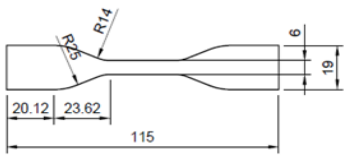

Fig.2: Drawing of ASTM D638 type-IV specimen

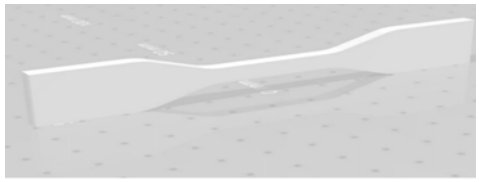

Fig.3: CAD design of specimen in .STL format

2.3 Fabrication method

Fused deposition modelling additive manufacturing technique was used in this research work for the preparation of test specimens. Three different materials were used for the fabrication of the specimen viz., acrylonitrile butadiene styrene (ABS), polylactic acid (PLA) and polyethylene terephthalate glycol (PETG). Printer used for the fabrication of test specimens was PRUSA MK3. This printer can manufacture the component of single material only. Additional machine mosaic pallet 2 was attached with PRUSA MK3 for fabrication of multi materials samples. For fabrication of specimens, all the process parameters were fixed and used at optimum levels. The process parameters used for the fabrication of samples are shown in table 3. Three different reinforcement percentages were used for the preparation of test samples viz., 15%, 25% and 35%. Fig. 4 shows the research methodology used for the improving part strength in the flow diagram. Experimental plan used in this research work is presented in Table 4. Figure 5 shows the schematic representation of dual extrusion nozzle used to fabricate test specimen. Figure 6 shows the fabricated samples, with and without reinforcement.

Table 3 Process parameters used for the sample fabrication

Process parameters	Value
Nozzle Diameter	0.4 mm
Infill Density	100%
Print Speed	60mm/s
Raster Angle	45°
Orientation	0° with respect to x axis
Layer Thickness	0.2 mm
Infill Pattern	Hexagonal

8	PLA	PETG	25%	46.72
9	PLA	PETG	35%	46.85

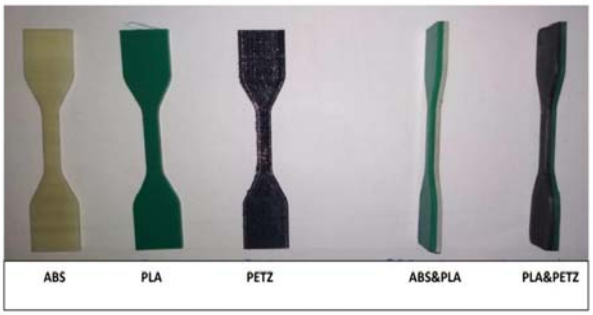

Fig.6: Fabricated specimen along the flat orientation

2.4 Experimental setup for tensile test

The tensile test of the fabricated specimen was conducted on universal testing machine Instron. The actual experimental set-up image is shown in Fig. 7. The specimen was hold between the cross head of UTM machine and axial tensile load was applied on the material at the one end. The corresponding stress-strain diagram was traced on computer according to the load. The specimens were tested at a rate of 1.5 mm/min.

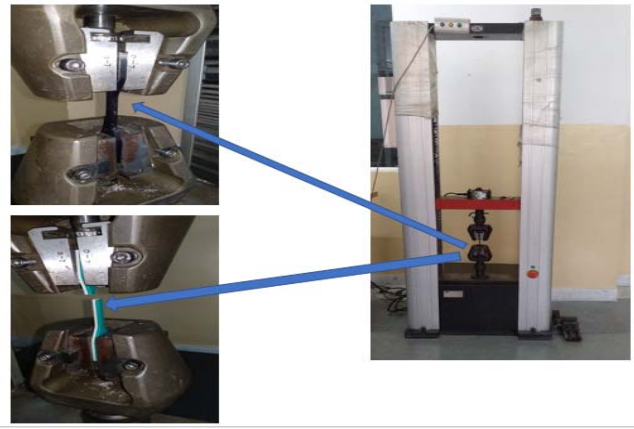

Fig.7: UTM Instron tensile testing machine

3. Computational analysis

For computational analysis, 3D CAD model of ASTM-D638 (tensile test specimen) was created by using Autodesk Fusion 360 software. The CAD model has been simulated by FEA Autodesk Fusion 360 software. A 8-node linear brick, reduced integration, hourglass control element was used for meshing of tensile specimen. After performing several mesh convergence studies 7284 elements with 1.0 seed size has been chosen for current simulation as shown in Fig.8.The bottom end of the specimen is fixed with the boundary condition Ux, Uy, Uz, Rx, Ry, Rz = 0, where Ux, Uy, and Uz are the translation in x, y and z direction respectively. Further, Rx, Ry and Rz are the rotation in x, y and z direction respectively. A velocity of 1.5 mm/min has been applied at the top surface of the specimen as shown in Fig. 9. A tie constraint has been applied to assemble the PLA and PETG in a common specimen for providing the mix effect of properties.

Total nine simulations were carried out to investigate the impact of reinforcement on mechanical properties of ABS and PLA (material). First three simulations were carried out without reinforcement to check the Von mises stress in the ABS, PLA and PETG (material) respectively. In this study, two cases were considered for the analysis. In case–I, ABS material was considered as matrix material and PETG was treated as reinforcement material. Unidirectional reinforcement material was placed between the matrix materials. The direction of reinforcement was considered in the loading direction. Three different reinforcement percentage was used i.e. 15%, 25% and 35%. In case-II, PLA was considered as matrix material and PETG (material) was considered as reinforcement material. However, the reinforcement percentage was used similar to case-I.

Material properties used for the simulation are shown in table 5. For simulation of samples without reinforcement, material was considered as single solid geometry. In case of reinforcement, two different materials system were defined; one for the matrix material and other was used for the reinforcement material

Table 5 Mechanical properties for FEA simulation

Material	Elastic modulus (E)	Shear Modulus (G)	Poisson's ratio (μ)
ABS	2110MPa	14605 MPa	0.39
PLA	30140 MPa	2310MPA	0.33
PETG	2300MPa	1640MPa	0.38

4. Results and discussion

4.1 Experimental result analysis

The average value of tensile strength for ABS, PLA and PETG materials with and without reinforcement has been calculated using 3 samples each. The effect of PETG reinforcement on tensile strength of ABS and PLA materials can be clearly seen in Fig.10. Due to reinforcement of PETG material, tensile strength of ABS and PLA material have significantly improved. Due to the uncertainty of experimental results, tensile strength is shown within the range of 5% error bar chart. The value of tensile strength of ABS material was improved by about 70% and tensile strength of PLA material was improved by about 8%.

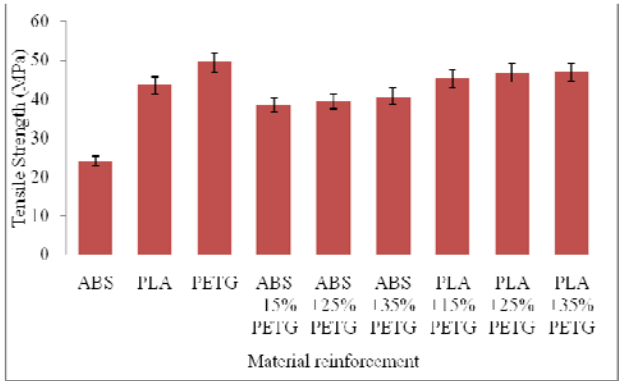

Fig.10: Effect of reinforcement on mechanical properties

4.1 Computational result analysis

Fig. 11 shows the Von mises stress of ABS and PLA materials with and without reinforcement of PETG material. It can be observed that the tensile strength of ABS and PLA materials was improved due to the reinforcement.

Results of computational study depicted that ABS samples was failed at a load of 577.2 N. The value of Von mises stress was observed 25.37 MPa at failure

point. Specimen of PLA material was failed at a load of 1044 N and value of Von mises stress was found to be 46.61 MPa. Sample of PETG material was failed at a load of 1188N and value of Von mises stress was observed 53.06 MPa. Fig. 12(a), (b) and (c) shows the Von mises stress in the specimen of ABS, PLA and PETG materials respectively. The value of Von mises stress was observed maximum in PETG material.

The effect of PETG reinforcement on mechanical properties of PLA was simulated with different reinforcement percentage. Fig. 13 shows the effect of reinforcement on Von mises stress of reinforced composite. Result shows that due to the reinforcement, the maximum value of Von mises stress for the PLA composite was found to be 50.51 MPa at 35% PETG reinforcement. It can be concluded that the tensile strength of PLA material was improved about 8% due to the reinforcement.

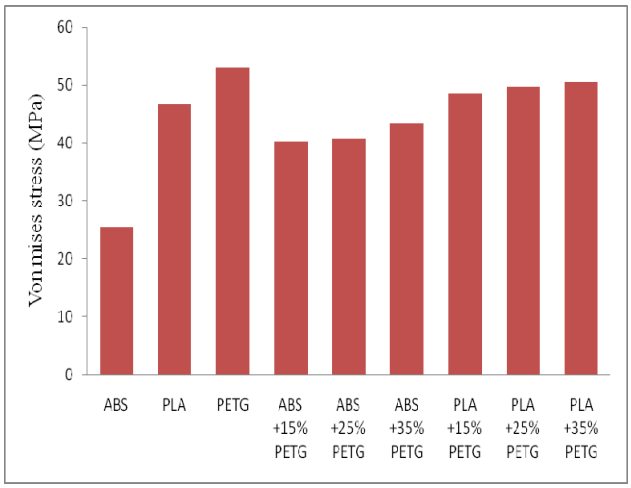

Fig. 11: Von mises stress in ABS and PLA materials

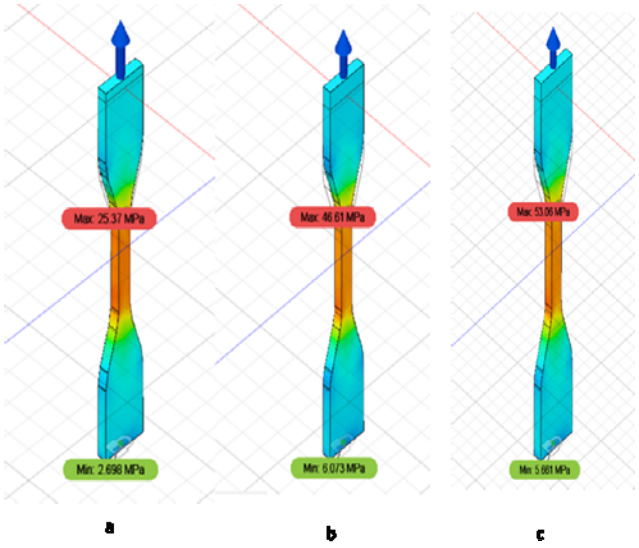

Fig.12: Von mises stress without reinforcement

(a) ABS material (b) PLA material (c) PETG material

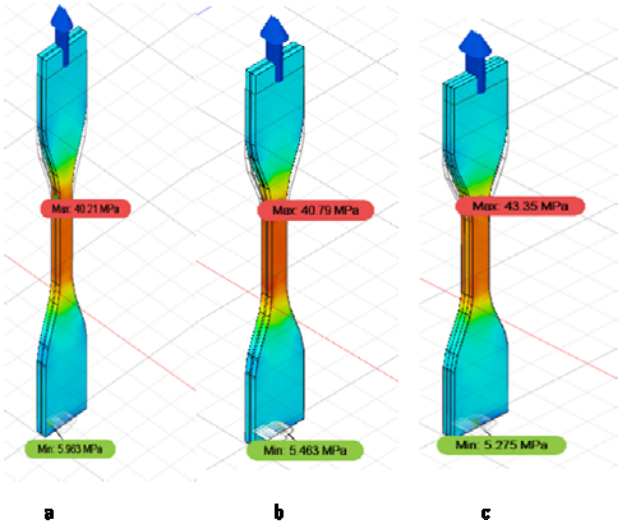

Fig.13: Von mises stress of PETG reinforced PLA composite

(a) 15% PETG (b) 25% PETG (c) 15% PETG

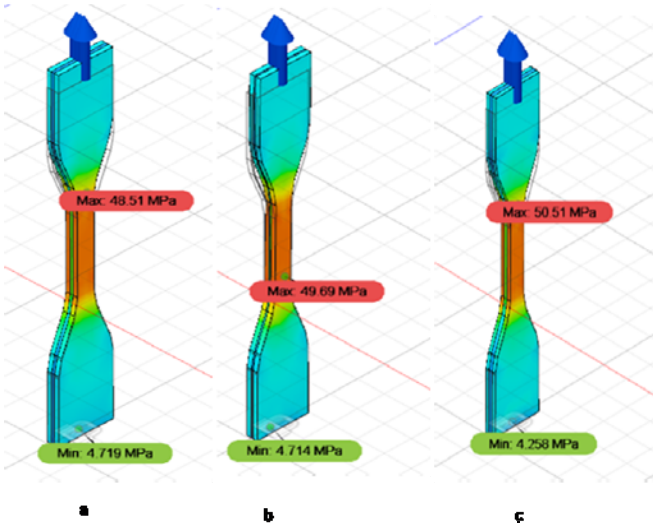

Fig.14: Von mises stress of PETG reinforced PLA composite

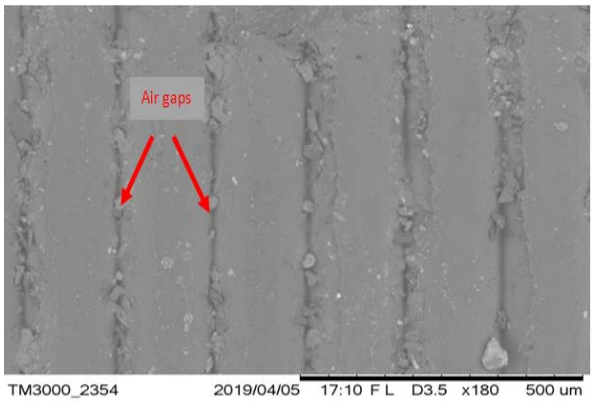
(a) 15% PETG (b) 25% PETG (c) 15% PETG

Fig.14 shows the effect of PETG reinforcement on Von mises stress of ABS material. Owing to reinforcement of PETG material, maximum value of Von mises stress of ABS was observed about 43.35 MPa at a reinforcement of 35%. Result depicted that the mechanical properties of ABS material was significantly improved. Due to the reinforcement mechanical properties of ABS was improved about 70%.

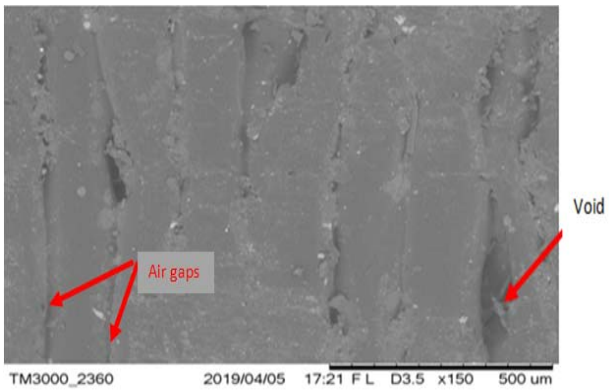
4.3 Surface morphology of fabricated specimen

For selecting the suitable orientation, surface morphology was performed. A scanning electron microscope (SEM) was used to visualize the defects in the fabricated samples. Fig.15 (a) shows the SEM image of ABS sample fabricated along flat orientation and Fig.15 (b) shows the SEM image of ABS samples

prepared along the edge orientation. It was observed that Voids were present in the component fabricated along the edge orientation, which yields poor tensile strength. For analysis of tensile test all the samples were fabricated along the flat orientation.



(a)



(b)

Fig.15: SEM image of ABS samples

(a) Flat orientation (b) Edge orientation

4.3 Comparison of experimental and computational results

Fig.16 shows the results of experimental and computational analysis. It can be concluded that results of computational analysis was close approximation to the experimental results. However, the experimental value of tensile strength was found to be less as compared to computational results. From SEM analysis, it was observed that there were some air gaps and voids present in the fabricated samples, which yields lower tensile strength.

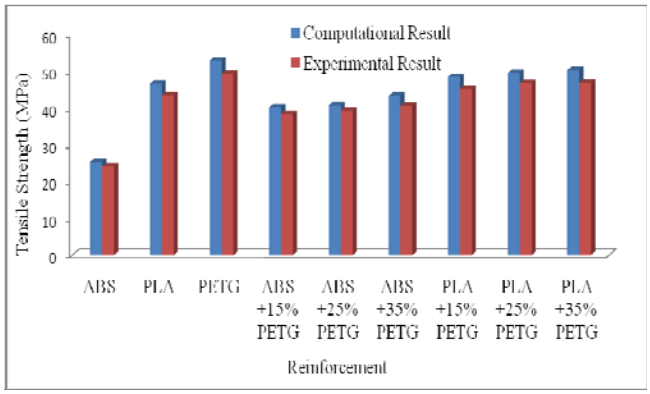


Fig. 16: Comparison of experimental and computational results

5. Conclusions from Present Work

In this study, effect of PETG (material) reinforcement on tensile strength of ABS and PLA materials were experimentally investigated. Computational analysis was also carried out in this investigation. The main conclusions of these studies are as below.

- It was depicted through surface morphology that components fabricated along the flat orientation have less defects as compared to edge orientation.
- Unidirectional reinforcement of PETG material have improved the tensile strength of ABS material by about 70% and strength of PLA material was improved by about 8%.
- From Fig. 16 it can be concluded that computational results were close approximation to the experimental results.
- However, computational results were slightly more as compared to experimental results which may be due to the presence of void and air gap between the layers of fabricated samples.

Experimental investigation of joining of aluminum alloy 5083 by friction stir welding (FSW)

R.S. Mishra, Preety Rani

Department of Mechanical, Production, Industrial and Automobiles Engineering, Delhi technological University, Delhi, India

Abstract

This study represents the Friction stir welding of aluminum alloy 5083 with vertical milling machine as a machine tool and specially designed heat treated high carbon steel as a tool. In the present investigation, three different process parameters i.e. tool rotation speed, transverse speed and pin diameter are selected with their three different levels. The DOE by L9 array is consisted of nine trial runs. The analysis of the results obtained has been performed according to the standard procedure recommended by Taguchi. Analysis of Variance (ANOVA) is employed to analyze the influence of these parameters on % elongation during welding process

Keywords: Friction stir welding (FSW), Tool rotation speed (TRS), Welding speed (WS) .Green Technology

1. Introduction

In friction stir welding a rotating tool is slowly plunged between the parting line of the two plates that need to be weld. The friction between rotation tool and the work piece produces frictional heat which softens the work piece material without reaching its melting point. The material aluminum alloy 5083 is chosen for the optimization of friction stir welding process parameter, which finds widespread application in aerospace industry, shipbuilding industry, pressure vessel and cryogenic tank in space craft.

1.1 Literature Review

Uzun et al. [1] has joined, aluminum alloy 6013-T4 with stainless steel X5CrNi18-10 by using FSW techanique. The aluminum alloy 6013-T4 plates of 4 mm thickness were welded with the plates of X5CrNi18-10 stainless steel of 4mm using FSW using milling machine. Zhang et al. [2] optimized the parameters of welding magnesium AZ31 by using friction-stir-welded to get defect-free weld. The hot rolled AZ31 (5*100* 200) mm was used as parent metal. The plates were welded by friction-stir-welding at different WS from 40 to 600mm/min and TRS 1000 RPM was same. Zhang and Zhang [3] joined two plates of Al 6061-T6 by using FSW. The tool consisting of the pin and the shoulder of radii were 5 and 22.7mm, resp. The two plates were of (100* 40 * 8) mm. Zhang et al. [4] joined the plate of AA 6061-T6 using FSW having tool of pin radius of 3mm and the shoulder radius of 7.5 mm. The welding plates were of 100*30*3 mm in length, width and thickness respectively. Kulekci et al. [5] made lap joints by FSW of AA 5754 plates by using a semi-automatic conventional milling machine. The AA 5754 plates were of thickness 3 mm, length 200 mm and width 100 mm. Fratini et al. [6] studied the flow of materials using finite element analysis (FEA), which occurs in friction welding and forms a T-joint. A thin piece of brass is used as a marker and placed on the boundary of the two necessary plates for welding. Sakthivel et al. [7] joined two plates of aluminum of dimensions (300*150*6) mm by using friction stir welding at a constant TRS of 1,000 rpm with different WS. The tool having a cylindrical threaded (1mm pitch 6mm) pin of length 5.75-mm with 15 mm shoulder dia. Zimmer and others. [8] Optimized the friction welding process parameters for force and torque generated by AA 6082-T651 with a thickness of 6 mm. Aval et al. [9] found a relationship between heat input and the microstructures of thermo mechanically affected zone of the joint of AA 5086 by friction stir welding. Jonckheere et al. [10] investigated the effect of tool and friction welding tool dimensions on fracture and shear properties at the friction stir point. Husain Mehdi et. al., [11-15], analyzed that the mechanical properties of FSW joint are mainly dependent on chemical composition and processing parameters of alloying element. The

http://doi.org/10.36037/IJREI.2019.3504

microstructural analysis of FSW joints shows the formation of new grain size in the weld zone with different amount of heat input by controlling the processing parameter. Rajakumar et al. [16] predicted the value of hardness and grain size of nugget region of friction stir welded AA-6061 weld joints. AA 6061 has huge applications in the production of light weight structures with good corrosion resistance and high strength/weight ratio. Liu et al. [17] carried out welding of aluminum 2219-T6 alloy using FSW and investigated effects of transverse speed on mechanical and micro structural properties. Ravindra [18] studied the effect of the tool rotation speed (rpm) and the tool probe profile on Friction Stir Processing in AA5083 of 2.5 mm thick. The experimentation was carried out using five different cylindrical, straight, square, triangular and conical pin profiles and using three tool rotation speeds that were 900, 1400 and 1800 rpm with a constant transverse speed of 16 mm / min. Yuvral et al.[19] investigate the effect of parameters and reinforcement of TiC nano particles of size 10-30nm . Shuhan et al. [20] made defect-free butt welds of titanium alloy with steel by FSW. Wwas done at TRS varied at 600 and 950 rpm with a constant weld speed of 47 mm/min. the result showed that increment in TRS increase the thickness of intermetallic compound layer. Wenya et. al [21] improve the tensile properties of magnesium AZ31 joining by friction stir welding zone by using a stationary shoulder.

2. Experimentation

A universal vertical milling machine used as the experimental machine in this study with a fixture used for clamping the workpiece with locking nut. The size of table is 254×1370 mm on which a fixture or backing plate is mounted which is used to hold the work-piece during welding. Two aluminium alloy 5083 plates of size 75mm×60mm×6mm are mounted on the fixture of vertical milling machine for making butt joint by using friction stir welding. The parameters which selected for this investigation are: tool rotation speed, transverse speed and tool pin diameter. Various experiments are conducted for optimize the response parameter i.e. %Elongation. Taguchi's robust design of experiments (DOE) methodology is used to plan the experiments statistically. Table 1 details the different control variables and their levels.

Table 1: Control variables and their levels

Parameters	Level 1	Level 2	Level 3
Tool rotation speed	1200 rpm	1950 rpm	3080 rpm
welding speed	20mm/min	25mm/min	30mm/min
Tool Pin diameter	5mm	6mm	7mm

All the selected parameters have equal levels. L9 and L27 orthogonal array has come out as the possible solutions for designing the experiments. Hence, L9 array was selected for the present investigation. The DOE by L9 array is consisted of nine trial runs as shown in table2.

The welding of two plates of AA 5083 is done according to the entire nine trail run. The joined plates after welding are shown in fig.1.

Figure 1: Plate after friction stir welding

Then two tensile test specimens are extracted from each welded piece. The dimensions of the test specimens are according to American Society for Testing of Materials (ASTM) standard and after extract from the welded plates are shown in fig.2**.** The values of % elongation were recorded and plotted as per Taguchi design of experiments methodology. Table.3 & Table .4 shows the values of % elongation against the input parameter setting for L9 orthogonal array.

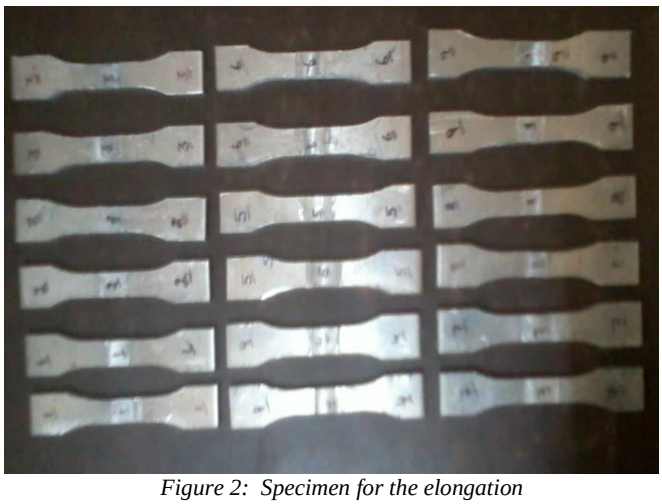

Figure 2: Specimen for the elongation

The analysis of the results obtained has been performed according to the standard procedure recommended by Taguchi. The main effects are studied by the level average response analysis of % elongation raw data or of S/N data. The analysis is done by averaging the % elongation data and/or S/N data at each level of each parameter and plotting the values in graphical form. The factor effects of different input parameters with their corresponding levels on S/N ratio and average response for % elongation are tabulated in table-3 & table 4 respectively.

Total	8	20.0846					

2.1 Analysis of Variance (ANOVA)

The purpose of ANOVA is to investigate the parameters, whose combination to total variation is significant. The ANOVA for Means of %elongation are given in table-5.

3. Results and Discussion

The main effect of input parameters on the response parameters (% elongation) are discussed on the basis of mean of response, ANOVA and plots between response parameters and input parameters. The plots show that how response parameters are varying at different levels of input parameters. The plots for mean and S/N ratio for % elongation are shown in fig. 3-4. It can be observed from fig. 3 that the Tool rotation speed, welding speed and tool pin diameter affects the % elongation very significantly. Moreover, the different input parameters used in the experimentation can be ranked in the order of decreasing %elongation as tool rotation speed, welding speed and tool pin diameter.

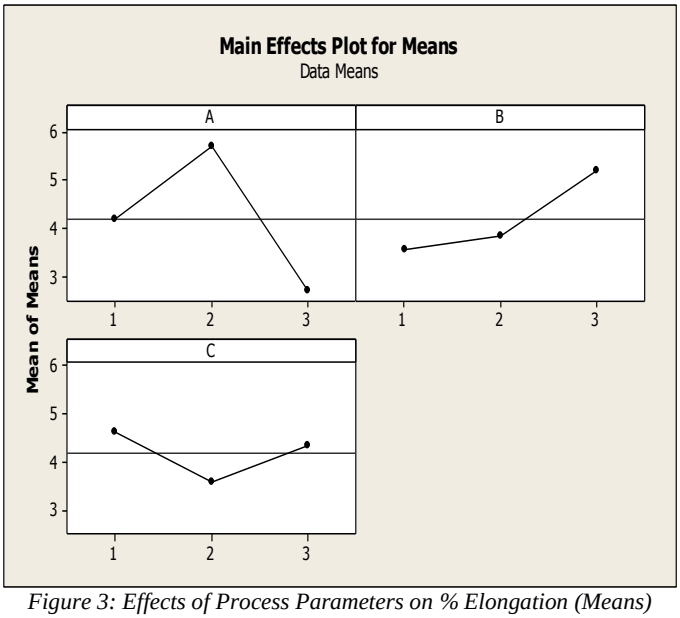

Figure 3: Effects of Process Parameters on % Elongation (Means)

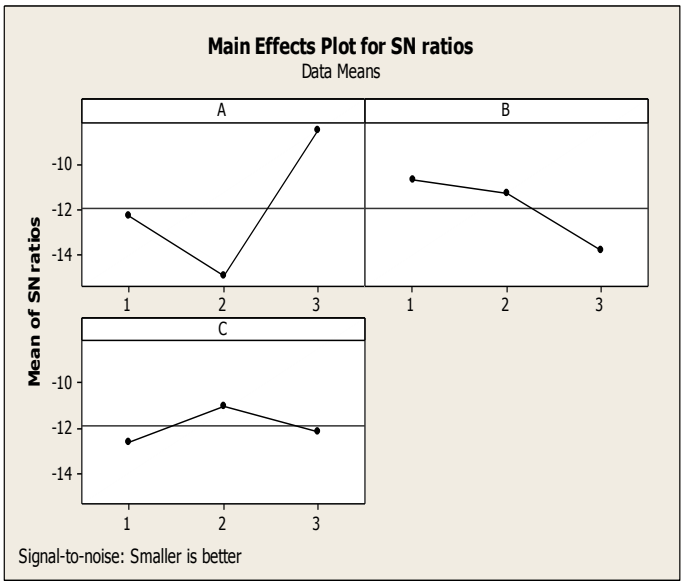

Figure 4: Effects of Process Parameters on % Elongation (S/N Ratio)

4. Conclusion

Following conclusions were drawn

1. In Friction stir welding, the Tool rotation speed is most significant factor for decreasing % elongation, welding speed is the second significant factor and Tool pin diameter is the third significant factor.
2. The most effective parameter with respect to %Elongation is tool rotational speed. Whereas the effect of welding speed and tool pin diameter on the %elongation was also significant.
3. By increasing the tool rotation speed, the %elongation first increases and then decreases. By increasing the welding speed, the %elongation is increased. By increasing the tool pin diameter, %elongation is first decreases and then increases increased.
4. The Computed results using ANOVA also showed that the tool rotational speed is the most effective factor with a percent contribution of 67.78%. The percent contribution tool shoulder dia. and welding speed is 23.24% and 08.58% respectively.
5. The input parameters settings tool rotation speed at 3080 rpm, welding speed at 20 mm/min, and tool shoulder dia. at 6 mm have given the optimum results for %elongation; in friction stir welding on AA 5083.

ABSTRACT

Abrasive flow machining (AFM) is a micro finishing methodology applied to achieve complex geometries which are not easy to obtain using other conventional techniques. AFM removes the material in form of small chips using abrasion mechanism. It gives good surface finishing but has a limitation of low material removal. To overcome the limitation, various hybridizations of AFM process have been developed. AFM process parameters such as pressure, velocity of media and temperature distribution on work piece play a major role in micro finishing. In order to enhance the AFM process capability, it is required to analyze the critical conditions of AFM process parameters using any commercially available software's. Therefore, in present study, three dimensional modelling of the media flow path in abrasive flow machining was developed and analyzed to obtain the effect of the parameters using ANSYS® and Fluent® software. Further to overcome the major limitation of the AFM process that is low material removal, an experiment was conducted using abrasive media with carbon nano tube (CNT) and alumina. To enhance productivity, AFM process was optimized using Taguchi L_9 OA. Also, the work piece wear during AFM process obtained from the experiments was compared with Reye–Archard–Khrushchov wear law.

Journal Pre-proofs

1. Introduction

It is a well known fact that finishing of a machine part / component / product generally improves its aesthetics and functional performance i.e. the fine finished parts have better dimensional controls, endurance strength and thus more useful life. Merchant [1] has analyzed the need and trends of future of manufacturing technology with assumption that past and present manufacturing activity can be conveniently mixed. In recent past, due to requirements of the better quality product with high precision, there was a need to develop close dimensional control along with increasing complexity in their shapes. For such finishing requirement, abrasive flow machining (AFM) process has evolved and since its invention, it has been convincingly used for the finishing of complex shapes product [2]. Among all non conventional finishing processes, AFM is most suitable to produce economically better finished surface in the complex geometric shapes. In AFM metal removal mechanism, extrusion of abrasives laden media (made up of a liquid polymer with abrasive particles) through a controlled passage is done that results in abrasion of the required surfaces. The abrasives are oriented randomly that act as flexible grinding tools. Abrasives laden medium is prepared with abrasives and polymer, has low viscosity and good abrading capability [3]. It removes the material layer thickness in the range of 1-10μm and can produce best surface finish achieved up to 50 nm [4].

The general conclusion drawn from the experiments reported in the literature review [4-25], is that the extrusion pressure should be high for better surface finish. If low extrusion pressure is used with low abrasive concentration and smaller grain size, the surface finish will be decreased. If low extrusion pressure is used with larger grains, it causes uneven distribution that result in variation in the surface finish of work pieces. So, for better surface finish optimum combination of extrusion pressure, grain mesh size and abrasive concentration is required [5].

AFM process has a major limitation of low material removal and also it cannot be used for large surface irregularities because it removes material uniformly from all surfaces. Therefore, imperfections in the shape cannot be improved [6]. Various researchers have hybridized AFM process with other non conventional processes to enhance the material removal by using centrifugal force, magnetic force, vibration, chemical action and so on in the media flow path. Walia et al. [7] used centrifugal force in the media flow path of AFM to reduce amount of cycles for removing the same material in comparison to simple AFM process. When centrifugal force is added in the simple AFM process, dynamic abrasive grains in the media is increased. The experimental results showed that CFAAFM produces no affect on the surface layers of work piece during finishing and also produced better surface finish in comparison to simple one way or two way AFM process after specific number of cycles [8-10]. Sushil et al. [11] used AFM nano finishing process to finish EDM generated surface. The result showed that extrusion pressure and material of work piece were the significant parameters in the finishing process and also provided better finish by removing the cracks and recast layer produced during the EDM process. Wang et al. [12] studied three process parameters during the experimentation viz. space between the helical edge and the work surface, helical slot thickness and amount of helical turns. The results show that the surface and helical edge space, amount of helical turns plays a crucial role in the

material removal. Sambharia et al. [13] proposed a unidirectional set up of AFM process and found that finishing time and viscosity of media provided a better finishing performance during the machining process. Venkatesh et al. [14] used Ultrasonic assisted AFM process to finish the bevel gear made of EN 8 material using the input variable as frequency of vibration, extrusion pressure, operating time and flow rate of media and observed that use of vibration during the machining removed higher peaks of the work surface in comparison to the other processes. Brar et al. [15] hybridized AFM process with ECA^{2}FM that enhanced the material removal by producing the electrochemical dissolution effect. Marzban et al. [16] tried to apply a spin motion along with the rotation of the work piece and found significant change in the material removal rate. Wan et al. [17] used zero order semi mechanistic approach for two way AFM process to decrease the time required for machining and found that using zero order methodology would be better for internal passages in Abrasive Flow Machining. Types of abrasive laden media also have an influential effect on material removal rate. SiC based media is found better in comparison to Al_2O_3 based media in terms of material removal rate [18]. A highly concentrated abrasive laden media corresponds to more viscous media which improves the surface roughness due to better abrasive holding capacity [19]. Mali et al. [20] reported that mesh size of abrasive particles was the most effective parameter for material removal. Mollah et al. [21] compared two algorithms for prediction of outputs and found better results in case of GA-trained RBFN as compared to BP- trained RBFN. A simulation analysis was carried out on ANSYS FLUENT software to calculate the material removal which was dependent upon the axial and radial stress. Seifu et al. [22] found that velocity of media was maximum at the converging section and was minimum at the walls of the work piece. Venkatesh et al. [23] observed from the computational approach that the media flow in UAAFM process did not follow the axial path as in conventional AFM, while it provided better axial movement to abrasives in UAAFM process. Chen et al. [24] demonstrated a simulation how to find the optimum design of polygonal passageways, having four helix core and found that polygonal passageways produce more deviation in strain rate in comparison to the helical passageways. Fu et al. [25] observed irregular streamlines near trailing edge during the movement in axial direction and also observed a huge pressure reduction towards the flow. Wei et al. [26] proposed a new media based on guar gum hydrogel having better machining capability at higher shear strain rate conditions. From the experimental results it was found that guar gum based hydrogel media provided better surface finish in comparison to styrene butadiene based media under shear thickening condition. Bouland et al. [27] used combination of numerical and experimental approach to predict the results of the finishing process. It was found that simulation and experimental results were very close for the material removal. Han et al. [28] finished 15-5 PH stainless steel internal channel surfaces using AFM process and studied about the residual stress profiles generated over the surface. It was observed that this process generates compressive residual stress over the surface because temperature rise in AFM process was not comparable to grinding and turning. Lv et al. [29] numerically investigated the erosion mechanism in hard brittle materials. From the results it was observed that the radial and lateral cracks were the main mode of fracture during the finishing process. Wang et al. [30] finished different types of coated and uncoated milling cutter through Abrasive Flow Machining process to

Journal Pre-proofs

sharpen its cutting edges. The researcher found that micro sized diamond films raised the roughness of both rake and flank faces and reduced the radius of cutting edges. Shao & Cheng [31] analyzed the surface roughness and topography profile generation in AFM process and found that abrasive media volume creates largest difference in the machining system.

In present research, CNT additive with alumina has been used as abrasive media to study the critical parameters of AFM such as pressure, velocity and temperature distribution of media on the work piece surface through simulation in ANSYS® and Fluent® software. The material removal obtained from both experimental as well as computational model has also been compared. Further AFM process was also optimized using Taguchi L_9 OA.

2. Materials and Methods

The two way AFM setup was used, which pressurizes the abrasive media to flow through the internal cylindrical surface [32, 33, 34]. The AFM components include hydraulic power pack, hydraulic cylinders, media cylinders, nylon fixture, machine frame (Fig. 1 (a) & (b)). The AFM used a non-Newtonian liquid polymer containing nano tubes CNT particles along with aluminium oxide abrasive particles as shown in fig. 2. The Aluminium work pieces used in the experiment are as described in fig. 2 & 3.

2.1 Material Removal

Material removal signifies the material removed from the specimen in a specified to and fro motion of the media. Material removal was calculated from the formula as follows:

MR= weight of specimen prior machining - weight of specimen after machining

2.2 (% improvement in R_a)

% improvement in R_a = (Initial Roughness - Final Roughness)/(Initial Roughness) * 100

DOE was used to identify the effects of the parameters being taken on response characteristics (material removal & % improvement in surface roughness) of AFM process. Taguchi parametric design methodology was adopted. The experiments were performed by using orthogonal array (OA) of L_9 standard with 3-levels of orthogonal array and consists 8 degree of freedom. The process parameter affecting the performance and their levels are given in the Table 1.

Table 1 Process Parameters and their values at different levels

Symbol	Process Parameters	Unit	L1	L2	L3
P	Extrusion Pressure	MPa	11	22	33
C	Amount of CNT	Gram	With-out CNT	5	10
N	No. of Cycles	Number	3	6	9
Polymer to Gel ratio: 1:1, Work piece Material- Aluminium, Abrasive type- Al_2O_3& CNT in the ratio (1:2), Al_2O_3 Mesh Size: 180, Media Flow Volume: 290 cm^3, Temperature: 32± 2 °C, Initial surface roughness: 1.1 - 2.96 microns					

The three process parameter pressure, amount of CNT, no. of cycles was selected as shown in Table 1. Experiments were performed according to the standards described by the L_9 OA. Every experiment was performed for three times. Because of 9 operations performed three times each, twenty seven test specimens were selected whose initial surface was in the range of (1.1 – 2.96 micron). For each sample operation and its replications, the material removal and % improvement in R_a was measured and has been shown in Table 2.

Table 2 Experimental Results of Material Removal as per Taguchi L_9 OA

3. Modelling of 3- dimensional media flow path in AFM process

Modelling of Abrasive flow machining was carried out to know the critical parameters (pressure, velocity of media and temperature distribution on work piece surface) during the machining to increase the efficiency of the process. Also this analysis was used further to predict the wear using the Reye–Archard–Khrushchov wear law. The equation given by the law is as follows [36]:

$$Q = \frac{K.W.L}{H}$$

Where, Q = Total volume of the wear debris

K= Dimensionless Constant

W= Total Normal Load

L= Sliding distance

H= Hardness of the softest contacting surfaces

The wear obtained from the computational analysis was compared with the experimental results.

Sachin et al. [37] performed FEM modelling to obtain the finishing forces and found experimentally that the process was capable of producing mirror like surfaces.

A 3-dimensional model of Abrasive Flow Machining with the flow domain and boundary conditions is shown in fig. 4. Assumptions made during the modelling of abrasive flow machining, are as following-

- This model is pressure based model.
- The analysis is based on the Green Gauss cell based.
- The formulation used is absolute velocity and implicit.
- The media flows in a 3- dimensional path.
- The media flows symmetric to the path of hollow surface.
- Media is homogeneous and isotropic.
- The flow of media is steady in nature.
- Flow is laminar.
- There is sliding motion between the abrasive particle and work piece surface.
- It is assumed that the area of asperities is circular in shape.
- Abrasive particles will completely pass the asperities.
- Wear occurs in hemispherical shape.
- Each asperity will not participate in the material removal.

Journal Pre-proofs

Fig. 4(d) and (e) shows the top view and cross-sectional view of the model which includes abrasive particles, CNT particles and work piece which is taken as aluminium in this analysis. Properties taken for CNT, Polyborosiloxane, alumina and aluminium work piece during analysis are given in Table 3.

Table 3 Properties taken for Analysis

CNT density	1340 kg/m^3
CNT thermal conductivity	3000 W/m-K
CNT strength	40 GPa
Polyborosiloxane viscosity	414 kg/m-sec
Density of Polyborosiloxane media	1219 kg/m^3
Polyborosiloxane thermal conductivity	0.22 W/m-K
Density of Alumina	3890 kg/m^3
Specific heat of Alumina	451 J/kg-K
Thermal conductivity	12 W/m-K
Density of Aluminium	2700 kg/m^3
Elastic Modulus of Aluminium	69 GPa
Specific heat of Aluminium	900 J/kg-K
Thermal conductivity of Aluminium	205 W/m-K

To analyze the variables in AFM, Fluent software® was also used for final analysis of results. Figure 4 (c) shows the flow domain and boundary conditions used in the analysis. Fluid inlet and outlet was selected and then meshing was done in ANSYS® 15 as shown in figure 4 (f). After meshing, it was imported to fluent software® for further analysis. For analyzing the model, the media was taken as the mixture of polyborosiloxane and alumina abrasive along with CNT particles. The applied pressure was 40 MPa on the inlet side and at the outlet side pressure was 20 MPa because the media flow in the abrasive flow machining was due to pressure difference between the upper and lower cylinder. For the media movement from the upper to lower chamber, upper cylinder was maintained at high pressure and lower cylinder was maintained at low pressure.

4. Calculation of Total Wear debris

If it is assumed that the asperities are circular in shape then area of asperity will be = $\pi.a^2$

Where a = radius of circular asperity

Acting Load W = P. $\pi.a^2$. N_a

Where P = Pressure exerted on the work piece surface during the media flow

N_a = dynamic number of abrasive particles participating in the material removal process

Sliding length for one asperity L = 2a

Number of abrasive particle in full volume of media (N), [8] = $\frac{V_a}{V_o}$

Where V_a = Volume of abrasive grain in full volume of media

V_o = Volume of one abrasive particle

= $\frac{4}{3}.\pi.(\frac{d}{2})^3$

$V_a = \frac{C.V_m.d_m}{d_a}$

Where C = Concentration of abrasive in the media

d_m = density of media

V_m = Volume of media

d_a = Density of abrasive particle

Total number of abrasive particle in contact with the work surface (N_a), [8] = $\frac{4.V_a(D.d-d^2)}{V_o.D^2}$

Fraction of abrasive particle participating in Material removal = $\frac{N_a}{N}$

5. Synthesis of Carbon Nanotubes

This section deals with the growth mechanism and production of carbon nanotubes using chemical vapor deposition (CVD) technique. In CVD technique, the carbon source in the gas phase and an energy source as heated coil for transferring the energy to the gaseous carbon molecule were used. The CVD technique has an advantage of low power consumption, better purity, low range of temperature. The CVD method can be used for producing both single wall and multi wall CNT depending upon the range of temperature. A carbon nano tube structure consists a long and thin cylinder of carbon atoms. The carbon nano tubes are two types; single wall and multi-wall. The difference between the single wall and multi-wall is due to atomic layer of CNT. CNT single walled is formed by a single atomic layer whereas in multi-walled CNT, the wall is formed with more than one atomic layer. Single wall has better distributed carbon atoms structure while multi-wall has defects in its. The tube diameter of single wall ranges between 0.5-4.8 nm. Multi-wall nanotube has its inner diameter in the range of 1.4-14 nm and outer diameter in the range of 2.4-48 nm.

To synthesis CNT, in the CVD method, a hydrocarbon vapor is passed through the tubular reactor which consist a catalyst material having temperature in the range of 600-1200 ^oC to decompose the hydrocarbon. CNTs grow on the catalyst in the reactor on cooling it at the room temperature. For synthesizing CNTs some metal particles are required which can decompose hydrocarbon at a lower temperature. Normally used metals are Fe, Co, Ni and so on [38]. The reason for using such metals is high solubility of carbon in these metals at a very high temperature and carbon diffuse at a faster rate in these metals. Catalyst acts in a different manner in different materials. In CVD method normally substrates used are silicon, silicon carbide, alumina etc. For better growth of CNT,

Journal Pre-proofs

there should be proper interaction between the catalyst and the substrate. The interaction between the catalyst and the substrate will form a chemical bonding.

The main apparatus used to make CNT, is as shown in Fig. 5(a). CNT particles were synthesized by the chemical vapour deposition (CVD) method. Major parts of CNT equipments were oven, tube, beaker, cylinders of argon and hydrogen for shielding. A quartz tube of the dimension as inner diameter of 3.5 cm and length of 60 cm was used to generate CNT vapour. The machine had two zones preheating zone and heating zone. The temperature of the preheating zone varied from 100-150 ^{o}C and its length was 10 cm. The heating zone was 15 cm long and its temperature ranges from 700-825 ^{o}C. 50 ml solution of ferrocene / toluene with the ratio of ferrocene as 0.02 gram in 1 ml of toluene was sonicated and then it was dropped into the preheating zone for evaporation. Argon gas was supplied to carry out the vapours of ferrocene/ toluene to the reaction zone. As the evaporation process completed, then system was allowed to cool. CNT particles were scratched off from the inner wall of the quartz tube [38].

To overcome the major limitation of AFM that is low material removal, iron based carbon nano tubes particles were used along with aluminium oxide (AI_2O_3), because CNT particles are harder than the aluminium oxide. The TEM and SEM images shown in Fig. 5(b) and 5(c) describe iron filled CNT at various locations. The image also shows that the CNT growth has lesser number of carbon impurities which improves its strength and the sharp edges of CNT will not deteriorate easily during the abrasion process.

6. Results and discussion

The final analysis of modelling was performed in Fluent® software to identify the critical conditions of the selected parameters (Pressure, Velocity of media and temperature distribution on work piece surface). The effects were taken on the plane (0,0,0) & (1,0,0) in the geometry. Fig. 6 shows the media velocity along Z axis, where the media was entering and continuously decreasing as it was reported similarly in the literature [39]. As shown in Fig. 7, the velocity of the media flow was maximum at the centre after striking on the work piece surface [40]. When abrasive particles in the media impacts over the work surface, it increases the velocity of the media due to gain of energy after impact [40]. The figure also shows that the media velocity decreases near the wall [41]. This is due to continuously energy loss caused by the frictional forces developed between the fluid particles as already documented [39]. The result also showed that as the media started flowing, continuously from one media cylinder to another (Fig. 8), there would be increase in the media temperature, which was reported previously [6]. The influence of media temperature on the work efficiency is very critical. Figure 8 also shows hot spots on the surface. These hot spots on the surface are observed due to media temperature rise. The rise in the media temperature occurs due to frictional resistance offered by the media particle and outer boundary. Media temperature increases continuously with the increase in number of cycles [42]. This may be the reason of increasing hot spots over the surface. It increases the media temperature that will reduce the viscosity of the media which corresponds to less abrasive holding capacity. The wear rate of the particles increases initially but more increment in the temperature of media results in reduction of the wear rate. Fig. 9 shows the variation of extrusion pressure from inlet to outlet of media fixture chamber in abrasive flow machining setup. The total pressure in the flow is the combination of static and dynamic pressure. Static pressure is due to the random movement of molecules in the fluid and dynamic pressure is due to the motion of the fluid. In AFM process media flows between the media cylinders due to the pressure difference created between both the hydraulic cylinders. Figure 9 shows that as the media flow start from the higher pressurized region to the lower pressurized region, pressure reaches its maximum value at the centre, where minimum standoff distance occurs between the flexible tool and work piece surface [40]. After increasing pressure again it starts decreasing gradually till its outlet. The reason of the pressure reduction is the friction losses in media flow.

6.1 Material removal calculation using CFD model

Hardness of Aluminum work piece = 1049 MPa

Pressure exerted by the abrasive particle over the surface = 2.997 X 10^7 Pa

a = 16.5 micron

C= 0.6, d_m = 1219 kg/m^3, V_m = 290 X 10-6 m^3,

d_a = 1340 kg/m^3

On putting the values,

V_a = 159.37 X 10^{-6} m^3,

V_o = 0.188 X 10^{-13} m^3,

Number of abrasive particle in full volume of media = N = $\frac{V_a}{V_o}$ = 847.71 X 10^7,

N_a = 1.392 X 10^8,

K = $\frac{N_a}{N} = 0.0164$,

W = 3.565X10^6 N,

Total wear debris = 1.84 mg

6.2 Experimental observations

The experiments were performed as per L_9 OA table. For every trial conditions three work pieces were used for finishing at random run order according to Table 2. The response parameters were MR and % improved R_a.

Weight of the work piece was obtained by precision weighing machine (SHIMADZU AUX220) having 0.1 mg resolution. Surface roughness was taken at five different surfaces of the work piece and average of these values was taken for the initial and final value of surface roughness.

% improvement in R_a

= (Initial Roughness- Final Roughness)/(Initial Roughness) * 100

Surface roughness was measured by Taylor Hobson precision machine having resolution of 0.01 micrometer. The % improved R_a value for each trial condition is shown in Table 2. Higher the better quality characteristic was taken for the responses and for calculating the signal to noise ratio (Table 2) as given in equation 1 [43, 44].

$$(S/N)_{HB} = -10 \log[\frac{1}{n} \sum_{j=1}^{R} \frac{1}{Y_j^2}] \quad (1)$$

It can be seen from the Fig.10 that up to level 2 of extrusion pressure, material removal increases and after level 2 the material removal decreases. It is due to fact that on increasing the pressure cutting force increases and due to large cutting force, abrasives cut the peaks of the surface; therefore material removal is more [42]. However, when the pressure increases further, abrasives in the media cannot roll properly and so media may be drifted as a block with less number of cutting edges with contact of the work surface that slows down the rate of material removal.

From Fig.11, it is found that on increasing amount of CNT particles, material removal also increased. Using conventional abrasives like alumina, silicon carbide has major limitation that during the finishing operation its sharp edges go blunt easily and breaks into small pieces because of low strength and brittle in nature, which reduces the material removal. But CNT particles have a greater strength in comparison to the other conventional abrasives and maintain its sharp edges for a long time. It also does not break easily during the impact on the work surface. This greater strength makes it perfect to use as an abrasive and will reduce the energy requirement during the finishing process.

From Fig. 12, it was found that as the number of cycle were increased initially, the MR value decreased but after sometime as the number of

Journal Pre-proofs

cycle further increased from 6 cycle to 9 cycle, material removal also increased. It may be due to, up to some number of cycles media is very viscous and leads to number of active abrasive particles decrease. As soon as number of cycle's increases, more abrasive particles can contact the work piece due to some decrement in the viscosity and can provide more indentation.

Sankar et al. [45] reported that as the no. of cycle increased, the total no. of indentations by abrasive also increased, so material removal increased. But when the number of cycles was further increased material removal would decrease. Liang et al. [46] investigated that as the no. of cycle increased the temperature continuously increased that caused less material removal. It was reported in the literature, number of cycles was the most significant parameter among various parameters towards the responses such as material removal and improvement in surface finish [47].

		L3-L2	-0.42	-2.99	0.25	3.26	0.22
Difference (L3-L2)–(L2-L1)		-0.98	-9.98	-0.05	-0.32	0.64	8.23

L1, L2, L3 represent levels 1, 2 and 3 respectively of parameters. (L2-L1) is the average main effect when the corresponding parameter changes from Level 1 to Level 2. (L3-L2) is the main effect when the corresponding parameter changes from Level 2 to Level 3

To analyze the effects of parameters on the response character, which is material removal in this study, analysis of variance was used. Table 5 and Table 6 respectively represent the ANOVA of raw and S/N data. It is denoted from the tables that the parameters extrusion pressure, amount of CNT and No. of Cycle [35] affects the mean and the variability in the material removal values.

Table 5 Shown the ANOVA for Raw Data (MR)

Source	SS	DOF	V	F-Ratio	SS’	P%
Pressure	1.56	2	0.78	17.90*	1.47	32.22

*Significant at 95% confidence level, F critical =19(Tabular Value)						

The optimal material removal was determined and related confidence intervals were predicted. The mean at the optimal is estimated as

$$\mu = \bar{P}_2 + \bar{C}_3 + \bar{N}_1 - 2\bar{T} \quad (2)$$

$\overline{T}$= total mean of the response = 0.81 mg [Table 2]

$\bar{P}_2$ = Average material removal at the 2nd level of Pressure = 1.14 mg [Table 4]

$\bar{C}_3$ = Average material removal at the 3rd level of CNT= 1.08 mg [Table 4]

$\bar{N}_1$ = Average material removal at the 1st level of no. of cycle = 1.02 mg [Table 4]

On putting the values, Mean MR = 1.62 mg

$$CI_{COE}\ [48,50] = \sqrt{F_a(1, f_e) V_e \left[\frac{1}{n_{eff}} + \frac{1}{R}\right]} \quad (3)$$

$$CI_{POPU} = \sqrt{\frac{[F_a(1, f_e)\, V_e]}{n_{eff}}} \quad (4)$$

Where CI_{COE} = Confirmation experiments confidence interval

CI_{POPU} = confidence interval of population

f_e = Error degree of freedom = 20

N = Entire number of experiments

=27 (experiment =9, Iteration =3)

R = Confirmation experiments size = 3

V_e = 0.04 (Table 5)

n_{eff} [44, 49]=

$$\frac{N}{1+[Degree\ of\ freedom\ for\ the\ estimated\ mean\ response]} \quad (5)$$

= 3.86

So, CI_{COE} = ± 0.29

and CI_{POPU} = ± 0.19

The optimal range for the confirmation runs of the repetition at 95% confirmation interval:

Average MR – CI_{COE}< Material Removal < Material Removal + CI_{COE}

1.33< Material Removal <1.91

Predicted mean for 95% confirmation interval is:

Average Material Removal – CI_{POPU}< Material Removal < Material Removal + CI_{POPU}

1.43< Material Removal <1.81

Journal Pre-proofs

Journal Pre-proofs

The mean values of % improved R_a and S/N ratio for every input variable at all the levels were calculated and given in Table 7.

Table 7 Average values and Main Effects: Percentage improvement in surface roughness

Process Parameter	Level	Pressure(P)		Amount of CNT(C)		No. of Cycle (N)	
Type of Data		Raw Data	S/N Ratio	Raw Data	S/N Ratio	Raw Data	S/N Ratio
Average Values(%R_a)	L1	13.70	22.24	11.86	20.99	15.48	22.84
	L2	24.14	27.33	20.67	25.77	16.34	24.23
	L3	13.04	22.17	18.36	24.98	19.07	24.68
Main Effects(%R_a)	L2-L1	10.44	5.09	8.81	4.78	0.86	1.39
	L3-L2	-11.10	-5.16	-2.31	-0.79	2.73	0.45
Difference (L3-L2)–(L2-L1)		-21.54	-10.25	-11.12	-5.57	1.87	-0.94

It can be clearly noticed from the Fig.13 that as the pressure increased, the surface finishing of the work piece increased initially but after level 2 (i.e 22 MPa) of pressure, the value of improvement in surface finishing decreased. Because of more material removal, initially greater surface finishing was achieved but after level 2, due to higher pressure the abrasive in the media could be drifted and less number of abrasive could contact to the work surface that reduces the material removal. Therefore it can lower improvement in surface finishing. It can also be seen from the Fig. 14 that as the amount of CNT increased, percentage increase in R_a also increased but after level 2, percentage improvement in R_a started decreasing at a slow rate. Carbon nano tubes are strong and elastic in nature. When the pressure is being applied at the tip of the nano tube it starts bending without being damaged. Again when the pressure is relieved, it comes to the original position if the pressure applied is within the limit. That is the reason it may remove more material from the surface and provides better surface quality initially.

Fig. 14 shows that on increasing the amount of CNT, more material removal caused better surface finish. But after 5 gram of CNT less surface finishing was obtained. The reason may be that on further increasing CNT amount, the material removal would deteriorate the level of finishing and the rate of % increment in R_a would slow down. From Fig. 15, it is defined whenever the number of cycle is increased; the percentage increase in surface finish is increased. It may be that on increasing the number of cycle, the contact area of the abrasive and work surface can be more which corresponds to the better surface finishing.

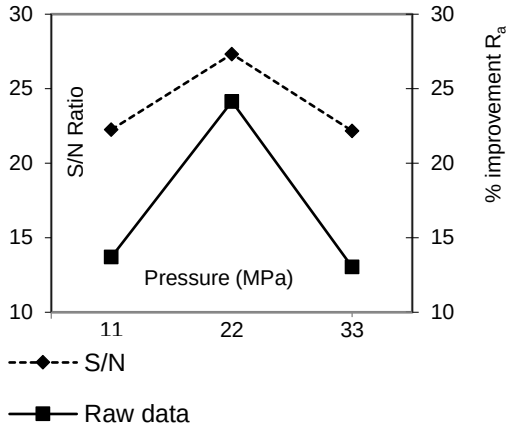

Fig 13 Shown effect of pressure on S/N ratio and % improvement in R_a

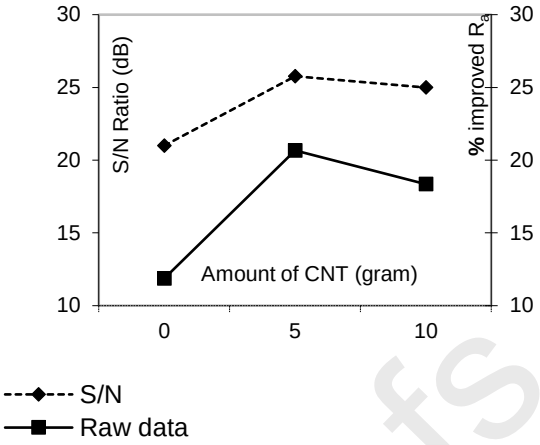

Fig 14 Shown effect of Amount of CNT on S/N ratio and % improvement in R_a

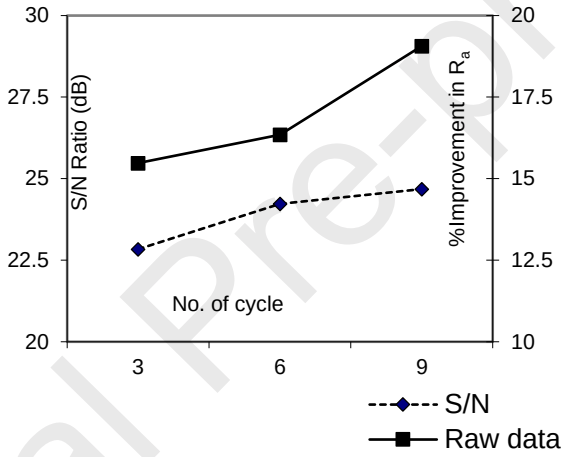

Fig 15 Shown effect of No. of Cycle on S/N Ratio and % improvement in R_a

To analyze the significance of the parameters against the % improved R_a, (ANOVA) was used. The pooled versions of Analysis of variance for both raw and S/N data against % improved R_a are provided in Table 8 and 9.

Table 8 Pooled ANOVA (Raw Data)(ΔR_a)

Source	SS	DOF	V	F-Ratio	SS'	P%
Pressure	697.78	2	348.89	107.95*	691.32	57.58
Amount of CNT	375.21	2	187.60	58.047*	368.75	30.71
No. of Cycle	63.08	2	31.54	9.76*	56.61	4.72

Total (T)	1200.70	26	*	-------	1200.70	100
*Significant at 95% confidence level, F critical =3.4928(Tabulated Value)						

Journal Pre-proofs

Table 9 Pooled ANOVA (S/N Data)(ΔR_a)

Source	SS	DOF	V	F-Ratio	SS'	P%
Pressure	52.43	2	26.22	279.77*	52.24	53.61
Amount of CNT	39.30	2	19.65	209.70*	39.11	40.14
No. of Cycle	5.53	2	2.76	29.50*	5.34	5.48
e	0.19	2	0.09	------	0.75	0.77
Total (T)	97.45	8	--------	-------	97.45	100
*Significant at 95% confidence level, F critical =19(Tabulated Value)						

The optimum values of % improved R_a is estimated as:

$\mu = \bar{P}_2 + \bar{C}_2 + \bar{N}_3 - 2\bar{T}$ (6)

$\bar{T}$ = Total mean = 16.96 %

$\bar{P}_2$ =Average % age improvement in R_a at the 2nd level of extrusion Pressure = 24.14%

$\bar{C}_2$ =Average % age improvement in R_a at the 2nd level of CNT = 20.67 %

$\bar{N}_3$ = Average % age improvement in R_a at the 3rd level of No. of Cycle =19.07%

Putting the given values, % improvement in R_a = 29.96 %.

So, $CI_{COE} = \pm 2.58$

and $CI_{POPU} = \pm 1.70$

f_e =3.49 (Tabulated Value)

f_e =error Degree of freedom = 20

N= Entire number of experiments =27 (experiment =9, Iteration =3)

R = Confirmation experiments size = 3

V_e = Error variance =3.23

By using equation no. (5), one may achieve

n_{eff} = 3.86

The optimal range for the confirmation runs of the iteration at 95% confirmation interval:

27.38< % improved ΔR_a<32.54

Predicted mean for 95% confirmation interval is:

28.26<% improved ΔR_a <31.66

From the confirmation experiments, the optimal levels of the process parameter for material removal are $P_2C_3N_1$.

Whereas for the maximum % improved R_a, the optimal parameters settings are $P_2C_2N_3$.

P_2 = Extrusion Pressure at second level =22 MPa

C_2 = Amount of CNT at second level =5 gram

C_3 = Amount of CNT at Third level =10 gram

N_1 =No. of Cycle at first level =3

N_3 = No. of Cycle at third level =9

The results are presented in Table 10 for material removal and % improved R_a both.

Journal Pre-proofs

The values of material removal and % improved R_a obtained through the confirmation experiments are inside the specified range.

Table 10 Predicted Optimal Values, Confidence Intervals and Results of Confirmation Experiments

Response Characteristic	Optimal Process Parameters	Predicted Optimal Value	Confidence Intervals 95%	Actual Value
MR	$P_2C_3N_1$	1.62 mg	CI_{CE} 1.33<MR<1.91 CI_{POP}:1.43<MR<1.81	1.73 mg
%Improvement ΔR_a	$P_2C_2N_3$	29.96 %	CI_{CE}:27.38<%ΔR_a<32.54 CI_{POP}:28.26<%ΔR_a<31.66	30.93%

7. Conclusions

Using carbon nano tubes along with alumina as abrasives in AFM for which the results are reported in this study can be one way to get highly precision components. Following conclusions can be made:

1. The simulation and experimental results were quite similar for the material removal; minor discrepancies might be minimized through the adjustments in the boundary conditions.
2. On comparing the material removal results obtained from experimental and modeling, it can be observed that material removal for the model is slightly higher (6.35 %) in comparison to experimental results. This reduction in material removal for experimental results may be due to losses occurring during the media flow.
3. The ANSYS® modelling shows that the velocity of the media is maximum at the centre when the abrasive particle is impacting over the surface and is least at the outlet point. It can also be observed that velocity of media continuously decreases after the impact on work surface. From modelling it can also be concluded that temperature of media starts increasing with the flow and is maximum at the outlet, while pressure continuously decreases between the initial and final point.
4. The addition of carbon nano tubes as abrasive along with the alumina enhances the Material Removal and R_a of the work piece.
5. The experimental results show that Pressure is contributing a maximum as 32.22%, amount of CNT is contributing 27.36% and number of cycle is contributing 15.65% in the material removal.
6. The experimental result shows that on using CNT as abrasive particle, 0.6 mg more material removal is obtained at 10 gram of CNT and also gives 10 % more percentage improvement in surface roughness at 5 gram amount of CNT compared to the conventional abrasives.
7. In terms of percentage improvement of surface roughness during finishing process pressure is contributing 57.78%, amount of CNT contributes 30.71% and number of cycle contributes 4.72 % in surface finishing.
8. The predicted optimal range for material removal is 1.33 < Material Removal (mg) < 1.91 and that for % increase in ΔR_a is 27.38<%ΔR_a< 32.54.
9. The 95% confidence interval of the material removal is 1.43 < Material Removal (mg) < 1.81

Journal Pre-proofs

and that for % increase in ΔR_a is 28.26< $\%\Delta R_a$< 31.66.

10. The result shows that the optimum process parameter for the material removal is second level of pressure i.e 22 MPa, third level of amount of CNT i.e 10 gram and first level of number of cycle i.e 3, which gives the optimum value 1.73 mg for the material removal.

11. The result shows that the optimum process parameter for the % improvement in surface roughness is second level of pressure i.e 22 MPa, second level of amount of CNT i.e 5 gram and third level of number of cycle i.e 9 and gives the optimum value 30.93% for the % increment in surface roughness.

Journal Pre-proofs

Highlights

- Three dimensional modelling of the media flow path to visualize in AFM
- Developed abrasive media with CNT and alumina to enhance material removal in AFM
- AFM process parameters; pressure, CNT amount, number of cycle were analysed using Taguchi L9 OA.
- Reye–Archard–Khrushchov law through computational approach was used to predict the wear

ARTICLE HISTORY

Paper Nomenclature: Review of literature (RoL)

Paper Code: V11N2AJ2019ROL3

Originality Test Ratio: 4%

Submission Online: 6-April-2019

Manuscript Acknowledged: 10-May-2019

Originality Check: 14-May-2019

Peer Reviewers Comment: 24-June-2019

Blind Reviewers Remarks 20-July-2019

Author Revert: 21-Aug-2019

Camera-Ready-Copy: 28-Aug-2019

Editorial Board Citation: 05-Sep-2019

Published Online First: 20-Sep-2019

EDITORIAL BOARD EXCERPT Initially at the Time of Submission (ToS) submitted paper had a 4% plagiarism which is an accepted percentage for publication. The editorial board is of an observation that paper had a successive close watch by the blind reviewers which at a later stages had been rectified and amended by authors (Surabhi & Seema) in various phases as and when required to do so. The comments related to this manuscript are noticeable related to **Start-up Ecosystem and its Structural impact** both subject-wise and research-wise. As we all know Start-ups are effective in promoting innovation and Setting up start-ups is a driving force for the development of worldwide economy. The study has made a deliberate attempt in identify the emerging nature of start-ups and to discover factors helping in the development of start-up ecosystems. By and large all the editorial and reviewer's comments had been incorporated in paper at the end and further the manuscript had been earmarked and decided under "**Review of Literature**" category as the paper critically analyze the research studies describing the stages of start-ups, attributes of start-up ecosystem and their inter-relationship.

ABSTRACT

Purpose: Present research focus has primarily been around the management and development about the startup ecosystem framework but research on relative significance of start-up ecosystem factors are yet to be done. The purpose of the research is to identify the emerging nature of start-ups and to identify factors helping in the development of start up ecosystems

Design/Methodology Approach-Review based approach findings- The paper critically analyze the research studies describing the stages of start-ups, attributes of start-up ecosystem and their inter-relationship

Originality/Value-The study has made a comprehensive literature review of the area to understand the evolution of the field, development of startup through various stages and growth of effective start-up ecosystem. The study summarizes briefly each section, integrate the knowledge and suggest entrepreneurial and academic significance, contribution in the area of the startup ecosystem.

Introduction

Setting up start-ups is a driving force for the development of worldwide economy (Lederman et al., 2013)[1]. Start-ups are effective in promoting innovation. In present Era, countries' potential to transform innovations, to successful ventures and creating high returns with multiple jobs is of high importance for resource utilization and to develop a quality life for its citizens (Europe 2012)[2].

Entrepreneurship is series of action which gives scope for novel products or services to be discovered, analyzed and exploited (Shane and Venkatamaran,2000)[3]. Start-up establishments are formed by a group of two, three people having burning ideas and zeal to form new business and by the help of a small number of employees, pilot runs different possibilities to produce viable product or service and float in the market within few months of idea formation (Blank and Dorf 2012)[4].

There is an escalation in entrepreneurship around the globe as well "outburst start-up ecosystem all over the world" (Start-up Genome, 2012)[5]. Start-ups contribute to the economic growth of a nation through an increase in employment, exports as well as the GDP. Entrepreneurship drives the economy and society of almost all nations (Brock and Evans, 1989[6]; Acs,1992[7]; Carree and Thurik, 2002[8]).

Through time memorial the USA has been the cradle of high-growth start-ups primarily through startup ecosystems. The startup ecosystems power the high-growth start-ups through a combination of multiple factors like support to creative, marketable ideas, market potential, policy support as well as open market environment. Start-ups help in bringing structural change in an economy by initiating knowledge base products, promotes innovation, steers productive growth and employment (OECD, 2013)[9].

While start-ups have the potential to generate jobs and contribute to regional and national economic growth, they have been identified with a high rate of failure, and therefore, have a very limited rate of survival and growth (Robinson, 1998[10] ; Song et al., 2008[11]). More often, they suffer from scarce resources, skeptical customers, inaccessible apt human resources, inadequate or inaccessible or prohibitively high cost, support services (Bala Subrahmanya, 2010)[12]. Start-ups have certain important predictors or influential factors – internal and external (Gilbert, et al., 2006[13]; Folta, et al., 2006[14]). Given the internal set of factors, start-ups are based on local environment for "diverse resources" to a huge extent to maintain their operations (Romanelli and Schoonhoven, 2001)[15].

The present government has taken major steps to refine ease of doing business. In fact, the '*Doing Business Report 2008*' (published by the World Bank-IFC) states that "India can jump 55 places from its current rank of 120th if some of the local best practices are adopted nationwide."

A start-up is a new venture developed around a creative idea for commercial purpose. It is an innovative concept for changing the existing system. India has recently seen an increase in start-ups. For some every new business is a start-ups , while for some the technology driven and innovative businesess are startups.

Startup Definition

Start-ups may belong to any sector, manufacturing or services or both. The start-up may be using technology extensively or trying to promote technologically based products or services. A start-up may explore an inventive business model which may churn existing organizations or markets. The startup entrepreneur would have gained the knowledge about his main product/ service through a high level of self-motivation, creativity, learning capabilities and desire to succeed.

More about start up and start up ecosystem can be learned through literature review in the next section.

Author	Definition
Blank and Dorf 2012 [4]	"A startup is a temporary organization in search of a scalable, repeatable, profitable business model."
Certo, 2003[16]	"A start-up, in general, is defined as a new venture with no previous history of operations. They suffer from the liability of newness since they are unfamiliar and without any precedence."
OECD, 2013[8]	"Start-ups focus on performance, using terms such as high-impact, high growth, and gazelles. The OECD defines high-growth enterprises as those with average annualized growth greater than 20% regarding growth in the number of employees or growth in sales volume over a three-year period, with ten or more employees at the beginning of the observation period. Gazelles are the youngest of these enterprises, typically in existence for less than five years)."
Ministry of Commerce and Industry, (2019)[17]	"An entity shall be considered as a 'startup'- a) Up to ten from the date of its incorporation/registration, b) If its turnover for any of the financial years has not exceeded Rupees 100 crore, and c) If it is working towards innovation, development or improvement of products or processes or services, or if it is a scalable business model with a high potential of employment generation or wealth creation. "
Blank (2010)[18]	"An organization formed to search for a repeatable and scalable business model."
Graham (2012)[19]	"A startup is a company designed to grow fast. The only essential thing is growth. Everything else we associate with start-ups follows from growth."
Stokes (1995)[20]	"A start-up means creating a new business, which stands alone and is not tied to other organizations, except in the normal course of trading. It does not mean that the idea is necessarily new, it is only the vehicle which is set up to exploit it."

Stages of Start-up Development

Understanding of different stages of start-up development is essential, as every stage pose a challenge for the organization survival. Many research works have been done earlier to understand the framework and model of the new firm. Each framework, the model provides insight and to draw a conclusion for it. The stages of development by different authors share several common traits but have a deviation about event, durations, etc. The author shares their distinct perspective to start-ups growth stages.

Greiner's (1972)[21]	Churchill and Lewis (1983)[22]	Aldrich, H.E. (1999)[23]	(Blank and Dorf 2012)[4]	(Marmer et al 2011)[24]
Organization age –Attitude change with age of firm is required	**existence stage-** broadening initial customer, the initial money	**Variation-** reviewed the formulation of various organization structures	**Customer Discovery-** identify consumer need, extent of product or service capability to reach consumer needs form a business model, test the hypothesis through feedback, validate it, and to develop solution fit.	**Discovery- the** minimum viable product is generated. Initial funds are traced
Organization size- with expansion of business, more inter relation is required	**survival stage-** break even stage and increase the business size	**Adaptation-** the traits and techniques adopted by entrepreneurs for survival of organization	**Customer Validation-** scalability of business model	**Validation-** acceptance for product, product refinement, metrics to trace user growth is implemented
Evolution stage- smooth growth of firms	**success stage-**business expansion with strategic planning	**Selection-** the factors that led to success of organization	**Customer Creation-** increases its investment and sales	**Efficiency-** refining values proposition, revamping users' experience, discovering scalable routes
Revolution stage- sudden change due to change in technology, expansion,management	**take off stage-** maintain cash debt ratio, expansion with an adequate delegation of duty	**Retention-** the way the path of success tend to be replicated by other entrepreneurs	**Company Building-** startup transforms itself to the company and makes structural changes to make large establishment.	**Scale-** pitch for larger funds, expand the administrative and infrastructure base
Growth stage- brings creativity, direction, decentralization, coordination and collaboration	**resource maturity-** amalgamation and control of financial resources, the flexibility of response as in small firms.			**Profit Maximisation-** Huge funding round takes place with further expansion of production and operations.
				Renewal/Decline Success leads to IPO; Failiure leads to business decline

Startup Ecosystem in General

A start-up ecosystem, also commonly named as "entrepreneurial ecosystem" **(Mason & Brown, 2014)[25]**, "entrepreneurial system" **(Spilling, 1996[26]; Neck *et al.*, 2004[27])**, "entrepreneurial environment" **(Gnyawali & Fogel, 1994[28]; Fogel, 2001[29])**, or "local entrepreneurial climate" **(Roxas *et al.*, 2007)[30],** consists of factors intermingled to promote entrepreneurship spirit, contribute in startup process and development of entrepreneurship **(Gnyawali & Fogel, 1994)[28].**

Isenberg (2010)[31] defines an entrepreneurial ecosystem (he uses the term "entrepreneurship ecosystem)" as a "set of individual elements such as leadership, culture, financial and human capital, which are intertwined in a complex manner".

Such framework, denominated of "ecosystem", was first coined by James Moore, who claimed that "successful business can't evolve in vacuum, necessitating to attract resources of all types, such as capital, partners, suppliers and customers to create cooperative networks, where companies can work jointly and competitively to support new products, satisfy customer needs, and eventually incorporate the next round of innovations" **(Moore, 1993)[32].**

In general, a typical entrepreneurship ecosystem has innumerable features. The following organizations and activities are the most active ones: Universities, Venture Capitalists, Angel Investors, Incubation Center, Accelerators, Crowd funding, Meetup groups, Services such as legal, financial and consultancy, Competition of start-ups and other supporting organizations.

The research studies are mainly divided into two outlooks to study startup ecosystem: **Attribute Centred Research and Framework Centred Research**.

Start-up Ecosystem Attributes Centered Research

Many researchers look at the perspective to assure specific city; the region is enriched with requisite features to have **start-up clusters, funding support, university or educational institute of excellence (Whittington et al. 2009[33]; Cooke 2002[34])**. Silicon Valley has 6,000 innovative companies. Unique eleven characteristics, values, goals for a healthy ecosystem of Silicon Valley are regarded as Mecca of start-ups. The attributes are **high ranked university(Stanford University); Highly motivated entrepreneurs, investors, and academicians; Ethical cycle of Venture capital industry where entrepreneurs who have gained success invest their exit earnings in new ventures; welfare ethics and quality life with non-hierarchical communication models; entrepreneurial risks embraced; well established infrastructure; savvy entrepreneurs; strong network with free flow of ideas; established patent industry; fearless, risk-taking, idea-driven, resilient people; encouragement for immigrants having skills to shift their base to urban areas (Piscione 2013)[35]** The Silicon Valley successful culture is based not only because of **skilled labour, infrastructure, and technology** but people have **distinctive behaviour** in Valley **(Hwang and Horowitt 2012)[36].**

The advantageous seven attributes of New York City contributes towards its successful start-up ecosystem which includes **easy access to capital, in proximity to world financial centre; Tie with Cornell University and Technion and ambitious Major Bloomberg program to convert New York into biggest innovation hub; tolerance involved for high risk and failure; high networking and love for community; New York Tech Meetup having more than 36,000 members; a big investor group spirit to make good to society; bigger community with approach to global business (Cometto and Piol 2013)[37].** Leading factors endowed in Washington D.C. start-ups ecosystem are its **nascent entrepreneurs, support from society, investors support, universities encouraging entrepreneurial culture; start-up support services (Feldman 2001)[38].** Local Governments in the USA assisted in investments to start-ups to enhance start-up ecosystem culture with flexible policies comprising guidance, infrastructure, business investments and entrepreneurship education. However, the magic of highly established entrepreneurial ecosystems can't be established. Very few internationally successful start-ups have emerged in the USA **(Lerner2009)[39].**

(Feld 2012)[40] in his Boulder thesis and book 'Startup Communities' found four presuppositions necessary for vibrant start-up community: (1). **Entrepreneurs driven start-up community** instead of decisions by policymakers, professors etc. 2) **Penetrative boundary** in society especially among serial entrepreneurs and nascent founders 3) **Organized events** which involve people in the entrepreneurial state of affairs. 4). **The commitment of entrepreneurial community trendsetters** for minimum twenty years. The university of Colorado Boulder provided only indirect support to start-ups by providing space for meetings and events. Ecosystem capacity to enhance innovation drives from a talent pool of human capital, belief beyond the societal barrier, inspiration beyond momentary logic, experiential learning among people and culture that promote to work together **(Hwang and Horowitt 2012)[36]. A helpful culture** like tolerance of risk and mistakes, entrepreneur personality, entrepreneur income; **policies and leadership** through government incentives, government support for start-up etc; **finance** support from angels investors, venture capital, microloans, public capital markets; **human capital** in form of talent pool, training programs; **Strong network among stakeholders**; **Infrastructure support** comprise basis of successful start-up ecosystem **(Isenberg (2011)[41].**

Metropolitan cluster and Sector Specific for flourishing requisite **skills such as IT, Education** is major factors of start-up ecosystem (**Reynolds and Storey 1994)[42]**. However **(Kakati 2003)[43]** found that **Entrepreneur traits, resource-utilisation potential, competitive strategy** form key attributes of success for start-up growth while analysing twenty-seven venture capitalists according to their experience rated one successful and one unsuccessful venture in six areas i.e. entrepreneur traits, resource-utilisation potential, competitive strategy, product features, market traits and financial return. Products compared to competition bring success rather than a unique approach that firm tries to bring. **Accommodation of knowledge from all sectors and regions** has a positive influence on start-up survival and growth as a rapid change in technologies can either drive start-up success or lead to closure **(Folta 2006)[14]**. For start-up survival funding at the right time and amount plays a vital role. Funds from **Venture Capitalist, Angel Investors, and support from Incubators and Accelerators** form 90% of aggregate funds invested in start-ups (**Joshi, K. & Satyanarayana, K. 2014)[44].** The rise in **funding** has a productive transformation on the development of start-ups. **Policy changes** which increase **institutional credit** would help in the creation of new start-ups and increase exports **(Kasturi, S.V. and Bala Subrahmanya, M.H. 2014)[45]** The rise of **New Technology Ventures (NTV)** as well as the development of start-up ecosystem improves

employment contribution and growth of the economy **(Bala Subrahmanya, M H 2015)[46].** Development in the **talent pool** of human resources increases the number of start-ups in the region. Start-up firms which concentrate on intermediate goods and services fuel the growth of the regional economy. The start-ups with a high rate of returns would encourage other entrepreneurial start-ups **(Gries & Naudé, 2009)[47]**.

The above Attributes-centred research attempts to find the presence of factors across regions, cities that attributes essential for growth and survival of start-ups, be physical infrastructures such as university of excellence promoting entrepreneurial culture **(Feldman 1994)[48]**, creative workforce **(Florida 2002)[49]**, or favorable region features **(Saxenian, A. 1994)[50].** The key attempt of such research is to determine such attributes. These attempts will draw the focus of region or city to attain and develop attributes to flare entrepreneurship activities for swift economic growth.

For Attribute-centered research, following attributes are necessary to for startup clusters **(Feldman 1994[48]; Saxenian1994[50]; Cooke 2002[34]; Kakati 2003[43]; Isenberg 2011[41]; Feld 2012[40]; Florida 2002[49]; Braunerhjelm 2006[51]; Whittington et al 2009[33]; Smilor et al 1990[52]; Piscicone 2013[35]; Hwang and Horowitt 2012[36]; Cometto and Piol 2013[37];Feldman2001[38])**

1. Entrepreneurial Culture
2. Skilled Human Personnel
3. Favourable Policies
4. Beneficial City Features
5. Education Excellence Research University
6. Market
7. Funding
8. Rich network connection

Attributes of Startup Ecosystems

Funding

Funding is the lifeline of startup clusters. Financial access is the biggest hurdle to achieving entrepreneurial growth in India (NKC Entrepreneurship Report). Avenues of seed capital are unorganized and mainly government is initial seed capital provider in India (World Bank 2015).

Venture Capital and private equity fund have shown a notable increase in India. However, Investment Trends by venture capital and private equity are basically on established firms having high potential and involves high risk (Nahata, 2008)[53]. Venture Capitalist helps new ventures to overcome problems related to new organization formation and protect them from failure through expertise and in investment (Stinchcombe, 1965)[54]. They provide strategic guidance, open new avenues, help them to acquire legal status, play a major role in startups decisions and are a board of directors of the company (Berglund 2007[55]; Elfring & Hulsink 2003[56]). In India, Venture Funds are regulated by SEBI, 1992 and 1996. In India, there are approximately 200 VC registered with SEBI. According to SEBI regulations, Venture capital fund means fund instituted in the form of a company, trust which lend money as a loan, donation, and securities for investment with regulated guidelines. According to Newscorp VCEdge, a risk capital data monitoring service, Venture capital deals comparison of first six months of year 2014-2016 found that Venture deals were167 of $863million on first six months of 2014, which rose to 278 deals of value $2.8 billion in first six months of 2015 but declined to 183 deals of value $2.8 billion. The fall is due to the focus on unit economics and cash crunch for later stage companies (Chanchani, 2016)[57].

Angel Investor

Angel Investor provides initial capital to early stage ventures. Angel investor invests money in startups in debt or equity form from funds possessed by him. Investment by angel helps to make money and participates in new learning, acts as motivator for startups and community (Shane 2000)[3]. In India startups has raised Rs 113.6 crores through angel investment with 69 deals in year 2016. The total number of deals on angel investments were172 in 2014 which has increased to 368 deals in 2016.

Beneficial city features

Beneficial city features play as a catalyst for firms growth and give an edge to firms from the one located in other regions (Casper 2007[58], Saxenian 2001[59], Feld 2012[40], Piore et al 1994[60]). This factor has been recognized as one of the important features and consistently recognized by researchers to make its mark in regional economic success and decline at the times of economic setback and progress.(Safford 2009[61], McDermott 2007[62]). The local cultural embeddedness of entrepreneurship sparks innovation in the region and encourages policy makers and people associated with the ecosystem to enhance growth through consistently reforming the system (Herriegel 1993[63], Storper 1997[64], Uzzi 2005[65]). Urban agglomeration and discipline expertise are important characteristics of startup region (Reynold and Storey 1993)[42]. External knowledge gets easily accommodated in some of the entrepreneurial region (Cooper and Folta 2000)[66].

Favourable policies

Favourable policies by government play an important role in startup growth. Government actions in form relaxation

of taxes, policies initiative, and encouragement through entrepreneurship program plays key role in firms' growth and survival (Gurley et al.2008)[67]. A higher tax on self employment demotes entrepreneurship. Indian Government has launched action plan on 16th January 2016 to promote startup. Startup friendly policies by present government are: Single window mechanism for Startups, no Capital Gains tax for startups, special incentives for women, bringing incubators investing in particular sectors, startup profits not taxable for first three years, patent fees for startups reduced to eighty percent and Rs 10,000 cr fund for startups @ 2500 crore each year for the first 4 years. (Startup Action Plan 2016)

Entrepreneurial culture

Entrepreneurial culture is necessary for startup growth. An entrepreneur capacity to take risk, drives to achieve goals, accepts ambiguity and thrives to give full effort and time to make organization a successful venture (Schere 1982[68], Mc Clelland 1961[69], Aldrich 1999[23]). Firms' ability to learn, strategy for growth, is essential features to encourage entrepreneurial growth (Sandberg 1986[70], Geroski 1995[71])

Skilled personnel

The skilled personnel of the age between 18-34 years provide resourceful human capital to technology based company. (Cortright and Colleta 2006)[72]. Skilled personnel in different domains provide rich, diverse experiences and helps in generating high-quality life (Saxenian 2001[51], Breshnahan 2001). Rich human capital provides an edge over to confront barriers related to finance as educated people know how to find more avenues to obtain credit, are skillful in forming network and able to find domains to market their products (Kim et al.2006)[74].

Network

Clusters help in technology transfer and encourage learning (Cooke 2002[34], Lester and Piore 1994[64], Breznitz 2005[75]). With increased competition, there is a consistent flow of information and enhance learning and innovation (Asheim and Conenon 2006)[76]. The cluster development helps to build social capital which has multiple fold effect in the growth of startup ecosystem (Lencher and Leyronas 2012)[77]. Multiple ties with a different organization with the entrepreneurial region help in rapidly transmitting collective information and enable startup ecosystem in achieving common goals (Putnam1993)[78].

Incubator

India has 120 incubators and science parks and has funded 2700 companies till 2014 (Fuelling Entrepreneurship 2014). NSTEDB has established 87 Technology based Incubator (TBI) with universities and research institute collaboration and has invested 100 crores. Incubated companies has earned 595 crores till 2014 (Fuelling Entrepreneurship 2014)[79].

Accelerator

Accelerator program designed for 3-6 months to take scalable startup to next level.. Besides incubating the startups, its structured program helps the startups to maintain success. The accelerator besides mentoring the startups help in accomplishing other goals too. The accelerator program runs in batches. The help startups in each stage, from idea development to finding new business opportunities, providing network to gain higher opportunities to scale. It lays hands on team development and host investors meet for start up to pitch and scale. (DST NIDHI)

(Sharma, Joshi, & Shukla, 2013)[80] found that the mortality of the start-ups attending the Accelerator programme is reduced to 20%. Fund raising chances of start-ups through accelerators increase to 78%. Accelerated start-ups have higher chances of getting series A, which is the next round funding. Chances of Accelerated start-up getting acquired are high.

Universities

Universities and educational institutes having entrepreneurship culture helps in the spin-off and provide skilled labor (Breznitz and Alan 2008[81], Huggins et al 2012[82]). Research institutes advance innovation and capabilities. Theses institutes provide skilled personnel and enable to develop clusters (Florida 2002[49], Hervas et al. 2012[83])

Conclusion and Recomendation

Entrepreneurial ecosystem approach cannot be copied from other established system without understanding its evolution under local context (Isenberg 2010)[31]. The situational consideration of ecosystem helps to develop insight on understanding functioning or dis-functioning of the system. The Entrepreneurial or start-up ecosystem is path dependent, and existing structures create barriers in developing new path (Henning et al. 2013)[85].

Various researchers tried to scale entrepreneurial ecosystem. Feld (2012)[40] described cities (Boulder City), (Saxenian 1994)[50] consider region (Silicon Valley) and studied other regions, (Hamel 1999)[86] perceived companies and (Senor and Singer 2009)[84] studied countries (Israel's ecosystem. All outlooks for measuring ecosystem are relevant, and can be encapsulated in cities and shared among the nation. The entrepreneurial ecosystem acts like a magnet. Europe shares international boundaries with many countries and attracts entrepreneurial activities from all interlinked nations (Holmes 2014)[87]. Corporate entrepreneurial ecosystem can reach to many communities in cities and villages. City-

based entrepreneurial ecosystem also stretches its reach to regional, national and international level. The policy level changes may have a conscious and unconscious effect on all levels (Bosma and Stam 2012)[88]. Entrepreneurial ecosystem flourishes through interaction and connections which could be between the ecosystem builders or between communities, regions, nation and international ecosystem.

Reviewers Comments

Reviewer's comment 1:
The paper is crafted in a structured manner. The introduction portion is quite impressive.

Reviewer's comment 2:
The paper has tried to cover almost all the attributes of start-up ecosystem. And every attribute has been explained through supportive studies.

Reviewer's comment 3:
Studies on management and development about the startup ecosystem framework are the need of the hour. And author has tried to satisfy this need by the manuscript which critically analyze the research studies describing the stages of start-ups, attributes of start-up ecosystem and their inter-relationship.

Keywords: Friction stir processing, Rice Husk Ash, silicon carbide, boron carbide

Abstract

In the present research, work is carried out for the parametric effects like tool rotation speed, tool profile and reinforcement in friction stir processing (FSP) of AA7075 on the microhardness and microstructural properties. The experiment design was carried out using Taguchi L_9 orthogonal array with three factors at three levels. Three different tool pin profiles viz. circular, triangular and square were used to experiment. The AA7075 matrix material was reinforced with SiC, RHA, and B_4C. The tool rotational speed was chosen as 700, 1000 and 1300 rpm. Using the Taguchi method, the optimum level of each of these parameters was obtained. It was found that rotational speed is the most influential parameter followed by the type of reinforcement and tool profile respectively. The average microhardness of AA7075/B_4C composite was found to be increased by 1.5–1.6 times of the base indicating that B_4C is better compared to SiC and RHA in improving the microhardness value of the composites.

1. Introduction

Materials having a good ratio of strength to weight are exhibiting tremendous importance in modern-day applications especially in the field of automobile and aerospace engineering where importance is placed on improved efficiency and reduced fuel consumption [1]. The fields of automotive, aerospace, defense, marine and recreation require materials with enhanced characteristics of wear resistance, fatigue resistance, temperature withstanding ability, and fracture toughness with cost considerations [2, 3]. Modern infrastructure, equipment, and machinery require a complex mix of material properties to meet the demands [4]. Metal Matrix Composites are an entirely new generation of composites that can satisfy the broad spectrum of demands of the modern-day applications with their characteristic isotropic properties, and try to develop HMMC using ceramics particles and natural fibres like SiC,RHA and, GSA as a reinforced material [2, 5, 6]. Al-based MMC have aluminum as matrix metal that has properties which are well concerned with the automobile industry [3]. The highlighting properties of aluminum and magnesium matrix composites are lower density, better wear resistance, better corrosion resistance, and high formability, especially under condition, which promote creep for which these can be employed for automotive, aerospace and various other technologies [3, 6]. Aluminum matrix composites can be reinforced with silicon carbide, boron carbide, aluminum oxide, titanium carbide, titanium oxide, etc there is an enhancement in the properties of hybrid composites so formed on addition of these reinforcing materials to aluminum composites [7].

A schematic of the Friction stir process is shown in figure 2(a) and FSW setup shown in figure 2(b)illustrates the basic working principle of FSP. Friction stir processing has been developed as a non- consumable rotating tool was inserted into the base metal that developed severe plastic deformation of the materials due to combined action of tool stirring and friction heat for materials processing and modification. Stirring was created through the tool pin and heat was generated by the axial force of the tool. After achieving the direction from advancing to retreating side of the base metal, a non- consumable tool, rotating at high rpm and traverse along the length of the base metal and to achieve the desired surface composite [8, 9]. Around 80 million tons of RHA is produced

© 2019 IOP Publishing Ltd

annually worldwide which poses as a major environmental threat to the areas in which it is dumped. Thus, the use of RHA for making composites is beneficial to the environment.

There are various ways to synthesize reinforced AMCs, some of the techniques used come from liquid metallurgy processing routes and solid route processing. There are many liquid metallurgy processing techniques, which include the process of stir casting, compos casting, liquid infiltration and many more [1]. Solid route processing includes the method of powder metallurgy and friction stir processing can be used on aluminum alloy [10]. Without disregarding the technical proficiency of any of the processing routes available, friction stir processing is the technique used for synthesizing AMCs. Friction stir processing is a short route, solid-state processing technique with one-step processing that can achieve microstructural homogeneity and refinement densification [11]. Friction Stir Processing (FSP) is one of the most effective techniques for fabrication of MMCs. FSP can be considered as a derivative of Friction stir welding, which was used to join materials with low melting temperatures such as aluminum alloys [12]. Surface Composites are being widely used nowadays, owing to their improved surface properties, and FSP provides an effective way for their fabrication [13]. This process makes up for the shortcomings of liquid-phase processing techniques, employment of a process for composite fabrication which can be conducted below melting points of given matrix material can go a long way to improve and consequently optimize the MMCs design and fabrication issue [14]. A non-consumable tool having specially designed pin as well as shoulder undergoes rotational motion during the FSP [15]. During FSP, softening and plastic deformation of the base materials occur owing to frictional heat generation between the tool rotation and base materials [16]. As the tool traverses, the material which comes in contact with the front face of the pin undergoes plastic deformation as a consequence of the friction between the tool and the workpiece. This FSP region results in a stirred zone (SZ) with a fully recrystallized, equiaxed and very fine-grain microstructure and refinement of constituent particles [17, 18].

Friction stir processing has also been used in various types of particle reinforced aluminium composite materials and among them, SiC particle reinforced aluminium alloys have been the ones which are studied the most. Wang *et al* [19] concentrated their work on the feasibility of making silicon carbide (SiC) reinforced aluminium metal matrix composites. Good interface bonding was observed between the particles and the base metal. The volume percentage of silicon carbide particles is kept at 1.5% in the reinforced region. The microhardness value of the reinforced metal matrix composites was found to be nearly about 10% higher as compared to the base metal Al-6Mg-Mn. Shafiei-Zarghani et al [20] had used Friction stir processing (FSP) to incorporate the nano-sized Al_2O_3 particles into AA6082 aluminium alloy in order to form a particulate composite surface layer. The Al_2O_3 particles had an average particle size of approximately 50 nm. The microhardness value of the fabricated composite surface had improved by nearly three times when compared to that of the non-processed aluminum alloy. After this work, a lot of work on surface composite fabrication is reported. Initially, FSP was used to modify aluminium alloys but over time, FSP gains shining role in the modification of other alloys like magnesium alloys, copper alloys, titanium alloys and even steel [21]. Optimum combinations of process parameters were determined for higher microhardness and ultimate tensile strength respectively using signal/noise ratio graphs, response tables, and analysis of variance method [22]. AA6xxx series aluminium alloys are heat treatable whose properties are affected with the exposure of heat and experience annealing effect during FSP. With the reduction of heat exposure time, i.e. reduction of grain growth time or accelerating the cooling effect, larger grain refinement occurs which results in enhanced mechanical characteristics of SCs [23]. Analysis of microstructures and distribution of SiC particles in the fabricated Surface composite were studied by optical microscope and FESEM, respectively and found in good corroboration with the mechanical properties [24]. Some researchers have been reported that different reinforcement like SiC, TiC, ZrO2, and B4C particle are investigated and also to study the effect of different pin profile on the distribution of reinforcement and it concluded that TiC particle exhibit higher hardness value compared to others [25]. In another researcher investigated that the fabrication of AA6061/TiB2 composite and the effects of process parameter like tool rotation, tool traverse, axial load and reinforcement on mechanical and microstructure were studied. Using ANOVA results it indicates that tool rotation speed was found to be the most influencing process parameter followed by the reinforcement, axial load and traverse speed [26].

The objective of this research is to establish the effects of Friction stir processing (FSP) parameters viz. tool profile, reinforcements and tool rotation speed on the microhardness of AA7075 surface modification and to the utilization of ceramics and agro-waste particles to influence the properties of the base material.

2. Experimental method

The experiment was conducted in two phases. In the first phase, capping pass was performed with a pin-less tool on each groove to cover the reinforcement and maximum load during the capping pass was 590 N. In the second

phase, the tool profile and rpm of the tool were adjusted per the design of the experiment prepared in table 2, and the maximum load during processing is around 850 N. For both the phases, traverse speed was kept constant at 40 mm min^{-1}. The tilt angle for capping pass was kept at 0° while for the second phase it was set at 2°. The process parameter were fixed at constant value given in table 3. In figure 1, different pin profile FSP tool was made of H13 tool steel is hot worked chromium-molybdenum steel that is prominently used in hot work as well as cold work tooling applications. The hot hardness of this tool steel resists thermal fatigue cracking which occurs due to the repeated cycles of heating and cooling while performing hot working.

2.1. Matrix material

The base material used here is AA7075, which has zinc as its primary alloying element. The size of workpiece used is (200 × 80 × 8) mm as per the requirements of Friction stir processing setup. Grooves were made in the workpiece lengthwise with the help of a milling slitting cutter. Milling cutter had a bore (inner diameter) of 1.25 inch and outer diameter of 4 inch. The grooves made, were of 3.5 mm depth and 2 mm width. The alloy composition of AA7075 is given in table 1.

2.2. Reinforcements

Several agro-waste and industrial materials have been deeply investigated to use them as reinforcement but the prominent ones include coconut shell ash(CSA), bagasse ash and rice husk ash (RHA) [27, 28]. Several experiments have been carried out by the researchers and several other researchers on the utilization of ground-nut shell ash (GSA) as reinforcing materials [1–3]. These composites provide improved physical properties such as low density and low thermal coefficient of expansion. Moreover, their cost is reduced too. Mechanical properties and features of the composite has been investigated to establish the viability of RHA, SiC and B_4C in development of the composites.

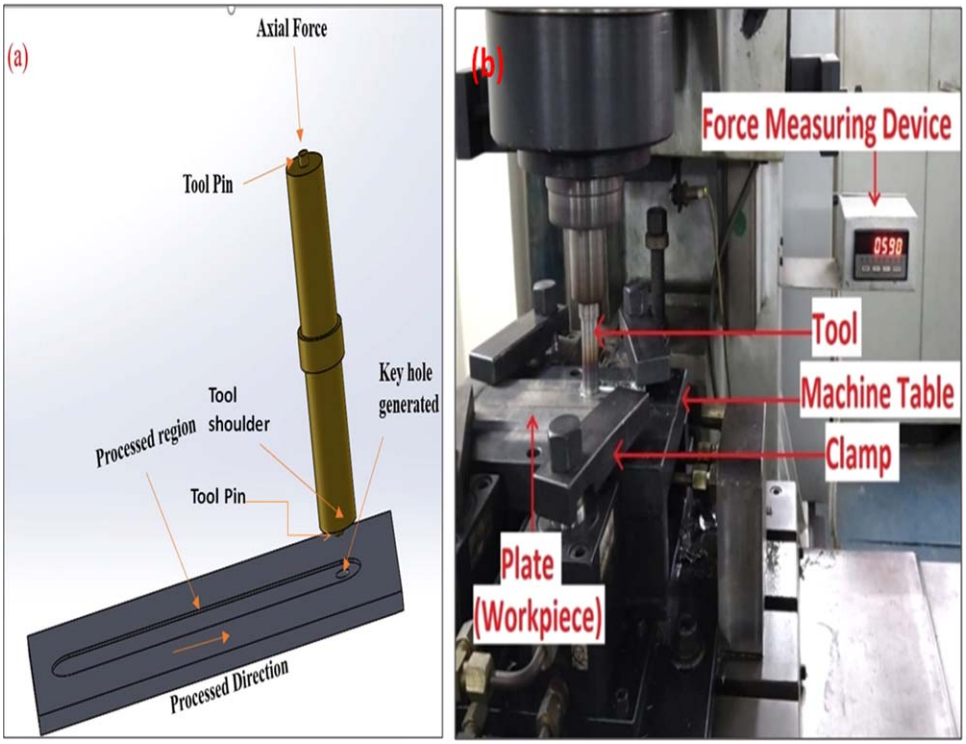

Figure 2. (a). Schematic of Friction stir processing, 2(b) FSW Setup.

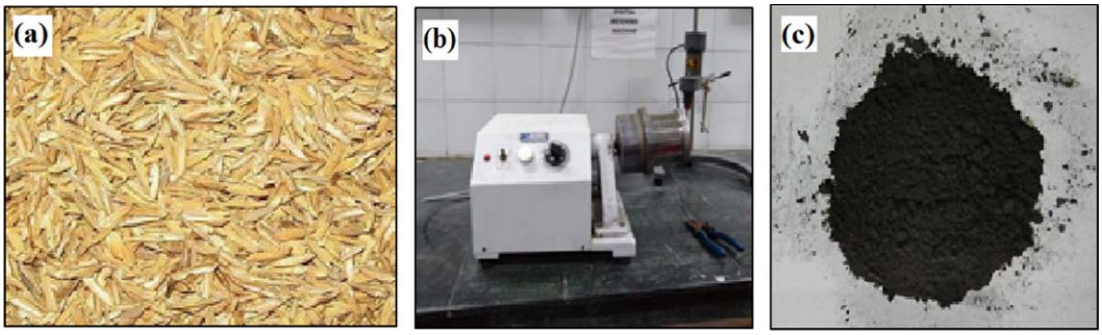

Figure 3. (a) Rice Husk Ash (b) Ball milling machine (c) Fine Rice husk ash powder obtained after sieving.

Table 3. Process parameters.

Process paramters	Value taken
Tool shoulder profile	Flat
Tool shoulder dia	19.95 mm
Tool pin profile	Triangular, Circular, Square
Tool pin length	3.5 mm
Tool plunge depth	0.50 mm
Tool tilt angle	2° constant
Type of reinforcement	SiC, RHA, and B_4C

2.2.1. Rice Husk Ash (RHA)

Rice Husk was obtained from rice mill near Hisaar shown in figure 3(a). It was burned overnight and the ash was collected in a plastic container. To reduce the size of the RHA particles shown in figure 3(c), ball milling shown in figure 3(b)were done in sand testing lab.

Ball milling works on the principle of impact and size reduction of the particles as steel balls jiggle in a cylindrical shell. Ball milling was performed for 8 h using 16 steel balls. Sieve testing of the obtained ash particles

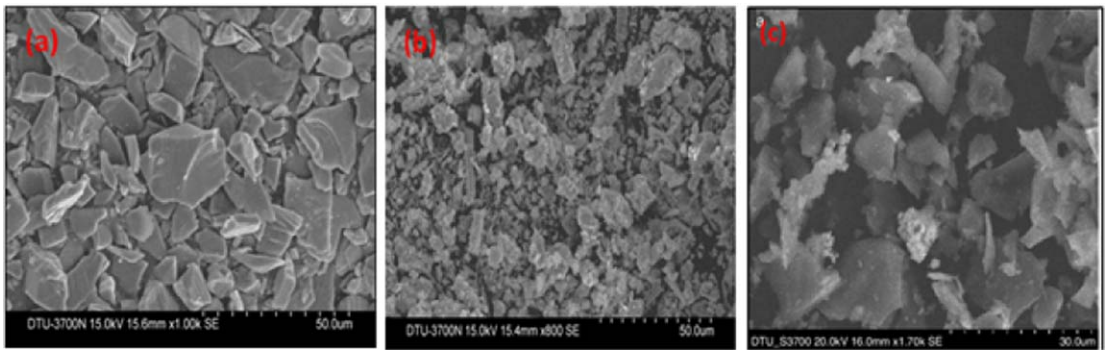

Figure 4. (a) SEM image of SiC at 50 um (b) SEM image of RHA at 50 um (c) SEM image of B_4C at 30 um.

was performed to segregate particles of size 53 or less microns. For this purpose, a sieve of aperture size ASTM 270 was used. SiC, RHA, B_4C SEM images are shown in figures 4(a)–(c), were used as a reinforcement.

2.2.2. Silicon carbide (SiC)

Silicon carbide is also known by the name of carborundum, and contains silicon and carbon. The main use of SiC powder is it being used as an abrasive. The mesh size of SiC used is 400, which corresponds to the average particles size of 37 microns.

2.2.3. Boron carbide (B_4C)

Boron carbide is known to be the third hardest material and is a boron carbon ceramic. It is used in bullet-proof vests, tank armor and engine sabotage powders. For the experiment, B_4C of average particles size less than 30 nm was used.

3. Experimental design using Taguchi methods

DOE is an experiment technique in which we analyze the effect of process parameters by varying them simultaneously at different levels. In this manner we are able to capture how different factors interact with each other. Three three-level parameters (rotation speed, tool profile, type of reinforcement) are selected for this study using L_9 orthogonal array design. It should be mentioned that only the main factor effects are taken into consideration and not the interactions. A total of nine runs of the experiment need to be conducted using the combination of levels for each process parameters. The full factorial experimental design would have required $3^*3^*3 = 27$ runs. Thus using Taguchi experiment design, we have eliminated 18 FSP runs. This helps to save a lot of time and resources. The experimental design carried out with the help of MINITAB 17 software.

3.1. Filling of reinforcements in the groove

Before filling the reinforcements, the plates were cleaned by keeping them dipped in 500 ml of acetone overnight. The filling of reinforcements has been done considering volume fraction in case of RHA and SiC while for B_4C the same was done considering molar solution.

$$Volume\ Fraction = \frac{w^*\mathrm{d}}{t^*\mathrm{d}_p} \tag{1}$$

where,

w denotes width of slot cut
d is depth of slot
t is pin length
d_p is effective diameter of pin

Based on experimental work, volume fraction of 20% were chosen for filling RHA and SiC in the slots whereas in case of B_4C, one molar solution with acetone was prepared and 5 ml solution was poured in each of the three slots.

3.2. Samples preparation for microhardness and microstructure

Specimens of dimensions 10 mm × 10 mm × 4 mm were cut from the processed region through wire EDM cutting. Dry polishing of the specimens were done using emery paper of grit sizes 220, 320, 400, 600, 800, 1000,

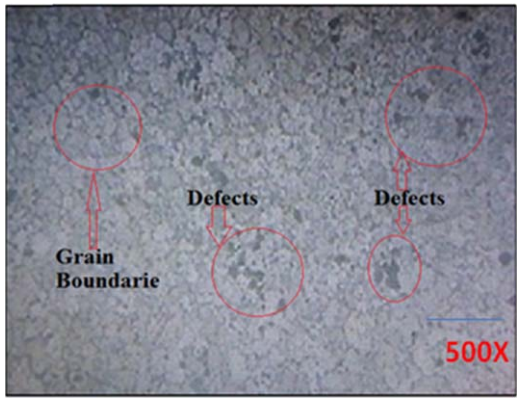

Figure 5. Microstructure of base metal at 500× resolution.

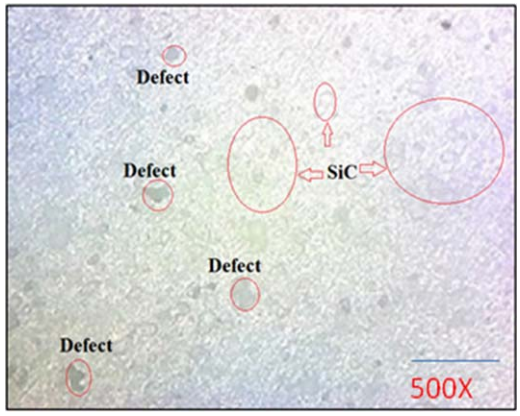

Figure 6. Microstructure of specimen 1 at 500× resolution.

1200, 1500 and 2000. After dry polishing, wet polishing is done on abrasive wheel to obtain smooth surface of specimens.

4. Results and discussion

4.1. Microstructure

The square cross-section samples were prepared especially for their microstructure analysis. Samples for the microstructure analysis were cut perpendicular to the processed line at the center of the plate. After the wet polished specimens were then etched in an acidic medium comprised of Hydrochloric acid and Nitric acid mixed in an optimal molar ratio. The process of etching helps to identify the presence of grain boundaries, which is shown in figure 5. Viewing the microstructure was important because one of the most significant effects of FSP was to be the resultant refinement of the grain structure and reinforcement particles like SiC,RHA and B_4C, which is shown in figure 6, figure 7 and figure 8. This would be translated into superior mechanical properties imparted to the composite material. For microstructure observations, we used an Olympus GX41 inverted metallurgical optical microscope. The images were taken at 500× for all the square cross-section samples.

4.2. Microhardness

The Vickers microhardness testing of the specimens was performed using Fischer scope HM2000 S microhardness tester. The indenter makes an impression on the polished specimen surface under a designated load for a specified period. Microhardness test has been carried out at 0.300 N or 0.03 kg and the dwell time was 20 s. Repeated measurements of the hardness value were taken at different positions on the specimen surface and subsequently, the arithmetic mean was used for further calculations. The average hardness was calculated using 3 readings on the same load. The average hardness value of FSP processed sample is found to be more than that of base metal alloy. The reason behind this result is the fine dispersion of B_4C hard particle in the aluminium

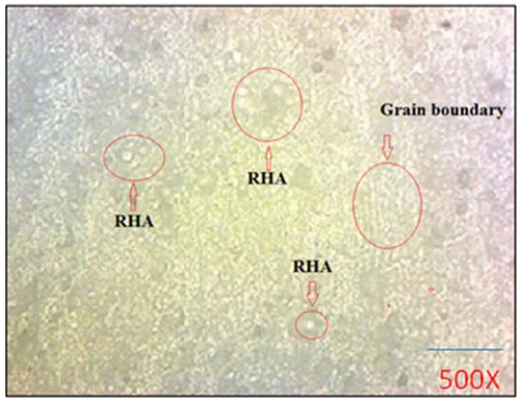

Figure 7. Microstructure of specimen 2 at 500× resolution.

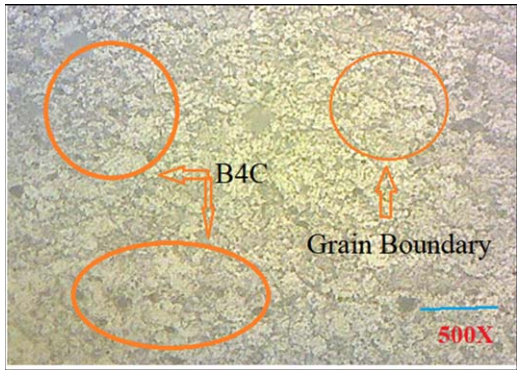

Figure 8. Microstructure of specimen 3 at 500× resolution.

substrate. Increase in hardness value of FSPed sample is also due to the Hall-Petch strengthening or grain boundary strengthening. In this, the material strengthens through the changing grain size. In FSP due to friction between base metal and tool probe grain at the surface of the matrix, become fine. The hardness of the parent metal was 68.7 Hv. During the microhardness test, an average of 3-hardness value was taken in the entire sample, see figure 11. Show the hardness bar graph of the entire processed and unprocessed sample with micro and nanoparticle. This observation in micro and Nanoparticle size reinforcement is investigated by literature review in various other material systems. Asadi *et al* [29] have been reported that the hardness of SiC nanocomposite to be increased due to the uniform distribution of SiC particle and refinement of grain size. Dolatkhah *et al* [30] have achieved a maximum hardness of 116 Hv in the surface composite of Al 5052 with 50 nm SiC particle size due to grain reduction of the particle. Shamsipur *et al* [31] reported that the microhardness value of Ti/SiC nano surface composite is three-time greater than the base metal due to the uniform distribution of nano-size reinforcement particles size. Due to the presence of nanoparticles, size reinforcement contributes to producing ultra-fine grain size. The microhardness of the surface composite using B4C nanoparticle reinforcement is higher comparison with SiC or RHA microparticles.

For optimization purpose, Taguchi method utilizes signal to noise (S/N) ratio. The signal to noise ratio signify that the effects of noises on the average responses are computed by the influence on the deviations from the average responses, which will help to gauge the responsiveness of the output of experiment relative to the involved noise factors [32]. In this study, microhardness value of the friction stir processed (FSPed) material is measured. The S/N ratio of the performance characteristic is analyzed according to the criterion higher-the-better which can be expressed as:

$$\frac{S}{N} = -10 \times log\left(\frac{1}{n}\sum_{n}^{i=1}\frac{1}{Y_i^2}\right). \tag{4.2.1}$$

where, n = number of repetitions

Y_i = value of performance characteristic for the test in ith run

Table 4. Experimental results and calculate mean and S/N ratio.

S. No.	Rotation speed (rpm)	Tool Profile	Reinforcement	HV (mean)	S/N Ratio
1	700	Triangular	SiC	75.3	37.536
2	700	Circular	RHA	73.8	37.361
3	700	Square	B_4C	87.6	38.850
4	1000	Triangular	RHA	79.2	37.974
5	1000	Circular	B_4C	122.8	41.784
6	1000	Square	SiC	136.1	42.677
7	1300	Triangular	B_4C	110.1	40.856
8	1300	Circular	SiC	74.9	37.489
9	1300	Square	RHA	76.2	37.639

Table 5. Main effects response table of HV (mean).

Level ↓	Rotation speed	Tool profile	Reinforcement
1	78.90	88.20	95.43
2	112.70	90.50	76.40
3	87.07	99.97	106.83
Delta	33.80	11.77	30.43
Rank	1	3	2

Table 6. Main effects response table of HV (S/N ratio).

Level ↓	Rotation speed	Tool profile	Reinforcement
1	37.92	38.78	39.23
2	40.81	38.88	37.66
3	38.65	39.72	40.49
Delta	2.90	0.94	2.83
Rank	1	3	2

Using the above expression S/N ratio for HV value of each specimen is calculated. The result obtained from micro-hardness testing of the samples is provided in table 4.

Minitab 17 software is used to carry out analysis of this Taguchi experiment design. Table 5 represents the response table for mean HV value. The response table clearly explains that rotation speed is most influential factor in the determination of HV value followed by type of reinforcement and tool profile.

Table 6 is the response table for the S/N ratio. The S/N ratio is used as a performance measurement characteristic to develop process which is insensitive to the variance factors. For this experiment the process parameter with high S/N ratio gives the optimum setting with least variance. The response table clearly indicates that rotation speed is the most influential factor followed by type of reinforcement and tool profile.

The main effects plot for means (figure 9) shows the variation of response variable (HV value) with process parameters i.e. rotation speed, tool profile and type of reinforcement. The horizontal dashed line represents the overall mean value of the response variable. From the plot it is evident that HV value is maximum at second level of rotation speed (1000 rpm), third level of tool profile (square profile) and third level of reinforcement type (B_4C).

Figure 10 show the main effects plot for S/N ratios. From the plot it is evident that S/N ratio is maximum at second level of rotation speed (1000 rpm), third level of tool profile (square profile) and third level of reinforcement type (B_4C).

Repeated measurements were also done to determine the HV value of the base metal and it was found to be 68.7. A bar graph is plotted to visualize the HV values of the nine specimens with respect to the base metal. It is clearly evident from figure 11, that the microhardness value of all FSPed samples is improved with respect to the base metal.

The improvement achieved in micro hardness value of the processed zone is very significant and evident from the bar graph shown in figure 11. The results of this study are in complete agreement with the previous works carried out by distinguished researchers.

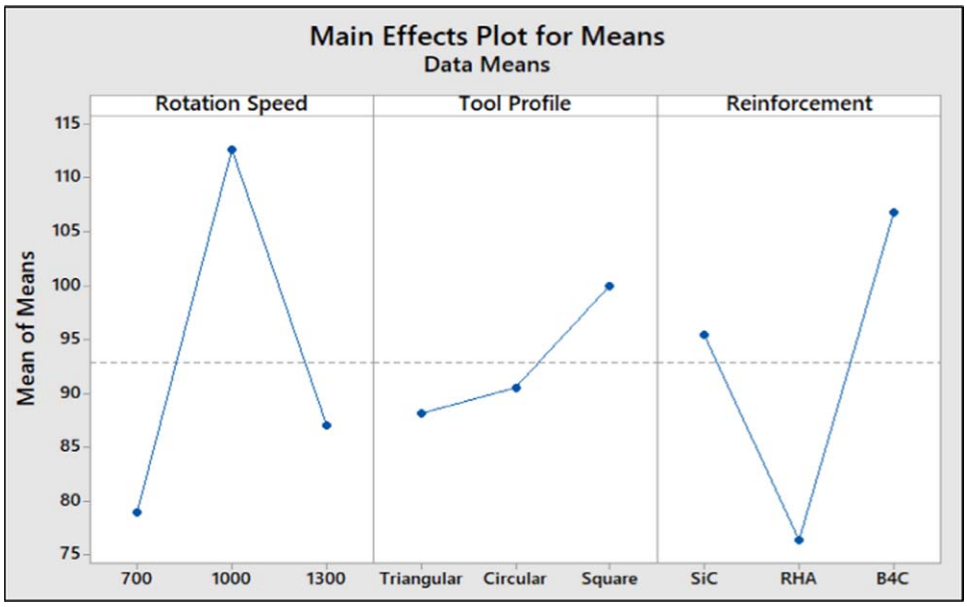

Figure 9. Main effects plot for means.

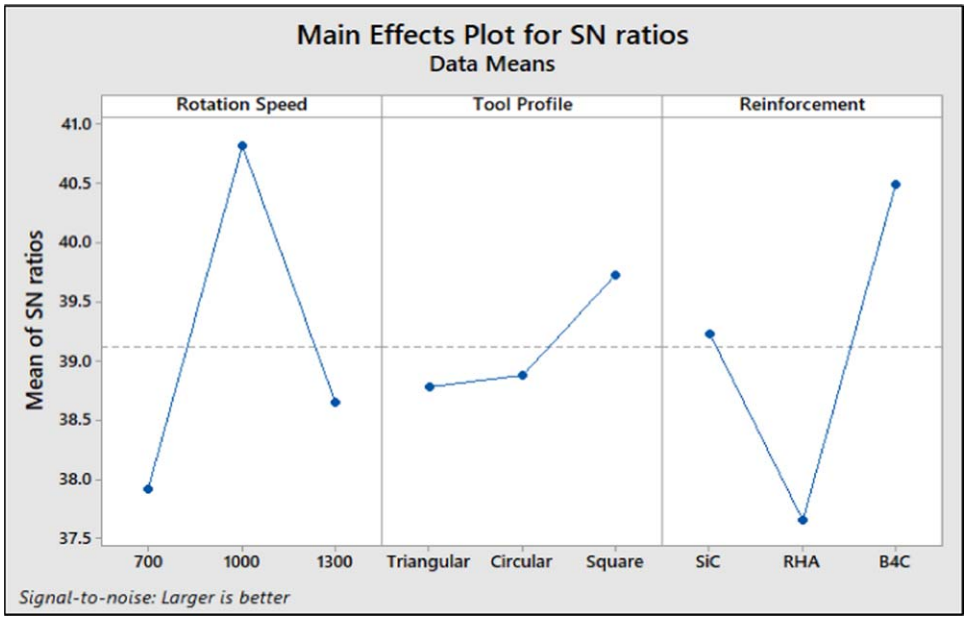

Figure 10. Main effects plot for S/N ratios.

4.3. Analysis of variance (ANOVA)

Each of the FSP process parameter responses were estimated and significant contribution using ANOVA to understand their significance. The ANOVA responses along with the related terms are summarised in table 7. Percentage contribution of individual FSP parameter for different responses was summarised in the ANOVA.

Table 7 indicates that tool rotational speed in rpm as the most influential factor for microhardness followed by the type of reinforcement and tool profile. In the previous literature survey, ANOVA was used to evaluate the process parameter and find out the most influencing parameter for micro hardness and UTS [21]. Taguchi method was used to establish the relation between input and output parameter and ANOVA was used to determine the significance of the parameters [33]. In another research, using ANOVA was performed to find the influence of reinforcement on the mechanical properties like hardness, % elongation, UTM and yield strength of the composite material [28]. It is a systematic method to determine the relationship between factors affecting a process and the output of that process. It is used to find cause-and-effect relationships. This information is

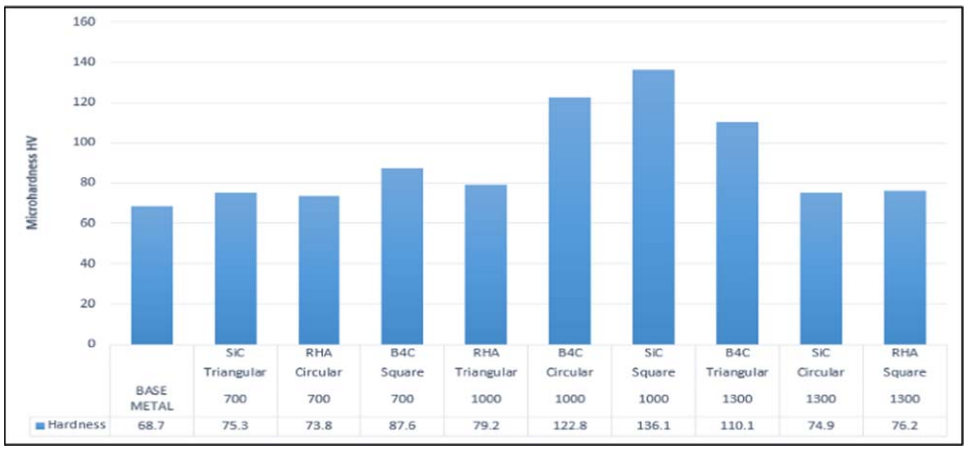

Figure 11. Bar graph of microhardness (HV value) of all specimens.

Table 7. ANOVA result for various responses.

FSP Parameter	SS	DOF	Variance	% Contribution	F-ratio
Microhardness Tool Rotation(rpm)	5122.0201	2	2561.01	35.1604	14.0425

needed to manage process inputs to optimize the output. DOE gives the optimized result of given experimental values or the outcome of the experiment performed [34, 35].

5. Conclusion

A detailed account of fabrication of AA7075 surface composite with different process parameters is presented. The results of the present investigation can be concluded as follows:

1. With the help of Taguchi technique, optimum condition was obtained to achieve the maximum value of microhardness. Increase in rotation speed from 700 rpm to 1000 rpm led to increase in HV value but further increase to 1300 rpm decreased the Hv value. Thus, 1000 rpm is the optimal choice.
2. Percentage contribution of the process parameters towards microhardness was achieved. Tool rotation speed is found to be the most influential factor followed by the type of reinforcement and tool profile.
3. Tool profile had much less significance on the Hv value compared to other parameters. Still square tool profile was found to be the optimal choice. This is attributed to the high pulsating action generated from square tool profile.
4. The average hardness value of AA7075/B_4C composite is found to be increased by 1.5–1.6 times of base metal, which was around 68 Hv. B_4C is found to be the most effective reinforcement compared to SiC and RHA in improving the microhardness value of the composite.
5. The average hardness value of AA7075/RHA composite was observed to be 76.4 which is about 11 % more than the base metal thus instead of dumping, RHA can be used to make aluminium composites with improved microhardness.

Abstract

Tin-based perovskite material is one of the promising candidates used in lead-free perovskite solar cells. In the present study, the use of graphene material as charge transport layers is suggested and the structure n-Graphene/$CH_3NH_3SnI_3$/p-Graphene is simulated in AFORS-HET (Automat for Simulation of Heterostructures) software. The effect of layer properties on the performance of the proposed structure is analyzed. After optimizing the layer parameters, the best possible structure gives a $V_{oc} = 687.1$ mV, $J_{sc} = 19.93$ mA cm^{-2}, FF = 77.92% and efficiency = 10.67%. The textured nature of front surface enhances the efficiency of the cell from 10.67% to 13.28%. The effect of operating temperature is observed on the performance of the cell. The proposed structure is also modelled using one diode model in MATLAB software for comparison with AFORS-HET results. The results of the simulated and modelled structure are in good agreement with each other. To the best of our knowledge, the proposed structure and the corresponding results reported herein are new for the research community.

1. Introduction

Perovskite solar cells (PSCs) based on $CH_3NH_3PbX_3$ material as the absorber layer are becoming the most studied photovoltaic technology as compared to other solar cells due to the broad absorption spectra, fast exciton separation, band gap tuning, and ambipolar charge transport nature of the material [1–4]. The chemical formula for perovskite compounds is ABX_3 (here A is an organic cation, B is a divalent metal ion, and X is a halide). The PSCs are manufactured by simple solution processing [5–7] or scalable vapor phase deposition method [8, 9]. The power conversion efficiency (PCE) of $CH_3NH_3PbX_3$ based PSC has been significantly improved from 3.8% [9] to 22.1% [10].

However, the toxicity of lead in $CH_3NH_3PbX_3$ material is a major concern. The lead material can be replaced by another same group element such as Sn or Ge. The band gap of $CH_3NH_3SnI_3$ is 1.3 eV as confirmed by theoretical and experimental studies [11, 12]. This amount of energy band gap can cover the wide range of visible spectrum as compared to the band gap of lead-based PSC (1.5 eV). The lead-free, tin-based PSC (TPSC) has been fabricated using $CH_3NH_3SnI_3$ with planar heterojunction architecture [13–15]. Although, the major problem with the TPSC is its chemical instability due to oxidation of Sn^{+2} to Sn^{+4} states, the advancement in fabrication techniques has improved the stability of these cells. The incorporation of SnF_2 in the system decreases the Sn^{+4} caused by the oxidation of Sn^{+2} [16]. Therefore, TPSCs provide a good platform for developing non-toxic PSCs [16, 17]. Noel *et al* [18] studied TPSC on a mesoporous TiO_2 scaffold, and obtained an efficiency of 6% under 1 Sun illumination. Koh *et al* [19] analyzed the formamidinium tin based perovskite ($FASnI_3$) material as absorbing layer in PSC with 1.41 eV energy gap and a PCE of 2.10% was obtained with the incorporation of SnF_2. Lee *et al* [20] fabricated the $FASnI_3$ PSC with high reproducibility and achieved a PCE of 4.8%. The cell presented a stable performance for 100 days and retained 98% of its starting efficiency. Shao *et al* [21] studied PSC with planar p-i-n device structure for $FASnI_3$ and achieved a PCE of 9.0%. Hao *et al* [22] reported the TPSC with

spiro-OMeTAD as organic hole transporting layer, giving the absorption at 950 nm, which is remarkably red shifted compared with the lead-based PSC. The band gap was tuned to overcast much of the visible spectra, thus enabling a PCE of 5.73% under simulated sunlight. Recently, Jokar *et al* [23] studied the TPSC with hybrid organic cation and attained 8.5% efficiency.

Till now, the frequently used electron transporting layer (ETL) and hole transporting layer (HTL) for PSCs are TiO_2 and spiro-OMeTAD respectively, but nowadays, to improve the charge collection and injection at the electrode; graphene is being used as HTL/ETL to enhance the PCE of the solar cell. In particular, when charge carriers are transported to the ETL or HTL from the perovskite layer, the non-radiative recombination is reduced and degradation of the device is slowed down. Currently, it is observed that the graphene material and its derivatives such as graphene oxide and graphene quantum dots are introduced as device layers to boost the performance of PSCs [4, 24–26]. This is due to the extraordinary properties of graphene such as high value of Young modulus (1.0 TPa), charge carrier mobility (2×10^5 cm^2 V^{-1} s^{-1}), optical transmittance (97.7%) and thermal conductivity (5000 Wm^{-1} K^{-1}) [27, 28]. The electronic and optical properties of graphene can be adjusted by doping a heteroatom because doping is the most suitable method to control the semiconducting properties. The boron and nitrogen atoms are the natural candidates for graphene doping because of their similar size and form [29–33]. The boron doping, regarded as hole doping, in graphene leads to the shifting of Fermi level below the Dirac point and forms p-graphene [34–36]. The nitrogen atom has one extra electron than carbon atom, and behaves as electron doping, i.e., the Fermi level shifts above the Dirac point and forms n-graphene [34–36]. The change in the Fermi level of the graphene accounts for the change in the work function of the graphene. The energy band gap can be increased from 0.13 eV to 0.54 eV for one boron atom or one nitrogen atom in 5×5 (concentration 2%) and 2×2 (concentration 12%) supercells respectively [37]. Nevis *et al* [38] experimentally confirmed the energy gap of graphene to be 0.5 eV.

The first observed Schottky junction of graphene/silicon solar cell was constructed in 2010, obtaining an efficiency of 1.65% [39]. Song *et al* reported a good hike in the efficiency of graphene/Si Schottky junction solar cell and obtained up to 15% within less than a decade [40], but Patel *et al* simulated and optimized the structure of n-graphene/p-silicon and p-graphene/n-silicon heterostructures solar cell and achieved an efficiency of 11.38% and 9.81% for 40 layers of n-graphene and 20 layers of p-graphene, respectively [41]. Sho *et al* [42] replaced the hole transporting layer, spiro-OMeTAD, by graphene layer in a PSC and obtained a PCE of 7.1% with J_{sc} of 21.3 mA cm^{-2}. Their experimental studies also indicate that the performance of the cell can be improved by modifying the work function of graphene layer and suggested doping as a mean to vary the work function of the graphene. Graphene has also been added into the ZnO electron selective contact layer, which resulted into the increase in efficiency of PSC by a factor of 47.5%, i.e., from $7.01 \pm 0.66\%$ to $10.34 \pm 0.18\%$ [43]. Wang *et al* [44] found that TiO_2 nanoparticles and graphene nanoflakes behave as an electron selective electrode at a temperature of 150 °C, i.e., the solar cell with graphene-TiO_2 nanocomposite layer yielded an efficiency of 15.6%. Agresti *et al* [45] also achieved large area PSC by dispersing the graphene flakes in mesoscopic TiO_2 and obtained an efficiency of 12.6%. The performance of PSCs utilizing graphene as one of the transporting layers or as an additive are summarized in table 1.

The above theoretical and experimental studies indicate that graphene material can act as ETL and HTL in PSC. Till date, there is no publication reported in literature for the use of graphene in TPSC. Keeping the above

literature studies and fundamental concepts in mind, the structure of TPSC with n-graphene as ETL and p-graphene as HTL was simulated as shown in figure 1. The layer parameters were optimized for obtaining the best performance of the device. The effect of operating temperature and textured front surface on the device performance is investigated. The studies demonstrated that graphene can act as an efficient charge transporting layer in TPSC and promising devices may be realized with high performance. The simulated structure was also modelled using one diode model in MATLAB software and the current density–voltage (J-V) characteristics and power-voltage (P-V) characteristics are analyzed for best optimized results. There is a considerable agreement between the simulated and modelled results. The use of doped graphene as charge transport layers in TPSC is new in this field.

2. Simulating structure

Many theoretical and experimental researches are available on the use of graphene and its derivative as efficient transport layers in PSCs [4, 26, 42–45]. Till now in literature, no research papers are published on design and simulation of the TPSC structure with graphene as charge transport materials. We designed and simulated the structure as n-Graphene /$CH_3NH_3SnI_3$/p-Graphene which is a n-i-p structure, having ITO (indium doped tin oxide) as front contact and Ag (silver) as back contact in AFORS-HET software [46–48] and the simulation is carried out under the standard AM 1.5 G spectrum. This software is designed based on the 1D semiconductor equations linked to Shockley Reed Hall statistics solver and Lambert-Beer law for optical parameters of different photovoltaic devices. The complete device structure is ITO (80 nm)/n-Graphene (0.334–13.36 nm)/Sn-Perovskite (50–700 nm)/p-Graphene (0.334 nm)/Ag (0.001 cm) as shown in figure 1(a).

The work function of graphene can be tuned depending upon the doping of heteroatoms such as Boron and Nitrogen atoms. These atoms are more suitable for graphene doping. The work function of pure graphene is 4.6 eV as verified by theoretical and experimental studies [35, 49]. The doping of nitrogen atom in graphene results into n-graphene, because it contains one extra electron that is donated to graphene. The work function of graphene increases, i.e., shifts up to 4.25 eV [50]. The boron doping in graphene results into p-graphene because of the deficiency of one electron. The work function of graphene decreases up to 5.14 eV depending upon the number of dopant atoms [35].

In the present manuscript, we considered the work function of n-graphene and p-graphene as 4.25 eV and 5.14 eV respectively. The energy band diagram for the simulated structure is given in figure 1(b). The working of the device can be explained based on this diagram. As light falls on the device from n-graphene side, most of it reaches the active layer due to the high transmittance of graphene, and generates electron-hole pairs. As seen from the energy level diagram, it is favorable for the electrons to jump from n-graphene to ITO. The down shift in energy level of 4.6 eV to 4.25 eV provides a gradual transition to the collecting electrode. Similarly, the up-shift of work function from 4.6 eV to 5.14 eV assists in hole transfer from active layer to Ag electrode by removing the barrier between graphene and Ag, and acts as an electron blocker as well. The transfer of both the charge carriers from their interface region takes place rapidly due to high charge carrier mobility of graphene transport layers. The recombination of charge carries at the interface regions reduces and thus, the device performance improves.

Further, to enhance the device performance, we optimized the device layer parameters like, energy band gap (E_g), layer thickness, electron affinity, dielectric constant, doping concentrations (N_D/N_A), effective conduction/valence band density (N_C/N_V) to observe the effect on the efficiency, fill factor (FF), open circuit voltage (V_{oc}), and current density (J_{sc}) of the TPSC. The realistic parameters that we have used in our simulating work are taken from various experimental and theoretical studies [18, 22, 23, 28–32, 41, 51]. To analyze the front surface influence on the device performance, the front surface can be considered as textured surface. The textured surface helps in light trapping and reduces the light reflection, due to which, the performance of device may increase.

3. Results and discussion

3.1. n-graphene parameter optimization

As we know that Fermi level of graphene is always either in valence band or in conduction band due to gapless nature of graphene. After nitrogen doping, the Fermi level as well as the work function of graphene are shifted. The graphene behaves as n-graphene with some energy gap introduced after doping. It has been experimentally shown that the incorporation of n-doped graphene in PSC enhances the performance of the cell and results in improved morphology and surface passivation [52]. On the basis of the parameters given in table 2, the values of performance parameters calculated for the solar cell are: efficiency = 10.65%, J_{sc} = 19.92 mA cm^{-2},

Table 2. Summary of the optimized parameters used in simulation.

Input parameter	n-Graphene	Sn - perovskite	p-Graphene
Layer thickness (nm)	0.334	700	0.334
Dielectric constant	10	6.5	7.1
Electron affinity (eV)	4.8	4.17	4.8
Band gap (eV)	0.5	1.3	0.5
Optical band gap (eV)	0.5	1.3	0.5
Valence band density (cm^{-3})	3×10^{9}	1×10^{18}	3×10^{19}
Conduction band density (cm^{-3})	3×10^{9}	1×10^{19}	3×10^{19}
Hole mobility ($cm^2 V^{-1} s^{-1}$)	10	1.6	10
Electron mobility ($cm^2 V^{-1} s^{-1}$)	1×10^{5}	1.6	1×10^{5}
Thermal velocity of electron($cm\ s^{-1}$)	1×10^{7}	1×10^{6}	1×10^{7}
Thermal velocity of hole($cm\ s^{-1}$)	1×10^{7}	1×10^{6}	1×10^{7}
Doping concentration(cm^{-3})	1×10^{26}	3.2×10^{15}	1×10^{18}
Layer density ($g\ cm^{-3}$)	2.328	2.328	2.328

$V_{oc} = 691.5$ mV and FF = 77.28%. To analyse how graphene influences the device working, the optimization of various parameters is carried out keeping other layer parameters at fixed values. The value of dielectric constant for n-graphene is in the range 10–20 [41]. As we varied the dielectric constant from 10–20, the device performance remains constant and the simulated results are shown in figure 2(a). The value of dielectric constant is therefore taken 10 for n-graphene. The value of energy band gap for n-graphene is varied from 0–0.5 eV, depending upon the doping concentration. The energy band gap (E_g) is optimized in the range of 0–0.5 eV for a single layer graphene. As the E_g varies from 0–0.5 eV, the efficiency, V_{oc}, J_{sc} and FF are increased up to 0.25 eV and remain constant beyond the value 0.25 eV. This is due to the difference in the work function of graphene and $CH_3NH_3SnI_3$ layers which creates a built-in voltage at the interface of the two layers. The V_{oc} is increased from 689.8 mV to 691.5 mV as the built-in voltage increases. The built-in voltage increases the barrier height, which separates the photo generated carriers. The J_{sc} is related to barrier voltage and hence increases from 19.17 mA cm^{-2} to 19.92 mA cm^{-2}. Therefore, the efficiency is increased from 10.21% to 10.65%. The FF slightly varies from 77.22% to 77.28%. The complete behaviour of performance parameters with E_g are presented in figure 2(b). After dielectric constant and energy band gap optimisation, the parameter N_C/N_V is varied in the range of 3×10^{9} cm^{-3} to 3×10^{22} cm^{-3}. On increasing the value of N_C/N_V of n-graphene layer, the recombination rate of photo-generated carrier is higher near the junction which probably causes the reduction in minority carrier densities. The Fermi level of n-graphene was pinned in the absence of free minority charge carriers; this makes barrier height independent of work function of graphene and trimmed down the collection of free charge carriers. Therefore, J_{sc} is reduced from 19.92 mA cm^{-2} to 17.59 mA cm^{-2} and V_{oc} sharply falls from 691.5 mV to 514.9 mV due to trapping of charge carriers. Thus, the reduced values of V_{oc} and J_{sc} correspond to drop in efficiency to 4.72% at 3×10^{22} cm^{-3} of N_C/N_V value but highest efficiency is obtained at 3×10^{9} cm^{-3} of N_C/N_V having value 10.65% and the results are shown in figure 2(c).

The donor concentration (N_D) i.e. doping of nitrogen atom in n-graphene layer is optimized, keeping other parameters at fixed value. The nitrogen atom doping reduces the work function of graphene and increases the Fermi level of graphene from the Dirac point and results in a significant increase in carrier density. The conductivity of graphene layer is increased with increase in donor concentration (N_D). As N_D is varied from 1×10^{8} cm^{-3} to 1×10^{22} cm^{-3}, V_{oc} rises from 222.6 mV to 691.5 mV, FF increases from 38.76% to 77.20% and the efficiency rises from 1.38% to 10.63%. If the donor concentration is further increased, only small changes are observed in the performance parameters of TPSC. It has been reported that both the sheet resistance and series resistance reduce due to increase in donor concentration, therefore, an increase in efficiency is observed. At $N_D = 1 \times 10^{26}$ cm^{-3}, the efficiency slightly changes and is found to be 10.65%. The variation of TPSC performance parameters with N_D are shown in figure 2(d). After this, we optimized one of the important parameters that relates with the cost of solar cell, i.e., layer thickness of n-graphene. To further enhance the performance of the device, we analysed the effect of multilayer graphene. We simulated the cell up to 40 layers of n-graphene by taking the thickness of single layer graphene as 0.334 nm, i.e., the thickness of n-graphene layer is varied from 0.334 nm to 13.36 nm. The transmittance and sheet resistance of graphene is controlled by the thickness of graphene. As we increase the n-graphene layer, the transmittance as well as sheet resistance of the graphene decreases. Both these effects are in opposition to each other. On one hand, the decrease in transmittance reduces the light reaching the active layer and consequently, a lower current is obtained. On the other hand, a reduced sheet resistance should aide in charge collection [53]. However, it is observed in the present case that the cell performance decreases with increase in thickness implying that the transmittance of

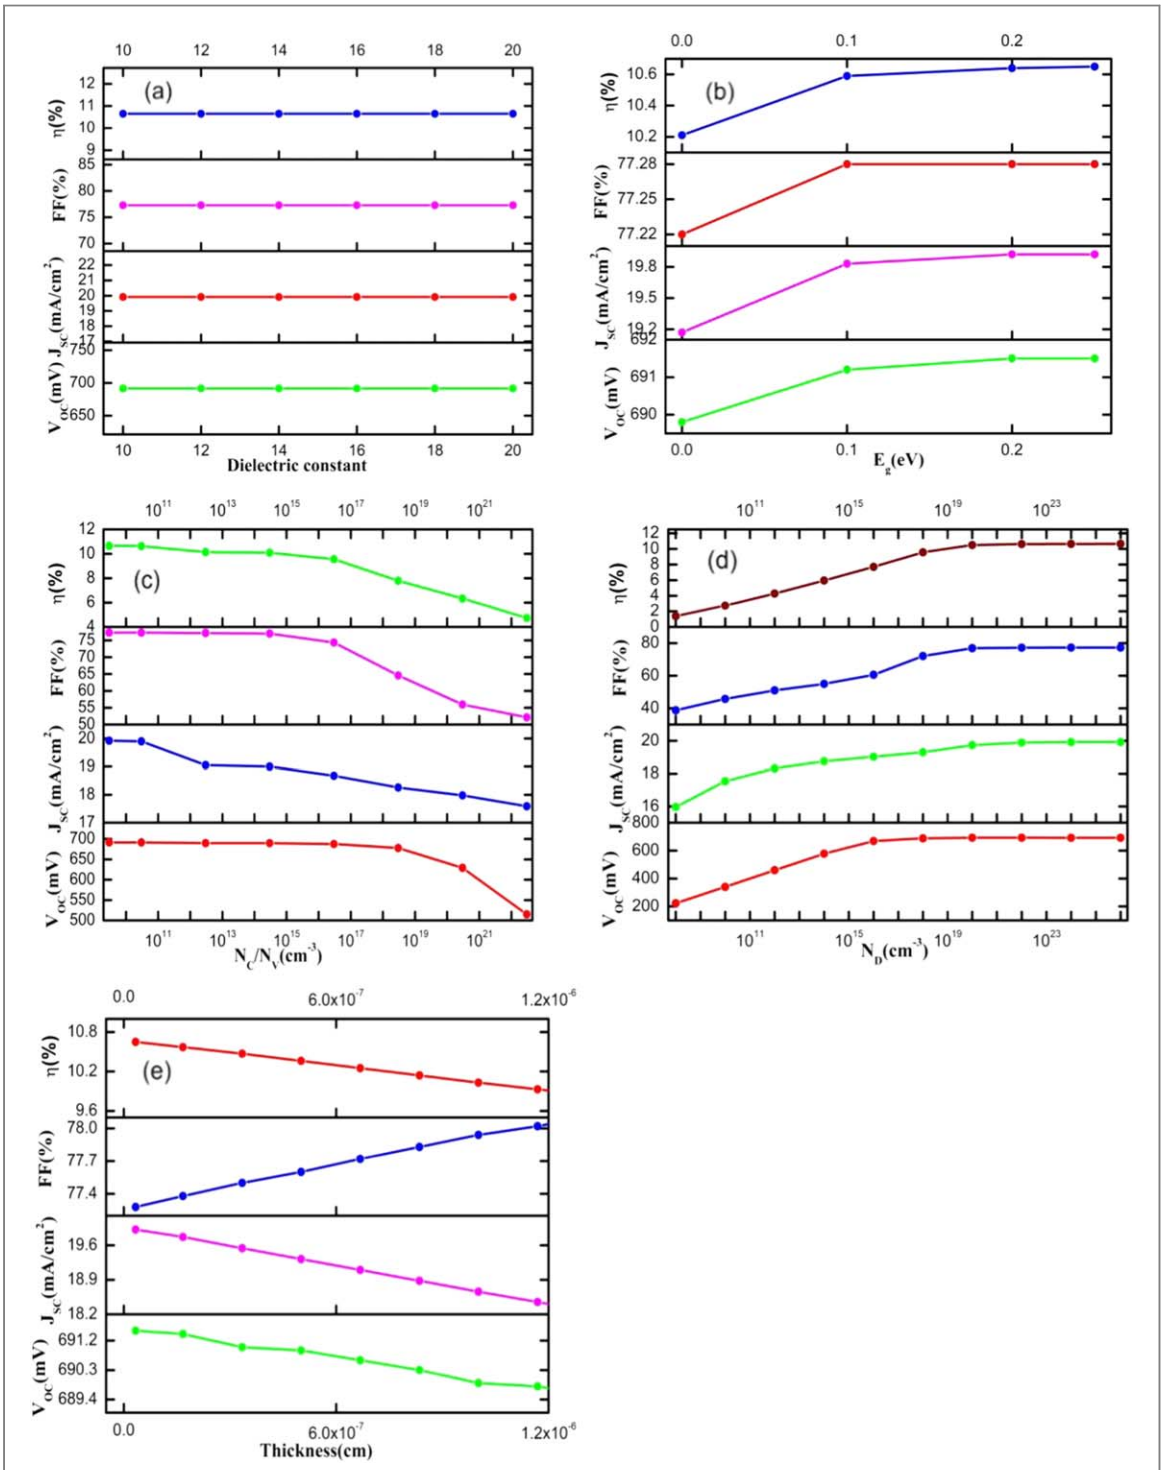

Figure 2. TPSC performance with the n- graphene parameters (a) dielectric constant, (b)energy gap E_g (eV), (c) N_C/N_V (cm^{-3}), (d) N_D (cm^{-3}), (e) thickness, keeping other layer parameters constant.

graphene dominates in effect. This may be supported by the findings that each additional layer of graphene reduces the transmission percentage by ~3% [54]. The detailed variations in cell parameters with n-graphene thickness are given in figure 2(e).

3.2. Active layer parameter optimization

Furthermore, to incorporate the impact of active layer parameters on the cell performance, we optimised the active layer parameters by keeping n-graphene layer parameter at optimized values as mentioned in table 2. Firstly, the thickness of the active layer was varied in the range from 50–700 nm. The efficiency, J_{sc} and V_{oc},

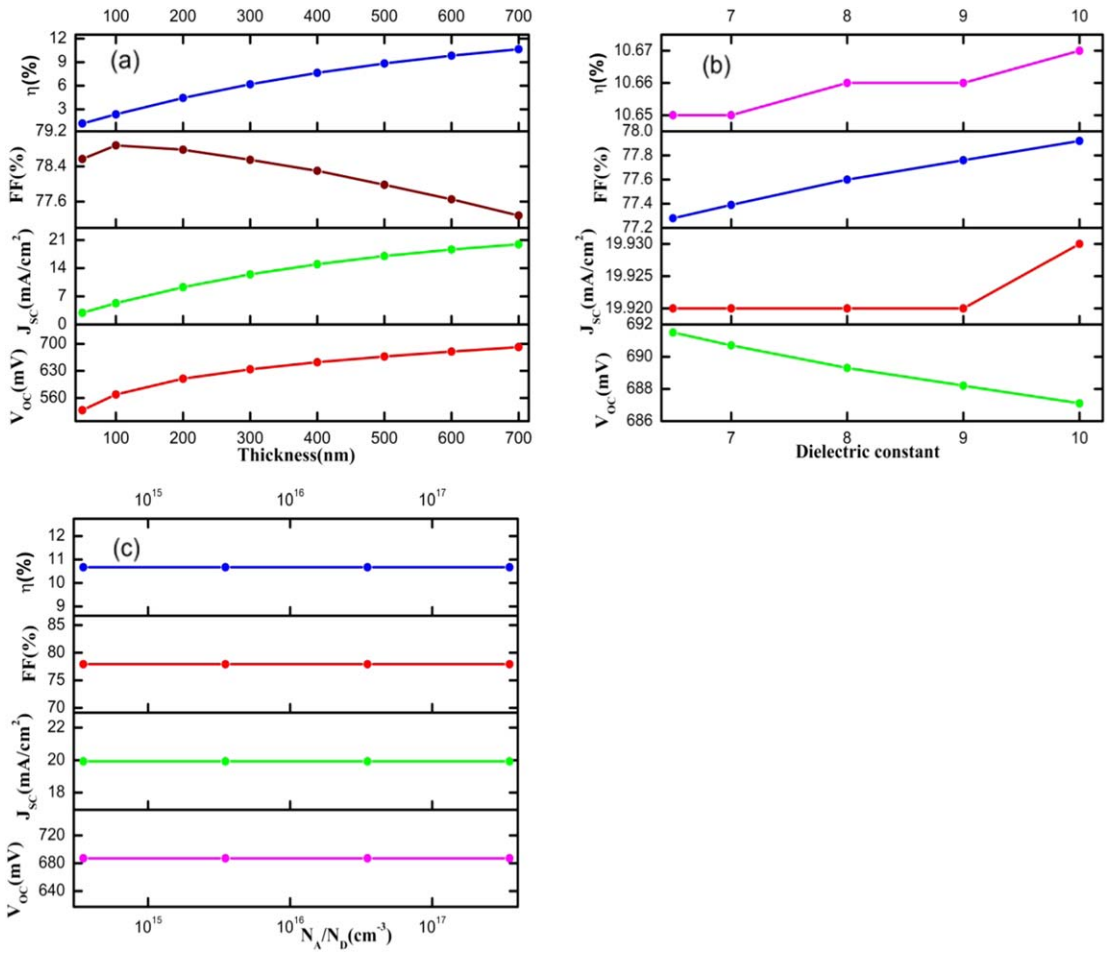

Figure 3. TPSC performance with active layer parameters optimization (a) thickness (nm) (b) Dielectric constant and (c) N_A/N_D (cm^{-3}). The optimized parameters of n- Graphene layer are kept constant.

drastically increased from 1.19% to 10.65%, 2.28 mA cm^{-2} to 19.92 mA cm^{-2} and 528.4 mV to 691.5 mV, respectively, but the FF decreased from 78.57% to 77.28% with the active layer thickness. The overall performance of solar cell parameters is mentioned in figure 3(a). The concept behind this increase in performance of device is that the absorption of light is increased with the thickness of the active layer, leading to higher carrier generation. The increase in efficiency tends to saturate around 700 nm. The effect of increased carrier generation is counter-balanced by the increase in carrier recombination since charge carriers are not able to transport through the active layer towards the electrodes. The charge diffusion length is an important factor in deciding the perovskite layer thickness. The exciton diffusion length of TPSC is found to be more than 500 nm [55, 56], which is consistent with the results obtained. Konstantakou *et al* [56] experimentally obtained the efficiency of 1.7% for $CH_3NH_3SnI_3$ absorber layer having thickness 200 nm. Noel *et al* also studied the lead-free perovskite layer of thickness 300 nm and obtained the efficiency around 6% [18], which in our case is 6.19%. Therefore, to check the influence of thickness of the absorber layer beyond 300 nm, we varied the thickness up to 700 nm and the efficiencies obtained are higher as compared to the literature studies [18, 22, 23, 56].

After the optimization of thickness, the dielectric constant of the active layer was varied in the range of 10–13.6. As we increase the dielectric constant, the J_{sc}, V_{oc}, FF and efficiency change from 19.92 mA cm^{-2} to 19.93 mA cm^{-2}, 691.5 mV to 687.1 mV, 77.28% to 77.92% and 10.65% to 10.67% respectively, and the results are shown in figure 3(b). Thereafter, the value of N_A/N_D is varied from 3.5×10^{14} cm^{-3} to 3.5×10^{17} cm^{-3} to observe its effect on the performance parameters. The variation in performance parameters with acceptor and donor densities of active layer are mentioned in figure 3(c). From the figure, we observed that the dopant concentration i.e. N_A/N_D does not affect the performance parameters.

3.3. Optimization of p-graphene layer

After optimization of ETL and active layer parameters, we optimised the HTL, i.e., p-graphene layer parameters. The acceptor concentration (N_A) that makes the graphene act as p-graphene is varied from 1×10^{14} to

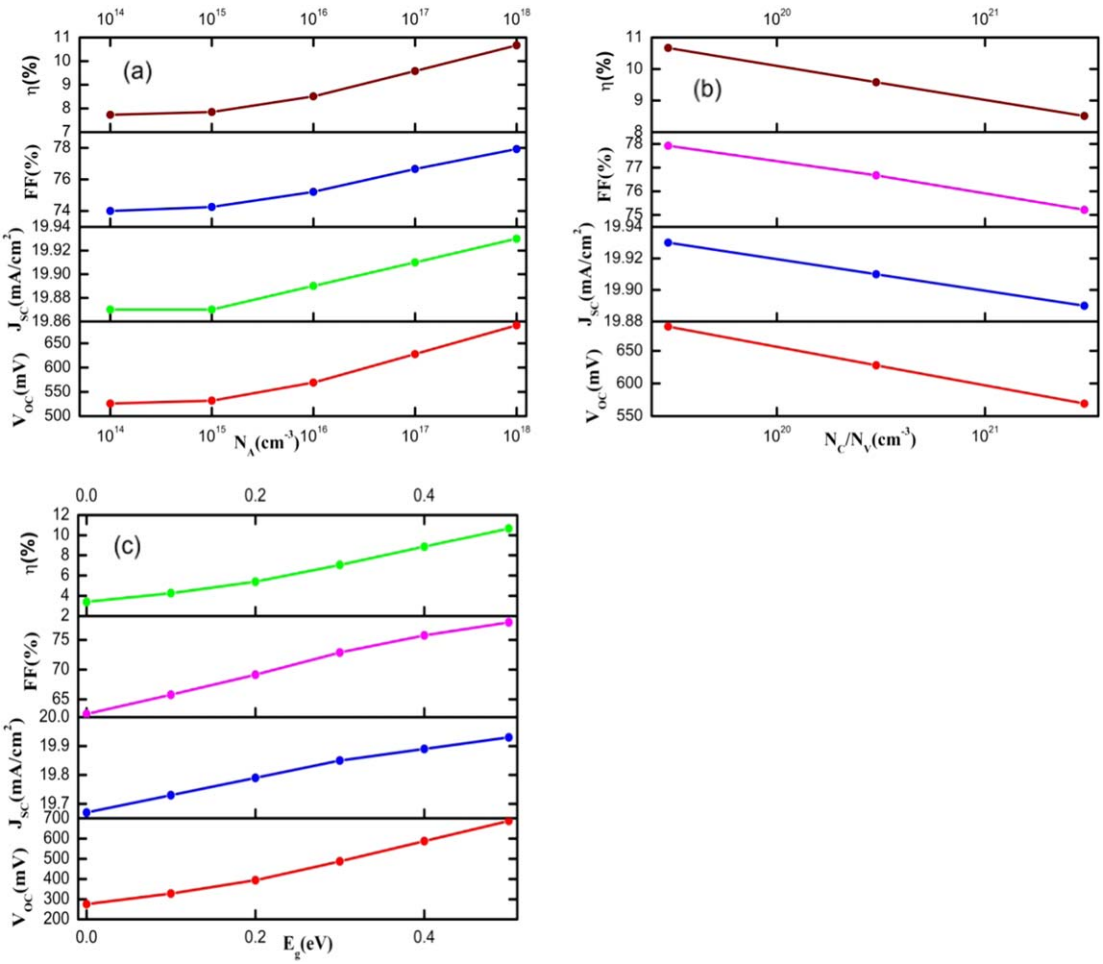

Figure 4. TPSC performance with the optimization of p-graphene parameters, (a) N_A (cm^{-3}), (b) N_C/N_V (cm^{-3}), (c) E_g (eV) and (d) keeping optimized parameter of n- graphene and active layer constant.

1×10^{18} cm^{-3}, to observe its effect on the performance parameters. The efficiency is increased from 7.73% to 10.67% with the increase in N_A. This might be due to rise in the work function of the graphene. The holes are rapidly injected by the p-graphene electrode. The sheet resistance of graphene layer is also reduced [53]. Referring to figure 1(b), p-doping of graphene leads to better alignment of energy levels between HOMO (highest occupied molecular orbital) of perovskite and Ag electrode. The value of J_{sc} is slightly changed from 19.87 mA cm^{-2} to 19.93 mA cm^{-2}. The $V_{oc,}$ and FF of the TPSC also increased from 525.9 mV to 687.1 mV and 74% to 77.92% with N_A. The detailed variations are presented in figure 4(a).

The values of N_C/N_V are changed from 3×10^{19} cm^{-3} to 3×10^{21} cm^{-3} to analyse its effect on the performance of TPSC. As from the figure 4(b), we noticed that with the increment in N_C/N_V value, the V_{oc} is reduced from value 687.1 mV to 569.1 mV, due to increase in minority carrier density. The efficiency and FF are reduced from 10.67% to 8.51% and from 77.9% to 75.21% respectively. The J_{sc} is decreased from 19.93 mA cm^{-2} to 19.89 mA cm^{-2}. This happens due to short lifetime of photo-generated charge carrier and trapping of free charge carrier because of increase in minority charge carrier density.

The effect of energy band gap of p-graphene is seen on the performance of TPSC. The energy band gap is varied from 0–0.5 eV. The variation of TPSC performance parameters with the E_g are presented in figure 4(c). From the graph we observed that the efficiency, FF, J_{sc} and V_{oc} varies from 3.38% to 10.67%, 62.53% to 77.92%, 19.67 mA cm^{-2} to 19.93 mA cm^{-2} and 275.6 mV to 687.1 mV respectively. This is due to increase in built-in voltage at the perovskite/p-graphene interface which might due to the difference in the work function at the interface. This voltage separates the electron-hole pair at the interface and holes are collected by p-graphene layer. The thickness of p-graphene layer does not influence the performance of simulated structure further. Therefore, the best optimized value of performance parameters corresponding to each layer are given as $J_{sc} = 19.93$ mA cm^{-2}, $V_{oc} = 687.1$ mV, FF = 77.92% and the efficiency is 10.67% respectively. The J-V characteristics and quantum efficiency with wavelength of the best simulated cell is given in figures 5(a) and (b) respectively.

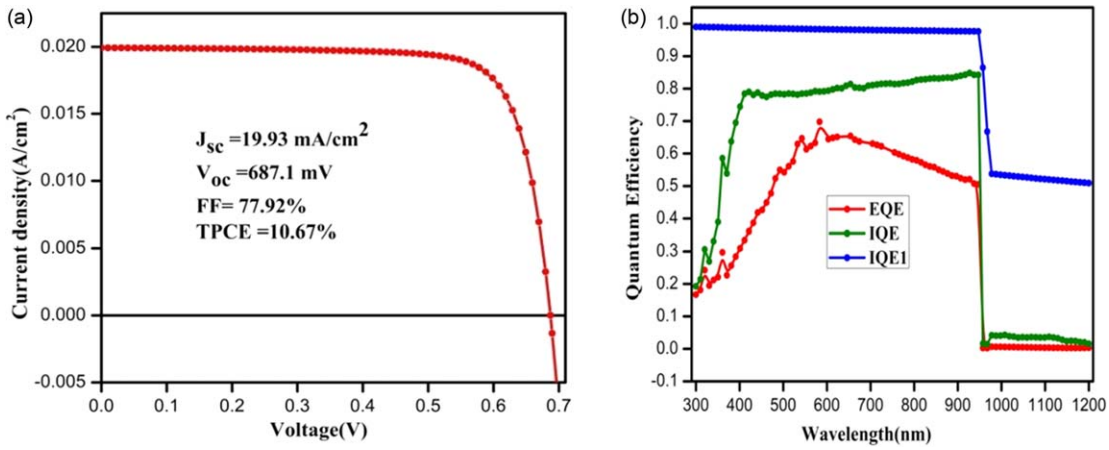

Figure 5. (a) J-V curve and (b) quantum efficiency with wavelength for best optimized parameters of the solar cell.

3.4. Operating temperature influence on the cell performance

The impact of operating temperature on the device performance is observed in the temperature range of 300–900 K. The efficiency, FF, J_{sc} and V_{oc} are significantly affected with the rise in temperature. The efficiency of the device and FF of the device are maximum i.e. 10.67% and 77.92% respectively at temperature 300 K. The efficiency and FF vary from 10.67% to 0.06%, and 77.92% to 21.49% respectively with the rise in temperature. The variation in V_{oc} with temperature is given by the following formula [57]:

$$\beta_{Voc} = \frac{10^6}{V_{oc}(25\ ^\circ\mathrm{C})} - \frac{V_{oc}(Tc - V_{oc}(25\ ^\circ\mathrm{C})}{T_C - 25\ ^\circ\mathrm{C}}$$

Here β_{Voc} is the temperature coefficient in parts per million (ppm)/°C and T_C is the temperature of the solar cell.

The V_{oc} is declining from 687.1 mV to 15.14 mV with the rise in temperature, because of increase in diode saturation current with the temperature. Recombination rate is also increased due to change in intrinsic carrier concentration which is mainly affected by the diode saturation current. The J_{sc} also decreased from 19.93 mA cm^{-2} to 18.62 mA cm^{-2} with temperature because of reduction in ideal current due to increase in energy band gap, whereas the collection fraction enhances typically with temperature. Hence, depending upon which of these conditions dominate, J_{sc} might either lower or higher with temperature. But overall report indicates that for higher temperature J_{sc} gets reduced. The detailed performance of TPSC parameters with temperature are presented in figure 6.

3.5. Effect of textured surface on the TPSC performance parameters

The nature of front contact surface also affects the performance of solar cell i.e. it may be plane or textured. The textured surface is preferred for increasing the efficiency of TPSC. The textured surface absorbed more photons from Sun light as compared to plane surface and hence reduction in light reflection from surface. This is due to the fact that when incident light falls on the surface of the cell, a certain amount of light is bounced back, but if the surface is textured then the light falls on one side of pyramid and bounces to the side of another pyramid. Hence more area is utilized to absorb the incident light and efficiency can be improved due to multiple reflections.

As shown in the figure 7, the texture angle is varied from 0° to 80° for textured surface and the performance of TPSC parameters is observed. The efficiency is increased from 10.67% for plane front surface to 13.28% for front textured surface. It means that solar cell with textured surface has higher photo-absorption rate. The J_{sc} is enhanced from a value of 19.93 mA cm^{-2} to 24.03 mA cm^{-2}.

3.6. Modelling of TPSC

We modelled the best optimised TPSC structure as one diode model in MATLAB software. The TPSC as diode can be represented through an equivalent circuit as shown in figure 8.

The value of material constant is varied from 2.6 to 4.6 for perovskite solar cell [58, 59]. The values of series resistance R_s (6.89 Ω) and shunt resistance R_p (2910.53 Ω) are obtained from the J-V characteristics of TPSC given in figure 5(a). The values of efficiency and FF are obtained as 10.73% and 78.42% respectively, from diode model using numerical programming in MATLAB. In this work, the value of material constant a = 3.5 gave

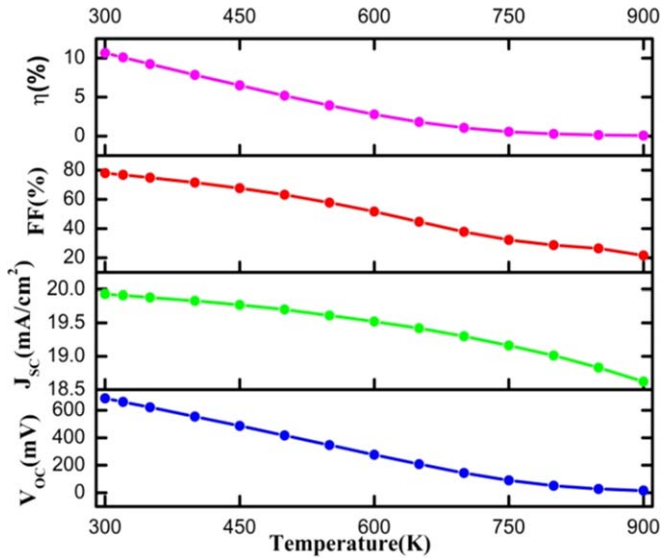

Figure 6. TPSC parameters variations with operating temperature.

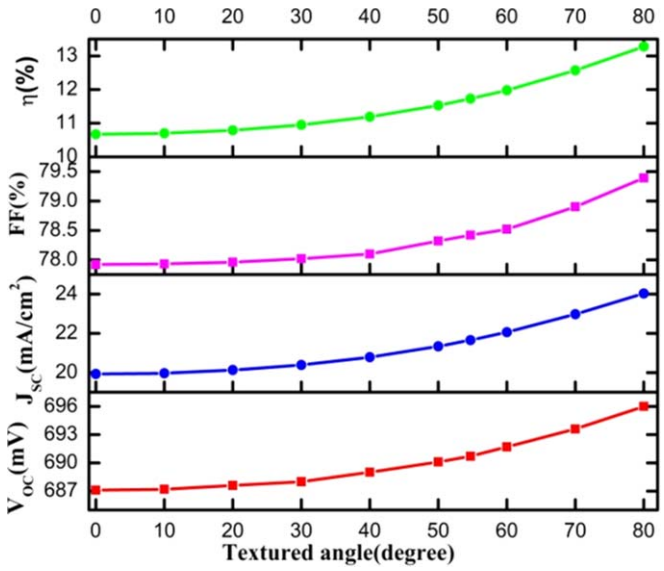

Figure 7. TPSC parameters variations with textured front surface.

better agreement with AFORS-HET simulation results. The J-V and P-V characteristics of TPSC are given in figures 9(a), (b) respectively. The above results reveal that simulation results are in good agreement with the modelling results for plane front surface.

4. Conclusion

In the present theoretical work, we studied the graphene-based charge transport layers in the tin based perovskite solar cell using AFORS-HET software. After optimizing the layer parameters, a maximum efficiency of 10.67% is obtained for plane front surface. The textured front surface increases the efficiency of the device up to 13.28%. The effect of operating temperature has been observed on the performance of the solar cell. We also presented a diode model of tin based perovskite solar cell in MATLAB software. The results of the simulation and modelling are in agreement with each other. The performance and optimization of the device produced here are useful for commercialization of lead-free perovskite solar cell.

Abstract: A two-element super-wideband MIMO antenna is proposed in this article. A step impedance microstrip feed line structure is introduced to achieve a super-wideband impedance bandwidth of 185%. This antenna is designed to be circularly polarized at 1.575GHz (L_1-band) and 26.0GHz (K-band) by using closed ring resonator on the radiating patch. The EBG structures are used to improve FBR in lower (1.5-5GHz) and higher band (25-35GHz). The proposed antenna is designed with compact size 55.6×50.5×1.6mm^3 on FR-4 substrate including exotic diversity performance. This MIMO antenna is suitable for defence and handheld devices covering GPS/ DCS/ PCS/ UMTS/ Wi-BRO/ ISM/ IRNSS/ LTE (M/HB)/ BLUETOOTH/ IoT/ WiMAX/ X/ Ku/ K/ Ka-band and it is also suitable for 5G (sub-6GHz/mm) applications with channel capacity of 11.34bps/Hz. Simulated results of MIMO antenna like radiated power based ECC and diversity parameters are also verified experimentally, which are in the acceptable range. Finally, this antenna is tested in a realistic environment for SAR application.

1. INTRODUCTION

Due to rapid advancement in wireless communication systems, better channel capacity with seamless high-data-rates connectivity is required. In order to fulfill the requirements, MIMO-communication systems are deployed that use multiple antennas on the transmitter and receiver end as depicted in Fig. 1. MIMO system is a state-of-art technology which improves the reliability of the communication systems by utilizing the diversity technique to mitigate the multi-path fading issues, where signals may come together contentiously at the receiver antennas. Spectral efficiency is also improved by the total transmitted power spreading over the MIMO antennas. Thus, MIMO antennas can increase channel capacities as well as the reliability of the communication system without sacrificing extra transmitted power or power spectrum. MIMO antennas have been designed to improve their characteristics in terms of impedance bandwidth, miniaturization & isolation. Several decoupling techniques are used in MIMO antennas to improve isolation and diversity performance [1-5]. For size miniaturization, a Yagi-shaped antenna is designed with better FBR [6]. Electromagnetic Band Gap (EBG) structures are also used to improve isolation in X-band MIMO antenna [7-9] which is useful for efficient wireless communication without affecting the adjacent antenna. In order to mitigate interference in UWB MIMO antenna, a WLAN notch is introduced using T-shaped open slots [10-12]. A Defected Ground Structure (DGS) mechanism has been introduced in MIMO antenna design to avoid correlation between two antenna and fast data rates [13]. Similarly, Split Ring Resonator (SRR) and Complementary Split Ring Resonator (CSRR) structures near the microstrip feeding line and ground plane were used respectively for high isolation [14-15]. The dual band-notched UWB MIMO antenna was tailored by cutting two rectangular slits on the patch and a fin-shaped decoupling structure was also introduced to get better ECC and directive gain [16]. MIMO antennas for sub 5G application (3.4-3.7GHz) is constructed without introducing any decoupling structure [17-18]. So, the advantages and disadvantages of the decoupling techniques over the proposed design are explained in Table 1 which has been used in MIMO antenna designs.

Table 1 Performance comparison of the decoupling techniques over the proposed design

Isolation Level (-dB)/Refs	Isolation Techniques	Advantages	Disadvantages
20 [3]	EBG WITH FSS, Double-layer EBG, Mushroom-shaped EBG	Improved isolation, increased diversity gain	Complex geometry
15 [10]	T-shaped	Improved isolation	Limited to UWB only
20 [11]	Defected Ground Structure (DGS)	Improved isolation at a lower frequency, compact structure	Complex structure
17 [14]	Split Ring Resonator (SRR)	Compact structure and high isolation bandwidth	Limited to a wide bandwidth
15 [15]	Complimentary Split-Ring Resonator (CSRR)	Compact structure and high isolation bandwidth	Limited to a wideband bandwidth
24 [16]	Funnel-shaped decoupling	Provided good isolation for 173% bandwidth	Large in size
20 [18]	F-shaped decoupling structure	Good isolation for UWB bandwidth	Poor isolation at low frequency (>2GHz)
16 [20]	Fractal uni-planar compact EBG	Improved isolation and FBR	Complex structure with narrow bandwidth
20 [25]	Flag-shaped stub on the ground plane	Good isolation for dual-band	Complex structure for the wideband only
13 [29]	Coupled-feed structure	Improved ECC, DG, MEG	Up to 6GHz only
20 [Proposed]	Mushroom-shaped EBG including E-shaped decoupling structure	Improved isolation for 1-40GHz band width with reduced cross-polarization	Complex structure

Specific Absorption Rate (SAR) is an important parameter for handheld devices. Therefore, it has been investigated for 1g and 10g tissue as per the Federal Communication Commission (FCC) [19]. Various types of decoupling techniques for antennas are deployed to enhance isolation which is responsible for good diversity parameters like ECC, DG, TARC, and CCL [20-25]. Furthermore, to enhance the throughput in the communication system, a cognitive radio LTE700 was demanded in wireless communication [26-30]. This type of antennas is also useful for IoT/WLAN/Wi-MAX/LTE and other multi-band applications. A technique is investigated to reduce Radar Cross Section (RCS) and enhance gain by using a polarized meta-surface with solid blocks of EBG structure in [31-32]. A semi-crescent cascaded structure is also designed for good diversity performance with circular polarization [33]. The circular polarization antennas are beneficial for moving handhold or mobile communications like GPS which needs at least half power when the object is movable so the antenna is required below 3dB axial ratio in a prescribed band [34]. The strip integrated circular polarized antenna is designed for radiofrequency energy harvesting application [35].

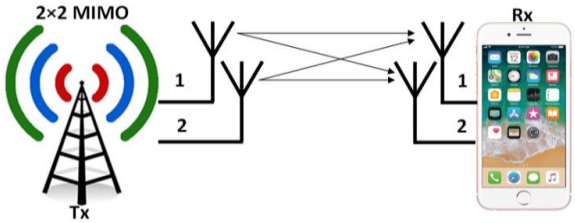

Fig.1. *A block-diagram of 2×2 SWB-MIMO antenna transceiver network*

In this paper, a compact super wideband (1.5-40GHz) dual-band circularly polarized MIMO antenna including notched-band characteristic (5.9-7.1GHz) is presented. The super-wideband (SWB) bandwidth of an antenna is attained by introducing a step impedance microstrip line to feed the radiator. Furthermore, two rectangular-shaped slots are etched on the ground plane to attain band-notched characteristic. Unequal E-shaped stubs and mushroom-shaped EBG structure is used for high isolation. Circular-shape (Closed Ring Resonator-CRR) is etched on the patch to achieve circular polarization in two bands. Section 2 explains the antenna design procedure. Section 3 demonstrates the simulated and measured results. Section 4 depicts the diversity performance of the antenna along with a comparison from literature. Section 5 concludes the results in terms of different parameters. The proposed antenna is designed using computer simulation technology-CST microwave studio simulation tool.

2. MIMO ANTENNA DESIGN PROCEDURE

The designed 2-element MIMO antenna including notched-band (5.9-7.1GHz) characteristic is fabricated on FR4 substrate of height (h) 1.6mm with relative permittivity (ε_r) of 4.4 and loss tangent (tanδ) of 0.02 having an overall dimension of 55.5mm×50.6mm as shown in Fig. 2 (a) - (b). All dimensions of the proposed antenna are given in Table 2. To achieve SWB impedance bandwidth (1.5-40GHz), the impedance feeding mechanism comprises of three feeding subsections having an impedance of 50, 65 and 81Ω respectively with different length. To improve the intended bandwidth, some other steps also discussed later. The current is accumulating along the periphery of the circular radiator which is affecting the bandwidth in a low-frequency range, Therefore, to improve the low-frequency bandwidth, a "Closed Ring Resonator-CRR" of radius 5.3mm is etched at circular patch without affecting the antenna performance.

Table 2 Proposed SWB MIMO antenna dimensions in mm

R_1	R_2	D_1	D_2	D_3	D_4	D_5	E_1	E_2	E_3
11	5.3	3.2	1.9	1.2	6.85	11.7	5.8	5.5	10.6
E_4	**E_5**	**G_1**	**G_2**	**C_1**	**C_2**	**C_3**	**C_4**	**C_5**	**C_6**
7.92	9.35	0.45	0.6	0.6	1.3	12.7	1.2	3.3	5.7
C_7	**C_8**	**C_9**	**B_1**	**B_2**	**B_3**	**B_4**	**B_5**	**B_6**	**B_7**
8.7	24.3	55.6	5.5	1.5	1.5	1.5	1.5	24	26.5

This antenna consists of a circular patch and a circular slot etched out of it to achieve circular polarization in dual-band. Further, E-shaped stubs are used with unequal arm length to achieve the intended isolation between antennas because E-shaped stubs of equal length cause poor isolation at a lower frequency. Stubs of unequal length are also helpful to extend bandwidth. The number of stubs is optimized to provide maximum decoupling at a high frequency so it cannot be improved further by increasing the number of stubs. Now, super-wideband including band-notch characteristic is obtained by using a stepped impedance feed line with a partially tailored ground plane together with rectangular slots. The diameter of the EBG slots (R_3) is 1.2mm. The fundamental resonance frequency (f_r) of the circular-shaped monopole antenna is calculated by equation (1) in Ref-2.

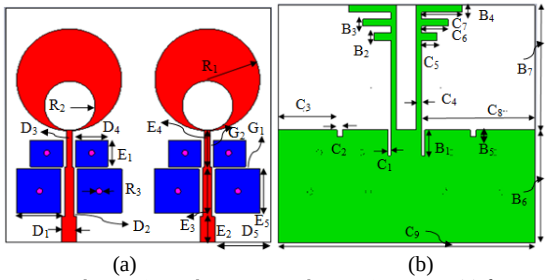

Fig.2. *Two-element SWB planar monopole MIMO antenna (a) front sight (b) bottom sight*

$$f_r(\mathrm{GHz}) = \frac{144}{C_9 + R_1 + h + \frac{A_1}{2\pi\sqrt{\varepsilon_r + 1}} + \frac{A_2}{2\pi\sqrt{\varepsilon_r + 1}}} \quad (1)$$

where A_1, A_2 is the area of anticipated radiation patch and ground plane, C_9 is the length of a ground plane, R_1 is a diameter of circular radiated patch depicted in Fig. 2 (a) - (b). The step by step design modus operandi of the proposed SWB-MIMO antenna is represented in Fig. 3 and analogous return losses and isolations are presented in Fig. 4 (a) - (b) respectively. Ant-1 provides unsatisfactory return loss and isolation in SWB bandwidth. By changing the feeding line width of Ant-1, return loss and isolation is improved as depicted in Ant-2 but return loss is not acceptable in the lower frequency range. Since charges are accumulated on the etched portion of patches, the discontinuity is added to improve the return loss with compromised isolation in the intended band. Therefore, in Ant-3, a circular slot is etched from the patches. Further, in Ant-4, mushroom-shaped EBG is designed near the feed line which improves the reflection coefficient and isolation in the intended bandwidth.

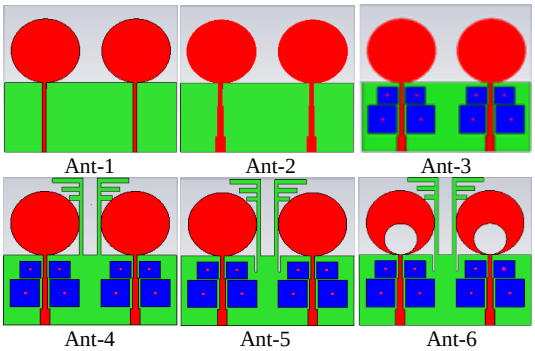

Fig.3. *Geometrical design steps of the proposed super-wideband MIMO antenna with band notch characteristics*

This article has been accepted for publication in a future issue of this journal, but has not been fully edited.
Content may change prior to final publication in an issue of the journal. To cite the paper please use the doi provided on the Digital Library page.

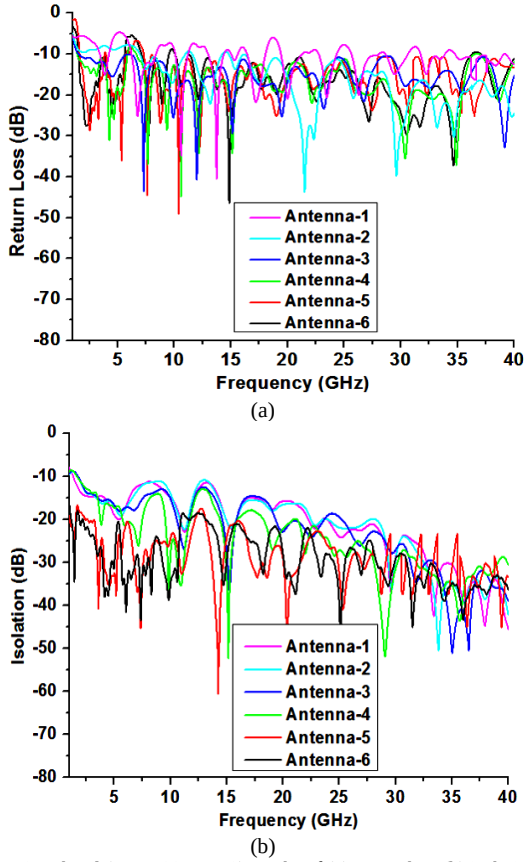

Fig.4. *Simulated (using CST MWS) results of (a) return loss (b) isolation of the antennas shown in Fig. 3*

Unequal E-shaped decoupling structure is made in the ground plane of Ant-5, to improve isolation (greater than -20dB) in the entire SWB range. Further, vertical slots are engraved in the ground plane to get better isolation in the frequency range 2.1 to 4.8GHz and it also creates a notch band characteristic for avoiding the interference from E-S satellite communication (5.9-7.1GHz) as shown in Fig.-3 Ant-6. The bandwidth of the notched band can be controlled by changing the ground slot length (B_1) at the notch frequency, $\mathbf{f_n = c/(2 \times B_1 \times \sqrt{\varepsilon_{reff}})}$, where c is the speed of the signal in a vacuum (3×10^8m/sec) and ε_{reff} is the effective relative permittivity [36] of a substrate. Center frequency of the intended notched-band is 6.5GHz at B_1.

EBG structures including a microstrip feed line and its equivalent circuit model with simulated results represented in Fig. 5 (a) - (d) and center frequency of the designed EBG is calculated by equation (2)

$$f_{EBG} = \frac{1}{2\pi\sqrt{L_{eq}(C_{gap\,eq} + C_{plate\,eq})}} \qquad (2)$$

C_{gap} is the gap capacitance between step impedance feeding line and square mushroom-shaped EBG structures having length E_1 & E_5 respectively and it is calculated by equation 3(a)-(b).

$$C_{gap1} = \frac{E_1\varepsilon_o(1+\varepsilon_r)}{\pi}\text{Cosh}^{-1}\left(\frac{E_1+G_2}{G_2}\right)F = 49.69\times10^{-15}\ F \qquad 3(a)$$

$$C_{gap3} = \frac{E_5\varepsilon_o(1+\varepsilon_r)}{\pi}\text{Cosh}^{-1}\left(\frac{E_5+G_2}{G_2}\right)F = 143.74\times10^{-15}\ F \qquad 3(b)$$

As C_{gap1} & C_{gap2} are equal and parallel therefore the total $C_{gap1,\,2}$ is $= C_{gap1} + C_{gap2} = 99.38\times10^{-15}$ F , similarly C_{gap3} & C_{gap4} are also equal and parallel so $C_{gap3,\,4}$ is $= C_{gap3} + C_{gap4} = 287.49\times10^{-15}$ F .

C_{plate} is the plate capacitance associated with EBG plate and ground plane, it is calculated by equation 4 (a)-(b) respectively

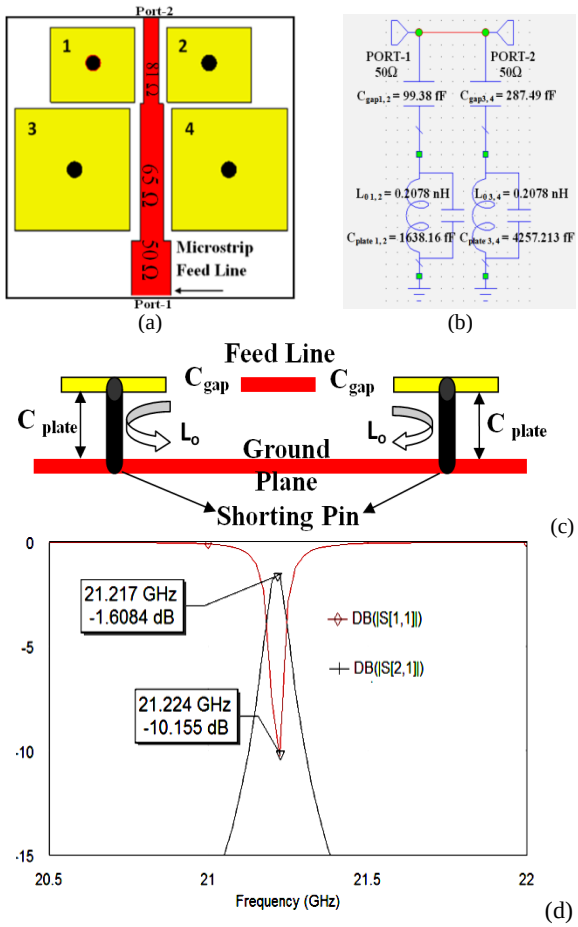

Fig.5. *Circuit analysis of Electromagnetic Band Gap structures (a) Mushroom-shaped EBG designs near to the microstrip stepped feed line (b) Equivalent circuit model of EBG (c) Front cross-sectional view of EBG (d) Simulated results of the equivalent circuit model of EBG with its resonance frequency*

$$C_{plate1} = \frac{\varepsilon_0\varepsilon_r E_1 D_4}{h}F = 819.08\times10^{-15}\ F \qquad 4(a)$$

$$C_{plate3} = \frac{\varepsilon_0\varepsilon_r E_5^2}{h}F = 2128.606\times10^{-15}\ F \qquad 4(b)$$

C_{plate1} & C_{plate2} are equal and parallel, therefore, $C_{plate1,2}$ is $= C_{plate1} + C_{plate2} = 1638.160$ fF , similarly C_{plate3} & C_{plate4} are equal and parallel so $C_{plate3,\,4}$ is $= C_{plate3} + C_{plate4} = 4257.213$ fF .

L_O is the inductive loading of centrally located shorting pin in EBG structure and it is calculated by equation (5)

$$L_O = 2\times10^{-7}\times h\left[\ln\left(\frac{2\times h}{R_3/2}\right) + 0.5\left(\frac{R_3}{h}\right) - 0.75\right]H = 0.4156\times10^{-9}H \qquad (5)$$

Four equal and parallel shorting pins associated with four mushroom-shaped EBG structures, therefore total equivalent inductance (L_{eq} = Lo/4) is 0.1039×10^{-9} H.

Hence, the calculated resonance frequency of the EBG structure is 21.224GHz by equation (2).

The proposed step quarter-wave impedance transformer technique without EBG is verified by a circuit simulation tool "Microwave Office" as shown in Fig. 6(a) and the proposed feeding mechanism is compared with existing feeding mechanism in Table 3. Stepped impedance feed line with EBG, shown in Fig. 5(a), provide permissible scattering results in the proposed antenna.

Table 3 Comparison of proposed step impedance feeding mechanism with an existing feeding mechanism

Techniques	Return Loss (dB)	Frequency (GHz)	Features	Disadvantages
Quarter-wave impedance transformer technique (50Ω to 110Ω) [42]	25	0.6-1.6	Three transmission zero at θ = 60^0, 90^0, 120^0	Design for wideband only
Quarter-wave impedance transformer technique [43]	35	1.6,2.5,5.3	CP at a different frequency band	Design for multi-band with narrow bandwidth only
Coupled transmission line impedance transform technique (50Ω to 100Ω) [44]	20	0.4-1.7	Three transmission zero at θ =40^0, 90^0, 140^0	Design for wideband only
Step quarter-wave impedance transformer technique (50Ω to 81Ω) [Proposed]	10	1.5-40	Transmission coefficient near to 0dB for maximum power transfer	Poor return loss and only suitable for antenna

The return loss is less than -10dB throughout the SWB (1.5GHz-40GHz), which means that maximum input power appears at port-2 as shown in Fig.6 (b). In addition, E-field cross-polarization of the antenna is also improved due to the EBG structure.

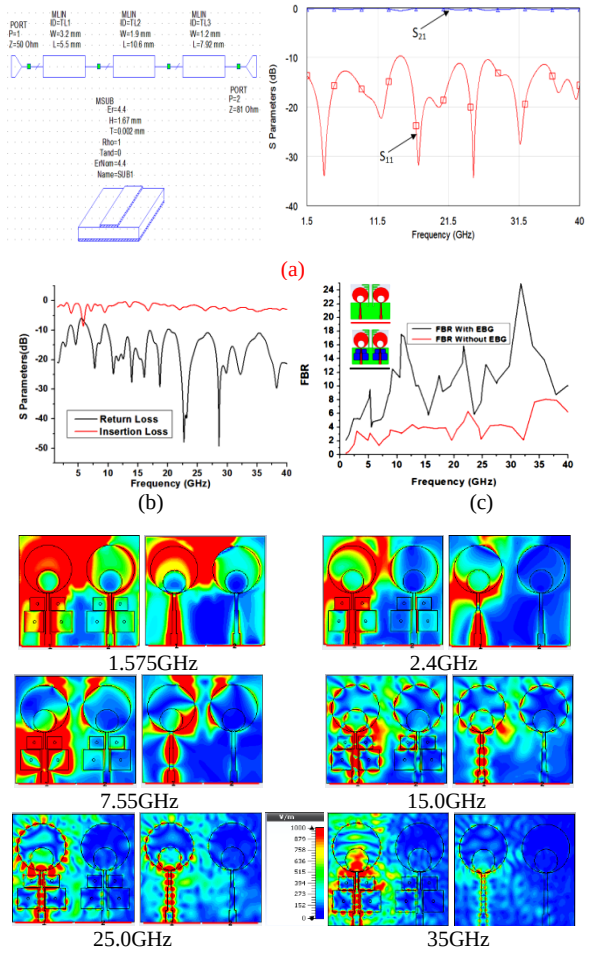

Fig.6. *Electromagnetic field analysis of stepped impedance feeding line and EBG structures (a) Simulated scattering results of stepped impedance feeding line only (b) Simulated scattering results of stepped impedance feeding line with EBG designs (c) Simulated FBR of SWB-antenna with and without EBG structures (d) Field distribution with and without EBG at 1.575, 2.4, 7.55, 15, 25, 35 GHz frequency when port-1 excited and port-2 terminated with a matched load*

FBR (Front to Back Ratio) is calculated with and without EBG to represent the existence of EBG in proposed antenna design as shown in Fig. 6 (c). As EBG is used to prevent the surface wave loss and direct the radiated power in the intended direction, therefore, the FBR of the antenna with EBG is higher than that of without EBG throughout the SWB bandwidth. Fig. 6 (d) represents the electric field distribution over the antenna, with EBG, and without EBG. It is shown that more fields are confined around EBG which improves the FBR in intended bandwidth.

3. Results And Discussion

Measured and simulated return loss, isolation, constant group delay, and peak gain of the designed antenna, as represented in Fig. 7 (a) – (b), are less than -10dB, -20dB, almost 1.0ns, and 7.6dB respectively, throughout the SWB bandwidth except notched band. The return loss begins to deteriorate at high frequencies especially above 35GHz because at high frequency, inductance effect starts to dominate in the proposed impedance matching mechanism. Also, the current is confined on the surface of the conductor due to skin effect which creates impedance mismatch and provides poor return loss. But the simulated return loss is still less than -10dB. Mobile phone and other movable handheld device antennas require at least half power in every plane for effective communication link so circular polarization of antenna for GPS and mm-wave 5G applications is planned. The proposed antenna is circularly polarized in dual-band which is achieved by etching circular slot (Closed Ring Resonator: CRR) out of the radiating patch.

All steps of the proposed antenna design from linear to circular polarization is given in Fig. 3 with its axial ratio shown in Fig. 7(c)-(d). It is observed from the results of antennas (Ant-1 to Ant-5) that the axial ratio of antennas in Fig.7 (c) and (d) w.r.t. frequency is greater than 6dB throughout the Superwideband. Hence, all antenna designs (Ant-1 to Ant-5) are linearly polarized. Although, the proposed Ant-6 with an etched CRR of the optimized radius produces circular polarization at 1.575GHz and 26.0GHz having an axial ratio less than 3dB. The optimized radius of the circular patch and etched CRR are 11.0mm (R_1) and 5.3mm (R_2) respectively.

The simulated current density of antenna at 1.575, 2.40, 2.45, 3.50, 5.50, 8.69, 15.0, 25.0, 35.0GHz frequencies is represented in Fig. 8. The main cause behind the mutual coupling between the adjacent antenna elements is the flow of surface current from the energized antenna 1 (left) to antenna 2. Extremely low surface current on antenna-2 is observed due to the excitation of antenna-1 as shown in Fig.8. Hence, the level of mutual coupling between antenna-1 and antenna-2 is very low. Means, this proposed decoupling mechanism is useful in various antenna applications without affecting the adjacent antenna. In the present case, E-shaped stubs in a ground plane are used for achieving reduced mutual coupling between antennas. Therefore, better isolation is acquired in the intended frequency band.

The radiation distinctiveness of the MIMO antenna is investigated in the SWB bandwidth. To measure radiation from antenna-1, antenna-2 is terminated with a matched load. 3D radiation patterns are shown in Fig. 9 (a), where the peak of the radiation patterns of an antenna is in one direction at all frequencies. When antenna 2 (right) is excited, the power is radiating towards the right of the yz- plane. Thus, the proposed antenna gets pattern diversity which contributes to better isolation between the two antennas. The designed MIMO antenna is fabricated on an FR4 substrate using photolithography technique, shown in Fig. 9 (b). Antenna under test is placed in an anechoic chamber associated with VNA (Vector Network Analyzer) for measurement of antenna characteristics, represented in Fig. 9 (c).

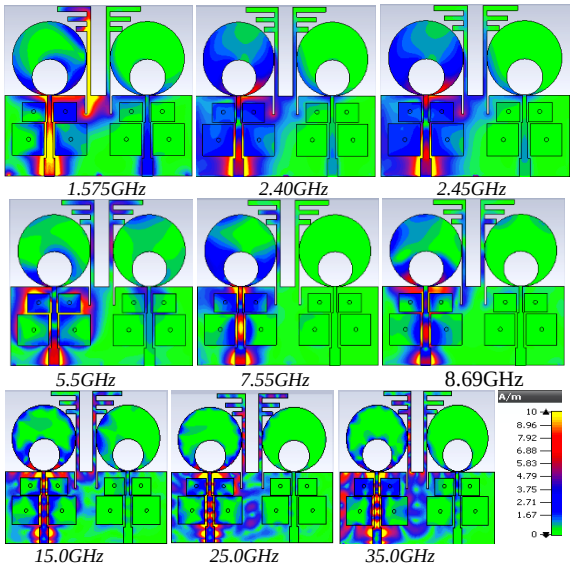

Fig.8. Surface current density distribution at 1.575, 2.40, 2.45, 5.50, 7.55, 8.69, 15.0, 25.0, & 35.0GHz when antenna 1 (left) is energized and antenna 2 (right) terminated with match load

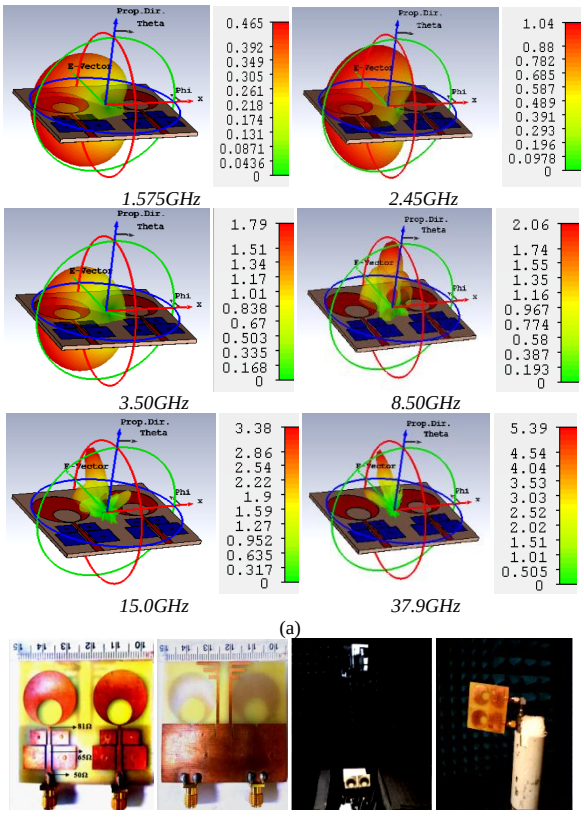

Fig.9. 3-D radiation pattern of designed MIMO antenna at (a) 1.575, 2.45, 3.50, 8.50, 15.0, & 37.9GHz (b) fabricated prototype top and bottom view (c) antenna under test in anechoic chamber for radiation pattern measurement

Fig.10 presents the measured & simulated yz-plane (left) and xz-plane (right) 2D radiation patterns of the designed antenna at 1.575, 2.40 and 28.0GHz frequencies respectively with an acceptable agreement. It is noted that the patterns at operating frequency band are omnidirectional at $\Phi = 0^o$ (*xz*)-plane and dipole like at $\Phi = 90^o$ (*yz*)-plane except notched band (5.9-6.9GHz). At higher frequency, the splitting of the radiation lobes is also noted

This article has been accepted for publication in a future issue of this journal, but has not been fully edited.

due to higher-order mode propagation. The EBG structure is helpful in preventing cross-polarization in the proposed antenna.

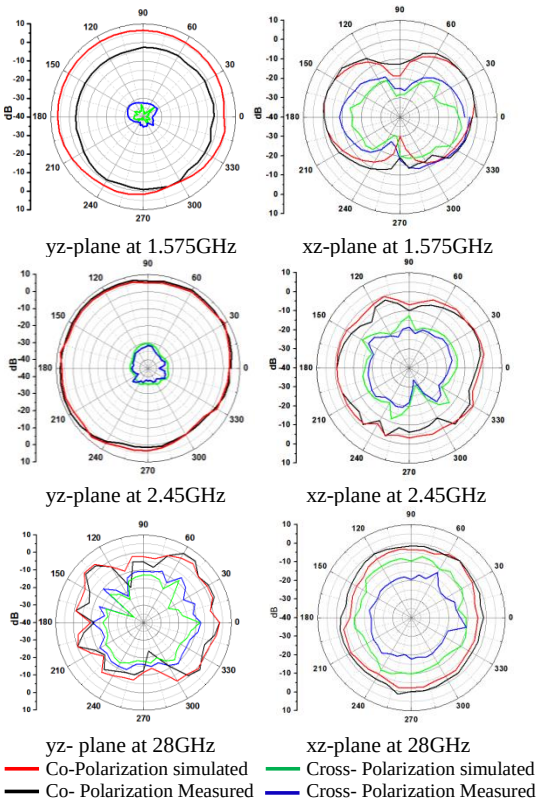

Fig.10. *Measured & simulated 2D radiation patterns at 1.575, 2.45, and 28.0GHz for yz- plane (left) and xz- plane (right), antenna 1 is energized and antenna 2 is terminated by a matched load*

Specific Absorption Rate: SAR is a vital parameter in the antenna at which electromagnetic energy is consumed by the human body when it is exposed, as shown in Fig 11. SAR is explained as "the power absorbed per mass of tissue". SAR is usually averaged either over a small sample volume (typically 1g or 10g of tissue) or over the whole body. The SAR value of any RF and microwave electronic devices is obtained by penetration of electric field intensity in the human head tissue (Table 4) near field environment [37-38]. Furthermore, SAR estimation on the head at 1.575, 2.40 and 5.50GHz frequencies are listed in Table 5. For the estimation of SAR, the values used for radius of skin, bone, and brain are 79.324, 75, and 65mm respectively.

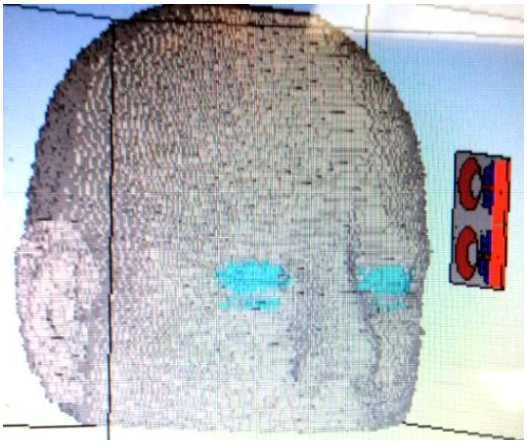

Fig.11. *Calculation of specific absorption rate near the human head in presence of the designed MIMO antenna*

Table 4 Parameters of the human head used for calculation of specific absorption rate by the proposed antenna at constant permeability

Type	Density (ρ) kg/m^3	Thermal Conductivity (σ) S/m	Heat capacity kJ/K/kg	Blood flow W/K/m^3	Metabolism rate W/m^3
Bio-tissue skin	1100	0.293	3.5	9100	1620
Bio-tissue Bone	1850	0.41	1.3	3400	610
Bio-tissue Brain	1030	1.13	3.675	40000	7100

Table 5 SAR values near the human head at the different resonant frequencies when the distance between the human head and MIMO antenna is 15mm

Specific Absorption Rate (W/kg)					
1.575GHz		2.4GHz		5.5GHz	
1(g)	10(g)	1(g)	10(g)	1(g)	10(g)
0.041	0.021	0.048	0.026	0.053	0.032

The calculated value of SAR is less than 1.6W/kg for the proposed antenna as shown in Table 5, for all parameters listed in Table 4. This SAR performance is investigated without any plastic jacket or cover. The SAR of electromagnetic energy is calculated by equation (6)

$$\text{Specific Absorption Rate} = \frac{1}{V}\int \frac{\sigma(r)|E(r)|^2}{\rho(r)} dr \qquad (6)$$

Where σ(r) is thermal conductivity of model in S/m, $E_{rms}(r)$ is rms electric field in V/m, ρ(r) is sample density in kg/m^3, V is the volume of the sample in m^3. SAR is the function of the input power and 100mW power is used for calculation.

4. MIMO Diversity Performance

MIMO diversity performance of the designed antenna is evaluated in terms of Envelope Correlation Coefficient (ECC), Total Active Reflection Co-efficient (TARC), Diversity Gain (DG), Channel capacity loss (CCL). The mutual coupling between two radiators and the amount of correlation between them is calculated by ECC.

It is calculated through S-parameters by equation (7) (a) and this equation is only valid for lossless uniformly distributed power through antennas

$$ECC = \frac{\left|S_{11}^{*}S_{12}+S_{21}^{*}S_{22}\right|^2}{\left(1-|S_{11}|^2+|S_{21}|^2\right)\times\left(1-|S_{22}|^2+|S_{12}|^2\right)} \qquad 7(a)$$

But it provides a hypothetical result which varies from empirical result so, the computation the ECC of the MIMO antenna by equation (7) (b) in terms of radiated fields

$$ECC = \frac{\left|\iint_{4\pi}\left[E_i(\theta,\phi)\times E_j(\theta,\phi)\right]d\Omega\right|^2}{\iint_{4\pi}\left|E_i(\theta,\phi)\right|^2 d\Omega \times \iint_{4\pi}\left|E_j(\theta,\phi)\right|^2 d\Omega} \qquad 7(b)$$

where E_i & E_j are the radiated electric fields vector of the ith and jth elements of the MIMO antenna system.

The ideal value of ECC is zero for uncorrelated MIMO antenna but their acceptable value for practical MIMO antenna is ≤0.5. In Fig.12 (a), the value of ECC of designed MIMO antenna by using S-parameters and radiated fields in super-wideband is observed to be less than 0.005 and 0.03 respectively, excluding the notched-band. Hence, the above results show a pretty low

This article has been accepted for publication in a future issue of this journal, but has not been fully edited.
Content may change prior to final publication in an issue of the journal. To cite the paper please use the doi provided on the Digital Library page.

correlation between the two antennas, which indicates excellent diversity performance.

The diversity gain of the MIMO antenna is calculated approximately by the formula given by $DG = 10 \times \sqrt{(1 - ECC^2)}$ and for satisfactory operation of MIMO antenna, diversity gain should be close to 10dB. The value of diversity gain of the designed super-wideband antenna is 9.99dB apart from the notched band. The ECC and DG with and without EBG structures are varying from 0.0125 to 0.005 and 9.7dB to 9.99dB respectively as depicted in Fig.12 (b). In order to optimize, the channel capacity and multiplexing efficiency of an antenna is a maneuver parameter which is not only account the total antenna efficiency but also the correlation and efficiency imbalance. In addition, multiplexing efficiency (η_{MUX}) is the ratio of the power requirement of an antenna to the reference antenna. The multiplexing efficiency (η_{MUX}) of the designed MIMO antenna is calculated by $\sqrt{(1 - |\rho_c|^2)\eta_1\eta_2}$, where ρ_c is a complex correlation between two side by side antenna i.e. ECC = ρ_c^2 and η_1, η_2 is the total efficiency of the designed MIMO antenna elements. Hence, the total efficiency and multiplexing efficiency are almost identical and its value goes down at the notched band only.

Channel Capacity: Channel capacity parameter of the MIMO, used to evaluate the system performance, is a function of bandwidth and the SNR (signal to noise) ratio, similar to the SISO system. Power is equally feed-in transmitting antenna elements without knowing the channel conditions. The designed 2 element array SWB antenna channel capacity is verified by Ergodic MIMO channel capacity and it is calculated by equation 8. From Fig.13, the minimum and maximum channel capacity of the 2 element array antenna system is 7.5bps/Hz and 11.34bps/Hz respectively at 20dB SNR in a uniform environment.

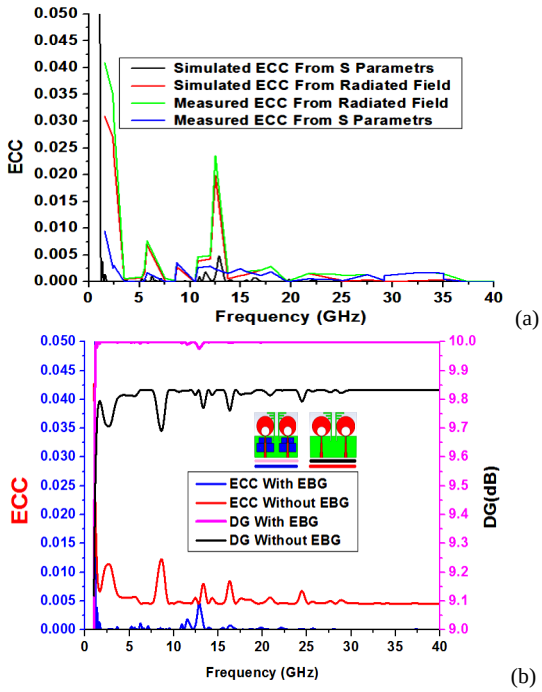

Fig.12. *Diversity performance of proposed SUWB antenna (a) Measured and simulated results of envelope correlation coefficient and diversity gain (b) Simulated results of ECC and DG with and without EBG*

The correlation matrix of MIMO system is R_{xx} (α) = (α) [I] + (1-α) [H][H*], where, 0< α < k / (k-1) and k is the number of antenna elements, For minimum channel Capacity, the value of channel correlation coefficient (α) is zero, therefore, all channels are correlated to each other. Furthermore, the value of α is one for maximum channel capacity, hence all channel has no correlation and fading matrix [H][H*] is converted into an identity matrix. The maximum value of the channel capacity of the 2×2 MIMO antenna system is calculated by the equation 8 (a)

$$C_{2\times2\ MIMO\ Max.} = k\left\{\log_2\left[\det\left([I]+\frac{SNR}{k}[H][H^*]\right)\right]\right\} \qquad (8)$$

= 4 × $\log_2$ (1+50) = **22.68 bits/sec/Hz**

Where, SNR is 20dB for Rayleigh fading environment i.e. SNR = 100. As the permissible limit of channel capacity of the 2×2 MIMO antenna system is 65% of its maximum value [39] (22.68 bits/sec/Hz) = 22.68 ×0.65 = **14.74 bits/sec**/Hz by using Monte Carlo simulation for correlated Rayleigh channel.

The upper level of channel capacity of proposed 2 elements MIMO is calculated by equation (8)

$C_{2\text{-element MIMO}}$ = 2×$\log_2$ (1+50) =11.344bits/sec/Hz

Permissible level of channel capacity is 65% of its maximum value (11.344 bits/sec/Hz) = 11.344 × 0.65 = 7.38 bits/sec/Hz [39]. [I] is the identity matrix, SNR is the ratio of signals of device terminal and distributed channels (independent & identical) with Rayleigh fading environment i.e. SNR = 20dB. k is the number of transmitting antenna elements. [H] is the fading matrix and [H*] is Hermitian transpose of a fading matrix.

Channel capacity of MIMO system is linearly increasing with increasing the number of elements; the element matrix properly characterizes the performance of a MIMO system as it provides the information about the phase and gain characteristic of the transmitting and receiving elements. However, in the presence of the correlation factor in MIMO antennas, the channel capacity losses are also increased. Therefore, the diversity performance of the proposed antenna is affected due to channel capacity losses. It is calculated by the equation (9)

$$CCL\ (dB) = -\log_2[\det(\varphi^c)] \qquad (9)$$

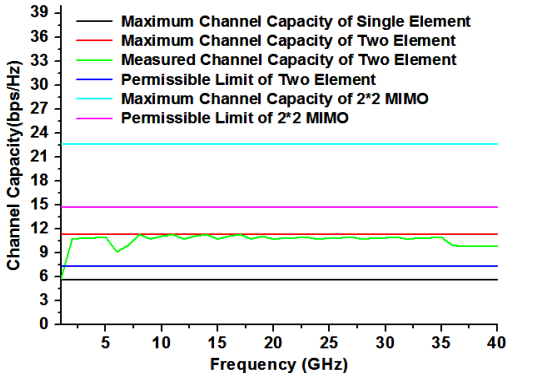

Fig.13. *Comparison of channel capacity of 2 element antennas array with a maximum and permissible limit of a 2×2 MIMO antenna system*

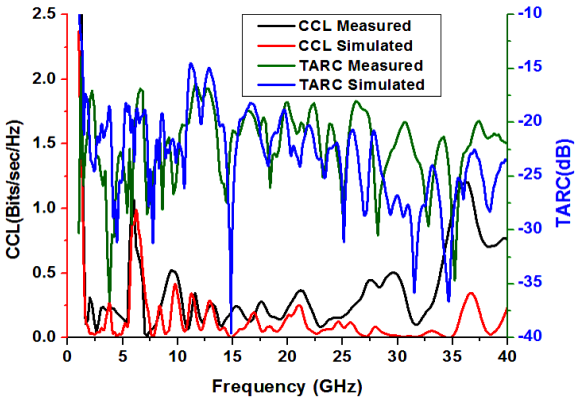

Fig.14. *Simulated and measured results of channel capacity loss (CCL) and total active reflection coefficient (TARC) of proposed MIMO antenna*

Table 6 Simulated MEG results of proposed MIMO antenna at various frequencies

Frequency (GHz)	MEG(dB) Isotropic medium		MEG(dB) Gaussian medium	
	XPR = 1dB	XPR = 6dB	XPR = 1dB	XPR = 6dB
1.575	-3.4	-4.7	-4.2	-6.6
15	-3.1	-3.4	-3.4	-4.5
30	-3.0	-2.5	-4.3	-2.9
39	-3.0	-2.3	-3.8	-2.8

where φ^c is 2×2 S-parameter correlation matrix $\varphi_{ii} = 1 - |S_{ii}|^2 - |S_{ij}|^2$, $\varphi_{ij} = -(S_{ii} \times S_{ij} + S_{ji} \times S_{jj})$. Fig.14 shows the CCLs and it is less than 0.35bps/Hz over the entire bandwidth except for the notched band, which offer a better diversity result of the proposed MIMO antenna.

In the two-port antenna system, contiguous antenna elements impinge on each other when they are working concurrently. This influences the overall desirable gain, efficiency, and bandwidth. Hence, actual MIMO antenna system performance cannot be predicted by s-parameters only, so TARC is also calculated to account for this effect. "TARC is the square root of the ratio of total reflected power to the total incident power" and hence, it gives the information about the apparent return loss of the MIMO antenna system. For side by side two-port radiated antenna system, it can be evaluated by equation (10)

$$\text{TARC} = \sqrt{\frac{(S_{ii}+S_{ij})^2+(S_{jj}+S_{ji})^2}{2}} \quad (10)$$

Ideally, TARC should be less than 0dB for MIMO antenna system. The simulated and measured TARC of the designed MIMO antenna is less than -15dB in the complete super-wideband bandwidth except for the notched band, again it shows the excellent diversity performance of a designed antenna.

Moreover, the mean effective gain (MEG) is the ratio of the mean received power by the i[th] antenna to the mean incident power of the j[th] antenna with the same route, $MEG_i = \varepsilon_{Total}/2$, where ε_{Total} is implying total effective efficiency of the i[th] antenna, *i.e.* $\varepsilon^i_{Total} = \varepsilon^i_{mis} \times \varepsilon^i_{rad}$, and where $\varepsilon^i_{mis} = 1 - \sum_{j=1}^{N}|S_{ij}|^2$, $\varepsilon^i_{rad} = \sum_{j=1}^{N}|S_{ij}|^2$ where, ε^i_{mis}, and ε^i_{rad} are mismatch efficiency and radiation efficiency of i[th] antenna. MEG ratio for the proposed MIMO antenna is extracted by equation (11)

$$MEG_i = \frac{P_{rec}}{P_{inc}} = \iint\left[\frac{XPR \times G_{\theta i}(\Omega)+G_{\phi i}(\Omega)\times P_{\phi}(\Omega)}{1+XPR}\right]d\Omega \quad (11)$$

Where XPR is the cross-polarization ratio and $G_{\theta i}(\Omega)$, $G_{\Phi i}(\Omega)$ & $P_{\Phi}(\Omega)$ is the gain and power density functions of the incident wave, Ω is beam area. The acceptable ratio of mean effective gain of i[th] and j[th] antenna elements should be less than or equal to ±3dB.

The MEG is also represented in isotropic and Gaussian mediums, to investigate the diversity performance at XPR = 1.0dB (outdoor) and 6.0dB (indoor) as shown in Fig. 15 and Table 6. The MEG for the isotropic medium at 1.0dB XPR is varying in the span of -3.4dB to -3.0dB and at 6.0dB XPR is lying between of -4.7 to -2.3dB. Similarly, the MEG for Gaussian medium at 1.0dB XPR and 6.0dB XPR is lying among -3.4dB to -4.2dB, and -6.6 to -2.8dB respectively for entire super-wideband bandwidth. From Fig.15, the MEG ratio of the proposed antenna is found in acceptable limit throughout the super-wideband bandwidth, Hence, it is as well a high-quality channel performance of antenna for wireless communication.

Fig.16 shows the power loss, power accepted, power outgoing to all ports, power radiated and power stimulated of proposed MIMO antenna for SAR calculations. 0.5W stimulated power is used to calculate the diversity performance parameters. Power loss in metal is very less in mW order so most of the power is radiated. Power accepted is almost the same as input power or stimulated power except for notched band because, in that band, maximum power returns back to the same ports. The radiated power is high in super-wideband range except for notch band. The radiated power is always less than stimulated and accepted power because of dielectric, conductor, and surface wave loss in a microstrip line. Power going to all ports is highly interfere at notched-band (5.9-6.9GHz) due to correlation.

It is noted from the Table 7 & 8 that the designed antenna achieves better results in comparison with the referred MIMO antennas at various specifications, which is highly appreciable as the designed antenna is small in size with super-wideband impedance bandwidth. Group delay (ns) is also calculated to verify the time-domain characteristic of the MIMO antenna. The two identical antennas are aligned in front of each other as a receiver and transmitter kept 100cm apart to obtain group delay deviation. It is found to be almost constant in the super-wideband bandwidth excluding notched band.

5. CONCLUSION

In this article, a dual-band circularly polarized two-element MIMO antenna with band-notch characteristic has been proposed for super-wideband applications having -20dB isolation. All simulated results of antenna have been verified with measured results to the entire impedance bandwidth including the notched-band (5.9-7.1GHz) which mitigates the interference from E-S satellite communication. The antenna achieved 7.6dBi peak gain including stable omnidirectional radiation patterns with excellent ECC, less than 0.005. The SAR performance of the antenna is also demonstrated which under the permissible limits and the average channel capacity is 11.34bps/Hz. The performance of the proposed antenna proved that it is a good candidate in various portable wireless applications.

Magnetoelectric composites combining ferromagnetic cobalt ferrite (CFO) and ferroelectric barium titanate (BT) are prepared using conventional solid-state reaction. Dielectric measurements reveal that CFO and CFO-BT composites exhibit Maxwell–Wagner polarization and temperature-dependent relaxation originating due to the presence of ions/defects vacancies. Prominently, CFO-30%BT composite showed an unexpected low dielectric loss ≈ 0.5 above 1 kHz and has potential for device application. Impedance spectroscopy confirms the thermally activated relaxation mechanism and high impedance behavior in the samples. Modulus analysis affirms the statistically distributed non-Debye-type behavior existing in CFO-BT composites. The electric conductivity takes place via correlated barrier hopping in CFO and CFO-10BT composite and overlapping large polaron tunneling in CFO-30BT composite. The addition of BT in CFO initiates the structural modification and results in conductivity cross-over with improved conductivity. These results are useful for exploring devices based on CFO-BT composites.

Key words: Dielectric, impedance, conductivity, modulus

INTRODUCTION

Magnetoelectric (ME) composites are promising candidates for transducers, sensing and phase shifting devices owing to their product property.[1–4] These composites are magnetically polarized on application of an electric field and *vice versa* as they contain both electric and magnetic dipoles.[2] Moreover, ME composites offer an additional degree of coupling arising from mechanical coupling between the electric and magnetic phases.[4] This particular feature has attracted much research attention around the globe. The extent of coupling can be modified by tuning the connectivity and orientations between these phases and thereby rendering ME materials useful for scientific and technological devices.[5]

(Received April 23, 2019; accepted September 28, 2019)

Spinel cobalt ferrite ($CoFe_2O_4$) is a vastly studied material because of its remarkable magnetostriction property, which is promising for application in the field of electronics, electrochemical science and magnetic devices.[6–9] Cobalt ferrite exhibits a physically and chemically stable structure with notable electrical properties making it suitable for electronic and magnetic devices. The magnetism of cobalt ferrite is grain size and temperature dependent.[10] Recently, substantial research has been made to enhance the structure and electrical properties of CFO-based systems. Significant efforts have been dedicated to partially substituting Fe^{3+} ions,[11,12] composites with ferroelectric/piezoelectric materials,[13–15] nanoparticles[16] and core/shell structures.[17] Among these heterostructural systems, CFO-based composites combining the ferromagnetic CFO with ferroelectric phase stand out distinctively because of their outstanding ME coupling. Interestingly, CFO and barium titanate ($BaTiO_3$) are observed to give promising results for

Published online: 21 October 2019

magnetoelectricity in both bulk and nanocomposite systems.[18–20] The incorporation of pervoksite $BaTiO_3$ in spinel CFO is observed to bring structural modification and lattice disorder,[21] which may effect the electrical behavior and impedance properties in CFO-BT composites. Complex impedance spectroscopy (CIS) is a very elegant technique used to understand the electrical behavior by separating the grain impedance from impedances of other sources like grain boundary and electrode interface.[22] This measurement provides information regarding distribution of relaxation processes over a frequency range.

In our previous work, we have reported the structural, ferroelectric, ferromagnetic and enhanced magnetoelectric behavior in CFO-BT composites.[21] The presence of cubic as well as tetragonal structures in CFO-BT composites that display a magnetoelectric coupling coefficient of 22 mV/cm/Oe has been already established.[21] In this work we report the comprehensive investigation on the electrical behavior and conductivity phenomena using impedance spectroscopy of the CFO-BT composites as a function of BT content. In the subsequent sections the experimental methodology, microstructural analysis and electrical properties of CFO-BT composites are presented. This work will aid the understanding of electrical behavior and will be useful in exploring the application of CFO-BT composites in high-frequency applications with suitable tuning for device formation.

EXPERIMENTAL

$CoFe_2O_4$-$BaTiO_3$ (CFO-BT) composites with composition CFO, $CoFe_2O_4$-10%$BaTiO_3$ (CFO-10BT) and $CoFe_2O_4$-30%$BaTiO_3$ (CFO-30%BT) have been prepared from bulk CFO and BT using conventional solid-state reaction and have been labeled as CFO, CFO-10BT and CFO-30BT.[21] Surface morphological studies are carried out using scanning electron microscopy (SEM). The electrical measurements were made using a Nova Control Impedance Analyzer with frequency ranging from 100 Hz to 1 MHz and over temperatures 100–400°C.

RESULTS AND DISCUSSION

Microstructure and Dielectric Studies

Figure 1a, b, and c shows the SEM images of CFO, CFO-10BT and CFO-30BT composites, respectively. The SEM images display a uniform, homogenously dispersed structure with more or less narrow grain size distribution. In addition, some amount of coagulation can be observed in the SEM pictures

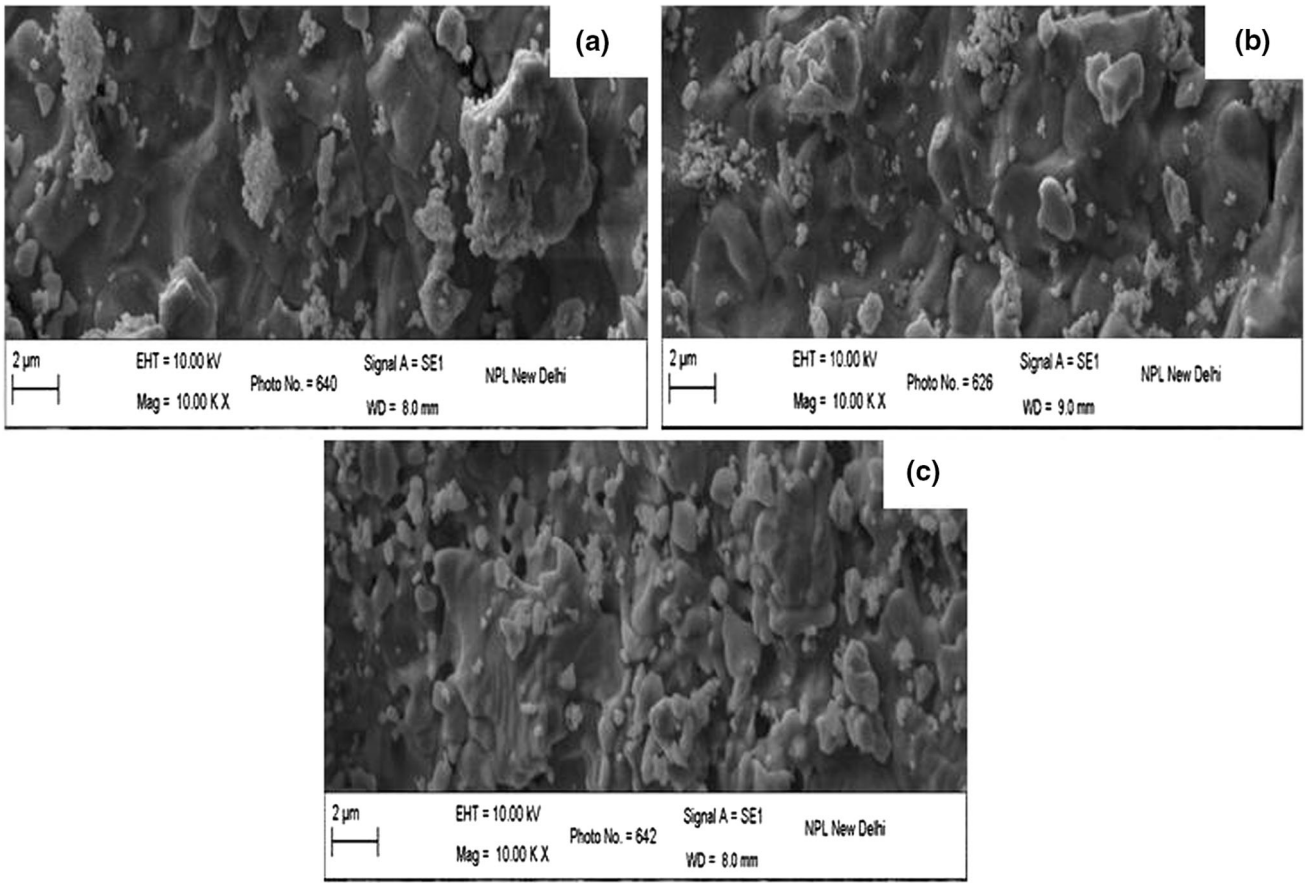

Fig. 1. SEM micrographs of (a) CFO, (b) CFO-10BT, and (c) CFO-30BT composites.

due to strong magnetism in CFO. It can also be observed from the SEM images that all the composites are tightly bound with low porosity and have an average grain size $\approx (5 \pm 1)\ \mu$m.

The variation of dielectric constant (ε') with frequency for CFO, CFO-10BT and CFO-30BT composites at different fixed temperatures is shown in Fig. 2a, b, and c, respectively. The composites of CFO-BT display a decrease in dielectric permittivity with frequency arising from the presence of a conventional dielectric relaxation process and following Maxwell–Wagner polarization. The decrease is mainly because the electric dipoles cannot adjust to the change in frequency of applied electric field.[23] It can be observed from Fig. 2 that the permittivity increases with temperature and BT content in CFO. The dispersion in permittivity in the low and high frequency regions confirms the presence of space charge polarization.[23] The composites of CFO-BT display higher permittivity than pure CFO. The dielectric constant increases from 450 to 700 at 100 Hz for CFO and CFO-30BT composite, respectively. Figure 3a, b, and c displays change of loss (tan δ) with frequency for CFO, CFO-10BT and CFO-30BT composites, respectively. The high dielectric loss in CFO is attributed to hopping of divalent charge carrier Fe^{2+}/Fe^{3+} ions. This prominent feature decides the dielectric parameters in CFO-BT composites despite the strong dielectric nature of BT.[24] It is surprising to find that the dielectric loss decreases prominently from 10 to less than unity for CFO and CFO-30BT composites, respectively. The minimum loss obtained is 0.5 for CFO-30 BT composite at 1000 Hz which remains more or less constant over the experimentally studied frequency range.

Impedance and Modulus Spectroscopy

Complex impedance spectroscopy is a useful technique to understand electrical behavior and electrical relaxation processes by dividing the grain–grain boundary contributions and other sources. The Nyquist Cole–Cole plots of CFO, CFO-10BT and CFO-30BT composites, respectively, are displayed in Fig. 4. All Nyquist plots start from the origin at 100°C suggesting the dominant grain

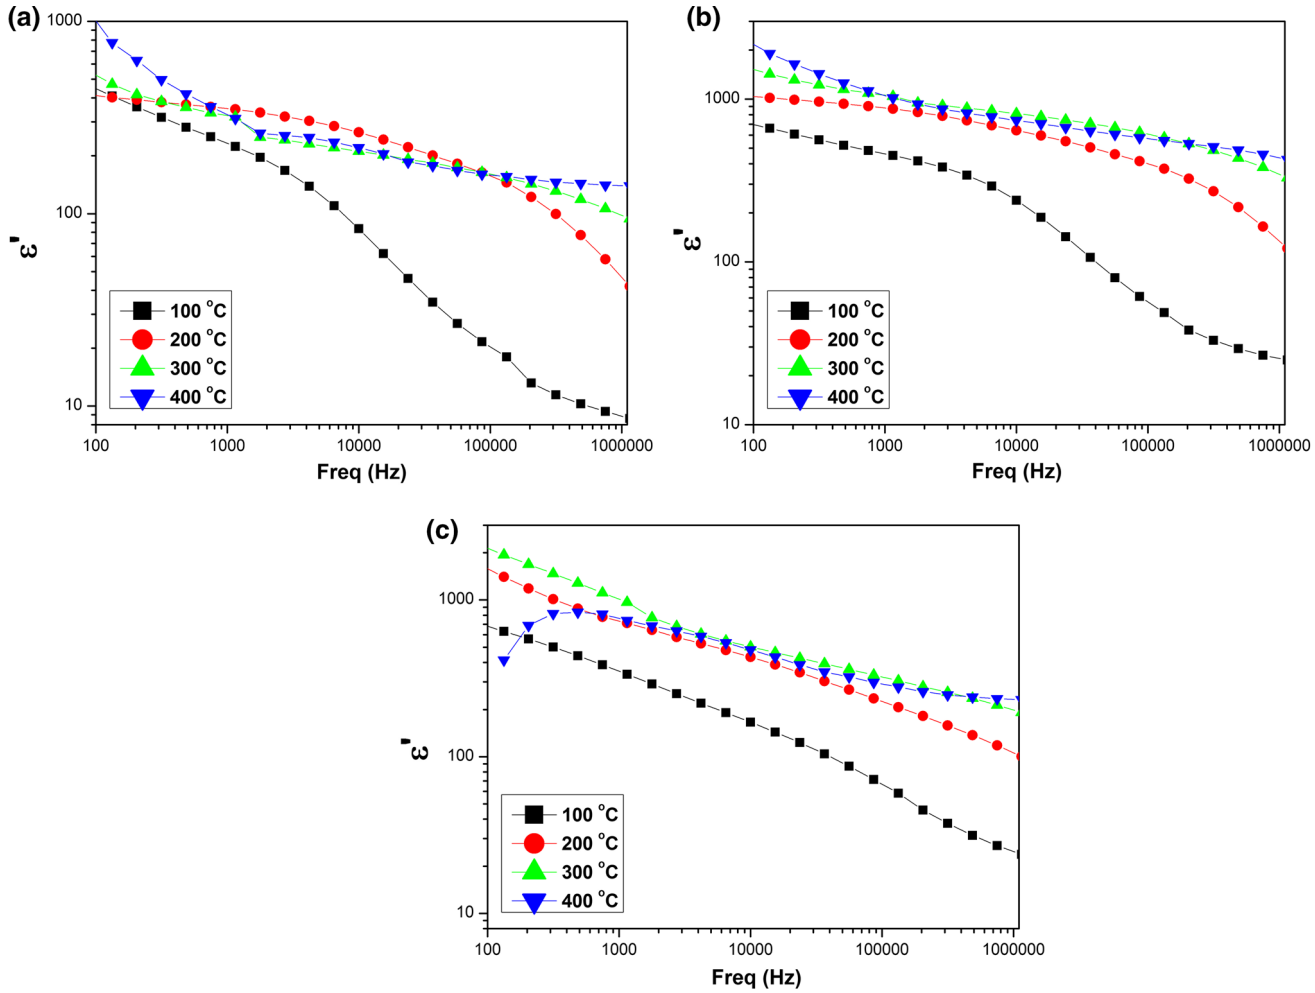

Fig. 2. Frequency dependence of real part of dielectric constant (ε') for (a) CFO, (b) CFO-10BT, and (c) CFO-30BT composites.

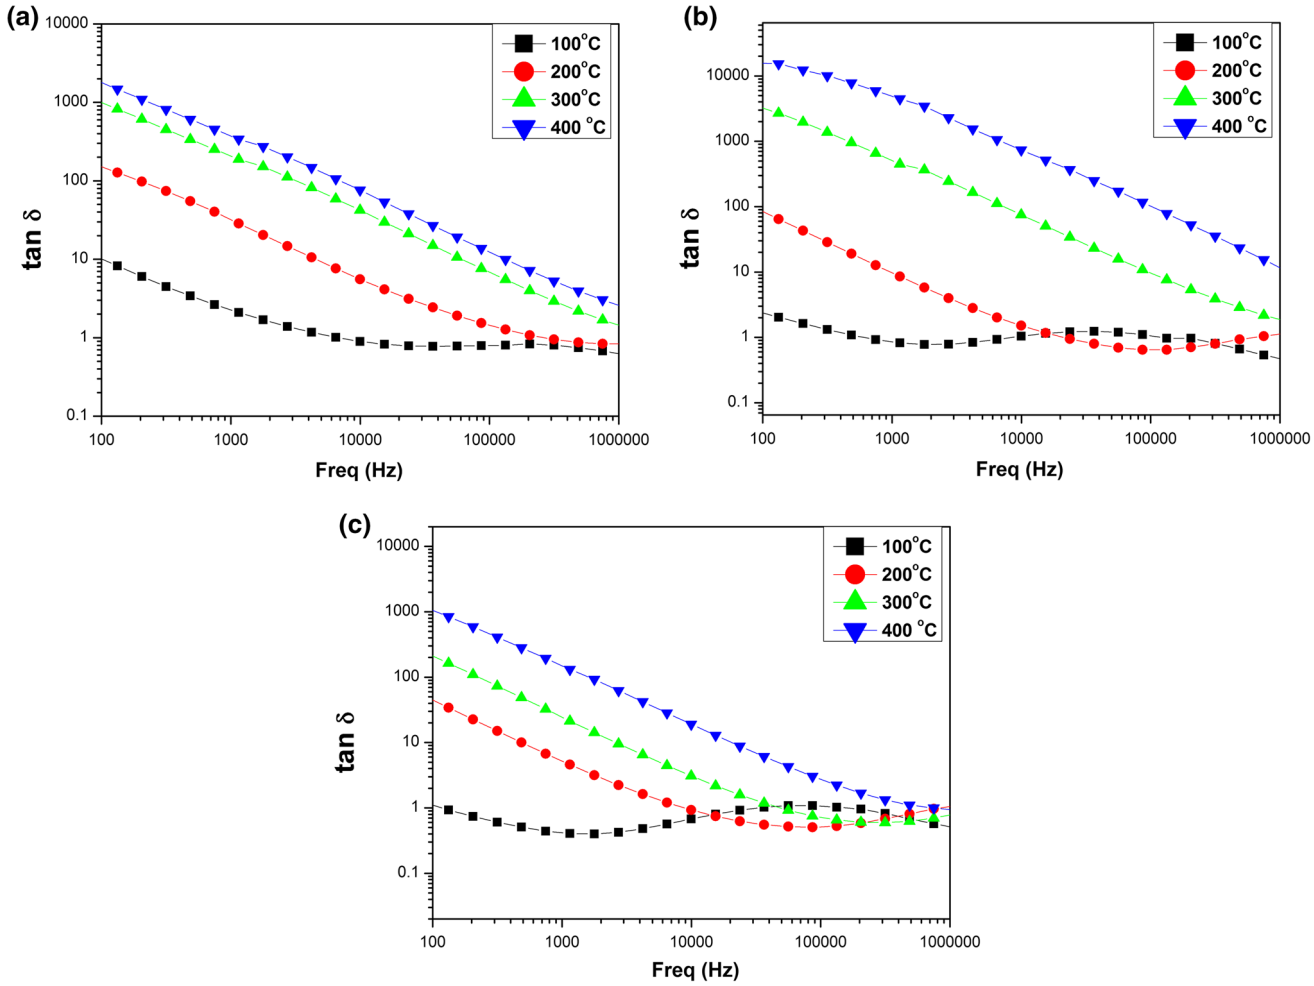

Fig. 3. Frequency dependence of dielectric loss (tan δ) for (a) CFO, (b) CFO-10BT, and (c) CFO-30BT composites.

contributions. The increase in the temperature from 100°C to 200°C sets significant contributions of grains and grain boundaries in all the compositions. As the temperature reaches 400°C, the samples CFO and CFO-BT composites tend to exhibit dominant contributions from the grain boundaries along with a small extension in the low frequency region. The radius of the semicircle increases on addition of BT in CFO up to 10% due to the dielectric nature of BT. However, the CFO-30BT composite displays a relative decrease in the Nyquist semicircle radius as compared to the CFO-10BT composite which could be possibly due to extensive hopping of Fe ions. Furthermore the radius of the semicircles in Nyquist plots decrease invariably with temperature for CFO and CFO-BT composites owing to the presence of statistically distributed relaxation processes.[25,26] The centers of semicircles in Nyquist plots for CFO and CFO-BT composites lie below the Z' axis and suggest a typical non-Debye behavior in CFO-based materials.[22] Moreover, based on the assumption that the semicircle of the Nyquist plot is composed of combinations of RC circuits connected in parallel and using the frequency equation $f = 1/2\pi RC$, the relaxation time (τ) can be estimated as the reciprocal of frequency in the maxima of Nyquist plots.[27]

The non-Debye behavior and grains/grain boundary contributions present in CFO and CFO-BT composites can be assessed by modeling the Nyquist plots as R–C equivalent circuits respectively employing altered brick layer model.[28–30] The equivalent electric circuit may consist of an arrangement of more than one circuit, comprising a resistor and/or CPE and/or capacitor connected in parallel, representing the contributions arising

from the grains, grain boundaries and interfaces. The Nyquist plots of CFO and CFO-BT composites are fitted using Zview software, and two equivalent circuits containing resistance and a constant phase element are found to be suitable in following the plots. Figure 5a, b, c, d, e, f, g, h, and i shows correspondence between the Nyquist plots and fitted data indicated by the black circle and solid red line, respectively, for CFO (Fig. 5a, b, and c), CFO-10BT (Fig. 5d, e, and f) and CFO-30BT (Fig. 5g, h, and i) composites, respectively. The parameters obtained from fitting of Nyquist plots are shown in Table I. The experimental results and fitted graphs as seen in Fig. 5 are in consonance with each other. The occurrence of CPE combinational electric circuit governed by equation $Z_{CPE} = 1/(j\omega)^n$CPE confirms the non-Debye behavior exhibited by CFO and CFO-BT composites.

The change in impedance Z' with frequency for CFO, CFO-10BT and CFO-30BT composites, respectively, at fixed temperatures is shown in Fig. 6a, b, and c. The plots in Fig. 6 show that Z' is large at low frequencies region and decreases continually with frequency for the studied temperature range. It can be observed that Z' coincides at higher temperatures and higher frequencies which is possibly due to space charge release originating because of reduction in hopping potential barrier in CFO and CFO-BT composites. With the increase in BT content and temperature Z' decreases confirming the thermal dependence in dispersion of conductivity existing in CFO-BT composites. This is dominantly attributed to the decrease in resistance of

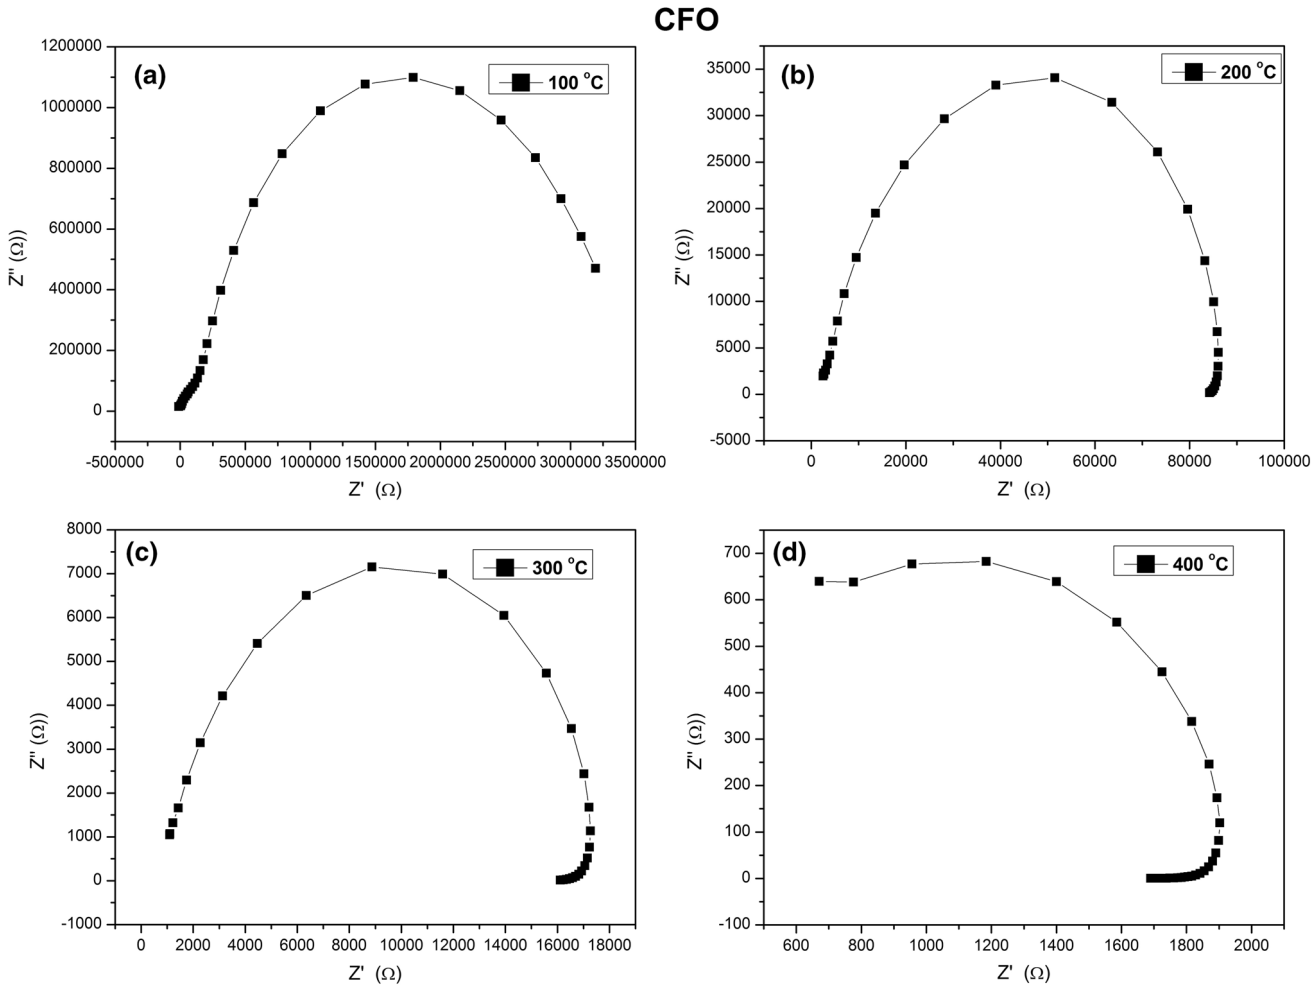

Fig. 4. Nyquist plot of CFO-BT composites measured at different temperatures.

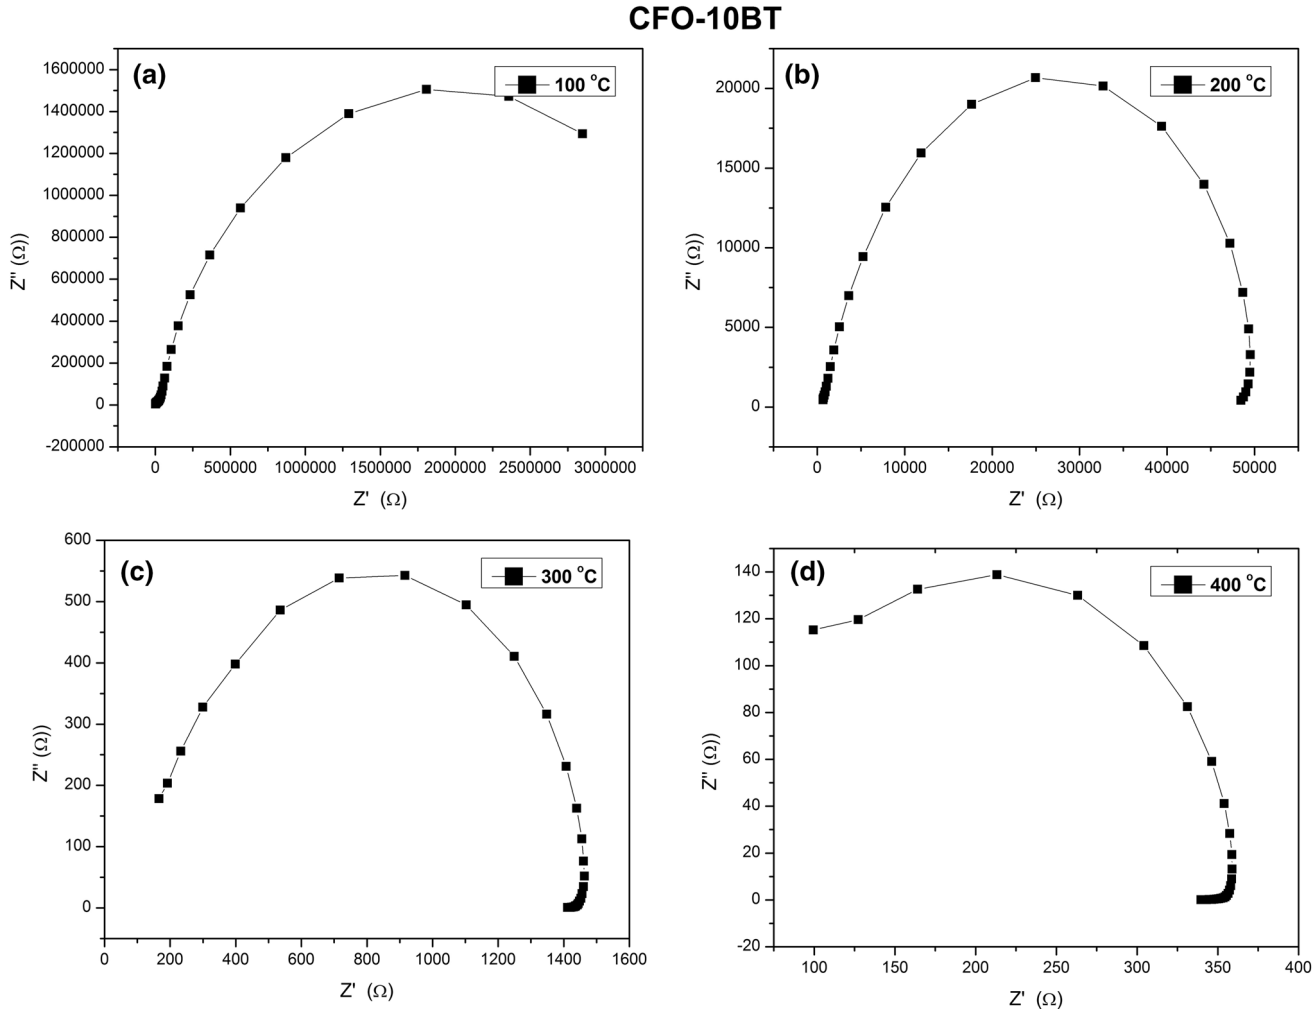

Fig. 4. continued.

grain/grain boundaries.[21,31] Figure 6 also shows the variation in complex part of impedance Z'' with frequency for CFO, CFO-10BT and CFO-30BT composites, respectively. Variation of complex Z'' is essential in examining presence of impedance phase in composites. The graphs of Fig. 6 attain peaks at all measured temperatures for all the compositions. The maxima of Z'' (Z''_{max}) drifts to the high-frequency regime, indicating the existence of thermally activated relaxation processes in CFO and CFO-BT composites arising from thermal agitation of charges present in the grains and at the grain boundaries.[31] The Z'' peaks exhibit thermal decrement with broadening which confirms the thermally activated relaxation mechanism related to the existence of static charges and defects/vacancies at low and high temperatures, respectively.

The electrical response can be analyzed using the modulus spectroscopy analysis. Figure 7a, b, and c depicts the frequency dependency of real part of modulus (M') for CFO, CFO-10BT and CFO-30BT composites, respectively. Figure 7 shows that M' is negligible at low frequencies and becomes saturated at high frequencies owing from the movement of short range charge carriers. As the amount of BT is increased in CFO, a decrease in the saturated value is observed due to the localization of charge carriers. The variation of complex modulus (M'') with

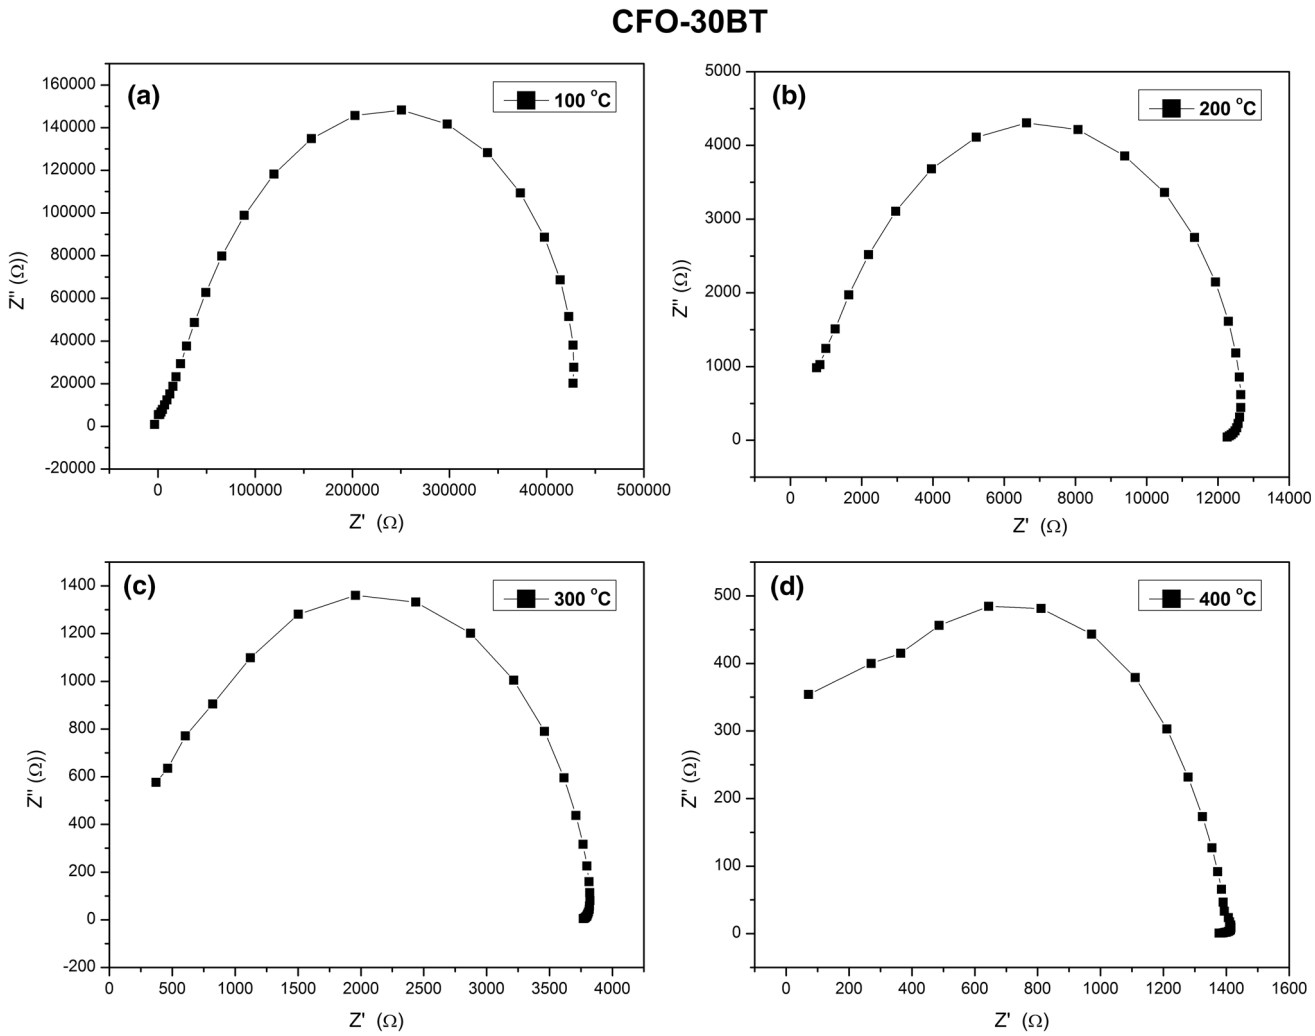

Fig. 4. continued.

frequency is also shown in Fig. 7. It can be seen that all samples display a maxima at 100°C which broadens and shifts to high frequency with the increase in temperature and confirms the presence of temperature-dependent conductivity behavior in CFO and CFO-BT composites. All the peaks are asymmetric in nature owing to the presence of a multi-relaxation process and usual non-Debye nature of CFO based samples.

Electrical Properties

Variation of the real part of conductivity (σ') for CFO, CFO-10BT and CFO-30BT composites, respectively with temperature as well as frequency is shown in Fig. 8a, b, and c. At low frequencies up to 1 kHz, the conductivity spectrum shows negligible variation and is frequency independent. This contribution originates from the dc conductivity and is attributed to the movement of charge around grain boundaries. The data show dispersion at higher frequencies for CFO and CFO- BT composites, suggesting the onset of ac conductivity. This dispersion arises from increased mobility in charges. For temperatures except 100°C, the spectra tend to merge at the high-frequency regime which is indicative of structural disordering. At higher temperatures, the frequency dispersion decreases radically due to dominant dc conductivity part. It can also be observed from the data that conductivity increases with BT content as a result of an increase in the conduction path due to structural distortion in CFO-BT composites.[20] Moreover, all the composites display a thermally activated conduction mechanism.

It can be assumed that whenever the conductivity increases and saturates at high frequencies, then a single particle is hopping around in a double well with infinite barriers.[32,33]

The conductivity behavior in CFO, CFO-10BT and CFO-30BT can be understood by separating the dc and ac conductivity from the real part of conductivity (σ') as:

$$\sigma' = \sigma_{dc} + \sigma_{ac} \tag{1}$$

The thermal variation of σ_{dc}—dc conductivity can be exploited to determine the activation energy (E_a) in CFO and CFO-BT composites and is governed by the Arrhenius equation as

$$\sigma_{dc} = \sigma_o e^{-E_a/k_B T} \tag{2}$$

where the terms σ_o, k_B, T represent usual notations.[12] The thermal dependence of σ_{dc} and its linear fit is represented in Fig. 9. On the studied temperatures separate slope values and activation energies have been obtained for CFO, CFO-10BT and CFO-30BT composites, respectively, and are tabulated in Table II. The activation energies (E_a) obtained are found to be less than one in case of CFO and CFO-BT composites and affirms that thermal activated conductivity is controlled by singly ionized oxygen.[34–36] These oxygen ions/defect vacancies are produced during the synthesis at high temperatures which reduces the Ti^{4+} ions to Ti^{3+} ions following the Kroger–Vink equation of defects:

$$O_o^x \rightarrow \frac{1}{2}O_2 + V_o^{**} + e^- \tag{3}$$

where V_o^{**} is the ionized metal. These defects produced affect the inter-granular impedance.

The ac conductivity term usually follows Jonscher's power law of frequency given by

$$\sigma_{ac} = A\omega^n \tag{4}$$

where A and n vary with temperature. However, for the case of CFO and CFO-BT composites, Jonscher's law alone did not yield a completely positive fit for ac conductivity. To supersede this condition,

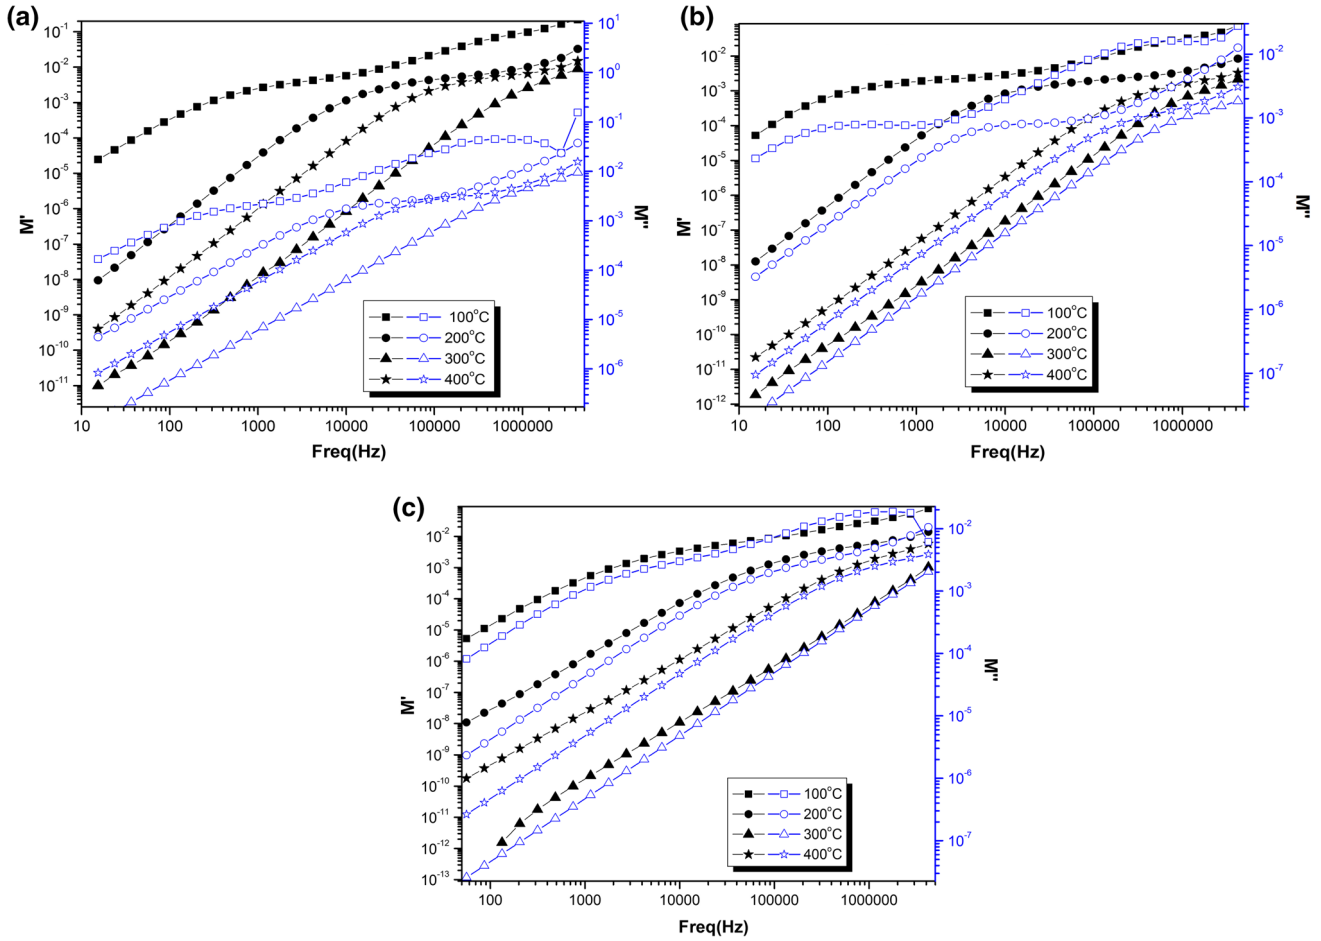

Fig. 7. Variation of M' with respect to frequency of (a) CFO, (b) CFO-10BT, and (c) CFO-30BT composites. Inset shows variation of M'' with respect to frequency of (a) CFO, (b) CFO-10BT, and (c) CFO-30BT composites.

modified Jonscher's law, consisting of multiple relaxations was used:

$$\sigma_{ac} = A\omega_1^{n1} + B\omega_2^{n2} \tag{5}$$

where the constants A, B, $n1$ and $n2$ are temperature dependent. These terms ω_1 (= ω/ω_1) and ω_2 (= ω/ω_2) denote the low and high hopping frequencies. The exponents $n1$ and $n2$ represent restricted ion hopping and two level systems.[37] Modified Jonscher's law yielded a satisfactory fit. The obtained values of $n1$ and $n2$ are plotted in Fig. 10. The conductivity phenomena present in CFO-BT composites can be understood by observing the frequency and temperature dependence of exponents n1. The temperature-independent nature up to ω_1 is due to the diffusive nature of charge carriers in uniform potentials which gets sub-diffusive above and below ω_1 and ω_2. It can be realized that the vacancies accumulated at interfaces become conducting by recovering the oxygen vacancies from interfacial traps. Jonscher's law for conductivity describes that variation in exponent n is used for understanding the type of conduction behavior present in the samples. Usually, there are three types of conductivity phenomena which exist viz., quantum mechanical tunneling (QMT), correlated barrier hopping (CBH) and overlapping large-polaron tunneling (OLPT) depending on exponent n variation. In the case when the value of exponent n is nearly 0.8, remains constant with temperature, and changes with frequency alone, then QMT behavior occurring via barrier localized sites is present. The thermal dependence of exponent n can be explained on the basis of QMT by assuming that the charge carriers form and move by means of

non-overlapping small polaron tunneling (NSPT). As per this theory, n increases with temperature. However, a decreasing variation in exponent n with temperature, implied the CBH conduction existing in the sample. Lastly, whenever the exponent n exhibits frequency as well as thermal variation by obtaining a minima on increasing the temperature and increases thereafter implies an OLPT dominated conduction behavior.[21,38]

It is seen from Fig. 10 that exponent n displays thermally dominated dispersion and confirms the

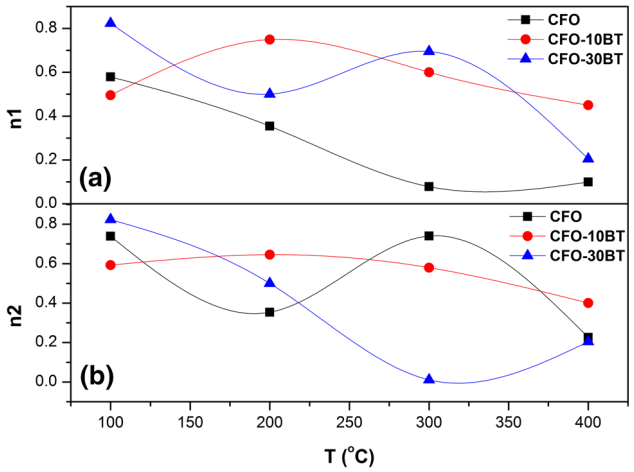

Fig. 10. Variation of exponent *n*1 and *n*2 as a function of temperature for CFO, CFO-10BT, CFO-30BT composites.

existence of two or more different conductivity phenomena in CFO-BT composites. The conduction phenomena for CFO and CFO-10BT composite display the usual CBH of charges between barriers.[39,40] Interestingly, in the case of the CFO-30BT composite, a crossover from CBH to OLPT in the conductivity behavior is observed arising from structural distortion.[41] Most importantly, the values of exponent n are below 1 and confirms the dominant translational motion.

CONCLUSIONS

Ferromagnetic-ferroelectric $CoFe_2O_4$-$BaTiO_3$ (CFO-BT) composites were prepared using conventional solid-state synthesis. SEM images display homogenously dispersed structure with average grain size of $\approx (5 \pm 1)\ \mu$m. The variation of dielectric properties with frequency display Maxwell–Wagner polarization and temperature dependent relaxation phenomena in CFO-BT composites. Electrical conduction studies exhibit a shift in conductivity behavior from CBH to OLPT mechanism from CFO to CFO-30BT composite occurring due to structural disordering. The activation energy obtained from the Arrhenius equation is below unity in CFO-BT composites and confirm presence of singly ionized ions determining conductivity phenomena. The complex impedance spectroscopy and modulus analysis confirm the presence of thermally reliant non-Debye type relaxation mechanism in the CFO-BT system. The current outcomes offer important information for sophisticated examinations in CFO-BT-based composites appropriate for high-frequency devices and other industrial applications.

RELIABILITY PAPER

Improving system reliability by optimal allocation of resources for discovering software vulnerabilities

Abstract

Purpose – The purpose of this paper is to provide a mathematical framework to optimally allocate resources required for the discovery of vulnerabilities pertaining to different severity risk levels.
Design/methodology/approach – Different sets of optimization problems have been formulated and using the concept of dynamic programming approach, sequence of recursive functions has been constructed for the optimal allocation of resources used for discovering vulnerabilities of different severity scores. Mozilla Thunderbird web browser data set has been considered for giving the empirical evaluation by working with vulnerabilities of different severities.
Findings – As per the impact associated with a vulnerability, critical and high severity level are required to be patched promptly, and hence, a larger amount of funds have to be allocated for vulnerability discovery. Nevertheless, a low or medium risk vulnerability might also get exploited and thereby their discovery is also crucial for higher severity vulnerabilities. The current framework provides a diversified allocation of funds as per the requirement of a software manager and also aims at improving the discovery of vulnerability significantly.
Practical implications – The finding of this research may enable software managers to adequately assign resources in managing the discovery of vulnerabilities. It may also help in acknowledging the funds required for various bug bounty programs to cater security reporters based on the potential number of vulnerabilities present in software.
Originality/value – Much of the attention has been focused on the vulnerability discovery modeling and the risk associated with the security flaws. But, as far as the authors' knowledge is concern, there is no such study that incorporates optimal allocation of resources with respect to the vulnerabilities of different severity scores. Hence, the building block of this paper contributes to future research.

Keywords Reliability, Resource allocation, Severity, Dynamic programming, Software vulnerability
Paper type Research paper

Nomenclature

n	number of severity levels pertaining to a software system	N_i	number of vulnerabilities present in the software in the ith severity level ($i = 1, \ldots, n$)
$\Omega_i(X_i(t))$	cumulative number of vulnerabilities discovered using resources in $(0, t]$ in ith severity level	r_i	vulnerability discovery rate ($i = 1, \ldots, n$)

This research did not receive any specific research funding.

DOI 10.1108/IJQRM-07-2019-0246

$x_i(t)$	resource expenditure at time t for ith severity level		(i.e. corresponding to nth stage in dynamic programming algorithm)
X_i, Z	the amount of vulnerability discovery resources to be allocated to the ith severity level	N_{io}	aspiration level of the ith severity level (i.e. number of vulnerabilities desired to be discovered from ith severity level)
T	total time for the discovery process		
X_i^*	optimal value of X_i, $i = 1, \ldots, n$	p_i	the minimum proportion of total vulnerabilities to be discovered from ith severity level
$f_n(Z)$	optimal number of vulnerabilities discovered upto nth severity level		

1. Introduction

Advancement in the secure software system has motivated the software vendors to allocate funds for the discovery and mitigation of vulnerabilities encountered during its operational period. A huge share of vulnerabilities in the wild is reported by end users and based on their severity rating its remedy is provided. Severity also plays an important role in judging a flaw's damage potential. In order to make the system reliable, it is important for the software managers to utilize correct tools and procedures to allocate the resources in order to anticipate all the vulnerabilities present in software. Exploitation of vulnerabilities is not only affecting the vendor but is also a threat for human beings. As the security is criticality linked with a software usage, discovery of vulnerabilities by the security team and the white hat hackers is generally a major concern. Therefore, software managers must allocate appropriate efforts for the discovery of vulnerabilities. The discovery phenomenon is basically carried with the aim of discovering vulnerabilities and it requires empirical illustration. The mathematical linkage between the number of vulnerabilities discovered in a software and the discovery time is regarded as vulnerability discovery models (VDMs) in the literature (Ozment, 2007).

Many researchers have tried to formulate different vulnerability discovery conditions through VDMs. VDMs have been utilized to monitor the security profile of a software, to understand the security trends, deployment of patches and updates. The models are likewise to quantify the vulnerabilities discovery phenomenon in the operational phase. Efforts required in the discovery of vulnerabilities comprise of various factors which can be number of reporters, number of hours worked, usage efforts, etc. To mathematically study the discovery phenomenon of software vulnerabilities, various mathematical models have been proposed in the literature. Researcher considered various discovery patterns by considering different distribution functions such as exponential, Weibull, logistic, hump-shaped, normal and so on (Rescorla, 2005; Alhazmi and Malaiya, 2005; Kapur *et al.*, 2015; Anand and Bhatt, 2016; Anand *et al.*, 2017; Bhatt *et al.*, 2017, 2018; Kaur *et al.*, 2019). The model proposed by Rescorla (2005) is the first and most representative attempt to describe the vulnerability discovery rate. Alhazmi and Malaiya (2005) and Alhazmi *et al.* (2007) discussed that the discovery phenomenon follows s-shaped logistic curve and showed the importance of effort in the discovery of vulnerabilities. Later, Anand and Bhatt (2016) analyzed the vulnerability discovery phenomenon of software showing a hump-shaped vulnerability discovery rate.

It was Alhazmi and Malaiya (2005) who first studied the discovery process using the equivalent effort based on the installed user base in discovering the vulnerabilities more precisely than time alone. Later, Sommestad *et al.* (2012) evaluated the amount of efforts required by a penetration tester in an enterprise-based web application. The VDMs are considered as an interdisciplinary mathematical modeling framework build upon the principles of software reliability growth models (SRGMs) wherein various SRGMs based on testing effort functions have been deduced for the detection of faults underlying in a software (Kapur *et al.*, 2011). Authors such as Ohtera and Yamada (1990) developed an

optimization problem which minimizes the testing resources spent during the testing of modular software. Yamada *et al.* (1995) discussed an optimization problem considering the minimization of resources such that the count of leftover faults present in each module remains equal to the desired level when the resources are constrained. The importance of allocation of resources in understanding the testing and maintaining a software system is shown. Although allocation of resources has been successfully employed to designate faults in software, the usefulness of these methods to indicate vulnerabilities has not been extensively studied yet. Authors such as Berman and Ashrafi (1993) and Khan *et al.* (2008) showed the utility of the dynamic programming approach in the allocation of resources for the software systems. Of late, Anand *et al.* (2019) studied the resource allocation problem for a multi-upgraded software system using this approach.

Numerous studies (Kapur *et al.*, 2010; Cao *et al.*, 2017; Inoue *et al.*, 2017; Wei *et al.*, 2018) showed the importance of allocation of resources in understanding the testing and maintaining a software system. However, few authors associate effective bug bounty policies for the vulnerability discovery. Finifter *et al.* (2013) performed an experimental study to understand the vulnerability rewards programs based on the severity of vulnerability discovered. Zhao *et al.* (2017) developed an economic model that focuses on strategies for enhancing the effectiveness of bug bounty programs. Another study by Maillart *et al.* (2017) uses the notion of Brady *et al.* (1999) by validating the influence of bug bounty programs in the discovery of bugs. As mentioned in a report, the Google Chrome vulnerability program cost around $2.9m in 2017 and has paid incentives to 1,230 individuals based on different severity levels (Keller, 2018). All the aforesaid works have either focused on time-based vulnerability discovery modeling, formulated effort-based modeling or studied regarding the rewards paid to hackers through bug bounty programs. But, as per our knowledge, no previous work describes about optimal allocation of resources for the software vulnerability discovered based on their severity level. This is the first study that explores this ideology.

As per our understanding, it has been assumed that whenever software is released in the market, firms are likely to spend high expected payout for high and critical severity vulnerabilities. Although aiming just a high severity flaw will not only exclude a low or medium severity flaw but also results in an unequal distribution of resources, i.e., many times lower severity flaws are heavily allocated and for the critical severity bugs might remain with a smaller amount of funds for their discovery. Based on the severity level, vulnerabilities can be exploited as a critical/high severe vulnerability may impact the software significantly. It is an important task for a security manager to allocate sufficient funds for the discovery of vulnerabilities corresponding to different severity levels.

Our primary optimization objective is to discover a maximum number of vulnerabilities with different severity levels to be discovered based on the available set of resources. Second, another problem is considered that inculcated advancement in the first problem in terms of least proportion of vulnerabilities sought to be discovered from each severity rating. In doing so, dynamic programming approach is employed (Hadley, 1964). The application of dynamic programming has been utilized for the first time under the concept of vulnerability discovery modeling phenomenon in software. To validate the proposed approach, an empirical evaluation has been performed to show the applicability of resources in the discovery of vulnerabilities.

The major implications of this research are as follows. First, different optimization problems are formulated that will assist software managers in allocating optimal allocations of resources to discover and mitigate the risk pertaining to vulnerabilities of different severity. Another implication can be made from this research is that the technique allows the resources to be allocated in such a way that advocates in discovering a maximum number of vulnerabilities in each severity class.

The rest of the paper is structured as follows. In Section 2, we discuss the mathematical formulation for an effort-based VDM and discuss in detail the proposed

resource allocation problem in discovering vulnerabilities of different severity levels. Section 3 shows an empirical validation of the proposed approach. Finally, we conclude the paper in Section 4.

2. Building blocks for the proposed framework

2.1 Severity levels

A vulnerability discovered in the wild attains different severity levels based on the set of parameters that measures the vulnerability impact and exploitation to software (CVSS/First). As per the CVSS score computed based on different factors defined in FIRST.org, vulnerability is assigned with any of the four different severity ratings as follows: critical, high, medium and low as given in Table I. A vulnerability whose score lies in the critical range can be used by the attackers to run arbitrary code and require no user authorization and have a high likelihood of exploitation. For these types of vulnerabilities, it is advised to provide a patch as soon as possible. A vulnerability having a high-key impact may gather sensitive data and require partial user interaction for the exploitation. A medium severity level requires the attacker to manipulate individual victim via gaining respective privileges for successful exploitation. A low severity level vulnerability has a very little impact on an individual user and requires local or physical access in order to exploit vulnerability.

2.2 Effort-based vulnerability discovery phenomenon

VDMs are time-dependent parametric functions describing the behavior of vulnerability discovery process. The purpose behind the time dependency is that the vulnerabilities can be easily recorded based on their time of discovery. However, this does not inculcate the efforts advocated by a software firm used for the discovery of vulnerabilities in software. A vulnerability model discussed by Alhazmi *et al.* (2007) considered the vulnerability detection rate is proportional to the leftover vulnerabilities with respect to the effort. To mathematically model the discovery phenomenon, following differential equation can be formulated for *i*th severity level:

$$\frac{d\Omega_i(t)}{dt}/x_i(t) = r_i(N_i - \Omega_i(t)), \quad i = 1, \ldots, n. \tag{1}$$

Solving Equation (1) with the initial condition that, at $t = 0$, $X_i(t) = 0$, $\Omega_i(t) = 0$ we get:

$$\Omega_i(t) = N_i\left(1 - e^{-r_i X_i(t)}\right),\ i = 1, \ldots, n. \tag{2}$$

To describe the behavior of effort function, Alhazmi *et al.* (2007) used exponential distribution. In this study, we have also considered the exponential form of discovery resources such that the effort rate is proportional to the available resources. Hence, the mathematical form considering the efforts for *i*th severity level can be stated as follows:

$$\frac{dX_i(t)}{dt} = e_i(\alpha_i - X_i(t)), \tag{3}$$

Table I. Severity rating system

CVSS score range	Severity in advisory
0.1–3.9	Low
4.0–6.9	Medium
7.0–8.9	High
9.0–10	Critical

where e_i corresponds to the rate by which the available resources will be spent in ith severity level and α_i represents the total resources available for ith severity level. Upon solving Equation (3) under the initial condition $X_i(0) = 0$, we get:

$$X_i(t) = \alpha_i\left(1-e^{-e_i t}\right),\ i = 1, \ldots, n. \tag{4}$$

To study the resource allocation for discovering the vulnerabilities above set of equation is utilized for different set of severity levels.

2.3 Resource allocation problem

Software consists of different types of vulnerability having different severity levels. Majority of software firms, such as Mozilla Firefox and Google Chrome web browser, do maintain a Vulnerability Reward Program with the aim to minimize the exploitation likelihood of vulnerabilities by providing adequate incentives to the security community. As mentioned previously, in discovering of vulnerability of different severity levels such as low, medium, high and critical security researchers are awarded with incentives. Hence, in order to maximize the discovery potential of vulnerabilities, firms often schedule resources during the operational period of software.

Enormous amount of funds is spent during the development of software ranging from its initial development to its final deployment. The majority of resources are often consumed during its development phase; however, after release, maintenance has also played an important role in the recent time. The vulnerabilities present in a software are generally discovered after its eventual release. Taking into consideration the fact that a vulnerability belonging to different severity levels can be exploited in the wild. Let us consider a software consisting of vulnerabilities of different severities, which are being discovered independently such that firms wishes to maximize the vulnerabilities discovery, we can state the optimization problem:

$$\left.\begin{aligned} &\text{Max} \sum_{i=1}^{n} \Omega_i \\ &\text{Subject to} \\ &\sum_{i=1}^{n} X_i \leqslant Z,\ X_i \geqslant 0,\ i = 1, \ldots, n \end{aligned}\right\}, \tag{5}$$

where Ω_i is the expected count of vulnerabilities to be discovered of the ith severity level using X_i amount of resources and the Z is the threshold limit of resources available in the operational phase for the discovery.

We can restate the problem (5) by substituting the mean value function as defined in Equation (2) as follows:

$$\left.\begin{aligned} &\text{Max} \sum_{i=1}^{n} \Omega_i(X_i) = \sum_{i=1}^{N} N_i\left(1-e^{-r_i X_i}\right) \\ &\text{Subject to} \\ &\sum_{i=1}^{n} X_i \leqslant Z,\ X_i \geqslant 0,\ i = 1, \ldots, n \end{aligned}\right\}. \tag{6}$$

In order to obtain optimal allocation of resources for discovering vulnerabilities pertaining to different severity levels, we have used the dynamic programming approach by constructing recursive functions. It is an optimization technique that usually simplifies a

decision problem by constructing a sequence of multistage decisions in a recursive fashion. As per Bellman's principle of optimality, we can write the forward recursive functions as follows (Hadley, 1964).

For $i=1$ we have:

$$f_1(Z) = \max_{X_i=Z_1} \{N_1(1-e^{-r_1X_1})\}. \tag{7}$$

And for $i=n$, we have:

$$f_n(Z) = \max_{0 \leqslant X_n \leqslant Z} \{N_n(1-e^{-r_nX_n}) + f_{n-1}(Z-X_n)\};\ \text{for } 2,\ldots,n. \tag{8}$$

Using Equations (7) and (8), allocation of resources can be made to discover vulnerabilities of different severity levels. To calculate the optimal value of resources required in discovering vulnerabilities from each severity level, we make the use of theorem given in the study of Kapur *et al.* (2003) to calculate the values of X_i^*. The allocation of resources is done in a sequential fashion and there might be some instances in which the vulnerabilities index with higher number may not get any allocation due to a lower discovery index (N_ir_i). Even if the allocation of resources is optimal, there might be some cases in which an adequate amount of resources is not allocated to maintain some minimum discovery count of vulnerabilities in each severity level. This may increase the likelihood of any exploitation by the black-hats if the vulnerabilities of any specific severity type are left undetected by the vendor. Therefore, it is expected that a certain proportion of vulnerabilities are desired to be discovered for each severity level. Hence, (6) needs to be reformulated by considering a constraint that will specify a minimum desired level of vulnerabilities to be discovered from each severity level. The resulting problem can be described as follows:

$$\left.\begin{aligned} &\text{Max} \sum_{i=1}^{n} \Omega_i(X_i) = \sum_{i=1}^{n} N_i(1-e^{-r_iX_i}) \\ &\text{Subject to} \\ &\sum_{i=1}^{n} X_i \leqslant Z,\ X_i \geqslant 0,\ i=1,\ldots,n \\ &\Omega_i = N_i(1-e^{-r_iX_i}) \geqslant p_iN_i = N_{i0},\ i=1,\ldots,n \end{aligned}\right\}, \tag{9}$$

where p_i is the least expected proportion of vulnerabilities and N_{i0} denotes a minimum number of vulnerabilities required to be discovered from each severity level. The above problem (9) can be solved either by a method of reducing the dimensionality by using the Lagrange multiplier approach or by considering the substitution process. The prior approach may lead to an increased complexity in finding an optimal solution at each stage and does not provide a closed form solution. Our aim is to alter (9) into a problem that have a comparable structure as of (6) such that an optimal solution can be obtained. For that very reason that add-on constraint in (9) can be altered as follows:

$$\Omega_i(X_i) \geqslant N_{i0} \Rightarrow N_i(1-e^{-r_iX_i}) \geqslant N_{i0}. \tag{10}$$

The above equation can be further simplified as:

$$X_i \geqslant -\frac{1}{r_i} \log\left[1-\frac{N_{i0}}{N_i}\right] = Z_i(\text{say}),\ i=1,\ldots,n. \tag{11}$$

Equation (9) can be further amended by making use of Equation (11) as:

$$\left.\begin{aligned} &\text{Max} \sum_{i=1}^{n} \Omega_i(X_i) = \sum_{i=1}^{n} N_i\left(1-e^{-r_i X_i}\right) \\ &\text{Subject to} \\ &\sum_{i=1}^{n} X_i \leqslant Z,\ X_i \geqslant 0,\ i = 1, \ldots, n \\ &X_i \geqslant Z,\ i = 1, \ldots, n \end{aligned}\right\}. \tag{12}$$

The above problem is again converted into a simpler form by considering $Y_i = X_i - Z_i$; ($i = 1, 2, \ldots, n$). Equation (12) is reduced to (13) as follows:

$$\left.\begin{aligned} &\text{Max} \sum_{i=1}^{n} \Omega_i = \sum_{i=1}^{n} \overline{N_i}\left(1-e^{-r_i Y_i}\right) \\ &\text{Subject to} \\ &\sum_{i=1}^{n} Y_i \leqslant Z - \sum_{i=1}^{n} Z_i = \overline{Z}\,(Let) \\ &Y_i \geqslant 0,\ i = 1, \ldots, n \\ &\overline{N_i} = N_i - N_{i0},\ i = 1, \ldots, n \end{aligned}\right\}, \tag{13}$$

where we let $Z - \sum_{i=1}^{n} Z_i = \overline{Z}$ such that the obtained (13) can be solved using the theorem proposed by Kapur *et al.* (2003) as its structure is similar to (6). To obtain the optimal solution, we have performed an empirical evaluation in the next section.

3. Numerical illustration

In order to determine the optimal allocation of resources numerically, we have considered a case of software application Mozilla Thunderbird web browser (NVD, 2018). The National Vulnerability Database (NVD) consists of a CVSS label to classify vulnerabilities into different severity levels. For simulating the data based on our requirement, we have categorized the CVSS score into six levels in order to have a sufficient count of vulnerabilities in each level. As mentioned in Table I, the CVSS scores are categorized into four severity level based on their CVSS scores. But, in our case the distribution of vulnerabilities is done such that some least number of vulnerabilities lies in each clubbed category so that the estimation of vulnerabilities makes sense. Hence, the vulnerabilities underlying in the following score distribution: 0.1–3.4, 3.5–4.4, 4.5–5.4, 5.5–7.4, 7.5–8.4 and 8.5–10 are clubbed together for a time period of 2003–2008. As per the criticality of vulnerabilities, the resources are often allocated for the discovery of vulnerabilities that have a higher severity score. The vulnerabilities having a lower severity rating may not trigger any severe risk. Hence, the security manager always tries to capture as much vulnerabilities that have a high risk by allocating as much resources to minimize the exploitation risk. Here, we have assumed total resources that are available for the discovery process as $Z = 1{,}000$ (in thousand dollars). To examine the optimum allocation of resources, we first estimated the parameters N_i and r_i for the software Mozilla Thunderbird pertaining to the considered six severity levels which are given in Table II.

Here, we first solve (6) for generating the optimal values of X_i^* for the various severity levels associated with the vulnerabilities by making the use of recursive Equations (7) and (8) and the obtained values are presented in Table II (Schrage, 1999). The table also provides

information related to the expected number of vulnerabilities discovered, percentage of vulnerability discovered and leftover vulnerabilities in each severity level. It can be observed that out of 636 vulnerabilities only 458 vulnerabilities are discovered through this allocation of resources and contributing around 71 percent discovery of vulnerabilities. Moreover, we also find the proportion of vulnerabilities discovered in each clubbed CVSS score and found that only 67 percent of critical vulnerabilities are discovered as per the current allocation. And the remaining 33 percent of vulnerabilities which are left undetected and can be exploited if discovered by a black-hat. In context to the security of software, management will aim to discovery a maximum number of vulnerabilities corresponding to critical and high severity risk. Hence, for the analysis, we consider at least 90 percent of vulnerabilities for the severity level corresponding to 8.5–10 score are required to be discovered and similarly a minimum of 80, 70, 60, 55 and 50 percent of the vulnerabilities to be discovered for the severity level pertaining to the CVSS score of 7.5–8.4, 5.5–7.4, 4.5–5.4, 3.5–4.4 and 0.1–3.4, respectively.

For the allocation of new resources, we solve (9) in that we consider the discovery of some least proportion of vulnerabilities. The results are summarized in Table III. Here, we allocate the remaining resources for the discovery of vulnerabilities leftover after the allocation of resources as per Equation (11).

It is apparent that as per the initial allocation around 458 vulnerabilities were discovered as a whole and were reduced to a count of 419 vulnerabilities. The reduction in the discovery can be attributed due to the capping of vulnerabilities placed as per the associated risk present in each severity level, thus, leading to a decline in overall discovery percentage of vulnerability to 66 percent whereas the initial percentage was close to 72 percent. In addition to this, if the management wants a certain fraction of vulnerabilities to be discovered then additional resources would be required. In order to maintain the tradeoff between the overall discovery percentage, it is required to allocate extra resources in the discovery. In the present case, if the management desires to allocate an extra of 200 (in thousand dollars) then the current case is summarized in Table IV.

Table II. Parameter estimates and initial resource allocation (6)

CVSS score distribution	N_i	r_i	X_i^*	Ω_i^*	% of vulnerabilities discovered	% of vulnerabilities remaining
0–3.4	203.792	0.005	303.153	160.011	78.517	21.483

7.5–8.4	205.408	164.326	456.061	0.000	0.000	456.061	164.326	80.000	20.000
8.5–10	53.219	47.897	184.118	0.000	0.000	184.118	47.897	90.000	10.000
Total	636.145	418.557	993.729	206.271	69.735	1200.000	488.292	76.758	23.242

Table IV.
Allocation after addition of extra resources (13)

From Table IV, we may notice that as a whole about 77 percent of vulnerabilities are discovered and at the same time maintaining the respective percentage of vulnerabilities discovered from each severity level. Hence, as per the above calculations, we can advocate that allocation of resources has a major impact on the discovery of vulnerabilities. Moreover, the decision regarding splitting of resources among different severity levels minimizes the risk of exploitation for a vulnerability belonging to a critical level.

4. Conclusion

This paper considers an important aspect by providing an optimization approach accounting for the allocation of resources in the discovery of vulnerabilities belonging to various severity levels. Here, we have formulated different sets of optimization problems to describe how the resources are allocated in order to attain an aspirational level for vulnerability discovery in each severity level. We consider dynamic programming methodology and utilizing recursive set of conditions to obtain optimal resources that are required to be fulfilled. Allotting more resources often increases the discovery intensity, as a greater number of vulnerabilities are detected. Although firms aim to discovery as many vulnerabilities exist in the software either inhouse or via white hat users but the vulnerabilities having a high severity rating are required to be discover at the earlier and to be allocated sufficient funds.

About the authors

Navneet Bhatt is presently pursuing his PhD Degree from the University of Delhi, Delhi, India. He received his MPhil and Master's Degrees from the Department of Operational Research, University of Delhi, Delhi, India in 2015 and 2013, respectively. His research areas include software reliability, software security and vulnerability assessment through machine learning techniques.

Adarsh Anand did his Doctorate in the area of Innovation Diffusion Modeling in Marketing and Software Reliability Assessment. Presently, he is working as Assistant Professor in the Department of Operational Research, University of Delhi (INDIA). He has been conferred with Young Promising Researcher in the field of Technology Management and Software Reliability by Society for Reliability Engineering, Quality and Operations Management (SREQOM) in 2012. He is a lifetime member of the Society for Reliability Engineering, Quality and Operations Management (SREQOM). He is also on the editorial board of *International Journal of System Assurance and Engineering Management* (Springer). He has Guest edited several Special Issues for Journals of international repute. He has edited two books, namely "System Reliability Management (Solutions and Technologies)" and "Recent Advancements in Software Reliability Assurance" under the banner of Taylor and Francis (CRC Press). He has publications in journals of national and international repute. His research interest includes modeling innovation adoption and successive generations in marketing, software reliability growth modeling and social media analysis. Adarsh Anand is the corresponding author and can be contacted at: adarsh.anand86@gmail.com

Deepti Aggrawal is currently working as Assistant Professor at USME, Delhi Technological University, India. She obtained her PhD Degree from Department of Operational Research, University of Delhi. She was Operations Manager in Axis Bank till she joined as a research scholar in the Department of Operational Research in 2011. Her research areas include marketing and software reliability. She is a life member of SREQOM and has publications in journals of national and international repute.

Abstract *The organizational flexibility finds a substantial place in the literature; however, limited evidence of its institutionalization by managers is noticed. This paper analyzes the managerial paradox toward flexibility in managing business complexity, uncertainty handling, organizational reorientation, and structuring decisions across organizational functions. Thematic analysis is used to investigate the managerial flexibility paradox. The literature is identified in three categories related to workplace, frameworks or concepts, and business environment. It further shows two kinds of orientations: the first one deals with concerns in the implementation of flexibility, and the second showcases the concomitant benefits or performance. The literature related to concerns deals with uncertainty and risk management, while the performance-related literature deals with the augmentation of flexibility theories. The practicing manager seeks advice in the literature to implement the concepts of flexibility and finds its limited availability. This is the prime reason for the emergence of managerial paradox. This paper recommends that future contributions should emphasize the guidelines for flexibility adoption while expounding the flexibility theories. The findings presented in this paper can potentially draw the attention of academicians and practitioners to devise the ways to implement and enhance organizational flexibility.*

Introduction

Managerial flexibility is valued as a strategic asset (Ten-Dam 1987). The importance of managerial flexibility resulted in "Managerial Flexibility Act 2001" introduction in the US senate (Managerial Flexibility Act 2001). This is legislator visualization flexibility that provides freedom to manage and influence the employee's management, retirement, personal property, separation, and retirement provisions. The literature suggests the need for flexibility for organic structure, innovation, planning, and entrepreneurial organizations in the dynamic environment (Eppink 1978; Mintzberg 1980, 1989). Managerial flexibility institutes positive changes in top and bottom line performers (Sullivan 1994).

Two distinct types of contributions are observed on managerial flexibility. The first deals with how managerial flexibility helps the organization performance, and the second deals with how the managerial flexibility is impacted by organizational policies and resources. Flexibility is a capability nurtured systematically over a period of time through various initiatives. The flexibility enhances the organizational efficiency and performance which attracts managerial attention. The convergence of efficiency, agility, systems thinking, strategy, and performance

Published online: 12 October 2019

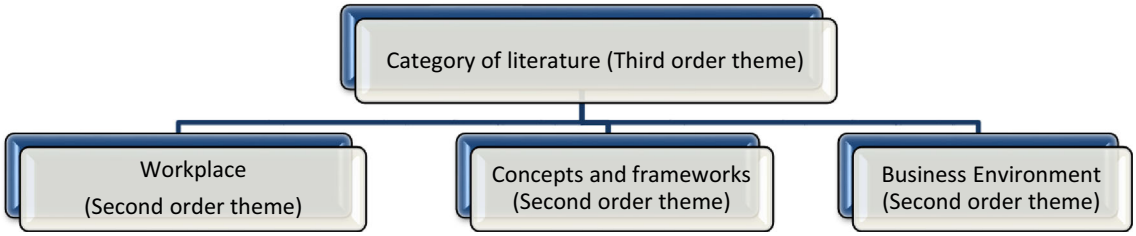

Fig. 1 Organization of the literature

for flexibility is observed (Ebben and Johnson 2005; Nadkarni and Narayanan 2007; Sharma et al. 2010a; Subramanyam et al. 2012; Chowdhury and Jangle 2018; Khorasani 2018; Shukla and Sushil 2018, 2020a, b). The flexible systems focus on core activities, avoid wastage of effort, and institute reconfiguration capabilities enabling organizations to adapt to a new situation for strategic goals (Melnik et al. 2019). The process-based flexibilities result in well-organized manufacturing, productive R&D effort, and financial performance (Narasimhan et al. 2004; White et al. 2005; Sherehiy et al. 2007; Deng et al. 2014). The sustenance and vitality are other predominant upshots of flexibility facilitated by organizational change (Sushil 2012a, b, 2013). The flexibility helps to hedge against the uncertain business environment and build performance (Marschak and Nelson 1962; McKeown 2012). Competitiveness and organizational design endorse viable actions for flexibility (Volberda 1992, 1996, 1997). The supply chain integration, flexibility, and barriers are a special concern of uncertainty management (Chowdhury et al. 2018; Lu et al. 2018). Incorporating flexibility in strategy has been advised by Mintzberg et al. (1995). The literature has also put considerable focus on enablers and inhibitors of flexibility (Chow and Cao 2008; Bottani 2009; Avazpour et al. 2014; Sopelana et al. 2014).

The benefits offered by flexibility stimulate its institutionalization into organizational practices. The limited availability of work practices, guidelines, operating procedures, and strategies for effective implementation of flexibility causes its ignorance leading to paradoxical behavior. Some literary debates show the contradictions and paradox toward flexibility. For example, the "Flowing stream strategy framework" by Sushil (2012a) explains the institutionalization of flexibility by maintaining vital factors of organizational continuity while proceeding for desired change. However, De Leeuw and Volberda (1996) noted the paradox of flexibility results from change and continuity. Few authors suggest flexibility as mediator or driver of performance rather than considering its direct impact on the performance (Sharma et al. 2010; Acharya 2019; Shalender and Yadav 2019). There are few studies related to the paradoxes in the context of risk and inter-organizational collaborations, covert resistance, convergent policy and divergent practice, new product development, cognitive functioning, and high-variety and low-volume manufacturing (Leonard-Barton 1992; Clarke 2002; Couchman and Fulop 2002; Fleming and Spicer 2002; Katic and Agarwal 2018; Ganuthula and Sinha 2019). However, the managerial paradox toward flexibility is largely ignored which this paper addresses. This study has been done in two parts: in the first part, literary gap between practice and theory, intention and execution of flexibility is analyzed, and the second part synthesizes the findings and builds recommendation to handle the managerial paradox of flexibility.

The selection criteria emphasize the theory- and practice-related contributions for managerial action within the boundary of organizational control for building flexibility. Three categories of literature, i.e., workplace, business environment, and concepts and frameworks, have emerged from thematic analysis. These categories capture all the dimension of flexibility relevant to managerial attention and depicted in Fig. 1 and examined further.

The contributions related to performance and concerns of flexibility are specially searched. The performance and concern are used as codes in the thematic analysis. Three types of managerial paradoxes toward flexibility have been identified during analysis.

First Managerial Paradox Toward Flexibility

The first managerial paradox toward flexibility has emerged after analyses of the gap between the literature dealing with the benefits of flexibility and advice to obtain it.

Second Managerial Paradox Toward Flexibility

The second paradox reflects the attitude of lower and higher management toward flexibility. The top management decides the strategy where flexibility finds its place. The lower and middle managerial strategies seek workable advice and have a different perception than top management. The difference is primarily in the approach related to strategic and operational aspects from where this paradox emerges.

Third Managerial Paradox Toward Flexibility

As the flexibility initiatives require resources, the extent and scope of initiatives create a third kind of paradox. The management has to identify relevant flexibility and define optimal flexibility between total flexibility at a much higher cost and rigidity at minimal cost in the absence of literary support to define such optimality (Sushil 2015b).

Methodology

Thematic analysis is used to investigate the managerial paradox. The paradox is identified by finding themes associated with managerial functions. The explicit meaning associated with a given context can be easily identified using this method than other methods such as content analysis (Saldana 2009). Thematic analysis helps to build the perspectives and social construction of representation (Braun and Clarke 2013). The exploration of the benefit of flexibility initiatives in organizations and impediments or concerns in the implementation of these management actions is identified using thematic analysis to build the perspective. Following research questions analyze the managerial paradox toward flexibility using a thematic analysis.

- What are the benefits of flexibility initiatives undertaken by management in the sphere of organizational control?
- What are concerns, hurdles, and mechanisms in implementing flexibility initiatives?

Thematic Analysis

Six stages of thematic analysis have been used to find themes in the literature in qualitative research pertaining to research questions. The approaches demonstrated by Braun and Clarke (2006), Fereday and Muir-Cochrane (2006), and Gibbs (2007) have been used for the identification of the common pattern of managerial interest toward flexibility in different contributions.

Stage 1: Familiarity with the Data

Managerial flexibility strongly relates to planning and execution. The criterion of identifying the relevant literature is defined in light of managerial paradox. The keywords, i.e., flexible, flexibility, agile, agility in title, abstract, and body of papers, are used to search the literature. The flexibility in contexts like integration, agility, cost-effectiveness, responsiveness, quickness, sustainability, speed, leanness, aspects of continuity, change, dynamic capabilities, and organizational control are used to get comprehensive set of literary contributions (Volberda 1997; Qumer and Henderson-Sellers 2008; Sushil 2013; Avazpour et al. 2014; Borland et al. 2016). The literature related to agile methodology is used to identify the management concerns in agility adoption. Further to it, only those contributions are considered which make recommendations within organizational controls. Flexibility evaluation papers are considered if they recommend workable practices. The literature related to the measurement of specific flexibilities is grouped in the performance category since it uses enhancement of independent variables, i.e., organizational effort/investments, to increase the dependent variable, i.e., flexibility performance.

Stage 2: Generating Initial Codes

The "concern" and "performance" are used as the codes (Table 1). The papers in the performance category put less focus on action and elaborate niche flexibility benefit which invites management attention. The performance-related papers also give a broad recommendation for flexibility based on simulation, results, and reviews. The decision to put the literature into concern orientation is made if the recommendation of papers significantly deals with advice validated by example or field data that can be potentially utilized by managers as the guideline to enhance organizational flexibility. These papers also deal

Table 1 Code used for thematic analysis

Code 1	Label	Performance
	Definition	Organizational performance due to flexibility
	Description	1. The context in the literature explicitly or implicitly mentioning situations where flexibility provides organizational performance or benefit
Code 2	Label	Concern
	Definition	Organizational concern in implementing flexibility initiatives
	Description	1. The context in the literature explicitly or implicitly mentioning situations where management deliberates on resource requirement and feasibility of such initiatives. 2. The literary context exploring ways and methods of implementing such initiatives

with flexibility practices that potentially address the management concern and primarily action-oriented.

Stage 3: Searching For Themes

The relationship with codes "concern" and "performance" has been further looked in the context of flexibility for identifying the first-order, clustered, second-order, and third-order themes.

Stage 4: Reviewing Themes

The first-order, clustered, second-order, and third-order themes provide "Focus of literature," "Orientation of literature," "Subcategory of literature," and "Category of literature," respectively.

Stage 5: Defining and Naming Themes

Themes are named and grouped after iterative review and summarized in Figs. 2, 3, and 4.

Stage 6: Production of Report

The subsequent analysis is based on the commonality and discrepancies across themes in all the three categories of the literature.

Results of Thematic Analysis

Thematic analysis has been performed iteratively, and the results are summarized under various themes. The third-order themes represent broad categories of the literature, i.e., workplace, concepts and frameworks, and business environment. The context of flexibility is noted in first-order themes and aggregated in second-order themes, and clustered themes as per descriptions and tabulation of data in this section. The trends of literary work for managers are focused on risk and uncertainty mitigation strategies while substantial work is underway for advancing flexibility concepts. The detailed analysis shows that the gap between practice and theory is more prevalent. The literature in the area of strategy, practice, and operations in flexibility context is identified under "workplace." The literature dealing with concepts, frameworks, relationships, performance analysis of systems in the context of flexibility is incorporated under "concept and framework" category. The context outside organization refers to the volatile "business environment" with the recommendation of managerial action from within the organizations. The comparative distribution of contributions utilized for setting the context of study, analysis, and validation of findings is summarized in the "Appendix".

Third-Order Theme: Workplace

This category of the literature refers to the people and organizational processes to improve performance. The second-order themes are related to business processes, sustainability, strategy, network/supply chain, and actors. Figure 2 provides a summary of observations of workplace flexibility related to all themes.

Second-Order Theme: Business Process

Organizational communication is an important business process. The technological aid in this process results in flexible and adaptable communication across the organization (Moore 2001). Different communication modes in the integrated form are crucial for interactivity and strategic intent (Struweg 2014). Organizational communication is an important factor considered to examine managerial flexibility by Bamel et al. (2013). The impact of information systems (IS) on flexible work plans and business processes finds extensive focus in the literature. Earlier work envisaged the planning for flexibility in manufacturing systems using optimal cost and capacity analysis (Tang 1991). The literature also addressed the challenges in the enablement of flexible work plans using information systems in functional, behavioral, and operational perspectives (Reichert and Weber 2012). The substantial use of information and communication technologies enhances business process flexibility which also impacts business alignment, communication, and collaboration (Steinbring et al. 2013). The reuse of objects and first-time-right design in the information technology industry is emphasized for instituting the flexibility and speeding up the development process (Favaro et al. 1998; Tseng and Lin 2011). For a software product, different scenarios are to be considered to meet the risk and uncertainty in the final usage, and incorporate flexibility (Chastek et al. 2009). In the information technology organizations, the service orientation in design process enables flexible products (Gulledge and Deller 2009).

The relationship of business processes with flexibility is noticed by many authors. The flexibility in business processes handles market dynamics and builds a value proposition in the IT sector (Raghuveer et al. 2014). The innovation performance results from interaction among multiple resources facilitated by coordination flexibility (Li et al. 2017). There exists a strong relationship between knowledge management, agile methodology acceptance, and strategic flexibility that facilitates innovation (Chan and Thong 2009; Kamasak et al. 2016). The vertical

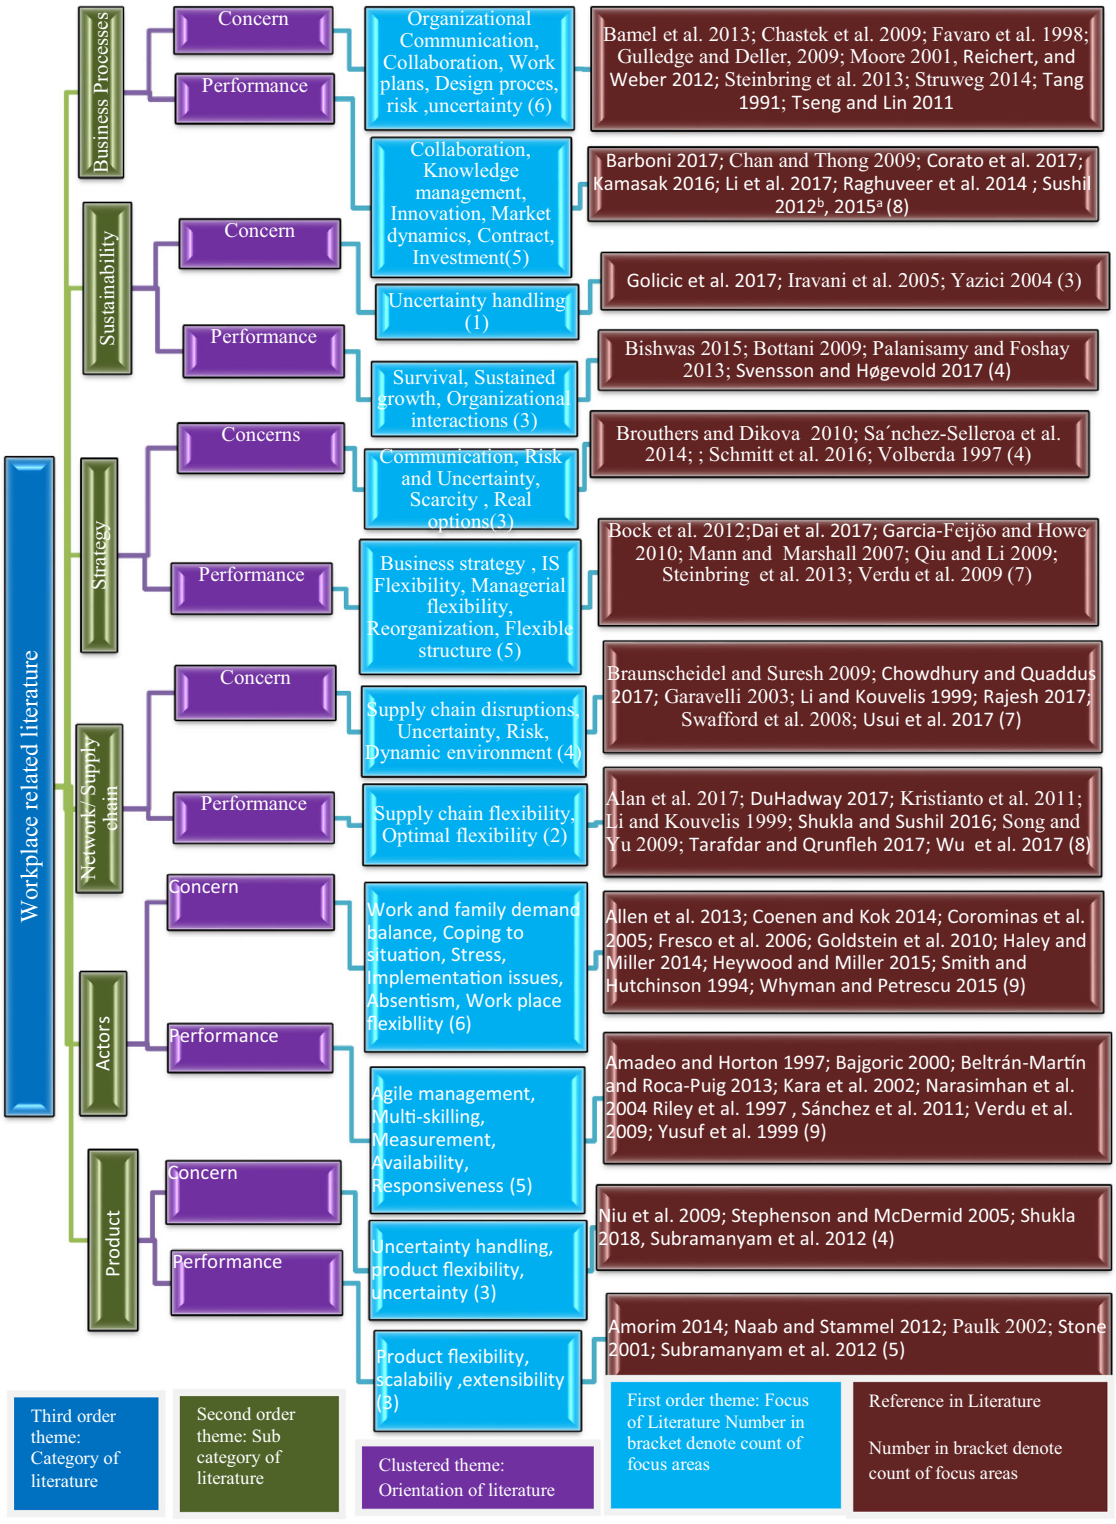

Fig. 2 Summary of the literature for flexibility in the workplace

flexibility enables multiple ways of investment for hedging strategies (Corato et al. 2017). The flexible contract enables the timely decision (Barboni 2017). The flexibilities in business processes, value network, and entire ecosystem impact the organizational performance (Sushil 2012a, 2015a, 2016).

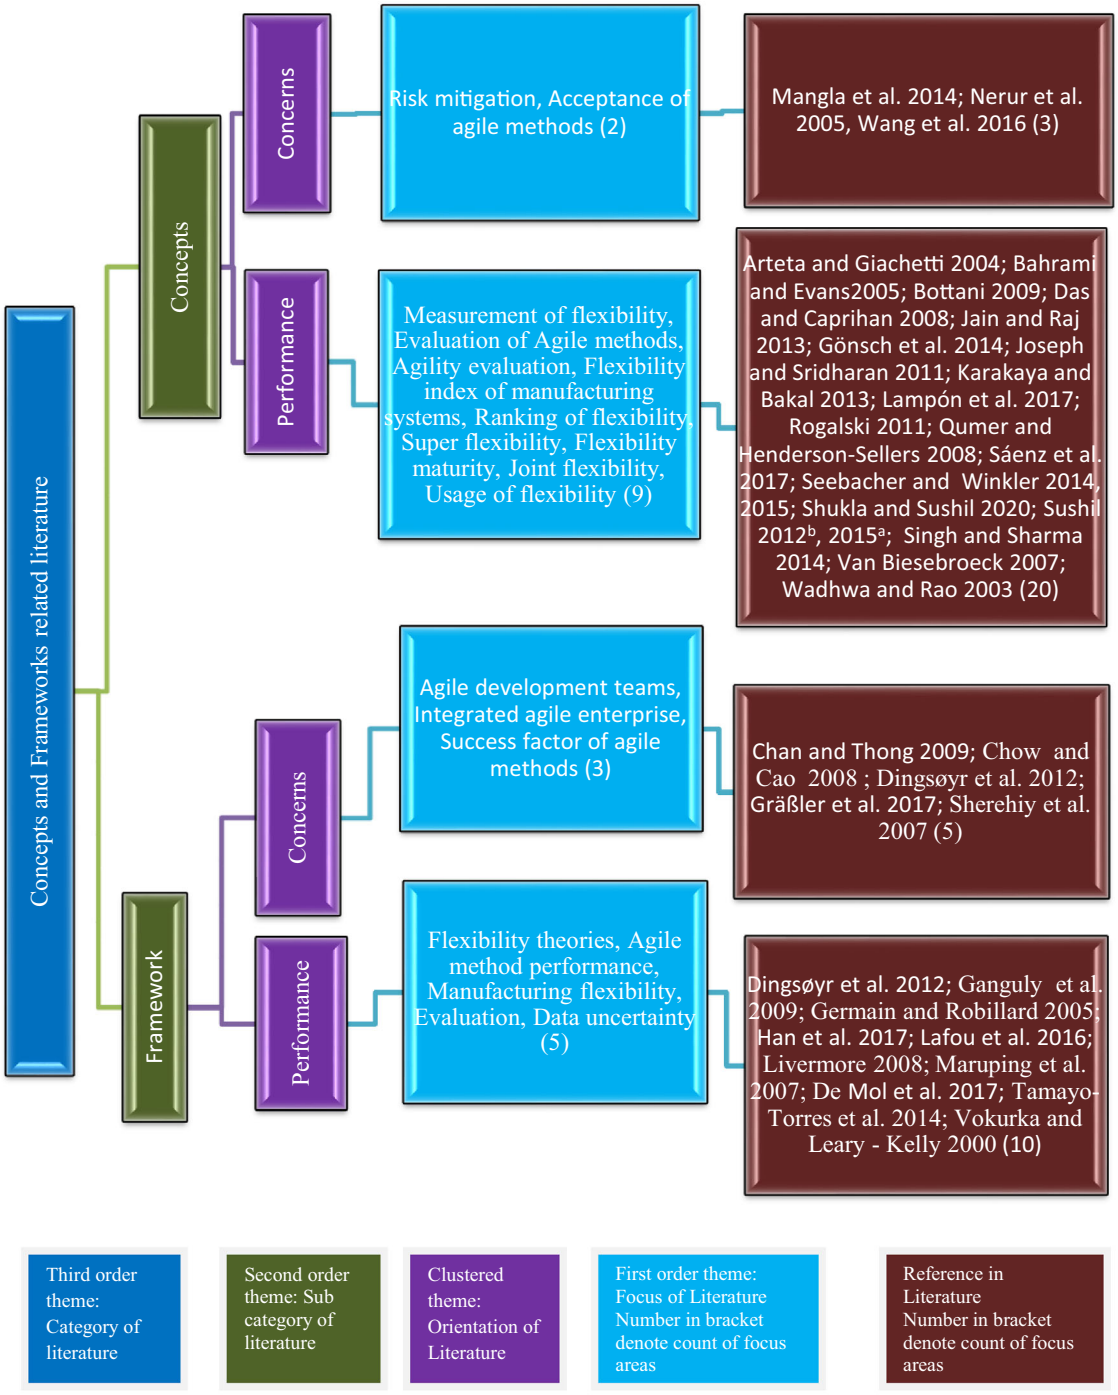

Fig. 3 Summary of the literature for flexibility in framework and concepts

Second-Order Theme: Sustainability

The sustained growth is the long-term objective of flexibility. During the volatility of demand, the sustenance of supplies requires the organization to have volume, mix, routing, and labor flexibilities (Yazici 2005). The proper utilization of capacity and suitable system structure is recommended for cushioning against uncertainty (Iravani et al. 2005). Sustainability through experimentation and resources allocation is advised by Golicic et al. (2017). The flexibility provides strength to an organization in the form of vitality, survival, and growth (Bishwas 2015). The result-oriented interactions among organizational functions facilitate sustained growth. For the flexible enterprise, the

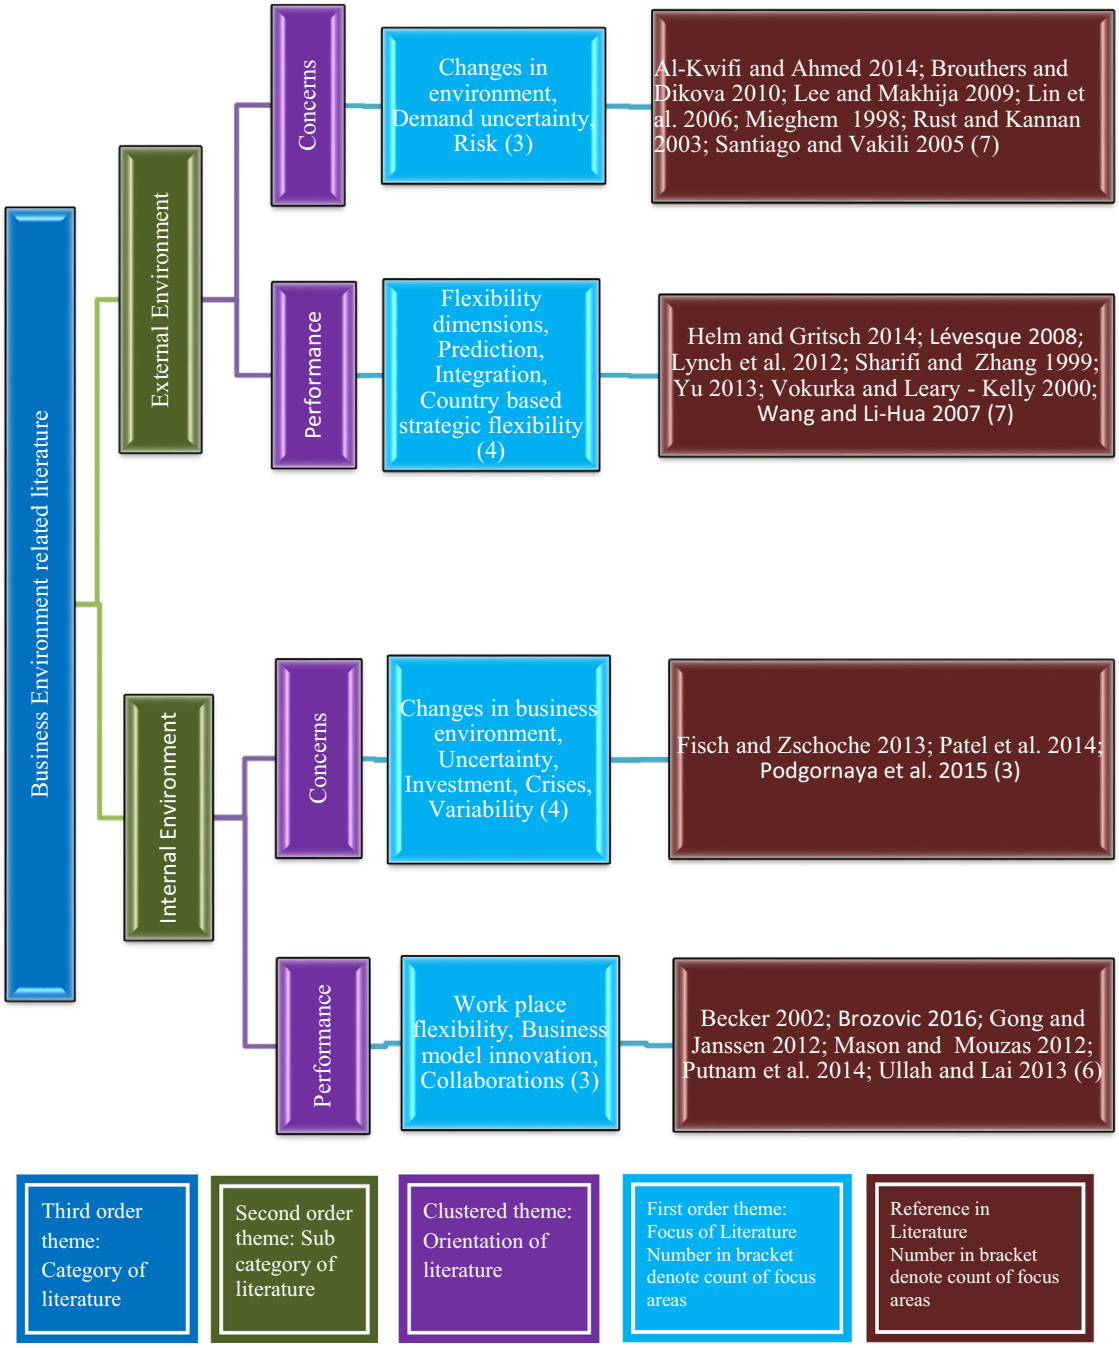

Fig. 4 Summary of the literature for flexibility in a business environment

interdependence of quality parameters, competitive bases, several types of flexibilities, and agility attributes has been noticed (Bottani 2009). Palanisamy and Foshay (2013) noticed that internal flexibility is necessary for information technology infrastructure exploitation. The business sustainability effort evolves over a period of time through adaptation to change (Svensson and Høgevold 2017).

Second-Order Theme: Strategy

The strategy and flexibility are jointly addressed in the literature under strategic flexibility and alignment. The strategic flexibility enhances the ability of the organizations to cope up with the business environment by changing the strategies. The flexible structure emerges from strategic flexibility. The flexible structure is facilitated by

good communication (Sánchez-Sellero et al. 2014). The new product and market combinations are strongly recommended for uncertainty and strategic flexibility (Volberda 1997). The reorganizational capability in resource allocations in the value network is required for showing strategic renewal behavior under scarcity (Schmitt et al. 2016). The investment in real options is required to mitigate the high level of uncertainty for strategic flexibility (Brouthers and Dikova 2010).

The organizational and system structures provide significant support to strategic flexibility. The information system flexibility and visibility positively impact business strategic factors (Qiu and Li 2009). The managerial flexibility is the reasonably good indicator of overall flexibility which top management strives to achieve. The contractual provisions enhance managerial flexibility that benefits the organization (García-Feijóo and Howe 2010). The system structure, formalization, and strategic flexibility are important for uncertainty mitigation (Steinbring et al. 2013). There are encouraging effects of structure and culture on the business model and strategic flexibility (Bock et al. 2012). The flexible organizations show the resource reorganization capability in value network. The benefit of team dynamics and reorganization has been noticed at national level also (Mann and Marshall 2007). Flexible structures are less formal. The organic structure and less formalization are crucial to organizational flexibility (Verdu et al. 2009). The utilization of loosely coupled resources is recommended for strategic flexibility (Dai et al. 2017).

Second-Order Theme: Network/Supply Chain

In the supply chain area, there is ample literature to visualize multiple facets of flexibility. The integration of information systems in supply chain positively impacts flexibility (Swafford et al. 2008). The cultivation of agility for risk management allows a firm to answer rapidly to marketplace variations as well as to anticipate the interruptions in the supply network (Braunscheidel and Suresh 2009). The contract for firms in terms of a number of units without specifying an exact time to purchase provides benefit in the uncertain situation (Li and Kouvelis 1999). The supply chain flexibility is advised in three stages for start-up firms by building relational governance with the suppliers through exercising dynamic economic power concentration, secondly by providing technical support to suppliers, and thirdly by enforcing non-exclusivity arrangements (Usui et al. 2017). The supply chain agility has been advised for competitive advantage through the integration of processes, information, and strategic alliances (Wu et al. 2017). The risk and vulnerability are emerging as a major concern which is mitigated through robustness, resilience, and supplier development (Behzadi et al. 2017; Kurniawan et al. 2017). The resilience can be improved by instituting planning and design capability proactively and reactively (Chowdhury and Quaddus 2017; Rajesh 2017).

The flexibility helps the industry sectors and organizations for business performance. Multiple options in sourcing demand flexibility in network for large industry sector (Shukla and Sushil 2016a, b). There is a positive influence of advance planning on the flexibility of supply chain (Kristianto et al. 2011). The supply network elements consist of logistics, distributor, integration platforms, and sourcing activities. Different supply chain configurations are possible with available suppliers. The same configurations can cost differently for different organizations. The organization may exercise limited, total flexibility or optimal flexibility by including needed supply chain elements (Garavelli 2003). The trust among supply chain partners also plays a significant role in enabling flexibility in the supply chain. There is a positive association between flexibility, trust of distributors, and legitimacy in the supply network (Song and Yu 2009). The supply chain flexibility has a direct and noteworthy impact on strategic and manufacturing flexibilities which affect the firm performance (Alan et al. 2017). The flexibility in the supply network helps to improve the information systems capability (Tarafdar and Qrunfleh 2017). DuHadway et al. (2017) analyzed the source of risk mitigation strategies and supply chain interruptions for recovery of operations.

Second-Order Theme: Actor

The flexibility context in actors includes its enabler and associated benefits. Actor flexibility is the output of many organizational endeavors and integral to managerial flexibility. The main actors for the organization are the workforce along with suppliers, partners, and customers. The work interference with the family has an impact on employees in the form of flexitime, flexiplace, and availability (Allen et al. 2013). On gender equality in management, Smith and Hutchinson (1994) made the observations regarding the participation of women and their concerns for flexibility of accommodation of family demands along with the ongoing job. The human resource policies affect the individual flexibility which further affects other flexibilities of the organization. The coping and explanatory flexibilities affect the depression and anxiety symptoms of employees (Fresco et al. 2006). The flexibility of individuals and stress is impacted by the provision of short leave to the employee which relieves the stress and sleep difficulties (Haley and Miller 2014). The impact of human resource in agile methods finds considerable attention. The ground management strategies for agile execution are

especially encouraged (Goldstein et al. 2010). The workforce flexibility is related to the adaptability to move between different jobs necessitating skill in different domains. For workers, family-oriented practices, flexitime, and job sharing practices result in low absenteeism (Whyman and Petrescu 2015). The family-friendly policies and flexible schedules especially for women employees enhance productivity (Heywood and Miller 2015). Coenen and Kok (2014) noted the importance of flexibility in the workplace resulting in new product development. The concept of annualized hours can effectively be used for operative flexibility and work hours planning (Corominas et al. 2005).

The significance of flexibility in the context of the actor is noted by multiple authors. Sound human resource practices are required for building skill and behavioral flexibility (Beltrán-Martín and Roca-Puig 2013). The other important actors for organizations are suppliers, partners, and customers. Bajgoric (2000) emphasized the efficacy of information sharing among stakeholders for agile management. The participation of outside actors and their responsiveness are required for flexible enterprises (Narasimhan et al. 2004). For flexibility in actors, Verdu et al. (2009) analyzed the measurement of responsiveness by defining the fit between organizational and contextual variables. They identified key elements to determine flexibility; these are time, cost, and intention. The measurement of flexibility is based upon these factors and their derivatives like speed, rapid deployment, cost involved, and defensive or proactive measures for intention. The attributes of agility, i.e., multi-skilling and concurrent execution, are attributed to workforce flexibility (Yusuf et al. 1999). The evaluation of functional flexibility is related to the adaptability of employees to handle different tasks and perform successfully (Riley and Lockwood 1997). The flexible human resource practices promote innovativeness under environmental dynamism (Martínez-Sánchez et al. 2011). The actor's flexibility is primarily envisaged for productivity (Amadeo and Horton 1997). The human flexibility is impacted by external factors resulting from turbulent trading conditions. The human resource practices impact the inter flexibility elements, i.e., organizational structure, technology, and information system (Kara et al. 2002).

Second-Order Theme: Product

The flexibility associated with the product helps the organization to cater for different kinds of markets and customers. The software products are evolving at a fast pace as compared with other sectors. The requirement aiding the product flexibility can be extracted by deriving indicators of customer uncertainty (Stephenson and McDermid 2005). Product flexibility helps common architecture exploitation to generate multiple products (Shukla 2018). The requirement of variety of users enhances the product flexibility and handles the uncertainty (Niu et al. 2009). The granularity of software promotes efficiency and flexibility (Subramanyam et al. 2012). The flexibility in products can be defined and measured using a mathematical framework by utilizing the parameters like extensiveness and scalability which enhances the functional flexibility (Stone 2001). The product flexibility measures extensibility and scalability that further impacts the business issues in ecosystem (Amorim et al. 2014). The flexibility-aware plans with real-time feedback provide faster improvement opportunities (Naab and Stammel 2012). The technical design parameter also improves the agility (Paulk 2002).

Third-Order Theme: Concepts and Frameworks of Flexibility

The large chunk of the literature is devoted to flexibility concepts and frameworks. It is categorized into two second-order themes and summarized in Fig. 3. The second-order theme, i.e., concept, enhances flexibility theories. Another second-order theme, i.e., framework, deals with strategic advice and operational strategies to enhance agility and overcome hurdles in organizational adoption. The clustered themes deal with performance and concerns.

Second-Order Theme: Concepts

The theories explore the relationship between organizational performance parameters and motives of flexibility. The conceptual papers explore the origin of organizational flexibility. The concern in conceptual papers points to need for an operational method for enhancing flexibility. Mangla et al. (2014) noticed that a flexible framework is required for risk mitigation strategy in the supply chain. The limited bureaucracy and formalism along with organization cultures are conducive to innovation and required agile methodology acceptance in IT organizations (Nerur et al. 2005). The flexibility analysis of process operation and supply chain requires a mechanism to measure several types of flexibilities at a conceptual level (Wang et al. 2016).

The application of agile concepts in the organization enables responsiveness; however, the cost implication for such initiatives is also noticed (Van Biesebroeck 2007). The choice of agile methods among available options for organizations shall be properly evaluated using criteria and tools for adoption (Qumer and Henderson-Sellers 2008). There are mechanisms to evaluate the agility in the organization (Arteta and Giachetti 2004). The measurement of specific flexibilities also finds a reasonable place in the

literature. Das and Caprihan (2008) formulated a mechanism to evaluate manufacturing flexibility by quantifying underlying factors and proposed flexibility index of manufacturing systems. A generic mechanism to evaluate the organization-wide flexibility is also feasible in different maturity levels (Shukla and Sushil 2020a, b). The comprehensive framework of evaluation and measurement of select flexibility for the production system is provided by Rogalski (2011). Singh and Sharma (2014) identified the flexibility factors and used them for developing a framework to measure supply chain flexibility.

The benefit of flexibility initiatives, their combined impact, and interrelationship are conceptualized by authors. Al-Kwifi and Ahmed (2014) described the simulation scenario for the impact of a pallet, and routing flexibilities and their combined impact in the production environment. The concept is enhanced to accommodate the interactions of various types of flexibilities and other organizational functions. The quality parameters, competitive bases, agile attributes, and enablers show mutual interdependence (Bottani 2009). The concept of joint flexibility of the product is elaborated by Karakaya and Bakal (2013) for sourcing of components. Joseph and Sridharan (2011) examined the impact of sequencing and routing flexibilities, and sequencing rules on manufacturing systems and concluded significant relationship among them. The prioritization of initiatives is natural phenomena where cost is expected to be incurred. It has been noticed that program flexibility ranks the highest and production flexibility ranks the lowest in flexible manufacturing system (Jain and Raj 2013).

The flexibility maturity model further enhances concepts. It categorizes organizational flexibility into maturity levels for comprehensive analysis (Wadhwa and Rao 2003; Sushil 2012a, 2015a). The more intense concept of super-flexible organization has been put forward to mitigate any kind of uncertainty by changing the business model of organizations within a very short time (Bahrami and Evans 2005). The contingency view of flexibility analyzes the upstream and downstream relationship with suppliers and customers (Sáenz et al. 2017). The flexibility relates to an observable aspect of organizational indicators of performance. The lead time, cost deviations in process chain, efficiency, and performance have been utilized to measure the dyadic supply chain and manufacturing flexibilities (Seebacher and Winkler 2014, 2015). Gönsch et al. (2014) advised usage of product flexibility for revenue management using the deterministic linear program. The relocation theories about operational flexibility and decision making have been given by Lampón et al. (2017).

Second-Order Theme: Framework

The framework-oriented literature relates to the application and acceptance of agile methods. It also addresses the managerial concern in agile method adoption along with advice to management. Dingsøyr et al. (2012) studied the performance of various agile methodologies in a decade starting in the year 2000 that are mainly related to concerns and acceptance of different agile methods. Information technology and manufacturing organizations emphasize on agile methodologies. The issues related to acceptance of agile methods for software development is a special concern in the literature (Chan and Thong 2009). The integrated view of agile enterprise has been the major concern due to multiple agile methodologies and characteristics of organizations (Sherehiy et al. 2007). A large chunk of the literature identifies the success factors of agile methodology. It covers the wide range of performance factors that include quality, scope, time, engineering techniques, cost impacting delivery strategy, project management process, team capability, customer involvement, and team environment (Chow and Cao 2008). The decoupling of production system environment with products characteristics leads to flexibility in entire systems (Gräßler et al. 2017).

The agile methods are further enhanced to manage uncertainty, risk, and performance. Managing the changing user requirements using controls in agile methods, building effective capability, and technology exploration for manufacturing flexibility have been addressed in the literature (Vokurka and Leary Kelly 2000; Maruping et al. 2009; Tamayo-Torres et al. 2014). All the flavors of agile methods cause the organizations to focus on core and productive work and enhance the organizational size (Germain and Robillard 2005, Livermore 2008). These benefits can potentially attract higher management attention. The flexible way of delivery and investments leads to cost-effectiveness, increased market share, responsiveness, better products, flexible interface, and good relationship (Ganguly et al. 2009, Lafou et al. 2016). The frameworks are extended to identify the flexibility aspects emerging due to uncertain and probabilistic data for extracting the information for decision making (De Mol et al. 2017). The theoretical model also includes operational, strategic, and transactional IT flexibility in the supply chain (Han et al. 2017).

Third-Order Theme: Business Environment

The business model innovation is the result of careful scanning of the environment. The organizations often do investments in other countries, which is influenced by organizational strategy in a given business environment. Some literary contributions suggest the use of crises management methods in the highly turbulent environment. The collaborations, use of network, and entrepreneurship are an important part of crises management endeavor. Collaboration and integration are compulsory for

predictable and effective strategy under uncertainty. The second-order themes related to the business environment are categorized into the internal and external environment impacting organizational strategy and flexibility together. Figure 4 summarizes all the themes pertaining to the business environment.

Second-Order Theme: External Environment

The investments are required to institute flexibility and hedge against uncertainty (Mieghem 1998). The strategic flexibility is associated with the acquisition of real option under demand uncertainty (Brouthers and Dikova 2010). The investment in R&D projects provides increased payoff and value under uncertainty (Santiago and Vakili 2005). The e-service is emphasized to stay competitive in the turbulent business environment (Rust and Kannan 2003). The organizational resources and decision making mandate the integration process to be very effective for incorporating flexibility in the strategy process. Lin et al. (2006) recommended a collaborative relationship as a strategy for the agile enterprise. There are case studies on global brands for being successful in crises (Al-Kwifi and Ahmed 2014). The investment to enhance the agility is especially noted in the literature. The foreign and export investments have an optimistic impact on organization flexibility and help in economic crises (Lee and Makhija 2009).

The business environment impacts the organizational processes for flexibility assimilation. There is a significant relationship between the external environment and flexibility (Yu 2013). The agile manufacturing recommends management of change in the business environment for a strategic response (Sharifi and Zhang 1999). There is a strong association among manufacturing flexibility with strategy, organizational structure, environmental uncertainty, and technology development (Vokurka and Leary Kelly 2000). The business aspects indicated by markets and products have a strong association in steady and unstipulated business environment (Lynch et al. 2012). The international entrepreneurship provides better ways to deal with uncertain environment than the use of networks (Helm and Gritsch 2014). The country-specific measures of strategic flexibility in an auto part industry in China are discussed by authors (Wang and Li-Hua 2007; Lévesque 2008).

Second-Order Theme: Internal Environment

The internal environment-related literature deals with options available to management that impacts the organization in whole or in parts. Risk management, uncertainty mitigation, prediction, and effective entrepreneurship are important for organizational flexibility. Podgornaya et al. (2015) studied the flexibility with a choice of business models and recommended strategies for risk reduction. Under increasing erraticism, entrepreneurship provides better performance (Patel et al. 2015). The organizations can predict the establishment of a new site based upon the net present value, growth option value, operational flexibility, and value of the existing production network (Fisch and Zschoche 2012).

There is a positive impact of initiatives for flexibility on factors like workplace planning and design (Becker 2002), workplace flexibility initiatives (Putnam et al. 2014), business model innovation (Mason and Mouzas 2012), organization's resources (Gong and Janssen 2012), etc. The utilization of information systems for the changed business scenario is highly recommended (Ullah and Lai 2013). Brozovic (2016) analyzed strategic flexibility in the context of uncertainty through a literature review and given a conceptual framework and means of evaluation.

Interpretive Synthesis

The concern and performance of all three categories of the literature have been analyzed, and common focus areas are noted. The process and issues in the implementation of flexibility initiatives denote the concerns and benefits due to flexibility initiatives which denote the performance. The concepts and framework-related papers are dominated by agile methodology. In the business environment category, it is observed that concerns are mostly related to uncertainty, crises, and risk management in first-order themes, i.e., focus of the literature. The mitigation of risk, uncertainty, and overcoming of hurdles in the adoption of the agile methodology are primarily being dealt with concerns in "concepts and frameworks." In the workplace category and concern-related literature, a large chunk is devoted to handling uncertainty, stress, risk, supply chain disruption, and organizational communication using flexibility. The common concerns are uncertainty and risk mitigation in "business environment," "concepts and framework," and "workplace" categories. Figure 5 represents the views emerged from an analysis of concern-related contributions.

The performance-related literature of business environment encompasses the flexibility aspects of business model innovation, integration, and collaboration. The success factors of agile methodology acceptance, performance, expansion of framework, evaluation, and raking of flexibility are dealt in the performance category of "concepts and frameworks." The inclusive performance of the organizational function, collaboration, design process, knowledge management, reorganization, flexible strategies, managerial flexibility, supply chain flexibility, agile methodology, multi-skilling, and measurement of

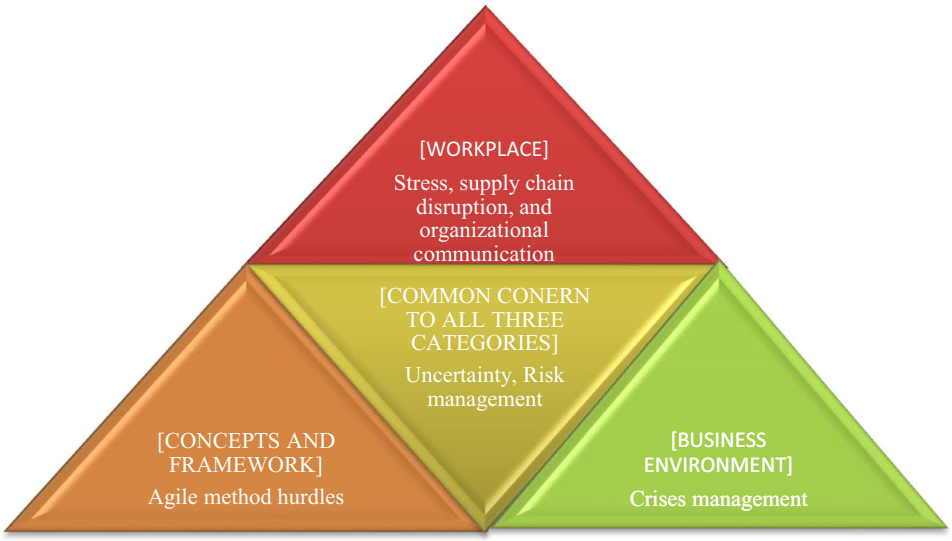

Fig. 5 Consolidation of the literature pertaining to concerns for all three categories

flexibility find a place in workplace-related literature. The enhancement of flexibility theories, measurement, and ranking is common to all three categories of the literature in performance orientation. Figure 6 offers consolidated view of common performance under all three categories.

The commonality and differences are also analyzed quantitatively. The number of contributions and context in different order themes is visually depicted in Fig. 7. The inferences are made for validating the flexibility paradox.

Discussion on Managerial Paradox

The managerial flexibility touches all spheres of operations and strategy and theoretical and practical knowledge base. These are comprehensively captured under various first-order themes. The first-order theme in category "Workplace" is organizational communication, collaboration, work plans, design process, knowledge management, innovation, market dynamics, contract, investment, survival, sustained growth, organizational interactions, communication, risk, scarcity, business strategy, information systems (IS) flexibility, managerial flexibility, reorganization, flexible structure, supply chain disruptions, risk, dynamic environment, supply chain flexibility, optimal flexibility, work and family demand balance, coping with situation, stress, implementation issues, absenteeism, workplace flexibility, agile management, multi-skilling, measurement, availability, responsiveness, uncertainty handling, product flexibility, scalability, and extensibility. Clustered themes pertain to performance and concerns. The

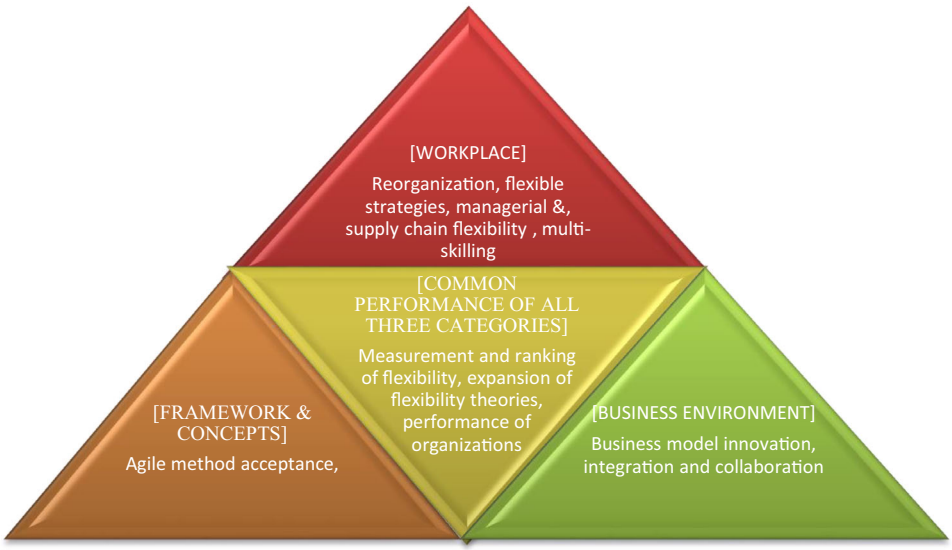

Fig. 6 Consolidation of the literature pertaining to performance for all three categories

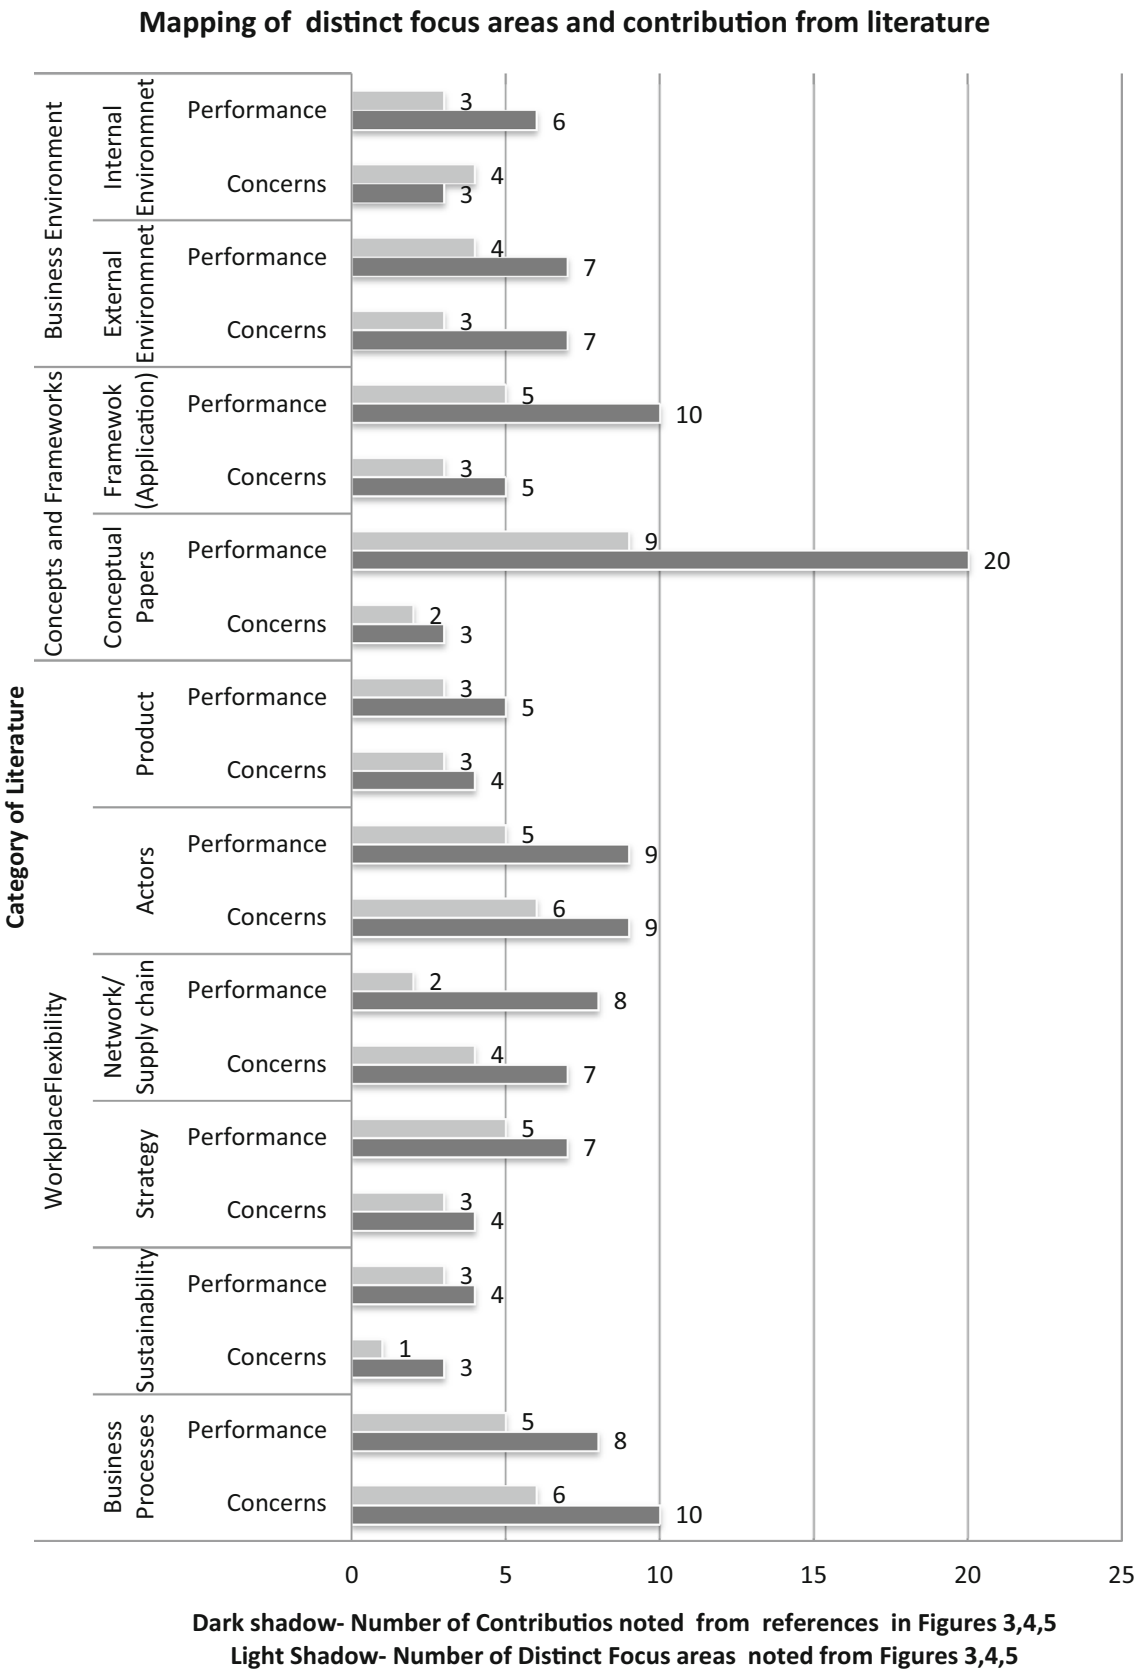

Fig. 7 Mapping of distinct focus areas and contribution in the literature

second-order themes are business processes, sustainability, strategy, network/supply chain, and actors.

The first-order themes of "Concepts and Framework" are risk mitigation, acceptance of agile methods, measurement of flexibility, evaluation of agile methods, agility evaluation, flexibility index of manufacturing systems, ranking of flexibility, super-flexibility, flexibility maturity, joint flexibility, usage of flexibility, agile development teams, integrated agile enterprise, success factor of agile methods, flexibility theories, agile method performance, manufacturing flexibility, and data uncertainty. The clustered themes examine the relationship with performance and concern of flexibility. Two themes (second-order) are identified in this category.

The first-order themes in category "Business Environment" are changes in the environment, demand uncertainty, risk, flexibility dimensions, prediction, integration, country, country-based strategic flexibility, changes in the business environment, uncertainty, investment, crises, variability, workplace flexibility, business model innovation, and collaborations. The clustered themes point to the relationship of flexibility reported in the literature w.r.t performance and concern. The second-order themes relate to the internal and external perspectives of organizations.

The common concerns and performance for all three categories are used to substantiate the flexibility paradoxes. The quantitative and qualitative analyses of commonalities lead to inferences about first and second managerial paradoxes, respectively.

First Managerial Flexibility Paradox

The observations are noted from Fig. 7. The contributions in performance orientation are significantly higher as compared with concern in "Concept and Framework" category. In subcategory "Actors" and "External environment," an equal number of contributions are observed in both performance and concern orientations because the contributions are identified from human resource and business environment literature. In subcategory, i.e., "Business process," the number of contributions related to concern is higher. The contributions in performance orientations are asymmetrically higher as compared with concern in most of the subcategories. It is observed that these subcategories primarily relate to operations and strategy. It is also noted that subcategories, where contributions in concerns are equal or higher, require the involvement of senior management for investment toward flexibility. The generic behavior of a lower number of contributions in concern generates the first flexibility paradox which is built on the assumption of limited advice to implement the advanced flexibility concepts.

Further investigation reveals that risk and uncertainty-related literature find considerable support in non-flexibility and practice-oriented literature. The widely utilized methodologies such as capability maturity model and project management frameworks put significant emphasis on risk and uncertainty mitigation through standard operating procedures (PMI 2009; CMMI-DEV 2010; Hopkin 2017). For risk and uncertainty management, the available literature points to usage of tools and techniques (Raz and Michael 2001). The context in which the risk and uncertainty management to be used is also echoed in the literature (Ward and Chapman 2003; Cicmil et al. 2017). Enough literature is available to showcase the benefit of risk management for project success (De Bakker et al 2010). The impact of risk on decision process is elaborated in the literature (Froot and Stein 1998; Cole et al. 2017). The extreme form of the use of risk management in case of failures is also noted (Chopra and Sodhi 2004). This shows that integrated view has emerged in area of risk management only that expressively widens the first managerial paradox.

Second Managerial Flexibility Paradox

Second paradox toward flexibility related to the difference in approach toward flexibility in higher and lower management. The different topics covered in the literature are identified as focus areas. The number of focus areas in performance orientation is more than concern orientation in most of the subcategories. This creates a different perception of flexibility to top and lower management and is evident in Fig. 7. The multiple contributions deliberate the same flexibility aspects which narrow the scope of discussion. The central focus of performance and concerns noted from Figs. 5 and 6 is the enhancement of flexibility theories and risk management. This denotes a wide gap between theory and practice of flexibility hinting at the second managerial paradox.

The context associated with the product, people, and processes for managerial direction for flexibility has unique benefits. The strong relationship of business strategy, flexibility, and performance has relevance to top management (Gupta and Somers 1996). The requirement of organizational flexibility is recognized by top management firstly by scanning the business environment and secondly through literature support. The flexibility adoption requires standard procedures to be followed up. Pailles et al. (1997) noted that decision on flexibility is taken at higher levels,

while it is promulgated in parts to the working level where the empirical evidence exists for implementation. The need for flexibility from lower managerial functions is mandated if an organization is operating efficient value network. Manders et al. (2016) found that in supply chain context the organization's endeavors for flexibility cater to direct need of next member. The non-availability of clear guidelines will create indifference to top management advice for flexibility. Wang et al. (2015) noted that top management's shared vision neither facilitates nor impedes the organizational flexibility; however, it positively influences the technological flexibility. The discussion points to indifference of managerial endeavor for implementing the concepts of flexibility understood by top management and supports second managerial paradox.

Third Managerial Flexibility Paradox

The third paradox is related to the extent and scope of flexibility initiatives and finding optimality. There are various modes of flexibility initiatives; some are emergent and others are pre-planned strategic measures. The limit of flexibility measures is decided in terms of how far and a fast current system can cope (Slack and Correa 1992). Treville et al. (2007) found that 40% of flexibility improvement initiatives are unsuccessful. This required ample resources in hand for organizations to venture for flexibility initiatives. But once the initiatives are successful, the competitive advantage comes in. Even the flexibility as capability to handle risk mitigation and innovation is also questioned in the literature (Sushil 2017; Jena and Memon 2018). The strong focus on the flexibility literature toward the benefits and lower success rate of flexibility initiative will create the paradoxical situation for management practitioners who will look for optimality of resource allocation for this purpose. This creates the third managerial paradox and holds back the flexibility initiatives.

Conclusion, Limitations, and Future Research

Managerial flexibility is the ability to adapt to situations w.r.t time and scale to take advantage of business decisions (Business Directory n.d). The most cited benefit is investment and cost decision. It impacts the relationship between investment and uncertainty (Xie 2009). The clearly defined construct of managerial flexibility is largely missing in the literature. The uncertainty and risk are other focus areas that eventually relate to cost optimization. The manifold options reflect the managerial flexibility and evident from numerous contexts identified in first-order themes. Still these options lead to option pricing analysis and real options investment. The important point is ignoring long-term goals enabled by managerial flexibility in the literature. Flexibility is envisaged for vitality and sustainability (Sushil 2011). Very few contexts in the first-order themes relate to long-term agenda. This necessitates broadening the ambit of managerial flexibility through setting the research agenda. A highly relevant subject pertains to the execution of project orders where impact of managerial flexibility is ignored. This is clearly visualized by absence in first-order themes. For managerial action and attention toward flexibility, it is advised to look in concern-related contribution. This will help them to exploit the benefits of flexibility by deploying envisaged resources. The dealing of uncertainty with flexibility has resulted in many contributions using metric-based approaches; these are approaching maturity. The contributions relating managerial flexibility with real options decisions are evolving rapidly with potential of maturity in the near future. The real options evaluations along with valuations of acquisitions and returns are noted as important indicator of managerial flexibility (Jain et al. 2018). A closed-loop behavior is seen for flexibility benefits and its enablers. The commonly understood benefit of managerial flexibility is increased motivation, concentration, and productivity derived from flexible work options (Sweet and James 2013). However, the same contributes to workforce flexibility (Patil and Suresh 2019). The study of the literature suggests that flexibility has been used along with other strategic tools and objectives. The social and organizational theories put flexibility along with structure and culture for performance (Birasnav et al. 2019). This leads to a broad conclusion that it has been used as a mediator of organizational performance. The direct influence of managerial flexibility on performance is largely ignored in the extant literature.

The discussion on paradoxes reveals that two categories of contributions are expected from future work: one is concerned with advice for the strategic purpose for top management, and the other is guidance for operational aspects dealing with flexibility. In this paper, the reason that drives the flexibility has been investigated along with deliberation of future scenarios. The paradoxical behavior of management is built upon this finding where the practicing manager seeks advice from the literature to implement the advanced concepts of flexibility, while the

practices of implementation are focused on risk and, uncertainty mitigation strategies. The non-availability of literary advice to management will result in ignoring the flexibility benefits. The analysis of focus of the literature provides broad dimension of paradox resulting from concentration of contributions in different focus areas. The analysis shows that there is ample literature dealing with uncertainty and risk, while there is limited contribution on severe form of uncertainty in the form of crises, supply chain disruption, and flexibility in organizational communication. Future researchers can focus on these areas. This paper has explored all the aspects of managerial flexibility falling within ambit of organizational boundaries. However, the influence of outside factors impacting the managerial flexibility can be explored by future researchers using thematic analysis.

This paper also suggests future research direction in an area of flexibility adoption leading to organizational competitiveness and performance. The flexibility-related theories start from measuring certain types of flexibility and end up with comprehensive treatment toward maturity models. Some of theories and practices are widely used, while others are still evolving. It is also observed that process definition and application methodology supported by empirical studies for practicing managers are primarily available for risk and uncertainty management functions. The same is lacking in advanced concepts and frameworks of flexibility which make it difficult for practicing managers. The substantial gap opens up a new research area for defining workable methods to practice flexibility. There is evidence of a methodological gap in the application of flexibility and agility in the supply chain (Fayezi et al. 2016). Yu et al. (2015) dealt with operational flexibility and performance outcomes aspects simultaneously. The three paradoxes provide the avenues to prospective researchers to fill the gap between operation and concepts through operational means. The flexibility in business model innovation, integration, collaboration, flexible strategies, and agile method acceptance is identified for further exploration by researchers as limited contributions are seen in these areas. This paper has made inferences instead of conclusions regarding the managerial paradoxes. These inferences can be changed in light of more advanced contributions on the subject. This paper has made an attempt to highlight various aspects of managerial flexibility which is central to overall organizational flexibility but still ignored in practice and theory.

Compliance with Ethical Standards

Conflict of interest The authors declare that they have no conflict of interest.

Appendix

Number of contributions and focus areas

Category of the identified literature	Context of the literature	Relevant contributions	Distinct focus areas
Contributions used for finding managerial flexibility paradox			
Workplace			
Business processes	Concerns	10	6
	Performance	8	5
Sustainability	Concerns	3	1
	Performance	4	3
Strategy	Concerns	4	3
	Performance	7	5
Network/supply chain	Concerns	7	4

He held senior positions in academics as Dean and executive council member of leading universities.

Modelling Of Viscoelastic Fluid In Finishing Processes

Krovvidi Srinivas, Q. Murtaza, A.K Agarwal

Abstract: The Traditional Finishing process mostly lapping, honing, buffing, superfinishing etc contains various disadvantages like labour intensive work, high Production cost and time. Moreover, the quality of surface finish achieved is not up to the mark but in present era there is requirement of better quality of products with desired surface finish, in order to overcome this finishing issue Abrasive Magnetic Finishing and Abrasive Flow Machining process comes into the consideration. Both the Process uses a Viscoelastic media which contains an adequate amount of Polymer, gel, Oil and abrasives. Magnetic Abrasive Finishing includes polymer media with carbonyl particle which align along the magnetic field and results in effective machining. This paper includes solid modelling of the process and simulation on Ansys Fluent module and analyse the Flow parameters of the viscoelastic polymer media and its effect on material removal.

Index Terms: viscoelastic Magnetic Abrasive Finishing (VMAF), Magnetic Abrasive Finishing (MAF), Material Removal (MR), Surface Finish, Ansys Maxwell, Polymer Media, Abrasive Flow Finishing (AFF).

1 INTRODUCTION

Magnetic abrasive finishing is an effective machining process in which magnetic field is used to machine the target surfaces of the workpiece by influencing the carbonyl particles and directing them towards the wall of the workpiece for machining. In conventional abrasive machining process both the workpiece and the target surface are polarised and due to the interplay of magnetic field, a Brush of abrasive is formed which results in the effective machining of the workpiece. This effective concept of machining got the eyeball of many scholar and initiated a large number of researches in this field like Kang and Yamaguchi [1] developed a multipole dip- system for the machining of internal surface of the capillary tube. The researchers highlighted the difficulties faced in machining of the capillary tube mainly in controlling the magnetics abrasive in MAF process, the researchers suggested that the multipole system with alternate magnetics and nonmagnetic region simultaneously applied on the workpiece which results in the effective machining of the long capillary tube. This process has allowed the application of MAF on long Capillary tube as well which was earlier confined to the short length tube only. The final conclusion of the researcher was that the double pole system finishes the workpiece in half a time as compare to the single pole system. V.K Jain [2] explained various non-traditional machining process which are used in modern times which involves the use of abrasive and the media to support it. The various process which he discussed in its paper was Abrasive Flow Finishing (AFF), Magnetic Abrasive Finishing (MAF), Magnetorheological Finishing, Magnetorheological Abrasive Flow Finishing, Elastic Emission Machining (EEM) and Magnetic Float Polishing. he laid attention on the magnetic abrasive finishing process and gave some important conclusion like involvement of slot in the magnet over non machining zone and the use of pulse Dc supply rather than smooth DC supply in the system. Wani et al. [4] gave stress on Magnetic Abrasive flow finishing which is a process made by combining the advantage of both abrasive flow machining and the magnetic abrasive finishing process, and used finite element method to find distribution of magnetic potential in the magnetic brush. Through this distribution the researcher evaluated machining pressure, surface finishing and material removal. After the successful evaluation of the results the researcher claims that these results are similar to those present in the literature. Kala et al. [4] developed a setup which aims to catch the force signature for double disc magnetic abrasive finishing process and the conventional abrasive magnetic abrasive finishing process and by these properties the researchers aims to understand the working of the flexible magnetic abrasive brush. Thus, to do this the researchers performed the magnetic abrasive finishing operation in single as well as double disc and finally understood the property of flexible magnetic abrasive brush behaviour from it. Wu et al [5] developed a model of magnetic abrasive finishing process and analyzed its properties based on the rotational speed, cutting fluid and the magnetic pole and current frequency and its effect on change in material removal and surface finish are invested. The researchers finally claimed that the neat cutting oil is required for processing which results in higher material removal and finer finish. They also concluded that finishing is better with the increasing in rotational speed and as the current frequency increases the angle variation of the particle increases and if frequency is low the surface requirement is up to few nanometers. Rathod et al. [6] correlated the difference shape factor with wide range of particle size. The researcher made use of slurry abrasion tester with silica sand slurry and commented on the effect of sliding distance slurry abrasion volume, where they argued that volume loss is proportional to the sliding distance. They also studied the effect of micro ploughing and cutting. Srivastav et al. [7] simulated a model of electrochemical magnetic abrasive finishing process in which the researchers used stainless steel workpiece whose radius was ten mm and thickness was 2.5 mm. the researchers used chromium oxide as the abrasive particle whose average diameter was 387 micrometers, the intensity of magnetic field was around 1 tesla and the rotational speed of tool was taken as 5835 rpm and its diameter was 6 mm. the electrolyte used for the experiment was brine solution with twenty percent concentration. The researchers study the thermal model in both steady and transient model. Srivastav and Amit [8] did the thermal analysis of work-brush interface and along the workpiece depth in magnetic abrasive finishing process with the help of ANSYs R15 software in both steady and thermal state. The value of magnetic field intensity given to 6 mm diameter tool was 1 tesla. The researcher used chromium oxide abrasives of about 387 micrometer Diameter. The workpiece has a radius of 10 mm and 2.5 mm thickness and the material of the workpiece was silicon nitride. Singh et al. [9] used Taguchi L orthogonal array to design an experiment which could measure surface temperature of the finishing surface of mild steel using MAF process. The researchers used current, working gap, Rotational speed and abrasive weight as

its important process parameters. After the Taguachi optimization the Fuzzy logic is used by researcher through which prediction of surface temperature is and also it is validated. Jaiswal et al. [10] made FEM model of MAF and investigated the distribution of magnetic force on the workpiece. The researcher also made a theoretical model for computing the material removal and surface roughness. For this the workpiece was considered of uniform surface without statically distribution. Numerical experiments were also computed which were validated later on through literature. Yan et all [11] performed the experiment on MA genetic abrasive finishing based on a simulated model which is based on FEM model of electromagnetic inductor. He then compared the simulated model with the actual electromagnetic inductor and predicted a marginal error of only 7 percent. Li et all [12] developed a finishing setup having new media for finishing the rotatory surface ANSYS Maxwell was used to determine the optimum angle between the poles and the mathematical model was made to compute the MRR in which pressure and velocity was computed based on arced wear model. The MRR computation model was made which predicted MRR as a function of pole rotational speed, Magnetic flux density, cam rotational speed and the ferromagnetic and abrasive particles' diameter. Li et all [13] proposed a new viscoelastic magnetic Abrasive based on analysis of field characteristic and existing finishing process. They also discussed the motion locus of the abrasives. The present scenario, abrasive flowing finishing, grinding, abrasive brush deburring, magnetorheological finishing, manual deburring etc. are broad name in term of finishing but still they possess some limitations in finishing quality and efficiency. Shimamura et al. [14], [15] modelled and tested that magnetic abrasive particles are subjected to the pressure for machining and that pressure is a function of magnetic flux density, number of abrasive particles and the permeability of abrasive medium. Fox et al [16] observed that the magnetic force (function of the volume and magnetic susceptibility of the ferrous particles in the magnetic field, magnetic field intensity and the gradients at the finishing area). Srinivas et al. [17] studied the distribution of the magnetic field intensity along with the computation of torque and force and related flow parameters of Viscoelastic Magnetic Abrasive finishing process with magnetic field intensity. The Researchers used ANSYS Maxwell and ANSYS Fluent in order to find co relation between the flow parameters and magnetic field intensity and commented on the successful application of the proposed viscoelastic media. The researchers also plotted the graph between the magnetic field intensity and the current which is applied on the single pole electromagnet to produce the desired magnetic field for machining in the magnetic abrasive finishing process. Srinivas and Anant [18] studied the pressure variation in abrasive flow machining process with the help of a simulated model made on Ansys Fluent and commented on the effect of pressure variation in the machining operation. They used viscous media similar to that used in viscoelastic magnetic abrasive finishing with the difference that in later process there is an addition of carbonyl particles which gets activated by magnetic field. The researcher computed pressure difference between 40 MPa and 20 MPa and the value of pressure so obtained was validated with the help of literature review. Ali et al. [19] reviewed various researches on AFM which uses a viscoelastic media and semisolid media which can support various abrasive based finishing process including both magnetic and non-magnetic based finishing process. Bhardwaj et al [20] compiled the researches which contained the use of viscoelastic media in various hybrids of abrasive flow machining process, the researchers also commented on the tooling and fixturing in various hybrids of AFM and the compatibility of the viscoelastic media with the hybrid process. So it can be seen that Viscoelastic Magnetic Abrasive Finishing has a vital role in Finishing department and must be consider for effective machining operation.

2 SIMULATION AND MODELING

A simulation model was proposed to overcome the research gap in the process of magnetic abrasive finishing process. For this purpose, ANSYS Fluent was used so a basic geometry was made in CREO 3.0 software and was then transferred to ANSYS fluent as an IGES File. The basic model contains a brass workpiece with alumina abrasive mixed in the viscous fluid whose property are listed in the tables. When a geometry is port into the ANSYS fluent software, it undergoes 5 steps. The first step (Figure 1) is the geometry where we do name selection and perform the Boolean operations if required. So, we did name selection in which the selections were Inlet, Outlet, workpiece and fluid Domain, next was the Boolean operation where we created path for the fluid flow within the internal surface of the workpiece. Then the file was transferred into the meshing section in which the mesh was created which is depicted by figure 2 and 3. The total elements in mesh was about $3X\ 10^3$ and the shape of the element was majorly tetragonal. After successful meshing the next step was to load the fluent setup for which is shown in figure 4. This is the major step in which we select the type of simulation, energy equation, material assignment, boundary condition and select the number of iterations for the process of simulation. For the process the laminar simulation with the boundary condition on was chosen and the adequate material is assigned to the parts. The boundary condition used for the simulation was Pressure inlet of 40 MPa and the outlet at 20 MPa, the workpiece and walls were stationary. The detail of boundary condition is given in table 2. Initially the fluid is not given any velocity but its movement would be there through the pressure difference which would do machining. The effective machining may be done when we will be placed magnet inside the system which cannot be done on ANSYS fluent, although for that ANSYS Maxwell must be taken into consideration. After all this assignment the simulation is allowed to run for iteration and the plot of energy along with the X, Y and Z velocity was plotted against the number of iterations, which is shown in figure 6.

4.	Outlet	Outlet Pressure: 20 MPa

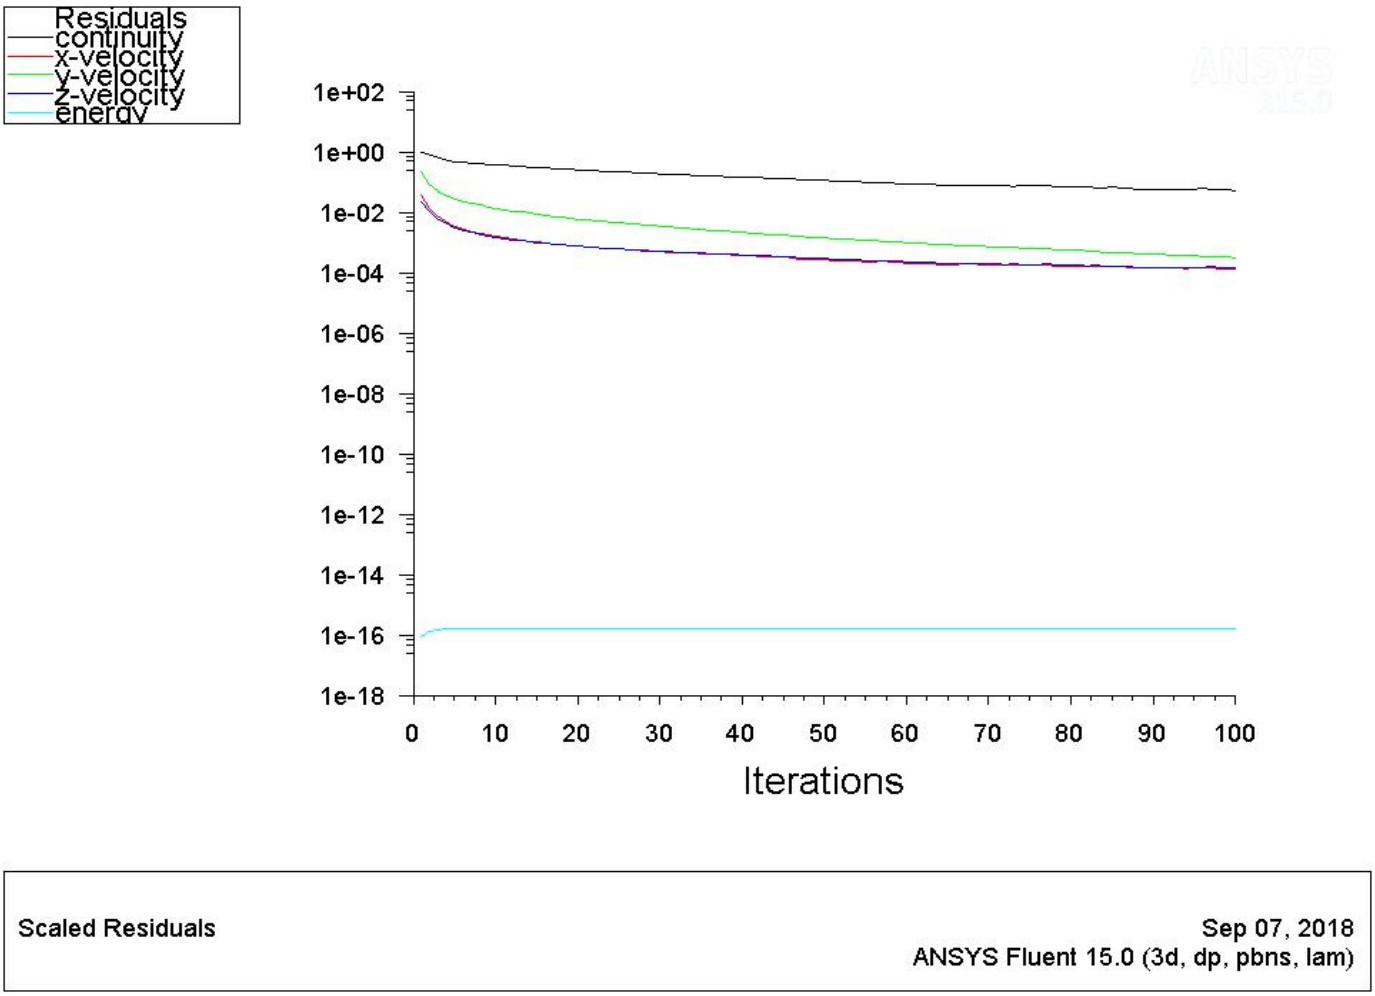

***Fig**. 5. Energy Vs Iteration curve*

3 Results and Discussions

As The results show the maximum pressure is 26.2455 MPa and the minimum Pressure obtained after the analysis is 10.4519 MPa which is an optimum value for machining the brass workpiece at the pressure range of 40 MPa to 20 MPa (Figure 7). The pressure drops in the reason of the workpiece due to the bell effect, When the surface area decreases at the neck region the velocity of the media decreases resulting in the increase in the pressure value at the neck region which is at the starting of workpiece in the direction of the flow, But the value of the pressure decreases throughout the flow of the polymer media which can be seen through the subsequent figure in which the pressure variation along the plane is given, in which the drop in the pressure is shown. Figure 8 shows the streamline variation of the Polymer media. As observed from the figure the stream lines are uniform and smooth and representing the flow due to the pressure difference only. The effective machining may also be achieved by putting a magnet around the workpiece which will attract the carbonyl particle present in the media which would further hit the magnetic particles. The figure 9 shows the force applied by the polymer media on the workpiece, though the force applied would be uniform as the abrasive would be uniformly mixed with the polymer media which results in the application of force on the workpiece. Though the maximum value of the force is 5440 N. The force would be maximum at the point where the abrasives strikes the surface of the workpiece. The figure 10 shows the distribution of velocity of the polymer media on the workpiece, the polymer media is specially made by combining various polymer, gel, oil and abrasives blended together to form a semisolid putty which is extruded up and down with the pressure difference to achieve the effective machining of the process. As Described by the process the maximum velocity is 183.2 m/s and the minimum velocity is 6.94 m/s, again this point must be taken care of that the figure is showing the velocity distribution at the region of the workpiece and not along the flow. The distribution of velocity along the flow would be different. The figure 11 shows the pressure variation along the entire length of the cylinder in the abrasive flow machine rather than the workpiece regions. It shows the pressure at the upper side is 29 MPa and at the lower side is 10.45 MPa the region for the pressure drop and is already discussed. Hence simulation was successful in showing machining characteristic of Viscoelastic media

New Failure Rate Model for Iterative Software Development Life Cycle Process

Sangeeta, *Member, IEEE,* Kapil Sharma, *Member, IEEE,* and Manju Bala

***Abstract*—Software reliability models are one of the most generally used mathematical tool for estimation of reliability, failure rate and number of remaining faults in the software. Existing software reliability models are designed to follow waterfall software development life cycle process. These existing models do not take advantage of iterative software development process. In this paper, a new failure rate model centered on iterative software development life cycle process has been developed. It aims to integrate a new modulation factor for incorporating varying needs in each phase of iterative software development process. It comprises imperfect debugging with the possibility of fault introduction and removal of multiple faults in an interval as iterative development of the software proceeds. The proposed model has been validated on twelve iterations of Eclipse software failure dataset and nine iterations of Java Development toolkit (JDT) software failure dataset. Parameter estimation for the proposed model has been done by hybrid Particle Swarm Optimization and Gravitational Search Algorithm. Experimental results in-terms of goodness-of-fit shows that proposed model has outperformed Jelinski Moranda, Shick Wolverton, Goel Okummotto Imperfect debugging, GS Mahapatra, Modified Shick Wolverton in 83.33 % of iterations for eclipse dataset and 77.77% of iterations for JDT dataset.**

I. Introduction

With the growing advances in the digital world, software development demand from industries is growing at an exponential rate. Due to enormous demand and lack of time and budget, software companies are not able to develop fault-free software. Latest tools and techniques have been applied for the development of defect-free software, but still, it is not possible for software developers to develop defect-free software practically. Software must go through exhaustive testing and debugging, which requires time and money to enhance the reliability [1] [*2*]. The occurrence of fault is inevitable in the current demand of software. There should have some means to avoid software failures so that devastating losses whether related to life or any other field could be evaded.

According to IEEE standard 729 [*3*], reliability is the most significant quality aspect of the software. If we could measure the reliability of software under development, better we can predict whether the software would be operational in the future or not. Reliability estimation process must be precise to provide information to the manager like what should be the release time of the software and amount of man-hour consumption etc. while developing any software [4]. Software reliability models are one of the ways to simulate software reliability estimation curve to predict the reliability of the system under study. Numerous reliability estimation models for software have been developed, and all are working on specific applications, specific environments, datasets and

assumptions made by them. Then, what is the need for developing new software reliability models?

First need lies in the fact that, among the available research in software reliability model development [5] [6] [7] [8] [9] [10], all developed models are basically made for reliability estimation of software's developed under traditional waterfall SDLC process. Second, research publications are screening no more than 31% experimental researches and among this only 13 % are purely experimental [11]. This low number is due to the reason that public experimental data sets in software reliability estimation are very narrow and producing reliability data through experimentation usually require long time cluster. Third, most generally developed models are NHPP based and very few failure rate based models [12] [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [*23*].

Failure rate-based models are among the earliest software reliability estimation models used in industrial and academia. These models are grounded on JM software reliability model [9]. They need further enhancement, so that more realistic assumptions like imperfect debugging and factors for exact reliability growth estimation can be incorporated into the model. Further, all software reliability models are developed under waterfall SDLC process. Waterfall SDLC process for the development of software assumes that requirements from the end users are stable and it delivers whole software at one shot in the end [24] [25]. This may generate risks for the users as they do not have information till end what they will get. These limitations construct a need for the use of another methodology while modeling software reliability. Yet now, no research in software reliability assessment has been found which are based on latest SDLC process.

Software reliability is primarily dependent on the process of software development. The software developed using latest SDLC approach can capture and implement all the user requirements within time and budget. Earlier waterfall SDLC process based reliability estimation models are very much stable and found to be unsuitable for the software industries because there are high risk and uncertainty of change in requirements. An iterative SDLC process [26] is the latest methodology of software development and is a practical method of step-wise top-down refinement approach to the software development that replaces the waterfall SDLC process. It gathers user requirements in each iteration of software development and implements software with less uncertainty in risk and user satisfaction. Nowadays the latest software development processes are based on iterative software development process and these are like Rational Unified Process (RUP) [27], Adaptive method [28] [*29*] (Agile methodology), XP (Extreme Programming) [*30*], spiral [31] model and AZ [*32*] development processes. These SDLC processes are considered as an aid of producing reliable software based on iterative model in development. Moreover, these are found to be used practically in industries and academia for software development and promote iterative development process.

Further accurate software reliability estimation is dependent on the selection of optimum parameter values of the models. The techniques for optimizing parameter values of the software reliability models are available, through the various classical methods of parameter estimation [5] [*33*]. These methods are based on number of constraints and may fall in local maxima and do not converge to global maxima in the multimodal cases. An alternative to these classical mathematical optimization methods are nature-inspired optimization algorithms for the solution of non-differential, non-linear and multimodal problems [34] [35] [36].

The proposed failure rate model incorporates iterative SDLC process by replacing earlier waterfall based SDLC process. Further, it assumes imperfect debugging during each of iteration. There is always a possibility of fault introduction with feature addition in each of the iterations of software development. All latest iterative SDLC processes can be used to predict the reliability by applying the proposed failure rate model. Existing failure rate model cannot be applied to the current Software development methodology. The proposed model takes care of complexity and paradigm shift of iterative based software development process by introducing modulation factor.

Rest of the paper is schematized as follows: Section 2 exposes the existing literature of the software reliability models and parameter estimation algorithms used for software reliability modeling. In section 3 a new classification scheme for software reliability models based on iterative SDLC process is discussed. In Section 4 a new software reliability model is proposed. Section 5 discusses the experimental setup and results of the proposed model and the last section concludes the paper.

II. Literature Review

For reliability estimation of the software more than 300 SRGMs have been developed under various categories of reliability estimation models like [6] [*5*] [37] [*38*] [39] [40] [41] [42] [43]. Experimental research work for software reliability estimation is found to be very few, reason being limited failure data and requisite of long time period. From the developed models, no model is well applicable in all type of applications and fits only with a specific application. Some of the model groups are having assumptions that are considered better and have higher predictive quality than other models. Most of the model development comprises NHPP based models and very few are centered on the failure rate behavior. Literature in this paper discusses well-known failure rate behavior-based models.

Jelinski-Moranda model [9] is the first software reliability estimation model. This model is perfect debugging based and assumes that there is fixed, constant and unknown number of initial faults in the software. The time between failures is assumed as independent and exponentially distributed. Shick-Wolverton (SW) model [10] assumed that failure rate function is proportional to the current total number of faults and the time since last failure. This idea has been evolved after modification from the basic JM Model. L.I.A. Turk and E.G. Alsolami developed a model using JM model by applying Weibull distribution function for the amount of debugging time between fault occurrences [44]. Modified Shick-Wolverton model [6] [5] [12] modified the SW model by incorporating a cumulative amount of faults at a time. These

models incorporate perfect debugging process while making assumptions for the model development. Goel and Okumotto first time proposed imperfect debugging based model that incorporates imperfect debugging phenomenon by introducing fault removal probability [5]. JM Geometric Model [13] modified JM model by assuming a geometric decrease in program failure rate at failure times. Littlewood and Sofer [14] proposed a model with Bayesian modification in the JM model and provided improvement for estimating the correct reliability of the software. Further modification to the JM model based on the cloud theory has been applied by Luo, Cao, Tang, and Wu [15]. Y.C. Chang and C. Liu proposed a generalized model by extending the JM model using a truncated distribution that matches up a self-exciting point process [45]. Mahapatra and Roy proposed a model and assumed the imperfect debugging behavior of the software with fault removal probability, probability of fault not removed and probability of fault introduction [16]. This model introduced fault introduction probability while removing any fault during debugging.

In failure rate behavior-based models, JM model assumed perfect debugging with single failure between time intervals after that multiple failure were proposed by SW but considers perfect debugging. Imperfect debugging based GOI model consider single failure in a time interval. Littlewood and Luo modified JM model according to the Bayesian and cloud theory respectively. Mahapatra *et al*. introduced probability for fault introduction in the software. In these enhancements to the earliest failure rate model, multiple faults with imperfect debugging have not been covered by any model. These entire model enhancements are made for software's developed under most basic waterfall development life cycle process. There is a need to incorporate latest software development processes for precise estimation of software reliability.

Parameter estimation process plays a crucial role in estimating accurate reliability of software product. There are number of models which are based on the classical methods for parameter estimation [33] [46]. These are numerical technique based methods (like Newtonian method, Gauss-Siedal method, etc.) [47], and these methods are doing well in a number of mathematical optimization problems. Nowadays meta-heuristic based optimization methods are found to be performing well in different domains. The algorithms like Particle Swarm Optimization [48] inspired by the bird flocks and Genetic Algorithm [49] inspired by the natural evolution phenomenon have been well applied in various fields including the field of software reliability estimation. A. Sheta and Jordan Al-Salt [50] applied PSO for SRGM parameter estimation. Malhotra and Negi applied PSO for reliability modeling [51]. Jin and Jin [52] applied improved swarm intelligent approach for parameter optimization of SRGM based on s-shaped testing effort function. Hybrid nature-inspired algorithms are found to be performing well in various domains. Mirjalili and Hashim proposed a hybrid PSO-GSA algorithm by hybridizing PSO and Gravitational Search Algorithm for mathematical function optimization [53]. Abraham *et al*. proposed a hybrid differential and ABC algorithm [54]. Mirjalili and Wang proposed a binary optimization for hybrid PSO-GSA algorithm [55]. As hybrid algorithms are performing well in different fields, these algorithms could be applied in software reliability model parameter estimation so that accurate software reliability could be estimated.

III. Classification of Software Reliability Models

This paper classifies software reliability models based on iterative SDLC process. Iterative model is like a cyclic process that mainly focuses on initial very simple implementation that progressively gains complexity and wider set of features till the final system is completed. Most recently built iteration and its feedback from evaluation are used in the next iteration, and accordingly, refinements are made in future iterations. Each of iteration provides enhancements and at-least found to be better than the last. Iterative model adapts rapidly to ever-changing needs of projects and clients within lowest time and budget.

Sharma *et al*. [56] has given classification of software reliability models according to waterfall SDLC process. In this paper, keeping iterative software development practice in mind software reliability models are categorized in Fig. 1. Every phase in iterative software development process is associated with specific requirements and future plans. Fig. 1 shows that each of the iteration is associated with a modulation parameter showing the added functionality and user acceptance level in each iteration. Initially, system is least reliable, and as the number of iterations proceeds, system moves towards refinement and gains reliability. Models are grouped into five categories. Each model category is assigned to a specific phase in iterative software development process for reliability estimation.

IV. Proposed Model

Keeping new SDLC processes and technologies, a new failure rate model centered on iterative SDLC process has been proposed. The proposed model has derived from the general class of failure rate behavior-based models and exploits iterative behavior of software development process.
In iterative process of software development, entire software is built and delivered to the end user in iterations. The process starts with simple implementation of key samples of a problem and iteratively enhances existing software releases until full system is implemented [57]. At each of iteration release feedback from the iteration is available for next iteration [58] [59] [60]. Feedback is mainly about the functionality and user aspect of the software. At each released stages of software, not only extensions but design modifications may be made. Each of the iteration makes step wise refinements in an effective way to converge to the full implementation of a problem. Main focus of feedback analysis is to find the amount of defects in an iteration that gets injected in the upcoming iteration [61]. Using feedback in each iteration, analysis of changing needs in an up-coming iteration can be made. These changing needs in each iteration are essential to know because these tells information about how much more defects may occur and how much more

effort and functionality is needed in making extensions and design modifications to the released iteration.

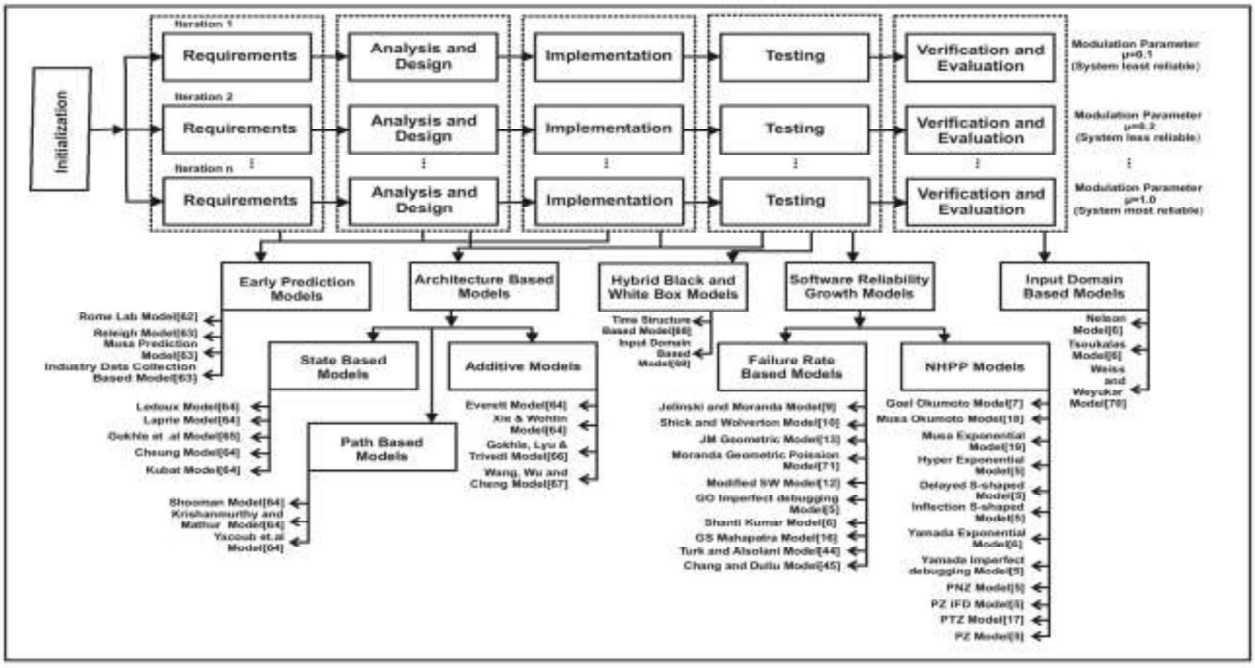

Fig. 1. Classification of Software Reliability Models based on Iterative approach.

In modeling software reliability, there is a need to introduce a factor that will engulf all the changing needs depending on the defect analysis in each of iteration. The varying needs in each of iteration of software development include bug reports, additional functionalities, and testing effort required to find the amount of defects that gets injected / removed in each upcoming iteration. These changing needs are incorporated in proposed failure rate model using modulation factor γ given in (1), so that precise reliability growth of the system could be estimated. The proposed model assumes that fault removal process is imperfect. Due to imperfect debugging regenerated faults are induced in successive iterations.

A. Proposed Model Assumptions

i. Initial software fault is unknown and constant in an iteration.
ii. Each fault in an iteration is independent and it may be equally likely to cause a failure while testing.
iii. The interval of time between fault occurrences in each iteration is independent and follows an exponential distribution.
iv. Software failure rate remains constant over the intervals between fault occurrences.
v. The software failure rate is proportional to the number of faults that remain in the software and modulation factor γ.
vi. In each iteration the detected fault is removed with a probability p, not removed perfectly with a probability q and new fault may be introduced with a probability r. Here $p+q+r=1$ and the probability $p > r$.

Faults are injected from previous iterations along with newly introduced faults in the current iteration. Newly induced faults are caused by added and modified functionalities in a respective iteration of software development. Depending on the number of initial iterative faults, there is a need to modify the amount of resources allocated for debugging in each iteration. The modulation factor γ as defined in (1) reflects the modified needs that integrate iterative development processes in software failure rate models. Modulation factor changes its value according to the modulation parameter μ as shown in (1). Moreover, changing needs in each iteration is different and vary according to (1).

$$\gamma = \mu + (1-\mu)/\mu, \quad (0 < \mu \le 1.0) \tag{1}$$

Here, μ is the modulation parameter that represents newly added functionality and user acceptance in the current iteration. Its value is almost 0 at the beginning and becomes 1.0 in the final iteration of iterative software development process. Modulation parameter μ takes its value from 0 to 1.0 by assuming that with growing number of iterations, level of user acceptance increases from lower to higher. It shows abrupt changes in its value in initial iterations due to preliminary design changes, testing effort, and user acceptance. When it's values reaches near to one then software under development is assumed to be reliable enough and has achieved all the required functionalities to fulfill the end user needs.

B. Model Formulation

Failure rate function ($\lambda(t_i)$) with imperfect debugging is modeled in (2).

$$\lambda(t_i) = \phi[\mathrm{N} - \frac{(n_{i-1})(\gamma)}{(i-1)}(p\text{-}r)], \quad i\text{-}1, 2....N \tag{2}$$

Where

γ	Modulation factor for representing changing needs in each of the iteration of software development
$n_{i\text{-}1}$	Cumulative number of failures at $(i\text{-}1)^{th}$ failure interval
N	Number of initial faults in software
ϕ	Proportionality constant

Cumulative Density Function $\mathrm{F}(t_i)$ and Reliability Function $\mathrm{R}(t_i)$ is calculated in (3) and (4)

$$F(t_i) = 1 - e^{[-\phi[\mathrm{N} - \frac{(n_{i-1})\gamma}{i-1}(p\text{-}r)]t_i]} \tag{3}$$

$$R(t_i) = e^{[-\phi[\mathrm{N} - \frac{(n_{i-1})\gamma}{i-1}(p\text{-}r)]t_i]} \tag{4}$$

When $p = 1, r = 0$ and γ varies as in (5), proposed model behaves as JM model.

$$1, \frac{2i}{i+1}, \frac{3i}{i+4}, \frac{4i}{i+8}, \frac{5i}{i+13}.... \tag{5}$$

Following a variation of γ in (5) and considering p being the probability of fault removal and r as the fault introduction probability then model behaves as the GS Mahapatra *et al.* model [*16*].

C. Parameter Estimation

In the proposed model there are three unknown parameters N, n , and ϕ these parameters are estimated at different values of the γ . MLE has been used to estimate the values of the parameters. Parameter estimation by MLE method requires solutions of complex equations by maximizing the likelihood of model parameters. Probability density function $\mathrm{f}(t_i)$ for the proposed model is given in (6).

$$\mathrm{f}(t_i) = \phi[\mathrm{N} - \frac{(n_{i-1})\gamma}{i-1}(p\text{-}r)] \cdot e^{[-\phi[\mathrm{N} - \frac{(n_{i-1})\gamma}{i-1}(p\text{-}r)]t_i]} \tag{6}$$

The likelihood function $\mathrm{L(N)}$ is calculated in (7) using (6).

$$\mathrm{L(N)} = \prod \mathrm{f}(t_i) = \prod_{i=1}^{n} [\phi[\mathrm{N} - \frac{(n_{i-1})\gamma}{i-1}(p\text{-}r)] e^{[-\phi \sum_{i=1}^{n} [\mathrm{N} - \frac{(n_{i-1})\gamma}{i-1}(p\text{-}r)]t_i]} \tag{7}$$

Taking the log of $\mathrm{L(N)}$, LLF is calculated in (8).

$$LLF = \ln L(N) = n \ln \phi + \sum_{i=1}^{n} \ln[N - \frac{(n_{i-1})\gamma}{i-1}(p-r)] - \sum_{i=1}^{n} \phi[N - \frac{(n_{i-1})\gamma}{i-1}(p-r)]\, t_i \tag{8}$$

Solution using log likelihood function for parameter estimation involves calculation of its partial derivatives with respect to N, n and ϕ respectively and then equating them to value zero. MLE of the parameters are calculated from (9), (10) and (11).

$$\frac{n}{\phi} = \sum_{i=1}^{n} [N - \frac{(n_{i-1})\gamma}{i-1}(p-r)]\, t_i \tag{9}$$

$$n = \phi \sum_{i=1}^{n} [N - \frac{(n_{i-1})\gamma}{i-1}(p-r)]\, t_i \tag{10}$$

$$\frac{1}{\sum_{i=1}^{n} [N - \frac{(n_{i-1})\gamma}{i-1}(p-r)]} = \phi \sum_{i=1}^{n} t_i \tag{11}$$

V. Experimental Setup and Results

A. Application Datasets used for Experimentation

Suitability of the proposed model has been tested using Tera Promise repository bug report files of Eclipse (DS1) and JDT (DS2) open source software at https://zenodo.org/record/268486#.W-QsPpMzY2w. These data sets have been given by An Ngoc Lam. The bug reports contains table having contents as bug_id, summary, description, report time, report time status, commit, and commit time files. Datasets have been extracted from these bug reports and reformatted in time domain format. DS1 includes eight minor releases and four major releases starting from the year 2001 to the year 2013. DS2 includes 3 major releases and 6 minor releases starting from the year 2002 to the year 2014.

Model parameters include N, n, ϕ, γ, p and r . Fault removal probability p and fault introduction probability r cannot be estimated from DS1 and DS2 and depends on the project type and skill set of persons involved in development and testing. Based on these two factors fault removed during testing is assumed 95 % and fault introduced is assumed 3%. Parameters N, n, ϕ, γ are estimated using hybrid PSO-GSA algorithm and MLE technique in (6), (7) and (8) to maximize the log-likelihood function value using (9), (10) and (11). The goodness of fit for the proposed model is measured using SSE and MSE for each application datasets [56]. These statistics are used for comparison of the proposed model with existing failure rate models.

The values of μ with respect to iteration are different for different software projects and depend on the type of project and user acceptance levels. Fig. 2 depicts variation in μ values with respect to number of iterations for DS1. The value of μ decreases in successive iterations 1.0 to 2.0, 2.1 to 3.0 and 3.3 to 3.4 by difference of 0.064, 0.081 and 0.045 respectively. These little deeps in μ values represent

Table 1 SUMMARY OF FAILURE RATE BASED SOFTWARE RELIABILITY MODELS

Sr. No.	Model Name	Failure Intensity
1	Jelinski-Moranda Model (JM) [9]	$\lambda(t_i)=\phi[\mathrm{N}-(i-1)]$
2	Schick &Wolverton Model (SW) [10]	$\lambda(t_i)=\phi[\mathrm{N}-(i-1)]t_i$
3	Goel Okumotto imperfect debugging Model(GOI) [5]	$\lambda(t_i)=\phi[\mathrm{N}-p(i-1)]$
4	G.S.Mahapatra *et al.* Model [16]	$\lambda(t_i)=\phi[N-p(i-1)+r(i-1)]$
5	Modified S-W Model(MSW) [5]	$\lambda(t_i)=\phi[\mathrm{N}-(n_{i-1})]t_i$
6	Proposed Model	$\lambda(t_i)=\phi[\mathrm{N}-\frac{(n_{i-1})(\gamma)}{(i-1)}(p-r)]$

variation in compliance of functionality requirements and lower values of user acceptance levels for eclipse software dataset (DS1). Overall values of μ shows increasing trends with successive iteration as shown in Fig. 2 and finally it reaches near to 1.0 in final iteration release.

Fig. 3 is revealing the change in functionalities and its corresponding increase in user acceptance for DS2 of JDT software product. At each of the iteration release there is increase in user acceptance level and it is illustrated with the values of μ in all successive iterations. For major iteration releases the value of μ are 0.0869, 0.1108 and 0.2144, for minor iteration these values are 0.1381, 0.2684, 0.3677, 0.6787, 0.7241 and 0.9539. The user acceptance increases in all iterations but a large variation of 0.31102 in user acceptance level is found in 3.4 to 3.5 iteration. It represents enhanced functionality and accomplishment of all requirements at end-users. Overall values of μ in successive iterations are reflecting variation in functionalities and user acceptance level in Fig. 3 that increases by small amount in each iteration and finally reaches near to 1.0 in last iteration release.

B. Result Analysis

1) CASE 1: Eclipse Software Dataset (DS1)

In this section, the goodness-of-fit of the proposed model is calculated and compared it with existing models given in Table 1 for DS1. The value of γ for major iterative release 1.0, 2.0, 3.0 and 4.1 are 2.2666, 2.8763, 3.7891 and 1.1258 respectively. In minor iteration release, the value of γ for iterative release 2.1, 3.1, 3.2, 3.3, 3.4, 3.5, 3.6 and 4.2 are 2.6343, 3.2217, 2.5788, 2.3121, 2.7295, 2.6434, 2.0435 and 1.00009 respectively.

The value of γ shows large changes in successive major iterations as compared to successive minor iterations due to varying needs in major and minor iterations. The goodness of fit of the models is shown in Table 2. From the analysis of results, it is found that proposed model fits well in term of SSE in all iterations of DS1 except at iteration number 3.1 where GOI model, GS Mahapatra model, and SW model outperforms proposed model.

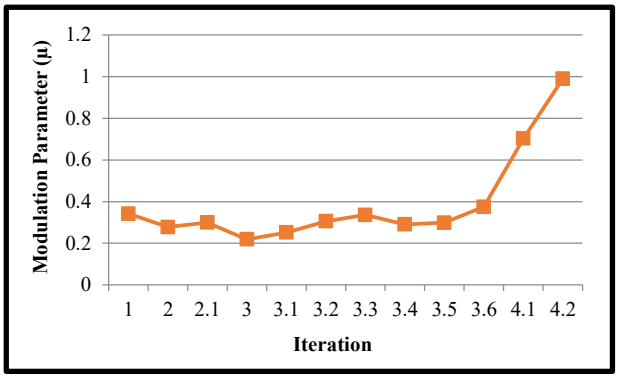

Fig. 2 Plot of μ versus Iteration for DS1

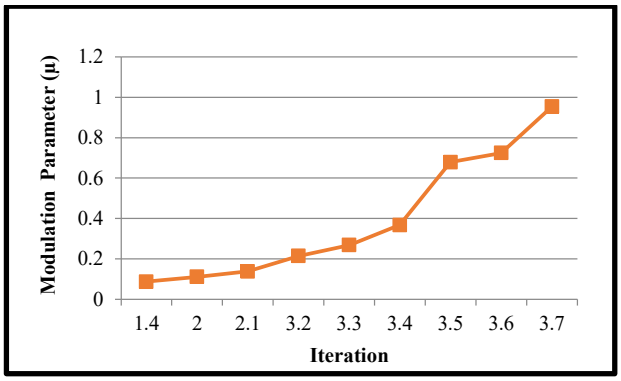

Fig. 3 Plot of μ versus Iteration for DS2

The proposed model has clear-cut outperform all models under comparison in 11 iterations for DS1. It shows the lowest values of SSE in 91.6 % iterations. In term of MSE proposed model is winner in nine iterations. In iteration 2.1 MSW model is performing well than the proposed model. In iteration 3.3, GOI model, SW model, and GS Mahapatra model are performing well than the proposed model. There is a tie among proposed model and GS Mahapatra model in iteration 2.0, where both of them outperform all other models. The proposed model has clear-cut outperform other models in 75 % iterations by achieving lowest value of MSE. Result shows that proposed model has given a significantly better fit to iterative data by adapting according to varying needs of different iterations.

The evaluation and comparison of goodness-of-fit of all models in Table 1 in terms of SSE and MSE for all iterations shows that the proposed model has promising technical merit in the sense that it provides development terms with both iterative SDLC requirements and traditional reliability measures.

2) CASE 2: JDT Dataset

To test the applicability of the proposed model in this case, dataset DS2 is used. Table 3 is showing the estimated values of model parameters and goodness of fit criteria. The value of γ for major iterative release 1.4, 2.0 and 3.2 are 10.5954, 8.1358 and 3.8778 respectively. In minor iteration releases the value of γ for iterative release 2.1, 3.3, 3.4, 3.5, 3.6 and 3.7 are 6.3815, 2.9946, 2.0872, 1.1521, 1.1052 and

1.0022, respectively. These values of γ are showing large deviations in successive major releases as compared to successive minor releases due to the varying needs in each of the major and minor iterations. Table 3 is showing the goodness-of-fit measures of all models depicted in Table 1 for DS2. Out of total nine iterations in DS2, proposed model outperform other models under comparison in eight iterations, in terms of SSE values. JM model performs well than proposed model in iteration 3.4. Proposed model attains lower-most value of SSE in 88.8 % of iterations. In terms of MSE values for nine iterations proposed model out-performs other models in six iterations. In iteration 2.0, GS Mahapatra model and GOI model are performing better than the proposed model. In iteration 3.7, proposed model outperforms JM, GOI, SW and MSW models except GS Mahapatra model. The proposed model outperforms GOI , SW, GS Mahapatra and MSW model except JM model in iteration number 3.6. The proposed model has performed better than all other models under comparison in 66.6% iterations by attaining the minimum value of MSE. Result analysis in Table 3 shows that the proposed model has significantly better fit to iterative data by fine-tuning to varying needs of different iterations.

VI. CONCLUSION

Failure rate models available in literature are centered on most traditional waterfall SDLC process. However, new software development processes have been developed and found to be more beneficial than waterfall SDLC process, like iterative life cycle processes. Keeping in view, new software development environments and technologies, a new failure rate model by exploiting iterative behavior of software development process is proposed. The changing needs in each of the iteration are reflected in the proposed model using a modulation factor. Calculated values of γ parameter are significantly reflecting all changing requirements for each upcoming iterations numerically. These values are meaningfully representing how much impact is of adding and removing new features with the level of user acceptance in each of upcoming iteration. In order to compare the performance of the proposed model, five well-known software failure rate models JM, GOI, SW, GS Mahapatra and MSW have been applied for dataset DS1 and DS2. The proposed model is a clear-cut winner in 11 iterations in SSE and 9 iterations in MSE out of 12 iterations and 8 iteration in SSE and 6 iterations in MSE out of 9 iterations for DS1 and DS2 respectively. Overall, in 83.33 % of iterations for DS1 and 77.77 % of iterations for DS2, the proposed model has shown better results in terms of goodness of fit by successfully incorporating varying needs in each of iteration.

The data collected from real applications and comparison of goodness of fit shows that the proposed model successfully incorporated varying needs in each of iteration and performed better than JM, GOI, SW, GS Mahapatra and MSW models.

Abstract

With the expansion of IoT and device-to-device communication applications, the security and privacy of the information have been kept at the forefront. The existence of a secondary eavesdropper, which attempts to access the confidential information of the legitimate partners, makes the data communication insecure. In this regard, we study the effect of randomness caused by the Beaulieu-Xie fading channel on the performance of physical layer security. To this end, the analysis for the secrecy outage probability (SOP) and average secrecy capacity (ASC) is carried out. Further, we derived the closed-form expressions for lower-bound of secrecy outage probability and strictly positive secrecy capacity (SPSC) for the said channel. To get more insight into the system, the high-power and low-power analysis of the ASC are also provided. Besides, the impact of different fading parameters on the system matrices is also investigated. Finally, the theoretical results are verified via extensive Monte Carlo simulations.

Keywords: Secrecy capacity; physical layer security; fading channel; secure communications

1. Introduction

With the advancement of 5G communications, where the increasing number of smart devices in IoT and device-to-device networking applications, the issue of privacy and security has been considered as the forefront requirement for the design engineer [1]. These applications work in the broadcast mode so data communications over these networks are more vulnerable to intruders i.e., a threat to the privacy and security of the host. There are some traditional cryptographic techniques, which are used for the secure transmission of information [2] between the two legitimate partners. These traditional techniques assume that the link between the trans-

mitter (Tx) and receiver (Rx) was error-free, which was not always the case. There have been attempts in the literature where the random nature of signal propagation was captured using different multipath and shadowing models. In some cases, the channel estimation and modeling over different frequencies and propagation scenarios have been studied [3, 4, 5, 6]. More recently, attempts have been made to use the random nature of the wireless channel to guarantee the secure transmission of messages [7, 8]. The model of the wire-tap channel was first proposed by Wyner in which two familiar nodes interact with each other over the main channel, and a third party tries to access the information of the legitimate partners [9]. In this model, the trade-off between the information rate and the achievable secrecy level for a wire-tap channel has been proposed. The secrecy performance of wire-tap channel was provided in terms of the secrecy capacity (SC), which was defined as the difference between the capacity of the main channel and the wire-tap channel. In other words, it can be defined as the maximum rate at which the secure data transmission can be achieved. Recently, there has been an increasing interest in studying the SC of the wireless systems over different fading scenarios. Secrecy analysis over Nakagami-*m* fading channel in the presence of imperfect channel state information (CSI) was studied in [10]. The physical layer security performance of the mobile vehicular networks over *N*-Nakagami fading channels was proposed in [11]. The effect of various fading parameters on the secrecy performance of generalized fading channel has been investigated in [1, 12, 13, 14, 15]. The closed-form expressions for strictly positive secrecy capacity (SPSC) and lower-bound of secrecy outage portability (SOP) for $\kappa-\mu$ fading channel has been presented in [1] while the probability of positive secrecy capacity and upper-bound of SOP has been studied in [12]. Recently in [13], average SC (ASC) and SOP over the more generalized $\alpha-\eta-\kappa-\mu$ fading channel has been analysed. Although the results produced in [13] are novel but not in closed-form. Closed-form expressions for the SOP and ASC over the Fox-H and mixture Gamma distribution are derived and discussed in [14, 15]. In [16] and [17], secrecy performance analysis over generalized-*K* (GK) fading channel was conducted. The authors have derived the expressions of SOP, SPSC and average SC in closed-form over generalized-*K* (GK) fading channels using a mixture Gamma distribution [17]. This work was extended for single-input-multiple-output (SIMO) system in [18]. In [19] SOP performance over correlated Nakagami-*m*/Gamma composite fading channel was analyzed while $\kappa-\mu$ shadowed composite fading channel was considered in [20] and [21] for studying the performance of physical layer security. The expressions for SOP and SPSC were derived in closed-form in terms of Meijer's-

G function in [20]. A similar analysis for SPSC using moment matching method was presented in [21].

Given the benefits of the Ricean and Nakagami-*m* fading models, these models have the limitations in characterizing the broad range of signal-fades from reflections and shadowing in the case of Ricean model and both LOS and NLOS components in the case of Nakagami-*m* model. To overcome these challenges, both these models were recently merged into a new fading model by Beaulieu and Xie [22]. The Beaulieu-Xie fading model acquires the benefits of the Nakagami-*m* fading model, in that it has a flexible fading parameter and the benefits of the Ricean fading model, in that its use of a non-central chi-distribution allows it to characterize both LOS and NLOS channels. This new fading model has been shown to have a relationship with the generalized Ricean distribution and the $\kappa - \mu$ distribution [22], which makes the performance analysis of this fading model to be of utmost importance. Moreover, the new fading models can characterize the indoor propagation scenario in a femtocell or small cell areas and high-speed train channels that has applications in 5G and beyond networks [22]. The second-order characteristic of the Beaulieu-Xie fading channel has been derived in [23], while the asymptotic tight bound of the said correlated channel for different diversity combining techniques were evaluated in [24, 25]. The physical layer security performance of Beaulieu-Xie fading channel is not present in the literature and yet to be done.

Therefore we have derived the performance matrices of physical layer security over Beaulieu-Xie fading channel in this work. The main contributions of our work are listed as follows:

- We obtained and analysed the physical layer security performance parameters like ASC, SOP, and SPSC over independent Beaulieu-Xie fading channel.
- We propose new closed-form expressions for lower-bound of SOP over Beaulieu-Xie fading channels.
- The high power analysis of the ASC has been provided. The ASC result for low power 5G network applications has also been investigated.
- All the results obtained from derived expressions are verified with the help of Monte-Carlo simulations.

The benefits of our study is to provide the efficient analytical expressions over Beaulieu-Xie fading channel that do not exist in the literature for the secrecy performances as functions of system parameters. In doing this, insights on the system performances can be obtained, as shown in Section 4.

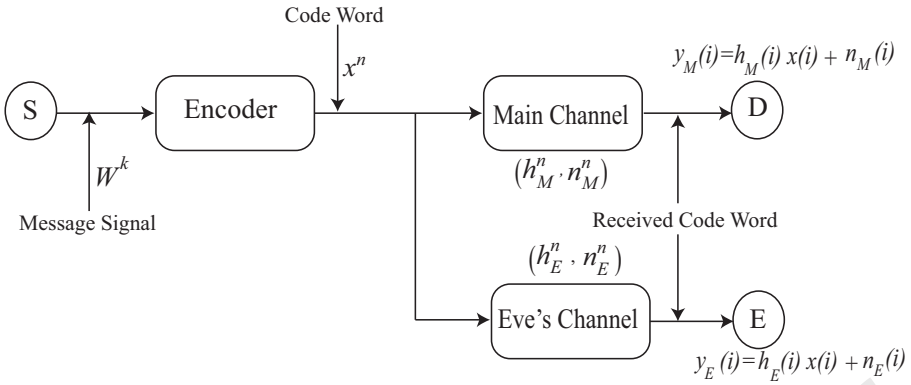

Figure 1: System model for SISO channel

The rest of this paper is organized as follows: In Section 2, the system model is introduced. Section 3 derives the expressions of the performance parameters. Numerical results and discussion are given in Section 4. Finally, Section 5 concludes this work.

2. System Model and fundamental channel statistics

The system model of the secure data transmission over single-input and single-output (SISO) channel is shown in Fig. 1. The legitimate source node (S) wishes to communicate secretly with the legitimate destination node (D), while an Eve node (E) is attempting to eavesdrop. The channel statistics of both the main and eavesdropper channel is assumed to undergo Beaulieu-Xie fading with CSI available at Tx. At the Tx, the message W^k is encoded into a code word, x^n for transmission over the channel. The signal at the receiving end, can be written as

$$y(i) = h(i)x(i) + n(i) \tag{1}$$

where $h(i)$ and $n(i)$ are the quasi-static Beaulieu-Xie fading coefficients and additive white Gaussian noise (AWGN) random variable with zero mean and unit variance at the receiving ends, respectively

The signal-to-noise-ratio (SNR) probability density function (PDF) of Beaulieu-Xie fading is given by [26, eq. (2)]

$$f_Y(\gamma) = \left(\frac{\sqrt{2}}{\lambda}\right)^{m-1} \left(\sqrt{\frac{m}{\bar{\gamma}}}\right)^{m+1} \gamma^{\frac{m}{2}-\frac{1}{2}} e^{-\frac{\lambda^2}{2}} e^{-\frac{m\gamma}{\bar{\gamma}}} I_{m-1}\left(\sqrt{\frac{2m\gamma}{\bar{\gamma}}}\lambda\right) \tag{2}$$

where $I_a(.)$ is the modified Bessel function of type 1 and order a. The fading parameters m, $\bar{\gamma}$, and λ controls the shape, spread, height, and location of the PDF.

The definition of the cumulative distribution function (CDF) is given by [27, eq. (2)]

$$F_Y(\gamma_{th}) = \int_0^{\gamma_{th}} f_Y(\gamma) d\gamma \tag{3}$$

where γ_{th} is the threshold SNR. Now substituting (2) into (3) and with the aid of [28, eq. (8.445)] and [28, eq. (3.381.1)] yields

$$F_Y(\gamma_{th}) = e^{-\frac{\lambda^2}{2}} \sum_{l=0}^{\infty} \frac{\left(\frac{\lambda}{\sqrt{2}}\right)^{2l}}{\Gamma(l+1)\Gamma(l+m)} \mathcal{G}\left(m+l, \frac{m\gamma_{th}}{\bar{\gamma}}\right) = 1 - Q_m\left(\lambda, \sqrt{\frac{2m\gamma_{th}}{\bar{\gamma}}}\right) \tag{4}$$

where $\Gamma(.)$ is the Gamma function, $\mathcal{G}(,)$ is the lower incomplete gamma function and $Q_m(,)$ is the generalised Marcum-Q function.

3. Secrecy analysis

In this section, we derive analytical expressions of SC, SOP, and strict positive secrecy capacity (SPSC) along with approximate solutions.

3.1. Secrecy capacity

The maximum data rate achieved under the eavesdropper scenario where perfect secrecy of the transmitted message is guaranteed a key assumption of the physical layer security. The instantaneous secrecy capacity is given by [1, eq. (11)]

$$S_c = \begin{cases} \log_2(1+\gamma_M) - \log_2(1+\gamma_E) & \gamma_M > \gamma_E \\ 0 & \gamma_M \leq \gamma_E \end{cases} \tag{5}$$

where $\log_2(1+\gamma_M)$ and $\log_2(1+\gamma_E)$ are the capacity of the main and the eavesdropper channel with instantaneous SNR γ_M and γ_E, respectively and $\log_2(.)$ is the logarithmic function with base 2.

Under the practical environment where fading arises the average secrecy capacity $\bar{S}_c$ (the average of the maximum transmission rate reached in a secure channel) expression is given by

[17]

$$\bar{S}_c = \int_0^{\infty} \log_2(1+\gamma_M) f_M(\gamma_M) \left(\int_0^{\gamma_M} f_E(\gamma_E) d\gamma_E \right) d\gamma_M - \int_0^{\infty} \log_2(1+\gamma_E) f_E(\gamma_E) \left(\int_{\gamma_E}^{\infty} f_M(\gamma_M) d\gamma_M \right) d\gamma_E$$
$$= \underbrace{\int_0^{\infty} \log_2(1+\gamma_M) f_M(\gamma_M) F_E(\gamma_M) d\gamma_M}_{I_1} + \underbrace{\int_0^{\infty} \log_2(1+\gamma_E) f_E(\gamma_E) F_M(\gamma_E) d\gamma_E}_{I_2} - \underbrace{\int_0^{\infty} \log_2(1+\gamma_E) f_E(\gamma_E) d\gamma_E}_{I_3} \tag{6}$$

where $f_E(\gamma_E)$, $f_M(\gamma_M)$ are the PDFs of the eve and the main channel, respectively. Putting (2) and (4) into I_1 and (2) into I_3, we get

$$I_1 = \mathcal{A}_m \int_0^{\infty} \log_2(1+\gamma_M) \gamma_M^{\frac{m_M}{2}-\frac{1}{2}} e^{-b\gamma_M} I_{m_M-1}\left(\sqrt{2b\gamma_M}\lambda_M\right) \left(1 - Q_{m_E}\left(\lambda_E, \sqrt{2\tilde{b}\gamma_M}\right)\right) d\gamma_M \tag{7}$$

$$I_3 = \mathcal{A}_E \int_0^{\infty} \log_2(1+\gamma_E) \gamma_E^{\frac{m_E}{2}-\frac{1}{2}} e^{-\tilde{b}\gamma_E} I_{m_E-1}\left(\sqrt{2\tilde{b}\gamma_E}\lambda_E\right) d\gamma_E \tag{8}$$

where $b = \frac{m_M}{\bar{\gamma}_M}$, $\tilde{b} = \frac{m_E}{\bar{\gamma}_E}$, $\mathcal{A}_M = \left(\frac{\sqrt{2}}{\lambda_M}\right)^{m_M-1} b^{\frac{m_M+1}{2}} e^{-\frac{\lambda_M^2}{2}}$ and $\mathcal{A}_E = \left(\frac{\sqrt{2}}{\lambda_E}\right)^{m_E-1} \tilde{b}^{\frac{m_E+1}{2}} e^{-\frac{\lambda_E^2}{2}}$. The previous integral with marcum-Q function in I_1 possess analytical intractability while evaluating the closed-form solution. Thus, using alternate expression of $F_E(\gamma_M)$ with lower incomplete Gamma function given in (4) and then employing [28, eq. (8.352.1)] and [28, eq. (8.445)], (7) can be written as

$$I_1 = \exp\left(-\frac{\lambda_M^2+\lambda_E^2}{2}\right) \sum_{l=0}^{\infty} \sum_{l_1=0}^{\infty} \frac{\left(\frac{\lambda_M}{\sqrt{(2)}}\right)^{2l_1} \left(\frac{\lambda_E}{\sqrt{(2)}}\right)^{2l} b^{m_M+l_1} (m_E+l-1)!}{\Gamma(l+1)\Gamma(l+m_E)\Gamma(l_1+1)\Gamma(m_M+l_1)} \left[I_1' - \sum_{l_2=0}^{m_E+l-1} \frac{\tilde{b}^{l_2}}{l_2!} I_1'' \right] \tag{9}$$

where $I_1' = \int_0^{\infty} \gamma_M^{l_1+m_M-1} \log_2(1+\gamma_M) e^{-b\gamma_M} d\gamma_M$ and $I_1'' = \int_0^{\infty} \gamma_M^{l_1+m_M+l_2-1} \log_2(1+\gamma_M) e^{-(b+\tilde{b})\gamma_M} d\gamma_M$. With the aid of [29, eq. (2.6.23.4)], the solution to I_1' and I_1'' is evaluated as

$$I_1' = \frac{\pi \log_2(e)}{(l_1+m_M) sin((m_M+l_1)\pi)} {}_1F_1\left(m_M+l_1; m_M+l_1-1; b\right) - \Gamma(m_M+l_1) b^{-m_M-l_1}$$
$$\times \left(\left[\ln(b) - \psi(m_M+l_1)\right] + \frac{b}{(1-m_M-l_1)} {}_2F_2\left(1,1; 2, 2-m_M-l_1; b\right) \right) \tag{10}$$

$$I_1'' = \frac{\pi \log_2(e)}{(\mathcal{T})sin(\mathcal{T}\pi)} {}_1F_1\left(\mathcal{T}; \mathcal{T}-1; b+\tilde{b}\right)$$
$$-\Gamma(\mathcal{T})\left(b+\tilde{b}\right)^{-\mathcal{T}} \left\{\left[\ln\left(b+\tilde{b}\right) - \psi(\mathcal{T})\right] - \frac{\left(b+\tilde{b}\right)}{(1-\mathcal{T})} {}_2F_2\left(1,1;2,2-\mathcal{T}; b+\tilde{b}\right)\right\} \tag{11}$$

where $\mathcal{T} = m_M + l_1 + l_2$, ${}_1F_1(.)$, ${}_2F_2(.)$, $\psi(.)$, and $\ln(.)$ are the confluent hypergeometric function and generalised hypergeometric function, psi function, and the natural logarithmic function. Similarly, analytical solution to I_2 can be written as

$$I_2 = \exp\left(-\frac{\lambda_M^2+\lambda_E^2}{2}\right) \sum_{l=0}^{\infty}\sum_{l_1=0}^{\infty} \frac{\left(\frac{\lambda_E}{\sqrt{(2)}}\right)^{2l_1}\left(\frac{\lambda_M}{\sqrt{(2)}}\right)^{2l} \tilde{b}^{m_E+l_1}(m_M+l-1)!}{\Gamma(l+1)\Gamma(l+m_M)\Gamma(l_1+1)\Gamma(m_E+l_1)} \left[\hat{I} - \sum_{l_2=0}^{m_M+l-1} \frac{b^{l_2}}{l_2!}\tilde{I}\right] \tag{12}$$

where the solution to $\hat{I}$ and $\tilde{I}$ is obtained from (10) and (11) by replacing the suffix $M \longleftrightarrow E$. The solution to integral (8) is deduced by employing [28, eq. (8.445)] and [29, eq. (2.6.23.4)]

$$I_3 = \exp\left(-\frac{\lambda_E^2}{2}\right) \sum_{l_1=0}^{\infty} \frac{\log_2(e)\left(\frac{\lambda_E}{\sqrt{(2)}}\right)^{2l_1}}{\Gamma(l_1+1)} \begin{cases} \dfrac{\pi\tilde{b}^{m_E+l_1} {}_1F_1\left(m_E+l_1; m_E+l_1-1; \tilde{b}\right)}{\Gamma(l_1+m_E+1)sin(\pi(m_E+l_1))} \\ -\left[\ln(\tilde{b}) - \psi(m_E+l_1)\right] \\ -\dfrac{\tilde{b}^{m_E+l_1+1} {}_2F_2\left(1,1;2,2-m_E-l_1;\tilde{b}\right)}{(1-m_E-l_1)} \end{cases} \tag{13}$$

The above solutions given by (10), (11), and (13) are valid for $2-m_{M/E}-l_1 > 0$ and $2-m_{M/E}-l_1-l_2 > 0$. Further at high SNR $\gamma \longrightarrow \infty$ $\log_2(1+\gamma) \approx \log_2(\gamma)$, thus (6) becomes

$$\bar{S}_c^{\rightarrow\infty} = \underbrace{\int_0^{\infty} \log_2(\gamma_M) f_M(\gamma_M) F_E(\gamma_M) d\gamma_M}_{I_1^{\rightarrow\infty}} + \underbrace{\int_0^{\infty} \log_2(\gamma_E) f_E(\gamma_E) F_M(\gamma_E) d\gamma_E}_{I_2^{\rightarrow\infty}}$$
$$\underbrace{-\int_0^{\infty} \log_2(\gamma_E) f_E(\gamma_E) d\gamma_E}_{I_3^{\rightarrow\infty}} \tag{14}$$

Now substituting (2) and (4) in the above equation and finally using [28, eq. (8.445)], [28, eq. (8.352.1)], and [29, eq. (2.6.21.2)], the solutions to $I_1^{\rightarrow\infty}$, $I_2^{\rightarrow\infty}$, and $I_3^{\rightarrow\infty}$ are deduced as follows

$$I_1^{\rightarrow\infty} = \exp\left(-\frac{\lambda_M^2+\lambda_E^2}{2}\right) \sum_{l=0}^{\infty}\sum_{l_1=0}^{\infty} \frac{\left(\frac{\lambda_M}{\sqrt{(2)}}\right)^{2l_1}\left(\frac{\lambda_E}{\sqrt{(2)}}\right)^{2l} b^{m_M+l_1}(m_E+l-1)!}{\Gamma(l+1)\Gamma(l+m_E)\Gamma(l_1+1)\Gamma(m_M+l_1)} \left[P_1 - \sum_{l_2=0}^{m_E+l-1} \frac{\tilde{b}^{l_2}}{l_2!}P_2\right] \tag{15}$$

Journal Pre-proofs

where $P_1 = b^{-m_M-l_1}\Gamma(m_M+l_1)\log_2(e)\left[\psi(m_M+l_1)-\ln(b)\right]$ and $P_2 = (b+\tilde{b})^{-\mathcal{T}}\Gamma(\mathcal{T})\log_2(e)\left[\psi(\mathcal{T})-\ln\left(b+\tilde{b}\right)\right]$. Similarly, solution to $I_2^{\rightarrow\infty}$ is obtained by doing the replacement of suffix as $M \longleftrightarrow E$ in (15).

$$I_3^{\rightarrow\infty} = \exp\left(-\frac{\lambda_E^2}{2}\right)\sum_{l_1=0}^{\infty}\frac{\log_2(e)\left(\frac{\lambda_E}{\sqrt{(2)}}\right)^{2l_1}}{\Gamma(l_1+1)}\left[\psi(m_E+l_1)-\ln\left(\tilde{b}\right)\right] \tag{16}$$

Further at low SNR $\gamma \to 0$, $\log_2(1+\gamma) \approx \gamma\log_2(e)$, thus utilising the previous definition in 6, it follows immediately that

$$\bar{S}_c^{\rightarrow 0} = \log_2(e)\left[\underbrace{\int_0^{\infty}\gamma_M f_M(\gamma_M)F_E(\gamma_M)d\gamma_M}_{I_1^{\rightarrow 0}} + \underbrace{\int_0^{\infty}\gamma_E f_E(\gamma_E)F_M(\gamma_E)d\gamma_E}_{I_2^{\rightarrow 0}} - \underbrace{\int_0^{\infty}\gamma_E f_E(\gamma_E)d\gamma_E}_{I_3^{\rightarrow 0}}\right] \tag{17}$$

Substituting (2) and (4) into $I_1^{\rightarrow 0}$, setting $\sqrt{\gamma} = t$, and finally utilising the identities [28, eq. (8.352.1)] and [30, eq. (2.15.5.4)], one obtains

$$I_1^{\rightarrow 0} = \mathcal{A}_M e^{-\frac{\lambda_E^2}{2}}\sum_{l=0}^{\infty}\frac{\left(\frac{\lambda_E}{\sqrt{2}}\right)^{2l}(m_E+l-1)!}{\Gamma(l+1)\Gamma(l+m_M)}\left[\bar{P}_1 - \sum_{l_2=0}^{m_E+l-1}\frac{\tilde{b}^{l_2}}{l_2!}\bar{P}_2\right] \tag{18}$$

where $c = \sqrt{2b}\lambda_M$, $\bar{P}_2 = \frac{c^{m_M-1}\Gamma(m_M+l_2+1)}{2^{m_M-1}(b+\tilde{b})^{m_M+l_2+1}\Gamma(m_M)}{}_1F_1\left(m_M+l_2+1; m_M; \frac{c^2}{4(b+\tilde{b})}\right)$, and $\bar{P}_1 = \frac{c^{m_M-1}\Gamma(m_M+1)}{2^{m_M-1}b^{m_M+1}\Gamma(m_M)}{}_1F_1\left(m_M+1; m_M; \frac{c^2}{4b}\right)$. The result for $I_2^{\rightarrow 0}$ is deduced by replacing the suffix $M \longleftrightarrow E$ in (18).

The closed-form solution to $I_3^{\rightarrow 0}$ is obtained by putting (2) into $I_3^{\rightarrow 0}$ and employing the identity [30, eq. (2.15.5.4)] as

$$I_3^{\rightarrow 0} = \mathcal{A}_E\frac{\hat{c}^{m_E-1}\Gamma(m_E+1)}{2^{m_E-1}\tilde{b}^{m_E+1}\Gamma(m_E)}{}_1F_1\left(m_E+1; m_E; \frac{\hat{c}^2}{4\tilde{b}}\right) \tag{19}$$

where $\hat{c} = \sqrt{2\tilde{b}}\lambda_E$.

3.2. Secrecy outage probability

The probability of outage occurs when instantaneous secrecy capacity falls below a target secrecy rate. Thus, it is defined as

$$P_{out}(R_s) = \mathcal{P}(C_s < R_s) \tag{20}$$

where the secrecy rate R_s is expressed in terms of threshold SNR γ_{th} as $R_s = \log_2(1+\gamma_{th})$. After performing mathematical manipulations, (20) can be defined as [1, eq. (27)]

$$\begin{aligned} P_{out}(\gamma_{th}) &= \mathcal{P}\left[\gamma_M \le (1+\gamma_{th})(1+\gamma_E) - 1\right] \\ &= \int_0^{\infty} f_E(\gamma_E) F_M(\gamma_{th} + \gamma_{th}\gamma_E + \gamma_E) d\gamma_E \end{aligned} \tag{21}$$

Plugging (2) and (4) into (21) and employing [28, eq. (8.352.1)], it immediately follows

$$P_{out}(\gamma_{th}) = \mathcal{B}\begin{cases} \int_0^{\infty} f_E(\gamma_E) d\gamma_E - e^{-b\gamma_{th}} \sum_{l_2=0}^{m_M+l-1} b^{l_2} \dfrac{\mathcal{A}_E}{l_2!} \\ \int_0^{\infty} \gamma_E^{\frac{m_E-1}{2}} (\gamma_{th} + \gamma_{th}\gamma_E + \gamma_E)^{l_2} e^{-\chi\gamma_E} I_{m_E-1}\left(\sqrt{2\tilde{b}\gamma_E}\lambda_E\right) d\gamma_E \end{cases} \tag{22}$$

where $\mathcal{B} = e^{-\frac{\lambda_M^2}{2}} \sum_{l=0}^{\infty} \dfrac{\left(\frac{\lambda_M}{\sqrt{2}}\right)^{2l} (m_M + l - 1)!}{\Gamma(l+1)\Gamma(l+m_M)}$ and $\chi = b(1+\gamma_{th}) + \tilde{b}$. Next, using the binomial expansion with the aid of [28, eq. (1.111)], setting $\gamma_E = t^2$ and [30, eq. (2.15.5.4)], one can deduce the analytical expression of SOP as

$$P_{out}(\gamma_{th}) = \mathcal{B}\begin{cases} 1 - e^{-b\gamma_{th}} \sum_{l_2=0}^{m_M+l-1} b^{l_2} \dfrac{\mathcal{A}_E}{l_2!} \sum_{k=0}^{l_2} \binom{l_2}{k} {\gamma_{th}}^{l_2-k} (1+\gamma_{th})^k \\ \dfrac{\hat{c}^{m_E-1}\Gamma(m_E+k)}{2^{m_E-1}\chi^{m_E+k}\Gamma(m_E)} {}_1F_1\left(m_E+k; m_E; \dfrac{\hat{c}^2}{4\chi}\right) \end{cases} \tag{23}$$

Further assuming that both destination and Eve nodes are super close to source such that received instantaneous SNR γ_M and γ_E are high, then usually the lower-bound of the SOP $SOP_L(\gamma_{th})$ is considered. The development for $SOP_L(\gamma_{th})$ is as follows

$$P_{out}(\gamma_{th}) \ge SOP_L(\gamma_{th}) = \int_0^{\infty} f_E(\gamma_E) F_M(\gamma_{th} + \gamma_{th}\gamma_E) d\gamma_E \tag{24}$$

Plugging (2) and (4) into (24), employing [28, eq. (8.352.1)], it immediately follows

$$SOP_L(\gamma_{th}) = \mathcal{B} - \mathcal{B}e^{-b\gamma_{th}} \sum_{l_2=0}^{m_M+l-1} b^{l_2} \frac{\mathcal{A}_E \gamma_{th}^{l_2}}{l_2!} \int_0^{\infty} \gamma_E^{\frac{m_E-1}{2}} (1+\gamma_E)^{l_2} e^{-\hat{b}\gamma_E} I_{m_E-1}\left(\sqrt{2\tilde{b}\gamma_E}\lambda_E\right) d\gamma_E \quad (25)$$

where $\hat{b} = b\gamma_{th} + \tilde{b}$. Similarly, following the identical steps as stated in (22)-(23), the lower-bound of SOP is eventually deduced as

$$SOP_L(\gamma_{th}) = \mathcal{B}\left\{1 - e^{b\gamma_{th}} \sum_{l_2=0}^{m_M+l-1} b^{l_2} \frac{\mathcal{A}_E \gamma_{th}^{l_2}}{l_2!} \sum_{k=0}^{l_2} \binom{l_2}{k} \frac{\hat{c}^{m_E-1}\Gamma(m_E+k)}{2^{m_E-1}\hat{b}^{m_E+k}\Gamma(m_E)} {}_1F_1\left(m_E+k; m_E; \frac{\hat{c}^2}{4\hat{b}}\right)\right. \quad (26)$$

The previous derived solution is valid only for integer values of m_M. Thus, more generalised solution $SOP_L(\gamma_{th})$ can be deduced by putting (2) and (4) into (21) and employing identities [28, eq. (8.445)] and [30, eq. (2.10.3.2)]

$$\begin{aligned} SOP_L(\gamma_{th}) = e^{-\left(\frac{\lambda_M^2}{2}+\frac{\lambda_E^2}{2}\right)} \sum_{l=0}^{\infty} \frac{\left(\frac{\lambda_M}{\sqrt{2}}\right)^{2l}}{\Gamma(l+1)\Gamma(m_M+l)} \sum_{l_1=0}^{\infty} \frac{\left(\frac{\lambda_E}{\sqrt{2}}\right)^{2l_1}}{\Gamma(l_1+1)\Gamma(m_E+l_1)} \\ \times \frac{\bar{\chi}^{m_M+l}\Gamma(m_M+m_E+l+l_1)}{(m_M+l)\tilde{b}^{m_M+l}} {}_2F_1\left(m_M+l, m_M+m_E+l+l_1; m_M+l+1; -\frac{\bar{\chi}}{\tilde{b}}\right) \end{aligned} \quad (27)$$

where $\bar{\chi} = b(1+\gamma_{th})$ and ${}_2F_1(.)$ is the Gauss hypergeometric function.

3.3. Strict positive secrecy capacity

Existence of the SPSC is guaranteed when $R_s = 0$, thus it can be defined using [1, eq. (19)] as

$$\begin{aligned} P_0 &= \mathcal{P}(C_s > 0) \\ &= 1 - \underbrace{\int_0^{\infty} F_M(\gamma_E) f_E(\gamma_E) d\gamma_E}_{I_7} \end{aligned} \quad (28)$$

Now substituting (2) and (4) into the integral part of (28), setting $\gamma_E = t^2$, and finally employing [28, eq. (8.352.1)] and [30, eq. (2.15.5.4)] results

$$I_7 = \mathcal{B}\left[1 - \mathcal{A}_E \sum_{k=0}^{m_M+l-1} \frac{b^k \hat{c}^{m_E-1}\Gamma(m_E+k)}{2^{m_E-1}k!(b+\tilde{b})^{m_E+k}\Gamma(m_E)} {}_1F_1\left(m_E+k; m_E; \frac{\hat{c}^2}{4(b+\tilde{b})}\right)\right] \quad (29)$$

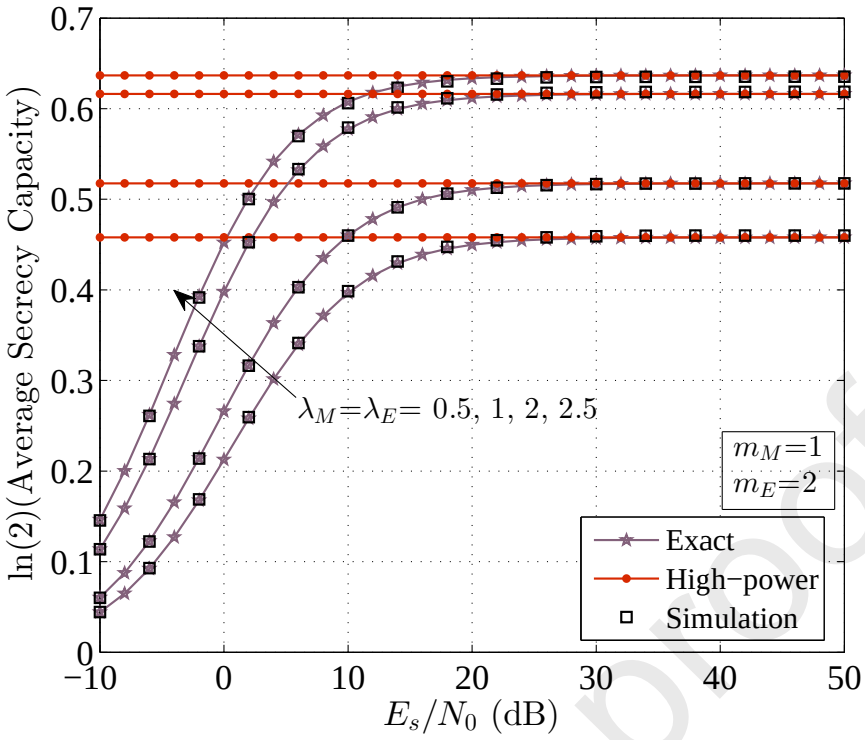

Figure 2: ASC as a function of E_s/N_0 for various values of λ_M and λ_E.

Plugging (29) into (28), one can easily deduce the analytical expression of the SPSC.

4. Numerical analysis

In the present section, the numerical results obtained in the preceding sections are plotted and discussed. Useful insights into the system performance has also been provided. Monte-Carlo simulations are used to verify the accuracy of the solutions provided here. In the Monte-Carlo simulations 10^6 random samples are generated, which are sufficient for the desired accuracy of the proposed methodology.

In Fig. 2, the ASC versus E_s/N_0 for different values of λ_M and λ_E is depicted. It can be seen that with the initial increase in E_s/N_0, the value of ASC increases and the plots get saturated with further increase in E_s/N_0. Early saturation in the value of ASC is attained for higher values of λ_M and λ_E. The high power approximation plots are also shown along with simulation plots. The analytical plots exactly match with their simulated counterpart. The variation of ASC with different values of m_M and m_E is shown in Fig. 3. The similar behaviour of ASC as discussed in Fig.1 is observed with the different fading parameters. It is noticed that as the channel severity increases the communication on the main channel becomes more secure. In 5G applications most of the devices operate in low-power mode. For this reason the low SNR ASC results are

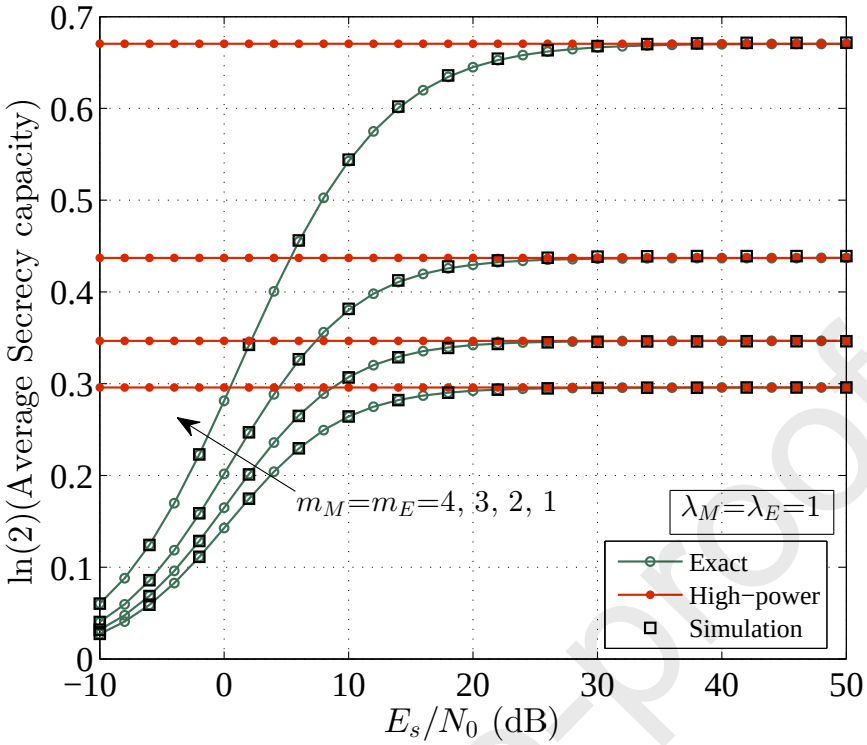

Figure 3: ASC as a function of E_s/N_0 for various values of m_M and m_E.

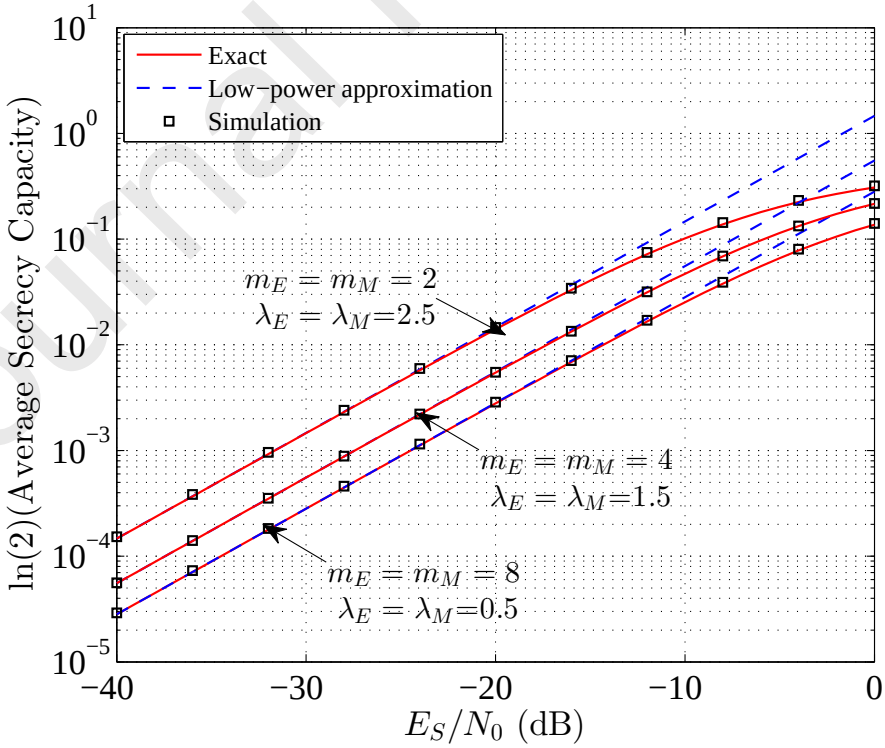

Figure 4: Low-power ASC as a function of E_s/N_0 with different fading parameters.

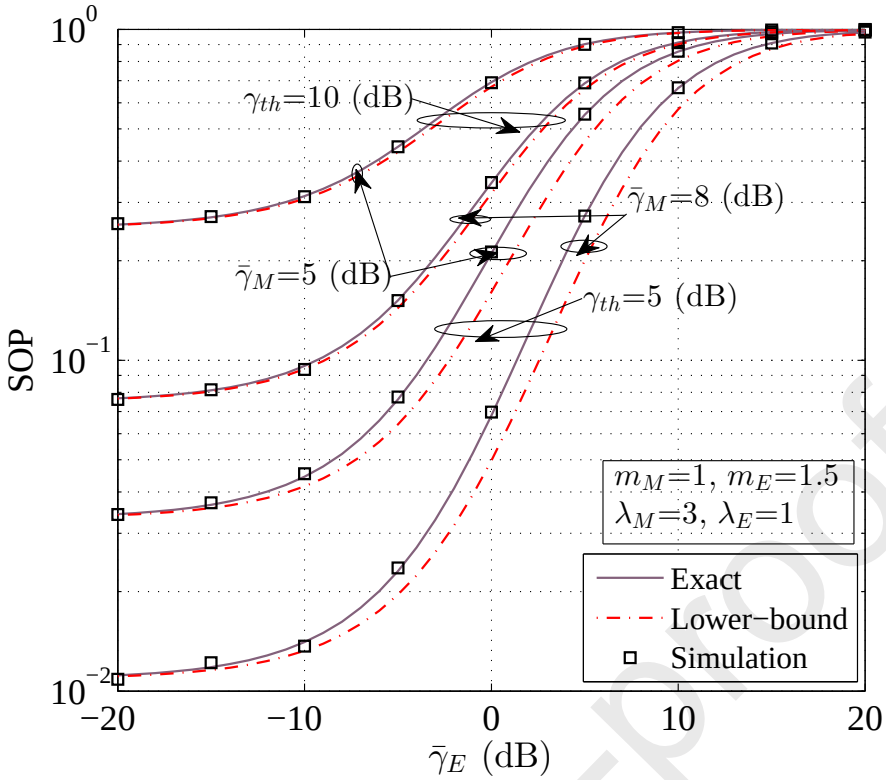

Figure 5: SOP and lower bound of SOP as a function of $\bar{\gamma}_E$

demonstrated in Fig. 4, where plots perfectly follow the simulation results at low SNR.

The SOP plots are shown in Fig. 5 and Fig. 6. As shown in Fig. 5, the plot shifts upwards with an increase in γ_{th} while it move downwards with increase in $\bar{\gamma}_M$. The lower bound of SOP plot exactly matched with the SOP plot for lower values of $\bar{\gamma}_E$ and the gap between the two increases with increase in $\bar{\gamma}_E$. It is clearly seen from the plots that the difference between the SOP and lower bound of SOP is decreasing with increase in γ_{th} while the opposite behaviour is observed for $\bar{\gamma}_M$. As shown in Fig. 6 the gaps between the SOP and its lower-bound are less for small values of $\bar{\gamma}_E$. The variation of SPSC for different values of system parameters are shown in Fig. 7. As expected, the SPSC decreases with the increase in severity fading parameter, m of the main or/and the wire-tap channels while it increases with the increase in the value of $\bar{\gamma}_M$. The simulation results almost match with the closed-form results, verify the accuracy of the proposed methodology. Finally, we remark that the results achieved in this section strongly support the concept of secure communication over the main channel in severe fading scenarios.

5. Conclusion

In this study, the impact of Beaulieu-Xie channel fading parameters on the physical layer security performance matrices has been investigated. The work derived the closed-form ex-

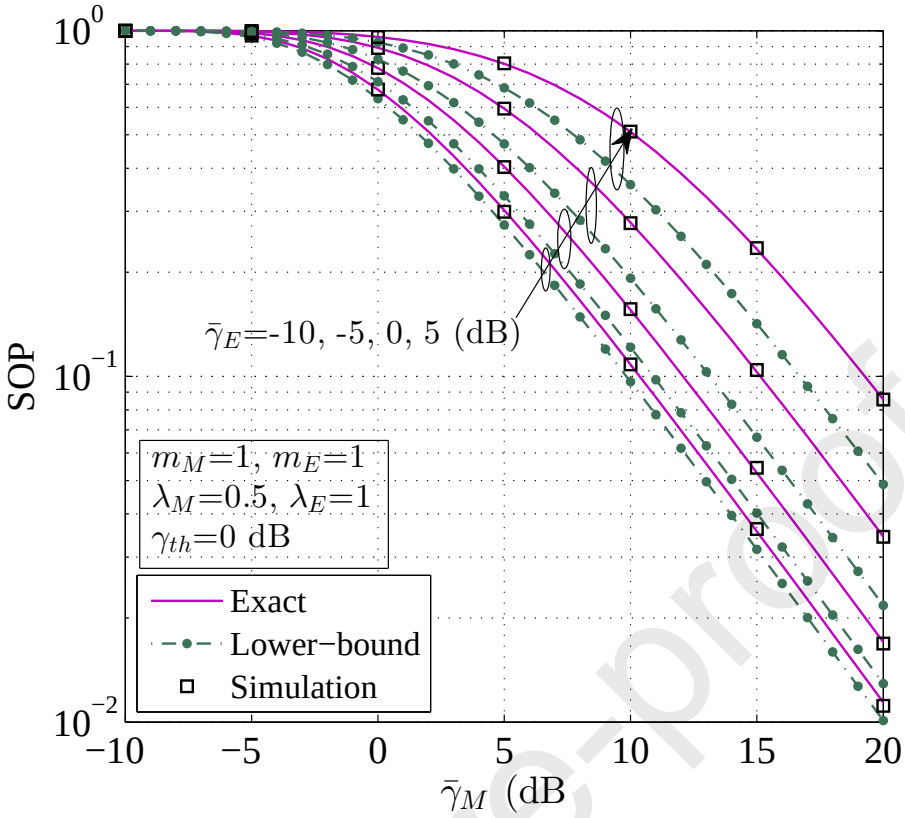

Figure 6: SOP and lower bound of SOP as a function of $\bar{\gamma}_M$

Journal Pre-proofs

pressions for ASC, SOP, lower-bound of SOP, and SPSC. To get more insight into the system, the high power analysis of the ASC has been provided. The low SNR ASC results were also produced for low power 5G network applications. Besides, the impact of different fading parameters on the system matrices a investigated. Finally, our theoretical results were verified via extensive Monte Carlo simulations. It has been observed that the expressions obtained in this work can be easily evaluated using the standard mathematical software packages such as MATLAB and MATHEMATICA..

Keywords: Bio diesel, Cooking oil, Alternative fuel, CI Engine

Abstract
Compression ignition (CI) engine is the un-debated choice for power applications, stationary or mobile. There is an urgent need of alternative high potential fuel for CI engines in order to fulfill energy needs without hampering the thermal performance and stringent emission standards. Here waste cooking oil is chosen as an alternative fuel, which is upgraded into biodiesel in the laboratory using mechanical stirring and ultrasonic cavitation technique of biodiesel production.
Four blends of cooking oil are made by increasing 20% its amount in conventional diesel fuel. Performance is analyzed for two compression ratios, 15 and 17.5, on the existing VCR diesel engine set up interfaced with "Engine Soft" software. The results show that as bio-diesel concentration in a blend increases, the thermal performance (i.e., brake thermal efficiency) and emissions (i.e., CO, HC and NOx, and smoke intensity) are observed to be marginally higher; on the other hand, as compression ratio increases, the thermal performance improves; CO and smoke opacity decreases.

1.Introduction

The scarcity of fast diminishing resources of fossil fuels, increasing prices of crude oil, and environmental concerns have been the various reasons for exploring the use of vegetable oils as alternative to diesel oil [1-4]. Vegetable oils offer almost the same output with slightly lower thermal efficiency when used in diesel engines [5]. Reduction of engine emissions is a major research aspect in engine development with the increasing concern over environmental protection and the stringent exhaust gas regulation [6]. The use of neat vegetable oils poses some problems such as coking and trumpet formation on the injectors, carbon deposits, oil ring sticking and thickening and gelling of lubricating oil, when subjected to prolonged usage in CI engines. These problems are attributed to high viscosity, low volatility and polyunsaturated character of vegetable oils [7]. Some of the common problems posed by using vegetable oils in diesel engines are as a result of contamination by the vegetable oils Different methods such as preheating, blending and trans stratification are being used to reduce the viscosity and to produce bio-diesel, suitable for engine applications. In the present investigation, bio-diesel is prepared from waste cooking oil. The performance and emission characteristics were studied on a four-stroke, single cylinder, variable compression ratio direct-injection diesel engine to ensure its suitability as CI engine fuel.

2. Experimental System Development for Bio Diesel Production

2.1 Methodology

Huge quantities of waste cooking oils and animal fats are available throughout the world, especially in the developed countries. Management of such oils and fats pose a significant challenge because of disposal problems and possible contamination of the water and land resources. Even though some of this waste cooking oil is used for soap production, a major part of it is discharged into the environment. The use of waste cooking oil as a biodiesel source has a potential to reduce CO2, particulate matter and other greenhouse gases as the carbon contained in biomass-derived fuel is largely biogenic and renewable.
Waste cooking oil, which is otherwise wasted, is one of the most economical choices to produce biodiesel. It is recognized that the production of waste cooking oil will be the function of the frying temperature and length of use as well as the material used for frying. In this experiment, waste cooking oil was collected from an hotelier industry.

2.2 Magnetic Stirring Technique

In this process mixing of oil and alcohol is done by a magnetic stirrer. A magnetic capsule is dipped in the immiscible liquid (oil and alcohol are not miscible with each other), as the capsule starts rotating, a whirl is formed which disturb the phase boundary between two immiscible liquid and resulted in emulsification of mixture. Magnetic stirrer used is as shown in figure 1.

Fig. 1: Mechanical Stirrer

2.3 Ultrasonic Cavitation Technique

Methanol is immiscible with the cooking oil. The mixture of oil, methanol and catalyst is poured in ultrasonic processor transducer (model TU-50). Test is performed for the ultrasonic frequency (28.5 KHz). During the reaction the temperature of mixture is kept between 45-60^{0}C When reaction is completed the beaker is kept for the separation. Fatty acid has higher specific weight therefore it will settle at bottom. Separation of methyl ester and glycerol will take 2 to 3 hr duration. After complete separation bio-diesel (methyl Ester) is visible in the upper layer and glycerol at the bottom as shown in figure 2.. Bio-diesel is separated from beaker for purification process. The catalyst present in the methyl ester is impurity. Excess methanol present in biodiesel has been removed by vaporization process.

3. Experimental Setup

The setup consists of single cylinder, four stroke, VCR (Variable Compression Ratio) Diesel engine connected to eddy current type dynamometer for loading. The compression ratio can be changed without stopping the engine and without altering the combustion chamber geometry by specially designed tilting cylinder block arrangement. Provision is also made for interfacing airflow, fuel

flow, temperatures and load measurement. The setup has stand-alone panel box consisting of air box, two fuel tanks for duel fuel test,manometer, fuel measuring unit, transmitters for air and fuel flow measurements, process indicator and engine indicator. Rota meters are provided for cooling water and calorimeter water flow measurement. The setup enables study of VCR engine performance for brake power, indicated power, frictional power, BMEP, IMEP, brake thermal efficiency, indicated thermal efficiency, Mechanical efficiency, volumetric efficiency, specific fuel consumption, A/F ratio and heat balance. The blends B20, B-40, B-60, B-80 and B100 were prepared in the laboratory by mixing appropriate volume of diesel with waste cooking oil.

Fig. 2: Biodiesel from WCO

A set of reading was obtained first by running the engine with diesel at CR of 17.5 and varying the load from idle to rated load of 3.5 KW in steps of 1 up to 3 KW and then to 3.5 KW. The engine performance characteristics were recorded by using the software Engine Soft and instrumentation provided by the National Instruments. The emissions were recorded for each load by using Gas Analyzer (Model: AVL DI Gas 444) and the opacity was recorded by Smoke meter (Model: AVL 437).

The engine was started at compression ratio of 17.5 and then the compression ratio was changed by using the tilting head arrangement. The compression ratio was indicated by the rings made on the lever of the arrangement. The VCR engine test rig is shown in figure 3.

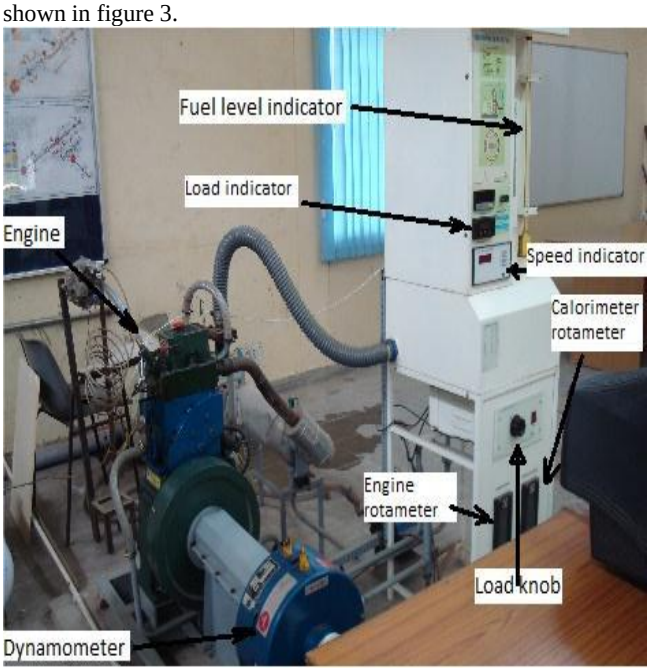

Fig. 3: VCR Engine Test Rig

4. Results and Discussion

4.1 Engine Performance

4.1.1 Brake Power

The effect of variation of brake power output at two different compression ratios has been studied for thermal performance (in terms of brake thermal efficiency, specific fuel consumption, mechanical efficiency volumetric efficiency) and emissions (in terms of carbon-monoxide, nitrogen oxides, hydrocarbons emissions and smoke opacity.

4.1.2 Brake Specific Fuel Consumption

Brake specific fuel consumption (bsfc) as a function of load obtained during engine operation on bio-diesel blends and diesel fuel at compression ratio of 17.5:1 is shown in Figure 4. For all fuels tested, bsfc decreased with increase in load at both compression ratios. At the compression ratio 15: 1, the bsfc of 0.29 kg/kWh was obtained for the Diesel fuel and at compression ratio 17.5:1 the bsfc of 0.27kg/kW/h. The data showed that at higher compression ratio there is slightly decrease in brake specific fuel consumption., the fuel blends B20 maintain about the same bsfc as that of diesel fuel, The brake specific fuel consumption at compression ratio 17.5:1 at B40 and brake specific fuel consumption at compression ratio 15:1 at B20 are same i.e 0.31kg/Kw/h. The reason for the above trend is more likely due to lower calorific values of bio-diesel blends compared to those of neat diesel [8]. So in order to produce equivalent power to that of diesel more bio-diesel blended fuel is required. The reason for increase in bsfc for all loads is the lower calorific value of bio-diesel blends than pure diesel.

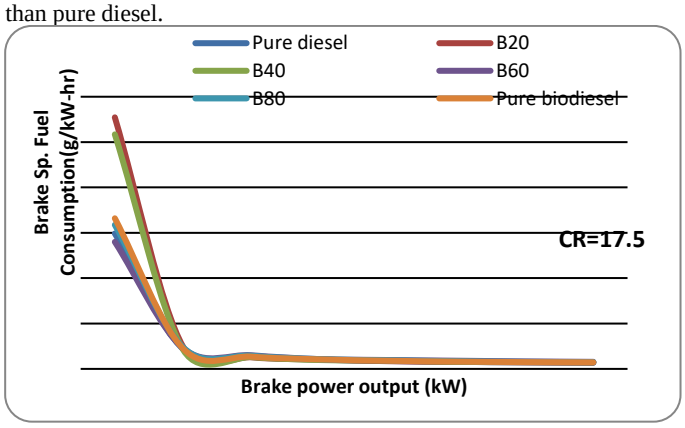

Figure 4: bsf vs. BP at CR 17.5:1

4.1.3 Brake Thermal Efficiency

The brake thermal efficiency increases with an increase in load at different compression ratios and at various biodiesel blends. This can be attributed to reduction in heat loss and increase in power with increase in load. The maximum brake thermal efficiencies obtained is about 31.18% for B40 at 17.5:1 and at 15:1 the brake thermal efficiencies is about 29.77% as shown in figure 5.

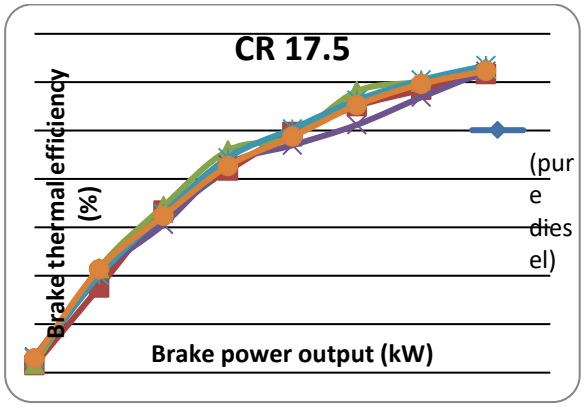

Figure 5 Break thermal efficiency at CR 17.5:1

This shows that at lower compression ratio there is decrese of 1.41% for the B40 biodiesel blends. The mixing of bio-diesel in diesel oil yields good thermal efficiency curves. Initially the thermal efficiency of the engine is improved by increasing concentration of the bio-diesel in the blend. The possible reason for this is the additional lubricity provided by bio-diesel. The molecules of bio-diesel (i.e. methyl ester of the oil) contain some amount of oxygen,

which takes part in the combustion process. It is noticed that after a certain limit with respect to diesel ester blend, the thermal efficiency trend is reversed and it starts decreasing as a function of the concentration of blend.

4.2 Emission Parameters

4.2.1 Carbon Monoxide

Figure 6 shows the plots of carbon monoxide (CO) emissions of blends and diesel fuel at different load conditions and compression ratio of 17.5:1.

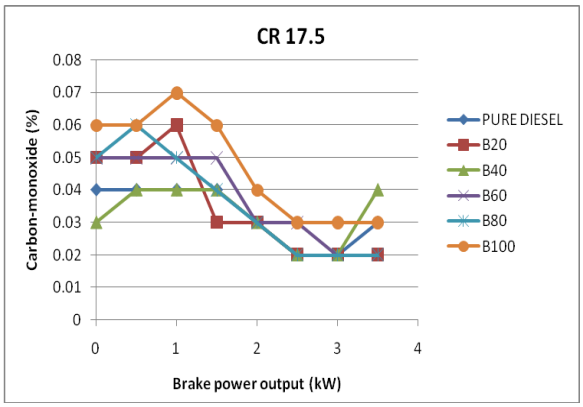

Figure 6 CO emissions at CR 17.5:1

This is typical with all internal combustion engines since air/fuel (A/F) ratio decreases with increased load. Also the data showed increase in CO emissions as the load was increased up to 50% when running on bio-diesel blends.

4.2.2 Un- burnt Hydrocarbon

The emission of un-burnt hydrocarbons (HC) for all fuels and compression ratios is small, 25-122 ppm, increasing slightly with load and proportion of fuel injected. It is quite difficult to determine any reliable dependencies; the waste cooking oil operation showed very low HC emissions throughout the load range. The plot indicates that HC emissions peaked at a particular A/F ratio and then dropped with further increase in load. The plot showed increase in HC emissions as the quantity of diesel fuel in the blend increases. A very significant difference was noted at low and high load conditions at the compression ratio 17.5:1 as shown in figure 7.

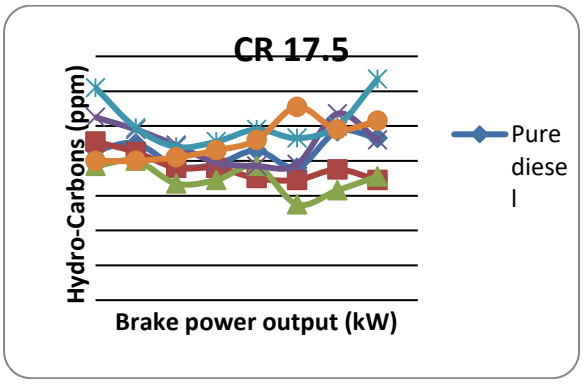

Fig. 7. HC emissions at CR 17.5:1

The increase in diesel/WCO blend showed highest HC concentration in the exhaust when compared with the results of increase in WCO/diesel blend. However at light load, the biodiesel blends did not show any marked difference in HC emissions irrespective of compression ratios. For minimum load the reduction was practically unaffected by the addition of bio-diesel in the diesel fuel at all Compression ratios. The most beneficial reduction appeared at intermediate loads. Hydro carbon emissions as a function of engine load at various compression ratios.

4.2.3 Oxides of Nitrogen

The emission of nitric oxide (NO) increases gradually with load, (figure 8) reaching the maximum values of 1578 ppm for blend80 at compression ratio 17.5:1 and its value decreases to 1478 ppm for blend 100 at the same compression ratio When operating at the compression ratio of 15:1, the minimum NO emissions at adequate loads were maintained by the B20 blend. Biofuels with higher oxygen contents, 1.45% to 4.075%, and neat bio-diesel produce higher or a bit lower NO emissions, depending on the load.

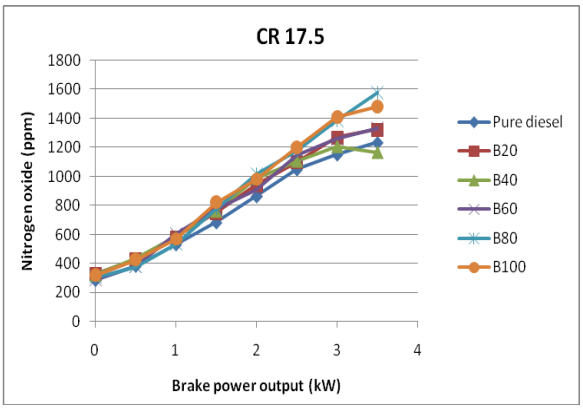

Figure 8. NO emissions at CR 17.5:1

The reason for the decrease in NO was that the cetane number of the bio-diesels was higher than that for diesel fuel and this is associated with lower NO emissions [9]. Increasing cetane number reduces the size of the premixed combustion by reducing the ignition delay. This results in lower NO formation rates since the combustion pressure rises more slowly, giving more time for cooling through heat transfer and dilution and leading to localized gas temperatures [9].Furthermore the emission of nitrogen oxide from engine exhaust are highly dependent on oxygen concentration and thus the combustion temperature.

4.2.4 Smoke Opacity

The smoke (soot) opacity with brake mean effective pressure of exhaust gas for neat diesel fuel and bio-diesel blends is shown in figure 9.

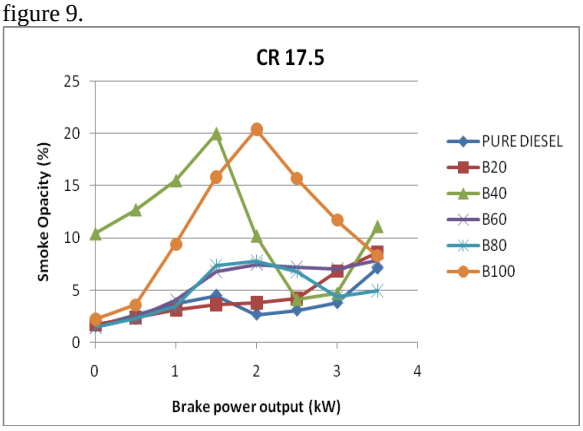

Figure 9 Smoke Opacity at CR 17.5:1

One can observe that soot emitted by all bio-diesel blends is lower than neat diesel at low loads and lower compression ratio. This is attributed to the combustion being mixed controlled for these blends, as is also the case for neat diesel, which is however assisted by the presence of the fuel bound oxygen [10]. However, there is no definite trend observed in smoke density with increase in blend percentage of bio-diesel. At all compression ratios, B100 was found to emit maximum smoke at full load. The minimum and maximum smoke opacities produced for B60 and B100.The smoke emissions generally increase or decrease in relation to the sulphur concentration. Sulphur in the fuel, results in sulphates that are absorbed on soot particles and increase the smoke emitted from diesel engines. In addition, the increase of oxygen content in the

fuel contributes to a complete fuel oxidation even in locally rich zones, leading to a significant decrease of smoke [9-10].

5. Conclusions

Four blends of cooking oil are made by increasing 20% its amount in conventional diesel fuel. Performance is analyzed for two compression ratios, 15 and 17.5, on the existing VCR diesel engine set up interfaced with "Engine Soft" software. The results show that as bio-diesel concentration in a blend increases, the thermal performance (i.e., brake thermal efficiency) and emissions (i.e., CO, HC and NOx, and smoke intensity) are observed to be marginally higher; on the other hand, as compression ratio increases, the thermal performance improves; CO and smoke opacity decreases.

ABSTRACT : *A magnetorheological fluid is a type of smart fluid which when subjected to a magnetic field, its viscosity tends to increase. The overall purpose of the research carried out in this paper is to develop low cost MR fluids without affecting its important characteristics such as sedimentary stability and a suitable increase in viscosity with increase in magnetic field. Two MR fluids were prepared and compared on the basis of their performance in the sedimentary stability test. Also, an experiment was conducted to see how the viscosity of the fluid reacted to change in the magnetic field. With the help of these two experiments, it is shown that one of the fluids can be used for practical purposes.*

Keywords: *Magnetorheological, Magnetoviscometer, Sedimentation, Surfactant, Viscosity*

I. INTRODUCTION

The advent of microprocessors and electronic technology has allowed us to incorporate electronic control into a lot of machines and materials and hence the demand for "smart materials" like Electrorheological and Magnetorheological fluids in applications like Automotive and Biomechanical components is increasing rapidly [1]. However, the magnetorheological fluids available in the market currently do not prove to be financially viable in most of their application and hence the need to develop low cost Magnetorheological fluid. Hence, development of a low cost Magnetorheological fluid is the need of the hour. A lot of work has been done on the use of mineral oils as the carrier fluid [2] in MR Fluids but the work wasn't focused towards reducing the cost of the fluid.

The aim of the organization of this paper is to develop a low cost magnetorheological fluid using carrier fluids like soybean oil and heavy paraffin oil along with Electrolytic Iron particles and suitable surfactants and then conducting tests to determine their suitability for practical purposes.

II. LITERATURE REVIEW

Horia Chiriac and George Stoian [3] have investigated the influence of two aspects which characterize magnetic powders on the magneto rheological (MR) fluids: particles size and particles size distribution. Fe powders were obtained with micrometric particles of different sizes and narrow size distribution by sieving commercially available Fe powder by means of a sieve shaker. Also, three powders with particles having normal size distributions with the same mean size and different variances were tailored using the sieved Fe powders. They prepared MR fluids based on the resulting magnetic powders and studied them by means of a rheometer with a magneto rheological module. Further, a correlation between the MR performance and particles size/particles size distribution was observed. MR fluids in 10% volumic concentrations of magnetic particles in the fluid were prepared using these powders. The MR fluid's behaviour in magnetic field was studied by means of a rheometer provided with a magneto rheological cell. For each fluid, yield stress curves were traced having the magnetic field as parameter, and based on these curves, the dependence of the yield stress as function of applied magnetic

field was plotted. The data indicated that the particles size and also the particles size distribution have an influence on the MR fluid performance.

They found out that greater stress responds to bigger particles. Therefore, there is a direct correlation between yield stress and particle size. But, larger particles lead to a more rapid sedimentation of the solid particles in the fluid, but this problem can be overcome in a large extent by using a suitable formulation of the MR fluid. Also it seems that powder comprising particles with sizes following a Gaussian distribution, it is preferable to have the particles within a narrower size distribution. It was suggested that for future work, to study some magnetorheological fluids with bi-disperse particle mixes using, for example, two powders with particle size situated at the extremities of the normal distribution T.M. Simon et al. [4] have studied the effective magnetic behaviour of an MR composite as a function of the inter-particle distance. They have presented and employed a mathematical model for the effective magnetic properties of MR fluids with periodic microstructure that is based on the theory of homogenization. They have also discussed an interpolating formula for the effective permeability of MR fluids. They have further presented an experimental setup for calculating the permeability of an MR fluid sample from the experimental B-H curve. Experiments were conducted (at the Lord Corporation) to measure the magnetic properties of three MR fluids with particle loadings of l0%, 20%, and 30% by volume. This relation showed good agreement with experimental data Ji Eun Kim et al. [5] measured the MR characteristics of the CI dispersed in PIB/PB by both static and dynamic tests using a rotational rheometer with and without an external magnetic field. Static and dynamic yield stress, shear stress, and storage modulus from the rheological measurements were obtained to be increased with applied magnetic field strengths. The system also showed improved sedimentation stability due to the elastic property of PIB/PB viscoelastic fluid. The CI-PIB/PB based MR viscoelastic fluid was found to overcome the sedimentation problem, demonstrating that the system which consists with a Boger fluid has a potential to be used as an MR fluid without sedimentation.

III. PREPARATION OF FIRST SAMPLE

Magnetorheological fluids consist of three main components namely carrier fluid, additives and ferromagnetic particles. We prepared two samples of the magnetorheological fluid by selecting two different materials for each of the three components.

Magnetic Particles

We did a thorough market research and searched for different types of metal particles, carrier fluids and additives. After completing the survey of the market, we found that sourcing Carbonyl Iron particle which is solely manufactured by BASF, will not justify our aim of manufacturing cost effective MR Fluid. So we went with the best alternative particle that is Electrolytic Iron.

Table II: ***Properties of Magnetic Material***

Carbonyl Iron		Electrolytic Iron	
Iron as (Fe)	99.5%	Iron as (Fe)	> 95%
Apparent Density “Carney”	1.1-1.3g/cc	Apparent Density “Carney”	2.5-2.7g/cc
Particle Size	3-10 µ	Particle Size	20-45 µ

Carbonyl Iron powder has a spherical particles with size between 1-8 microns and has excellent compaction and sintering properties. Moreover it has a high chemical purity (99.5%) and an excellent electromagnetic performance. Electrolytic Iron powder has roughly spherical particle with slightly larger size of 20-45 microns and has a high purity of about (>95%). It also shows decent electromagnetic properties.
Therefore based on the above mentioned properties and due to its easy availability we chose Electrolytic Iron powder. Price of electrolytic iron is $1/10^{th}$ that of carbonyl iron.

Figure 1: Electrolytic Iron Particles

Carrier Fluid

For the purpose of manufacturing a cheaper alternative to the commercially available MR Fluids we decided to use an easily and cheaply available vegetable oil. We made a list of the commonly available mineral oils and noted down their physical properties for the purpose of comparison. The listed comparisons helped us narrow down the list of more than 10 to two oils, coconut and soybean oil.
Properties of commonly available vegetable oils are as follows:

Table III: ***Properties of Carrier Fluid***

Vegetable Oil	**Kinematic viscosity (mm_2/s)**	**Flash Point (ºC)**	**Density (kg/l)**
Coconut	30	230 ºC	0.924
Rapseed	37	246 ºC	0.911
Castor	227	230 ºC	0.961
Palm	36	164 ºC	0.880
Peanut	39.6	271 ºC	0.902

Soybean	32.6	254 ºC	0.914
Sunflower	33.9	174 ºC	0.916
Damper Oil	40	220 ºC	0.860

Although Coconut Oil was the closest to the damper oil in terms of properties but due to its high freezing temperature (25 ºC) we chose the Soybean Oil due to its easy availability and low freezing temperature (-20 ºC).

Figure. 2: Carrier Fluid

Additives

Since the nanoparticles are difficult to procure we decided to use surfactants to improve the sedimentation properties of the MR Fluid.

Commonly available surfactants are:

- Oleic Acid -
  Density: 0.895g/cc, Boiling Point: 360 ºC
  Oleic acid is a fatty acid that occurs naturally in various animal and vegetable fats and oils. It is an odourless, colourless oil, although commercial samples may be yellowish.

- Tetramethyl Ammonium Hydroxide -
  Density: 1.01g/cc, Boiling Point: Decomposes
  Tetramethyl Ammonium Hydroxide (TMAH or TMAOH) is a quaternary ammonium salt and the solid and solutions are colourless, or yellowish if impure.

- Soy Lectin -
  Density: 0.92g/cc, Boiling Point: 150 ºC
  Lecithin is a generic term to designate any group of yellow-brownish fatty substances occurring in animal and plant tissues composed of phosphoric acid, choline, fatty acids, glycerol, glycolipids, triglycerides, and phospholipids
  Lecithin has emulsification and lubricant properties, and is a surfactant.
- Glycerol -
  Density: 1.26g/cc, Boiling Point: 290 ºC
  Glycerol is a simple polyol (sugar alcohol) compound. It is a colourless, odourless, viscous liquid that is widely used in pharmaceutical formulations.

Due to the easy availability and the relatively high boiling point, we decided to use Glycerol as the surfactant.

Figure. 3: Surfactant (Glycerine)

Preparation of MR Fluid

We took 50 ml of the chosen carrier fluid (soya oil) in a beaker. Then we measured 14 gms of iron powder (300 mesh) and added glycerine as a surfactant to it so as the surface tension can be reduced when the iron powder is mixed with the carrier liquid. Then the carrier fluid was mixed with the mixture of iron powder and glycerine. The resulting mixture was 70% by weight of iron. The mixture was then stirred with the help of a electric motor powered fan for 3-4 hrs. The rpm of the fan was fixed at 1400. A similar approach was taken to make a mixture of 60% and 80% by weight of iron.

IV. PREPARATION OF SECOND SAMPLE

Magnetic Particles

We continue using the same magnetic particle as the first sample, that is the electrolytic iron as it satisfies our most criteria.

Carrier Fluid

We had already gone over all the suitable mineral oils in the first sample, so we decided to use synthetic oil as the carrier fluid in the second sample. Many types of synthetic oil satisfy most of the criteria we look for in a carrier fluid, but the viscosity of most mineral oils is highly dependent on temperature which is undesirable[6] and the process of sealing of synthetic oils is tough. Thus, taking into consideration all the desirable properties, we came to the conclusion that Heavy Paraffin oil would be the best choice.

Table IV: ***Properties of Paraffin oil***

Appearance	Colorless and clearly oily liquid free from odour
Solubility	Insoluble in alcohol and water, soluble in chloroform and solvents
Weight/100 ml (in gm)	86
Kinematic Viscosity (37.8 C)	67 CST

The kinematic viscosity of paraffin oil is nearly double to that of the soybean oil (33 CST) we used in the first model.

Surfactant

Since the nanoparticles are difficult to procure we decided to use surfactants to improve the sedimentation properties of MR Fluid. [7]
Commonly available surfactants are:

1. Oleic Acid
2. Glycerol
3. AP 3 Grease.

We chose AP3 Grease because of its anti-friction properties, better stabilizing ability and similar density to that of base liquid i.e. heavy Paraffin oil.

Preparation Technique

Apparatus

For the preparation of Magneto Rheological Fluid material, we designed and fabricated an electrical stirrer as shown in the Fig. 4. The stirrer has an RPM range of 1400 -1800.

Figure 4: Mechanical Stirrer

We also prepared a mount to hold the stirrer in position. The stirrer head was machined from Nylon 6 which has four vertical blades which was fixed at the end of the 15cm long rod.

Specifications of the Stirrer:

- 50Hz at 220V
- 1400-1800 RPM
- 50 Wattage
- 4 Nylon-6 blades

Procedure

To prepare the Magneto Rheological fluid samples, the material composition is fixed. From the literary survey it was found that there are two methods by which the constituents of the Magneto Rheological fluid are selected

- Volume Percentage
- Weight Percentage

In this work, the constituents are used as per the volume percentage method. Two samples are prepared by using different volumes of Magneto Rheological fluid components. We varied the percentages of components used in the sample. The levels fixed for preparing those two samples are shown in the Table 5.

Table V: Fluid Composition

Sample Name	Fe Particle (ml)	Paraffin Oil (ml)	Grease (ml)	Vol % of materials w.r.t total fluid volume		
				Fe Particles	Paraffin Oil	Grease
Sample 1	60	120	20	60	30	10
Sample 2	50	140	10	70	25	5

V. EXPERIMENTATION

Sedimentation Rate

Sedimentation is the tendency of the particles in suspension to settle down in the fluid in which they are entrained and come to rest against a barrier. This is due to their motion through the fluid in response to the forces acting on them. These forces may be due to gravity, centrifugal acceleration or electromagnetism. The sedimentation of particles, in the M R Fluid, is determined by neglecting the magnetic effect on the M R Fluid particles. The inherent density difference of the carrier fluid and the iron particles results in the sedimentation of the particles, leaving an upper volume as supernatant fluid (the clarified fluid above the mud line). The upper mud line is the boundary between the supernatant fluid and turbid part of carrier oil. The sedimentation of particles is measured by visually observing the position change of the mud line. [2]

For determination of the sedimentation of the Magneto Rheological Fluid samples, a setup is used and is shown in Fig. 5. This set up contains a tube holding device and a ruler which is placed adjacent to the test tube to measure the height of supernatant fluid. With passage of time, the height of supernatant fluid increases and the height of turbid part decreases.

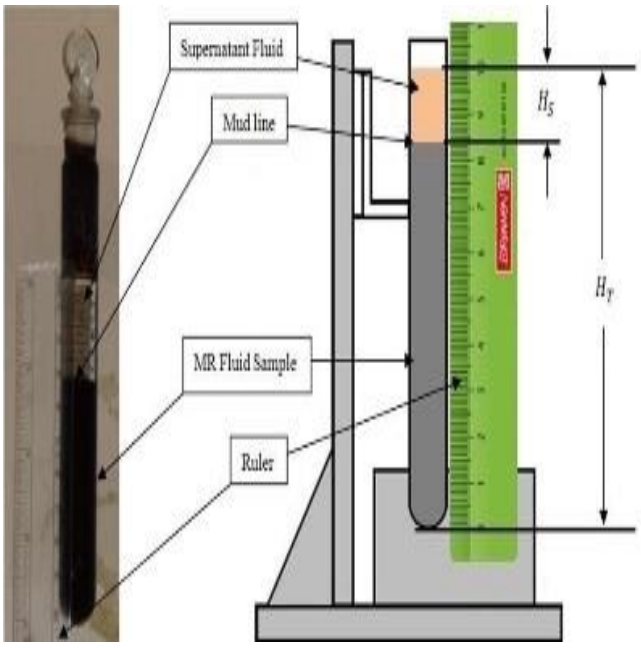

Fig 5: Sedimentation test rig

The sedimentation is observed visually under light to get a clear view of the observation being made for the height of supernatant and the turbid part of the MR Fluid sample 2. Prepared samples were filled up to 10 cm in a cylindrical glass test tube for few hours at vertical stationary position. The height of the supernatant fluid (Hs) is measured after every 5 minutes with the help of ruler and stop watch. Thus, sedimentation ratio (SR) is calculated. The sedimentation ratio is defined as the ratio of the height of the supernatant oil to the total height of the M R Fluid filled and is given as

$$SR = (HS/HT) X 100 \%$$

Where, SR is the sedimentation ratio, HS is the height of supernatant fluid and HT is the total height of fluid filled in the tube. [2]

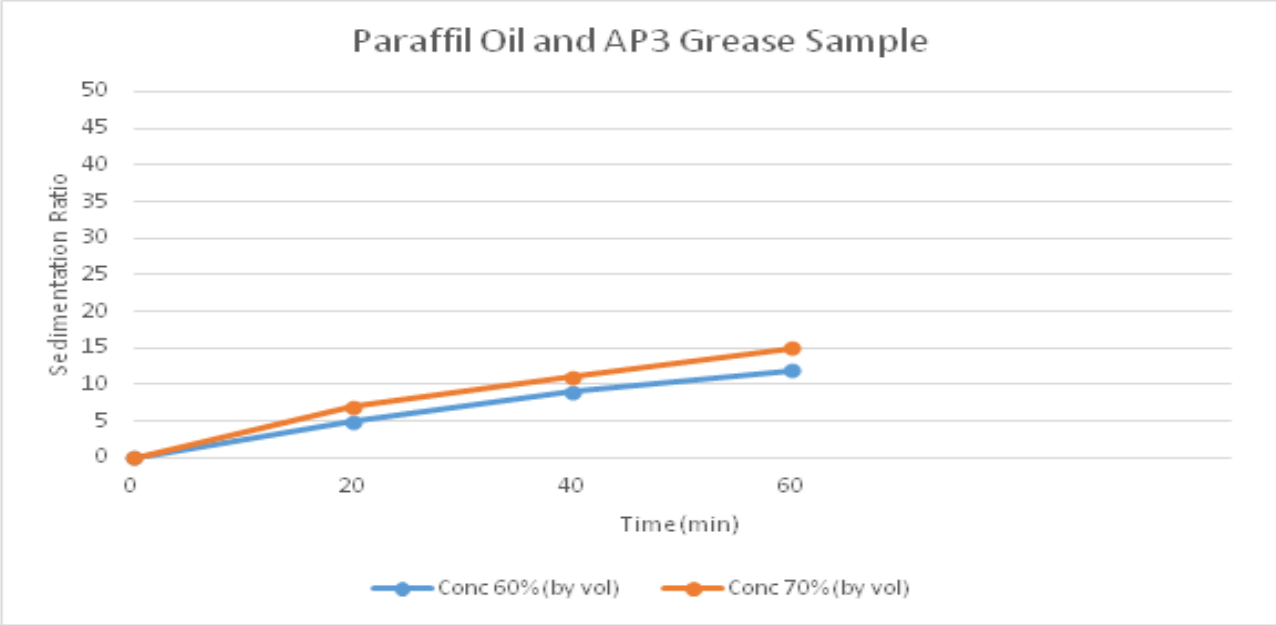

Fig. 6: Sedimentation vs. Time graph (Paraffin Oil and Ap3 Grease)

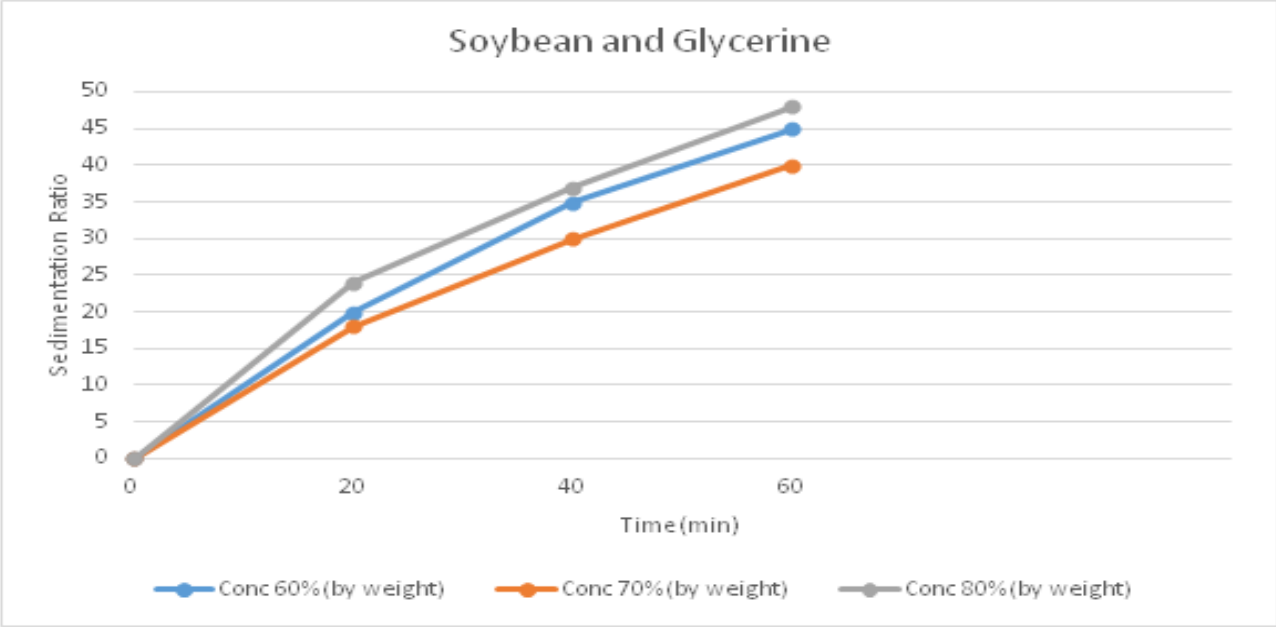

Fig. 7: Sedimentation vs. time graph (Soybean Oil and Glycerin)

Magnetoviscometer

The purpose of this experiment was to determine the coefficient of viscosity of a Magneto-Rheological fluid for different values of the magnetic field and to determine the relationship between them to develop a mechanism for controlling the damping characteristics of an automobile shocker. To determine the coefficient of viscosity, a method of indirect measurement [8] was implemented using a reference fluid with known properties.

Apparatus:

To determine the influence of the magnetic field strength on the viscosity of a fluid, a test stand was constructed, as shown in the Fig. 8. The component parts of the stand are Glass Capillary, Electrical Coil mounted coaxially with the capillary, DC power adapter making it possible to regulate voltage and current, and a manual stop watch for measurement of time. The stand is additionally equipped with magnetic field strength gauge for measurements inside in the capillary, inside the electrical coil.

Fig. 8: Test Stand

The rest of the apparatus is as shown in the figure 9.

- Stand
- Glass Capillary
- Electric Coil
- DC Current Source with means to control voltage and current
- Manual Stop watch
- Gauge of Magnetic field strength with a Hall's Probe
- Observer
- 100ml of MR Fluid sample

Fig. 9: Testing Rig

The coefficient of the viscosity of the magneto-rheological fluid was determined by an indirect method, using paraffin oil as a reference fluid of the known properties. A formula derived by Poiseuille was used for this purpose.

$H = (\rho.t)/ (\rho_g.t_g) X \eta_g$

where:

ρ – Density of the Magnet- Rheological fluid.

T – Outflow time of magneto-rheological fluid from the capillary

ρ_g – Density of reference fluid

t_g – outflow time of the reference fluid from the capillary

η_g – viscosity coefficient of the reference fluid

Procedure

1. The capillary was at first filled with the reference fluid and the capillary was allowed to drain off completely and the time taken by it to drain off was measured with the help of the stop watch.
2. The capillary was then filled with the MR fluid sample and the time taken for the fluid to drain out was measured.
3. Now a magnetic field was applied using a solenoid placed coaxially to the capillary tube. The ends of the solenoid were connected to a DC power source.
4. Step 2 was now repeated for different values of the applied magnetic field by varying the voltage applied to the solenoid.

Observations and Calculations

Table VI: Readings of Viscosity Test

Magnetic Field (mT)	Current (A)	Voltage (V)
0.4	0.1	1.0
0.5	0.4	1.5
0.8	1.1	4.0
3.1	1.8	6.5
3.4	2.5	9.0
5.2	3.5	15.0

The value of viscosity for different values of magnetic field is calculated using the given formula.

$H = (\rho.t)/ (\rho_g.t_g) X \eta_g$

Table VII: Viscosity vs. Magnetic field readings

Viscosity (Pascal-sec)	**Magnetic Field (m-Tesla)**
1.98	0
2.3	0.4
2.42	0.8

2.64	3.1
2.79	3.5
2.94	3.9
3.01	4.1
3.45	4.5

A graph is plotted between viscosity and the applied magnetic field.

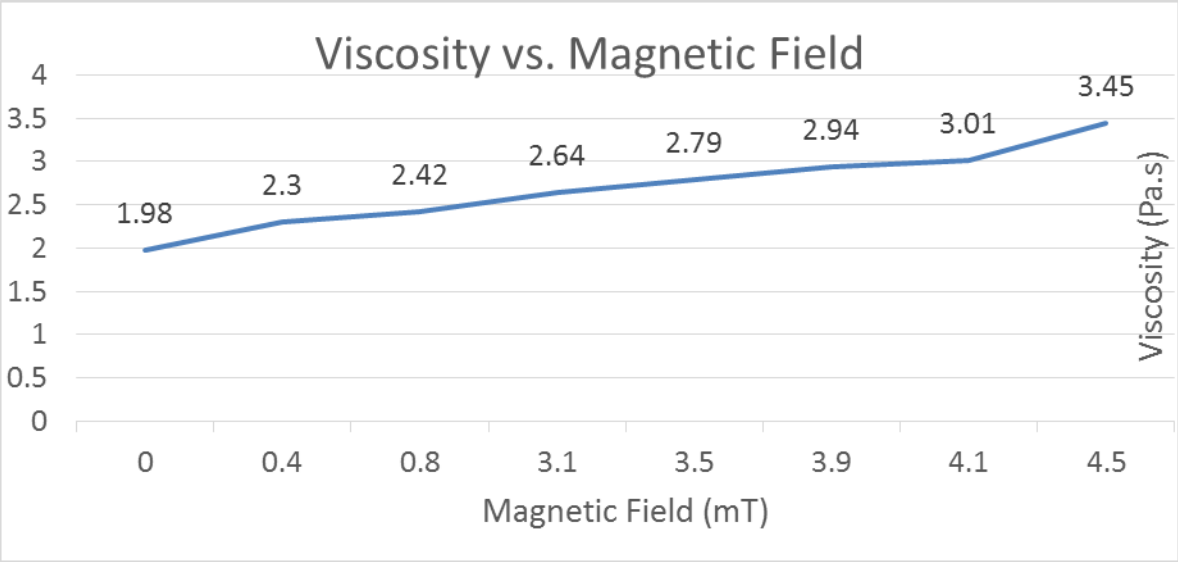

Fig 10: Viscosity vs. Magnetic Field graph

Conclusions

- After performing the sedimentation tests on the different fluid samples, we found that soybean oil and glycerin are not suitable components for making a magneto-rheological fluid. It was also observed that heavy paraffin oil and AP3 grease can be used to prepare a more stable magneto-rheological fluid.
- The aim of the second experiment was to determine the viscosity of a magneto-rheological fluid at different values of the magnetic field. From the graph in Fig. 10, it is clear that the viscosity of the fluid increases with the increasing magnetic field. The theoretical aim of this experiment was to determine this range of viscosity variations that is useful for control purposes.

Resumption of International Civil Nuclear Cooperation

A Diplomatic Triumph based on Strength in Science

1. Introduction

Energy is the driver for economic growth, and of the various options available for carrying energy, electricity is the best from the consideration of convenience of end use. As compared to the size of its population, India is poor in energy resources. Domestic production of crude and gas is very modest, therefore, coal is the mainstay of electricity generation. Considering growing electricity demand, early in this century, it was realised that coal is not going to last beyond this century and it is necessary to look for alternate sources for electricity generation. This realisation was quantified, based on a study by the Department of Atomic Energy, in a report in 2004, which was later published (Grover and Chandra 2006). The study concluded that generation by nuclear needs to be stepped up as soon as possible. However, uranium resources, as estimated at that time, were considered sufficient to support an installed capacity of only 10,000 MW of Pressurised Heavy Water Reactors (PHWRs) and it was concluded that growth in nuclear installed capacity has to come from fast breeder reactors. As we will see later in this paper, an installed capacity of 10,000 MW based on PHWRs is very modest. A two-pronged strategy was formulated by the country: (i) launch aggressive campaign to locate more uranium resources in the country, and (ii) pursue a policy initiative to open international civil nuclear trade with the objective of importing uranium, which was denied to India for not having signed the Treaty on the Non-Proliferation of Nuclear Weapons (NPT).

The NPT divides the globe into 'haves' and 'have-nots' (that is states with, and states without nuclear weapons) and it provides for peaceful nuclear explosions. In early 1970s, the International Atomic Energy Agency (IAEA) organised annual conferences on peaceful application of nuclear explosions. Once India conducted a Peaceful Nuclear Explosion (PNE) in 1974, the concept of peaceful nuclear explosion disappeared from the lexicon on the subject and IAEA stopped organising conferences. According to NPT, states that have built and exploded a nuclear device before 1 January 1967 are classified as Nuclear Weapon States (NWS). After peaceful nuclear explosion by India in 1974, votaries of the NPT cast India "into a netherworld" (Tellis 2005) and it was abruptly denied international collaboration on the peaceful uses of nuclear energy. While the NPT is based on the motto, "early bird gets the nuke" (ElBaradei, 2003), even

now there are calls[1] on India by NPT votaries to sign NPT as a Non-Nuclear Weapon State (NNWS). India's opinion is the direct opposite that India can sign NPT as an NWS, (Fidler and Ganguly 2010).[2]

A two-pronged strategy was formulated by the country: (i) launch aggressive campaign to locate more uranium resources in the country, and (ii) pursue a policy initiative to open international civil nuclear trade with the objective of importing uranium.

Returning to electricity requirements, it is desirable to understand the necessity of having nuclear energy as a part of India's electricity mix. Figure 1 is a plot of Human Development Index (HDI) versus per capita electricity consumption. HDI increases rapidly as per capita electricity consumption increases, but saturation effect is seen around per capita consumption of 5000 units.[3] One can argue that correlation between two variables cannot be called causation; but the messaging from the plot is clear that for achieving a high (close to 0.9) HDI, it is necessary to provide about 5000 units of electricity per annum per capita to the citizens of India. It is pertinent to note that some of the countries in our neighbourhood (that is with similar climate conditions) have a per capita electricity consumption, much higher than India. For example, per capita consumption in Malaysia is 4656 units, Thailand – 2621 and the world average is 3052 units (IEA 2018). In the year 2018-19, India generated about 1600 billion units (including generation from both utilities and non-utilities). Assuming India's population to be about 135 crore, in per capita terms, generation was about 1200 units. Assuming India's population will stabilise at 1.6 billons,[4] transmission and distribution losses will come down to about 7 percent, then to provide 5000 units per capita per annum, and India has to generate 8600 billion units per annum. This is about five and half times the generation in 2018-19.

After peaceful nuclear explosion by India in 1974, votaries of the NPT cast India "into a netherworld" and it was abruptly denied international collaboration on the peaceful uses of nuclear energy. […] while the NPT is based on the motto, "early bird gets the nuke", even now there are calls on India by NPT votaries to sign NPT as a Non-Nuclear Weapon State (NWS).

There are calls, at the global level as well as at the national level, by many to meet all electricity requirements by renewable sources. These calls are based on an under-estimation of total electricity requirements based on the principle of frugality and an over-estimation of the potential of renewable sources. Renewable sources, including large and small hydro, solar and wind, cannot provide more than a quarter of the total projected electricity requirements of India (Grover 2017a). The balance has to come from coal and nuclear. Climate change imperative calls for deep decarbonisation and over a period of time India has, to the extent possible, substitute nuclear for coal. Thus, nuclear has to be an essential part of India's electricity mix and the sooner its share is ramped up, better it is for climate change. That can be done only if uranium is available to fuel the reactors. Therefore, it was necessary for the Government of India to launch a policy initiative to enable India to access international market to buy uranium.

2. The Beginning of the Atomic Energy Programme

To harness the power of atom, Atomic Energy Commission was set up in 1948, that is within months of getting independence. To take care of governance issues, Atomic Energy Act was enacted in 1948 and the Department of Atomic Energy was set up in 1954. A swimming pool type research reactor APSARA was constructed in Trombay and achieved first criticality in 1956. It was followed by construction, in collaboration with Canada, of a 40 MWt research reactor CIRUS in 1960. Collaboration was established with several other countries as well including the USA, the UK, France, and Russia. As the programme was moving ahead very fast, need was felt to modernize the Atomic Energy Act and, therefore, Atomic Energy Act, 1962 replaced the 1948 Act.

Renewable sources, including large and small hydro, solar and wind, cannot provide more than a quarter of the total projected electricity requirements of India. The balance has to come from coal and nuclear.

During early years of the programme, science diplomacy was at work and India did derive benefit from international collaboration. Two Boiling Water Reactors were set up in 1960s at Tarapur, near Mumbai, on turn-key basis by a US company. Two PHWRs were set up at Rawatbhata in Rajasthan in collaboration with Canada, but the second unit had to be completed by indigenous efforts as all collaborations came to an abrupt halt after the PNE in 1974.

Nuclear has to be an essential part of India's electricity mix and the sooner its share is ramped up, better it is for climate change. That can be done only if uranium is available to fuel the reactors.

India remained steadfast in its resolve to develop nuclear technologies and achieved notable successes. Early on it was clear that India's domestic reserves are modest[5] and, therefore, it was decided to pursue a closed fuel cycle approach. It was articulated by Bhabha as a three-stage programme, which is a brilliant way to convey science-based complexities to all citizens. Over the years, technological capability has been developed for (i) exploration and mining of uranium, (ii) fabrication of a variety of fuels, (iii) heavy water production, (iv) designing and setting up research reactors, PHWRs, compact Pressurised Water Reactors (PWRs) and fast breeder reactors, (v) spent fuel reprocessing, and waste management including partitioning of actinides.

In parallel with the development of the nuclear power programme, India conducted three underground tests on 11 May 1998 and two on 13 May 1998. India became a declared nuclear weapon state.[6] Intense diplomatic activity followed, which can be gauged by the fact that there were fourteen meetings between India and the U.S. with India represented by Jaswant Singh and the U.S. by Strobe Talbott (Talbott, 2004). India's technical achievements were appreciated at the global level and became a trigger for the resumption of international civil nuclear cooperation.

3. Triggers for the Initiative and the Joint Statement of July 18, 2005

Early on it was clear that India's domestic reserves are modest and, therefore, it was decided to pursue a closed fuel cycle approach. It was articulated by Bhabha as a three-stage programme, which is a brilliant way to convey science-based complexities to all citizens.

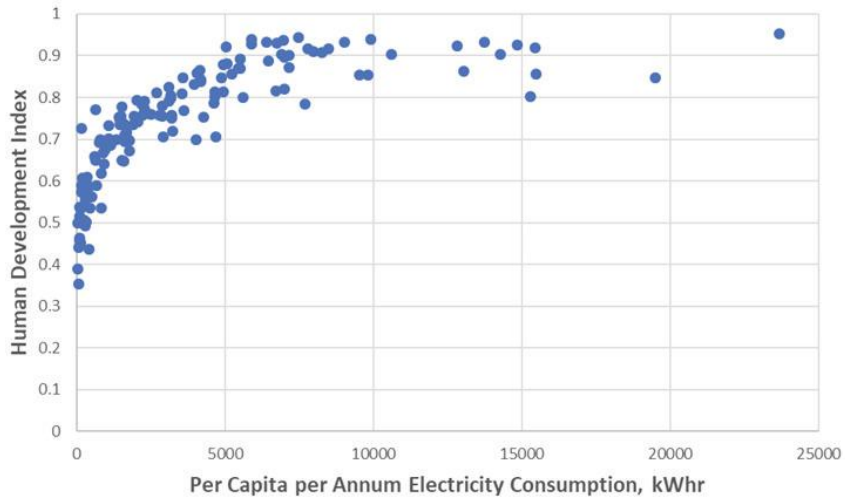
3.1 Trigger on the Indian side

Having realised the importance of nuclear as a part of electricity mix of the country, trigger for India was to have access to international uranium supplies. Uranium shortage was so acute that capacity factors of the operating reactors started coming down, reaching as low as 50 percent in 2008-09, and India could not think of constructing more PHWRs.

3.2 Triggers on the US side

On the US side, there were two different narratives for triggering the initiative: one strategic and the other scientific. Monographs by Itty Abraham and Ashley Tellis provide details about the debate in the USA (Abraham 2007; Tellis 2005) and a brief summary is given here. First public hint of the thinking about India by the US President Bush was provided during his election campaign by Condoleezza Rice (Rice 2000). She talked about the role of India in providing regional balance

Figure 1: Human Development Index versus Electricity Consumption for Different Countries



Source: Author's Compilation; Data for electricity consumption is from Key World Energy Statistics, 2018 published by International Energy Agency (IEA, 2018). Data for HDI is from "Human development Indices and Indicators" 2018 Statistical Update, published by United Nations Development Programme (UNDP, 2018).

Note: (2) HDI is a composite index calculated based on three dimensions health, education and living standard. Indicators for three dimensions are life expectancy at birth, mean years of schooling and expected years of schooling, and gross national income per capita; (2) Some important points are India (918, 0.640), Vietnam (1616, 0.694), Thailand (2868, 0.755), China (4279, 0.759), Malaysia (4656, 0.802), USA (12825, 0.924) and Iceland (not plotted) (53913, 0.938)

in Asia. After Bush took over as President, intense diplomatic engagement followed. First result was the release of a matched set of statements (Next Steps in Strategic Partnership) on 13 January 2004 by the PM of India in New Delhi and the President of the USA in Washington. Its benefit for the nuclear industry was symbolic. However, it did become a building block for a future dialogue.

Condoleezza Rice visited India on 15 March 2005, and the two sides agreed on a dialogue on energy including nuclear energy and she extended an invitation to Prime Minister to visit the USA. As a first step, the External Affairs Minister, Natwar Singh, led a delegation to the USA for a strategic dialogue in April 2005. The two visits paved the way for the visit of the Prime Minister of India to the USA in July 2005.

A few days prior to the visit of the Prime Minister to the United States, Carnegie Endowment for International Peace released a monograph "India as a global nuclear power: An action agenda by the US" (Tellis 2005). In the monograph, Tellis advocated that nothing should be done to cap India's nuclear deterrent as it would put it at a severe disadvantage vis-à-vis Beijing. He outlined several options in terms of what he called as six end states. Fifth end state proposed permitting India to have access to safeguarded nuclear fuel in return for bringing all present and future power reactors[7] under safeguards with no restriction on producing fissile material from research reactors. Sixth end state envisaged integrating India as a legitimate NWS with all privileges. Itty Abraham writes about the rise of China and a need to balance its rise, and adds India's economic growth as an important factor (Abraham 2007).

We'll return to the trigger provided by India's scientific strength in a later section.

In parallel with the development of the nuclear power programme, India conducted three underground tests on 11 May 1998 and two on 13 May 1998. India became a declared nuclear weapon state. […] India's technical achievements were appreciated at the global level and became a trigger for the resumption of international civil nuclear cooperation.

3.3 The Joint Statement

Ashley Tellis did write about growing capability of India in science and technology,[8] and an acknowledgement of scientific strength of India was embedded in the joint statement itself. Long after the Joint Statement, there was an explicit indication about the scientific strength of India having triggered the USA to act. To keep the historical perspective, let us look at the Joint Statement first. It was issued on 18 July 2005 in Washington during the visit of Prime Minister Manmohan Singh to Washington DC and involved tense negotiations. Relevant extracts are given in Annex 1. In the Joint Statement, the USA:

- appreciated India's commitment to prevent WMD proliferation and stated that as a responsible state with advanced nuclear technology, India should acquire the same benefits and advantages as other such states;

An acknowledgement of scientific strength of India was embedded in the joint statement itself. Long after the Joint Statement, there was an explicit indication about the scientific strength of India having triggered the USA to act.

India reciprocally agreed to assume the same responsibilities and practices and acquire the same benefits and advantages as other leading countries with advanced nuclear technology, such as the United States.

- committed to work to achieve full civil nuclear energy co-operation with India to enable it to realize its goals of promoting nuclear power and achieving energy security;
- agreed to seek agreement from Congress to adjust U.S. laws and policies;
- agreed to work with friends and allies to adjust international regimes to enable full civil nuclear energy co-operation and trade with India;
- agreed to consult with partners about India's interest for participation in the ITER[9] project; and
- offered to consult with the other participants in the Generation IV International Forum[10] with a view toward India's inclusion.

India reciprocally agreed to assume the same responsibilities and practices and acquire the same benefits and advantages as other leading countries with advanced nuclear technology, such as the United States. These responsibilities and practices consist of:

- identifying and separating civilian and military nuclear facilities and programmes in a phased manner;
- voluntarily placing its civilian nuclear facilities under IAEA safeguards;
- signing and adhering to an Additional Protocol with respect to civilian nuclear facilities;
- continuing India's unilateral moratorium on nuclear testing;
- working with the United States for the conclusion of a multilateral Fissile Material Cut-off Treaty;
- refraining from transfer of enrichment and reprocessing technologies to states that do not have them and supporting international efforts to limit their spread; and
- ensuring that the necessary steps have been taken to secure nuclear materials and technology through comprehensive export control legislation and through harmonization and adherence to Missile Technology Control Regime (MTCR) and Nuclear Suppliers Group (NSG) guidelines.

. Identification of facilities as civilian or military is a determination by India and is not linked to any condition. Further, placing its civilian facilities under safeguards by IAEA by India is on a voluntary basis. This again raises the status of India to an NWS

3.4 An Acknowledgement of India's Scientific Strength

Certain words in the Joint Statement are very important. These include recognition of India as "a state with advanced nuclear technology", which is a diplomatically acceptable equivalent for being a nuclear weapon state and is a recognition of India's scientific strength. Identification of facilities as civilian or military is a determination by India and is not linked to any

condition. Further, placing its civilian facilities under safeguards by IAEA by India is on a voluntary basis. This again raises the status of India to an NWS. IAEA has a standard template for the additional protocol for NNWS, but here the words are "an additional protocol" and not "the additional protocol."

A clear of recognition of India's scientific strength is also reflected in the offer to enable India's participation in the ITER project, and Generation IV international forum. India's scientific strength was explicitly acknowledged by Anish Goel,[11] when he commented that during the period of isolation, "India continued to indigenously develop its nuclear program to ever-increasing sophistication." He also wrote that the decision to negotiate with India was taken "[a]fter years of careful analysis and foundational work, supported by scientific expertise" and that India had carried extensive research in thorium technologies (Goel 2014). It appears that the US scientific community has been monitoring scientific progress in India and reporting it to the Government as can be seen by the testimony given by Hecker[12] at a Hearing of the US Senate Committee on Appropriations, Subcommittee on Energy and Water Development, on April 30, 2008: "I found that whereas sanctions slowed progress in nuclear energy, they made India self-sufficient in nuclear technologies and world leaders in fast reactor technologies. While much of the world's approach to India has been to limit its access to nuclear technology, it may well be that today we limit ourselves by not having full access to India's nuclear technology developments. Such technical views should help to advise the diplomatic efforts with India."

A clear of recognition of India's scientific strength is also reflected in the offer to enable India's participation in the ITER project, and Generation IV international forum.

One may also note the commitment made by India regarding refraining from transfer of enrichment and reprocessing technologies reflects the fact that India had developed these technologies.

The commitment made by India regarding refraining from transfer of enrichment and reprocessing technologies reflects the fact that India had developed these technologies

Growing technological capability of India was a source of concern for the USA as no treaty-based obligation to enforce export controls was applicable to India. It was realised that the pursuit of a closed fuel cycle will leave India "awash with more plutonium than it could ever use either for energy production or nuclear weaponry." (Tellis 2005: 18). While it is not correct to say that India cannot use all the plutonium for energy production, Tellis does bring out the main concern of the USA. Resulting from this concern, the US considered, tightening India's export controls far more important for its national security than capping and rolling back of India's strategic programme. Regarding export controls, India had been following and continues to follow a virtuous path, but the outside world was imposing costs by denying international trade. Ashley Tellis (2005) writes, "Beyond a certain point,

virtue cannot remain its own reward….." (P. 26). Having a deal with India was a way to ensure sustainability of India's export controls.

Growing technological capability of India was a source of concern for the USA as no treaty-based obligation to enforce export controls was applicable to India. It was realised that the pursuit of a closed fuel cycle will leave India "awash with more plutonium than it could ever use either for energy production or nuclear weaponry."

3.5 Dialogue with Other Countries

The joint statement paved the way for a dialogue to finalise the text of a Nuclear Cooperation Agreement with the USA and also other countries, notably France and Russia.

4. Core Issues Important for India and the Separation Plan

4.1 The Debate on the Likely Contour of the Separation Plan

Between July 2005 and March 2006, there was an intense debate in India on the likely contours of the initiative to resume international civil nuclear trade. Debates included views regarding economics and safety of nuclear power, perceived opaqueness of India's nuclear programme, and how conditions associated with various agreements then under negotiations would influence ongoing strategic programme. It is relevant to discuss issues related to influence on the strategic programme. Expanding and paraphrasing the list proposed by Itty Abraham (Abraham 2007: 28), the issues were the following:

The joint statement paved the way for a dialogue to finalise the text of a Nuclear Cooperation Agreement with the USA and also other countries, notably France and Russia.

- Finalising a credible and defensible separation plan;
- Ensuring that there is no moratorium on fissile material production for the strategic programme;
- Moratorium on testing;
- Costs imposed by safeguards;
- Intrusiveness of the Additional Protocol;
- Ensuring reciprocity of actions by India and the U.S.

First criticism came from a former Director of Bhabha Atomic Research Centre, AN Prasad (Varadarajan 2005), when he opined that the course of actions proposed by the Joint Statement was against national interest, fast reactor programme would be undermined and the cost of nuclear weapon programme would dramatically escalate. Note the concerns related to fast reactor programme going under safeguards. He was also concerned about the additional protocol.

Kakodkar clarified important issues early in the debate (Subramanian 2005) when he said that (i) classification of facilities as civilian would be an Indian decision, (ii) only the facilities having no strategic significance would be classified as civilian, (iii) fissile material production would not be capped,

(iv) no developmental programme including Prototype Fast Breeder Reactor (PFBR) would be offered for safeguards, (v) in view of large energy needs, India would look at imports as externalities and facilities would be offered for safeguards in a phased manner.

Concerns regarding offering facilities for safeguards were dispelled based on the fact that several Indian facilities were already under safeguards and this never posed any concern. This includes two reactors at Tarapur and two reactors at Rawatbhata in Rajasthan. Two reactors then under construction at Kudankulam in technical collaboration with Russia were also under safeguards.

The debate regarding influence on strategic programme continued and amidst this debate Kakodkar, in an interview to Pallava Bagla, provided explanation on all important issues (Bagla 2006). He extensively referred to the DAE study about electricity needs covering a 50-year horizon (Grover and Chandra, 2006) and spoke about (i) not compromising country's strategic interest and energy interest, (ii) the criticality of the fast breeder programme for the nuclear power programme of the country as well as for maintaining minimum credible deterrent, (iii) the linkage of the fast reactor programme to the indigenous PHWR programme through the fuel cycle[13] and hence, the impossibility of offering fast reactors for safeguards and also keeping sufficient PHWR capacity outside safeguards. He clarified that research and development could be done only in an autonomous manner and that India needed additional capacity [for production of fissile material from power reactors] for strategic needs.

This interview became a decisive factor in defining the contours of the Separation Plan. Commenting on the interview, Siddharth Varadarajan wrote, "Indeed, the supporters of Indo-U.S. nuclear cooperation should realise that by drawing a thick red line out in the open, Dr. Kakodkar has done the only thing which can still salvage the deal: telling the Americans that if they don't blink, the agreement will die a natural death" (Varadarajan 2006).

Between July 2005 and March 2006, there was an intense debate in India on the likely contours of the initiative to resume international civil nuclear trade. Debates included views regarding economics and safety of nuclear power, perceived opaqueness of India's nuclear programme, and how conditions associated with various agreements then under negotiations would influence ongoing strategic programme.

Concerns regarding offering facilities for safeguards were dispelled based on the fact that several Indian facilities were already under safeguards and this never posed any concern. This includes two reactors at Tarapur and two reactors at Rawatbhata in Rajasthan. Two reactors then under construction at Kudankulam in technical collaboration with Russia were also under safeguards.

4.2 The Separation Plan

While the debate was ongoing, considering responsibilities and practices identified in the Joint Statement, India started working on a plan to separate facilities. The Separation Plan was drafted to include the list of facilities as well as the basis for doing so. Several core issues important to India were embedded in the Separation Plan and their embedding in the Separation Plan was helpful in negotiating the Nuclear Cooperation Agreement with the USA.

Research and development could be done only in an autonomous manner and that India needed additional capacity [for production of fissile material from power reactors] for strategic needs.

The Separation Plan emphasises the centrality of nuclear energy in meeting the challenges of energy security and environmental sustainability. It refers to India's growing technological prowess and points to the fact that "the strategic programme is an offshoot of research on nuclear power programme and consequently, it is embedded in a larger undifferentiated programme." It brings out strengths of India's research and development efforts and dismisses grid-connectivity as irrelevant to the separation exercise. It states that "India will:

- Include in the civilian list only those facilities offered for safeguards that, after separation, will no longer be engaged in activities of strategic significance.
- The overarching criterion would be a judgement whether subjecting a facility to IAEA safeguards would impact adversely on India's national security.
- However, a facility will be excluded from the civilian list if it is located in a large hub of strategic significance, notwithstanding the fact that it may not be normally engaged in activities of strategic significance.
- A civilian facility would therefore, be one that India has determined not to be relevant to its strategic programme."

Taking the above into account, the Separation Plan offers eight indigenous reactors for safeguards by IAEA in addition to six which were already under safeguards. It offers certain facilities at Nuclear fuel Complex for safeguards and also offers a reprocessing plant for safeguards under campaign mode. It designates only three heavy water plants[14] as civilian. India did not offer Fast Breeder Test Reactor (FBTR) and under construction PFBR for safeguards as the fast breeder programme was still under development and its technology would take time to mature. India reserved its right to determine future facilities as civilian or strategic.

The Separation Plan was drafted to include the list of facilities as well as the basis for doing so. Several core issues important to India were embedded in the Separation Plan and their embedding in the Separation Plan was helpful in negotiating the Nuclear Cooperation Agreement with the USA.

The Separation Plan also addresses the important issue of fuel supply assurances in great detail (See relevant extracts in Annex 2), makes a clear linkage of fuel supplies with IAEA safeguards, and provides for India taking corrective measures to ensure uninterrupted operation of its civilian nuclear power reactors. It also brings in the concept of the safeguards agreement being India-Specific. As explained later, these features were woven into both the Nuclear Cooperation Agreement with the USA and also the India-Specific Safeguards Agreement.

DAE supports several research and development centres, industrial units, and grant-in-aid institutions. All grant-in-aid institutions, one research and development centre, and one industrial unit were declared as civilian (See Annex 2 for

the complete list) and it was specifically stated that they are safeguards irrelevant.[15]

The Separation Plan was discussed and agreed between India and the USA during the visit of President Bush to India during 2nd-4th March 2006. The Prime Minister made a Suo Moto statement in the Lok Sabha on 7 March 2006 on the Separation Plan and the Separation Plan was tabled in Parliament on 11 May 2006, communicated to IAEA and issued by IAEA for information and wider circulation (IAEA 2008a).

The Separation Plan didn't impose any restrictions on the production of fissile material and was defensible from strategic considerations. It also paved the way for addressing the remaining issues that is IAEA safeguards, additional protocol, reciprocity of actions, in documents yet to be negotiated as discussed in subsequent sections.

Separation Plan offers eight indigenous reactors for safeguards by IAEA in addition to six which were already under safeguards. It offers certain facilities at Nuclear fuel Complex for safeguards and also offers a reprocessing plant for safeguards under campaign mode. It designates only three heavy water plants as civilian.

5. Adjustment of Laws and Policies by the US

5.1 India joins ITER

In the Joint Statement, the US agreed to seek agreement from Congress to adjust U.S. laws and policies. The first action by the US was to agree[16] to India joining the ITER project. India was invited to present its case before the meeting of negotiators held at Cadarache, France on 12 September 2005. India's case was well received and after that there was a flurry of activity and Indian delegation joined the meeting of the Negotiators' Senior Support Group (NSSG) at Jeju, South Korea during early in December 2005. During NSSG meeting, the list of in-kind contributions to be made by India was negotiated and finalised. NSSG meeting was followed by a meeting of Negotiators and on 6 December 2005, where the then ITER partner countries unanimously approved Indian accession to the negotiations for finalizing the Joint Implementation Agreement (JIA) for setting up ITER. India signed the JIA along with others during a Ministerial meeting held in Paris on 21 November 2006.

India did not offer Fast Breeder Test Reactor (FBTR) and under construction PFBR for safeguards as the fast breeder programme was still under development and its technology would take time to mature. India reserved its right to determine future facilities as civilian or strategic.

5.2 The Hyde Act

Chapter 11 of the US Atomic Energy Act deals with international activities including international and export controls. Nuclear cooperation agreements are governed by the provisions of section 123 and that is why, colloquially, US refers to cooperation agreements as '123' agreements. Being not a signatory to NPT and having an active nuclear weapons programme, India didn't satisfy many provisions of the Act. To proceed with a nuclear cooperation agreement, the US Congress passed "Henry J. Hyde United States-India Peaceful Atomic Energy Cooperation Act of 2006" and it was signed into law by the President with his signature on 8 December 2006.

The Separation Plan didn't impose any restrictions on the production of fissile material and was defensible from strategic considerations. It also paved the way for addressing the remaining issues that is IAEA safeguards, additional protocol, reciprocity of actions, to name a few.

Being not a signatory to NPT and having an active nuclear weapons programme, India didn't satisfy many provisions of the Hyde Act. […] For Indian negotiators, core issues were very clear and for the US side clarity was provided by the Hyde Act. To start with, reconciling the two seemed like a challenge. It was clear that standard US templates for cooperation agreement would not work and real hard work lay ahead.

For Indian negotiators, core issues were very clear and for the US side clarity was provided by the Hyde Act. To start with, reconciling the two seemed like a challenge. It was clear that standard US templates for cooperation agreement would not work and real hard work lay ahead. The next section provides details as to how the core issues have been addressed in the Nuclear Cooperation Agreement.

6. The Nuclear Cooperation Agreements

6.1 Addressing the Core Issues

Finalisation of the Separation Plan and the passage of the Hyde Act paved the way for negotiations to arrive at the text of the Nuclear Cooperation Agreement. In view of the intense debate in the Indian media, core issues to be addressed were clear to the Indian negotiating team and as a result, the finalisation of the text took long time. Text of the Agreement was finalised after several rounds of internal discussions involving scientists from DAE and officials from MEA and PMO, and negotiations with the US team. While one has to look at the Agreement as a whole, the core issues have been addressed in the Nuclear Cooperation Agreement in the following manner.

6.1.1 Maintaining Integrity and Reliability of India's Strategic Programme, Continued Pursuit of Closed Fuel Cycle (Three-stage Nuclear Power Programme), and R&D

- Article 2.4 affirms that the Nuclear Cooperation Agreement will not affect the un-safeguarded programme thereby precluding any moratorium on production of fissile material. It mandates implementation of the agreement without any hindrance or interference with independent development activities.
- Article 1 (H) defines 'information' and is worded to provide precision in understanding. Lack of precision could have led to misunderstanding or even disputes over issues such as replication or infringement of confidentiality.
- Article 12 makes it clear that the Agreement is to be implemented in a manner that avoids hampering or delaying or interference in other activities and the provisions of the Agreement are not to be used to interfere with nuclear policy or programmes.

6.1.2 IAEA Safeguards Agreement and Fuel Supply Assurances

- Article 2.2e. includes development of a strategic reserve of nuclear fuel in the scope of cooperation.
- Article 5.6 reproduces verbatim para 15 of the 'separation plan' related to fuel supply assurances, safeguards and corrective measures (reproduced in Annex 2).

- Article 10.2 on IAEA safeguards starts with the words, "Taking into account Article 5.6 of this Agreement", thereby provides a linkage between safeguards and fuel supply assurances.
- Article 14 on 'Termination and cessation of cooperation' in its para 8 states: "It is not the purpose of the provisions of this article regarding cessation of cooperation and right of return to derogate from the rights of the Parties under Article 5.6." Article 5.6 deals with important issues related to fuel supply, safeguards and corrective measures.
- Article 14.5 refers to uninterrupted operation of nuclear reactors.

Intensity of the dialogue between the Indian and the US negotiators can be judged from the following quote, "A U.S. official who had negotiated 123 Agreements with other countries told me he had never had to explain, discuss, and argue about text and language to the degree he had done with the Indians".

6.1.3 IAEA Safeguards

- Title of the article related to safeguards is "IAEA safeguards." This is further reiterated in Article 10.2, which refers to "India-Specific Safeguards Agreement between India and the IAEA".
- Article 10.4 states, "If the IAEA decides that the application of IAEA safeguards is no longer possible, the supplier and recipient should consult and agree on appropriate verification measures."
- Article 14.3 says that finding of safeguards non-compliance has to be made only by the Board of Governors of IAEA.
- The definition of the by-product material (Article 1(A)) was chosen to ensure precision in understanding.

6.1.4 Full Civil Nuclear Cooperation

- Article 2.2 covers scope of cooperation and Article 2.2d says that scope includes nuclear reactors and aspects of associated nuclear fuel cycle including technology transfer.
- Article 5.2 provides for cooperation in sensitive nuclear technologies only after amendment.[17] This article does permit transfer of dual use items for use in sensitive facilities as per applicable laws, regulations and policies.
- Article 6 iii) grants consent for reprocessing[18] of spent fuel and provides a time limit (one year) for agreeing on arrangements and procedures for reprocessing.

The US nuclear cooperation policies are embedded deep in their domestic law, while it is not so in case of France and Russia. As a result, there was a difference in the intensity of negotiations. […] Being not a part of policy of France and Russia, reprocessing consent was not an issue for negotiations.

6.1.5 Cessation of Cooperation and Right of Return

- Article 14 is a long article and it provides a layered approach for termination. Article 14.2 provides for consultation to carefully consider the circumstances and agree to take into account concerns arising out of security environment.
- Article 16.4 provides for implementation of the Agreement in good faith and in accordance with the principles of international law.

- Article 14.3 refers to 'material violation' as per the definition of Vienna Convention on the Law of Treaties and violation of non-compliance of safeguards agreement to be determined by the Board of Governors of the IAEA.
- Article 14.5 provides for caution before exercising right of return and refers to negative consequences on on-going projects.

Countries who have not signed NPT have to accept safeguards on nuclear facilities that are established by them based on international cooperation. […] India had no obligation to offer facilities designed and constructed indigenously for safeguards by IAEA as long as it used indigenously produced fuel to operate them.

6.2 Intensity of Negotiations

It is to be noted is that core issues have been addressed in multiple ways and it can be argued that the Agreement has become verbose. However, such verbosity drives home the importance of core issues and is an insurance to protect the interests of the country in case of any dispute in the future. Intensity of the dialogue between the Indian and the US negotiators can be judged from the following quote, "A U.S. official who had negotiated 123 Agreements with other countries told me he had never had to explain, discuss, and argue about text and language to the degree he had done with the Indians" (Menon 2016: 85).

6.3 Negotiations with France and Russia

In parallel to negotiations with the USA for arriving at the text of a nuclear cooperation agreement, negotiations were also held with France and Russia. The US nuclear cooperation policies are embedded deep in their domestic law, while it is not so in case of France and Russia. As a result, there was a difference in the intensity of negotiations. Negotiating team felt that negotiators from the three countries might have been in touch and so once an agreement on an issue was reached with the US team, it was easier to deal with the other teams. Being not a part of policy of France and Russia, reprocessing consent was not an issue for negotiations.

One can categorically state that the approach followed by India is consistent with its legal obligations. All safeguards agreement referred to in paragraph 7.1 have since been subsumed in ISSA. All facilities identified as civilian in the Separation Plan have been offered for safeguards.

7. India-Specific Safeguards Agreement (ISSA)

7.1 Origin of Safeguards

Article 3 of the NPT begins with, "Each Non-nuclear-weapon State (NWS) Party to the Treaty undertakes to accept safeguards, as set forth in an agreement to be negotiated and concluded with the International Atomic Energy Agency in accordance with the Statute of the International Atomic Energy Agency and the Agency's safeguards system, for the exclusive purpose of verification of the fulfilment of its obligations assumed under this Treaty with a view to preventing diversion of nuclear energy from peaceful uses to nuclear weapons or other nuclear explosive devices." Safeguards for NWS Parties to NPT are thus

binding and comprehensive[19] in scope as all of their nuclear facilities come under safeguards. NWS offer some of their civilian facilities for safeguards to IAEA on voluntary basis. Countries who have not signed NPT have to accept safeguards on nuclear facilities that are established by them based on international cooperation.[20] There is no obligation on non-signatories to the NPT, to offer their indigenous facilities for safeguards. India had no obligation to offer facilities designed and constructed indigenously for safeguards by IAEA as long as it used indigenously produced fuel to operate them.

7.2 India's Prior Safeguards Agreements

When negotiations for ISSA began, several facilities set up based on international collaboration were already under safeguards. In addition, India had negotiated safeguards agreements for supply of nuclear fuel and heavy water. The list of all such safeguards agreements follows.

- INFCIRC/154, 3 September 1971, for safeguards for the reactors TAPS-1 & 2. (This provided for safeguards for a period of 25 years).
- INFCIRC/211, 6 November 1974, for safeguards for the reactors RAPS 1 & 2.
- INFCIRC/260, 1 July 1978, for safeguards on heavy water supplied by Soviet Union for use in RAPS-1 & 2.
- INFCIRC/374, 1 January 1990, for safeguards on nuclear fuel supplied by France for use in TAPS-1 & 2.
- INFCIRC/433, 1 May 1994 and amended on 1 November 1994 for extension of safeguards to TAPS-1 & 2 beyond the initial 25 years.[21]

Thus, India had enough prior experience in implementing safeguards on nuclear facilities and material and was never in violation of any safeguards commitment.

7.3 Important Issues for India

While negotiating ISSA, the following were the important issues:

- There should be an acknowledgement of the fact that a part of India's programme is not civilian. Applicability of ISSA should be limited to civilian facilities and there should be no interference in activities not offered for safeguards.
- ISSA must reflect India-US understandings and facilitate cooperation with all other member-states of IAEA.
- It should be an umbrella agreement and all facilities offered by India should come under it. This was necessary to avoid spending of time and efforts in negotiating safeguards agreement time and again and to preclude the possibility

The international law principle of *rebus sic stantibus*, which suggests that the duration of a binding commitment is linked to a continuation of the circumstances extant at the time of the original binding commitment. This tends to support an interpretation that India would be able legally to insist on the removal of safeguards from its civil nuclear program if there is a disruption in fuel supply."

of addition of any more conditions in future agreements. It should also provide for subsuming all earlier safeguards agreements. This was to facilitate implementation.

- Reciprocity should be built into it to ensure that India should not end up offering facilities for safeguards without reciprocal actions by the world community.

7.4 An Analysis of ISSA

As a part of the Joint Statement, India undertook to ensure that the necessary steps have been taken to secure nuclear materials and technology through comprehensive export control legislation and through harmonization and adherence to MTCR and NSG guidelines. In fact, even at the time of issuing the Joint Statement, India was implementing export controls based on a law-based regime and the regime is under continuous review for possible strengthening.

Using the guidance provided by the standard template for item-specific safeguards agreement as included in INFCIRC/66, Rev 2 (IAEA 1968), ISSA was negotiated and all the above issues were addressed. The following is an analysis of ISSA (IAEA 2009) with respect to the issues above.

- The title of the agreement includes the word 'civilian', making a subtle reference to the fact that a part of India's programme is not civilian. Third pre-ambular paragraph refers to "nuclear research and development for the welfare of its people and other peaceful purposes." This phrase was borrowed from Atomic Energy Act, 1961 and one should note that "welfare of its people" has a broad meaning including defence of the country. Article 5 states that implementation of safeguards shall not hinder or otherwise interfere with India's independent activities.
- Ninth pre-ambular paragraph refers to India-US understandings as reflected in the Joint Statement: (i) access to fuel supplies from the international market as an essential basis for India going in for ISSA, (ii) facilitating development of a strategic reserve of nuclear fuel, and (iii) India's right to take corrective measures. Twelfth pre-ambular paragraph refers to "the need to avoid hampering the peaceful uses of nuclear energy, economic and technological development or international cooperation in the peaceful uses of nuclear energy". The preamble is tightly coupled to the main agreement by the text, "NOW THEREFORE, taking into account the above, India and the Agency have agreed as follows:". Article 3 states: "The application of safeguards under this agreement is intended to facilitate implementation of relevant bilateral or multilateral arrangements to which India is a party, which are essential to the accomplishment of the objective of this Agreement."
- To make it an umbrella agreement, it provides for bringing the following three kind of facilities under its scope:
  - » Facilities identified by India in the separation plan as civilian (Article 14 (a)).
  - » Any further facilities identified by India as civilian (Article (14(a)), and

» All existing safeguarded facilities (Article 22).

Inclusion of all above makes ISSA an umbrella Agreement.

- According to ISSA, safeguards on a facility shall come into force after the following steps have been taken:
  - » Approval of the Agreement by the Board of Governors of the IAEA.
  - » Signatures on the Agreement.
  - » Notification by India about its entry into force
  - » Filing a declaration by India about its civilian facilities after all conditions conducive to the accomplishment of the objectives of the Agreement have been met (Article 13), and
  - » Notification by India offering civilian facilities for safeguards (Article 14) according to a timeframe decided by India.

All these steps ensure reciprocity.

ISSA has an Annex and to start with it had no entry. India submitted first notification on 16 October 2009 after all conditions conducive to implementation of international cooperation were met. Inclusion of all the above points makes the text of the agreement India-specific.[22]

7.5 Some Remarks about ISSA

IAEA doesn't have any template for implementing safeguards on research centres not handling nuclear material and, therefore, all such institutes remain outside the purview of ISSA. Civilian heavy water plants also remain outside ISSA. Text of the ISSA did create an unease in the non-proliferation lobby as can be seen from the following quote from Dean Rust: "According to IAEA documents and published reports, IAEA Director-General Mohammed ElBaradei asserted that the safeguards agreement meets all IAEA legal requirements, is of indefinite duration, and that the safeguards termination provisions in the operative sections of the agreement conform to longstanding IAEA principles. However, he also cited the preamble as an integral part of the agreement; the preamble contains India's position that fuel assurances are an "essential basis" for India's acceptance of safeguards under the agreement. ElBaradei also noted the international law principle of rebus sic stantibus, which suggests that the duration of a binding commitment is linked to a continuation of the circumstances extant at the time of the original binding commitment. This tends to support an interpretation that India would be able legally to insist on the removal of safeguards from its civil nuclear program if there is a disruption in fuel supply." (Rust 2008).

Essentially India follows a unique nomenclature, but items on the control lists of India are the same as in the NSG lists. Based on the list of items and guidelines for export existing in 2008, it was possible for India to convince the Nuclear Suppliers Group that India's has a robust export control system.

Nuclear fuel would remain under safeguards for all times as Article 29 of ISSA refers to termination according to GOV/1621 (20 August 1973). This is a decision of the Board of Governors of IAEA and ties duration of safeguards to actual use of the supplied items and material by the recipient state (Rockwood 2013: 17). Statement by Rust is, thus, a wrong interpretation of IAEA principles.

Approval of ISSA, with all the features referred to in para 7.4 embedded in it, by the Board of Governors was indeed a diplomatic triumph for India. Articles by academics criticising ISSA (Robertson and Carlson 2016; Carlson 2018), and response thereto (Ramakumar 2019) keep appearing. One can categorically state that the approach followed by India is consistent with its legal obligations. All safeguards agreement referred to in paragraph 7.1 have since been subsumed in ISSA. All facilities identified as civilian in the Separation Plan have been offered for safeguards. Additional facilities which came up afterwards have also been offered for safeguards. An updated list of facilities included in the annex to ISSA is given in Annex 3. This will keep getting updated as and when India offers facilities for safeguards.

Acceptable technical conditions include the fact that any nuclear reactor constructed in India has to pass India's regulatory approval. Viable tariff regime will result from a low capital cost and a financial package based on soft loan. Affordability re-emphasises viable tariff regime.

8. Export Controls

8.1 India's Export Controls in 2008

As a part of the Joint Statement, India undertook to ensure that the necessary steps have been taken to secure nuclear materials and technology through comprehensive export control legislation and through harmonization and adherence to MTCR and NSG guidelines. In fact, even at the time of issuing the Joint Statement, India was implementing export controls based on a law-based regime and the regime is under continuous review for possible strengthening. Export controls are implemented in India based on the Atomic Energy Act, 1961 (AE Act) and the Foreign Trade (Development & Regulations) Act, 1992 (FTDR Act). The FTDR Act and the rules and policies formulated thereunder constitute the basic laws governing foreign trade, whereas the AE Act provides legal framework for controlling the export of nuclear items. The Weapons of Mass Destruction and their Delivery Systems (Prohibition of Unlawful Activities) Act, 2005 (WMD Act), was enacted to prevent unlawful activities pertaining to Weapons of Mass Destruction and further strengthens India's export controls. It provides specific provisions to prohibit the export, transfer or re-transfer of nuclear weapons, nuclear explosive devices or any item usable for such purpose.

Under FTDR, a national export control list known as Special Chemicals, Organisms, Materials, Equipment and Technologies (SCOMET) has been notified. The SCOMET list has eight categories. Category '0' in the SCOMET list is defined as 'Nuclear materials, nuclear-related other materials, equipment and technology' and corresponds to Trigger List items of the Nuclear Suppliers Group. These items are notified under the AE Act as prescribed substances, prescribed equipment and related technology. Nuclear-related dual-use equipment, materials, software, and related technology are covered by Category '4' of SCOMET and corresponds to the list of dual-use items by NSG. Essentially India follows a unique nomenclature, but items on the control lists of India are the same as in the NSG lists. Based on the list of items and guidelines for export existing in 2008, it was possible for India to convince the Nuclear Suppliers Group that India's has a robust export control system.

8.2 Updating India's Export Controls

The export controls have been further updated and according to information on Directorate General of Foreign Trade (DGFT) portal, "India is a signatory to the major multilateral export control regimes, namely, Missile Technology Control Regime (MTCR), Wassenaar Arrangement (WA) and Australia Group (AG) and adherent to Nuclear Suppliers Group (NSG). India is also a signatory to international conventions on non-proliferation, namely, Chemical Weapons Convention (CWC) and Biological and Toxic Weapons Convention (BWC). Accordingly, the SCOMET control list is aligned to the control lists of the all the multilateral export control regimes and conventions" (DGFT 2018a). Various categories and licensing authorities in SOCMET are given in Annex 4. Details regarding lists and guidelines issued by the DGFT and DAE can be seen in the following documents:

- India's Export Control System, dated 4 September 2018 (DGFT 2018a).
- Special Chemicals, Organisms, Materials, Equipment and Technologies (SCOMET) export of which is regulated dated 31 January 2018 (DGFT 2018b).
- Guidelines for Nuclear Transfers (Exports) dated 28 April 2016 (DAE 2016a), and
- Updation of List of Prescribed Substances, Prescribed Equipment and Technology Under Atomic Energy Act 1962 dated 28 April 2016 (DAE 2016b).

There was a debate in India whether the waiver granted to India is 'clean' that is free of conditionalities. It appears to be free of conditionalities, but paragraphs 6 and 7 of the NSG guidelines were amended by NSG in 2011 and NPT membership was made a criterion for the transfer of enrichment and reprocessing equipment and technology. Indian press was quick to pick up the amendment and call it as converting a 'clean' waiver to an 'unclean' waiver.

9. Relaxation of NSG Guidelines

9.1 Steps Completed by India

By the middle of 2008, India had completed the following steps:

- A dialogue with the USA, France and Russia to negotiate nuclear cooperation agreements and all three texts were ready for signature;
- Formulation of a separation plan and its wider circulation as an information circular (IAEA 2008a);
- Negotiating an India-Specific Safeguards Agreement with the secretariat of the IAEA and its approval by the Board of Governors on 1 August 2008;
- Dialogue at the diplomatic level[23] with all the members of the NSG with a view to explain India's credentials including law-based export controls and seek support for a waiver from NSG for resumption of civil nuclear trade; and
- Release of a statement by EAM on 5th September 2008 to reiterate India's stand on disarmament and non-proliferation.
- WMD Act, 2005, SCOMET list and licensing guidelines issued by the DGFT, Guidelines issued by the DAE in 2006 were taken as harmonization of export controls by India.

India-Specific safeguards Agreement and the NSG waiver resulting into resumption of international civil nuclear trade have been described as the biggest foreign policy triumph by India in recent decades.

9.2 The Decision by Relaxation

As a result of this massive effort, guidelines for civil nuclear trade with India were relaxed by NSG on 6th September 2008 and have been issued by the IAEA as INFCIRC 734c (IAEA 2008b) and is reproduced here as Annex 5. The statement issued by the External Affairs Minister is a crucial link for this waiver and is reproduced as Annex 6.

It may be noted that the Statement by NSG,

- doesn't direct India to sign CTBT;
- doesn't direct India to stop producing fissile material for strategic use;
- does refer to paragraphs 6 and 7 of the NSG guidelines, as revised, which cover the transfer of enrichment and reprocessing technology; and
- doesn't ask Participating Governments to terminate cooperation in the event of a nuclear test by India, but does refer to the statement by India's External Affairs Minister (Annex 6).

9.3 Debate on the Text of the Waiver in India

There was a debate in India whether the waiver granted to India is 'clean' that is free of conditionalities. Based on the above, it

appears to be free of conditionalities, but paragraphs 6 and 7 of the NSG guidelines were amended by NSG in 2011 and NPT membership was made a criterion for the transfer of enrichment and reprocessing equipment and technology. Indian press was quick to pick up the amendment and call it as converting a 'clean' waiver to an 'unclean' waiver (Varadarajan 2011). This has the potential to add to capital costs of reprocessing and enrichment plants as explained earlier.[24]

10. Signing of Nuclear Cooperation Agreements

10.1 Intent to Purchase Reactors from the USA

NSG waiver cleared the deck for the signing of the Nuclear Cooperation Agreement with the USA as well as other countries. The US nuclear industry was looking to benefit from this initiative and therefore, an assurance was given by India to the USA about the intent to buy reactors from companies in the USA. In his testimony to the Senate Foreign Relations Committee on 18 September 2008, the Undersecretary of State William Burns said, "The Indian government has provided the United States with a strong Letter of Intent, stating its intention to purchase reactors with at least 10,000 Mega Watts (MWe) worth of new power generation capacity from U.S. firms." India, he added, "has committed to devote at least two sites to U.S. firms" (Varadarajan 2008). Negotiations with one US company for purchase of reactors.[25] are proceeding. The main issue of negotiations with companies in the USA and other countries is to arrive at "mutually acceptable technical and commercial terms and conditions that enable a viable tariff regime for electricity generated" (MEA 2010).

Indian negotiators had taken care to commit to sign only an Additional Protocol in the Joint Statement. Accordingly, India negotiated with the IAEA an Additional Protocol that limits additional obligations to provision of additional information regarding nuclear exports from India and grants no extra physical access to the IAEA

Acceptable technical conditions include the fact that any nuclear reactor constructed in India has to pass India's regulatory approval. Viable tariff regime will result from a low capital cost and a financial package based on soft loan. Affordability re-emphasises viable tariff regime. The process of negotiations for setting up reactors is likely to take more time as India insists on seeing a reference plant and the plant which India can consider as a reference plant is still under construction in the USA.

10.2 Concerns about Statements from Washington

Concerns were expressed in India about certain statements included in the documents coming from Washington, but the Government of India was very clear about what is applicable as can be seen in the following statement issued by New Delhi on 12 September 2008: "The text of the 123 agreement has

been agreed upon by the Governments of India and the US. It is a public document. The rights and obligations of the two governments are clearly spelt out in the terms and provisions of the 123 agreement. Once this Inter-governmental agreement enters into force, the agreement would become a legal document in accordance with well recognised principles of international law and the Law of Treaties" (MEA 2008).

IAEA approach to safeguards and physical security have evolved over the years, but the USA continues to follow policies that were initiated by it before the evolution and, therefore, the document on Arrangements and Procedures in a mere re-iteration of what is included in IAEA documents.

10.3 Signing of Agreements

The nuclear cooperation agreement between India and the USA was signed on 10 October 2008.

As stated earlier, negotiations with France and the USA were going on in parallel and texts of the agreements had been finalised prior to NSG granting its waiver. Agreements were signed one by one; with France on 30 September 2008 and with Russia on 5 December 2008. India-Specific safeguards Agreement and the NSG waiver resulting into resumption of international civil nuclear trade have been described as the biggest foreign policy triumph by India in recent decades with two former foreign secretaries writing extensively about it in their respective books (Menon 2016; Saran 2017).

11. India's Additional Protocol

As a part of the Joint Statement, India had agreed to sign and adhere to an Additional Protocol with respect to civilian nuclear facilities. IAEA applies safeguards to nuclear facilities declared by its Member States. Following discovery of certain undeclared programme in an NNWS, "In February 1992, the Board of Governors [of IAEA] affirmed that the scope of comprehensive safeguards agreements was not limited to verification of the non-diversion of nuclear material actually declared by a State, but included verifying the absence of undeclared nuclear material and activities in the State" (Rockwood 2013: 19). In 1997, IAEA approved the text of a new document called the model additional protocol, INFCIRC/540, with the objective to detect undeclared nuclear activities. It is not a standalone document, but an addition to the safeguards agreement between a State and IAEA. All NNWS are expected to use the standard template, while NWS can choose measures identified by them as capable of contributing to the non-proliferation and efficiency aims of the protocol. The Board also authorised the DG to negotiate protocols with "other states" "that are prepared to accept measures provided for in the Model Protocol in pursuance of safeguards effectiveness and efficiency objectives," (IAEA 1997).

Indian negotiators had taken care to commit to sign only an Additional Protocol in the Joint Statement. Accordingly, India negotiated with the IAEA an Additional Protocol that limits

additional obligations to provision of additional information regarding nuclear exports from India and grants no extra physical access to the IAEA. India's Additional Protocol also adds to safeguards obligation a commitment to provide IAEA inspectors multiple-entry visas and to allow the IAEA "free communications … including attended and unattended transmission of information generated by Agency containment and/or surveillance or measurement devices" from India's safeguarded facilities (IAEA 2014).

Overall, India's additional protocol do not impose any onerous obligations on India.

12. Arrangements and Procedures for Reprocessing

As stated earlier, the Nuclear Cooperation Agreement signed by India with the USA grants India consent for reprocessing of spent fuel, but it also states that: "To bring these rights into effect, India will establish a new national reprocessing facility dedicated to reprocessing safeguarded nuclear material under IAEA safeguards and the Parties will agree on arrangements and procedures under which reprocessing or other alteration in form or content will take place in this new facility." The Agreement goes on to prescribe time limits for arriving at arrangements and procedures. Negotiations to arrive at arrangements and procedures were started soon after signing the nuclear cooperation agreement and concluded as per the time limit.

The Nuclear Cooperation Agreement goes on to prescribe time limits for arriving at arrangements and procedures. Negotiations to arrive at arrangements and procedures were started soon after signing the nuclear cooperation agreement and concluded as per the time limit.

Article 1 of the document deals with notification and effectiveness of right to reprocess. The most difficult part in negotiating this article was regarding number of facilities India would establish. Difficulty arose because the Nuclear Cooperation Agreement uses the words 'a new national reprocessing facility'. After negotiations, this was interpreted broadly and the agreed document states 'two new reprocessing facilities' including their 'future expansion, modifications, renovations or additions'.

Article 2 relates to IAEA safeguards and includes provisions as are applied by IAEA. Article 3 provides for consultation and Article 4 covers physical protection and storage. For implementing physical protection, it refers to IAEA documents, which have been developed with the participation of experts from India. Article 5 covers environment protection and Article 6 deals with management of plutonium. In pursuit of a fast reactor programme, India will at a future date have plutonium stocks to ensure uninterrupted operation of reactors. Therefore, Article 6 begins with: "India is committed to the management

of separated plutonium in ways that are consistent with its national decisions on the civil nuclear fuel cycle."

Article 7 deals with suspension of arrangements and procedures, and provides a layered approach as in Article 14 of the Nuclear Cooperation Agreement for termination and cessation of cooperation. The remaining are routine articles.

IAEA approach to safeguards and physical security have evolved over the years, but the USA continues to follow policies that were initiated by it before the evolution and, therefore, the document on Arrangements and Procedures in a mere re-iteration of what is included in IAEA documents.

While the work on drafting a liability legislation was ongoing, the Government of India launched the initiative to resume civil nuclear cooperation as described in this paper. USA was looking forward to India joining an international liability regime, particularly the Convention on Supplementary Compensation.

13. Administrative Arrangements

Article 17 of the Nuclear Cooperation Agreement provides for establishing administrative arrangements. This also has been done. The only contentious issue in this regard was 'flagging'. India might import nuclear material from several countries and one of the countries could be say 'X'. Spent fuel might arise after irradiation in a reactor constructed in collaboration with a country say 'Y'. Nuclear material becomes obligated to both X and Y. USA requires complete material accounting for any material that is obligated to it. IAEA maintains accounting of nuclear material as a whole. India didn't want to maintain country-wise accounts of materials. This issue was resolved by making the USA agree to get material accounting reports from the IAEA. To satisfy their legal requirements, US will do calculation of their share of material based on operating record of nuclear reactors constructed by India in collaboration with companies from the USA.

Similar approach was adopted for solving the issue of flagging with two other countries who had raised this issue.

14. Civil Liability for Nuclear Damage

Nuclear liability is an area of intense debate amongst policy makers, legal community and nuclear industry professionals. India started looking at this issue towards the end of 1990s when it was decided to set up two large reactors at Kudankulam in collaboration with Russia (Grover, 2017b). To understand the issue, a study-project was awarded and the recommendation of the study included that India should enact a liability legislation and join the Convention on Supplementary Compensation. While the work on drafting a liability legislation was ongoing, the Government of India launched the initiative to resume civil nuclear cooperation as described in this paper. USA was looking forward to India joining an international liability regime, particularly the Convention on Supplementary

Compensation.[26] Ongoing drafting work was completed and "The Civil Liability for Nuclear Damage Act, 2010" was enacted. Rules under the Act were also notified.

As explained by Grover (2017b), the legislation follows established international norms regarding no-fault and strict liability regime, channelling of liability to the operator, a single court of jurisdiction etc. In addition, Indian legislation has a unique feature and that is right of recourse as included in section 17 of the Act and elaborated by Rule 24. Section 17 reads as follows:

"17. The operator of a nuclear installation, after paying the compensation for nuclear damage in accordance with section 6, shall have a right of recourse where –

i) such right is expressly provided for in a contract in writing;

ii) the nuclear incident has resulted as a consequence of an act of supplier or his employee, which includes supply of equipment or material with patent or latent defects or sub-standard services;

iii) the nuclear incident has resulted from the act of commission or omission of an individual done with the intent to cause nuclear damage."

While NPCIL is going ahead with the programme to construct PHWRs based on its own technology and Indian industry is participating in the new-build programme, an agreement for setting up reactors in collaboration with companies from France or the USA is yet be concluded.

While the section cited above uses the word 'supplier', the Act doesn't define it or use it elsewhere in the Act. It is explained by Rule 24 as follows:

""Supplier" shall include a person who –

(i) manufactures and supplies, either directly or through an agent, a system, equipment or component or builds a structure on the basis of functional specification, or

(ii) provides build to print or detailed design specifications to a vendor for manufacturing a system, equipment or component or building a structure and is responsible to the operator for design and quality assurance; or

(iii) provides quality assurance or design services."

Being a unique feature, section 17 has been debated by the industry. This debate has not taken full account of the explanation included in Rule 24. Grover (2017b) has explained it in detail and concludes: "Rule 24 provides explanation about a supplier and when one looks at the explanation along with practices in the nuclear industry, one concludes that it is the plant system designer, who is the supplier. The 'explanation' has been formulated based on an analysis of engineering practices followed by the nuclear industry. Any examination of the Indian law without studying the 'explanation' will lead to erroneous conclusions. To protect his interest against the Right of Recourse, the system designer can avail of the insurance policy that is meant for the suppliers. Sub-vendors have no liability under the Right of Recourse."

Based on the legislation, India has joined and ratified CSC. While NPCIL is going ahead with the programme to construct PHWRs based on its own technology and Indian industry is participating in the new-build programme, an agreement for setting up reactors in collaboration with companies from France or the USA is yet be concluded.

15. Outcome of the initiative

15.1 Tangible Outcomes

India started its nuclear programme in cooperation with other countries and resumed cooperation after a lapse of more than three decades in 2008. Science diplomacy was at play in the beginning of the programme when India benefited from international cooperation.

One can look at the outcome of the initiative in different[27] ways and one is to identify tangible benefits India has derived as a result on the waiver from NSG. This has been examined by Grover (2017c) and is further elaborated here:

- At the time of approval of the waiver by NSG in 2008, two reactors were under construction at Kudankulam in technical collaboration with Russia based on an inter-governmental agreement signed in 1988. The agreement was limited to construction of two reactors. Subsequent to 2008, agreements to construct four more reactors at Kudankulam have been signed with Russia. In addition, an Action Plan to construct six more reactors, 1200 MW each, at a new site was signed in October 2018. Action plan also proposes to increase the level of participation of Indian industry. The Action Plan also envisages implementation of projects jointly in third countries (Chaudhury 2018).
- Due to a mismatch between uranium production and its requirements for the operating requirements, it was not possible to operate the reactors at high capacity factors and average capacity factor dropped to 50 percent in 2008-09. Since then, India has been able to import uranium to fuel its PHWRs and their capacity factors have gone up as can be seen from Table 1. Assured of availability of imported uranium, the government has approved construction of additional PHWRs. Table 2 provides details.
- Dialogue with companies in France and USA is ongoing and one can expect agreements on more reactors to be set up in India. Sites where these reactors are proposed to be set up have already been identified.
- Post PNE in 1974, scientific collaboration between India and advanced countries slowed down not only in nuclear field, but in other fields as well. Of course, based on their personal contacts and expertise, some Indian scientists continued to collaborate with their counterparts abroad in various fields. This started changing in mid-1990s when India accepted to collaborate with CERN. Joint Statement of 2005 made a major change when the US committed to

consult with partners to secure India's participation in the ITER[28] project. India joined ITER[29] and requests to join mega-science projects keep pouring in. As written by Grover (2017c), "India has joined Joule Horowitz Reactor (JHR) being constructed by France, Facility for Antiproton and Ion Research (FAIR), Square Kilometre Array (SKA), Thirty Meter Telescope (TMT), High Intensity Proton Accelerator of Fermi Lab and recently Laser Interferometer Gravitational-Wave Observatory (LIGO)." India has also become an associate member of CERN.

- India has started building a strategic reserve of uranium. Building a reserve needs investment and cannot be done in one step. Therefore, a stepwise approach is being followed to build the reserve.

Table 1: Improvement in Capacity factors of Indian reactors over the past few years.

Total installed capacity: 6780 MW

S. No.	Year	Capacity factor %	Generation in million kW-hours
1	2008-09	50	14927
2	2009-10	61	18831

Though India never signed NPT, yet it became a reason for denying all cooperation to India when India demonstrated its scientific strength by going in for a PNE in 1974.

15.2 Intangible Outcomes

Alternate way of looking at the outcome is to examine all intangibles, which have their own importance.

- India has joined three export control regimes namely Missile Technology Control Regime (MTCR), Wassenaar Arrangement (WA) and Australia Group (AG). It enhances India's prestige and also provides possibilities to access high technology.
- This initiative has transformed the relationship between India and the USA. To quote Menon (2016:82), "While both countries have always fought shy of saying that their partnership is to balance China, it is clear that the rise of China was one of the major spurs." He continues:"There is a creative tension at the heart of India-U.S. relations. India clearly needs U.S. technology, markets, and support to transform itself and create the stable and peaceful environment that the country needs to grow. The United State finds a stronger and more active India useful since there is a clear strategic congruence between the countries' goal in the Asia-Pacific."

India has been able to import uranium, signed contracts for building additional four reactors at Kudankulam, announced construction of several PHWRs as uranium availability is not a constraint and joined three export control regimes. India has been trying to join the fourth regime that is NSG, but due to opposition by China, NSG has not been able to come to a consensus about India's membership

16. Concluding Thoughts

Resumption of international civil nuclear trade has been transformative in several ways as described in the previous section. All steps taken by the Government were subjected to a detailed scrutiny by the country as well as international non-proliferation experts, and the government of the day had to even go through a vote of confidence in Parliament. All technical steps have been already described earlier, but to recap, Annex 7 lists important milestones (including political milestones); details of political steps have been covered by other authors (Tellis 2005; Abraham 2007; Chari (ed) 2009, Menon 2016; Saran 2017).

India started its nuclear programme in cooperation with other countries and resumed cooperation after a lapse of more than three decades in 2008. Science diplomacy was at play in the beginning of the programme when India benefited from international cooperation. It was at play when the world was divided into 'haves' and 'have nots' by NPT. Though India never signed NPT, yet it became a reason for denying all cooperation to India when India demonstrated its scientific strength by going in for a PNE in 1974. Subsequent emergence of technology control regimes is also a demonstration of how diplomacy and science are intertwined.

Despite disruption in scientific cooperation and denial of advanced technologies, India continued to grow scientifically and industrially and this was noticed by the global community.

The result was resumption of international civil nuclear trade and this was achieved without influencing ongoing strategic programme.

Beginning from the unveiling of the Joint Statement on 18 July 2005, and until the grant of the waiver by the NSG on 6 September 2008, there was an intense debate in India advising the Government about the steps it should take, red lines that should not be crossed, and even the desirability of the initiative itself. Global non-proliferation experts were worried about crumbling of the narrative built by them ever since NPT came into force.

Prior to the finalisation of the Separation Plan, differing views were expressed by individuals involved in drafting the Separation Plan, but the differences changed into a unity of purpose once the Separation Plan was finalised. The Separation Plan maintains strategic autonomy and provided clarity about what was expected by the nation from the negotiating teams. Several teams were involved in various negotiations: agreements for cooperation with the USA, France and Russia, ISSA and an additional Protocol with the Secretariat of the IAEA, arrangements and procedures for reprocessing with the US, administrative arrangements for implementing the cooperation agreements and so on.

The Separation Plan maintains strategic autonomy and provided clarity about what was expected by the nation from the negotiating teams. Several teams were involved in various negotiations: agreements for cooperation with the USA, France and Russia, ISSA and an additional Protocol with the Secretariat of the IAEA, arrangements and procedures for reprocessing with the US, administrative arrangements for implementing the cooperation agreements and so on.

Membership of the negotiating teams was chosen to ensure that scientific and diplomatic expertise is available in the team. While the author had the privilege of being associated with all the teams, to provide specific scientific expertise, domain-specific subject experts were also added to the teams. For example, an expert in reprocessing was a member of the team for discussing arrangements and procedures for reprocessing, and a nuclear chemist having experience in implementing nuclear material accounting and control was a member for discussing ISSA and India's additional protocol. Embedding experts having knowledge of nuclear science and engineering in the negotiating teams, prior experience by India in implementing safeguards on several nuclear facilities, and clarity about the goal to be achieved were important factors that helped in shaping the text of the agreements. Paying attention to domain specificity along with general science diplomacy is necessary for achieving success.

This was a landmark initiative and was achieved because of scientific strength of the research establishment, industrial capability, and clear guidelines provided by the leadership of the country, and by the joint efforts of scientists and diplomats. India has been able to import uranium, signed contracts for building additional four reactors at Kudankulam, announced construction of several PHWRs as uranium availability is not

a constraint and joined three export control regimes. India has been trying to join the fourth regime that is NSG, but due to opposition by China, NSG has not been able to come to a consensus about India's membership. While continuing diplomatic efforts regarding the membership of NSG, India should work to increase exports of components, equipment and systems for the nuclear island of reactors and provide services for construction of reactors. Efforts should also be made to export PHWRs as many developing countries may be interested in small and medium size reactors currently being built and operated by India. Countries going for a nuclear power plant for the first time also need regulatory services and this should also be explored. Increasing nuclear exports would require joint efforts by diplomats and the nuclear industry in India. The tripartite memorandum of understanding for cooperation in the construction of the Rooppur nuclear power plant in Bangladesh signed by India, Bangladesh and Russia on 1 March 2018 is a step in this direction. Overall objective should be to become a de facto nuclear supplier prior to becoming a de jure member of NSG.

Efforts should also be made to export PHWRs as many developing countries may be interested in small and medium size reactors currently being built and operated by India. Countries going for a nuclear power plant for the first time also need regulatory services and this should also be explored.

Endnotes

1. In October 2017, speaking at the UN General assembly committee, on behalf of New Agenda Coalition comprising Brazil, Egypt, Ireland, New Zealand, South Africa and Mexico, Mexico's Alternate Permanent Representative said that they were introducing a resolution urging "India, Israel and Pakistan to accede to the (Non-Proliferation) Treaty as non-nuclear-weapon states promptly and without conditions, and to place all their nuclear facilities under International Atomic Energy Agency safeguards." Accessed on 03 February 2019 at https://www.news18.com/news/india/at-un-india-denounces-call-to-give-up-nuclear-arsenal-and-sign-npt-1545073.html.
2. "On November 29, 2009, Manmohan Singh, India's Prime Minister, stated on Fareed Zakaria's GPS show that India wants to join the NPT as a nuclear-weapons state (NWS) and become the sixth NPT-recognized nuclear power." (Fidler and Ganguly, 2010)
3. The word 'Unit' is colloquial equivalent of the scientific term 'kWhr' and is used throughout the text.
4. This may be considered as a low estimate. This was chosen to give a lower value for the estimate of projected electricity requirements.
5. As mentioned in the Introduction, an aggressive campaign was launched to locate more reserves and increase domestic production of uranium and that is now showing results. More mines have been opened in Jharkhand and mining in Andhra Pradesh has also been started. Even after all these efforts, reserves continue to be modest in view of large energy requirements of the country. However, this paper is focused on resumption of international trade.
6. Excerpts from the statement by the Prime Minister Atal Bihari Vajpayee in Lok Sabha on 27 May 1998, "India is now a nuclear weapon state. This is a reality that cannot be denied. It is not a conferment that we seek; nor is it a status for others to grant. It is an endowment to the nation by our scientists and engineers."
7. Emphasis added.
8. Ashley writes, "Moreover, as successive U.S. chairmen [of Nuclear Regulatory Commission] who have visited India have come to appreciate, Indian nuclear science could actually contribute to the success of these research efforts, thanks, paradoxically, to the enormous repository of indigenous theoretical and engineering capability that has been developed as a result of decades of forced isolation." (Tellis, 2005: 21)
9. When first proposed, ITER was an abbreviation for International Thermonuclear Experimental Reactor. Iter is Latin for 'the way' and the earlier detail has been dropped. ITER began in 1985 as a Reagan–Gorbachev initiative with the equal participation of the Soviet Union, European Union, the United States, and Japan. Detailed design was completed in 2001 under the auspices of IAEA. Negotiation for the launch of the project started thereafter and over the years more Parties joined the original four.
10. As per the information on its website, the Generation IV International Forum (GIF) is a co-operative international endeavour which was set up to carry out the research and development needed to establish the feasibility and performance capabilities of the next generation nuclear energy systems. At present, the forum has 14 members. Based on goals adopted by GIF, six nuclear energy systems have been selected by it for further development. Selected systems do include systems based on closed fuel cycle approach, which India has been pursuing right from the beginning of the nuclear power programme. After a careful analysis of pros and cons, it was decided not to join GIF.
11. When nuclear cooperation agreement was being negotiated, Anish Goel was working in the White House.
12. Siegfried S. Hecker served as the Director of the Los Alamos National Laboratory from 1986 till 1997 and is now with Stanford University. He visited India several times and interacted with the scientific community.
13. Spent fuel arising from PHWRs is reprocessed to recover Plutonium, which is fabricated into fuel for the Fast Breeder Reactors. To keep fast breeder reactors outside safeguards, it is necessary to keep PHWRs also outside safeguards.
14. Heavy water plants at Thal, Tuticorin and Hazira were designated as civilian. All three are ammonia based, are co-located with fertilizer plants and draw feed synthesis gas from the fertilizer plant. Hydrogen-sulphide-based plants at Kota and Manuguru are independent plants. The sixth plant at Baroda is ammonia based, and is collocated with a fertilizer plant. Baroda plant has been modified by adding an Ammonia Water Exchange Front-End unit making it independent of the co-located fertilizer plant.
15. IAEA has standard templates for implementing safeguards: one template for implementing comprehensive safeguards (see information circular INFCIRC/153, (IAEA1972)) which is applicable to a NNWS as a whole; and the other for item-specific safeguards (see information circular INFCIRC/66, (IAEA 1966)). Non-signatories to the NPT have to offer facilities established based on international cooperation for item-specific safeguards. Both these templates are meant for safeguarding nuclear reactors and fuel cycle facilities. While comprehensive safeguards cover everything by definition, there are no guidelines for safeguarding research institutes or heavy water plants in the item-specific template that is INFCIRC/66.
16. Section 57 of the US Atomic Energy Act prohibits transfer of technologies for the production of special nuclear materials. Informal dialogue with colleagues from USA gives an indication that a determination was made that ITER has no such possibilities.
17. India has developed all three sensitive nuclear technologies namely heavy water production, spent fuel reprocessing and uranium enrichment. While the complete process flow sheet has been designed by the units of DAE based on indigenous

efforts, equipment for setting up plants are sourced from industry. From past experience, one finds that cost of setting up plants can be brought down if equipment are sourced from global market based on open global tenders. Indian negotiators wanted to include cooperation in sensitive nuclear technology with the objective of sourcing equipment from the global market, but the US side responded that it was not possible and so opted for a forward-looking language which says that transfer of sensitive technologies would become possible only after an amendment.

18. Granting consent for reprocessing on a programmatical basis is not a normal part of the US policy. Such a consent is included only in the nuclear cooperation agreement concluded by the US with Japan. Pursuit of closed fuel cycle is an integral part of India's policy and it has been explicitly included in the Agreement. However, as per the US law, for giving consent it is necessary to have arrangements and procedures for implementing the consent and these were negotiated subsequently within the time limit specified. More on arrangements and procedures is covered in a later section.
19. Please see endnote xv.
20. Please see endnote xv.
21. The agreement of cooperation between India and the United States for setting up TAPS-1 & 2 expired n 24 October 1993. According to the terms of the agreement, the safeguards agreement also expired on that date. A new safeguards agreement was negotiated to continue safeguards on TAPS-1 & 2 on voluntary basis by India.
22. In the initial stages, there was some criticism from experts in India about the agreement not being India specific. This subsided after all questions were answered in a Press Conference on 12 July 2008 (Smith and Chakravarthi, 2008).
23. Shivshankar Menon has described in detail about the position of various countries during the debate and how they were brought on board (Menon 2016:72). Shyam Saran lobbied with various NSG countries (Saran 2017: 227). China's opposition was formidable. It looked at the US-India nuclear agreement as a major blow to the international non-proliferation regime (Kumara and Jayasekera, 2008).
24. Please see endnote xvii.
25. An incident narrated by Shivshankar Menon provides an interesting insight, "On September 25, 2008, President Bush hosted a small private dinner for Prime Minister Manmohan Singh in the white house for about ten persons, when the 123 Agreement was awaiting approval by the U.S. senate. Secretary of State Rice leaned over and asked Singh when India would be ordering reactors from Westinghouse. Bush cut her off immediately and said that this was not about reactor sales but about much bigger things. Singh did not have to reply" Menon 2016: 82)
26. HYDE Act, SEC 103 (b) (3) (E) says, "Secure India's ratification of or accession to the Convention on Supplementary Compensation for Nuclear damage, done at Vienna on September 12, 1997."
27. Itty Abraham has approached the issue of outcomes from a different perspective. He poses several hypothetical questions and gives his response. My short response to questions posed by him is that this deal is about civilian programme, India has been and will continue to follow a law-based export control regime, research collaborations and nuclear installed capacity in India will grow as result of this deal.
28. EU was looking at India to join ITER even prior to the US taking the initiative. However, without the support by the US, it would not have been possible for India to join ITER.
29. In view of its high cost, ITER project came in for criticism in the USA, but a recent report from National Academies Press has strongly supported the project (USNAP 2018). High project cost remains a concern for all Parties.
30. Low capacity factors for the years 2017-18 and 2018-19 are due to initial problems with reactors at Kudankulum.
31. This has indeed happened. Institute for Plasma Research is the lead institute for India's participation in ITER.
32. Adapted and expanded from the version published by "India Today", Indo-Asian News Service, Washington, 2 October 2008.

Annexure 1

Extracts from the Joint Statement

Recognizing the significance of civilian nuclear energy for meeting growing global energy demands in a cleaner and more efficient manner, the two leaders discussed India's plans to develop its civilian nuclear energy programme.

President Bush conveyed his appreciation to the Prime Minister over India's strong commitment to preventing WMD proliferation and stated that as a responsible state with advanced nuclear technology, India should acquire the same benefits and advantages as other such states. The President told the Prime Minister that he will work to achieve full civil nuclear energy cooperation with India as it realizes its goals of promoting nuclear power and achieving energy security. The President would also seek agreement from Congress to adjust U.S. laws and policies, and the United States will work with friends and allies to adjust international regimes to enable full civil nuclear energy cooperation and trade with India, including but not limited to expeditious consideration of fuel supplies for safeguarded nuclear reactors at Tarapur. In the meantime, the United States will encourage its partners to also consider this request expeditiously. India has expressed its interest in ITER and a willingness to contribute. The United States will consult with its partners considering India's participation. The United States will consult with the other participants in the Generation IV International Forum with a view toward India's inclusion.

The Prime Minister conveyed that for his part, India would reciprocally agree that it would be ready to assume the same responsibilities and practices and acquire the same benefits and advantages as other leading countries with advanced nuclear technology, such as the United States. These responsibilities and practices consist of identifying and separating civilian and military nuclear facilities and programmes in a phased manner and filing a declaration regarding its civilians facilities with the International Atomic Energy Agency (IAEA); taking a decision to place voluntarily its civilian nuclear facilities under IAEA safeguards; signing and adhering to an Additional Protocol with respect to civilian nuclear facilities; continuing India's unilateral moratorium on nuclear testing; working with the United States for the conclusion of a multilateral Fissile Material Cut Off Treaty; refraining from transfer of enrichment and reprocessing technologies to states that do not have them and supporting international efforts to limit their spread; and ensuring that the necessary steps have been taken to secure nuclear materials and technology through comprehensive export control legislation and through harmonization and adherence to Missile Technology Control Regime (MTCR) and Nuclear Suppliers Group (NSG) guidelines.

The President welcomed the Prime Minister's assurance. The two leaders agreed to establish a working group to undertake on a phased basis in the months ahead the necessary actions mentioned above to fulfill these commitments. The President and Prime Minister also agreed that they would review this progress when the President visits India in 2006.

Annexure 2

Extracts from the Separation Plan

14 vii) **Research Facilities**: India will declare the following facilities as civilians:

α) Tata Institute of Fundamental Research

β) Variable Energy Cyclotron Centre

χ) Saha Institute of Nuclear Physics

δ) Institute for Plasma Research

ε) Institute of Mathematical Sciences

ϕ) Institute of Physics

γ) Tata Memorial Centre

η) Board of Radiation and Isotope Technology

ι) Harish-Chandra Research Institute

These facilities are safeguards irrelevant. It is our expectation that they will play a prominent role in international cooperation.[31]

15. Safeguards:

a) The United States has conveyed its commitment to the reliable supply of fuel to India. Consistent with the July 18, 2005, Joint Statement, the United States has also reaffirmed its assurance to create the necessary conditions for India to have assured and full access to fuel for its reactors. As part of its implementation of the July 18, 2005, Joint Statement the United States is committed to seeking agreement from the U.S. Congress to amend its domestic laws and to work with friends and allies to adjust the practices of the Nuclear Suppliers Group to create the necessary conditions for India to obtain full access to the international fuel market, including reliable, uninterrupted and continual access to fuel supplies from firms in several nations.

b) To further guard against any disruption of fuel supplies, the United States is prepared to take the following additional steps:

ι. The United States is willing to incorporate assurances regarding fuel supply in the bilateral U.S.-India agreement on peaceful uses of nuclear energy under Section 123 of the U.S. Atomic Energy Act, which would be submitted to the U.S. Congress.

ιι. The United States will join India in seeking to negotiate with the IAEA an India-specific fuel supply agreement.

ιιι. The United States will support an Indian effort to develop a strategic reserve of nuclear fuel to guard against any disruption of supply over the lifetime of India's reactors.

ιϖ. If despite these arrangements, a disruption of fuel supplies to India occurs, the United States and India would jointly convene a group of friendly supplier countries to include countries such as Russia, France and the United Kingdom to pursue such measures as would restore fuel supply to India.

c) In light of the above understandings with the United States, an India-specific safeguards agreement will be negotiated between India and the IAEA providing for safeguards to guard against withdrawal of safeguarded nuclear material from civilian use at any time as well as providing for corrective measures that India may take to ensure uninterrupted operation of its civilian nuclear reactors in the event of disruption of foreign fuel supplies. Taking this into account, India will place its civilian nuclear facilities under India-specific safeguards in perpetuity and negotiate an appropriate safeguards agreement to this end with the IAEA.

Annexure 3

List of facilities subject to safeguards under ISSA

	Facility offered for Safeguards by India	Date of receipt of notification
1.	Uranium Oxide Plant (Block A), Nuclear Fuel Complex, Hyderabad	16 October 2009
2.	Ceramic Fuel Fabrication Plant (Pelletizing)(Block A), Nuclear Fuel Complex, Hyderabad	16 October 2009

Annexure 5

Nuclear Suppliers Group's Statement on Civil Nuclear Cooperation with India (IAEA, 2008b)

1. At the Extraordinary Plenary Meeting on 6 September 2008 the Participating Governments of the Nuclear Suppliers Group decided that they:
   a. Desire to contribute to the effectiveness and integrity of the global nonproliferation regime, and to the widest possible implementation of the provisions and objectives of the Treaty on the Non-Proliferation of Nuclear Weapons;
   b. Seek to avert the further spread of nuclear weapons;
   c. Wish to pursue mechanisms to affect positively the non-proliferation commitments and actions of all states;
   d. Seek to promote fundamental principles of safeguards and export controls for nuclear transfers for peaceful purposes; and
   e. Note the energy needs of India.
2. Participating Governments have taken note of steps that India has voluntarily taken with respect to the following commitments and actions:
   a. Deciding to separate civilian nuclear facilities in a phased manner and to file a declaration regarding its civilian nuclear facilities with the IAEA, in accordance with its Separation Plan (circulated as INFCIRC/731);
   b. Concluding negotiations with the IAEA and obtaining approval by the Board of Governors on 1 August 2008 for an "Agreement between the Government of India and the IAEA for the Application of Safeguards to Civilian Nuclear Facilities," in accordance with IAEA standards, principles, and practices (including IAEA Board of Governors Document GOV/1621;)
   c. Committing to sign and adhere to an Additional Protocol with respect to India's civil nuclear facilities;
   d. Refraining from transfer of enrichment and reprocessing technologies to states that do not have them and supporting international efforts to limit their spread;
   e. Instituting a national export control system capable of effectively controlling transfers of multilaterally controlled nuclear and nuclear-related material, equipment and technology;
   f. Harmonizing its export control lists and guidelines with those of the Nuclear Suppliers Group and committing to adhere to the Nuclear Suppliers Group Guidelines; and
   g. Continuing its unilateral moratorium on nuclear testing, and its readiness to work with others towards the conclusion of a multilateral Fissile Material Cutoff Treaty.
3. Based on the commitments and actions mentioned above, as reiterated by India on September 5, 2008, and without prejudice to national positions thereon, Participating Governments have adopted and will implement the following policy on civil nuclear cooperation by Participating Governments with the IAEA-safeguarded Indian civil nuclear programme:
   a. Notwithstanding paragraphs 4(a), 4(b) and 4(c) of INFCIRC/254/Rev.9/Part 1, Participating Governments may transfer trigger list items and/or related technology to India for peaceful purposes and for use in IAEA safeguarded civil nuclear facilities, provided that the transfer satisfies all other provisions of INFCIRC/254/Part 1, as revised, and provided that transfers of sensitive exports remain subject to paragraphs 6 and 7 of the Guidelines.

b. Notwithstanding paragraphs 4(a) and 4(b) of INFCIRC/254/Rev.7/Part 2, Participating Governments may transfer nuclear-related dual-use equipment, materials, software, and related technology to India for peaceful purposes and for use in IAEA safeguarded civil nuclear facilities, provided that the transfer satisfies all other provisions of INFCIRC/254/Part 2, as revised.

c. At each Plenary, Participating Governments shall notify each other of approved transfers to India of Annex A and B items listed in INFCIRC/254/Part 1, as revised. Participating Governments are also invited to exchange information, including about their own bilateral agreements with India.

d. With a view to intensification of dialogue and cooperation with India, the Chairman is requested to confer and consult with India and keep the Plenary informed of these consultations.

e. Participating Governments will maintain contact and consult through regular channels, including the Consultative Group and Plenary, for the purpose of considering matters connected with the implementation of all aspects of this Statement taking into account relevant international commitments or bilateral agreements with India. In the event that one or more Participating Governments consider that circumstances have arisen which require consultations, Participating Governments will meet, and then act in accordance with paragraph 16 of the Guidelines.

4. In order to facilitate India's adherence to INFCIRC/254/Parts 1 and 2 and to remain current in its implementation of the Guidelines, the NSG Chair is requested to consult with India regarding changes to and implementation of the Guidelines and inform the Plenary of the outcome of the dialogue with India. Consultations with India regarding proposed amendments will facilitate their effective implementation by India.

5. Upon request by Participating Governments, the Chairman is requested to submit this Statement to the IAEA Director General with a request that it be circulated to all Member States.

Annexure 6

Statement by External Affairs Minister of India Shri Pranab Mukherjee on the Civil Nuclear Initiative

September 05, 2008

To reiterate India's stand on disarmament and nonproliferation, EAM has made the following statement:

A Plenary meeting of the Nuclear Suppliers Group to consider an exception for India from its guidelines to allow for full civil nuclear cooperation with India is being held in Vienna from September 4-5, 2008.

India has a long-standing and steadfast commitment to universal, non-discriminatory and total elimination of nuclear weapons. The vision of a world free of nuclear weapons which Shri Rajiv Gandhi put before the UN in 1988 still has universal resonance.

We approach our dialogue with the Nuclear Suppliers Group and all its members in a spirit of cooperation that allows for an ongoing frank exchange of views on subjects of mutual interest and concern. Such a dialogue will strengthen our relationship in the years to come.

Our civil nuclear initiative will strengthen the international non-proliferation regime. India believes that the opening of full civil nuclear cooperation will be good for India and for the world. It will have a profound positive impact on global energy security and international efforts to combat climate change.

India has recently submitted a Working Paper on Nuclear Disarmament to the UN General Assembly, containing initiatives on nuclear disarmament. These include the reaffirmation of the unequivocal commitment of all nuclear weapon States to the goal of complete elimination of nuclear weapons; negotiation of a Convention on the complete prohibition of the use or threat of use of nuclear weapons; and negotiation of a Nuclear Weapons Convention prohibiting the development, production, stockpiling and use of nuclear weapons and on their destruction, leading to the global, non-discriminatory and verifiable elimination of nuclear weapons within a specified timeframe.

We remain committed to a voluntary, unilateral moratorium on nuclear testing. We do not subscribe to any arms race, including a nuclear arms race. We have always tempered the exercise of our strategic autonomy with a sense of global responsibility. We affirm our policy of no-first-use of nuclear weapons.

We are committed to work with others towards the conclusion of a multilateral Fissile Material Cut-off Treaty in the Conference on Disarmament that is universal, non-discriminatory and verifiable.

India has an impeccable non-proliferation record. We have in place an effective and comprehensive system of national export controls, which has been constantly updated to meet the highest international standards. This is manifested in the enactment of the Weapons of Mass Destruction and their Delivery Systems Act in 2005. India has taken the necessary steps to secure nuclear materials and technology through comprehensive export control legislation and through harmonization and committing to adhere to Missile Technology Control Regime and Nuclear Suppliers Group guidelines.

India will not be the source of proliferation of sensitive technologies, including enrichment and reprocessing transfers. We stand for the strengthening of the non-proliferation regime. We support international efforts to limit the spread of ENR equipment or technologies to states that do not have them. We will work together with the international community to advance our common objective of non-proliferation. In this regard, India is interested in participating as a supplier nation, particularly for Thorium-based fuel and in establishment of international fuel banks, which also benefit India.

India places great value on the role played by the IAEA's nuclear safeguards system. We look forward to working with the IAEA in implementing the India-specific Safeguards Agreement concluded with the IAEA. In keeping with our commitment to sign and adhere to an Additional Protocol with respect to India's civil nuclear facilities, we are working closely with the IAEA to ensure early conclusion of an Additional Protocol to the Safeguards Agreement.

New Delhi

5th September 2008

Annexure 7

Milestones[32] leading to resumption of international civil nuclear trade

13 January 2004: The release of a matched set of statements (Next Steps in Strategic Partnership) by the PM of India in New Delhi and the President of the USA in Washington.

18 July 2005: Prime Minister Manmohan Singh and President George W. Bush sign a joint statement in Washington on India-US civil nuclear cooperation.

6 December 2005: India is admitted to the negotiations for finalising the Joint Implementation Agreement for setting up ITER.

2 March 2006: India and the US agree on a Separation Plan during President Bush's visit to Delhi. In exchange, US agrees to work towards full civil nuclear cooperation with India.

21 November 2006: India signs Joint Implementation Agreement to set up ITER.

9 Dec 2006: Both houses of US Congress approve the Henry J. Hyde US-India Peaceful Atomic Energy Cooperation Act of 2006.

18 Dec 2006: Bush signs the enabling legislation permitting full civilian nuclear cooperation with India into law.

27 July 2007: India and the US announce the finalization of bilateral Nuclear Cooperation Agreement.

October 2007: Left allies of the UPA government declare that the Nuclear Cooperation Agreement is against the country's interests and compromising to its sovereignty.

November 2007-June 2008: United Progressive Alliance (UPA) and its Left allies set up a joint panel and agree to allow the government to carry on negotiations with IAEA on finalising the text of ISSA.

May 2008: Indian negotiators complete negotiations with the secretariat of the IAEA for the text of the ISSA.

25 June 2008: The Left parties give an ultimatum to withdraw support if the government goes ahead with signing the ISSA with IAEA.

7 July 2008: While on way to Japan to attend the G8 summit, Prime Minister Manmohan Singh informs accompanying media persons about the plan of the government to go ahead with finalising the ISSA with IAEA.

9 July 2008: The Left parties withdraw support to the UPA government and call for a vote of confidence.

22 July 2008: The UPA government wins the vote of confidence.

1 Aug 2008: Board of Governors of IAEA approves ISSA.

6 Sep 2008: The 45-member Nuclear Suppliers Group (NSG) grants waiver to India facilitating international civil nuclear trade with India.

10 Sep 2008: President Bush notifies Congress to take up the India-US nuclear deal and give it the approval. Also, India's Foreign Secretary issues a letter to his counterpart regarding India intention to conclude agreements for the construction of nuclear power units at least at two sites capable of generation a minimum of 10,000 MWe.

23 Sep 2008: The US Senate Foreign Relations Committee approves the agreement but its new provisions stating that the deal will be subject to the Hyde Act create some uncertainty.

25 Sep 2008: President Bush tells Prime Minister Manmohan Singh in Washington that the administration is working to get the Nuclear Cooperation Agreement approved by the US Congress.

26 Sep 2008: US House of Representatives Foreign Affairs Committee chairman Howard Berman introduces the approval resolution to Agreement.

27 Sep 2008: House of Representatives passes the 123 Agreement for civil nuclear cooperation between India and the US by a margin of 298-117.

30 September 2008: India and France sign the Nuclear Cooperation Agreement.

1 Oct 2008: Senate passes the approval bill 86-13.

10 October 2008: India and the USA sign the Nuclear Cooperation Agreement.

5 Dec 2008: India and Russia sign the Nuclear Cooperation Agreement.

30 Jul 2010: India and the USA sign Arrangements and Procedures for Reprocessing

15 May 2009: India signs the Additional Protocol

16 Oct 2009: India notifies first set of facilities to IAEA for implementing safeguards under ISSA

11 Nov 2011: India notifies the Civil Liability for Nuclear Damage Act, 2010.

12 Dec 2014: India completes separation plan by offering last set of facilities identified in the Separation Plan as per the agreed time table.

4 Feb 2016: India deposits its instrument of ratification for the Convention on Supplementary Compensation for Nuclear Damage (CSC).

Science Diplomacy Case Study Series

Forum for Indian Science Diplomacy

As part of its ongoing research studies on Science &Technology and Innovation (STI), RIS together with the National Institute of Advanced Studies (NIAS), Bangalore has endeavoured a major project for Science Diplomacy this year, supported by the Department of Science and Technology. The programme was launched on 7 May 2018 at New Delhi. Forum for Indian Science Diplomacy (FISD), under the RIS–NIAS Science Diplomacy Programme envisages harnessing science diplomacy in areas of critical importance for national development and S&T cooperation.

The key objective of the Forum is to realize the potential of Science Diplomacy by various means, including Capacity building in science diplomacy, developing networks and Science diplomacy for strategic thinking. It aims for leveraging the strengths and expertise of Indian Diaspora working in the field of S&T to help the nation meet its agenda in some select S&T sectors.

Abstract

The work in this paper involves intelligent modelling techniques i.e. fuzzy logic, Artificial Neural Network (ANN) Adaptive Neural Fuzzy Inference System (ANFIS) methodologies for estimating the power in a solar photovoltai system. Since, the generation of power is subjective to environmental factors such as ambient temperature, variatio conditions and solar insolation, therefore, an intelligent modelling techniques have been proposed for forecasting the p solar photovoltaic system employing 210 W Heterojunction with Intrinsic Thin layer (HIT) photovoltaic modules for diff sky-conditions such as clear sky, hazy sky, partially foggy/cloudy sky and fully foggy/cloudy sky conditions respecti composite climate zone and performance has been evaluated using statistical indicators

Keywords: ANFIS (adaptive neural fuzzy inference system); ANN (artificial neural network); forecasting; fuzzy logic; s condition; SPV system

DOI: http://dx.doi.org/10.4314/ijest.v11i4.5

1. Introduction

Last few years have seen tremendous growth in the field of renewable power generation especially in the field of solar energ which employs PV system comprising a number of solar cells (Chauhan and Saini, 2004; Singh, 2003; Zhou et al., 2010). Its advantage is that it generates green house gas emissions and simple scalability in terms of power needs while its disadvantage is that the output power diminishes due to dust, clouds and other obstructions in the atmosphere (Al-Lawati et al., 2015; Jimenez-Perez and Mora-Lopez, 2016). Therefore, an intelligent modelling technique has been introduced to accurately estimate the power generation in SPV system based on sky conditions.

Detailed literature analysis reveals that the intelligent model available in the literature have been defined for clear sky-condition, however, very few models are available in the literature that discussed about variation in sky condition. The objective of the present research is to do the comparative analysis of Fuzzy logic, ANN and ANFIS models in forecasting short-term PV power of SPV systems employing HIT PV modules for different sky conditions i.e. sunny sky, hazy sky, partially foggy/cloudy sky and fully foggy/cloudy sky conditions and for composite climate zone. The performance has been evaluated based on statistica indicators.

The work has been arranged as follows: The data and methodology are presented in Section 2. Section 3 discusses the performance characterization of SPV system. Section 4 is developed to statistical error tests. Results and discussions are prese in Section 5. Conclusion followed by references is presented in Section 6.

2. Data and Methodology

2.1 Meteorological data: In this work, the parameters namely solar irradiance and cell temperature have been achieved from the collaboration of Indian Meteorological Department and National Institute of Solar Energy for composite climate zone (Ajit, 2009; Bansal and Minke, 1988). Further, the normalization of the parameters in 0.9-1.1 range has been done to avoid convergence issues.

2.2 Intelligent modelling for estimating the power of SPV system: Intelligent modelling methods namely fuzzy logic, ANN and ANFIS have been employed to forecast the power in a solar photovoltaic system (Perveen, 2019). The details of methodologies are discussed section-wise as follows:

2.2.1 Fuzzy logic: The first section discusses the fuzzy logic modelling where the membership functions are defined in 0.1-0.9 range and a set of rules are explained in fuzzy logic toolbox of MATLAB. The model has been developed using Mamdani-Sugeno in fuzzy inference system to forecast the power of SPV system for input parameters namely solar cell temperature and solar insolation while the PV power is the output and presented in Fig. 1 (Chen, 2013; Rizwan et al., 2014; Perveen et al., 2018).

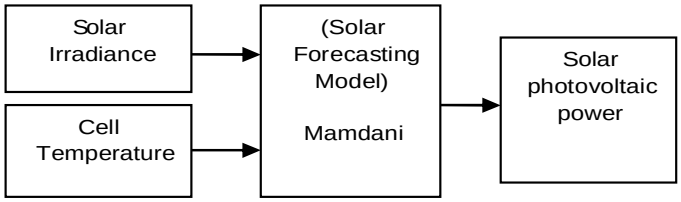

Figure 1. Fuzzy logic based model for estimating power in a solar photovoltaic system.

2.2.2 Artificial Neural Network (ANN): The second section presents an artificial intelligent modelling technique artificial Neural Network (ANN) employing a feed-forward neural network. Model-based on ANN are planned and designed in such manner that output is simulated from the input variables for power forecasting in the SPV system and are presented in Fig. 2 (Azadeh et al., 2013; Azimi et al., 2016; Al-Waeli et al., 2019; Notton et al., 2019).

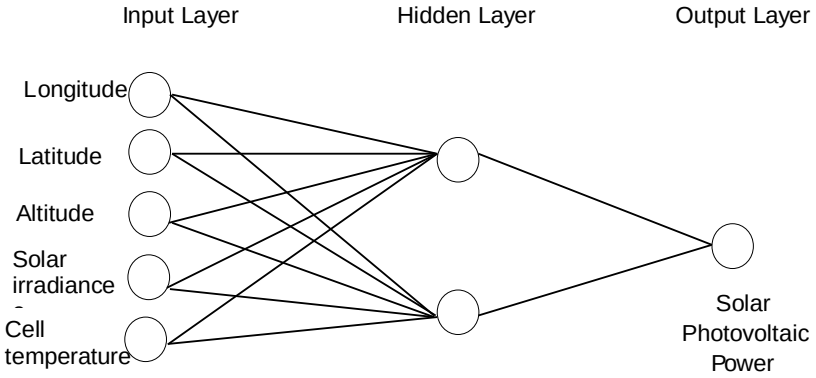

Figure 2. ANN architecture for estimating power in the SPV system.

2.2.3 Adaptive Neural Fuzzy Inference System (ANFIS): The third section presents the combination of ANN and fuzzy logic modelling. ANFIS applies the graphical analysis of Fuzzy-Sugeno system lying within the framework of adaptive networks and relates back-propagation and least squares method using MATLAB software for training and testing the data. The main advantage of using ANFIS methodology is that the convergence rate is much faster (Abbod et al., 2013; Jang and Sun, 1995).

3. Performance Characterization of SPV System

In the present work, 210 W HIT solar PV module is chosen and operated at Maximum Power Point (MPP) conditions. Influenced by parameters namely solar irradiance and cell temperature and based on the standard test condition, the power generation can be defined by Eq. (1) as shown below (Riffonneau et al., 2011):

$$Q_{PV} = \quad * \qquad (1)$$

and - 20) (2)

where $Q_{PV,STC}$ is the photovoltaic system rated power output at standard test conditions, Q_{PV} is the power output of photovoltaic array at MPP, G_T is solar irradiance in W/m^2 at standard test condition, N_{PVS} is the photovoltaic arrays in series in number, is a temperature parameter at maximum power point, N_{PVP} is photovoltaic arrays in parallel in number of, T_j is the junction temperature of solar panel in °C. Given the efficiency of the module is 16.7%, T_m is ambient operating temperature range between - 4°F to 115°F and N_{OCT} (Normal operating cell temperature) is 114.8°F.

4. Statistical Error Tests

For evaluating the performance of the models, statistical error tests namely MAPE, NMAE, and nRMSE respectively have been used for analysis (Dolara et al., 2018).

4.1 Mean absolute percentage error (MAPE):

$$MAPE_{\%} = \qquad (3)$$

4.2 Normalized mean absolute error (NMAE):

$$NMAE_{\%} = \qquad (4)$$

4.3 Normalized root mean square error (nRMSE):

$$nRMSE_{\%} = \qquad (5)$$

where n is the number of observed data, a_i and e_i are the i_{th} measured and estimated data respectively, and $E_i = e_i - a_i$ is the absolute error. This definition of error is normalized over the maximum hourly measured data.

5. Results and Discussions

Intelligent models have been developed for SPV system which uses 210 W HIT solar PV module operated at Maximum Power Point Tracking (MPPT) conditions. The data at the input layer comprises cell temperature, solar irradiance and the output layer is the PV power. Fuzzy logic, artificial neural network and ANFIS methodologies have been employed in forecasting power of SPV systems for composite climate zone and are presented in Table 1.

It has been observed from Table 1 that the average mean absolute percentage error by using fuzzy logic methodology is 0.10 with ANN methodology the mean absolute percentage error reduced to 0.04%; and with ANFIS methodology the mean absolute percentage error further reduced to 0.01% which reveals that the obtained results are precise and accurate. This is due to reason that it employs both fuzzy logic approach and artificial neural network. Further, the graphical representation between the measured and forecasted power employing different methodologies has been presented in Fig. 3.

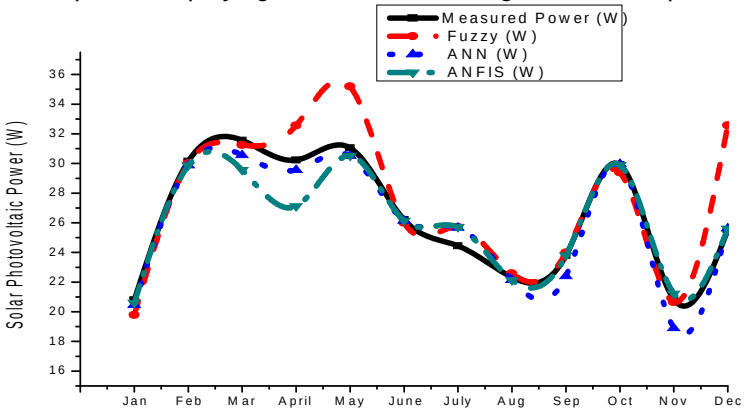

Figure 3. Graphical analysis of measured and forecasted PV power employing fuzzy logic, ANN and ANFIS methodologies.

From Figure 3, it has been revealed that the forecasted power employing ANFIS methodology closely follows the measured power as compared to others methods such as fuzzy logic and artificial neural network. Furthermore, the power generation in SPV system is greatly influenced by external environmental factors namely sky conditions, ambient temperature and solar insolation. Therefore, sunny, hazy, partially foggy/cloudy and fully foggy/cloudy sky conditions are considered and performance has been evaluated based on statistical error tests and are presented in Table 2.

Table 2. Short-term PV power forecasting employing HIT solar PV module under composite climate zone

Following inferences can be drawn from Table 2 shown as:

Sunny/Clear sky: 1st June 2015 is considered as a sunny day based on the annual analysis of solar radiation data and availability of sunshine hours. Further, the graphical representation between measured and forecasted power for sunny sky condition has been shown in Figure 4 from which it has been concluded that the forecasted power employing ANFIS methodology represented by cyan colored dash-dot line on hour basis closely follows the measured power represented by the black solid line, whereas some deviation can be seen in terms of fuzzy logic approach represented by red colored dashed line and ANN approach represented by blue colored dot line. The maximum power output is observed to be 62 W during the day with average MAPE of 0.0610% using the fuzzy logic methodology; and the error reduced to 0.0014% by employing ANN methodology; and with ANFIS methodology the mean absolute percentage error has further reduced and is observed to be 0.0010% respectively.

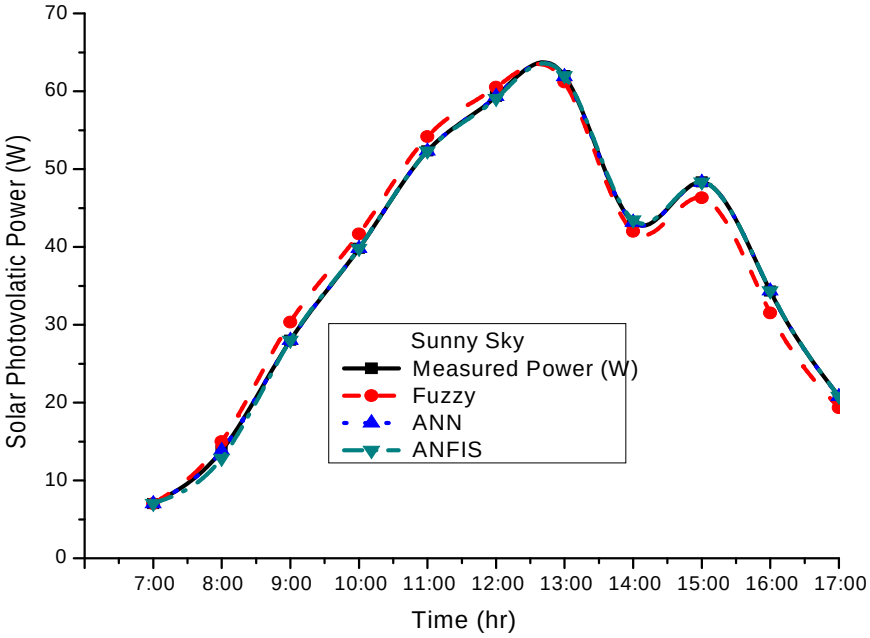

Figure 4. Graphical analysis of measured power and forecasted power employing fuzzy logic, ANN and ANFIS methodologies for sunny sky condition.

Hazy sky: 26th December 2015 is considered as a hazy day based on the annual analysis of solar radiation data and availability of sunshine hours. Further, the graphical representation between measured and forecasted power for hazy sky condition has been shown in Figure 5 from which it has been concluded that the forecasted power employing ANFIS methodology represented by cyan dash-dot line on hour basis closely follows the measured power represented by the black solid line, whereas some deviation can be seen in terms of fuzzy logic approach represented by red dashed line and ANN represented by blue dot line. The maximum power output is observed to be 50 W during the day with averaged mean absolute percentage error by employing fuzzy logic methodology is 0.0561%; by employing ANN methodology the mean absolute percentage error is 0.0422%; and by employing ANFIS methodology the error is 0.0068% respectively.

Partially foggy/cloudy sky: 3rd August 2015 is considered as partially foggy/cloudy day based on the annual analysis of solar radiation data and availability of sunshine hours. Further, the graphical representation between measured and forecasted power for partially foggy/cloudy sky condition have been shown in Figure 6 from which it has been concluded that the forecasted power employing ANFIS methodology represented by cyan dash-dot line on hour basis closely follows the measured power represented by the black solid line, whereas some deviation can be seen in terms of fuzzy logic approach represented by red dashed line and ANN represented by blue dot line. The maximum power output is observed to be 44 W during the day with averaged mean percentage error by employing fuzzy logic methodology is 0.2687%; by employing ANN methodology the mean absolute percentage error is 0.0305%; and by employing ANFIS methodology the error is 0.0170%.

Fully foggy/cloudy sky: 3rd January 2015 is considered as fully foggy/cloudy day based on the annual analysis of solar radiation data and availability of sunshine hours. Further, the graphical representation between measured and forecasted power for fully foggy/cloudy sky condition have been shown in Figure 7 from which it has been concluded that the forecasted power employing ANFIS methodology represented by cyan dash-dot line on hour basis closely follows the measured power represented by the black solid line, whereas some deviation can be seen in terms of fuzzy approach represented by red

dashed line and ANN represented by the dot line. The maximum power output is observed to be 12 W during the day with averaged mean absolute percentage error by employing fuzzy logic methodology is 0.1311%; by using ANN methodology the error is 0.0301%; and by employing ANFIS methodology the mean absolute percentage error is 0.0198% respectively.

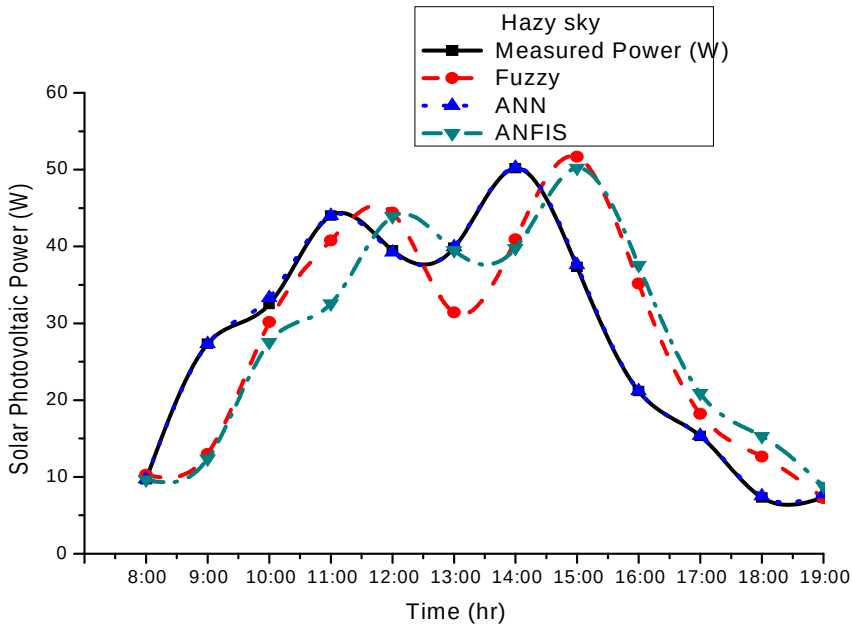

Figure 5. Graphical analysis of measured power and forecasted power employing fuzzy logic, ANN and ANFIS methodologies for hazy sky condition.

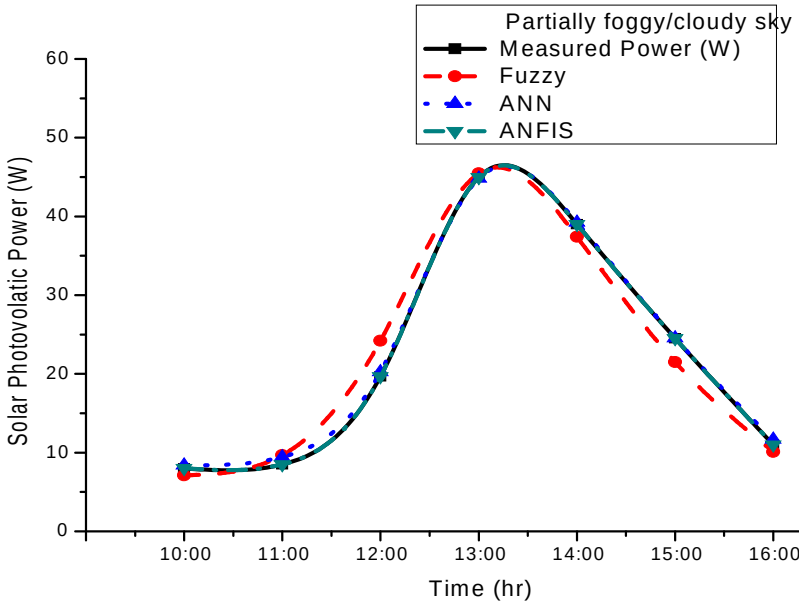

Figure 6.Graphical analysis of measured power and forecasted power employing fuzzy logic, ANN and ANFIS methodologies for partially foggy/cloudy sky condition.

From Table 2, it has been observed that out of the four models, especially the hazy sky model perform well with mean absolute mean percentage error of 0.0008% in forecasting the power of SPV system followed by sunny sky model with mean absolute percentage error of 0.0010%, partially foggy/cloudy sky model with mean absolute percentage error of 0.0170%, and fully foggy/cloudy sky model with mean absolute percentage error of 0.0198% respectively by using ANFIS methodology.

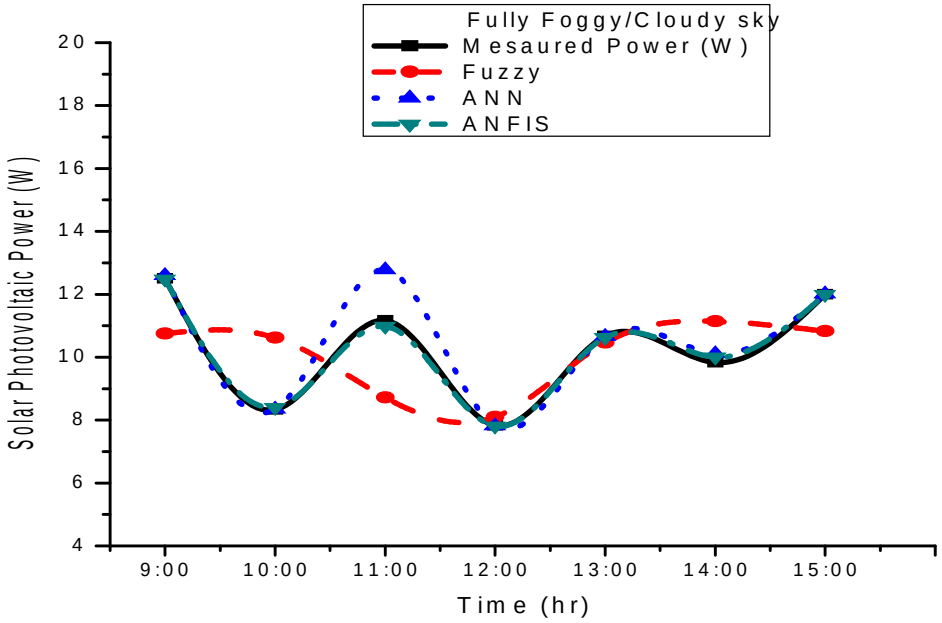

Figure 7. Graphical analysis of measured power and forecasted power employing fuzzy logic, ANN and ANFIS methodologies for fully foggy/cloudy sky condition.

6. Conclusion

In the present work, intelligent modelling techniques have been employed for estimating the power of a SPV system for composite climate zone. Simulations have been carried out using fuzzy logic, ANN and ANFIS methodologies for varying sky-conditions i.e. sunny sky, hazy sky, partially foggy/cloudy sky and fully foggy/cloudy sky conditions. Three criteria namely mean absolute percentage error, normalized mean absolute error and normalized root mean square error verifies the forecasting errors of the model. Obtained results reveal the accuracy of the ANFIS model which is far accurate and better than the artificial neural network and fuzzy logic models. ANFIS model has certain advantages such as the ease of design, robustness and adaptability with the non-linearity associated with the data. The ANFIS methodology integrates the features of both fuzzy logic and ANN which increases the system accuracy and makes the system response much faster. The result reveals the model implementation for a broad series of applications. The prediction of solar energy makes it suitable for installation of a monitoring station for a remote place and furthermore, can be extended for sizing of standalone PV system as a part of the future work.

Nomenclature

e_i	i_{th} estimated data (dimensionless)
MAPE	mean absolute percentage error (%)
m_i	i_{th} measured data (dimensionless)
nMAE	normalized mean absolute error (%)
nRMSE	normalized root mean square error (%)
N_{PVP}	photovoltaic arrays in parallel (number)
N_{PVS}	photovoltaic arrays in series (number)
O_{PV}	power output of photovoltaic array at MPP (W)
$O_{PV,STC}$	rated power output of photovoltaic array (W)
T_m	measured ambient temperature (^{0}C)
T_j	temperature of solar panel (^{0}C)
T_o	maximum ambient temperature (^{0}C)
	temperature parameter at MPP

ABSTRACT

In our day to day life, communication plays important role for conveying information from one person to another person. But it becomes very difficult for the people who are deaf and dumb to communicate with normal people. Sign language is the only one way to communicate with them. But normal people are unaware of sign language. So there is only one way and that is to covert sign language into text & speech & vice versa. That is known as sign recognition. Sign language is a combination of body languages, hand gestures and facial expressions. Among those hand gestures are provides majority of the information

In this paper we will discuss the method proposed by author for Sign Language Interpretation and its conversion to text.

Index Terms- Pattern Recognition, Media pipe Framework, Image Pre-Processing, Feature Extraction.

I. INTRODUCTION

Over 5% of the total population on Planet are deaf people. 5% may seem like a small number, but that totals over 360 million-! Being specially abled of this type, it is very difficult to communicate with ordinary people. To help them communicate among themselves and others, there is a sign language through which they communicate. However, ordinary people find it hard to learn this language and hence, interaction with specially abled people is difficult.

To overcome this problem, several methods had been proposed. However, some are expensive and others rather inaccurate. Here we propose an accurate, affordable and easily accessible method to solve the problem. In the proposed method, we make use of the image recognition and deep learning, to make machine act as a translator. Through camera image of the sign alphabet will be captured and the interface (machine) will output the sign alphabet in text.

II. LITERATURE REVIEW ON DIFFERENT SYSTEMS.

The hand gesture recognition system builds a natural, interactive and the most favorable environment for the Human-Computer Interaction. Due to its utmost importance in the present scenario, and more importantlyin the future, many techniques have been thought about, developed and implemented till now. Mostly sign language recognition is done by two approaches: Image based [1].sensor-based approach.

Truong*et al.* [2] presents a work on applying AdaBoost and Haarlike classifiers for recognizing American Sign Language with complex background from live videos and translates into text and speech. The key factor of the high accuracy result was the big dataset in the training process.

Fu*et al.* [3] proposed a wavelet enhanced image preprocessing and neural networks for hand gesture recognition approach. Collected images are processed to extract the contour of the hand gestures also provide the neural networks for hand gesture learning with wavelet-based feature extraction.

Since many proposed methods does not works on geometric properties and require any extracted features. Vishwakarma*et al.* [4] implemented method which works on geometric properties and does not require any extracted features also works well on low-resolution images which is a great advantage for developers regarding data storage.

Vishwakarma et al. [5] presents a novel hand gesture recognition system, for the efficient human-computer interaction. Also proposed algorithm for hand gesture recognition in the complex background in proposed based on shape and texture feature.

Kumar et al. [6] proposed an idea for feasible communication between hearing impaired and normal person with the help of machine learning approach. Instead of preprocessing techniques, like filtering and segmentation of hand patch images, features are extracted from dataset by discrete wavelet transform.

Anup Kumar et al. [7] propose the design for a basic yet extensible system that is able to recognize static and dynamic gestures of American Sign Language. Mapping of the spoken alphabet to text is done by proposed algorithm.

III. THE PROPOSED SYSTEM

Communication plays a major role in human life, but deaf and dumb people find it difficult to communicate with normal people. To minimize this communication gap, we introduce a handgesture recognition system to recognize the alphabets of Sign Language. We propose an easy-to-use and inexpensive approach to recognize single and double handed gestures accurately. We intend to develop the said project in total of three modules namely:

1. Image Input Module:
This Module will consist of capturing the image of hand to recognize the gesture within the given resolution from camera.

2. Image Processing Module:
This module will give 21 3D key points of the given image of hand. It will be essentially a hand tracking module implemented using Media pipe framework.

3. Classification Module:
With provided points from the Image Processing Module, the classifier will decide thesign alphabet by taking reference from the training set by the help of classificationalgorithm. The output will be generated as text corresponding to the Sign alphabet decided by Classifier.

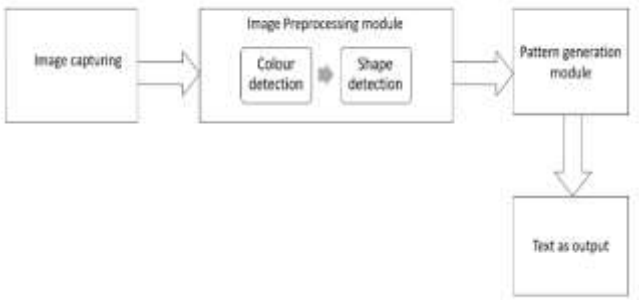

Fig 1. Architecture of the Proposed System.

Fig1 demonstrates the working of sign language interpretation system. Initially the image is captured which is then pre-pre-processed. The pre-processing consists of colour detection and shape detection module. The processed image is then given as input to pattern generation module further to which the generated pattern is converted to its equivalent text.

IV. ALGORITHM AND MATHEMATICAL MODEL

I. Sign Language Detection.
1. Capture image.
2. Retrieve key points of the hand.
3. Calculate distances between the focus of the given image and the clusters of different sign alphabets.
4. Whichever is nearest to the given image, give it as an output text.

CNN Algorithm:
Convolution operation: Prepare feature detector for the input image. Feature detector will be images of sign language. Make a corresponding feature map for it.

Rectified Linear Unit (ReLU): Apply Rectifier Function to increase the non-linearity of image.

Pooling: Apply max pooling on the image to make the network realize whichever the condition of the image, CNN must be able to identify it. Roughly 75% of information is filtered after this step.

Flattening: Flatten the 2*2 matrix to single dimensional array.

Full connection step : After Flattening feed the flattened array to the fully connected trained network and whichever class has the highest value as output, return the label of that class.(Here class represents alphabets of sign language) Mathematical model for Hand Gesture Recognition System as follows:
Let us consider S be the system such that

S= {I, F, O}

Where,
I = Set of Input
as a images captured by camera or by video such as raw video.
F = Set of Functions
F = {I, TD, IF, SS, G}
where,

I = Input images extracted from video or captured by camera.
TD = {T1, T2, T3....T n| T is the train data used to compare the captured images.
IF = {IF1, IF2, IF3.... IFn| IF is the important frames calculated by score function

$$F[V, S, w] = w^t f(V, S)$$

where F is the score function, V and S stands for the feature matrix of images and its candidate summary, w is the property weight

SS = Storage server
SS is used to store the extracted imported frames.

G = Generate the recognized images of Hand Gesture.

O = Output
Textual or Verbal result

V. ACTIVITIES AND EVENTS:

EVENT 1
User will make registration on SYSTEM and Storage Server. Let f(U) be a function of User.
Thus, f(U) →{U Ds}

EVENT 2
Let f(C) be a capture function of System.
Thus, f(C) → {I1,I2, I3In} ε C

EVENT 3
Pre Processing is performed on detected images. Let f(I) be a image processing function.
Thus, f(I) →{I1,I2,I3In} ε T
EVENT 4
Let f(FT) be an function used to extract the features on basis of train dataset
Thus, f(FT) →{T,I} ε FT

EVENT5
Let f(E) be be the Character Detection on extracted features using CNN .

Thus, f(E) → {FT} ε T

FLOWCHART
Object Detection using media pipe.

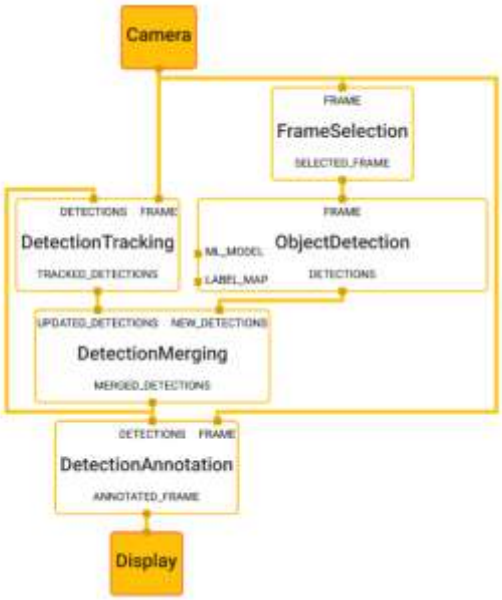

Fig 2. Object Detection using mediapipe.[8]

VI. CONCLUSION

In this paper we have proposed a sign language interpretation system and its conversion to text for deaf and dumb people. The system will make use of camera to capture hand gestures further media pipe framework will detect the hand gesture and the this gesture will be classified by matching it with the sample dataset which is used for the conversion of gesture into its equivalent text.

ABSTRACT
Nonlinear control techniques are applied on mechanical systems namely two link robot manipulator to study the effect of the controllers on the tracking performance of the two system. A design of sliding mode control(SMC) for the position tracking of two link robot manipulator based on the sliding mode control technique and the Lyapunov stability theory is carried out to eliminate the perturbation and asymptotical stability can be achieved when the system is subjected to the sliding mode. A sliding mode control method based on RBF(radial basis function) neural network is addressed which has the capability of learning uncertain control actions shown by the several industrial robots. In RBFNN-SMC method the algorithm for tuning the parameters are extracted from the RBF function. The comparative study is done based on the evaluated parameters for the system

Keywords
Sliding mode control, RBF Neural Network, Two-link robot manipulator.

1. INTRODUCTION
Sliding mode control has been the vast topic for research in the field of control engineering. This section discuss Extensive research work has been done on sliding mode control of the system as well as the integration of compensation technique with this control methodology.[1] It is shown that the adaptive sliding mode control to control a 2 link robot manipulator having uncertain parameters. An adaptive algorithm is used which is based on the sliding mode control concept to ease the chattering phenomena. Lyapunov stability is applied to achieve the stability of robot manipulator system. Controller scheme proposed in that assures robustness and attain good trajectory tracking performance.[2] Conventional design methods for controllers for a MIMO plant like a multi-joint robot require minimum knowledge of the structure and accurate mathematical model of the plant. [3] The dynamic model and the terminal sliding mode control for two link robot manipulators. Lagrangian method is used to derive the closed loop dynamic equations for the robot manipulators. This technique has been used to design the controller. This technique gives the output tracking error to converge at zero in a given period of time. [4] A radial basis function network with SMC is designed for the link positions of two link robot manipulator. The learning techniques has degrades its transient performance also This neural technique uses the curve fitting mode to get nonlinear mapping. A sliding mode effectively used to eliminate thenonlinearities and has given a fast response but this control created chattering. The Lyapunov and the back propagation algorithm creates switch gain and an update law respectively.[5] Computed torque control is one of such schemes, which is based on the exact cancellation of the nonlinear dynamics of the manipulator system.[6]]Robot manipulators are very important in the field of flexible automation as they have been widely used for increasing productivity and reduce losses. A lot of research effort is been made to design their controller.[7]]Robot manipulators are very important in the field of flexible automation as they have been widely used for increasing productivity and reduce losses. A lot of research effort is been made to design their controller.[8] Neural Networks are being applied in many fields such as learning, pattern recognition, signal processing and system control. The major advantages this parallel structure, learning ability, non- linear function approximation, fault tolerance. This benefits make a wide range of applications..[9] Robot manipulators are very important in the field of flexible automation as they have been widely used for increasing productivity and reduce losses. A lot of research effort is been made to design their controller.[10] The payload of the robot manipulator varies during its operation and is not known advance. To face such problems, adaptive control strategies for robot manipulators have been developed.[11] Research from the past shows that universal approximation theorems on RBF has shown that any nonlinear function over a compact set with arbitrary accuracy can be approximated by RBF neural network.[12] The RBF network adaptation improves the control performance against large uncertainty of the system. The adaptation law can be derived by Lyapunov method which guarantees the stability of the system. RBF neural networks. A schematic diagram of two link robot manipulator is shown in figure 1.

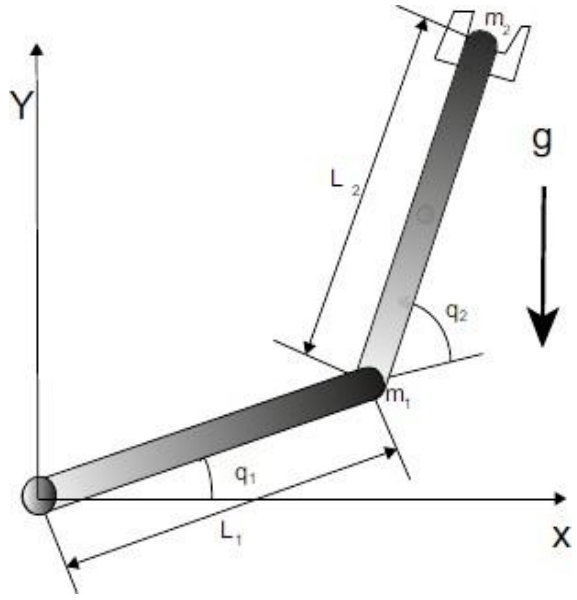

Figure 1: A two link robot manipulator

2. SLIDING MODE CONTROL

Sliding mode control deals with the problem of model uncertainties as these uncertainties can have strong adverse effects on nonlinear control systems. A major approach to deal with the model uncertainly is adaptive control and another approaches which can be used to solve the control problems includes the sliding mode techniques. These techniques are generating greater interest nowadays. Discrepancies may occur between the actual plant and the mathematical model established for the controller design. Various factors may be responsible for this mismatch. The engineer's role is to ensure required performance levels for the system instead of such mismatches. A set of robust control methods have been developed to eliminate any error. One such method is sliding mode control methodology(SMC). This is a specific type of variable structure control system (VSCS). SMC has been used for several systems including nonlinear system, multi-input multi- output(MIMO) systems, discrete-time models, large-scale and infinite-dimension systems, and stochastic systems. SMC is completely insensitive to parametric imprecisions and external disturbances during sliding mode. VSC uses a high-speed switching control law to accomplish two objectives. Firstly, the nonlinear plant's state trajectory is taken onto a specified and user-chosen surface in the state space which is called the sliding or switching surface. This is called as the switching surface because a control path has a unique gain if the state trajectory of the plant is "above" the surface and a different gain if the trajectory falls "below" the surface. Secondly, it keeps the plant's state trajectory on this surface for all consequent times. During this process, the control system's structure changes from one to another and thus given the name variable structure control(VSC). The control is also named as the sliding mode control to accentuate the importance of the sliding mode. Sliding mode controller can stabilize the trajectory of a system. Control structures are designed so as to ensure that trajectories will always move towards a switching condition. Therefore, the ultimate trajectory will not exist completely within one control structure. Instead, the ultimate trajectory will slide along the boundaries of the control structures. The motion of the system as it slides along these boundaries is termed as a sliding mode and the geometrical locus consisting of the boundaries is called the sliding (hyper) surface. The sliding mode phases are shown in figure 2

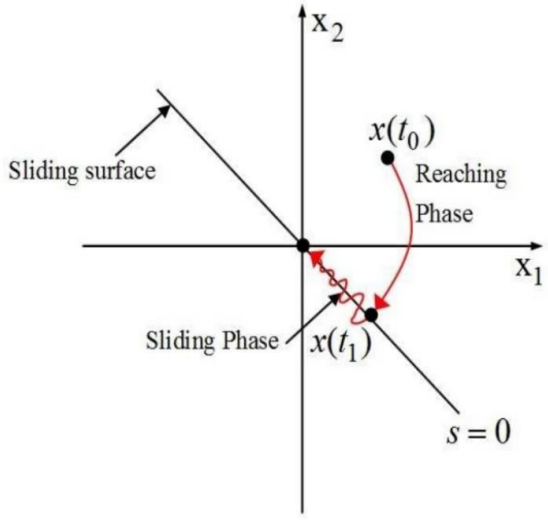

Figure 2: Sliding mode phases

3. LYAPUNOV STABILITY

The Lyapunov stability analysis is based upon the concept of energy and also depends on the relation of stored energy with the stability of system. But in general there is no way of relating the energy function with the given set of equations which describes the system. There is no uniqueness about the total energy of the system which associates with the system stability. There are scalar functions present which describe this relation and this ides is given by the mathematician A.M Lyapunov. The scalar functions are known as the Lyapunov Function and the method used for evaluating the stability of the control system is known as the Lyapunov's direct method. Following are some of the scalar functions which are described as the follows by the Lyapunov direct method. Based on these functions, stability can be evaluated.

(a)Positive Definiteness of Scalar Functions :V(x) which is a scalar function is said to be positive definite in the region $\|x\| \leq k$ if $V(x)>0$ at all the points of the region except origin since it is zero at origin.

(b)Negative Definiteness of Scalar Functions: V(x) which is a scalar function is said to be negative definite if [-V(x)] is positive definite.

(c)Positive Semi definiteness of Scalar Functions: V(x) which is a scalar function is said to be positive semidefinite in the region $\|x\| \leq k$ if its value is positive at all points of the region and at origin too.

(d)Negative Semi definiteness of Scalar Functions: V(x) which is a scalar function is said to be negative definite if [-V(x)] is positive semidefinite.

4. RBF NEURAL NETWORK

This is an alternative approach for multilayer perceptron which is trained by the backpropagation algorithm. It is the basic component of feedforward network. A gaussian function has two parameters: center for defining its position and for determining its shape, parameter called spread is there. In one dimensional gaussian function spread is same as the standard deviation σ.

The input vector is given by

$$x = [x_1 \;\; x_2 \ldots\ldots\ldots x_n] \quad (1)$$

and the output of the RBF network is given below

$$x(x, c, \sigma) = \exp\frac{-||x-c||^2}{2\sigma^2} \quad (2)$$

there is no weights between the input and the RBF unit. c and σ represents the weight which is shown in figure 3.

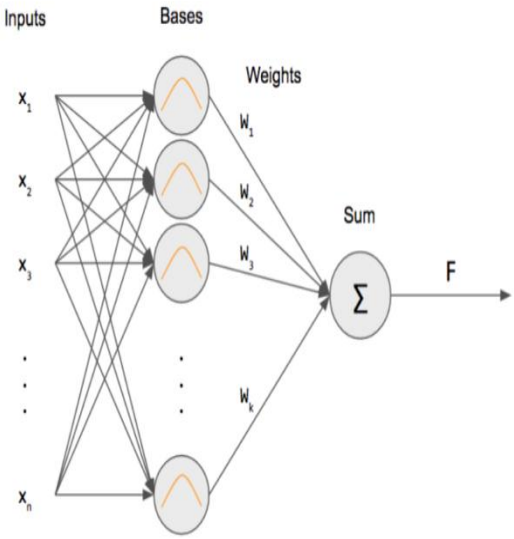

Figure 3: **Gaussian function in RBF neuron model**

5. SLIDING MODE CONTROLLER FOR A TWO LINK ROBOT

The plant model is given by equation (3)

$$\dot{x_1} = \dot{\theta} = x_2$$

$$\dot{x_2} = \ddot{\theta} = f(x) + g(x)\tau \quad (3)$$

Where

$$x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} x_{11} \\ x_{12} \\ x_{21} \\ x_{22} \end{bmatrix} = \begin{bmatrix} \theta \\ \dot{\theta} \end{bmatrix} = \begin{bmatrix} \theta_1 \\ \theta_2 \\ \dot{\theta}_1 \\ \dot{\theta}_2 \end{bmatrix}; \tau = \begin{bmatrix} \tau_1 \\ \tau_2 \end{bmatrix} \quad (4)$$

θ_1 and θ_2 are the angles of the two links defined in figure, and τ_1 and τ_2 are the torques applied by the actuators to control the angles θ_1 and θ_2 respectively.

Variable structure sliding mode controller design consists of the following two phases:

(a)Designing of sliding surface to obtain the desired system behaviour, when restricted to the surface. The system will remain at that surface for further times. The plant dynamics will always be limited to the surface and is robust towards the disturbances.

(b)Selection of the feedback gains of the controller, so that the closed loop system is stable to the sliding surface.

For a two link robot manipulator, our aim is to track the desired motion trajectory $\theta_d(t)$

The tracking error is defined a

$$e(t) = \theta_d(t) - \theta(t)$$

$$\dot{e(t)} = \dot{\theta_d}(t) - \dot{\theta}(t); \ddot{e}(t) = \ddot{\theta_d}(t) - \ddot{\theta}(t)$$

Defining $\widetilde{x_1} = e$ and $\widetilde{x_2} = \dot{e}$ robot dynamics can be written in the form:

$$\dot{x_2} = \ddot{\theta} = f(x) + g(x)\tau \quad (5)$$

Now we use linear sliding surface which is defined by the equation

$$\sigma(\tilde{x}) = \lambda\widetilde{x_1} + I\widetilde{x_2} \quad (6)$$

Or

$$\begin{bmatrix} \sigma_1(\tilde{x}) \\ \sigma_2(\tilde{x}) \end{bmatrix} = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix} \begin{bmatrix} \widetilde{x_{11}} \\ \widetilde{x_{12}} \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \widetilde{x_{21}} \\ \widetilde{x_{22}} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} (7)$$

$$\sigma_1(\tilde{x}) = \lambda_1\tilde{x}_{11} + \widetilde{x_{21}} = \lambda_1(\theta_{1d} - \theta_1) + (\dot{\theta_{1d}} - \dot{\theta}_1)$$

$$\sigma_2(\tilde{x}) = \lambda_2\tilde{x}_{12} + \widetilde{x_{22}} = \lambda_2(\theta_{2d} - \theta_2) + (\dot{\theta_{2d}} - \dot{\theta}_2) \quad (8)$$

Assume the coefficient of $\widetilde{x_{21}}$ to be unity.

Now combine the equations of the plant and the sliding surface (Eqns (7) and (8))

$$\dot{\widetilde{x_1}} = -\lambda\widetilde{x_1} \quad (9)$$

Therefore

$$\widetilde{x_2} = -\lambda\tilde{x}_1 \quad (10)$$

The above equations describes the system dynamics in sliding. The response is specified by the selection of the parameters λ_1 and λ_2 of the switching surface. In sliding mode, the system is not affected by the model uncertainties. After designing the sliding surface, we build a feedback controller. The objective of the controller is to derive the plant state to the sliding surface and maintain it on the surface for further time. A Lyapunov approach has been used for building the controller.

The Lyapunov function is given below

$$V = \frac{1}{2}\sigma^T\sigma = \frac{1}{2}(\sigma_1^2 + \sigma_2^2) \quad (11)$$

The above function is used as the Lyapunov function and the time derivative of the chosen Lyapunov function comes out to be negative definite with respect to switching surface and ensuring the motion of the state trajectory to the surface. We have to find τ so that

$$\frac{d}{dt}\frac{1}{2}\sigma^T\sigma = \sigma^T\dot{\sigma} < 0$$

$$\sigma^T\dot{\sigma} = \sigma^T[\lambda\dot{\widetilde{x_1}} + I\dot{\widetilde{x_2}}] \quad (12)$$

The controller structure form is given below

$$\tau = g^{-1}(x)\left[-f(x) + \dot{x_{2d}} + \lambda(\dot{x_{1d}} - \dot{x_1}) + \begin{Bmatrix} k_1 sgn(\sigma_1) \\ k_2 sgn(\sigma_2) \end{Bmatrix}\right] \quad (13)$$

where k_1>0 and k_2>0 are the gains which has to be determined so that the condition $\sigma^T\dot{\sigma} < 0$ is satisfied. We substitute τ, given by (3.52) into the expression $\sigma^T\dot{\sigma}$

$$\sigma^T\dot{\sigma} = -[\sigma_1 \quad \sigma_2]\begin{bmatrix} k_1 sgn(\sigma_1) \\ k_2 sgn(\sigma_2) \end{bmatrix} = -\sigma_1 k_1 sgn(\sigma_1) - \sigma_2 k_2 sgn(\sigma_2) = -k_1|\sigma_1| - k_2|\sigma_2| < 0 \quad (14)$$

The sliding surface $\sigma(\tilde{x}) = 0$ is therefore asymptotically attractive. The larger the value of gains, faster the trajectory converges to the sliding surface. The tolerance of the sliding mode control to the model imprecision and disturbances, is high and thus satisfying stability requirement. The Simulink model for the sliding mode control of the two link robot manipulator is given in figure 3.2

Simulation of this controller for a two link robot manipulator was done in MATLAB and results are attached at the end.

The specifications of the robot manipulator is taken as:

$m_1 = 1kg; m_2 = 1kg; l_1 = 1m; l_2 = 1m; g =$

$\frac{9.8kgm}{s^2}; \theta_{d1}(t) = \sin(\pi t); \theta_{d2}(t) = \cos(\pi t)$ (15)

Now the objective is to construct an RBF network sliding mode control for robot manipulator. This is completely opposite to the SMC technique so far used as the unknow disturbances are approximated by RBF neural network.

6. RBF NETWORK ADAPTIVE SLIDING MODE CONTROL FOR ROBOT MANIPULATOR

The dynamic equation of 2-joint manipulator is as follows:

$$H(q)\ddot{q} + C(q,\dot{q})\dot{q} + G(q) = \tau - F(\dot{q}) - \tau_d$$

where H(q) is a 2x2 positive definite integral matrix, G(q) is a 2x1 inertial vector, $C(q,\dot{q})$ is a 2x2 inertial matrix, τ_d is the unknown disturbance, $F(\dot{q})$ is friction force, and τ is the control input

The tracking error is denoted as:

$e(t) = q_d(t) - q(t)$ (17)

Sliding variable is selected as:

$s = \dot{e} + \dot{\Lambda} e$ (18)

where Λ is a symmetric positive definite matrix and $\Lambda = \Lambda^T > 0$, therefore , we have

$\dot{q} = -s + \dot{q_d} + \Lambda e$ (19)

$$H\dot{s} = H(\ddot{q_d} - \ddot{q} + \Lambda\dot{e}) = H(\ddot{q_d} + \Lambda\dot{e}) - H\ddot{q}$$

$$= H(\ddot{q_d} + \Lambda\dot{e}) - Cs + C(\dot{q_d} + \Lambda e) + G + F + \tau_d - \tau$$

$$= H(\ddot{q_d} + \Lambda\dot{e}) + C\dot{q} + G + F + \tau_d - \tau$$

$= -Cs - \tau + f + \tau_d$ (20)

Where f(x) = $H(\ddot{q_d} + \Lambda\dot{e}) + C(q_d + \Lambda e) + G + F$

as f(x) is unknown, hence RBF network is adopted to approximate f(x). input is selected based on expression of f(x):

$x = [e^T \quad \dot{e}^T \quad q_d^T \quad \dot{q}_d^T \quad \ddot{q}_d^T]$ (21)

The controller is designed as follows:

$\tau = \hat{f}(x) + K_v s$ (22)

where Kv is a symmetrical positive definite constant matrix, $\hat{f}(x)$ is the output of RBF

network, approximates f(x). The RBF-NN weights are adjusted using adaptive laws

From equations (21) and (22) we have

$H\dot{s} = -Cs - \hat{f}(x) - Kvs + f(x) + \tau_d$ (23)

Where

$f(x) = -(K_v + C)s + \tilde{f}(x) + \tau_d = -(K_v + C)s + \varsigma_0$

Lyapunov function is selected as:

$L = \frac{1}{2}s^T H s$ (24)

$\dot{L} = s^T H s + \frac{1}{2}s^T \dot{H} = -s^T K_v s + \frac{1}{2}s^T(\dot{H} - 2C)s + s^T\varsigma_0$ (25)

$\dot{L} = s^T\varsigma_0 - s^T K_v s$ (26)

It shows that with Kv, the stability of control system depends on ς_0, the magnitude of τ_d

The algorithm suggested to approximate f(x) is given below

$\phi_i = g(\frac{||x - c_i||^2}{\sigma_i^2})$ (27)

$y = W^{*T}\varphi(x), f(x) = W^{*T}\varphi(x) + \varepsilon$ (28)

Where x is the input state of network,

$$\varphi(x) = [\phi_1 \quad \phi_2 \quad \ldots\ldots \quad \phi_n]^T$$

ε is the approximation error, W^* is the desired weight vector.

7. SIMULATION AND RESULTS

Kinetic equation of two joint robot manipulator is:

$H(q)\ddot{q} + C(q,\dot{q})\dot{q} + G(q) = \tau - F(\dot{q}) - \tau_d$ (29)

Where

$$\boldsymbol{H(q)} = \begin{bmatrix} \boldsymbol{p_1 + p_2 + 2p_3 cosq_2} & \boldsymbol{p_2 + p_3 cosq_2} \\ \boldsymbol{p_2 + 2p_3 cosq_2} & \boldsymbol{p_2} \end{bmatrix}$$ (30)

$$C(q,\dot{q}) = \begin{bmatrix} -p_3 q_2 sinq_2 & -p_3(\dot{q_1} + \dot{q_2})sinq_2 \\ p_3\dot{q_1}sinq_2 & 0 \end{bmatrix}$$ (31)

$$G(q) = \begin{bmatrix} p_4 g cosq_1 & p_5 g cos(q_1 + q_2) \\ p_5 g cos(q_1 + q_2) \end{bmatrix}$$ (32)

$F(\dot{q}) = 0.02sgn(\dot{q})\ ; \tau_d = [0.2sint \quad 0.2sint]^T$ (33)

Let

$$\mathbf{p} = [\boldsymbol{p_1} \quad \boldsymbol{p_2} \quad \boldsymbol{p_3} \quad \boldsymbol{p_4} \quad \boldsymbol{p_5}]$$
$$= [\mathbf{2.9} \quad \mathbf{0.76} \quad \mathbf{0.87} \quad \mathbf{3.04} \quad \mathbf{0.87}]$$

Gaussian function of the RBF network is selected to control the neural network. If the parameter is not suitable then mapping of the gauss function cannot be obtained and the RBF network is unavailable. The model for this is given in the figure 4.

8. CONCLUSIONS

The mathematical model of two DOF robot manipulator is designed in the form of differential equations and then feedback linearization technique is applied to obtain the plant model and two control techniques that is adaptive sliding mode control and RBF neural network based sliding mode control have been successfully applied to improve the stability of this system.it is seen that position tracking is instantly and correctly achieved in case of RBF-SMC model, also the system implemented with RBF-SMC is more stable. A comparative study of the parameters for the links of robot manipulator has been carried out.

ORIGINAL PAPER

Stability behavior of a nonlinear mathematical epidemic transmission model with time delay

Received: 28 June 2019 / Accepted: 23 September 2019
© Springer Nature B.V. 2019

Abstract In this article, we study a time-delayed susceptible–infected–recovered mathematical model along with nonlinear incidence rate and Holling functional type II treatment rate for epidemic transmission. The mathematical study of the model demonstrates that the model exhibits two equilibria, to be specific, disease-free equilibrium (DFE) and endemic equilibrium (EE). We obtain the basic reproduction number R_0 and investigate that the model is locally asymptotically stable at DFE if $R_0 < 1$ and unstable if $R_0 > 1$ for the time lag $\nu > 0$. The stability of DFE at $R_0 = 1$ is also investigated for the time lag $\nu \geq 0$, and we show that for $\nu > 0$, the DFE is linearly neutrally stable, whereas for $\nu = 0$, the model exhibits backward bifurcation whereby the DFE will coexists with two endemic equilibria, when $R_0 < 1$. We also investigate the stability of the model at the EE and find that oscillatory solution may appear via Hopf bifurcation, taking the delay as a bifurcation parameter. Further, global stability of the model equilibria has also been analyzed. Finally, numerical simulations have been presented to illustrate the analytical studies.

1 Introduction

Mathematical modeling is progressively used in various fields such as biology, engineering, and economics [1–5]. In epidemiology, mathematical modeling is an effective method to study a diverse range of infectious diseases, for a better understanding of transmission dynamics. Many authors have proposed numerous epidemic models, such as susceptible–infected–recovered (SIR) [2,6–8], SEIR [9], SVEIR [10], etc., and studied the spread of infectious diseases mathematically and quantitatively. A major goal of the epidemiological study is to develop an understanding of the transmission of epidemics and interventions that can be taken to prevent and control the spread of infectious diseases. For the most part, an exemplary condition for the elimination of an infection is for the basic reproduction number (BRN) [11] to be less than one whereby the disease-free equilibrium is stable; the unique endemic equilibrium will be asymptotically stable as far as when the BRN is greater than one, implies that the disease-free equilibrium will be unstable. However, many authors have exhibited that it is feasible for the disease-free

Published online: 10 October 2019

equilibrium to exist together with two endemic equilibria even when the BRN is less than one, leading to the phenomenon of backward bifurcation [12,13]. This phenomenon demonstrates that for disease control and destruction, relying on the BRN to be less than one is now only necessary but no longer sufficient. Therefore, the occurrence of backward bifurcation has important public health implications. Many authors have studied epidemic models characterized by backward bifurcation, for both generic and specific diseases [3,14–16]. The phenomenon of backward and forward bifurcation is based on the center manifold theory.

Incidence rate has a major role in the study of transmission dynamics of infectious disease. The term incidence refers to the number of new cases of a disease occurring in a given period. The incidence rate is calculated by dividing the total number of new cases of the disease in a certain period into the total number of people in the population. The type of the incidence rate that is used in the classical Kermack Mckendrick model (1927) [1] is the basic mass action (bilinear) λSI where S and I denote the number of susceptible and infected individuals, respectively, and λ is known as the infection coefficient. But, this bilinear incidence rate is not reasonable for large population because if the number of susceptibles increases, then the incidence rate also increases, i.e., the number of infected individuals per unit time also increases. So this unreasonable bilinear incidence rate is needed to be modified. Due to this unrealistic situation, several authors [6,7,9,17–21] have focused on the nonlinear type of incidence rate. Nonlinear incidence rate permits to incorporate social/behavioral changes and prevent unbounded contact rates. Thus, changing the form of incidence rate can potentially fill the gap in the transmission behavior of the system. There are several types of nonlinear incidence rates like Holling type II, Crowley–Martin type and many others that have already been used by the researchers in their model to understand the transmission dynamics of epidemics. In 1975, Beddington [22] and DeAngelis [23] independently presented a nonlinear incidence rate of the form $\frac{\beta SI}{1+\alpha S+\gamma I}$ $(\beta, \alpha, \gamma > 0)$, called Beddington–DeAngelis functional type incidence rate. After that some authors [24–26] introduced the same incidence rate in their disease transmission models. This incidence rate has a significant role in studying transmission dynamics as it includes inhibition measures taken by both susceptible and infected individuals. If individuals are familiar with the diseases and have knowledge about the transmission modality of infection, then they can take necessary preventive measures to avoid infections. These measures are called the measure of inhibition. In the present article, we take the Beddington–DeAngelis type incidence rate. The Beddington–DeAngelis type incidence rate of susceptible individuals through their contacts with infectious individuals is a more general and realistic form for the study of diseases transmission dynamics as it contains three forms: bilinear incidence rate if $\alpha = \gamma = 0$; saturated incidence rate for the susceptible if $\gamma = 0$; and saturated incidence rate for the infectives if $\alpha = 0$. Preventive anti-epidemic measures represent a set of measures aimed at preventing the occurrence and slowing down the spread of infections in a population such as the decreased contact rate, quarantinization of the infected individuals, introductory examinations before being employed, improvement of the hygienic level of population, treatment for infectives. To study the realistic phenomenon of disease transmission, we must consider the inclusion of the time delay into the model as when a disease emerges, there will be an initial delay in recognizing it. Therefore, present article incorporates the impact of time delay into Beddington–DeAngelis incidence rate and investigate its effect on the transmission dynamics. Inhibitions are effective measures to control the spread of infectious diseases but to control the spread of further infection and to eliminate the infection from the society; there is a need for effective treatment also. Treatment rate has a substantial role in reducing complications and preventing the transmission of infectious diseases to others. Appropriate and timely treatment strategy can significantly lessen the effect of disease on society. The basic idea behind any treatment is to cure a disease and to control its spread. In classical epidemic models, the treatment rate of infectives is considered to be either constant or proportional to the number of infectives. But, as the community has low treatment resources availability, therefore, choosing a suitable treatment rate of disease becomes of grave importance. In the presence of insufficient treatment resources and vaccines availability, the epidemical control systems depend on taking suitable preventive measures. Preventive measures refer to measures that are applied to prevent the occurrence of a disease. In 2004, Wang and Ruan [27] considered an SIR epidemic model with constant treatment rate (i.e., the recovery from infected subpopulation per unit time) as given below:

$$h(I) = \begin{cases} b, & I > 0 \\ 0, & I = 0 \end{cases}$$

where b is a positive constant and I denotes the number of infected individuals. They investigated the stability of the model and proposed that their model could exhibit various bifurcations. This kind of treatment rate is appropriate for the situation when there are small numbers of infectives and treatment resources are sufficient and inappropriate when the number of the infected individuals is large, and treatment resources are limited. Therefore, Zhang and Liu [28] presented the improved continuous, differentiable nonlinear treatment rate function which saturates at its maximum value. This saturated treatment rate is known as the Holling type II treatment rate [9]. For any outbreak of epidemic disease, the treatment capacity of Holling type II is initially very slow which develops gradually with improved treatment facilities. Further, Holling type II treatment rate refers to the condition that when there is a large number of infected people, then the treatment capacity reaches to its maximum because of limited treatment facilities which mimic the more realistic phenomena.

Delay differential equation reveals more complex dynamical behavior than an ordinary differential equation. The time delay is an influential parameter in the dynamical behavior of infectious diseases, and it can change the behavior of the dynamical system. The present paper aims to study the effect of latent period (the period between exposure and infection is called latent period, since the pathogen is present in a latent stage, without clinical symptoms or signs of infection in the host) on the SIR model and analyze the transmission of epidemics into the susceptible host with the impact of inhibitions taken by both susceptible and infected individuals. We also aim to study the impact of treatment rate in which we have considered the fact of the limited availability of resources, which allows us to reach more realistic phenomena. For this, we have considered an SIR epidemic model along with Beddington–DeAngelis functional type incidence rate by incorporating time delay as latent period, and Holling functional type II treatment rate. We derive the basic reproduction number for the proposed model, and we study the dynamical behavior of the model through stability analysis. We give a precise indication of the bifurcation phenomenon using center manifold theory, ensuring that either forward or backward bifurcation occurs. We also discuss the Hopf bifurcation near the endemic equilibrium by considering time delay as a bifurcation parameter.

The organization of the paper is as follows: In Sect. 2, we introduce the model formulation. Basic properties of the solutions are discussed in Sect. 3. In Sect. 4, we investigate the existence of equilibria and present the qualitative analysis through stability at disease-free equilibrium and endemic equilibrium. We also perform the bifurcation analysis whereby both forward and backward scenarios are derived. Further, by considering the time delay as a bifurcation parameter, we obtain the conditions for the occurrence of Hopf bifurcation around the endemic equilibrium. Furthermore, global stability of the disease-free equilibrium and endemic equilibrium has been discussed with the help of Lyapunov direct method. Numerical simulations have been performed in Sect. 5 using MATHEMATICA 11, to demonstrate the theoretical results. Finally, significant findings are discussed in Sect. 6.

2 Mathematical model

The fundamental approach in studying epidemic models is to divide the total population into mutually exclusive compartments according to epidemic status. We assume that the total size of population N is constant. Therefore, the total constant population is divided into three disjoint compartments $S(t)$, $I(t)$, and $R(t)$, where $S(t)$, $I(t)$, and $R(t)$ denotes the size of compartment of susceptible, infected, and recovered at time t, respectively. We assume that each population of SIR is well mixed and interact homogeneously with each other [29]. That is, $N \equiv S(t)+I(t)+R(t)$ which means that N is a fixed population and $S(t)$, $I(t)$ and $R(t)$ may vary at time t.

Latent period has been considered as time delay ν which means that the force of infection at present is determined by the number of infectives in the past.

The model we present is under the framework of the following system of nonlinear delay differential equations:

$$\begin{aligned} \frac{\mathrm{d}S}{\mathrm{d}t} &= A - \vartheta S - \frac{\beta S(t-\nu)I(t-\nu)}{1+\alpha S(t-\nu)+\gamma I(t-\nu)}, \\ \frac{\mathrm{d}I}{\mathrm{d}t} &= \frac{\beta S(t-\nu)I(t-\nu)}{1+\alpha S(t-\nu)+\gamma I(t-\nu)} \end{aligned}$$

Table 1 Summary of symbols

Symbol	Description
N	Total constant population
$S(t)$	Susceptible individuals
$I(t)$	Infected individuals
$R(t)$	Recovered individuals
ν	Latent period (time delay)
A	Recruitment rate of susceptible individuals
α	Inhibitions taken by susceptibles
β	Transmission rate
ϑ	Natural death rate
d	Disease-induced death rate
γ	Inhibitions taken by infectives
ζ	Recovery rate
a	Cure rate
b	Rate of limitation in treatment availability
$\Phi(S(t), I(t))$	Beddington–DeAngelis functional type incidence rate
$h(I(t))$	Holling type II treatment rate of infected individuals

$$- (\vartheta + d + \zeta)I - \frac{aI}{1+bI},$$
$$\frac{\mathrm{d}R}{\mathrm{d}t} = \frac{aI}{1+bI} + \zeta I - \vartheta R. \tag{1}$$

The model (1) is considered with the following initial conditions:

$$S(\theta) = \phi_1(\theta), I(\theta) = \phi_2(\theta), R(\theta) = \phi_3(\theta)\ \phi_i(\theta) \geq 0, \theta \in [-\nu, 0], \phi_i(\theta) > 0\ (i = 1, 2, 3) \tag{2}$$

where $(\phi_1(\theta), \phi_2(\theta), \phi_3(\theta)) \in C([-\nu, 0], R^3_+)$. Here, C denotes the Banach space of continuous functions mapping the interval $[-\nu, 0]$ into R^3_+, and $\nu > 0$ denotes the latent period.

The description of the parameters used in the model (1) is as follows [Table 1]: A represents the recruitment rate of the susceptible population by birth or immigration. ϑ and d are the natural death rate and disease-induced death rate, respectively. ζ is the recovery rate of infectives. The term $\frac{\beta S(t-\nu)I(t-\nu)}{1+\alpha S(t-\nu)+\gamma I(t-\nu)}$ describes the Beddington–DeAngelis type nonlinear incidence rate, where β is the force of infection, α is the measure of inhibitions taken by susceptibles, i.e., social awareness among the susceptibles, and γ is the measure of inhibition taken by infected individuals, i.e., the magnitude of interference among the infectives. This incidence rate represents the rate at time $(t - \nu)$ at which susceptible individual leaves the susceptible compartment and enters in the infectious compartment at time t. The term $h(I) = \frac{aI}{(1+bI)}$ is the Holling functional type II treatment term, where a denotes the cure rate of infectives and b denotes the limitation in the availability of resources.

3 Basic properties

Under the assumption that the population size N is constant, the model (1) may be reduced to a two-dimensional system for analysis purpose only. The equation for $R(t)$ is traditionally omitted; it is easy to see that under the assumption of constant population size, this equation is decoupled from the first and second equations of the model (1). The condition $N = S + I + R =$ constant may be used to find R [29,30]. In this manner, it is equivalent to study the following reduced system:

$$\frac{\mathrm{d}S}{\mathrm{d}t} = A - \vartheta S - \frac{\beta S(t-\nu)I(t-\nu)}{1+\alpha S(t-\nu)+\gamma I(t-\nu)}, \tag{3}$$
$$\frac{\mathrm{d}I}{\mathrm{d}t} = \frac{\beta S(t-\nu)I(t-\nu)}{1+\alpha S(t-\nu)+\gamma I(t-\nu)} - (\vartheta + d + \zeta)I - \frac{aI}{1+bI} \tag{4}$$

with initial conditions

$$S(\theta) = \phi_1(\theta), I(\theta) = \phi_2(\theta), \phi_i(\theta) \geq 0,\ \theta \in [-\nu, 0], \phi_i(\theta) > 0\ (i = 1, 2) \tag{5}$$

where $(\phi_1(\theta), \phi_2(\theta)) \in C([-\nu, 0], R^2_+)$. Here, C denotes the Banach space of continuous functions mapping the interval $[-\nu, 0]$ into R^2_+.

We assume that $\Phi(S(t), I(t)) = \frac{\beta S(t) I(t)}{1+\alpha S(t)+\gamma I(t)}$ and $h(I(t)) = \frac{aI(t)}{1+bI(t)}$ are always positive, continuously differentiable, and monotonically increasing for all $S, I > 0$, i.e., the following postulates are satisfied:

P1. $\Phi(S(t), I(t)) > 0$, $\Phi'_S(S(t), I(t)) > 0$, $\Phi'_I(S(t), I(t)) > 0$ for $S(t) > 0$ and $I(t) > 0$.

P2. $\Phi(S(t), 0) = \Phi(0, I(t)) = 0$, $\Phi'_S(S(t), 0) = 0$, $\Phi'_I(S(t), 0) > 0$ for $S(t) > 0$ and $I(t) > 0$.

P3. $h(0) = 0, h'(0) > 0$ for $I(t) \geq 0$.

For biological reasons, we consider that all the parameters of the system (3)–(4) are positive, i.e., $A, \vartheta, \beta, \alpha,$

$d, \gamma, \zeta, a, b > 0$. The equations of the system (3)–(4) monitor populations; therefore, it is essential to prove the positivity of the state variables, i.e., $(S, I) \in R^2_+$.

Lemma 1 *Any solution of system* (3)–(4) *with* $\phi_i(\theta) > 0$, $\theta \in [-\nu, 0]$ *remains positive whenever it exists and bounded in the region*

$$D = \left\{(S, I) \in R^2_+ : S(t) + I(t) \leq \frac{A}{\vartheta}\right\}.$$

Proof Note that

$$\frac{\mathrm{d}S}{\mathrm{d}t} + \frac{\mathrm{d}I}{\mathrm{d}t} = A - \vartheta S - (\vartheta + d + \zeta)I - \frac{aI}{1 + bI} \leq A - \vartheta(S + I). \tag{6}$$

and so,

$$\lim_{t\to\infty}(S + I) \leq \frac{A}{\vartheta}. \tag{7}$$

It follows that the system is point dissipative. Without loss of generality, we assume that $S(t) + I(t) \leq \frac{2A}{\vartheta}$ for all $t \geq -\nu$. A consequence of this is that we may assume I is bounded above, which in turn implies $\frac{dS}{dt}$ is positive for small S, and so S is positive for $t > 0$ [31]. □

We now prove the positivity of $I(t)$. Using the variation of constants formula and applying step by step integration method, for $0 < t \leq \nu$, we integrate Eq. (4) from 0 to t , we get

$$I(t) = I(0) \cdot e^{(\vartheta+d+\zeta)} \cdot e^{\int_0^t f(S(\omega-\nu), I(\omega-\nu), I(\omega))\mathrm{d}\omega} \tag{8}$$

We see that $I(t) > 0$ for all $\nu \leq t \leq 2\nu$. Proceeding in the same way, this process will carry on. Hence, it is proved that $I(t) > 0$ for all $t > 0$.

Also, from (7), it follows that (S, I) is bounded in the region

$$D = \left\{(S, I) \in R^2_+ : S(t) + I(t) \leq \frac{A}{\vartheta}\right\}.$$

Hence, we state the following lemma:

Lemma 2 *The solutions* $(S(t), I(t))$ *of the system* (3)–(4) *with initial conditions* (5) *uniquely exists in the region* $D = \{(S, I) \in R^2_+ : S(t) + I(t) \leq \frac{A}{\vartheta}\}$.

Proof We already have proved the positivity and the boundedness of solution $(S(t), I(t))$. Now, we will prove the existence and uniqueness of this solution. We notice that the right-hand side of the model (3)–(4) is completely continuous and locally Lipschitzian on D. Then, it follows that the solution of model (3)–(4) exists and is unique. This completes the proof of Lemma 2. □

4 Equilibria and stability analysis

In this section, we show the existence of the equilibria of the system (3)–(4) and investigate the local and global stability behavior of the obtained equilibria. We obtain the equilibrium points of time-delayed system by setting the right-hand side terms of the system (3)–(4) to zero since equilibrium solutions of a system with time delays are equivalent to the corresponding system with zero delay [18].

4.1 The disease-free equilibrium (DFE) and its analysis

The equilibria are acquired by equating the rate of change of all the compartment to zero. Consequently, we see that the system (3)–(4) has a unique DFE of the form $E_0\left(\frac{A}{\vartheta}, 0\right)$.

The characteristic equation of the system (3)–(4), evaluated at E_0 is as follows:

$$(\vartheta + \lambda)\left(\frac{\beta A}{\vartheta + \alpha A}e^{-\lambda\nu} - \vartheta - d - \zeta - a - \lambda\right) = 0. \tag{9}$$

Equation (9) has one negative real root $\lambda_1 = -\vartheta$, and other roots are the solutions of

$$\frac{\beta A}{\vartheta + \alpha A}e^{-\lambda\nu} - \vartheta - d - \zeta - a - \lambda = 0. \tag{10}$$

The term $\frac{\beta A e^{-\lambda\nu}}{(\vartheta+\alpha A)(\vartheta+d+\zeta+a)}$ at $\nu = 0$ is known as the basic reproduction number. The basic reproduction number is defined as "the expected number of secondary cases produced, in a completely susceptible population, by a typical infective individual" [11]. Hence, the basic reproduction number of our model is

$$R_0 = \frac{\beta A}{(\vartheta + \alpha A)(\vartheta + d + \zeta + a)}.$$

4.1.1 Analysis for $\mathbf{R_0 \neq 1}$

As mentioned above, Eq. (9) has one negative real root $\lambda_1 = -\vartheta$ and other roots satisfy the equation

$$\zeta(\lambda) := \lambda + \vartheta + d + \zeta + a - \frac{\beta A}{\vartheta + \alpha A}e^{-\lambda\nu} = 0 \tag{11}$$

I. Assuming that $R_0 > 1$, then

$$\zeta(0) = \vartheta + d + \zeta + a - \frac{\beta A}{\vartheta + \alpha A} < 0$$

Therefore, $\zeta(0) < 0$. Since $\lim_{\lambda\to\infty}\zeta(\lambda) = +\infty$, there exists at least one positive real root of (11) if $R_0 > 1$.

II. Let be $R_0 < 1$.
Our goal is to prove that for any values of the parameters, the characteristic roots cannot reach the imaginary axis. This means that for any values of the parameters and all delays ν, it happens that $\mathrm{Re}\,\lambda < 0$. On the contrary, suppose that $\mathrm{Re}\,\lambda \geq 0$. Note that

$$\mathrm{Re}\,\lambda = \frac{\beta A}{\vartheta+\alpha A}e^{-\mathrm{Re}\,\lambda\nu}\cos(Im\lambda)\nu - \vartheta - d$$
$$-\zeta - a < \frac{\beta A}{\vartheta+\alpha A} - \vartheta - d - \zeta - a < 0.$$

a contradiction to our assumption. Hence, if $R_0 < 1$ then all the roots of Eq. (11) must have the negative real part. Using the Routh–Hurwitz criterion, we have the following result:

Theorem 1 *The DFE E_0 is locally asymptotically stable if $R_0 < 1$ and unstable at $R_0 > 1$ for time lag $\nu \geq 0$.*

4.1.2 Analysis for $R_0 = 1$

We analysis the system (3)–(4) at $R_0 = 1$ for $\nu > 0$ and $\nu = 0$ separately.

$\nu > 0$: If $R_0 = 1$, then $\lambda = 0$ is a simple characteristic root of Eq. (11). Let $\lambda = \alpha + \iota\omega$ any of the other solutions, then (11) turns into:

$$\alpha + \iota\omega + \vartheta + d + \zeta + a - \frac{\beta A}{\vartheta+\alpha A}e^{-(\alpha+\iota\omega)\nu} = 0. \tag{12}$$

Applying Euler's formula and parting real and imaginary parts, we can write

$$\alpha + \vartheta + d + \zeta + a = \frac{\beta A}{\vartheta+\alpha A}\cos(\omega\nu)e^{-\alpha\nu}, \tag{13}$$

$$\omega = -\frac{\beta A}{\vartheta+\alpha A}e^{-\alpha\nu}\sin(\omega\nu). \tag{14}$$

Observing that $R_0 = 1$ implies $\beta A = (\vartheta+\alpha A)(\vartheta + d + \zeta + a)$. Moreover, if there exist roots satisfying both Eqs. (13) and (14), then they also satisfy the equation obtained by squaring and adding them member to member, we obtain

$$(\alpha+\vartheta+d+\zeta+a)^2+\omega^2 = (\vartheta+d+\zeta+a)^2e^{-2\alpha\nu}. \tag{15}$$

For Eq. (15) to be verified, we must have $\alpha \leq 0$. Therefore, DFE E_0 is linearly neutrally stable.

$\nu = 0$: Note that the system (3)–(4) evaluated at $R_0 = 1$ and bifurcation parameter $\beta = \beta^* = \frac{(\vartheta+\alpha A)(\vartheta+d+\zeta+a)}{A}$ have a simple zero (null) eigenvalue, and other eigenvalue is real and negative. Hence, when $R_0 = 1$, the DFE E_0 is a non-hyperbolic equilibrium. To investigate the stability of DFE at $R_0 = 1$, we use the bifurcation theory approach based on the center manifold theory [32]. For this, we redefine $S = x_1$ and $I = x_2$ then the system (3)–(4) can be rewritten as

$$\frac{\mathrm{d}x_1}{\mathrm{d}t} = A - \vartheta x_1 - \frac{\beta x_1 x_2}{1+\alpha x_1+\gamma x_2}, \tag{16}$$

$$\frac{\mathrm{d}x_2}{\mathrm{d}t} = \frac{\beta x_1 x_2}{1+\alpha x_1+\gamma x_2} - (\vartheta+d+\zeta)x_2 - \frac{ax_2}{1+bx_2} \tag{17}$$

Let $J(E_0, \beta^*)$ denotes the Jacobian matrix of the system (16)–(17) evaluated at $R_0 = 1$, $\beta = \beta^*$. Then

$$J(E_0,\beta^*) = \begin{bmatrix} -\vartheta & -\frac{\beta^* A}{(\vartheta+\alpha A)} \\ 0 & 0 \end{bmatrix}$$

The left eigenvector $u = [u_1, u_2]$ of the Jacobian matrix $J(E_0, \beta^*)$ is given by $u \cdot J(E_0, \beta^*)$. We obtain:

$$u_1 = 0, u_2 = 1.$$

The right eigenvector $w = (w_1, w_2)^{\mathrm{T}}$ of the Jacobian matrix $J(E_0, \beta^*)$ is by $J(E_0, \beta^*) \cdot w$ We obtain:

$$w_1 = -\frac{\beta^* A}{\vartheta(\vartheta+\alpha A)}, w_2 = 1.$$

Let $f_i, i = 1, 2$ denotes the right-hand side of the system (16)–(17). It can be checked that:
$\left(\frac{\partial^2 f_2}{\partial x_1 \partial x_2}\right)_{E_0} = \frac{\beta^*\vartheta^2}{(A\alpha+\vartheta)^2}$, $\left(\frac{\partial^2 f_2}{\partial x_2 \partial x_1}\right)_{E_0} = \frac{\beta^*\vartheta^2}{(A\alpha+\vartheta)^2}$,
$\left(\frac{\partial^2 f_2}{\partial x_2^2}\right)_{E_0} = 2ab - \frac{2A\beta^*\gamma\vartheta}{(A\alpha+\vartheta)^2}$, $\left(\frac{\partial^2 f_2}{\partial x_2 \partial \beta^*}\right)_{E_0} = \frac{A}{A\alpha+\vartheta}$.

Then, by [15], we obtain the bifurcation constants a_1 and b_1 as:

$$a_1 = \sum_{k,i,j=1}^{2} u_k w_i w_j \left(\frac{\partial^2 f_k}{\partial x_i \partial x_j}\right)_{E_0}$$
$$= \frac{2(ab(A\alpha+\vartheta)^3 - A\beta^*\vartheta(\beta^* + \gamma(A\alpha+\vartheta)))}{(A\,\alpha+\vartheta)^3},$$

$$b_1 = \sum_{k,i=1}^{2} u_k w_i \left(\frac{\partial^2 f_k}{\partial x_i \partial \beta^*}\right)_{E_0} = \frac{A}{A\alpha + \vartheta}.$$

It can be seen that b_1 is always positive. Therefore, by theorem 4.1 of Castillo-Chavez and Song [15], the local dynamics of the system (16)–(17) depends on the sign of the bifurcation constant a_1. Evaluating a_1 at bifurcation constant β^*, we get

$$a_1 = -\frac{2(\vartheta a^2 + (-Ab(A\alpha+\vartheta) + \vartheta(2d + A\gamma + 2(\zeta+\vartheta)))a + \vartheta(d+\zeta+\vartheta)(d+A\gamma+\zeta+\vartheta))}{A(A\alpha+\vartheta)}, = -\frac{g(a)}{A(A\alpha+\vartheta)},$$

where,

$$\begin{aligned} g(a) &= \vartheta a^2 + (\vartheta(2d + A\gamma + 2(\zeta+\vartheta)) \\ &\quad - Ab(A\alpha+\vartheta))a \\ &\quad + \vartheta(d+\zeta+\vartheta)(d+A\gamma+\zeta+\vartheta) \\ &= A_1 a^2 + A_2 a + A_3, \end{aligned} \tag{18}$$

with

$$\begin{aligned} A_1 &= \vartheta, \\ A_2 &= \vartheta(2d + A\gamma + 2(\zeta+\vartheta)) - Ab(A\alpha+\vartheta), \\ &= \vartheta(A(-b+\gamma) + 2(d+\zeta+\vartheta)) - A^2 b\alpha, \\ A_3 &= \vartheta(d+\zeta+\vartheta)(d+A\gamma+\zeta+\vartheta). \end{aligned}$$

It can be seen that A_1 and A_3 are always positive. Let D denotes the discriminant of the quadratic $g(a)$ given in Eq. (18). We obtain that

$$\begin{aligned} D &= A_2^2 - 4A_1A_3 \\ &= A^2\gamma^2\vartheta^2 + Ab(A\alpha+\vartheta)(A^2 b\alpha + \vartheta(A(b-2\gamma) \\ &\quad - 4(d+\zeta+\vartheta))). \end{aligned} \tag{19}$$

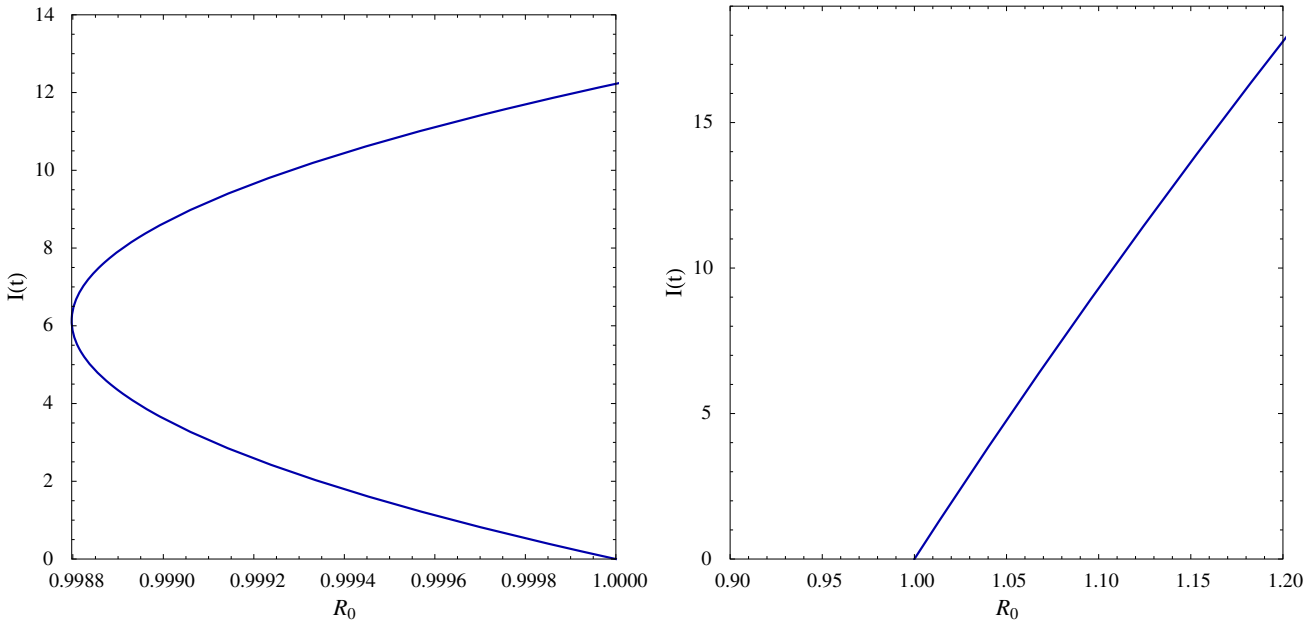
Let a_1^* and a_2^* be two positive roots of the quadratic Eq. (18), given by $a_1^* = \frac{-A_2-\sqrt{D}}{2A_1}$, and $a_2^* = \frac{-A_2+\sqrt{D}}{2A_1}$.

With the help of theorem 4.1 [15], it can be concluded that if $g(a) > 0$, a forward bifurcation occurs, whereas if $g(a) < 0$, the system (16)–(17) exhibits a backward bifurcation. We discuss these two cases separately.

1. Backward bifurcation
The system (16)–(17) exhibits a backward bifurcation when $g(a) < 0$. The existence of a backward bifurcation implies a range which shows the region of coexistence of DFE and two endemic equilibria: a smaller endemic equilibrium (i.e., there is less number of infectives), and a larger endemic equilibrium (i.e., there are a large number of infectives). In this case, the smaller endemic equilibrium is unstable, whereas larger endemic equilibrium is stable. Thus, the occurrence of backward bifurcation shows that R_0 less unity does not confirm the eradication of infection. Therefore, we now find the range of a for which backward bifurcation occurs. Now, $g(a) < 0$ if and only if the discriminant $D > 0$, $A_2 < 0$, and $a_1^* < a < a_2^*$. Thus, the conditions obtained for the occurrence of backward bifurcation are stated below:

$$\begin{cases} A_2 < 0, \\ D > 0, \\ a_1^* < a < a_2^*. \end{cases} \tag{20}$$

2. Forward bifurcation
The presence of forward bifurcation confirms the eradication of the disease when $R_0 < 1$. It shows that the DFE is stable when $R_0 < 1$ and if R_0 cross unity, then the model admits a unique stable endemic equilibrium. From this analysis, we will be able to know that if there is a stable coexistence equilibrium bifurcating from E_0 and E_0 changes its stability from stable to unstable. This behavior is known as forward bifurcation. Therefore, it is very important to find the range for which forward bifurcation occurs. We see that the system (16)–(17) exhibits a forward bifurcation if $g(a) > 0$. $g(a) > 0$ if either $A_2 > 0$ or $D > 0$, $A_2 < 0$, and $a < a_1^*$ or $a > a_2^*$. These cases are described below:



(a) Backward bifurcation. **(b)** Forward bifurcation.

Fig. 1 Bifurcation diagram in the plane (R_0, I). **a** The case when $D > 0$, $A_2 < 0$ and $a_1^* = 0.00644085 < a < 0.847559 = a_2^*$, showing backward bifurcation. **b** The case: $D > 0$, $A_2 < 0$ and $a = 0.005 < a_1^* = 0.00644085$, showing forward bifurcation

$$\begin{cases} A_2 > 0 \text{ or, } b < \dfrac{(2d\vartheta + A\gamma\vartheta + 2\zeta\vartheta + 2\vartheta^2)}{A(A\alpha + \vartheta)}. \end{cases} \tag{21}$$

or

$$\begin{cases} A_2 < 0, \\ D > 0, \\ a < a_1^* \text{ or } a > a_2^*. \end{cases} \tag{22}$$

These bifurcations are illustrated in Fig. 1a, b. We consider the parameter values $A = 5, \alpha = 1, \vartheta = 0.05, d = 0.001, \gamma = 0.01, \zeta = 0.002, b = 0.002$. Most of the parameter values are taken from [33]. At these values of parameters, we obtain that $D = 0.0420559$ and $A_2 = -0.0427$. According to (20), we have a backward bifurcation at $\beta = \beta^*$, for $a_1^* = 0.00644085 < a < 0.847559 = a_2^*$. Setting $a = 0.8$, the system (16)–(17) exhibits a backward bifurcation as shown in Fig. 1a. A forward bifurcation occurs by choosing $a < a_1^*$ or $a > a_2^*$, as stated in (22). Setting $a = 0.005 < a_1^* = 0.00644085$, we see the occurrence of forward bifurcation as shown in Fig. 1b.

Now, in order to satisfy inequality (21), we use the parameter $A = 5, \alpha = 0.004, \gamma = 0.01, \vartheta = 0.05, d = 0.001, \zeta = 0.002, b = 0.002, a = 0.005$.

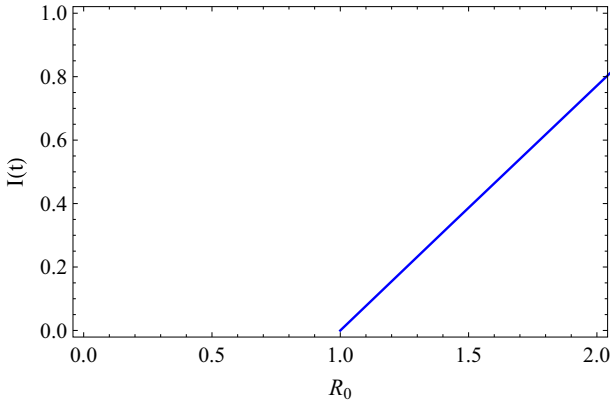


Fig. 2 Forward bifurcation diagram in the plane (R_0, I), when the inequality (21) holds

At these parameter values, we see that the inequality (21), $b = 0.002 < \frac{(2d\vartheta + A\gamma\vartheta + 2\zeta\vartheta + 2\vartheta^2)}{A(A\alpha + \vartheta)} = 0.0222857$ is satisfied and forward bifurcation occurs as shown in Fig. 2.

Theorem 2 *The disease-free equilibrium* $E_0 = \left(\frac{A}{\vartheta}, 0\right)$ *of the system* (3)–(4) *at* $R_0 = 1$ *is linearly neutrally stable for* $\nu > 0$.

Theorem 3 *When* $R_0 = 1$, *then the system* (16)–(17) *exhibits backward (forward) bifurcation at disease-free equilibrium* E_0 *if and only if* $g(a) < 0$ (> 0).

Remark 1 The theorem above states that at $\nu = 0$ and for values of R_0 greater than 1 but close to 1, the system admits a unique infected equilibrium, which is locally asymptotically stable.

4.2 Endemic equilibrium and its stability

To investigate the stability of the system (3)–(4) around the endemic equilibrium $E_e(S^*, I^*)$, we equate the second equation of the system (3)–(4) to zero:

$$\frac{\beta S^* I^*}{1+\alpha S^*+\gamma I^*} - (\vartheta + d + \zeta) I^* - \frac{a I^*}{1+bI^*} = 0. \tag{23}$$

After solving Eq. (23), we get S^* as follows:

$$S^* = \frac{(1+\gamma I^*)(a+(1+bI^*)p)}{(\beta - \alpha a - \alpha p)+bI^*(\beta-\alpha p)}, \; p = \vartheta + d + \zeta. \tag{24}$$

We see that $S^* > 0$ if and only if

$$\beta - \alpha a - \alpha p > 0 \quad \text{i.e.,} \quad \beta - \alpha p > \alpha a > 0. \tag{25}$$

Plug in the value of S^* from Eq. (24), into Eq. (3), we get the cubic equation in I^* as follows

$$H_0 + H_1 I^* + H_2 I^{*2} + H_3 I^{*3} = 0, \tag{26}$$

where

$$\begin{aligned}
H_0 &= (\vartheta + \alpha A)(\vartheta + d + \zeta + a)(1 - R_0),\\
H_1 &= -a^2\alpha - (d+\zeta+\vartheta)(-\beta - 2b\vartheta - \gamma\vartheta\\
&\quad + \alpha(d+\zeta+\vartheta)) + a(Ab\alpha + \beta + b\vartheta + \gamma\vartheta\\
&\quad + Ab(-\beta + \alpha(d+\zeta+\vartheta)),\\
H_3 &= b^2(d+\zeta+\vartheta)(\gamma\vartheta + \beta - \alpha(\vartheta + d + \zeta)).
\end{aligned} \tag{27}$$

Note that $H_3 > 0$ according to the condition given in Eq. (25).

Theorem 4 *If $R_0 > 1$, then there is either a unique or three positive endemic equilibria if all equilibria are simple roots.*

Proof Suppose that $R_0 > 1$. From (27), it follows that H_0 is negative. From equation (26), we have a third-degree polynomial in I^*:

$$H_0 + H_1 I^* + H_2 I^{*2} + H_3 I^{*3} = 0.$$

Since H_3 is positive and H_0 is negative, we have the following possibilities of signs of H_1 and H_2:

$$\begin{aligned}
&\text{(i)}\, H_1 > 0, \text{ and } H_2 < 0,\\
&\text{(ii)}\, H_1 < 0, \text{ and } H_2 > 0,\\
&\text{(iii)}\, H_1 > 0, \text{ and } H_2 > 0,\\
&\text{(iv)}\, H_1 < 0, \text{ and } H_2 < 0.
\end{aligned} \tag{28}$$

Using Descartes' rule of signs [34], it follows that Eq. (26) has either three positive roots or a unique positive root. Hence, the proof. □

To analyze the local stability of endemic equilibrium E_e, we obtain the characteristic equation of the system (3)–(4) at E_e as follows:

$$\lambda^2 + p_0\lambda + q_0 + (p_1\lambda + q_1)e^{-\lambda\nu} = 0, \tag{29}$$

where

$$\begin{aligned}
p_0 &= 2\vartheta + d + \zeta + \frac{a}{(bI^*+1)^2},\\
q_0 &= \vartheta(\vartheta + d + \zeta) + \frac{a\vartheta}{(bI^*+1)^2},\\
p_1 &= \frac{\beta(-S^*(1+S^*\alpha) + I^*(1+I^*\gamma))}{(1+S^*\alpha+I^*\gamma)^2},\\
q_1 &= \frac{\beta(aI^*(1+I^*\gamma) + (1+bI^*)^2(I^*(1+I^*\gamma)(d+\zeta) + (-S^*(1+S^*\alpha) + I^*(1+I^*\gamma))\vartheta))}{(bI^*+1)^2(1+S^*\alpha+y\gamma)^2}.
\end{aligned}$$

Theorem 5 *At $\nu = 0$, E_e is locally asymptotically stable if $p_0 + q_0 > 0$, and $p_1 + q_1 > 0$.*

Proof The characteristic equation of the system (3)–(4) evaluated at E_e and $\nu = 0$ is

$$\lambda^2 + (p_0 + p_1)\lambda + (q_0 + q_1) = 0. \tag{30}$$

Using the Routh–Hurwitz criterion, it can be said that the endemic equilibrium E_e of the system (3)–(4) is locally asymptotically stable when $\nu = 0$ if $p_0 + p_1 > 0$ and $p_1 + q_1 > 0$ are satisfied simultaneuously. □

Theorem 6 *For $\nu > 0$, E_e is locally asymptotically stable if both $p_0^2 - 2q_0 - p_1^2 > 0$ and $q_0^2 - q_1^2 > 0$ are satisfied simultaneuously.*

Proof For $\nu > 0$, if instability occurs for a specific value of the time delay ν, then a characteristic root of (29) must cross the imaginary axis [7].

Assume that $\lambda = \iota\xi, \xi > 0$ is a root of the characteristic Eq. (29). Substituting $\lambda = \iota\xi$ into Eq. (29), we get

$$\begin{aligned}&(-\xi^2 + q_0 + p_1\xi \sin\xi\nu + q_1 \cos\xi\nu)\\ &\quad + \iota(p_0\xi + p_1\xi\cos\xi\nu - q_1\cos\xi\nu) = 0.\end{aligned} \tag{31}$$

On separating real and imaginary part of Eq. (31), we get:

$$p_1\xi \sin\xi\nu + q_1\cos\xi\nu = \xi^2 - q_0, \tag{32}$$

$$p_1\xi\cos\xi\nu - q_1\cos\xi\nu = -p_0\xi. \tag{33}$$

Eliminating ν by squaring and adding Eqs. (32) and (33), we obtain a polynomial in ξ as follows:

$$\xi^4 + (p_0^2 - 2q_0 - p_1^2)\xi^2 + (q_0^2 - q_1^2) = 0. \tag{34}$$

Letting $\xi^2 = x$, $p_0^2 - 2q_0 - p_1^2 = A$, and $q_0^2 - q_1^2 = B$, Eq. (34) becomes

$$x^2 + Ax + B = 0. \tag{35}$$

Using the Routh–Hurwitz Criterion, it can be observed that Eq. (35) has roots with negative real part, if $A > 0$ and $B > 0$ are satisfied simultaneously. It contradicts the assumption that Eq. (29) has a root $\lambda = \iota\xi$. Hence, the endemic equilibrium E_e of the system (3)–(4) is locally asymptotically stable for $\nu > 0$ if $p_0^2 - 2q_0 - p_1^2 > 0$ and $q_0^2 - q_1^2 > 0$ are satisfied simultaneuously. □

4.2.1 Hopf bifurcation

If $q_0^2 - q_1^2 < 0$, then there is a unique positive ω_0 satisfying Eq. (35), i.e., there is a single pair of purely imaginary roots $\pm\iota\omega_0$ to Eq. (29).

Using Eqs. (32) and (33), we obtain ν_k corresponding to ω_0

$$\nu_k = \frac{1}{\omega_0}\arccos\left(\frac{\omega_0^2(q_1 - p_0p_1) - q_0q_1}{p_1^2\omega_0^2 + q_1^2}\right) + \frac{2k\pi}{\omega_0}, \quad k = 0, 1, 2\ldots \tag{36}$$

For $\nu < \nu_0$, the endemic equilibrium E_0 is stable if transversality condition holds, That is, $\frac{\mathrm{d}}{\mathrm{d}t}(\mathrm{Re}\,\lambda)\Big|_{\lambda=i\omega_0} \neq 0$.

Differentiating Eq. (29) with respect to ν, we get

$$\begin{aligned}&\left(2\lambda + p_0 + p_1e^{-\lambda\nu} - (p_1\lambda + q_1)\nu e^{-\lambda\nu}\right)\frac{\mathrm{d}\lambda}{\mathrm{d}\nu}\\ &= \lambda(p_1\lambda + q_1)e^{-\lambda\nu}\\ &\left[\frac{\mathrm{d}\lambda}{\mathrm{d}\nu}\right]^{-1} = \frac{2\lambda + p_0 + p_1e^{-\lambda\nu} - (p_1\lambda + q_1)\nu e^{-\lambda\nu}}{\lambda(p_1\lambda + q_1)e^{-\lambda\nu}}\\ &= \frac{2\lambda + p_0}{\lambda(p_1\lambda + q_1)e^{-\lambda\nu}} + \frac{p_1}{\lambda(p_1\lambda + q_1)} - \frac{\nu}{\lambda}\\ &= \frac{2\lambda + p_0}{-\lambda(\lambda^2 + p_0\lambda + q_0)} + \frac{p_1}{\lambda(p_1\lambda + q_1)} - \frac{\nu}{\lambda}.\\ &\frac{\mathrm{d}}{\mathrm{d}\nu}(\mathrm{Re}\,\lambda)\Big|_{\lambda=\iota\omega_0} = \mathrm{Re}\left(\frac{\mathrm{d}\lambda}{\mathrm{d}\nu}\right)^{-1}\Big|_{\lambda=\iota\omega_0}\\ &= \mathrm{Re}\left(\frac{2\iota\omega_0 + p_0}{-\iota\omega_0(-\omega_0^2 + \iota p_0\omega_0 + q_0)}\right.\\ &\quad \left. + \frac{p_1}{-p_1{\omega_0}^2 + \iota q_1\omega_0} + \frac{\iota\nu}{\omega_0}\right)\\ &= \frac{1}{\omega_0}\left(\frac{2\omega_0(\omega_0^2 - q_0) + p_0^2\omega_0}{(p_0\omega_0)^2 + (\omega_0^2 - q_0)^2} - \frac{p_1^2\omega_0}{(p_1\omega_0)^2 + q_1^2}\right)\\ &= \frac{2(\omega_0^2 - q_0) + p_0^2}{(p_0\omega_0)^2 + (\omega_0^2 - q_0)^2} - \frac{p_1^2}{(p_1\omega_0)^2 + q_1^2}\\ &= \frac{2\omega_0^2 + (p_0^2 - 2q_0 - p_1^2)}{p_1^2\omega_0^2 + q_1^2} \text{ (Using Eqs. (32) and (33),}\\ &\quad (p_1\omega_0)^2 + q_1^2 = (p_0\omega_0)^2 + (\omega_0^2 - q_0)^2).\end{aligned} \tag{37}$$

Under the condition $p_0^2 - 2q_0 - p_1^2 > 0$, we have $\frac{\mathrm{d}}{\mathrm{d}\nu}(\mathrm{Re}\,\lambda)\Big|_{\lambda=\iota\omega_0} > 0$. Hence, transversality condition holds and Hopf bifurcation occurs at $\nu = \nu_0$ and ω_0. Thus, we state the following theorem:

Theorem 7 *If the condition $q_0^2 - q_1^2 < 0$ is satisfied, then the endemic equilibrium E_e of the system (3)–(4) is asymptotically stable for $\nu \in [0, \nu_0)$ and it undergoes Hopf bifurcation at $\nu = \nu_0$.*

4.3 Global stability analysis

This subsection is devoted to analyze the global stability behavior of the disease-free and endemic equilibria.

4.3.1 Global stability of disease-free equilibrium

For the global stability of the disease-free equilibrium $E_0\left(\frac{A}{\vartheta}, 0\right)$, we assume the following postulates:

P4. $\Phi_I'(S(t), 0)$ is increasing with respect to $S(t) > 0$.

P5. $\frac{\Phi_I'(S_0,0)}{\Phi_I'(S(t),0)} < 1$ for $S(t) > S_0$, $\frac{\Phi_I'(S_0,0)}{\Phi_I'(S(t),0)} > 1$ for $S(t) \in (0, S_0)$, where $S_0 = \frac{A}{\vartheta}$.

P6. $\Phi(S(t), I(t)) \leq I(t) \left(\left(\frac{\partial \Phi(S(t),I(t))}{\partial I}\right)_{(S_0,0)} - \left(\frac{\partial H(I)}{\partial I}\right)_{I=0}\right) + H(I(t)), I(t) > 0,$
where $H(I(t)) = (\vartheta + d + \zeta)I(t) + h(I(t))$

Under these assumptions, we have the following theorem:

Theorem 8 *Assume that (P1.)–(P6.) are satisfied then, the disease-free equilibrium $E_0(S_0, 0)$ of the system (3)–(4) is globally asymptotically stable for any $\nu \geq 0$ if $R_0 \leq 1$.*

Proof From the conditions (P1.) and (P2.), it follows that the disease-free equilibrium $E_0(S_0, 0)$ is the only equilibrium of the system (3)–(4). We define the following Lyapunov functional:

$$L(t) = L_1(t) + L_2(t)$$

where

$$L_1(t) = S(t) - S_0 - \int_{S_0}^{S(t)} \lim_{I\to 0^+} \frac{\Phi(S_0, I(t))}{\Phi(\sigma, I(t))} \mathrm{d}\sigma + I(t),$$

$$L_2(t) = \int_0^{\nu} \Phi(S(t-\rho), I(t-\rho))\mathrm{d}\rho.$$

The postulates (P1.)–(P3.) imply that $L_1(t)$ is defined and continuously differentiable for all $S(t) > 0$ and $I(t) > 0$, and $L(t) = 0$ at $E_0(S_0, 0)$. We will show that $\frac{\mathrm{d}L(t)}{\mathrm{d}t} \leq 0$ for all $t \geq 0$. For this, first we calculate $\frac{\mathrm{d}L_1(t)}{\mathrm{d}t}$ as follows:

$$\frac{\mathrm{d}L_1(t)}{\mathrm{d}t} = \left(1 - \lim_{I\to 0^+} \frac{\Phi(S_0, I(t))}{\Phi(S, I(t))}\right) S'(t) + I'(t)$$

Since, $A - \vartheta S = -\vartheta\left(S - \frac{A}{\vartheta}\right) = -\vartheta(S - S_0)$, we get

$$\begin{aligned}\frac{\mathrm{d}L_1(t)}{\mathrm{d}t} = &\left(1 - \lim_{I\to 0^+} \frac{\Phi(S_0, I(t))}{\Phi(S, I(t))}\right)(-\vartheta(S - S_0) \\ &- \Phi(S(t-\nu), I(t-\nu))) \\ &+ \Phi(S(t-\nu), I(t-\nu)) - H(I(t)).\end{aligned}$$

We now calculuate $\frac{\mathrm{d}L_2(t)}{\mathrm{d}t}$ as follows:

$$\frac{\mathrm{d}L_2(t)}{\mathrm{d}t} = -\Phi(S(t-\nu), I(t-\nu)) + \Phi(S(t), I(t))$$

Thus, $\frac{\mathrm{d}L}{\mathrm{d}t}$ is given by:

$$\begin{aligned}\frac{\mathrm{d}L(t)}{\mathrm{d}t} &= \frac{\mathrm{d}L_1(t)}{\mathrm{d}t} + \frac{\mathrm{d}L_2(t)}{\mathrm{d}t} \\ &= \left(1 - \lim_{I\to 0^+} \frac{\Phi(S_0, I(t))}{\Phi(S, I(t))}\right)(-\vartheta(S - S_0) \\ &\quad -\Phi(S(t-\nu), I(t-\nu))) \\ &\quad + \Phi(S(t-\nu), I(t-\nu)) \\ &\quad - H(I) - \Phi(S(t-\nu), I(t-\nu)) + \Phi(S(t), I(t)) \\ &= \vartheta\left(1 - \lim_{I\to 0^+} \frac{\Phi(S_0, I(t))}{\Phi(S, I(t))}\right)(S_0 - S(t)) \\ &\quad + \Phi(S(t-\nu), I(t-\nu))\left(\lim_{I\to 0^+} \frac{\Phi(S_0, I(t))}{\Phi(S, I(t))} - 1\right) \\ &\quad + \Phi(S(t), I(t)) - H(I).\end{aligned}$$

Further, (P4.)–(P6.) implies that

$$\begin{aligned}\frac{\mathrm{d}L(t)}{\mathrm{d}t} &\leq \vartheta\left(1 - \frac{\Phi_I'(S_0, 0)}{\Phi_I'(S(t), 0)}\right)(S_0 - S(t)) \\ &\quad + \Phi(S(t-\nu), I(t-\nu))\left(\frac{\Phi_I'(S_0, 0)}{\Phi_I'(S(t), 0)} - 1\right) \\ &\quad + I(t)\left(\left(\frac{\partial \Phi(S(t), I(t))}{\partial I}\right)_{(S_0,0)} \right. \\ &\quad \left. - \left(\frac{\partial H(I)}{\partial I}\right)_{I=0}\right) \\ &= \vartheta\left(1 - \frac{\Phi_I'(S_0, 0)}{\Phi_I'(S(t), 0)}\right)(S_0 - S(t)) \\ &\quad + \Phi(S(t-\nu), I(t-\nu))\left(\frac{\Phi_I'(S_0, 0)}{\Phi_I'(S(t), 0)} - 1\right) \\ &\quad + I(t)\left(\frac{\partial H(I)}{\partial I}\right)_{I=0}(R_0 - 1).\end{aligned}$$

Thus, for $R_0 \leq 1$, $\frac{\mathrm{d}L(t)}{\mathrm{d}t} \leq 0$ for all $t \geq 0$. Also, $\frac{\mathrm{d}L(t)}{\mathrm{d}t} = 0$ if $S(t) = S_0$.

Hence, it follows from the system (3)–(4) that the largest invariant set $\left\{\left(S(t), I(t) \in R_+^2 \middle| \frac{\mathrm{d}L(t)}{\mathrm{d}t} = 0\right)\right\}$ is singleton set $E_0(S_0, 0)$. From the Lyapunov–LaSalle asymptotic stability theorem [35–37], E_0 is the only equilibrium of the system (3)–(4) and globally asymptotically stable. □

4.3.2 Global stability of endemic equilibrium

We now study the global stability of the endemic equilibrium $E_e(S^*, I^*)$ of the system (3)–(4) by Lyapunov direct method. For this, the following hypothesis has been proposed:

P7. $\left(\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)} - \frac{I^*}{I(t)}\right) \leq 0$; $\left(\frac{\Phi(S(t),I(t))}{\Phi(S^*,I^*)} - 1\right) \leq 0$; $\left(\frac{\Phi(S(t),I^*)}{\Phi(S(t),I(t))} - \frac{I(t)}{I^*}\right) \leq 0$ for $I \geq I^*$.

P8. $\left(\frac{h(I^*)}{h(I(t))} - \frac{I^*}{I(t)}\right)\left(\frac{I(t)}{I^*} - 1\right) \leq 0$ for $I \geq I^*$.

Under these conditions, we have the following theorem:

Theorem 9 *Suppose that the conditions (P1.)–(P3.) and (P7.)–(P8.) are satisfied then the endemic equilibrium $E_e(S^*, I^*)$ of the system (3)–(4) is globally asymptotically stable for any $\nu \geq 0$ if $R_0 > 1$.*

Proof We assume the following Lyapunov functional

$$M(t) = M_1(t) + M_2(t)$$

where,

$$M_1(t) = S(t) - S^* - \int_{S^*}^{S(t)} \frac{\Phi(S^*, I^*)}{\Phi(\phi, I^*)} \mathrm{d}\phi + I(t) - I^* - I^* \ln \frac{I(t)}{I^*},$$

$$M_2(t) = \Phi(S^*, I^*) \int_0^{\nu} \left(\frac{\Phi(S(t-\theta), I(t-\theta))}{\Phi(S^*, I^*)} - 1 - \ln \frac{\Phi(S(t-\theta), I(t-\theta))}{\Phi(S^*, I^*)}\right) d\theta.$$

By (P1.)–(P3.), $M(t) = M_1(t) + M_2(t)$ is defined and continuously differentiable for all $S(t), I(t) > 0$ and $M(0) = 0$ at $E_e(S^*, I^*)$.

At $E_e(S^*.I^*)$, the system (3)–(4) has

$$A - \vartheta S^* = \Phi(S^*, I^*) = (\vartheta + d + \zeta)I^* + h(I^*) \tag{38}$$

The time derivative of $M_1(t)$ along the solution of system (3)–(4) is given by

$$\begin{aligned}
\frac{\mathrm{d}M_1(t)}{\mathrm{d}t} &= \left(1 - \frac{\Phi(S^*, I^*)}{\Phi(S(t), I^*)}\right) S'(t) \\
&\quad + \left(1 - \frac{I^*}{I(t)}\right) I'(t) \\
&= \left(1 - \frac{\Phi(S^*, I^*)}{\Phi(S(t), I^*)}\right) \big(\vartheta S^* - \vartheta S(t) \\
&\quad + \Phi(S^*, I^*) - \Phi(S(t-\nu), I(t-\nu))\big) \\
&\quad + \left(1 - \frac{I^*}{I(t)}\right) (\Phi(S(t-\nu), I(t-\nu)) \\
&\quad - \frac{(\Phi(S^*, I^*) - h(I^*))}{I^*} I(t) - h(I(t))\Bigg) \\
&= \vartheta(S^* - S(t)) \left(1 - \frac{\Phi(S^*, I^*)}{\Phi(S(t), I^*)}\right) \\
&\quad + \Phi(S^*, I^*) \left(1 - \frac{\Phi(S^*, I^*)}{\Phi(S(t), I^*)} \right. \\
&\quad \left. + \frac{\Phi(S(t-\nu), I(t-\nu))}{\Phi(S(t), I^*)}\right) \\
&\quad - \frac{\Phi(S(t-\nu), I(t-\nu))}{I(t)} I^* \\
&\quad + \Phi(S^*, I^*) \left(1 - \frac{I(t)}{I^*}\right) \\
&\quad + \left(h(I^*) - \frac{h(I(t))}{I(t)} I^*\right) \left(\frac{I(t)}{I^*} - 1\right)
\end{aligned}$$

Further, the time derivative of $M_2(t)$ is given by

$$\begin{aligned}
\frac{\mathrm{d}M_2(t)}{\mathrm{d}t} &= \Phi(S^*, I^*) \frac{\mathrm{d}}{\mathrm{d}t} \int_0^{\nu} \left(\frac{\Phi(S(t-\theta), I(t-\theta))}{\Phi(S^*, I^*)} \right. \\
&\quad \left. - 1 - \ln \frac{\Phi(S(t-\theta), I(t-\theta))}{\Phi(S^*, I^*)}\right) \mathrm{d}\theta. \\
&= \Phi(S(t), I(t)) - \Phi(S(t-\nu), I(t-\nu)) \\
&\quad + \Phi(S^*, I^*) \ln \frac{\Phi(S(t-\nu), I(t-\nu))}{\Phi(S(t), I(t))}.
\end{aligned}$$

Then, we have

$$\begin{aligned}
\frac{\mathrm{d}M(t)}{\mathrm{d}t} &= \frac{\mathrm{d}M_1(t)}{\mathrm{d}t} + \frac{\mathrm{d}M_2(t)}{\mathrm{d}t} \\
&= \vartheta(S^* - S(t)) \left(1 - \frac{\Phi(S^*, I^*)}{\Phi(S(t), I^*)}\right) \\
&\quad + \Phi(S^*, I^*) \left(1 - \frac{\Phi(S^*, I^*)}{\Phi(S(t), I^*)}\right)
\end{aligned}$$

$$
\begin{aligned}
&+\frac{\Phi(S(t-\nu),I(t-\nu))}{\Phi(S(t),I^*)}\Big)\\
&-\frac{\Phi(S(t-\nu),I(t-\nu))}{I(t)}I^*\\
&+\Phi(S^*,I^*)\left(1-\frac{I(t)}{I^*}\right)\\
&+\left(h(I^*)-\frac{h(I(t))}{I(t)}I^*\right)\left(\frac{I(t)}{I^*}-1\right)\\
&+\Phi(S(t),I(t))-\Phi(S(t-\nu),I(t-\nu))\\
&+\Phi(S^*,I^*)\ln\frac{\Phi(S(t-\nu),I(t-\nu))}{\Phi(S(t),I(t))}\\
&=\vartheta(S^*-S(t))\left(1-\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)}\right)\\
&+\Phi(S^*,I^*)\left(1-\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)}+\ln\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)}\right)\\
&+\Phi(S(t-\nu),I(t-\nu))\left(\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)}-\frac{I^*}{I(t)}\right)\\
&+\Phi(S^*,I^*)\left(1-\frac{I(t)}{I^*}+\ln\frac{I(t)}{I^*}\right)\\
&+\left(\frac{h(I^*)}{h(I(t))}-\frac{I^*}{I(t)}\right)\left(\frac{I(t)}{I^*}-1\right)h(I(t))\\
&+\Phi(S^*,I^*)\Big(1-\frac{\Phi(S(t-\nu),I(t-\nu))}{\Phi(S(t),I(t))}\\
&\cdot\frac{\Phi(S(t),I^*)}{\Phi(S^*,I^*)}\cdot\frac{I^*}{I(t)}\\
&+\ln\frac{\Phi(S(t-\nu),I(t-\nu))}{\Phi(S(t),I(t))}\cdot\frac{\Phi(S(t),I^*)}{\Phi(S^*,I^*)}\cdot\frac{I^*}{I(t)}\Big)\\
&+\Phi(S^*,I^*)\left(\frac{\Phi(S(t),I(t))}{\Phi(S^*,I^*)}-1\right)\\
&+\Phi(S(t-\nu),I(t-\nu))\\
&\cdot\frac{I^*}{I(t)}\left(\frac{\Phi(S(t),I^*)}{\Phi(S(t),I(t))}-\frac{I(t)}{I^*}\right).
\end{aligned}
$$

The function $\Phi(S(t),I(t))$ is monotonically increasing for all $S(t)>0$. Therefore,

$$\big(S^*-S(t)\big)\left(1-\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)}\right)\le 0. \tag{39}$$

The function $f(x)=1-x+\ln x,(x>0)$ has its global maximum $f(1)=0$. Hence, for $x>0$, $f(x)\le 0$ and we have the following inequalities:

$$
\begin{aligned}
&\left(1-\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)}+\ln\frac{\Phi(S^*,I^*)}{\Phi(S(t),I^*)}\right)\le 0,\\
&\left(1-\frac{I(t)}{I^*}+\ln\frac{I(t)}{I^*}\right)\le 0,\\
&\left(1-\frac{\Phi(S(t-\nu),I(t-\nu))}{\Phi(S(t),I(t))}\cdot\frac{\Phi(S(t),I^*)}{\Phi(S^*,I^*)}\cdot\frac{I^*}{I(t)}\right)\\
&\quad+\ln\frac{\Phi(S(t-\nu),I(t-\nu))}{\Phi(S(t),I(t))}\cdot\frac{\Phi(S(t),I^*)}{\Phi(S^*,I^*)}\cdot\frac{I^*}{I(t)}\\
&\le 0.
\end{aligned}
\tag{40}
$$

Hence, by (P7.)–(P8.) and inequalities (39)–(40), it follows that $\frac{\mathrm{d}M(t)}{\mathrm{d}t}\le 0$ for all $S(t)\ge 0$, $I(t)\ge 0$. It can be verified that the largest invariant in $\left\{(S(t),I(t))\in R_+^2:\frac{\mathrm{d}M(t)}{\mathrm{d}t}=0\right\}$ is singleton $\{E_e\}$. By the Lyapunov–LaSalle asymptotic stability theorem [35–37], E_e is globally asymptotically stable. □

5 Numerical simulations

In this section, we present numerical simulations of the proposed model. Parameter description and values are given in Table 2, and the total population size is considered as $N=100$.

Initial conditions are given by

$$S(0)=90,\quad I(0)=8,\quad R(0)=2.$$

Figure 3 shows the behavior of susceptible–infected–recovered populations at time delay $\nu=1$. At the parameters values given in Table 2, we obtained that $S^*=23.5845$, $I^*=42.5367$. From this S^*, and I^*, R^* can be evaluated as: $R^*=N-S^*-I^*=100-23.5845-42.5367=33.8788$. This is also verified from Fig. 3. This figure shows that as time increases, all the subpopulations reach to their endemic equilibrium $(S^*,I^*,R^*)=(23.5845,42.5367,33.8788)$.

Figure 4 shows the effect of time delay on the population with respect to time t. In this figure, susceptible, infected population, and recovered populations are being drawn for the time delay $\nu=0$, 3, and 6, respectively. It can be seen that with the increased values of time delay ν, the infected individuals increases, whereas susceptible and recovered individuals decrease, and finally settle down to its endemic equilibrium (23.5845, 42.5367, 33.8788). Thus, the time delay is an influential parameter in the transmission dynamics of infection.

Figure 5 depicts the infected population with and without the effect of the Holling type II treatment rate. This figure shows the major difference between the progression of treated infected individuals and non-treated infected individuals. When Holling type II treatment rate is considered, then the infected individuals first increase, and then stabilize to steady state at a lower

Table 2 List of parameters

Parameter	Description	Value	References
A	Recruitment rate	5	Assumed
α	Inhibitions taken by susceptibles	0.004	[33]
β	Transmission rate	0.0045	Assumed
ϑ	Natural death rate	0.05	[33]
d	Disease-induced death rate	0.001	[33]
γ	Inhibitions taken by infectives	0.002	[33]
ζ	Recovery rate	0.002	[33]
a	Cure rate	0.04	Assumed
b	Rate of limitation in treatment availability	0.002	Assumed

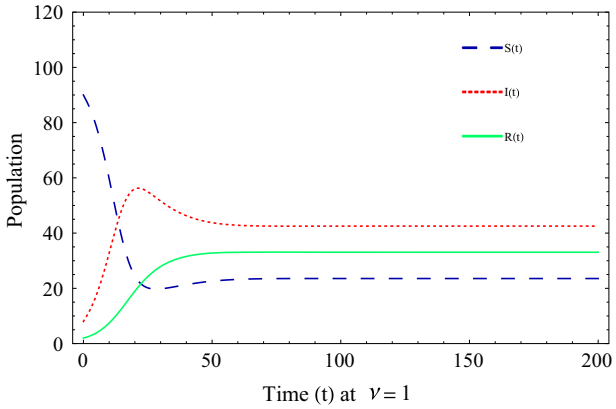

Fig. 3 Behavior of susceptible–infected–recovered populations at time delay $\nu = 1$

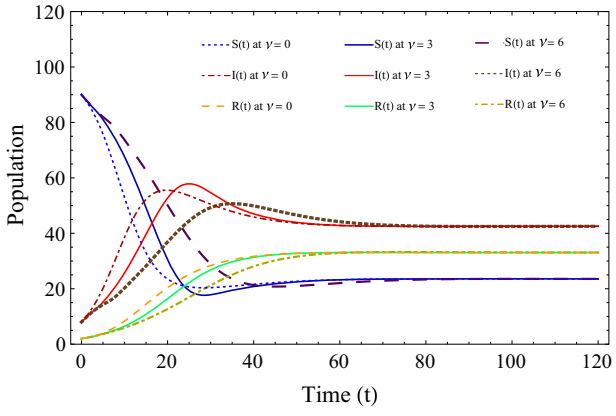

Fig. 4 Impact of time delay ν on susceptible, infected and recovered populations

level, whereas in the absence of treatment rate, infections increase at a higher rate and then settle down to steady-state with a big difference.

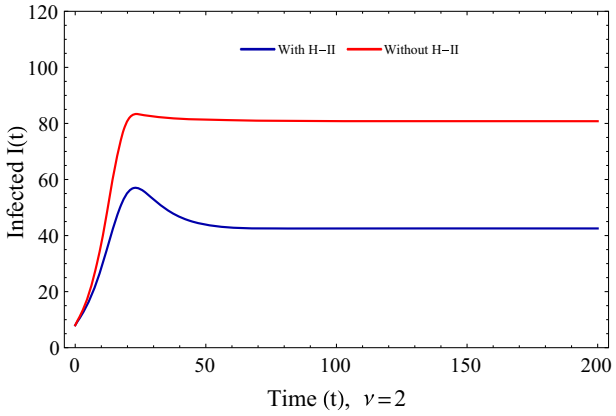

Fig. 5 Infected population with and without Holling type II treatment rate

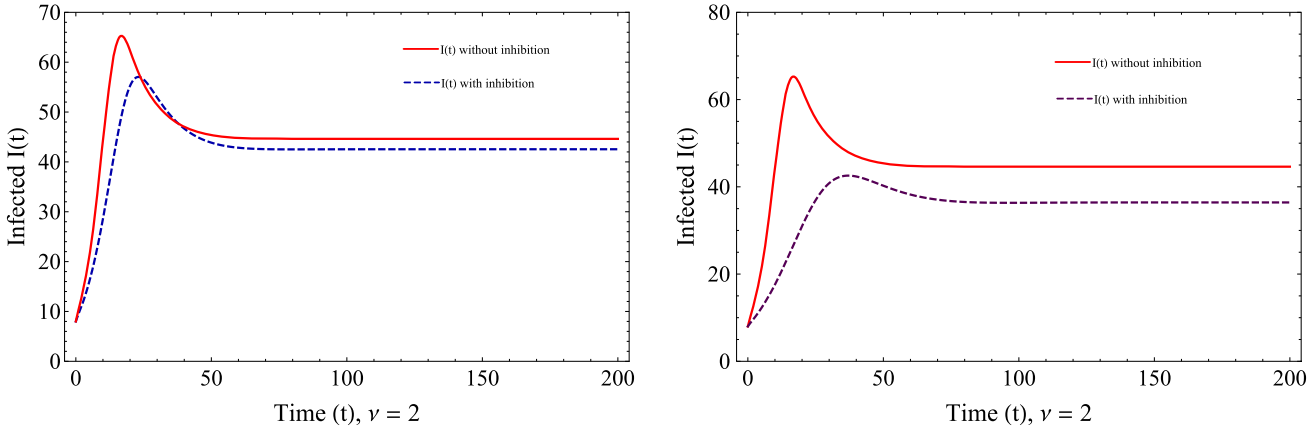
Figure 6 shows the impact of the measure of inhibitions taken by susceptible and infected individuals. Figure 6a, b shows the difference between the infected population with and without inhibition effects. The solid red line shows the infected population without inhibition effects. When there is no inhibition taken by susceptible and infectives, then infectives are increasing at a higher rate. The dashed blue line shows the infected population when we consider $\alpha = 0.004$ and $\gamma = 0.002$, whereas dashed-purple line shows the infected population when $\alpha = 0.01$ and $\gamma = 0.01$. Thus, the higher the inhibitions rate, the higher the decline in the infected population.

Figure 7 shows the occurrence of Hopf bifurcation at different values of time delay ν in the plane (S, I). We find that $q_0^2 - q_1^2 = -0.0000587362 < 0$, $p_0^2 - 2q_0 - p_1^2 = 0.00573205 > 0$, and there is a unique pair of purely imaginary roots $\pm\iota\omega$ to characteristic equation (29) with $\omega = \pm 0.105111$.



(a) $\alpha = 0.004, \gamma = 0.002.$ **(b)** $\alpha = 0.01,\ \gamma = 0.01.$

Fig. 6 Graphs depicting the effect of inhibitions taken by both susceptible and infected individuals

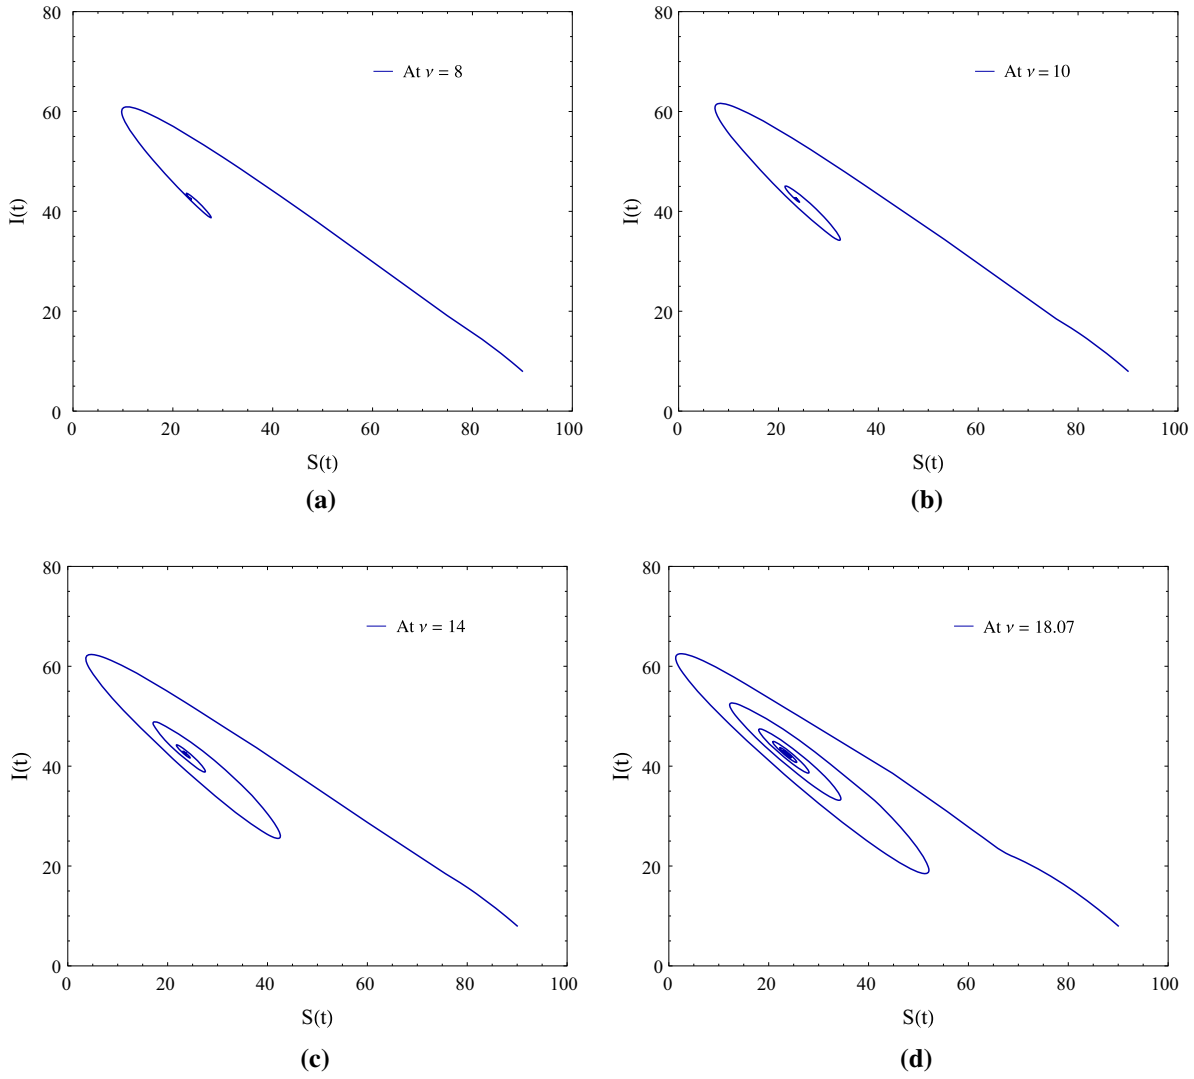


Fig. 7 Hopf bifurcation in the plane (S, I) for various values of time delay ν

Hence, the hypothesis of the occurrence of Hopf bifurcation is satisfied. According to the algorithm given in (36), we obtain the value of ν_0 which is $\nu_0 = 18.07$. Figure 7a–c shows the oscillatory solutions for the time delay $\nu = 8, 10, 14 \in [0, \nu_0]$, respectively. Theorem 7 implies that E_e is asymptotically stable for $[0, \nu_0)$ which follows from Figure 7a–c, and thus, periodic solution appears and endemic equilibrium is locally asympotitically stable which converges to $E_e = (23.5845, 42.5367)$. Also, Hopf bifurcation occurs at $\nu_0 = 18.07$ which confirms Theorem 7.

6 Discussion and conclusion

In this article, we investigate the role of time delay and effects of inhibition measures, and treatment on the SIR model with a nonlinear Beddington–DeAngelis type incidence rate and Holling type II treatment rate. We obtained that the model exhibits two equilibria: disease-free equilibrium E_0 and endemic equilibrium E_e, respectively. Stability analysis is resorted to getting a sense of the behavior of solutions. We investigated the local stability of the model near disease-free equilibrium point E_0 by deriving the basic reproduction number R_0. We observed that the disease-free equilibrium E_0 is locally asymptotically stable when the basic reproduction number R_0 is less than one, unstable when R_0 is greater than one and linearly neutrally stable when R_0 equals to one for the time delay $\nu > 0$. By applying center manifold theory, we investigate the stability behavior of the undelayed system at E_0 when R_0 is one, and showed that the model exhibits a backward (forward) bifurcation under certain conditions. Backward bifurcation plays a relevant role for disease control and eradication. We find the bifurcation range for the occurrence of backward (forward) which depends on the cure rate a. More accurately, if the cure rate a lies in a specific range, $a_1^* < a < a_2^*$, then there is an occurrence of backward bifurcation, and if a is sufficiently small or sufficiently large, i.e., if $a < a_1^*$ or $a > a_2^*$, then forward bifurcation occurs, as shown in inequalities (20) and (22). Also, forward bifurcation may occur if the limitation in the availability of resources is below a certain quantity, as shown in inequality (21). This shows that for eradication of the epidemic when $R_0 < 1$, the resource limitation should be minimized. Thus, the Holling type II treatment rate has a significant role in determining the eradication of disease transmission. Further, we found the conditions for the existence of endemic equilibrium E_e and investigated the local stability behavior of the system near endemic equilibrium E_e and obtained some interesting results stated in Theorems 3 and 4. We also discussed the Hopf bifurcation near endemic equilibrium by considering delay (ν) as a bifurcation parameter, and we obtained that the endemic equilibrium is asymptotically stable for $\nu \in [0, \nu_o)$ and the model undergoes Hopf bifurcation at the critical value ν_0. Moreover, the global stability of disease-free and endemic equilibria has been investigated and obtained that the disease-free equilibrium is globally asymptotically stable when $R_0 \leq 1$, as stated in Theorem 8, whereas, the endemic equilibrium is globally asymptotically stable when $R_0 > 1$, as stated in Theorem 9, epidemiologically this means that the disease will die out or persist in a population with respect to certain restrictions on the parameters.

In addition, we presented the numerical simulations of the proposed model to illustrate our theoretical results. We observed that when the time delay is high, then the infection occur at a higher rate in comparison to the situation when there is no delay. Further, when the Holling type II treatment rate is given to the infected individuals at the appropriate time, then there is a major difference in the occurrence of infection. Hence, to eliminate the disease, there is a need to improve medical technology and invest more medicines, beds, etc. in giving the patients timely treatment. Also, it is depicted that if treatment is not available, then infection is high even if inhibitions are taken into consideration. Therefore, the Holling type II treatment rate led to a diminished level of infection. Impact of inhibitions is also shown in the numerical simulation, which guarantees the control of infection in society if inhibitions are taken properly. From the data, it is observed that critical value ν_0 is 18.07 and for the time lag $\nu \in [0, \nu_0)$, E_e is asymptotically stable as shown in Fig. 7a–c, implies that the disease will persist in society, and at $\nu = \nu_0$, periodic solution appears, which confirms the occurrence of Hopf bifurcation at ν_0.

The epidemic model without delay shows the backward bifurcation which demonstrates that the disease-free equilibrium coexists with the endemic equilibrium when basic reproduction number is less than one. It has important qualitative implications since

reducing the basic reproduction number below one is not sufficient for the eradication of the disease from society. Thus, it is important to explain those components that can control or maintain a strategic distance from such backward situations. Our theoretical results suggest that the existence of backward bifurcation depends on the therapeutic treatment of infected individuals. Under the point of view of the disease control campaigns, public policymakers might try to prevent the dangerous backward scenario by keeping the therapeutic treatments of infected individuals suitably low. In this case, the disease control may straightly follow the classic road of reducing R_0 below 1. If the backward scenario cannot be avoided, then by decreasing contact rates with infected individuals through aimed public sensitization programs which, affecting individual behaviors, can act appropriately to reduce the disease transmission. The nonlinearity in epidemic model due to the latent period (time delay) can give rise to periodicity via a Hopf bifurcation, which shows the oscillatory behavior of the disease at the critical value of time delay.

The findings of the model consisting of Beddington–DeAngelis incidence rate with latent period as time delay and Holling type II treatment rate are capable of demonstration of substantial role of latent period, social awareness among susceptibles, magnitude of interference among infectives, and limitation in available facilities. The results are capable of understanding the transmission dynamics of the outbreak of newly emerging diseases and hence further suggesting the control strategies to prevent the spread of diseases at large scale. For example, largest ebola outbreak in 2014 in the parts of West Africa.

Like all mathematical models, our model also has limitations. For the simulation of our model, we have considered a hypothetical data to investigate the behavior of the system. The estimation of parameters from real data is an important aspect, and we leave it for future study.

In the future, for the memory effect or long-term interactions, fractional-order derivative can be applied in the present epidemic model.

THE NEED FOR INNOVATIVE TOOLS IN MULTIMEDIA APPROACH TO REACH THE UNREACHED IN SOCIAL AWARENESS PROGRAMS

R. PRANAVA KUMAR

Assistant Professor, Department of Visual Communication & Electronic Media, Bharathiar University, PSG College of Arts and Science, Coimbatore, Tamil Nadu, India

ABSTRACT

This is essentially a research paper as part of the doctoral thesis work, with a purpose of discerning a myriad social welfare programs and the mode of communicating to the intended target groups. Five case studies have been taken from different secondary source of information to understand the efficacy of communication tools in various social awareness program initiated by Government of India. Case Study 1 covers Water and Sanitation program of DANIDA of Cuddalore district of Tamil Nadu; Case Study 2, discusses the MGNREGA (Mahatma Gandhi National Rural Employment Guarantee Act, 2005) and its performance; Case Study 3 GPDP (Gram Panchayat Development Program) with three criteria in their proposal - hunger free, poverty free and good sanitation; Case Study 4 TSC (Total Sanitation Program) of Melapuram provides information about successful implementation of TSC in rural area and Case Study 5 WASH strategy (water, sanitation and hygiene) to control diarrhea by using potable water for drinking, washing hands and for sanitation. Upshot of the paper is that, no single tool would suffice to communicate all different programs, which in turn necessitate the identification of suitable communication tool and try and use different methods depending upon the program and target group.

Original Article

INTRODUCTION

Any welfare state shall endeavor to promote welfare of its citizens through various measures, and it is their prime duty to do so. Initial step is to provide basic amenities to all people of the State and proceed towards development on all sectors. Development encompasses positive changes in social, economic, cultural, environmental and physical components of humanity. Amartya Sen defines development as a tool enabling people to reach the highest level of their ability, through granting freedom of action i.e. freedom of economic, social and family actions etc. On the basis of development, the World has been divided into developed, developing and under developed nations. India has reached the slot of developing nation, and has been striving to attain developed nation status. Considering the natural resources, manpower, Government's strategies and brain power, India has a huge potential to become a developed nation on par with western countries. The moot question is why India is slow in the progress towards attaining the higher position despite having all resources. Numerous detrimental factors play a role to dampen the process of progress leading to inequitable distribution of wealth, socio cultural taboos, caste and religious intolerance, inadequate health care lack of quality education, corruption on all levels of Government, and lack of awareness among people regarding their rights and so on. The purpose of this paper is to take stock of existing programs at the global, national and state levels with a view to identify the mandates, modalities of

implementing the programs, the degree or response to mass communication modes and the need for improvising the existing methods to achieve the intended targets. It is a preliminary attempt as part of a research work leading to doctoral degree.

Communication is one of the tools to reach a large group of people, spread information, instill ideas, create awareness, change their mindset and create social amity. Mass communication has been used since the inception of newspapers, radio, televisions to reach out to every individual in the nook and corner of the country. Technology has advanced at such a rapid pace that the audio visual medium has attained enormous outreach that instant transmission of videos is possible to every part of the country. This innovate, interactive tool has been used in advertisements, education, politics, entertainment, social issues and creation of social awareness for many years. Innovative formats, new techniques, interactive communication has witnessed advancement from time to time to make communication more effective. Though communication tools spread the message, educate people, entertain and advocate; only a long lasting impression that creates a change in mindset would bring the desired result. Considering the case of creation of social awareness, the desired result would be acceptance of change and sustainable practice of the alternate method. In this context, just information and education would not suffice, though initial results may be encouraging, as people tend to stick to their old methods and customs in the long run. Thus, the search for effective communication tool arises and a strategy to customize the project to suit the stakeholders is mandatory.

Uniqueness of Social Welfare Programs in India

Social welfare, social security or social awareness, vary in their exact meaning but the underlying ideology is human welfare in pursuit of creation of informed society. The social welfare measures adopted vary among developed and developing countries in accordance to the aspirations of the ruling Government and the needs of the countrymen. Each individual is entitled to social security benefits by virtue of just being a citizen of that country, whether he contributes to economy or not. Persistent inequality in the society upholds the need for creation of social equity through advocating social awareness programs. Inequality is an inherent character of any society but the range of difference in the quality of life needs to be minimized. Consequently, the rich poor gap bridged through creation of social awareness and paving the path for all individuals in the society to achieve a better standard of living. Provision of all the basic needs may fulfill *necessary condition* like food, clothing and shelter but *sufficient condition* for development includes parameters like education, health, social status, gender equality etc. Good governance focuses on holistic development on all sectors so as to achieve well-being of its people. The social welfare measures of any Government could be classified as two types; programs which render financial assistance by direct cash or facilities and programs which educate people on various topics- the ultimate goal being improvement in the standard of living.

Comparison of HDI ranking (Human Development Index) among countries rank India at 131 among 188 countries, and it could be construed as the index for development of a country. The components of HDI are three viz. health, education and Gross Domestic Product (GDP), and a combined improvement in all three aspects would only improve the ranking of a country. Central and State Governments of India has been planning and implementing various social welfare schemes since Independence, but the desired effect is lagging and not reaching the whole population. Along with Government, many NGOs work hand in hand to improve the life style of the oppressed groups and create equity, with only partial success. This paper aims to discuss the factors that deter equitable distribution of benefits in India and analyze few factors that could be modified to create a better result.

All nations, be it developed, developing or under developed have charted out a list of welfare programs in accordance to the need of its citizens. Analysis of the various programs of United States of America (Developed) and India (developing) countries (Annexure 1) gave a picture of similarities in the main sectors but marked dissimilarities in many sub sectors. India being a developing country with diversity in socio-cultural parameters in each State, the social welfare measures included schemes for the marginalized through education, health and employment in a special basis so as to create equity. Careful examination of the aforesaid, fairly exhaustive though not complete list, the extra effort and schemes that were incorporated by the Indian Government showed the robust quality of planning and inclusiveness. Women and child health care, old age pension, education for all, housing, disabled care and so on are common to both USA and India. But promotion of sex ratio, assistance to widows, marriage assistance, supplementary nutrition to adolescent girls, scholarship to backward and minority students with supply of free text books and uniforms, free technical education to minorities, SC& STs., free coaching and tuition for weaker economic status students, free hostel for male and female students, vocational training, night shelters, promotion of handloom and handicrafts, public distribution system, Annapurna scheme, mobile dispensary vans, agricultural loans and implements supply, co-operative societies formation, insurance scheme for laborers are few schemes unique to a developing nation like India. Departments concerned with each sector directly appoint staff to carry out various activities or entrust the role to select NGOs by providing them financial assistance. Since the emoluments need to reach every nook and corner of the state at correct time interval, a concerted effort is needed to manage these programs by the Government and NGOs.

Other than Central Government, each State government supplements many programs for its citizens and such programs are specific to the socioeconomic, cultural, and educational and health needs of the people. Each State in addition to Centre's program creates new ones to suit the needs and aspirations of its citizens. Social welfare board of Tamil Nadu has its schemes planned and executed by their ministry Social welfare and the schemes of Tamil Nadu are broadly classified under the following heads, as recorded by the Tamil Nadu Social Welfare Board. Other than the stated programs, every time the government changes, once in five years, new schemes are announced and adequate funds allotted to implement such projects. Success of any scheme depends on the stakeholders, they must be aware of the scheme, its intent, the change it will bring to their lives, acceptance, and sustainability. Thus introduction of the schemes alone would not bring development, only a change in the mindset of the people and their propensity to carry forward the project on a continuous basis would create the real development aspired. Creation of social awareness about the projects, inculcating the idea into the mindset, creating a change in the traditional habits, following the new idea on a sustainable basis would be only possible through communication. Mass communication assumes importance here by serving as a tool to create social awareness and thereby development

Communication Tools

Social awareness programs and its modalities of propagation vary according to the requirements of the particular society. Choice of the communication tool depends on the type of project and the target stakeholders. Consequently, successful implementation of any social welfare or security program depends on creation of awareness through various modes of communication. The tools of communication ranges from lectures, personal talks, posters, banners, pamphlets, newspaper, street songs, puppets, street plays, radio, cinemas, TV, advertisements and so on. Each tool has its own target groups and reach; the selection of tool to be used varies according to the stakeholders. No single medium could be construed as the most effective in all situations as the target population varies in their socioeconomic status, education,

access to the medium, their understanding and capabilities to accept change.

India in general and Tamil Nadu in particular, has a host of good values to be carried on as well as bad outdated customs that need to be changed. 'The Vision of Tamil Nadu 2023' envisages provision of world class facilities to all residents irrespective of caste or class in the form of housing, water, sanitation, energy transport, irrigation, connectivity, transport, health care and education. Open air defecation is one such outdated unhealthy practice that needs to be completely removed from the society. Total Sanitation Program, one of the major components of Vision 2023, the state of Tamil Nadu is far away from achieving it. It is heartening to note that access to connectivity is progressing at a faster pace than access to toilets. *"There are 45 countries including India, where less than half the population has access to improved sanitation facility. Despite increase in sanitation coverage, a vast section of people of India do not have access to improved sanitation facilities"* 2014 update, WHO & UNICEF. "As per 2011 Census, in Tamil Nadu 48 percent of households have access to latrine within their premises and 5 percent use public toilets, remaining 47 percent resort to open air defecation. In rural areas, the proportion is 73.27 percent using open air defecation, in urban areas it is 16.21 percent practicing open air defecation in Tamil Nadu", as per the information provided at the Workshop on Converging Strategies 2015.

"With the declaration of 100 panchayats as ODF (open air defecation Free), nearly one-fourth of the 420 panchayats would become ODF in Madurai district" 2016, B. Rohini Ramdas, continued " the bigger challenge though is to ensure people are consistently using toilets, we had difficulties in convincing people on the need for toilets, but now, that has changed a lot" The strategy would be to motivate people to accept toilets as their fundamental right and practice in door defecation in order to maintain ones dignity and health. In urban areas, the lack of space and absence of toilets in rented buildings lead to open air toilets in crowded slums, whereas in rural areas, irrespective of socio economic status people follow open defecation as this tradition has been inculcated into their minds. Change in the mindset, understanding the health hazards and implementation of indoor defecation among the rural masses need social and behavioral change communication, which is development communication. Thus, communication for development forms the major tool to inculcate changes in the habits of people on a sustainable basis.

Human nature varies from individual to individual that the perception, interpretation and reaction to mass media varies widely. " *It was discovered that audience of mass media were not isolated individuals but remained tied to friends, families, work associates community etc. called the theory of selectivity based on social relationship",* 2011, Rajesh Kumar. *"Reviews of successful BCC- Behaviour Change Communication, campaigns in India indicate that evidence based long term campaigns spanning 4-5 years, an integrated multi-media approach, ongoing monitoring and program modification, if necessary are critical for ensuring sustained behaviour change."* Shalini Prasad and Manisha Singh,2010.

Taking the example of Open air defecation and Swacch Bharath program, it could be understood that communication was not effective to change the habits of the people. Both Central and State Governments have been consistent in building public toilets, giving monetary assistance for construction of household toilets, creation of sanitary marts where you can buy the implements at a nominal rate, educating people about the health hazard of open air defecation, encouraging ODF status by giving awards to Panchayats, door to door talks, posters, advertisements, educational films and creation environmental awareness. These efforts have produced some changes but the desired effect has not been attained. The reason behind such status is lack of mind set change, belief in old customs and traditions, religious causes, lack of maintenance, failure in sustainable use of toilets even when it is available.

Discussion in the preceding pages brings out the fact that there exists a gap between the intended outcome and the actual in all cases of social welfare programs; giving raise to question about the efficacy of the methods of propagation. The solution to one problem may seldom be suitable for another and any methodology could hardly be claimed as the best. How to find which is the best method for spreading the awareness among the people in raising their level of awareness? In this milieu, a study of few success stories published, could throw some insights as to which is best suited for a particular project. Five case studies published in various journals were taken and the methodologies were studied. Each case spelt out a different method depending on their target, budget, stakeholders and time. Some showed success by including women, some using IEC tools, stakeholders' involvement, gram saba meetings and direct door to door canvassing. The main aim, the method and results of the five projects, as culled out from the available literature, are given as case studies below

Case Study 1

Water and Sanitation program of DANIDA carried out in more than hundred villages of Cuddalore district of Tamil Nadu, reiterated people's participation and women empowerment as major focus to achieve the desired result in their projects. Their project motto was *demand driven approach*, wherein they send messages to all villages about their project plan and villagers need to involve voluntarily in the project according to their demand. One such village was Vella Kollai village in Cuddalore district with defunct and poor water supply. Vella Kollai gram panchayat president S. Sundaram, attended the block level meeting and he initiated the project of water supply to his village with the funds from DANIDA. Total project cost of Rs. 3, 09, 485 (year 2000), villagers contributed one –seventh and the rest by DANIDA. Planning, execution and maintenance were done by village groups particularly women. Bore wells, water head tanks, pipes were laid and supply for 4 hours in a day from 20 taps constructed at appropriate sites solved the problem of water supply in that village totally. Similarly sanitation project was carried out in a village called Keerapalayam, Cuddalore district. This was totally a women initiated project, though the panchyat president was a male, K. Paneer Selvam, all households were provided with toilets with the help of DANIDA funding and one – fourth contribution by villagers. The strategy for this project were-strengthening local bodies, peoples' participation, gender equality, women empowerment, maintenance by women user groups. As an example to female involvement, Ms. Suda of Vella Kollai village got trained in pump mechanism and was always ready to rectify any repairs that would arise in the water supply program. Another Ms. Kamalamma trained as mason built most of the toilets in Keerapalayam village.

Case Study 2

MGNREGA (Mahatma Gandhi National Rural Employment Guarantee Act) offers 100 days of work per year to all eligible rural poor in India, and is one of the largest social protection schemes in the world. Since implementation in 2006, it has spreaded to all villages in India covering almost 50 million rural households in 2013-14. Analysis of the project showed marked disparities among and within States of India. ESID, 2012, reports the following, *"Employment outcomes are lower in states with higher poverty levels • MGNREGA implementation depends on the supply of work rather than demand for it • Supply is determined by differences in state capacity and commitment, local power relations, the role of lower-level functionaries, and political competition • Improving employment outcomes requires strengthening the demand-driven aspects of MGNREGA through a focus on local level social audits, funding and tracking of outcomes • States should be provided with support to improve their capacity and allowed a degree of flexibility in MGNREGA implementation "*

Such large projects could not be designed with a common methodology as the needs and aspirations of people vary among states and within it. From the report we incur that, the projects should be demand driven and the funds should be channeled through gram panchayat to villagers rather than district level.

Case Study 3

Gram Panchayat Development Program (GPDP)

The gram panchayat development program plans to formulate their proposals under three major criteria, hunger free, poverty free and good sanitation. On the Tamil Nadu front, there are 12,524 gram panchayats in the 31 districts wherein the GPDP programs has been in vogue. A recent report, puts forth the failures and success of such initiatives in perspective, *There has been a partial success on the implementation of this program and the concluding remarks was, "Only awareness generated on the scope and need of SDGs (Sustainable Development Goals)," would lead to better results in future (2017, Workshop)*

The IEC (Information, Education and Communication) tools play a major role in the successful outcome of these projects. The IEC tools may be in the form of charts, pamphlets, hand books, posters, books, audio, videos and short films. In spite of using various modes of communication, the desired effect was not achieved and the workshop suggested more effective awareness or sensitization of the stakeholders to improve the success rate. The choice of IEC tools must be appropriate to the socio-economic and cultural status of the target leading to customized tools and newer tools of communication to reach the audience more effectively.

Case Study 4

Total Sanitation Program of Melapuram, a success story, was analysed and projected as a model for replication in other parts of the state. Block coordinators and field staff were given adequate inputs and training regarding TSC and entrusted with multi-media tools to sensitize people and help them solve issues that might arise in implementation of the program. Monitoring was carried out through coordinated mechanism from grassroot level through computers by creating a network among all 10 computers of the village panchayat. Adequate training in Computer operation was given to field staff (local residents), which helped to maintain accounts and data. Local NGOs were also involved to make the program robust and sustainable. This model disseminated by creating a web page for this block and spread to all other blocks for replication. In this case, effective use of stakeholders' participation, modern technology and multimedia helped in achieving the desired result.

Case Study 5

The impact of WASH (water, sanitation and hygiene) in controlling diarrhea was studied and found the desired effect lagging far behind the expected outcome. A review of 18 studies revealed that provision of adequate water and sanitation facilities did not effectively bring down the out breaks in cholera. Lack of knowledge that unclean water is responsible for the disease, clean hands form the basis of prevention, proper sanitation can only reduce the incidence were the prime lacunae discovered to impede the success of WASH strategy in prevention of cholera out breaks. Certain cases of improved knowledge had only limited response that those even with awareness did not adhere to clean practices in the long run. Most case studies exhibited success in the first few months followed by back to old practice. As conclusion, it was reiterated that there was a gap in assessing the correct strategy to a particular section of people. More innovative strategies using the limited resources to improve the WASH intervention program, tailored to the target, should be effective in

control of cholera.

DISCUSSIONS

Social welfare programs are stakeholder oriented unlike others, where the project proposer also stands to gain. For example, if a company producing sanitation products like toothpaste or soap advertise their products reiterating the importance of cleanliness and health, through newspapers, TV or posters, their aim is only business. Their target audience is consumers with the capacity to buy their products, others who are in low socio economic strata who are not their customers are out of their concern. They aim at users wooing and maintaining their brand loyalty. Conversely, social welfare program of the Government aims at equity, the program envisages inculcating sanitary practices by changing the mindset of the people. The program aims to cover the whole population. Bringing about a change in their lives and increasing their standard of living. The above case studies are projects implemented by Government or NGOs and their success could not be measured by monetary scale but by the sustainable achievement of the desired result. Thus, the search for different methodology, innovative tools, inclusive participatory modes and new strategies must be delved to fit a project. In this context, *no one size fits all* becomes true as each example project has been designed differently and carried out through various modes and made successful. The common thread is stakeholders' participation, demand driven approach and monitoring by locals. The tools of communication vary with each project, direct talks, *gram sabha* announcements, posters, IEC tools, digital platforms, etc.

The social welfare program chosen for the thesis work is sanitation encompassing construction of toilets, hand washing and safe disposal of waste. Analyzing a few success stories as mentioned above, in search for a suitable tool for creation of awareness towards sanitation, school children was selected as target population, as it would be easier to inculcate sanitary practices and its benefits in young minds rather than old ones who are bound by their traditions and customs. In such a scenario, a clearer understanding of case studies presented in the preceding pages helped and directed the research, as the authors become inquisitive to probe whether animated audio visuals would lead to a better understanding and long standing effect on young minds or not? The animated video is being designed by the authors in line with the principles of development communication to make it more interesting, target oriented, grasp the imagination of the youngsters and create a lasting impression in their minds. The story line would be proactive rather than advisory so that children tend to implement the project at each level with a strong note of do it yourself.

Social welfare forms the major duty of Government that most of its resources are directed in creating an equitable social welfare of its citizens. Comparing the list of social welfare programs of a developed country like USA and a developing country like India, the broad categories like health, education, employment etc. remain the same. But, the exhaustive list documented brings out the variations in the programs between these two countries. More emphasis is given to child health, old age security and rehabilitation of destitute, addicts, juvenile delinquents, immigrants and poor. In India, there is a need to provide special relief to marginalize like minorities, SC, ST and other backward classes. Gender issues need to be taken more effectively to create gender discrimination less society wherein all citizens could enjoy the rights equally irrespective of their gender. Health and sanitation programs require innovative approaches to change the mindset of the people in order to realize MDG (Millennium Development Goals). Other variations are farmer's subsidy, free rations to BPL families, disability pension, old age pension, widow pension and so on. Notwithstanding the disparities among USA and India social welfare programs, the strategy to implement is the hallmark of the project success and communication tools play a major role in translating any social welfare program to reach its target population. Here again "no one size fits

all", each project is unique in its nature, target, resources, and goal. Analysing five of the success stories of Indian social welfare programs, the strategy and methodology differences employed in each program vary reiterating the fact that each program has to be treated unique and tools used customized to the target population and their requirements. The case studies also bring out the difficulties faced and the corrections carried out to make the project more amenable to implement.

The case study of the five projects with all its methodology for successful implementation puts forth the necessity to design the project from conception level. Involvement of stakeholders at the planning level, understanding their views before formulation of a strategy, using local people and language to propagate the idea, identify the target people whose mindset could be influenced, use locals as leaders in bringing a change, use multiple combination of communication tools, upgrade the communication tool to be more interactive and innovative, plans must be personalized for each community or changed in accordance with the necessity of that group.

CONCLUSIONS

Research in media and mass communication is fairly new, when compared to natural, physical and social sciences. Mass communications, although aims to reach the target group as a whole, the success rate has proved to be partial so far. The reasons are manifold; one of the reasons is sticking to anyone particular mode to communicate to the whole lot. This paper infers that new modes need to be tried by taking into account the age, gender, socioeconomic status and cultural background of the target group. Animation as a tool has been tried sporadically with varying degree of success and failure. The authors of this paper, in the backdrop of knowledge gained through the above review of case studies, have been attempting to test the efficacy of animated models to communicate to the younger target group on sanitation practices. In sum, this may be a pointer for researchers to try innovative tools for social awareness communication.

ANNEXURE

Social Welfare Programs of USA

Social- old age assistance, Temporary assistance to needy, Foster care, Adoption assistance, General assistance in cash, Refugee assistance, and General assistance to Indians, however the list is not exhaustive.

Health- Medicaid, Health insurance, Medical general assistance, Health centers, Maternal & Child health, Medical assistance to refugees, Healthy start

Food- Food stamps, School lunch, Women, Infant & Children Food, School breakfast, Nutrition program for elderly, Commodity supplemental food, Temporary emergency food, Needy families, Farmers market Nutrition program, Special milk program, Summer program

Housing- Section 8 housing, Public housing, Low income housing, Home investment partnership, Assistance to homeless, Rural housing insurance, Housing for elderly, Assisted housing program, Housing for disabled persons

Energy- Low income home energy assistance, Subsidized low income phone service, Weatherization

Education- Pell grants, Grant for local education authorities, 21st century learning centres, Special program for disadvantaged, Supplement educational opportunity, Adult basic education grant, Migrant education, State student incentive grant, Education for homeless children, Aid for graduate & professional study for minorities

Training- Work activities and training, Job corps, Summer youth development, Adult employment & training, Foster grandparents, Youth build, Migrant training, Native American training

Service- block grant services, Social service block grant, Community services grant, Safe & stable families, Aging Americans act, Family planning, Emergency food and shelter, Responsible fatherhood grant, Foster care independence grant, Independent living & training, Maternal, infants and child home visits

Child- Child care & development, Child care entitlement to state, Block grant child care

Community- Block grant, Economic development grant, Appallachian regional development, Empowerment zone, Enterprise communities renewal.

Social Welfare Programs of Central Government of India

- **Social Welfare Schemes** - old age pension, National family benefit, Jan shree bhima yojana- insurance cover to poor, Scholarship to disabled person, Unemployment allowance to disabled person
- **Women and Child Development** - Pension to widows, LADLI - promotion of sex ratio, Financial assistance to lactating and nursing mothers of weaker section, Financial assistance to poor widows for their daughters marriage and marriage assistance to orphan girls, Scheme of Bhagidari- care of Women senior citizens
- **Nutrition Programs** - Supplementary nutritional program, Kishori Sakthi Yojana- improve nutritional status of adolescent girls, National program for adolescent girls.
- **General Education** - Scholarship to students of economically weaker section, Welfare of educationally backward minority students, Lal Bhahadur Sastri Scholarship to meritorious students of economic weaker section, Subsidy for school uniform to students, Free supply of text books, Welfare program for children of MCD school, Welfare scheme for children of NDMC schools, Incentive as scholarship for promoting education among girls/SC/ST/OBC in class I to V
- **Technical Education** - Strengthening facilities to students of SC/ST/OBC/Minorities in polytechnics, Coaching class for SC/ ST/ Weaker sections in Delhi college of engineering, Coaching class for SC/ ST/ Weaker sections in Netaji Subash Institute of technology, Academic development of SC/ST students in College of Art
- **Welfare of SC/ST/OBC/Minorities** - Financial assistance for purchase of stationery, Scholarship, Merit scholarship from class Vi to XII, Merit scholarship foe college and professional courses, Vocational and technical scholarship, Hostel for student boys, Hostel for student girls, Pre- exam coaching, Reimbursement of tuition fees in public schools, Financial assistance/ loan for self-employment, Vocational training, Improvement of living condition
- **Urban Development** - Swaran Jayanthi Sahari Rozqar Yojana- gainful employment to urban unemployed poor, Urban basic services program, Construction of community halls, Environment improvement in urban slum,

Construction of pay and use Jansuvidha complexes

- **Housing** - Houses for weaker sections, Night shelters
- **Industry** - Society for self-employment, Promotion of handlooms, Handloom weavers welfare- insurance, thrift cum security, weavers colony, Promotion of Handicrafts
- **Civil Supplies** - Streamlining of PDS with focus on BPL families- targeted PDS, Antyodaya Anna Yojana- poorest given subsidized wheat and rice, Annapurana Scheme- free grain of 10 Kg per head per month above 65 years.
- **Medical** - Mobile van dispensaries for JJ clusters, Delhi state health mission
- **Science and Technology and Environment** - Involve weaker sections in improvement and upgradation of environment, Labour and Labour welfare- Rashtriya Swasthiya Bhima Yojana- Health cover to BPL families, Technical training for self-employment, Coaching cum guidance facility for ITI students
- **Agriculture and Allied services** - Grant for land improvement and agricultural implements, Training for SC/ST in modern poultry farming, Co-Operation- Credit for SC/ST in cooperative societies
- **Aam Aadmi Bheema Yojana** - Life insurance cover for landless labourers.

Social Welfare Programs of Tamil Nadu

- **20 Point Program**

Agriculture, Children, crime, labour, rural, demography, SC ST, tourism, economy, education, urban, welfare, women, energy, environment, health, housing, industry, infrastructure

- **Backward Class Schemes**

National Backward classes Finance and Development Corporation (NBCFDC), Backward regions grant fund, National Scheduled caste Finance and Development Corporation (NSFDC), National Scheduled Tribes finance and development Corporation (NSTFDC), Aids to NGOs, Financial assistance to upgrade technical and Entrepreneurial skills, Term loan scheme,

- **Child Schemes**

Anganwadi, Balika Samriddh Yojana, ICDS(Integrated child development scheme), ICPS (Integrated child protection scheme), Juvenile justice, Mid day meals, National creche fund, RCH (reproductive and child health, Shishu Greh scheme, others

- **Disabled Schemes**

Educational schemes, vocational training, rehabilitation, artificial limbs, scheme for mental retardation and rehabilitation, special schools for mentally challenged, purchase of aids and appliances, concession certificates.

- **Foreign Contribution**

Regulation of foreign contribution through NGOs., Foreign contribution regulation act, Funds utilized by NGOs.

- **Labour and Employment Schemes**

MGNREGS Mahatma Gandhi National Rural Employment Guarantee Scheme, EAS (Employment Assurance Scheme), Food for work Program, Jawahar Rozgar Yojana (JRY), Million Wells Scheme, National Maternity Benefits Scheme (NMBS), Prime Minister's Rozgar Yojana (PMRY), Rural Employment Generation Program (REGP), Sampoorna Grameen Rozgar Yojana (SGRY), Scheme for working women's hostel, Rehabilitation and bonded labourers, (STEP) Support to Training and Employment Program for Women, Swarnjayanti Gram Swarozgar (SGSY), Training of rural Youth for Self- Employmant (TRYSEM)

- **Minorities Schemes**

Fellowships, National Minorities development and Finance corporation NMDFC, multi sectoral development, Scholarships, Educational loans, micro finance, vocational training, coaching scheme, welfare and development of SC and STs, disbursement of loans, micro credit

- **Rural Schemes**

Rural water supply, Accelerated Rural water supply program(ARWSP), agriculture and rural debt relief, Anti-poverty, Bharath Nirman, Bhoodan Movement, Central schemes, credit cum subsidy, Desert development, District rural development agencies, Drought prone area programs, Employment assurance scheme, Food for work, Indira Awaas Yojana, Integrated rural development program, Integrated wasteland development, Jawahar Geam samridhi, yojana, Jawahar Rozgar Yojana, Million wells, Watershed development, Rural infrastructure development, rural sanitation, land development, self-help groups, updating land records, Toolkits to rural artisans, Rural drinking water, Training for rural youths

- **Social Schemes**

Members of Parliament Local area Development scheme (MPLADS), Prohibition, annapurna, NGO assistance, CAPART sponsor, Freedom fighter's pension, Growth centres, Liberation and rehabilitation, Family benefit, Old age pension, National Social Assistance Program (NSAP), Short stay homes, Social defence schemes

- **Tribal Schemes**

Vocational training, Central sector, centrally sponsored schemes, educational schemes, special component plan, Tribal Co-operative Marketing Federation of India (TRIFED), tribal sub-plan.

- **Urban Schemes**

Accelerated Urban Water Supply Program AUWSP), Jawaharlal Nehru National Urban Renewal Mission (JNNURM), urban infrastructure development for small and medium towns (UIDSSMT), Valmiki Ambedkar Awas Yojana (VAMBAY), Swarna Jayanthi Shahari Rozgar Yojana (SJSRY)

- **Voluntary Schemes**

Schemes and measures taken by Voluntary organisations and Non government organisations NGOs.

- **Women Schemes**

Awareness generation projects for rural and poor women, education for adult women, CSWB scheme, Distance education family counselling, Janani Surakshe Yojana, Kishori Shaki Yojana National Maternity Benefits Scheme (NMBS), NORAD scheme, Rashtriya Mahila KOSH, Working Women's hostel, Science and technology for women, Training and employment program for women, Swa Shakti Project, Swayamsidha Scheme, Vocational rehabilitation for disable women, Vocational training.

Concentration ratio
Heptane /R245fa
Zeotropic mixture

ABSTRACT

In current study, an effort is made to improve the overall performance of the solar powered organic Rankine system to meet increasing energy demand and mitigate the resulting menace caused by environmental imbalance. Hourly performance evaluation of Solar powered Organic Rankine Cycle (ORC) system is done for varying concentration ratio in terms of collector output temperature, heat gain in evaporator, combined thermal and exergetic efficiency. The Heptane/R245fa is used as working fluid at fixed (0.1/0.9) fractional mass component. Organic Rankine system is coupled with reversed absorber hybrid photovoltaic thermal compound parabolic concentrator (PVTCPC). The highest collector outlet temperature 125.45 °C, heat gain 3.21×10^5 W, combined thermal efficiency 7.8%, and exergetic efficiency 14.38% is observed at 13:00 h for 6 concentration ratio of the concentrator. This study establishes the utility of low-grade renewable heat source conversion into solar electrification, solar irrigation, solar cooling and solar water purification.

1. Introduction

Over-utilization of fossil fuels to meet the world's growing energy demand causes several problems, such as shortage in fossil fuel reserves, global warming, air pollution and depletion in ozone layer. Alternatively, various renewable energy sources such as solar [1], geothermal [2], biomass [3] and ocean-thermal [5,6] have been used in order to curb these concerns. Solar thermal applications leads among these resources due to freely available in nature, easily exploitable, cost-effective and no adverse effect to the atmosphere [7,8]. Therefore, an attempt has been made to utilize solar thermal energy for power generation through organic Rankine cycle (ORC).

Power generation technologies include; organic Rankine cycle [1], Kalina cycle [9], Goswami cycle [10] and Trilateral cycle [11]. Organic Rankine cycle is best among these as simpler structure, flexible, reliable, lower operational cost and improved power generation [12]. The selection of the working fluid is important facet for ORC system [13,14]. The performance of ORC system using the pure fluid as working media is not desirable due to substantial exergy loss in the two-phase region. This is because of thermal mismatch in the evaporator (collector) [15]. Pure working fluids exhibits constant pressure and temperature on phase change process which leads to mismatch of temperature in heat exchangers. The pure working fluids; R245fa, R12, R123, R134a, R1234yf, R290, Ethanol, R141b, R718, water, ammonia, CO_2 were employed in ORC system ([16–19]. Further, flammable pure working fluids such as: R600 (Butane), R600a (Isobutane), R6001 (Benzaldehyde), benzene, isobutene, isopentane, cyclohexane are also used in ORC system [13,17,18,21,22].

The ORC system performance is improved by using zeotropic fluid owing to reduction of exergy destruction in a two-phase

0960-1481/© 2019 Elsevier Ltd. All rights reserved.

region (Xi et al., 2017). Therefore, zeotropic mixture is recommended as working fluid in ORC systems. The zeotropic mixtures exhibits isobaric and non-isothermal phase change processes and lead to improved temperature match in heat exchanger [23,24].

Comparisons of thermo-physical properties for some working fluids are summarized in Table 1. The considered working fluid heptane belongs to a hydrocarbon group. The ozone depletion potential (ODP) of heptane is zero and exhibit negligible global warming potential (GWP) however, it is flammable. The working fluid R245fa is non-inflammable with zero ozone layer depletion potential but exhibits some GWP. Moreover, the GWP of the working fluid heptane/R245fa will be lower than the GWP of pure R245fa. Flammability of heptane is suppressed by blending with more fraction (0.9) of incombustible working fluid mixture component R245fa in whole mixture of (heptanes/R245fa) in comparison to flammable mixture component heptane (0.1) (Xi et al., 2017; [23]. Moreover, heptane and R245fa are dry Working fluids therefore possibility to erode the turbine blade gets reduced [25,26].

Solar collectors are responsible for converting solar radiation into useful heat energy. The selection of solar collector significantly affects the overall Solar powered ORC system performance [13,16]. The collector outlet temperature for flat plate, evacuated and for parabolic collectors are found in the range 80–90 °C, 130–150 °C, 150–165 °C, respectively [22]. Flat plate collector has lowest outlet temperature among reverse two absorber flat plate collector, parabolic collector, evacuated collector owing to substantial radiation and convective heat losses [27]. The flat plate collector is costlier than conventional compound parabolic concentrator because of its higher collector area [28]. Radiation and convectional heat losses of conventional compound parabolic concentrator are substantially reduced which increases collector outlet temperature.

The exit fluid temperature of the concentrator is in the range of 300–550 °C which is higher than the flat plate collector with approximate thermal efficiency of 25–30% [29,30]. Performance of reversed absorber PVT/CPC collector covered with glass is best among unglazed reversed PVT/CPC, inclined PVT/CPC and horizontal PVT/CPC systems in terms of collector outlet water temperature and overall exergetic efficiency [28].

The traditional solar thermal collector converts solar radiation into heat, whereas PV system directly into electricity. The important limitation of PV system is reduction of solar cell efficiency with increases in PV cell surface temperature. The absorbed heat in the PV system is being wasted. Therefore, in order to enhance thermal heat gain and reduction of surface temperature of the PV cell, a traditional solar thermal collector can be interfaced with PV system [31]. Moreover, PVT/CPC exhibits better electrical efficiency than single PV system [32]. Parabolic trough collector exhibits 1500 °C at the concentration ratio 600 to 2000 whereas linear Fresnel reflector gives 500 °C for the concentration ratio 30 to 80 [29,30]. [33] performed thermal analysis for combination of photovoltaic and thermal system by varying concentration ratio. It was observed that at an increased concentration ratio, the electrical, as well as thermal performance, gets improved. According to the best knowledge of authors, some specific studies have been carried out using different zeotropic mixtures and solar collectors for solar powered ORC system which is summarized in Table 2 [1,13,14,16,34]. It is observed that, very few works have been done on energy and exergy analysis of solar collector and ORC system employing zeotropic mixture [1,21,34–36] [37];

The integration of reversed absorber hybrid PVTCPC system is a novel concept (Wang et al., 2011; [18,22,38,39]. The use of reverse absorber (PVTCPC) in low-grade solar heat source power generation for ORC system using zeotropic mixture with low global warming and negligible Ozone depletion potential is being rarely carried out. Therefore, a thermodynamic investigation for Solar powered ORC system system using heptane/R245fa as working fluid coupled with hybrid reversed absorber partially covered photovoltaic thermal compound parabolic concentrator (PVTCPC) system is decided to carry out.

First part of the research describes the introduction, research gaps and objectives. Second part deals with the description of the proposed system, simulation methodology and then third part describes about the mathematical Modelling of the proposed system. Moreover, manuscript describes the analyzed results and finally concludes it.

2. Proposed system description and simulation works

2.1. Basic ORC system

Fig. 1 depicts the basic solar powered ORC system. It consists of a solar collector (evaporator), expander, condenser and pump [14]. The working fluid is pressurized by the pump is shown in (1–2) process and enters to evaporator (solar collector) is shown by state (3). In evaporator, working fluid is heated and changes into the saturated vapor by absorbing incoming radiations ((2–4) process). The saturated working fluid vapor with raised pressure and temperature from evaporator move to expander at state (4) where it gets expand and generate power by reduction in enthalpy ((4–5) process). The working fluid with low pressure and temperature is condensed through condenser and convert into saturated liquid is shown by (5–1) process. The saturated liquid again sent back to the pump and thus cycle is completed. Fig. 2 shows T-s diagram of a basic ORC system when zeotropic working fluid is taken as working fluid. Fig. 3 shows the reversed absorber hybrid photovoltaic thermal compound parabolic concentrator. Its salient parts are; aperture surface, fluid flowing in tubes and metal absorber plate.

The solar beam radiations fall on the aperture area of concentrator and move ahead to the aluminum reflector (Fig. 5) and travels to the bottom part of CPC. The reflected rays further get reflected from the circular glass reflector and received by metal reversed absorber system. The photovoltaic modules are pasted at the base of the metal absorber and the fluid carrying copper tubes are brazed at the top of the system. The upper most portion of the tube in the plate system is glazed. The thermal energy is transferred indirectly from the back of solar cells to the absorber plate and directly from the non-packing area of the PV module which raises thermal energy of the fluid. Moreover, the convection losses are reduced significantly because reversed absorber system faces in

downward direction leading improvement in collector system performance.

The design and development of the PVTCPC collector gives the solution to existing energy shortage problems [40]. investigated experimentally performance of hybrid photovoltaic thermal compound parabolic concentrator (PVTCPC) system. It was found that such hybrid systems are cost effective owing to generation of both thermal and electrical energy as well as reduced number of solar cells [41]. studied concentrating photovoltaic thermal system. It was concluded that the system has improved thermal and electrical performance [42]. proposed PVTCPC system used for building integrated purposes. It was observed that CPC-PVT system have increased thermal and electrical efficiencies as compared to flat PVT system [28]. have suggested that PVTCPC collector produces both electrical and thermal energy at reduced cost.

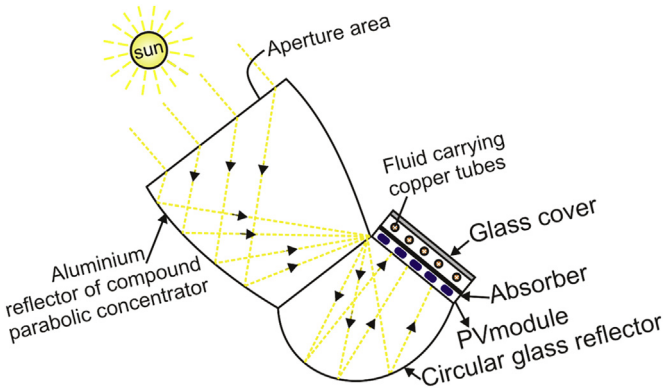

Fig 3. Reverse absorber PVT/CPC.

2.2. Thermal modelling of ORC system

The methodology of this paper has been described Fig. 4. On the basis of detail literature review the methodology of this study includes definition of the research problem, selection appropriate Working fluid, assumption in process parameters, selection of input conditions for ORC-PVTCPC system, determinations of thermodynamic properties at different desired location, application of balance of mass, energy and exergy for solar powered ORC-PVTCPC system and hourly overall evaluation of performance indicators for solar powered ORC system. The thermo-dynamic Modelling of the proposed solar powered system has been completed in MATLAB 2018a computer software. The hourly ambient parameters such as solar radiations and ambient temperature for the month of Jan 2017 of Delhi have been taken from India Meteorological Department (IMD), Pune. The properties of Working fluid can have been evaluated by MATLAB linking with REFPROP 9.0 [43]. The input

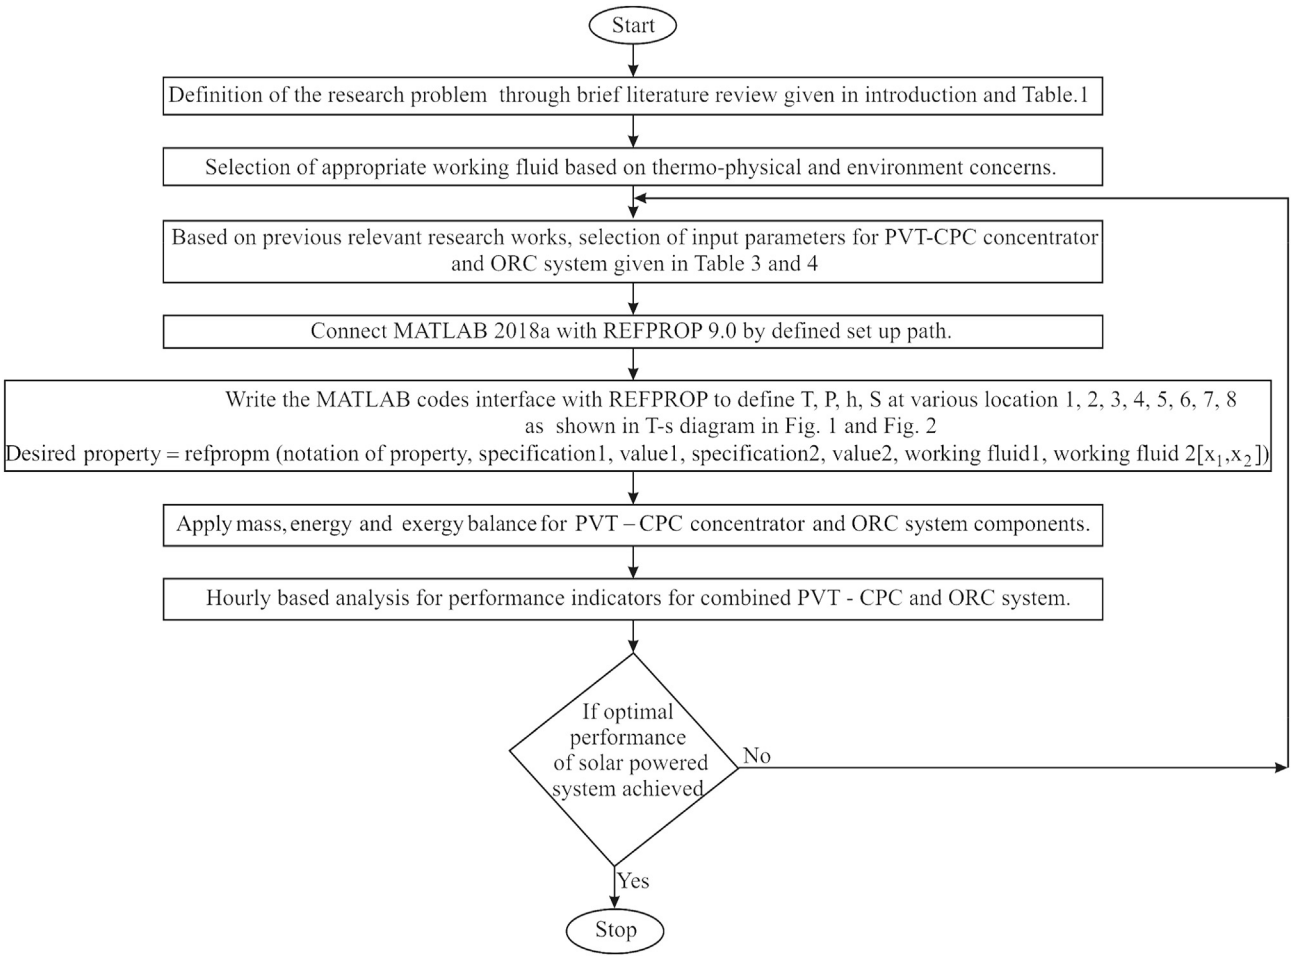

Fig 4. Simulation procedure.

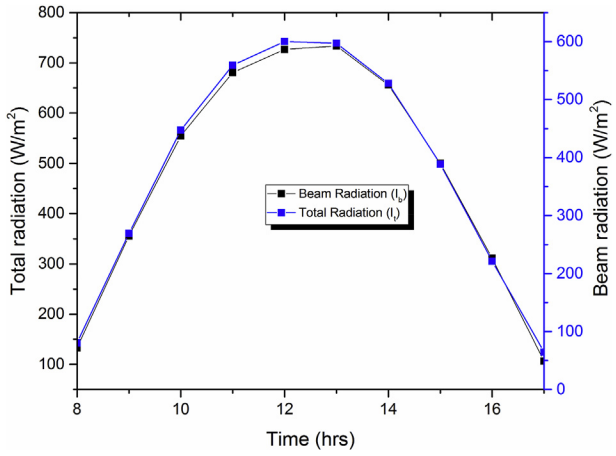

Fig 5. Hourly variation of radiations.

parameters for PVTCPC, and ORC system are given in Tables 3 and 4, respectively.

Assumptions made in order to simplify thermodynamic model of proposed system are given as [1,44].

- No pressure drops and heat losses in heat exchangers.
- The fractionating and shifting in composition for zeotropic mixture are neglected.
- No changes in kinetic and potential energy.

Thermodynamic relations for conservation of mass, energy and exergy balance for control volume system are given as [45]:

2.2.1. Conservation of mass

$$\frac{dm}{dt} = \dot{m}_i - \dot{m}_e \tag{1}$$

where '$\dot{m}$' shows mass flow rate, '*i*' and '*e*' denote the inlet and exit state.

2.2.2. Conservation of energy

$$\frac{dE}{dt} = \dot{Q} - \dot{W} + \sum_i m_i\left(h_i + \frac{V_i^2}{2} + gz_i\right) - \sum_e m_e\left(h_e + \frac{V_e^2}{2} + gz_e\right) \tag{2}$$

where '*E*' denotes energy of the system,' $\dot{Q}$' and '$\dot{W}$ 'denotes heat and work transfer rate, '*h*' denotes enthalpy, '*i*' refers inlet whereas 'e' exit.'*V*' denotes velocity of flowing stream where as '*Z*' height of flowing stream from datum.

2.2.3. Exergy balance

Net exergy destruction rate carried by any fluid stream in control volume is expressed as [46]:

$$\frac{dE_{cvD}}{dt}=\sum\left(1-\frac{T_o}{T_k}\right)\dot{Q}_k-\dot{W}+\dot{m}\left[\left(h_i-T_os_i\right)-\left(h_e-T_os_e\right)\right]-\dot{E}_D \tag{3}$$

where 'cv' defines control volume,'E_D' denotes exergy destruction of flow,'$\dot{m}$' denotes mass flow rate of flowing stream,'T_o' denotes ambient temperature, $\dot{Q}_k$ shows the heat transfer rate at temperature ''T_k' whereas 'k' shows location and 's' denotes entropy.

2.2.4. Energy analysis for ORC system

Thermodynamic relations for difference components are given as:

(i) Pump

The isentropic efficiency of the pump is:

$$(h_{2s}-h_2)=\eta_p(h_2-h_1) \tag{4}$$

where, subscript 's' denotes the isentropic.

The pump work is evaluated by the expression:

$$W_p=\dot{m}\,(h_2-h_1) \tag{5}$$

(ii) Expander (Turbine)

The isentropic efficiency is evaluated as:

$$h_4-h_5=\eta_{\exp}(h_4-h_{5s}) \tag{6}$$

The expander work is evaluated as:

$$W_{\exp}=\dot{m}\,(h_4-h_5) \tag{7}$$

(iii) Evaporator (Solar collector)

Heat gain in evaporator (Collector) is calculated as:

$$Q_s=\dot{m}\,(h_4-h_2) \tag{8}$$

(iv) Condenser

Heat rejection from the condenser is calculated as:

$$Q_r=\dot{m}\,(h_5-h_1) \tag{9}$$

(v) Net work done is evaluated as:

$$W_{net}=\left(W_{\exp}-W_p\right) \tag{10}$$

(vi) Thermal efficiency of the ORC is as:

$$\eta_{th}=\frac{(W_{\exp}-W_p)}{Q_S} \tag{11}$$

2.2.5. Exergy analysis of ORC system

(i) The destruction of exergy in pump is as:

$$\dot{E}\,D_P=\dot{m}\,T_o(s_2-s_1) \tag{12}$$

where, 'T_o' denotes ambient temperature in (K).

(ii) The destruction of exergy in evaporator is calculated as:

$$\dot{E}\,D_{ev}=\dot{m}\,T_o\left[(s_4-s_2)-\frac{(h_4-h_2)}{T_{hs}}\right] \tag{13}$$

where 'T_{hs}' is the temperature of the heat source in 'K'.

(iii) The condenser exergy destruction in condenser is calculated as:

$$\dot{E}\,D_c = \dot{m}\,T_o\left[(s_5 - s_1) - \frac{(h_5 - h_1)}{T_o}\right] \tag{14}$$

(iv) The total exergy destruction in ORC system is given as:

$$\dot{E}\,D_{Total} = (\dot{E}\,D_{\exp} + \dot{E}\,D_p + \dot{E}\,D_c + \dot{E}\,D_{ev}) \tag{15}$$

(v) The exergy input to the ORC system is evaluated as:

$$EX_{in} = \left[Q_s\left(1 - \frac{T_o}{T_h}\right) + W_p\right] \tag{16}$$

where 'EX_{in}' is input exergy in 'W'.

(vi) The exergetic efficiency is obtained by the expression as follows:

$$\eta_{ex,ORC} = \frac{W_t}{EX_{in}} \tag{17}$$

'W_t' denotes expander output in 'W'

2.2.6. Energy analysis of (PVTCPC) system

(i) The concentration ratio of the concentrator is evaluated as [28]:

$$CR = \frac{Area\ of\ the\ absorber(A_a)}{Area\ of\ the\ receiver\ (A_r)} \tag{18}$$

$$(\alpha\tau)_{c,eff} = \rho(\alpha_c\tau_g\beta_c - \eta_m)CR \tag{19}$$

(ii) The expression to compute the exit fluid temperature of the (PVTCPC) concentrator is expressed as [47]:

$$T_{fo} = \left[\frac{PF_c(\alpha\tau)_{c,eff}I_b}{U_{l,c}} + T_a\right]\left\{\frac{A_{rc}U_{l,c}\frac{\dot{m}_f c_f}{U_{l,c}A_{rc}}\left[1 - \exp\left\{\frac{-F'U_{l,c}A_{rc}}{\dot{m}_f c_f}\right\}\right]}{\dot{m}_f c_f}\right\} + \left[\left[\frac{PF_2(\alpha\tau)_{m,eff}I_b}{U_{l,m}} + T_a\right]\left\{\frac{A_{rm}U_{l,m}F_{rm}}{\dot{m}_f c_f}\right\} + T_{fi}\exp\left\{\frac{-F'U_{l,m}A_{rm}}{\dot{m}_f c_f}\right\}\right]\exp\left\{\frac{-F'U_{l,c}A_{rc}}{\dot{m}_f c_f}\right\} \tag{20}$$

where 'PF_c' denotes penalty factor of glass cover, 'I_b' beam radiation in (W/m^2), 'A_{rc}', 'A_{rm}' are receiver and PV module area respectively (m^2),'$\dot{m}_f$' water mass flow rate (kg/s),'c_f' shows specific heat of the water (J/kg K) 'PF_c', is penalty factor for the portion covered by the glass, '$U_{l,c}$' is overall loss coefficient for the cover (W/m^{2}K), 'F_{rm}' shows rate flow factor, 'F'' denotes efficiency factor for flat plate collector, 'PF_2' second penalty factor for absorber/receiver.

The estimated exit fluid temperature of the (PVTCPC) concentrator has been validated with the experimental observations given as [47]:

(iii) The expression to calculate the thermal energy obtained from (PVTCPC) system in (W) is as:

$$Q_{th} = \dot{m}_f\,c_f\left(T_{fo} - T_{fi}\right) \tag{21}$$

(iv) Equation (22) to compute the thermal efficiency of the concentrator [48].

$$\eta_{th,cl} = \frac{\dot{m}_f\,c_f\left(T_{fo} - T_{fi}\right)}{(I_b A_a)} \tag{22}$$

2.2.7. Exergy analysis of (PVTCPC) system

(i) The exergy of (PVTCPC) working fluid,'$\dot{E}_{x,cl}$', in W is given as [48]:

$$E_{x,cl} = \dot{m}_f c_f\left(T_{fo} - T_{fi}\right) - \dot{m}_f c_f(T_o + 273)\ln\frac{\left(T_{fo} + 273\right)}{\left(T_{fi} + 273\right)} \tag{23}$$

(ii) The exergy supplied by sun in Watt, is:

$$E_{x,\mathrm{sun}} = [A_a I_b + A_r I_t]\left[1 - \frac{4}{3}\left(\frac{T_o}{T_s}\right) + \frac{1}{3}\left(\frac{T_o}{T_s}\right)^4\right] \tag{24}$$

where, 'T_s' is temperature of the sun (6000 K), and 'I_t' denotes total beam radiation in (W/m^2).

(iii) The exergy efficiency of the compound parabolic concentrator is:

$$\eta_{ex,ccpc} = \frac{E_{x,cl}}{E_{x,sun}} \tag{25}$$

The electrical power developed by the PV module system is evaluated by equation (26) in 'W' [28]:

$$\dot{E}_{e,pv} = \eta_{\mathrm{pv}} I_b \rho\rho' A_{am} \tag{26}$$

where ρ′ denotes the reflectivity and 'A_{am}' shows the area of the module. However, the power consumed in pumping process or by motor (DC) is evaluated by the expression [49].

$$\dot{E}_{e,pv,net} = \eta_{\mathrm{pv}} I_b \rho\rho' A_{am} - W_p \tag{27}$$

(iv) The electrical exergy of (PVT CPC) system from the photovoltaic module in 'W' is:

$$\dot{E}_{pv} = \eta_{ex,\mathrm{pv}} I_b \rho A_{am} \tag{28}$$

'$\eta_{ex,pv}$' exhibit the exergy efficiency of the PV module.

(v) The overall exergy of (PVT CPC) system is calculated by combining thermal exergy and electrical exergy:

$$\eta_{ov,ex,pvtcpc} = \eta_{ex,ccpc} \times \eta_{ex,pv} \tag{29}$$

The combined thermal efficiency efficiency of the solar collector as well as organic Rankine cycle system is calculated as [13]:

Table 5
Validation of present basic ORC with model of [26]].

Working fluids	Mass fractions	Thermal efficiency (η_{th}) Present Work	Thermal efficiency (η_{th}) Wu et al.(2016)	Deviation (%)
R227ea/R245fa	0.1/0.9	8.95	9.07	0.45
Butane/R245fa	0.1/0.9	8.94	8.99	0.55
R227ea/R245fa	0.1/0.9	8.95	9.07	0.88

$$\eta_{ov,th,SORC} = \eta_{th,cl} \times \eta_{ORC} \quad (30)$$

Similarly overall exergy efficiency of solar powered ORC is as:

$$\eta_{ov,ex,\text{sorc}} = \eta_{ov,ex,\text{pvtcpc}} \times \eta_{ex,orc} \quad (31)$$

3. Results and discussion

Thermal efficiency from First Law of Thermodynamics is evaluated in present research which shows the fair agreement with results obtained by Ref. [26] in terms of percentage deviation (less than 1%) as shown in Table 5. Further, Table 6 shows the comparison of the outlet temperature for the PVTCPC concentrator of the present study with [28] at different concentration ratio with same given input parameters (Table 3). It clearly explains the better match of collector outlet temperature of the reversed absorber hybrid PVTCPC at various concentration ratio 1, 2 and 3 of the present study with [28]. The data for fluid inlet temperature, total radiation and beam radiation of the collector has been collected from (Indian metrological department (IMD), Pune) for January 17, 2017 for Delhi, India.

3.1. Hourly variation in beam radiations, total radiations and collector outlet temperatures

Fig. 5 exhibits hourly (08:00 h to 16: 00 h), beam radiations, total radiations for January 17, 2017, Delhi. The maximum value of total radiation (733 W/m^2) occurs at 12:00 noon whereas beam radiation (600 W/m^2) at 013:00 h (Fig. 5). Maximum collector temperature 125.45 °C occurs at 13:00 h for concentration ratio 6 (Fig. 6). The collector outlet temperature increases when concentration ratio increases. It can explain this, when concentration ratio the aperture area gets increased which facilitate to significant absorption of beam radiation over the aperture surface. The collector outlet temperature increases by increasing concentration ratio up-to 13:00 h and then decreases because after 13:00 h beam radiation decreases.

3.2. Effect of mass fraction of zeotropic mixture on glides in temperature for evaporator and condenser

Fig. 7 exhibits the variation in condensation and evaporation temperature glides when mass fraction of considered zeotropic mixture heptane/R245fa changes from (0.1–0.9). The maximum temperature glide (51.64 K) in evaporator occurs at 0.58/0.42 mass fraction whereas condensation temperature exhibits its maximum value (49.26 K) at (0.63/.37) mass fraction.

In this zeotropic mixture the first working fluid is heptane and second R245fa. The temperature glide is isobaric temperature difference between heat transferring and heat receiving fluid during evaporation and condensation process. When mass fraction of zeotropic mixture changes the boiling point of the mixture component also changes. The difference in boiling point of the mixture component creates temperature glide [23]. The temperature glide becomes largest when highest difference between the boiling point temperatures of the mixture component appear [50]. Thus, the temperature glide in condensation and evaporation process is dependent on variation in mass fraction of the zotropic mixture component. The temperature glide brings a good thermal match during phase change which improves the thermal and exergetic efficiency of the system [51,52].

3.3. Heat gain in collector

Fig. 8 exhibits the hourly heat gain in collector at mass fraction (0.1/0.9). The highest heat gain (3.21×10^5 W) occurs at 13:00 h for concentration ratio (6). It occurs because when concentration ratio increases the aperture area of the concentrator also increases whereas receiver area of the photovoltaic-cell decreases. Therefore, more beam radiations are entrapped and get absorbed over the increased surface area of the aperture leading to enhanced heat gain in the collector.

3.4. Overall thermal efficiency of solar ORC system

Fig. 9 shows variation of combined thermal efficiency of solar ORC system at a various concentration ratio of the concentrator for the mass fraction 0.1/0.9. Maximum value of overall thermal efficiency (7.8%) occurs at 13:00 h at collector concentration ratio 6. It occurs because at the same time and with same concentration ratio, when collector exhibits a maximum value of heat gain (3.21×10^5 W). Moreover, owing to maximum heat gain in collector working fluid temperature inlet to the expander increases leading

Table 6

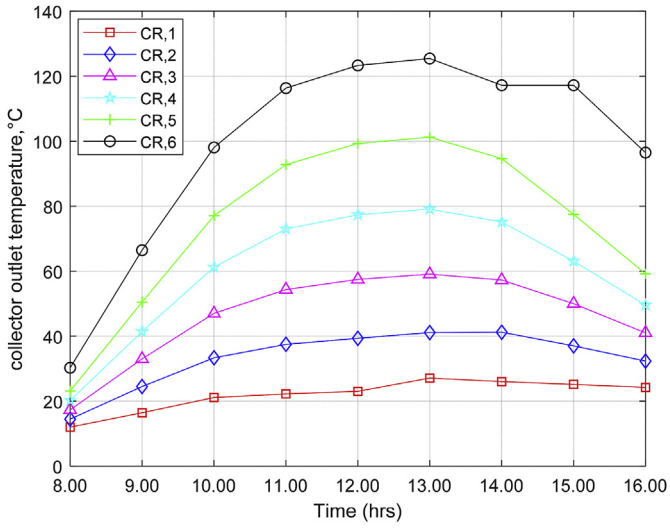

Fig 6. Hourly collector outlet temperatures at various concentration ratios.

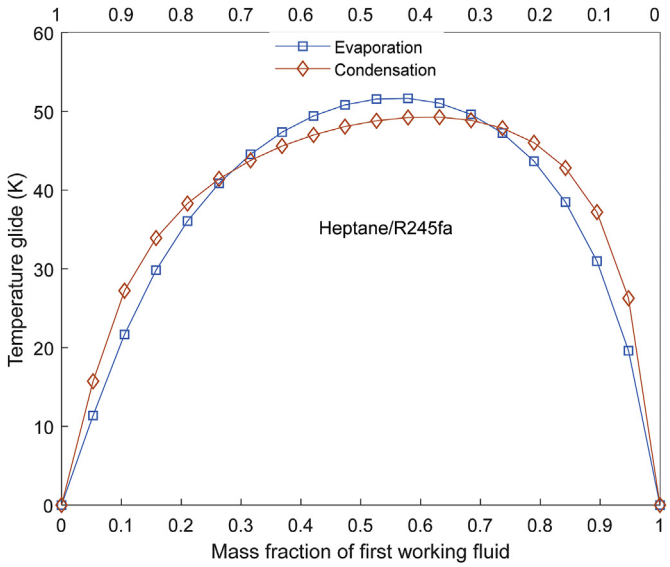

Fig 7. Condensation and Evaporation temperature glide.

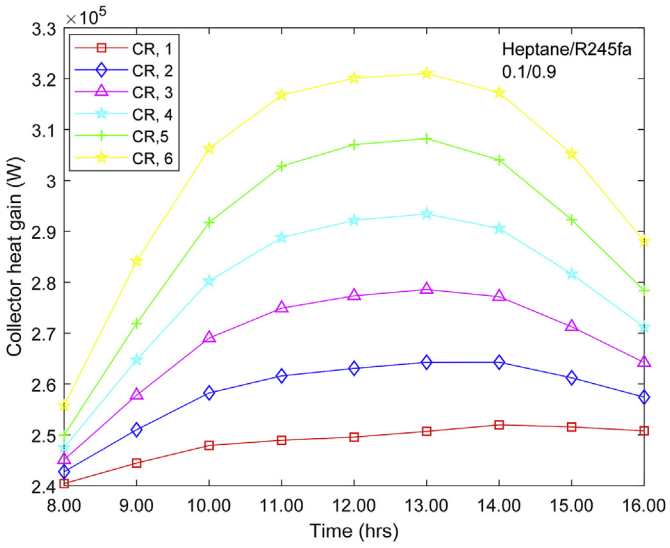

Fig 8. Hourly heat gain at various concentration ratio.

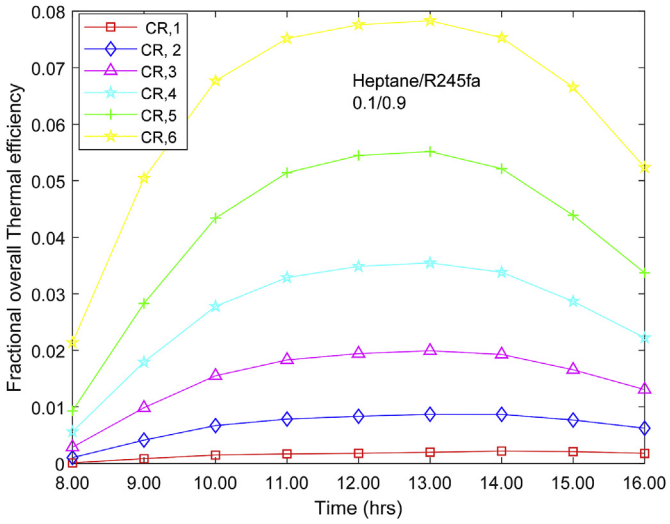

Fig 9. Hourly overall thermal efficiency at various concentration ratio.

to improvement in thermal efficiency.

3.5. Overall exergetic efficiency of solar ORC system

Fig. 10 shows variation of overall exergetic efficiency on hourly basis at 0.1/0.9 fixed mass fraction of the mixture. The overall exergetic efficiency (14.38%) is maximum at 13:00 h for mass fraction 0.1/0.9. It occurs, because with increasing concentration ratio (1–6) heat accumulation in collector gets increased. Therefore the temperature of the working fluid inside the evaporator (collector) increases. Due to the increased working fluid temperature in evaporator, the mean temperature of heat addition gets increased. Therefore the temperature difference between heat source and heat absorbing fluid gets reduced. The reduction in temperature difference during heat transfer improves the exergetic efficiency and reduces the exergy destruction.

3.6. Loss of exergy in components of ORC system

Fig. 11 shows the extent of destruction in exergy occurred in ORC system components at the mass fraction (0.1/0.9). It is observed that highest exergy destruction (40%) in evaporator followed by the condenser (38%), expander (21%) and pump (<1%). The major part of the exergy destruction has been developed in condenser and evaporator due to larger temperature difference in heat addition and heat rejection processes.

4. Conclusions

In this present work, hourly (8–16, hrs) thermodynamic investigation for Solar powered ORC system has been carried out coupled with hybrid reversed absorber partially covered PVTCPC system using heptane/R245fa as working fluid in ORC system. Further, the effect of variation in concentration ratio has also been observed on overall system performance of Solar powered ORC. The following conclusions are drawn from aforementioned results and discussion.

- The collector gets maximum total radiation (733 W/m^2) at 12:00 h whereas maximum beam radiation is available (600 W/m^2) at 13.00 h.

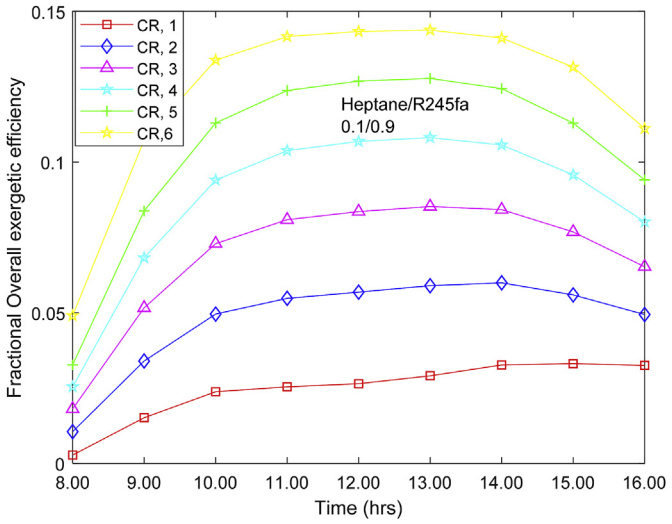

Fig 10. Hourly overall exergetic efficiency at various concentration ratio.

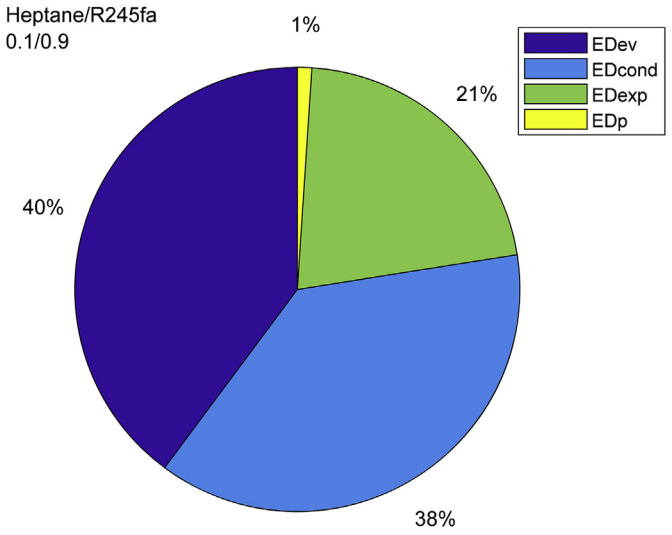

Fig 11. Exergy destruction in ORC components.

- At the mass fraction 0.58/0.42 the zeotropic mixture Hepatne/R245fa exhibits highest temperature glide (51.64 K) in evaporator whereas in condenser (49.26 K) at 0.63/0.37 mass fraction.
- The outlet fluid temperature and heat gain of the collector are improved by increasing concentration ratio. At concentration ratio 6 the collector exhibit highest outlet temperature (125.45 °C) and maximum heat gain (3.21×10^5 W) for 13:00 h.
- The combined thermal efficiency of Solar powered ORC system is 7.8% and exergetic efficiency of 14.38% are achieved at 13:00 h for concentration of ratio of 6.
- The evaporator exhibits (40%) of total exergy destruction and (38%) contributed by condenser, (21%) appeared in expander and approximately (1%) in pump at (0.1/0.9) mass fraction of zeotropic mixture.

This study deals with the combined application of photovoltaic thermal and compound parabolic concentrator using low-grade heat source for power generation using safe reliable zeotropic mixture. The findings of the study are fruitful in identifying salient aspects while making mathematical Modelling and also for installation of experimental setup.

s	specific entropy (kJ/kg K)
T	temperature (K)
$\dot{W}$	work transfer rate (W)

Greek letters

$(\alpha\tau)_{cl,eff}$	product of effective absorptivity and transmissivity of the collector
ρ	reflectivity
τ	transmittivity
α	absorptivity
η	efficiency
β	packing factor

Subscripts

a	aperture
b	beam
c	condenser
c	solar cell
ccpc	conventional compound parabolic concentrator
cl	collectror
c	cell
ex, x	exergetic
ev	evaporator
g	glass
in	inlet
f	fluid
f_i	fluid inlet
f_o	fluid outlet
m	module
o	ambient, overall
ov	overall
p	pump
p	palte
pv	photovoltaic
r	receiver
s	supply
$\dot{E}\,D$	Exergy destruction

th thermal

Abbreviations

CR	Concentration Ratio
GWP	global warming potential
ORC	organic Rankine cycle
ODP	ozone depletion potential
(PVTCPC)	photovoltaic thermal compound parabolic concentrator
SORC	solar ORC

Appendix A. Supplementary data

Supplementary data to this article can be found online at https://doi.org/10.1016/j.renene.2019.10.018.

Dedicated
to my family, comprising
Sudipta, my wife,
Sumantra, my elder son,
Sroddha, my elder daughter-in-law,
Shoubhik, my younger son,
Parul, my younger daughter-in-law,
Soham, my elder grandson,
and
Malhar (Tutu), my younger grandson.

Acknowledgements

I owe so much to so many that it is not possible to acknowledge all of them in this limited space. To the ones whose credit I have not been able to mention, I ask for forgiveness.

To the President of the IETE, Prof. (Dr.) K. T. V. Reddy, I am indebted for his enthusiasm and support.

To the successive Publication Committee Chairpersons and Members of the Governing Council, I would like to say a big thank you for approving the proposal for writing this book.

To Shrimati Sandeep Kaur Mangat, I would like to express my deep gratitude for successfully leading this project to a conclusion, with her immense patience and love and passion for work, much beyond her duty and for carrying out all the necessary hard work.

To all the workers of the Publications Section and the Secretariat in general, I have no words to convey my heartfelt appreciation for their diligent work.

To my students—particularly, the research students, I would like to express my love and best wishes for making me learn many things. In fact, I learnt more from them than they from me.

Suhash Chandra Dutta Roy

About This Book

This book, in common with my first book, is for you—students, teachers and researchers. I hope you would enjoy reading it.

Starting from 1962, I have written and published a large number of articles in IETE Journals. At various points of time, starting from 1982, I have been requested by students,as well as teachers and researchers, to publish a book of collected reprints, appropriately edited and sequenced. Of late, this request has intensified, and the demand for reprints of some of the tutorial papers I wrote has increased considerably, not only from India, but also from abroad, because of my five video courses related to Circuits, Systems and Signal Processing (CSSP) successfully uploaded by NPTEL on YouTube. I thought it would be a good idea to venture into such a project at this time. This is the reason for my first book, *Circuits, Systems and Signal Processing*, published by Springer in 2018. Its performance encouraged me to venture into working on a second book, entitled *Topics in Signal Processing*, and I am glad that Springer has agreed to publish this book also. As in the first book, this also is a book for you, students, teachers and researchers in the subject Signal Processing. It is a collection of research papers published by me in collaboration with some of my colleagues and students in IETE Journals, duly edited and sequenced by me.

As you would notice, I have written this book also in a conversational style to make you feel at ease while reading it.

The contents of the book are divided into five parts—Parts I–IV dealing with Analog Signal Processing and Part V dealing with Digital Signal Processing. There are a total of 28 chapters. For details, see Contents.

I hope students and teachers will benefit from the book. It is only then that I shall feel adequately rewarded. For any mistakes/confusions/clarifications, please feel free to contact me via email at s.c.dutta.roy@gmail.com. I take such mails on top priority, I assure you.

Happy learning!

New Delhi, India Suhash Chandra Dutta Roy

Contents

Part I Analog Signal Processing: Signal Processing by Passive Networks

1 Finite Zero Butterworth and Chebyshev Filters 3
References 5

2 Bandwidth Enhancement with the Asymmetrical Bridged T-coil Network 7
2.1 Introduction 7
2.2 Analysis of the General BTC 9
2.3 Symmetrical BTC 12
2.4 BWER of the Asymmetrical BTC 13
2.5 Technology Simulation Results 16
2.6 Concluding Discussion 16
References 17

3 Multiple Frequency Impedance Matching by Frequency Transformation 19
3.1 Introduction 19
3.2 The Basic Network 20
3.3 Impedance Matching at a Single Frequency 21
3.4 Application of Frequency Transformation 21
3.5 Dual-Frequency Impedance Matching 23
3.6 Triple-Frequency Impedance Matching 24
3.7 Impedance Matching at Four Frequencies 25
3.8 Impedance Matching at Five Frequencies 26
3.9 Summary of the Procedure 27
3.10 Concluding Discussion 27
References 28

4 Triple Frequency Impedance Matching by Frequency Transformation 29
4.1 Introduction 29
4.2 General Theory 30
4.2.1 Basic L-Network for Impedance Matching 30
4.2.2 Single-Frequency Matching 31
4.2.3 Application of Frequency Transformation 31
4.3 Triple Frequency Matching Network 32
4.4 Alternative Circuits for Triple Frequency Matching 34
4.5 Conclusions 35
References 35

Part II Analog Signal Processing: Signal Processing by Distributed Networks

5 Application of Topological Formulas to Distributed Parameter Networks 39
5.1 Introduction 39
5.2 Topological Formulas 40
5.3 Formulas for Ladder Networks and Extension to Non-uniform Transmission Lines 40
References 44

6 On Equivalent Representation of Lossy Transmission Lines 45
6.1 Introduction 45
6.2 Derivation 46
6.2.1 Two-Port Equivalence 47
References 48

7 Efficient Approximation of Variable Delay Using Tapped Delay Line 49
7.1 Introduction 49
7.2 Derivation of Formulas for the Weighting Coefficients 50
7.2.1 Recursive Formula 50
7.2.2 Explicit Formula 51
7.3 Implementation 52
7.4 Performance 52
7.5 Conclusions 53
References 53

Part III Analog Signal Processing: Signal Processing by Active Networks

8 Second-Order Active RC Filters Using a Single Operational Amplifier 57
8.1 Introduction 57
8.2 Basic Circuit 58
8.3 Low-Pass Realization 59
8.4 Bandpass Filter Realizations 61
8.4.1 First Bandpass Realization 62
8.4.2 Second Bandpass Realization 62
8.5 High-Pass Realization 63
8.6 Band Stop Realization 65
8.6.1 Second Band Stop Realization 68
8.6.2 Third Band Stop Realization 69
8.7 Economic Aspect of Filter Realizations 70
8.8 Conclusion 71
References 72

9 Tolerance Minded Design of Active RC Bandpass Filters 73
9.1 Introduction 73
9.2 Butterworth Approximation 74
9.3 Conclusion 77
References 78

10 Active RC Filters Using a Single Differential Input Operational Amplifier 79
10.1 Introduction 79
10.2 The New Method 80
10.3 Two Examples 82
10.4 A Comparison of the Two Methods 83
10.5 An Illustration of the Flexibility of the New Method 84
References 86

11 Second-Order Active RC Bandpass Filters Using Operational Amplifier in Low-Gain Connection 87
11.1 Introduction 87
11.2 The Circuit Configuration 88
11.3 Sensitivity Considerations 89
11.4 Design Equations 90
11.4.1 Case A: Unity Gain Configuration 90
11.4.2 Case B: General K Configuration 91

11.5 Frequency Limitation 92
11.5.1 Case A: OA in Unity Gain Configuration 92
11.5.2 Case B: OA in Gain = 2 Configuration 93
11.6 Conclusion 95

About the Author

Suhash Chandra Dutta Roy was fortunate enough to be educated at the Calcutta University, where great professors and researchers like C V Raman, S N Bose, M N Saha and S Radhakrishnan taught and made a name, globally, not only for them, but also for the university and the country. Immediately after my master's, I had to take up a job in a Government Research Institute. I soon discovered that many things are done at the Institute, but not research. I therefore quit and shifted to the newly established University of Kalyani as a lecturer. There I spent a few years, and after my Ph.D., I left the country to take up an Assistant Professorship at the University of Minnesota. A few years passed by, but I felt increasingly guilty that I was not doing anything for my motherland. I therefore returned to the country and joined IIT Delhi, as an Associate Professor where I served for more than four decades as Professor, Head of the Department and as a Dean. The last two positions were imposed upon me, and I suffered because they cut down on the time available for my research and interactions with my dear students. I formally retired at the age of 60, but continued to teach and carry out research, as an Emeritus Fellow, followed by INSA Senior Scientist and INSA Honorary Scientist. Later, when my term as an Emeritus Fellow was over, I did not take any money from IIT Delhi and served voluntarily, simply for the love of teaching and research. I finally left IIT Delhi

permanently, 12 years after the retirement. I am now settled at Hauz Khas, New Delhi, where I live happily with my wife, but still continue to do research. We enjoy good health because of Yoga and strict diet.

I have been extraordinarily lucky to have had gems of Ph.D. students, 30 of them, who have done exemplary work in research and innovation. Some of them have figured in 'Contributors'. In fact, I feel myself shining with reflected glory.

I have also been lucky to have received high recognition through Fellowship of IEEE, Distinguished Fellowship of IETE and Fellowship of all the relevant national academies. I have been awarded some prestigious national awards, including the Shanti Swarup Bhatnagar Prize. Over and above all the awards and recognitions, however, what I value most is the love and affection of my students.

I now spend time giving professional lectures on innovations in teaching and research, in general, and also on how to improve their standards in the country. I have the hobby of listening to Hindustani classical music and researching on its maestros. I also love spending quality time with my grandson, Soham. Reading political history and detective stories are my other hobbies. I also read poetry and compose some poems and short stories, for my own pleasure.

–In short, I have lived a complete life, with nothing to complain about.

Contributors[1]

Prof. Amalendu Bhushan Bhattacharyya did his M.Sc. (Physics) and Ph.D. from BHU, and was the Head of the Centre for Applied Research in Electronics (CARE) at IIT Delhi. I collaborated with him in the Analog Signal Processing Systems (ASPS) project of the Department of Electronics, Government of India. In this project, fabrication and applications of the charge-transfer device (CTD)—both bucket-brigade device (BBD) and charge-coupled device (CCD)—formed a major

[1]I shall now introduce my co-authors in some of the papers on which the book is based. The first four were my colleagues in the Institute. The next eleven were my Ph.D. students, listed in alphabetical order. The last person listed here was my M.Tech. student.

part. After retirement, he joined ITM Gurgaon, as Director. He then transferred to Goa University as Professor and Director, VLSI Design program, and finally to the JP University, Noida, as Emeritus Professor. He lives in Noida.

Dr. Alladi Prabhakar was a colleague of mine in the Electrical Engineering Department (EED) of IIT Delhi. An IISc Ph.D. holder specializing in Graph Theory, he later transferred to ITI Bangalore, became its Managing Director, and is now settled at Bangalore after retirement.

Prof. Surendra Prasad did his B.Tech. at IIT Kharagpur and M.Tech. and Ph.D. from IIT Delhi. After M.Tech., he joined CARE as a lecturer, and after Ph.D., he became an assistant professor in the EE Department, where he later became a professor. He also became a dean, Deputy Director (Faculty) and finally retired as Director. He is now Emeritus Professor at IITD.

Prof. Prem Saran Satsangi was a dear colleague of mine at IITD. He did his bachelor's degree from BHU, master's from Michigan State University, East Lansing, USA, and Ph.D. from Waterloo at Canada. On return from Waterloo, he became an associate professor, and later a full professor. He occupied several important positions at IIT Delhi, including Head of the Department, Dean and Managing Director, FITT. Later, he took voluntary retirement to take up Directorship of the Dayalbagh Educational Institute (DEI), Agra, a deemed university. After retirement, he was elected to head the Satsang Community and is now the most respected Guruji Maharaj there.

Prof. Juzer Vasi is a B.Tech. graduate from IIT Bombay and a Ph.D. holder from Harvard. He joined CARE at IIT Delhi as an assistant professor and transferred to IIT Bombay for family reasons. He established a state-of-the-art microelectronics facility at IITB. Now retired, he is settled at Mumbai.

Monica Agrawal was jointly registered with me and Surendra Prasad for her Ph.D. After graduation, she worked with Hughes Software for a few years and then returned to IITD as an assistant professor in CARE. She is now a full professor there, doing important work in Underwater Signal Processing.

Muslim Taj Ahmed was a B.Sc. (Engg) graduate from AMU, who also served as a lecturer there. Later, he came to IIT Delhi for his M.Tech., and seeing his extraordinary performance in course work, he was transferred to Ph.D. Program with me as the guide. After Ph.D., he went back to AMU, became an assistant professor and later a professor there. After a few years, he went to Dubai and Saudi Arabia with teaching assignments. After returning to AMU, he served the Zakir Hussain College of Engineering, as its Principal. Unfortunately, he died prematurely.

Vuppuluri Gurusharan Das a B.Sc. (Engg) graduate from Dayalbagh Engineering College (DEI, then under Agra University) and an M.Tech. graduate from IIT Kanpur, came as a QIP candidate to IITD to work for his Ph.D. under my supervision. He was exceptionally brilliant and completed his research in record time. He worked on the CCD as part of the ASPS project. After completion, he went back to DEI, became a full professor there and finally DEI's Director. After retirement, he rejoined DEI as Professor Emeritus and remained active in teaching and project supervision there. He passed away recently in May 2018.

Shail Bala Jain did B.Sc. (Engg) from the Delhi College of Engineering (DCE) and M.Tech. from IITD. She was a faculty in DCE for many years. During this, she registered for Ph.D. at Delhi University with me as her guide and Prof. A. K. Sinha (DCE) and Balbir Kumar (DIT, now NSIT) as co-guides. She became a full professor at IGIT, GGSIP University, and later joined the Indira Gandhi Delhi Technical University for Women as an academic advisor. She is now leading a retired life.

Navin Kapur did his B.Tech. at IIT Delhi and then took up a job in CDIL. After a few years, he came to me for Ph.D. I got him a research associateship in the ASPS project to work on CCDs. He did good work, got his Ph.D. and went back to CDIL. After retirement from there, he worked in a private institution as Professor and later became its Director. On superannuation from there, he settled at Delhi. He also passed away recently.

Balbir Kumar did his B.E. from Punjab Engineering College (now a deemed university) and was commissioned in the Indian Navy. He came as a sponsored candidate from the Navy to do his M.Tech. at IITD. He worked for his M.Tech. thesis with me and then rejoined the Navy. After a few years, he took voluntary retirement and joined IITD for his Ph.D. He did excellent work on digital differentiators. After Ph.D., he joined the newly established Delhi Institute of Technology (now Netaji Subhas Institute of Technology [NSIT]) as an assistant professor and was promoted to full professorship after a few years. At NSIT, he also worked as an acting director for some time. After retirement, he worked in a private institution for some years. Unfortunately, like Ahmed and Das, he also died prematurely.

Shailey Minocha registered for her Ph.D. with me when she was working on a project in CARE. She only had a bachelor's degree from DCE, but with some course work, she did excellent research. After her Ph.D., she took up a job with TCS, which was followed by a postdoctoral fellowship at Technical University, Braunschweig, Germany. On completion of her fellowship, she moved to the UK and is now a full professor at UK's Open University.

Rakesh Kumar Patney came to do his M.Tech. at IIT Delhi, after a B.Tech. from IIT Kanpur. He did his M.Tech. thesis with me and continued for his Ph.D. After graduation, he was inducted to the faculty. He recently retired as full Professor and is continuing at IIT Delhi as Emeritus Fellow.

L. R. Rajagopal is a graduate of the National Defence Academy, Khadakwasla, Pune, and the Naval College of Engineering at Lonavala, Pune, and was sponsored by the Indian Navy to do his M.Tech. at IITD. He did his M.Tech. thesis with me and Rakesh. Then, he continued at IIT Delhi for his Ph.D. under my supervision. The use of Bernstein polynomials in DSP was his innovation, and the work is widely cited in the literature, even today. After Ph.D., he went back to the Navy and did commendable work in the WESEE project. After superannuation, he started his own industry at Chennai, named 'Signals and Systems', which is now well established and reputed for their high-quality power instruments.

L. Shankaranarayanan came to work in the ASPS project after his M.Sc. (Physics) from Anna University. Shankar registered for his Ph.D. with Prof. Bhattacharyya and me. He later went to work with Philips and rose to the position of Research Director. I do not know his whereabouts at the present time.

Mahesh Chandra Srivastava came to do his Ph.D. under the supervision of Prof. Satsangi and me. He was sponsored by the MMM Engineering College, Gorakhpur. After his Ph.D., he joined BIT Mesra, Ranchi. After a few years, he changed to KNIT Sultanpur and then served several institutions till he came to Jaypee Institute of Technology, Noida. That is what I last knew about him. Recently, I came to know that Mahesh is no more.

Phani Bhushan Tholetti was an M.Tech. student. The paper in which he collaborated and contributed to the work in this book was done by him while taking my course on DSP. He is now working in industry at Bangalore.

Part I
Analog Signal Processing: Signal Processing by Passive Networks

This part contains 4 chapters. Chapter 1 deals with finite zero filters of the Butterworth and Chebyshev types. Chapter 2 contains one of my best works. I show that the bandwidth enhancement capability of the asymmetrical bridged T-coil, used as the inter-stage network, is virtually unlimited. This is something new and may open up new investigations, because it offers a technological challenge. Chapters 3 and 4 deal with multiple frequency impedance matching by using the frequency transformation techniques.

Chapter 1
Finite Zero Butterworth and Chebyshev Filters

Abstract An accurate expression is derived for the minimum order of a finite-zero Butterworth filter (Dutta Roy in IEEE Trans AU-19(1):58–63, 1971) [1], which has a steeper cut-off slope than the corresponding Chebyshev filter (Agarwal and Sedra in IEEE Trans AU-20(2):138–141, 1972) [2]. The inaccuracy occurring in the latter is illustrated by a numerical example.

Keywords Finite-zero filters · Butterworth filters · Chebyshev filters · Cutoff slope

This chapter is concerned with a comparison of the finite-zero, low-pass, Butterworth filter, defined by the magnitude squared function [1]:

$$|F_{mn}(j\omega)|^2 = \frac{1}{1+\omega^{2n}[(\omega_0^2-1)/(\omega^2-\omega_0^2)]^{2m}} \tag{1.1}$$

with the corresponding Chebyshev filter, defined similarly by [2]:

$$|T_{mn}(j\omega)|^2 = \frac{1}{1+\varepsilon^2 C_n^2(\omega)[(\omega_0^2-1)/(\omega^2-\omega_0^2)]^{2m}} \tag{1.2}$$

where, in either case, n denotes the order of the filter, m is the order of zeros at $\pm j\omega_0$, $\omega_0 > 1$ and $n \geq 2\,m+1$. In Eq. (1.2), $C_n(\omega)$ denotes the Chebyshev polynomial of the first kind, of order n, and ε^2 is a ripple controlling factor. We define the cut-off slope in either case as the negative differential coefficient of the magnitude with respect to ω, evaluated at $\omega = 1$, and denote it by S_{bmn} in the Butterworth and S_{tmn} in the Chebyshev case. Further, for the purpose of comparing the two cut-off slopes, we set $\varepsilon^2 = 1$; then it can be shown that [1, 2].

$$S_{bmn} = [n/(2\sqrt{2})]\{1 + 2m/[n(\omega_0^2-1)]\} \tag{1.3}$$

and

S. C. Dutta Roy, *Topics in Signal Processing*,
https://doi.org/10.1007/978-981-13-9532-1_1

$$S_{tmn} = [n^2/(2\sqrt{2})]\{1 + 2m/[n^2(\omega_0^2 - 1)]\} \tag{1.4}$$

Let n_B denote the *minimum* order of the modified Butterworth function in Eq. (1.1) with m_B pairs of zeros at $\pm j\omega_0$ for which the cut off slope is steeper than that given by Eq. (1.4). Then from Eqs. (1.3) and (1.4), it follows that

$$n_B + \{2m_B/(\omega_0^2 - 1)\} \geq n^2 + \{2m/(\omega_0^2 - 1)\} \tag{1.5}$$

Note that if $m_B = m$, then n_B is simply equal to n^2. To allow the Butterworth function to have the highest possible slope, we set

$$m_B = (n_B - r)/2 \tag{1.6}$$

where, since m_B is to be an integer,

$$r = \begin{cases} 1, & \text{for odd } n_B \\ 2, & \text{for even } n_B \end{cases} \tag{1.7a, b}$$

Substituting Eq. (1.6) into Eq. (1.5), we get

$$n_B \geq (1/\omega_0^2)[2m + r + n^2(\omega_0^2 - 1)] \tag{1.8}$$

which, combined with Eq. (1.7a, b), gives

$$n_B = \text{Lower of} \begin{cases} \text{odd} & < (1/\omega_0^2)[2m + 1 + n^2(\omega_0^2 - 1)] > \\ \text{even} & < (1/\omega_0^2)[2m + 2 + n^2(\omega_0^2 - 1)] > \end{cases} \tag{1.9}$$

where the notation <a> means the lowest integer greater than or equal to a.

Agarwal et al. [2] have assumed Eq. (1.7a), without regard to the possibility of an even n_B, and the resulting equation can be written in our notations as

$$n_B = \ <(1/\omega_0^2)[2m + 1 + n^2(\omega_0^2 - 1)] > \tag{1.10}$$

As an example of the inaccuracy of Eq. (1.10), let $n = 5$, $m = 2$ and $\omega_0 = 2.0$; then Eq. (1.10) gives $n_B = 20$ and according to Eqs. (1.6) and (1.7a), $m_B = 9.5$. Since m_B has to be an integer and $m_B = 10$ is not allowed, the highest possible value of m_B is 9. Under these conditions, the left-hand side of inequality (1.5) becomes 26 while the right-hand side becomes 26.33.

In the above situation, Eq. (1.9), on the other hand, gives n_B = lower of {odd <20>; even <20.25>} = 21 and from Eqs. (1.6) and (1.7a), one obtains, $m_B = 10$. With these values, the left-hand side of inequality (1.5) is 27.67 which is greater than 26.33, the value of the right-hand side.

As another example of the application of Eq. (1.9), let $n = 5$ and $m = 2$, as in the previous case, but $\omega_0 = \sqrt{6}$. Then Eq. (1.9) gives n_B= lower of {odd <21.67>; even <21.83>} = 22 and hence $m_B = 10$. It may now be verified that these satisfy the inequality (1.5).

Chapter 2
Bandwidth Enhancement with the Asymmetrical Bridged T-coil Network

Abstract This chapter presents the results of a theoretical investigation of the asymmetrical bridged T-coil (BTC) bandwidth enhancement network under the condition of maximally flat magnitude (MFM) response. Conventionally, the BTC is used in the symmetrical configuration and it is well known that, as compared to the commonly used RC load, the maximum bandwidth enhancement ratio (BWER) under the MFM condition is $2\sqrt{2}$. It is shown here that by introducing asymmetry, even under the constraint of MFM response, the maximum achievable BWER is theoretically unlimited, the limit being set only by practical considerations. Unlimited BWER has never been considered possible, even theoretically, with BTC or any other network, and the result reported here is believed to be a breakthrough in the design of wide-band and ultra wide-band amplifiers. Simulations for a few designs indicate that practical realization of the full potential of the asymmetrical BTC may have to wait for improved technologies which facilitate tight coupling between the two parts of the coil and also minimize parasitic effects.

Keywords Bandwidth enhancement · Bridged T-coil · Maximally flat magnitude · Wide-band amplifiers

2.1 Introduction

Considerable interest has been shown in the analysis, design, and applications of the bridged T-coil (BTC) network during the past three decades [1–30]. While major application of the BTC is in wide-band amplifiers [1–25], several recent papers relate to its application in replacing transmission line sections required in ultra wide-band power dividers and bandpass filters, thereby significantly reducing the circuit size without affecting the performance [26–28]. This equivalence was first proposed in [29] for modelling low-temperature co-fired ceramic embedded inductors. Yet another very recent application of the BTC has been reported in [30] in the design of all-pass networks and phase-shifters.

This chapter will focus on the application of the BTC in wide-band amplifier design only, a typical stage of which is shown in Fig. 2.1, where the active device is an NMOS transistor. As mentioned in [13] and [16], the BTC has been used for about four decades by Tektronix Inc. in oscilloscope circuitry, but its design remained a trade secret for a long time. A US patent on a bridged T-termination network, which can be considered as a lossy BTC was granted as early as 1964 [31], but the first public disclosure of analysis and design of the BTC appeared in 1982 [1] (not 2004 [13], as mentioned in [16]). Most of the contributions reported so far used the symmetrical form of the BTC, and it has been well established that under the maximally flat magnitude (MFM) condition, the maximum bandwidth enhancement ratio (BWER), as compared to the commonly used RC load, is $2\sqrt{2}$. Asymmetrical BTC was considered in [6, 7, 9] and [14]. In [6] as well as [9], the maximum BWER achieved was the same as that of the symmetrical BTC under the MFM condition. It was mentioned in [7] that the BWER considerably exceeded the conventional limit but no theoretical analysis or the condition (MFM or otherwise) under which the same was achieved was given. There are indications in [14] of achieving, with an asymmetrical BTC, a BWER greater than 4 with zero-dB ripple; however, zero-dB ripple does not necessarily mean the MFM condition, and no theoretical analysis was provided. If ripples are allowed, [14] shows that the BWER can even exceed 5. It is worth mentioning here that in [32], published as early as 1954, the circuits labelled D are asymmetrical BTCs; again, there was no theoretical analysis, but the plots of gain frequency characteristics given in Fig. 2.2 of that paper indicated a BWER much in excess of $2\sqrt{2}$.

A comprehensive theoretical investigation of the general asymmetrical BTC is carried out in this chapter, and it is shown that even under the MFM constraint, the BWER achievable by this network is theoretically unlimited, the realizable limit being set only by practical considerations. This result is believed to be a breakthrough in the design of wide-band and ultra wide-band amplifiers.

Some of the theoretical designs were simulated using models of 130 nm technology, which show that parasitic effects severely limit the bandwidth enhancement, and lead to the conclusion that improved technologies, which allow tight coupling

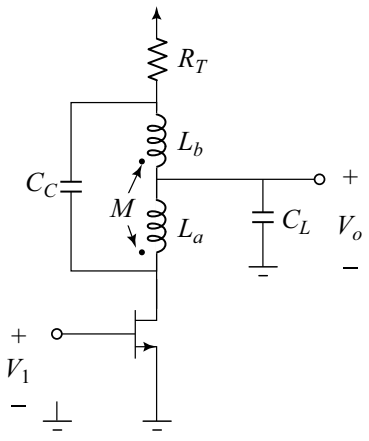

Fig. 2.1 A common source NMOS amplifier stage with a bridged T-coil network in the drain circuit

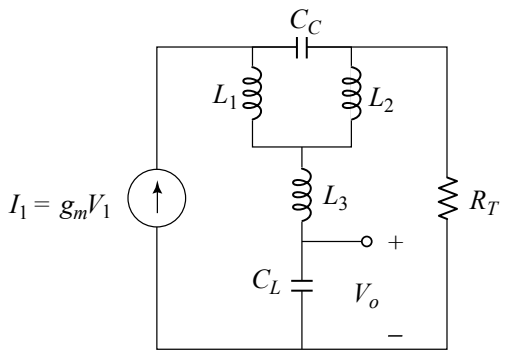

Fig. 2.2 Small-signal equivalent circuit of Fig. 2.1, where $L_1 = L_a + M$, $L_2 = L_b + M$, and $L_3 = -M$

between the two parts of the asymmetrical BTC, and also minimize the parasitic effects, will be needed to realize the full potentials of the BTC.

The chapter is organized as follows. In the next section, we give the equivalent circuit of Fig. 2.1 and the expression for its transfer impedance, which is of order 4. This transfer function is then reduced to one of order 2 by following [16] and the conditions under which this can be done are stated. Section 2.3 deals with the application of these results to a symmetrical BTC, where a misconception in the existing literature [13] is cleared. Section 2.4 contains the details of derivation needed to find the BWER of the asymmetrical BTC under the MFM constraint, and establishes the fact that in theory, the BWER can be infinitely large. A plot of BWER versus the coefficient of coupling is given and some specific designs are given in the form of a table. Section 2.5 comments on the results of simulation of a few designs while Sect. 2.6 contains the concluding discussions.

2.2 Analysis of the General BTC

The small-signal equivalent circuit of Fig. 2.1 is shown in Fig. 2.2, where g_m is the transconductance of the NMOS transistor. In [16], this circuit was analysed by using the extra-element theorem [33] whereas in [17], a much simpler analysis was carried out by using classical techniques.

In either case, the result obtained is the following:

$$\begin{aligned} Z_T &= V_0/I_i = R_T N(s)/D(s) \\ N(s) &= s^2 C_c(L_a + L_b + 2M) + s((L_b + M)/R_T) + 1 \\ D(s) &= s^4 C_c C_L(L_a L_b - M^2) + s^3 C_c C_L R_T(L_a + L_b + 2M) \\ &\quad + s^2(C_c(L_a + L_b + 2M) + C_L L_b) + s C_L R_T + 1. \end{aligned} \tag{2.1}$$

The transfer impedance Z_T is of the fourth order, and it is difficult to proceed further analytically. Following [16], we, therefore, convert it to a second-order one by forcing pole-zero cancellation, i.e. we write

$$D(s) = (ps^2 + qs + 1)N(s) \tag{2.2}$$

and determine the constraints on the element values by equating the coefficients of powers of s on both sides. Carrying out these steps, we get [16]

$$p = C_L(L_aL_b - M^2)/(L_a + L_b + 2M), \tag{2.3}$$

$$q = C_L R_T - \frac{C_L(L_aL_b - M^2)(L_b + M)}{C_c R_T(L_a + L_b + 2M)^2}, \tag{2.4}$$

$$\frac{q(L_b + M)}{R_T} + p = C_L L_b, \tag{2.5}$$

and

$$q = C_L R_T - \frac{L_b + M}{R_T}. \tag{2.6}$$

Comparing Eqs. (2.4) and (2.6) gives

$$\frac{C_c}{C_L} = \frac{L_aL_b - M^2}{(L_a + L_b + 2M)^2}. \tag{2.7}$$

Also, by substituting Eqs. (2.3) and (2.6) in Eq. (2.5) and carrying out some algebraic simplifications, we obtain

$$C_L R_T^2 = \frac{(L_b + M)(L_a + L_b + 2M)}{L_a + M}. \tag{2.8}$$

Let $L_a = L$, $L_b = bL$, and $M = mL$; then the coefficient of coupling between the two inductors in Fig. 2.1 is given by

$$k = \frac{M}{(L_aL_b)^{1/2}} = \frac{m}{\sqrt{b}} \tag{2.9}$$

Also, Eq. (2.8) gives

$$L = \frac{C_L R_T^2(1 + m)}{(b + m)(1 + b + 2m)} \tag{2.10}$$

and Eq. (2.7) gives

$$\frac{C_c}{C_L} = \frac{b - m^2}{(1 + b + 2m)^2}. \tag{2.11}$$

When L and C_c obey Eqs. (2.10) and (2.11), respectively, Z_T/R_T becomes a second-order function of the form

$$\frac{Z_T}{R_T} = \frac{1}{ps^2 + qs + 1}, \tag{2.12}$$

where

$$p = \frac{LC_L(b - m^2)}{1 + b + 2m} \text{and } q = C_L R_T - \frac{(b + m)L}{R_T}. \tag{2.13}$$

Equation (2.12) can be recast in the standard form

$$Z_T/R_T = \omega_0^2/(s^2 + 2\varsigma\omega_0 s + \omega_0^2). \tag{2.14}$$

Comparing Eqs. (2.12) and (2.14) and using Eqs. (2.10), (2.11), and (2.13), we get, after simplification,

$$\omega_0 = \frac{1}{\sqrt{p}} = \frac{1 + b + 2m}{C_L R_T}\sqrt{\frac{b + m}{(1 + m)(b - m^2)}} \tag{2.15}$$

and

$$2\varsigma = \frac{q}{p\omega_0} = \sqrt{\frac{(b + m)^3}{(1 + m)(b - m^2)}}. \tag{2.16}$$

As is well known [34], the transfer function given by Eq. (2.14) has MFM response when $\varsigma = 1/\sqrt{2}$ (critically damped case). For $0 < \varsigma < 1/\sqrt{2}$ (underdamped case), the magnitude response exhibits a peak of value $1/[2\varsigma(1 - \varsigma^2)^{1/2}]$ at the frequency $\omega_0(1 - 2\varsigma^2)^{1/2}$. When $\varsigma = 1/\sqrt{2}$ (overdamped case), the magnitude response decays monotonically. Typical plots of the magnitude of Eq. (2.14) for underdamped, critically damped and overdamped cases are shown in Fig. 2.3.

The 3-dB bandwidth of Eq. (2.14) is given by

$$\omega_3 = \omega_0\sqrt{(1 - 2\varsigma^2) + \sqrt{(1 - 2\varsigma^2)^2 + 1}} \tag{2.17}$$

The 3-dB bandwidth of the amplifier with the commonly employed $R_T C_L$ load is given by $1/(R_T C_L)$. Hence, the BWER with the BTC load is given by

$$\eta = \omega_3 R_T C_L \tag{2.18}$$

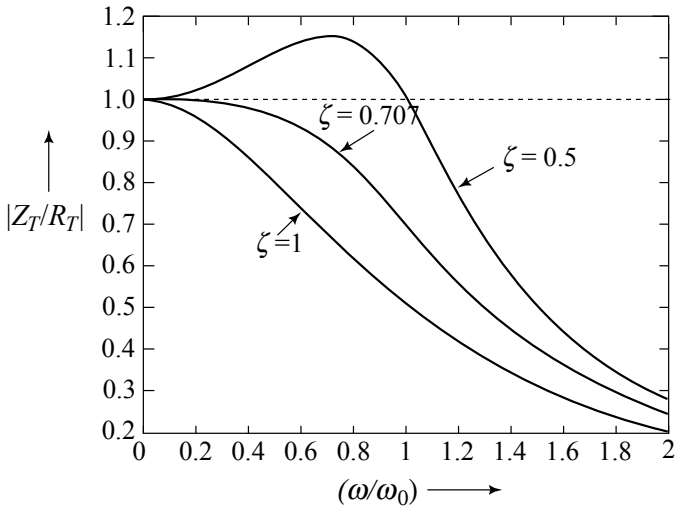

Fig. 2.3 Frequency response of (2.14) for $\varsigma = 0.5$ (underdamped), 0.707 (critically damped), and 1 (overdamped)

2.3 Symmetrical BTC

For the symmetrical BTC, $b = 1$, and Eqs. (2.15) and (2.16) simplify to the following:

$$\omega_3 = \frac{2}{C_L R_T}\sqrt{\frac{1+m}{1-m}} \tag{2.19}$$

and

$$2\varsigma = \sqrt{\frac{1+m}{1-m}} \tag{2.20}$$

With $b = 1$, Eq. (2.9) gives $k = m$, and from Eq. (2.20), we get

$$k = \frac{4\varsigma^2 - 1}{4\varsigma^2 + 1} \tag{2.21}$$

Putting $b = 1$ in Eqs. (2.10) and (2.11), and using Eq. (2.21), we get

$$L = \frac{C_L R_T^2}{4}\left(1 + \frac{1}{4\varsigma^2}\right) \text{ and } C_c = C_L/(16\varsigma^2). \tag{2.22}$$

These results agree with those derived by many authors earlier.

Now combine Eqs. (2.18) with (2.17) and then use Eqs. (2.19)–(2.21), along with the fact that $k = m$. The result is

$$\eta = 4\varsigma\sqrt{(1-2\varsigma^2) + \sqrt{(1-2\varsigma^2)^2 + 1}} \tag{2.23}$$

Equation (2.17) shows that as ς increases from 0 to 1, ω_3 decreases monotonically from $(\sqrt{2}+1)^{1/2}\omega_0$ to $(\sqrt{2}-1)^{1/2}\omega_0$, passing through the value ω_0 at $\varsigma = 1/\sqrt{2}$.

In Eq. (2.23), however, because of the factor ς, the BWER will show a maximum at some value of ς, and it is not difficult to show that $\varsigma = 1/\sqrt{2}$ is this value. Thus, the condition for MFM response is also the condition for maximum BWER. Except for [25], this fact has not been explicitly mentioned in the literature. The maximum η is calculated from Eq. (2.23) as $2\sqrt{2}$.

Lee [13] mentions that a bandwidth greater than ω_0 and a value of η almost equal to 3 are possible to be achieved by using $\varsigma = 0.7507$. However, the analysis given here does not corroborate this assertion. In fact, for $\varsigma = 0.7507$, Eq. (2.23) gives $\eta = 2.8184$, less than $2\sqrt{2}$, as expected, because η is a maximum when $\varsigma = 1/\sqrt{2}$.

2.4 BWER of the Asymmetrical BTC

For a general transfer function of the form of Eq. (2.14), combining Eqs. (2.17) and (2.18) with Eq. (2.15), we get the following expression for the BWER of the asymmetrical BTC:

$$\eta = (1 + b + 2m)\sqrt{\frac{b+m}{(1+m)(b-m^2)}} \times \sqrt{(1-2\varsigma^2) + \sqrt{(1-2\varsigma^2)^2 + 1}} \tag{2.24}$$

For MFM, $\varsigma = 1/\sqrt{2}$ and Eq. (2.24) becomes

$$\eta = (1 + b + 2m)\left(\frac{b+m}{(1+m)(b-m^2)}\right)^{\frac{1}{2}}. \tag{2.25}$$

Further, putting $\varsigma = 1/\sqrt{2}$, we get

$$2 = \frac{(b+m)^3}{(1+m)(b+m^2)}. \tag{2.26}$$

Thus for MFM response, b and m have to satisfy Eq. (2.26) and for any such set, η is given by Eq. (2.25). Combining Eqs. (2.25) with (2.26), the expression for η gets further simplified to the following:

$$\eta = \sqrt{2}\left(1 + \frac{1+m}{b+m}\right) \tag{2.27}$$

It is difficult to find, analytically, the variation of b with m from Eq. (2.26) or that of η with m from Eq. (2.27). One way is to simplify Eq. (2.26) to get a cubic equation in b and to solve it; however, as is well known [35, 36], an explicit expression for b in terms of m cannot be written and one has to take recourse to numerical computations. An alternative, and a simpler way, is to introduce the variable $\beta = b/m$; which converts

Eq. (2.26) to the following quadratic equation in m:

$$((\beta+1)^3+2)m^2+2(1-\beta)m-2\beta=0 \tag{2.28}$$

The solution of Eq. (2.28) is

$$m=\frac{(\beta-1)\pm\sqrt{(\beta-1)^2+2\beta((\beta+1)^3+2)}}{(\beta+1)^3+2} \tag{2.29}$$

The sign in Eq. (2.29) is dictated by the fact that b has to be positive. Thus if β is taken as positive, then m has to be positive; hence only the positive sign in Eq. (2.29) is acceptable.

A discussion on the possible range of values of m and b is in order at this point. Figures 2.1 and 2.2 show that m has been assumed to be positive, i.e. the coupling between L_a and L_b is negative. Can m be negative, i.e. is it possible to achieve a BWER > 1 with positive coupling? This question has been answered in the negative in the past, see e.g. [14] and [21].

Note that $m = 0$ means that there is no coupling between the two coils and the advantages of using the BTC are lost. Also, from Eq. (2.26), m is calculated as 1/3 when $b = 1$, which corresponds to the symmetrical case. Hence the range of m to be considered is $0 < m < 1/3$. The range of b is of course $0 < b < 1$. What about $b > 1$? Computation shows that $b > 1$ leads to BWER $< 2\sqrt{2}$. These points need to be kept in mind in interpreting Eqs. (2.28) and (2.29).

We computed the values of m for about two decades of values of β, and also the corresponding values of b, the coupling coefficient $k = m/\sqrt{b}$, and the BWER η. The results are given in Table 2.1 along with the design values of the normalized inductance $L/(C_L R_T^2)$ calculated from Eq. (2.10) and the capacitance ratio C_C/C_L calculated from Eq. (2.11). The variation of η with k is shown in Fig. 2.4.

Table 2.1 Some specific designs for the asymmetrical BTC

β	m	β	$k = m/\sqrt{b}$	η	$L/(C_L R_T^2)$	C_c/C_L

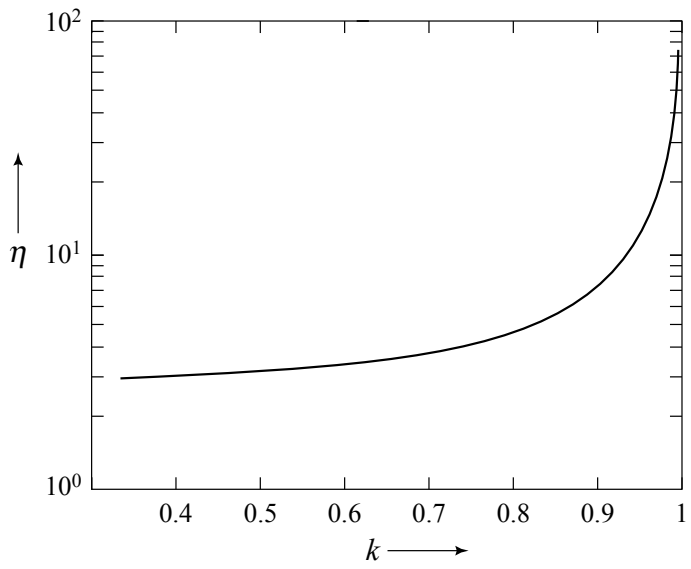

Fig. 2.4 Plot of BWER (η) versus coefficient of coupling (k)

The results for η in Table 2.1 and Fig. 2.4 are truly amazing, because they show that the BWER achievable by the asymmetrical BTC is theoretically unlimited, the realizable limit being set only by practical limitations of tight coupling and large inductance and capacitance spreads needed for large η. Parasitics will also play a major negative role, as discussed under Sect. 2.5.

The capability of unlimited BWER can also be justified from the expression (2.27), which can be rewritten in terms of β and m as follows:

$$\eta = \sqrt{2}\left(1 + \frac{1 + (1/m)}{1 + \beta}\right) \tag{2.30}$$

This clearly shows that $\eta \to \infty$ when $m \to 0$.

The values of the intermediate variable β are retained in Table 2.1 so as to facilitate the design for any value of η which lies in between two successive entries. Note that the last row in the table corresponds to the symmetrical BTC.

In order to display the possibility of achieving large BWERs with the asymmetrical BTC, we have calculated, for typical values of R_T and C_L, the element values corresponding to the fifth row in Table 2.1, along with those for the commonly used $R_T C_L$ load and the case of symmetrical BTC corresponding to the last row in Table 2.1. These are given below.

Design A with simple $R_T C_L$ load:
$R_T = 50\ \Omega$ and $C_L = 5$ pF.
Design B with symmetrical BTC ($b = 1$):
$R_T = 50\ \Omega$, $C_L = 5$ pF, $L_a = L_b = 4.688$ nH, and $C_C = 0.625$ pF.
Design C with asymmetrical BTC ($b = 0.0354$):
$R_T = 50\ \Omega$, $C_L = 5$ pF, $L_a = 49.85$ nH, $L_b = 1.765$ nH, and $C_c = 0.01055$ pf.

The corresponding expected values of the -3 dB frequencies are 0.6366, 1.8002, and 5.889 GHz, respectively. These designs were simulated with P Spice and the

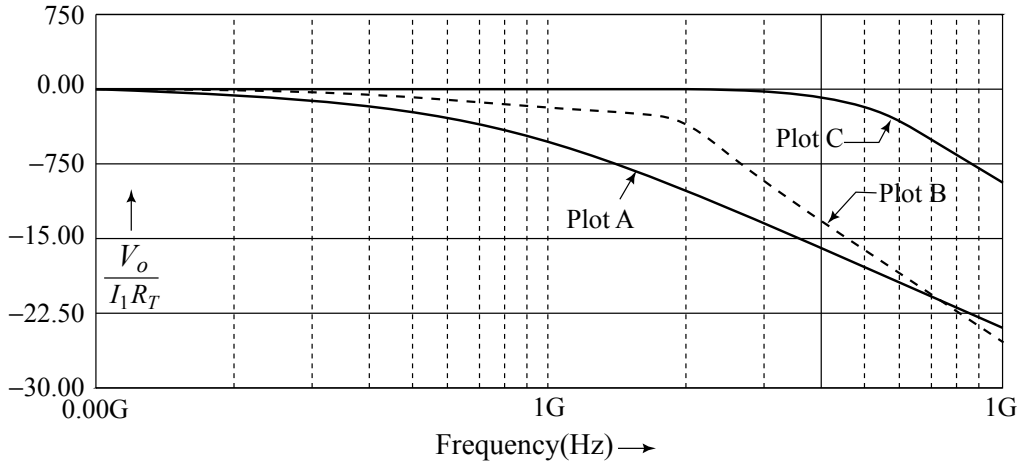

Fig. 2.5 Frequency response for designs A, B, and C obtained by P Spice simulation

resulting magnitude responses are shown in Fig. 2.5. These results agree with the expected ones, thus validating the theoretical investigations reported in this chapter.

2.5 Technology Simulation Results

Using Agilent's Advanced Design System tools with models of United Microelectronics 130 nm (1P8M) technology, simulation studies were carried out for a few specific designs of Table 2.1 with $R_T = 50\ \Omega$ and $C_L = 5$ pF. The results of simulation are rather disappointing and indicate that parasitics cause appreciable deviations from the ideal characteristics and that the distortions increase with increasing coefficient of coupling. Simulations with only the device parasitics indicate that the BTC parasitics have dominant effect on the deviations from maximal flatness and reduction of the BWER. Realizing the full potential of the theoretical results derived here will therefore have to wait for improved technologies for inductor fabrication in future.

2.6 Concluding Discussion

A comprehensive theoretical analysis has been carried out in this chapter of the general asymmetrical BTC network used as the load of a wide-band amplifier, and it has been shown that the BWER achievable is unlimited, the limit being set only by practical considerations of tight coupling, large spreads in inductance and capacitance values, and of course, parasitics. Unlimited bandwidth has never been reported earlier, by either the BTC or any other network, and it is believed that the results of this chapter will set a new trend in the design of wide-band and ultra wide-band amplifiers.

Simulation results indicate that the realization of the full potential of the asymmetrical BTC in wide-band amplifiers will have to wait for substantial improvements in the technology of inductance fabrication.

Chapter 3
Multiple Frequency Impedance Matching by Frequency Transformation

Abstract It is shown that the application of frequency transformation to a single-frequency impedance matching network simplifies the design of networks for impedance matching at any number N of frequencies. The required design procedure has been presented in formal network theoretic terms. A systematic procedure is given for generating all the equivalent networks for this purpose, from which the best one can be chosen according to a predefined criterion. Illustrative designs and some of the relevant circuits are given for some low values of N.

Keywords Frequency transformation technique · Multiple frequency impedance matching · Network design

3.1 Introduction

Frequency transformation is a well-known technique in filter design [1, 2], by which a normalized low-pass filter with a cutoff at 1 rad/s can be transformed to any other kind of filter, be it high-pass, bandpass, bandstop or a multi-bandpass [3] one. That this technique can be applied to design networks for impedance matching at multiple frequencies has recently been explored in [4]. The basic philosophy is that the frequency transformation technique simply transforms a frequency of 1 rad/s to a number of frequencies ω_i, $i = 1$ to N (henceforth assumed to be in ascending order), thereby reproducing the performance at 1 rad/s at the transformed frequencies. In filter design, performance refers to cutoff at a certain level of magnitude. However, there is no reason why performance cannot refer to some other feature like impedance matching. Basically, if one can design a network for matching the load impedance to the source impedance at a single frequency ω_0, which is normalized to 1 rad/s, then frequency transformation applied to this network should produce another network which exhibits the same phenomenon of impedance matching at multiple frequencies.

The purpose of this chapter is to supplement the work of [4] in several ways. First, we formulate the procedure in formal network theoretic terms. Second, we show that this allows us to generate, systematically, all possible networks for impedance matching at the given set of frequencies. From these, one can select the best one according to a predefined criterion. Next, we present the design formulas and some relevant circuits for matching at 2, 3, 4 and 5 frequencies. Finally, some general observations are made and scope of further work is indicated in the concluding section.

We shall assume in this chapter that the load is resistive, of value R_L, and likewise, the source has a resistive impedance, of value R_S.

3.2 The Basic Network

Consider the simplest configuration for impedance matching, namely, the L-network shown in Fig. 3.1. Z_s is an LC impedance and Y_p is an LC admittance such that when the network is terminated in R_L, the input impedance is R_S at the frequencies of interest. Let, at $s = j\omega$, $Z_s = jX_s$ and $Y_p = jB_p$, where X denotes reactance and B denotes susceptance. Then, at the frequencies of interest, we should have

$$R_S = jX_s + 1/\left(jB_p + G_L\right) \tag{3.1}$$

where $G_L = 1/R_L$. Cross multiplying, simplifying, and equating the real and imaginary parts on both sides give the two equations

$$X_S B_p = 1 - R_S G_L \text{ and } R_S B_p = X_S G_L \tag{3.2}$$

The second equation shows that X_s and B_p must be of the same sign, both positive or both negative. Combining this fact with the first Equation in (3.2), *we note that* $R_S G_L$ *must be less than unity,* i.e. R_S *must be less than* R_L. However, *this is no restriction because the other situation*, i.e. $R_S > R_L$, *can be taken care of* by simply interchanging the positions of R_S and R_L in Fig. 3.1. Eliminating B_p from the two Equations in (3.2), we get

$$X_s^2 = R_S(R_L - R_S) = R_1^2, \text{ say} \tag{3.3}$$

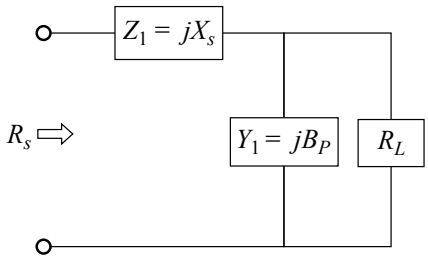

Fig. 3.1 The basic L-network

Or,

$$X_s = \pm R_1 \tag{3.4}$$

Combining this with the second Equation in (3.2) gives

$$B_p = \pm R_1/(R_L R_S) = \pm G_2, \text{ say} \tag{3.5}$$

As already stated, the signs in Eqs. (3.4) and (3.5) should be either both positive or both negative.

3.3 Impedance Matching at a Single Frequency

For matching R_L to R_S at a single frequency ω_0, we can choose either an inductance L_s for X_s and a capacitance C_p for B_p, or a capacitance C_s for X_s and an inductance L_p for B_p. In the first case, to be referred to as Design 1 (D1)

$$L_s = R_1/\omega_0 \text{ and } C_p = G_2/\omega_0 \tag{3.6}$$

while for the alternative design, to be called Design 2 (D2),

$$C_s = 1/(R_1\omega_0) \text{ and } L_p = 1/(G_2\omega_0) \tag{3.7}$$

We shall mostly use D1 in our further discussions, it is being implied that D2 is equally applicable, giving another set of solutions.

3.4 Application of Frequency Transformation

Let ω_0 be normalized to 1 rad/s and let S denote the complex frequency variable in the single-frequency matching network. Then the problem of multiple frequency impedance matching reduces to that of transforming $S = \pm j1$ to another set of frequencies $s = \pm j\omega_i$, $i = 1$ to N, where s denotes the complex frequency variable in the transformed network. It is well known [1, 2] that the functional relationship between S and s is an LC impedance or admittance function of the general form

$$S = (k_0/s) + k_\infty s + \sum\nolimits_i k_i s/\left(s^2 + q_i\right) \tag{3.8}$$

Using Eq. (3.8) on D2, for example, $C_s = 1/R_1$ (recall that ω_0 has been normalized to unity) transforms to a parallel connection of a capacitance of value k_∞/R_1, an inductance of value R_1/k_0, and a number of series LC circuits, the number being the

same as the upper limit in the summation of Eq. (3.8). The ith series LC circuit will have an inductance of value R_1/k_i and a capacitance of value $k_i/(q_i R_1)$. Similarly, the inductance $L_p = 1/G_2$ transforms to a series connection of an inductance of value k_∞/G_2, a capacitance of value G_2/k_0 and a number of parallel LC circuits, the number being the same as in the case of C_s. The ith parallel LC circuit will have an inductance of value $k_i/(q_i G_2)$ and a capacitance of value G_2/k_i. Similarly, Eq. (3.8) can be used on D1 to derive another circuit which can be used for the same purpose.

In addition, note that applied to an inductance, Eq. (3.8) results in a Foster 1 (F1) form of realization, while applied to capacitance, the result is a Foster 2 (F2) form of realization. Each of them can be converted to the other Foster form or Cauer 1 (C1) or Cauer 2 (C2) form. By different combinations of these forms for the two LC networks, a large number of competing circuits can be generated. The set can be further expanded by synthesizing each LC impedance by combining two or more of F1, F2, C1 and C2 forms to generate more circuits having the same impedance-matching properties.

A further dimension is added to the generation of competing circuits by the flexibility in choosing the transformation function. In general, for odd N, one can choose either of the first two terms in Eq. (3.8) and the summation with $i = 1$ to $(N - 1)/2$. For even N, one can choose both of the first two terms in Eq. (3.8) and the summation with $i = 1$ to $(N - 2)/2$; alternatively, one can use only the summation with $i = 1$ to $(N/2)$. The number of circuits that can be generated is, therefore, virtually indefinite. These can be compared, and the best one can be selected according to some appropriate criterion.

However, for small values of N, the number of alternative circuits is limited and the designer need not feel uncomfortable in leaving out some a from consideration. For example, for $N = 2$, we can choose either the first two terms only or a single term in the summation in Eq. (3.8). However, the latter is of the form of reciprocal of the former, and it is easily verified by choosing either of the two options, and using D1 as well as D2 suffice. Also, a single series or parallel LC circuit cannot be converted to any other form, thus giving only two alternative circuits for impedance matching at two frequencies. We shall investigate this case in more details in the next Section.

For $N = 3$, either of the first two terms and a single summation in Eq. (3.8) can be selected and applied to D1 as well as D2, giving four alternative circuits. In addition, each Foster form can be converted to the other, and four combinations, namely, (F1, F1), (F1, F2), (F2, F1) and (F2, F2), are possible for the series and shunt arms of Fig. 3.1. Converting a Foster form of three elements to either of the Cauer forms is not useful here because it gives the other Foster form. It is also not possible to make partial synthesis with one of the Foster or Cauer forms and switching to another form. Thus, a total of eight competing circuits can be found. We shall investigate this case in Sect. 3.6, but shall work out only one design.

It can be easily appreciated that the number of alternative circuits grows with increasing N. We shall not discuss this issue further.

For finding the element values in any circuit, we require the values of $k_i's$ and $q_i's$ in terms of $\omega_i's$. These can be obtained by the following procedure. Put $S = +j1$ and $s = j\omega$ in the chosen transformation equation and simplify. This will give an algebraic

equation in ω of order N, containing the constants $k_i's$ and $q_i's$ in the coefficients. To find how these constants are related to $\omega_i's$, one way is to make a reactance plot of the transformation, i.e. a plot of S/j versus s/j to find out at which values of ω, S/j becomes $+1$. These frequencies must correspond to $\omega_i's$, but not all with positive signs. A simpler way is to use the facts that the reactance (or susceptance) is an odd function of ω and its slope is strictly positive. From these, it is easily shown that if S has a pole at $s = 0$, i.e. if the first term in Eq. (3.8) is included in the chosen transformation, then the required frequencies are $-\omega_1$, ω_2, $-\omega_3$. On the other hand, if S has a zero at $s = 0$, then the required frequencies are ω_1, $-\omega_2$, ω_3. Note that the signs alternate, and it is adequate to find the sign of ω_1 only. Now equate the previously obtained equation to $(\omega + \omega_1)\ (\omega - \omega_2)\ (\omega + \omega_3)\ldots. = 0$, or $(\omega - \omega_1)\ (\omega + \omega_2)\ (\omega - \omega_3)\ldots. = 0$, as the case may be. By comparing the coefficients, one can easily find the required $k_i's$ and $q_i's$. The procedure will be amply clear from the examples worked out in the following Sections.

3.5 Dual-Frequency Impedance Matching

Let the frequencies at which matching is needed be ω_1 and ω_2. We use the transformation

$$S = (k_0/s) + k_\infty s \tag{3.9}$$

As mentioned in the previous section, using this on D1 and D2 suffices to find the only possible competing networks. Note, in passing, that Eq. (3.9) is the well-known low-pass to bandpass transformation. By putting $S = +j1$ and $s = j\omega$ in Eq. (3.9) and simplifying, we get the following quadratic equation in ω:

$$\omega^2 - (1/k_\infty)\omega - (k_0/k_\infty) = 0 \tag{3.10}$$

Since S has a pole at $s = 0$, the roots of this equation are $-\omega_1$ and ω_2, so that Eq. (3.10) should be identical to the following:

$$\omega^2 - (\omega_2 - \omega_1)\omega - \omega_1\omega_2 = 0 \tag{3.11}$$

Comparing coefficients, we get

$$k_\infty = 1/(\omega_2 - \omega_1) \text{ and } k_0 = \omega_1\omega_2/(\omega_2 - \omega_1) \tag{3.12}$$

The networks obtained by using Eq. (3.9) on D1 and D2 are shown in Fig. 3.2a and b, respectively.

We shall now compare the two designs with the help of a numerical example. Let $\omega_1 = 0.5$ rad/s and $\omega_2 = 0.7$ rad/s; these are normalized frequencies and the results can be applied to any situation where $\omega_1{:}\omega_2 = 5{:}7$ by appropriate frequency

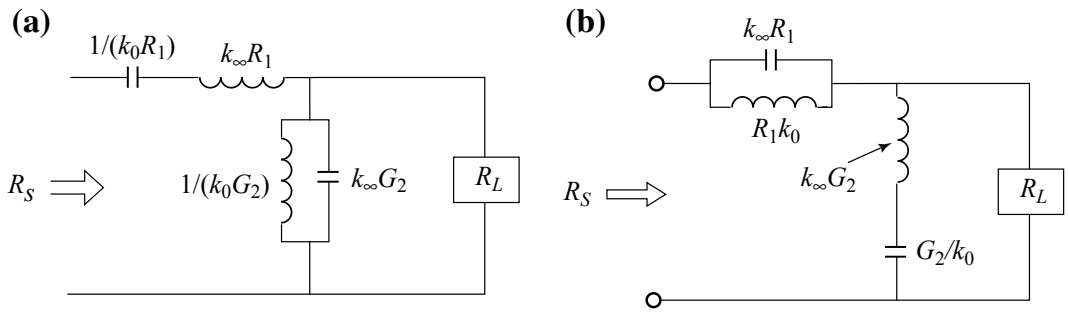

Fig. 3.2 Circuits obtained by application of Eq. (3.9) to **a** D1 and **b** D2

Table 3.1 Comparison of the two circuits of Fig. 3.2

Parameter	(a)	(b)
Total inductance	7.5 H	10.5714 H
Total capacitance	1.7142 F	5.2857 F
Highest inductance	5 H	10 H
Highest capacitance	1.1428 F	5 F
Inductance spread	2	17.5
Capacitance spread	2	17.5

scaling. Also, let $R_L = 2$ Ohms and $R_S = 1$ Ohms; again, the results can be applied to any situation where R_L: $R_S = 2$:1 by impedance scaling. Calculation gives $k_\infty = 5$, $k_0 = 1.75$, $R_1 = 1$ Ohms, and $G_2 = 0.5$ mho. The element values, from left to right, are calculated as 5H, 0.5714F, 2.5H and 1.1428F for Fig. 3.2a and 0.5714H, 5F, 10H and 0.2857F for Fig. 3.2b. Table 3.1 shows a comparison of the two circuits for some relevant implementation parameters. Clearly, the circuit of Fig. 3.2a would be a better choice from all considerations. Note that the inductance and capacitance spreads are the same in each circuit; this is expected from the general values given in Fig. 3.2.

3.6 Triple-Frequency Impedance Matching

To bring variety into experience, let us use the transformation

$$S = k_\infty s + k_1 s/\left(s^2 + q_1\right) \tag{3.13}$$

Applied to D1, this gives the circuit shown in Fig. 3.3. By following the procedure given in Sect. 4 and illustrated in the previous Section, the two cubic equations to be compared are obtained as follows:

$$\omega^3 - (1/k_\infty)\omega^2 - [q_1 + (k_1/k_\infty)]\omega + (q_1/k_\infty) = 0 \tag{3.14}$$

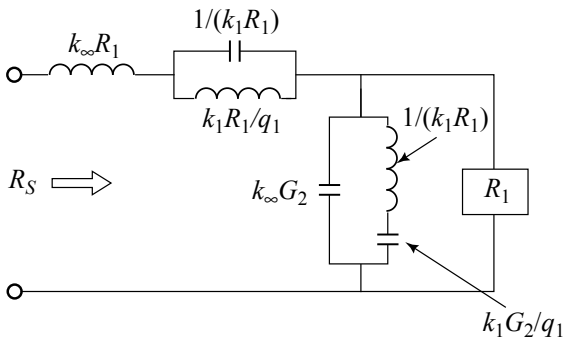

Fig. 3.3 Circuit obtained by applying Eq. (3.19) to D1

And

$$(\omega - \omega_1)(\omega + \omega_2)(\omega - \omega_3) = \omega^3 - (\omega_1 - \omega_2 + \omega_3)$$
$$\text{or,} \quad \omega^2 - (\omega_1\omega_2 + \omega_2\omega_3 - \omega_1\omega_3)\omega + \omega_1\omega_2\omega_3 = 0 \tag{3.15}$$

Comparison gives

$$k_\infty = \omega_1 - \omega_2 + \omega_3, q_1 = \omega_1\omega_2\omega_3 k_\infty, \text{ and}$$
$$k_1 = k_\infty(\omega_1\omega_2 + \omega_2\omega_3 - \omega_1\omega_3 - q_1) \tag{3.16}$$

The element values of the circuit in Fig. 3.3 can now be calculated.

3.7 Impedance Matching at Four Frequencies

In this as well as the next Section, for brevity, we shall skip the routine steps and the circuit diagrams, and shall only give the design equations. We choose the transformation

$$S = \left[k_1 s/\left(s^2 + q_1\right)\right] + \left[k_2 s/\left(s_m^2 + q_2\right)\right] \tag{3.17}$$

The roots of the quartic equation obtained from Eq. (3.17) should be ω_1, $-\omega_2$ ω_3 and $-\omega_4$. The equations for finding $k_i's$ and $q_i's$ are

$$k_1 + k_2 = -\omega_1 + \omega_2 - \omega_3 + \omega_4 = A, \text{ say} \tag{3.18}$$

$$q_1 + q_2 = \omega_1\omega_2 - \omega_1\omega_3 + \omega_1\omega_4 + \omega_2\omega_3 - \omega_2\omega_4 + \omega_3\omega_4 = B, \text{say} \tag{3.19}$$

$$k_1q_2 + k_2q_1 = \omega_2\omega_3\omega_4 - \omega_1\omega_3\omega_4 + \omega_1\omega_2\omega_4 - \omega_1\omega_2\omega_3 = C, \text{say} \tag{3.20}$$

$$q_1q_2 = \omega_1\omega_2\omega_3\omega_4 = D, \text{say} \tag{3.21}$$

q_1 and q_2 can be found from Eqs. (3.19) and (3.21) by solving a quadratic equation. This gives two solutions, one being the reciprocal of the other. Either of them can be chosen for q_1; then the other is q_2. Substituting these values in Eq. (3.20) and combining with Eq. (3.18), one can find k_1 and k_2. The final results are

$$q_1 = (1/2)[B + \sqrt{B^2 - 4D})], q_2 = D/q_1, k_1 = (Aq_1 - C)/(q_1 - q_2), \text{ and } k_2 = A - k_1 \tag{3.22}$$

It is easily shown that interchanging the values of q_1 and q_2 has the effect of interchanging the values of k_1 and k_2, so that the circuit does not change.

3.8 Impedance Matching at Five Frequencies

Let the transformation function be

$$S = (k_0/s) + \left[k_1 s/\left(s^2 + q_1\right)\right] + \left[k_2 s/\left(s^2 + q_2\right)\right] \tag{3.23}$$

By applying Eq. (3.23) to D1 or D2, the resulting circuit configuration can be easily drawn. For the constants, the equations to be solved are obtained as

$$k_0 + k_1 + k_2 = \omega_1 - \omega_2 + \omega_3 - \omega_4 + \omega_5 = A, \text{ say} \tag{3.24}$$

$$q_1 + q_2 = \omega_1\omega_2 - \omega_1\omega_3 + \omega_1\omega_4 - \omega_1\omega_5 + \omega_2\omega_3 - \omega_2\omega_4 + \omega_2\omega_5 + \omega_3\omega_4 - \omega_3\omega_5 + \omega_4\omega_5 = B, \text{ say} \tag{3.25}$$

$$\begin{aligned} k_1q_2 + k_2q_1 + k_0(q_1 + q_2) = {} & \omega_1\omega_2\omega_3 - \omega_1\omega_2\omega_4 + \omega_1\omega_2\omega_5 + \omega_1\omega_3\omega_4 \\ & - \omega_1\omega_3\omega_5 + \omega_1\omega_4\omega_5 - \omega_2\omega_3\omega_4 + \omega_2\omega_3\omega_5 \\ & - \omega_2\omega_4\omega_5 + \omega_3\omega_4\omega_5 = C, \text{ say} \end{aligned} \tag{3.26}$$

$$q_1q_2 = \omega_1\omega_2\omega_3\omega_4 + \omega_1\omega_2\omega_4\omega_5 - \omega_1\omega_2\omega_3\omega_5 - \omega_1\omega_3\omega_4\omega_5 + \omega_2\omega_3\omega_4\omega_5 = \mathrm{D}, \text{ say} \tag{3.27}$$

$$k_0q_1q_2 = \omega_1\omega_2\omega_3\omega_4\omega_5 = E, \text{ say} \tag{3.28}$$

As in the case of the previous Section, q_1 and q_2 can be solved from Eqs. (3.25) and (3.27) by solving a quadratic equation, whose solutions are reciprocals of each other. Also, as in the previous case, interchanging q_1 and q_2 has the effect of interchanging the values of k_1 and k_2. Once q_1 and q_2 are determined, k_0 is found from Eq. (3.28), and k_1 and k_2 are found from Eqs. (3.24) and (3.26). The final results are as follows:

$$\begin{aligned} & q_1 = (1/2)[B + \sqrt{B^2 - 4D}], q_2 = D/q_1, k_0 = E/D, \\ & k_1 = \{[A - (E/D)]q_1 - [C - (BE/D)]\}/(q_1 - q_2) \text{ and } k_2 = A - k_0 - k_1 \end{aligned} \tag{3.29}$$

3.9 Summary of the Procedure

The steps in the design of networks for impedance matching at multiple frequencies can be summarized as follows:

Step 1. Design the basic network D1 or D2 or both for the given R_L and R_S with $\omega_0 = 1$ rad/s.
Step 2. Choose the transformation function as follows. For $N = 2$, choose either the first two terms only or a single term in the summation in Eq. (3.8). For odd $N \geq 3$, choose either of the first two terms in Eq. (3.8) and the summation with $i = 1$ to $(N - 1)/2$. For even $N \geq 4$, choose the first two terms in Eq. (3.8) and the summation with $i = 1$ to $(N - 2)/2$; alternatively, use only the summation with $i = 1$ to $(N/2)$.
Step 3. Apply the transformation to D1 (or D2 or both) to obtain the circuit configuration (s) and element values in terms of $k_i's$ and $q_i's$.
Step 4. Put $S = j1$ and $s = j\omega$ in the transformation function and simplify to get an Nth order algebraic equation in ω.
Step 5. Identify the roots of the equation obtained above as $\omega_1, -\omega_2, \omega_3, \ldots$ or $-\omega_1, \omega_2, -\omega_3, \ldots$ depending on whether S has a pole at the origin or not. Write the equation in terms of $\omega_i's$ and compare its coefficients with those of the equation obtained in Step 4.
Step 6. Find the $k_i's$ and $q_i's$ in terms of $\omega_i's$ from the results of Step 5, and substitute them in the circuit (s) obtained in Step 3.
Step 7. Find some alternative circuits from the results of Step 6 by synthesizing the series and shunt LC impedances by Foster or Cauer techniques or a combination of them. Also, explore other possible transformations, if necessary, and finally, choose the best one according to a predefined criterion.

3.10 Concluding Discussion

In this chapter, we have presented the application of frequency transformation technique to impedance matching at multiple frequencies in formal network theoretic terms. This allows a multiplicity of solutions to be found out, from which one can make a selection based on an appropriate criterion. Explicit design equations have been given for $N = 2$ to 5.

While we have confined the discussion to only L-configuration, it should be obvious that the technique can be applied to other basic configurations like T or π. In all cases, however, the solution is far from being canonic. In fact, in the circuits considered in this chapter, we require 2 N number of components for matching at N frequencies. A reduction in component count may be possible by using other configurations of the basic network or by using two-port synthesis techniques.

We have considered only resistive source and load impedances and have assumed lossless inductances and capacitances. Some useful discussions on complex load

impedances, and component losses have been included in [4], but there is scope for formalizing the procedures in network theoretic terms and evolving design procedures for the general case.

In this chapter, we have not considered the bandwidth over which impedance matching takes place with a certain level of tolerance. There is a short discussion on this aspect in [4], but again, there is scope for further research, particularly because of the fact that if the $\omega_i's$ are not far apart, then the response around any ω_i is affected by that around other $\omega_i's$ close by. The positive aspect of this interaction is that one may be able to design wideband-matching circuits by placing $\omega_i's$ close together.

Chapter 4
Triple Frequency Impedance Matching by Frequency Transformation

Abstract The purpose of this chapter is to bring to the attention of students and teachers of circuit theory, as well as of practising design engineers, a recently reported technique for impedance matching at multiple frequencies. This will be done through a specific example, namely that of design of a lumped network for matching a given load resistance R_L to a given source resistance R_S at three given frequencies ω_1, ω_2 and ω_3. The method is based on the application of the frequency transformation technique, commonly used in analog filter design, to a basic single-frequency matching network. By comparison with the existing approach of assuming a network configuration and solving a set of simultaneous equations, as reported in a recent paper, the new method is shown to have the advantages of design by synthesis, elegance and simplicity. Further, by virtue of the synthesis approach, the method allows a number of alternative networks to be designed, so that the best one can be selected on the basis of a predetermined criterion.

Keywords Frequency transformation · Network design · Impedance matching · Multiple frequency matching

4.1 Introduction

Modern multi-band mobile communication has created the need for microwave systems which can handle several frequencies by the same hardware, without the necessity for switching. This, in turn, requires networks which can match a given load to a given source at multiple frequencies. Most of the work reported in the literature on this subject has focussed on dual-band matching, using distributed networks [1–5]. Triple frequency matching has also been reported [6] using such networks. Distributed network systems become bulky, particularly when the operating frequencies are not very high, and lumped or hybrid systems have therefore been developed for compact devices [7, 8].

Most of the network topologies used so far have been based on a design by analysis, i.e. by assuming a possible network configuration from heuristic considerations and experience, analysing it, and then solving a set of simultaneous equations to derive the component values. The purpose of this chapter is to bring to the attention of students and teachers of circuit theory as well as of practising design engineers a recently proposed method [9, 10] for the same purpose, which is based on the frequency transformation technique, as commonly used in analog filter design [11]. This will be done through a specific example, namely that of designing a network for matching a load resistance R_L to a given source resistance R_S at three given frequencies ω_1, ω_2 and ω_3. The reason for this specific choice is to compare the method with the existing approach for the same design, as reported in a recent paper [8]. It is shown that the new method is characterized by design by synthesis, elegance and simplicity. The circuit configuration evolves automatically, and by virtue of the synthesis approach, a number of alternative circuits can be easily found, from which the best one can be selected in accordance with a predetermined criterion.

First, for ready reference, we give a brief review of the general theory, and then discuss the design of the triple frequency transformer.

4.2 General Theory

4.2.1 Basic L-Network for Impedance Matching

We first consider the general L-network shown in Fig. 4.1 (called network D2 in [10]), where X_s is a reactance and B_p is a susceptance. For matching, we require the relation

$$R_s = 1/\left[jB_p + 1/(R_L + jX_s)\right] \tag{4.1}$$

to be satisfied at the frequency or frequencies of interest. Simplifying Eq. (4.1) and equating the real and imaginary parts on both sides give the following equations:

$$R_s\left(1 - X_s B_p\right) = R_L \tag{4.2a}$$

and

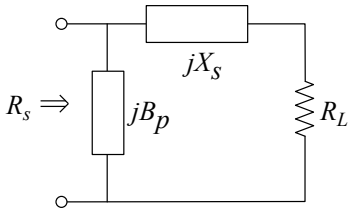

Fig. 4.1 The basic L-network for impedance matching

$$B_p R_L R_s = X_s \tag{4.2b}$$

Equation (4.2b) shows that B_p and X_s should be of the same sign. Also, combining Eq. (4.2a, b) to eliminate B_p, we get

$$X_s^2 = R_L(R_s - R_L) \tag{4.3}$$

Equation (4.3) shows that the configuration is applicable only if $R_s > R_L$. This is no restriction, however, because for the other case, i.e. $R_s < R_L$, the positions of the source and the load are to be interchanged. Equation (4.3) gives

$$X_s = \pm\sqrt{[R_L(R_s - R_L)]} = \pm R_1, \text{ say} \tag{4.4}$$

and correspondingly,

$$B_p = \pm R_1/(R_L R_S) = \pm G_2, \text{ say.} \tag{4.5}$$

As mentioned earlier, B_p and X_S should both be either positive or negative.

As discussed in the comprehensive network theoretic formulation of the technique by Dutta Roy [10], one could have a parallel development with the L-network having the shunt arm B_p across R_L and the series arm X_S in series with the source (this is called network D1 in [10]). As mentioned later in this chapter, this alternative is important in deriving other alternative equivalent circuits for matching.

4.2.2 Single-Frequency Matching

For matching at a single frequency ω_0, one choice is to have an inductor L_1 for X_s and a capacitor C_2 for B_p, while the other choice is to have C_1 for X_s and L_2 for B_p. Using the first choice, the element values are: $L_1 = R_1/\omega_0$ and $C_2 = G_2/\omega_0$.

4.2.3 Application of Frequency Transformation

Frequency transformation is a well-known technique in analog filter design [11] by which a normalized lowpass filter with a cut-off at 1 rad/sec can be transformed to any other kind of filter, be it high-pass, bandpass, band-stop or multi-bandpass, with the same tolerances as in the prototype. Basically, it transforms the frequency of 1 rad/sec to the cut-off frequencies of the desired filter. In more general terms, the performance at 1 rad/sec is reproduced in the transformed filter at the desired frequencies. There is no reason why performance cannot be impedance matching, as demonstrated in [9, 10] and this chapter.

Let S denote the complex frequency variable in the single-frequency matching network and let ω_0 be normalized to 1 rad/sec. Then the problem reduces to that of transforming $S = \pm j1$ to the multiple frequencies $s = \pm j\omega_k$, where, in general, $k = 1, \ldots, N$, s being the complex frequency variable in the transformed network. As is well known [12, 13], the transformation function is an LC immittance (impedance or admittance) function of the form

$$S = k_0/s + k_\infty s + \sum k_i s/\left(s^2 + q_i\right) \tag{4.6}$$

where the limits of the summation are determined by the number of frequencies at which matching is required. For example, if $N = 2$, then the first two terms in Eq. (4.6) suffice. Alternatively, one can use only the first term in the summation, which, in fact, is of the same form as the reciprocal of the first two terms. For $N = 3$, as is the case in the example to follow, either of the first two terms and one term in the summation serve the purpose. In general, for N odd and ≥ 3, either of the first two terms is to be taken along with the summation with i ranging from 1 to $(N-1)/2$. For N even and ≥ 4, there are two choices, viz. (1) take the first two terms and the summation with i ranging from 1 to $(N-2)/2$ or (2) take only the summation with i ranging from 1 to $(N/2)$. In addition, as already mentioned, there are two choices for the basic single-frequency matching network. Clearly, with the flexibility in choosing the basic network and the transformation function, one can generate a number of matching networks having the same performance. Some more alternative networks can be generated by synthesizing each of the reactance and susceptance functions by the other Foster or Cauer or mixed canonic forms. From this multiplicity of networks, one can choose the best one using some appropriate criterion like the total inductance or capacitance or the spread in the values of the components.

4.3 Triple Frequency Matching Network

We shall now illustrate the simplicity, elegance and flexibility of the frequency transformation technique by designing a triple-frequency matching network. The basic network is shown in Fig. 4.2a, where the fact that ω_0 has been normalized to 1 rad/sec has been taken into account. One appropriate transformation for this case is

$$S = k_0/s + k_1 s/\left(s^2 + q_1\right) \tag{4.7}$$

The impedance of L_1 (=R_1) thus transforms into

$$SL_1 = (k_0 R_1)/s + k_1 R_1 s/\left(s^2 + q_1\right) \tag{4.8}$$

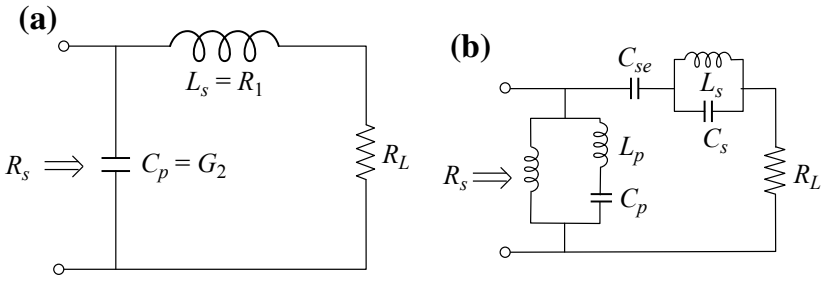

Fig. 4.2 Triple-frequency impedance transformer: **a** basic single-frequency matching circuit and **b** triple-frequency matching circuit with element values given in the text

The right-hand side of Eq. (4.8) represents a series connection of a capacitance $C_{\text{se}} = 1/(k_0\, R_1)$ and a parallel L_sC_s circuit with $L_s = k_1R_1/q_1$ and $C_s = 1/(k_1R_1)$, as shown in Fig. 4.2b.

Similarly, the admittance of C_2 (=G_2) transforms to the circuit shown in the shunt arm of Fig. 4.2b with the following element values: $L_{pe} = 1/(k_0\, G_2)$, $C_p = k_1\, G_2/q_1$ and $L_p = 1/(k_1\, G_2)$.

Now the only task that remains to be done is to find the values of k_0, k_1 and q_1. For this purpose, put $S = j1$ and $s = j\omega$ in Eq. (4.8); after simplification, we get the following equation in ω:

$$\omega^3 + (k_0 + k_1)\omega^2 - q_1\omega - k_0q_1 = 0 \tag{4.9}$$

The roots of this equation should give ω_1, ω_2 and ω_3, but not all with positive signs. To find which one(s) would be positive, we sketch the reactance function of Eq. (4.8) as shown in Fig. 4.3 and find the frequencies at which $S/j = 1$. Clearly, the roots of Eq. (4.9) are $-\omega_1$, ω_2 and $-\omega_3$. Figure 4.3 also shows that had we taken $S/j = -1$ in Eq. (4.8), the resulting cubic equation would have the roots ω_1, $-\omega_2$ and ω_3. Returning to Eq. (4.9), we see that the left-hand side should be equal to

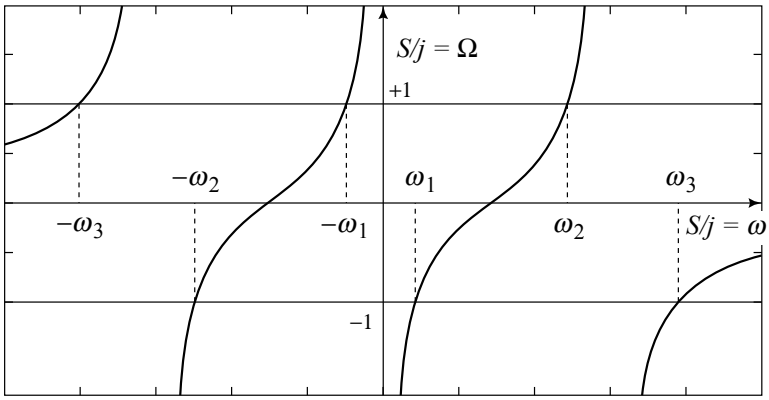

Fig. 4.3 Reactance sketch of Eq. (4.8)

$$\begin{aligned}&(\omega+\omega_1)(\omega-\omega_2)(\omega+\omega_3)\\&=\omega^3+(\omega_1-\omega_2+\omega_3)\omega^2-(\omega_1\omega_2+\omega_2\omega_3-\omega_3\omega_1)\omega-\omega_1\omega_2\omega_3\end{aligned}\tag{4.10}$$

Comparing the right-hand side of Eq. (4.10) with the left-hand side of Eq. (4.9), we get the following three equations:

$$\begin{aligned}k_0+k_1&=\omega_1-\omega_2+\omega_3,\\q_1&=\omega_1\omega_2+\omega_2\omega_3-\omega_3\omega_1,\ \text{and}\ k_0q_1=\omega_1\omega_2\omega_3\end{aligned}\tag{4.11}$$

Solving these equations, we finally get

$$\begin{aligned}q_1&=\omega_1\omega_2+\omega_2\omega_3-\omega_3\omega_1,\\k_0&=\omega_1\omega_2\omega_3/q_1,\ \text{and}\ k_1=\omega_1-\omega_2+\omega_3-k_0\end{aligned}\tag{4.12}$$

The circuit of Fig. 4.2b was previously derived by Lin, Chen and Zhao [8] following the conventional approach, i.e. by assuming the circuit, analysing it and then setting up and solving the equations obtained at the three frequencies. As a numerical example, they considered the following specifications: $R_L = 25\ \Omega$, $R_S = 50\ \Omega$ and $\{\omega_1, \omega_2, \omega_3\} = \{0.225, 0.425, 0.625\}$ GHz. Calculations from Eq. (4.12) and the expressions for the element values given under Eq. (4.8) give $C_{\text{se}} = 23.5$ pF, $L_s = 2.78$ nH, $C_s = 41.31$ pF, $L_{\text{pe}} = 29.38$ nH, $C_p = 2.22$ pF and $L_p = 51.64$ nH. These are exactly the same as those obtained in [8]. Simulation and experimental results given in [8] validate the design.

4.4 Alternative Circuits for Triple Frequency Matching

As mentioned in the previous section, several alternative circuits for the triple frequency impedance matching can now be obtained. Figure 4.2b network, as it is, has the shunt arm in Foster 2 form (henceforth abbreviated as F2) and the series arm in Foster 1 form (henceforth abbreviated as F1). The shunt arm can also be realized in F1 and the series arm can also be realized as F2. Accordingly, we have four alternative circuits, viz. (F2, F1), (F2, F2), (F1, F2) and (F1, F1). Note that for a three-element network, Cauer forms will reduce to either F1 or F2.

Second, using an inductance for B_p and a capacitance for X_s in the basic network of Fig. 4.1, and then applying the transformation of Eq. (4.7), one obtains a different circuit which also allows four different circuits to be generated.

Third, if the basic network is chosen as D1 of [10], in which there is a shunt arm B_p across R_L and a series arm X_s in series with R_S, then as in the case of D2 discussed so far, another eight networks can be generated, thus making a total of 16 alternative circuits for the same impedance matching purpose.

As mentioned in Sect. 2.2, an alternative transformation for triple-frequency impedance matching is

$$S = k_\infty s + k_1 s/\left(s^2 + q_1\right) \tag{4.13}$$

The values of the constants have been worked out in [10] along with a possible circuit by transforming the basic network D1, in which the series arm is F1 and the shunt arm is F2. Following the same procedure as in the case of Eq. (4.7), another 16 different circuits can be generated, thus making a grand total of 32 alternative circuits for any specified triple-frequency impedance matching problem.

All these circuits can now be compared in terms of total inductance, total capacitance, maximum inductance, maximum capacitance, inductance spread, and capacitance spread, as done in [10] for a dual-frequency impedance matching circuit, and the best one can be chosen in accordance with a predetermined criterion.

4.5 Conclusions

As discussed and demonstrated in this chapter, the application of frequency transformation on the basic single-frequency impedance matching network eases the problem of designing multiple frequency matching networks. It gives multiple solutions and facilitates the choice of the most suitable network in a given situation.

Part II
Analog Signal Processing: Signal Processing by Distributed Networks

This part contain three chapters. In Chap. 5, we show that the familiar topological formulas to representation network can be extended to distributed networks also as a limiting case. Chapter 6 deals with equivalent circuits of lossy transmission lines. It is shown that short circuited lossy transmission lines are equivalent to a lossless line terminated in a resistance and that the equivalence is valid in two port sense also. Finally, in Chap. 7, we deal with the approximating a variable delay using a tapped delay line.

Chapter 5
Application of Topological Formulas to Distributed Parameter Networks

Abstract Topological formulas for lumped electrical networks are extended to distributed parameter networks, and explicit expressions are obtained for the two-port parameters of a non-uniform transmission line. The results agree with those derived earlier by Protonotarios and Wing, following a different procedure.

Keywords Topological formulas · Distributed network · Non-uniform transmission line

Nomenclature

$T_{2_{i_1 i_2 \ldots j_1 j_2}}$	a two-tree in which the sets of vertices $\{i_1, i_2, \ldots\}$ and $\{j_1, j_2, \ldots\}$ are in different connected parts.
$U_{i_1 i_2 \ldots, j_1 j_2 \ldots, k_1 k_2 \ldots}$	sum of admittance products of three-trees in each of which the sets of vertices $\{j_1, j_2, \ldots\}$, $\{j_1, j_2, \ldots\}$ and $\{k_1, k_2, \ldots\}$ are in different connected parts.
$V(Y)$	sum of admittance products of trees.
$W_{i_1 i_2 \ldots j_1 j_2 \ldots}(Y)$	sum of admittance products of two-trees $T_{2_{i_1 i_1 \ldots, j_1 j_2 \ldots}}$.
$[z]$	matrix of open-circuit impedance parameters of a two-port network.

5.1 Introduction

Topological formulas have now been well established for lumped electrical networks, both passive and active [1–3]. However, no attempt appears to have been made so far to apply these formulas to distributed parameter networks. In this chapter, topological formulas are used to obtain explicit expressions for the open-circuit

impedance parameters of one example of a distributed parameter network, viz. a non-uniform transmission line. Although essentially the same results have already been derived by Protonotarios and Wing [4] by a different procedure, it is believed that the approach adopted here is new, and it is hoped that it will stimulate further interest in the application of graph-theoretic techniques to distributed parameter networks.

5.2 Topological Formulas

We first recall the well-known topological formulas [1, p. 170] for the open-circuit impedance parameters of a two-port network (Fig. 5.1)

$$[z] = \frac{1}{V(Y)} \times \begin{bmatrix} W_{1,1'}(Y) & W_{12,1'2'(Y)} - W_{12',1'2}(Y) \\ W_{12,1'2'}(Y) - W_{12',1'2}(Y) & W_{2,2'}(Y) \end{bmatrix} \tag{5.1}$$

where

$$\det[z] = U(Y)/V(Y) \tag{5.2a}$$

and

$$U(Y) = U_{12',2,1'} + U_{1,2,1',2'} + U_{12,2',t'} + U_{1,2',1'2} \tag{5.2b}$$

5.3 Formulas for Ladder Networks and Extension to Non-uniform Transmission Lines

Consider a section of non-uniform transmission line of length l, for which $z(x)$ and $y(x)$ denote the series impedance and shunt admittance, respectively, per unit length of the line, at a distance x from the input port. We approximate the line by an n-section ladder as shown in Fig. 5.2, with

$$\Delta x = l/n,\ Z_k = z(k\Delta x)\Delta x \text{ and } Y_k = y(k\Delta x)\Delta x \tag{5.3}$$

In applying Eqs. (5.1) and (5.2a, 5.2b) to Fig. 5.2, we first note that

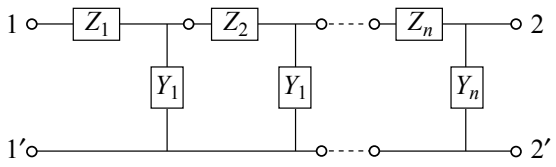

Fig. 5.2 Non-uniform line approximated by ladder

$$W_{12,1,2}(Y) = U_{12,2,1} = U_{12,2,1} = U_{1,2,12} = 0 \tag{5.4}$$

We may, therefore, rewrite $[z]$ and $\det[z]$ in the form

$$[z] = \frac{1}{\left(\prod_{i=1}^{n} Z_i\right) V(Y)} \times \begin{bmatrix} \left(\prod_{i=1}^{n} Z_i\right) W_{1,1'}(Y) & \left(\prod_{i=1}^{n} Z_i\right) W_{12,1'2'}(Y) \\ \left(\prod_{i=1}^{n} Z_i\right) W_{12,1'2'}(Y) & \left(\prod_{i=1}^{n} Z_i\right) W_{2,2'}(Y) \end{bmatrix} \tag{5.5}$$

and

$$\det[z] = \frac{\left(\prod_{i=1}^{n} Z_i\right) U_{1,2,1'2'}}{\left(\prod_{i=1}^{n} Z_i\right) V(Y)} \tag{5.6}$$

where the factor $\prod_{i=1}^{n} Z_i$ has been introduced in the numerator and denominator for later convenience.

Now, every tree of the ladder must contain at least one of the shunt arms. A tree is formed by any non-empty subset of the shunt arms, together with all the series arms preceding the first shunt arm in the subset, all the series arms succeeding the last shunt arm in the subset and all but one of the series arms between any two successive shunt arms in the subset. Finding out all the trees, multiplying each tree admittance product by $\prod_{i=1}^{n} Z_i$, and summing, we obtain

$$\left(\prod_{i=1}^{n} Z_i\right) V(Y) = \sum_{\substack{j=1 \\ i_1 < i_{2'} \le i_2 < \cdots < ij' \le ij}}^{n} Y_{i_1} Z_{i_{2'}} Y_{i_{2'}} Z_{i_3} \ldots Z_{ij'} Y_{ij} \tag{5.7}$$

Thus, a typical term in the right-hand side of Eq. (5.7) is obtained by choosing an arbitrary set of shunt admittances and exactly one of the series impedances between each pair of successive shunt admittances of this set, and taking their product. We may expand Eq. (5.7) in the form

$$\left(\prod_{i=1}^{n} Z_i\right) V(Y) = \sum_{i} Y_i + \sum\sum\sum_{i<j\le k} Y_i Z_i Y_k + \sum\sum\sum\sum\sum_{i<j\le k<m\le p} \times Y_i Z_j Y_k Z_m Y_p + \cdots \tag{5.8}$$

Applying similar arguments to the two-trees and three-trees, we get

$$\left(\prod_{i=1}^{n} Z_i\right) W_{1,1'}(Y) = 1 + \Sigma\Sigma_{i\le j} Z_i Y_j + \Sigma\Sigma\Sigma\Sigma_{i\le j<k\le m} Z_i Y_j Z_k Y_m + \cdots \tag{5.9}$$

$$\left(\prod_{i=1}^{n} Z_i\right) W_{1,2,1',2'}(Y) = 1 \tag{5.10}$$

and

$$\left(\prod_{i=1}^{n} Z_i\right) U_{1,2,1',2'}(Y) = \sum_i Z_i + \Sigma\Sigma\Sigma_{i\le j<k} Z_i Y_j Z_k + \sum\Sigma\Sigma\Sigma\Sigma_{i\le j<k\le m<p} Z_i Y_j Z_k Y_m Z_p + \cdots \tag{5.11}$$

The formula for $W_{2,2'}(Y)$ can be written in the same fashion as $W_{1,1'}(Y)$. In calculating $W_{12,1,'2'}(Y)$, we note that there is exactly one two-tree $T_{2_{12,1',2'}}$ and this two-tree is comprised of all of the series arms and none of the shunt arms, and hence the result of Eq. (5.10).

The formulas given above for the n-section ladder are equivalent to those proposed earlier [5, 6] for non-recurrent ladder networks. However, the above formulas have a simple topological interpretation, as stated in Eq. (5.7), and, in addition, the determinant of the z-parameters has been written in an explicit form, so that conversion to other types of parameters will be simple and routine.

We shall now extend the above formulas to the situation under consideration, viz. the non-uniform transmission line. For this, we allow Δx to approach zero, so that n approaches infinity. Consider the expansion on the right-hand side of Eq. (5.8), for example. It is easy to see that

$$\operatorname*{Lim}_{x\to\infty} \sum_i Y_i = \int_0^l y(x)\cdot dx \tag{5.12}$$

$$\operatorname*{Lim}_{\substack{x\to\infty \\ \Delta x\to 0}} \Sigma\Sigma\Sigma_{i<j\le k} Y_i Z_j Y_k = \int_0^l \int_0^{x_3} \int_0^{x_2} y(x_1) z(x_2) y(x_3) \times dx_1 dx_2 dx_3 \tag{5.13}$$

and so on. In a similar fashion, the integral equivalents of Eqs. (5.9) through (5.11) can be obtained. Finally, we have the following explicit formulas for the z-parameters of a non-uniform transmission line:

$$[z] = \frac{1}{a}\begin{bmatrix} b & 1 \\ 1 & c \end{bmatrix} \tag{5.14}$$

and

$$\det[z] = d/a \tag{5.15}$$

where

$$a = \int_0^l y(x) + \int_0^l \int_0^{x_3} \int_0^{x_2} y(x_1)z(x_2)y(x_3)dx_1dx_2dx_3 + \int_0^l \int_0^{x_5} \int_0^{x_4} \int_0^{x_3} \int_0^{x_2} y(x_1)z(x_2)y(x_3)z(x_4)y(x_5)dx_1 \times dx_2dx_3dx_4dx_5 + \cdots \tag{5.16}$$

$$b = 1 + \int_0^l \int_0^{x_2} z(x_1)y(x_2)dx_1dx_2 + \int_0^l \int_0^{x_4} \int_0^{x_3} \int_0^{x_2} z(x_1)y(x_2)z(x_3)y(x_4)dx_1dx_2 \times dx_3dx_4 + \ldots \tag{5.17}$$

$$c = 1 + \int_0^l \int_0^{x_2} y(x_1)z(x_2)dx_1dx_2 + \int_0^l \int_0^{x_4} \int_0^{x_3} \int_0^{x_2} y(x_1)z(x_2)y(x_3)z(x_4)dx_1dx_2 \times dx_3dx_4 + \ldots \tag{5.18}$$

and

$$d = \int_0^l z(x)dx + \int_0^l \int_0^{x_3} \int_0^{x_2} z(x_1)y(x_2)z(x_3)dx_1dx_2dx_3 + \int_0^l \int_0^{x_5} \int_0^{x_4} \int_0^{x_3} \int_0^{x_2} z(x_1)y(x_2)z(x_3)y(x_4)z(x_5) \times dx_1dx_2dx_3dx_4dx_5 + \cdots \tag{5.19}$$

In order to demonstrate the similarity of conversion to other parameters, we now obtain the chain parameters of the line

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} = \frac{1}{z_{21}} \begin{bmatrix} z_{11} & \det[z] \\ 1 & z_{22} \end{bmatrix} = \begin{bmatrix} b & d \\ a & c \end{bmatrix} \tag{5.20}$$

These expressions for the chain parameters are seen to agree with those derived earlier by Protonotarios and Wing [4].

Chapter 6
On Equivalent Representation of Lossy Transmission Lines

Abstract For short-duration surges, it was demonstrated that a short-circuited lossy transmission line is approximately equivalent to a lossless line terminated in a resistance, in so far as the output current is concerned. The same result is derived here in an alternative manner, which is believed to be simpler and more revealing. Further, the equivalence is also shown to hold in the two-port sense.

Keywords Lossy transmission lines · Equivalent representation

6.1 Introduction

In [1], Shah and Yavin demonstrated that for short-duration surges, a short-circuited dissipative transmission line can be equivalently represented as a lossless line terminated in a resistance $Z_0 \tanh [Rd/(2Z_0)]$. In deriving this result, the authors assumed an exciting voltage $v(0, t) = V_m \sin(\omega t + \theta)$ and compared the time domain solutions for the output current $i(d, \mathrm{t})$ in both the cases. We present here an alternative derivation of this result by carrying out analysis in the frequency domain only, starting from the expressions for the line voltage and current in terms of the sending end quantities. Our derivation is believed to be simpler and more revealing than that in reference [1]; simpler, because it does not require inversion of Laplace transforms, and more revealing, because it brings out the conditions for the validity of the equivalence in a straightforward manner and, in addition, also suggests a modification to obtain a closer equivalence. Finally, in this chapter, we point out that although the term 'equivalence' has been used by Shah and Yavin [1] to mean equality of y_{21} and y_{12}, (by reciprocity) parameters of the two lines only, it also holds good with regard to the other two-port parameters, viz. y_{11} and y_{22}, to the same extent of approximation.

6.2 Derivation

Consider a uniform transmission line of length d, characterized by the per unit length parameters R, L, G and C, which has been terminated in an impedance of Z_L. The voltage and current at any point x measured from the source end are given by Potter and Fich [2]

$$V(x) = V_s \cosh(\gamma x) - I_s Z_0 \sinh(\gamma x) \tag{6.1}$$

$$I(x) = I_s \cosh(\gamma x) - (V_s/Z_0) \sinh(\gamma x) \tag{6.2}$$

where V_s and I_s are the sending end voltage and current; $Z_0 = [(R + sL)/(G + sC)]^{1/2}$ is the characteristic impedance; and $\gamma = [(R + sL)(G + sC)]^{1/2}$ is the propagation constant of the line. At $x = d$, the boundary condition is

$$V(d) = Z_L I(d) \tag{6.3}$$

Combining Eqs. (6.1), (6.2) and (6.3), it is a matter of simple algebra to show that

$$I(d)/V_s = 1/\left[Z_0 \sinh(\gamma d) + Z_L \cosh(\gamma d)\right] \tag{6.4}$$

For a lossless line, $R = G = 0$, $Z_0 = (L/C)^{1/2}$ and $\gamma = s(LC)^{1/2}$; thus

$$I(d)/V_s|_{\text{lossless}} = 1/\left\{(L/C)^{1/2} \sinh\left[sd(LC)^{1/2}\right] + Z_L \cosh\left[sd(LC)^{1/2}\right]\right\} \tag{6.5}$$

For a lossy line with $G \cong 0$ (as in reference [1]),

$$[Z_0' = (L/C)^{1/2}[1 + R/(sL)]^{1/2} \text{ and } \gamma' = s(LC)^{1/2} \times [1 + /(sL)^{1/2} \tag{6.6}$$

where the prime has been used to distinguish this case from the previous one. For short-duration surges, $|s| \gg R/L$, and Eq. (6.6) can be approximated as

$$[Z_0' \cong (L/C)^{1/2}[1 + R/(2sL)] \text{ and } \gamma' \cong s(LC)^{1/2} \times [1 + R/(2sL)] \tag{6.7}$$

If this transmission line is shorted at the output end, i.e. $Z_L = 0$, then from (6.4) and (6.7), we get

$$I(d)/V_s|_{\text{lossy,shorted}} = 1/\left\{(L/C)^{1/2}[1 + R/(2sL)] \times \sinh\left[sd(LC)^{1/2} \cdot (1 + R/(2sL))\right]\right. \tag{6.8}$$

This can be put in the form

$$I(d)/V_s|_{\text{lossy,shorted}} = \frac{1}{[1 + R/(2sL)]\cosh[Rd/(2Z_0)]}$$

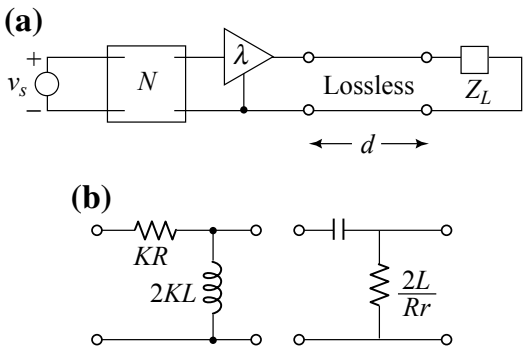

Fig. 6.1 **a** An equivalent circuit of a shorted lossy transmission line, where N stands for one of the two networks shown in (**b**) [$\lambda = 1$ if only condition (6.10) is to be eliminated, whereas $\lambda = \text{sech}\,[Rd/(2Z_0)]$ if both (6.10) and (6.11) are to be eliminated]. **b** Forms of N required in (**a**) [K is an arbitrary constant and r is an arbitrary resistance]

$$\times \frac{1}{(L/C)^{1/2}\sinh[sd(LC)^{1/2}] + (L/C)^{1/2}\tanh[Rd/(2Z_0)] \times \cosh[sd(LC)^{1/2}]} \tag{6.9}$$

Comparing Eqs. (6.9) with (6.5), we see that the shorted lossy line is equivalent to the lossless terminated line if

$$1 + R/(2sL) \cong 1 \tag{6.10}$$

$$\cosh\,[Rd/(2Z_0)] \cong 1 \tag{6.11}$$

and

$$Z_L = Z_0 \tanh\,[Rd/(2Z_0)] \tag{6.12}$$

where Z_0 refers to the lossless line.

The restriction given by Eq. (6.10) can be avoided by using the modified equivalent model shown in Fig. 6.1a, where N stands for either of the two networks shown in Fig. 6.1b, and $\lambda = 1$. It is obvious that the condition Eq. (6.11) can also be eliminated by using $\lambda = \text{sech}\,[Rd/(2Z_0)]$ in Fig. 6.1a. The resulting equivalent circuit is then exact as long as the approximation $[1 + R/(sL)]^{-1/2} \cong 1 + R/(2sL)$ is valid, and can be used for analog modelling as well as for digital computer studies of transients.

6.2.1 Two-Port Equivalence

The term equivalence as used in Ref. [1] and this chapter so far is in a restricted sense only. Considering the lossy and the lossless lines as two-port networks, as shown in Fig. 6.2, we have so far attempted to equate the y_{21} and y_{12} parameters only. Two-port equivalence will be valid if, in addition to y_{21}, the y_{11} and y_{22} parameters of the two

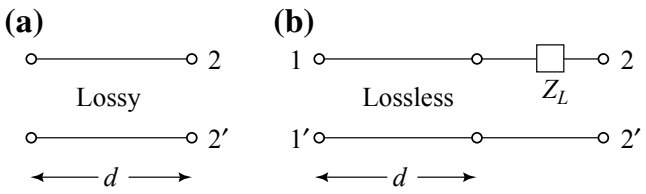

Fig. 6.2 Lossy and lossless lines considered as two ports

networks are also equal. To investigate this, we consider Fig. 6.2b first. Putting $x = d$ in Eqs. (6.1) and (6.2), combining with Eq. (6.3) and eliminating $I(d)$, we get

$$\left.\frac{1}{y_{11}}\right|_{\text{Fig.6.2b}} = Z_0 \frac{Z_L \cosh\left[sd(LC)^{1/2}\right] + Z_0 \sinh\left[sd(LC)^{1/2}\right]}{Z_0 \cosh\left[sd(LC)^{1/2}\right] + Z_L \sinh\left[sd(LC)^{1/2}\right]} \tag{6.13}$$

For the lossy case (Fig. 6.2a), it can be easily shown that

$$1/y_{11}|_{\text{Fig.6.2a}} = Z_0' \tanh(\gamma' d) \tag{6.14}$$

Combining this with Eq. (6.7) and simplifying, it can be shown that

$$\left.\frac{1}{y_{11}}\right|_{\text{Fig 6.2(a)}} \cong Z_0\left(1 + \frac{R}{2sL}\right) \times \frac{Z_0 \sinh\left[sd(LC)^{1/2}\right] + Z_0 \tanh\left[Rd/(2Z_0)\right] \times \cosh\left[sd(LC)^{1/2}\right]}{Z_0 \cosh\left[sd(LC)^{1/2}\right] + Z_0 \tanh\left[Rd/(2Z_0)\right] \times \sinh\left[sd(LC)^{1/2}\right]} \tag{6.15}$$

Comparing this with Eq. (6.13), we see that the y_{11} parameters of the two networks of Fig. 6.2 will be equal if Eqs. (6.10) and (6.12) are satisfied.

By symmetry, $y_{22} = y_{11}$ for Fig. 6.2a; however, for Fig. 6.2b,

$$1/y_{22}|_{\text{Fig.6.2.(b)}} = Z_L + Z_0 \tanh\left[sd(LC)^{1/2}\right] \tag{6.16}$$

Putting the value of Z_L from Eq. (6.12), we get

$$\left.\frac{1}{y_{22}}\right|_{\text{Fig.6.2b}} = \frac{Z_0 \sinh\left[sd(LC)^{1/2}\right] + Z_0 \tanh\left[Rd/(2Z_0)\right] \times \cosh\left[sd(LC)^{1/2}\right]}{Z_0 \cosh\left[sd(LC)^{1/2}\right]} \tag{6.17}$$

Comparing this with Eq. (6.15), we see that they are not equal even if Eq. (6.10) is satisfied; however, with Eq. (6.11) also satisfied, $\sinh\left[Rd/(2Z_0)\right] \cong \tanh\left[Rd/(2Z_0)\right) \cong 0$ and y_{22} of the two networks of Fig. 6.2 would be approximately equal.

Chapter 7
Efficient Approximation of Variable Delay Using Tapped Delay Line

Abstract A variable delay is required for beam steering in an adaptive antenna array. This chapter presents an efficient design for approximating such a delay for broadband applications by using only one phase shifter and real coefficients. Exact mathematical formulas for determining the required weighting coefficients have also been derived.

Keywords Variable delay · Tapped delay line · Approximation

7.1 Introduction

Adaptive array systems have the ability to automatically respond to an unknown interference environment, by steering nulls and reducing the sidelobe levels in the direction of interference. The pattern of the array is steered by applying weighting across the antenna array elements. A tapped delay line filter, realizing a variable delay, is used in each channel of wideband adaptive arrays.

We, in this chapter, derive explicit as well as recursive mathematical formulas for determining the weights required for the structure, using the same criterion of approximation as used by Ko and Lim [1]. For calculation of N weights, the approach of reference [1] requires the inversion of an $N \times N$ matrix, needs N phase shifters, besides other involved evaluations. Our suggested formulas are in elegant forms and are shown to be computationally faster. Moreover, the proposed realization requires only one fixed phase shifter of 90 degrees, thereby making the structure simple and efficient.

7.2 Derivation of Formulas for the Weighting Coefficients

7.2.1 Recursive Formula

The ideal frequency response of delay τ is given by

$$\overset{\approx}{H}(\omega) = \exp(-j\omega\tau) \tag{7.1}$$

where ω is the radian frequency. We approximate Eq. (7.1) by the frequency response, *H(ω)*, of a tapped delay filter with *N* complex weights, i.e. by

$$H(\omega) = \sum_{i=1}^{N} c_i \exp[-j\omega(i-1)T] \tag{7.2}$$

where c_i are the desired weighting coefficients, T is the intertap delay, usually chosen to equal $m/(4f_o)$, where m is an integer and $f_o = \omega_o/(2\pi)$ is the centre frequency of the array; this choice of T, it can be shown, minimizes the complexity of the design.

We define the error of approximation by

$$E(\omega) \underline{\underline{\Delta}} |\overset{\approx}{H}(\omega) - H(\omega)| \tag{7.3}$$

The aim is to minimize the error in the frequency band of interest centred around fo. Choosing the criterion of approximation as the minimization of *E(ω)* in the maximally flat sense [1]. That is, by forcing

$$E(\omega)\,|_{\omega=\omega_o} = 0 \tag{7.4a}$$

and

$$\mathrm{d}^i E(\omega)/\mathrm{d}\omega^i\,|_{\omega=\omega_o} = 0, \quad i = 1, 2, \ldots, N-1 \tag{7.4b}$$

the following matrix equation results:

$$[a_{mn}][x_m] = [b_m], \quad m, n = 1, 2, \ldots, N \tag{7.5a}$$

where

$$a_{mn} = (n-1)^{m-1}$$

$$b_m = (\tau/T)^{m-1} \exp(-j\omega_o\tau) \tag{7.5b}$$

and

$$x_m = c_m \exp[-j\omega_o T(m-1)] \tag{7.5c}$$

This system of linear equations can be solved by Crout's method [4]. Following the steps of this method and after involved algebraic manipulations, Eq. (7.5a) is transformed to

$$[a'_{mn}][x_m] = [b'_m] \tag{7.6a}$$

where

$$a_{mn} = \begin{cases} 0, & n < m \\ 1, & n = m \\ \binom{n-1}{m-1}, & n \geq m \end{cases} \tag{7.6b}$$

$$b'_m = [1/(m-1)!](\tau/T)^{m-1}[\exp(-j\omega_o\tau)]\prod_{p=1}^{m-2}[1-(pT/\tau)] \tag{7.6c}$$

On solving Eq. (7.6), we finally get the following recursive formula for the weighting coefficients $c_{i:}$

$$c_i = \exp[j\omega_o T(i-1)]\left[\begin{array}{l} \frac{\exp(-j\omega_o\tau)}{(i-1)!}(\tau/T)^{i-1}\prod_{p=1}^{i-2}[1-(pT/r)] \\ \sum_{r=1}^{N-1}\binom{i+r-1}{i-1}c_{i+r}, \exp[-j\omega_o T(i+r-1)] \end{array}\right] \tag{7.7}$$
$$i = N, N-1_2, \ldots 1 \text{(descending order)}$$

7.2.2 *Explicit Formula*

Equation (7.6a) may also be written as

$$[x_m] = [a'_{mn}]^{-1}[b'_m] \tag{7.8}$$

where $[a'_{mn}]^{-1}$ is the inverse of the matrix $[a'_{mn}]$. Using Eqs. (7.5), (7.6) and (7.8), we obtain the following explicit formula for $c_{i:}$

$$c_i = \exp\{j\omega_o[(i-1)T-\tau]\}\left[\sum_{k=i}^{N}\frac{(-1)^{i+k}(\tau/T)^{k-1}}{(k-i)!(i-1)!}\prod_{p=1}^{k-2}[1-(pT/\tau)]\right] \tag{7.9}$$
$$i = 1, 2, 3 \ldots, N$$

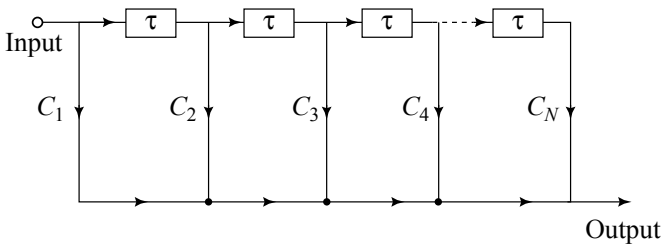

Fig. 7.1 General tapped delay line filter with N complex weights for realizing a delay of τ

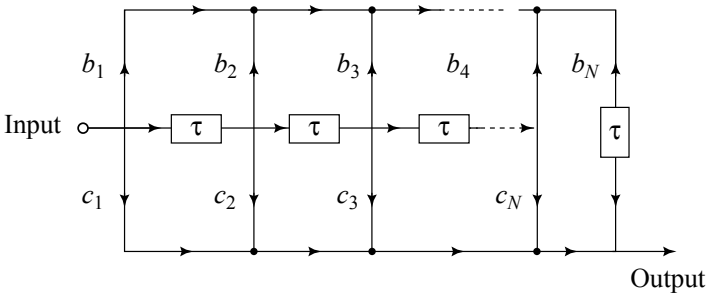

Fig. 7.2 Realization of the proposed design for the approximation of a variable delay τ, by using only one phase shifter

7.3 Implementation

The tapped delay line filter with N complex weights (c_i) is shown in Fig. 7.1. Let $c_i = a_i + j\, b_i$ $i =$ I, 2, 3,…, where a_i and b_i are real. Thus, the structure of Fig. 7.1 can be implemented as shown in Fig. 7.2 where only one phase shifter of 90 degrees (corresponding to multiplication by j) is required. Such an arrangement is highly efficient, besides being economical. The design proposed in reference [1], incorporating N phase shifters, suffers from inaccuracies of the phase shifters [2] (e.g. attenuation, phase instability, non-linearities, etc.). Our structure is relatively free from such drawbacks. The j factor, used in Fig. 7.2, can be efficiently realized by various methods, e.g. by the use of a Hilbert transformer [3].

7.4 Performance

The computation time of the weighting coefficients with the ICL 2960 system, for $N = 1$ to 7, has been plotted in Fig. 7.3 for $f_o\ \tau = 0.125$ and $f_o T = 0.25$. Curves (a) and (b) of Fig. 7.3 give, respectively, the computation time in milliseconds using the explicit formula and the recursive formula. Recursion, when used for evaluation of the weighting coefficients, is computationally faster than the direct or the explicit formula since a recursive formula makes use of the previously generated weight values in the algorithm. It is apparent (as expected) from Fig. 7.3 that the proposed recursive formula, Eq. (7.7), is more efficient than the explicit formula, Eq. (7.9), when the speed of computation is of prime importance. However, in recursion, there is a need to set aside memory storage arrays for the previously computed weights. Therefore, the explicit formula may be preferred when the economy of memory of the

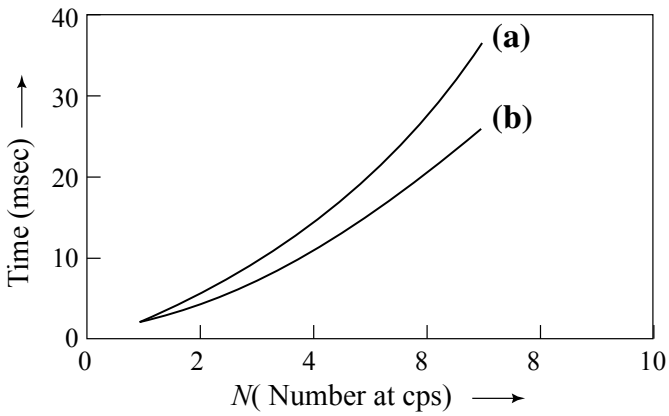

Fig. 7.3 Computation time for coefficients, c_i for delay of 0.5T for $N = 1$ to 7, **a** by using explicit formula (9), **b** by using recursive formula (7)

computer is the main concern. As is well known [4], it takes about $2\,N^3/3$ operations to solve a linear system of equations.

$\underset{\sim}{A}\,x = ba$, of order N, by Crout's method and about $8\,N^3/3$ operations for finding the matrix inversion $\overset{-1}{\underset{\sim}{A}}$. It is thus obvious that the computation time, if we adopt the matrix inversion approach of [1], is approximately four times the values given by curve (b) of Fig. 7.3.

7.5 Conclusions

Exact mathematical formulas for computation of the weighting coefficients, required for the variable delay structure, have been derived. The proposed design is efficient and requires only one fixed phase shifter in contrast to N phase shifters needed in the structure suggested in reference [1].

Part III
Analog Signal Processing: Signal Processing by Active Networks

This part has six chapters, dealing with realization of various types of filters and an inductor, using Op-amp RC networks. Chapter 8 deals with such filters using a single operational amplifier. Tolerance minded design of an active RC filter form the contents of Chap. 9, while Chap. 10 is a supplement to Chap. 8, with more circuits using a single Op-amp and its different inputs. Second order active RC filters using Op-amps in low gain connection form the subject of Chap. 11. Inductor simulation and its applications are dealt with in Chap. 12. The effect of frequency limitation of Op-amp active RC filters is explored by the dominant pole technique in Chap. 13. Finally, Chap. 14 deals with 'Shadow' filters which is a recent innovation.

Chapter 8
Second-Order Active RC Filters Using a Single Operational Amplifier

Abstract The chapter deals with economic realizations of second-order active *RC* filters employing a single differential input operational amplifier as the active element. All the basic types of filters are considered and the sensitivities of Q and undamped natural frequency with respect to various parameters are evaluated. Further, it is shown that one circuit configuration can lead to several types of filter realizations having the same Q, simply by short circuiting or open circuiting certain elements, thereby reducing the manufacturing cost.

Keywords Active RC filter · Operational amplifier

8.1 Introduction

In [1], Dutta Roy proposed a procedure, alternative to that proposed by Mitra [2, 3] for realization of any rational transfer function with a single differential input operational amplifier. The new procedure requires the predetermination of three resistances and synthesis of three RC one ports, whereas Mitra's method requires synthesis of six RC one ports. Dutta Roy's method also allows much more flexibility in the choice of element values compared to that due to Mitra. The purpose of this chapter is to develop various second-order active RC filter realizations with as few passive components as possible. Starting with a basic circuit containing fifteen elements, as obtained with Dutta Roy's procedure for a general second-order transfer function. Further, it is shown that with one circuit configuration, low pass and bandpass realizations having the same Q, and, similarly from another circuit configuration, a high-pass, bandpass and band stop realizations having Q of the same order, may be obtained by short circuiting or open circuiting certain elements, thereby reducing the manufacturing cost.

8.2 Basic Circuit

The basic circuit from which the various second-order realizations will be derived is shown in Fig. 8.1. The transfer function of this circuit can be expressed as

$$T(s) = \frac{V_0}{V_i} = \frac{Y_A(Y_D + Y_F) - Y_B(Y_C + Y_E)}{Y_F(Y_A + Y_C) - Y_E(Y_B + Y_D)} \tag{8.1}$$

In our realizations $Y_D = 0$; therefore, the transfer function reduces to

$$T(s) = \frac{Y_A Y_F - Y_B(Y_C + Y_E)}{Y_F(Y_A + Y_C) - Y_E Y_B} \tag{8.2}$$

By choosing the time constants of series RC impedances equal, removing two series RC impedances or by removing one series RC impedance and setting the time constants of remaining two series RC impedances equal, the transfer function $T(s)$ becomes a biquadratic one

$$T(S) = \frac{a_2 s^2 + a_1 s + a_0}{b_2 s^2 + b_1 s + b_0} \tag{8.3}$$

Next, by setting the appropriate numerator coefficient(s) to zero, a particular filter realization, with elements less than those hitherto used, can be obtained.

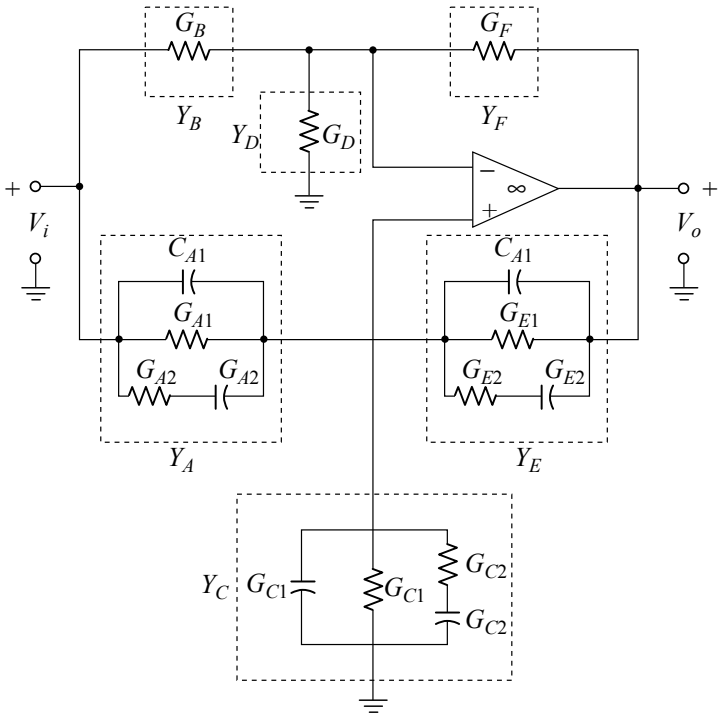

Fig. 8.1 Basic circuit for realizing various second-order transfer functions

8.3 Low-Pass Realization

To realize a low pass transfer function, we set in Fig. 8.1

$$\left.\begin{array}{l} G_{A2} = G_{C1} = G_{C2} = G_D = G_{E1} = 0 \\ C_{A2} = C_{C2} = C_{E1} = 0 \end{array}\right\} \tag{8.4}$$

with the admittances

$$\left.\begin{array}{ll} Y_A = C_{A1}s + G_{A1} & Y_B = G_B \\ Y_C = C_{C_1}s & Y_D = 0 \\ Y_E = \frac{G_{E2}s}{(G_{E2}/C_{E2})+8} & Y_F = G_F \end{array}\right\} \tag{8.5}$$

as shown in Fig. 8.2a. The coefficients of the transfer function, given by Eq. (8.3), become

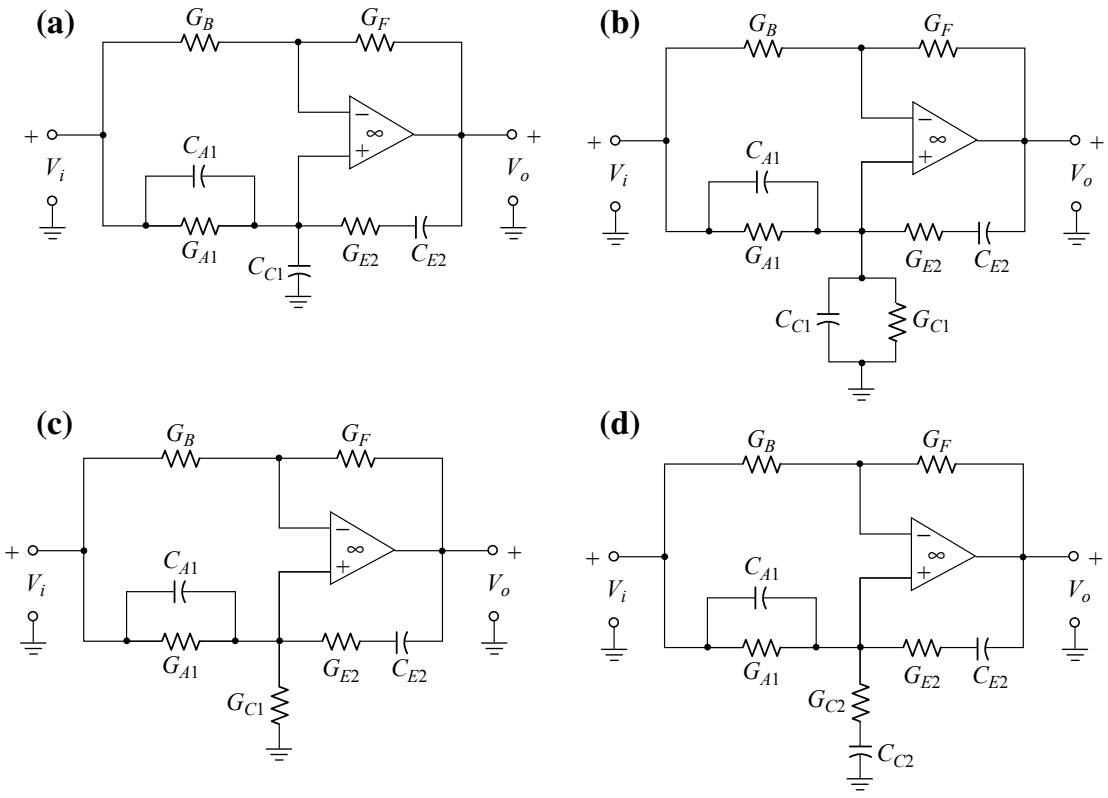

Fig. 8.2 **a** Low pass filter realization and second band stop filter realization with $a_0' > b_0'$. **b** Bandpass filter realizations. **c** High-pass filter realization and third band stop filter realization with $a_0' < b_0'$. **d** First band stop filter realization with $a_0' > b_0'$

$$\left.\begin{aligned} a_2 &= C_{A1}G_F - C_{C1}G_B \\ a_1 &= G_{A1}G_F - G_{E2}G_B + \tfrac{G_{E2}}{C_{E2}}(C_{A1}G_F - C_{C1}G_B) \\ a_0 &= \tfrac{G_{E2}}{C_{E2}}G_{A1}G_F \\ b_2 &= (C_{A1} + C_{C1})G_F \\ b_1 &= G_{A1}G_F - G_{E2}G_B + \tfrac{G_{E2}}{C_{E2}}(C_{A1} + C_{C1})G_F \\ &\text{and} \\ b_0 &= \tfrac{G_{E2}}{C_{E2}}G_{A1}G_F \end{aligned}\right\} \tag{8.6}$$

The general expressions for quality Q and natural frequency ω_n of this realization of seven elements are given by

$$\omega_n = \left[\frac{G_{A1}G_{E2}}{C_{E2}(C_{A1} + C_{C1})}\right]^{1/2} \tag{8.7}$$

and

$$Q = \frac{G_F[G_{A1}G_{E2}C_{E2}(C_{A1} + C_{C1})]^{\frac{1}{2}}}{G_{E2}(C_{A1} + C_{C1})G_F + C_{E2}(G_{A1}G_F - G_{E2}G_B)} \tag{8.8}$$

Setting $a_2 = 0$ and $a_1 = 0$ for low pass realization, we have

$$\left.\begin{aligned} &C_{A1}G_F = C_{C1}G_B \\ &\text{and} \\ &G_{A1}G_F = G_{E2}G_B \end{aligned}\right\} \tag{8.9}$$

If $C_{Al} = C_{Cl}$, $G_B = G_F$, $G_{A1} = G_{E2}$, the nominal values of Q and ω_n become

$$\omega_n = \frac{G_{A1}}{(2C_{A1}C_{E2})^{\frac{1}{2}}} \tag{8.10a}$$

$$Q = \left(\frac{C_{E2}}{2C_{A1}}\right)^{\frac{1}{2}} \tag{8.l0b}$$

and the transfer function reduces to

$$T(s) = \frac{G_{A1}^2/2C_{A1}G_{E2}}{s^2 + \frac{G_{A1}}{C_{E2}}s + \frac{G_{A1}^2}{2C_{A1}C_{E2}}} \tag{8.11}$$

From Eqs. 8.10a, b, it is evident that a very high Q may be obtained by appropriate choice of C_{E2} and C_{A1}

The sensitivities of Q and ω_n to the various parameters for this realization are

$$\left.\begin{array}{ll} S^Q_{C_{A1}} = S^Q_{C_{C1}} = -\frac{1}{4}, & S^Q_{CE2} = \frac{1}{2} \\ S^Q_{G_B} = Q^2, & S^Q_{GF} = -Q^2 \\ S^Q_{G_{A1}} = \frac{1}{2} - Q^2, & S^Q_{GE2} = -\frac{1}{2} + Q^2 \end{array}\right\} \tag{8.12}$$

and

$$\left.\begin{array}{ll} S^{\omega_n}_{C_{A1}} = S^{\omega_n}_{C_{C1}} = -\frac{1}{4}, & S^{\omega_n}_{C_{E2}} = -\frac{1}{2} \\ S^{\omega_n}_{G_{A1}} = S^{\omega_n}_{G_{ER}} = \frac{1}{2} & \end{array}\right\} \tag{8.13}$$

8.4 Bandpass Filter Realizations

The bandpass realization of eight elements shown in Fig. 8.2b may be obtained by setting

$$\left.\begin{array}{l} G_{A2} = G_{C2} = G_D = G_{E1} = 0 \\ C_{A2} = C_{C2} = C_{E1} = 0 \end{array}\right\} \tag{8.14}$$

With the admittances

$$\left.\begin{array}{ll} Y_A = C_{A1}s + G_{A1} & Y_B = G_B \\ Y_C = C_{C1}s + G_{C1} & Y_D = 0 \\ Y_E = \frac{G_{E_2}s}{\frac{G_{E2}}{C_{E2}}+s} & Y_F = G_F \end{array}\right\} \tag{8.15}$$

shown in Fig. 8.2b, the coefficients of the transfer function given by Eq. (8.3) and the general expressions for Q and ω_n may be written as

$$\left.\begin{array}{l} a_2 = C_{A1}G_F - C_{C1}G_B \\ a_1 = G_{A1}G_F - G_{C1}G_B - G_BG_{E2} \\ \qquad + \dfrac{G_{E2}}{C_{E2}}(C_{A1}G_F - C_{C1}G_B) \\ a_0 = \frac{G_{E2}}{C_{E2}}(G_{A1}G_F - G_{C1}G_B) \\ b_2 = (C_{A1} + C_{C1})G_F \\ b_1 = (G_{A1} + G_{C1})G_F - G_BG_{E2} + \frac{G_{E2}}{C_{E2}}(C_{A1} + C_{C1})G_F \\ b_0 = \frac{G_{E2}}{C_{E2}}(G_{A1} + G_{C1})G_F \end{array}\right\} \tag{8.16}$$

$$Q = \frac{G_F[(G_{A1} + G_{C1})/(C_{A1} + C_{C1})G_{E2} \cdot C_{E2}]^{\frac{1}{2}}}{G_{E2}(C_{A1} + C_{C1})G_F + C_{E2}(G_{A1}G_F + G_{C1}G_F - G_{E2}G_B)} \tag{8.17}$$

and

$$\omega_n = \left[\frac{G_{E2}(G_{A1} + G_{C1})}{C_{E2}(C_{A1} + C_{C1})}\right]^{1/2} \tag{8.18}$$

Setting $a_2 = 0$ and $a_0 = 0$, we obtain two BP realizations.

8.4.1 First Bandpass Realization

If we make $G_B = G_F$, $G_{A1} = G_{C1}$ and $C_{E2} = 2C_{A1} = 2C_{Cl}$, the nominal values of ω_n and Q become

$$\omega_n = \frac{1}{C_{A1}}\left[\frac{G_{E2}G_{A1}}{2}\right]^{1/2} \tag{8.19}$$

$$Q = \left(\frac{G_{E2}}{2G_{A1}}\right)^{1/2} \tag{8.20}$$

and the transfer function reduces to

$$T(s) = -\frac{(G_{E2}/2C_{A1})s}{s^2 + \frac{G_{A1}}{C_{A1}}s + \frac{G_{E2}G_{A1}}{C_{A1}^2}} \tag{8.21}$$

It may be seen that a very high Q may be obtained by appropriate choice of G_{E2} and G_{A1}.

The Q and ω_n sensitivities for this realization are

$$\left.\begin{aligned} &S_{C_{A1}}^{Q} = S_{C_{C1}}^{Q} = \tfrac{1}{2}\left(\tfrac{1}{2} - Q^2\right), \quad S_{C_{E2}}^{Q} = \left(Q^2 - \tfrac{1}{2}\right) \\ &S_{G_B}^{Q} = Q^2, \quad S_{G_F}^{Q} = -Q^2 \\ &S_{G_{A1}}^{Q} = S_{G_{C1}}^{Q} = -\tfrac{1}{4}, \quad S_{G_{E2}}^{Q} = -\tfrac{1}{2} \end{aligned}\right\} \tag{8.22}$$

$$\left.\begin{aligned} S_{C_{A1}}^{\omega_n} = S_{C_{C1}}^{\omega_n} = -\tfrac{1}{4}, \quad S_{CE2}^{\omega_n} = -\tfrac{1}{2} \\ S_{G_{A1}}^{\omega_n} = S_{G_{C1}}^{\omega_n} = \tfrac{1}{4}, \quad S_{G_{E2}}^{\omega_n} = \tfrac{1}{2} \end{aligned}\right\} \tag{8.23}$$

8.4.2 Second Bandpass Realization

If we set $G_B = G_F$, $G_{E2} = 2G_{A1} = 2G_{C1}$ and $C_{A1} = C_{C1}$, the nominal values of ω_n and Q become

$$\omega_n = G_{A1}\left(\frac{2}{CA_1\, C_{E2}}\right)^{\frac{1}{2}} \tag{8.24}$$

$$\text{and } Q = \left(\frac{C_{E2}}{2C_{A1}}\right) \tag{8.25}$$

and the transfer function reduces to

$$T(s) = -\frac{(G_{A1}/C_{A1})s}{s^2 + \frac{2G_{A1}}{C_{E2}}s + \frac{2G_{A1}^2}{C_{A1}C_{E2}}} \tag{8.26}$$

In this case, a high Q may be obtained by choosing $C_{E2} \gg C_{A1}$.
The Q sensitivities for this realization are

$$\left.\begin{aligned} &S_{C_{A1}}^{Q} = S_{C_{C1}}^{Q} = -\tfrac{1}{4}, \quad S_{C_{E2}}^{Q} = \tfrac{1}{2} \\ &S_{G_B}^{Q} = Q^2, \quad S_{G_F}^{Q} = -Q^2 \\ &S_{G_{A1}}^{Q} = S_{G_{C1}}^{Q} = \tfrac{1}{2}\left(\tfrac{1}{2} - Q^2\right), \quad S_{G_{E2}}^{Q} = Q^2 - \tfrac{1}{2} \end{aligned}\right\} \tag{8.27}$$

The ω_n sensitivities are same as in the case of first bandpass realization.

8.5 High-Pass Realization

To realize a high-pass transfer function, we set in Fig. 8.1

$$\left.\begin{aligned} G_{A2} = G_{C2} = G_D = G_{E1} = 0 \\ C_{A2} = C_{C1} = C_{C2} = C_{E1} = 0 \end{aligned}\right\} \tag{8.28}$$

With the admittances

$$\left.\begin{aligned} Y_A = C_{A1}s + G_{A1}, \quad & Y_B = G_B \\ Y_C = G_{C1}, \quad & Y_D = 0 \\ Y_E = \frac{G_{E2}s}{\frac{G_{E2}}{C_{E2}} + s}, \quad & Y_F = G_F \end{aligned}\right\} \tag{8.29}$$

as shown in Fig. 8.2c, the coefficients of the transfer function given by Eq. (8.3) and the general expressions for ω_n and Q may be obtained as

$$a_2 = C_{A1}G_F = b_2$$

$$\left.\begin{aligned} a_1 &= G_{A1}G_F - G_{C1}G_B - G_{E2}G_B + \tfrac{G_{E2}}{C_{E2}}C_{A1}G_F \\ a_0 &= \tfrac{G_E}{C_{E2}}(G_{A1}G_F - G_{C1}G_B) \\ b_1 &= (G_{A1} + G_{C1})G_F + \tfrac{G_{E2}}{C_{E2}}C_{A1}G_F - G_{E2}G_B \\ b_0 &= \tfrac{G_{E2}}{C_{E2}}(G_{A1} + G_{C1})G_F \end{aligned}\right\} \tag{8.30}$$

$$\omega_n = \left[\frac{G_{E2}(G_{A1} + G_{C1})}{C_{A1}C_{E2}}\right]^{\frac{1}{2}} \tag{8.31}$$

and

$$Q = \frac{G_F[(G_{A1} + G_{C1})G_{E2}C_{A1}C_{E2}]^{\frac{1}{2}}}{G_{E2}G_FC_{A1} + (G_{A1}G_F + G_{C1}G_F - G_{E2}G_B)C_{E2}} \tag{8.32}$$

Setting $a_1 = 0$ and $a_0 = 0$ for high-pass realization, we have C_{A1}= C_{E2}, G_B= G_F and G_{A1}= G_{C1} and nominal values of ω_n and Q become

$$\omega_n = \frac{(2G_{A1}G_{E2})^{1/2}}{C_{A1}} \tag{8.33}$$

$$Q = \left(\frac{G_{E2}}{2G_{A1}}\right)^{1/2} \tag{8.34}$$

The transfer function reduces to

$$T(s) = \frac{s^2}{s^2 + \frac{2G_{A1}}{C_{A1}}s + \frac{2G_{E2}G_{A1}}{C_{A1}^2}} \tag{8.35}$$

Q for this realization can be made very high by making $G_{E2} \gg G_{A1}$.

The sensitivities of Q and ω_n to the various parameters for this realization of seven elements are given by

$$\left.\begin{aligned} S_{C_{A1}}^{Q} &= \tfrac{1}{2} - Q^2, & S_{C_{E2}}^{Q} &= Q^2 - \tfrac{1}{2} \\ S_{G_B}^{Q} &= Q^2, & S_{G_F}^{Q} &= -Q^2 \\ S_{G_{A1}}^{Q} &= S_{G_{C1}}^{Q} = -\tfrac{1}{4}, & S_{G_{E2}}^{Q} &= \tfrac{1}{2} \end{aligned}\right\} \tag{8.36}$$

and

$$\left.\begin{aligned} S_{C_{A1}}^{\omega_n} &= S_{C_{E2}}^{\omega_n} = -\tfrac{1}{2} \\ S_{G_{E2}}^{\omega_n} &= \tfrac{1}{2}, & S_{G_{A1}}^{\omega_n} &= S_{G_{C1}}^{\omega_n} = \tfrac{1}{4} \end{aligned}\right\} \tag{8.37}$$

8.6 Band Stop Realization

Three band stop realizations have been obtained for the zeroes lying on imaginary axis at $s = \pm j\omega_n$, $s > \pm j\omega_n$ and $s < \pm j\omega_n$.

First Band Stop Realization with Zeroes at $s = \pm j\omega_n$

The band stop realization of eight elements shown in Fig. 8.2d may be obtained by setting

$$\left.\begin{aligned} G_{A2} = G_{C1} = G_D = G_{E1} = 0 \\ C_{A2} = C_{C1} = C_{E1} = 0 \end{aligned}\right\} \tag{8.38}$$

With the admittances

$$\left.\begin{aligned} Y_A &= C_{A1}s + G_{A1}, & Y_B &= G_B \\ Y_C &= \frac{G_{C2}s}{\frac{G_{C2}}{C_{C2}}+s}, & Y_D &= 0 \\ Y_E &= \frac{G_{E2}s}{\frac{G_{E2}}{C_{E2}}+s}, & Y_F &= G_F \end{aligned}\right\} \tag{8.39}$$

shown in Fig. 8.2d, the transfer function given by Eq. (8.2) may be written as

$$T(s) = \frac{s^3 + a_2 s^2 + a_1 s + a_0}{s^3 + \delta_2 s^2 + \delta_1 s + \delta_0} \tag{8.40}$$

where

$$\left.\begin{aligned} a_2 &= \left[\left(\frac{G_{C2}}{C_{C2}} + \frac{G_{E2}}{C_{E2}}\right) + \frac{G_{A1}}{C_{A1}} - \frac{G_B(G_{C2}+G_{E2})}{C_{A1}G_F}\right] \\ a_1 &= \left[\frac{G_{C2}}{C_{C2}} \cdot \frac{G_{E2}}{C_{E2}} + \left(\frac{G_{E2}}{C_{E2}} + \frac{G_{C2}}{C_{C2}}\right)\frac{G_{A1}}{C_{A1}} - \frac{G_B G_{C2} G_{E2}}{C_{A1}G_F}\left(\frac{1}{C_{C2}} + \frac{1}{C_{E2}}\right)\right] \\ a_0 &= \frac{G_{A1}G_{C2}G_{E2}}{C_{A1}C_{C2}C_{E2}} \\ \delta_2 &= \left[\left(\frac{G_{C2}}{C_{C2}} + \frac{G_{E2}}{C_{E2}}\right) + \frac{(G_{A1}+G_{C2})}{C_{A1}} - \frac{G_B G_{E2}}{C_{A1}G_F}\right] \\ \delta_1 &= \left[\left(\frac{G_{C2}}{C_{C2}} + \frac{G_{E2}}{C_{E2}}\right)\frac{G_{A1}}{C_{A1}} + \left(\frac{C_{A1}}{C_{C2}} + 1\right)\frac{G_{E2}}{C_{E2}} \cdot \frac{G_{C2}}{C_{A1}} - \frac{G_B G_{C2} G_{E2}}{C_{A1}C_{C2}G_F}\right] \\ \delta_0 &= \frac{G_{A1}}{C_{A1}} \cdot \frac{G_{C2}}{C_{C2}} \cdot \frac{G_{E2}}{C_{E2}} \end{aligned}\right\} \tag{8.41}$$

If we set

$$\left.\begin{array}{l} \frac{G_{E2}}{C_{E2}} = \frac{G_{C2}}{C_{C2}} = \alpha \\ G_{A1} = G_{C2},\ G_B = G_F \text{ and } C_{A1} = C_{E^2} \end{array}\right\} \tag{8.42}$$

the nominal values of coefficients δ_2, δ_1 and δ_0 and nominal values of ω_n and Q become

$$\left.\begin{array}{l} \delta_2 = \alpha + 2\frac{G_{A1}}{C_{A1}},\ \delta_1 = 3\alpha\frac{G_{A1}}{C_{A1}} \\ \delta_0 = \alpha^2\frac{G_{A1}}{C_{A1}} \end{array}\right\} \tag{8.43}$$

$$\omega_n = \frac{(G_{E2}G_{A1})^{\frac{1}{2}}}{C_{A1}} \tag{8.44}$$

$$Q = \frac{1}{2}\left(\frac{G_{E2}}{G_{A1}}\right)^{\frac{1}{2}} \tag{8.45}$$

and the transfer function reduces to

$$T(s) = \frac{s^2 + \alpha\frac{G_{A1}}{C_{A1}}}{s^2 + \frac{2G_{A1}}{C_{A1}}s + \alpha\frac{G_{A1}}{C_{A1}}} \tag{8.46}$$

This transfer function is of the form

$$T(s) = \frac{s^2 + a_0'}{s^2 + b_1's + b_0'} \tag{8.47}$$

where $a_0' = b_0'$, i.e. zeroes of transfer function are at $s = \pm j\omega_n$

In [4], Soderstrand and Mitra derived expressions relating to Q and ω_n, sensitivities of a third-order filter to the denominator polynomial coefficient sensitivities. Following them, the Q and ω_n sensitivities for a third-order system

$$T(s) = \frac{(s + r)(s^2 + a_1''s + a_0'')}{s^3 + \delta_2 s^2 + \delta_1 s + \delta_0} \tag{8.48}$$

may be expressed as

$$S_{x_i}^{Q} = \frac{[\delta_0(2\omega_n Q^2 + rQ - \omega_n)S_{x_i}^{\delta_0} + \delta_1(\omega_n^2 Q - 2\omega_n r Q^2)S_{x_i}^{\delta_i} + \omega_n^2(Qr - 2\omega_n Q^2)\delta_2 S_{x_i}^{\delta_2}]}{2\omega_n^2[(\omega_n^2 + r^2)Q - \omega_n r]} \tag{8.49}$$

$$S_{x_i}^{\omega_n} = \frac{(Qr - \omega_n)\delta_0 S_{x_i}^{\delta_0} + Q\omega_n^2\delta_1 S_{x_i}^{\delta_i} - Q\omega_n^2 r\delta_2 S_{x_i}^{\delta_2}}{2\omega_n^2[(\omega_n^2 + r^2)Q - \omega_n r]} \tag{8.50}$$

where

$S_{x_i}^{\delta_j}$ = denominator polynominal coefficient sensitivity with respect to an element x_i.

$$= \frac{\partial \delta_j / \delta_j}{\partial x_i / x_i} \tag{8.51}$$

and the coefficients δ_2, δ_1 and δ_0 are related to ω_n, Q and r as follows:

$$\left.\begin{aligned} \delta_2 &= (\omega_n/Q) + r \\ \delta_1 &= \omega_n^2 + (\omega_n/Q)r \\ \delta_0 &= \omega_n^2 r \end{aligned}\right\} \tag{8.52}$$

From Eqs. (8.43), (8.44), (8.45) and (8.52), we get

$$r = \alpha \tag{8.53}$$

Substituting the nominal values of coefficients δ_2, δ_1 and δ_0 and r as given by Eqs. (8.43) and (8.53) in Eqs. (8.49) and (8.50), we obtain

$$S_{x_i}^{Q} = S_{x_i}^{\delta_0} - (3/2)\mathrm{S}_{x_i}^{\delta_1} \tag{8.54}$$

and

$$S_{x_i}^{\omega_n} = \frac{(2Q^2-1)S_{x_i}^{\delta_0} + (3/2)S_{x_i}^{\delta_1} - (2Q^2+1)S_{x_i}^{\delta_2}}{(4Q^2-1)} \tag{8.55}$$

Thus Q and ω_n sensitivities with respect to elements of the circuit may be computed as

$$\left.\begin{aligned} S_{C_{A1}}^{Q} &= \tfrac{1}{2} - 2Q^2, \; S_{C_{C2}}^{Q} = -\tfrac{1}{2} \\ S_{C_{E2}}^{Q} &= 2Q^2, \qquad S_{G_{A1}}^{Q} = S_{G_{C2}}^{Q} S_{G_{E2}}^{Q} = 0 \\ S_{G_B}^{Q} &= +2Q^2, \qquad S_{G_F}^{Q} = -2Q^2 \end{aligned}\right\} \tag{8.56}$$

and

$$\left.\begin{aligned} S_{C_{A1}}^{\omega_n} &= -\tfrac{1}{2}, \quad S_{C_{C2}}^{\omega_n} = \tfrac{1}{2(4Q^2-1)} \\ S_{C_{E2}}^{\omega_n} &= -\tfrac{2Q^2}{(4Q^2-1)}, \quad S_{G_{A1}}^{\omega_n} = \tfrac{1}{2} \\ S_{G_{C2}}^{\omega_n} &= -\tfrac{(2Q^2+1)}{(4Q^2-1)}, \quad S_{G_{E2}}^{\omega_n} = \tfrac{2Q^2}{(4Q^2-1)} \\ S_{G_B}^{\omega_n} &= S_{G_F}^{\omega_n} = 0 \end{aligned}\right\} \tag{8.57}$$

8.6.1 Second Band Stop Realization

The low-pass filter configuration shown in Fig. 8.2a may also realize a band stop action with modified constraints on the elements. Relations (8.4)–(8.8) can be directly used for band stop realization as well.

By setting $a_1 = 0$, the following constraints on the elements of band stop filter may be obtained:

$$\left.\begin{array}{l} C_{A1}G_{A1} = G_{E2}C_{C1} \\ G_B = G_F,\ C_{A1} = C_{E2} \end{array}\right\} \tag{8.58}$$

The transfer function to given by Eq. (8.2) is reduced

$$T(s) = K\frac{s^2 + a_0'}{s^2 + b_1's + b_0'} \tag{8.59}$$

where

$$\left.\begin{array}{l} K = \frac{(1-G_{A1}/G_{E2})}{(1+G_{A1}/G_{E2})} < 1 \\ a_0' = \frac{G_{A1}G_{E2}}{C_{A1}^2[1-(G_{A1}/G_{E2})]} \\ b_0' = \frac{G_{A1}G_{E2}}{C_{A1}^2[1+(G_{A1}/G_{E2})]} \\ b_1' = \frac{2G_{A1}}{C_{A1}[1+(G_{A1}/G_{E2})]} \end{array}\right\} \tag{8.60}$$

$$a_0' > 0, a_0' > b_0', G_{E2} > G_{A1}$$

Thus, the zeroes of the transfer function are at $s > \pm j\omega_n$. The nominal values of ω_n and Q are given by

$$\omega_n = \frac{G_{E2}}{C_{A1}}\left[\frac{G_{A1}}{(G_{A1} + G_{E2})}\right]^{\frac{1}{2}} \tag{8.61}$$

and

$$Q = \frac{1}{2}\left(1 + \frac{G_{E2}}{G_{A1}}\right)^{\frac{1}{2}} \tag{8.62}$$

If $G_{E2} \gg G_{A1}$, a very high Q may be obtained.

Using general expressions given by Eqs. (8.7) and (8.8) for ω_n and Q and the constraint Eq. (8.58), Q and ω_n sensitivities for this realization may be obtained as

$$\left.\begin{array}{ll} S_{C_{A1}}^{Q} = 1 - \frac{1}{8Q^2} - 2Q^2, & S_{C_{C1}}^{Q} = -\frac{1}{2} + \frac{1}{8Q^2} \\ S_{C_{E2}}^{Q} = 2Q^2 - \frac{1}{2}, & S_{G_B}^{Q} = 2Q^2 - \frac{1}{2} \\ S_{G_F}^{Q} = -2Q^2 + \frac{1}{2}, & S_{G_{A1}}^{Q} = S_{G_{E2}}^{Q} = 0 \end{array}\right\} \tag{8.63}$$

and

$$\left.\begin{array}{l} S_{G_{A1}}^{\omega_n} = S_{G_{E2}}^{\omega_n} = \frac{1}{2} \\ S_{C_{E2}}^{\omega_n} = -\frac{1}{2}, \quad S_{C_{A1}}^{\omega_n} = -\frac{G_{E2}}{2(G_{A1}+G_{E2})} \\ S_{C_{C1}}^{\omega_n} = -\frac{G_{A1}}{2(G_{A1}+G_{E2})} \end{array}\right\} \tag{8.64}$$

8.6.2 Third Band Stop Realization

The high-pass filter configuration shown in Fig. 8.2c may also realize a band stop filter with modified constraints on the elements. Expressions given by Eqs. (8.28)–(8.32) can be directly carried over for band stop realization.

By setting $a_1 = 0$ in Eq. (8.30), the following constraints on the elements of band stop filter may be obtained:

$$\left.\begin{array}{l} G_{C1}C_{E2} = G_{E2}C_{A1} \\ G_B = G_F, G_{A1} = G_{E2} \end{array}\right\} \tag{8.65}$$

The transfer function for this realization is thus reduced to

$$T(s) = \frac{s^2 + a_0'}{s^2 + b_1' s + b_0} \tag{8.66}$$

where

$$\left.\begin{array}{l} a_0' = \frac{G_{A1}^2}{C_{A1}C_{E2}}\left(1 - \frac{G_{C1}}{G_{A1}}\right) \\ b_0' = \frac{G_{A1}^2}{C_{A1}C_{E2}}\left(1 + \frac{G_{C1}}{G_{A1}}\right) \\ b_1' = \frac{2G_{C1}}{C_{A1}} \\ a_0' < b_0' \text{ and } a_0 > 0 \\ \text{for} \\ \frac{G_{C1}}{G_{A1}} < 1 \end{array}\right\} \tag{8.67}$$

In this case, the zeroes of transfer function are at $s <\pm j\omega_n$.

The nominal values of ω_n and Q are given by

$$\omega_n = \left[\frac{G_{A1}(G_{A1} + G_{C1})}{C_{A1}C_{E2}}\right]^{\frac{1}{2}} \tag{8.68}$$

and

$$Q = \frac{1}{2}\left(1 + \frac{G_{A1}}{G_{C1}}\right)^{\frac{1}{2}} \tag{8.69}$$

If $G_{A1} \gg G_{C1}$, a very high Q may be obtained.

Using the general expressions given by Eqs. (8.31) and (8.32) for ω_n and Q and the constraints of Eqs. (8.65), Q and ω_n sensitivities may be obtained as

$$\left.\begin{array}{l} S_{C_{A1}}^{Q} = 0, \quad S_{C_{E2}}^{Q} = 0 \\ S_{G_B}^{Q} = 2Q^2 - \frac{1}{2}, \quad S_{G_F}^{Q} = \frac{1}{2} - 2Q^2 \\ S_{G_{A1}}^{Q} = 1 - \frac{1}{8Q^2} - 2Q^2 \\ S_{G_{C1}}^{Q} = -\frac{1}{2} + \frac{1}{8Q^2}, \quad S_{G_{E2}}^{Q} = 2Q^2 - \frac{1}{2} \end{array}\right\} \tag{8.70}$$

and

$$\left.\begin{array}{l} S_{C_{A1}}^{\omega_n} = S_{C_{E2}}^{\omega_n} = -\frac{1}{2} \\ S_{G_{E2}}^{\omega_n} = \frac{1}{2}, \quad S_{G_{A1}}^{\omega_n} = \frac{G_{A1}}{2(G_{A1}+G_{C1})} \\ S_{G_{C1}}^{\omega_n} = \frac{G_{C1}}{2(G_{A1}+G_{C1})} \end{array}\right\} \tag{8.71}$$

8.7 Economic Aspect of Filter Realizations

A few filter realizations described here are such that by addition or deletion of one or two elements one may obtain another realization having Q of the same order.

With the circuit configuration shown in Fig. 8.3a, second-order low pass filter realization with specifications may be obtained by short circuiting one resistor element G_{A1} of G_{E2} and open circuiting or blowing off the resistor G_{C1}. Bandpass filter having the same Q and the following other specifications may be obtained by open circuiting or blowing off the short circuit across G_{A1}.

$$\left.\begin{array}{l} \omega_n = \dfrac{G_{A1}}{(2C_{A1}C_{E2})^{\frac{1}{2}}}, \quad Q = \left(\dfrac{C_{E2}}{2C_{A1}}\right)^{\frac{1}{2}} \\ C_{A1} = C_{C1}, G_B = G_F \text{ and } G_{A1} = G_{E2} \end{array}\right\} \tag{8.72}$$

Bandpass filter having the same Q and the following other specification

$$\left.\begin{array}{l} \omega_n = G_{A1}\left(\dfrac{2}{C_{A1}C_{E2}}\right)^{\frac{1}{2}} \\ C_{A1} = C_{C1}, G_{E2} = 2G_{A1} = 2G_{C1} \end{array}\right\} \tag{8.73}$$

and

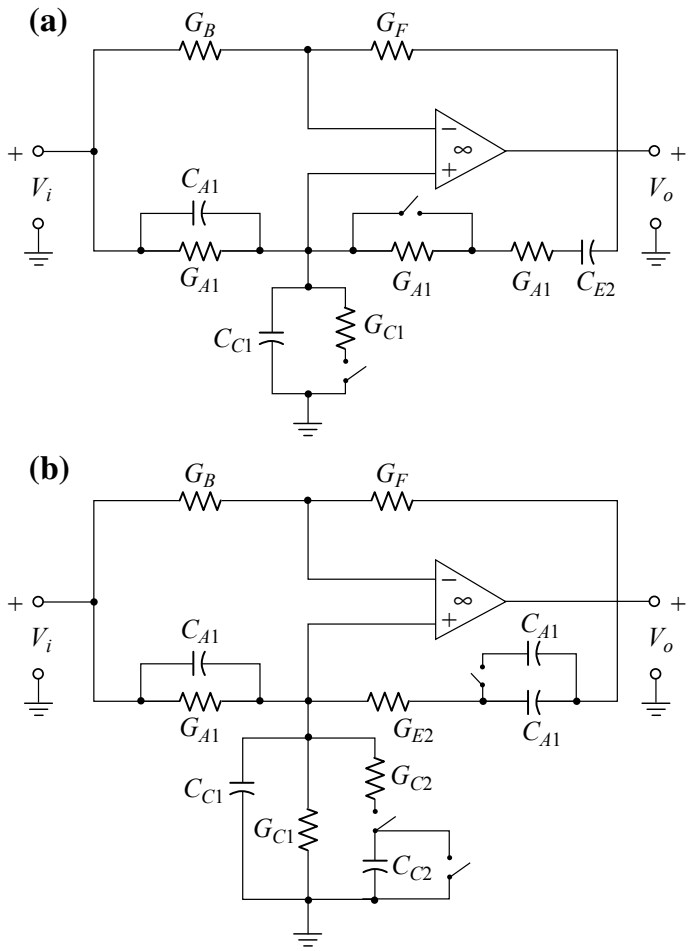

Fig. 8.3 **a** Circuit for low-pass or bandpass realization ($G_{E2} = G_{A1}$ or $2G_{A1}$). **b** Circuit for high-pass, bandpass or band stop filter ($a_0 = b_0'$) realizations with $C_{E2} = C_{A1}$ (or $2C_{A1}$, $G_{C1} = G_{C2} = G_{A1}$)

$$G_B = G_F$$

maybe obtained by open circuiting or blowing off the short circuit across E_{A1}.

Similarly, with another circuit configuration shown in Fig. 8.3b, high-pass realization, first bandpass and first band stop realization discussed earlier, may be obtained by appropriately short circuiting and open circuiting of elements.

Realization of various filter circuits from one common configuration thus reduces the cost.

8.8 Conclusion

It has been shown that a second-order filter having a high Q may be realized with seven or eight elements by employing a differential input operational amplifier. From the same circuit configuration, other filter realizations having Q of the same order may be obtained, thereby reducing the manufacturing cost. It has been observed that with these realizations, Q sensitivities are of high value and in certain cases, proportional to Q^2. Further, the Q sensitivity is not much affected by addition of other elements,

for example, series RC impedances of Fig. 8.1. The realizations would, therefore, be useful in low and moderate Q applications.

Chapter 9
Tolerance Minded Design of Active RC Bandpass Filters

Abstract The chapter deals with a simple transformation which allows the result of Zeheb for tolerance-minded design of active RC low-pass filters to be conveniently extended to active RC bandpass filters.

Keywords Tolerance minded design · Active RC bandpass filter

9.1 Introduction

In his 1970 paper, Zeheb [1], suggested a new approach for the tolerance minded design of Butterworth and Chebyshev low-pass and high-pass filters, which are realized as RC active networks. It is shown here that with suitable transformations, the results of Zeheb can be extended for the tolerance minded design of active RC bandpass filters.

Whereas for LC networks, transformation from low-pass to bandpass filters are well known in the literature, no such transformation appears to be generally available for filters which are realized as RC networks. A simple and convenient transformation for this purpose is presented here, based on the approximations used in the theory of stagger tuned amplifiers and commonly applied to LC bandpass filters [2]. This development presupposes that the frequencies under consideration are relatively large and that the associated bandwidth covers a narrow range.

The underlying transformation is from $s = \sigma + j\omega$ to $p = \Sigma + j\Omega$, where $\Sigma = \sigma/(\omega_p - \omega_0)$, $\Omega = (\omega - \omega_0)/(\omega_p - \omega_0)$ and ω_0 is the algebraic mean of the upper and lower cut-off frequencies ω_p and $2\omega_0 - \omega_p$, respectively (defining ω_0 in this fashion provides symmetrical response specifications on either side of ω_0). It is seen that as a result of this transformation, practically all results of Zeheb for low-pass filter carry over to bandpass case by simply replacing Zeheb's $X = \omega/\omega_1$ and $\mu = \omega_2/\omega_1$ by Ω and the quantity $(\omega_2 - \omega_0)/(\omega_p - \omega_0)$, respectively, where ω_2 is the 'critical' frequency in the stopband.

9.2 Butterworth Approximation

The transfer function of n units of cascaded second-order bandpass filters can be expressed as

$$T(s) = \frac{s^n}{(s - s_1)(s - s_1^*)(s - s_2)(s - s_2^*) \ldots (s - s_n)(s - s_n^*)} \tag{9.1}$$

where asterisk denotes conjugate, and $s_i = \sigma_i + j\omega_i$, $i = 1, 2, \ldots n$.

As an example, the locations of poles and zeroes of a high Q bandpass filter with $n = 4$ are shown in Fig. 9.1 together with a phasor representation of Eq. (9.1) for $s = j\omega$. Note that for a high Q, $|\sigma_i| \ll |\omega_i|$, i.e. the poles are located close to the imaginary axis.

Let the frequencies under consideration be relatively large and the associated bandwidth cover a narrow range. Under such an assumption, the effect of single or multiple zeroes at the origin and the poles in the lower half s plane on the transfer function are insignificant relative to the effects of the poles in the upper half-plane in the proximity of the narrow range of frequency under consideration. Thus, the transfer function of the bandpass filter given by Eq. (9.1) can be approximated for $s = j\omega$ as

$$T(s) \cong \frac{k_0}{(j\omega - s_1)(j\omega - s_2) \ldots (j\omega - s_n)} \tag{9.2}$$

where

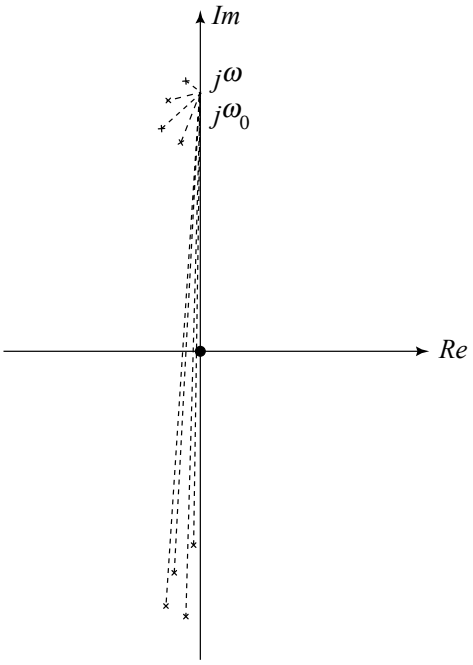

Fig. 9.1 Pole zero locations of a high Q bandpass filter with $n = 4$

$$k_0 = \frac{(j\omega_0)^n}{(j\omega_0 - s_1^*)(j\omega_0 - s_2^*)\ldots(j\omega_0 - s_n^*)} \tag{9.3}$$

and ω_0 is the algebraic mean of the upper and lower cut-off frequencies ω_p and $2\omega_0 - \omega_p$, respectively (defining ω_0 in this fashion provides symmetrical response specifications on either side of ω_0).

Let us make the response maximally flat at $\omega = \omega_0$ for Butterworth transfer function. To achieve this, we change the frequency variable from s to p such that

$$p = \frac{\sigma + j\bar{\omega}}{\omega_p - \omega_0} = \Sigma + j\Omega \tag{9.4a}$$

where

$$\bar{\omega} = \omega - \omega_0 \tag{9.4b}$$

This gives a change in the scale and a translation along the imaginary axis, such that when $s = 0 + j\omega_0, p = 0$ and the poles of the transfer function given by Eq. (9.1) are transformed to

$$p_i = \frac{\sigma_i + j(\omega_i - \omega_0)}{\omega_p - \omega_0}, \quad i = 1, 2, \ldots n \tag{9.5}$$

in the p-plane. The transfer function can now be approximated as

$$T(p) \cong \frac{k_0'}{(p - p_1)(p - p_2)\ldots(p - p_n)} \tag{9.6}$$

where

$$k_0' = \frac{k_0}{(\omega - \omega_0)^n} \tag{9.7}$$

For sinusoidal frequencies, the magnitude of this transfer function is of the form

$$|T(j\Omega)| = \frac{k'}{(\Omega^{2n} + A_1\Omega^{2n-1} + A_2\Omega^{2n-2} + \cdots + A_{2n-1}\Omega + A_{2n})^{\frac{1}{2}}} \tag{9.8}$$

where

$$k' = \left|k_0'\right|.$$

For maximally flat response at $\Omega = 0$ (i.e. $\omega = \omega_0$), $A_1 = A_2 = \ldots = A_{2n-1} = 0$, and hence

$$|T(j\Omega)| = \frac{k}{(1+\lambda\Omega^{2n})^{\frac{1}{2}}} \tag{9.9}$$

where

$$\lambda = \frac{1}{A_{2n}} = \left|\frac{1}{p_1 p_2 \ldots p_n}\right|$$

and

$$k = \frac{\omega_0^n/(A_{2n})^{\frac{1}{2}}}{\left[\{(\omega_0+\omega_1)^2+\sigma_1^2\}\ldots\{(\omega_0+\omega_n)^2+\sigma_n^2\}\right]^{\frac{1}{2}}(\omega_p-\omega_0)^n} \tag{9.10}$$

The magnitude function (attenuation) $\alpha(\bar{\omega})$ of the bandpass filter, having a narrow bandwidth remote from $\omega = 0$, may now be expressed as

$$\alpha(\bar{\omega}) = \ln(1+\lambda\Omega^{2n})^{\frac{1}{2}}$$

or

$$\exp[2\alpha(\bar{\omega})] = 1+\lambda\Omega^{2n} \tag{9.11}$$

Following Zeheb, for a first-order approximation, we have

$$\Delta\alpha(\bar{\omega}) = K\bar{\omega}\frac{\partial\alpha(\bar{\omega})}{\partial\bar{\omega}} \tag{9.12}$$

where

$$K = \frac{\Delta R}{R} + \frac{\Delta C}{C} \tag{9.13}$$

$\Delta R/R$ and $\Delta C/C$ being the extreme relative deviation from nominal value, overall resistors and all capacitors, respectively. $\Delta\alpha(\bar{\omega})$ is the deviation of $\alpha(\bar{\omega})$ from the theoretical magnitude which is arrived at if nominal value elements are used and no variations occur.

Equation (9.12) will now be applied to specific approximations for bandpass filter and deviation of α from the specifications will be expressed as an explicit function of K. Let the filter characteristic be approximated by delete this space and continue with Eq. (9.11).

Equation (9.11) and filter requirements be

$$\alpha(\bar{\omega}) \le \alpha_p \text{ for } \omega_0 - \omega_p \le \bar{\omega} \le \omega_p - \omega_0 \tag{9.14a}$$

and

$$\alpha(\bar{\omega}) \geq \alpha_a \text{ for } \bar{\omega}_2 \leq \bar{\omega} < \infty \text{ and } -\infty < \bar{\omega} \leq -\bar{\omega}_2 \tag{9.14b}$$

where ω_2 (ω_2 in $\bar{\omega}$ scale) is the 'critical' frequency in the stopband, α_a, α_p are in nepers ($\alpha_a \gg \alpha_p$) and ω_p, ω_0, ω_2, $\bar{\omega}$, $\bar{\omega}_2$ are in rad/sec.

From Eqs. (9.11) and (9.14a, b), we have

$$\alpha(\Omega)|_{\Omega=\pm 1} = \alpha_p \tag{9.15}$$

and

$$\alpha(\Omega)|_{\Omega=\pm\bar{\omega}_1/(\omega_p-\omega_0)} \geq \alpha_n \tag{9.16}$$

from which the constants λ and n of Eq. (9.11) be evaluated as

$$\lambda = \exp(2\alpha_p) - 1 \tag{9.17}$$

and

$$n = \frac{\left[\ln\{\exp(2\alpha_a) - 1\} - \ln\{\exp(2\alpha_p) - 1\}\right]}{2\ln\left[\bar{\omega}_2/(\omega_p - \omega_0)\right]} \cong \frac{2\alpha_a - \ln\{\exp(2\alpha_p) - 1\}}{2\ln\mu} \tag{9.18}$$

where

$$\mu = \frac{\bar{\omega}_2}{\omega_p - \omega_0} = \frac{\omega_2 - \omega_0}{\omega_p - \omega_0} \tag{9.19}$$

Using Eqs. (9.11)–(9.13), we have

$$\Delta\alpha(\Omega) = K\lambda n \frac{\Omega^{2n}}{1 + \lambda\Omega^{2n}} \tag{9.20}$$

Equation (9.20) is similar to the one derived by Zeheb for low-pass filter, with his $X = \omega/\omega_1$ replaced by Ω in our derivation. Further, it is seen that all the results and the design procedure of Zeheb for low-pass filter carry over to bandpass case by simply replacing Zeheb's X and $\mu = \omega_2/\omega_1$ by Ω and the quantity $(\omega_2 - \omega_0)/\left(\omega_p - \omega_0\right)$ respectively.

9.3 Conclusion

In this chapter, it has been shown that with suitable transformations, the results of Zeheb for the design of active RC low-pass Butterworth filter can be extended to

active RC bandpass filters. In a similar manner, one can obtain an expression for Chebyshev approximation of bandpass characteristics and extend Zeheb's results to this case also.

Chapter 10
Active RC Filters Using a Single Differential Input Operational Amplifier

Abstract A procedure, alternative to that proposed by Mitra, is given for realizing any real rational transfer function by using RC one ports and a single differential input operational amplifier. It is shown, with the help of examples, that the new procedure admits of much more flexibility in the choice of element values than Mitra's method.

Keywords Active RC filter · Differential input operational amplifier · Mitra's method

10.1 Introduction

The commercial availability of high-quality differential input operational amplifiers in the integrated form makes it profitable to develop synthesis procedures using this device as the active element. Many such techniques have appeared in the recent literature, for both driving point and transfer functions [1, 2]. The present chapter is concerned with the circuit of Fig. 10.1, which was proposed by Mitra [3] for realizing any arbitrary real rational transfer function. Assuming the operational amplifier to be ideal, analysis of this circuit yields

$$T(s) = \frac{V_0}{V_i} = \frac{Y_A(Y_B + Y_D + Y_F) - Y_B(Y_A + Y_C + Y_E)}{Y_F(Y_A + Y_C + Y_E) - Y_E(Y_B + Y_D + Y_F)} \tag{10.1}$$

In order to be able to express both numerator and denominator of Eq. (10.1) as the difference between two RC admittances, Mitra assumed [3].

$$Y_A + Y_C + Y_E = Y_B + Y_D + Y_F \tag{10.2}$$

The synthesis of a specified function

$$T(s) = N(s)/D(s) \tag{10.3}$$

starts by choosing a polynomial $Q(s)$ having distinct negative real roots and of degree satisfying

$$\text{deg } Q(s) + 1 \geq \text{higher of}[\text{deg } N(s), \text{deg } D(s)] \tag{10.4}$$

The next step is to make partial fraction expansions of $[N(s), D(s), D(s) - N(s)]/[sQ(s)]$; from these, the various admittances are identified as

$$\left.\begin{aligned} N(s)/Q(s) &= Y_A - Y_B \\ D(s)/Q(s) &= Y_F - Y_E \\ [D(s) - N(s)]/Q(s) &= Y_C - Y_D \end{aligned}\right\} \tag{10.5}$$

It can be shown that such identification of RC one ports satisfies the starting assumption given by Eq. (10.2).

We present here an alternative procedure for synthesizing any real rational $T(s)$ by the circuit of Fig. 10.1 without the need for assuming Eq. (10.2). The major advantage of the new procedure is shown to be a greater flexibility in the choice of element values, as compared to Mitra's method.

10.2 The New Method

We assume the upper tee of admittances in Fig. 10.1 to obey the relations

$$Y_D/Y_B = a \quad \text{and} \quad Y_F/Y_B = b \tag{10.6}$$

where a and b are arbitrary constants. In principle, Y_B may be an arbitrary RC admittance but, for practical convenience, we may choose Y_B to be a suitable conductance. Combining Eqs. (10.1) and (10.6), we get

$$T(s) = \frac{(a+b)Y_A - (Y_C + Y_E)}{b(Y_A + Y_C) - (1+a)Y_E} \tag{10.7}$$

Let the specified $T(s)$ be of the form of Eqs. (10.3) and let $Q(s)$ be chosen as in Mitra's method. Then we can write

$$N(s)/Q(s) = Y_1 - Y_2 \text{ and } D(s)/Q(s) = Y_3 - Y_4 \tag{10.8}$$

where $Y_1, \ldots, Y_4$ are realizable RC admittances. From Eqs. (10.7) and (10.8), we get the equations

$$(a+b)Y_A - Y_C - Y_E = Y_1 - Y_2 \tag{10.9}$$

and

$$Y_A + Y_C - [(1+a)/b]Y_E = Y_3/b - Y_4/b \tag{10.10}$$

Adding Eqs. (10.9) and (10.10) gives

$$Y_A - Y_E/b = [1/(1+a+b)][(Y_3/b + Y_1) - (Y_4/b + Y_2)] \tag{10.11}$$

Let

$$Y_A = [1/(1+a+b)][(1+m)Y_1 + (1+n)Y_3/b + pY_2 + qY_4/b] \tag{10.12}$$

Then Y_E is given by

$$Y_E = [b/(1+a+b)][mY_1 + nY_3/b + (1+p)Y_2 + (1+q)Y_4/b] \tag{10.13}$$

where m, n, p and q are constants. From Eqs. (10.9), (10.12) and (10.13), Y_C is obtained as

$$Y_C = [1/(1+a+b)][(ma-1)Y_1 + (ap+a+1)Y_2 + (an+a+b)Y_3/b + (aq-b)Y_4/b] \tag{10.14}$$

From Eqs. (10.12), (10.13) and (10.14), we see that *sufficient* conditions for RC realizability of Y_A, Y_C and Y_E are

$$p \geq 0, n \geq 0, m \geq 1/a \text{ and } q \geq b/a \tag{10.15}$$

That these conditions are not necessary will be shown with the help of an example in the last section. To simplify matters, we let conditions Eq. (10.15) to be satisfied with the equality signs. Then we get

$$\left.\begin{aligned} Y_A &= [1/(1+a+b)][(1+1/a)Y_1 + Y_3/b + Y_4/a] \\ Y_C &= [1/(1+a+b)][(1+a)Y_2 + (1+a/b)Y_3] \\ Y_E &= [1/(1+a+b)][Y_1/a + Y_2 + (1/b+1/a)Y_4] \end{aligned}\right\} \tag{10.16}$$

Note that the factor $1/(1+a+b)$ has the function of scaling the admittances. Any non-zero finite values of a and b can be chosen to complete the synthesis. For

example, if $a = b = 1$, then Eq. (10.16) become

$$Y_{\mathrm{A}} = (2Y_1 + Y_3 + Y_4)/3,\ Y_C = 2(Y_2 + Y_3)/3$$

and

$$Y_E = (Y_1 + Y_2 + 2Y_4)/3 \tag{10.17}$$

The examples worked out in the next section are based on the above identifications.

10.3 Two Examples

Example 1 Consider the synthesis of a notch filter characterized by

$$T(s) = N(s)/D(s) = \left(s^2 + 2.0\right)/\left(s^2 + 0.1s + 1.2\right) \tag{10.18}$$

Choosing $Q(s) = (s + 1)$ and making partial fraction expansions of $N(s)/[sQ(s)]$ and $D(s)/[sQ(s)]$, we identify

$$Y_1 = s + 2,\ Y_2 = 3s/(s + 1),\ Y_3 = s + 1.2 \text{ and } Y_4 = 2.1s/(s + 1) \tag{10.19}$$

Applying Eq. (10.17), we get

$$\begin{aligned} &Y_A = s + 1.733 + 0.7s/(s + 1),\ Y_C = 2s/3 + 0.8 + 2s/(s + 1) \text{ and} \\ &Y_E = s/3 + 2/3 + 2.4s/(s + 1) \end{aligned} \tag{10.20}$$

The synthesis of these one ports is elementary and the complete network is shown in Fig. 10.2a.

Choosing the same $Q(s)$ and applying Mitra's method, we get the network shown in Fig. 10.2b.

Example 2 Consider the all-pass function

$$T(s) = N(s)/D(s) = \left(-s^3 + 2s^2 - 2s + 1\right)/\left(s^3 + 2s^3 + 2s + 1\right) \tag{10.21}$$

Let

$$Q(s) = (s + 1)(s + 2) \tag{10.22}$$

Then by the usual procedure, we identify

$$\left.\begin{aligned} &Y_1 = \tfrac{1}{2} + (21/2)s/(s + 2),\ Y_2 = s + 6s/(s + 1), \\ &Y_3 = s + \tfrac{1}{2} \text{ and } Y_4 = (3/2)s/(s + 2) \end{aligned}\right\} \tag{10.23}$$

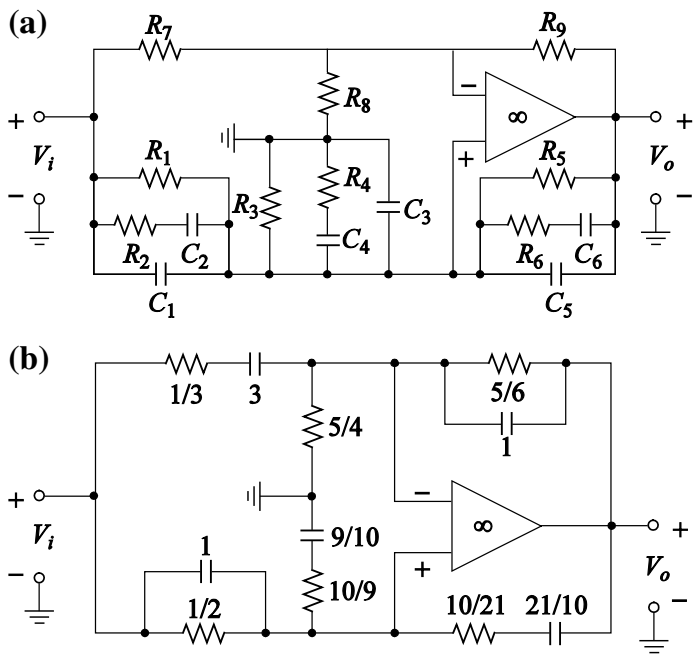

Fig. 10.2 **a** Example 1, synthesized by the new method (Element values are: $R_7 = R_8 = R_9 = R$ (arbitrary); $C_1 = 1$, $C_2 = 0.7$, $C_3 = 2/3$: $C_4 = 2$, $C_5 = 1/3$ and $C_6 = 2.4$: $R_1 = 3/5.2$, $R_2 = 1/0.7$; $R_3 = 1.25$, $R_4 = 1/2$. $R_5 = 1.5$ and $R_6 = 1/2.4$). **b** Example 1, synthesized by Mitra's procedure

Applying Eq. (10.17), we get

$$\left.\begin{aligned} Y_A &= \tfrac{1}{2} + s/3(15/2)s/(s+2),\ Y_C = 1/3 + (4/3)s \\ &\quad +4s/(s+1) \text{ and } Y_E = 1/6 + s/3 + 2s/(s+1) \\ &\quad +(9/2)s/(s+2) \end{aligned}\right\} \tag{10.24}$$

The complete network is shown in Fig. 10.3a. Figure 10.3b shows the network designed by Mitra's method to realize Eq. (10.21) with $Q(s)$ given by Eq. (10.22).

10.4 A Comparison of the Two Methods

In the new method, we require three predetermined resistances (which can be made equal) and three RC one ports to be synthesized, whereas Mitra's method requires the synthesis of six RC one ports. Compared to Mitra's method, a distinctive feature of the present approach is that it allows much more flexibility in the choice of clement values. This flexibility arises because in our method, besides $Q(s)$, one has the additional parameters a, b, m, n, p and q. These six parameters can be judiciously chosen for minimizing one or more of the following: sensitivity, number of passive components and the spread of element values. In Mitra's method, in contrast, the solution for RC one ports is unique, once $Q(s)$ is chosen. Another feature worth mentioning is that in our method, the two tees in the network of Fig. 10.1 can be independently scaled without changing the transfer function [this is because scaling

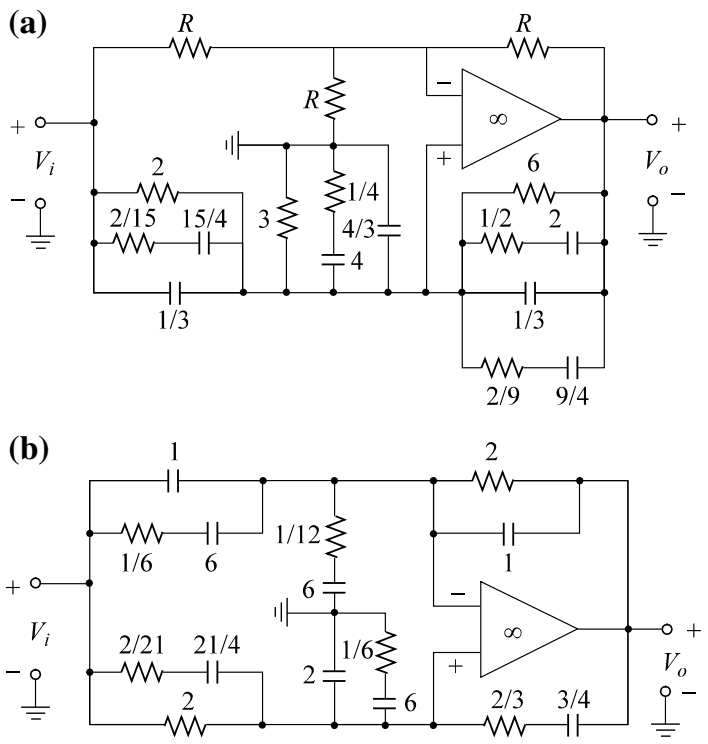

Fig. 10.3 **a** Example 2, synthesized by the new method; **b** Example 2, synthesized by Mitra's procedure

Y_B does not affect the transfer function given by Eq. (10.7)]. On the other hand, in Mitra's method, all the RC one ports have to be scaled by the same factor if $T(s)$ is not to be disturbed.

In the following section, we illustrate the flexibility of the new procedure with the help of Example 1.

10.5 An Illustration of the Flexibility of the New Method

The examples discussed previously show that our method requires more number of circuit elements than Mitra's method. Except the resistance spread in Example 1, the spreads are also seen to be higher in the networks designed by the new method. However, this is not true in general. The examples were worked out with the particular set of values $a = b = m = q = 1$ and $n = p = 0$. In what follows, we show that by taking advantage of the flexibility in choosing these six parameters, we are able to reduce the spreads to much lower values than the ones obtained in the circuits of Fig. 10.2a, b. Further, it will be shown that by choosing the six parameters properly, we may also reduce the number of circuit elements.

Consider Example 1 again. Combining Eq. (10.19) with Eqs. (10.12), (10.13) and (10.14) and letting $a = b = 1$, we get

$$\left.\begin{aligned} Y_A &= (1/3)[(2+m+n)s + (3.2+2m+1.2n)] + (3p+2.1q)s/(s+1)] \\ Y_B &= (1/3)[(1+m+n)s + (0.4+2m+1.2n) + (3p+2.1q+3.9)s/(s+1)] \\ Y_E &= (1/3)[(m+n)s + (2m+1.2n) + (5.1+3p+2.1q)s/(s+1)] \end{aligned}\right\} \tag{10.25}$$

We see from Eq. (10.25) that conditions in Eq. (10.15) are not necessary in this case. The complete network will be of the form shown in Fig. 10.2a with

$$\begin{aligned} &R_7 = R_8 = R_1 = R(\text{arbitrary}) \\ &C_1 = (2+m+n)/3,\ C_2 = P + 0.7q,\ C_3 = (m+n+1)/3 \\ &C_4 = p + 0.7q + 1.3,\ C_5 = (m+n)/3 \text{ and } C_6 = 1.7 + p + 0.7q; \end{aligned}$$

$$\left.\begin{aligned} &R_1 = 3/(3.2+2m+1.2n),\ R_2 = 1/(p+0.7q), \\ &R_3 = 3/(0.4+2m+1.2n),\ R_4 = 1/(p+0.7q+1.3), \\ &R_5 = 3/(2m+1.2n) \text{ and } R_6 = 1/(1.7+p+0.7q) \end{aligned}\right\} \tag{10.26}$$

If we choose $m = n = p = 10$ and $q = 0$, we get

$$\left.\begin{aligned} &R_7 = R_8 = R_9 = R(\text{arbitrary}) \\ &C_1 = 7.33,\ C_2 = 10,\ C_3 = 7,\ C_4 = 11.3,\ C_5 = 6.67 \text{ and } C_6 = 11.7, \\ &R_1 - 1/11.73,\ R_2 = 1/10,\ R_3 = 1/10.8,\ R_4 = 1/11.3, \\ &R_5 = 1/10.67, \text{ and } R_6 = 1/11.7 \end{aligned}\right\} \tag{10.27}$$

Choosing R anywhere between the highest and the lowest of the resistances R_1, …, R_6, we get resistance spread $\rho = 1.17$ and capacitance spread $\gamma = 1.755$, as compared to the figures $\rho = 3.6$ and $\gamma = 7.2$ in Fig. 10.2a and $\rho = 3.75$ and $\gamma = 3.33$ in Fig. 10.2b. Since the ideal values of ρ and γ are unity, we see that the design worked out above is indeed a very suitable one from the point of view of spread.

Next we consider minimizing the number of passive elements. In Eq. (10.26) if we put $m = n = p = q = 0$, then we get

$$\left.\begin{aligned} &R_7 = R_8 = R_9 = R(\text{arbitrary}) \\ &C_1 = 0.67,\ C_2 = C_5 = 0,\ C_3 = 0.33,\ C_4 = 1.3 \text{ and } C_6 = 1.7; \\ &R_1 = 1/1.07,\ R_2 = R_5 = \infty,\ R_3 = 1/0.133, \\ &R_4 = 1/1.3 \text{ and } R_6 = 1/1.7 \end{aligned}\right\} \tag{10.28}$$

Thus we get a total of 11 elements, as compared to 15 in Fig. 10.2a and 11 in Fig. 10.2b. Another desirable feature of the above design is that we have used only 4 capacitors instead of 6 in Fig. 10.2a and 5 in Fig. 10.2b.

Chapter 11
Second-Order Active RC Bandpass Filters Using Operational Amplifier in Low-Gain Connection

Abstract A critical study is made of a canonic second-order bandpass realization using a single-operational amplifier in low-gain (unity or two) connection. The circuit is suitable for low- and medium Q applications and features good stability, wide frequency range of operation and versatility of conversion to a high-pass filter. An all-grounded-capacitor version of the filter is also given; which is a desirable feature for integrated circuit (IC) implementation. The unity gain configuration presents component minimization over other similar circuits.

Keywords Active RC Bandpass filter · Second order · Operational amplifier · Low-gain connection

11.1 Introduction

A number of circuits have been proposed in the literature for the realization of second-order bandpass (BP) filters using one, two or more operational amplifiers (OA) along with an appropriate passive RC network [1–4]. All these circuits require a gain proportional to Q^2, thus posing stability problems and giving low-operating frequency range for high Q realizations. In order to obviate these disadvantages, Sedra [5] proposed a circuit using an OA in the unity gain connection (UGOA). In this chapter, a critical study is made of a different circuit which also requires a low-gain (unity or two) amplifier, but it enjoys component reduction over Sedra's circuit by two elements, thus making it a canonic structure in both active and passive components. Complex pole loci are plotted and an analysis is made of the frequency limitation based on the one-pole roll-off model of the OA. The upper bound on the frequency is calculated for the filter with OA in (a) unity gain (UG) (b) low-gain ($K_1 = 2$) connections, and it is shown that $K_1 = 2$ realization gives higher operating frequency range for $Q > 2\sqrt{2}$. The UGOA circuit has active sensitivity proportional to Q^2, but very low passive sensitivities. With a gain of 2, the active Q-sensitivity becomes proportional to Q, but passive sensitivities increase. In either

S. C. Dutta Roy, *Topics in Signal Processing*,
https://doi.org/10.1007/978-981-13-9532-1_11

case, the configuration has zero centre-frequency active sensitivity, $S_{K_1}^{\omega_0}$. An all-grounded version of the filter is also given. This feature coupled with the versatility of conversion to a high-pass (HP) filter makes the circuit attractive for IC hybrid realization for low and medium Q applications.

11.2 The Circuit Configuration

The circuit under consideration is shown in Fig. 11.1a and is essentially the Berndt and Dutta Roy's [6] inductor simulator (shown with the dotted lines), with a low-pass RC section cascaded at the input. The circuit has been briefly discussed by Russel [7]. It is canonic [8] and uses an OA with only five passive components. The transfer function obtained from the equivalent circuit in Fig. 11.1b is of the form

$$T(s) = Hs/\left(s^2 + \omega_0 s/Q + \omega_0^2\right) \tag{11.1}$$

with

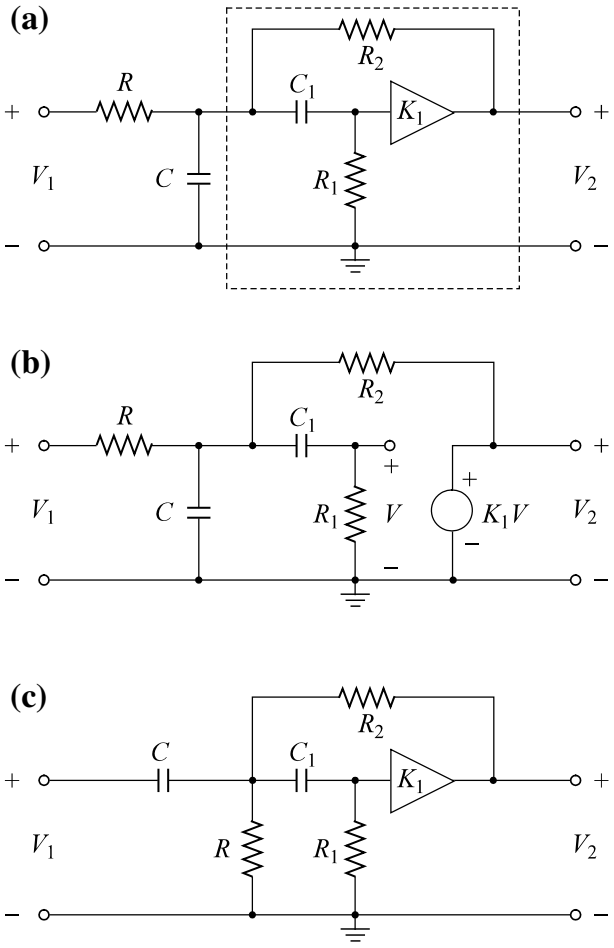

Fig. 11.1 **a** Bandpass filter with Berndt and Dutta Roy's inductor simulator shown within dotted lines. **b** Equivalent circuit of Fig. 11.1a. **c** High-pass filter from Fig. 11.1a

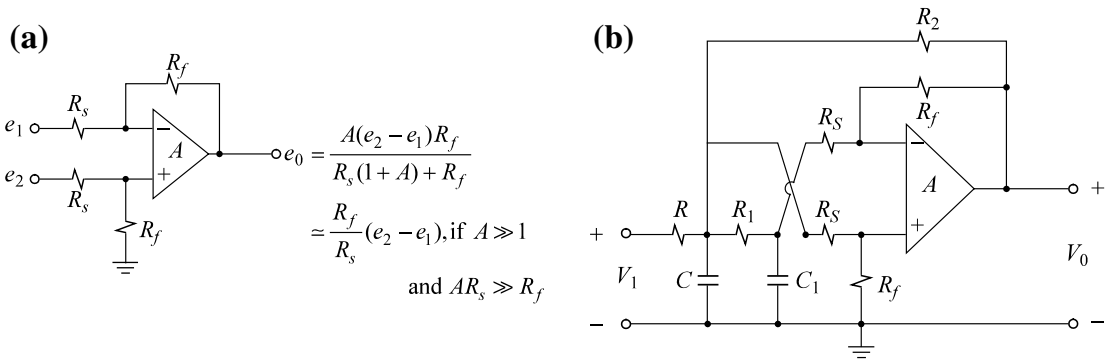

Fig. 11.2 **a** Difference amplifier. **b** All-grounded equivalent of the bandpass filter of Fig. 11.1a

$$H = K_1/RC \tag{11.2}$$

$$\omega_0 = [(R + R_2)/(CC_1RR_1R_2)]^{\frac{1}{2}} \tag{11.3}$$

and

$$Q = [CC_1RR_1R_2(R + R_2)]^{\frac{1}{2}}/[C_1R_2(R + R_1) + CRR_2 + C_1RR_1(1 - K_1)] \tag{11.4}$$

It can easily be verified that if R and C of the input section are interchanged, as in Fig. 11.1c, we get a second-order HP filter with the same ω_0 and Q as in Eqs. (11.3) and (11.4). If R in Fig. 11.1c is infinite, then one gets the Sallen and Key [4] HP circuit.

An all-grounded-capacitor version of the bandpass filter of Fig. 11.1a is shown in Fig. 11.2b, which is suitable for hybrid IC implementation [9]. This filter has the same ω_0 and Q as in Eqs. (11.3) and (11.4) and has been obtained by replacing the non-inverting OA stage by a differential-amplifier stage shown in Fig. 11.2a with its output $e_0 = K_1(e_2 - e_1)$, where $K_1 = R_f/R_s$. The structure is still canonic in capacitors and OA; however, the number of resistors has increased by two.

11.3 Sensitivity Considerations

The most important parameters for the filter performance are the pole Q and the pole-centre frequency ω_0. For the sensitivity of X to e_i, we use the standard definition

$$S_{e_i}^X = \frac{e_i}{X} \cdot \frac{\partial X}{\partial e_i} \tag{11.5}$$

It is apparent from Eq. (11.3) that $S_{K_1}^{\omega_0} = 0$, which is a desirable feature. Also from Eqs. (11.4) and (11.5), we get

$$S_{K_1}^{Q} = K_1 C_1 R R_1 / D \tag{11.6}$$

where D denotes the denominator in Eq. (11.4). The sensitivity of ω_0 to the passive elements are, from Eqs. (11.3) and (11.5)

$$S_R^{\omega_0} = -\frac{R_2}{2(R+R_2)}, \quad S_{R_2}^{\omega_0} = -\frac{R}{2(R+R_2)}, \quad S_{R_1}^{\omega_0} = S_C^{\omega_0} = S_{C_1}^{\omega_0} = -\frac{1}{2} \tag{11.7}$$

Thus $\left|S_{ei}^{\omega_0}\right| \leq \frac{1}{2}$. From Eqs. (11.4) and (11.5), the Q sensitivities can be calculated as

$$\left.\begin{aligned} S_R^Q &= (R + R_2/2)/(R+R_2) - [RR_2(C+C_1) + RR_1C_1(1-K)]/D \\ S_R^Q &= (R_2 + R/2)/(R_2+R) - [R_2C_1(R+R) + RR_2C]/D \\ S_{R_1}^Q &= \tfrac{1}{2} - R_1[C_1R_2 + RC_1(1-K_1)]/D \\ S_C^Q &= \tfrac{1}{2} - (CRR_2)/D \\ S_{C_1}^Q &= \tfrac{1}{2} - [C_1R_2(R+R_1) + C_1RR_1(1-K_1)/D] \end{aligned}\right\} \tag{11.8}$$

The order of S_{ei}^{Q} will be discussed in the following sections.

11.4 Design Equations

11.4.1 Case A: Unity Gain Configuration

Let $K_1 = 1$ and ω_0 be normalized to unity. Further, we preselect $C = C_1 = 1$; then Eqs. (11.3) and (11.4) can be written as

$$G_1(G + G_2) = 1 \text{ and } C = (1/Q) - 2G_1 \tag{11.9}$$

where $G_i = \mathrm{l}/R_i$. Eliminating G and solving for G_1 gives

$$G_1 = \frac{1}{4}\left\{(G_2 + 1/Q) \pm [(G_2 + 1/Q)^2 - 8]^{\frac{1}{2}}\right\} \tag{11.10}$$

For real G_1, we must have

$$G_2 \geq 2\sqrt{2} - (1/Q) \tag{11.11}$$

If G is to be positive, the second equation in (11.9) dictates that $G_1 < 1/(2Q)$. Combining this with Eq. (11.10) and taking negative sign (positive sign in Eq. (11.10) gives negative G) and simplifying, we get the additional restriction $G_2 > 2Q$. The final equations are

$$C = C_1 = 1, K_1 = 1, G_1 < 1/(2Q), G_2 > 2Q,$$

$$G = (1/Q) - 2G_1 \tag{11.12}$$

Under these conditions, Eq. (11.6) gives

$$S^Q_{K_1} = G_2/(G + 2G_1) > 2Q^2 \tag{11.13}$$

As is well known, when unity gain is obtained with an OA of gain A of the order of 10^6, $K = A/(1 + A) \approx 1$; so that $S^Q_A = S^Q_{K_1} \cdot S^K_A 1 > 2Q^2/A$. This shows a reduction of the sensitivity by the factor A. If $A = 10^6$, a Q of 500 will give S^Q_A of the order of $\frac{1}{2}$; the gain-sensitivity product (GS) is, however, of the order of $2Q^2$.

It has already been shown that $\left|S^{\omega_0}_{e_i}\right| \leq \frac{1}{2}$. Also, if $K = 1$, it is evident from Eq. (11.8) that $\left|S^Q_{e_i}\right| \leq 1$. For practical design values, $\left|S^Q_{e_i}\right|$ will be within $\frac{1}{2}$. As an example, let $C = C_1 = 1$, $K_1 = 1$, $R = R_1 = 3Q$, $R_2 = 1/3Q$; then the sensitivities are, for medium to high Q.

$$\left.\begin{array}{l} S^{\omega_o}_A = 0,\ S^Q_A = 3Q^2/A \\ S^{\omega_o}_R \simeq S^{\omega_o}_{R_2} \simeq -\frac{1}{2} = S^{\omega_o}_R = S^{\omega_o}_{C_1} = S^{\omega_o}_{R_1} \\ S^Q_R \approx 1/3,\ S^Q_{R_2} \simeq -\frac{1}{2},\ S^Q_{R_1} = S^Q_C = -S^Q_{C_1} = 1/6 \end{array}\right\} \tag{11.14}$$

The UGOA circuit has thus very low passive sensitivities and also presents component reduction. However, because of the high value of gain-sensitivity product (GS), the usefulness is limited to low and medium Q's only. It has been found that increasing the spread in capacitors does not lead to any marked improvement.

11.4.2 Case B: General K Configuration

For a general K_1, proceeding on similar lines, the following result is obtained for the case of minimum possible $S^Q_{K_1}$:

$$S^Q_{K_1 \min} = 2\sqrt{2}.Q - 1,\ K_1 > 2 - 1/(\sqrt{3}Q) \tag{11.15}$$

This implies that $K_1 = 2$ suffices to get any Q; and this can be obtained by using a high gain OA with equal resistors. The value of GS for this case is proportional to Q and the design equations are

$$K_1 = 2, C = C_1 = 1, G_2 = \sqrt{2} - 1/(2Q), G_1 = 1/\sqrt{2}, G = 1/(2Q) \tag{11.16}$$

Sensitivity calculation gives $\left|S^{\omega_o}_{ei}\right| \leq \frac{1}{2}$ as before; however, S^Q_C, $S^Q_{C_1}$, $S^Q_{R_1}$ and $S^Q_{R_2}$ become proportional to Q whereas $S^Q_R \simeq 3/2$. These passive Q sensitivities

agree with the order given by Mitra [10] for the denominator of the form $D(s) = (s+\alpha_1)(s+\alpha_2) - K_1 s$, to which Eq. (11.1) belongs. Thus only for $K_1 = 1$, there is a very significant reduction in the passive Q-sensitivity.

11.5 Frequency Limitation

In this section, frequency limitations are discussed for cases A and B and expression are derived for the highest usable frequency (ω_{0h}) for a given percentage deviation from nominal ω_0 and Q. The analysis and the pole-loci are based on the one-pole roll-off model of the OA. Assuming a finite gain-bandwidth product (GB), an infinite input impedance and $\{R_a A/(R_a + R_b)\} \gg 1$, the gain of the non-inverting amplifier is

$$K_1 = GB/\{s + (GB/K)\} \tag{11.17}$$

where A is the open-loop gain of OA and $K = 1 + R_b/R_a$ is the gain corresponding to infinite gain-bandwidth product (GB) and R_a, R_b are the biasing resistances.

11.5.1 Case A: OA in Unity Gain Configuration

With $K_1 = 1$, on substituting Eq. (11.17) in Eq. (11.1), the normalized denominator of the transfer function becomes

$$D(s_n) = (s_n^2 + s_n/Q + 1) + \frac{1}{GB_n} \cdot s_n[s_n^2 + (1/Q + L)s_n + 1] \tag{11.18}$$

where $s_n = s/\omega_o$, $GB_n = GB/\omega_o$, and

$$L = \{RR_1/[R_2(R+R)]\}^{\frac{1}{2}} \tag{11.19}$$

Using Budak–Peterela method [11], Eq. (11.18) can be put as $P_1(s_n) + (1/GB_n)P_2(s_n)$, with

$$\left.\begin{aligned} P_1(s_n) &= s_n^2 + (s_n/Q) + 1 \\ P_2(s_n) &= s_n[s_n^2 + (1/Q + L)s_n + 1] \end{aligned}\right\} \tag{11.20}$$

giving

$$\left.\begin{aligned} \frac{dP_n}{d(1/GB_n)} &= -P_2(s_n)/\frac{dP_1(s_n)}{ds_n}\Big|_{s_n=p_n} \\ &\triangleq -\frac{d\alpha_n}{d(1/GB_n)} + j\frac{d\beta_n}{d(1/GB_n)} \end{aligned}\right\} \tag{11.21}$$

where

$$p_n = -\alpha_n + j\beta_n = -(1/2Q) + j[1 - 1/4Q^2]^{\frac{1}{2}} \tag{11.22}$$

Following Budak et al. [11], the above equations can be manipulated to give

$$\frac{d\alpha_n}{d(1/GB_n)} = \frac{-L}{2Q}, \frac{d\beta_n}{d(1/GB_n)} = -\frac{(4Q^2-2)L}{8Q^2[1-1/4Q^2]^{\frac{1}{2}}} \tag{11.23}$$

$$\simeq -L/2 \tag{11.24}$$

where Eq. (11.24) holds for medium and high Q. Using Budak [11], Eqs. (11.13) and (11.14), and substituting Eq. (11.23) yields

$$\frac{d\omega_o}{d(1/GB_n)} = -\frac{\omega_o L}{2}; \frac{dQ}{d(1/GB_n)} = \frac{QL}{2} \tag{11.25}$$

Thus after the first-order correction to the nominal values of ω_0 and Q_1, the actual values are

$$\begin{aligned} \omega_{oa} &= \omega_o(1 - \omega_o L/2GB) \\ Q_a &= Q(1 + \omega_o L/2GB) \end{aligned} \tag{11.26}$$

Equations in (11.26) are the frequency limitation equations of the filter with UGOA. For a prescribed variation in ω_0 and Q of x percent from the nominal values, the highest usable frequency is

$$\omega_{o\hbar} \leq x \cdot GB/(50L) \tag{11.27}$$

11.5.2 Case B: OA in Gain = 2 Configuration

Proceeding as in case A it can easily be shown that Eq. (11.18) still represents the pole-defining equation with $GB'_n (= GB_n/2)$ replacing GB_n. The differential change in the real and imaginary parts of the complex poles and the actual ω_0 and Q can easily be shown to be

$$\frac{d\alpha_n}{d(1/GB'_n)} = \frac{-L}{Q}; \frac{d\beta_n}{d(1/GB'_n)} = -\frac{(4Q^2-2)L}{4Q^2[1-1/4Q^2]^{\frac{1}{2}}} \tag{11.28}$$

$$\left.\begin{aligned} \omega_o a &= \omega_o(1 - 3\omega_o L/GB) \\ Q_a &= Q(1 + 2\omega_o L/GB) \end{aligned}\right\} \tag{11.29}$$

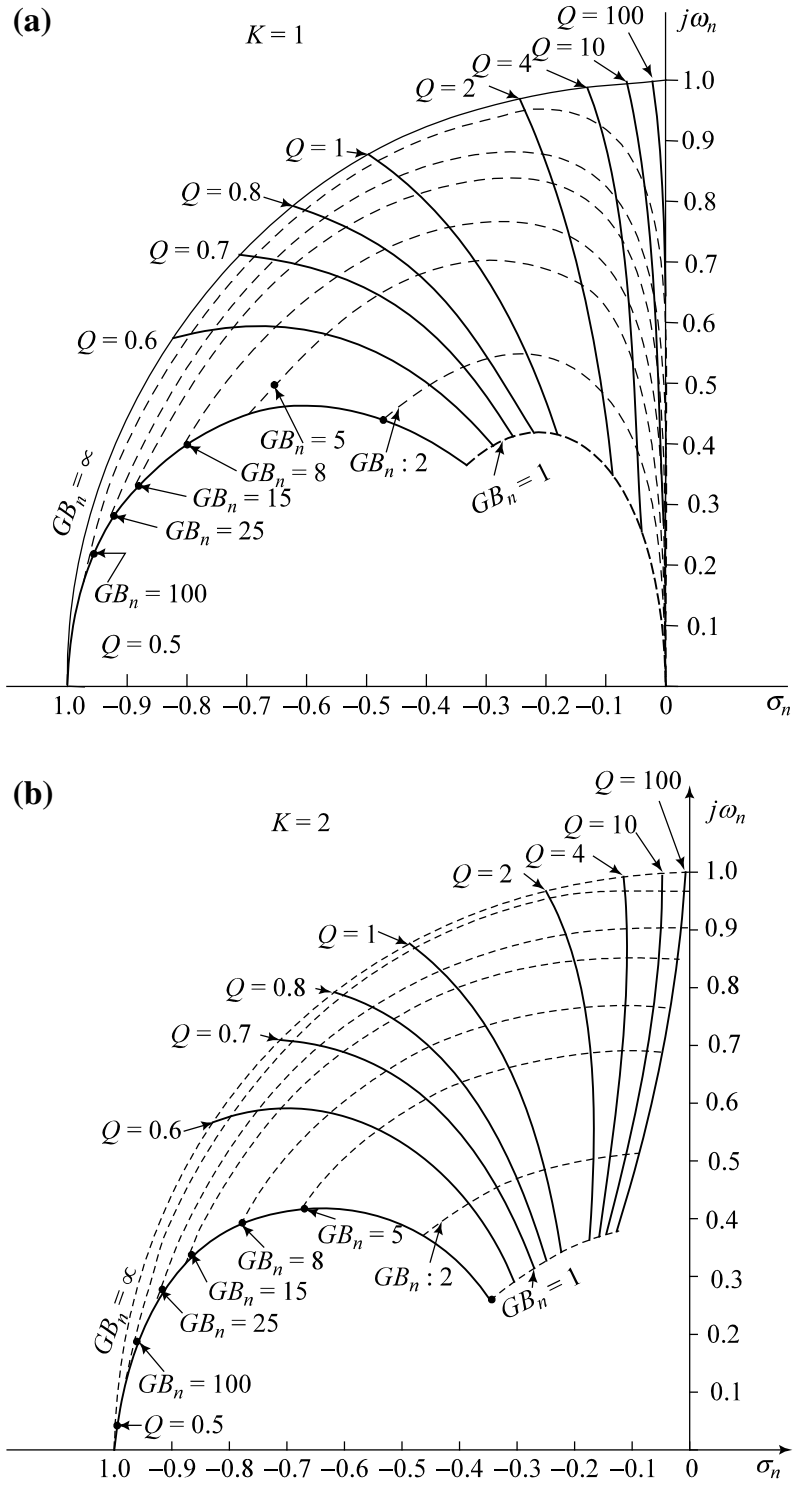

Fig. 11.3 **a** Pole-loci for UGOA realization. **b** Pole-loci for general low-gain ($K = 2$) realization

Thus the highest usable frequency for x percent allowed variation is

$$\omega_{0\hbar} < x \cdot GB/(200L) \tag{11.30}$$

The quantity given by Eq. (11.19) is an important design parameter for determining the value of ω_{0a}, Q_a and $\omega_{0\hbar}$. In order to compare the frequency limitations of the two cases, we find from the design Eqs. (11.12) and (11.16) developed in Sect. 11.4,

$$L\Big|_{K}^{\min} = 1 > 2Q \text{ and } L\Big|_{K}^{\max} = 2 < \sqrt{2} \tag{11.31}$$

giving

$$\left.\begin{aligned} \omega_{o\hbar}|K = 1 &< x/100(GB/Q) \\ \omega_{o\hbar}|K = 2 &> x/200(GB/\sqrt{2}) \end{aligned}\right\} \tag{11.32}$$

Then for $Q > 2\sqrt{2}$, OA in $K_1 = 2$ connection can realize higher $\omega_{0\hbar}$ compared with the UGOA case for the same percentage deviation in ω_o and Q from nominal values.

Equation (11.18) is used for plotting the complex pole-loci as shown in Fig. 11.3a, b for cases A and B, respectively, as a function of Q and GB_n for L determined from the design equations. The two sets of curves are similar in nature and show that a decrease in GB_n from the nominal value results in a new pole location having lower ω_0 (and probably also Q). With increasing Q, the curves of Fig. 11.3a approach the $j\omega_n$—axis faster than those of Fig. 11.3b. However, the poles are always confined to the left half-plane in both the cases, thus ensuring stable operation.

11.6 Conclusion

This chapter discusses canonic bandpass filters using OA in unity gain and low-gain configurations and thus giving a large frequency range of operation. A detailed study is made of the two cases with regard to sensitivity, gain-sensitivity product and the frequency limitations. The UGOA circuit has low passive sensitivity besides giving passive component minimization over similar circuits. By increasing the gain to $K_1 = 2$, a marked improvement is shown in the active Q-sensitivity, the gain-sensitivity product and the frequency limitations (for $Q > 2\sqrt{2}$) over the UGOA case. The improvement is however at the cost of passive Q-sensitivity, thus demanding higher tolerances in R's and C's. An all-grounded-capacitor equivalent of the filter is given which, coupled with the other advantages already discussed, makes it attractive for IC implementation. The circuit enjoys $S_{K_1}^{\omega_o} = 0$.

Chapter 12
Some Recent Contributions to Inductor Simulation and Applications to Low-Sensitivity Biquad Design

Abstract Following a brief discussion on the advantages of inductor simulation approach to active filter design, some recent circuits for grounded as well as floating inductors are discussed. The application of simulated inductors to insensitive biquadratic design is illustrated by reference to two recently published techniques.

Keywords Inductance simulation · Active RC networks

12.1 Introduction

As is well known, active RC filters can be designed either in direct form or in cascade form. In the latter, the prescribed transfer function is realized as a cascade of lower order sections, usually active second order and passive first-order ones. In the direct form, no such decomposition is necessary and the realization is in terms of one structure. Of the various techniques available for this purpose, the more well-known ones are the inductance (L) simulation, the frequency-dependent negative resistance and the generalized impedance converter approaches. It is the first approach that the present chapter is concerned with. In this, a conventional RLC filter is first designed, and then each inductor is replaced by an equivalent active RC one port. There are two advantages of this simple minded procedure. First, the well-established passive synthesis procedures and extensive tables can be used conveniently. Second, as pointed out in [1], this technique often leads to a more stable and a less sensitive realization as compared to other methods. The advantages with regard to sensitivity can be illustrated by considering the doubly terminated lossless network of Fig. 12.1. Let

$$Z_i(j\omega) = R + jX \tag{12.1}$$

The power input P_i (and hence the power delivered to the load, P_L) is given by

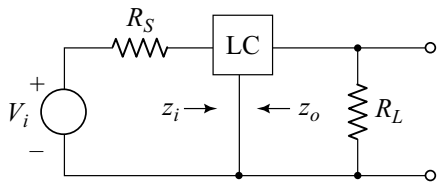

Fig. 12.1 A doubly terminated LC network

$$P_i = P_L = |V_i|^2 R/\left[(R + R_s)^2 + X^2\right]. \tag{12.2}$$

Let x be a parameter of the LC network. Then the sensitivity of P_L to x is

$$S_X^{P_L} = (x/P_L)[(\partial P_L/\partial R)(\partial R/\partial x) + (\partial P_L/\partial X)(\partial X/\partial x)] \tag{12.3}$$

From Eq. (12.2)

$$\partial P_L/\partial R = |V_i|^2(R_s^2 - R^2 + X^2)/[(R + R_s)^2 + X^2]^2 \tag{12.4}$$

and

$$\partial P_L/\partial X = -2|V_i|^2 RX/[(R + R_s)^2 + X^2]^2. \tag{12.5}$$

Normally, doubly terminated LC filters are designed to have maximum power transfer at frequencies of minimum loss in the passband. This implies that at these frequencies,

$$R = R_s \text{ and } X = 0$$

which, combined with Eqs. (12.4) and (12.5), lead to the conclusion that P_L is insensitive to small variations in the components of the LC network. Similar arguments can be given to show that the output impedance Z_0 should equal R_L for zero sensitivity in the passband.

The essential task in L simulation approach to active filter design is, obviously, that of designing insensitive active RC one ports having impedances proportional to the complex frequency s. Also, for successful implementation of this technique, the circuits for both grounded and floating inductor simulation are required.

12.2 Gyrator Based Methods

Essentially, all active RC circuits for simulating an inductor can be viewed as the realization of gyrators, a gyrator being a nonreciprocal two port, ideally described by the z-matrix

$$[z] = \begin{bmatrix} 0 & -r \\ r & 0 \end{bmatrix} \tag{12.6}$$

The symbolic representation of a gyrator and its use in simulating a grounded inductor are shown in Fig. 12.2. When two gyrators are cascaded with a capacitor interposed between the two, as shown in Fig. 12.3, one gets a floating inductor. It appears, therefore, that all problems of L simulation are solved if one can realize the z-matrix of Eq. (12.6). A large number of circuits using discrete components and integrated gyrators have been proposed in the literature, of which the Riordan circuit [2] is the most popular; a variation of the Riordan circuit, proposed by Antoniou [3] is shown in Fig. 12.4 and is considered as the best circuit for the purpose.

In general, a practical gyrator deviates from the ideal one, described by Eq. (12.6), in that $z_{11} \neq 0$, $z_{22} \neq 0$, and $z_{12} \neq -z_{21}$. The active element phase shifts cause additional complications. These lead to stability and sensitivity problems, but the most important effect is that the realized L becomes frequency dependent and lossy with a finite maximum Q [4].

The problem becomes much more serious in the case of floating-L simulation because, in addition to realizing two ideal gyrators, we also need an exact match between their gyration resistances. Many solutions have so far been proposed, but it

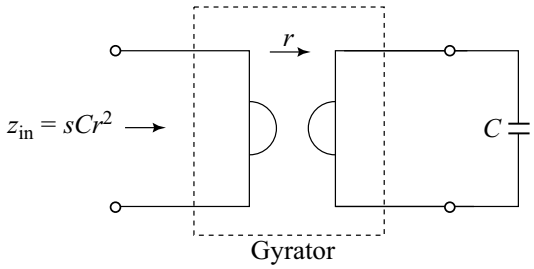

Fig. 12.2 Schematic of a gyrator and its use in L simulation

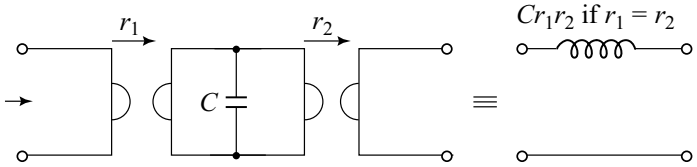

Fig. 12.3 Two gyrators used to simulate a floating L

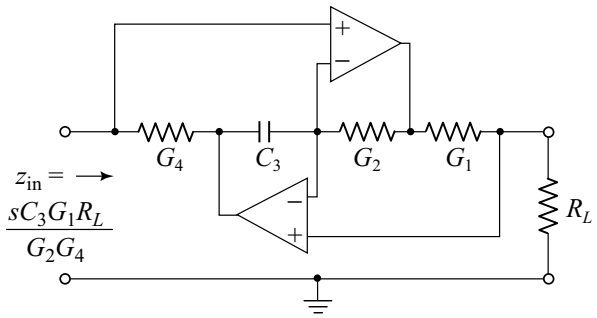

Fig. 12.4 Antoniou's circuit for a gyrator

has been appreciated that all such gyrator based realizations suffer from the need for accurate matching, in addition to excessive number of active and/or passive elements.

It has been amply demonstrated in recent years that what can be achieved by nonideal gyrators can also be obtained by using much simpler and more economic circuits. For example, a lossy grounded inductor circuit may typically consist of one operational amplifier (OA) connected in the unity gain (UG) configuration, two resistors and a capacitor. Similarly, a lossy floating inductor can be made from two UG amplifiers (UGA), three resistors and two capacitors. It is with some of these circuits and their applications that we concern ourselves in the rest of this chapter [5].

As already mentioned, we deal here with some selected contributions only; for other recent contributions, one may refer to the bibliography prepared by the author as referred to in [6], which lists papers published during the period 1971–early 1975. For literature published earlier, reference is made to Beddoes and Morin [7], Mitra [8] and Miller and Newcomb [9].

12.3 General Characteristics of Lossy, Grounded *L* Simulators

All L simulators using a single capacitor realize a bilinear RL impedance of the form

$$Z(s) = H(s\tau_1 + 1)/(s\tau_2 + 1),\ \tau_1 > \tau_2 \tag{12.7}$$

Two canonical passive realizations of Eq. (12.7) are shown in Fig. 12.5. An important special case arises when $\tau_2 = 0$, thus giving a series RL impedance; this will be designated as type A. A parallel RL impedance is obtained when $H \to 0$, $\tau_1 \to \infty$, but $H\tau_1$ is finite, this will be called type B. The general case of Fig. 12.5 will be referred to as type C. Setting $s = j\omega$ in Eq. (12.7), it is easy to show that the realized L and its Q are

$$L = H(\tau_1 - \tau_2)/(1 + \omega^2\tau_2^2)\ \&\ Q = \omega(\tau_1 - \tau_2)/(1 + \omega^2\tau_1\tau_2) \tag{12.8}$$

with the Q reaching a maximum value of

$$Q_0 = (1/2)\left(\sqrt{\tau_1/\tau_2} - \sqrt{\tau_2/\tau_1}\right) \tag{12.9}$$

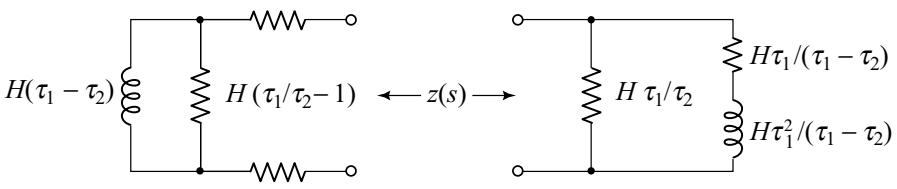

Fig. 12.5 Canonical representations of a bilinear RL impedance

at the frequency

$$\omega_0 = 1/\sqrt{\tau_1 \tau_2} \tag{12.10}$$

At $\omega = \omega_0$, the inductance value is

$$L_0 = L_{dc}/(1 + \tau_2/\tau_1) \cong L_{dc} \tag{12.11}$$

where L_{dc} is the dc value of L and the approximation is valid for high Q_0. For types A and B, L and Q are, respectively, given by

$$L = H\tau_1 \text{ and } Q = \omega\tau_1 \tag{12.12}$$

and

$$L = H\tau_1/(1 + \omega^2\tau_2^2) \text{ and } Q = 1/(\omega\tau_2) \tag{12.13}$$

The sensitivities of L and Q to any parameter can be found by routine calculations. For type C, evaluating the sensitivity at $\omega = \omega_0$, it can be shown that

$$S_X^Q = (1/2)[(\tau_1 + \tau_2)/(\tau_1 - \tau_2)](S_X^{\tau_1} - S_X^{\tau_2}). \tag{12.14}$$

Since a single capacitor, C, is used, both τ_1 and τ_2 must be proportional to C; thus

$$S_C^Q|_{\text{Type C},\omega=\omega_0} = 0 \tag{12.15}$$

12.4 Simple Circuits for Lossy Grounded Inductance

12.4.1 Four-Component Circuits

Two remarkably simple circuits were forwarded by Prestcott [10] and Berndt and Dutta Roy [11] and are shown in Fig. 12.6a and b, respectively. Note that the only

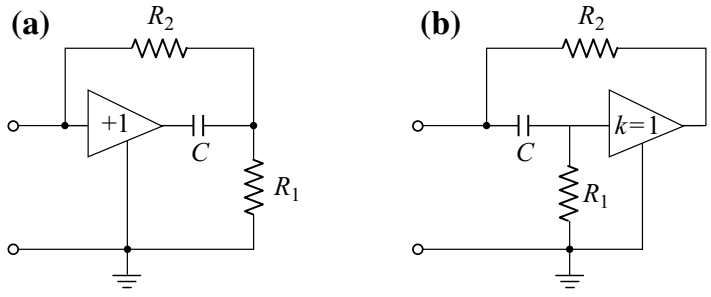

Fig. 12.6 **a** Prestcott circuit for grounded L simulation. **b** Berndt–Dutta Roy circuit for the same purpose

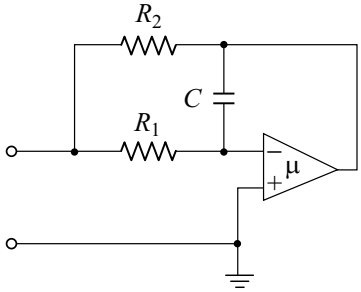
Table 12.1 Performance characteristics of Prestcott and Berndt–Dutta Roy circuits

	Prestcott	Berndt–Dutta Roy (at $\omega = \omega_0$)
Type	A	C
R-spread	May be unity	$4Q_0^2$
S_μ^L (μ = OA gain)	$\cong 2/\mu$	$\cong 3/\mu$
$S_{C,R_1R_2}^L$	1	$\cong 1$
S_C^Q	1	0
$\left\lvert S_{R_1,R_2}^Q \right\rvert$	1/2	$\cong 1/2$
S_μ^Q	$\cong 2Q^2/\mu$	$\cong 2Q_0^2/\mu$
Gain Sensitivity Product (GSP)	$\cong 2Q^2$	$\cong 2Q_0^2$

Fig. 12.7 Ford and Girling scheme for L simulation



difference between them is the position of the CR differentiating network. This, however, leads to quite different characteristics, as given in Table 12.1. A non-zero input admittance (G_i) and output impedance (R_0) of the active element can be absorbed in R_1 and R_2, respectively in Berndt–Dutta Roy circuit; the effect of either or both in Prestcott circuit is to convert this to a type C circuit.

Figure 12.7 shows a circuit proposed by Ford and Girling [12]. With $\mu = \infty$, which is a rather ideal situation, it behaves as type B, with the following characteristics:

R-spread may be unity;

$$S_\mu^{L,Q} = 0;\ S_{C,R^1,R^2}^L \cong 1;$$

$$S_C^Q = -1;\ \left\lvert S_{R^1,R^2}^Q \right\rvert - 1/2 \text{ and GSP} = 0. \tag{12.16}$$

where GSP = Gain Sensitivity Product.

With finite μ, however, we get a type C circuit with deteriorated characteristics, the major effect being that the GSP now becomes $2Q_0^2$. Further, since the OA is used here without any negative feedback other than that provided by the R_1 R_2 C network, the performance of the circuit will be severely frequency limited.

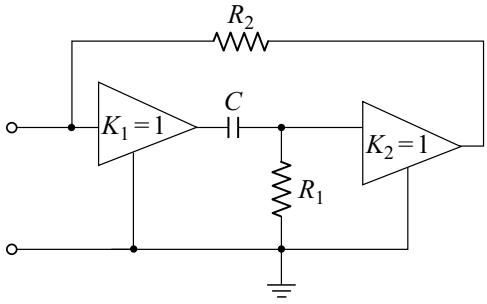


Fig. 12.8 Rao–Venkateswaran generalization of Prestcott and Berndt–Dutta Roy circuit

12.4.2 Five-Component Circuit

A generalization of Prestcott and Berndt–Dutta Roy circuits was proposed by Rao and Venkateswaran [13] and is shown in Fig. 12.8. This is a type *A* circuit with the following characteristics:

R-spread may be made unity;

$$\begin{aligned} S^{L}_{\mu_1,\mu_2} &= 1/(\mu_{1,2}+1); \\ S^{L}_{C,R_1,R_2} &= 1;\ S^{Q}_{\mu_1,\mu_2} = (1+Q^2)/(\mu_{1,2}+1);\ S^{Q}_{C,R_1} = 1; \end{aligned} \tag{12.17}$$

$S^{Q}_{R} = 0$; $(\mathrm{GSP})_1 \cong (\mathrm{GSP})_2 \cong Q^2$; and L can be adjusted independent of Q.

12.4.3 Circuits Using Six Components

The Berndt–Dutta Roy circuit of Fig. 12.6b realizes an impedence

$$Z(s) = R_2(sCR_1+1)/\{sC[R_2+R_1(1-k)]+1\} \tag{12.18}$$

If we let

$$k = 1 + (R_2/R_1) \tag{12.19}$$

in the manner shown in Fig. 12.9, we get a six-component type *A* circuit. However, this circuit is potentially unstable because, if due to any reason, for example, a change of temperature, k becomes greater than $1 + (R_2/R_1)$, i.e. $R_1\ R_A$ becomes greater than R_2R_B, a pole is created in the right half-plane.

The Caggiano circuit [14] has the same topology as that of Fig. 12.9 but the impedance is now measured across R_1. It suffers from the same stability problem as in the circuit just discussed. With k in the range $1 < k < (1 + R_2/R_1)$ in either of these two circuits, one obtains a type *C* performance with no improvement over the Berndt–Dutta Roy circuit.

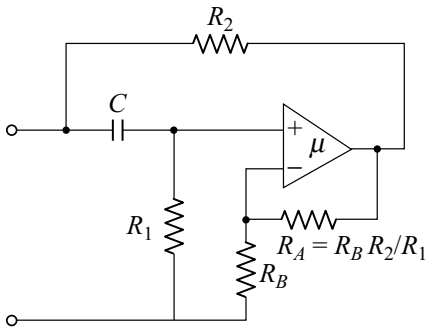

Fig. 12.9 Berndt–Dutta Roy circuit operated as type *A*

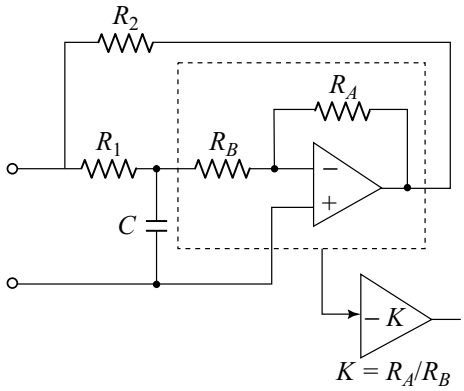

Fig. 12.10 Musiedlak and McPherson circuit

The circuit shown in Fig. 12.10 uses a negative gain amplifier and has been suggested by Musiedlak and McPherson [15]. Note that this circuit can be derived from the low-sensitivity Sallen and Key [16] resonator in Geffe [17], by interchanging the resistors and capacitors and short circuiting the input capacitor.[1] This is a type-C circuit with the following features.

Minimum gain required, $k = 4Q_0^2$; R-spread $= 16Q_0^4$;

$$S_\mu^L \cong -4Q_0^2/\mu;\ \left|S^L_{RA,B,C_1,2}\right| \cong 1;\ S_\mu^Q \cong 2Q_0^2/\mu;\ \left|S^Q_{RA,B}\right| \cong 1/2;\ \left|S^Q_{R_1,2}\right| \cong 1/(8Q_0^2);$$
$$S_C^Q = 0 \text{ and } GSP = 2Q_0^2 \tag{12.20}$$

The sensitivities are seen to be low, and the grounded capacitor is a desirable feature for IC implementation; however, the requirement of high gain severely limits the frequency range of application. Another disadvantageous feature is the high *R*-spread, and the design constraint of $R_B \gg 1/(\omega C)$ at the frequencies of interest.

By changing the position of the R_1C integrating network in Fig. 12.10 to the output, we obtain the circuit of Fig. 12.11, which has the same sensitivity and other performance characteristics as those of the parent circuit, but has the advantage that the finite input impedence R_B of the gain block does no longer put a design constraint.

If the capacitor in Fig. 12.10 is returned to the output instead of ground, as shown in Fig. 12.12, we get the finite gain version of Ford and Girling circuit. Compared to

[1]The Prestcott and Berndt–Dutta Roy circuits may also be so derived from the Sallen and Key catalog [17].

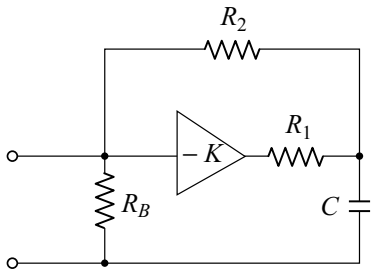

Fig. 12.11 Circuit derived from Fig. 12.10 by changing the position of the R_1C network

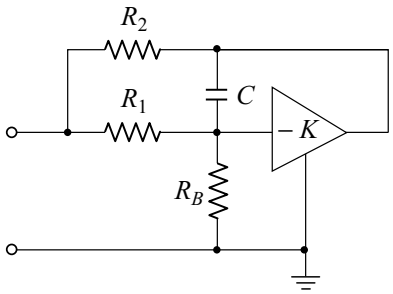

Fig. 12.12 Circuit derived from Fig. 12.10 returning C to amplifier output

Fig. 12.10, it loses the advantage of a grounded capacitor but has the advantage of reducing S^L_{μ,R_A,R_B} by the factor $1/(4Q_0^2)$.

12.4.4 Comments

A major conclusion of this presentation of grounded inductance simulators is that while the sensitivity of L and Q to passive elements can be made reasonably small, the sensitivity of Q to the active element and the gain itself cannot be reduced simultaneously. In fact, in all the circuits discussed, the gain sensitivity product is proportional to Q^2. An improvement in this figure is possible only at the expense of an excessive number of elements.

In concluding this section, some comments on the effect of finite OA gain and its low-pass frequency response on the realized L and its Q appear to be in order. This study has been conducted by Ahmed and Dutta Roy [18] on the tuned circuits formed by connecting a capacitor across the simulated L. With ideal OA, the zeros of the admittance of the tuned circuit are determined by the equation

$$sC_t + (1/H)(s\tau_2 + 1)/(s\tau_1 + 1) = 0 \tag{12.21}$$

where C_t is the tuning capacitor. On simplification, Eq. (12.21) yields

$$s^2 + [(\tau_2 + HC_t)/(HC_t\tau_1)]s + 1/(HC_t\tau_1) = 0 \tag{12.22}$$

from which the quality factor Q_t and the resonance frequency ω_t are determined to be

$$Q_t = (HC_t\tau_1)^{1/2}/(\tau_2 + HC_t) \tag{12.23}$$

and

$$\omega_t = (HC_t\tau_1)^{-1/2} \tag{12.24}$$

If each OA is represented by its one-pole roll-off model, *viz.*

$$\mu_i = \mu_{0i}/\{1 + (s/\omega_i)\} \tag{12.25}$$

then for an n-OA circuit, Eq. (12.22) gets changed to an equation of the form

$$S^{n+2} + \lambda_{n+1}s^{n+1} + \cdots + \lambda_1 s + \lambda_0 = 0 \tag{12.26}$$

where λ_i's are constants. Equation (12.26) must have a dominant complex root pair and can be written as

$$\left(s^2 + \{s\omega_{te}/Q_{te}\} + \omega_{te}^2\right)\left(s^n + \beta_{n-1}s^{n-1} + \ldots + \beta_0\right) = 0$$

where β_i's are constants and ω_{te} and Q_{te} are, to a good order of approximation, the effective ω_t and Q_t. A computer algorithm FLAC (Frequency Limitations of Active Circuits) has been written to find Q_{t0} and ω_{t0} and hence the percentage deviation, with Q_t, ω_t, μ_{0i} and ω_i as the input data. The results show that the Rao–Venkateswaran circuit has the best performance amongst all such circuits. The negative gain circuits, as expected, have a very low highest usable frequency compared to unity gain circuits.

12.5 Lossy Floating Inductance Simulation

A simple, lossy floating inductance simulator circuit is presented in [19]. Consider the Prestcott circuit of Fig. 12.6a with R_2 removed from ground, to form the two port of Fig. 12.13.

Routine analysis shows that the y-parameters of this circuit are

$$y_{11} = -y_{12} = 1/(R_1 + R_2 + sCR_1R_2) \tag{12.27}$$

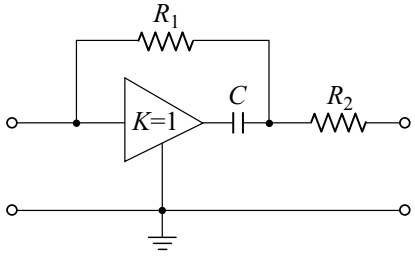

Fig. 12.13 Prestcott circuit converted to a two port

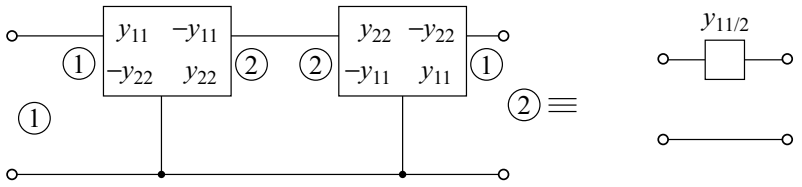

Fig. 12.14 Basic principle of floating immittance simulation

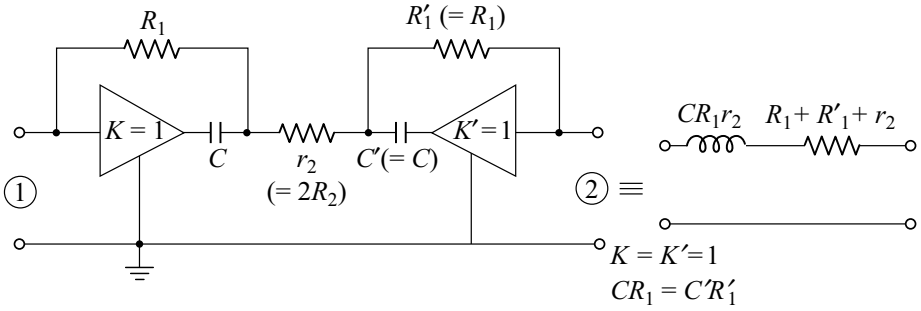

Fig. 12.15 Dutta Roy's floating-L simulator

and

$$y_{22} = -y_{21} = (sCR_1 + 1)(R_1 + R_2 + sCR_1R_2). \tag{12.28}$$

If two such two ports are cascaded back to back, as in Fig. 12.14, it is easy to show that the result is a floating inductor of impedence

$$Z(s) = R + sL = 2(R_1 + R_2) + 2sCR_1R_2. \tag{12.29}$$

The complete circuit is shown in Fig. 12.15, where the values within brackets represent nominal ones.

Although the two-component blocks in Fig. 12.14 were assumed identical, it can be shown that this is not essential for obtaining a floating L. For this, one has to analyse Fig. 12.15 with general element values; assuming $k \cong k' \cong 1$ (with OAs used to realize k and k', this assumption is quite well justified in practice), the only condition required to be satisfied for a floating L turns out to be

$$CR_1 = C'R'_1. \tag{12.30}$$

The resulting floating admittance is

$$Z(s) = R_1 + R'_1 + r_2 + sCR_1r_2. \tag{12.31}$$

where $r_2 = R_2 + R'_2$. In practice, Eq. (12.31) can be realized by adjusting a single resistance (R_1 or R'_1) so that the voltages at ports 1 and 2 are indistinguishable.

In order to study the sensitivity characteristics, a general analysis of Fig. 12.15 has been done. The resulting y-parameters are written as $Y_{mn}(j\omega) = \pm 1/(R_{mn} + j\omega L_{mn})$, where $m, n = 1, 2$ and the negative sign is used for $m \neq n$. The sensitivities of L_{mn} and $Q_{mn} = \omega L_{mn}/R_{mn}$ are evaluated with respect to various parameters and finally, the nominal values of the parameters are substituted. When this is done, it is found that for $\mu = \mu'$ and reasonably high Q's (> 10),

$$S_{\mu'}^{L_{11},Q_{11},L_{21},Q_{21}} \; S_{\mu}^{L_{22},Q_{22},L_{12},Q_{12}} = 0 \tag{12.32}$$

$$S_{\mu}^{L_{11}} = S_{\mu'}^{L_{22}} = (2 + 1/\Psi)/\mu$$

$$S_{\mu}^{Q_{11}} = S_{\mu'}^{Q_{22}} = (2 + 1/\Psi)Q^2/\mu$$

where $\Psi = R_1/r_2$. All other sensitivities are found to be less than or equal to unity, some approaching zero as Q increases. With $\mu = \mu' \leq 10^5$, L_{mn} and Q_{mn} sensitivities to respective μ's also approach zero provided Ψ is not very small and $Q^2 \ll \mu/(2 + 1/\Psi)$. In practice, $\Psi = 1$, i.e. $r_2 = R_1$ is a good choice because then one can fabricate the circuit with equal resistors and equal capacitors.

Compared to the earlier known circuits for floating inductor simulation, the circuit just discussed has the following attractive features : low component count; unity spread in resistors, capacitors and active elements; easy adjustment; low sensitivities; absolutely stable configuration; UG connection of OA's leading to widest possible frequency range of operation; and easy conversion to grounded inductance simulator.

Instead of the Prestcott circuit, one could also start from Berndt–Dutta Roy or Rao–Venkateswaran circuit and obtain floating-L simulations. These circuits have been studied by Ahmed [20] together with the frequency limitations of all the three circuits. The Prestcott derived circuit is found to have a superior high-frequency performance as compared to others. However, all three of them are found to be useful up to only a small fraction of the gain bandwidth product of the OA's.

The approach discussed here for floating-L simulation has been independently reported by Wise [21].

12.6 Applications of Simulated L in the Design of Insensitive Biquadratic Sections

Leach and Chan [22] proposed a method of insensitive biquadratic design using a perfect simulated L. Dutta Roy and Ahmed [23] showed that one could use a lossy simulated L in this situation with the low-sensitivity feature maintained, and with the added advantage of lower component count. Consider, for example, the circuit of Fig. 12.16, where the (r, L) combination is derived using the Prestcott circuit of Fig. 12.6a. Note that

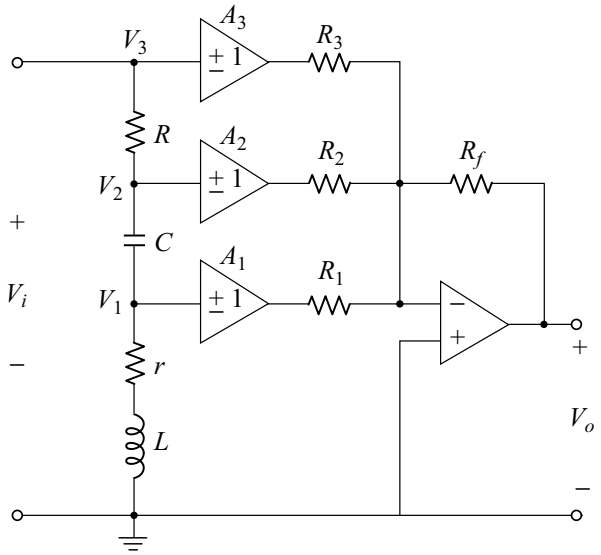

Fig. 12.16 Insensitive biquad scheme using an L-simulator

$$
\begin{aligned}
V_3 &= V_{\text{in}} \\
V_2 &= V_{\text{in}}\left[s^2 + sr/L + 1/(LC)\right]/\left[s^2 + s(r+R)/L + 1/LC\right)] \\
V_1 &= V_{\text{in}}\left(s^2 + sr/L\right)/\left[s^2 + s(r+R)/L + 1/(LC)\right]
\end{aligned} \tag{12.33}
$$

and that

$$
V_0 = -\sum_{i=1}^{3} V_i A_i R_f / R_i \tag{12.34}
$$

Denoting—$A_i\ R_f/R_i$ by a_i, and substituting for V_i/V_{in} from Eq. (12.33), it is easy to show that the transfer function $H(s) = V_0/V_{\text{in}}$ is given by

$$
H(s) = \left\{s^2(a_1 + a_2 + a_3) + s[r(a_1 + a_2 + a_3) + Ra_3]/L + (a_2 + a_3)/(LC)\right\}/\left[\left(s^2 + s(r+R)/L + 1/(LC)\right]\right. . \tag{12.35}
$$

Choosing a_i's, i.e. R_i's and A_i's appropriately, one obtains all types of second order transfer functions. For example,

$R_2 = \infty, R_1 = R_2, A_1 = -A_2 = \pm 1$ gives low-pass;
$R_2 = R_3 = RR_1/r, A_1 = A_2 = -A_3 = \pm 1$ gives high-pass;
$R_1 = \infty, R_2 = R_3, A_2 = -A_3 = \pm 1$ gives bandpass;
$R_1 = \infty, R_2 = R_3[1 + R/(r)], A_2 = -A_3 = \pm 1$ gives bandstop
and
$R_1 = \infty, R_2 = R_3[1 + R/(2r)], A_2 = -A_3 = \pm 1$ gives all-pass

filters. The Q and ω_0 sensitivities can be calculated in the usual manner and it is found that the passive sensitivities are all less than unity, some of them being zero and some 1/2. The multiparameter sensitivities are

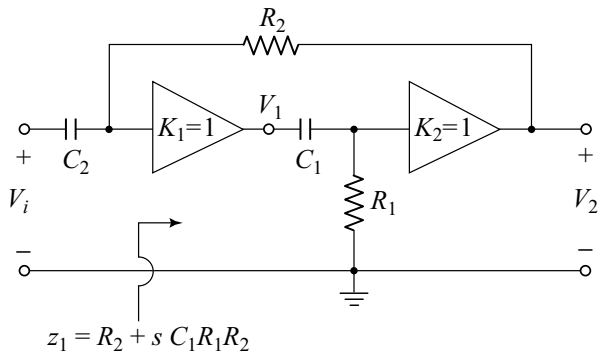

Fig. 12.17 Dutta Roy's insensitive biquad scheme using the circuit of Fig. 12.8

$$\sum\nolimits_{\omega_0} = \sum\nolimits_i \left|S_{X_i}^{\omega_0}\right| = 2 \text{ and } \sum\nolimits_Q < 3. \tag{12.36}$$

A different method of insensitive biquadratic design with a simulated L has been recently proposed by Dutta Roy [24]. The basic structure for this is the Rao–Venkateswaran (*loc. cit.*) circuit of Fig. 12.8 with an additional capacitor C_2 added at the input, as shown in Fig. 12.17. From the fact that $Z_i = R_2 + sC_1\,R_1\,R_2$, it is easy to show that

$$V_{1;z} = V_i\left[s^2 + s/\left(C_1R_1, s^2\right]/\left[s^2 + \mathrm{s}/(C_1R_1) + 1/(C_1R_1C_2R_2)\right].\right.$$

By appropriate linear combinations of $V_{i,1,2}$ in another OA, one can again obtain any specified biquadratic transfer function. The advantage with respect to the previous scheme is that no isolating UGA is needed in this case, thus leading to component saving. For example, the basic structure of Fig. 12.16 is a high-pass filter with V_2, as the output; comparing with the previous high-pass circuit, we get a saving of three OAs and five resistors.

12.7 Conclusion

From the account of some recent developments given here, it can be concluded that L simulation approach to active filter design is a fairly developed technique, and can be used for biquadratic or higher order filter designs with the important advantages already mentioned. Designing with lossy, but high Q simulated inductors create no additional problems as compared to the design of doubly terminated LC filters with lossy coils.

Chapter 13
Evaluating the Frequency Limitations of Operational Amplifier RC Networks by the Dominant-Pole Technique

Abstract A general computer-based technique is given for investigating the high-frequency performance of second-order active RC networks employing an arbitrary number of operational amplifiers. It uses the dominant-pole technique for finding deviations in Q and ω_0 from their nominal values as a function of the gain bandwidth product of the operational amplifiers. The technique is applied to active RC circuits simulating a nonideal grounded inductance and curves are given for the highest usable frequency for permissible deviation in Q and ω_0 for some typical circuits.

Keywords Active RC filters · Dominant-pole technique · Frequency limitations

13.1 Introduction

The actual performance of an operational amplifier (OA)–RC network differs considerably from that predicted by conventional design, based on the assumption of ideal OA, due to two major reasons, viz. (i) the sensitivity of the network function to the variations of active and passive components from their nominal values and (ii) frequency limitations introduced by the practical OA. Sensitivity has been a subject of extensive research in the past two decades, and well-established methods are now available for its evaluation and minimization [1]. Frequency limitation due to OA is a relatively recent topic; some of the notable contributions in this direction are due to Budak and Petrela [2, 3], and Faulkner and Grimbleby [4, 5]. These are based on one-pole roll-off model of the OA and are particularly suitable for circuits using one OA. Applied to multiple OA networks, both the methods have some inherent limitations; in the method of Budak and Petrela [6], for example, one may have to sacrifice accuracy by neglecting the fourth and higher order terms in the denominator of the transfer function. In the Faulkner–Grimbleby method [5], the developed procedure is to be repeated as many times as are the number of OA's in the circuit.

In the present chapter, a general technique, based on the dominant-pole approximation, is developed for the study of a second-order active RC network using an arbitrary number, n, of OA's. The technique is applied to low-component count, non-ideal, grounded, inductance simulator (IS) circuits reported by Dutta Roy [7]. The effect of finite gain bandwidth product (η) of the OAs has been displayed in the form of curves giving the highest usable frequency (ω_h) for prescribed deviations in Q and ω_0 from their nominal values.

13.2 Dominant-Pole Technique

Consider an active RC network containing n-OAs which realizes, nominally, the second-order transfer function

$$T(s) = \frac{N(s)}{D(s)} = \frac{N(s)}{s^2 + a_1 s + a_0}. \tag{13.1}$$

The degree of $N(s)$ is 0, 1 or 2 depending upon the type of filter desired. The two most important performance criteria characterizing Eq. (13.1) are

$$Q = (\sqrt{a_0})/a_1 \text{ and } \omega_0 = \sqrt{a_0}. \tag{13.2}$$

Identical OAs are assumed, each having an open-loop gain function

$$A(s) = -\frac{A_0\omega_a}{s + \omega_a} = -\frac{\eta}{s + \omega_a} \tag{13.3}$$

where $A_0 = A(0)$; ω_0 is the 3 dB open-loop bandwidth of the OA and $\eta = A_0\omega_a$ stands for the gain bandwidth product. When Eq. (13.3) is substituted for each OA gain in the n-OA circuit being considered, it is obvious that the denominator polynomial of the resulting transfer function will be changed to an $(n + 2)$th-order polynomial. Denoting this by $D'(s)$,

$$D'(s) = B_{n+2}s^{n+2} + B_{n+1}s^{n+1} + \cdots + B_1 s + B_0 \tag{13.4a}$$

$$= (s^2 + a_1' s + a_0')(b_n s^n + b_{n-1}s^{n-1} + \cdots + b_1 s + b_0) \tag{13.4b}$$

where, nominally (i.e. when $A_0 = \infty$, $\omega_a = \infty$), $a_1' = a_1$, $a_0' = 0$, $b_n = b_{n-1} = \ldots = b_1 = 0$ and $b_0 = 1$. The quadratic factor in Eq. (13.4b) represents the effect of perturbation of the quadratic $D(s)$ due to finite η of the OA's and is the dominant complex root pair of $D'(s)$ (Ghausi [7]; Millman and Halkias [8]). If this factor can be found out, then the effective Q and ω_0 denoted by Q_e and ω_{0e}, respectively, can be calculated as

$$Q_e \simeq \left(\sqrt{a_0'}\right)/a_1', \ \omega_{0e} \simeq \sqrt{a_0'} \tag{13.5}$$

The percentage deviations in Q and ω_0 are, therefore,

$$\Delta Q = 100(Q_e - Q)/Q, \Delta\omega_0 = 100(\omega_{0e} - \omega_0)/\omega_0. \tag{13.6}$$

A computer program FLAC (Frequency Limitations of Active Circuits) has been written to evaluate the dominant quadratic factor of $D'(s)$ and hence ΔQ and $\Delta\omega_0$ for a large number of second-order circuits. The results for grounded inductance simulators will be presented in the next section. A flow diagram for FLAC is given in Fig. 13.1.

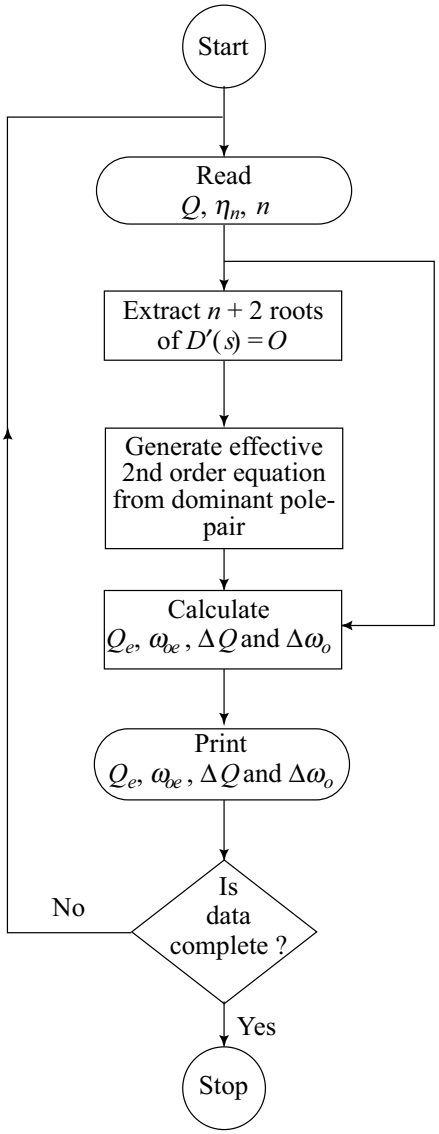

Fig. 13.1 Flowchart of FLAC

13.3 Frequency Limitations of Lossy Grounded Inductance Simulators

Figure 13.2 shows the various circuits for simulating a grounded nonideal inductance, as considered by Dutta Roy [6], where each voltage amplifier is realized by an OA, with or without suitable resistances. Each of these circuits, assuming a frequency-independent OA gain, realizes a bilinear RL-impedance of the form

$$Z(s) = H(s\tau_1 + 1)/(s\tau_2 + 1),\ \tau_1 \geq \tau_2 \tag{13.7}$$

For evaluating the high-frequency performance, we convert each inductance simulator to a tuned circuit by connecting a capacitance C_t across the input terminals. Then, nominally, the quality factor Q_t and the resonance frequency ω_t of the tuned circuit are given by

$$Q_t = (HC_t\tau_1)^{1/2}/(HC_t + \tau_2) \tag{13.8}$$

$$\omega_t = (HC_t\tau_1)^{-1/2} \tag{13.9}$$

The values of H, τ_1, τ_2, Q_t, ω_t and the design equations and constraints for each circuit have been given by Dutta Roy [6]. Taking the frequency dependence of OA gain into account, the polynomial $D'(s)$, which determines effective Q_t and ω_t becomes of the form of Eq. (13.4a). When this is equated to zero, the resulting equation can be written in the form

$$s^{n+2} + c_{n+1}, s^{n+1} + \cdots + c_1 s + c_0 = 0 \tag{13.10}$$

where $c_j = B_j/B_{n+2}$. The values of the coefficients are given in Table 13.1 for each circuit; these are functions of Q_t and the normalized gain bandwidth product $\eta_n = \eta/\omega_t$ both forming the input data to FLAC. The coefficients are used for evaluating the dominant complex root pair of Eq. (13.10) and hence finding Q_{te} and ω_{te} and ΔQ_t and $\Delta\omega_t$ for a given range of Q_t and η_n.

Computations using the dominant-pole technique (DPT) were carried out for a large range of Q_t and η_n. High values of Q, in general, lead to large element spread, and hence are not realizable if the circuit is to be fabricated in IC form; nevertheless, Q values up to 200 have been taken to demonstrate the frequency limitations at high Q's. Some of the results are shown in Table 13.2, which gives the maximum η_{n}^{-1} corresponding to a given Q_t and percentage deviation in either Q_t or ω_t. If all the three quantities Q_t, ΔQ_t and $\Delta\omega_t$ are specified, then one has to use the lower of the two values of η_n^{-1} corresponding to $(Q_t, \Delta Q_t)$ and $(Q_t, \Delta\omega_t)$. The highest usable frequency for a particular OA being used in the circuit can easily be found from

$$\omega_h = \eta \times \eta_n^{-1}. \tag{13.11}$$

I	$p \triangleq 4Q_t^2;\ c_0 = \eta_n^2/p,\ c_1 = \eta_n(4\eta_n Q_t + p + 1)/p^2,$ $c_2 = \left(\eta_n^2 + 1\right)/p + 4\eta_n Q_t(p + 1)/p^2,$ $c_3 = [\eta_n(p + 1) + 4Q_t]/p$
J	$p \triangleq 4Q_t^2;\ c_0 = \eta_n^3,\ c_1 = \eta_n^2\left[\eta_n/(2Q_t) + 2\eta_n Q_t/p + p + 1 + 1/\mathrm{p}\right],$ $c_2 = \eta_n 2[\eta_n + (p + 2)/(2Q_t) + 2Q_t(2p + 1)/p] + \eta_n(p + 2)$ $c_3 = \eta_n[\eta_n(p + 2) + (2p + 1)/(2Q_t) + 2Q_t(p + 2)] + p,$ $c_4 = p[\eta_n + (p + 1)/(2Q_t)] + \eta_n(p + 1)$

In this sense, Table 13.2 gives universal values for the calculation of ω_h. A close glance at the Table indicates that, basically, the circuits of Fig. 13.2 can be classified into three groups depending upon their operational frequency range. Circuits characterized by medium and high-Q realizations at high frequencies will be called class I. Class II circuits are the ones for low Q (<25) realizations at low frequencies. Circuits showing a variable frequency range of operation will be called class III; their range depends on the ratio $\omega_{an} = \omega_a/\omega_t$. For low ω_{an}, these realizations behave as class I circuits, whereas for high ω_{an} they fall in class II circuits. For a typical representative of each class, universal curves will be given which show the variations of η_n^{-1} with Q_t at various $\Delta\omega_t$ and ΔQ_t as parameter. From these curves, ω_h can easily be calculated by using Eq. (13.11).

It is evident from Table 13.2 and Fig. 13.2 that the active inductors using non-inverting OA belong to class I. Using commercial OAs (with external compensation), the computer results show that these circuits are suitable for high-Q applications in the range of 500 kHz within 5% allowed deviations in Q_t and ω_t. Table 13.2 shows that Fig. 13.2c, using two non-inverting OAs, has the best performance amongst all

Note a(b) stands for 'a' multiplied by 10^b. A blank indicates that these inductance simulators are unsuitable for realizing the corresponding specifications

the active inductances investigated; the frequency limitation curves for this circuit are given in Fig. 13.3.

As expected, the effect of η on circuits using inverting OA is quite appreciable, especially, on the Q of the circuits. The DPT results indicate these realizations to be suitable only for low frequency, low Q (<20) applications, inspite of their excellent sensitivities [6]; consequently, these are class II active inductors. A typical representative of this class is Fig. 13.2f, and its frequency limitation curves are also given in Fig. 13.3. An exception to the inverting OA circuits is provided by Fig. 13.2h. The feedback via the condenser seems to improve the high-frequency performance considerably and makes it a class I instead of class III circuit.

Figure 13.2i, j, using one inverting and one non-inverting OA, show a marked difference from each other in their frequency limitation characteristics. Whereas the first circuit is found to behave as class II, the second one suits more to the family of class I.

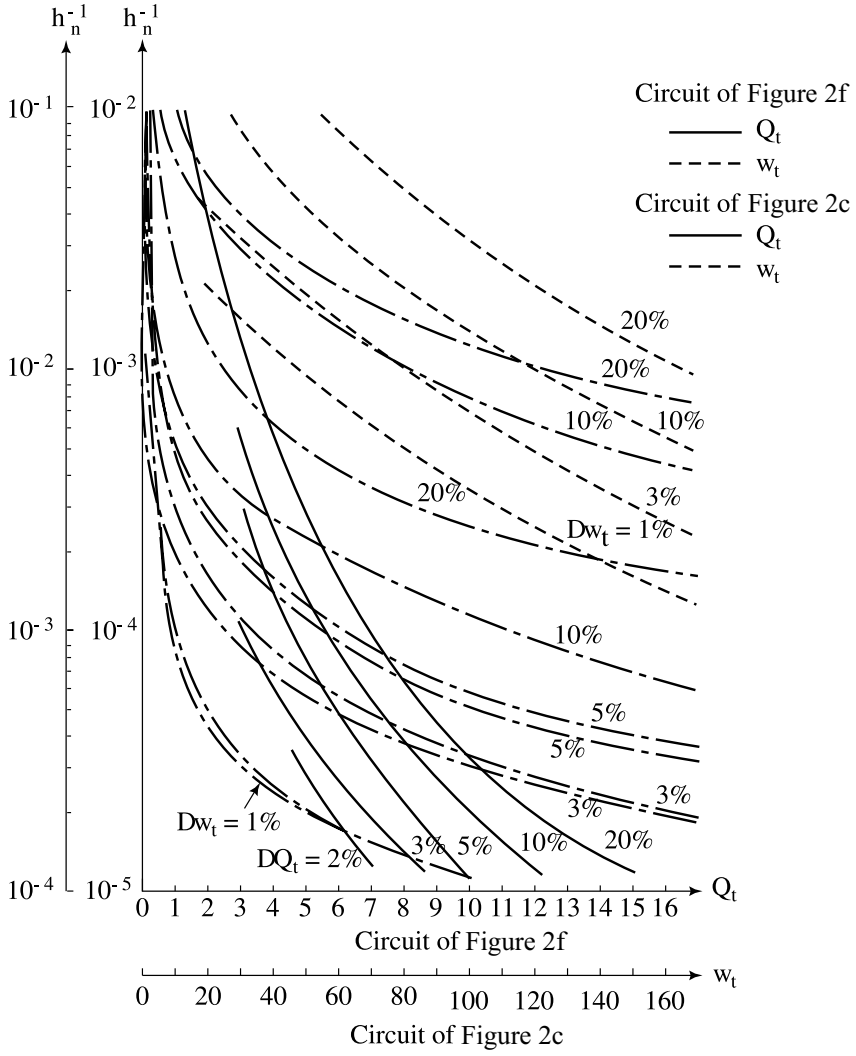

Fig. 13.3 Maximum $\eta_n^{-1}/(\omega_h)$–curves for allowable deviations in Q_t and ω_t for inductance simulators of Fig. 13.2c (Class I) and Fig. 13.2f (Class II)

Figure 13.2e, using OA in the infinite-gain connection is a class III active inductor. Here the coefficient c_1, being a function of the parameter ω_{an} (see Table 13.1), makes the frequency limitation characteristics variable and critically dependent on this parameter. Investigation with ω_{an} varying between 10 and 10^{-3} have been made to cover the practical frequency range of commercially available OA's. Figure 13.4 gives universal curves for this circuit with ω_{an} as parameter; these are similar to the curves of class II circuits at high ω_{an} ($\approx$10). For low ω_{an} ($\approx 10^{-3}$), the frequency limit improves considerably and the characteristics depicted are those of class I circuits. Moreover, the effect of ω_{an} variation is more prominent on the Q_t deviations as compared to ω_t deviations, the latter being noticeable only at high $\Delta\omega_t$ and low Q_t values.

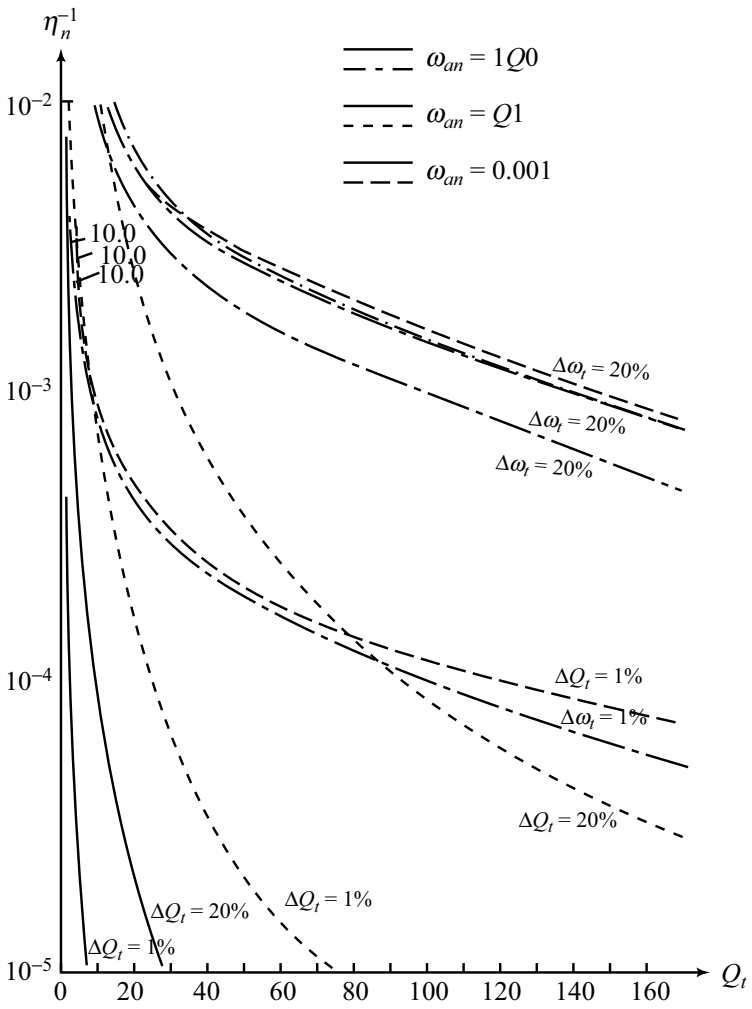

Fig. 13.4 Maximum $\eta_n^{-1}/(\omega_h)$–curves for allowable deviations in Q_t and ω_t for Fig. 13.2e (Class III)

13.4 Experimental Investigations

Experimental investigations were conducted on a bandpass filter circuit (Dutta Roy and Ahmed [9]), shown in Fig. 13.5a, which is, basically, the circuit of Fig. 13.2b, with a low-pass RC section cascaded at the input. The filter was designed and fabricated to realize a nominal Q of 10 and variable ω_0. Internally compensated operational amplifier SMC 741 was intentionally chosen to be of poor quality ($\eta \simeq 0.7$ MHz) with a view to avoid the difficulties and inaccuracies encountered in the measurements at high frequency.

The experimental curves along with the ones obtained by using Budak–Petrela [3] method and the dominant-pole technique are shown in Fig. 13.5b. They show the percentage deviations in Q and ω_0 from the nominal values at various frequencies. It is observed that there is a close agreement between the practical values and $\Delta\omega_0$-curves obtained by the DPT. However, the ΔQ-curves obtained from the DPT are optimistic, whereas, both the $\Delta\omega_0$ and ΔQ-curves predicted by Budak–Petrela method are pessimistic. It is important to note that the filter uses only one OA for

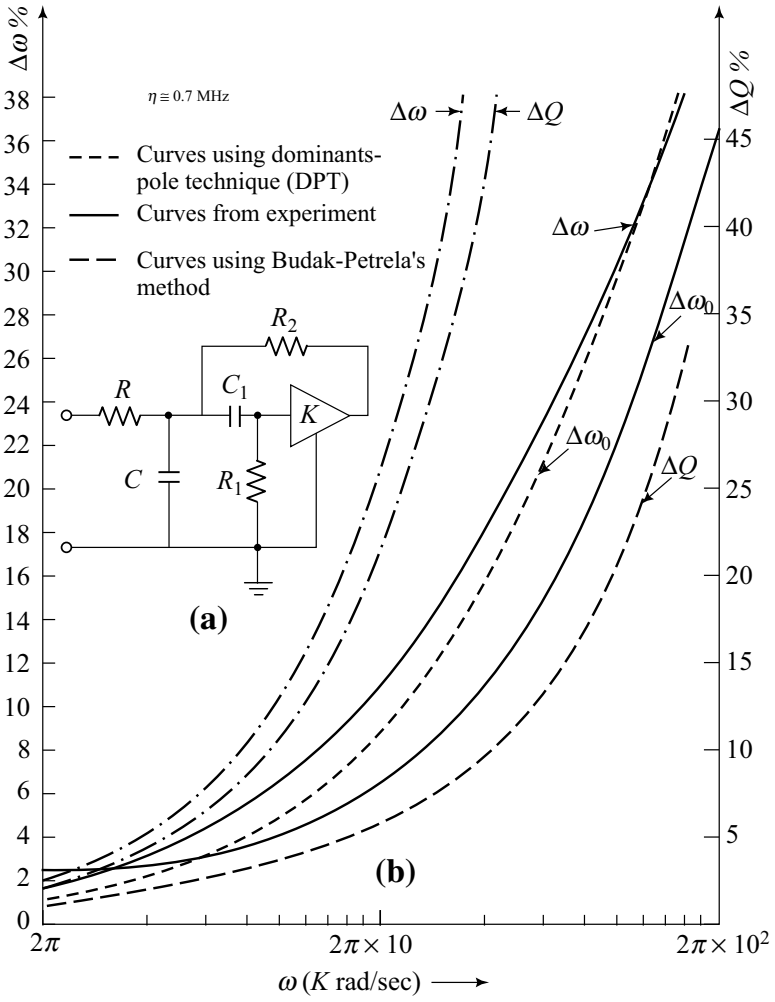

Fig. 13.5 **a** Bandpass filter, **b** comparative frequency limitation curves

which Budak–Petrela theory has least approximation (because there is no truncation of terms). But Fig. 13.5b indicates a closer agreement between practical results and the ones obtained by using DPT as compared to those obtained by Budak–Petrela method. As the DPT is equally accurate for multiple OA networks, it can logically be presumed that when used on circuits having more than one OA, it will continue to give closer results than those obtained from Budak–Petrela method.

13.5 Conclusion

A dominant-pole technique has been presented for the frequency limitations of second-order active RC networks using n operational amplifiers. The method is applied to nonideal grounded inductance simulators and based on their frequency limitation characteristics, they are classified into three groups of active inductances. The frequency behaviour and, hence, classifications are largely influenced by the mode in which the OA is used. A comparative frequency limitation study of a band-pass filter was made using the Budak–Petrela method and the DPT. The experimental results indicate a closer correlation with the dominant-pole technique.

Chapter 14
'Shadow' Filters—A New Family of Electronically Tunable Filters

Abstract It is shown that the 'shadow' filter, introduced recently by Lakys and Fabre, is capable of achieving not only a constant bandwidth bandpass filter, but also several other interesting characteristics depending upon the choice of the desired output port and the port from which feedback signal is derived. Two such characteristics are illustrated in this chapter, namely constant centre frequency, variable Q, and constant value of the product of centre frequency and Q. A problem is also posed for further investigation. Finally, a suggestion is made for the design of a simple but interesting experiment for undergraduate students, using only resistors, capacitors and op-amps, which illustrates the basic concepts of filters and what the shadow technique can do to improve their quality.

Keywords Shadow filters · Versatility · Open problems

14.1 Introduction

In their 2010 paper, Lakys and Fabre [1] introduced a new family of second-order filters, called 'shadow' filters for electronically tuning the characteristics of a basic filter. A general block diagram of the scheme is shown in Fig. 14.1, in which the authors of [1] considered $H(s)$ to be a bandpass transfer function while $H_1(s)$ is a low-pass transfer function, both being of second order with the same denominator. They show that thereby the characteristics of the modified transfer function $H'(s) = V_0/V_{\text{in}}$ retains the bandpass characteristic, but with variable centre frequency and variable Q, in such a manner that the bandwidth remains a constant.

The purpose of this chapter is to make a more general analysis of the scheme and to demonstrate that by properly choosing $H(s)$ and $H_1(s)$, various types of interesting characteristics of practical importance can be obtained. Two such characteristics are illustrated in this chapter, namely constant centre frequency, variable Q and constant value of the product of centre frequency and Q. A problem is also posed for further investigation.

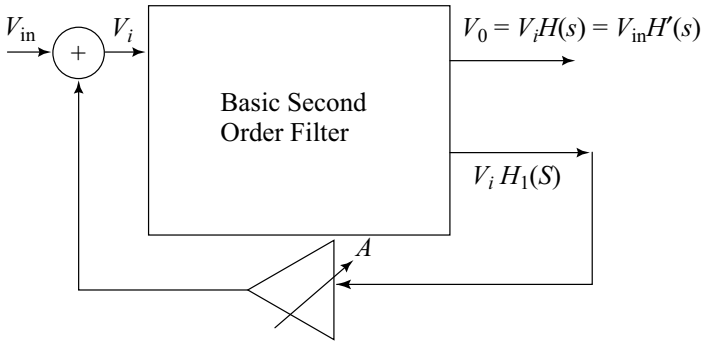

Fig. 14.1 Schematic diagram of the shadow filter

Finally, a suggestion is made for the design of a simple but interesting experiment for undergraduate students, using only resistors, capacitors and op-amps, which illustrates the basic concepts of filters and how the shadow technique can be used to improve their quality.

14.2 Analysis

Consider a basic second-order filter, which can be active or passive, and which is capable of realizing any of the four possible characteristics, viz. low-pass, high-pass, bandpass or band-stop or a combination of these. Such realizations can, for example, be a simple series *RLC* circuit [2] or an active biquad [3] or a simple combination of RC filters connected in parallel at the input as shown in Fig. 14.2. Similarly, the feedback signal is taken from any of these outputs or a combination of them. Thus, $H(s)$ and $H_1(s)$ are of the forms

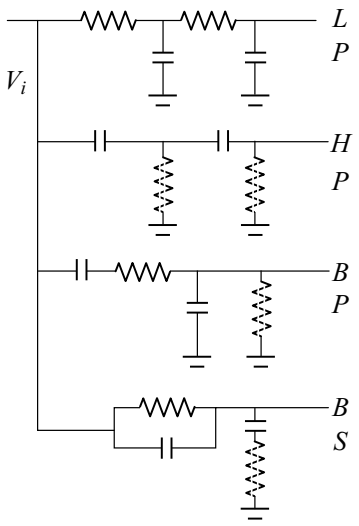

Fig. 14.2 A passive RC basic filter. All resistors are of value *R* and all capacitors are of value *C*

$$H(s) = \frac{d + es + fs^2}{s^2 + (\omega_0/Q)s + \omega_0^2} \tag{14.1}$$

and

$$H_1(s) = \frac{a + bs + cs^2}{s^2 + (\omega_0/Q)s + \omega_0^2} \tag{14.2}$$

By analysis of Fig. 14.1, we get

$$H'(s) = \frac{H(s)}{1 - AH_1(s)} \tag{14.3}$$

Combining Eqs. (14.1), (14.2) and (14.3) gives

$$H'(s) = \frac{d + es + fs^2}{s^2(1 - Ac) + [(\omega_0/Q) - Ab]s + \omega_0^2 - Aa} \tag{14.4}$$

This can be rewritten as

$$H'(s) = \frac{d' + e's + f's^2}{s^2 + (\omega_0'/Q')s + \omega_0'^2} \tag{14.5}$$

where

$$(d', e', f') = (d, e, f)/(1 - Ac);$$

$$\omega_0' = \sqrt{(\omega_0^2 - Aa)/(1 - Ac)};$$

$$Q' = \sqrt{(1 - Ac)(\omega_0^2 - Aa)}/(\omega_0 - AbQ) \tag{14.6}$$

14.3 Special Cases

In [1], the authors considered $b = 0$ and $c = 0$ (it would be wrong to write $b = c = 0$ because b and c are dimensionally different) so that

$$\omega_0' = \omega_0\sqrt{(1 - Aa/\omega_0^2)}; \qquad Q' = \sqrt{(1 - Aa/\omega_0^2)} \tag{14.7}$$

Thus the centre frequency and Q change proportionately and the bandwidth $\Delta\omega' = \omega_0'/Q'$ remains the same as the original bandwidth $\Delta\omega = \omega_0/Q$.

An interesting variation of the circuit is obtained by taking the high-pass output of the basic second-order cell for $H_1(s)$, i.e. by taking $a = 0$ and $b = 0$. Then we get

$$\omega_0' = \omega_0/\sqrt{(1 - Ac)}; Q' = Q\sqrt{(1 - Ac)} \tag{14.8}$$

In this case, the product $\omega_0' Q'$ remains invariant, i.e. we get higher Q at lower frequencies and vice versa. This is a remarkable feature because achieving high Q at low frequencies is a perennial problem in passive filters because of the large values of inductance and capacitance required and the difficulty of constructing high valued, high Q inductors. This is also a problem in active filters because of the large ratios of resistors and capacitors required for the purpose.

If the feedback signal is taken from the bandpass output itself in Fig. 14.1, then $a = 0$ and $c = 0$ so that from Eq. (14.6),

$$\omega_0' = \omega_0;\ Q' = Q/(1-AbQ/\omega_0) \tag{14.9}$$

In this case, one obtains a variable Q with fixed centre frequency. The corresponding bandwidth is given by

$$\Delta\omega' = \Delta\omega(1-Ab/\omega_0) \tag{14.10}$$

This case is also of practical interest.

14.4 Range of Variation

Obviously, A can be positive as well as negative. The range of positive A (assuming a, b and c to be positive) is determined from the constraint that ω_0', Q' and $\Delta\omega'$ cannot be negative or imaginary. The range of negative A is unlimited in theory and would be limited only from practical considerations. Accordingly, depending upon the particular case under consideration, the parameters ω_0', Q' and $\Delta\omega'$ can be varied from 0 to infinity in theory, and from very low to very high values in practice.

14.5 An Open Problem and a Suggestion

Is it possible to have a constant Q and a variable centre frequency (or bandwidth)? No combination of a, b and c was found to yield this feature. The question is therefore left as an open problem.

The shadow filter concept discussed here can be used, in a variety of ways, to design an experiment for undergraduate students which will illustrate the various basic filters and their tuning/quality improvement by adding feedback through the

amplifier A. For example, the basic second-order cell can be breadboarded with identical resistors and capacitors, as in Fig. 14.2, to give low-pass, high-pass, bandpass and band-stop characteristics. The relevant transfer functions are:

$$\begin{gathered} LP : \omega_0^2/D(s);\ HP : s^2/D(s);\ BP : \omega_0 s/D(s);\ BS :\ (s^2 + 2\omega_0 s + \omega_0^2)/D(s) \\ D(s) = s^2 + (\omega_0/Q)s + \omega_0^2;\ \omega_0 = 1/(CR);\ Q = 1/3 \end{gathered} \tag{14.11}$$

The gain block A can be a single op-amp in inverting or non-inverting configuration; in the latter case, the resistance from the input to the inverting terminal of the op-amp has to be large enough so as not to load the filter to which it is connected. The summer can be realized by another op-amp.

14.6 An Example

In the three special cases considered, $H(s)$ was a bandpass filter. Since the features discussed here apply to the denominator of $H'(s)$ it is clear that the same effects will occur if $H(s)$ is low-pass, high-pass, bandpass or band-stop, thus facilitating adjustment of bandwidth and sharpness of cutoff. As an example, consider Fig. 14.2 and let $H(s)$ be the transfer function of the band-stop filter. The magnitude characteristic of this filter is rather poor because the dc and infinite frequency transmissions are unity but the minimum transmission occurring at $\omega_0 = 1/(CR)$ is only 2/3, while ideally, one would like to have zero transmission at this frequency. To get a deeper minimum, apply feedback from the bandpass output. The minimum value then becomes $2/(3-A)$. For example, with $A = -47$, the minimum value becomes 0.04. Note also that interestingly, when A is positive and lies between 1 and 3, this minimum becomes a maximum. In fact, when A is close to 3, the maximum value can go very high and the filter becomes a bandpass one. It will also be instructive to see what happens when A is gradually increased towards the value 3 and beyond. At some point near 3, the circuit will break into oscillations and produce sinusoidal oscillations at the frequency $\omega_0 = 1/(CR)$.

14.7 Conclusion

The versatility of an interesting active filter, which can be electronically tuned by varying the gain of an amplifier, has been discussed in this chapter. The filter can be quickly breadboarded in the laboratory for experimentation and self-learning by the undergraduate student.

Part IV
Analog Signal Processing: Signal Processing by Discrete Time Networks

In discrete time networks, the signals are still analog, but are in the form of samples. These occur in charge transfer devices (CTD), which are of two types, *viz*. Bucket Brigade Device (BBD) and Charge Coupled Device (CCDs); when the sampled signals are quantized to a finite number of bits, then the signal becomes truly digital. The mathematical description and tools for signal processing are the same for sample data as well as digital signals.

This part contains three chapters, dealing with some aspects of CTD and digital signal processing, (Chap. 15), Signal Processing applications of CTDs (Chap. 16) and Linear phase versus minimum phase CTD transversal filters (Chap. 17).

Chapter 15
Some Aspects of Digital and CTD Signal Processing

Abstract The work done by me and my students in the fields of digital and charge transfer device signal processing is briefly described. Some general comments on the future scope of work in these two related fields are included.

Keywords DSP · CTD signal processing

15.1 Introduction

In this chapter, I shall discuss some aspects of digital and charge transfer device (CTD) signal processing with which I and my students had been involved in the past. In a personal narrative like this, it is neither possible to review the progress and discuss the future promises of the subject, nor shall I attempt to do this. I would therefore mention others' work only in the context of development of our ideas, and, of course, for critical comparison.

15.2 Our Early Work in Digital Signal Processing

Signal processing was one of the latest additions to my research interests at that point of time. Prior to, and also concurrently with signal processing, I and my research group (which, of necessity, has a time-varying composition) had been involved mostly with analysis and synthesis of active and passive circuits, of lumped as well as distributed types, with emphasis on applications in analog integrated circuits (ICs). It was in 1969, shortly after I joined IIT, Delhi that a colleague of mine, S. N. Hazra, expressed an interest in working with me on digital filters. I had, till then, only a casual interest in the subject through the research papers appearing in different professional journals, particularly in *IEEE Transactions on Audio and Electroacoustics*

(whose title was later changed to *IEEE Transactions on Acoustics, Speech and Signal Processing*, and later to *IEEE Transactions on Signal Processing*, to reflect the importance of signal processing). I was, however, convinced in my mind that digital signal processing would be a very active and dynamic field of research during the 70s, and it appeared to be an appropriate time to start learning about it. I, therefore, agreed to study, with Hazra, some of the key papers in the field, and there followed long hours of discussions. It was about a year later, after making many mistakes, that we started appreciating the mathematical intricacies and practical importance of the subject, particularly in view of the commercial availability of digital hardware in the form of IC chips. My previous experience in active and passive filters naturally led me to suggest that we concentrate on digital filter design, starting from well-documented analog filters. One method of designing digital filters is to start with the magnitude-squared function of an analog low-pass filter and replace, ω/ω_c, where ω_c is the cutoff frequency, by either $(\tan \omega T/2)/(\tan \omega_c T/2)$ or $(\sin \omega T/2)/(\sin \omega_c T/2)$, T being the sampling period [31, 32]. This results in the so-called digital tan or sine filter. Our first study was concerned with a critical comparison of these two types of filters with the generating analog filter, in respect of performance in the transition as well as stopbands, using Butterworth, Chebyshev and Papoulis optimum filters as specific examples. We found [1] that the tan filter is superior to both analog and sine filters. The cutoff slope and asymptotic loss depend on ω_c and both of them increase in the case of the tan filter, and decrease in the case of the sine filter, as ω_c approaches the Nyquist frequency.

Stimulated by the work of [33], I had worked on sharpening the cutoff of analog filters by introducing multiple $j\omega$—axis zero [34]. We looked into the possibility of extending this technique to digital filters and succeeded. An interesting result emerging from this study is that the Butterworth tan filter is a special case of maximally flat sine filter with coincident transmission zeros at the Nyquist frequency, whose multiplicity equals the order of the filter [2].

15.3 Linear-Phase Recursive Filters

Our next effort in digital filtering was concerned with achieving linear phase in recursive digital filters. Here, the approach of transformation of analog filter does not serve the purpose and one has to resort to a direct approximation. We started from a well-established result in analog filters viz. that an infinite array of poles at equal intervals on a line parallel to the $j\omega$-axis in the left half of the s-plane leads to an equal ripple delay characteristic in the entire frequency range [35, 36]. We, therefore, argued that if all the poles of a digital filter are distributed uniformly on a circle of radius $r < 1$ in the z-plane, there should result an approximation to linear phase. Indeed, the transfer function having the above distribution of poles is

$$H_o(z) = 1/(r^m + z^m) \tag{15.1}$$

and its phase is given by

$$\phi_o(w) \cong -m\omega T + r^m \sin(m\omega T) \tag{15.2}$$

where the approximation is valid for large m. The error in linear phase is seen to be periodic with a maximum value of r^m, which can be made arbitrarily small by choosing r and m suitably. The magnitude response of Eq. (15.1) is

$$M_o(\omega) \cong 1 - r^m \cos(m\omega T) \tag{15.3}$$

and has an equal ripple all-pass characteristic. The filter can be made low-pass by cancelling the stopband poles by introducing zeros at these locations. Retaining linear phase requires their mirror image zeros also to be introduced. Using this simple idea, we worked out an analytical design procedure [3, 4] for a low-pass filter: satisfying prescribed specifications on delay, maximum delay error and asymptotic slope. In contrast to this, other known design procedures [37, 38] for similar specifications require numerical techniques for solving a set of simultaneous nonlinear equations.

15.4 Discrete Hilbert Transform and Its Applications in Digital Filtering

I went to England in 1973 as a Visiting Professor for a year, to work at the University of Leeds, where I interacted with two very renowned circuits specialists, J. O. Scanlan and J. D. Rhodes. I also delivered invited seminars at a number of UK Universities, a Canadian University, and at the IEE Headquarters, London, which gave me an opportunity of holding personal discussions with a number of experts in digital signal processing. This experience at UK inspired me to devote a major part of my research efforts to this field after I returned to IIT in 1974. One problem I worked on concerned a matrix formulation of the discrete Hilbert transform (DHT), which plays an important role in signal processing and communication systems. A matrix formulation of the DHT was given independently by Sabri and Steenaart [39] and Burris [40], in which the vector $[\phi] = [\phi(0)\phi(1)\ldots\phi(N-1)]^T$, representing the DHT of the periodic sequence $a(n)$, $n = 0$ to $N-1$, was expressed as the product of an $N \times N$ coefficient matrix $[c_{n,v}]$ and the vector $[A] = [A(0)\ A(1)\ldots\ A(N-1)]^T$, where $A(k)$ is the discrete Fourier transform (DFT) of $a(n)$. By exploiting certain properties of the coefficient matrix, I succeeded in showing that [5] an alternative formulation is possible in which $[\phi]$ is expressed as $[\hat{A}][\hat{C}]$ where $[\hat{C}]$ is a column vector and $[\hat{A}]$ has elements of the form $A_i - A_j$. The advantage of this formulation is that the number of multiplications, which accounts for most of the processing time, is reduced by a factor of two. Assisted by an M. Tech. student, A. Agarwal, I applied this formulation to a digital low-pass filter, and showed that this leads to less storage requirement and

improved noise performance, in addition to reduced computations [9]. This approach was later extended to two-dimensional filtering by Bose and Prabhu [41].

15.5 Roundoff Noise in Digital Filters

Digital signal processing algorithms such as linear filtering are realized either as programmes in a general purpose computer or by a special-purpose hardware. In either case, the signal and the coefficients are stored as binary numbers in finite length registers. This finite wordlength constraint gives rise to two main sources of error, viz. coefficient quantization error and multiplication roundoff error. Unless carefully analysed and accounted for, these errors can lead to very undesirable effects like limit cycles and overflow oscillations. These errors are intimately connected with the structure or the architecture of the processor. For a specific case, viz. a second-order digital notch filter, R. K. Patney, a doctoral student and I studied the roundoff noise properties of various canonical structures and established that depending upon the zeros of the noise transfer functions (NTFs), such structures fall in three distinct groups. The group showing low noise magnitudes has NTF zeros which are simply related to the coefficients of the transfer function [6].

For the general digital filter, the variance of the multiplication roundoff error at the output due to a noise source is given by

$$\sigma_o^2 = (q^2/12)[1/(2\pi j)] \oint_\Gamma H(z)H(z^{-1})z^{-1}dz \tag{15.4}$$

where q is the quantization step size, Γ is the unit circle and $H(z)$ is the NTF. Various methods are available for the evaluation of Eq. (15.4) (see, e.g. Mitra et al. [42] and the references cited there). We obtained two alternative methods [17] for this purpose, both of which are based on the decomposition of the given NTF in terms of digital all-pass transfer functions. In the first method, the NTF is expressed as the sum of first-order all-pass functions, the motivation being that for each component, the integral in Eq. (15.4) simply reduces to $q^2/12$. The method requires somewhat complex arithmetic calculations, but takes less computation time than that of [42]. The second method utilizes the concept of polyphase digital filtering [43] to express the NTF as a sum of all-pass functions, of first- and second orders. The accuracy obtained in this method is not as good as in the first method, but it has the advantage of a drastic reduction in computation time, specially for higher order NTF's. Both of these methods, we believe, offered new insights into the roundoff noise problem in digital filters.

15.6 Quantized Coefficent Design of Digital Filters

As to the coefficient sensitivity problem in digital filters, we investigated the possibility of reducing the deterioration in filter characteristics due to coefficient quantization by an optimal choice of the coefficients from a discrete parameter space, once the worldlength is decided by considerations of cost. Let $F(c_i', \omega)$ be a function describing some characteristic of a digital filter, where c_i', $i = 0, 1, \ldots n$ are the coefficients determined to infinite accuracy by some design method. Let c_i be the coefficients obtained after quantization of c_i' to a desired accuracy of $b + 1$ bits, i.e.

$$c_i = c_{io} \sum_{j=1}^{b} c_{ij} 2^{-j}, \quad c_{ij} \in \{0, 1\} \tag{15.5}$$

where c_{io} denotes the sign of c_i. The resulting deteriorated function is $F(c_i, \omega)$. The following question now arises: Is it possible to modify the last bit of c_i such that the maximum of the error $|F(c_i, \omega) - D(\omega)|$, where $D(\omega)$ is the desired function, is minimized? The answer turns out to be in the affirmative; however, the existing techniques for this purpose use nonlinear optimization methods, in which a global optimum is not guaranteed. Further, most of these methods are not computationally attractive. We, therefore, looked for an entirely different approach, and an exhaustive search finally led us to conclude that pseudo-Boolean (PB) techniques [44], based on a combination of dynamic programming and Boolean techniques, should be eminently suitable for the problem at hand. We studied this technique in-depth, including some of its highly successful applications in transportation and network flow problems. We found that the problem of quantized coefficient design of digital filters essentially reduces to that of modifying c_i to $c_i + {}_{\text{a}}c_i$, where ${}_{\text{a}}c_i = c_{io} S_{ci} q y_{ci}$; $q = 2^{-b}$ (quantization step); $y_{ci} \in \{0, 1\}$ are bivalent variables whose values, to be determined; and $S_{ci} \in \{-1, 0, 1\}$ define the direction of modification of c_i. To start with, we set $S_{ci} =$ sign of $(c_i' - c_i) - c_i)$. If ω_r is the frequency at which the extrema of the error $|F(c_i, \omega) - D(\omega)| = \delta_r$ is maximum, we can write

$$|F(c_i + a_{ci}, w_r) - D(w_r)| \leq \delta_r. \tag{15.6}$$

This is a PB inequality in the variables y_{ci} and has to be solved. From the possible solutions, we select the one giving the largest improvement in the error function, by evaluating $F(c_i + {}_{\text{a}}c_i, \omega)$ at a grid of frequency points. Corresponding to the best solution, we prepare for the next iteration by modifying c_i again as in the previous step, i.e. S_{ci} is replaced by $S_{ci}(2y_{ci} - 1)$, while δ_r is replaced by its new lower value, and inequality in Eq. (15.6) is reformulated. The procedure is repeated till no further improvement in δ_r results.

The nature of PB inequalities in Eq. (15.6) is different for finite-impulse response (FIR) and infinite-impulse-response (IIR) digital filters. For the former case, Eq. (15.6) becomes a linear PB inequality, the solution of which, we showed,

can be made non-iterative [13, 16]. The method is simple to use, takes much less computer time as compared to the existing techniques, and yet has much better chances of converging to a global optimum. We applied the method to a number of sample designs, including that of a DHT, and obtained excellent results.

For the IIR case, $F(c_i, \omega)$ is a rational function of the form $P(a_i, \omega)/Q(b_i, \omega)$, where P and Q are nonlinear functions of a_i and b_i, the maximum order of nonlinearity being equal to the order of the filter. In this case, Eq. (15.6) becomes

$$P(a_i + \alpha_{ai}, \omega_r) - \delta Q(b_i + \alpha_{bi}, \omega_r) \leq 0 \tag{15.7}$$

where $\delta_r = D(\omega_r) \pm \delta_r$. This set of PB inequalities is nonlinear and the usual method of solution by linearizing each nonlinear variable is computationally expensive. To overcome this difficulty, we formulated an alternative method for solving nonlinear PB inequalities [7, 16] and applied it successfully to a number of useful IIR designs.

15.7 Variable IIR Digital Filters

In many applications, such as speech processing and spectrum analysis, it is often required to change the cutoff frequency of a digital low-pass filter or the bandwidth or centre frequency of a digital bandpass filter, by controlling, preferably, a single parameter in the filter structure. In view of the importance of such variable digital filters, and in view of the fact that the available techniques are either not wholly satisfactory or not adequate for handling a number of important situations, including bandpass filters, I suggested to S. S. Ahuja, a Ph.D. student, to concentrate on this topic.

The usual approach for achieving variable digital filtering is to use a frequency transformation. For example, if each delay element in the prototype filter is replaced by an all-pass network, a variable filter results, the control being affected by the all-pass parameter(s) [45]. If the prototype filter is IIR, then this approach leads to delay-free loops in the structure, which cannot be implemented digitally. Schussler, therefore, suggested the use of an FIR prototype; later, Johnson [46] indicated a general approach for removal of delay-free loops by computation of modified coefficients through a filtering process. We first established the desirability of IIR prototypes by showing that variable digital filters with FIR prototypes are highly inefficient with regard to the number of multiplications and have very high roundoff noise variance at the output. We next obtained a very simple method for eliminating delay-free loops. We argued that since the usual realization of IIR will be either cascade or parallel combinations of first- and second-order sections, all we have to do is to rewrite the transfer function of each such section, after transformation, in such a way that it can be realized without delay-free loops [18]. As compared to Johnson's method, our procedure offers, besides simplicity, a reduction in computations by a factor of 3 for first order and 2.5 for second order; this can be of great advantage in reducing the settling time in adaptive IIR filters.

15.8 Variable FIR Digital Filters

For variable cutoff linear-phase FIR filters, Oppenheim et al. [47] suggested using the transformation

$$\cos\omega = \sum_{k=0}^{P} A_k (\cos\Omega)^k \tag{15.8}$$

where ω and Ω refer, respectively, to the prototype and transformed filters. This transformation preserves the frequency response but distorts the frequency axis. The first order (1°) form of Eq. (15.8), where $P = 1$ and single parameter control is achieved by constraining the DC gain to unity, has been found particularly useful, one reason being that it results in a canonic realization of the transformed filter. We investigated this approach to variable digital filters in-depth, and obtained the following new and useful results:

(i) In the 1° case, we showed that the variable parameter A_o ($A_1 = 1 - A_o$, for invariant DC gain) should lie in the range 0 to $\cos^2(\omega_c/2)$, where ω_c is the cutoff frequency of the prototype filter (corresponding to $A_o = 0$). We also showed that in the transformed filter, the cutoff frequency Ω_c increases, while the cutoff slope decreases, monotonically, with increasing A_o. To overcome these two drawbacks, we formulated the following optimum 2° transformation:

$$\cos\omega = A_o + \cos\Omega - A_o\cos^2\Omega \tag{15.9}$$

This retains single parameter control and achieves a two-way variation of Ω_c as well as cutoff slope. The most important feature of Eq. (15.9) is that the computational load of the transformed filter is approximately half of that of a double-length prototype with 1° transformation, the performance in the two cases being comparable [12].

(ii) We extended the 1° transformation to design a bandpass filter with fixed centre frequency but variable bandwidth, again with single parameter control. The transformation cannot, however, be used to obtain constant bandwidth and variable centre frequency. We showed, however, that if the transformed bandwidth $\Delta\Omega$ is larger than the prototype bandwidth $\Delta\omega$, then it is possible to maintain $\Delta\Omega$ fixed and vary Ω_o (transformed centre frequency) above or below ω_o (prototype centre frequency). One, therefore, has to choose $\Delta\omega$ appropriately [10]; this increases the filter order.

(iii) To overcome the difficulty of increased bandwidth of the 1° transformed variable bandwidth, constant centre frequency digital bandpass filter, we formulated a new 3° transformation, given by

$$\cos\omega = A_o + A_1\cos\Omega - A_3\cos^3\Omega \tag{15.10}$$

where A_1 and A_0 are related to A_3 through $\omega_{1,2}$ and $\Omega_{1,2}$ (the subscripts 1 and 2 refer to the lower and upper cutoff frequencies, of the prototype and transformed filters). We showed that by appropriately constraining the parameters and prescribing A_3 as 2^{-n}, n being an integer (so that multiplication by A_3 amounts to a simple shifting operation only), it is possible to achieve constant $\Delta\Omega = \Delta\omega$, and single element controlled variable centre frequency without increasing the computational load, as compared to the 1° transformation. The number of delay elements has, of course, to be increased three times [14].

(iv) We extended the 1° transformation to two-dimensional variable cutoff digital low-pass filters. Also, the drawbacks of the 1° transformation, viz. higher cutoff frequencies and wider transition bands, have been shown to be overcome by an appropriately formulated 2° transformation. As in the one-dimensional case, the order of the filter is doubled thereby, but the computational load remains unchanged [8].

15.9 Nested Structures for FIR Filters

It has already been mentioned that the finite word length effects are intimately related to the structure of the digital filter. While a large number of such structures have been reported for the IIR filters, much less is known about the FIR case. I, therefore, suggested to a Ph.D. student, A. Mahanta, to study the various existing structures and to search for new ones which have the potential of reducing the finite wordlength effects. We first investigated a special FIR filter viz. the discrete Hilbert transformer (DHT). For a symmetric DHT of length $N = 2M + 1$ (M odd), the transfer function is

$$H(z) = z^{-M}[h_1(z - z^{-1}) + h_3(z^3 - z^{-3}) + \ldots + h_M(z^M - z^{-M})] \tag{15.11}$$

For the optimal DHT (ODHT) [48], we observed that the impulse response coefficients $\{h_n\}$ fall more or less inversely with n. This encouraged us to rewrite Eq. (15.11) as

$$H(z) = z^{-M} g_1(z - z^{-1} + g_3(z^3 - z^{-3} + \ldots . + g_M(z^M - z^{-M})) \tag{15.12}$$

where $g_k = h_k/h_{k-2}$, k odd, and $g_1 = h_1$. In general, g_k's are all distinct, but beyond a certain k, all g_k's are approximately equal. Thus if we let $g_k = , k = K$ to M, then

$$\begin{aligned} H(z). = z^{-M} g_1(z - z^{-1} + g_3(z^3 - z^{-3} + \ldots + \alpha(z^K - z^{-K} \\ + \alpha(z^{K+2} - z^{-(K+2)} + \ldots + \alpha(z^M - z^{-M}) \ldots) \end{aligned} \tag{15.13}$$

When Eq. (15.13) is implemented in the direct form, it still requires, the same processing time, but the coefficient storage requirement is now reduced to $(K + 1)/2$,

instead of $(N + 1)/4$. We investigated this modified implementation (NDHT) for various lengths and found that its performance is only slightly inferior to that of the ODHT in terms of deviations, and that in terms of coefficient quantization error, the NDHT is as good as, if not better, than the ODHT, especially for small wordlengths. Also, the multiplication roundoff noise of the NDHT is much less than that in the direct form implementation [11].

Encouraged by these results, we next investigated the general linear-phase FIR filter, having the transfer function (length $N = 2M + 1$):

$$H(z) = z^{-M}[a_o + a_1(z + z^{-1}) + \ldots + a_M(z^M + z^{-M})] \tag{15.14}$$

We observed that, in most cases of filter design, a_n decreases (in magnitude) with n, as in DHT, or oscillates with decreasing amplitude, as in bandpass filters, and that there are usually several orders of magnitude difference between the largest and the smallest a_n. Consequently, when the coefficients are quantized to fixed number of bits, all a_n's cannot be represented with the same degree of relative accuracy, and this results in error in the filter response. As in the DHT case, we, therefore, rewrite Eq. (15.14) as

$$H(z) = z^{-M}b_o[1 + b_1(z + z^{-1}) + \ldots + b_M(z^M + z^{-M})\ldots] \tag{15.15}$$

where $b_n = a_n/a_{n-1}$, $n = 1$ to M and $b_o = a_o$, and argued that b_n's should all be comparable in magnitude. As a result, effects of quantization should be less pronounced than in the case in which Eq. (15.14) is directly implemented. We carried out a deterministic as well as a statistical analysis of the filter response error for the direct and the alternate forms, and found that in majority of cases of practical importance, the new structure, which we called the 'nested structure', gives rise to less error; further, we found that multiplication round off error in the nested form is much lower than that in the direct form [15].

Later, we made a comprehensive investigation of the generalized nested structures, in which the coefficients to be implemented had been made to lie in the range $\frac{1}{2}$ to 1, by suitable decomposition and scaling. We have shown that using fixed-point arithmetic, these structures achieve the same accuracy and about the same roundoff noise as those obtained in the floating-point implementation. The optimum structure to achieve the minimum roundoff noise can be found; however, the search in that direction was not as involved as in the cascade form, and in most cases, near-optimum results are easily obtained by mere inspection of the impulse response coefficients [19].

15.10 Fourier Transform at Arbitrary Frequencies

A major development in digital signal processing is the discovery of the fast Fourier transform (FFT), which now plays a central role in many signal processing applications, particularly in spectral analysis. As is well known, the FFT achieves its efficiency by exploiting the uniformity of its samples in the time domain; however, it finds the discrete FT (DFT) at uniformly spaced frequencies only. While this is indeed the requirement in a variety of applications, there do exist a few important spectral analysis situations where one has to estimate the spectrum at nonuniform frequencies. Typical examples are: constant-Q spectral analysis [48], speech processing for enhancement of formant resonances; correction of nonlinear distortion in frequency [50]; and detection and estimation of a narrow band spectral peak [49]. Available techniques for this purpose are either computationally inefficient, or applicable to some restricted situations only, and it appeared worthwhile to find alternative efficient techniques, which are of general applicability. This is what R. C. Agarwal, a colleague, and I suggested to a Ph.D. student, R. Sudhakar, to persue. We indeed came up with a new general method which retains the order of computation at FFT levels, but allows the flexibility of choosing arbitrary frequencies for a uniformly sampled signal. The method is based on the fact that the FT of a finite length sequence at any arbitrary frequency can be expressed as a weighted sum of its DFT coefficients. These weights are suitably approximated such that the FT is very nearly equal to the sum total of a few dominant terms of the weighted sum, which are computed directly, and the DFT of a derived sequence formed by multiplying the original sequence with a sawtooth function. The number of directly computed terms is so chosen that the error does not exceed the desired limits [20].

15.11 Inefficiency Compensation in CTD Delays and Signal Processors

The charge transfer device (CTD) is a monolithic IC analog sampled data delay line, first disclosed in 1970. CTDs are of two types, viz. bucket brigade device (BBD) and charge coupled device (CCD), and though only a decade old at that time, they proved to be uniquely suitable for many analog signal processing situations. They were successfully applied in MTI radar, TV ghost suppression, spectrum analysis, matched filtering ,etc. Being analog, CTDs can, at least theoretically, achieve all the advantages of digital signal processors, without the need for A/D conversion and without suffering from quantization errors [25].

CTDs, however, have their own limitations, the most important being the charge transfer inefficiency (CTI), which causes magnitude as well as delay distortions. CTDs operate by storing charge, proportional to the sampled value of a signal, in MOS capacitors, and transferring it from one stage to the next under the influence of external clock signals. The charge transfer, unfortunately, is not perfect; the fraction

of the charge which fails to get transferred is a measure of the CTI. If all the stages of the CTD are identical, then each delay stage can be modelled by the z-transfer function

$$z_{\varepsilon}^{-1} = (1 - \varepsilon)z^{-1}/(1 - \varepsilon z^{-1}) \tag{15.16}$$

instead of z^{-1} to which it reduces when $= 0$.

I was attracted to CTD's while in England, mainly because of the similarity between digital signal processing and CTD signal processing. After returning to IIT in 1974, I started thinking about the possibility of compensating for CTI by using a technique similar to predistortion in analog filter design. Along with a graduate student, R. K. Arora, I evolved the following simple procedure. Given a transfer function $H(z)$ to be realized, replace z by its equivalent expression in terms of z, viz.

$$z = (1-\varepsilon)z_e + \varepsilon \tag{15.17}$$

to yield a transfer function $G(z)$, which is, of course, identical to $H(z)$. $G(z)$ can now be realized by the nonideal CTD; the resulting structure, which is necessarily recursive, is an exact realization of $H(z)$. We applied this technique for realizing an ideal delay and a second-order resonator [21].

The preceding method was based on the assumption that all CTD stages had the same CTI and that there were no transfer losses. Later, V. G. Das, a Ph.D. student and I worked on the more general case where these assumptions are not valid, and obtained expressions for the feedback coefficients for exact compensation of a CTD delay. We also developed a tuning algorithm for the critical adjustment of all the feedback coefficients. One of the criticisms of this compensation technique was that a large number of feedbacks necessary for compensation would be difficult to fabricate on the chip. We, therefore, looked into the extent of compensation obtained by using a limited number of feedbacks, theoretically [28] as well as experimentally [23]. For the latter, we used a simple experimental set up with a highly inefficient CTD (obtained as a gift from Dr. H. Wallinga of Twente University, Netherlands) delay comprising of dissimilar stages, and to our pleasant surprise, we found that good compensation could be achieved using only the first two feedbacks.

Towards the end of 1977, Professor A. B. Bhattacharyya of IIT Delhi, and his group fabricated the first CCD in India, and by 1978, we got a sizeable number of CCDs to play with. The initial successes obtained in compensation by using a small number of feedbacks encouraged us to carry out more elaborate investigations. We argued that the whole compensating structure, consisting of one or two feedbacks, could be fabricated as a separate block and used as a pre-or post-filter. As a pre-filter, the compensation block simply serves to pre-distort the input signal in a manner, which is opposite to that introduced by the CTD. By extension of this concept, we evolved a simple, but accurate method for measurement of CTI. We fed a signal $K_1u(n) - K_2u(n - 1)$, where $u(n)$ stands for the unit discrete step, and found, from theoretical analysis, that the first two consecutive output samples will be equal when $K_2/K_1 = \sum\varepsilon_i$. In a simple experimental set up, we obtained a low-frequency square wave signal by

frequency division of the clock signal, and used a shift register and a summer to obtain the required signal, K_1 and K_2 being implemented by potentiometers [24]. As compared to other methods, which involve measurement of the difference between two pulse heights, our method has all the advantages of a null measurement.

A method of compensating for CTI in a CTD delay was proposed by Caywood and Buss [51] in which q CTD's each having M/q stages, are operated in parallel through an input steering circuit and an output multiplex circuit. Such a multiplexed CTD (MCTD) achieves a delay of M stages, but with reduced CTI, as shown by an approximate analysis by Caywood and Buss. We carried out a vigorous analysis of the MCTD and showed that the magnitude and delay responses are an equal ripple. Further, the magnitude ripple decreases with increasing q, but the delay ripple is independent of q and is determined by only the CTI [22].

I went to the United States in 1978, to work for a year at the Iowa State University, as a Visiting Fellow. At Iowa, I interacted with an outstanding researcher, Professor A. N. Michel. I visited several US Universities and one Canadian University for invited seminar lectures, and also gave an invited talk at a Workshop on Algebraic Complexity of Computations. I also interacted with an industry, Rockwell International, through a graduate course offered on TV, with frequent personal visits. All these gave me excellent opportunities for an in-depth exploration of state of the art in research and development in the fields of digital and CTD signal processing. In particular, I found that application of CTD in the industry mostly uses transversal structures, and that major efforts are being directed to the use of this structure in spectrum analysis. On my return to India, in 1979, the first problem I tackled, concerned the compensation of CTI in such structures. One of the very early suggestions for this purpose consists of predistorting the tap weights [52]. If the desired transfer function is

$$H_i(z) = \sum_{k=0}^{N} h_k z^{-k}, \tag{15.18}$$

and $h_k's$ are predistorted to h_k', then the realized transfer function will be

$$\begin{aligned} H_a(z) &= \sum_{k=0}^{N} h_k'(1-\varepsilon)^k z^{-k}/(1-\varepsilon z^{-1})^k \\ &\triangleq \sum_{k=0}^{\infty} h_k'' z^{-k} \end{aligned} \tag{15.19}$$

One way of choosing h_k' is to set $h_k'' = h_k$, $k = 0$ to N; following this, Buss et al. [52] established an iterative formula for h_k', which has been widely cited in the literature and used in CTD signal processor design. We found that h_k' can be expressed explicitly in terms of h_k and that this formula is rather simple. We also derived an explicit formula for h_k'', $k > N$, and used it for estimating the error in this method of compensation [26].

15.12 CTD Linear Phase Versus Minimum Phase Design

CTD transversal filters are usually designed for linear-phase characteristic; the resulting time delays are acceptable in most situations but not so in some telecommunication applications, e.g. in voice lines, due to the problems of echo and singing. To avoid this, Foxall [53] investigated an example of minimum phase design, and observed that besides reducing group delay, the minimum phase design is less sensitive to CTI and tap weight error. As a starting problem, I suggested to a Ph.D. student, Navin Kapur, to make a detailed analysis of the sensitivity of general linear and minimum phase designs to CTI in order to find out the validity or otherwise of Foxall et al.'*s* conclusions in general. We found that the answer is in the negative and that the sensitivity to CTI is a sensitive function of the zero locations. We also derived conditions under which the minimum phase design would be superior to linear-phase design [30].

15.13 Coefficient Sensitivity in CTD Filters

CCD transversal filters are most commonly implemented, using the split-electrode technique and the resulting tap weight errors constitute a major factor limiting the stopband performance. This error increases with decreasing tap weight, and unfortunately, in typical frequency-selective filters, there is a large number of small tap weights, the ratio of the smallest to the largest coefficient being of the order of a few thousands! For low-pass filters, however, we observed that the difference between the adjacent coefficients has a much smaller spread than the coefficients themselves. We exploited this fact to formulate a new implementation technique for reducing coefficient sensitivity. Instead of realizing a given

$$H(z) = \sum_{n=0}^{N-1} h(n) z^{-n} \tag{15.20}$$

directly, we formed a new sequence

$$h_1(n) = h(n) - h(n-1) \tag{15.21}$$

with $h_1(0) = h(0)$ and $h_1(N) = -h(N-1)$. Implementing a filter with the weights $h_1(n)$ gives a transfer function $H_1(z)$, which, upon multiplication by $H_2(z) = 1/(1 - z^{-1})$, gives $H(z)$. $H_2(z)$, we argued, can be realized by a switched capacitor differential integrator, which can be fabricated along with the CCD, by the same technology. The resulting structure does not use any extra hardware as compared to the usual realization of $H(z)$ because the differential integrator is a replacement of the differential amplifier, required in the latter. We also showed that the following additional advantages are obtained in the modified implementation: (i) Since $\sum h_1(n) = 0$,

the parallel channel present in earlier designs to cancel the output DC offset due to fat zero and clock transients, is not required. This implies a saving of chip area and simplified design layout and (ii) Passband gain G is higher, implying a smaller insertion loss and hence, a larger dynamic range [29].

15.14 Spectrum Analysis by CTD

A large part of Navin Kapur's Ph.D. thesis work related to the use of CCD for spectrum analysis. One published work relates to the implementation of prime transform algorithm (PTA) using CCD programmable transversal filters (PTF) [26]. The PTA converts the problem of computation of DFT into a circular convolution, and when the number of points N is large, the chip area increases considerably and the CTI has a significant effect on the performance. Previously reported systems employing a PTA used a $(2N - 3)$ stage fixed tap weight CCD filter for each convolution. Using a CCD programmable transversal filter based on a new concept viz. storing the signal to be analysed, and passing the basis vector sequence through the CCD, we showed that it is possible to implement an N-point DFT using the PTA with an $(N - 1)/2$ stage PTF, for each convolution. This represents a factor of four reductions in CCD stages over previously reported fixed tap weight systems.

15.15 Looking Ahead

In this chapter, I have briefly described our efforts and some new results arising from them in the areas of digital and CTD signal processing. After about a decade of interaction with these areas, we felt that we had solved only a few problems of contemporary interest at that time and that much remained to be done. One major problem which should warrant the attention of serious workers in digital signal processing concerns the heavy (and sometimes undue) reliance on analog filter techniques and computer-aided methods. A direct approach in the z-plane, independently of the s-plane, leading to analytical, rather than computer-aided methods, was yet to be developed for this young field to mature. This, I felt, required dedicated work by individuals who would accept potential failures as the key to future success, and to whom a negative result means one step forward to the ultimate goal.

Since the analysis and design of CTD and digital signal processors were very much alike, any development in the latter field would have definitely benefited the former. In addition, much efforts were needed to overcome the limitations of the device, imposed by fabrication technology and the physics of operation, while, concurrently, new applications of the device and improvement of performance in known applications by new design methods will continue. Also, a realistic assessment of what is better in a particular situation, digital or CTD signal processing, is long overdue, and deserves serious consideration, ignoring the claims of overenthusiastic workers in either field.

Digital and analog signal. processing techniques, as I commented in an earlier paper [53] are 'two arrows in the quiver', which are always 'better than one', A judicious combination of the two will, perhaps, lead the field of signal processing beyond presently known boundaries, particularly because of the capability of the CTD to perform analog as well as digital signal processing.

Acknowledgements I would like to take this opportunity to express my grateful appreciation to the IETE for bestowing a great honour upon me through the award of the Fifth Ram Lal Wadhwa Gold Medal, and for inviting me to deliver a memorial lecture on which the chapter is based. I have been very privileged to have studied under great teachers like (Late) Professor H. P. De, (Late) Professor J. N. Bhar, Professor A. K. Choudhury, Professor S. Deb, Professor M. K. Dasgupta, Professor A N. Daw and Professor B. R. Nag, to all of whom I express my gratitude. I have also been lucky to have worked in wonderful academic environments provided by the IIT Delhi, University of Minnesota, USA, University of Leeds, England, and the Iowa State University, USA; to all those responsible for creating and maintaining this environment, I owe deep indebtedness. Finally, I have been exceptionally lucky in working with a band of very brilliant and dedicated students, some of whom I have specifically named during the course of this lecture, and a group of outstanding colleagues; to all of them, I owe a special word of appreciation and thanks.

Chapter 16
Signal Processing Applications of Charge-Coupled Devices

Abstract The charge-coupled device, first disclosed in the Bell System Technical Journal in 1970, is an analog, sampled data delay line and has made a significant impact in the field of signal processing. In this chapter, a brief introduction to the device is followed by the considerations, which make it so important and convenient in signal processing applications. A number of specific applications are outlined and their advantages and limitations are briefly discussed. In particular, the effect of the most important limiting factor, namely, charge-transfer inefficiency is discussed in some detail and several methods of compensation are outlined. The chapter concludes with an indication of the work being done at IIT Delhi on the various aspects relating to theory, fabrication and signal processing applications of the device.

Keywords Charge-coupled devices · Signal processing · Charge-transfer inefficiency · Transversal filters · Spectral analysis

16.1 Introduction

A charge-transfer device (CTD) can store a charge proportional to the sampled value of a signal and transfer it from one stage to the next under the control of external clock signals. These devices can store and transfer both analog and digital signals and provide a convenient, electrically variable delay for signal processing applications. Two types of monolithic IC realizations of these devices are available; these are known as 'bucket-brigade devices' (BBD) and 'charge-coupled devices' (CCD).

Bucket-brigade devices, which can be implemented in both discrete and IC versions, consist of a series of capacitors coupled by FET or bipolar switches, which can be switched ON or OFF in a controlled fashion by external clock pulses. Although the underlying principle of these devices was known for a long time [1], the first implementation in discrete version, using bipolar transistors as switches, was reported in 1967 [2]. The first integrated analog-sampled delay using MOS capacitors and MOSFET switches was developed in 1970 [3].

The ‘charge-coupled device’ was developed in the year 1970 by Boyle and Smith [4] at the Bell Telephone Laboratories. This device, for which no discrete equivalent exists, consists of closely spaced metal or poly-silicon electrodes on a silicon surface separated by a thin oxide layer. A signal can be stored in these MOS capacitors, as minority carrier charge, in the potential wells created by applying certain voltage pulses to these electrodes. By applying these pulses in proper sequence, the signal charge packet can be transferred from one electrode to the next. Due to their operational simplicity and novelty, CCDs stimulated a large number of workers throughout the world, to work on the development and applications of these devices. This resulted, in a very short time, in a large number of variations of the original 3-phase structure [4] and made a revolutionary impact in the fields of image sensing, signal processing and digital memories.

In the field of imaging, CCDs provide a compact and convenient device as it can store a charge proportional to the intensity of light falling on each of its cells and the charge can be transferred and obtained serially at the output in a natural way. This has led to the development of all solid-state TV cameras and facsimile systems [5–7]. Due to their low inherent noise characteristics, they are sensitive even at extremely low-light levels.

As digital memories, CCDs fill a gap between the low-cost discs and the fast-access-time semiconductor RAMs and are already available as single chips with as much as 64 K bit capacity. However, because of their dark current, the memories are volatile, and the stored information must be regenerated periodically. Access times of the order of tens of microseconds have been achieved by an intelligent organization of the storage elements and the peripheral circuitry.

Charge-transfer devices, and in particular, charge-coupled devices, are uniquely suitable for many signal processing functions and have found many applications in radar, TV, sonar and other areas of communications. They provide a simple and compact way of obtaining an accurate clock-controlled time delay of analog signals covering a range of a few 100 ns to several seconds. The analog signal is processed in its natural domain as there is no need to quantize the sampled signal. With split-electrode structures, compact transversal filters are realized, which have very sharp cutoff characteristics, and low in-band ripple. Devices suitable for signal correlation, matched filtering and spectrum analysis have been developed. These devices hold an advantage over other comparable techniques in terms of size, cost and power requirements.

As with all other devices, CTDs have their own limitations. Significant among these limitations is the dark current and the charge-transfer inefficiency, which are responsible for the degradation of the analog signal during processing. Dark current is the leakage current in CCDs produced due to thermally generated minority carriers. This adds charge at a constant rate, and eventually fills up the potential well, thus causing the signal to be swamped. To avoid this, the signal has to be swept out at a fast enough rate, which therefore limits the maximum delay achievable. Charge-transfer inefficiency is a more serious limitation of a CTD and results due to the incomplete transfer of a charge packet from one well to the next. This causes frequency-dependent attenuation and consequent distortion of signals. Efforts have been made to reduce

inefficiency by optimizing the device geometry and by improvements in the technology, e.g. by using buried channel techniques in CCDs. By these improvements, low values of inefficiencies are obtained even at high clock frequencies, and figures of the order of 5×10^{-5} at 135 MHz have been quoted [8]. Nevertheless, for a specified limit of distortion, the maximum number of stages that can be used are limited. Several ingenious circuit-theoretic techniques have also been developed for the compensation of the effect of transfer inefficiency on the propagated signal. The effect of transfer inefficiency and techniques for its compensation will be discussed in greater detail later in this chapter.

This chapter reviews the progress made in the field of signal processing with CCDs. As a prelude to this review, the basic operation and the physics of CCDs are given in the next section. The following aspects are discussed: the input and output schemes; a study of the effect of transfer inefficiency, and the various techniques for the measurement and compensation of its effect; a study of the transversal filters and various functions realizable with such filters; spectral analysis using CCDs; and examples of some of the numerous applications in radar and TV.

16.2 Physics of Charge-Coupled Devices

A charge-coupled device is a special kind of integrated circuit shift register, whose structure is similar to an MOS transistor with the difference that instead of one gate electrode, it has a number of them, between the source and the drain, as shown in Fig. 16.1. By alternately pulsing the series of gate electrodes, charge can be transported from the source to the drain. The transfer of charge is greatly influenced by the clocking waveforms. Originally, a three-level stepped clocking scheme was suggested for operating a three-phase CCD. Presently, a simpler two-level clocking scheme is used in practice, as described below. Let us consider a p-channel CCD. Initially, let the charge be under the electrode ϕ_2 at the instant t_1 when ϕ_1 and ϕ_3 are at the resting potential, say -5 V and ϕ_2 are at, say, -15 V (Fig. 16.2). At the instant t_2, when ϕ_3 turns on, charge is transported to the ϕ_3 well. For the duration in which the voltages on ϕ_2 and ϕ_3 are simultaneously on, charge will be shared equally between them (t_3). When ϕ_2 is being withdrawn, further charge transport

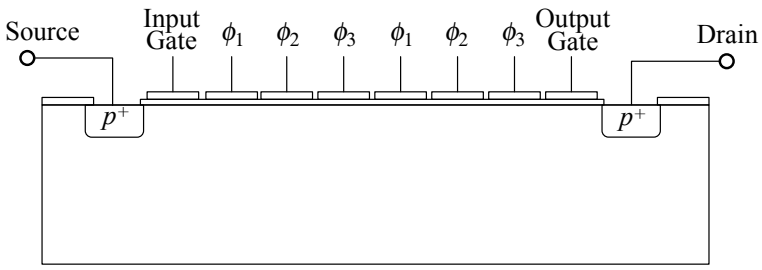

Fig. 16.1 Cross section of a 3-phase CCD showing the basic features

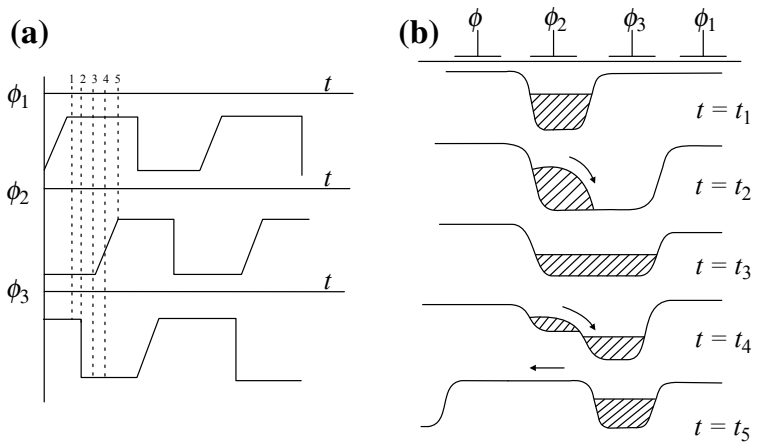

Fig. 16.2 Two-level clocking waveform for use in a 3-phase *CCD* and the potential diagram showing flow of charge, including possible 'back flow' at $t = t_5$

will take place from ϕ_2 to ϕ_3 (t_4). At the end of turn-off (t_5), a small fraction of charge remains under ϕ_2. What is important in this process is that a certain amount of charge flows backward. If the turn-off times are small and comparable to transfer time of the charge packet, the total charge will be significantly shared between the collecting electrodes (t_6). The 'Back Flow' of charge results in a loss of charge from the original packet [9].

A charge packet is not completely transferred to an adjacent electrode in the direction of transfer for many other reasons. First, due to the finite mobility of carriers, they require a certain time to travel the distance of an electrode and reach the next electrode. If the clocking frequency is high, all the charges are not in a position to be transferred, resulting in transfer loss [10]. Smaller electrode length and higher mobility of carriers (n-channels) will minimize such losses.

Surface state trapping is also a dominant mechanism of loss of charge from the travelling packet. This is so because surface traps are almost instantaneously filled but emptying time constants are dependent on energy, and there is a large dispersion in the value of these time constants. When the charge packet is transferred to the adjacent site, the trapped carriers in the surface states will gradually get released, but not all will be able to join the parent packet and those which cannot, get lost to the original signal [11, 12]. Such an inefficiency can be countered by using a non-empty zero known as 'Fat Zero'. The Fat Zero will attempt to keep the traps filled, thus making them inoperative during the presence of the signal.

Various models have been proposed for the discharging mechanism of the MOS capacitor containing a charge packet. The continuity equation describing the charge dynamics is given by

$$q\frac{\partial p(x,t)}{\partial t} = -\frac{\partial j(x,t)}{\partial x}. \tag{16.1}$$

The current consists of three components; (x is the direction of charge travel):

(a) Thermal diffusion,

$$j_D = qD\frac{\partial p(x,t)}{\partial x} \tag{16.2}$$

(b) Self-induced drift,

$$j_s = qp(x,t)\mu_p E_s(x,t) \tag{16.3}$$

(c) Fringing field drift,

$$j_f = qp(x_2 t)\mu_p E_f(x,t) \tag{16.4}$$

where q is the electronic charge, p is the number of charge carriers per unit volume, E is the electric field, j is the current density, D is the diffusion coefficient and μ is the carrier mobility.

In the absence of fringing fields, the thermal diffusion term dominates the long transfer times [10]. The fringing field becomes effective for short gate length [13]. The self-induced term manifests itself due to the charge gradient and is given by

$$E_s(x,t) = \frac{q}{C_{ex}}\frac{\partial p(x,t)}{\partial x} \tag{16.5}$$

The continuity equation may be solved numerically [14] or by charge-control approach [15, 16] the latter giving a closed-form solution. The charge-control method, though convenient to handle, suffers from the limitations that the space-charge distribution is assumed and the effect of transferred profile is not considered.

16.3 The Input and Output Schemes

16.3.1 Input Circuit

Input circuit is meant to introduce a charge packet proportional to the input signal into the device. The input scheme consists of a diode followed by two gates as shown in Fig. 16.3. The basic objective is to charge the surface capacitance below G_2, by a signal charge which subsequently is to be transferred. The function of the gate G_1 is to switch the diode on and off from the gate G_2. This provides the built-in sampling capability in the device.

There are two basic techniques of injecting/controlling the input charge.

(i) *Potential equilibration*: The surface potential below G_1 and G_2 are made equal to the source (diode) potential. The mobile charge under G_2 is given by

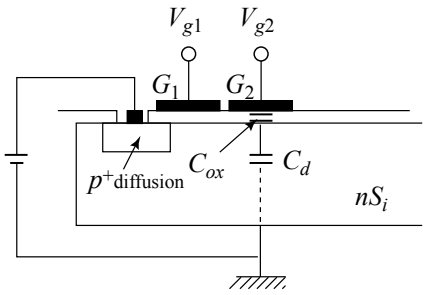

Fig. 16.3 Basic input scheme of a CCD

$$Q_{sig} = C_{o^x}(V_{g2} - V_T) \tag{16.6}$$

Equation (16.6) shows that the amount of charge can be controlled by (a) the applied gate voltage V_{o2}, and (b) the threshold voltage V_T which in turn depends on V_s.

(ii) *Current charging*: A certain amount of current is allowed to charge the surface capacitance below G_2 for a controlled duration. The diode (input), gates G_1 and G_2 may be regarded as constituting an MOS transistor as shown in Fig. 16.4. Charging takes place during the overlap time between the pulses on G_1 and G_2. The collecting potential under G_2 is the field-induced drain. Since the surface potential under G_2, simulating the MOST drain is a function of charge, the MOST may be characterized by a drain with time-varying drain voltage.

Amount of charge below G_2, in this scheme, is given by

$$Q_{sig} = \int_{t_1}^{t_2} I \, \mathrm{d}t \tag{16.7}$$

The operating conditions are such that I is saturated, making it time independent.

Here again, Q_{sig} may be controlled in two ways: (a) by controlling the duration of current charging out (b) by controlling the magnitude of current which depends on V_{g_1} and V_T, the latter being a function of the source potential V_s.

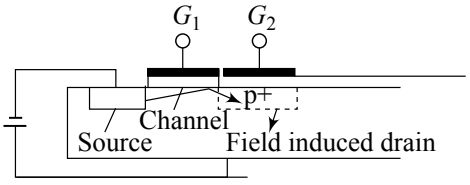

Fig. 16.4 MOST action between source and field-induced drain

16.3.2 Output Circuit

The simplest output scheme consists of dumping the charge out of the CCD through a drain diffusion, and measuring the current that flows at the output (Fig. 16.5). An output gate, usually maintained at a constant dc potential, is interspersed between the phase electrodes and the drain, to minimize clock pickup at the output.

On-chip amplification, and consequent improvement in noise characteristics, are provided by a scheme, by using reset and output MOS transistors [17–20], as shown in Fig. 16.6. In this scheme, the output charge is stored momentarily in the floating p^+ diffusion, which is connected to the gate of an on-chip output MOS. The output of this transistor, is, therefore proportional to the charge stored. To prepare the system for accepting the next charge packet, the reset gate is turned on, which resets the floating diffusion potential to a predetermined value.

More complex schemes, such as the use of correlated double sampling (Broderson and Emmons [19]) to reduce noise further, and the use of a floating gate, instead of the diffusion (Wen [20]), are also possible.

An important output method in which the outputs are tapped after every bit, and which is important in signal processing devices, is subsequently discussed in detail.

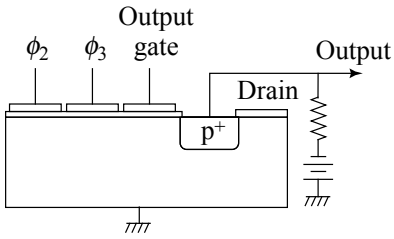

Fig. 16.5 Basic output scheme of a CCD

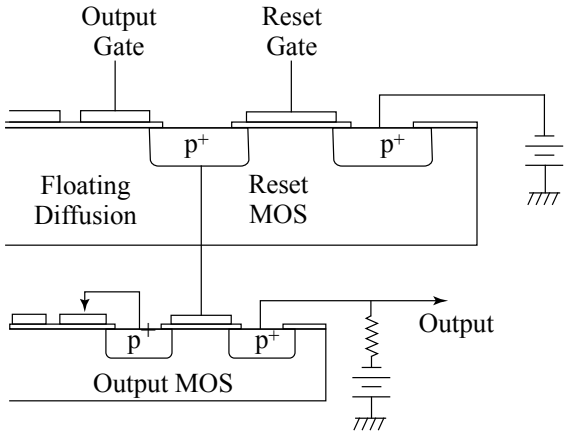

Fig. 16.6 Output scheme using a floating diffusion, reset MOS and output MOS to provide on-chip amplification

16.4 Characterization, Measurement and Compensation of Charge-Transfer Inefficiency

The basic function of a CTD is to give a time delay to the sampled analog signals. For obtaining a distortionless delay of signals, the signal charge packet integrity must be maintained, as it transfers from stage to stage. It is not, however, possible to obtain a complete transfer of the charge packet. A small proportion α of it is left untransferred in each transfer. Thus, in a p-phase device, $p\alpha$ times the charge packet remains back, and gets added to the next sampled signal charge packet. This proportion is called transfer inefficiency (ε) and the proportion of charge that gets transferred is known as transfer efficiency (η), their sum being equal to unity in most of the devices. In certain devices, a small proportion of the charge is lost irrevocably in which case their sum becomes less than unity. Thus,

$$\varepsilon + \eta \leq 1 \tag{16.8}$$

The transfer process is generally characterized by means of a simple block diagram of the CTD stage, as shown in Fig. 16.7. Here, z^{-1} represents an ideal delay of one clock period (T seconds), in the Z-transform notation. For sinusoidal excitation, we can write

$$z^{-1} = \exp(-j\omega T) \tag{16.9}$$

The transfer function of this stage (z_1^{-1}) is given by

$$z_1^{-1} = \eta z^{-1} / \left(1 - \varepsilon z^{-1}\right) \tag{16.10}$$

and the transfer function for the N-stage CTD is given by

$$H(z) = \left(z_1^{-1}\right)^N = \eta^N z^{-N} / \left(1 - \varepsilon z^{-1}\right)^N \tag{16.11}$$

The transfer function $H(z)$ of the N-stage CTD delay, given in Eq. (16.11), differs from that of an N-stage ideal delay, given by z^{-N}, due to the term $\eta^N(1-\varepsilon z^{-1})^{-N}$ which is responsible for attenuation and distortion. This distortion causes a train of spurious pulses in the unit sample response of the device. The frequency response deviates in magnitude as well as phase from that of an ideal delay. The unit sample response of the device can be obtained by taking the inverse Z-transform of Eq. (16.11), the result is

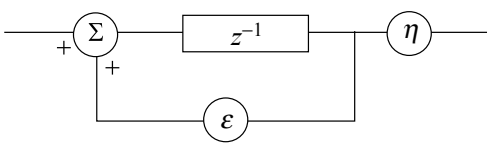

Fig. 16.7 Block diagram of a CTD stage

$$h(n) = \eta^N \Bigg[\delta(n-N) + \binom{N}{1} \in \delta(n-N-1) + \binom{N}{2} \in^2 \delta(n-N-2) + \cdots \Bigg] \tag{16.12}$$

where $\delta(n)$ is the unit sample function defined by

$$\delta(n) = \begin{cases} 1 \text{ for } n = 0 \\ 0 \text{ for } n \neq 0 \end{cases} \tag{16.13}$$

The delayed sample output, $\delta(n-N)$, which is the desired output, is attenuated by the factor η^N, and is followed by an infinite train of spurious pulses.

By replacing Z by exp. $(j\omega T)$ in Eq. (16.11), the frequency response of the inefficient CTD can be obtained as

$$H\left(e^{j\omega T}\right) = \eta^N e^{-j\omega T}\left(1 - \in e^{-j\omega NT}\right)^{-N} \tag{16.14}$$

For small values of $\in$, Eq. (16.14) may be approximated as

$$H(e^{j\omega T}) \cong \eta^N e^{-jN\omega T} e^{N\in(\cos\omega T - j\sin\omega T)} \tag{16.15}$$

The magnitude and phase components of Eq. (16.15) can be separated as

$$\left|H(e^{j\omega T})\right| \cong \eta^N e^{N\in\cos\omega T} \tag{16.16}$$

and

$$H(e^{j\omega T}) = \phi(\omega) \cong -N\omega T - N \in \sin\omega T \tag{16.17}$$

where ϕ stands for phase. The magnitude and phase responses of an ideal delay are given by unity and $-N_\omega T$, respectively. The inefficient CTD delay has a non-uniform magnitude response; its magnitude is unity at $\omega = 0$ and gradually reduces as frequency is increased, becoming equal to $e^{-2N\in}$ at half the sampling frequency (Nyquist limit). The phase response also deviates from the ideal by—$N\in\sin\omega T$. Both magnitude and phase responses violate the conditions for distortionless transmission.

Techniques for the measurement of inefficiency normally constitute measurement of this deviation either in time domain or in frequency domain, and by correlating this distortion with the expressions given in Eqs. (16.12), (16.16) and (16.17), the value of $\in$ is found out. In the time domain, strength of the spurious pulses in impulse response is compared with the strength of the desired impulse output [21–23]. From Eq. (16.12), one can see that the ratio of the second and the first output pulses is equal to $N\in$. Similarly, with a unit step input, expressions for $N\in$ can be obtained in terms of the ratio of the difference of pulse heights to the actual pulse heights at the output. These techniques normally require measurement of small pulse differences,

which is difficult and prone to several inaccuracies. To increase the magnitude of these differences in pulse heights, Levine [24] suggested a technique of multiple looping the signal, thus increasing the effective number of stages. In this method, the unit sample input fed to the CTD is made to pass through the device several times, by means of a feedback loop which feeds the output of the CTD to its input. This increases the effective number of transfers, thus making the trailing charge packet large enough for convenient measurement.

A simple method known as 'Pre-distortion technique' has been proposed by Dutta Roy and Das [25] for the measurement of the average transfer inefficiency of an N-stage CTD. This technique consists of introducing a known distortion in the square wave input to the CTD, so as to equalize two consecutive pulses at the output. The amount of distortion introduced gives a measure of the sum of inefficiencies of all the stages.

A variety of techniques have been suggested for reducing the effect of transfer inefficiency on the signal propagated through a CTD delay. By demultiplexing the sampled signal components into several parallel channels and combining them properly after the required delay, it has been shown that the effect of transfer inefficiency can be reduced [26, 27]. This is possible because the individual charge packet goes through less number of transfers. Another technique, several variations of which were proposed, is to store the signal in alternate stages only and to store zeros in the remaining stages [28–30]. The effective inefficiency, in this case, reduces to the order of $\in^2$.

Boonstra and Sangster [31] presented a simple technique for a first-order compensation of the output of a CTD for the effect of incomplete transfer. The technique employs a single feedback of coefficient $N\in$. The feedback, which is between two adjacent storage sites (in contrast with two adjacent stages), requires a negative amount of charge to be held at a storage site. Such a charge storage is possible with BBDs only, and is not physically possible with CCDs even with 'fat' zeros.

Thornber [32] presented a technique for compensation by linear filtering by means of a sampled data filter at the output of the CTD. The filter is matched to cancel out the distortion introduced by the transfer inefficiency. Two types of realizations of such filters have been proposed. The direct realization given in Fig. 16.5a uses an FIR filter and the feedback realization, given in Fig. 16.5b makes use of an IIR filter. In both the schemes, an infinite number of stages are required for achieving ideal compensation. It has been shown, however, that a good approximation can be achieved with only two stages in both cases for CTDs with $N\in \ll 1$ (Fig. 16.8).

A scheme for perfect compensation of the effect of transfer inefficiency has been proposed by Dutta Roy and Arora [33]. The scheme employs negative feedback, from the output of each stage to the input. It has been shown that any given transfer function can be realized exactly by this method using inefficient CTDs. The scheme consists of replacing z^{-1} in the given transfer function $H(z)$, by an expression consisting of terms of z_1^{-1}, which can be obtained from Eq. (16.10). This yields a new transfer function $G(z_1)$ which can be realized using inefficient CTD's. It may be recalled that z_1^{-1} represents the transfer function of the inefficient CTD. When used to realize an N-stage ideal delay, this requires negative feedbacks from the output of each of the

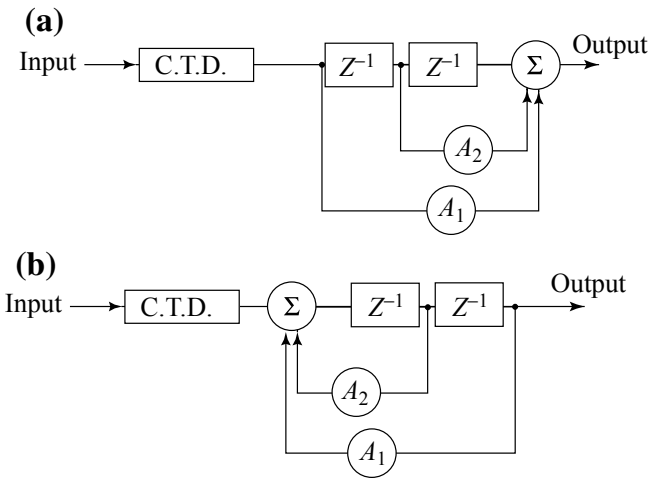

Fig. 16.8 Linear filtering techniques for the compensation of transfer inefficiency **a** direct filter technique **b** feedback filter technique

N stages to the input with coefficients $(h_1, -h_2, \ldots, -h_N)$ which are all functions of $\in$ and an amplifier of gain $A = \eta^{-N}$. Figure 16.9 gives the block diagram for this realization.

The scheme has been extended to cover the case of a CTD with non-identical stages by Dutta Roy and Das [34]. An 18-stage CTD with $N\in = 0.8$ and with non-identical stages, consisting of 2-stages of a discrete BBD and a 16-stage CCD, has been compensated by limiting the feedbacks to the first two stages only. This results in considerable improvement in the frequency response of the device.

Compensation schemes mentioned above require external circuitry for their implementation. Transfer inefficiency being a function of several parameters like clock frequency, wave shape, temperature, the feedback coefficients, which are functions of $\in$ require resetting, which is difficult to implement in practice. Due to these reasons, the tendency seems to be to live with it and till now compensation has been rarely adopted.

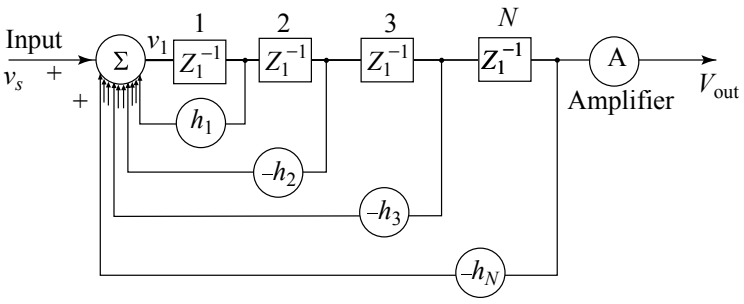

Fig. 16.9 Feedback compensation scheme for the realization of N-stage ideal delay using inefficient charge-transfer devices

16.5 CCD Transversal Filters

Transversal filters as a general class use time-delayed waveforms of a given input signal, weighted and summed with the proper signs to generate a wide range of filter characteristics [35].

Charge-coupled delay lines, when provided with taps along the channel, provide a versatile implementation of transversal filters; this is the building block for most systems using CCDs for signal processing [36, 37]. The output of an N-stage transversal filter is given in (Fig. 16.10).

$$V_0(nT_0) = \sum_{K=0}^{N-1} h_K V_K = \sum_{K=0}^{N-1} h_K V_i(nT_c - KT_c)$$
$$= \sum_{K=0}^{N-1} h_K V_i\{(n-K)T_c\} \tag{16.18}$$

where $h_K =$ Kth tap weighting coefficient, $V_K =$ Voltage on the Kth tap at the instant of time, nTc = value of the input voltage K sample periods earlier, $V_0 =$ output signal (sampled) at the instant of time and $T_c =$ delay per stage $= 1/f_c$ and $f_c =$ clock frequency.

This is a non-recursive technique, i.e. no feedback elements are used. In general, a transversal filter cannot yield as sharp a response characteristic as a recursive filter for a given number of delay stages, However, it has the following advantages which make it attractive [38]: (i) It is always stable, (ii) It can be designed to give an exactly linear phase characteristics and (iii) Response characteristics depend only on the relative values of the coefficients and not on their absolute values, thereby making the frequency response less sensitive to coefficient errors.

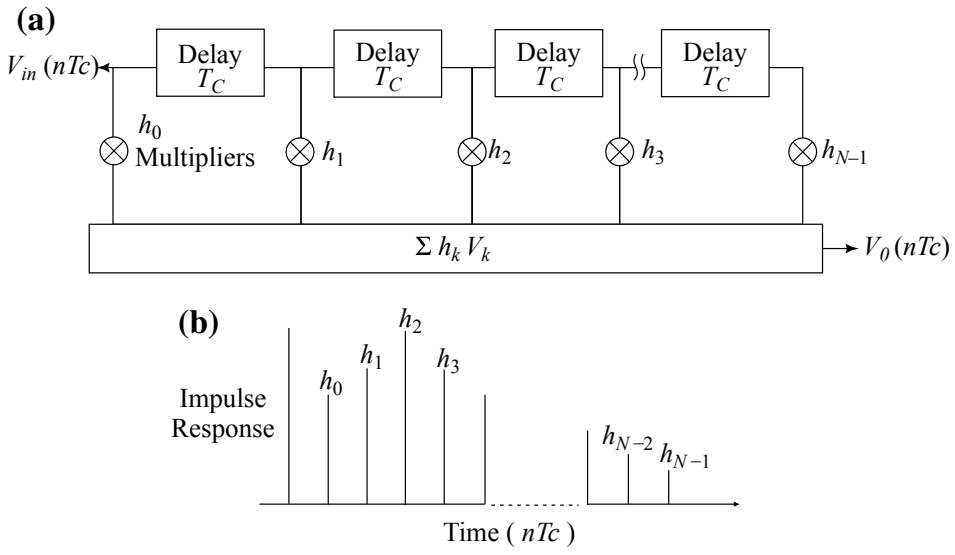

Fig. 16.10 Depicting an N-stage transversal filter **a** block diagram **b** impulse response

The most common implementation of a transversal filter employing CCDs is the split-electrode technique [39–44]. This structure provides fixed tap weights, and these are obtained by sensing the image charge of the signal in the transfer channel, by using sensing electrodes placed over the channel. To give the appropriate weight at each tap (h_K), these electrodes are split into two parts, which are connected independently (Fig. 16.11a) to two sense lines. The position of the cut defines the tap weight at this point which varies from + 1 to −1 as the slot position is varied from one edge of the charge-transfer channel to the other, i.e. the lengths of the two sides of the split electrode are chosen in the ratio $(1 + h_K)$: $(1 - h_K)$, so as to produce the net weight h_K at each node. The weighted sum of all the image charges of the signal packet in the register can then be sensed on the two sense bus lines, either by using a differential current metre, or by sensing the change in voltage when signal charges flow under the floating-sense electrodes.

The accuracy of the split-electrode technique is limited by several factors [45], viz. (i) Voltage dependence of the depletion capacitance; in this scheme, it is assumed that the oxide capacitance is much larger than the depletion capacitance and the latter can be considered constant, (ii) Variations in oxide thickness, (iii) Accuracy of locating electrode gaps, (iv) Transfer inefficiency and (v) DCI (differential current integrator) noise, due to (a) KTC noise [13] on the split-electrode clock lines, and (b) voltage amplifier noise. Of these, (b) is predominant in the devices tested to date.

The above sources of error will place a practical limit on the accuracy of the coefficients which can be realized. In frequency-selective filters, any coefficient errors will tend to have a more adverse effect on the stopband, rather than in the passband

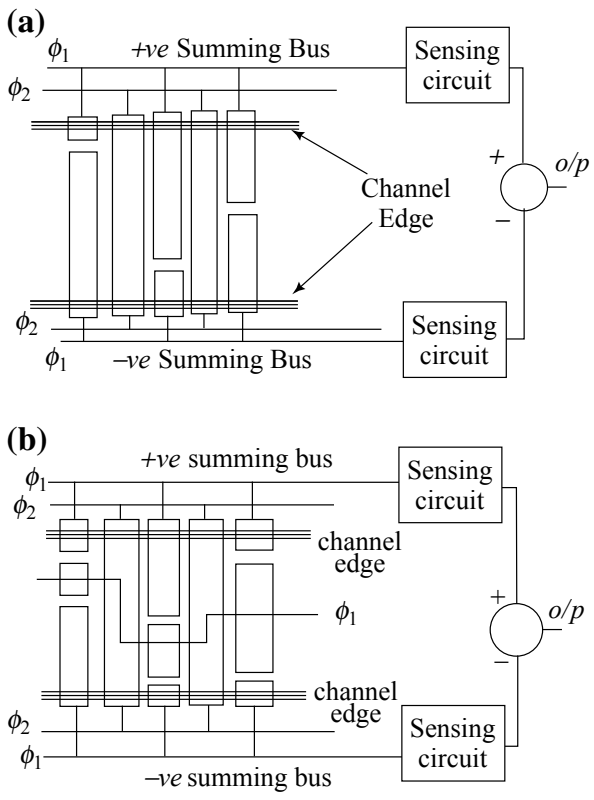

Fig. 16.11 Split-electrode CCD transversal filter
a single split-electrode weighting structure
b improved, double-split electrode weighting structure

regions of the filter. Thus, the technique is limited to some practical value of attenuation which can be realized. However, one could cascade several filters to obtain the desired attenuation. In particular to reduce the effect of the DCI noise, a new 'double-split electrode' structure has been fabricated [46] which provides improved filter performance over the signal-split approach by reducing the common mode signal and noise pick up (Fig. 16.11b).

The other tapping technique is the floating-gate reset (FGR) method [47]. This is also a non-destructive sensing scheme and is shown in Fig. 16.12. The relevant equations are

$$\Delta V_{\text{out}} = \frac{Q_{sig} C_{ox}}{C_{ox} C_L + C_D C_L + C_D C_{ox}} \tag{16.19a}$$

where

C_{ox} Total oxide capacitance under the tap electrode
C_D Total depletion capacitance under the tap electrode
C_L Total external load capacitance on each tap

The above expression can be approximated as

$$\Delta V_{out} \cong Q_{sig}/C_L \tag{16.19b}$$

for $C_{ox} \gg C_D$ and $C_L \gg C_D$. This is a very good approximation when the substrate resistivity is large (greater than 10 Ω cm).

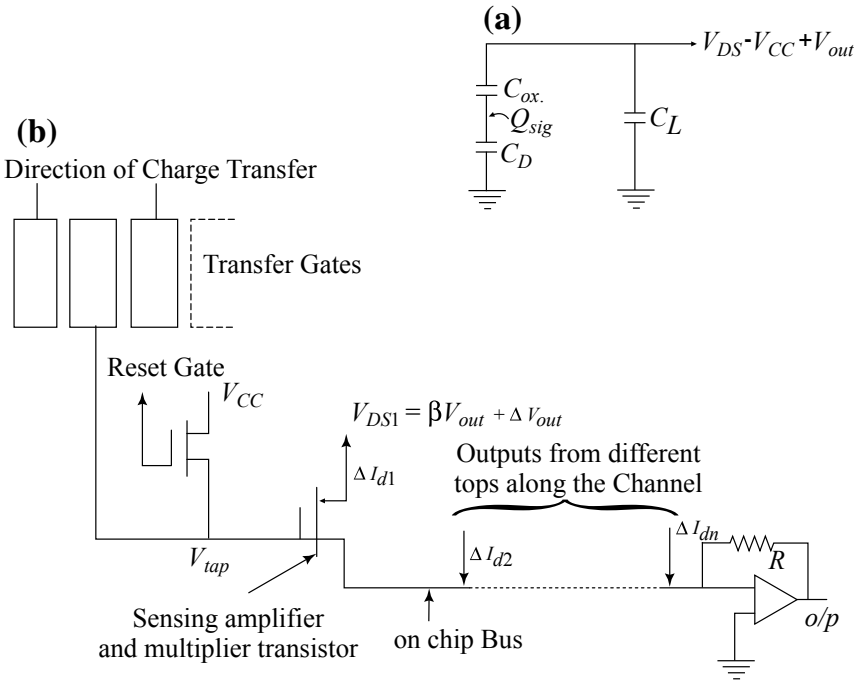

Fig. 16.12 **a** Capacitive model of floating-gate tap. **b** Circuit implementation of floating-gate tapping four-quadrant multiplication and convolution summing

A conventional clocked electrode in the CCD structure is replaced by a floating-gate reset-sense electrode. The electrode is first reset to a bias voltage whilst there is no signal charge underneath it. It is then isolated and any charge subsequently injected under the electrode (as a result of CCD clocking action) causes a related change in the electrode potential. The signal may be sensed via an MOS transistor amplifier to provide a voltage output at a low impedance. Now, for general-purpose signal processing, four-quadrant multiplication of the tapped signal and the tap weights are required at each convolution point. An economical multiplication technique is based upon the essentially linear transconductance of an MOS transistor operating in the non-saturation region. A first-order expression for the drain current of such a transistor is given by

$$I_D = \beta\{(V_{GS} - V_T)V_{DS} - \tfrac{1}{2}V_{DS^2}\} \tag{16.20a}$$

from which the change in drain current obtained upon disturbing the gate voltage by an amount ΔV_{GS} is ($\Delta V_{GS} = \Delta V_{\text{out}}$),

$$\Delta I_D = \beta V_{DS}\Delta V_{GS}. \tag{16.20b}$$

This provides an accurate four-quadrant multiplication. β is a process-dependent parameter and V_{DS} can be adjusted externally to provide the correct tap weight. Changes in drain current of the multiplier transistors at each tap can then be summed via a sense bus bar feeding an operational amplifier to provide the output V_0 (KT_c). Since the voltages V_{DS} are programmable, this structure offers a promising realization of a powerful signal processing element. Using this technique, fabrication of a completely monolithic 64-point programmable transversal filter has been completed [48]. Initial results confirm operation of the device in both frequency and matched-filtering configurations over a range of frequencies suitable for sonar and other sub-megahertz applications.

16.5.1 Limitations of This Technique

From the above, we see that the programmable filter consists of a signal register, a reference register, a multiplier and a summer suitably interfaced to provide the convolution sum. The sources of error in each of these blocks are the following.

Signal Register

(a) transfer inefficiency and
(b) dark current

Reference Register

(a) information decay due to charge leakage from the sample-and-hold capacitor (external to the CCD chip) and

(b) capacitive breakthrough of the sample waveform into the hold capacitor via gate overlap capacitance.

Multiplier

(a) changes in drain current may modulate the reference voltage due to the finite output admittance of the reference amplifiers and
(b) variations in the value of β of the multiplier transistor due to processing non-idealities.

Summer

The summing amplifier is a limiting factor in terms of speed in that its output must settle within the time period for which the signal is true. Although the intrinsic CCD/MOS circuitry may be designed to operate at clock frequencies up to 10 MHz, it is difficult to achieve sampling rates at the summing amplifier much above I MHz without resorting to bulky, high-power amplifiers.

Effects of these error sources at the output of the convolver are as follows. Charge-transfer inefficiency ($\in$) in the CCD register degrades the signal information at high frequencies, this being a cumulative effect with increasing $N\in$ products. In terms of frequency filtering applications, the net effect at low frequencies is a shift in the transition edges between passband and stopband of a factor $(1 - \in)$, regardless of the number of filter stages. The effect upon correlator performance is signal-dependent but $\in$ is known to cause a slump in the correlation peak and an increase in the sidelobe levels. Random gain errors in the multiplication process are analogous to tap weight errors in split-gate CCD filters and as such may be expected to impair stopband suppression in frequency filtering applications. Correlation applications are more tolerant to these errors due to the processing gain of the filter.

The signal distortion term imposed by the finite output admittance of the multiplier stages causes dc and second harmonic distortion for a pure sinusoidal signal. In correlation applications, additional peaks are to be expected whenever a match is detected between the generated harmonic signal component and the reference waveform. Refreshing and subsequent decay of reference values results in a modulation noise of the output waveform, since it is not generally synchronized with the incoming data.

Finally, although several potential error sources have been identified, not all will be operative for a single application and quantitative effects depend on the signal.

Having gone over the chip implementations of the CCD transversal filters, let us now consider some of the important signal processing applications of CCDs.

The transversal filter performs real-time convolution by non-destructively sampling the charge packet at each stage of delay, multiplying each sample by a weighting coefficient and summing the resulting products at each sampling instant. Hence by proper selection of the weighting coefficients, one can achieve a very wide variety of filtering or correlation functions such as low-pass, bandpass, band-stop, matched filters and cross-correlators. Note that the tap weights $h_K = h\ (KT_c)$ arc nothing but sequential elements of the impulse response of the tapped delay line. Also, all of these functions are tunable, i.e. the cutoff frequency, centre frequency and bandwidth

can be varied by simply changing the clock frequency. There exists a vast literature on the techniques of designing digital nonrecursive (FIR) filters, which are directly applicable to the design of CCD weighting coefficients [49]. We shall now take up some specific filter types [41, 42, 50].

16.5.2 CCD Low-Pass Filters

By choosing the h_K as equispaced discrete values of the sin x/x function, a low-pass filter can be realized which will have repetitive passbands spaced f_e apart in the frequency domain. Applications of CCD low-pass filters include a channel filter for a frequency division multiplex communication system, an anti-alias filter for a time division multiplex communication system, an anti-alias filter for a digital monitoring system and an interface between two asynchronous sampled data systems, e.g. a video communications system [42, 43].

Low-pass filters, as such, are required in a large number of systems. In some cases, the required filter characteristics are easily obtained with simple passive networks but in many cases system performance can be improved, if higher performance filters are used. Until now, it may not have been economically attractive to use higher quality filters in these applications, but with the availability of low-cost CCD filters having very sharp cutoff characteristics, and low in-band ripple, many opportunities now exist for upgrading the quality of low-pass filters.

Sampled data analog systems, for example, all require a low-pass filter for the elimination of alias responses. This filter must have a passband that is adequate for the signal bandwidth, but for typical applications, it must be down by 40–50 dB at the Nyquist frequency. In the past, this has been accomplished by oversampling the data by a factor of 3 or 4, so as to move the Nyquist frequency sufficiently far above the signal passband, so that a relatively simple filter can suffice. Now, although this practice simplifies the filter, it requires that three or four times as many samples be stored, processed or transmitted, as are actually needed. More storage means a larger memory, more processing means increased CPU loading and more samples to be transmitted means increased channel bandwidth, all adding up to increased cost. In such cases, a CCD low-pass filter with a sharper cutoff, and a reasonable stopband attenuation provides a convenient solution.

16.5.3 Bandpass Filters

Bandpass filters have numerous applications in speech and data processing. We discuss briefly the design of a bandpass filter and illustrate the application of window functions for apodization to control sidelobe response (out-of-band rejection). Truncation of the impulse response of an ideal bandpass filter (in order to permit an economical realization) inherently leads to lower rejection in the stopband, i.e. higher

sidelobe levels. Windowing techniques modify the coefficients of the ideal filter so as to minimize the effects of termination of the response at a finite number of samples. Since weighting coefficients can be easily modified by relocating position of the slot in the split-electrode structure, high-quality bandpass filters are obtainable using CCDs.

The weighting coefficients for a bandpass filter with a narrow bandpass centred at f_0 can be written in the form

$$h_K = \omega_K \sin(2\pi K f_0/f_c) \tag{16.21}$$

where ω_K's are samples of a window function. The particular selection of a window function depends on the desired passband shape and sidelobe levels. The price one pays for higher sidelobe rejection is a greater width of the passband. Practical results show that a 101-stage filter gives a sidelobe level of −13.2 dB and a 3-dB bandwidth of 3.5% of the centre frequency; however, the apodized filter gives a maximum sidelobe of −42.8 dB and a 3-dB bandwidth of 5.1% of the centre frequency [51].

With CCD transversal filters, it is difficult to achieve filters of high Q because of the finite time duration of the impulse response, and because tap weight error limits the out-of-band rejection. Recursive filters are potentially useful for achieving high Q as has been demonstrated using BBDs with off-chip feedback (Buss et al. [36]). CCD transversal filters are most useful when the magnitude and phase of the frequency response must be accurately determined and can be used for signal levels down to 50 V together with a large dynamic range [37].

16.5.4 Matched Filtering

Consider a filter whose weighting coefficients are chosen to represent an impulse response $h(t)$, which is matched to a particular signal waveform $V_s(t)$

$$h(t) = (1/A)V_s = (T_d - t), 0 < t < T_d \tag{16.22}$$

where A is the amplitude of the signal waveform and $h(t)$ is normalized so that its maximum amplitude is unity. When V_s is applied to an ideal filter ($\in = 0$), the output is given by

$$V_{out}(nT_c) = A \sum_{K=1}^{M} h_K h_{M-n+K} \tag{16.23}$$

and the correlation peak occurring at $t_M = MT_c$ is

$$V_{out}(t_M) = A \sum_{K=1}^{M} h_{K^2}. \tag{16.24}$$

Charge-transfer loss, however, introduces a mismatch between the filter and the signalling waveform and results in loss of sensitivity, i.e. degradation of peak-to-sidelobe ratio [42, 52].

16.5.5 Hilbert Transformer

A Hilbert Transform consists of a convolution with t^{-1} and can be implemented with a CTD transversal filter [36] having weighting coefficients,

$$h_k = \left\{ K - \left(\frac{M+1}{2} \right) \right\}^{-1}, \quad K = 1, \ M; \ M \text{ even} \sqrt{a^2 + b^2} \tag{16.25}$$

Such a filter can be used to generate single sideband signals and has a wide potential application in communication equipment [5, 53]. It may be pointed out that, so far, the complexity of modulation equipment was the major inhibiting factor towards greater use of SSB transmission.

16.5.6 Adaptive Filtering

Due to the changing characteristics of a telephone channel, adaptive equalization is required in a MODEMs, as to permit error-free detection of data [42]. This requires a variable tap weight convolution filter (VTWCF) which is most easily implemented using CCDs with FGR sensing and four-quadrant multiplication, as described earlier. Such a filter would be useful not only in MODEMs, but in other adaptive filtering applications such as voice recognition, adaptive beam forming, remote intrusion detection [54].

16.5.7 Complex Coding

CTD filters can be used to generate as well as to detect arbitrary waveforms (Buss and Bailey [41]). This presents the possibility of choosing M waveforms to represent $K = \log_2 M$ bits of information. This type of coding employed in MODEMs, but the choice of waveform is limited by the available equipment and the waveforms actually used are not optimized to the transmission medium. CTDs offers a great deal of flexibility in the selection of waveforms. In addition, the relative case with which CTD filters can be matched to arbitrary waveforms may make possible the use of 1-ary (instead of binary) communication, where it has not been previously practical.

16.5.8 Interference Rejection Filter Using CCDs

A multiple notch filter has been realized, which can be used to track and remove a periodic interfering signal and its harmonics [55]. It has also been shown that to a first-order filter, notch depths are not dependent on transfer inefficiency and tap weight errors, provided the inefficiency value is spatially uniform, i.e. is constant throughout the CCD. Calculations show that even for inefficiency products as high as 0.2, notch depths of 40 dB are possible.

16.5.9 Linear Regression Analysis Using CCDs

A common requirement in signal processing is that of detecting a slowly varying signal against a background of noise. In a typical situation, if a system of low-pass filtering and threshold detection is used, there is the problem of matching the threshold to the noise level, and a slowly changing baseline can therefore cause considerable errors. If, however, several successive samples of the signal are available over the region of interest, statistical techniques of straight-line fitting can provide an estimate of the continuous waveform [56]. Equations for straight-line fitting reduce to the manipulation of weighted sums of sampled data, which can be easily implemented using transversal filters.

16.5.10 Radar Display System Using CCDs for Time Expansion

A system using the Fairchild CCD 321 has been built, which allows real-time signal processing, and display of radar data; the video data is read in parallel into eight CCDs, and read out sequentially at a much slower rate (time expanded), to match the subsequent display circuit capabilities [57].

16.5.11 Waveform Generation Using CCDs

The impulse response of a transversal filter has the same form as the tap weights of the CCD. It is realized by propagating a single charge pulse along the CCD. In this way, arbitrary waveforms of finite length arc easily generated at the summing point of the tap weights. Amplitude is controlled by amplitude of the impulse, and the rate may be controlled by the clock frequency.

16.5.12 Cost and Performance Trade-Offs in Various Approaches to Signal Processing

Both analog and digital methods have been used for analog signal processing. In the analog approach, a desired response (specified in the frequency domain) is approximated by a number of poles and zeros in the complex frequency plane, and these are implemented with passive discrete components, and possibly some operational amplifiers. This approach has three important advantages [39, 40, 50]: (a) negligible power is consumed, (b) involves low cost and (c) the filter realization is direct.

There are also some disadvantages: (a) separate filter hardware must be dedicated to each channel, i.e. a single filter cannot be multiplexed between several channels, since the processing is 'all analog', and not on the basis of Nyquist sampling, (b) the only designs that can be implemented are those which require a modest number of poles and zeros and (c) values of the discrete components must be precisely determined. Often they must be individually adjusted and temperature drift and ageing can cause problems, (d) impedance matching has to be achieved and (e) very low-frequency realizations are a problem because the R, L, C elements become expensive and accuracy is impaired.

In the digital approach, the signal is sampled and digitized and is processed numerically. This approach solves the problems cited above, but has two major drawbacks: (a) A/D conversion is required which adds considerably to cost and complexity and (b) the multiplication is performed in a digital multiplier, which apart from its cost consumes a large amount of power and time. However, the high accuracy of this technique is a very compelling reason for adopting it.

The importance of charge-transfer technology for analog signal processing is that it combines the best features of both approaches—namely, it permits an arbitrary impulse response to be implemented easily, it provides high precision, without requiring individual adjustment of components, and A–D conversion is inherent and exact. Also, the additional circuit complexity required to convert a CCD delay line into a transversal filter is marginal and the computational power of a CCD transversal filter, when measured in number of multiplications per second is very large. Moreover, time delays are stable with time and temperature depending only on the master clock (as for digital filters).

However, the CCD filter retains to some extent the problem of realizing very low-frequency (Hertz range) filter functions, because of storage time (dark current) limitations, which arise mainly from material imperfections and process-induced defects. A significant development effort is in progress to alleviate this problem. At this point, it is pertinent to mention another charge-transfer device similar to the CCD—the BBD [45, 58–67]. This is a sequence of MOS transistors coupled together by diffusion enhanced Miller capacitance. Although these devices do not operate at frequencies as high as CCDs, they have better low-frequency performance since, they include active devices. Transfer efficiencies are, however, poorer for BBDs.

Further, since the impulse response of a CTD filter can be chosen arbitrarily, CTD filters can be matched to arbitrary signalling waveforms in much the same

way that surface wave devices are used to perform matched filtering, CTDs do not compete directly with SWDs for this application, however, because SWDs have higher bandwidth (GHz) and limited time delay (tens of microseconds). CTDs, on the other hand, are capable of processing signals up to 1 s. in time duration but are more restricted in bandwidth.

Compared with digital implementations, CTD filters are less flexible and are limited to time-bandwidth products of 10^3 or less. On the other hand, when CTDs can be used for a particular matched-filtering function, overwhelming advantages in cost, power consumption, size, weight and reliability can be realized. Let us take an illustrative example:

It is required to implement a 100-point convolution filter with a dynamic range which requires 8-bit digital logic. An analog signal is to be sampled at 100 kHz, filtered and presented at the output in analog form. When this filtering operation is implemented using TTL, the cost and power consumption are determined primarily by the 8-bit A/D converter ($2 000, 5 W) and the digital filter consisting of approximately 400 TTL networks costing $5 per piece and dissipating 100 mW each. In evaluating the cost of the CTD implementation, the important factor of part volume enters. The digital filter can be implemented with standard catalogue items, whereas, the CTD is a custom IC and as such the cost is dependent on the volume sold since the development cost is high up to $80 000. Assuming a sale of 100 000 devices, the following cost comparison emerges

	Digital	CCD
Cost:	$4 000	$56
Power	45 W	600 mW

The cost of the CCD implementation includes the cost of clock drivers, output amplifiers and output sample-and-hold circuits—this comes to about $50. This comparison is an oversimplification of real systems and it is heavily weighted in favour of CTDs, because it is based upon a simple convolution filtering operation for which CTDs are ideally suited. However, it illustrates the saving in cost and power, which is possible with CCDs—and this cost and power advantage has been responsible for widespread use of CTDs in military communication systems.

The advent of the microprocessor and LSI memory means that powerful and versatile filtering systems can be programmed and controlled (Mavor and Denyer [48]). Such an arrangement is extremely important in the signal processing context as any desired filtering function can be realized by simply programming its impulse response. Interfaced with a microprocessor, this system could provide intelligent adaption of the filter response, to optimize performance. Potentially, new areas include sonar, instrumentation and mobile communication equipment.

Single-chip (monolithic) programmable transversal filters have an enormous potential in applications where space and power arc crucial and high computing precision is not essential.

16.6 Spectral Analysis Using CCDs

Analysing a signal for its different frequency components is a vital area of signal processing. The bulk of spectrum analyzers, use a sweeping local oscillator to cover the frequency interval of interest and so require continuous input waveforms. Furthermore, the time required to scan the frequency interval with a narrow band filter can be substantial, being proportional to the ratio of the swept bandwidth to the square of the filter bandwidth. There are a number of situations where the Fourier transform of a finite number of time samples is required—for example, in Sonar and Radar target signature analysis. The conventional spectrum analyzer is of limited use in these areas, and other techniques are required. The most popular alternative is to use a digital processor, which evaluates the discrete Fourier transform (DFT) of a set of samples, by using a fast Fourier transform (FFT) algorithm [68]. However, such processors may be too slow to allow the data to be processed in real time, or consume excessive power and cost so much so that liberal use of them cannot be made. The FFT algorithm is most efficient when the number of samples N is a power of 2—a situation which can always be achieved by augmenting N with zeros.

An alternative approach [69] restructures the DFT in such a way that the bulk of the computation is in the form of a complex convolution of the input data with a set of fixed weights. Such a convolution is very conveniently performed in a CCD transversal filter, fabricated on a single substrate, giving substantial savings in size, weight and power consumption over a comparable digital solution. This modified approach known as the 'Chirp-Z transform' algorithm has been implemented practically using CCDs with 100 taps, which is capable of working up to 1 MHz clocking frequency [70]. The input data samples, taken at time intervals of T_c, propagate along a set of storage locations in discrete steps under the control of an external clock. At each storage location, the signal is non-destructively tapped—that is, the tapping process leaves the propagating signal unchanged. The signal from each tap is then multiplied by a weighting coefficient before the final summation, which forms the output. It is the simultaneous execution of these multiplications, which makes the transversal filter so powerful. The CCD Discrete Fourier Transform Processor can also be used to compute the power density spectrum. It may be pertinent to point out that the Chirp-Z-transform (CZT) is one of the classes of fast Fourier transforms [71] that has had limited use in the past, because it does not provide any significant advantages over the more common FFTs in a digital implementation; however, it is the preferred algorithm for CCD implementation [44].

Further, a significant reduction in hardware (over that of the CZT) are possible with the CCD implementation of the Prime Transform (Jack et al. [72]) for purely real input data, the prime transform uses two CCD filters as compared to four for the CZT filters. CCD prime transform processors, which give an output accuracy of 2% rms have been reported. Although the accuracy of CCD transforms is inferior to the digital FFT, they offer low-power compact analog processors which can operate at

bandwidths up to 5 MHz in real time. It is therefore in systems applications which require such engineering advantages at the expense of transform accuracy, e.g. sonar and speech processing (analysis) that the analog CCD transforms will find application [51, 70, 72–76].

16.7 MTI Radar and Television Ghost Suppression Applications

Charge-transfer devices provide a cheap serial memory, replacing complex digital circuits in MTI (moving target indicator) and ECM (electronic countermeasure) radar applications. The MTI radar system accepts the reflected signals from moving targets only, and rejects all signals from stationary objects, by making use of simple cancelling filters. Digital signal processing, with its high internal stability, has become an integral part of new radar systems, which need sharp out-off Notch filters (cancelling filters). The major disadvantage of high-performance digital systems, as discussed earlier, has been the expense and complexity of A/D converters, whenever a large dynamic range is required in conjunction with high bandwidth (5 MHz or more). The solution to this problem is to use charge-coupled devices (CCDs) as low-cost analog-sampled data processors [77]. In CCDs used as analog data processors, the input signal is Nyquist-sampled, and the samples are stored and processed as discrete analog packets of charge. This eliminates the need for A/D conversion entirely or in the case of a CCD preprocessor, reduces the cost of subsequent A/D conversion to the more economical realm of low-bit high-speed technology. The following device parameters, furthermore, favour the application of CCD delay lines in MTI filters (Bounden et al. 1974): (a) Signal storage and delay times up to ≅100 ms, (b) Clock rates up to 10 MHz, (c) Dynamic range >40 dB, (d) Serial access to data is simple, (e) Simpler, faster, smaller and cheaper than digital systems and (f) Delay is variable, and can be accurately controlled.

16.7.1 Simple Cancelling Filter

Figure 16.13a shows a simple cancelling filter incorporating a time delay element (τ_c) introduced by a CCD analog delay line. It has a frequency response as shown in Fig. 16.13b in which cancellation occurs at frequencies, which are multiples of pulse repetition frequency (f_r) where $f_r = 1/\tau_c$ Such a filter can be used as a coherent MTI for a pulse radar system, if τ is the pulse repetition interval (PRI) of the radar transmitter. Thus in such a radar set, the reflected return signals at radio frequency are mixed with a reference signal at the transmitter frequency. If the target giving the reflection is moving, there will be a change in phase of the returned signal between consecutive transmitter pulses, and hence, the mixer output shows a beat at the

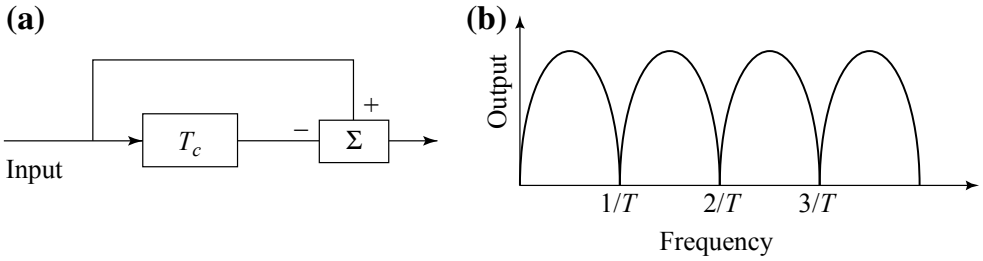

Fig. 16.13 **a** Block diagram of a simple cancelling filter. **b** Frequency response of the cancelling filter

Doppler frequency. If this signal is applied to the cancelling filter, the output will be obtained only for moving targets, because the subtraction cancels the 'clutter' signals, which are stationary from pulse to pulse. Targets with speeds corresponding to Doppler frequencies, which are multiples of f_r (PRF) are also cancelled. The extent to which suppression of signals from stationary objects and of Doppler frequencies, which are multiples of f_r, can be achieved over the full video bandwidth of the system is determined by the characteristics of the delay line. The total clutter power reduction can be improved by having a broad clutter rejection notch, obtained by placing two cancellers in series. This configuration processes three pulses simultaneously, and the magnitude response will be that of a squared sine wave. In the simple cancelling filter, the input–output transfer function is written as

$$H(j\omega) = 1 - e^{-j\omega T} \tag{16.26}$$

The magnitude response of this is

$$|H(j\omega)| = 2|\sin(\pi f T)| \tag{16.27}$$

This is shown in Fig. 16.13b. Preliminary experimental circuits with CCD delay lines demonstrated notch depths of up to 40 dB in the output frequency response characteristics [78]. A simple CCD canceller using an N-element CCD takes N samples of the incoming waveform every pulse repetition interval, and can cover the acquisition of targets in N range elements (range gates).

16.7.2 Application to Practical MTI Filters

In practice, MTI filters usually operate with several hundred range gates and with a PRI of the radar of 1 ms, so that the use of a serial–parallel–serial or linear CCD delay line is appropriate. The total required delay T could be several milliseconds, depending on system requirements, which is within the limits imposed by the dark current, which adds a charge to the charge packets as they travel through the CCD. To minimize target smearing, the charge-transfer inefficiency must be kept small.

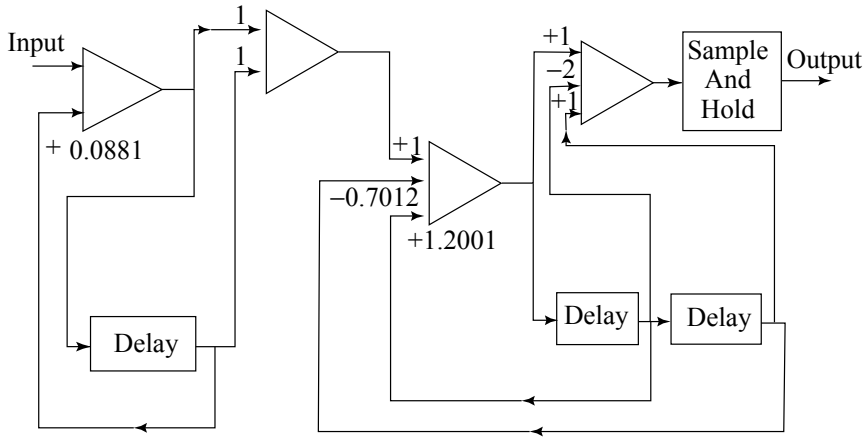

Fig. 16.14 3-pole Chebyshev analog filter for Radar MTI applications using CCD delay lines

Its allowed value depends on the number of range gates and the practical frequency response required. Also the smearing effect is found to increase when the Doppler frequency is near the edge of the filter passband. The linearity of the CCD output as a function of input is important as it determines the cancellation ratio attainable. In a realizable MTI filter using operational amplifiers, the bandwidth and settling time parameters must be carefully chosen when clocking speeds in excess of 1 MHz are contemplated (Fig. 16.14).

A three-pole Chebyshev analog filter [79] using CCD delay lines for MTI cancellation has been implemented. The advantage of the Chebyshev filter over the simple canceller is that the frequency response is better matched to real clutter which has a finite spectral width, and also shows a more uniform passband response. Figure 16.15 shows the practical circuit of a 3-pole Chebyshev filter, with the signal weightings fed into the summing amplifiers (15-MHz bandwidth, IC operational amplifiers) indicated. The CCDs used were 8-element, 3-phase surface *p*-channel devices operated at a clock frequency of 330 kHz [80]. The mode of clocking used was interrupted

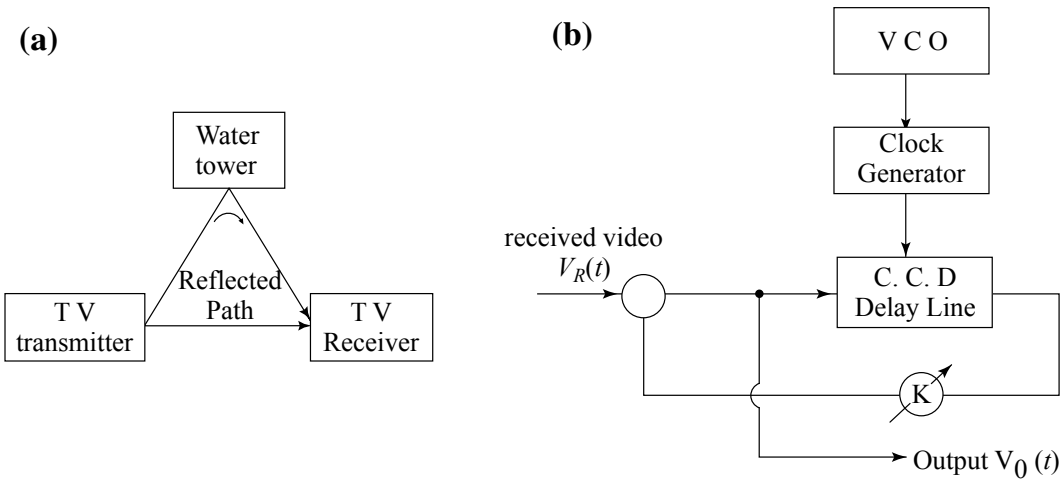

Fig. 16.15 **a** Depicting the reflection problem. **b** Block diagram of ghost-suppressor circuit

clocking, in which the clocks are stopped for a rest period t_r during which ϕ_2, one of the phases remains on. So the analog information in the CCD remains stored under the ϕ_3 electrode. In this case, T is given by

$$T = 1/f_r = t_x + N/f_c \tag{16.28}$$

where f_c is the clocking frequency. If we are operating with t_r= 2 μs, T will be 26 μs and f_r will be 38.4 kHz.

The response with the above filter parameters showed the occurrence of minima at frequencies 0, 38.4 and 76.8 kHz (i.e. PRF of MTI Radar is 38.4 kHz).

16.7.3 Processor for Pulse-Doppler Radar

CCD and surface acoustic wave (SAW) techniques [81] have been combined to advantage for processing coherent radar signals, in order to extract target range and velocity informations. This will replace the complex and costly bank of Doppler filters for each range gate, which might otherwise be needed to extract the information.

The essential functions of the processor are to segregate echoes from different ranges and to separately detect the presence of the resolvable frequency components present in each range cell. The spectral resolution required might typically be 100 Hz, so that a processor capable of storing data over a period of milliseconds is needed, with the facility of sorting it into 100 or more (range) channels for spectral analysis in real time. CCDs now achieve the bandwidths needed for radar signals and can store sampled analog data for tens of milliseconds. The external control of time scale by means of the clock rate means that the same CCD data store can be used with radars of different bandwidth. The flexibility of timing also allows the data input and output to be at different rates, which means that the duration of the stored data can be compressed by a large factor.

The spectrum analyzer for this can conveniently be implemented using SAW 'chirp' filters, the inflexiblity of the filter parameters being unimportant, because processing time and bandwidth can be matched to the requirement by the CCD store.

16.7.4 Charge-Transfer Memory for ECM

The objective of the Radar ECM memory system is to generate synthetic or false targets. This is achieved by acquiring the Radar pulse of interest, storing it for a maximum of one or more PRIs, and recalling and retransmitting it in command at any time within the storage period. But the requirement of transfer efficiency of the CCD used for ECM is higher than MTI requirement due to the demand of reasonably large time delay-bandwidth products.

16.7.5 Television Ghost Suppression Using CCD

TV ghosts are commonly generated by reflections from objects such as water towers, buildings etc. A system was experimented upon (Butler [78]) at General Electric Company for suppression of ghost images in TV employing charge-transfer devices. Geometry of a simple single-reflection problem is illustrated in Fig. 16.15a. The net signal received at the receiver is the sum of desired signal collected over a direct path and a reflected signal, that is attenuated and delayed with respect to the desired signal.

The amplitude of the detected video signal can be approximated by

$$V_R(t) = V(t) + \alpha V(t - \tau) \cos \omega_c \tau \tag{16.29}$$

where α is the attenuation characteristic of the reflected path, ω_c is the RF carrier frequency, and τ is the differential delay between paths. The $\cos \omega_c \tau$ term varies with τ, changing from positive to negative, as the relative propagation path lengths of the desired and ghost signals change by $\lambda_c/2$ (λ_c = carrier wavelength). The ghost signal can therefore be negative or positive, depending on the phase relationships of the main and the reflected RF carriers, and the ghost suppression circuit must be capable of phase reversal as well as gain control, in order to cancel all ghosts. Also, note that the ghost amplitude and polarity is a function of the relative motion of the transmitting and receiving antennas and of the ghost reflecting surface. This is especially so at UHF, where the wavelength is very short (34–64 cm). Automatic adjustment of a ghost suppression circuit would be a highly desirable feature at these frequencies during a windstorm, for example.

The basic principle of the ghost-suppressor circuit is to use the desired signal to synthesize a ghost of the correct magnitude polarity and differential delay so that when the 'synthetic' ghost is summed with the required signal, the synthetic ghost cancels the real ghost and yields a ghost-free picture. A block diagram of a circuit that accomplishes this is shown in Fig. 16.15b. The received signal is fed to a summing node, where it is differentially summed with the weighted output of the CCD analog delay line. The output of the summing node is fed to the TV receiver and entered into the delay line. The parameters of the circuit, i.e. K and throughput-time delay of the delay line T_d are adjusted so that $T_d = \tau$ and $K = \alpha \cos \omega_c \tau$. The adjustment is accomplished manually, while viewing the TV picture. Control of T_d is achieved by varying the clock frequency K is simply a gain variable. The extent to which one can achieve complete cancellation of the ghost is thus dependent only on the capability of the CCD to accommodate the full bandwidth video signal.

In a serial CCD structure capable of storing n signal samples, the clock frequency f_c is equal to the sampling frequency f_s and $T_d = n/f_c$. Since the maximum bandwidth of a sampled data device is $f_s/2$, it follows that the maximum ωT_d (ω= bandwidth) product of the CCD is $n/2$. In practice, ωT_d will be less than $n/2$ because of incomplete charge transfer. For TV video signal processing applications, bandwidths of the order of 4–5 MHz are required, and depending on this specific application delays, ranging

from a few μs up to a full TV frame of delay (33 ms) and more, may be necessary. Thus ωT_d products, from as low as 10 s to as high as several 100 s or 1000 s may be required. Charge-transfer inefficiency, which ultimately limits the maximum ωT_d product of a CCD is therefore one of the most important operating parameters of these devices. Experimental results from high-speed bulk channel CCDs show ωT_d products in excess of 100. The most objectionable ghosts are often those with short time delays (<10 μs); charge-transfer technology thus appears to be well suited to this application.

16.8 Concluding Remarks

It is usual in a concluding section to refer to prospects for the future. However, such comments have been well documented elsewhere, for example, in some papers [82–84]. We would rather conclude this paper by describing some of the work on CCDs that were undertaken at lIT Delhi.

The two major efforts at lIT Delhi in CCDs have been in device characterization and fabrication and in circuit techniques for compensating ∈. In device fabrication, two CCD structures were successfully made. One is a 3-bit 3-phase CCD, which achieves small inter-electrode spacings (less than 1 micron) by a process known as shadow masking [71, 85]. These small inter-electrodes gaps, which cannot be achieved by using standard photolithography, are necessary for efficient transfer of charge from one electrode to the next.

This CCD can be clocked at frequencies from 500 Hz to 50 kHz, thereby providing an electronically variable analog delay of 60 μs–6 ms. The upper frequency range is limited by the large (60μ) electrode length of this experimental CCD. Within this frequency range, the inefficiency ∈ is less than 10^{-2}. It also has output taps at each bit for possible use in compensating circuits and transversal filters.

The other CCD structure which has been fabricated is a novel 2-phase 4-bit double-dielectric device which achieves narrow inter-electrode spacings by the anodic oxidation of aluminium to provide a thin separation of Al_2O_3 between electrodes. This has the advantage over the shadow masked CCD in that it is more stable and reliable. It can be clocked from 1 to 60 kHz with an ∈ less than 10^{-2}. This CCD includes on-clip amplification in the form of reset and output transistors.

Work was also undertaken at IIT Delhi to grow oxides which gave rise to large storage times, or in other words, low dark currents. This is specifically useful in CCDs to be used as low-frequency signal processing devices and imaging devices. Using controlled amounts of trichloroethylene in the oxygen, used to grow the oxides, has resulted in devices with storage times as high as 500 s, so that very low-frequency operation of such devices is possible.

The other major thrust at IIT had been the development of special techniques and circuits for the compensation of ∈ in lossy CCDs. Several techniques for the compensation of transfer inefficiency had been developed. A method using external feedback was proposed for exact realization of any given transfer function. An 18-

stage CTD delay using both BBD and CCD stages had been compensated with suitable modifications taking practical limitations into account. Several FIR and IIR filter structures were developed which compensate for the effect of $\in$ to a good approximation, when connected in series with the device.

Chapter 17
Linear-Phase Versus Minimum-Phase CCD Transversal Filters

Abstract It is shown that the effect of charge-transfer inefficiency on the frequency response of CCD transversal filters is a sensitive function of the actual zero locations and in contrast to the observation made in the paper by Foxall et al. (1977), the minimum phase design is not always less sensitive than its linear-phase prototype.

Keywords Linear phase · Minimum phase · Transversal filters

17.1 Introduction

In order to avoid the long time delays associated with the linear-phase CCD transversal filters, Foxall, Ibrahim and Hupe investigated, in [1], an example of the minimum-phase design. Besides reducing the group delay, the latter design was observed to be less sensitive to transfer inefficiency and tap-weight error. In this chapter, a detailed analysis is carried out of the sensitivity of general linear and minimum-phase designs to transfer inefficiency and it is shown that the observation made by Foxall et al. [1] is not always valid. The conditions for the superiority of minimum-phase design are given, along with examples in which the linear-phase design shows less sensitivity to transfer inefficiency.

17.2 Analysis

Consider a linear-phase CCD FIR filter having the quad of zeros at $z = re^{\pm j\theta}$ and $(1/r)re^{\pm j\theta}$, where $r > 1$. The transfer function will be given by

$$H_{I_o}(Z) = \left(Z^{-1} - \frac{1}{r}e^{j\theta}\right)\left(Z^{-1} - \frac{1}{r}e^{-j\theta}\right)(Z^{-1} - re^{j\theta})(Z^{-1} - re^{-j\theta}) \quad (17.1)$$

S. C. Dutta Roy, *Topics in Signal Processing*,
https://doi.org/10.1007/978-981-13-9532-1_17

A minimum-phase FIR filter having the same magnitude response as of Eq. (17.1) will have a transfer function

$$H_{mo}(Z) = \left(1 - \frac{1}{r}e^{j\theta}Z^{-1}\right)\left(1 - \frac{1}{r}e^{-j\theta}Z^{-1}\right)(Z^{-1} - re^{j\theta})(Z^{-1} - re^{-j\theta}) \tag{17.2}$$

Let the first factors in Eqs. (17.1) and (17.2) be denoted by $L_o(Z)$ and $M_o(Z)$, respectively. When the charge transfer is not perfect, the term Z^{-1} changes to $Z_\varepsilon^{-1} = (1-\varepsilon)Z^{-1}/(1-\varepsilon Z^{-1})$, where ε denotes the transfer inefficiency. Let

$$L_\varepsilon(Z) \underline{\underline{\Delta}}\, L_O(Z_\varepsilon^{-1}) \text{ and } M_\varepsilon(Z) \underline{\underline{\Delta}}\, M_o(Z_\varepsilon^{-1}) \tag{17.3}$$

The frequency response of these factors can be obtained by putting $Z = e^{j\omega}$, where the clock period has been normalized to unity. After some simplifications, the magnitude responses can be shown to be given by

$$|L_o|^2 = \left[r^2 + 1 - 2r\cos(\omega + \theta)\right]/r^2 \tag{17.4}$$

$$|L_\varepsilon|^2 \cong \left[1 + r^2(l - 2\varepsilon) + 2\varepsilon r\cos\theta - 2r(l - \varepsilon)\cos(\omega + \theta) - 2\varepsilon\cos\omega\right]/\left[r^2(l - 2\varepsilon\cos\omega)\right] \tag{17.5}$$

$$|M_\varepsilon|^2 \cong \left[r^2 + (1 - 2\varepsilon) + 2\varepsilon r\cos\theta - 2r(1 - \varepsilon)\cos(\omega + \theta) - 2r^2\varepsilon\cos\omega\right]/\left[r^2(1 - 2\varepsilon\cos\omega)\right], \tag{17.6}$$

where, in Eqs. (17.5) and (17.6), terms containing ε^2 and higher powers of ε are neglected. It may be easily verified that Eqs. (17.5) and (17.6) reduce to Eq. (17.4) when $\varepsilon = 0$, as should be the case. Define the fractional errors in the magnitude-squared functions, $|L_\varepsilon|^2$ and $|M_\varepsilon|^2$ due to non-zero ε, as

$$\alpha_1 = \left(|L_\varepsilon|^2 - |L_o|^2\right)/|L_o|^2 \text{ and } \beta_1 = \left(|M_\varepsilon|^2 - |M_o|^2/|M_o|^2\right) \tag{17.7}$$

then it can be shown that

$$\alpha_1 = f(\varepsilon, \omega, r, \theta)\left\{r^2(\cos\omega - 1) + r[\cos(\omega + \theta) - \cos(2\omega + \theta)]\right\} \tag{17.8}$$

$$\beta_1 = f(\varepsilon, \omega, r, \theta)\{(\cos\omega - 1) + r[\cos(\omega + \theta) - \cos(2\omega + \theta)]\} \tag{17.9}$$

where,

$$f(\varepsilon, \omega, r, \theta) = 2\varepsilon/\left\{(1 - 2\varepsilon\cos\omega)\left[r^2 + 1 - 2r\cos(\omega + \theta)\right]\right\} \tag{17.10}$$

Now consider the term $(Z^{-1} - re^{j\theta}) \underline{\underline{\Delta}}\, N_o(Z)$ which is common to Eqs. (17.1) and (17.2). Let

$$N_\varepsilon(Z) = N_o(Z_\varepsilon^{-1}) \tag{17.11}$$

Then proceeding in an exactly similar manner, it can be shown that the fractional error

$$\gamma_1 = \left(|N\varepsilon|^2 - |N_o|^2\right)/|N_o|^2 \tag{17.12}$$

is the same as β_1 given by Eqs. (17.9) and (17.10).

Let the fractional errors due to the second and fourth factors in Eq. (17.1) be denoted by α_2 and γ_2 respectively; these can be obtained from Eqs. (17.8) and (17.9), respectively, along with Eq. (17.10), by replacing θ by $-\theta$. Also let

$$H_{1\varepsilon}(Z) \underline{\underline{\Delta}} H_{1_0}(Z_\varepsilon^{-1}) \tag{17.13}$$

Then it is obvious that

$$\left|H_{1\varepsilon}(e^{j\omega})\right| / \left|H_{1_0}(e^{j\omega})\right| = [(1+\alpha_1)(1+\alpha_2)(1+\gamma_1)(1+\gamma_2)]^{\frac{1}{2}} \cong 1 + (\alpha_1+\alpha_2+\gamma_1+\gamma_2)/2 \tag{17.14}$$

where, the approximate expression results from the fact that $\alpha_{1,2}$ and $\gamma_{1,2}$ are each proportional to ε and their magnitudes are, in practice, small compared to unity. Proceeding in a similar fashion with the minimum-phase transfer function, given by Eq. (17.2), and defining

$$H_{m\varepsilon}(Z) \underline{\underline{\Delta}} H_{mo}(Z_\varepsilon^{-1}) \tag{17.15}$$

it follows that

$$\frac{\left|H_{me}(e^{j\omega})\right|}{\left|H_{mo}(e^{j\omega})\right|} \cong 1 + \frac{1}{2}(\beta_1+\beta_2+\gamma_1+\gamma_2) = 1 + (\gamma_1+\gamma_2) \tag{17.16}$$

In general, let there be n quads of zeros in the linear-phase transfer function. Then it is obvious that the percentage error in the linear-phase magnitude response will be

$$\delta_1 = \frac{1}{2}\sum_{i=1}^{n}(\alpha_{1i}+\alpha_{2i}+\gamma_{1i}+\gamma_{2i}) \times 100\% \tag{17.17}$$

Similarly, the percentage error in the corresponding minimum phase magnitude response will be

$$\delta_m = \sum_{i=1}^{n}(\gamma_{1i}+\gamma_{2i}) \times 100\% \tag{17.18}$$

From Eqs. (17.8), (17.9) and (17.10), it should be apparent that α's and γ's can be positive or negative depending on the values of r, θ and ω. A detailed investigation is

therefore necessary to establish the superiority or *otherwise* of the minimum-phase transfer function over the linear-phase one. From the preceding results, it should be clear that further analytical investigation in this direction would be difficult, if not impossible. Extensive numerical computations were, therefore, undertaken to obtain the nature of dependence of errors on r, θ and ω. These and other results are given in the next section.

17.3 Results of Numerical Computations

Numerical investigations reveal that for a particular quad and fixed value of θ, there exists a critical value of r, above which the magnitude error is less in the minimum phase case, for the entire frequency range $0 \leq \omega \leq \pi$. A plot of this critical value as a function of θ is shown in Fig. 17.1. If r is less than this critical value, the linear phase design is superior to the minimum phase case, but only over a part of the frequency $0 \leq \omega \leq \pi$. In other words, it is not possible to have a linear phase design, which is superior to the minimum-phase case over the entire frequency range of interest. The performance of a general n-quad filter will depend on the contribution due to the individual quads.

Two illustrative examples will now be presented.

Example 1 Consider a multiple band-pass linear phase filter and its corresponding minimum-phase case characterized by the sets[1] of r and θ given in Table 17.1. The variations of percentage error in the magnitude response due to $\theta = 10^{-3}$ are shown

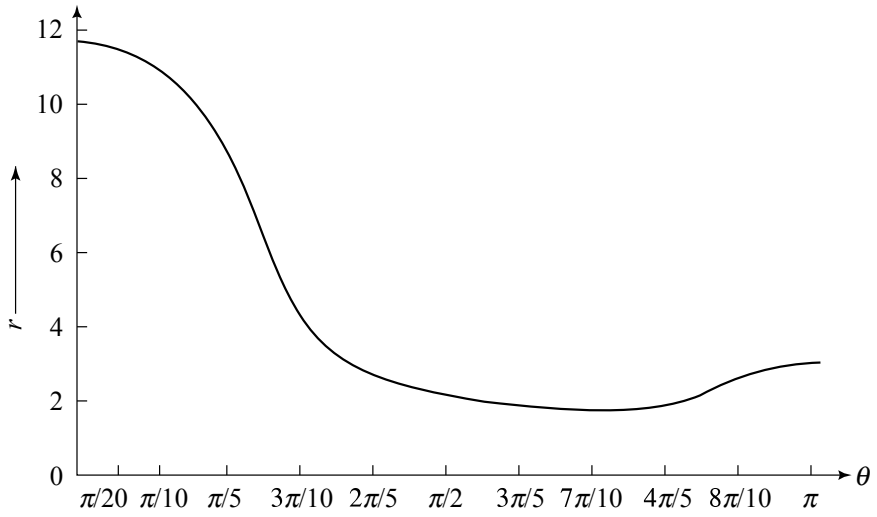

Fig. 17.1 Plot of the critical value of r versus θ. If r is greater than this critical value, the minimum-phase design is superior to the linear-phase design over the entire frequency range $0 \leq \omega \leq \pi$

[1]For a given r ($\neq 1$) and θ ($\neq 0$ or π), the linear-phase case has zeros at $re^{\pm j\theta}$ and $\frac{1}{r}e^{\pm j\theta}$, while the minimum-phase design has double zeros at each of the two positions $\frac{1}{r}e^{\pm j\theta}$. For $r = 1$ and $\theta \neq 0$ or π, each design has two zeros at $e^{\pm j\theta}$. For $r = 1$ and $\theta = 0$ (or π) each design has only one

Table 17.1 Zero locations* for example 1

r	θ	No. of Zeros
1.5833	0	2
1.2	2π/20	4
1.15	3π/20	4

17.4 Conclusion

It has been shown by analysis as well as numerical investigations that the minimum-phase CCD transversal filter is not always less sensitive to transfer ineffictency as compared to the linear-phase design. Sufficient conditions for the former to be superior are depicted in Fig. 17.1.

Part V
Digital Signal Processing

This part contains 11 chapters. We start with a survey of linear phase digital filters in Chap. 18, and then delve into generalized linear phase conditions in Chap. 19. Chapter 20 reviews the application of Pseudo-Boolean techniques in digital filter design. Maximally linear digital differentiators form the subject of Chap. 21, while Maximally Flat and Monotonic FIR filters using the Bernstein polynomial are discussed in Chap. 22. Design of FIR notch filters form the contents of Chap. 23. Chapter 24 deals with analytic inversion of Van der Monde and confluent Van der Monde matrices. Chapters 25–28 deal with the solution of an outstanding problem in DSP, *viz*. Canonical lattice realization. Chapters 25 and 26 deal with FIR lattice, while Chaps. 27 and 28 deal with IIR lattices.

Chapter 18
A State-of-the-Art Survey on Linear Phase Digital Filter Design

Abstract Following a brief review of digital filters and associated terminology, the problem of linear phase design is stated in precise form. The relative difficulty of IIR design as compared to FIR design is discussed and a state-of-the-art survey is presented for both cases.

Keywords Linear phase · Digital filter

18.1 Introduction

The subject of digital filters can be called a relatively recent development in filter theory and design. The upsurge of interest in digital filters was caused by many factors, the most important of which was the increased use of digital hardware, rather than analog ones, for processing of signals. This, in turn, was stimulated by advances in microelectronic technology, leading to the availability of low cost, high-speed digital circuits. Also, in many applications, the data to be processed is basically discrete, so that digital processing is the most natural thing to do. Digital filtering finds applications in many practical situations like radar and sonar signal processing, speech communication, geophysical data processing.

Digital filtering has many advantages over analog filtering, some of them being (i) accurate, drift-free operation with predictable performance and a high degree of precision, (ii) exact realization of linear phase transmission, (iii) absence of any matching problem, (iv) high degree of component utilization arising due to the use of multiplexing, (v) ability to realize a greater variety of filter functions and (vi) economy at very low frequencies when an aggregate of such filters is needed. On the other hand, a digital filter is more complex than an analog filter and its advantages are felt only for filters with certain minimum critical size.

There are many aspects into which recent developments in digital filters can be categorized. This chapter is specifically concerned with some recent research on linear phase design, with particular reference to the work done at the Indian

Institute of Technology, New Delhi. As a prelude to this presentation, it would be of advantage to review, very briefly, some basic concepts and definitions pertaining to digital filters. First, we note that a digital filter accepts a quantized time series $\{x(kT)\}$ and produces another quantized time series $\{y(kT)\}$ through the solution of a linear difference equation

$$y(kT) = \sum_{i=0}^{m} a_i x(kT - iT) - \sum_{i=1}^{n} b_i y(kT - iT) \tag{18.1}$$

It should be clear from this description that a general-purpose digital computer can be used for digital filtering. Alternatively, a special-purpose hardware, consisting of delays, multipliers and adders, can be built to perform the calculations prescribed by Eq. (18.1). Because of finite length registers used in either implementation, the consideration of multiplication errors or noise, as it is commonly called, becomes very important. If the signal to be processed is analog, we need additional hardware, viz., bandlimiter (analog), sampler and A/D converter. Because of finite bit capacity of A/D converters, an additional component of noise is thereby introduced. If the output signal is desired to be in analog form, we need a D/A converter, followed by a data reconstructor and a simple analog low-pass filter.

The frequency-domain description of the digital filter is obtained through the z-transform, defined by

$$X(z) \triangleq Z\{x(kT)\} = \sum_{k=0}^{\infty} x(kT) z^{-k} \tag{18.2}$$

where the z-plane is related to the s-plane by $z = e^{sT}$. Combining Eqs. (18.1) and (18.2), it is possible to define a z-domain transfer function as

$$H(z) = \frac{Y(z)}{X(z)} = \left(z^{n-m} \sum_{i=0}^{m} a_{m-i} z^i \right) \Bigg/ \left(\sum_{i=0}^{n} b_{n-i} z^i \right) \tag{18.3}$$

where $b_0 = 1$. The frequency response is obtained by putting $z = e^{j\omega T}$; it is clear that $H(e^{j\omega T})$ is periodic in T, with the baseband $-\pi \leq \omega T \leq \pi$. It should also be clear that for stability, poles of $H(z)$ must be located within the unit circle in the z-plane, but there are no such restrictions on zeros of $H(z)$. For real time realization, $H(z)$ must be rational, i.e. $H(z) = N(z)/D(z)$, where degree of $N(z)$ is less than or equal to degree of $D(z)$. If this is not the case, an appropriate number (p) of poles at $z = 0$ has to be introduced; then the magnitude, $M(\omega) = \left| H(e^{j\omega T}) \right|$ remains unaffected while $\phi(\omega) =$ angle of $H(e^{j\omega T})$ is decreased by the amount $p\omega\, T$.

The impulse response of a digital filter is defined as the response $\{y(kT)\}$ to a signal $\{x(kT)\} = \{1, 0, 0, \ldots\}$. Based on the duration of the impulse response, digital filters are classified into two categories ,viz., finite duration impulse response (FIR) and infinite duration impulse response (IIR). The former type is obtained when $H(z)$

has poles at $z = 0$ only; this is commonly known as 'nonrecursive'. If $H(z)$ poles are not so restricted, then we obtain an IIR filter, which is commonly known as 'recursive'. The terms 'recursive' and 'nonrecursive' used in the above sense, are misleading, because they refer to how a filter is realized and not to the duration of the impulse response. As shown by Gold and Jordan [1], FIR filters can also be realized recursively and IIR filters can also be realized nonrecursively.

For a given specification, IIR filters are computationally more efficient and require less storage capacity than FIR filters. On the other hand, as will be discussed shortly, a strictly linear phase can be achieved only by FIR filters.

18.2 The Problem of Linear Phase and FIR Design

For any transmission channel or network, which is required to transmit a band of frequencies, the group delay $\tau(\omega)$ should be invariant with frequency in the passband, i.e. the transfer function should be a linear phase one. It is a fact of life that analog filters cannot realize this exactly; however, various approximations are known, of which the Bessel type approximates constant delay in the maximally flat (MF) sense. In linear phase digital filter design, we aim for a low-pass $M(\omega)$, because, as will be seen shortly, by multiplying the resulting transfer function by a suitable polynomial, all other types of $M(\omega)$ can be approximated, without affecting the linear phase characteristic or its approximation. We can, therefore, state the problem as follows: to find a transfer function $H(z)$ such that for $z = e^{j\omega T}$,

$$M(\omega) = \begin{cases} 1 \text{ for } 0 \le \omega T \le \omega_c T < \pi \\ 0 \text{ for } \omega_c T < \omega T \le \pi \end{cases} \tag{18.4}$$

and

$$\tau(\omega) = -\frac{d\phi(\omega)}{d\omega} = \begin{cases} \tau_0 \text{ for } 0 \le \omega T \le \omega_0 T \\ \text{arbitrary for } \omega_c T < \omega T \le \pi \end{cases} \tag{18.5}$$

where τ_0 is a constant.

We first consider the FIR case. Consider the following transfer function[1]

$$H(z) = \left\{ \begin{array}{l} (z-1)^{n_1}(z+1)^{n_2} \prod_{i=1}^{n_3} \left[(z-q_i)(z-q_i^{-1})\right] \prod_{i=1}^{n_4} [(z+1)(z+u_i^{-1})] \cdot \prod_{i=1}^{n_5} [(z-e^{j\theta_i})(z-e^{-j\theta_i})] \\ \prod_{i=1}^{n_6} [(z-r_i e^{j\psi_i})(z-r_i e^{-j\psi i}) \cdot (z-r_i^{-1}e^{j\psi i})(z-r_i^{-1}e^{-j\psi_i})] \end{array} \right\} / z^n$$
$$= N(z)/D(z) \tag{18.6}$$

[1] This is a more generalized form of the transfer function considered by Nowak [2] in that the zeros on the positive as well as the negative real axis and those on the z-plane unit circle are shown explicitly.

where $n = n_1 + n_2 + 2n_3 + 2n_4 + 2n_5 + 4n_6$; all the constants are positive; and further q_i, u_i and r_i are not allowed to have a value of unity. For $z = e^{j\omega T}$, is easy to show that

$$\phi(\omega) = -n\omega T/2 + \pi[(\text{number of unit circle zeros between } \omega T = 0 \text{ and } \omega T) + (n_1/2) + n_3] \tag{18.7}$$

Thus, if there are no unit circle zeros in the range $0 \leq \omega T \leq \omega_0 T$, the phase response is strictly linear with no phase jumps.

In Eq. (18.6), the term $(z+1)^{n_2}$ and each term with the square brackets have the property that if the order of the polynomial is p, then the coefficients of z^i and z^{p-i} are equal. Such polynomials are called mirror image polynomials (MIP) [3]. If the coefficients of z^i and z^{p-i} are equal in magnitude but opposite in sign, the resulting polynomial is called a negative MIP (NMIP) [2]. The term $(z-1)^{n_1}$ is an MIP if n_1 is even and an NMIP if n_1 is odd. The product of MIPs is an MIP while the product of MIPs and NMIP is an NMIP; the $N(z)$ in Eq. (18.6) is either an MIP or $(z-1)$ time an MIP. For $z = e^{j\omega T}$, $M(\omega)$ will obviously be a Fourier series in cos (ωT) or sin (ωT) depending on whether $N(z)$ is MIP or NMIP. As an example when n_1 and n are even,

$$M(\omega) = \sum_{i=0}^{n} d_i \cos(i\omega T) \tag{18.8}$$

The problem of FIR linear phase design therefore effectively reduces to that of choosing d_i, $i = 0 \rightarrow$ such that Eq. (18.8) approximates Eq. (18.4) in a desired fashion. If $M(\omega)$ is constrained to be MF in the passband, it has been shown in [4] that $M(\omega)$ can be expressed in the following elegant form:

$$M(\omega) = (1-\beta)^m \sum_{i=0}^{n-m} {}^{m+i-1}C_i \beta^i \tag{18.9}$$

where

$$\beta = \sin^2(\omega T/2)$$

and m is chosen to satisfy a certain cutoff point at $\beta = \lambda$ according to the relation

$$m = n - (n\lambda + 1/2) \tag{18.11}$$

Except for this special case, analytical solution cannot, in general, be contained for d_i's in Eq. (18.8) to satisfy a prescribed $M(\omega)$. Iterative techniques, however, can be applied to obtained optimum results. Several such techniques have been proposed, of which the windowing, frequency sampling and equiripple designs are the most popular ones. These have been well documented in the literature [5].

18.3 Linear Phase IIR Design

Owing to stability constraints, IIR filters cannot achieve a strictly linear phase. However, in situations where the high degree of FIR filters is not acceptable, one is led to approximate a linear phase by an IIR filter. The most common method of IIR digital filter design is based on the design of the corresponding analog filter, followed by a suitable transformation from the s- to the z-plane. Examples are the impulse invariance, bilinear transformation and the matched z-transform techniques. Such methods provide good results for a filter having piecewise constant frequency response but fail to give satisfactory results for linear magnitude or phase characteristics. For example, bilinear transformation of the analog Bessel filter yields a digital filter which does not have an MF delay characteristic. The synthesis of linear phase IIR filters, therefore, necessitates direct approximation.

For MF delay, Thiran [6] showed that the required transfer function is of the form

$$H(z) = \frac{(2n)!/\left[n!\sum_{i=n+1}^{2n}(2\tau_0+i)\right]}{\sum_{k=0}^{n}(-1)^k \prod_{i=0}^{n}\{2\tau_0+i)/(2\tau_0+k+i)\}z^{-k}} \tag{18.12}$$

where the denominator can be shown to be the Gauss's hypergeometric function $F(-n, 2\tau_0; 2\tau_0 + n + 1; z^{-1})$, and that Eq. (18.12) is always stable. No such elegant solution could, however, be found for equal ripple delay. Starting with the transfer function

$$H(z) = K/D(z^{-1}) = K/\sum_{i=1}^{n}(z^{-1} - z_i^{-1}) \tag{18.13}$$

and putting equal ripple constraints on the group delay, Thiran [7] obtained a set of n simultaneous nonlinear algebraic equations for the pole locations. Explicit solutions can be obtained for the trivial case of $n = 1$ and for the nontrivial case $\omega_0 T = \pi$; for the latter case,

$$D(z^{-1}) = z^{-n} + (-1)^n \in / \tau_0 \tag{18.14}$$

where $\in$ is the ripple amplitude in delay; and, $\in$ and τ_0 are restricted to certain combinations for a stable $H(z)$. Note that for this special case, the poles are uniformly distributed over a circle of radius less than unity. Starting from this explicit solution, a generalized Newton–Raphson procedure was adopted by Thiran for solving the nonlinear equations for an arbitrary $\omega_c T < \pi$.

A conceptually simpler solution for equiripple delay was proposed by Deczky [8]. The method is based on the observation that the group delay of the transfer function

$$H_i(z) = K_i z/\{z - r_i \exp(j\theta_i)\} \tag{18.15}$$

when plotted versus $(\omega T - \theta_i)/\pi$, has a resonance type characteristics, with the sharpness of the peak depending only on r_i while its position is a function of θ_i. Clearly, the superposition of a number of such responses with appropriate r_i's and θ_i's, subject to complex poles occurring in conjugate pairs, should achieve an equal ripple delay. This ultimately leads again to n number of nonlinear equations, with the same explicit solution for the special case $\omega_c T = \pi$. With this as the initial approximation, an iterative solution can be obtained for $\omega_c T < \pi$ using numerical techniques.

Compared to the equiripple designs of Thiran [7] and Deczky [8], a remarkably simple design has been obtained by Hazra and Dutta Roy [9]. The method is based on the observation that the transfer function

$$H_0(z) = 1/(r^m + z^m) \tag{18.16}$$

having poles at $z_k = r\, e^{j\theta_k}$; $\theta_k = (2k+1)\pi/m$; $k = 0 \rightarrow m-1$, is stable when $r < 1$ and has a phase angle for $z = e^{j\omega T}$, given by

$$\begin{aligned} \phi_0(\omega) &= -m\omega T + \arctan\{[r^m \sin(m\omega T)]/[1 + r^m \cos(m\omega T)]\} \\ &\cong -m\omega T + r^m \sin(m\omega T) \end{aligned} \tag{18.17}$$

The approximation in Eq. (18.17) is valid for large m. $H_0(z)$, therefore, approximates a linear phase with a maximum periodic error of r^m radians, which can be made as small as desired by choosing r and m suitably. The magnitude of $H_0(e^{j\omega T})$, viz.

$$\begin{aligned} M_0(\omega) &= [1 + r^{2m} + 2r^m \cos(m\omega T)]^{-1/2} \\ &\cong 1 - r^m \cos(m\omega T) \end{aligned} \tag{18.18}$$

has an equiripple all-pass characteristic. To make the filter a low-pass one, the poles of $H_0(z)$ in the stopband are cancelled by introducing zeros at these points. The resulting transfer function, $H_0(z)\, U(z)$ say, will no longer be linear phase; to retain the linear phase approximation, an equal number of zeros are introduced on a circle of radius $1/r$ at the same angles as those of the zeros of $U(z)$. The new filter function, $H(z) = H_0(z)\, U(z)\, V(z)$ say, will now be linear phase, because $U(z)\, V(z)$ is an MIP having a strictly linear phase characteristics. To be specific, let m be even and let $2n < m$ be the number of passband poles. Then $U(z)\, V(z)$ is an MIP of order $2(m-2n)$, and the angle of $H(e^{j\omega T})$ becomes

$$\phi(\omega) = -2n\omega T + r^m \sin(m\omega T) \tag{18.19}$$

Finally, for real time realization and minimum delay, the numerator and denominator degrees of the transfer function are equalized, resulting in the new transfer function

$$H(z) = K\, H(z)/z^{m-4n} \tag{18.20}$$

The phase angle of $H(e^{j\omega T})$ is

$$\phi(\omega) = -(m - 2n)\omega T + r^m \sin(m\omega T) \tag{18.21}$$

Investigation of the magnitude response of $H(e^{j\omega T})$ shows that for $\theta_k \ll \omega T$ and $(1 - r)^2/r \ll [(\omega T - \theta_k)/\pi/]^2$,

$$M(\omega) \leq \text{constant}/\omega^{4n} \tag{18.22}$$

which leads to the conclusion that the asymptotic decibel loss is upper bounded by $24n$ dB/octave. Thus, in addition to linear phase approximation, the method also provides a certain degree of freedom in shaping the magnitude characteristic. For a prescribed delay τ_0, a maximum delay error $\in$, and an asymptotic slope S in dB/octave, the filter can be designed through the following simple relations

$$n \geq S/24;\ m = 2n + \tau_0/T \text{ and } r = [\in /(2n + \tau_0/T)]^2/(2n + r_0/T) \tag{18.23}$$

18.4 Conclusion

Explicit solutions to the problem of linear phase digital filter design have so far been obtained in a few special cases only. Specifically, these are the MF magnitude FIR filter and the MF delay IIR filter. For equal ripple magnitude or delay, numerical techniques have to be resorted to in general. The technique of Hazra and Dutta Roy for equiripple IIR delay is an exception to this. With a negligibly small deviation from the strictly equiripple condition, it achieves a remarkably simple solution without the need for solving a set of simultaneous nonlinear equations, as required in the other approaches available for the purpose. Besides $r < 1$, there are no additional stability constraints to be set or tested for. Also, it provides a certain degree of flexibility on the magnitude response.

Chapter 19
Generalized Linear Phase Conditions for Causal FIR Systems Revisited

Abstract It is well known that a causal FIR system has generalized linear phase when its impulse response is either symmetric or antisymmetric. Most textbooks demonstrate the sufficiency of these conditions; that they are also necessary has been dealt with by only a few authors. In this chapter, we give a critical review of these methods, including a recent one, proposed by the author, which is based on a different way of looking at the problem.

Keywords Digital signal processing · FIR systems · Generalized linear phase · Linear phase conditions

19.1 Introduction

In this section, we first review the basic concepts, including definitions of the terms linear phase, generalized linear phase, phase delay, and group delay, and the importance of linear phase. This will be followed by demonstrating the sufficiency of the linear phase conditions and listing the types of linear phase systems. The necessary and sufficient conditions for linear phase will then be specifically mentioned, along with the scope of the chapter.

19.1.1 Basic Concepts

Any system, analog or digital, is said to have generalized linear phase (GLP) if the phase $\varphi(\omega)$ is of the form

$$\varphi(\omega) = -\alpha\omega + \beta \tag{19.1}$$

where α and β are constants. For analog systems, $\omega = 2\pi f$ is the angular frequency in radians/s, with f being the frequency in Hz, while for digital systems, $\omega = 2\pi f/f_s$ is the normalized digital frequency in radians, with f_s being the sampling frequency. The phase delay is defined as $-\varphi(\omega)/\omega$, while the group delay is defined as $-d\varphi(\omega)/d\omega$. Obviously, for $\beta = 0$, the phase and group delays are the same, each being equal to α, while for $\beta \neq 0$, the phase delay varies with frequency but the group delay is a constant, being equal to α. In signal processing, it is the constancy of group delay which is more important than that of phase delay. The underlying reason is that any information-carrying signal will contain a group or band of frequencies, which are together at the input of the processor. If the group delay depends on frequency, then different signals will arrive at the output at different times, causing what is known as delay distortion.

This chapter is concerned with finite impulse response (FIR) digital system, and the conditions for it to have GLP.

19.1.2 Conditions for GLP and Proof of Sufficiency

Consider a causal FIR system with impulse response $h(n)$, $n = 0$ to $N - 1$. The frequency response of the system, which is the Fourier transform (FT) of $h(n)$, is given by

$$H(e^{j\omega}) = \sum_{n=0}^{N-1} h(n)e^{-j\omega n} \tag{19.2}$$

If the impulse response is symmetric, i.e. $h(n) = h(N - n - 1)$, and the length of $h(n)$, N, is odd, then Eq. (19.2) can be rewritten as

$$H(e^{j\omega}) = h(0)[1 + e^{-j\omega(N-1)}] + h(1)[e^{-j\omega} + e^{-j\omega(N-2)}] + \ldots + h((N-1)/2)e^{-j\omega(N-1)/2} \tag{19.3}$$

By taking $e^{-j\omega(N-1)/2}$ common from each term, Eq. (19.3) can be simplified to the following:

$$H(e^{j\omega}) = e^{-j\omega(N-1)/2}\left[h((N-1)/2) + 2\sum_{n=1}^{(N-1)/2} h((N-1)/2 - n\cos(\omega n)\right] \tag{19.4}$$

The expression within the square brackets of Eq. (19.4) is real, but it can be positive or negative. Hence, it is called pseudo-magnitude, not magnitude. The phase of $H(e^{j\omega})$ is $-\omega(N-1)/2$ as long as the pseudo-magnitude does not change sign; every time it does, there will be an increment of π in phase. Hence, the phase is linear, piecewise linear to be precise, and the group delay is $(N-1)/2$ samples. The

significance of linear phase, as mentioned earlier, is that a signal passing through the system will undergo magnitude filtering, as needed, but will have no delay distortion. This feature is not realizable in either analog systems or digital systems having infinite impulse response (IIR), and is a distinct advantage of FIR digital systems.

The case we have just considered is given the name Type 1 linear phase in the literature. If $h(n)$ is symmetric but N is even, then the summation in Eq. (19.4) shall remain the same, except that the last term will be

$$e^{-j\omega(N-1)/2}h((N-2)/2)[e^{j\omega/2}+e^{-j\omega/2}] \tag{19.5}$$

Once again, taking $e^{-j\omega(N-1)/2}$ common from each term, and simplifying, the frequency response can be written as

$$H(e^{j\omega}) = 2e^{-j\omega(N-1)/2}\sum_{n=1}^{N/2} h((N/2)-n)\cos(\omega[n-(1/2)]) \tag{19.6}$$

This case is designated as Type 2 linear phase.

In a similar manner, one can show that if $h(n)$ is antisymmetric, i.e. $h(n) = -h(N-1-n)$, the frequency responses are given by

$$H(e^{j\omega}) = 2je^{-j\omega(N-1)/2}\sum_{n=1}^{(N-1)/2} h((N-1)/2)-n)\sin(\omega n) \tag{19.7}$$

for N odd, and

$$H(e^{j\omega}) = 2je^{-j\omega(N-1)/2}\sum_{n=1}^{N/2} h(N/2)-n)\sin[\omega(n-(1/2))] \tag{19.8}$$

for N even. These are designated as Type 3 and Type 4 linear phase FIR systems, respectively. Note that all the four types have GLP, because the pseudo-magnitude can be positive or negative, while for types 3 and 4, in addition, the factor j contributes an additional phase of $\pi/2$.

19.1.3 Necessary and Sufficient Conditions

We have just demonstrated that if the impulse response is symmetric or antisymmetric, then the system has GLP. These are sufficient conditions; are they also necessary? To show that they are necessary, we have to prove that if the system has GLP, then the impulse response must be symmetric or antisymmetric. Barring a few, most of the textbooks do not deal with this aspect. Various methods have been used in the literature to prove necessity; we shall review them critically in the next few sections,

including a recent method proposed by the author. This last method is based on a different approach to the problem, and is believed to be crisper and more straightforward than the other methods.

19.2 Method 1

This method appeared in Ref. [1] and is based on Fourier series properties. In this, it is argued that a linear phase FIR frequency response can be expressed as

$$H(e^{j\omega}) = A(\omega)e^{-j\omega\alpha+j\beta} \tag{19.9}$$

where $A(\omega)$ is real, α is the delay (in number of samples), and β is a constant. This expression is validated by the four transfer functions given in Eqs. (19.4) and (19.6)–(19.8), where for the first two, $\beta = 0$, and for the last two, $\beta = \pi/2$, and for all of them, $\alpha = (N-1)/2$. Note that writing the four transfer functions with a negative sign would not have affected the GLP character. Thus, what we have to prove is that if the transfer function has GLP, then we must have (1) $\alpha = (N-1)/2$ and either (2) $e^{j\beta} = \pm 1$ and $h(n) = h(N-1-n)$ or (3) $e^{j\beta} = \pm j$ and $h(n) = -h(N-1-n)$.

Equating Eqs. (19.2) and (19.9), we can write

$$A(\omega) = \sum_{n=0}^{N-1} h(n)e^{-j[\omega(n-\alpha)+\beta]} \tag{19.10}$$

Since $A(\omega)$ is real, the imaginary part of Eq. (19.10) must vanish, i.e.

$$\sum_{n=0}^{N-1} h(n)\sin[\omega(n-\alpha)+\beta] = 0 \tag{19.11}$$

This is a Fourier series type expression which implies that any solution for α and β must be unique. It is easily verified that Eq. (19.11) can be satisfied in two ways: (1) for $\beta = 0$, $h(n) = h(N-1-n)$ and (2) for $\beta = \pi/2$, $h(n) = -h(N-1-n)$, and in both cases, $n - \alpha = -(N-1-n-\alpha)$, i.e. $\alpha = (N-1)/2$.

Two questions arise at this point. First, Eq. (19.11) is not a Fourier series, even if truncated, because $\omega(n-\alpha)$ is not a harmonic frequency if α is not an integer. Secondly, it is not clear how these special values of β were arrived at. When these points were raised in a paper, an anonymous reviewer commented that 'Fourier methods are essentially based on orthogonality of certain sets of functions, the sine functions in this case, and as such, are far more general than just Fourier series, which is based upon orthogonality properties of particular countable subsets of these functions (again sine functions in this case)'. Hence, 'deductions from Eq. (19.11) by Fourier methods are entirely appropriate'.

Readers who are not comfortable with the line of reasoning followed in this method may look at method 6 given later in this chapter, where also summations with non-integer values of $n - \alpha$ occur, but the orthogonality argument does not have to be evoked, at least not explicitly.

19.3 Method 2

In this method, given in Refs. [2] and [3], the possible values of β are first established and then symmetry or antisymmetry conditions are proved. Since $h(n)$ is real, $H(e^{j\omega})$ must be Hermitian symmetric (both Refs. [2] and [3] mention conjugate symmetry; that Hermitian symmetry is the correct property was pointed out by the anonymous reviewer mentioned in the previous section), i.e.

$$H(e^{j\omega}) = H^*(e^{-j\omega}) \tag{19.12}$$

as can be easily verified from Eq. (19.2). In Eq. (19.12), the superscript * denotes complex conjugate. Combining Eq. (19.12) with (19.9), we get

$$A(\omega)e^{-j\omega\alpha+j\beta} = A(-\omega)e^{-j\omega\alpha-j\beta} \tag{19.13}$$

Since the magnitudes of $H(e^{j\omega})$ and $A(\omega)$ are equal, $A(\omega)$ must be either even or odd, i.e. $A(-\omega) = \pm A(\omega)$. If $A(\omega)$ is an even function, then the positive sign is applicable, and Eq. (19.13) gives

$$e^{j2\beta} = 1 \tag{19.14}$$

Thus, $\beta = 0$ or π, and from Eq. (19.10), we can write

$$A(\omega) = \pm \sum_{n=0}^{N-1} h(n)e^{-j\omega(n-\alpha)} \tag{19.15}$$

and

$$A(-\omega) = \pm \sum_{r=0}^{N-1} h(r)e^{-j\omega(r-\alpha)} \tag{19.16}$$

The positive signs in Eqs. (19.15) and (19.16) hold for $\beta = 0$ and the negative signs hold for $\beta = \pi$. Note that the variable in Eq. (19.16) has been changed from n to r, without any loss of generality, for convenience of carrying out the next step, which is to put $r = N - 1 - n$. The result is

$$A(-\omega) = \pm \sum_{n=0}^{N-1} h(N-1-n) e^{j\omega(N-1-n-\alpha)} \tag{19.17}$$

Equating (19.15) and (19.17), we arrive at the conditions

$$h(n) = h(N-1-n) \text{ and } \alpha = (N-1)/2 \tag{19.18}$$

On the other hand, if $A(\omega)$ is odd, i.e. $A(-\omega) = -A(\omega)$, then Eq. (19.13) gives

$$e^{j2\beta} = -1, \tag{19.19}$$

i.e. $\beta = \pm\pi/2$, and Eq. (19.10) gives

$$A(\omega) = \pm j \sum_{n=0}^{n-1} h(n) e^{-j\omega(n-\alpha)} \tag{19.20}$$

By following a similar procedure as in the previous case (i.e. change of variable), it is easy to show that

$$A(-\omega) = \pm j \sum_{n=0}^{N-1} h(N-1-n) e^{j\omega(N-1-n-\alpha)} \tag{19.21}$$

In the above two equations, the positive signs hold for $\beta = -\pi/2$ and the negative signs hold for $\beta = +\pi/2$. Now using $A(-\omega) = -A(\omega)$, we get from Eqs. (19.20) and (19.21), the conditions

$$h(n) = -h(N-1-n) \text{ and } \alpha = (N-1)/2 \tag{19.22}$$

This completes the proof.

19.4 Method 3

As compared to the other methods, method 3, given in Ref. [4], has the distinctive feature that it does not assume the system to be FIR to start with. Instead, it starts with the fact that $H(e^{j\omega})$ is periodic with period 2π. Thus from Eq. (19.9), we should have

$$A(\omega) e^{-j\omega\alpha + j\beta} = A(\omega + 2\pi) e^{-j(\omega+2\pi)\alpha + j\beta} \tag{19.23}$$

On simplification, this gives

$$A(\omega) = A(\omega + 2\pi)e^{-j2\pi\alpha} \tag{19.24}$$

Since $A(\omega)$ is real, 2α must be an integer. Note, in passing, that if α is an integer, then $A(\omega)$ is periodic with period 2π and that if α is an integer plus 1/2, then $A(\omega)$ is periodic with period 4π. If neither is the case, then $A(\omega)$ is not periodic.

Now, as in method 2, real $h(n)$ implies that $H(e^{j\omega})$ is Hermitian symmetric, i.e. Eqs. (19.12) and (19.13) are valid, and from the latter, in general, we can write

$$e^{j2\beta} = A(-\omega)/A(\omega) \tag{19.25}$$

Again, since $A(\omega)$ is real, it follows that $e^{j2\beta}$ is necessarily real. As before, even $A(\omega)$ implies $\beta = 0$ and odd $A(\omega)$ implies $\beta = \pi/2$. In retrospect, it is clear that Ref. [4] uses essentially the same procedure as in Refs. [2] and [3] to establish the possible values of β, but does not admit the values π and $-\pi/2$.

From this point onwards, the procedure deviates from that of Refs. [2] and [3]. In general, from Eq. (19.9), one can write

$$A(\omega) = H(e^{j\omega})e^{j\omega\alpha - j\beta} \tag{19.26}$$

The sample $h(2\alpha - n)$ of the impulse response can be obtained from the inverse FT as follows:

$$h(2\alpha - n) = [1/(2\pi)] \int_{-\pi}^{\pi} He^{j\omega} e^{j\omega(2\alpha - n)} d\omega \tag{19.27}$$

For $\beta = 0$, combining Eqs. (19.9) and (19.27) gives

$$h(2\alpha - n) = [1/(2\pi)] \int_{-\pi}^{\pi} A(\omega) e^{j\omega(\alpha - n)} d\omega \tag{19.28}$$

Since $h(2\alpha - n)$ is real, we can replace the right-hand side of Eq. (19.28) by its complex conjugate to get

$$h(2\alpha - n) = [1/(2\pi)] \int_{-\pi}^{\pi} A(\omega) e^{j\omega(n - \alpha)} d\omega \tag{19.29}$$

where we have used the fact that $A(\omega)$ is real. Now combine Eq. (19.29) with (19.26) for $\beta = 0$; the result is

$$h(2\alpha - n) = [1/(2\pi)] \int_{-\pi}^{\pi} H(e^{j\omega}) e^{j\omega n} d\omega = h(n) \tag{19.30}$$

Since the system is causal, $h(n) = 0$ for $n < 0$, and therefore, also for $n > 2\alpha$. Thus, the system is FIR, and if $h(n)$ exists for $n = 0$ to $N - 1$, 2α must be $N - 1$, i.e. $\alpha = (N - 1)/2$, and by Eq. (19.30), $h(n) = h(N - 1 - n)$. Note that this procedure involves going back and forth between $A(\omega)$ and $H(e^{j\omega})$.

In the second case of $\beta = \pi/2$, Eq. (19.9) becomes

$$H(e^{j\omega}) = jA(\omega)e^{-j\omega\alpha} \tag{19.31}$$

Putting this in Eq. (19.27) gives

$$h(2\alpha - n) = [j/(2\pi)] \int_{-\pi}^{\pi} A(\omega)e^{j\omega(\alpha-n)}d\omega \tag{19.32}$$

Again take the complex conjugate of both sides, and take account of the realness of $h(2\alpha - n)$ and $A(\omega)$ to get

$$h(2\alpha - n) = [j/(2\pi)] \int_{-\pi}^{\pi} A(\omega)e^{j\omega(n-\alpha)}d\omega \tag{19.33}$$

Finally, substitute for $A(\omega)$ from Eq. (19.31) to get

$$h(2\alpha - n) = -[1/(2\pi)] \int_{-\pi}^{\pi} H(e^{j\omega})e^{j\omega n}d\omega = -h(n) \tag{19.34}$$

By similar arguments as in the previous case, we conclude that $h(n)$ is of finite length N, with $\alpha = (N - 1)/2$, and by Eq. (19.34), $h(n) = -h(N - 1 - n)$.

19.5 Method 4

This method appeared in Ref. [5] and has the interesting feature that it does not assume $h(n)$ to be real to start with. In general, $h(n)$ is the inverse FT of $H(e^{j\omega})$, i.e.

$$h(n) = [1/(2\pi)] \int_{-\pi}^{\pi} H(e^{j\omega})e^{j\omega n}d\omega \tag{19.35}$$

Combining this with Eq. (19.9), we get

$$h(n) = e^{j\beta}([1/(2\pi)] \int_{-\pi}^{\pi} A(\omega) e^{j\omega(n-\alpha)} d\omega) \tag{19.36}$$

Recognize that the quantity which multiplies $e^{j\beta}$ in Eq. (19.36) is the sample $a(n - \alpha)$ in the inverse FT of $A(\omega)$. Hence,

$$h(n) = e^{j\beta} \alpha(n - \alpha) \tag{19.37}$$

which can also be written as

$$\alpha(n) = e^{-j\beta} h(n + \alpha) \tag{19.38}$$

Since $A(\omega)$ is real, $a(n)$ must be Hermitian symmetric (as can be easily verified from the inverse FT expression), i.e.

$$a(n) = a * (-n) \tag{19.39}$$

Combining this with Eq. (19.38) gives

$$h(n + \alpha) = e^{j2\beta} h * (-n + \alpha) \tag{19.40}$$

Putting $n = -\alpha$ in Eq. (19.40) gives

$$h(0) = e^{j2\beta} h * (2\alpha) \tag{19.41}$$

From this, it is argued in Ref. [5] that if $h(n)$ is causal and of finite duration, from $n = 0$ to $n = N - 1$, one must necessarily have

$$\alpha = (N - 1)/2 \tag{19.42}$$

With regard to this step, the author of Ref. [6] commented that 'there is a logic flaw in this derivation', and that 'in the next addition of the same text in Ref. [7], the authors side-step the mistake by providing a weaker version under the assumption that the group delay is a multiple of 1/2 sample, which is short of the most general conclusion'.

However, we shall 'side-step' this criticism and proceed further, as in Ref. [5]. Replacing n by $n - \alpha$ in Eq. (19.40) and using Eq. (19.42) gives

$$h(n) = e^{j2\beta} h * (N - 1 - n) \tag{19.43}$$

which is the general equation that the coefficients of a linear phase FIR system must satisfy. When $h(n)$ is real, $h(n) = h^*(n)$, and Eq. (19.43) implies that $\beta = k\pi/2$, where k is an integer, positive or negative; thus Eq. (19.43) gives

$$h(n) = (-1)^k h * (N - 1 - n) \tag{19.44}$$

i.e. the impulse response must be either symmetric or antisymmetric. Finally,

$$H(e^{j\omega}) = A(\omega)e^{-j\omega[(N-1)/2]+j(k\pi/2)} \tag{19.45}$$

For all practical purposes, it is sufficient to consider only $k = 0$ and 1 because all other values of k will be equivalent to one of these cases. Accordingly, $k = 0$ and N odd gives Type 1; $k = 0$ and N even gives Type 2; $k = 1$ and N odd gives Type 3; and $k = 1$ and N even gives Type 4 linear phase filters.

19.6 Method 5

This method appeared in Ref. [6], where, with regard to Eq. (19.11), the author commented that 'this result is inconvenient to use for further derivation', but did not explain why. In this method, $h(n)$ is assumed real, and it is first proved that the group delay α must be an integer or half integer, 'an issue which is overlooked or not carefully dealt with in most texts on digital signal processing' [6].

Note that Eq. (19.1) can be expressed as

$$H(e^{j\omega}) = H_R(e^{j\omega}) + jH_I(e_{j\omega}) \tag{19.46}$$

where the subscripts R and I stand for the real and imaginary parts, respectively, with

$$H_R(e^{j\omega}) = \sum_{n=0}^{N-1} h(n)\cos(\omega n) \tag{19.47}$$

and

$$H_I(e^{j\omega}) = \sum_{n=0}^{N-1} h(n)\sin(-\omega n) \tag{19.48}$$

Using Eqs. (19.46)–(19.48) in Eq. (19.26), we get after simplification,

$$A(\omega) = A_R(\omega) + A_I(\omega) \tag{19.49}$$

where

$$A_R(\omega) = H_R(e^{j\omega})\cos(\alpha\omega - \beta) - H_I(e^{j\omega})\sin(\alpha\omega - \beta) \tag{19.50}$$

and

$$A_I(\omega) = H_R(e^{j\omega}) \sin(\alpha\omega - \beta) + H_I(e^{j\omega}) \cos(\alpha\omega - \beta) \tag{19.51}$$

Since $A(\omega)$ is real, its imaginary part must be identically zero. As in method 3, the author then invokes the periodicity of $H(e^{j\omega})$ to conclude that $e^{j2\pi\alpha}$ must be a real number, i.e. α must be an integer or half integer. The next step is to use the same argument as in method 2, viz. that $H(e^{j\omega})$ must be Hermitian symmetric, which leads to the conclusion that $e^{j2\beta}$ must be either $+1$ or -1.

Instead of considering the specific possibilities for the value of β, Ref. [6] considers, as in method 3, the sample $h(2\alpha - n)$ of the impulse response. Replacing n by $2\alpha - n$ in Eq. (19.35), and using Eq. (19.9), we get after simplification,

$$h(2\alpha - n) = [1/(2\pi)] \int_{-\pi}^{\pi} A(\omega)^{j\omega\alpha + j\beta} e^{-j\omega n} d\omega \tag{19.52}$$

which can be rewritten as

$$\begin{aligned} h(2\alpha - n) &= e^{j2\beta} \left([1/(2\pi)] \int_{-\pi}^{\pi} A(\omega) e^{j\omega\alpha + j\beta} e^{-j\omega n} d\omega \right) * \\ &= e^{j2\beta} \left([1/(2\pi)] \int_{-\pi}^{\pi} H(e^{j\omega}) e^{j\omega n} d\omega \right) * \\ &= e^{j2\beta} h * (n) \end{aligned} \tag{19.53}$$

Here we have used the facts that $h(n)$ and $A(\omega)$ are real. Note that as in method 3, this method also involves going back and forth between $A(\omega)$ and $H(e^{j\omega})$. The proof is now complete, showing symmetry or antisymmetry of $h(n)$, depending on whether $e^{j2\beta}$ is $+1$ or -1.

It is clear that method 5 uses part of method 2 [2, 3], and has been significantly influenced by method 3 [4]. However, it is surprising that although the author comments on methods 1 and 4, he makes no reference to [2–4] in his paper in Ref. [6].

19.7 Method 6

We finally present here yet another method proposed by the author [8], which looks at the problem from a different perspective. We use the same method as in Refs. [2] and [3] to derive the possible values of β. Next, we rewrite Eq. (19.9) as

$$A(\omega) = e^{-j\beta} \sum_{n=0}^{N-1} h(n) e^{-j\omega(n-\alpha)} \tag{19.54}$$

Denoting the summation in Eq. (19.54) by $G(e^{j\omega})$ and letting $m = n - \alpha$ and $g(m) = h(m + \alpha)$, we get

$$G(e^{j\omega}) = \sum_{m=-\alpha}^{N-1-\alpha} g(m) e^{-j\omega n} \tag{19.55}$$

When α is an integer, $G(e^{j\omega})$ is clearly the FT of $g(n)$. When α is not an integer, $G(e^{j\omega})$ is like the FT of $g(n)$ with the difference that n takes non-integer values, but at intervals of unity. In a sense, this is time-domain dual of the case in Eq. (19.11), which is in the frequency domain, when α is not an integer.

If $\beta = 0$ or π, then since $A(\omega)$ is real, Eq. (19.54) dictates that $G(e^{j\omega})$ must necessarily be a real quantity, which is possible only if $g(n)$ is an even sequence starting at $n = -\alpha$ and ending at $N - 1 - \alpha$. This implies that

$$N - 1 - \alpha = \alpha \tag{19.56}$$

or

$$\alpha = (N - 1)/2 \tag{19.57}$$

Further, $g(n) = g(-n)$ leads to $g(n - \alpha) = g(\alpha - n)$, and therefore,

$$h(n) = h(2\alpha - n) = h(N - 1 - n) \tag{19.58}$$

i.e. $h(n)$ is symmetric.

Similarly, when $\beta = \pm\pi/2$, $e^{-j\beta} = \pm j$, and Eq. (19.54) dictates that $G(e^{j\omega})$ must be purely imaginary. This is possible only if $g(n)$ is an odd sequence. This implies Eq. (19.57) and $g(n) = g(-n)$, which, as in the previous case, translates to

$$h(n) = -h(2\alpha - n) = -h(N - 1 - n) \tag{19.59}$$

Thus $h(n)$ is antisymmetric. This completes the proof.

19.8 Conclusions

In this chapter, the importance of a linear phase system has been explained and the sufficient conditions for an FIR system to have GLP have been demonstrated by deriving the four types of such systems. For proving the necessity of these conditions,

six methods have been critically examined. These methods have varying degrees of ingenuity and innovation. Except for method 4, where a crucial step has not been adequately justified, all other methods appear to be sound, if one accepts the explanation offered by the anonymous reviewer for method 1. However, even with this explanation, method 6 appears to have an edge over method 1 because it is based on clear logic, and is believed to be crisper and more direct than the other four methods.

To be fair, it must be pointed out that method 6 is not as crisp as it appears, because it uses method 2 for finding the possible values of β, and then takes a different route to find α and the symmetry or antisymmetry of the impulse response.

This chapter supports the universal truth, stated in the Rig Veda as '*Ekam satyam vipra bahudha vadanti*', or in the English saying [9], 'Our paths may be different. Our destination is the same', or in what Thakur Ramakrishna Paramahamsa said in Bengali, '*Jato mat tato path*'.

Acknowledgements The author thanks the anonymous reviewer mentioned under method 1 for his comments, Professor P. S. R. Diniz for supplying the relevant pages of Refs. [5] and [7], and Sumantra Dutta Roy for his help in the preparation of this chapter.

Chapter 20
Review of Pseudo-Boolean Methods with Applications to Digital Filter Design

Abstract The technique of pseudo-Boolean methods which forms the basis for bivalent (0, 1) programming, has been used for many socio-economic and engineering problems in the past. In this chapter, we review these methods and discuss their applications to the quantized coefficient design of digital filters. Some other applications of these methods are also briefly described.

Keywords Pseudo-Boolean methods · Digital filters · Coefficient quantization

20.1 Introduction

There exists a number of socio-economic and engineering problems, which can be solved through integer programming formulation, since the variables in these problems take only integer values [1]. There is a subset of these problems in which the variables take only two values, viz. 0 and 1 [2, 3]. Although integer programming methods can be applied to this subset also, bivalent programming, based on a combination of dynamic programming with Boolean techniques, are particularly suited to them. These are called Pseudo-Boolean (PB) methods [4, 5].

Our attention was drawn to PB methods during the course of investigation of some coefficient sensitivity problems in digital filters [6], and a number of useful design procedures resulted from the application of these methods. In this chapter, we first review some important aspects of PB methods. In particular, we will describe methods for obtaining the solutions of PB equations and inequalities and also, for finding the minima of a PB function. This is followed by a discussion on the application of PB methods to the quantized coefficient design of digital filters. Such design procedures, necessitated by the finite word-length implementation in digital filters, yield the set of quantized filter coefficients in a discrete-parameter space, optimally. The chapter is concluded with a brief overview of some other applications of PB methods.

20.2 Pseudo-Boolean Functions

We start by defining a Boolean algebra B, consisting of two elements 0 and 1, and the operations of disjunction (U), conjunction (.) and negation which can be performed on them.

A PB function is defined as a real-valued function $F(x_1, \ldots, x_n \ldots)$, where $x_i's$ are bivalent variables i.e. $x_i \in \{0, 1\}$, $i = 1, 2, \ldots n$. An important property of PB functions is that they can be written in terms of an arithmetic expression. This is possible because the basic operations of B can be expressed in arithmetic form i.e. for $x, y \in \{0, 1\}$, $xUy = x + y - xy$, $x \,.\, y = xy$ and $\bar{x} = 1 - x$, where bar denotes negation. Another useful property is that every PB function can be made linear in any one of its bivalent variables. In other words, we can write

$$F(x_1, \ldots, x_n) = x_i F_1(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n) + F_2(x_1, \ldots, x_{i-1}, x_{i+1} \ldots, x_n) \tag{20.1}$$

which is linear in the variable x_i; in Eq. (20.1)

$$F_1(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n) = F(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n) - F(x_1, \ldots, x_{i-1}, 0, x_{i+1}, \ldots, x_n) \tag{20.2}$$

and

$$F_2(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n) = F(x_1, x_{i-1}, 0, x_{i+1} \ldots, x_n) \tag{20.3}$$

As an example, consider $F = x_1 + x_2 + 2x_1x_2 + 4x_2x_3 + x_1x_2x_3$ for which $F_1 = 1 + 2x_2 + x_2x_3$ and $F_2 = x_2 + 4x_2x_3$, if F is made linear in x_1.

20.3 Linear PB Equations and Inequalities

A major task in PB methods is to find the solutions of a PB equation or inequality. We first consider a linear PB equation which is given in its arithmetic form as

$$a_1z_1 + a_2z_2 + \cdots + a_nz_n = t \tag{20.4}$$

where a_i, ($i = 1, 2, \ldots, n$) and t are real numbers and z_i ($i = 1, 2, \ldots n$) $\in \{0, 1\}$. In order to solve Eq. (20.4), the following substitution is made

$$x_i = \begin{cases} z_i & \text{if } a_i > 0 \\ \bar{z}_i = 1 - z_i & \text{if } a_i < 0 \end{cases} \tag{20.5}$$

Then Eq. (20.4) can be written in its canonic form

$$c_1x_1 + c_2x_2 + \cdots + c_nx_n = d \tag{20.6}$$

where, $c_i = |a_i|, i = 1, 2, \ldots n, x_i\ (i = 1, 2, \ldots, n) \in \{0, 1\}$ and $d = \sum_r |a_r| + t$ for all r such that $a_r < 0$. Also the terms in Eq. (20.6) may be reindexed such that $c_1 \geq c_2 \geq c_n > 0$. Out of a total 2^n possible combinations of the set $\{x_i\}$, the solutions of Eq. (20.4) can be very easily tracked by following a simple set of rules as given in Table 20.1. For example, if in Eq. (20.6), $d > \sum_i c_i$, there exist no solutions, while if $d = 0$ then the unique solution is $x_i = 0$ for all i. After all the solutions of Eq. (20.6) are obtained, the inverse of the transformation (20.5) is applied to get all the solutions of Eq. (20.4).

If the equality sign in Eq. (20.4) is replaced by an inequality sign ($\geq$),[1] we get a linear PB inequality. This can also be converted to its canonic form

$$c_1x_1 + c_2x_2 + \cdots + c_nx_n > d \tag{20.7}$$

by making use of the transformation given in Eq. (20.5). The solutions of Eq. (20.7) come grouped into families, a family of solutions being one in which some variables take fixed values and the remaining ones can take any arbitrary value from the set $\{0, 1\}$. These families of solutions of Eq. (20.7) can be tracked by using the set of

Table 20.1 Rule for tracking the solutions of PB equation (20.6)

No.	Case	Conclusions
1.	$d < 0$	No solutions
2.	$d = 0$	The unique solution is $x_1 = x_2 = \ldots = x_n = 0$
3.	$d > 0$ and $c_1 \geq \ldots \geq c_p \geq d \geq c_{p+1} \geq \ldots \geq c_n$	The solution, if any, satisfy $x_1 = \ldots = x_p = 0$ and $\sum_{j=p+1}^{n} c_j x_j = d$
4.	$d > 0$ and $c_1 = \ldots = c_p = d > c_{p+1} \geq \ldots \geq c_n$	There are $p + 1$ approaches: $a_k)\ x_k = 1, x_1 = \ldots = x_{k-1} = x_{k+1} = \ldots = x_n = 0$ for each $k = 1, 2, \ldots p$ and $a_{p+1})$ The other solutions, if any, satisfy $x_1 = \ldots = x_p = 0$ and $\sum_{j=p+1}^{n} c_j x_j = d$
5	$d > 0, c_i < d$ for all i and $\sum_{i=1}^{n} c_i < d$	No solutions
6.	$d > 0, c_i < d$ for all i and $\sum_{i=1}^{n} c_i = d$	The unique solution is $x_1 = x_2 = \ldots = x_n = 1$
7.	$d > 0, c_i < d$ for all i, $\sum_{i=1}^{n} c_i > d$ and $\sum_{j=2}^{n} c_j < d$	The solution, if any, satisfy $x_1 = 1$ and $\sum_{j=2}^{n} c_j x_j = d - c_1$
8.	$d > 0, c_i < d$ for all i, $\sum_{i=1}^{n} c_i > d$ and $\sum_{j=2}^{n} c_j \geq d$	There are two approaches: $\beta_1)\ x_1 = 1$ and solutions, if any, of $\sum_{j=2}^{n} c_j x_j = d - c_1$ $\beta_2)\ x_1 = 0$ and solutions, if any, of $\sum_{j=2}^{n} c_j x_j = d$

[1] Note that other forms of inequalities i.e. $<$, $\leq$ and $>$ can easily be converted to the form $\geq$.

rules given in Table 20.2, this being similar to the use of Table 20.1 for the case of a PB equation.

A system of PB equations and inequalities, whose members have been transformed into their canonic forms, is similarly solved by applying the set of rules in Table 20.1 or Table 20.2, to a choice member of the system depending upon whether this choice member is an equation, or an inequality. The information so obtained about the values of some of the variables is used to reduce the order of the whole system. This process is repeated until all the solutions of the system are obtained. The key to the efficiency of this method lies in determination of the choice member of the system, which is subjected to either Table 20.1 or Table 20.2; a stepwise method for doing this is available in the literature [3, 4].

20.4 Nonlinear PB Equations and Inequalities

In order to obtain the solutions of a nonlinear PB equation or inequality, it is first linearized. This is easily done for the case of PB functions by observing that if $y_1, y_2 \ldots y_m$ are bivalent variables, then so is $x_k = y_1, y_2 \ldots, y_k$, $k \leq m$. Thus, a nonlinear equation or inequality

$$F(y_1, y_2, \ldots, y_m) \square 0 \tag{20.8}$$

where '$\square$' is either '=' or '$\geq$', can be converted to a linear equation of the form (20.6) or a linear inequality of the form (20.7), which can be solved by using Table 20.1 or Table 20.2 respectively. Let $(x_1^*, x_2^* \ldots x_n^*)$ be a solution of the linearized form of Eq. (20.8). Then there is a Boolean function f^* such that $f^*(x_1^*, x_2^*, \ldots x_n^*) = 1$. This is called the characteristic equation, f^* being the characteristic function of the solution (*) [3]. The characteristic function f of all the solutions of the linearized form of Eq. (20.8) is then given by $f = f^1 \mathrm{U} f^s U \ldots U f^2$.

Now if each x_k in f is given its corresponding expansion in terms of $y_i's$ then f will represent the solutions of Eq. (20.8), which can be obtained after simplifying this expression, by inspection.

As an example, consider the equation

$$4y_1y_2y_3 + 3y_1y_2 + 2y_1 + y_3 = 5 \tag{20.9}$$

If we let $y_1y_2y_3 = x_1, y_1y_3 = x_2, y_1 = x_3$ and $y_3 = x_4$, we get a linear Eq. $4x_1 + 3x_2 + 2x_3 + x_4 = 5$ whose solutions, by using Table 20.1, are (a) $x_1 = x_4 = 1, x_2 = x_3 = 0$, and (b) $x_1 = x_4 = 0, x_2 = x_3 = 1$. Thus $f(x_1, x_2, x_3, x_4) = x_1\bar{x}_2\bar{x}_3x_4 \,\mathrm{U}\, \bar{x}_1x_2x_3\bar{x}_4$. Substituting for $x_i's$ in terms of $y_i's$, and simplifying gives $f(y_1, y_2, y_3) = y_1y_2\bar{y}_3$. Therefore, the only solution to Eq. (20.9) is $y_1 = y_2 = 1$ and $y_3 = 0$.

Note that while Eq. (20.9) has three bivalent variables, its linearization increases the number of bivalent variables, and hence the computational effort. In order to overcome this difficulty, an alternate method of solving a nonlinear PB inequality [6] is now given.[2] A similar method for nonlinear equations is easily obtained.

The method is based on linearizing a nonlinear PB function $F(y_1, y_2, \ldots, y_m)$ in any one of its variables, as was done in Eq. (20.1). Thus, if F is made linear in say, y_1, we may write inequality (8) as

$$y_1G_1(y_2, \ldots, y_n) \geq H_1(y_2, \ldots y_m) \tag{20.10}$$

where G_1 and H_1 are nonlinear *PB* functions of reduced order. Inequality given by Eq. (20.10) can be easily solved for y_1, using linear methods, for a given set of values

[2]The method in its preliminary form was presented in 1978 IEEE International Conference on Acoustics, Speech and Signal Processing [6].

of the variables $y_2, \ldots y_m$. The values of these variables are determined by making use of the following set of rules which help to further reduce the order of the problem.

Case-A If G_1 is always[3] >0 and H_1 is always <0, then Eq. (20.10) is a redundant inequality i.e. it is satisfied for all arbitrary y_i.

Case-B If G_1 is always >0 and H_1 is always >0, then there are two possibilities: (i) G_1 always $<H_1$, (i.e. $G_1 - H_1 < 0$) gives no solutions; (ii) otherwise, we need to solve $F_1 = G_1 - H_1 \geq 0$. For all possible solutions of this inequality, $y_1 = 1$.

Case-C If G_1 is always >0 and nothing can be said about H_1, we consider, in H_1, a variable y_k whose corresponding coefficient c_k has the largest magnitude. Let $y_k = 1$ and consider the following two possibilities: (i) If $c_k < 0$ and its magnitude is such that H_1 is always <0, then one solution to Eq. (20.10) is $y_k = 1$, y_i (i = 1, … $k-1, k+1, \ldots, m$) = arbitrary. The other solutions, if any, are obtained by solving Eq. (20.10) after substituting $y_k = 0$ in it. (ii) If $c_k > 0$ and its magnitude is such that H_1 is always $<G_1$ then the solutions, if any, are obtained by solving (20.10) after substituting $y_k = 0$ in it.

Case-D If G_1 is always <0, we replace y_1 in (10) by $(1 - \bar{y}_1)$ so that a new inequality $\bar{y}_1(-G_1) \geq H_1 - G_1$ replaces Eq. (20.10). To this, the procedure is applied again starting with Case *A*.

Case-E If H_1 is always <0 and nothing is known about G_1, then one family of solutions to Eq. (20.10) is $y_1 = 0$ and y_i ($i = 2, \ldots m$) = arbitrary. The remaining solutions are $y_1 = 1$ and solutions, if any, of the inequality $F_1 = G_1 - H_1 \geq 0$.

Case-F If Eq. (20.10) does not fall into any of these cases, we consider the inequality $-F_1 = H_1 \leq 0$ or $F_1 \geq 0$. For each of its solutions, we can find G_1 and H_1 numerically. Then, $y_1 = 0$ if $G_1 < H_1$, while if $G_1 \geq H_1$ y_1 = arbitrary.

Further, if $f_1(y_2, \ldots, y_m)$ is the characteristic function of the solutions of $F_1 \geq 0$, then $f_1(y_2, \ldots, y_m) = 0$ gives all the solutions of the inequality $F_1 < 0$, the two being complementary to each other. For all sets of variables $y_2, \ldots, y_m$ for which $f_1 = 0$ is satisfied, we have $y_1 = 1$ if $G_1 \geq H_1$.

In most of the cases discussed above, a new inequality $F_1(y_2, \ldots, y_m) \geq 0$ is required to be solved. This is similar to Eq. (20.8) but with less number of variables. It can now be made linear with respect to another variable, thus bringing it to the form of Eq. (20.10), and the procedure can be applied again. This process of reducing the order of inequality continues till we obtain

$$y_n G_n \geq H_n, n \leq m \tag{20.11}$$

such that G_n and H_n are merely numerical quantities. Thus Eq. (20.11) is easily solved for y_n using linear PB methods and this value of y_n can be substituted in

[3] Whether a given nonlinear PB function F is always >0 (<0) can easily be determined by considering the constant term in F. If this term is positive (negative) and its magnitude is greater than the sum of all negative (positive) coefficient sin F, then F is always >0 (<0).

$y_{n-1}\ G_{n-1}\ (y_n) \geq H_{n-1}$ to make it a linear inequality. Thus, going backwards, all the solutions to Eq. (20.10) are obtained.

20.5 Minimization of PB Functions

Minimization of objective functions is an important aspect of all programming methods. In the case of bivalent (0, 1) programming the objective function

$$F(y_1, \ldots, y_m) \tag{20.12}$$

will be a PB function. We first consider the *unconstrained* minimization of Eq. (20.12), starting with F expressed as

$$\begin{aligned} F &= F_1(y_1, \ldots y_m) \\ &= y_1 G_1(y_2 \ldots, y_m) + H_1(y_2, \ldots, y_m) \end{aligned} \tag{20.13}$$

i.e. we linearize it with respect to a variable $y_1 \cdot$ The method depends upon the simple fact that a linear PB function $\sum_i a_i y_i$ is minimum when y_i's are chosen equal to 1 if the corresponding $a_i < 0$ and equal to 0 otherwise. Since the right hand side of Eq. (20.13) is linear in y_1, we can choose y_1 as

$$y_1 = \begin{cases} 1 & \text{if } G_1 < 0 \\ 0 & \text{if } G_1 > 0 \\ p_1 = \text{arbitrary} & \text{if } G_1 = 0 \end{cases} \tag{20.14}$$

The last condition in Eq. (20.14) is added because we do not yet know the value of the PB function $G_1(y_2, \ldots, y_m)$. Let, now, $f_1(p_1, y_2, \ldots y_m)$ denote the characteristic function describing the relationship Eq. (20.14); then we may write

$$y_1 = f_1(p_1, y_2 \ldots, y_m) = f_{11}(y_2, \ldots, y_m) + p_1 f_{12}(y_2, \ldots, y_m) \tag{20.15}$$

where, f_{11} and f_{12} are characteristic functions of the solutions of $G_1 < 0$ and $G_1 = 0$ respectively. Substituting Eq. (20.15) into Eq. (20.13) gives

$$F_1 = (f_{11} + p_1 f_{12}) G_1 + H_1 \tag{20.16}$$

Note that $f_{12} G_1$ is always zero since when $G_1 = 0, f_{12} = 1$ while if $G_1 \pm 0, f_{12} = 0$. Thus Eq. (20.16) may be written as

$$F_1 = f_{11} G_1 + H_1 \underline{\Delta} F_2(y_2, \ldots, y_m) \tag{20.17}$$

which is a function only of $y_2, \ldots, y_m$, The above procedure is now applied to F_2 to finally get $F_3\ (y_3, \ldots, y_m) = f_{21} G_2 + H_2$. This is continued till we get,

$$F_m(y_m) = y_m G_m + H_m \tag{20.18}$$

where, G_m and H_m are real numbers. The minimum of F_m is easily obtained and, it can be proved [3] that, this will be the minimum of the original function F also.

We have obtained the minimum value of F but have not got its minimizing points. This is done by finding the value of $y_m = f_m\ (p_m)$ from Eq. (20.18), and substituting it in $y_{m-1} = f_{m-1}\ (p_{m-1}, y_m)$. This gives the value of $y_{m-1} = f_{m-1}\ (p_{m-1}, f_m)$. Thus, going backwards, we finally get $y_1 = f_1(p_1, f_2 \ldots, f_m)$ which can also be written as $y_1 = f_1(p_1, \ldots, p_m)$. This gives all the minimizing points of F.

It should be remarked that $x_i's$ do not always depend upon all the $p_i's$. In general, the number of $p_i's$ coming in the expressions for $y_i's$ is very small. Also, if at any stage of the minimization method, $F_k, k \leq m$, becomes a constant, then the remaining variables $y_{k+1}, \ldots, y_m$ can assume any arbitrary value.

We now consider minimization of Eq. (20.12) subject to the equality constraints

$$F_j(y_1, \ldots, y_m) = 0, \quad j = 1, 2, \ldots, n, \tag{20.19}$$

with the restriction that $F_j \geq 0$ for all sets of values of $(y_1, \ldots, y_m)$. To solve this problem we define S^+ and S^- as the sums of positive and negative coefficients of F. Then it can be proved [4] that a vector $(y_1^*, \ldots, y_m^*)$ minimizing Eq. (20.12), when subjected to Eq. (20.19), also minimizes the PB function:

$$G(y_1, \ldots, y_m) = F + (S^+ - S^- + 1) \sum_{j=1}^{n} F_j \tag{20.20}$$

Further, if (*) minimizes G and $G(y_1^*, \ldots, y_m^*) \leq S^+$, then (*) minimizes F under the constraints (19), while if $G(y_1^* \ldots, y_m^*) > S^+$ then the conditions Eq. (20.19) are inconsistent. Clearly, then the method requires unconstrained minimization of Eq. (20.20) and checking whether, at the minimizing point, $G \leq S^+$.

The general problem of constrained minimization, where (20.12) is to be minimized subject to the constraints.

$$F_j = (y_1, \ldots, y_m) \square\, 0, \quad j = 1, 2, \ldots, n, \tag{20.21}$$

$\square$ being either an equality or an inequality sign, can be solved using any of the following methods.

Method A: The simplest of the methods is to obtain the solutions of the constraints Eq. (20.21) simultaneously and, for each solution, find the value of the objective func-

tion. The solutions will be the solutions to the problem of constrained minimization of *F*.

Method B: In this method also, the first step is to get the solutions satisfying the constraints of Eq. (20.21). If $f(y_1, \ldots, y_m)$ is the characteristic function of these solutions, then the problem reduces to minimizing F subject to the constraint

$$f(y_1, \ldots, y_m) = 1 \tag{20.22}$$

The problem is the same as that described earlier of minimization subject to equality constraints since the Boolean equation (20.22) can be written in its equivalent PB form.

Method C: In this method an upper bound M_o of F is first found. If M_o is not known then it can be taken as equal to $S+$, the sum of all positive coefficients of *F*. We then consider the system of constraints in Eq. (20.21) along with the additional inequality $F \leq M_o$. Let $(y_1^1, y_2^1 \ldots, y_m^1)$ to get the first solution satisfying this new system. Then $F(y_1^1 \ldots y_m^1,) \underline{\underline{\Delta}} M_1$ modifies the value of the upper bound for *F*. We now consider the constraints in Eq. (20.21) along with the inequality $F \leq M_1$. This process is continued till we can no longer modify the bound for *F*. Thus we obtain the minimum of F subject to Eq. (20.21).

PB methods can also be used to minimize a *fractional* PB function

$$F(y_1 \ldots, y_m) = \frac{a_0 + a_1 y_1 + \cdots + a_m y_m}{b_0 + b_1 y_1 \cdots + \cdots + b_m y_m}, \tag{20.23}$$

where, $b_0 > 0$. One algorithm for doing this is as follows. Let I and J be the sets of all indices $i > 0$ and $j > 0$ satisfying $(a_i/b_i) \leq (a_0/b_0)$ and $(a_0/b_0) < (a_j b_j)$. The following set of rules are applied to find the minimum of Eq. (20.23):

(i) Whenever $a_k = 0$ and $b_k > 0$, put $x_k = 1$
(ii) Whenever $a_k > 0$ and $b_k < 0$, put $x_k = 0$
(iii) Determine the sets I and J
(iv) For each $j \in J$, put $x_j = 0$
(v) Let i_1 be the first index for which

$$(a_{i_1}/b_{i_1}) = \min_{i \in I}(a_i/b_i)$$

Then, if $(a_{i_1}/b_{i_1}) < (a_0/b_0)$, put $x_i = 1$ and replace a_0 by $a_0 + a_{i_1}$, b_0 by $b_0 + b_{i_1}$ and go to step 3 while if $(a_{i_1}/b_{i_1}) = (a_0/b_0)$, put $x_i = p_i$ arbitrary for each $i \in I$.

It can also be proved that Eq. (20.23) attains its minimum value if the following are satisfied.

$$Q_i^*(x_1^*, \ldots, x_n^*) \leq 0, i = 1, 2, \ldots, n \tag{20.24}$$

where

$$Q_i^* = (x_i^* - \overline{x_i^*}) \left(b_i \sum_{j=1}^{n} a_j x_j - a_i \sum_{j=1}^{n} b_j x_j \right) \tag{20.25}$$

This forms the basis for another method of minimizing Eq. (20.23) in which we start with an initial set of values $(x_1' \ldots, x_n')$ of the variables for which we compute the quantities Q_i'. We then replace x_i' by $\bar{x}'_i$ for each i for which $Q_i' > 0$. For the new set of the values of the variables, Q_i' are computed again. The process is continued till $Q_i' \leq 0$ for all i; the corresponding set of values of the variables minimizes Eq. (20.23).

After this brief review of the various PB methods, we next outline how they have been effectively employed to find a solution of the coefficient sensitivity problem in digital filters [7].

20.6 Applications to Digital Filters

In most of the digital filter design methods [10, 11], the filter coefficients are assumed to be specified to an infinite accuracy. To implement them on a digital machine, these parameters have to be quantized to a prespecified number of binary digits in order that they may fit the available word length. The resulting deterioration in filter characteristics will depend upon the word length of the filter, and the manner in which the quantized coefficients are chosen in the discrete parameter space. While the word length is decided by the cost of implementation, an optimal choice of the coefficients in discrete parameter space helps in reducing the deterioration in filter characteristics.

The easiest approach to this optimization is an exhaustive search in a predefined region of the discrete-parameter space [12]. Another approach is to use Univariate search methods [13–15]. The problem has also been solved using some continuous [16] and mixed optimization methods [17, 18]. In yet another method, a random-search technique in discrete-parameter space has been employed [19]. Since these approaches do not guarantee a global optimum, efforts have been directed to reducing the computation time needed to obtain a local optimum. The use of PB methods for this problem appreciably reduces the computation time [8, 9]. Besides, the method has various other advantages.

Let $T\left(c_i', \omega\right)$ be a function describing some characteristics of a digital filter. This function is, in general, rational in c_i', $i = 0, 1, \ldots, n$, and in trignometric functions of ω. It is assumed that c_i' are known from any of the continuous parameter design methods. Let c_i be the coefficients obtained by either rounding or truncating c_i' to a desired accuracy of $b + 1$ bits.

We may write

$$c_i = c_{i_0} \sum_{j=1}^{b} c_{ij} 2^{-j}, \quad c_{ij} \in \{0, 1\} \tag{20.26}$$

where c_{io} denotes the sign of c_i. The quantized coefficients result in a deteriorated magnitude response $T(c_i, \omega)$. The purpose of our design method is to modify the last bit of c_i, as

$$c_i \rightarrow c_i + \alpha_{ci} \tag{20.27}$$

such that the maximum of the error $|T(c_i, \omega) - D(\omega)|$, where $D(\omega)$ is the desired magnitude response, is minimized. In Eq. (20.27), $\alpha_{ci} = c_{io}\, S_{ci}\, q y_{ci}$ where $q = 2^{-b}$, is the minimum quantization step size, $y_{ci} \in \{0, 1\}$ are the bivalent variables whose values are to be determined; $S_{ci} \in \{-1, 0, 1\}$ define the direction of modification of c_i. To start with, we set $S_{ci} = \text{sign of}(c_i' - c_i)$.

Let now ω_r be the frequency at which the extrema of the error $|T(c_i, \omega) - D(\omega)| \underline{\underline{\Delta}}\, \delta_r$ is maximum. We may write the following inequality

$$|T(c_i + \alpha_{ci}, \omega_r) - D(\omega_r)| \leq \delta_r \tag{20.28}$$

This is a PB inequality in the variables y_{ci}, and can be solved by the methods described earlier in this chapter. From its solutions, we choose the one giving largest improvement in the error function. This is done by evaluating $T(c_i + \alpha_{ci}, \omega)$ at a grid of frequency points. Corresponding to the best solution, we prepare for the next iteration by modifying c_i as in (20.27), replacing δ_r in Eq. (20.28) by its new lower value and modifying S_{ci} as

$$S_{ci} \rightarrow S_{ci}(2y_{ci} - 1) \tag{20.29}$$

With the new c_i, S_{ci}, ω, and δ_r, inequality Eq. (20.28) can be formulated again, and the procedure is repeated till no more improvement in δ_r can be obtained.

The nature of the *PB* inequalities in Eq. (20.28) is different for the two cases of FIR and IIR filters. For the case of linear phase FIR filters, $T_{(ci,\omega)} = \sum_{i=0}^{n} c_i G(\omega)$ where, n depends upon the order N of the filter and $G(\omega)$ is a trignometric function. For example, for an even-ordered low-pass filter $n = (N/2) - 1$ and $G(\omega) = \sin\left(i + \frac{1}{2}\right)\omega$. For this case, then, Eq. (20.28) will be a linear PB inequality; only linear PB methods need to be applied for their solutions [8].

The magnitude response of an IIR filter is a rational function of the form $P(a_i, \omega)/Q(b_i, \omega)$, where a_i and b_i are the numerator and denominator coefficients, respectively, and P and Q are nonlinear functions of a_i, and b_i, the maximum order of the nonlinearity being N, the order of the filter. Then Eq. (20.28) can be rewritten as

$$P(a_i + \alpha_{ai}, \omega_r) - \delta Q(b_i + \alpha_{bi}, \omega_r) \leq 0 \tag{20.30}$$

where $\delta = D(\omega_r) \pm \delta_r$. The usual method of solving Eq. (20.30), by linearizing each nonlinear variable is computationally very expensive, because of an increase in the number of variables. To overcome this, the alternate method for solving nonlinear inequalities discussed earlier can be applied [8].

As an example of the design, we consider a fourth-order low-pass IIR filter with Chebyshev pass-band characteristics. The filter is to be realized in cascade [10]. With the continuous filter coefficients, the pass band varies between 1.000 and 0.891; these limits are shown in Fig. 20.1. In the same figure, curves *a* and *b* show the characteristics with rounded continuous and with PB modified coefficients, respectively.

The design method described above may be programmed to get many almost-equally-best solutions to the problem. The best solution can then be chosen depending upon an appropriate criterion, like minimum number of 1's in the solution, or their behaviour in the transition region. Also, while solving for the PB inequalities (20.28), no computations are needed on the coefficients of the filter, thus, avoiding any error due to limited word length of the computer. Finally, it is possible to implement the design method with different word lengths for different coefficients by simply modifying the quantizing condition Eq. (20.26).

The design method discussed in this section yields an optimal set of filter coefficients such that the maximum of the error is minimized. In case, the criteria is to minimize the mean-squared error, we can use a similar iterative method in which each iteration modifies the last bit of the coefficient c_i of T(c_i, ω) as in Eq. (20.27) such that

$$F = \int_{-\pi}^{\pi} (|T(c_i + \alpha_{ci}, \omega)| - |D(\omega)|)^2 d\omega \tag{20.31}$$

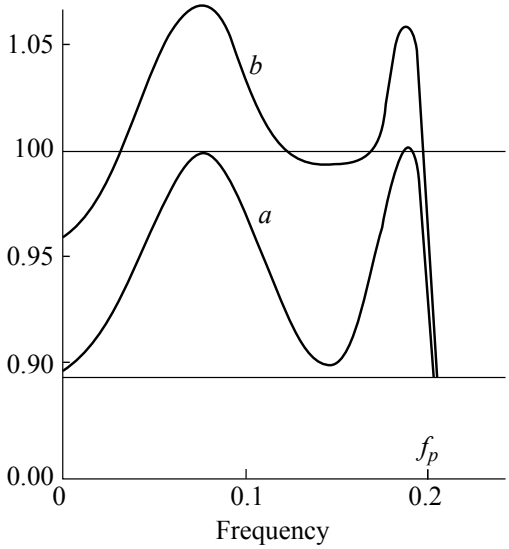

Fig. 20.1 Passband magnitude characteristics of the low-pass filter example with rounded continuous (curve a) and with PB modified (curve b) co-efficients

is minimized. This is a PB function in the bivalent variables y_{ci} whose values can be obtained by using one of the minimization algorithms described in the previous section.

Note that the algorithms used will be different for the design of FIR and IIR filters. In the case of linear phase FIR filters, Eq. (20.31) will be of the form of Eq. (20.12) and we can use the unconstrained minimization method described earlier. On the other hand if $T(c_i, \omega)$ corresponds to an IIR filter, Eq. (20.31) can be written in the following form:

$$F = F_1 + F_2 + \cdots + F_m, \tag{20.32}$$

where, F_j, $j = 1 \ldots, m$, are fractional PB functions in y_{ci}. Starting with an initial guess for the values of y_{ci}, we can evaluate the functions Q_{ij}, as in Eq. (20.25), for each F_j. It can then be proved that F in Eq. (20.32) attains its minimum value if the following are satisfied

$$\sum_{j=1}^{m} Q_{ij} \leq 0, \quad i = 1, 2, \ldots, n. \tag{20.33}$$

The values of the variables y_{ci} that minimize Eq. (20.30) also modify c_i and S_{ci} as in Eqs. (20.27) and (20.29), respectively, for the next iteration. We continue till the optimal set of c_i is obtained.

20.7 Discussion

The PB methods described in this chapter find applications in many fields, some of which we have briefly described. One example is that of problems in coding theory where the algorithms to choose the best codes for transmission over a binary channel, subject to certain error criteria, is to be found. PB methods also find applications in some problems in automata theory, as for example, in minimization of Boolean functions; note that the characteristic functions of the solutions of PB systems are also Boolean functions. These problems can be formulated in terms of minimization of a PB function subject to certain constraints. Another example where PB methods can be applied is that of graph theory, in which the connectedness and path concepts involve only two values 0 and 1.

There are many transportation and scheduling applications, where the problem is naturally formulated in PB terms e.g. in the case of selecting the location for a power generation plant, so as to reduce transmission costs subject to certain feasibility constraints.

We have mentioned earlier that the set of problems having bivalent variables can be solved using integer programming methods. It is also possible to convert the Integer Programing problems in PB terms by replacing each integer variable $\beta_i \leq$

M_i, by several bivalent variables since we can write $\beta_1 = \Sigma \beta_{ij}\, 2^{-j}$, $\beta_{ij} \in \{0, 1\}$. It has also been shown (Hammer and Rudeanu *loc. cit.*) that the linear and quadratic programming problems can also be transformed to solving a system of PB equations simultaneously.

Chapter 21
Maximally Linear FIR Digital Differentiators: A Review

Abstract Digital differentiators (DD) are extensively used in various computational systems. An ideal DD has the frequency response given by $\tilde{H}_d(\omega) = j\omega, -\pi \leq \omega \leq \pi$. The most popular FIR design for the differentiators is the minimax relative error (MRE) approximation, proposed by Rabiner and Schafer [1]. The MRE-DDs are, in general, suitable for wideband frequency ranges with moderate accuracy, (say, 100 $\pm$ 1%) but are not flexible enough to be efficiently adopted for limited (low, mid or high) frequency bands. Moreover, the required weighting coefficients for these DDs are computed by using an optimization algorithm [2]. In this chapter, we discuss a new class of digital differentiators, investigated by us, which have maximally linear (ML) frequency response at $\omega = 0$ or $\omega = \pi/2$ or $\omega = \pi$. Correspondingly, this design yields efficient approximations for low, mid or high frequency ranges, giving extremely low relative errors (RE). A universal digital differentiator has also been obtained, which covers the frequency range $0 \leq \omega \leq 0.90\pi$. Mathematical formulas for computing the exact values of the weighting coefficients have also been given.

Keywords Digital filters · Digital differentiators

21.1 Introduction

Digital differentiators (DD) form integral parts of many computational systems and find extensive use in a large number of practical applications, including radars [3, 4], sonars [5], speech processing systems and modulation schemes [6]. For obvious advantages, the DDs are usually realized as Finite Impulse Response (FIR) configurations [7–9], rather than the Infinite Impulse Response (IIR) ones. The literature available on DDs is rather limited. Rabiner and Steiglitz [10] proposed a design of FIR, wideband DDs in 1970, by using an algorithm to minimize the absolute error of the frequency response. However, this design was heavily biased against low frequencies. Rabiner and Schafer [1], in 1974, brought out various properties of FIR-DDs. They designed the differentiators by using the minimax relative error (MRE) as the

criterion of optimization, by making use of McClellan et al. algorithm [2]. Hamming [11], in 1977 suggested a mathematical formula for the weighting coefficients by modifying the Fourier expansion for $\tilde{H}(\omega) = \omega, -\pi \leq \omega \leq \pi$ through Lanczos factor. However, the order, N of the approximation becomes unusually high, if one follows Hamming's method.

The most popular FIR design remains the MRE approximation [1]. However, the MRE-DDs suffer from inflexibility, in the sense that these cannot be efficiently adopted for differentiators required to perform over a limited frequency range at low, mid-band and high frequencies. Moreover, the minimax approach necessarily requires an algorithm [2] for computing the weighting coefficients required in the design. The optimization methods, in general, are very sensitive to finite word length effects, so degradation of frequency response occurs for fixed point implementations. As such, no mathematical formulas are known through which the coefficients could be exactly computed. In this chapter, we present a consolidated review of our work on a different class of design viz. maximally linear DDs (ML-DDs), which are particularly efficient over a limited range at low, mid-band or high frequencies. Mathematical formulas for computing the exact values of the weighting coefficients for the designs have also been given. A novel, efficient structure of DDs for variable frequency range of operation has also been discussed, whereby a differentiator structure designed for odd order N can operate as a 'universal configuration' for all possible odd orders less than or equal to N.

The frequency response of an ideal digital differentiator is given by

$$\tilde{H}_d(\omega) = j\omega \triangleq j\tilde{H}(\omega), -\pi \leq \omega \leq \pi \tag{21.1}$$

where $\tilde{H}(\omega) = \omega$ and is purely real. The curve for $\tilde{H}(\omega)$ is shown in Fig. 21.1. We approximate $\tilde{H}(\omega)$ by using the maximal linearity of frequency response at $\omega = 0$ or $\pi/2$ or π as the optimality criteria of the various frequency bands. The following notations will be used in the sections to follows:

$H_1(\omega)$: DDs for low frequencies, maximally linear at $\omega = 0$.
$H_2(\omega)$: $H_3(\omega)$: DDs for mid-band frequencies, maximally linear at $\omega = \pi/2$.
$H_4(\omega)$: DDs for high frequencies, maximally linear at $\omega = \pi$.
$H_H(\omega)$: digital Hilbert transformer, maximally flat at $\omega = \pi/2$.

The relative error (RE) in the approximations of digital differentiators, say for $H_1(\omega)$, is defined as

$$RE \triangleq |[H_1(\omega) - \tilde{H}(\omega)]/\omega| \tag{21.2}$$

The factor j in (21.1) shows that the differentiators have a constant phase response, equalling $\pi/2$, for all the frequencies. In most of the practical applications, however, the highest accuracy of the magnitude response is more important than the phase response.

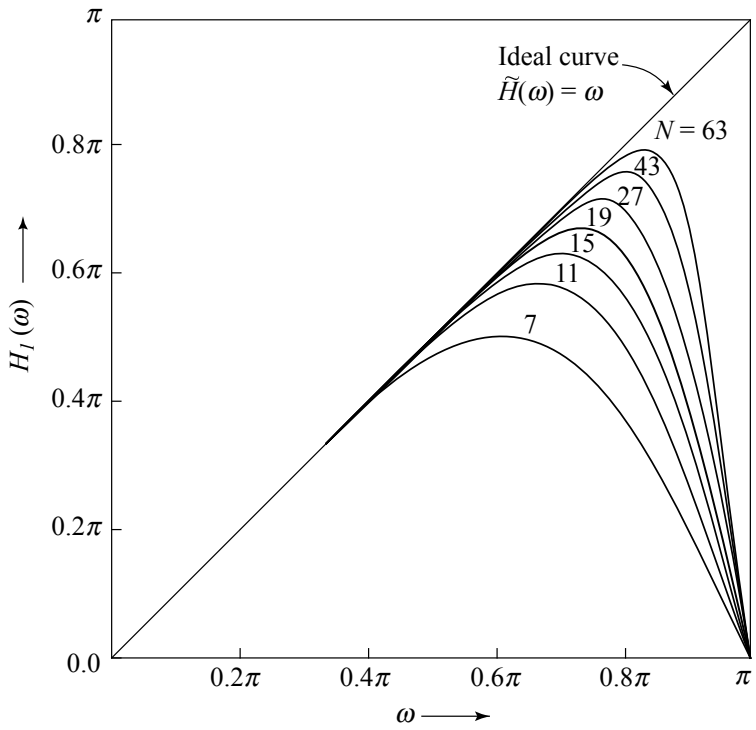

Fig. 21.1 Frequency response, $H_1(\omega)$, of the maximally linear (at $\omega = 0$) digital differentiators for order $N = 7$, 11, 15, 19, 27, 43 and 63

21.2 DDs for Low Frequencies: $H_1(\omega)$

In a host of applications such as autopilotage, autonavigation, autotracking, weapon control systems and in high precision processes [4, 12], differentiation is required to be performed over a limited range in the low-frequency region. Achieving the highest possible accuracy of operation becomes the primary requirement in such cases and as shown in this section, this may be met through the ML-DDs.

21.2.1 Design for Approximation to $H_1(\omega)$

To realize the factor j in Eq. (21.1), we assume the approximation for low frequencies to be of the equation form [1, 13].

$$H_1(\omega) = \sum_{i=1}^{n} d_i \sin i\omega, n = (N-1)/2 \tag{21.3}$$

where a non-recursive configuration has been chosen, and N is the order of the DD, assumed to be odd, for well-known reasons [7]. Maximal linearity of $H_1(\omega)$ at $\omega = 0$ demands:

$$H_1(\omega)|_{\omega=0} = 0 \tag{21.4a}$$

$$dH_1(\omega)/d\omega|_{\omega=0} = 1 \tag{21.4b}$$

$$d^v H_1(\omega)/d\omega^v|_{\omega=0} = 0, v = 2, 3, 4, \ldots, 2n-1 \tag{21.4c}$$

Clearly, $H_1(\omega)$ given by Eq. (21.3) satisfies Eq. (21.4a). Differentiating $H_1(\omega)$, $2n-1$ times successively, and imposing conditions on Eqs. (21.4b) and (21.4c), we get n non-trivial equations. Using the notations $D_i \triangleq id_i$, these equations can be put in the following matrix form:

$$\begin{bmatrix} 1 & 1 & 1 & \ldots & 1 \\ 1 & 2^2 & 3^2 & \ldots & n^2 \\ 1 & 2^4 & 3^4 & \ldots & n^4 \\ \vdots & \vdots & 3^{2n-2} & & \vdots \\ 1 & 2^{2n-2} & 3^{2n-2} & \ldots & n^{2n-2} \end{bmatrix} \begin{bmatrix} D_1 \\ D_2 \\ D_3 \\ \vdots \\ D_n \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \tag{21.5}$$

Equation (21.5) is of the form $[a_{ij}][D_i] = [b_i]$, and can be solved by Crout's method [14]; the solution can be expressed in the following recursive form:

$$d_i = \left\{ (-1)^{i+1} \Big/ \left[i \binom{2i-1}{i-1} \right] \right\} - \sum_{r=1}^{n-i} \binom{2i+r-1}{2i-1} d_{i+r},$$

$$i = n, n-1, n-2, \ldots, 1 \text{(descending order)} \tag{21.6}$$

where

$$\binom{n}{k} \triangleq \frac{n!}{k!(n-k)!} \tag{21.7a}$$

and

$$\binom{0}{k} \triangleq \begin{cases} 1, & k = 0 \\ 0, & k \neq 0 \end{cases} \tag{21.7b}$$

Following an alternative procedure, it is also possible to derive an explicit formula for $d_i's$ [15].

21.2.2 Performance of $H_1(\omega)$

The coefficients d_i calculated by using Eq. (21.6) have been given in Table 21.1. Figure 21.1 shows the curves of $H_1(\omega)$ for selected values of N in the range 7–63. Figure 21.2 gives the relative errors (in decibels) of the approximation $H_1(\omega)$ for $n = 3$–19. As expected, $H_1(\omega)$ achieves extremely high accuracies near $\omega = 0$. In the low-frequency ranges, these DDs are more efficient as compared to the MRE-DDs [1]; for $\omega = 0$ to 0.20π, for example, the minimax design requires an order $N = 127$ to achieve a RE $\leq$ –200 dB, whereas the ML-DDs can accomplish the same with $N = 21$ only. In general, the lower the frequency range of differentiation, the better is the performance of the ML-DDs.

21.3 DDs for Mid-band Frequencies with Zero Phase: $H_2(\omega)$

In many practical cases, it is not necessary to have differentiator approximations to cover the entire band of $\omega = 0$ to π. Almost all the communication systems, for example, demand the highest accuracy over the mid-band frequencies of the spectrum only, since the most vital information is contained therein. Rabiner and Schafer [I] proposed the use of half a sample delay/advance together with an even order N, for the MRE-DDs, to achieve high accuracies. In large signal processing systems, the use of non-integral delays is undesirable. Moreover, choosing an even N deprives the system of possible advantages e.g. accomplishing differentiation through FFT on a

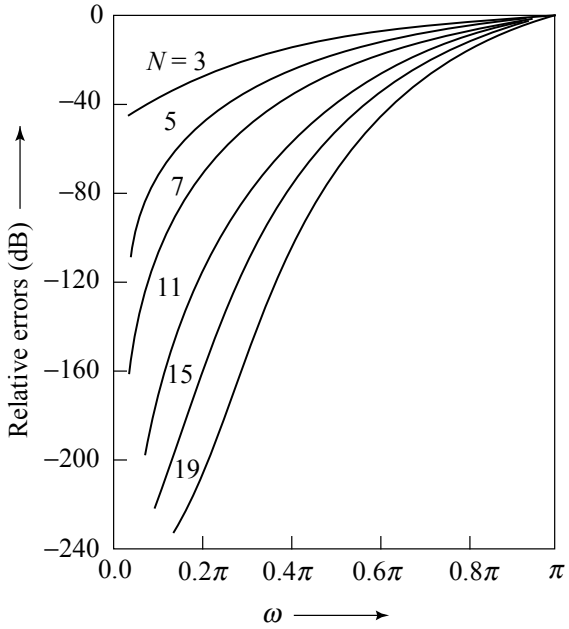

Fig. 21.2 Relative errors (in dB) of $H_1(\omega)$ for order $N =$ 3, 5, 7, 11, 15 and 19

general purpose computer, when N is large. As shown in this section, ML-DDs for mid-band frequencies overcome the aforementioned problems.

21.3.1 Design for Approximation to $\mathbf{H_2(\omega)}$

We aim at a DD approximating the magnitude $|\tilde{H}_d(\omega)| = |\omega|$ in an optimal manner in the mid-band frequency range. Let such an approximation be

$$H_2(\omega) = d_0 + \sum_{i=1}^{n} d_i \cos i\omega, n = (N-1)/2, N \text{ odd} \tag{21.8}$$

Maximal linearity of $H_2(\omega)$ at $\omega = \pi/2$ requires:

$$H_2(\omega)|_{\omega=\pi/2} = \pi/2 \tag{21.9a}$$

$$dH_2(\omega)/d\omega|_{\omega=\pi/2} = 1 \tag{21.9b}$$

$$d^u H_2(\omega)/d\omega^u|_{\omega=\pi/2} = 0, u = 2, 3, 4, \ldots, n \tag{21.9c}$$

lt may be noted that in $(\omega - |\tilde{H}_d(\omega)|)$ plane, $|\tilde{H}_d(\omega)|$ is: (i) periodic in ω with period 2π, (ii) symmetric about the origin (0, 0) and (iii) antisymmetric about the point $(\pi/2, \pi/2)$. We choose an $H_2(\omega)$ which also satisfies these conditions. $H_2(\omega)$ given by Eq. (21.8) is of course symmetric about (0, 0). If we shift the origin of $(\omega, H_2(\omega))$ plane to $(\pi/2, \pi/2)$, and call the new coordinates $(\omega', H_{22}(\omega'))$, then $H_2(\omega) = H_{22}(\omega') + \pi/2$ and $\omega = \omega' + \pi/2$, and we get, from Eq. (21.8)

$$H_{22}(\omega') = (d_0 - \pi/2) + \sum_{i=1}^{n} d_i \cos i(\omega' + \pi/2) \tag{21.10}$$

For $H_{22}(\omega')$ to be antisymmetric function of ω', we must have

$$d_0 = \pi/2; d_i = 0, i = 2, 4, 6, \ldots \tag{21.11}$$

Under the conditions of Eq. (21.11), Eq. (21.8) reduces to

$$H_2(\omega) = \pi/2 + \sum_{\substack{i=1 \\ i \text{ odd}}}^{n} d_i \cos i\omega, n \text{ odd} \tag{21.12}$$

Applying criteria of Eqs. (21.9b) and (21.9c) on Eq. (21.12), and using the notation $B_i = -(2i + l)d_{2i+1}$, $i = 0, 1, 2, \ldots, m$ where $m = (n - 1)/2$, we can write the

resulting equations in the matrix form:

$$\begin{bmatrix} 1 & -1 & 1 & \dots & (-1)^m & (2m+1)^0 \\ 1 & -3^2 & 5^2 & \dots & (-1)^m & (2m+1)^2 \\ 1 & -3^4 & 5^1 & \dots & (-1)^m & (2m+1)^4 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 1-3^{2m} & 5^{2m} & \dots & & (-1)^m & (2m+1)^{2m} \end{bmatrix} \begin{bmatrix} B_0 \\ B_1 \\ B_2 \\ \vdots \\ B_m \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \tag{21.13}$$

Solving these equations by Crout's method [14], we finally arrive at the recursive formula [16]:

$$-id_l = \binom{i-2}{(i-1)/2}\left[2^{-(2i-3+\binom{0}{i-1})}\right] + \sum_{k=(i+1)/2}^{(n-1)/2} (-1)^{(2k+i-1)2} \times (2k+1)\binom{(2k+i-1)/2}{(2k-i+1)/2} d_{2k+1}, \tag{21.14}$$

$$i = n, n-2, n-4, \dots, 3, 1 \text{(descending order)}$$

$$n = (N-1)/2;\ n \text{ and } N \text{ odd}$$

Equations (21.11) and (21.14) collectively give all the coefficients d_i, $i = 0, 1, 2, \dots, n$ needed for the approximation $H_2(\omega)$. The weighting coefficients d_i computed by using Eq. (21.14) are shown in Table 21.2 for $n = 1$–15 ($N = 3$–31).

21.3.2 Performance of $\mathbf{H_2(\omega)}$

The frequency response curves for $H_2(\omega)$ are shown in Fig. 21.3 for $n = 1$–17 ($N = 3$–35), and the curves for REs are shown in Fig. 21.4. As expected, the frequency response $H_2(\omega)$ has zero RE at $\omega = \pi/2$ for all N, and extremely low REs are obtainable for narrow mid-band frequencies for reasonably low order N. The ML-DDs, for example, are capable of achieving an RE ≤ -100 dB over the frequency band from 0.45π to 0.55π with just three multiplications (against eight in MRE-DDs) per input sample. These differentiators are more efficient as compared to MRE-DDs for the frequency band $0.15\pi \leq \omega \leq 0.90\pi$ (i.e. over 75% of the complete spectrum). The order N of $H_2(\omega)$ being odd, no non-integral delay is needed.

21.4 DDs for Mid-band Frequencies with $\pi/2$ Phase: $H_3(\omega)$

ln a few typical applications, it is necessary to use a differentiator which realizes the (constant) phase response of $\pi/2$, besides the desired accuracy of the magnitude response $|\tilde{H}_d(\omega)|$. One of the options would be to cascade $H_2(\omega)$ (which gives a zero

phase response) with a digital Hilbert transformer (DHT). However, it is also feasible to design ML-DDs for mid-band frequency range, meeting the dual requirements of frequency and phase responses [17].

21.4.1 Design for Approximation to $\mathbf{H_3(\omega)}$

To realize the factor j, for $\pi/2$ phase response, in (21.1), $H_3(\omega)$ should have only sine terms [1] i.e.

$$H_3(\omega) = \sum_{i=1}^{n} b_i \sin i\omega,\ n = (N-1)/2,\ N \text{ odd} \tag{21.15}$$

Without loss of generality, we can write Eq. (21.15) as

$$H_3(\omega) = (\pi/2) \sum_{\substack{i=1 \\ i \text{ odd}}}^{n-1} d_i \sin i\omega - (1/2) \sum_{\substack{i=2 \\ i \text{ even}}}^{n} d_i \sin i\omega,\ n \ even \tag{21.16}$$

We have chosen an even value of n, since actual calculations show that it yields a better approximation than that obtainable with an odd n. The criteria of maximal linearity of $H_3(\omega)$ at $\omega = \pi/2$ are similar to those given by Eqs. (21.9a–21.9c). Differentiating $H_3(\omega)$ given by Eq. (21.16), successively, n times and imposing the optimality conditions, we get two sets of linear equations. Solving these, we arrive at the solutions [17]:

$$d_i = \left[\binom{i-2}{(i-1)/2} \Big/ 2^{2i-3+\binom{0}{i-1}} \right] + \sum_{k=(i+1)/2}^{(n-2)/2} (-1)^{(2k+i+1)/2} \times \binom{(2k+i-1)/2}{(2k-i+1)/2} d_{2k+1} \tag{21.17a}$$

$i = n-1, n-3, n-5, \ldots, 5, 3, 1$ (descending order) i odd; n even
and

$$d_i = \left\{ 2/\left[i \binom{i-1}{i/2} \right] \right\} + \sum_{r=1}^{(n-i)/2} (-1)^{r+1} \binom{i+r-1}{r} d_{i+2^r} \tag{21.17b}$$

$i = n, n-2, n-4, \ldots, 6, 4, 2$ (descending order)
i even; n even.

The values of d_i computed by using the formulas of Eqs. (21.17a) and (21.17b) have been given in Table 21.3 for $n = 2$–12 ($N = 5$–25). It may be seen that all the coefficients d_i turn out to be positive by taking $H_3(\omega)$ in the format of Eq. (21.16).

Table 21.3 The weighting coefficients d_i and h_i (i) d_i: for maximally linear digital differentiators, $H_3(\omega)$, for mid-band frequencies (with $\pi/2$ phase response) (ii) h_1: for maximally flat digital Hilbert transformers, $H_H(\omega)$, for mid-band frequencies

21.4.2 Performance of $\mathbf{H_3(\omega)}$

The frequency response $H_3(\omega)$ has been shown in Fig. 21.5, and the relative error for these differentiators are shown in Fig. 21.5, for $N = 5$–49. The ML-DDs are again seen to be superior to the MRE-DDs when extremely high accuracies are desired for narrow bands of frequencies around $\omega = \pi/2$. The differentiators $H_3(\omega)$ are particularly efficient over 25% of the mid-band frequency spectrum and may be gainfully exploited in applications such as interferometer radar and phase comparison monopulse radar [3, 4]. If we let

$$H_H(\omega) \triangleq \sum_{\substack{i=1 \\ i \text{ odd}}}^{n-1} h_i \sin i\omega, \quad n \text{ even} \tag{21.18}$$

where

$$h_i = -d_i, \quad i \text{ odd} \tag{21.19}$$

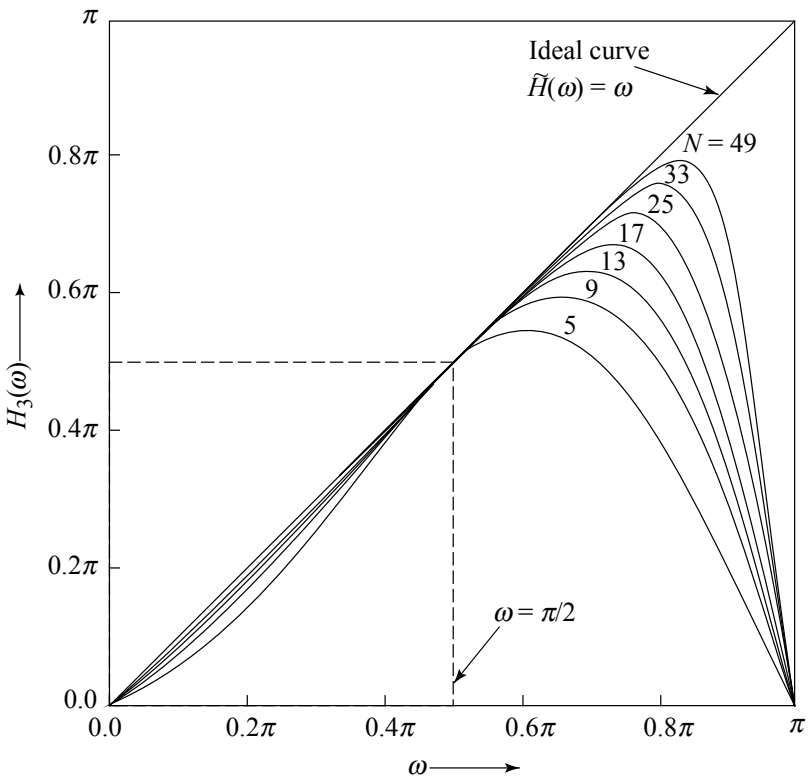

Fig. 21.5 Frequency response, $H_3(\omega)$, of the maximally linear (at $\omega = \pi/2$) digital differentiators, with phase response equalling $\pi/2$, for order $N = 5$, 9, 13, 17, 25, 33 and 49

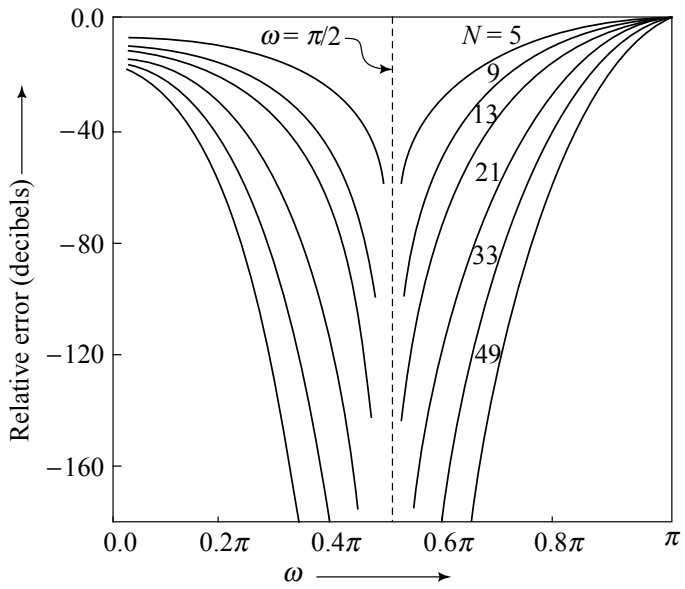

Fig. 21.6 Relative errors (in dB) of $H_3(\omega)$ for order $N = 5, 9, 13, 21, 33$ and 49

and d_i are given by Eq. (21.17a), then it is observed that $H_H(\omega)$ represents DHT's which are maximally flat at $\omega = \pi/2$. The frequency response $H_H(\omega)$ is shown in Fig. 21.7 for values of N from 5 to 49. The cascaded structure '$H_H(\omega) \cdot H_H(\omega)$' gives a differentiator akin to $H_3(\omega)$.

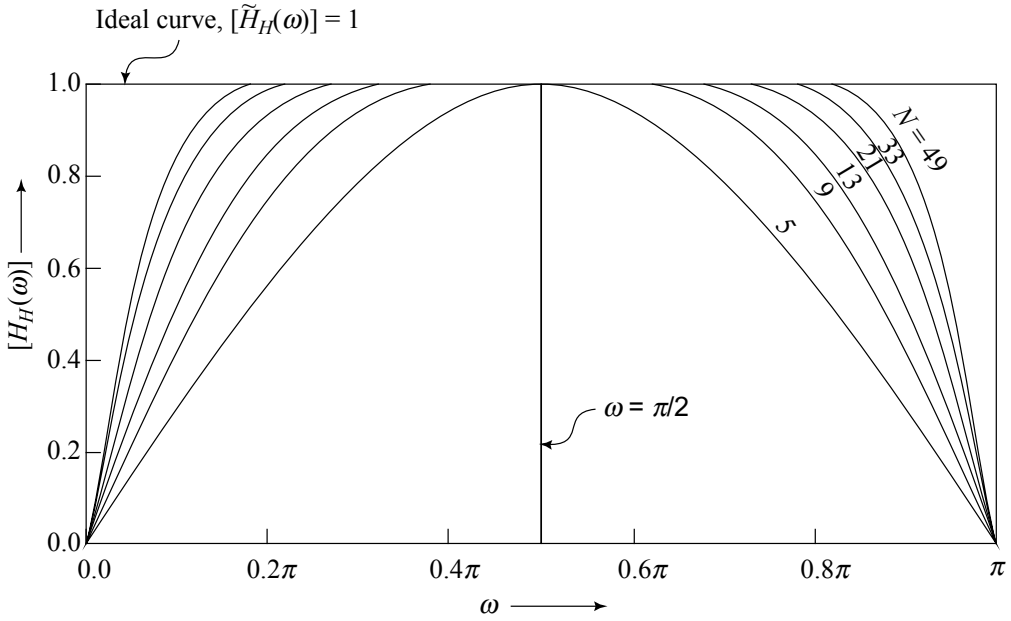

Fig. 21.7 Frequency response, $H_H(\omega)$, of maximally flat (at $\omega = -\pi/2$) digital Hilbert transformers for order $N = 5, 9, 13, 21, 33$ and 49

21.5 DDs for High Frequencies: $H_4(\omega)$

In a number of situations, we need a digital differentiator for high frequencies only. To ensure realization of the factor j in Eq. (21.1), any approximation of $\tilde{H}(\omega)$ must take the form $\sum_{i=1}^{(N-1)/2} \sin i\omega$. Such a summation, of course, is identically zero at $\omega = \pi$, whereas the ideal frequency response $\tilde{H}(\omega)$ demands the highest value (=π) at $\omega = \pi$. To overcome this problem, introduction of half a sample delay (i.e. a factor $z^{-1/2}$) in the structure becomes necessary [1]. For achieving very high accuracy of differentiation for the frequency band $0.5\pi \leq \omega \leq \pi$, the MRE-DDs assume very high order N, whereas the ML-DDs behave more efficiently, as shown in this section.

21.5.1 Design for Approximation to $\mathbf{H_4(\omega)}$

Let the approximation for high frequencies be given by

$$H_4(\omega) = \pi \sum_{i=1}^{n} c_i \sin(i - 1/2)\omega - \sum_{i=1}^{n} d_i \sin i\omega, n = N/2 \tag{21.20}$$

where c_i and d_i are the weighting coefficients and N is the order of the approximation. The terms in the first summation will have additional delays of half sample (i.e. $z^{-1/2}$), when realized. Maximal linearity of $H_4(\omega)$ at $\omega = \pi$ demands:

$$H_4(\omega)|_{\omega=\pi} = \pi \tag{21.21a}$$

$$dH_4(\omega)/d\omega|_{\omega=\pi} = 1 \tag{21.21b}$$

$$d^u H_4(\omega)/d\omega^u|_{\omega=\pi} = 0, u = 2, 3, 4, \ldots, 2n - 1 \tag{21.21c}$$

Forcing conditions given by Eqs. (21.21a–21.21c) on Eq. (21.20) give us two sets of linear equations. Solving these, we finally arrive at the following results [18]:

$$c_i \left[\binom{2i-3}{i-1} \Big/ 2^{\left(4i-5+\binom{0}{i-1}\right)} \right] + \sum_{k=i}^{n-1} (-1)^{k+i} \binom{k+i-1}{k-i+1} c_{k+1}, \tag{21.22a}$$

$i = n, n-1, n-2, \ldots, 2, 1$ (descending order)
and

$$d_i = \left\{ 1 \Big/ \left[i \binom{2i-1}{i-1} \right] \right\} + \sum_{r=1}^{n-i} (-1)^{r-1} \binom{2i+r-1}{2i-1} d_{i+r}, \tag{21.22b}$$

$i = n, n-1, n-2, \ldots, 2, 1$ (descending order)

The values of c_i and d_i, calculated by using Eqs. (21.22a) and (21.22b) have been given in Table 21.4 for $n = 1$–6 ($N = 2$–12).

The transfer function, $G(z)$, corresponding to causal realization of $H_4(\omega)$ is given by

$$\begin{aligned} G(z) &= jz^{-n} H_4(\omega)|_{e^{j\omega}=z} \\ &= (\pi/2)z^{-1/2} \sum_{i=1}^{n} c_i z^{-n+i}(1 - z^{-2i+1}) \\ &\quad - (1/2) \sum_{i=1}^{n} d_i z^{-n+i}(1 - z^{-2i}) \end{aligned} \tag{21.23}$$

A possible structure of $G(z)$, for $n = 3$ ($N = 6$), is shown in Fig. 21.8. We require only one half sample delay ($z^{-1/2}$) to realize $G(z)$, as in the case of MRE-DDs [1] (Fig. 21.6).

21.5.2 Performance of $\mathbf{H_4(\omega)}$

The frequency response of $H_4(\omega)$ is shown in Fig. 21.9 for $n = 1$–10 ($N = 2$–20) and the relative errors are shown in Fig. 21.10. Extremely low REs are indeed achievable near $\omega = \pi$ through the differentiators $H_4(\omega)$, for attractively low orders; for example, with $N = 16$, the ML-DDs can achieve an RE $\leq$ –60 dB for frequency range $\omega = 0.5\pi$ to π, whereas the minimax DDs would require $N \geq 128$ to accomplish a comparable performance. The ML-DDs, $H_4(\omega)$, are therefore, particularly suitable in homomorphic processes [8] and image enhancement applications [19].

21.6 Variable Frequency DDs: Universal Differentiators

It is often of interest to implement, in hardware, a digital differentiator for which the operating range of frequencies can be varied. A number of techniques [20–23] are available to transform a prototype filter to variable cutoff ones. However, all these transformations are applicable only to such filters, in which the ideal frequency response of the prototype filter is piecewise constant.

These cannot, therefore, be meaningfully adopted for achieving variable frequency range digital differentiators. We have obtained a universal canonic structure which can function as a ML-DD at $\omega = 0$ or at $\omega = \pi/2$, and which provides a variable operating frequency range around these values, simply by changing the point at which the output is derived.

Table 21.4 The weighting coefficients (c_i and d_i). *For* maximally linear digital differentiators, $H_4(\omega)$, *for* high frequencies

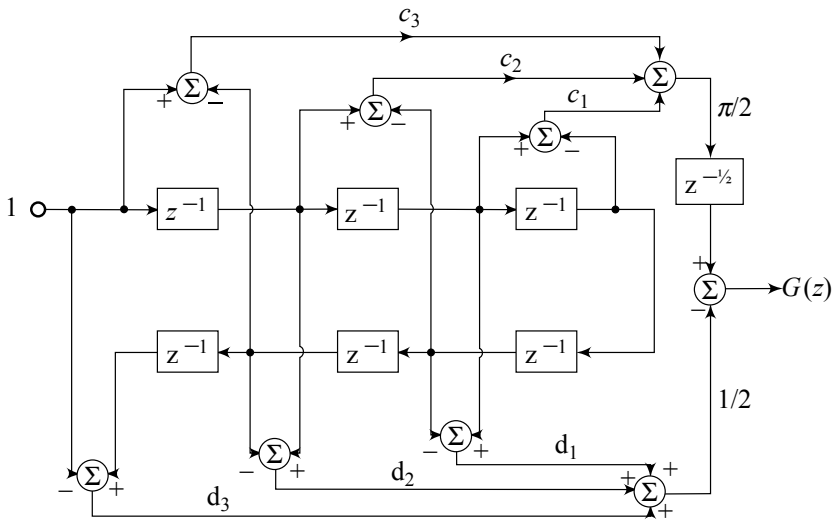

Fig. 21.8 Realization of transfer function $G(z)$ for maximally linear (at $\omega = \pi$) digital differentiators with order $N = 6$

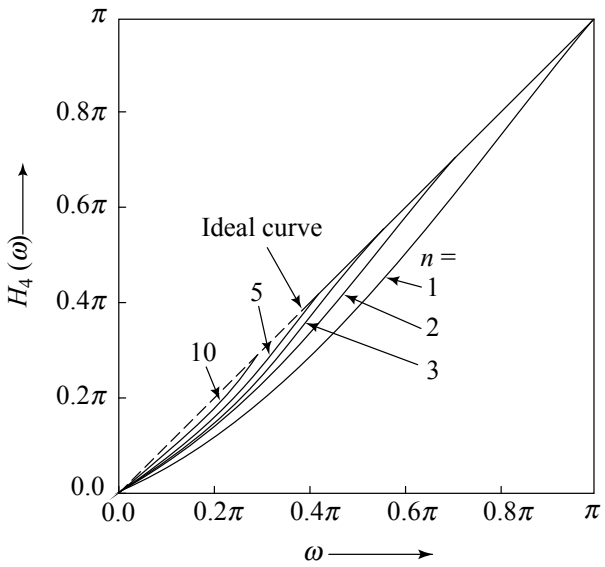

Fig. 21.9 Frequency response, $H_4(\omega)$, of maximally linear (at $\omega = \pi$) digital differentiators for $n = 1, 2, 3, 5$ and 10 (order $N = 2n$)

21.6.1 Design of Universal Digital Differentiators

The DDs with frequency response $H_2(\omega)$, are maximally linear at $\omega = \pi/2$ and give efficient performance in the mid-band frequencies. Now

$$H_2(\omega) = \sum_{i=0}^{n} d_i \cos i\omega, \quad n = (N-1)/2 \tag{21.24}$$

can be expressed as

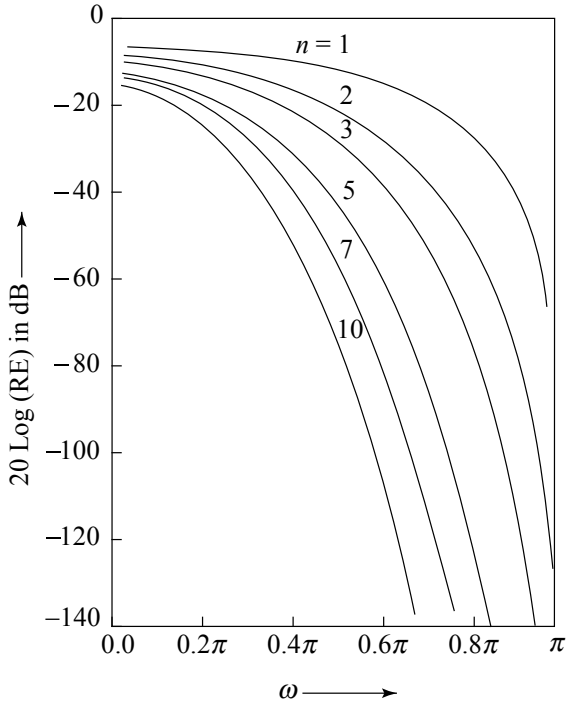

Fig. 21.10 Relative errors (in dB) of $H_4(\omega)$ for $n = 1, 2, 3, 5, 7$ and 10 (order $N = 2n$)

$$H_2(\omega) = \sum_{i=0}^{n} p_i (\cos\omega)^i, \quad n = (N-1)/2 \tag{21.25}$$

where N is the order of the differentiator and d_i's are given by Eqs. (21.11) and (21.14). The coefficients p_i are related to d_i through the coefficients of the Chebyshev polynomials. We can derive an explicit relation between p_i and d_i, provided an explicit formula for d_i (rather than the recursive formula Eq. (21.14)) is available. Following involved calculations and lengthy mathematical manipulations [24], the values of p_i are finally obtained as:

$$\left.\begin{aligned} p_0 &= \pi/2;\ p_1 = -1 \\ p_j &= 0,\ j = 2, 4, 6, \ldots \\ p_i &= -[1, 3, 5, \ldots, (i-2)]^2/i! \\ i &= 3, 5, 7, \ldots \end{aligned}\right] \tag{21.26}$$

It is important to note that the coefficients p_i are independent of n. We exploit this property for realization of variable bandwidth differentiators. The values of the first few p_i's, calculated by using Eq. (21.26) are:

$$\begin{aligned} p_3 = -1/6 \qquad p_5 = -3/40, \qquad p_7 = -5/112 \\ p_9 = -35/1152,\ p_{11} = -63/2816,\ p_{13} = -231/13312, \end{aligned}$$

Now if we change the coordinate axes from $[\omega, H_2(\omega)]$ to $[\omega', H_1(\omega')]$ by using the transformation (see Fig. 21.3 for new axes):

$$\omega = \omega' + \pi/2;\ H_2(\omega) = H_1(\omega') + \pi/2 \tag{21.27}$$

the criterion of maximal linearity would hold at $\omega' = 0$. Using Eqs. (21.26) and (21.27) in Eq. (21.25) and dropping the primes, we get

$$H_1(\omega) = \sum_{\substack{i=1 \\ i \text{ odd}}}^{n} -p_i (\sin\omega)^i, \quad n = (N-1)/2 \tag{21.28}$$

Using Eqs. (21.25) and (21.26), the transfer function of causal, FlR digital differentiators corresponding to $H_2(\omega)$ (i.e. ML-DDs for mid-band frequencies) is given by

$$\begin{aligned} \hat{H}_2(z) &= z^{-n} H_2(\omega)|_{e^{i\omega}=z} \\ &= (\pi/2)2^{-n} + \sum_{\substack{i=1 \\ i \text{ odd}}}^{n} p_i z^{-n+i} \left(\frac{1+z^{-2}}{2}\right)^i \end{aligned} \tag{21.29}$$

Proceeding in a similar manner, the transfer function of causal, FIR digital differentiators for low frequencies is found to be

$$\hat{H}_1(z) = \sum_{\substack{i=1 \\ i \text{ odd}}}^{n} (-1)^{(i+1)/2} p_i z^{-n+i} \left(\frac{1-z^{-2}}{2}\right)^i \tag{21.30}$$

$\hat{H}_1(z)$ and $\hat{H}_2(z)$ can be realized through a composite structure as shown in Fig. 21.11. The outputs from the tappings numbered 1, 3, 5, …, etc. correspond to those of differentiators with $n = 1, 3, 5, \ldots$, respectively.

21.6.2 Performance of Universal Differentiators

The expression for $H_2(\omega)$ in Eqs. (21.24) and (21.25) are mathematically equivalent. Hence the transfer function $\hat{H}_2(z)$ gives ML (at $\omega = \pi/2$)-DDs for mid-band frequencies and the corresponding frequency response is as shown in Fig. 21.3. $\hat{H}_1(z)$ gives maximally linear (at $\omega = 0$)-DDs for low frequencies, as shown in Fig. 21.12. Due to the criteria of maximal linearity, the allied advantages, as brought out in the earlier sections, are also available in the universal DDs. Table 21.5 gives the performance of universal differentiators for REs of |±0.1%|, |±0.5%| and |±1.0%|. This Table may be used to select the appropriate tapping point (i.e. the value of n) to achieve the desired accuracy of differentiation in the specified frequency band from $\omega = 0$ to 0.90π. No change of the weighting coefficients p_i *is* required in the structure. A DD structure of order N can be used for all odd orders from 3 to N. The proposed

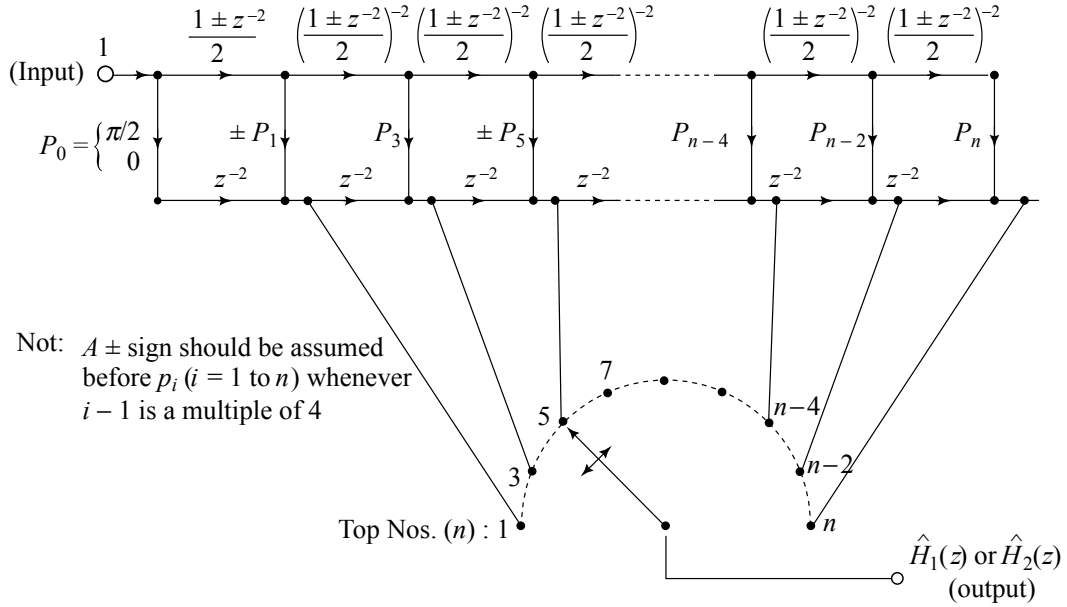

Fig. 21.11 Realization of transfer functions for variable frequency, FIR digital differentiators $\hat{H}_1(z)$: for low frequencies (take $p_0 = 0$ and –ve for $\pm$ signs) $\hat{H}_2(z)$: for midband frequencies (take $p_0 = \pi/2$ and +ve for $\pm$ signs)

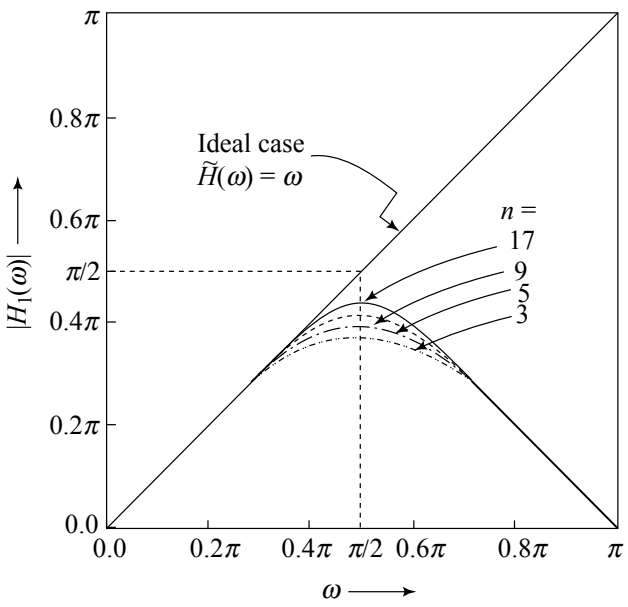

Fig. 21.12 Frequency response, $\hat{H}_2(e^{j\omega})$, of variable frequency digital differentiators for low frequencies at output tap Nos. 3, 5, 9 and 17 (order $N = 2n + 1$)

universal DD would find ready use in various applications in communication and instrumentation such as electronic scanning, beam steering [4] and adaptive image enhancement processes [25], to mention a few.

21.7 Conclusions

A new class of digital differentiators covering low ($0 \leq \omega \leq 0.5\pi$), mid ($0.15\pi \leq \omega \leq 0.90\pi$) and high ($0.5\pi \leq \omega \leq \pi$) frequency bands of operation has been discussed. A universal differentiator performing over $0 \leq \omega \leq 0.90\pi$ has also been presented. Exact mathematical formulas for computing the weighting coefficients, required in the structures, have been given. The designed differentiators are shown to be highly efficient in their respective frequency bands, and are capable of achieving extremely low relative errors with attractively low orders. The flexibility available in the choice of designs for various situations makes these differentiators particularly suitable for numerous applications.

Chapter 22
Design of Maximally Flat and Monotonic FIR Filters Using the Bernstein Polynomial

Abstract This chapter presents a recently introduced technique for the design of Maximally flat (MAXFLAT) FIR filters by using the Bernstein polynomial, and reviews its applications in (i) establishing the equivalence between the earlier known methods, and (ii) formulating a matrix approach for determining the coefficients of MAXFLAT FIR filters efficiently. We also review a new, optimal design procedure for MAXFLAT filters and extend the method to generate monotonic FIR filters with arbitrary magnitude specifications, for which, presently, no method exists. Further, these concepts have been used here to design Quadrature Mirror Filters (QMF), with extremely low reconstruction error.

Keywords Digital filters · Maximally-flat FIR filters · Monotonic FIR filters · Quadrature mirror filters

22.1 Introduction

Linear-phase FIR filters find wide applications where frequency dispersion due to nonlinear phase is harmful, as in speech processing and data transmission. Presently, a variety of design procedures are available for the design of this class of filters, and most of them result in ripples in the passband, as well as the stopband. However, there are some applications, as in the design of filter banks, where we desire monotonic frequency response, to overcome the problem of inter-channel interference. Maximally Flat (MAXFLAT) FIR filters, characterized by flat response in both passband and stopband, are useful in such applications, and has been a topic of interest for quite some time [1–12]. Besides direct applications, MAXFLAT FIR filters have been used to design a class of monotonic FIR filters meeting the prescribed specification of the passband cutoff frequency exactly [13, 14]. Vaidyanathan [15] used this class of filters as building blocks to design filters with monotonic frequency response and narrow transition width. He has further extended the use of MAXFLAT FIR filters to improve the performance of optimal filters [16].

Herrmann [1], who was the first to propose a design method for this class of filters, arrived at the desired transfer function through the use of general Hermite interpolation. Miller [2] identified the design problem to that of a classical analog maximally flat filter, while Fahmy [3] used a special integral to generate a suitable MAXFLAT polynomial. None of these contributions give a method to determine the order of the filter, an essential parameter required in the design. Kaiser and Reed [6] gave a design method, based on empirical relations, for a specific case of 95 to 5% transition width, which is widely used to design this class of filters. Indeed, even at this time, this is the only method available, and, as yet, no method exists for arbitrary magnitude specifications. This deficiency, in effect, has greatly restricted the use of this class of filters. Besides, although a number of direct and indirect methods [5–13] are available for computing the coefficients of MAXFLAT FIR filters, all of them are involved, and require a large dynamic range of the computing machine.

In this chapter, we start with a review of the work done by us on the design of MAXFLAT filters, and then extend these results to design a new class of monotonic and Quadrature Mirror Filters (QMF). Thus, the aim of this chapter is to enable one to start from the given arbitrary magnitude specifications, and arrive at the impulse response weights required to implement the filter; a concise work of this nature was not so far available in the literature. The chapter is organized as follows. In the next section, we briefly review the existing methods for the design of MAXFLAT and monotonic FIR filters. We introduce the new technique for the design of MAXFLAT filters, and show the equivalence between this and the existing techniques. A matrix approach is also presented for determining the coefficients of MAXFLAT filters. An optimal design procedure, suited for the design of this class of filters with arbitrary magnitude specifications, is also given. Then we present a new technique for the design of FIR filters with monotonic frequency response, which meets the specification of magnitude at the passband and stopband edges exactly. We have shown that, for a set of given specifications, this class of filters yields considerable saving in order of filter, as compared to MAXFLAT filters. Finally, we consider the design of QMFs with monotonic response and low reconstruction errors.

22.2 Review

The transfer function of an FIR filter of order *2N*, expressed in terms of its impulse response coefficients, is

$$H_D(z) = \sum_{i=0}^{2N} h_i \, z^{-1}, \tag{22.1}$$

The phase response of the transfer function $H_D(z)$ could be made linear by constraining the impulse response to be symmetrical or antisymmetrical. However, in the discussions to follow, we shall consider only the symmetrical case, that is,

$$h_i = h_{2N-1},\ i = 0 \text{ to } N-1. \tag{22.2}$$

Although a similar relationship can be obtained for odd order filters, we shall restrict our discussions to only even order filters. The transfer function of a symmetric (linear-phase) FIR filter of order $2N$ is obtained by combining Eqs. (22.1) and (22.2), as

$$H_D(z) = z^{-N} \sum_{i=0}^{N} b_i \frac{(z^i + z^{-i})}{2} = z^{-N} H(z), \tag{22.3}$$

where

$$b_0 = h_0 \text{ and } b_i = 2h_i,\ i = 1 \text{ to } N.$$

The factor z^{-N} in Eq. (22.3) accounts for the linear-phase characteristic, while the zero-phase transfer function $H(z)$ determines the magnitude characteristic. As noted earlier, the symmetric impulse response guarantees linear-phase response and hence we shall be primarily concerned with designing a suitable zero-phase transfer function $H(z)$ meeting the given magnitude specifications. By putting $z = e^{j\omega}$, the frequency response of $H(z)$ can be written in terms of the angular frequency ω, as

$$H(e^{j\omega}) = \sum_{i=0}^{N} b_i \cos(i\omega). \tag{22.4}$$

Specifically for some applications, it is convenient to express the transfer function in the form

$$H(e^{j\omega}) = \sum_{i=0}^{N} a_i (\cos\omega)^i. \tag{22.5}$$

Thus, the design of a linear-phase FIR digital filter starts with the given set of specifications and aims at finding a suitable transfer function $H(z)$, defined by a value of N and a set of coefficients, b_i's or a_i's which meet the specifications exactly or 'to the best possible extent'. In this chapter, we are concerned with the design of suitable MAXFLAT and monotonic FIR filters meeting the given specifications.

A MAXFLAT lowpass (or highpass) filter is characterized by the maximum possible total order of tangencies at either of the extreme points, $\omega = 0$ and $\omega = \pi$. The filter is said to be lowpass and maximally flat if the following conditions are satisfied:

$$H(e^{j\omega})|_{\omega=0} = 1, \tag{22.6a}$$

$$H(e^{j\omega})|_{\omega=\pi} = 0, \tag{22.6b}$$

$$\left.\frac{d^n H(e^{j\omega})}{d\omega^n}\right|_{\omega=0} = 0, \text{ for } n = 1, 2, \ldots, 2L-1, \tag{22.6c}$$

and

$$\left.\frac{d^n H(e^{j\omega})}{d\omega^n}\right|_{\omega=\pi} = 0, \text{ for } n = 1, 2, \ldots, 2K-1, \tag{22.6d}$$

L and K represent the orders of flatness at $\omega = 0$ and $\omega = \pi$ respectively, and are related to N by

$$N = L + K - 1 \tag{22.6e}$$

Herrmann [1] used the transformation

$$\cos\omega = 1 - 2x \tag{22.7}$$

on $H(e^{j\omega})$ of Eq. (22.4) to yield an N-th order polynomial. The coefficients of this polynomial and hence the impulse response weights, are obtained by using the general Hermite interpolation [17]. Besides, Herrmann gave the following empirical relation to determine the order of tangency, L, at $\omega = 0$ required to select one of the N possible magnitude characteristics:

$$L = int(NX_c) + 1. \tag{22.8}$$

where *int* (p) denotes the integer part of p. On the other hand, Miller [2] used the conformal mapping

$$z^{-1} = \frac{1-q}{1+q}, q = \sum + j\Omega, \tag{22.9}$$

on $H(z)$ of Eq. (22.3) to get a rational function. By imposing the necessary derivative conditions and substituting $q = j\Omega$, the resulting analog MAXFLAT transfer function is obtained as

$$H_a(j\Omega) = \frac{\sum_{i=0}^{L} \binom{N}{i} \Omega^{2i}}{(1+\Omega^2)^N}, \tag{22.10}$$

where L is the order of flatness in the passband. Miller then reverted back to the z-plane to obtain the desired MAXFLAT FIR filter transfer function.

Although the methods of Herrmann [1] and Miller [2] give a design approach, they do not give a method to determine the order of the filter required to meet a set of given specifications. Kaiser and Reed [6] gave the empirical relation

$$N = \left[int \geq (\pi/\Delta\omega)^2 \right] \tag{22.11}$$

where $\Delta\omega$ is the transition band as measured by the region, where the filter response magnitude varies from 95% (passband edge) down to 5% (stopband edge). Once the order is estimated, the orders of tangency required at $\omega = 0$ can be determined by using the results of Herrmann [1]. Generally, it has been observed that the filters derived through these steps do not meet the given specifications satisfactorily. Kaiser and Reed [6] proposed a design procedure for a special case of specified 95 to 5% transition width. In this, N is computed by using Eq. (22.11), but in determining L by using Eq. (22.8), the centre frequency of the transition band is used as the parameter, rather than the cutoff frequency, ω_c. Besides, with these initial values of N and L, the filter order is permitted to change by a factor of two over that estimated by using Eq. (22.11), in order to adjust the transition band centre to as close to the prescribed value as possible. Though this method gives satisfactory results over the first, it cannot obviously be used for arbitrary magnitude specifications.

Having estimated the values of N and L, we need to compute the coefficients to realize the transfer function. In the usual situation, we are interested in the coefficients of MAXFLAT filters, expressed in terms of the cosines of multiple angles, i.e. b_i's of Eq. (22.4). Kaiser and Reed [6] proposed a method in which the filter coefficients are determined by first evaluating the frequency response characteristic at N equally spaced set of frequency points, and then performing an inverse discrete Fourier transform on this point set. The results related to MAXFLAT FIR filter in [6] are consolidated in [7]. Gumacos [8] derived a closed form solution for the coefficients of MAXFLAT lowpass filter, having equal passband and stopband widths. Bromba and Zeigler [9] developed a general formula for the coefficients by the use of modified Krawtchouk polynomials, and claimed to have overcome the limitations of [8]. However, it is observed that the results of [9] are advantageous for either high or low passband and stopband width ratios. Jinaga and Dutta Roy proposed two methods—an explicit expression [10] and a recurrence relation [11]—for computing the coefficients directly, in contrast to Kaiser's indirect method. Both of these methods require a large dynamic range of the computing machine.

Fahmy [3] has expressed the coefficients a_i's of Eq. (22.5) in terms of N and L; however the formula is computationally expensive. Explicit expressions for the coefficients a_i's have also been reported by Jinaga and Dutta Roy [12]. The method of derivation was based on Kaiser-Hamming amplitude change function, and is neither straight forward nor simple. Thus, it can be concluded that the existing methods are neither simplistic in their approach, nor computationally efficient.

Generally, in the filter design problem, we are interested in meeting the passband edge specifications exactly. However, in the design procedure outlined earlier, more often, this condition is not met. One of the solutions to this problem is to design suboptimal filters, which meet the requirement of passband edge exactly. Thajchayapong

et al. [13] obtained a transitional filter between two adjacent values of L, say L_1 and L_2 with $L_2 = L_1 + 1$, by adding an extra term in the numerator of (22.10) to get

$$H_0(j\Omega) = \frac{\sum_{i=0}^{L} \binom{N}{i} \Omega^{2i} + v\Omega^{2L_2}}{(1+\Omega^2)^N}, \tag{22.12}$$

If in Eq. (22.12), the value of v is allowed to vary in the range $0 \leq v \leq \binom{N}{L_2}$, infinite number of transitional filters whose magnitude responses lie between those with flatness parameters L_1 and L_2 are obtained. Thus the coefficient v in Eq. (22.12) can be chosen to meet the magnitude specification at any one desired point and the authors of [13] have specifically considered the case of 3 dB cutoff.

A different method to generate this class of filters was reported in [14], where the authors worked directly on the digital transfer function. They considered two transfer functions $H_1(z)$ and $H_2(z)$, orders of flatness at $\omega = 0$ being L_1 and $L_1 + 1$, respectively. They generate a class of filters $H_0(z)$ by considering a weighted linear combination of $H_1(z)$ and $H_2(z)$ as,

$$H_0(z) = \frac{H_1(z) + \beta H_2(z)}{1+\beta}, \tag{22.13}$$

where the weight β is adjusted to make the magnitude response pass through a prescribed cutoff frequency. Later, in this chapter, we shall prove that, in this class of filters, the magnitude characteristic is forced to pass through an arbitrary cutoff frequency at the cost of one degree of flatness. Thus, these transitional filters of [13, 14], although claimed as MAXFLAT, are really suboptimal; hence the problem of designing MAXFLAT FIR filters meeting arbitrary specifications is yet an unsolved one.

The theory of MAXFLAT FIR filters has been extended to design other class of digital filters like the MAXFLAT QMF [18]. QMFs are largely used in the field of speech transmission/reception, where the signal is split into two or more sub-bands at the transmitter and recombined at the receiver with minimum aliasing error. Two sub-band coding is achieved by a pair of orthogonal lowpass and highpass filters. Bergeron [18] proposed a numerical method for the design of MAXFLAT QMF, based on the work of Herrmann [1]. In brief, the method aims at searching all the orders of filters over the entire range of L and pick out those characteristics, which approximate a pair of orthogonal filters, with fairly low aliasing errors. He has left the optimal search procedure as an open problem.

22.3 The Bernstein Polynomial and Design of Maxflat Filters

Let $f(x)$ be a function defined in the interval (0, 1). The N-th ($N \geq 1$) order Bernstein polynomial for $f(x)$ is given by [17] and [19]:

$$B_N(x) = \sum_{i=0}^{N} f\left(\frac{i}{N}\right)\binom{N}{i}x^i(1-x)^{N-1}. \tag{22.14}$$

Here, the interval (0, 1) is divided into N equal intervals and the values $f(x)$ at these $(N + 1)$ points only are used to evaluate the polynomial $B_N(x)$.

The Bernstein polynomial has some very interesting properties and has been extensively studied by Lorentz [19]; some of the properties of this polynomial in real domain are dealt with by Davis in [17]. A few of the important properties that are of interest in the present context of design of MAXFLAT FIR filters are:

(i) At the extreme points, the approximating polynomial is exactly equal to the value of the function, that is,

$$B_N(0) = f(0) \text{ and } B_N(1) = f(1) \tag{22.15}$$

(ii) This polynomial yields smooth approximants, in contrast to the well-known Chebyshev approximation, which is characterized by ripple behaviour.

(iii) This polynomial provides simultaneous approximations of the function and its derivatives, that is, if the p-th derivative of $f(x)$ exists, then,

$$\lim_{N\to\infty} B_N^{(p)}(x) = f^{(p)}(x), \tag{22.16}$$

where $f^{(p)}$ denotes the p-th derivative of the function f.

Thus the Bernstein polynomial 'mimics the behaviour of the function to a remarkable degree' [17]. In fact, it is the statement of Davis, which motivated us to study the possibility of using this polynomial to design MAXFLAT FIR filters. Although this polynomial has extremely good approximation properties, the disadvantage is that it has very slow convergence, and this fact has precluded any numerical application of this polynomial. However, as we shall demonstrate, the use of this polynomial has added a new dimension to the design of MAXFLAT and monotonic filters, by generating numerous interesting and useful results.

Consider the approximation problem of a lowpass function, shown in Fig. 22.1, by using the Bernstein polynomial. If L is the number of successive discrete points at which the function is unit valued, then

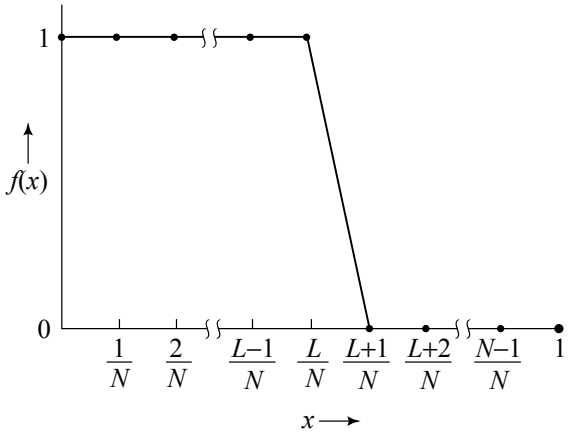

Fig. 22.1 Lowpass function

$$f\left(\frac{i}{N}\right) = \begin{cases} 1, & 0 \le i \le L \\ 0, & L+1 \le i \le N \end{cases}. \tag{22.17}$$

Substituting the functional values of Eq. (22.17) in Eq. (22.14), and by using an additional subscript L for $B_N(x)$, we get

$$B_{N,L}(x) = \sum_{i=0}^{L} \binom{N}{i} x^i (1-x)^{N-i} \tag{22.18}$$

In [20], it is shown that, by using suitable transformations, the expression given in Eq. (22.18) reduces to those obtained by Herrmann [1] and Miller [2] for a MAXFLAT filter with $(L+1)$ as the degree of tangency at $\omega = 0$, thus establishing an equivalence between the three techniques. Further, as noted in [20], this new approach has led to an analytical assertion of the empirical relation of Eq. (22.8).

22.4 Transformation Matrix

In the previous Section, it was shown that the MAXFLAT lowpass FIR filters can be easily designed by using a functional vector, whose entries are either 1 or 0, where the number of 1s and 0s determine the degrees of flatness at $\omega = 0$ and $\omega = \pi$ respectively. In this Section, we shall relate this simple functional vector and the coefficients of MAXFLAT filter, either a_i's of Eq. (22.5) or b_i's of Eq. (22.4), by a transformation matrix.

22.4.1 *Coefficients* $\mathbf{a_i}$*'s*

Let the coefficient vector $[a] = [a_0, a_1, \ldots, a_N]^t$ be related to the functional vector $[f] = [f(0), f(1/N), f(2/N), \ldots, f(N/N)]^t$ via a constant matrix $[P_N]$ of order $(N + 1)$, such that

$$[a] = \alpha[P_N][f], \tag{22.19}$$

where α is a normalizing constant, so chosen that all the elements of $[P_N]$ are integers. We are interested in finding the entries of the matrix $[P_N]$.

Starting with the explicit formula for the coefficient given in [12], we arrive at a simple matrix relation [21]:

$$[P_N] = [Q_N][D_N] \text{and} \, \alpha = 2^{-N} \tag{22.20}$$

where $[Q_N]$ is the matrix used in the bilinear transformation [22–24], and $[D_N]$ is a diagonal matrix with nonzero elements, equal to $\binom{N}{m}$ for $m = 0, 1, \ldots, N$. It is interesting to note that the elements of $[D_N]$ are the same as the elements of the first column of $[Q_N]$, and hence need not be computed explicitly. Besides, in [22, 23], it has been shown that the knowledge of the elements in the first column is sufficient to generate all the other entries of $[Q_N]$. The simple relation, repeated here for the sake of completeness, is

$$\begin{aligned} Q_{0,j} &= 1 \; j = 0 \text{ to } N \\ Q_{i,j} &= Q_{i,j-1} - Q_{i-1,j-1} - Q_{i-1,j} \quad i = 1 \text{ to } N \\ &\qquad\qquad\qquad\qquad\quad j = 1 \text{ to } N. \end{aligned} \tag{22.21}$$

By observing the symmetry properties of $[Q_N]$, only about half the elements need to be computed. The simplicity of this approach would soon be illustrated by an example.

22.4.2 *Coefficients* $\mathbf{b_i}$*'s*

Here, the problem can be formulated in terms of a transformation matrix $[R_N]$ as

$$[b] = \beta[R_N][f] \tag{22.22}$$

where β is a normalizing constant. It is known that the b_i's of Eq. (22.4) are related to a_i's of Eq. (22.5) through Chebyshev polynomials [25]. Taking advantage of this observation and the earlier results of this Section, we have

$$[R_N] = [C_N][P_N] \tag{22.23a}$$

and

$$\beta = 2^{2N-1}, Z \tag{22.23b}$$

where $[C_N]$ is the Chebyshev matrix, which is an upper triangular one, with merely one-fourth nonzero elements, and hence its pre-multiplication with $[P_N]$ can be done efficiently. Further, $[C_N]$ can be decomposed into product of two simpler matrices:

$$[C_N] = [\hat{C}_N][\hat{D}_N], \tag{22.24}$$

where the elements of $[\hat{C}_N]$ are derived from the binomial coefficients, and $[\hat{D}_N]$ is a diagonal matrix whose nonzero elements are expressible as powers of 2. A simple method to generate the matrices in Eqs. (22.20) and (22.24) is given in [26].

Example 1 Consider the case when $N = 4$, then

$$[Q_4] = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ 4 & 2 & 0 & -2 & -4 \\ 6 & 0 & -2 & 0 & 6 \\ 4 & -2 & 0 & 2 & -4 \\ 1 & -1 & 1 & -1 & 1 \end{bmatrix}, \quad [D_4] = \begin{bmatrix} 1 & & & & \\ & 4 & & & \\ & & 6 & & \\ & & & 4 & \\ & & & & 1 \end{bmatrix}$$

$$[\hat{C}_4] = \begin{bmatrix} 1 & 0 & 1 & 0 & 3 \\ 0 & 1 & 0 & 3 & 0 \\ 0 & 0 & 1 & 0 & 4 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \quad [\hat{D}_4] = \begin{bmatrix} 8 & & & & \\ & 8 & & & \\ & & 4 & & \\ & & & 2 & \\ & & & & 1 \end{bmatrix} \tag{22.25}$$

By multiplying $[Q_4]$ and $[\hat{D}_4]$, we get $[P_4]$ as

$$[P_4] = \begin{bmatrix} 1 & 4 & 6 & 4 & 1 \\ 4 & 8 & 0 & -8 & -4 \\ 6 & 0 & -12 & 0 & 6 \\ 4 & -8 & 0 & 8 & -4 \\ 1 & -4 & 6 & -4 & 1 \end{bmatrix}, \tag{22.26}$$

Pre-multiplying $[P_4]$ in Eq. (22.26), with $[C_4]$ and $[D_4]$ of (22.25), we get $[R_4]$ as

$$[R_4] = \begin{bmatrix} 35 & 20 & 18 & 20 & 35 \\ 56 & 16 & 0 & -16 & -56 \\ 28 & -16 & -24 & -16 & 28 \\ 8 & -16 & 0 & 16 & -8 \\ 1 & -4 & 6 & -4 & 1 \end{bmatrix}, \tag{22.27}$$

For $L = 1$, by using Eq. (22.26), we get $[a] = [5, 12, 6, -4, -3]^t$ with $\alpha = 16$ and by using Eq. (22.25), we get $[b] = [55, 72, 12, -8, -3]^t$ with $\beta = 128$.

A recursive method to generate the transformation matrix $[R_N]$ is given in [26]; the advantage of this method is that it does not require all the matrices in Eq. (22.25) to be computed independently. Thus, with the results of this Section and those in [26], given a functional vector corresponding to the desired N and L of MAXFLAT FIR filter, we can generate the required coefficient vector. However, one needs to address a more general problem, that is, for a given set of specifications, 'what are the optimal values of N and L?'. In the next Section, we discuss this problem and propose a solution.

22.5 Maxflat FIR Filters

Consider the design of a lowpass linear-phase MAXFLAT FIR filter transfer function $H(z)$ to satisfy the following arbitrary magnitude specifications (Fig. 22.2):

$$H(e^{j\omega}) \begin{cases} > \delta_1, & 0 \le \omega < \omega_c, \\ = \delta_1, & \omega = \omega_c, \\ \le \delta_2, & \omega_s \le \omega \le \pi \end{cases} \tag{22.28a, b, c}$$

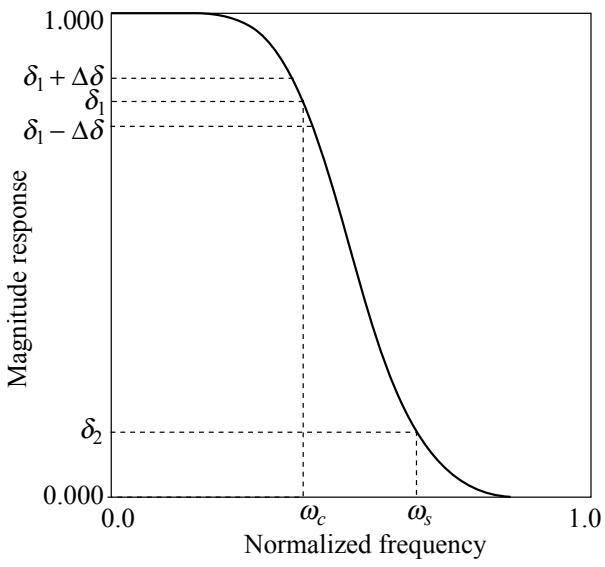

Fig. 22.2 A typical MAXFLAT FIR lowpass filter specifications

Besides these, the filter is, of course, required to meet the constraints of Eq. (22.6a, 22.6b, 22.6c, 22.6d, 22.6e). As mentioned earlier, for a given N-th order MAXFLAT filter, there are only N possible characteristics, and we need to choose one amongst these, parameterized by L, which meets the specifications given in Eq. (22.28a, b, c). Generally, it has been observed that the specification of Eq. (22.28b) cannot be met exactly with nominal order of filter. In view of this, we allow a magnitude tolerance of $\Delta\delta$ at the passband edge ω_c; consequently, Eq. (22.28b) is modified as

$$\left|H\left(e^{j\omega}\right) - \delta_1\right| \leq \Delta\delta, \omega = \omega_c. \tag{22.28d}$$

Now the problem of design of MAXFLAT filter is the same as choosing a MAXFLAT characteristic, parameterized by N and L, which satisfies the conditions of Eq. (22.28a, b, c).

The proposed method is based on the use of Bernstein polynomial for the design of MAXFLAT FIR filters. Now, the filter design problem is reduced to identifying a suitable Bernstein polynomial, which satisfies the equivalent conditions of Eq. (22.28a, b, c). The optimal method, proposed for this purpose, uses the following set of recurrence relations [27–29]:

$$B_{N+1,\,L}(x) = B_{N,\,L}(x) - \binom{N}{L} \times b_{N,\,L}(x) \tag{22.29a}$$

and

$$B_{N+1,L+1}(x) = B_{N,L}(x) - \binom{N}{L+1} \times b_{N,L}(x), \tag{22.29b}$$

where the auxiliary polynomial $b_{N,L}(x)$ satisfies

$$b_{N,L}(x) = (1-x)b_{N-1,L}(x) \tag{22.29c}$$

We start the search procedure with second-order Bernstein polynomial, and search for the optimum order of filter and the orders of tangency at $\omega = 0$ and $\omega = \pi$, simultaneously, in a 'stair case' like manner. The procedure is depicted in the flow-diagram of Fig. 22.3. This being an optimal method, it results in the minimum order of the filter required to meet the given specifications, and a detailed comparison with the earlier methods establishes the superiority of this approach. The details of this method and exhaustive comparative study based on examples is discussed in [28, 29].

Generally, in the filter design problem, we are interested in meeting the passband edge specifications exactly. However, in the design procedure outlined in this Section, we need to accept a tolerance of $\Delta\delta$ at the passband edge and more often, if this value is small, then the required N is very high. One of the solutions to this problem is to design suboptimal filters, which meet the requirement of passband and stopband edges exactly.

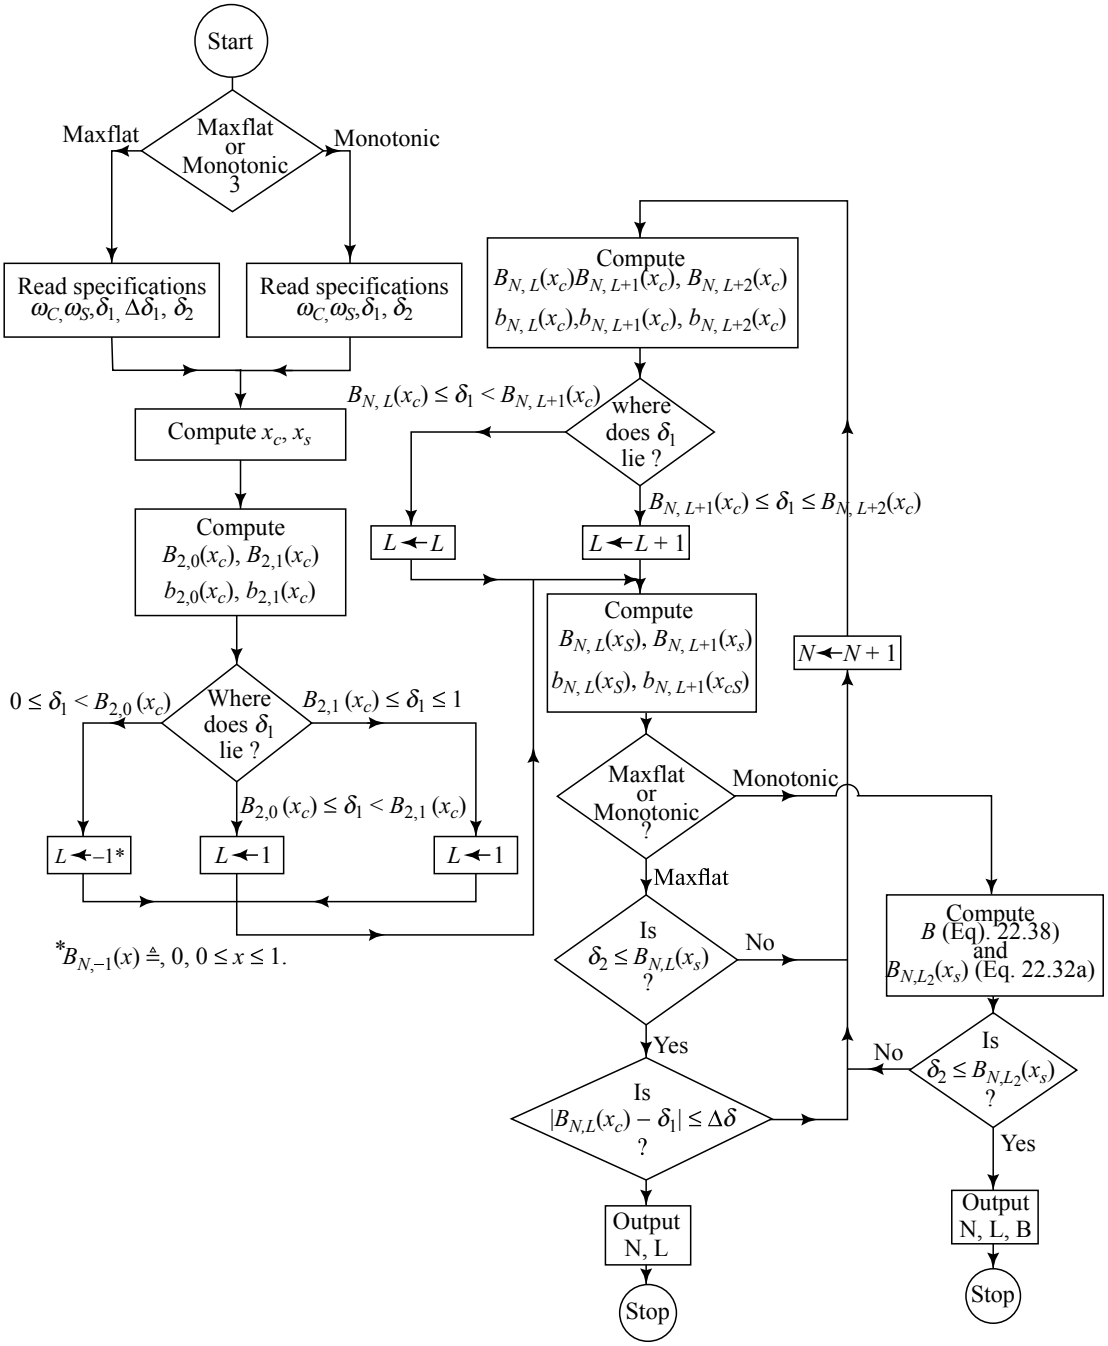

Fig. 22.3 Flow diagram depicting the procedure for designing MAXFLAT and monotonic FIR Iowpass filters

22.6 Monotonic FIR Filters

As is clear from earlier discussions, the design of MAXFLAT 1owpass filter evolves from the Bernstein polynomial approximation of an ideal 1owpass function, with transition width 1/*N* (Fig. 22.1) and obviously, we can not exercise control over the behaviour of the characteristic in the transition region. However, it is possible to

overcome this difficulty by increasing the ideal transition width of the approximating function to either $2/N$ or $3/N$, thus, resulting in a new class of monotonic filters.

22.6.1 Monotonic Filters with Transition Width 2/N

Consider the approximation problem of a lowpass function, defined in the interval (0, 1), as shown in Fig. 22.4. Here,

$$f\left(\frac{i}{N}\right) = \begin{cases} 1, & 0 \le i \le L \\ \alpha, & i = L+1, 0 < \alpha < 1 \\ 0, & L+2 \le i \le N. \end{cases} \tag{22.30}$$

The Bernstein polynomial for this lowpass function, obtained by using the functional values of Eq. (22.30) in Eq. (22.14), and is given by

$$B_{N,L_2}(x) = \sum_{i=0}^{L} \binom{N}{i} x^i (1-x)^{N-i} + \alpha \binom{N}{L+1} x^{L+1} (1-x)^{N-L-1} \tag{22.31}$$

where the suffix L_2 has been added to indicate an ideal transition width of $2/N$. Here, we have a parameter α, which can be suitably selected to control the behaviour of the response in the transition region as well. Simplifying Eq. (22.31), we get

$$B_{N,L_2}(x) = \frac{B_{N,L}(x) + \beta B_{N,L+1}(x)}{1+\beta}, \tag{22.32a}$$

where

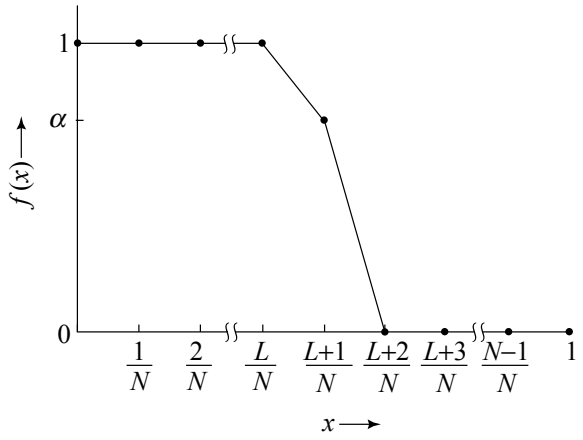

Fig. 22.4 Lowpass function with transition width $2/N$

$$\beta = \frac{\alpha}{1-\alpha} \tag{22.32b}$$

The order of flatness at the extreme points, $x = 0$ and $x = 1$, found by the simple method given in [20], are L and N–L–2, respectively; a maximum degree of tangency $(N - 2)$ only, in contrast to $(N - 1)$ for MAXFLAT function. Hence, although this approximating polynomial is monotonic, it is not maximally flat, because the total degree of flatness is one less than the maximum possible.

Now we shall show that two of the previous works, [13] and [14], are special cases of this class of filters, and thus establish a link amongst the three methods. Using the conformal mapping given by Eqs. (22.9), (22.31) simplifies to

$$H_0(\Omega) = \frac{\sum_{i=0}^{L} \binom{N}{i} \Omega^{2i} + v\Omega^{2(L+1)}}{(1+\Omega^2)^N} \tag{22.33a}$$

where

$$v = \alpha \binom{N}{L+1}. \tag{22.33b}$$

It is seen that Eq. (22.33a) is identical to the result in [13]. Now, it is obvious that the 'transitional maximally flat filters' of [13] are not strictly maximally flat.

Transforming equation (22.32a) to the z-domain by using the inverse-transformation of Eq. (22.7), we get,

$$H_0(z) = \frac{H_{N,L}(z) + \beta H_{N,L+1}(z)}{1+\beta}. \tag{22.34}$$

This result is identical to the one in [14]. Both the methods discussed so far have been used to generate monotonic filters with specified cutoff frequency, by a suitable choice of v and β. Though v or β can be computed for arbitrary magnitude at the cutoff frequency, the choice of N and L need to be known before-hand. Since no method exists for estimating N and L for arbitrary magnitude specifications, the authors of [13] and [14] have restricted the use of this class of filters to meet only a specified 3 dB cutoff frequency. Before we discuss the design procedure for this class of filters, let us extend this concept to generate another class of filters with monotonic response, but with both the passband and stopband edge specifications being met exactly. The special interest in this class of filters would become evident from the requirements of the next Section on QMF.

22.6.2 Monotonic Filters with Transition Width 3/N

Consider the approximation of a lowpass function with an ideal transition width 3/*N*, as shown in Fig. 22.5. The Bernstein polynomial for this lowpass function is given by

$$\begin{aligned} B_{N,L_3}(x) = &\sum_{i=0}^{L} \binom{N}{i} x^i (1-x)^{N-i} \\ &+ \alpha_1 \binom{N}{L+1} x^{L+1} (1-x)^{N-L-1} \\ &+ \alpha_2 \binom{N}{L+2} x^{L+2} (1-x)^{N-L-2}, \end{aligned} \tag{22.35}$$

where L_3 has been used to indicate the ideal transition width of 3/*N*. After simplification, we get,

$$B_{N,L_3}(x) = \frac{B_{N,L}(x) + \beta_1 B_{N,L+1}(x) + \beta_2 B_{N,L+2}(x)}{1 + \beta_1 + \beta_2}, \tag{22.36}$$

where α_i's and β_i's are related by

$$\beta_1 = \frac{\alpha_1 - \alpha_2}{1 - \alpha_1} \quad \beta_2 = \frac{\alpha_2}{1 - \alpha_1} \tag{22.37}$$

Here, for $B_{N,L3}(x)$ to be monotonic, the conditions $0 \le \alpha_2 \le \alpha_1 \le 1$ need to be satisfied, and this requires both β_1 and β_2 to be positive.

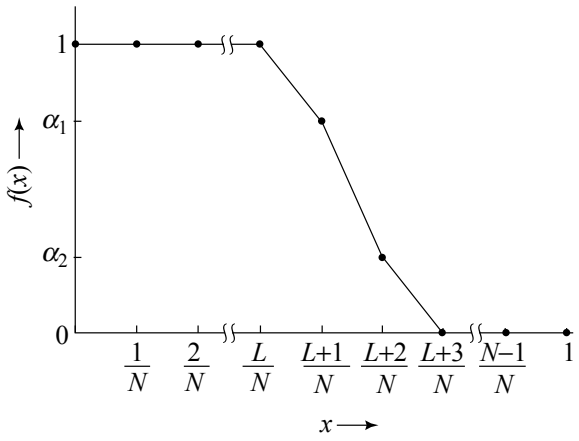

Fig. 22.5 Lowpass function with transition width 3/*N*

22.6.3 The New Method

First, we discuss the design procedure for generating monotonic filters meeting only the passband cutoff frequency exactly. The procedure is conceptually similar to that used for designing optimal MAXFLAT filters [27–29]. We start the search procedure with all the possible second-order Bernstein polynomials, and evaluate the magnitudes at $x = x_c$ for all of them. The two values of L are chosen for which the desired magnitude δ_1 lies in one of the following ranges $\{0, B_{2,0}(x_c)\}$, $\{B_{2,0}(x_c), B_{2,1}(x_c)\}$, $\{B_{2,1}(x_c), B_{2,2}(x_c)\}$. The value of β is computed by using the relation

$$\beta = \frac{\delta_1 - B_{2,L}(x_c)}{B_{2,L+1}(x_c) - \delta_1}. \tag{22.38}$$

With this value of β, α is computed from Eqs. (22.32a, 22.32b) and is used to obtain the required polynomial $B_{2,L2}(x)$ satisfying the magnitude specifications at the passband cutoff frequency exactly. It should be pointed out that $B_{2,L2}(x)$, which is derived through linear combinations of $B_{2,L}(x)$ and $B_{2,L+1}(x)$, will be monotonic if and only if β is positive (which is satisfied if $0 \leq \alpha \leq 1$). It is obvious that in this design, this is always guaranteed. Though the magnitude at the passband cutoff frequency is met exactly, the stopband specifications may not be met. Hence, the magnitude at $x = x_s$ is computed for those two values of L which are of interest. Using the values of β, $B_{2,L}(x_s)$ and $B_{2,L+1}(x_s)$, we compute the magnitude at x_s by using Eq. (22.32a). If this magnitude is less than or equal to δ_2, then the desired conditions have been met. If not, the order of the polynomial is incremented by one and a set of three values of L are chosen so that δ_1 lies in either of the following two ranges $\{B_{3,L}(x_c), B_{3,L+1}(x_c)\}$, $\{B_{3,L+1}(x_c), B_{3,L+2}(x_c)\}$. The three values of magnitude at $x = x_c$ are computed by using the recurrence relations (22.29a, 22.29b, 22.29c), and two values of L are chosen, corresponding to the range which includes δ_1. Now we compute β, and hence the magnitude at $x = x_s$, and check if the stopband conditions are satisfied. If not, the search procedure continues with the higher order of polynomial till the desired conditions are met. The design procedure is depicted in the flow-diagram shown in Fig. 22.3. We now consider an example to illustrate the design procedure.

Example 2 Consider the design of a monotonic FIR filter with the following specifications: $\omega_c = 1.047198$, $\omega_s = 2.094395$, $\delta_1 = 0.707$ and $\delta_2 = 0.04$. The transformed passband and stopband edges, in the interval (0, 1), are 0.25 and 0.75 respectively. The estimated order of optimal MAXFLAT filter is 11, that too, with an error of $\Delta\delta = 0.00631$ at the passband cutoff frequency. However, by the method proposed here, the same specifications are met with a sixth order filter. The intermediate results obtained from various steps are shown in Table 22.1. The three frequency responses, $H_{6,2}(e^{j\omega})$, $H_{6,3}(e^{j\omega})$ and $H_{6,2_2}(e^{j\omega})$ are shown in Fig. 22.6. Here, $H_{6,2_2}(e^{j\omega})$ denotes the linear combination of two transfer functions of same order ($N = 6$), but with different degrees of tangency at $\omega = 0$, that is, $L = 2$ and $L = 3$. It should be noted that the value of L associated with digital transfer function $H_{N,L}(^{ej\omega})$ is one higher than the corresponding value of $B_{N,L}(x)$; this is due to the fact that the transformation

Table 22.1 Example 2. Details of intermediate steps for the design meeting the specification of pass band exactly

N	Pass band cutoff point (x_c)					Stop band edge (x_s)		
	L	$B_{N,L}(x_c)$	$B_{N,L+1}(x_c)$	$B_{N,L+2}(x_c)$	β	L	$B_{N,L}(x_s)$	$B_{N,L+1}(x_s)$
3	0	0.42188	0.84375	0.98438	2.08501	0	0.01563	0.15625
4	0	0.31641	0.73828	0.94922	12.48637	0	0.00391	0.05078
5	1	0.23730	0.73281	0.89648	0.39152	1	0.01563	0.10352
6	1	0.53394	0.83057	0.96240	1.40057	1	0.00464	0.03760

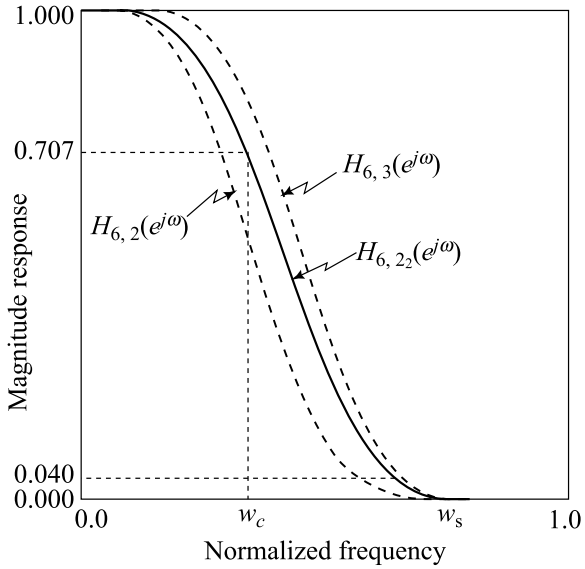

Fig. 22.6 (Example 2). The magnitude response of MAXFLAT filters and monotonic filter meeting the prescribed passband cut-off specification exactly

of Eq. (22.7) increases the degree of flatness at the extreme points by one [5]. The coefficients of the transfer function given by Eq. (22.4) are:

$$\begin{aligned} b_0 &= 0.4084574 \quad b_1 = 0.5615292 \\ b_2 &= 0.1251097 \quad b_3 = -0.0610438 \\ b_4 &= -0.0353989 \; b_5 = -0.0004853 \\ b_6 &= 0.0018318 \end{aligned}$$

Now let us consider the design of a monotonic filter to meet the specifications of both passband and stopband edge frequencies exactly. The conditions to be satisfied are:

$$\frac{B_{N,L}(x) + \beta_1 B_{N,L+1}(x) + \beta_2 B_{N,L+2}(x)}{1 + \beta_1 + \beta_2} = \delta_1 \tag{22.39a}$$

and

$$\frac{B_{N,L}(x) + \beta_1 B_{N,L+1}(x) + \beta_2 B_{N,L+2}(x)}{1 + \beta_1 + \beta_2} = \delta_2 \tag{22.39b}$$

The design procedure has already been outlined; here, in each iteration, the magnitude at x_s is computed for all the three values of L, unlike in the previous case where only two values were used. The search stops when both β_1 and β_2 turn out to be positive. Using these values of β_i's, α_i's are computed and the necessary Bernstein polynomial satisfying the given conditions is derived by using Eq. (22.35). For the example considered earlier, this method results in $N = 6, L = 2, \beta_1 = 0.80501$ and $\beta_2 = 0.28814$. The various steps involved are shown in Table 22.2. The four frequency responses are shown in Fig. 22.7. As defined earlier, $H_6{,}2_3\ (e^{j\omega})$ denotes the linear combination of three transfer functions of same order ($N = 6$), but with different degrees of tangency at $\omega = 0$, that is, $L = 2$, $L = 3$ and $L = 4$. The coefficients of the transfer function given by Eq. (22.4) are:

$$\begin{aligned} b_0 &= 0.4156528 \quad b_1 = 0.5579589 \\ b_2 &= 0.1125626 \quad b_3 = -0.0556665 \\ b_4 &= -0.0282291 \quad b_5 = -0.0022778 \\ b_6 &= 0.0000394. \end{aligned}$$

22.6.4 Comparative Study

We illustrate the advantages of this new design procedure by three sets of examples with diverse specifications. The specifications and the results of all the filters for transition widths $1/N$ (MAXFLAT design), $2/N$ and $3/N$ are shown in Table 22.3. The value of $\Delta\delta$ corresponds to the maximum permissible error at the passband cutoff frequency for the MAXFLAT filters.

It is observed that savings in the order of the filter are significant for the new method, and is, of course, at the cost of one degree of flatness. For Examples 3a and 3b in Table 22.3, the filters with 3 dB cutoff, the saving in N is significant. However, for Examples 4a and 4b, the design criteria being 95 to 5% transition width, the gain in N is not significant. This is obvious, because the magnitude characteristics are closely spaced at $\delta_1 = 0.95$. The saving in N becomes significant if lower values of $\Delta\delta$ are specified. This fact is clearly brought out by Examples (5a and 5b).

Apparently there seems to be no advantage if we use three polynomials, but by this method, with the same order of filter, we are able to exercise control over the magnitude characteristics in the stopband as well. Although this method is not of importance for simple lowpass/highpass filter design, undoubtedly, it has a significant use in orthogonalizing the bands of Quadrature Mirror filters; this is dealt in details in the next Section.

Table 22.2 Example 2. Details of intermediate steps for the design meeting the specification of passband and stopband exactly

N	Pass band cutoff point (x_c)						Stop band edge (x_s)			
	L	$B_{N,L}(x_c)$	$B_{N,L+1}(x_c)$	$B_{N,L+2}(x_c)$	β_1	β_2	L	$B_{N,L}(x_s)$	$B_{N,L+1}(x_s)$	$B_{N,L+2}(x_s)$
3	0	0.42188	0.84375	0.98438	3.54760	−0.72108	0	0.01563	0.15625	0.57813

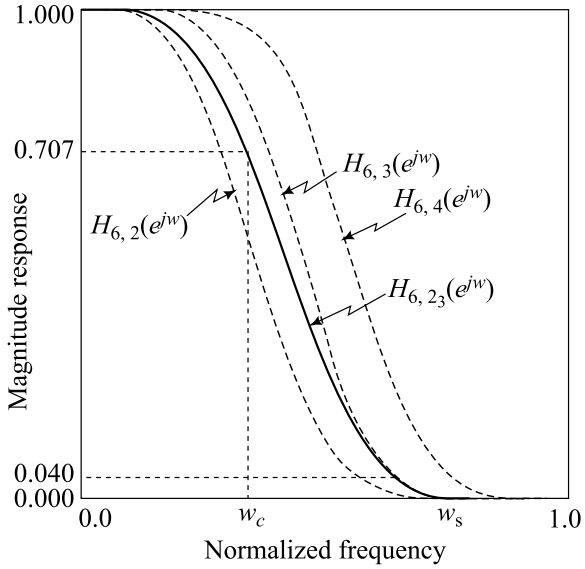

Fig. 22.7 (Example 2). The magnitude response of MAXFLAT filters and monotonic filter meeting the specifications at both passband and stopband exactly

22.7 Quadrature Mirror Filter

The theory of MAXFLAT FIR filters developed earlier can be used to design other classes of filters like the QMF, multi-band filters and two-dimensional MAXFLAT FIR filters. In this paper, we restrict our study to the first case in details and propose an efficient method for designing MAXFLAT and monotonic QMFs.

As mentioned earlier, Burgeron [18] proposed a computationally inefficient numerical method for the design of MAXFLAT QMF and arrived at two specific values of $N = 13$ and 30. As we shall see soon, the method described earlier, for the design of MAXFLAT filters, can easily be extended to design MAXFLAT QMF efficiently. However, the disadvantage of MAXFLAT QMF is that there are very few magnitude characteristics, which qualify for the purpose, and hence they are of little practical significance. Here, we propose a method by which a monotonic QMF structure with fairly low reconstruction error is generated for all values of N, by considering a linear combination of two MAXFLAT characteristics. The reconstruction error can be further reduced by the linear combination of three MAXFLAT characteristics.

A basic two-band QMF structure is shown in Fig. 22.8. In the two-band system, the aliasing error due to decimation in the analysis structure needs to be exactly cancelled by the imaging due to interpolation in the synthesis filter. To meet this end, the overall design of analysis/synthesis can be easily translated to a prototype lowpass filter $H(^{ej\omega})$, satisfying the following conditions [30]:

$$H_{lp}(e^{j\omega}) = \quad H(e^{j\omega}) \tag{22.40a}$$

$$H_{hp}(e^{j\omega}) = \quad H(e^{j\omega+\pi}) \tag{22.40b}$$

$$G_{lp}(e^{j\omega}) = \quad 2H(e^{j\omega}) \tag{22.40c}$$

Table 22.3 Comparative study based on Examples (3a)–(5b)

Example	ω_c	ω_s	δ_1	$\Delta\delta$	δ_2	Transition width					
						1/*N* (MAXFLAT)		2/*N*		3/*N*	
						N	*L*	*N*	*L*	*N*	*L*

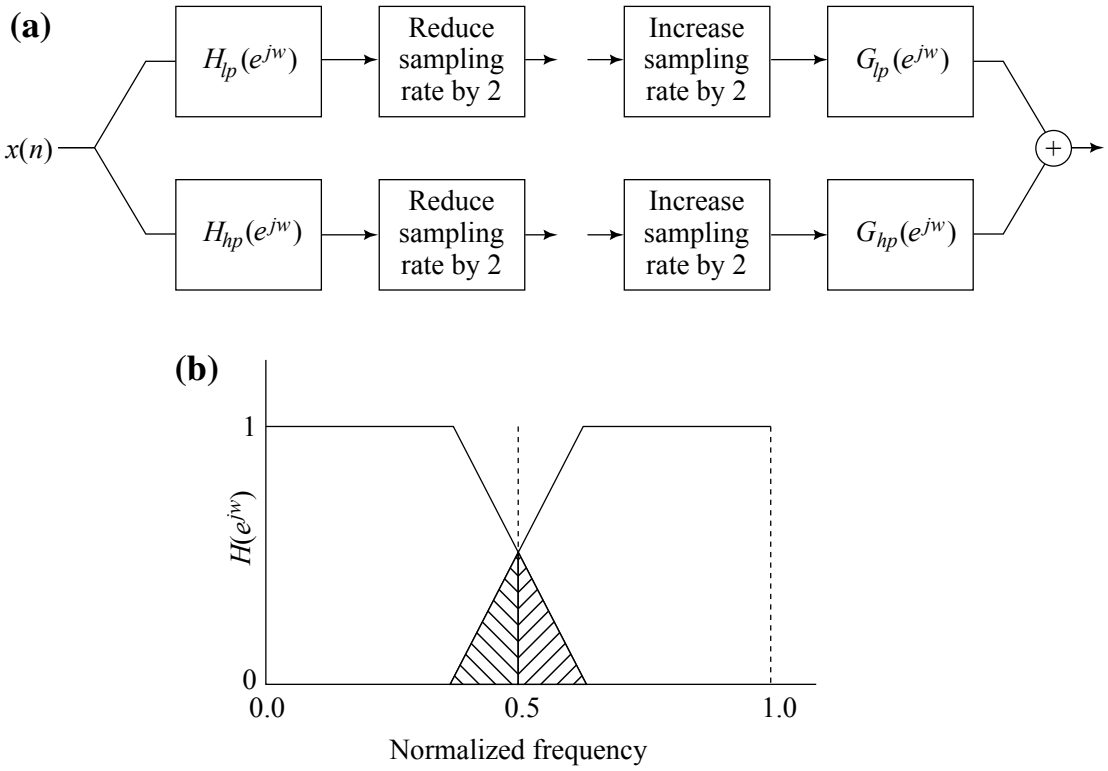

Fig. 22.8 Two-band analysis/synthesis structure for QMF design

$$G_{hp}(e^{j\omega}) = \quad -2H(e^{j\omega+\pi}) \tag{22.40d}$$

The conditions of Eqs. (22.40a) and (22.40b) imply that the filters $Hlp(e^{j\omega})$ and $H_{hp}(^{ej\omega})$ have mirror-image symmetry about the frequency $\omega = \pi/2$, as shown in Fig. 22.8b. The shaded parts indicate the regions where aliasing and imaging between the two bands occur.

The prototype lowpass filter $H(^{ej\omega})$ could be designed as either an FIR or an IIR structure. Specifically, a symmetric FIR filter with even-length impulse response can be designed to satisfy the condition

$$\left|H(e^{j\omega})\right|^2 + \left|H(e^{j\omega+\pi})\right|^2 = 1, 0 \leq \omega \leq \pi, \tag{22.41}$$

which is required to yield a QMF structure with zero reconstruction error and an overall gain of unity. Besides, the prototype lowpass $H(^{ej\omega})$ should approximate the ideal lowpass condition i.e.

$$H(e^{j\omega}) = \begin{cases} 1, & 0 \leq \omega \leq \pi/2 \\ 0, & \pi/2 \leq \omega \leq \pi. \end{cases} \tag{22.42}$$

Conditions given by Eqs. (22.41) and (22.42) impose constraints not only on the behaviour of $H(^{ej\omega})$ in the passband and stopband but also on its behaviour in the transition band.

It is well known that both the conditions of an ideal QMF and lowpass filter cannot be met *exactly;* although, a two tap FIR filter meets Eq. (22.41) exactly, its lowpass characteristics are poor. Therefore, we are required to design a symmetric even-length prototype lowpass filter with frequency response.

$$H(e^{j\omega}) = \sum_{i=1}^{N} b_i \cos[(2i-1)\omega/2] \tag{22.43}$$

which closely *approximates* the ideal requirements of Eqs. (22.41) and (22.42). It should be remembered that in all the designs discussed earlier, the resulting transfer function given by Eq. (22.4) of the MAXFLAT and monotonic FIR filters has always an odd-length impulse response. Since we intend to use the earlier methods for designing QMFs, naturally, we would arrive at unrealizable QMF transfer functions. Therefore, we need to convert the impulse response of Eq. (22.4) into those of Eq. (22.43). This conversion can easily be accomplished by interpolating the odd-length impulse response of (22.4), by a factor of two and subsampling to yield an equivalent even-length [18]. An alternate and simpler approach, would be to use a method similar to the one used by Kaiser and Reed [6]. In this method, we first compute the magnitude at $2N + 1$ points, then pad the sequence with $2N + 1$ zeros, and, finally, perform IDFT on this augmented point set. By suitably subsampling this sequence, we can easily generate the desired even-length impulse response. Although both the methods yield identical results [31], the latter is computationally simpler; hence, we shall use this method to compute the coefficients of the realizable QMF structure. Thus, in the designs to follow, first, we shall design an odd-length filter (on the assumption that it is possible to generate a QMF structure), and subsequently convert it to an equivalent even-length, by using the method just outlined. Of course, this process of conversion introduces an error in the derived magnitude characteristics.

22.7.1 Design of MAXFLAT QMF

In the design of MAXFLAT QMF, it has been well established that we are unable to exercise control over the response in the transition band, while facility for control is a positive requirement to generate QMF structure with low reconstruction error. Owing to this limitation, we need to select only those characteristics, which approximate conditions Eqs. (22.41) and (22.42) satisfactorily. The numerical method of Bergeron [18], as already mentioned, involves searching the entire two-dimensional plane of N and L, and select the characteristics of interest.

The new design method being proposed here is based on the use of Bernstein polynomial for designing MAXFLAT FIR filters [35]. Corresponding to the term QMF in z-domain, we shall use the term quadrature mirror function (qmf) in x. Since the function (22.18) is monotonic in the interval (0, 1), we have

$$E_{N,L}(x) = [B_{N,L}(x)]^2 + [B_{N,L}(1-x)]^2 - 1 \tag{22.44}$$

where $E_{N,L}(x)$ represents the error in approximating (22.41). As a first step in the design, we shall locate the points of maximum error, and then attempt to minimize the errors at these points. The problem of locating the points of maxima/minima of $E_{N,L}(x)$ is reduced to finding the roots of the polynomial $dE_{N,L}(x)/dx$ (denoted by $E'_{N,L}(x)$). Differentiating Eq. (22.44), and equating to zero, we get

$$E'_{N,L}(x) \triangleq e_{lp}(x) + e_{hp}(x) = 0 \tag{22.45a}$$

where

$$e_{lp}(x) \triangleq B'_{N,L}(x)B_{N,L}(x) \tag{22.45b}$$

and

$$e_{hp}(x) \triangleq B'_{N,L}(1-x)B_{N,L}(1-x). \tag{22.45c}$$

It can be shown that for MAXFLAT qmf (22.24), the error function can have atmost three maxima/minima, including the one at $x = 0.5$ (Appendix A). Generally, in the designs that have been verified, for $N = 5$ to 55, the absolute maximum error occurs at $x = 0.5$, with the exceptions of $N = 13$, 30, 32 and 34. As a result of this observation, we shall first design MAXFLAT qmf structures with minimum error at $x = 0.5$, and extend this design to include the exceptional cases as well.

The design of N-th order MAXFLAT QMF, with minimum reconstruction error, involves selecting the correct value of L for which the magnitude characteristic is close to –3 dB at $\omega = \pi/2$. The same search procedure, as used for designing MAXFLAT filters, can be used for generating MAXFLAT QMFs. Besides the two specific values of $N = 13$ and 30, we have $N = 51$, 53 and 55, with extremely low errors (in the range searched $N = 5$ to 55. The plot of error at $\omega = \pi/2$ versus N is shown in Fig. 22.9. As will be seen, if one permits a slightly higher error tolerance specification, say 0.025, then there are many values of N which qualify for the purpose. Some of the values of N and L which generate satisfactory responses are given in Table 22.4. In the new design procedure, the search for the values of L, which generate minimum error, is done recursively, and is confined to a maximum of three values for every N. Hence, this method is computationally more efficient than the exhaustive search procedure of Bergeron [18].

For a given N, the method just outlined yields the optimal L for which the error at $x = 0.5$ is minimum. As mentioned earlier, there are cases in which the maximum error does not occur at $x = 0.5$, and hence this value of L may not be optimum. Here, we shall propose a method to choose a suitable L for these special cases. Starting with the value of L, which gives minimum error at $x = 0.5$, we compute the maximum error for $E_{N,L+1}(x)$ and $E_{N,L-1}(x)$. If the maximum error in either of these two cases is less than that of $E_{N,L}(x)$, then the value of L is further incremented or decremented

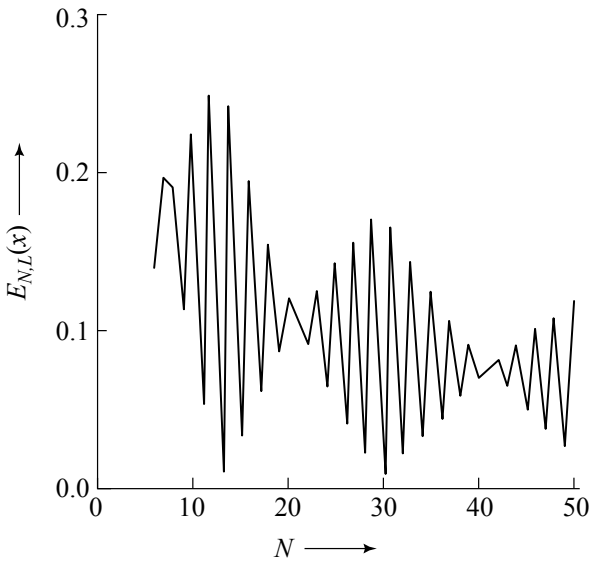

Fig. 22.9 Plot of error at $\omega = \pi/2$ versus N for MAXFLAT QMFs

Table 22.4 Some of the MAXFLAT QMFs with low reconstruction errors

N	L	Maximum reconstruction error
13	8	0.009864
28	16	0.020180
30	17	0.012409
32	18	0.020149
49	27	0.025067
51	28	0.014104
53	29	0.011994
55	30	0.015814

depending on whether the best choice was $E_{N,L+1}(x)$ or $E_{N,L-1}(x)$ respectively. It should be pointed out that in all the designs that have been verified, $N = 5$ to 55, the optimal L obtained for minimum error condition at $x = 0.5$, was also the optimum for these special cases. Hence there may not be a requirement to initiate the search procedure outlined here; the procedure has been mentioned mainly for the sake of completeness.

22.7.2 Monotonic QMF with Zero Reconstruction Error at the End and Mid Points

In the previous subsection, it was shown that generally, MAXFLAT QMFs have maximum error $\omega = \pi/2$, and, therefore, we opted to choose the characteristic which is close to -3 dB at this point. As observed, there are very few values of N which qualify for the purpose of QMF structure and hence this class of QMF has limited

applications. It would be a useful proposition to generate QMFs with low reconstruction errors for all N, and, in particular, QMFs with monotonic response. In designing such monotonic QMFs, we use the result of the earlier section, where we evolved a method to control the behaviour of the magnitude characteristics in the transition band as well—a feature not available in MAXFLAT filters.

Earlier, we have discussed a method for designing monotonic filters satisfying the specified cutoff frequency exactly by using the expression of Eq. (22.32a). In designing monotonic QMF with zero reconstruction error at $\omega = \pi/2$, we need to satisfy only one condition and hence the procedure outlined in the previous section can be used directly. Since we are interested in generating QMFs for all N, the test for stopband specification may be inhibited.

The magnitude and error characteristics of the QMF for $N = 7$, $L = 3$ and $\beta = 3.12232$ ($\beta = 0.757419$) are shown in Fig. 22.10. The error curve exhibits some interesting features and has a definite number of minima and maxima. At this point, it is worth mentioning that in the computer-aided design procedure as in [32, 33], the error surface has many local minima and the optimization routine can converge to any of the local minima rather than the global minimum. Hence, special care should be taken in the choice of the initial starting points and manual intervention may be desired while the optimization is in progress. However, in this design, as we shall see soon, we do not encounter such problems.

Let $E_{N,L2}(x)$ represent the error function corresponding to the lowpass function given by Eq. (22.32a). It can be shown that $E_{N,L2}(x)$ can have at most five max-

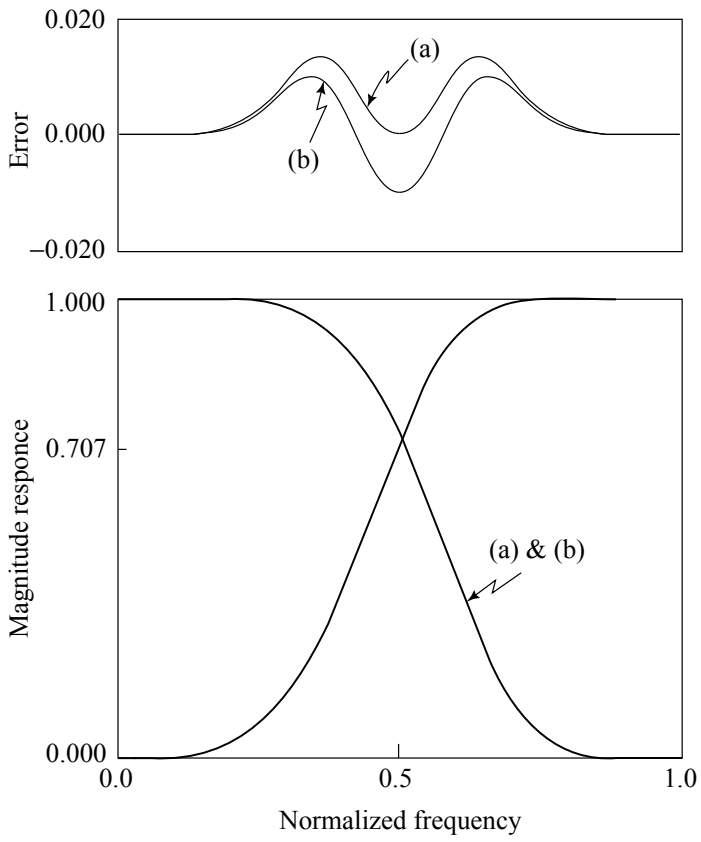

Fig. 22.10 The magnitude and error response of QMF with $N = 7$ and $L = 3$. **a** $\beta = 3.12232$ **b** $\beta = 3.35825$

ima/minima in the open interval (0, 1), (Appendix B). Since $E_{N,L2}(x)$ is constrained to have zero error at $x = 0.5$, and also observing that $E'_{N,L2}(x)$ is an anti-symmetric function about the same point, we can conclude that there can be two maxima and three minima in the interval (0, 1). The absolute value of the minima, on either extremes, is greatly reduced by the multiplying factors x^L and $(1 - x)^L$ in $E_{N,L2}(x)$. Hence the absolute maximum error is given by the value at the two maxima x_m and $(1 - x_m)$, located symmetrically about $x = 0.5$. This assertion has been verified in all the orders $N = 5$ to 55. A plot of $E'_{N,L2}(x)$ for $N = 7$ and $L = 3$, with different values of α., is shown in Fig. 22.11. It is seen that, for all values of α except for $\alpha = 0.8$, the maximum error occurs at $x = 0.5$, while for $\alpha = 0.8$, there are three such points. Although the upper limit on the number of maxima/minima is five, generally it is confined to a figure of only three or one.

The maximum error of some of the designs obtained by the method discussed in this Section is listed in Table 22.5, along with those of MAXFLAT QMFs. It is observed that the maximum error of monotonic QMF is lower than that of MAXFLAT QMF for all N, except for $N = 13$. This is expected, because the MAXFLAT error function for this specific N has positive value at $x = 0.34$, and negative value at $x = 0.5$; thus, while minimizing the absolute error at $x = 0.5$, the error at $x = 0.34$ increases. Hence, for some values of N, the monotonic QMF designed by this method, does not yield improvement over that of MAXFLAT QMF. In view of this, it would be desirable to distribute the peak error at x_m equally on either side of zero and thus minimize the maximum error. This can easily be achieved by iteratively adjusting the value of β, obtained for zero error at $x = 0.5$. Adopting this method for the case $N = 13$, we get $\beta = 0.005025$ and an error of 0.009150; the improvement is not, therefore, significant. However for $N = 7$ with $\beta = 3.35825$, the peak error is 0.010133, which amounts to a reduction of about 30%. The magnitude and error characteristics for this case are also shown in Fig. 22.10. It will be observed that

[a]Designs in which $E_{N,L3}(x_m)$ can be reduced to zero

the magnitude response has not changed appreciably. To sum up the procedure for designing monotonic QMF, the first step is to obtain the value of β for which the reconstruction error is zero at $\omega = \pi/2$, and adjust it to distribute the maximum error equally on either side of zero. Although the maximum error of monotonic QMF designed by this method is smaller compared to that of MAXFLAT QMF, the improvement is not a drastic one. In the following subsection, we shall attempt to minimize the maximum error at x_m.

22.7.3 Minimization of the Reconstruction Error at $\mathbf{x_m}$

In the previous subsection, we found that the points of maximum error are placed symmetrically about $x = 0.5$ and this results in QMF structures with maximum error at two points, x_m and $1 - x_m$. Here, we shall minimize the maximum error at these two points, with an added constraint of zero error at $x = 0.5$. Since the error function is symmetric, it is sufficient to reduce the error at x_m only.

Consider the monotonic lowpass function given by Eq. (22.36) discussed in previous section. Here, we have two parameters β_1 and β_2 and hence two conditions can be satisfied. For a given N and L, a linear condition relating β_1 and β_2 which

satisfies zero error condition at $x = 0.5$ can easily be obtained from Eq. (22.36). Also, as observed earlier, for $B_{N,L3}(x)$ to be monotonic, it requires both β_1 and β_2 to be positive; hence, the range of β_1 and β_2 of interest is restricted to a line segment in the first quadrant. The point of intersection of this line segment with β_1 axis corresponds to the previous case, where only one condition of zero error at $x = 0.5$ was met. Thus, it is possible to find a point along this line for which the error at x_m can be made lower than that of the previous case.

Let $E_{N,L3}(x)$ denote the error function corresponding to the lowpass function given by Eq. (22.36). The various steps involved in minimizing the error are:

(i) Locate the point x_m at which the error is maximum for the previous design.
(ii) Evaluate the magnitudes of the functions $B_{N,L}(x)$, $B_{N,L+1}(x)$ and $B_{N,L+2}(x)$ at x $= 0.5$ and x_m.
(iii) Obtain the linear condition for β_1 and β_2 for which the reconstruction error is zero at $x = 0.5$.
(iv) Minimize $E_{N,L3}(x)$ at x_m, by using Hooke and Jeeves optimization [34] routine and arrive at the optimal values of β_1 and β_2. The search procedure terminates when $E_{N,L3}(x_m)$ reduces to zero, or the condition for monotonicity is violated, that is, β_1 becomes negative.

At this point, a question that naturally arises is as follows: by minimizing the error only at x_m, does the point of maximum error shift and result in a value greater than the one with which we started at x_m? Although no analytical reason could be formulated, we have not found any contradiction to the assumption in any of the designs which have been verified for $N = 5$ to 55. The plot of the magnitude and the error characteristics of the QMF structure for $N = 7$, designed by using the present method, is shown in Fig. 22.12; as will be seen, the error is virtually zero. The maximum error of some of the designs, obtained by the method discussed, is also listed in Table 22.5. As is obvious, the maximum error in this design is much lower than in the previous one; the reduction is particularly significant for lower order filters.

Generally, it has been found that for most cases, the error at x_m could not be reduced to zero, because the limiting value of $\beta_1 = 0$ is attained first. The error can be reduced further, provided we compromise on the monotonic behaviour of the response characteristic; this is not a topic of interest in the present discussion. However, in those cases where we have been able to reduce the error at x_m to zero, it has been observed that the maximum error occurs at four other points but the values are extremely low, as seen from Table 22.5.

In all the results discussed so far, we have made the basic assumption that it is possible to design the QMF structure with an odd-length impulse response. As stated earlier, we need to generate an equivalent even-length for a realizable QMF structure, which satisfies Eq. (22.41). The magnitude and the error characteristics of an equivalent even-length for $N = 7$, is also shown in Fig. 22.12. It is observed that the process of conversion has introduced ripples in the error function, but the transition width has decreased considerably, a compromise that always exists.

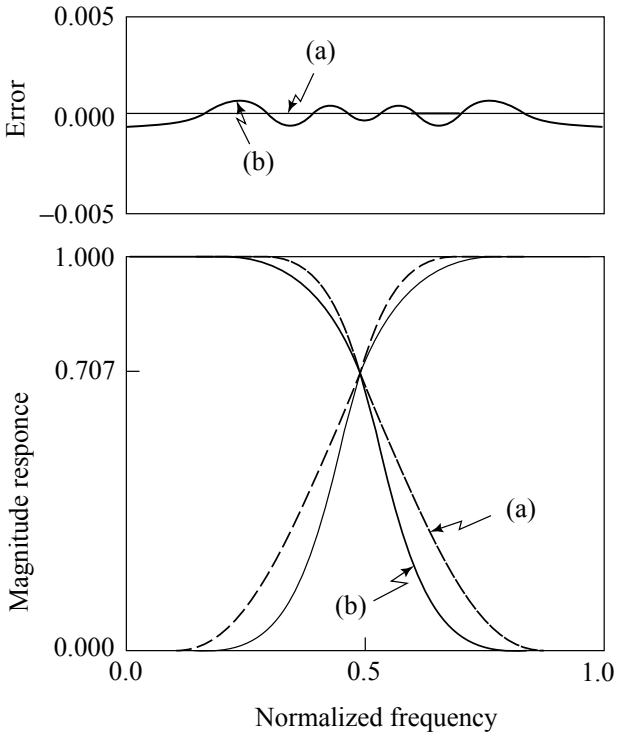

Fig. 22.12 The magnitude and error response of a monotonic QMF with $N = 7$, **a** odd-length $H(z)$ **b** even-length $H(z)$

A true comparison of performance between the class of QMF studied here and those obtained by using the optimization techniques cannot really be carried out because of the difference in the formulation of the problems. In the designs developed here, we are primarily interested in the monotonic behaviour of the magnitude characteristics, while the optimization techniques aim at minimizing the average error. Obviously, the numerical methods can result in ripples in both passband and stopband. However as an illustrative example, different responses of a 16th order filter are shown in Fig. 22.13. The designs named 16A and 16B are those which are obtained by the method in [32]; the coefficients for these designs are readily available in [30]. The QMF structures developed here generally have lower reconstruction error and greater transition width than those resulting from numerical methods.

22.8 Conclusion

In this chapter, we have discussed a new approach for the design of MAXFLAT FIR filters by using the Bernstein polynomial and have established a simple relationship between the other known methods for this purpose. We proposed a novel method to design MAXFLAT filters with arbitrary magnitude specifications. A new, matrix approach for determining the coefficients of MAXFLAT filters has also been discussed. For the case where the coefficients are associated with powers of cosine, it was shown that the transformation matrix is a product of a Q-matrix and a sim-

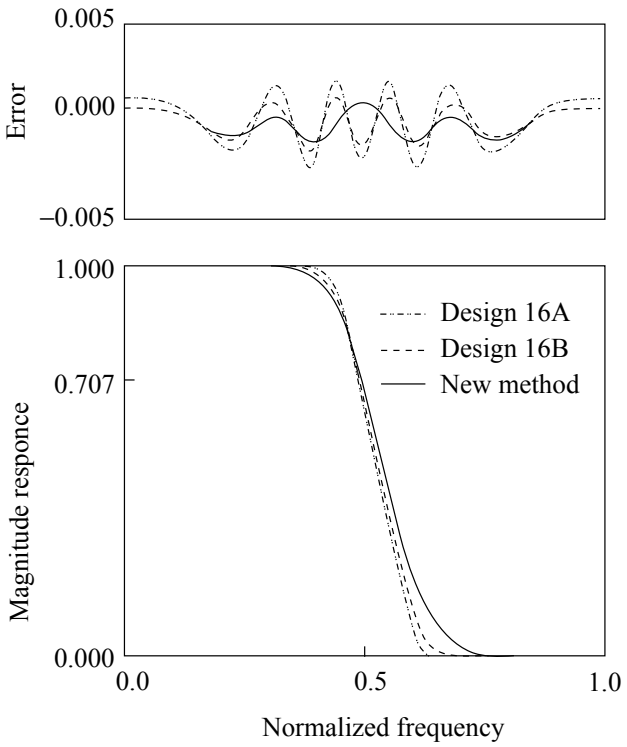

Fig. 22.13 The magnitude and error response of QMFs with $N = 8$

ple diagonal matrix. The transformation matrix required to generate b_i's could be generated either directly or recursively.

We proposed a new technique for the design of monotonic filters meeting the desired magnitude specification at the passband edge exactly. We have also established a link between the earlier works in this area. We have brought out the advantages of the new method by example of diverse specifications. The application of MAXFLAT and monotonic FIR filters to the design of QMFs is discussed in details. First, we discussed an optimal method for designing MAXFLAT QMF structures. Next, we extended the design to generate a new class of monotonic QMFs with zero reconstruction error at $\omega = \pi/2$, by using a linear combination of two MAXFLAT characteristics. Finally, we minimized the maximum error resulting from the previous design, by a simple two-variable optimization technique. Monotonic QMFs, discussed here, can become a good starting point for the optimization techniques, a problem generally faced in these methods.

Chapter 23
On the Design of FIR Notch Filters

Abstract A novel approach for designing linear phase FIR notch filters has been proposed. Mathematical formulas for computing the weights required in the design have been derived. Exact notch frequency point, as specified, can be achieved through the proposed technique. Design examples have also been given.

Keywords Notch filters · FIR digital filters · Signal processing

23.1 Introduction

Digital notch filters find extensive use in various fields such as automatic control, biomedical engineering, communication and radar. A variety of approaches are available for the design of IIR as well as FIR notch filters [1–3]. We present here a novel approach for designing linear phase FIR notch filters, which is based on the transformation of a lowpass filter. The method allows realization of the desired notch frequency (ω_d) exactly besides resulting in a 3-dB rejection bandwidth ($\overline{\text{BW}}$), which is better than the specified one. The notch filter may be designed with a maximally flat (MF) or equiripple characteristics. We shall discuss the MF design in detail, and then briefly mention the equiripple case.

23.2 Design

Let $H_{LP}(\omega)$ be the frequency response of a zero-phase lowpass FIR filter such that

$$H_{LP}(0) = 1, \tag{23.1a}$$

$$H_{LP}(\omega_d) = 1/2, \tag{23.1b}$$

S. C. Dutta Roy, *Topics in Signal Processing*,
https://doi.org/10.1007/978-981-13-9532-1_23

and

$$H_{LP}(\pi) = 0 \tag{23.1c}$$

We can obtain a notch filter by using the transformation [2]

$$H(\omega) = 2H_{LP}(\omega) - 1 \tag{23.2}$$

Using Eq. (23.1a–23.1c) in Eq. (23.2), results in the notch filter with

$$H(0) = 1, \tag{23.3a}$$

$$H(\pi) = -1, \tag{23.3b}$$

and

$$H(\omega_d) = 0, \tag{23.3c}$$

If $H_{LP}(\omega)$ is maximally flat with flatness distributed between $\omega = 0$, and $\omega = \pi$, then so is $H(\omega)$. The design problem of a notch filter is thus reduced to that of designing a maximally flat lowpass filter $H_{LP}(\omega)$ such that $H_{LP}(\omega) = 1/2$ at $\omega = \omega_d$.

A maximally flat lowpass filter $H_{LP}(\omega)$ can be obtained from the technique suggested by Thajchayapong et al. [4] which is a modification of Miller's design [5]. Miller has suggested transforming the zero phase polynomial

$$H_0(z) = \sum_{i=0}^{n} C_i(z^i + z^{-i}) \tag{23.4}$$

into a rational function $\hat{H}(q)(q = \sigma + j\Omega)$ through the bilinear transformation $z^{-1} = (1 - q)/(1 + q)$. Then by imposing the condition of maximal flatness of $\hat{H}(q)$, for $q = j\Omega$ with mth degree of flatness at $\Omega = \infty$ (i.e., $\omega = \pi$; because $\Omega = \tan \omega/2$), the resulting analog filter has the transfer function [4], Eq. (23.2)

$$\hat{H}(j\Omega) = \frac{1}{(1 + \Omega^2)^n} \left\{ \sum_{l=0}^{n-m} \binom{n}{l} \Omega^{2l} \right\} \tag{23.5}$$

Clearly, for a given n, Eq. (23.5) yields n different lowpass filters as m varies from 1 to n. Thajchayapong et al. [4] have suggested a method of obtaining transitional filters between two adjacent values of m, say m_1 and $m_2 = m_1 - 1$, by modifying Eq. (23.5) as follows:

$$\hat{H}_1(j\Omega) = \frac{1}{(1 + \Omega^2)^n} \left\{ \sum_{l=0}^{n-m_1} \binom{n}{l} \Omega^{2l} + C_{n-m_2} \Omega^{2(n-m_2)} \right\} \tag{23.6}$$

The value of constant C_{n-m_2} in Eq. (23.6) is found by forcing $\hat{H}_1(j\Omega)|_{\Omega=\Omega_d} = 1/2$, where $\Omega_d = \tan(\omega_d/2)$. This gives us

$$C_{n-m_2} = \frac{1}{\Omega_d^{2(n-m_2)}}\left[\frac{(1+\Omega_d^2)^n}{2} - \sum_{l=0}^{n-m_1}\binom{n}{l}\Omega_d^{2l}\right] \tag{23.7}$$

Equation (23.6) is now transformed back to the z-plane by using the transformation $j\Omega = (1-z^{-1})/(1+z^{-1})$,

$$\left.\begin{aligned}\bar{H}_1(z) &= \hat{H}_1(j\Omega)|_{j\Omega=(1-z^{-1})/(1+z^{-1})} \\ &= 2^{-2n}(1+z^{-1})^{2n}z^n\left\{\sum_{l=0}^{n-m_1}\binom{n}{l}(-1)^l((1-z^{-1})/(1+z^{-1}))^{2l}\right. \\ &\quad \left. + C_{n-m_2}(-1)^{(n-m_2)}((1-z^{-1})/(1+z^{-1}))^{2(n-m_2)}\right\}\end{aligned}\right. \tag{23.8}$$

Using the Binomial expansion for generic power k, i.e.

$$(1+z^{-1})^k = \sum_{q=0}^{k}\binom{k}{q}z^{-q} \tag{23.9}$$

and rearranging the terms (after somewhat involved algebraic manipulations), we can write Eq. (23.8) as

$$\begin{aligned}\bar{H}_1(z) = 2^{-2n}z^n\Bigg[\sum_{i=0}^{2n}\Bigg\{&\sum_{l=0}^{n-m_1}\sum_{q=0}^{2l}(-1)^{l+q}\binom{n}{l}\binom{2l}{q} \\ &\times\binom{2n-2l}{i-q} + C_{n-m_2}(-1)^{n-m_2}\sum_{q=0}^{2m_2}(-1)^{i-q}\binom{2m_2}{q} \\ &\binom{2n-2m_2}{i-q}\Bigg\}z^{-i}\Bigg]\end{aligned} \tag{23.10}$$

A causal, FIR lowpass filter $\bar{H}_2(z)$ is related to a zero phase FIR lowpass filter $\bar{H}_1(z)$ by

$$\bar{H}_2(z) = z^{-n}\bar{H}_1(z) \tag{23.11}$$

Also, we know,

$$\bar{H}_2(z) = \sum_{i=0}^{2n}h(i)z^{-i},\ n = (N-1)/2 \tag{23.12}$$

where N is the filter length. Comparing Eqs. (23.10), (23.11) and (23.12), we obtain

$$h(i) = 2^{-2n}\left[\sum_{l=0}^{n-m_1}\sum_{q=0}^{2l}(-1)^{l+q}\binom{n}{l}\binom{2l}{q}\binom{2n-2l}{i-q} + C_{n-m_2}(-1)^{n-m_2}\sum_{q=0}^{2m_2}(-1)^{i-q}\binom{2m_2}{q}\binom{2n-2m_2}{i-q}\right] \tag{23.13}$$

Changing i to $(n-i)$ in Eq. (23.13), we may express $h(n-i)$ as

$$h(n-i) = A(i) + C_{n-m_2}B(i) \tag{23.14a}$$

where

$$A(i) = 2^{-2n}\sum_{l=0}^{n-m_1}\sum_{q=0}^{2l}(-1)^{l+q}\binom{n}{l}\binom{2l}{q}\binom{2n-2l}{n-i-q} \tag{23.14b}$$

$$B(i) = 2^{-2n}\sum_{q=0}^{2m_2}(-1)^{q+m_2+i}\binom{2m_2}{q}\binom{2n-2m_2}{n-i-q} \tag{23.14c}$$

The frequency response $H_{LP}(\omega)$ of zero phase lowpass filter ($\bar{H}_1(z)$) is given by

$$H_{LP}(\omega) = \bar{H}_1(z)|_{z=e^{j\omega}} \triangleq \sum_{i=0}^{n} a_i \cos(i\omega) \tag{23.15}$$

Also, a zero phase, notch filter $H(\omega)$ is expressed as

$$H(\omega) = \sum_{i=0}^{n} d_i \cos(i\omega) \tag{23.16}$$

Using Eqs. (23.2), (23.15) and (23.16), we finally obtain

$$d_i = \begin{cases} 2h(n) - 1, & i = 0 \\ 4h(n-i), & i = 1, 2, \ldots, n \end{cases} \tag{23.17}$$

Hence, the coefficients d_i of the desired notch filter (having notch at $\omega = \omega_d$) are computed from Eqs. (23.14a–23.14c) and (23.17).

The values of n and m_1, required for computation of $h(n-i)$ are obtained from the empirical formulas, proposed earlier by the authors in [6], and reproduced here for completeness.

$$n \geq \text{Integer part of } [1/2\{(\pi/\overline{\text{BW}})^2 - (\pi/\overline{\text{BW}}) + 3\}] \tag{23.18}$$

$$m_1 \geq \text{Integer part of } [n(0.55 + 0.5\cos\omega_d)] \tag{23.19}$$

We now study the performance of the aforementioned design of the notch filter.

23.3 Design Examples and Performance

Example Design a linear phase FIR notch filter with notch frequency $\omega_d = 0.2\pi$ radian; and 3-dB rejection bandwidth $\overline{\text{BW}} \leq 0.5$ rad

(i) Compute the values of n and m_1 from Eqs. (23.18) and (23.19), respectively. These are found to be $n = 18$ and $m_1 = 17$.

(ii) By using $\Omega_d = \tan(\omega_d/2)$, we get $\Omega_d = \tan(0.1\pi) = 0.324919$ rad. From Eq. (23.7), we obtain the value of C_{n-m_2}, with $n = 18$ and $m_2 = m_1 - 1 = 16$ as 12.953.

(iii) By using Eqs. (23.14a–23.14c), we get $A(i)$, $B(i)$ and $h(n-i)$, for $i = 0$–18 and then compute d_i from Eq. (23.17). These values are given in Table 23.1.

Table 23.1 Values of $A(i)$, $B(i)$, $h(n-i)$ and weights d_i, $i = 0, 1, 2, \ldots, 18$ for a notch filter example with $\omega_d = 0.2\pi$ rad and $(\overline{\text{BW}}) \leq 0.5$ rad

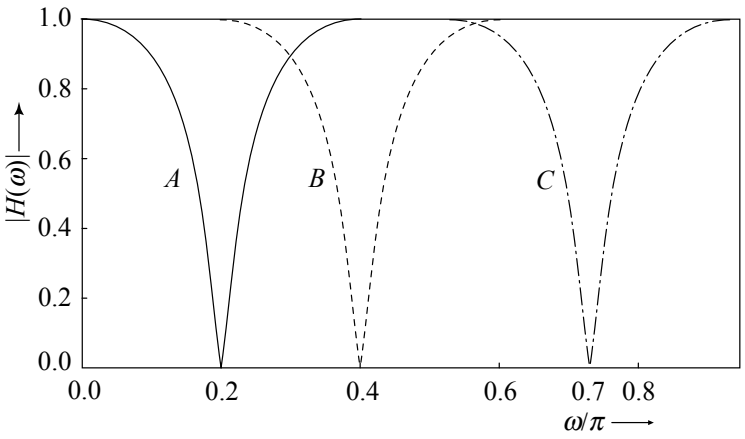

Fig. 23.1 Frequency response $|H(\omega)|$ of the designed notch filters A, B, C, whose parameters are given in Table 23.2

Table 23.2 Various parameters for Fig. 23.1

Response curve	ω_d (rad)	$\overline{\text{BW}}$ (rad)		$\left(n = \frac{N-1}{2}\right)$	m_1	C_{n-m_2}
		Specified	Realized			
A	0.2π	0.50	0.490	18	17	12.953
B	0.4π	0.45	0.446	22	15	15912.430
C	0.7π	0.40	0.399	28	7	310229.079

(iv) The magnitude response of the $\left(\sum_{i=0}^{18} d_i \cos i\omega\right)$ designed notch filter is shown in Fig. 23.1 (curve A). The value of 3-dB rejection bandwidth ($\overline{\text{BW}}$) is found to be 0.49 rad, which is better than the specified one. The magnitude responses for a few other designs using the above methodology are also shown in the same figure (curves B and C) and the related parameters are given in Table 23.2.

23.3.1 Equiripple Design

The proposed design procedure can also be adapted for an equiripple notch filter, $\bar{H}(\omega)$ by using an equiripple LPF $\bar{H}_{LP}(\omega)$ in Eq. (23.2). If we constrain $\bar{H}_{LP}(\omega)$ as

$$\bar{H}_{LP}(\omega) = \begin{cases} 1/2(2 \pm \delta_1), & 0 < |\omega| < B_1 \\ 1/2(1 \pm \delta_2), & |\omega| = \omega_d \\ \pm\delta_1/2, & B_2 < |\omega| < \pi \end{cases} \tag{23.20}$$

where $B_2 - B_1 = (\overline{\text{BW}})$, δ_1 and δ_2 are, respectively, the maximum ripples in the passband and the stopband of the LPF, then the resulting notch filter will have

$$\bar{H}(\omega) = \begin{cases} 1 \pm \delta_1, & 0 < |\omega| < B_1 \\ \pm\delta_2, & |\omega| = \omega_d \\ -1 \pm \delta_1, & B_2 < |\omega| < \pi \end{cases} \tag{23.21}$$

The equiripple linear phase LPF $\bar{H}_{LP}(\omega)$ may be obtained by any of the conventional methods such as the McClellan and Parks algorithm.

23.4 Conclusion

An analytical approach by which explicit formulas for computation of the exact weights of a linear phase FIR notch filter has been proposed. This design approach is particularly attractive when the available memory is limited. Also, we obtain the exact notch frequency by the suggested method. Moreover, the design procedure presented in this chapter has an edge over the design methods, based on optimization/iterative techniques, since the latter requires more time of computation.

Chapter 24
A Simple Solution for the Analytic Inversion of Van der Monde and Confluent Van der Monde Matrices

Abstract In this chapter, a simple and elegant approach is suggested for the explicit, analytic inversion of the Van der Monde and Confluent Van der Monde matrices, based on known results for certain polynomial interpolation problems. These matrices arise in a number of signal processing applications, and the closed-form results should be of interest to the signal processing community.

Keywords Matrix inversion · Van der Monde matrix

24.1 Introduction

Inversion of a Van der Monde matrix is often required in many signal processing situations, such as signal reconstruction, spectral estimation, DOA estimation via sensor array, system identification, etc. [1, 2]. Neagoe [3] has recently derived an exact expression, for the inverse of a Van der Monde matrix, using the classical approach of determinants.

In this chapter, we suggest a much simpler, alternative approach for the explicit inversion of this matrix, which makes use of the well known connection between Van der Monde matrices and the Lagrange interpolation formula [1, 4]. It is shown that this approach can also be easily extended for the explicit inversion of a related matrix, viz, the Confluent Van der Monde matrix [4] associated with a class of interpolation problems, with derivative constraints, which are often formulated in beamforming problems [2].

24.2 Inversion Formula for Van der Monde Matrix

Let **A** be a Van der Monde matrix of size $N \times N$ over C^N, given by

$$\mathbf{A} = \begin{bmatrix} 1 & a_1 & a_1^2 & \cdots & a_1^{N-1} \\ 1 & a_2 & a_2^2 & \cdots & a_2^{N-1} \\ & & & & \\ & & & & \\ 1 & a_N & a_N^2 & \cdots & a_N^{N-1} \end{bmatrix} \quad a_i \neq a_j \quad \forall i \neq j \tag{24.1}$$

Consider the set of linear equations given by

$$\mathbf{Ay} = \mathbf{b} \tag{24.2a}$$

so that

$$\mathbf{y} = \mathbf{A}^{-1}\mathbf{b}, \tag{24.2b}$$

which is guaranteed to exist for distinct $\{a_i, i = 1, \ldots, N\}$. It is well known that the equation set (24.2a, 24.2b) arises in the problem of finding the coefficients of a polynomial of order $N - 1$ which passes through N given points. Let $f(x)$ be the required polynomial s.t.

$$f(a_i) = b_i \; i = 1, 2, \ldots, N \tag{24.3}$$

The Lagrange interpolation formula yields the unique and well-known solution for such a polynomial viz,

$$f(x) = \sum_{i=1}^{N} b_i l_i(x) \tag{24.4a}$$

where b, is the ith element of the vector **b** and $l_i(x)$ is given by

$$l_i(x) = \prod_{j-1, j \neq i}^{N} \frac{x - a_j}{a_i - a_j} \quad i = 1, 2, \ldots, \; N \tag{24.4b}$$

The polynomial $l_i(x)$ can be expanded as

$$l_i(x) = \alpha_0^{(i)} x^{N-1} - \alpha_1^{(i)} x^{N-2} + \cdots + (-1)^k \alpha_k^{(i)} x^{N-k-1} + \cdots + (-1)^{N-1} \alpha_{N-1}^{(i)}, \quad i = 1, 2, \ldots, N \tag{24.5a}$$

where

$$\alpha_k^{(i)} = \frac{1}{\prod\limits_{j=i, j\neq i} (a_i - a_j)} \sum_{i_1 \neq i}^{N} \sum_{i_2 \neq (i_1, i)}^{N} \cdots \sum_{i_k \neq (i_1 \cdots i_{k-1}, i)}^{N} a_{i_1} a_{i_2} \ldots a_{i_k}$$
$$i = 1, 2, \ldots N; k = 1, 2, \ldots N + 1 \tag{24.5b}$$

Using Eq. (24.5a) in Eq. (24.4a), and combining the terms of same power, we get

$$\begin{aligned} f(x) = {} & x^{N-1}(\alpha_0^{(1)} b_1 + (\alpha_0^{(2)} b_2 + \cdots + a_0^{(N)} b_N) - x^{N-2}(\alpha_1^{(1)} b_1 \\ & + \alpha_1^{(2)} b_2 + \cdots + \alpha_1^{(N)} b_N) + \cdots + (-1)^k x^{N-k-1}(\alpha_k^{(1)} b_1 \\ & + \alpha_k^{(2)} b_2 + \cdots + \alpha_k^{(N)} b_N) + \cdots + (-1)^{N-1}(\alpha_{N-1}^{(1)} b_1 + \alpha_{N-1}^{(2)} b_2 \cdots + \alpha_{N-1}^{(N)} b_N) \end{aligned} \tag{24.6}$$

Comparison of Eq. (24.6) with Eq. (24.2a, 24.2b) yields the ith coefficient of $f(x)$ (i.e. coefficient of the term x^i) which forms the $(i + 1)$th element of the vector y. Hence Eq. (24.3) becomes

$$\mathbf{y} = \begin{bmatrix} (-1)^{N-1}\alpha_{N-1}^{(1)} & (-1)^{N-1} & \alpha_{N-1}^{(2)} & \cdots & (-1)^{N-1}\alpha_{N-1}^{(m)} & \cdots & (-1)^{N-1} & \alpha_{N-1}^{(N)} \\ (-1)^{N-k}\alpha_{N-k}^{(1)} & (-1)^{N-k} & \alpha_{N-k}^{(2)} & \cdots & (-1)^{N-k}\alpha_{N-k}^{(m)} & \cdots & (-1)^{N-k} & \alpha_{N-k}^{(N)} \\ \alpha_0^{(1)} & & \alpha_0^{(2)} & \ldots & \alpha_0^{(m)} & & & \alpha_0^{(N)} \end{bmatrix} \begin{bmatrix} b_1 \\ b_k \\ b_N \end{bmatrix} \tag{24.7}$$

This gives

$$\mathbf{A^{-1}} = \begin{bmatrix} (-1)^{N-1}\alpha_{N-1}^{(1)} & (-1)^{N-1} & \alpha_{N-1}^{(2)} & \cdots & (-1)^{N-1} & \alpha_{N-1}^{(m)} & \cdots & (-1)^{N-1} & \alpha_{N-1}^{(N)} \\ (-1)^{N-k}\alpha_{N-k}^{(1)} & (-1)^{N-k} & \alpha_{N-k}^{(2)} & \cdots & (-1)^{N-k} & \alpha_{N-k}^{(m)} & \cdots & (-1)^{N-k} & \alpha_{N-k}^{(N)} \\ \alpha_0^{(1)} & & & \alpha_0^{(2)} & \ldots & \alpha_0^{(m)} & & & \alpha_0^{(N)} \end{bmatrix} \tag{24.8}$$

which is identical to the result in [3].

24.3 Inversion Formula for the Confluent Van der Monde Matrix

An interesting and useful application of this method arises in the inversion of a matrix **A** defined by

$$\mathbf{A} = \begin{vmatrix} 1 & a_1 & a_1^2 & \cdots & a_1^{2N-1} \\ 1 & a_2 & a_2^2 & \cdots & a_2^{2N-1} \\ . & . & . & . & . \\ 1 & a_N & a_N^2 & \cdots & a_N^{2N-1} \\ 0 & 1 & 2a_1 & \cdots & (2N-1)a_1^{2N-2} \\ 0 & 1 & 2a_2 & \cdots & (2N-1)a_2^{2N-2} \\ . & . & . & . & . \\ 0 & 1 & 2a_N & \cdots & (2N-1)a_N^{2N-2} \end{vmatrix} a_i \neq a_j, \forall i \neq j \tag{24.9}$$

where the top N rows correspond to a Van der Monde matrix and the bottom N rows to the derivatives of top rows w.r.t. $\{a_1, a_2, \ldots, a_N\}$, respectively.

This matrix is the well-known Confluent Van der Monde [4] matrix. It arises in the following kind of polynomial interpolation problems: find a polynomial $f(x)$ of degree $(2N-1)$ such that

$$f(a_i) = b_i; \quad f'(a_i) = b_{N+i} 1 \leq i \leq N \tag{24.10}$$

Such problems are often formulated in the context of beamforming when, in addition to steering nulls of a sensor array in certain desired directions, one may want to flatten these nulls so as to handle wideband and moving jammers [2].

Returning to the inversion of A, it is well known that the solution to the interpolation problem of (24.10) is obtained by choosing $f(x)$ to be the Hermite polynomial [5] given by

$$f(x) = \sum_{i=1}^{N} [1 - 2(x - a_i) l_i^2(a_i)]\, l_i'(x) b_i + \sum_{i=1}^{N} (x - a_i) \quad l_i^2(x) b'_{N+1} \tag{24.11}$$

Using this result and repeating the steps earlier, it is easy to obtain the inverse of A as given in Eq. (24.12a).

$$A^{-1} = \begin{bmatrix} \beta_0^{(1)} t_1 & \cdots & \beta_0^{(m)} t_m & \cdots & \beta_0^{(N)} t_N - \beta_0^{(1)} a_1 & \cdots & -\beta_0^{(m)} a_m & \cdots & -\beta_0^{(N)} a_N \\ \beta_k^{(1)} t_1 + 2l_1' \beta_{k-1}^{(1)} \cdots \beta_k^{(m)} t_m + 2l_m' \beta_{k-1}^{(m)} \cdots \beta_k^{(N)} t_N + 2l_N' \beta_{k-1}^{(N)} - (\beta_k^{(1)} a_1 + \beta_{k-1}^{(1)}) \cdots - (\beta_k^{(m)} a_m + \beta_{k-1}^{(m)}) \ldots - (\beta_k^{(N)} a_N' + \beta_{k-1}^{(N)}) \\ -2l_1' \beta_{2N-1}^{(1)} & \cdots & -2l_m' \beta_{2N-1}^{(m)} & \cdots & -2l_N' \beta_{2N-1}^{(N)} & \beta_{2N-1}^{(1)} & \cdots & \beta_{2N-1}^{(m)} & \cdots & \beta_{2N-1}^{(N)} \end{bmatrix} \tag{24.12a}$$

where

$$\beta_k^{(i)} = (-1)^{k+1} \sum_{j=1}^{N} \alpha_j^{(i)} \alpha_{2N-1\cdot k-j}^{(i)} \quad i = 1, 2, \ldots, N; k = 0, 1, \ldots, 2N-1 \tag{24.12b}$$

and

$$l_i' = l_i'(x)|_{x=a_i}; \quad t_i = 1 + 2a_i l_i' \quad i = 1, 2, \ldots, N \tag{24.12c}$$

Chapter 25
A New Canonic Lattice Realization of Arbitrary FIR Transfer Functions

Abstract A new lattice structure is presented for realizing a pair of arbitrary FIR transfer functions of the same order, which is canonic in multipliers as well as delays. By a simple modification of the procedure, one can also obtain a canonic realization of a single FIR transfer function. The problem cases have been discussed, along with their solutions, and the limitations of the method have been pointed out. Examples have been worked out to illustrate the theory.

Keywords FIR lattice · Canonic realization · Linear phase design · Digital filter

25.1 Introduction

The FIR lattice has received considerable attention in the digital signal processing literature because of modularity and robustness to coefficient quantization errors [1, 2]. The most popular form of the structure is shown in Fig. 25.1, with $k_a^{(i)} = k_b^{(i)} = k_i$ and $H_0(z) = G_0(z) = 1$. It realizes the transfer function

$$H_N(z) = X_N(z)/X_0(z) = 1 + a_1^{(N)} z^{-1} + a_2^{(N)} z^{-2} + \cdots + a_N^{(N)} z^{-N} \tag{25.1}$$

and its mirror image transfer function

$$G_N(z) = X'_N(z)/X_0(z) = z^{-N} H_N(z^{-1}) \tag{25.2}$$

Note that $H_N(z)$ and $G_N(z)$ have the same magnitude but equal and opposite phase on $|z| = 1$. Hence for designing a single digital filter with prescribed magnitude specifications, it is wasteful in multipliers, requiring double the number as compared to canonic realization. By a clever manipulation of the relevant equations, Makhoul [3] showed that each two multiplier section can be converted to a single multiplier one, but scaling is needed for the overall lattice—either at the input or at the output or at selected nodes, and thereby achieve near canonicity.

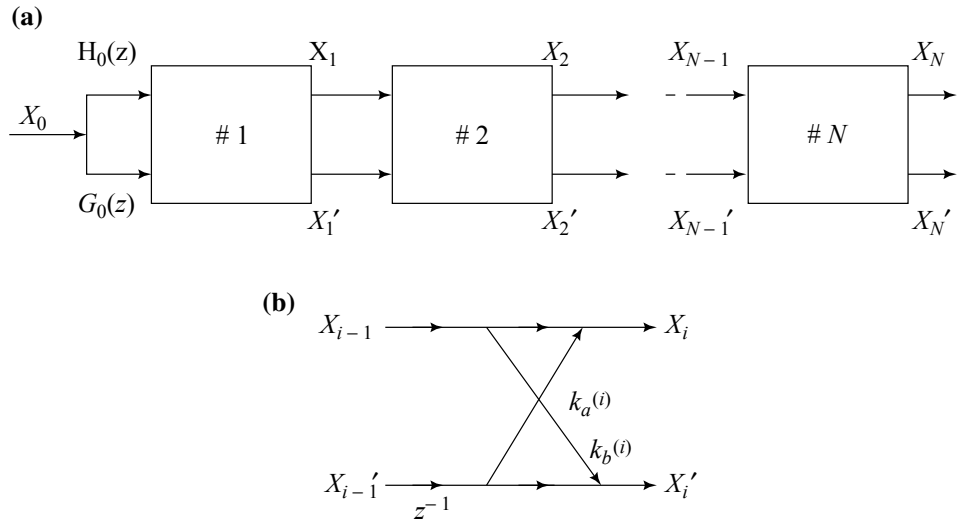

Fig. 25.1 **a** A generalized FIR lattice structure; **b** composition of the i-th section of (**a**). For the conventional structure, $H_0(z) = G_0(z) = 1$ and $k_a^{(i)} = k_b^{(i)} = k_i$

The usual treatment of the FIR lattice is to assume the structure of Fig. 25.1, with $k_a^{(i)} = k_b^{(i)} = k_i$ and $H_0(z) = G_0(z) = 1$, and then to analyse it to derive the following properties and design equations:

$$H_i(z) = X_i(z)/X_0(z) = 1 + a_1^{(i)} z^{-1} + a_2^{(i)} z^{-2} + \cdots + a_i^{(i)} z^{-i} \tag{25.3}$$

$$G_i(z) = X_i'(z)/X_0(z) = z^{-i} H_i(z^{-1}), \tag{25.4}$$

$$k_i = a_i^{(i)}, \tag{25.5}$$

$$a_n^{(i-1)} = [a_n^{(i)} - k_i a_{i-n}^{(i)}]/(1 - k_i^2), \quad 1 \le n \le (i-1), \tag{25.6}$$

$$i = N, N-1, \ldots, 1. \tag{25.7}$$

In [4], this lattice structure was derived from the digital two-pair approach of Mitra [1], where the question was also raised as to whether relationships other than that given by Eq. (25.4) are possible to be realized. In a subsequent paper [5], this question was answered in the affirmative by deriving a new lattice structure for satisfying the relationship

$$G_i(z) = z^{-i} H_i(-z^{-1}) \tag{25.8}$$

Equation (25.8) implies that $H_i(z)$ and $G_i(z)$ are complementary filters, i.e. if $H_i(z)$ is low-pass, then $G_i(z)$ is high-pass and vice versa. Such filters, as is well known, are required in cross-over networks for digital stereo and in multi-rate signal processing. This structure has cascade sections of the form of Fig. 25.1 with $H_0(z) = G_0(z) = 1$

and $k_a^{(i)} = -(1)^i k_b^{(i)}$; obviously, if i is even, then the two multipliers are equal, as is the case for Eq. (25.2), while if i is odd, then they are equal and opposite.

The present chapter is a generalization of [5], in which $H_N(z)$ and $G_N(z)$ are two arbitrary transfer functions, given by

$$H_N(z) = a_0^{(N)} + a_1^{(N)} z^{-1} + a_2^{(N)} z^{-2} + \cdots + a_N^{(N)} z^{-N}, \tag{25.9}$$

$$G_N(z) = b_o^{(N)} + b_1^{(N)} z^{-1} + b_2^{(N)} z^{-2} + \cdots + b_N^{(N)} z^{-N}. \tag{25.10}$$

This is achieved by using the structure of Fig. 25.1 as it is i.e. by using two different parameters in each lattice section and by keeping $H_0(z)$ and $G_0(z)$ unspecified. It is shown that the resulting structure is canonic in delays as well as multipliers. A simple modification of the procedure is shown to be applicable to a situation where a single transfer function is required to be realized canonically. Some examples are included to illustrate the application of the theory.

There exist some cases where the new procedure cannot be applied directly. It is shown that simple modifications obviate the problems without changing canonicity. There exist some other cases where the new procedure yields non-canonic solutions only; these have been pointed out.

25.2 Derivation of the New Structure

Consider the lattice section shown in Fig. 25.1b with $i = N$ and $H_N(z) = X_N(z)/X_0(z)$ and $G_N(z) = X'_N(z)/X_0(z)$ as given by Eqs. (25.9) and (25.10), respectively. It will now be explored whether by choosing $k_a^{(N)}$ and $k_b^{(N)}$ appropriately, one can make the transfer functions $H'(z) = X_{N-1}(z)/X_0(z)$ and $G'(z) = X'_{N-1}(z)/X_0(z)$ to be of order $N - 1$. It is easily shown that

$$H_N(z) = H'(z) + z^{-1} k_a^{(N)} G'(z) \tag{25.11}$$

$$G_N(z) = z^{-1} G'(z) + k_b^{(N)} H'(z) \tag{25.12}$$

Solving Eqs. (25.11) and (25.12), we get

$$H'(z) = K_N [H_N(z) - k_a^{(N)} G_N(z)] \tag{25.13}$$

$$G'(z) = K_N z [G_N(z) - k_b^{(N)} H_N(z)] \tag{25.14}$$

where

$$K_N = 1/[1 - k_a^{(N)} k_b^{(N)}] \tag{25.15}$$

Substituting for $H_N(z)$ and $G_N(z)$ from Eqs. (25.9) and (25.10), we get

$$H'(z) = K_N\{[a_0^{(N)} - k_a^{(N)}b_0^{(N)}] + [a_1^{(N)} - k_a^{(N)}b_1^{(N)}]z^{-1} + \cdots + [a_N^{(N)} - k_a^{(N)}b_N^{(N)}]z^{-N}\} \tag{25.16}$$

$$G'(z) = K_N z\{[b_0^{(N)} - k_b^{(N)}a_0^{(N)}] + [b_1^{(N)} - k_b^{(N)}a_1^{(N)}]z^{-1} + \cdots + [b_N^{(N)} - k_b^{(N)}a_N^{(N)}]z^{-N}\} \tag{25.17}$$

Note that if one chooses

$$k_a^{(N)} = a_N^{(N)}/b_N^{(N)} \text{ and } k_b^{(N)} = b_0^{(N)}/a_0^{(N)} \tag{25.18}$$

then both $H'(z)$ and $G'(z)$ will be of order N—l and can be re-designated as $H_{N-1}(z)$ and $G_{N-1}(z)$, respectively. Also note that the coefficients of the two transfer functions are given by

$$\begin{aligned} a_n^{(N-1)} &= K_N[a_n^{(N)} - k_a^{(N)}b_n^{(N)}], \\ b_n^{(N-1)} &= K_N[b_{n+1}^{(N)} - k_b^{(N)}a_{n+1}^{(N)}] \\ n &= 0, 1, 2, \ldots, N-1 \end{aligned} \tag{25.19}$$

We have thus achieved our objective and the procedure can now be repeated till we get

$$H_1(z) = a_0^{(1)} + a_1^{(1)}z^{-1}, G_1(z) = b_0^{(1)} + b_1^{(1)}z^{-1} \tag{25.20}$$

so that by applying Eqs. (25.18) and (25.19) with $N = 1$, we get

$$\begin{aligned} &k_a^{(1)} = a_1^{(1)}/b_1^{(1)}, k_b^{(1)} = b_0^{(1)}/a_0^{(1)}, \\ &H_0(z) = a_0^{(0)} = a_0^{(1)} \text{ and } G_0(z) = b_0^{(0)} = b_1^{(1)}. \end{aligned} \tag{25.21}$$

Summarizing, then, the design equations for the FIR lattice are as follows:

$$\begin{aligned} k_a^{(i)} &= a_i^{(i)}/b_i^{(i)} \text{ and } k_b^{(i)} = b_0^{(i)}/a_0^{(i)}, \\ i &= N, N-1, \ldots 1 \\ a_n^{(i-1)} &= [a_n^{(i)} - k_a^{(i)}b_n^{(i)}]/[1 - k_a^{(i)}k_b^{(i)}], \\ b_n^{(i-1)} &= b_{n+1}^{(i)} - k_b^{(i)}a_{n+1}^{(i)}]/[1 - k_a^{(i)}k_b^{(i)}], \\ n &= 0, 1, 2, \ldots i-1, \\ H_0(z) &= a_0^{(1)} \text{ and } G_0(z) = b_i^{(1)}. \end{aligned} \tag{25.22}$$

Before proceeding further, we consider an example.

Example 1 Let it be required to realize the transfer functions

$$H_3(z) = 1 + z^{-1} + z^{-2} + z^{-3}, \tag{25.23}$$

$$G_3(z) = 1 + 2z^{-1} + 3z^{-2} + 4z^{-3} \tag{25.24}$$

Using Eq. (25.22), we get

$$\begin{gathered} k_a^{(3)} = 1/4, k_b^{(3)} = 1, \\ a_0^{(2)} = 1, a_1^{(2)} = 2/3, a_2^{(2)} = 1/3, \\ b_0^{(2)} = 4/3, b_1^{(2)} = 8/3, b_2^{(2)} = 4, \\ k_a^{(2)} = 1/12, k_b^{(2)} = 4/3, \\ a_0^{(1)} = 1, a_1^{(1)} = 1/2, b_0^{(1)} = 2, b_1^{(1)} = 4, \\ k_a^{(1)} = 1/8, k_b^{(1)} = 2, H_0(z) = 1, G_0(z) = 4, \end{gathered} \tag{25.25}$$

The realization diagram can now be easily drawn, and is omitted for brevity.

Note, from this example, that $a_0^{(3)} = a_0^{(2)} = a_0^{(1)} = a_0^{(0)} = 1$. Is this in general true? The answer is in the affirmative because $a_0^{(i)} = 1$, (25.22) gives $a_0^{(i-1)} = 1$. This is a simplifying feature, and can be used in actual design. As can easily be verified, this simplification is not valid for the $b_0^{(i)}$ coefficients.

25.3 Cases Requiring Modification of the Procedure

We shall now discuss some cases where the algorithm given in Eq. (23.22) cannot be applied as it is, but some simple modifications overcome the problems. In all these cases, we illustrate the modifications by considering the first step of the procedure, but it should be obvious that such modifications will also work if any of these arise at any intermediate stage.

Case 1 If $b_N^{(N)} = 0$, then $k_a^{(N)} \to \infty$ and the synthesis procedure breaks down. Obviously, we have to synthesize the pair $H_N(z)$ and $G_{N-1}(z)$. The solution to the problem is to synthesize $H_N(z)$ and $G_N(z) = H_N(z) \pm G_{N-1}(z)$, both of which are now of degree N. Finally, one recovers $G_{N-1}(z)$ as $\mp [H_N(z) - G_N(z)]$.

Case 2 If $a_0^{(N)} = 0$, then $k_b^{(N)} \to \infty$. In this case, synthesize $H'_N(z) = H_N(z) \pm G_N(z)$ and $G_N(z)$, and recover $H_N(z)$ as $H'_N(z) \mp G_N(z)$.

Case 3 If $b_N^{(N)} = a_0^{(N)} = 0$, then realize $H'_N(z) = 1 + H_N(z)$ and $G_{N-1}(z)$, as in Case 1, and recover $H_N(z)$ as $H'_N(z) - 1$.

Case 4 If $k_a^{(N)} k_b^{(N)} = 1$, i.e. from (18), $a_N^{(N)} b_0^{(N)} = b_N^{(N)} a_0^{(N)}$, then one cannot proceed to the next stage. One remedy is to realize $H'_N(z) = 1 + H_N(z)$ and $G_N(z)$ as a pair and then recover $H_N(z)$ as $H'_N(z) - 1$.

25.4 Realization of a Single Transfer Function

When it is required to realize a single transfer function of the form Eq. (25.1) by a lattice, the existing procedure, as already mentioned, is wasteful in terms of multipliers. A canonical realization can be obtained by splitting the transfer function into two parts as follows. First, let N be odd; then we decompose $H_N(z)$ as

$$H_N(z) = H_{(N-1)/2}(z) + z^{-(N+1)/2} G_{(N-1)/2}(z) \tag{25.26}$$

where

$$H_{(N-1)/2}(z) = 1 + a_1^{(N)} z^{-1} + \cdots + a_{(N-1)/2}^{(N)} z^{-(N-1)/2}, \tag{25.27}$$

$$G_{(N-1)/2}(z) = a_{(N+1)/2}^{(N)} + a_{(N+3)/2}^{(N)} z^{-1} + \cdots + a_{(N)}^{(N)} z^{-(N-1)/2}. \tag{25.28}$$

Now realize $H_{(N-1)/2}(z)$ and $G_{(N-1)/2}(z)$ as a pair by the new procedure, and combine them as per Eq. (25.26). This realization will be canonic in delays as well as multipliers.

If N is even, then decompose $H_N(z)$ as

$$H_N(z) = H_{(N-2)/2}(z) + z^{-N/2} G_{N/2}(z) \tag{25.29}$$

where

$$H_{(N-2)/2}(z) = 1 + a_1^{(N)} z^{-1} + \cdots + a_{(N-2)/2}^{(N)} z^{-(N-2)/2}, \tag{25.30}$$

$$G_{N/2}(z) = a_{N/2}^{(N)} + a_{(N+2)/2}^{(N)} z^{-1} + \cdots + a_N^{(N)} z^{-N/2} \tag{25.31}$$

We then follow the same procedure as in the odd N case. Here we have exploited the fact that the last term in Eq. (25.9) can be zero but not that in Eq. (25.10). Alternatively, in this case, one could have written $H_N(z)$ as $H_{N/2}(z) + z^{-N/2} G_{N/2}(z)$ by assigning half of the term $a_{N/2}^{(N)} z^{-N/2}$ to each of $H_{N/2}(z)$ and $G_{N/2}(z)$. However, the decomposition given by Eqs. (25.29)–(25.31) is a better one because $k_a^{(N/2)} = 0$. We now illustrate the procedure by two examples.

Example 2 As an example of odd N, let it be required to realize

$$H_3(z) = 1 + z^{-1} + 2z^{-2} + 3z^{-3} \tag{25.32}$$

We first write

$$H_3(z) = (1 + z^{-1}) + z^{-2}(2 + 3z^{-1}) = H_1(z) + z^{-2} G_1(z) \tag{25.33}$$

and then use Eq. (25.22) on the pair $H_1(z)$ and $G_1(z)$; we get

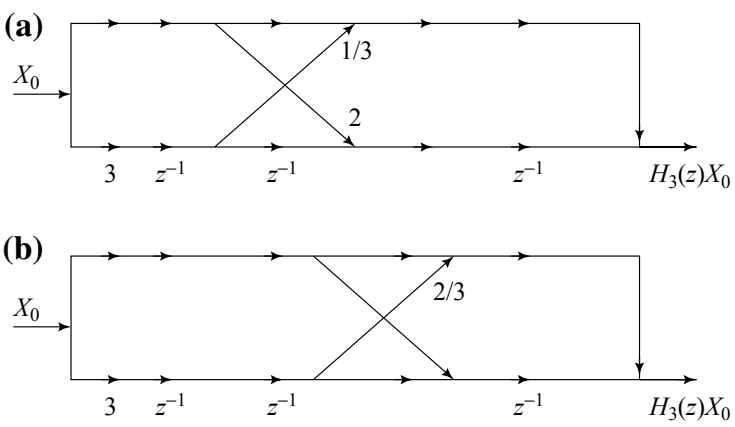

Fig. 25.2 **a** Realization of Eq. (25.32) as per the decomposition of Eq. (25.33) **b** alternative realization of Eq. (25.32) as per the decomposition of Eq. (25.35)

$$k_a^{(3)} = 1/3, k_b^{(3)} = 2, H_0(z) = 1, G_0(z) = 3 \tag{25.34}$$

The realization takes the form shown in Fig. 25.2a. It should be obvious that the decomposition is not unique. For example, we could also have taken

$$H_3(z) = (1 + 2z^{-2}) + z^{-1}(1 + 3z^{-2}) = H_2(z) + z^{-1}G_2(z) \tag{25.35}$$

Using Eq. (25.22) on the pair $H_2(z)$ and $G_2(z)$, we get

$$k_a^{(2)} = 2/3, k_b^{(2)} = 1, k_a^{(1)} = k_b^{(1)} = 0, H_0(z) = 1, G_0(z) = 3. \tag{25.36}$$

This realization is shown in Fig. 25.2b.

Example 3 We next consider the case of even N. Let the required transfer function be

$$H_4(z) = 1 + z^{-1} + 2z^{-2} + 3z^{-3} + 4z^{-4}. \tag{25.37}$$

One possible decomposition is

$$H_4(z) = (1 + z^{-1}) + z^{-2}(2 + 3z^{-1} + 4z^{-2}) = H_1(z) + z^{-2}G_2(z). \tag{25.38}$$

Applying Eq. (25.22) to the pair of transfer functions in Eq. (25.38), we get

$$k_a^{(2)} = 0, k_b^{(2)} = 2, k_a^{(1)} = 1/4, k_b^{(1)} = 1, \quad H_0(z) = 1, G_0(z) = 4. \tag{25.39}$$

The resulting realization is shown in Fig. 25.3a. Alternatively, we could have decomposed $H_4(z)$ as

$$H_4(z) = (1 + z^{-1} + z^{-2}) + z^{-2}(l + 3z^{-1} + 4z^{-2}) = H_2(z) + z^{-2}G_2(z) \tag{25.40}$$

Proceeding exactly as in the previous case, we get

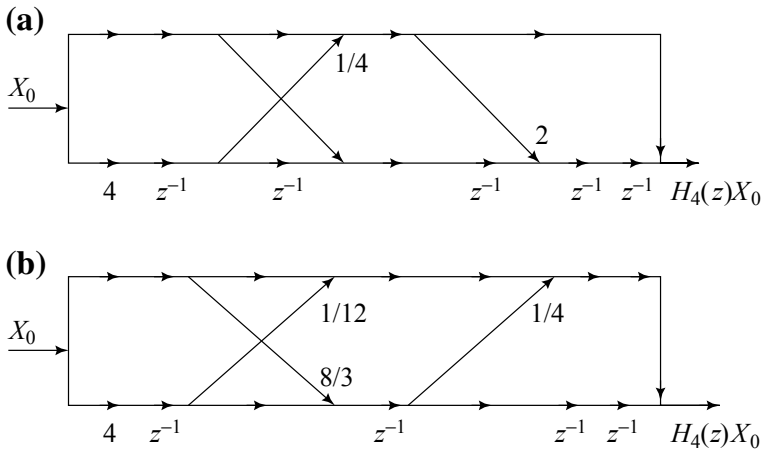

Fig. 25.3 **a** Realization of Eq. (25.37) as per the decomposition of Eq. (25.38) **b** alternative realization of Eq. (25.37) as per the decomposition of Eq. (25.40)

$$k_a^{(2)} = 1/4, k_b^{(2)} = 1, k_a^{(1)} = 1/12, k_b^{(1)} = 8/3, = H_0(z) = 1, G_0(z) = 4. \quad (25.41)$$

This realization is shown in Fig. 25.3b; compared to this, obviously, Fig. 25.3a realization is simpler.

25.5 Limitations of the New Procedures

Consider, first, the existing well-known case, in which $H_N(z)$ and $G_N(z)$ satisfy (2) so that $b_n^{(i)} = a_{i-n}^{(i)}$. Application of Eq. (25.22) then gives $k_a^{(i)} = k_b^{(i)} = a_i^{(i)}/a_0^{(i)} = k_i$. Next, consider the case in which $H_N(z)$ and $G_N(z)$ satisfy Eq. (25.8); this gives $b_n^{(i)} = (-1)^{i-n} a_{i-n}^{(i)}$ so that from Eq. (25.22), we get $k_a^{(i)} = (-1)^i k_b^{(i)}$. Thus the existing known cases follow as special cases of the new procedure. Another way of looking at these results is that in both of these cases, the new procedure fails to produce canonic realizations. This will be true for any pair of transfer functions, which are specially related to each other, so that the coefficients in one appear in the other also.

The same limitation arises in the case of a single linear phase transfer function. As is well known, the existing procedure, with two identical multipliers per lattice section, breaks down for a linear phase transfer function because $k_N = \pm 1$ and $a_N^{(N-1)}$ cannot be obtained from Eq. (25.6). The solution for this problem was given in [6] and a tutorial presentation of the solution was given in [7] through typical examples. However, that solution also utilized the conventional lattice structure. It is easily verified that the new procedure given in the previous section, when applied to a linear phase transfer function, gives the same realizations as in [6] and [7]. The underlying reason is that the two parts of the linear phase transfer function are specially related to each other. For this case, as well as for the case of Eq. (25.2),

the technique of [3] can be applied to obtain near canonic solutions. Whether such solutions can be obtained for other special relationships remains an open question.

25.6 Concluding Comments

A method has been presented for realizing two arbitrary FIR transfer functions of the same order by a canonic lattice structure. Problem cases have been considered, along with their solutions. A single transfer function is also shown to be realizable canonically by first splitting it into two parts, and then applying the new method. The limitations of the method have also been discussed.

A question that arises at this point is the following: Can an IIR transfer function be realized canonically by the same technique of using two non-identical lattice parameters in each section? A companion paper [8] answers this question in the affirmative.

Chapter 26
A Note on Canonic Lattice Realization of Arbitrary FIR Transfer Functions

Abstract This chapter presents some simple alternative solutions to the cases requiring modification of the procedure given in (Dutta Roy in IETE J Res 53:13–18, 2007) [1] for canonic lattice realization of arbitrary transfer functions.

Keywords FIR lattice · Canonic realization · Digital filter

26.1 Introduction

In the paper [1], a canonical lattice realization of a pair of arbitrary FIR transfer functions was presented by this author. By a simple modification of the procedure, one could also obtain a canonical lattice realization of a single transfer function. The procedure was shown to require some modifications in a few cases. The purpose of this chapter is to present simple alternative solutions to these exceptional cases.

First, we give a summary of the new procedure as given in [1].

26.2 The New Procedure

The new procedure realizes the pair of transfer functions

$$H_N(z) = a_0^{(N)} + a_1^{(N)} z^{-1} + a_2^{(N)} z^{-2} + \cdots + a_N^{(N)} z^{-N} \tag{26.1}$$

and

$$G_N(z) = b_0^{(N)} + b_1^{(N)} z^{-1} + b_2^{(N)} z^{-2} + \cdots + b_N^{(N)} z^{-N} \tag{26.2}$$

in the form of a cascade of N sections as shown in Fig. 26.1a, where the i-th section, $i = N$ to 1, is of the form shown in Fig. 26.1b. The procedure is based on determining

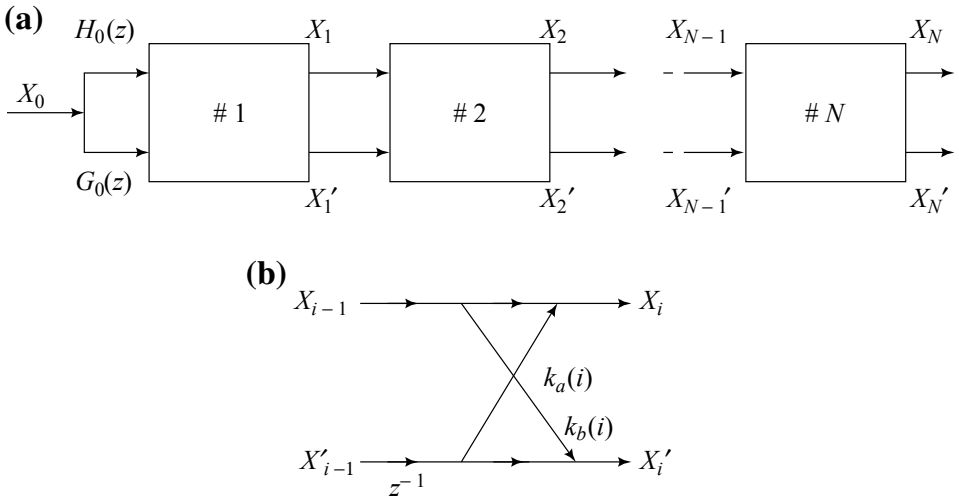

Fig. 26.1 **a** A generalized FIR lattice structure; **b** composition of the *i*th section of (**a**)

a series of N lower order transfer function pairs, of the same forms as Eqs. (26.1) and (26.2) with N replaced by i through the following algorithm:

$$k_a^{(i)} = a_i^{(i)}/b_i^{(i)}, k_b^{(i)} = b_0^{(i)}/a_0^{(i)}, i = N, N-1, \ldots 1;$$

$$\begin{aligned} a_n^{(i-1)} &= K_i[a_n^{(i)} - k_a^{(i)} b_n^{(i)}], b_n^{(i-1)} \\ &= K_i[b_{n+1}^{(i)} - k_b^{(i)} a_{n+1}^{(i)}], n = 0, 1, 2, \ldots i-1 \end{aligned} \tag{26.3}$$

$$K_i = 1/[1 - k_a^{(i)} k_b^{(i)}]; H_0(z) = a_0^{(1)} \text{and} G_0(z) = b_1^{(1)}$$

Obviously, if $b_i^{(i)} = 0$, then $k_a^{(i)} \to \infty, \infty$ and the procedure breaks down; we called this as Case 1 in [1]. Similarly, if $a_0^{(i)} = 0$, then $k_b^{(i)} \to \infty$ and one cannot proceed further; we designated this case as Case 2. If both $b_i^{(i)}$ and $a_0^{(i)}$ are zero, we get Case 3. Finally, if $k_a^{(i)} k_b^{(i)} = 1$, i.e. $a_i^{(i)} a_0^{(i)} = b_i^{(i)} b_0^{(i)}$, then one cannot proceed to the next stage; this was called Case 4. Modifications for each of these cases were presented in [1]. We present here simpler modifications for the first three cases.

Case 1 Let

$$H_i'(z) = G_i(z) = b_0^{(i)} + b_1^{(i)} z^{-1} + b_2^{(i)} z^{-2} + \cdots b_{i-1}^{(i)} z^{-(i-1)}, \tag{26.4}$$

and

$$G_i'(z) = H_i(z) = a_0^{(i)} + a_1^{(i)} z^{-1} + a_2^{(i)} z^{-2} + \cdots + a_i^{(i)} z^{-1}, \tag{26.5}$$

Realize the primed pair of transfer functions by the usual procedure. Here

$$k_a^{(i)'} = 0, \text{and} k_b^{(i)'} = a_0^{(i)}/b_0^{(i)} \tag{26.6}$$

and there is no breakdown.

Case 2 In this case, we let

$$H_i'(z) = G_i(z) = b_0^{(i)} + b_1^{(i)} z^{-1} + b_2^{(i)} z^{-2} + \cdots + b_i^{(i)} z^{-1} \tag{26.7}$$

and

$$G_i'(z) = H_i(z) = a_1^{(i)} z^{-1} + a_2^{(i)} z^{-2} + \cdots + a_i^{(i)} z^{-1} \tag{26.8}$$

and realize the primed pair of transfer functions by the usual procedure. Here

$$k_a^{(i)'} = b_i^{(i)} / a_i^{(i)} \text{ and } k_b^{(i)'} = 0 \tag{26.9}$$

and one can proceed further.

Case 3 In this case, we have to realize the transfer functions

$$H_i(z) = a_1^{(i)} z^{-1} + a_2^{(i)} z^{-2} + \cdots + a_i^{(i)} z^{-i} \tag{26.10}$$

and

$$G_i(z) = b_0^{(i)} + b_1^{(i)} z^{-1} + b_2^{(i)} z^{-2} + \cdots b_{i-1}^{(i)} z^{-(i-1)} \tag{26.11}$$

We can rewrite Eqs. (26.10) and (26.11) as

$$H_i(z) = z^{-1}(a_1^{(i)} + a_2^{(i)} z^{-1} + \cdots + a_i^{(i)} z^{-(i-1)} = z^{-1} H_{i-1}(z)) \tag{26.12}$$

and

$$G_i(z) = b_0^{(i)} + b_1^{(i)} z^{-1} + b_2^{(i)} z^{-2} + \cdots + b_{i-1}^{(i)} z^{-(i-1)} = G_{i-1}(z) \tag{26.13}$$

Now realize the pair $H_{i-1}(z)$ and $G_{i-1}(z)$ in the usual manner, and finally, add a delay at end of the upper line to get $H_i(z)$.

Case 4 Several alternative solutions can be worked out, but none of them appears to be simpler than that given in [1].

Chapter 27
A New Canonic Lattice Realization of Arbitrary IIR Transfer Functions

Abstract A new lattice realization is presented for any arbitrary stable IIR transfer function, which is always canonic in multipliers as well as delays, except for two degenerate cases, which require one (or more) additional delay(s), but no additional multipliers. In contrast to the existing lattice realization of such a transfer function, which uses an all-pass lattice combined with a ladder, the new structure is a truly lattice one. Also, for achieving multiplier canonicity in the conventional structure, one has to use special single multiplier lattice sections; in the new structure, canonicity evolves automatically.

27.1 Introduction

In realizing an arbitrary stable N-th order IIR transfer function

$$H_N(z) = \frac{A_N(z)}{B_N(z)} = \frac{a_0^{(N)} + a_1^{(N)} z^{-1} + \cdots a_N^{(N)} z^{-N}}{b_0^{(N)} + b_1^{(N)} z^{-1} + \cdots + b_N^{(N)} z^{-N}} \tag{27.1}$$

by the lattice structure, one first realizes an auxiliary all-pass lattice having the transfer function

$$H'_N(z) = \frac{z^{-N} B_N(z^{-1})}{B_N(z)} \tag{27.2}$$

In the next step, one combines a set of weighted output signals of this lattice to obtain $H_N(z)$, as illustrated in Fig. 27.1 [1, 2] for $N = 3$. This approach was originally proposed by Gray and Markel [3] and is the only one known so far for arbitrary IIR transfer functions. Obviously, the structure is delayed canonic but not so in terms of multipliers. However, it was also shown in [3] that by a simple manipulation, each

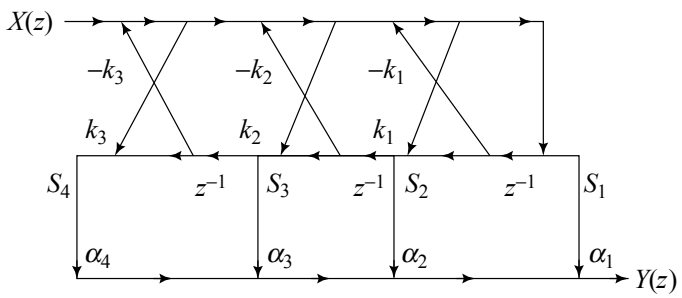

Fig. 27.1 The Gray-Markel structure for realizing a third order IIR transfer function

two multiplier lattice section can be converted to a single multiplier one, to achieve multiplier canonicity.

In this chapter, we present a new lattice structure for an arbitrary stable IIR transfer function, which does not require the additional ladder of Gray and Markel. In that sense, it is truly a modular lattice structure. It is always canonic in delays, as well as in multipliers, and the latter feature evolves automatically. In two degenerate cases, however, one (or more) extra delay(s) is (are) needed, but no extra multipliers.

The key to the new structure is very simple indeed. Instead of using two equal and opposite lattice parameters in each section ($\pm k_i$), as in Fig. 27.1, we use, in the new structure, two different lattice parameters to reduce the order of the transfer function by one.

27.2 Derivation of the New Structure

Since our aim is to realize Eq. (27.1) by a cascaded lattice structure, we explore the possibility of using the lattice section shown in Fig. 27.2, where $Y(z)/X(z)$ is required to be $H_N(z)$ and the terminating transfer function $G(z)$ is to be determined. If, by appropriate choice of $k_a^{(N)}$ and $k_b^{(N)}$, we can find a $G(z)$ of order $N-1$, then our purpose will be served and we can repeat the procedure till we get a terminating transfer function of order zero, which is, of course, a constant. By analysing Fig. 27.2, we get

$$\frac{Y(z)}{X(z)} = \frac{k_a^{(N)} + z^{-1}G(z)}{1 - k_b^{(N)} z^{-1} G(z)} \tag{27.3}$$

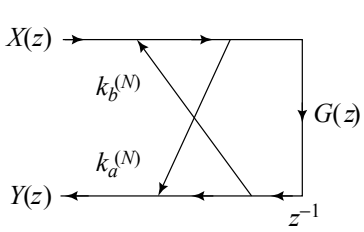

Fig. 27.2 New lattice section with unequal parameters

It can be verified that if $k_a^{(N)} = -k_b^{(N)}$ and $G(z) = 1$, then we get a first order all-pass function, as expected. Equating (27.3) to $A_N(z)/B_N(z)$, and simplifying, we get

$$G(z) = \frac{A_N(z) - k_a^{(N)} B_N(z)}{z^{-1}[B_N(z) + k_b^{(N)} A_N(z)]} = \frac{C(z)}{D(z)} \tag{27.4}$$

Substituting for $A_N(z)$ and $B_N(z)$ from Eq. (27.1), we get

$$\begin{aligned} C(z) = {} & (a_0^{(N)} - k_a^{(N)} b_0^{(N)}) + (a_1^{(N)} - k_a^{(N)} b_1^{(N)}) z^{-1} \\ & + (a_2^{(N)} - k_a^{(N)} b_2^{(N)}) z^{-2} + \cdots + (a_N^{(N)} - k_a^{(N)} b_N^{(N)}) z^{-N} \end{aligned} \tag{27.5}$$

and

$$\begin{aligned} D(z) = {} & z^{-1}[(b_0^{(N)}\theta + k_b^{(N)} a_0^{(N)}) + (b_1^{(N)} + k_b^{(N)} a_1^{(N)}) z^{-1} \\ & + (b_2^{(N)} + k_b^{(N)} a_2^{(N)}) z^{-2} + \cdots + (b_N^{(N)} + k_b^{(N)} a_N^{(N)}) z^{-N}] \end{aligned} \tag{27.6}$$

Now let

$$k_a^{(N)} = \frac{a_0^{(N)}}{b_0^{(N)}} \text{ and } k_b^{(N)} = -\frac{b_N^{(N)}}{a_N^{(N)}} \tag{27.7}$$

Then the constant term in $C(z)$ disappears, and so does the highest power term in $D(z)$. Thus $G(z)$ becomes a transfer function of order N—1, and can be re-designated as $H_{N-1}(z)$. It has the same form as Eq. (27.1) with N replaced by N—1, and its coefficients are related to those of $H_N(z)$ as follows:

$$a_i^{(N-1)} = a_{i+1}^{(N)} - k_a^{(N)} \theta b_{i+1}^{(N)},\ b_i^{(N-1)} = b_i^N + k_b^N a_i^N \qquad i = 0, 1, 2, \ldots N-1 \tag{27.8}$$

As mentioned earlier, this step can be repeated another N—1 times, to end up in a terminating transfer function, which will be a constant. The necessary design equations and the recurrence relations are obtained by replacing N in Eqs. (27.7) and (27.8) by a general index m, where $m = N - 1, N - 2, \ldots 1$. These will not be repeated here, for brevity. Using Eq. (27.8), we get the final terminating transfer function, $H_0(z)$ as

$$H_0(z) = \frac{a_0^{(0)}}{b_0^{(0)}} = \frac{a_1^{(1)}}{b_0^{(1)}} \tag{27.9}$$

It may be argued that we could have taken $b_0^{(N)} = 1$ in (27.1), without any loss of generality. However, note from Eq. (27.7), and the second recurrence relation in Eq. (27.8), that

$$b_0^{(N-1)} = b_0^{(N)} - b_N^{(N)} a_0^{(N)} / a_N^{(N)}, \tag{27.10}$$

which may not, in general, be unity, and we have to scale all the numerator and denominator coefficients of $H_{N-1}(z)$ by $b_0^{(N-1)}$ in order to be able to continue. This introduces another step of computation, and the recurrence relations will also get modified.

27.3 Examples

We shall now work out a number of examples, including some, in which the procedure, as presented, is not applicable as such, and some modifications are needed. As will be shown, these modifications are simple, and do not pose much of a problem. For simplicity, we shall confine ourselves only to the third order transfer function

$$H_3(z) = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + a_3 z^{-3}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} \tag{27.11}$$

whose realization by the new procedure will, in general, be of the form shown in Fig. 27.3.

Example 1 Let $a_0 = 1$ and $a_1 = a_2 = a_3 = 0$; then from Eq. (27.7), we get $k_a^{(3)} = 1$ and $k_b^{(3)} = -\infty$. We cannot therefore proceed further. However, this difficulty can be removed by first realizing

$$H_3'(z) = 1 - H_3(z) = \frac{b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} \tag{27.12}$$

By applying Eqs. (27.7) and (27.9) to Eq. (27.12), we get for $H_3'(z)$,

$$\begin{aligned} k_a^{(3)} &= 0 \text{ and } k_b^{(3)} = -1; \\ k_a^{(2)} &= b_1 \text{ and } k_b^{(2)} = 0; \\ k_a^{(1)} &= b_2 \text{ and } k_b^{(1)} = 0; \text{ and} \\ H_0(z) &= b_3 \end{aligned} \tag{27.13}$$

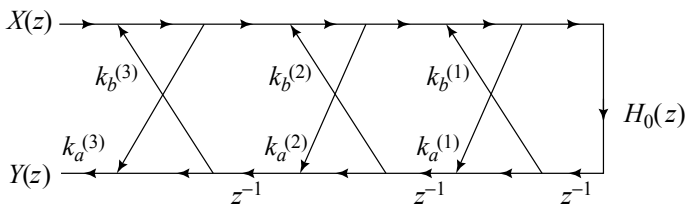

Fig. 27.3 General canonic lattice structure for a third order IIR transfer function

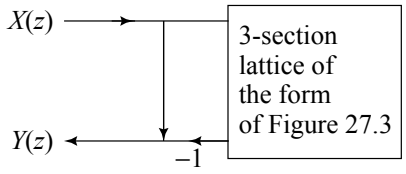

Fig. 27.4 Lattice structure for Examples 1–3. Parameter values are given in Eq. (27.13) for Example 1, Eq. (27.14) for Example 2 and Eq. (27.15) for Example 3

These results lead to the final realization shown in Fig. 27.4. Note that we require only three delays and three multipliers, viz. $k_a^{(2)}, k_a^{(1)}$ and $H_0(z)$, thus confirming canonicity.

Instead of Eq. (27.12), we could have also taken $H_3'(z) = 1 + H_3(z)$. The resulting structure is also canonic but, as may be verified, the structure obtained from Eq. (27.12) is somewhat simpler.

Example 2 Let $a_0 = 1$ and $a_2 = a_3 = 0$. Here also we face the same problem as in Example 1, and by proceeding in an exactly similar manner, we get the same realization as in Fig. 27.4, with the following changed parameters:

$$\begin{aligned} k_a^{(3)} &= 0 \text{ and } k_b^{(3)} = -1; \\ k_a^{(2)} &= b_1 - a_1 \text{ and } k_b^{(2)} = 0; \end{aligned} \tag{27.14}$$

$$\begin{aligned} k_a^{(1)} &= b_2 - a_1(b_1 - a_1) \text{ and } k_b^{(1)} = -a_1/b_3; \text{ and} \\ H_0(z) &= b_3. \end{aligned} \tag{27.15}$$

Here we require four multipliers and three delays, thus making the structure canonic.

Example 3 Let $a_0 = 1$ and $a_3 = 0$. Proceeding exactly as in the previous example, we get the realization of Fig. 27.4 with the following parameters:

$$\begin{aligned} k_a^{(3)} &= 0 \text{ and } k_b^{(3)} = -1; \\ k_a^{(2)} &= b_1 - a_1 \text{ and } k_b^{(2)} = -a_2/b_3; \\ k_a^{(1)} &= \frac{b_3[b_2 - a_2 - a_1(b_1 - a_1)]}{b_3 - a_2(b_1 - a_1)} \text{ and} \\ k_b^{(1)} &= \frac{a_1[b_3 - a_2(b_2 - a_2)]}{b_3[b_3 - a_2(b_1 - a_1)]}; \text{ and} \\ H_0(z) &= b_3. \end{aligned}$$

The requirement of five multipliers and three delays confirm canonicity,

Example 4 Let $a_0 = a_1 = a_2 = 0$. No modification of the transfer function is necessary in this case and application of Eqs. (27.7)–(27.9) leads to a realization with the following parameters:

$$
\begin{aligned}
k_a^{(3)} = 0 \text{ and } k_b^{(3)} &= -b_3/a_3; \\
k_a^{(2)} = 0 \text{ and } k_b^{(2)} &= -b_2/a_3; \\
k_a^{(1)} = 0 \text{ and } k_b^{(1)} &= -b_1/a_3; \text{ and} \\
H_0(z) &= a_3. \qquad (27.16)
\end{aligned}
$$

There are four multipliers and three delays, as needed for canonicity.

Our next example is a degenerate case, in which canonicity in multipliers can be assured but one (or more) extra delay(s) will be needed.

Example 5 Let $a_0 = a_3 = 0$. If we proceed as in Examples 1–3, we get, for $H_3'(z) = 1 - H_3(z)$, the following parameters:

$$k_a^{(3)} = 1 \text{ and } k_b^{(3)} = -1; \qquad (27.17)$$

and

$$k_a^{(2)} = a_0^{(2)}/b_0^{(2)} = -\infty;$$

We cannot therefore proceed further. In general, one can observe from Eq. (27.10) that this difficulty will occur in synthesizing Eq. (27.1) whenever

$$\frac{a_0^{(N)}}{b_0^{(N)}} = \frac{a_N^{(N)}}{b_N^{(N)}} \qquad (27.18)$$

We shall consider such a case in the next example.

For the present example, there are two alternatives. First, instead of $H_3(z)$, we realize $H_3'(z) = z^{-1}H_3(z)$, whose realization poses no problem. In most practical cases, this will be satisfactory because the magnitude function remains unaltered while the phase has an added linear term—ω. The resulting realization is multiplier canonic but requires an extra delay.

The second alternative is to rewrite the given transfer function as

$$
\begin{aligned}
H_3(z) &= \frac{(a_1 z^{-1} + a_2 z^{-2})(1 \pm 1/2z^{-1})}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} \cdot \frac{1}{(1 \pm 1/2z^{-1})} \\
&= H_3'(z) H_3''(z) \qquad (27.19)
\end{aligned}
$$

The realization of $H_3'(z)$ poses no problem; the resulting structure has to be cascaded to that of the first order transfer function $H_3''(z)$. Again, multiplier canonicity is maintained, but one extra delay is needed.

Example 6 Let $a_0 = a_2 = a_3 = 0$. We can follow the same procedure as in Example 5. In the first alternative, we realize $H_3'(z) = z^{-2}H_3(z)$, while in the second alternative, we multiply both numerator and denominator by $(1 \pm 1/2\ z^{-1})^2$. In either case, multiplier canonicity is achieved, but two extra delays are needed. Note that instead

of the constant 1/2 in the multiplying factor, in general, one can use 2^{-q} (where q is an integer greater than or equal to 1), which requires only shifting and no multiplication.

Example 7 As the last example, we consider a case which satisfies Eq. (27.18). Let, in Eq. (27.11), $a_3 = a_0 b_3$. In this case, we write

$$H_3'(z) = H_3(z) - a_0 \tag{27.20}$$

which gives the same transfer function as that of Example 5, and we apply either of the two techniques discussed there. The resulting structures are still multiplier canonic, but not so in delays.

27.4 Conclusions

In this chapter, we have presented a true lattice realization of an arbitrary N-th order IIR transfer function, which is canonic in multipliers, as well as in delays, except for two degenerate cases: one defined by Eq. (27.18) and the other by $a_0^{(N)} = a_N^{(N)} = 0$. Even in these cases, methods have been formulated for achieving multiplier canonicity.

While designing the Gray-Markel structure, the stability of the given transfer function is automatically tested for; this is not so in the procedure presented here. It is also not possible to incorporate such a test in the new procedure, because stability involves only the coefficients of $B_N(z)$, while our lattice parameters involve the coefficients of $A_N(z)$ as well. One, therefore, has to test for stability before proceeding with the design. Also, the Gray-Markel structure for a stable transfer function remains stable, even under finite word length implementation because the basic recursive unit is an all-pass filter, which remains all-pass even under coefficient quantization. This is not so in the new lattice structure.

A natural question that arises at this point is whether an arbitrary FIR transfer function can also be realized by a lattice, which is canonic in multipliers as well as delays. A companion paper [4] answers this question in the affirmative.

Chapter 28
A New Feedback Configuration for Canonical Realization of IIR Filters and Its Application to Lattice Realizations

Abstract A feedback configuration is presented for canonical realization of an arbitrary IIR transfer function $H(z) = P(z)/Q(z)$ with $M = P(z)^0 < N = Q(z)^0$, which does not appear to have been discussed in the literature. It consists of an IIR transfer function $F(z)$ of degree R. In the forward path, where $M \leq R < N$, and an FIR transfer function $G(z)$ of degree $N - M$, in which the first $R - M + 1$ terms are absent in the feedback path. $F(z)$ and $G(z)$ can be realized by any structure including lattice, if applicable. Application of this method is shown to solve the problem of canonical lattice realization of any IIR transfer function $H(z) = P(z)/Q(z)$ in which $M < N$ and the constant term in $P(z)$ is absent.

Keywords IIR filters · Feedback configuration · Canonical realization · Lattice structures

28.1 Introduction

Many different structures exist for canonical realization of an arbitrary IIR transfer function, examples being direct, cascade, parallel, ladder and lattice [1]. We present here another method, which does not appear to have been discussed in the literature. It is particularly suitable for transfer functions of the form $H(z) = P(z)/Q(z)$ with $M = P(z)^0 < N = Q(z)^0$, and consists of an IIR transfer function $F(z)$ of degree R in the forward path, where $M \leq R < N$, and an FIR transfer function $G(z)$ of degree $N - M$, in which the first $R - M + 1$ terms are absent, in the feedback path, $F(z)$ and $G(z)$ can be realized by any structure, including lattice, if applicable. Even in the case $M = N$, the numerator degree can be reduced by one by subtracting a constant term, and the new method can then be applied to the reduced transfer function.

In [2], a canonical lattice structure was presented for the arbitrary transfer function.

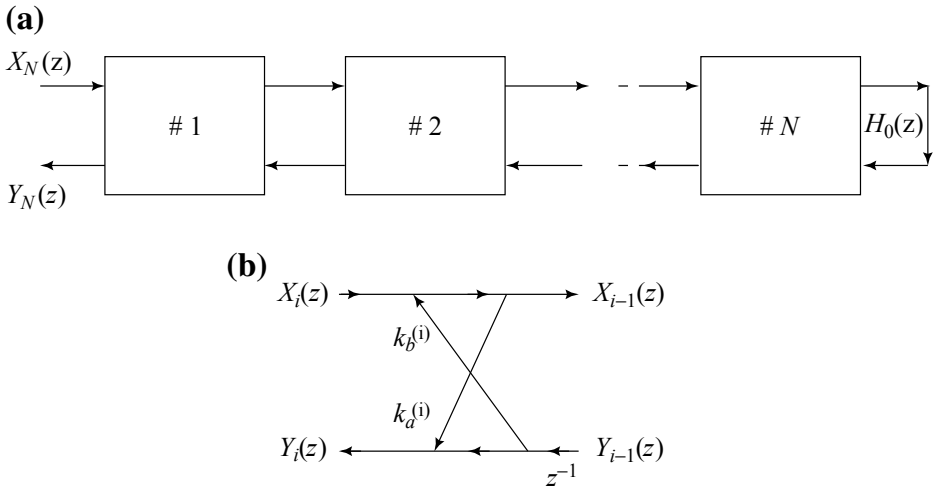

Fig. 28.1 **a** A general cascade of N sections **b** architecture of a typical section

$$H_N(z) = \frac{Y_N(z)}{X_N(z)} = \frac{a_0^{(N)} + a_1^{(N)} z^{-1} + \cdots + a_N^{(N)} z^{-N}}{1 + b_1^{(N)} z^{-1} + \cdots b_N^{(N)} z^{-N}} = \frac{P(z)}{Q(z)} \tag{28.1}$$

in the form shown in Fig. 28.1a, where the ith section, $i = N$ to 1, has the lattice architecture shown in Fig. 28.1b. The design equations are as follows:

$$k_a^{(i)} = \frac{a_0^{(i)}}{b_0^{(i)}} \text{ and } k_b^{(i)} = -\frac{b_i^{(i)}}{a_i^{(i)}}, \tag{28.2}$$

$$a_n^{(i-1)} = a_{n+1}^{(i)} - k_a^{(i)} b_{n+1}^{(i)}, \; b_n^{(i-1)} = b_n^{(i)} + k_b^{(i)} a_n^{(i)},$$
$$n = 0, 1, 2, \ldots i-1, \qquad i = N, (N-1), \ldots 1; \tag{28.3}$$

and

$$H_0(z) = \frac{a_1^{(1)}}{b_0^{(1)}} \tag{28.4}$$

Problem arises when one of the k parameters tends to infinity. Several illustrative cases and their solutions were presented in [2], except for those cases in which the first and the last terms in (28.1) are both absent, and a case in which

$$\frac{a_0^{(N)}}{b_0^{(N)}} = \frac{a_N^{(N)}}{b_N^{(N)}} \tag{28.5}$$

In each of these exceptional cases, one or more extra delays were needed for the solution. The feedback configuration presented here will be shown to solve the problem with $F(z)$ realized canonically by the method of [2], and $G(z)$ realized canonically by an FIR lattice by the method of [3].

Examples will be given to illustrate the applications of the method.

28.2 The Method

Consider the transfer function given by Eq. (28.1) with $a_i^{(N)} = 0$, $i = M+1, M+2, \ldots, N$, $M < N$, and the feedback configuration shown in Fig. 28.2 for which

$$H(z) = \frac{P(z)}{Q(z)} = \frac{F(z)}{1 + F(z)G(z)} \tag{28.6}$$

Let

$$F(z) = \frac{P(z)}{1 + c_1 z^{-1} + c_2 z^{-2} + \cdots c_R^{z^{-R}}} = \frac{P(z)}{D_R(z)} \tag{28.7}$$

where $M \leq R < N$. Then Eq. (28.6) becomes

$$H(z) = \frac{P(z)}{D_R(z) + P(z)G(z)} \tag{28.8}$$

Since $P(z)$ and $D_p(z)$ are both polynomials, of degrees M and R, respectively, it is clear that $G(z)$ is required to be a polynomial of degree $N - M$ i.e. $G(z)$ is an FIR transfer function. Further, since there are N known coefficients in $Q(z)$ and R unknown coefficients in $D_R(z)$, it is necessary to have only $N - R$ coefficients in $G(z)$, i.e. the first $R - M + 1$ coefficients will be missing in $G(z)$. Thus $G(z)$ is of the form

$$G(z) = g_{R-M+1} z^{-(R-M+1)} + g_{R-M+2} z^{-(R-M+2)} + \cdots + g_{N-M} z^{-(N-M)} \tag{28.9}$$

Thus from Eqs. (28.1), (28.8) and (28.9), we get

$$\begin{aligned} &1 + c_1 z^{-1} + c_2 z^{-2} + \cdots + c_R z^{-R} + [a_0^{(N)} + a_1^{(N)} z^{-1} + \cdots + a_M^{(N)} z^{-M}] \\ &\quad \times [g_{R-M+1} z^{-(R-M+1)} + g_{R-M+2} z^{-(R-M+2)} + \cdots + g_{N-M} z^{-(N-M)})] \\ &\quad = 1 + b_1^{(N)} z^{-1} + \cdots + b_N^{(N)} z^{-N} \end{aligned} \tag{28.10}$$

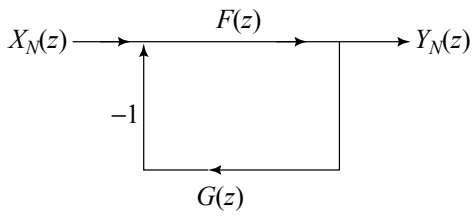

Fig. 28.2 The feedback configuration

Equating coefficients on both sides of (28.10) and solving the set of linear equations, we get the required values of c_i's and g_i's. Obviously, $F(z)$ and $G(z)$ are simpler transfer functions and can be realized by any existing method, including lattice, if applicable.

We now illustrate the method with an example.

Example 1 Let it be required to realize

$$H_3(z) = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} \tag{28.11}$$

The only choice for $F(z)$ is

$$F(z) = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2}}{1 + c_1 z^{-1} + c_2 z^{-2}} \tag{28.12}$$

and, correspondingly,

$$G(z) = g_1 z^{-1}. \tag{28.13}$$

Thus, from Eq. (28.10),

$$1 + c_1 z^{-1} + c_2 z^{-2} + (a_0 + a_1 z^{-1} + a_2 z^{-2}) g_1 z^{-1} = 1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3} \tag{28.14}$$

Equating coefficients on both sides of Eq. (28.14), we get

$$c_1 + a_0 g_1 = b_1,\ c_2 + a_1 g_1 = b_2 \text{ and } a_2 g_1 = b_3 \tag{28.15}$$

Solution of Eq. (28.15) gives

$$g_1 = b_3/a_2,\ c_1 = b_1 - a_0 b_3/a_2 \text{ and } c_2 = b_2 - a_1 b_3/a_2 \tag{28.16}$$

The complete realization is shown in Fig. 28.3 with $F(z)$ realized in direct canonic form.

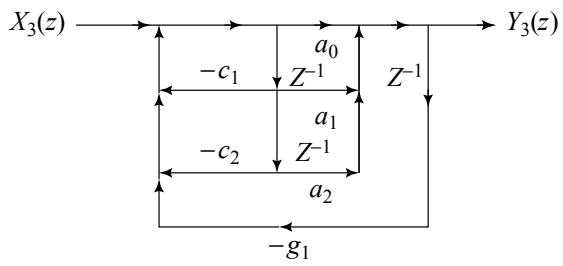

Fig. 28.3 Realization of Eq. (28.11) by the feedback configuration. Parameter values are given in Eq. (28.16)

Even if $M = N$, one can write the transfer function as the sum of a constant and another transfer function whose numerator is one degree less than the denominator. The next example illustrates this modification.

Example 2 Let

$$H_3(z) = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + a_3 z^{-3}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} \tag{28.17}$$

We can write

$$H_3(z) = \frac{a_3}{b_3} + \frac{a_0' + a_1' z^{-1} + a_2' z^{-2}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} = \frac{a_3}{b_3} + H_3'(z) \tag{28.18}$$

where

$$\begin{aligned} &a_0' = a_0 - a_3/b_3,\ a_1' = a_1 - b_1 a_3/b_3, \\ &\text{and} \\ &a_2' = a_2 - b_2 a_3/b_3 \end{aligned} \tag{28.19}$$

$H_3'(z)$ can be realized as in Example 1, and the complete realization takes the form shown in Fig. 28.4, where c_1, c_2 and g_1 are given by Eq. (28.16) with a_i replaced by a_i', $i = 0, 1, 2$. The next example illustrates the multiplicity of choice possible for $D_R(z)$.

Example 3 Let

$$H_5(z) = \frac{a_0 + a_1 z^{-1}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3} + b_4 z^{-4} + b_3 z^{-5}} \tag{28.20}$$

The denominator polynomial of $F(z)$ can be any of the following:

$$D_1(z) = 1 + c_1 z^{-1}, \tag{28.21}$$

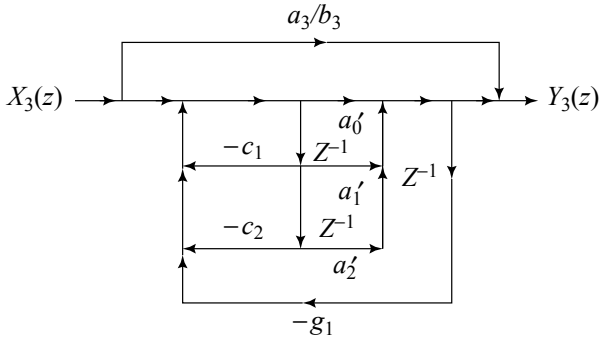

Fig. 28.4 Realization of Eq. (28.17) by the feedback configuration. Parameter values are given in Eq. (28.19)

$$D_2(z) = 1 + c_1 z^{-1} + c_2 z^{-2} \tag{28.22}$$

$$D_3(z) = 1 + c_1 z^{-1} + c_2 z^{-2} + c_3 z^{-3} \text{ and} \tag{28.23}$$

$$D_4(z) = 1 + c_1 z^{-1} + c_2 z^{-2} + c_3 z^{-3} + c_4 z^{-4}. \tag{28.24}$$

the corresponding $G(z)$ will be, respectively,

$$G_1(z) = g_1 z^{-1} + g_2 z^{-2} + g_3 z^{-3} + g_4 z^{-4}, \tag{28.25}$$

$$G_2(z) = g_2 z^{-2} + g_3 z^{-3} + g_4 z^{-4}, \tag{28.26}$$

$$G_3(z) = g_3 z^{-3} + g_4 z^{-4} \tag{28.27}$$

and

$$G_4(z) = g_4 z^{-4}. \tag{28.28}$$

In each of the last three variations, the feedback configuration can be applied to $F(z)$ as well.

28.3 Applications to Canonical IIR Lattice Realizations

In addition to $P(z)$ being of degree $M < N$, let, in Eq. (28.1), $a_0^{(N)} = 0$. As shown in [2], subtracting unity or any other constant from the transfer function creates the situation given by Eq. (28.5), and the procedure for lattice realization breaks down in the next step. We show here that the problem is solved by application of the new method presented here. We shall illustrate the solution with the same problems for which extra delays were required in [2].

Example 4 Let

$$H_3(z) = \frac{a_1 z^{-1} + a_2 z^{-2}}{1 + b_1 z^{-1} b_2 z^{-2} + b_3 z^{-3}} \tag{28.29}$$

Proceeding as in Example 1, we get

$$F(z) = \frac{a_1 z^{-1} + a_2 z^{-2}}{1 + b_1 z^{-1} + [b_2 - (a_1 b_3 / a_2) z^{-2}]} \tag{28.30}$$

and

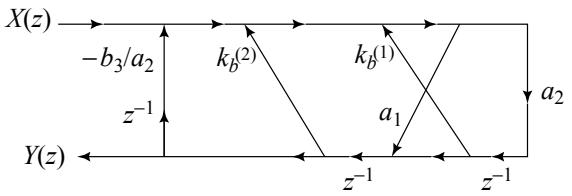

Fig. 28.5 Canonical lattice realization of Eq. (28.29) using the feedback configuration. Parameters are given in Eq. (28.31)

$$G(z) = (b_3/a_2)z^{-1}.$$

$F(z)$ can be realized by a lattice, following the procedure given in [2]. The required parameters are calculated from the design equations summarized in Eqs. (28.2)–(28.4) as:

$$\begin{aligned} k_a^{(2)} &= 0, k_b^{(2)} = (a_1b_3 - a_2b_2)/a_2^2, k_a^{(1)} = a_1 \\ k_b^{(1)} &= -\{(b_1/a_1) + [(a_1b_3 - a_2b_2)/a_2^2]\} \\ \text{and } H_0(z) &= a_2. \end{aligned} \tag{28.31}$$

The resulting complete realization is shown in Fig. 28.5.

Example 5 Let

$$H_3(z) = \frac{a_1z^{-1}}{1 + b_1z^{-1} + b_2z^{-2} + b_3z^{-3}} \tag{28.32}$$

Following the same procedure as in Example 1, we get

$$F(z) = \frac{a_1z^{-1}}{1 + b_1z^{-1}} \text{ and } G(z) = (b_2/a_1)z^{-1} + (b_3/a_1)z^{-2} \tag{28.33}$$

For the lattice realization of $F(z)$, the parameters are

$$k_a^{(1)} + 0,\ k_b^{(1)} = -(b_1/a_1) \text{ and } H_0(z) = a_1 \tag{28.34}$$

The complete realization is shown in Fig. 28.6.

Example 6 Let

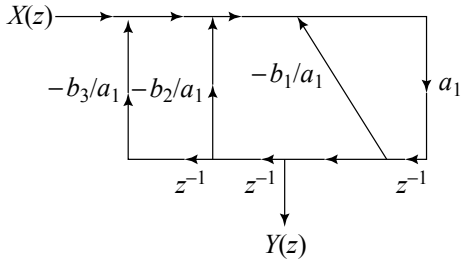

Fig. 28.6 Canonical lattice realization of Eq. (28.32) using the feedback configuration

$$H_3(z) = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + a_0 b_3 z^{-3}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} \tag{28.35}$$

This is an example of the case in which Eq. (28.5) is valid. Subtracting a_0 from $H_3(z)$, we get the new transfer function

$$H_3'(z) = \frac{(a_1 - a_0 b_1) z^{-1} + (a_2 - a_0 b_2) z^{-2}}{1 + b_1 z^{-1} + b_2 z^{-2} + b_3 z^{-3}} \tag{28.36}$$

This is of the same form as Eq. (28.29) and can be handled in the same manner as in Example 4. In the three examples considered in this section, the realization of $G(z)$ was simple. For a higher order $G(z)$ having many terms, one can use the canonical FIR lattice realization method given in [3], except for the case in which $G(z)$ is a linear phase polynomial. In the latter case, any other canonic FIR realization will have to be resorted to.

28.4 Conclusions

A new method has been presented for realizing an arbitrary IIR transfer function $H(z) = P(z)/Q(z)$ with $M = P(z)^0 < N = Q(z)^0$ in the form of two blocks, one of which is IIR and the other is FIR, in a feedback configuration. Both transfer functions are of lower order and can be realized by any known method, including lattice, if applicable. It is shown that the method is particularly useful in providing a canonical solution to the problem cases in IIR lattice synthesis, as reported in [2].

Acknowledgements After the publication of [2], it was pointed out by Professor S. K. Mitra of the University of California, Santa Barbara, that the idea of using two different parameters in a lattice section was exploited earlier in [4]. However, the approach, algorithms and the final realizations are, in general, different.
