Fabrication, Characterization and Evaluation of Mechanical Properties of Aluminium Hybrid Matrix Composite (Al6063/SiC-Bagasse Fly-Ash)

Getachew Gashaw, Perumalla Janaki Ramulu and Ch. Venkatesh

Abstract The fabrication and mechanical performance of Al-Mg-Si alloy matrix composites reinforced with silicon carbide (SiC) and bagasse fly-ash has been explored in this work. The fabrication and experimental investigation of mechanical properties of aluminium matrix (Al/SiC) composite with and without addition of bagasse fly-ash by varying wt% of reinforcements were investigated. Chemical composition of reinforcement, weighted required amount of matrix and reinforcements, powder mixing, stirring the slurry at 500 rpm speed and 5–10 min were the parameters used to develop the Al/SiC-bagasse fly-ash hybrid composite. Bagasse fly-ash particulates added with 7.5, 10, and 12 wt% SiC were utilized to prepare 10 and 12 wt% of the reinforcing phase with Al-Mg-Si alloy as matrix using stir casting method. The cast samples were machined for evaluating the properties by performing tensile testing, compression strength testing, and micro-hardness measurement. The results disclosed that the hardness of the hybrid composites increased with increase in bagasse fly-ash content with a maximum increment of 17% observed for the Al6063-7.5% SiC-10% bagasse ash composition (in comparison with the Al-10 wt% SiC-7.5 fly-ash reinforced composition). Tensile strength reduced of maximum value of 90–68 MPa at 7.5 SiC-7.5 bagasse ash compositions.

62.1 Introduction

Aluminium matrix composites (AMCs) have significant properties than other metal matrix composites with respect to high strength to weight ratio. The mechanical properties and wear resistance were improved by using SiC, TiC, TiB2 and fly-ash particulates to reinforce Al alloys [1]. Among all reinforcements, SiC was chemically compatible with aluminium and forms an adequate bond with the matrix without developing inter-metallic phase and had other advantages such as excellent thermal conductivity, good workability and low cost revealed in the literature [2]. In recent years, the use of fly-ash as reinforcement material in Al alloys was reported to be desirable from both environmental and economic significance due to its low cost. To overcome this, many research and development programmes were focused on Al metal matrix composites using low-cost industrial waste by-products as the reinforcement particulate [3]. Investigation of mechanical behaviour of aluminium alloy reinforced by nano- and micro-hard particles such as Al_2O_3 and SiC was a motivating area of research [4]. The present work, Aluminium hybrid matrix composite with reinforcements such as, SiC particle and waste of sugar cane bagasse fly-ash particle. Al/SiC-bagasse fly-ash composite provides more wear resistance, high coefficient of thermal expansion and high strength. Silicon carbide (SiC) is hard, wear resistance, high heat resistance ceramic material. With respect to low cost, less density and availability bagasse fly-ash is one of them which has inexpensive, low density reinforcement and available in large quantities by-product during combustion of coal in thermal power plants as solid waste. By which, composite material made with fly-ash as reinforcement are likely to overcome the cost barrier for extensive applications in automotive industries.

Metal matrix hybrid composites are the second-generation composite materials that have potential to substitute single-reinforced composite by improving properties [5, 6]. Vijayakumar et al. [7] studied the tensile strength and hardness of Al6061/SiC composite by varying the wt% SiC reinforcements 3–18%. The composite was manufactured by using stir casting of 600 rpm, 5 min stirring speed, and stirring time, respectively. The ultimate tensile strength and hardness results showed that the tensile strength and hardness of the developed metal matrix improved during increasing the wt% of SiC. Imran et al. [8] fabricated Al7075/bagasse ash–graphite of hybrid metal matrix composite (HMMC) by stir casting method. Reinforcements were added with three cases: in first case, 2% constant of bagasse ash with varying graphite 1, 3 and 5%; in second case, 4% bagasse ash and in third case, 6% constant with varying graphite percentage. Results showed that 6% bagasse ash with varying graphite 1, 3 and 5% more enhanced mechanical properties achieved as compared to case one and two of bagasse–ash combination. The hardness, ultimate tensile strength and yield strength of the developed composites were gradually increased with increasing the wt% of reinforcement, while

ductility decreased. Similar studies were also carried out on MMCs and their characterizations with respect to their mechanical behaviour [9, 10]. Failure prediction of FRP laminates was studied for a new generation of materials to an aerospace application [11]. The present work significance is natural fibres have good mechanical property, but a finite resource. The usage of their wastage, such as fly-ash and plant wastes from industries as reinforcement, is recommendable. Bagasse fly-ash is a waste by-product of coal combustion in thermal power plants which is available in large quantities in Ethiopian sugar factories. The usage of this waste fly-ash particle reinforced into aluminium alloys, which can effectively enhance the various mechanical properties of the aluminium alloy. Automotive heavy components fabricated from metals, Due to an increase in the weight of components, consumption of fuel increases. Increasing volume percentage of SiC reinforcement the weight of the composite increase. Bagasse fly-ash leads to decrease in the density of the composite when using some percentage with silicon carbide as reinforcement for developing Al/SiC/fly-ash composite.

62.2 Experimental Methodology

62.2.1 Matrix and Reinforcement Materials

Base material-AA 6063 alloy

The Al6xxx alloys were chosen because of its wide use in automotive components and architectural materials, including pistons, disk rotors, cylinder liners and decorative parts, rivets, etc. AA 6063 was the most widely used because of its extrudability and used for the automotive space frame parts [12].

Reinforcement material–Silicon carbide (SiC)

Silicon carbide material was chosen as a reinforcement material because it is used in high hardness and high thermal resistance applications, such as automotive brakes, cylinders, clutches, valves and bullet proof vests, semiconductor electronics etc. It is also applicable in abrasive cutters, cutting tools, grinding wheels, nuclear reactors due to high temperature resistance, high thermal conductivity and low nuclear activation [13]. The grain size of silicon carbide varies micro to nano sizes. One way of improving mechanical properties of composite is reducing grain size of reinforcements depends on processing methods. The very small sizes of powder particle of SiC create agglomeration (mud) during casting of poor stirring. To overcome such problems, proper stirring action is used from 5–10 min. Figure 62.1 shows the micron-level silicon carbide powders which are used as a reinforcement ceramic material to fabricate Al/SiC-bagasse fly-ash hybrid composite.

Bagasse fly-ash

Bagasse is produced from sugarcane plant during processing in sugar production. For the present work, the bagasse ash was taken from Wonji Shewa Ethiopian

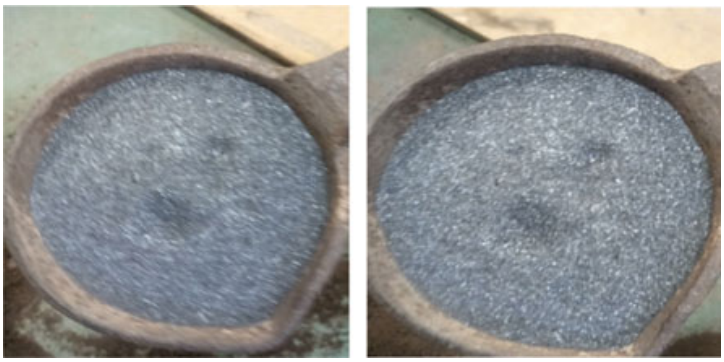

Fig. 62.1 Silicon carbide powders

Sugar Factory. Bagasse fly-ash was chosen due to low weight, density and increase in the strength. The ash was manually crushed and screened using sieves to make fine powder particles.

62.2.2 Methods

Physical Properties and chemical composition of bagasse fly-ash.

Density—1.96 g/cc and the specific gravity of fly-ash varies in the range of 0.6–2.8 gm/cc. Table 62.1 shows the chemical composition of the bagasse fly-ash by chemical analysis. The chemical composition analysis was performed on Dangote cement industries in Ethiopia.

The sugarcane bagasse ash is rich in SiO_2, which is good to replace SiC and used as reinforcement for metal matrix composites. In [14] research work, it was reported that alumina (Al_2O_3) also promise reinforcement material for production of metal matrix composite.

Powders mixing

Al-5% volume of SiC powders are mixed by stirrer on milling machine. The calculation for mass of aluminium, silicon carbide and bagasse fly-ash powder is needed for a sample of 130 mm length and 15 mm diameter. Pre-hearing of reinforcements from 600–700 °C of temperature before added in molten metal. Weight of powder added into matrix depends on the sample size. The blade of stirrer assembled on rotating part of milling machine speed of 500 rpm, 5–10 min stirring speed and time respectively, used to mix matrix and reinforcements.

Table 62.1 Chemical composition of bagasse ash in weight percentage

Composition wt%	SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO
	%	%	%	%	%
	66.55	10.25	5.48	3.26	1.17

Mould preparation and fabrication the composite
To facilitate the easy removal of compacted specimen, tapered section has been used. The size of the mould depends on the size of samples which were used for tests. The required amount of reinforcements and matrix for each sample weighed and added in the crucible. Three samples were manufactured on one mould with the same composition of reinforcement. This is for the reputation of three experiments.

62.2.3 Sampling and Sample Method

In total, 8 number of experiments were conducted with three reputations for each type of mechanical testes. The wt% composition of reinforcements was taken as per available literatures, which has highest improvement in mechanical properties. The composition was 7.5, 10 wt% of SiC and 7.5, 10, 12 wt% of bagasse fly-ash and form eight combination of experiments. For specimen preparation with different percentage, composition of reinforcements manufactured was shown in Tables 62.2 and 62.3.

62.2.4 Equipment Used for This Work

Table 62.4 shows the equipment used for testing mechanical properties of the developed composite. Casting set-up was used to melt the matrix aluminium alloy during fabrication of Al/SiC–bagasse ash composite.

Table 62.2 Composite content in wt% of reinforcements

S. No	wt% of silicon carbide (SiC)	wt% of bagasse fly-ash	Al/SiC/bagasse fly-ash
1	7.5	7.5	Al6063-7.5% SiC-7.5% bagasse ash
2	7.5	10	Al6063-7.5% SiC-10% bagasse ash
3	7.5	12	Al6063-7.5% SiC-12% bagasse ash
4	10	7.5	Al6063-10% SiC-7.5% bagasse ash

6	10	12	Al6063-10% SiC-12% bagasse ash

Table 62.3 Composite content in wt% of silicon carbide only

S. No.	wt% of Al	wt% of SiC	Al/SiC
1	92.5	7.5	Al6063-7.5% SiC
2	90	10	Al6063-10% SiC

Table 62.4 Equipment used for this work

S. No.	Equipment	Task (Test name)	Machine model
1	Universal test machine (UTS)	Tensile test	WP 310 HYDROLIC UTM-Gunt Hamburg
2	Casting set-up	To melt and stir materials	

62.2.5 Mould Preparation and Fabrication

The sand mould was prepared for fabrication of Al/SiC/fly-ash hybrid composite based on the size of required specimens. 30 mm diameter and 150 mm length, 20 mm diameter and 60 mm length, specimen sizes were prepared for tensile test and compression test, respectively.

Fabrication

The matrix aluminium melted in a crucible which is placed inside furnace. It was melted at a temperature of 700 °C and reinforcements added and stirring with a molten metal for 5–10 min. The stirrer blade was assembled on hand drilling machine.

62.2.6 Tensile Test Specimen

The tensile test specimens of metal matrix composites were prepared based on the ASTM Standard D 3552. The flat and round configurations of metal matrix specimens are adopted. If the composite produced by diffusion bonding, flat shape of specimen would produce. In other case, metal matrix composite produced by various liquid infiltrations and other methods used for producing massive materials is better suited to circular cross-sectional shapes.

62.3 Results and Discussion

62.3.1 Fabrication of Al/SiC/Bagasse Ash Composite

Figure 62.2 shows the manufactured samples removed from moulds which were ready for machining and prepare samples.

Machining
Machining is performed on laze machine using carbide cutting tool. The specimens prepared based on ASME standard to conduct tensile, compression and hardness. Figure 62.3 shows the specimens machined and prepared for tensile tests.

Fig. 62.2 Manufacturing of Al/SiC-bagasse ash composite

Fig. 62.3 Specimens for tensile and compression test

62.3.2 Mechanical Tests of the Al/SiC-Bagasse Ash Composite

Tensile test

Tensile strength of a material is the ability of resist loads which applied in the longitudinal direction of sample. Circular specimens were machined with a specific gage length, specimen diameter (D), notch diameter (d) and fillet radius (r) of 100,

Fig. 62.4 Failure of tensile test specimens

12, 7.5, and 9 mm, respectively. The tensile test was conducted on WP 310 computerized hydraulic universal testing machine (UTM) and the test specimens were shown in Fig. 62.4. The test was carried out on WP-300 hydraulic testing machine of 50 kN capacities with at a constant piston speed of 5 mm/min. Table 62.5 presented the complete test results of tensile data. The compared results are between single-reinforced composite (Al/SiC) and hybrid metal matrix composite (Al/SiC-bagasse ash) in addition to the base metal (Al6063). The variation of average tensile strength in each single and hybrid composite is presented in Table 62.6. Tensile test results showed that increasing percentage of reinforcement (SiC) only in the matrix reduces average tensile strength while increasing reinforcements, SiC and bagasse ash improves the tensile strength of Al/SiC-bagasse ash composite. At 10% SiC-10% bagasse ash hybrid composite have better improvement than other single and hybrid composites.

Table 62.5 Tensile strength of the developed hybrid metal matrix composites

S. No.	Al/SiC/fly-ash composite	Ultimate tensile strength (MPa)			Average ultimate tensile strength (MPa)
		Test 1	Test 2	Test 3	
1	Al6063-7.5% SiC-7.5% bagasse ash	52.49	81.71	70.4	68.2
2	Al6063-7.5% SiC-10% bagasse ash	88.5	76.43	60.7	75.2
3	Al6063-7.5% SiC-12% bagasse ash	74.5	61.12	78.98	71.6
4	Al6063-10% SiC-7.5% bagasse ash	76.8	68.8	76.32	73.89
5	Al6063-10% SiC-10%bagasse ash	84.71	87.53	76.62	82.95
6	Al6063-10% SiC-12% bagasse ash	87.5	79.00	85.09	83.86

Table 62.6 Tensile strength of the developed Al/SiC matrix composites

S. No.	Al/SiC composite	Ultimate tensile strength (MPa)			Average ultimate tensile strength (MPa)
		Test 1	Test 2	Test 3	
1	Al6063-7.5% SiC	78.46	45.4	64.87	62.91
2	Al6063-10% SiC	74.24	65.34	47.5	62.36

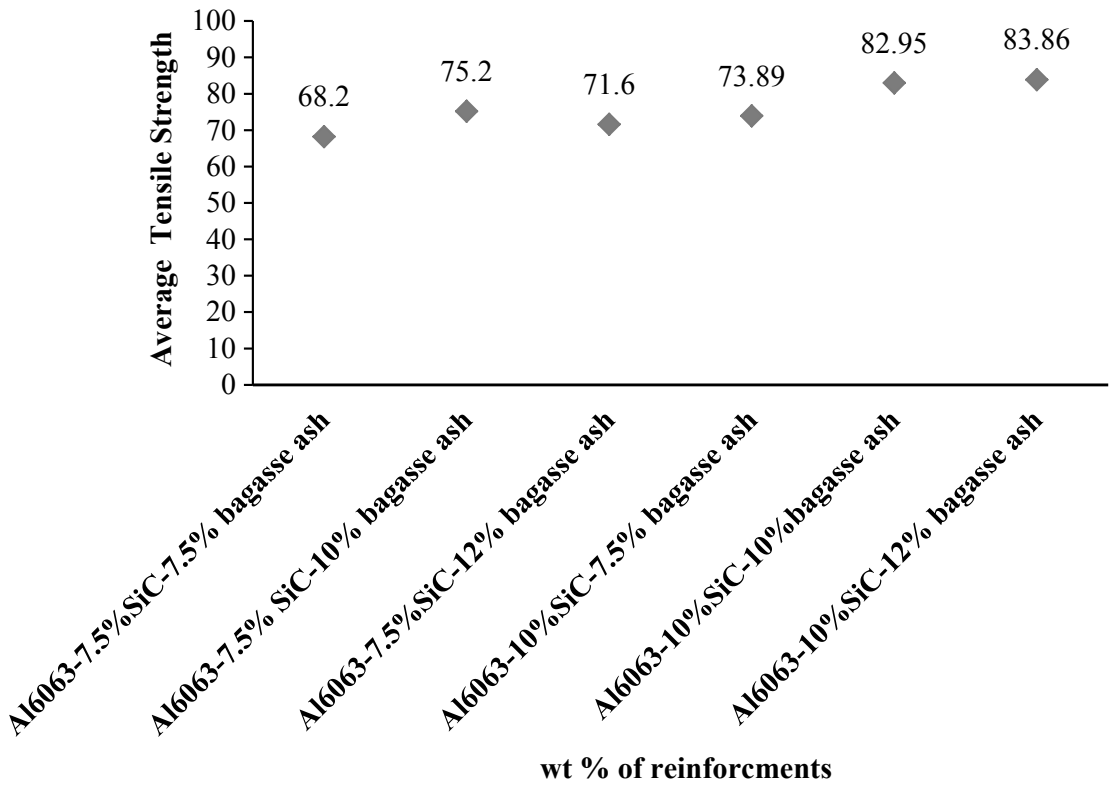

Fig. 62.5 Tensile strength and weight percentage of reinforcements

SiC and FA particles are very effective in improving the tensile strength of the composite. The addition of SiC and fly-ash particles in the matrix induces much strength to matrix alloy by offering more resistance to tensile stresses. It is well known that the thermal expansion coefficient of SiC and fly-ash particle is 3.25 × 106/°C and for aluminium alloy is 23 × 106/°C. The thermal mismatch between matrix and the reinforcement causes higher dislocation density in the matrix and load-bearing capacity of the hard particles which subsequently increases the composite strength. Figure 62.5 reveals the fracture surface of AA6063 10 wt% SiC 7.5 wt% fly-ash composite. It shows a network of dimples whose size is smaller compared to matrix alloy. The fly-ash and silicon carbide refined the grain size of matrix alloy and reduced the ductility which resulted in smaller size dimples.

62.4 Conclusions

The Al/SiC-bagasse fly-ash hybrid composite is successfully manufactured with different weight percentage of SiC and bagasse fly-ash reinforcements (7.5 and 10 wt% of SiC and 7.5, 10, and 12 wt% bagasse fly-ash). The mechanical properties of the developed composite are studied with conducting different tests.

The conclusions drawn from the present investigation are as follows:

- Bagasse fly-ash, the waste generated from sugarcane plant can be successfully used as a reinforcing material to produce metal matrix composite (MMC) component in aluminium matrix to be used in lightweight of automotive parts.
- The tensile strength, compression strength and hardness of the hybrid composite improved with increasing wt% of reinforcements.
- The hybrid Al/SiC-bagasse ash composite were better mechanical properties with compared single-reinforced Al/SiC composite.

Fuzzy-EDAS (Evaluation Based on Distance from Average Solution) for Material Selection Problems

Divya Zindani, Saikat Ranjan Maity and Sumit Bhowmik

Abstract This present work proposes a novel fuzzy-based multi-criteria decision-making (MCDM) approach for addressing material selection problem under uncertain environment. The integrated framework integrates fuzzy decision making with evaluation based on distance from average solution (EDAS) MCDM method. Proposed framework fulfills the gap of restricted exploration of fuzzy decision-making tools in the domain of material design. The applicability of the proposed framework has been evidenced through a case study of a material selection of the casting plate used in sand casting. The selection was done considering five material alternatives and seven criteria. The presented fuzzy-based approach considers the objective weights while calculating the weights of the considered criteria.

Keywords Soft computing · Fuzzy theory · Material selection · Multi-criteria decision making

63.1 Introduction

Decision-making problems of the real world are complex and have to be solved under the influence of conflicting criteria. The decision-making problems when solved considering single criterion results in unrealistic solutions [1]. Therefore, in order to obtain suitable solutions, models for such problems are constructed considering multiple criteria. Systematic and scientific tools in the form of multi-criteria

decision-making (MCDM) tools have been developed to deal with real-world problems considering multiple factors and criteria [2].

Material selection is a decision making problem that involves the selection of the best material from amongst the number of material alternatives. The rankings are obtained under the influence of multiple criteria that are often conflicting in nature. Therefore, material selection problems have been addressed with different MCDM tools. As for instance, the applicability of different preference ranking-based MCDM methods, i.e., operational competitiveness rating analysis (OCRA), organization, arrangement Et synthesize de donors relationnelles (ORESTE), grey system theory-based COPRAS (COPRAS-G) and extended preference ranking organization method for enrichment evaluations (EXPROM2) was evidenced by Chatterjee and Chakraborty [3] through the gear material selection problem. Rastogi et al. [4] employed the TOPSIS method for obtaining the final rankings of material for the phase change material. Material selection of brake friction material was addressed by Singh et al. [4] using combined VIKOR and AHP methodology. TODIM was applied by Zindani et al. [5] for the material selection problems of flywheel and spur gear. Evaluation based on distance from average solution (EDAS) with the design of experiments (DOE) was used recently by Chatterjee et al. [6] and the applicability was justified using gear material selection problem.

However, the problem becomes relatively more complex because of the associated uncertainty. The decision-making process then becomes relatively more challenging. In order to deal with qualitative criteria in material selection problems, fuzzy logic has been employed by the decisionmakers. Simplified fuzzy logic was used for dealing with qualitative properties of materials by Khabbaz et al. [7]. The applicability of the proposed methodology was demonstrated using material selection problems of the liquid nitrogen storage tank, the spar of an aircraft wing, and mast for a sailing boat. To deal with problems involving both the qualitative and quantitative properties, fuzzy-based MCDM models have been proposed and applied by the decisionmakers. Some of the examples include fuzzy-TOPSIS [8], fuzzy-VIKOR [9], etc.

EDAS method has been extended to solve under uncertain environments such as interval type-2 fuzzy sets [10], interval grey numbers [11], neutrosophic soft sets [12], interval-valued fuzzy soft sets [13], interval-valued neutrosophic sets [14], and intuitionistic fuzzy sets [15].

Although EDAS methodology has been evidenced for material selection problem, its applicability to address material selection problem under uncertain environment is yet to be explored. Therefore, the present work is a modest effort to fulfill this gap by proposing a fuzzy-EDAS methodology for material selection problems wherein triangular fuzzy numbers are used to represent linguistic information. The applicability of the proposed material selection framework has been demonstrated using material selection problem of casting plates used in sand casting. Rest of the paper has been organized into the following sections: basic concepts and arithmetic related to fuzzy set have been elaborated in Sect. 63.2. Section 63.3 presents a fuzzy-EDAS method to deal with material selection

problems under an environment of uncertainty. An illustrative example of material selection problem has been demonstrated in Sect. 63.4 of the paper. Paper finally terminates with concluding remarks in Sect. 63.5.

63.2 Fuzzy Theory and Some Definitions

Zadeh [16] developed a fuzzy set theory to handle the problems comprising vague information. Some of the basic definitions pertaining to the fuzzy theory that will be essential in the present work have been delineated in this section.

63.2.1 Definition Number 1

Let $\tilde{b}$ denote a fuzzy set. A membership function $\mu_{\tilde{b}}(x)$ characterizes the fuzzy set which maps x to a real number lying in the interval [0, 1]. Value of the function $\mu_{\tilde{b}}(x)$ is known as the grade of membership of x in $\tilde{b}$.

63.2.2 Definition Number 2

A fuzzy set $\tilde{a}$ is a triangular fuzzy number when $\tilde{b} = (b_1, b_2, b_3)$. Membership function $\mu_{\tilde{b}}(x)$ for a triangular fuzzy number $\tilde{b}$ is denoted by Eq. (63.1):

$$\mu_{\tilde{b}}(x) = \begin{cases} 0, x \leq b_1, \\ \frac{x-b_1}{b_2-b_3}, b_1 \leq x \leq b_2, \\ \frac{b_3-x}{b_3-b_2}, b_2 \leq x \leq b_3, \\ 0, x > b_3, \end{cases} \tag{63.1}$$

where, b_1, b_2, and b_3 denote real numbers such that $b_1 < b_2 < b_3$.

63.2.3 Definition Number 3

Main operations between two triangular fuzzy numbers $\tilde{b} = (b_1, b_2, b_3)$ and $\tilde{c} = (c_1, c_2, c_3)$ can be expressed as follows:

Addition $\tilde{b}$ (+) $\tilde{c}$ = $(b_1 + c_1, b_2 + c_2, b_3 + c_3)$
Subtraction $\tilde{b}$ (−) $\tilde{c}$ = $(b_1 - c_3, b_2 - c_2, b_3 - c_1)$

Multiplication $\tilde{b}\ (\times)\ \tilde{c} = (b_1 \times c_1, b_2 \times c_2, b_3 \times c_3)$
Division $\tilde{b}\ (/)\ \tilde{c} = (b_1 \times c_1, b_2 \times c_2, b_3 \times c_3)$

63.2.4 Definition Number 4

Operations between a triangular fuzzy number and a real number k are described as below:

Multiplication $k\ (\times)\ \tilde{b} = (kb_1, kb_2, kb_3)$
Division $\tilde{b}/k = (b_1/k, b_2/k, b_3/k)$
Division $k/\tilde{b} = (k/b_1, k/b_2, k/b_3)$

63.2.5 Definition Number 5

The crisp value of a triangular fuzzy number $\tilde{b} = (b_1, b_2, b_3)$ is defined as by Eq. (63.2):

$$k(\tilde{b}) = \frac{1}{6}(b_1 + 4b_2 + b_3) \tag{63.2}$$

63.2.6 Definition Number 6

The maximum of zero and a triangular fuzzy number can be established using Eq. (63.3):

$$\psi(\tilde{b}) = \begin{cases} \tilde{b} \text{ if } k(\tilde{b}) > 0 \\ \tilde{0} \text{ if } k(\tilde{b}) \leq 0 \end{cases} \tag{63.3}$$

63.3 The Conceptual Framework of Fuzzy-EDAS Methodology

EDAS methodology was developed by Keshavarz Ghorabaee et al. [17] and the method ranks material on the basis of the average solution. The average solution is arrived at by calculation of the positive distance from average (PDA) and negative

distance from average (PDA). The alternative that has higher PDA values and lower NDA values are the best-ranked material alternative.

In the case of fuzzy-EDAS methodology, alternatives are ranked in accordance with the decreasing value of defuzzified appraisal score. The steps involved in the fuzzy-EDAS method have been delineated in the ensuing discussion. Let $\tilde{A}$ denote the fuzzy decision matrix, i.e.,

$$\tilde{A} = \left[\tilde{a}_{ij}\right]_{n\times m} = \begin{bmatrix} \tilde{a}_{11} & \tilde{a}_{12} & \cdots & \tilde{a}_{1m} \\ \tilde{a}_{21} & \tilde{a}_{22} & \cdots & \tilde{a}_{2m} \\ \vdots & \vdots & \vdots & \vdots \\ \tilde{a}_{n1} & \tilde{a}_{n2} & \cdots & \tilde{a}_{nm} \end{bmatrix} \tag{63.4}$$

where j is the number of alternatives and i signify the criteria.

Following steps are traced in order to solve a decision-making problem using fuzzy-EDAS methodology.

63.3.1 Step 1

In this step of the proposed framework, objective weights are determined for each of the criteria Ci using Eqs. (63.5) and (63.6). Objective weights are determined for the decision matrix supplied by all the decisionmakers.

$$w_j^* = \frac{\sum_{i=1}^{m}\sum_{r=1}^{m}\left|p_{ij} - p_{rj}\right|}{\sqrt{\sum_{j=1}^{m}\left[\sum_{i=1}^{m}\sum_{r=1}^{m}\left|p_{ij} - p_{rj}\right|\right]^2}} \tag{63.5}$$

$$w_j^o = \frac{w_j^*}{\sum_{j=1}^{m} w_j^*} \tag{63.6}$$

63.3.2 Step 3

A fuzzy average decision matrix is developed with respect to all the considered criteria using Table 63.1 and Eq. (63.7):

$$\mathrm{AV}_j = \frac{\sum_{i=1}^{n}\tilde{a}_{ij}}{k} \tag{63.7}$$

Table 63.1 Linguistic terms for alternatives ratings

Linguistic term	Membership function
Very low (VL)	(0,0,0.1)
Medium low (ML)	(0, 0.1, 0.3)
Low (L)	(0.1,0.3, 0.5)
Medium (F)	(0.3, 0.5, 0.75)
High (H)	(0.5,0.75,0.9)
Medium High (MH)	(0.75,0.9,1)
Very high (VH)	(0.9, 1, 1)

63.3.3 Step 4

The distance of optimal solution from negative feasible solutions must be maximum whereas it should be minimum from the negative feasible solution. In this step of the fuzzy-EDAS methodology, matrices for fuzzy positive distance from average (PDA) and fuzzy negative distance from average (NDA) are calculated using Eqs. (63.8) and (63.9), respectively.

$$\mathrm{PDA} = \left[\mathrm{pda}_{ij}\right]_{n\times m} \tag{63.8}$$

$$\mathrm{NDA} = \left[\mathrm{nda}_{ij}\right]_{n\times m} \tag{63.9}$$

where for beneficial criteria

$$\mathrm{pda}_{ij} = \begin{cases} \dfrac{\psi\left(\tilde{a}_{ij} - \mathrm{AV}_j\right)}{k\left(\mathrm{AV}_j\right)} \end{cases} \tag{63.10}$$

and

$$\mathrm{nda}_{ij} = \begin{cases} \dfrac{\psi\left(\mathrm{AV}_j - \tilde{a}_{ij}\right)}{k\left(\mathrm{AV}_j\right)} \end{cases} \tag{63.11}$$

and for non-beneficial criteria

$$\mathrm{pda}_{ij} = \begin{cases} \dfrac{\psi\left(\mathrm{AV}_j - \tilde{a}_{ij}\right)}{k\left(\mathrm{AV}_j\right)} \end{cases} \tag{63.12}$$

and

$$\mathrm{nda}_{ij} = \begin{cases} \dfrac{\psi\left(\tilde{a}_{ij} - \mathrm{AV}_j\right)}{k\left(\mathrm{AV}_j\right)} \end{cases} \tag{63.13}$$

63.3.4 Step 5

In this step of the methodology, matrices are developed for fuzzy weighted positive and fuzzy weighted negative distances. Equations (63.14) and (63.15) are used for this purpose

$$\mathrm{sp}_i = \sum_{j=1}^{m} \left(\tilde{w}_j + \mathrm{pda}_{ij}\right) \tag{63.14}$$

and

$$\mathrm{sn}_i = \sum_{j=1}^{m} \left(\tilde{w}_j + \mathrm{nda}_{ij}\right) \tag{63.15}$$

63.3.5 Step 6

Fuzzy normalized values for fuzzy weighted positive and fuzzy weighted negative distances are computed using Eqs. (63.16) and (63.17)

$$\mathrm{nsp}_i = \frac{\mathrm{sp}_i}{\max_i(k(\mathrm{sp}_i))} \tag{63.16}$$

and

$$\mathrm{nsp}_i = 1 - \frac{\mathrm{sn}_i}{\max_i(k(\mathrm{sn}_i))} \tag{63.17}$$

63.3.6 Step 7

In the penultimate step, fuzzy appraisal score for different alternatives is calculated using Eq. (63.18)

$$\mathrm{as}_i = \frac{\mathrm{nsp}_i + \mathrm{nsn}_i}{2} \tag{63.18}$$

63.3.7 Step 8

In the last step, alternative materials are ranked in accordance with the decreasing value of defuzzified appraisal score. The best choice of the alternative material is the one with the highest value of appraisal score.

63.4 Illustrative Example

In this section, a case study on material selection of pattern used in sand casting has been solved using the above-proposed methodology. The material alternatives identified from literature survey [19] were wood (A_1), aluminum (A_2), steel (A_3), plastic (A_4), and cast iron (A_5). The criteria considered for the problem under consideration were machinability (C_1), wear resistance (C_2), strength (C_3), weight (C_4), reparability (C_5), resistance to corrosion (C_6), and resistance to swelling (C_7). Excluding weight, all the other criteria are benefited criteria. Three decisionmakers were asked to provide their performance rating. Table 63.2 depicts the performance rating for decisionmakers 1, 2, and 3. Each of the decision matrices was then converted to a triangular fuzzy number using information from Table 63.1. Table 63.3 depicts the fuzzy converted matrix for all the decisionmakers considered. Equations (63.4) and (63.5) were then used to obtain the objective weights for

Table 63.2 Performance ratings as given by decisionmakers

all the decision matrix obtained from the three decisionmakers. The aggregate weights were finally obtained by taking the average of all the objective weights for particular criteria. Table 63.4 depicts the individual objective weights and the aggregated objective weights. In the next step, the average decision matrix was formulated and has been tabulated in Table 63.5. Equation (63.7) was then used to arrive at the average solution which has been depicted in Table 63.6 which also shows the crisp value of the average solution obtained using Eq. (63.2). Positive distance from average (PDA) and negative distance from average (NDA) values were obtained using Eqs. (63.8–63.13) and Tables 63.7 and 63.8 represent these values. Fuzzy normalized values for fuzzy weighted positive and fuzzy weighted negative distances were computed using Eqs. (63.16) and (63.17). In the penultimate step, fuzzy appraisal score for different alternatives is calculated using Eq. (63.18). Finally, the alternatives were ranked on the basis of the defuzzified appraisal score. Table 63.9 portrays all these values. Aluminum was found to be the best alternative material.

63.5 Result and Discussion

Present work proposes a fuzzy-based integrated methodology in the form of fuzzy-EDAS for solving material selection problem. The proposed methodology aids the decisionmaker in addressing the linguistic performance rating of material alternatives with respect to the criteria. The presented material selection framework, therefore, aids in handling the complexity associated with the uncertain environment. However, the presented methodology only considers objective weights and does not take into consideration the subjective importance. To justify the applicability of the proposed method, material selection problem of casting pattern plate was solved. A total of five material alternatives and seven criteria were considered. Aluminum was found to be the best-ranked material alternative, whereas wood was the worst performing of all. As a future scope of the work, subjective weights could also be considered while arriving at the aggregated weights for each criterion. Further, quantitative properties in the decision matrix could also be given due consideration.

Chapter 64
Tensile and Flexural Property Analyses of Glass/Carbon Embedded Hybrid Natural Fibre Composites

Jobin G. Jose, E. Sivakumar, Jibin T. Philip, Kore Mahesh and Basil Kuriachen

Abstract The composites developed from natural fibre have brought indisputable advantages over synthetic materials in terms of nontoxicity, efficient waste disposability, comparable strength, etc. Some automotive structures such as in aerospace and motor racing vehicles, strength-to-weight ratio is precisely imperative and fibre-reinforced composite materials are used to develop such structures with critical stiffness and weight sensitivities. The environmental effect and the subsequent failure of the fibre-reinforced polymers (FRP) have led to the study of its different mechanical properties. In this work, the fibre-reinforced composite material was fabricated with hybrid jute–coir fibre and polyester resin matrix embedded with glass/carbon fibres. Tensile and flexural strength of the developed natural fibre composites are tested using universal testing machine (UTM) as per the ASTM standards. The sample C2 [jute 75% + coir 25% and carbon 100% of 30% and 15% of total composite composition in weight percentage (wt%)] with yield, ultimate and flexural strength of 118, 122 and 81.04 MPa in-errantly proved to possess an upper edge over jute–coir–glass composites upon testing.

Keywords FRP · Natural Fibre · Composites

64.1 Introduction

Fibre-reinforced composite materials have made a drastic influence on the technology of part designing and manufacturing. Natural fibres are being used as reinforcements due to their good mechanical properties, cost-effectiveness,

biodegradability and lightweight [1, 2]. Moreover, the hybridization of natural fibre increases its mechanical, thermal and water absorption properties [3–5]. Fibre composites have various industrial as well as commercial applications. Nowadays, the metals/metal matrix composites are being replaced by polymers in various fields of their utilization. The orientation and stacking of fibres effect greatly on the properties of any developed composite [6]. Further, in continuous fibre composites, the reinforcements are arranged in the form of layers in different orientations to obtain the required properties with fibre volume up to 60–70% [7].

E-glass fibres have good properties such as high tensile strength high dimensional stability and high chemical resistance and thus it is preferred as the reinforcement material in most of the industries [8]. Carbon fibre is mostly used where lightness and high stiffness are required. Synthetic fibres are not eco-friendly and there comes the importance of using natural fibres to develop environment-friendly composite materials. Generally, these natural fibres do not possess any substantial properties to replace synthetic fibres when used as such. Hence, the natural fibres are hybridized with synthetic fibres to develop good property composites and reduce their impact on the environment. Mostly used natural fibres are jute, sisal, kenaf, hemp, etc. due to their desirable properties and availability in nature. E-glass fibres are often used for hybridization with jute fibre. In some cases, the natural fibre composites have properties better than glass fibre composites [9]. Coir natural fibres are found to have poor mechanical properties. Precisely, coir fibre composites showed only average values for tensile, flexural and impact strength which are poor when compared to glass fibre-reinforced polymer (GFRP) composites [10]. Nevertheless, natural fibres have good mechanical properties with polyester resin matrix [11].

The present work investigates the tensile and flexural strength of hybrid jute–coir fibre composite material compared with glass and carbon fibre at varying compositional ratios (wt%) with polyester resin as matrix. Methyl ethyl ketone peroxide and cobalt naphthenate are the catalyst and accelerator, respectively. Compression moulding technique was used to develop the samples and then subjected to property analyses on universal testing machine (UTM).

64.2 Experimental Methodology

64.2.1 Materials

In this work, the jute, coir, glass and carbon fibres are used as raw materials for the composite specimen preparation. Polyester resin was the matrix used, methyl ethyl ketone peroxide and cobalt naphthenate are the catalysts and accelerators, respectively. Jute fibre was imported from Jaipur, Rajasthan, India; coir fibre has been purchased from Alappuzha, Kerala, India; glass and carbon fibres are obtained from Sharon Enterprises, Ernakulam, Kerala, India. Polyester resin along with its

catalysts and accelerators are also procured from Sharon Enterprises, Ernakulam, Kerala, India.

64.2.2 Composite Preparation

The specimens were prepared by compression moulding process. Stainless steel mould of dimension (200 × 200 × 3) mm was used for moulding the composite sheet specimens. Specimens were prepared according to proportion as described in Table 64.1. Calculation was done to find the required volume for moulding. The matrix and the reinforcement are taken in the ratio 55:45. A calculated amount of polyester resin along with its accelerator and catalyst was mixed thoroughly. Mixing of the matrix is done gently to avoid formation of voids and instantaneously poured onto the reinforcement in order to avoid curing in room temperature. Separator sheets were placed at the inner surface of the mould for quick and easy removal of the moulded sheet. A thin layer of matrix mixture was poured on the separator sheet and the fibres were kept on top. The fibres were arranged in a layer by layer manner in which natural fibres were kept outside and glass/carbon fibres were kept inside. Polyester resin mixture was poured on top of the fibres and spread all around. Separator sheet was placed on it and the mould was closed. Care was taken to avoid formation of air bubbles. Mould was kept in compression moulding machine and pressure was applied. The mould was allowed to cure at room temperature for 48 h. Further, the specimens were taken out of the mould and sides were shaped as shown in Fig. 64.1. The specimen was then cut into standard shapes required for tensile and flexural tests using counter cutting machine.

Fig. 64.1 Composite sheet specimen

64.2.3 Mechanical Property Testing

The tensile and flexure tests were carried out on the prepared specimens using standard instruments to study their mechanical properties. The data values such as displacement, force stress and strain at different time intervals were obtained from the system connected to the UTM, from which the mechanical property trend graphs of different specimens were plotted. The detailed methodology followed for various test methods are as follows.

Tensile Test. The tensile testing samples were cutted using a counter cutting machine according the ASTM standard D638 [12]. The edges of the samples were finished for tensile testing as shown in Fig. 64.2. The sample was fixed vertically on the UTM by clamping both ends on to the holder and load was applied gradually

Fig. 64.2 Sample for tensile testing as per ASTM D638

until it fractures. The test was repeated for all the samples and its elongation value at the gauge section was recorded.

Flexural Test. Flexural test samples were prepared as per the ASTM standard D790 [13] as shown in Fig. 64.3. Three-point flexure test procedure was employed to carry out the entire sequence of methodology using UTM. The specimen was placed horizontally on the UTM as per standard procedural specifications by providing support at the end points. The force was applied gradually at the midsection of the sample until fracture occurs. The procedure was repeated for all the test specimens developed using different compositions of the fibres. The flexural strength values were recorded for all the test samples.

64.3 Results and Discussion

64.3.1 Tensile Properties

The tensile test results for all the samples are obtained and their yield stress and ultimate stress of glass and carbon fibre composite specimens are tabulated separately in Tables 64.2 and 64.3. It is observed that jute–coir composite samples are having less tensile strength when compared with jute composite samples. This is due to the hybridization of coir fibres in it. These samples show ductile behaviour. Comparing Tables 64.2 and 64.3, it is observed that the carbon composite specimens are having better tensile strength than glass composite specimens. It can also be observed that G3 and C3 samples are having less tensile properties. This is due to lack of proper adhesion between jute–coir–glass/carbon specimens as they are of equal fibre volume.

The force–displacement graph for jute–coir–glass and jute–coir–carbon fibre for tensile testing is as shown in Figs. 64.4 and 64.5, respectively. Comparing both the plots it can be interpreted that the samples G2 and C2 with jute 75% and coir 25% possess better properties than those samples with higher percentages of coir. Moreover, jute–coir–carbon fibre (C2) has greater withstanding capacity of 5990 N before breakdown than the jute–coir–glass fibre (G2) which has a value of 4160 N. So, the general trend is that the increase in percentage of coir with corresponding decrease in percentage of jute causes a reduction in tensile properties of the composite fibre. Hence, optimum value near to the sample compositions of G2 and C2 must be chosen for significant results.

Fig. 64.3 Sample for flexural testing as per ASTM D790

C3	21.1	33
C4	69.8	110
C5	71	80

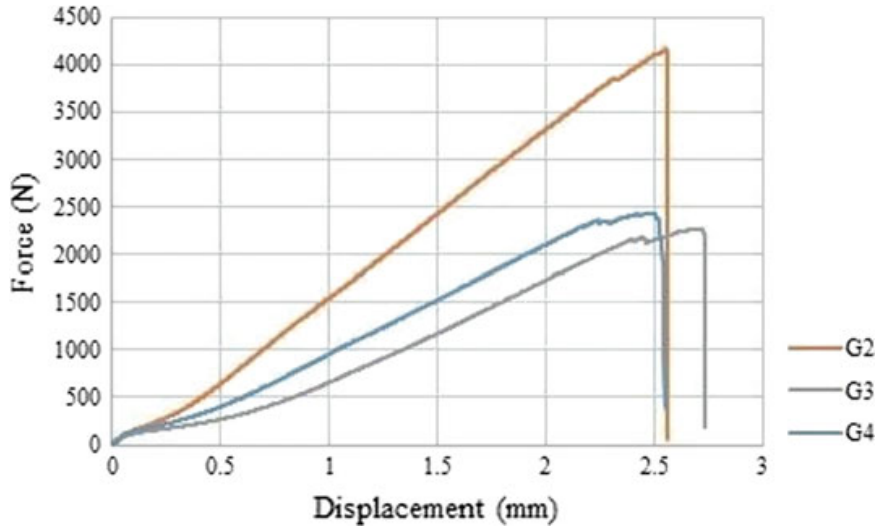

Fig. 64.4 Force–displacement plot for jute–coir–glass fibre for tensile test

64.3.2 Flexural Properties

The three-point flexural test values are obtained and are tabulated in Tables 64.4 and 64.5 separately for glass and carbon fibre composites. It is observed that flexural strength for jute–glass composite is less than jute–carbon composite. On investigation of hybridized jute–coir composite samples, it was observed that G3 is having greater flexural strength as 98.16 MPa and C3 is having the lowest as 54.05 MPa. Comparatively, jute-coir–carbon composite samples have good flexural strength than jute–coir–glass composite samples. The force–displacement graph for jute–coir–glass and jute–coir–carbon fibre for flexural test is as shown in Figs. 64.6

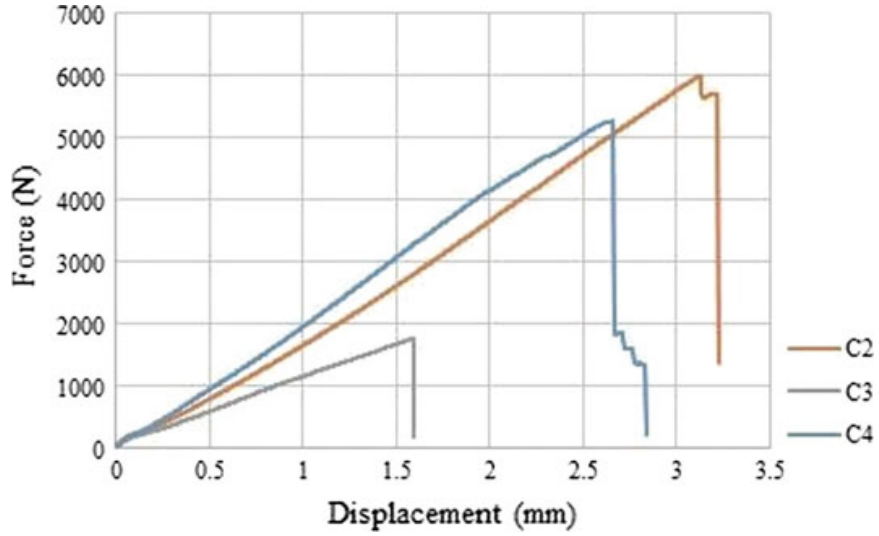

Fig. 64.5 Force–displacement plot for jute–coir–carbon fibre for tensile test

Table 64.4 Flexural strength of jute–coir–glass fibre composites

Sample	Flexural strength (MPa)
G1	100.22
G2	82.88
G3	98.16
G4	86.51
G5	77

Table 64.5 Flexural strength of jute–coir–carbon fibre composites

C1	125.8
C2	81.04
C3	54.05
C4	90.90
C5	80

and 64.7, respectively. Comparing both the plots, it can be noted that the samples G3, G4, C2 and C4 possess better withstanding capabilities to bending force. When considering the tensile properties discussed in the previous section along with the flexural properties, the samples G3 and G4 can be eliminated due to inconsistent behaviour in properties. Although these samples could withstand flexural loads of 170 and 198.2 N, their tensile load bearing capabilities are insignificant. Interestingly, the samples C2 and C4 sustained its consistency in both tensile and flexural property tests. On considering Fig. 64.6, it can be precisely noted that the samples C2 and C4 were able to withstand the flexural loads up to 145 N and 163.3 N, respectively. The depleting effect of the coir fibre with increase in its

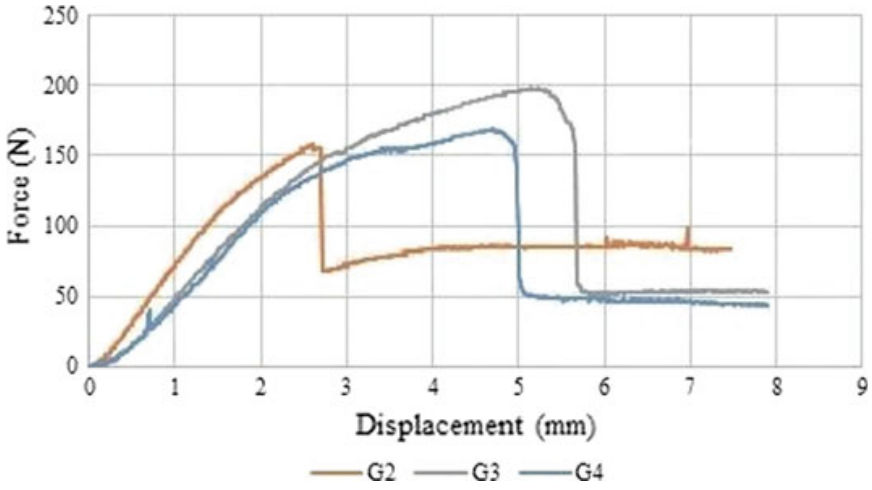

Fig. 64.6 Force–displacement graph for jute–coir–glass fibre for flexural test

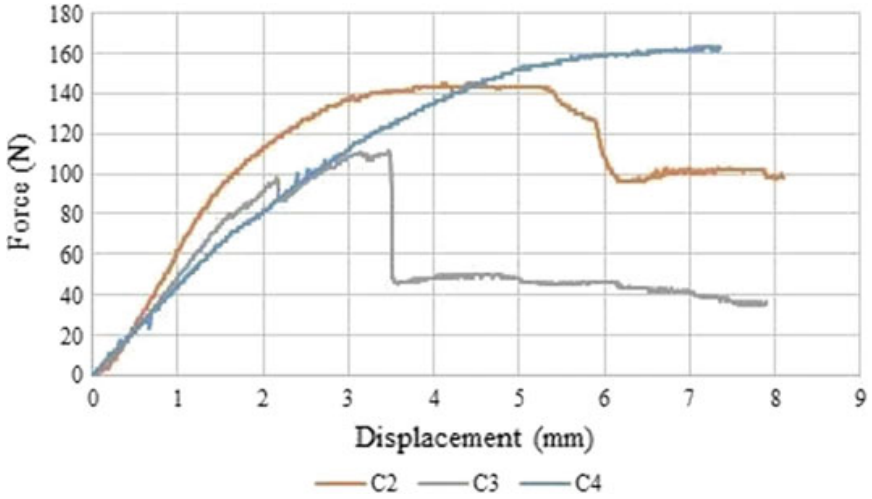

Fig. 64.7 Force–displacement graph for jute–coir–carbon fibre for flexural test

percentage is not much evident in the case of flexural tests. Hence, the jute–coir–carbon fibre is found to have an upper hand compared to the jute–coir–glass fibre.

64.4 Conclusions

The various proportions of jute–coir–glass fibre polyester resin composites and jute–coir–carbon fibre polyester resin composites were prepared and subjected to tensile and flexural tests for the comparative study. The following conclusions were derived from the experiment.

- Jute–carbon composites showed good tensile and flexural properties in comparison with jute–glass composites. Addition of coir into the composites

decreased the mechanical properties of both jute–glass and jute–carbon fibre composites.

- Jute–coir–glass/carbon at equal volume proportion showed the lowest tensile strength due to lack of adhesion between fibres and the resin.
- The samples C2 and C3 showed the maximum and minimum tensile strengths among hybrid jute–coir fibre composites. Flexural strength was highest for G3 (98.16 MPa) and lowest for C3 (54.05 MPa) samples of the jute–coir fibre composites. Further, all the composites investigated showed ductile behaviour.
- The samples C2 and C4 of the jute–coir–carbon fibre composites possess better properties compared to the other samples tested for its mechanical properties. Specifically, the sample C2 was found to have consistent property of all the samples considered. The samples G1, G2 and G3 of the jute–coir–glass fibre composites were eliminated due to inconsistency in properties tested under various conditions.
- Finally, jute–coir–carbon fibre composites had greater tensile and flexural properties over jute–coir–glass fibre composites, comparatively.

Chapter 65
Mechanical Characterization of Hybrid Carbon–Glass-Reinforced Polypropylene Composites

Ansuman Padhi and Debiprasada Sahoo

Abstract In the present work, an attempt has been made to investigate the effect of varying wt% of short carbon fiber on the hybrid carbon–glass fiber/polypropylene (PP) composites. Composites of PP reinforced with short glass fibers and carbon fibers were prepared using two-roll milling machine and compression molding techniques with different vol. fraction and wt. percentage. The wt% and vol. fraction of glass fibers were kept constant, by varying the other two materials. Different mechanical properties such as tensile and impact properties were investigated by using suitable experimental setup. In tensile test, with the increase in carbon fiber wt% the strength (MPa) initially decreases but afterward it increases and is giving highest value for maximum wt% of carbon fiber. But for the impact test, the energy absorbed (J) gradually increases by increasing the carbon fiber wt%. From the test results, it shows that the material properties have been improved significantly compared to the polypropylene with only glass fiber, which encourages to use and opt for hybrid composite.

Keywords Hybrid composites · Carbon fiber · Glass fiber · Polypropylene · Mechanical properties

65.1 Introduction

Any single material may not be able to satisfy all the stringent requirements of properties to be used in high-end structural applications. This leads to the development and use of multi-phase integrated composite material systems. Composite materials are formed by macro-scale combination of two or more chemically distinct phases whose performances are superior to their constituent materials and often exhibit qualities that neither constituent possesses. FRP composites consist of

fibers of high strength and modulus embedded or dispersed in matrix (polymer) with distinct interfaces between them.

In the past few years, the thermoplastic polymers have become most preferred materials for various applications due to several attractive properties including less weight, easy to process and cost-effectiveness. Hence, efforts have been made significantly to utilize polymers in various industrial applications, using different types of reinforcements including various kinds of fibers that are integrated into the polymers to increase their physical and mechanical properties. Thus, fiber-reinforced polymer matrix composites are comprehensively used due to their lightweight, high strength, biodegradability ability to be processed rapidly, high stiffness and good corrosion resistance. Among the synthetic fibers, carbon fiber is having high strength and stiffness with significantly light weight compared to same volume of glass fiber. But due to its cost, it can not be used in day-to-day applications. So in this paper, an attempt has been taken to manufacture a hybrid composite in which carbon fiber is added with different weight percentage ratios to the glass fiber polypropylene composite.

However, a number of studies have been carried out on hybrid composites with thermoplastic material (polypropylene) as matrix. Some of the significant findings are discussed below. Fu et al. [1] prepared and investigated the tensile properties of polypropylene (PP) composites reinforced with short carbon fibers (SCF) and short glass fibers (SGF) with extrusion compounding and injection molding techniques. Karsli et al. [2] studied the hybrid reinforcement effect of surface treated or untreated glass fiber (GF)/carbon nanotube (CNT) on the mechanical and electrical properties as well as morphology of polypropylene matrix composites. Gamstedt et al. [3] have studied the strength properties of polypropylene (PP) and polypropylene modified with maleic anhydride (MA-PP) reinforced by continuous longitudinal glass fibers. Ferreira et al. [4] have concerned studies of fatigue on polypropylene/glass fiber-thermoplastic composites produced from a bi-directional woven cloth of co-mingled E-glass fibers and polypropylene. Suresh et al. [5] discussed the influence of the forming pressure and coupler concentration on the mechanical behavior of polypropylene composite laminates reinforced with glass fiber. Ashori et al. [6] worked on improvement in the mechanical and thermo-mechanical properties of short carbon fiber (SCF)/polypropylene (PP) composite, resulting from coating of the SCFs with exfoliated grapheme nanoplatelets (xGnPs). The adhesion enhancement of xGnP–SCF/PP interface was clearly shown by scanning electron microscopy (SEM) images of the surfaces from tensile failure. Rezaei et al. [7] studied the thermal stability of short carbon fiber-reinforced polypropylene (SCF/PP) composite were prepared with melt blending and hot-pressing techniques. Swolfs et al. [8] prepared composite hybrids by taking bonding between carbon fiber prepregs and PP tapes. For a weak bonding, high penetration impacts resistance and the 20% ultimate tensile failure strain of self-reinforced PP were maintained. For a strong bonding, the ultimate tensile failure strain was reduced marginally, but the flexural performance was improved. Unterweger et al. [9] evaluated the mechanical properties of injection-molded CF-reinforced polypropylene (PP) composites under the influence of carbon fibers

(CF) surface properties and the amount of a coupling agent. Khan et al. [10] found that the damping ratio of the hybrid composites is enhanced with the addition of CNTs, which is attributed to sliding at the CNT–matrix interfaces. Arikan et al. [11] present the impact response of E-glass fiber-reinforced composites that have been manufactured with two types of resin, polypropylene and epoxy (thermoplastic and thermoset). Swolfs et al. [8] found that in the prepregs for a homopolymer PP matrix, the weak bonding among fiber and matrix affected the penetration impact resistance according to a linear rule-of-mixtures. Zhang et al. [12] investigated the influences of stacking sequence on the strength of hybrid composites comprising materials with differing stiffness and strength. Sullins et al. [13] worked on the effects of material treatment(s) on the mechanical behaviors of hemp fiber-reinforced polypropylene (PP) composites.

In this work, the composites have been prepared by taking polypropylene as matrix reinforced with short glass and carbon fiber, where the wt% of glass fiber kept constant in order to visualize the effect of CF. The above materials are prepared by using two-roll mill and compression molding techniques. This study mainly aimed to investigate the effect of carbon fiber hybridization on the glass-reinforced PP composites. The tensile properties as well as the energy absorption during impact were primarily considered in the experimentation.

65.2 Experimental Details

Materials used

The materials employed in this investigation were polypropylene, E-glass fiber roving and carbon fiber rovings. The mechanical and physical properties of these materials are listed in Table 65.1. The composition and volume fraction of each specimen are given in Table 65.2. The wt% of glass fiber was kept constant, while the wt% of other two materials is varied.

Specimen Preparation

The glass fiber and carbon fiber are cut into 3–5 mm in length by help of a scissor and make it to chopped fiber form. After that the polypropylene which is already procured is mixed with the above two fibers in the specified ratios with the help of a two-roll mill machine. These machines are extensively used for mixing and

Table 65.1 Mechanical properties of materials

Materials	Tensile strength (MPa)	Young's modulus (GPa)	Density (g/cm^3)
Glass fiber	2450	81.3	2.65
Carbon fiber	3665	230	1.75
Polypropylene	23.9	1.28	0.904

Table 65.2 Volume fraction and weight composition in different specimens

Specimen code	Polypropylene (PP) wt %/(Mass in gm.)	Carbon fiber (CF) wt%/ (Mass in gm.)	Glass fiber (GF) wt%/ (Mass in gm.)
A	0.8/400	0.05/25	0.15/75

C	0.7/350	0.15/75	0.15/75

kneading raw rubber, thermoplastics or EVA with chemicals, synthetic rubber into uniform materials. The uniform materials can be fed to calendar, hot presses or other processing machinery for preparing rubber or plastic products. Two-roller mills are the most simple in operation, where the material is crushed between two rollers before it continues on to its final destination. The spacing can be adjusted in between these two rollers by the operator. Smaller pieces are produced when the material is crushed in thinner spacing. The front roller in this study was set to 170 °C, 15 rpm and rear roller to 175 °C, 10 rpm and a gap of 2 mm kept in between the two rollers, after that the mixing process will start (Fig. 65.1).

By setting the rollers quite tightly to each other, refined rubber in thin-sheet form (∼0.10 mm) is produced. A smooth, uniform and free of grain or lumps sheet is produced. The impurities contained in reclaimed rubber are pressed by rolls to the both sides of rubber sheet which can be removed. Consequently, the purity of the reclaimed rubber is increased in refiner mills. Earlier, the finished sheet was pulled toward a wind-up attachment and layered few times to increase the thickness of the sheet (approx. 25 mm), after which they are cut using a hand knife. The cut sheets are then cleaned and stacked (Fig. 65.2).

Compression molding The final product is manufactured using the compression molding machine. Compression molding is a high-pressure and high-volume method suitable for molding intricate and high-strength fiberglass reinforcements. Advanced composite thermoplastics can also be compression molded with

Fig. 65.1 Mixing of fibers with polypropylene in two-roll mill

Fig. 65.2 Sheets obtained after two-roll mill operation

unidirectional tapes, woven fabrics, randomly oriented fiber mat or chopped strand. Compression molding is having ability to mold large and fairly complex parts. Also, it is one of the cost-effective molding methods compared with other methods such as transfer molding and injection molding; moreover, it trashes reasonably little material, giving it an advantage when working with expensive compounds.

The molding material is positioned in the mold cavity and the heated platens are closed by a hydraulic ram. The mold is subjected to pressure and heated until the curing reaction occurs. Temperature history during molding process is shown in Fig. 65.3. Holding time is set for 90 s for maximum temperature of the mold surface at 200 °C. To heat up from 50 to 200 °C, it took only 50 and 130 s for the cooling process from 200 to 50 °C. Altogether, molding was completed in 270 s. In this way, the three different compositions of composite sheets are prepared by compression molding as shown below. For quick and easy removal of composite sheets, polyester film applied at the inner surface of the mold. The dimension of the die is 160 × 160 × 3 mm^3. Care is taken to avoid formation of air bubbles. The die was allowed to cool at room temperature. Then the samples were taken out of the die, cut by hacksaw into different sizes for further experimentation as per standard (Table 65.3; Fig. 65.4).

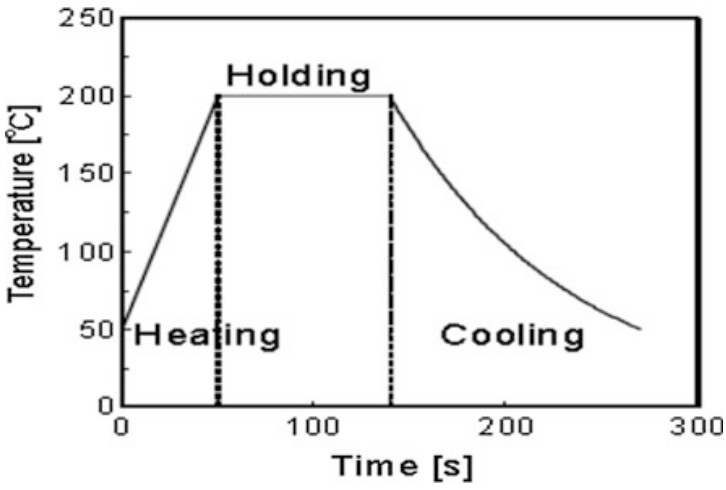

Fig. 65.3 Temperature versus time during a typical compression molding process

Table 65.3 Specimen dimensions for Tensile & Impact test

Test	Length (mm)	Width (mm)	Thickness (mm)
Tensile	165	12.7	3.2
Impact	63.5	12.7	3.2

Fig. 65.4 Compression molding machine

65.3 Results and Discussion

65.3.1 Tensile Test

Tensile tests were conducted on Instron universal testing machine (model 3382) in accordance with ASTM D638. The testing speed was 1 mm/min with at least three samples of each specimen were tested (Figs. 65.5 and 65.6; Table 65.4).

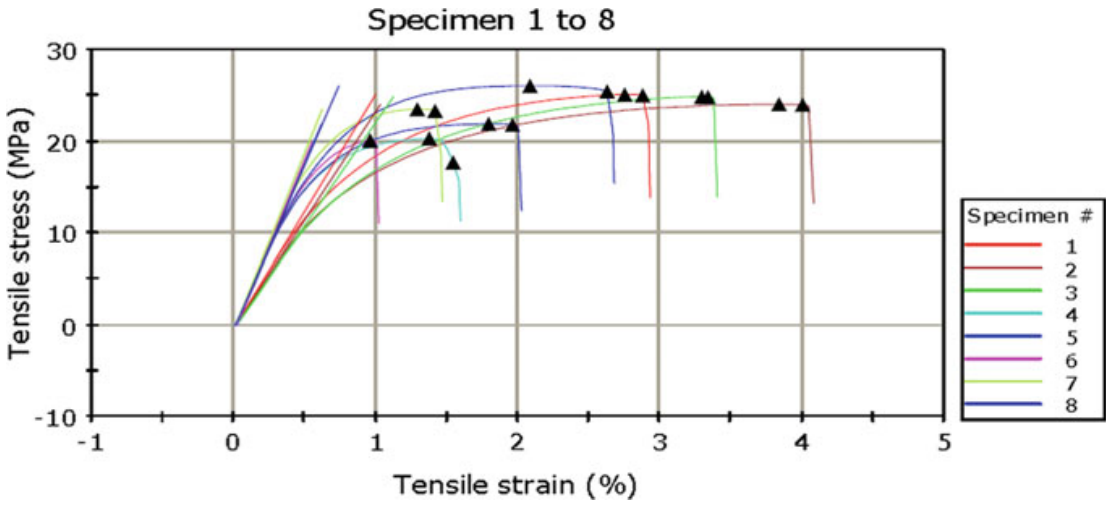

Fig. 65.5 Stress–strain curve of 8 specimens of three different compositions

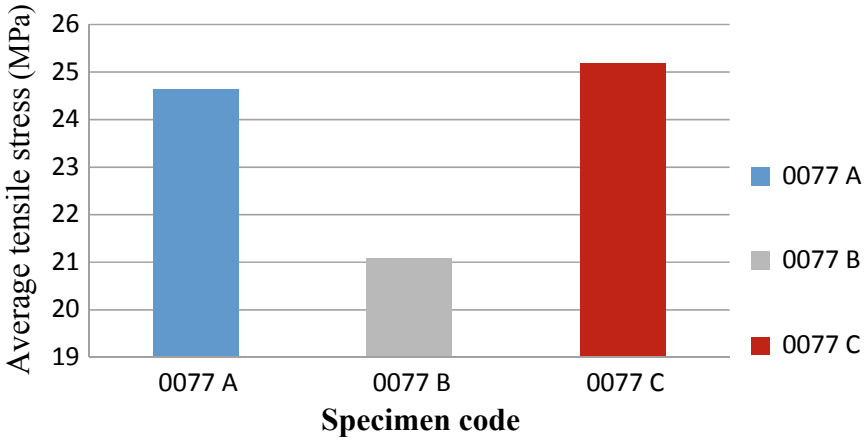

Fig. 65.6 Average ultimate tensile strength of three Specimens

65.3.2 Impact Test

The impact properties of the three specimens were determined using three samples for each composition with the dimensions as mentioned in Table 65.3. The Charpy impact test is a standardized high strain-rate test which measures the amount of energy absorbed by a material during fracture. This absorbed energy is a degree of a given material's notch toughness. The thickness of the specimen and the dimensions of the un-notched length were measured. The pendulum was raised to the left until it indicates the maximum energy range on the upper indicator unit. The specimen was placed horizontally across supports with the notch away from the pendulum. The pendulum was released to measure the energy absorbed during the impact. The energy absorbed during the impact test by different specimens was shown in Fig. 65.7. The test is done in accordance with the ASTM D 256.

It is observed that, the tensile test results shown in Fig. 65.6, specimen 8 have a better strength compared to all other seven specimens. The specimen 8 is having the composition of PP 70%, CF 15%, GF 15%. It has been noted that 5% CF content composition has more tensile strength compare to 10% CF content composition, but when 15% CF is added to PP and GF, it gives the maximum value of tensile strength and this value is 26.04 MPa.

Impact test results are shown in Fig. 65.7. It can be seen that impact strength of code "A" composition is 51.67 J/m. After that when CF% changes from 5 to 10%, the impact energy is increased to 66.67 J/m. But finally when the CF% changes from 10 to 15%, it gives a maximum value of impact energy and that value is 116.33 J/m.

Table 65.4 Tensile strength data sheet of all the 8 specimens

S. No.	Specimen code	Rate 1 (mm/min)	Width (mm)	Thickness (mm)	Maximum load (N)	Tensile stress at maximum load (MPa)	Average tensile stress (MPa)	Tensile strain at break (Standard) (%)	Tensile stress at break (MPa)

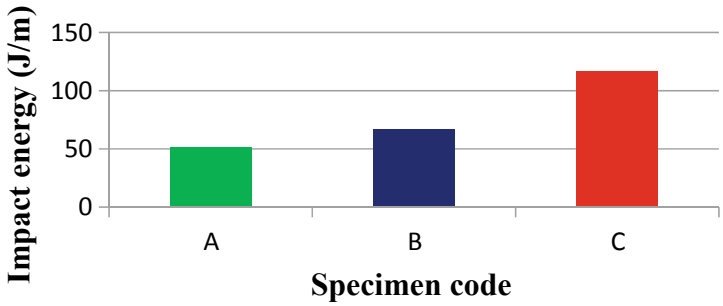

Fig. 65.7 Impact energy (J) of three different compositions

65.4 Conclusion

After conducting the tensile test and impact test of these three compositions, the following conclusions are derived.

- In tensile test the composition of 80% polypropylene, 5% carbon fiber and 15% glass fiber gives the maximum value as compared to 75% polypropylene, 10% carbon fiber and 15% glass fiber. But when the carbon fiber is changed from 10 to 15%, it gives a maximum value.
- In impact test, the value of the impact energy is gradually increased by increasing the carbon fiber %.
- So from the above two test, out of the three combinations the specimen code "C" showed the best result in terms of tensile strength and shock absorption properties.
- Hence, it is the best-suited mixture combination.
- The addition of carbon fiber plays a vital role in case of the glass fiber polypropylene composite. In order to make the specimen cost-friendly, less weight percentage of carbon fiber is taken over glass fiber.
- The test results show that the material properties have been improved significantly compared to the polypropylene with only glass fiber, which encourages to use and opt for hybrid composite.

Chapter 66
Effect of Temperature on the Fracture Strength of Perfect and Defective MonoLayered Graphene

Kritesh Kumar Gupta and Sudip Dey

Abstract Graphene is one of the carbon allotropes which have one atom thickness. It is a monolayer of carbon atoms, which are bonded in a two-dimensional hexagonal lattice. It is a unit layer of graphite; stacking the monolayer graphene one over another forms the graphite. The exceptional electromechanical properties of graphene attracted the researchers and scientists to explore the wide application areas so that the properties of graphene could be harnessed. In this regard, the present paper analyses the perfect single-layer graphene sheet (SLGS) and defective graphene sheet by depicting the effect of temperature variations on the fracture strength of both of the sheets. To this end, the molecular dynamics (MD) simulations based on AIREBO interatomic potential field and Nose–Hoover thermostat technique are carried out. It is concluded by the study that with the increasing temperature, the fracture strength of the graphene reduces remarkably. It is also evident that introducing random vacancy of 2.5% in perfect graphene causes the yielding phenomenon at lower strains which remains absent in the perfect graphene. Also, the defective graphene shows the ductile fracture, confirming considerable yielding before complete fracture.

Keywords Fracture strength · Graphene · Molecular dynamics · AIREBO potential · LAMMPS

66.1 Introduction

The extraordinary characteristics of graphene have been used to develop nanoresonators [1], biosensors [2], nanocomposites [3] and many more nanoelectromechanical systems (NEMS). So far research has been conducted in order to determine the exact mechanical properties and strength of the monolayered graphene sheet.

Graphene is found to be one of the lightest (0.77 mgm^{-2}) and still stiffest material known. Its fracture strength and Young modulus are recorded as 130 GPa and 1 TPa, respectively. Finding the mechanical properties of graphene through experimental procedures are limited due to the fact that setting up the experimentation for the nanoscale material has its own complications and limitations. Experimentally, one of the common methods to extract graphene from graphite is chemical vapour decomposition (CVD), which is performed at elevated temperatures, it is obvious that during extraction some defects may be introduced to the graphene structure by vacancy, chemical reactions with foreign elements or by a change in the bond structure at elevated temperatures. This leads to getting incorrect desired results from the experimentation. The defect such as vacancies remarkably reduces the strength of graphene, which in return affects the performance of the NEMS.

In the past, researchers have carried out a vast study to accurately characterize the SLGS. To this end, Tsai et al. [4] explored the elastic properties of the graphene along with graphite flakes through molecular dynamics simulation and concluded that the single graphene layer has the higher value of Young's modulus of elasticity and shear modulus in comparison with graphite flakes. The effective characterization of graphene has been a challenge so far as there are a lot of discrepancies recorded regarding its exact characteristics, to address this Thomas and Ajith [5] performed the atomistic simulations using Tersoff interatomic potential and determined the mechanical, thermal and structural properties of the SLGS. The defects in graphene are prone to induced while its extraction, in this contrast Ansari et al. [6] performed the atomistic simulation using Tersoff–Brenner potential energy function to determine the mechanical properties of perfect and defective single-layered graphene, while Dewapriya and Rajapakse [7] investigated the rate of strain and temperature dependence of the failure criteria of single-layer graphene sheet and proposed a fracture mechanics model based on the continuum to characterize the toughness of defected graphene sheet. To explore the effect of Stone–Wales defect, Wang et al. [8] studied the fracture strength of defective graphene sheet using molecular dynamic simulation, the study was carried out at various temperature and it was concluded that the strength of SLGS is affected by the presence of defects, loading directions and temperature, whereas Wang et al. [9] investigated the mechanical responses of graphene membrane with various orientations of 5-8-5 defect using molecular dynamics simulation, and it was concluded from the study that the introduction of 5-8-5 defect in graphene sheet reduces its fracture strength and strain. To address the irregularities based on interatomic potential field, Anastasi et al. [10] presented the MD simulation of single-layer graphene under tensile loading. In order to carry out the simulation, several potential functions such as the bending angle, Morse, Lennard-Jones and torsion potential functions have been used from the mdFOAM library of openFOAM software. It was concluded from the study that graphene is anisotropic, and its fracture strength depends on the sheet size, while Singh et al. [11] predicted the elastic properties of graphene sheet at infinitesimal and finite strains by combining MM3 potential with the Cauchy–Born rule and compared the results with the outcome of a study carried out using

Tersoff–Brenner potential field and second-generation REBO potential field. The MD simulation utilizes different ensembles such as NPT, NVT and NVE for averaging the atomistic properties, and to differentiate the usage of NPT and NVT in the MD simulations, Clavier et al. [12] computed the elastic stiffness tensor at 1 bar and 60 K of FCC argon and compared the result obtained in both the cases. The graphene could be the potential reinforcement material for strengthening the nanocomposites in this context, and Papageorgio et al. [13] reviewed the mechanical properties of graphene and described the strategies to prepare the bulk graphene-based nanocomposites. It was concluded from the study that graphene as reinforcement in composites may improve the strength of the composite up to the next level.

Performing experimentation on graphene is a challenging task due to obvious limitations in experimental set-up for nanoscale analysis. Therefore, using MD simulation as the analysis tool gives the edge over understanding the complex nanomaterials in a better way. In the past, a lot of research is executed in order to determine the exact characteristics of pristine and defected SLGS. However, there is limited study available dealing with concentrations of defect present in the monolayer graphene. In this study, the mechanical properties and fracture strength of the perfect graphene and the graphene sheet with 2.5% vacancy concentration are determined using MD simulation. In order to observe the effect of temperature variation over the fracture strength of graphene, the analysis is carried out at various temperatures, i.e. at 1, 300, 900 and 1200 K. Young's modulus, fracture strength and failure strain are determined for both the directions (armchair and zigzag) of graphene, and results are compared.

66.2 Molecular Dynamics Simulation

66.2.1 Molecular Dynamics

Nanomechanical modelling is one of the best methods to analyse the properties of nanomaterials. Nanomechanics model may be differentiated into three main categories—the first principle approaches such as DFT, semi-empirical methods such as molecular dynamics simulation and the third is the modified continuum model.

The molecular dynamics is computationally affordable in comparison with the first principle approaches. Although it relies on several assumptions associated with the interatomic potential function. In the molecular simulations, materials are viewed as the collection of individual atoms which interact by exerting forces on each other and follow Newton's law of motion. In order to perform molecular dynamics simulations, three important ingredients are required; first, an initial system configuration such as position and velocities of the atoms [$r\ (t = 0)$, $v\ (t = 0)$], interaction potential for the system and a way to integrate Newton's equation of motion. Simulation procedure in MD initiates by determining the forces

acting on an individual atom by the neighbouring atoms. Force acting on an individual atom i may be represented as

$$f_i = -\frac{\partial E_i}{\partial r_i} \tag{66.1}$$

where E_i refers to the potential energy of the atom which is approximated by the interatomic potential field. After the determination of forces, the accelerations are determined using Newton's equation of motion

$$f_i = m_i \frac{\mathrm{d}^2 r_i}{\mathrm{d}t^2} = m_i a_i \tag{66.2}$$

Further atoms are allowed to accelerate with the determined acceleration for a certain duration known as a time step. At the end of each time step, the new positions and velocities are recorded and integrated using numerical integration algorithms such as velocity Verlet algorithm. The use of statistical ensembles such as NPT, NVT and NVE allows controlling the temperature and pressure of the system [14].

66.2.2 Modelling and Simulation

The graphene sheet of 5 nm × 5 nm with 1008 carbon atoms is modelled using visual molecular dynamics (VMD) [15], and the output file received from VMD is fed to Avogadro (an open-source atom manipulator) [16] in order to introduce a 2.5% vacancy in the perfect graphene sheet. Both the sheets (perfect and defected) were uniaxially deformed in x-direction using LAMMPS. LAMMPS [17] is an open-source code package by Sandia National Laboratories, USA. To avoid free edges, all three directions were applied with periodic boundary conditions. The sheets were firstly equilibrated to minimize the energy of the system and relax the graphene structure, over 30 ps prior to applying strain using a time step of 0.5 fs. In the relaxation period, the pressure component of the x- and y-directions was maintained zero using NPT ensemble. The NPT ensemble holds the no. of atoms, pressure and temperature of the system constant, and it uses Nose–Hoover thermostat to control the temperature of the system. Furthermore, to uniaxially deform the sheets a strain was imposed by elongation of the simulation box in both (armchair and zigzag) dimension and the applied strain rate was 10^9 s^{-1}. The stress components in y- and z-directions were kept at zero during simulating the tensile deformation of graphene by keeping in check the pressure component in the said directions using NPT ensemble. Figure 66.1 shows the topology of the perfect graphene sheet and graphene introduced to 2.5% vacancy concentration.

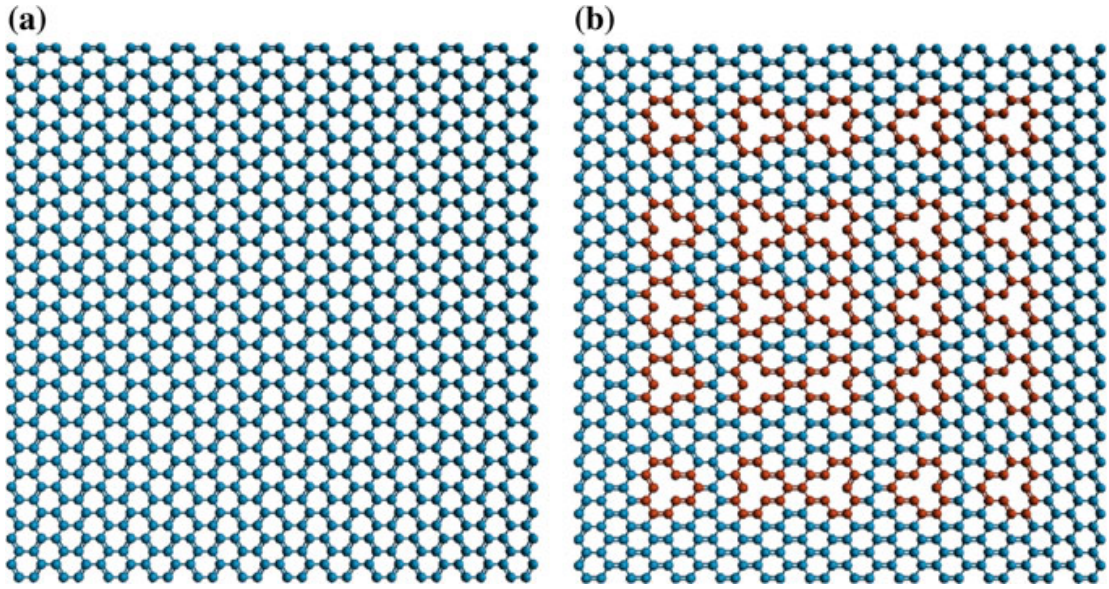

Fig. 66.1 Graphene sheet **a** perfect, **b** with 2.5% vacancy concentration

66.2.3 Potential Field

In molecular dynamics simulation, the potential field is an element which signifies the energy interactions between the atoms. The adaptive intermolecular reactive empirical bond order (AIREBO) potential is employed in the present study. The AIREBO potential is made by combining three different potential fields first, the original REBO potential, second the Lennard-Jones (LJ) and third the torsion potential. The original REBO term imparts the interatomic attractive and repulsive energy, the Lennard-Jones to account for the intermolecular interaction that includes dispersion and short-range repulsion and torsion component to signify the torsional interactions between the carbon–carbon bonds.

The general form to represent the AIREBO potential can be expressed as

$$E = \frac{1}{2}\sum_{i=1}\sum_{i\neq j}\left[E_{ij}^{\text{REBO}} + E_{ij}^{LJ} + \sum_{k\neq i}\sum_{l\neq i,j,k} E_{ijkl}^{\text{TORSION}}\right] \tag{66.3}$$

where E refers to the total potential energy with atoms i, j, k and l. The REBO term which refers the interatomic attraction and repulsion is represented as:

$$E_{ij}^{\text{REBO}} = V_{ij}^{R}\left(r_{ij}\right) + b_{ij}V_{ij}^{A}\left(r_{ij}\right) \tag{66.4}$$

where V^A and V^R refer the attractive and repulsive parts of the potential, respectively; r_{ij} signifies the distance between i and j atom up to the cut-off distance, and b_{ij} refers the bond order which allows for a change in the strength of the bond depending on the environment.

The LJ term of the potential can be described as:

$$E_{ij}^{\mathrm{LJ}} = f\left(r_{ij}\right) V_{ij}^{\mathrm{LJ}} \tag{66.5}$$

$$V_{ij}^{\mathrm{LJ}} = 4\varepsilon_{ij}\left[\left(\frac{\sigma_{ij}}{r_{ij}}\right)^{12} - \left(\frac{\sigma_{ij}}{r_{ij}}\right)^{6}\right] \tag{66.6}$$

where $f\left(r_{ij}\right)$ represents the set of cut-off functions σ_{ij}, and ε_{ij} are the distance at which interparticle potential is zero and the potential barrier, respectively.

Finally, the torsion term can be represented as:

$$E_{ijkl}^{\mathrm{TORSION}} = f\left(r_{ij}, r_{jk}, r_{kl}\right) V^{\mathrm{TORSION}}\left(w_{ijkl}\right) \tag{66.7}$$

$$V^{\mathrm{TORSION}}\left(w_{ijkl}\right) = \varepsilon\left[\frac{256}{405}\cos^{10}\left(\frac{w}{2}\right) - \frac{1}{10}\right] \tag{66.8}$$

where r_{ij}, r_{jk} and r_{kl} are the bond lengths and w_{ijkl} is the dihedral angle and ε is the barrier height of the potential [18].

66.2.4 Calculation of Stress

In the molecular dynamics simulation, stress may be interpreted as Cauchy stress or virial stress. When it comes to the computational efficiency, the Cauchy stress is proved to be more considerable than virial stress. However, some amount of initial stress (when strain is zero) is induced by the Cauchy stress at higher temperatures. In this study, the computation of virial stress is carried out through atomistic simulation. Virial stress can be defined as:

$$\sigma_{ij} = \frac{1}{V}\sum_{\alpha}\left[\frac{1}{2}\sum_{\beta=1}^{N}\left(R_i^{\beta} - R_i^{\alpha}\right)F_j^{\alpha\beta} - m^{\alpha}v_i^{\alpha}v_j^{\alpha}\right] \tag{66.9}$$

where α and β refer to the serial number allocated to an atom and the number allocated to the neighbouring atom, respectively, while i and j signify the directional indices, and m^{α} and v_i^{α} are the mass and velocity of the atom α, respectively. R_i^{β} is the location of an atom β in the i direction; $F_j^{\alpha\beta}$ is the force due to an atom β on atom α along the j direction and V refers to the total volume of the material system. The virial stress represents a product of stress and volume, i.e. the stress value computed by LAMMPS would be in the units of pressure*volume, in order to extract the stress from the computed value it is essential to divide the value calculated by the LAMMPS with the total volume. Furthermore, in order to calculate the virial stress, the instantaneous volume is used, i.e. when the imposed strain is

'ε', the value of volume at the given instant would be $V_0(1+\varepsilon)$, where V_0 represents the initial volume of the system [19].

66.2.5 Constant Strain Method

In order to determine the elastic constants of graphene, it is subjected to a constant strain in the desired direction. As in this study, a strain rate of 10^{-9}/s is applied and the simulation box is allowed to deform in the applied direction. At the end of the time step, the resultant atomistic stresses are recorded in each direction. The relation between in-plane stress and stiffness matrix is written in terms of [4]

$$\begin{pmatrix} \sigma_{11} \\ \sigma_{22} \\ \tau_{12} \end{pmatrix} = \begin{pmatrix} C_{11} & C_{12} & 0 \\ C_{21} & C_{22} & 0 \\ 0 & 0 & C_{66} \end{pmatrix} \begin{pmatrix} \varepsilon_{11} \\ \varepsilon_{22} \\ \gamma_{12} \end{pmatrix} \tag{66.10}$$

Due to symmetry in the stiffness matrix, the values of elastic constants are as [4]

$$\begin{aligned} C_{11} &= C_{22}, \\ C_{12} &= C_{21}, \\ C_{66} &= \frac{C_{11} - C_{12}}{2}, \end{aligned} \tag{66.11}$$

As the applied strain is known and the atomistic stresses can be recorded, using these values the elastic constants can be determined. Once the elastic constants are known the value of Young's modulus and Poisson's ratio can be determined as [4]

$$E = \frac{C_{11}C_{22} - C_{12}C_{21}}{C_{22}} \tag{66.12}$$

$$\upsilon_{12} = \frac{C_{12}}{C_{22}} \tag{66.13}$$

66.3 Effect of Temperature Variation

The value of Young's modulus, elastics constants, Poisson's ratio and ultimate strength are determined, which shows a good agreement with the literature values. The said values are determined for the perfect graphene, which is as follows (Table 66.1)

Table 66.1 Validation of mechanical properties of graphene

Properties	Present study	Literature values
C_{11} (in GPa)	887.2	1094 (Thomas and Ajith [5])
C_{12} (in GPa)	153.1	136 (Thomas and Ajith [5])
Young's modulus (in TPa)	0.860	1.020 (Lee et al. [20])
Poisson's ratio	0.172	0.1248 (Thomas and Ajith [5])
fracture strength (in GPa)	145.4	130 (Lee et al. [20])

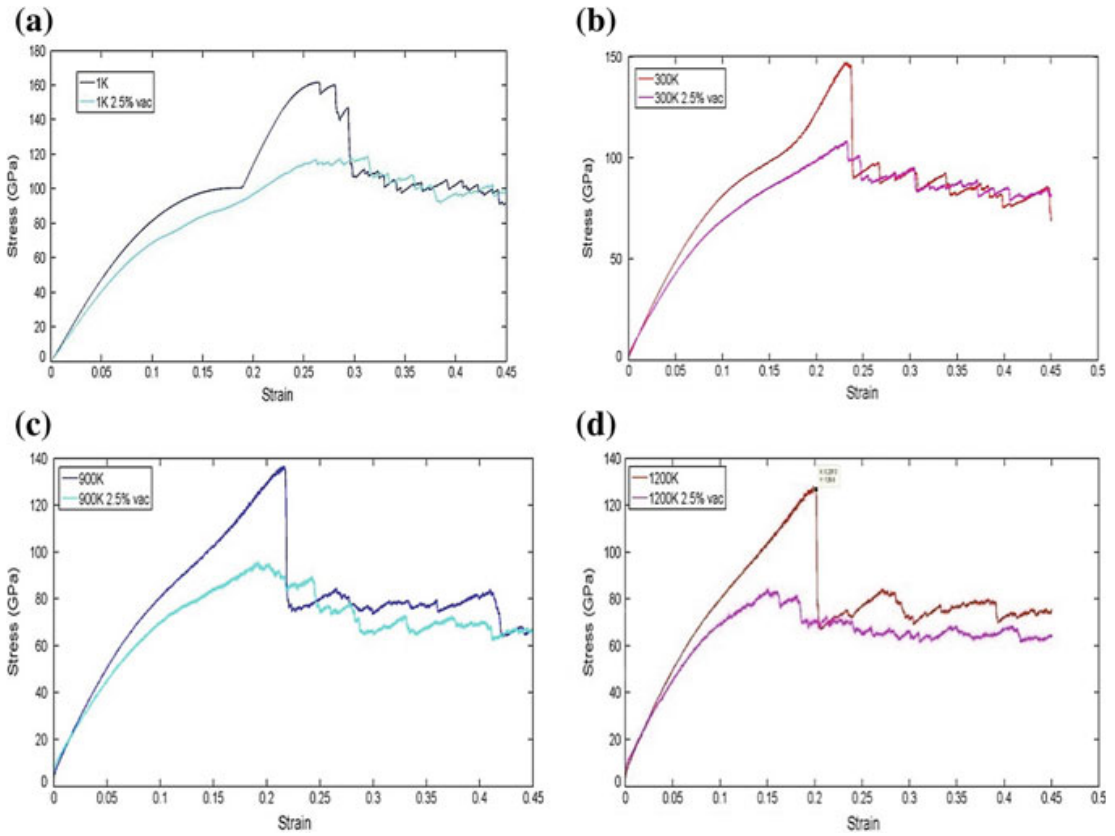

Fig. 66.2 Stress–strain behaviour of perfect and defective graphene loaded in an armchair direction **a** at 1 K, **b** at 300 K, **c** at 900 K, **d** at 1200 K. Defective sheets have 2.5% of randomly distributed vacancies

The stress–strain behaviour of perfect graphene and defected graphene at different temperatures, i.e. 1, 300, 900 and 1200 K is recorded in both armchair and zigzag directions, which is shown in Figs. 66.2 and 66.3, respectively. It is evident by the recorded values that the increment in temperature drastically reduces the fracture strength of the graphene in both the directions and failure occurs at fewer strain values. However, it is observed that the graphene depicts more resistance to failure in the transverse direction (zigzag) as compared to its longitudinal direction (armchair). It can also be seen that on uniaxially loading graphene in both the

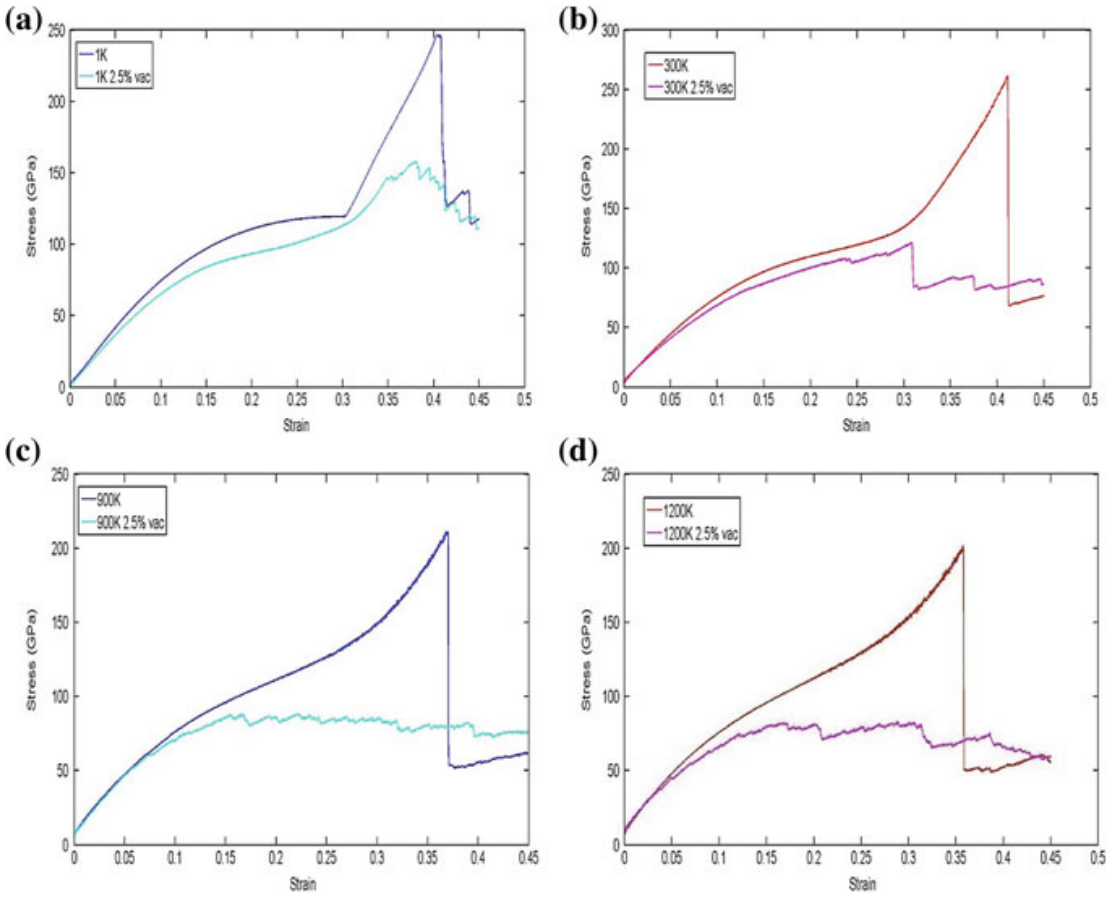

Fig. 66.3 Stress–strain behaviour of perfect and defective graphene loaded in a zigzag direction **a** at 1 K, **b** at 300 K, **c** at 900 K, **d** at 1200 K. Defective sheets have 2.5% of randomly distributed vacancies

directions (armchair and zigzag) at 1 K, it shows the sharp yielding point before fracture.

In both the cases, i.e. loading in an armchair and zigzag direction, the defected graphene does not show the instant fracture, and it is observed that on introducing the 2.5% vacancy to the graphene sheet, it shows the ductile fracture instead of brittle fracture. However, after some strain, it starts showing the yielding.

The given Tables 66.2 and 66.3 represent the recorded values of Young's modulus (E), fracture strength and failure strain of perfect graphene sheet at various temperatures in an armchair and zigzag directions, respectively.

Table 66.2 Young's modulus (E), fracture strength and failure strain of perfect graphene sheet loaded in an armchair direction due to variation in temperature

Temperature (K)	E (in TPa)	Fracture strength (in GPa)	Failure strain
1	0.814	146.9	0.293
300	0.812	145.4	0.236
900	0.809	135.7	0.217
1200	0.799	126.6	0.201

Table 66.3 Young's modulus (E), fracture strength and failure strain of perfect graphene sheet loaded in a zigzag direction due to variation in temperature

Temperature (K)	E (in TPa)	Fracture strength (in GPa)	Failure strain
1	0.745	246.3	0.407
300	0.756	261.9	0.411
900	0.764	211.4	0.370
1200	0.760	200.9	0.357

66.4 Conclusion

In summary, an MD simulation of uniaxial loading the perfect graphene sheet and defective graphene sheet (2.5% vacancy concentration) is carried out at various temperatures (1, 300, 900 and 1200 K) in both armchair and zigzag directions. The AIREBO potential field is used to incorporate the interatomic interactions between the constituent carbon atoms of the graphene sheet and to control the temperature of the system Nose–Hoover thermostat is employed, using NPT ensemble. The fracture strength of perfect and defective graphene sheet is observed at various temperatures, and it is concluded that the temperature has a profound impact over the fracture strength of the graphene sheet. It has been pointed in the study that how sometimes it is obvious that the extracted graphene sheet may have some defects, inherited by the way it is produced. The stress–strain behaviour of the perfect and defective graphene sheet is recorded at various temperatures by loading the graphene in both the directions, and it is concluded that graphene sheet possesses higher fracture strength in the zigzag direction as compared to its armchair direction. Furthermore, it is also been observed that the defective graphene sheet does not depict the brittle fracture, although the defected graphene starts yielding at lower strain than a perfect graphene sheet. The findings of the study provide the insights of variability in the fracture strength of graphene with respect to increasing temperature and with vacancy defects, using which the usability of graphene could be decided for the applications at elevated temperatures and where defects are unavoidable.

Chapter 67
Effect of Process Parameters of Plasma Arc Preheating on Low Carbon Steel

Abhishek Kumar and Pankaj Biswas

Abstract In this study, both experimental and numerical investigations were performed for plasma preheating of AISI 1018 low carbon steel plates. The finite element (FE) software package ABAQUS 6.14 was used to perform the transient thermal analysis using Gaussian distribution as a heat source for plasma preheating. In this FE model, temperature-dependent thermal material properties of low carbon steel (AISI 1018) were used. The influence of different parameters, i.e., traverse speed, plasma arc power on thermal history was determined. Experimentally obtained transient temperature distribution and peak temperature compared fairly well with FE results with a maximum percentage error of around 6.8% and 7.53%, respectively.

Keywords Plasma heating · Finite element analysis · Transient thermal analysis · Heat generation · Process parameters

67.1 Introduction

Plasma heating has been come into the picture since the late 1800s. Around 30 years ago, NASA simulated the very high temperatures of reentry into the atmosphere of earth through plasma heating. The applications of plasma heating are widespread, especially in welding and preheating of the materials. The plasma can achieve 11,100 °C temperatures with very little combustion. The finite element method (FEM) has been the most common technique for the analysis of preheating

problems which involve thermal, metallurgical and mechanical phenomena simultaneously. The plasma arc preheating system offers better temperature control, quicker reaction time, better control on process, efficient use of energy and lesser capital costs as compared to the other conventional methods.

Nandan et al. [1] observed the influence of a supplementary heat source in front of the friction stir welding (FSW) tool. This reduces the heat input for welding required from the FSW tool and thus the plunging loads of the FSW tool. Wu et al. [2] developed a modified three-dimensional conical heat source model and quasi-steady state for plasma arc heat source to reflect the thermomechanical process of plasma arc welding. Cabage et al. [3] implemented laser as a heat source in front of the FSW tool and reported 50% drops in the friction stir welding tool plunging forces. Kou et al. [4] patented a tungsten inert gas arc preheating system, which reduces FSW tool wear, extends the capability of FSW tool to weld harder materials and also helps weld dissimilar metals. Deshpande et al. [5] developed a conical heat source model to simulate the relationship between welding parameters and welding efficiency. They proposed that the relationship is useful for selecting a combination of weld parameters and keyhole welding.

From the above published literatures, it was observed that only a few number of researchers studied plasma arc preheating process. In this paper, a finite element (FE)-based 3-D heat transfer model was developed to calculate the effects of plasma preheating on temperature history over the AISI 1018 steel plates and validated it with the experimental results.

67.2 Experimental Details

The experiment was conducted for preheating AISI 1018 low carbon steel plate, and the temperature was measured during the preheating of the butt-joint configuration shown in Fig. 67.1. The dimension of the workpiece was 200 mm × 100 mm × 4 mm as shown in Fig. 67.2a. The edges of the workpieces were machined to obtain proper contact of butt joint and clamped to the bed without root opening. The plasma arc torch was clamped at 2 mm standoff distance in the designed fixture, and the steel plates were fixed on the horizontal moveable bed. Transient temperature was measured by using K-type thermocouples over the top surface of the plate at 10, 20, 30 and 40 mm far from the weld line as shown in Fig. 67.2b.

67.3 Finite Element Analysis and Model Details

A numerical investigation by physical modeling gives a better understanding of physics involved in the process. A 3-D finite element transient thermal model was developed to analyze the heat flow and temperature distribution in preheating. The quality of the numerical model majorly depends on type, size and number of the element. A coarse mesh generally gives the wrong results; whereas, too much fine mesh increases the computational time. Therefore, to get reliable results, the

optimum choice of the mesh should be present. The commercial finite element ABAQUS code was used to develop thermal model. In the thermal model, the actual welding conditions were taken as far as possible. The following assumptions were made to develop the thermal model:

- Heat flux was considered as a heat load.
- The plasma arc heat source was moving with a constant speed over the work piece.
- The material was homogeneous and isotropic.

In this numerical model x-coordinate was considered for plasma arc moving direction. The differential equation for conduction of heat without heat generation in the rectangular coordinate system is expressed as

$$\frac{\partial\left[K(T)\frac{\partial T}{\partial x}\right]}{\partial x}+\frac{\partial\left[K(T)\frac{\partial T}{\partial y}\right]}{\partial y}+\frac{\partial\left[K(T)\frac{\partial T}{\partial z}\right]}{\partial z}=\rho C(T)\frac{\partial T}{\partial t} \tag{1}$$

where ρ, C, K and T stands for density, specific heat, thermal conductivity and temperature of the material, respectively. The initial conditions for the FE model that covers all the elements of the workpieces are expressed as

$$T=T_{\mathrm{a}} \quad \text{for } t=0 \tag{2}$$

where T_{a} is the atmospheric temperature for the present study. A convective heat transfer coefficient 25 W/m^2 °C for natural convection and ambient temperature 25 °C was used as a boundary condition for thermal analysis. At the bottom surface, a high value of heat transfer coefficient was assigned for considering the impact of the backing plate. The mathematical expression for combined convection and radiation heat loss is given as

$$k\frac{\partial T}{\partial n}=h(T-T_{\mathrm{a}})+\epsilon\sigma\left(T^4-T_{\mathrm{a}}^4\right) \tag{3}$$

where n, h, ε and σ are the normal direction vector of the boundary, convection coefficient, emissivity and Stefan-Boltzmann constant, respectively.

67.3.1 Heat Source Model

A three-dimensional thermal model for the preheating process was developed by using the temperature-dependent thermal properties and Newtonian convective heat loss for all surfaces open to the air. The plasma arc Gaussian distribution [6] heat flux is expressed as

$$q(r) = \frac{3Q_{\max}}{\pi R^2} e^{-3\left(\frac{r}{R}\right)^2} \tag{4}$$

where $q(r)$ indicates the heat flux at radius r, R indicates the radius over which maximum arc energy falls, and $Q_{\max}$ is the heat input to the plasma preheating source and given by

$$Q_{\max} = \eta \times V \times I \tag{5}$$

where η, V and I indicate power efficiency, voltage and heating current, respectively. In three-dimensional modeling, DC3D8 or 8-node linear heat transfer brick element was employed. The total number of elements and nodes used in this numerical model was 62,400 and 79,395, respectively. The workpiece was divided into three different mesh zones shown in Fig. 67.3. In the central region up to 15 mm away from the welding line, the element size was kept fine with 1 mm in size while out of this zone, gradually increasing mesh was assigned.

67.5 Results and Discussion

In this present FE model, experimental validation and effect of variation in parameters for plasma heating have been addressed. The 3-D numerical model results were developed and compared with the experimental data. The temperature distribution was computed using finite element simulation as shown in Fig. 67.5. The simulation was carried out on ABAQUS using DFLUX subroutine and validated it through experimental investigation. The parameters considered for performing numerical calculation and experimental investigation are presented in Table 67.2.

67.5.1 Transient Temperature Profiles of Plasma

The comparison between the thermal model and data collected from K-type thermocouple for plasma preheating is shown in Fig. 67.6. From the combined numerical and experimental thermal profiles, it is observed that experimental data is much closer to the simulated data. The transient temperature curve plotted at different locations away from the center of weld line over the surface of the plates.

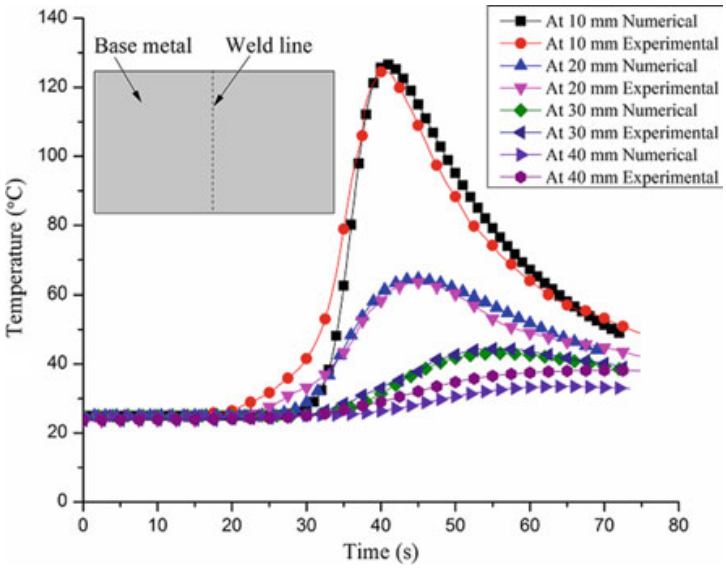

Fig. 67.6 Comparison between thermal model and experimental data at various distances from the weld line

Table 67.3 Percentage error between simulated and experimental data at various distances for preheating

Distance from the center of the plate (mm)	Average percentage error
10	10.82
20	4.77
30	3.39
40	8.35

The following Table 67.3 is representing the average percentage error between modeling results and experimental results for plasma preheating at 10, 20, 30 and 40 mm away from the weld line.

67.5.2 Peak Temperature–Distance Profiles on Top Surface

For comparing the results of temperature with respect to the perpendicular distance away from the center of weld line toward the traverse direction, the temperature is given by K-type thermocouple at four distinct locations 10, 20, 30 and 40 mm away from the weld line. Figure 67.7 shows the comparison between the experimental results and the results obtained from the numerical model for temperature distribution in the traverse direction of the weld line. The present numerical model is found to be in well agreement with the experimental data with an average error of 7.53% for peak temperature.

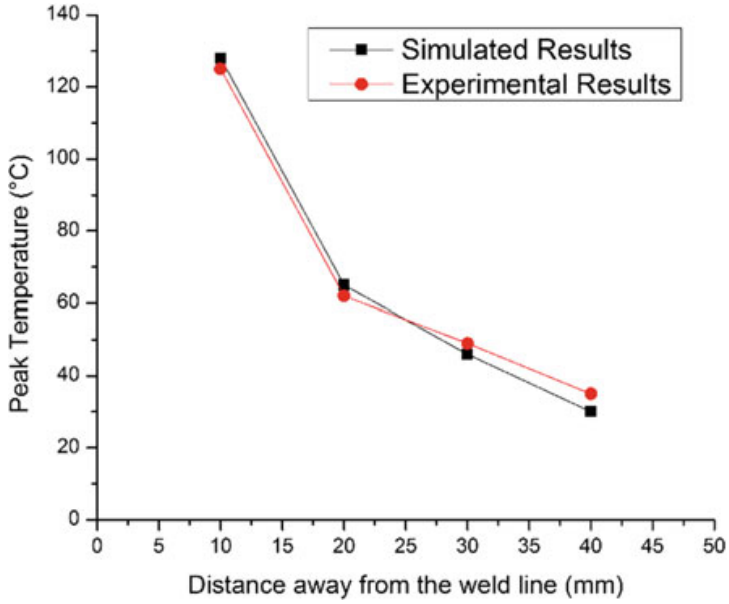

Fig. 67.7 Comparison of peak temperature profile for plasma preheating

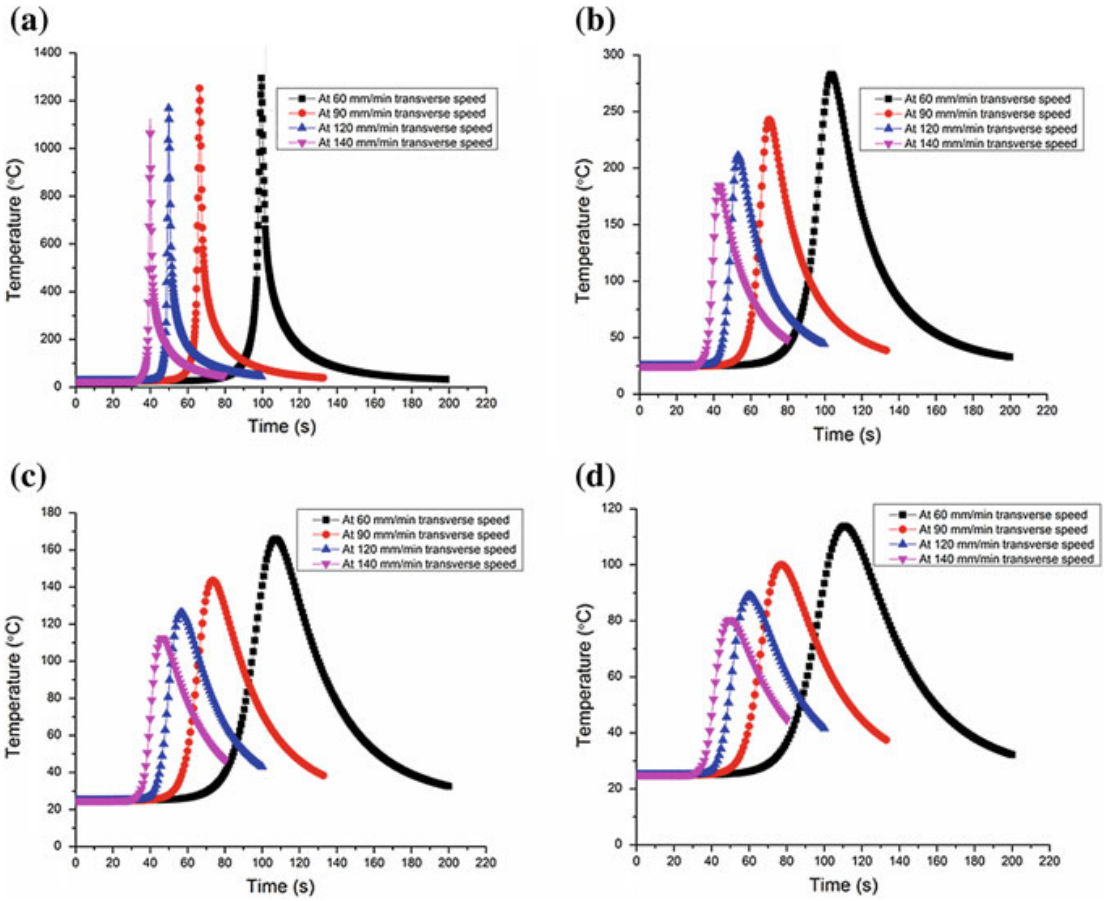

Fig. 67.9 Temperature profile at **a** center; **b** 5 mm; **c** 10 mm; **d** 15 mm away from the weld line at 20 A and 13.2 V

67.5.3 Effect of Variation in Traverse Speed on Transient Temperature Profile at Different Power Supply

The effect of variation in traverse speed on plasma at different power supply is shown in Figs. 67.8 and 67.9. The transient temperature curves were obtained from the numerically developed model at various locations showing that increase in traverse speed leads to a decrease in temperature of the plate.

67.6 Conclusion

In the present study, the plasma was used to preheat two AISI 1018 mild steel plates. The impact of plasma preheating on the thermal profile has been examined experimentally and numerically. The major conclusions are made from the analysis;

- A finite element thermal model was successfully developed for plasma preheating for AISI 1018 low carbon steel plate.
- It was found that finite element modeling of plasma preheating validated with the experimental results with around 6.8% and 7.53% error in transient profile and in peak temperature, respectively, which specifies that the developed thermal model can successfully implement in investigating the thermal histories during the plasma preheating.
- The influence of the power supply of plasma arc on temperature profile has been successfully observed over AISI 1018 low carbon steel plate. It was found that beyond 30 A current, the AISI 1018 steel plate starts melting. Hence, for preheating, the supply current should be less than 30 A.

Chapter 68
Reduced-Order Finite Element Analysis of Rough Surface Contact Using Reduced Integration Elements

Ahad Noor, Saipraneeth Gouravaraju and Sachin Singh Gautam

Abstract This paper presents a reduced-order finite element analysis of rough surface contact. Frictionless, elastic contact between a rough deformable block with Gaussian roughness and a rigid flat plate is considered. An equivalent one-dimensional rough surface of a two-dimensional rough surface is generated using MATLAB. Generated rough surface is superimposed on ten layers of generated mesh of the block and analysis is done in commercial finite element software Abaqus. Four-noded quadrilateral elements with reduced-order integration are used to decrease the computational time. The rigid plate is placed close to the largest asperity of the rough surface and is then displaced in small steps. Contact force and real area of the contact are calculated. Results are compared with the results of the full-scale finite element analysis in the literature and are found to be in good agreement.

Keywords Finite element analysis · Rough surface · Gaussian roughness · Elastic contact · Abaqus

68.1 Introduction

Almost all the machines have contact interfaces which work under different types of loading conditions. It is a well-known fact that whatever be the manufacturing process, one cannot eliminate surface roughness. So roughness is important in determining the behaviour of the contacting surfaces. Roughness directly or indirectly affects friction, stress fluctuation, wear, leakage of liquid, and energy transfer

between the surfaces. The study of rough surface contact plays an important role in many industries like bearing, lens, household items, electronics, brake and clutch, medical equipment, and medical implants manufacturing industry. For better tribological design and performance, analysis of the contact between rough surfaces is very important. The high points on a rough surface are known as asperities/peak/summit/hill, and the low points are known as valleys. When two rough surfaces are brought into contact, the actual contact occurs at the peaks/asperities. Because of surface roughness, contact occurs only at these discrete contact locations. Then, the real area of contact can be calculated by summing all the discrete areas of contact at each asperity. Moreover, in many cases the actual area of contact is limited to only 20–25% of the nominal contact area [1]. As the contact area of these asperities is very small compared to the total or nominal contact area, very high stresses develop in the asperities causing the material to yield. In some applications where two rough surfaces are brought into contact repeatedly, the increase in interfacial stress leads to damage of the materials resulting in wear. So, roughness and complexity of the contact surface have emerged as an important factor in analysis of strength, fatigue, wear, damage, friction, and energy dissipation. Hence, analysing the contact behaviour of the rough surfaces is an interesting domain for researchers.

Hertz [2] has performed the first contact analysis to investigate the optical properties of lenses in contact. Hertz considered two elastic smooth spheres in contact. He considered the contact zone to be a circle and solved considering minimum deformation energy. He concluded that the contact area is proportional to the $(2/3)$rd power of the applied load. In analytical as well as numerical analysis, to create rough surface a distribution of height of asperities must be defined. Many researchers have considered Gaussian distribution. Moreover, Gaussian distribution of asperities is experimentally verified by Celedón et al. [3]. They measured surface roughness of a gold film and concluded that the height of asperities follows Gaussian distribution. Greenwood and Williamson [1] in their pioneering work on nominally flat rough surface contact developed one of the first elastic contact models. This model represents a rough surface by a number of hemispheres with the same curvature radius R, but the height of asperities is varied according to the Gaussian distribution. Each asperity was assumed to deform elastically according to the Hertz contact theory. The flat plate is considered to be at some distance from mean of rough surface asperities and using the probability theory calculated number of asperities in contact at that distance. Then, using the Hertz contact theory, the authors solved for the real area of contact and the contact pressure. They concluded that actual area of contact varies linearly with the applied load. Lu et al. [4] studied the initial contact between a rough surface and a flat plate using Greenwood-Williamson model (GW model) for low loads over a small area of contact. They considered an exponential distribution of rough surface. They proposed a modification for the initial position of the flat plate. They set it so that the flat plate is just in contact with the highest asperity, while the GW model considers the initial position of the flat plate somewhere in the middle. However, they considered initial contact so they limited their analysis to low loads only. Yastrebov et al. [5, 6] have done the analysis of self-affine fractal rough surface in elastic,

frictionless, non-adhesive contact. They have created Gaussian rough surfaces numerically. They have used Fourier forward technique. They have applied pressure loading in small increments and have observed the evolution of real contact area under increasing pressure from zero up to full contact between rough surfaces. Later, they have done the analysis of contact between elasto-plastic rough surface and a rigid plane with two approaches: full-scale finite element analysis and to save computation time a reduced model with displacement boundary condition. In their reduced model, they considered single asperity, and to incorporate interaction between asperities, they have proposed a displacement boundary condition for the asperity outside the contact zone.

From the literature survey, it is clear that many researchers have extensively studied the contact between rough surface. Experimental calculation of actual area of contact is very difficult. So, researches mainly focused on analytical and numerical analyses. Due to the assumptions made in analytical studies, their accuracy is limited. Although the full-scale three-dimensional numerical simulations as in [5] give good results, the computational times are very high. So, in order to reduce the computational time without compromising on the accuracy in estimating the contact behaviour, in the present work, the method proposed by Scaraggi et al. [7] is used to generate an equivalent one-dimensional rough surface from a two-dimensional rough surface. A Gaussian, one-dimensional equivalent rough surface is created in MATLAB. This one-dimensional equivalent rough surface has all the information of two-dimensional rough surface. Finite element analysis is performed in commercial finite element software Abaqus. The rough surface is superimposed on the top surface of a two-dimensional block. To save the computational time, elements with reduced integration are considered. It is observed that the results obtained in the finite element analysis are consistent with the results of full-scale finite element analysis at low loads.

The remainder of the paper is structured as follows: Sect. 68.2 describes the representation and generation of rough surface. Section 68.3 presents the generation of the finite element mesh of the deformable block. Section 68.4 details the boundary conditions used and the methodology of the numerical simulations using Abaqus. Section 68.5 presents the obtained numerical results. Conclusions drawn from the study are presented in Sect. 68.6.

68.2 Description of the Rough surface Geometry

Any random rough surface can be represented by its power spectral density (PSD) denoted by $\Phi(k_x, k_y)$ of a profile in any direction [8] where k_x and k_y are the wavenumbers in x- and y-directions, respectively. In the present work, spectroscopic wavenumber which is the inverse of wavelength is used. It is normalized with the domain length L, i.e., $k = L/\lambda$. PSD contains all the statistical information

of the surface topography and is unbiased by the particular scan size and pixel resolution used. Mathematically, PSD is the Fourier transform of the signal's autocorrelation function and is a function of wave vector. In the present work, isotropic self-affine fractal surfaces are used whose power spectral density is defined as [5]

$$\Phi\left(k_x, k_y\right) \sim \left(\sqrt{k_x^2 + k_y^2}\right)^{2(H+1)} \tag{68.1}$$

where H is Hurst exponent.

In the present work, the following form of PSD is considered [5]:

$$\Phi_{2D}(|\mathbf{k}|) = \begin{cases} C_0 & \text{if } k_l < |\mathbf{k}| < k_r, \\ C_0 \frac{|\mathbf{k}|}{k_r} & \text{if } k_r \leq |\mathbf{k}| \leq k_s, \\ 0 & \text{otherwise} \end{cases} \tag{68.2}$$

where C_o is the constant that determines the roughness amplitude and $k = |\mathbf{k}|$ is the magnitude of the wave vector. In all the simulations, there is no plateau, so $k_l = k_r$.

Then, an equivalent one-dimensional rough surface profile is generated using the corrected equivalence condition between the mean square slopes of one-dimensional (1D) and two-dimensional (2D) rough surfaces. This is given by [7]

$$\Phi_{1D}^{eqv}(k) = \left(k_{1D}/k_{2D}\right)^2 \pi \Phi_{2D}(k) \tag{68.3}$$

where $\left(k_{1D}/k_{2D}\right)^2 \approx 1.56$ is the correction factor. This equivalence increases the root mean square height of one-dimensional rough surface

$$\sqrt{(h^2)_{1D}} = \left(k_{1D}/k_{2D}\right)\sqrt{(h^2)_{2D}} \tag{68.4}$$

For given PSD and surface area A, the surface heights can be calculated as

$$h(\mathbf{x}) = \sum_{|\mathbf{k}} \tilde{h}(|\mathbf{k}) \mathrm{e}^{i(|\mathbf{k}|.\mathbf{x} + \phi(|\mathbf{k}))} \tag{68.5}$$

where $\left|\tilde{h}(|\mathbf{k})\right| = \frac{2\pi}{\sqrt{A}}\sqrt{\Phi(|\mathbf{k})}$.

Then, the two-dimensional and the equivalent one-dimensional rough surfaces are generated using the inbuilt fast Fourier transforms (FFTs) and inverse Fourier transforms (IFFTs) functions in MATLAB. These are shown in Figs. 68.1 and 68.2, respectively.

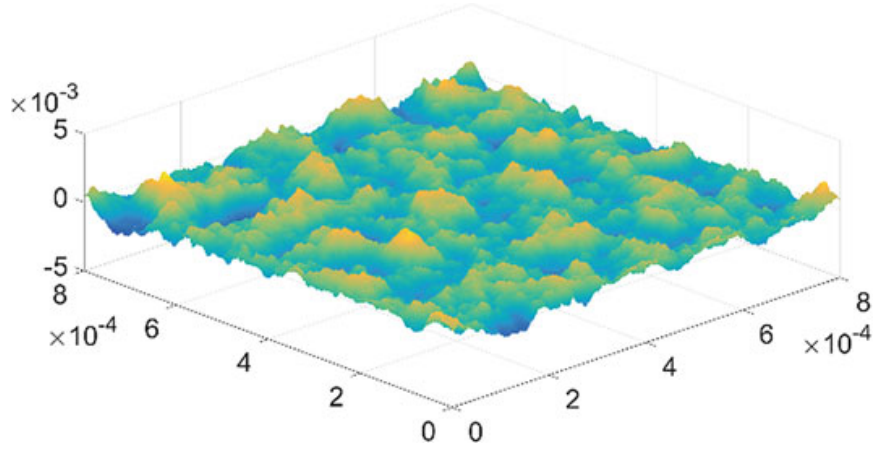

Fig. 68.1 Generated two-dimensional rough surface

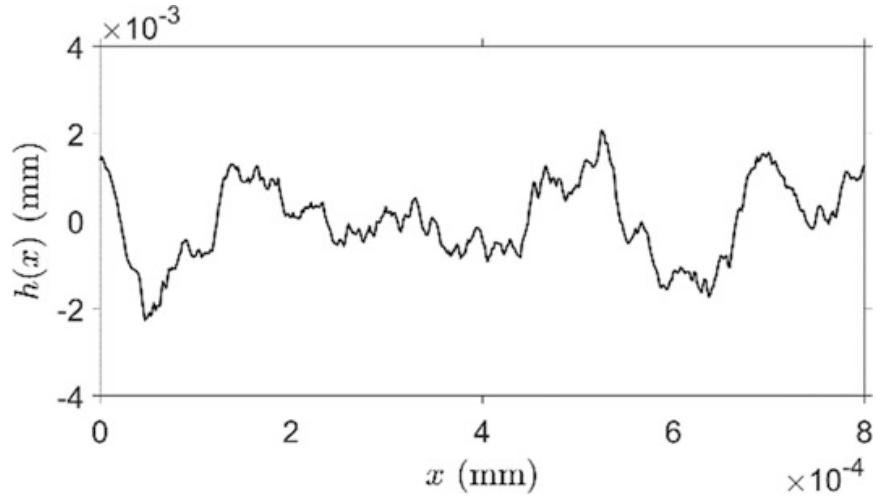

Fig. 68.2 Generated equivalent one-dimensional rough surface

68.3 Mesh Generation

To perform numerical analysis first, a mesh of the block having the dimensions 0.8 × 0.15 mm is considered. The finite element mesh is generated in Abaqus. It consists of 511 and 200 elements in the x- and y-directions, respectively. Four-noded plain stress quadrilateral element CPS4R with reduced integration is used for meshing. Since Abaqus does not have any option to create rough surface, it is generated in MATLAB. The height of the highest asperity is 0.0021 mm (2.1 μm). The generated rough surface heights $h(x)$ (see Fig. 68.2) are supposed to be superimposed onto the top layer of the initial mesh to create rough surface. But, this may produce badly distorted elements. In the worst case, it can produce negative Jacobians. Jacobian is the ratio of the area/volume of the deformed element to the undeformed element in a finite element mesh. So, if the Jacobian is negative, the

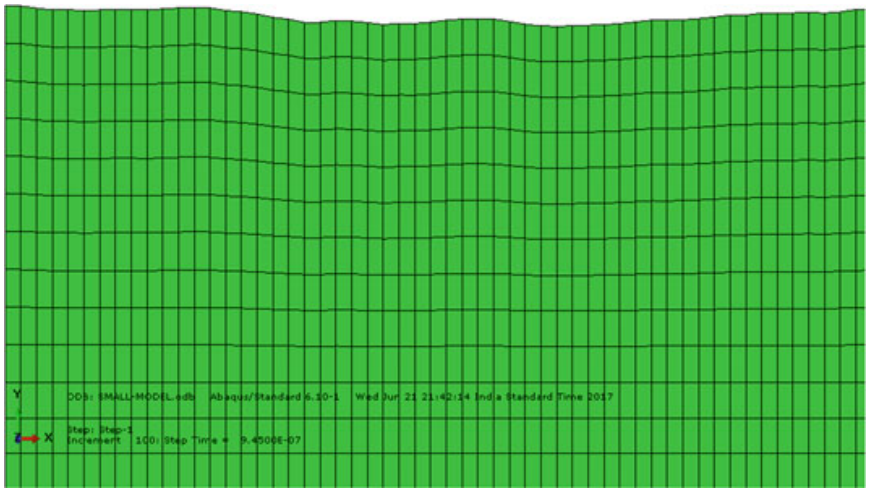

Fig. 68.3 Magnified view of generated roughness superimposed on ten layers of the block to avoid negative Jacobians

Table 68.1 Mechanical properties of steel

E (GPa)	v	ρ (Kg/m^3)
200	0.3	7800

elements have undergone a non-physical movement. To avoid this, all the nodes in top 10 layers are moved by a fraction of the heights of the top surface and change in height is gradually brought to zero in tenth layer (see Fig. 68.3). This is done in following steps: Coordinates of calculated height in MATLAB is added on the nodes of top layer. Then, nodes of second layer are moved by adding 0.9 times height of rough surface; similarly, third layer is moved by 0.8 times, and this is done up to tenth layer nodes. The rigid surface is modelled as a straight horizontal line with its initial position at the 0.0001 mm from the highest point on the top surface. The resulting finite element mesh (zoomed view near the top surface) is shown in Fig. 68.3. The material for the rough surface is considered to be steel. Material properties of steel are given in Table 68.1. In the present work, only elastic contact is considered.

68.4 Boundary Conditions

In this simulation, fixed boundary conditions are applied on the bottom surface of the block in both the x- and y-directions. The vertical surfaces of the block are fixed in the x-direction. The top surface is in contact with a rigid flat plate which is placed at a distance of 0.0022 mm from the smooth surface (without roughness) and

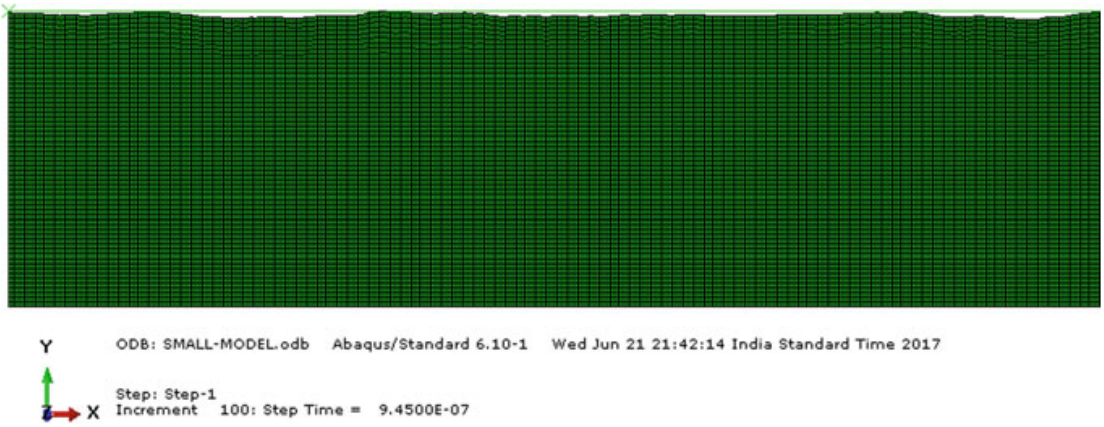

Fig. 68.4 Assembly of rigid plate and rough surface

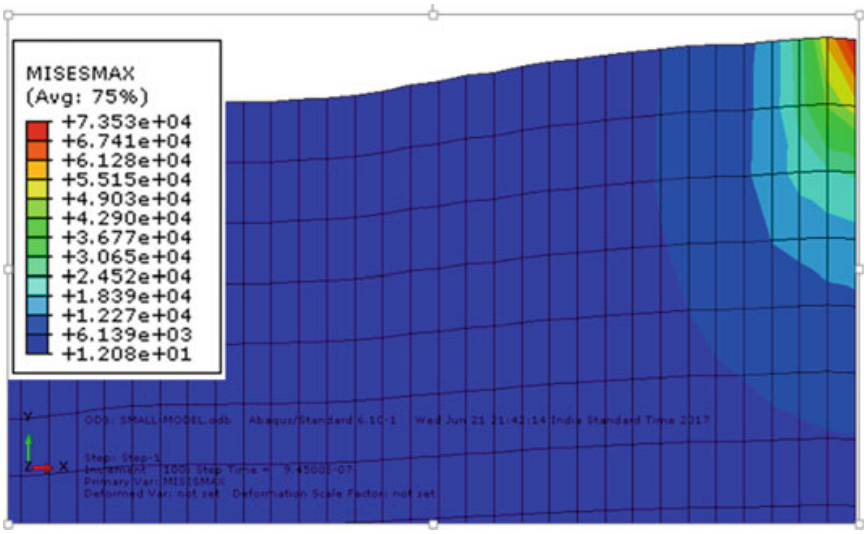

Fig. 68.5 Deformed surface with superimposed von Mises stress

0.0001 mm from the highest asperity as shown in Fig. 68.4. The rigid plate is given a total displacement of 0.002 mm in hundred time steps. However, it is worth mentioning that the Abaqus can reduce the time step to account for change in contact status. It is observed that initially the time step is nearly 10^{-8} s but as more and more asperities start to come in contact, Abaqus made the time step in the range of 9×10^{-9} s.

In Abaqus static analysis, the movement of upper rigid plate is guided by displacement boundary condition rather than velocity. Figure 68.5 shows the deformed surface at the end of simulation with superimposed von Mises stress. The problem is simulated on a Dell T620 workstation (32 GB RAM and 16 cores). The whole simulation is completed in approximately 4 min only.

68.5 Results and Discussion

The actual or real area of contact A_r and the corresponding contact force F are calculated at each load step. Total contact area is sum total of contact area of each asperity. Analytically, contact area is calculated by calculating the number of nodes in contact. Then, ratio of nodes in contact and total number of nodes on the top layer is calculated. This ratio is multiplied with nominal area to give actual area of contact. The same algorithm is used in numerical methods to calculate actual area of contact. Actual area is normalized with nominal area A_o to give dimensionless area of contact $A^* = A_r/A_o$. Contact force is normalized with the product of elastic modulus E and nominal area A_o to give dimensionless pressure $P^* = F/EA_o$. Figure 68.6 shows the evolution of normalized area of contact A^* with the normalized pressure P^*. The results obtained by Yastrebov et al. [6] for the contact of a two-dimensional rough surface with a rigid block are also included. It can be seen that the results from the present work match well with the numerical results of Yastrebov et al. [6] for low deformation regime while there is some discrepancy at higher deformation. It is important to note that the results of Yastrebov et al. [6] are obtained from a full-scale finite element simulation of two-dimensional rough surface which took 220 h, whereas in the current work the results are obtained from the analysis of an equivalent one-dimensional surface and at a much reduced computational time of 4 min. Although plot between actual area of contact and contact pressure is not linear in the present analysis, variation from linear behaviour as predicted by the full-scale FE model of Yastrebov et al. [6] is not very high for low loads, i.e., $P^* < 0.1$. However for loads $P^* > 0.1$, the current analysis predicts a nonlinear behaviour.

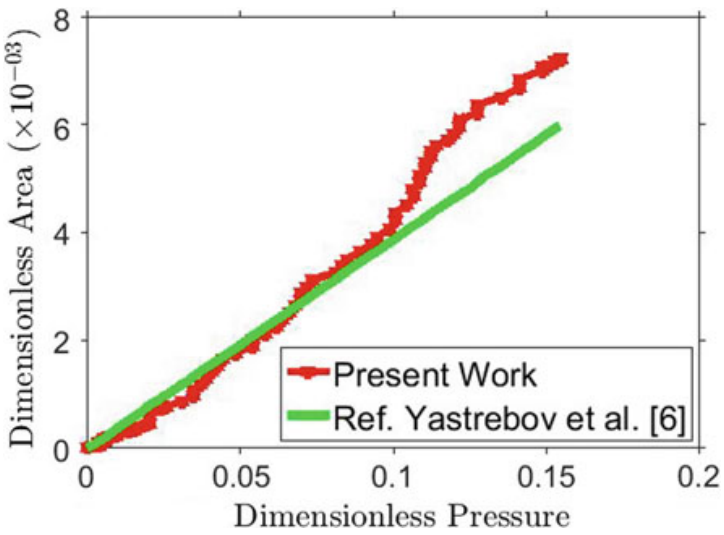

Fig. 68.6 Variation of dimensionless contact and dimensionless contact pressure

68.6 Conclusion

Numerical analysis of the contact between a linear elastic block and a self-affine rough surface is carried out using the finite element analysis software Abaqus. To save computational time, one-dimensional equivalent rough surface with reduced integration elements is used for analysis. Actual area of contact and contact force are calculated. It is observed that the variation of real area of contact with the applied contact pressure is close to linear in low load regime, and at higher loads, the variation is observed to be nonlinear. This behaviour can be explained in many ways. First, to decrease computational time, finite element approximation elements with reduced integration are considered which contain single Gauss point. So accuracy of result is compromised at the cost of calculation time. Full-scale analysis took 220 h [6] while this analysis of one-dimensional equivalent rough surface is completed in four minutes only. Second, equivalent one-dimensional rough surface used in this analysis can capture the essential features of its two-dimensional counterpart, and it is not exact. Although equivalent rough surface with reduced integration results showed some discrepancy at higher loads, computational time is reduced from 220 h to 4 min. Third, fixed boundary conditions are used at the vertical sides of the rough surface. This boundary condition is easy to apply. This can be applied by selecting "Encastre" option in Abaqus, but it can be used for approximation only because in real condition elements at the edges will not be fixed and show some deformation. For example, as rigid plate approaches the block, it will crush the rough surface and elements at edges will try to move outside. For exact results, more complex boundary conditions are needed which will be considered in the future work.

FEM-Based Modeling of Drilling-Induced Delamination in Laminated FRP Composites

Vishwas Divse, Deepak Marla and Suhas S. Joshi

Abstract In fiber-reinforced plastics (FRP) laminate, different laminae are adhesively bonded to each other. The interfaces between plies are weak because these are resin rich; therefore, there is a low-resistance path for crack propagation. As a result of this, delamination is a frequent mode of failure in the FRP laminate. The drilling of laminated FRP is always associated with delamination damage; therefore, delamination-free drilling is a major concern for aerospace industries. Experimental investigations of drilling-induced delamination have been widely studied in the literature, whereas very few studies are available related to its modeling. In this paper, the effect of the chisel-edge length of drill-bit on push-out delamination was studied. Finite element modeling (FEM) approach was used to model interfaces of laminae, and it was further extended to model delamination in drilling of FRP laminate. Cohesive zone method (CZM) based on traction–separation law was used in FEM to model the interfaces of laminae. It was observed that load-carrying capacity of beam in double cantilever beam (DCB) test reduced by 50% for '1 mm' initial crack length. Also, push-out delamination increased by around 10% with an increase in the chisel-edge length of drill bit from '0 mm' to '0.35 mm.' The FE models developed in this work were able to simulating delamination phenomenon with enough accuracy.

69.1 Introduction

Composite materials are increasingly used as a structural material in aerospace and other engineering applications. Among different composites, FRP composites have wide applications in aerospace industries due to their high specific strength and stiffness. While assembling the FRP components, holes are required for fasteners like bolts or rivets. Mechanical drilling is widely used to create holes in these components [1]. However, this operation is always associated with damages such as fiber pullout or breakage, matrix cracking or thermal degradation, delamination due to its poor machinability [2]. Consequently, this could result in strength and stiffness degradation and may lead to failure of a component in service. Additionally, they also cause poor assembly tolerance and reduction in structural integrity. Delamination is a failure of an interface between plies. This is a highly undesirable problem because it affects the mechanical properties of FRP composites [3]. A number of methodologies have been adopted for the purpose of minimization of delamination. The quantification of delamination is done by the delamination factor (F_d). Several researchers developed empirical models to predict delamination factor in drilling [1, 4, 5]. They identified that drilling speed and feed have the highest effect on delamination. These models are applicable only for particular drilling conditions and materials. Artificial neural networks (ANNs) can predict delamination factor at different values of spindle speed, feed rate, drill diameter, drill point geometry, etc. [6–8]. It requires huge experimental data to train an ANN, and therefore, it is a tedious process to apply for different materials. Experimental techniques used to characterize delamination factor are challenging and costly. Hence, modeling of delamination is seen as an effective tool to predict delamination in drilling. FEM is a potential technique to model the delamination phenomenon in FRP composites [9]. FE models developed by some researchers can predict drilling-induced delamination [10–12]. These models are very complex in nature and have not considered the effect of drill-bit geometry. Most of the models presented in the literature to predict delamination are empirical and focused only on drilling parameters and neglected the geometry of the drill bit.

In this paper, a simple 2D FE model of drilling is presented to predict drilling-induced delamination. The main objective is to study the effect of chisel edge of drill bit on the push-out delamination. In Sect. 69.2, the modeling techniques of FRP laminate and their interfaces are discussed. Further, in Sect. 69.3, FE models of the double cantilever beam (DCB) and drilling of FRP laminate are presented. The results and conclusions based on simulations performed in this work are summarized in the last section.

69.2 Modeling Approach

FRP laminates are composed of a number of plies with different orientations. Each FRP ply is assumed to be homogeneous with orthotropic elastic properties. These plies are glued together with a resin-rich interface. A two-phase (FRP ply and interface) model (Fig. 69.1) is required to simulate the delamination process. The associated material and damage models of FRP ply and interface adhesive are described in the following subsections.

69.2.1 Fiber-Reinforced Plastics (FRP)

While modeling of FRP laminate, an individual ply in a laminate is assumed to be homogeneous, orthotropic, and in a state of plane stress [13]. Hashin's failure criterion [14] has been used to model the damage initiation in FRP material. The criterion considers the failure of both fibers and matrix under both tension and compression. Failure mechanisms of fibers are governed by the longitudinal stress with reference to the fiber orientation. Meanwhile, failure mechanisms of the matrix are governed by the transverse and tangential stresses to the fiber. Failure is said to occur if the failure criterion of that failure mode is equal to or greater than one.

69.2.2 Cohesive Zone Method (CZM)

The interface between the plies is resin rich; hence, it is weaker compared to the plies. Therefore, the delamination occurs only at the interface. Special elements such as cohesive elements are used in the FE model to simulate delamination. The

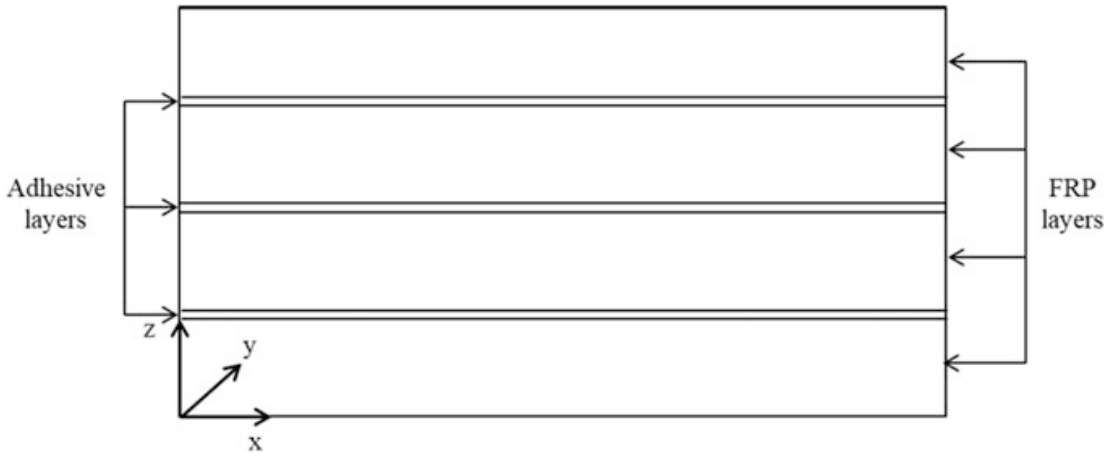

Fig. 69.1 Schematic representation of an FRP laminate

cohesive zone method (CZM) is based on traction–separation law [15]. The law has the capability to simulate the behavior of an interface from an initial linear elasticity to the final failure. Quadratic nominal stress criterion is used as a failure criterion [16]. The criterion assumes damage is initiated when a quadratic interaction function involving all nominal stress component ratios reaches a value of one. Damage evolution law based on fracture energy is incorporated in the model to simulate fracture at the interface. When the material is fully damaged, a crack will grow according to the quadratic fracture energy criterion.

69.3 Finite Element Modeling

2D FE models are developed to study the phenomenon of delamination based on the cohesive zone method. A commercial FE code Abaqus© is used for the simulations of the double cantilever beam test and the drilling of FRP laminate. DCB test is performed to understand delamination at interfaces of FRP laminate. Then, this approach is further extended to simulate push-out delamination in drilling process.

69.3.1 Double Cantilever Beam (DCB) Test

DCB test [17] is used to calculate the fracture energies of different modes of interface failure. Figure 69.2 shows an FE model of a DCB specimen. Two FRP layers are adhesively bonded together with an adhesive (here epoxy) layer. Each FRP layer is of 10 mm in length and 0.5 mm in thickness. Their elastic behavior is modeled with orthotropic elasticity, and damage initiation is modeled with Hashin's damage model [14]. An interface of 0.01 mm thickness between two

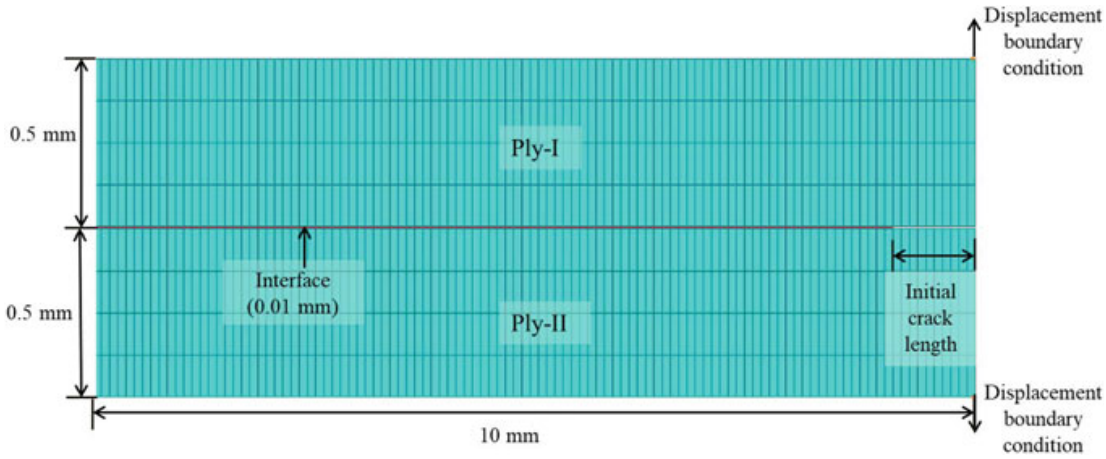

Fig. 69.2 FE model of double cantilever beam test

FRP layers is modeled based on CZM (see Sect. 69.2.2). Plain stress elements, 'CPS4R,' and cohesive elements 'COH2D4' are used to mesh FRP layers and interface layer, respectively.

The number of nodes on the adhesive layer and FRP layers is the same to achieve nodal connectivity at the interface. A displacement boundary condition is applied on the top and bottom corner of the nodes of FRP layers. Displacement of the nodes induces stresses in the elements which causes failure of the weakest section, i.e., interface. Quadratic damage criterion with an element deletion technique is used to simulate crack propagation along the interface. The load-carrying capacity of the interface in the mode-I type of delamination is predicted for different initial crack lengths.

69.3.2 Drilling of FRP Laminate

CZM can be effectively used to predict delamination of FRP laminate in a complex loading. Here, an attempt is made to predict delamination in drilling of FRP laminate. Drilling is a complex machining operation; hence, it is simplified by assuming no rotation of drill bit and a simple 2D FE model is developed. The main objective of the FE model is to predict the effects of thrust forces on the push-out delamination. Due to the simplification of the drilling process, this model does not take drilling torque into consideration. This model can predict delamination results with enough accuracy because push-out delamination is largely affected by thrust forces in drilling. The FE model of drilling (Fig. 69.3) shows a drill bit and four FRP plies that are adhesively bonded together with adhesive layers (epoxy). Drill bit is assumed to be rigid as it is 3–4 times harder than the FRP laminate. To minimize the computational time, whole geometry is scaled down. Each FRP layer is of 10 mm in length and 0.5 mm in thickness, and the diameter of a drill bit is taken as 1 mm. Their elastic behavior is modeled with orthotropic elasticity, and damage initiation is modeled with Hashin's damage model. Interfaces of 0.01 mm in thickness between the FRP layers are modeled based on CZM. Plain stress elements, 'CPS4R,' and cohesive elements 'COH2D4' are used to mesh the FRP layers and the interface layers, respectively. Element deletion technique is applied to delete failed elements based on damage criterion.

The interaction between the drill bit and workpiece is modeled using surface–surface contact available in Abaqus/Explicit. The contact is defined between the drill-bit surface and the FRP laminate nodes using sliding friction model with a coefficient of friction equal to 0.3. End nodes are fixed, and linear velocity in the vertical direction is applied to the drill bit. The effect of three different chisel-edge lengths on push-out delamination is predicted. The results obtained are discussed in the next section.

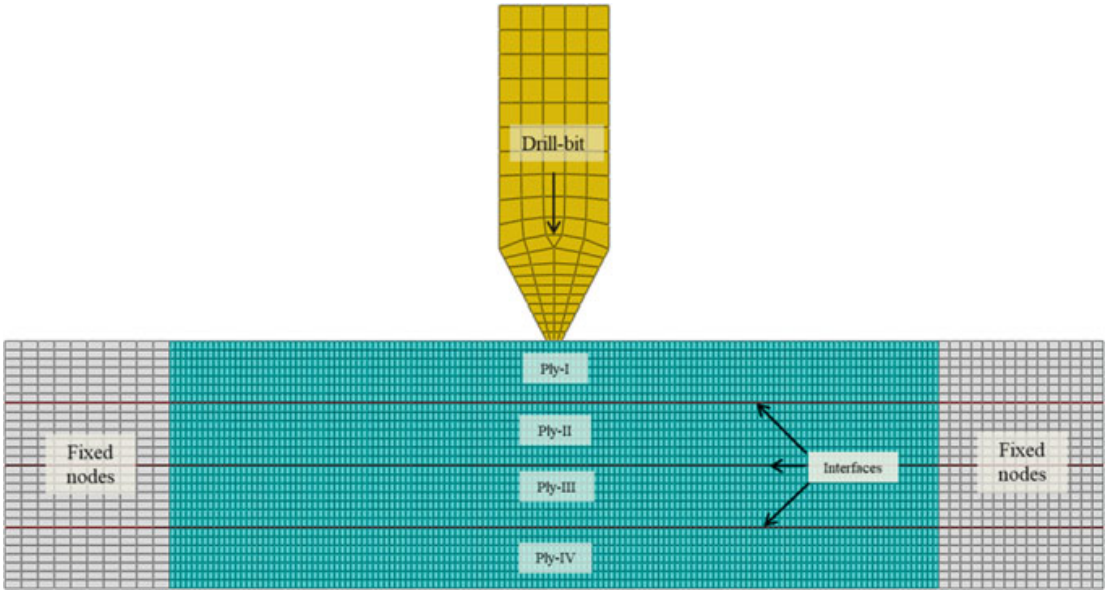

Fig. 69.3 FE model of drilling of FRP laminate

69.4 Results and Discussion

The results obtained in the simulation of double cantilever beam test and drilling of FRP laminate are discussed in the section.

69.4.1 Double Cantilever Beam (DCB) Test

These simulations were performed to predict the resistance offered by an interface for various initial crack lengths. Figure 69.4 shows a separation achieved at the interface by deleting the failed elements. Stresses in the *y*-direction (S22 in MPa) are the highest in the next critical elements at the interface. In this way, the crack propagates along the interface and delamination occurs. The simulation of DCB is run for five different initial crack lengths (0, 0.05, 0.25, 0.5, 1 mm). The initial crack helps in delamination; hence, the resistance offered by the interface layer reduces. This results in a reduction in load-carrying capacity with the size of initial crack length as shown in Fig. 69.5.

The shape of the load–displacement curve is triangular like a typical traction–separation curve that governs the behavior of an interface. The displacement indicates the separation between the nodes at the interface at the right edge of the beam (Fig. 69.4). The initial linear rise in the curves indicates the elastic behavior of the interface. The peak point is the maximum load-carrying capacity of the interface where the damage is initiated. Once the damage is initiated, the interface becomes weaker, its load-carrying capability goes down, and then it follows a linear softening law (Fig. 69.5). The load-carrying capacity is a strong function of an

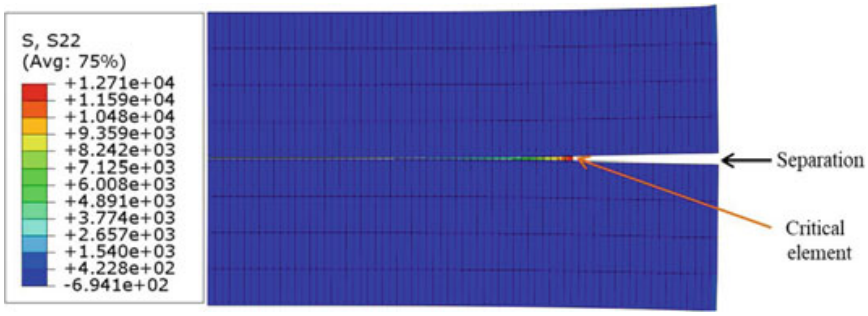

Fig. 69.4 Crack propagation along the interface during delamination

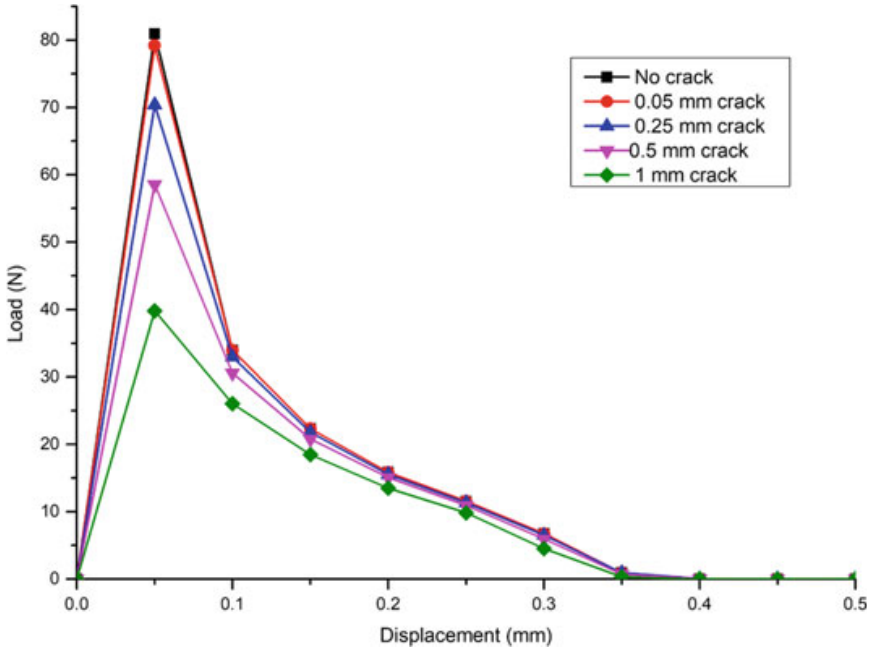

Fig. 69.5 DCB test results of load versus displacement for different initial crack lengths

initial crack length. The maximum resistance offered is 80 N with no initial crack, whereas 40 N was observed with a 1 mm initial crack.

69.4.2 Drilling of FRP Laminate

Simulation of drilling is performed for different chisel-edge lengths. For a given chisel edge, the drilling is achieved by deleting the failed elements (Fig. 69.6). As the drill bit moves in a vertically downward direction, the elements of the work-piece in contact with the drill-bit deform excessively. As the end nodes of the

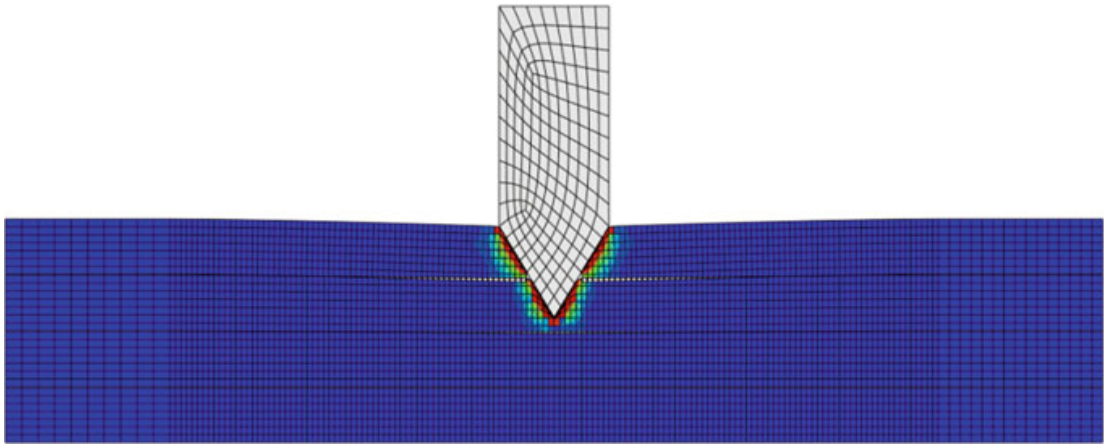

Fig. 69.6 Elements on the onset of failure in contact with drill bit

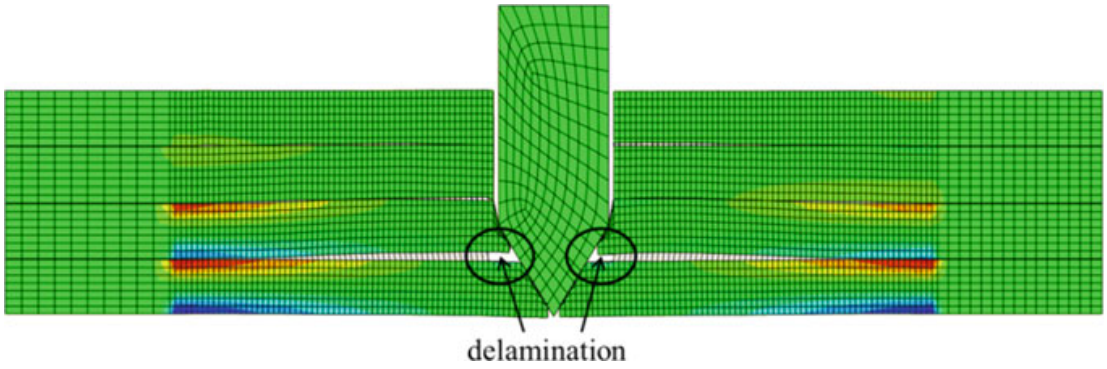

Fig. 69.7 Push-out delamination at the last interface in the drilling of FRP laminate

laminate are fixed, compressive and tensile stresses are induced in the laminate. When these stresses are enough to fail the FRP material, the damage is initiated based on Hashin's damage criterion.

Deletion of interface elements is based on quadratic damage criterion. In this way, simulation of a drilling process is accomplished in the 2D FE model. Drilling simulations are performed for three different chisel-edge lengths: 0, 0.15, and 0.35 mm, respectively. Figure 69.7 shows the delamination occurred at the last ply with a drill bit of '0 mm' chisel edge. The quantification of delamination is done using delamination factor $(F_d = D_{\max}/D)$, where $D_{\max}$ indicates the maximum diameter of the damaged zone and D is the actual hole diameter. As the length of the chisel-edge increases, there is an increase in the thrust force in drilling. Therefore, it is observed that delamination also increases with an increase in a chisel-edge length of a drill bit (Fig. 69.8).

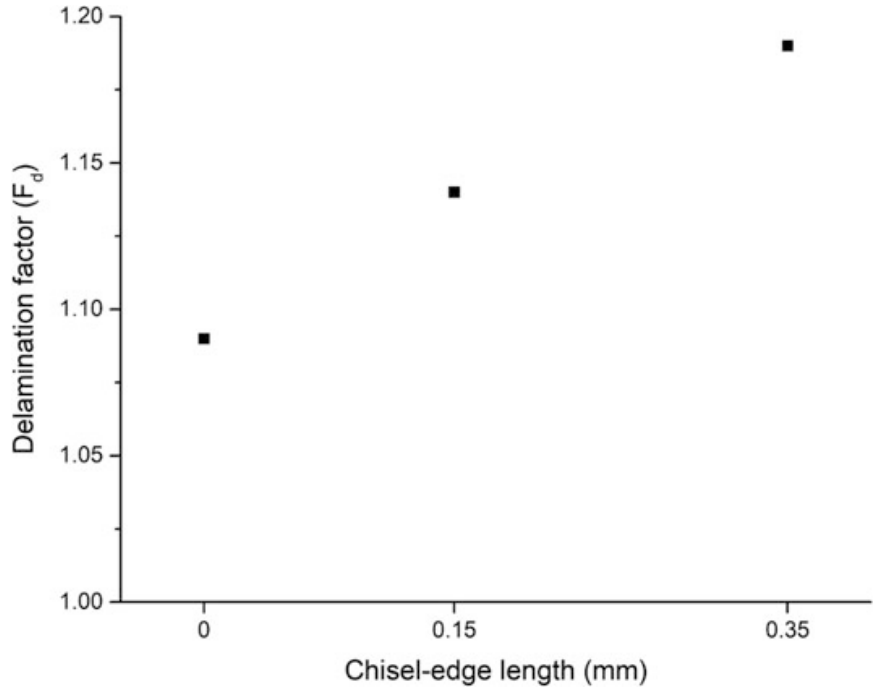

Fig. 69.8 Effect of the chisel-edge length on delamination

69.5 Conclusions

The finite element method can be effectively used to predict delamination in DCB test as well as in drilling of laminated composites. It was observed that load-carrying capacity of beam in double cantilever beam (DCB) test reduced by 50% for '1 mm' initial crack length. The available models to predict delamination in drilling are either analytical or the complex finite element models. These models have neglected the effect of chisel-edge length on the delamination. The present FE model is simple, takes less computational time, and produces results with enough accuracy. It takes a chisel-edge length effect into account. It was observed that push-out delamination increased by around 10% with an increase in the chisel-edge length from '0 mm' to '0.35 mm.' In addition, these models can be easily extended to predict the delamination for different drilling conditions and different FRP laminates.

Fuzzy Inference System-Based Neuro-Fuzzy Modeling of Electron-Beam Welding

Sanjib Jaypuria and Dilip Kumar Pratihar

Abstract Electron-beam welding, one of the high-energy density welding processes, is preferred for welding of nuclear, aerospace, and automotive materials. However, the input–output modeling of the welding is a challenging problem faced by many of the welding experts because of addition of new alloys to the industries. Soft computing techniques have been evolved in recent days to address this issue efficiently. This paper discusses two potential approaches of fuzzy inference system (FIS)-based neuro-fuzzy system for modeling of electron-beam welding response parameter. The following adaptive neuro-fuzzy inference systems (ANFIS): grid partition-based fuzzy interference system (G-ANFIS) and subtractive clustering-based fuzzy inference system (S-ANFIS) have been incorporated for the determination of depth of penetration in electron-beam welded copper plate in bead-on-plate configuration. In this study, the performances of above networks are compared on the basis of accuracy and computation time. Coefficient of correlation for S-ANFIS and G-ANFIS are found to be 0.98 in both approaches. Prediction of S-ANFIS is found to be 4 and 6% more accurate than results of G-ANFIS and regression model, respectively. Grid ANFIS consumes around 42 min to complete the computation, while it takes only 9.819 s for S-ANFIS. Based on the comparison, it is observed that the S-ANFIS model has the better prediction capability and less computational complexity than G-ANFIS and nonlinear regression model.

70.1 Introduction

Electron-beam welding (EBW) is an advanced fusion welding process, in which a high-speed electron beam is injected to the joining area of materials. The materials melt as the kinetic energy of the electrons transforms into heat upon impact. As a high-energy density process, EBW has inherent advantage of low-heat-affected zone and high aspect ratio, which yields relatively deep and narrow weld profile [1]. Electron-beam technologies are particularly useful in the industries like automotive, aviation, nuclear, medical, and railway. The primary input parameters, which affect the mechanical and metallurgical properties, are acceleration voltage, beam current, scanning velocity, focusing distance, and beam oscillation parameters [2]. Precipitated hardened Cu–Cr–Zr alloys have been selected as heat dissipation materials for the components of international experimental thermonuclear reactor (ITER) with high heat flux (HHF), such as the diverter, the limiter, and the first wall of the vacuum reactor [3].

Design of experiments, soft computing, and evolutionary computational networks have developed promptly and used for input–output modeling and optimization of welding [4]. Dutta and Pratihar [5] had modeled the dependence between input–output of gas tungsten welding (TIG) with three approaches, namely conventional regression, multilayer backpropagation neural network (BPNN), and genetic algorithm-tuned neural network (GANN). From the results, it was concluded that neural network is more robust in nature as compared to conventional regression. Moreover, GANN was found to outperform BPNN, as the former has fair chance of reaching the globally optimal solution. Jaypuria et al. [6] investigated the influence of EB welding input variables on mechanical properties and weld geometry of CuCrZr butt joint. A linear regression model had been developed to study the input and output relationship. Kim et al. [7] used a GA and a RSM simultaneously to predict the optimal welding conditions in the metal inert gas arc (MIG) welding process. Koleva [8] used statistical multiple regression techniques to estimate the depth and width of the welding schedule of EB welded stainless steels. Kanigalpula et al. [9] carried out electron-beam welding of copper plate and these bead-on-plate experiments were performed according to the central composite design. A statistical regression was performed to establish the input–output relationship of the EB joint. An optimization problem without constrains had been formulated to minimize the problem of spiking phenomena with maintaining the maximum average bead penetration. Results of genetic algorithm approach showed high accuracy with the real experiment results. Kanigalpula et al. [10] used genetic algorithm with penalty function approach to solve the complex constrained optimization problem associated with the EB welding of Cu–Cr–Zr alloy plates. They used four welding input parameters, namely voltage, beam current, scanning speed, and focusing distance to get suitable values of bead penetration, bead width, hardness of weld, and heat-affected zone.

Although many researches modeled input–output relation of EB welding for automation with respect to the accuracy of the model, there is no comparative study

about the computational complexity. A few studies have been reported on fuzzy logic (FL)-based analysis related to welding process. Most of the articles concentrated their studies regarding fuzzy inference system (FIS) parameter optimization through genetic algorithm (GA) and particle swarm optimization (PSO) algorithm. However, no literature is available for different kinds of FIS-based ANFIS model for EB welding. Here, the modeling of EBW is done through two proposed neuro-fuzzy approaches to predict the response. The following systems: (i) grid partition-based fuzzy inference system, known as G-ANFIS and (ii) subtractive clustering-based fuzzy inference system, known as S-ANFIS, have implemented for establishing the nonlinear dependence between the EBW input and output parameters. Accelerating voltage, beam current, welding speed, and focusing distance are used as inputs to the FIS model to predict the bead penetration. The performance and computational complexity are compared for all the developed approaches.

70.2 Experimentation and Data Collection

Bead-on-plate (BOP) welding of Cu–Cr–Zr alloy plates of the dimensions 100 mm × 65 mm × 10 mm is taken in the present consideration. The input process variables which influence the bead penetration (BP) of EB welding are accelerating voltage (V), beam current (I), welding speed (S), and focusing distance (D). These experiments were conducted by using response surface central composite design (CCD) matrix with three center points. Hence, a total of $2^4 + 2\times4 + 3 = 27$ combinations of experimentation were conducted. Since the factors were expected to have quadratic effects, three central points were taken and three replicates were considered for each combination of input variables. The CCD matrix having 81 experimental data is utilized for this study. The weld geometry of the finished and etched samples was studied under optical microscope and macroscope. To test the performances of the developed input–output models, 12 random cases out of the 81 combinations were selected after maintaining their respective ranges unviolated. Training and test data set for verification of developed model was taken from Kanigalpula et al. [10]. Table 70.1 shows the test data matrix with different combinations of process parameters.

70.3 Adaptive Neuro-Fuzzy Inference System (ANFIS)—Based Modeling

Adaptive Neuro-Fuzzy Inference System (ANFIS) is a combination of artificial neural network (ANN) and fuzzy Takagi–Sugeno system [11]. It is a powerful tool, for carrying out various supervised learning tasks, such as regression and classification. The membership function parameters of initial FIS are fine-tuned by the use

Table 70.1 Test data matrix for testing proposed methods

60	90	800	370	5.181
55	90	800	370	5.121
50	110	1000	365	4.74

of backpropagation algorithm or in combination with the least square method. Then, the network learns and trains the FIS-based network on the data provided. This popular fuzzy system consists of following components: (1) a rule base, (2) a database, and (3) a decision-making mechanism [12]. The rule base consists of all possible rules from the number and levels of input variables. The membership function is decided form the database and the inference mechanism helps to establish the relation between input variables and rules. In ANFIS architecture, the initial FIS clusters the entire region and describes the behavior of the rules in the fuzzy embedded region.

70.3.1 Grid Partition-Based Fuzzy Inference System (G-ANFIS)

G-ANFIS is first reported by Abonyi et al. [13] in 1999. G-ANFIS works on the principle of generating single-output Sugeno-type fuzzy inference system using a grid partition on the data. The initial FIS generates the membership function parameters randomly just like any ANFIS network. G-ANFIS uses the grid partition (axis-paralleled partition) of fuzzy on the basis of predefined number of membership functions and their dimension. ANFIS starts from zero output during the training; it gradually learns and refines the fuzzy rules and functions parameters. The number of fuzzy rules increases exponentially, when the number of internal input variables increases, so with the increase of number of rules, it becomes computationally expensive and impractical for industries where a large number of variables are associated with the process. The grid partition might be useful for the

system with small number of input variables mostly less than six and a large size of training data [14]. Here, four input variables are considered in this study. The proposed approaches have been developed with MATLAB 2015.

70.3.2 Subtractive Clustering-Based Fuzzy Inference System (S-ANFIS)

S-ANFIS [15] uses Sugeno-type FIS structure with subtractive grouping. S-ANFIS network is comparatively faster because of the faster estimation of cluster and cluster center in a given dataset. Here, each data point is assumed as cluster center and then defines the suitable cluster center of the dataset by calculating potential density of surrounding data points. In this manner, the first cluster center is chosen among the given data points and subsequently, the potential of data points near the cluster center is destroyed and second cluster center will be chosen based on potential density of surrounding data points. So, it becomes crucial to determine influence radius to construct one specific cluster and subsequent number of clusters with given data points. S-ANFIS returns a Sugeno-type FIS structure that models the data behavior and contains a set of fuzzy rules to cover the feature space [16].

70.3.3 ANFIS Models for Prediction of Depth of Penetration

In this work, both methods (G-ANFIS and S-ANFIS) are used for training of ANFIS and an attempt has been made to model and predict the response of EBW. Figure 70.1 shows the schematic view of developed ANFIS architecture for this study. A graphical user interface (GUI) of the updated rule base for a specific combination of input parameters is given in Fig. 70.2.

In the present study, out of the 81 input data pairs, 69 combinations are considered for training the FIS and 12 data pairs are used to test the accuracy and computation time. Takagi–Sugeno-type FIS structure of zero-order is used in both developed approaches. Gaussian and linear membership functions are considered in the current work for input and output layer, respectively. The reason behind choosing Gaussian function in input layer is the capability of the same to map the nonlinear process efficiently. The initial parameters associated with the membership function are randomly generated by ANFIS and tuned after subsequent training of FIS. A hybrid optimization algorithm, which is a mixture of backpropagation and least square method, is used to minimize the error (with error goal = 0) and a maximum iteration of 200. The number of membership functions is kept fixed at

five, representing the linguistic variables like very low, low, medium, high, and very high. Table 70.2 represents the internal parameters associated with G-ANFIS and S-ANFIS.

Table 70.2 Internal parameters for proposed methods

Internal parameters	G-ANFIS	S-ANFIS
Number of nodes	1297	227
Number of linear parameters	3125	110
Number of nonlinear parameters	40	176
Total number of parameters	3165	286
Number of training data pairs	69	69
Number of checking data pairs	12	12
Number of fuzzy rules	625	22

70.4 Results and Discussion

70.4.1 Grid Partition-Based Fuzzy Inference System (G-ANFIS)

G-ANFIS model has been established to predict bead penetration as a function of welding input variables. The root-mean-square error (RMSE) values of G-ANFIS model are 0.15797 and 0.24419 for training and test data sets, respectively. The regression plots of the training data and test data sets are shown in Fig. 70.3 with the goodness of fit (R^2) values as 0.99635 and 0.98907, respectively. The total CPU time for execution of the program is 2510.9725 s. The computational complexity can be easily understood from 625 number of fuzzy (if-then) rules and 3165 number of internal parameters, which leads to curse of dimensionality [12, 14].

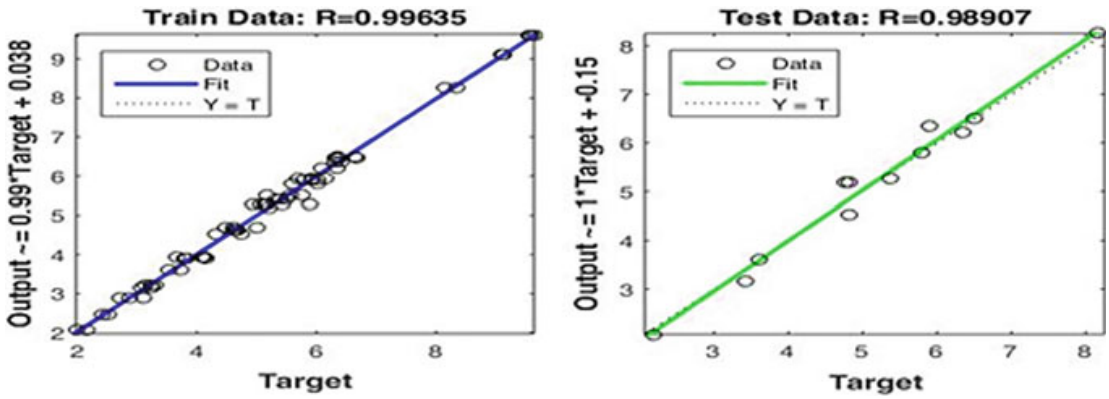

Fig. 70.3 Regression plots for training data and test data in G-ANFIS

70.4.2 Subtractive Clustering-Based Fuzzy Inference System (S-ANFIS)

The root-mean-square error (RMSE) values calculated for S-ANFIS architecture are 0.15507 and 0.23323 for the training and test data sets, respectively. The regression plots of the training data and test data sets are displayed in Fig. 70.4 with the (R^2) values as 0.99646 and 0.98915, respectively. The total CPU time for execution of the program is 9.819 s. Here, computation time is found to be quite less as compared to G-ANFIS because of elimination of unnecessary rules and dealing with only a few rules and internal parameters [15, 16].

70.4.3 Nonlinear Regression

A nonlinear statistical regression analysis is considered from available literature [10] to establish input–output relationships of the process and compare the results with other discussed ANFIS approaches. The generalized nonlinear regression expression is shown in below Eq. (70.1).

$$y = \beta_0 + \sum_{i=1}^{k} \beta_i x_i + \sum_{i=1}^{k} \beta_{ii} x_i^2 + \sum_{i=1}^{k} \sum_{i<j}^{k} \beta_{ij} x_i x_j + \varepsilon, \tag{70.1}$$

where y is the response parameter; $\beta_0, \beta_i, \beta_{ii}$ …. are the coefficients to be computed using a least-squares method. Here, ε stands for the error in fitting. Nonlinear regression equation for bead penetration is evaluated following Eq. (70.2), and given below.

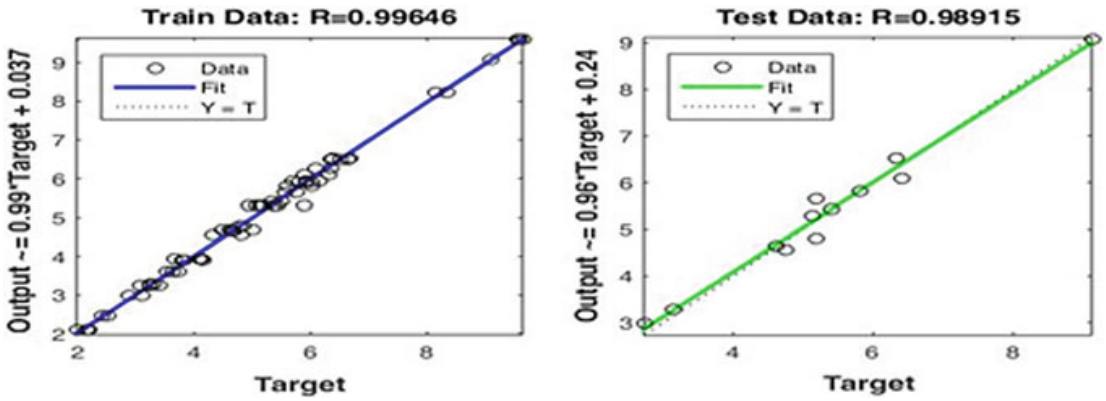

Fig. 70.4 Regression plots for training data and test data in S-ANFIS

$$\begin{aligned} BP_{uncoded} = {} & 5857.98 + 8.02798\,V + 0.0920434\,I + 0.0623438\,S - 33.0775\,D \\ & - 0.0313765\,V^2 - 0.00146853\,I^2 + 0.00000207134\,S^2 + 0.0456195\,D^2 + 0.0000113958\,VI \\ & - 0.0002530645\,VS - 0.0113766\,VD - 0.000145435\,IS + 0.00100352\,ID - 0.000114410\,SD \end{aligned} \tag{70.2}$$

70.4.4 Discussion

The RMS values for both training and test dataset in various developed ANFIS approaches are represented in Table 70.3. The least RMS value of 0.15507 and 0.23323 for training and test cases of S-ANFIS signifies a better convergence rate because of efficient tuning of internal parameters. Here, the model uses subtractive clustering technique with Gaussian and linear membership function for input and output layers, respectively. It is very fast enough to extract the set of rules that models the input–output relationship of a given system by effectively calculating the number of clusters and cluster center. Figure 70.5 shows distinctly that there is a satisfying similarity between the experimental value and the forecasted assessment of depth of penetration. The percentage of deviation of predicted data with respect to the test cases is also seen to be minimum in S-ANFIS-based approach, which is shown in Fig. 70.6. The computation time involved in S-ANFIS approach is least of all approaches. It is due to the selected number of rules chosen for the training of a specific response, so it deals with less number of fuzzy rules and internal parameters.

Grid portioning or G-ANFIS is also showing comparable RMS error values for both the training and test cases. This may be due to the inclusion of all possible combinations of fuzzy rules in the FIS, which ensure all relevant rules are accounted in the training process. Although this approach is precise, the computational complexity involved in this FIS is complex [17]. So, here, both the performance criteria, i.e., RMSE and computation time of the FIS are opposing in nature. The observed trend is certainly due to the involvement of all possible rules and accumulation of internal parameters during training. In addition to this, the RMSE value of train and test cases of nonlinear regression model was found to be larger than train and test results of S-ANFIS and G-ANFIS, respectively. The prediction accuracy of nonlinear regression and G-ANFIS models has shown 6 and 4% inferior results than that of S-ANFIS model. The computation complexity of S-ANFIS is also found to be significant lower than that of G-ANFIS.

Table 70.3 Performance comparison of the proposed approaches

Performance criteria	G-ANFIS	S-ANFIS	Nonlinear regression
RMSE (training cases)	0.15797	0.15507	0.21936
RMSE (test cases)	0.24419	0.23323	0.24644
Computation time (s)	2510.972	9.819	

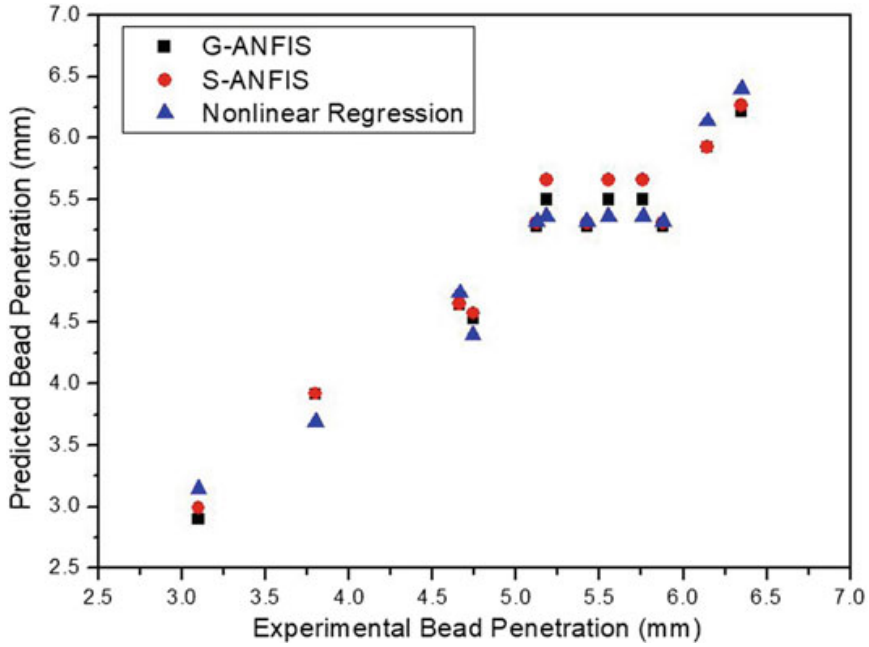

Fig. 70.5 Comparison of proposed approaches in terms of % deviation in prediction of bead penetration in test cases

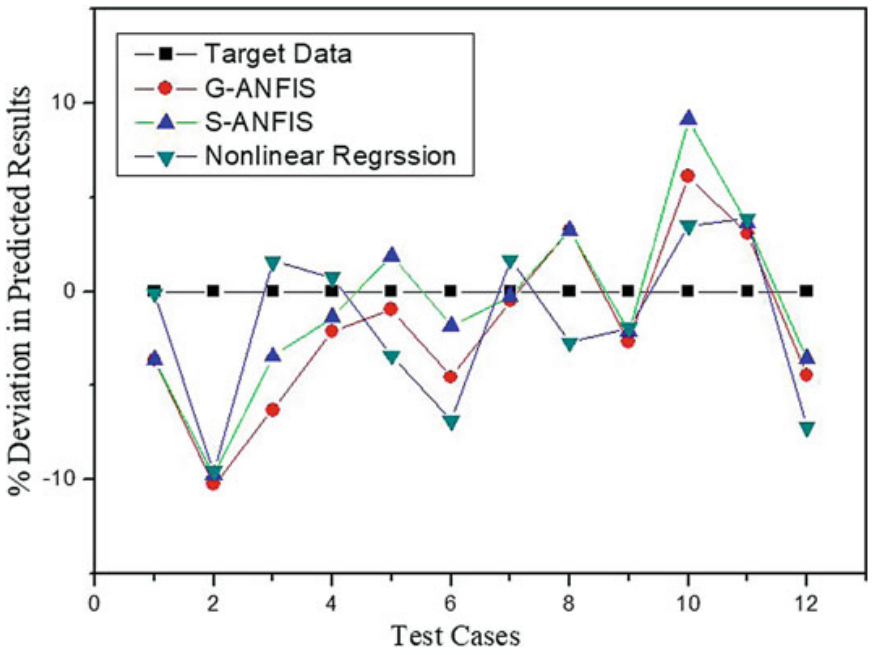

Fig. 70.6 Comparison between predicted and actual depth of penetration for the proposed approaches

Percentage deviation (Refer Fig. 70.6) result of S-ANFIS also signifies the good agreement with target data. Although the coefficient of correlation of both discussed approaches is nearly 0.98, the computational complexity of G-ANFIS creates difficulty for G-ANFIS model for real-time prediction. Therefore, it can be concluded

that S-ANFIS architecture is the more suitable one to make predictions without hampering the accuracy and computational complexity. It can also be used for real-time prediction due to their less consumption of computational resources and relatively higher accuracy in prediction.

70.5 Conclusion

The prediction of bead penetration using input variables of EBW is approximated by the FIS architecture based on grid partition and subtractive clustering. The developed model is verified with the test data. From the results, the following conclusions have been drawn:

1. Two different kinds of FIS generated models, namely G-ANFIS and S-ANFIS, are used to train the ANFIS network. The developed models have a good agreement with the experimental results. It can be validated with high value of coefficient of correlation value, which is 0.98 in both cases. Root-mean-squared error of the test cases is found to be equal to 0.24419 and 0.23323 for G-ANFIS and S-ANFIS, respectively. The computation time for G-ANFIS and S-ANFIS is found to be equal to 2510 s and 10 s, respectively.
2. The performance of above-discussed ANFIS models is also compared with nonlinear regression model, which is taken from the literature. S-ANFIS prediction accuracy in terms of RMSE is found to be 6% more accurate than the nonlinear regression results.
3. S-ANFIS model is found to be suitable among discussed approaches in terms of prediction accuracy and computational complexity. S-ANFIS is also more preferred for real-time prediction due to less consumption of computational resources.

In future, the performances of proposed approaches can be compared with that of fuzzy C-means clustering (FCM) approaches and evolutionary-tuned ANFIS approaches to check the suitability of the algorithm for automation and online inspection.

These tools are very useful for automation and controller design of any manufacturing process, where it involves costly trial and error experiments to find the suitable parameters for a desired response. The application of this tool is not limited to manufacturing industries, it can also be widely used for all domains of industries, where real-time or online modeling is required.

Chapter 71
Numerical Analysis of Erosion of Rough Surface

Ahad Noor, Saipraneeth Gouravaraju and Sachin Singh Gautam

Abstract This paper presents a numerical analysis of solid particle erosion of a rough surface. A total of ten particles are modelled to impact the target surface. For validation, first a smooth surface is impacted with rigid particles and the erosion results are compared with experimental results in the literature. After validation, erosion of rough surface is simulated using the finite element software ABAQUS. Rough surfaces with different average surface roughness are generated using inbuilt fast Fourier transform and random distribution functions in MATLAB. The coordinates of the generated rough surfaces are then imported to and superimposed on the mesh of the target surface generated in ABAQUS and finite element analysis is performed. It is observed that surface roughness affects the erosion rate significantly. For impact angles of 30° and 40° erosion is found to be less than that of the smooth surface.

71.1 Introduction

Precise prediction of lifespan of machine elements and replacement (wherever necessary) can avoid industrial hazards. There are several reasons due to which premature failure of engineering machine elements take place. Solid particles moving at high velocity is considered to be one of the main reasons for premature failure of machine elements. Study of erosion is very important in engineering

applications where fluid travels at very high speed like oil and gas pipeline, rocket nozzles, compressor blades, drilling platforms, etc. When solid particles hit the surface repeatedly it causes material removal from the surface, this phenomenon is known as solid particle erosion (SPE). So, it would be beneficial to industries to predict life of machine elements for which the phenomena of erosion must be understood extensively. Understanding of erosion phenomena includes understanding loading condition, response of materials, materials properties, failure mechanism, and environmental factors like temperature and pressure. Erosion due to the impact of solid particle is one of the most extensively researched areas since 1960.

Finnie [1] performed analytical study of erosion. He considered a single non-spherical particle which has two sides, viz. flat side and cutting edge. He made an assumption that when particle strikes with flat side, erosion does not take place, and when it strikes with cutting edge, erosion takes place. He proposed a simple mathematical expression for prediction of erosion rate at different angles. When compared with experimental results, his equation was able to predict correct results at lower impact angles but not at normal impact. Later Bitter [2, 3] proposed that solid particle erosion cannot be explained with one model. He proposed that solid particle erosion takes place due to cutting action and plastic deformation. He solved energy equation for both the cases and provided mathematical expression to predict erosion rate at different impact angles. He developed concept of threshold velocity, according to which if a particle hits the surface with a velocity more than threshold velocity then only erosion takes place. His formula was simple but needed a constant, which was supposed to be determined experimentally.

By the era of Finnie and Bitter, it was well established that erosion is highly influenced by the impact angle. Although mechanism proposed by researchers mentioned above can predict erosion of ductile material, a generalized agreement could not be obtained even for simpler cases. So, to understand the erosion phenomena, some researchers concentrated on microscopic analysis by experiment. Hutching and Winter [4] attempted to explain the mechanism of erosion by scanning electron micrograph of impact zone. They used a 3 mm steel ball to impact surface of different samples made of aluminium, copper, and steel. They concluded that erosion of materials takes place due to shearing of material ultimately leading to lip formation.

Yerramareddy and Bahadur [5] performed experiments on Ti–6A–4V alloy substrate using silicon carbide particles at different impact angles. They studied the effect of heat treatment which includes effect of precipitation hardening microstructure. They reported that the temperature of heat treatment changes microstructure and so affects erosion rate. To understand mechanism of erosion, they studied scanning electron microscope image of impact zone. They reported that erosion rate depends on the particle's shape, i.e., blunt or sharp-edged. Depending on the shape, erosion takes place by different mechanism like cutting, ploughing, lip information, etc.

Oka et al. [6] performed an experimental analysis of solid particle erosion of 304 steel at different impact angles. They considered the effect of surface hardness also.

Based on the results of their experiment they proposed a predictive equation to estimate the erosion rate.

$$E_{90} = K(H_v)^{k_1}(v)^{k_2}(D)^{k_3} \tag{71.1}$$

where E_{90} is erosion in normal impact. H_v, v, and D are hardness, velocity, and diameter of particle, respectively. K accounts for the particle property factor, which includes angularity, hardness, etc., of the particle. k_1, k_2, and k_3 are exponents.

Erosion at a particular angle of impact $E(\alpha)$ is considered to be related to the erosion in normal impact E_{90} as

$$E(\alpha) = g(\alpha)E_{90} \tag{71.2}$$

where $g(\alpha)$ denotes the dependency of erosion on impact angle and is given as

$$g(\alpha) = (\sin\alpha)^{n_1}(1 + H_v(1 - \sin\alpha))^{n_2} \tag{71.3}$$

Although these equations as proposed by Oka et al. [6] predict the erosion rate correctly, they did not consider the effect of roughness.

Phenomena of solid particles erosion involve very high-velocity impact and very low interaction time, which makes it very difficult to study experimentally. So researchers were attracted by numerical methods to study erosion phenomena. Shimizu et al. [7] performed FE analysis of impact of a single particle at different angles. They concluded that for impact of spherical particle there is significant plastic deformation before failure. Before the development of numerical methods, it was very difficult to study the behaviour of erosion resistance coating and composite materials. Their thickness was determined with a trial and error basis. But numerical methods emerged as an important tool for analysis of coating and composite materials. Many researchers like Bielawski and Beres [8] performed a numerical analysis of composite materials.

Woytowitz and Richman [9] studied the effect of gap between impacting particles. Eltobgy et al. [10] performed finite element analysis of Ti–6A–4V composite and studied effect of impact angle and speed. Giriffin et al. [11] performed finite element analysis of steel coated with Al_2O_3. He used two different failure models for Al_2O_3 steel. Lui et al. [12] performed numerical analysis to investigate the effect of shape of the impacting particle.

Nelson et al. [13] performed erosion experiment at 30° impact angle with different rough sample made of mild steel. Yildierim and Muftu [14] have done analysis of particle impact on rough surface but they have not considered damage as they have performed their analysis in context of shot peening process. Anaraki et al. [15] has performed the analysis of erosion on rough surface and investigated effect of velocity, density, and diameter of particle but they have taken surface roughness value much high rather than in practical range and also they have not considered damage they assumed elements with 0.2% plastic strain as eroded volume.

From the literature survey, it was observed that extensive work has been done to analyse the effect of angel impact, size of particle, velocity of impact, etc. So it was decided to investigate the effect of surface roughness on erosion. We first validated our model which is described in the next section with experimental results of Oka et al. [6] Then different roughness were included in the model. Results were found to be consistent with the experimental results of Nelson et al. [13].

71.2 Model Description

In the present work, impact of ten particles striking at two closely spaced locations on the target material is simulated in ABAQUS/Explicit as shown in Fig. 71.1. The material considered here is 4340 steel. A stainless steel block of size 2 mm × 1.6 mm × 0.6 mm is considered as the target material. The bottom surface and all the vertical surfaces of the surface are assumed to be fixed (called the Encastre boundary condition in ABAQUS). The impacting particles are considered rigid. The diameter of particles is taken as 326 μm and mass of each particle is taken as 4.717×10^{-8} kg, which resembles with mass of silicon carbide particle of similar size. Rotary inertia of the particles is ignored. Particles are arranged such that each particle strikes the surface just after the impact of previous striking particle is complete, i.e., a rebound has occurred. Particles are placed at desired angles using rotation option in assembly module of ABAQUS. The particles are given an initial velocity of 104 m/s using predefined field option in ABAQUS. Particles are given velocity in *X*-and *Y*-direction depending on the angle of impact such that their resultant velocity comes to 104 m/s. Contact interaction between the particles and the rough surface is defined using surface to surface node contact algorithm, where the particle is considered as the master surface and all nodes of target are considered as slave surface. This contact algorithm provides an interaction between particle and target only, so no particle

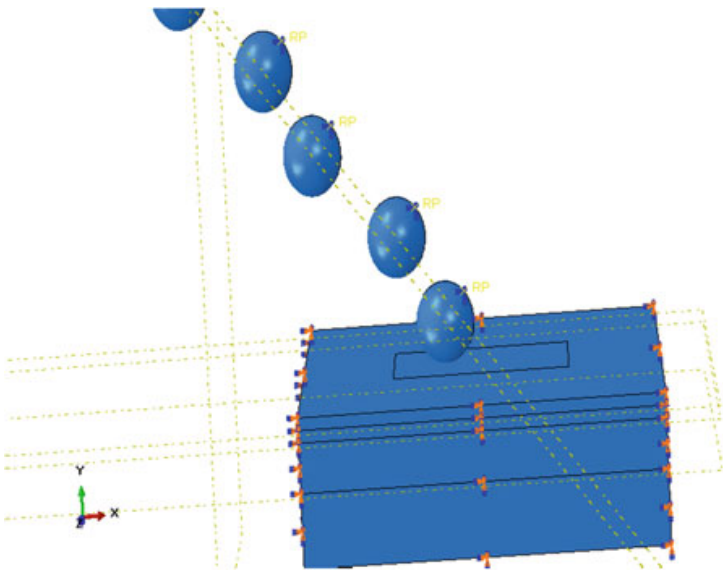

Fig. 71.1 Assembly of rigid particles and target material at an impact angle of 45° (only four particles are shown)

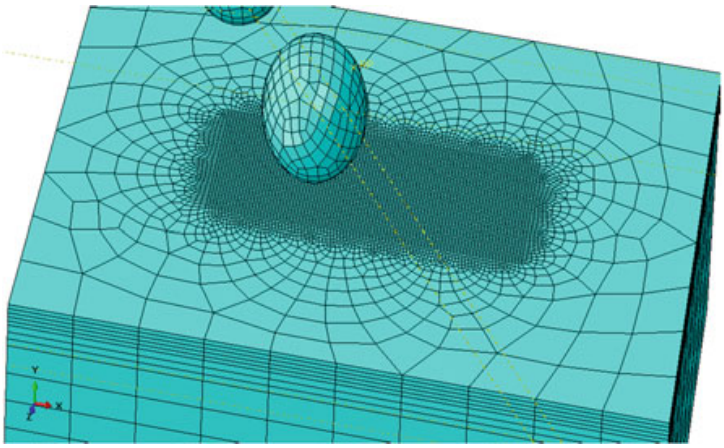

Fig. 71.2 Fine mesh near impact zone of 0.01 mm size while coarse mesh at other locations

collides during rebound of the previous particle. This helps us in placing particles closely and shortening the total simulation time. Friction between the surfaces is also considered with coefficient of friction value of 0.2, which was implemented using penalty, using interaction property option in ABAQUS. Heat generation due to friction and impact of particles were also considered. Eight nodded brick element (C3D8RT) with displacement degree of freedom is used for the analysis. Fine mesh of size 0.01 mm was used near impact zone while relatively coarse mesh was used in rest of the region as shown in Fig. 71.2.

The material data for 4340 steel is given in Table 71.1 [16].

Plastic properties are implemented using Johnson-Cook material model, which relates flow stress with equivalent plastic strain, temperature, and strain rate as shown in equation. Parameters of material model are given in Tables 71.2 and 71.3.

Table 71.1 Mechanical properties of 4340 steel

E (GPa)	v	ρ (kg/m^3)
200	0.3	7800

Table 71.2 Parameters for Johnson-Cook plasticity of 4340 steel

A (MPa)	B (MPa)	n	c	m	D_1	D_2	D_3	D_4	D_5
792	510	0.26	0.014	1.03	0.05	3.44	−2.12	0.002	0.61

Table 71.3 Composition of 304 and 4340 steel (%)

	C	Mn	Si	Ni	Cr	S	P
304 Steel	0.08	2.0	0.75	8–12	18–20	0.08	0.045
4340 Steel	0.42	0.70	0.28	1.83	0.79	0.0012	0.0009

$$\sigma_Y = \left(A + B\epsilon_p^n\right)(1 + C\ln\epsilon^*)(1 - T^*) \tag{71.4}$$

where ϵ_p is equivalent plastic strain, $\dot{\epsilon}^* = \frac{\dot{\epsilon}}{\dot{\epsilon}_0}$ is dimensionless plastic strain rate for $\dot{\epsilon}_0 = 1\ \mathrm{s}^{-1}$ and T^* is homologous temperature defined as

$$T^* = \left(\frac{T - T_{\text{room}}}{T_m - T_{\text{room}}}\right) \tag{71.5}$$

The Johnson-Cook fracture model is considered in this work to simulate damage. The damage parameter D is defined as

$$D = \Sigma\frac{\Delta\epsilon}{\epsilon_f} \tag{71.6}$$

where $\Delta\epsilon$ is increment in equivalent plastic strain and ϵ_f is the equivalent strain to fracture. Fracture is assumed to occur when D reaches value of 1. The expression for equivalent strain to fracture ϵ_f is given by

$$\epsilon_f = (D_1 + D_2\exp(D_3\sigma^*))(1 + D_4\ln\epsilon^*)(1 + D_5T^*) \tag{71.7}$$

where $D_i(i = 1, 2, 3, 4, 5)$ are the five constant. Their values are given in Table 71.2 [16].

In their erosion experiments, Oka et al. [6] used 304 stainless steel. Reliable Johnson-Cook damage parameters for 304 steel are not available in the literature [17]. So, in the current work, the results of Oka et al. [6] are compared with the results in the current work obtained with 4340 steel in a qualitative manner. Liu et al. [12] also considered the properties of ARMCO Iron for their FE simulations while comparing with the results of Oka et al. [6]. Although both the steels are of different grade, trend of failure follows the same pattern. A comparison of composition of both materials is shown in Table 71.3.

71.3 Results and Discussion

In this section, first the erosion from a smooth surface is discussed for impact velocity of 104 m/s and at six different impact angles, viz. 10°, 20°, 30°, 40°, 60°, and 90°, respectively. Results are validated with the experimental results of Oka et al. [6]. Then the erosion from the rough surface is simulated.

Initially, up to the impact of four to five particles no erosion occurred as the plastic flow and plastic deformation of the material is observed. With further impact, damage to the material starts and erosion takes place. Eroded volume is calculated and normalized with eroded volume in case of normal impact, i.e., for 90°. For calculation of eroded volume, number of elements deleted after the impact

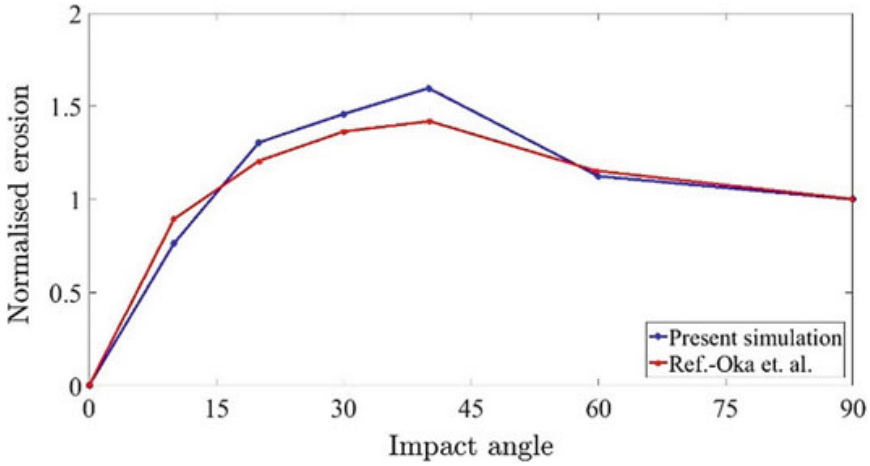

Fig. 71.3 Result for smooth surface and comparison to reference result

is counted. Then summing the volume of all the deleted elements gives us the total eroded volume. To convert eroded volume to dimensionless volume it is divided with eroded volume in case of normal impact. Results from the current finite element simulation are compared with results obtained by Oka et al. [6]. A comparison of present work and results obtained by Oka et al. [6] in their experiment is shown in Fig. 71.3. It can be seen that they are in good agreement. It is also observed that maximum depth occurs at normal impact but maximum volume occurs at 40° impact.

After validation, the effect of surfaces roughness on the erosion is studied. Four different rough surfaces with average surface roughness of 0.5 μm, 1 μm, 1.5 μm, and 2 μm are considered. Rough surface with autocorrelation length of 0.01 mm and mentioned average roughness values are generated using inbuilt Fourier transform and inbuilt random distribution function in MATLAB. Generated rough

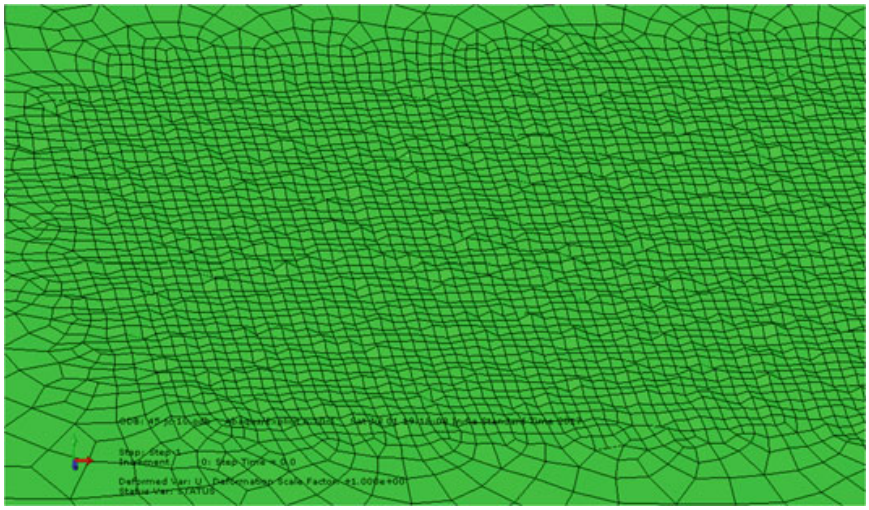

Fig. 71.4 Sample mesh of the target surface of the block after superimposing the coordinates of the generated rough surface

surface is superimposed on the top of the smooth surface discussed in the previous section (see Fig. 71.4). Then particle with a velocity of 104 m/s at different angles is impacted on the rough surface. Similar to smooth surface, eroded volume is calculated and normalized with volume of normal impact. Interestingly it is observed that at low impact angles, erosion decreased, and high angle is increased. Nelson et al. [13] also reported a decrease in erosion with increase in roughness for most of the cases but in one case they observed opposite trend also. At 30° impact angle, similar trend was observed in the current finite element simulation.

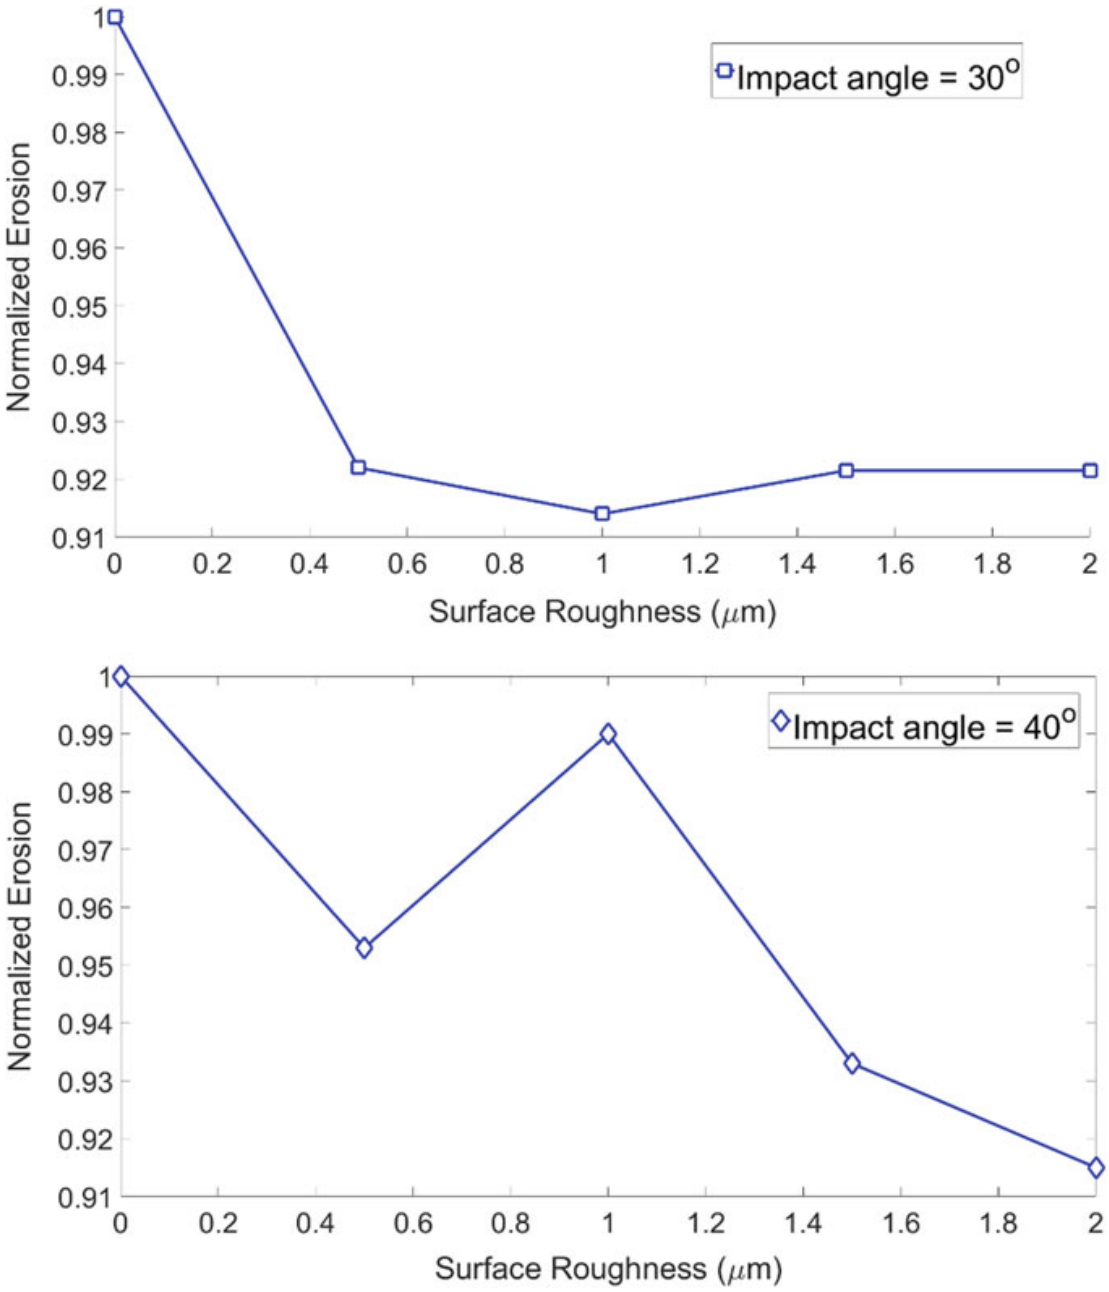

Fig. 71.5 Evolution of normalized erosion with surface roughness at impact angles of 30° and 40°

To quantify the effect of roughness, the eroded volume is normalized with the eroded volume of the smooth surface at each angle. Figure 71.4 shows the variation of normalized volume of erosion for rough surface with surface roughness for different impact angles. It can be seen that at lower impact angles, as the surface roughness increases, the erosion decreases. But at higher impact angles, erosion increases with increase in roughness. This observed behaviour is consistent with the observations of Nelson et al. [13] at an impact angle of 30°. (Figure 71.5)

71.4 Conclusion

A finite element analysis is carried out to study the erosion characteristics of a rough surface due to particle impact at different angles of impact. It is observed that surface roughness affects the erosion rate significantly. In the present analysis, two angles of impact are considered for the rough surface impact, viz. 30° and 40°. In both the cases, erosion rate is observed to be lesser than the erosion of smooth surface. This can be explained by Finnie's theory [1]. Finnie [1] argued that the surface roughness changes actual angle of contact for 30° impact. Results of the present numerical analysis follow the similar trend which was observed by Nelson et al. [13] experimentally.

Chapter 72
Numerical Simulation and Experimental Validation of Nanoindentation of Silicon Using Finite Element Method

Borad M. Barkachary and Shrikrishna N. Joshi

Abstract This paper reports finite element method-based numerical simulations of nanoindentation of Silicon to extract the mechanical properties, viz. Young's modulus and hardness. The simulations were carried out by using the Drucker–Prager constitutive model assuming a rigid spherical indenter of radius 300 nm to mimic the Hertzian contact which is typically observed underneath the Berkovich indenter. The dispalcement controlled boundary conditions comprising the depths of indentation as 45, 75, 95, 115, 130, and 140 nm were applied. Oliver–Pharr analytical method was used to obtain load-displacement plots. By using these plots, the values of Young's modulus and hardness were estimated. The results from the developed finite element simulation have also been validated by using the published experimental results. The estimated results from our simulations were found to be fairly matching with the experimental results. It was noticed that the FEM-based simulations provide an economical and fast option to the physical experiments in the estimation of mechanical properties of a material.

72.1 Introduction

Nanoindentation testing is useful to obtain the unknown mechanical properties such as hardness and Young's modulus. This method comprises of pressing the substrate material (specimen) against a harder material (usually a diamond indenter), and the material properties are estimated based on the force–displacement plots obtained during the loading and unloading sequence. Over the decades, various techniques such as tensile/compressive test, shear test, triaxial, and scratch test, nanoindentation have been developed to measure the mechanical properties of materials, viz. Young's modulus, Poisson's ratio, yield strength, strain-hardening, shear strength, hardness, etc. Out of these techniques, the tensile/compressive are commonly used for characterization of ductile materials. However, these are not suitable for brittle materials such as Silicon, because the brittle materials have higher yield strength than the fracture strength. Thus, during these tests, brittle materials fail before yielding. The applied stress reaches the fracture strength first, thereby fracturing the specimen before any appreciable strain can form. Nanoindentation test is a simple method, which determines the mechanical properties of materials such as hardness and Young's modulus. It is also used to obtain strain-hardening exponent, creep, fracture toughness, viscoelastic properties, and stress-strain data.

While some experimental work on Silicon exists, little theoretical work, especially in the arena of numerical simulations, has been reported. Our motivation is to simulate the Nanoindentation of Silicon using the currently available material models and evaluate how well the results from such models compare to those obtained in experiments. In sum, the objectives of this study were (i) to explore nanomechanical response of Silicon to quasi-static nanoindentation, (ii) to demonstrate the feasibility of modeling a typical hardness test using finite element analysis, (iii) to show how basic mechanical properties can be extracted from such simulated results, and (iv) to compare and contrast the simulated results with the experimental results.

72.2 Theoretical Background

Nanoindentation is a robust technique used to investigate the nanomechanical properties of materials, such as hardness, Young's modulus, fracture toughness, and incipient plasticity, all of which are vital for designing structural/functional elements of MEMS/NEMS devices. Nanoindentation entails a simpler setup and specimen preparation is compared to other mechanical experimental characterization methods. Typical nanoindentation involves pressing a hard indenter into a substrate material whose properties are to be determined.

During a nanoindentation process, the indenter is pressed into the material as shown in Fig. 72.1a, due to which both elastic and plastic deformation processes

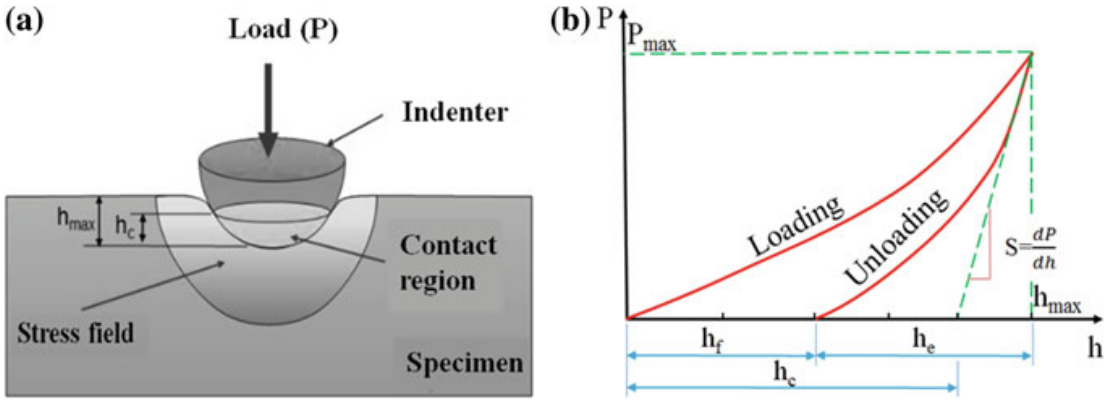

Fig. 72.1 Schematic of **a** nanoindentation process and **b** load–displacement plot

occur. This process produces an impression with a projected area A_p and surface area A_s of contact. This area depends on the geometry of the indenter and the contact depth, h_c. Basically, the nanoindentation process includes a loading and unloading cycle with or without dwell cycle. Figure 72.1b shows the indentation load (P) plotted against the displacement of the indenter tip (h) with respect to the top of the surface (before deformation) for one complete indentation cycle. The important parameters that have to be noted are the maximum depth (h_{max}) of penetration at peak load, the peak load (P_{max}) and the final residual depth after unloading (h_f). The slope S, also known as contact stiffness is determined by linearly fitting the upper 1/3th portion of the unloading curve. The contact stiffness, hardness, and Young's modulus are determined by using the Oliver–Pharr method [1, 2] as described in following Sects. 72.3.1 and 72.3.2 which is also mentioned in ISO 14577 and ASTM E2546.

72.3 FEM Modeling and Simulation of Nanoindentation of Silicon

With the advent of the computational techniques, it is now possible to use the FEA for analyzing complex engineering problems in a variety of engineering areas. Some of these problems include the study of heat transfer, contact mechanics, fluid dynamics, and electromagnetism [3]. In the present study, a commercial FE package ABAQUS™ was used to model the nanoindentation process of Silicon with a spherical rigid indenter of a known radius (300 nm). The use of a spherical indenter introduces a wider yet small stress field resulting in elasto-plastic deformation at shallow loads. Details of the model development are presented below.

72.3.1 Assumptions

As with any other engineering problem, there were several assumptions made while undertaking this study. First, it was assumed that no slippage occurs at the interface. Second, the contact between the indenter and the surface of the work material is assumed to be frictionless [4–6]. Workpiece and diamond indenter materials are assumed to be homogeneous and isotropic. The indentation process was carried out in quasi-static condition, so, temperature effect was neglected in the current simulation.

72.3.2 Geometric Modeling

The axisymmetric FEM model with its geometric dimensions is shown in Fig. 72.2. The dimensions of the work material were chosen in such a way that the deformation-induced stress waves reflected back from the fixed boundary can be avoided. Accordingly, the work material in this model was set to be an axisymmetric rectangular block of 2 μm × 2 μm. These dimensions are large enough to simulate a semi-infinite half-space for indentation with a maximum depth of 140 nm in this model. The rigid indenter was modeled with a radius of 0.3 μm.

72.3.3 Material Model

In this present simulation, a nanoindentation problem was considered to be based on continuum mechanics, where quasi-static loading of the indenter is applied. Since the von Mises yield criterion imply the dependence of material yielding solely on second deviatoric stress tensor and is independent of the first stress invariant, the yielding sensitivity to hydrostatic stress tensor is not incorporated for

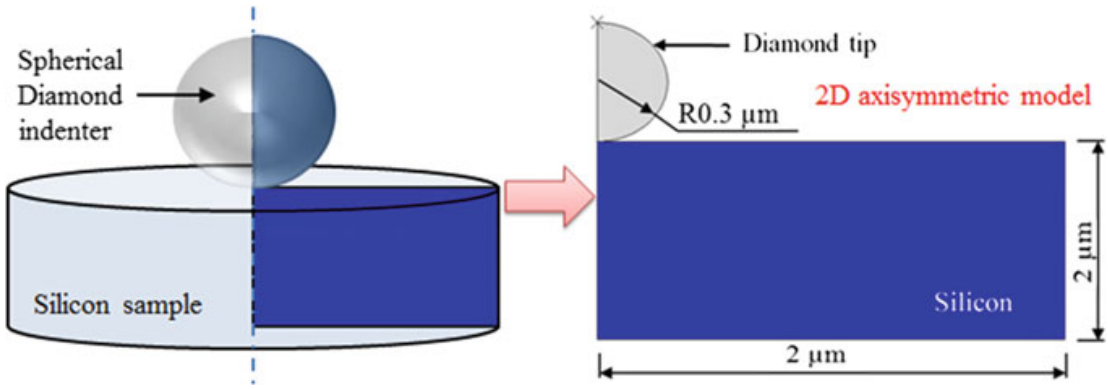

Fig. 72.2 Schematic of 2D axisymmetric indentation simulation model

pressure-sensitive materials. Drucker–Prager material model is used to model the material behavior of Silicon along with the elastic material properties. The Drucker–Prager yield criterion given by ref. [7] is a pressure-dependent model for determining whether the material has failed or undergone plastic yielding. The Drucker–Prager yield criterion can be described as a simple modification of the von Mises criterion, in which the hydrostatic stress component is also included to introduce pressure-sensitivity. The Drucker–Prager yield criterion is given by the following:

$$\sqrt{3 \cdot J_2} + I_1 \cdot \alpha - \kappa = 0 \tag{72.1}$$

where I_1 is the first invariant of the stress tensor, J_2 is the second invariant of the deviatoric stress tensor, α is the pressure-sensitivity coefficient, and κ is a material constant.

The quantity J_2 is given by the following:

$$J_2 = \frac{1}{6}\left[(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2\right] \tag{72.2}$$

where σ_i are the principal stresses. The quantity κ is given by the following, which is equal to the yield stress in the case, when $\sigma_c = \sigma_t$, that is, no pressure dependency:

$$\kappa = \frac{2\sigma_c\sigma_t}{\sigma_c + \sigma_t} \tag{72.3}$$

where σ_c and σ_t are the yield stress in tension and compression, respectively.

The elastic materials properties for diamond and silicon are listed in Table 72.1 and Drucker–Prager material constants for silicon are listed in Table 72.2.

Table 72.1 Material properties of Diamond [7, 8] and Silicon [9]

Parameters	Unit	Diamond	Silicon
Density (ρ)	(kg/m^3)	3350	2328
Young's modulus (E)	(GPa)	1141	130
Shear modulus (G)	(GPa)	512	79.9
Poison's ratio (υ)		0.07	0.27
Fracture toughness (K_c)	(MPa m$^{1/2}$)	5.3 – 8	0.9
Thermal conductivity (k)	(W/m K)	700	150
Specific heat	(J/kg K)	520	700

Parameters	Angle of friction (°)	Flow stress ratio	Dilation angle (°)	Yield stress (Nm^{-2})
Si	26	0.82	−20	15,867

72.3.4 Element and Meshing

Figure 72.3 shows the meshed models of the diamond tip and the workpiece. In the present work, two-dimensional, four-node quadrilateral element CAX4R was employed to discretize the model geometries. It is four-node quadrilateral element and provides reduced integration with hourglass control.

This element is chosen here because it is relatively inexpensive in terms of computation cost and time for problems involving non-linear constitutive behavior. For this type of element, the material calculations are only done at one point in each element by integrating all four nodes. Moreover, quadrangle element is one order higher than triangular element due to which it gives more accurate results. Also, by using this type of element, the symmetrical three-dimensional results can be viewed. The solution accuracy is dependent upon the type of mesh and its

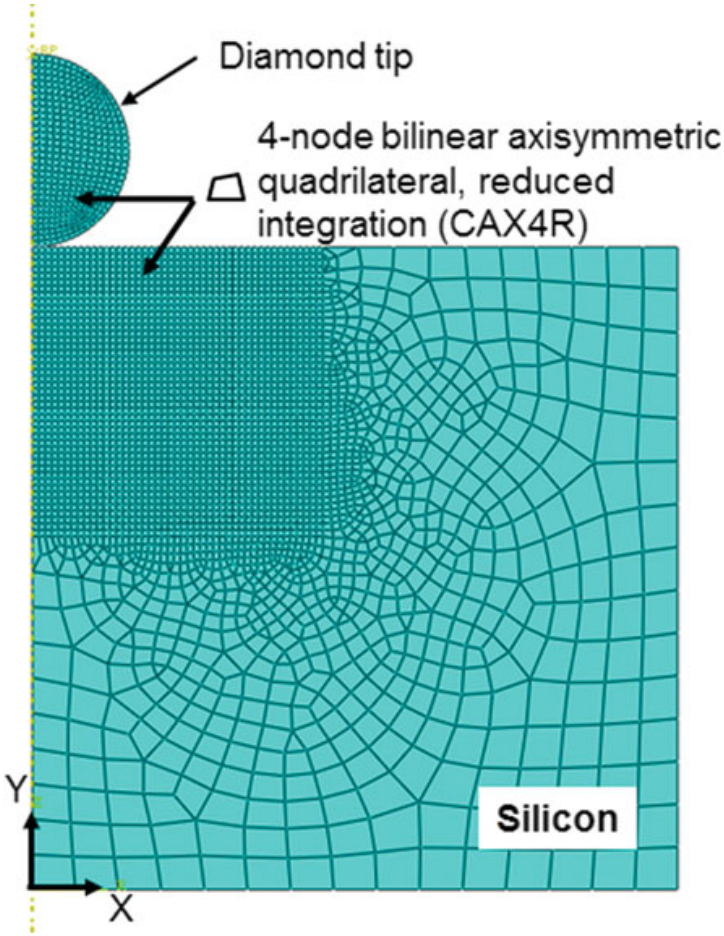

Fig. 72.3 Meshed geometries of the diamond tip and the workpiece

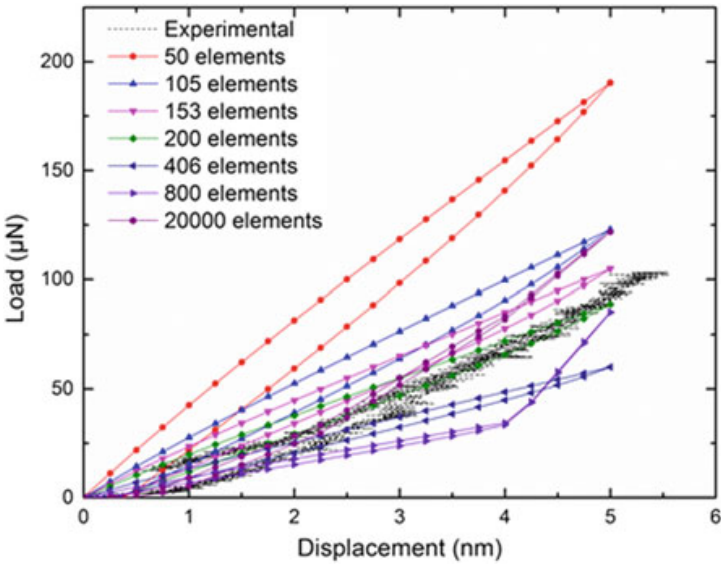

Fig. 72.4 Comparison of load–displacement plot with no of elements in indentation zone

refinement. Modification of mesh, known as *mesh refinement* is important to obtain a more accurate solution in any FEM simulation. The silicon block is discretized using fine mesh near the indentation zone, and coarse meshing is done away from the indenter to reduce the computational time without compromising the accuracy. The mesh sensitivity analysis has been carried out for a typical process condition: indenter tip radius—300 nm, max loading depth—45 nm, loading speed—0.1 mm/s. These process conditions are the same as that of the experimental conditions mentioned in the published literature by Rao et al. [11]. From the analysis, it was seen that the load–displacement plots at 20,000 elements are closer to the experimental results [11] in comparison with those obtained for the remaining cases as shown in Fig. 72.4. Therefore, the element size of 0.00001 mm, which generates 20,000 elements to discritze the geometries, was chosen for the discretization of the indentation zone.

72.3.5 Modeling of Surface Contact

The bottom surface of the indenter and the top surface of work materials formed a contact pair in the present numerical model. Surface-to-surface contact has been assigned between the contact pairs. Based on the suggestions from the literature ref. nos. [5, 6, 12], frictionless contact property is enabled between the two contact surfaces. It is because only a small portion of the indenter is considered to be in contact with the surface of the workpiece.

72.3.6 Boundary Conditions

Figure 72.5 shows the boundary conditions applied to the tool and workpiece. A fixed boundary condition is applied to the base of the work material. All the nodes on the base cannot move in any directions. The X-symmetry boundary condition is applied to the vertical surface of the workpiece as shown in Fig. 72.5.

It means that the workpiece geometry and diamond tip are symmetric along with the symmetry line and both form a revolving 3D geometry around the line. Rigid body constraint is applied to the diamond indenter at the reference point. First, it is restrained in the *X*-direction along with all the rotational degrees of freedoms. Since the process is very slow, i.e., quasi-static loading condition is assumed. Therefore, the load applied to the indenter is the displacement/velocity load of 0.1 mm/s in the current simulation. It is applied to the reference point of the diamond tip. As the contact area is very small and the loading speed is very slow, the effects of variation in temperature are not considered in the current simulation.

72.3.7 Solution Methodology

The numerical simulation of nanoindentation has been carried out in two steps: loading and unloading. The nanoindentation process includes complex interaction between the diamond tip and the workpiece along with large elastic-plastic

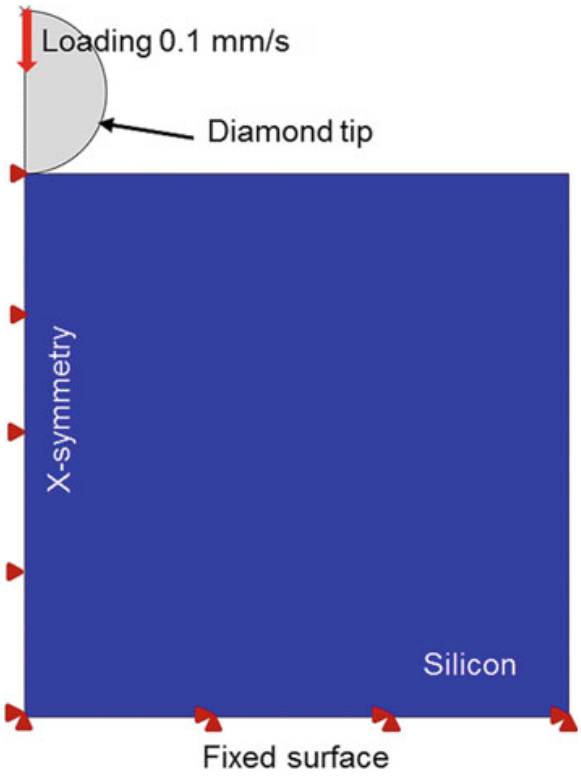

Fig. 72.5 Schematic of the boundary conditions applied

deformation of the workpiece during the nanoindentation process. Due to this complexity, both the steps have been solved by following the non-linear dynamic explicit solution step method with automatic (self-adaptive) time-step algorithm. In the dynamic explicit automatic time-step algorithm, the time increment is adjusted automatically to meet the corresponding convergence rate. The loading behavior of nanoindentation is simulated by increasing the indenter displacement in small increments. During the loading steps, the indenter is moved in the negative *Y*-direction, i.e., downward direction with a velocity of 0.1 mm/s and indents the work material to the maximum indentation depth. During the unloading step, the indenter returns to its original position incrementally. For each loading and unloading steps, 20 frames have been generated to reduce the data size.

72.4 Results and Discussion

The most common method for measuring hardness and Young's modulus using nanoindentation methods is the Oliver–Pharr analytical method. The underlying assumptions for the analytical model are:

(i) Deformation upon unloading is purely elastic
(ii) The compliance of the sample and the indenter tip is considered as springs in series
(iii) The process continuum is considered to be a homogeneous isotropic elastic half-space.

72.4.1 Measurement of Young's Modulus

From the extracted load–displacement plot, maximum load, corresponding maximum displacement at maximum load and the final displacement after the unloading was recorded. In the present case, the maximum load is 1275 μN, and maximum displacement is 45 nm. The displacement after unloading is 38.18 nm. It has been noted that there is no fixed rule for considering the unloading data points. The unloading data points are needed to be chosen by looking at the graphical data before deciding on the fitting parameters for analysis. Usually between 25 and 100% of the unload curve data are commonly used for the fitting function depending on the quality of the data [2, 13]. In the present case, we have found that 1/3th of the data points give good results while calculating Young's modulus and hardness. From the unloading curve, 1/3rd data points of the total unloading data points are linearly fitted, and the corresponding slope values were obtained as shown in Fig. 72.6.

Corresponding hardness and Young's modulus values were calculated for each depth of indentation following the Oliver–Pharr method. The stiffness of the contact

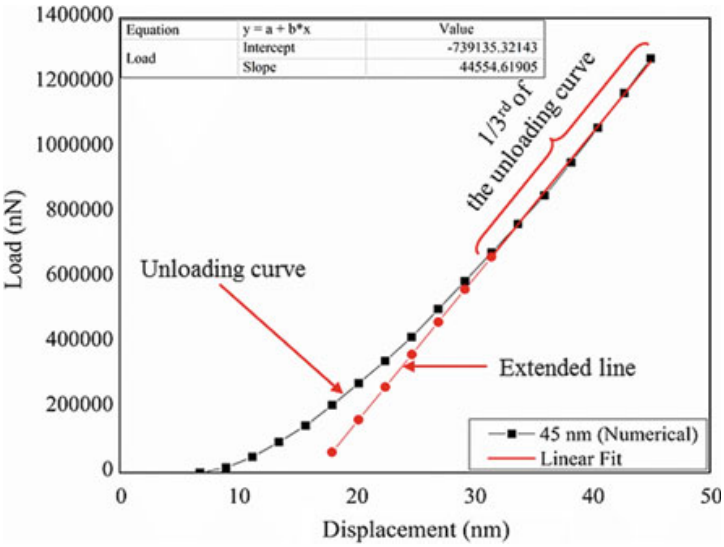

Fig. 72.6 Fitting the unloading curve and finding the slope

between the indenter and the material being tested is required to determine the mechanical properties of interest. The stiffness, S, is determined from the initial slope of the unloading curve.

$$\text{Stiffness}\,(S) = \frac{\mathrm{d}P}{\mathrm{d}h} \tag{72.4}$$

From the linearly fitted line, the slope is calculated using the linear line equation as shown in Fig. 72.6, which is nothing but the stiffness (S) = 44555 N/m^2. Once the stiffness is measured using (72.4), the reduced modulus E_r can be determined as:

$$E_r = S\frac{\sqrt{\pi}}{2\beta\sqrt{A}} \tag{72.5}$$

where S is the contact stiffness, A is the contact area, and E_r is the reduced modulus which accounts for the measured elastic displacement contributing both from the sample and the indenter tip. Depending on the indenter tip used, contact radius is calculated. In the present case, for spherical indenter, the contact radius is computed as

$$\text{Contact radius}, a = \sqrt{h(D-h)} = \sqrt{45(600-45)} = 158\,\text{nm} \tag{72.6}$$

where D is the diameter of the spherical indenter, and h is the maximum depth at maximum load. The contact area between the indenter tip and workpiece at maximum displacement is calculated as

$$\text{Contact area}, A = \pi a^2 = 7.85 \times 10^{-14}\ \text{m}^2 \tag{72.7}$$

After finding out the stiffness (S), contact area (A), and taking indenter geometry correction factor β = 1, the reduced modulus (E_r) is calculated as 1.41×10^{11} N/m^2

(by using the Eq. (72.5)). Next, the reduced modulus can be used to calculate the actual modulus of the sample, using the following relationship:

$$\frac{1}{E_r} = \frac{1 - \upsilon_i^2}{E_i} + \frac{1 - \upsilon_s^2}{E_s} \tag{72.8}$$

where $E_i = 1141$ GPa and $\upsilon_i = 0.07$ are the known values of the Young's modulus and Poisson's ratio for diamond indenter, respectively. Thus, by using Eq. (72.8), the actual modulus E_s for silicon sample is found to be $E_s = 153$ GPa.

72.4.2 Measurement of Hardness

Hardness is the resistance to the permanent plastic deformation-induced in the material and is expressed as the ratio of the applied force ($P_{\max}$) to the corresponding projected contact area (A) as shown in Eq. (72.9):

$$\text{Hardness}, H = \frac{P_{\max}}{\text{Contact area}} \tag{72.9}$$

By using Eq. (72.9), the hardness value of silicon were calculated as $H = 16.25$ GPa for $P_{\max} = 1275$ μN and $A = 7.85 \times 10^{-14}$ m^2. After determining the required output parameters, the results were validated with the published experimental results. These are presented in the following section.

72.5 Experimental Validation of Nanoindentation Simulation

Nanoindentation simulations were carried out for silicon workpiece to validate the developed finite element-based nanoindentation model with experimental results [11]. All the process conditions in the simulations were set similar to the experimental process conditions mentioned in the Rao et al. [11] except the indenter geometry as the simulation was carried out in 2D. In numerical simulation spherical indenter tip with a diameter of 600 nm was considered, whereas, in the experiment, indentations were performed with a Berkovich indenter. The approximation of Berkovich indenter with a spherical indenter with nanometric radius is still valid as the tip of the Berkovich indenter is not completely sharp. Plots of experimental and numerical simulation results in terms of the load–displacement graph for indentation depths 45, 75, 95, 115, 130, and 140 nm are shown in Fig. 72.7. From the figure, it was observed that numerical results are in good agreement with the experimental results; however, the numerical results over predict the experimental results. Using Oliver–Pharr analytical procedure explained in previous Sects. 72.4.1

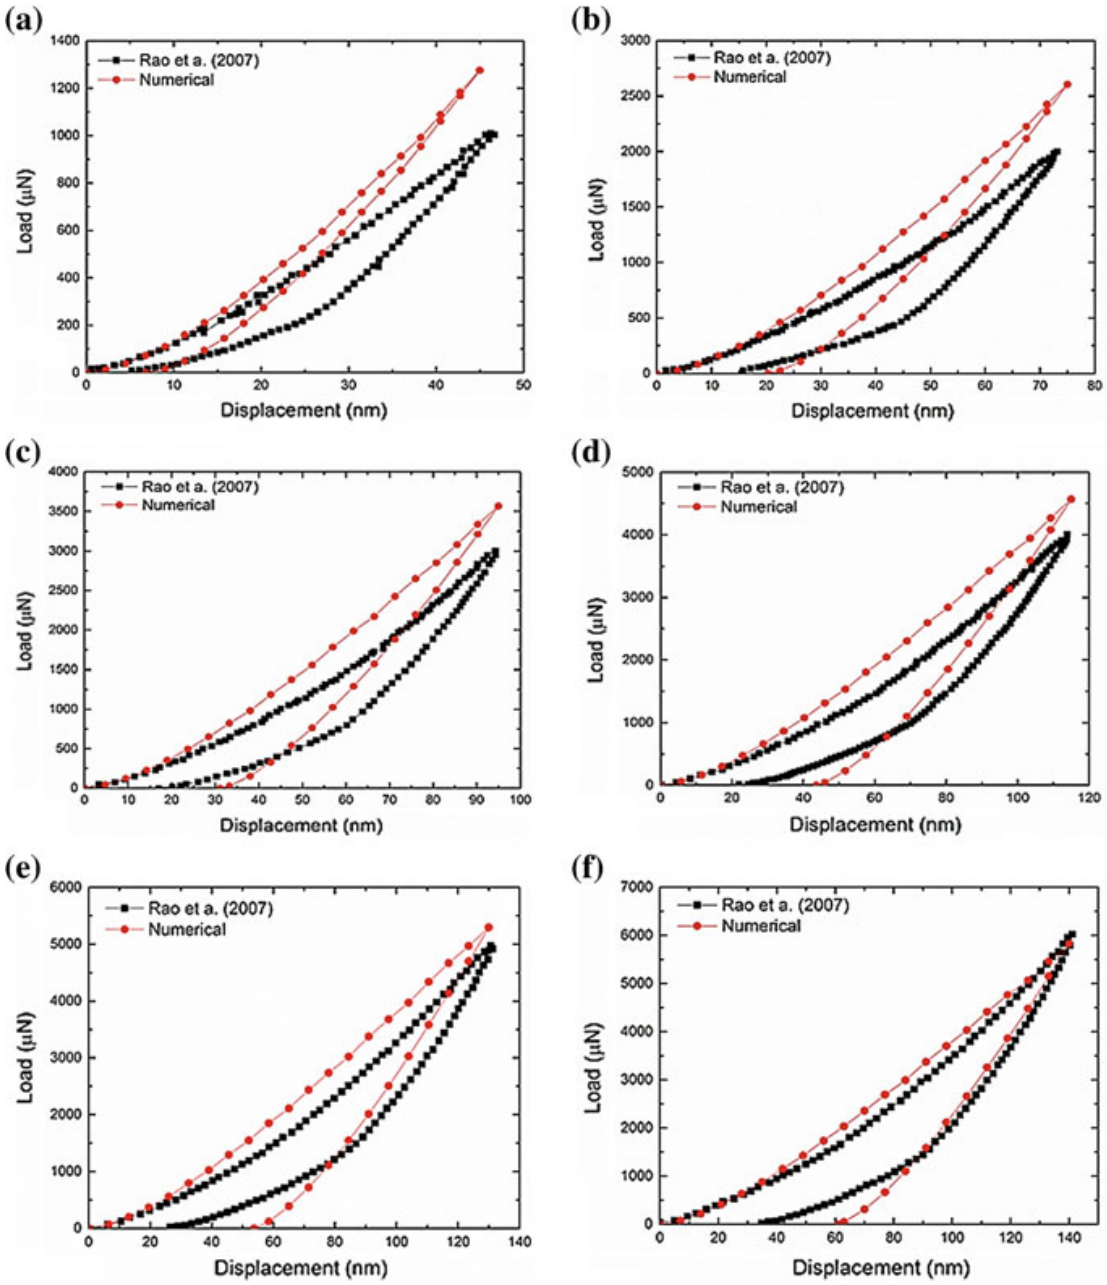

Fig. 72.7 Experimental [11] versus numerical comparison of P-h graph

and 72.4.2, Young's modulus and hardness values were calculated and shown in Table 72.3.

Table 72.3 also depicts the comparison of experimental results with numerical results, such as peak loads, projected area, calculated Young's modulus, and hardness values obtained for various levels of indentation depths. From the table, it is observed that peak load for simulations are higher than the experimental peak load. However, the projected area, Young's modulus, and hardness are found to be similar with minimal prediction error. The simulations are found to be predicting well with an overall prediction error of 10.9%. The projected area is found to be

Table 72.3 Comparison of Young's modulus and hardness at different indentation depth

Peak displacement	Peak load (μN)			Projected area (nm^2)			Young's modulus (GPa)			Hardness (GPa)		
	Experiment	Simulation	Prediction error (%)	Experiment	Simulation	Prediction error (%)	Experiment	Simulation	Prediction error (%)	Experiment	Simulation	Prediction error (%)
45 nm	1004.2	1275.2	27	81,157.7	78,492.9	−3	139	153	10	12	16	31
75 nm	2000.4	2604.4	30	121,056.3	123,750.0	2	176	167	−5	17	21	27
95 nm	3000.0	3566.8	19	149,824.4	150,778.6	1	196	176	−10	20	24	18
115 nm	4001.7	4568.5	14	173,974.9	175,292.9	1	193	185	−4	23	26	13
130 nm	4975.3	5296.1	6.4	192,637.2	192,028.6	−0	211	191	−9	26	28	7
140 nm	6026.0	5826.6	−3	203,447.6	202,400.0	−1	243	196	−19	30	29	−3
Average prediction error			16.6			1.3			9.2			16.5

similar to the experimental value with 1.3% prediction error. The average prediction error of Young's modulus and hardness were found to be 9.2 and 16.5%, respectively with the modified method.

From Fig. 72.6 and Table 72.3, it is observed that the calculated Young's modulus, hardness, and projected area obtained from the experiment and numerically simulated load–displacement graph are in good agreement. Furthermore, it is to be noted that the established values of Young's modulus and hardness values for silicon are 190 GPa and 12 GPa, respectively [14]. The slight variations in the results between the experiments and numerical simulations may be due to the consideration of rigid spherical indenter, isotropic and homogeneous material properties in the numerical model. Moreover, the presence of residual stresses strongly affects Young's modulus and hardness which may cause both to decrease [15–17]. Because, in the nanoindentation experiment, samples are prepared by mechanical means (such as machining), due to which residual stresses are left over the workpiece surface. Also, during the mechanical processing, brittle material undergoes amorphization, which generally has less Young's modulus and hardness as compared to pristine sample [18]. Further, Young's modulus calculation is largely dependent on an empirical factor presented by the Oliver–Pharr. However, despite all these limitations, the FEA fairly estimates the Young's modulus and hardness without conducting physical experiments, which saves a considerable time and cost.

72.6 Conclusions

In the present work, FEA-based simulations of displacement controlled quasi-static nanoindentation were performed on a silicon specimen using a spherical (300 nm tip radius) indenter. The simulations were primarily carried out as a testbed study to evaluate the mechanical properties, viz. Young's modulus and hardness of silicon. The computed values were found in good agreement with the experimental results. Calculated Young's modulus and hardness from the load–displacement plots were 153–196 GPa and 16–29 GPa, while the experimental values were noted to be 139–243 GPa and 12–30 GPa, respectively. The difference between the numerical and published experimental results may be due to (a) residual stresses (tensile or compressive) present in the experimental specimen, (b) experimental process may not follow the continuum assumption due to the presence of voids and dislocations, and (c) diamond indenter may not be that stiff as it is considered in the numerical model. Overall, it is found that finite element simulation provides an economical and quicker alternative to the costly and time-consuming physical experiments in obtaining the mechanical properties of the materials.

Chapter 73
Effect of Microchannel Pattern on Fluid Flow and Heat Transfer Characteristics

Dungali Sreehari and Apurbba Kumar Sharma

Abstract Three different patterns (rectangular-serpentine, U-serpentine and V-serpentine) of microchannels were modelled to investigate the fluid flow and heat transfer characteristics using the commercially available finite element analysis software—CFD Fluent. The microchannel models were based on 0.525-mm-thick silicon wafer substrate. The hydraulic diameter (0.4 mm) and channel length (114 mm) were kept constant in all the three different patterned microchannels to compare the performance of the microchannels. Three-dimensional (3D) simulations were performed to simulate near practical condition using the conjugate method in which heat transfer was considered in both solid and fluid zones. Reynolds number was varied in the range of 100–400, and uniform heat flux (30 kW/m^2) was applied at the bottom wall of the microchannels to investigate the effect of microchannel pattern on pressure drop, temperature, velocity profile and heat transfer coefficients. Results confirm that the higher heat transfer coefficient was obtained in U-serpentine microchannel, indicating better performance among the three.

Keywords Microchannel · Channel pattern · Heat transfer · Simulation

73.1 Introduction

With increasing the importance of microchannels in various fields of applications, especially in the electronics industry for cooling of microelectronic components, the research on the design, fabrication and performance evaluation of microchannels has increased. Due to the dense packing of the several microelectronic components in an electronic device, heat dissipation is a major concern. The microchannel is one

of the best solutions to bring down these rising temperatures. Large surface-area-to-volume ratio and low weight and volume attribute the microchannel as an effective heat sink. The concept of the microchannel was introduced by Tuckerman and Pease [1] in the early 1980s. They fabricated microchannels on silicon by an orientation-dependent etching technique and concluded a maximum heat carried out was about 790 W/cm^2 from 1 cm^2 area. After their pioneering study, research on the microchannels application was performed by several researchers across the globe. Peiyi and Little [2] fabricated very fine microchannels on a silicon wafer by the photolithography technique and revealed that the width, depth and surface roughness of the microchannel affect the values of friction factor in the application of microminiature refrigerator. Weisberg et al. [3] numerically analysed the silicon microchannels using conjugate heat transfer method and presented some design formulations for the selection of channel dimensions. Experimental and numerical investigations were carried out by Qu et al. [4] on trapezoidal cross-sectional silicon microchannels. They predicted surface roughness of the microchannel could be the reason to obtain a significant difference between the experimental and numerically determined Nusselt number. Heat transfer characteristics such as temperature, Nusselt number and effect of Reynolds number were numerically analysed in three-dimensional (3D) rectangular silicon microchannels by Qu and Mudawar [5] using conjugate heat transfer method. Lee et al. [6] investigated rectangular microchannels of hydraulic diameter ranging from 318 to 903 μm by experimental and numerical analysis considering both thin wall model and 3D conjugate method. To investigate the geometrical effect of the microchannels on flow and heat transfer characteristics, Gunnasegaran et al. [7] numerically analysed three different cross sections (rectangular, trapezoidal and triangular) and concluded that rectangular cross-sectional microchannels have better heat transfer coefficients.

In general, the microchannel heat sinks are straight channels in which the streamlines of the coolant are nearly straight. Due to poor mixing of fluid in the straight microchannels, the heat transfer is ineffective. Therefore, an alternative wavy microchannel was proposed by Sui et al. [8]. They numerically investigated the performance of straight and wavy microchannels with the same rectangular cross sections using CFD simulations. From their results, it was observed that the performance of wavy microchannel is better than the straight microchannels. Lin et al. [9] further investigated the performance of wavy microchannels varying the wavelength and amplitude of the microchannels in the flow direction. Flow and heat transfer analysis was done in serpentine channels by Karale et al. [10]. They have compared the performance of general serpentine, sinusoidal serpentine and sawtooth serpentine microchannels. Different channel configurations such as nonlinear, wavy, spiral, pin-finned and fractal-shaped were explored to enhance the heat transfer rate [11–14] further.

Although several serpentine microchannels were analysed in previous work, still it is not well understood which serpentine is more appropriate for high heat transfer

with moderate pressure drop. Therefore, in the present work, three different patterns (rectangular-serpentine, U-serpentine and V-serpentine) of microchannels were modelled and analysed to compare the fluid flow and heat transfer characteristics.

73.2 Geometric Models of Microchannels

Silicon wafer (0.525-mm-thick) was selected as substrate material as it is commonly used to fabricate IC chips in the electronic devices. The schematic of three serpentine microchannels is shown in Fig. 73.1. The selection of dimension was based on the fabrication and substrate thickness constraints. Microchannels with a constant length of 114 mm were fabricated by micro-ultrasonic machining technique on the silicon wafer to a depth of 0.3 mm using 0.6-mm-diameter cylindrical tungsten carbide tool [15]. Hence, the same dimensions ($L \times W \times H$: 114 mm 0.3 mm × 0.6 mm) were used to model and analyse the fluid flow and heat transfer characteristics in all the three serpentine microchannels. However, it was observed, to maintain the constant length of the microchannel in all three different serpentines, the base areas of the microchannels vary significantly. The base areas of the rectangular-serpentine, U-serpentine and V-serpentine microchannels are 336, 244.5 and 384 mm^2, respectively. Therefore, a new dimensionless parameter

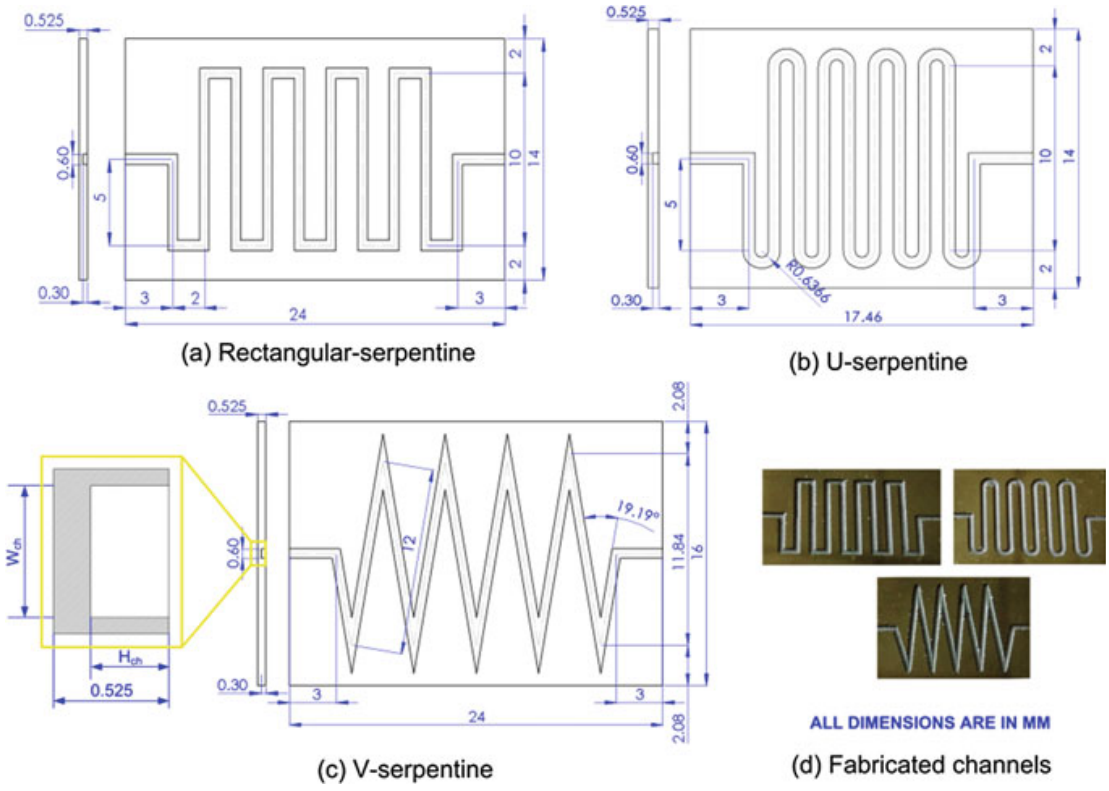

Fig. 73.1 Schematics of **a** rectangular-serpentine, **b** U-serpentine and **c** V-serpentine microchannels and **d** image of fabricated microchannels

Table 73.1 Sink area factors of microchannels

Pattern of microchannel	Total channel wall area (mm^2)	Base area (mm^2)	Sink area factor (%)
Rectangular-serpentine	136.8	336	40.71
U-serpentine	136.8	244.5	55.95
V-serpentine	136.8	384	35.63

—sink area factor (SAF) defined as the ratio of the total channel wall area to the total base area (Eq. 73.1)—was introduced to compare the performance of different serpentine microchannels with constant channel length and different base areas.

$$\text{Sink Area Factor (SAF)}(\%) = \frac{\text{Total channel wall area}}{\text{Base area}} \times 100\% \tag{73.1}$$

Table 73.1 gives the calculated values of sink area factors (SAFs) of the serpentine microchannels. The total channel wall area is the actual convective area responsible for heat transfer, i.e. the bottom wall area ($0.6 \times 114 = 68.4$ mm^2) and the two side wall areas ($2 \times 0.3 \times 114 = 68.4$ mm^2) of the microchannel.

73.3 Numerical Study

The fluid flow in the modelled microchannels was based on the continuity, momentum and energy equations. The flow was assumed to be steady, laminar and incompressible. Uniform heat flux (30 kW/m^2) was applied at the bottom wall of the microchannels. The inlet velocity of the fluid was based on the Reynolds number which was varied in the range of 100–400.

73.3.1 Boundary Conditions

The boundary conditions used in the simulation are as follows:

(i) Inlet fluid temperature was constant ($T_{in} = 300$ K).
(ii) A constant heat flux (30 kW/m^2) was given to the bottom wall, keeping the top and side walls as adiabatic.
(iii) Inlet velocity (V_{in}) was calculated using Eq. (73.2)

$$V_{in} = \frac{Re\mu}{\rho_f D_h} \tag{73.2}$$

$$D_h = \frac{4A}{P} = \frac{2W_{ch}H_{ch}}{W_{ch} + H_{ch}} \tag{73.3}$$

where Re—Reynolds number, μ—viscosity (Kg/m s), ρ_f—density of the fluid (kg/m^3), D_h—hydraulic diameter (μm), W_{ch} and H_{ch} are the width (μm) and depth (μm) of the microchannel.

(iv) Outlet pressure (P_{out}) was assigned a zero gauge pressure.

73.3.2 Grid Independence Test

The grid independence of the solution for rectangular serpentine was performed by considering the computational cells 2849658, 3289705 and 3951850. A variation of 1–2% was observed in the results of temperature and pressure using the computational cells of 3289705 and 3951850; while comparing the results obtained by the computational cells 2849658 and 3289705, a variation of 5–6% was observed. Therefore, 3951850 cells were considered for computation purpose in the numerical simulation study of rectangular-serpentine microchannels. Similar grid independence tests were performed for U-serpentine and V-serpentine microchannels. After obtaining the nearly identical solutions using the different number of cells, 5879476 and 6522096 cells were considered for computation purpose for U-serpentine and V-serpentine microchannels, respectively. It took nearly 60, 75 and 105 min to converge the solution in the rectangular-, U- and V-serpentine microchannels, respectively.

73.3.3 Model Validation

The model was validated with the work of Qu and Mudawar [5] to obtain the accurate results from the present numerical analysis. The boundary conditions, material—silicon substrate and fluid medium (liquid water) were considered to reproduce the results of Qu and Mudawar [5]. In order to compare the result, one of the operating conditions, i.e. wall heat flux of q = 50 W/cm^2 and Re = 140, was simulated. Figure 73.2a, b shows the comparative result of temperature distribution across a vertical plane at the middle of the substrate. It was observed that the present model showed similar results as of Qu and Mudawar [5].

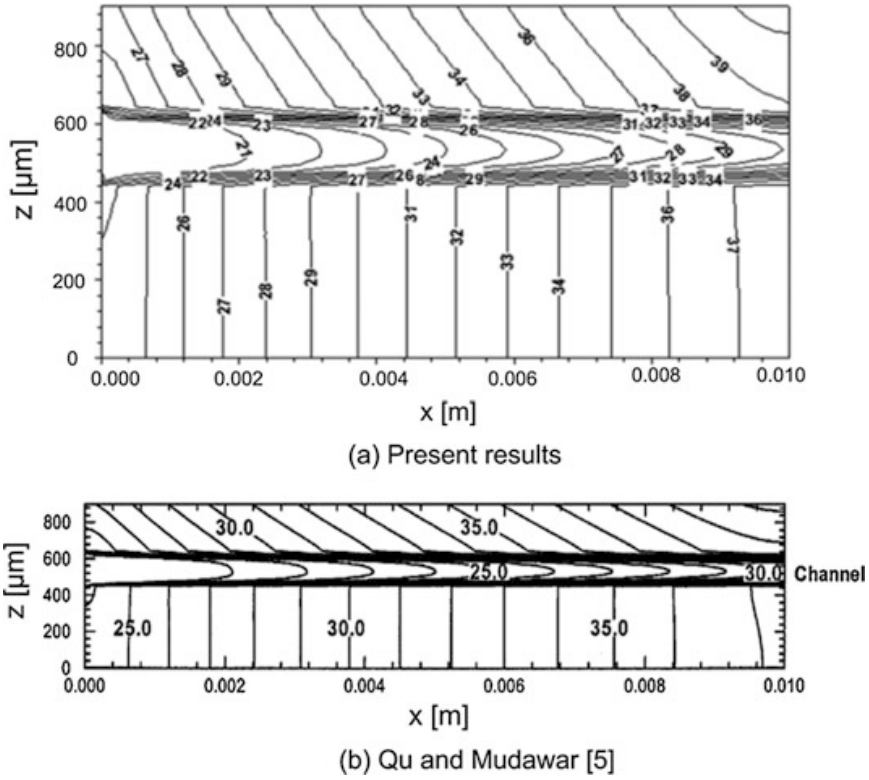

Fig. 73.2 Validation of the present model with Qu and Mudawar [5] results

73.4 Results and Discussion

The numerical simulations were carried out on the three patterns of microchannels considering a constant heat flux (30 kW/m^2) at the bottom wall and varying the Reynolds number from 100 to 400 in steps of 100. In the present section, comparative results in terms of pressure drop, temperature, velocity and heat transfer coefficient are presented.

73.4.1 Pressure Drop

Fig. 73.3 shows the variation of pressure drop (the difference between outlet pressure and inlet pressure) in different serpentine microchannels at different Reynolds numbers (*Re*). It was observed that the pressure drop increases with increase in the Reynolds number, irrespective of the serpentine. The reason is that as the Reynolds number increases, the velocity of the fluid flow increases which in turn increases the pressure drop as it is directly proportional to the square of the velocity. The results are in good agreement with the previous work of Gunnasegaran el al. [7]. Further, it was also observed that pressure drop in all the three serpentines is near similar at *Re*—100 and 200; highest in U—serpentine

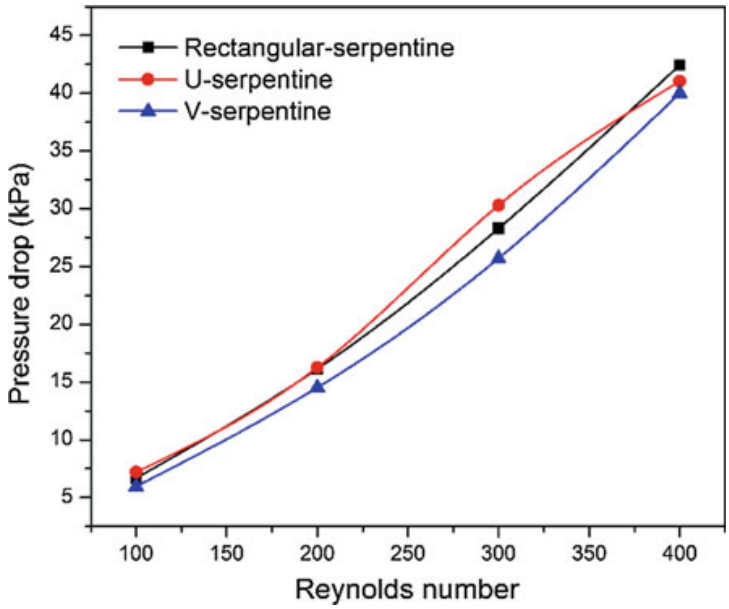

Fig. 73.3 Pressure drop variation with Reynolds number in different pattern microchannels

microchannels at *Re*—300 was observed compared to the other two serpentines. However, at higher Reynolds number (400), the pressure drop variation was marginal.

73.4.2 Temperature

The inlet temperature of the fluid was taken as one of the boundary conditions and was kept constant at 300 K in every simulation of the serpentines. The temperature at the outlet of the fluid was estimated from the simulation results. A difference of the inlet and outlet fluid was calculated in all the serpentine microchannels at different Reynolds numbers. A plot was drawn for the fluid temperature differences at different Reynolds numbers in rectangular-serpentine, U-serpentine and V-serpentine as shown in Fig. 73.4. It was observed that the fluid temperature difference decreases with increasing the Reynolds number, indicating that as the Reynolds number increases, the amount of heat carried away by the fluid was more. However, at higher Reynolds number (beyond *Re*—300), the rate of temperature difference was less. From Fig. 73.4, it was observed the V-serpentine microchannels have a larger fluid temperature difference compared to the remaining microchannels. The reason could be that due to the larger base area of V-serpentine, the amount of heat input was more and hence results in more outlet fluid temperature. Figure 73.5 indicates the contours of the temperature difference in the microchannel and substrate material.

The average base temperature of the substrate was considered from the simulation results, in order to investigate further. The same was plotted against the Reynolds number in Fig. 73.6. It was observed that the base temperature decreases with increase in the Reynolds number. The reason is that due to higher velocities at

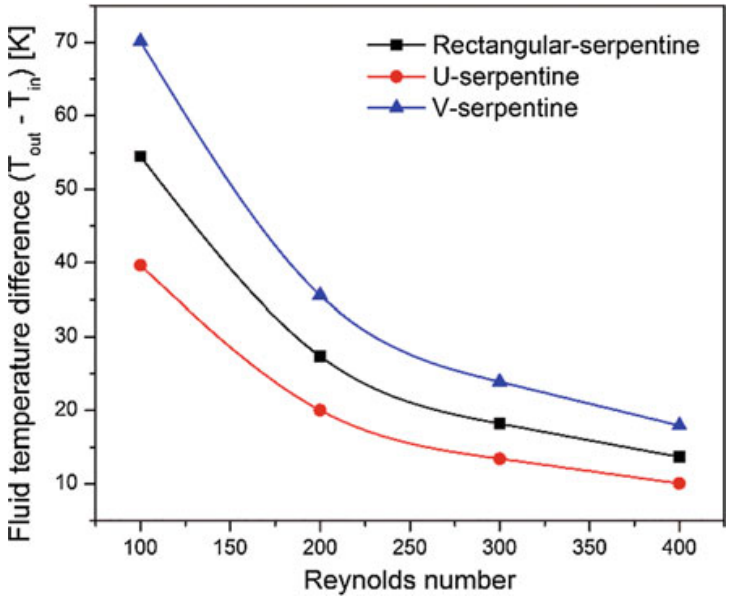

Fig. 73.4 Fluid temperature difference versus Reynolds number

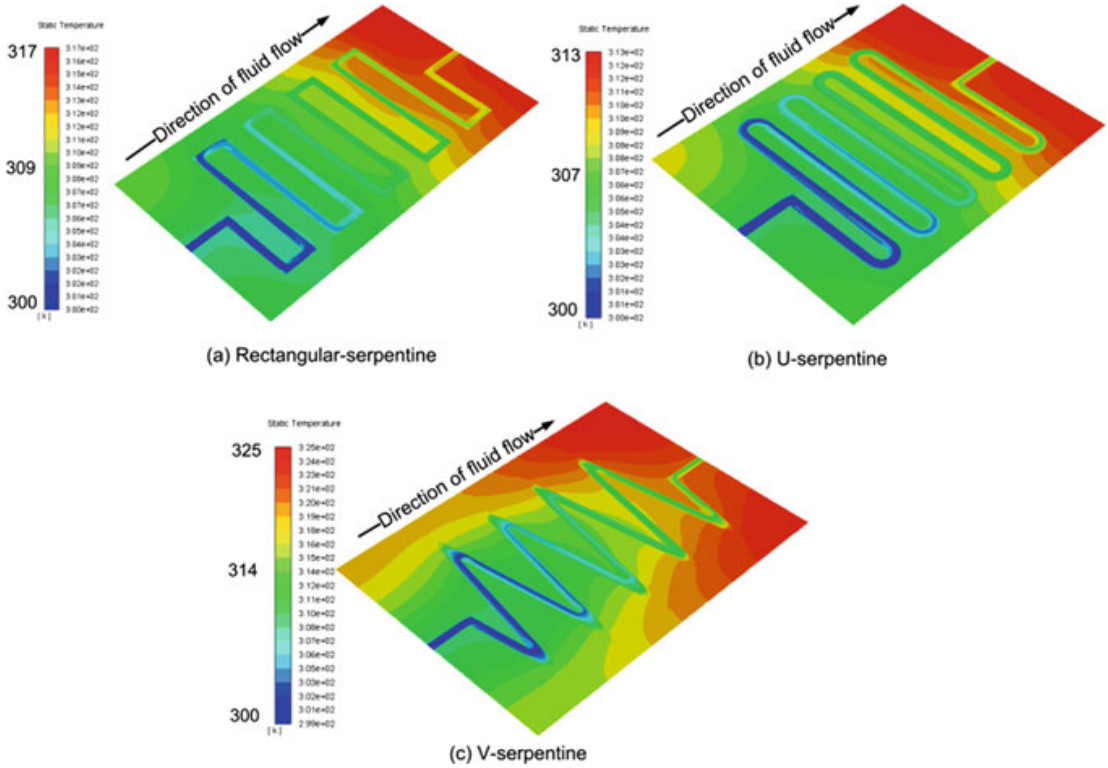

Fig. 73.5 Contours of temperature distribution

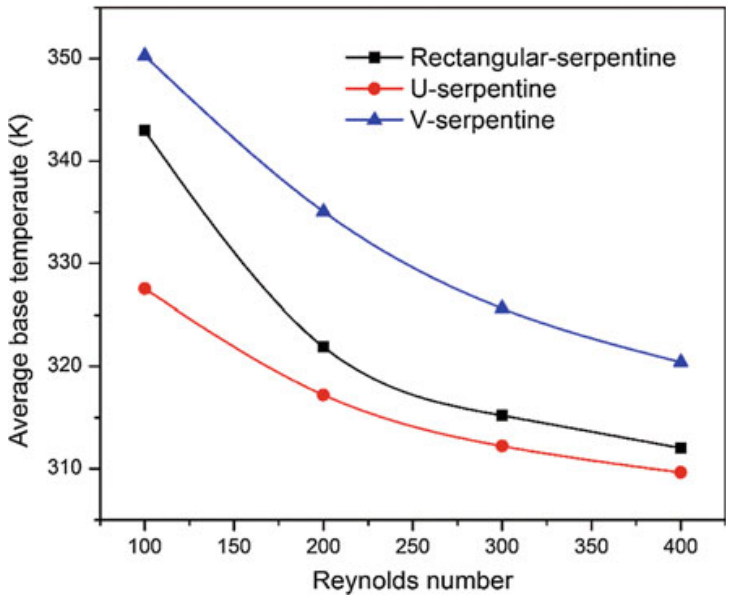

Fig. 73.6 Variation of the base temperature of the substrate with Reynolds number in different serpentine microchannels

higher Reynolds numbers, mixing of fluid was more to carry out more amount of heat from the substrate. However, at any particular Reynolds number, the base temperature of the V-serpentine microchannel was more. This attributes that the cooling effect on the V-serpentine was less compared to the other two serpentine channels. The reason could be that due to the presence of sharp corners in the V-serpentine, the possibility of fluid stagnation was more which results in higher base temperatures.

73.4.3 Velocity Profile

Figure 73.7 indicates the velocity profiles of all the three serpentine microchannel bends. From Fig. 73.7, it is clearly visible that the more amount of fluid was stagnated at the sharp corners of the V-serpentine followed by rectangular and least

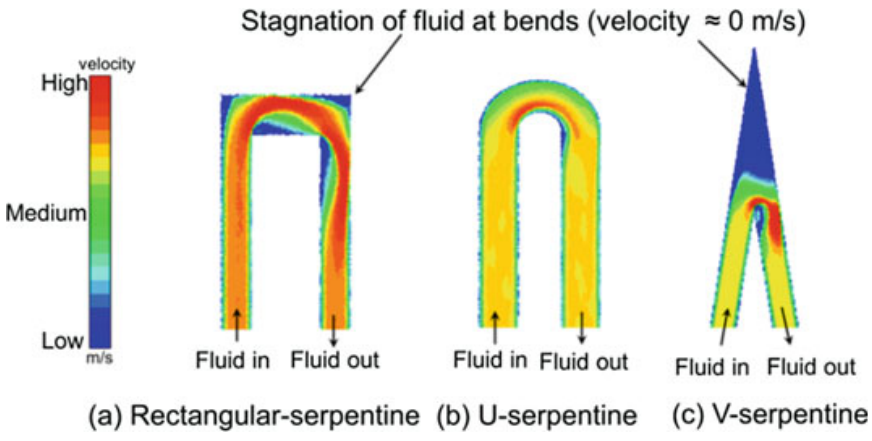

Fig. 73.7 Velocity profiles at bends of serpentine microchannels

in the U-serpentine microchannel. Therefore, the contribution of the fluid in these regions in heat transfer was very low. As the stagnant fluid region was high in V-serpentine, this leads to higher base temperatures. However, the stagnation region of fluid in U-serpentine was very less and hence lowers substrate base temperature (Fig. 73.6).

73.4.4 Heat Transfer Coefficient

The heat transfer coefficient of the fluid passing through the microchannels was calculated using Eq. (73.4).

$$h = \frac{q}{(T_{aw} - T_{af})} \tag{73.4}$$

where

T_{aw} Average bottom wall (base) temperature, K
T_{af} Average fluid temperature = $(T_{in} + T_{out})/2$, K.

In the calculation of heat transfer coefficient, both the substrate bottom wall (base) temperature and average fluid temperature were considered. Therefore, this parameter was used to compare the performance of the serpentine microchannels. Figure 73.8 shows the heat transfer coefficient of different serpentine microchannels at different Reynolds numbers. At higher Reynolds number, the velocity of the fluid is more which results in increased heat transfer coefficients as it maintains a

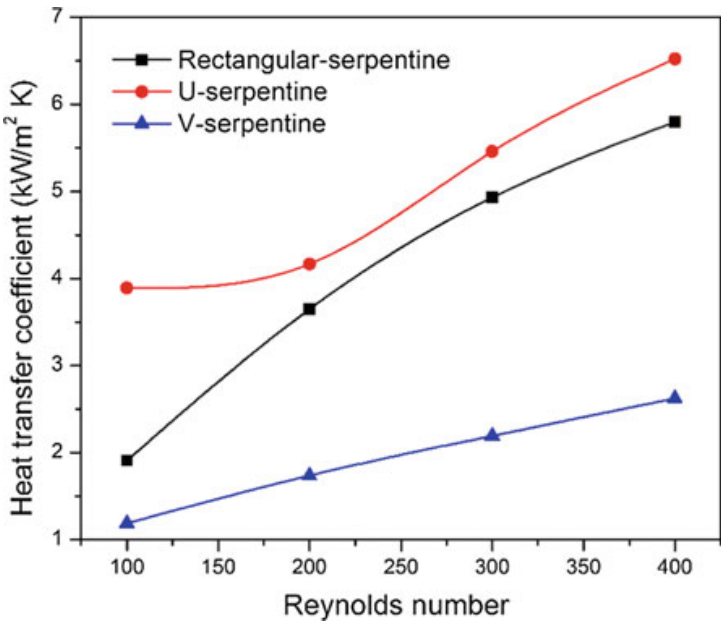

Fig. 73.8 Heat transfer coefficient variation with Reynolds number in different serpentine microchannels

high-temperature difference per unit time. At every *Re,* the value of heat transfer coefficient is more in U-serpentine microchannel, indicating better performing serpentine microchannel.

73.5 Conclusions

The characteristics of fluid flow and heat transfer such as pressure drop, temperature of fluid and substrate, velocity profile and heat transfer coefficient in three different serpentine microchannels at different Reynolds numbers were investigated numerically, and the results were discussed. The major conclusions drawn are as follows:

(a) Pressure drop was nearly similar in every microchannel. At *Re*—300, U-serpentine microchannel exhibits higher pressure drop compared to the remaining two microchannels.
(b) V-serpentine microchannel has the highest values of fluid temperature difference and average substrate temperatures.
(c) A larger amount of stagnation of fluid (velocity $\approx$ 0 m/s) was observed at the sharp bends of V-serpentine microchannels from the velocity profiles. However, smooth passage of the fluid was observed in U-serpentine microchannels.
(d) Among the three serpentine microchannels, the overall heat transfer coefficient in the U-serpentine microchannel has shown better performance compared to the other two.

Chapter 74
Comparative Analysis of GPU-Based Solver Libraries for a Sparse Linear System of Equations

Utpal Kiran, Subhajit Sanfui, Shashi Kant Ratnakar, Sachin Singh Gautam and Deepak Sharma

Abstract In this paper, a comparison of GPU-based linear solver libraries for the solution of sparse positive-definite matrices is presented. These large sparse matrices arise in a number of computational disciplines seeking a solution for partial differential equations. The solution of these matrices is often a time-consuming process that can be reduced by parallel computing. Since the development of GPU for general-purpose computing, a number of numerical solver libraries have evolved that can accelerate the solution procedure. The performance of three solver libraries has been evaluated in this paper for five different test matrices. These test matrices have been taken from different application domains with different sparsity patterns. Results demonstrate a higher speedup from the iterative solver over the direct solver on GPU and also over a multithreaded CPU implementation.

74.1 Introduction

Most of the physical phenomena are governed by partial differential equations (PDEs). In various problems of engineering and science, it is not always possible to analytically solve the governing PDE to get the required solution. Most of the time simplifying approximations are made to reduce the PDE to a set of algebraic equations, using numerical methods [1].

Numerical simulations of manufacturing processes also use these numerical approximation techniques. Finite element analysis (FEA) is one of the most popular and widely used numerical methods. FEA facilitates construction, refinement, and optimization of a mechanical component before the start of manufacturing. This substantially reduces the cost and effort involved in production. The advantage of numerical simulation such as FEA is that it makes virtual testing possible in the early stages of production. Furthermore, the widespread availability of modern FEA software makes it very convenient to analyze the performance of the product and make the necessary improvements in the design.

The FEA formulation of the problem gives a system of algebraic equations. Solving this system of equations provides approximate values of the primary unknown, at a number of discrete points over the problem domain [2]. The resulting system of equations from FEA can be very conveniently represented in the form of matrices. Since FEA subdivides a large problem into smaller parts, due to local correlation in PDE discretization, the final matrix is sparse in nature [3].

There are two methods to solve the system of equations, the direct method and iterative method [1]. Direct methods are the procedures based on algebraic elimination. Gauss elimination and LU factorization are some of the most known algorithms in this category. Iterative methods start by assuming a trial solution or initial guess which is substituted in the system of equations, and then the difference between the obtained solution and the actual solution is determined, also known as an error or residual. Using the information from error value, the initial guess is improved iteration by iteration, so that it reaches closer to the actual solution. The conjugate gradient (CG) method is one of the most widely used iterative solvers [4].

In all practical FEA problems usually, the number of variables involved is very large, thus making the size of the sparse matrix huge. Solving a system of equations consisting of millions of variables becomes a very time-consuming exercise. In various studies, it has been observed that the solver may take anything between 70 and 90% of the total computation effort required (depending upon the problem size) [5]. Due to the facts discussed earlier, sparse matrix solver is an active research area.

74.1.1 Parallel Computing

One of the remedies to overcome a higher computational time of the solver is to use parallel computing, where a large problem is subdivided into small tasks and

executed by multiple computing units (processors) simultaneously, with or without communicating with each other [6].

There are different types of parallel computing architecture. The choice of architecture is subjected to many factors, such as the requirement of the problem, availability of hardware, and cost. One of the most popular architectures is the distributed memory architecture, where each processor has its own memory system at its disposal, which it can use directly. Another is the shared memory architecture, where each processor has access to a centralized memory system from which they have to share. Usage of memory by each processor depends on its current requirement. These two architectures are generally referred to as traditional architectures.

A distributed memory architecture setup generally consists of a large number of CPU cores. This results in high setup and maintenance cost, making it somewhat impractical for common use. Shared memory architecture does not need any separate communication channel. All the CPU cores in shared memory architecture access a common global memory. Here, the changes made in memory by one processor are visible to all other processors. This may lead to inaccurate memory operation when more than one processor is trying to access the same memory location. This issue is commonly known as race condition [7].

In the literature, the parallelization of solver has been performed using traditional computing such as the shared memory architecture [5, 8, 9] and also distributed memory architecture [10–13]. Considering the inconvenience posed by the traditional architectures, in recent years, the novel architecture of graphics processing unit (GPU) has gained popularity among the researchers. After the launch of general-purpose GPU (GPGPU) by NVIDIA in 2007, the GPUs can be used for general-purpose computing. GPU is advantageous in the sense that they are relatively cheaper, maintenance-free, and portable. They can be used for parallel computing using the programming interface like Compute Unified Device Architecture (CUDA) [14] or OpenCL [15].

GPU has a highly parallel, multithreaded, many-core processor architecture, which is well suited for problems that can be expressed as data-parallel computations with high arithmetic intensity. Hence, GPU can be a viable choice for a sparse matrix solver. It has been used for the parallelization of solver in a few research works [16–19]. Moreover, some libraries compatible with GPU are also developed for a sparse matrix solver. However, these libraries have not been compared on a common platform on the problems of different domains. Therefore, the main contributions of this paper are (i) to compare the popular linear sparse solver libraries that are developed for GPU, with respect to the multithreaded CPU implementation, and (ii) to analyze the performance of the popular libraries by solving some sparse matrices evolved from different applications that have different matrix sizes, sparsity pattern, and nonzero entries.

The paper is organized into four sections. Section 74.2 presents the existing sparse matrix solver libraries developed for GPUs. In Sect. 74.3, the matrices evolved from different problems are discussed and the libraries are used to find the solution for a system of the linear system. The computation time is reported, and the speedup is shown. Section 74.4 concludes the paper.

74.2 Sparse Matrix Solver Libraries

Given the importance of the large sparse linear equation system solver, there are several libraries available in the literature, which takes the sparse matrix as an input and provides the solution as an output. The majority of works in the literature focus on CPU implementation, while a few of them have been developed to work on GPU hardware so that the solution can be obtained in a lesser amount of time. Many of these solver libraries can work with a user-defined matrix-vector product, which is the basic operation of any iterative solver.

Solver libraries provide highly optimized functions that perform many times faster than CPU-only solvers. They can be very useful for compute-intensive applications such as structural optimization, computational mechanics, heat flow problems, earthquake simulations to name a few. In the following subsections, a few of GPU sparse linear equation system solver libraries are discussed.

74.2.1 CUSP

CUSP is an open-source library written in C++ for sparse linear algebra on GPUs with CUDA architecture. It provides a flexible programming interface for operating on sparse matrices and solving sparse linear systems. CUSP uses iterative methods and also includes multiple pre-conditioners. This library supports many popular sparse storage formats such as COO, CSR, DIA, ELL, and HYB. The library is developed by NVIDIA [20].

74.2.2 cuSolver

Also developed by NVIDIA, the cuSolver library provides a collection of direct solvers for both dense and sparse matrices. This library comes in-built with the CUDA toolkit. For dense matrices, it has common matrix factorization and

triangular solve routines, and for sparse matrices, a least square solver is used. This library also comes with an eigenvalue solver. It can be called from a C/C++ routine [21].

74.2.3 SuiteSparse

SuiteSparse is an open-source library, which has a Cholesky factorization accelerated by CUDA. It has a collection of a number of very popular sparse matrix packages such as UMFPACK, CHOLMOD, and SPQR [22].

74.2.4 PETSc

Portable, Extensible Toolkit for Scientific Computation (PETSc) is an open-source suite of data structures and routines for the parallel scalable solution of applications which are modeled by PDEs [23]. It has the capability of solving both linear and nonlinear systems of equations. It is available in C/C++ and Python. It uses MPI for message passing and supports GPU through CUDA or OpenCL. PETSc is the world's most widely used parallel numerical software library for partial differential equations and sparse matrix computations.

74.2.5 MAGMA

MAGMA is a collection of GPU-accelerated dense linear algebra libraries. It has been specifically developed to work with heterogeneous computing environment such as multicore CPUs and multi-GPUs [24].

74.3 Results and Discussion

In the present work, three libraries have been selected for solving the matrices using the direct and iterative methods on the GPU. The speedups of the GPU-based solvers are obtained with respect to a multithreaded implementation of Cholesky decomposition (CHOLMOD) provided by SuiteSparse library. The details of the three test libraries are provided in Table 74.1. The test matrices have been chosen

Table 74.1 Methods to solve a linear system of equations

	Library	Solution method	Architecture
Method 1	CUSP	Conjugate gradient (CG)	GPU
Method 2	cuSolver	Cholesky decomposition	GPU
Method 3	SuiteSparse	Cholesky decomposition	GPU
Ref. code	SuiteSparse	Cholesky decomposition	CPU multithreaded

from different applications of FEM and solved using libraries mentioned in Table 74.1. Five matrices with a different range of order and number of nonzeros have been selected from the Suitesparse matrix collection [3] for benchmarking. The details of these matrices are presented in Table 74.2. All the five test matrices are sparse and positive definite. The sparsity pattern of all test matrices is shown in Fig. 74.1. As can be seen from the figure, the sparsity pattern as well as the density of nonzeros can greatly vary for different applications. Since the focus of this paper is to analyze the performance of different solver libraries on matrices having different sparsity patterns, the problem formulation or mathematical modeling for the applications shown in Fig. 74.1 is not presented. However, the details of these applications can be found in [3], which is not included due to brevity. In the present work, the performance of solver libraries on matrices with significantly varying sparsity pattern is evaluated.

The hardware for the numerical experiment consists of Intel Xeon E5-2650 processor and NVIDIA Tesla K40 GPU. The CPU processor has 128 GB of memory and 12 physical cores clocked at 2.2 GHz. The GPU has 12 GB of memory, and the cores are clocked at 745 MHz.

The execution time for the matrices for different libraries is listed in Table 74.3. Execution time refers to elapsed GPU time for all three methods and CPU time for the reference code. The last column of Table 74.3 lists the time required by the reference multithreaded version. The speedups of the three solvers are computed with reference to this version and plotted in Fig. 74.2, using a semi-logarithmic scale. From the figure, it can be clearly seen that among all the libraries, the CG method in CUSP library takes the least amount of time for solving all the matrices. It can also be observed from the figure that the speedup for 'parabolic_fem' and 'thermal2' is significantly more pronounced than the other matrices. This can be

Table 74.2 Details of test matrices

Matrix	Application	Rows/columns	Nonzeros
thermal1	Steady-state thermal problem	82,654	574,458
thermal2	Steady-state thermal problem	1,228,045	8,580,313
nd6k	ND problem set	18,000	6,897,316
parabolic_fem	Diffusion–convection reaction	525,825	3,674,625
consph	FEM concentric spheres	83,334	6,010,480

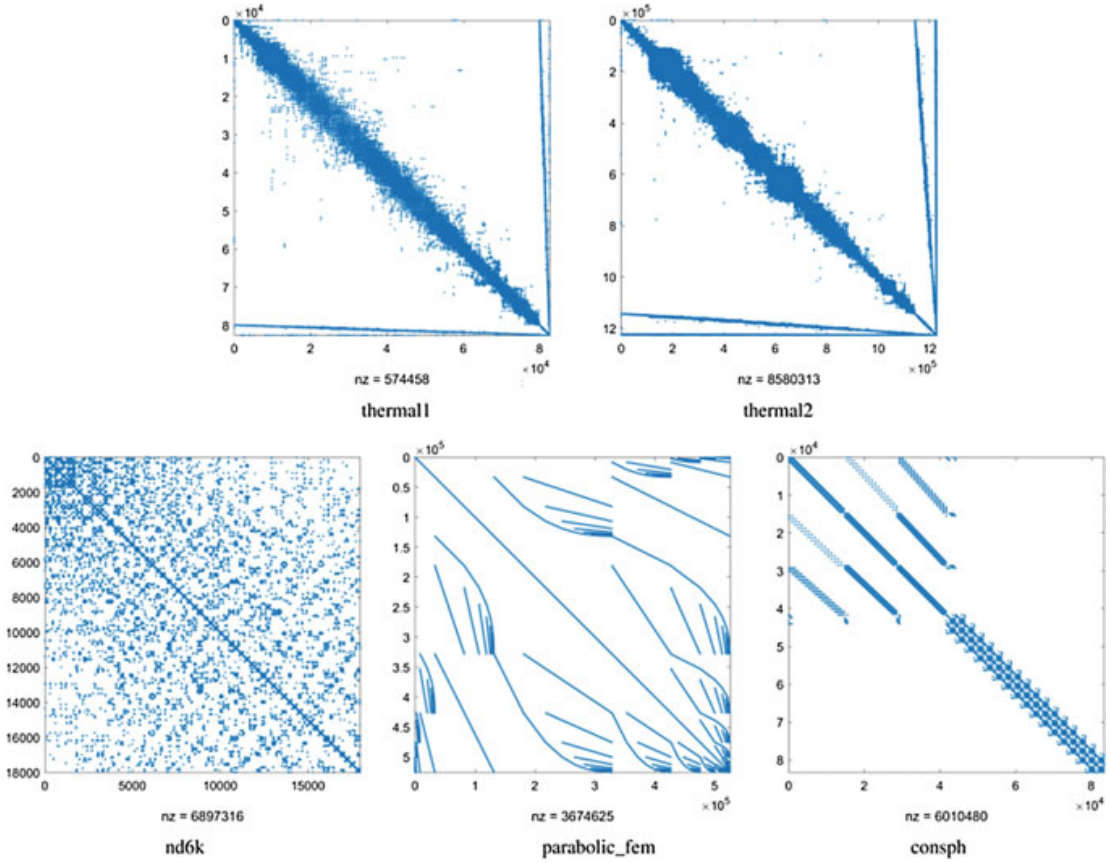

Fig. 74.1 Sparsity pattern of test matrices is represented by dots

Table 74.3 Execution time (in seconds)

Matrix	Method 1	Method 2	Method 3	Ref. code
thermal1	1.92	46.32	17.94	14.22
thermal2	18.11	–	195.92	262.74
nd6k	17.58	69.09	23.85	19.95
parabolic_fem	3.23	–	114.25	158.46
consph	27.84	–	153.85	177.08

attributed to the higher dimension of the said matrices. In the case of SuiteSparse library, the GPU implementation of CHOLMOD is seen to outperform the reference multithreaded CPU implementation for all matrices except 'thermal1' and 'nd6k'. This is due to the small size of the two matrices. It can be further concluded from the figures that the execution times of all the libraries are more dependent on the dimension of the matrix than the number of nonzeros in the matrices. For example, 'nd6k', despite having a high number of nonzeros as compared to the other matrices, suffers from a poor performance in all the methods as seen in Fig. 74.2.

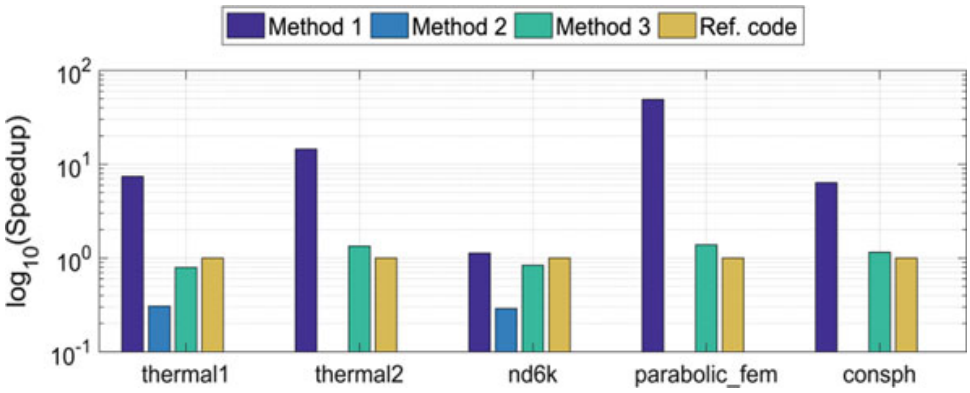

Fig. 74.2 Speedup of GPU solver libraries with respect to multithreaded ref. code

74.4 Conclusion

This paper presents a study of a solution of a sparse system of linear equations using a GPU. The performance of solver libraries, which use a GPU to accelerate the computation, is evaluated over a range of matrices. Five test matrices of varying sparsity pattern as well as a different number of nonzeros and dimension are taken. The matrices are solved by three popular libraries over GPU, and result is compared with a multithreaded CPU implementation. The GPU-based CUSP library achieves the least solution time for all the matrices. The other libraries that use GPU to accelerate computation also achieve lesser time than their CPU variants. It was observed that the effect of GPU acceleration becomes more apparent when matrix size increases. The highest speedup is achieved for the matrix of the largest dimension. The number of nonzeros is also found to be affecting the solution time.

Chapter 75
Hybridizing Evolutionary Multi-objective Algorithm Using Random Mutations and Local Searches

Riddhiman Saikia and Deepak Sharma

Abstract Multi-Objective Evolutionary Algorithms (MOEAs) have been successful in solving mathematical and real-world multi-objective optimization problems by evolving a set of optimal solutions, which are known as Pareto-optimal solutions. However, there are certain limitations with those algorithms such as slow convergence, lack of effective terminating condition to name a few. To address such challenges, hybrid MOEAs are being designed and studied where the global exploration power of MOEAs are combined with local exploitation modules of various numerical optimization techniques. However, hybridization itself brings new challenges in its implementation. In this work, a hybrid MOEA is presented in which random mutations are performed on the initial population to start with a better and diverse set of solutions. Moreover, a local search module is coupled to execute periodically on a least crowded non-dominated solution at a certain interval of generations. The proposed algorithm is tested on a set of benchmark multi-objective optimization problems and compared with the NSGA-II. The convergence plots demonstrate the superiority of the proposed algorithm over NSGA-II.

75.1 Introduction

In Operations Research, multi-objective optimization is a sub-field of multi-criterion decision making in which optimal solutions are generated by simultaneous optimization of two or more conflicting objectives. Mathematically, the formulation of a multi-objective optimization problem is

$$\begin{aligned} &\text{Min } F(x) = \{f_1(x), f_2(x), \ldots, f_M(x)\} \\ &\text{subject to } x \in S \subset R^n \end{aligned} \tag{75.1}$$

Here, M is the number of conflicting objectives. Any optimal solution x^* is considered as Pareto-optimal, if there does not exist another $x \subset S$ that dominates x*. Meaning, a solution x is said to dominate x^* if it is not worse than x^* in any objective, and better in at least one [1]. Symbolically, it can be represented as $x \prec x^*$ (x dominates x^*), if $f_i(x) \leq f_i(x^*)$ for all $i = 1, \ldots, M$ and $f_j(x) < f_j(x^*)$ for at least one objective $j \in (1, \ldots, M)$ for the problem given in Eq. (75.1).

No solution to any multi-objective optimization problem can be considered as best since trade-offs between conflicting objectives are inevitable. Hence it is necessary to generate a set of solutions. The optimization problem in Eq. (75.1) can be solved using any numerical optimization technique by converting it into a single-objective composite function or converting all but one objective into a set of constraints. However, such approaches fail many a time to generate a well-distributed Pareto-optimal front. Evolutionary algorithms (EAs), however, have been an ideal candidate for solving such optimization problems because they work on a population of solutions. With appropriate operators for convergence and diversity, these EAs can well evolve a set of Pareto-optimal solutions.

In the literature, many multi-objective evolutionary algorithms (MOEAs) have been suggested, such as NSGA-II [2], SPEA-II [3], DoD [4], MOPSO [5], ASREA [6] to name a few. Despite excellent performances, MOEAs are being criticized for their slow convergence toward the Pareto-optimal front, lack of proof of convergence, lack of proper termination condition etc. To address some of these issues, many authors added various modifications to the MOEAs, commonly being modules for local search (LS), which is exploitation of an already-found solution in an attempt to improve its fitness. It is performed on one or many solutions at a time which can lead to a faster convergence if applied correctly [7].

While LS has many advantages, it is not a straightforward task to synchronize it with MOEAs. The first challenge with LS is that it is computationally exhaustive, since extra function evaluations consume extra resources. Too much of LS demands more computational resources and too less can lead to a sub-optimal solution [8]. Therefore, the challenges are when to execute LS and how much to execute? Another challenge is about a selection of solutions on which LS is applied. Since MOEAs are population-based optimization algorithms, the basis of choosing solution(s) for LS poses additional challenges [9].

There have been numerous attempts at answering such challenges. A remedy to overcome the difficulty of choosing weights for weighted scalar or composite function approach was proposed in [10], where the authors used three populations for generation update: the current population, the one after genetic operations and also after LS. If a solution after LS is degraded, then a better choice from other two populations is likely to be chosen over it for the next generation. Secondly, the authors used an acceptance rule for LS. Ishibuchi et al. [11] addressed the issue on how to choose solutions for LS. The authors used tournament selection based on fitness for choosing the best solutions of a population and performed LS on them. The authors noted improved performances and concluded that choosing better individuals for LS had a significantly positive impact. On the other hand, in some studies [12, 13], all non-dominated solutions have been considered for LS. Sindhya et al. [14] made an attempt to obtain good a balance between local and global search. The authors developed a concurrent hybrid MOEA where a probability based LS model was proposed. It has been argued that initial local searches can be wasted as GA operators would change the schema of solutions. But in later stages, it is desired that the solutions converge quickly towards the Pareto-optimal front. In this paper, an attempt is made in hybridizing NSGA-II with random mutations on the initial population and also coupled with local search during the generations. The initial mutations can help to further diversify the initial population and the local searches can help for faster convergence.

The rest of the paper is organized into four sections. Section 75.2 discusses the framework of hybrid MOEA. In Sect. 75.3, the performance of the proposed algorithm is presented after solving some benchmark multi-objective optimization problems. Section 75.4 concludes this paper with plans for future research.

75.2 Framework for Hybrid MOEA (HMOEA)

The framework for hybrid MOEA is shown in Fig. 75.1. The non-dominated sorting genetic algorithm, which is known as NSGA-II, has been chosen for hybridizing with the proposed ideas of random mutations and local searches. The hybrid NSGA-II is referred to as HMOEA in this paper. As can be seen from Fig. 75.1, an initial random population of size N is generated at the beginning. Since the initial population can affect the convergence of MOEAs [15], HMOEA is equipped with a module called 'initial mutation' which uses the polynomial mutation operator on every solution of the initial population with a high mutation probability of $(p_m = 0.5)$. The purpose of 'initial mutation' module is to bring diversity among the solutions of the initial population. After mutation, the total number of solutions is greater than N, which needs to be reduced to N. The environment selection of NSGA-II is chosen for selecting the best N solutions in which all solutions from the initial population and after random mutation are ranked using the non-dominated sorting operator which assigns a rank to every solution and store them in different fronts. Thereafter, the crowding distance operator is

applied front-wise to choose less crowded solutions. Based on the rank and crowding distance, the best *N* solutions are selected. This is referred to as 'Evaluate population (P)' module in the HMOEA as shown in Fig. 75.1 after initialization.

At this stage, the termination condition is imposed on HMOEA in the decision box as shown in Fig. 75.1, which gets terminated after a fixed number of generations. It is noted that a sufficiently large number of generations are provided here so that the convergence of HMOEA can be observed with respect to the original NSGA-II. If the termination condition is not met, the population [which is now referred to as parent population (P)] is considered for 'selection' module. In the selection module, the binary tournament selection is used to choose better solutions for a mating pool. On this pool, the SBX crossover operator is applied to create new solutions in 'Crossover' module followed by polynomial mutation, which is referred to as 'Mutation' module in Fig. 75.1. The population consisting of new solutions is referred to as offspring population (Q). The parent population and offspring population are mixed together and the non-dominated sorting is applied to rank all solutions and store them into different fronts. The crowding distance is applied front-wise. The environment selection of HMOEA, which is same as NSGA-II, selects the best *N* solutions.

The random mutation brings diversity into the population while the environmental selection selects better fitness solutions in order to maintain a balance between diversity and selection pressure. The module for environment selection is shown as 'Environment Selection (P + Q)' in Fig. 75.1.

At this stage, a module of 'Local Search' is used which chooses a least crowded solution from the set of the non-dominated solution, that is, the front-1 solution.

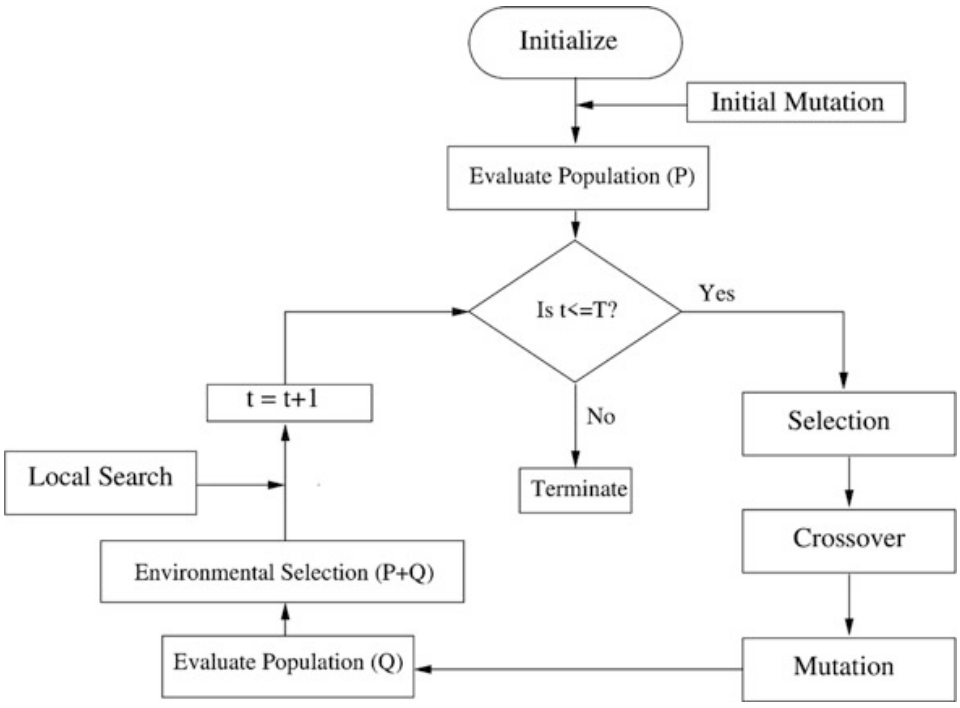

Fig. 75.1 Flowchart of hybrid multi-objective evolutionary algorithm

Thereafter, the multi-objective problem given in Eq. (75.1) is converted into a single-objective optimization problem using $\epsilon-$ constraint method [1]. The modified formulation for LS is given as

$$\begin{aligned} &\text{Minimize} f_i(x) \\ &\text{subject to } f_j \leq \epsilon_j, \forall j = (1, \cdots, M) \text{ and } j \neq i, \\ &x \in S \subset R^n. \end{aligned} \tag{75.2}$$

The single-objective problem of Eq. (75.2) is solved using the method of multipliers [16] in which the Cauchy's steepest descent method is used as the local search technique [16]. The solution after local search replaces its parent solution in the population. The challenge for the frequency of local searches is addressed by executing it once every $(T/5)$ generations, in which T refers to the fixed number of generations for which HMOEA is executed.

75.3 Results and Discussions

In this section, HMOEA is tested on five bi-objective benchmark problems, which are known as ZDT problems [17]. Among the ZDT problems, ZDT1, ZDT2, ZDT3, ZDT4, and ZDT6 problems are chosen. ZDT1, ZDT2, and ZDT3 have 30 number of variables and rest of ZDT problems have 10 number of variables. All variables are having the range from zero to one. ZDT5 problem is not considered because it has binary variables. The details of ZDT problems can be found in [17] which are not included in this paper due to brevity. HMOEA is also compared with the results of NSGA-II. Both MOEAs are run for the same population size of $N = 100$, number of generations $(T = 200)$, crossover probability of $p_c = 0.9$ and mutation probability of $(p_m = 0.1/$ number of variables). For local search, a maximum number of sequences for the method of multipliers is 40 and a maximum number of iterations for the Cauchy's steepest descent method is 20. The penalty parameter is kept 0.1 and the error for terminating the method of multiplier is 0.001.

75.3.1 Effect of Random Mutations

As part of HMOEA, random mutations were performed on the initial population for all test problems. Figure 75.2 shows the effect of initial mutation on the initial population. As can be seen, the population after random mutations is diverse and improved as compared to the randomly generated population after initialization. Due to the characteristics of ZDT6, many solutions are evolved at the extreme of 'f1' objective. As shown by [15], a better initial population helps MOEA for improved and faster convergence.

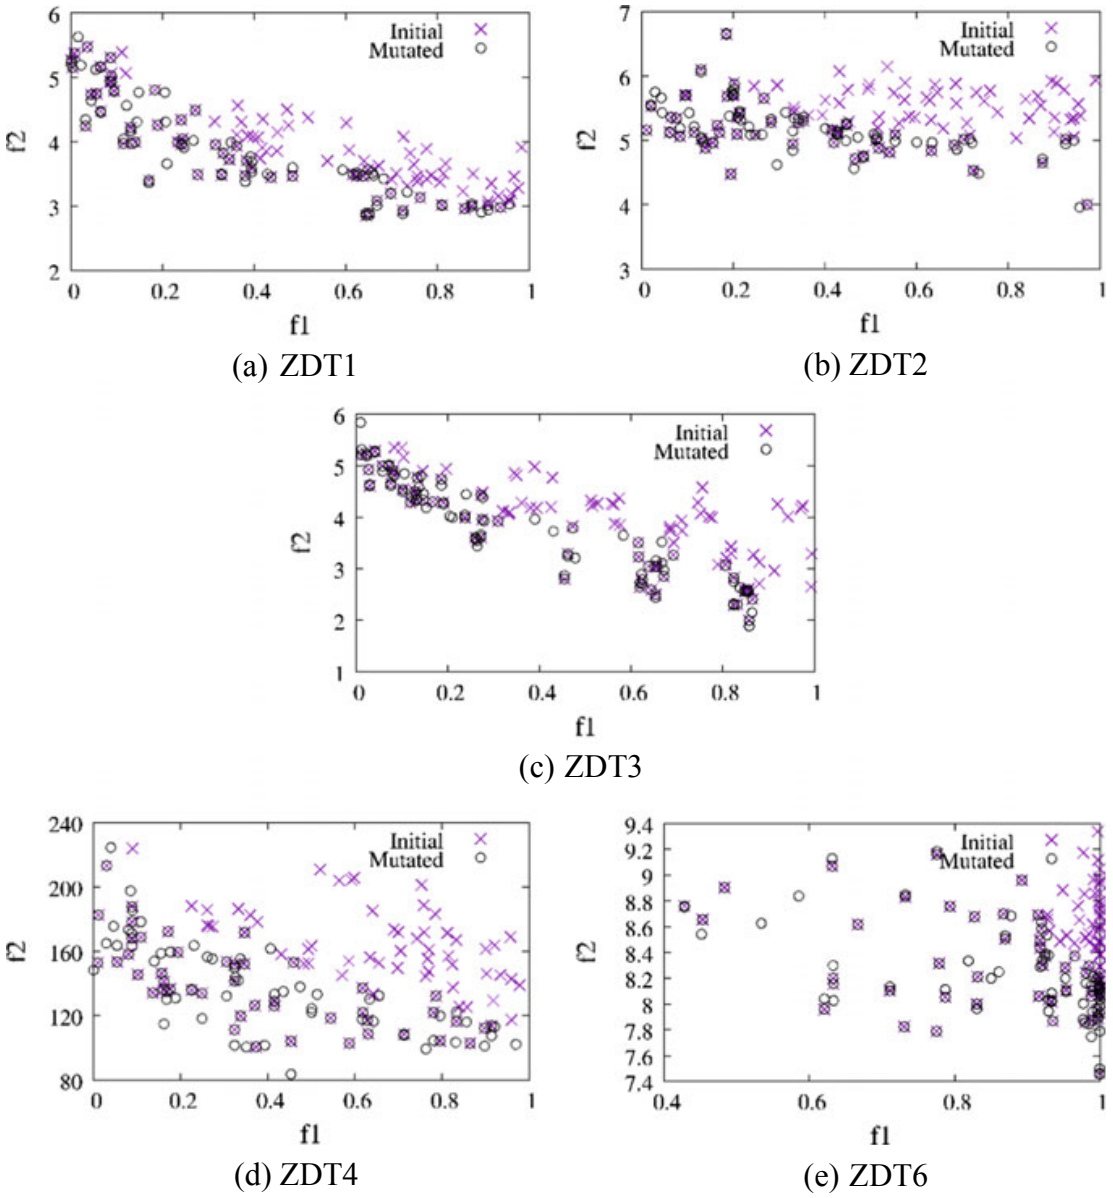

Fig. 75.2 Effect of random mutation on the initial population of HMOEA

75.3.2 Pareto-Optimal Solutions

The non-dominated solutions obtained by HMOEA for the chosen set of problems are shown in Fig. 75.3. It can be seen that HMOEA is able to generate non-dominated solutions that converge to the known Pareto-optimal fronts, for all the problems. It can be seen that ZDT1 has a non-convex Pareto-optimal front, ZDT2 has a convex Pareto-optimal front, ZDT3 has the discontinuous Pareto-optimal front, ZDT4 has a nonconvex Pareto-optimal front, and ZDT6 has nonlinearity along the convex Pareto-optimal front.

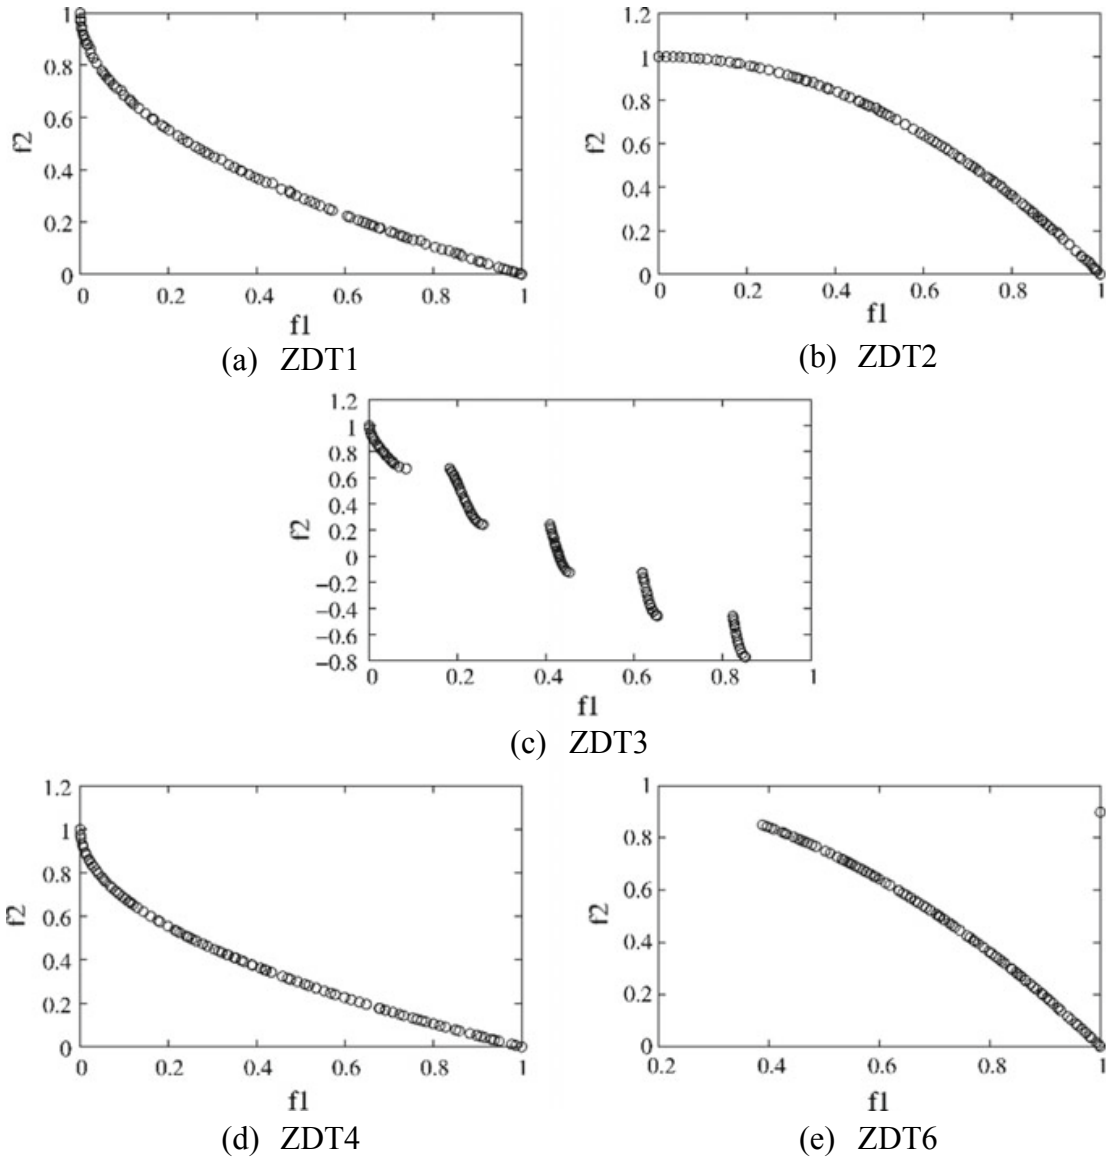

Fig. 75.3 The non-dominated solutions obtained from HMOEA

75.3.3 Convergence Plots

The convergence plots for HMOEA and NSGA-II for all five problems are shown in Fig. 75.4. These plots are made using the hypervolume (HV) indicator which signifies the volume occupied by the approximate set of non-dominated solutions generated by MOEAs and bounded by the reference point such that the reference point is weakly dominated by all the non-dominated solutions in the approximate set [1]. A semi-$\log_{10}$ scale is used for HV values over generations of MOEAs.

It can be seen from the figures that HMOEA has converged and stabilized faster than NSGA-II. The exact generation of convergence for both the algorithms is presented in Table 75.1, in which t_H and t_N denote generations required by

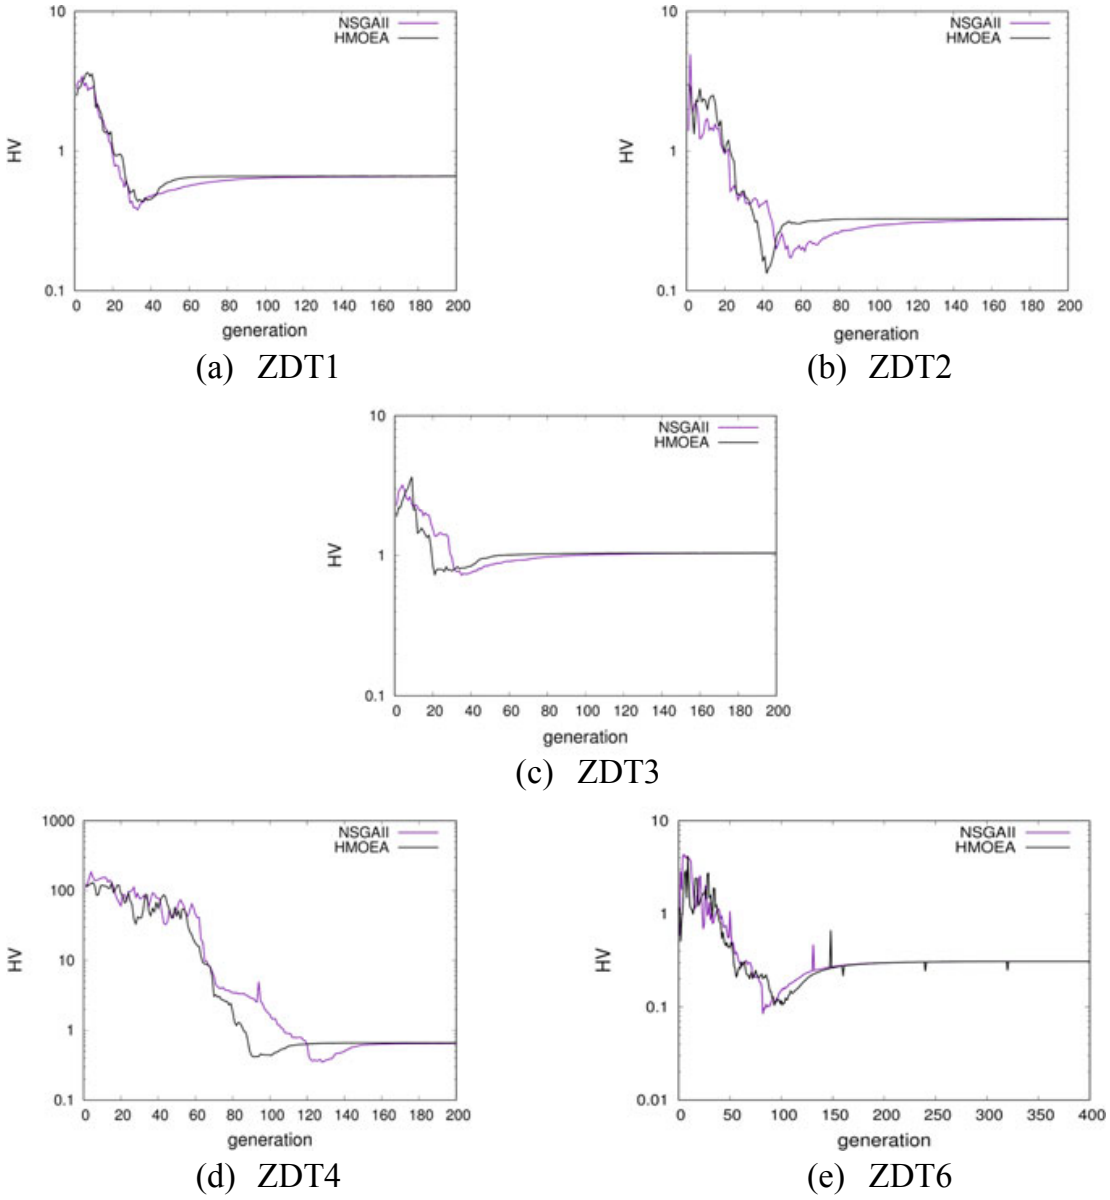

Fig. 75.4 Convergence plots of HMOEA over NSGA-II for all problems. HV values are plotted with $\log_{10}$ scale

Table 75.1 Number of generations required by HMOEA and NSGAII for solving ZDT problems

Problems	ZDT1	ZDT2	ZDT3	ZDT4	ZDT6
t_H	65	80	70	120	200
t_N	120	140	95	170	200
t_S	55	60	25	50	0

HMOEA and NSGA-II respectively, and t_S denotes the total generations saved by HMOEA over NSGA-II. Except for ZDT6, HMOEA is found to be superior over NSGA-II in saving a handful of generations.

75.4 Conclusions

This paper was an attempt to hybridize an existing MOEA with random mutations and local searches. From the results, it can be concluded that the random mutations with high mutation probability improved the diversity of the initial population. The convergence plots showed that local searches helped HMOEA to converge faster and saved a handful number of generations (or computations). Since the local search was performed on only one solution from the population and at the rate of $(T/5)$ generations, a well converged and nicely distributed set of non-dominated solutions was evolved that converged to known Pareto-optimal fronts. As a note on future work, HMOEA can be further improved by including an adaptive termination condition based on some performance indicators like HV. HMOEA also needs to be tested on other benchmark and engineering optimization problems and can be compared with other benchmark hybrid MOEAs.

Chapter 76
Local Search Heuristics-Based Genetic Algorithm for Capacitated Vehicle Routing Problem

Deepak Sharma, Sukhomay Pal, Aayush Sahay, Puneet Kumar, Gaurav Agarwal and Katravath Vignesh

Abstract Vehicle routing problem (VRP) is an NP-hard problem, which looks for the optimal route for vehicles to deliver goods to the customers with minimum transportation cost. Since transportation and logistics incur a good percentage of cost on to the basic price of the products delivered, VRP has been an interest in many organizations and also for many researchers. Due to the limitations of exact algorithms, the heuristics/meta-heuristics have been a choice for evolving an optimal solution for VRP. In this paper, various local search heuristics are coupled with genetic algorithm (GA), and two more intense local search heuristics are proposed. GA is tested on six different capacitated VRP instances. Results demonstrate the efficacy of GA in obtaining the solutions close to the best-known solutions that too in less computation time.

76.1 Introduction

Vehicle routing problem (VRP) is an NP-hard problem, which is difficult to solve in polynomial time [1]. It mainly finds optimal routes in transportation and logistics for people and organizations. In a typical supply chain, a requirement for VRP can be seen at different levels of the same organization ranging from transporting from its subsidiaries and manufacturing unit, delivering products to the users, or transporting employees from home to the organization and vice versa.

VRP has been solved by using sophisticated exact or heuristic algorithms in the literature. Exact algorithms aim to find a strict optimal solution, while heuristics are best in finding a good feasible solution. Another set of algorithms is hybrid approaches in which exact algorithm is coupled with heuristic to solve VRP. Due to the size of modern problems getting bigger day by day, heuristics and hybrid algorithms have been mostly used to solve VRP.

In specialized literature, the first GA to successfully solve the VRP was proposed by Prins [2] in which GA without trip-delimiters was hybridized with a local search procedure. GA showed competitive results with that of Tabu search (TS) and other heuristics. Nagata [3] proposed an edge-assembly crossover that was coupled with GA for solving capacitated VRP. Perboli et al. [4] proposed a hybrid GA in which the chain mutation was introduced with the *k*-chain local search. Masum et al. [5] in another effort represented trips of the route as chromosome of an individual. The authors used two types of crossover in which information from one individual was inserted into another to create a new child. Nazif and Lee [6] proposed a crossover operator, which was designed using a complete undirected bipartite graph. Vidal et al. [7] proposed a bi-criteria evaluation of individuals to maintain diversity in the population in order to avoid pre-mature convergence. The memetic algorithm proposed by Cattaruzza et al. [8] combined the split and local search procedure of Prins [2] along with the population diversity management of Vidal's approach [7]. Instead of single crossover and mutation, Contreras-Bolton and Parada [9] explored different combinations of crossover and mutation operators for better exploration and creation of new solutions. Pop and Horvat-Marc [10] considered theoretical aspects of seven neighborhoods motivated from VRP structure. These neighborhoods have been used in their local search approach such as intra-route and inter-route neighborhoods. For intra-route neighborhoods, the authors used the two-point move and three-opt move for improving single-vehicle routes. The shortest route was then selected. Similar steps were used for inter-route neighborhoods in which variations of opt moves to improve the solutions were performed. Kumar and Panneerselvam [11] studied different types of crossover operators used in GA in solving VRPs. Apart from that the authors also proposed 'sinusoidal motion crossover (SMC)' operator. Subramanian et al. [12] implemented a sequence of set partitioning in which an iterated local search-based heuristics and set partitioning were coupled. Wang and Lu [13] proposed a nearest addition method and sweep algorithm to solve the VRPs. Furthermore, an elitism conservation strategy was also used to hold superior chromosomes which can replace

inferior chromosomes in the population. Chen et al. [14] proposed a hybrid heuristic method called 'iterated variable neighborhood descent (IVND)' algorithm which used perturbation strategy designed by a crossover operator that helped the algorithm to move out from the local minima.

From the above studies, it can be observed that many efforts have been made to make GA effective for solving VRP by introducing heuristics either at crossover and mutation or by introducing local search and moves. Since in the study [10], various local search and moves have been discussed but not implemented together, and the contribution of this paper is to implement those local search moves with GA along with two proposed intense local search heuristics and test on the known set of capacitated VRPs.

The paper is organized into five sections. Section 76.2 presents a formulation for capacitated VRP. Section 76.3 presents the description of GA which is coupled with various local search heuristics. Section 76.4 presents results and discussion. In Sect. 76.5, the paper is concluded with future work.

76.2 Problem Formulation for Capacitated VRP

VRP is represented as a set of nodes with the depot at index 0, a heterogeneous fleet of vehicles with load capacity W, and individual cost constraint L. Here, L can represent any cost, monetary, or otherwise. It is used to represent distance in our problem statement since cost incurred by a vehicle is proportional to the distance covered by it.

The mathematical model is defined on a complete undirected network $G = (N, E)$. N consists of node 0 and C, where node 0 is the depot and C represents the customers with a non-negative demand d_i. E represents the set of all connected edges where every edge (i,j) has a travel cost c_{ij} associated with it. The set of vehicles is represented by V. We define a decision variable X_{ij}^v, which is 1 if there is a vehicle in V going from node i to j, and 0 otherwise. Our main objective is to minimize the cost as represented in (76.1), and the constraints are defined in (76.2)–(76.6).

$$\text{Minimize} \sum_{v \in V} \sum_{(i,j) \in E} c_{ij} X_{ij}^v \tag{76.1}$$

$$\sum_{v \in V} \sum_{j \in N} X_{ij}^v = 1, \quad \forall i \in N \tag{76.2}$$

$$\sum_{i \in \mathrm{N}} d_i \sum_{j \in N} X_{ij}^v \leq W, \quad \forall v \in V \tag{76.3}$$

$$\sum_{j \in \mathrm{N}} X_{0j}^{v} = 1, \quad \forall v \in V \tag{76.4}$$

$$\sum_{i \in N} X_{ik}^{v} - \sum_{j \in N} X_{kj}^{v} = 0, \quad \forall v \in V, \quad \forall k \in \mathrm{N} \tag{76.5}$$

$$X_{ij}^{v} \in \{0, 1\}, \ \forall (i,j) \in E, \quad \forall v \in V. \tag{76.6}$$

Equation (76.2) represents that each customer is visited by only one vehicle. Equation (76.3) imposes constraints on the capacity of a vehicle. Equation (76.4) represents that a vehicle can leave the depot only once. Equation (76.5) is designed such that the number of vehicles entering the depot or customer k is equal to the number of vehicles leaving. Equation (76.6) represents binary variable X_{ij}^{v}.

76.3 Local Search Heuristics for Genetic Algorithm

GA has been chosen for implementing local search heuristics for solving VRPs. Following are the steps of GA:

Step 1: Initialize random population (π) without duplicate. Set generation counter $t = 1$ and a maximum allowed generations $T = 1000$;
Step 2: Calculate fitness of each chromosome in π by using the split algorithm [2];
Step 3: Select two random parent chromosomes by using binary tournament selection from π;
Step 4: Perform crossover on the selected parent chromosomes to create a new chromosome by using specialized single-point, multi-point, and orderly crossover operators;
Step 5: Perform local search heuristics on the new chromosome with a probability p_m by using randomized or comprehensive local search method;
Step 6: Select new chromosome if it is unique (no duplicate) and has better fitness value than the worst fitness chromosome in π. Replace the worst fitness chromosome by the new chromosome in π. Else, do not select the new chromosome;
Step 7: Perform intense local search after every $\tau = 500$ generations;
Step 8: Increase count $t = t + 1$. If $t \leq T$, go to **Step 3**. Else, terminate.

GA starts with an initial random population (π) of size (σ) in Step 1. A real-valued chromosome is chosen to represent a solution. An example is shown

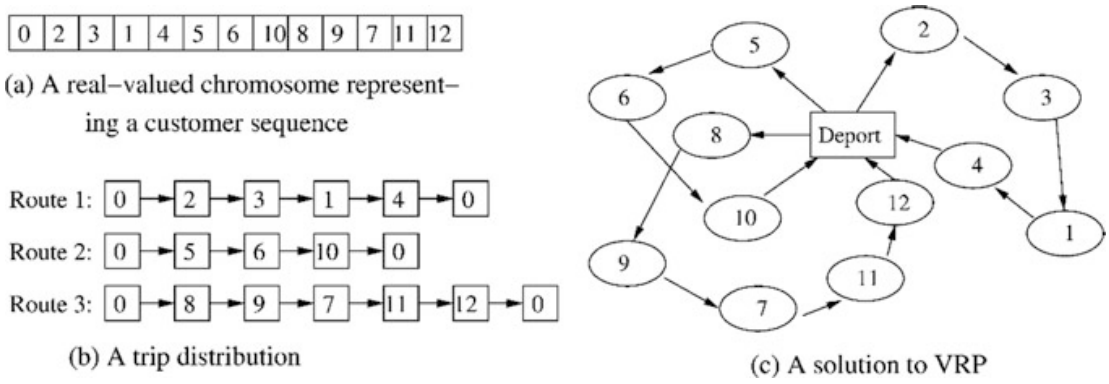

Fig. 76.1 A chromosome representation and trip distribution. Note that node 0 represents the depot

in Fig. 76.1a in which the customer sequence is represented the sequence in which vehicles are going to visit them. In Fig. 76.1b, the trips are distributed such that constraint on the capacity can be satisfied. Finally, a solution to VRP is shown in Fig. 76.1c.

The duplicate chromosomes are removed from the population for which an idea of spacing is used [2] in which the chromosomes should have the least similarity. Therefore, a split algorithm [2] is used that arranged the sequence of nodes in a chromosome such that least fitness of the chromosome can be found. An example is shown in Fig. 76.2 in which a chromosome, which is a solution to VRP, is shown before and after the split algorithm for making trips and calculating the least fitness for the given chromosome.

Once the initial random population is generated and the fitness is calculated for each chromosome, GA enters into its standard loop of generation at Step 3 at which two parent chromosomes are selected by using the binary tournament selection. The crossover operators are then applied to these two chosen chromosomes in order to create one new chromosome at Step 4. Three types of crossover operators are used with equal probability, which is referred to as single-point, multi-point, and orderly crossover operators. These operators are explained with the help of Fig. 76.3.

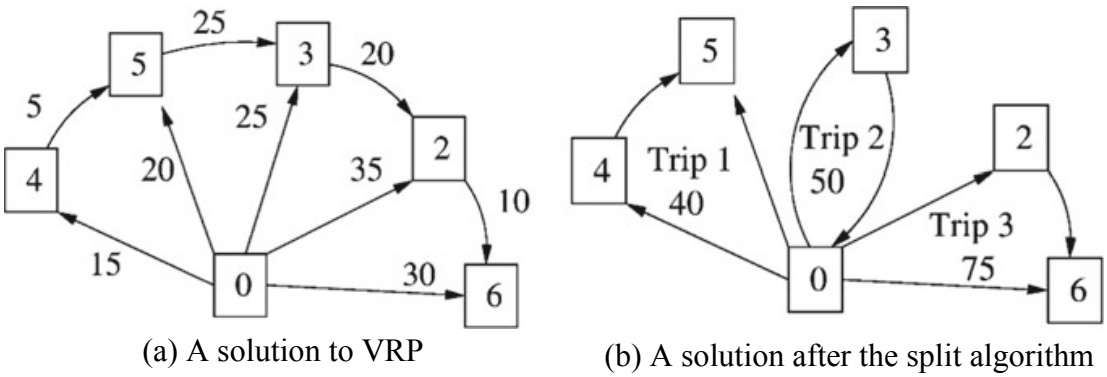

Fig. 76.2 Fitness evaluation of chromosome using the split algorithm [2]

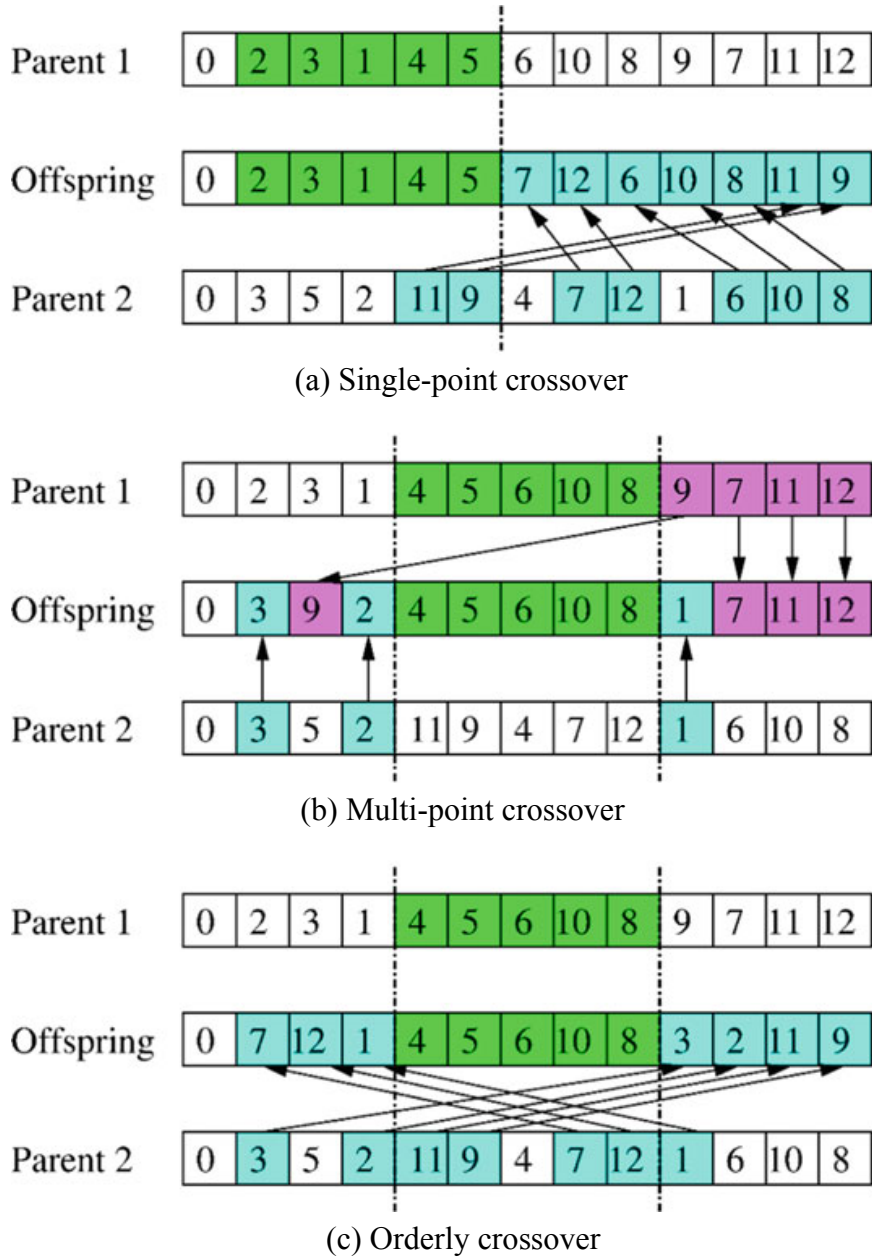

Fig. 76.3 Different crossover operators used with GA

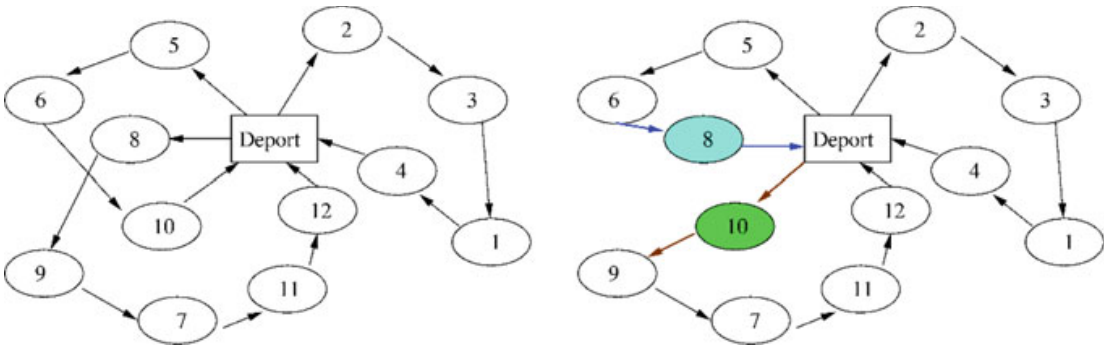
In a single-point crossover, a mating site is chosen randomly, say at node 5. All the nodes of parent 1 copied into the new chromosome. Thereafter, the remaining nodes are copied from parent 2 such that there is no duplicate node in the new chromosome, but in the given sequence of parent 2. In multi-point crossover operator, two random sites are chosen so that a sequence between these sites can be copied to the new chromosome as shown in Fig. 76.3b. At the empty places of a new chromosome, the nodes are copied in the same places as of parent 2, but without repetition of nodes in the new chromosome. There can be a few places in the new chromosome are not filled, which can be filled from the sequence of parent 1 as shown in the figure. In orderly crossover operators, two sites are chosen randomly, and then

the sequence from parent 1 is copied into the new chromosome at the places. Thereafter, the nodes, which do not appear in the new offspring, are copied in the given order/sequence as given in the parent 2.

After performing crossover, mutation is performed with a probability of p_m either by using randomized local search or comprehensive local search method at Step 5. Both of these random search methods are adopted from [2], in which the two nodes are selected randomly in the randomized local search. In the comprehensive local search method, two nodes are selected after scanning through all pairs of nodes. After selecting two nodes, six local search heuristics adopted from [10] are implemented which consist of (i) one-point move, (ii) two-point move, (iii) two-opt move, (iv) Or-opt move, (v) three-point move, and (vi) four-point move. Due to page restriction, the details for these moves are not given. However, the same can be found in [10].

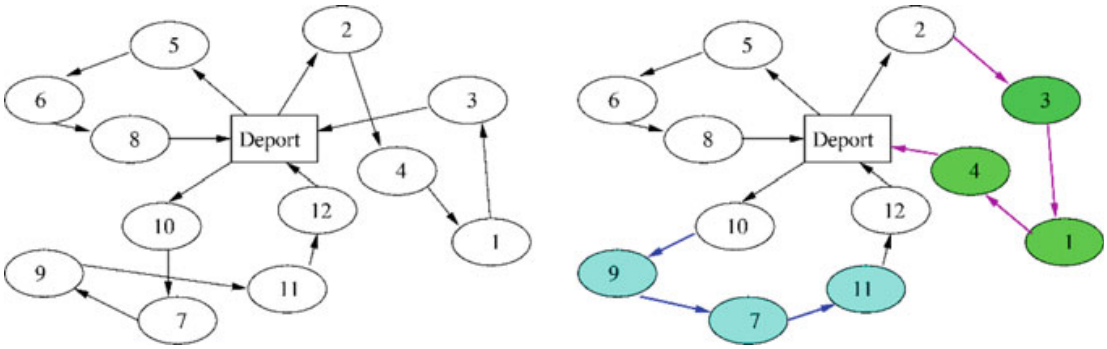
At Step 6, the new chromosome is checked for insertion in the population. Its fitness is found by using the split algorithm. If the fitness of the new chromosome is better than the worst fitness chromosome in the population and also there is no duplicate, then it is selected. Otherwise, it is removed.

The main contribution of this paper is the proposed intense local search which is performed at Step 7. It has been observed through simulation that the local search performed at Step 6 gets stuck at the local optima. In order to escape from these local optima, intensive local search is done on all the chromosomes in the population after every $\tau = 500$ generation. First intense local search is 'k-nearest neighbors local search' in which the nodes, which are close by based on Euclidean distance, bring closer in the sequence as well. We loop through all nodes one by one, find that particular node's k-nearest neighbors, and apply local search between that node and the ith nearest neighbor, where $1 \leq i \leq k$. Each iteration of this local search stops at the first improving move. For a graphical representation, the k-nearest neighbors local search is shown in Fig. 76.4. Another intense local search is 'trip-wise improvement procedure.' It has been observed through simulations that the improvement in the solution fitness is very low and by minor tweaking the sequence of a chromosome, the solution can converge to the global optimal



(a) Before local search (b) After local search

Fig. 76.4 An intense local search by using the k-nearest neighbors local search



(a) Before local search (b) After local search

Fig. 76.5 Trip-wise improvement procedure for local search

solution. In this method, every solution is scanned in every trip and the nodes' sequence in the given trips is tweaked. A graphical presentation is shown in Fig. 76.5. At last, the generation counter is increased by one and the termination condition is check. If not terminated, GA then starts from Step 3 till it gets terminated.

76.4 Results and Discussion

GA with local search heuristics is now tested on a set of benchmark CVRPs from the literature. The chosen set of the problems belong to four Augerat instances [15], one Christofide instance [16], and one Fisher instance [17]. These instances have a different number of nodes, which are presented in Table 76.1. The best-known solution from the literature is also presented in the table to compare the outcome of the proposed GA with various local search heuristics.

For all instances, GA starts with an initial population of size 15, and it runs for 1000 generations. The probability of mutation is set to $p_m = 0.1$. GA runs on Intel core i7 with 1.8 GHz processor.

Table 76.1 Details of Augerat, Christofide, and Fisher instances. The letter 'C' refers to Christofide instance, the letter 'A' refers to Augerat instance, and the letter "F' refers to Fisher instance. The number signifies a number of nodes

Instances	A33	A48	A54	A61	C76	F72
Nodes	33	48	54	61	76	72
Best-known solution	661	1073	1167	1035	832	238

Table 76.2 Solutions obtained for different instances of CVRP

S. No.	Problem instance	Solution obtained	Number of vehicles	Average time (s)
1	A33	662	5	0.945
2	A48	1170	7	2.494
3	A54	1428	7	4.189
4	A61	1040	9	2.083
5	C76	846	10	2.876
6	F72	241	4	3.389

76.4.1 Obtained Solutions and Computational Time

The solutions obtained by solving various instances are presented in Table 76.2. It can be seen that the local heuristics coupled with GA can generate the solutions close to the best-known solutions given in Table 76.1. Since a homogenous fleet of vehicles is assumed for solving CVRP, the minimum of vehicles are also presented in the table. The average computation time is also reported which is calculated after running GA 30 times from different initial population. It can be seen that the developed GA is not expensive for solving CVRP having a maximum of 76 nodes. It is noted that the instances are different from each other; therefore, the computation time is not linear with the number of nodes in the problem instances.

76.4.2 Convergence Plots

The convergence plots for all test instances are shown in Fig. 76.6. It can be seen that the best fitness solution is improved drastically in very early generations and

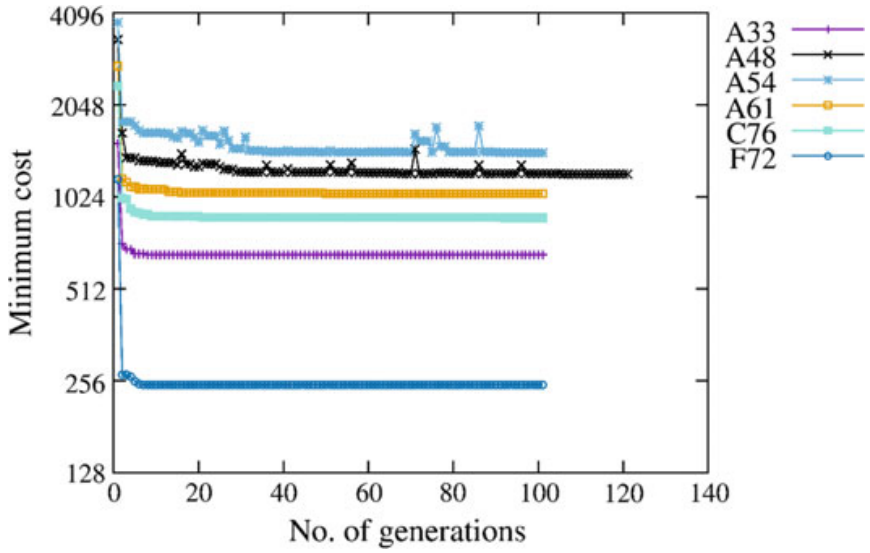


Fig. 76.6 Convergence plot of GA for different instances of CVRPs. The minimum cost values are plotted on a $\log_2$ scale

further their performance improved very slowly. The local search heuristics coupled with GA are able to make it efficient by improving chromosome drastically in the early generations.

76.5 Conclusions

In this paper, various local search heuristics were coupled with GA to improve its performance for solving various test instances of CVRP. From the results, it can be concluded that the hybrid GA can be used for generating a solution for CVRP as it was able to find the solution close the best-known solutions of the test instances. Since the computation time of GA was small, it can also be used for a large test instance and for application problems of CVRP. In the future, GA can be improved further so that it can generate the best-known solutions. Also, a large set of CVRP test instance needs to solve for assessing its performance.

Performance Evaluation of Adhesive Spur Gear with the Influence of Properties of Adhesive

R. Shailesh, M. Ramu, M. Govindaraju, K. Karthikeyan and V. Satheeshkumar

Abstract The effect of adhesive properties on performance of spur gear made of adhesive system referred to as adhesive spur gear is investigated. In addition, the repair ability and reusability of adhesive spur gear towards sustainability are also investigated. Two-part epoxy adhesive system constituting resin and hardener was used to fabricate spur gear samples. In order to modify adhesive properties, the hardener to resin ratio was varied. The repair ability and reusability of spur gear made by the adhesive system were checked by breaking a few teeth of the adhesive spur gears and repaired by adhesive. The repaired gears were tested and compared with the performance of actual spur gears made of adhesive. The gears were tested by a gear test rig developed indigenously. The performance of the gears with different hardener to resin ratios was evaluated by monitoring the number of cycles. The results show that the number of cycles increases with decrease in hardener to resin ratio. This is due to the better strength of the adhesive system with the resin-rich formulation. There is not much difference in performance between repaired gear and the corresponding actual gear. This ensures the sustainability of adhesive gears over conventional polymer gears.

77.1 Introduction

Performance evaluation of the spur gears made of the adhesive system with the influence of adhesive properties and checking repair ability and reusability of the gears made of adhesive are the key activities of the present study. In this regard, White [1] invented a composite plastic metal gear in which different plastic materials were used for having gear mesh, and the gear hub was made of metal. In this case, the hybridization of plastic gear and metal gear hub together eliminates distortion and slip. Beddoe [2] invented a composite gear employing a set of deformable teeth disposed slightly in advance of the hard teeth to transfer load through hard teeth only when it exceeds a critical level. Santi [3] invented composite gears made from a rigid material like metal and from a thermoplastic material for the abnormal conditions like abrupt stop occurs. Kurokawa et al. [4] investigated the performance of injection-moulded spur gears with different types of composites made of poly-ether-ether-ketone with different types of carbon fibres (CFs). It was found that a composite gear reinforced with CF of the highest density indicated the highest load carrying capacity irrespective of the test conditions. Kim [5] proposed a method to evaluate the wear and durability of plastic spur gears made of acetal and nylon materials. In the results, acetal gears exhibited a large amount of wear with the development of plastic deformation and increased tooth stiffness due to brittle nature of the material. In the case of nylon gears, reduced amount of wear and prolonged service life with less gear temperature were observed due to the polymer softer in nature. Mao [6] proposed a design method for polymer composite gear by relating polymer gear surface temperature and wear rate. It was found that polymer gear wear rate increases with an increase in critical load for a specific geometry and then decreases. Nozawa et al. [7] investigated the tribological behaviour of polymer sheets adhered to steel gear teeth. It was found that noise suddenly increased when only one of the polymer sheets was failed from the gear surface due to low adhesive strength.

Kansal et al. [8] addressed the problem of evaluating the temperature distribution and thermal residual stresses that are developed due to the non-uniform cooling of the injection-moulded polystyrene gear. Senthilvelan and Gnanamoorthy [9, 10] investigated the influence of the gear rotational speed on performance of polymer composite gear tooth. It was found that gear rotational speed affects the performance of gears made of both the materials at different high running speeds and torques. The glass fibre reinforced nylon six gears showed better performance when compared with unreinforced gears due to its better mechanical strength and thermal deformation resistance. It was reported that the rise in the gear temperature under loading is due to hysteresis effects and friction. Kirupasankar et al. [11] reported the effect of applied torque on the transmission efficiency of polyamide nanocomposite spur gears. The increase in gear tooth temperature affects the tooth shape and thereby affects the gear performance. The improvement in mechanical properties of polyamide nanocomposite gears results in better power transmission efficiency. Anand Mohan and Senthilvelan [12] evaluated fatigue performance of

polypropylene symmetric gears and asymmetric gears with and without the reinforcement of glass fibre. The results showed better load-carrying capacity of asymmetric gears when compared with symmetric gears due to the increased gear tooth width at the root region. Chaubey and Jain [13] conducted a detailed review on meso- and micro-gears used in various micro-systems and devices used for transmitting power and/or motion due to their reduced weight, dimensional accuracy, zero backlash, compact ability, better functional and operating characteristics, longer service life and sustainable performance. The review reveals about the manufacturing of meso- and micro-spur gear by various advanced manufacturing processes and the directions towards manufacturing quality gears. Hoskins et al. [14] generated a sound frequency spectrum with the influence of various polymeric gear materials and operating conditions. Results showed that there is a significant effect of surface characteristics, wear and temperature corresponding to the respective sound power levels. The effects of material, reinforcement and geometry show that the tribological properties of gear materials could be used to predict noise generated and the inaccuracy significance in polymer gear trains. Dearn et al. [15] described friction and wear by controlling the running temperatures by using a series of solid lubricant coatings like molybdenum disulphide, graphite flake, boron nitride (hexagonal) and poly-tetra-fluoro-ethylene (PTFE) deposited on flanks of the polymer gear teeth. Results showed a significant reduction in frictional forces with PTFE.

In line with adhesive materials, mostly the adhesive systems with two parts, namely resin and hardener are used for structural applications. In a compression testing of an adhesive system that is made of epoxy group resin and amine group hardener with different mixing ratios, the results show brittle behaviour with the epoxy-rich systems. This is due to the evolution of a rigid macromolecular structure. The adhesive mixture with hardener-rich formulation shows ductile behaviour [16]. Satheeshkumar and Ganesh Narayanan [17] demonstrated the mechanical performance of adhesive with two parts, namely resin—bisphenol A epichlorohydrin and hardener—polyamidoamine. It was postulated that resin-rich formulation turns the adhesive sample stronger, and hardener-rich formulation turns the adhesive sample more ductile.

In the above detailed literature review, it is observed that numerous investigations have been carried out on the manufacturing of polymer gears with different polymer materials. Different types of filler materials and reinforcements have been used for improving the gear performance. The polymer gears have been used predominantly, and efforts have been taken to achieve equivalent and better performance than metal gears. The polymer gear conventionally manufactured by the injection moulding process is replaced with a new gear once it is damaged. The damaged thermoplastic gears may be melted and reused. In the case of thermoplastic gears with typical fillers and reinforcements, repair ability is one of the major issues. The idea here is to develop polymer gears by using adhesive materials by choosing suitable properties for having better performance and to check the repair

ability and reusability of adhesive gears in line with sustainable gear manufacturing. In the present preliminary study, the influence of hardener to resin ratio of adhesive on the performance of adhesive gear is investigated with actual and repaired gears.

77.2 Methodology

77.2.1 Materials Used and Mechanical Properties

Commercially available structural adhesive was used as a polymer matrix in this study. The adhesive system is a combination of two parts, namely resin (bisphenol A epichlorohydrin) and hardener (polyamidoamine). The suitable mixing ratio of the adhesive system is of 1:0.8 by weight as per supplier's instruction.

Gear Test Rig. Figure 77.1 shows the schematic of the test rig for evaluating the adhesive spur gear performance. It has a 0.5 HP DC shunt motor with maximum speed up to 1500 rpm. It is coupled with an alternator having the same capacity. The input to the motor and the field of the alternator is controlled externally by two separate autotransformers. The autotransformer is used to adjust speed and torque. There is an additional rectifier circuit consisting of diodes and capacitor for the AC to DC conversion. A 100 Ω rheostat is used as the load across the alternator. The testing gear is connected to the alternator shaft while the standard steel gear is connected to the motor shaft.

Evaluation of Adhesive Spur Gear Performance. Figure 77.2 shows the schematic of spur gear used for fabrication. Table 77.1 shows the parameters of the adhesive spur gear (Anand Mohan and Senthilvelan [12]). The adhesive mixture with different properties by varying hardener to resin (H/R) ratio like 0.6:1, 0.7:1, 0.8:1, 0.9:1 and 1:1 was cast into the suitable mould with a thickness of 6 mm (Fig. 77.3a). The cast adhesive mixture into the mould was allowed to cure for more than 24 h and removed from the mould carefully. Figure 77.3b shows fabricated spur gear made of epoxy adhesive system and a steel gear for a reference.

Root circle diameter	47 mm
Fillet radius	1.14 mm

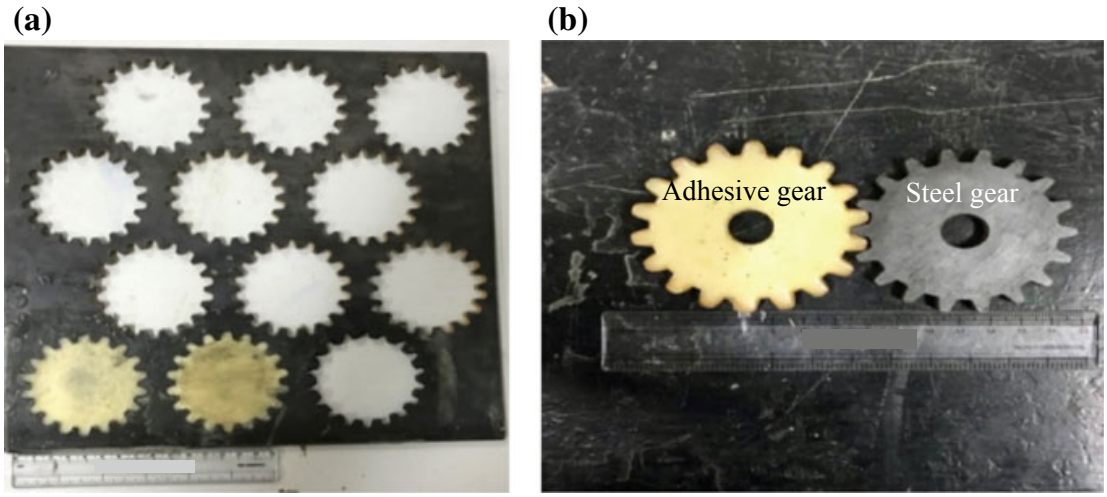

Fig. 77.3 **a** Making of adhesive gear using mould and **b** fabricated adhesive gear and steel gear

Further, a tooth in each fabricated adhesive gear with varying hardener to resin ratio was broken deliberately and inserted into the mould. The damaged location was repaired with the adhesive mixture maintaining the corresponding hardener to resin ratio. In the present work, the gear tested directly from the moulding process is referred to as actual gear, and the gear deliberately broken and repaired is referred to as repaired gear.

The adhesive gears were tested at a constant motor speed of 300 rpm and applied torque of 2 Nm. The platform of the testing setup was made rigid and heavy to minimize vibration. Initially, using a pre-test gear attached to the alternator, electrical equivalent of all torque conditions were calculated by measuring the voltage and current across the input of DC motor. The voltage and current were measured to be 35 V and 1.8 A, respectively. The voltage, current and speed transformation to equivalent torque were calculated by the Eqs. (77.1), (77.2).

$$P = V \times I \tag{77.1}$$

where P—power, V—voltage in V and I–current in A.

Also

$$P = \frac{2\pi NT}{60} \tag{77.2}$$

where N—Motor speed in rpm and T—torque in Nm.

During testing of gears, gear life was evaluated by monitoring the number of cycles. The failure of gear was ensured by sound difference and followed by tooth breakage. Three gears were tested in each case, and the fourth gear was tested in the case of not observing good repeatability.

77.3 Results and Discussion

77.3.1 Effect of Hardener to Resin Ratio of Adhesive on Failure Pattern of Gears

Figure 77.4a, b shows the failure pattern of actual gears and repaired gears with varying H/R ratios of adhesive. It is found that 1 or 2 teeth have failed in all cases. There is not much difference in failure pattern between actual gears and repaired gears. In the case of repaired gears, the failure of gear teeth is observed randomly, and not at the repaired location always.

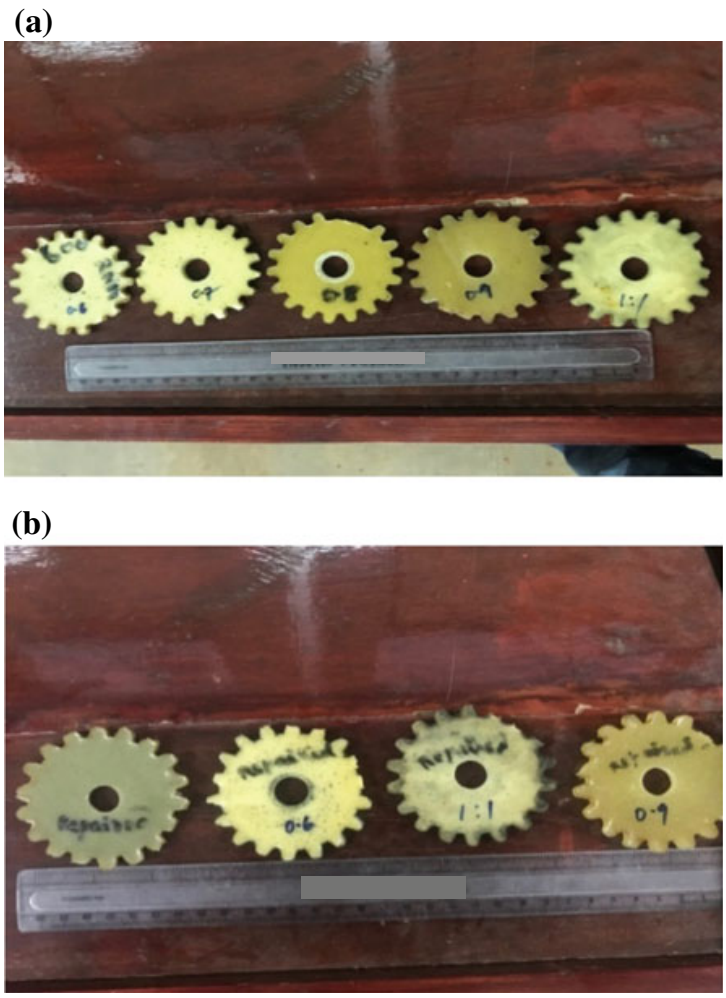

Fig. 77.4 Failure pattern of adhesive gears: **a** actual gears and **b** repaired gears

77.3.2 Effect of Hardener to Resin Ratio of Adhesive on Gear Performance

Figure 77.5 shows a comparison of maximum number of cycles achieved by the adhesive gears with different hardener to resin ratios. The comparison of maximum number of cycles between actual and repaired adhesive spur gears is also shown. It is observed that the number of cycles of adhesive spur gear increases with decrease in H/R ratio of adhesive. The maximum number of cycles of about 40200 is observed for H/R ratio of 0.6:1. Based on the maximum number of cycles, the decrease in the percentage of maximum number of cycles is calculated as 19.4, 28.4, 44.8 and 60.4% with hardener to resin ratios of 0.7:1, 0.8:1, 0.9:1 and 1:1, respectively. This is due to the rich formulation of the resin increases the strength of the adhesive (Satheeshkumar and Ganesh Narayanan [17]) and thereby increases the gear performance. There is not much difference between actual and repaired adhesive spur gears.

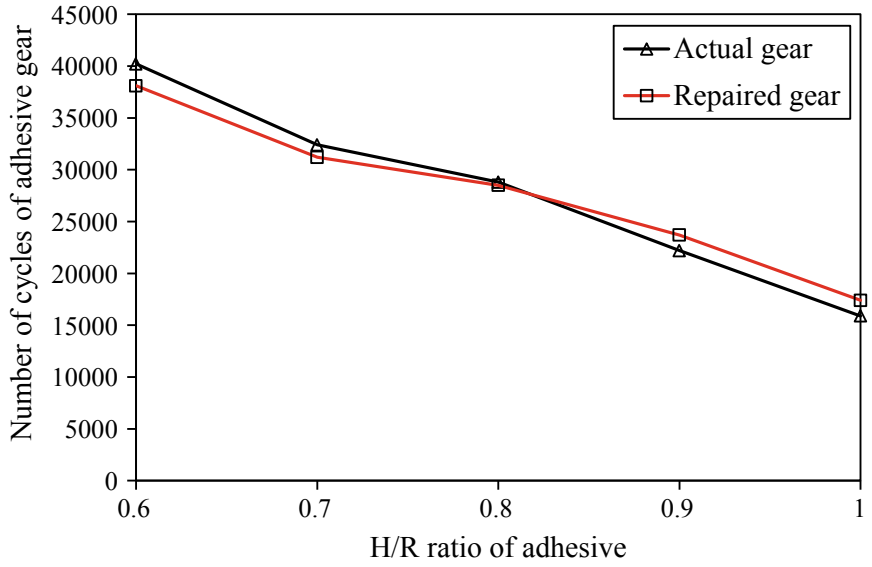

Fig. 77.5 Comparison of maximum number of cycles of adhesive spur gear between actual and repaired cases with different hardener to resin ratios (Data Variation: ±1200 cycles)

77.4 Conclusions

From the present study, the conclusions are summarized as follows:

- The performance of adhesive spur gears in terms of number of cycles increases with decrease in hardener to resin ratio of the adhesive system. This is due to the rich formulation of resin that improves the strength of adhesive. It is understood that improved strength of adhesive with a rich formulation of resin increases the strength of gear and thereby increases the number of cycles.
- There is not much difference in the performance of actual and repaired adhesive spur gears irrespective to hardener to resin ratio. This ensures that the adhesive gear has good repair ability and reusability. In the case of conventional thermoplastic gears made by injection moulding process, reusability is possible by melting the damaged gears and reinjection moulding process. But, the repair ability of those gears is difficult by injection moulding process and not suggestible as well.
- It is suggested that the adhesive with resin-rich formulation could be fabricated in sheet or plate form, and water jet cutting process could be used for spur gear cutting process in the case of mass production.

Chapter 78
Design Analysis and Modification of Sugarcane Fibrizer Hammer at Wonji Shoa Sugar Factory (WSSF) Ethiopia

Tesfaye Mathewos, Perumalla Janaki Ramulu and Esmael Adem Esleman

Abstract Wonji Shoa Sugar Factory (WSSF) is one of the top sugar factories in Ethiopia which produces sugar and electricity from sugarcane using three critical plants: mill plants, sugar processing plant, and a cogenerating power plant. Among three plants, the mill plant is the most important plant used to crush the cane for separating sugar juice from bagasse. In this plant, Fibrizer hammer device is used for cruising sugarcane. The Fibrizer performs the major share in milling process for fibrizing the chopped cane after set of cane knives using rotating knives. Most of the times, WSSF is facing breakages of Fibrizer hammer by which losses incurring to the factory. The main aim of the paper is to analyze the failure causes of existing Fibrizer hammer with respect to design and modify the necessary changes in design for Fibrizer hammer at WSSF. By which, get high preparation index (PI) and optimize in power consumption and cost. In addition, hardness of the existing Fibrizer hammer was tested to know the mechanical strength. For modification of existing Fibrizer hammer: comparison was made in terms of design, and load along with harmonic simulation analyses performed using finite element analysis. The results from finite element analysis revealed that the modified Fibrizer hammer

having minimum deformation, minimum shear stress, and more centrifugal force has a relation to achieve better preparation index.

Keywords Fibrizer hammer · Harmonic analysis · Preparation index (PI) · FEM · Wonji Shoa Sugar Factory

78.1 Introduction

For completing the preparation of cane juice in the sugar industries, Fibrizer hammer is used after knifing. Formerly to break the cane, initial knifing was followed by heavy crusher. In this method, cane was not crushed properly in most of the time which leads to more power consumption and increase miscellaneous tasks. To overcome these issues, a few researchers studied and suggested the upgradation of technology to the sugarcane industries, in which Fibrizer hammer is the upgradated technology to all the sugarcane industries for crushing the cane. With this technology, betterment in level of preparation of index (PI) and reduction in the power consumption are attained during processing. For the best operations, less maintenance, low power consumption, and slip ring motors with high capacities are used, whereas steam turbines were used formerly for roller crushing instead of electric motors [1–4]. There were some of the studies carried out based on the Fibrizer hammer, i.e., design of hammer, modification, and optimization of Fibrizer hammer, etc. Podany et al. [5] dealt hammer construction for cane shredder, in which the hammer functions in shredder comprises crushing sugarcane stalks for further sugar production processing. For protection of hammer against wear and dynamic loading, hammer loading and other related calculations were made and suggested the weld deposit materials for strengthening the hammer. Ransing et al. [6, 7] studied about cane roller crusher for attaining good cane preparation for extraction of juice from cane in favor of cane Fibrizer. Cane knifing in chopper, cane crushing in Fibrizer, and extraction of juice in milling like three processes were performed on it. Based on the plant capacity, Fibrizer was changed in size and model, resulting in high PI. Nikam et al. [8] designed and analyzed a new flexible blade-type sugarcane leveler by numerical analysis. They concluded that the efficiency of cane leveler increased by changing design from fixed bitter to flexible blades. By modifying design cane lever, one can overcome the limitations of existing cane leveler. It also increases the productivity of milling section. Efficiency of cane leveler increases, and then it also increases the production.

From the above literature, it is observed that many of the researchers were carried out the research on the functional aspects of Fibrizer hammer, parameters effect, shredder design, power consumption, etc. No researchers discussed the Fibrizer hammers breakages and its consequences in the breakdown of the industry. In the present work, design, analyze and modification of the existing Fibrizer hammer for improvement of sugar production process at Wonji Shoa Sugar Factory (WSSF). In the case industry, i.e., at WSSF, frequent hammer breakage was

observed at the hard-faced welded part and at the tail part of the Fibrizer hammer. Also, at hammer head tip wear, shearing of tip fixing bolt leads to huge crushing downtime. The recorded downtime during 2014–2017 period was 121 h in terms of cost 14,82,421.3 USD. The other problem in the factory was overtime payments during repair of Fibrizer hammer and electrical loss due to interruption of cane bagasse from mill plant to boiler. Based on these issues, the significance of this work is to improve the current Fibrizer hammer to increase juice extraction by improving the preparation index from 85 to 92%; to reduce overtime payments caused by Fibrizer hammer breakage; to supply continuous electrical power by continuous crushing; to save excess bagasse by continuous crushing which is used as a row material for pulp.

78.2 Experimental Methodology

To realize the stated objective, pertinent methodology was followed. The relevant data were collected from both WSSF and existing literature. The detailed specifications of the existing Fibrizer hammer at WSSF are shown in Table 78.1. The material used for Fibrizer hammer was structural steel. Fibrizer hammer bolt was made of mild steel with diameter, length, and thread length 22, 130 and 85 mm,

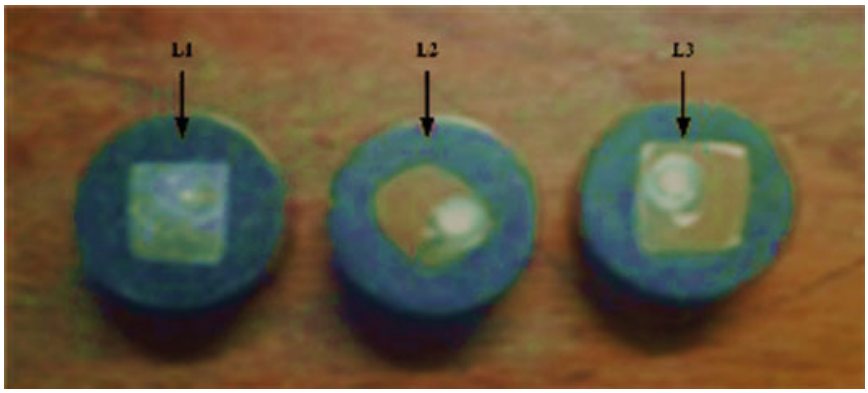

Fig. 78.1 Cut pieces from current Fibrizer hammer

respectively. The material of the Fibrizer hammer was tested at three different locations as L-1, L-2, and L-3 as shown in Fig. 78.1.

78.2.1 Experimental Analysis

Indian made Fibrizer hammer was submitted for failure cause analysis. The hammer was broken at the tail patron during operation. Failure causes were examined with following techniques.

78.2.1.1 Visual Examination

The part was broken and detached from rest of the part. The fracture surfaces were found corroded; the broken part was cleaned using a hydrochloric acid solution fetching from sugar processing department to enable them to be examined more closely. The nature of the failure parts was the same and similar. The welders were welding the worn out Fibrizer hammers and cane knife continuously to use like a spare part.

78.2.1.2 Stress Concentration Factor Analysis

In any machine, machine parts and structures' effect of stress concentration can arise from internal holes or voids formed from any manufacturing process [9].

Stress Concentration Factor Analysis of the Existing Fibrizer Hammer

Figure 78.2 is indicating the complete dimensions of the existing Fibrizer hammer. Center of gravity for load analysis was calculated at different zone of areas (A1, A2, A3, and A4 shown in Fig. 78.2). Parameters considered for existing Fibrizer

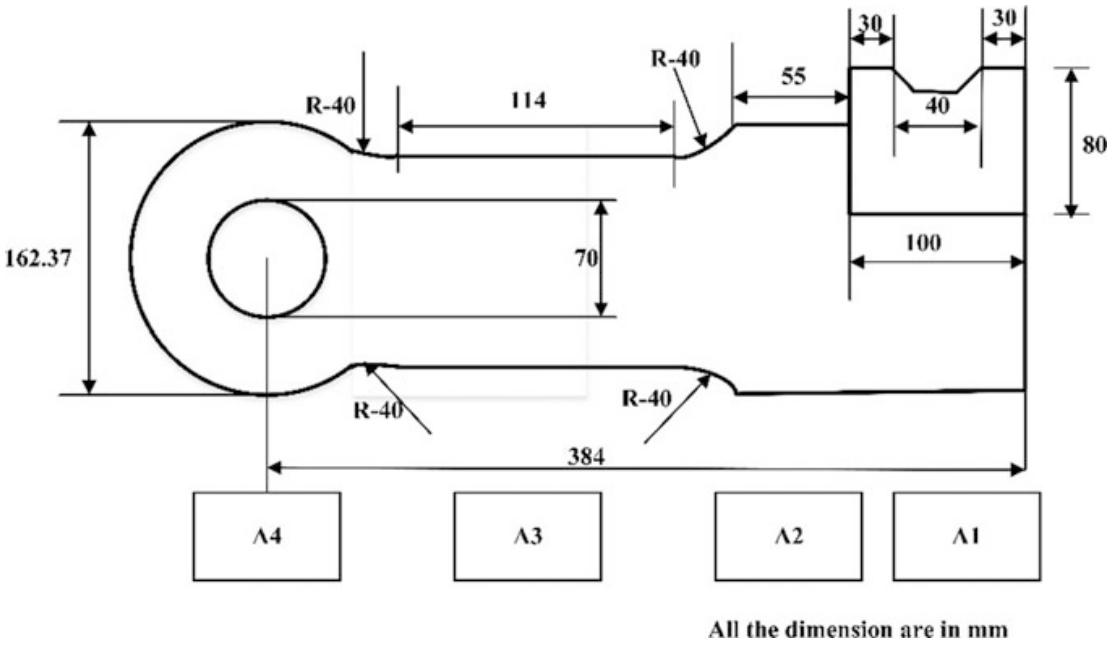

Fig. 78.2 2D schematic representation of current Fibrizer hammer

hammer design analysis were height at tail part of hammer H = 180 mm; web height h = 110 mm; and radius of the fillet of Fibrizer hammer r = 40 mm. From these parameters r/h; H/h; moment of inertia (I) and C which is distance from the neutral axis to the point of interest of hammer. By which, bending moment (M) and maximum shear stress $\left(\delta_{\max} = k_t \frac{MC}{I}\right)$ were evaluated considering a constant factor (k_t) value as 1.58.

78.2.1.3 Load Analysis of Current Fibrizer Hammer

Load analysis of current Fibrizer hammer was evaluated by using speed of Fibrizer (N) = 750 rpm and motor power = 2 MW. By calculating the center of gravity ($Y = (A1Y1 + A2Y2 + A3Y3 + A4Y4)/A1 + A2 + A3 + A4)$), angular speed ($\omega = 2\pi N/60$); linear velocity ($v = \omega \times Y$) and Torque ($T = 60P/2\pi N$).

Figure 78.3 indicates the forces which are acting on Fibrizer hub and hammer during the process. There were three major forces acting on the hub and hammers such as force created by the pin (F_p), centrifugal force (F_c), and force generated by cane being shredded (F_s). Centrifugal force (F_c) was calculated by $mr\omega^2$, where m is mass of hammer and r is distance of gravity center from rotation axis. Loading of one hammer during normal operation was value of tangential force, i.e., force created by pin (F_p) during conventional operation of Fibrizer. For this the force the following presumption were taken such as first hammer carries 75% of loading, second 20% and third 5% and evaluated the exact F_p.

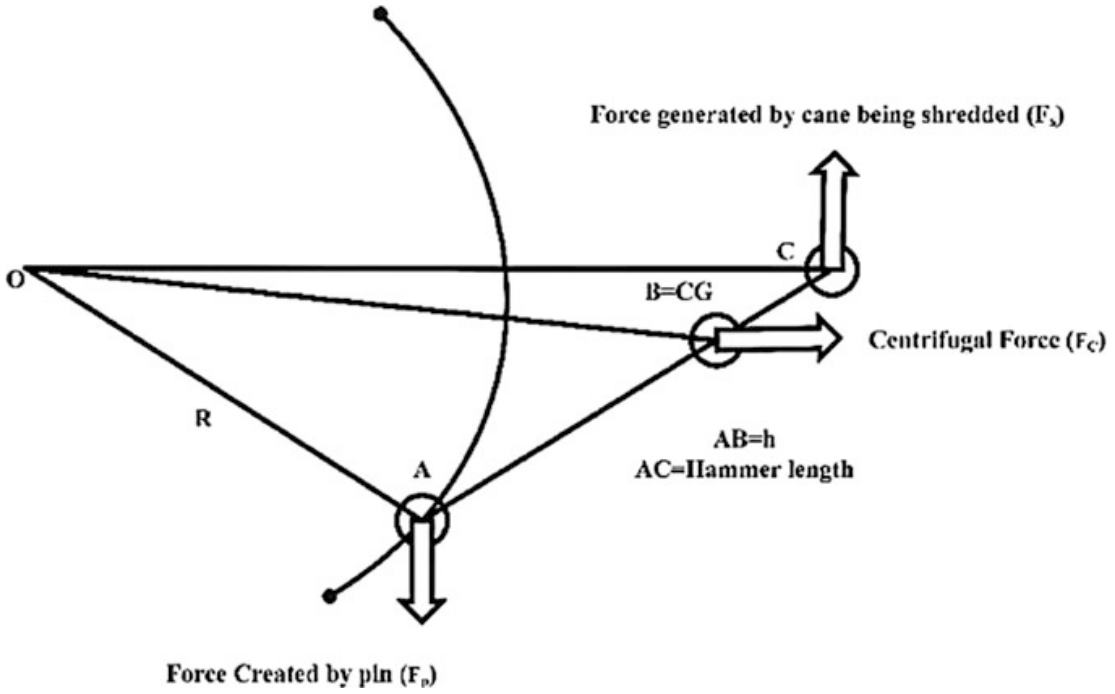

Fig. 78.3 Schematic of skeleton force diagram of Fibrizer hub and hammer

78.2.1.4 Hardness Measurement

The sample was taken from Fibrizer hammer at three places such as L-1, L-2, and L-3 indicated in Fig. 78.4. The hardness of the Fibrizer hammer was tested by Vickers hardness testing machine.

Fig. 78.4 Broken parts of Fibrizer hammer

78.2.1.5 Design Modification of Fibrizer Hammer

Necessity for Modification

The current Fibrizer hammer breakage problems at WSSF are happening frequently. The breakages locations were observed to be at the hard-faced welded part, at the tail part, and sometimes at the hole in which the Fibrizer hammer was fixed with rotatable shaft. The other problem is geometrical structure which exposed the Fibrizer hammer. This problem is not only at WSSF but also other sugar industries in Ethiopia and may be in the world sugar industries where this technology is under implementation. The details of the cost downtime losses were indicated in Table 78.2 in US dollars.

Load analysis of Modified Fibrizer Hammer

Figure 78.5 indicated the complete dimensions of the modified Fibrizer hammer. For this hammer also, the center of gravity for load analysis at different zone of areas such as A1, A2, A3, and A4 as shown in Fig. 78.5 was evaluated. Similar to existing Fibrizer hammer, Center of gravity (C.G), angular velocity (ω), linear velocity (v), torque (T), Centrifugal force (F_c), Work done in shredding per revolution, Force generated by pin (F_p), Force generated by cane being shredded (F_s) and Stress concentration analysis by which maximum shear stress were calculated for modified Fibrizer hammer. In addition to that, cost comparison was also made between existing and modified Fibrizer hammer.

Table 78.2 Loss through downtime

Year	Month	Nature of failure	Recorded downtime (h)	Loss due to downtime in Quintal	Cost of production in USD	Total in USD
2014	December–April	Fibrizer Hammer breakage	60	13,636.4	750,000	1,512,503
2015	April	Fibrizer hammer breakage & shearing of bolts	40.5	9204.6	506,253	
2016	May	Fibrizer hammer breakage & shearing of bolts	20.5	4659.1	256,250	

Note For 1 Qt = 55USD

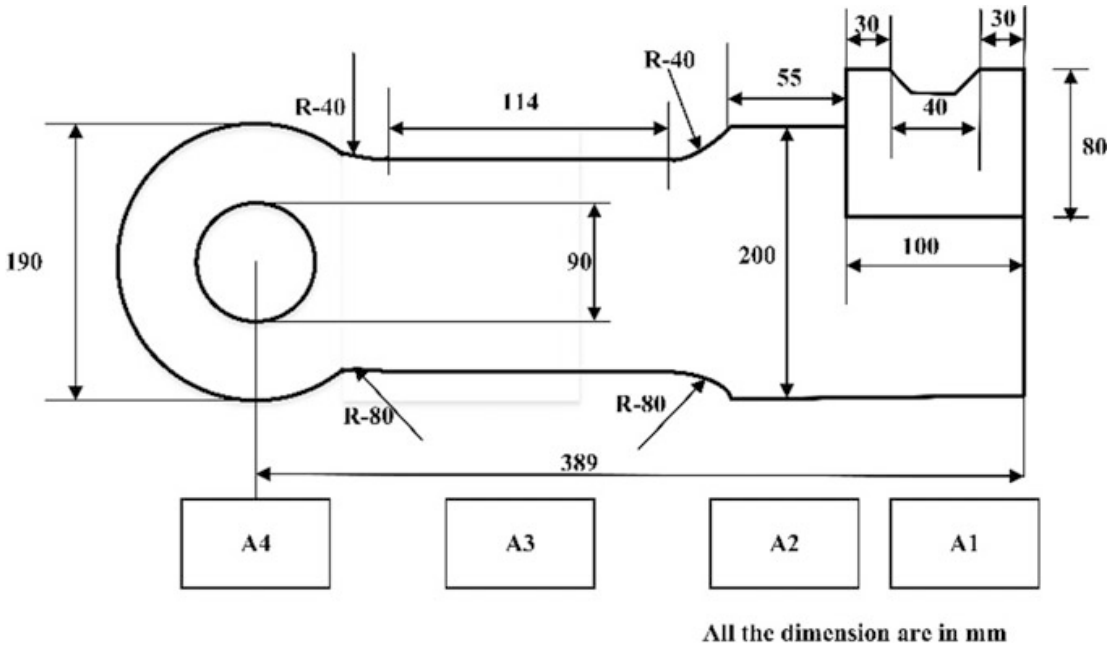

Fig. 78.5 2D schematic diagram of modified Fibrizer hammer

78.2.1.6 Harmonic Analysis Using Finite Element Simulation

A three-dimensional model of Fibrizer hammer was developed in a modeling software SOLDWORKS by comprehensively considering the structural feature, processing requirements, and solution calculation amount for current and modified Fibrizer hammers. This model was imported into ANSYS 18.0, a finite element software as shown in Fig. 78.6. The hammer part adopted the structural steel as per the records. Automatic mesh generation was activated and obtained that the number of nodes were 81,074, unit number was 48,701 for current Fibrizer, whereas 42,601 and 24,487 nodes and units were for modified Fibrizer.

One end of hammer where circular hole existed was fixed and other end of Fibrizer hammer was given the point load of 7136.6 N as boundary conditions. Load was applied along positive y-axis. Simulation results were recorded on harmonic response, total deformation, von Mises stresses, maximum shear stress, and

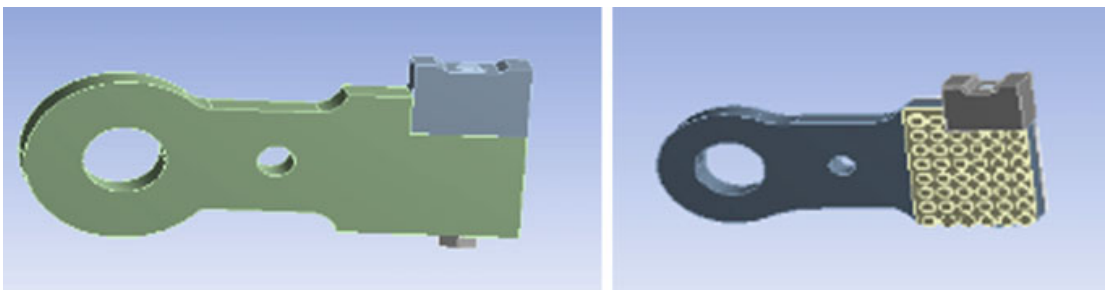

Fig. 78.6 3D model of from solid works to ANSYS current and modified with hard-facing Fibrizer Hammer

maximum amplitude. Young's modulus and passions ratios were 210 GPa and 0.3 considered.

78.3 Results and Discussion

78.3.1 Stress Concentration Factor Analysis Result of the Existing and Proposed Fibrizer Hammer

Stress concentration factor is evaluated with respect to the dimension of exiting Fibrizer hammer and proposed hammer. The final results are tabulated in Tables 78.3 and 78.4.

As the above results shows that the maximum shear stress of the new modified Fibrizer hammer is reduced compared to existing, it indicates that there is less shear stress and less stress concentration factor in modified Fibrizer hammer. The large H/h and the small r/h values give worse stress concentration (k_t).

78.3.2 Load Analysis Result

The result of load analysis for existing and proposed Fibrizer hammer results has been indicated in Table 78.5. The results show that maximum load can be derived with the modified Fibrizer hammer in all directions.

Table 78.3 Stress concentration factor analysis result for existing Fibrizer hammer

H (mm)	h	r	r/h	H/h	k_t	$I = 1/12bc$	$\delta_m = k_tMC/I$ (MPa)
180	100	25	0.25	1.9	1.58	0.0000042	22.6
180	110	40	0.27	1.7	1.34	0.0000055	16.1
180	120	50	0.33	1.58	1.28	0.0000072	13
180	130	60	0.38	1.46	1.23	0.0000092	10.9

Table 78.4 Stress concentration factor analysis for proposed

H (mm)	h	r	r/h	H/h	k_t	$I = 1/12bc$	$\delta_m = k_tMC/I$ (MPa)
190	150	80	0.53	1.27	1.2	0.0000114	8.8

Table 78.5 Load analysis comparison between existing and modified Fibrizer hammer

Hammer	F_c (N/Hammer)	F_p (N)	F_s (N)
Existing Fibrizer hammer	6623	406	314.2
Modified Fibrizer hammer	7170.6	529	342.5

In Table 78.5, the result of centrifugal force of the modified Fibrizer hammer is increased which does work. The higher the centrifugal force, the more would be the preparation index.

78.3.3 Vickers Hardness Results

The test is carried out on each sample at five different locations with three reputations. These results show that the hardness of the material is not the same throughout the hammer. At the hard-facing welded part, the hardness is high and less at the tail part. Due to this, the Fibrizer hammer frequently breaks at the welded part. The welding heat input is important welding parameter, which effects on the structure and properties of the weld metal. At location-1, sample harness result shows that the hardness varied between 110 and 124 VHN. At the location-2, Fibrizer hammer hardness is between 146 and 151 VHN, and at the location-3, hardness is between 152 and 167 VHN.

78.3.4 Cost Comparison Between Existing and Modified Fibrizer

Table 78.6 indicates the cost comparison between existing and modified Fibrizer. The difference in cost between them is $11,088.00.

78.3.5 Harmonic Analysis Results of Existing and Modified Fibrizer Hammers

ANSYS finite element software is used for the simulation to performing harmonic analysis. From the simulation results, total deformation, direction deformation, von Mises stresses, maximum shear stresses, and maximum amplitude are evaluated for existing and modified Fibrizer hammers.

Table 78.6 Cost Comparison

Hammer	No. of hammers	Unit cost in USD	Total cost in USD
Imported Fibrizer hammer	176 pcs	$167	$29,392.00
New fabricated Fibrizer hammer	176 pcs	$104	$18,304.00
	Difference	$63	$11,088.00

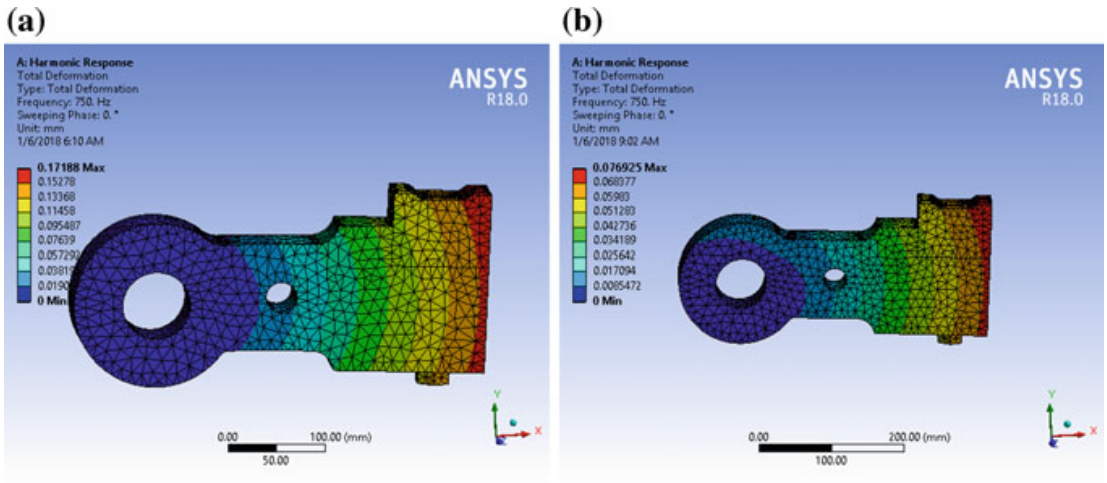

Fig. 78.7 Total deformation of **a** existing and **b** modified FH

From Figs. 78.7, 78.8, 78.9, and 78.10 analysis, results are tabulated in Table 78.7. From the results, it is understood that the total deformation in the modified Fibrizer hammer is lesser than the total deformation of the existing hammer. This shows that the modified Fibrizer hammer is more reliable than the current one. As the result shows that the maximum equivalent (von Mises) stress of current FH is increased by double, the higher the stress, the more the material will be exposed to be broken. The maximum shear stress result in the current Fibrizer hammer is more than the modified Fibrizer hammer. The smaller the radius (r) and web (h) in stepped plate of the Fibrizer hammer, the higher will be the stress.

In Table 78.7, analysis results show that there is less total and directional deformation in modified Fibrizer hammer. The equivalent (von Mises) stress and max. shear stress result also much less by half from the existing.

Similar manner frequency responses are verified for other surfaces also and tabulated in Table 78.8. From Table 78.8 data, the output of harmonic response has been taken in the form of amplitude which can be understood as mean stress development in any engineering components. Modified FH has more amplitude initially and gradually decreased compared to current FH. The overall behavior modified FH is taking less deformations and stresses by which life span of FH definitely will improve.

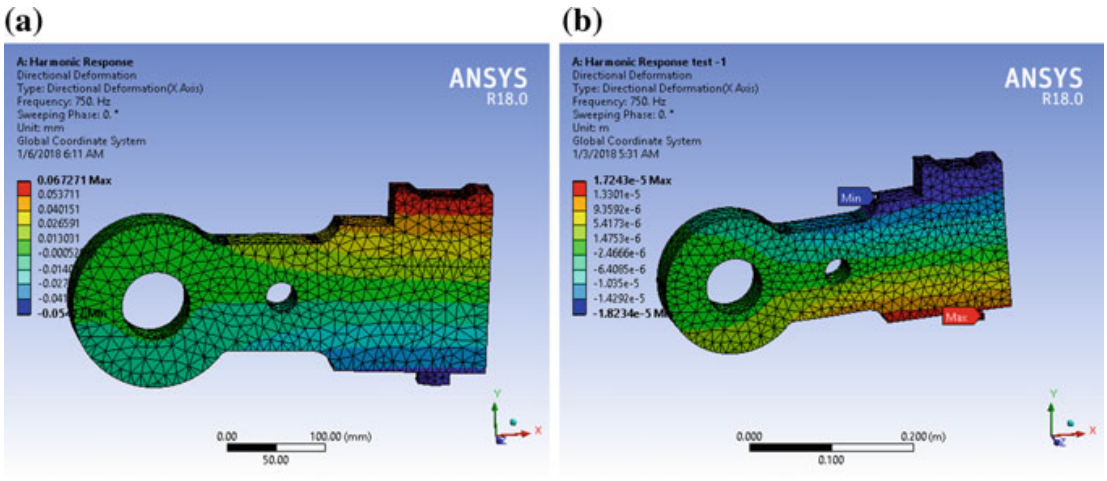

Fig. 78.8 Directional deformation of **a** existing and **b** modified FH

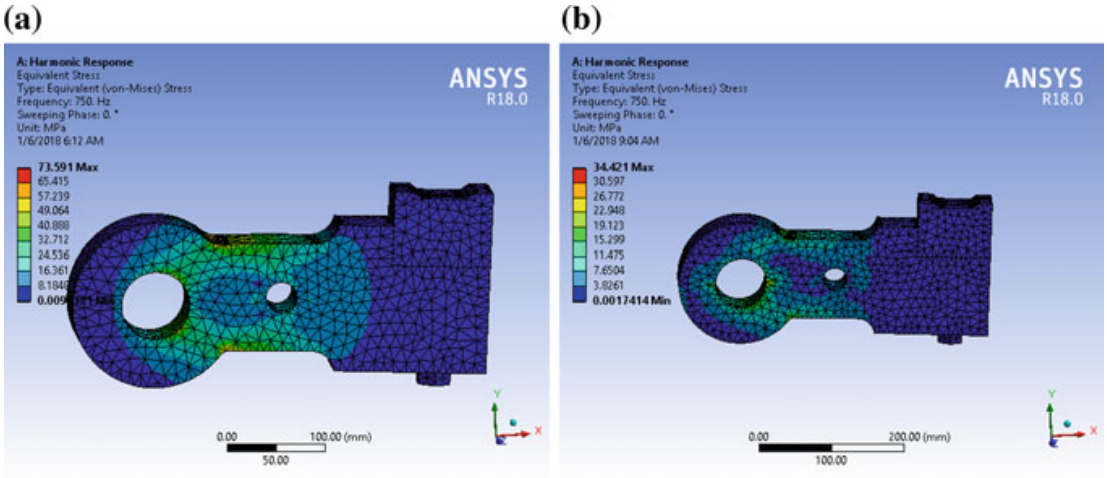

Fig. 78.9 Equivalent (von Mises) stresses of **a** existing and **b** modified FH

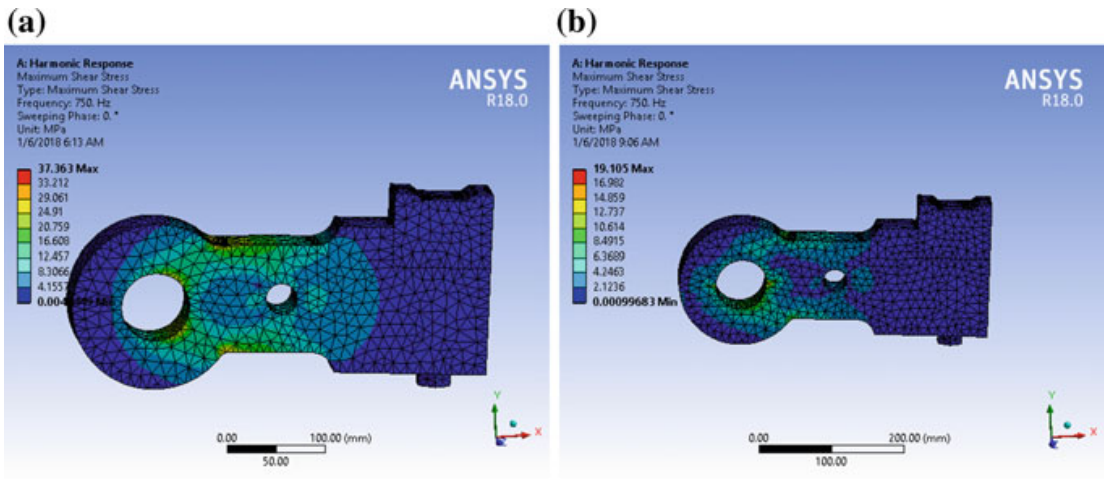

Fig. 78.10 Max. shear stresses of **a** existing and **b** modified FH

Table 78.7 Simulation results on current and modified FH

Parameter	Existing FH	Modified FH
Total deformation	0.1788 mm	0.076925 mm
Max. directional deformation	0.0672 mm	1.7243e − 5 = 0.0116 mm
Equivalent (von Mises) stress	73.591 MPa	34.421 MPa
Max. shear stress	37.363 MPa	19.105 MPa

Table 78.8 Frequency response of modified and current FH

Frequency responses at different surfaces	Modified FH max. amplitude (MPa)	Current FH max. amplitude (MPa)
1	114.9	127.91
2	216.1	184.94
3	28.1	37.25
4	4.5	5.97
5	0.29	0.44
6	0.26	0.24
7	0.59	0.28
8	0.59	0.44
9	0.2	12.07
10	0.38	43.24

78.4 Conclusions

Load and stress analysis of the existing Fibrizer hammer and the new modified Fibrizer hammer are performed. From the results, the stress concentration factor analysis revealed that there is high stress concentration factor on the fillet radius of the existing Fibrizer hammer and less at web thickness (h) that is the cause of the hammer to be broken at the tail part. It shows that the current Fibrizer hammer having design problem and stress concentration factor on the fillet radius of the modified designed Fibrizer hammer is reduced by half. The experimental result of hardness analysis at different locations reveals that the average Vickers hardness of existing Fibrizer is 140.76 VHN. From this experimental result, one can understand that the material property of the Fibrizer hammer is not uniform throughout the hammer. Total deformation, directional deformation, equivalent von Mises stress, max. shear stress and harmonic response analysis of current, and modified Fibrizer hammer were analyzed and compared using FEM software. The result confirmed that the modified Fibrizer hammer having less total deformation, directional deformation, equivalent von Mises stress, max. shear stress, and harmonic response analysis than the current Fibrizer hammer. Using the modified Fibrizer hammer will solve Wonji Shoa Sugar Factory Fibrizer hammer breakage.

Chapter 79
FEA Validation of Experimental Results of First Ply Failure of Composite Structure

Ishan Sonawane and A. Muthuraja

Abstract Laminated composite has gained popularity (despite of their higher cost) in high-performance products that need to have high corrosion resistance, good thermal stability, excellent fatigue resistance, lightweight and high specific strength to take harsh loading conditions such as aerospace components. Based on the literature survey, it is observed that Tsai–Wu criterion is widely used because of its accuracy. In the current study, finite element analysis is being carried out by using MSC Nastran and MSC Patran to identify the critical ply location and strength of first ply failure within laminated composite material plates. Tsai–Wu failure criterion is used to predict the maximum failure indices on each ply of laminated composite material. The results obtained from FEA are validated by comparing with the experimental result.

Keywords Laminates · Composite materials · First ply failure · Finite element analysis

79.1 Introduction

Laminated composite materials have recently gained popularity for different applications in the construction of mechanical, aerospace, marine and automotive structures. In general, these structures require high reliability. Within the laminated structure, plies are oriented in a different direction so as to make the composite structure tailor able when multi-directional loads are applied. This makes the laminated structure highly anisotropic and structurally inhomogeneous. So for reliability conformance, we need to predict accurately that maximum load a ply can sustain before failure. During the design phase of aerospace composite structures,

first ply failure is considered as critical phenomena in composite failure. However, after the first ply failure other ply will carry the loads till the complete failure of composites happens. First ply failure analysis of laminated composite has drawn close attention in recent years. Turvey [1] used analytical methods to study the linear and nonlinear first ply failure loads of simply supported symmetrically and anti-symmetrically laminated composite plates based on the classical lamination theory. Tsai–Hill failure criterion has been used to facilitate an initial flexural failure analysis [2, 3]. Initial flexural failure was analyzed under uniform or non-uniform loading [2]. It was obtained that the initial failure loads decreased with corresponding plate center deflections as plate patch size increases during loading at Z-direction. Tsai–Hill failure criterion was used for angle ply laminates of GFRP and CFRP [3]. It was concluded that the initial failure loads decrease rapidly as theta increases, and the simply supported GFRP strips were obtained to be insensitive to the number of constituent laminas under initial failure loads. Turvey [4] obtained that the initial failure loads were direction-dependent, and simply supported strips were shown superior and increase with increasing number of laminas. Kam and Jan [5] formulated a finite element model for a thick laminated composite plate on the basis of layer wise linear displacement theory. Finite element results were compared between experimental and analysis results for displacements and stresses. Reddy and Pandey [6] developed a finite element computational procedure for the first ply failure analysis of laminated composite based on the first-order shear deformation theory and for a tensor polynomial failure criterion like maximum stress, maximum strain, Tsai–Hill, Tsai–Wu and Hoffman. Kam et al. [7] used a nonlinear finite element method to study the deformation and first ply failure of thin laminated composite plates. This study was based on the principle of minimum total

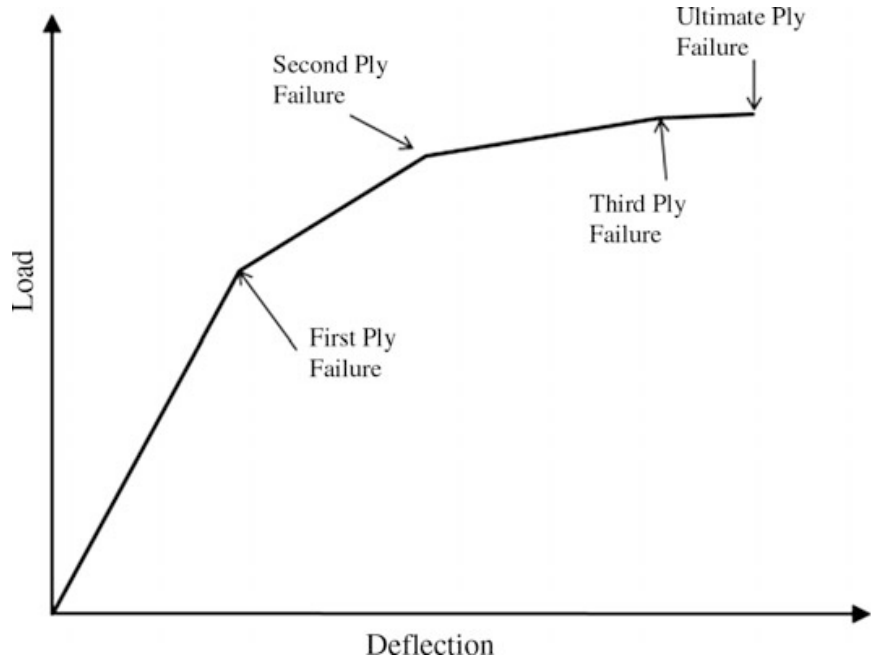

Fig. 79.1 Progressive ply failure

potential energy and von Karman–Mindlin plate theory. Reddy and Reddy [8] developed a finite element computational procedure to find first ply failure loads of composite laminates subjected to in-plane and transverse loads. This analysis was carried out for linear and nonlinear loading conditions, based on the first-order shear deformation theory and other failure criteria.

In the current study, finite element analysis software MSC Patran/Nastran is used to analyze the composite failure. Patran is used as pre-/post-processing, and Nastran is used as a solver. Nastran program was originally developed for NASA (Fig. 79.1).

79.2 Finite Element Method

79.2.1 Finite Element Modeling

In this paper, the finite element method is used to determine the first ply failure strength of laminated composite plate of 100 × 100 mm dimensions. The laminated composite plate is made with equal ply thickness of 0.121 mm and different orientations. Stacking sequence of $\left[45_3^0/0_3^0/-45_3^0/90_3^0\right]_S$ is used to construct the composite laminate. The lamina (graphite/epoxy) properties are considered from the experiments conducted [9] (Table 79.1).

The plate is modeled with 2D elements as the thickness is very less in comparison with other two dimensions. Also, the 2D elements have the ability to capture the bending stiffness. Elements are created on the mid surface and thickness is assigned. Vertically downward concentrated loads of 500, 1000 and 1335 N are applied independently at the center of the plate. It is observed from the result that the first ply failure occurs at a load of 1335 N. Thus, in this paper, a load of 1335 N

Table 79.1 Composite material properties

Material properties (linear elastic)	
Elastic modulus 1 (E11)	139,400 MPa
Elastic modulus 2 (E22)	7650 MPa
Shear modulus 12 and 13 (G12 and G13)	4350 MPa
Shear modulus 23 (G23)	1020 MPa
Poisson ratio (ϑ_{12})	0.29
Strength properties	
Tension stress limit (X_T)	1537.2 MPa
Tension stress limit (Y_T)	42.7 MPa
Compressive stress Limit (X_C)	1722.4 MPa
Compressive stress limit (Y_C)	213.9 MPa
Shear stress limit (S and T)	102.4 MPa
Interaction term	−3.215E − 6
Bonding shear stress limit	5000 MPa

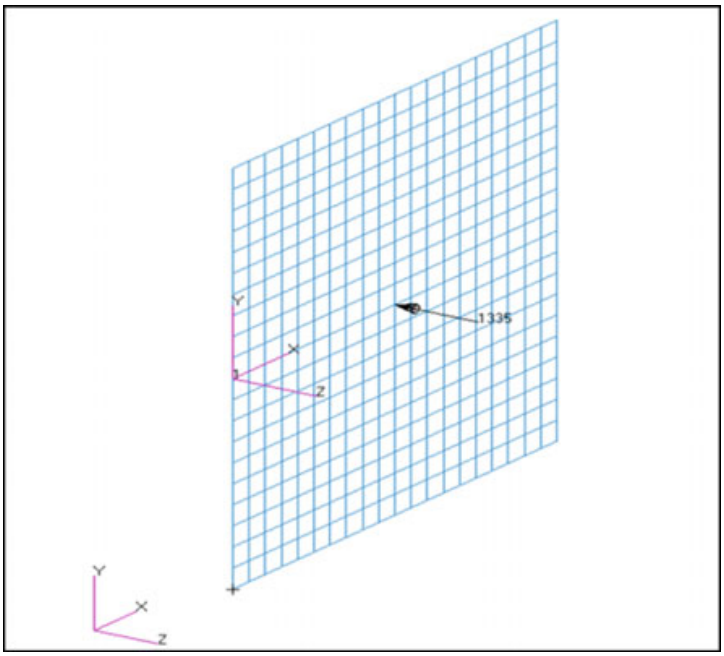

Fig. 79.2 Applied load

is applied as shown in Fig. 79.2, and all results are extracted at 1335 N applied load.

In accordance with experimental method carried out by [5], the model is constrained in all six directions at all four edges as shown in Fig. 79.3.

79.2.2 Results and Discussion

The strength of the composite plate is determined by using Tsai–Wu failure criteria. Figure 79.4 shows that the maximum failure index for non-layered plate occurs at the center of plate. Figure 79.5 shows that Tsai–Wu failure index of 1 is observed at the bottom ply location at the center location. During experimental tests, T. Y. Kam and F. M. Lai found that the first ply failure occurs at the bottom location with applied load of 1320 N. The FEM result is compared with the experimental result [5] and found that there is 1% difference of failure load between the experimental and FEA results. In both cases, first ply failure occurs at the bottom location.

79.3 Theoretical Approach

The constitutive model is considered in the linearly elastic region, and Tsai–Wu criterion is used to predict the first ply failure of the laminated plate using the maximum failure index. A number of failure criteria for composite laminate proposed over the years are maximum stress, maximum strain, Hill–Tsai, Tsai–Wu. Stress interaction between the laminates is ignored for maximum stress and

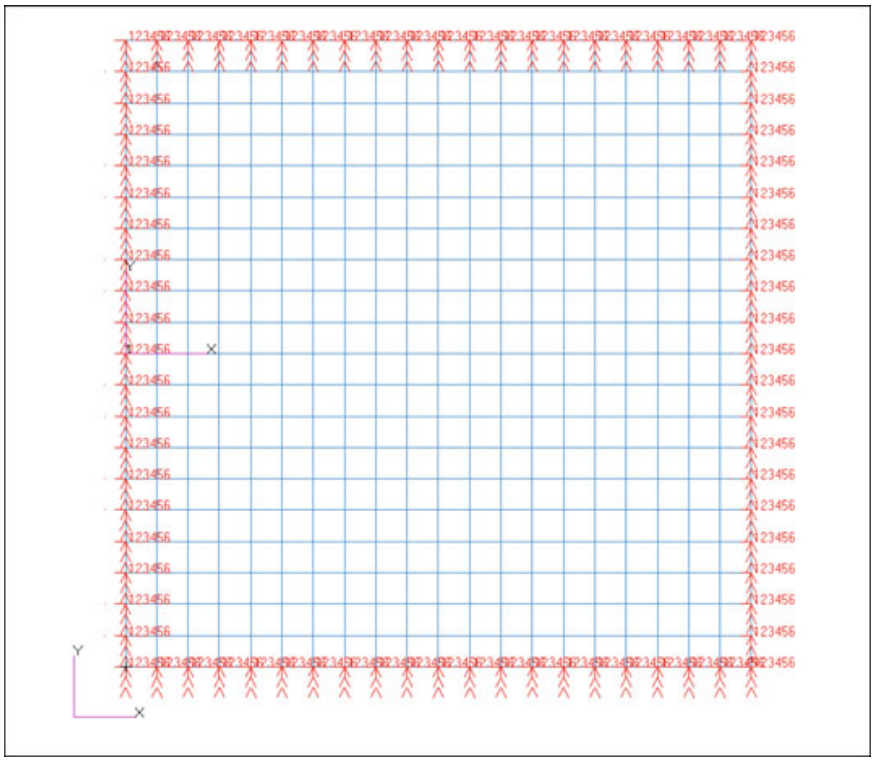

Fig. 79.3 Boundary conditions

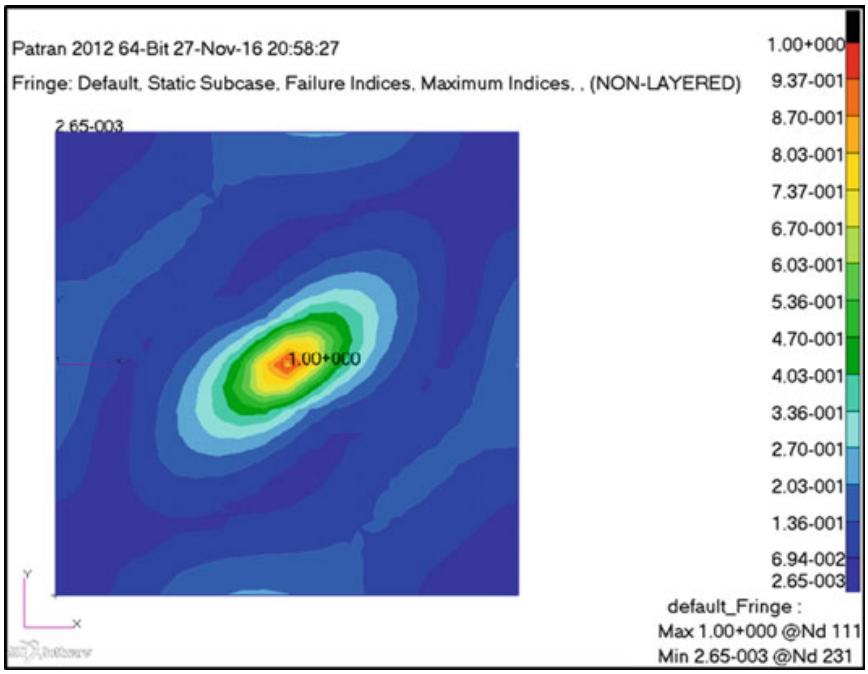

Fig. 79.4 Maximum failure index

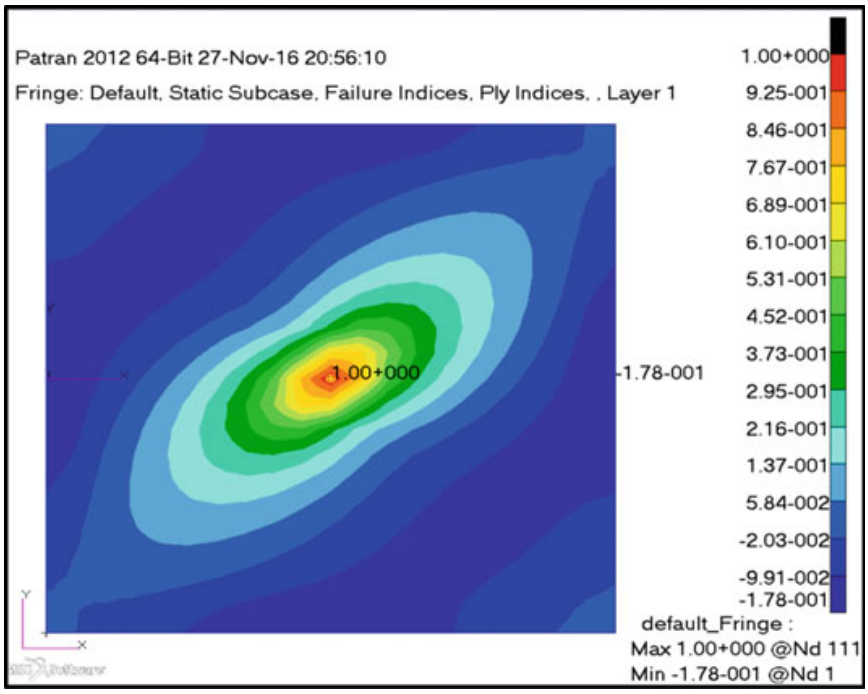

Fig. 79.5 First ply failure

maximum strain criteria; whereas, Hill–Tsai and Tsai–Wu criteria include full stress interaction.

The Tsai–Wu failure criterion is a macro-mechanical failure theory which is prominently used for anisotropic composite materials which have different strengths in tension and compression. Tsai–Wu uses strength tensors (F_i and F_{ij}) established through experiment. Theoretical predictions of Tsai–Wu criterion match very well compared with the experimental data.

Tsai–Wu theory predicts that the failure occurs when below criteria is satisfied

$$F_i\sigma_i + F_{ij}\sigma_i\sigma_j \geq 1 \text{ where } i,j = 1,2\ldots6$$

(Summation is done for repeated indices)

$$F_1 = \frac{1}{X_T} - \frac{1}{X_C} \quad F_2 = \frac{1}{Y_T} - \frac{1}{Y_C} \quad F_3 = \frac{1}{Z_T} - \frac{1}{Z_C} \quad F_{11} = \frac{1}{X_T X_C} \quad F_{22} = \frac{1}{Y_T Y_C}$$

$$F_{33} = \frac{1}{Z_T Z_C} \quad F_{44} = \frac{1}{R^2} \quad F_{55} = \frac{1}{S^2} \quad F_{66} = \frac{1}{S^2}$$

$$F_{12} = -\frac{1}{2\sqrt{X_T X_C Y_T Y_C}} \quad F_{13} = -\frac{1}{2\sqrt{X_T X_C Z_T Z_C}} \quad F_{23} = -\frac{1}{2\sqrt{Y_T Y_C Z_T Z_C}}$$

X_T, Y_T, Z_T (X_C, Y_C, Z_C) Lamina normal tensile (compressive) strength in 1, 2 and 3 directions.

R, S	Shear strengths in the 23 and 12 planes, respectively.
σ_1, σ_2, σ_3	Normal stress components; σ_4, σ_5, σ_6: shear stress components

For the analysis, shear strengths in the 12 and 13 planes are assumed to be same and $Y_T = Z_T$.

79.4 Conclusions

First ply failure strengths of laminated composite plates with different layups were determined using FEA, and the results were validated by using experimental data. The Tsai–Wu failure criterion is used to calculate the failure index.

1. It is observed that there is 1% difference of failure load between the experimental and FEA results. Bottom most layer shows the maximum failure index under 1335 N loading condition comparatively other layers. It shows the accuracy of first ply failure prediction from both the methods.
2. In composite laminate, the stacking sequence plays an important role in improving the strength with different loading conditions. During the design phase, stacking sequence changed frequently so as to obtain feasible design. By experimental methods, we can evaluate the first ply failure strength and location. But experimental setup and procedure results are in high cost. During design phase, it is difficult to go for experimental results every time, which results in

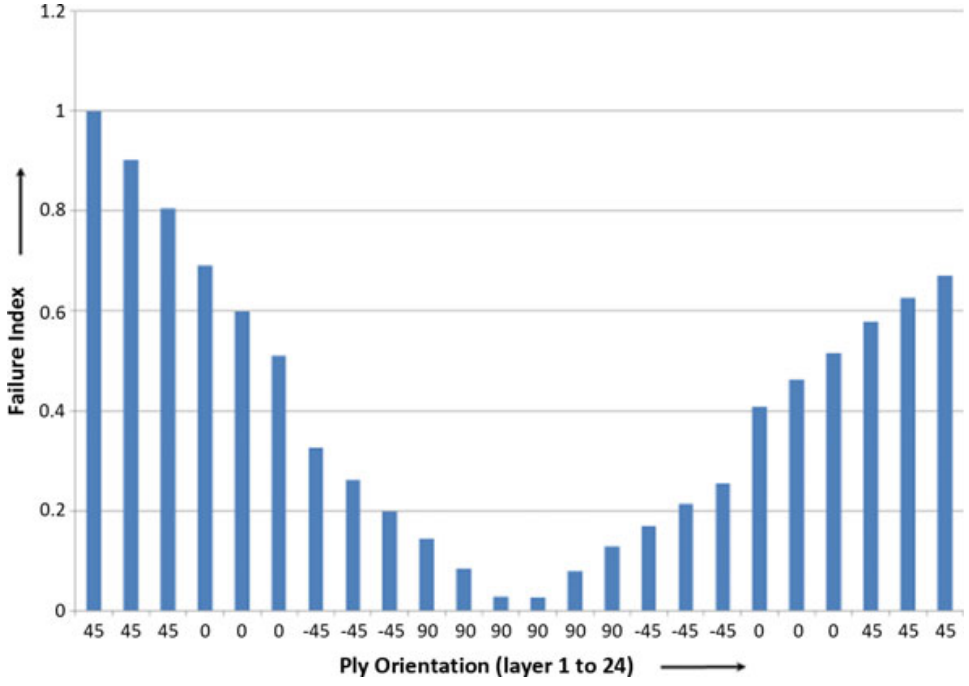

Fig. 79.6 Failure indices of different ply orientation

high cost. By FEA, we can predict the first ply failure strength and location. Also, we can predict the strength of other critical plies as shown in Fig. 79.6.

3. After the first ply failure, the composite will not fail suddenly, and the loads are transferred to other plies. It is important to detect the remaining strength in the structure till final failure. In many cases, composite structures are connected with metallic joints. Composites are weaker at the joint location. So, further study needs to be done on the first and progressive ply failure analysis at composite joint location.

Acknowledgements First and foremost, we praise and thank our almighty God whose blessings have bestowed on us the will power and confidence to carry out this paper. We would also like to thank all our friends and our parents who have prayed and helped us during the project work.

Chapter 80
Triply Periodic Minimal Surface-Based Porous Scaffold Design and Analysis Subjected to Hard Tissue Reconstruction

Verma Rati, Nishant Singh, Sanjay Rai and Shekhar Kumta

Abstract Porous structures based on triply periodic minimal surfaces (TPMS) have occurred as appropriate candidates for scaffold design with high level of porosity and promising strength for bone replacement. This work describes a suitable procedure for design and modeling of 3D architecture of TPMS-based gyroid and primitive structures and identifying the optimal architecture for scaffold designing. Different models with varying porosity were reconstructed and analyzed to access the effective elastic moduli and compressive strength of each model. An optimal model that can be utilized in bone tissue replacement is identified eventually. Ti6Al4V which is considered as the best material for producing implants in conjunction with biocompatibility and strength is used in the study. The compression test performed by FEM revealed that the scaffold models with porosity level of 65 and 60% are best suited for cortical bone replacement and the model with 90% porosity can be used on the anatomical location, which are more inclined to cancellous bones.

80.1 Introduction

The field of tissue engineering aims to develop an efficient biological substitute in order to preserve, maintain, or enhance the function of tissue. Scaffolds play a significant part in deciding mechanical characteristics of desired tissue formed in it at a macroscopic or microscopic scale and also provides the vascularization needed by the newly forming tissues [1]. Scaffold must be biocompatible, bio-inert, bioactive, bioresorbable, and biodegradable so as to work efficiently to possess long term results [2]. Porous scaffold, therefore, provides necessary temporary atmosphere for adhesion, propagation, and differentiation of cell [3], together with the transport phenomena and degradation behavior [4]. Other advantages of these porous scaffolds include its flexibility in terms of mechanical properties, a large surface area that enables bio-functionalization and infection prevention and accelerates bone ingrowth as well as facilitates drug delivery in implants [5]. To establish a balance between the mechanical properties of scaffold and porosity is a challenge [1, 6]. Tissue regeneration efficiency is greatly affected by scaffold pore size [3].

Triply periodic minimal surface (TPMS) is an emerging area of interest for designing the scaffolds because of its unique properties like the ability to mimic the organic system and to build self-supportive structures for additive manufacturing [7, 8]. Another reason for TPMS-based scaffolds to draw the attention toward it is because of its capability to provide site-specific biological performance [9]. TPMS is defined in mathematical terms as surface curvatures which are infinite and periodic in 3D Euclidian space that owes to a surface capable of generating highly controllable and homogeneous scaffold design [10]. TPMS have implicit periodic surfaces in three independent Cartesian directions with mean curvature equal to zero [11]. These minimal surfaces play a very essential role in guiding chemical, cellular, and biochemical processes [10]. The TPMS-based porous structures have the potential to attain the lightweight bone models and medical requirements of bone tissue, thus providing a solution for the production of biomimetic bone in biomaterials and tissue engineering [12].

Observing the TPMS topology for Schoen's gyroid that perfectly suits the porous-solid structural configuration ideal for tissue engineering scaffolds [4, 13–16], this paper emphasizes on TPMS surface geometry and gyroid surface, particularly.

The present study aims to develop a porous scaffold based on TPMS geometry that possesses the mechanical properties (elastic modulus and compressive strength) proximate to bone. The study utilizes Schwarz's primitive (P) and Schoen's gyroid surface (G) structures to design bone scaffolds as their macroscopic structure is analogous to bone. Ti6Al4V (Grade 5) regarded as a biocompatible material is employed with its mechanical properties with scaffold porosities within the range of 60–90%. Unit cell length and pore size are varied with wall thickness kept constant at 102 μm for G and 133 μm for P, respectively, to achieve porosities within the desired range for both the structures (P and G). Finite element analysis was performed in ANSYS® software with static loading and boundary conditions for the

determination of compressive strength based on von-Mises criteria to study the deformation behavior and to estimate the effective elastic moduli and compressive yield strength.

80.2 Materials and Method

80.2.1 TPMS-Based Porous Scaffold-Primitive (P) and Gyroid (G) Surface Modeling

Both the primitive (P) as well as gyroid surface are designed from the basic parametric equations with implicit functions described in Eqs. (80.1) and (80.2).

$$\text{Primitive}\,(P)\text{: } \cos(x) + \cos(y) + \cos(z) = 0 \tag{80.1}$$

$$\text{Gyroid: } \sin(x) * \cos(y) + \sin(y) * \cos(z) + \sin(z) * \cos(x) = 0 \tag{80.2}$$

The unit cell of TPMS is designed with a MATLAB code, executed in the MATLAB® (v. R2016a) software. "MESHGRID" command along with "ISOSURFACE" command was used to extract the isosurface 3D data from the volume 3D data generated by "MESHGRID" command.

The unit cell was extended periodically in x, y, and z directions by modulating the Eqs. (80.1) and (80.2) as described in Eqs. (80.3) and (80.4) [17].

$$\text{Primitive}\,(P)\text{: } F_P = \left[\cos\left(\frac{2\pi Nx}{L}\right) + \cos\left(\frac{2\pi Ny}{L}\right) + \cos\left(\frac{2\pi Nz}{L}\right)\right] - P \tag{80.3}$$

$$\begin{aligned}\text{Gyroid: } F_G(x,y,z) = \Bigg[&\sin\left(\frac{2\pi Nx}{L}\right) * \cos\left(\frac{2\pi Ny}{L}\right) + \sin\left(\frac{2\pi Ny}{L}\right) * \cos\left(\frac{2\pi Nz}{L}\right) \\ &+ \sin\left(\frac{2\pi Nz}{L}\right) * \cos\left(\frac{2\pi Nx}{L}\right)\Bigg] - P\end{aligned} \tag{80.4}$$

where N defines the number of unit cells, L is length of the unit cell, and P is the strut thickness parameter that controls the volume fraction in a unit cell. For a scaffold with 3 × 3 × 3 unit cells (Fig. 80.1), value of N was fixed at $N = 3$, unit cell length L was varied due to which the pore diameter and total scaffold length were altered accordingly as listed in Table 80.1. Seven models for each surface (primitive: P_1–P_7 and gyroid: G_1–G_7) type were designed. As a result, a total of fourteen models were designed. P is kept constant at $P = 0$ to fix the volume fraction at 50%. "STLWRITE" command was added to the MATLAB code to export the geometry as stl file which can be imported to other software for finite element analysis (FEA).

Pore size (D) (μm)	1654	1074	776	600	488	407	340

80.2.2 Design and Formulation of Finite Element Model for FEA

The surface models of P surface and gyroid were imported in 3-matic software as stl files and fixed for any errors in the surface. Wall thickness was developed and the model was exported to ANSYS software for FEA after performing surface and volume meshing. The complete procedure is explained in the following subsections.

Developing wall thickness and preparing Finite Element Models

Stl files generated through MATLAB software were imported in 3-matic software for assigning wall thickness to the surface and carrying out surface and volume meshing. The surface of the models of gyroid and P were thickened with a uniform offset of 102 µm and 133 µm, respectively (Fig. 80.1). Since, offsetting the surface disturbed the surface geometry (mesh) of gyroid structures, surface meshing was performed with specific 3-matic tools to improve the quality of surface mesh. Additionally, to reduce the density of the triangles and improve the quality of mesh, quality preserving reduce triangles tool followed with uniform meshing with a target triangle edge length of 0.2 was performed in a manner that element quality is preserved. The shape-quality threshold and maximum geometrical error values were fixed to 0.5 and 0.05, respectively [7].

The generated models were checked for errors and fixed accordingly. Consequently, the number of inverted normal, noise shells, bad contours, planar holes, overlapping triangles, and intersecting triangles present in each model were fixed manually to obtain a single shell with no errors. Volume meshing was done to solidify the surface models with voxel size of Tet4 elements. The volumetric models of all scaffolds generated in 3-matic software were imported to Ansys software as stl files.

Assigning Material properties, Boundary conditions, and Load parameters

Ti6Al4V (Grade 5) material considered suitable in terms of a compatible biomaterial for implants is used for FEA [18]. The elastic isotropic material properties of Ti6Al4V adopted in the study include Young's modulus of 114 GPa, Poisson's ratio of 0.33, density of 4.43 g/cc, and compressive yield strength of 1070 MPa [19].

Remeshing with 4-node SHELL181 hexahedral element was performed for each model (Fig. 80.2). Two rigid plates are fixed at the top and bottom of each scaffold to assign the boundary conditions and loading. The bottom plate is constrained in all directions while a static compressive load of 75 N is applied in negative Y direction at the top plate (Fig. 80.3).

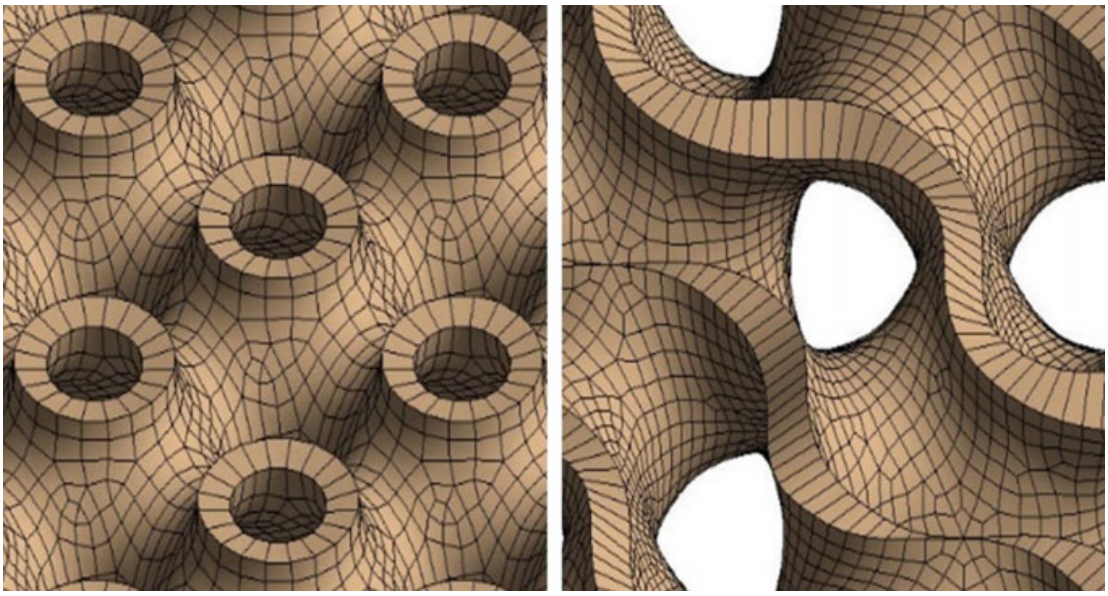

Fig. 80.2 Remeshed models with four-node hexahedral elements for primitive (left) and gyroid (right) surfaces

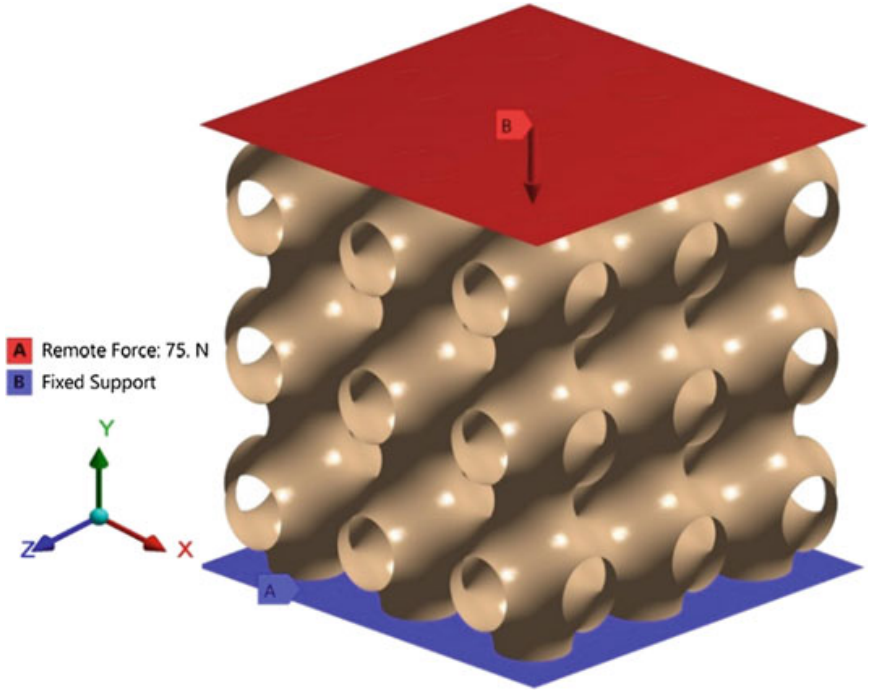

Fig. 80.3 Application of boundary conditions and load parameters. Two rigid plates, red and blue are fixed at top and bottom of designed scaffold structure and compressive load of 75 N is applied in negative Y direction

Table 80.2 Porous volume (V_P) and solid volume (V_S) of primitive (P_1–P_7) and gyroid (G_1–G_7) models

	P_1	P_2	P_3	P_4	P_5	P_6	P_7
(V_P) (μm^3)	2897.9	1287.9	763.62	495.08	348.26	260.81	195.89
(V_S) (μm^3)	28333.5	8395.1	3832.3	2000.8	1180.2	764.9	497.9
	G_1	G_2	G_3	G_4	G_5	G_6	G_7
(V_P) (μm^3)	3123.7	1402.2	780.92	499.79	352.65	262.7	198.37
(V_S) (μm^3)	31006490	9325.9	3875.8	1984.2	1176.2	756.207	496.191

80.3 Porosity

Porosity was calculated from the relation expressed in Eq. (80.3) [20].

$$N = 1 - \left(\frac{V_P}{V_S}\right) \tag{3}$$

where V_S is the solid volume and V_P is the volume of porous construct. The solid volume constitutes the total volume of cubic construct. Solid volume (V_S) and porous volume (V_P) were calculated all primitive (P_1–P_7) and gyroid surface (G_1–G_7) models with different porosity levels (60–90%) as listed in Table 80.2.

80.4 Results

The effective elastic modulus as well as compressive strength was calculated for each model. Effective elastic moduli were determined from Hooke's law ($\sigma = \varepsilon E$) and compressive strength was obtained from von-Mises criteria. The performance characteristics of scaffold structure with 3 × 3 × 3 unit cells were observed under static compressive load of 75 N. Total von-Mises stress distribution and maximum deformation were measured for scaffolds with varying length and porosity (Fig. 80.4). Compressive strength for each model was determined by the load of 75 N that caused the maximum stress of 909.24 and 1102.5 MPa in P surface model and gyroid surface model, respectively, with 70% porosity (Fig. 80.4a, b). Maximum deformation of 28.542 and 22.875 µm was obtained for P surface model and gyroid surface model, respectively, with 70% porosity (Fig. 80.4c, d). Variation in elastic modulus and compressive strength with respect to porosity has been plotted (Fig. 80.5).

80.5 Discussion

Numerous studies have been carried out the design and manufacturing of TPMS-based porous scaffold materials because of the challenges imposed in this field [9, 20–22]. In order to obtain a scaffold that perfectly mimics mechanical properties similar to bone, the effective elastic moduli in addition to compressive strength of the scaffolds are obtained proximate to the bone [23, 24]. Elastic modulus for cortical bone has been noted in the range of 3–30 GPa, whereas for cancellous bone, it is in the range of 0.02–0.2 GPa. Also, the compressive strength for cortical and cancellous bone is reported as 100–230 MPa and 2–12 MPa, respectively [25]. Although, the mechanical characteristics of bone with compressive load show a discrepancy with according to various factors (age, gender, and anatomical locations) within a human body [26–28]. Therefore, a scaffold is designed in such a way so that a balance between the porosity level and mechanical properties can be maintained [29–31]. This prevents the bone from stress shielding as well as reabsorption due to bone–scaffold interaction [32, 33]. TPMS-based porous scaffolds also enhance the bone ingrowth and weight-bearing capacity due to their exceptional porous architecture that are lightweight in comparison with the conventional solid scaffolds [12, 33–35].

Figure 80.5 characterizes the mechanical properties comprising the effective elastic moduli along with stress distribution for primitive and gyroid surface models with varying porosity under a compressive load of 75 N in inverse Y direction. Effective elastic modulus and compressive strength for both structures (primitive and gyroid) was maximum for minimum porosity of 60% and followed a pattern to decrease with increasing porosity.

Observing the characteristics of effective elastic moduli (Fig. 80.5a), a maximum effective elastic modulus of 43.73 MPa for *P* surface and 39.36 MPa for gyroid surface was obtained in case of 60% porosity. However, a minimum value of 6.625 MPa for *P* surface and 5.628496 MPa for gyroid surface was obtained in case of maximum porosity of 90%.

Likewise, the compressive strength (Fig. 80.5b) was also observed to be maximum in case of 60% porosity for both primitive surface (100.519 MPa) and gyroid surface (96.029 MPa). A minimum value of von-Mises stress was obtained in case of 90% porosity for primitive surface (25.52178 MPa) and gyroid surface (21.06333 MPa). However, it can be noted that, for 80% porosity, the compressive strength was approximately equal for *P* surface (49.78 MPa) and gyroid surface (48.68 MPa).

As a result, it can be concluded that effective elastic moduli of gyroid surface models were lower than *P* surface models for all the porosity levels. Similar to the pattern of effective elastic moduli, compressive strength was also observed to be low for gyroid surface models as compared to *P* surface models for all the porosity levels ranging from 60 to 90%.

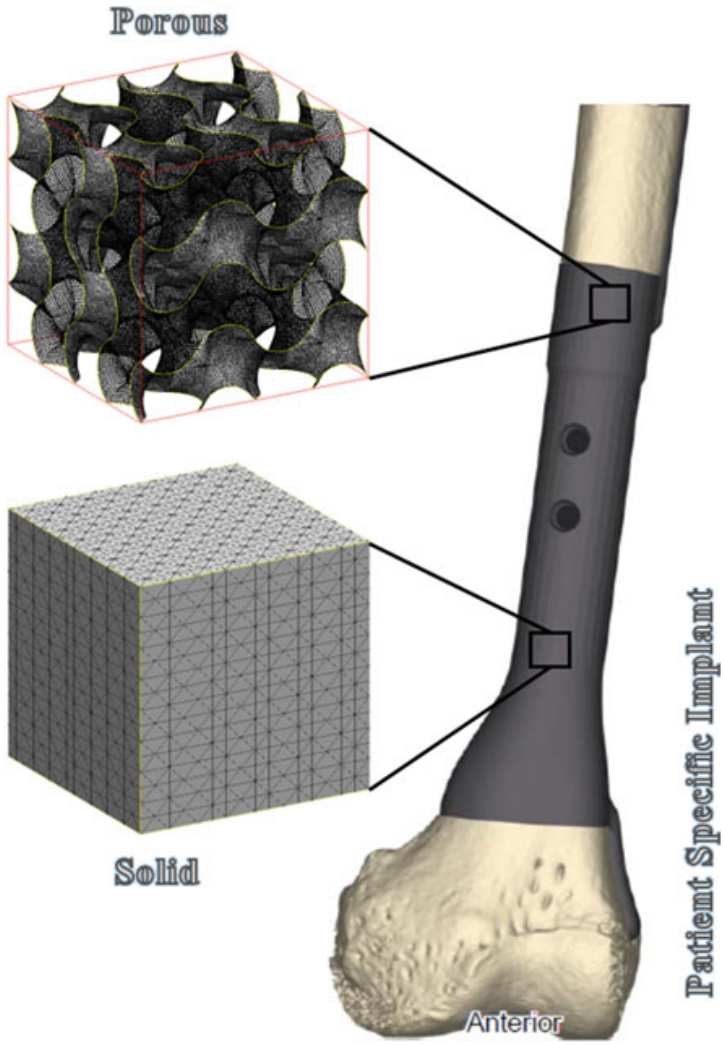

Fig. 80.6 Illustration of mapping of developed porous scaffold to treat large segmental bone defect

The conclusions of this pre-clinical analysis study elucidated the proficiency of design criterion for selecting an efficient scaffold structure in order to obtain the preferred value of the mechanical properties intended for patient-specific implant manufacturing that can be used for treating large segmental bone defects [36], where high porosity scaffolds are greatly needed (Fig. 80.6).

The overview of outcomes achieved in accordance with the mechanical properties of TPMS-based porous scaffold recommended their applicability at different anatomical locations according to the porosity level and suggested them to be appropriate structures for applications in bridging the bone gaps. However, the result is effective merely for desired scaffold structure requirements. The working fundamentals can be followed for other porous scaffold structures and biomechanical bone properties.

Chapter 81
Design of Medical Device Product Using Multiphysics Simulations

Rajesh Kapuganti

Abstract The primary function of kidneys is to remove waste and other impurities from the blood of a human being on a daily basis. When the kidneys stop functioning properly, the toxins from the blood have to be removed through an external device, dialyser. The dialyser mimics the kidney and draws the blood out of the patient, purifies the blood and infuses them back into the patient's body. When the blood is infused back to the human body, it has to be at 37.6 °C failing which would lead to hypothermia, a fatal condition. To avoid this fatal condition, the body is heated to human body blood temperature 37.6 °C. The blood flow rate in the bloodline can vary over a wide range but still the blood has to be heated to 37.6 °C which is human body blood temperature. To raise the human body temperature to 37.6 °C, a sub-component in the dialyser machine called blood warmer takes care of heating. Since it is a medical device which interacts with the patient, the precision of 0.5 °C is expected over a range of flow rates based on patient's medical condition. The scope of this work is the design of a precise blood warmer which is effective than existing. The multiphysics simulations helped the engineers to visualize, observe and understand the physics involved during the design stage.

Keywords Multiphysics · Blood warmer · Product design · Flow rate and heat supply

81.1 Introduction

Dialysis is a process through which waste products artificially removed from the blood to compensate for the presence of an abnormally functioning kidney. In a healthy kidney, excess fluids and electrolytes such as sodium and potassium are removed from the body in the form of urine. In the case of kidney disease, the loss

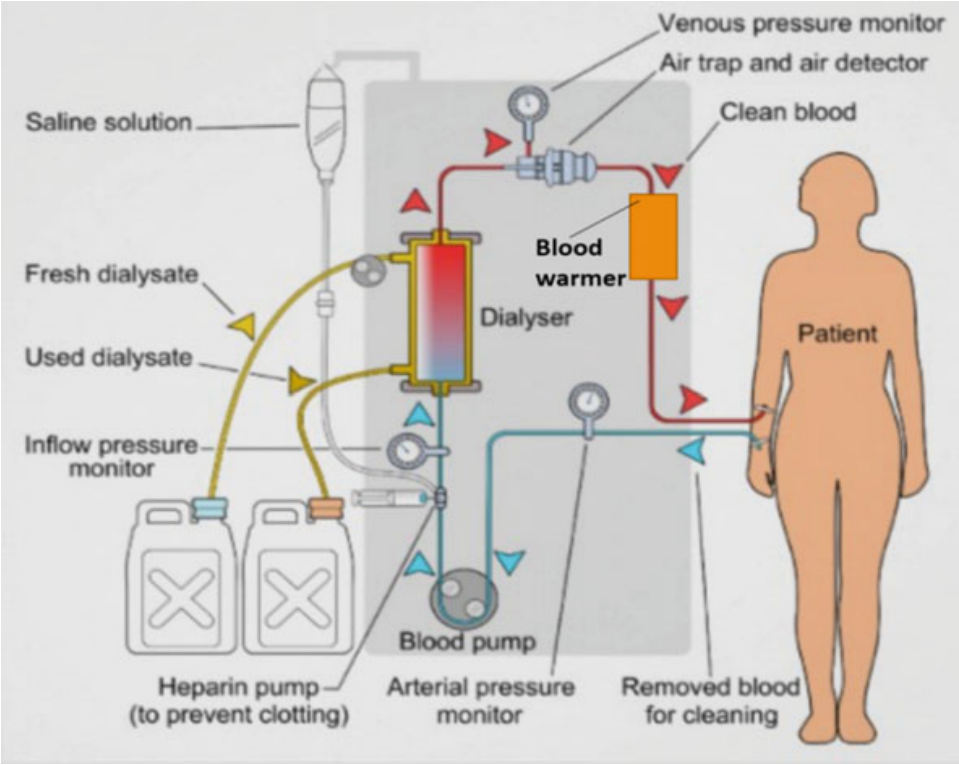

Fig. 81.1 Blood warmer

of kidney function results in the accumulation of excess waste, toxins or fluids in the body thereby causing other complications such as hypertension, heart failure, metabolic acidosis and hypokalemia [1]. Dialysis is performed in the situations of acute kidney failure and to remove toxins in blood from the body (Fig. 81.1).

81.1.1 Blood Warmer

Blood warmer is a sub-component in dialyser machine which is intended to deliver the blood or fluids before to transfusion to a human body at 37 °C which is the set temperature. Malfunctioning of the blood warmer device could lead to hypothermia. The blood warmer heats the blood to the desired temperature (37 °C) that is non-toxic for infusion.

The resistance heating technology which has a silicone heater patch and aluminium plates between which the fluid tubing passes was selected based on the thermal efficiency results. In designing the heating plate in the blood warmer, the data needed are type of plate material, plate dimensions, the effective area of the heating plate, the upper and lower temperature limits of the heating plate and the discharge of blood flow [1].

Though current blood warmers can heat blood to the human body blood temperature, the challenges are temperature management, heat mapping across the plate, optimum sensor location and the determination of the right compensation factor for dynamic control algorithm. This study was performed to improve the performance and functional aspects of the blood warmer design.

The device manufacturer supplied the complete list of product requirement specifications which had all the details of constraints, functionalities and geometric details. The design and development of blood warmer subassembly involved a multidisciplinary team which consisted of simulation, software, hardware, CAD, electrical, testing, industrial design and materials engineers.

However, in this paper, only the electro-thermo-fluid interactions of the multiphysics simulations are discussed. The multiphysics simulation procedure and the results are discussed.

81.2 Multiphysics Simulation Procedure and Results

81.2.1 Simulation Procedure

The multiphysics simulations were performed to determine the power input required for eight different flow rates to reach a desired set temperature of 37.6 °C from the inlet temperature of 30 °C. The range of flow rates used in the simulation are 100, 150, 200, 250, 300, 350, 400 and 450 ml/min. By varying the power input applied on the heating coils of heater plates, the power required to achieve the desired set temperature was determined. A convective heat transfer coefficient of 10 W/m^2 K was assumed considering that the heating unit is placed in an enclosure. The operating fluid was assumed as water instead of blood to avoid the nonlinearities. Humidity effects were not considered in the simulation.

The voltage difference was applied on the coil path of the top plate and the bottom plate (to generate joule heating in the plates). A perfect thermal contact was assumed between the disposable and heater plates.

The blood warmer assembly used in the dialysis machine consists of four components, the fluid domain, blood flow path, the heater coil and the two aluminium heater plates. The material properties of the different components used in the simulations are as listed in Table 81.1 (Fig. 81.2).

81.2.2 Simulation Results

The power required for the flow rates 100, 150, 200, 250, 300, 350, 400, 450 (ml/min) are 60, 89, 118, 148, 177, 206, 234, 264 (W), respectively, as listed in the Table 81.2.

Table 81.1 Material properties of the blood warmer assembly

S. No.	Component	Material	Property	Values	Unit
1	Fluid	Water	Specific heat	4181.8	J/kg K
			Density	1000	kg/m^3
			Dynamic viscosity	1.002	(Pa-s, N-s/m^2) $\times 10^{-3}$
			Kinematic viscosity	1.004	(m^2/s) $\times 10^{-6}$
			Thermal conductivity	0.58	W/(m K)
2	Blood flow path	Polyethylene	Specific heat	1800	J/kg * K
			Density	1500	kg/m^3
			Thermal conductivity	0.209	W/(m K)
3	Heater plate	Aluminium	Specific heat	956	J/kg * K
			Density	2699	Kg/m^3
			Thermal conductivity	165	W/(m K)

Table 81.2 Heat energy required versus mass flow rate

S. No.	Mass flow rate (ml/min)	Heat energy required (W)
1	100	60
2	150	89
3	200	118
4	250	148
5	300	177
6	350	206
7	400	234
8	450	264

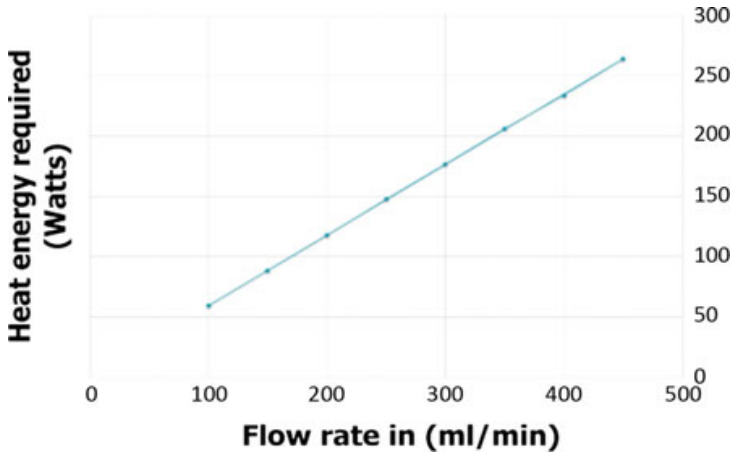

Fig. 81.3 Relationship between heat energy and flow rate

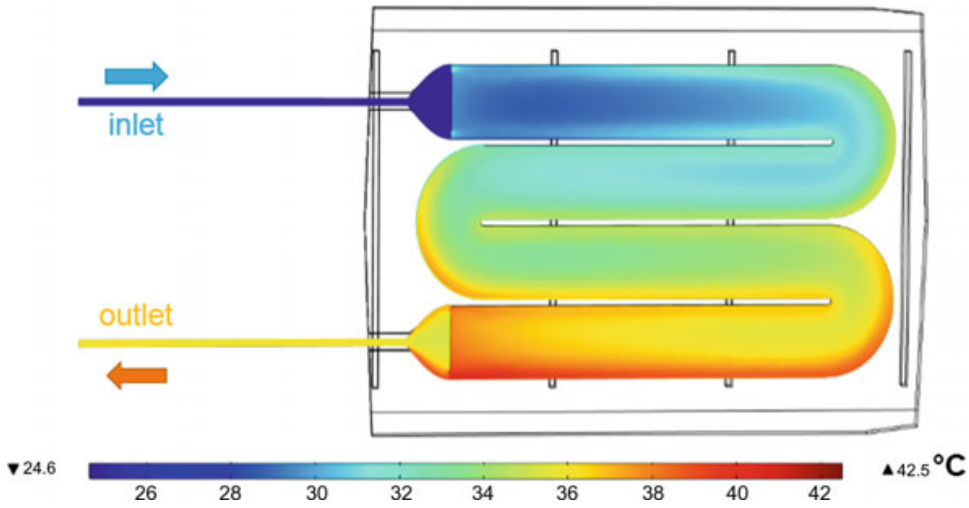

Fig. 81.4 Temperature distribution along the blood flow passage

There is a linear directly proportional relationship between the mass flow rate and heat energy required as depicted in the Fig. 81.3. The spatial thermal distribution of the blood flow path is depicted in the Fig. 81.4. The temperature of the fluid increases along the blood flow passage.

The temperature distribution is higher in the exit region of the blood warmer and lower at the entry region of the blood warmer. The spatial thermal variations on the heater plate are depicted in Fig. 81.5.

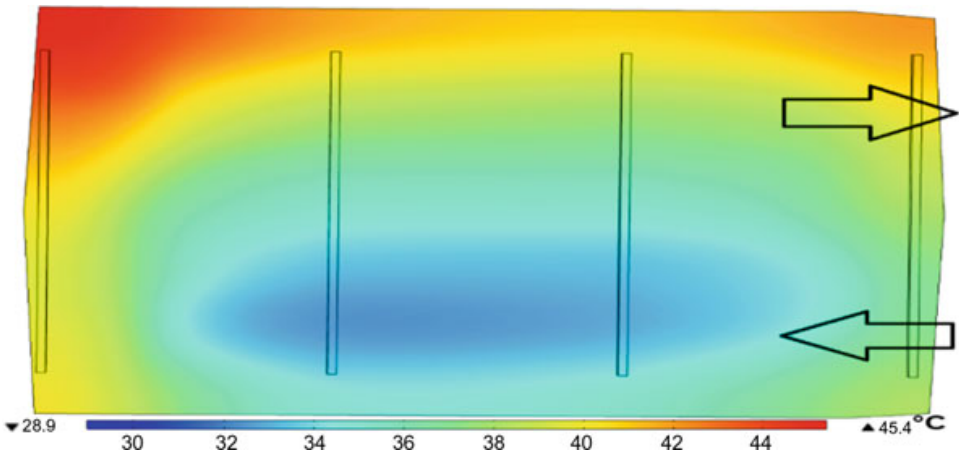

Fig. 81.5 Temperature distribution in the heater plate

81.3 Conclusion

1. Based on the simulation results, the heat energy required at different flow rates to heat the blood to 37 °C was obtained. This information was useful for further developments in the product design cycle. There is a linear relationship between the flow rate and heat energy required.
2. The temperature gradient is observed across flow passage as it gets heated up.
3. The correlation between testing and multiphysics simulation results was good. The multiphysics simulations were coupled with MATLAB for creating the algorithms, which was possible because of the virtual prototyping capability of COMSOL.
4. The product development process has been shortened in the concept and prototyping phase by effectively using multiphysics simulations.

Chapter 82
Finite Element Analysis of a Disc Brake Mounted on the Axle of a Train

E. Madhusudhan Raju, Somayajula Kavya Geetika and Devireddy Jitesh Krishna

Abstract Axle-mounted disc brakes are generally employed in high-speed trains owing to the lesser weight and sustainable thermal properties. Most widely used material for manufacturing of the disc brake is grey cast iron (GCI), because of its availability. However, it being a brittle material has certain limitations. Hence, an aluminium composite material (AlSiC) is considered for analysis under different loading conditions. Three models of brake discs are developed on which both structural analysis and coupled analysis were done and results are compared.

Keywords Brake disc · Finite element analysis · Stress analysis

82.1 Introduction

In the olden days, the braking system of railway coaches consisted of wheel thread braking system. But they are not applicable to high-speed trains, as they damage the wheel thread. Hence, axle-mounted disc brakes are being employed in coaches. The braking system of a train involves a very complex process and is of great importance by making an essential contribution to the passenger's safety. This complexity results from numerous mechanical, thermal, pneumatic and electrical phenomena occurring during the process of braking. The actions of the above processes act on the different parts of the train with variable intensities. Also, the thermal deformation and overheating of the disc brake system during braking are turning out to be crucial. It is difficult to determine beforehand and analyse discs and linings separately, due to the amount of heat transferred to the discs, which may depend on their design and the train speed. In this paper, the effects of thermal and structural loads coupled together on the brake disc are analysed with different materials.

82.2 Literature Review

Reibenschuh et al. [1] used two brake discs (new and old) for both structural and thermal analysis. The material used for both the discs was spheroidal graphite cast iron. They found that the stresses developed in the new disc were more than worn disc, but stress values for both the discs were within the limits.

Maleque et al. [2] has developed a method of selection for selecting a better material in terms of optimization for the brake disc system, highlighting on substitution of cast iron by any lightweight material. Requirements for the material performance were scrutinized, and alternate solutions were assessed among different materials like cast iron, aluminium alloy, titanium alloy, ceramics and composites. The analysis led to a conclusion of usage of an aluminium metal matrix composite as the most appropriate and optimum material for brake disc system.

Yildiz and Duzgun et al. [3] had studied the stress analysis of ventilated brake discs by means of the finite element method. During this study, three different designs of ventilated brake discs were manufactured, and their braking system performances were examined experimentally together with a solid disc. These assessments indicate that the application of variable force along the brake pads leads to a reduction of the stress on ventilated discs from 8.8% to 19.1%.

Jung et al. [4] had studied shape optimization and the thermal characteristics of a ventilated disc. In this study, an analysis technique was developed to estimate the temperature rise and thermal deformation of the ventilated disc. Also, the braking condition and properties of the disc and pad could be estimated by this technique. Mathematical explanations for the analytical process of the braking power generation were developed.

82.3 Problem Definition

82.3.1 Aim of the Project

The primary objective of this paper is to present the various stresses and deformations induced in the brake disc models made up of grey cast iron (GCI) and aluminium composite materials (AlSiC) under static structural and coupled (structural and thermal) loading conditions. Three models were developed for the estimation of stresses, one of which is similar to the existing design, whereas the other two are new designs suggested to overcome the limitations of the existing one. The existing model is of the bolted joint type, and the other models are of push fit type. Model 2 is the push fit type of the existing model, and Model 3 is push fit type with cross-drills to reduce the weight. To determine the boundary conditions for the problem, an emergency braking situation of 160 kmph to stop on a flat horizontal track was utilized. The input loads, pressure, rotational velocity and heat flux induced were calculated and applied on the disc, and the output in terms of von

Mises stresses, total deformation and temperature induced in the brake disc was recorded and used for the finite element analysis.

82.4 Research Methodology

82.4.1 Theoretical Background

Introduction. Due to the complex nature of the loading on the disc brake, the von Mises stresses induced due to the loading conditions are examined to determine the failure conditions of the model. The von Mises yield criterion (also known as the maximum distortion energy theory of failure) suggests that the yielding of a ductile material begins when the second deviatoric stress invariant reaches a critical value. This theory works well for most cases, especially when the material is ductile in nature behaviour.

Structural load calculations. Refer Appendix (Table 82.3).

82.4.2 Solution Methodology

The solution methodology to determine the better material and better geometry for railway brake disc is given by the following steps:

Table 82.3 Boundary conditions

S. No.	Analysis	Boundary conditions
1	Static structural	Pressure on disc—1.5 MPa Rotational velocity—97.12 rad/s
2	Coupled (static structural + thermal)	Temperature, as derived from transient thermal analysis for different materials and above-mentioned structural load

1. Dimensions, as given in Table 82.1, are taken from Railway Specification No. RDSO/2015/CG-03 'Brake disc for LHB-type coaches' [5] for modelling of brake discs.
2. Brake discs are modelled using SOLIDWORKS 2016 software and saved as an IGES file.
3. Import 3D model of brake discs into ANSYS WORKBENCH 16.
4. Analysis of brake discussing ANSYS WORKBENCH 16 by applying the boundary conditions as given above.
5. Static structural analysis is done by applying the pressure on each side of the disc surface and rotational velocity to investigate the von Mises and total deformation developed in the models.
6. The coupled analysis is carried out at all time points with respective temperatures by applying structural loads to obtain the stresses, deformation and strain under the coupled load of thermal and structural.
7. The obtained results are tabulated and compared. The material and geometry with the least values are considered as better material and better geometry.

82.5 Results and Discussions

82.5.1 Static Structural Analysis

The models developed in SOLIDWORKS 2016 were converted into IGES file and imported back into ANSYS WORKBENCH R16 for the finite element analysis. Boundary conditions as calculated in Sect. 82.3.1 were applied on the brake disc models. The constant pressure of 1.5 MPa was applied on both sides normal to the frictional surface of the discs. A rotational velocity of 97.12 rad/sec (ramped) was given at the axis of the disc. Fixed support was provided in the eye of fixing bolt. Both disc temperature and surrounding environment temperature are taken as 45 °C. The analysis was run for 36 s, i.e. the time taken by the vehicle to stop due to the application of the emergency brake. The output results of von Mises stress and total deformation developed in the model were recorded (Figs. 82.4, 82.5 and 82.6).

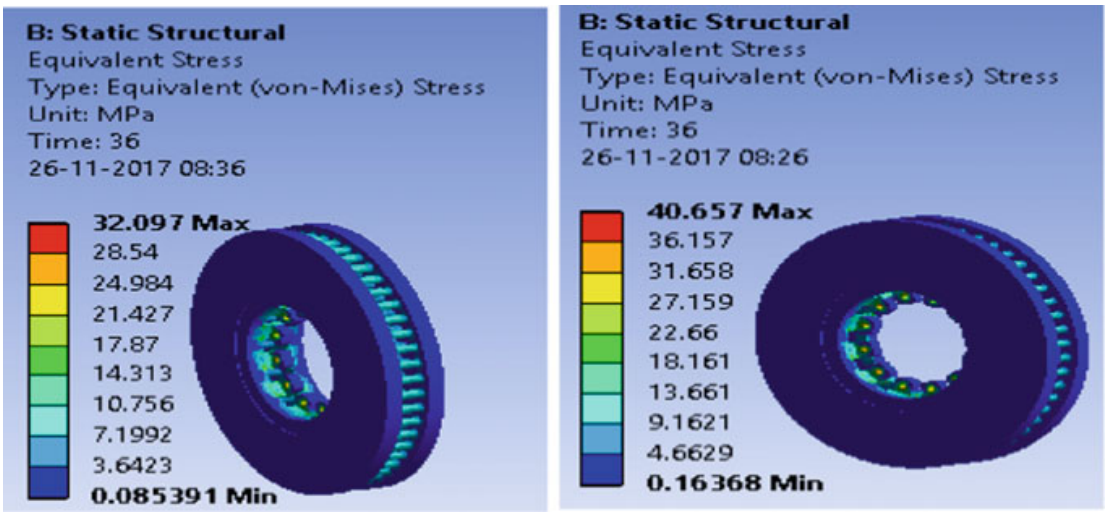

Fig. 82.4 SS GCI and AlSiC profile of von Mises stress (Model 1)

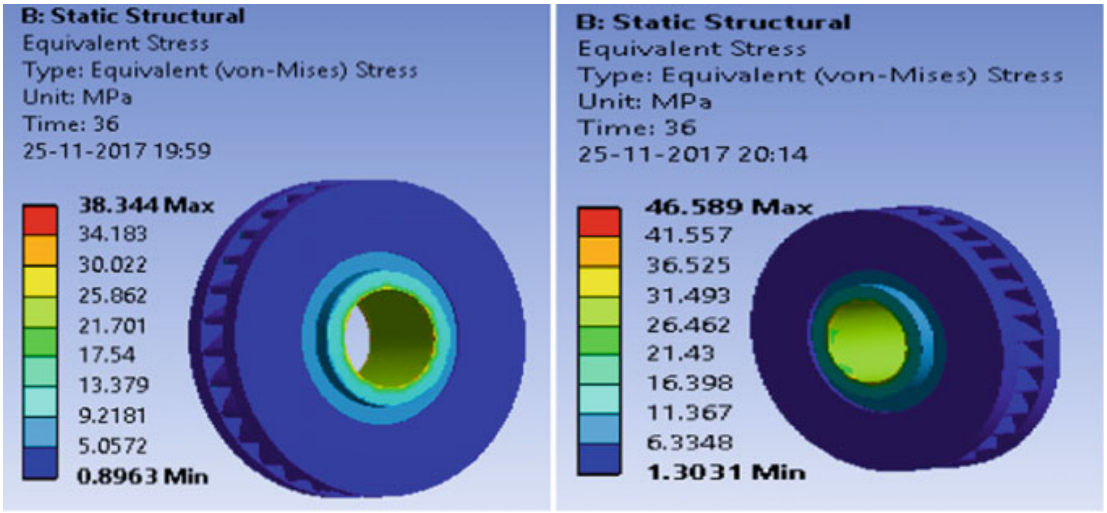

Fig. 82.5 SS GCI and AlSiC profile of Von Mises stress (Model 2)

82.5.2 Coupled Analysis

In the coupled analysis, the thermal load was coupled with the structural load to find out the combined effect on brake disc models. The temperature induced at various time points was imported into static structural, and then structural loads were applied. The analysis was run for 36 s, i.e. the time taken by the vehicle to stop due to the application of the emergency brake. The output results of von Mises stress and total deformation developed in the model were recorded (Figs. 82.7, 82.8 and 82.9).

Some important points that can be drawn from the analysis are:

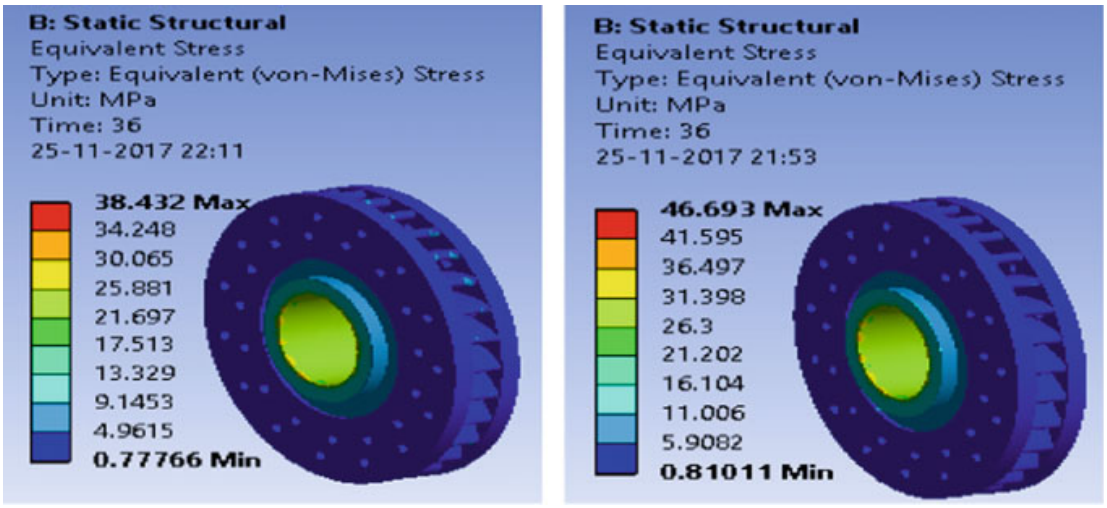

Fig. 82.6 SS GCI and AlSiC profile of von Mises stress (Model 3)

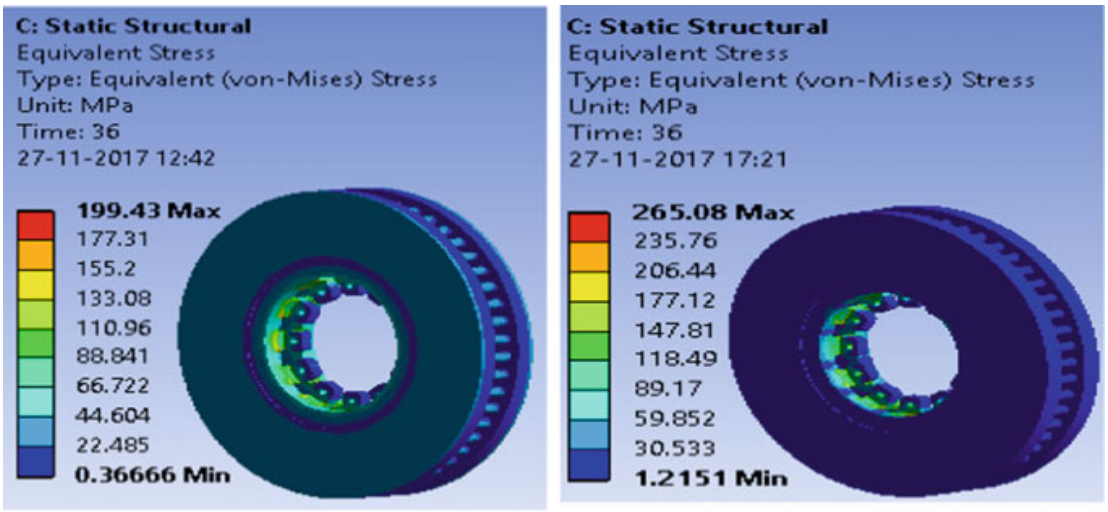

Fig. 82.7 CA GCI and AlSiC profile of von Mises stress (Model 1)

- When compared to the Factor of Safety offered by the GCI models, the AlSiC models offer higher Factor of Safety.
- For the same applied load, the AlSiC models have lower thermal stresses than the GCI models, as AlSiC material has greater thermal conductivity and heat dissipation capability.
- The weight of AlSiC models is lesser when compared to the GCI models (GCI model having a weight of about 134 kg gets reduced to 54 kg in case of AlSiC material).

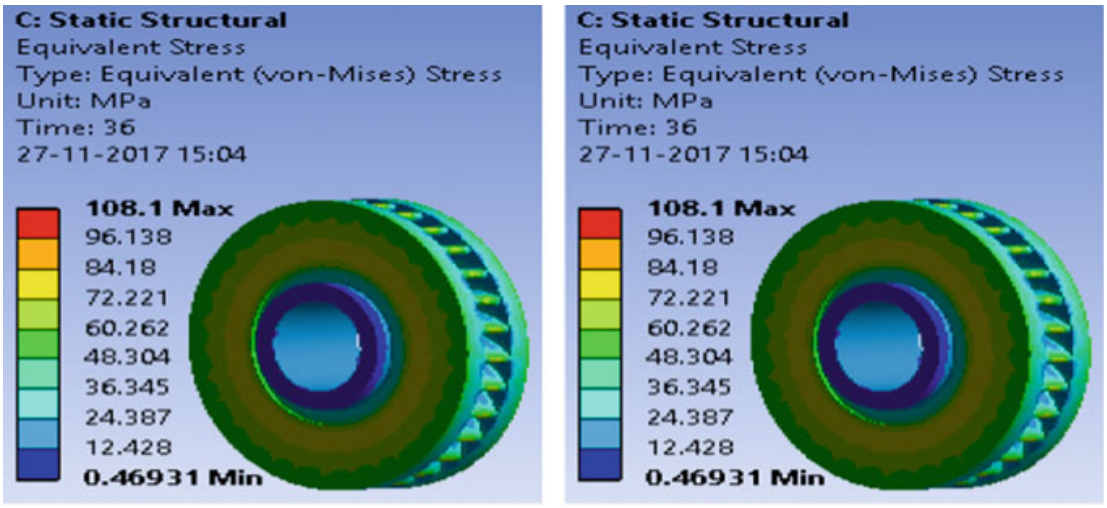

Fig. 82.8 CA GCI and AlSiC profile of von Mises stress (Model 2)

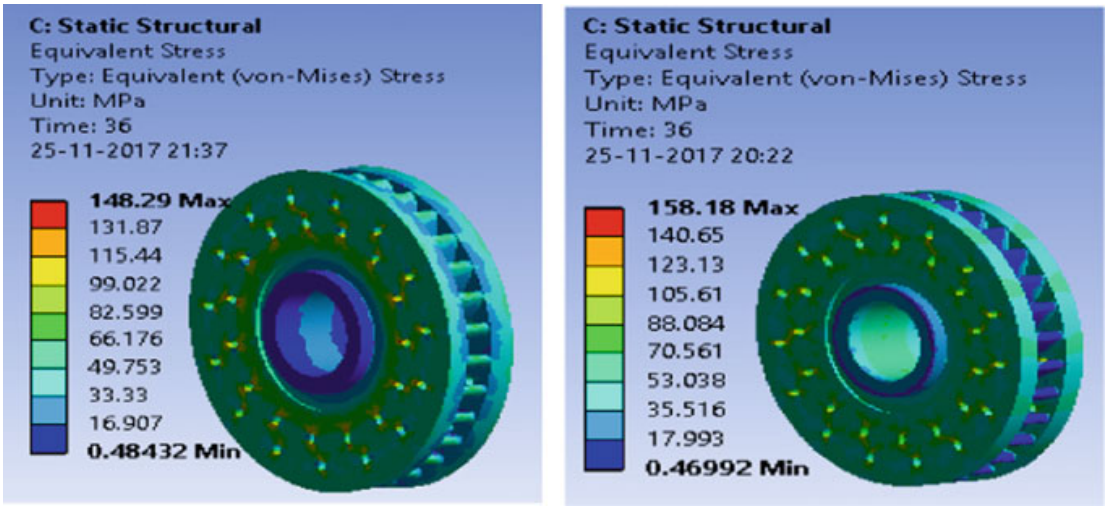

Fig. 82.9 CA GCI and AlSiC profile of von Mises stress (Model 3)

82.6 Future Scope

- Suggested models of brake discs are of a solid design which needs to be pressed on to the axle before pressing of the wheels. For replacement of these brake discs, wheels are necessary to be pressed out, which is not required if the models are of a split type. Hence, further experiments may be done with split-type brake disc models.
- Carbon matrix composites may be used to reduce the sound barrier and higher resistance to temperatures.
- Brake pad analysis with various materials suitable to the disc material may be carried out to optimize pad material.

Appendix

Structural load calculations: In this case, a railway vehicle travelling at a speed of 160 kmph on a horizontal track stops due to application of emergency brake was considered. Time of travel before stopping, deceleration, weight of the vehicle, clamping force on the brake disc, brake pad area, coefficient of friction, etc., for calculating the loads are taken from the railway specification. Value of Mass of railway vehicle—M = 64000 kg, No. of axles per vehicle = 4, Maximum load per axle = 16000 kg, no. of brake discs per axle = 2, Load on each wheel = 8000 kg, Start speed v_0 = 44.4 m/s, Deceleration a = 1.2 m/s^2, Braking time t_a = 36 s, Effective radius of the brake disc r_{disc} = 0.247 m, Radius of the wheel r_{wheel} = 0.458 m, Mean coefficient of friction brake pad μ = 0.35, Clamping force F_c = 42.1 kN, Surface area of brake pads A_c = 400 cm^2, Maximum temperature under sun = 70 °C, Maximum temperature under shade = 45 °C, Factor of Safety = 1.5 (Fig. 82.10).

Stopping distance

$$S = v_o t_s - \frac{1}{2} a t_s^2 = 822.24m \tag{82.1}$$

Determination of pressure on disc

Pressure acting on the brake disc,

$$P = \frac{F_c}{A_c \times \mu} = \frac{42.1 \times 1000}{800 \times (10)^{-4} \times 0.35} = 1.5\,\text{Mpa on each side} \tag{82.2}$$

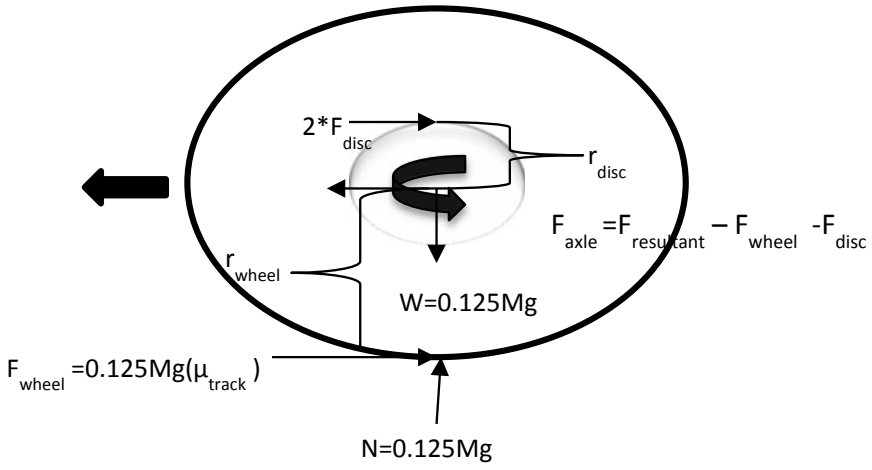

Fig. 82.10 Representation of forces acting on wheel and disc brake

where

F_c Clamping force (i.e. 42 kN)
A_c Contact area of brake pad on each side (i.e. 400 cm^2)
μ Coefficient of friction (i.e. 0.35).

Angular velocity

$$\omega = \frac{\text{Velocity}}{\text{radius}} = \frac{v_0}{r_{\text{wheel}}} = \frac{44.44}{0.458} = 97.12\,\text{rad/s} \tag{82.3}$$

Thermal load

The kinetic energy for one wheel (disc brake) is equivalent to the energy balance

$$\begin{aligned} 0.125 * \frac{1}{2} * M * v^2 &= \int_0^{t_s} P(t)\mathrm{d}t \\ &= 2 * F_{\text{disc}} \int_0^{t_s} v_{\text{disc}}(t)\mathrm{d}t \end{aligned} \tag{82.4}$$

The energy change at the moment is equal to the heat flux on the surface of the disc.

Equation (82.4) is valid in the case of constant braking deceleration. The braking force on the disc is equal to Eq. (82.7)

$$F_{\text{disc}} = \frac{0.125 * \frac{1}{2} * M * v_0^2}{2 * \frac{r_{\text{disc}}}{r_{\text{wheel}}}\left(v_0 * t_s - \frac{1}{2} * a * t_s^2\right)} = 8940\,\text{N} \tag{82.5}$$

The heat flux at the moment, which affects one half of the disc, is calculated according to the

$$\begin{aligned} Q(t) &= F_{\text{disc}} * v_{\text{disc}}(t) = F_{\text{disc}} * \frac{r_{\text{disc}}}{r_{\text{wheel}}}(v_0 - a * t) \\ &= 8940 * \frac{0.247}{0.458}(44.44 - 1.2 * t) = 214261 - 5786 * t\,\text{Watts} \end{aligned} \tag{82.6}$$

$$\text{Area of friction surface} = \frac{\pi}{4}\left(0.64^2 - 0.35^2\right) * 2 = 0.45\,\text{m}^2$$

$$Q(t) = \frac{214261 - 5786 * \mathrm{t}}{0.45} \ \mathrm{W/m^2} \tag{82.7}$$

For the case of emergency braking on horizontal track from 160 kmph to stop, the analysis was carried out in 36 steps, each step being 1 s long.

Modelling and Analysis of Composite Conical Space Adapter

Rajesh Addanki, Pranay Narinder Kumar, Ayush Mahajan and Manoj Kumar Buragohain

Abstract This paper is concerned with the development of model for the finite element analysis of the conical space adapter which is subjected to axial compression. It also provides the information about the parameters required for generating the input for modelling the structure. Analysis is performed using Ansys, i.e. software for finite element analysis. The results of analysis include the behaviour of the adapter under axial compression, e.g. stresses in the helical and circumferential ribs, displacement of the space adapter, critical buckling load and global buckling. Modal analysis has been carried out to study the modes of vibrations and obtain the frequency of vibration of the structure.

Keywords Composite lattice structures · Finite element analysis · Buckling analysis · Critical buckling loads · Modal analysis

Nomenclature

β Semi-cone angle
α_0 Geodesic angle at the start (at larger radius)
α_f Geodesic angle at the end (at smaller radius)
θ Angle of rotation of fibre
D Larger diameter of the adapter
d Smaller diameter of the adapter
b Width of the fibre
t Thickness of the fibre
H Height of the space adapter
W Width of the fibre

83.1 History of Lattice Structures

The development of grid-stiffened structures dates back to WWII English bomber Wellington. The application of these structures is not limited to space applications. Earlier, grid-stiffened structures were made by machining metals, e.g. aluminium isogrid structures by machining aluminium slabs. But today the material has changed from metal to carbon fibre composites. Currently, the fabrication methods of a lattice structure are done by grooving the fibre path over the mandrel of required dimensions, and fibres coated in epoxy resin are wound over it. After curing it at a required temperature, the desired shape is obtained.

One of the earliest lattice structures was developed by Russian-based laboratory. Central Institute of Special Machine Building (CRISMB) was Moscow radio tower [1] designed by Shukov in 1921. It stands 148.3 m tall and marks the advent of the development of lattice structures for Russians. It looks quite similar to modern-day lattice structures.

In 1985, US navy developed a launch vehicle adapter fitting for their satellite named as [2] Petite Amateur Navy Satellite (PANSAT) for communication purposes. The study conducted on this adapter fitting provides a basis for structural design and analysis for the adapter. The thesis gives an in-depth knowledge about the finite element analysis of such structures.

Since the inception of space adapters, they were manufactured in various shapes and sizes [3–6] offering flexibility in design to the user, such as using a cylindrical and conical adapter. A conical configuration of the shaped adapter has been modelled out for easiness of mounting the payload with available space and thereby reducing the additional stage. Even though the manufacturing of such structures is limited to axisymmetric shapes, the use of these structures remains dynamic.

83.2 Introduction

A typical space adapter consists of helical and circumferential ribs as shown in Fig. 83.1 wherein the impregnated fibres are laid along the grooves for circumferential and longitudinal pattern to form a lattice structure. When the structure is subjected to axial compression, the helical ribs transfer the load to circumferential ribs as tensile force. Now, this tensile force is transferred to a member to the adjacent structure which stabilizes its shape and increases the load carrying capacity. The load-carrying capacity is greatly influenced by dimensions of lattice structure. Therefore, keeping the space constraints in mind, the roadmap of designing process is laid down.

The space adapter is used to install payload over the last stage of the composite rocket motor casing. The conical-shaped adapter is made of carbon fibre with epoxy resin which provides higher strength to weight ratio than conventional metallic

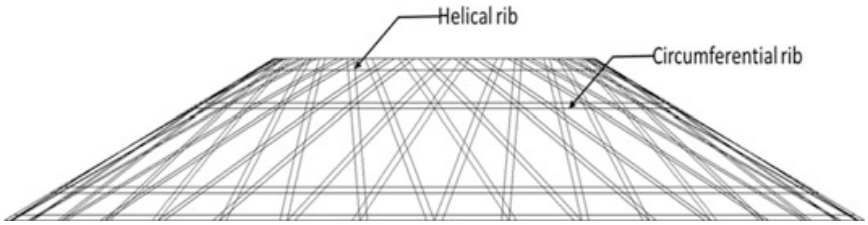

Fig. 83.1 Schematic of space adapter

structure made of steel or aluminium. Further, handling and installation of the adapter becomes easy due to its low weight.

In the present context, a space adapter is designed and modelled for finite element analysis [7]. The analysis consists of static analysis followed by buckling analysis. For calculating the natural frequency, modal analysis is carried out. The boundary conditions and load cases are explained in further sections. The results obtained from the analysis are also discussed in the paper. Further, prospects and research areas are also discussed which can be explored in the future for further research.

83.3 Configuration

The conical adapter is designed with two circumferential stiffeners in addition to metallic stiffeners at top and bottom and 20 crossed axial stiffeners with varying helical angle. A total of 40 layers with 0.5 mm thickness are considered for analysis. The helical angles with fibre path variation cater for a height of about 300 mm with outer diameter to inner diameter ratio of three. The helical ribs of cross section 8 × 8 to 20 × 20 in multiples of four have worked out to cater the axial payload of about 50 kg with 10 g axial force. A typical 2D view of space adapter is shown in Fig. 83.2.

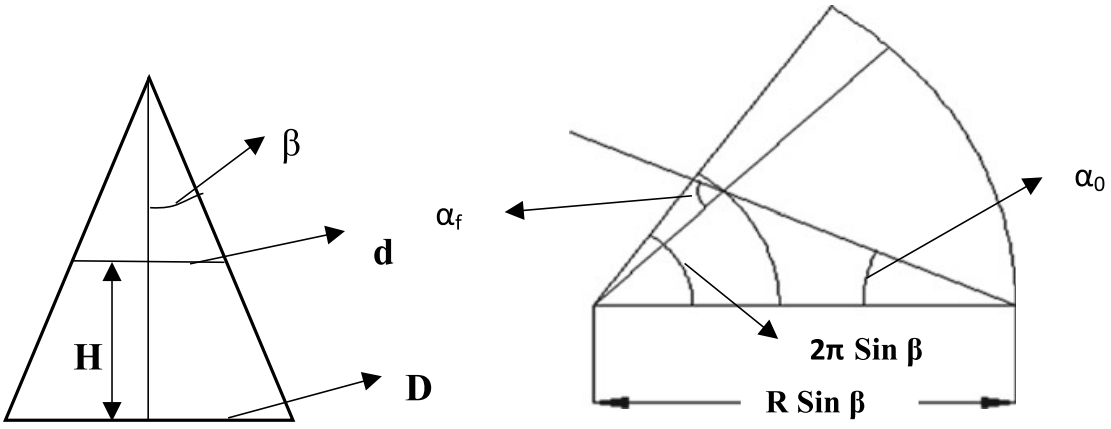

Fig. 83.2 Development of the cone

The empirical relations for calculating the path, angle and radii are as given below (from Eqs. 83.1 to 83.6).

$$\frac{r\varnothing}{\sin\beta} = r\theta \tag{83.1}$$

$$\theta = \frac{\varnothing}{\sin\beta} \tag{83.2}$$

$$\varnothing = \alpha - \alpha_0 \tag{83.3}$$

Also, as per Clairut's equation

$$R\ \sin\alpha_0 = r\ \sin\alpha \tag{83.4}$$

$$\alpha = \sin^{-1}\left(\frac{R\ \sin\alpha_0}{r}\right) \tag{83.5}$$

Substituting Eqs. 83.2 and 83.5 in Eq. 83.3, we get,

$$\theta = \frac{1}{\sin\beta}\left[\sin^{-1}\left(\frac{R\ \sin\alpha_0}{r}\right) - \alpha_0\right] \tag{83.6}$$

83.4 Input Generation

The geometric parameters used for the design and modelling the conical space adapters serve as the inputs. Equations which are used for modelling are stated in the previous section. Various cross sections were designed and analysed to arrive at a final configuration. The parameters used are as follows:

- Radius of the frustum of the cone (both smaller and larger)
- No. of helical ribs
- No. of circumferential ribs
- Winding angle at start and end
- Width of fibre
- Cross section of the rib.

Once the above parameters are finalized then model becomes ready for analysis. The values of above parameters are used in the governing equations refered in Sect. 83.2 to obtain the set of coordinates. The properties of composites, which were experimentally evaluated from the sample test as per ASTM standards, are used for the analysis by testing the small specimens constructed in the scale down model of the full-scale prototype. After the characterization of the high-strength carbon fibre with epoxy resin, the following properties are obtained which are given

Table 83.1 Carbon epoxy composite properties

Parameter	E_{xx} (MPa)	E_{xy} (MPa)	E_{yz} (MPa)	μ_{xx}	μ_{xy}	μ_{yz}	G_{xx} (MPa)	G_{xy} (MPa)	G_{yz} (MPa)

Properties	Value (MPa)
E	201,000
μ	0.3

below in Table 83.1. Also, the material input properties for the steel are listed in Table 83.2.

83.5 Modelling

The helical path with circumferential ribs has been modelled in ANSYS which is software based on finite element analysis. The relations mentioned in the previous sections are used to create a set of coordinates of fibre path. With +θ coordinates and −θ coordinates have been developed the path is fed to software. In the similar lines, 90° path (circumferential ribs) was also modelled. The nodal points and the element generation were done by brick node 185. In total, 20 helical ribs with an angular difference of 18° between any two +θ helical ribs are considered. The nodes are merged to eliminate any discrepancy at the crossovers. While modelling, a special attention must be given to crossovers (where ribs are meeting each other) because crossover points act as single unit not different one, otherwise results obtained may be erroneous or not at all accurate. The adapter model with helical and circumferential ribs is shown in Fig. 83.3. Figure 83.4 shows the element detail depicting the nodal merging at the crossover points.

83.6 Boundary Conditions and Load Cases

The space adapter is modelled in global Cartesian system in such a way that the bottom surface lies in *X-Y* plane and positive *z*-axis is aligned with axis of the cylinder. Following are the boundary conditions applied on the mode for the analysis:

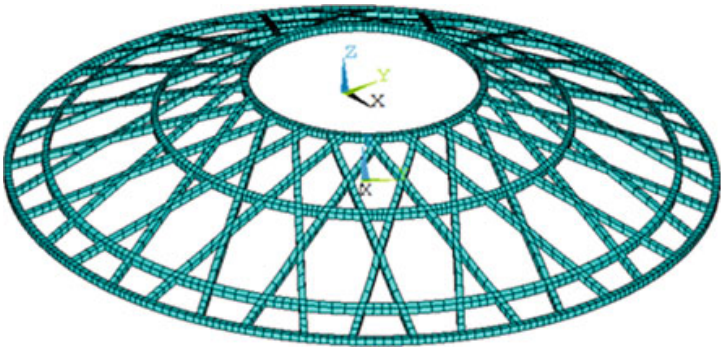

Fig. 83.3 FEA model of space adapter

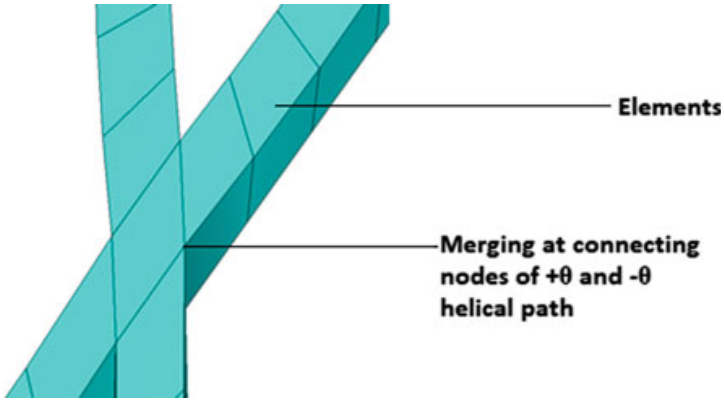

Fig. 83.4 Elements in the model

- Displacement of the bottom surface has been arrested and at the top of it is kept free where the load is applied, i.e. at $z = 0$ $U_x = 0$, $U_y = 0$, $U_z = 0$ and at $z = H$ U_x, U_y, $U_z \neq 0$.
- A uniform load is applied on the top nodes at $z = H$.
- To have the interface, a metallic bulkhead at top and bottom of the adapter (lower and higher Diameter) steel is considered with properties as follows.

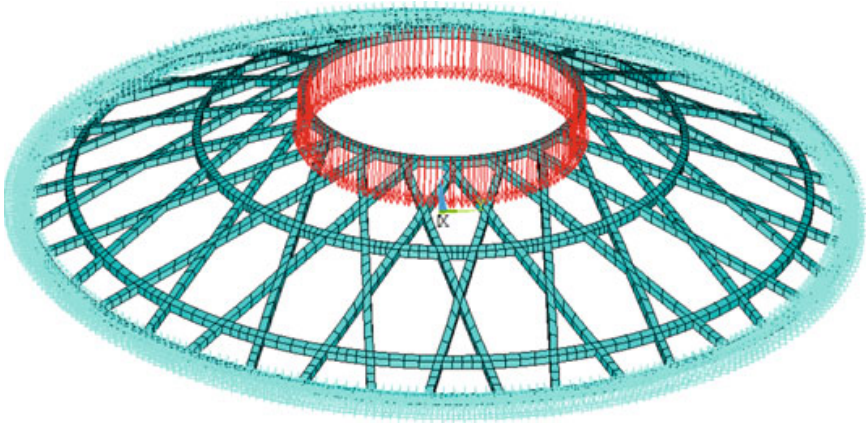

Fig. 83.5 Load application and boundary condition for the adapter

Design load, in this model, is applied for two types of analysis, i.e. static and buckling. Axial compressive load used for analysing the structure is 10 tons and the loading pattern is shown in Fig. 83.5.

The model is fixed at the bottom and load is applied at the top. A load of 10 tons is applied on 280 nodes at the top. Then load per node comes out to be 357.14 N.

In addition to static analysis, modal analysis was also conducted on the space adapter model (20 × 20) to study the vibrations and calculate frequency of the adapter.

Modal analysis is used to calculate the natural frequency and mode shapes of a continuous structure. A continuous structure has infinite degrees of freedom, but finite element approximates with a finite number of degrees of freedom.

Block Lanczos method is used for performing the modal analysis, which uses an algorithm for finding the null space of a matrix over a finite field. The same method is used in the present study for the matrix functions and in calculating buckling factor. The eigen buckling analysis is performed and three modes are extracted for the buckling factor.

The results of modal analysis serve as the basis for harmonic analysis. Harmonic analysis solves time-dependent equations of motion for linear structures undergoing steady state vibrations.

83.7 Results and Discussions

Several models were configured with different cross sections ($w \times t$) varying as 8 × 8, 16 × 16, 18 × 16, 20 × 20. Few results are represented to validate the strength and configuration of the space adapter, and the buckling factors variations are tabulated in Table 83.3.

A typical buckling mode is also represented in Fig. 83.6.

It is observed that, as the rib cross section increases, the load carrying capacity of the adapter also increases. The buckling factor of 5.62 indicates that critical load is 5.62 times of applied load. Higher buckling factor ensures that design will not fail under the action of axial compressive loads. The stresses are developed in the layers of the model.

The graphical plot in Fig. 83.7 demonstrates the behaviour of stress in 40 layers of the model at three different heights, i.e. top, middle and bottom of the adapter.

Table 83.3 Buckling factor variations

SI No.	Cross section of the ribs (w × t)	Buckling factor
1.	8 × 8	0.2295
2.	16 × 16	0.9122
3.	18 × 16	1.1011
4.	20 × 20	5.6200

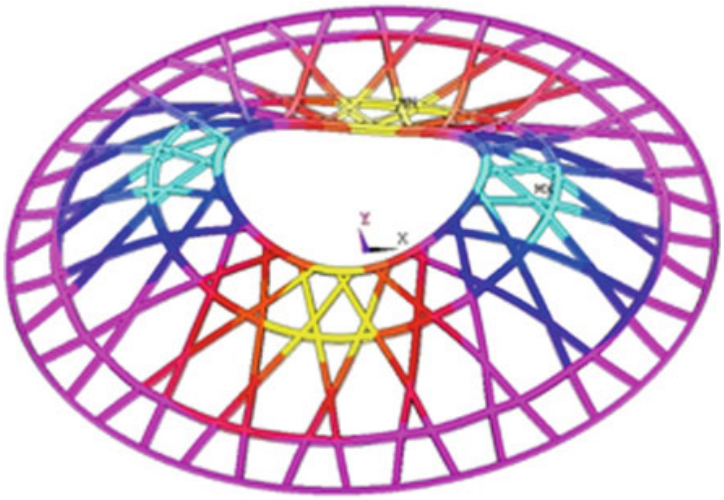

Fig. 83.6 Buckling mode of the adapter

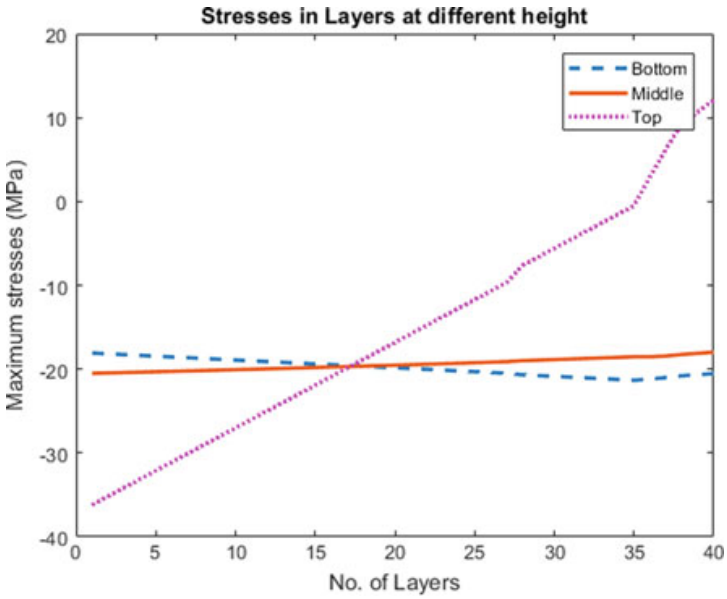

Fig. 83.7 Stress pattern in the helical plies at various height

The behaviour of stress shown in the graph indicates that the layer between 15 and 20 experiences same stress and behaves as the neutral layer.

The graphical plot in Fig. 83.8 depicts the stress in layers at the crossovers of the helical rib. The plot indicates that stresses start as compressive but as we move along the transverse direction to the layers, the nature of stress starts changing. The topmost layer, i.e. layer 40, experiences lesser compressive force compared to lowermost one. Up to layer no. 35, the reduction in compressive stress is gradual, but later there is drastic reduction in the compressive stress value.

The graphical plot in Fig. 83.9 shows that stresses in layers of circumferential rib are largely tensile attributing to the fact that helical ribs transfer compressive stress to the circumferential ribs which change it into tensile. There is gradual decrease in the stress in the transverse direction indicating that the load is distributed uniformly.

As we noted earlier, that nature of stress is different in helical and circumferential rib, the stress pattern changes from compressive to tensile is clearly seen in

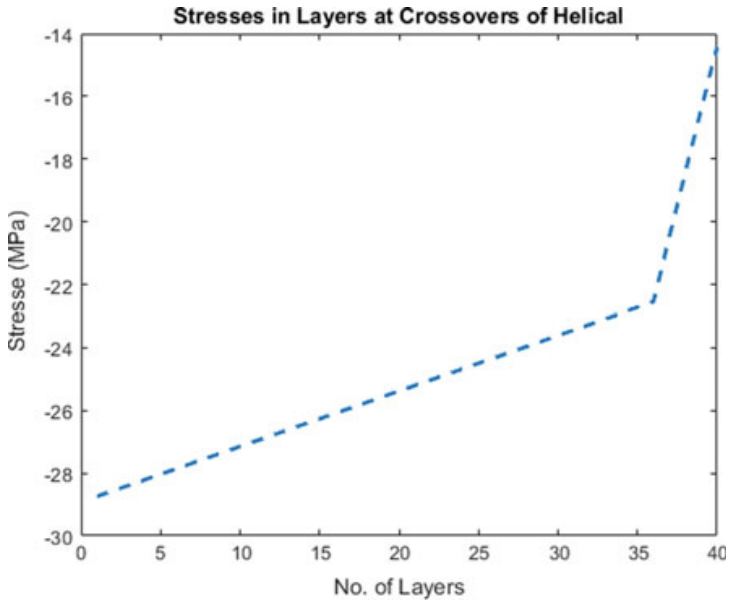

Fig. 83.8 Stress pattern in the helical plies at crossover

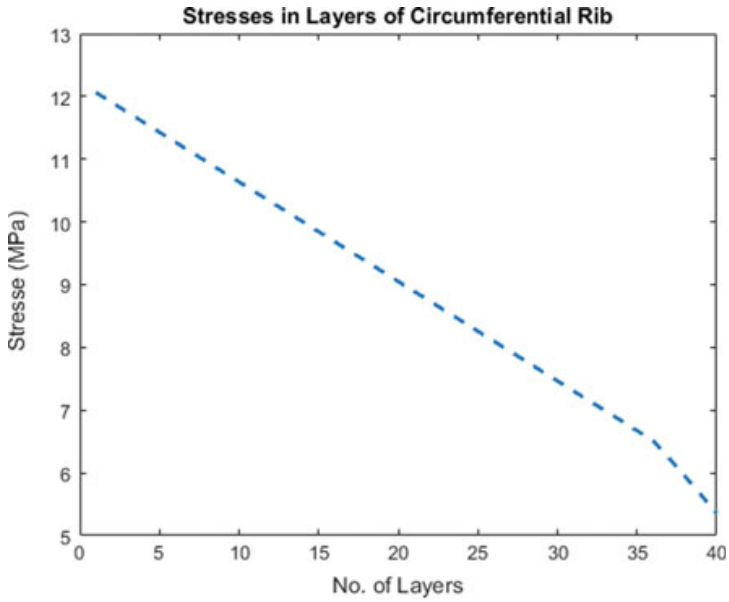

Fig. 83.9 Stress pattern in the circumferential ribs

Fig. 83.10. It can be seen, at the crossover, the stresses change from compressive to tensile indicating the transfer of the loading and is evident from the plot that the load is transferred from lowermost ply to topmost ply. Since, the value as well as the nature of the stress changes gradually up to layer 35 and the slope is high.

Figure 83.11. shows that as load is increased, the displacement also increases in the negative z-direction, i.e. along the height of the adapter and also follows a linear relationship. The deformed shape of the adapter superimposing onto the undeformed configuration is shown in Fig. 83.12.

The results obtained from static analysis have been saved and further utilized for extraction of mode shapes in modal analysis. In modal analysis, three modes were

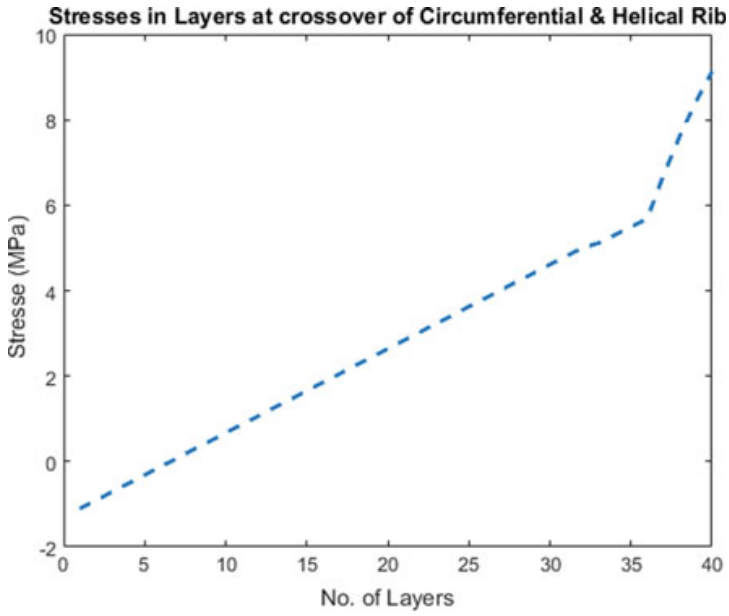

Fig. 83.10 Stress pattern in the circumferential and helical crossovers

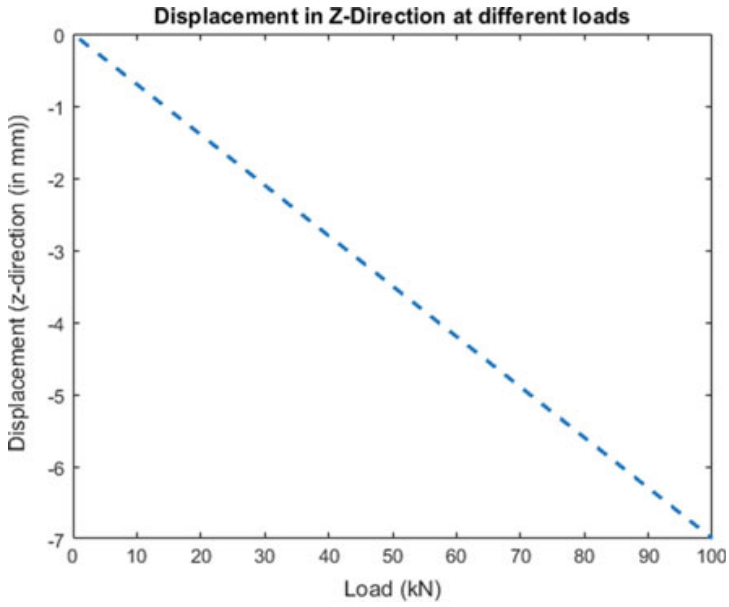

Fig. 83.11 Displacement in z-direction at different loads

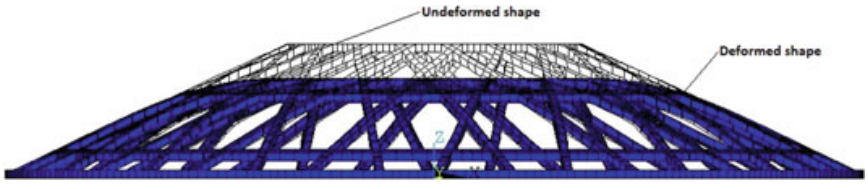

Fig. 83.12 Deformed shape versus original shape

extracted and the results obtained in modal analysis are as follows (refer Fig. 83.13):

The modal frequencies are listed in Table 83.4.

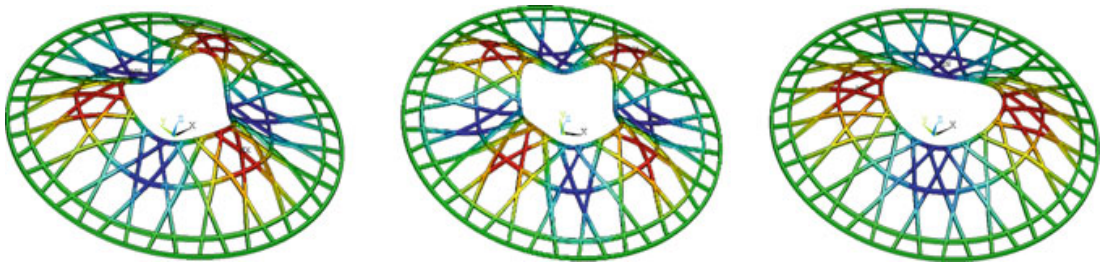

Fig. 83.13 Three mode shapes of the adapter

Table 83.4 Frequency of the mode shapes

Modes	First	Second	Third
Frequency (Hz)	5.09	5.15	6.56

83.8 Conclusion

The results from different models are studied and found that if there is increase in the cross section of the helical groove of carbon fibre, the buckling factors increase. Also, if two circumferential ribs are used, it contributes in increasing buckling factor. It can also be noted that, the bottommost layer in the ply sequence is the critical layer in the helical ply as it is experiencing the highest value of stress (in both the ribs circumferential and helical plies).

The modal analysis shows the structures that have three modes. Since the value of natural frequency is low it can be concluded that the stiffness of the structure is high enough to tolerate the load fluctuations during the actual application as stiffness is inversely proportional to frequency.

Further studies can be made considering the change in winding angle (helical rib angle), varying circumferential rib location, total no. of helical ribs and total no. of helical plies to find out buckling load capacity. The present structure designed is having a weight of approximately 15 kg and weight optimisation studies with higher modulus carbon fibre can be studied.

Acknowledgements A sincere thanks to the Director, ASL and CRMC team for their valuable inputs in the process.

Chapter 84
Parametric Study of Axisymmetric Circular Disk Subjected to Rotational Autofrettage

S. M. Kamal and R. Kulsum

Abstract Rotational autofrettage is a potential strengthening technique for thick-walled circular disks/cylinders used in many engineering applications. In particular, the rotating disks used as a rotor in an aircraft engine, rotating impeller wheel of a compressor and fasteners in high pressure pipelines are the important application areas, where rotational autofrettage is useful in mitigating the detrimental tensile stresses during operation. The process induces compressive residual stresses in the disk on unloading a previously applied plastically deforming centrifugal load. The amount of residual stresses generated during the process depends upon different influencing parameters. The geometrical dimension of the disk, rotational speed and material properties are the important parameters to be considered for assessing the effectiveness of rotational autofrettage of a disk. In this paper, a parametric study of the different influencing parameters during the rotational autofrettage of a thick-walled axisymmetric circular disk is carried out.

Keywords Rotational autofrettage · Hydraulic autofrettage · Rotational speed · Residual stress

84.1 Introduction

Usually, autofrettage is performed in thick-walled cylinders to induce compressive residual stresses in the vicinity of the bore surface by a process of loading and unloading of a plastically deforming load applied at the inner surface of the cylinder. The process may also be useful in strengthening thick-walled hollow circular disks such as fastener holes and rotating disks used in automobile and aerospace industries. During the process, the material at the neighborhood of the inner bore surface is subjected to plastic deformation and the material at the outer portion of the cylinder is in the elastic state. The early known autofrettage processes

are hydraulic [1], swage [2] and explosive autofrettage [3]. The hydraulic autofrettage employs a very high internal pressure, whilst the swage autofrettage employs an oversized solid mandrel to be pushed through the bore of the cylinder to achieve the desired plastic deformation in the cylinder wall. The explosive autofrettage utilizes explosive charge to achieve the beneficial effect of autofrettage. The hydraulic and swage autofrettage processes have received considerable attention of the researchers attempting theoretical and experimental studies on the processes [4–11]. The explosive autofrettage process has been less investigated. Recently, researchers have developed some new methods of achieving autofrettage, viz. thermal autofrettage [12] and rotational autofrettage [13] to circumvent certain disadvantages associated with the earlier processes. In thermal autofrettage, a high radial thermal gradient is used for achieving plastic deformation at the inner side of the vessel. Detailed theoretical and experimental studies of the process have been carried out in Refs. [12, 14, 15]. Some recent works on thermal autofrettage have been reported in [16, 17].

Rotational autofrettage is a process where the beneficial compressive residual stresses are generated in the vicinity of a thick-walled disk/cylinder by rotating the component at sufficiently high speed and then gradually reducing its angular velocity to zero [13, 18]. The high angular velocity initiated to the disk/cylinder produces a large centrifugal force plasticizing the inner bore region keeping the region near the outer surface in the elastic state. This phase is called the loading phase. In a later stage when the centrifugal force is made zero by ceasing the rotation of the disk/cylinder, the material near the bore surface is subjected to compressive residual stresses. This phase is called the unloading phase. When the disk/cylinder with compressive residual stresses is put in the actual working environment, it mitigates the magnitude of tensile stresses induced in the component due to service load. This eventually enhances the load-bearing capacity of the component. The rotational autofrettage was first conceptualized by Zare and Darijani [13] in 2016. They carried out a theoretical analysis of the process for thick-walled cylinders assuming plane strain condition. The analysis was based on Tresca yield criterion and its associated flow rule, elastic-perfectly plastic material model with the incorporation of Bauschinger effect. The authors further extended their analysis to incorporate linear kinematic hardening [19]. Most recently, the rotational autofrettage has been studied for thick-walled hollow circular disks by Kamal [18]. He assumed plane stress condition and Tresca yield criterion and its associated flow rule for the analysis. The effect of strain hardening was taken into account using Ludwik's hardening law. The author carried out the numerical simulation of the model considering aluminum and SS304 disks. It was shown that the rotationally autofrettaged disk could enhance its working internal pressure, temperature difference and centrifugal load individually during service. Kamal [18] also carried out a three-dimensional finite element method (FEM) analysis of the rotational autofrettage of a disk. The FEM results were compared with the analytical models, and it was found that the FEM stresses were in close agreement with the theoretical stresses.

It has been observed that there are only a few research papers [13, 18, 19] available in the open literature so far in the area of rotational autofrettage. All the

literatures deal with the theoretical analysis of the process revealing it as a potential process. In any process, the process parameters play an important role in satisfying certain design requirements. For example, in an autofrettage process, the ultimate design requirement is to achieve the compressive residual stress at the inner surface of the component and the corresponding increase in the load carrying capacity as per the actual working condition. In order to achieve the required design objectives in rotational autofrettage process, the process parameters such as the geometrical dimension of the component, rotational speed and material properties should be selected appropriately. No literature is available studying the effect of process parameters on rotational autofrettage. Thus, in this work, a parametric study of the various process parameters in the rotational autofrettage of a thick-walled disk is carried out. The effect of different parameters on the residual stress and on different load-carrying capacity is studied. The study is based on the work of Kamal [18]. Before carrying out detailed parametric study of the process, the plane stress model of Kamal [18] is briefly described in Sect. 84.2.

84.2 Plane Stress Model of Rotational Autofrettage Proposed by Kamal [18]

An axisymmetric disk with inner radius a and outer radius b is considered. Under plane stress condition, the wall of the circular hollow disk splits into two deformed zones, viz. the inner plastic zone and the outer elastic zone when subjected to a plastically deforming centrifugal force by rotating the disk at sufficiently high rotational speed. The details are described in [18]. The radial and hoop stresses induced in the disk due to rotation, when the centrifugal force is not sufficient to deform the disk plastically, are given by

$$\sigma_r = (3+\nu)\frac{\rho\omega^2}{8}\left(a^2+b^2-\frac{a^2b^2}{r^2}-r^2\right) \tag{84.1}$$

$$\sigma_\theta = \frac{\rho\omega^2}{8}\left\{(3+\nu)\left(a^2+b^2+\frac{a^2b^2}{r^2}\right)-(1+3\nu)r^2\right\}, \tag{84.2}$$

where ρ is the density of the disk material, ω is the rotational speed, ν is the Poisson's ratio, a is the inner radius and b is the outer radius of the disk. The yield onset speed of the disk is given by

$$\omega_i = \left[\frac{4\sigma_Y}{\rho\{(1-\nu)a^2+(3+\nu)b^2\}}\right]^{1/2} \tag{84.3}$$

where σ_Y is the yield strength of the material. On increasing the rotational speed beyond ω_i, the material at the inner surface and some portion beneath it deforms

plastically, whereas the outer region remains in the elastic state. Thus, an inner plastic zone, $a \leq r \leq c$ and an outer elastic zone, $c \leq r \leq b$ are formed within the wall of the disk. The radial position, c is known as the radius of elastic–plastic interface. The stresses in the plastic and elastic zones are given by the following equations:

Plastic zone, $a \leq r \leq c$

$$\sigma_r = \frac{c}{r}\left(\frac{c^2-b^2}{b^2+c^2}\right)\left\{\sigma_Y + (1+3v)\frac{\rho\omega^2c^2}{8}\right\} + \sigma_Y\left(1-\frac{c}{r}\right) + (3+v)\left(\frac{\rho\omega^2b^2}{8}\right)\left(\frac{c}{r}\right)\left(\frac{2b^2}{b^2+c^2}-\frac{c^2}{b^2}\right) + \frac{\rho\omega^2}{3}\left(\frac{c^3}{r}-r^2\right) - \frac{K}{r}\int_r^c \left(\varepsilon_{eq}^p\right)^n \mathrm{d}r_1 \tag{84.4}$$

$$\sigma_\theta = \sigma_{eq} = \sigma_Y + K\left(\varepsilon_{eq}^p\right)^n \tag{84.5}$$

Elastic zone, $c \leq r \leq b$

$$\sigma_r = \left(\frac{1+3v}{b^2+c^2}\right)\frac{\rho\omega^2c^2}{8}\left(c^2-\frac{b^2c^2}{r^2}\right) + (3+v)\frac{\rho\omega^2b^2}{8}\left\{1-\frac{c^2}{b^2+c^2}+\frac{b^2c^2}{(b^2+c^2)r^2}-\frac{r^2}{b^2}\right\} + \left(\frac{c^2}{b^2+c^2}\right)\sigma_Y\left(1-\frac{b^2}{r^2}\right) \tag{84.6}$$

$$\sigma_\theta = \left(\frac{1+3v}{b^2+c^2}\right)\frac{\rho\omega^2c^2}{8}\left\{c^2+\frac{b^2c^2}{r^2}-\frac{(b^2+c^2)r^2}{c^2}\right\} + (3+v)\frac{\rho\omega^2b^2}{8}\left\{1-\frac{c^2}{b^2+c^2}-\frac{b^2c^2}{(b^2+c^2)r^2}\right\} + \left(\frac{c^2}{b^2+c^2}\right)\sigma_Y\left(1+\frac{b^2}{r^2}\right) \tag{84.7}$$

The residual stresses induced in the disk are obtained by subtracting the elastic stresses (Eqs. 84.1 and 84.2) from the respective stresses in the plastic and elastic zones. It is assumed that the unloading process is purely elastic devoid of Bauschinger effect. The unknown radius of elastic–plastic interface c can be obtained from Eq. (84.4) by using the boundary condition of vanishing radial stress at the inner radius. A numerical solution procedure such as bisection method may be employed for this. The present parametric study is based on the equations presented in this section.

84.3 Parametric Study

In this section, a parametric study of different process parameters influencing rotational autofrettage of thick-walled disk is carried out. The geometrical parameter such as wall thickness ratio, rotational speed, density and yield stress of the material influences the performance of rotational autofrettage of a thick-walled disk. In the following subsections, the influence of these parameters on the rotational autofrettage of typical thick-walled disks is studied in detail.

84.3.1 Influence of the Wall Thickness Ratio (b/a)

In any autofrettage process, the geometric parameter, wall thickness ratio (b/a) has significant influence on the load requirement, residual stresses and increase in service load-carrying capacity. In the following subsections, the effect of wall thickness ratio on different factors is discussed in detail.

Effect of Wall Thickness Ratio on Rotational Speed In rotational autofrettage, the disk is subjected to a sufficiently high rotational speed in the loading phase. Yielding onsets at a rotational speed ω_{i} at the inner radius of the disk according to Eq. (84.3). Expressing Eq. (84.3) in non-dimensional form, one obtains

$$\Omega_i = \frac{2}{\left\{(1-\nu)+(3+\nu)\left(\frac{b}{a}\right)^2\right\}^{1/2}} \tag{84.8}$$

where Ω_i is the non-dimensional yield onset rotational speed given by

$$\Omega_i = \omega_{\mathrm{i}} a \left(\frac{\rho}{\sigma_Y}\right)^{1/2} \tag{84.9}$$

Figure 84.1 shows the variation of normalized yield onset rotational speed Ω_i with the wall thickness ratio (b/a). It is observed that the initial normalized rotational speed required to cause yielding decreases with the increase of wall thickness ratio. This indicates that for higher b/a ratios, the disk requires comparatively lesser rotational speed for partially plasticizing the wall of the disk during loading phase for attaining the maximum residual stress at the inner side after unloading. For wall thickness ratios up to five, there is a significant reduction in the autofrettage rotational speed requirement. The subsequent increase of wall thickness ratio beyond five provides less than 5% reduction in speed.

Effect of Wall Thickness Ratio on Residual Stress The wall thickness ratio also influences the residual stress induced at the inner surface of the disk. In order to assess the effect of wall thickness ratio on the residual stress, a typical SS304 disk is

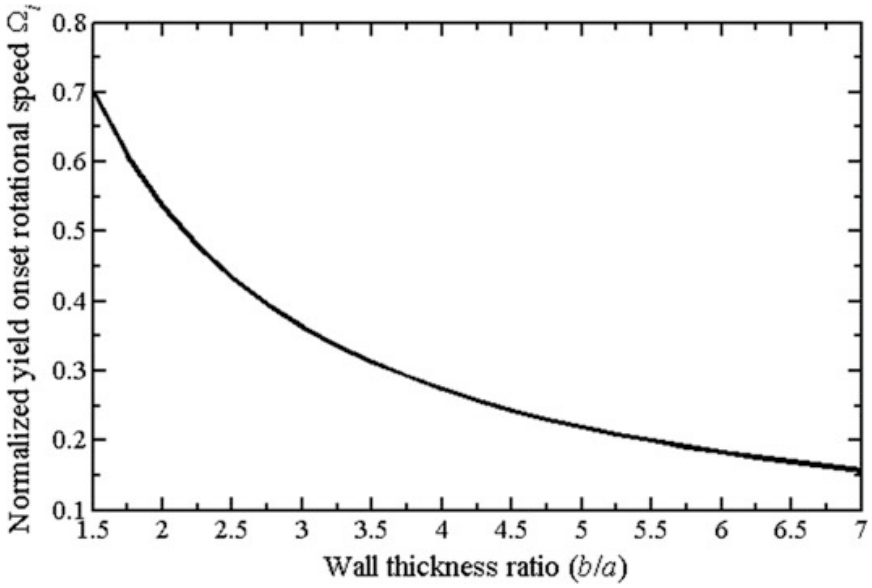

Fig. 84.1 Variation of normalized yield onset speed with wall thickness ratio

considered with the material properties given as follows: Young's modulus of elasticity, E = 193 GPa, yield stress, σ_Y = 205 MPa, Poisson's ratio, ν = 0.3, density, ρ = 8000 kg/m^3. The numerical simulation of the residual stresses is carried out for the disk as described in Sect. 84.2. The detailed expressions are available in Ref. [18]. In Ref. [18], the author has discussed the effect of strain hardening and found that its effect is not very significant. Hence, in the present study, the effect of strain hardening is neglected. Consequently, for numerical simulation, the hardening parameter K is taken as zero in Eqs. (84.4) and (84.5) in Sect. 84.2. The simulated results are presented in Table 84.1 showing the variation of normalized residual hoop stress at the inner and outer radii with the wall thickness ratio (b/a). The residual hoop stress distribution along the positive radial direction of the disk for all (b/a) ratios is also shown in Fig. 84.2.

It is observed from Table 84.1 that as the wall thickness ratio is increased, the normalized compressive residual hoop stress increases at the inner radius. In all cases, the maximum rotational speed of the disk during loading phase is also shown. The maximum rotational speed is considered in such a way that it causes maximum overstrain level (ε)[1] in the disk, and at the same time the residual stresses should not initiate reyielding after unloading. The maximum speed in the loading phase follows an increasing trend with the wall thickness ratio as expected. The normalized tensile residual hoop stress induced at the outer surface of the disk is also presented in Table 84.1 for different wall thickness ratios. It is observed that the normalized tensile residual stress at the outer surface increases up to b/a = 4.5. This indicates that the sensitivity to stress corrosion cracking of the outer surface of

[1]The overstrain level, ε is defined as the percentage of disk's wall thickness that undergoes plastic deformation.

Table 84.1 Variation of normalized residual hoop stress at the inner and outer radii with wall thickness ratio

Wall thickness ratio (b/a)	Normalized maximum rotational speed in the loading phase $\Omega = \omega a\left(\frac{\rho}{\sigma_Y}\right)^{1/2}$	Normalized residual hoop stress $\left(\frac{\sigma_\theta^{Res}}{\sigma_Y}\right)$

5	0.309	−0.9969	0.3218

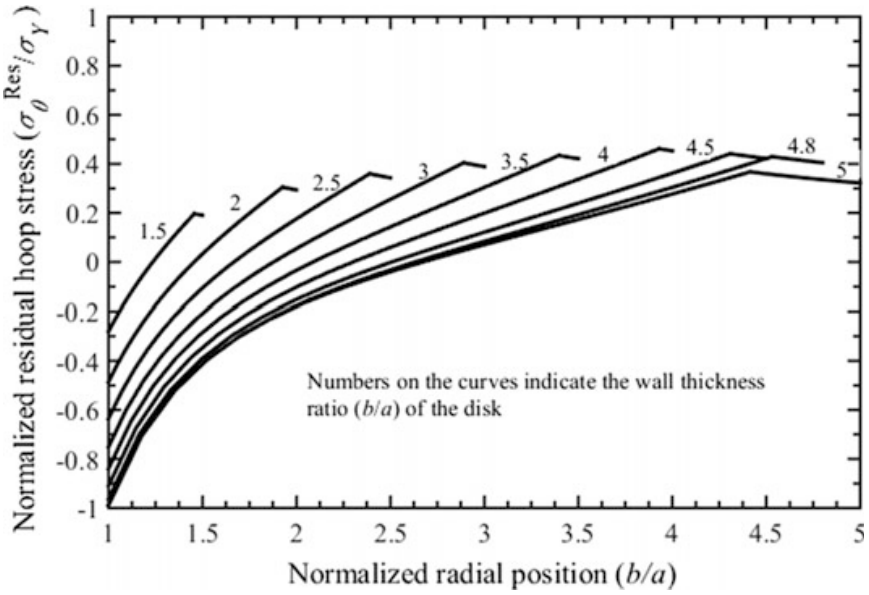

Fig. 84.2 Normalized residual hoop stress distribution in the disk for different wall thickness ratios corresponding to maximum rotational speed

the disk increases with the wall thickness ratio of the disk up to 4.5 for the maximum rotational speed. However, from b/a = 4.8, the maximum normalized tensile hoop stress at the outer surface of the disk starts decreasing. This may be due to the decrease of relative percentage overstrain in the disk. Thus, for the disks with b/a = 4.8 and above, it appears that the maximum compressive residual stress at the inner surface is almost the order of the yield stress of the material. It is observed that the tensile residual hoop stress at the outer surface increases gradually up to

b/a = 4, and thereafter it follows a decreasing trend. The lowering of the tensile hoop stress at the outer surface may be considered as relatively advantageous along with the maximum possible compressive residual stress at the inner surface. The residual hoop stress distribution in Fig. 84.2 shows that the maximum magnitude of the compressive residual hoop stress appears at the inner surface of the disk. It is to be noted that the maximum tensile residual hoop stress occurs at the radius of elastic–plastic interface for all (b/a) ratios. Figure 84.2 shows that the variation of the maximum tensile residual stress follows an increasing trend up to b/a = 4.5, and thereafter it starts decreasing with the increase of b/a.

Effect of Wall Thickness Ratio on Different Load Carrying Capacities The rotationally autofrettaged disk can bear significantly higher loads in service when it is subjected to internal pressure, temperature difference and rotational speed individually [18]. The effect of b/a on the different load-carrying capacities of the disk is also studied corresponding to the cases presented in Table 84.1. In Fig. 84.3, the maximum percentage increase in the service load for different wall thickness ratios is shown when the disk is subjected to internal pressure, radial temperature difference and rotational speed individually. The percentage increase in all service loads is estimated with reference to a corresponding non-autofrettaged disk. The maximum load-carrying capacity of the non-autofrettaged disk is decided based on the respective yield onset load following Tresca yield criterion. For internal pressure and radial temperature difference, the yield onset loads in non-dimensional form are given by [20].

$$\bar{P}_{\mathrm{Y}} = \frac{P_{\mathrm{Y}}}{\sigma_{\mathrm{Y}}} = \frac{1}{2}\left(1 - \frac{a^2}{b^2}\right) \tag{84.10}$$

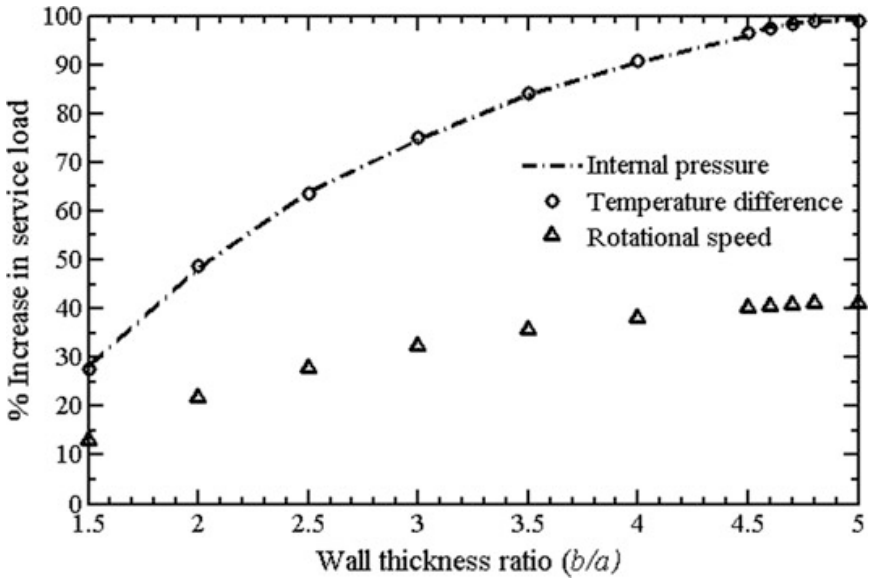

Fig. 84.3 Variation of percentage increase in the maximum different service loads as a function of wall thickness ratio

$$\theta_{\mathrm{Y}} = \frac{E\alpha\Delta T_{\mathrm{Y}}}{\sigma_{\mathrm{Y}}} = \frac{2}{\left\{\frac{\ln\left(\frac{b}{a}\right)-1}{\ln\left(\frac{b}{a}\right)} + \frac{1}{\left\{\left(\frac{b}{a}\right)^2-1\right\}}\left\{\left(\frac{b}{a}\right)^2+1\right\}\right\}} \tag{84.11}$$

where P_{Y} is the yield onset pressure, ΔT_{Y} is the yield onset temperature difference and α is the coefficient of thermal expansion. The yield onset rotational speed is given by Eq. (84.8). The maximum load during service in the autofrettaged disk is obtained by superposing the loading stresses with the rotational residual stresses as discussed in Ref [18] such that the autofrettaged disk does not yield.

It is observed from Fig. 84.3 that the percentage increase in the internal pressure loading and temperature difference of the autofrettaged disk compared to the non-autofrettaged one is of the same order for all wall thickness ratios. The percentage increase in the rotational speed of the disk in service is comparatively lesser than the increase in the other two loads. The percentage increase in all the loads is increased significantly up to the wall thickness ratio 4.6. There is no significant change in the percentage increase of the relative load-carrying capacities as the wall thickness ratio is increased beyond $b/a = 4.6$. Thus, for attaining the maximum load carrying capacity in a disk, the maximum wall thickness ratio can be considered as $b/a = 4.6$. The maximum increase in the internal pressure and the radial temperature difference is about 97% and that in the rotational speed is about 41% during operation corresponding to the wall thickness ratio $b/a = 4.6$.

84.3.2 Influence of Autofrettage Rotational Speed

In rotational autofrettage, the plastically deforming load is in the form of a centrifugal force due to a sufficiently high rotational speed. Thus, the rotational speed plays an important role during rotational autofrettage of a disk. In Table 84.1, it is shown that the maximum rotational speed requirement for rotational autofrettage increases with the increase of wall thickness ratio. Consequently, the residual hoop stress generated at the inner and outer surfaces of the disk is also estimated for all wall thickness ratios up to five. Here, in this section, keeping the wall thickness ratio constant, the effect of rotational speed on the residual stress and the corresponding load-carrying capacity when subjected to different individual loads are assessed. For instance, the wall thickness ratio is taken as three for a typical SS304 disk. The normalized rotational speed for initiation of yielding at the inner side for $b/a = 3$ is 0.363, and the normalized rotational speed for completely plasticizing the disk wall is 0.481. Thus, for all simulations the rotational speed is taken in the range, $0.363 \leq \Omega \leq 0.481$. Within this range, the residual stress at the inner and outer surfaces of the disk is presented in Table 84.2 along with the percentage overstrain (ε) and the percentage increase in different individual loads during operation.

Table 84.2 Effect of rotational speed on percentage overstrain, residual stress and different load-carrying capacities

Normalized rotational speed (Ω)	Percentage overstrain $\varepsilon = \frac{c-a}{b-a} \times 100\%$	Normalized residual stress $\left(\frac{\sigma_\theta^{Res}}{\sigma_Y}\right)$		% increase in the maximum service load		
		At the inner surface	At the outer surface	Pressure	Temperature difference	Rotational speed
0.381	5.50	−0.1036	0.001453	10.30	10.86	5.05
0.399	12.79	−0.2148	0.007219	21.28	21.74	10.22
0.418	22.37	−0.3314	0.02043	33.13	33.69	15.38
0.437	35.07	−0.4533	0.04743	45.32	45.65	20.55
0.456	52.11	−0.5805	0.1033	58.05	58.69	25.72
0.475	78.19	−0.7131	0.2488	71.22	71.73	30.88
0.480	98.79	−0.7537	0.4367	74.51	75	32.43

It is observed from Table 84.2 that as the rotational speed in the loading phase is increased for a constant wall thickness ratio, the percentage overstrain, level of normalized residual stresses at the inner and outer surfaces and the percentage increase in the individual pressure loading, temperature difference across the wall thickness and the rotational speed during working increases. The maximum percentage increase in the respective individual service load is achieved for $\Omega = 0.480$. In order to attain a high rotational speed of the disk, high power/torque motor will be needed in practice. This may increase the equipment cost. However, one can choose the autofrettage speed depending upon the strength requirement of the disk in the actual working environment and accordingly select a motor of required capacity. It is also observed from Table 84.2 that at lower rotational speed, the outer surface of the disk is subjected to very low tensile residual stresses. Thus, at lower rotational speed, the outer surface of the disk is less sensitive to the stress corrosion cracking.

84.3.3 Influence of Material Properties

In rotational autofrettage of thick-walled disk, the properties of the disk material plays a very important role on the rotational speed during loading phase and residual stresses. The yield stress (σ_Y) of the material and density (ρ) are the two dominating material properties which influences the rotational autofrettage of a disk. It follows from Eq. (84.3) that for materials with high density and low yield stress predicts yielding at low rotational speed. In order to assess the effect of ρ and σ_Y, disks of different materials with different combinations of ρ and σ_Y are considered as listed in Table 84.3. The radial dimensions for all disks are kept constant

Table 84.3 Materials with different combinations of ρ and σ_Y

Materials	ρ (kg/m^3)	σ_Y (MPa)
Aluminum	2700	50.3
SS304	8000	205
Ti-0.3Mo-0.8Ni	4510	380
Titanium unalloyed	4510	170
ASTM-A723	7850	1050

and is taken as $a = 0.1$ m and $b = 0.3$ m for instance. The Poisson's ratio for all materials is taken as 0.3.

Now, the rotational autofrettage for all disks is numerically simulated such that the inner surface is subjected to the maximum possible compressive residual stress. The results are presented in Table 84.4. It is observed that in order to generate the maximum possible compressive residual stress ($-0.7537\sigma_Y$ in all disks), the rotational speed increases proportionately for higher yield stress. For the low values of yield stress and density, e.g., aluminum, the rotational speed required to achieve the maximum possible compressive residual stress is lower. Thus, for such materials the speed required for rotational autofrettage can be attained using a low power/low torque electrical motor. This makes the process comparatively inexpensive. However, for high values of yield stress and density, e.g., ASTM-A723, makes inconvenience in achieving the rotational autofrettage in terms of the high speed requirement. For ASTM-A723 disk, the rotational speed required to achieve the maximum possible compressive residual stress is 1756.86 rad/s (16776.78 rpm), which is very high. This requires a high power motor to induce high speed in the disk. Also, in such cases, extra care needs to be taken for dynamic balancing of the rotating system. Materials possessing same density (e.g., Ti-0.3Mo-0.8Ni and titanium unalloyed) require higher rotational speed with the higher yield stress. The materials with medium density and lower yield stress, e.g., SS304 requires moderate speed, which is also convenient for rotational autofrettage.

Table 84.4 Effect of material properties on rotational autofrettage

Materials	ω_i (rad/s)	ω (rad/s)	Compressive residual stress at the inner surface
Aluminum	495.1027	655.66	$-0.7537\sigma_Y$
SS304	580.6643	768.96	$-0.7537\sigma_Y$
Ti-0.3Mo-0.8Ni	1052.9	1394.39	$-0.7538\sigma_Y$
Titanium unalloyed	704.2541	932.64	$-0.7538\sigma_Y$
ASTM-A723	1326.6	1756.86	$-0.7538\sigma_Y$

84.4 Conclusions

In this work, a parametric study of a new method of rotational autofrettage for a thick-walled axisymmetric circular disk is carried out. The study is based on the theoretical analysis of Kamal [18]. The influence of different process parameters on the performance of rotational autofrettage of thick-walled disk is carried out. First, the effect of wall thickness ratio on the rotational speed is studied followed by its effect on the residual stresses and different load-carrying capacities. Then, the effect of rotational speed, material density and yield stress on the residual stress and load-carrying capacities is considered. It is found that as the wall thickness ratio is increased the rotational speed required to cause plastic deformation for achieving rotational autofrettage in the disk is decreased. The rotational speed requirement is the minimum for wall thickness ratio of five with less than 5% reduction in speed upon subsequent increase of wall thickness ratio. It is also found that with the increase of wall thickness ratio, the compressive residual stress induced at the inner surface increases corresponding to the maximum rotational speed. For $b/a = 4.8$ and above, the maximum compressive residual stress induced in the disk is $-0.99\ \sigma_Y$. The study of the influence of wall thickness ratios on the different load-carrying capacities shows that with the increase of wall thickness ratio, the percentage increase in the individual pressure loading, temperature difference and rotational speed of the disk in service increases. It is found that the maximum load-carrying capacities in all the three individual loads is achieved for $b/a = 4.6$ with an error of less than 1%. The percentage in the working pressure loading and temperature difference are of the same order for all wall thickness ratios. However, the percentage increase in the centrifugal load (rotational speed) is lesser compared to the increase in working pressure and temperature difference for wall thickness ratios. The effect of rotational speed for constant wall thickness ratio of the disk shows that on increasing the rotational speed, the residual stresses at the inner and outer surfaces and the percentage increase in the different individual loads during working increases for a typical disk. The yield stress of the material and density also influence the rotational autofrettage of a disk. It is observed that the lower the yield stress of the material, the lower the rotational speed necessary to achieve a certain level of autofrettage. Materials with high yield stress and high density require very high rotational speed to achieve rotational speed. The necessary high speed may be produced by utilizing a high power/high torque motor in such cases. However, this will make the process comparatively expensive. High rotational speed may also cause dynamic imbalance of the system. Thus, rotational autofrettage is convenient for low yield stress and low density materials. Finally, it may be concluded that for the applications of the disks as a rotating component in aircraft and automobile industries or as fastener holes subjected to high pressure/temperature, rotational autofrettage is a very useful strengthening method. For this purpose, the process parameters in the rotational autofrettage of the disk should be selected as per the strength requirement of the disk against the working load during operation.

Chapter 85
Influence of Varying Fully Constrained Circular Boundary Condition Area on Damage Mechanism of GFRP Laminate Under Low Velocity Impact Loading

Mahesh and K. K. Singh

Abstract Modern aircrafts, automobiles, space crafts, etc., need light weight and high-performing structures or materials to reduce the total weight of the structure without compromising in strength which highly influences the efficiency of that structure and fuel cost associated with it. Thus, fiber-reinforced polymer (FRP) laminates are the most suitable materials for these kinds of applications due to their high specific strength to weight ratio which is better than many other conventional metal or alloy materials. But these materials are highly prone to catastrophic and sudden failure because of their unpredictable and undetectable crack growth and formation in the laminate structure. These undetectable cracks, also known as barely visible impact damage (BVID), which are induced into the laminate under low velocity impact. Example includes dropping of a tool in an assembly line. Low velocity impact (LVI) is a highly complex phenomenon as it consists of subsurface micro cracks (fiber and matrix cracking), debonding, delamination, and fiber breakage. Due to anisotropic nature of the material, prediction of damage induced becomes difficult. Hence, in this numerical analysis, LS-DYNA is used to carry out the LVI loading onto a bidirectional plain woven glass fiber-reinforced polymer (GFRP) laminate using a hemispherical striker of mass 20 kg with a nose radius of 5 mm impacted at a velocity of 2 m/s. During the analysis, fully constrained circular boundary condition (FCCBC) is used and the radius of the circular boundary condition (CBC) is varied from 15 to 35 mm with an increment of 10 mm. Effect of variation in boundary condition diameter on damage area is examined using von Mises stresses, energy versus time, force versus time, and displacement versus time graphs.

Keywords GFRP · Low velocity impact (LVI) · Boundary condition · Damage mechanism

85.1 Introduction

FRP composites gained widespread application during the World War-II due to their high strength to weight ratio. Since then, it is used in various industries. Impact is one of the critical loading conditions for FRP composites particularly low velocity impact is fatal because it creates subsurface or barely visible impact damages or nonvisible cracks to the naked eyes. These cracks, over a prolonged period of time grows throughout the laminate and reduces strength of the laminate or structure which leads to sudden or catastrophic failure of the structure. Even though experimental investigation can be carried out to study the damage mechanism, understanding the damage behavior and evolution becomes complex because these materials are highly anisotropic in nature. Moreover, damage mechanism involves various failure mechanisms such as fiber breakage, matrix cracking, delamination, etc. Thus, numerical analysis helps in better understanding of damage mechanism. Damage mechanism and its pattern are influenced by various aspects such as impactor shape, impacting angle, etc., which are all considered as impact loading parameters. One among them is boundary condition because this determines the material space available for absorbing energy from the impactor to the laminate particularly if the boundary condition (BC) is fully constrained clamped type. Although wave propagation in FRP laminate influences the damage pattern and deformation of the material but only at high velocity impact, and this effect is less observed for low velocity impact (LVI).

An extensive literature review was conducted by [1–3] on low velocity impact behavior of FRP laminates and covered various aspects of laminates as well as impact parameters. Moreover, these review works covered the various finite element analysis tools used particularly LS-DYNA. Li et al. [4] studied the GFRP laminates behavior under LVI loading using drop-weight impact machine and simulated the experimental results using ABAQUS FEA tool with edge constrained boundary condition. Both experimental and numerical results showed that central deflection and extent of damage at front as well as back surface behaved linearly with respect to the impact energy. Both numerical and experimental results were reasonably in good agreement. Rawat et al. [5] used LS-DYNA to study the behavior of symmetric and asymmetric GFRP laminates with and without pre-cracks under low velocity impact. From results, it was clear that without pre-crack symmetric laminate performed better than symmetric with pre-crack and asymmetric laminate with and without pre-crack. Author's used circular boundary condition for both symmetric and asymmetric laminate design. Finally, concluded that energy absorption is influenced by symmetric nature of the plies arranged in the laminate about the mid-plane. Rawat et al. [6] investigated the influence of impactor shape on damage area and damage shape under LVI. Eight ply symmetric GFRP

laminate was impacted with flat, hemispherical, spherical, and oval-shaped impactor. LS-DYNA numerical simulation showed that flat-headed impactor caused maximum damage area while oval-shaped impactor caused minimum damage area but it fractured maximum fibers in the laminate. It was concluded that contact surface area with the laminate primarily influenced the damage extent and pattern. Ansari and Chakrabarti [7] examined the influence of boundary condition and impactor nose angle on GFRP laminates under impact loading. Experimental work is carried out on pneumatic gun with flat-and conical-headed impactor and ANSYS was used for numerical simulation. Clamped and simply supported boundary conditions were considered during the analysis. From experimental and numerical analysis, it was concluded that the blunt impactor showed more resistance to penetration under simply supported boundary condition. Liu et al. [8] investigated the satin weave and unidirectional hybrid carbon fiber laminates damage resistance under LVI. Drop-weight impact tester was used for experimentation while ABAQUS was used for numerical validation. From experimental and numerical analysis, it was concluded that damage resistance was affected by lay-up sequence. Delamination was found to be the major failure mode and observed a good correlation between numerical and experimental results. Hashin failure criteria was used by Kim et al. [9] to develop a three-dimensional progressive damage model for GFRP laminate. Developed model was simulated using LS-DYNA and experimental validation was done by conducting impact and flexural testing. Author's concluded that to predict the behavior of impact, interlaminar delamination, and damage progression, three-dimensional progressive failure can be used. Constant Menna et al. [10] investigated GFRP laminates made of different thickness under low velocity impact using LS-DYNA numerical analysis tool. From analysis, it was found that delamination was the major damage mode of failure and majorly observed at mid-plane. Both experimental and numerical analysis found to be in good agreement.

Many available literature is related to behavior of FRP laminate under different boundary conditions, impactor nose shapes, laminate ply orientation, symmetric nature of laminate about the mid-plane, etc. But there is no work that correlates the damage area or energy absorption by the laminate with the boundary condition area. Thus, in this simulation work bidirectional woven glass fibers-reinforced with epoxy is considered. Laminates are made of eight plies with symmetric configuration [11] and impacted with a hemispherical impactor made of mild steel. Circular boundary condition with varying area is considered and LS-DYNA is used to carry out the numerical simulation. To author's knowledge more work is done on different boundary conditions and impactor shapes but a very less work is done on influence of varying boundary condition area and its effect on damage mechanism of FRP laminates under LVI.

85.2 Numerical Simulation

85.2.1 Materials Used

Bidirectional plain woven glass fiber and epoxy laminate are considered for laminates. All the materials properties are provided in Table 85.1 and orientation of the plies is $[(0/90)/(+45/-45)/(+45/-45)/(0/90)]_S$. A mild steel hemispherical-shaped impactor of diameter 10 mm is considered.

85.2.2 Numerical Modeling

MAT_59_SOLID_COMPOSITE_FAILURE_SOLID_MODEL is used to model the GFRP laminate. This card considers the material as orthotropic material and is modeled for enhanced damage modeling. MAT_20_Rigid is used to model the mild steel impactor. Contact between plies and impactor is modeled using AUTOMATIC_SURFACE_TO_SURFACE while TIED_SURFACE_TO_SURFAC- E is used to model the contact between the plies. BOUNDARY_ CONDITION_ SPC is used to model the circular boundary condition with varying radius of 15, 25, and 35 mm. Area of boundary conditions is 706.85, 1963.49, and 3848.45 mm^2. These boundary condition from here onwards are referred as boundary condition 15 (BC 15), boundary condition 25 (BC 25), and boundary condition 35 (BC 35), respectively.

85.3 Results and Discussion

As the boundary condition area is varied, the response time and von Mises stresses generated during the impact are also varied. Effective von Mises stresses (Fig. 85.1) are high for boundary condition 15 at midplies when compared to other two boundary conditions because less material space or region is available to absorb the

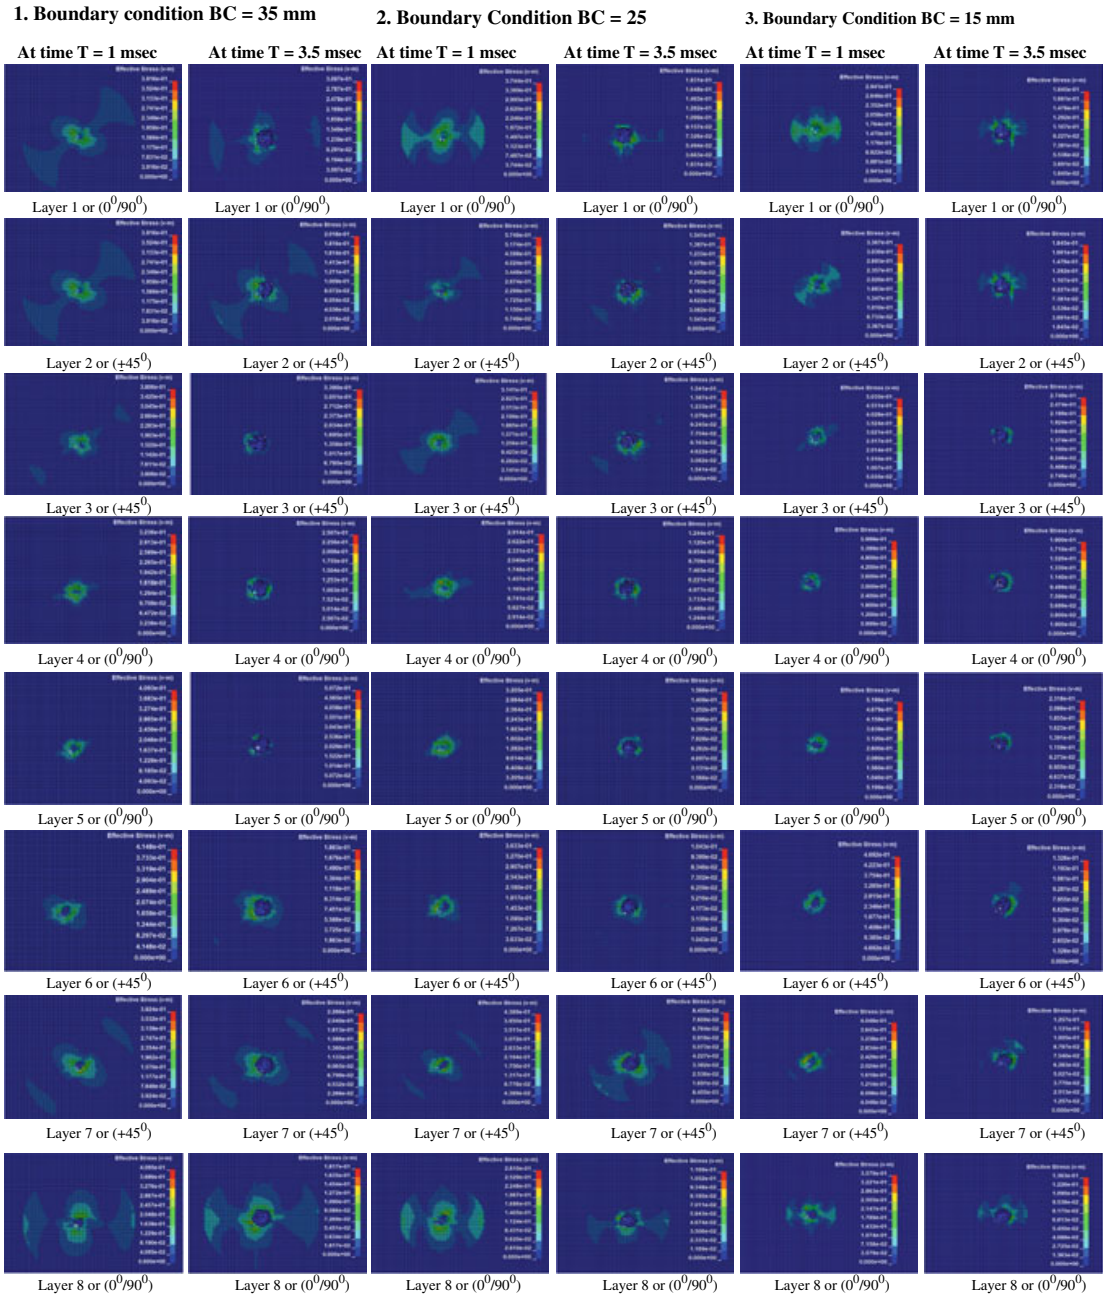

Fig. 85.1 Effective von Mises stresses at time T = 1 ms and T = 3.5 ms

impacted energy. Whereas, at boundary condition 35, the increase in von Mises stresses is gradual because sufficient material space is available for the material to react with the impacted energy. Table 85.2 provides the maximum effective von misses stresses generated in each plies at time T = 1 ms and it is observed that at boundary condition area 35, there is gradual drop in the effective von Misses stresses from top ply to the mid ply and then gradual increase from midply to the bottom ply while exactly opposite is observed in case of boundary condition 25, while a sudden increase in effective von Mises stresses and reaches maximum value at mid ply and then starts declining gradually from mid ply to the bottom ply

Table 85.2 Maximum von Mises stresses under varying boundary condition at time $T = 1$ ms

Ply position in laminate from top to bottom	Boundary condition = 15	Boundary condition = 25	Boundary condition = 35
1	2.941e−1	3.744e−1	4.732e−1
2	3.367e−1	5.749e−1	3.916e−1
3	5.035e−1	3.141e−1	3.806e−1
4	5.999e−1	2.914e−1	3.236e−1
5	5.199e−1	3.205e−1	4.093e−1
6	4.692e−1	3.633e−1	4.148e−1
7	4.048e−1	4.389e−1	3.924e−1
8	3.579e−1	2.810e−1	4.095e−1

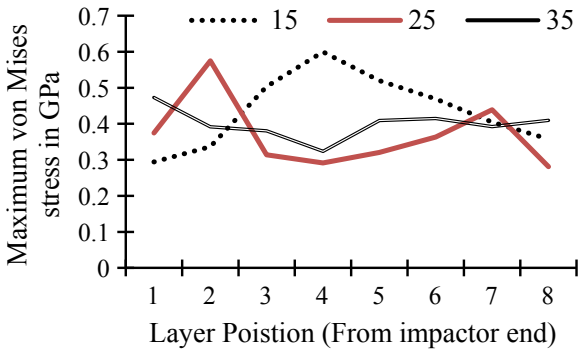

Fig. 85.2 Effective von Mises stresses generated at time $T = 1$ ms

(Fig. 85.2). This kind of behavior is mainly influenced by the boundary condition area and this transaction in behavior is observed from boundary condition 25 which bridges between boundary condition 15 and 35.

Complete fiber fracture is observed in case of boundary condition 15 at time $T = 3.5$ ms, while no such fracture is observed for boundary condition 35 whereas, boundary condition 25 showed mixed behavior as shown in Fig. 85.1. Effective von Mises stresses is high for boundary condition 35 in each ply when compared to boundary condition 15 (Table 85.3). Here, gradual increase and then decrease trend is observed for boundary condition 15, while exactly opposite characteristic is exhibited by boundary condition 35 as seen in Fig. 85.3.

Almost square damage is observed in all boundary conditions. Initially, at time $T = 1$ ms, damage area for boundary condition 15 is high when compared to other boundary conditions, while at time $T = 3.5$ ms damage area is high for boundary condition 35 then boundary condition 25 and boundary condition 15 (Fig. 85.4) because boundary condition 15 at initial stage reacted to impactor with all available material space. But over a period of time, damage area gets saturated for boundary condition 15 while for BC 35, there is enough material space available to react with the impactor to absorb the energy over a period of time through deformation. But boundary condition 15, after saturation absorbed energy is dissipated in terms of damage height, and maximum damage height is also observed for boundary condition 15 (Fig. 85.5 and Tables 85.4, 85.5).

Table 85.3 Maximum von Mises stresses under varying boundary condition at time $T = 3.5$ ms

Ply position in laminate from top to bottom	Boundary condition = 15	Boundary condition = 25	Boundary condition = 35
1	1.845e−1	1.831e−1	3.097e−1
2	2.674e−1	1.541e−1	2.018e−1
3	2.749e−1	1.183e−1	3.390e−1
4	1.900e−1	1.244e−4	2.507e−1
5	2.318e−1	1.566e−1	5.072e−1
6	1.326e−1	1.043e−1	1.863e−1
7	1.257e−1	8.455e−1	2.266e−1
8	1.363e−1	1.169e−1	1.817e−1

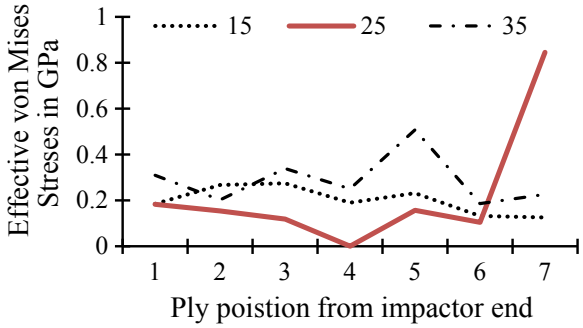

Fig. 85.3 Effective von Mises stresses at time $T = 3.5$ ms

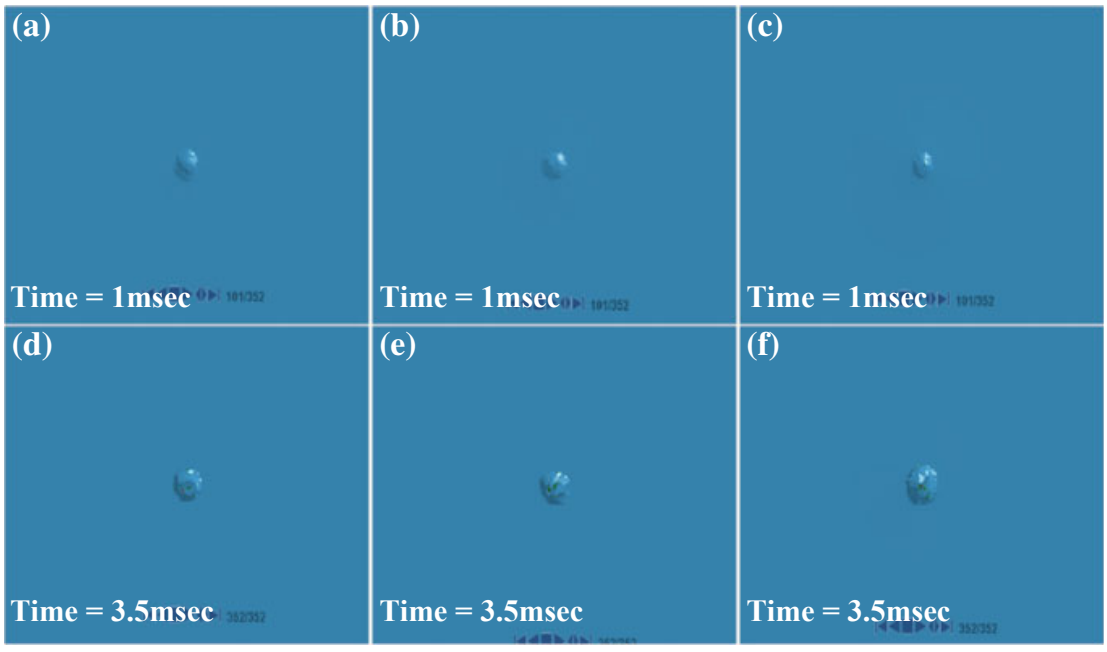

Fig. 85.4 Damage along X-and Y-direction at time $T = 1$ ms **a** and **d** boundary condition 15, **b** and **e** boundary condition 25, and **c** and **f** boundary condition 35

Table 85.4 Approximate damage area

Time = 1 ms	Damage length in mm		Approx. damage area at base mm^2
Boundary condition	*X*-direction	*Y*-direction	
15	10.135	10.0464	101.8202
25	10.0703	8.2277	82.8554
35	8.2384	8.1574	67.2039

Table 85.5 Approximate damage area and damage height

Time = 3.5 ms	Damage length in mm		Approx. damage area at base in mm^2	Approx. damage height in mm^2
Boundary condition	*X*-direction	*Y*-direction		
15	11.1415	10.167	113.2746	8.3503
25	11.9445	10.2682	122.6485	7.4180
35	13.0267	12.663	164.9571	8.3008

Energy absorption is more for boundary condition 35 than 15 and 25 (Fig. 85.6) but this difference is very small and causes for this variation is material space availability during the impact. Maximum resultant displacement is shown by boundary condition 35 and is more compared to BC 15 and 25. Moreover, BC 15 showed linear displacement because there is no deformation in material instead involves fiber breakage. But BC 25 indicates the transaction form linear displacement to more elongate or bell-shaped deformation (Fig. 85.7). More fiber breakage

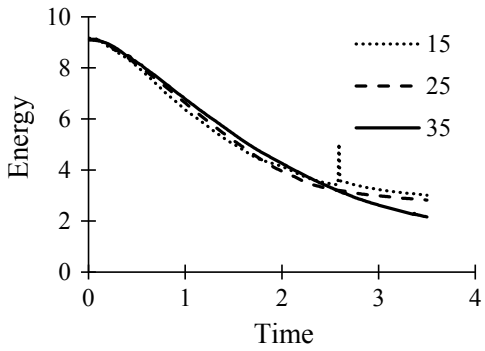

Fig. 85.6 Impact energy (J) versus time (ms)

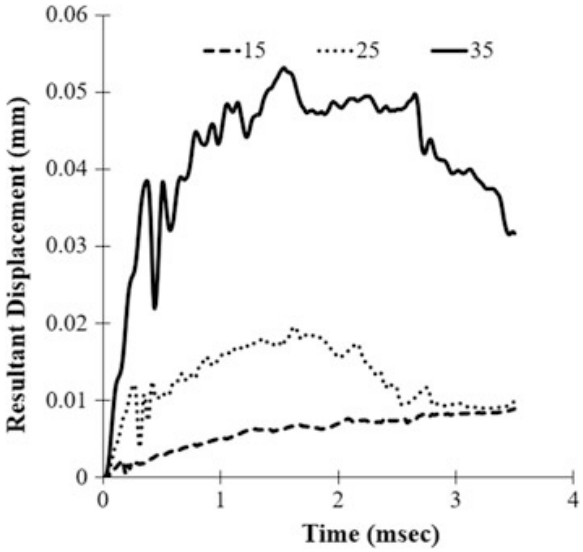

Fig. 85.7 Resultant force (N) versus time (ms)

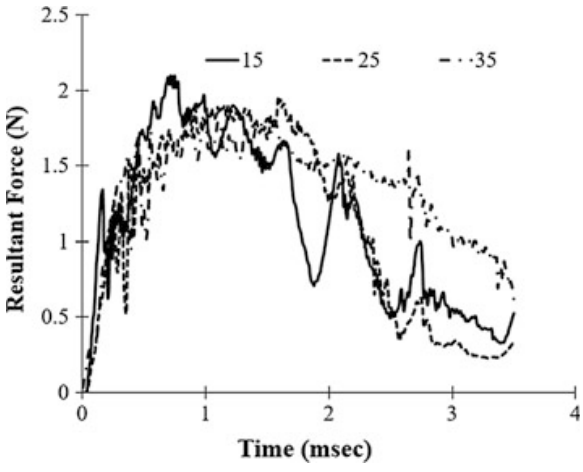

Fig. 85.8 Resultant displacement (mm) versus time (ms)

is observed in case of boundary condition 15 than other boundary conditions (Fig. 85.8). because there is more space available at boundary condition 35 for material to undergo sufficient deformation.

85.4 Conclusion

Influence of boundary condition area is studied for GFRP laminate under LVI using LS-DYNA. Three circular boundary conditions 15, 25, and 35 mm in radius are considered for simulation. Damage length in *X*-and *Y*-direction, damage height, effective von Mises stresses, resultant displacement, energy absorption, and resultant force are evaluated. From numerical simulation results and observation following points were concluded.

- As the boundary condition area reduces, the damage area reduces by 31% at 3.5 ms for boundary condition 15 when compared to boundary condition 35 but fiber breakage and damage height increases in case of boundary condition 15.
- As the boundary condition area reduces, the deformation associated with the material also reduces. Reduction in deformation for boundary condition 15 is found to be 69% less when compared to boundary condition 35 at time $T = 3.5$ ms.
- As the boundary condition reduces, the energy absorption capacity reduces but this reduction is less when compared to higher boundary condition. In case of boundary condition 35 absorbed 9% more energy compared to boundary condition 15.
- As the boundary condition area is reduced from 35 to 15, stress generation is also increased because in case of boundary condition area 15, the material space availability is less compared to 35. Moreover, maximum stress generation is also due to the fiber breakage which is maximum in case of boundary condition area 15 than 35.
- Stresses generated in the material show drastic and sudden increase for small boundary condition area.

Chapter 86
Process Capability Index for Geometrically Distributed Quality Characteristics

N. K. Singh

Abstract Process capability indices play a very important role in the control and the improvement of quality characteristics of products during the production process. Various process capability indices have been developed for quality characteristics which follow normal, Weibull, exponential and other distributions. Many researchers have also developed process capability indices for quality characteristics which follow bivariate normal and exponential distributions, respectively. Some of these indices are being used by industries for the quality improvement of products during the production process for competing in global markets. Some quality characteristics of the products should be treated as discrete random variables following distributions like geometric distribution rather than widely known continuous distribution like normal. Such situations are encountered while dealing with quality characteristics like number of operations before the failure of electrical, electronic or mechanical switches and components. The control and the improvement of such quality characteristics of such products during the production process, in order to ensure the conformity to the specification (usually one-sided), are quite important. No much work has been done so far to develop process capability index applicable to such quality characteristics following the geometric distribution. In this paper, the author proposes a process capability index for a number of successes or operations before the first failure of a component or product assumed to follow a geometric distribution and derives the expectation and variance of the estimated index. The optimal choice of process capability interval related to the said index has also been discussed. The said process capability index may be low for a highly capable process and for the minimum variation of the index, the percentage area lying outside natural tolerance limit may be low as 0.02, and the probability of successes or operations before the first failure may be high as 0.99.

86.1 Introduction

Process capability index C_p is a simple relative number or numerical value comparing the value of required process variability (required tolerance interval) to natural process variability (natural tolerance interval). Kane [1] introduced the process capability index C_p, also called process potential index, which considers spread only.

$$C_p = \frac{(U - L)}{6\sigma} \tag{86.1}$$

$$C_p \geq 1 \quad \text{For a capable process}$$

where U and L are upper and lower specification limits, respectively.

However, C_p focuses on the dispersion of the studied process and does not take into account the centering of the process. To overcome this problem, Kane [1] introduced the process performance index, C_{pk} as,

$$C_{pk} = \min\left\{\frac{\text{USL} - \mu}{3\sigma}, \frac{\mu - \text{LSL}}{3\sigma}\right\} \tag{86.2}$$

where μ is the process mean and σ is the process standard deviation of the in-control process.

The reason for six in the denominator in Eq. (86.1) is that under the assumption of normality, 6σ spread covers 99.73% of the data, leaving only 0.27% in non-conforming range. Larger values of C_p indicate high process capability while smaller values (less than 1.0) indicate lower process capability and incapable process.

The indices C_p and C_{pk} do not take into account the target value. Chan et al [2] point out that the index while ensuring that the process spread is within the specification limits, fails to take into account the target value, T of the process. To correct this, the authors suggested a modified version of C_p, Thus, this index is defined as

$$C_{pm} = \frac{U - L}{6\tau} = \frac{C_p}{\sqrt{1 + \left(\frac{\mu - T}{\sigma}\right)^2}} \tag{86.3}$$

where $\tau^2 = \sigma^2 + (\mu - T)^2$

It is obvious that C_{pm} is smaller than C_p.

The index C_{pm} was also proposed independently by Taguchi and Hsiang [3]. C_{pm} is, sometimes, called Taguchi capability index.

A capability index, which is more sensitive than C_{pk} and C_{pm} with regards to departures from the process mean to the target value, was introduced by Pearn et al. [4] as

$$C_{pmk} = \min\left\{\frac{\text{USL} - \mu}{3\sqrt{\sigma^2 + (\mu - T)^2}}, \frac{\mu - \text{LSL}}{3\sqrt{\sigma^2 + (\mu - T)^2}}\right\} \tag{86.4}$$

A superstructure or family of capability indices, containing C_p, C_{pk}, C_{pm} and C_{pmk} involving two parameters, is introduced by Vannman [5] as,

$$C_p(u, v) = \frac{d - u|\mu - m|}{3\sqrt{\{\sigma^2 + v(\mu - T)^2\}}} \tag{86.5}$$

where $d = \frac{U-L}{2}$ and $m = \frac{U+L}{2}$

By letting $u = 0$ or 1 and $v = 0$ or 1 in the above equation, we can obtain four basic indices, i.e., $C_p(0,0) = C_p$, $C_p(1,0) = C_{pk}$, $C_p(0,1) = C_{pm}$ and $C_p(1,1) = C_{pmk}$.

Wang and Hubele [6] discussed geometric distance approach to reduce the dimensionality of the multivariate (normal and non-normal) data to univariate data and used established univariate process capability index (PCI) for process performance analysis.

Castagliola [7] extended the paper of Castagliola and Castellanos [8] for the estimation of bivariate PCIs in the case of non-normal bivariate distributions. The proposed method is based on the use of Johnson's distribution/transformation in order to transform the bivariate non-normal distribution into an approximate bivariate normal distribution. Numerical examples have been presented and some criteria are given in order to choose the appropriate Johnson's distribution.

Raut and Attar [9] provided a case study based on process capability in the vehicle industry. In this case study, area of analysis was the measurement section for which they selected the body shop production. The main highlights of the case study were to go through a comprehensive explanation of the entire body shop and the departments covered in it.

Senvar and Sennaroglu [10] examined Clements' Approach (CA), Box-Cox transformation (BCT) and Johnson transformation (JT) methods for process capability evaluations through Weibull-distributed data with dissimilar parameters to figure out the effects of the tail behaviors on process capability and matched their performances in terms of accuracy and precision.

In Sect. 86.2 of this paper, the author proposes a process capability measure for the number of success or operations before the failure assumed to follow a geometric distribution and derives the expectation and sampling variance of the estimated index. The optimum choice of process capability interval has been discussed in Sect. 86.3.

86.2 Process Capability Index for Geometric Distribution

*86.2.1 Process Capability Index (*Ig*)*

The probability density function (pdf) for geometric distribution is given by

$$f(x) = qp^x \tag{86.6}$$

$$\text{Let } \sum_{x=0}^{y} f(x) = 1 - p^{y+1} = \alpha \tag{86.7}$$

where x is the number of operations/successes before the first failure of the equipment or component, and p and q are probabilities of success and failures, respectively. α is the percentage area lying outside natural tolerance limit.

The natural process interval may be taken as (y, α) with the probability content $1 - \alpha$.

From Eq. (86.7), we get

$$y = \frac{\log\left(\frac{1-\alpha}{p}\right)}{\log p}$$

Then the process capability index (Ig) can be proposed as

$$Ig = \frac{L}{y} = \frac{L.\log p}{\log(\frac{1-\alpha}{p})} \tag{86.8}$$

Assuming y, the number of successes/operations follows a geometric distribution, L is the lower specification limit and U, the upper specification limit is ignored. It is also assumed that there is no measurement error.

It may be noted that process capability indices, e.g., C_p, C_{pk}, C_{pm} *and* C_{pmk}, mentioned in Sect. 86.1 should always be greater than unity for a capable process, but in Eq. (86.8) Ig may be taken less than unity for a capable process.

The sample estimate of Ig comes out to be

$$\hat{I}g = \frac{L}{\widehat{y}} = \frac{L.\log \hat{p}}{\log\left(\frac{1-\alpha}{\hat{p}}\right)} = LG(\hat{p}), \quad \text{say} \tag{86.9}$$

where $\widehat{y}$ = Sample quantile of order α

86.2.2 Estimation of $\hat{\mathbf{I}}\mathbf{g}$

We have (from Johnson and Kotz [11]).

$$E(x) = \frac{p}{q}$$

From Eq. (86.6)
Maximum likely estimate $m.1.e$ of $\hat{p}$ comes out to be,

$$\hat{p} = \frac{\bar{x}}{\bar{x}+1},$$

where $\bar{x}$ = Average number of successes before the first failure.
Then putting this value of $\hat{p}$ in Eq. (86.9), it is found that,

$$\hat{I}g = \frac{L.\log(\frac{\bar{x}}{\bar{x}+1})}{\log\left\{\frac{(1-\alpha)(\bar{x}+1)}{\bar{x}}\right\}} = L\psi(\bar{x}), \quad \text{say} \tag{86.10}$$

86.2.3 Sampling Properties of $\hat{\mathbf{I}}\mathbf{g}$

Bias of $\hat{Ig}$
From standard results in large sample theory (see, e.g., Kendall and Stuart [12]).

$$E(\hat{I}g) = L.E\{\psi(\hat{p})\} \approx L.\psi(p) = Ig$$

Thus, $\hat{I}g$ is asymptotically unbiased for Ig.

Sampling variance of $\hat{Ig}$
It is known that

$$\mathrm{Var}(\hat{I}g) = L\left(\frac{\delta\psi}{\delta\bar{x}}\right)^2 \mathrm{Var}(\bar{x}) \tag{86.11}$$

$$\bar{x} = \frac{p}{q}$$

where $\mathrm{Var}\,(\bar{x}) = \frac{\mathrm{Var}_x}{n} = \frac{1}{n}\cdot\frac{p}{q^2}$

On differentiation of $\psi(\bar{x})$ in Eq. (86.10) with respect to $\bar{x}$, it is found that

$$\frac{\delta\psi}{\delta\bar{x}} = \frac{L.\log(1-\alpha)}{\bar{x}(\bar{x}+1)\left[\log\left\{\frac{(1-\alpha)(\bar{x}+1)}{\bar{x}}\right\}\right]^2}$$

On putting this value in Eq. (86.11) and on simplification, it is found that

$$\mathrm{Var}(\hat{I}g) = \frac{L^2}{n}\frac{(1-p)^2}{p}\frac{\{\log(1-\alpha)\}^2}{\left\{\log\left(\frac{1-\alpha}{p}\right)\right\}^4} \tag{86.12}$$

86.3 Optimum Choice of α

Usually, the percentage area α lying outside natural tolerance limit will be given from assurance (confidence) requirement. However, one may, even for the sake of the theoretical interest, try to choose the value of α such that, for a given process parameter p, will result in the most stable estimate of process capability index *Ig* (in repeated sampling).

On differentiation of Var $(\hat{I}g)$ in Eq. (86.12) with respect to α and equating it to zero, it is found that for minimum variation of Var $(\hat{I}g)$.

α = 0 or 1 which are not feasible solutions.

So, the variance minimizing choice of α depends on *p* and vice versa.

From Eq. (86.12) and Table 86.1, on numerical analysis, it is observed that when α increases, Var $(\hat{I}g)$ decreases, *p* remaining constant. It means that the variation in the process capability may be less when the percentage area lying outside natural tolerance is more resulting in less Nos. of successes or operations of products. It is also observed from Table 86.2 that when *p* increases Var $(\hat{I}g)$ increases, α remaining constant. It means that the variation in the process capability may be more in order to achieve a high probability of successes or operations. More efforts may be needed for the improvement of the process to achieve high Nos. of successes or operations of products.

So, for the minimum variation of process capability index *Ig*, α may be chosen as low as possible, corresponding to a fixed *p*. For example, choice of α may be chosen as 0.02 if *p* (or its estimate) comes out to be 0.99.

Table 86.1 Values of Var $(\hat{I}g)$ corresponding to α at constant *p*

Values of α at $p = 0.99$	(n/L^2) x Var $(\hat{I}g)$
0.02	19.787
0.03	2.864
0.04	0.983
0.05	0.487

Table 86.2 Values of variance Var ($\hat{Ig}$) corresponding to p at constant α

Values of p at $\alpha = 0.02$	$(n/L^2) \times$ Var ($\hat{Ig}$)
0.99	19.787
0.985	736.95
0.97	181.43
0.96	19.95
0.95	6.099
0.94	2.747

86.4 Typical Applications

The process capability index (Ig) may be applied in finding out capability or variability of process or system having Nos. of flights or Nos. of landings before the first failure after planned repair and preventive maintenance of an aeroplane. This may also prove to be helpful in taking decision on the variability of the process for the production of electrical, electronics and computer components and hardware in order to increase their probability of success (p) resulting in their reliability as required in reliability-centered maintenance in special case.

86.5 Conclusion

The process capability index (Ig) may be less than unity and positive for a capable process for the quality characteristics following the geometric distribution and for the minimum variation of Ig, the percentage area (α) lying outside natural tolerance limit may be low as 0.02 and probability of successes or operations before the first failure may high as 0.99.

Chapter 87
Thermomechanical Analyses of Single Sided Single Pass Submerged Arc Welding of AISI 304 Austenitic Stainless Steel

P. V. S. S. Sridhar, Vishnu Nair, Pankaj Biswas and Pinakeswar Mahanta

Abstract The submerged arc welding (SAW) is an automated process that is capable to weld thick and thin plates of steel and non-ferrous materials due to its ease of operation, less spatter and high deposition rates. SAW is extensively used to fabricate bridges, pipe lines, pressure vessel construction, ship building and surface cladding. In present study numerical simulation on effect of welding speed on residual stresses for SAW with square butt geometry of austenitic stainless steel is explored. A moving heat source model considering heat generation is used in this present study. The element birth and death technique is used to incorporate the effects of filler metal deposition. The peak temperatures observed in experimentation were correlated with that of numerical results and the variation was observed to be 4.77%. At higher welding speeds the low peak temperatures were observed which is due to less heat penetrating into the joint. It was observed in the present study at higher welding speeds the residual stress and von Mises stress were in increasing trend whereas normal and transverse stresses are negligible along the weld line.

87.1 Introduction

The submerged arc welding is a popular production process due to its ease of automation, high deposition, deeper penetration, no spatter and fumes and ability to produce sound quality welds in thin and thicker section of materials. The process is extensively used to weld ferrous metals including all varieties of stainless steels and nonferrous alloys like copper and titanium [1]. In fusion welding heat is applied introduced through a heat source which is responsible for fusion between the plates to be joined, in addition to that several phenomena like distortion, residual stresses and metallurgical structural changes are inevitable as a result of applied heat. In order to get a sound weld, it is necessary to understand the effect of heat flow in a welding process. The residual stresses, distortion, microstructure and HAZ hardness introduced into the weld have direct bearing on the applied welding power. The local heating and cooling occurring during the welding process affects the structural changes in the material. Hence, the knowledge of heat flow and its resultant effects need to be predicted for establishing optimum welding parameters.

The heat source from which heat flows into the material is different for various welding processes. The analytical model and its solution for heat flow during welding was first, introduced by Rosenthal. In his famous paper, he assumed that conduction is the predominant mechanism of heat transfer, while assuming the shape of the weld pool in 2D and 3D [2, 3]. However, the Rosenthal model's yields poor predictions. The model developed by Ohring and Lugt [4] for gas metal arc welding (GMAW) considered all possible physical phenomena like evaporation, heat transfer by convection, radiation and viscous deformable free-surface conditions. The main drawback of his model is they assumed constant material properties. Brown and Song [5] considered 3D model of heat source for better understanding of the underlying phenomena. The essential parameters that are to be incorporated in the simulation, a moving heat source, welding parameters like speed, voltage and current, deposition of filler material into the joint. Goldak et al. [6] proposed double ellipsoidal heat source and incorporated the size and shape of heat source for shallow and deeper penetrations welds. Biswas and Mandal [7] formulated a numerical model and macros to simulate a distributed moving heat source, and also considered for deposition of filler metal in submerged arc welding for predicting weld distortions and residual stresses. Podder et al. [8] developed a generalized solution for a heat source model for submerged arc welding of low carbon and M.S. plates. The physical phenomena like forces of buoyancy, Lorentz and Marangoni were taken into account while formulating the model. The principal objective of modeling of welding heat source is to represent the true source of heat, which is the welding arc. The heat is dissipated from the weld pool by conduction, convection and radiation. In the present work effect of process variable i.e., welding speed on residual stress in the austenitic stainless steel is explored.

87.2 Experimental Details

The temperature measurement during was carried out using *K*-type thermocouples. This method was used during the submerged arc welding of butt welded single pass single sided joints from 304 austenitic stainless steel and the results were compared with those of finite element method. The thermocouples were located on the top surface of the plate using a thermocouple attachment setup. Temperatures were measured at two distances from the weld melt line on one side of the plates. The location of thermocouple was 17 mm from weld center line. Figure 87.1 Schematic of test specimen with location of thermocouple. The dimensions of weld sample are 200 mm × 100 mm × 8 mm. A data acquisition and controller (Make: AGILENT 34972A) is used to collect the signals, which was interfaced to a PC. It was set to collect temperature data for interval of 500 ms. Figure 87.1 shows Schematic of test specimen and actual SA welding.

The work pieces were welded in square butt condition, in a single pass with reverse polarity (DCEP). After conducting several trial runs, the welding parameters were decided. The voltage (*V*), current (*I*) and travel speed (*S*) in each joint were given in Table 87.1. The arc efficiency (η) was taken as 0.85 [9, 10] and was used to calculate the heat input per mm Q_w.

$$Q_w = \frac{\eta VI}{S} \tag{87.1}$$

Table 87.1 Parameters considered for analysis of variation of speed

Exp.	Welding arc power (W)	Thickness (mm)	Speed (m/hr)
1.	24 V × 430 A = 10,320	8	20
2.	24 V × 430 A = 10,320	8	22
3.	24 V × 430 A = 10,320	8	24

87.3 Thermomechanical Analysis

The present study involves transient thermal analysis to predict the temperature distribution in a welded sample and mechanical analysis to study structural impacts on the weld caused due to thermal load. A three dimensional finite element model was developed to study thermos-mechanical behavior of weld.

87.3.1 Assumptions for Thermo-Mechanical Analysis [7]

Following are the assumptions made to develop the model for welding process:

- All the thermal properties are considered as a function of temperature.
- No forced convection is considered unless mentioned.
- Linear Newtonian convection cooling is considered on all the surfaces except the weld zone.
- Radiation loss being small, the same is neglected.
- Arc efficiency is incorporated to account for other losses.
- Phase change is not considered.

87.3.2 3D Finite Element Model

A three dimensional finite element model was developed using ANSYS 18.0 to study the temperature distribution and heat transfer in a SAW process. In the thermal model actual conditions were incorporated as far as possible. The governing differential equation for heat conduction for a homogenous, isotropic solid in the rectangular coordinate system (x, y, z) is:

$$\frac{\partial}{\partial x}\left[K\frac{\partial T}{\partial x}\right]+\frac{\partial}{\partial y}\left[K\frac{\partial T}{\partial y}\right]+\frac{\partial}{\partial z}\left[K\frac{\partial T}{\partial z}\right]=\rho C\frac{\partial T}{\partial t} \tag{87.2}$$

where ρ = density of plate material (kg/m^3), C = specific heat (J/kg °C) and K = thermal conductivity (W/m °C). The initial condition and boundary conditions applied on the model are mention below.

Initial Condition
An initial temperature was assumed for the entire plate equivalent to ambient temperature.

$$T = T_\infty \quad \text{for } t = 0$$

where T_∞ is the ambient temperature.

Boundary Condition
As the heat flows over the weld surface, the same is conducted to the rest of the plate. The following equation represents the same:

$$q_n = -q_{\text{sup}} \tag{87.3}$$

Here q_{sup} represents the heat supplied from an external welding arc. And q_n represents the component of the conduction heat flux vector normal to the work surface.

As the heat losses due to convection from the plate surface. Considering h_f as convection coefficient, the heat loss q_{conv} is evaluated as:

$$q_{\text{conv}} = h_f(T - T_\infty) \tag{87.4}$$

Structural Analysis
The residual stress and plastic strain were evaluated post heat transfer analysis where in temperature distribution in heat affected zones was studied. Tack weld condition was applied and using the results of thermal analysis the structural analysis was carried out. The following are the formulations for stress-strain evaluation used in the current study:

$$\nabla\sigma + F = 0 \tag{87.5}$$

where

∇ Differential operator
σ Stress
F Body force

The stress strain relationship is as follows:

$$\{\sigma\} = [D]\{\varepsilon\} \tag{87.6}$$

where

$\{\sigma\}$ Stress tensor
$[D]$ Stiffness matrix
$\{\varepsilon\}$ Strain tensor

The von Mises yield criterion is used to analyze the stress and strain behavior post thermal analysis.

87.4 Modelling Details

The model was developed in ANSYS 18.0. For transient thermal analysis an eight-node SOLID70 element was considered. As the results of thermal analysis was further used to determine the residual stress and strain induced in the plate, thus

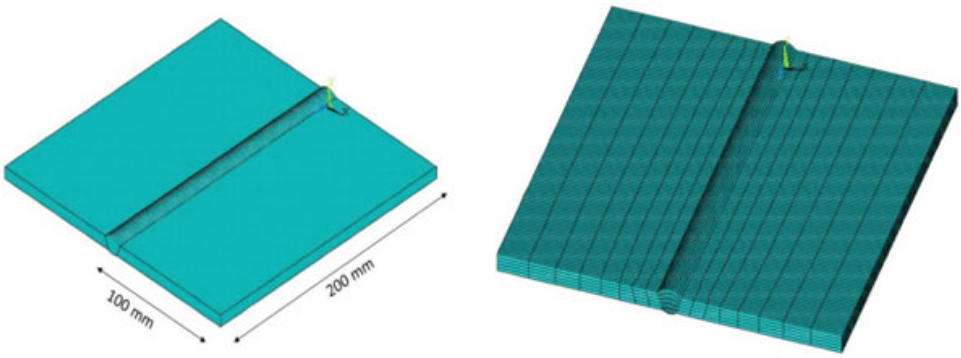

Fig. 87.2 3D solid model and FE Meshed model

the eight- node SOLID70 element was later replaced to eight-node SOLID185 element to perform structural analysis. The weld beads obtained from experiments were analyzed using Nikon SMZ25 microscope with magnification of 0.5× and 30 W scanning power. The bead geometry thus obtained was used for developing FE model. The modelling details single sided SAW is shown in Fig. 87.2.

The solid model was built based on actual experimental bead cross section, further the model was meshed using ANSYS 18.0. Fine mesh was carried out along the weld region to obtain better temperature gradient along weld zone and to reduce computation time coarse mesh was used away from the bead zone. The 3D solid model and FE mesh model was shown in Fig. 87.2. The temperature dependent material properties [11] of austenitic steel is mentioned in Figs. 87.3 and 87.4.

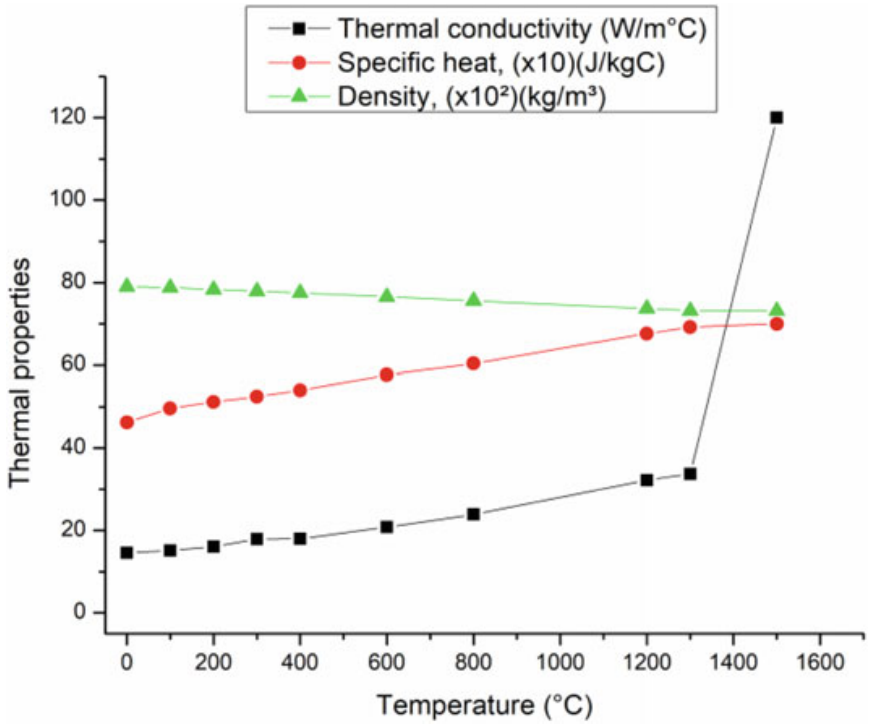

Fig. 87.3 Transient thermal properties of 304 stainless steel [11]

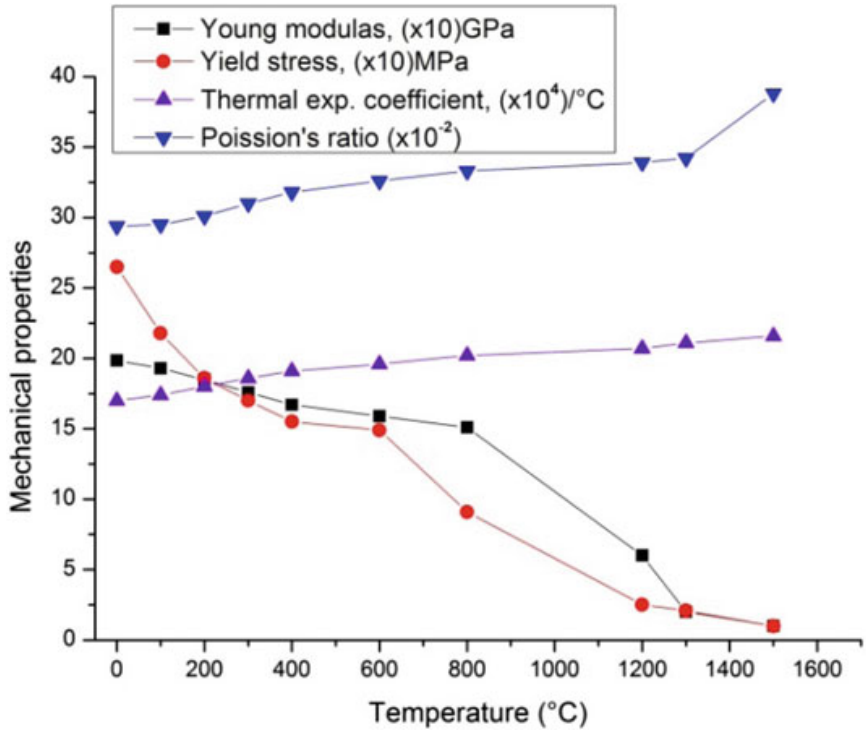

Fig. 87.4 Transient mechanical properties of 304 stainless steel [11]

87.4.1 Modelling the Moving Heat Source

The modelling of a transient thermal analysis with arc moving from one location to another with respect to time in order to generate uniform weld bead, the element birth and death technique was used. The entire weld pool was divided into multiple elemental volumes and subsequently with respect to time, heat was added and removed consecutively from one bead to another, thus attaining a moving heat source model. The quantity of heat added and removed was determined by following equation:

$$Q = \frac{\eta W}{v} \tag{87.7}$$

where Q is the quantity of heat added and removed, η is the efficiency of welding process, v is the volume of the individual weld bead considered, W is the welding power.

87.5 Results and Discussions

The heat applied to create a weld joint is dissipated by conduction to the base metal and by convection to the environment. Thus incorporating all possible conditions, and by varying the process parameter the numerical analysis was carried out in

order to study the variation in thermal and mechanical behavior of the weld. The same process parameters used to develop weld during experiments were considered for numerical analysis. The model is cooled till 500 secs after application of thermal load.

87.5.1 Moving Heat Source and Thermo-Mechanical Analysis

The simulated moving heat source model obtained numerically is shown in Fig. 87.5 for the welding variable voltage of 24 V, current of 430 A and speed of 20 m/h.

The tack weld boundary condition was applied and the results from thermal analysis were imposed to analyze the mechanical behavior of the model. Figures 87.6 and 87.7 shows the contour of transverse residual stress and residual stress along thickness; longitudinal residual stress and von Mises stress respectively.

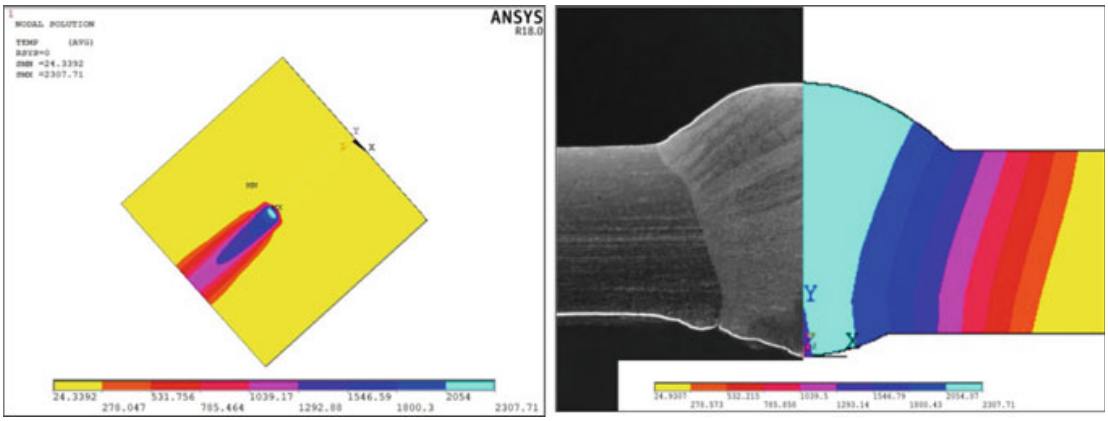

Fig. 87.5 FE model moving heat source and Experimental and numerical bead cross section

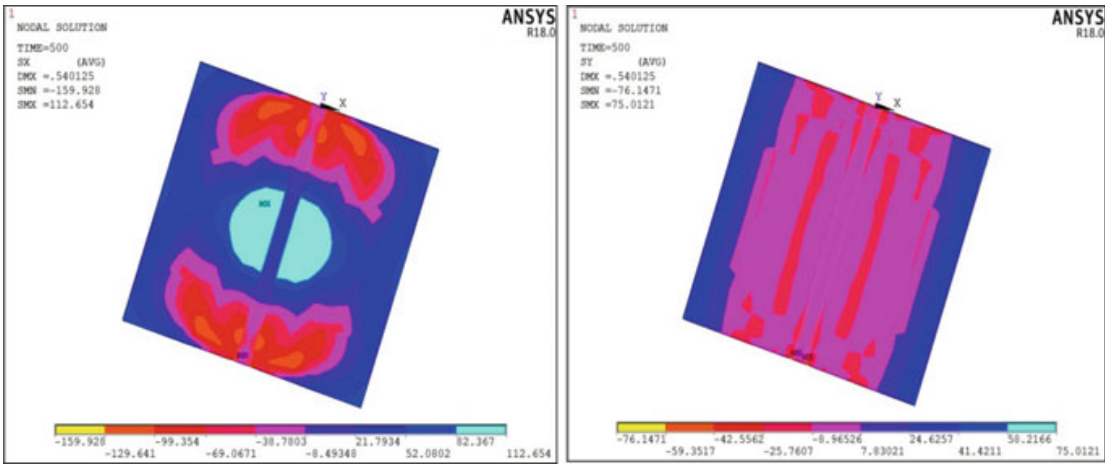

Fig. 87.6 Contour plots of transverse residual stress and residual stress across thickness

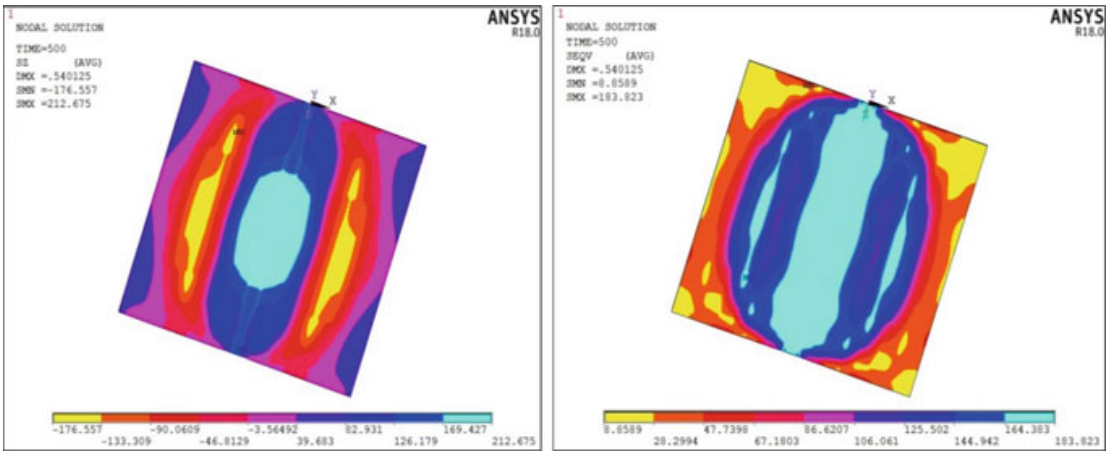

Fig. 87.7 Contour plots of longitudinal residual stress and von Mises stress

Due to variation in temperature gradient along the width direction (away from the weld), there are variation in shrinkage pattern which lead to development of tensile stress contour in the weld zone and its vicinity, and to balance the same compressive stresses are generated in rest of the portion of plate [12]. The stress reversal takes place between molten zone and adjoining zone due to drastic change in physical and mechanical properties of molten material and solid material [13]. Also at the start and end of a weld, large shrinkage pattern causes the variation in stress contour, as compressive stresses are generated in the ends and tensile stress are generated along the weld. This variation is evident in transversal and longitudinal stress contour [13]. As, the model is cooled after thermal loading cycle, phase transformation occurs in the welded plate establishing plastic deformation which is measured in terms of plastic strain in this study [16]. The material closer to weld path faces tensile strain, as a result of contraction due thermal loading, which is later balanced by compressive strain away from the weld zone [14]. As material is deformed plastically, significant intergranular residual strains develop in the loading direction owing to strain redistribution due to slip along the preferred systems. The repeated expansion and contraction during a thermal loading cycle along with consequent cooling effect increases the dislocation density along the weld [15]. Since heat transfer is more turbulent along the thickness direction than along the width, this affects the plastic strain contour along the thickness direction [16].

87.5.2 Effect of Welding Speed

The major process parameters that influenced the shape and quality of weld bead are arc power and welding speed. In the present study effect of welding speed on residual stress is considered for analysis. Three samples were considered to analyse effect of residual stresses on varying of welding speed. The results were analysed based on observations from peak temperature distribution, residual stress on the

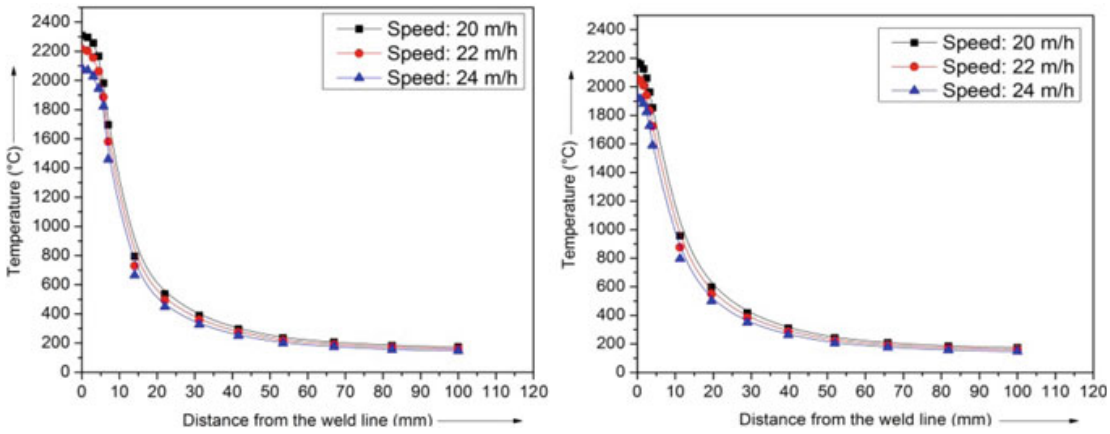

Fig. 87.8 Peak temperature perpendicular to weld line top and bottom surface

plate. The residual stress and plastic strain were observed along the weld centre line and perpendicular to the weld centre line. Residual stresses were considered for all three directions: transversal, longitudinal and along thickness direction of the plate. Also, von Mises stresses were calculated.

The various parameters used to study the effect of variation of welding speed are tabulated in Table 87.1.

The variation of peak temperature perpendicular to the weld line for three welding speeds for top surface and bottom surface of the plate is plotted in Fig. 87.8.

It was observed from the above temperature pattern that peak temperature reduces with increase in welding speed on both top and bottom side of the plate. Further analysis is carried out to determine the pattern of the residual stresses for top and bottom portion of the welded plates along and perpendicular the weld line.

Figure 87.9 shows the variation in residual stress for both top and bottom side of the plate along the weld line. Transversal residual stress (S_x), residual stress along

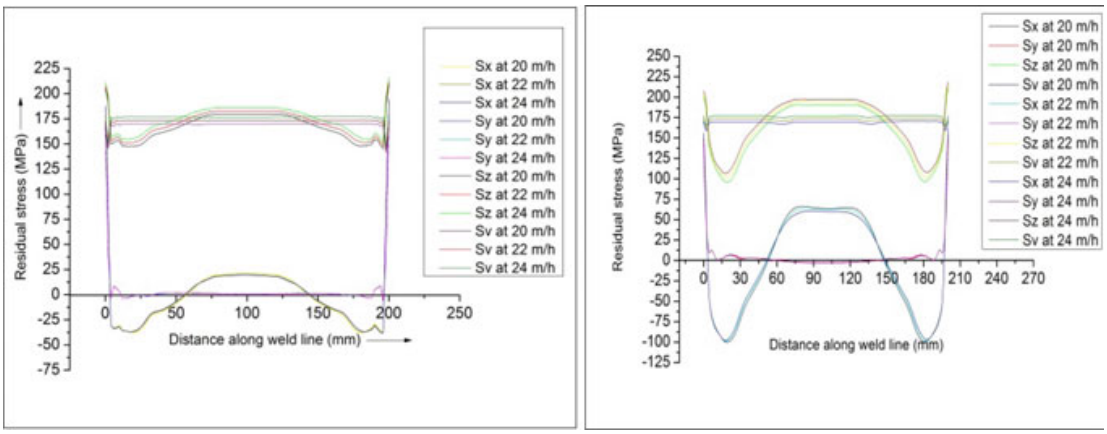

Fig. 87.9 Residual stress in *X*, *Y*, *Z* direction and von Mises stress along weld line for top side of plate and for bottom side of plate respectively

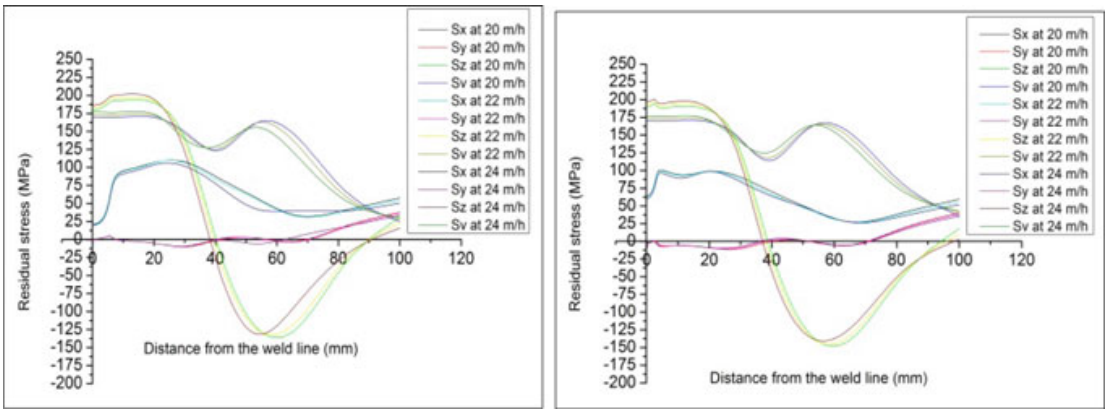

Fig. 87.10 Residual stress in *X*, *Y*, *Z* direction and von Mises stress perpendicular to weld line on top surface on bottom surface respectively

thickness direction (S_y), longitudinal residual stress (S_z) and von Mises stress (S_v) are considered for study. Figure 87.10 shows the residual stress in *X*, *Y*, *Z* direction and von Mises stress perpendicular to weld line on top surface on bottom surface respectively.

87.5.3 Analysis of Residual Stress on Top Surface of Plate

With increase in speed, longitudinal tensile stress and von Mises tensile stress increases, whereas, the variation in normal stress and transverse stress were negligible along the weld line. Both longitudinal tensile stress and von Mises tensile stress increases with increase in welding speed in the weld zone and in its near vicinity but reduces with increase in welding speed in the portion away from weld indicating increase in longitudinal compressive stress, but maximum value of longitudinal compressive stress was observed to decrease with increase in welding speed. Whereas transversal tensile stress reduces with increase in speed away from the weld center line, and negligible variation was noticed in normal stress away from the weld center line on the top surface. It is also noticed that the magnitude of normal stress both along the weld and away from the weld is not as evident as that of other components of stresses.

87.5.4 Analysis of Residual Stress on Bottom Surface of Plate

With increase in speed, longitudinal tensile stress and von Mises tensile stress increases, whereas, the variation in normal stress was negligible along the weld line. And transversal stress (both tensile and compressive) decreases with increase in

welding speed along the weld center line. Both longitudinal tensile stress and von Mises tensile stress increases with increase in welding speed in the weld zone and in its near vicinity but reduces with increase in welding speed in the portion away from weld. The maximum longitudinal compressive stress decreases with increase in welding speed which is located away from the weld vicinity. The Transverse residual tensile stress diminishes away from the weld center line with increase in welding speed, and negligible variation in normal stress was noticed away from the weld center line. It is also noticed that the magnitude of normal stress both along the weld and away from the weld is not as evident as that of other components of stresses.

87.6 Validation of the Model

The temperature profile was recorded for all welding parameters. For purpose of validating the numerical model, Experiment No. 1 thermal couple profile was matched with numerically obtained result for distance of 17 mm from the weld centre line. Figure 87.11 depicts that close agreement of experimental observation with FE model.

The peak temperature obtained at 17 mm from weld line was co-related with numerical values and is in good agreement with a maximum deviation of 4.77%. Hence the developed heat source model is validated with the experimental result.

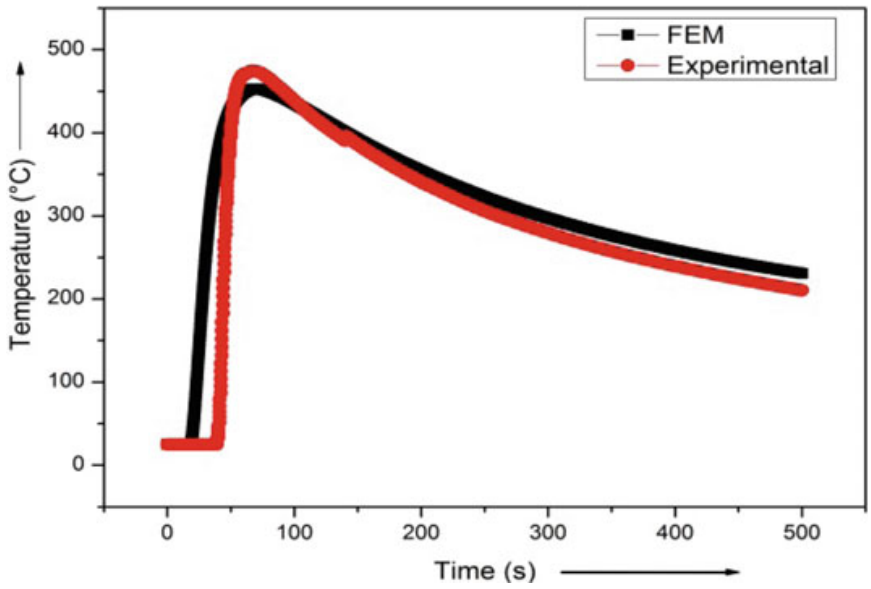

Fig. 87.11 Validation of experimental and numerical temperatures at 17 mm from weld line

87.7 Conclusions

1. The SA welding successfully conducted on AISI 304 stainless steel with a square butt configuration.
2. The temperature distribution obtained from the experiments is matched with that of developed heat source model and variation in peak temperatures is around 4.77%.
3. It was observed that with increase in welding speed the peak temperatures observed were low as higher speeds reduce the heat input into the material.
4. Thermomechanical analysis was done to determine the residual stress in *X*, *Y*, *Z* direction and von Mises stress for top and bottom of the plate.
5. With increase in speed, longitudinal tensile stress and von Mises tensile stress increases, whereas, the variation in normal stress and transversal stress were negligible along the weld line.

Chapter 88
Stochastic Longitudinal Vibration of Single Walled Carbon Nanorods—A Non Local Elasticity Approach

Tanmoy Loha and Sudip Dey

Abstract The present study deals with stochastic nonlocal non-dimensional natural frequencies of single walled carbon nanorods and rotating cantilever beam. In this study, the chordwise bending–vibration behavior of nanocantilever is analyzed. The nonlocal parameter focused on the small-size effects when dealing with nanosize structures such as single-walled carbon nanotubes (SWCNTs). The Eringen's nonlocal elasticity theory in conjunction to the governing differential equations are utilized to solve the problem. The stochastic nonlocal natural frequencies for rotating nano cantilever are observed by employing the differential quadrature method (DQM). The effects of the scale is computationally analyzed based on Monte Carlo simulation (MCS). In another case free longitudinal frequency of a nanorods considering two types of boundary condition is observed, namely, clamped-clamped and clamped-free. The longitudinal vibration of the system are described by a set of partial differential equations, derived by using D'Alembert's principle and using by employing Fourier infinite series in conjunction to separation of variables. The nanoscale effects implement a important role on the frequency response of nanorods subjected to rotation. The statistical analysis are carried out based on stochastic input parameters such as material properties (elastic modulus, density) and geometric properties (length).

eminent effectiveness of usability in nanodevices also its eminent characteristics draws attention on the improvement of nanodevices and nanomachines. These nanomaterials contains superior mechanical, thermal, electrical, chemical and electronic properties. In classical continuum mechanics strain field of distant point to reference point is eliminated but whereas in non local elasticity approach, nonlocal elasticity and the differential quadrature method (DQM) application in order to determine flapwise bending vibration of a rotating nanocantilever consider these distance effect between surroundings atoms. Therefore stress field at a reference point depends not only that particular point but also on the strain at every other points at that corresponding domain. An experimental approach at nano scale is quite difficult and time consuming because handling all influencing parameters of a nanostructure simultaneously and obtained result by considering all parameters together is critical task and trouble worthy task. Furthermore employing molecular dynamics (MD) simulation needs large time and high computational efficacy.

In the present work the size effect and surroundings effect of molecule, strain field effect of nearby atoms on a structural element familiar as nonlocal theory is taken into consideration. The nonlocal elasticity theory was first introduced by Eringen's [2] to study nanomaterials behaviour and utilization of nanomaterials. Vibrational response of various nano or micro level structures like as single and multiple beam, rod, nanoplate and nanodisc in conjunction with elastic, visco elastic or other varieties of sheet thickness has been explored by various authors [3–5]. The actual significance of nonlocal elasticity theory stimulated us to study various features of nano/micro structure and implements that specific properties into nanodevices. The viability of nonlocal continuum theory in the field of nanotechnology was first reported by Peddieson et al. [6]. Various efforts related to nonlocal elasticity theory have been reported on several well established literature e.g. [7–9]. Recently Lee and Chang [10] have analysed vibrational response of single-walled carbon nanotube (SWCNTs) filled with fluid embedded in an elastic medium using winkler-type model. Further Murmu and Pradhan [11] established a single non local beam model to evaluate flapwise bending vibration behaviours of a rotating cantilever. They observed that vibration responses of a rotating nano cantilever is strongly effected in small scale. Recently Pradhan [12] has carried out finite element analysis for getting various mechanical response buckling, bending and vibration for non local beam under various boundary conditions like hinged-hinged, clamped-hinged, and clamped-free are extended their results to taper beams. According to Wang [13] a modified non local beam model was developed and they have found that nano scale non local parameter and critical flow velocity has a great impact on vibration and stability response of a nanotube carrying fluid. Danesh et al. illustrated the scale effect on tapered nanorod subjected to longitudinal vibration using the nonlocal theory. The authors have used the differential quadrature method to solve motion equations for three different boundary conditions [14]. Aydogdu, was modelled Carbon nanotube immersed into elastic medium i.e. a nanorod encompassed by elastic layers using the Eringen's nonlocal theory. The author distinguished the longitudinal frequencies between the nonlocal and classical continuum models [15]. Abdollahi [16] implement the EBFs on bounded domains, the effects of the

boundary conditions are handled by truncating the kernel/attenuation function in the constitutive relations. This helps to found residuals in the governing equations, also to minimize the residuals near the boundary region by using weighted residual approach. Danilo Karličić et al. applied nonlocal Kirchhoff-Love plate theory to illustrate mechanical behaviours of single-layered and multi layered graphene sheets used as an orthotropic material. Here they have derived the governing equation of motion of a simply supported orthotropic nanoplate. They also had showed that magnetic field could be successfully implemented to enhance sensitivity of nanomechanical sensors [17]. Bahaadini [18] defined the instability behaviour of cantilever nanotubes on dynamic structural fluid and they have incorporated end concentrated follower force and distributed tangential load to improve accuracy of the results like surface elasticity and residual stresses. The frequency response function is an important structural parameter which is defined as the ratio of output response of a structure due to an applied force. Such modal response can be measured in the form of displacement, velocity, and acceleration. In spite of recent development the model which considered in published work [11], stochasticity effect based on parametric study has not yet been considered. Uncertainty quantification on various properties of the above said model has not yet been considered because geometric and material uncertainties leading to unpredictable system response on natural frequencies. Reliability based failure analysis of single walled carbon nanorods structure still not observed. Based on carbon nanostructure various design configuration of nanomachines are found but for that proper understanding of mechanical behaviour is needed. One such nano machines is nano turbine whose performance depends upon dynamics properties of beam like nanocantilever elements. From design point of view study of bending vibration on nanocantilever, nanorod are essential for complexity in its lattice structure. Due to interdependency of large number of parameters in complicated fabrication processes, the system properties are inevitably random in nature resulting in uncertain response of the nano structures. Many researchers worked on nano structures in past but mainly focused on deterministic analysis [1–4]. The stochastic natural frequency responses are solved by random eigenvalue problem with an improved nonlocal elasticity based approach. Eringen's nonlocal elasticity theory is idealized as nanocantilever beam to study the flapwise bending vibrational frequencies of rotating nanocantilever. The longitudinal frequency responses of nanorod is determined by using methods of separation of variables on ordinary differential governing equation. The various effects of nonlocal parameters, small scale effects and nondimensional angular velocities on nanostructure are investigated in the present study.

88.2 Nonlocal Parameter and Nonlocal Elastic Model

The basic parameter in non local model e_o remains constant for each nanostructure. The parameter e_o should be taken in such way so such non local model yields certain approximation when dispersion curve due to lattice effect on plane waves

are considered. The term $e_o a$, $e_o l_c / l_a$ are the nonlocal parameters or the scale coefficient. Non-local elasticity theory has the capability to envisage the statistical behaviours on longitudinal vibration response and to predict buckling characteristics of CNTs. However, main distinguishable features of nonlocal theory is to optimize nonlocal parameter's value to get better effective outcomes from any systems. In this theory nanoscale effects are taken into consideration when lattice dimensions of atoms considered as material parameter. The most generalized form of the constitutive relations for nonlocal elasticity involves an integral over the whole body. The nonlocal linear homogeneous equations are explained by Pradhan and Murmu [19]. Based on Euler–Bernoulli hypothesis nonlocal constitutive relations for general one dimensional beam can be expressed as

$$\sigma(x) - (e_o a)^2 \frac{\delta^2 \sigma}{\delta^2 x} = E\varepsilon(x) \tag{88.1}$$

where σ and ε denote the normal stress and strain due to nonlocality respectively. E denotes Young's modulus of the element. The term $(e_o a)$ is nothing but nonlocal parameter or the scale-coefficient as depicted in a well-established literature [19].

88.3 Materials

In general, during synthesis of nanostructures, high stiff and light-weight materials are employed so that the structure can sustain large external load without failure. In the present study, single walled carbon nanotube is used because of its extraordinary material properties. It is made of graphene sheet which is idealized to construct the present model. Carbon nanotubes (CNTs) being the allotrope of carbon have a cylindrical closed packed structures. These CNTs have unusual properties, which are valuable for nanotechnology, optics, electronics industry and other fields of materials science and technology. Owing to the material's exceptional strength and stiffness, nanotubes are constructed with length-to-diameter ratio of up to 132,000,000:1 significantly larger than for any other material.

88.4 Methodology

88.4.1 Governing Equation of Motion of Rotating Nanocantilever

Let us assume a nano cantilever whose length is L and one end fixed at point O to a rigid hub of radius r rotates at a constant angular speed Ω rad/s in counter clockwise direction shown in Fig. 88.1. From different literature survey it is observed that the classical Euler-elastic beam theory offers a most reliable model for mechanical

deformation due to axial loading in one-dimensional nanostructures, such as carbon nanotubes, nanowire, nonobeam, nanoplate. Further it can also be assumed that plane of cross section normal to longitudinal axis remains plane before and after deformation and deformation due to bending is considered as very small. Thus rotating nanocantilever model is considered as an Euler–Bernoulli beam model. In the present theory the plane cross sections of the beam remain plane during flexure and that the radius of curvature of a bent beam is larger compared to the beam's depth. Here W denote deflection along flapwise deformation direction.

The moment stress resultant relation can be expressed as $M(x,t) = \int_A z\sigma_x \mathrm{d}A$

Using Eq. (88.1) and from moment relation, nonlocal moment relation can be expressed as

$$M - (e_o a)^2 \frac{\delta^2 M}{\delta x^2} = -EI \frac{\delta^2 W}{\delta x^2} \tag{88.2}$$

Now based on Euler-Bernoulli's hypothesis is applied in basic differential form of Euler Lagrange's equation as follows

$$\frac{\delta^2 M}{\partial x^2} + \frac{\delta}{\delta x}\left(\Gamma \frac{\delta}{\delta x}\right) - \rho A \frac{\delta^2 W}{\delta t^2} = 0 \tag{88.3}$$

where Γ denotes the tensile force due to centrifugal action of rotation of cantilever beam. The force $\Gamma(x) = \int_x^L \rho A \Omega^2 (r + x)\mathrm{d}x$. Here r is taken as the hub radius which denote length of beam from centre point of rotation to edge of cantilever beam, Ω denotes angular velocity with which cantilever rotates. Now The second order derivative of M is determined from Eq. (88.2) by substituting into Eq. (88.1) it is found that

$$M = -EI \frac{\delta^2 W}{\delta x^2} + (e_o a)^2 \left[-\frac{\delta}{\delta x}\left(\Gamma \frac{\delta W}{\delta x}\right) + \rho A \frac{\delta^2 W}{\delta t^2} \right] \tag{88.4}$$

Now substituting the expression for M from Eq. (88.3) into Eq. (88.4), the governing partial differential expression for vibration of rotating cantilever are obtained as

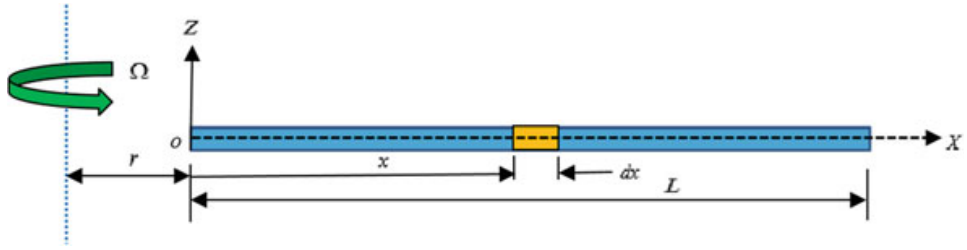

Fig. 88.1 Basic layout of a rotating nanocantilever based on Euler–Bernoulli approach

$$\frac{\delta^2}{\delta x^2}\left(EI\frac{\delta^2 W}{\delta x^2}\right)-\frac{\delta}{\delta x}\left(T\frac{\delta W}{\delta x}\right)+\rho A\frac{\delta^2 W}{\delta t^2}+(e_o a)^2\frac{\delta^2}{\delta x^2}\left[\frac{\delta}{\delta x}\left(T\frac{\delta W}{\delta x}\right)-\rho A\frac{\delta^4 W}{\delta t^4}\right]=0 \tag{88.5}$$

The four boundary conditions for a nanocantilever beam at two ends are expressed as

when $x = 0$, $W = \frac{\delta W}{\delta x} = 0$ and $\frac{\delta^2 W}{\delta x^2} = \frac{\delta^3 W}{\delta x^3} = 0$ at $x = L$,

After non-dimensionalization, the principal parameter employing differential quadrature (DQ) method [19], the Eigen value equation can be obtained as $K_{\text{total}}\{W\} = \lambda^2\{W\}$, where K_{total} denotes the cumulative DQ matrix. From the above Eigen matrix, the Eigenvalues are solved and the fundamental frequencies are calculated for longitudinal vibration of nanocantilever based on nonlocal elasticity approach [20].

88.4.2 Characteristics Equations of Nanorod

In present study, a nanorod having length L and arbitrarily selected area of cross section A is considered as illustrated in Fig. 88.2a. It is assumed that cross-sectional area along X-direction remains constant. The materials of nanorod are considered to be homogeneous and isotropic in nature. To find out fundamental frequencies of nanorods vibrating longitudinally, it is assumed to be vibrated along X-direction. For analysing of present model, it is considered as an infinitely small element having length dx at location x and the equilibrium condition is based on D'Alembert's principle as furnished in Fig. 88.2b. A normal resultant force N is applied due to normal stress σ_x in axial direction. In addition, the continuously distributed axial loads f (x, t) are neglected. On the right side of infinitesimal element elementary force $+\mathrm{d}N$ is considered.

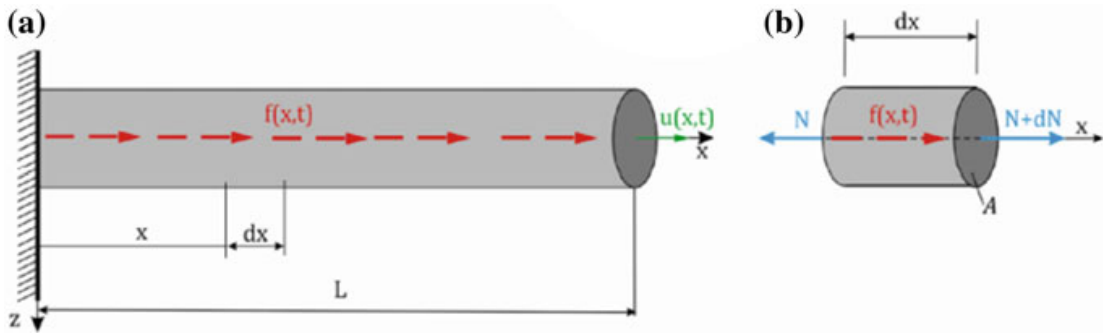

Fig. 88.2 **a** Model of a nanorod vibrating longitudinally; **b** corresponding infinitesimal element subjected to resultant stresses in axial direction [21]

By considering D'Alembert's equilibrium equation, equating sum of all forces acting along x axes is equal to zero which states

$$-N + (N + \mathrm{d}N) + f(x, t)\mathrm{d}x = \rho A \mathrm{d}x \frac{\partial^2 u}{\partial t^2} \tag{88.6}$$

where $dN = \frac{\partial y}{\partial x} dx$ is the resultant stress N of the small infinitesimal element, $u = u(x, t)$ is the axial deformation along x-direction. After some transformations the following equilibrium equation is obtained in the differential form,

$$\frac{\partial N}{\partial x} + f(x, t) = \rho A \frac{\partial^2 u}{\partial t^2} \tag{88.7}$$

where, N denotes the resultant axial stress over whole cross section area defined by $N(x, t) = \int_A \sigma_x \mathrm{d}A$, where σ_x represent normal stress in infinitesimal element.

According to Eringen's nonlocal elasticity model the constitutive equations in differential form are specified as follows

$$\sigma_x - (e_o a)^2 \frac{\partial^2 \sigma_x}{\partial x^2} = E\varepsilon_x \tag{88.8}$$

$$N - (e_o a)^2 \frac{\partial^2 \sigma_x}{\partial x^2} = E\varepsilon_x. \tag{88.9}$$

By substituting (88.7) into (88.9) the following governing differential equation of motion based on D'Alembert's principle and Eringen's model of nonlocal elasticity in terms of axial displacement is obtained

$$\rho A \frac{\partial^2 u}{\partial t^2} - f(x, t) - EA \frac{\partial^2 u}{\partial x^2} = (e_o a)^2 \frac{\partial^2}{\partial x^2} \left(\rho A \frac{\partial^2 u}{\partial t^2} - f(x, t) \right) \tag{88.10}$$

In the present study two types of boundary conditions are considered.

(a) -Clamped-Clamped- $U(0, t) = U(L, t) = 0$
(b) -Clamed-Free- $U(0, t) = N(L, t) = 0$

where $N(L, t)$ is nonlocal axial resultant force acting at the end of a nanorod. From (88.7) and (88.9) the following equation can be derived

$$N(x, t) = (e_o a)^2 \frac{\partial^3 u}{\partial x \partial t^2} + EA \frac{\partial u}{\partial x}. \tag{88.11}$$

Considering oscillatory motion of nanorod with time and using separation of variables methodology, the expression of governing equation is assumed as $\theta(x, t) = \sum_{n=1}^{\infty} X_n(x) T_n(t)$, where $T_n(t) = e^{i\omega_n t}$ is the time harmonic function

$X_n(x)$ is the mode shape function corresponding to longitudinal vibration which is governed by some end boundary condition of the system. Neglecting continuously distributed axial load $f(x,t)$ the following ordinary differential expression with corresponding mode shape function $X_n(x)$ can be obtained as

$$\frac{\mathrm{d}^2 X_n(x)}{\mathrm{d}x^2} + \alpha_n^2 X_n(x) = 0 \tag{88.12}$$

where α_n is the characteristics value of the mode shape function corresponding to longitudinal vibration, which depends on corresponding boundary condition

$$\alpha_n = \frac{\omega_n^2}{\frac{E}{\rho} - (e_o a)^2 \omega_n^2}. \tag{88.13}$$

The nonlocal frequencies of a nanorod subjected to the longitudinal vibration can be determined by using boundary condition given below (Figure 88.3).

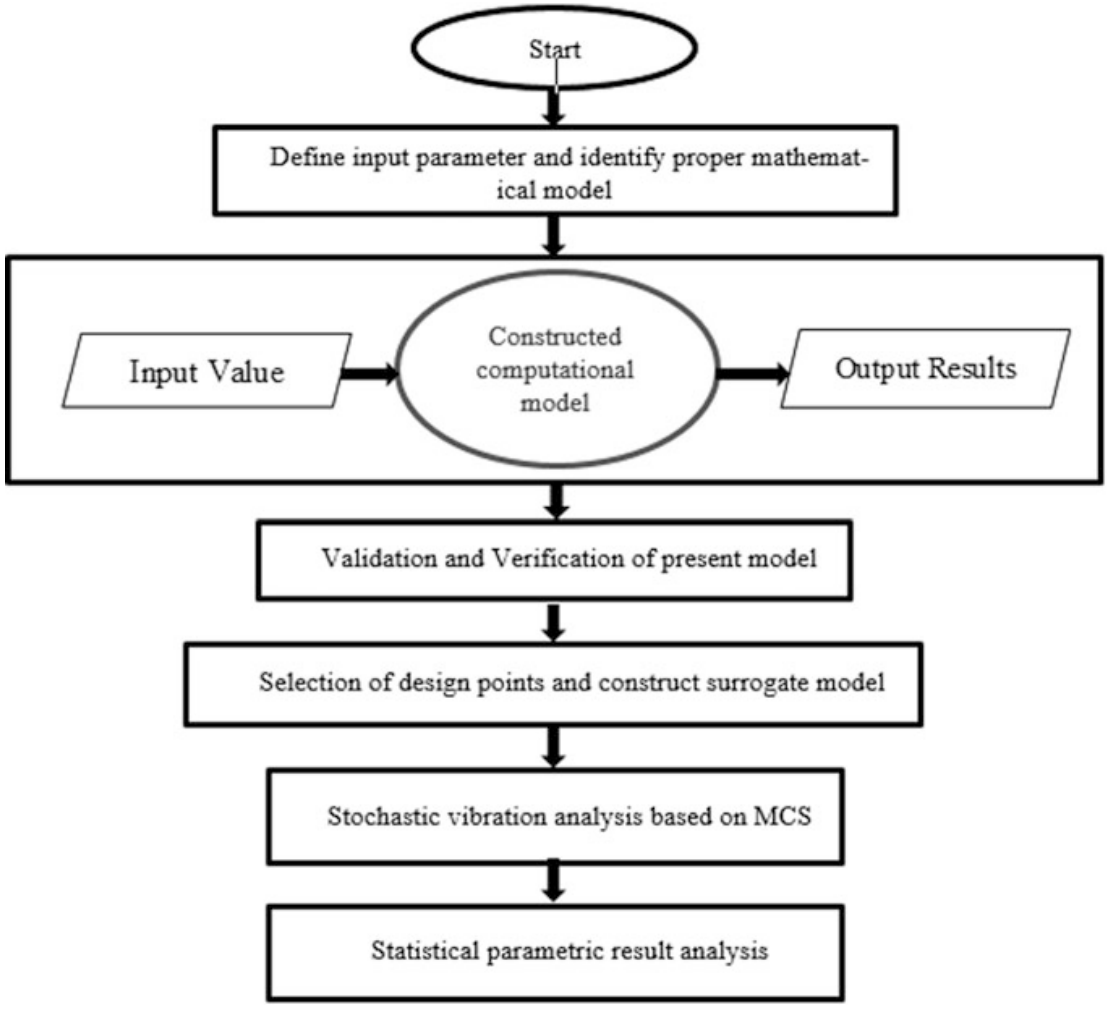

Fig. 88.3 Flow diagram of present methodology

$$\omega_n = \sqrt{\frac{E\alpha_n^2}{\rho\left(1+(e_o a)^2\alpha_n^2\right)}}. \tag{88.14}$$

88.5 Result and Discussion

In the present study, the following assumptions are considered such as, body force is neglected and employed the D'Alembert's Principle for equilibrium equation. Any contribution of shear force in cross section to transverse deformation is ignored i.e. transverse shear force is neglected, only deformation due to force applied in longitudinal is taken into consideration in this study. The method of separation of variable is considered using Fourier infinite series to solve ordinary differential equation (ODE). The fundamental mode is considered for validation and verification while the scale effect is considered to be caused by small internal molecular distance. Moreover, single walled carbon nanotubes formed by rolling graphene sheet is considered having material properties such as, Young's Modulus (E) 6.85 TPa and density (ρ) 9517 kg/m^3 [21].

Nonlocal elasticity theory is used to illustrate small scale effect on rotating nano cantilever beam. In present study, nonlocal elasticity model based on Eringen's theory is solved by differential quadrature method and the fundamental natural frequencies are obtained by considering the nonlocal parameter. After solving governing differential equation, the solution of governing differential equation is analysed by MATLAB code. The results are validated and verified based on Murmu and Pradhan [11] wherein the stochasticity analysis is carried out. The accuracy of fundamental natural frequencies and mode shapes depend on mode and material properties. The small scale effects on angular velocity and mode number is also investigated. For local model nonlocal parameter is assumed to be zero. But when non local parameter is taken into consideration then fundamental frequencies value corresponding to each curve becomes very close together. It is also observed that as the nondimensional angular velocity raised (see Fig. 88.4), non-dimensional fundamental frequencies are also found to increase due to effect of centrifugal force.

Moreover it can be observed that in nonlocal model of nano cantilever beam considered has been greatly influenced by angular velocity on the fundamental frequencies of nonobeam. Moreover local and nonlocal models is considered then more significantly small scale effect on mechanical vibration and buckling response are raised when cantilever rotates at high speed angular speed. It is also observed that higher frequency at high angular velocity zone is because of the simultaneous effect of both nonlocal parameter and angular velocity due to rotation. Fatigue effect on mechanical structure are also dependent on number of reversal of cyclic frequency applied on that particular structure. This investigation provides good information for the design of carbon nanotubes blade of nano turbine. It has been observed that when the fact of non local parameters are disregard longitudinal

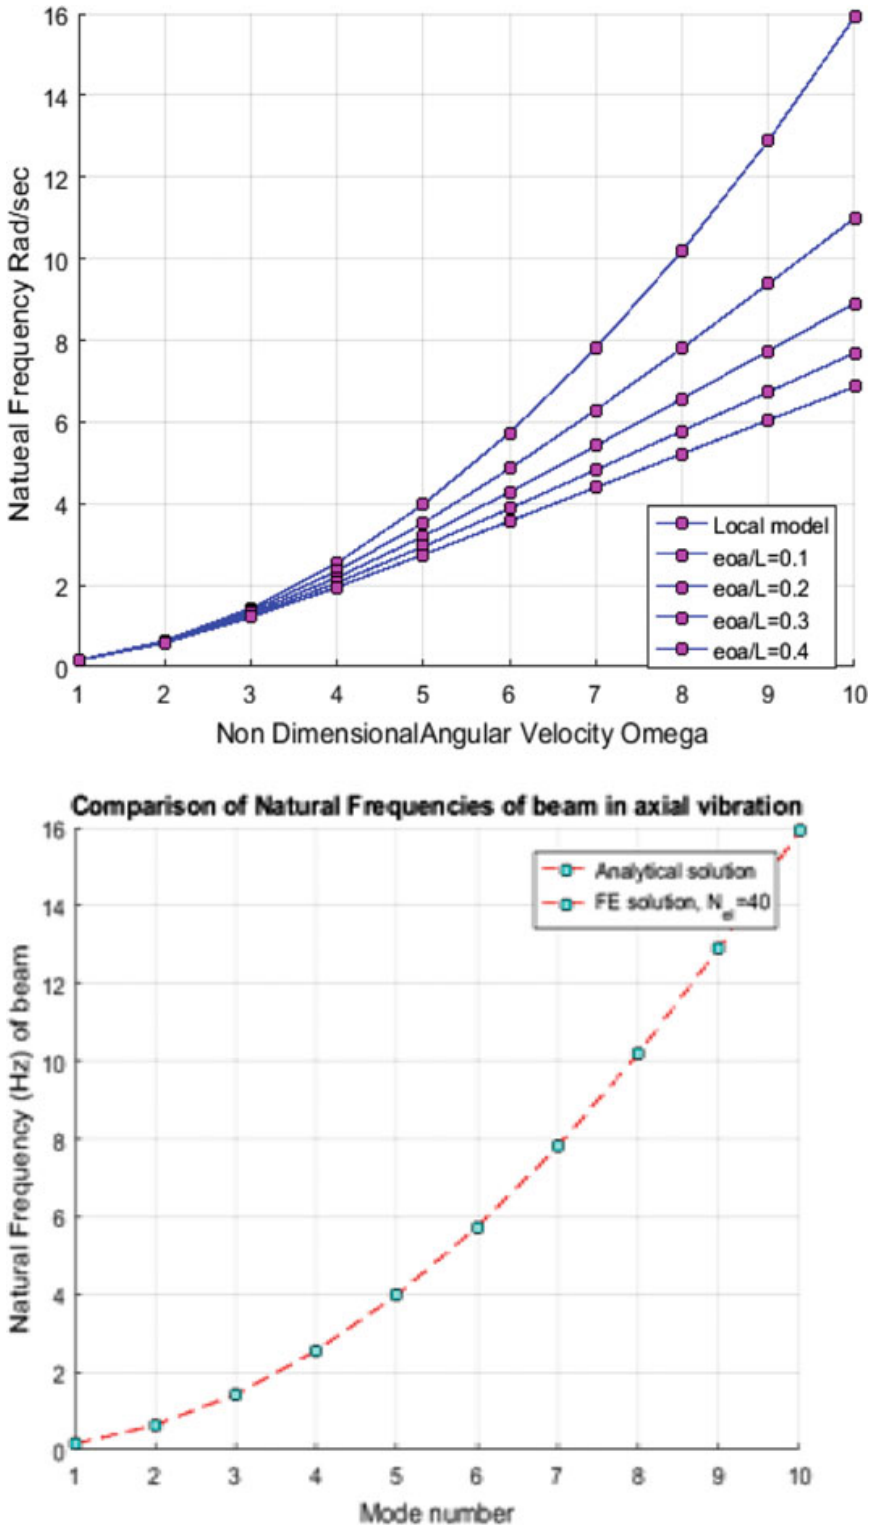

Fig. 88.4 Validation of non-dimensional natural frequency with corresponding angular velocity for different nonlocal parameters of a rotating nanocantilever beam and mode number with published literature [19]

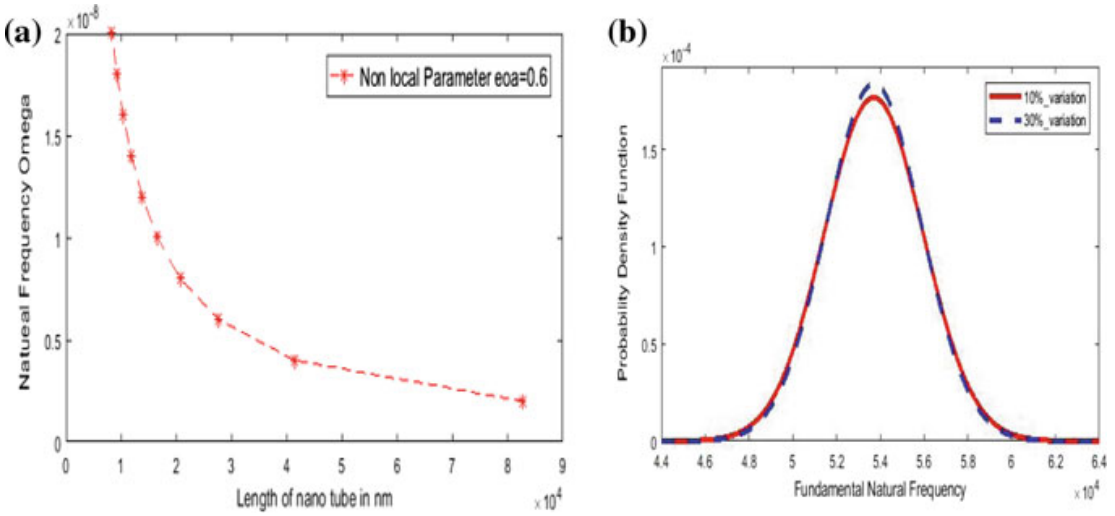

Fig. 88.5 **a** Validation of fundamental frequency changes with variation in length of nanorod with clamped free condition [21]. **b** Stochasticity analysis of fundamental natural frequencies of carbon nanorod based on randomness on input parameter (Non local parameter and Mode number)

vibrational frequencies are overestimated. Unlike transverse vibration of nanorod, natural frequency has got decreased with an increase in nonlocal parameter (see Fig. 88.5). Non local effect on longitudinal frequency of a nanorod has more prominent and distinguishable effect when any higher vibrational modes are considered. In the following table comparison and validation of the fundamental natural frequency of nanorod obtained from non local theory and those obtained from lattice dynamics based on MD simulation.

The following parameters and dimensions have been employed to validate the results as in given Table 88.1: ρ = 9517 kg/m^3, E = 6.85 TPa, L = 12.2 nm. Here fundamental frequencies are compared with the MD simulation for single walled carbon nanorod after obtaining results for clamped-free vibration using nonlocal elasticity theory. More consistent results are obtained when non local parameter goes to unity (see Table 88.1).

Since the value of internal length parameter a is fixed for SWCNT so in order to fit the result natural frequency optimization of parameter e_o is required for each mode of vibration corresponds to variation in geometrical properties of nanorod. However molecular dynamics (MD) simulation has been restricted to smaller scale because of higher time and cost consumption therefore nonlocal theory is used for more complex nanostructures analysis.

Above Fig. 88.5 indicates the effect of length non local parameter and of nanorod on fundamental frequency and it also shows characteristics of natural frequency of carbon nanorod based on random variation of material property. In present study each outcomes i.e. natural frequency on 10, 20, 30% are varied by using normal distribution and it can be observed that for small variation in material property within a certain limit natural frequency follows an normal distribution with a mean value constant and certain standard deviation. This parametric study helps us to observe uncertainty determination due to variation in material property due to

Table 88.1 Comparison and validation of nonlocal parameter influences on natural frequency of longitudinal vibration of nanorod

Non Local Parameter ($e_o a$)	Mode Number (n)	Present Analysis of Fundamental Frequency using MATLAB	Fundamental Frequency on Murmu and Adhikari published book [21]	Fundamental frequency using molecular dynamics on G. 0	1	0.488	0.549	0.544	11.11	10.29
0.5	1	0.536	0.548	0.544	2.19	1.47

structural inhomogeneity and anisotropic behaviour of structure in nanoscale. A notable decrease in fundamental frequencies with increase in length is observed (see Fig. 88.5). However, the fundamental nondimensional frequency has a decreasing in nature exponentially with a raises in the non-local parameter but this effect becomes insignificant with a greater length of the nanorod.

88.6 Conclusion

Present work shows the non local longitudinal frequency analysis of a single walled carbon nanorod and rotating nanocantilever, where first a non local mathematical model based on Eringen's non local stress theory has been used, then uncertainty effect based on parametric study of randomness on material property has been observed. It can be observed that nonlocal parameter has an important role when scale effect is considered on nanostructure. It has also been well established that when first vibrational mode consider, the fundamental non dimensional frequencies evaluated with nonlocal based models have higher magnitude than those obtained by local model. With increase in magnitude of angular velocity natural frequency on cantilever beam increased and also when length increases natural frequency of nanorod decreases exponentially.

The novelty of present study includes the computational investigation on stochastic frequency response analysis using computational code of a nanorod with uncertainty in the material properties i.e. young's modulus, density and non local parameter, mode number. Computational code is very accurate as compared with published work. Also when randomness is incorporated in material property natural frequency responses like a normal distribution curve then central tendency of frequency for continues variation of various material property can easily be evaluated. Stochasticity has also been investigated based on randomness in input parameter which shows uniform variation in fundamental frequency curves with very effective manner.

Present work is helpful in manufacturing point of view because Present study deals a significant contribution on stochastic behaviour of fundamental frequencies for a nanoscale structure so that structure become safe when that particular structure used in some specific domain of a machine element basically Nano Electro Mechanical System (NEMS) systems manufacturing like turbine blade, centrifugal pump blade etc. As manufacturing of any systems requires first fully structural analysis like bending, buckling, vibrational behaviours of any static or dynamic structures then according to structural analysis report manufacturings are being carry forwarded. From the physical point of view, it can be summarized that the non-local parameter dampened away fundamental natural frequencies. Fatigue response of a nanorod as well overall stiffness also depends on frequency response of the nanorod. To the best of authors' knowledge, this is the first attempt for applying Nonlocal elasticity in uncertainty quantification of nanostructure. Finally it is concluded that the present methodology can also be extended to analyse statistical behaviour of nanoplates as well as buckling behaviour analysis of nanoplate.

Chapter 89
Finite Element Analysis and Three-Point Bend Testing of Indian Rice Grains with Fissure Effects

P. V. Gharat, D. K. Shinde and D. N. Raut

Abstract In today's world, one of the major problems faced by the rice-milling industries is breakage of rice during processes like de-husking/de-hulling, whitening, and polishing. For designing of milling machinery and for reducing the breakage of different rice varieties while processing, it is important to understand the rupture force of rice kernels of different varieties under the three-point breaking test. In this study, the different varieties of rice grains with different fissure conditions were investigated. The rupture force investigated by using three-point breaking test which is conducted on Instron UTM with specially designed adjustable support fixture, in which span can be adjusted for different varieties of rice grains. Five brown rice varieties—Rashi Poonam, Kolam, Komal, Basmati, and Daptari tested at a rate of 1 mm/min. The finite element analysis has helped to validate the result of the flexural stresses in the rice grain induced during test and then the crack propagation is simulated in the analysis. It was seen that out of the five rice varieties under tests, Rashi Poonam has the highest average rupture force of value 32.29 N. The results obtained from this test and computational analysis can help for developing methods and types of equipment used for whitening and polishing processing of rice with different varieties.

89.1 Introduction

Rice is the seed of the grass species Oryza sativa, and it is one of the most important cereals in the world. The worldwide production of rice in 2014 was 741 million tonnes. India is one of the world's largest producers of rice. India's rice production is 20% of all worldwide rice production. In India, rice is pre-eminent crop and the staple food of the people of the various parts of the country. For the year 2013–2014, India's rice production was 106.54 million tonnes. In India, rice is a major crop and staple food for more than 70% of the population, thus plays a vital role in the national economy [1]. Rice passes through various processing like harvesting, de-husking, whitening, and polishing which may lead to breakage of rice grains. Rice is preferably consumed as whole grains. The percentage of unbroken rice grains gives good economical value to farmers and millers. Therefore for accurate design of the de-husking, whitening and polishing machines to minimize the grains breakage, information on physical properties such as length, width, and thickness and mechanical properties of rice grains such as breaking force and graph of force versus deformation must be provided [2].

The various physical properties like length, thickness, and mass of rice variety PR-106 were measured by Gadge. The moisture content of rice was 13.34% (wet basis). The average length, width, and thickness were 6.61, 1.75, and 1.40 mm, and unit mass volume of rice kernels were 0.017 g, and 0.051 cm^3, respectively. The mean diameter and surface area and aspect ratio were 2.52 mm, 20.1 mm^2, and 26.58%, respectively [3]. The study by Zareiforoush et al., the rupture force of paddy grains was measured under quasi-static compressive loading. The Alikazemi and Hashemi varieties of paddy rice were tested in horizontal and vertical orientations at two different loading rates of 5 and 10 mm/min. For Alikazemi variety of paddy rupture force values decreases as the loading rate increased from 5 to 10 mm/min. The rupture force values for horizontal orientation were 125.69 and 33.51 N at a loading rate of 5 mm/min and 10 mm/min, respectively. Similarly, the rupture force values for vertical orientation were 117.38 and 33.51 and the loading rate of 5 mm/min and 10 mm/min respectively [2]. In another study, Lu et al., the compressive force and bending force of rough rice, brown rice, and white rice were determined by conducting compression and three-point bending tests. It was observed that thinner kernels required low breaking force and therefore lead to more breakage during milling [4].

I. Bagheri et al., investigated the mechanical strength of 12 varieties of brown rice at four levels of moisture content 8, 10, 12, and 14 wet basis. Brown rice grains were quasi-statically loaded at two rates 10 and 15 mm/min. The results show that the breaking force decreases with increasing moisture content and also with an increase in a loading rate. The breaking of brown rice with a lower level of moisture content was a sudden failure with less deformation and breaking of brown rice with a higher level of moisture content was gradually crushing with more deformation [5]. For three different levels of amylase ratio, the mechanical properties of different varieties of rice grains were invested by Y. J. Shu et al. The mechanical properties

were measured using compression and three-point breaking test. According to their study, the rice variety with the high amylose ratio has the highest compression strength. Their study can help to develop methods and devices used for milling processing of rice with different levels of amylose to reduce the milling losses [6]. The another study carried out by Ponlakrit Kumklam, in which the strength of rice grains measured by breaking force and study done on the correlation of breaking force and head rice yield. Bending test was done by keeping fixed base support distance of 3.5 mm with flat loading head of thickness 1.5 mm and deformation rate was 1.5 mm/min. From the test, the bending force was closely related to the head rice yield [7].

The main objective of this research was to measure physical properties such as length, width, and thickness and to determine the mechanical property of five different varieties of brown rice grains in terms of rupture force under three-point breaking test and examining the effect of rice variety and number of fissures on rupture force.

89.2 Materials and Methods

The brown rice varieties Rashi Poonam, Kolam, Komal, Basmati, and Daptari used for this test were obtained from one of the rice mills from Palghar, Maharashtra, India. The hot-air oven-drying method was used to determine initial moisture content of the rice samples. The initial moisture contents of grains were 5.35, 5.69, 4.98, 6.13, and 5.42% (wet basis) for Rashi Poonam, Kolam, Komal, Basmati, and Daptari varieties, respectively.

89.2.1 Detection of Fissures in Rice Grains

This study investigates the rupture force for five different rice varieties with the number of fissures in rice grains. To detect fissures in rice grains, fissure detection technique is newly developed. Imaging of the fissures in rice kernels was done with the help of DSLR camera. Camera used was Nikon D5200 with 18–55 primary lens and close up lenses/secondary lenses (numex 52 mm close up +1, +2, +4 and +10) were additionally attached for better zooming. For better zooming without the use of secondary lenses can be achieved by attaching a primary lens in reverse direction to the camera. For better results, the camera was on a tripod stand.

The light source was white LED bulb (Wipro LED, 9 W). All samples were placed in plain brown-colored glass, and images were captured using DSLR camera. After capturing the images of rice grains, all are edited in Lightroom CC image-editing software (version 3.4) for better clarity of fissures. While editing, clarity was increased to full value, highlights, shadow, and whites reduced to zero value and exposure, the contrast was adjusted according to images and finally, the

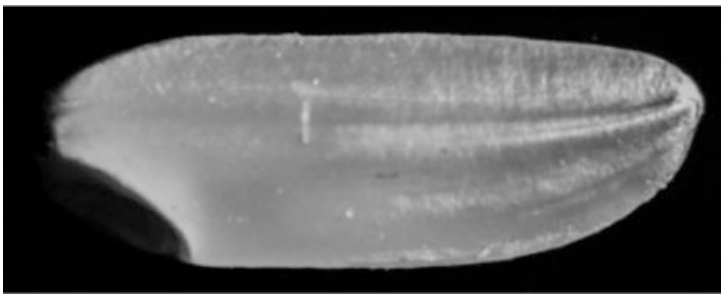

Fig. 89.1 Image of brown rice with no fissure

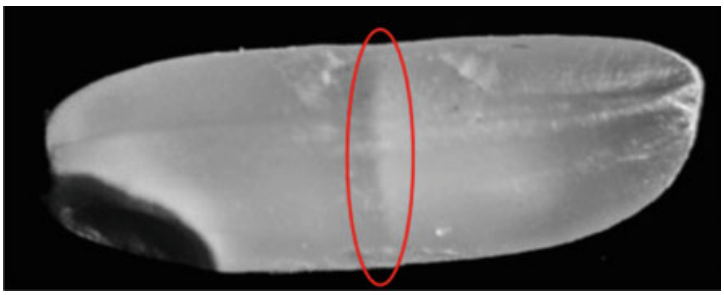

Fig. 89.2 Image of brown rice with one fissure

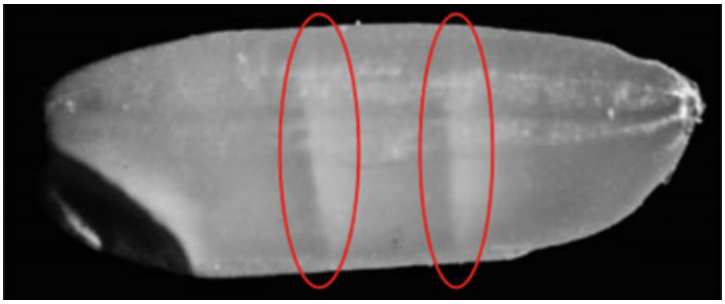

Fig. 89.3 Image of brown rice with two fissures

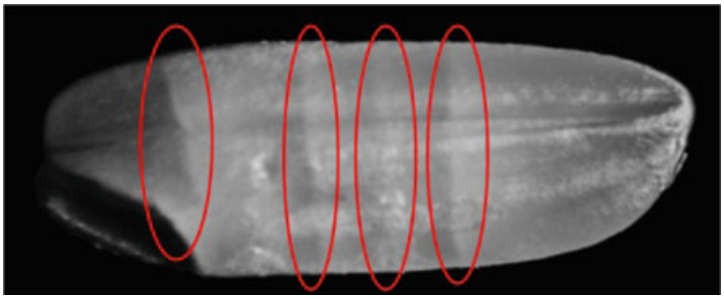

Fig. 89.4 Image of brown rice with more than two fissures

black and white effect was given to images. Figure 89.1 shows the images of brown rice with a different number of fissures. Figures 89.1, 89.2, 89.3, and 89.4 show the brown rice with 0, 1, 2, and more than 2 fissures, respectively.

89.2.2 Types of Fissures Observed in Rice Grains

Various types of fissures are mentioned in Figs. 89.5 and 89.6 show the image of brown rice grains (Basmati rice) with different types fissures.

From Fig. 89.5,

Type A fissures—Fissures perpendicular to longitudinal axis of grain—Non-terminating type: The fissures present in a rice grain which are perpendicular to the longitudinal axis of grain and ended somewhere in rice grain.

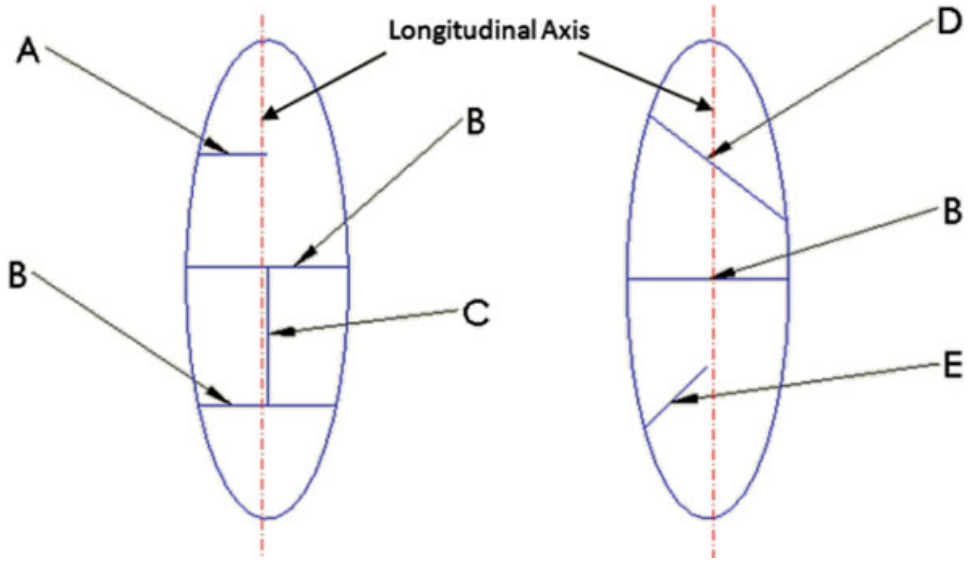

Fig. 89.5 Types of fissures in rice grains

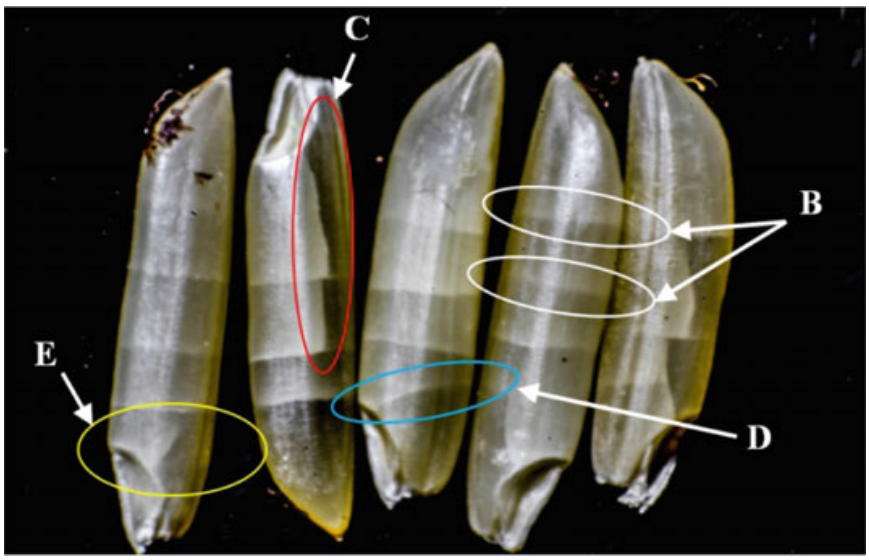

Fig. 89.6 Image of detection of different types of fissures in rice grains

Type B fissures—Fissures perpendicular to longitudinal axis of grain—Terminating type: The fissures present in a rice grain which are perpendicular to the longitudinal axis of grain and passed throughout the rice grain along that axis.
Type C fissures—Fissures parallel to longitudinal axis of grain—Terminating type: The fissures present in a rice grain which are parallel to the longitudinal axis of grain and passed throughout the rice grain along that axis.
Type D fissures—Cross fissure—Terminating type: The fissures present in a rice grain which are neither parallel nor perpendicular to the longitudinal axis of grain and ended somewhere in rice grain.
Type E fissures—Cross fissure—Non-terminating type: The fissures present in a rice grain which are neither parallel nor perpendicular to the longitudinal axis of grain and passed throughout the rice grain.

It was observed that in the case of fissured kernels the percentage of fissures perpendicular to longitudinal axis of grains (A and B-types) was more than any other types of fissures. Each and every fissured kernel had A and B type of fissures present in it. Percentage of fissures parallel to longitudinal axis of grains(C type) were more in Basmati rice variety than any other rice variety.

89.2.3 Physical Characteristics of Rice Grains

The shape of the rice kernel was found to be ellipsoid shape with three dimensions —length, width, and thickness. The physical dimensions of 20 kernels of each variety were measured using micrometer screw gauge (Mitutoyo Corporation) having least count of 0.01 mm.

The measured lengths of Rashi Poonam, Kolam, Komal, Basmati, and Daptari rice grains were found 5.79 ± 0.2 mm, 5.41 ± 0.19 mm, 6.64 ± 0.21 mm, 7.66 ± 0.33 mm, 5.45 ± 0.18 mm, respectively. From the dimensions of rice grains, it can be seen that the length of Basmati rice variety was more than other types of rice varieties. So, Basmati was long rice grain while others were short/medium rice grains. Physical dimensions of five types of rice varieties are given in Table 89.1.

Table 89.1 Physical dimensions of five types of rice for three-point breaking test

S. No.	Type of rice	Length (mm)	Width (mm)	Thickness (mm)
1	Rashi Poonam	5.79 ± 0.2	2.0 ± 0.08	1.57 ± 0.04
2	Kolam	5.41 ± 0.19	1.65 ± 0.07	1.52 ± 0.05
3	Komal	6.64 ± 0.21	2.08 ± 0.07	1.57 ± 0.04
4	Basmati	7.66 ± 0.33	1.97 ± 0.06	1.75 ± 0.06
5	Daptari	5.45 ± 0.18	1.62 ± 0.15	1.54 ± 0.05

89.2.4 Three-Point Breaking Test

The mechanical property of brown rice grains was determined in terms of average rupture force in three-point breaking test for five different varieties Rashi Poonam, Kolam, Komal, Basmati, and Daptari. The experiment was performed at a loading rate of 1 mm/min. Three-point breaking test was performed using a Universal testing machine (Instron Universal Testing Machine-3345, Fiest Laboratory, MEMS Department, IIT Bombay).

For testing, all rice grains were de-husk by hand. In each batch, 20 rice samples were taken for testing. Rice samples were sorted out according to the number of fissures present in it. Fissured were observed by fissured detection technique which was newly developed with the use of DSLR camera. For three-point bending tests, the whole rice grain was kept on an adjustable base support in which span was adjustable. The diameter of the end of support and compression tip was 1.45 mm. As rice shape is narrow toward the ends, the 15% of overhang was considered for three-point breaking test so that rice grains cannot break at their end due to the small area as compared to the middle portion. The adjustable base supports for three-point test apparatus for the breaking of a rice grain is shown in Fig. 89.7.

Different parts of the adjustable fixture for three-point breaking test are:

1. Base of fixture.
2. Two guiding shafts: for guiding movable supports.
3. Two movable supports: for support the rice grain while testing.
4. Circular tip on each support: for reducing stress concentration.
5. Main threaded shaft: half anticlockwise and another half clockwise threading.
6. Handle for rotation of the main threaded shaft.

The position of three points for breaking test:

The position of three contact points while loading is shown in Fig. 89.8. Compression Pouch is always in the middle of rice grain.

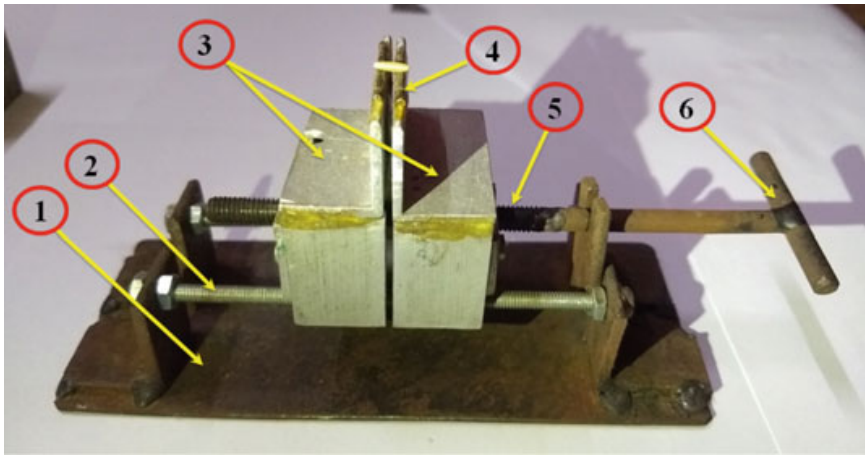

Fig. 89.7 Adjustable base supports for three-point breaking test

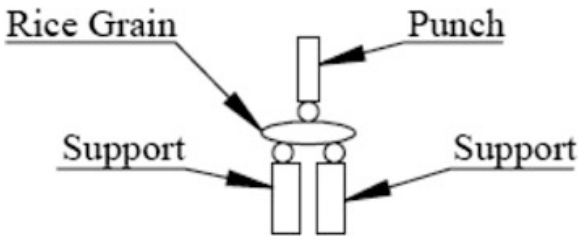

Fig. 89.8 Position of three contact points

89.3 Results

Table 89.2 shows the rupture force value for different varieties of brown rice grains. Data shows that variety and number of fissures affect the rupture force. In the case of Basmati variety, the average force to rupture the grain was obtained as 18.69 ± 6.98 N, 9.56 ± 5.63 N, 6.32 ± 3.36 N, and 3.49 ± 1.38 N for grains without fissures, with 1 fissure, 2 fissures, and more than 2 fissures, respectively. Similarly, rupture force values for Kolam, Komal, Daptari, and Rashi Poonam variety are given in Table 89.2. From data, it can be seen that rupture force value decreases as fissures increase in rice grains. Rashi Poonam variety has the highest average rupture force of value 32.29 N for grains without fissures. While Komal variety, the rupture force value 28.52 N which is much closer to the value of rupture force for Rashi Poonam variety.

89.3.1 Finite Element Analysis of Rice Grain (Three-point Breaking Test)

Finite element analysis of rice grain under three-point breaking test was done in ANSYS Workbench Software. As rice grain is having complex geometry, for analysis, rice grain is considered as a cylindrical object with diameter equal to equivalent diameter of rice grain calculated using formula:

Table 89.2 Rupture force by three-point breaking test

S. No.	Type of rice	Breaking force (N)			
		0 fissure	1 fissure	2 fissures	More than 2 fissures
1.	Basmati	18.69 ± 6.98	9.56 ± 5.63	6.32±3.36	3.49 ± 1.38
2.	Kolam	15.44 ± 6.57	10.30 ± 4.72	5.21 ± 4.69	3.81 ± 2.08
3.	Komal	28.52 ± 4.41	16.83 ± 4.39	11.29 ± 3.56	6.34 ± 2.21
4.	Daptari	16.23 ± 5.98	12.36 ± 3.87	7.12 ± 2.28	4.51 ± 1.13
5.	Rashi Poonam	32.29 ± 6.55	14.68 ± 5.89	9.90 ± 2.70	6.96 ± 3.06

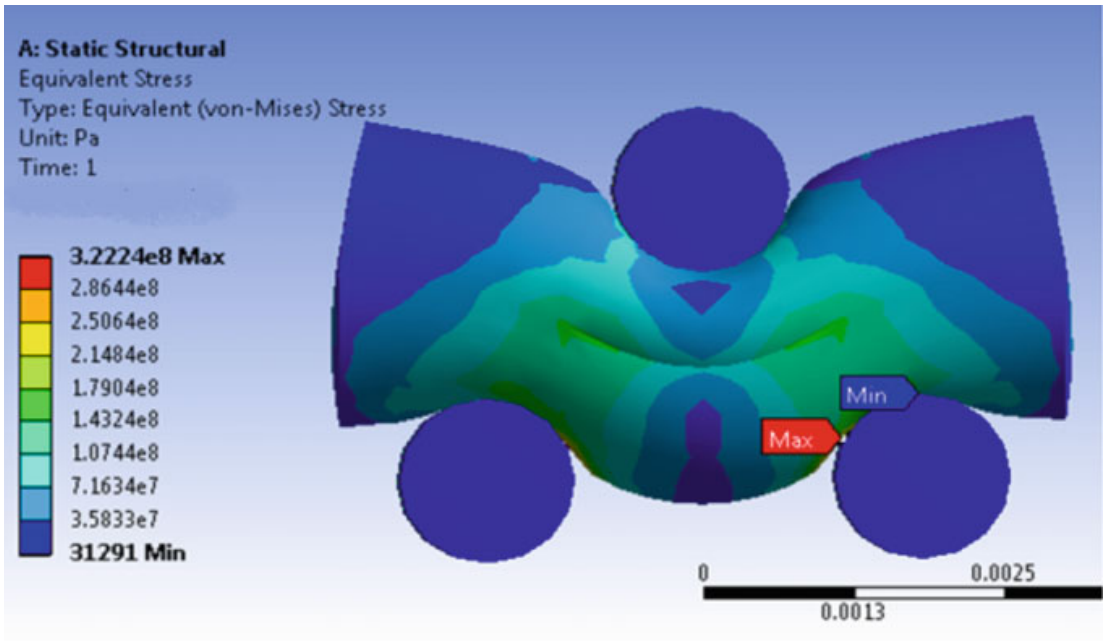
$$\mathrm{De} = \left(L * \frac{(W+T)^2}{4} \right)^{1/3}$$

where L = Length, W = Width of rice grain, T = Thickness of rice grain [8]. Mechanical properties of rice grains considered for analysis were: Young Modulus = 417MPA, Poisson's ratio = 0.4476, density 2700 kg/m^3 [9]. Physical dimensions of Rashi Poonam rice variety were taken for analysis. Figure 89.13 shows the finite element analysis of rice grain under three-point breaking test, and Fig. 89.9a, b shows the analysis results for the equivalent stress and equivalent strain, respectively.

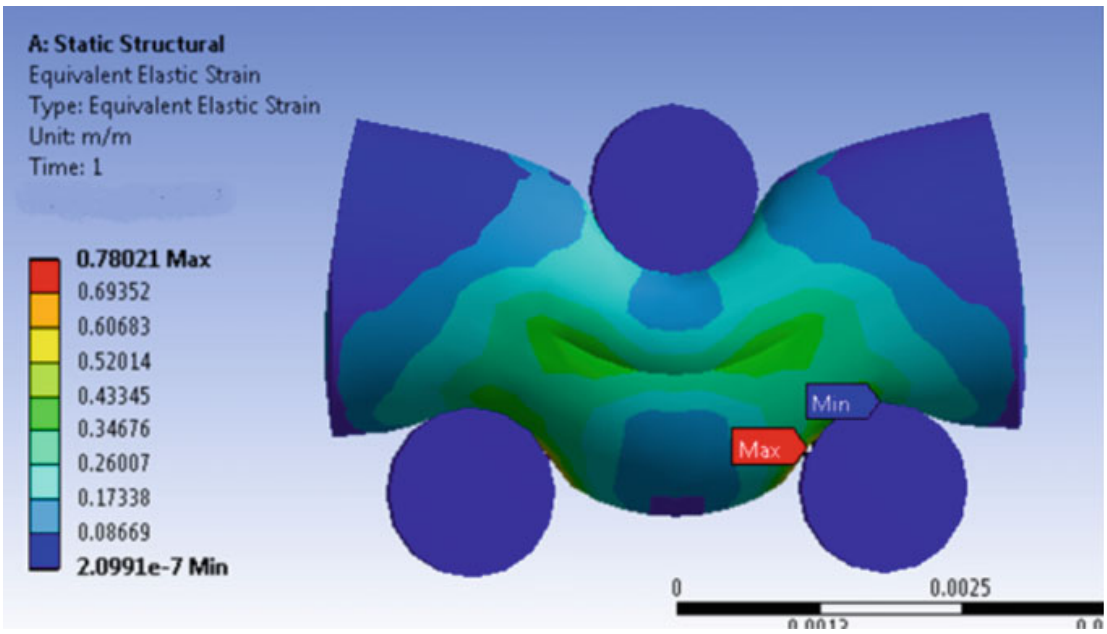
From analysis result, it can be seen that for 7% of strain, the equivalent stress in rice was 322 MPa which at the contact of rice bottom surface and support. The crack may occur at contact of support and bottom surface of rice grain where the stress intensity is maximum. In experimental results for Rashi Poonam rice variety without any fissure, the maximum stress was found was 430 MPa and maximum strain was 9%. In three-point bending test, the crack started at contact of bottom surface of rice grain and support and then propagate toward the contact of punch to rice grain as shown in Fig. 89.10. High-speed camera used for recording the crack propagation was Phantom MIRO M110 with supporting software—Phantom Camera Control Application for controlling operation of camera. Illumination is done by fiber optic dual light illuminator (White light source).

89.3.2 A Typical Graph of Load (N) Versus Deformation (mm) Obtained After Three-point Breaking Test of Rice Grains

From load (N) versus deformation graph as shown in Fig. 89.11, the testing starts at point A, i.e., punch moves downward with a set speed (1 mm/min). The region from point A to point B is almost parallel to *X*-axis. This region shows that up to point B, there is no contact of punch with rice grain. (This is due to we touch punch to rice grain manually, so for every sample, it may vary). From point B, actual loading gets started. The region from point B to point C shows the linear relationship between load and extension. At point C, the breaking of rice grains occurs.



(a) Analysis for Equivalent Stress



(b) Analysis for Equivalent Strain

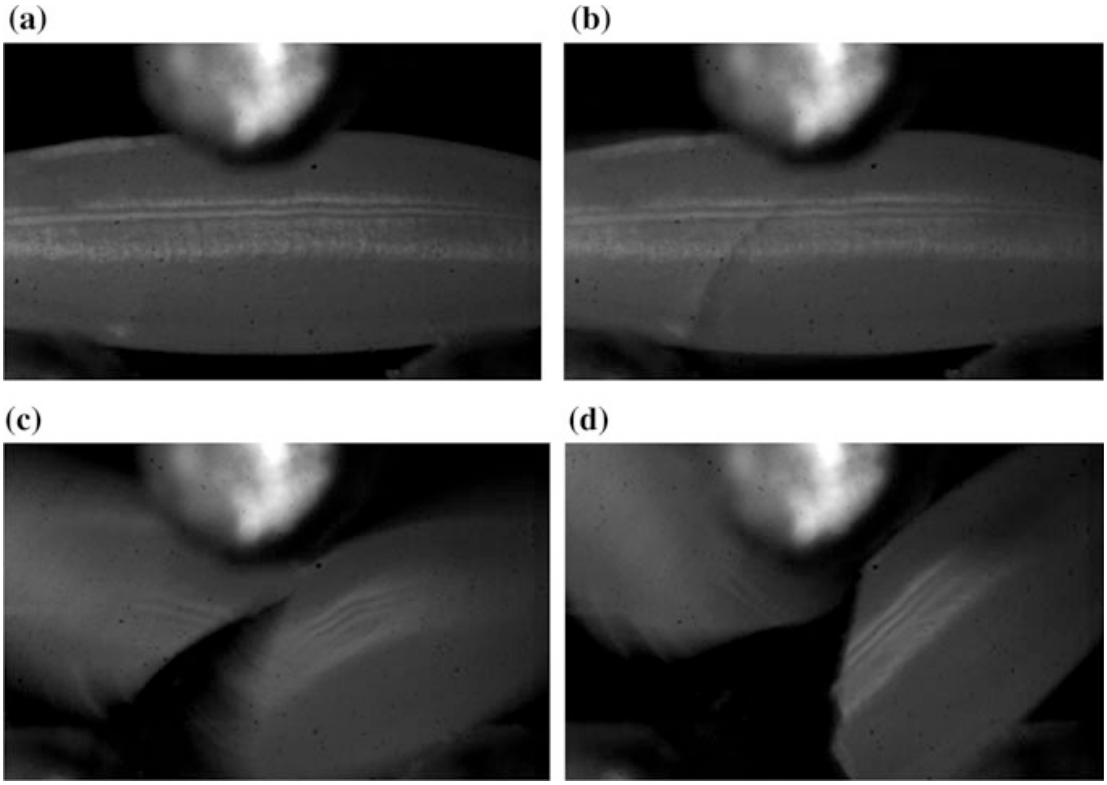

Fig. 89.10 Images of the crack propagation in rice grain while applying the load

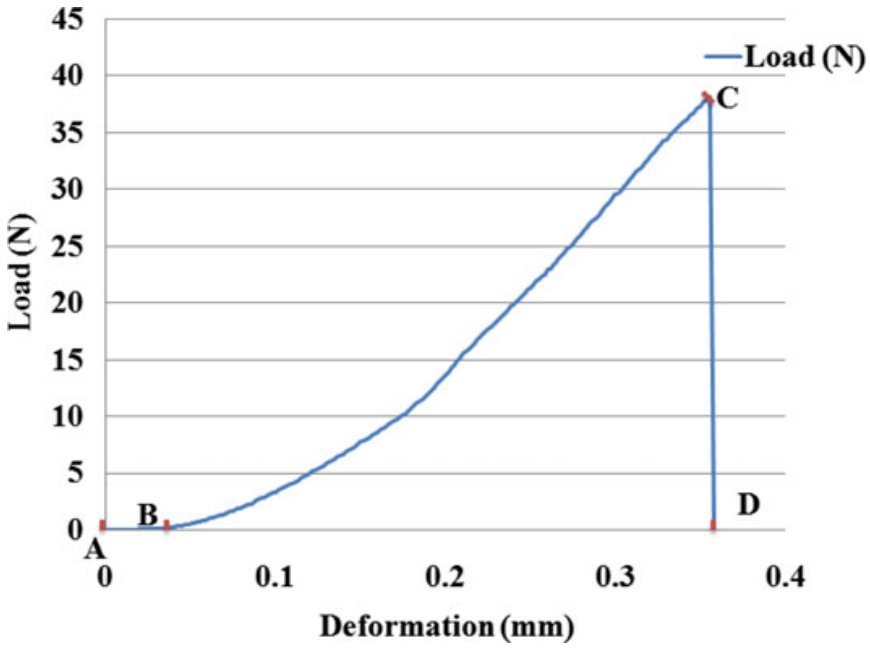

Fig. 89.11 Typical graph of load (N) versus deformation (mm)

89.3.3 Modified Graph of Load (N) Versus Deformation (mm) Obtained After Three-Point Breaking Test of Rice Grains

This graph is obtained by removing Region A-B and Region C-D is from the typical graph. This graph shows the linear relationship between load and deformation (Fig. 89.12).

89.3.4 Graph of Breaking Force Versus no of Fissures for Five Varieties of Rice Grains

Figure 89.13 shows the graph of breaking force value for five different types of rice varieties with a different number of fissures present in the rice kernel. From the

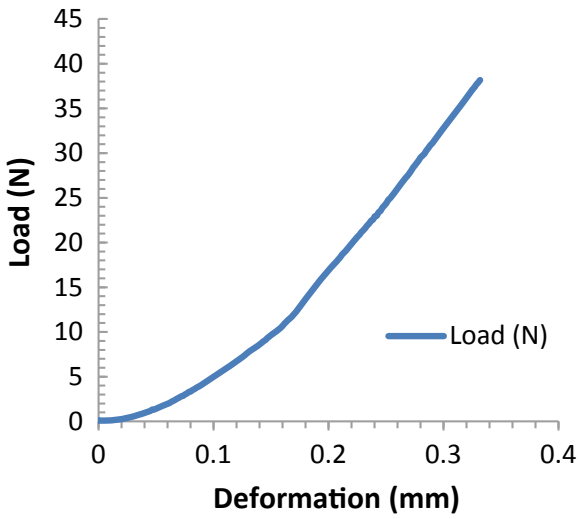

Fig. 89.12 Graph of load (N) versus deformation (mm)

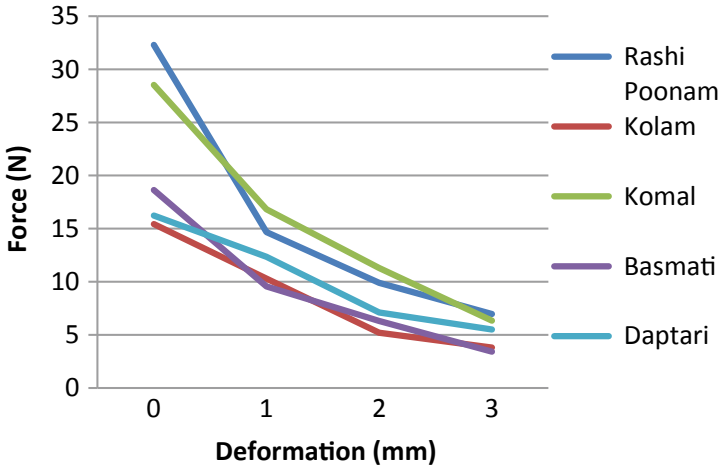

Fig. 89.13 Graph of breaking force versus number of fissures (*On X-axis: Point 3 indicates more than two fissures)

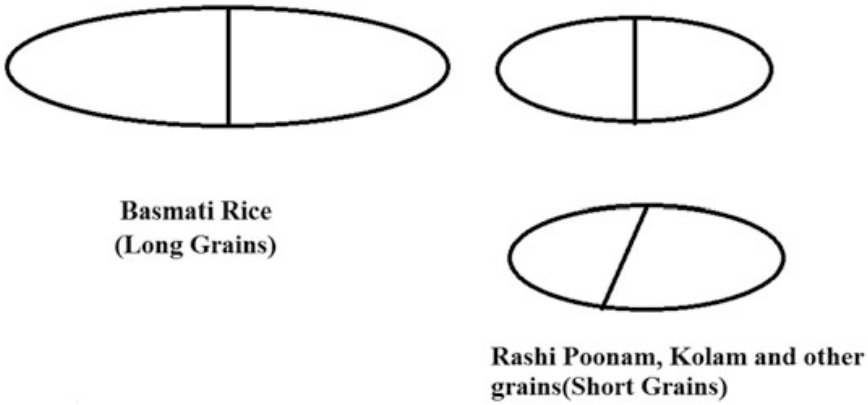

Fig. 89.14 Breaking patterns of rice grains while three-point breaking test

graph, it can be clearly seen that the breaking force required decreases as the number of fissures increases in rice grain. Rice grains become so weak if there are more than two fissures in a grain and for those rice grains breaking force values are much closed irrespective of rice varieties.

89.3.5 Different Breaking Patterns of Rice Grains While Three-Point Breaking Test

After testing and imaging of rice grain it is oberved that rice kernels with fissures subjected to 3-point breaking test, crack initiated at big fissure. When there was no fissure in rice grain, then crack is initiated from the contact point of one of the base support and propagates upward toward the point of contact between rice grain and punch. Each case of the rice grain, crack propagated from bottom surface to top surface of rice grain while loading because of bottom surface always in tension while 3-point breaking tests (Figure 89.14).

89.4 Conclusions

The three-point breaking test has been performed on five varieties of brown rice grains with different types of fissures present in brown rice grains. The values of the rupture force of brown rice grains Rashi Poonam and Komal rice varieties were taken higher than rupture force value of brown rice grains. So, it can be concluded that the Rashi Poonam and Komal varieties have more resistant to breakage than the Basmati, Kolam and Daptari varieties during the various operations such as de-husking, milling, and polishing. The results obtained from three-point breaking test of brown rice grains can help for developing of methods and types of equipment used for whitening and polishing processing of rice with different varieties.

Finite element analyis is result have validated the cracks are likely to occur due to the applied the rupture forces on the rice grain in the three point bending test. If rice millers able to find breaking force value for particular variety of rice grains before processing, then it may easy for rice millers to adjust correct pressure for processing that particular batch of rice grains so further breaking can be avoided. The testing of rice grain can be done on the low load capaicty carrying universal testing machine shall be recommeded for better rupture analysis of rice grain in the experimental testing.

Acknowledgements We thank Prof. Uday Sheorey and Prof. Rakesh Mote (Professor, Mechanical Department, Indian Institute of Technology, Bombay) for their excellent guidance throughout the project. We also thank Metallurgical Engineering and Material Science Department, IIT Bombay, for support to carry out various testing.

Chapter 90
Finite Element Analysis of Potential Liner Failures During Operation in Spherical Pressure Vessel

R. Pramod, N. Siva Shanmugam, C. K. Krishnadasan and K. Sankaranarayanasamy

Abstract Composite overwrapped pressure vessel (COPV) is widely used in aerospace industry to contain pressurized gases. The behaviour of pressure vessel components (liner and composite overwrap) at applied pressure and potential failures during its operation requires adequate study. The finite element (FE) analysis is performed for potential failures occurring in a 420 mm diameter aluminium alloy (AA) 6061-T6 lined spherical pressure vessel. In the present study, the design of spherical liner with apt manufacturing techniques is presented. The liner contribution towards sustaining the minimum burst load is determined and liner burst test is conducted to check the location of failure. Further, typical liner failures like buckling and bond failure occurring due to inefficient contact between the liner and composite overwrap, which eventually forms a debond region are also studied. The liner burst pressurization results predicted the location of failure in liner at transition region as the liner is undergoing thickness changes in that particular region. The mode of liner buckling, buckling load is predicted when liner is subjected to compression during depressurization cycle. Further, at debond region, the liner is unable to transfer pressure load effectively to composite overwrap experiencing severe deformation.

90.1 Introduction

Launch vehicle and satellite require pressure vessels during operation for managing fluids and propulsion systems. Composite overwrap pressure vessel (COPV) with inclusion of a metal liner offers less vessel weight in comparison to conventional metal pressure tanks [1]. Aluminium and titanium alloys are generally used materials for liner because of less density and corrosion-resistant properties exhibited by these materials, respectively [2]. Non-load sharing and load sharing are the two types of liner. In the first case, liner is having minimum thickness and weight designed primarily to provide permeation barrier for preventing escape of gases. In the latter case, the liner contributes towards sharing the applied pressure load with higher thickness and weight [3]. Lee et al. [4] designed a spherical pressure tank using the Ti-15 V-3Al-3Cr-3SN material. Hemispheres were made by hot spin forming and blow forming process followed by TIG welding to join the two hemispheres. Pressurization test was conducted; the strain and acoustic emission signals were obtained to examine the outcome of selected manufacturing technique on the modes of failure and working performance of the tank. Chandran et al. [5] performed FE analysis by designing and analysing the COPV using titanium liner and T-300 carbon fibre composite. The effect of debonding location and length of debond in the liner-composite interface for weld and transition region was investigated. Almeida Jr et al. [6] investigated the effect of load sharing ability of aluminium and stainless steel liner material with various thicknesses in cylindrical liner geometry. Further, analyzed the stress and strain distribution at various regions of liner and composite structure. Many research works have been carried out in developing pressure vessels using AA 6061-T6 liner. The numerical analysis performed mainly focused on the modelling techniques and analysis of composite overwrap, failure analysis of composite overwrap and methods to analyse filament wound COPV [7–9]. From the literature review, it is noted that the research work has not focused on the analysis of failure and its modes in liner under applied internal pressure. Studying the behaviour of liner by physically testing the pressure vessel by subjecting it to repeated testing shall be economically high and time-consuming as it comprises of conducting several trials to obtain in-depth information generally involved in a design process. Instead, numerical analysis is conducted using the FE method, as an alternative to experimental testing [10]. In the present case, it is emphasized on cost reduction by replacing titanium with aluminium liner material and will be helpful in meeting quality conditions effectively. Hence, in the present analysis using ABAQUS and FE analysis software, liner analysis is conducted to study its behaviour, when subjected to internal burst pressure. Also, contact failure issues such as buckling and debonding, which lead to loss of COPV are also analyzed.

90.2 Materials and Design

The selected liner material in COPV is aluminium alloy (AA) 6061-T6. Assigned physical [11] and mechanical material properties are shown in Tables 90.1 and 90.2, respectively. The spherical liner design is shown in Fig. 90.1, as being a non-contributory type liner, the thickness in dome region is kept minimum to achieve weight savings. The formed part is fabricated by forming a 3.5 mm thick

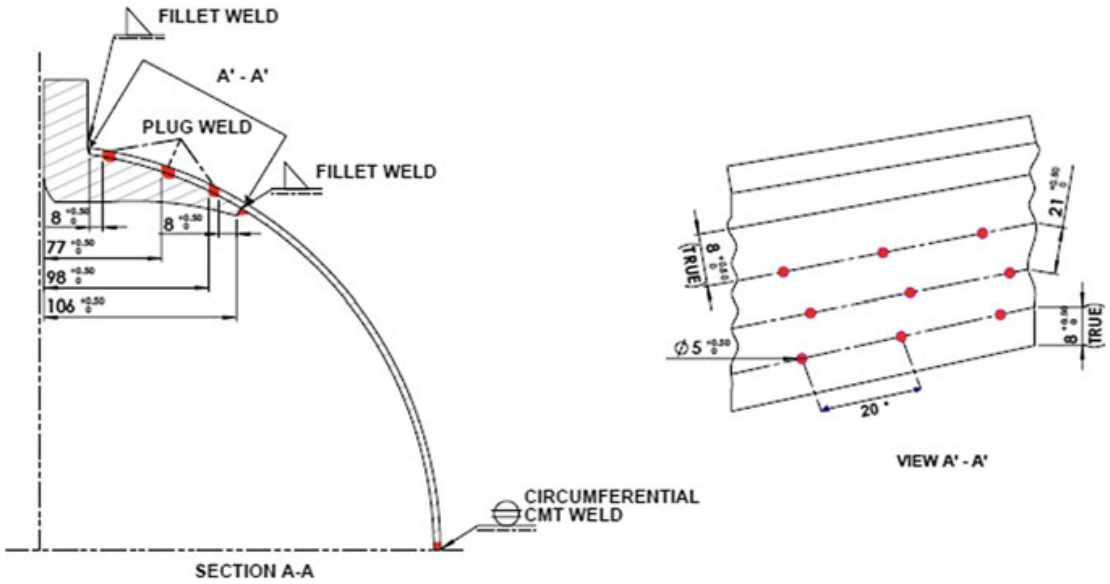

Fig. 90.2 Representation of plug, fillet and CMT welding locations in the liner

sheet using die and punch system, and forged part for end boss is obtained by machining a solid block of AA 6061-T6. The parts are further joined by plug welding technique, and welding the hemispheres circumferentially using cold metal transfer welding (CMT) technique as shown in Fig. 90.2. The true distance between the points of laying plug weld to edge of fillet weld is maintained at 8 mm with each plug having radius of 5 mm. Between each plug weld, a distance of 21 mm is maintained and positioned at three stages with pitch angle of 20° as shown in Fig. 90.2 (section A′–A′).

90.3 Finite Element Modelling

The liner is modelled as solid part. The effect of welding process changes the inherent base material properties in aluminium. Hence, by considering the effects due to welding, weld metal properties are assigned at pole and equator region, and length to be assigned is determined from an experimental trial. The length for assigning weld metal properties in liner is determined from Fig. 90.3. A miniature level AA 6061-T6 tube test specimen (replicating the large-scale liner structure) having a thickness of 3.5 mm were subjected to CMT welding to determine the weld bead width (BW) and heat-affected zone (HAZ). It was observed that BW and HAZ comprised of 15 mm (refer Fig. 90.3a) and this was measured using Struers welding expert with magnification of 20X. Due to less heat input of CMT process, various researchers have observed narrower heat-affected zone in AA 6061

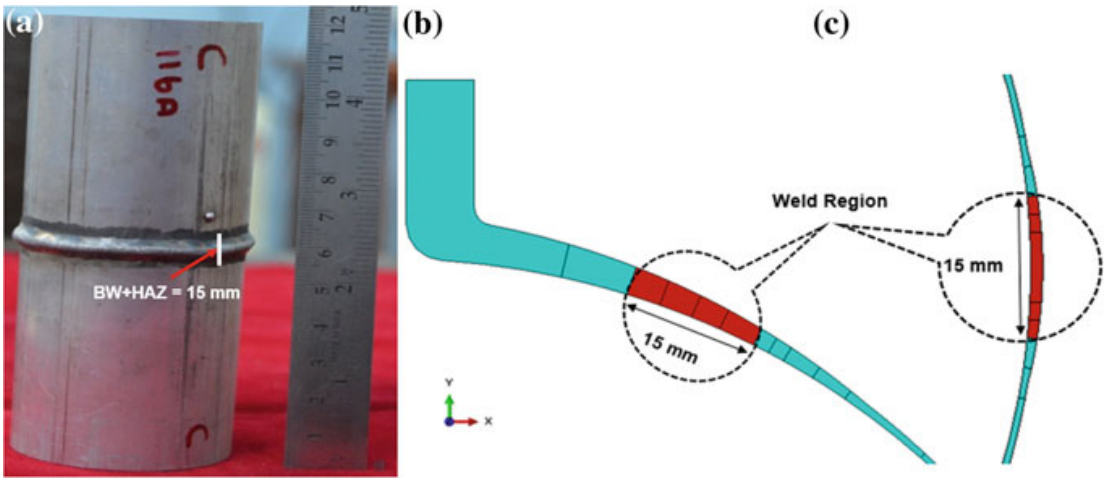

Fig. 90.3 Weld bead and HAZ measurement in CMT weld AA 6061-T6 pipe specimen (Left) and Weld region assignment in the FE modelled liner (Right)

weldment using CMT [12, 13]. In the present experimental trial, (refer Fig. 90.3a) the HAZ is found negligible as measured along with weld bead. Hence, weld bead + HAZ is considered as a single region and measured to be 15 mm in length. In the present analysis, weld material properties are assigned for a length of 15 mm as shown in Fig. 90.3b in the pole region and Fig. 90.3c in the equator region. The symmetric boundary condition is applied on side faces of liner by restricting *Z*-axis movement (U3 = 0). Also, bottom face of liner is restricted by *Y*-axis movement (U2 = 0) and inlet face movement is restricted by *X*-axis movement (U1 = 0), respectively as shown in Fig. 90.4. The internal pressure load is applied on the interior face of liner (refer Fig. 90.4). Liner burst test is conducted to determine its pressure load contribution and check the failure location due to applied load. The applied burst pressure load on the liner is determined using the Eq. 90.1.

$$P = \frac{2 * \sigma * t}{R}$$
$$P = \frac{2 * 290 * 1.5}{210} = 4.15\,\text{MPa} \tag{90.1}$$

where σ = Ultimate tensile strength of AA 6061-T6, t = Minimum thickness of liner and R = Radius of liner. Dynamic explicit analysis is conducted with non-linear geometric effects. For prediction of failure, Johnson–Cook (JC) damage material model is utilized. The failure is expected when parameter $D = 1$. The mathematical expression is shown in Eqs. 90.2 and 90.3. The constants for the JC model used in the evaluations for AA 6061-T6 is shown in Table 90.3 [14]. Load angle (ξ) effect is considered as $\xi = 0$.

Table 90.4 Description of meshing parameters

Part	Shape of element	Meshing technique	Elements
Plugs	Hex-dominated	Sweep	5891
Formed part	Hex-dominated	Free	7158
Forged part	Hex-dominated	Sweep	1038
Fillet	Hexagonal	Sweep	168

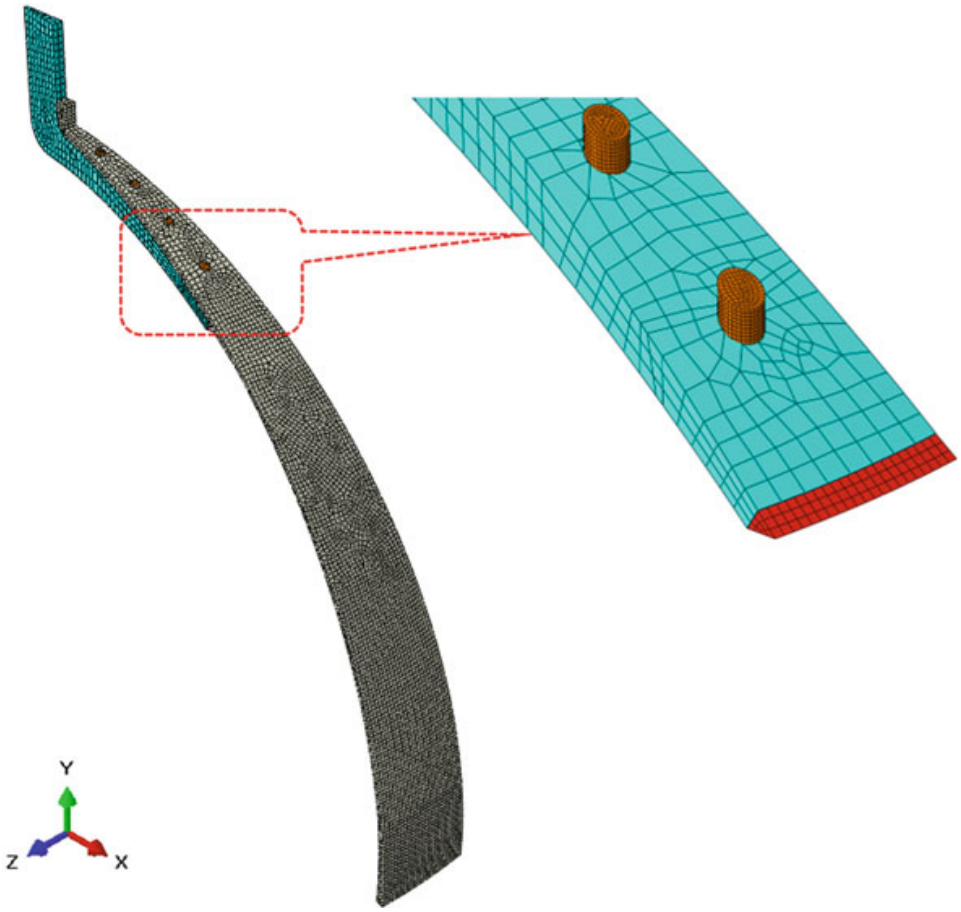

Fig. 90.5 Meshed model of liner and mesh profile in plug, fillet weld (inset)

The meshing of liner is performed by maintaining fine mesh near the plug weld region and on plug welds. The primary element type used for meshing parts is C3D8R (An eight node linear brick, reduced integration with hourglass control).

Table 90.4 shows a brief description of meshing parameters utilized in meshing of parts and Fig. 90.5 shows the meshed model of liner and mesh profile in plug and fillet weld.

The stable bond between liner and composite overwrap shall fail in case of design irregularities, complex curvatures in liner, thus creating a debond region. In the present analysis, a debond region is created by removing the contact interaction between liner and composite overwrap to study the ill-effects on liner. The eigenvalue linear analysis is performed for determining the load at which liner buckles during depressurization with subsequent buckling modes.

90.4 Results and Discussion

The burst load of 4.32 MPa applied on inner surface of liner at plastic stage showed severe yielding with Von Mises stress of 309 MPa (refer Fig. 90.6a) and plastic strain of 0.76% (refer Fig. 90.6b) at the transition regions near to pole and equator region. Further, the first failure location of liner is seen at transition region near the

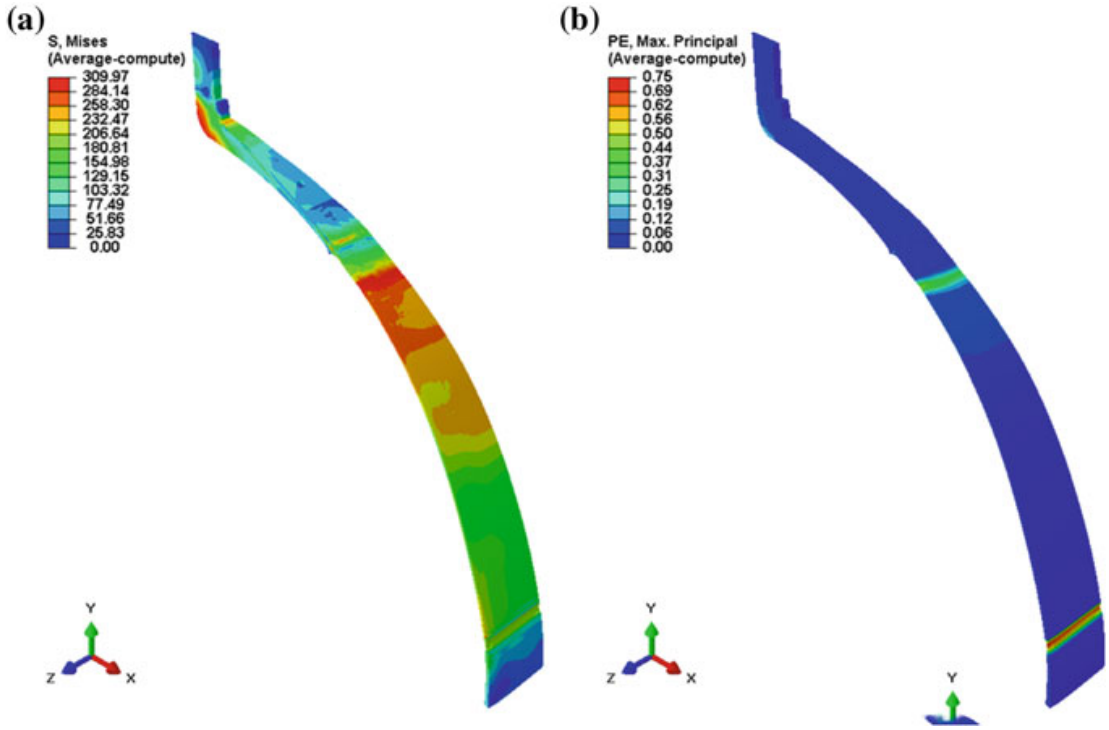

Fig. 90.6 Distribution of Von Mises stress **a** and plastic strain **b** at plasticity stage in liner

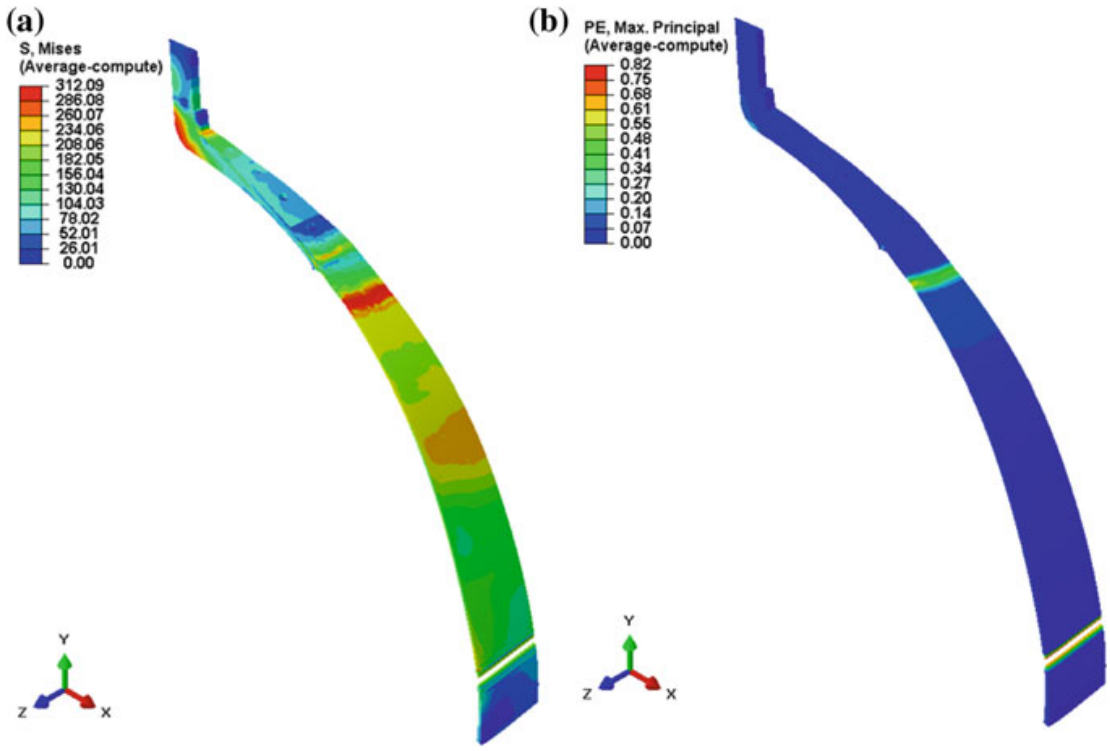

Fig. 90.7 Distribution of Von Mises stress **a** and plastic strain **b** at first failure stage in liner

equator section. Failure is observed in terms of crack appearing in liner and complete rupture is observed as equator region gets completely detached from the liner section at Von Mises stress of 312 MPa (refer Fig. 90.7a) and plastic strain of 0.82% (refer Fig. 90.7b). From the analysis, it was also required to know, if the failure is occurring in weld zones of liner as weld specimen has lower strength (refer Table 90.2). Observation showed that second failure of liner in terms of crack propagated at the transition region in dome section at Von Mises stress of 358 MPa (refer Fig. 90.8a) and plastic strain of 0.99% (refer Fig. 90.9a). Also Figs. 90.8c, d and 90.9c, d shows the enlarged view of the failure regions with complete separation of ruptured parts. It is also noted from Figs. 90.8b and 90.9b the Von Mises

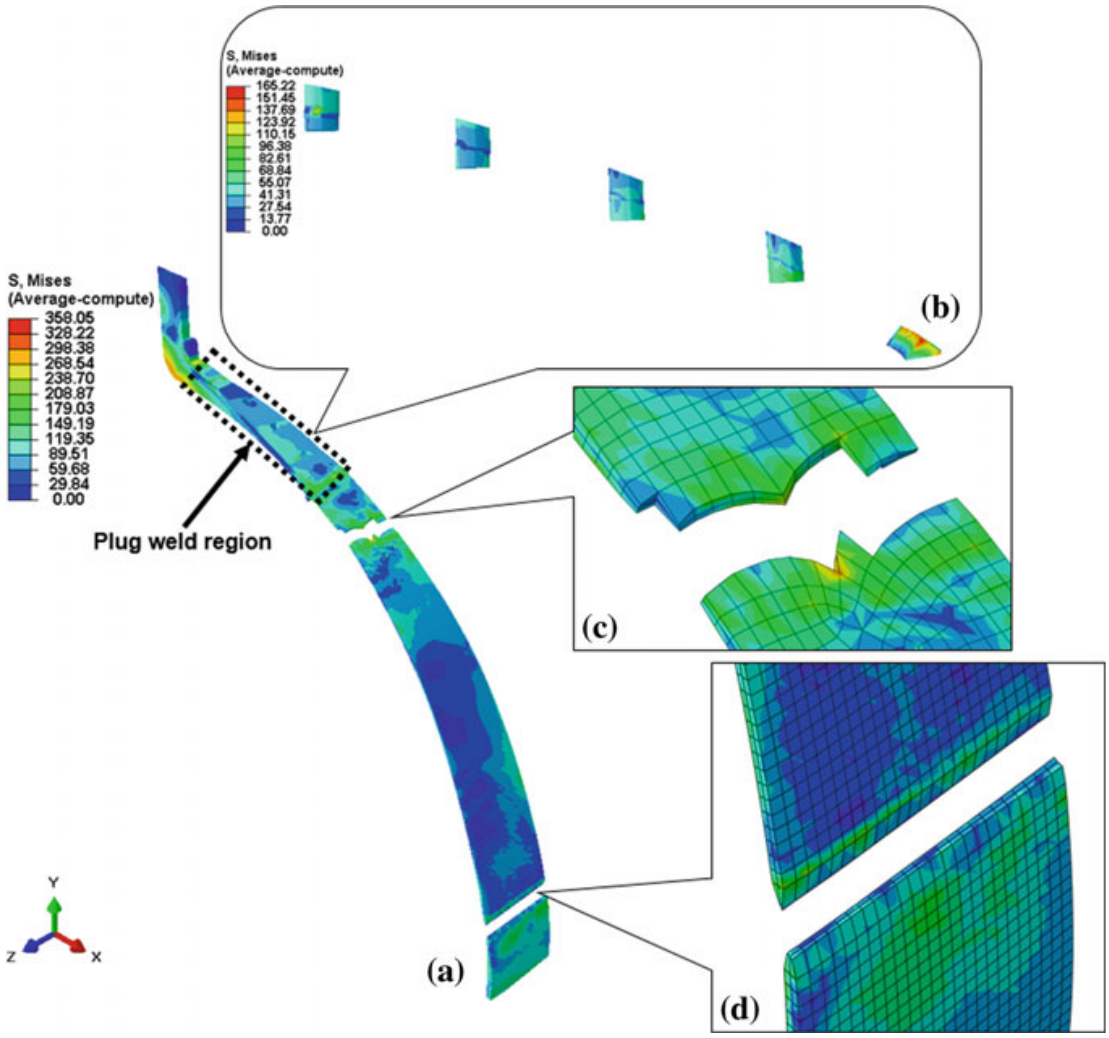

Fig. 90.8 Distribution of Von Mises stress in liner **a**, plug and fillet weld **b**, ruptured locations near dome **c** and equator **d** regions in liner

stress (165 MPa), plastic strain (0.056%) at the plug and fillet weld at the time of liner failure proved that it was intact and these welds can successfully take the impact of burst load and provide effective welding medium to join forged and formed part.

At debond regions, the internal pressure load applied on liner will not be effectively transferred to composite overwrap. This occurs because of improper bonding and insufficient bond pressure between liner-composite overwraps. Hence

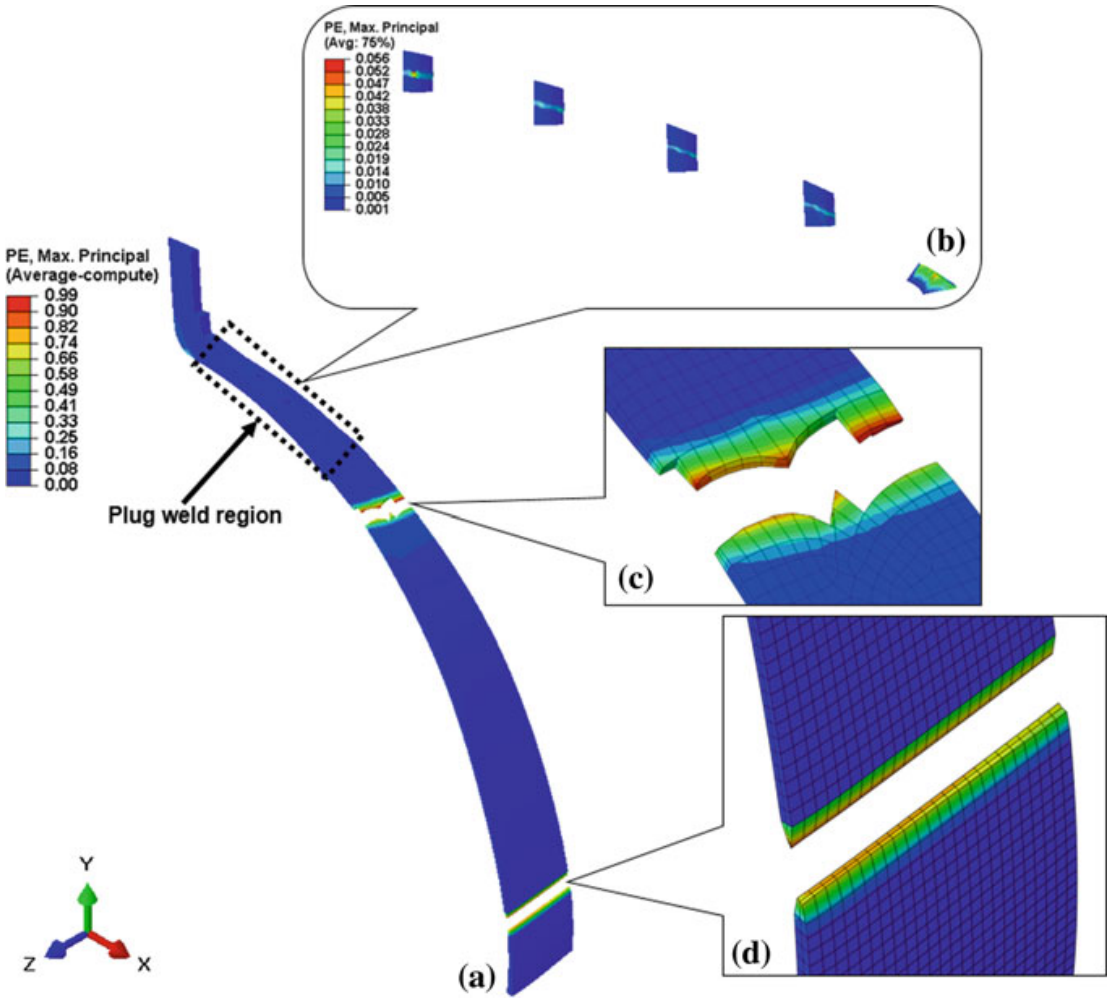

Fig. 90.9 Distribution of plastic strain in liner **a**, plug and fillet weld **b**, ruptured locations near dome **c** and equator **d** regions in liner

a void created in-between will allow liner to consume pressure load more than its capability, which will allow it to deform excessively as it cannot effectively transfer the load to composite overwrap. Peak Von Mises stress of 293 MPa (refer Fig. 90.10) is seen at the debond locations. The obtained stress of 293 MPa is 3 MPa more than the ultimate tensile strength of AA 6061-T6 proving that liner will fail in presence of debond. Graphical representation of Von Mises stress along the axial length of liner is shown in Fig. 90.11. Figure 90.12 shows the maximum deformation (7.93 mm) in liner at debond location. This plastic deformation causes

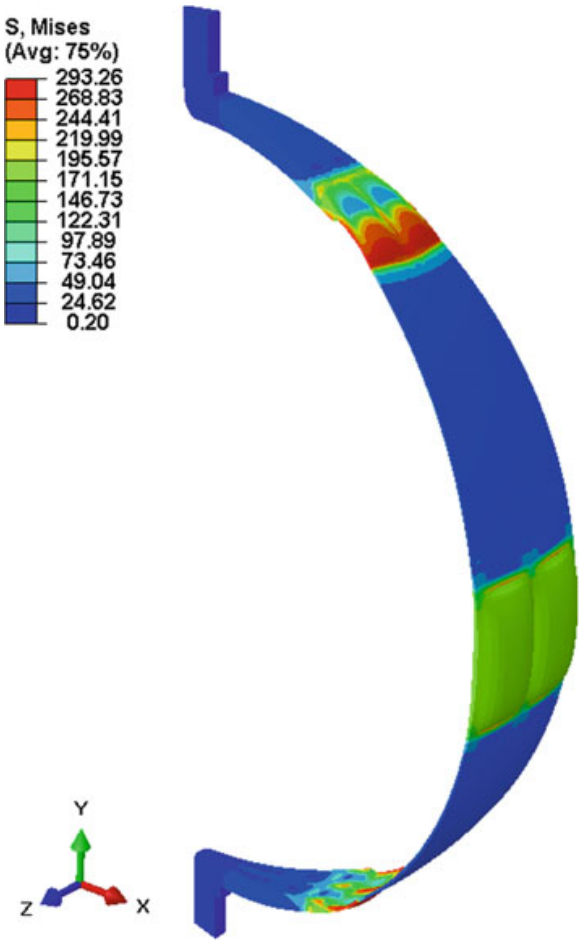

Fig. 90.10 Von Mises stress distribution in the debond model

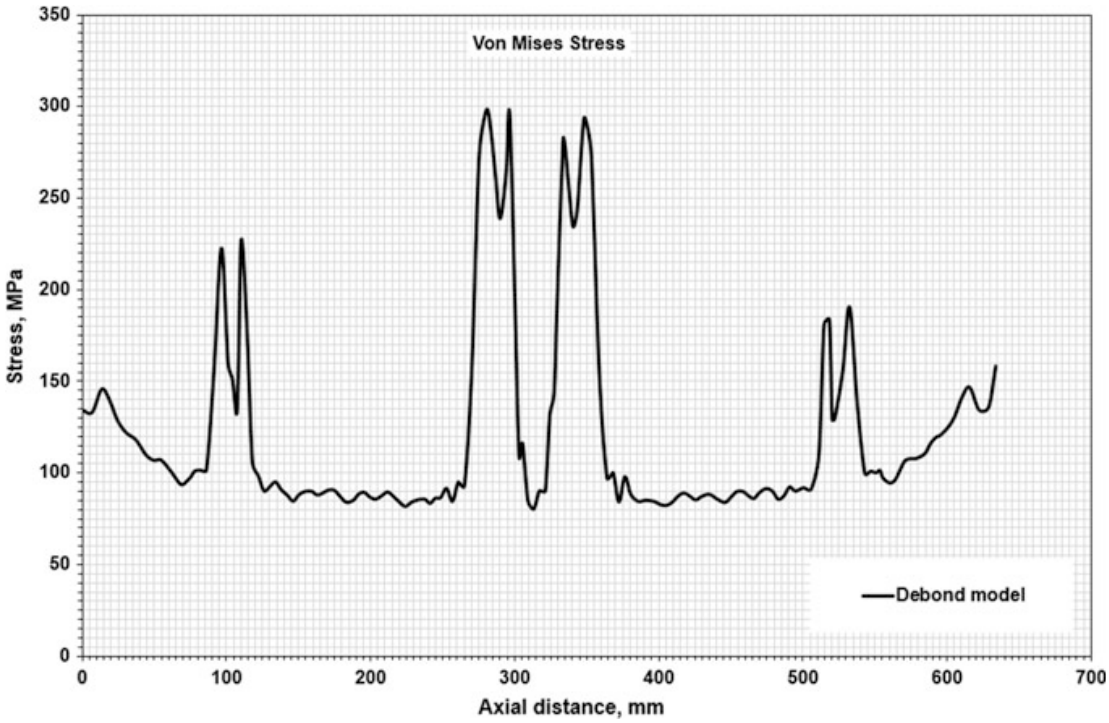

Fig. 90.11 Graphical representation of Von Mises stress distribution in the debond model

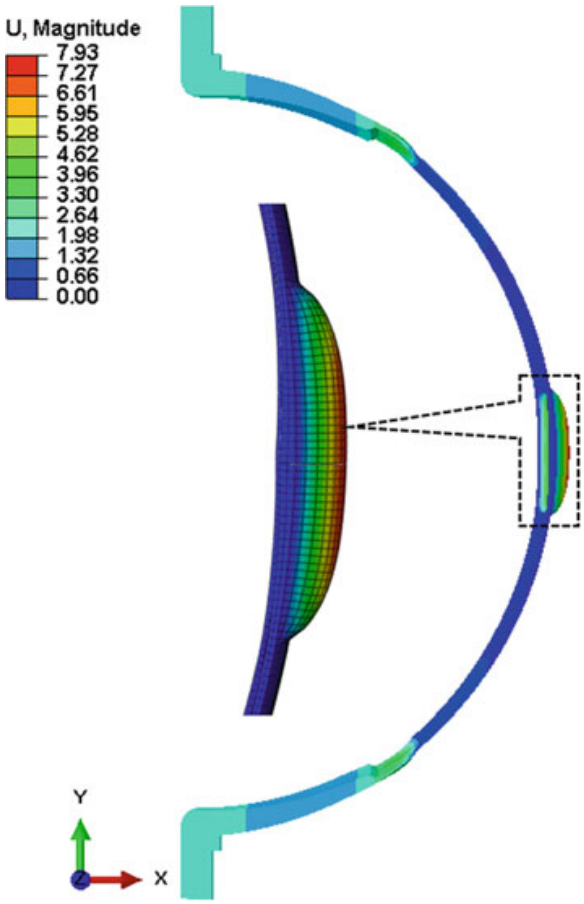

Fig. 90.12 Displacement plot in the debond model

additional problem, as during consecutive pressurization-depressurization cycles, it may cause liner to buckle; hence, bringing down the efficiency of liner and possible failure during operation. The eigenvalue linear buckling analysis is conducted to observe the buckling of liner (plastic condition) when a compressive load of 1 MPa is assigned to obtain load at which the liner buckles. During the depressurization phase, if the external load on the liner exceeds the critical buckling load of F_{cr} = 5.04 MPa the liner will buckle as seen in Fig. 90.13.

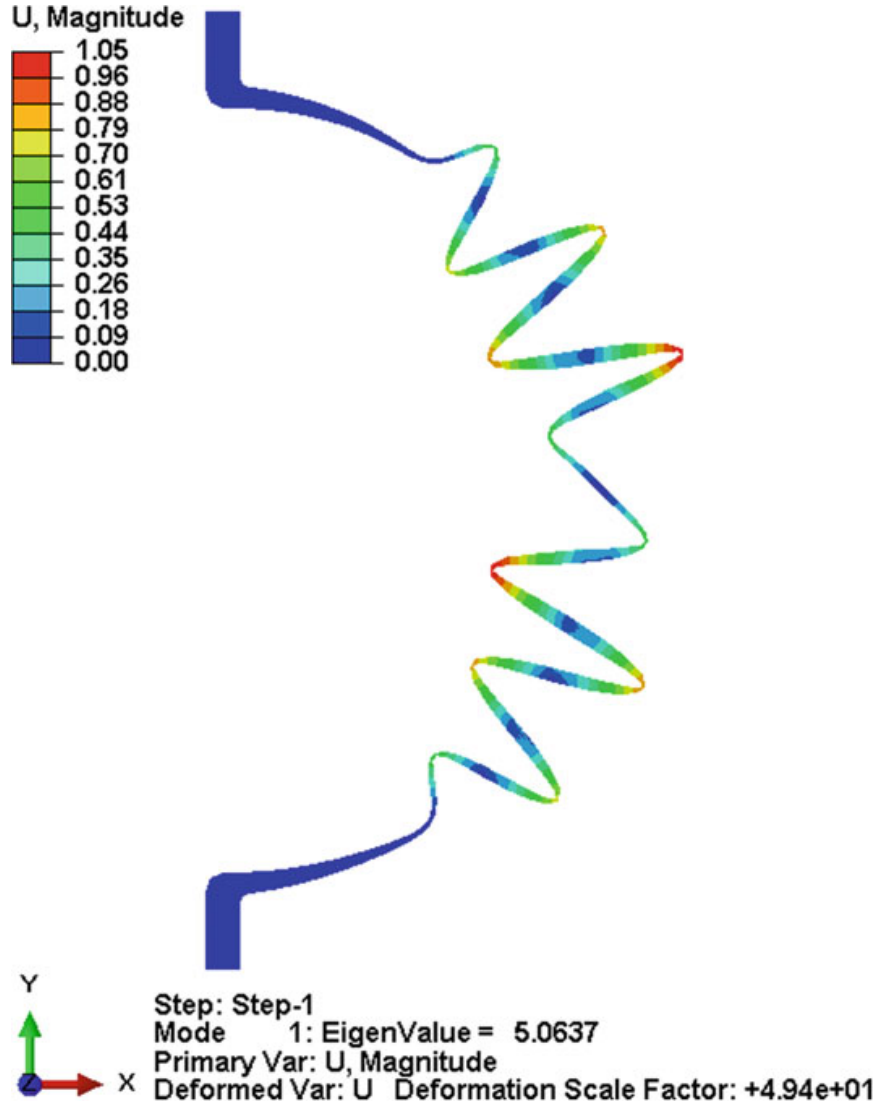

Fig. 90.13 Buckling of liner during depressurization

90.5 Conclusions

The three types of failures occurring in liner during operation are analyzed and the following conclusions are drawn:

- The presence of thickness variation in liner forms a transition region. Burst pressure load of 4.32 MPa, applied on liner showed that failure of liner occurred at these transition regions, i.e. equator region (312 MPa Von Mises stress and 0.82% plastic strain) and dome region (358 MPa Von Mises stress and 0.99% plastic strain). Further, results revealed that plug and fillet weld regions are safe from failure (165 MPa Von Mises stress and 0.056% plastic strain) due to applied burst pressure load.

- The presence of debond region had a major effect on liner as the observed Von Mises stress (293 MPa) exceed the ultimate tensile strength (290 MPa) of AA 6061-T6 proving that liner fails in presence of debond region.
- The predicted eigenvalue buckling load shows if the external pressure acting on the outer surface of liner exceeds of 5.04 MPa (depressurization phase) then the liner will buckle.

Digital Transformation in Business and Society

"This is a great book full of information for those who want to better understand the digital revolution and how it is changing the whole of society, and business in particular. This book is a good guide to see this reality in a completely different way, through the scope of technology, and to better understand the exponential future we are living in."

—Dr. Besa Shahini, *Professor of Economics and Finance, University of Tirana, Albania*

"The book offers thoughtful, comprehensive insights into the far-reaching capacity of the digital footprint to reconfigure and remap every aspect of business and societal behavior. The authors have crafted a trailblazing compendium of digital transformation thought and action related to micro- and macro aspects of business and society. The book has the potential to become the defining work in this body of literature."

—Dr. Alvin Williams, *Professor and Chair, Department of Marketing, University of South Alabama, USA*

"One of the best books I have had the opportunity to read, I strongly recommend that you take it into account for your graduate programs."

—Dr. Sergio Garcia Agreda, *Director of the Master's Program in Digital Business, Universidad Privada Boliviana, Bolivia*

"This book is a timely text that will inform readers on a wide range of business and societal applications in the area. This text will help organizational psychologists understand the human factor in business decision-making and execution to then fully grasp the potential for digital transformation both in Business 4.0 and Society 5.0."

—Dr. Mervyn Jackson, *Head, Discipline of Psychology, RMIT University, Australia*

Contents

1 **Introduction** 1
Babu George

2 **Human Flourishing in Smart Cities** 13
Maria Lai-Ling Lam and Kei-Wing Wong

3 **On How Big Data Revolutionizes Knowledge Management** 39
Asha Thomas and Meenu Chopra

4 **Social Media in Marketing Communications: A Synthesis of Successful Strategies for the Digital Generation** 61
Ogechi Adeola, Robert Ebo Hinson, and Olaniyi Evans

5 **Social Media Technologies and Export Marketing** 83
Frederick Avornyo, Mahmoud Abdulai Mahmoud, Ogechi Adeola, Robert Ebo Hinson, and Richard Boateng

6 **Data Analytics and Predictive Analytics: How Technology Fits into the Equation** 103
Brian J. Galli and Gabrielle Muniz

7 **Effective Engagement of Digital Natives in the Ever-Transforming Digital World** 113
Anju Varghese Philip and Zakkariya K. A.

8 **Robotics, Artificial Intelligence, and the Evolving Nature of Work** 127
Craig Webster and Stanislav Ivanov

9 **The Dark Side of Big Data: Personal Privacy, Data Security, and Price Discrimination** 145
Yang Liu and Connor Greene

10 **Digital Finance for Financial Inclusion and Inclusive Growth** 155
Md. Nur Alam Siddik and Sajal Kabiraj

11 **Understanding Consumer Behavior in Technology-Mediated Spaces** 169
İlayda İpek

12 **An Evaluation of the National Open Government Data (OGD) Portal of the United Arab Emirates** 191
Stuti Saxena

13 **Artificial Intelligence and Robotics Technology in the Hospitality Industry: Current Applications and Future Trends** 211
Li Yang, Tony L. Henthorne, and Babu George

14 **Risk Management in the Digital Era: The Case of Nigerian Banks** 229
Tankiso Moloi and Oluwamayowa Olalekan Iredele

15 **Digital Technology to Enhance Project Leadership Practice: The Case of Civil Construction** 247
John Ekechukwu and Thorsten Lammers

16 The Making of Data-Driven Sustainable Smart City Communities in Holiday Destinations 273
Sudipta Kiran Sarkar, Michalis Toanoglou, and Babu George

Index 297

Notes on Contributors

Ogechi Adeola is a fellow/senior lecturer in the Marketing/Operations Department of Lagos Business School Pan-Atlantic University, Nigeria.

Frederick Avornyo is a doctoral student in the Department of Marketing and Entrepreneurship, University of Ghana Business School, Ghana.

Richard Boateng is an associate professor in the Department of Operations and Management Information Systems at the University of Ghana Business School, Ghana.

Meenu Chopra is an academician and researcher by profession and spirit. She is pursuing a doctorate program as a full-time research scholar from the prestigious Delhi Technological University (DTU) (formerly Delhi College of Engineering) under the DTU Fellowship program. She has worked as an assistant professor in the Department of Management Studies, Deen Dayal Upadhyaya College, University of Delhi, teaching BBS/BMS students, which is the only undergraduate management program run by the University. Her areas of interest include knowledge management, human resource management, and advertising and branding.

John Ekechukwu is a civil engineer leading transport infrastructure design at Turnbull Engineering, Sydney, NSW, Australia. He has recently organized and facilitated the Turnbull Engineering Transport Infrastructure Design School of Excellence in partnership with the University of New South Wales. Engineering leadership and development through digital transformation is one of his primary areas of interest.

Olaniyi Evans is a lecturer in the School of Management and Social Sciences of Pan-Atlantic University, Lagos.

Brian J. Galli works as Assistant Professor of Management Engineering at Long Island University—Post (LIU Post). He also owns Apex Strategies, Ltd, a company that specializes in continuous improvement consulting and training initiatives. The author's major field of study is continuous improvement and project management integration. He has over 11 years of experience in applying industrial engineering and continuous improvement tools and concepts in a wide variety of arenas, including health care, manufacturing, transactional, and service environments.

Babu George is an associate professor in the Robbins College of Business and Entrepreneurship, Fort Hays State University, KS, USA. His research examines various dimensions of technology as it interacts with business and society. Of these, human behavior in technology-mediated spaces constitutes one of his key focus areas.

Connor Greene is an undergraduate student in the Finance and Economics Department of Southern New Hampshire University, NH, USA.

Tony L. Henthorne is a professor and Associate Dean of Graduate Programs at the University of Nevada, Las Vegas. Technological innovations in the service industry and its marketing implications constitute one of his research streams.

Robert Ebo Hinson is a professor in the Department of Marketing and Entrepreneurship, University of Ghana Business School, Ghana.

İlayda İpek is a research assistant at the Faculty of Business, Dokuz Eylül University, Turkey. Her research interests primarily concentrate on international marketing, brand management, and consumer behavior. Her articles have appeared in the *International Business Review*, *Journal of Consumer Behavior*, and *Journal of Retailing and Consumer Services.*

Oluwamayowa Olalekan Iredele holds a PhD in Accounting. He is a postdoctoral research fellow in the School of Accounting, University of Johannesburg. His interest is in environmental management accounting and reporting.

Stanislav Ivanov is a professor and Vice Rector (Research) at Varna University of Management, Bulgaria. Ivanov is the Founder and Editor-in-Chief of the *European Journal of Tourism Research* and serves in the editorial boards of more than 30 other journals. His research interests

include robonomics, robots in tourism/hospitality, revenue management, destination marketing, tourism and economic growth, political issues in tourism, and so on.

Sajal Kabiraj is a full professor at the International Business College, Dongbei University of Finance and Economics, Dalian, China. He has taught at postgraduate level in universities in Sweden, Austria, Malaysia, Canada, UAE, China and India. Information technology and digital inclusion is one of his primary areas of interest.

Maria Lai-Ling Lam is Professor of Business at Calvin College, Grand Rapids, MI, USA. She has been a senior consultant of AJ-Great Limited for several years. She has taught at two Christian universities in the United States for 14 years and several universities in Hong Kong and China for seven years She holds a PhD in marketing and organization behavior from the George Washington University, an MA degree in Religion Studies, and an MBA and a BBA from the Chinese University of Hong Kong. She has authored one book and 99 peer-reviewed articles and book chapters. Her areas of research interest are managing diversity and inclusion, yoga meditation, management education, leadership development, and corporate social responsibility.

Thorsten Lammers is a senior lecturer at the School of Information, Systems and Modelling, Faculty of Engineering and IT at the University of Technology Sydney, NSW, Australia. Informed by a previous career in strategy and technology management consulting, his main research interest lies in the impact of digital technologies on the future of work.

Yang Liu is an assistant professor in the Business Administration Department, Fitchburg State University, MA, USA. She holds a PhD in International Business, major in Marketing, from Southern New Hampshire University, NH, USA, and she also has a master's degree in Economics and Business from Sweden and a bachelor's degree in Accounting, major in Enterprise Financial Management, from China.

Mahmoud Abdulai Mahmoud is a senior lecturer in the Department of Marketing and Entrepreneurship, University of Ghana Business School, Ghana.

Tankiso Moloi is Professor of Accountancy at the School of Accounting, University of Johannesburg. He holds a PhD in Accounting and Finance as well as three master's degrees in Accounting, Financial Management, and International Relations. His interest is corporate governance, especially risk management.

Gabrielle Muniz is a freelance writer and editor. She recently graduated from Long Island University—Post (LIU Post), as she has lived in Long Island all her life. Gabrielle has extensive editing experience in the field of management engineering, with topics such as continuous improvement, project management, and change management. Aside from her freelance work, she has been writing many articles on topics that vary from dessert recipes to movie reviews for two online magazines: *Witty Serendipity* and *Her Track*. Overall, Gabrielle hopes to gain a fulfilling career in the writing industry.

Justin Paul is Professor of Marketing and International Business at Rollins College, FL, USA, and the Graduate School of Business, University of Puerto Rico. He is known as an author/co-author of text books such as *Business Environment* (4th ed) and *International Marketing, Export-Import Management* (2nd edition). Two books turned out to be best-sellers in Asia. He has served as a full-time faculty member with premier institutions such as the University of Washington, Nagoya University of Commerce & Business, Japan and Indian Institute of Management. Paul serves as a senior/guest/associate editor with the *International Business Review*, *Journal of Retailing & Consumer Services*, *Small Bus Economics*, *European Journal of International Management*, *Journal of Promotion Management*, and *International Journal of Emerging Markets*. In addition, he has taught full courses at Aarhus University, Denmark; Grenoble Eco le de Management, France; Universite De Versailles, France; ISM University, Lithuania; Warsaw School of Economics, Poland, and has conducted research paper development workshops in countries such as Austria, the United States, Croatia, and China. Paul has been a program director for training diplomats from different countries and served as a consultant to the Government of India. He has been an invited speaker at several institutions such as the University of Chicago, Fudan & UIBE-China, Barcelona, and Madrid, and has authored over 50 research papers and best-selling case studies with Ivey and Harvard. His articles have been downloaded over 300,000 times. He introduced the Conservative, Predictable and Pacemaker (CPP) model for internationalization and massage model/measure for brand management.

Anju Varghese Philip is a full-time doctoral student at the School of Management Studies, Cochin University of Science and Technology, India. Her research interests include human-computer interaction, specifically in the area of need satisfaction through technology use.

Sudipta Kiran Sarkar is an assistant professor at Sol International School, Woosong University, South Korea. The role of social media technologies in business is one of his major areas of research.

Stuti Saxena is a PhD student at the Central University of Haryana. Her research explores the use of information technology by governmental organizations.

Md. Nur Alam Siddik is an associate professor in the Department of Finance and Banking, Begum Rokeya University, Rangpur, Bangladesh. He holds a PhD degree in Finance from Dongbei University of Finance and Economics, Dalian, China. Digital finance and financial technologies is one of his primary areas of interest.

Asha Thomas is an assistant professor at Jagan Institute of Management Studies (JIMS), New Delhi, India. Her areas of research interest include knowledge management, organizational behavior, and marketing. She has about nine years of experience in teaching, as well as over three years of experience in the IT and telecom industry. She is pursuing a doctorate program as a part-time research scholar from the prestigious Delhi Technological University.

Michalis Toanoglou is the department chair and an assistant professor in International Department of Hospitality Management (SIHOM) of Sol International School (SIS) in Woosong University in South Korea. He has several years of experience as an executive in the hospitality industry in Greece.

Craig Webster is an associate professor in the Department of Management at Ball State University, Muncie, IN, USA. His research interests include the political economy of tourism, public opinion analysis, and event management. His most recent book is *Robots, Artificial Intelligence and Service Automation in Travel, Tourism, and Hospitality*, co-edited with Stanislav Ivanov. He teaches courses in hospitality management at Ball State University's Miller College of Business.

Kei-Wing Wong is a graduate student of Architecture, University of Michigan, Ann Arbor, MI, USA. She also has a Bachelor of Science degree from Calvin College, Grand Rapids, MI, USA. Her major was Environmental Science (Chemistry). Her minor was Architecture and Geography. She has worked for different sustainable cities projects. Her passion is to develop a universal and affordable design for people to flourish in hospitals and to cope with the threat of climate change.

Li Yang recently graduated from the master's program at W.H. Harrah College of Hotel Administration, University of Nevada, Las Vegas. His graduate thesis investigated how artificial intelligence might revolutionize the future of hospitality.

Zakkariya K. A. is Professor of Marketing and Human Resource Management at the School of Management Studies, Cochin University of Science and Technology, India, and is also the Director of DDU KAUSHAL Kendra, the Centre for Vocational Education in the university. With more than 20 years of teaching and research experience, he has been a member of various academic and administrative bodies of different universities in the country. He has more than 60 research publications in journals and books of national and international repute and is reviewer to many journals, including *Gender in Management* and *Journal of Management Development*.

CHAPTER 1

Introduction

Babu George

Introduction

Businesses are being transformed in fundamental ways as a result of the data revolution and societal drivers of change (Aral, Dellarocas, & Godes, 2013). The new era inaugurated by digital 2.0 technologies created a discontinuity and a fundamental shift in our ideas of business and society. Fundamental concepts that constituted the definitional parameters of business are undergoing a re-definition process. Technological revolutions brought to us increase in processing power, bandwidth, user-friendly interfaces with technology, the 'internet of things', to list a few benefits. Also, we live in a society that loves to consume radical change. These drivers together have transformed our situated existence in the human society (Uhl & Gollenia, 2016). For businesses, these changes mean the blurring of industry boundaries, modular business architectures, distributed innovation micro-structures, 'just-in-time' definitions of business performance, among others.

Most major businesses in our times are in the business of transforming themselves by the power of data and the technological assets that make it possible for them to use the data in the best possible ways (Matt, Hess, & Benlian, 2015). Systematic improvement in business performance is

achieved by means of re-engineering every aspect of the firm, including its external relationships, with technologies that promise scope and scale enhancements and also flexibility to create new business models (Davidson, 1993). There is a widespread realization that the path to competitive advantage is through data (McAfee, Brynjolfsson, Davenport, Patil, & Barton, 2012). In this backdrop, this volume brings together different perspectives from experts on how the data revolution has shaped different regions, industries, and domains. The authors in this volume have identified and distinguished the driving forces that make radical shifts in our society and businesses possible.

The Digital Transformation of Businesses and Societies

Knowledge has gained predominantly as a factor in contemporary consumption (Antons, Joshi, & Salge, 2018). Consumers are eager to be part of the knowledge sharing process—they co-create what they consume. In many situations, the boundaries between the buyers and the sellers are now permeant, observe Ranjan and Read (2016). Also, since most of the purchases are made online, it is vital to provide these consumers sensory experiences as close to what they would get while visiting brick and mortar shops. There is huge scope for innovation in this area and digital technologies fueled by the power of big data could provide the main lever for the same (Caputo, Evangelista, Perko, & Russo, 2017).

On the one hand, we have some evidence to support the claim that the digital revolution has helped us improve not just our business enterprises but our overall standard of living as a community of people, around the world. On the other hand, constant disruptions in the technology sphere need individuals and societies to pace up relentlessly. The digital divide is stark in certain regions of the world and also in certain demographic groups. Governments and the civil society have to come up with ways and means to bring the digital have-nots up to speed. This could be achieved by means of a combination of education, training, and other incentives. The private sector's role in this regard should be examined more, too.

Digital revolution has impacted and transformed almost every realm of human affairs (Makridakis, 2017). So, almost every current topic on business and society will have a certain aspect of it. When we look at issues with a thin focus, it is natural to see certain things as outliers. However, technology myopia encountered by their leaders has caused many

businesses their very survival and we need to be mindful about unduly limiting the scope of the digital revolution (Vega-Jurado, Juliao-Esparragoza, Paternina-Arboleda, & Velez, 2015). It is impossible to make sense of our contemporary life without referencing it with technologies that laced the fabric of it (Brooke, 2016).

Will people work in the future? No, especially if we continue to define work the way we do it now (Cook, 2017). Are we ready for the new kind of work? What characteristics will define human workers and how will these be able to give them a competitive advantage over the robots? Will artificial intelligence evolve to the extent of making humans entirely replaceable in the workplace? These are but a sample from the cross section of the questions that futurists pose (Aronowitz, 1994; Collin & Young, 2000; Stiegler, 2018). These questions cannot be avoided when we discuss business implications of the fourth industrial revolution.

That said, for practical reasons, this volume needed to be delimited to certain key dimensions of it. The diagram given below is an attempt to distill the characteristic themes that the chapters contained in this volume represent. This is by no means an exhaustive or mutually exclusive list of themes. Several chapters cut across the theme boundaries—which, again, is a characteristic feature of the seamlessly networked lives of the digital natives that we are.

The key themes included in this volume are represented in Fig. 1.1.

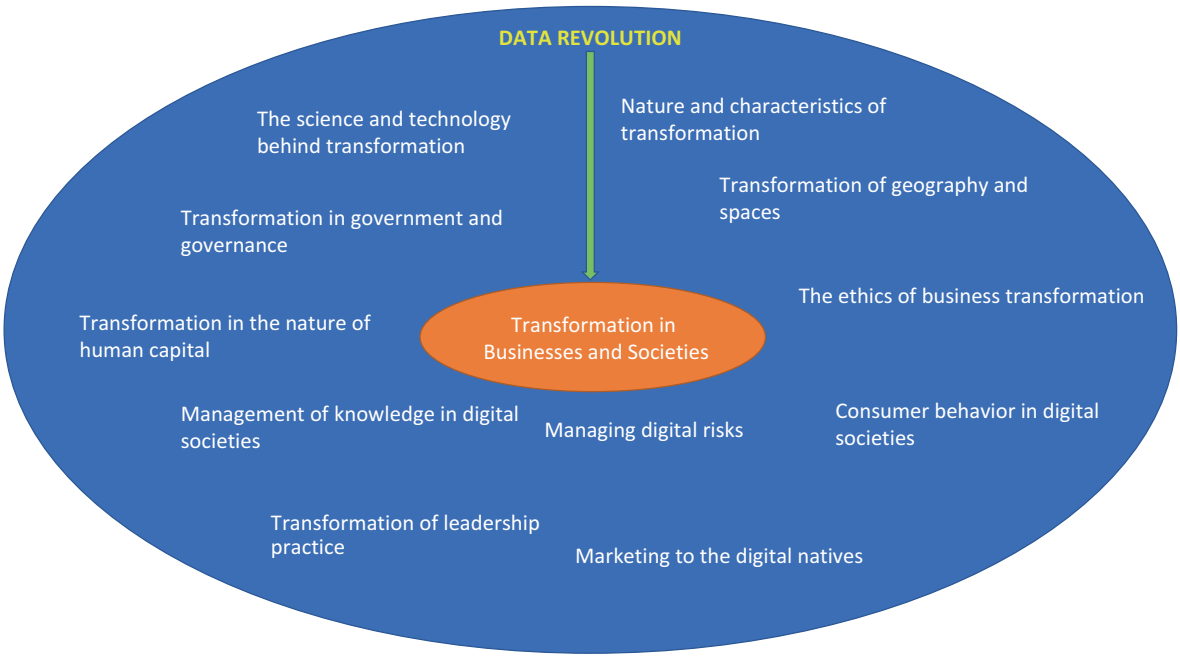

Fig. 1.1 Key themes included in this volume

A Brief Overview of the Chapters

Human ecological systems will not be the way we are currently familiar with them, as a result of our ability to manipulate big data (Graham & Shelton, 2013; Hampton et al., 2013). Ecology will not remain an esoteric pursuit, too. In the chapter titled 'Human Flourishing in Smart Cities', Maria Lai-Ling Lam calls for the importance of the development of enlightened citizens, rather than consumers, as the guardians of the smart cities managed by data-driven systems. As observed by Blagojević and Tufegdžić (2016), while technologies are disrupters, they also help preserve and refresh heritage of our geographical areas. 'The Making of Data Driven Sustainable Smart City Communities in Holiday Destinations' by Sudipta Kiran Sarkar, Michalis Toanoglu, and Babu George explains how data-centered technologies create smart and sustainable destinations for travelers. These chapters recognize the need for understanding digital technologies and data-driven systems as foundations of sustainable urban spaces.

Management of knowledge has gained a new meaning, as a result of our increased abilities to see insights in big data (Ding, Wang, & Wu, 2013). The industrial revolution 4.0 has brought in its associated phase of knowledge management 4.0 (Neumann, 2018). Asha Thomas and Meenu Chopra in their chapter 'On How Big Data Revolutionizes Knowledge Management' elaborate on this. To be able to see patterns as an emergent phenomenon needed newer heuristics and ways of thinking (Lv, Song, Basanta-Val, Steed, & Jo, 2017).

Social media is the frontline poster boy of digital transformation as the layman knows it. Social media strategy, more than social media technologies, drives the digital transformation directions of a vast majority of our organizations, observe Kane, Palmer, Phillips, Kiron, and Buckley (2015). While planning to revamp businesses through digital transformation, social media strategy cannot be let to the periphery (Westerman & Bonnet, 2015). Social media has become a central means by which to engage with the digital natives accustomed to this, and the decentralized nature of the social media makes engagement a complex enterprise (Stiver, Barroca, Minocha, Richards, & Roberts, 2015). The chapter 'Social Media Technologies and Export Marketing' by Frederick Avornyo et al. highlights aspects of it, in the particular context of changes in the age-old practice of exporting. Ogechi Adeola, Robert Ebo Hinson, and Olaniyi Evans, in their chapter 'Social Media in Marketing Communications: A

Synthesis of Successful Strategies for the Digital Generation', take a broader view and offer a synthesis of strategies for the digital generation.

Analytics is the backbone of what could be called a learning society (Larson & Chang, 2016). There is no exaggeration if someone calls it the religion of the digital society. In the chapter 'Data Analytics and Predictive Analytics: How Technology Fits in the Equation', Brian J. Galli and Gabrielle Muniz explain data analytics and predictive analytics through their various applications and examples of their benefits. Several insightful examples are provided to bring home the views. In a sector-focused chapter titled 'Artificial Intelligence and Robotics Technology in the Hospitality industry: Current Applications and Future Trends', Li Yang, Tony L. Henthorne, and Babu George explain the transformation of the hospitality industry, thanks in particular to advancements in robotics. All these chapters have a heavy emphasis upon the science and technology backbones of the data revolution that transformed businesses and societies.

Project management as an area of practice has changed dramatically, thanks to the power of information and communication technologies (Hoegl & Muethel, 2016). Strategy is traditionally distinguished from tactics and operations, in terms of time span and decisional level in the organizational hierarchy (Cascio & Montealegre, 2016). In the flat and fluid organizations in the networked economy, these distinctions have blurred away (Kahler, 2015). 'Digital Technology to Enhance Project Leadership Practice: The Case of Civil Construction' by John Ekechukwu and Thorsten Lammers portray how technologies increase the efficiency and effectiveness of project management, in the specific case of construction practices.

Organizations can now run on autopilot, except when major game changes are required (Goldspink & Kay, 2003). This also changes the role of people in organizations (Wirtz et al., 2018). To be a digital native is a radically new conception of life (Akçayır, Dündar, & Akçayır, 2016). In 'Effective Engagement of Digital Natives in the Ever-Transforming Digital World', Anju Varghese Philip and Zakkariya K. A. attempt to throw some light on how to manage digital natives both as internal as well as external stakeholders of the businesses. In the chapter titled 'Robotics, Artificial Intelligence, and the Evolving Nature of Work', Craig Webster and Stanislav Ivanov argue that humans will have to see their relationship to the job market differently and there will have to be an appropriate political response to the new economic landscape with changes in taxation and new ways of ensuring economic and political stability.

Big data does offer the promise of data-driven decision-making and change management. It has helped us identify subtle trends and relationships among key variables (Kshetri, 2009). Yet, the panacea has attracted so much unwanted attention from unscrupulous elements, too (Zhang, Xiao, Ghaboosi, Zhang, & Deng, 2012). Yang Liu, in the chapter titled 'The Dark Side of Big Data: Personal Privacy, Data Security, and Price Discrimination', shares some of these concerns. Dealing with cybercriminals needs new tactics and tools—many law enforcement departments are at the trailing edge of the curve in this regard. Given this, community policing has found a new reason for existence. Nonprofits and private sector corporations have taken the lead over government agencies in cyber defense—which, many consider to be problematic. On a related topic, 'Risk Management in the Digital Era: The Case of Nigerian Banks' by Tankiso Moloi and Oluwamayowa Olalekan Iredele examines an associated issue—the management of risks in the banking industry, using digital technologies.

Harford (2014) wonders if big data is a big mistake. Say, are we safe from computer hackers, and is the government doing enough to prepare? While the answer is not simple, this is a question worth asking, as also observed by Cuzzocrea (2014). Despite the risks, the inclusive process of knowledge creation and free flow of knowledge together could make our organizations significantly more responsive to stakeholder expectations and environmental cues (Boyd & Crawford, 2012). In 'Digital Finance for Financial inclusion and Inclusive Growth', Md. Nur Alam Siddik and Sajal Kabiraj elaborate on how technologies are levelers that could expand the inclusiveness of the financial sector.

Once upon a time, digital governance meant merely building websites for government agencies and using emails for communications (Pardo, 2000). West (2005) indicates that digital technologies have improved the efficiency and effectiveness of governments worldwide. Open data promises to open new vistas, expand our horizons, and stimulate innovation as never before. E-governance has replaced many traditional structures in governance, brought in transparency and interoperability (Gottschalk, 2009). It has made decision-making quicker and qualitatively better. 'An Evaluation of the National Open Government Data (OGD) Portal of the United Arab Emirates' by Stuti Saxena is an attempt to portray the success of one such initiative.

Current level of development of digital technologies offer new possibilities of thinking and doing. A particular issue that we need to overcome is the fact that, even as our societies have become data rich, they are still

connection poor. 'Understanding Consumer Behavior in Technology Mediated Spaces' by İlayda İpek details the relations between consumers and sellers have transformed by means of various technologies that permit co-creation experiences.

Conclusion

Human beings were always social animals, but our wealth and its transfer could not have been embedded into the social relations until very recently. Digital currencies like bitcoins decentralized wealth from the clutches of the central banks and the nation states (Tapscott & Tapscott, 2016). Barter system is making a new homecoming, albeit with digital coins. The digital technologies have made innovations happen in unexpected corners of the world (Iansiti & Lakhani, 2017). Also, innovations have become more democratic and decentralized thanks to the 'networked brains' behind many of these innovations. The dissemination of innovations now happens at pace hither to unimaginable—actually, many new products launches now happen in the peripheral corners of the world, even before people in the developed countries get to buy them.

The increased choices online imply reduced loyalty (Connor, 2018). Cut throat competition also means reduced product lifecycles (De Bettignies & Duchêne, 2015). The existence of abundant online spaces for consumer activism means increased need for investing in customer relationship activities. Corporations increasingly employ big data analysis to gain key insights about consumers and markets. It is interesting to observe the challenges and solutions in digital marketing, as they evolve in increasingly digitized societies. In fact, most contemporary discussions on digital transformations directly or indirectly refer to digital marketing in general and social media marketing in particular. There is no better combined reflection of the impact of technological revolutions upon business and societies than social media and no wonder several chapters in this volume mentions social media in some way or other.

Digital technology integration into more traditional products means there is potential for disruption there, too (Yaqoob et al., 2016). Overall, digital technologies are enablers of disruption in every aspect of life. For instance, the idea of leadership is not anymore tied to hierarchy and structure. Knowledge leaders are a new breed. Isolated people sitting in different corners of the world but working together virtually as a team was unimaginable until recently. Geography is no longer a barrier. So also, is

the traditional hierarchy built around mechanical principles: seamless cooperation and collaboration across organizations mean greater chances to synergize organizational resources.

With people spending significant portions of their lives online, criminals too migrated to the cyberspace (Saini, Rao, & Panda, 2012). Digital crimes do not end in financial fraud and malpractices. People's physical safety and security could seriously be compromised, too. Intrusions into the privacy of individuals have similar dimensions. Our increasing reliance upon big data results in the sidetracking of morals and meaning from the equations. Also, big data cannot effectively identify the micro-level nuances impacting grassroot levels—be it in organizations or in the civil society. The massive surge of data analytics as a profession is fueled by our need to tie everything to measurable data. If data science does not grow up enough to reveal the 'truth beyond data', many futurists believe we will be faced with stale robotic existence.

It is our collective amnesia that makes us think technological revolutions did not have a history. It is to be noted that mankind has used technologies ever since the dawn of civilizations. Most often, technologies have helped us advance—or, advances in technologies reflect our quest for leading better lives. However, there are also waypoints in our technological development wherein we made mistakes. Certain technologies not just failed, but also failed us. It is important to learn from these mistakes, as we design our future societies around a new set of technologies.

CHAPTER 2

Human Flourishing in Smart Cities

Maria Lai-Ling Lam and Kei-Wing Wong

Introduction

What cities *Homo sapiens* will choose to live will reflect the expectations of what our good life will be. The European Parliament (2014, p. 9) defined a smart city as "a city seeking to address public issues via ICT-based solutions on the basis of a multi-stakeholder, municipally based partnership." Smart cities, with all information and communication technologies (ICT), are assumed qualities to make us live well. Hollands (2015, p. 62) criticized that smart cities hid many issues, as information technology was assumed to "automatically make cities more economically prosperous and equal, more efficiently governed and less environmentally wasteful." Are we truthfully living happier in smart cities? Are we becoming a part of a predictable, efficient, and controllable system? Will we be disempowered and even lose our humanity in the highly rationalized system? What norms and values about a good life have been presented in the smart-city litera-

ture? How should we deconstruct these norms? Are there other alternatives for us to live happier in smart cities?

During the period between 2010 and 2017, we reviewed the literature, visited more than 40 international cities in Asia, Europe, and North America, interviewed their citizens about their respective cities, and explored the thinking of how we should lead our students in colleges to have critical engagement with the pervasive and affordable digital technology in their respective cities. We chose two leading smart cities in Asia to illustrate how economic prosperity and global competitiveness are used to frame their well-being. Singapore and Songdo in Republic of Korea were chosen, as their respective national governments were highly ranked in the area of provision of online services, telecommunication connectivity, and human capacity by the United Nations' 2016 E-government survey (United Nations, n.d.). Singapore and Republic of Korea both were named as Asian Dragons in the 1980s and aggressively adopted information technology to sustain its economic growth in the twenty-first century. They also compete with each other for global investments and are often ranked very closely in terms of smart cities development. Their governments have invested heavily in the development of smart city as their national industrial strategy (Central Policy Unit, 2015; Kim, Jung, & Choi, 2016; Team Finland Future Watch Report, 2017). They both inspire what future cities in China will be and what needs to be done for human flourishing in our higher education.

This chapter proceeds with five sections. Section "Socially Constructed Norms and Values of Smart Cities" describes the socially constructed norms and values of smart cities. Section "A Tale of Two Cities: Singapore and Songdo" describes Singapore and Songdo. Section "Critique of Smart Cities and Human Flourishing" includes the critiques of smart cities and human flourishing. Section "A Paradigm for Human Flourishing in Smart Cities" proposes a new paradigm of the development of smart cities that enhances human well-being. Section "Implications to Public Policy and Higher Education" discusses the necessary changes in our public policy and our higher education.

Socially Constructed Norms and Values of Smart Cities

The smart city has become popular when cities are aggressively marketed to create economic prosperity, global competitiveness, environmental sustainability by major ICT (information and communications technology)

firms, engineering, property development, and construction companies (Hollands, 2015). The well-being of human lives will be improved in the densely connected, highly rational, and largely real-data analytic and programmable decision-making process in the smart cities (IBM, n.d.; Cicso, n.d.). White (2016) critically reviewed the marketing materials of smart cities provided by these global large ICT corporations, including Cisco and IBM, and learned that the technological intervention in the development of a smart city is legitimated by these three recurring crises: resource pressures brought on by rapid urbanization and an aging population, global climate change, and fiscal austerity and interurban competition for foreign direct investment and highly skilled workers. The need for the development of smart cities has been reframed as essential when the fear of quick urbanization, climate change, aging, meager public resources, and keen intercities competition are legitimated as the truth. Many issues related to data protection acts, inclusivity, costs, benefits re-distribution, and civil participation are not addressed in the rhetoric of technology-driven smart cities. The following section will explain how the development of smart cities has been legitimated and become part of our criteria for having a good life.

Characteristics of Smart Cities

The concept of smart cities is still quite vague. Smart cities are also named as intelligent, rational, green, sensor, wired, creative, sentient, digitized, or ubiquitous (u) cities…etc. The smart cities are equipped with all advanced technological devices such as the internet of things and multiple sensors and have become a promising discipline, industry, and academic discipline (Vanolo, 2014). Caragliu, Del Bo, and Nijkamp (2009, pp. 47–49) reviewed the literature about smart cities and summarized the characteristics of a smart city that is common to many research findings:

1. The utilization of networked infrastructure to improve economic and political efficiency and enable social, cultural, and urban development.
2. An underlying emphasis on business-led urban development.
3. A strong focus on the aim to achieve the social inclusion of various urban residents in public service.
4. A stress on the crucial role of high-tech and creative industries in long-run urban growth.

5. Profound attention to the role of social and relational capital in urban development.
6. Social and environmental sustainability as a major strategic component of smart cities.

Thus, a smart city relies on the use of the internet of things to improve economy and political efficiency. It mainly relies on business-led urban development through high-technology and creative industries. It provides many new business opportunities that lead to urban development. These opportunities are like Airbnb and Uber. It also emphasizes social inclusion, and social and environmental sustainability in the urban development. It provides technology-enabled participatory platforms such as New York City Big Apps. The smart-city proponents advocate the effective implementation and integration of smart technologies in a smart city will "improve quality of life, boost economic growth, mitigate the negative effects of climate change, and even foster more active citizenship" (Gaffney & Robertson, 2018, p. 49). People will flourish when there are synergies between economic growth and environmental protection in the smart cities.

Frost and Sullivan (2013), a global research and consulting company, estimated the size of smart-city market would be US 1.565 trillion by 2020. It defined a smart city consisting at least five of the following eight elements: "smart energy," "smart buildings," "smart mobility," "smart healthcare," "smart governance," "smart education," "smart security," and "smart citizens" (p. 2). Citizens are assumed to be better when they are smart enough to adopt various smart concepts or products in their daily lives. The smart-city industry can drive the development of other industries such as ICT, construction, communication, transportation, banking, insurance, health care, and education industry. Thus, smart city can be used as an instrument to improve national competiveness, which enhances community and quality of life. Kim et al. (2016) verified the positive impact of the smart-city industry on the national economy of Korea in terms of higher production, value-added, and employment induction effects. They learned that the key to the success of the smart-city industry was to acquire the competitive edge of the ICT and construction industries. The national wealth would be assumed to spill over into many people in different locations in the activated knowledge networks. They concluded that their study and numerous empirical studies have showed that "the various ICT applications in smart cities ultimately led to the build-up of intellectual capital or the creation of wealth by means of

the interconnection of human and social capital via activated knowledge networks" (p. 16).

Chourabi et al. (2012) reviewed six working definitions of a smart city and concluded that a smart city is like a large organic system connecting many subsystems and components to collect, connect, and analyze real-live data in different urban domains for a better city. They proposed eight critical factors for the success of government-driven smart-city initiatives: management and organization, technology, governance, policy context, people and communities, economy, built infrastructure, and natural environment. Sadly, the current practices of smart cities in many countries are used to prioritize technology more than other factors.

Indeed, there is no clear shared definition or global consensus about the concept of smart cities. The concept of smart city can be easily manipulated as a government software-driven urban managerial tool and an opportunistic public policy (Cowley, Joss, & Dayot, 2017). There is no such research about people and communities in smart cities. Gaffney and Robertson (2018, p. 49) condemned the vague definitions and outcomes of smart cites as follows:

> This lack of clarity and consensus in the academic literature opens space for city government and ICT companies to apply the term 'smart city' flexibly according to their needs and desires. Furthermore, the stated aims of smart cities—such as sustainability, livability, intelligence—are often abstract goals that are difficult to measure and define in themselves. The abstract aims allow cities to declare smartness without great accountability.

Neirotti, De Marco, Cagliano, Mangano, and Scorrano (2014) analyzed 70 international cities' smart initiatives and learned that the main focus was in the area of transportation and mobility, natural resources, and energy. "Government is the domain in which the cities included in the sample report the lowest number of initiatives" (p. 18). Asian cities have exhibited a lower coverage in the smart initiatives related to human capital and government practices than European cities. They concluded, "cities that are more active in the domains that are aimed at improving their capacity to 'sense and act' through ICT systems are less likely to differentiate the initiatives launched for soft domains related to human capital, cultural heritage, and innovation" (p. 24). Without much investment in the human capital and government in the civil society, will the wealth creation in the industries in Asian smart cities be more concentrated than in European smart cities?

Logical Reasons for the Rise of Smart Cities

The rise of smart cities is framed as an effective strategy to solve many problems in the urban cities given the demand of new urbanism and the supply of inexpensive interconnected of things. The business-led technological innovations proposed by the smart city seemed to be a response to the failure in the city development in the 1980s in the United States: suburban sprawling, car-oriented cities, serving elites all at the expense of the public. The rise of the smart city is related to the concept of smart growth and new urbanism which originated in the United States in the 1980s and later transferred to Europe. Vanolo (2014, p. 887) stated, "New urbanism in planning was aimed at improving the urban environment and the quality of life in cities by promoting communitarian ideas and limiting urban sprawl, land consumption, and proliferation of forms of development inspired by the logic of the automobile and personal mobility." Later, a group of researchers in Vienna ranked 70 medium-sized smart cities by six criteria: smart economy, smart mobility, smart governance, smart environment, smart living, and smart people. The ranking of cities in the European smart cities' reports determine the competiveness of a country. There are many voices about smart cities such as World Bank Smart Cities Knowledge Silo Breaker (KSB) and European Union Smart Cities Assessment. The objective behind the development of smart cities in Europe is to compete effectively with rival global economics as China and India aggressively develop smart cities (European Parliament, 2014). Smart city is becoming a tool to sustain its own country's economic growth and results in higher human capital and quality of life.

The supply of inexpensive processing devices, wireless coverage, rich analytic data, easy apps, and visualized output enable policy makers to estimate the risk level of each location and efficiently allocate resources. Many data in the cities are collected and translated to relevant information in a format of simple diagrams. The large information and communication companies are pursuing smart cities as their core strategies. For example, Siemens has "sustainable cities" logo, and IBM has "smarter planets and smarter cities" logo. They are assumed to provide many technocratic solutions to solve our pressing urbanization problems and even deal with natural disasters such as earthquakes. More and more professional conferences and initiatives are disseminated to use smart cities as our panacea. The rhetoric of smart cities is changing the criteria of measuring a city. A successful city needs to fulfill the criteria of being smart. Thus, smart cities

may help many governments to achieve their social, environmental, and economic targets at lower cost. This is the testimony from the assessment of smart city in the European Union (European Parliament, 2014, p. 19):

> In view of the challenges associated with growing European urbanization, as well as the wider agenda to tackle economic recovery poverty, unemployment and environmental damage, *the Europe 2020 strategy incorporates a commitment to promote the development of Smart Cities throughout Europe and to invest in the necessary ICT infrastructure and human and social capital development*. Smart Cities may play a part in helping to meet the targets set out in Europe 2020 by adopting scalable solutions that take advantage of ICT technology to increase effectiveness, reduce costs and improve quality of life.

The Europe 2020 strategy believes that the incorporation of advanced ICT technologies in smart cities will improve global competitiveness, sustainability, diversification of functions (or authority), and quality of life because European cities will also use ICT to enhance human and social capital in the universities, industries, government, and civil societies. One Polish scholar told the author that the term "smart city" was mainly used by her government to access funding from the European Union and be aligned with the Europe 2020 strategy. Smart city can be easily politically manipulated for particular design and management of cities (Vanolo, 2014).

Why Do Smart Cities Matter?

By 2030, 60% of world's population will live in urban areas and 95% of urban expansion will take place in the developing world. Fresh water supplies, sewage, public health, and the living environment will be seriously affected by the rapid urbanization. China and India will build more and more smart cities to deal with increasing urbanization problems (Central Policy Unit, 2015). According to IHS Markit (2014) research, the number of smart cities will rise from 13 to 88 within 12 years. Some notable global large information and communication corporations aggressively pursue the concept of the "smart city." IBM has "smarter planet" and "smarter cities." CISCO has "the internet of everything for cities." These big corporations always promise to have an open, distributed, collaborative, and accessible global neural system. They are assuming leadership roles in the collaboration process among government, corporations, and

civil society. They continue to play prominent roles into urban governance structure around the world. They advocate that the densely connected, highly rational, and largely real-data analytic and programmable decision-making process in the smart cities improve the well-being of their clientele.

The development of an inclusive, safe, resilient, and sustainable city is one of the 17 United Nation's sustainable development goals (United Nation, 2017). With the usage of technological innovations and the high density of cities, smart cities may be a good alternative to achieve the United Nation's sustainable development goals. The local government can collect sundry real-time data and monitor the urban system in a more centralized, holistic, and automated manner. Engineers, scientists, designers, and city planners can use the digital technology to model the realities and visualize better structures that use less energy and are more resilient to disaster. These abstract visual models can be manipulated and socially communicated to the public for the development of an inclusive, safe, resilient, and sustainable city.

The smart cities can provide the technology-enabled participatory platforms such as New York City Big Apps and Urban Mechanics initiated in Boston. These platforms are used by local governments to keep citizens informed, solicit input from citizens about improving the city, and collaborate with the citizens. Thus, smart cities can redefine how the local government connects with citizens, fosters thoughtful collaboration, and improves the internal function and quality of public service delivery. Desouza and Bhagwatwar (2014) examined the role of government and citizens in the 25 most populated US cities' technology-enabled participatory platforms and learned that there were four archetypes: citizen-centric and citizen data, citizen-centric and government data, government-centric and citizen data, and government-centric and citizen-developed solutions. They expect that there will be more citizen-initiated technology-enabled platforms that shape, implement, and evaluate public policy and the governance mechanism in smart cities.

A Tale of Two Cities: Singapore and Songdo

Over the last decade, there are favorable conditions for the investment in smart cities in Singapore and the Republic of Korea: "a centralized governance favoring shorter decision-making processes for public investments and more rapid development time for their executive, a higher economic development rate, a low political risk, and unique weather conditions that

determine particular needs, with special regard to transportation systems" (Neirotti et al., 2014, p. 15). Singapore and Korea central governments are key drives for the development of smart cities as a global competitive industry (Central Policy Unit, 2015; Kim et al., 2016; Team Finland Future Watch Report, 2017). Will these two smart cities, Singapore and Songdo in Republic of Korea, allow people to flourish in all-efficient designs? Will these two cities treat citizens' involvement as necessary benefits or barriers? Are citizens engaged in the process of designing their own cities and making changes for better future?

Singapore

Singapore is a city state and has committed to develop its country and city around the internet. It has Singapore's iN2015 and wants to become an intelligent country (Arun & Yap, 2000). It is claimed to be the smartest city on the earth according to a 2016 UK research (Juniper Research, 2016) and has a high financial well-being but a low score in well-being according to the Gallup Study (2015). Singapore's smartness is mainly driven by its long-term development in an information technology policy (Central Policy Unit, 2015). During 1981–1985, the Singapore government funded information technology initiatives to computerize government ministries, improve public service, and produce a group of computer experts. During 1985–1990, the government developed a strong export-oriented information technology industry through its National Technology Plan. During 1991 to the present, the city/state has to be transformed as information technology permeates into every part of life. Hollands (2008) concludes that the basic objective of the development of smart Singapore is to enhance national competitiveness and the quality of life of citizens. Its success is through progressively institutionalizing information technology in the government, business sector, and civil society. When one author visited Singapore in 2011, one university professor told her, "We had to work harder and harder as our economy grew faster in the past 10 years." One smart-city engineer told the author in a smart-city conference in August, 2016 in Hong Kong, "In terms of smart city practice, European cities are doing much better than Singapore as there are more privacy protections and community involvements in Europe." One Singaporean also lamented, "We have many intelligent devices in the city. We have to pay a higher tax." Singaporeans experience much less chance to be consulted about smart-city strategy or develop citizen initiatives than Europeans do

(Council of the European Union, 2010). One expert who has developed smart cities in Europe and Singapore told the author that Singapore has just moved from its baby-stage smart-city development since it enacted the Personal Data Protection Act 2012. A group of Finland experts stated the main hurdle in Singapore's smart-city development was the lack of citizens' participation. They said, "Singapore's smart city endeavors are nearly entirely state-directed, and the lack of consultation with citizenry and other constituents could result in applications falling short of needs" (Team Finland Future Watch Report, 2017, p. 6).

Songdo, Republic of Korea

Songdo in the Republic of Korea is always claimed as an exemplar of smart cities. It is named as "the city of the future," "the world's smartest city," or "Korea's high-tech utopia" (Overview of Eco Cities, n.d.). This city is a symbol of synergy between economic growth and environmental protection. It is driven by the central government's ubiquitous city policy and system. It represents a new paradigm shift as it has been moved from the use of conventional infrastructure to an intelligent one (Shwayri, 2013). It is framed as a city that consists of the best of different cities in the world. There are combinations of commercial buildings, residential areas, parks, streams, animals, humans, and interconnected technologies. It is "smart. It is the model for next generation cities" (Songdo IBD website, n.d.). It was built from the reclaimed wetland from the Yellow Sea and was near the Incheon international airport starting in 1994 after numerous political fights between the Central government and the local Incheon City government during 1991 and 1994. During the financial crisis in 1997, the central government had set appropriate legislations to attract global companies and related foreign business using high-end technologies and to create a world-class city in Songdo. The local and municipal governments had to secure foreign investments and expand exports. The Incheon City had to choose to partner with the private sector for the development of buildings in Songdo. "In 2001, the local government had to turn to POSCO Engineering and Construction, a South Korea chaeobol, granting it the development rights with specific instructions to partner with an American developer to plan and build Sondgo International Business District (IBD), an area covering six square kilometers from the 53 square kilometers reclaimed from the Yellow Sea to build Songdo city" (Shwayri, 2013). New Songdo International City, Inc. was formed by New York

City-based Gale International (61%), POSCO E&C (30%), and Morgan Stanley Real Estate (9%). New Cities (2014) quoted the speech of the CEO of Gale International, Mr. Stanley Gale, from metropolis now: "We want to crack the code of urbanism, then replicate it. We want to build at least twenty Songdo ourselves: G20-Gale 20." Mr. Gale showed his ambitious dreams of producing 20 Songdo smart cities in the future. CISCO, a key information technology company, was chosen to connect and optimizes everything. The city was expected to be completed by 2013.

However, when the author and her research assistant visited the city and interviewed the marketing manager of New Songdo International City, Inc. in May, 2016, we were surprised there were many empty buildings and few residents in the park. The city had to be finished by 2020. The Gale International did not succeed to attract enough foreign investors in the district. The Korean government had to change the targets and to provide more infrastructure to attract residents to relocate in the city. People have to move in after the buildings are built. One developer of an information technology engineering company told us the company was blamed when it really installed smart devices because the city just wanted to look environmentally friendly to attract foreign investment. Many smart garbage collection bins were demolished because there were not enough maintenance and residents. The Songdo city is too big to fail. The government must use taxpayer money to finance this project and continue maintaining the area. During 2003 to 2013, the investment in the city was more than US$ 100 billion, while the budget amount was US$ 35 billion. The city is framed as a smart city with all computerized accessible buildings and electrical sensors such that the city can be responsive to the needs of residents. However, it was centralized developed and mainly constructed for the attraction of multinational investments (Townsend, 2013).

As more multinational investments are in China, Songdo city is now used to attract Chinese investors to reside in this city. The development of Songdo still needs daily huge investments, while South Korea would like to keep Songdo as an exemplar of a smart city. The cost of the removal of huge habitat land for birds and the resettlement of many fishermen near Yellow Sea have not been addressed in the Songdo's development report. The city was originally designed to enable foreigners or tiny proportion of local employees working for foreign corporations to enjoy a quality of life that was like the expatriates' Western cities. In summary, the key criteria to measure the success of this smart city is to attract foreign investments and increase its international competiveness. The quality of life is mainly

measured in terms of economic success created by the development of smart cities. Kim et al. (2016) reviewed the negative critiques of Songdo and specified that Songdo is "criticized as being motivated by real estate initiatives, in which the 'smart' city label is reduced to the mere adoption of ICT features for the apartments" (para. 1 under section 2.3). Many civil voices about the establishment of the city were suppressed. The top-down approach only "promotes private business interests while ignoring social needs" (Shwayri, 2013, p. 43). This is the comment done by Sennett (2012, para 7):

> Songdo represents the stupefying smart city in its architectural aspect—massive, clean, efficient housing blocks rising up in the shadow of South Korea's western mountains, like an inflated 1960s British housing estate—but now heat, security, parking and deliveries are all controlled by a central Songdo 'brain'. The massive units of housing are not conceived as structures with any individuality in themselves, nor is the ensemble of these faceless buildings meant to create a sense of place.

Lessons Learnt from Singapore and Sondgo

Singapore and Sondgo both are driven by the centralized government policies for national competitiveness and economic interests. Sondgo in the Republic of Korea is established from scratch and is an assemblage of pre-existing urban imaginaries (Vanolo, 2014). The image of Songdo cannot relate to its history and culture. It is placeless. It can be reproduced and was implemented without paying attention to the social and political inequality in different context. The seamlessly connected world in Singapore and Songdo's virtual images ignores how the existing social and political structure limits many people's human capacities to make choices and to live well. It seems that the smart-city model can be reproduced and solve cities' problems without knowing the causes of those problems. The development of smart city continues a McDonaldization effect and just wants to have more people to be in the city. Citizens can work as sensors to help their government to identify potholes or other problems by using their smartphones. Citizens are treated as consumers and entrepreneurs in these smart cities. When cities are created to be responsible for being smart according to a defined criterion in relation to technological development, environmental protection, and economic attractiveness, the public policy makers can be easily tempted not to invest their resources in helping

their citizens to increase their capacities to enjoy the benefits of smart cities. Sometimes citizens might be treated as commodities to fulfil the political agenda. Citizens have to become smart people in order to help their cities to have higher ranking and assessment of the smartness for a better global competitive score.

Critique of Smart Cities and Human Flourishing

Many smart cities are controlled by corporations, and there is no distinction between public and private space when data is collected everywhere (Boyer, 2015). The public space is coded and the privatization of public space is disturbing. Individual's right of privacy is violated when data protection act is not enacted. Cities are assumed to be efficiently managed through the centralized operating system, data analytics, big data, and urban informatics. The complexity of a city can be abstract and distanced as simple informatics. The urban development was skewed toward the positive side of technology and attracted global capital for making industrial cities. Many alternatives of promising urban development are ignored (Caragliu et al., 2009; Hollands, 2008). The management of urban development is saturated with technological devices instead of the development of social and human capital. The city of the future has been sold to the corporations without much public officers' accountability to their people. Once corporations finish their projects, they often leave these to ill-prepared local government to run and maintain with all advanced technologies.

Many citizens are vulnerable to cyberattack and ransoms without much government protection. It is difficult to attribute the cause of the problem when many sensors are interconnected and there are time gaps between the causes and results in environmental and social performance. No one has complete expertise about the function of the complex technological system adopted in the smart cities. There are multiple uncertainties, multiple normative frameworks, and multiple scenarios of future in the complex technological system (Sarlwitz, 2016). Citizens with less resources living in highly connected technologies are foreseen to be more vulnerable than before the implementation of smart cities.

Cowley et al. (2017) reviewed the role of the public in five prominent smart UK cities and found that "the public is positioned as part of the city's routine functionality, rather than assigned 'co-creational' agency" (p. 12). These five-star smart cities emphasized service-user publicness and entrepreneurial publicness and ignored political and civic publicness. The

practice of smart city in the public policy was quite opportunistic and did not draw much attention from the public. The development of smart-city initiatives in the United Kingdom comes from the Department of Business, Skills, and Innovation, not from the Department of Communities and local government. Public policy makers are eager to use the smart cities' initiative to provide economic and political efficiency. Smart cities are "politically inclusive and culturally creative in only limited ways" (Hollands, 2008, p. 304).

There are serious problems of surveillance, discrimination, and freedom infringement in the development of smart cities. The big data collected by the smart cities can be a powerful tool to exclude or include particular data. The entire process of keeping or deleting particular data can be very political. There are significant power differences between knowledge of experts and citizen operators, the public and managers of information in these highly rationalized cities. Many data in smart cities are collected, coded, and operated with algorithms that are invisible or incomprehensible to the users and actors. The self-contained step-by-step set of operation in the algorithms is programmed without much transparency and public involvement. The algorithm may come from the set of data that affirms the existing social and political discrimination. It is questionable whether the public has the capability to meaningfully interact or engage in the discussion of the existing algorithm that governs the daily operation of the city. How can the existing algorithm be undergoing continuous improvement when so many people are incapable to criticize it even when the algorithm is claimed to be transparent to the public? It is the question who owns the data and who will not be tempted to sell the data. There are different social structures using different algorithms to make sense of data as information and form opinions about a person. There is information and power asymmetric in different social structures that can result is serious reputation losses to those who have less power. Sadly, those who cannot access the facilities in smart cities will be excluded from the network and may even bear a higher cost of living because the presence of many smart buildings and technology in their cities.

Rio de Janeiro (Brazil) can be a good case to illustrate how it was created in the idea of IBM and poorly managed by the local government. The city got the "2013 Smart City of the Year" in the Smart City Expo (Enbysk, 2013), is the exemplar of IBM's "smarter planet" and "smarter cities" marketing campaign. Gaffney and Robertson (2018) examined critically the implementation and functioning of two "smart

cities" systems in Rio de Janeiro and learned that the smart technologies exacerbated pre-existing digital and social economic inequalities and served the rich more in limited wealthy areas. The notable security development Rio de Janeiro was around sporting venues, tourist areas, and key transportation infrastructures. The information collected was not used for long-term decision-making. More crimes happened outside the monitored areas. The smart technology was used to "consolidate the territorial, financial, and political gains realized during a major event" (p. 58). When there were protests in 2013–2014, the government used the smart technology to disrupt activist network. The smart technology only consolidates power, accumulates wealth, and generates honor for mayors and a few people through mega sports events in Rio de Janeiro! The smart technology does not solve the existing problems of radical inequality or systematic poor governance. Gaffney and Robertson (2018, p. 48) concluded as follows:

> the smart city paradigm is not capable of addressing the most pressing needs of cities with chronic deficits in urban infrastructure and an absence of robust civil society institutions. As such, smart city systems may actually contribute to the securitization and fragmentation of urban space, exacerbating social and political divides.

Another case is the authors' home town, Hong Kong. It was ranked fourth in the Asia Pacific after Seoul, Singapore, and Tokyo in the 2013 Cohen study of smart cities (Central Policy Unit, 2015) according to Boyd Cohen's definition of smart cities:

> Smart cities use information and communication technologies (ICT) to be a more intelligent and efficient use of resources, resulting in cost and energy savings, improved service delivery, quality of life, and reduced environmental footprint—all supporting innovation and low-carbon economy. (Footnote 3, p. 1)

Hong Kong is effective at using technology to improve operation efficiency in daily lives by adopting the Octopus electronic transaction system and its robust ICT infrastructure. The mobile and household broadband penetration rates are very high. However, the quality of life of people has dropped in the recent 10 years while the city is regarded as the world's second-most unequal city in terms of household income distribution (South China Morning Post, 2017, June 9). More and more people are

complaining about the public policy and over-compact living environment. Although Hong Kong Planning department has advocated smart, green, and resilient strategy in the Hong Kong 2030+ document (Hong Kong 2030+ Website, 2016), there is not much public engagement and excitement about the policy. The public treats it as an opportunistic public policy. The 2030+ blueprint was criticized to run "counter to the goal of a true livable city" (South China Post, 2016, November 9). It was criticized not to develop actions to reach the standards listed in the 2030+ plan. Holloway (2017), CEO of Habit for Humanity Hong Kong, comments Smart Hong Kong Consultancy study only increases the income disparity as the inclusiveness of the city is missed in the 2030+ blueprint. The claim of smart-city development in Hong Kong cannot give comfort to the public who have to deal with serious economic and political inequality in their daily lives.

A Paradigm for Human Flourishing in Smart Cities

The new paradigm must be community-led urban development, not business-led urban development. The city is governed by the public who are empowered by technology. The development of smart cities should not be opportunistic in public policy and needs the involvement of the public and the awareness of the public about the values behind the decision that was made. This new paradigm embraces the investment in the soft domain of smart city including human capital and governance structure in Asian countries. Increasing the quality of people and inclusivity of the community should be the heart of the smarter city process. The government should develop data protection act to enact the rights of privacy of citizens.

ICT infrastructure and technology are used to empower the people and community to exercise their choices and to be engaged in the economic, social, and political activities in the smart cities. These technological companies need to inform citizens how their data are used and protected. Internet of people should exceed over internet of things. Multiple stakeholders must work within their perceived capabilities and values. They have to do civic experiments and also encounter technological problems in the limitations of our human brains and bodies. "But building smart cities is going to take time. It will by necessity be a long, messy, incremental process" (Townsend, 2013, p. 11). Developing smart cities for people needs to understand the perception of people about the cities and the priorities of values to precede the development. It values connectivity and

practices empathy in a culture of care and justice. Human flourishing, human connectivity, and inclusiveness would be seriously addressed.

In this new paradigm, a sustainable flourishing city is derived from the social meaning of the people in the community (James, 2015). The vision of the future of the city should come from the people, not from those who sell the technology. The evolving expectations of households and neighbors about their cities will be captured in the community dialogues. In this new paradigm, the inhabitants' symbolic meaning and collective historical memory of the city are captured and highly advocated by Christopher Alexander in his numerous books (Alexander, 1979; Alexander et al., 1977; Alexander, Davis, Martinez, & Corner, 1985; Alexander, Neis, Anninou, & King, 1987). He advocates the new paradigm of human flourishing as the rediscovery of the lost "pattern language" from the hidden memories of ordinary people about the buildings and the cities. He explains this new paradigm in urban planning and building design as the timeless way and "quality without name":

> A building or a town will only be alive to the extent that it is governed by the timeless way….This quality in buildings and in towns cannot be made, but only generated, indirectly, by the ordinary actions of the people, just as a flower cannot be made, but only generated from the seed (Alexander, 1979, ix-xi).

Without the help of architects or planners, if you are working in the timeless way, a town will grow under your hands, as steady as the flowers in your garden (Alexander, 1979, 8).

For example, when Christopher Alexander designed Eishin School in Tokyo, he listened to the voices of all future users including principals, school teachers, and students; he also designed the building on the site based on the hand-on experience. Thus, the design of smart cities for people needs to be evolved slowly based on the needs of users and achieve "timeless way" and "quality without name" through the in-depth understanding of pattern languages commonly used in the city.

The new paradigm has been practiced by Lynch (1960) in his book titled *The Image of City*. He has visited the places and interviewed the residents of Boston, New Jersey, and Los Angeles cities. He has found that people in urban cities orient themselves through the means of mental maps, which provide them emotional security. The designer needs to understand how the environment is constructed through the interrela-

tions of different groups and individuals and provides obvious structure with open patterns that allows the incorporation of participants' more complex mental representations of cities:

> Cities are the habitat of many groups, and only with a differentiated understanding of groups and individual images and their interrelations can an environment be constructed that will be satisfying to all until such knowledge is at hand, the designer must continue to rely upon the common denomination, or public image, and otherwise provide as great a variety of types of image-building material as he can devise. (p. 157)

> A city must have both an obvious structure that can be grasped immediately and also a potential structure which allow one gradually to construct a more complex and comprehensive picture. (p. 158)

In his book titled *What Time Is This Place* (Lynch, 1972), he describes how our innate sense of time affects the way we view and change our physical environment, especially in cities. He said, "Since we cannot be certain what will be most relevant in the future, we have an obligation to save some characteristic evidence of every major period—to establish an environment archive." To practice this new paradigm is to enable people to be connected to the historical meaning of the place and also to allow for future new developments.

The new paradigm is human-centered development and accepts our community-led urban development within our social and ecological limits. Ordinary people need to be equipped with the skills to know how to use the technology and to be included. They also need to be educated to know the pattern, quality, symbolic images, and mental representations of their cities when they are empowered to govern their own cities. Thus, the community-led growth is related to the grass-root smart growth movement that promotes sustainability by design and inclusive engagement from the public. "Sustainability emphasizes finiteness, limits, and ways of life that will advance that priority, rather than a continued emphasis on pursuing traditional forms of growth, but in a 'smarter' manner" (Beatly & Collins, 2000, p. 297). Thus, the symbolic meanings of the city need to be translated in a comprehensive human-centered city vision. The vision has to be articulated to the citizens, end-users, finance and corporate ICT firms, engineering, property development and construction companies, urban planners, and government.

The vision of the city is evolving and the design of the city for people comes from doing. Technology is only one of the alternatives that affects the future prosperity and development of human communities. Each individual is allowed to build the city which promotes environmental friendly habits by creating walkable neighborhoods containing a wide range of housing and job types. The government needs to be regulated by the community and then develop expertise to know how to equip the communities to develop their own cities for being resilient (Jacobs, 1961). Newman, Beatley, and Boyer (2009) urge cities to be prepared for short-term contingencies such as alternative transport availability, alternative fuel programs, and household awareness programs. Without these preparations, cities will begin to crumble and fall apart.

In summation, in the new paradigm of the development of smart city for people, we need to be patient with the complexity and ethical uncertainties in the process of developing a sustainable flourishing community that is aligned with existing social capital and structure. Policy makers must develop governance structure to protect citizens' data privacy. They also need to mobilize more engagement from the public, develop a process for social reflections about the values behind the public choices, need to develop contingent consensus, and learn by doing in the policy making. The new paradigm also challenges the major corporate ICT firms, engineering, property development and construction companies, and government to develop the city for people, not for quick financial interests and economic competitiveness.

Implications to Public Policy and Higher Education

Through the research of smart cities and the Asian exemplars, including Singapore and Songdo, we affirm the importance of development of citizens rather than consumers in our teaching and research. We need to facilitate our college students to practice community-led urban growth and embrace their civil responsibilities. We need to help our college students to wisely navigate through a vast ocean of digitized urban technology and solutions (Eshelman, Lam, & Cook, 2012; Lam, 2017; Vaill, 2007). We have to invest more smart initiatives in people and community, and governance in our home town, Hong Kong. It is essential for Hong Kong policy makers to develop trusting relationships with their citizens through responsible data policy, open and collaborative governance structure, and heavy investment in human resources if the economic benefits of

a "smart city" are expected to spillover and improve the quality of life of local citizens. Citizens flourish when they can live in cities with dignity and wisely exercise their human capacities, including rational, emotional, bodily, sensory, relational, imaginative, and language-using abilities. Their basic capabilities of humanity need to be nurtured and respected before they can exercise their freedom and make their own choices in smart cities.

Here are some suggestions to Hong Kong policy makers.

Responsible Data Policy

Need to address the issues of data ownership, data protection, data interpretation, data regulation, and data security in the Data Policy. Citizens have rights to be deeply informed about how their personal data is collected and is selected for particular decisions. Data providers should know their risks of losing their reputation when their personal data have been chosen to form opinions about themselves. The open data, big data, the chosen algorithms used in the smart-city development should be managed with integrity and be accountable to citizens. The local government needs to learn from the best practices of other smarter cities and practice a citizen-focused data policy (Eurocities, 2016). The local government needs to strengthen its internal government and provide e-government solutions for the citizens. For example, citizens can access the real data about the gas emission of our monopolized utility companies.

Open and Collaborative Governance Structure

Need to foster community-level social capital that allows citizens to develop their own cities and treasure the symbolic meaning of the city with the support of technology. Cities should not be written in the language of a few powerful ICT companies and real-estate developers. They need to practice transparent governance and allow citizens to be partners, collaborators, and co-creators in the design and implementation of the city that has her "quality without name," and comprehensive human-centered city vision. Leaders from the private and public sectors need to examine what can be measured, monitored, and addressed in the smart city having significant moral implications to humanity. For example, the tender specifications of private projects in the development of smart cities need to be consulted. The public and private parties have to be accountable for the quality of lives of citizens who have to live with the consequences of the projects.

Heavy Investment in People and Community

They need to develop robust civil society institutions; need to reach out to, engage with, and empower people to find better solutions for urban problems and develop communities with compassion; need to educate people to be creative users of those ICT solutions for better community and quality of life; need to invest people's basic knowledge and skills of using those technologies; and need to allow people to question what "smart city" models are being used and what social norms and codes that guide the practices for the smart cities. For example, Hong Kong 2030+ plan should allow people to have numerous feedback about the proposed smart-city system and question the public values behind the plan. People should be empowered to develop social capacities for reflection about the social norms or algorithms for the interpretation of data as information, and participate in the political processes balancing the needs of the community, local government, and corporations in the development of smart cities.

In the development of smart cities, citizens require new public services, regulations, and accountability from policy makers and corporations. A city in which people reside is the smartest city when people care and work on it. "We want cities that work well enough, but are open to the shifts, uncertainties, and mess which are real life" (Sennett, 2012). Hirschman (1965, p. 35) reminded us of our high degree of initial ignorance and uncertainty when we implement the technological innovations to solve the problems of the city. He said,

> The term "implementation" understates the complexity of the task of carrying out projects that are affected by a high degree of initial ignorance and uncertainty. Here "project implementation" may often mean in fact a long voyage of discovery in the most varied domains, from technology to politics.

Educators need to enrich students' interpretations of these visual data of urban city solutions and guide them to ask many questions about human well-beings in smart cities. These are some suggested questions: (1) What does it mean for us humans to live well in smart cities? (2) What various issues can arise from an account that makes room for such a variety of human lives in smart cities? (3) What practices are used that undermine the flourishing of our families, our communities, our political groupings, and our culture in smart cities? (4) Will we continue to use these open-ended human capacities to construct valuable lives that yet are not seen in smart cities?

CHAPTER 3

On How Big Data Revolutionizes Knowledge Management

Asha Thomas and Meenu Chopra

Introduction

The present century being a knowledge economy, there is significant reliance on information and the availability of intellectual capital (IC). In this scenario, knowledge management (KM) has emerged to become an integral part of every organization. Increasingly, organizations are relying on the knowledge possessed by their employees for decision-making processes. Erstwhile KM practices and platforms were driven toward capturing and codifying the available explicit knowledge into digital artifacts, which made the collective organizational knowledge available to a much wider set of practitioners. These KM practices and tools were extremely successful across diverse industries, particularly in knowledge-driven sectors such as Consulting, Information Technology (IT), life sciences, and others. However, they were limited in that they were primarily focused on codifying the explicit knowledge artifacts and providing services for searching and retrieving these artifacts from the database.

B. George, J. Paul (eds.), *Digital Transformation in Business and Society*, https://doi.org/10.1007/978-3-030-08277-2_3

In the present scenario, one of the major challenges facing organizations is the reconstruction of knowledge from one form to another. To successfully navigate this challenge, organizations are required to take consistent and strident steps to attain their identified goals through the efficient use of tacit knowledge. This leads to the creation of a contextual relationship between big data analytics and the management of the explicit knowledge (Davenport & Patil, 2012; Khan & Vorley, 2017). It is in this context, Khan and Vorley (2017) have identified the seminal role that big data analytics plays in capturing, acquiring, and sharing large volumes of explicit knowledge and how they may be interpreted through tacit insight. It has thus been proposed that big data and KM have a similar objective of disseminating knowledge and producing conclusive outcomes for organizations.

Technology-Driven Business Transformation

Technology has helped transform business processes and models over the years. Enterprise resource planning (ERP) and customer relationship management (CRM) helped to digitize organizational data and streamline flow of information, the new technologies like cloud computing, innovative, and cost-effective communication systems have made it possible even for small and medium enterprises (SMEs) to join the technology highway. As a result, the entire value chain has been digitized.

All the links in the chain—suppliers, distributors, retailers—were now in position to stay connected by means of these technologies. This led to a streamlined delivery process and higher efficiency of the entire system. As more and more organizations joined this technology highway, the cost of tech products decreased, starting a virtuous cycle of high demand and low price. The result was adoption of these technologies in the mainstream across the entire ecosystem.

Another simultaneous change was in progress—customer technology was being commoditized very rapidly. Widespread use of smartphones, e-commerce platforms, and availability of mobile internet were some of the major contributors in bringing technology closer to the end consumer. This new generation of consumer was not only shopping online, they were also pretty open about voicing their choices and opinions and sharing feedback on social media platforms. This information came directly from the horse mouth hence was not only true and reliable but also instantaneous. The intersection of digital technology across all ends

of the spectrum is generating colossal data every minute, and this data, if processed and analyzed, can provide extremely useful information for all stakeholders.

Advantages:

1. Transformation of business models
2. Generate new sources of revenue
3. Resource optimization
4. Maximize shareholder wealth

Challenges:

1. A centralized approach for identifying and analyzing big data may not be present—though there are talks about it, not many organizations have the process and technology to identify, capture, and analyze the data coming in from various sources.
2. Talent is another limiting factor. Capable data scientists with knowledge about the industry/firm ecosystem may not be available.
3. Change needed in strategic intent—using knowledge assets to build practices around insights drawn from data is required.

The knowledge pyramid of conversion of data–information–knowledge–wisdom holds immense opportunity for organizations, countries, and the world at large. The emergence of new technologies, proliferation of the internet and smartphones, and dominance of the industry by tech giants like Apple, Amazon, Facebook, etc. has produced humungous amount of data. This has made it imperative for the field of knowledge management to develop new ways and means of analyzing and utilizing this information for global transformation.

This revolution is not just restricted to technology—it has made rapid advances to areas like manufacturing, warehousing, and logistics. Professionals of the area believe that the emergence of Industry 4.0 will be ruled by the following four:

- data volume
- computational power and connectivity
- business intelligence and analysis capabilities
- human machine interaction advances like touch screen, voice recognition, and augmented reality

Knowledge Management

The study of KM is close to touching a 25-year mark. With initial talks about knowledge in organizations in early 1990s, "knowledge creation company" by Nonaka and Takeuchi (1995)) provided a solid ground for KM to be established as a discipline in the industry. The concept garnered a lot of attention, and numerous research papers have been published in the area since.

The literature on KM speaks about these two views of a firm—resource-based view (RBV) (Barney, 1991; Penrose, 1959; Wernerfelt, 1984) and knowledge-based view (KBV) (Grant, 1996; Kogut & Zander, 1992; Spender, 1996; Teece, 1998). While the RBV focuses on the tangible and intangible resources an organization possess, the KBV takes stock of knowledge that exists within an organization and propounds that this knowledge is the source of unique and sustainable advantage the firm enjoys in the market. Both these views are based on the premise that an organization's performance is dependent more on its internal factors and less on its product positioning in the market place.

KM and intellectual capital (IC) together identify and manage knowledge assets to provide a competitive edge to a firm. IC clearly demarcates between human capital, structural capital, and relational capital (Bontis, 1999). Human capital refers to job-related skill set, structural capital refers to knowledge that exists within the organization, and relational capital exists by virtue of relations with customers, suppliers, etc.

The study of KM focuses on:

1. Tacit/explicit knowledge—based on easier or harder to capture/share (Nonaka & Takeuchi, 1995)
2. Complexity and stickiness (Kogut & Zander, 1992; McEvily & Chakravarthy, 2002)
3. Tools and techniques employed for KM like communities of practice (COPs)
4. Organizational factors like culture, trust, infrastructure, and so on, which influence the existence and smooth flow of KM processes in the organization.

Choice of the correct KM approach is a complex process and varies with a firm's circumstances.

KM refers to the process of identification of collective knowledge that exists in an organization and leveraging it to help the organization compete in the market place (Von Krogh, 1998).

From the above, it is clear that KM and strategy must work hand in hand to achieve the desired results. Linkage between the two has been suggested earlier (Hansen, Nohria, & Tierney, 1999; Hunter, Beaumont, & Lee, 2002; McDermott & O'dell, 2001; Pan & Scarbrough, 1999). KM in an organization should link to and flow from the organization's overall strategy. Researchers have emphasized on enablers, processes, and organizational performance as part of KM strategy (Lee & Choi, 2003).

KM processes typically refer to basic operations of knowledge—creation, sharing, storage, dissemination, and usage; KM enablers provide the right environment, support, and infrastructure for these processes to exist in the organization.

It is generally recognized that KM is cross-functional and touches various aspects of an organization. Many researchers have worked on this integration between different links of KM enablers, KM processes, and organizational performance (Andreeva & Kianto, 2012; Darroch, 2005; Gloet & Terziovski, 2004; Gold, Malhotra, & Segars, 2001; Hislop, 2003; Kianto, 2011; Lee & Choi, 2003; Palacios Marqués & José Garrigós Simón, 2006; Singh, Shankar, Narain, & Kumar, 2006; Zack, 2009).

Big Data and the 3V Model

In 2001, Doug Laney, an analyst at Garter (formerly META), put forth a preliminary definition of big data using a 3V model, namely, volume, velocity, and variety. Almost a decade later, in 2011, the International Data Corporation (IDC) proposed another definition for big data, stating that "big data technologies describe a new generation of technologies and architectures, designed to economically extract value from very large volume of a wide variety of data, by enabling the high-velocity capture, discovery, and/or analysis" (Sumbal, Tsui, & See-to, 2017). In recent years, much speculation and interest has surrounded big data, largely due to the availability of colossal amounts of data. This has been made possible due to the widespread dispensation of information through electronic devices and rising innovation in the field of IT.

Big data has been identified as having the potential to revolutionize the large amount of data available in present times (Davenport & Patil, 2012).

This large volume of available data has opened business organizations to the realization that there is a critical need to manage this data efficiently by storing and using it for improving accuracy in decision-making (George et al., 2014). While traditionally businesses have been dependent on the transactional data stored in relational databases for making key decisions, critical data can, however, serve as a potential reservoir for non-traditional, less-structured data forms in the present times such as emails, weblogs, social media, photographs, sensors, etc. that can unearth useful information. What makes this data even more accessible is the declining cost of storage as well as computer power. Consequently, companies everywhere are leaning toward incorporating unconventional yet potentially very valuable data, or big data, alongside the traditional enterprise data that was hitherto being used in their business intelligence analyses (Rajpathak & Narsingpurkar, 2013).

McAfee, Brynjolfsson, Davenport, Patil, and Barton (2012) observe that big data creates a potential for basing decisions on factual information as opposed to instincts, which can serve companies advantageously by providing them with a competitive edge. The vast amount of data available in present times cannot be processed adequately by the existing and predominantly traditional technologies, and it is here that big data steps in as a superior tool to extricate knowledge from this data (Kabir & Carayannis, 2013). This has led to a realization within businesses and organizations that big data holds tremendous scope in enhancing the competitive edge by serving as a treasure trove of novel ideas, valuable insights, and new knowledge.

However, it needs to be underscored that the true potential of big data can be achieved only when it is used in decision-making processes. But it is significant to note that the conventional approach of data analysis practices cannot be applied to big data. It is here that the 3V approach to big data—Variety, Velocity, and Volume—becomes significant (Kabir & Carayannis, 2013). Each of these aspects is explained as follows:

- *Variety*: The proliferation of IT has caused a significant increase in the sheer number of sources for data in present times, which in turn has led to an immense variety in the data available. Further, these resources are classed into three distinct categories, viz., structured, semi-structured, and unstructured. Structured data is that which is stored in a secure file and can be readily accessed. Data collated from vague sources and is difficult to analyze is unstructured data. Semi-structured

data is that which is not organized in any special format but nevertheless contains some tags or identifiers which make it easier to process as compared to raw unprocessed data.

- *Volume*: The volume of data available is a challenge for organizations as the amount may run into terabytes and petabytes, making it difficult for the prevailing techniques of data analysis to process them.
- *Velocity*: Another challenge nowadays is the speed at which the data is generated and analyzed. Faster speeds of analysis are of utmost importance to organizations, as it will enable them to implement this processed data for better decision-making for the benefit of the organization.

The Contextual Relationship Between Big Data and Knowledge Management

Knowledge has been acknowledged as a fundamental aspect of any theorization on big data (Pauleen & Wang, 2017). Big data and analytics will fail to achieve the desired results in the absence of knowledge, as it is the latter that has led to the expansion and identification of the true potential of big data. Collection and analysis of data through the use of the appropriate techniques is dependent on the experience of the humans. It is human knowledge which will determine how the information extracted from big data is used and whether it will be applied in operational, tactical, or strategic domains. Consequently, the impact of knowledge on the role that big data will play in different sectors cannot be underestimated. This is further elucidated through an analysis of the major objectives of KM and the role that big data plays in their realization.

One of the key goals of KM is effective decision-making, which is currently accomplished by using the knowledge generated from big data analytics. This also serves to evidence the relationship between KM and big data (Crane & Self, 2014; Sumbal et al., 2017). As big data has been viewed as a potential source for generating new knowledge, it is a challenge for organizations to identify and positively exploit the true potential of digital transformation. For this, it is important to undertake a cohesive strategy to set up effective communication systems and processes to facilitate the exchange of information and data analytics, which will create a holistic approach toward KM in the digital context and foster a culture of data-driven decision-making within organizations.

Another goal of the KM system is the effective codification and sharing of the key knowledge assets. Unlike in the case of the traditional KM system, big data and the information herewith can be a source of new knowledge. That both KM and big data are concerned with some intangible asset in the form of data, information, knowledge or intelligence has also led to the development of what has been perceived as a "natural connection" between the two (Erickson & Rothberg, 2014). To ensure that these resources are efficiently utilized and meet the advanced requirements of the organizations, it has been recommended that advanced KM systems replace the erstwhile systems of rudimentary text mining tools, document analysis mechanisms, and knowledge-sharing systems (Intezari & Gressel, 2017). To generate higher value for the existing KM systems of organizations, these advanced KM systems will need to assimilate big data into their knowledge databases.

Big data analytics also becomes of crucial importance in the big picture, playing a vital role in capturing and sharing explicit knowledge by furthering its dissemination via tacit cognizance using big data analytics. In decision-making within organizations, this leads to gaining new insights into knowledge for effective and fastidious actions (Khan & Vorley, 2017).

The model presented below underlines projecting light on the contextual relationship between big data and knowledge management. At the base of the KM pyramid lies data that is composed of discrete facts and when viewed from the perspective of explicit knowledge, it refers to the movement of actions and processes in any organizational system, without any context. However, when the data is viewed in terms of a frame of reference or context, it acquires the form of information, often as metadata. When this information is further transformed through intuition, reflective thinking, personal experience, and learning of the user, it is converted into knowledge. In contrast, big data refers to the structured, unstructured, or semi-structured data collated from different sources. The application of analytics to large amounts of operational and transactional data, or explicit data, by relating it to its context gives rise to meaningful and valuable information, which directs the user toward the complete picture by studying and organizing the underlying trends and patterns revealed from the information (Fig. 3.1).

Clearly, information is a core aspect of knowledge. When meaningful information is supplied to business intelligence tools, it leads to the creation of actionable knowledge, or in other words, KM.

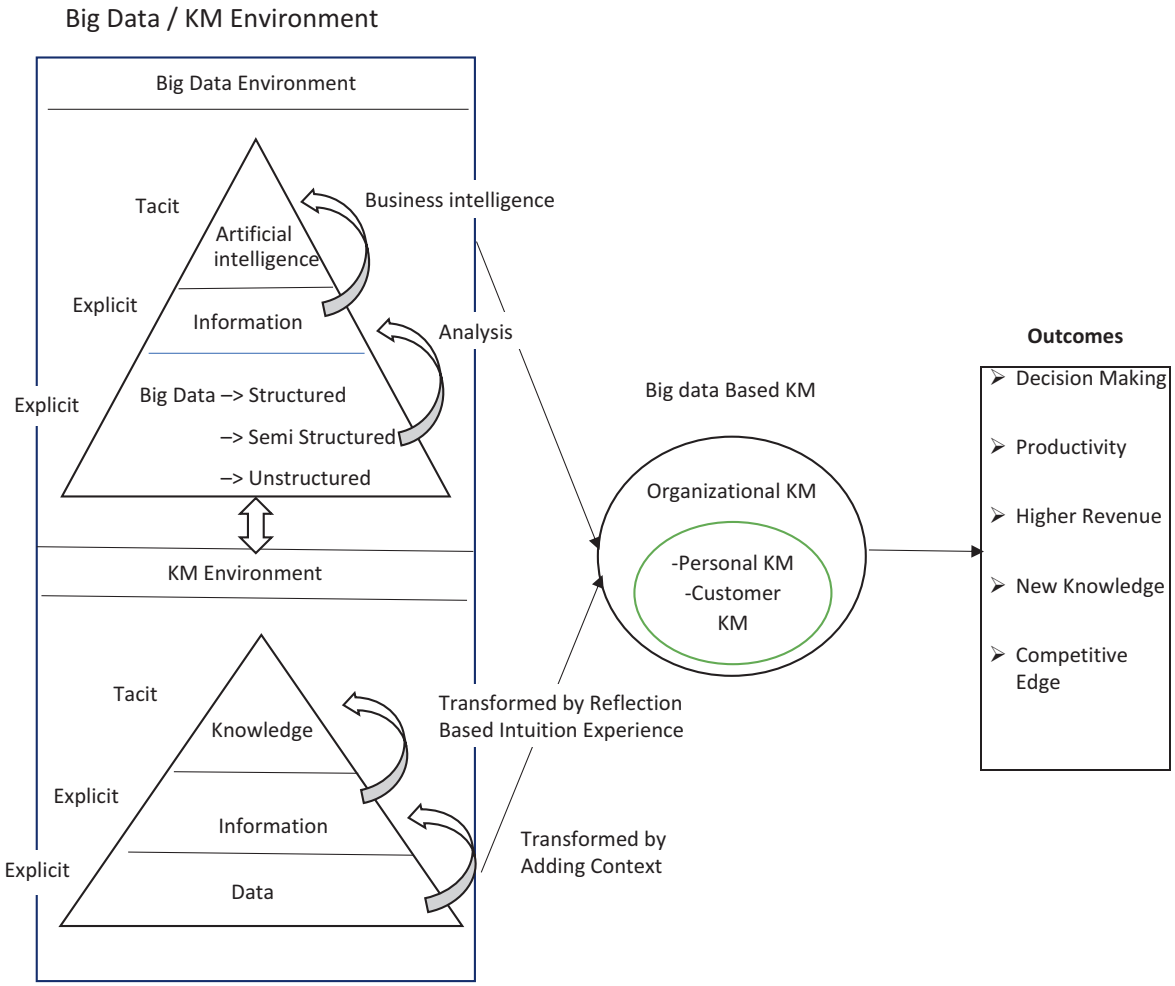

Fig. 3.1 Intersection of big data and KM in business

According to the Socialization, Externalization, Combination, and Internalization (SECI) model proposed by Nonaka, knowledge can be distinguished into two types: explicit knowledge and tacit knowledge. The former, also known as digital knowledge, is the formal and codified form of knowledge, which is captured in databases and archives and is similar to big data. On the other hand, tacit knowledge is that which exists in the minds of people and is hence much more difficult to codify. For any organization, it is the tacit knowledge of experienced employees which is significant for decision-making using big data. By bringing together the tacit knowledge of employees with the explicit knowledge that is obtained from big data, the creation of actionable knowledge and innovation is stimulated (Sumbal et al., 2017).

Clearly, big data in the form of digital data generates explicit knowledge. However, this occurs only when the available data is managed,

analyzed, and embedded in the proper context. This is done by individuals, thus making tacit knowledge a pivotal aspect of big data management (Kudyba, 2014). To this has been added the generation of predictive knowledge from big data as an ancillary goal for KM decision-making (Sumbal et al., 2017).

Big data analytics has tremendous potential for organizations, and this can be realized only by leveraging it to boost decision-making (Gandomi & Haider, 2015; Sasson, Ravid, & Pliskin, 2017) Additionally, both KM and big data were conceptualized as agents that would provide deeper insights and promote better decision-making, improve productivity, generate higher revenue, and provide a competitive edge to organizations (Elgendy & Elragal, 2014; Ohlhorst, 2012; Pauleen, 2017). The conception of novel information and knowledge or explicit knowledge from big data and its implementation in decision-making alongside the use of tacit knowledge can be extremely beneficial for enhancing the accuracy of decision-making in organizations. By focusing on such aspects as the storage and dissemination of knowledge, a more informed insight may be obtained into when and how big data can serve organizations better. At the same time, a study of variables such as the nature of knowledge (tacit or explicit), can be useful for predicting the types of knowledge apt for use in different situations and industries. This will also enable the users to gain a better understanding of when and where further inputs of big data may be advantageous (Erickson & Rothberg, 2014). Analytics can also serve useful for effective KM, leading to further improvement in the functioning of organizations, thus promoting a stronger case for the intersection of big data and KM (Sumbal et al., 2017).

Role of KM in Big Data

Role of Big Data in Personal Knowledge Management (PKM)

The manner in which individuals build knowledge by utilizing such knowledge management tools which involve the collection, absorption, and the use of knowledge and the process of innovatively using knowledge has been referred to as personal knowledge management (PKM). In PKM, the focus is on the individual and his/her quest to imbibe more information, enhance work efficiency, and socialize. One of the key attributes of PKM

is that it provides individuals with an opportunity to improve how they manage knowledge processes and interaction and collaborate to exchange knowledge and information with others (Huang, Pauleen, Scahill, & Taskin, 2018). Razmerita, Kirchner, and Sudzina (2009) have determined that the goal of PKM is to facilitate the work of individual knowledge workers instead of aiding the formation of organizations. Through this, PKM encourages the creation of personal knowledge for individuals by helping them discover and value information as a significant variable.

In recent times, with the application IT tools across sectors, several studies have sought to evaluate PKM in the context of the internet and Web 2.0, especially in terms of their use and management of personal knowledge (Rao & Chen, 2013; Razmerita et al., 2009) still PKM is an under-researched area (Pauleen, 2009). One of the core components of PKM is technology that enhances the efficiency and effectiveness of individual workers. This technology is useful for classifying ideas and information, and for archiving communication such as emails and other items so that they are easily accessible. In PKM, technology tools are considered to be imperative for enhancing the efficiency and confidence of the users as well as for the development of more effective information and knowledge management skills and dissemination and receipt of up-to-date information (Agnihotri & Troutt, 2009; Benitez & Pauleen, 2009). Liu, Wang, and Lin (2017) in their study on the applications of big data in PKM concluded that five domains:

1. *Time management*: Increased information sharing through facilitation of provision of resources which were earlier not available like software for converting the earlier not-so-easy convertible files to now free availability of such resources
2. *Computer usage efficiency management*: Retrieval of contextual information while using computers and internet gets facilitated as an individual's behavior is understood and reciprocated to through the use of Big Data.
3. *Mobile devices using behavioral management*: Behavioral parts of individuals can be analyzed using mobile phones without time and space constraints, this data is of massive use to organizations and individuals.
4. *Healthcare management*: Individuals users of mobile technology have access to unlimited apps and software, which may be of help in managing personal health by providing timely updates and reminders

about food, medicine, walk, etc. Technology has gone to the extent of being able to provide even ECG of the wearer, which may go a long way in avoiding cardiac problems by early diagnosis (Murdoch & Detsky, 2013).

5. *Browsing surfing management*: Interface between big data and an individual's surfing behavior can help in finding relevant information faster than usual. Tech devices can be made to remember the more frequently used, searched, visited websites/places hence improving the surfing experience.

The Role of Big Data in Customer Knowledge Management(CKM)

One of the key assets for any organization is customer knowledge, and hence, customer knowledge management or CKM is an important aspect for business. CKM facilitates the exchange of customer knowledge both within firms and between customers and firms in order to facilitate learning from, about, and with customers (Gibbert, Leibold, & Probst, 2002; Martín-de Castro, 2015). When customers are involved in the firm's practices through CKM, the external environment of the firm is linked to its internal environment. This, in turn, enables the transfer and sharing of information within the firm and with customers. However, there have been identified several challenges in converting customers' tacit knowledge (experience, ideas, information, difficulties, requirements, data, etc.) to explicit knowledge (useful ideas for resolving the problems of customers, for innovative services, or for upgrading current services (Taherparvar, Esmaeilpour, & Dostar, 2014).

Major retail companies such as Amazon.com, eBay, Walmart, and others have been able to successfully manage large amounts of knowledge and communicate with customers through the inclusion of real-time KM for the generation of knowledge using big data and analysis techniques (Davenport & Patil, 2012; McAfee et al., 2012; Waller & Fawcett, 2013; Sumbal et al., 2017). In these companies, the data accumulated from different sources is converted into business intelligence and knowledge via analytics. Big data analytics is also crucial in the assessment of the behavioral patterns of consumers, which is accomplished using such technology as machine-to-machine platforms and social media. The main objective here is to encapsulate the structured and unstructured data

through big data in a manner that will transform it into actionable insights by using CKM and lead to the generation, sharing, and storage of knowledge (Chan, 2014). This integration of big data and CKM for the generation of actionable insights for businesses support the creation of value for organizations.

Integration of Knowledge Management and Big Data

While both these systems are being implemented in activities like consumer survey, performance appraisal, capacity enlargement, etc., it can be observed that the independent framework of these two technologies share association with each other at multiple levels with KM playing the foundational role because of its earlier inception and time-tested performance in assisting with the installation of big data systems. However, big data is slowly adding benefits to KM in exponential ways that will make it a productive necessity for the future prospects of KM. Figure 3.2 presents the integration of the two. This integration is based on the premise that knowledge is central to all meaningful human activity. While analyzing big data, use of knowledge management is imperative as the problem or opportunity analysis must be clearly stated and form the base of the entire exercise. In the former case, big data analytics may be utilized to plan for agricultural management through geographical information or planning a city through the use of traffic patterns and trends. Opportunity identification may be purpose at hand, Google cloud platforms and Amazon web services help in the same. Organizations IT infrastructure, collaborative technologies act as the backbone for such analysis. Knowledge possessed by the employees of an organization (Tacit) and easily available coded/explicit knowledge helps us enter into the realm of big data possessed with the right weapons. Big data sources such as media, social networking sites, sensor data, archives, and log data provide humongous amount of raw data, which can be processed to find meaningful trends and opportunities by identifying and classifying the useful from the rest.

The process yields extremely useful actionable insights for managers who are in a better position to make informed decisions now. This in turn results in various benefits for the organization in terms of economic value, supply chain efficiency, and innovation.

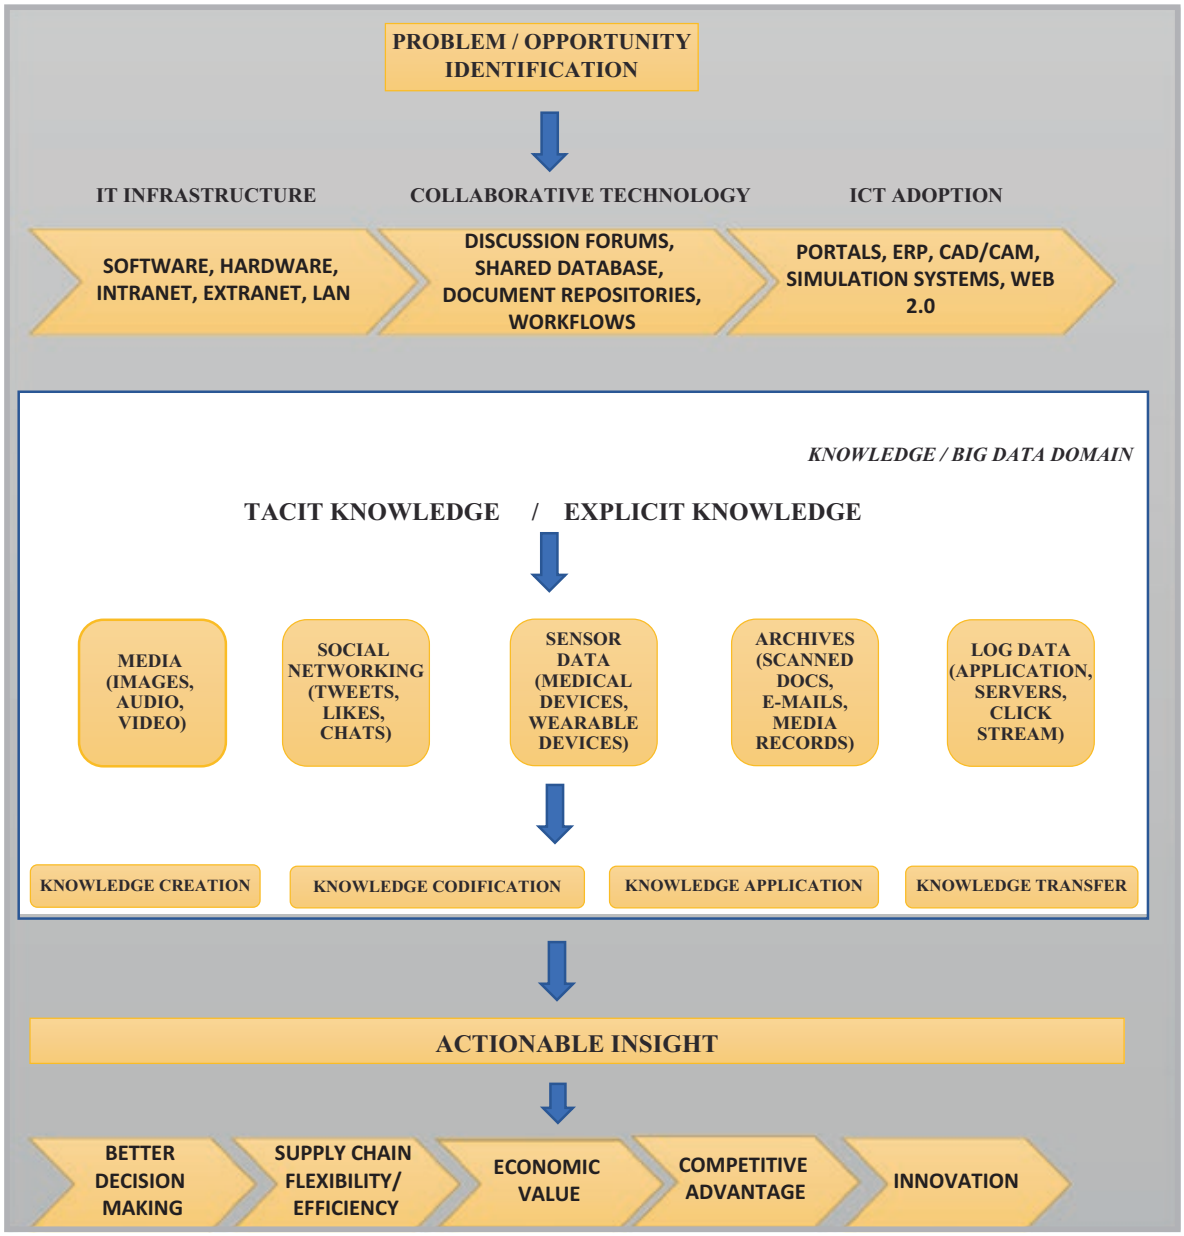

Fig. 3.2 Knowledge management—harnessing the power of big data

Therefore, the interaction of two different yet associated practices paved way to the illustrated model that can provide new business value and faster return on economic investments, enhance business operations through better decision-making, incorporate trust, promote personal and organizational-level learning, and ultimately the perks of a hybrid system that is adaptable to future needs is what comes as a bonus.

Conclusion

The twenty-first century has witnessed a major transition toward a knowledge economy of unlimited scope. During the past few years, the world has rapidly grown to connect products and services that were earlier perceived as impossible and all this can be attributed to the rising technological advancements of the second millennium. Along the same timeline, the inclusion of KM as a pivotal partner in productive practices inside companies and organizations have taken a huge leap to withstand the competition. The inevitable use of big data in a world that is run by networking has also penetrated into KM and its future, making it prone to theoretical and practical evolution on a continuous basis.

Digital transformation is inevitable in the current times. The need of the hour is that organizations understand and realize the importance of potential learning opportunities that may result from the analysis of big data. Organizations with a futuristic leadership have already woken up to the fact that "digital" is the new mantra. They are in the process of taking a stock of their current capabilities and working on a digital agenda to reskill their employees and introduce them to new learning environments and opportunities. They are in full recognition of the myriad changes' customer expectation has undergone during the last decade and appreciate the fact that some major changes will be required to meet them.

The traditional organization trained and updated their employee base by providing technical and managerial skill set training programs from time to time. While recognition of gaps in technical skills could be done using skill matrix and competence models, and appropriate training could be provided; managerial skills could be honed through communication, negotiation, and decision-making programs.

These programs were effective and yielded the desired results until the rate of change in business was incremental and the conventional theories of economics applied on the markets. With the current disruptive changes occurring in business environment across the globe, the need of the hour is development of short, situation-specific, on-the-go solutions and suggestions being provided to the employee, which may be used and referred to at their convenience of time and space.

Organizations' collective knowledge must be digitized and prioritized according to the current demands of the market. Knowledge management needs to be innovative and creative in its approach to adapt and realign itself to the changing information needs of organizations. Setting up

centers to leverage knowledge assets of the organization, data driven insights which aid decision making and alignment of strategy with business objectives will lead to success of knowledge management.

Hence, the quantitative and real-world analysis of the meeting of a robust KM with an emerging big data technology forms the framework of this study. By identifying the correlation between these big data and KM, a connection that links both together could be discovered that shed light on its different functionalities. The results of this convergence for a sole entity can be termed as personal knowledge management (PKM), expanding into customer knowledge management (CKM) and finally into organizational knowledge management (OKM) (Pee & Kankanhalli, 2009).

The same convergence also results in the advent of a new corporate methodology, which is increasingly being used in all forms of organizations; big and small for informed decision-making. This is basically the enhanced version of decision-making, which is infused by leveraging the added potential of existing KM practices and new big data capabilities, but the effectiveness of this intersection lies on how well these two practices mingle and co-exist in a corporate's workflow. It is this co-existence that has to be closely moderated for successful implementation and enhancement of KM by featuring big data as the prime contributor.

Deliberate, timely, and careful alignment of knowledge management with big data is the key to success in the current business scenario.

Limitation and Future Scope

Although big data is gaining attention in research but limited research exists putting big data and KM in one framework; hence, it remains underdeveloped within the KM literature. This chapter is a conceptual study that need empirical testing. The literatures found to the subject in discussion depicted association between big data and only few variables of knowledge management but not all areas have been thoroughly studied. The prevalent studies have only considered a few sectors to demonstrate the association between big data and knowledge management. Thus, there is still a huge scope of testing this linkage empirically in other sectors to understand its effectiveness on other industries. The review of the literature studied between big data and various areas of knowledge management, but its linkage in a broader framework still needs to be empirically tested, which opens up the scope for future research.

Appendix

Linkage between the variables

Title of the research paper	*Main findings*	*Source of literature*
Interrelationship Between Big Data and Knowledge Management: An Exploratory Study in the Oil and Gas Sector	• Generation of predictive knowledge • Improve KM capabilities • Effective decision-making	Sumbal et al., *Journal of Knowledge Management* (2017)

CHAPTER 4

Social Media in Marketing Communications: A Synthesis of Successful Strategies for the Digital Generation

Ogechi Adeola, Robert Ebo Hinson, and Olaniyi Evans

Introduction

Numerous studies have investigated social media in marketing communications and have advanced our understanding of how it unfolds (e.g., Berthon, Pitt, Plangger, & Shapiro, 2012; Hudson & Thal, 2013; Kumar, Choi, & Greene, 2016). We currently have a mounting body of (1) evidence which shows that social media influences marketing outcomes (e.g., Agnihotri, Dingus, Hu, & Krush, 2016; Chung & Austria, 2010; Erdoğmuş & Cicek, 2012), and (2) several frameworks that offer an explanation of the complex social media marketing process (e.g., Effing & Spil, 2016; Felix, Rauschnabel, & Hinsch, 2017; Kietzmann, Hermkens, McCarthy, & Silvestre, 2011).

In recognition of its critical importance, according to Gallaugher and Ransbotham (2010), many companies have established online presence and continuous conversations with their consumers (e.g., Old Spice, TEDx, Starbucks, Pampers, Xbox, Zappos, Ford Motor Company, Cisco, JetBlue, Uber). These companies have shifted relationships with consumers from dialogue to trialogue, with consumers engaging one another and the firms in meaningful relationships (Lipsman, Mudd, Rich, & Bruich, 2012; Mangold & Faulds, 2009). With the use of social media, these organisations have forged relationships with new as well as existing customers and formed virtual communities that interactively join forces to recognise problems and advance solutions (Tsimonis & Dimitriadis, 2014).

These interactions, in turn, have changed the traditional roles of both the customer and the seller in exchange relationships. The consumers, on their part, have reduced their dependence on the traditional media (i.e., television, radio, newspapers, and magazines) as a source of information to guide their purchasing decisions. They now demand more control over their media consumption and prefer on-demand and immediate access to information, at their convenience (Vollmer & Precourt, 2008). By utilising the social media to conduct their information searches and make purchasing decisions (Vollmer & Precourt, 2008), the consumers increasingly perceive social media as a more trustworthy source of information on products and services than corporate-sponsored communications (Foux, 2006). In particular, the consumers respond to this information in a manner 'that directly influence all aspects of consumer behaviour, from information acquisition to post-purchase expressions of satisfaction and dissatisfaction' (Mangold & Faulds, 2009, p. 361). They add value to the information by generating content, and they can influence purchase decisions of others in peer-to-peer interactions (Sashi, 2012).

Additionally, from giants like IBM and Starbucks to the local barber, organisations have realised the fact that vast amounts of information about their products and services are communicated by individual consumers on social media. They know that social media, today, provides one of the best opportunities available to a brand for connecting with prospective consumers (Neti, 2011). In recognition of these processes, therefore, managers, who consistently wield a high level of control over company-to-consumer messages, must learn new strategies to influence discussions in the social media space. Whether it is an individual, a startup, small business, or a large corporation, successful strategies must be put in place to leverage the power of social media.

However, despite the recognition that social media is effective in connecting with customers (Selina & Milz, 2009; Hackworth & Kunz, 2011; Tsimonis & Dimitriadis, 2014), there is limited understanding regarding the successful strategies for social media marketing. Most of the relatively few studies in the literature consider social media as a novel marketing tool (e.g., Berinato, 2010; Kirtiş & Karahan, 2011; Bowen & Bowen, 2016), which can boost marketing communication effectiveness (e.g., Trusov, Bucklin, & Pauwels, 2009; Dholakia & Durham, 2010), and very few focus on specific strategies for social media marketing (e.g., Mangold & Faulds, 2009). To the best of our knowledge, there appears to be limited research examining the successful strategies that firms use for their corporate fan pages on social media like Twitter, Facebook, or YouTube.

Considering this gap, the increasing recognition of the significance of social media in marketing communications, its rapidly expanding evidence base, and the numerous social media marketing frameworks that are emerging, this study seeks to increase the understanding of social media in marketing communications by undertaking a conceptual synthesis of the successful strategies in literature and from business practices. The study identifies the successful strategies in social media marketing and includes specific actions related to these strategies that can be utilised to achieve success. This study, therefore, differs from other studies in the literature, as it delves into the 'how-to' of social media marketing (i.e., specific procedures and strategies). Systematically identifying these action-oriented strategies can serve as practical guidance related to specific tasks to include in the planning and/or execution of social media marketing. It is believed that the explicit focus on specific strategies that can be used to operationalise social media in marketing communications would make a significant contribution to the literature.

In the next section, we present a brief historical overview of social media; and issues related to social media marketing are described. The following section further discusses the electronic word-of-mouth (eWOM) framework. In the fourth section, the social media marketing strategies are synthesised; while the last section covers the concluding thoughts of this study.

Brief History of Social Media Marketing

In the last decade, social media has enjoyed phenomenal success. As at 2019, Facebook, a social networking website, has 2.27 billion active users worldwide; Twitter, a micro blogging website, currently hosts more than

349 million active users with about 500 million tweets per day; and YouTube, a video-sharing website, has over 3 billion daily video views (Internetlivestats.com, 2019).

The origin of social media marketing can be traced back to the 1990s when scholars began to highlight the implications of the Internet's interactivity for marketing and suggesting the possibility of IT developments rendering traditional marketing practices obsolete (van Raaij, 1998). Within a few years, the huge impacts of the web on consumer behaviour can be described as similar to those of the Industrial Revolution, of the printing press, or the railroads (Sharma & Sheth, 2004). Due to the impact of the web, consumer preferences are no longer only influenced by the traditionally defined controllable and uncontrollable stimuli, but also by the web experience, or the online atmospherics consisting of online controllable factors such as website usability, interactivity, aesthetics, and online marketing mix (Constantinides, 2009; Fotis, 2015), and by the website's interface, quality, satisfaction, and experience (Darley, Blankson, & Luethge, 2010).

The Internet had become a great enabler of consumer power, causing a steady decline in the influence of traditional mass media (Constantinides, 2009; Urban, 2003). As noted by Sharma and Sheth (2004, p. 696), 'the web is fundamentally changing, and will continue to change marketing thought and practice', social media realigned marketing focus from a supplier to a customer standpoint, aiding a customer-centric rather than a mass-market approach. Therefore, it is the customer now, and not the product, that initiates marketing activities (Fotis, 2015). In other words, the key lies with the change in the consumer's mindset, leading to 'a culture of active engagement, immediate access to anyone and for anything and constant communication. This is, of course, something that the traditional advertisement and other marketing methods could not ever achieve' (Kaushik, 2012, p. 92).

The first companies to use social media for marketing were Usernet in 1979, Bulletin Board System in 1979, Online Service in early to mid-1980s, CompuServe in 1980, AOL in 1983, Genie in 1985, Internet Relay Chat in 1988, and ICQ in mid-1990. The earliest social media were dating sites and online forums, such as Six Degrees in 1997 and Asian Avenue, MiGente, and Black Planet in 1997–2001, Live Journal in 1999 and Massive Multiplayer Online and Role Playing Games in early 2000. Then came along Friendster in 2002, LinkedIn in 2003, Myspace in 2003, Photo bucket in 2003, Delicious in 2003, Digg in 2004, Flickers in 2004,

Facebook in 2004, YouTube in 2005, Twitters in 2006, Kontain in 2008, and Posterous in 2009 (Kaushik, 2012).

With these platforms and more in the cyberspace, social media evolved into eight types of applications, namely, social networking sites, blogs, wikis, microblogs, consumer review sites, content community sites, Internet forums, and location-based social media. These applications created a virtual space within which users listen, express, share, discuss, engage, and interact through user- and brand-generated content. As social media became popular and the number of users increased, the commercial value soon became apparent. Marketers started to consider this shift in the media landscape, rewrote conventional strategies, and transformed the basic campaigning structure.

In the last decade, social media has transformed 'the web from a "one to many" to a "many to many" communication channel, and simultaneously to a "one to one" channel of interaction, allowing users not only to communicate but also to interact and engage' (Fotis, 2015, p. 34). This transformation has implications for marketing in the form of consumer empowerment, greater information transparency, possibility for product co-creation and personalisation, content generation and publishing, capacity to sanction/reward brands for product performance, and ethical and social responsibilities (Buhalis & O'Connor, 2005; Rodriguez-Ardura Meseguer-Artola, 2010).

There are also unintended implications. Social media makes consumers highly individualistic, more information-intensive, more time-driven and demanding, dictating time and mode of communication, and with bigger expectations (Akehurst, 2009). Moreover, the huge volume of information on the web leads to information overload, negatively affecting users' ability to locate information tailored to their specific needs, and causing other pathologies of information such as infobesity and information anxiety (Bawden & Robinson, 2009).

Theoretical Framework: Electronic Word-of-Mouth (eWOM)

The framework we used addresses the linkage between word-of-mouth (WOM) and social media (see Fig. 4.1). WOM can be defined as 'the act of exchanging marketing information among consumers and plays an essential role in changing consumer attitudes and behaviour towards prod-

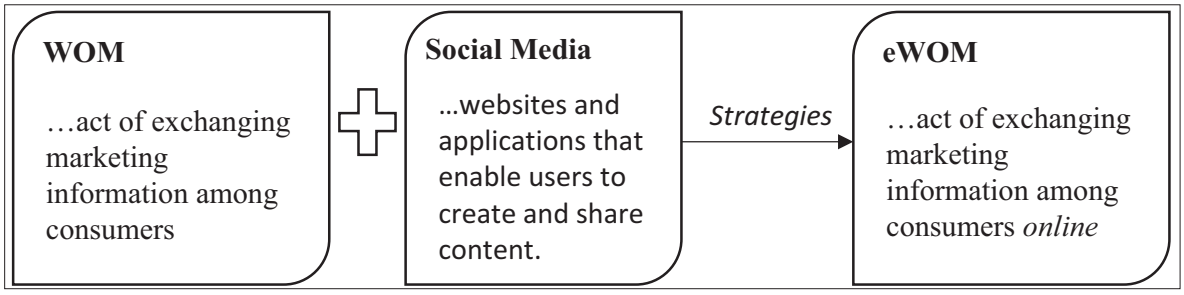

Fig. 4.1 The linkage between WOM and eWOM. Source: Authors' representation

ucts and services' (Chu & Kim, 2011, p. 47). WOM has been shown to significantly affect consumer attitudes and is seven times more effective than traditional print advertising in influencing brand-switching decisions (Engel, Kegerreis, & Blackwell, 1969; Katz & Lazarsfeld, 1955). Consumers often rely on WOM when they are in need of information to aid their purchase decisions. This is due to the fact that WOM is created and delivered by friends and family and therefore is a more trustworthy source of information than company-generated messages (Chu & Kim, 2011; Crotts 1999).

The emergence of WOM in social media has led to eWOM (electronic WOM) (see Fig. 4.1). According to Hennig-Thurau et al. (2004, p. 39), eWOM is 'any positive or negative statement made by potential, actual, or former customers about a product or company, which is made available to a multitude of people and institutions via the Internet'. eWOM occurs in a wide variety of online media, such as blogs, emails, virtual consumer communities, social networking sites, and consumer review websites and forums (Thorson & Rodgers, 2006). This eWOM acquired from friends and family is construed to 'be more credible, honest, and trustworthy than that generated from marketers, since the communicators are not compensated for the referral. Advancements in the Internet and Web 2.0 technologies now allow consumers to access personally meaningful critiques not only from friends and relatives but from strangers' (Pan & Crotts, 2012, p. 43).

In the social media marketing literature, there has been an increasing interest in understanding how eWOM affects sales, diffusion, and other marketing performance outcomes (i.e., Bruce, Foutz, & Kolsarici, 2012; Chevalier & Mayzlin, 2006; Godes & Mayzlin, 2004; Onishi & Manchanda, 2012; Trusov et al., 2009; Van den Bulte & Lilien, 2001; Villanueva, Yoo, & Hanssens, 2008). For example, Godes and Mayzlin

(2004) showed that online discussion forum activities influence television show ratings. Chevalier and Mayzlin (2006) demonstrated how user-generated online book reviews affect book sales. Trusov et al. (2009) showed that referrals to join an online social media platform affect a website's growth. Further, Onishi and Manchanda (2012) depicted that blog activity affects sales of a set of Japanese brands.

Consistent with the findings of the literature above on how eWOM affects a product's marketing performance, marketing managers combine WOM and social media to create eWOM, via effective social media marketing strategies (Fig. 4.1). Using effective strategies, the marketing managers engage the consumers in social interactions with the firm and the product and thereby get rewarded with likes, comments, or dissemination to the consumers' social connections. Consumers freely create and disseminate brand-related eWOM to friends, family, and acquaintances (Vollmer & Precourt, 2008). Through these social media interactions, consumers can show their brand preference to their connections, thus leading to eWOM (Chu & Kim, 2011). Utilising effective strategies, therefore, a firm can employ WOM on social media to generate eWOM (i.e., buzz marketing) and make its products go viral.

Successful Strategies

As more firms incorporate social media into their marketing communications, emphasis needs to be placed on creating and adopting effective strategies that can generate eWOM and make the brand go viral. The strategies outlined in this study are discrete social media practices that researchers have identified as universally beneficial for organisations to adopt. The aim here is not to generate radically new ideas for social media marketing in a discrete sense; each of the strategies is being operationalised in some organisations today. Rather, the purpose of this synthesis is to provide a measure of coherence, purpose, and success to social media marketing.

By synthesising these strategies, this study is able to aggregate the critical themes from the available literature and international experience to suggest actions that marketing practitioners can employ to ensure success. In order for a firm to achieve its goals in a social media campaign, it has to identify the successful strategies first and ensure that those strategies run in tandem with its overall marketing strategy. The strategies could serve well to nurture the creative and adaptive marketing capabilities of the organisation.

Create Good Content

Social media and content have a symbiotic relationship: without social media, the content cannot be accessible, and without great content, social media is pointless (Kaplan & Haenlein, 2011; Kietzmann et al., 2011). Studies such as Dolan (2016) have shown that social media content design and delivery influence the engagement behaviour of Facebook fans. Consumers are more likely to generate eWOM about the firm and its products when they have adequate knowledge (Mangold & Faulds, 2009). For example, Starbucks gives tips to help people use its products on its 37-million-fans Facebook page. Pages are actually a great means of connecting with audiences where they hang out.

There are three main components to social media content strategy: type of content, time of posting and frequency of posting (Chauhan & Pillai, 2013). The type of content relies on form (i.e., how the information is presented—text only, images, links, video, amongst others) and context (i.e., company voice and platform trends). Since each audience is unique, firms must identify the best type of content, time of posting, and frequency of posting in order to accrue more engagement or more likes and follows. Moreover, to get more engagement, likes and shares, firms may need to continue to inspire their audience; make their content shareable, fun and useful; use great graphics and video; and cross-promote to other channels (Berthon et al., 2012).

Get the Right People to Spread the Message

Creating successful social media marketing requires the right people to spread the message (Pfeffer, Zorbach, & Carley, 2014; Tuten & Solomon, 2014). To effectively transform an ordinary message into an eWOM phenomenon, three groups of messengers are needed: market mavens, social hubs, and salespeople. In line with the conversion theory (Moscovici, 1980), these minority group of messengers have a huge effect on the majority. According to Kaplan and Haenlein (2011, p. 256), '[c]onsistent with classical laws of concentration, 20% of messengers can be expected to carry 80% of the load; it is, therefore, especially crucial to select wisely the initial hosts' for the message.

Market mavens are individuals with access to vast marketplace information, and proactively discuss and diffuse information (Feick & Price, 1987). The market mavens first receive the message and transmit it to

their immediate social hub, who begins the eWOM phenomenon. Social hubs are people with large social connections (Goldenberg, Libai, & Muller, 2001), who facilitate immediate transmission of the message to a large number of consumers. In cases where market mavens are not particularly convincing in transmitting the message, salespeople would be needed to amplify and transmit it to the immediate social hub for further dissemination (Kaplan & Haenlein, 2011).

Create Virtual Communities of Individuals with Common Interests

The literature has shown that consumers like to network with people of similar interests and desires (e.g., Mangold & Faulds, 2009; Weber, 2009). Organisations can, therefore, leverage on this desire by creating virtual communities of like-minded individuals, centred on shared interests and values (Rolls, Hansen, Jackson, & Elliott, 2016; Weber, 2009). Virtual communities encourage interaction, sometimes focusing on a particular interest or just to communicate. Users can interact over a shared passion through various means, namely, chat rooms, message boards, virtual worlds, or social networking sites. Since a virtual community potentially crosses geographical and political boundaries, it provides unprecedented leverage to grow and maintain a firm's network, as well as create eWOM.

For example, Roadrunner Records' website, www.roadrunnerrecords.com, has a forum for fans of rock and metal music where users connect and share interests. The Obama 2008 presidential campaigns leveraged on their online presence to attract supporters and provide information. Toyota leveraged on a blog written by a team of a father and a son who embark on annual 5000-mile adventures to unusual destinations in their Toyota FJ Cruiser. Readers respond to the blog by posting their own observations, insights, and stories. For many firms, these virtual communities provide various types of information for users, with opportunities for increased interaction via forums, chat rooms, and message boards (Mangold & Faulds, 2009). Such communities provide excellent consumer engagement.

Careful Planning and Little Intervention

As with any communication exercise, it is necessary to plan social media marketing campaigns carefully prior to their launch. Once the process is set in motion, intervention may be disastrous (Berthon et al., 2012;

Kaplan & Haenlein, 2011). Specifically, a truly compelling social media marketing campaign should be able to run independently and develop its own dynamics. Firms should, therefore, develop a comprehensive and robust social media strategy which can generate eWOM dynamically. A good example is Evian, whose Roller-Skating Babies campaign was crowned by the Guinness Book of Records as 'the most viewed advertising spot', with more than 45 million online views. Evian engaged in careful planning before launching the video: it chose the right topic (10 years earlier the company had an advertising campaign based on babies), the right music (a remix of a 30-year-old rap song), and the right messengers. Once the eWOM was unleashed, the company restricted itself to reacting to the eWOM phenomenon, instead of proactively swaying the message.

Create Separate Strategies for Each Channel

Users interact with content in different ways on different social channels (Entrepreneur, 2015). While some users may find pleasure in multiple channels, some have found a single community they love and are sticking with it, even when the lures of a new social channel arise. Some may favour one network today and in six months discover that another meets their needs better. A firm must follow such customers and prospects so it can network in all the right places. It needs to adapt its strategy accordingly while maintaining the same voice across channels. A firm can also seek out inspiration by checking out its top competitors. Investigating what the competitors are doing and how they engage with their followers, can help the firm to meet its consumers' needs better (Dixon, 2000).

Design Products that Create Buzz

To stimulate conversations, products and services should be designed with consumers' desired self-images in mind (Mangold & Faulds, 2009), and must be capable of generating buzz for the business. The key is products and services that are easy to use, fun, intriguing, highly visible, and engaging are more likely to inspire eWOM (Dobele, Lindgreen, Beverland, Vanhamme, & van Wijk, 2007; Dobele, Toleman, & Beverland, 2005). The iPhone is likely to be bought and discussed among consumers who want to be perceived as 'cool'. BMW cars are likely to be discussed and purchased among auto-enthusiasts who value 'the ultimate driving experience'.

Make the Message Memorable and Interesting

The message must be sufficiently memorable and interesting to have the potential to spur eWOM. To make a message more memorable and interesting, Kaplan and Haenlein (2011, p. 257) suggested minor adjustments to the message: 'One option is to rely on true stories about real people ("My brother has a friend, John Doe …"), which are often more persuasive than corporate advertising. Another option is to use rumours, especially positive ones that reflect well on the person telling them, as they have a particularly high chance of being transmitted to others. Moreover, there are the obvious safe bets like practical short lists (e.g., "The ten best ways to lose weight"), humorous or even hilarious messages'. In general, the message must trigger the receiver's emotions (Dobele et al., 2007), often with an element of surprise, joy, or fear. Also, marketing managers must exercise caution in using messages that may be too provocative or inappropriate.

Leverage Emotional Connections

People discuss topics or subject matters in which they are emotionally connected (Sashi, 2012). Customers may be emotionally connected to finding cures for diseases such as diabetes, cancer, and heart disease. Other emotional linkages include animal rights, environmental issues, child welfare, and education. To leverage emotional connections and generate eWOM, Mangold and Faulds (2009) suggest that organisations can embrace one or more causes important to their consumers. Pepsi, for example, decided not to run any ads during the 2010 Super Bowl. Rather, it spent an estimated US$20 million of the saved budget on the Pepsi Refresh Project, an interactive online platform where users can submit and vote on ideas that have positive impacts and can help make the world a better place (Kaplan & Haenlein, 2011). Ice cream producer Ben and Jerry's supports causes that are important to the founders and its customers. These causes range from investing in the nation's children, supporting family farms, avoiding the consumption of meat from cloned animals, and promoting social and environmental concerns.

Offer Exclusivity

Everyone likes to feel special (Leung, 2013; Mangold & Faulds, 2009). By offering products, information, and special deals exclusively to the consumers, feelings of specialness can be created (Mangold & Faulds, 2009).

For example, Starbucks' stand-out feature on social media is its active online consumer engagement. Starbucks provides its customers with the option to manage and reload their coffee cards online. It also makes it possible for its consumers to locate nearby locations, check out international Starbucks spots, and apply for jobs at its stores. Likewise, Unilever gives its reader's coupons and product samples from Dove's 'Campaign for Real Beauty'. Another example is XBox's Twitter page an interesting resource, with news update, slick advertising photos, and promotions. Gamers can get instantaneous responses to their issues at its @XboxSupport handle. Also, Xbox provides phone numbers and addresses common topics online.

Harness the Power of Storytelling

Stories can be memorable; they provide the connection between facts to make them memorable (Kosara & Mackinlay, 2013). The more memorable the stories are, the more likely they are to generate eWOM (Mangold & Faulds, 2009). Refined stories that depict a real, but still discreetly created image of a business are key to humanising a brand to existing customers, and potential sales leads. For example, the Adidas campaign 'Impossible is nothing' was successful because it communicated a true story; so authentic, that it touched consumers. It left the story of Messi, the concept of the campaign, and the brand impregnated in consumers' memory for years. The phrase 'Impossible is nothing' resonated like a scream of glory in people's ears, and since then Adidas has been associated with that spirit. Such stories create vivid memories that are likely to generate eWOM, as well as traditional WOM (Mangold & Faulds, 2009). Firms must, therefore, harness the power of social media, not just to 'share' content, but to 'tell it', and to 'narrate' the brand. Social media platforms need to be seen as a conversation channel; a transmission of experiences, values, dreams, feelings, failures, successes, and truths.

Solicit Feedback

Feedbacks are important for consumer engagement. Consumers become more involved with products and organisations when they can submit feedback (Mangold & Faulds, 2009). For example, Toyota solicits and gets feedbacks from consumers in the form of accolades, criticism, and helpful suggestions on a broad range of issues through its 'Open Road

Blog'. The feedback provides a sense of community in which open communications are stimulated, and customer engagement is boosted. An organisation can leverage its network, for example, before launching products to solicit the feedback of its virtual communities (Heller Baird & Parasnis, 2011). One of the greatest benefits of social media is that a firm's network probably consists of not only existing customers, but also target customers, prospects, and industry influencers. Indeed, a firm can get a wide range of feedback on new products (i.e., whether they are worth launching in the first place; whether they are easy to use; or what should be next in the development queue) and get the all-important community buy-in for greater adoption rates at launch time.

In line with the theory of social influence (Friedkin, 2006), people are strongly influenced by how they perceive their relationship with the influencer. Likewise, consumers are more likely to communicate when they have a relationship with the product or service. In particular, some companies have been encouraging consumers to submit photos or recorded footage of their product in action. For example, a promotion for Procter and Gamble's quick-clean product, *Swiffer* challenged consumers to make short videos recounting 'how they left their old cleaning method for a new romance with Swiffer'. Then, the top ten videos were posted on YouTube and consumers were asked to vote on the winner. The contest sparked a huge amount of attention. Such online voting provides Internet users with a sense of ownership and increased engagement.

Intensify Social Media Presence to Increase Reach

Search engines are beginning to adopt signals from social media sites into their search ranking design (e.g., Bing Social Search, TripAdvisor). Social media presence can therefore greatly increase a firm's search rankings (Demers, 2015). Recent studies (i.e., Ghose, Ipeirotis, & Li, 2014) have found that a consumer utility-based ranking mechanism on product search engines, that integrates multidimensional consumer preferences and signals from social media sites leads to significant surplus gain for consumers. As with most search ranking strategies, there is one basic principle: the better experience you give your users, the higher you rank in Google. Going by the norm of reciprocity (Burger, Sanchez, Imberi, & Grande, 2009), if a firm gives its users a better experience, it has opened the widest possible channel for new potential customers to find its brand.

Include the Rest of the Marketing Communications Mix

Despite all the advantages of social media in marketing communications, it needs to be accompanied by concerted efforts with the rest of the marketing communications mix (Mangold & Faulds, 2009). The buzz surrounding social media marketing usually dies out quickly. 'Nothing tends to be more boring than yesterday's news', the old saying goes. To maintain the eWOM momentum, social media marketing must be complemented with more traditional forms of communication. Kaplan and Haenlein (2011, p. 261) illustrated this by relating the story of Wilkinson's Fight for Kisses advertisement as follows: 'To support the launch of its newly-developed disposable razor, Quattro Titanium, the company relied on a viral marketing story about a baby fighting his father for kisses from the baby's mother. This campaign consisted of an animated video and an interactive computer game, combined with a series of press announcements, radio spots, and sponsorship of the France—Ireland rugby match that took place during the same time period. Despite its limited budget of only s62,000 (about US$90,000), the campaign was a huge success and resulted in a five-percentage-point market share increase within the target group'. Social media marketing promotes satisfactory results when utilised in combination with the rest of the marketing communications mix.

The literature has also demonstrated that social media play a significant role in driving traditional media activity (Kaplan & Haenlein, 2011; Mangold & Faulds, 2009). For example, Stephen and Galak (2012) analysed 14 months of daily sales and media activity data from a microlending marketplace using a multivariate autoregressive model. The authors found that both traditional and social earned media affect sales. However, because of the higher frequency of social earned media activity after adjusting for event frequency, social earned media's sales elasticity is significantly higher than traditional earned media's. Further, social earned media tends to play a significant role in driving traditional earned media activity. Organisations should, therefore, combine social media and the traditional media in order to achieve marketing success.

Managerial Implications

The study has shown that, in social media marketing, emphasis needs to be placed on creating and adopting effective strategies that can generate eWOM and make the brand go viral. The strategies synthesised in this study will, therefore, help managers to modify their marketing input. The

budding field of social media marketing tends to borrow many of the traditional off-line techniques for managing interpersonal influence (i.e., stimulating and creating opinion leaders) while at the same time creating new techniques aided by the special characteristics of social media. Marketing managers must understand that their consumers are going online in increasing numbers and that, on the social media, they are being exposed to and influenced by their competitors. Marketing managers should, therefore, take the lead in understanding and utilising the emerging technology and strategies of social media marketing.

This study has identified a series of available strategies for harnessing the power of the social media for firms to stimulate their marketing efforts. Firstly, as with any communication exercise, it is necessary to plan social media marketing campaigns extensively before their launch. Once the eWOM is launched, the company should limit itself to reacting to the eWOM phenomenon, instead of proactively swaying the message. Additionally, in contrast to traditional marketing, which involves limited customer participation, managers need to develop new forms of advertorial content that encourage user engagement. Marketing managers are more likely to generate eWOM if they continue to inspire their audience; make their content shareable, fun and useful; use great graphics and video; and cross-promote to other channels. As well, it is necessary to create separate strategies for each channel because users interact with content differently on every social channel. A firm must follow such customers and prospects so it can network in all the right places.

Creating successful social media marketing requires the right people to spread the message. To effectively transform an ordinary message into an eWOM phenomenon, therefore, a firm must employ the three identified groups of messengers (i.e., market mavens, social hubs, and salespeople) to spread the message. While spreading the message, organisations should create virtual communities of individuals with common interests, centred on shared interests and values. Such communities provide excellent consumer engagement.

To further stimulate eWOM, products and services should be designed with consumers' desired self-images in mind to create buzz. The message must be sufficiently memorable and interesting to have the potential to spur eWOM. Marketing messages must trigger the consumer's emotions. Firms must leverage emotional connections because people discuss things to which they are emotionally connected. Likewise, people like to feel special. To leverage on this, managers must provide exclusivity.

Also, marketing managers must harness the power of stories. Stories can be memorable. The more memorable the stories are, the more likely they are to generate eWOM. Feedbacks are, as well, important for consumer engagement. Indeed, a firm can get a wide range of feedback on new and existing products and get the all-important community buy-in for all the ranges of its products. Firms must also increase social media presence in order to greatly increase their search rankings. If a firm gives its users a better experience, it has opened the widest possible channel for new potential customers to find its brand. Also, social media marketing must be complemented with the rest of the marketing communications mix. To maintain the eWOM momentum, therefore, firms should combine social media and the traditional media in their marketing campaigns.

Limitations and Implications for Future Research

Given the conceptual nature of the study and the fact that social media is an emerging field of research, the strategies should be considered exploratory. Although many global companies have successfully created eWOM with the identified strategies, surveys should be carried out to provide a better-grounded view of the social media strategies. Also, a longitudinal examination of social media strategies is necessary in order to determine how firms adjust their strategies over time.

Further, the strategies offered in this chapter suggest a number of interesting research questions. What strategies are most consistent with successful social media marketing? Some strategies have been offered, but that list is by no means exhaustive. What range of marketing strategies and associated practices flows from social media? How do the connective processes in social media contribute to the development of marketing practices?

Some social media strategies emerge over time and are not always preplanned. Investigation into those strategies means focusing qualitatively on the connective capabilities of social media and on the psychology of e-conversations that can lead to transformative change in marketing. One way to approach some of these questions would be to construct some high-level, exploratory hypotheses tying a marketing approach on social media to perceived strategic resources to organisational outcomes. One could construct a hypothesis concerning the significance of a social media strategy, and another pertaining to the degree of usage of the strategy, covering the intention and execution. For instance:

- Competitive advantage flows from appropriate marketing strategies on social media.
- Greater usage of social media marketing strategies is associated with greater relative industry performance.

A possible method for exploring these hypotheses might be to pick comparator companies, who have relatively equal strategic positions in the same industry, and gather qualitative data on their respective social media marketing schemes. Qualitative and quantitative comparisons of high-and low-performing firms in the same industry could as well be constructed to explore the hypothesis and to help in the construction of others more specific. Most significant and perhaps generalisable findings out of such a study would be not just the particular strategies themselves but the mechanism and rationale within the firm of drafting such strategies (e.g., the participants, time frames, conversations, and inputs).

Beyond the above macro-oriented questions, managers should, on a practical level, initiate their own studies focused on their specific products and services to assess the level of current eWOM and explore different strategies to increase it.

CHAPTER 5

Social Media Technologies and Export Marketing

Frederick Avornyo, Mahmoud Abdulai Mahmoud, Ogechi Adeola, Robert Ebo Hinson, and Richard Boateng

Introduction

Social media marketing is a major enabler of small- and medium-scale enterprises (SMEs) venturing into the international markets (Berthon, Pitt, Plangger, & Shapiro, 2012; Okazaki & Taylor, 2013). Social media, as a resource to drive marketing, enables small firms with limited resources to improve their international communication, be more efficient with market transactions with customers abroad, achieve foreign customer satisfaction and loyalty, and generally develop international network relationships (Alarcón-del-Amo, Rialp, & Rialp, 2015). These qualities, defined as international social media competencies by Alarcón-del-Amo et al. (2015), lead to the rapid internationalisation of SMEs through exports

(Alarcón-del-Amo, Rialp, & Rialp, 2017). SMEs generally struggle to internationalise due to inadequate resources (Paul, Parthasarathy, & Gupta, 2017). A key challenge is the ability to communicate effectively with foreign customers (Paul et al., 2017), but this appears to be changing with the advent of social media, justifying the position by scholars that social media is changing the conduct of business, and internet technology, in general, has reduced the cost of international business (Galati, Crescimanno, Tinervian, & Fagnani, 2017; Kaplan & Haenlein, 2010; Paniagua, Korzynski, & Mas-Tur, 2016; Sinkovics, Sinkovics, & Jean, 2013). The changes in the conduct of business triggered by social media, therefore, require that more scholarly attention should be directed towards the phenomenon.

The ability of the internet technology to facilitate export has been attested to and gained much scholarly attention (Gregory, Ngo, & Karavdic, 2017; Hinson, 2010; Sinkovics et al., 2013). However, high cost and reliability of internet technology (emails and websites) have been found to be impairing its successful adoption by SMEs in developing countries (Boateng, Heeks, Molla, & Hinson, 2011; Hinson, 2010). This narrative could also be changing with the emergence of social media, the revolutionary internet-based technology, which is offering firms new ways of interacting with their stakeholders (Alarcón-del-Amo et al., 2015; Kaplan & Haenlein, 2010). Importantly, social media is cheaper and easier to use, provides global reach, breaks time and distance barriers, makes communication immediate and engenders networking between the firm and the foreign consumer (Alarcón-del-Amo, Rialp, & Rialp, 2016; Berthon et al., 2012; Genc & Oksuz, 2015; Odoom, Anning-Dorson, & Acheampong, 2017; Okazaki & Taylor, 2013). The ability to access social media via the mobile phone, which has high penetration rate, is considered an added advantage, making it an important and easy-to-use resource (Packer, 2011) for owner-managers of SMEs.

The impact of social media resource on exports is indisputable (Alarcón-del-Amo et al., 2017), as affirmed by recent findings by a few scholars. The global logistics company UPS also confirms that 'social media is having a profound effect on exporters, and in particular, on small businesses, that often find their goods in demand from overseas customers long before they have thought about breaking into international markets' (compass.ups.com, n.d.). This claim by UPS is consistent with international marketing literature which suggests that social media is enabling

otherwise cash-strapped firms or SMEs, which could not afford physical presence on the international market, to be in a position to have their products on the international market (Alarcón-del-Amo et al., 2017).

However, some authors argue that firms' mere presence on social media cannot be the reason for the rapid internationalisation of SMEs (Alarcón-del-Amo et al., 2017), rather success is achieved when firms are able to align the social media resource and other complementary resources, to the needs of consumers in foreign markets (Seggie & Griffith, 2008). This assertion is further buttressed by the argument that technology on its own cannot lead to performance, while firm resources alone can neither produce significant gains in firm performance (Bharadwaj, 2000; Trainor, Andzulis, Rapp, & Agnihotri, 2014). Scholars posit that firm performance is possible when technological resources such as social media is combined with firm's strategic resources to achieve distinctive capabilities (Alarcón-del-Amo et al., 2017; Trainor et al., 2014). This is consistent with the assertion by the Resource-Advantage (R-A) theorists, who argue that firms combine resources, both tangible and intangible, to achieve superior performance (Hunt & Arnett, 2003; Hunt, & Morgan, 1995).

Scholars have empirically verified that social media utilisation leads to firm performance (Luo, Zhang, & Duan, 2013; Paniagua & Sapena, 2014) and export performance specifically (Alarcón-del-Amo et al., 2017). However, the issue as to what resource combination SMEs on social media are aligning to the needs of foreign consumers, to achieve this export performance, appears not to have been adequately addressed by extant literature (Alarcón-del-Amo et al., 2017). Social media is considered nascent (Killian & McManus, 2015) and social media application to international marketing is still considered emerging (Okazaki & Taylor, 2013), and therefore not surprising that research into social media marketing and export is scanty (Paniagua et al., 2016). This chapter, therefore, seeks to understand which resources firms are integrating with social media to achieve superior performance. The study is linked to the central focus of the resource-advantage theory (R-A) theory and is, therefore, premised on the approach. The rest of the chapter looks at the theoretical foundation of the study, a review of the literature on social media marketing, a discussion on social media export marketing capabilities, social media and export performance measurement, proposes a framework and presents its conclusions.

Theoretical Foundation

Social media is a resource (Paniagua et al., 2016; Wang & Kim 2017) which firms efficiently and effectively combine with other resources to achieve superior performance (Alarcón-del-Amo et al., 2016; Wang & Kim, 2017). This assertion is in sync with the R-A theory that firms are combiners of dynamic and heterogeneous resources to create a comparative advantage leading to competitive advantage and superior financial performance (Hu & Wang, 2009; Hunt, 2011; Hunt & Morgan, 1995; Thoeni, Marshall, & Campbell, 2016). The theory places emphasis on innovation, market segments, heterogeneous firm resources, a comparative market advantage/disadvantage in resources and a marketplace position of competitive advantage/disadvantage (Hunt, 2001, 2012). R-A theory enumerates seven resources which it argues are available to firms. They include financial, physical, legal, human, organisational, informational and relational (Barua & Michie, 2014; Hunt 2001, 2012). The theory posits that firms combine both tangible and intangible resources to deliver value for a segment of the market which is akin to what exporting SMEs present on social media do. They combine social media marketing with other firm resources to deliver value to customers in the international segment of the market.

R-A theory was propounded in 1995 by Shelby Hunt and Robert Morgan in an article titled 'The Comparative Advantage Theory of Competition'. It is an interdisciplinary and evolutionary general theory of competition that evolved from ten different research traditions (Seggie & Griffith, 2008) and has 12 foundational premises and a structure (Hunt & Arnett, 2003). Hunt and Arnett posit that R-A is

> an evolutionary, disequilibrium-provoking, process theory of competition, in which innovation and organisational learning are endogenous, firms and consumers have imperfect information, and in which entrepreneurship, institutions, and public policy affect economic performance.

This suggests that firms will avail themselves of innovations (such as social media), and as they combine resources available to them to achieve superior performance (such as in export), they will learn internally (since organisational learning is endogenous) which resources would deliver better outcomes, so they can determine, in which resources more investment commitment should be made (Rest & Roper, 2013).

The theory also argues that firms combine an assortment of resources available to them in order to have a comparative advantage in resources

(Hunt 2012; Hunt and Morgan, 1995, 1997). For firms, this will result in a marketplace position of competitive advantage and hence superior performance (Hunt, 2012; Hunt & Arnett, 2003). On the other hand, a comparative disadvantage in resources will lead to a marketplace position of competitive disadvantage and inferior performance, with a third position being where there is parity (Hunt, 2011). It, therefore, becomes relevant for firms to appreciate what resource combinations deliver comparative advantage and ultimately superior performance and which ones deliver the opposite outcomes.

Since its seminal paper in 1995, several other researchers have contributed to the theory by using it as basis to explain various phenomena including resource matching and globalisation of services (Seggie & Griffith, 2008), to demonstrate that Corporate Social Responsibility is core to firm operations (Hu & Wang, 2009), while others have extended the theory into firm's pricing strategy (van der Rest & Roper, 2013). However, a review of the extant literature on R-A theory did not reveal its usage to explain the social media marketing and export performance phenomenon. This is in spite of the fact that R-A theory is considered a marketing strategy theory, while social media marketing has become an integral part of marketing strategy for firms (Akar & Topçu, 2011; Barua & Michie, 2014; Schlegelmilch, 2011). Additionally, the list of seven resources as provided for by the R-A theory cannot be exhaustive as marketing practice is dynamic (Grönroos, 1994). The list of resources could, therefore, be extended. The chapter also argues that not all the seven resources can be of equal importance to a firm. The Competitive Position Matrix of R-A theory demonstrates that some resources will lead to marketplace position of competitive advantage, while others may not (Hunt, 2001). On that basis, it is argued that some resources may be of higher importance than others. The most relevant resources can be classified as core and the rest secondary. This qualification of the resources is considered relevant, as the complementarity or otherwise of the resources could influence how they are converted into capabilities and eventually to superior performance (Trainor et al., 2014).

Literature Review

Social media marketing is one of the contemporary marketing concepts, and business practitioners are seeking to understand how to apply it effectively in order to achieve superior performance (Packer, 2011). It has unique features which could explain the special traction it has received in

recent times in preference to the older internet-based technologies (Elena, 2016; Mangold & Faulds, 2009). These features include the easy and quick unfettered access to the global market, content co-creation, real-time interactivity and engagement between the firm and the consumer as well as among consumers (Martin, Goncalves, Oliveira, Cota, & Branco, 2016; Wang & Kim, 2017). Social media marketing emerged following the advent of social media platforms such as Facebook, Twitter, Instagram and several other forms such as Pinterest, YouTube, WhatsApp, LinkedIn, Google+, Snapchat (Paniagua et al., 2016; Socialpilot.co, n.d.). It consists of text, pictures, videos and networks (Berthon et al., 2012). Attempts have been made to categorise the various social media platforms into

1. collaborative projects such as Wikipedia,
2. blogs and user-generated content communities such as YouTube,
3. social networking sites such as Facebook,
4. microblogs such as Twitter,
5. virtual game worlds such as EverQuest and
6. virtual social worlds such as Second Life (Berthon et al., 2012; Kaplan & Haenlein, 2010; Okazaki & Taylor, 2013).

Social media is a Web 2.0 application which allows for two-way and many-to-many ways communication (Ananda, Hernández-García, & Lamberti, 2016). Scholars have explained Web 2.0 to be the interactive component of Web 1.0 (Yadav & Rahman, 2017), as Web 1.0 is only a one-way application such as websites (Constantinides, 2014). One of the scholars cited as a pioneer, Tim O'Reilly (Berthon et al., 2012) sees social media in the light of Web 2.0 and defines it in a technical sense as 'a set of principles and practices that tie together a veritable solar system of sites that demonstrate some or all of those principles, at a varying distance from that core' (O'Reilly, 2007). Subsequently, Kaplan and Haenlein (2010) simplify it as an internet-based application that allows for the creation and exchange of user-generated content, but they also draw the linkage with Web 2.0.

Though the definitions found in extant literature are varied, there are commonalities which include the fact that social media is an internet-based technology (Kaplan & Haenlein, 2010), modelled on Web 2.0 (Constantinides, 2014; Wang & Kim, 2017) that allows users to interact, share information and co-create content (Berthon et al. 2012). Based on these various definitions, and others in extant literature, this chapter

conceptualises social media as a social Web 2.0 platform that allows for real-time interactivity and content co-creation among users, in the form of text, picture, video, audio and network (Berthon et al., 2012; Constantinides, 2014; Kaplan & Haenlein, 2010).

Social media marketing on the other hand involves the use of social media technology for firms' promotional activities (Akar & Topçu, 2011; Kaplan & Haenlein, 2010) to achieve a firm's goal by creating value for its various stakeholders (Felix, Rauschnabel, & Hinsch, 2017; Tuten & Solomon, 2015) and for relationship building (Chang et al., 2015). Based on these cited expert views (i.e. Chang et al., 2015; Felix et al., 2017), we define social media marketing as the use of social media for marketing activities, including research, promotion, distribution and engagement with and among stakeholders, for value creation.

Thematic Areas

We reviewed 133 articles to address various issues which were synthesised into ten thematic areas for the purpose of this chapter. A significant number of articles (27.8%) examined factors that influence social media adoption in order to determine how firms can be successful with its application (Chikandiwa, Contogiannis, & Jembere, 2013; Galati et al., 2017). Some examined social media and branding (Bruhn, Schoenmueller, & Schäfer, 2012; Nguyen, Yu, Melewar, & Chen, 2015), and how social media could predict consumer behaviour (Godey et al., 2016; Kim & Drumwright, 2016). Other scholars delved into how social media influences electronic word of mouth and its impact on the operations of firms (Erkan & Evans, 2016; Teng, Khong, Chong, & Lin, 2017). Other thematic areas identified include social customer relationship management (Malthouse, Haenlein, Skiera, Wege, & Zhang, 2013; Trainor et al., 2014; Wang & Kim, 2017), social media and marketing communications (Mangold & Faulds, 2009; Wang, Pauleen, & Zhang, 2016), and social media marketing strategy (Ananda et al., 2016; Felix et al., 2017). There are also articles that addressed how social media impact firm performance (Luo et al., 2013; Moro, Rita, & Vala, 2016), social media challenges (Kaplan & Haenlein, 2010; Schultz & Peltier, 2013) and finally social media and internationalisation (Alarcón-del-Amo et al., 2017; Berthon et al., 2012; Paniagua et al., 2016).

Three thematic areas namely social media adoption, social media and branding as well as social media and consumer behaviour jointly accounted

for 62.4% of the literature examined, while social media marketing strategy, social media challenges and social media and internationalisation, which included export, were among the least researched areas. This finding is consistent with the suggestion by Paniagua et al. (2016) and Alarcón-del-Amo et al. (2017) that the theme, social media and export is under-researched and requires more scientific research attention.

Social Media Adoption and Exporting SMES

Businesses have adopted social media to enhance their marketing operations. Some have achieved success (Felix et al., 2017) others have not witnessed the corresponding improvement in firm performance (Zhu & Chen, 2015). These two outcomes have engendered scholars to research into factors that influence a successful adoption of social media (Martin et al. 2016; Packer, 2011), and the various adoption models and how they impact success (Chikandiwa et al., 2013; Felix et al., 2017).

Chikandiwa et al. (2013) identify two social media adoption models. The first is based on how social media is managed within the organisation; whether it is decentralised or not. They list centralised, distributed, 'coordinated hub and spoke', as well as 'multiple hub and spoke', as forms of adoption frameworks. According to the authors, the 'coordinated hub and spoke' is the adoption model where tactical decision considering a single higher department takes the adoption and usage of social media, but the implementation is decentralised at the various departments within the firm. In the case of 'multiple hub and spoke', again the tactical decision is a top management action, but the implementation is further decentralised beyond departments to smaller units such as product lines. However, in the case of the centralised model, both tactical decision and implementation is the sole responsibility of a dedicated department or unit, and the reverse holds for the distributed model. The second category of social media adoption model by Chikandiwa et al. (2013) examines the various social media adoption stages. They include the social media strategy learning curve, social media adoption curve, social engagement journey and social media maturity model. The authors then explicate the intricacies of each stage and how firms behave at those stages of maturity in the adoption of social media.

Felix et al. (2017) also propose a four-dimensional model which looks at the scope, the culture, the structure and the governance. The scope is concerned with whether firms use social media to engage a few stakehold-

ers or it is an imbibed and holistic philosophy that ensures that both employees and external stakeholders are engaged using social media. In terms of culture, the scholars seek to address the question whether a firm adopts a conservative or modern approach towards the use of social media. Structure, on the other hand, is similar to Chikandiwa et al.'s (2013) first category, which looks at the centralisation or otherwise. Felix et al. (2017) however use the term hierarchies to denote centralisation, and networks to represent a decentralised system of social media usage in a firm. The last dimension is governance. Where there are strict regulations as to who is permitted to use social media within the firm, it is referred to as autocracy, but where there is no strict compliance, it is termed anarchy. Felix et al. (2017) however suggest that in adopting social media, firms should be flexible and have a blend of the dimensions and also use influencers within the firm to lead the social media adoption model.

It should be noted that the studies conducted by Chikandiwa et al. (2013) and Felix et al. (2017) are not specific to SMEs, particularly exporting SMEs. SME-biased researches, however, are extremely important because they dominate most economies (Opoku, Abratt, Bendixen, & Pitt, 2007; Stoian, Rialp, & Rialp, 2011) and more importantly exhibit unique characteristics such as the dominance of owner-managers, inadequate resources to have a full-fledged organisational set up, but quick and flexible in decision making (Lu & Julian, 2008; Mehrtens, Cragg, & Mills, 2001; Paul et al., 2017). This chapter posits that the decision as to which social media adoption model to opt for is constrained by the social media competence of the owner-manager, the strength and quality of the human resource available to the firm, and financial resources to outsource the role of managing the firm's social media marketing implementation. A study conducted on SMEs' social media adoption model, should, therefore, bring out these perspectives unique to SMEs. This chapter, therefore, takes the position that the unique characteristics of SMEs would influence their social media adoption model. A resource-strapped but social media savvy owner-manager of an exporting SME, for instance, may also be constrained by time availability, to continually update its page, respond and regularly engage with online customers who may be of different time zones.

The argument that SMEs could have different social media adoption model is supported by Genc and Oksuz (2015) who clearly demonstrate the large-scale and small-scale business dichotomy by indicating that small businesses have a more liberal approach to social media compared to their

large-scale counterparts. Where there is no difference between large and smaller firms is the compelling reason for social media adoption which is the attainment of superior performance (Genc & Oksuz, 2015; Martin et al., 2016), and this can be achieved if firms succeed in effectively and efficiently combining resources available to them. The mere presence of exporting SMEs on any of the social media platforms would not guarantee them superior performance but rather their ability to combine it with the right set of resources (Bharadwaj, 2000; Gregory et al., 2017; Hunt & Morgan, 1997; Trainor et al., 2014). This assertion makes the ability to identify the set of resources that integrates well with social media for exporting SMEs an important scientific enquiry.

Social Media Export Marketing Capabilities

Marketing capabilities have been studied by previous researchers (Barney, 1991; Day, 1994; Hunt, 2011) and also the issue of technology capabilities (Bharadwaj, Bharadwaj, & Konsynski, 1999; Rasiah & Myint, 2013; Wignaraja, 2002). Capabilities have been defined as 'an organisation's ability to assemble, integrate and deplore resources in combination to achieve a competitive advantage' (Trainor et al., 2014). In social media marketing, Alarcón-del-Amo et al. (2016) define social media capabilities 'as an integrated set of strategic resources and capabilities that can create, through the use of social media applications, sound competitive advantages and superior firm performance based upon a more effective information management'. This is distinct from 'an integrated set of technological resources' which is termed as social media competence (Alarcón-del-Amo et al., 2015). Some scholars have tried to explain social media internationalisation capabilities. For instance, Paniagua et al. (2016) list identity, conversation, sharing, presence, relationship, reputation and group as social media resources. They, therefore, argue that converting these social media resources into capabilities that enable a firm to internationalise will constitute social media internationalisation capabilities. The assertion, however, does not explain how the social media resource is converted into capabilities.

Based on various explanations, this chapter attempts to define social media export marketing capabilities as a firm's ability to effectively and efficiently combine social media marketing resources with key strategic firm resources to achieve superior export performance (Alarcón-del-Amo

et al., 2017; Hunt & Morgan, 1997; Trainor et al., 2014). The more significant concern though is the ability to determine which firm resources combined with social media marketing can create the export capabilities. This chapter agrees with R-A theorists that resources available to firms are financial, physical, legal, human, organisational, informational and relational. It however opines that since SMEs are dominated by owner-managers (Paul et al., 2017) and are constrained financially, the owner-manager who is social media savvy is likely to be the key or even sole person updating the social media platforms, responding to customer enquiries and regularly engaging with customers, some of whom may be living in places with different time zones. As a result, an own-manager will require enough time to effectively and efficiently utilise the social media resource. Time availability, therefore, becomes an important factor in the operations of exporting SMEs. Scholars such as Klein (2007) have suggested that though some researchers consider time as a commodity, time also exhibits features that qualify it as a resource. In corroboration with the argument by Klein (2007), this chapter considers time as a resource that exporting SMEs present on social media require. Premised on the R-A theory, it is advocated that exporting SMEs would need to effectively and efficiently combine social media marketing with financial, physical, organisational, legal, human, relational, informational (market intelligence) and time to develop capabilities for export performance. This study, therefore, extends the R-A theory by proposing time as an 8th resource to the existing seven. It further argues that resources could produce different outcomes as held by the R-A competitive position matrix (Hunt, 2001; Hunt & Arnett, 2003). Some will generate a marketplace position of competitive advantage and others competitive disadvantage (Hunt, 2012). It also postulates that some resources may be more complementary compared to others. The eight resources can, therefore, be categorised into core and secondary resources. These set of firm resources can, therefore, be empirically verified to determine which ones can be considered as core, secondary or irrelevant to exporting SMEs.

Social Media and Export Relationship Performance

Export performance has been measured using financial and accounting ratios such as return on investment, return on equity and the various profitability ratios (Lages & Lages, 2004) or through the use of other absolute values such as export sales volume or export market share (Beleska-

Spasova, 2014). It has also been measured using non-financial performance indicators which are considered subjective but relevant in determining export performance (Morgan, Vorhies, & Mason, 2009). The inclusion of non-financial export performance measurements has been largely necessitated by the difficulty in gathering financial data on SMEs in particular (Ibeh & Wheeler, 2005). However social media is first of all a social online technology (Schultz & Peltier, 2013) and thrives on networking and relationship which are also essential ingredients for SME success (Felix et al., 2017; Kaplan & Haenlein, 2010; Kietzmann, Hermkens, McCarthy, & Silvestre, 2011; Nguyen et al., 2015; Trainor et al., 2014). This chapter, therefore, argues that the measurement of export performance of SMEs on social media platforms cannot ignore the firm's success at maintaining relationships with foreign customers, as one of the performance indicators. An export performance tripod is proposed with the third leg categorised relationship performance.

Although export relationship performance can be categorised as a non-financial measurement, the centrality of networking and relationship to social media marketing, requires that export relationship should be treated as the third leg of export performance measurement. Trainor et al. (2014) conceptualised relationship performance within the social media context, developed a scale and tested it. This study adopts this and terms it 'export relationship performance'. It is defined in this chapter as the level of relationship between exporting firms and their foreign customers (Trainor et al., 2014). Adapting from Trainor et al. (2014), export relationship performance measures

1. how long foreign customers have worked with firms,
2. how long new foreign customers tend to stay,
3. how loyal they perceive foreign customers to be,
4. how satisfied they perceive foreign customers to be and
5. how important customer retention is to the firm.

These five measurable variables will help to determine how successfully a firm on social media has effectively utilised the social media technology to engage customers in the export market segment. Introducing the third measurement, which has not received adequate attention in the area of export performance, is considered an important contribution to the literature on export performance.

Conceptual Framework

Following from the discourse, it is argued that SMEs can achieve export performance because they are successful at efficiently and effectively integrating the social media (platforms) resource with complementary strategic resources and aligning them to the interest of the foreign customer (Seggie & Griffith, 2008; Trainor et al., 2014). This study, therefore, proposes a framework that encapsulates the various social media platforms that exporting SMEs are leveraging on and the resources they combine to achieve export performance which includes relationship performance as demonstrated in Fig. 5.1.

Notably, WhatsApp, Facebook, YouTube, Facebook Messenger and Instagram are amongst the topmost social media platforms in the world (Genc & Oksuz, 2015). However, since Facebook messenger is an application on Facebook, this research merges it with Facebook as one platform. The study then adopts the seven resources listed by R-A theory: financial, physical, legal, human, organisational, informational and relational (Hunt, 2012), and includes 'time' as the eighth resource. The chapter posits that exporting SMEs should integrate these resources with social media, effectively and efficiently to achieve financial, non-financial and export relationship performances (Fig. 5.2).

Conclusion

Social media, a relatively cheap resource available to otherwise cash-strapped SMEs (Alarcón-del-Amo et al., 2016) is creating a new era for businesses, with the competency to improve international communication, efficiency in the international market transaction, loyalty with foreign customers and development of international network (Alarcón-del-Amo et al., 2015). It facilitates firm internationalisation by enabling firms to reach out to customers in other countries, while avoiding the cost and hurdles of physically setting up in the foreign market (Berthon et al., 2012; Okazaki & Taylor, 2013). However, research on social media marketing and export is scanty (Paniagua et al., 2016). Although few studies in the area have affirmed the positive relationship between social media marketing and export performance, there is limited focus on the combination of firm resources that enables performance.

This chapter therefore posits that since firms combine resources (Hunt, 2012), and firm performance is enhanced by the conversion of combined resources into capabilities (Alarcón-del-Amo et al., 2016; Bharadwaj, 2000; Bharadwaj et al., 1999; Trainor et al., 2014), exporting SMEs are

able to achieve export performance by efficiently and effectively combining social media marketing with financial, physical, legal, organisational, human, relational and informational, and the new addition, time, resource. The chapter further suggests that firm resources are not of equal importance and therefore advocates a further qualification of the resources into core and secondary. The study also posits that to investigate social media marketing and export, export performance should not be assessed solely based on the traditional financial and non-financial indicators but also on an additional factor, export relationship performance. However, the arguments made can only be generalised if they are empirically validated. Further research is therefore proposed to test the assertions made.

CHAPTER 6

Data Analytics and Predictive Analytics: How Technology Fits into the Equation

Brian J. Galli and Gabrielle Muniz

Introduction

Throughout the years, technology has changed considerably. In the mid-1960s, mainframe computers were state of the art in the information-processing kingdom. Although IBM has existed since 1952, behemoths were produced by the 1960s and 1970s. The term "mainframe computer" was largely synonymous with IBM because of the company's dominant market share at the time. These things were room-filling metal contraptions of vacuum tubes and wires that had to be air-cooled to avoid overheating. The cost was upwards of $3 million in 1960s dollars (Klimberg, 2016)! Also, memory was about 5121 KB, and hard drive storage was about 350 MB, while processing speed was a scorching 1 MIPS (million instructions per second). This, of course, mirrors Bill Gates's (in)famous 1981 statement: "640 KB ought to be enough for anybody."

However, there was quite a reversal by 2016 with the iPhone 6. This phone featured 32 GB (+9300%) of memory and was pocket sized. Author and futurist Ray Kurtzweil notes that cell phones are much cheaper, more

B. George, J. Paul (eds.), *Digital Transformation in Business and Society*, https://doi.org/10.1007/978-3-030-08277-2_6

powerful, and more compact than a standard computer. Compared to the computer at Massachusetts Institute of Technology (MIT) in 1965, the cell phone is a billion times more capable per dollar/euro (Klimberg, 2016). Though most corporate executives would suggest that their two most valuable corporate assets are their people (employees) and their products, a closer look at the products and their composition reveals that data is often listed as a primary component. That would include customer data and the actual product data required for creating output. Many businesses have now come to embrace this concept and have built analytics or intelligence units to better understand and utilize the data within their control (Buchanan, 2017).

According to IBM, there are many advanced analytics capabilities that come from predictive analytics, for example ad hoc statistical analysis, real-time scoring, predictive modeling, text analytics, and data mining, to name only a few. With these tools, patterns can be found in data to help businesses to predict the future. The field of "big data" has also expanded to include activities around data mining, machine learning, and artificial intelligence to better optimize the "10,000-foot view" of a company's business. The term "predictive analytics" can be thought of as a catch-all for disciplines, which includes regression analysis: a technique that looks at values of correlated variables to prove or disprove a specific set of assumptions (Marvin, 2016).

Furthermore, predictive analytics is about recognizing patterns in data to project probability, according to Allison Snow, senior analyst of business-to-business (B2B) marketing at Forrester. One must realize that analytics is centered on probabilities, rather than facts. It is impossible to know what data is significant with predictive analytics, while it is usually the opposite case for traditional analytics. With predictive analytics, one can indicate the predictive data for the particular outcome that is being predicted (Marvin, 2016). For example, a company may have a model for predicting how much a particular customer may purchase over time. The model could also be based on purchases that the customer has already made, which predicts the next product that they are likely to buy. Sales forecasting and the use of marketing models to plan where best to place advertising buys are examples of predictive analytics (Davenport, 2014).

Thomas H. Davenport, a distinguished professor in management and information technology at Babson College, is a research fellow at the MIT

Initiative on the Digital Economy. He observes that the three components of supporting predictive analysis—the data, the statistics, and the assumptions—are all critical contributors to the final product. They are compared to the legs of a three-legged stool, each of which can cause a collapse if it is not functioning correctly. Davenport points out that the assumptions underlying a data set or statistical evaluation process are equally important to the data and the statistics. The primary assumption in a predictive analysis is often that the future always mirrors the past. For instance, the financial crisis between 2008 and 2009 was the result of invalid models that predicted the likelihood of mortgage customers repaying their loans, since the decline of house prices was not considered. As house prices fell, the models were useless in predicting mortgage repayment, given that a hidden assumption was that housing prices would always rise (Davenport, 2014). Clearly, the data and the statistics provide a necessary balance for conclusions drawn from the assumptions.

Moreover, both data analytics and predictive analytics are potent tools for extrapolating conclusions from data. Data analytics and predictive analytics are usually associated with being effective means of information analysis that exchange privacy for results. Also, there are staggering numbers of applications for this kind of analysis, especially with the various methods of recording information. Many companies are already applying these analytical techniques, and they will continue to refine them as the field expands. As more technology is being incorporated into products, those products provide more data for the producing companies. When data is made more readily available, then companies can find correlations between trends based on that data. Thus, they can draw different conclusions from the premises of their research.

Though data analytics and predictive analytics can be used to learn many things, they are not without their downsides. To reveal these downsides, we will explore both current and future applications of data analytics and predictive analytics, as well as how they function in different environments. We will explore how the flexible nature of the fields allows for data analytics and predictive analytics to apply to many purposes and contexts. Afterwards, we will explore the various benefits and drawbacks of using data analytics. Understanding how this type of analytics will be used, what is required, and the results that it provides will help to reveal which fields will most benefit from this kind of analytics.

The Value of Analytics

Essentially, there are a vast number of opinions about the usefulness and reliability of data and predictive analytics, since data analytics is applicable to many different fields. The uses of data analytics are innumerable, but more often than not they will relate back to theory testing. For example, someone will generate a theory based on existing data, a hypothesis, or even a whim, and will then create a model to process data to find correlations between that theory and the accumulated data. There is a great amount of data within scientific fields (i.e., medicine, biology, physics, etc.), so big data analytics can open the door for many scientific breakthroughs (Zhao, Gao, & Liu, 2018).

Regarding how the data is being processed, it is somewhat different for comprehensive data analytics and predictive analytics. Data analytics requires the manipulation of a data set for information, either about the evidence itself or a specific conclusion. Information about evidence is typically referred to as metadata, and it helps to observe trends, patterns, and so on. Predictive analytics works on a different level, while also working from a base data set. It uses both data and metadata to determine the likelihood of an event. Furthermore, predictive analytics is an excellent technique for determining risk management, but its accuracy is determined both by the data size and by the accuracy of existing data. Subsequently, we will be observing the uses of data and predictive analytics from medicinal, governmental, business, personal, scholastic, and financial perspectives.

The highest concentration of predictive analytics appears to be located in the pharmaceutical world, at least from the pool of information that can be observed. Healthcare professionals can make use of these techniques to determine which medications are right for individual patients, as models can forecast the risks and benefits of using medications (Flynn & Stevenson, 2018). This would require large companies to share data and existing predictive models, such as with the US Food and Drugs Administration's (FDA) Sentinel Initiative. Flynn and Stevenson also discuss the potential of wearable technology to give medication providers valuable data, as well as the tradeoff that many users may not want their information to be shared with those companies (Flynn & Stevenson, 2018). Trading privacy for better-tailored products, whether it is medicine or something else, is a common theme with these analytics (Manisha & Lathwal, 2016).

On the other hand, government institutions, such as the US Internal Revenue Service (IRS), make use of data analysis, but it is done in a somewhat dubious manner. While data mining often goes hand in hand with

government bodies, such as the National Security Agency (NSA) or the Department of Defense (DOD), it can be used to determine a variety of different things for other than security purposes. The IRS has moved on to creating profiles of taxpayers that are constructed from both public and commercial data sets, with the data processed using analytics. However, Houser and Sanders argue that these practices work against fair information practices and are a substantial threat to privacy. While these practices are very cost efficient for the IRS, they are invasive of taxpayer privacy and can lead to further government overreach (Houser & Sanders, 2017).

Additionally, data and predictive analytics can be applied in the workplace environment. Tasks such as hiring, training, and employee performance can also be enhanced by data analytics. Many companies use data analytics to make observations about their environment, but rarely do they use them to improve their training and business development. A business can analyze its data to figure out more cost-effective means of operating, as well as which hires are more likely to be successful (Giacumo & Breman, 2016).

Another newer method of data collection is coming from automobiles, specifically from electric vehicles. Analysts are referring to the information that is collected from these cars to make future improvements to their design without using any personal information about the consumer. Various aspects are recorded, such as charging time, charger style, driving distances, daily drives, charging frequencies, and other information about product use. By observing the typical usage patterns for their vehicles, designers can design better and newer versions of those products to cater to the data collected (Ahmed & Kapadia, 2017).

Outside of a business environment, predictive analytics can be applied to personal uses: identifying and preventing spam e-mails, for instance. Due to the variable nature of spam, it is tough to filter out completely. A system that can analyze e-mail logs and make use of predictive analytics can build trust criteria to determine which senders are considered spam (Vesely, 2017). Examining previous instances of spam would allow for the system to recognize spam behavior and to act accordingly when e-mails that fit the behavior profile are sent. Such a system could update its behavioral patterns based on newly formed spam (Yuksel, Cankaya, & Uncu, 2017).

In the scholastic setting, predictive analytics used analytical techniques to measure how likely students were to succeed. The documented system was referred to as Predictive Analytics Reporting or PAR. The method developed could be applied to show a student's likelihood of passing a

class, but Wagner and Longanecker make clear that the framework was designed with both conventional and non-conventional students in mind. Most federal data collection only focused on full-time students, which led to an incomplete data set. PAR was created to analyze the unchanging rates of postsecondary education success, as they have not changed for the past 40 years, despite attempts being made to improve them (Wagner & Longanecker, 2016).

Lastly, predictive analysis has various applications in a financial setting. John Blossom calls the multiple devices that collect and analyze data the "signal economy." More specifically, this is an economy that is driven by analysis of the data collected by those numerous different devices. In other words, it is significant data that has been processed to pinpoint trends. By subjecting economic data to the same processes that one may run to find the likeliness of an event's occurrence, one can figure out all sorts of potential areas of growth. Due to the staggering amount of data available from all kinds of different sources, markets, news outlets, universities, and even social media, software is required to process all of that data. Such data is continuously being collected and handled by software for hedge funds, the government, or some other private institution. Clearly, the information that comes from this kind of inquiry can predict how markets will act if enough data is being appropriately processed (Blossom, 2014).

As one can see, there are many applications for data analytics and predictive analytics that span pretty much every field. Many institutions, both public and private, make use of these analytical practices, and these processes are improving over time. In its current state, predictive analytics is more or less a means of trying to go as close as possible to determine the likelihood of a future event. The more data that is used, the more probability there will be of precision. With the advent of technological convergence, more devices can record information which will make it possible to map out the conditions for any event. From that point, analyzing the states that surround events will lead to the development of more accurate predictive analysis tools.

How Technology Impacts Analytics

Evidently, these analytics have proven to be beneficial in many aspects of human life. Predicting the future is a coveted tool in one's lifetime, especially within organizations. No one could dislike the ability to foresee success when creating a product, as investments could be much more easily

made with little to no error. With these tools, many types of success could be guaranteed.

However, there can be a cost to such powerful tools if they are not used responsibly. In Thomas Davenport's foreword for Eric Siegel's book *Predictive Analytics: The Power to Predict Who Will Click, Buy, Lie or Die*, he observes that the developing science of predictive analytics has, by and large, been for the good of humanity. Davenport asserts that predictive analytics can save lives, such as with healthcare, crime, and terrorism. He also addresses how these approaches can be detrimental, as one must exercise responsibility so as not to abuse this power. Large amounts of data would be required from people and companies, so predictive models can be compared to other powerful technologies or disruptive human innovations (Davenport, 2014). Davenport further suggests that Siegel counterpoints Nassim Nicholas Taleb's *The Black Swan* and other works. Taleb posits that most predictive efforts must be doomed to fail from the inherent unpredictability of things, but Siegel is the first to acknowledge that black swan events occur beyond prediction (Siegel, 2013). Furthermore, potential business applications continue to multiply. Models range from how predictive analytics is changing the retail industry to fintech start-ups using predictive modeling on fraud analysis and financial transaction risk. In essence, we have not fully tapped into the ways for industries to integrate data analysis and how predictive analytics tools can redefine business methods. After the breakthrough of mapping an artificial brain through creating a computer, there are infinite possibilities (Marvin, 2016).

Applications of Technology in Analytics

There are numerous examples of predictive analytics applications in multiple industries, especially involving technology. Primarily, marketing intersects with many sectors, as marketing campaigns have become much more scientific through the use of predictive analytics and big data. The ability to predict and recommend future purchases and actions is the principal benefit for many companies, and predictive analytics and big data are gateways to such a benefit.

With these tools, customer satisfaction and network safety can both be improved for some major corporations. For example, one of the largest users of predictive analytics is Amazon. The website uses past purchases and known "likes" to identify, predict, and offer other items to a customer. Similarly, fraud detection is a field where analyzing past patterns is key in

detecting future threats or criminal activity. Cybersecurity has become a huge budget item at many large corporations, such as banks, insurance companies, investment firms, credit card issuers, social media companies, and even law enforcement agencies (Moghaddass, Zuo, Liu, & Huang, 2015). PayPal avoids network breaches by using historical payment data, device type, country of origin, and user profiles to develop algorithms that detect fraud during any transaction. Even insurance companies, such as Liberty Mutual, use predictive analytics techniques to help evaluate lifestyle, health, and other factors to calculate life expectancy and related premiums. Furthermore, airlines use providers to analyze dynamic fare pricing that is based on the predicted number of travelers over a given period, for instance Virgin Atlantic utilizes Amadeus. Hotels do the same with room rates based on anticipated future travel volume (Farooq, 2016). Clearly, predictive analytics can help many corporations to gain a competitive edge.

By studying the company called Endor, one can find that *social physics* can also provide a massive amount of data in a matter of minutes. The science of social physics uses machine learning and algorithmic models to understand and predict crowd behaviors. It is comparable to Google, as it provides simple and fast results for any question (Matheson, 2017). Endor was recently spun out of the MIT Media Lab incubator, and it has developed a new platform that allows businesses to ask real-time questions: "Where should we open our next store?" or "Who is likely to try product X?" In one recent exercise, Endor analyzed Twitter data for an unnamed US defense agency to detect potential terrorist activity. Endor gathered 15 million data points with examples of 50 Twitter accounts of known ISIS activists that were based on identifiers in the metadata. The challenge was to detect new accounts with identifiers extremely well hidden in the metadata. Someone at Endor completed the task on a laptop in 24 minutes, detecting 80 "lookalike" ISIS accounts, 45 of which were from the pool of well-hidden accounts that were suspected by the agency (Ghofrani, He, Goverde, & Liu, 2018). As one can see, social physics was able to provide helpful results in a matter of minutes.

Endor is becoming a well-known company that is making great strides with predictive analytics. It was co-founded by Alex "Sandy" Pentland, Toshiba Professor of Media Arts and Sciences, and Yaniv Altshuler, a former MIT postdoctoral researcher. Early testing on the platform was done with the US Defense Advanced Research Project Agency (DARPA). It analyzed mobile data from individual cities in times of civil unrest to show how emerging patterns can help predict future riots. Lastly, Endor recently

won "Cool Vendor" status from Gartner, reserved for industry disrupters, and was acknowledged as a "Technological Pioneer" by the World Economic Forum (Matheson, 2017). It is evident that the merging of analytics and technology can guarantee more opportunities than one could have ever imagined over the history of industrialization.

How Technology and Analytics Come Together

The two types of analytics considered in this chapter, data and predictive, are powerful means for analyzing data in any number of different fields. Evidently, the results of the analyses can provide information to keep people safe, to make people money, to save people time, and so forth. Unfortunately, there is a cost in relation to privacy, as large amounts of data have to be analyzed to attain such results. With smart technology and smart environments, more data can be collected and processed, which will increase the results from data analytics and predictive analytics. These are great tools that are sure to grow and evolve with their related industries because they are derived from data. The immense applicability of these analytical methods ensures that they will be around for quite some time. Overall, it will be exciting to see how these analytical methods are applied to both new and existing fields, as it is inevitable that even more areas will jump on the bandwagon.

CHAPTER 7

Effective Engagement of Digital Natives in the Ever-Transforming Digital World

Anju Varghese Philip and Zakkariya K. A.

Introduction

According to the latest estimates, more than 4.2 billion people worldwide have access to the Internet (Internet World Stats, 2018). That number is more than half of the world's present population. The digital divide is being demolished every second of every day and we are fast moving into a hyper-connected networked world where past boundaries of geographical distances, time zones, and cultural differences are ceasing to matter. The average person uses more than four connected devices every day, and digital technology has arrived as the invisible but all-knowing, all-controlling dimension of our everyday lives.

Modern-day businesses have to thrive in a data-driven culture where the only thing that does not change is change itself. And the speed at which the changes happen is increasing so exponentially that it feels like everyone is on a constant learning loop. Jumping off this loop is equivalent to committing professional suicide as you can no longer refuse to embrace constant learning and change. How can businesses negotiate a world where everything is digital and connected and your customers are at

A. V. Philip (✉) • Zakkariya K. A.

B. George, J. Paul (eds.), *Digital Transformation in Business and Society*, https://doi.org/10.1007/978-3-030-08277-2_7

times more informed than you are? The best solution is by letting go of the scary connotations of the phrase 'digital disruption' and embracing the possibilities and opportunities of 'digital transformation.'

Digital transformation can be defined as the acceleration of business activities, processes, competencies, and models to fully leverage the changes and opportunities of digital technologies and their impact in a strategic and prioritized way (Edmead, 2016). It can also be called digital business transformation, since digital transformation is in essence transformation of the underlying framework of your business too. Technology innovation, customer behavior and demand, and external environmental factors are some of the reasons why a business might want to undergo a digital business transformation (Edmead, 2016). For this we need to build 'digital fluency' among our employees as well as increase the 'digital readiness' of our organizations (Briggs & Makice, 2012).

Digital fluency is an ability to reliably achieve desired outcomes through use of technology. It is the maximum individual potential to achieve desired outcomes through the use of digital technology (Briggs & Makice, 2012). It is not enough to know how to use the technological tools but one has to understand how to use them to achieve the desired outcomes. Therefore, being digitally fluent is a step up from mere digital literacy. A digitally literate person will have the basic skills required to participate in the digitally enabled social sphere, but, in contrast, a digitally fluent person will be able to navigate the same with an ease that comes from constant practice and immersion in the technology. Companies can be described as being 'digitally ready' when they are able to support the digital fluency of their employees by aligning their resources, culture, and purpose with the tasks they are asked to undertake (Briggs & Makice, 2012). Digital fluency is not a static state of being. It is a state of constant learning, up-gradation, and up-skilling because of the speed with which digital technologies change.

Like for any language, being digitally fluent implies that you have a level of comfort with the digital world that implies that you were born speaking the digital language. And that is where the digital natives or millennials enter the discussion. Who are the digital natives? Why are they important in a discussion about digital transformation of business? Digital natives (Prensky, 2001) is the terminology used to describe that part of the world's population who were born after 1980 and have been immersed in a technological environment all their lives, thereby making them especially adept at handling changing technology with an almost effortless flair.

Digital immigrants, on the other hand, lived part of their lives in a simpler time where technology was not the driving force of their lives and hence have a more difficult time navigating in and adapting to today's technology led milieu. It is expected that by 2025, digital natives will comprise 75% of the workforce, thereby making them the most economically powerful demographic group in history (dmresourcecenter.com, 2018).

In this scenario, it is important for businesses to understand who the digital natives are so that they can better leverage them as employees and also understand what makes them tick as customers. An organization that has to manage a successful digital business transformation will require a workforce that consists of both digital natives and digital immigrants to cooperate with the process and successfully make the transition so that no one is left feeling overwhelmed and falls behind in the process. This chapter attempts to throw some light on how to manage digital natives both as internal and as external stakeholders of the business.

Getting Familiar with the Digital Natives

To quote Mark Prensky (2001), digital natives are '"native speakers" of the digital language of computers, video games and the Internet.' 'Digital immigrants' are those who need to learn the digital language, they are not born speaking it, so they carry an 'accent' no matter how proficient they become at using digital tools. Digital immigrants prefer to use e-mail for online communication, whereas digital natives prefer the more synchronous forms of instant messaging. With mobile phones, digital immigrants favor speaking to people, whereas digital natives prefer speed texting. Digital natives prefer to share differently as well. Blogging is increasingly becoming popular among both digital immigrants and digital natives, but once again for different reasons. Digital natives use blogging to share personal experiences and treat personal blogging websites as forms of online journals. By contrast, digital immigrants tend to use blogging sites more as intellectual tools to share and discuss ideas with their peers (Prensky, 2001).

Not only do digital natives use technology differently—their lives are also being impacted by technology differently to the extent that their self-presentation, self-image, self-esteem, and wellbeing are influenced (Colbert, Yee, & George, 2016). They are often described as digitally literate, highly connected, experiential, social, and in need of immediate gratification (McMahon & Pospisil, 2005). Digital natives consider the

digital world to be part of their personalities. They expect to be connected at all times (Vodanovich, Sundaram, & Myers, 2010).

Digital is almost coded into the genes of the millennial generation; it is that natural for them. They are digital by default. Research has shown that they spend 41% of their free time on their devices (Morrison, 2015). They own an average of 2.4 devices, which might include smartphones, laptops, notebooks, iPads, and music streaming gadgets. Prensky (2001) says that brain scans show that their increased use of digital devices has actually caused changes to their brain structure. They relate to technology in a different way and are naturals at interacting and understanding with technology.

Among the adverse consequences of this constant connectedness is what is called FOMO in urban slang—the Fear Of Missing Out. It is a compulsive need to be up to date in what is going on within their social circles as well as in the outer world, which can even lead to disruption of healthy sleep patterns as people take their smartphones to bed with them and check messages and other updates during the nights and first thing in the morning.

At the same time, many among digital natives say they feel a sense of social fatigue, which is 'a feeling that being connected all the time is too much. A desire to disconnect and be offline and to regulate and bring down the time spent on social media' (techopedia.com). As a result, the more conscientious among them try to limit their time spent on social media by prioritizing their social media use and limiting themselves to being active on only a handful of social media sites rather than trying to be everywhere all at once and getting overwhelmed by it.

Many digital natives have grown up playing video games and have acquired a set of unique skills such as the ability to take risks and overcome obstacles, to learn from failures, to manage diverse teams, solve conflict, distribute rewards equitably, and so on as a result (Colbert et al., 2016). These skills make them invaluable assets in the workplace. Similarly, businesses that are looking to implement 'design thinking' for their innovation process will do well to inculcate the gaming skills of learning by trial and error (Beck & Wade, 2004; Glen, Suciu, & Baughn, 2014).

The digital workforce will likely be comfortable with technology-based instruction (Kraiger & Ford, 2006), giving organizations a low-cost, replicable solution for helping employees develop the skills that they need. Some tools that are currently in use are Google Drive for collaborative writing, Trello for collaborative project management, and Yammer or

Slack for communication and enterprise-level social networking. With more organizations using firm-generated social media content to connect with customers and build their brands, employees who understand and can leverage the power of social media will also be valuable to organizations (Kumar, Bezawada, Rishika, Janakiraman, & Kannan, 2016).

On the other hand, many millennials experience a decrease in face-to-face communication skills and nervousness during telephone calls because most communication is conducted via texting which is seen as more efficient and gives the opportunity to self-present in a favorable manner. Also they display decreasing levels of empathy probably because of increasing levels of technology immersion (Colbert et al., 2016).

Technology has blurred the lines between work and nonwork domains (Ramarajan & Reid, 2013). While email, the Internet, and even social media are integral tools for doing work, they also provide easy access to family, friends, online shopping, and other nonwork purposes while at work. Inability to disconnect from technology during nonwork hours can lead to higher levels of stress and work-life conflict (Ramarajan & Reid, 2013) adversely affecting employee wellbeing (Colbert et al., 2016).

What Can Companies Do for Digital Natives?

As Employees

Digital natives are highly cause driven and will love to work for companies that measure performance not just in financial terms but also in terms of contribution to social good. They are also aware of and support brands that have a social cause (dmresourcecenter.com, 2018).

While digital natives boast a strong work ethic, how, when, and where they accomplish the work should be left to them. Companies that expect a 9–5, 5-day workweek from them can expect a dissatisfied bunch of employees (Lovelock, 2018). Work-life balance is very important to them, especially because they have the technological tools that make this balance easier to achieve. While they want to earn enough to facilitate their life goals, they also want the free time to pursue their interests outside of work (Ramarajan & Reid, 2013).

They have grown up in a culture where collaboration is important (Commonplaces, 2014) and companies should provide the necessary internal knowledge management tools to accomplish this. They seek opinions and inputs from various quarters and believe that this gives them better solutions

to problems. Companies should be open to setting up collaborative teams not limited by location or department. Virtual teams are a great way to accomplish this (Gilson, Maynard, Jones Young, Vartiainen, & Hakonen, 2015).

Digital natives are not intimidated by titles, seniority, or positions. They see their superiors as mentors rather than bosses and will expect to be treated as equals. They are highly ambitious and expect to make managerial positions in two years of joining the work force (Ashridge and MSLGroup, 2014).

Loyalty to a particular organization is not important to them and they will switch jobs if they get bored. Millennials will not stay in a company and wait for a promotion every 3–5 years (Ashridge and MSLGroup, 2014). Companies should function as corporate lattices where employees are moved horizontally across business functions for different projects rather than as corporate ladders where the only movement is vertical (Benko, Anderson, & Vickberg, 2011).

Mobility is an important factor for millennials (Gilson et al., 2015). Companies should provide the necessary technological support to enable this. A combination of cloud computing and use of light technological solutions to enable mobility will increase efficiency in the workplace too. Also an option to bring your own technology (BYOT) will be a boon to this workforce (Puybaraud, 2012).

As Customers

For marketers and brands seeking to engage their millennial audience, it is first of all imperative to realize that as a result of living all their lives in an environment where information is available at their fingertips, they are impossible to fool and incredibly impatient with slow responses and campaigns that don't really speak to them. They carry their idealism proudly and will happily purchase brands and products that espouse a social cause. They are also vociferous in speaking out about anything that they dislike, so companies need to be very careful about how they engage with this audience online (dmresourcecenter.com, 2018). Be quick at apologizing for any mistakes and try to rectify them at the earliest. Best strategy will be to not make any mistakes at all!

Millennials are also characterized by their focus on accumulating life experiences rather than owning property. So they might opt to use their income to travel rather than settling down into a typical middle-class lifestyle buying homes, cars, and other large immovable investments

(Niewiadomski & Anderson, 2015). This demography is moving from a lifestyle of ownership to a lifestyle of easy access, instead of buying a car they will use a ride aggregator such as Uber, instead of investing on office space, they might prefer to work from shared office spaces. This type of thinking gives them all the conveniences of modern life that money can provide access to without having to bother with the hassles that come with ownership such as maintenance and upkeep.

They are constantly digitally networked at all times (Sørensen, 2016), which means they have easy access to information at all times and this means that they are attuned to an on demand lifestyle and have a growing sense of entitlement. Millennials handle half their ecommerce transactions from a mobile device and are the largest online audience and have more buying power than any other previous generation (dmresourcecenter.com, 2018).

Therefore, given their high buying power, their influence on the online market, their active social media presence, and most of all their impatience with delay, it is imperative that brands make all effort to understand and engage them. This is especially pertinent in a country like India, which is expected to become the youngest country in the world by 2022, with the average age of 29 years (Financial Express, 2017).

Firms should wake up to the advantages of using social media as a business tool to engage their digitally savvy audience (Lovelock, 2018). An effective social media marketing strategy can help increase an organization's brand awareness, improve customer engagement and satisfaction, and allow the company to establish their voice. Social media provides an accessible platform for direct communication between a company and a client and allows for a more human-centric approach to customer success and support. Firm-generated content (FGC) has a greater effect on customers with a longer customer–firm relationship, who are technologically savvy, and who are more prone to social networking. It is social media's ability to give 'voice' to customers in the form of likes and comments that makes FGC more effective. FGC can play a key role in strengthening customers' relationship with the firm by encouraging them to buy across several product categories (Kumar et al., 2016).

Statistics show that desktop sales are falling rapidly, while smartphones are being used for everything ranging from work to leisure. So the way to engage the consumer of today is by going mobile and social and being entertaining while doing so. That is spend more on mobile and digital

campaigns. Give your target consumers a chance to connect with their friends and other like-minded people through your campaign.

Use the trails of digital data that is left on the Internet by your consumers to really understand them. Social Media Analytics and Big Data should be seen as an opportunity to understand consumers and customize and individualize your offerings rather than as an insurmountable challenge best left to the geeks. While designing platforms for customer engagement remember to personalize, interact, be intuitive, attractive, and social (Vodanovich et al., 2010). Companies can work on enhancing the customer experience through understanding customers by using digital trails, analytics-driven customer segmentation, and digitally enhanced selling.

Skills That Are Needed for the Digital Workplace

Many times the obstacle toward implementing a successful digital transformation is people and not technology (Bonnet & Nandan, 2011). This is because digitalization changes the ways of working and increases the rate of change of the organization. It will require the manpower to rapidly acquire new skills and competencies, and also usher in a new organizational culture. Leadership also has to change to new forms to accommodate and enable this transformation to digital. Digital transformation requires the continuous alignment of people, technologies, organizational structures, and ultimately organizational culture (Briggs & Makice, 2012). Effective change management is required to manage this process well and adopting a design thinking style will help with the implementation (Gruber, De Leon, George, & Thompson, 2015). Design thinking can be defined as 'a human-centered approach to innovation that puts observation and discovery of often highly nuanced, even tacit human needs right at the forefront of the innovation process. It considers not just the technological system constraints but the socio-cultural system context' (Glen et al., 2014).

The speed and complexity of digitalization will change how we handle information (find, filter, and use information from many sources), interact with people (choosing an identity or identities to engage with others through multiple channels), inspire, and involve people to act in support of organizational goals, and empower them to move toward a future reality. To succeed in the digital age, a person must be able to appropriately weight the practical risks and future benefits of new tech. New

levels of skilling required to make the transition to digital fluency transcend from basic computer skills such as conducting a basic search for information, creating a profile on different social media apps to performing basic troubleshooting tasks to more advanced ones such as editing and uploading photos, tagging content, crafting semi-public content for various contexts, navigating complex privacy controls, and editing a wiki page. Some of the skills exhibited by an email-able person remain useful: good typing skills, writing a persuasive argument, and finding an optimal time to communicate.

Adaptation is what allows us to use our abilities effectively when shifting between contexts, usually as the world changes around us. Adaptation is an *ability of abilities*, drawing from the knowledge and relevant skills one accumulated from previous experience. Adaptation requires a mindset that sees all of this change as an opportunity to learn.

Briggs and Makice (2012) listed the skills and abilities needed for employees to make a successful digital transition as enumerated by Jenkins (2006) and summarized them as given below:

1. *Networking*: The ability to search for, synthesize, and disseminate information
2. *Play*: The capacity to experiment with one's surroundings as a form of problem-solving
3. *Performance*: The ability to adopt alternative identities for the purpose of improvisation and discovery
4. *Simulation*: The ability to interpret and construct dynamic models for real-world processes
5. *Appropriation*: The ability to meaningfully sample and remix media content
6. *Multitasking*: The ability to scan one's environment and shift focus as needed to salient details
7. *Distributed cognition*: The ability to interact meaningfully with tools that expand mental capacities
8. *Collective intelligence*: The ability to pool knowledge and compare notes with others toward a common goal
9. *Judgement*: The ability to evaluate the reliability and credibility of different information sources
10. *Transmedia navigation*: The ability to follow the flow of stories and information across multiple modalities

11. *Negotiation*: The ability to travel across diverse communities, discerning and respecting multiple perspectives, and grasping and following alternative norms
12. *Visualization*: The ability to interpret and create data representations for the purposes of expressing ideas, finding patterns, and identifying trends

A number of tools are now available to measure the new skills needed. These include the iSkills assessment (Katz, 2007), New Literacies (Lankshear & Knobel, 2006), and the New Media Literacies (NML) framework (Literat, 2014).

Discussion and Conclusion

Digital natives are a great mascot for organizational transformation programs, as they have the ability to come into a company unhindered by previous experience with legacy technologies and provide new solutions to modernize business processes and drive a truly digital workplace. As digital natives join the workforce, they bring with them a willingness to embrace technology as a driver of not just productivity, but also profitability. Organizations must adopt this mindset and plan for digital disruption in the modern workplace, or risk being left behind.

Digital natives can help their older colleagues use technology more efficiently and effectively, thereby increasing productivity. The technology gap between generations will lessen as elder generations learn to embrace and understand new technologies like their digital native peers. Digital natives' higher level of intuition when it comes to technology, coupled with the fact that new products are easier to use than their predecessors, means that integration with technology will be less of an issue for all generations (Gilson et al., 2015). In addition, digital natives have a healthy level of respect for the older generations' work ethic and values and will want to imbibe these from their seniors at work.

Ultimately, digital natives seek the same things from their employer as any other generation that came before them. A sense of belonging and value and an opportunity to contribute to the success of their employer. They seek to be respected and nurtured and to work for companies that work for social causes and innovation and have a sense of social responsibility. They want their work and lives to be an extension of their own

identities and will want to work in and buy from companies that provide them this avenue for self-expression.

As customers, digital natives are highly tech savvy, value conscious, and cause driven. They desire instant gratification and quick responses for their issues. Companies should set in place efficient teams to monitor, engage, and address their millennial customers, as this is considered the most economically powerful demographic that the world has ever seen. The most effective customer touch point for this audience would be some form of social media outreach in addition to the usual sales and promotion activities. Companies that go the extra mile to really understand their digital native market will be able to target their offerings in a way that truly speaks to the identity of the millennial.

To conclude, business leaders should acknowledge the direction that technology is leading the world in, embrace the future, and ride the waves of technology into the hearts and minds of their digital native stakeholders. Since the number of digital native stakeholders are continuously increasing and leading to a world filled only with digital natives in the long run, companies should have short-term and long-term plans and strategies for attracting, engaging, and managing digital native to retain them as loyal stakeholders. Digital transformation is a never-ending process as the technology is growing and transforming every day, and this poses a challenge to organizations, as they need to cater to the ever-changing needs and behaviors of the digital native. No company would be able to continuously either engage or satisfy the digital native without having continuously upgraded technologically based plans, strategies, and actions.

CHAPTER 8

Robotics, Artificial Intelligence, and the Evolving Nature of Work

Craig Webster and Stanislav Ivanov

Introduction

In their thought-provoking paper Brynjolffson and McAfee (2015) ask the question 'Will humans go the way of horses?' and they have good ground to do so. Human labour has been largely replaced by machines in ways that consumers can understand and this has been going on for decades. For example, many will have a historical memory of going to a bank during the bank's hours of operation to make a withdrawal of cash. Now, consumers regularly go to machines to make cash withdrawals from the accounts and the labour for making the transaction is largely mechanized. While much work in the service industry is still based upon human labour, manufacturing is much more automated. While humans may still be needed to perform many commercial operations, human labour is much less critical than it had been at any time before in history.

B. George, J. Paul (eds.), *Digital Transformation in Business and Society*, https://doi.org/10.1007/978-3-030-08277-2_8

Recent advances in robotics, artificial intelligence, and automation technologies (RAIA) (Bhaumik, 2018; Miller & Miller, 2017; Neapolitan & Jiang, 2013; Russell & Norvig, 2016; Warwick, 2012) have allowed companies from various sectors of the economy to adopt RAIA in search of lower costs, faster production time, provision of consistent product quality, management of supply chain operations, etc. While initially it was the manufacturing that used industrial robots (Colestock, 2005; Cubero, 2007; Low, 2007; Pires, 2007), currently all other sectors of the economy and society intensively adopt RAIA technologies: from supply chain management (Min, 2010), agriculture (Driessen & Heutinck, 2015), autonomous vehicles (Maurer, Gerdes, Lenz, & Winner, 2016), and warfare (Crootof, 2015; Sparrow, 2007), through travel, tourism, and hospitality (Ivanov & Webster, 2018; Ivanov, Webster, & Berezina, 2017; Murphy, Hofacker, & Gretzel, 2017), education (Ivanov, 2016; Timms, 2016), journalism (Clerwall, 2014), provision of legal (Remus & Levy, 2015), and other services (Huang & Rust, 2018; Wirtz et al., 2018), to trading on the financial markets (Dunis, Middleton, Karathanasopolous, & Theofilatos, 2017), and implementing medical operations (Kaur, 2012; Mirheydar & Parsons, 2013; Schommer, Patel, Mouraviev, Thomas, & Thiel, 2017). Both large and small companies use chatbots to communicate and maintain their relationship with customers (Hill, Ford, & Farreras, 2015; Xu, Liu, Guo, Sinha, & Akkiraju, 2017). Social robots enter actively our lives (Agah, Cabibihan, Howard, Salichs, & He, 2016; Nørskov, 2016; Royakkers & van Est, 2016), and already redefine our understanding of 'sex' (Cheok, Devlin, & Levy, 2017; Lee, 2017). These brief examples reveal the overwhelming intertwining of RAIA technologies into the fabric of society, leading to huge transformations of the ways humans live, work, and do business (Makridakis, 2017; Talwar, 2015; Talwar, Wells, Whittington, Koury, & Romero, 2017). Some authors even state that economists and marketers need to broaden their definition of a 'consumer' to include robots in it (Ivanov & Webster, 2017).

The advances in RAIA technologies are expected to accelerate in the future and some researchers consider the possibility that artificial intelligence might at one point surpass human intelligence—a point of time usually referred to as 'technological singularity' (Callaghan, Miller, Yampolskiy, & Armstrong, 2017; Kurzweil, 2005; Shanahan, 2015). While we do not know whether silicon will surpass carbon in terms of intelligences and whether transhumanism and human augmentation through microchip brain implants is a viable future and not science fiction,

we are sure that technological advances in RAIA, Industry 4.0 (Andelfinger & Hänisch, 2017; Schwab, 2016; Skilton & Hovsepian, 2018), and the Internet of things (Sendler, 2018) are challenging the role of human labour as a production factor to a point when all or an overwhelming share of goods and services are delivered by RAIA technologies instead of human employees. Such an economic system is called 'robonomics' (Crews, 2016; Ivanov, 2017). Experts' opinions about that automated robot-based economy and society are not uniform. One group of researchers expresses explicit fear of AI technologies (Barrat, 2013; Bostrum, 2014; Crews, 2016; Leonhard, 2016), considers the self-aware AI as 'our final invention' (Barrat, 2013) and paints dystopian dooms-day Terminator-like scenarios for the human species. Others seem overly optimistic and perceive technology as the ultimate utopian solution to all human problems, including the merger between humans and machines (Kurzweil, 2005). The majority of authors, however, take a more pragmatic approach and see the opportunities that AI and robonomics as an economic system would create like extended life expectancy, improved health and quality of life, more time for activities people value, to name just a few (Brynjolfsson & McAfee, 2014; Frank, Roehring, & Pring, 2017; LaGrandeur & Hughes, 2017; Talwar, 2015; Talwar et al., 2017), although the expected radical abundance of goods and services that technology experts promise (Drexler, 2013) may not benefit all stakeholders.

Within this domain of thought, the future of human's work and the impacts of digitalization and automation on the labour market have received a great deal of attention by researchers (e.g., Alasoini, 2017; Association for Advancing Automation, 2017; Daugherty & Wilson, 2018; Ford, 2009, 2015; Frank et al., 2017; Harteis, 2018; Kaplan, 2015; Kauhanen, 2016; West, 2018). As a matter of fact, in a recent highly cited research, Frey and Osborne (2017) assess that 47% of US jobs are already susceptible to computerization. Some jobs are very obviously on the brink of extinction. For example, the most common job in 29 of the 50 states in the United States is the 'truck driver,' according to 2014 data (NPR, 2015) and the self-driving car/truck (a technology on the brink of being viable on the road) will almost immediately lead to the unemployment of these workers (Solon, 2016).

This raises justified concerns among researchers, politicians, and industry representatives how people, companies, economies, governments, and societies as a whole would need to adapt to the new technological, economic, social, and political realities that robonomics would create. For

example, in 2016, the Executive Office of the President of the United States, National Science and Technology Council, and the Committee on Technology published three documents intended to prepare the US economy for the age of automation: *The National Artificial Intelligence Research and Development Strategic Plan* (2016), *Preparing for The Future of Artificial Intelligence* (2016), and *Artificial Intelligence, Automation, and the Economy* (2016). In the same manner, in 2017, OECD published an extensive report dedicated to the implications of automation for businesses and governments (OECD, 2017), while the World Economic Forum published annual reports on the future of jobs (WEF, 2016, 2018).

This chapter contributes to the body of knowledge by elaborating on the impacts of RAIA technologies on the labour market and the nature of work. This chapter looks into such things as the employment dilemma (Giarini & Liedtke, 1996), an issue related to the human need to have productive work and the modern industrial capability for productivity. It also looks into the issue of the human Luddite possibilities, as humans should have a fear of being replaced by robots (Lehman, 2015; McClure, 2017). In addition, the chapter also looks into the issue of the ethical use of robots (Lin, Abney, & Bekey, 2014), as robots are not merely replacements of human labour but also entails a real impact upon the human population.

The Economics of Robotics and AI

The first element to look into is the issue of why RAIA technologies are being implemented. The obvious reasons for the implementation are the overlap between the technological abilities that now exist and the need for efficiency and cost-effective production. While the concept of the robot was invented in 1920 (NPR, 2011), the robot (and more importantly the intelligent robot) was a thing of the future and not entirely practical. By the 1980s, robots were being utilized widely in manufacturing, although service industries have generally lagged behind in the use of robots.

At its heart, the current robotic economy undermines the economic principle of the labour theory of value was ascribed to by such thinkers as Karl Marx, Adam Smith, and David Ricardo. While traditional economic theory identifies land, labour, and capital (and sometimes also 'enterprise' or 'entrepreneurship' as the factors of production), we see a shift in the stress on which of these factors is most critical. Traditional economic theory holds that human labour is a necessary factor for the production of

wealth, meaning that human labour is critical in the productive process, something that any casual reading of Marx makes very clear. However, with the rapid advances in robotics and artificial intelligence, human labour is much less stressed as a necessary input, and this will be increasingly true once robots are used to produce robots.

The widespread implementation of a robotic economy will lead to a new economic and social landscape in which there will be winners and losers. Since the technological capability to replace human labour with increasingly sophisticated technologies exists, those humans with labour to sell that can be replaced easily and cheaply with new technologies will be replaced, leading to a new political economy of robots (Kiggins, 2018). This will be a new world in which most labour in terms of production of goods and services is created by machines, meaning that humans will be increasingly marginalized from the productive process, although there is the enduring question of whether robots will largely be used as complements to human labour or substitutes to human labour (DeCanio, 2016).

Another political and economic trend that will impact upon the new economy is a by-product of the globalized economy. Since economies are now interconnected as never before and there are massive advantages to those who conquer a market early, since markets tend to be big and the ability to penetrate such markets. What we can expect in markets is the markets will increasingly gravitate towards 'winner-take-all' markets (Brynjolfsson & McAfee, 2014). There are a number of reasons for this, including the digitalization, improvements in communications (and transportation), and the increased importance of networks and standards. In other words, the economy is now different, as global markets enable consumers to have access to information with regards to goods and services and information costs with regards to products and transportation of products is dropped, and networks enable the spread of information and good and services as never before. Economies of scale develop, enabling the establishment of near monopolies, as penetrating markets outside of prevailing channels and networks becomes increasingly difficult for start-ups.

The value of labour and the way that labour is treated can be understood by its value in the market. The relationship between increased labour productivity and wages in the United States tell an interesting story. While the data in the United States show massive increases in productivity per worker since the 1950s, by the mid-1970s, increases in salaries have not kept up with increases in productivity (Watson, 2018). It seems that companies see

no need to compensate workers for their productivity, resulting in an outcome that has a massive impact upon the economy and society, people who are employed and productive but do not experience salary/wage increases as a result of their labour. It is also suggestive that workers are so productive that there are underemployed populations driving the real wages down. What is most interesting is that this is occurring in economies in which there are demographic declines, meaning that the available labour pool is generally shrinking and will continue to shrink. Another issue is the question of the sustainability of such economies, as machines do not consume many goods nor services, unlike humans (Ford, 2015, p. 196). This means that economies may suffer in the future, as machines do not consume the way that humans do. Manufacturers may be producing high-quality goods at a low price per unit, but the question remains who will be able to purchase the goods and services, when salaries remain relatively flat in many countries.

Directions of RAIA Impacts on the Labour Market

For us human mortals living today, we will have to contend with the massive changes that robotics and artificial intelligence will do to the labour market in the next 10, 20, or more years. While we understand that in 100 years, the production and service landscape will change dramatically because the capability of technologies that we now are impressed with will seem very primitive, we have to prepare for the nearer future. In the nearer future, we can expect some major impacts that are almost predictable, such as the automation of a great deal of the transportation with self-driving trucks and cars. At any rate, there will be an impact upon different countries in different ways based upon the country's current level of development and social/technological factors. There will also be some impact upon social structures and the mobility of populations, as well as the mobility of production. At any rate, legislation will have to change a great deal and the legal/political elements as well.

The first and major impact of technologies will be the elimination of jobs via automation (Frank et al., 2017), although there will be many jobs lost, there will also be the creation of new jobs and the changing face of other jobs. Some publications have discussed various solutions to how technological unemployment can be dealt with (Stevens & Marchant, 2017; Swan, 2017). Many of the jobs we now see exist in the market will be changed a great deal with many jobs being de-skilled, re-skilled, or

upskilled in terms of their tasks associated with them. There is also a geographical element to this, as well. There is an indication that automation of many tasks may enable production to take place in places in which labour costs are notoriously high such as Germany, where shoe production is now taking place (Wiener, 2017) presumably because the other factors of production are equal to or lower than in Asia and labour costs approach zero because of automation. Production may return to the Western economies, as labour costs will largely be bypassed and production may now be done in ways that lower transportation costs.

Another major impact that will occur is the quality of the jobs that persist. Humans will likely continue to do some of the work that robots and computers will not yet be able to do and some of the jobs are rather surprising. For example, while we can reasonably expect that artificial intelligence can handle most of service complaints and inquiries from humans, most robots have a hard time doing some activities that many humans find very simple, such as opening doors. It seems that there will be a need for humans to do many of the physical tasks that machines cannot do or at least do well, although it is possible that social changes may work in ways to bypass this. For example, while currently no robots can change the sheets on a bed well, it is possible that hotels in the future could hand guests clean sheets and insist that the guests make their own beds, bypassing the need to pay for human labour to change the sheets on the bed. Such a social/cultural shift may be accepted by hotel guests, if there are cost advantages.

Because of the disruption of advanced robotics and artificial intelligence into the production of goods and services, humans will likely have to find a niche in the world's gig economy. Since human labour will be increasingly relegated to physical or mental tasks that humans can still perform better than machines, humans will have to hustle, doing jobs that machines cannot yet do well nor as effectively as machines. One of the problems that will be a political outcome of this is that many people will be reliant upon short-term tasks and jobs that may exist below the radar of tax authorities and do not supply the human with the legal and social protections that a person would have with a full-time job that exists above the board. How males and females will work under these conditions and survive under such conditions will be interesting, but it is so far unknown how the sexes will either react or flourish under such unstable and shifting work environments (Schwab, 2016).

The class differences will increase, as has been the case in nearly all developed countries in recent decades, since labour will consist of skilled knowledge-based workers and less-skilled workers. Those that are less skilled will constantly run into competition with robots and artificial intelligence that will undermine the value of labour (Economic Times, 2018). There will be some specializations that remain difficult to replace with robots or artificial intelligence, and these positions will continue to function, although there will be downward pressures upon such jobs, as the demand remains equal, the supply of labour for such jobs will decrease the returns for those working such jobs. However, those who feel secure with skills and are knowledge workers should not feel too secure, as there are technological changes that can make their labour redundant. For example, university professors now teach many online courses. Such courses are generally done for the convenience of the students, but there are risks for the teachers, as many courses may rely on exams/tests that are multiple choice and can already be graded with very basic computer technology, and it may not be long before computers can grade and give intelligent feedback to students on essays (see also Ivanov, 2016).

We can also expect that the disruptions that will take place will have a massive reaction among the public and there should be political responses. Since humans may be less key to the production of goods and services and many humans will be replaced with robotic/AI labour, what should be done to sustain the economy and sustain the political economy? A likely answer spoken about is guaranteeing humans a universal basic income (Santens, 2017; Sheahen, 2012). This income would have the stabilizing impact by ensuring that human consumers can purchase the goods and services that a largely automated economy would produce. Paying for such a plan would require a different form of taxation from how taxation is now considered, as a great deal of taxation in economies stems from the taxation of the wages of working people. So with a reduction in the number of humans working and paying taxes on their incomes and the reduction of jobs, entire new systems of taxation will have to be created. The current economy and its laws presume human labourers paying taxes upon their salaries and presumes that such human labour is necessary to sustain economies. Laws also presume that people are engaged in full-time employment in which people have stable incomes and benefits, meaning that many of the laws that now exist regulating labour presume an old-fashioned industrial model of labour. But the new economy, to a large extent, depends upon gigs and short-term contracts and laws have not kept up with these changes.

Staying Competitive on the Labour Market

The future, at least the near future, is one that requires a skilled workforce. Table 8.1 lists the top ten job skills the World Economic Forum (2018) feels the workforce should have in 2020. The list of skills seems to be uniquely intellectual and emotional in nature. There is no mention of physical strength or physical agility. According to the World Economic Forum (2018), the skills needed are intellectual and emotional in nature, including solving complex problems, critical thinking, and coordinating with others.

These key skills identified by the World Economic Forum presumes that the competitive advantage that humans have over robots and artificial intelligence is not based upon physicality but upon intellectual capabilities and the ability to interpret the emotional landscape of the workplace. The development of such skills would reasonably thought to be developed by people through education/training, experience, and naturally occurring intellectual ability. What this implies is that education will have to work in ways to cultivate those talents that only humans at this point in time can develop in ways that are useful in the economy (creativity, complex communication skills, emotional intelligence, etc.). The need to further develop these very human capabilities will have to depend upon an educational system that is based upon an old industrial model from a previous century, presuming a tiered system of education that would build skills that are permanent. The new economy will likely need a new approach to education, one that is based upon the development of human skills rather than building of knowledge and will have to retool to consider the needs

Table 8.1 Top ten job skills needed in 2020

Rank	*Skill*
1.	Complex Problem Solving
2.	Critical Thinking
3.	Creativity
4.	People Management
5.	Coordinating with Others
6.	Emotional Intelligence
7.	Judgement and Decision Making
8.	Service Orientation
9.	Negotiation
10.	Cognitive Flexibility

Source: World Economic Forum (2018)

of people in the workforce who will have to pick up new skills to be relevant in a flexible and changing economy. Since many employees will change jobs and industries, they will need relevant education that will enable them to have relevant skills in the new positions that they take in different companies and fields. Companies will also have to pick up some of the responsibility for the training and retraining of employees and such responsibility should not be the sole responsibility of universities, entities comfortably insulated from the economy in many respects.

Apart from how individuals and how the educational systems will have to change, industry will also have to change. In the short run, for companies to stay relevant and competitive, companies will have to invest in robots and artificial intelligence. While such investments may require investments upfront, such investments will assist in the transition to the new economy, despite the risks and hiccups in the system. The changeover for most industries is a sure thing. While adopting some technologies later may offer some advantages, adopting early may enable the customers and workforce to adjust to the new realities and work in ways that are more effective and efficient.

Conclusion

Humans have been on the Earth for quite some time and we hope that the species will persist. While humans probably will not go the way of the horses (Brynjolffson & McAfee, 2015), there are massive changes caused by technological advances that humans need to be aware of and must adjust to. First, we expect that humans will be removed increasingly from the production of goods and services. Human labour will remain one the factors of production but is decreasingly the key component in the production process. The qualities that the human labourer has and brings to the table in the factors of production will remain the ability to create, to interpret, and to work with others. The human will also be prized in the near future for the physical ability to do things that many robots have a hard time doing well and quickly (opening doors, walking, and other physical things), the human will remain a great multi-purpose tool that can negotiate the geography of a house or office space. But the flooding of labour markets with labour displaced by robots and artificial intelligence will mean that such physical jobs will be flooded.

For humans, those lacking the skills to compete in the new economy will be competing against each other. Skills that so far are unique to

humans will have to be developed for many workers to remain relevant. Problem solving, emotional intelligence, interpersonal communications, and other skills that humans can do well if they are sophisticated enough to do it will enable humans to remain relevant in the new economy. But the traditional establishments that train humans will have to adjust to the needs of the new economy and the demands upon workers.

Second, the political and legal system has to take account of the new economy. As labour becomes more flexible and concentrated upon gigs and contracts, governments and taxation systems have to keep up with the new economic reality. From the perspective of the government, the traditional way of taxing working people will be less prevalent and the persistence of the gig economy/sharing economy will mean that taxation systems will have to be amended to remain relevant in an economy that has changed. Taxation will change and keeping the new economy stable and healthy will have to rely on different thinking. With a large number of workers who are not needed, guaranteeing that people have a reliable way of living, especially if they are not needed in the workforce, is a necessity. One easy way to adjust for this is the guarantee of a minimal income for all, an idea that may seem radical but has a long history and has become quite popular to speak about in recent years (see, for example, Caputo, 2012; Stern, 2016). The stability of the political economy rests upon the need to have consumers who use products and services and the lack of the need for much of the labour available in the economy means that much of the workforce will be competing for de-skilled jobs and with people who have lost their jobs due to increasing robotization of the workplace.

Finally, there is the major concern about the assumptions of the human's ability to be able to be relevant in the new economy. While the World Economic Forum (2018) can identify skills needed in the workplace, it is a question as to whether all humans have the ability to develop skills that are needed by industry. While there are some who may contend that IQ is a meaningful concept (Gould, 1996), most agree that there is variation in each human's ability to absorb, retain, and process information. Unless it is found that all humans have roughly the same intellectual capacity to develop the skills needed for the new economy, it would seem that many would be excluded from the new economy, simply because of their incapacity to develop the skills needed. It could be, then, that a substantial portion of humanity could be excluded from the new economy, simply because of a lack of the ability to develop the skills needed to compete as a human in the economy.

In conclusion, humans are entering a new age, an age of mechanical reproduction that is unlike anything envisioned before. While humans may remain a factor of production, they may be decreasingly critical in terms of the terms of physicality of work and even more critical in terms of the intellectual needs of the workplace. At any rate, the role of the human will be different. As a result, many of the institutions that are part of the economy, such as government and education, will have to change to be relevant and consistent with the needs of a society that has an increasingly automated productive base.

CHAPTER 9

The Dark Side of Big Data: Personal Privacy, Data Security, and Price Discrimination

Yang Liu and Connor Greene

Introduction

According to Furman and Simcoe (2015), the Council of Economic Advisers released a study, "Big Data and Differential Pricing", in February 2015. In terms of this study (2015), big data is defined as the capability to collect a huge amount of data from various sources for investigating, analyzing, and understanding consumers, and forecasting market demand and affordable prices for consumers. In turn, the way firms do business has been changed by this new technology. Consequently, the whole of society has been changed, with this new technology both bringing benefits and generating challenges.

Benefits and Challenges to Business and Society since the Big Data Era

Personal Privacy and Data Security

When the big data era finally arrives, firms will cheer up because of this smart technology for which they have been waiting for years. Web browsers or the owners of websites normally generate a "cookie", which is a file on a user's computer. This file saves all the information on the user. Therefore, web browsers or the owners of websites can draw a picture from the details of any user based on the information they accessed. TRUSTe, a technology compliance and security company, reported in 2014 that the top 100 websites browsed the most are monitored by more than 1300 firms. Some of the data collected by these firms is "shared" (also known as "piggybacking") with outsiders. Normally this monitoring process is unknown to web users. For example, an advertising technology company, RadiumOne, puts cookies on users without notifying them, when they click on a link sent by a friend (Big Data and Differential Pricing, 2015; Chen, Choe, & Matsushima, 2018; The Economist, 2014).

New information technology platforms offer applications (or apps) for maps, search engines, social media, and so on to enrich people's daily lives. In turn, the omnipresent online search, payment transactions, and social interactions leave a trail of personal information, containing emotions, tastes, behaviors, locations, affordable prices, and so on. These apps do not support cookies, but they can access and record the unique device identification (UDID) number of the mobile device to recognize individual users. PubMatic is a company helping publishers increase sales. It provides around 50 to 70 points of user information on desktops and around 100 on mobiles, which includes the mobile device user's location (Chen et al., 2018; The Economist, 2014).

New Business Pattern

According to Kamenica, Mullainathan, and Thaler (2011), the more information cell-phone providers and data collectors gather and analyze, the more they understand consumer behavior. Given enough time to collect enough data, data analytics can understand a consumer more than him- or herself. Calo (2014) explains personalized advertising as the ability of firms to detect when is the best time to deliver a commercial or how

to build an emotional relationship with consumers based on their personal experience. Duhigg (2012) observes that Target can distinguish pregnant consumers based on their shopping record and directly deliver related advertisements regarding baby products to them.

These big data enable firms to reach their target consumers directly and save millions of dollars that they are wasting on people who will not purchase their goods or services no matter how hard they try, because the firms are able to analyze consumers' current situation, such as pregnancy, divorce, relocation, and so on. Before the big data era, marketing researchers would design, deliver, collect, and analyze surveys to understand their potential consumers. This process took months, even years, to provide a rough understanding based on a sample group that was never big enough. All business plans and marketing designs would be built on that information, until the day that big data ended it.

Big data change the way firms do business, make marketing plans, and deliver advertisements. With big data, firms can directly locate a potential consumer, deliver an advertisement at an appropriate time, and charge an affordable price to make a deal. For example, when consumers search for a business suit online, advertisements do not pop up randomly but in a logical layout regarding what they purchased before. This technology matches consumers with the goods or services they are looking for. Consumers can benefit from this personalized advertising as well, since it saves them time. They can find what they need more quickly.

Price Discrimination

On the other hand, big data bring new challenges to this world as well. There are some side effects accompanying big data. Nowadays we face new situations that we could not imagine years ago, such as personal privacy, data security, and price discrimination.

Big Data and Differential Pricing (2015) points out that one main concern with big data is price discrimination, which means charging different consumers different prices for similar products. Price discrimination can be divided into three types. First-degree price discrimination is personalized pricing, meaning there is no fixed sales price. Every consumer can negotiate the price, and they eventually pay different prices. Second-degree price discrimination is quantity discounts. In other words, buy more, save more. Third-degree price discrimination is a demographic discount, which means a specific group of people can get specific treat-

ment. For example, universities provide students who serve in the military with a specific scholarship or free tuition (Big Data and Differential Pricing, 2015).

In some cases, even though price discrimination sounds unfair, it is not, due to the factual situation. For example, children normally can get a specific discount, not only because they are in a specific age range but also because they increase the expenditure with their entire family. For example, parents have to accompany their children to the Disneyland, the cinema, the arcade, and so on. Therefore, children stimulate demand for certain goods and services that would not otherwise be consumed by adults. An airplane ticket is more expensive when the booking day is closer to the departure day, due to the increase in overall demand on that given date, as well as the finite number of available seats.

In some other cases, price discrimination may be really unfair. According to Townley, Morrison, and Yeung (2017), Amazon.com sold DVDs to different people for different prices in 2000. After a public protest, Amazon refunded the consumers who were charged a higher price and claimed that this was a test. However, a similar issue happened again in 2012. A consumer found that the price of a set of mahjong tiles in her shopping basket suddenly jumped from $54.99 to $79.99; when she emptied the basket and added the same goods into it again, the price went back to $59.99. The *Wall Street Journal* reported in 2012 that Staples Inc. was displaying different prices to people based on their location. Staples.com showed a lower price to consumers who lived within 20 miles of a rival store (Townley et al., 2017). According to Michael and Mohammed (2015), in international travel bookings for US hotel and car rental, the situation is the same.

According to Newcomer (2017), Uber Technologies Inc. uses a "route-based pricing" system, which charges consumers differently depending on the expectation of how much they would like to pay. This system is different from the traditional pricing model, which charges consumers only based on the quantity of a service they purchase. The pricing system Uber used before calculates fares by adding up time, mileage, and multipliers based on geographic demand. The new "route-based pricing" system charges some consumers a higher price not because they ride to a farther location, but because it is considered they would pay a higher price.

A similar situation was reported by Consumer Intelligence Research Partners (CIRP) in 2013: that among all smartphone consumers, iPhone consumers were charged the highest average monthly carrier bill in the

USA. CIRP co-founder Michael Levin believes this situation happens not because consumer behaviors are different among smartphone users, but because of their data plans and carriers (Keller, 2013; Paczkowski, 2013). In other words, iPhone users are charged a higher price for their carrier bills in the USA, not because the same apps cost more in data streaming than on an Android phone, nor because iPhone users spend longer on their phone than Android users, but possibly because they are considered richer, since the price of an iPhone is higher than that of an Android phone.

More evidence can be observed internationally. For example, according to Wu (2018), among 2008 participants, 51.3% suffered price discrimination when they purchased tickets, booked hotels, and subscribed for memberships online in China. There are several different types of price discrimination. (1) More refreshes, higher price. When booking flight tickets and hotels, the more times consumers refresh the website, the higher the price they will see. Once consumers clean the website's cache, cookies, and history, the price decreases. (2) Members pay more. Consumers may purchase a membership for movie ticket discounting, but some of them find that their price is higher than for consumers who do not have a membership. (3) Consumers pay a higher price on iPhone than on Android. Many iPhone consumers are charged a higher price when they subscribe to a membership or pay a taxi. Some firms explain this situation by saying that mobile payment services (Apple Pay, Alipay, etc.) offer convenience to their clients and users while charging a higher service fee on the iPhone than on Android.

Machlup (1955) may not be the first economist who has noticed that the definition of price discrimination ("the practice of a firm selling a homogeneous commodity at the same time to different purchasers at different prices") is somewhat vague, but he is the first to clarify this definition as "the practice of a firm or group of firms of selling (leasing) at prices disproportionate to the marginal costs of the products sold (leased) or of buying (hiring) at prices disproportionate to the marginal productivities of the factors bought (hired)". Moreover, according to Thomas (2012), in the insurance context the concept of price discrimination, which is selling products with similar marginal costs at different prices to different clients, is "non-risk" price discrimination. However, insurance is a risk-related product. Various price segments of it exhibit different marginal costs. This is why the data on (potential) consumers' health is so important for both insurance companies and consumers. With the data, the insurance company can charge a consumer a personalized price which may be signifi-

cantly different from the price without the data. Consumers may even do not know that their price is personalized and higher than that for others. Big Data and Differential Pricing (2015) explains the risk-based pricing policy of insurance companies as finally helping the whole of society by charging drivers with risky behaviors or a history of traffic accidents a higher price. Therefore, these drivers will change their behaviors and society will become safer for everyone.

It is not hard to understand that firms have plenty of reasons to treat their clients differently. This is considered necessary and motivation for them to pay for big data, especially service firms. Different from goods companies, service companies have a long-term relationship with their clients. They provide services constantly, which means the relationship between a service company and a consumer keeps changing with time. For instance, insurance companies service their clients from cradle to grave. Some clients have good health while some others do not. Therefore, insurance companies could separate them into different segments (high risk, moderate, low risk) and foresee the future revenue compared to the expected underwriting expense. Thus, insurance companies charge different prices to match the health situation of their clients.

Discussion and Conclusion

Podesta, Pritzker, Moniz, Holdren, and Zients (2014) believe that it deserves more serious concern when data impact decisions on individuals' credit, housing, education, healthcare, or employment. Moreover, personal privacy is another critical concern (Big Data and Differential Pricing, 2015). According to Payton, Schmidt, and Claypoole (2014), the core of privacy is not about information but about choice. According to Hacker and Petkova (2017), both greater social equality and inequality have been generated with big data. Because of big data, technology, education, and business are more efficient than before. However, consumer protection and discrimination bring greater inequality to society. Big data provide firms with opportunities for personalizing services. Before the new big data era, consumers were exposed to the same advertisements. They had an equal chance with the same offers at the same price. However, big data collection and analytics are changing this situation. With the new technology, firms know exactly what consumers want and how much they can afford. On the other hand, consumers do not know that they are being treated differently from one another. In other words, with detailed data,

companies can manipulate their consumers individually. Consumers are guided by an invisible hand to a place they think will satisfy their needs. However, they may pay a higher price or make a suboptimal decision because of firms obtaining their data and using them inappropriately. Big Data and Differential Pricing (2015) suggests that enhancing the transparency of how firms collect, use, and trade consumers' data would promote competition in the market and provide consumers with choices. In addition, Hacker and Petkova (2017) point out that transparency is important during this new big data era. Citron and Pasquale (2014) state that people have the right to access and correct their information and they have the right to know how they are rated and ranked as well. In other words, consumers have the right to keep their privacy, especially when they do not buy insurance from certain insurance companies. In addition, even though it may be necessary for insurance companies to obtain these data to lower their risks and costs, do they have the right to do so?

First of all, who owns the data? Or we may consider this from another angle: where is the line drawn when collecting data without notifying people that their data are collected, retained, and will be used to manipulate them later? Before the big data era, when companies had to collect data by sending out surveys, they had to send an obvious notification to the participants regarding this concern. They had to tell the participants it was voluntary. In some cases, they paid participants to collect their data. Moreover, normally, the participants were anonymous. They did not provide their personal information, such as name, date of birth, and address. Therefore, they did not need to worry about how these data would be used. However, the new technology changed this. The new technology enables web browsers and apps to collect and retain personal data on a continual basis. Because of this process, eventually, consumers get personalized advertisements. In some cases, this is harmless. On the contrary, it is convenient. On the other hand, it is a trap. Under the manipulation of a marketing strategy provided to companies based on specific data analytics, consumers purchase something that they do not need or are charged a higher price just because they are (considered) richer than others.

Consumers may not know that their data are being collected and their behaviors are being manipulated. They may enjoy the convenience. For example, a pregnant woman does need to prepare for the upcoming baby, and advertisements and coupons for baby products are useful to her. Or for a resident who has just moved to a new apartment, information about furniture discounts and internet services is helpful.

However, price discrimination is not a convenient experience. For example, ticket selling or hotel booking websites manipulate consumers by increasing prices according to their refresh frequency. This manipulates consumers to close the deal as soon as possible by implying that the price will keep increasing or that tickets are selling out. Consumers waste money as a result of their actions being recorded and analyzed by data analytics.

In conclusion, we believe that transparency of data collection is important and necessary. Individuals have the right to access data held on them and to have greater control over their own information. They should be notified when their information is collected and traded. They should have the right to say no to certain firms whose business is to dig, gather, collect, and analyze data. Furthermore, firms should be restricted by regulations regarding their operations. On the other hand, consumers who would like to enjoy personalized services, such as advertisements or coupons, can choose to allow data-gathering firms to collect their data with their permission.

CHAPTER 10

Digital Finance for Financial Inclusion and Inclusive Growth

Md. Nur Alam Siddik and Sajal Kabiraj

Introduction

The notion of financial inclusion emerged in early 2000 and thus was given policy priority by governments and international organizations to reduce poverty and achieve inclusive growth. Consequently, governments and policy makers formulated policies to foster financial inclusion in developing and emerging economies (GPFI, 2010). Nowadays, digital finance has gained much attention from policy makers as a mechanism for reducing poverty and achieving financial stability, because digital finance expands financial inclusion, which ultimately promotes financial stability.

Digital finance has numerous benefits to all stakeholders, including financial service users, digital finance service providers, governments, policy makers and the economy. For example, it expands access to finance among the poor and disadvantaged, it can reduce the cost of service for

banks and fintech suppliers by employing a branchless technology-based banking system, and it can lead to a rise in total expenditure for governments. The World Bank Group President Jim Yong Kim indicated that by 2020, digital financial instruments such as e-money cards, debit cards and low-cost bank accounts will significantly expand the scope of financial access for excluded people.[1] Notwithstanding its benefits, the issue of digital finance, financial inclusion and financial stability has not been addressed in the literature. This study aims to fill this gap by addressing the link among digital finance, financial inclusion and financial stability.

This research contributes to the financial inclusion campaigns initiated by the World Bank as an operational solution for poverty eradication in developing and emerging economies. The findings of this study can help policy makers to understand the issues related to the prompt expansion of digital financial services, strategies for its effective delivery to the poor and the risks involved in digital financial inclusion. Secondly, this study adds to the existing literatures on emerging digital finance and financial inclusion, which will enable academics and researchers to attend to the effects of digital financial services on financial inclusion.

Conceptualizing Digital Finance

Manyika, Lund, Singer, White, and Berry (2016) defined digital finance as financial services delivered through a digital infrastructure such as a mobile phone and internet network, which eventually encourage less usage of cash and the traditional brick-and-mortar banking system.

According to Gomber, Koch, and Siering (2017), digital finance comprises a magnitude of new financial products, financial services, financial management software and new ways to communicate and interact with customers. Digital finance implies a procedure of a certain blend of related money management tools that are conveyed using a portable or Web-based system (Peake, 2012).

Klapper, El-Zoghbi, and Hess (2016) demonstrate that digital finance permits people to access finance from distant places and at any time, which enables them to manage their funds well at times of need and thus shrinks the possibility that they will fall into poverty.

While there is no universal description of digital finance, there is a consensus that it incorporates financial products, financial services, technolo-

[1] https://www.worldbank.org/en/news/speech/2016/04/14/remarks-by-world-bank-group-president-jim-yong-kim-at-the-global-connect-initiative

gies and infrastructure that empower people to have access to payments, savings and credit facilities along with other required financial services through online means and without a physical visit to a bank branch.

Conceptualizing Financial Inclusion

Financial inclusion aims to ensure access to and use of financial services such as accounts, savings and credit for everyone, including the poor and disadvantaged. It targets the unbanked, people who have not been offered financial services, bringing them under the umbrella of the formal financial system, and the under-banked, people who have access to but have not used financial services. The overriding goal is to create an environment in which all people will have easy access to financial services to ensure the participation of everyone in the course of economic growth and receiving the benefits of economic growth accordingly.

Siddik, Sun, and Kabiraj (2015) describe financial inclusion as a means of providing easier and timely access to finance to all sections of society, including disadvantaged groups, which in turn will promote inclusive growth.

Hannig and Jansen (2010) state that financial inclusion programs aim to offer greater opportunity with easier access to proper financial services to people, including disadvantaged groups, which in turn fosters the economic development of a country. Sarma (2015) defines financial inclusion as a procedure which warrants easier access, readiness and usage of financial services for all people of a country. This explanation strictly emphasizes access to and usage of formal financial services for entire segments of society, which is one of the most vital factors in the economic growth of a nation. Following the definition of Sarma (2015), we focus on the access and usage dimensions of financial inclusion and define it as a process which aims to expand the financial network among people including the unbanked and the under-banked. In developing economies, the banking sector is reflected as the key pillar and the most contributive sector to economic growth. Thus, we focus on financial inclusion by commercial banks.

Effect of Digital Finance on Financial Inclusion

The impact of digital finance on financial inclusion is now evident. Digital financial services have the substantial prospect of magnifying the delivery of financial services to a large segment of society, including the poor, through innovative technologies such as mobile banking solutions,

e-money systems and digital payment infrastructure at a reasonable cost, in appropriate modes and in a safe environment. According to the 2016 annual report of the International Telecommunication Union (ITU), 95% of the world population lives in areas which are covered by a mobile cellular signal and in 2016, 47% of the world population was online, which indicates progress, but at the same time over half of the world's population, or roughly 3.9 billion people, was not online. This suggests that there is huge potential to settle financial matters digitally.

Digital finance adds new stratums to financial inclusion, proposing new methods of expanding the inclusion of groups profiled as poor and disadvantaged in mainstream financial activities (Gabor & Brooks, 2017).

Manyika et al. (2016) point out that the wide-ranging usage of digital finance could increase the annual gross domestic product (GDP) of all economies by 6% by 2025. Arguing the same, Ghosh (2016) employs data from 2001–2012 on Indian states and observes that mobile telephony as a means of digital financial services has significant effects on economic growth. Proposing similar contributive effects of digital finance on financial inclusion, we first examine world data and then provide case studies on India.

Methodology

To determine whether digital finance promotes financial inclusion, in this section we present the effects of digital finance on financial inclusion. In this study financial inclusion is measured by outstanding loans with commercial banks (% of GDP; log of outstanding loans or LOL) and digital finance is measured by three widely used proxies: the number of automated teller machines (ATMs) per 100,000 adults (ATM); the percentage of the population using the internet (INT); and mobile money transaction value (percentage of GDP; MMT). Based on the availability of data, we collected data from 2004 to 2016 on 189 countries. Variable measurements and data sources are presented in Table 10.1. Taking the average of each variable for each year, firstly we conducted trend analysis and secondly we produced two case studies in support of our hypothesis.

Empirical Findings

We divide this section into two parts. In the first part we conduct a trend analysis with linear regression, and in the second part we provide case studies. In Figs. 10.1, 10.2 and 10.3 we represent the financial inclusion

Table 10.1 Variables, their proxies, legend and source

Variable	*Measurement*	*Legend*	*Sources*
Financial inclusion	Natural log of outstanding loans with commercial banks (% of GDP)	LOL	FAS*
Digital finance	Natural log of number of automated teller machines (ATMs) per 100,000 adults	ATM	FAS
	Individuals using the internet (% of population)	INT	WDI**

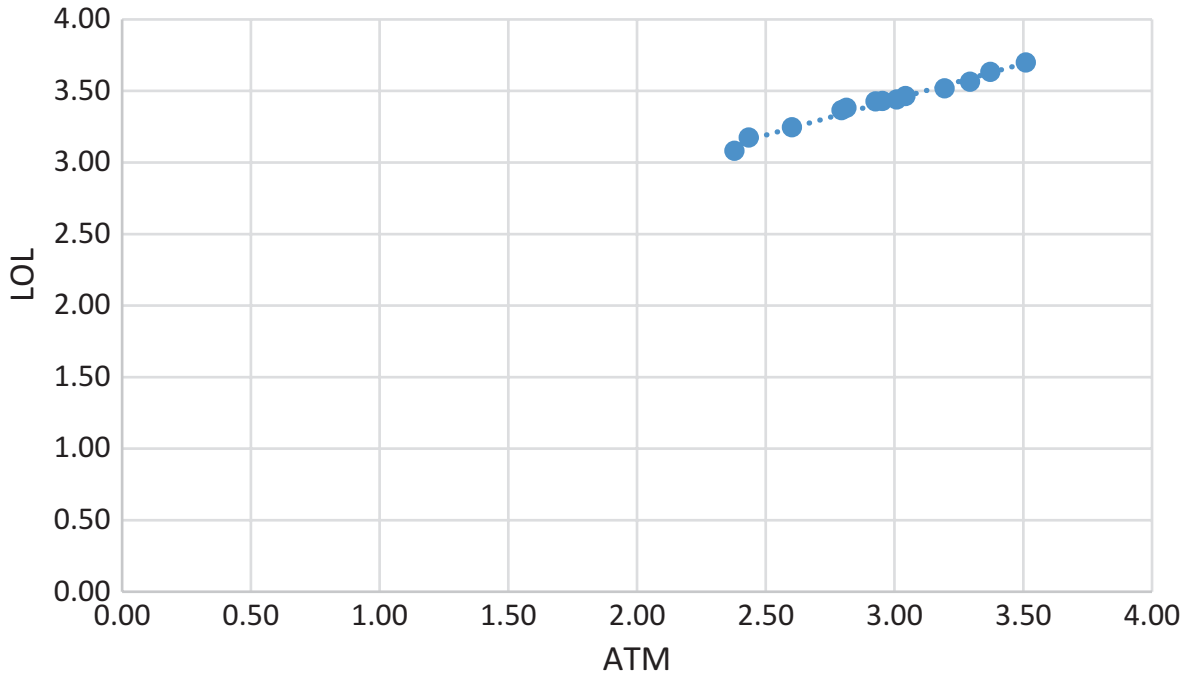

Fig. 10.1 Impact of ATM on LOL

variable, LOL, on the Y axis and digital finance proxies on the X axis. These figures represents the association of digital finance proxies (ATM, INT and MMT) with financial inclusion, LOL. Figure 10.1 depicts an upward, straight trend line between the number of ATMs per 100,000 adults and outstanding loans with commercial banks, which means that there is a positive relation between ATM and LOL.

Figure 10.2 exhibits the relation between internet penetration and financial inclusion. With linear trend analysis, we see that the higher the number of internet users, the higher the degree of financial inclusion. In other words, there is a positive effect of INT on LOL.

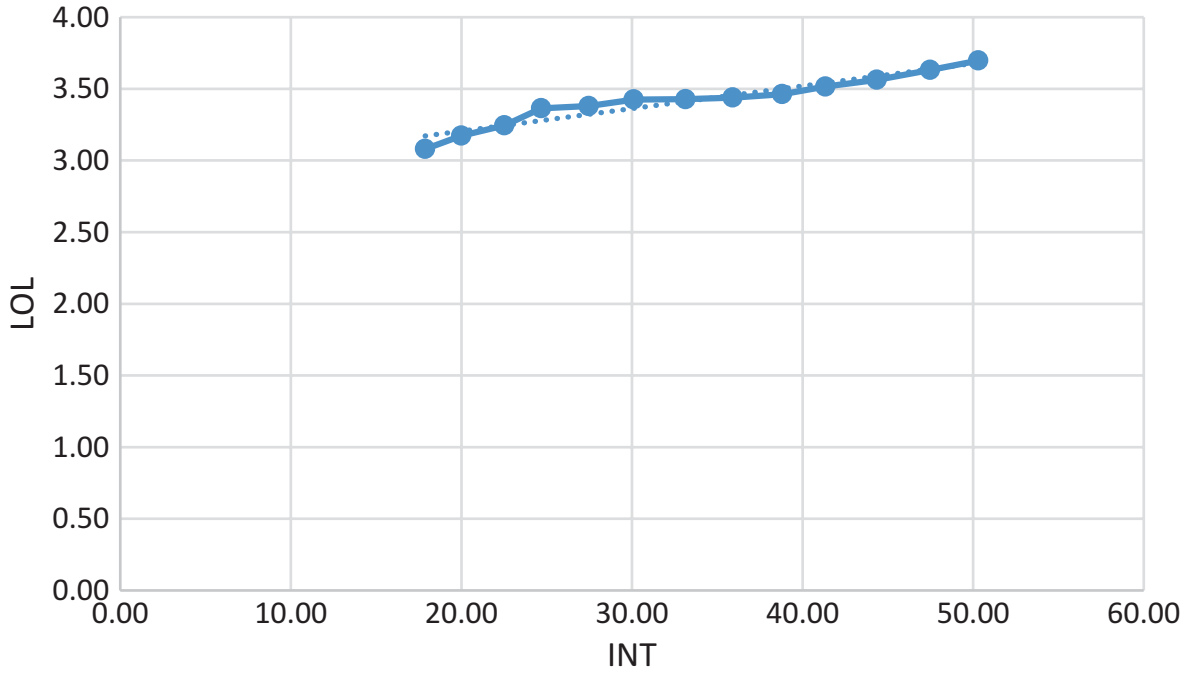

Fig. 10.2 Impact of INT on LOL

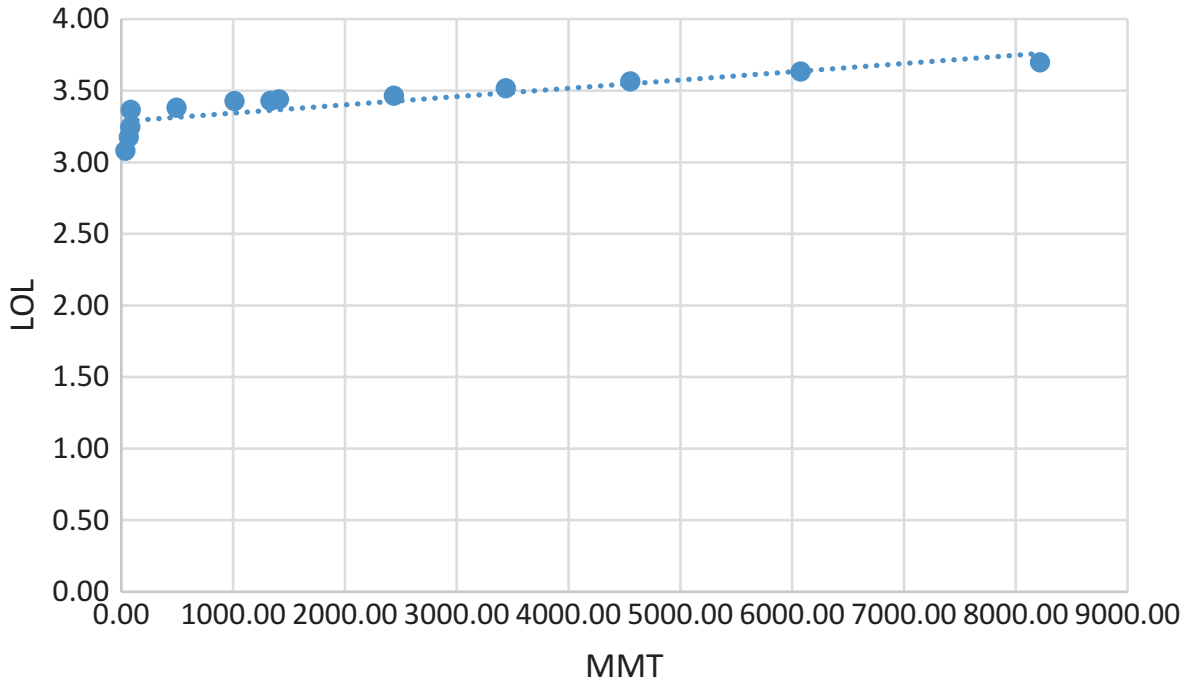

Fig. 10.3 Impact of MMT on LOL

The third proxy we use is the value of mobile money transactions. Since mobile money is one of the most widely used instruments of digital finance which has great global penetration, we have used this proxy to examine whether this contributes to financial inclusion or not. The results of the trend analysis indicate that there is positive movement between MMT and LOL. Thus, we argue that digital finance promotes financial inclusion. Our findings are similar to those of Ozili (2018).

Case Study

In this section we look at India, which is well and truly in the digital era and is a good example of digital financial inclusion. The essence of the case study is the use of technology to support the country's flagship benefit transfer programs and open doors for the poor to the financial mainstream. India is a leading case study of commitment to digital transformation and financial inclusion. With over a billion mobiles, 325 million broadband connections and 306 million new bank accounts, the country has become a case study in digital financial inclusion. The 500-million mobile connections in rural areas offer an opportunity to achieve full financial inclusion.

To make this happen, India has been launching strategic innovations to improve the design and drive a faster rollout of large benefit programs. The innovations pointedly track the delivery of entitlements to beneficiaries and help engage with the excluded millions using mobile-based tools. India's Digital Financial Inclusion program has piloted an integrated cashless digital platform to bring the farming community to center stage, while supporting a technological solution to fund and track rural projects. Another pilot infuses transparency into the delivery of nutrition across anganwadis, or rural childcare centers. A notable new entry is a technology platform to support a nationwide welfare scheme for pregnant and lactating mothers.

The Digital Financial Inclusion program uses insights drawn from work in both the corporate social responsibility (CSR) and government spaces to develop collaborative information technology (IT) platforms that bring corporates and governments together for community development. Moving upstream to benefit design, the program has also deployed analytical tools that use complex information on existing government schemes and databases to help design new programs.

Together with non-governmental organizations (NGOs) and the government, India's Digital Financial Inclusion program collaborates,

conceptualizes and develops innovative solutions for enabling direct benefit transfer (DBT), financial inclusion and financial literacy. The program conducts research studies to understand and analyze factors that could possibly lead to the greater adoption and use of digital services by the poor. Postal accounts offering digital bank accounts could lead the way in this. Recently, the India Post Payments Bank (IPPB) has offered facilities for deposits, money transfers, DBTs and bills and utility payments, among other things.

Case 1: India Post Payments Bank: A Case Study of Digital Financial Inclusion

IPPB offers three types of zero-balance savings accounts: regular savings, digital savings and basic savings bank deposit accounts.

October 9 is celebrated as World Post Day. It also marks the beginning of National Postal Week, which is celebrated until October 15. India Post, which runs postal services in the country, sent greetings to its followers on the occasion, as did the government to its employees. India Post, which has a network of 155,015 post offices, also started the India Post Payments Bank in the year of 2018. IPPB has 650 branches and 3250 access points.

IPPB offers three types of savings account: regular savings account, digital savings account and basic savings bank deposit account.

- *India Post Payments Bank regular savings account*

This regular savings account allows for unlimited cash deposits and withdrawals. The zero balance account offers an interest rate of 4% per annum on end-of-day balances. The interest is paid on a quarterly basis.

This account does not require any monthly average balance and it can be opened with a zero balance. The maximum end-of-day balance that can be maintained is USD 1458.61.

- *India Post Payments Bank digital savings account*

IPPB's mobile app allows customers to open this account on their own, instantly. A maximum end-of-day balance of USD 1458.61 is allowed and a maximum yearly cumulative deposit of USD 2917.73.

This zero balance account is subject to closure if "know your customer" (KYC) verification is not completed within 12 months of opening. KYC

helps banks verify their customers' identities. Aadhaar and PAN cards are mandatory for opening a digital savings account at IPPB.[2]

- *India Post Payments Bank basic savings bank deposit account*

This savings account has all the features and benefits offered by the regular savings account, except that it allows only four cash withdrawals in a month. It also does not require maintenance of any monthly average balance. It can be opened with a zero balance and offers an interest rate of 4% annum, paid quarterly.[3]

Financial inclusion products must be founded on the following principles:

E1: Effectiveness
How effective it is to use, how useful the product is and how it can make a difference in daily life.
E2: Efficiency
How efficient it is to use, whether it is easy to use, easy to handle, child compliant, suitable for senior citizens and differently abled people.
E3: Economical
How affordable it is for people at the bottom of the pyramid. The pricing of the product should be according to the cost of the technology. It should be accessible in small quantities to the majority of consumers.
E4: Environment
The product should be sustainable, eco-friendly and able to be recycled easily.

The earnings from these products can be reflected as a measure of the 3Ps (People, Planet and Profits):

Earnings = E1, E2, E3, E4 $\propto$ P1, P2, P3

[2] Aadhaar number is a unique 12-digit biometric-based random number issued by the UIDAI (Unique Identification Authority of India) to the residents of India after satisfying the verification process and the enrolment process is totally free of cost. A permanent account number (PAN) is a unique 10-digit alphanumeric number, issued by the Indian Income Tax Department, to any "person" who applies for it or to whom the department allots the number without an application and it is valid across India and is unaffected by a change of name, address within or across states in India or other factors.

[3] Sunil Dhawan (2017), 'This savings account doesn't require any minimum balance: Find out if it suits you', article published in Economic Times, India, dated 29 September 2017.

Digital finance products could be subjected to A/B testing. In web analytics, A/B testing (bucket tests or split-run testing) is a randomized experiment with two variants, A and B. It includes the application of statistical hypothesis testing or "two-sample hypothesis testing" as used in the field of statistics. A/B testing is a way to compare two versions of a single variable, typically by testing a subject's response to variant A against variant B, and determining which of the two variants is more effective.

The two versions that are compared are identical except for one variation that might affect a user's behavior. Version A might be the currently used version (control), while version B is modified in some respect (treatment). For instance, on an e-commerce website the purchase funnel is typically a good candidate for A/B testing, as even marginal improvements in drop-off rates can represent a significant gain in sales.

A/B testing has been marketed by some providers as a change in philosophy and business strategy in certain niches, though the approach is identical to a between-subjects design, which is commonly used in a variety of research traditions. A/B testing as a philosophy of web development brings the field into line with a broader movement toward evidence-based practice. The benefits of A/B testing are considered to be that it can be performed continuously on almost anything, especially since most marketing automation software now typically comes with the ability to run A/B tests on an ongoing basis.

Based on the results of A/B testing, products could be redesigned to meet the specific needs of customers within a period of 24 hours. Real-time tracking may not be possible due to the small amount of capital involved. However, A/B testing could produce good results.

Case 2: Direct benefit transfer—a game-changer for financial inclusion in India

History is replete with evidence of the role played by monetary and financial systems in people's lives. Observers describe "golden age" periods in which the quality of life was better, the spirit of innovation encouraged and prosperity widespread. To the extent that this was indeed the case, it was so because of wider participation in formal financial systems.

Today, the extent of such participation is an indicator of economic well-being made possible through opportunities in savings, payments, investments and insurance. Financial services also help small businesses grow, create employment and contribute to economies.

Yet a reported 2.5 billion adults worldwide are excluded from formal financial systems. In India, nearly half of the country's 1.25 billion people have no access to banking services, and close to 300 million people live below the official poverty line. To realize India's potential, its leaders need to ensure that this excluded segment can take part in formal banking and benefit from it.

The majority of people who live below the poverty line—as well as just above it—in India rely on government welfare payments such as those from the National Rural Employment Guarantee Act, old age pensions, scholarships, widows' pensions, discounted liquid petroleum gas (LPG) for cooking, and other subsidies. The government of India makes these payments, whose estimated value is a huge $60 billion per year, through the Direct Benefit Transfer (DBT) scheme, covering beneficiaries under 59 individual schemes.

The sheer extent of its reach and impact makes DBT an excellent platform to bring banking closer to the unbanked masses, but achieving that objective requires long-term vision, not short-term or ad hoc measures.

Over the last decade, technological developments have fast-tracked the way we do financial transactions. Financial inclusion efforts, too, have felt the impact of emerging technologies, with biometrics leading the way in extending banking reach. Technology-aided DBT delivery is the way forward.

However, the issues plaguing the existing transfer system need to be addressed, including broadband and mobile connectivity, lack of power, inaccurate data on beneficiaries, leaks and frauds due to corruption, and so on. This is where technology-driven solutions come into the picture.

JAM (Jan Dhan, Aadhaar, Mobile) is a combination of three platforms intended to drive financial inclusion efforts as envisaged by the government of India. The first is Jan Dhan Yojana, a project for opening bank accounts for all. The second is Aadhaar, a 12-digit unique identity number issued by the Unique Identification Authority of India. And the third is mobile technology, especially the increasing adoption of smartphones. The JAM trinity, as it is called, has the potential to completely digitize DBT delivery and promote financial inclusion.

Under this digital program, the first scheme to be rolled out using DBT is the LPG subsidy payment to nearly 150 million registered beneficiaries. Welfare payments for the National Rural Employment Guarantee Act and kerosene subsidy are expected to roll out next. Intended beneficiaries get their welfare payments directly credited to a bank account and can do financial transactions from multiple access points as is convenient—ATM,

bank branch or business correspondent point—with the unique identity number for authentication (see Fig. 10.4).

Source: National Payments Corporation of India. Infographics by FINO PayTech.

The latest government reports say that the implementation of DBT for LPG subsidy beneficiaries has led to savings of more than $3 billion during the last two years. This was possible because of two primary reasons: weeding out over 30 million fake beneficiaries using the unique identity number, and ensuring that the right beneficiary gets the right amount through the safety of a bank account.

If a single scheme can realize such savings, imagine the potential when $60 billion in welfare payments is seamlessly and directly credited to the bank accounts of all beneficiaries. Gradually, as hitherto unbanked and under-banked people start using bank accounts to make transactions, various other relevant financial products can be made available, allowing them to save, invest and insure their future. This innovative model can thus be a game-changer in promoting financial inclusion and fueling economic growth in India.

Conclusions

In the age of the digital economy, digital finance with its unique features has been playing an important role in countries' inclusive growth process. It extends the opportunity for all, including the poor and disadvantaged, to participate in economic activities. This study has explored the effects of digital finance on financial inclusion by two methods. Via the first method, using data from 2004 to 2016 on 189 countries, the authors conducted trend analysis and found that all digital finance proxies have positive effects on economic growth. For the second method, considering India as a highly promising country for digital finance, we studied two cases and observed the positive effects of digital finance on financial inclusion. Thus, based on the findings, we argue that policy makers should adopt such policies to promote digital finance, which in turn will promote financial inclusion, resulting in the inclusive growth of the country.

Depending on the availability of data, future research could attempt to examine the relation between digital finance and financial stability with a special focus on periods of financial crisis, so that the economy will have the capacity to meet the challenge of such crises. Digital finance may not serve as an overall panacea for the world's poor, but it can definitely facilitate the better establishment of services to meet working capital requirements, thereby contributing to a corruption-free system leading to better dissemination of services. Predictive analytics combined with biometrics could be one of the futuristic areas of digital finance as the discipline matures and includes more stakeholders across the value chain, making it more inclusive and holistic. The future of digital finance and its implementation is here to stay and would provide ample opportunities for future researchers to expand its aim and scope.

CHAPTER 11

Understanding Consumer Behavior in Technology-Mediated Spaces

İlayda İpek

Substantial improvements in technology have been influencing not only strategies and structures of firms but also consumers' social and economic lives. In terms of the former, in order to respond to the alterations in the technological environment, and ultimately, to stay ahead of the competition, firms have been making continuous attempts to fit their internal resources and competencies with the external circumstances. Concerning the latter, having an enormous impact on the manner of communicating, consuming, and progressing, technological advancements have been shaping consumers' daily lives. Specifically, digital technology has affected consumers' routines and habits, which in turn has led to changes in consumer behavior.

Currently, along with the benefits of the Internet, consumers have the ability to easily reach all information regarding firms, which increases the bargaining power of consumers. They have had a more tendency to shop online; however, the critical thing is that they desire to have unique experiences, which stresses the significance of effective customer relationship management (CRM) activities. Being aware of the strength of technology

on consumer behavior, firms have been more inclined to enhance their offerings, with a particular emphasis on the design of positive consumer experiences. Additionally and remarkably, together with the advances in technology, the roles of firms and consumers have differed considerably. In this sense, firms have been working interdependently with their customers, who are highly involved in co-creating value. Correspondingly, digital marketing has gained huge importance in every aspect of business activities. Building on the aforementioned issues, by drawing on digital marketing, the main purpose of this chapter is to identify how consumer behavior has evolved through the digital transformation in recent decades.

Digital Marketing

Dating back to the early 1990s, the Internet has been commercially utilized since almost three decades (Tiffin & Rajasingham, 2003). Coupled with this digital evolution, boundaries across firms and cultures have been seriously decreased (Wymbs, 2000). In today's business world, rivalry among firms is not based on products or services, but instead on business models, which aim to generate customer value by the combination of digital technologies (Yoffie & Cusumano, 1999). Nevertheless, maintaining competitive advantage in a marketplace is much more burdensome than before by reason of high business risks related to the extremely dynamic nature of the digital environment (Hamel & Sampler, 1998). As it has been well emphasized by Bill Gates (1999), "the Internet changes everything".

Increase in the availability of the Internet; and thus, its extensive commercial usage, have led new players to stand out in today's modern economy. Those players have recorded huge success; such that, according to Forbes (2018a), Google, Facebook, and Amazon have been among the world's five most valuable brands in this year. E-commerce has been dramatically growing; for instance, current retail tendencies indicate that more than half of Americans (51%) have been engaged in online shopping in 2018, with the e-commerce growth rate of 23% year-over-year (BigCommerce, 2018). In addition, it has been expected that US consumers' spending on online shopping will total $632 billion by 2020 (Business Insider Intelligence, 2016).

Moreover, as another distinctive alteration in the technological environment, Web 2.0 has begun to replace Web 1.0. Whereas the contents of Web 1.0 tools are created by providers, Web 2.0 technologies incorporate

interactive and user-generated content (Munar & Jacobsen, 2014). In conjunction with the widespread acceptance of Web 2.0 technologies, a substantial switch from firms to consumers has been reflected (Berthon, Pitt, Plangger, & Shapiro, 2012). In spite of its technological nature, Web 2.0 has also yielded to sociological revolutions, which have exerted an enormous influence on business operations (Berthon et al., 2012). Relying on these facts, in recent years firms have been more inclined to enhance "digital relationships" with their customers (Phillips, 2015).

In order to keep pace with the digital transformation of consumer behavior, firms have been oriented to reshape and restructure their functions, with a special stress on marketing operations (Edelman & Heller, 2015). Accordingly, over the past decades, marketing scholars and practitioners have registered a significant change in the nature of marketing, specifically due to the emergence of new marketing communication channels derived from technological innovations (Lamberton & Stephen, 2016). Currently, digital technology has critically altered the way firms formulate their targeting strategies and interact with their customers. In this respect, "digital marketing" arises as a crucial concept.

The digital marketing term is defined as "an adaptive, technology-enabled process by which firms collaborate with customers and partners to jointly create, communicate, deliver, and sustain value for all stakeholders" (Kannan & Li, 2017, p. 23). Digital marketing represents a novel perspective, not only traditional marketing reinforced by digital components; hence, it includes idiosyncratic characteristics that need to be in-depth evaluated (Taiminen & Karjaluoto, 2015). Instead of concentrating on technology, an effective digital marketing strategy necessitates to comprehend how consumers adopt technology, and correspondingly, to look for channel alternatives in an attempt to strengthen the engagement between consumers and brand (Ryan & Jones, 2009). Without a proper analysis, digital marketing communications may not make sense for target customers, which in turn may result in big losses. Dealing with change and innovation seems to be problematic for all marketing practitioners; however, the situation is notably difficult for digital marketers (Chaffey, 2010).

Being aware of the role of digital marketing in consumers' decision making process, in today's business world, it is imperative for firms to apply digital marketing solutions in an effort to reach their target customers. This is especially valid for both large and small- and medium-sized enterprises to stay competitive in market (Taiminen & Karjaluoto, 2015). Newly, digital advertising expenditures provide evidence on this notion;

digital ad spending worldwide accounted for $283.35 billion in 2018, with a growth rate of 21.4% (eMarketer, 2019). In addition, it has been also anticipated that worldwide spending on digital advertising will amount to $517.51 billion by 2023 (eMarketer, 2019). Critically, the amount of digital touchpoints is rising by more than 20% in every year, because more number of consumers prefers to use digital technologies and "younger, digitally oriented consumers enter the ranks of buyers" (Bughin, 2015). Contacting with consumers by means of digital media is therefore recognized as one of the most promising approaches in the area of strategic marketing for the coming decades (Smith, 2011).

Accompanied by digitization, traditional marketing communication tools started to be supported by new digital channels. These digital tools, providing new and exciting platforms, enable firms to reach target markets in various and creative manners (Ryan & Jones, 2009). Importantly, besides its impact on targeting strategies, digital marketing also allows to leverage existing brand equity (Chaffey, 2010). Augmented reality practices, social media, and mobile apps constitute some late communication channels in digital marketing, which have been broadly preferred by today's success-oriented firms. As an illustration, Uber symbolizes an achievement story, mainly by virtue of the right mixture of targeting and digital media. Operations of the firm are managed with a mobile app and the firm has largely employed online advertising in social media to cultivate its business activities. Presently, Uber announced $48 billion valuation (Donnelly, 2018), which signifies an outstanding accomplishment obtained in just nine years. Another similar example in the sharing economy focusing on digital marketing is Airbnb founded in 2008, with the reported value of $31 billion as of March 2017 (Forbes, 2018b). In a nutshell, it has been strongly suggested that "technology has facilitated novel market behaviors, interactions, and experiences" (Lamberton & Stephen, 2016, p. 146).

It is a foregone conclusion that digital marketing strategies are of vital importance in today's highly dynamic environment; nevertheless, it has been also firmly advocated that firms should be careful about the decisions regarding digital marketing channels. Specifically, firms cannot perform in all digital communication channels, because "being active" is the first and foremost factor of success (Kaplan & Haenlein, 2010). The appropriate digital medium needs to be determined on the basis of customers to be targeted and message to be delivered (Kaplan & Haenlein, 2010). Moreover, the number and engagement degrees of customers in a digital

platform remarkably influence performance (Trusov, Bodapati, & Bucklin, 2010). As a result, pros and cons of each communication medium require to be deeply scrutinized before resources are assigned to digital marketing activities.

E-Customers

It has been widely acknowledged that increase in consumers' involvement in digital devices has given rise to changes in consumer behavior. In particular, information technology innovations have affected to a greater extent how consumers respond to different market settings (Lamberton & Stephen, 2016). The Internet usage rates all over the world have been growing in each year; the statistical report offered by the World Bank (2018) demonstrates that 45.79% of the world's population used the Internet in 2016, while this number was 43.08% in the previous year. Even more stunning is the Internet adoption statistics in some developed countries; for example, in the UK, Japan, and United Arab Emirates more than 90% of the country's whole population utilized the Internet in 2016 (World Bank, 2018).

Consumers' rising inclination toward using the Internet and digital channels can be well explained by the principles of the Technology Acceptance Model (TAM) (Davis, 1989) and Diffusion of Innovations (Rogers, 1962). In line with the TAM, since digital technology encompasses both perceived usefulness and perceived ease of use (Davis, 1989), consumers have been more willing to accept the transformations in the technological environment. As for the Diffusion of Innovations, on the basis of the fit between the digital technology and the characteristics, which affect the acceleration of innovation (i.e., relative advantage, compatibility, complexity, trialability, and observability) (Rogers, 1962), consumers have become more interested in engaging in the Internet and digital tools (Rodriguez, Peterson, & Krishnan, 2018; Takacs & Freiden, 1998). Hence, progresses in the Internet and Web-based platforms have cultivated online consumer behavior, which has shaped the nature of consumers' daily activities (Tiago & Veríssimo, 2014).

The essence of the interaction between firms and customers is not like before, since "The Internet is not just another marketing channel; it's not just another advertising medium; it's not just a way to speed up transactions; the Internet is the foundation for a new industrial order" (Hamel & Sampler, 1998). Web 2.0 technologies have dramatically resulted in a shift

in value creation and power from firms to customers (Berthon et al., 2012). Currently, customers are more empowered than before because of the advantages associated with the employment of digital devices, covering, information access, product variety, competitive pricing, and convenience (Pires, Stanton, & Rita, 2006; Tiago & Veríssimo, 2014). Without much effort, they are able to spread word-of-mouth information about products/services via social networks even with individuals they do not know (Kannan & Li, 2017). Further, as another concern for digital marketers, customers are becoming increasingly sophisticated and their expectations are incessantly expanding (Udo, Bagchi, & Kirs, 2010).

Customers are actively taking part in different digital communication channels such as social media, web forums, blogs, and mobile apps. Whereas previously for product/service purchases, customers were more relying on worth-of-mouth communication with membership reference groups such as family and friends, today they prefer more to gather information about products/services through online reviews, to compare and contrast different offerings' aspects and prices on websites, and to talk over alternatives through social-networking platforms (Edelman, 2010). In conjunction with customers' high authority in digital world, brand messages formed by firms have lost their effect and the possibility of conversion has declined on average (Bughin, 2015). Realizing their bargaining power on firms, customers want firms to build close bonds with them, rather than to command (Edelman, 2010).

Especially, social media acts a critical role for digital customers; in social media customers have an interaction with brands and they exchange information and experiences with others (Lamberton & Stephen, 2016), which have been considered to have a significant influence on buying behavior (Berthon et al., 2012). It has been revealed that in globe 135 minutes were daily spent in social media in 2017, with an increase from 126 minutes in the prior year (Ward, 2018). And interestingly, the statistics referring to the time devoted for mobile devices have indicated that in the US individuals consume more than 90% of their Internet time on smartphone apps (eMarketer, 2017).

In some cases, customers' high involvement in digital mediums may be seen as problematic in terms of firms. As it has been already highlighted, today customers are identified as "unfettered" (Nunes & Cespedes, 2003), and correspondingly, they are free to spread positive and negative words about a firm's offerings and strategies with or without getting permission of the firm (Kietzmann, Hermkens, McCarthy, & Silvestre, 2011). This makes firms defenseless as their offerings' quality, availability, and prices

are completely obvious and any weak points are swiftly disseminated all over the world (Nunes & Cespedes, 2003). Such kinds of online customer-to-customer information exchanges are attempted to be managed by firms with word-of-mouth marketing methods such as social media marketing, viral marketing, and guerilla marketing (Kozinets, de Valck, Wojnicki, & Wilner, 2010), because customers are highly dependent on other customers' opinions and feelings while making buying decisions.

Online Customer Experiences

Developments in technology; logistics, payment systems, and trust in particular—together with the escalation in the Internet usage—have formed a $1.9 trillion global online shopping market, in which "millions of consumers no longer 'go' shopping, but literally 'are' shopping - at every moment and everywhere" (KPMG, 2017, p. 2). Primarily due to the benefits provided by online retailing to consumers such as freedom of shopping in any time and place, online sales have smoothly reached double-digit growth numbers in some countries (Nielsen, 2017). Notably, in the world's biggest online market, China, the growth rate of 32.2% year-on-year in online retailing was recorded in 2017, while this number decreased by 2.1% in the first two quarters of 2018 (National Bureau of Statistics of China, 2018a, 2018b). The nature of online shopping is assumed to alter at an even faster speed coupled with the expansion of voice search and omni-platform/omni-channel alternatives (Popomaronis, 2017).

Apart from these online shopping trends, it is indisputable that consumers are not rational decision makers anymore. During the stages of the decision making process, they are more relying on their feelings and they want to have unique experiences. Accordingly, the present situation is more challenging for firms, since they have to devote more time and effort to improve their offerings through well-designed and positive customer experiences. This fact is not only true for brick-and-mortar businesses; by virtue of highly competitive environment, online operations need to be also strengthened by favorable experiences in order to leverage conversion rates. However, this is much more painful, as providing and managing "a balanced experience" on a digital platform is severely complicated (Chaffey, 2010).

Consumers collect information about products/services either by direct experience, such as trial, or by indirect experience, such as exposure to advertising (Li, Daugherty, & Biocca, 2001). Consumer experiences in digital environment are considerably different; such that, this concept has been viewed as indirect experiences; but it also includes social

and interpersonal cues (Liao & Keng, 2014). Moreover, in Web-based platforms consumers rest solely on sight and sound, whereas in traditional marketplace experiences encompass all senses (Straker, Wrigley, & Rosemann, 2015). In this regard, online consumer experiences are described as psychological and emotional conditions faced by consumers, meanwhile having interaction with products online (Li et al., 2001). Widespread preference of online shopping has resulted in the evolution of the e-customers' buying behavior, allied with the attainment of e-purchasing experiences (Hernandez, Jimenez, & Martín, 2009).

Increase in the strength of online consumer behavior has caused firms to expand their digital existence (Nielsen, 2017); and hence, to look for the ways to create a unified experience across various channels. On the other hand, it has been shown that one of the most important obstacles of online shopping is the lack of delightful experiences and social interplay (Barlow, Siddiqui, & Mannion, 2004). Consumers remark that online transactions are not specific to a certain customer and they do not feel comfortable while purchasing unusual and intricate products; they therefore expect firms to offer customer assistance not only in offline but also in online environments (Holzwarth, Janiszewski, & Neumann, 2006), that places a high emphasis on the significance of unified customer experience. In this respect, customer experiences have been recognized as the pivotal drivers of online shopping behavior (Childers, Carr, Peck, & Carson, 2001).

Further, as a consequence of the diffusion of digital marketing tools, currently, customers have become more engaged with brands; for example, they receive regular e-mails about new season products, they utilize mobile apps to take the advantage of discount prices, or they visit the brand's social media pages to learn about the upcoming events (Edelman, 2010). Nevertheless, considering customers' involvement in different digital channels at once, firms should be more inclined toward generating multi-channel experiences (Straker et al., 2015). This approach has been thoroughly underlined by the term of "perfect customer experience", which is firmly intertwined with the firm's capability "to gather and deploy customer information from all channels and to integrate it with other relevant information" (Payne & Frow, 2005, p. 173). In this sense, digital channels help firms consolidate customer experiences, which in turn produce high online traffic and superior customer loyalty at the end (Edelman, 2010).

Currently, many firms have leaned toward the integration of online and offline customer experiences. L'Oreal is one of those firms which successfully creates unique experiences for its customers through the combination

of online and offline aspects. As an illustration, L'Oreal's Makeup Genius app offers opportunity for customers to virtually try various kinds of makeup products through a webcam (Edelman & Heller, 2015). As another example, last year IKEA introduced IKEA Place app—an augmented reality application, which aims to form memorable customer experiences by enabling people to virtually design their homes, offices, and so on with different furniture (IKEA, 2017).

Furthermore, in recent decades retailing industry has also registered substantial alterations, mainly due to the improvements in online mediums and continuous digitalization (Verhoef, Kannan, & Inman, 2015). In an effort to respond to changes in retailing, firms have begun to simultaneously operate both in traditional and online channels; however, at this point the critical thing is that those retailing activities require to be carried out in an integrated fashion. Assuming that retailing operations are dependent on autonomous systems, fragmented supply chains emerge, which fail to create a coherent and trustworthy customer experience (Saghiri, Wilding, Mena, & Bourlakis, 2017). Concordantly, in the latest years, a shift from multi-channel retailing to omni-channel retailing has been noticed (Verhoef et al., 2015).

Whereas multi-channel retailing fundamentally concentrates on retail channels, in omni-channel retailing the stress is placed on the integration between channels and brands (Picot-Coupey, Huré, & Piveteau, 2016). Symbolizing a challenge for traditional retailers (Rigby, 2011), omni-channel retailing is defined as "the synergetic management of the numerous available channels and customer touchpoints, in such a way that the customer experience across channels and the performance over channels is optimized" (Verhoef et al., 2015, p. 176). It puts a particular emphasis on the interplay of "disparate channels into a single seamless omni-channel experience" (Rigby, 2011, p. 67). The concept has gained a considerable importance in retailing together with increase in customers' demands for unified brand experiences. Concisely, the effective management of the multi-channel customer experiences is particularly vital for outstanding business success and performance in today's highly digital environment.

E-Customer Relationship Management

Relationship marketing, focusing on creating, expanding, and sustaining sufficient relational exchanges, has been seen as a big transformation for both marketing scholars and practitioners (Morgan & Hunt, 1994). It has

been strongly suggested that establishing long-term relationships with internal and external partners generates more positive returns compared to discrete transactions (Morgan & Hunt, 1994); that view has caused a fundamental shift from a transaction-based perspective to a relationship-centered orientation. In this regard, within the context of CRM, in what manner customers should be dealt to establish effective bonds with them has become a crucial concern in marketing theory and practice (Reinartz, Krafft, & Hoyer, 2004).

Drawing on the relationship marketing theory, CRM rests primarily on the notion that in order to be successful and survive in the market, instead of looking for ways to sell products/services, firms should consistently direct themselves toward building high customer value, which in turn creates value for the firm (Boulding, Staelin, Ehret, & Johnston, 2005). The main tenets of CRM defend that as long-term customers are more profitable than short-term ones, firms should maintain their relationships with customers to improve customer retention and loyalty (Zeithaml, Berry, & Parasuraman, 1996). Correspondingly, firms have increasingly started to appreciate that the economic worth of customers to the firm is not the same; and thus, they need to tailor their products/services and marketing communications on the basis of various customers (Reinartz et al., 2004).

Even though CRM is frequently adopted to refer to technology-oriented customer solutions (e.g., sales force automation), the breadth of the concept is wider; such that, CRM covers a strategic vision with a particular stress on the interrelationship of organizational culture, information technology, and customer service (Payne & Frow, 2005). Nevertheless, whereas CRM comprises diverse types of applications, a technology-based view is widely accepted (Keramati, Mehrabi, & Mojir, 2010). The fast progress in information technology has allowed firms to adopt new technology-based tools, entitled CRM technology, which aims to support the process of CRM (Jayachandran, Sharma, Kaufman, & Raman, 2005). Currently, many firms make huge investments in CRM technology in an attempt to effectively manage their CRM activities (Powell, Noble, Noble, & Han, 2018).

In the increasingly digitalized world, CRM technology is of great importance; CRM was identified as the biggest software market in 2017, with the worldwide revenue totaling $39.5 billion (Gartner, 2018). In addition, it has been estimated that CRM will grow by 16% in 2018 and will therefore represent the fastest expanding software market in the same year (Gartner, 2018). Adoption rates also signify the strength of CRM in

current topics of marketing; with approximately 47% in 2017, on average (Lazar, 2017). Firms prefer to employ CRM technology for different purposes such as more accurate customer profitability evaluation, integrated customer data management, and superior customer lifetime value (Powell et al., 2018). However, albeit its popularity, the consequences of CRM technology are questionable in terms of either customers or firms (Jayachandran et al., 2005).

By virtue of the substantial effect of technological advancements on business processes, CRM operations have been also influenced by Internet-based technologies in a considerable way. In recent decades, an increasing integration between CRM and Internet technology has been noticed, that formed a novel approach for CRM strategy. Being called as electronic CRM (e-CRM), traditional CRM applications have been replaced with a more interactive nature, depending fundamentally on regular and effective customer communication (Kımıloğlu & Zaralı, 2009). Together with exploiting the benefits of Internet technology, e-CRM enables to expedite the handling of customer relationships (Harrigan, Ramsey, & Ibbotson, 2008).

A comprehensive definition of e-CRM involves "the marketing activities, tools and techniques, delivered over the Internet (using technologies such as Web sites and e-mail, data-capture, warehousing and mining) with a specific aim to locate, build and improve long-term customer relationships to enhance their individual potential" (Lee-Kelley, Gilbert, & Mannicom, 2003, p. 241). In this sense, e-CRM offers important advantages in respect of scrutinizing customer data, since at the right time it signals what customers really expect (Harrigan et al., 2008). Thanks to this attribute, it prevents resource losses in production operations systems (Harrigan et al., 2008). Importantly, by means of e-CRM, firms are more able to personalize their bonds with customers, notably owing to higher number of customer touchpoints and greater opportunity to customize marketing communications (Day & Hubbard, 2003).

Referring to the reality of digital consumer behavior and the significance of e-CRM with respect to both efficiency and effectiveness, today firms have been more apt to apply online CRM solutions to attain competitive advantage. Besides, in parallel with the late trends in consumer behavior and the growing impact of Web 2.0 technologies, within the context of e-CRM, new concepts also emerged. Among these, social CRM (or CRM 2.0) serves as a popular philosophy that combines social media and dynamic capabilities of traditional CRM (Greenberg, 2010). This new concept has been recognized as a more cooperative and network-driven

perspective to deal with customer relationships (Trainor, Andzulis, Rapp, & Agnihotri, 2014).

Customers have become highly involved in social media channels not only to keep in touch with their friends or colleagues but also to interact with firms (Trainor, 2012). In this regard, the brief purpose of social CRM is to respond to the expectations of social customers (Greenberg, 2010). Via social CRM applications firms endeavor to cultivate their bonds with customers in social networks both with regard to quality and quantity; and thus, to reinforce brand image and overall brand loyalty (Wongsansukcharoen, Trimetsoontorn, & Fongsuwan, 2015). Seen as a new breath in CRM, social CRM is of great benefit to firms. such that it has been found that customer retention rates increase by 26%, thanks to social CRM applications (Lazar, 2017). Considering these facts, traditional CRM service providers (e.g., Salesforce.com and SAP) have begun to merge data from social media channels such as Facebook and Twitter to actively monitor customers and quickly respond to customer requirements (Owyang, 2010).

Customer Co-Creation

Traditional value creation approach is based on the thought that firms establish value and transfer it to customers (Prahalad & Ramaswamy, 2004a). Specifically, with limited or without interaction with customers, firms independently decide on which products to be manufactured, which marketing messages to be delivered, which distribution channels to be used, and so on so forth (Prahalad & Ramaswamy, 2004b). On the other hand, fundamentally because of the upheavals in customers' roles in recent decades, the main tenets of the traditional value creation view started to be doubted (Prahalad & Ramaswamy, 2004a). It has been suggested that this passive perspective regarding customers should be changed with an active approach, since the real value of a product/service can be best reflected in the eyes of customers (Witell, Kristensson, Gustafsson, & Löfgren, 2011).

Coupled with the big transformation in the essence of the relationship between customers and firms, the process of value building has considerably altered; currently, customers have tended toward taking an active part in each step of firms' value creation processes (Prahalad & Ramaswamy, 2004b). Being described as "co-creation" of value, customers have begun to have an impact not only on product development stages but also on service designs (Heidenreich, Wittkowski, Handrich, & Falk, 2015). Based on this, it has been contended that marketing has recorded a significant

change from a goods-dominant logic, focusing mainly on "tangible output and discrete transactions", to a service-dominant logic, which depends strictly on "intangibility, exchange processes, and relationships" (Vargo & Lusch, 2004, p. 2).

Rather than following the traditional definitions of the term, the service-dominant approach identifies services as "the application of specialized competences (knowledge and skills) through deeds, processes, and performances for the benefit of another entity or the entity itself" (Vargo & Lusch, 2004, p. 2) and it places special emphasis on the collaboration between the firm and its stakeholders, which are highly involved in the co-creation of value (Lusch, Vargo, & O'Brien, 2007). This perspective claims that customers represent stakeholders, who consistently make contributions to value generation, whereas firms refer to enterprises with an opportunity to only propose value (Vargo & Lusch, 2004).

Growing engagement in the usage of the Internet and social media channels has facilitated the implementation of co-creation activities. Accordingly, in conjunction with the benefits of digital technology, firms have been increasingly formulating successful co-creation strategies. For instance, Dell's Ideastorm exemplifies one of those impressive applications in value co-creation (Saarijärvi, Kannan, & Kuusela, 2013). In this platform, customers of Dell express their opinions and suggestions about how to improve the offerings of the firm. Owing to this, Dell has an access to customers' actual ideas in relation to Dell's products, and at the same time customers see that their contributions are of great prominence for Dell, that is likely to strengthen customer participation and citizenship behavior (Yi & Gong, 2013).

In this context, Threadless.com also sets a good example (Saarijärvi et al., 2013). The firm calls its customers to design different range of products, covering t-shirts, accessories, and home decor, and so on, and to load their drafts on its website. All customers can give scores for the sketches and total customer scores determine which products will be sold under the name of Threadless.com. By means of this co-creation of value, customers are able to purchase their favorite products and the firm can anticipate future customer demands (Saarijärvi et al., 2013). Furthermore, BMW also cooperates with its customers to put its cars into final form (BMW Group, 2010). In particular, the firm introduced the Co-Creation Lab, which serves as a virtual gathering place where customers are encouraged to comment on automotive world in the future. BMW utilizes the sharing of the customers in order to plan the upcoming projects.

Building on the foregoing, in an effort to exploit the advantages of value co-creation, firms have been trying their best to employ customer resources in an efficacious manner. By means of co-creation activities, firms collect information about future customer requirements and expectations (Gustafsson, Kristensson, & Witell, 2012), which cultivate open innovation (Martini, Massa, & Testa, 2014). By virtue of this close interaction with customers in value creation, firms are able to achieve a competitive positional advantage both in terms of efficiency and effectiveness (Grissemann & Stokburger-Sauer, 2012). The benefits of value co-creation are not confined to firms; but also include customers (Dong, Evans, & Zou, 2008). For example, co-creation of value allows customers to enjoy getting quick response to their demands and having products/services with lower prices (Dong et al., 2008).

Conclusion

In the light of the aforementioned issues, considerable developments in technology have been exerting an enormous impact on both firms and consumers. From the firms' standpoint, necessary adjustments in organizational structures and strategies need to be made in order to keep pace with the latest technological progress; however, more critically, firms should be simultaneously involved in scrutinizing deeply and understanding ever-changing consumer behavior. This is notably because in today's highly digitalized world the way consumers use products/services, communicate with their environment, and interact with firms has been experiencing a huge change. In this sense, tremendous alterations in consumer behavior have been putting a great pressure on firms to be more leaned toward utilizing novel marketing programs and solutions in general, and digital marketing activities in particular.

Importantly, together with the increase in the extension rate of information and communication technologies, the authority of market knowledge has started to be passed from suppliers to consumers, which has yielded to the transformations of consumer empowerment, and ultimately, marketing implications (Pires et al., 2006; Tiago & Veríssimo, 2014). Currently, e-consumers are more able to easily compare and contrast features, prices, and varieties of products/services offered by various firms and even more significant to contact with firms and other consumers without difficulty. Hence, consumers have been considered being more sophisticated and holding more bargaining power than before (Berthon

et al., 2012; Udo et al., 2010), which puts special emphasis on the fact that digital engagement between firms and consumers has become much more prominent.

Specifically, relying on the notion that in conjunction with rational drivers, consumers take emotional factors into consideration during their decision making processes (Schmitt, 1999), a vital requirement emerges to provide positive and unique customer experiences not only through offline but also through online platforms in the contemporary marketplace. However, at this point, a critical concern that warrants attention by marketing practitioners pertains to the design of unified customer experiences which balance and harmonize experiences across different marketing channels. In this respect, omni-channel retailing arises as a valuable concept, of which applications are promising in terms of the management of customer experiences, since "the distinctions between physical and online will vanish, turning the world into a showroom without walls" (Brynjolfsson, Hu, & Rahman, 2013, p. 2).

Additionally, digital consumer behavior has also reflected in the revolution of value creation perspective; such that, customers have increasingly stood out as co-creators of value. In recent decades, the collaboration between firms and customers has been much greater and customers have been taking an active part more in establishing value, echoing successful real life examples. As customers represent the best sources of information regarding a value of a product/service (Witell et al., 2011), firms should be more inclined to work together with customers in an attempt to enhance their offerings and to gain a competitive advantage in the marketplace. Drawing on all of these important evolutions in consumer behavior, e-CRM applications have become even more paramount, which underline the significance of creating long-term and effective bonds with digital customers. All in all, this chapter spotlights how consumer behavior has remarkably changed on the basis of the digital metamorphosis, with the particular stress placed on the main tenets of digital marketing and e-customers.

CHAPTER 12

An Evaluation of the National Open Government Data (OGD) Portal of the United Arab Emirates

Stuti Saxena

Introduction

Conceived both as a philosophy and as a set of policies, open government data (OGD) relates to the data published by the government which is freely available for being re-used by different stakeholder groups (citizens, journalists, researchers, entrepreneurs, etc.) to derive value out of the same and improvise upon their services (Alexopoulos, Loukis, & Charalabidis, 2014; Attard, Orlandi, Scerri, & Auer, 2015; Kassen, 2013). Such data may relate to different socio-economic sectors like weather, agriculture, industry, energy, power, education, trade and so on. (Ubaldi, 2013). OGD is an advanced format of e-government which promotes transparency, accountability and citizen trust because the government publishes the hitherto-reserved data for wider usage (Mpinganjira, 2015). Apart from facilitating citizen engagement, OGD initiatives help in improvising upon public policies and contribute toward efficiency,

economy and effectiveness of the government. As such, open data may be defined as "machine-readable data (which is) discoverable, available, and downloadable through dedicated internet portals without cost to potential data users" (Dawes, Vidiasova, & Parkhimovich, 2016, p. 15). For earning benefits from the OGD initiative, it is important that the datasets are published in a timely manner and they should be complete in all aspects (e.g., metadata, data entries, legible formats, provision of visualization and analytical tools, etc.) (Jaeger, Bertot, & Shilton, 2012).

Open data initiatives spur innovation through co-creation activities of the government and the other stakeholders (Verhulst & Young, 2016). For instance, software developers and the government collaborate on the social coding platform GitHub to contribute toward the revamped version of the source code (Mergel, 2015). It has also been underlined that sustainable OGD initiatives help in the economic growth of the country (Charalabidis, Alexopoulos, & Loukis, 2016; Jung & Park, 2015; Saxena, 2017a; Wirtz & Birkmeyer, 2015). Implicitly, the OGD initiative of the United Arab Emirates (UAE) has the potential of facilitating the economic diversification of the country and meeting the goals of the Vision 2021 espoused by the government. However, to assess the potential of the OGD initiative, it is important that the datasets published by the government online are qualitatively and quantitatively adequate. This would facilitate optimum re-use of the datasets for deriving social and economic value out of them.

In line with the aforesaid, this chapter invokes the usability framework (Machova, Hub, & Lnenicka, 2018) and the website quality framework (Sorum, Andersen, & Clemmensen, 2013) to present a case study where we evaluate the national OGD portal of the UAE (https://bayanat.ae/) in terms of the data quality and underline the drivers and barriers in re-using the datasets published via the portal. The key research question guiding the case study is: "What are the drivers and barriers in re-using the datasets published via the national OGD portal of UAE?" Further, the findings from the case study emphasize the need for maintaining the quality of the datasets published therein. As the first detailed study to investigate the national OGD portal of the country, the case study is a significant contribution to the OGD literature.

The chapter is structured as follows: After summarizing the literature on OGD, a brief shall be provided about the research methodology invoked in the chapter wherein the case study on the UAE's national OGD portal shall be elaborated. Thereafter, concluding remarks shall be provided to summarize the major inferences. The penultimate sections of the chapter shall detail the social and practical implications of the case study and leave pointers for further research.

Related Research

OGD is an emerging phenomenon and academic interest in the field has been increasing over a period of time. While most of the studies are conducted in the West, where open data initiatives are being undertaken at an advanced level, studies in the developing countries are few and far between (Huijboom & Van den Broek, 2011; Janssen, Charalabidis, & Zuiderwijk, 2012; Saxena, 2017a; Saxena & Janssen, 2017; Zuiderwijk & Janssen, 2014). Implicitly, there is a need for conducting more research in the developing countries to underline the impediments in the implementation of the OGD initiative (Charalabidis et al., 2016) besides drawing lessons from the countries that have been successful in the implementation of the open data initiatives (Nugroho, Zuiderwijk, Janssen, & de Jong, 2015). Such contextual studies, including the empirical ones, provide cases of the success or failure of OGD initiatives. For instance, Rothenberg (2012) followed a case study approach wherein the OGD frameworks of the US, the UK, Canada and New Zealand were compared. The purpose of selecting these four countries lay in the marked similarities of culture among them. Likewise, a study based in Africa aimed at understanding the extent of OGD implementation regarding the characteristics of an "ideal" OGD portal and the study was conducted in five (Ghana, Kenya, Sierra Leone, South Africa and Tanzania) out of the seven (Ghana, Sierra Leone, Tunisia, Morocco, South Africa, Kenya and Tanzania) OGD centers (Afful-Dadzie & Afful-Dadzie, 2017). In another study, the Unified Theory of Acceptance and Use of Technology (UTAUT) model was adapted in order to conduct an empirical investigation in the Netherlands and identify the factors which impact the usage and adoption of OGD (Zuiderwijk, Janssen, & Dwivedi, 2015). In an empirical investigation conducted on a sample of 210 citizens in Germany, the extended Technology Acceptance Model (TAM) was deployed to underline the relationship between the constructs (ease of use, usefulness, transparency expectancy, participation expectancy, collaboration, intention to use OGD and word-of-mouth intention concerning OGD) and it was found that all the five constructs were significant predictors of intention to use OGD and to collaborate among each other using word-of-mouth (Wirtz, Weyerer, & Rosch, 2017). In another empirical investigation conducted in India with a sample of 244 respondents, OGD use and acceptance among different users was probed and it was concluded that OGD use has increased in

the country and men are more likely to tap OGD than women (Saxena & Janssen, 2017). All these studies underlined the reasons as to why OGD initiatives are yet to realize their cherished aims in terms of promoting accountability in administration and furthering citizen participation in policy-making.

Literature on OGD has provided an understanding that the demand-supply equation of any OGD initiative merits a careful consideration and this entails that the legal provisions regarding publication of datasets and the concern for privacy of the individuals (Martin, 2014). For instance, datasets are "supplied" by the government agencies and datasets may also be "suggested" or "recommended" by the users. Likewise, datasets may be "demanded" by the stakeholders for their purposes. The "supply" side may be bolstered by ensuring that the entire OGD publication value-chain is qualitatively and quantitatively superior and the "demand" side may be strengthened by the user engagement and involvement in the OGD initiative.

Many studies have provided frameworks for investigating OGD initiatives. For instance, Martin (2014) has provided a framework for underlining the social and technological aspects of OGD initiative. The framework includes five dimensions—digital technologies (configurations that include tangible artifacts, the skills of technologists and users and the interfaces of artifacts with the wider technical infrastructure), user practices (manner in which data is being re-used by a large cross-section of stakeholders), public management practices (includes the processes of data and ICT management and established data-related policies), institutions (include the sets of rules that connect data users and government organizations, including data markets and regulatory frameworks for government data) and resources (the resources drawn upon by actors shaping the OGD data agenda as including: social capital (the networks that connect actors); cultural capital (cultural goods and services, such as skills and knowledge); economic capital (money and other assets that can be directly and immediately converted to money); and symbolic capital: the means available on the basis of (perceived) prestige or legitimacy.

Another study provides a model which outlines the stages in the roll-out of any OGD initiative (Kalampokis, Tambouris, & Tarabanis, 2011a; 2011b). Kalampokis et al. (2011a) have classified OGD into "downloadable files" (data is available in simple formats), "linked data" (data is linked

with another one and re-used), "direct data provision" (all data is available via a portal and synchronized with time) and "indirect data provision" (actual data is provided and the user is responsible for further aggregation and processing of the data). Therefore, a four-stage model (aggregation of government data; integration of government data; integration of government data with non-government data; and integration of government data with non-government formal and social data) is identified by Kalampokis et al. (2011a). However, the drawback of the study lies in being more technical in approach wherein the emphasis was laid down on the crude mechanistic dimensions of linked data.

Saxena (2017b) provided a typology of countries on the basis of their OGD-adherence ("laggard," "caged," "forerunner" and "champ") wherein the "laggard" countries are the ones where there are hindrances associated with OGD implementation and OGD-usage; "caged" countries are those with less propensity to implement an OGD initiative but increased potential of usage by different stakeholders; "forerunner" countries as those which hold high potential of rolling out an OGD initiative but low potential of usage by different stakeholders; and "champ" countries as those which ranked high in terms of implementation of an OGD program as well as usage by a diverse set of stakeholders (p. 219).

In another study, another model expounds the degree of interaction among the stakeholders involved in the OGD initiatives directly or indirectly (Sieber & Johnson, 2015). Thus, Sieber and Johnson (2015) provide four models which deal with the "nature of (OGD) delivery (which) shapes the way the data is used" (Sieber & Johnson, 2015, p. 310). Table 12.1 summarizes the four models.

While the aforementioned models are descriptive, the overall comprehensiveness in terms of quality assessment of the datasets is missing. Therefore, the present case study seeks to adopt the evaluation framework proposed by Machova and his colleagues (2018). In their benchmarking framework derived from the reading of the literature on OGD, three dimensions (criteria) and 14 sub-criteria were defined which were a function of data discoverability, data accessibility and reusability. Table 12.2 reproduces the framework proposed by them.

Apart from this, the case study underlines the significance of maintaining the quality of the website dedicated for the publication of datasets. For this purpose, the website quality framework (Sorum et al., 2013) is being referred here. The basic premise of the framework is that the

Table 12.1 Citizen engagement models proposed by Sieber and Johnson (2015)

Model	*Description*
Data over the wall	This is the basic citizen engagement model wherein the government publishes datasets on the online portal directly. Basic features like downloading of datasets, visualization, mapping or sorting are allowed. Datasets are available in formats like PDF, Excel and so on. Programmatic access may be permissible via software-to-software interface (i.e., application programming interface or API). Users are encouraged to report errors in the form of feedback.
Code exchange	Government encourages the re-use of datasets for innovating products and services. Therefore, the government publicizes and promotes the OGD initiative by holding events, conferences, workshops or "app" contests. Software or application "app" developers, civic hackers and social entrepreneurs are encouraged to participate in such promotional activities.
Civic issue tracker	Citizens contribute to the existing datasets in many ways. For instance, citizens report of civic problems (e.g., fire, accidents, drainage problems, floods, potholes, etc.) which necessitate immediate action by the government authorities. By encouraging participation of citizens in the OGD initiative, the government is regularly informed about the civic issues and this facilitates in revising and updating the datasets (Alexopoulos et al., 2014; Dawes et al., 2016).
Participatory open data	As an ideal model wherein citizens and governments enter into a dialogue via the OGD initiative, there is active engagement and participation of citizens in the policy-making and policy-implementation stages. Citizens are encouraged to freely contribute toward the existing datasets via the online portal. Furthermore, all grievances of the citizens pertaining to the quality of the datasets are rectified in the prescribed manner. Datasets are qualitatively superior in this model with metadata and permit statistical analysis, interpretation, visualization and mapping.

website quality is linked with user-friendliness, effective website usage and content-related issues and accessibility. Four types of websites have been identified in the study (Table 12.3).

Furthermore, the website quality dimensions have been identified as presented in Table 12.4.

Table 12.5 summarizes the website attributes in terms of the quality parameters.

Table 12.2 Model proposed for evaluating OGD portals (Machova et al., 2018)

Dimension	*Criteria*	*Description*
1. *Open dataset specifications*	a. *Description of dataset*	Portal provides datasets together with their description and how and for what purpose they were collected
	b. *Publisher of dataset*	Portal provides information about organization that published datasets
	c. *Thematic categories and tags*	Portal provides thematic categories of datasets to address the main topics covered. It distinguishes categories (themes) from tags (keywords)
	d. *Release date and up to date*	Portal provides datasets associated with a specific time or period tag, that is, date published, date updated and its frequency
	e. *Machine readable formats*	Portal provides datasets formats that are machine-readable and allow for easy re-use
	f. *Open data license*	Portal provides license information related to the use of the published datasets
	g. *Visualization and analytics tools*	Portal provides visualization and analytics capabilities to gain information about a dataset, e.g., in charts or visualizations in maps
2. *Open dataset feedback*	a. *Documentation and tutorials*	Portal provides high quality of documentation and tutorials to help users in learning how to use the portal
	b. *Forum and contact form*	Portal provides an opportunity to submit feedback on a dataset from the users to providers and forum to discuss and exchange ideas among the users
	c. *User rating and comments*	Portal provides capabilities allowing the collection of user ratings and comments on a dataset
	d. *Social media and sharing*	Portal provides the integration with social media technologies to create a distribution channel for open data and sharing feedback
3. *Open dataset request*	a. *Request form*	Portal provides a form to request or suggest new type or format type of open data
	b. *List of requests*	Portal provides a list of requests that were received from users, including the current state of request processing
	c. *Involvement in the process*	Portal provides capabilities allowing the involvement in the active requests, that is, express interest in the same dataset

Table 12.3 Four types of websites and their attributes

Website	*Main attributes*
The inviting website (InvW)	Website should always make it possible for the user to make the right choice; Users should be able to find information fast as part of effective use; Website development is a continuous process where there is always room for improvement; Website should be lucid and it should be easy to find things; Personalization and speed; Well-developed content and use of pictures; Users should be satisfied and provided with help and support; More use of interactivity and new ways of presenting and visualization of web content; Presenting search functions in order to make it easier for finding relevant information, personalizing web content and making updates and continuous improvements
The intuitive website (IW)	Website appears to have a "logical structure" and this helps in the easy access and free movement across the website; Users are able to easily find information; Regular updating of the website contents
The easy-to-use website (EUW)	Website should be lucid, and it should be easy to find things on the web site; Supports user-satisfaction and efficiency of use; Information presented on the web site must be currently valid' Personalization of web content; Interactivity; Provision of true, updated and trustworthy information; Use of easy language; Providing faster response for users, fast mail response and feedback to users and deliberate responses; Fast response and feedback to users; Presenting content that users are looking for and expecting to find at websites
The simple website (SW)	Accessibility is highly important, together with user adoption and website content; Users should be able to find the services they need; Content should be organized in a way that clearly separates the different parts from one another; Content should be "easy to find" and well "organized" so that users can discover and retrieve relevant information and services; There is data dependability

Table 12.4 Quality aspects and their dimensions

Quality aspects	*Dimensions*
Information quality (captures the website/application content)	Content Dependability Updated
System quality (measuring the desired characteristics of a system or a website)	Accessibility (standard) Effective use Personalization Search functions Speed Uptime User-friendly
Service quality (covers the overall support delivered by the service provider)	Fast mail response Fast response for the users Service quality (easy help)

Table 12.5 Assessment of website types in terms of the attributes

Major attributes	*Simple website (SW)*	*Easy-to-use website (EUW)*	*Intuitive website (IW)*	*Inviting website (InvW)*

Evaluation of the National OGD Portal: A Case Study of the UAE's OGD Initiative

UAE occupies the 17th spot out of 137 countries in the Global Competitiveness Report (2017–2018). The country has been adopting economic diversification drives. Given the prospects of OGD initiatives in furthering economic growth, we posit that the OGD initiative of the country has the potential of aiding the country in its economic diversification moves. Apart from furthering economic growth, the OGD initiative should facilitate citizen participation and collaboration in improvising public services and making them more efficient and effective. Datasets published under the aegis of the OGD initiative may be re-used by a diverse set of stakeholders (academic community, scientists, researchers, public/private/non-profit professionals, journalists, software developers, etc.). By re-using the datasets, the stakeholders may derive social and economic value and spearhead innovation. However, to realize the benefits of re-using the datasets, it is important that the datasets published by the government are of good quality and the government is proactive in instituting a robust OGD initiative by contributing toward publishing datasets that are qualitatively and quantitatively superior. Datasets should be complete in themselves and they should be published in a regular manner. This would ensure a sustainable re-use of the datasets by the stakeholders. Therefore, we present an evaluation assessment of the national OGD portal of United Arab Emirates (https://bayanat.ae/) as a case study in order to analyze the quality of the datasets published via the portal. Specifically, the case study addresses the question: "What are the drivers and barriers in re-using the datasets published via the national OGD portal of United Arab Emirates (UAE)?"

The Federal Competitiveness and Statistics Authority (FCSA) is responsible for managing and updating the portal. The portal has a search option wherein keywords may be provided for accessing the datasets. In all, there are 776 datasets covering themes like agriculture (113), labor force (55), education (45), climate (31), and so on. Furthermore, the datasets are provided by organizations like Ministry of Education (40), Ministry of Health (32), Zakat Fund (18), Zayed University (16), Ministry of Energy (15), and so on. Datasets may be filtered using tags like education (53), crop (33), zone (33), federal (31), gender (27), region (27), and so on. Furthermore, datasets are available in two formats: Excel (XLSX) (774) and Excel (XLS) (2). Software applications that may be tapped via open

data portal of the country include Aamen (an application for handling employees' complaints about their wages), Absher (an application for achieving the goals and indicators of the national agenda of the country), Dubai Culture (an application for connecting the classical with the modern world), and so on. There is a "Youth Data" platform wherein the innovative efforts of the young generation are being showcased (https://data.youth.gov.ae/en). Visualization of datasets is possible only for select datasets. The government has been arranging hackathons for furthering innovation using open data. The "privacy policy" mentions that any personal information such as name and email address shared by the visitors shall be reserved for confidential purposes only. As per the "terms of use" of the portal, the datasets are available for "free use and reuse for commercial and non-commercial purposes." The portal mentions that the following procedures should not be violated:

- Accessing details that are not intended to be provided to this user or logging into a server or an account that the user is not authorized to access.
- Attempting to conduct any test or survey for finding weakness of any system or network of the UAE government or violating applicable procedures or documenting them without an official permit from the UAE government.
- Attempting to interfere in the provided service on the part of any user, host or network including but not limited to placing a virus on the website, increasing load to or immersing it, sending commercial messages to it or avalanching it with electronic messages or even destroying it.
- Sending unwanted electronic messages to the website including commercials and/or advertisements on services or products or falsifying any dispatch control protocol package address/internet protocol or any part of the address details in any electronic message or sending news messages.
- Using this portal by any means for sending an email, anything of it or on its behalf, by referring to it, or assuming the identity of its name involving offence or libel of the UAE government, website or any person whomsoever, announcing any untrue news or information and ascribing it to the UAE government unrightfully. There is a "contact form" for contributing datasets and soliciting datasets.

Conducting evaluation studies by underlining the features of the national OGD portals has been common till now (See, for instance, Kassen, 2013; 2017; Saxena, 2018). This case study adopts the usability evaluation framework proposed by Machova and her colleagues (2018) as well as the website quality evaluation framework by Sorum et al. (2013). We chose to refer this framework for the present study for three reasons—it is a recent contribution which is relevant for the evaluation of any OGD portal; it is comprehensive and all-encompassing; and it has been derived after a review of literature which shows that it is well-researched and may be subject to further reference for academic research. Table 12.6 summarizes the key

Table 12.6 Major facilitators and hindrances in re-using datasets via the national OGD portal of UAE

Criteria	*Facilitators to re-use datasets via the national OGD portal*	*Hindrances to re-use datasets via the national OGD portal*
1. *Open dataset specifications*		
a. *Description of dataset*	Portal is accessed in two languages—Arabic and English. There is a provision to "search" datasets via the main page. Metadata in the form of data publication date, last revision done, identifiers, spatial/geographical coverage, authorship and public access level are limited.	Portal provides datasets together with their description and how and for what purpose they were collected. However, real-time data is not being provided via the portal as of now.
b. *Publisher of dataset*	In all, there are 776 datasets covering themes like agriculture (113), labor force (55), education (45), climate (31), and so on. Furthermore, the datasets are provided by organizations like Ministry of Education (40), Ministry of Health (32), Zakat Fund (18), Zayed University (16), Ministry of Energy (15), and so on.	Not all listed publishers have contributed to the portal.
c. *Thematic categories and tags*	Datasets may be filtered using tags like education (53), crop (33), zone (33), federal (31), gender (27), region (27), and so on.	Portal provides thematic categories of datasets to address the main topics covered. It distinguishes categories (themes) from tags (keywords)

(*continued*)

Table 12.6 (continued)

Criteria	*Facilitators to re-use datasets via the national OGD portal*	*Hindrances to re-use datasets via the national OGD portal*
d. *Release date and up to date*	Metadata reveals some information regarding the date of publication of the datasets.	It is important that the metadata be relevant and complete in all aspects.
e. *Machine readable formats*	Datasets are available in two formats: XLSX (774) and XLS (2).	User-friendly formats should be provided for analysis and statistical interpretation.
f. *Open data license*	Data are regarded as a "natural resource" and should be available for all users.	N/A
g. *Visualization and analytics tools*	Datasets may be arranged in an ascending or descending order.	Visualization and mapping tools are required for optimum re-use of the datasets.
2. *Open dataset feedback*		
a. *Documentation and tutorials*	The manual of "Open Data Policy" provides information regarding the OGD initiative of the country and the utility of the same for the different stakeholders.	N/A
b. *Forum and contact form*	There is a "Contact" form where the users/portal visitors may place requests or contribute datasets.	A blog may be provided where the users may interact with each other and lend constructive views for the improvisation of the portal.
c. *User rating and comments*	Datasets may be ranked (five-star rating).	Users may provide "feedback" regarding the website via the "Contact" form.
d. *Social media and sharing*	Social media networks are not provided.	Social networking plugins may be provided (Twitter, Facebook and YouTube) to facilitate the sharing and discussion of datasets.
3. *Open dataset request*		
a. *Request form*	Only the government agencies may place "requests" for publishing the datasets.	Other stakeholders should be involved in the data publishing process.
b. *List of requests*	The provision of providing the list of requests made by the users is missing in the portal.	The portal should provide information regarding the recommendations and contributions of the users to the datasets via the portal.

(*continued*)

Table 12.6 (continued)

Criteria	*Facilitators to re-use datasets via the national OGD portal*	*Hindrances to re-use datasets via the national OGD portal*
c. *Involvement in the process*	Public participation has been encouraged wherein recommendations from the portal visitors are invited for supporting the OGD initiative of the country.	Events like contests for the stakeholders to improvise upon the datasets should be organized. For instance, software apps may be devised by the software professionals. Businessmen may showcase how they harnessed datasets for improvising their services. Implicitly, incentives should be provided for increased involvement of the stakeholder groups.

observations for the national OGD portal of the country in line with the model (Machova et al., 2018). From the table, it is clear that the OGD portal provides opportunities to re-use datasets and the re-use of the datasets by a large cross-section of stakeholders might result in innovation and improvisation of goods and services thereby contributing to economic development of the country. At the same time, there are challenges in re-using the datasets because the datasets need to be updated on a regular basis and a more proactive stance of the government agencies is required to facilitate publishing and interoperability of the datasets.

Table 12.7 summarizes the key observations from the perspective of Sorum et al. (2013). These observations are derived after a careful perusal of the national open data portal of UAE.

Conclusion

The case study sought to present an evaluation of the national OGD portal of the UAE. After a brief scan of the literature on OGD, the case study provided a brief regarding the drivers and barriers to re-use the datasets published via the OGD portal conceding that data re-use by a diverse group of stakeholders is one of the prime rationale for publishing them and making them available for all. The evaluation of the OGD portal was conducted using the recently-proposed framework (Machova et al., 2018)

Table 12.7 Key insights about the portal using the framework of Sorum et al. (2013)

Major attributes	*Major insights derived from the portal analysis*
Accessibility	The national open data portal is well-accessible for use and reference by the relevant stakeholders. Datasets must be made more accessible in terms of their qualitative and quantitative aspects.
Content	The content of the open data portal should be well-maintained and updated on a regular basis.
Deliberate	The national open data portal of the UAE needs to provide real-time information.
Dependability	It is important that the national open data portal provides datasets that are reliable and dependable.
Effective use	The open data portal must provide more user-friendly features for facilitating the re-use of datasets.
Fast mail response	It is important that the mail responses be provided at the right time.
Faster response for the users	The national open data portal must ensure that responses to any queries made by the visitors are being answered promptly.
Interactivity	The national open data portal must facilitate interactivity by incorporating more user-friendly features.
Personalization	The content of the national open data portal must ensure that there is personalization for ensuring that the visitors perceive that the portal is serving their ends well.
Search functions	The website offers a "search" facility so that the specific dataset may be accessed easily depending upon the keyword/s used.
Service quality (easy help)	The website needs to improve on this feature.
Speed	The national open data portal should provide datasets in a speedier manner.
Updated	It should be the priority of the government to publish updated datasets.
Uptime	It would be a better exercise if efforts are made to publish linked datasets on a real-time basis.
User-friendly	The website should provide user-friendly features in order to facilitate a wider range of stakeholders to re-use the datasets.

and the framework proposed by Solem et al. which are quite comprehensive. It may be deduced from this evaluation of the OGD platform that while the OGD initiative of the country is a forthcoming measure of the government for promoting transparency in administration and forging ties with the citizens, the portal needs to be improvised in terms of the quality of the datasets. Datasets should be published on a timely basis and regular

updates should be made whenever required. For ensuring increased participation and engagement of the users, incentives should be provided for data re-use. Users' contribution to the datasets should be encouraged and interaction via the platform is also encouraged such that the users may interact among themselves and discuss about the improvisation of the goods and services through data re-use. Datasets lack visualization and mapping tools and this is a bottleneck in analyzing the datasets. Likewise, datasets are not amenable to statistical interpretation on account of the absence of compatible features which may facilitate the re-use of datasets in an optimum manner.

Social and Practical Implications

The case study underlines that the success of any OGD initiative lies in its sustainability. For ensuring the sustainability of the OGD initiative, it is important that the datasets be re-used for creating value out of the same. For instance, datasets may be re-used by a cross-section of stakeholders (citizens, journalists, software experts, academia, entrepreneurs, etc.) for appreciating public administration and providing recommendations for policy-making and improvisation in public service delivery. At the same time, they may tap the datasets for improvisation and innovation of their services. On the other hand, the policy-makers may solicit views from the users regarding the portal and the quality of the datasets published via the same and this would help in improving upon the administrative services. In turn, this would lead to better relationship between the policy-makers and the citizens. It is also important for the government to ensure that a robust ICT infrastructure is in place for sustaining the OGD initiative. Thus, on the one hand, the public officials managing the OGD initiative should be trained with regard to the maintenance and monitoring of the OGD portal and data publishing process; and on the other hand, technological advancement should be upheld for providing real-time linked datasets in near future. This would further improvisation in public service delivery and facilitate citizen participation in the co-creation of services.

Further Research Directions

The case study leaves pointers for further research. For instance, further research is merited to assess the manner in which the OGD initiative is being perceived by the different stakeholder groups. Empirical

investigation is required to appreciate the utility of the datasets for different stakeholder groups. Future research may be conducted to analyze the perspectives of the government representatives regarding the factors that impact the data publishing processes. A comparative approach may be undertaken to analyze how lessons may be drawn from the successes of OGD initiatives elsewhere. Research cues may be derived from the significance of data mining and social networks in furthering OGD discussions by the stakeholders. Likewise, it may be interesting to evaluate the significance of Big Data analytics in understanding the efficacy of OGD initiatives (Saxena, 2016). Finally, further research is warranted to analyze the utility of the implementation of OGD initiatives at the regional and local levels of the country.

CHAPTER 13

Artificial Intelligence and Robotics Technology in the Hospitality Industry: Current Applications and Future Trends

Li Yang, Tony L. Henthorne, and Babu George

Introduction

Artificial intelligence (AI) and robotics science have been penetrating into different kinds of businesses and industries in recent years. AI can be defined as the experimental and theoretical study of perceptual and intellectual processes using computers and to make a computer perceive, understand, and act in ways now possible only for humans (Achacoso, 1990). Robots, as one kind of human-like AI, were first introduced into manufacturing industries for product processing in order to replace monotonous human work decades ago (Murauskiene, 2015). For now, the applications of AI and robotics science are extending into other industries, for example, into transportation as autonomous vehicles (Maurer,

Gerdes, Lenz, & Winner, 2016), into the medical industry for diagnoses and surgeries (Kaur, 2012; Mirheydar & Parsons, 2013), into the education industry for teaching or helping special kids (Fridin & Belokopytov, 2014; Timms, 2016), into the supply chain management for organizing warehouse (Min, 2010), and so on.

In the realm of hospitality and tourism, AI and robots have also arrived and they are catching peoples' attention. The world's first robotics hotel, The Henn-na Hotel, was opened in 2015 in Japan, which is fully staffed by robots (Rajesh, 2015). Meanwhile, in the United States, the Wynn Las Vegas announced in December 2016 that they are going to partner with Amazon to equip all of their hotel rooms with an Amazon Echo, a voice activated system (Raz, 2016). Besides the hotel sector, AI and robotics science are finding their way into other sectors of hospitality. In 2015, Eatsa, a futuristic restaurant where robot cubbies serve quinoa bowls, opened in San Francisco, and later opened another restaurant in NYC (Constine, 2015; Kowitt, 2016). A new bar on the Strip of Las Vegas, Tipsy Robot, featuring two robot bar tenders, started their business on June 30th, 2017 (Stapleton, 2017). AI and robotics science not only offers numerous opportunities to hospitality firms to enhance their daily operations, but also ensures hospitality firms provide consistent quality of products and services to their customers (Perez, 2014). The application of AI in the hospitality industry has caught a few, although not a sufficient amount of, scholars' attention (Borràs, Moreno, & Valls, 2014).

This paper will review current literature in the area of the application of AI and robotics science in the hospitality industry. Our examination will focus on the three areas of the application of AI and robotics science. First, it examines the current status and current application of robotics science in human daily life, highlighting their applications in each segment of the hospitality industry; further, it evaluates the impact of AI and robots on three areas: labor and employment, customers, and corporations and communities; lastly, it explores the future potential application of robots and AI in order to see what benefits or risks can be derived from their application in the hospitality industry.

Business Application of Robotics

The Robot Institute of America, a trade association of robot manufacturers and users, defines robots as follows: "a reprogrammable multifunctional manipulator designed to move material, parts, tools, or specialized

devices, through variable programed motions for the performance of a variety of tasks." (OTA, 1982, p. 8). Currently, robots are labeled as "intelligent physical devices" (Chen & Hu, 2013, p. 161) which have the capability of autonomy, mobility, and sensory to execute intended duties (International Organization for Standardization, 2012; Tan, Mohan, & Watanabe, 2016). Robotics science is definitely changing the way that humans live and work all over the world, and the application area of AI and robotics science is widening (Veruggio & Operto, 2008). Robots are extending their way out of the factories and into normal life: hospitals, schools, shopping malls, airports, hotels, restaurants, and even our homes. Robots are not just automated machines anymore; they are becoming consumer items (Veruggio & Operto, 2008). In certain scenarios, they are even more than an intelligent tool; they could even be considered a partner or a companion (Louie, McCaoll, & Nejat, 2014)

Types of Robots

The International Organization for Standardization (2012) claims most robots can be categorized into two groups: industrial robots and service robots. The categories are based on the robot's field of application as well as the industrial or non-industrial environments they operate in. Some scholars, further, separate service robots into two groups: professional service robots and personal service robots (Murphy, Hofacker, & Gretzel, 2017).

Industrial Robots

These are usually adopted to perform industrial tasks which can be indicated from the name. This is the initial field where robots were applied in manufacturing and production. According to the International Federation of Robotics, industrial robotics can be classified as either linear robots, Selective Compliance Assembly Robot Arm (SCARA) robots, articulated robots, parallel robots, or cylindrical robots based on the mechanical structure (IFR, 2016a).

Service Robots

"A service robot is a robot which operates semi or fully autonomously to perform services useful to the well-being of humans and equipment, excluding manufacturing operations" (IFR, 2016a). Different from industrial robots, service robots are designed to assist, serve, and interact with humans. International Federation of Robotics (IFR) claims that service

robots do not have to have arms, like industrial robots do. According to the definition, an industrial robot could also become a service robot when it is installed in a non-manufacturing environment (IFR, 2016b). Because of the increasing market demand and the different applications, the realm of service robots is expanding year by year, and the variety of service robots is becoming wider. Additionally, their diversity and application is becoming more varied each year. The shape and structure of service robots might change over time as well, but generally service robots can be classified into professional service robots and personal/domestic service robots (Ivanov, Webster, & Berezina, 2017; Murphy et al., 2017).

Professional Robots

From the name, they are deployed by formal organizations and companies. Professional service robots have a much bigger market than domestic/personal robots (IFR statistical department: World Robotics News, 2012). From those statistics, defense, field, logistic, and medical robots are the leading players for professional robots.

Personal/Domestic Robots

Personal/Domestic robots are robots used at home or at other private places by individuals for non-commercial purpose. There are two leading kinds of personal robots. One is cleaning robots, such as floor cleaning, lawn-mowing, and so on. The other is interactive robots, such as butler robots, that are usually equipped with autonomous navigation systems, touchscreens, voice, and face recognition systems. These additional systems can allow them to help or entertain people in public environments or deliver items (Ciupe & Maniu, 2014).

Current Status in Each Hospitality Segment

In the realm of the hotel and tourism industry, AI and robots have also arrived and are attracting great attention and interest from public (Ivanov et al., 2017). The current application of AI and robots in different segments of the hospitality industry, especially service robots will be discussed in this review.

Hotel

Service automation and robotic technologies have made their way into the lodging segment of the hospitality industry, affecting different areas of

hotel operations. At the front desk, hotel operators apply self-service kiosks which allow guests to check in and out by themselves in order to reduce waiting time and to improve service (Kim & Qu, 2014). Just like using a kiosk at the airport to get flight tickets, guests can quickly and efficiently check in to their room without human interaction. This is just the very basic application of service automation. In the concierge department, Connie, a robotic concierge agent, was introduced in Hilton Hotels last year, which is partnered with IBM. Connie is powered by AI and can communicate with hotel guests by answering their questions about hotel amenities and services and providing information for local attractions and activities. Because of the AI principle, Connie can also learn from its interactions with guests, and optimize its future answers (Hilton, 2016). In the housekeeping department, a robot called maidbot is created to provide better hotel room cleaning solutions (Maidbot, n.d.). A few hotels, such as Aloft at Cupertino, California, also implement the automated bellboy, a robot that delivers towels and bottled water at the requests of guests (Markoff, 2014).

Combining all these functions, as mentioned earlier in this paper, the world's first robotics hotel, the Henn-na hotel, was opened in 2015 in Japan (Henn-na Hotel, n.d.), which is fully staffed by robots. When guests check into their hotel room, two front desk agents (one human-like robot speaks Japanese, one dinosaur-like robot speaks English) will welcome them; automated trolleys take guest's luggage to their room; and a block-shaped robot does room service as well as delivers beverages and simple snacks.

Food and Beverage

AI and robots are also applied in the food and beverage industry, mostly in restaurant service and food preparation. In some restaurants, the food order is taken by robots (Curtis, 2016). Pizza Hut in Japan hires a humanoid robot named Pepper to take food orders from customers by voice. Pepper is equipped with a voice recognition and AI system, and talks with customers. In addition, Pizza Hut has partnered with MasterCard to program Pepper with a payment app. In other words, Pepper not only takes food orders from customers and sends them to the restaurant kitchen, but also processes orders for customers which saves time for both the restaurant and the customer. As mentioned earlier, a fully automated restaurant, Eatsa, which serves quinoa bowls, opened their first location in San Francisco. Customers place their order through an iPad in the lobby, and

their name will show up on one of the transparent LCD screen boxes. In less than 2 mins, customers can retrieve their personalized quinoa bowl out of the box. Similarly, Tipsy Robot, a new bar in Las Vegas, is staffed by two robot bar tenders that mix up and serve drinks (Stapleton, 2017). The guests just need to order their drinks on an iPad, and choose from 18 specialty cocktails or create their own drink. The two robotic bar tenders will get the drink ready for the customers in 60 to 90 seconds. In their spare time, the robots will slice fruit or dance to entertain the customers.

All of these robots utilized in the restaurant mitigate the customer's waiting time and eliminates human waiters and cashiers. Robotics technology definitely helps the food and beverage industry save labor cost and keep food quality consistent.

Meetings and Events

AI and robots are also applied in the meeting and convention industry to provide better service and make the demonstration of meetings easier. A lot of corporations and organizations employ interactive robots at their convention booths or at their trade show (S. P. Events, n.d.). Interactive robots at conventions are usually equipped with a mechanical head and arms, a voice and face recognition system, a message screen or iPad, a CD player, and a brochure holder. Some are also fully mobile so as to attract people's attention or sense people when they pass by. S.P. Events claims that this kind of robot is perfect for promotion events, exhibition stands, tradeshows, or products launched by using their AI tool to communicate with people, introduce products on a screen, or even just to greet people to get their attention. Moreover, this application creates a new robot rental business.

Another significant application of robots in the meeting and events industry are drones. For instance, the organizers of a music festival in South Africa deliver beer to over 150 guests by drone (Daily News, 2013). This application not only provides better service, but also saves the labor cost of delivery for the organizers. Drones are also used during weddings as photographers to take beautiful photos for the new couple.

These examples show that AI and robotics science not only offer numerous opportunities to hospitality firms to enhance efficiency of their daily operations, but also ensure they provide a consistent quality of products and services to their customers.

The Impact of Robots in the Hospitality Industry

Impact on Labor and Employment

Positive Impact

The rapid rise of advanced technology has caused deep uncertainty about the future of the job market (Yakowicz, 2016). There are many kinds of AI and robotics technologies in applied hotels, but there is very little academic research explicitly investigating the impact of robots on the workforce of the hospitality industry. Noone and Coulter (2012) argue that modern AI and robotics science can improve restaurant operations because of the two key features of robotics technologies: sensing for demand prediction and planning for production management. They also claim that robotics should be applied to augment workers' cognitive capability rather than direct labor replacement. Robots can help human staff work more efficiently, rather than replacing their jobs, which will positively impact the business (Pacurar, 2017). From a staff perspective, they also think robots do a great job helping out and making jobs better (Yakowicz, 2016).

Other scholars believe the application of AI in the point of sale system of quick service restaurants can avoid employee theft. The National Restaurant Association (1999) reported that the cost of employee theft for its members totaled over $8.5 billion, or 4 percent, of food sales. Stealing cash from an employer is a significant issue. From that number alone, manager and business runners should not underestimate the lure of quick money and the problem of stealing. Therefore, the most effective way to stop this kind of theft is to apply AI detection systems which aim to maintain solid cash controls for the restaurant (Collins, 2013)

Create New Jobs

Robots are becoming possible alternatives, and they have more of an economic advantage over human beings, in some fields. It is clear that robots are becoming a viable alternative to humans as the economic benefit of using a robot can far outweigh the use of a human. The impact of robots and AI could be dramatic on individuals due to different skillsets required in different industries (OTA, 1982). It is not surprising that labor-intensive and dangerous jobs are replaced by robots or AI. As robots are equipped with cognitive systems, the leading job replaced by robots might be transportation, logistics, customer service, and consumer services. Robots are

replacing humans in some of these jobs in order to reduce the human risk and prevent workers from being exposed to dangerous situations or hazardous environments (Chijindu & Inyiama, 2012; Yakowicz, 2016).

History shows the negative impact of technology on employment has been small enough to be insignificant or undetectable. For example, the wrongly created fear that was aroused in the early 1930s about whether vending machines will replace retail store clerks (Slade, 2007, p. 67). And the truth is people still go to the store. Hence, most experts believe robots or AI can create new jobs rather than replace jobs done by human beings (Veruggio & Operto, 2008; Chijindu & Inyiama, 2012). The production of robots and related technologies will create new jobs, but the amount of jobs created will depend on the growth of the robotics industry and the degree that robots can be automated or self-fixed.

Overall, the literature shows that robotics technology will eliminate some jobs, but create more jobs, thus life will get better in the long run.

Impact on Customers

The application of service robots in the hospitality industry is changing the nature of service, and influencing customers' service experiences and customers' relationships with service providers (Ostrom, Parasuraman, Bowen, Patrício, & Christopher, 2015; Rust & Huang, 2014). Because of this new environment, the interaction between customers and organizations might change significantly. To enhance customer experience, companies will need to optimize robotics technology for the customer's frontline experience, thus, to effectively engage customers and develop relationships. A few scholars are researching these topics. Pan, Okada, Uchiyama, and Suzuki (2015) conducted experiments that tested which style of speech attracted guests in a hotel. According to their experiment data "direct speech was more attractive than indirect speech at the beginning period of interaction between guests and the robot"; thus, they recommend the hotel assistive robots should be designed to provide direct verbal interaction with individual guests in order to engage with guests and to quickly attract their attention.

The Design of Human-like Robots or Machines

Other scholars investigate how the look of robots impacts customers. Mori, MacDorman, and Kageki (2012) suggest if artificial service agents look like a human too much, it would be perceived as creepy; therefore,

less warmth for the service. Likewise, Doorn et al. (2017) claim a similar impact will be perceived on the capability dimension of social cognition. In other words, the more the service robots look like a human, it would more likely be conceived as a human and feature lower capabilities. They also note a positive result that because of this verisimilitude, when the human-like robots cause service failures, the customers are more forgivable. Facial gender cues of human-like robots were also examined to investigate their influence on customer behaviors. Eyssel and Hegels' study (2012) shows that a short-haired, male robot is considered as more agentic while a long-haired, female robot is perceived as more communal. This result can inspire the design of service robots and have them change looks depending on what they are programmed to do. Other research is conducted to investigate if human-like features would influence if customers would repeat their service or not (Fan, Wu, & Mattila, 2016). Their results indicate that when customers are alone, they would prefer traditional services, such as talking to human through the phone instead of using touch screens or online services through the phone. This means hospitality firms can avoid adding human-like features to machines in private areas, such as in-room devices. Conversely, adding human-like machines could be practical when used in public, such as a self-service kiosk. Their findings also show that when serving powerful customers, hotels need to consider public image or social presence when using human-like machines. For those hospitality firms that serve more powerful customers in luxury hotels, such as wealthy people, celebrities, and executive corporate staff; these firms need to think of the location and size of the human-like machine to maximize VIP customer satisfaction.

Impact on Corporations and Communities

Increase Production and Reduce Cost

Most literature regarding this subject explores productivity in the context of industrial robotics. Researchers argue that the robotics technology significantly contributes to industrial productivity. The applications of robots to date have extended from large corporations to small businesses; further, AI and robotics technologies will impact small businesses in different areas positively as well, such as predicating demand and planning production (OTA, 1982; Noone & Coulter, 2012; Ivanov et al., 2017). The financial impact of robots in the hospitality firms cannot be ignored, Murphy et al.

(2017) state that industrial robots in the back of the house and service robots in the front of the house both have financial effects.

Cost will be another concern in the context of the application of robots. Many of the newest robots are less expensive than traditional industrial robots. For instance, industrial robots can cost from $100,000 to $500,000 while collaborative robots, which will be adopted in hotels, are priced from $20,000 to $50,000 each (Heires, 2016). A newly built Fairfield Inn & Suites in San Marcos deployed the service robot "Relay" to deliver food, towels, and other items to the guest rooms. Relay costs $2000 per month under a three-year contract with the robot company, Savioke (Hirsh, 2017). The article also mentioned that the application of robots can greatly reduce labor costs for the night shift in hotels and other hospitality segments. The robotics experts believe prices will drop when robots enter into bigger scale manufacturing. In addition, the development of modern batteries and electronics technologies will be lower the cost, advance performance, and broaden the availability of robotics and its related technologies.

The motivation of hotel operators to apply robotics technology is obvious. The trendy application of robots could easily improve their service to some extent, therefore, enhance their reputation and brand image. However, it is doubtful and unclear if hotels can get substantial financial value by implementing robotics technology and reducing labor costs. For example, recall that the Wynn Las Vegas is going to place an Amazon Echo in each their rooms (Raz, 2016). The price of an Amazon Echo is $180, and the Wynn Las Vegas has 2716 rooms for the Wynn location and 2034 rooms for Encore location. After doing a simple math, the total cost will be $855,000 for their initial installment. The Wynn might receive a discount from Amazon, but the future maintenance fee still cannot be underestimated. Yet, Heires (2016) also thinks the application of AI and robots is worth the cost when robots can collect data and map customers' purchasing behavior by directly interacting with them. In this regard, hotels will be able to offer personalization services and achieve higher customer satisfaction in the near future.

In conclusion, some types of the application of robotics science will increase costs while some will reduce costs. Those robots that are applied and on the right track will mostly prove to be valuable (Wells, 2003).

Education and Training

With the growth of robotics technologies, a number of education and training issues are raised by robotics. Some robotics experts also brought up the importance of improving the education system to help people fit into the evolution of the technology; they argued people should focus more on how to extend their knowledge and skills for the age of robots instead of being worried about being replaced by robots (Yakowicz, 2016). Murphy et al. (2017) argued that robotics technologies have impacts on successful tourism and hospitality education. A good start for the robotic world would be to learn about and more understand digital technologies.

Emerging Applications in Each Hospitality Segment

Hotel

Although AI and robots have already entered different hotel departments, the application of robotics is still nascent. The future potential use of robots for the hotel industry is predicted to be broad. It will include, but not be limited to, the laundry department: robots clean and fold sheets and towels; in-room voice-activated systems to help customers control the lighting, AC, and other devices in the room: such as the Amazon Echo mentioned earlier (Raz, 2016). To offer a seamless guest experience, hotel operators will keep chasing better technologies to develop an integrated mobile service ordering system for their guests. This system will eventually enable guest requests to be fulfilled instantly and in no time (Trejos, 2015). Hotels are going to become fully service automated through self-service devices and robotic technologies in the future.

Food and Beverage

For the future application of robotics technology in the food and beverage industry, Ivanov et al. (2017) stated that if AI can offer more advanced technologies, restaurants will also apply those service automation devices or technologies to pursue a fully automated business model similar to the Henn-na hotel, except a restaurant version. They also claim the must-have elements in the future for automated restaurants. These must-haves should contain both front of the house and back of the house automation: at the front of the house, customers can order food through self-service devices or with a robot waiter; at the back of the house, robot chefs will cook the

dishes and deliver the dishes through automation devices, such as conveyors in the sushi bar, or with a robot busser to the customers.

In the quick service restaurant segment, other scholars believe robotic technology or robotic management systems will provide small restaurants opportunities to compete with large chain restaurants, because of their scalability. In other words, although large chain restaurants will have the procurement power and brand equity as competitive advantages, in the scenario of applying affordable robotics management, small businesses will be productive and maintain high efficient daily operations. Robotic management would become the strength of small quick service restaurants (Noone & Coulter, 2012).

Meetings and Events

As mentioned previously, the current application of robots in the meetings industry is mainly to amuse attendees at the meetings. Base on this application, a future potential use of robotics science will combine with other technology, for example, telepresense (MantaroBot, n.d.). Telepresence is an innovative technology for the meeting industry, which allows people who are far away or not available to attend meetings and conventions through the MantaroBot. The key idea of this business model is to enable people to use robots as a physical presence indicator to attend meetings or events (Ivanov et al., 2017). MantaroBots will have screens, cameras, and be mobile like other service robots; in addition, they will have a video phone-call feature.

This technology will be very revolutionary for the meeting industry, and offer the opportunity for more people to attend meetings and conventions virtually without transportation costs, and to still have interaction with others even though they could not physically attend the meetings. A similar idea is to use virtual reality to attend meetings (Revvr Studios, 2017).

The Risks Posed by Developments in Robotics

After forecasting a potential use for robotics technology in the future, it is necessary to explore the possible factors that will influence the development. Kuo, Chen, and Tseng (2017) used expert panel research methods and concluded six factors that will influence the development of robots in the hospitality industry. These six factors are government support, capability for market development, future development of the robotics industry, capability for technology development, capability for raising money, and

capability for talent development. Some research also investigates other factors that could influence service robots. Gorle and Clive (2013) noted that a country with a high lifespan and low birth rate will more likely have an increasing demand for service robots, such as Japan.

Other studies investigate how to make the application of robotics technology successful in the hospitality industry. For example, strategic positions of the hotels in a market could impact the success of using robots (Melian-Gonzalez & Bulchand-Gidumal, 2016). Improving customer satisfaction and developing into new markets (Baker & Magnini, 2018), highlighted with the practical execution of the marketing campaigns, are also important elements to the success of advanced services with robots or AI (Nieves & Diaz-Meneses, 2016).

When hospitality companies enjoy the convenience and consistent service from robots, some of them also begin to be concerned about the risk and safety of adopting AI and robots, or possibly even "fire" robots due to certain defects (Mccrum, 2016). Some experts mention this concern is reasonable because of the self-learning skills and big data capabilities of the robots, especially those of the interactive robots (Heires, 2016). They also argued robots are originally safe, but if they mingle with other technologies or platforms that could modify or add other programs into the robots, the robots might not be safe anymore. So for now, the experts think the biggest risk related to robot industry is cybersecurity.

Conclusion

Artificially intelligence (AI) and robotics technology have already penetrated into different segments in the hospitality industry. As a service industry, the majority of robots used in the hospitality industry are service robots. This review mainly discusses the application of professional service robots in the hospitality industry. In hotels, robots are utilized in the front office, housekeeping, and the concierge department. In the food and beverage industry, robots could be servers, chefs, bartenders, and bussers. During meetings and events, robots aim to amuse people to promote products.

With the growth of the robotics industry, the impacts of AI and robots are more and more significant. The AI system can augment staff capability, thus, improve daily operations. Additionally, a robotics management system can eliminate internal staff theft. Although robots might replace a few human's jobs, they will still create more jobs in the labor market. AI and

robotics has a positive impact on labor and employment. The research in regard to how robots impact customers is mainly about how looks and interactions between robots and human influences customer behavior, especially with human-like robots. This academic area can help design future robots. AI and robots can have a financial impact on companies, increase their productivity, and reduce the labor costs.

The hotel industry wants to reap from these developments and aims to attain full automation. For meetings and events, robots will combine with other technologies in order to create a more innovative application. Telepresence, which can allow human beings to interactive with each other in a meeting without physical attendance, is a particularly interesting application.

Hotels or other hospitality segments invest a lot of money into AI and robots, to make it foolproof. The biggest risk of utilizing robots in the hospitality industry is cybersecurity, because most of the robots need to connect to the internet. To avoid the risk, they have to make sure that all of these new systems are safe and that hackers cannot recode them.

There is still not a lot of research into the application of robotics science or AI in the context of the hospitality industry. Future research may benefit by investigating the following areas: in what locations should robots be placed in a hotel, restaurant, or even at a meeting in order to influence customers' perceptions of robots; what characteristics (e.g. age, nationality, race) should robots have to improve the service experience? Robots have already entered our lives in various guises. Humans have a lot to do to optimize the application of robots and to make our lives even better.

CHAPTER 14

Risk Management in the Digital Era: The Case of Nigerian Banks

Tankiso Moloi and Oluwamayowa Olalekan Iredele

Introduction

Moloi (2018) argued that in the context of the public sector, more emphasis tends to be biased to processes and systems, discounting the role of people, which renders the enterprise risk management program unsuccessful. Patterson (2015) concurs with this point as he points out that the enterprise risk management program would only be effective if it is supported by people, processes and technologies. People, processes and systems are all recipes for a successful risk management program. This however requires that the organization has reliable data to base their analysis and decision on.

One of the main pitfalls of the risk management programs in organizations has been a lack of reliable information and data to base decisions on. Patterson (2015) points to two factors that result in unreliable data from the risk management perspective and that is risk data is often scattered across the organization and not shared across business unit, in essence, the culture of silos is an impediment. Further, Patterson points to the fact that

many risk management functions lack the tools they need to capture and use risk information more effectively. What this effectively means is that it could be expected that there could be opportunities that the organization fails to capture.

By utilizing technology, Ernst and Young (2014) assert that we could begin to see the reduction in missed opportunities and realized risks. This is due to the fact that technology facilitates "improved insight, efficiency and effectiveness in risk management activities, thus freeing up time for risk management resources to spend on risk identification, assessment and control of future risks". Knopjes (2017) supports this view by stating that organizations could take advantage of emerging technologies to integrate different systems, collect and analyze massive volumes of data from an unlimited number of sources across multiple locations. Through this process, organizations will achieve enhanced operational processes, improve timeliness of reporting and utilize data to drive preventative actions resulting in them being miles head of potential risks (Knopjes, 2017).

Due to the nature of their business, which includes being the repository of liquidity, the core payment mechanism and the principal source of finance to at least a large part of the economy, banks assume a variety of risks (Moloi, 2014; Liu, 2004). The traditional finance theory has limited these risks into major balance sheet risks, namely, liquidity risk, interest rate risk, capital risk and credit risk (Hempel, Coleman, & Simonson, 1990). Traditional finance theory had not extended itself to think about the manner in which these risks and many other facing banks should be governed. As can be noted, there had not been a realization that technology would rise and lead to the circumstance where banks are dominantly relying on it for almost all their activities.

Moloi (2014) argues that banks are important to the economy as they lubricate the financial system, serve as the point of connection between various sectors of the economy and reassure a significant level of specialization, competence, economies of scale, and settings conducive to execution of different economic policies of the government (Sanusi, 2011) and as such, there is a need to identify, understand and monitor the circumstances, which could result in the banking systems' vulnerability (Moloi, 2014). Akande (2016) and Tennant and Tracey (2014) concur with this and they point out that banks are involved in financial intermediation by sourcing for savings at a rate that will entice depositors and lend funds to creditors at an affordable rate to maximize profits in a competitive environment.

The manner in which these institutions function is even more critical in developing nations such as Nigeria as the country battles to attract foreign direct investments for infrastructure and other needs. The Nigerian banking sector has faced a tumultuous period in recent times which has led to the restructuring and consolidation exercise (Aransiola, 2013). The reform led to the reduction in the number of banks from 89 to 25.

It had been thought that the restructuring and consolidation exercise would lead to stability, however; this situation was short lived as the banks got affected by another financial crisis that resulted in the survival of only 24 banks (Akande, 2016). The challenges that lead to the collapse of these institutions were attributable to risk management. As of 2018, the Central Bank of Nigeria has indicated that there are only 22 commercial banks that are healthy and are standing in Nigeria (CBN, 2019).

As the institution battled the credibility question and lack of confidence, the CBN responded by instituting the CBN code of good governance in order to give guidance to the Nigerian banks on the minimum corporate governance requirements. The central bank indicated that this was developed with the primary purpose of promoting a transparent and efficient banking system that will engender the rule of law and encourage division of responsibilities in a professional and objective manner (CBN, 2014). Adeoye and Amupitan (2014) advise that the concept of good governance in banking industry would need to be stretched in order to empirically include total quality management, which has six performance areas, namely, capital adequacy, assets quality, management, earnings, liquidity and sensitivity risk. The degree of adherence to these parameters determines the quality rating of the banks.

Given the importance of banks in the economy, the recent challenges faced by the banking sector in Nigeria, we are of the view that the evolutions in computing and risk technology which has led to the developments in technologies that could be used to exploit big data, conduct complex analytics, these technical advancements offer the Nigerian banks and authorities such as the CBN with better abilities for enhancing risk management effectiveness, thereby reducing vulnerabilities and exploiting opportunities that could arise.

This study therefore investigated whether or not the Nigerian banking sector was exploiting technology in order to reduce missed opportunities and realized risks, whether technology has been exploited in order to integrate different systems, collect and analyze massive volumes of data from an unlimited number of sources across multiple locations. Essentially, our

research question was answered through the use of content analysis of integrated reports of selected Nigerian banks where the focus is on the manner and the way in which risks have been captured. We content-analyzed this section of the integrated report in order to determine whether Nigerian banks indicated in these reports have deployed technology or not and whether or not advanced technology would have been deployed in order to reduce missed opportunities and realized risks.

The remainder of the chapter is organized as follows: Section "A Brief Overview on Corporate Governance" provides a brief overview on corporate governance, Section "A Brief Overview on Recent Corporate Governance Challenges in Nigerian Banks" briefly provides an overview on recent corporate governance challenges in the Nigerian banking sector, Section "Code of Corporate Governance for Banks in Nigeria" discusses the manner in which the codes of good practices including the CBN code are guiding banking firms on the governance of risk and whether or not they do highlight the role of technology, Section "Risk Management in the Digital Age" discusses risk management in the era of digital infrastructure and Section "Empirical Analysis of the Current State of Risk Management of Banks in Nigeria" presents the findings relating to the use of technology and technological infrastructure in risk management.

A Brief Overview on Corporate Governance

The financial crisis around the world and the consequent collapse of major corporate institutions in both developed and developing economies has brought to the fore the issue of corporate governance. Today, corporate governance has attracted considerable attention of policy makers and academic researchers across the globe. The emphasis is on the need for the practice of good governance both at the public and private enterprises and this is due to the economic primacy of publicly quoted firms in most national economies. Corporate governance is increasingly understood among policy makers as a value enhancing strategy in a competitive environment and there is a growing consensus globally that corporate governance has a positive link to national growth and development (Akinkoye & Olasanmi, 2014).

According to Alushna (2017), codes of best practice represent the self-regulation of listed companies and provide a range of recommendations (Larcker & Tayan, 2011; Mallin, 2004; OECD, 2004, 2015; Tricker, 2012) addressing:

- Rights of shareholders, stressing the equal treatment of shareholders holding shares of the same class
- The procedures and rules shaping the functioning of the annual shareholder meeting (ASM) and measures empowering shareholders motivating them to active participation in ASM
- Responsibilities of executives who are accountable to shareholders and stakeholders
- The procedures and rules shaping the functioning of the board
- Transparency standards which describe the scope and content of information policy (company operation and strategy, financial situation, ownership structure, composition, structure and procedures of the board, company by-laws and regulations, executive compensation)

The Cadbury report was the first step where corporate governance code had required that companies follow the "comply or explain" principles, which means that listed firms had to comply with the code guidelines. Those companies that could not comply were expected to report the non-compliance and provide explanation for the non-compliance with the possible measures to be taken for improvement (Cadbury Report, 1992).

Today, pushing for higher governance standards has become a regular campaign with the participation of an increasing number of parties such as academics, media, regulatory authorities, corporations, institutional investors and international organizations shareholders right watchdog amongst others. Corporate failures have necessitated considerable interests on empirical research on the effectiveness of various corporate governance institutions and mechanisms. We note that particular attention has understandably been drawn to addressing and researching the underlying issues and factors that led to the financial and corporate crisis that characterized both the developed and developing economies. Many nations today have taken numerous initiatives such as the introduction of code of best practice, new listing/disclosure rule, mandatory training for board directors and enforcement of code of governance amongst other things; as measures to address and enhance the issue of corporate governance practice. International organizations such as the Basel Committee on Banking Supervision, International Monetary Fund (IMF) and Organisation of Economic Co-operation and Development (OECD) have become major proponents of governance (Moloi, 2009, 2014). In this regard, Akinkoye and Olasanmi (2014) point out that IMF, for instance, demands that governance improvement should be included in its debt relief program. These efforts to ensure good corporate governance practice had also been extended to the banking industry (Moloi, 2016a, b).

A Brief Overview on Recent Corporate Governance Challenges in Nigerian Banks

In the Nigerian banking context, corporate governance has recently received increased attention because of high-profile scandals involving abuse of corporate power, and in some cases, alleged criminal activities by those entrusted with governance. The abuse of corporate power and criminal activities has directly been attributable to weak corporate governance in banks. Recently, the Governor of the Central Bank of Nigeria, Godwin Emefiele went as far as indicating that that corporate governance practices in the Nigerian banking sector leaves much to be desired. His main concern in this regard appears to be the fact that these fraudulent incidents were capable of undermining financial stability by heightening vulnerability of financial institutions to external shocks (The Punch, 2017).

In the banking sector good corporate governance practices are regarded as important in reducing risk for investors, attracting investment capital and improving the performance of companies. The series of widely publicized cases of accounting improprieties recorded in the Nigerian banking industry in 2009, for instance cases involving Oceanic Bank, Intercontinental Bank, Union Bank, Afri Bank, Fin Bank and Spring Bank were related to the lack of vigilant oversight functions by the boards of directors. Accordingly, boards in these banks appear to relinquish governance to corporate managers who then pursued their own self-interests leading to the reported improprieties (Uwuigbe, 2011).

Due to the fact that banks have an important role in the intermediation process, any disturbance in this sector will likely affect the economy. Monnin and Jokipii (2010) posit that modern financial system contributes to economic development and the improvement in living standards by providing various services to the rest of the economy. These include clearing and settlement systems to facilitate trade, channeling financial resources between savers and borrowers and various products to deal with risk and uncertainty. The ability of the bank therefore to manage risk being a major threat to its going concern is crucial, not only for itself but for various stakeholders associated with its business.

Code of Corporate Governance for Banks in Nigeria

Following the conclusion of the consolidation program in 2005, a Code of Corporate Governance for Banks in Nigeria was issued to the banking industry. The code which became effective in April 2006 was designed to

enhance corporate governance practices within the banking industry in view of the fact that governance mechanisms in banks was notably weak and board members of financial institutions were unaware of their statutory and fiduciary responsibilities.

The update on the code of governance became necessary in view of the ambiguity in the code and its conflict with the provisions of Companies and Allied Matters Act (CAMA) 1990 as well as the need to align the 2005 code with contemporary developments and international best practices, hence the updated 2014 edition. With its promulgation, there was an expectation that the revised code would provide clear guidelines on all aspects of governance and that it would enhance Corporate Governance practices for banks in Nigeria.

The 2014 code covers seven key aspects of corporate governance as it affects the banking sector in Nigeria, namely, board and management, shareholders, right of other stakeholders, Disclosure in annual reports, risk management, ethics and professionalism and conflict of interest and finally, sanctions. The board has a special role in carrying out an oversight of functions and the effectiveness with which the boards of financial institutions discharge this responsibility is critical to the bank survival. The code requires that boards be free to drive their institutions forward, but exercise that freedom within a framework of transparency and effective accountability.

For the purpose of this study, we indicate that while other aspects of the code are relevant to the going concern of banks, risk management is central in view of the nature of the risks that banks face and the fact that they are in custody of other people's money (Moloi, 2014, 2016a). The CBN code makes it the responsibility of the board of a bank to ensure that policies, procedures and controls are put in place to manage the various types of risks with which it is faced. Given the multifaceted nature of risk, the complexities surrounding today's organizations, particularly banks, governing risks in an institution like a bank would be complex. The speed in which technology is emerging provides an opportunity to the boards to insist to managements of these complex organizations that technology that integrates different systems and collects and analyzes massive volumes of data from an unlimited number of sources across multiple locations is a step forward toward the enhanced operational processes, an improvement in timeliness of reporting and utilization of data for the purpose of driving preventative actions which would result in organizations being miles ahead of potential risks (Knopjes, 2017).

It is the purpose of this study to investigate whether or not the Nigerian banking sector is exploiting technology in order to reduce missed opportunities and realized risks, and further, how technology has been exploited in order to integrate different systems and collect and analyze massive volumes of data from an unlimited number of sources across multiple locations. The objectives of this study are achieved through content-analyzing integrated reports of selected Nigerian banks where the focus is on the manner and the way in which risks have been captured. We have content-analyzed this section of the integrated report in order to determine whether or not Nigerian banks indicate that they utilize technology in risk management and whether these reports mention advance risk management technology and have deployed the same in order to reduce missed opportunities and realized risks.

Risk Management in the Digital Age

The CBN Code of Corporate Governance for Banks and Discount houses provides that

> *[e]very bank shall have a risk management framework specifying the governance architecture, policies, procedures and processes for the identification, measurement, monitoring and control of the risks inherent in its operations. The Board is responsible for the bank's policies on risk oversight and management and shall satisfy itself that management has developed and implemented a sound system of risk management and internal control.*

We live in a rapidly changing world. There is no time in history when virtually every aspect of human life has been affected by the rapid change brought about through information technology (Harari, 2018). According to Marwala and Hurwitz (2017), the world has witnessed four phases of revolution in human history. These revolutions are described below:

- The first industrial revolution brought mechanical innovations with the development of steam engine which was key to the then industrial revolution;
- The second industrial revolution which started in the second half of the nineteenth century brought the oil-powered internal combustion engine and electrical communication. Major technological advances during this period included the telephone, light bulbs and phonograph (Marwala & Hurwitz, 2017);

- The third industrial revolution or digital revolution which came in the 1980s brought computerization, that is, mainframe computers, personal computers and the internet, and the information and communication technology (ICT) available today. This has been a period of advancement of technology from analog electronic and mechanical devices to the digital technology (Agrawal, Gans, & Goldfarb, 2018; Marwala & Hurwitz, 2017); and
- The fourth industrial revolution which has arrived at the beginning of the twenty-first century is the advent of cyber-physical systems representing new ways in which technology becomes embedded within societies, that is, business, government, civil society, and so on, and the human body; it is driven by the rapid convergence of advanced technologies across the biological, physical and digital worlds. It is marked by emerging technology breakthroughs in a number of fields, including robotics, artificial intelligence, biotechnology, and so on. All of these revolutions came with unique impacts on every aspect of human lives including business (Harari, 2018; Agrawal et al., 2018; Marwala & Hurwitz, 2017).

The banking sector is undergoing its own revolution as well with significant implications for risk management (Moloi, 2014; Moloi, 2016a). Risk management is very significant to the operations of any business entity due to serious consequences that the occurrence of risk portends (Moloi, 2016b). It implies that for a business organization to be rest assured of the achievement of its objectives besides survival and growth, risk management becomes imperative (Ayodele & Alabi, 2014). Risk is the exposure to loss arising from the variation between the expected and actual outcomes of investment activities (Nzotta, 2002; Owualla, 2000). Therefore, in a broad term, risk management can be related to a mechanism which embraces planning, organizing and controlling resources and operational activities of business for effective reduction or elimination of risk or the adverse effects of risks (Ayodele & Alabi, 2014). Management of risks is thus imperative for banks given the nature of their business.

According to Ayodele and Alabi (2014), Onyekwelu and Onyeka (2014) as well as Moloi (2014), some of the common risks that are managed by banks include:

- Credit (default) risk which is also known as default risk. It is related to a loss that may occur from the failure of repayment of a credit advance made by a bank to its customers. Credit risk is inherent to the business of lending funds. It may lead to losses when banks' customers experience deterioration in financial condition, making it impossible to recover principal and interest on loans, securities and other monetary claims outstanding. Management of this type of risk is the most fundamental task in banking operations. The objective of credit risk management therefore is to minimize the risk and maximize bank's risk adjusted rates of return by assuming and maintaining credit exposure within the acceptable parameters.
- Liquidity risk which refers to the ability of a bank to fund increases in assets and meet obligations as they come due, without incurring unacceptable losses. Liquidity risk therefore occurs when a bank is not able to meet the payment of commitment it has made. To manage liquidity risk, the banks must periodically examine the structure of fund sources and uses and implement measures needed to improve this structure.
- Market risk arises when financial institutions actively trade assets and liabilities (and derivatives) rather than holding them for longer-term investment, funding or hedging purposes. Market risk implies not merely the risk of loss but also the potential for gain from interest rate, equity return and foreign exchange risk in that as these risks increase or decrease, the overall risk of the financial institution is affected. Market risk could therefore be defined as the incremental risk incurred by a financial institution when interest rate, foreign exchange and equity return risks are combined with an active trading strategy, especially one that involves short trading horizons such as a day. Market risk can be in the form of interest rate risk, refinancing risk and reinvestment risk. It is therefore required that bank should conduct strict management and control of market risk based on the awareness that the possibility of substantial losses is inherent in the nature of market transactions.
- The Bank of International Settlement (BIS) (1997), views operational risk (inclusive of technology risk) as the risk of loss resulting from inadequate or failed internal processes, people and systems or from external events. The breakdown of internal controls and corporate governance leading to "error, fraud, performance failure, compromise on the interest of the bank resulting in financial loss". The

objective of operational risk management is to find out the extent of financial institutions operational risk exposure; understand what drives it; to allocate capital against it; and identify trends internally and externally that would help in predicting it.

- Strategic risk is viewed by Onyekwelu and Onyeka (2014) as the risk arising from the overall strategy of the bank that includes the quality of the strategic planning process and the implications of such strategy especially for risk appetite and track record of implementation. It explains risk associated with business targets as risk from bank's product, services and customers.

It is clear from the risks that are said to be managed by banks above that technology related risks have not received prominence. This is probably because of the manner in which we have traditionally viewed banks. Of importance here is that whatever package or transaction that banks offer today, technology has an important role. In developing countries such as Nigeria where risks have materialized and caused vulnerabilities in the banking system, we are of the view that exploiting technology in order to reduce missed opportunities and realized risks, and using this technology in order to integrate different systems and collect and analyze massive volumes of data from an unlimited number of sources across multiple locations for the benefit of stakeholders is important.

In highlighting the importance of adequate management of technological risk, the Centre of Excellence in Financial Services (COEFS, 2018) stated how in this era of the fourth industrial revolution, technological advancements like artificial intelligence means that human and digital systems can interact more profoundly than ever before. Applying this technology in financial services has the potential to reduce costs and improve efficiency, allow customers to transact seamlessly and in real time, and improve providers' understanding of customer behavior and needs, allowing for the personalization of financial services. On the other hand, the fast pace of technological innovation and adoption within financial services means that banks will increasingly face a common set of operational risks around new technology. If these risks are not properly managed by banks, they have the potential to create instability and undermine consumer trust in the banking system as instances of cybercrime, systems failure and compromised data increase in frequency.

Particularly, as the guardians of sensitive private and financial data, fraud and cybercrime is the greatest reputational risk facing banks in the

digital age. One obvious reason contributing to the intensity of this risk is that banks have a number of fronts they need to protect. The digitization of bank channels and underlying processes create multiple avenues through which virtual attacks can take place, notwithstanding the need to protect banks' physical premises and systems from intrusion. In addition to banks' internal systems and processes, the increasing use of outsourced service providers and the integration of banks' systems with external vendors adds another layer of vulnerability. It is difficult for banks to cover all of these fronts comprehensively (COEFS, 2018). All of these require banks to develop comprehensive cyber and data resilience strategies. Failure in this regards in the information revolution era could launch the banking sector into another round of crisis that may be difficult to recover from.

Previously, the digitization efforts of banks have been customer-centered (such as online marketing) and the operations that support those efforts (customer onboarding, customer servicing). Only recently have banks expanded their transformations into other parts of the organization, including the risk function. In this regard, it is clear that banks concede that there is value in deploying technology as part of managing risks.

A survey conducted by the Institute of International Finance/McKinsey shows that 70 percent of respondents reported that senior managers are paying moderate attention to risk-digitization efforts; 10 percent say that senior managers have made these efforts a top priority. Risk digitization is clearly an established topic in the executive suite (Institute of International Finance/McKinsey, 2018). The survey lays out seven key elements a bank must develop for a digital risk transformation, namely:

- Accordingly, enhanced data governance and operating models are likely to improve the quality of the data, make risk and business decisions more consistent, and ensure responsiveness to risk's data needs. The report is of the view that one important enhancement is the need to consider data risk as a key element of the risk taxonomy, linked to a specific risk-appetite statement and data-control framework and to accommodate far more varieties of data. The survey found that approximately 30 percent of the respondents say that new data sources will probably have a high impact on their work. This is in line with Agrawal et al.'s (2018) assertion that the power of artificial intelligence will allow resources to be focused somewhere else whereas technology will focus on predictions.

- On process and workflow automation, it is expected that as risk automates tasks such as collateral data entry, often through robotic process automation (RPA), it can combine several of them into smart workflows: an integrated sequence performed by groups of humans and machines across an entire journey (e.g., credit extension fulfillment). In addition to greater efficiency, smart workflows create a more seamless and timely experience for customers. The survey found that about a quarter of respondents believe that more than 15 percent of costs can be cut across different risk disciplines, except in credit, where the number is a bit above 60 percent. Around 30–45 percent of respondents see 5–15 percent cost-reduction potential from automation, depending on risk type. Ninety percent see benefits from increased precision and 55 percent believe automation will improve compliance with regulation. As a knock-on effect, risk resources will focus more on the value-adding activities they have been trained for. And 84 percent of respondents expect an increase in customer and employee satisfaction.
- On advanced analytics and decision automation, the survey is of the view that sophisticated risk models (e.g., those built on machine-learning algorithms) can find complex patterns (such as sets of transactions indicative of invoice fraud) and make more accurate predictions of default and other risk events. The survey found that nearly three-quarters of risk managers surveyed expect advanced analytics to have a significant impact on their work, while 50 percent say credit decision times will fall by 25–50 percent and a few respondents even believe that times could fall by 75–100 percent. This is in line with Agrawal et al.'s (2018) assertion that the power of artificial intelligence is on prediction, that is, it will make prediction accessible and faster.
- With regard to a cohesive, timely and flexible infrastructure, if risk infrastructure is digitized, it will evolve to support several other building blocks: innovative data-storage solutions, new interfaces, easier access to the vendor ecosystem, and so on. It will use techniques like application as a service, obtained from application service providers (even on open banking platforms). Approximately 45 percent of the respondents see innovative technologies as a high-impact building block. "No code" and "low code" solutions will put control further in the hands of risk executives and reduce the number of end-user computing tools. Nearly 60 percent of the respondents expect innovative data-storage structures to have a significant impact on risk management.

- On smart visualization and interfaces, risk digitization will deliver its insights in more intuitive, interactive and personalized ways through risk dashboards, augmented-reality platforms for customers, and other interfaces. The survey found that nearly 20 percent of risk managers expect nascent technologies, such as augmented reality, to have a high impact.
- On external ecosystem, risk digitization will facilitate easy partnerships with external providers to vastly improve customer on-boarding, credit underwriting, fraud detection, regulatory reporting and many other activities. The survey found that two-thirds of respondents see fintechs more as enablers than disruptors, while 63 percent of North American respondents plan to use industry utilities to deal with regulatory burdens.
- On talent and culture, risk digitization is expected to have a far greater share of digital-savvy personnel with fluency in the language of both risk and the business, operating within an agile culture that values innovation and experimentation. The survey reports that new profiles seen as most critical in a digitized risk function include data scientists and modeling experts. Accordingly, many risk leaders think that their teams will need to develop these skills rather than hire non-risk professionals and expect them to learn risk.

Empirical Analysis of the Current State of Risk Management of Banks in Nigeria

Given the recent challenges faced by the banking sector in Nigeria, we are of the view that the evolutions in computing and risk technology which has led to the developments in technologies could be used to exploit big data, conduct complex analytics and these technical advancements could offer the Nigerian banks and authorities such as the CBN better abilities for enhancing risk management effectiveness thereby reducing vulnerabilities and exploiting opportunities that could arise.

We set to investigate whether or not the Nigerian banking sector was exploiting technology in order to reduce missed opportunities and realized risks, whether technology has been exploited in order to integrate different systems and collect and analyze massive volumes of data from an unlimited number of sources across multiple locations. The results of content-analyzing integrated reports of selected Nigerian banks where the focus had been on the manner and the way in which risks have been cap-

tured and the determination whether Nigerian banks indicate in these reports whether they have deployed technology or not and whether or not the advanced technology would have been deployed in order to reduce missed opportunities and realized risks.

Table 14.1 presents the empirical investigation of 13 banks that rank within the top 40 firms in Nigeria in terms of market capitalization. The latest annual reports of the sampled banks were content-analyzed to extract information on the current risk management approach. Basically, four aspects of risk management approach were examined, namely, the specific risk management framework guiding the risk activities of the bank; the presence of risk committee whose responsibility is to provide oversight functions on behalf of the Board; basic technology employed to manage all forms of risks in the banks; and the application of advanced ICT for risk management in the information revolution era.

The first three aspects are fully manifest in the sampled banks. These are regarded as the traditional approach to managing risks in the banking industry and have existed for some time. Only two banks appear to be proactive in their risk management approach. Although the depth of risk digitization in these two banks are not verified, the latest annual reports issued by them have some elements of these advanced ICT technologies for managing risks.

Table 14.1 Current risk management approach in Nigerian banks

SN	*Banks*	*Risk management framework*	*Risk committee*	*Basic ICT for risk management*	*Advanced ICT for risk management*
1	GTBank	√	√	√

Conclusion, Recommendations and Policy Implications

It is clear in the integrated reports that banks have not embraced advanced technology for the purpose of managing risk. To reduce the likelihood of the reoccurrences of recent challenges faced by the banking sector in Nigeria, we are of the view that the evolutions in computing and risk technology which has led to the developments in technologies could be used to exploit big data, conduct complex analytics and these technical advancements could offer the Nigerian banks and authorities such as the CBN better abilities for enhancing risk management effectiveness thereby reducing vulnerabilities and exploiting opportunities that could arise.

With the rise of technology, majority of banking activities are already executed through technological instruments. As a policy recommendation, in addition to the traditional risk and audit committees that are clearly outlined in the code, the CBN would have to incorporate ICT committee in the codes of corporate governance for banks in Nigeria. Alternatively, the code should make it mandatory that some of the external members of the audit and risk committee should possess technological competencies.

CHAPTER 15

Digital Technology to Enhance Project Leadership Practice: The Case of Civil Construction

John Ekechukwu and Thorsten Lammers

Introduction

In business, the last few decades have belonged to a certain type of character or worker. A manager who initiates, plans, executes, monitors and controls. These people may be seen as reactive "firefighters", who put out flames, focus on completing tasks and respond to unfolding events (Barber & Warn, 2005). However, the future belongs to a very different kind of person, with a different kind of mind. Leaders, who are "creators, empathizers, pattern recognizers, and meaning makers" (Pink, 2006). These people are proactive "firelighters", who create change, envision the future and evoke passion (Barber & Warn, 2005). And as the complexities of organizational projects become more volatile, the demands for these characters heighten. As such management now also implies leadership.

Leadership, however, is conventionally associated with organizations, not projects (Cavaleri & Reed, 2008). Its theories and respective characteristics are rooted from the context of permanent organizations (Tyssen, Wald, & Spieth, 2014). These lasting forms of organizing facilitate a sense of autonomy and unbounded freedom that may enable leaders to imagine alternative visions for the future (Cavaleri & Reed, 2008). Yet, projects do not have the same magnitude of autonomy. A project environment of limited and predefined duration creates a sense of short-term orientation and hampers the development of deeper social relations such as trust and camaraderie (Tyssen et al., 2014). Additionally, a project evokes focus toward the management of daily objectives and immediate achievements, thus inhibiting actions of leadership and long-term vision (Toor & Ofori, 2008). Each project is unique and conditions for team selection and motivation are often far from ideal (Anantatmula, 2010). At times, project members are engaged in more than one project, causing additional burdens on focus and commitment (Anantatmula, 2010). Because of this, role ambiguity becomes an issue as well as the uncertainty of allocated control (Zhang & Fan, 2013).

Therefore, the role of a "project leader" is significantly different to that of an "organizational leader". Leading an organization allows for freedom, whereas leading a project, involves fulfilling a "promise" to a customer, ultimately constricting a leader to operate within the confines of such promise (Cavaleri & Reed, 2008). In this sense, a project leader is one who practices leadership within predetermined parameters. This makes the role of a project leader a rare commodity that is valued now more than ever before. So far, literature has focused on endorsing particular leadership behaviors and styles, while ignoring the difficulties faced by professionals in practicing these behaviors.

This study will explore digital transformation as a mechanism to facilitate leadership development using the case of the Australian civil construction industry. The focus is to shift the emphasis of digital advancements toward the social phenomenon of leadership. Digital technology alters the way people communicate, interact and relate to one another (Nagy & Koles, 2014). To neglect its potential to enhance project leadership development may be a substantial oversight in the evolution of leadership practice. To date, there have been few attempts to explore digital technology as project leadership technology, particularly within an industry such as construction, in dire need of support to elevate project managers into project leaders.

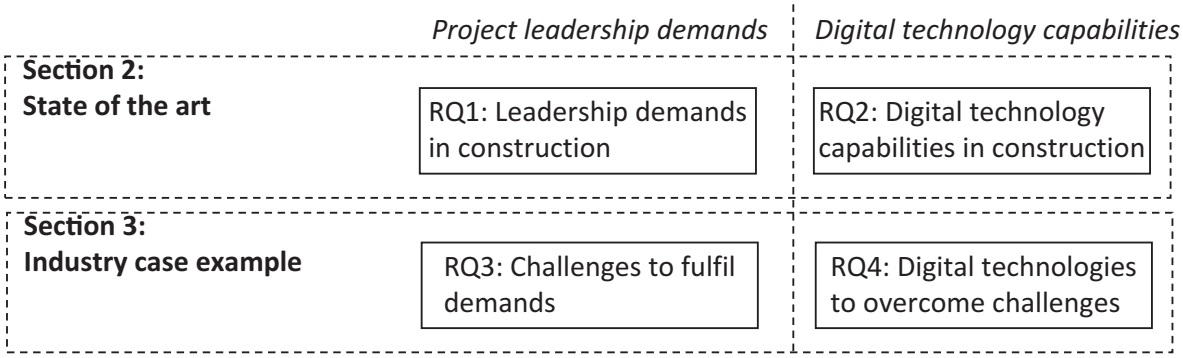

Fig. 15.1 Research design overview

This chapter aims to explore the potential for digital technology to enhance project leadership practice in construction projects. To investigate this potential, we will shed light on the following questions:

1. What are current leadership demands in construction?
2. What are current digital technological capabilities relevant to construction?
3. What challenges are construction professionals facing in meeting the leadership demands?
4. What is the feasibility of digital technology assisting professionals in overcoming these challenges?

The methodology employed to answer these questions involves a literature review coupled with a case example from the Australian civil construction industry (see Fig. 15.1).

Leadership Demands and Technological Capabilities in Construction

In the following section, we provide an academic assessment of the existing body of knowledge regarding leadership demands in the construction industry as well as capabilities of new digital technologies relevant for the construction sector. The focus is to discover important insights that can be used to guide and facilitate the investigation into the industry case example. In reviewing existing literature on those topics, the criteria listed in Table 15.1 have been established to ensure that relevancy and validity is maintained throughout the study.

Table 15.1 Overview of literature review

Source	The source is attainable in digital form.
Content	Content principally focuses on leadership and/or technology.
Keywords	Search is conducted using a combination of relevant words that depict leadership/technology (including plural or connotative equivalents).
Context	Sources are published within an international journal in the domain of construction, engineering, project management and the built environment.
Reliability	The source is academic/scholarly.
Relevancy	The source is published in English language within the date range specified (RQ = Research Question): • RQ1: sources published within the last ten years (from 2007 onward) • RQ2: sources published within the last three years (from 2014 onward)

Leadership Demands in Construction

Leadership challenges are amplified within the construction sector, an industry that will spend US$97.7 trillion globally in the next decade and account for 13.2% of world GDP by 2020 (Richardson, 2017). Construction projects are often large, multi-disciplinary and time-limited undertakings that exacerbate coordination and communication, as well as impose a great degree of uniqueness in setup, activities and content (Tyssen et al., 2014). Yet without tangible support, education and/or training, project managers are expected to "select, equip, train and influence" followers with diverse gifts, abilities and skills while operating within predefined parameters of time, budget and scope (Ameh & Odusami, 2014). The industry is suffering from a leadership crisis. Not from the professionals themselves, but from the disparity between the demands in project leadership and the investment and research in leadership development and training (Toor & Ofori, 2008). There is too much focus on the outcomes of leadership in neglect of the means in delivering these outcomes. Therefore, project managers need assisting tools and mechanisms that can balance the playing field and enable them to maximize their project leadership potential. As Khan (2015) claims, 80% of project failures are a result of poor project leadership or lack of project leadership skills. Management and technical competency alone are no longer sufficient for project success (Schuhmann, 2010). The following results highlight the variety of leadership demands relevant to the construction industry.

A US case study conducted by Cavaleri and Reed (2008) utilizes Seivert's five elements model to present a leadership strategy for improving project performance. The model constitutes of "Essence"

(defining purpose and values), "Air" (planning, analyzing and envisioning new possibilities), "Fire" (motivation and passion), "Water" (team building, loyalty, collegiality and camaraderie) and "Earth" (structure and policies). The expectation is that the project leader must be sensitive to the needs facing the team at the time and find a balance between the five elements. In teams in which the leader places emphasis on "Air" and "Fire" in neglect of "Water" and "Earth", projects are seen to fall behind, because important details that are necessary for execution are ignored. In a similar vein, when a project leader focuses on "Fire", "Water" and "Earth", while overlooking "Essence" and "Air", teams are likely to veer off in a direction that is misaligned with the project mission and objective.

Similarly, a study conducted by Patterson (2010) uses a case study of the Oresund Bridge construction (linking the cities of Copenhagen, Denmark and Sweden) to present a five-E model of leadership. "Envision", "Engage", "Energize", "Enable" and "Execute". By envisioning, "leaders see what the future could be rather than what it is". By engaging, leaders build relationships and seek collaboration. By energizing, leaders inspire and motivate. By enabling, leaders provide the necessary resources to facilitate followers in completing objectives. And by executing, leaders combine all elements together successfully.

These elements are further emulated in a study conducted by Slattery and Sumner (2011), who utilize the Leadership Practice Inventory (LPI) developed by Kouzes and Posner (2003) to examine the most favorable leadership characteristics among a group of 151 high potential construction project managers. The LPI purports to measure the ability of an individual to model the way (clarify values and set the example), inspire a shared vision (envision possibilities), challenge the process (take initiative, innovate and improve), enable others to act (foster collaboration, trust and facilitate relationships) and encourage the heart (provide emotional support).

Furthermore, surveys and structured personal interviews of 69 engineering professionals conducted by Anantatmula (2010) were used to develop a project management leadership model that consists of significant people-related leadership factors that influence project performance. These factors include: Create clarity in communication, define roles and responsibilities, communicate expectations, employ consistent processes, establish trust, facilitate support and manage outcomes.

The demand for authenticity and trust is accentuated throughout literature. Toor and Ofori (2008) conduct a literature review based in Singapore to rationalize the need for Authentic Project Leadership Development (APLD) for construction project leaders. The study explores four components of authenticity; "Awareness" (trust in one's motives and cognitions), "Unbiased Processing" (refraining from denying or distorting private knowledge), "Behavior" (acting in accord with one's values) and "Relational Orientation" (openness and truthfulness in relationships). Findings from this study argue that authentic leaders must know themselves, define their values, understand their motivations, build their support team, and "stay grounded by integrating all aspects of their life". Authenticity demands positive energy, integrity, moral character, self-discipline, optimism, resilience, clear purpose, concern for others and personal values.

As articulated by Kappagomtula (2017), without trust, leadership cannot function. Using investigative surveys of 36 experts in leadership across China and India, Kappagomtula models an analogy of a leadership "wheel" which must be maintained within cross-cultural and multicultural project teams. The model stipulates that the hub of the steering wheel is "Trust". The spokes of the wheel are "Loyalty", "Communication", "Integrity", "Competency" and "Consistency". The wheel itself represents "Culture", and the lubricant for the wheel is "Conflict Management". The emphasis of this analogy is the need for the leader to understand its components (the hub and spokes), maintain its integrity (lubricant) and steer the project team toward the destination of the drive. However, the leader must also learn when to let go of the "wheel" and surrender control.

This notion is also explored by Clarke (2012) who develops a theoretical understanding of shared leadership within projects. He argues that no individual performs all leadership functions, but rather members of the team collectively contribute to the leadership system. Therefore, a leader must focus on enriching established connections between team members and developing new connections to create a cohesive system in which leadership is distributed across all members.

Multiple studies have identified the need for project leaders to embody different leadership styles based on the varying stages of construction projects. Arain (2012) uses pilot questionnaires and interviews of 78 project management professionals working on the Suvarnabhumi

Airport (the largest construction project in Thai construction history) to develop a Quadrilateral Model of project leadership. The model focuses on a leader's ability to balance between four key leadership styles: "Coaching" (aligning goals and facilitating interaction among a team), "Connecting" (listening, empathizing, engaging and revering), "Controlling" (implementing rules) and "Charismatic" (supporting, inspiring and selling a vision). The research posits that leaders need variations in their leadership styles, at different stages of the project, until a balance between personal values, concerns for tasks and concern for people is maintained.

This concept is also explored in interviews across three Sri-Lankan construction projects conducted by Senaratne and Samaraweera (2015). This empirical study highlights the four stages of team development within projects: "Forming", "Storming", "Norming" and "Performing". The authors posit that a construction project manager should employ different leadership roles based on the needs and behaviors of the team members of each stage. For example, a leader should break down interpersonal barriers and establish team goals in the forming stages, but should only intervene where necessary in the performing stage.

This demand of leadership style adaptability is further reinforced by Oke's (2010) Multifactor Leadership Questionnaire (MLQ) of 57 Nigerian construction professionals. Findings from this study demonstrate that construction project leaders should possess the ability to adapt different leadership styles depending on the situation at hand. Leaders should embody a relations-oriented style at the beginning of a project, while adopting a much more task-oriented style during the closing of the project.

Leadership demands have also focused on the need for positive psychology and emotional intelligence among construction professionals. Emil Berg and Terje Karlsen (2014) conduct in-depth interviews with three experienced project managers to accentuate the need to encourage and develop positive emotions among followers. The study reveals how "Positive Meaning" (creating something), "Positive Emotions" (humor and optimism), "Positive Relations" (collaboration) and "Signature Strengths" (emotional intelligence) can create positive results within a project. These emotional elements play a major role in the development and trajectory of relationships within project settings (Pryke, 2015).

In a study, conducted by Pryke (2015), which uses surveys and live observations of 68 construction professionals, leaders are described as "managers of group emotions". Findings in this study demonstrate a clear correlation between emotional intelligence and project performance and further suggest that "Emotional Sensitivity" (ability to sense and interpret the non-verbal messages of others) and "Emotional Expressiveness" (ability to express emotions) are fundamental ingredients for "leader-follower chemistry". The expectation is that a leader should create a harmonious, smooth and in-tune connection between members of the team through emotional exchange and interaction.

Zhang and Fan (2013) further lament on emotional intelligence as a leadership requirement in their questionnaire-based survey covering 112 Chinese project managers. They find that characteristics of "Self-awareness", "Self-confidence", "Self-control", "Empathy", "Positivity" and "Cultural understanding" are key ingredients for project performance.

This is again emphasized by Galvin, Gibbs, Sullivan, and Williams (2014), who survey 38 project managers to define leadership competencies of "Emotional Resilience", "Intuitiveness", "Interpersonal Sensitivity", "Motivation" and "Conscientiousness". The study further postulates that an effective project leader must possess varying levels of sensitivity to political, technical and emotional elements of a project.

This is supported by Müller and Turner (2010), who use a web-based "Leadership Dimensions Questionnaire" on 400 project managers around the world to emphasize the need for project leaders to not only develop "Emotional Intelligence", but to balance between "Emotional", "Managerial" and "Intellectual Competencies".

Researchers have even attempted to appropriate religious teachings into necessary spiritual demands of leadership. Yngvason (2013) reviews the four gospels of the Bible to propose how project leaders can enhance their own practices by embracing the teachings of Jesus. The study proposes that Jesus utilized leadership tactics that enabled him to create a sense of purpose for a small number of followers that eventuated into a way of life for billions. The authors assume that like a project, the initial goal of spreading "the good news" was a planned endeavor, in which Jesus demonstrated transformational characteristics that included; "Individualized Consideration" (attentiveness to followers needs), "Intellectual Stimulation", "Inspirational Motivation" and "Idealized Influence" (a role model for ethical behavior).

Similarly, in a case study of eight Hungarian construction companies conducted by Lazányi and Dóka (2015), it is suggested that teachings from the Old Testament provide clues on leadership behavior. Leaders should be worthy, righteous men, who refrain from covetousness.

This is further explored from an Islamic perspective by Senam, Rashid, Sarkawi, and Zaini (2014), who review the Quran to highlight the need for authentic, servant and ethical leadership practices among construction professionals. The study unearths spiritual and moral values of leadership and emphasizes the need for leaders to carry out leadership activities with minimal waste or destruction and the upmost of ethical integrity.

Table 15.2 summarizes the demands identified in the above empirical studies of leadership relevant to the construction industry and groups them into three focus groups.

Digital Technology Capabilities Relevant to Construction

Digital transformation is the "application of digital technologies to fundamentally impact all aspects of business and society" (Gruman, 2016). The digital component involves technology, while the transformation component involves people (Del Rowe, 2017). It can enable individuals and organizations to transcend from one way of working to another.

This section focuses on reviewing the technological opportunities relevant to the construction industry. It provides a non-exhaustive list of technology examples, current and future trends of digital technology and their capabilities and application potentials for the construction industry.

Smartphones

Smartphones serve as the hubs of interconnectivity (Ahmed & Ahmad, 2014). They allow for knowledge sharing and exchange, as well as collaboration through a plethora of functionalities and applications. Smartphones can be used as a single mode of analysis for digital technology such as augmented reality (AR), to aid learning, understanding and remote collaboration (Joan, 2015); computer-aided design (CAD), to clarify important design details (Moreno, 2014); near-field communication (NFC), to track and monitor construction worker health and safety

(Akhavian & Behzadan, 2016); and credential verification services (CVS), to monitor employee training records and renewals. Smartphones are an extension of their users, and with the many applications that can be integrated within these devices, they act as a remote for digital transformation (Azhar, Jackson, & Sattineni, 2015).

Wearable Technology

Wearable technology (or "wearables") describes the integration of smart electronics within items that may be worn or implanted (Wright & Keith, 2014). Smart glasses, for example, incorporate an optical display that can advance information exchange at construction sites (Moon & Seo, 2015). In a split second, electronic documents, video and images can be shared, saved and retrieved (Heembrock, 2015), allowing construction professionals to be freed from the burden of holding paper documents, such as drawings and specifications (Moon & Seo, 2015). Wearable wristbands that measure sleep patterns and circadian rhythm can aid in managing unsafe working conditions by identifying fatigue, illness and other physical risk factors (Cullen, 2016). These functions can also be extended to mental health and well-being, by reminding construction professionals to stretch, hydrate and replenish (Heembrock, 2015). With the integration of woven sensors, wearable clothing can inform workers if they are exceeding lifting thresholds, have been overexposed to UV rays or are at risk of a slip and fall incident (Heembrock, 2015). Self-charging shoes that detect temperature and track location and motion can also ensure worker well-being is maintained when working alone (Linder, 2017). With the variety of sensors that can be integrated within clothing or accessories, leaders can understand the well-being of their team and advance their role in improving health and safety within construction projects (Linder, 2017).

Drones

Drones function as aerial imaging vehicles that can transcend data collection capabilities within construction projects. They allow for site progression and operations to be accurately tracked and reported (Dillow, 2016) and can enhance efficiency with site surveys, photography and mapping. With sensory features integrated, drones can turn data into 3D structural models, topographical maps and volumetric measurements (Dillow, 2016),

which can translate to enhanced productivity, safety, quality and security within projects. Additionally, "smart drones" possess the capability of recognizing objects and can incorporate a "sense-and-avoid-system" to self-monitor project operations (Hambling, 2015). These aerial capabilities add a greater dimension to project tracking and can allow project leaders to effectively communicate, mitigate potential issues, reduce costs and limit delays (Dillow, 2016).

Virtual Reality, Augmented Reality and Mixed Reality

Advanced visualization technologies can impact upon the way groups and individuals collaborate, communicate and engage (Phelps, 2014). Augmented reality (AR) overlays the visible natural world with a layer of digital content, while mixed reality (MR) integrates virtual objects into the natural world (Heiskanen, 2016). These capabilities for digital content to interact with the real world enable new possibilities for safety, planning, quality and management (Heiskanen, 2016). AR used through smart glasses can enable for a digitally enhanced view of the world that can facilitate the learning and awareness for student and professional development in construction (Kivrak, Arslan, & Tuncan, 2015; Ahmed & Ahmad, 2014). For example, the Smart Helmet by American augmented reality company DAQRI creates an intuitive experience as it connects users to the work environment and provides relevant information instantaneously (Heiskanen, 2016). Additionally, holographic technology such as Microsoft Hololens can allow remote teams to experience the spatial presence of the design model, collaborate and share information instantaneously over three-dimensional holograms (Heiskanen, 2016).

Virtual reality (VR) however creates a completely simulated environment (Sampaio & Viana, 2014) and can allow for four-dimensional viewing and interaction with all stages of the construction process. Project team members can therefore optimize planning and design and create an interactive environment for construction resourcing and scheduling VR can also be used to support learning and awareness for safety and risk management and develop a platform for users with limited knowledge to easily simulate the activities needed (Kassem, Benomran, & Teizer, 2017). These visual capabilities can aid in prediction and decision making by allowing users to view, interact and simulate their projects throughout its life cycle (Sampaio & Viana, 2014).

Building Information Modeling (BIM)

BIM is a three-dimensional (3D) model-based technology process for creating and managing project information (Succar, 2009). BIM will reduce the "blind spots" of two-dimensional (2D) construction drawings (Lee et al., 2015) and facilitate for extensive stakeholder collaboration (Kim et al., 2016). It can improve resource coordination, quality control, information exchange, safety, security, decision making and reduce manual tasks (Park, 2016). However, its collaborative platform (Lee et al., 2014) is what can facilitate project leaders to effectively communicate in real-time among project stakeholders (Park, 2016). Furthermore, new advancements of four-dimensional (4D) BIM and five-dimensional (5D) BIM enable further improvements in areas such as design, information management and sustainability. 4D BIM incorporates time to establish links between project activities and scheduling, which enables construction professionals to conduct constructability checks before construction (Kim, 2016). Whereas 5D BIM incorporates costing within the model to ensure the effective management of costs throughout a project life cycle, including cost estimation and budgeting (Kim, 2016).

Artificial Intelligence and Software

Artificial intelligence (AI) can redefine how processes are undertaken within the construction industry (Blanco, Fuchs, Parsons, & Ribeirinho, 2018). Collisions and inefficiencies within models such as BIM can be pre-empted, tracked and controlled (Garcia De Soto & Adey, 2016). Knowledge contained in daily reports, schedules, weather forecasts, and many more can be transformed into a living knowledge base and means of deductive and plausible conclusions (Klashanov, 2016). Garcia De Soto and Adey (2016) also believe that by integrating the case-based reasoning and neural networks of AI, resource estimates and decision support can be drastically enhanced.

Emotion aware technologies possess mood tracing capabilities with the potential to track and analyze an individual's emotional state (Morsy, 2016). This can enable construction professionals to keep mood journals and emotional data to understand what influences their emotion (Morsy, 2016). Additionally, authentication technology such as radio-frequency identification (RFID); quick-response codes; and fingerprint, vein, iris and facial recognition can allow for manpower management, credential verification and access control (Chin, Kim, & Choi, 2017).

Auto-Analytics

Auto-analytics and cognitive computing can be used to radically improve emotional intelligence and social relationships within the future construction workforce (Hansen, 2017). It is the process of intelligent logical analysis through technology, in which data is collected autonomously and used for analysis (RGA, 2013). Data can be collected through wearables such as watches, headbands and rings that can detect physiological data, such as heart rate, skin temperature and brain waves to accurately read a person's mood and provide real-time data to the user (ABI Research, 2017)

The Case of Australian Civil Construction

Construction has become one of the most important industries in Australia (Leviäkangas, 2017), and by 2020, Australia will become one of seven key countries that will account for 65% of the growth in global construction (Richardson, 2017). Using the case of a Sydney-based contract civil engineering firm specialized in design and asset management of transport infrastructure, land development and renewable energy projects, exploratory interviews were conducted to first unearth challenges faced by construction professionals in meeting leadership demands and expectations and then to explore the feasibility of existing digital technologies to assist in overcoming these challenges. The interviewees were a senior project manager with 16 years' experience, a project manager with 5 years' experience and a junior project manager with 2 years' experience.

Challenges in Addressing Leadership Demands in Civil Construction Projects

Interviewees expressed the significance of project leadership and its importance for the well-being of construction projects. They considered leadership as a critical component of their role and when asked whether they perceive themselves as a leader, one interviewee proclaimed "only because I have to be". Leading was considered as a way of being "consistent" and not allowing life experiences to interfere with project team experiences. The more junior respondents emphasized their thoughts on how leadership "comes with experience". Yet, the senior respondent did not entirely feel he had gained project leadership mastery or even gained a superior grasp of project leadership behavior. Rather, this respondent felt it was an ongoing challenge of his role.

The following sections outline the key challenges extracted from the interviews. They were clustered around the previously identified focus areas of leadership demands "team focus", "leader focus" and "project focus" (see Table 15.2).

Challenges Relating to the Team Focus

Respondents emphasized the necessity of cohesion and its importance to project success, highlighting that a difficult project with a "good team" can be successful, yet an easy project with a "poor team" may perform terribly. Interviewees felt that the difficulty in maintaining cohesion stemmed from the constant "chopping and changing" of project team personnel, which made it difficult to align team goals. Respondents also felt that leadership elements of team chemistry and cohesion were dependent upon "the people". As described, there are "different people" and "no one's good, no one's bad". It's all about "who they are, where they came from, and what their strengths and weaknesses are". This creates difficulties in dealing with the different types of personas, and aligning the way they operate with each other, with the best interests of the project. However, difficulties associated with cohesion were often related to difficulties associated with lack of control. With one respondent suggesting that "you don't necessarily build the team, you get given the team".

Respondents felt that the key challenges associated with communication arose from the need to communicate differently, with different types of people, and in different types of situations. As one respondent proclaimed; "it's not always rainbows and unicorns", at times you can "hurt people's feelings". This was further reinforced as interviewees lamented challenges with communicating with team members in the ways they expect to (or would like to) receive information. Getting the desired outcome from communicating was also seen as a pressing difficulty, with one respondent pointing out the difference in communicating, and "communicating effectively". "It's easy to tell someone to dig a hole, but it's more difficult to convince someone why they should be digging a hole". The challenge in communication is convincing people the reasoning behind what they are doing and "how it impacts the bigger picture".

Challenges Relating to Leader Focus

Respondents felt a key challenge in leadership awareness was in understanding people and how they operate. They believed that understanding which leadership style to adopt "takes up so much of your time" and if you get it wrong, "it can come back and bite you". Another interviewee raised the issue of proactivity, and the difficulty in being proactive in an environment that often imposes reactivity. Getting appropriate feedback was also deemed challenging as respondents felt they could never really judge how others perceived them or their practices. Furthermore, respondents felt that maintaining a consistent persona was a challenging feat, as personal issues could change their behaviors and often result in poor leadership practice that could have "spill-over" effects throughout the project. Respondents articulated that; "when you are at home, you are not always expected to be consistent with your leadership". But at work, leadership is a full-time commitment, and regardless of your situation, you still must be "calm", give "direction" and be able to "think" clearly.

Interviewees revealed the notion of fluctuating control. They felt that at times there were inconsistencies with regards to their control over and control within the project, with one junior respondent describing how it can often be confusing "who is in charge". The more senior interviewee emphasized how the lack of control can be "frustrating at times", and how "you just need to manage" working within the limits of your authority, whereas the junior project manager articulated the notion of leading "upward". Describing how leading also incorporates leading "your bosses" and the difficulties that arise when "convincing them to do things that you need". This respondent felt that you could only lead as much as you could and ultimately the final "decision can be out of your hands".

Challenges Relating to Project Focus

Respondents believed that operating as a leader within the civil construction industry was much more difficult than it would be in any other industry. One respondent highlighted the construction industry's culture of "resistance". He felt that there was a constant "resistance to change and resistance to do things differently" within the sector. Respondents also felt that there was a culture of "responsibility avoidance", in which industry professionals would constantly disassociate themselves from any levels of ownership or autonomy. Thus, making it much more difficult to lead, as individuals would often refuse to take ownership of their work. One

respondent also touched on the topic of health and safety appreciation and described how the civil construction industry is not "mature enough". This respondent felt that leading a safer environment was difficult due to the resistance from workers in which they perceive health and well-being initiatives "as making their job harder".

The overall consensus was that a project can significantly dictate leadership behavior. Respondents highlighted that the project setting meant that they were forced to "assess people quickly" and make "on the spot" decisions and judgments. They felt short projects imposed "minimal time upfront" to plan and implement leadership structure. Therefore, they lamented on "time" as an influential factor in leadership practice. There were many leadership activities that they wanted to adopt but felt they were unable to do so due to time and budget constraints. The emphasis from respondents was that they were not afforded the freedom to properly indulge in leadership practice, but given the time, they would have the opportunity to lead.

Table 15.3 summarizes the identified key challenges to meet leadership demands.

Table 15.3 Overview of challenges to meet leadership demands

Challenges relating to	
Team focus	• Effectively communicating in ways people expect to, or would like to receive information • Convincing members the reasoning behind what they are doing and how it impacts the bigger picture • Communicating differently, with different types of people, and in different types of situations • Constant changing of project team members • Understanding differences in styles, strengths and weaknesses • Difficulties with influencing the team you are given
Leader focus	• Understanding people and how they operate • Getting appropriate feedback • Pressures of maintaining consistency with leadership, even in times of difficult personal circumstances • Limits of authority • Final decisions are at times out of your control • Fluctuating levels of control can make authority ambiguous
Project focus	• Resistance of construction professionals to change • Responsibility avoidance among construction professionals • Lack of worker appreciation for health and well-being • Planning and thinking ahead with project time constraints • Budget doesn't allow for major leadership implementation • Project environment means you need to assess people very quickly

Potential for Digital Technology to Address the Leadership Challenges

In the second part of the exploratory interviews, the previous results were used to discuss how the capabilities of digital technologies could help overcome leadership challenges in the construction industry.

Respondents were able to articulate general and often vague methods they used in dealing with leadership challenges, ranging from "being consistent" to separating "work life from personal life". In short, the consensus was that "you just have to deal with it" as it comes. However, the junior respondent did suggest the use of the smartphone application "FaceTime" as a remedy to some communication difficulties faced. According to this interviewee, the lack of face-to-face communications was prominent in his position and made it difficult for him to effectively communicate. Therefore, the use of FaceTime allowed him to overcome these challenges and "bridge the gap" between less meaningful and meaningful communications. Respondents also felt that effectively communicating goals to all significant stakeholders could allow leaders to gain more authority within their positions. Furthermore, respondents believed that a great project leader could expand the objectives of the project itself beyond time, budget and quality, to involve "building" a "team" to "higher levels" of achievement in which everyone has "learnt", "grown" and "gained something".

Although the senior respondent was somewhat skeptical, the two more junior respondents could see immediate potential for digital technology to enhance leadership practice in some areas. One respondent made immediate connections with visual technologies, such as augmented reality, artificial reality, holographic display, as well as 3D, 4D and 5D BIM. He felt that these technologies would allow leaders to "sell the story" and help explain the reasoning behind objectives and goals. Moreover, this respondent felt that these technologies would be beneficial for leadership to "be able to show someone rather than tell them". "Having the capability of showing someone, having them see exactly what you are talking about, would help to sell that story". Respondents also felt that if the capabilities of auto-analytics were available, they would "use it tomorrow". The respondents were particularly excited about the capabilities to gauge factors like mood, sleep, physical and mental performance, as well as to provide real-time feedback on positive and negative words used in conversion, thus enhancing their leadership behavior. Furthermore, respondents believed that wearable technologies could assist with health and safety and would aid in a leader's responsibility to maintain workplace well-being and

Table 15.4 Digital technologies to assist with leadership challenges

Technology	*Capability*	*TF*	*LF*	*PF*
Smartphones	Can allow leaders to have a single mode of analysis for the project team, the project and themselves.	•	•	•
Wearables	Can allow leaders to maintain health and well-being of workers and positively influence organizational culture.	•		•
Drones	Can allow leaders to better track and report progress to team members, keeping them constantly informed and aware of their influence.	•	•	•
AR, VR & BIM	Can allow leaders to "show" rather than "tell", making it easier to "sell" the project story.		•	
Auto-analytics	Can allow leaders to understand themselves and their interactions with others.		•	

TF = team focus; LF = leader focus; PF = project focus

a positive environment. Respondents felt that utilizing wearables to build a cohesive team could influence the organizational culture, in which other organizations would "try to replicate" and "learn" from them, thus changing cultural perspectives within the industry.

However, all respondents argued that it would take more than technology to have an influence on the challenges outlined, and although they may assist with providing information, it would be up to the leader to use this information accordingly.

Table 15.4 outlines the key capabilities of digital technologies to assist with overcoming leadership challenges.

Discussion and Outlook

Digital transformation is fundamentally influencing all aspects of business and society. It can enable individuals and organizations to transcend from one way of working to another. In construction, emphasis is shifting from project management to project leadership, as professionals need assisting tools to not only aid in managing tasks and activities, but to aid in leading people.

Using the example of the Australian civil construction industry, we reviewed the existing body of knowledge on both industry-specific leadership demands and relevant digital technology capabilities to identify areas of improvement and to guide interviews with construction project managers. Findings indicate that digital technologies will have a positive influ-

ence on project leadership challenges. We find that project managers of civil contractors within Sydney understand the significance of leadership, but are often overwhelmed by its complexity. They demonstrate a willingness to adopt digital technologies as assisting mechanisms for leadership. Participants also lament on leadership challenges relating to project scope, industry attitudes and culture, level of authority, leadership habits/behavior, communication and team development. Construction professionals demonstrated specific examples in which they could utilize certain technologies to address challenges in their leadership practice.

Digital technologies can act as the catalyst that disrupts the behavior of a project team, which ultimately influences the environment in which the team operates. The input of digital technology within the leadership system can therefore transform leadership challenges into opportunities. As such, the adoption of digital technologies may hold the key in taking project leadership practice into the future. This chapter aims at opening up a discussion about exploring areas in which disruptive technologies can be used to create benefits beyond their primary technical applications.

CHAPTER 16

The Making of Data-Driven Sustainable Smart City Communities in Holiday Destinations

Sudipta Kiran Sarkar, Michalis Toanoglou, and Babu George

Introduction

Sustainable development is a term that emerged from the Brundtland Commission's report of 'Our Commons Future' in 1987 (Saarinen, 2006). The concept of sustainable development entails a responsible practice of resource consumption by current generations so that future ones are not deprived of the same resources for their basic survival (WCED, 1987; Saarinen, 2006). The argument in favour of advocating sustainable development got further impetus in institutional terms in the 'Earth Summit' in 1992 held in Rio de Janeiro, Brazil since the Rio Conference

in 1992 on account of the observation of manifold negative ecological and social impacts caused by decades of industrialization (Hanharan, 2010; Saarinen, 2006).

The perspectives of sustainability in tourism emanated from the Agenda 21, an action plan on sustainable development that emerged from the discourses of the Rio Conference. Sustainable development issues have become crucial in current tourism discourses (Roberts & Tribe, 2008)—given the negative impacts of tourism operations in terms of social, political, economic and environmental aspects. According to United Nations World Tourism Organization (UNWTO) 'Sustainability principles refer to the environmental, economic and socio-cultural aspects of tourism development, and a suitable balance must be established between these three dimensions to guarantee its long-term sustainability' (UNWTO, 2004).

Since the last three decades, several initiatives primarily by non-profit organizations as well as academic, governmental and inter-governmental organizations have pursued sustainability, both in practice and dialogue through regional, inter-regional and global projects, grassroots-based activism as well as workshops and conventions. In addition, private sector/industry initiatives towards sustainability have also been evident in spite of the conflicting interests emanating from a dominant neo-liberal economic environment that has shaped the industry perspectives in tourism. However, climate change issues and inequality in tourism destinations have been ever increasing despite various pursuits of sustainable development by different sectors in the tourism industry. Hence, the quest for sustainability in tourism is far from over due to the increasing environmental and social challenges faced globally.

Technological developments and innovations have brought us to a new phase in our modern society. Cutting edge technologies in digital, environmental and transportation domains have paved the way towards a new epoch of industrialization that provides accessibility, communication and socialization to the masses via affordable means. Developments in more efficient, faster and safe mass public transit systems, as well as developments in green energy that have made it relatively more affordable and cost-effective to a much larger section of consumers and businesses, have brought sustainability and technology closer and compatible with each other than ever before. Clean energy and cleaner modes of transportation driven by new innovative technologies and coupled with smart digital technologies have brought new opportunities to the process of transformation towards a sustainable future. Clean energy, cleaner modes of trans-

portation systems as well as smart digital systems have fostered the development of sustainable urban tourism by virtue of hospitality outlets and urban attractions increasingly adopting green energy technologies—clean modes of transportation providing affordable, environmentally clean and efficient mobility services to tourists and digital technologies (powered by widely available Wi-Fi services) enabling communication and availability of information critical for destination knowledge and travel decision-making. Public/state funded technological projects around the world are leading the way for more innovations in cleaner automobiles and cleaner energy production—ARPA-E in the United States and Germany's KfW, a state investment bank have funded a number of clean technology initiatives with relation to energy efficient and renewable projects in the recent past (Tate, 2017). Tesla, a leading producer of electric cars in the United States has been funded by the US Department of Energy for producing electric automobiles with cutting edge technology. Returns from green technology investments initiated both by state and the private sector has resulted in creation of wealth for the public providing more coherence and impetus to the role of technology in fostering sustainable development (Harris, 2017).

The bond between sustainability and technology will mostly be necessitated by the imperative needs in cities and urban areas of the world. Growing complexities in ever expanding cities of the world resulting from the demands for quality of life, environmental protection and competitiveness will drive the need for sustainable development powered by clean energy technology, soft mobility technology and more intelligent digital technologies (Siemens AG, 2013). Moreover, cities and other urban areas around the world, which currently produce approximately 70% of the greenhouse gas emissions, will increasingly become the epicentres of high volumes of consumption leading them to be major contributors to climate change (Siemens AG, 2013). Hence, the demand for innovative technologies that can facilitate sustainable and inclusive urban growth will necessitate effective solutions and strategies that can ensure resilient and environmentally compatible ways of urbanization of our cities in the future.

One of the prime areas of economic activity and consumption in cities around the world is tourism. Cities and urban areas vibrant with arts, culture, music, architecture and design and heritage along with centres generating robust volumes of business and commercial activity have attracted all kinds of visitors. Moreover, ease in mobility and communication due to rapid digitalization and internet connectivity via Wi-Fi as well as expansion

of different modes accessible and efficient public transportation networks have made tourism in urban areas grow manifold. Urban tourism as referred to by UNWTO (2012) is 'trips taken by travelers to cities or places of high population density'. Cities which are administrative capitals of nations are gateways to many destinations and the first point of reference for tourists in acquiring an impression of the nation as a destination. This makes large number of tourists travel to and via cities and hence crucial for destination management organizations to manage cities as destinations in a way that they can facilitate quality experiences and enhance satisfaction of such large mass of tourists.

This chapter discusses the magnitude of technology being strongly implanted in the process of sustainable development of cities as manifested through urban tourism—one of the main pillars of urban economy. The chapter identifies four critical dimensions of sustainability in urban tourism—urban ecotourism, food tourism, urban culturescapes and smart transportation. Correspondingly, critical dimensions of technology in urban tourism—social media and user-generated content, gamification, M-learning (mobile-based learning), green energy technologies and green/soft mobility, are also discussed comprehensively. The chapter then discourses the integration between technology and sustainability in urban tourism contexts based on existing cases and models around the world.

Dimensions of Sustainability in Urban Tourism

Culture, nature and communities in urban areas have been instrumental in shaping the tourism landscape of cities around the world. City-based parks, gardens and waterbodies as well as museums, arts galleries, performing arts, avant-garde arts and countercultural communities have attracted large number of culturally inclined independent travellers. On the rise are emerging forms of urban travel activities like food tourism combined with walking tourism that involves trips to areas of cities noted for local food—wet markets, restaurants, confectionaries and all other forms of eateries and food outlets. Also associated with such tours are the communities engaged with food tourism businesses, their enterprises, the aesthetic aspects of their culinary offerings, their skills as well as the socio-cultural environment they create and belong to as a whole. Another aspect that culture-oriented city walking tours involve are visitations to prime natural and cultural attractions of urban areas harnessing mass transit public transport systems. All these elements reflect socio-cultural inclusivity,

environmental compatibility and offer deeply engaging lived as well as socializing experiences to tourists. Such increasingly popular forms of urban tourism have been receiving adequate patronage from tourists and destination planners in the recent times as the modern tourism discourses progressively reflect the virtues and the essentiality of sustainability.

Urban Ecotourism

Towns and cities have large tracts of nature either in the form of national parks, sanctuaries, wildlife reserves and other organic forms or in modified or artificially created forms. Urban centres around the world are increasingly trying to harness the value of such nature tracts in providing sustainable living to both its residents and visitors. Urban tourism now significantly involves travel to nature-based areas in and around cities especially to such natural areas, which are of high significance in terms of flora or fauna or both. Such trips help both residents and visitors understand the value of nature as well as enable them to have a sustainable approach to experience cities. Such a phenomenon can be referred to as 'urban ecotourism'. Though the term 'urban ecotourism' was first coined in 1996, the phenomenon has been in practice since long. Planeta.com, an award-winning website on ecotourism, in a conference in 2004, described it as 'simply nature travel and conservation in a city environment' (Kastelein, 2004). The definition laid down by the Toronto Green Tourism Association (2006) was 'travel and exploration in and around a city that provides visitors and residents with a greater appreciation of the cities' natural resources and cultural resources'.

Cities like New York, Toronto, Singapore, Hong Kong and Kuala Lumpur have attracted local and international visitors towards both natural and modified nature-based attractions. Nature-based attractions in these cities offer opportunities for various leisure and adventure activities like bird-watching, nature-viewing, photography, caving, hiking and rock-climbing. Such opportunities have made nature-based attractions in these cities an integral part of their urban tourism offerings to all kinds of visitors. One of the prime features of urban nature-based attractions in most cases is that they are often well-connected by mass transit public transportation systems due to their location within or on the periphery of cities and major towns. Hence, travel to urban nature-based attractions or urban ecotourism contributes towards sustainable development as it creates opportunities for alternative recreational activities as against the traditional

highly consumptive urban tourism activities. Urban ecotourism apart from primarily focusing on travel to nature-based areas in urban areas also involves trips to cultural sites like museums, art galleries, handicraft streets, wet markets and food streets. This provides the social and anthropological element to the urban ecotourism phenomenon making it inclusive and environmentally inclined at the same time. Urban ecotourism offers the opportunity to all sections of the society to be educated on the value of ecology to human societies as nature-based attractions offers easy access by the virtue of being located within or close to cities and by being well-connected efficient and affordable mass transit transport systems.

Food Tourism

Food tourism is the phenomenon of travelling and experiencing other cultures through food (Herrera, Herranz, & Arilla, 2012). Food tourism is also sometimes referred to as culinary tourism or gastronomique tourism. Food tourism entails a sense of place in geography (or the link between land and people). Travel for the purpose of experiencing exquisite culinary offerings of a destination has become one of the main motivators of travellers in terms of their travel behaviour and activities at a destination (Herrera et al., 2012; OECD, 2012). Such culinary experiences are offered in an array of settings—the most exciting and engaging ones being local street food at popular street food enclaves of towns and cities, wet markets or night markets as well as local/traditional food outlets which by virtue of their unique offerings (taste, aroma and aesthetic style of presentation) for a considerable period of time have become transformed into a heritage due to the sustained popularity that they have enjoyed (Gillan, 2014; Nualkhair, 2015). Experiencing food related events like food festivals or experiencing hands-on cooking (participating in cooking classes) as well as food tasting and/or experiencing the attributes of specialist food production are also some of unique experiences that urban destinations offer to foodie travellers (Peltier, 2015).

Apart from the hedonic and consumptive aspects associated with the experiences of food tourism, the communal and cultural elements that are strongly embedded in it often construct the basis of such experiences (Peltier, 2017). A critical aspect associated with these communal and cultural elements is sustainability. Food tours are often characterized by walking tours for short durations of 4–5 hours as well as harnessing the services of mass transit public transportation systems. The use of such soft modes

of mobility enable food tours to deeply involve the communal element as it provides a social interface between foodie travellers and the communities engaged with food tourism businesses, the small scale nature of the enterprises they run as well as the aesthetic aspects of their culinary offerings along with their culinary skills (Gillan, 2014; Nualkhair, 2015). This social interface constructs a socio-cultural environment that immerses the visitors and their gazes with deeper social meanings of their experiences of local culinary cultures. Hence, the utilization of soft mobility and the socially immersive experience reflect the sustainable nature of the communal and cultural elements of food tourism.

Urban Culturescapes

Cultural activities ranging from visitations to art galleries and museums depicting different aspects of aesthetic and social scenes of modern society as well as radical/avant-garde and contemporary forms of arts and events mainly advocated by the urban youth shape the culturescapes of our cities (Merrick, 2011; Buffenstein, 2016). Urban areas around the world encompass both mainstream and alternative forms of visual and performing arts along with edifices of heritage like museums and monuments that attract a large number of travellers to urban areas.

Cities like Berlin, London and New York have attracted culturally inclined travellers to art galleries and art collectives that focus both on popular and 'avant-garde' forms of aesthetic expressions. Attractions like the Museum island in Berlin which consist of museums and galleries as well as alternative art centres like Kreuzberg, Friedrichshan and Prenzauler Berg attract all kinds of politically and art-inclined visitors. Many of such culture streets represent underground and alternative urban youth cultural expressions in the form of street musicians and street art collectives. Cultural centres like these in many instances have been the backdrop of radical urban socio-political movements that gave rise to countercultural thoughts challenging traditional Capitalist consumption models and advocating collective action and Do-It-Yourself ethos. Such actions and ethos have become underlying principles of many urban sustainable projects. Urban cultural centres like these often undergo continuous evolution and in the process have attracted a wide array of visitors—art-inclined people and artists themselves, youth belonging to avant-garde movements as well as with visitors based on socio-political factors like immigrants and anarchists. Urban culturescapes that involve such vibrant youth cultural vibes

offer visitors the experience and learning on ecological and social dimensions of urban sustainability through different artistic expressions and other culturally expressive activities.

As in the case of urban ecotourism and food tourism, visitations to urban landscapes also involve the harnessing of the urban mass transit public transport system that connect major centres of cultural sites with various important mass transit hubs.

Soft Mobility

Soft mobility refers to low emission transportation systems that provide mobility in urban spaces to the masses. Such low emission transportation systems operate in a variety of modes like inter-modal, waterborne, rail, public/collective transport and non-motorized individual mobility (Rocca, 2009). Soft mobility should involve—the consideration of the urban destination geographical features, legal and planning structures anticipated ecological, social and financial impacts of development as well as the needs and wants of the residents of the urban destination (Kramer, 2009; Transdanube, 2014).

Cycling/biking in urban streets has become a popular phenomenon around the world. Tourists and residents alike commute considerable distances in their daily schedules in cities with the help of cycling/biking. Several urban destinations have become bike-friendly cities encouraging visitors to utilize cycling paths as a way to reduce congestion and automobile-based pollution. Cheap and affordable mass transit systems like subway trains, monorails, trams and electric buses have provided easy accessibility to different cultural, nature-based and gastronomique streets to all types of visitors (Rocca, 2009). Therefore, one of the emphasizing factors emerging from soft mobility is to convert more tourist movement into sustainable modes of transport which can also be referred to as modal shift (Gebhardt et al., 2016). An inter-modal chain model of mobility for tourists involving the combination of waterborne, rail and public/collective transport as well as walking and cycling ensures a sustainable consumption from tourism movement within an urban destination (Gebhardt et al., 2016).

The rise of collective transport or transport options that have emerged under the sharing economy has also reduced the rate of consumption and offered a more convenient, reliable and safe mobility options for tourists in cities and towns. Sharing economy in transport refers to carpooling

services where car journeys are shared by more than one person. Several carpooling initiatives like Lyft, MyCotra and Uber have become commercially successful and are contributing towards less congestion and reducing individuals' travel costs.

In the Asian context, major cities like Singapore, Hong Kong, Seoul and Tokyo offer a combination of transport options ranging from subways or referred to as MTR and MRT (in Hong Kong and Singapore respectively) supported by extensive citywide bus networks along with options for biking-cycling at different parts wherever possible.

The Case of Hong Kong as a Soft Mobility Destination

In Hong Kong, the MTR (Mass Transit Railway), a combination of heavy rail, light rail and feeder bus service, is one of most extensive and profitable mass transit systems in the world and offers itself as a successful model for many other mass transit systems coming up around in the world and particularly within Asia. In addition, Hong Kong offers the option of using tram services in certain parts of the highly congested Hong Kong Island as well as extensive cycling opportunities in the new territories. Besides, waterways—a traditional mode of transport that have existed in Hong Kong since long still operates significantly offering services from Hong Kong Island (Central) and Kowloon ferry terminals to different parts of Kowloon, Hong Kong Island, New Territories and several outlying islands. The tram and ferry services are also a major part of the tourist experiences of Hong Kong. Tourist—centric transport like the furnicular rail or the Peak tram which covers a distance of 1.4 kilometres approx. starting from downtown Hong Kong Island to the Victoria Peak, a point of commercial and tourist importance at the higher elevations of Hong Kong Island enables both tourists and local residents a convenient commuting option. Another tourist-centric transport is the Ngong Ping cable car which starts from the Tung Chung MTR station to the tourist attractions in the higher elevations of Lantau island (Lantau peak) covering a distance of 5.7 kilometres and providing breathtaking views of the Hong Kong International Airport, the dense flora and topography of Ngong Ping plateau as well as the urban areas around. The Hong Kong International Airport and the

(*continued*)

(continued)
Hong Kong Disneyland are connected with the main commercial and residential areas of Hong Kong by means of MTR's special services—the Airport Express and the Disneyland Resort Line respectively. The urban bus network operated by different companies as well as the Green Liquified Petroleum Gas (LPG) light buses (minibuses) offers a comprehensive and highly well-connected system of road transportation to residents and tourists alike. Road transport in Hong Kong is also featured by three kinds of LPG run taxicabs—the red, green and blue taxicabs. The red taxicabs operate in the downtown areas of Hong Kong Island and Kowloon, the green taxicabs operate in the New Territories of Hong Kong and the blue taxi cabs operating only in the Lantau Island.

This comprehensive mass public transport system of Hong Kong offers a perfect example of an inter-modal model of soft mobility in an urban tourism destination. Firstly, the MTR services, the ferry services and bus network (especially the green LPG minibus services) as well as the extensive cycling-biking options which are highly interconnected enable tourists to commute to different famous and offbeat folk cultural, local culinary and heritage attractions of Hong Kong. Secondly, the 'Peak Tram' and the Ngong Ping Cable car offer exciting and safe tourist-specific experiential commuting to a large of urban tourists and resident visitors. Thirdly, the engaging experiences tourists obtain while availing ferry services and the tram services to commute around Hong Kong transform such transport services into tourist attractions. The extensive MTR network, cycling-biking options as well as the extensively operating LPG run cabs and minibuses along with tourist-centric transport options of the 'Peak Tram' and the Ngong Ping Cable car aptly manifest an eco-friendly and inclusive mass-oriented soft urban mobility system. Due to this dynamic nature of the urban inter-modal in the city, Hong Kong has been ranked first in terms of having the most sustainable transport as per the 2017 Sustainable Cities Mobility Index by Arcadis (Arcadis, 2017).

Dimensions of Technology and Their Integration with Dimensions of Sustainability in Urban Tourism

Cities and urban regions around the world are the most technologically vibrant in terms of use and applications. Urban infrastructure provides the basis and urban consumption patterns necessitate the presence and use of technology at considerable levels. Cities are connected with Wi-Fi technologies and its commercial activities are highly dependent on the use of innovative tech applications for various interconnected systems to work efficiently. Urban regions around the world are generally equipped with technological connectivity in terms of Wi-Fi availability, internet zones and social media sharing that benefits visitors and tourists to derive satisfaction and intention to re-visit urban attractions.

Social Media and User-Generated Content

Social media founded on the technological applications of user-generated content (Web 2.0) plays a major role in communication and socialization among tourists (Buhalis & Law, 2008; Kaplan & Haenlein, 2010). Urban destinations facilitated by easy availability of Wi-Fi services drive online activity of tourists who prefer to be connected while they are in the process of consumption of urban leisure-based experiential products (Bock, 2015). Facebook, which enjoys the highest number of users in the world, followed by Twitter and travel-oriented platforms like Trip Advisor—have been the widely used social media platforms by tourists for online social interactions, sharing of vital travel information influencing travel decision-making by tourists (Santos, 2011). Online social exchanges and sharing of information by tourists in online platforms have led to co-creation of collective knowledge (Seraj & Ayesugul, 2012).

Eco-conscious tourists in urban settings have the ability of setting ecological citizenship through continuous co-creation of knowledge that is collectively generated through their online social interactions and sharing of information on ecological and social elements they experience in nature-areas in urban settings (Rokka & Moisander, 2009; Sarkar, Au, & Law, 2013). The advent of Flickr, a photo-sharing social networking site and recently, Instagram—a photo-sharing social networking app has initiated online co-production of destination knowledge through pictures and photographs. This has enabled tourists create aesthetically credible pictorial connotations of destinations that have deeper influences on fellow-tourists.

Urban tourism destination-based authorities and promotional bodies have harnessed the co-creative and collective knowledge building potential of social media platforms like Facebook and Instagram (Sarkar et al., 2013). Promotional efforts on social media platforms and initiating co-creative practices among consumers have become a key innovative marketing strategy that transforms consumers into pro-sumers. Co-created content by tourists on social media can become invaluable marketing content for destination management organizations (Özdemir & Çelebi, 2015).

The advent of smartphones in the last 5–7 years have enhanced the role of social media use among urban tourists. With the increasing availability of Wi-Fi facilities and high-speed internet connectivity in public places, cultural sites as well as natural sites, smartphones have accelerated the volume of online activity of tourists. Smartphones have drastically reduced the time between tourists experiencing an attraction and their sharing of pictorial, audio-visual as well as textual information in various social media platforms based on such experiences. Tourists can very quickly engage in co-creative practices on social media platforms in the context of urban destinations due to the widespread availability of Wi-Fi and increasing use of smartphones and smartphone-based apps. Tourist-generated (and co-created) content in social media platforms primarily via smartphones have become more reliable and easily available than supplier-generated content resulting in effective travel decision-making and collective knowledge building by existing and prospective tourists.

In the context of urban tourism, both tour operators and tourists make use of social media platforms like Facebook and Instagram to co-create experiences and products of nature, culture and gastronomical tourism. Moreover, blogs maintained by tourists on urban nature, food and cultural attractions play a major role in initiating collective knowledge building through sharing and exchange of key information. Such collective knowledge or tourist/consumer generated knowledge become more intense and reliable than supplier-generated knowledge as it involves a dialectic process of critical and comprehensive introspection of content. Moreover, through such dialectical process of collective knowledge building, tourists establish and advocate ecological and cultural citizenship online.

Gamification in Tourism

Gamification in tourism is ‘the use of game mechanics and experience design to digitally engage and motivate people to achieve their goals’ (Burke, 2014). Gamification can be a great method to digitally engage

visitors with a use of their smartphones, tablets or other digital devices (Sever, Sever, & Kuhzady, 2015).

Gamified tourism experiences often involve challenges in the form of quizzes, puzzles, making and submitting photos according to a task. Scores based on these challenges determine how well the participant has accomplished the challenge (Kazakova, 2015). To monitor the participants there are leaderboards who keeps them updated how they are progressing in the game in terms of the rounds of challenges to be completed and the scores scored. Those completing all stages of the game successfully with high scores are rewarded in both virtual and real (tangible) forms (Kazakova, 2015).

Gamified tourism experiences are offered in different forms especially in the urban context. Some of the prominent forms are location-based augmented reality games, gamified tours specific to urban environments, augmented experiences of theme parks and transmedia storytelling, gamified immersive experiences in cultural and natural heritage and virtual cultural heritage experience, gamified restaurant and hotel experiences.

As mentioned earlier, one of the main aims to offer gamified experiences to tourists is to immerse them in a situation that is highly subjective and enduring in nature and therefore can provide high levels of satisfaction to them. Gamified experiences have the potential to bring loyalty among tourists for the destination and enable repeat visits. Gamified experiences are an attempt to add value to the generic trip experience of tourists while they are visiting an urban destination (Sever et al., 2015).

Applying gamified experiences in the area of sustainable tourism can facilitate social interactions, cultural understanding, inculcate sustainable consumption habits and bring about an enhanced quality of experience (Negruşa, Toader, Sofică, Tutunea, & Rus, 2015). Gamification in sustainable tourism is aimed at engaging as well as encouraging tourists to advocate and internalize new sustainable habits, sustainable consumption or even engage in new sustainable activities and visit new destinations that are sustainable. Gamified experience in the context of sustainable tourism has the potential to provide intrinsic incentives to tourists while they are engaging in activities that enable them to derive self-esteem and social recognition (Negruşa et al., 2015). The merits of applying gamification in sustainable tourism involve usher engagement before during and after any nature-based experience as well as marketing and promotional benefits. Gamification by means of improving the experience offers an opportunity to attract new visitors and new markets.

M-Learning or Mobile Learning

M-learning or mobile-based learning is a process of learning and education through the means of movable electronic computing devices like smartphones and tablets. The use of M-learning in the hospitality industry has been evident in the recent times in areas of hospitality workers' training and education. Hospitality chains like the Marriot and Hilton are applying M-learning applications for recruitment of new workforce in their respective hospitality properties.

The potential application of mobile learning in the context of the touristic use can be realized in the form of environmental interpretation and visitor education within the context of urban natural settings like botanical gardens, city parks, urban groves and other similar places. Utilizing the current developments and innovations in mobile broadband networks, smartphone technology and mobile software applications, the M-learning process can provide engaging interpretive programmes involving free-choice learning and mindful visitor experiences to tourists in urban natural settings.

Soft Mobility and Green Energy Technologies in Urban Tourism

As discussed earlier, soft mobility involves a set of different forms of low emission transport in urban destinations—an inter-model mode of transport. Soft mobility forms have facilitated accessibility to the masses and brought about social transformations and quality of life in many parts of the world. Inter-modal soft mobility has provided inclusivity and an egalitarian mode of transport in which lower income urban communities have found easy and convenient access to different parts of urban areas where they have to commute for earning a means of livelihood and education. Efficient and affordable inter-modal soft mobility available for local residents from all sections of the society also provide accessibility and connectivity to tourists and visitors in urban destinations. Such inter-modal soft mobility forms are driven by technologies that provide access to difficult terrains and dense settlements evident in urban destinations. Transport technologies like cable car and low emission automobiles using new forms of renewable fuel as well as electricity have provided greater social sustainability. These are the emerging smart mobility technologies that have enabled visitors from all economic sections or urban societies to affordably have access to attractions of ecological and socio-cultural interest.

The Case of Gondolas or Cable Cars in Latin American Cities and Hong Kong

Gondolas or cable cars are considered as a cheap option which requires lesser investment for infrastructure and lesser need of displacement of people and communities compared to other mass transit forms like subways or rail tracks. Gondolas may not have the ability alone to transport a large number of people from one to another but support significantly other forms of mass transit system by playing a major role in inter-modal connectivity (Barber, 2017). Gondolas on one hand can facilitate tourist movement within and to attractions in urban destinations and on the other hand also enable to move local residents from their neighbourhoods to major centres of cities at an affordable cost especially where the urban geographical landscape is characterized by challenging topographies. In particular, gondolas have been able to provide a faster, time-saving and affordable mode of transport to urban residents living in the poorer parts of cities and linking them with commercially important parts where there are opportunities for earning a livelihood. Latin American cities like La Paz (Bolivia), Medellin and Cali (Columbia) and Caracas (Venezuela) are major examples of such socially inclusive and effective gondola systems in commuting terms for the masses (Barber, 2017).

The Metrocable in Medellin city, Columbia is regarded as the world's first integrated multi-line gondola system. The Metrocable connects with major business and commercial centres of Medellin city with many outlying and less wealthy areas of the city in upper elevations of hillsides. The Metrocable was opened in 2004 and since then has been credited on one hand, in reducing commuting times, providing cheap and efficient connectivity to many low income residents of outlying areas and on the other hand, has been significantly instrumental in reducing crime rates and urban poverty levels in the city(Barber, 2017).

Mi Teleférico, the gondola system in La Paz, Bolivia is considered as one of the most developed and longest in the world. The Mi Teleférico was opened in 2014 and since then has enabled 50 million people to commute from poorer parts of the city to the upscale business and commercial areas. It has been reported to have saved 652 million minutes for all commuters it has served since 2014. The Mi Teleférico has been claimed to be a very effective project and the city authorities are considering to expand it to seven more lines which are expected to be covering a distance of 20 kilometres.

(*continued*)

(continued)

The Caracas Metrocable in Caracas, Venezuela operates with the similar philosophy of providing connectivity for the city's poorer parts with the affluent parts. It was built to avoid displacing people and providing poorer parts of Caracas like the San Agustin a safe and efficient mode of transport to commute especially within such areas. The Caracas Metrocable primarily connects with other major forms of public transport systems of Caracas and provides transportation within the San Agustin area of Caracas.

All the above examples manifest an environmentally significant and socially inclusive efficient form of urban soft mobility driven by the Cable car or gondola technology. Such a gondola system has proven to have provided safe and crime free transportation which becomes an important factor in tourist's use of such soft mobility systems.

The Ngong Ping 360 cable car in Hong Kong and the Singapore Gondola are on the other hand, urban projects that have been purpose-built for tourist mobility. These cable car projects have been able to divert tourist movement away from the vehicular traffic-prone areas of the city. Moreover, these projects have reduced the dependence of road transportation that involves automobiles run by fossil fuels especially in the case of Lantau Island, Hong Kong.

The Case of Electric Automobiles and Bio-Fuel-Driven Urban Buses

Another variety of smart mobility technologies are electric/hybrid vehicles exemplified in the form of electric cars and bio-fuel driven vehicles. These vehicles run on fuel from renewable sources like bio-fuels and electricity.

One of the recent and best examples of bio-fuel driven is the Bio-bus experimentations in the UK. Bio-bean, a London-based enterprise, has taken the initiative to run a project of Bio-buses driven by the bio-fuel made out by combining oil extracted from old coffee grounds and diesel (Hirtenstein, 2017). Utilizing old coffee grounds from major coffee shops across the UK, it is claimed that 6000 litres (1583 gallons) of bio-fuel or B20 bio-fuel can be produced to run a sizable fleet of buses for public transport in London city (Hirtenstein, 2017). Though bio-fuel is already used to run 9500 buses, the 'coffee-powered' bio-bus is an innovative soft mobility technology to be used for the first time in the city (BBC, 2017).

(*continued*)

(continued)

Another bio-fuel-driven bus project also from the UK is the Bio-Bus project also known as GENeco Bio-Bus. The Bio-Bus is a project powered by bio-fuel in the form of gas formed out of human wastes of food, sewage and commercial liquid wastes (Geneco, 2016). Though two Bio-Buses were operating in 2015, the Office for Low Emission Vehicles turned down the bid for funding and operating this project in 2016 (BBC, 2017). However, officials at GENeco—the enterprise which ran this project—believe the concept that emerged from this project can inspire other similar projects that can become successful since bio-methane gas powered buses have been found to reduce significant amount of air pollution in urban areas around the world (BBC, 2017).

Electric cars are now becoming popular in many countries around the world and in the United States, sales of electric cars rose to 37% in 2016 compared to the previous years and a 70% year-to-year increase in monthly sales (Rapier, 2017). This has made Hotel chains like the Marriot, Starwood and the Hilton to open Electric Vehicle (EV) charging stations in collaboration with Tesla (the largest electric automobile maker) and GE in many of their properties. This move by hotels to welcome electricity powered low emission vehicles also serves their strategic purpose of alluring high-end guests (Hanley, 2015). Such high-end guests who can afford the most expensive services offered by hotels also happen to have the ability to afford electric cars. Apart from hotels, car rental services are starting to offer electric car rentals in some parts of the world. The case of Enterprise Rent-A-Car electric car rental services in Orlando city exemplifies the use of electric cars in the travel industry. The electric car rental service named as Drive Electric Orlando (DEO) programme started in 2013 as a result of collaboration between Enterprise and Electrification Coalition and has grown considerably through the strength of tie-ups with hotels, theme parks and tourism promotional organizations like Visit Orlando (Padilla, 2017). The DEO programme offers opportunities to tourists for test drives of the latest versions of the electric car model—Chevy Volt, a hybrid electric car brand of Chevrolet (Hanley, 2015). Through such an opportunity, tourists are in turn provided the experience of new low emission vehicle technologies through car rental services and motivated to be owners of electric powered low emission vehicles in the near future (Padilla, 2017). The DEO programme is facilitated by 300 EV charging stations in different tourist centres of Orlando city and 40 partner hotels that provide free parking and valet services to the tourists who are clients of the program.

Green Energy Technologies

Green energy technologies are exemplified by the existence of energy conservation and cost-saving technologies primarily in the context of urban hotels. The casino destination of Las Vegas has demonstrated how major casino and convention facilities can be majorly dependent on renewable energy sources instead of conventional energy sources.

The hotel industry has also improvised its process of energy saving by installing digitally powered rooms and energy management systems that control and minimize energy consumption in guest rooms. Though this technology is not specific to urban hotels, its applicability has been possible more in such hotels. However, one of the best developments of green energy technology in the context of urban tourism has been in the case of Gardens by the Bay in Singapore.

Gardens by the Bay, Singapore

Gardens by the Bay opened in 2012 demonstrates a model of an iconic green urban attraction that involves the harnessing of a range of different renewable energy technologies like solar energy, biomass technologies and technologies providing the basis of sustainable design (Rowell, 2017). The most striking technological element of this attraction is the manmade supertrees. These supertrees ranging between 25–50 metres in height are built with a combination of green technology features—solar energy harvesting photovoltaic cells on the canopies as well as water harvesting inbuilt tanks that enable cooling of domes in the attraction containing 90,000 plants (Rowell, 2017). The supertrees themselves support 160,000 plants and the energy produced by the photovoltaic cells on their canopies are used for spectacular light, colour and sound displays from the attraction during nighttime (Rowell, 2017). The two domes or glass biomes in the attraction—the Flower dome and the Cloud Forest—are equipped also with sustainable features like green designing which allow sunlight to provide nourishment to the plants inside as well as rainwater capturing features that allow irrigation of the different flora species that they contain. The Gardens by the Bay attracts 25 million tourists every year from all over the world since it was opened in 2012 (Algie, 2014).

Gaming and entertainment companies in Las Vegas have moved away from conventional-energy-producing agencies like NV Energy. MGM Resorts International, one of the largest gaming and entertainment companies in Las Vegas exited from NV Energy paying an exit fee of $87 million (Hernandez, 2016). It is now considering a full-fledged transformation into a renewable energy agency in terms of fulfilling its energy needs by harnessing its phenomenal rooftop solar project as well as tie-ups with energy companies investing in solar energy as well as with solar photovoltaic developers and solar plants projects outside its premises (Hernandez, 2016). MGM developed rooftop solar projects in one of its principal Las Vegas projects—Mandalay Bay—which now has 26,000 solar panels spread across 28 acres and producing over 14 megawatts of energy. Other Las Vegas resorts like the Wynn Resorts and Las Vegas Sands are planning to buy more solar energy from the open market produced in surplus volumes in the solar farms in nearby places as well as produce renewable energy particularly solar energy themselves.

Conclusion

As the drive towards the enhancement of sustainable and smarter urban tourism grows (UNWTO, 2017), the connection between technology and sustainability will get further strengthened. On one hand, as the world moves towards the era of Industry 4.0, (technologically) smarter cities will receive more impetus entailing the growth of smart tourism destinations—driven by digital technologies, widespread availability of internet technology and smarter digital devices. On the other hand, as the climate crisis becomes increasingly significant, cities will have a larger role to play in the deployment of green tech and clean energy which will, in turn, become embedded in the functioning of major urban industries like tourism. Moreover, smart mobility options are being increasingly adopted by global cities in the world which focuses on offering efficient mass transit systems and clean energy/low emission automobile and inter-modal transport options to both tourists and local residents (Arcadis, 2017).

A summary diagram highlighting the interlinkages discussed in this chapter is presented in Fig. 16.1.

The World Economic Forum (WEF) considers innovation in technology to be the key for growth in the times to come principally in the areas of digitalization, smart systems (encompassing intelligent systems in clean energy, soft mobility and man-machine interfaces), artificial

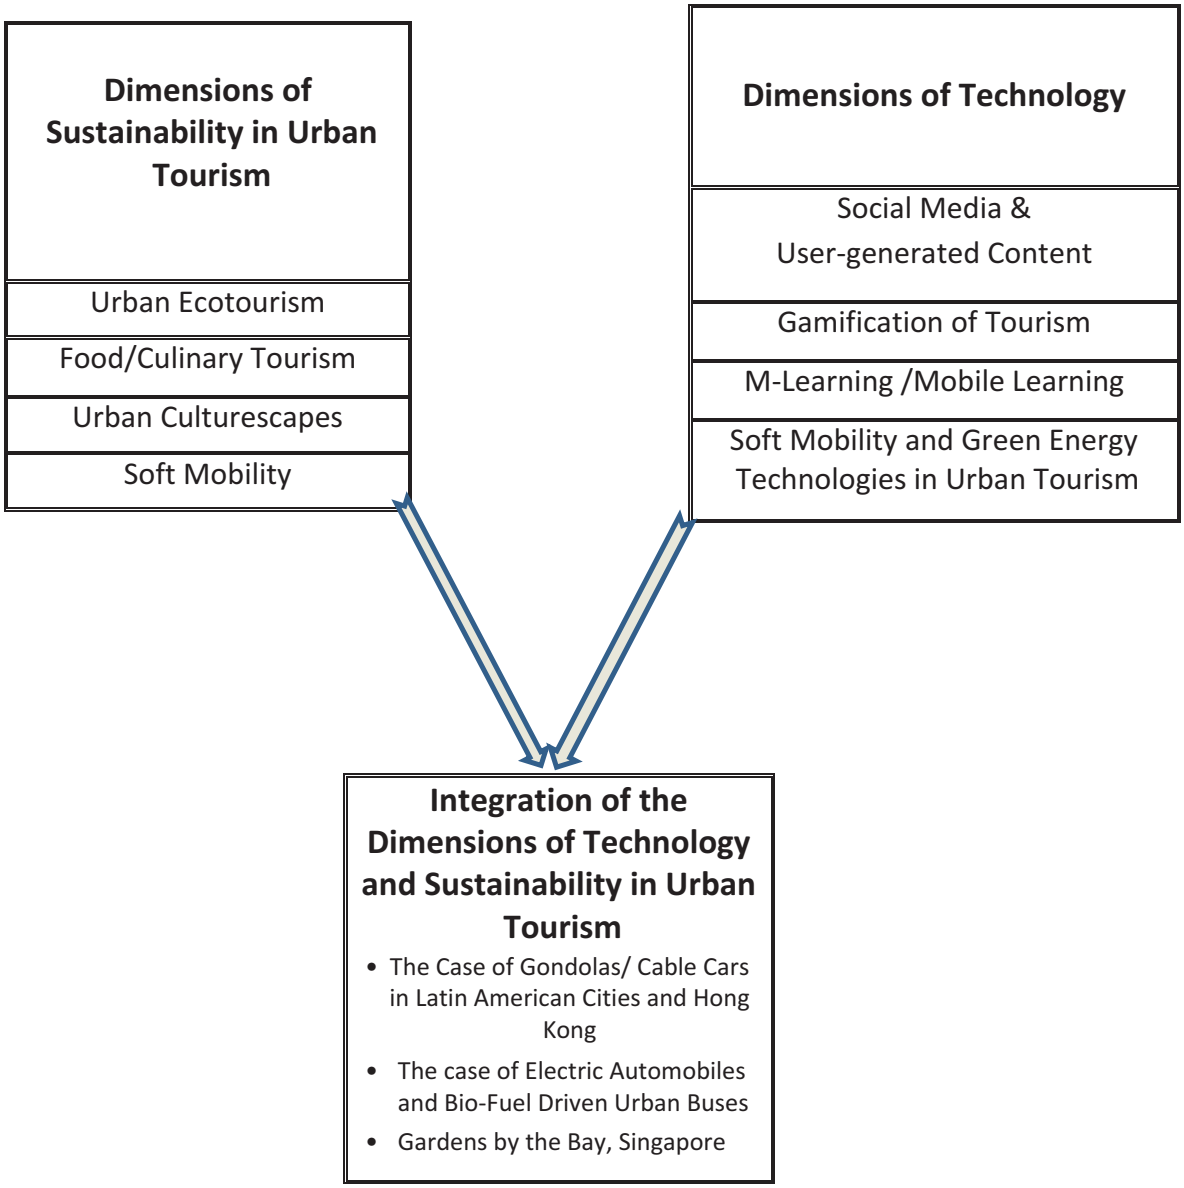

Fig. 16.1 Interlinkages between sustainability and technology in the urban tourism setting

intelligence and sustainable technologies (World Economic Forum, 2017). The UNWTO's call for a sustainable tourism for development in 2017 in the context encompasses social and economic inclusivity, cultural diversity, cultural mutualism and clean energy-driven environmental practice and (UNWTO, 2017). Therefore, the connection and integration of sustainability and technology in urban tourism contexts need to entail the social and cultural dimensions of both as their fundamental basis in addition to their environmental and innovational aspects.

The integration of sustainable forms of tourism and social and environmental dimensions of technology in urban contexts must yield benefits for all sections of visitors as well as all sections of the local resident population in urban destinations of the world.

One of the fundamental considerations for urban destination management organizations should be to put the sustainability-technology integration as the main underlying element in their destination marketing and branding process. Future studies focusing on the sustainability-technology integration may focus on the context of specific destinations—their scope in terms of sustainable forms of urban tourism attractions available as well as the available forms of digital and clean energy technology and their extent of use in such contexts.

Do Women on Boards affect Firm's Financial Performance? Evidence from Indian IPO Firms

Abstract
The objective of this paper is to study whether the presence of women on boards affects the financial performance of firms. This study builds upon other studies that have earlier tried to determine the impact of number of women directors in Indian corporates on their financial performances, in terms of market performance index, i.e. Tobin's Q. The new Companies Act, 2013 has mandated the appointment of at least one woman director in certain classes of listed companies in India as described in Section 149(1)(b), which could possibly bring about a change in the governance and thus the financial performance of firms. The focus of this study is on finding and analysing the impact of compliance with this provision on the financial performance of IPO firms. In order to test our hypotheses, we selected 41 Indian Companies that have made an Initial Public Offer (IPO) in the recent past and have been listed on Bombay Stock Exchange during the period 2012-2016. The performance of each of these firms has been measured in terms of Tobin's Q for 3 successive years after their listing (IPO) as well as by using two gender diversity index values- Blau Index and Shannon index. The study concluded that the proportion of women on board is insignificant and that it could not impact the financial performance of the firms. Neither has it caused any adverse impact on the performance of these firms.

1. INTRODUCTION

The subject of women on boards is a new and developing area of research. Many researchers have been carrying out studies to find out the impact of gender diversity on the performance of companies. This area of research has gained widespread interest after the institution of legal norms regarding the appointment of women directors on board in firms across the globe, beginning with the European corporate sector. It was in 2013, when the Companies Act came into force after revamping the old Companies Act of 1956, that the representation of women on board was paid heed to in India. It mandated the appointment of at least one woman director on boards of all the Indian listed companies and those public companies in India having a paid up capital of hundred crores or more and a turnover of three hundred crores or more in any year.

The reason for introducing this legal requirement was the low average numbers of women on the boards of Indian corporations, which is quite contrary to the principles of equality that the Indian constitution emphasizes. With the reservation of board seats for women in the European counterparts, the Ministry of Corporate Affairs, realizing the need of the hour and the importance of Indian women with respect to their leadership and managerial expertise, reserved a mandatory position for women on boards in the corporate sector.

The Gender Diversity Index reveals that in the year 2017, there has been a substantial rise in the number of board seats occupied by women in Fortune 1000 companies. It has been observed that out of 801 active Fortune 1000 companies, 55% of the companies have achieved the status of 'W' Companies, with more than 20% of their board seats held by women. The 'Z' companies, that is, those with no women directors, fell to an all time low of 7% in 2017. However, a high incidence of tokenism is observed in the Indian scenario with just one seat reserved for women on boards as against 40% reservation in Norway and Germany. If we consider the representation of women in the new firms coming up with their IPO, women hold just 9.2% of the board seats in the largest 25 IPO companies in 2017, which has increased from 8.2% of board seats in 2016.

This paper looks into the impact that women on boards could have, on the financial performance of the firms. In this respect, we have chosen 41 BSE listed Indian companies that have made Initial Public Offers (IPOs) during the period 2012-2016. We calculated the proportion of female directors in these firms to analyse the impact of gender diversity on board on the firm performance, calculated in terms of Tobin's Q, which is a proxy indicator for market performance for the 3 successive years immediately after their IPOs.

Many researchers have investigated the impact that the presence of women creates on corporate returns. Previous research has actually produced mixed results, given that the link between gender diversity and financial performance in a firm is both theoretically and empirically complex. However, most existing studies have used data from western countries rather than the developing nations. The management and leadership styles develop in synchronisation with the culture, which has a long lasting influence on the firm's financial health. This paper uses evidence from India, a developing country with a male dominated culture, like most of the Asian countries.

Our investigations focus on finding out how the presence of women directors on board would change the financial health after the institutionalisation of the women reservation norms by Companies Act 2013 under Section 149(1)(b) and Securities Exchange Board of India in Revised Clause 49 of the listing agreements. We have used updated data of the firms that

have stepped into the capital market by making new issue of shares, after the provisions of Companies Act 2013 came into effect.

The paper has been divided into five sections. Section 1 and Section 2 pertains to the introduction and literature review respectively. Section 3 deals with research gap, objectives and hypotheses. Research design is covered under Section 4 wherein the methods adopted, variables chosen and sources of data have been explained. Section 5 highlights the results and analysis. We conclude our paper with Section 6, highlighting the areas and Scope for future research and limitations of the study.

2. LITERATURE REVIEW

The corporate governance mechanism is something that has been a focus of attention in many countries in recent times. Corporate governance norms play a large role in building up the financial performance of any business concern. Lately, board gender diversity has been one of the most talked about aspect of corporate governance. It has been observed that the gender composition of the board may influence the performance of the company. It is time that productive resolutions are taken at the government and company levels for board level gender equilibrium.

2.1 Performance of IPOs

Singh and Maurya (2018) in their Indian study have shown that IPOs on National Stock Exchange (NSE) posted a very small gain of 4.63%, in short run, calculated on one month basis. About 64.21% of IPOs introduced on NSE were found to be under-priced and the rest were concluded to be overpriced. Also, except 1 firm, the issue price and the listing price was also found to be the same. Jain and Kini (1994), while investigating post IPO performance, noticed that they incurred a significant level of decline in post IPO performance, causing equity retention. It can also be said that the markets usually overreact to the news of an IPO and then slowly stabilises to normal. Coakley et al. (2007) also highlighted huge underperformance of the initial public offerings in the bubble years 1998-2000, while later the IPO performances have been more or less normal. Murthy and Singh (2016) show that for IPOs listed from the year 2000 to 2003, the long run variables have no relationship with short-run variables. Moreover, in the context of Indian new issues market, Singh and Maurya (2018) in their study concluded that it is the presence of independent directors, rather than non-executive directors, that provides for relevant information with respect to the post IPO returns.

Krishnan et al. (2011) noted a positive relationship between the image and goodwill of VC-backed IPOs and their long run performance. As per them, reputable venture capitalists are more actively involved in the governance of firms, post IPO, and thus are likely to influence long run performance positively in post IPO period. It has been found that market overreacts to the initial public offers, as is proved by the findings that majority of the IPOs have significant returns on the day of listing, but beyond that they do not give much return (Murthy & Singh, 2014).

2.2 Women and Board Diversity

Diversity refers to a variety of different characteristics put together in a common place. When it comes to board of directors, diversity can be in terms of ethnicity, gender, age, or the like. In a male dominated country like India, not much has been said about women representation

on the board of directors or top management positions in a company, until the onset of Companies Act 2013. Das and Dey (2016) have mentioned in their study that the number of women present on the board is indicative of firm's ethical behaviour and a balance on the board. Indian companies should learn how to build competitive advantage by putting up women on their board, thereby ensuring good reputation amongst the stakeholders (Kaur & Singh, 2017) which will ultimately lead to better financial health of the firms. Studies prove that women empowerment is likely to be advantageous for the corporations owing to the synergies brought in by gender diversity (Paul, 2017). Sanan (2016) reveals in her study that the number of companies with no independent women directors has reduced over time, which is good news as far as efficient corporate governance is concerned. But whether or not it is likely to improve corporate performance is a question that still needs to be answered.

2.3 Gender Diversity on Board and Positive Firm Performance

Taking into consideration the all-round benefits of gender diversity on boards, many researchers have come up with the idea that women on board have a positive impact on financial performance. Luckerath and Rovers (2013) believe that the presence of women on board will boost firm performance. Companies with women directors tend to be more ethical when it comes to dealing with their stakeholders, thus ensuring high firm value and better performance. Carter et al. (2003) also found a positive and direct relationship between firm value and fraction of women on board. In the Indian scenario, women have always faced challenges with respect to their position and appointment in the business organisations, primarily because of the glass ceiling that confronts them. Realising the importance, managerial and leadership abilities of women, there has been institutionalisation of norms across the globe with regards to appointment of women on board. These norms have forced the appointment of women on boards, and firms have given better results after such appointments. Adams and Ferreira (2008) have stated that gender diversity in top management is likely to bring a forward push in the financial health of the firms with weaker shareholder rights.

In a global study undertaken by Terjesen et al. (2016), it was found that firms having a higher proportion of female directors on board are going to have better Tobin's Q and return on assets as compared to those which have none. Another investigation that was conducted with respect to Indian context, in light of the mandated representation of women on board, also showed positive results on firm performance (Sanan, 2016). Studies have been conducted across various sectors and industries in India to find out the implications of one woman on board norm. Das and Dey (2016), while investigating large Indian corporations for the role of corporate governance in firm performance, have come across positive impact of board diversity on financial performance. However, the performance of the corporates may respond differently to board diversity in different sectors and different methodology used for analysis.

2.4 The Negative Implications of Gender Diversity on Board

While going through the available literature, we have come across some instances where gender diversity on board has worsened off the financials than before. In their study of FTSE 100 companies, Ryan and Haslam (2005) found that during periods of declining stock markets, companies who appointed women directors experienced worse performance than those with male directors. This trend has been experienced globally. McGuinness (2017), as per investigations conducted in Hong Kong, also envisages the idea of gender bias imposing a cost on stakeholders and thus affecting performance negatively. A similar study conducted in Norway by Ahern and Dittmar (2012), suggests that in companies with quota reserved for women on board, there is a decline in Tobin's Q over a period of time. Where on the one

hand, many authors have supported the idea of appointment of women on board, claiming that diversity would help in better decision making and problem solving, it has also been observed that diversity brings with it more chances of conflicts and makes decision making time consuming (Gallego et al., 2010). Wellalage and Locke (2013), in a study conducted in Sri Lankan context, have found that board heterogeneity has a negative impact due to increased chances of conflicts. In a country like India, where there are many family businesses running and operating since years, the mandate of appointing women directors has been complied with by putting the female relatives or family members on the boards.

A lot has been said about the positive and negative implications of the presence of women on board on corporate financial performance. A few authors have envisaged a direct relation between the two variables stating that gender diversity leads to more opinions and better decision making owing to different attributes of men and women. Better decision making leads to problem solving and thus, better performance. There are studies which show that the relationship between the two variables is negative, owing to more chances of conflicts and delays in working.

2.5 Women on Board and No Impact on performance

Noland et al. (2016), in a global study of 21,980 firms, found no impact of the gender quota on board on a firm's financial performance. Many studies have also been carried out in developing countries with the same results. A study conducted by Yasser (2012) in Pakistan showed no impact of gender diversity of board on the financials of the companies listed on the Karachi Stock Exchange. Gallego et al. (2010), while carrying out research in the context of Spain, have also concluded that high level of gender diversity may or may not influence performance.

However, the existing literature has raised questions on the new provision of Companies Act by calling it a mere tokenism, with just one independent woman director present on boards not making a significant difference. The number of companies with 2 or more women directors is substantially less (Sanan, 2016). In order to achieve better performance, Joshi (2017) concluded that there is a need for Indian companies to exploit the opportunity to build a strong talent pool of diverse directors.

3. RESEARCH GAP

The existing literature brings to light various instances where the presence of women brought positive results, negative results and there were instances with no impact on performance at all. The investigations conducted do not give a uniform result to throw light on the effect of gender diversity of board on the firm performance. Moreover, it is imperative to seek answer to this pertinent question whether the addition of a mandatory provision has led to any improvement or change in the performance or not. Firms coming out with an IPO in India are required to disclose their managerial board in their prospectus issued to the shareholders. Hence, it would be both essential as well as interesting to see whether having a diverse board will send a positive signal to investors so that the firms can take better informed decisions owing to access to diverse viewpoints. The impact of such perceptions would certainly be easy to measure in terms of the short term performance. In our study, we have examined 41 publicly listed IPO firms for their compliance with provision for appointment of women on board and how that impacts their performance. We seek to find answer to the question whether presence of women on board is just in letter or in spirit too, which will help firms take future decisions effectively.

4. OBJECTIVES

- To analyse the impact of the presence of women directors on boards on the short term performance of firms.
- To analyse the impact of gender diversity of boards on the short term financial performance of firms.
- To anlayse the impact of return on assets and leverage on the financial health of the firms.

5. HYPOTHESES

H_{o1}: The percentage of women on board has no effect on the short term firm performance.
H_{a1}: The percentage of women on board affects the short term firm performance.
H_{o2}: The size of a firm has no effect on the short term firm performance.
H_{a2}: The size of a firm affects the short term firm performance.
H_{o3}: Leverage in a firm has no effect on the short term firm performance.
H_{a3}: Leverage in a firm affects the short term firm performance.
H_{o4}: Return on assets of a firm has no effect on the short term firm performance.
H_{a4}: Return on assets of a firm affects the short term firm performance.

6. RESEARCH DESIGN

6.1 Sample size and Data sources

The data includes a secondary sample of 41 IPO firms listed on Bombay Stock Exchange, selected on the basis of purposive sampling technique, to investigate the impact of having women directors on the board of the firms and how they affect the performance of these firms. All the selected firms have made an initial public offer (IPO) during the period 2012-2016. Their performance for 3 financial years has been taken into consideration after the IPO listing.

The above sample has been chosen since the bill relating to the mandatory provision for the appointment of one woman on board was already in place and firms had started complying with the same to protect themselves from any unnecessary penal action. Hence, the purpose of selecting such new IPO companies is that when a firm goes public, there are various factors which are taken into consideration while making initial investments and one such element is the ability of the board to take well informed decisions.

We believe that IPO firms are the best form of sample to be chosen, as they would adequately reflect the impact of such diversity on board and its implications on financial performance. Hence, we tried to analyse how the appointment of at least one woman director as per the Companies Act 2013 affects the financial performance of firms after their listings (Welbourne, 1999). Their presence is likely to give a lot of signals to the prospective investors with regards to the functioning as well as other aspects of the firms.

The data about the IPO firms i.e. issue price, opening and closing date as well as other information related to the IPOs has been retrieved from the Chittorgarh website. The corporate governance variables have been taken from the corporate governance reports of these firms and the financial variables have been retrieved from the prowess database and cross checked with the annual reports of these companies.

6.2 Variables

Dependent Variable

Financial Performance is the major element that incentivises the investors to make investments into a firm in the expectations of gaining good returns, and it is on this basis that the performance of the board of directors is also evaluated. We measured financial performance by using a market based measure rather than the accounting based measure, since the accounting based measures are based on the past results and might not reflect the changes in the governance norms immediately (Haldar et al., 2015).

Tobin's Q

Tobin's Q is considered as one of the best market based measures due to multiple reasons: Firstly, it takes into account the risk factor, unlike other accounting measures, and is not subject to distortions. Secondly, it reflects the market's expectations of future earnings and is, thus, a good proxy for a firm's competitive advantage (Montgomery & Wernerfelt, 1988). Hence, Tobin's Q was used as a proxy for measuring the performance, based on the work of Ahern and Dittmar (2012), Haldar et al. (2015), and Campbell et al. (2008) for various years. Tobin's Q is calculated using the Chung and Pruitt (1994) formula, which is, market valuation of shares plus debt divided by the total assets. A unity value for the Tobin's Q ratio acts as a significant benchmark for the measurement of firm performance. All the firms having a value greater than 1 are construed to give better returns to the investors as compared to the firms having value less than 1. It is also a sine quo nun for efficient utilization of resources.

Independent Variables

Table I provides a brief description of the independent variables used in the study.

Table I: Independent variables

S.No	Independent Variable	Definition	Symbols
1	P-Women	Percentage of women directors on board with respect to the total directors.	P-Women
2	Blau Index	A measure of gender diversity.	SHANNON
3	Shannon Index	A measure of gender diversity.	BLAU
4	Return on Asset	Percentage of profits earned against the total assets employed by a firm.	ROA
5	Leverage	Computed as the ratio of total long term debt to the total assets.	LEVER
6	Firm Size	Measured in terms of the natural log of the total assets.	F-SIZE

Percentage of women on board (P-woman)

P-woman represents percentage of women on board with respect to the total number of directors. This variable is a proxy for measuring gender diversity at the board level. Many studies in the past have confirmed the benefits of having a diverse board, in terms of a positive relationship between women on board and organizational innovation, better decision making, different perspectives etc. (Torchia et al., 2018). Diversity on board provides various opportunities in terms of strategic alliances that firms can build, based on its relationships with other groups (Halder et al., 2015). Hence, P-woman has been used based on several

studies by Campbell and Mínguez-Vera (2008), Giraldez and Berenguer (2018), Welbourne(1999), and Halder et al. (2018).

Blau Index

The Blau Index, that has been used as a proxy for women directors on boards, is a Gibbs-Martin index of sociology, psychology and management studies which is calculated using the formula $1-\sum_{i=1}^{n} p_i^2$ where p denotes the proportion of board directors in each male and female category and n symbolises the total number of directors on board. The variable has been used to enhance the robustness of the study with respect to women on board (Campbell & Mínguez-Vera, 2008).

Shannon Index

The Shannon Index, a reputed diversity index found in the literature, aims to state in quantitative terms, the uncertainty in predicting the species identity of any person chosen randomly from a given set of data. It is calculated using the formula: $-\sum_{i=1}^{n} p_i \ln(p_i)$. This variable has also been chosen to enhance the robustness of the study in terms of gender diversity on board (Campbell & Mínguez-Vera, 2008). Here, p denotes the proportion of board directors in each male and female category and n symbolises the total number of directors on board, similar to the Blau index.

In our study, women directors on boards of companies has been selected as an independent variable, and amongst the independent variables, we have applied Blau Index and Shannon Index, which shall take into account the number of categories in terms of gender as well as the evenness in terms of the distribution of board members amongst them. These attributes can also be said to be the measure of 'variety' and 'balance' (Stirling, 1998).

Control Variables

Return on Assets (ROA)

Return on assets has been used as one of the control variables in our study, and has been measured as a percentage of profits earned against the total assets employed in a firm. Return on assets is one of the operational-based measures of financial performance and, thus, is likely to affect the market based performance of a firm (Alghifari et al., 2013; Campbell & Mínguez-Vera, 2008).

Leverage (LEVER)

The leverage of a firm is computed as the ratio of total long term debt to the total assets, indicating what percentage of total assets of a firm is financed by debt. Leverage of the firms affects the ability of the managers to take decisions, since the creditors would interfere in the working of the firm based on their own interests. (Chen & Jaggi, 2000; Hutchinson & Gul, 2004).

Firm Size

Firm size has been measured with respect to the natural log of the total assets. It has been observed in the literature that the success of women on board differs based on the size of the firm, and women achieve great success in smaller firms. This was later contradicted by Sealy et al. (2008). It is also imperative to take firm size into consideration because the firm financial performance is likely to be affected by the size of the firm, as large firms have larger abilities to influence performance (Short & Keasy, 1999). Hence, based on several

studies (Haldar et al., 2015; Campbell & Mínguez-Vera, 2008; Yasser et al., 2017), it was included as a control variable.

6.3 Empirical Model Specifications

We have used a balanced panel data in our study that provides various advantages as compared to the time series data or the cross section data. Firstly, panel data offers more flexibility in forecasting the behaviour of the cross sectional units as compared to the time series data analysis (Greene, 2008). Secondly, a panel framework allows for analysis of a larger number of observations as compared to the individual time series for comparison purposes.

Panel data is a methodology that is often used to eliminate any unobservable heterogeneity that might be present in the sample for the study. However, if any unobservable heterogeneity is found to be correlated with the explanatory variables, we undertake a conditional inference (that is, estimation by fixed effects). However, if the effects are not correlated with the independent variables, we instead carry out unconditional inference using the random effects method. We have used the Hausman test (Hausman & Taylor, 1981) to check the presence of any correlation between unobservable heterogeneity and the explanatory variables (Ahern & Dittmar, 2012). We found that the unobservable effect was not correlated with the explanatory variables; hence random effect model was used in running the OLS regression.

Three different ordinary least squares (OLS) regression analyses were run using the dependent variable as Tobin's Q and all the control variables, by changing the independent variables in each model as P-woman, Blau Index and Shannon index. Since we have used three proxy variables, i.e. P-woman, Blau Index and Shannon Index, three OLS regression models were developed and the results were obtained for each of them.

The economic model used is specified below-

Model 1: $Qit = \beta 0 + \Sigma \beta 1 \text{P-WOMAN}it + \Sigma \beta 2\ \text{LEVER}it + \Sigma \beta 3\ \text{ROA}it + \Sigma \beta 4\ \text{F-Size}it + \varepsilon it$

In Model 2, we replace P-woman with Blau Index which is another proxy variable for gender diversity on board.

Model 2: $Qit = \beta 0 + \Sigma \beta 1 \text{BLAU}it + \Sigma \beta 2\ \text{LEVER}it + \Sigma \beta 3\ \text{ROA}it + \Sigma \beta 4\ \text{F-Size}it + \varepsilon it$

Additionally, in Model 3, we replace Blau with another proxy variable i.e. Shanon Index.

Model 3: $Qit = \beta 0 + \Sigma \beta 1 \text{SHANNON}it + \Sigma \beta 2\ \text{LEVER}it + \Sigma \beta 3\ \text{ROA}it + \Sigma \beta 4\ \text{F-SIZE}it + \varepsilon it$

Where,
Qit = Tobins' Q, our proxy for financial performance of firm i in period t.
P-WOMANit = Percentage of women on board of firm i in period t.
BLAUit = Blau Index, which is a proxy for gender diversity, of firm i in period t.
SHANNONit= Shannon Index, which is a proxy for gender diversity, of firm i in period t.
ROA= Return on Assets of firm i in period t.
F-SIZE = Firm Size of firm i in period t.
LEVER= Leverage of firm i in period t.
Eit = random disturbance term

7. RESULTS & ANALYSIS

Table II: Descriptive Statistics for all the variables.

	Mean	Median	Maximum	Minimum	Standard Deviation
BLAU	0.267942	0.244898	0.46875	0.142012	0.081204
P-Women	0.166263	0.142857	0.375	0.076923	0.068923
LEVER	0.340035	0.115122	5.78	-1.3	0.985695
SHANNON	0.434102	0.410116	0.661563	0.271189	0.097206
F-SIZE	6440.087	929.42	194679.5	18.84	27437.67
ROA	2.680766	5.88	79.1	-578.23	54.08431
TOBINS-Q	3.388572	2.336391	17.37609	-0.14	3.158144

Source:Authors' own calculations

The above table provides descriptive statistics for the independent, dependent and control variables used, in the form of mean, median, standard deviation, maxima, minima etc. by using 123 observations. If we look at the mean of Blau index and Shannon index, it is approximately 0.26 and 0.43 respectively, whereas average Tobin's Q is 3.38 (approximately). This depicts that the diversity is too less to have any impact on financial performance. The average percentage of women on board is 16.62% only, amongst 123 observations. The average assets are Rs.6440.86 crores which suggests good financial health of the firms. The lower leverage ratios are considered to be good as it suggests that less assets are financed by debt. The above table also depicts a very low mean leverage of 0.34. These statistics support the results of our regression tests as shown below.

Table III: Hausman Test to check whether Random effect or Fixed effect Model shall be used.

Test Summary	Chi-Sq. Statistic	Chi-Sq. d.f.	p-value
Cross-section random	5.670113	5	0.3397

Source :Authors' own calcuations

We performed the Hausman test, which helps to differentiate between the fixed effects model and random effects model in the panel data, with random effects model being adopted on the non-rejection of the null hypothesis. From the test, we find the p-value to be equal to 0.3397 i.e. it is insignificant at 5% (Table III), which means that we do not reject the null hypothesis and therefore, choose the Random Effects Model to run our regression tests.

Table IV: Random Effects Model using the variable P-Woman and other control variables.

Variable	t-Statistic	p-value
C	1.275903	0.2053
P-WOMAN	0.089598	0.9288
F-SIZE	-0.669224	0.5051
LEVER	3.594660*	0.0005*
ROA	6.392905*	0.0000*

Source: Authors' own calculations (*at 5% significance level.)

The first multiple regression is run using P-WOMEN as an independent variable (Table IV) and three control variables, i.e., total assets, leverage and return on assets. On applying the test, we find that the p-value for P-WOMEN variable is 0.9288 which is statistically insignificant and therefore we do not reject the null hypothesis. This means that the proportion of women directors does not have any impact on Tobin's Q ratio. The p-value of total assets (0.5051) is also insignificant which means that the value of total assets of a firm will not impact its financial performance or Tobin's Q ratio. The p-value for leverage is 0.0005 which is significant, thus we reject the null hypothesis and conclude that the leverage ratio would impact Tobin's Q. A rise in leverage will help to increase the earnings per share for the shareholders, which would send a positive signal to the market about the financial status of the firm and thus affect the stock price and Tobin's Q. The variable ROA is also significant, and we conclude that ROA positively affects Tobin's Q. The rise in ROA would bring a rise in Tobin's Q and thus improve firm performance.

Table V: Random Effects Model using the variable Blau Index and other control variables

Variable	t-Statistic	P-Value
C	0.897421	0.3719
BLAU	0.213332	0.8316
LEVER	3.591204*	0.0005*
F-SIZE	-0.684969	0.4952
ROA	6.419894*	0.0000*

Source: Authors' own calculations (*at 5% significance level.)

The second regression model uses Blau index as an independent variable instead of P-WOMEN, rest all variables remaining the same. Table V shows the results. The p-value of Blau index is 0.8316 which indicates that it is insignificant at 5%. Thus, Blau index value, that depicts diversity, does not influence the Tobin's Q ratio. We also interpret the p-value (0.4952) of total assets in the second model to be statistically insignificant and hence do not reject the null hypothesis. Total assets do not impact the financial performance of firms in our sample. The p-value of leverage is 0.0005 which is statistically significant, thus leverage will impact the financial performance. Also, since ROA is significant, it positively impacts the Tobin's Q.

Table VI: Random Effects Model using the variable Shannon Index and other control variables

Variable	t-Statistic	P-Value
C	0.897421	0.3719
BLAU	0.213332	0.8316
LEVER	3.591204*	0.0005*
F-SIZE	-0.684969	0.4952
ROA	6.419894*	0.0000*

Source: Authors' own calculations (*at 5% significance level.)

The third regression model applied using the Shannon index (Table VI) gives us the same results as the previous one. The p-value of Shannon Index (0.8043) is insignificant; hence we cannot reject the null hypothesis. Therefore, Shannon index value depicting diversity does not have any impact on financial performance. The p-value of total assets is 0.4910, which is insignificant, thus we cannot reject null hypothesis and total assets have no effect on the Tobin's Q ratio. However, Leverage and ROA will positively impact the financial performance, as their p- values, 0.0005 and 0. 00 respectively, are statistically significant.

8. CONCLUSION

The study has made contributions to the extant literature and has supported the arguments that diversity on board will not impact the financial performance of the firm. The presence of women on boards does not influence Tobin's Q and hence the performance. The important aspect to be noted here is that most of the firms in our sample have appointed just one female director on their boards, where they could have appointed even more. Hence, we can say that the firms have appointed the women directors only to comply with the mandatory provisions of Companies Act 2013, which shows that this is practised in letter and not in spirit. The existence of women on boards is mere tokenism, as the appointment of a single woman director will not bring much change in a firm's overall decision making.

Examining the causes for no improvement in the performance of the firms, we could relate back to some of the major arguments, like poor women representation. A closed culture at board level, dominated by male directors, might have led to the negation of the diversity advantages. Also, male directors are likely to favour male directors over women due to the in-group favouritism (Hutchinson et al., 2015). Moreover, an essential theory in this regard from the psychological perspective, the similarity attraction theory, advocates the fact that directors feel more comfortable and trustworthy interacting with directors from same demographics (Chatman & O' Reilly, 2004). Another set of arguments in this regard is that there lies an empathetic concern towards facilitating advancement of those belonging to same class (Macdonald & Westphal, 2013). Finally, the argument based on the critical mass theory points out that the critical mass of women positively impacts board strategic tasks, but since in our sample firms, critical mass could not be achieved, there was little scope for improvement in the firm performance (Torchia et al., 2011).

The Firm size measured in terms of the total assets also shows no impact on financial performance. This is contrary to our expectations, as other studies have concluded that size of the firm has a positive effect on performance (Halder et al., 2018; Buallay, 2017; Torchia et al., 2011). This could be because of the short time period of 3 years that is studied. It is possible that in the long run, we are able to see the impact of firm size on firm performance. Also, a low debt to asset ratio and ROA is found to positively improve performance, consistent with Campbell and Mínguez-Vera (2008). This may be because of the operation of

signalling theory which says that favourable financial ratios send a positive signal to the investors. Higher leverage ratio is seen to positively affect the firm performance and is consistent with Yasser et al. (2017). The ROA also sends a positive signal to the general investors about good financial health of the company, as it may result in higher returns to the shareholders.

9. LIMITATIONS & FUTURE SCOPE

There are a few limitations to our study which open opportunities for future research. In our study, data for just three financial years were considered. Data for larger years would make the results much more robust.

The paper has just focussed on the short term performance; long term performance can also be tested after using data of five or more years in future. Also, only IPO firms were considered for the study. Other industries such as banking and financial companies could also be taken up for future studies.

Moreover, we have considered only the gender aspect of board diversity. Other variables such as education levels, experience of the women directors, directors coming from family firms, are also some crucial areas of research that could be considered in the future.

10. MANAGERIAL IMPLICATIONS

The results of the study do not present any improvement in the performance of the firms owing to the presence of women on board. The representation of women on board is very less and hence the benefits that could have been derived from the diversity were not available to the firms in our sample. It appears that the firms have not taken the mandatory clause in true spirits, but have affirmed the provision only as mere tokenism. Until and unless the proportion of women on board enhances, there is little room for improvement in firm performance. Based on the critical mass theory, it has already been highlighted that a minimum of three women directors are required to influence the decision making of the board. Hence, this paper urges firms to enhance the representation of women based on adequate qualification and experience to derive maximum benefits.

ABSTRACT

Fluorescence (FL) quenching of 5-aminoquinoline (5AQ) by Ag^+ ions has been studied in acetonitrile (ACN) using steady-state and time-resolved fluorescence techniques. In the absence of Ag^+ ions, FL shows a single band assigned to the intramolecular charge transfer (ICT) state. The FL intensity of 5AQ gradually reduces on the successive addition of Ag^+ ions to the solution containing 5AQ. The decrease of FL intensity is nearly ~ 17 fold in the presence of 60 mM Ag^+ ions. Together with the decrease in FL intensity, the FL band maximum is red-shifted. The Stern-Volmer plot has been employed to determine the quenching constant. The nature of quenching has been stated based on the decrease of FL intensity and lifetime in the presence of metal ions. Also, the Benesi-Hildebrand relation has been used to explore the binding mechanism between 5AQ and Ag^+ ions. Thus, 5AQ displays high affinity for Ag^+ ions over other competitive metal ions (Cu^{2+}, Ca^{2+}, Pb^{2+}, Fe^{2+}, Li^+, K^+). Therefore, the present system emerges to be quite important in sensing of Ag^+ ions in an aprotic environment in a concentration range of 4 μM to 60 mM.

1. Introduction

Quinoline and its derivatives have been an intriguing class of molecules in the field of organic and pharmaceutical chemistry and widely used as a prototype compound to many drugs. Multifarious experimental and theoretical researches in photophysics and photochemistry of quinoline-based compounds have found potential applications in preparation of various drugs and dyes. Photoexcited relaxation processes of variously substituted quinolines especially amino- and hydroxyl-quinolines have been considered broadly over the past few years [1–18]. In recent literature, quinoline fused heterocyclic derivatives have been developed that possess diverse biological activities, i.e., anticancer, antimicrobial, antimycobacterial, anticonvulsant, anti-inflammatory and cardiovascular activities [19].

Aminoquinoline (AQ) is an imperative group of fluorophore that plays a momentous role in supramolecular chemistry, electron transfer process, charge transfer, host-guest systems and sensing applications. Photoexcitation to the lowest excited state is usually associated with intramolecular charge transfer (ICT) from amino group to the aromatic ring in these compounds hence producing the ICT state. Enol to keto conversion occurs via excited state proton transfer (ESPT) reaction following photoexcitation. The position of NH_2 group in the quinoline ring and the surrounded solvent molecules/polymers influences the excited state properties of aminoquinolines [5,8–15].

The FL quenching-based studies have been an area of fundamental interest from decades since this can be valuable in elucidating the localization of fluorophores in protein and membrane and their absorptivity to quenchers. Quenching can occur through various mechanisms and become progressively significant due to its applications in fluorescence sensing and drug delivery systems. An array of substances like, metal ions, halides, molecular oxygen, amines etc. can act as quencher [17,18]. Quinoline based fluorescent sensors are extensively used to determine the fluorescence intensity variations and shift of fluorescence wavelength [19–30]. As an example, when halide ions come in contact with excited state 6-methoxyquinoline and 8-methylquinoline, the FL intensity of these probe molecules gets quenched regularly and follows the diffusional quenching mechanism [16–18], and acts as an optical sensor.

In heterocyclic quinoline, the nitrogen atom can act as a chelating site towards metal ions [20]. Photoinduced electron transfer (PET), intramolecular charge transfer (ICT), twisted intramolecular charge transfer (TICT), fluorescence resonance energy transfer (FRET), chelation enhancement quenching effect (CHEQ) or chelation-enhanced fluorescence effect (CEFE) are important mechanisms of fluorescence sensing in the design of quinoline-based fluorescence sensors [20–30]. The development and design of a fluorescent sensor for the variety of

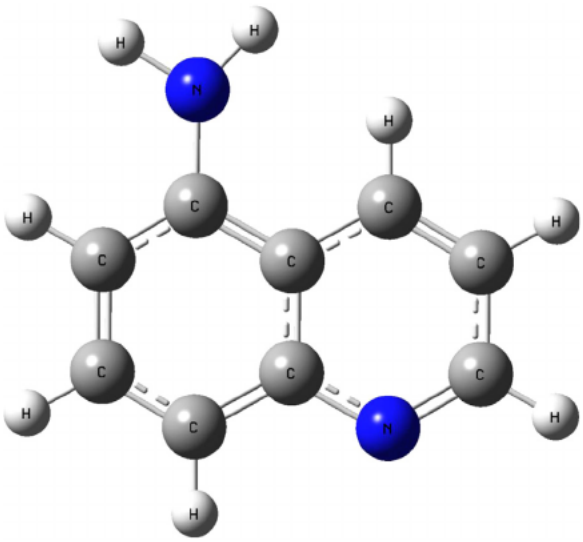
metal ions has acquired attention due to their essential role in medical, environmental and biological applications [22–30]. The FL of ligand may be quenched or enhanced by coordination depending on the influence of the metal ions on the non-radiative processes competing with the radiative process, i.e., FL. The FL resulting from the complex formation is a consequence of numerous factors; the relative position and behavior of the lower electronic excited state of organic ligands and those of metal ions, the heavy atom effects, the structural rigidity and the paramagnetic character of ions [31].

Silver ion, like other heavy metal ions; copper, zinc, lead, mercury, etc., is one of the indispensable toxic metal and has been broadly employed in chemistry, pharmacy, electrical industry, photographic and imaging industry [32–40]. The bioactive silver has gained interest in the domain of biology, such as antimicrobial activity, disinfectant, antibiotics and sterilization even at low concentration level [34]. However, in few cases, rapid absorption of Ag^+ ions causes bioaccumulation, toxicity and irreversible darkening of skin along with disruptive renal and neurological function [34,35]. Furthermore, Ag^+ ions can disable sulphydryl enzymes and bind with imidazole, amine, and carboxyl groups of different metabolites [35,37,41,42]. Since the d^{10} electronic configuration of Ag^+ ions is generally known as a fluorescence quencher following electron transfer and intersystem crossing processes, thus Ag^+ ions could be detected by chemosensors via fluorescence quenching mechanism [28]. Recent reports on fluorescent sensors for detection of Ag^+ ions comprise different fluorophores such as pyrene, oxadiazole, phenanthroline, coumarin, quinoline, gold nanoparticles etc [32–40].

In the present work, we have commenced a detailed study of FL quenching of 5AQ by Ag^+ ions, to comprehend the nature of possible quenching mechanism. Steady-state and time-resolved measurements confirm the quenching mechanism of probe 5AQ in the presence of Ag^+ ions. With the addition of Ag^+ ions, the FL maximum is red-shifted ($\sim$ 46 nm) with $\sim$ 17 fold quenching of fluorescence intensity. Interestingly, no fluorescence quenching and wavelength shift are noticed on addition of variant metal ions (Ca^{2+}, Cu^{2+}, Li^+, K^+, Fe^{2+}, Pb^{2+}). The molecular structure of 5AQ is given in Scheme 1.

2. Experimental section

5-Aminoquinoline (5AQ) purchased from Aldrich chemical company Inc., U.S.A. (with 99% purity) was used as received and matched with the reported FL spectrum to confirm its fluorescence purity (to make sure that there is no impurity). Silver nitrate and all other metal salts were obtained from Loba Chemie and SRL Pvt. Ltd. (with 98–99% of purity) and used as received. Spectroscopic or HPLC grade solvents were used for the present study. The purity of compounds was established by agreement of corrected excitation spectra with the electronic absorption spectra. The stock solution of $AgNO_3$ (0.1 M) was prepared from the stock solution of 5-aminoquinoline (10^{-4} M). From this solution, diluted solutions of $AgNO_3$ were prepared. This ensured that the probe concentration did not change on the addition of $AgNO_3$. Freshly prepared samples at room temperature were used in the present study. A similar method was used during preparation of diluted solutions of other metal ions.



Scheme 1. Molecular structure of 5-aminoquinoline.

2.1. Instrumentation

Steady-state absorption spectra were recorded by UV–visible Double beam spectrophotometer (Systronics Model no: 2203). Fluorolog-3 spectrofluorometer (Horiba Jobin Yvon Inc.) accompanied by available analysis software have been used to record and analyze the excitation and emission spectra. 450 W xenon lamp was used as the excitation source. Transparent quartz cuvette was used for the absorption and emission measurements and frontal geometry was used in recording emission to avoid inner filter effect. For all the measurements, excitation and emission slit widths were chosen about 2.0 nm, and the excitation wavelength was 345 nm. Time-correlated single photon counting (TCSPC) system (DeltaFlex-01-DD, Horiba Jobin Yvon IBH Ltd.) coupled with DeltaDiode (340 nm) and PMT (PPD 850) was used for fluorescence decay measurements and least square fitting and reconvolution methods were used to analyze the data. Instrumental response function was measured using Ludox scatterer. The numbers of counts in the peak channel were at least 10,000.

3. Results and discussion

Absorption, fluorescence (FL), FL-excitation spectra and FL-decays were measured for 5AQ in acetonitrile (ACN) in the absence and presence of varying concentration of silver ions (Ag^+) at room temperature.

Fig. 1 shows absorption spectra of 5AQ in ACN in absence and presence of various concentrations of Ag^+ ions. The absorption maximum appeared at 343 nm, and is ascribed to the $\pi \rightarrow \pi^*$ transition of quinoline group. In presence of a small concentration of Ag^+ ions, keeping the solute concentration fixed the optical density (absorbance) of 5AQ decreases, which is accompanied by broadening of the absorption spectrum. The corresponding optical density decreases from 0.65 to 0.45 with increasing concentration of Ag^+ ions from 0.0 to 7.0 mM. The change in spectral broadening and absorption maximum

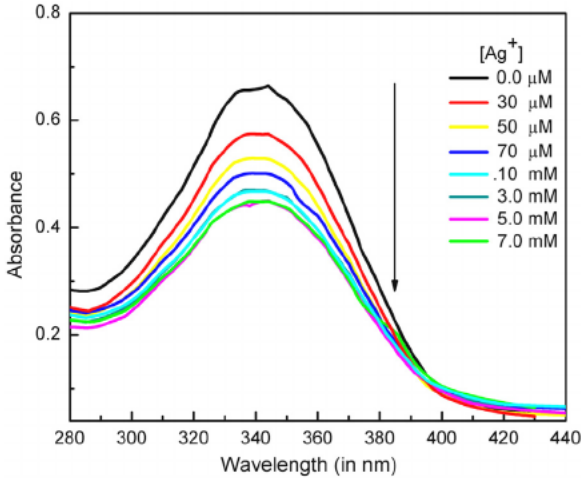


Fig. 1. Absorption spectra of 5AQ (1×10^{-4}M) in ACN in the presence of various concentration of Ag^+ ions.

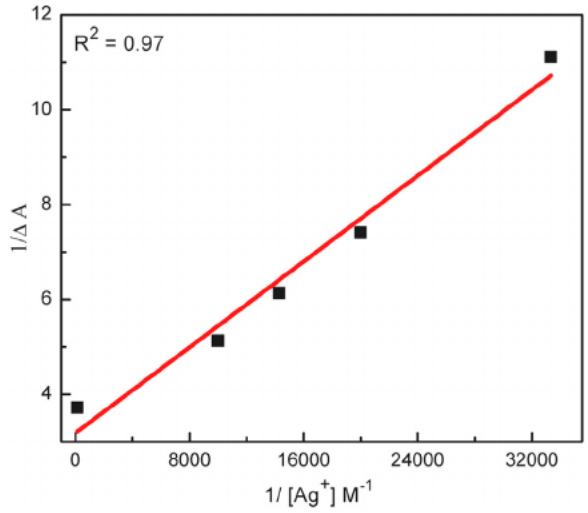

Fig. 2. Benesi-Hildebrand plot of 5AQ in ACN with increasing concentration of Ag^+ ions.

upon addition of Ag^+ ions suggests that there is a ground state complexation between 5AQ and Ag^+ ions. To understand the formation of complex between the probe and the quencher and to determine the binding constant, the well-known Benesi-Hilderband [32] Eq. (1) was applied.

$$\frac{1}{(A - A_0)} = \frac{1}{(A_{max} - A_0)} + \left[\frac{1}{K[M^{n+}]} + 1\right] \quad (1)$$

where A is the absorbance of 5AQ in presence of various concentration of Ag^+ ions, A_0 is the absorbance of 5AQ, A_{max} is the absorbance of 5AQ in the presence of the maximum concentration of Ag^+ ions, $[M^{n+}]$ is the concentration of metal ion and K is the binding constant. A plot between $1/\Delta A$ vs. the inverse of Ag^+ ions concentration is linear (Fig. 2) and demonstrates the 1:1 complex of 5AQ: Ag^+. The binding constant (K) determined from the ratio of intercept/slope of the plot comes out to be $1.407\times10^4 M^{-1}$.

Fig. 3(a,b) shows the fluorescence spectra of 5AQ in ACN in the absence and presence of varying concentration of Ag^+ ions at room temperature. The fluorescence maximum is around 482 nm upon excitation at 345 nm and is independent of excitation wavelength. The fluorescence of 5AQ reduced upon addition of small amount (about 4 μM) of Ag^+ ions. While increasing the concentration of Ag^+ ions from 4 μM, the fluorescence intensity is gradually decreased, as shown in Fig. 3(a). The FL intensity diminished nearly 17 folds in the presence of 60 mM concentration of Ag^+ ions. Thus, the FL of 5AQ is quenched significantly in the presence of Ag^+ ions in ACN. In addition to quenching, the FL spectrum is shifted towards red with the addition of Ag^+ ions. The red shift in the FL spectrum is about 46 nm for the highest concentration of Ag^+ ions taken in the study (60 mM), as shown in (Fig. 4). The excitation spectrum of 5AQ in ACN was found to be independent of monitored emission wavelength and exhibits well defined L_a and L_b bands and resembles to the absorption spectrum [10,11,13]. Fig. S1(a) shows the overlapped excitation spectrum of 5AQ in ACN on successive addition of Ag^+ ions. The excitation spectrum shifted from 345 nm to 360 nm with the addition of Ag^+ ions as shown in Fig. S1(b). Together with the spectral shift, the intensity of excitation spectrum gradually decreases with increasing concentration of Ag^+ ions. The change in the excitation spectrum is in agreement with that observed in absorption spectrum and demonstrates the ground state complex formation between Ag^+ ions and 5AQ in ACN.

The FL maximum shifted from 482 nm to 528 nm while changing the concentration of Ag^+ ions from 0.0 μ M to 60 mM. A linear relationship has been observed between the ratio of FL intensity at two

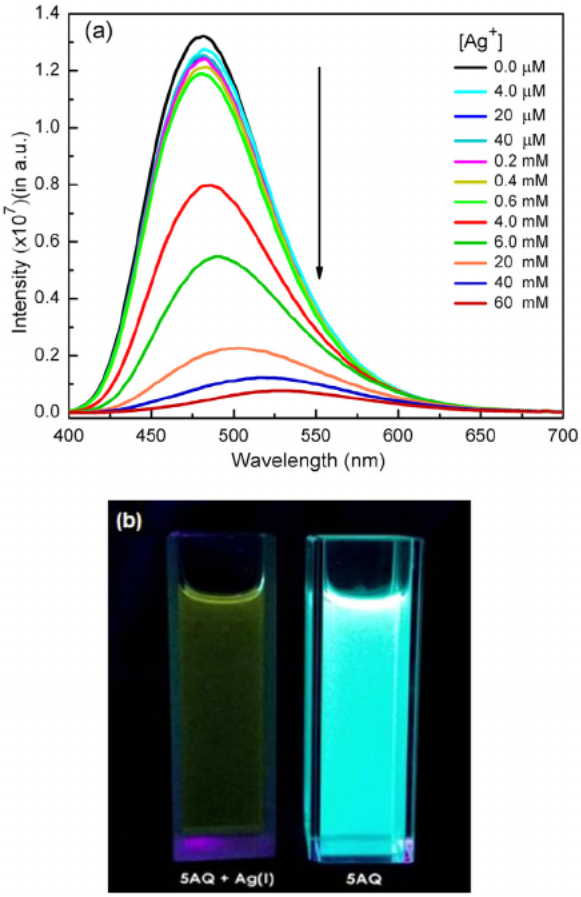

Fig. 3. (a) Fluorescence spectra of 5AQ $(1 \times 10^{-4}\ M)$ in ACN upon addition of various concentration of Ag^+ ions at excitation wavelength of 345 nm. (b) Fluorescence of 5AQ with UV light irradiation in the presence (left) and absence (right) of Ag^+ ions.

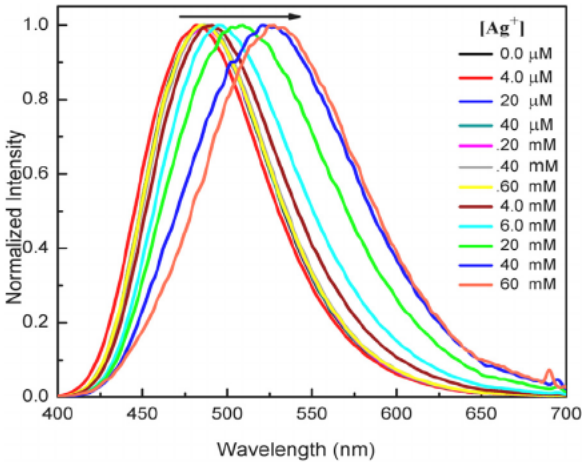

Fig. 4. Normalized fluorescence spectra of 5AQ in ACN in presence of various concentrations of Ag^+ ions.

wavelengths (I_{530}/I_{480}) and Ag^+ ion concentration (Fig. 5). In pure ACN, 5AQ shows a Stokes shift of ~ 8322 cm^{-1} and increases upto 10,058 cm^{-1} upon addition of Ag^+ ions (60 mM). The relation between Stoke's shift (Table 1) and Ag^+ ions concentration is shown in Fig. S2. This further demonstrates formation of complex in the ground state.

To understand the nature of FL quenching, the decrease of FL intensity is plotted as a function Ag^+ ions concentration following the so-called Stern-Volmer (S-V) relation Eq. (2) and modified S-V relation Eq.

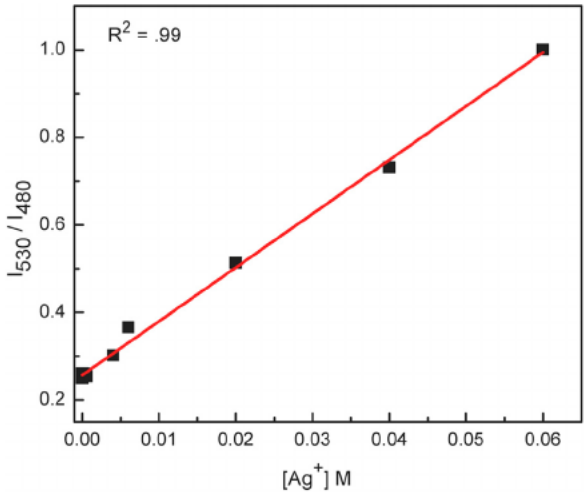

Fig. 5. Plot of the ratio of the intensity (I_{530}/I_{480}) of 5AQ in the presence of various concentration of Ag^{+}ions.

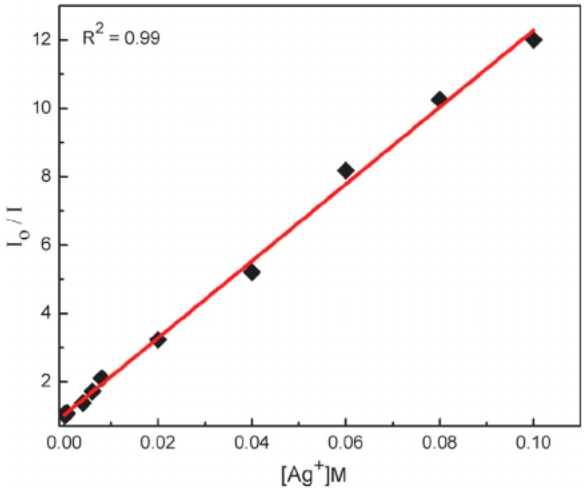

Fig. 6. The Stern-Volmer plot between the relative fluorescence intensity of 5AQ and Ag^{+} ions concentration.

Table 1
Steady-state parameters of 5AQ in acetonitrile in the presence of various concentration of Ag^{+} ions.

Concentration of Ag^{+} ions	$^{max}\lambda_{abs}$ (nm)	$^{max}\lambda_{em}$ (nm)	Stokes shift Δν (cm^{-1})
0.0 μM	344	482	8322
4.0 μM	344	482	8322
40 μM	344	483	8366
0.4 mM	344	484	8408
0.6 mM	344	484	8408
4.0 mM	344	485	8451
6.0 mM	344	490	8661
8.0 mM	344	495	8868
20 mM	344	502	9149
40 mM	344	525	10,019
60 mM	344	528	10,058

(3):

$$\frac{I_0}{I} = \frac{\tau_0}{\tau} = 1 + k_q\tau_0[Q] = 1 + K_{SV}[Q] \quad (2)$$

$$\frac{\left[\frac{I_0}{I} - 1\right]}{[Q]} = (K_{SV} + K_g) + K_{SV}K_g[Q] \quad (3)$$

where I_0 and I are the fluorescence intensities in the absence and presence of the quencher, respectively. [Q] is the quencher concentration and K_{SV} ($k_q\tau_0$) is the S-V constant, which represents the efficiency of fluorescence quenching. k_q is the bimolecular constant, τ_0 is the decay time in absence of quencher and K_g is ground state association constant. The value of K_{SV} can be determined from the slope of the graph displaying dependence of intensity or decay time on [Q], as expressed by Eq. (2). The obtained S-V plot for 5AQ in the presence of Ag^{+} ions is linear with Adj R^2 = 0.99, as shown in Fig. 6. The FL intensity may reduce either due to dynamic or static quenching, even with the linear relation of S-V plot. Thus, the steady-state spectral analysis only is not sufficient to confirm the nature of quenching. When decay time does not change with a decrease in fluorescent intensity, only static quenching is present i.e., K_{SV} = 0. A non-fluorescent complex is formed between the fluorophore and the quencher in case of quenching being static. The other case is that of dynamic quenching (i.e., K_g = 0) in which quenching response competes with emission in timescale and can be governed by the diffusion of quencher in any medium and its collision with excited probe molecule. These two quenching effects i.e., dynamic and static quenching, involve molecular interaction between the fluorophore and quencher. Simultaneous occurrence of static and dynamic quenching results in the positive deviation of plot I_0/I versus [Q] as Eq. (2) follows quadratic dependence with quencher concentration. The relation, $[I_0/I - 1]/[Q] = (K_{SV} + K_g) + K_{SV}K_g[Q]$ gives K_g after substituting the K_{SV} value retrieved from the data [1,17,18].

To ascertain the fluorescence quenching mechanism of 5AQ by Ag^{+} ions, time-resolved FL experiments were performed for various concentrations of Ag^{+} ions. FL decays were collected at λ_{ex} = 340 nm and λ_{em}= 530 nm. The FL decay of 5AQ fits to a bi-exponential function $\alpha_1 \exp(-t/\tau_1) + \alpha_2 \exp(-t/\tau_2)$ in an aprotic solvent (ACN). The term τ_1 and τ_2 are the lifetimes and α_1 and α_2 are the corresponding pre-exponential factors. The fitted lifetime are 1.26 ± 0.2 ns (0.93 %) and 11.60 ± 0.01 ns (99.07 %). The contribution of smaller decay constant is very small (< 1%). As an approximation, the decay fitted single exponential with a lifetime of 11.50± 0.01. Upon increasing the concentration of Ag^{+} ions, the lifetime decreases monotonically. It is interesting to note that, the lifetime component decreases from 11.50 ns to 3.14 ns on addition of 40 mM of Ag^{+} ions. The fitted overlapped decay curves obtained at varying concentrations of quencher are shown in Fig. 7 and the analyzed parameters are summarized in (Table 2). The decrease in FL lifetime plotted as a function of Ag^{+} ions concentration follow the S-V relation Eq. (2) again linearly, as shown in Fig. 8. Thus, the decrease in lifetime and the linear S-V plots demonstrate the dynamic quenching as a predominant mechanism. The value of K_{SV} constant for 5AQ obtained from the slope of the plot (Fig. 6) comes out to be 112.7 M^{-1} and k_q is around 9×10^{9} M^{-1} s^{-1}, respectively.

Furthermore, the absorption and fluorescence spectra of 5AQ in ACN in the presence and absence of different metal ions (Cu^{2+}, Ca^{2+}, Pb^{2+}, Fe^{2+}, Mg^{2+}, Li^{+}, K^{+}) were examined. The fluorescence response of 5AQ in the presence of various metal ions under UV is shown in Fig. S3 of the Supporting information. The FL of 5AQ upon addition of 40 mM concentration of various metal ions is illustrated in Fig. 9. As discussed, the fluorescence intensity of 5AQ is quenched significantly on addition of Ag^{+} ions whereas for other metal ions it shows minimal change. To investigate the interference from other metal ions we further conducted the competition experiment in the presence of 40 mM of various metal ions (Cu^{2+}, Ca^{2+}, Pb^{2+}, Fe^{2+}, Mg^{2+}, Li^{+}, K^{+}) with subsequent addition of 40 mM of Ag^{+} ions, as shown in Fig. 10. These results reveal that the recognition of Ag^{+} ion by probe 5AQ is not significantly influenced by other competitive metal ions. Thus, it is observed that the probe molecule 5AQ has good selectivity for Ag^{+} ions (as compared to the other metal ions under the same condition and concentration) and hence can be used to detect Ag^{+} ions in polar aprotic medium, which

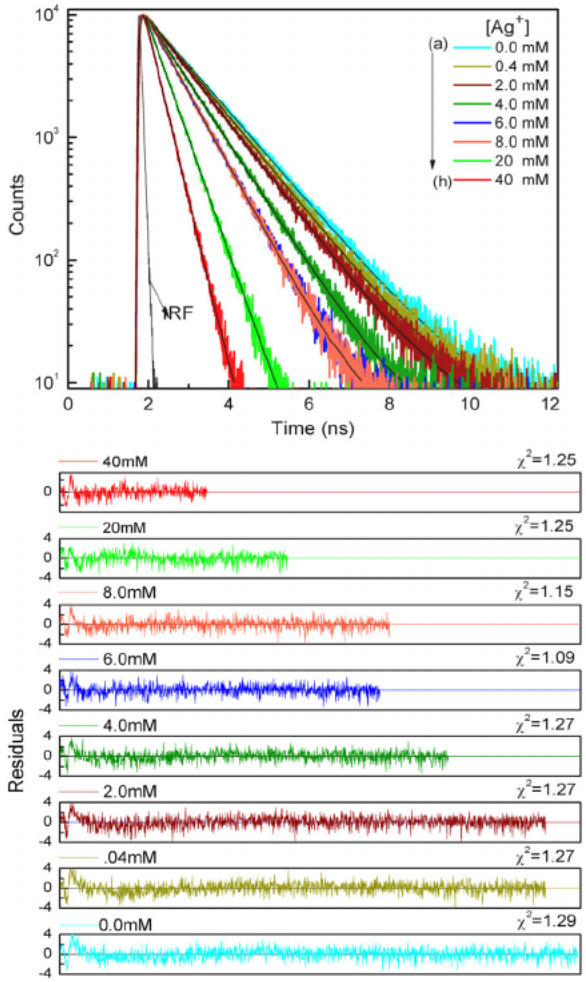

Fig. 7. Overlapped fitted fluorescence decay curves of 5AQ in presence of various concentration of Ag^+ ions and corresponding residuals at λ_{ex} = 340 nm and λ_{em} = 530 nm.

Table 2
Fluorescence lifetime parameters of 5AQ with various concentration of Ag^+ ions at λ_{ex} = 340 nm and λ_{em} = 530 nm.

Concentration of Ag^+ ions	τ (ns)	χ^2	τ_0/τ
0.0 mM	11.50 ± 0.01	1.29	1.0
0.4 mM	10.84 ± 0.01	1.27	1.060
2.0 mM	10.02 ± 0.009	1.27	1.148
4.0 mM	8.64 ± 0.008	1.27	1.331
6.0 mM	7.40 ± 0.09	1.09	1.554
8.0 mM	7.31 ± 0.007	1.15	1.573
20.0 mM	4.65 ± 0.005	1.25	2.473
40.0 mM	3.14 ± 0.004	1.25	3.662

might be due to high-affinity of Ag^+ ions to 5AQ as compared to other metal ions.

As discussed, in the absence of quencher, the FL decay of 5AQ is fitted with a bi-exponential function. The contribution of the shorter component is very small (< 1%) and contribution of the longer component is dominant in the overall decay function. The smaller lifetime component is assigned to the locally excited (LE) state while the longer lifetime component is assigned to the intramolecular charge transfer (ICT) state [10,11,13]. Thus, the ICT is probably responsible for the overall FL. However, there is no rise time component in the FL decay, indicating that ICT may be faster than the resolution of our experimental setup.

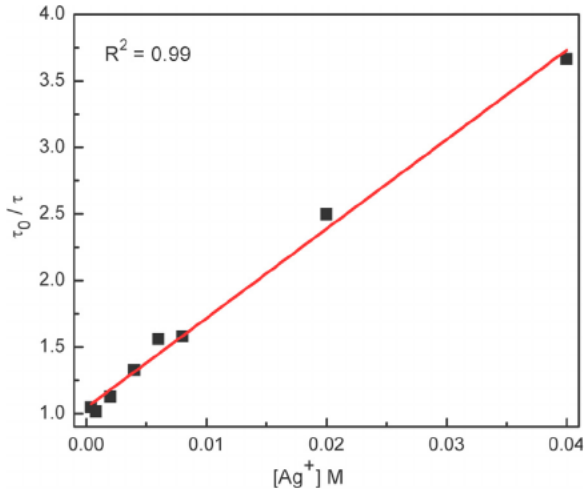

Fig. 8. Stern-Volmer plot between the lifetime of 5AQ and Ag^+ ions concentration.

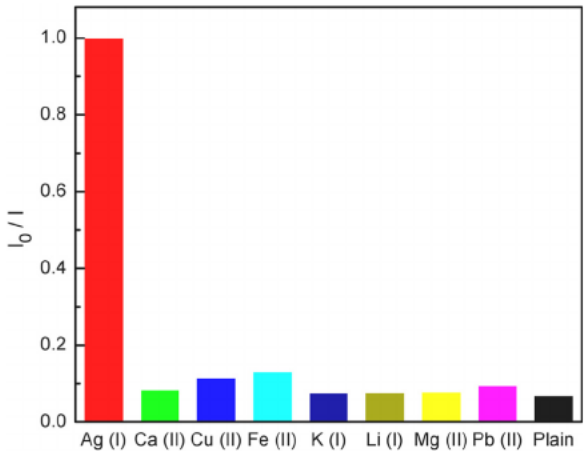

Fig. 9. Fluorescence response of 5AQ in ACN in the presence of various metal ions. The excitation wavelength was 345 nm.

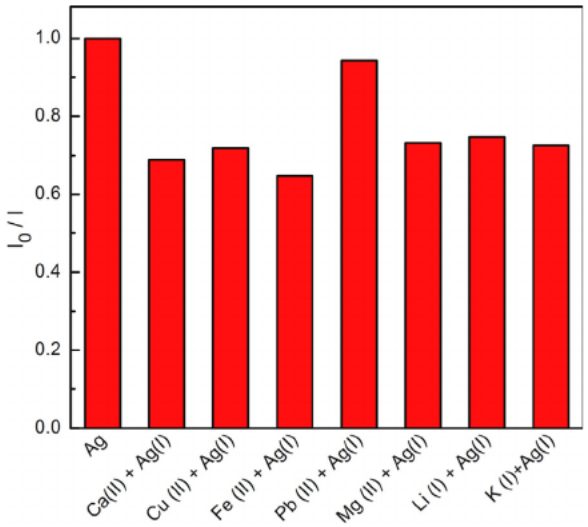

Fig. 10. Fluorescence response of 5AQ (10^{-4} M) in presence of 40 mM of various metal ions with subsequent addition 40 mM of Ag^+ ions to the solution at λ_{ex} = 345 nm.

In the presence of Ag^+ ions, the decay trend is very similar to that in the absence of quencher. However, the observed decay fits well with mono-exponential function with an approximation. The lifetime decreases with increasing the concentration of Ag^+ ions, which indicates that the FL corresponding to the ICT is quenched. This is due to the complexation between 5AQ and Ag^+ ions, as evident from the absorption and excitation spectra. While increasing the concentration of Ag^+ ions, the absorption/excitation intensity decreases and the spectra shift towards red. This may be due to the formation of a complex between 5AQ and Ag^+ ions, which has minimal oscillator strength/absorption intensity. The shift in the FL spectrum may probably be ascribed to the different ICT states formed by the interaction of 5AQ with Ag^+ ions. The decrease of FL lifetime also indicates the decrease of the FL of ICT state formed from the LE state.

Furthermore, it has been classified that metal ions, such as Ag^+ ions, being soft cations, prefer soft donors for complexation [32]. The nitrogen atom of 5AQ is involved in the coordination with Ag^+ ions. The interaction between Ag^+ ions and the nitrogen atom in 5AQ moiety enhances the electron-withdrawing ability of 5AQ that leads to a different state and results in a large red-shifted FL. The donation of the $-C = N$ nitrogen lone pair electrons to the Ag^+ may decrease the fluorescent intensity [21]. Generally, the FL of luminescent ligands is quenched by complexation of the ligand with transition metal ion due to paramagnetic quenching. In this case, the unpaired electrons of the metal ions actively interact with the π electrons of the ligand, providing a path way for inter system crossing from singlet excited state of the ligand to the higher multiplicity states (i.e., triplet state) due to interaction with metal ions [31].

It is important to mention that the present study has been performed in some other solvents also. Since 5AQ shows weak fluorescence in polar protic solvents (water, methanol, ethanol), therefore enhancement in FL intensity is noticed by adding different concentrations of Ag^+ ions. However, a small amount of quenching is observed in DMSO (dimethyl sulfoxide) as compared to that in ACN (acetonitrile) in the presence of Ag^+ ions. Thus, this makes the system attractive for FL quenching/sensing in ACN by Ag^+ ions.

4. Conclusions

In summary, we have studied fluorescence-quenching behavior of 5AQ for Ag^+ ions in ACN, which results in ~ 17-fold decrement in FL intensity upon addition of Ag^+ ions. The lifetime is reduced from 11.5 to 3.14 ns. The large Stokes shifted FL, which produces from ICT state is advantageous to avoid self-absorption and interference from the light source in fluorescence sensing technology. We demonstrate dynamic quenching for all concentration of silver ions used in the study. Stern-Volmer quenching constant (K_{SV}) as $112.7\ M^{-1}$, biomolecular quenching constant (k_q) as $9.8 \times 10^9\ M^{-1}s^{-1}$ and binding constant (K) as $1.407 \times 10^4\ M^{-1}$ have been determined for Ag^+ ions. In addition, 5AQ shows high affinity for Ag^+ ions over other competitive metal ions. Therefore, the proposed system emerges to be quite interesting in sensing/recognition of Ag^+ ions in protic environment in a concentration range of $40\ \mu M$ to $60\ mM$.

ORIGINAL PAPER

Edge detection based on type-1 fuzzy logic and guided smoothening

Abstract
Edge detection is an important phenomenon in computer vision. Edge detection is helpful in contour detection and thus helpful in obtaining the important information. Edge detection process heavily depends on chosen technique. Soft computing techniques are considered as powerful edge detection methods due to their adaptability. This paper presents a fuzzy logic based edge detection method where the quality of edges is controlled using sharpening guided filter and noise due to the sharpening is controlled using Gaussian filter. The accuracy of the method is judged using a variety of statistical measures. It has been found that by proper selecting the smoothening parameters a significant improvement in the detected edges can be obtained.

Keywords Edge detection · Image enhancement · Fuzzy logic · Guided filtering

1 Introduction

In numerous computer vision systems, edge detectors are very important. The process of edge detection is valuable in the analysis of images by decreasing the processed data (Shah 1997). The technique of edge detection is among prime methods applied in various field where processing of digital image is required. The purpose of using edge detection in the processing of an image is to get rid of useless data and preserve the important image characteristics. It includes certain methods like feature extraction, registration, interpretation and image segmentation which are very helpful in keeping the useful data only (Goswami and Chan 2011).

An edge could be defined as the object between boundary and image background (Gevers et al. 2012; Shih 2010). Soft computing is a developing research area that comprises of integral components of machine learning techniques, for example, fuzzy logic, artificial neural networks, adaptive neuro-fuzzy inference system, particle swarm optimization and genetic algorithms etc. These strategies are generally utilized for edge detection and image segmentation in the greater part of the critical applications. Out of these methods, fuzzy rule based classifiers have been used in various classes of engineering problems such as self localization and landmark recognition (Zhou and Angelov 2007), data density estimation (Angelov and Zhou 2008), real time object detection (Angelov et al. 2011) and human activity recognition (Sargano et al. 2017) etc.

It is important to note that a universal definition for edges cannot be created as each human has its own way of judging the edges in images. Therefore, edge is a subjective phenomenon, and outcome depends on individual perspective. Therefore, in this paper, we have discussed image sharpening and fuzzy logic based edge detection, and to control sharpening noise Gaussian kernel based filtering is proposed. The results are compared with notable statistical quality measures.

This paper is organized as follows, in Sect. 2 of the paper related works is presented. Edge detection steps are detailed in Sect. 3 of the paper. Proposed method is discussed in Sect. 4 of the paper. In Sect. 5 results of the paper are discussed, and finally in Sect. 6 of the paper major conclusions are discussed.

2 Related works

In this part of the article, we have examined various edge detection strategies and concentrate on digital images' edge detection. Taking about the standard images, the edges are used to define the boundaries of the subject and helpful for division, enlistment, identification. It removes the irrelevant data and interestingly of protecting the essential properties of a picture. There are different conventional systems useful in edges detection mechanism. Some of the popular techniques are Laplacian Roberts, Sobel and gradient (Shih 2010). With the help of masks, edge detection is possible by linear operators. These masks are representing the ideal edge steps in different ways both for intensity and color. Shih utilized similar technique for identification. The comparison of various types of edge detection methods are detailed in Table 1.

Roberts (Rogowska 2000), Prewit and Sobel (Rangarajan 2005) introduced edge detection on the basis of the principle of gradient which demonstrate the impact of these filters on the images which is based on the first derivative. A progressively successful operator is the Laplacian, which utilizes the second derivative in locating the edge (Rangarajan 2005).

Alshennawy and Aly (2009), Aborisade (2011) and Begol and Maghooli (2011) proposed soft computing based methodologies, for example, fuzzy logic. Mehrara et al. (2009) proposed another methodology that works on the concept of back propagation neural network. Zhang et al. (2009) introduced a hybrid technique works on the principle of adaptive neuro-fuzzy inference system (ANFIS) for the detection of edges.

Mathur and Ahlawat (2008) introduced a latest algorithm based on fuzzy relative pixel value. In this methodology, the relative pixel values are examined and subsequently reduce the image processing by the application of artificial intelligence. Table 2 demonstrates edge detection methods work on the concepts of fuzzy logic, neural network and ANFIS.

The other recent notable mechanisms in edge detection are: deep convolutional neural network (Marmanis et al. 2018), fuzzy cellular automata (Farbod et al. 2018), particle swarm optimization (Setayesh et al. 2013), cuckoo search optimization (Gonzalez et al. 2016), Anisotropic Gaussian Kernels (Zhang et al. 2017), convolution neural networks (CNNs) (Jeong et al. 2019; Liu and Lew 2016). Edge detection based on single pixel imaging was proposed in Ren et al. (2018). In recent published work; it is detailed that artificial intelligence and CNN based edge detection methods have shown that these methods fail in presence of small perturbations (Cosgrove and Yuille 2019).

This paper, proposes a technique based on type 1 fuzzy logic and guided image filtering is used for the sharpening of the images. Using sharpening, strength of the edges can be enhanced to detect them easily. Even in case of perturbation sharpening can be used to control edges. The proposed method is effective as it considers the advantages of both fuzzy logic design and guided image smoothening.

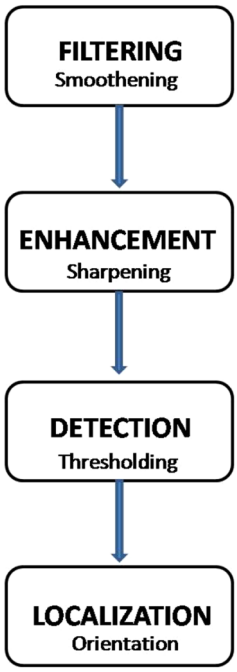

Fig. 1 Edge detection notable steps

3 Edge detection steps

The main aim of edge detection is to successfully locate and identify genuine edges. Edge detection is difficult in low resolution which is mostly found in colour images. In edge detection the main steps are filtering, enhancement, detection and localization which are utilized for detection of correct edges (Fig. 1).

We cannot use images straightway in light of the fact that it might be corrupted by arbitrary varieties in intensities, varieties in brightening, or uneven contrast. This irregular variety in intensity is known as noise. Image sharpening is needed to enhance the quality of image. In enhancing the quality of image, high pass filtering plays an important role. The sharpened image (I_s) signal is proportional to the high pass filtering of original signal and mathematically written as

$$I_S = I + \gamma\left[I - \underbrace{I \otimes H}_{\text{Smoothening}}\right] \tag{1}$$

where, I: original image, H: high pass filter and 'γ' is scaling factor (Fig. 2).

3.1 Canny edge detection

Canny edge detection is a well known method in edge detection; it is a multi-step algorithm and can detect edges in noisy environment by suppressing noise (Canny 1986). The main steps of the algorithms are as under

1. Use Gaussian filter to reduce noise and other redundant information:

$$f(i,j) = H(i,j) \otimes I(i,j)$$
$$\text{Where,} \quad H(i,j) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{i^2+j^2}{2\sigma^2}\right) \tag{2}$$

2. Compute gradient of $(f_i(i,j), f_j(i,j))$ of $f(i,j)$ using any of the gradient operators (Roberts, Sobel, Prewitt, etc.) to get:

$$M(i,j) = \sqrt{f_i^2(i,j) + f_j^2(i,j)} \quad \text{and} \quad \theta = \tan^{-1}\frac{f_j(i,j)}{f_i(i,j)} \tag{3}$$

3. Threshold M:

$$M_T(i,j) = \begin{cases} M(i,j) & \text{if} \quad M(i,j) > \gamma \\ 0 & \text{otherwise} \end{cases} \tag{4}$$

where, γ is threshold and is chosen carefully such that that all edges are preserved while major portion of the noise is suppressed.

4. Use non-maximal suppression in the pixels edges in M_T obtained above to thin the edge ridges.
5. Using two different thresholds τ_1 and τ_2 (where $\tau_1 < \tau_2$) obtain two binary images I_1 and I_2. Note that I_2 with greater τ_2 has less noise and fewer false edges but

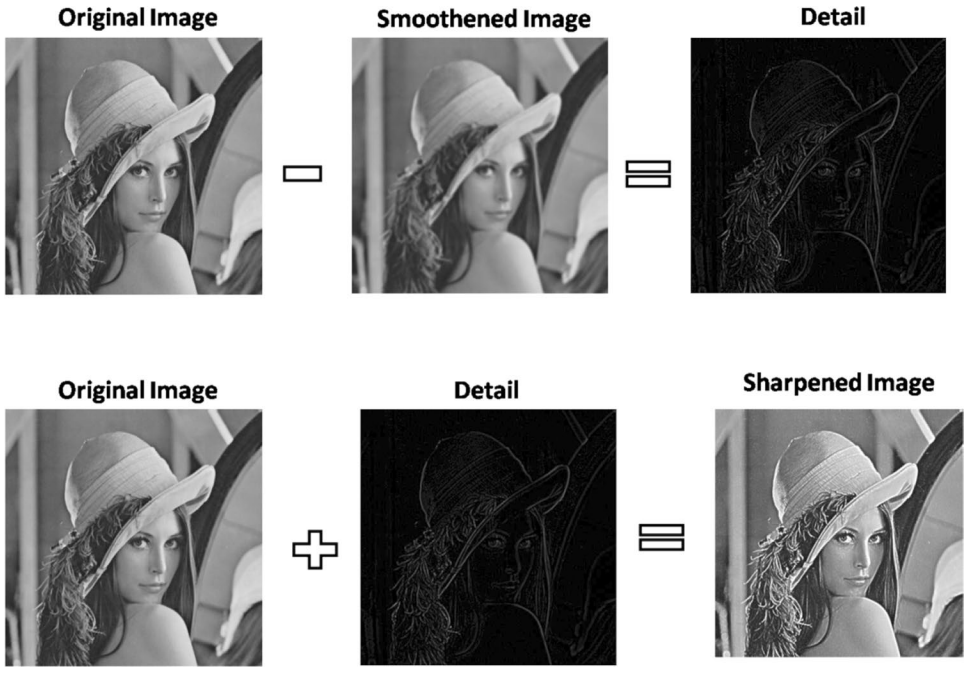

Fig. 2 Demonstration of image sharpening (Lena)

Fig. 3 Edge detected image using Canny method (Lena)

greater gaps between edge segments, when compared to I_1 with smaller τ_1.

6. Link edge segments in I_2 to form continuous edges (Fig. 3).

The canny edge detection is considered as one of the better methods in edge detection. However, without post processing of detected edges performance of canny edge detection is not good, and suffers from large number of falsely accepted edges.

4 Proposed method

In this section proposed method is detailed. The various steps are detailed and utility of various processes are discussed.

4.1 Fuzzy expert system

Figure 4 depicts the basic architectural layout of a fuzzy expert system. In this work three methods defined as M_1, M_2 and M_3 are presented. In method M_1 on the input image fuzzy logic is directly applied to detect edges. In method M_2 the input image is first passes through the sharpening filter and after this fuzzy logic is used to detect edges. In method M_3 the input image is first passes through the sharpening filter and then for Gaussian filter and finally fuzzy logic is applied to detect edges. In fuzzy logic based edge detection first input image is fuzzified using fuzzy input and output membership function and then apply IF-ELSE rules using Mamdani fuzzy inference engine and at the output defuzzification is done to obtain crisp values to obtain desired results (Fig. 5). The detailed description of the fuzzy based system, image sharpening using guided filter and finally use of Gaussian kernel for noise removal is discussed.

In this work, we use triangular membership function for both input and output and defined as: $triangle(x;a,b,c) = \max\left(\min\left(\frac{x-a}{b-a}, \frac{c-x}{c-b}\right), 0\right)$ (Figs. 6, 7).

4.2 Fuzzy rules

Fuzzy rules are developed using human expert system, and edge and non-edge pixels are decided on the basis of neighbourhood pixels. For the edge detection a total of 30 rules are defined. The rules are developed on a 3×3 mask as shown in Fig. 1. In the rule designing Img (x, y) represents pixel position, '1' represents white pixel and '0' represents black pixel value. For 3 black and 5 white pixels in neighbourhood 4 rules are defined, while for 4 black and 4 white pixels in neighbourhood, 8 rules are defined, for 5 black and 3 white pixels in the neighbourhood and for 6 black and 2

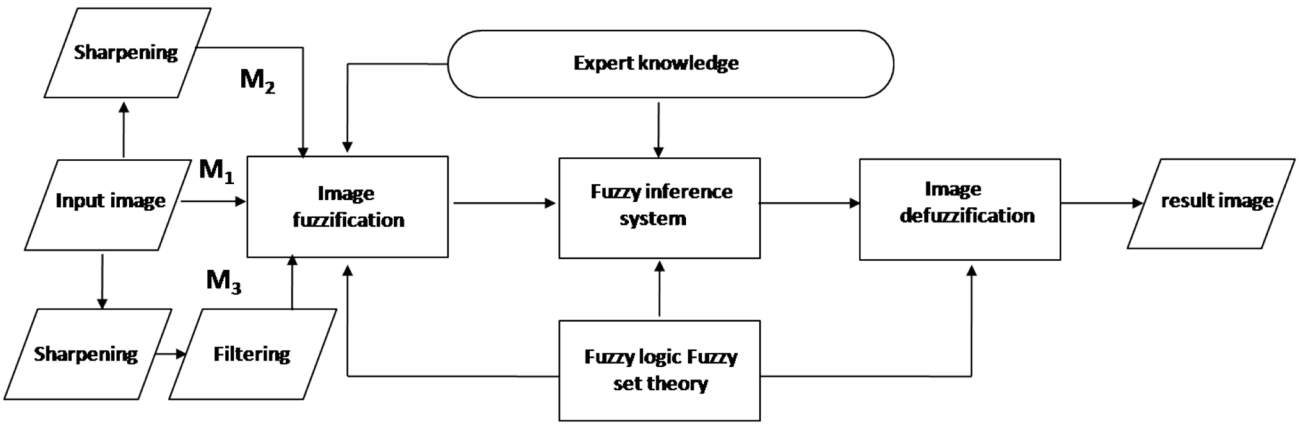

Fig. 4 Schematic of proposed edge detection mechanism (M_1: edge detection using fuzzy logic only, M_2: edge detection using fuzzy logic and sharpening filter and M_3: edge detection using fuzzy logic and sharpening filter)

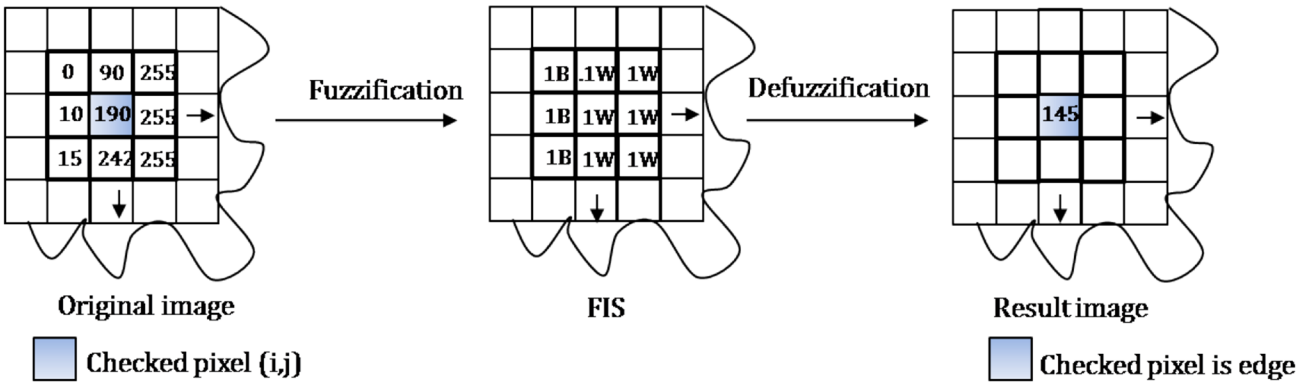

Fig. 5 Schematic view of fuzzy logic based edge detection

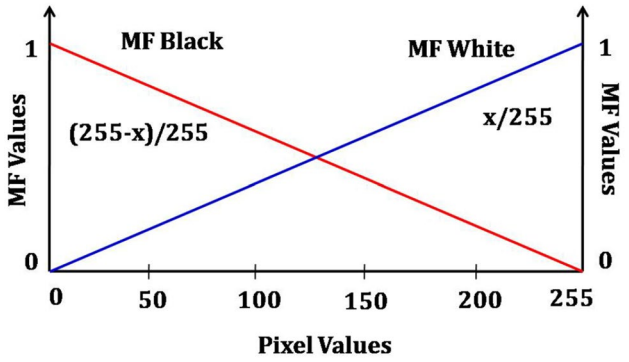

Fig. 6 Membership function for black and white pixels values

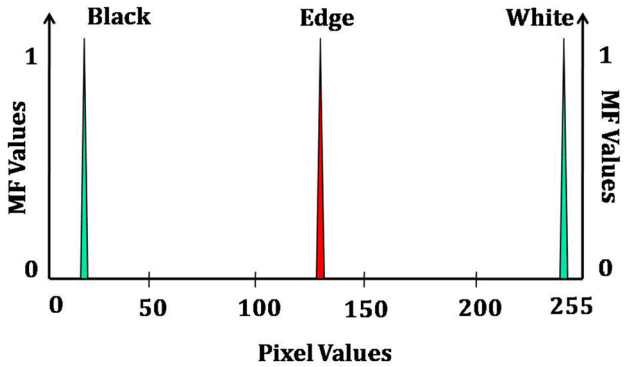

Fig. 7 Output membership function for black, white and edge

white pixels in the neighbourhood again for both the cases 8 rules are defined and finally for all black or white pixels in the neighbourhood 2 rules are defined. Various rules are detailed below (Fig. 8).

4.3 Guided image filtering and sharpening

In guided image filtering, the output image is linear transformation of guided image 'G' and is expressed as (He et al. 2013)

$$\hat{I}_n = a_i G_n + b_i, \quad \forall n \in w_i. \tag{5}$$

a_i and b_i are the co-efficient in window w_i. The guided image filtering problem can be formulated as the minimization of difference in input and output images, and ε is smoothness parameter and decides the degree of smoothness:

$$E(a_i, b_i) = \sum_{n \in w_i} ((a_i G_n + b_i - I_n)^2 + \varepsilon a_i^2). \tag{6}$$

The co-efficient are evaluated as

$$a_i = \frac{(1/|w|)\sum_{p \in w_i} G_n I_n - \bar{G}_i \bar{I}_i}{\sigma_i^2 + \varepsilon}$$
$$b_i = \bar{I}_i - a_i \bar{G}_i \tag{7}$$

where, bar represents the mean values of corresponding parameter. $|w|$ denotes the total number of pixel w_i:

$$\hat{I}_n = \left(\frac{1}{|w|}\sum_{i \in w_n} a_i\right) G_n + \left(\frac{1}{|w|}\sum_{i \in w_n} b_i\right). \tag{8}$$

In He et al. (2010) it is proved that GF can also be expressed as

$$W_{nm}^{GF}(G) = \frac{1}{|w|^2}\sum_{i:(n,m) \in w_i}\left(1 + \frac{(G_n - \bar{G}_i)(G_m - \bar{G}_i)}{\sigma_i^2 + \varepsilon}\right) \tag{9}$$

In general we have

$$\hat{I}_n = \sum_{m \in w_n} W_{nm}^{GF}(G) I_m. \tag{10}$$

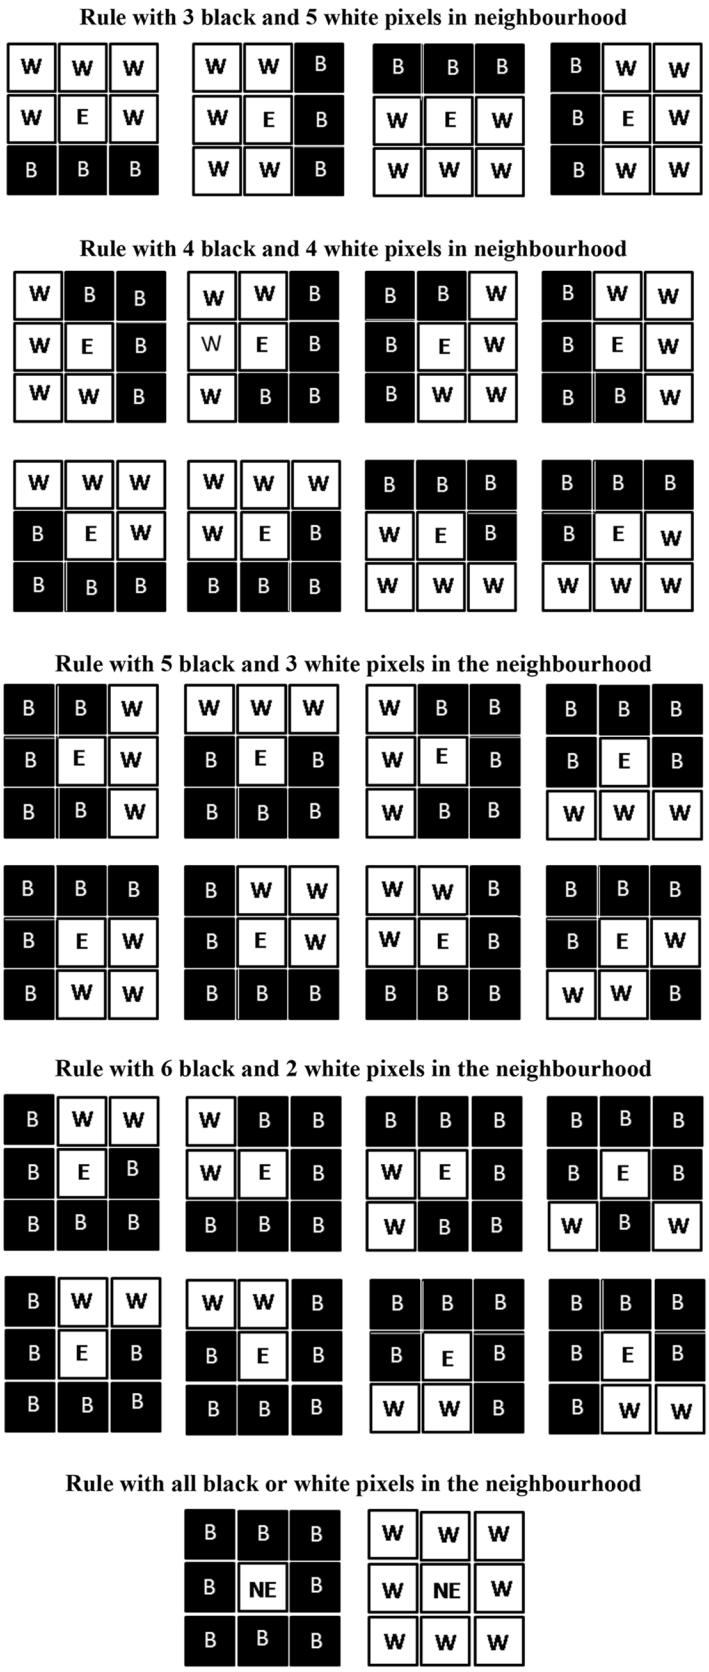

Fig. 8 Fuzzy rules black (B), white (W) and edge (E) and non-edge (NE)

The enhanced image can be written as

$$\hat{I}_s = \gamma(\hat{I}_n - G_n) + G_n \tag{11}$$

$$\hat{I}_s = \gamma[a_i G_n + b_i - G_n] + G_n \tag{12}$$

$$\hat{I}_s = [\gamma(a_i - 1) + 1]G_n + kb_i \tag{13}$$

The Gaussian 5×5 kernel is applied as filter for the removal of noise, with kernel as

$$\frac{1}{159}\begin{bmatrix} 2 & 4 & 5 & 4 & 2 \\ 4 & 9 & 12 & 9 & 4 \\ 5 & 12 & 15 & 12 & 5 \\ 4 & 9 & 12 & 9 & 4 \\ 2 & 4 & 5 & 4 & 2 \end{bmatrix}. \tag{14}$$

The Gaussian kernel is used in method M_3 only.

5 Results

This section presents the edge detection results under the considered method. The simulation is performed in MATLAB software. For performance evaluation various edge detection measures are considered as described below:

5.1 Edge detection performance measures

It is not easy to define the general-purpose evaluation for edge detection, as some edges are missed, some are falsely accepted, and some alters their positions. Before going into detail of edge detection method, let us consider basic properties and concept of edge detection. Throughout the paper we have defined, ground truth image as (I_{gt}) and edge detected image as (I_{ed}). Let the quality measure is denoted by Q and property as (P) then following properties must be satisfied:

Symmetry (P_1): $Q(I_{gt}, I_{ed}) = Q(I_{ed}, I_{gt})$

Ideal solution (P_2): $I_{gt} = I_{ed}$

Sensitivity to noise (P_3): if any pixel (p) does not belong to ground truth (I_{gt}) or edge detected image (I_{ed}) i.e., $p \notin (I_{gt} \cup I_{ed})$, then

$$Q(I_{gt}, I_{ed}) < Q(I_{ed} \cup \{p\}, I_{gt})$$

Sensitivity to improvement (P_4): if $p \in I_{gt}$ and $p \notin I_{ed}$, then

$$Q(I_{gt}, I_{ed}) < Q(I_{ed} \cup \{p\}, I_{gt})$$

First property is self explanatory, second property state that there is only one optimal solution. Third and fourth properties indicate that inclusion of correct and in-correct pixels will decrease or increase error respectively. However, these four properties are not good enough to describe edge detection as to include falsely excluded important edge sometime extra pixels are accepted. As considering $p \notin I_{gt}$ and to include p in I_{ed} will increase un-avoidable error. In edge detection the main requirements are the correct identification of edge pixels and also the correct location of edge pixels.

We classify the positives pixels as edges when the classification is binary. We can classify pixels edge into four unique classifications with the condition that ground truth is present. These four classes are: true positive (TP), false positive (FP), true negative (TN) and false negative (FN). Due to the fact that not a large portion of the pixels are edges, there will be an issue of imbalanced binary classification (Chawla et al. 2004), where the dominating class will be the negative class.

The issues related with the position of pixel can be solved with the help of the spatial tolerance during the matching of the edge pixels as the factor, which decides whether the pixel classification is accurate or not, is the least alteration in the position of the pixel. Normally, we cannot assume an edge pixel as fully accurate or not, relying upon the way that it is found at t or t+1 pixels from the true edge. According to the Liuand Haralick, a quality measure is exact in the event of small changes in value reflects small variations in the detect (Liu and Haralick 2002). The measures such as F-score, and χ^2 test, are precise when pixels positions are exact however fall flat when pixels position changes. These issues prompted penalizing an edge pixel relying upon its separation to a true edge, which encourages the concept of distance based Edge Measures (EMs).

5.2 Correlation coefficient

The correlation coefficient is obtained by means of the equation (Van Heel 1987)

$$|\rho| = \frac{\text{cov}[I_{gt}, I_{ed}]}{\sqrt{Var[I_{gt}]Var[I_{ed}]}}. \tag{15}$$

Under perfect matching $|\rho|$ is one theoretically lowest value is zero. This metric satisfies properties P_1 and P_2.

5.3 Pratt's figure of merit (FoM)

The Pratt's figure of merit (FoM) evaluates edge location exactness in edge detected image in comparison to ground truth image, by measuring the displacement of edge points that are detected from an ideal edge. The FoM is characterized by (Wesolkowski et al. 2000)

$$FoM = \frac{1}{\max(I_{gt}, I_{ed})} \sum_{i=1}^{I_{ed}} \frac{1}{1 + \mu d^2(p, I_{gt})} \tag{16}$$

Here, I_{gt} is ideal edge points (ground truth), I_{ed} is edge points detected, d is displacement of detected edges from ideal edges, μ is scaling constant.

It is essential to note that these measurements binarize information before assessing images; this implies assessment is done over images that have lost data. The above mentioned metrics return esteems in the vicinity of 0 and 1, where 0 would imply that we have no similarity between detected image and reference image, and 1 implying that high closeness was detected, or in other words, each of the pixels present in one image edges are recognized at the same place in other image.

5.4 Structure similarity image metrics (SSIM)

SSIM completes a greatly improved activity at measuring subjective image quality in comparison to MSE or PSNR. At a high state, SSIM endeavors to estimate the adjustment in luminance, contrast, and structure in a picture. The SSIM is given by (Hore and Ziou 2010)

$$SSIM(I_{gt}, I_{ed}) = \frac{(2\mu_{gt}\mu_{ed} + k_1)(2\sigma_{gted} + k_2)}{(\mu_{gt}^2 + \mu_{ed}^2 + k_1)(\sigma_{gt}^2 + \sigma_{gt}^2 + k_2)} \tag{17}$$

where, μ is mean, σ^2 is variance, σ is cross-correlation term and rest terms are fixed constants.

5.5 Hausdorff distance (HoD)

Considering two images $I_{gt}=\{a_1, \ldots,a_n\}$ and $I_{ed}=\{b_1, \ldots,b_n\}$, the Hausdoff distance calculated as (Ma and Grimson 2005):

$$\begin{aligned} &H(I_{gt}, I_{ed}) = \max(d(I_{gt}, I_{ed}), d(I_{ed}, I_{gt})) \\ &\text{Where} \quad d(I_{gt}, I_{ed}) = \max_{a \in I_{gt}} \min_{b \in I_{ed}} ||a - b|| \end{aligned} \tag{18}$$

The function $d(I_{gt}, I_{ed})$ is the directed Hausdorff distance from I_{gt} to I_{ed}. This method is based on distance among the points, and lesser distance means more closeness between the images.

5.6 Euclidiean distance (E_D)

The Euclidian distance between two images is evaluated as (Nadernejad et al. 2008)

$$E_D(I_{gt}, I_{ed}) = \frac{1}{ij} \sum_{m=0}^{i-1} \sum_{n=0}^{j-1} \left| I_{gt}(m,n) - I_{ed}(m,n) \right|^2 \tag{19}$$

5.7 Average point-to-set distances (D_K)

The average distance from the edge pixels in the image under consideration to those in the ground truth is obtained as (Peli and Malah 1982)

$$D_K = \frac{1}{I_{ed}} \sqrt[K]{\sum_{p \in I_{ed}} d^K(p, I_{gt})} \tag{20}$$

We have considered only one image Lena along-with the ground truth image which contain ideal edge to cover vast varieties of results.

5.8 Baddeley's delta metric (BDM)

Baddeley's delta metric (BDM) is modified form of the Hausdorff distance (Ma and Grimson 2005). It is based on the distance between the elements of each of the sets, and expressed as (Lopez-Molina et al. 2017)

$$\mathrm{B}_f^K = \left[\frac{1}{|P|} \sum_{p \in P} \left| fd(p, I_{gt}) - fd(p, I_{ed}) \right|^K \right]^{1/K}, \tag{21}$$

f is a function which is concave in nature, and modulates the point to point distance.

In Fig. 9a original Lena image is shown, while varying patch radius from r = 16,32,64 and 128, while keeping ε to a fixed level of 0.01 and γ equals 5 the obtained results are shown in Fig. 9b–e. the size of local patch is considered to be $(2r+1)\times(2r+1)$ For smaller radius, block size is smaller, and sharpening takes place in local patches, therefore edges becomes sharper but discontinuity points increases thus sharpness quality is not good, as we increase the radius, the sharpness in image is relatively more uniform, and for $r=64$ and 128 the sharpness in images is of good quality.

The above experiment is repeated again with $\varepsilon = 0.001$, while keeping other parameters fixed, the effect of regularization parameter can be observed the mean variance of Lena image under consideration is 0.0256 therefore the effect of regularization parameter (ε) is negligible and image quality does not alter significantly.

In Fig. 10, image enhancement for various values of γ is shown, here as γ increases the sharpness increases, but for larger values of γ the quality of the images changes considerably as compared to original image. Moreover a significant variation in the colours is also observed. It can be observed (marked region in original image) from the figures that the first with the rise in γ edges becomes sharper thereafter they start to diminish, therefore it can also be concluded that both ε and γ have significant effect on the overall quality of the sharpened images.

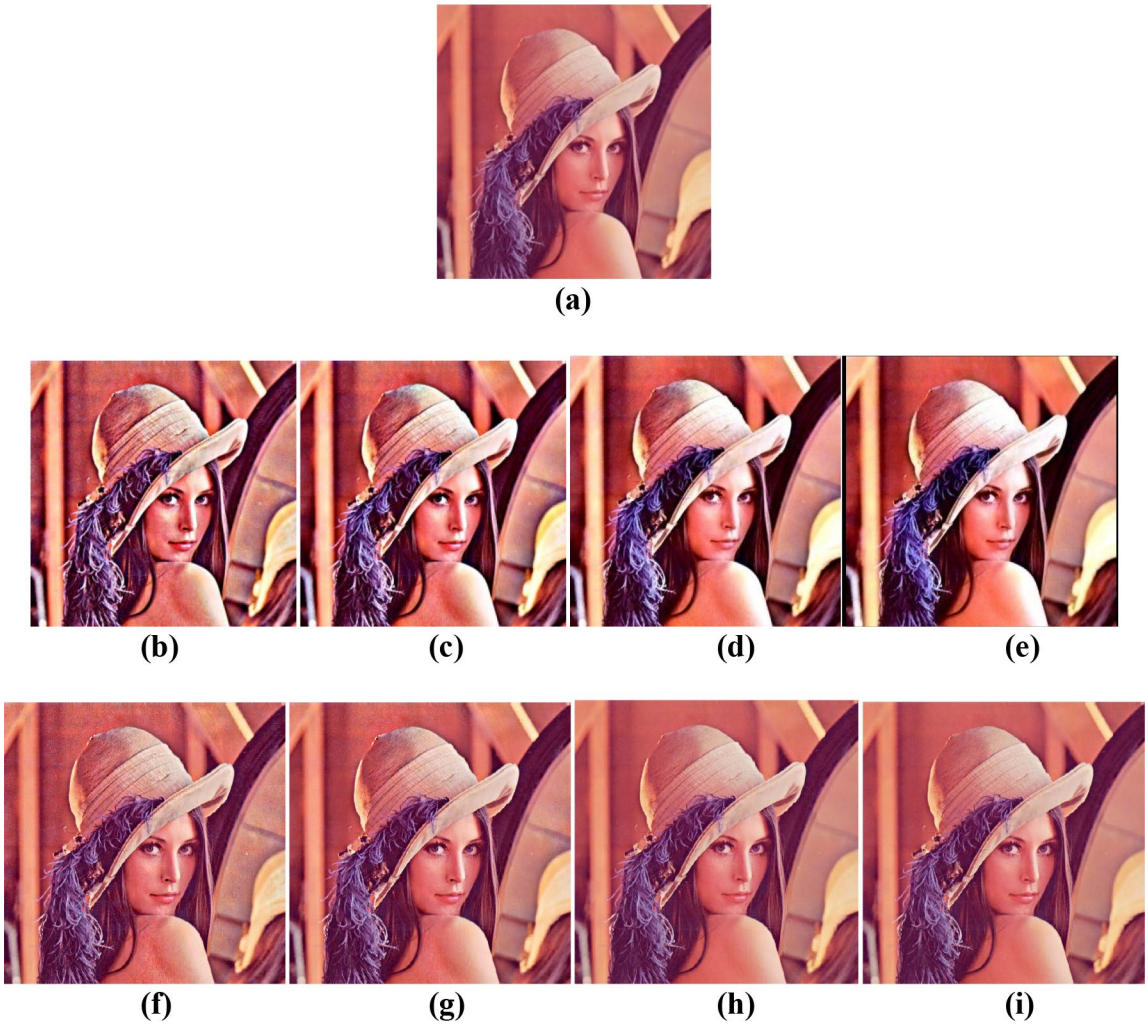

Fig. 9 Image Sharpening using guided filtering (k constant). **a** Original image. **b** $r=16$, $\varepsilon=0.01$, $\gamma=5$. **c** $r=32$, $\varepsilon=0.01$, $\gamma=5$. **d** $r=64$, $\varepsilon=0.01$, $\gamma=5$. **e** $r=128$, $\varepsilon=0.01$, $k=5$. **f** $r=16$,$\varepsilon=0.001$, $\gamma=5$. **g** $r=32$, $\varepsilon=0.001$, $\gamma=5$. **h** $r=64$, $\varepsilon=0.001$, $\gamma=5$. **i** $r=128$, $\varepsilon=0.001$, $\gamma=5$

In Fig. 11, results are presented for methods M_1 and M_2. In Fig. 11a edge detected image using fuzzy logic is shown for Lena image. In Fig. 11b–h results are shown for various values of γ as in Fig. 10. Consider the mark region in Fig. 10a, it is clear from Fig. 11a that fuzzy logic method in alone fail to capture edges in this region. Similarly around hat area noise is also added. As we increases the value of γ from 5 to 100, the noise around hat area diminishes but just above the mark area noise start to increases. These changes are shown in Fig. 12.

In Fig. 13, results are presented for methods M_3. It is clear from the figure that using filtering noise is suppressed significantly, and detected edges are much better as compared to shown in Fig. 11.

The discussion made above is based on human visualization. However, shifting in pixel positions cannot be identified using human vision system. Moreover, the regularization term also lead to the shifting of pixels. Therefore, distance based parameters for quality measurements provide the correctness of the chosen methods. In our results we have not done any further processing on detected image to clearly visualize the effect of each method.

In Table 3, listing of parameters results are shown, FoM is least for canny detection with value of 0.297 and it is best for $\gamma=5$, equals 0.483, SSIM for Canny is 0.451 and for $\gamma=20$, equals 0.560, while HoD is best for $\gamma=50$, and equals to 4.44/7, the Euclidian distance is minimum for canny method, which is an expected results as large number of edges are detected by canny method. BDM is least for $\gamma=5$, while it is at maximum for fuzzy method. D_K is best for Canny method. Finally the co-relation co-efficient is best for $\gamma=30, 50$. Therefore it can be inferred from the table that the performance of the fuzzy method in alone is poorest and among the chosen parameters for $\gamma=5$, the obtained results are better than other considered methods. In Table 4, results are compared for methods M_1 and M_3. Obtained results have

Fig. 10 Image sharpening using guided filtering (γ varying). **a** Original Lena image. **b** $r=64$, $\varepsilon=0.01$, $\gamma=5$. **c** $r=64$, $\varepsilon=0.01$, $\gamma=10$. **d** $r=64$, $\varepsilon=0.01$, $\gamma=20$. **e** $r=64$, $\varepsilon=0.01$, $\gamma=30$. **f** $r=64$, $\varepsilon=0.01$, $\gamma=50$. **g** $r=64$, $\varepsilon=0.01$, $\gamma=75$. **g** $r=64$, $\varepsilon=0.01$, $\gamma=100$

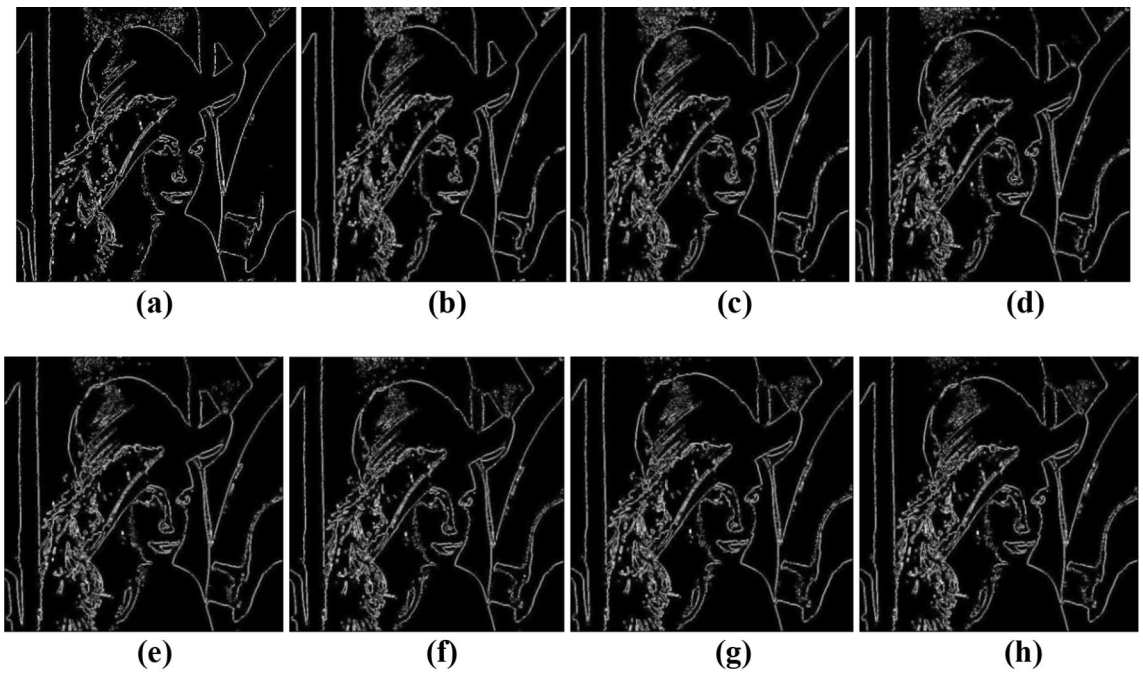

Fig. 11 Edge detected images **a** fuzzy logic, **b** M_2, $\gamma=5$, **c** M_2, $\gamma=10$, **d** M_2, $\gamma=20$, **e** M_2, $\gamma=30$, **f** M_2, $\gamma=50$, **g** M_2, $\gamma=75$, **h** M_2, $\gamma=100$

shown similar trend but obtain results are much better in comparison to the results in Table 3. In Table 4, FoM is maximum for $\gamma=20$, SSIM is maximum for $\gamma=30, 50$. HoD is maximum for $\gamma=50$. Still these performance measures are indicative, and do not provide clear information about exact edge detection mechanism. Therefore, in most of the recent research (Begol and Maghooli 2011; Mehrara et al. 2009; Zhang et al. 2009; Mathur and Ahlawat 2008; Marmanis

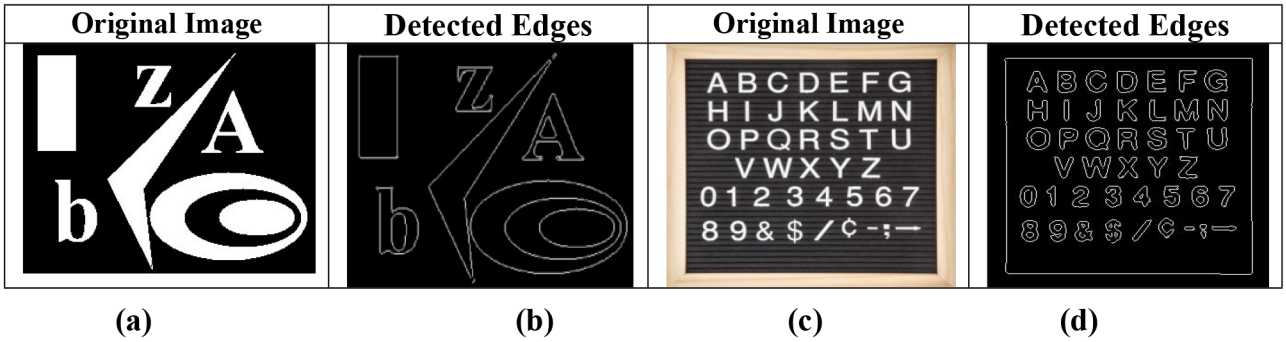

Fig. 17 Edge detection using fuzzy logic **a** original image, **b** detected edges, **c** original image, **d** detected edges

However, from (b) to (e) it is clear that as we increase sharpness the edges can be detected more correctly. From Fig. 15, it can be visualized that as sharpness increases; image detail is more clearly visible. Same effect is also obtained in detected edges.

In Fig. 16, results are obtained for tulip images and obtained response show similar trend as in Figs. 14 and 15. It is also clear from Figs. 15 and 16, sometime more sharpness leads to the generation of noise; therefore image should be sharpened to a level where effect of noise is minimal. However, if this noise is dominant, than this additional noise can be suppressed using filters as used in other edge detection methods (Shah 1997).

In the above discussed results it is found that fuzzy logic based method fails to detect some of the edges. Therefore, to check the validity of the considered fuzzy logic structure, in Fig. 17 results are generated for two images [(a) and (c)] where, edges are clearly visible, and it is found that considered fuzzy logic structure correctly detect all the edges in both the images. Thus, in case of clear edges images fuzzy logic structure gives accurate results.

In Fig. 18, animal alphabet image is taken which has more complex edges as compared to images considered in Fig. 17. Fuzzy logic based method fails to detect 'Tiger' and 'Orangutan' shapes and also letter mark on the animals are not detected. As we increase sharpness edges and letters are detected more clearly. In Fig. 19, zoomed version of fuzzy logic and sharpened image $\gamma = 20$ is shown, the name of animal is not clearly detected with fuzzy design, while with proposed method edges of both animal name and letter mark

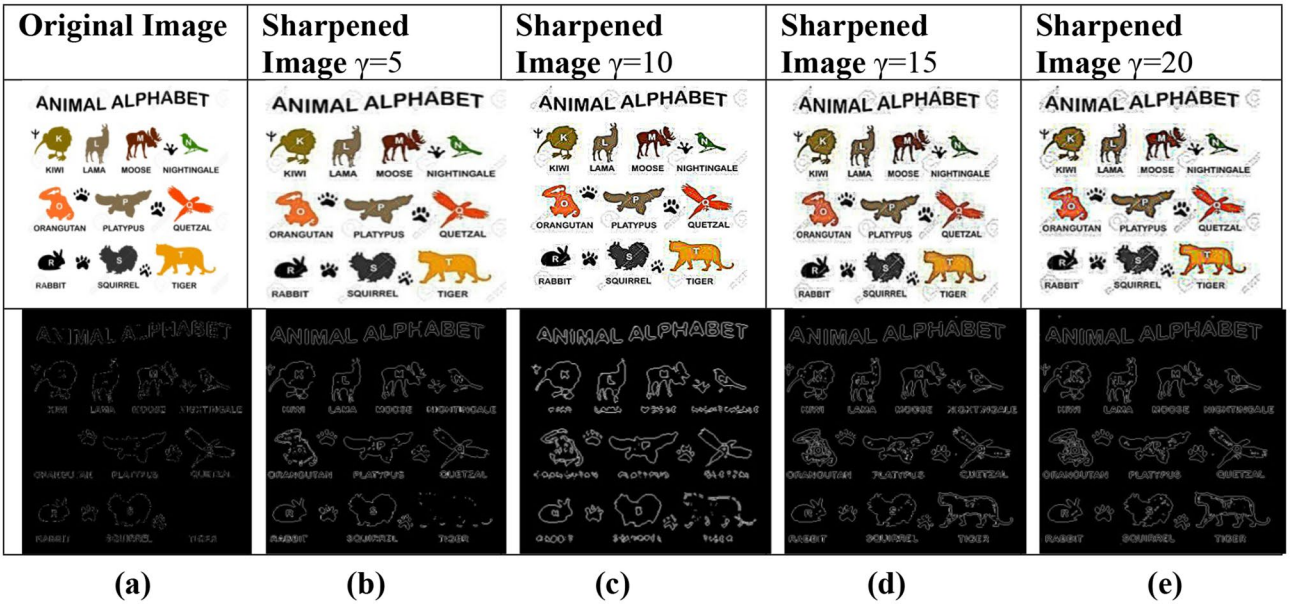

Fig. 18 Animal alphabet image **a** fuzzy logic, **b** M_3, $\gamma = 5$, **c** M_3, $\gamma = 10$, **d** M_3, $\gamma = 15$, **e** M_3, $\gamma = 20$

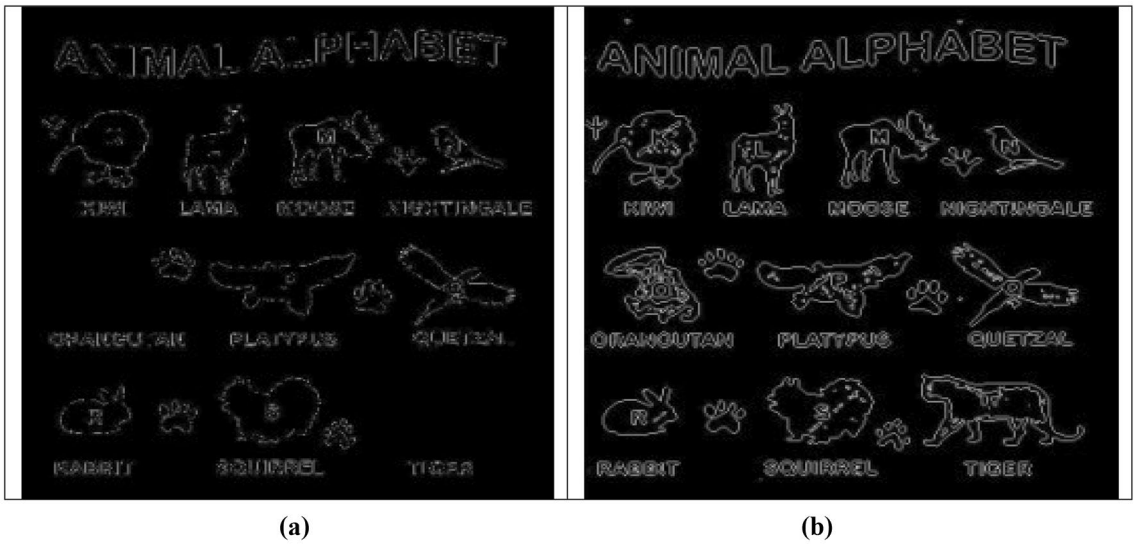

Fig. 19 Zoomed version of **a** Fig. 18a, **b** Fig. 18e

on the animals are detected. With our design claws and paws edges are clearly visible.

Finally, we can conclude that the proposed method is superior to fuzzy logic based method, and it overcomes the limitations of fuzzy logic structure. The membership function considered in this work is same as in previous works (Angelov et al. 2011; Sargano et al. 2017; Rogowska 2000; Rangarajan 2005; Alshennawy and Aly 2009; Aborisade 2011). However, to overcome the limitations of fuzzy logic method, further research can be carried out in developing fuzzy rules which are developed using human expert system and in choosing appropriate membership function.

6 Conclusions

This paper presents an edge detection method based on fuzzy logic, sharpening and filtering. The main aim of the paper is to design an edge detection method where edges can be controlled without deteriorating the considered image. It has been found that fuzzy logic method in alone falsely rejected some of the edges, noise is also added. To deal with this we have shown that sharpening of image can be done, which improves the results significantly. It is also shown that sharpening itself depends on parameters r, ε and γ, and these parameters should be chosen efficiently to get desired results. It is also notable that the regularization parameter (ε) should be kept within the sub-range of image variance as regularization parameter shift the pixel positions. It is also shown that noise generated due to fuzzy process can be significantly brought down by using Gaussian filter. The obtained results are compared with various statistical measures and it has been found that proposed methods M_2 and M_3 performs better in comparison to method M_1.

ABSTRACT

Fluorescence (FL) quenching of 5-aminoquinoline (5AQ) by Ag^+ ions has been studied in acetonitrile (ACN) using steady-state and time-resolved fluorescence techniques. In the absence of Ag^+ ions, FL shows a single band assigned to the intramolecular charge transfer (ICT) state. The FL intensity of 5AQ gradually reduces on the successive addition of Ag^+ ions to the solution containing 5AQ. The decrease of FL intensity is nearly ~ 17 fold in the presence of 60 mM Ag^+ ions. Together with the decrease in FL intensity, the FL band maximum is red-shifted. The Stern-Volmer plot has been employed to determine the quenching constant. The nature of quenching has been stated based on the decrease of FL intensity and lifetime in the presence of metal ions. Also, the Benesi-Hildebrand relation has been used to explore the binding mechanism between 5AQ and Ag^+ ions. Thus, 5AQ displays high affinity for Ag^+ ions over other competitive metal ions (Cu^{2+}, Ca^{2+}, Pb^{2+}, Fe^{2+}, Li^+, K^+). Therefore, the present system emerges to be quite important in sensing of Ag^+ ions in an aprotic environment in a concentration range of 4 μM to 60 mM.

1. Introduction

Quinoline and its derivatives have been an intriguing class of molecules in the field of organic and pharmaceutical chemistry and widely used as a prototype compound to many drugs. Multifarious experimental and theoretical researches in photophysics and photochemistry of quinoline-based compounds have found potential applications in preparation of various drugs and dyes. Photoexcited relaxation processes of variously substituted quinolines especially amino- and hydroxyl-quinolines have been considered broadly over the past few years [1–18]. In recent literature, quinoline fused heterocyclic derivatives have been developed that possess diverse biological activities, i.e., anticancer, antimicrobial, antimycobacterial, anticonvulsant, anti-inflammatory and cardiovascular activities [19].

Aminoquinoline (AQ) is an imperative group of fluorophore that plays a momentous role in supramolecular chemistry, electron transfer process, charge transfer, host-guest systems and sensing applications. Photoexcitation to the lowest excited state is usually associated with intramolecular charge transfer (ICT) from amino group to the aromatic ring in these compounds hence producing the ICT state. Enol to keto conversion occurs via excited state proton transfer (ESPT) reaction following photoexcitation. The position of NH_2 group in the quinoline ring and the surrounded solvent molecules/polymers influences the excited state properties of aminoquinolines [5,8–15].

The FL quenching-based studies have been an area of fundamental interest from decades since this can be valuable in elucidating the localization of fluorophores in protein and membrane and their absorptivity to quenchers. Quenching can occur through various mechanisms and become progressively significant due to its applications in fluorescence sensing and drug delivery systems. An array of substances like, metal ions, halides, molecular oxygen, amines etc. can act as quencher [17,18]. Quinoline based fluorescent sensors are extensively used to determine the fluorescence intensity variations and shift of fluorescence wavelength [19–30]. As an example, when halide ions come in contact with excited state 6-methoxyquinoline and 8-methylquinoline, the FL intensity of these probe molecules gets quenched regularly and follows the diffusional quenching mechanism [16–18], and acts as an optical sensor.

In heterocyclic quinoline, the nitrogen atom can act as a chelating site towards metal ions [20]. Photoinduced electron transfer (PET), intramolecular charge transfer (ICT), twisted intramolecular charge transfer (TICT), fluorescence resonance energy transfer (FRET), chelation enhancement quenching effect (CHEQ) or chelation-enhanced fluorescence effect (CEFE) are important mechanisms of fluorescence sensing in the design of quinoline-based fluorescence sensors [20–30]. The development and design of a fluorescent sensor for the variety of

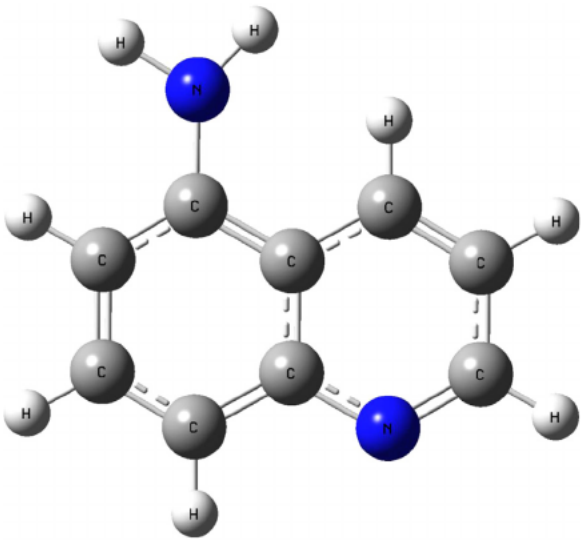
metal ions has acquired attention due to their essential role in medical, environmental and biological applications [22–30]. The FL of ligand may be quenched or enhanced by coordination depending on the influence of the metal ions on the non-radiative processes competing with the radiative process, i.e., FL. The FL resulting from the complex formation is a consequence of numerous factors; the relative position and behavior of the lower electronic excited state of organic ligands and those of metal ions, the heavy atom effects, the structural rigidity and the paramagnetic character of ions [31].

Silver ion, like other heavy metal ions; copper, zinc, lead, mercury, etc., is one of the indispensable toxic metal and has been broadly employed in chemistry, pharmacy, electrical industry, photographic and imaging industry [32–40]. The bioactive silver has gained interest in the domain of biology, such as antimicrobial activity, disinfectant, antibiotics and sterilization even at low concentration level [34]. However, in few cases, rapid absorption of Ag^+ ions causes bioaccumulation, toxicity and irreversible darkening of skin along with disruptive renal and neurological function [34,35]. Furthermore, Ag^+ ions can disable sulphydryl enzymes and bind with imidazole, amine, and carboxyl groups of different metabolites [35,37,41,42]. Since the d^{10} electronic configuration of Ag^+ ions is generally known as a fluorescence quencher following electron transfer and intersystem crossing processes, thus Ag^+ ions could be detected by chemosensors via fluorescence quenching mechanism [28]. Recent reports on fluorescent sensors for detection of Ag^+ ions comprise different fluorophores such as pyrene, oxadiazole, phenanthroline, coumarin, quinoline, gold nanoparticles etc [32–40].

In the present work, we have commenced a detailed study of FL quenching of 5AQ by Ag^+ ions, to comprehend the nature of possible quenching mechanism. Steady-state and time-resolved measurements confirm the quenching mechanism of probe 5AQ in the presence of Ag^+ ions. With the addition of Ag^+ ions, the FL maximum is red-shifted ($\sim$ 46 nm) with $\sim$ 17 fold quenching of fluorescence intensity. Interestingly, no fluorescence quenching and wavelength shift are noticed on addition of variant metal ions (Ca^{2+}, Cu^{2+}, Li^+, K^+, Fe^{2+}, Pb^{2+}). The molecular structure of 5AQ is given in Scheme 1.

2. Experimental section

5-Aminoquinoline (5AQ) purchased from Aldrich chemical company Inc., U.S.A. (with 99% purity) was used as received and matched with the reported FL spectrum to confirm its fluorescence purity (to make sure that there is no impurity). Silver nitrate and all other metal salts were obtained from Loba Chemie and SRL Pvt. Ltd. (with 98–99% of purity) and used as received. Spectroscopic or HPLC grade solvents were used for the present study. The purity of compounds was established by agreement of corrected excitation spectra with the electronic absorption spectra. The stock solution of $AgNO_3$ (0.1 M) was prepared from the stock solution of 5-aminoquinoline (10^{-4} M). From this solution, diluted solutions of $AgNO_3$ were prepared. This ensured that the probe concentration did not change on the addition of $AgNO_3$. Freshly prepared samples at room temperature were used in the present study. A similar method was used during preparation of diluted solutions of other metal ions.



Scheme 1. Molecular structure of 5-aminoquinoline.

2.1. Instrumentation

Steady-state absorption spectra were recorded by UV–visible Double beam spectrophotometer (Systronics Model no: 2203). Fluorolog-3 spectrofluorometer (Horiba Jobin Yvon Inc.) accompanied by available analysis software have been used to record and analyze the excitation and emission spectra. 450 W xenon lamp was used as the excitation source. Transparent quartz cuvette was used for the absorption and emission measurements and frontal geometry was used in recording emission to avoid inner filter effect. For all the measurements, excitation and emission slit widths were chosen about 2.0 nm, and the excitation wavelength was 345 nm. Time-correlated single photon counting (TCSPC) system (DeltaFlex-01-DD, Horiba Jobin Yvon IBH Ltd.) coupled with DeltaDiode (340 nm) and PMT (PPD 850) was used for fluorescence decay measurements and least square fitting and reconvolution methods were used to analyze the data. Instrumental response function was measured using Ludox scatterer. The numbers of counts in the peak channel were at least 10,000.

3. Results and discussion

Absorption, fluorescence (FL), FL-excitation spectra and FL-decays were measured for 5AQ in acetonitrile (ACN) in the absence and presence of varying concentration of silver ions (Ag^+) at room temperature.

Fig. 1 shows absorption spectra of 5AQ in ACN in absence and presence of various concentrations of Ag^+ ions. The absorption maximum appeared at 343 nm, and is ascribed to the $\pi \rightarrow \pi^*$ transition of quinoline group. In presence of a small concentration of Ag^+ ions, keeping the solute concentration fixed the optical density (absorbance) of 5AQ decreases, which is accompanied by broadening of the absorption spectrum. The corresponding optical density decreases from 0.65 to 0.45 with increasing concentration of Ag^+ ions from 0.0 to 7.0 mM. The change in spectral broadening and absorption maximum

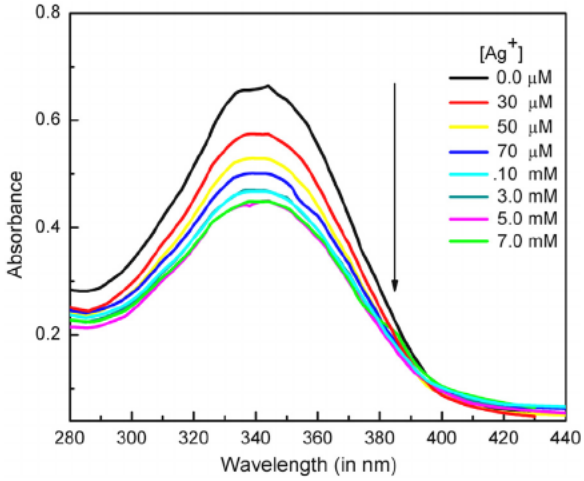


Fig. 1. Absorption spectra of 5AQ (1×10^{-4}M) in ACN in the presence of various concentration of Ag^+ ions.

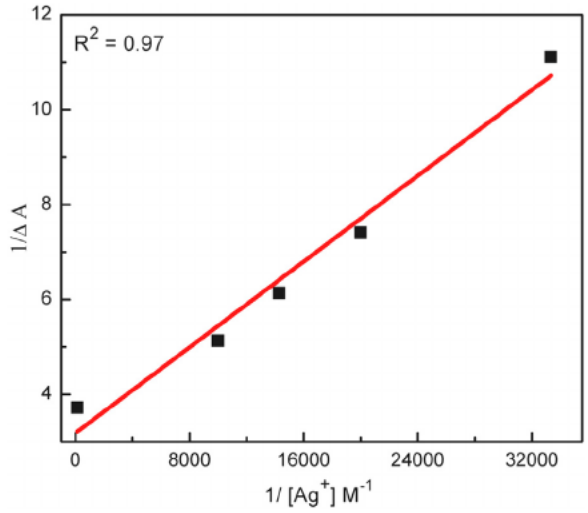

Fig. 2. Benesi-Hildebrand plot of 5AQ in ACN with increasing concentration of Ag^+ ions.

upon addition of Ag^+ ions suggests that there is a ground state complexation between 5AQ and Ag^+ ions. To understand the formation of complex between the probe and the quencher and to determine the binding constant, the well-known Benesi-Hilderband [32] Eq. (1) was applied.

$$\frac{1}{(A - A_0)} = \frac{1}{(A_{max} - A_0)} + \left[\frac{1}{K[M^{n+}]} + 1\right] \quad (1)$$

where A is the absorbance of 5AQ in presence of various concentration of Ag^+ ions, A_0 is the absorbance of 5AQ, A_{max} is the absorbance of 5AQ in the presence of the maximum concentration of Ag^+ ions, $[M^{n+}]$ is the concentration of metal ion and K is the binding constant. A plot between $1/\Delta A$ vs. the inverse of Ag^+ ions concentration is linear (Fig. 2) and demonstrates the 1:1 complex of 5AQ: Ag^+. The binding constant (K) determined from the ratio of intercept/slope of the plot comes out to be $1.407\times10^4 M^{-1}$.

Fig. 3(a,b) shows the fluorescence spectra of 5AQ in ACN in the absence and presence of varying concentration of Ag^+ ions at room temperature. The fluorescence maximum is around 482 nm upon excitation at 345 nm and is independent of excitation wavelength. The fluorescence of 5AQ reduced upon addition of small amount (about 4 μM) of Ag^+ ions. While increasing the concentration of Ag^+ ions from 4 μM, the fluorescence intensity is gradually decreased, as shown in Fig. 3(a). The FL intensity diminished nearly 17 folds in the presence of 60 mM concentration of Ag^+ ions. Thus, the FL of 5AQ is quenched significantly in the presence of Ag^+ ions in ACN. In addition to quenching, the FL spectrum is shifted towards red with the addition of Ag^+ ions. The red shift in the FL spectrum is about 46 nm for the highest concentration of Ag^+ ions taken in the study (60 mM), as shown in (Fig. 4). The excitation spectrum of 5AQ in ACN was found to be independent of monitored emission wavelength and exhibits well defined L_a and L_b bands and resembles to the absorption spectrum [10,11,13]. Fig. S1(a) shows the overlapped excitation spectrum of 5AQ in ACN on successive addition of Ag^+ ions. The excitation spectrum shifted from 345 nm to 360 nm with the addition of Ag^+ ions as shown in Fig. S1(b). Together with the spectral shift, the intensity of excitation spectrum gradually decreases with increasing concentration of Ag^+ ions. The change in the excitation spectrum is in agreement with that observed in absorption spectrum and demonstrates the ground state complex formation between Ag^+ ions and 5AQ in ACN.

The FL maximum shifted from 482 nm to 528 nm while changing the concentration of Ag^+ ions from 0.0 μ M to 60 mM. A linear relationship has been observed between the ratio of FL intensity at two

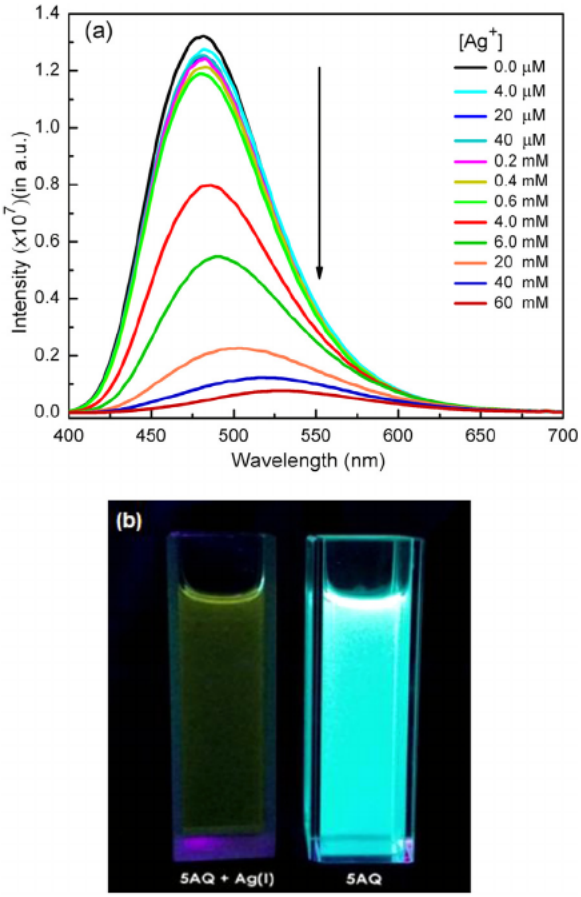

Fig. 3. (a) Fluorescence spectra of 5AQ $(1 \times 10^{-4}\ M)$ in ACN upon addition of various concentration of Ag^+ ions at excitation wavelength of 345 nm. (b) Fluorescence of 5AQ with UV light irradiation in the presence (left) and absence (right) of Ag^+ ions.

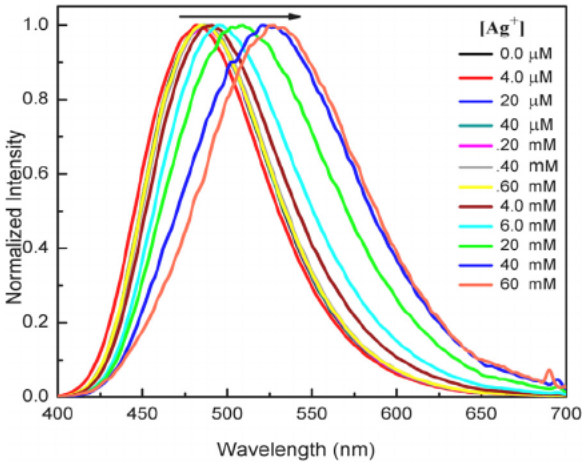

Fig. 4. Normalized fluorescence spectra of 5AQ in ACN in presence of various concentrations of Ag^+ ions.

wavelengths (I_{530}/I_{480}) and Ag^+ ion concentration (Fig. 5). In pure ACN, 5AQ shows a Stokes shift of ~ 8322 cm^{-1} and increases upto 10,058 cm^{-1} upon addition of Ag^+ ions (60 mM). The relation between Stoke's shift (Table 1) and Ag^+ ions concentration is shown in Fig. S2. This further demonstrates formation of complex in the ground state.

To understand the nature of FL quenching, the decrease of FL intensity is plotted as a function Ag^+ ions concentration following the so-called Stern-Volmer (S-V) relation Eq. (2) and modified S-V relation Eq.

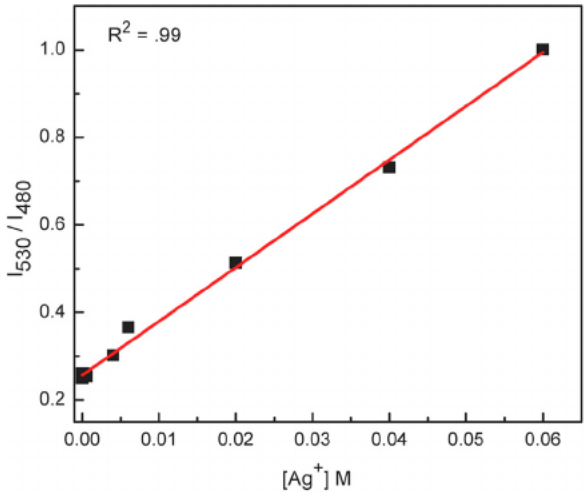

Fig. 5. Plot of the ratio of the intensity (I_{530}/I_{480}) of 5AQ in the presence of various concentration of Ag^{+}ions.

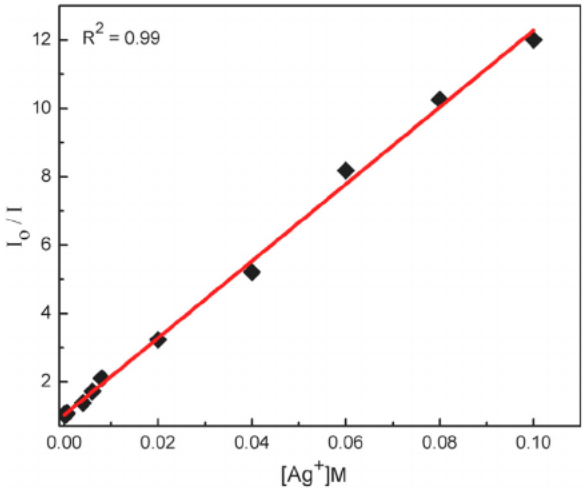

Fig. 6. The Stern-Volmer plot between the relative fluorescence intensity of 5AQ and Ag^{+} ions concentration.

6.0 mM	344	490	8661
8.0 mM	344	495	8868
20 mM	344	502	9149
40 mM	344	525	10,019
60 mM	344	528	10,058

(3):

$$\frac{I_0}{I} = \frac{\tau_0}{\tau} = 1 + k_q\tau_0[Q] = 1 + K_{SV}[Q] \quad (2)$$

$$\frac{\left[\frac{I_0}{I} - 1\right]}{[Q]} = (K_{SV} + K_g) + K_{SV}K_g[Q] \quad (3)$$

where I_0 and I are the fluorescence intensities in the absence and presence of the quencher, respectively. [Q] is the quencher concentration and K_{SV} ($k_q\tau_0$) is the S-V constant, which represents the efficiency of fluorescence quenching. k_q is the bimolecular constant, τ_0 is the decay time in absence of quencher and K_g is ground state association constant. The value of K_{SV} can be determined from the slope of the graph displaying dependence of intensity or decay time on [Q], as expressed by Eq. (2). The obtained S-V plot for 5AQ in the presence of Ag^{+} ions is linear with Adj R^2 = 0.99, as shown in Fig. 6. The FL intensity may reduce either due to dynamic or static quenching, even with the linear relation of S-V plot. Thus, the steady-state spectral analysis only is not sufficient to confirm the nature of quenching. When decay time does not change with a decrease in fluorescent intensity, only static quenching is present i.e., K_{SV} = 0. A non-fluorescent complex is formed between the fluorophore and the quencher in case of quenching being static. The other case is that of dynamic quenching (i.e., K_g = 0) in which quenching response competes with emission in timescale and can be governed by the diffusion of quencher in any medium and its collision with excited probe molecule. These two quenching effects i.e., dynamic and static quenching, involve molecular interaction between the fluorophore and quencher. Simultaneous occurrence of static and dynamic quenching results in the positive deviation of plot I_0/I versus [Q] as Eq. (2) follows quadratic dependence with quencher concentration. The relation, $[I_0/I - 1]/[Q] = (K_{SV} + K_g) + K_{SV}K_g[Q]$ gives K_g after substituting the K_{SV} value retrieved from the data [1,17,18].

To ascertain the fluorescence quenching mechanism of 5AQ by Ag^{+} ions, time-resolved FL experiments were performed for various concentrations of Ag^{+} ions. FL decays were collected at λ_{ex} = 340 nm and λ_{em}= 530 nm. The FL decay of 5AQ fits to a bi-exponential function $\alpha_1 \exp(-t/\tau_1) + \alpha_2 \exp(-t/\tau_2)$ in an aprotic solvent (ACN). The term τ_1 and τ_2 are the lifetimes and α_1 and α_2 are the corresponding pre-exponential factors. The fitted lifetime are 1.26 ± 0.2 ns (0.93 %) and 11.60 ± 0.01 ns (99.07 %). The contribution of smaller decay constant is very small (< 1%). As an approximation, the decay fitted single exponential with a lifetime of 11.50± 0.01. Upon increasing the concentration of Ag^{+} ions, the lifetime decreases monotonically. It is interesting to note that, the lifetime component decreases from 11.50 ns to 3.14 ns on addition of 40 mM of Ag^{+} ions. The fitted overlapped decay curves obtained at varying concentrations of quencher are shown in Fig. 7 and the analyzed parameters are summarized in (Table 2). The decrease in FL lifetime plotted as a function of Ag^{+} ions concentration follow the S-V relation Eq. (2) again linearly, as shown in Fig. 8. Thus, the decrease in lifetime and the linear S-V plots demonstrate the dynamic quenching as a predominant mechanism. The value of K_{SV} constant for 5AQ obtained from the slope of the plot (Fig. 6) comes out to be 112.7 M^{-1} and k_q is around 9×10^{9} M^{-1} s^{-1}, respectively.

Furthermore, the absorption and fluorescence spectra of 5AQ in ACN in the presence and absence of different metal ions (Cu^{2+}, Ca^{2+}, Pb^{2+}, Fe^{2+}, Mg^{2+}, Li^{+}, K^{+}) were examined. The fluorescence response of 5AQ in the presence of various metal ions under UV is shown in Fig. S3 of the Supporting information. The FL of 5AQ upon addition of 40 mM concentration of various metal ions is illustrated in Fig. 9. As discussed, the fluorescence intensity of 5AQ is quenched significantly on addition of Ag^{+} ions whereas for other metal ions it shows minimal change. To investigate the interference from other metal ions we further conducted the competition experiment in the presence of 40 mM of various metal ions (Cu^{2+}, Ca^{2+}, Pb^{2+}, Fe^{2+}, Mg^{2+}, Li^{+}, K^{+}) with subsequent addition of 40 mM of Ag^{+} ions, as shown in Fig. 10. These results reveal that the recognition of Ag^{+} ion by probe 5AQ is not significantly influenced by other competitive metal ions. Thus, it is observed that the probe molecule 5AQ has good selectivity for Ag^{+} ions (as compared to the other metal ions under the same condition and concentration) and hence can be used to detect Ag^{+} ions in polar aprotic medium, which

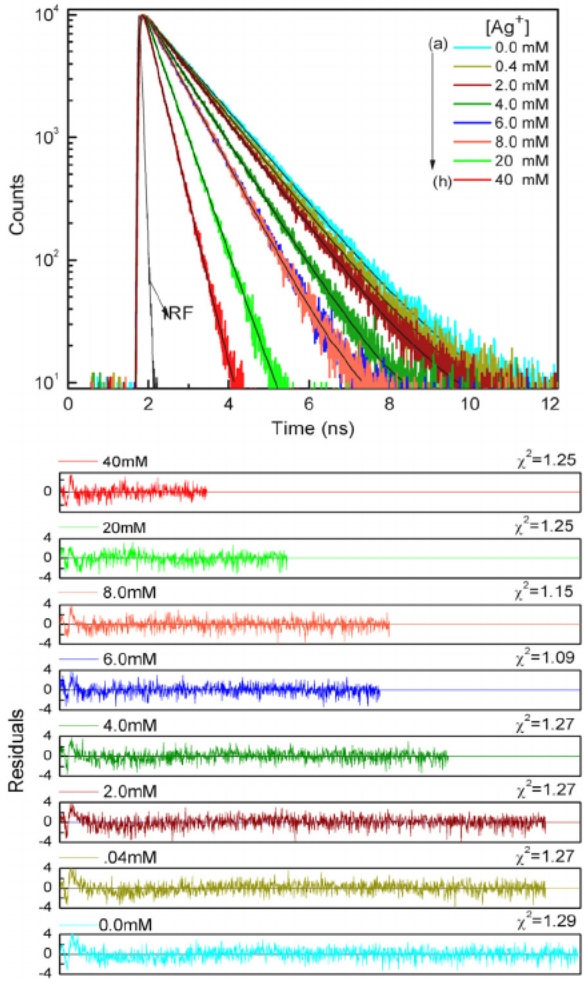

Fig. 7. Overlapped fitted fluorescence decay curves of 5AQ in presence of various concentration of Ag^+ ions and corresponding residuals at λ_{ex} = 340 nm and λ_{em} = 530 nm.

Table 2
Fluorescence lifetime parameters of 5AQ with various concentration of Ag^+ ions at λ_{ex} = 340 nm and λ_{em} = 530 nm.

Concentration of Ag^+ ions	τ (ns)	χ^2	τ_0/τ
0.0 mM	11.50 ± 0.01	1.29	1.0
0.4 mM	10.84 ± 0.01	1.27	1.060
2.0 mM	10.02 ± 0.009	1.27	1.148
4.0 mM	8.64 ± 0.008	1.27	1.331
6.0 mM	7.40 ± 0.09	1.09	1.554
8.0 mM	7.31 ± 0.007	1.15	1.573
20.0 mM	4.65 ± 0.005	1.25	2.473
40.0 mM	3.14 ± 0.004	1.25	3.662

might be due to high-affinity of Ag^+ ions to 5AQ as compared to other metal ions.

As discussed, in the absence of quencher, the FL decay of 5AQ is fitted with a bi-exponential function. The contribution of the shorter component is very small (< 1%) and contribution of the longer component is dominant in the overall decay function. The smaller lifetime component is assigned to the locally excited (LE) state while the longer lifetime component is assigned to the intramolecular charge transfer (ICT) state [10,11,13]. Thus, the ICT is probably responsible for the overall FL. However, there is no rise time component in the FL decay, indicating that ICT may be faster than the resolution of our experimental setup.

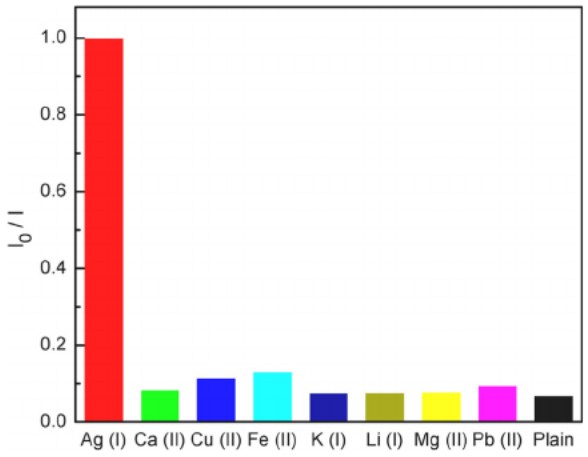

Fig. 9. Fluorescence response of 5AQ in ACN in the presence of various metal ions. The excitation wavelength was 345 nm.

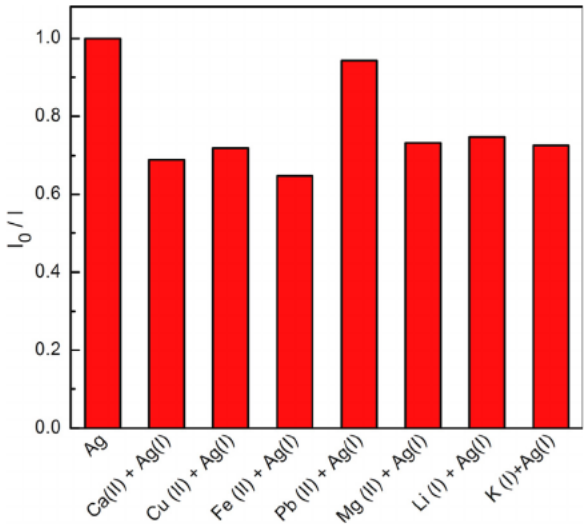

Fig. 10. Fluorescence response of 5AQ (10^{-4} M) in presence of 40 mM of various metal ions with subsequent addition 40 mM of Ag^+ ions to the solution at λ_{ex} = 345 nm.

In the presence of Ag^+ ions, the decay trend is very similar to that in the absence of quencher. However, the observed decay fits well with mono-exponential function with an approximation. The lifetime decreases with increasing the concentration of Ag^+ ions, which indicates that the FL corresponding to the ICT is quenched. This is due to the complexation between 5AQ and Ag^+ ions, as evident from the absorption and excitation spectra. While increasing the concentration of Ag^+ ions, the absorption/excitation intensity decreases and the spectra shift towards red. This may be due to the formation of a complex between 5AQ and Ag^+ ions, which has minimal oscillator strength/absorption intensity. The shift in the FL spectrum may probably be ascribed to the different ICT states formed by the interaction of 5AQ with Ag^+ ions. The decrease of FL lifetime also indicates the decrease of the FL of ICT state formed from the LE state.

Furthermore, it has been classified that metal ions, such as Ag^+ ions, being soft cations, prefer soft donors for complexation [32]. The nitrogen atom of 5AQ is involved in the coordination with Ag^+ ions. The interaction between Ag^+ ions and the nitrogen atom in 5AQ moiety enhances the electron-withdrawing ability of 5AQ that leads to a different state and results in a large red-shifted FL. The donation of the $-C = N$ nitrogen lone pair electrons to the Ag^+ may decrease the fluorescent intensity [21]. Generally, the FL of luminescent ligands is quenched by complexation of the ligand with transition metal ion due to paramagnetic quenching. In this case, the unpaired electrons of the metal ions actively interact with the π electrons of the ligand, providing a path way for inter system crossing from singlet excited state of the ligand to the higher multiplicity states (i.e., triplet state) due to interaction with metal ions [31].

It is important to mention that the present study has been performed in some other solvents also. Since 5AQ shows weak fluorescence in polar protic solvents (water, methanol, ethanol), therefore enhancement in FL intensity is noticed by adding different concentrations of Ag^+ ions. However, a small amount of quenching is observed in DMSO (dimethyl sulfoxide) as compared to that in ACN (acetonitrile) in the presence of Ag^+ ions. Thus, this makes the system attractive for FL quenching/sensing in ACN by Ag^+ ions.

4. Conclusions

In summary, we have studied fluorescence-quenching behavior of 5AQ for Ag^+ ions in ACN, which results in ~ 17-fold decrement in FL intensity upon addition of Ag^+ ions. The lifetime is reduced from 11.5 to 3.14 ns. The large Stokes shifted FL, which produces from ICT state is advantageous to avoid self-absorption and interference from the light source in fluorescence sensing technology. We demonstrate dynamic quenching for all concentration of silver ions used in the study. Stern-Volmer quenching constant (K_{SV}) as $112.7\ M^{-1}$, biomolecular quenching constant (k_q) as $9.8 \times 10^9\ M^{-1}s^{-1}$ and binding constant (K) as $1.407 \times 10^4\ M^{-1}$ have been determined for Ag^+ ions. In addition, 5AQ shows high affinity for Ag^+ ions over other competitive metal ions. Therefore, the proposed system emerges to be quite interesting in sensing/recognition of Ag^+ ions in protic environment in a concentration range of $40\ \mu M$ to $60\ mM$.

6. References

Introduction

- To fulfil the growing demand of clean energy rechargeable batteries are used as energy storage and conversion devices.
- The most commercialized rechargeable batteries are Li-ion batteries.
- In this work, evaluation of Li-ion batteries has been done to determine the battery characteristics[5] which helps in realizing more reliable and safe batteries.
- Two types of battery characterization techniques i.e. Thermal and electrical characterizations has been done.
- Thermal characterization has been obtained using Multiphysics Software.
- Electrical characterization is done using data acquisition software 'LabVIEW' and by interfacing hardware with software system[9].

Simulation using software

Snigdha Sharma

Model geometry and formulation

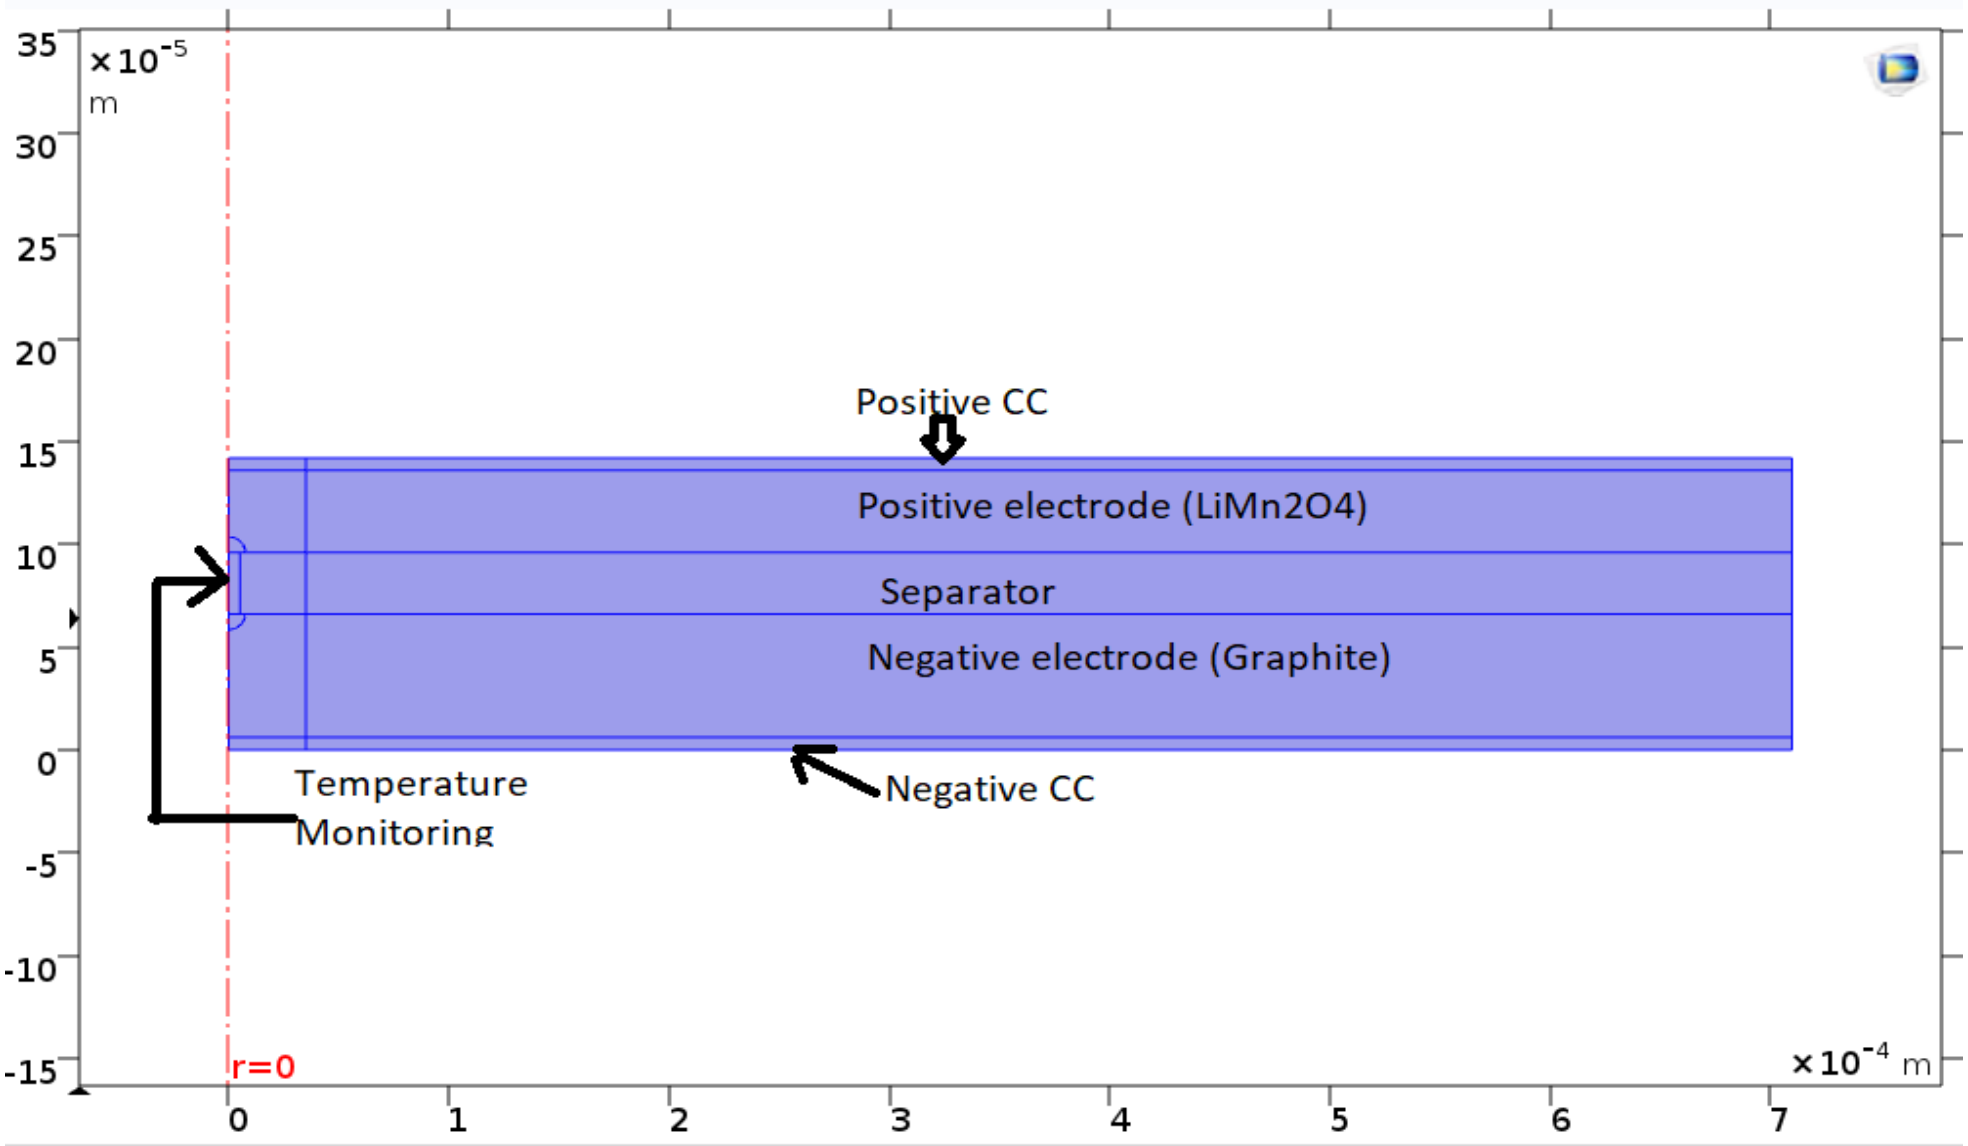

Fig. 1 Geometry of Lithium-ion Battery model

Model parameters

- Model contains 2D axisymmetric domain surrounded by infinite elements, that comprises the pseudo two- dimensional electrochemical structure.
- It allows heat transportation only in one direction.
- Characterization techniques provides thermal performances which contain various parameters for battery model as shown below.

Thermal properties for Battery model

Parameters	$LiMn_2O_4$	Graphite	$LiPF_6$	Aluminum CC	Copper CC
Thermal Conductivity(W(m.k))	3.4	1	0.15	400	238
Young Modulus (Pa)	$4.9*e^9$	$4.1*e^9$	-	$110*e^9$	$70*e^9$
Density (Kg/m^3)	3600	2260	940	8960	2700
Heat Capacity(J/Kg.k)	2500	881	1046	385	900

Measured and Identified Parameters for the Lithium-Ion Battery Model Simulation

Parameter	Units	Value	Description
E_cell	V	3.4	Cell Potential
L_tot	m	$1.42*e^{-4}$	Cell total Thickness
epsl_sep	-	0.4	Porosity of separator
$T_{initial}$	K	328	Initial Temperature
T_{final}	K	395	Final Temperature
Maximum electrodeSOC	SOCmax	0.79	Operational SOC
Minimum electrode SOC	SOCmin	0.02	Operational SOC
Q_B	A*h	12	Battery Capacity

Measured and Identified Parameters for the Lithium-Ion Battery Model Simulation

Parameter	Units	Value	Description
N_layers	-	25	No. of cell layers
kT_batt	L_batt/(L_pos/kT_pos+L_neg/kT_neg+L_pos_cc/kT_pos_cc+L_neg_cc/kT_neg_cc+L_sep/kT_sep)	0.87451 W/(m·K)	Battery thermal conductivity
Rho_batt	(rho_pos*L_pos+rho_neg*L_neg+rho_pos_cc*L_pos_cc+rho_neg_cc*L_neg_cc+rho_sep*L_sep)/L_batt	2189.3 kg/m³	Battery density
Cp_batt	(Cp_pos*L_pos+Cp_neg*L_neg+Cp_pos_cc*L_pos_cc+Cp_neg_cc*L_neg_cc+Cp_sep*L_sep)/L_batt	1391.8 J/(kg·K)	Battery heat capacity

Interfacing hardware with software

Simulation through Hardware

- **OVERVIEW OF EXPERIMENT**

1. Simple electronic circuit is connected with the Li-ion battery bank.
2. Discharge curves are optimized with the help of the software, LabVIEW.

- **MATERIALS AND EQUIPMENT USED**

1. A battery bank of six coin-cell of maximum 3.5V.
2. The variable resistance of 0-500 ohm.
3. Motor as a load, capacitors, three switches, wires,
4. A protoboard, a digital multimeter,
5. A personal computer connected with National Instrument 6001 DAQ card and commercial software LabVIEW with updated version were used.[11]

Experiment Setup

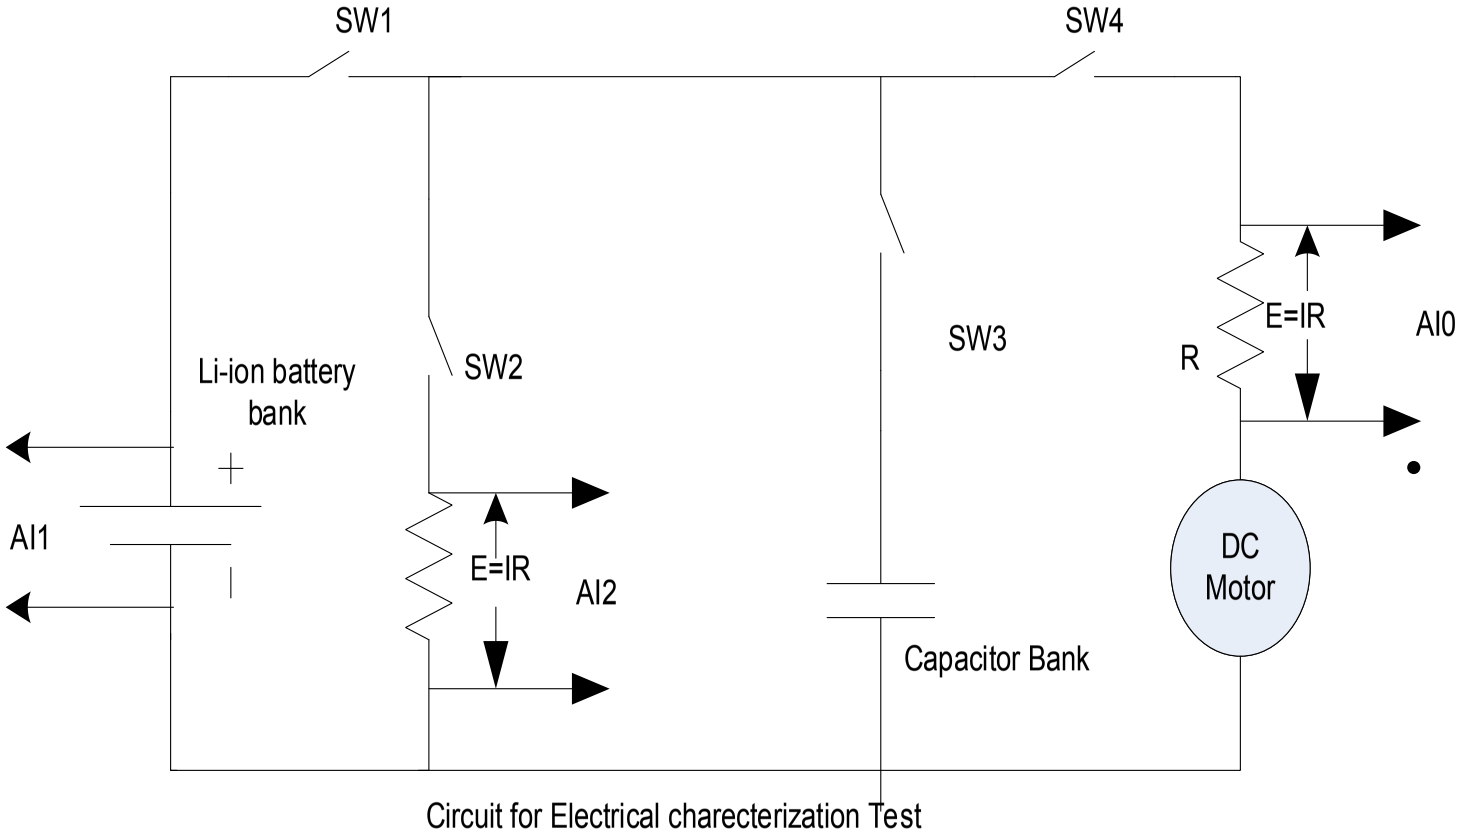

Fig 2. Circuit for Hardware design.

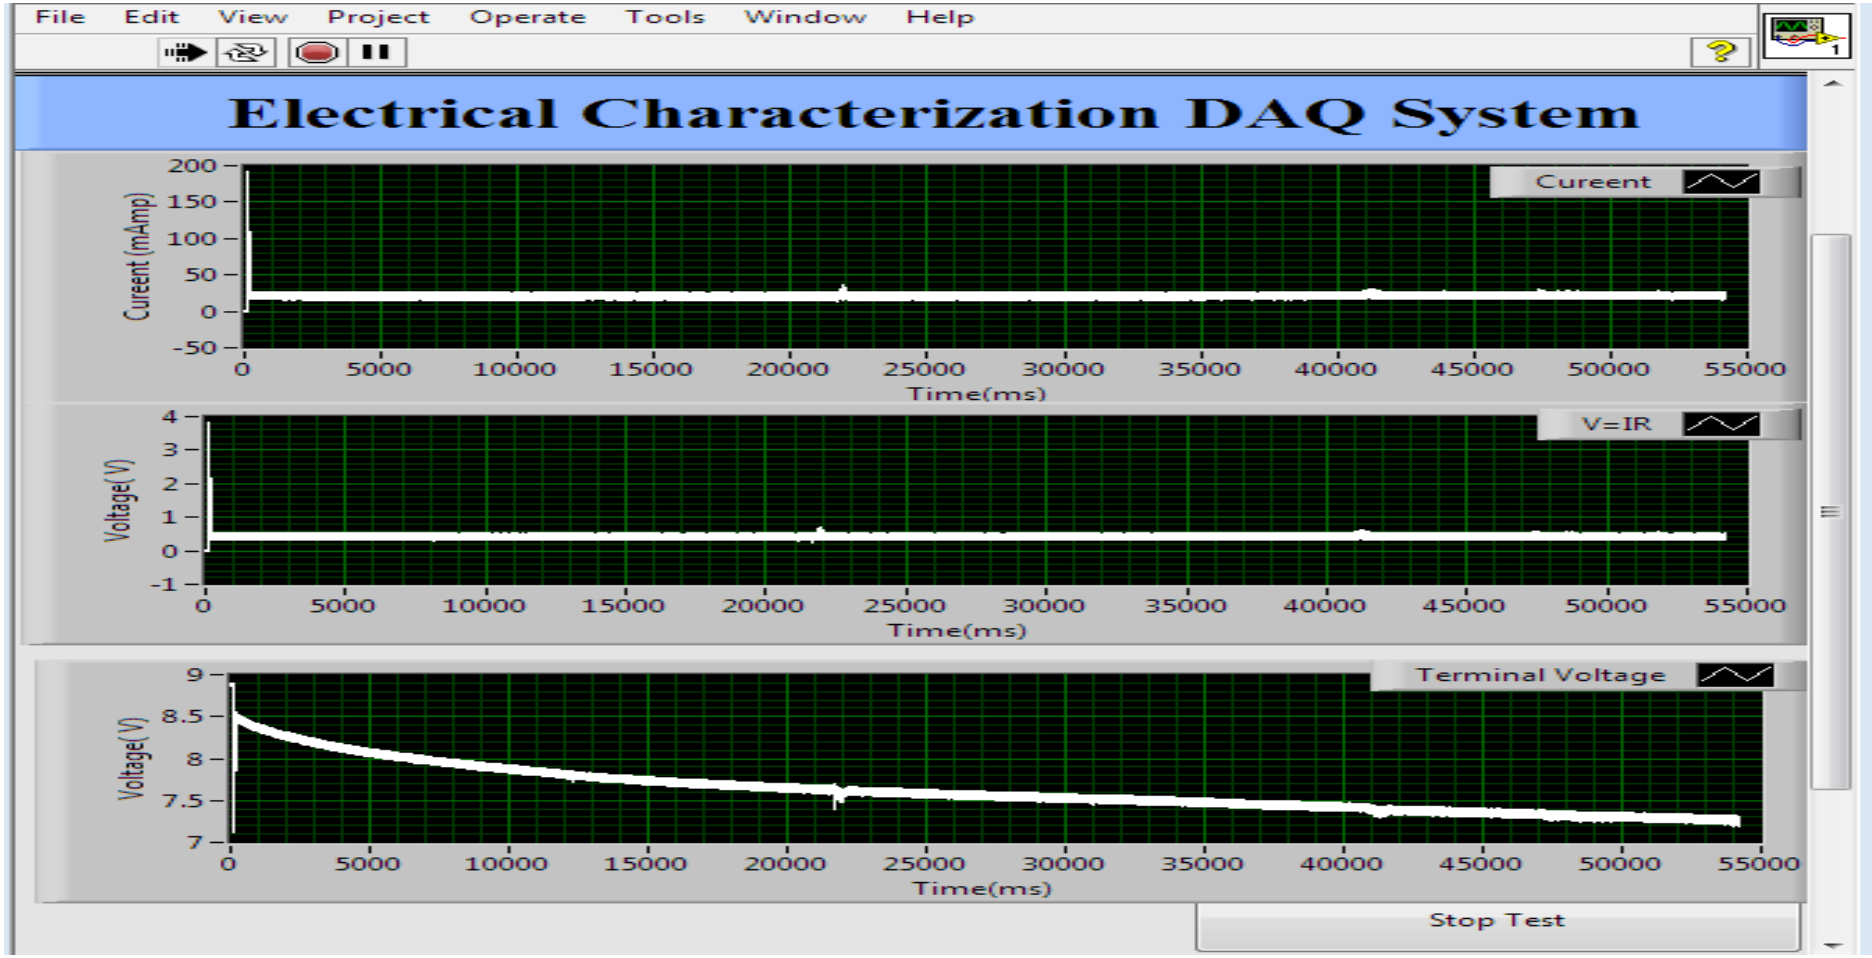
- Switch SW1, SW2 is closed for analyzing a short circuit current across the resistor through an analog input channel 2.

- Switch SW1, SW3, SW4 are closed for monitoring the battery characteristics, when the capacitor bank is connected parallel across the circuit.
- Three electrical tests were performed for optimization of different types of discharge curves.
- Switch SW1, SW4 is closed for monitoring the potential drop across the battery terminal

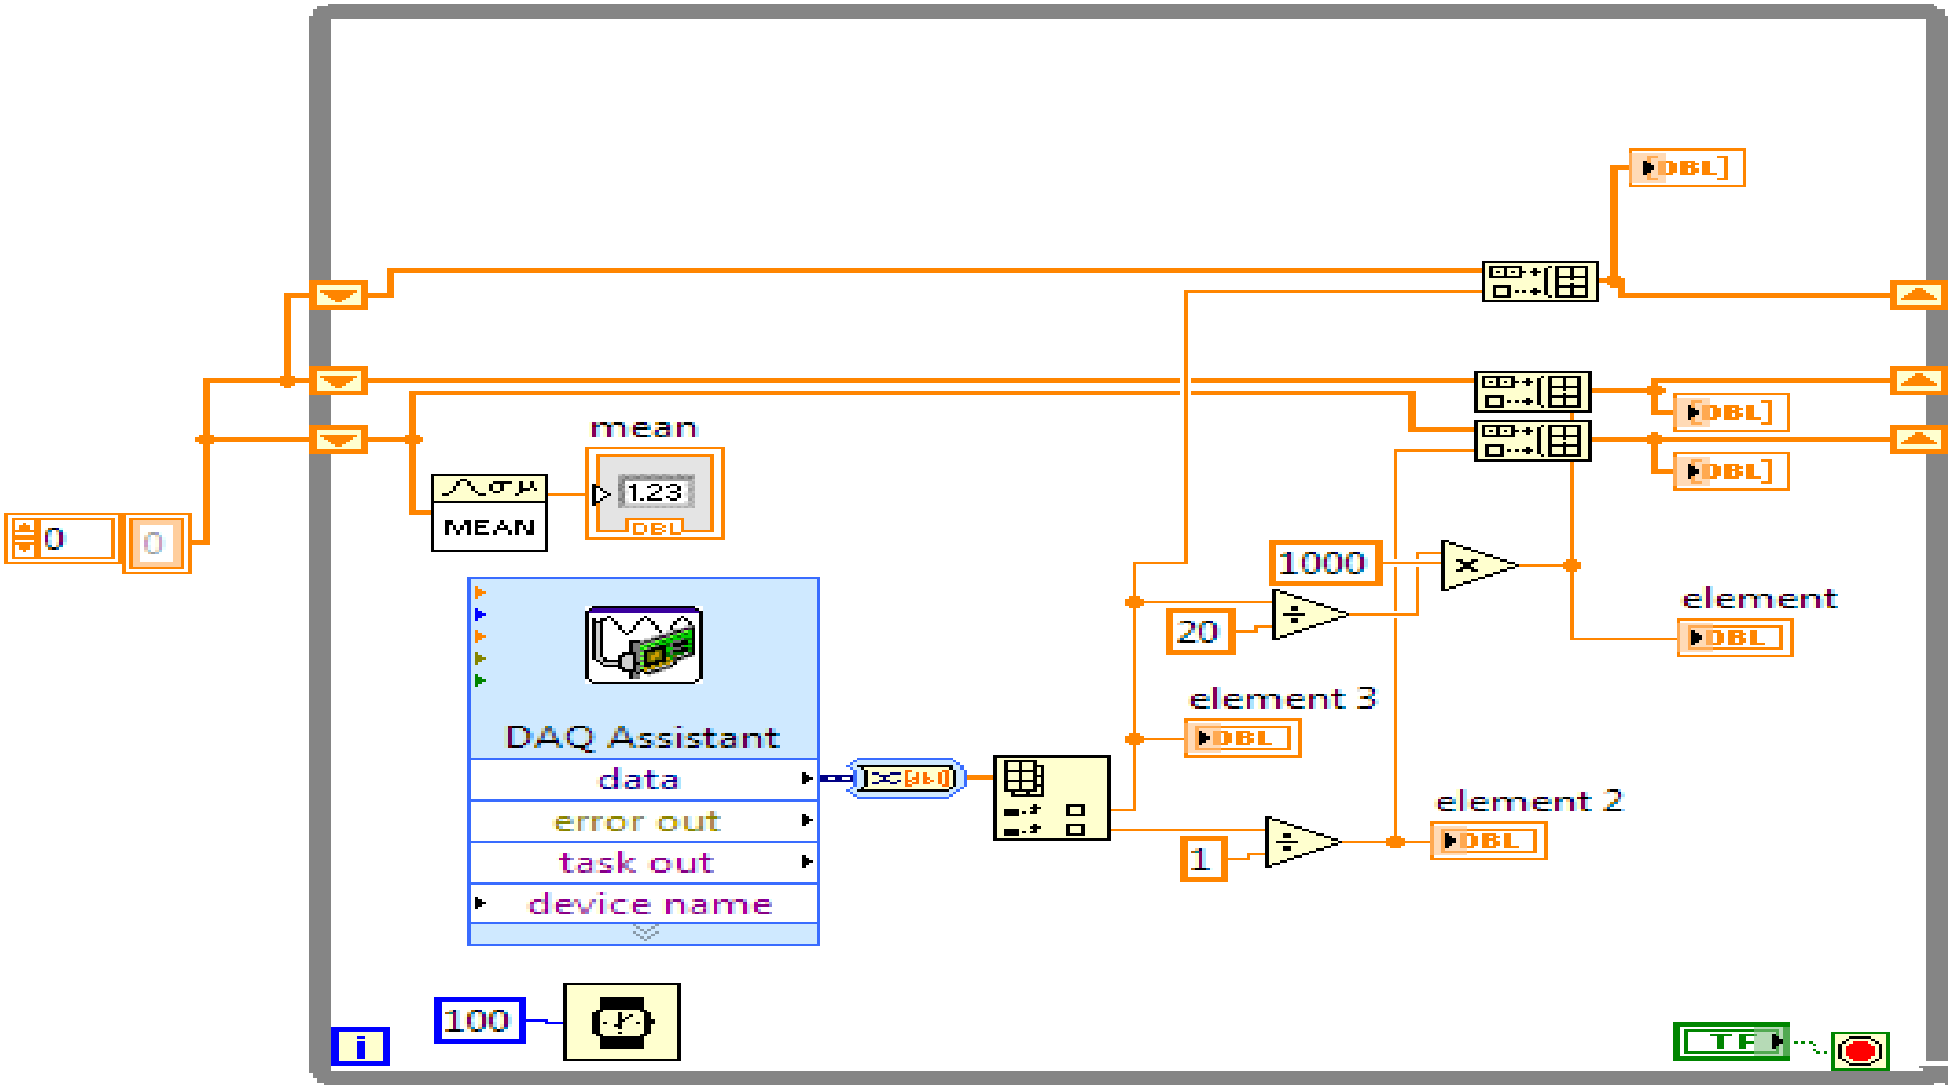
Battery discharge curve on the LabVIEW Front Panel



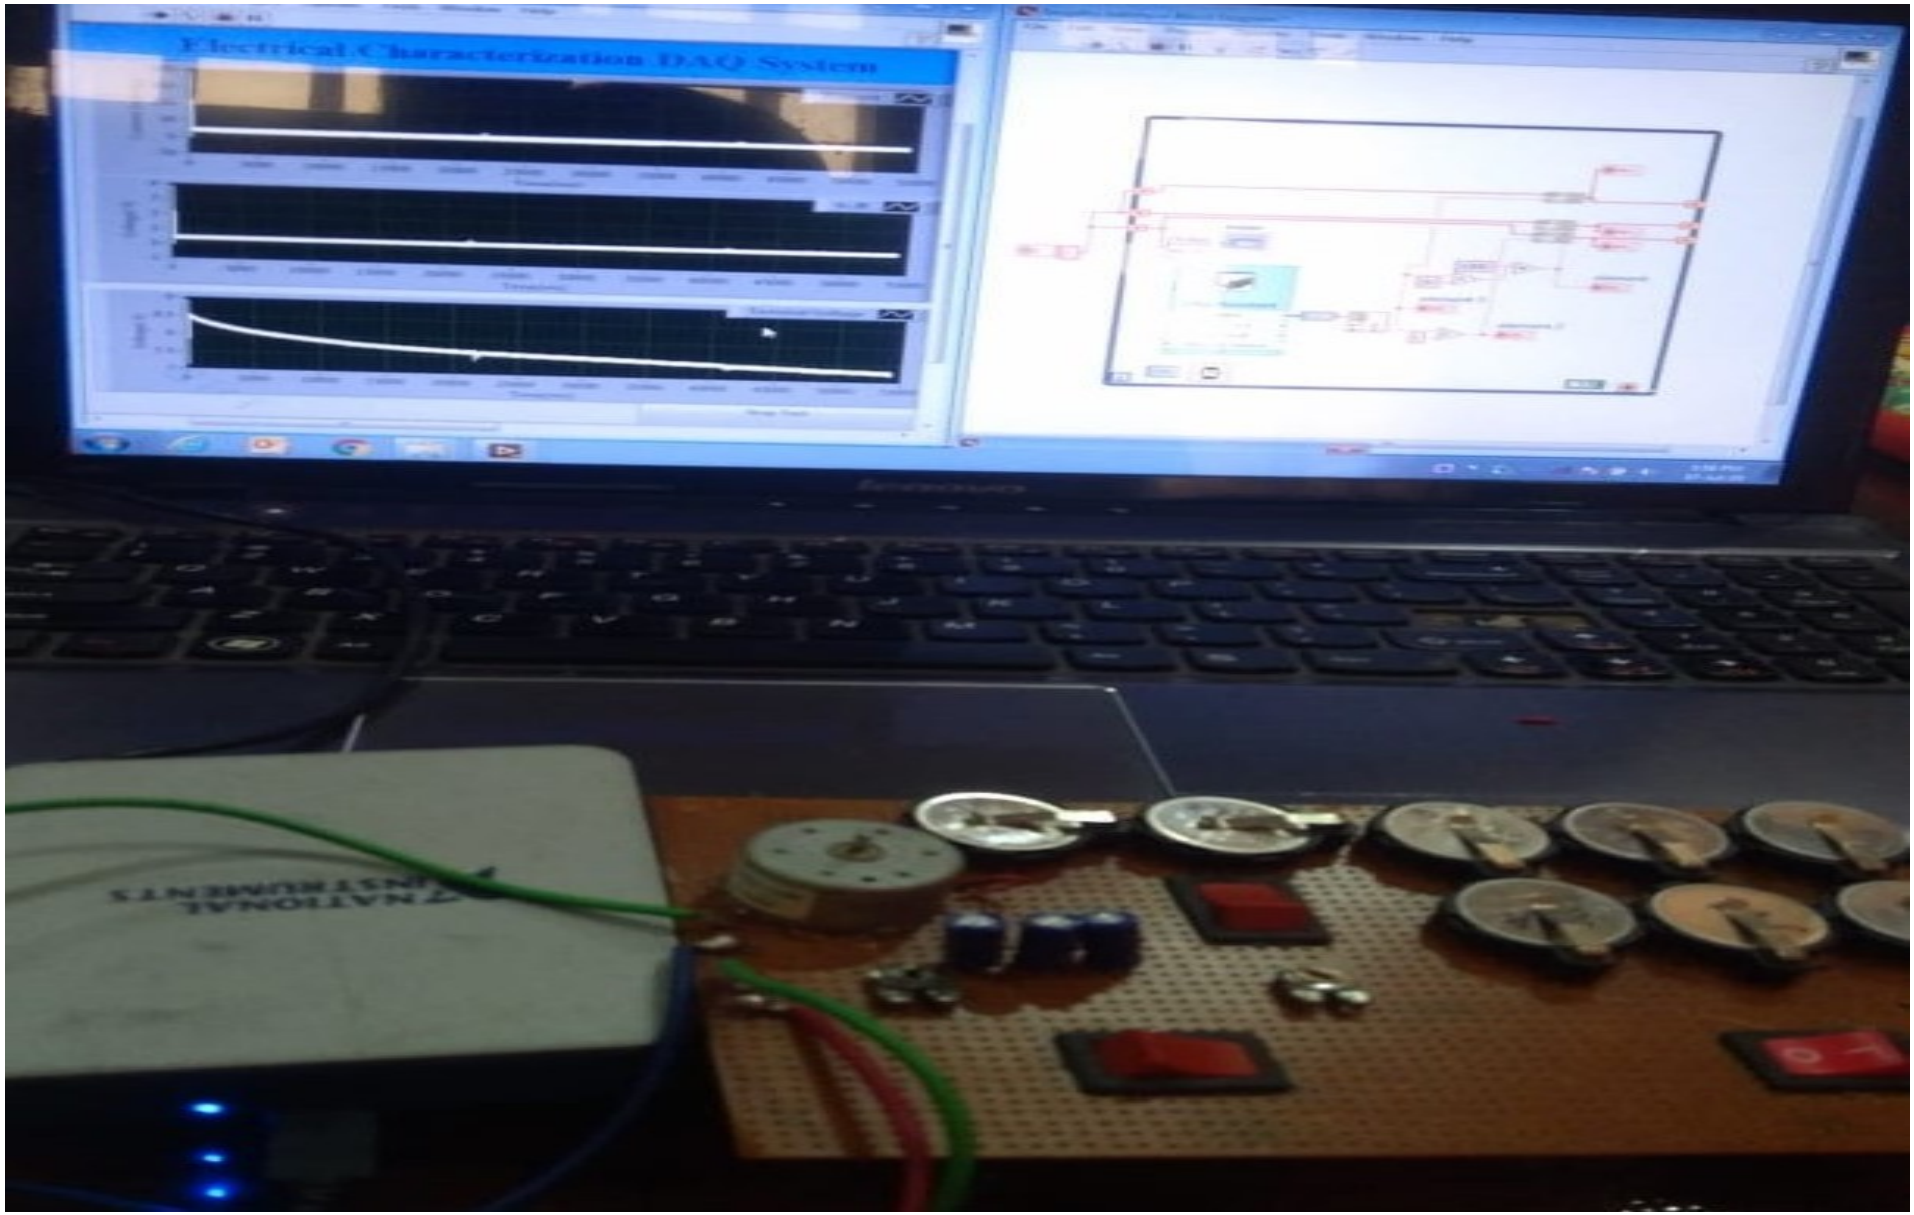
Front Panel works as an interface between the hardware and the PC[16].
It is also used for modifying the experimental condition and introduce virtual information across the panel and it is called a virtual instrument (VI).

Block Diagram of VI front panel

- The second panel is used for designing a block diagram and also provides a proper platform for writing a program by using various icons and connectors.



Hardware Setup for Electrical Characterization



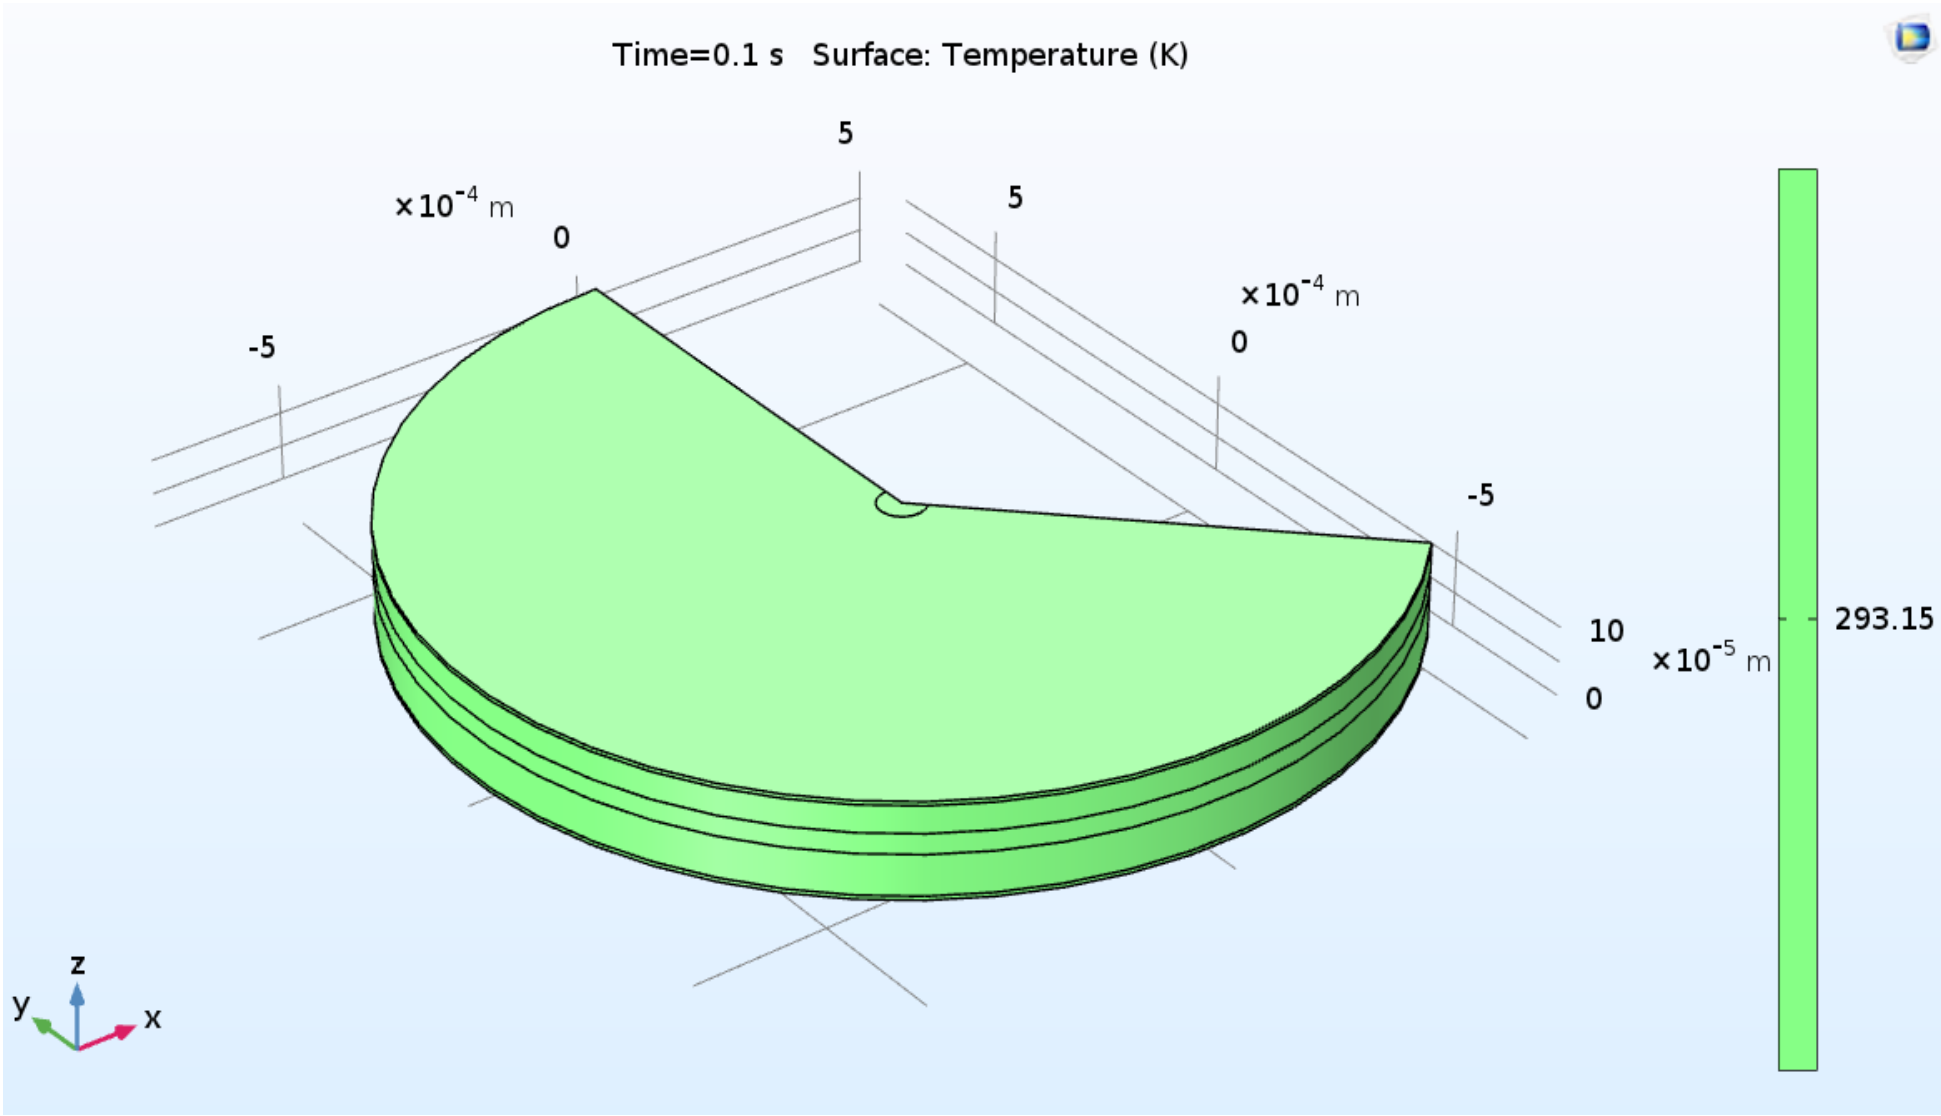
Results And Discussion

During battery characterization, the following two tests have been performed to optimize the behavior of the Li-ion battery.

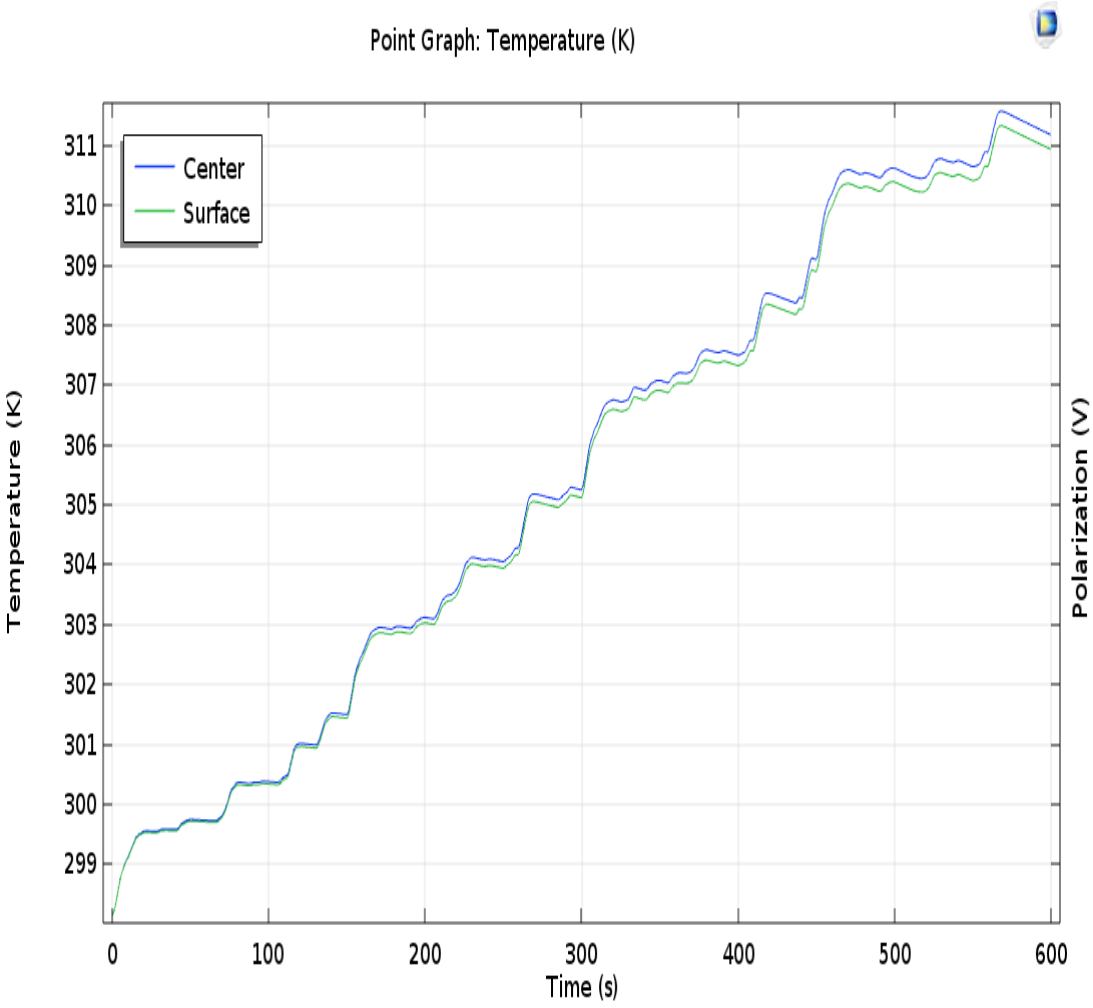
- Thermal Characterization
- Electrical Characterization

- All simulation results were analyzed at different boundary conditions.

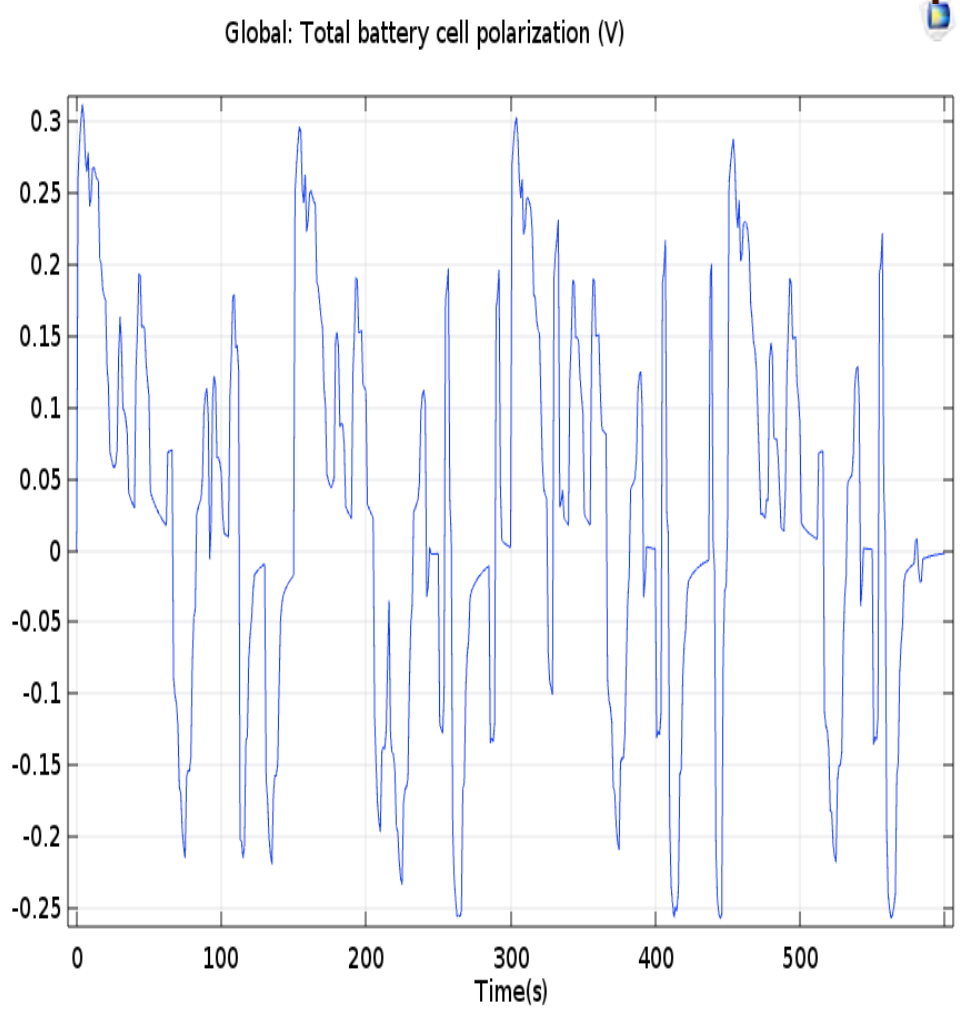
Thermal Characterization - Temperature distribution over the surface



Thermal Characterization

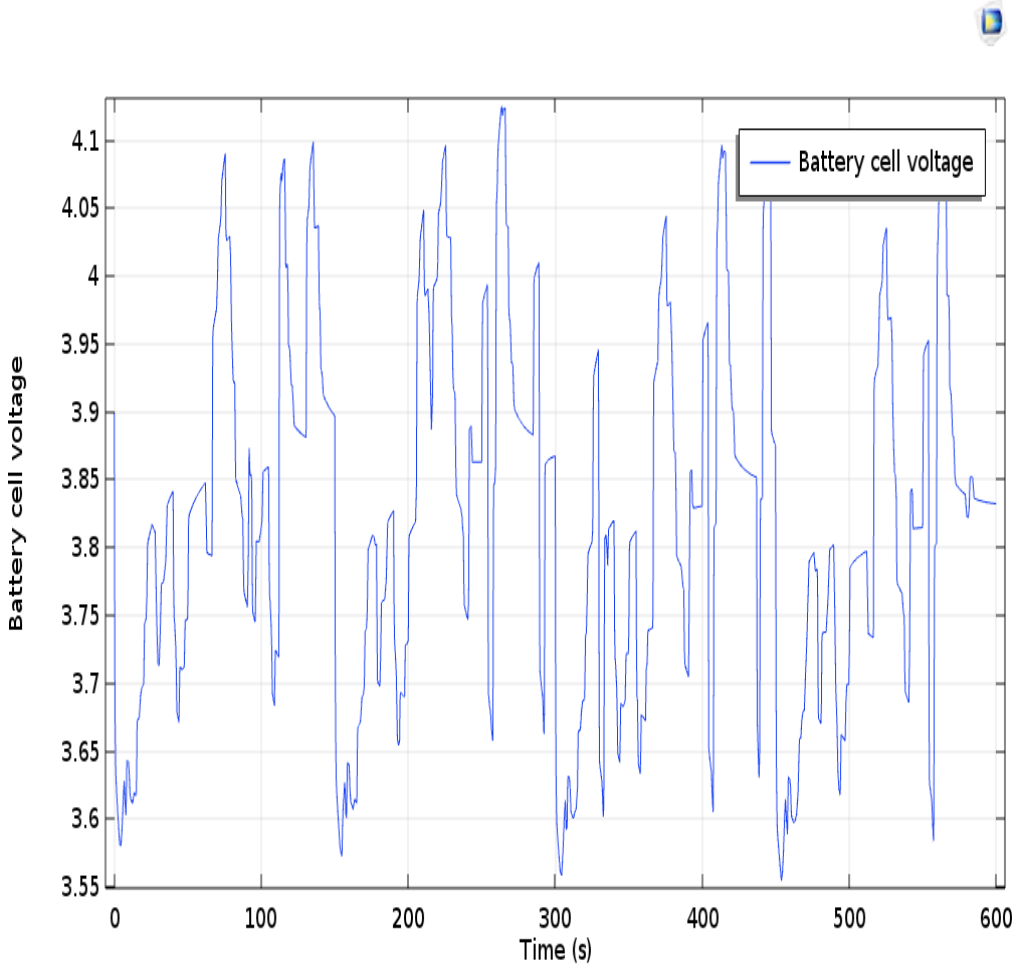


Temperature of the Battery During Drive Cycle

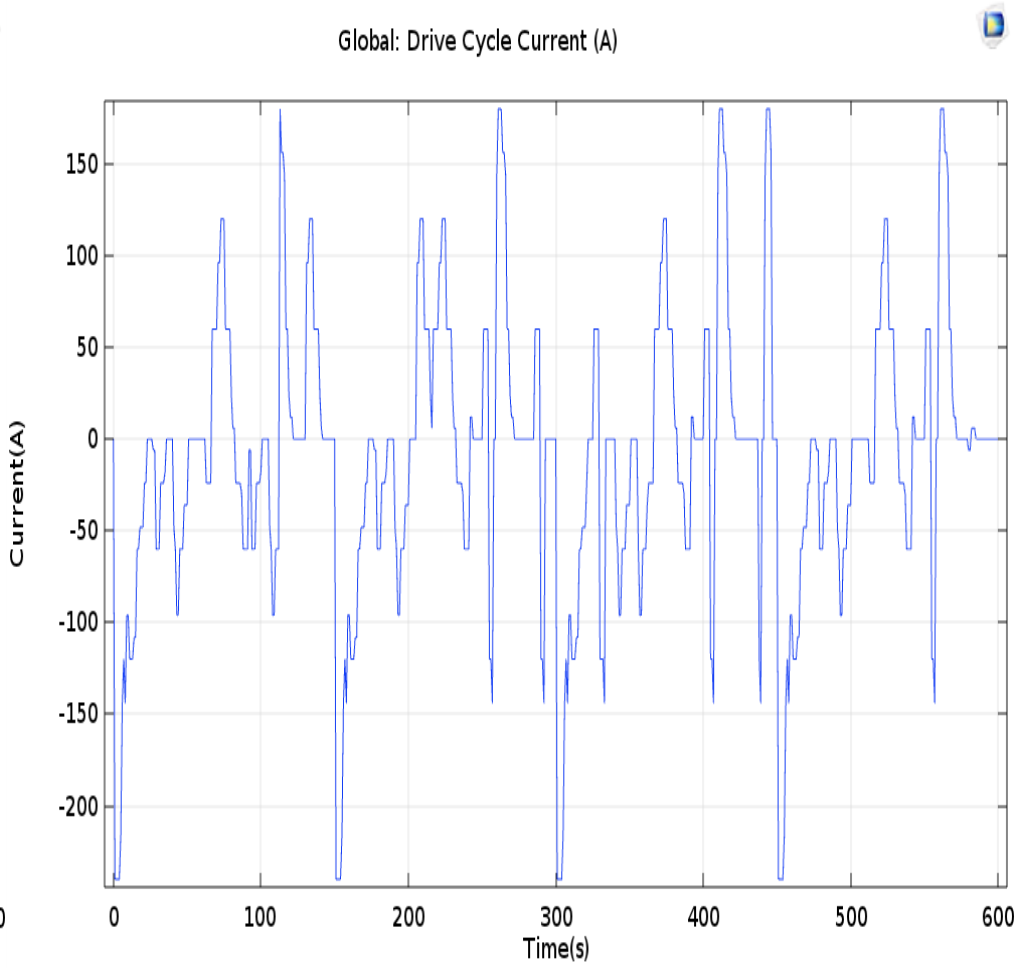


Total Polarization During Drive Cycle.

Thermal Characterization

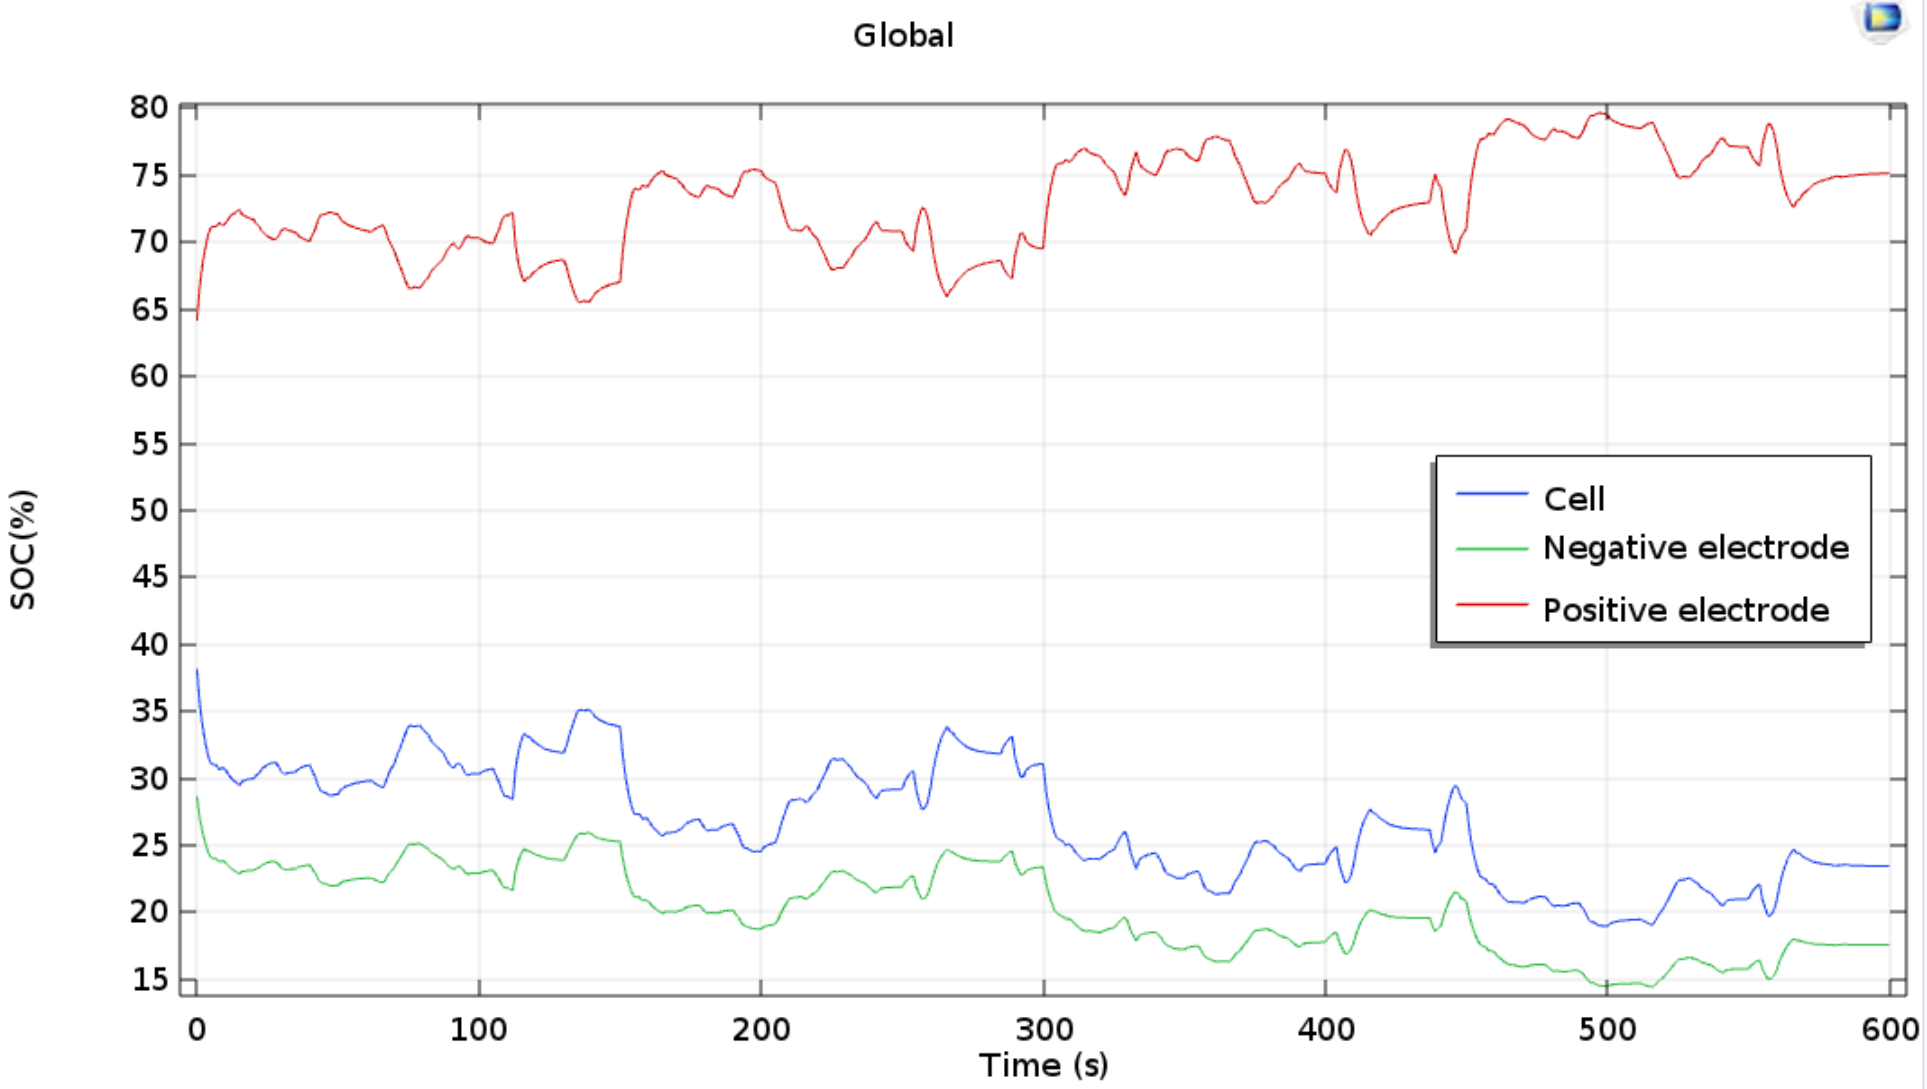


Cell Voltage during Drive Cycle.

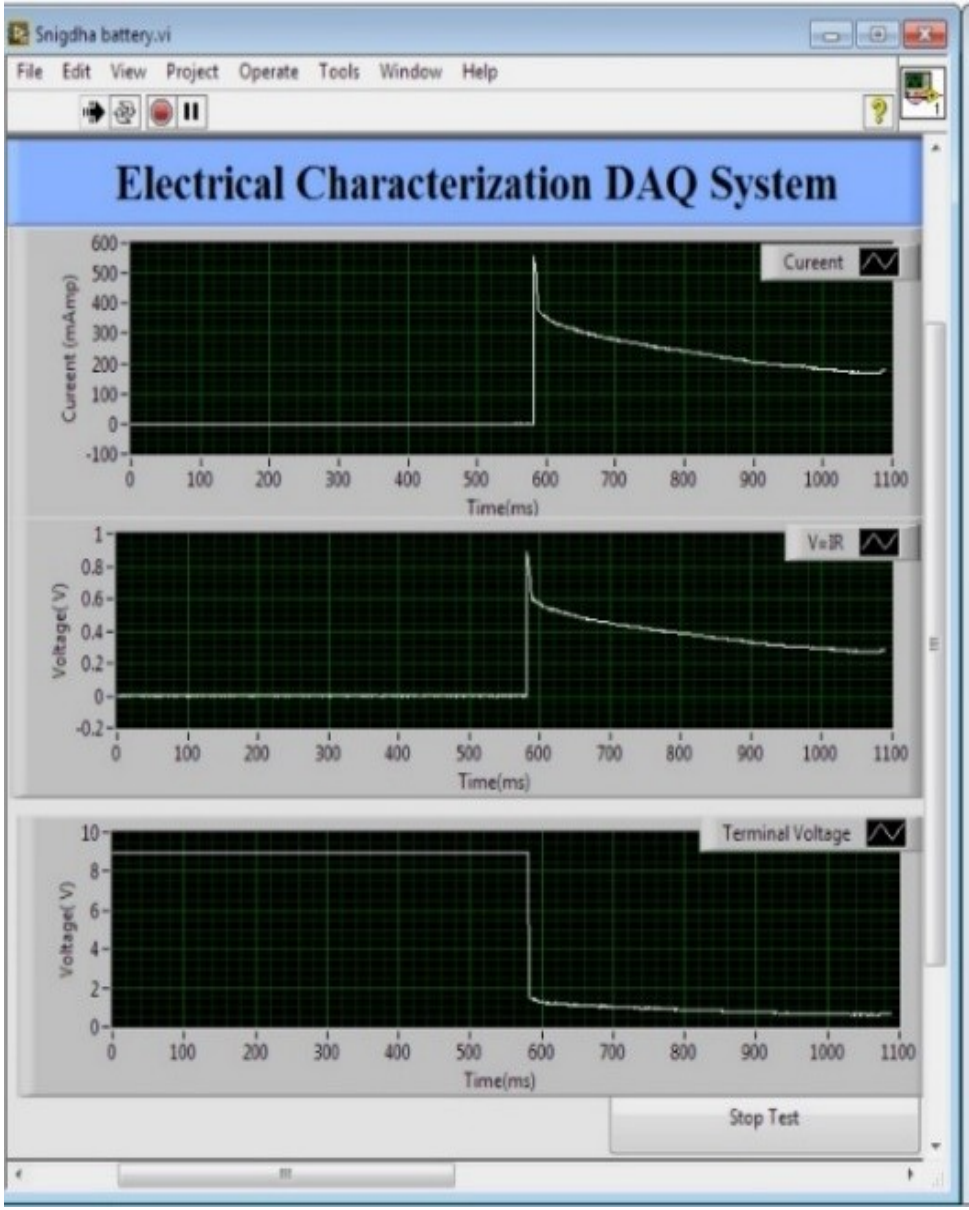


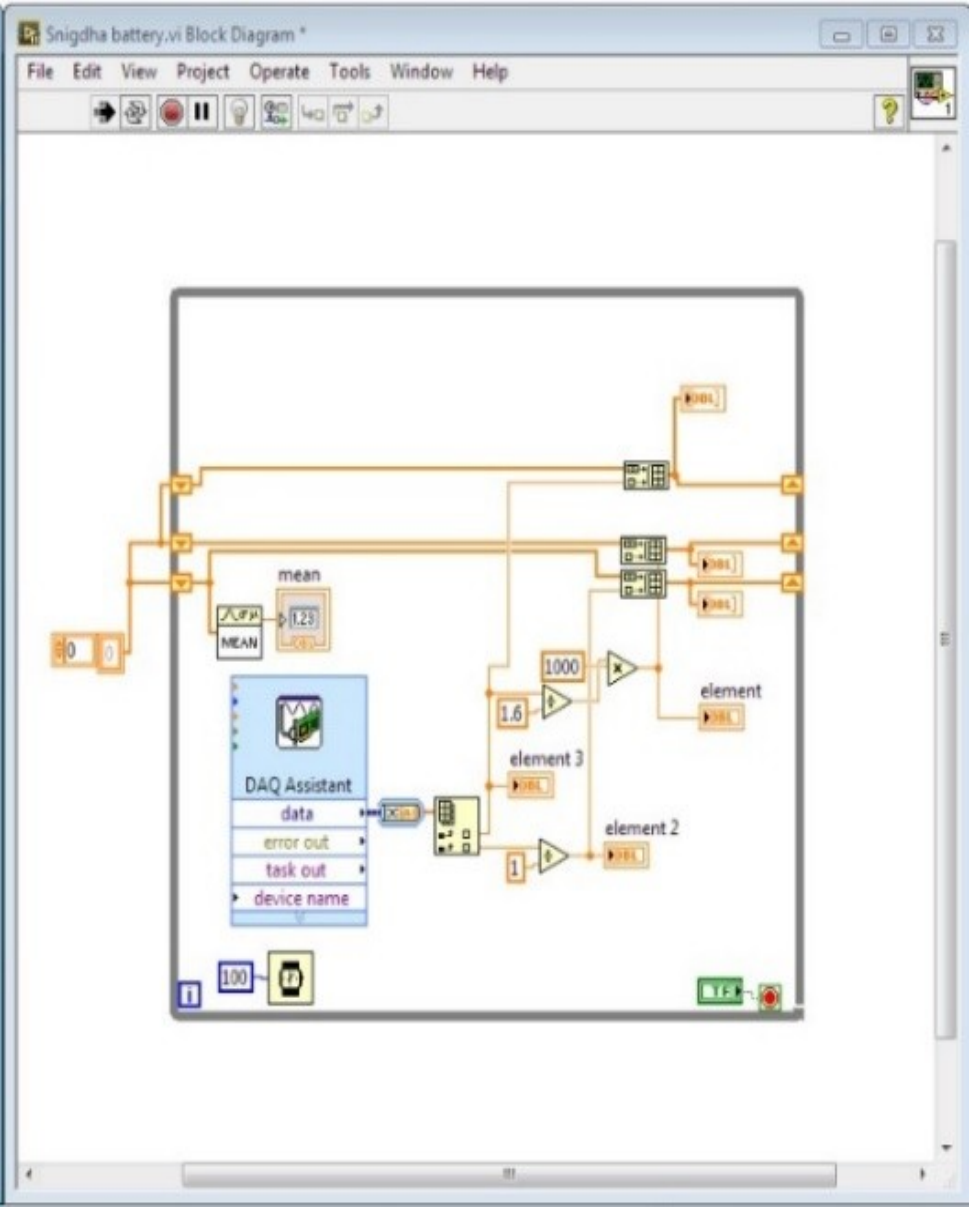
Drive Cycle Current on load.

Thermal Characterization- State of charge of battery during the drive cycle

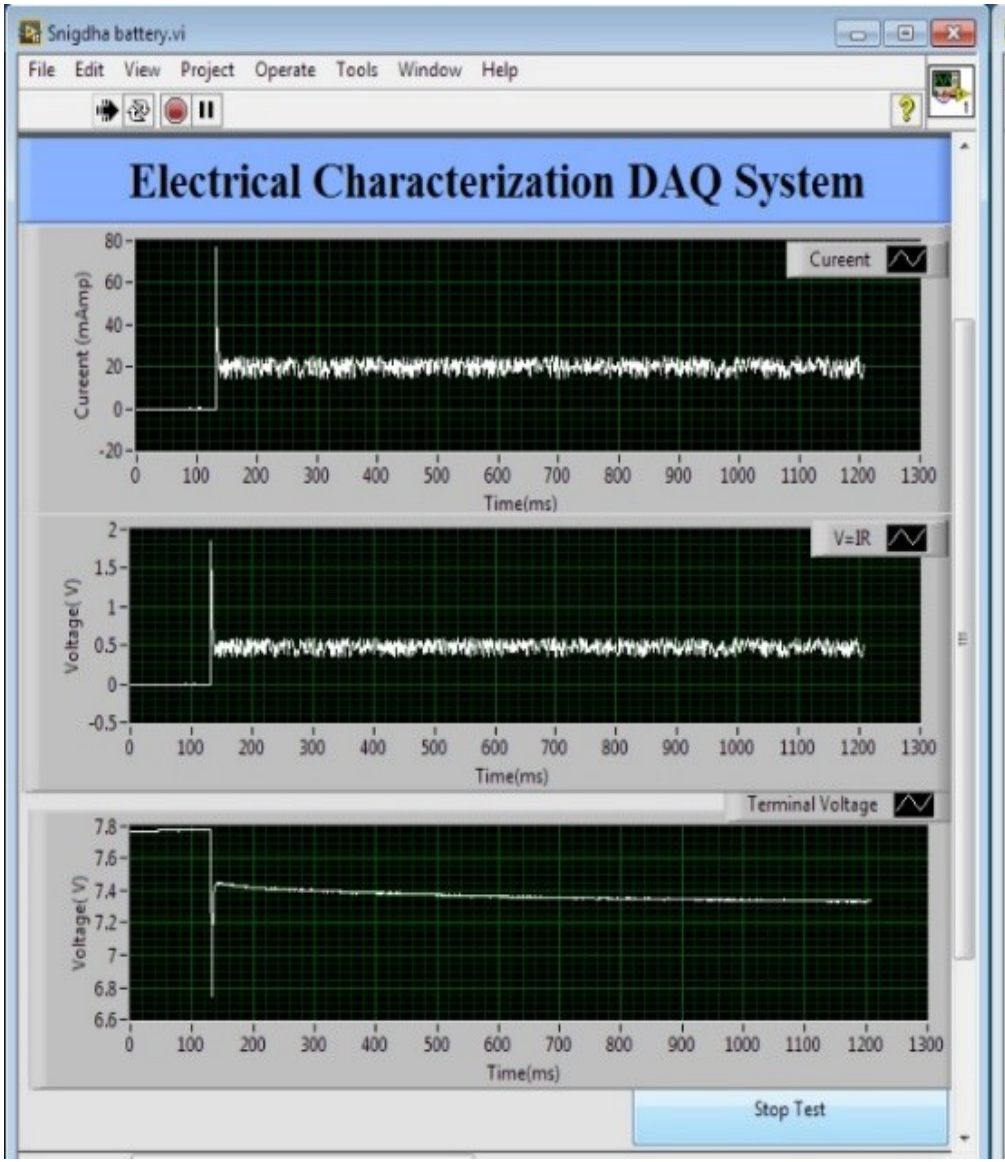


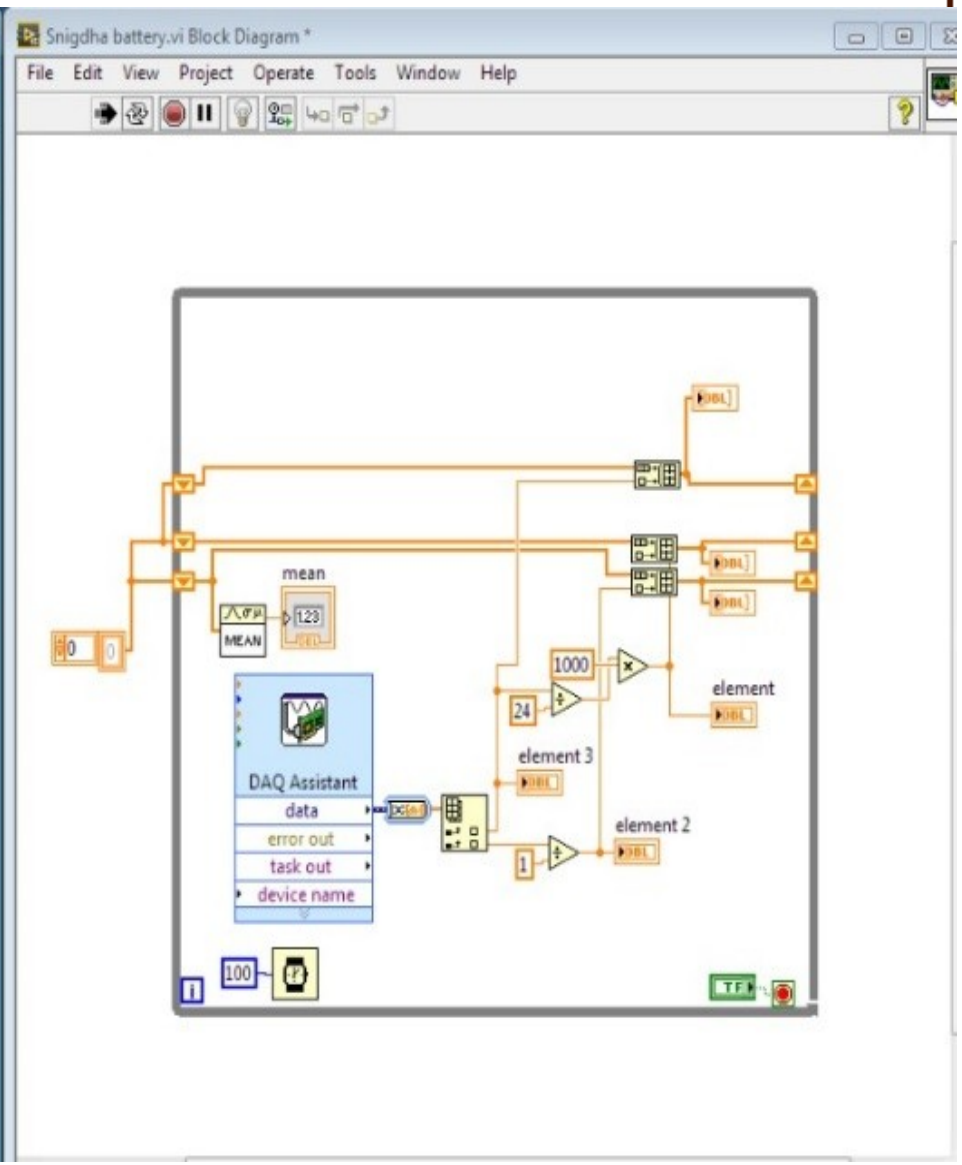
Electrical Characterization- Short Circuit Test Waveform



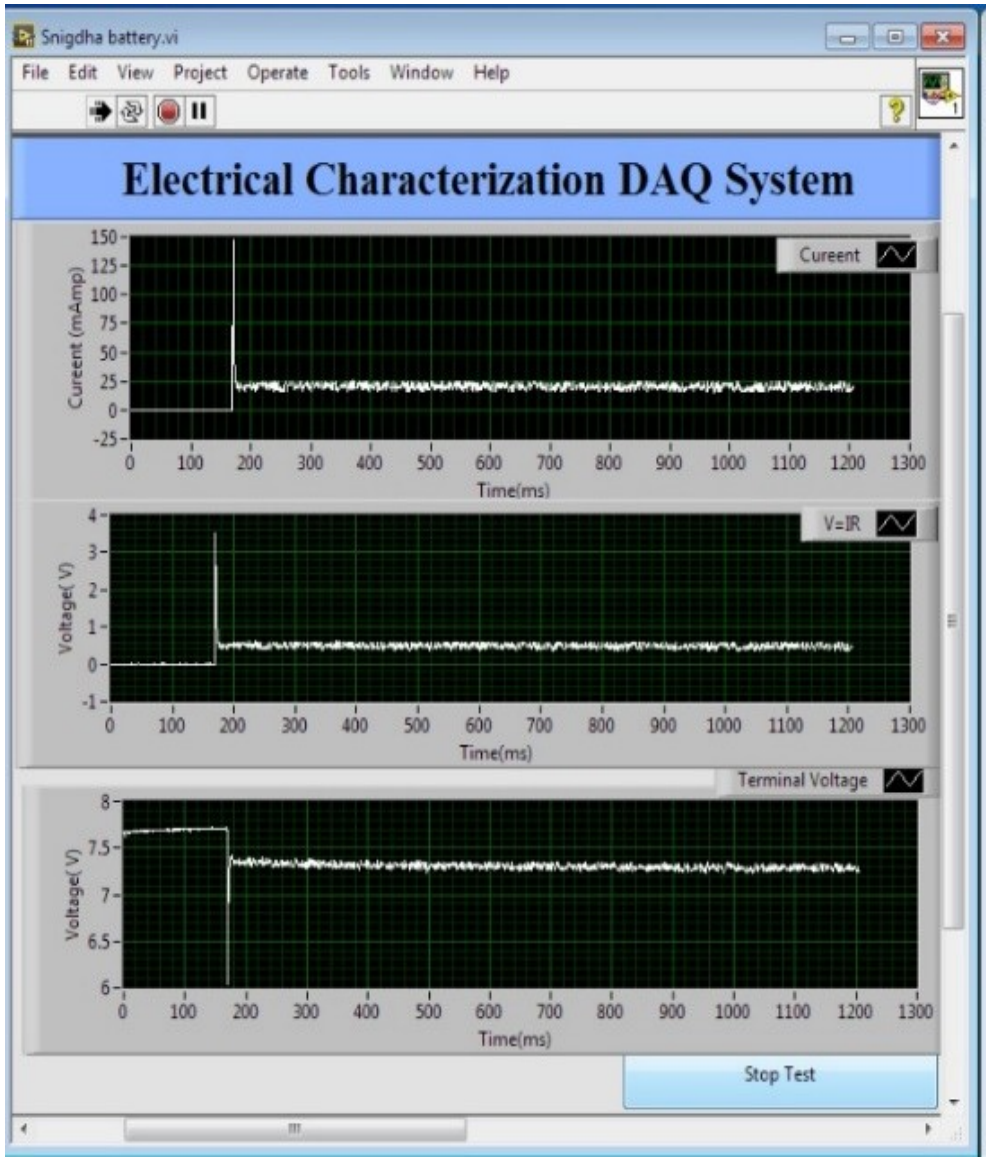


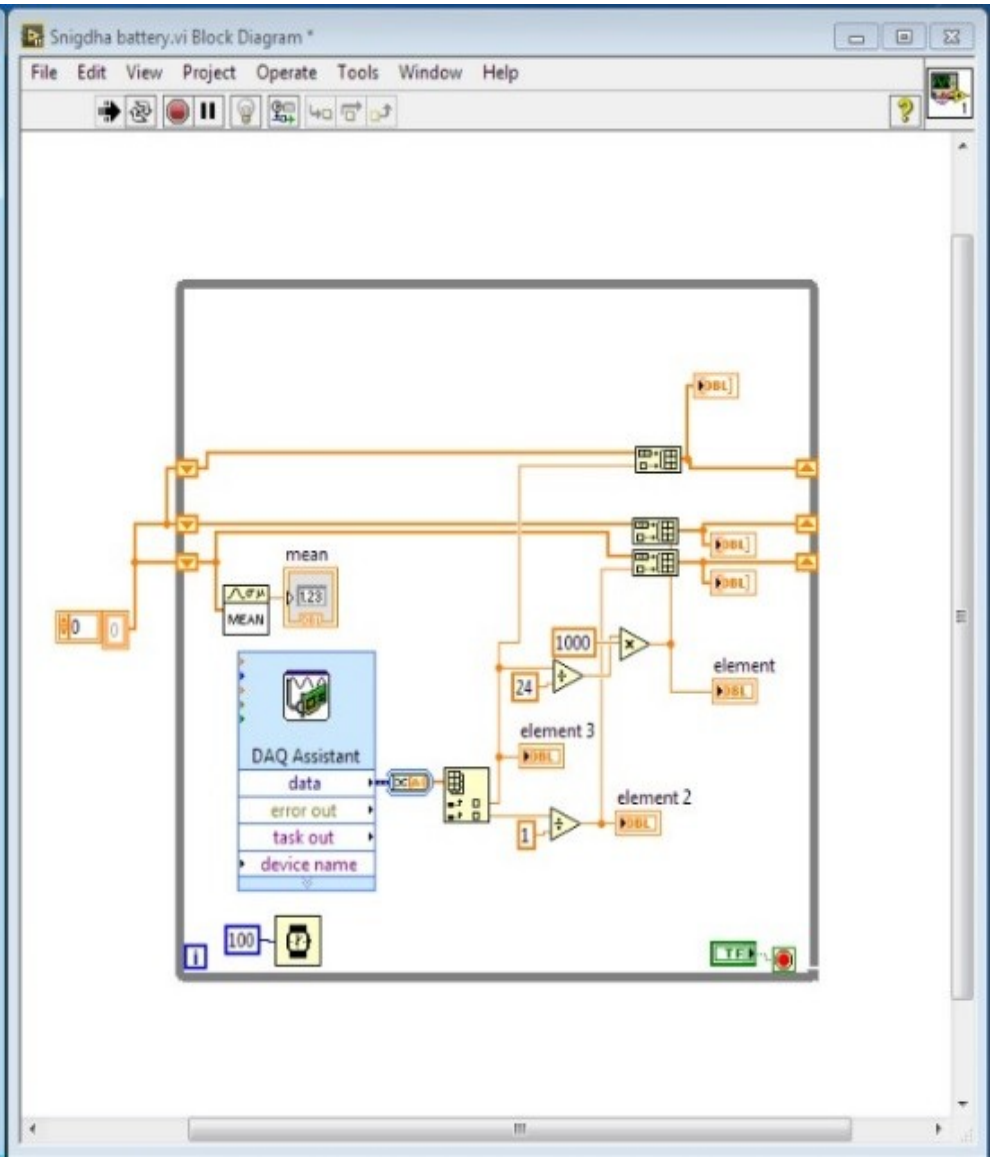
Electrical Characterization- Current And Voltage Waveform Without Capacitor Bank





Electrical Characterization-Current And Voltage Waveform With Capacitor Bank





Conclusion

- In this study, theoretical and hardware simulations were successfully performed using Multiphysics COMSOL and LabVIEW software for thermal and electrical characterization of Li-ion battery.
- Thermal characterization of Li-ion battery shows better heat management and good polarization capability with longer drive cycles for Li-ion batteries.
- During electrical characterization, a real-time hardware circuit was successfully designed to integrate the data acquisition unit with software.
- These electrical characterization results show good electrical behavior of the Li-ion battery bank as well as high accelerating current across the circuit in presence of a capacitor bank.

The series "Advances in Intelligent Systems and Computing" contains publications on theory, applications, and design methods of Intelligent Systems and Intelligent Computing. Virtually all disciplines such as engineering, natural sciences, computer and information science, ICT, economics, business, e-commerce, environment, healthcare, life science are covered. The list of topics spans all the areas of modern intelligent systems and computing such as: computational intelligence, soft computing including neural networks, fuzzy systems, evolutionary computing and the fusion of these paradigms, social intelligence, ambient intelligence, computational neuroscience, artificial life, virtual worlds and society, cognitive science and systems, Perception and Vision, DNA and immune based systems, self-organizing and adaptive systems, e-Learning and teaching, human-centered and human-centric computing, recommender systems, intelligent control, robotics and mechatronics including human-machine teaming, knowledge-based paradigms, learning paradigms, machine ethics, intelligent data analysis, knowledge management, intelligent agents, intelligent decision making and support, intelligent network security, trust management, interactive entertainment, Web intelligence and multimedia.

The publications within "Advances in Intelligent Systems and Computing" are primarily proceedings of important conferences, symposia and congresses. They cover significant recent developments in the field, both of a foundational and applicable character. An important characteristic feature of the series is the short publication time and world-wide distribution. This permits a rapid and broad dissemination of research results.

**** Indexing: The books of this series are submitted to ISI Proceedings, EI-Compendex, DBLP, SCOPUS, Google Scholar and Springerlink ****

Preface

These two volumes constitute the proceedings of the International Conference on *Data Management, Analytics and Innovation* (ICDMAI 2019) held from 18 to 20 January 2019. ICDMAI is a flagship conference of Society for Data Science, which is a non-profit professional association established to create a collaborative platform for bringing together technical experts across industry, academia, government laboratories and professional bodies to promote innovation around data science. ICDMAI 2019 envisions its role towards data science and its enhancement through collaboration, innovative methodologies and connections throughout the globe. The conference was hosted by Lincoln University College, Kuala Lumpur, Malaysia, and was supported by the industry leaders like IBM. Other partners for the conference were Wizer and DSMS College of Tourism & Management, West Bengal, India. The conference witnessed participants from 20 countries, 12 industries, 31 international universities and 94 premier Indian universities. Utmost care was taken in each and every facet of the conference, especially regarding the quality of the paper submissions. Out of 418 papers submitted to ICDMAI 2019, only 20% (87 papers) are selected for an oral presentation after a rigorous review process. Besides paper presentation, the conference also showcased workshops, tutorial talks, keynote sessions and plenary talks by the experts of the respective field.

The volumes cover a broad spectrum of computer science, information technology, computational engineering, electronics and telecommunication, electrical, computer application and all the relevant disciplines. The conference papers included in these proceedings are published post-conference and are grouped into the four areas of research such as data management and smart informatics; big data management; artificial intelligence and data analytics; and advances in network technologies. All the four tracks of the conference were very relevant to the current technological advancements and had Best Paper Award in each track. Very stringent selection process was adopted for paper selection, and from plagiarism check to technical chairs' review to double-blind review, every step was religiously followed. We compliment all the authors for submitting high-quality research papers to ICDMAI 2019. We would like to acknowledge all the authors for their contributions and also the efforts taken by reviewers and session chairs of the conference,

without whom it would have been difficult to select these papers. We appreciate the unconditional support from the members of the National and International Program Committee. It was really interesting to hear the participants of the conference highlight the new areas and the resulting challenges as well as opportunities. This conference has served as a vehicle for a spirited debate and discussion on many challenges that the world faces today.

We especially thank our General Chair, Dr. P. K. Sinha; Vice Chancellor and Director, Dr. S. P. Mukherjee, International Institute of Information Technology, Naya Raipur (IIIT-NR), Chhattisgarh; other eminent personalities like Mr. Eddy Liew, Cloud and Solutions Country Technical Leader at IBM, Malaysia; Kranti Athalye, Sr. Manager in IBM India University Relations; Dr. Juergen Seitz, Head of Business Information Systems Department, Baden-Wuerttemberg Cooperative State University, Heidenheim, Germany; Mr. Aninda Bose, Senior Publishing Editor, Springer India Pvt. Ltd.; Dr. Vincenzo Piuri, IEEE Fellow, University of Milano, Italy; Hanaa Hachimi, National School of Applied Sciences ENSA in Kenitra, Morocco; Amol Dhondse, IBM Senior Solution Architect; Mohd Helmy Abd Wahab, Senior Lecturer and Former Head of Multimedia Engineering Lab at the Department of Computer Engineering, Faculty of Electrical and Electronic Engineering, Universiti Tun Hussein Onn Malaysia (UTHM); Anand Nayyar, Duy Tan University, Vietnam; and many more who were associated with ICDMAI 2019. Besides, there was CSI-Startup and Entrepreneurship Award to felicitate budding job creators.

Our special thanks go to Janus Kacprzyk (Editor in Chief, Springer, Advances in Intelligent Systems and Computing Series) for the opportunity to organize this guest-edited volume. We are grateful to Springer, especially to Mr. Aninda Bose (Senior Publishing Editor, Springer India Pvt. Ltd.), for the excellent collaboration, patience and help during the evolvement of this volume.

We are confident that the volumes will provide the state-of-the-art information to professors, researchers, practitioners and graduate students in the area of data management, analytics and innovation, and all will find this collection of papers inspiring and useful.

About the Editors

Neha Sharma is the Founder Secretary of the Society for Data Science, India. She was the Director of the Zeal Institute of Business Administration, Computer Application & Research, Pune, Maharashtra, India, and and Deputy Director, of the Padmashree Dr. D.Y.Patil Institute of Master of Computer Applications, Akurdi, Pune. She completed her PhD at the prestigious Indian Institute of Technology (IIT-ISM), Dhanbad, and she is a Senior IEEE member as well as Execom member of IEEE Pune Section. She has published numerous research papers in respected international journals. She received the "Best PhD Thesis Award" and "Best Paper Presenter at International Conference Award" from the Computer Society of India. Her areas of interest include data mining, database design, analysis and design, artificial intelligence, big data, cloud computing, blockchain and data science.

Amlan Chakrabarti currently the Dean of the Faculty of Engineering and Technology, Professor and Director of the A.K.Choudhury School of Information Technology, University of Calcutta, India. He was a postdoctoral fellow at the School of Engineering, Princeton University, USA from 2011 to 2012. He has published around 130 research papers in refereed journals and conferences, and has been involved in research projects supported by various national funding agencies and international collaborations. He is a senior member of the IEEE and ACM, ACM Distinguished Speaker, Vice President of the Society for Data Science, and Secretary of the

IEEE CEDA India Chapter. He is also the Guest Editor of the Springer Nature Journal on Applied Sciences. His research interests include quantum computing, VLSI design, embedded system design, computer vision and analytics.

Valentina Emilia Balas is currently a Full Professor at the Department of Automatics and Applied Software at the Faculty of Engineering, "Aurel Vlaicu" University of Arad, Romania. She holds a Ph.D. in Applied Electronics and Telecommunications from the Polytechnic University of Timisoara. Dr. Balas is the author of more than 300 research papers in refereed journals and international conferences. Her research interests include intelligent systems, fuzzy control, soft computing, smart sensors, information fusion, modeling and simulation. She is the editor-in-chief of the International Journal of Advanced Intelligence Paradigms (IJAIP) and the International Journal of Computational Systems Engineering (IJCSysE), and is an editorial board member of several national and international journals.

Data Management and Smart Informatics

Empirical Study of Soft Clustering Technique for Determining Click Through Rate in Online Advertising

Akshi Kumar, Anand Nayyar, Shubhangi Upasani and Arushi Arora

Abstract Online advertising is an industry with the potential for maximum revenue extraction. Displaying the ad which is more likely to be clicked plays a crucial role in generating maximum revenue. A high click through rate (CTR) is an indication that the user finds the ad useful and relevant. For suitable placement of ads online and rich user experience, determining CTR has become imperative. Accurate estimation of CTR helps in placement of advertisements in relevant locations which would result in more profits and return of investment for the advertisers and publishers. This paper presents the application of a soft clustering method namely fuzzy c-means (FCM) clustering for determining if a particular ad would be clicked by the user or not. This is done by classifying the ads in the dataset into broad clusters depending on whether they were actually clicked or not. This way the kind of advertisements that the user is interested in can be found out and subsequently more advertisements of the same kind can be recommended to him, thereby increasing the CTR of the displayed ads. Experimental results show that FCM outperforms k-means clustering (KMC) in determining CTR.

1 Introduction

Online advertising has become an important source of revenue for a wide range of businesses. With the tremendous growth in online advertising each year, it has also taken over a major area of research. Most of the revenues generated by widely used search engines as well as prevalent websites come from advertisements. It is therefore important to display relevant advertisements (ads) to the users and avoid the advertisements that are often disliked by them.

Online advertising is more economical than traditional ways of advertising like mass markets and niche media. Internet ads have a wider audience and can be viewed for days and nights altogether, in contrast to ads on television and radios that last for shorter durations and are displayed with limited frequency. Market segmentation is much more effective over the Internet than in any other medium. Thorough study of markets, customer preferences and habits and segmenting consumers into cohesive groups can be done efficiently through online advertising. Online advertising also offers small businesses numerous benefits like robust targeting, consumer insights and more effective return on investment.

Advertisements fall into two broad categories—sponsored search advertisements and contextual advertisements. Sponsored search ads are displayed on the same web pages that show results of search queries entered by users. The core purpose behind sponsored advertising is to enhance the advertiser's brand image as the ads displayed have the same form and qualities as the advertiser's original content. Contextual advertising, on the other hand, uses automated systems that display ads relevant to the user's identity and website's content. Google AdSense is one of the many well-known examples of contextual advertising. Google robots display only those ads that the users find relevant and useful. When a user visits a website, features like ad size, ad placement, etc. are extracted from the search query and sent to a server. Relevant ads are selected based on user's past history, CTR and other data. Increasing the number of ads is not a good idea as it will shoot up the earnings only for a short time before the user switches to other search engines due to poor user experience. To maximize revenue, precise placements of ads are therefore required.

CTR refers to the number of times the advertiser's ad has been clicked (clicks) divided by number of times the ad appears on the screen (impression). Relevant placement of ad is a precondition for increasing the CTR for it. Ad performance can also be measured using CTR. CTR determination has several issues associated with it. The advertisers need to pay every time whenever an ad is clicked. It is on the basis of CTR that the search engine decides what ads are to be displayed and in what order of appearance. This is ensured by combining together the likelihood of an ad being clicked and the cost of the ad per click to create a display format that will yield maximum return. Many algorithms based on the supervised methodology have been designed to predict the CTR of advertisements like support vector machines, decision trees, Naïve Bayes, etc.

Motivated by this, the goal is to analyse and assess the application of unsupervised approach namely FCM for determining the CTR of an advertisement. This

clustering algorithm divides the total ads in the dataset into broad clusters based on whether they have been clicked or not by the user. This classification of ads helps in assessing the kind of advertisements that the user is really interested in and hence predict more of these kinds of ads. This would, in turn, result in a rise in the CTR of the displayed ads because of a greater number of clicks. The results obtained from FCM have been contrasted with KMC which has been used as a baseline model. The two techniques are assessed based on metrics like precision, recall and accuracy.

The following content is compiled as follows: Sect. 2 reviews work done by various researchers along with the brief idea of the algorithm used by them and their results. Section 3 elaborates the dataset taken, methods employed for preparing the data before implementing the algorithm and the algorithms used. The scrutiny of the experimental outcomes is done in the Sect. 4. Section 5 culminates the results along with the suggestions for future research prospects.

2 Related Work

After a thorough assessment of various studies in the past, it was found that a lot of algorithms have been proposed for the prediction of relevant ad to be displayed to the user. The author Avila Clemenshia et al. [1] in 2016, proposed a CTR prediction model using Poisson's regression, linear regression and support vector regression algorithms and displayed the ads accordingly. The dataset was provided by a digital marketing agency. Their results stated that support vector regression performed best among the three. Evaluation of the results was done on the basis of root mean squared error (RMSE) and correlation coefficient.

Authors Graepel et al. [2] in 2010 devised a new Bayesian CTR algorithm. The ad predictor presented showed better outcomes when compared to the baseline Naïve Bayes in terms of relative information gain (RIG) and areas under the curve (AUC). Hillard et al. [3] in 2010, implemented a model for estimating ad relevance. They refined it by including indirect feedback after consolidating the basic features of text overlap. In case of presence of adequate observations, click history was used. In case of no or few observations, a model was learned that could also be used for unpredicted ads. The precision, recall and f-score values were noted and improvement was observed with the new model.

A logistic regression approach was suggested by author Kondakindi et al. [4] in 2014, to predict whether an ad will be clicked or not. The dataset used for this purpose was from Avazu provided as a part of Kaggle competition. They started off with simple Naive Bayes followed by Vowpal Wabbit and finally got the best scores with logistic regression together with proper data preprocessing. Shi et al. [5] in 2016, designed a framework for prediction of CTR and average cost per click (CPC) of a keyword using some machine learning algorithms. The performance data for the advertiser's keywords was gathered from Google AdWords. The author had applied different machine learning algorithms such as regression, random forest

and gradient boosting to evaluate the prediction performance on both CTR and CPC. Results concluded that random forest transpires to be the best for both the metrics while gradient descent results are least reliable.

Wang et al. [6] in 2011, implemented a model for learning of user's click behaviours from advertisement search and click logs. Decision tree (DT), CRF, SVM and backpropagation neural networks (BPN) are the algorithms which were employed to carry out the imposition. The experimentation finally led to proving that CRF model outperformed the two baselines and SVM remarkably. Chakrabarti et al. [7] in 2008, developed a model for contextual advertising in which the revenue accrued by the site publisher and the advertising network depends upon the suitability of the ads displayed. This was followed by mapping the model to standard cosine similarity matching.

Cheng et al. [8] in 2010, developed the model for customization of click models in sponsored search. The results demonstrated that the accuracy of CTR could significantly be improved by personalized models in sponsored advertising. Edizel* et al. [9] in 2017, proposed the use of that deep convolutional neural networks for CTR prediction of an advertisement. One approach involved query-ad depiction being learned at character while the second entail word-level model by pretrained word vectors. The conclusion signified better outcome than the standard machine learning algorithms trained with well-defined features.

The analysis of the background work clearly connotes that most of the algorithm used in the past are supervised classification algorithms that involves two classes namely clicked and not clicked-demonstrating whether advertisement was clicked or not. The study of unsupervised clustering is still not much discovered in this domain to the extent of our understanding. This research paper is an endeavour to compare FCM and KMC algorithm using the dataset.

3 Data Characteristics

The following Fig. 1 demonstrates the system architecture of the research.

The following subsection explains the details.

3.1 Data Collection

The dataset is acquired from Avazu (Kaggle) for the purpose of writing this paper. It contains 11 days' worth of data in order to build and test prediction models using various machine learning algorithms. As the given data is approximately 6 GB, the data taken was 10 h of data for training and 2 h of data for testing. The data is ordered chronologically and the clicks and non-clicks are sampled according to different strategies.

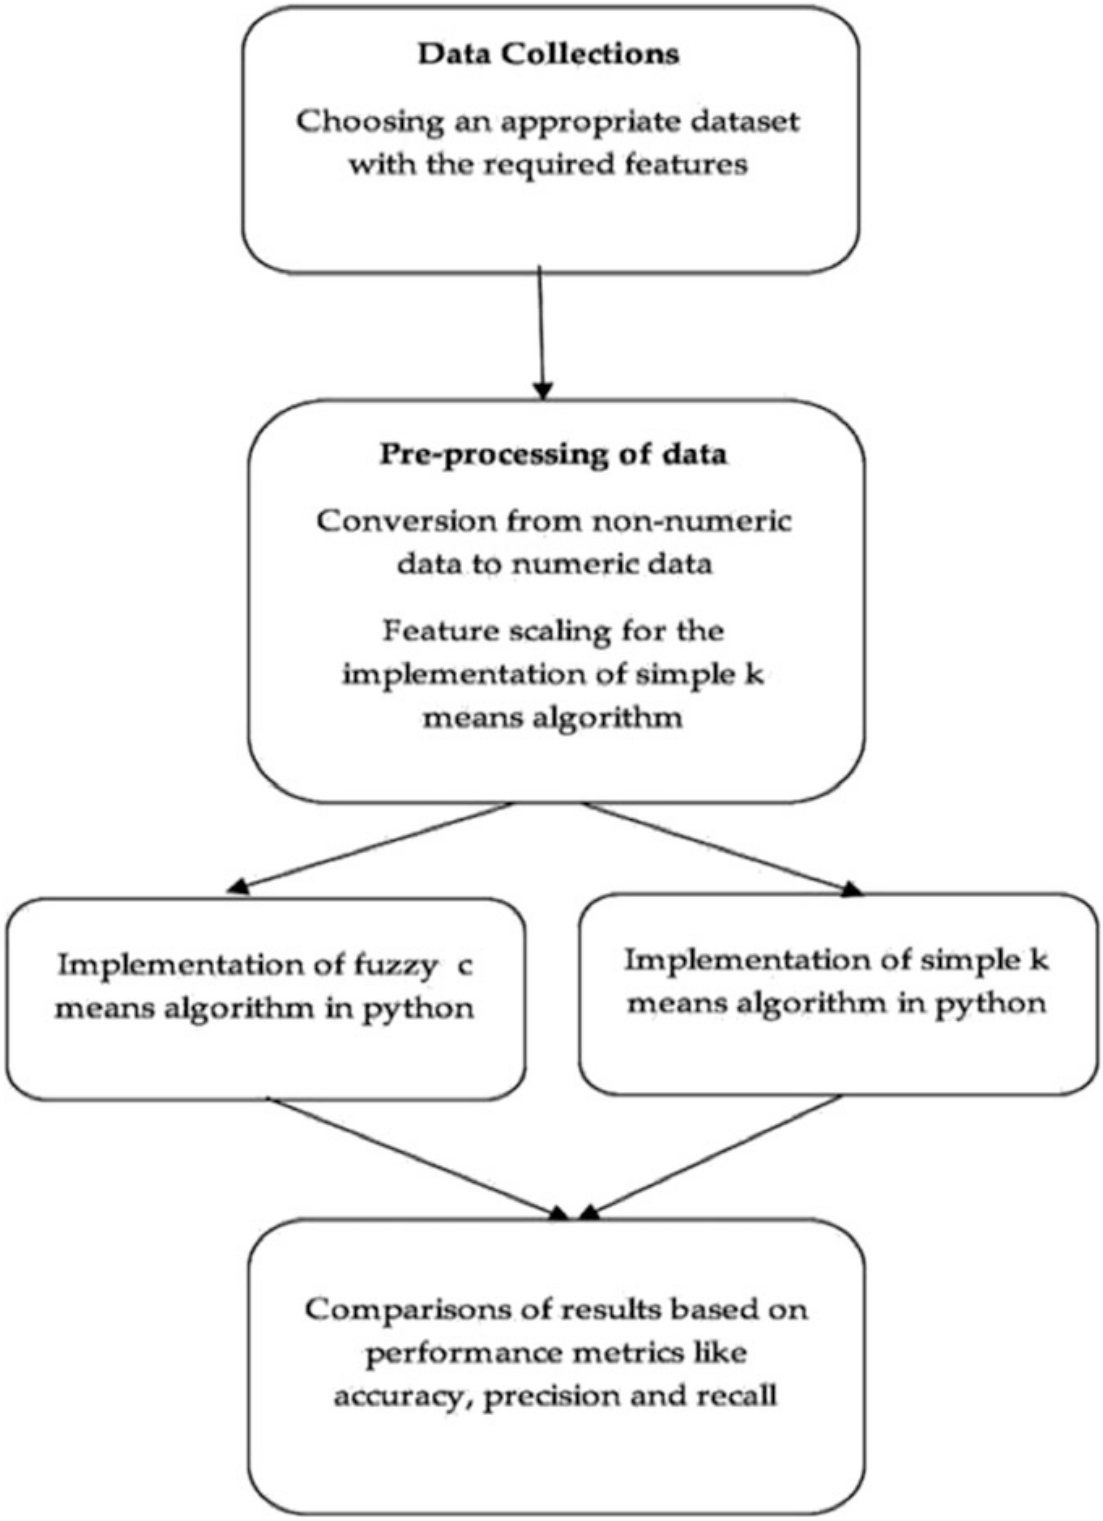

Fig. 1 System architecture

The following features are included in the dataset:

- id (unique id to identify advertisement)
- click (0 for not clicked and 1 for clicked)

- hour (in format of YYMMDDHH; it refers to the date and time the data is recorded)
- banner_pos (0 for top and 1 for bottom)
- site_id (refers to the website id)
- site_domain (website domain id)
- site_category (category to which website belongs)
- app_id (app id)
- app_domain (app domain)
- app_category (class to which app belongs)
- device_id (id of device from which ad was clicked
- device_ip (ip address of the device)
- device_model (model number of device)
- device_type (mobile/laptop/desktop)
- device_conn_type(internet connection type-wifi/mobile data)
- C1 and C14–C21 (anonymized categorical variables).

3.2 Preprocessing of Data

The class attribute is removed owing to the fact that unsupervised clustering is the technique applied which will learn from the data and classify it into two clusters. The dataset contains features in both integer and string format. In order to carry out the implementation, conversion of strings into integer is done. Pandas package in Python is used to load the csv file, i.e. the raw dataset into memory, identify the columns with string values and convert them into integer values using python standard hash function.

Feature scaling is done with the help of scikit-learn library in python in the case of KMC. It is done in order to ensure fast convergence to the optimal solution and normalize the range of variables.

3.3 Implementation of Machine Learning Algorithms

The following section explains the clustering algorithm used.

K-means Clustering: It is one of the most straightforward learning algorithms available for unsupervised learning [10]. The procedure basically follows two main steps to classify the dataset into k clusters. The number of clusters are fixed apriori. The algorithm starts by defining k cluster centers. Each value in the dataset is then associated to its nearest cluster. This is followed by a recalculation of the k cluster centers. A new binding is done between discrete units of information in the dataset and the new cluster centers and these steps are repeated till all units have been assigned to their respective clusters.

The pseudocode is given as follows (Fig. 2):

X = {x1, x2 …xn} be the collection of observations and u = {u1, u2 …uc} are the cluster centroids. We arbitrarily select 'c' cluster centers (1). Then, the distance

Given: a training set x(1),...,x(m) and feature vectors for each data point $x(i) \in \mathbb{R}^n$ with no labels $y^{(i)}$

(unsupervised learning problem).

Objective: Predict k centroids and a label $c^{(i)}$ for each datapoint

1. Initialize *k* points at random as cluster centers.
2. Assign data point to their closest cluster center according to the Euclidean distance function.

   For every i, set

   $$c(i) := arg\ min(j)||x^{(i)} - \mu j||^2$$

3. Find the new cluster centroid by calculating mean of all data points that belong to the cluster.

   For each j, set $\mu_j := \frac{\sum_{i=1}^{m} 1\{c^{(i)}=j\}x^{(i)}}{\sum_{i=1}^{m} 1\{c^{(i)}=j\}}$

4. Repeat steps 2 and 3 until the same points are assigned to each cluster in consecutive rounds.

Fig. 2 Pseudocode for k-means clustering

between each observation in dataset and center is calculated. Following this, each observation is assigned to that cluster for which the distance between the observation and the center is least from all the available centers (2). This assignment step is followed by a recalculation of the cluster centers (3) by executing step 1 again. If all observations belong to the clusters calculated in the previous iteration, then the algorithm is terminated.

1. Initialize $U=[u_{ij}]$ membership matrix, $U^{(0)}$
2. At k-step: calculate the centers vectors $C^{(k)}=[c_j]$ with $U^{(k)}$

$$c(j) = \frac{\sum_{i=1}^{N} u_{ij}^{m} . x_i}{\sum_{i=1}^{N} u_{ij}^{m}}$$

3. Update $U^{(k)}$, $U^{(k+1)}$

$$u_{ij} = \frac{1}{\sum_{k=1}^{c} \left(\frac{\| x_i - c_j \|}{\| x_i - c_k \|} \right)^{\frac{2}{m-1}}}$$

4. If $|| U^{(k+1)} - U^{(k)} || < \varepsilon$ then STOP; otherwise return to step 2.

Where u_{ij} is the degree of membership of x_i in the cluster j,

x_i is the ith of d-dimensional measured data,

c_j is the d-dimension center of the cluster

ε is a termination criterion between 0 and 1.

Fig. 3 Pseudocode for fuzzy c-means clustering

Fuzzy C-Means Clustering: FCM is also referred to as soft clustering [11]. Each observation can be a part of more than one cluster at the same time. The distance between each cluster center and value in the dataset is evaluated and based on this distance, the degree of membership is assigned to each observation. A higher degree of membership towards a cluster means that the observation is closer to that cluster center than compared to the rest of the clusters. The summation of the degree of membership of each point in dataset equals to one. Data points belong to distinct clusters in hard or non-fuzzy clustering. The degree of membership assigned to each observation plays a pivotal role here. This denotes the extent to which an observation belongs to each cluster. As we move from center to the boundary of the cluster, the degree of belongingness of the observation decreases.

The pseudocode for FCM is as follows (Fig. 3).

Let X = {x1, x2, x3 …, xn} be the collection of discrete units in dataset and V = {c1, c2, c3 …, ck} be the centers. Select 'k' cluster centers and initialize the membership matrix in step (1). Compute the centers 'cj' in step (2). Calculate the membership 'μij' in the membership matrix using step (3). Repeat step (2) and (3) until the smallest value of J is obtained.

4 Results and Analysis

The results were analysed using the accuracy, precision and recall [12] as an efficacy criterion. Accuracy is the measure of the closeness of the predicted observations to the actual value. It is the ratio of rightly predicted inspections to the total inspections made. Higher value of accuracy indicates more true positives and true negatives. Precision refers to the correctness of a model. It is simply the ratio of all the precisely predicted positives to the total number of positives predicted. More the number of true positives implies more precision. Recall is a measure of responsiveness or sensitivity of a machine model. It is the ratio of the correctly predicted positives to the count of values that belong to the class 'yes'. Recall and precision are inversely related. The following Table 1 depicts the performance analysis of FCM and KMC.

As Table 1 shows the accuracy, recall and precision values obtained for the two clusters, i.e. clicks/non-clicks predictions for the users is higher for FCM than for

Table 1 Comparison of results for k means and fuzzy c-means clustering

	k-means		Fuzzy c-means	
	Cluster 0	Cluster 1	Cluster 0	Cluster 1
Accuracy	43.85438544	43.85438544	76.61767177	76.61767177
Precision	15.62280084	81.0428737	17.12049388	83.51293103
Recall	52.05182649	42.16809357	91.03165299	9.345230918

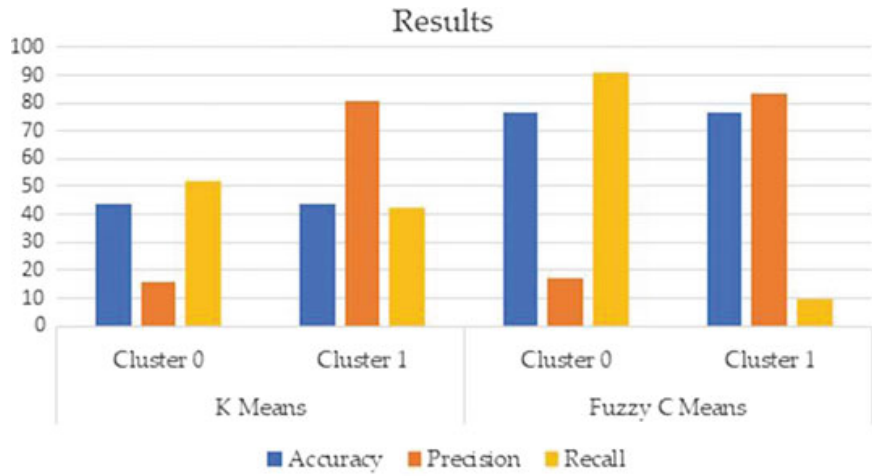

Fig. 4 Results

KMC. This means that the rightly predicted true positives and true negatives (accuracy), the degree of exactness (precision) and degree of completeness (recall) are relatively higher for FCM than for KMC.

Both the algorithms divide the data into two clusters, Cluster 0 and Cluster 1, which in turn represent a division of the dataset into two categories (Fig. 4). These categories are based on click/non-click classification for the ads, i.e. one cluster has all the ads clicked by the user. The other cluster has all ads which were not clicked by him. This gives a clear idea of the type of ads the user is inquisitive about and willing to click on.

After the classification of the ads in the dataset into categories—'Click' and 'Non-Click', we get a fair estimate of the kind of advertisements the user really wants to see. We can thereby predict more of such ads, hence increasing the CTR for the same.

The number of 'clicks' divided by the total number of times the ad is displayed, i.e. 'impressions' gives the CTR.

5 Conclusion

This paper compares the CTR as assessed by KMC and FCM algorithms. The outcome shows that FCM achieves better values of performance metrics than KMC. The results are better because it considers the fact that each data point can lie in more than one cluster and involves complex calculation of membership matrix. Conventional KMC, on the other hand, relies on hard clustering and definitively assigns each data point to the clusters.

The accuracy of the model can further be improved by assessing the shape of the clusters, including other more refined attribute selection and extraction methods that could assist in better modelling of the present system. Attribute selection is

concerned with selecting a subgroup of valid features for model selection whereas attribute extraction means deriving attributes from the already existing ones for subsequent learning. Superior results could be obtained by enhancing fuzziness coefficient. The degree of overlap between clusters is determined by the fuzziness coefficient. Higher value of m means larger overlapping between clusters. There exists a vast scope of application of other soft computing methodologies also, like swarm optimization, etc. that can be applied for determining CTR for other datasets as well.

ASK Approach: A Pre-migration Approach for Legacy Application Migration to Cloud

Sanjeev Kumar Yadav, Akhil Khare and Choudhary Kavita

Abstract Legacy application migration is a mammoth task, if migration approach is not well thought at the very start, i.e. pre-migration, and supported by robust planning especially at pre-migration process area. This paper proposes a mathematical pre-migration approach, which will help the enterprise to analyse existing/legacy application based on the application's available information and parameters an enterprise would like to consider for analysis. Proposed pre-migration assessment will help in understanding the legacy application's current state and will help in un-earthing the information with respect candidate application. Proposed pre-migration approach will help to take appropriate well-informed decision, whether to migrate or not to migrate the legacy application. As it is said that application migration is a journey, if kick-started once, needs to reach its destination else it can result into a disaster hence pre-migration is one of the important areas of migration journey.

Keywords Application migration · ASK approach · ASK confidence level (ACL) · LAMP2C · Legacy application · Migration process · Pre-migration

1 Introduction

Technology paradigm is changing at fast pace, so is the customer requirement. In order to serve the fast-changing customer requirement is to keep abreast with ever-changing technology. Important is, if enterprise does not embrace or adopt

N. Sharma et al. (eds.), *Data Management, Analytics and Innovation*, Advances in Intelligent Systems and Computing 1042, https://doi.org/10.1007/978-981-32-9949-8_2

new or up-coming technology then enterprise may face challenges such as unavailability or shortage of skilled manpower as they would have moved to other latest technology, which will impact software and hardware maintenance cost (complex patching and modifications/enhancement) because scarcity of people in market with the required technology will increase the manpower cost and at the same time even the hardware will also become costly. All this may put application scalability, business continuity, customers' experience and enterprise image [1] in jeopardize and may result in inability to meet current business needs.

Each of the challenges identified may have direct or indirect impact on one or more factors. At times these identified factors seem to be interrelated, refer Fig. 2. There may be other factors, which may be enterprise or legacy application specific.

Enterprises may be ardent and ready to adopt technology such as cloud computing, which delivers resource as virtualize service [2] and offers so many other benefits. However, the biggest challenge for an organization is that enterprise can't discard the investment made in the past in terms of existing business critical and in-use applications including its infrastructure. These business-critical applications/systems are referred as an asset. These assets are built or might have evolved over a span of 10–20 years; and have become core to business process, might have become complex and large enough to be understood by a person.

Cloud computing offers multiple benefits which any enterprise will be interested in such as lower operating cost, no up-front investment and ease of maintenance. Fact is that cloud reduces capital expenditure by leveraging cloud business model of pay-as-you use, which turns capital expenditure to operation expenditure.

As exiting applications cannot be discarded, so to embrace the new technology enterprise has below-mentioned three options for lasting benefits/goal, refer Fig. 1:

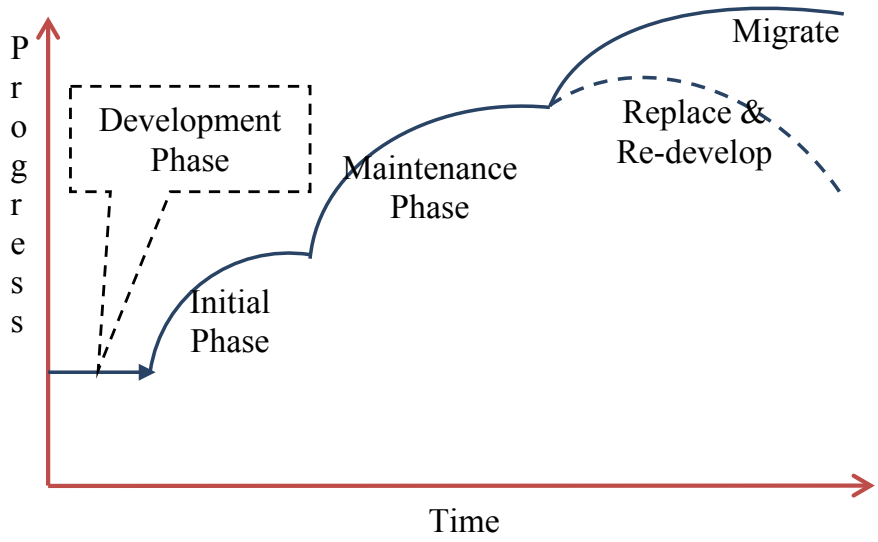

Fig. 1 Software life cycle phases and modernisation options©

i. Application Migration—Migrate legacy application migration to new platform.
ii. Application Replacement—Replace legacy application with off-the-shelf, available in market, application.
iii. Application Redevelopment—Redevelop the existing application all over again.

Two options, Option ii, i.e. Application replacement or option iii, i.e. Application redevelopment, does not seem to be feasible options because the existing business-critical application might have got developed with lot of effort, time and cost. Putting similar effort, cost and time all over again may not be feasible, so feasible option available with enterprise is option i, i.e. Application migration, which will help to migrate current application to new technology/ platform and embrace new technology, i.e. Cloud at the same time, will keep the business-critical application intact.

Paper is organized in six sections. Section 2 provides the literature review, which provides background of related work. Section 3 defines the problem. Section 4 provides the detail about the proposed framework. Section 5 details the ASK approach. Finally, the paper concludes with Sect. 6, which presents the concluding comments and future scope.

2 Literature Review

Cloud computing acceptance has increased over a period of time because of the benefits it brings in the area of operational and efficiency. Migration frameworks are proposed and are compared in the selected literature but none provides an end-to-end migration framework, especially in the pre-migration stage of the migration. The focus of literature review is to bring out any available pre-migration method/approach.

Summary of literature studied and identified research gap in context of chosen topic of the paper are detailed below:

Shoaib et al. [3] highlighted that due to technology advancement enterprises need to migrate from one platform to other, so existed framework was examined and reviewed. Based on this, the author is of view that multiple methods exists for migration and at the same time there are multiple risks involved during migration all these risks can be taken care if migration is performed properly. In this paper, the author describes different methods and frameworks which provides guideline for developers to enhance software migration process. As per the author, the focus area for migration is framework along with process and activities. The author concludes that there is research gap and need to be explored further.

Musale et al. [4] provided basic knowledge about the migration concept and initial factors required to migrate to cloud. The paper also highlighted that could computing is an emerging technology and there is substantial scope of operational

and efficiency improvement. If IT application is migration to cloud or some of the processes are migration to cloud environment, off premises. The author puts forward the cloud migration concept and discusses the essential points for migration and further discusses the after migration essential. The author is of view that migration to cloud is an art than it is a science.

Gholami et al. [5] highlighted that research around migrating legacy application to cloud has increased because of the adoption of cloud computing as an outsourcing strategy has grown in recent past. The author is of view that there is no integrated overarching cloud migration exists in current literature. In order to fulfil this gap, the author tries to propose cloud platform-independent conceptual view and reusable migration process, which has phases, activities and task. Validity of the proposed metamodel is demonstrated by analysing three existing cloud migration process models. Model can be extended by adding new constructs and can be customized for other migration paradigm.

Sabiri et al. [6] , the authors said that enterprises adopting cloud is increasing because of the significant advantage cloud computing brings in; however, the migration (move) to cloud has challenges. The authors studied and compared the existing cloud migration methods to understand the strengths and weaknesses of each model based on Model-Driven Engineering (MDE) approach. The author proposed and explained a cloud migration method based on Architecture Driven Modernization (ADM), which focuses on architectural modes instead of code artefacts.

Gouda et al. [7] highlighted that cloud migration can be of two types; either from on-site premises to the cloud or moving them from one cloud environment to another, where the information can be accessed over the Internet. The authors also highlighted that cloud migration is broadly classified into two categories, i.e. Big Bang Migration and Trickle Migration. The authors have suggested multiple cloud migration patterns or categories as their requirement. The authors also suggested migration to cloud-step wise approach or procedure which will help the user to successful and fruitful migration of its IT resources to cloud.

Shawky [2] highlighted that in order to utilize cloud's capability, the system should be migrated to cloud. The author also highlights that application migration to cloud leads multiple technical challenges and these challenges cannot be ignored. According to the author, the main challenge is mapping application to cloud services as multiple aspects need to be considered, which includes other system component dependencies.

Rashmi and Sahoo [8], 'A five-phased approach for cloud migration'; highlighted that cloud computing is the rapidly growing segment of IT. Organization is moving to cloud due to its long-term benefits but they are unsure about the migration process. The authors proposed a five-phased waterfall-based migration model to cloud having feedback path to earlier phase of the process but have not dwelled into the details of each phase of the proposed model.

Pahl et al. [9] mentioned in this paper that though cloud computing has gained the attention, adoption of the technology is yet to gain acceptance as how to migrate to cloud is unanswered for many. Point in case is highlighted with the help of three provider-driven case studies and tries to extract common layer-specific migration

process. Highlights that no common procedures and tools are exiting, however, establish migration core elements such as activities and steps.

Stavru et al. [10] acknowledged the fact that enterprises are unable to take full strategic and operational advantage as they are not able to migrate legacy application to cloud due to non-existence of mature process. The authors identified and extracted challenges with the help of systematic literature review. Using expert judgment, evaluates how different agile techniques, taken from Scrum and Extreme Programming (XP), could address or overcome the identified challenges in software modernization projects in specific context.

3 Problem Specification

Challenge can be in terms of skilled resource's scarcity, software maintenance cost, lack of software scalability, business continuousness, customers experience, reduced efficiencies, knowledge retention, enterprise image [1] and inability to meet current business needs. Each of the challenges identified may have direct or indirect impact on one or more factors, so identified impacted factors seem to be interrelated. Tried categorizing these challenges into the below category; refer Fig. 2. There may be other factors, which may at times be enterprise specific or legacy application specific.

- Customer
  - (a) Application inefficient in catering to business requirement will impact the enterprise interest.
  - (b) Applications may become inefficient in catering to any area of customer requirement (customer can be internal and/or external) over time; in terms of functionality/feature(s) and better service. Inefficient application will provide an edge to competition.
- Knowledge
  - (a) Lack of in-depth knowledge in terms of understanding the existing system and its related process will or may have direct impact on the system maintenance, i.e. developing new functionality and enhancements.

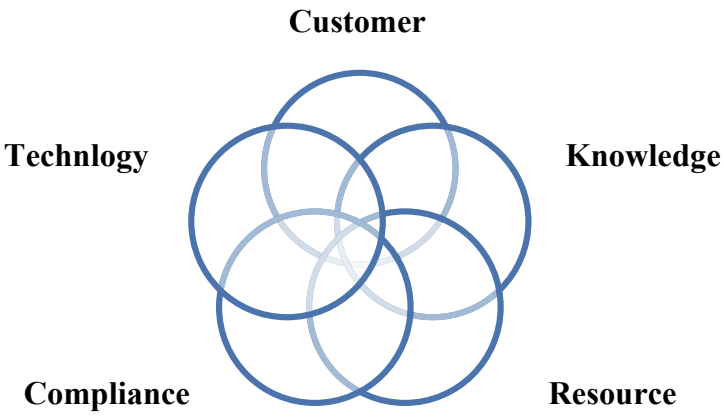

Fig. 2 System maintenance and enhancement challenges

(b) Due to non-availability of knowledgeable resources will have difficulty in getting best practices shared with respect to these legacy applications, i.e. knowledge sharing. It will increase the risk of knowledge concentration amount small set of people.

- Resources

(a) Reducing resource pool (attrition) or resource pool desire to move onto market relevant technology will have direct impact on resource availability for the maintenance/enhancement of legacy application.
(b) As legacy application knowledge gets concentrated into few resources, it will lead to increase in people retaining cost; related aspect will be increase cost of gaining resource in desired technology.
(c) Contracted resource pool will have risk of high dependency, in terms of understanding the existing system and its related process on to a very small set of people in an organization.

- Technology

(a) Enterprise may have multiple technologies in use for existing business-critical applications, so maintaining them will have high cost because the legacy application might have become unsupported due to non-existence of support from the product vendor as they might have stopped supporting the in-use version or vendor might release new version, i.e. vendor moved ahead in technology.

- Compliance

(a) Legacy applications may become non-regulatory compliance over a period of time if no enhancement is made due to multiple reasons mentioned above.
(b) Non-compliance to regulatory norms may have bigger impact than adopting new technology and moving legacy application to the technology.

Challenges highlighted above are few of the challenge, many other challenges will come which will be application or enterprise-specific challenges. These challenges motivate to come up with a framework, which will help the enterprise to migrate legacy application to cloud in an efficient manner.

4 Proposed Framework

Legacy application migration is a journey which requires a careful detailed planning irrespective of the size of the application identified for migration because no one-size-fit-approach will work in application migration. One of the biggest challenges an enterprise faces is the uncertainty of where to begin the migration process. If enterprises do not carefully plan, execute and monitor the transformation using

established processes [11] then migration can be fraught with pitfalls. Before we proceed further, it is essential to understand the reasons or trigger points for migration. At high level there are only two factors which trigger migration and these factors are either: Business Driven, Technology Driven or both. Whichever may the reason for migration, i.e. business and/or technology; one thing which will happen first is current portfolio analysis.

Cloud computing concepts and approach itself is very different from the traditional software concepts and approach. In fact, moving to cloud is a serious step to take in a holistic manner [1], which required a careful elaborate planning for successful migration because cloud computing brings changes such as economic, legal, privacy/security, [1] etc. especially the pre-migration area of the migration process.

Cloud covers all application layers, i.e. application (SaaS), platform (PaaS) and infrastructure (IaaS), which makes legacy application migration not a straightforward task as it looks like. Rashmi et al. [8], especially when migrating a legacy application, which is tightly coupled [12] as compared to cloud application.

In order to address this issue, a framework is proposed called '**L**egacy **A**pplication **M**igration **P**rocess Framework to **C**loud'; referred as LAMP2C, Fig. 3. LAMP2C migration framework acts as a guiding principle for migrating application to cloud and process to be followed while migrating legacy application. Scope of the proposed LAMP2C framework covers entire legacy application as shown in Fig. 3 and pre-migration is highlighted as ASK Approach is part and limited to the pre-migration area of the LAMP2C framework.

Framework helps to plan the migration in an effective and efficient manner and it also helps in speeding up migration execution process with clear and hazel free migration path.

LAMP2C, address pre-migration, migration and post-migration area of migration with an umbrella of governance area across three cloud layers. Framework is divided into area and area is further sub-divided into phases. The phases will have activities under it. LAMP2C—high-level framework is shown in Fig. 4.

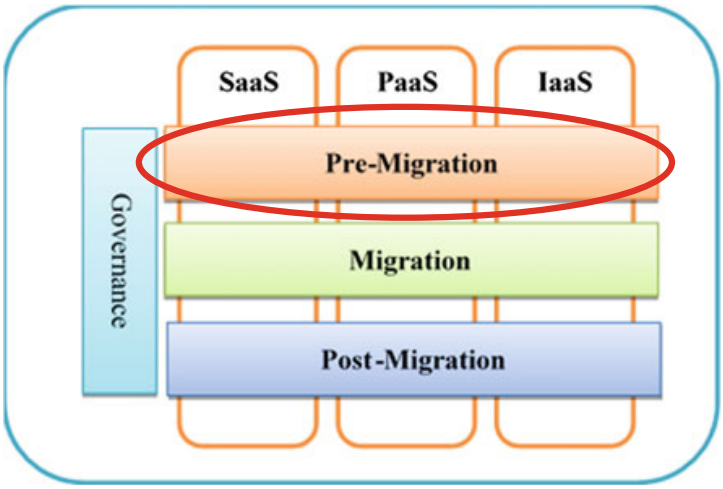

Fig. 3 High-level framework

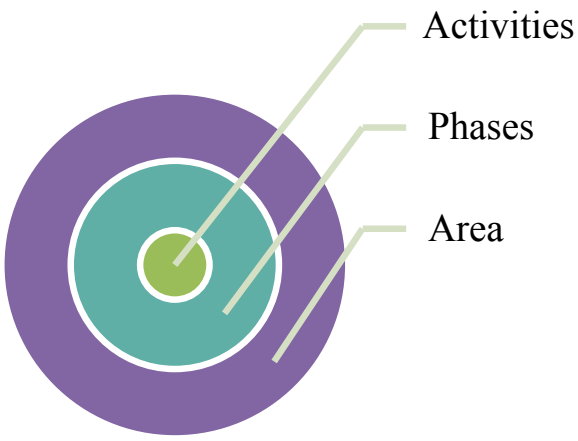

Fig. 4 LAMP2C constituents

LAMP2C is a flexible framework, which can be tweaked as per the enterprise's requirement as proposed framework does not force to follow the process end-to-end rather it suggests to go phased manner.

One of the important parts of LAMP2C is the pre-migration area, which helps in evaluating existing portfolio or application which in turn helps an enterprise in understanding the complexity, challenges and efforts that will be required for application migration. It will also address the uncertainty of 'where to begin' and other than whether to migrate or not to migrate to the cloud.

LAMP2C, Figs. 1 and 3 is copyright of the authors: Registration Number L-60550/2014.

5 Ask Approach

It is assumed that at high level there are only two factors which can trigger migration and they are either technical or non-technical (business) parameter, so assessment and its parameters are also clubbed into these two categories only. Another assumption is that a) technical assessment should consider all the three cloud's service model, i.e. IaaS, SaaS and PaaS; however, enterprise is free to choose one or more for assessment and their respective parameters. Parameters which cut across three models should be grouped into one as 'Common Parameters', as shown in Fig. 5.

Common parameters are to avoid the consideration of same parameter(s) across three layers of service model, however it will depend upon individual, how they would like to perform the pre-migration analysis. b) Non-technical, i.e. business parameter are those parameters, which are not technical in nature should be considered as one group or as suitable.

ASK Approach—a pre-migration assessment methodology is proposed to perform portfolio or application analysis under pre-migration are of LAMP2C framework. ASK Approach is an important constituent of the LAMP2C framework and its scope is limited to the pre-migration area of the LAMP2C framework as it

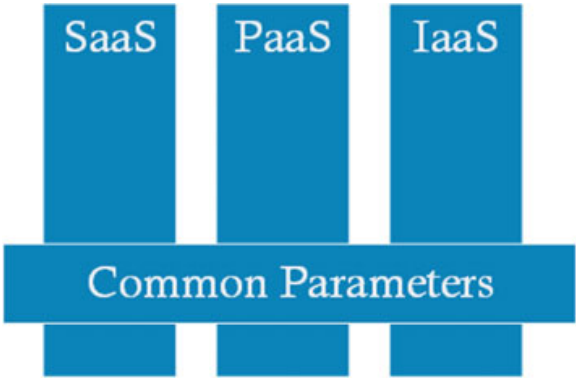

Fig. 5 Parameter identification area

Fig. 6 Pre-migration approach

provides inputs and helps in taking GO/No-Go decision with respect to legacy application migration to cloud. Proposed pre-migration assessment methodology is parameter based mathematical approach, which will be appropriate for any application identified for migration and will help enterprise to view and analyse the enterprises IT application portfolio in details based on parameters which are important for organization and application so assessment is carried out on any set of identified parameters under the mentioned category or both, i.e. technical and non-technical (business) aspect.

Pre-migration approach can be divided into five steps, as shown in Fig. 6 and detailed in subsequent paras:

As approach is parameter based, as a first step, all parameters and its sub-parameters needs to be identified. Each identified and considered parameter needs to be assigned the importance. Importance is rated between the range of 0.1, being the lowest to 5.0, being the highest, based on the parameter's impact, as tabled below (Table 1):

Table 1 Impact rating range

Importance	Impact rating range
Very high	4.1–5.0
High	3.1–4.0
Neutral	2.1–3.0
Low	1.1–2.0
Very low	0.1–1.0

Assuming that there are n number of parameters namely C_1, C_2, C_3 and so on till C_n. Based on parameters' importance an impact rating between the range of 0.1–5.0 will be assigned for each parameter. Adding all these integrals and dividing them by the total number of parameters (in this case n) considered for analysis will give us the mean value of the data, which is being referred as '**ASK Point**' (ASKP), i.e. μ_c.

$$\text{ASKP} = \mu_c = \frac{\int C_1 + \int C_2 + \int C_3 + \int C_4 \ldots + \int C_n}{\text{n}}$$

$\text{ASKP} = \mu_c = \textit{Parameters'Mean}$
$n = \textit{Number of parameters}$
$i = \textit{Importance of parameter}$
In reduced form the above formula can be written as follows:

$$ASKP = \mu_c = \sum_{1}^{n} \frac{\int C_n}{n}$$

Considering the same data calculate the standard, which will be referred as **ASK Confidence Level (ACL)**. ACL will be calculated by adding the squares of the values found from subtracting the ASKP from each parametric value. This summed value is divided by the total number of parameters. This will give us the standard deviation σ_c, i.e. ACL.

$$\text{ACL} = \sigma_c = \frac{\left(\int C_1 - \mu_c\right)^2 + \left(\int C_2 - \mu_c\right)^2 + \left(\int C_3 - \mu_c\right)^2 + \cdots \left(\int C_n - \mu_c\right)^2}{n}$$

$\text{ACL} = \sigma_c = \textit{Parameters' Standard Deviation}$
$\text{ASKP} = \mu_c = \textit{Parameters'Mean}$
$n = \textit{Number of parameters}$

In reduced form the above formula can be rewritten as follows:

$$ACL = \sigma_c = \sum_{1}^{n} \frac{\left(\int C_n - \mu_c\right)^2}{n}$$

In order to generate boundary for the identified parameter, which is going to be referred as **ASK Belt** (ASKB). ASKP and ACL will help to build ASK Belt. ASKB will have two components a) ASKB Right, i.e. ASKB_R and b) ASKB Left, i.e. ASKB_L. ASKB_R and ASKB_L can be calculated as shown below:

$$\text{ASKB}_\text{R} = \text{ASKP} + \text{ACL}$$
$$\text{ASKB}_\text{L} = \text{ASKP} - \text{ACL}$$

Once, ASKP, ACL and ASKB ($ASKB_R$ and $ASKB_L$); bell curve can be calculated using the below formula (Gaussian equation)

$$f(x) = \frac{1}{\sqrt{2\pi\sigma_c^2}} e^{\frac{-(x-\mu_c)^2}{2\sigma_c}}$$

The following are the value for the above formula:

π = 3.14
e = 2.71 and
x = Parameter Impact
μ_c = ASKP
σ_c = ACL

As fifth and the last step; calculate various other values required in the Gaussian function. The parameters have been arranged in the ascending order of the impact rating for facilitating the plotting process. Plotting the above $f(x)$ values versus x values, we get the following bell curve (as defined by the Gaussian function), refer Fig. 7.

Points which falls between $ASKB_R$ and $ASKB_L$ can be safely considered for legacy application migration, however, points which fall outside the belt need to be re-looked and considered with caution.

These inputs will provide enough data points to conclude as to Go ahead with the legacy application migration or still there are points/parameters, which need to be re-looked at. And will provide inputs to come up with migration plan.

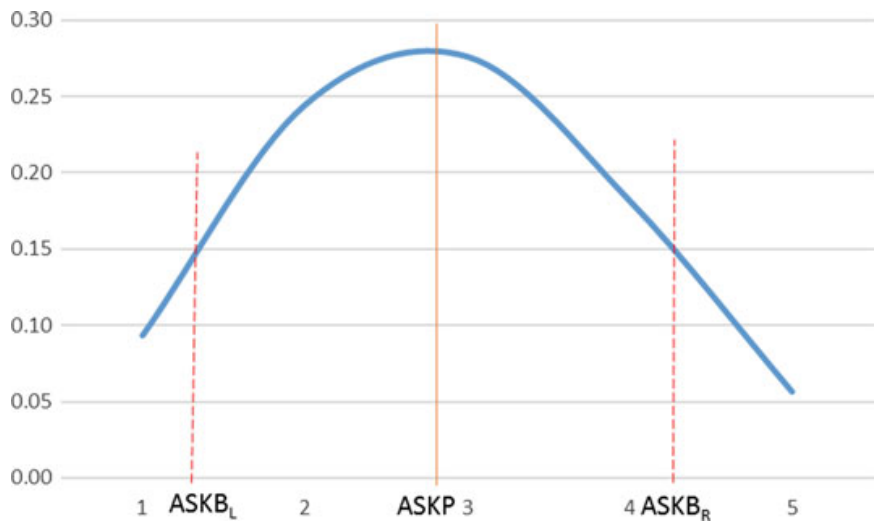

Fig. 7 Bell curve

6 Conclusion

Proposed mathematical pre-migration methodology called 'ASK Approach' under the LAMP2C migration framework. Important is, impact rating between the range of 0.1–5.0 is assigned to each identified and considered parameters. 0.1 being the lowest and 5.0 being the highest. Assigning an impact rating to each parameter will eliminate any guesswork among any of the person associated with respective application migration. Impact rating will help to drive ASKP, i.e. μ_c, which in turn will help to drive ACL, i.e. σ_c. ASKP and ACL will help to drive ASKB_R and ASKB_L which in turn will help to calculate $f(x)$ for each considered parameter. Bell curve can be plotted to identify the parameters, which helps to provide a view about, which legacy application parameters should be considered with confidence and which parameter needs more attention. It requires ultimate help to take informed decision of GO or NO-GO with respect to application migration. With the help of this pre-migration approach enterprise can also make phase or staggered legacy migration approach. Phased manner approach provides the required feel confident factor and return on their investment can be seen as migration project progress. Big bang migration approach may not provide the required feel good factor and always have a project failure risk.

Proposed ASK Approach is focused on parameter which falls with the ASK Belt, but does not provide any inputs as to what needs to be done with parameters, which are outside the ASK Belt, so ASK Approach can be further enhanced to come up with mathematical formula or otherwise, as to how to deal with the parameters, which falls outside the ASK Belt, i.e. ASKB_R and ASKB_L.

A Fuzzy Logic Based Cardiovascular Disease Risk Level Prediction System in Correlation to Diabetes and Smoking

Kanak Saxena and Umesh Banodha

Abstract The cardiovascular disease (CVD) is one of the major causes of death among the people having diabetes in addition to smoking habits. It will create tribulations for every organ of the human body. Smoking becomes fashion among the youth from their childhood which results in premature death. The intention of this paper is to explain the impact of diabetes and smoking along with high BP, high pulse rate, angina affect, and family history on the CVD risk level. The concept used is based on the knowledge-based system. We have proposed a fuzzy-logic-based prediction system to evaluate the CVD risk among the people having diabetes with smoking habits. The aim is to facilitate the experts to provide the medication as well as counsel the smokers well in advance. This will not merely save the individual but also an immense relief to concern. The data set is used from UCI (Machine Learning Repository). Most of the researchers worked on diabetes or smoking impact on CVD separately, but the proposed system demonstrates how drastically it will affect ones' health condition.

1 Introduction

Cardiovascular Diseases (CVD) are very widespread disease that becomes the ground of death and morbidity among the humans [3, 5, 19]. The data from the national heart association (2012) showed that 65% of people with diabetes die from some sort of heart disease or stroke. The Framingham study was the earliest sub-

stantiation to demonstrate that people with diabetes are more (near about 2–4 times) susceptible to CVD disease than those who did not have diabetes [12]. It is very clear that diabetes if not controlled then it becomes the unending cause of not only the CVD but many more diseases [16]. As the WHO the percentage of the affected group is of 30 million in the year 1985, which increased to 135 million in the year 1995, and in the year 2005 it became 217 million. The prediction is near about 366 million people will suffer from diabetes in 2030, either they belong to developing or developed countries. On the other hand, smoking is the most imperative avertable cause of death which also accelerates the chances of occurrence of CVD among people, i.e., enhances the risk level [4]. It is also stated that smoking is the second leading cause after the high BP for CVD mortality. The WHO reported that more than one billion people smoke and the frequency rising surprisingly [14]. According to [8] the risk level of CVD estimated 15- year long period ahead for a smoker in comparison to a nonsmoker. Nowadays, the health care domain is one of the key domain where research is going on in the area of knowledge base to predict the impending risk in a patient and future of a healthy person with bad habits. The importance of the knowledge base is that it analyzes the data using various techniques. The experts took advantage of using the computerized diagnosis system where the information draws together in direct as well as indirect form. Earlier the work is done manually, though the decisions were taken by the help of the computer-based decision support system. With the improvement in the technology, the manually collected data problems have solved and now the system acquires the data which are directly or indirectly related to the physical condition. Today, there are many health care apps which assist the users as well as the experts for quick evaluation, thus avoiding uninvited events in ones' life. The evaluation varies on the input parameters and the techniques applied for the evaluation. Currently, the focus is on the flexibility of the conditions with intelligent evaluation. For the proposed system the highly suitable basis is the fuzzy set theory and the logic. The concept helps us in the interpretation of the facts with its findings and enhances the system with the cross diagnosis and estimation of the risk level.

In the proposed prediction system the main focus is on the CVD in relation to diabetes and smoking (urine nicotine). For testing purpose, the data set from UCI is used with major eight attributes as shown in Fig. 1. Among these, the major inputs are eight (inclusion of smoking) with adding together and one is used for the output purpose.

2 Literature Survey

Phuong et al. [13] illustrated the use of fuzzy logic and its application in the field of medicine. Oad and DeZhi [10] described the fuzzy-rule-based system for prediction of heart disease. Neshat et al. [11] proposed a fuzzy expert for liver disorder. Anooj [1] developed the weighted fuzzy clinical decision support system for the heart disease risk level prediction. Alessandra Saldanha deMattosMatheus et al. discussed

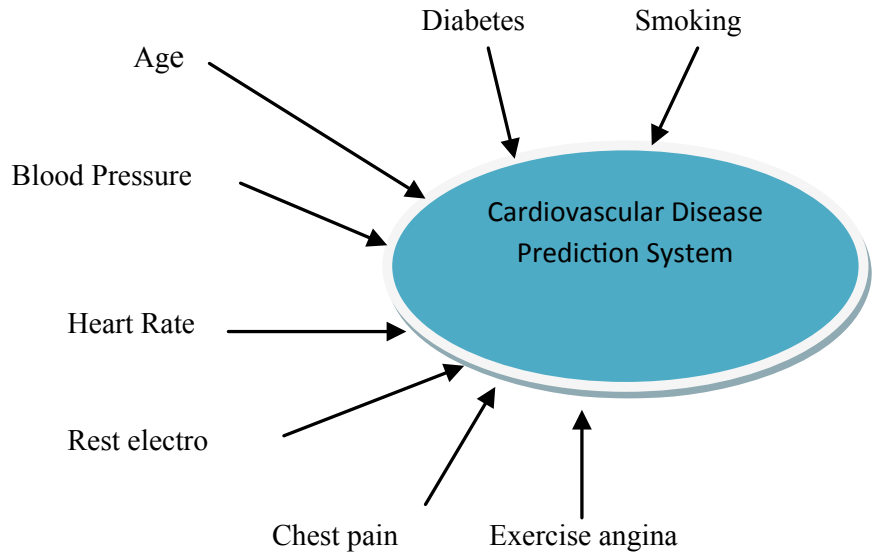

Fig. 1 Inputs of the cardiovascular disease risk level prediction system

the impact of the diabetes on the cardiovascular disease with obesity property in the patient. Rajeswari and Vaithiyanathan [15] developed heart disease diagnosis system using fuzzy logic and genetic algorithm. Anbe et al. [9] proposed the fuzzy set diagnosis system for the valvular heart disease. Kumar and Kaur [17] exemplified the fuzzy rules based on the six parameters to predict the heart disease. Phongsuphap and Pongsupap [18] evaluated the health care policies to assist the authorities on the basis of the survey data which consists of qualitative as well as qualitative. The authors surveyed on the epidemiology of the use of tobacco smoking in the United States. They also emphasized the study of the characteristics of the nicotine and the clinical applications of medication [6]. There is the correlation with the smoking and the cardiovascular disease as it may be one of the causes of altered lipid metabolism, increased demand for myocardial oxygen and blood and many more [20, 21]. In [2, 7], the group of the smokers was studied with the impact of the serum cotinine levels in smokers as well as in nonsmokers.

3 Cardiovascular Disease Prediction System

The proposed prediction system is based on the fuzzy logic technique which may feasibly be used to predict the risk level of the CVD in the patients with diabetes and smoking habits. The preference of the fuzzy techniques is through on the uniqueness of self-explanatory assessment making procedure. In fuzzy logic, its effectiveness depends on the formation of the set of acts. The biased predicament can be unconcerned if the set of acts be capable to form automatically without the intervention of the experts. According to Table 1 the stages and steps of fuzzy logic are illustrated, which commence with the preprocessing of the data followed by the

Table 1 Stages and Steps of Fuzzy Logic

Stages	Steps
Preprocessing	Mining of the parameters
Fuzzification	Define the linguistic variables with their ranges
	Construction of the membership functions for input as well as for output variables
	Conversion of crisp data into the fuzzy data sets with the help of membership functions
Fuzzy rule base	Construction of knowledge base rules
Defuzzification	Mapping to quantifiable risk
Decision-making	Selection of the choice on the basis of the relevant information available

fuzzification and the rules generation. Thus the prediction system instigates with the symptoms performance-based analysis. Further, it will also depict the risk level in the midst of investigation and lend a hand to the experts to take the suitable decision at suitable point in time.

Figure 2 demonstrates the steps used in the CVD prediction system. The preprocessing of the system that consists of patient clinical data pattern to facilitate the input into the system by converging the data into accessible form, by performing the data mining to find the missing values (if any), convert it into the permissible range and significant task is the selection of the attributes which directly or indirectly fatally affect the prediction system. As it's a nontrivial fact that the data

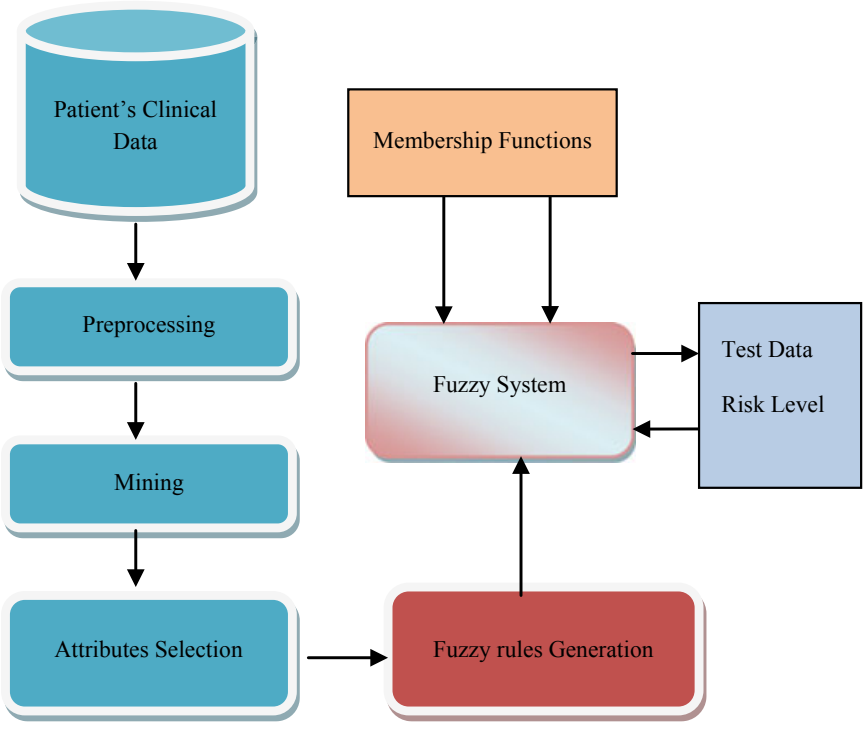

Fig. 2 Proposed fuzzy-based prediction system

which are not normalized cannot envisage the system procedure. The next step is to classify the data set in two categories, either suffering from the CVD or not.

The behavior of prediction system is uncertain. The fuzzy system is more appropriate to handle such type of formless medical events. The fuzzy system consists of the fuzzifier, fuzzy rules, fuzzy inference engine, and defuzzifier. In the fuzzification procedure, the crisp data set is to converted into a fuzzy value and the fuzzifier is the mapping from the data set to the fuzzy linguistic data value—a realistic approximation which is attained by the membership function. The fuzzy rule is to get fractioned into two parts as (1) condition and (2) conclusion. The inference engine interprets the rules logic with the appropriate reasoning, thus results in the form of the output—risk factor. Finally, the defuzzification is the reverse procedure of the fuzzification, where the mapping is to done from fuzzy value to the crisp data value. The system works with the identification of the input and output variables. Member function is used to characterize the fuzzy system and the suitable and succinct way is to characterize the member function mathematically. The significance of the mathematical formula is that it establishes contribution of the input variable to fuzzy set. The output of the prediction system has to be defuzzified, that is it has to be converted into a precise quantity, which can be the logical union of two or more fuzzy membership functions defined on the cardiovascular affect world.

The following process is to fuzzify all inputs and outputs and bring close to the contribution to which these inputs and outputs fit into each of the appropriate fuzzy sets. In the prediction system, the subsequent process is to discover the weighted fuzzy rules which have to engender from the various attributes resolution weighted rules. The method used for the automatic engenders the set of acts that are based on the structure of the state of fuzzy modals. The decision rules were attained from IF and THEN fractions of the specific class. These were acquired by converting into linguistic variables on the basis of the fuzzy membership functions. The first attribute used is age which is classified into four fuzzy sets (minor, young, adult, and old). The triangular as well as trapezoidal membership functions are used for the fuzzy sets. The same place into practice for blood pressure, chest pain, heart pain, blood sugar, rest electro, affected, and urine nicotine. In this, the fuzzy sets were separated into three or four levels that as follows.

Age (separated into 4 levels)			
Minor	Young	Adult	Old
$\mu_{minor}(x) = 1$, $x \in [1,15]$ $\mu_{minor}(x) = (18 - x)/(18 - 15)$, $x \in [15,18]$ $\mu_{minor}[x] = 0$, otherwise	$\mu_{young}(x) = (x - 15)/(24 - 15)$, $x \in [15,24]$ $\mu_{young}(x) = (42 - x)/(42 - 24)$, $x \in [24,42]$ $\mu_{young}(x) = 0$, otherwise	$\mu_{adult}(x) = (x - 33)/(40 - 33)$ $x \in [33,40]$ $\mu_{adult}(x) = (61 - x)/(61 - 40)$, $x \in [40,61]$ $\mu_{adult}(x) = 0$, otherwise	$\mu_{old}(x) = (x - 54)/(54 - 40)$, $x \in [40,54]$ $\mu_{old}(x) = (75 - x)/(75 - 54)$, $x \in [54,75]$ $\mu_{old}(x) = 0$, otherwise

Chest pain (separated into 3 levels)		
Alert	Risk	High risk
$\mu_{alert}(x) = (x - 1)/(2 - 1)$, $x \in [1, 2]$ $\mu_{alert}(x) = 0$, otherwise	$\mu_{Risk}(x) = (x - 2)/(3.5 - 2)$, $x \in [2,3.5]$ $\mu_{Risk}(x) = 0$, otherwise	$\mu_{HighRisk}(x) = (x - 3.5)/(4 - 3.5)$, $x \in [3.5,4]$ $\mu_{HighRisk}(x) = 0$, otherwise

Blood pressure (separated into 5 levels)				
Low	Normal	Alert	High	Very high
$\mu_{low}(x) = 1$, $x \in [1,100]$ $\mu_{low}(x) = (120 - x)/(120 - 99)$, $x \in [99,120]$ $\mu_{low}[x] = 0$, otherwise	$\mu_{normal}(x) = (x - 110)/(121 - 110)$, $x \in [110,121]$ $\mu_{normal}(x) = (132 - x)/(132 - 121)$, $x \in [121,132]$ $\mu_{young}(x) = 0$, otherwise	$\mu_{alert}(x) = (x - 125)/(143 - 125)$, $x \in [125,143]$ $\mu_{alert}(x) = (166 - x)/(166 - 143)$, $x \in [166\text{-}143]$ $\mu_{alert}(x) = 0$, otherwise	$\mu_{high}(x) = (x - 158)/(184 - 158)$, $x \in [125,143]$ $\mu_{high}(x) = (207 - x)/(207 - 184)$, $x \in [184,207]$ $\mu_{high}(x) = 0$, otherwise	$\mu_{very\ high}(x) = 0$ $x \in [1,157]$ $\mu_{very\ high}(x) = (x - 157)/(186 - 157)$, $x \in [157,186]$ $\mu_{very\ high}(x) = 1$, $x \in [207,350]$

Blood sugar (separated into 5 levels)				
Low	Normal	Alert	High	Very high
$\mu_{low}(x) = 1$, $x \in [1,65]$ $\mu_{low}(x) = (80 - x)/(80 - 65)$, $x \in [65,80]$ $\mu_{low}[x] = 0$, otherwise	$\mu_{normal}(x) = (x - 71)/(127 - 71)$, $x \in [71,127]$ $\mu_{normal}(x) = (139 - x)/(139 - 127)$, $x \in [127,139]$ $\mu_{normal}(x) = 0$, otherwise	$\mu_{alert}(x) = (x - 127)/(155 - 127)$, $x \in [127,155]$ $\mu_{alert}(x) = (167 - x)/(167 - 155)$, $x \in [167\text{-}155]$ $\mu_{alert}(x) = 0$, otherwise	$\mu_{high}(x) = (x - 148)/(155 - 148)$, $x \in [148,155]$ $\mu_{high}(x) = (250 - x)/(250 - 199)$, $x \in [199,250]$ $\mu_{high}(x) = 0$, otherwise	$\mu_{very\ high}(x) = 0$ $x \in [1,210]$ $\mu_{very\ high}(x) = (x - 210)/(250 - 210)$, $x \in [210,250]$ $\mu_{very\ high}(x) = 1$, $x \in [250,500]$

Heart pain (separated into 4 levels)			
Low	Normal	High	Very high
$\mu_{low}(x) = 1$, $x \in [1,55]$ $\mu_{low}(x) = (71 - x)/(71 - 55)$, $x \in [55,71]$ $\mu_{low}[x] = 0$, otherwise	$\mu_{normal}(x) = (x - 66)/(73 - 66)$, $x \in [66,73]$ $\mu_{normal}(x) = (98 - x)/(98 - 73)$, $x \in [73,98]$ $\mu_{normal}(x) = 0$, otherwise	$\mu_{high}(x) = (x - 87)/(123 - 87)$, $x \in [87,123]$ $\mu_{high}(x) = (123 - x)/(146 - 123)$, $x \in [123,146]$ $\mu_{high}(x) = 0$, otherwise	$\mu_{very\ high}(x) = 0$ $x \in [1,210]$ $\mu_{very\ high}(x) = (x - 172)/(198 - 172)$, $x \in [172,198]$ $\mu_{very\ high}(x) = 1$, $x \in [198,314]$

Rest electro (separated into 3 levels)		
Alert	Risk	High risk
$\mu_{alert}(x) = 1$, $x \in [1]$	$\mu_{Risk}(x) = 2$, $x \in [2]$	$\mu_{HighRisk}(x) = 3$, $x \in [3]$

Affected
$\mu_{affected}(x) = 1$, $x \in [1]$, $\mu_{affected}(x) = 0$, otherwise

Urine nicotine (separated into 3 levels)		
Alert	Risk	High risk
$\mu_{alert}(x) = (x - 225)/(243 - 225)$, $x \in [225,243]$ $\mu_{alert}(x) = (366 - x)/(366 - 243)$, $x \in [366\text{-}243]$ $\mu_{alert}(x) = 0$, otherwise	$\mu_{high}(x) = (x - 358)/(384 - 358)$, $x \in [358,384]$ $\mu_{high}(x) = (507 - x)/(507 - 384)$, $x \in [384,507]$ $\mu_{high}(x) = 0$, otherwise	$\mu_{very\ high}(x) = 0$, $x \in [1,557]$ $\mu_{very\ high}(x) = (x - 557)/(786 - 557)$, $x \in [557,786]$ $\mu_{very\ high}(x) = 1$, $x \in [631,1473]$

4 Proposed Algorithm

In this paper, we have used the conception of the fuzzy logic and establish the appropriate weights by normalizing the data set according to the derived fuzzy said rules. These normalized data sets are used to predict the risk level in any human being of cardiovascular disease with the impact of diabetics and/or smoking. These will also recognize the approximate acceleration of the disease in the case of smoking. The nicotine factors are included but a common value is considered instead of the type of smoking (cigarette, cigar, bidi, or huka). We have used the above rules and test it using the functions in SciLab.

Proposed Algorithm:

Step 1 [Preprocessing]
Normalized the given data set with respect to the input parameters fuzzy rules described in the Sect. 3. Let (F_1, D), (F_2, S), and (F_f, C) are the fuzzy sets, where (F_1, D) denotes the domination of the diabetics among the patients and (F_2, S) denotes the domination of smoking among the patients data sets and (F_f, D) is defined as (F_f, D X S), where $F_f(\alpha, \beta) = F_1(\alpha)$ ñ $F_2(\beta)$, $\forall\alpha \in D$ and $\forall\beta \in S$ and ñ is the fuzzy intersection operation of two fuzzy sets.

Step 2 [cardinal set]
Discover the cardinal set from the preprocessed data in Step 1.

Step 3 [Approximation Function]
Congregate the multiple aggregation functions of the symptoms to a single fuzzy set using the following

$$\frac{1}{|S|}\sum_{x\in S}\mu_c\Gamma_c(x)\mu_{\gamma c}(x)(p)$$

where S is the set of symptoms and p represents the patients with the membership and cardinal functions.

Step 4 [Decision-Making]
Finally, the maximum value has to be selected from the result obtained by

$$e_i = \sum_{j=1}^{n} p_{ij}$$

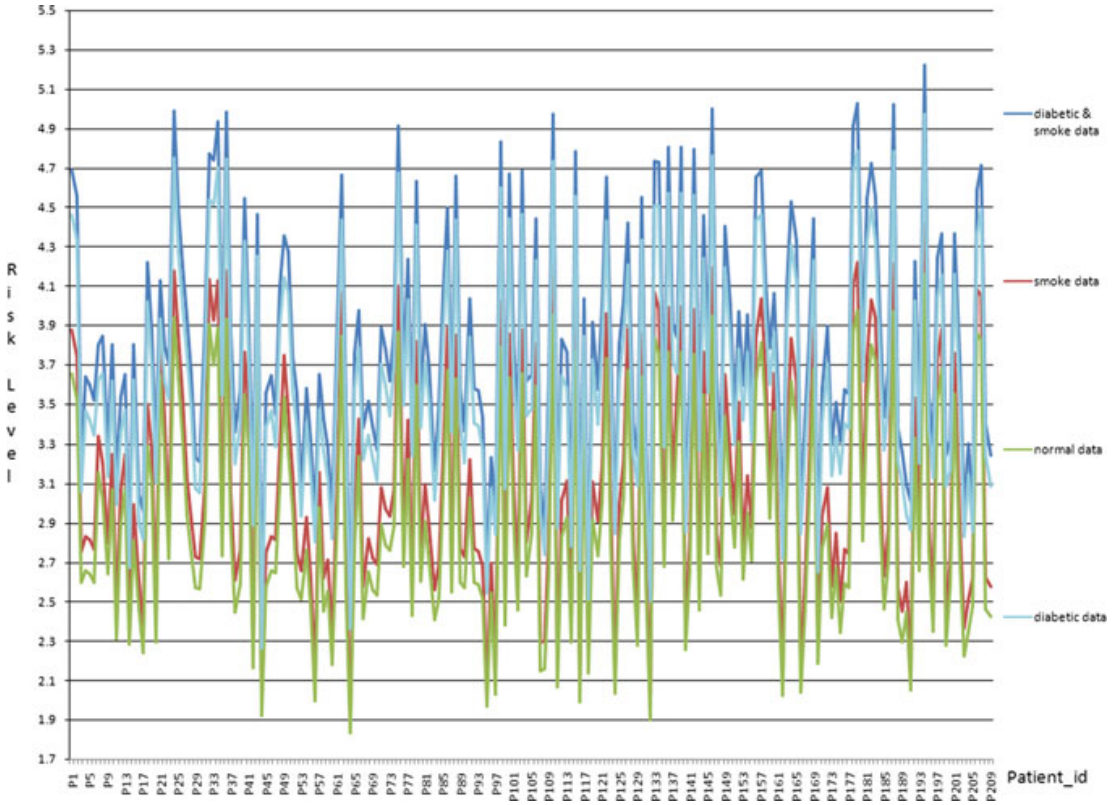
where i represents the signs and j represents the patients affected by that sign.

Thus, the sum of the ith row is represented by e_i and P_{ij} indicates the symptoms in which s_i dominates all the other patients. This will alarm the experts to take the appropriate action immediately.

The above algorithm is to apply on the data set with and without the diabetics as well as the urine nicotine (to find the consequence of smoking), in order to find out the impact of one of the cardiovascular disease. First, we applied the algorithm on the normal data set (data set of the patients with no diabetics and no smoking). Second, the algorithm is applied to the data where the patients are having sugar level (data set of the patients with the diabetics). Third, it is applied on the patients who used to smoke only (data set of the patients not having the diabetic but presence of the nicotine (smoking)) and lastly it is applied to the data of the patients with diabetic and nicotine (smoke). Thus, the algorithm determines the impact of the smoke on the cardiovascular disease with diabetics in the patients. This will not only predict the risk in the patient's life but also supports the experts to take the right and acceptable decision on time so that a person can save his/her precious life and can change the lifestyle accordingly. For this, the experts may treat them (if required) by means of counseling or proper medication.

5 Result Analysis

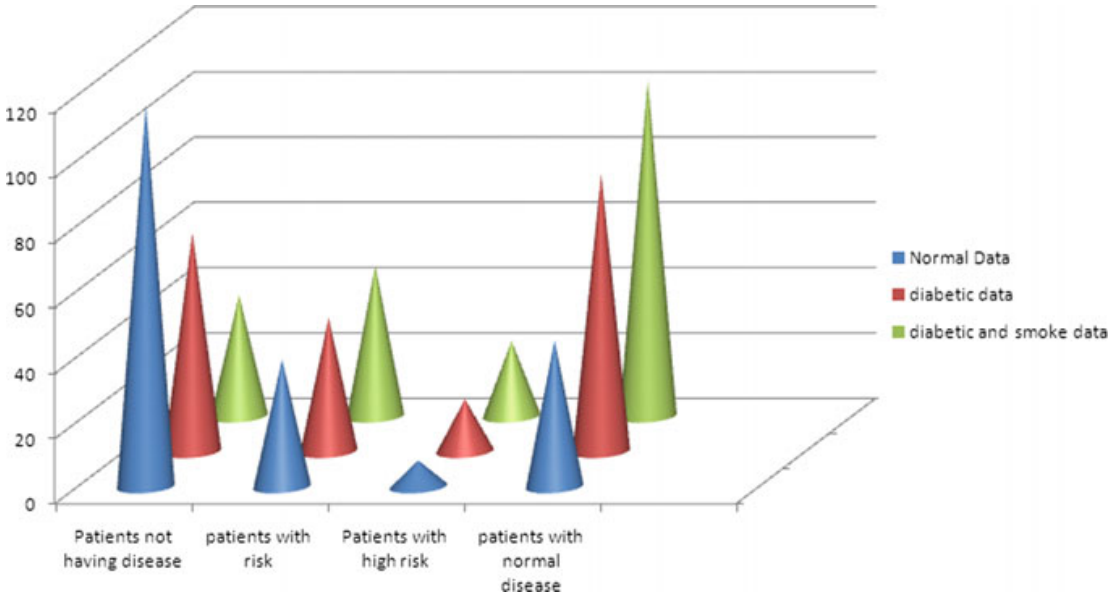
We applied the algorithm in SciLab on the normalized data set. Graph 1 represents the four responsiveness of the algorithm on the UCI data set of cardiovascular disease (in all 209 tuples in the data set, thus 209 patients are considered) which enhanced with the urine nicotine used to measure the smoking factor in the patients. The normal data stands for the input variables except the blood sugar (diabetic) and urine nicotine (smoke). Similarly, the diabetic data set contains the blood sugar, smoke data set consists of the urine nicotine, and diabetic and smoke data set comprise the blood sugar as well as the urine nicotine. Graph 1 represents the normal data (green color), smoke data (red color), diabetic data (light blue color), and smoke and diabetic data (dark blue color). By comparing the facts that diabetic data is more prominent and when it is enhanced with nicotine factor the risk level is at the highest level. The result is evidence for patients accelerating the chances of



Graph 1 Representation of the normal data, diabetic data, smoke data, and diabetic and smoke data

occurrence of the CVD who were not having the CVD initially. Thus, the diabetic and smoke factors augment the risk level of the cardiovascular disease in the patients who even do not have initially the CVD disease. For example, the patient P65 is not affected with the cardiovascular disease but when diabetic as well as smoke factors added the risk factor increased from 1.87 units to 4.26 units with the diabetics and enhanced to 4.63 units when smoking factor added with the diabetics. This illustrates the impact of the diabetic which enhanced it with the additional factor of smoking. This implies that smoking accelerates the risk factor of cardiovascular disease in any human being if he/she is not having the problem at present. On the other hand, the patient is suffering from CVD with the initial value approximately 2.7 augmented to approximately 5.3 with acceleration in the weighted values in presence of the blood sugar and nicotine.

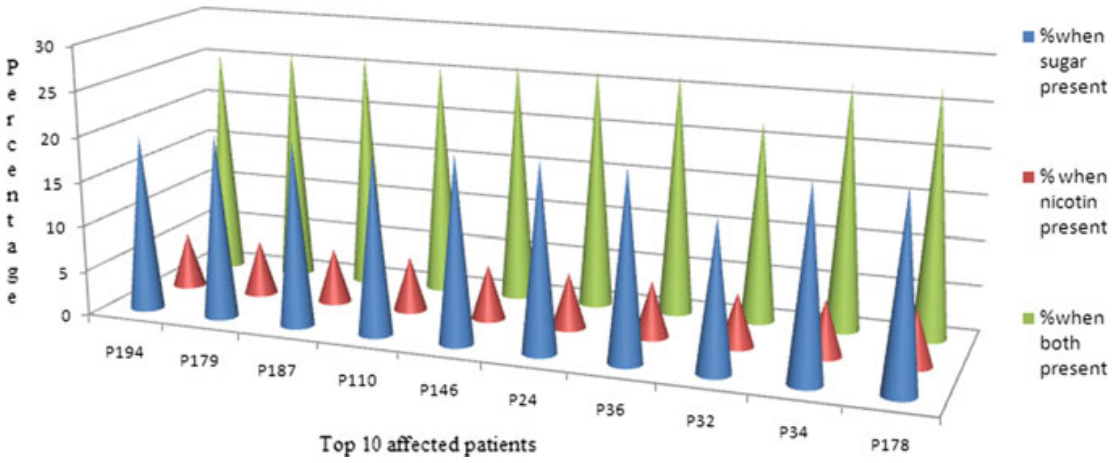
Graph 2 represents the result after the applicability of Step 3 of the algorithm. The approximation function demonstrates the enhancement in the number of patients from normal to risk and risk to high risk factor and more specific the number of the patient with CVD disease increases (earlier it was 117 which were not having the disease, but after the diabetic and with the impact of smoke it remains only 37 who were not yet affected with the cardiovascular disease). This implies that the high risk and risk patients were increased in the ratio of 17.9%, 65.21%, and more observing is 128.88% to the person who was not having the



Graph 2 Number of patients at various stages with respect to data

disease. In the above prediction, the weights of the other input factors were also considered and found that were more prominent with the inclusion of the blood sugar and urine nicotine. Hence, there is a leap in the increased percentage of patients with the risk and not of high risk. This demonstrates that the blood sugar (diabetic) and nicotine (smoke) comprise massive adverse impact on the other factors too. The result congregates the multiple aggregation functions of the symptoms to a single fuzzy set.

Graph 3 represents the patients' who were are at high risk and want an immediate medication. This is the result of Step 4 of the proposed algorithm. The detection of the enhancement in the patient status is based on the multiple-input sign data set. The Step 4 sums up the entire row, and then the difference is to calculate between the row sum and the column sum, in order to find the sign



Graph 3 The top 10 affected patients

overriding on the others. The results showed that the nicotine values were more prominent in the case of the patients with high sugar level. Thus, it is very clear that if a patient is having diabetic, the smoking accelerates the cardiovascular disease. The graph illustrates the top 10 affected patients' records only. It exhibits the amount of the percentage nicotine overrides the blood sugar in respect to the blood pressure, chest pain, angina, report of the electrocardiogram, and heart rate.

6 Conclusion

The concept is used of fuzzy theory which is very effective to handle the dynamic situations because of its characteristics. The proposed algorithm is designed to handle the multiple observations of the input variables which may or may not have the uncertain behavior. The algorithm dealt with the aggregation of the various observation functions based on the observed variables with and without the nicotine (smoke) factor inclusion and finally concludes with the recognition of critical patients who need immediate medication. This will not only facilitate the experts but also helps out in the prediction of the cardiovascular disease on the basis of the current lifestyle of the patient. At last, maybe our experiments results considered to be the starting point for the formation of the fuzzy prediction system for the evaluation of the cardiovascular risk where nicotine is one of the accelerating factors.

The limitation of the paper is of the data considered to be static. In reality, the data is of cumulative nature which augmented in due course time, if appropriately not assessed. Thus, the results will be more worst if the nicotine level amplifies in the body.

An Integrated Fault Classification Approach for Microgrid System

Ruchita Nale, Ruchi Chandrakar and Monalisa Biswal

Abstract In this paper, a moving windowing approach-based integrated fault classification algorithm is proposed for microgrid system. In a microgrid system, the nonlinear operation of control devices connected to distributed generation (DG) imposes problem for identifying the exact faulty class. In order to mitigate this issue, an integrated moving window averaging technique (IMWAT) is proposed. The method utilizes current signal at the line end. In this technique, first, the decision of the fault detection unit (FDU) is analyzed and based on that fault class is detected. The FDU uses the conventional moving window averaging technique. Different logics are framed to identify the symmetrical and unsymmetrical faults. The method is tested on a standard microgrid network and obtained results for different fault cases prove the efficacy of the proposed method.

photovoltaic cells providing a means to reduce greenhouse gas emissions and to supply clean and continuous power. These DG sources can be employed near loads for reliable power supply as it decreases the power transmission losses and enhances the energy efficiency of the power system [7–9]. Microgrids can be operated in two modes, i.e., when connected to grid and also when it is isolated from the main grid (islanded mode). The most significant feature of microgrid is its ability to operate in autonomous mode when there is fluctuation in voltage, deviation in frequency or when there is a fault in main grid. Hence, ensuring continuity of supply to critical loads. Enhanced service quality, improved reliability, and efficiency are the common advantages offered by the microgrid [10]. However, usage of different types of DG for generation of power poses challenges for operating, integrating, controlling, and protecting the microgrid [11–16].

Fault detection is an essential and critical issue in microgrid system because of the nonlinear operation of control devices connected with renewable sources and due to the wide variation in fault current magnitude in different operating modes such as grid-connected mode and islanded mode. Also, the presence of different types of DGs affect the magnitude of fault current. Owing to high penetration of inverter interfaced DG protection of microgrid is a tedious task. The contribution of fault current by inverter interfaced DGs is limited to two to three times the rated current [17].

Different solutions have been provided by different researchers to detect and classify the types of fault in microgrid system. The diagram of a general fault classification algorithm used in protective relay is provided in Fig. 1. In this diagram, the basic procedure for fault classification function performed by relay is presented. With the help of fault generated voltage and current signal, different sequence components are calculated and the relative angle between two quantities are used to estimate the exact faulty phase.

In [18], two new fault classification logics are proposed to identify the accurate faulty phase in microgrid system. The first method is based on voltage angle and magnitude and the second method used voltage angle to identify the fault class. A new approach-based on optimal wavelet functions is proposed to detect the exact faulty class and reported in [19].

In this paper, a new method is proposed. The method operates on the basis of two integrated logics. This IMWAT method overcomes the drawbacks of existing moving window averaging which fails to work correctly during high resistance fault, nonlinear operation of control devices connected to wind turbines, switching of nonlinear loads, and mode changing operation of microgrid. The proposed method is tested on a standard microgrid system, i.e., Aalborg distribution system model. The power system model is developed in EMTDC/PSCAD environment. The response of the method is verified for different symmetrical faults, unsymmetrical fault, high resistance fault, close-in fault, switching of nonlinear loads, and

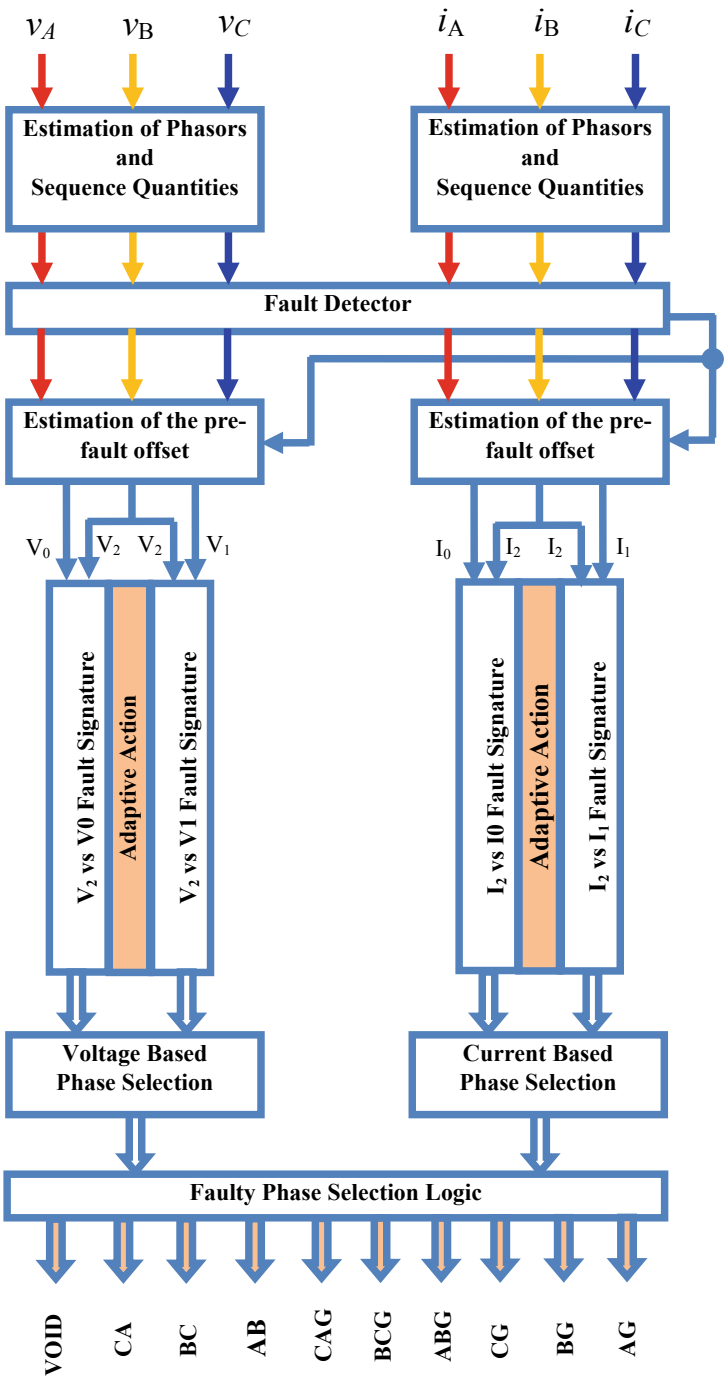

Fig. 1 Fault classification algorithm used in protective relay

different operating modes. From the analysis report, it is confronted that the proposed method is able to identify the exact faulty phase within half-cycle time period from the instant of fault occurrence and the decision time is fixed irrespective of the system and fault conditions.

The main body of the paper is organized as follows. In Sect. 2 fault classification based on IMWAT approach is described. Next, simulation results for different test conditions are provided in Sect. 3. The conclusion of the paper is provided in Sect. 4.

2 Fault Classification in Microgrid

2.1 Moving Window Averaging Technique

During transient phenomenon or fault scenarios, the average of one window current signal is a non-zero quantity. With suitable threshold value exact fault detection is possible. In this work, a moving window averaging technique based on fault detector unit is considered for processing the fault classification task using IMWAT technique.

Using moving window averaging technique, the magnitude of one cycle current samples can be modeled as

$$i_{\mathrm{MW}}(s) = \frac{1}{\mathrm{N}} \sum_{p=s-\mathrm{N}+1}^{s} i(p) \tag{1}$$

where s is the sampling instant, p is the instantaneous sample, and N is the number of samples per cycle.

The relation in recursive form can be represented as

$$i_{\mathrm{MW}}(s) = i_{\mathrm{MW}}(s-1) + i(s) - i(s-\mathrm{N}) \tag{2}$$

Using (2), a fault detector is developed in the proposed method. The decision of the FDU is employed in the classification algorithm to classify the exact faulty phase in microgrid system. From the several advantages, detection capability during high resistance fault is a unique feature of moving window averaging technique. Under far-end high resistance fault, the faulty phase current will be very less and can be in the same order as healthy phase. Even though the scenario is rare, but with the arrival of such an event, moving window averaging technique will fail to detect exact faulty phase within the stipulated time period. Such a case is undesirable and degrade the performance of protection function. From the study, it is observed that under faulty condition, the amplitude of affected phase moving window average value is more as compared to other phases if an observation is drawn on the basis of a fixed half-cycle calculated value just after fault inception. This unique feature can be incorporated for the detection of exact faulty phase in microgrid system. In order

to further enhance the reliability of relay, an integrated approach-based fault classification technique is devised that integrates the decision of FDU along with other computed paradigms which are described in the next section.

2.2 IMWAT Algorithm [19]

The proposed algorithm for classification of faults is as follows:

(1) The value of i_{MW} is computed using Eq. (1) by considering current sample for one cycle.
(2) Using recursive update formula mentioned in Eq. 2, value of i_{MW} for each phase is calculated.
(3) For detection of faults, threshold (β_t) is chosen to prevent false operation of relaying. For any further deviation above the threshold value, the threshold counter (j) counts 1. Each counter is provided for each phase.
(4) Check if $|i_{MW}| \geq \beta_t$

If yes, j = 1, otherwise 0. Then $j_{new} = j_{old} + 1$.

Then threshold counter continues to evaluate for consecutive three samples. If any time j = 0 comes in-between counter again reset to zero otherwise continue counting.

If $j_{new} = 3$, FDU = 1 otherwise 0.

The aforementioned process is performed for the fault detection task in three phases. FDU is reset to zero once the fault is detected. Next, the further steps of fault classification are evaluated and are explained below.

(5) Next the residual current through the ground can be calculated using formula,

$$i_g(s) = (|i_a(s) + i_b(s) + i_c(s)|) \tag{3}$$

In (3), i_a, i_b, and i_c represent the instantaneous current for phase a, b, and c, respectively. i_g aids in distinguishing ground fault from phase fault.

(6) Along with fault detection, the developed fault classification algorithm evaluates, $|i_{MW_a}|, |i_{MW_b}|, |i_{MW_c}|$, the summation and difference of two-phase moving sum current based on continuous half-cycle considering from the moment of occurrence of fault.

For example, the fault is detected at sth sample, so the proposed method initiates computing above data from (s − 2)th to (s + 7)th sample. The observation duration

is kept as half-cycle for better comparison and correct classification of different faults.

The computational procedure of consecutive phase summation and difference are provided below.

$$\mathrm{MS_{ab}}(s) = ||i_{\mathrm{MW_a}}(s)| + |i_{\mathrm{MW_b}}(s)||$$
$$\mathrm{MS_{bc}}(s) = ||i_{\mathrm{MW_b}}(s)| + |i_{\mathrm{MW_c}}(s)||$$
$$\mathrm{MS_{ca}}(s) = ||i_{\mathrm{MW_c}}(s)| + |i_{\mathrm{MW_a}}(s)||$$

Similarly,

$$\mathrm{MD_{ab}}(s) = ||i_{\mathrm{MW_a}}(s)| - |i_{\mathrm{MW_b}}(s)||$$
$$\mathrm{MD_{bc}}(s) = ||i_{\mathrm{MW_b}}(s)| - |i_{\mathrm{MW_c}}(s)||$$
$$\mathrm{MD_{ca}}(s) = ||i_{\mathrm{MW_c}}(s)| - |i_{\mathrm{MW_a}}(s)||$$

For each calculated value of i_g, $|i_{MW}|$, *MS*, and *MD* a data matrix of size 10 × 10 is devised. Suppose the data matrix of size n x n is denoted by D_{nn}, where n is equal to 10. D_{nn} can be expressed as,

$$\mathrm{D_{nn}} = \begin{bmatrix} \mathrm{D_{11}} & .. & .. & \mathrm{D_{n1}} \\ .. & .. & .. & .. \\ .. & .. & .. & .. \\ .. & .. & .. & .. \\ .. & .. & .. & .. \\ \mathrm{D_{1n}} & .. & .. & \mathrm{D_{nn}} \end{bmatrix}$$

where $D_{11} = i_{g1}$, D_{21} to D_{n1} are $|i_{\mathrm{MW_a}}|_1, |i_{\mathrm{MW_b}}|_1 |i_{\mathrm{MW_c}}|_1$,

$$MS_{\mathrm{ab_1}}, MS_{\mathrm{bc_1}}, MS_{\mathrm{ca_1}}, MD_{\mathrm{ab_1}}, MD_{\mathrm{bc_1}}, \text{and } MD_{\mathrm{ca_1}}.$$

(7) From each column indices are selected. For example, the maximum value in column 1 is *f*1 which denotes the maximum of i_g from a data matrix of size 10. As the calculated values are not constant so direct comparison is not possible, hence index values are selected.

Similarly, *f*2 = maxim $(|i_{\mathbf{MW_a}}|)$, *f*3 = maxim $(|i_{\mathbf{MW_b}}|)$, *f*4 = maxim $(|i_{\mathbf{MW_c}}|)$, *f*5 = maxim (MD_{ab}), *f*6 = maxim (MD_{bc}), *f*7 = maxim (MD_{ca}), *f*8 = maxim (MS_{ab}), *f*9 = maxim (MS_{bc}), *f*10 = maxim (MS_{ca}).The different indices are represented as *f*1 to *f*10 that will compare among each similar group with minim, maxim function. Rules for each fault type is developed and is given in Table 1.

Table 1 Fault classification logic

Fault Type	Logic-1	Logic-2	Logic-3	Logic	Output
	$f1$	minim ($f5$, $f6$, $f7$)	minim ($f8$, $f9$, $f10$)		
a–g	$\geq \beta_t$	$f6$	$f9$	AND	1
bg		$f7$	$f10$		2
c–g		$f5$	$f8$		3
		minim ($f5$, $f6$, $f7$)	maxim ($f8$, $f9$, $f10$)		
ab–g	$\geq \beta_t$	$f5$	$f8$	AND	4
bcg		$f6$	$f9$		5
cag		$f7$	$f10$		6
		minim ($f2$, $f3$, $f4$)	minim ($f5$, $f6$, $f7$)		
ab	$\leq \beta_t$	$f4$	$f5$	AND	7
bc		$f2$	$f6$		8
ca		$f3$	$f7$		9
abc		$f2 \geq \beta_t$ AND $f3 \geq \beta_t$ AND $f4 \geq \beta_t$			10

As mentioned in Table 1, if all the rules (rule 1,2 and 3) are satisfied at the same time for any fault in the line for which AND logic is applied then a particular fault case is recorded. For example, a fault occurred with $f1 \geq \beta_t$, AND minim ($f5$, $f6$, $f7$) = $f6$ AND minim ($f8$, $f9$, $f10$) = $f9$ then output is 1, i.e., a-g fault. To avoid ambiguity in decision of the relay during single-line-to-ground and double-line-to-ground fault two different functions are utilized. In double-line-to-ground fault both minim and maxim function is used, whereas in single-line-to ground fault only minim function is employed. Hence, Table 1 indicated that a secure fault classification algorithm can be devised using integrated moving sum technique.

3 Simulation Results

The performance of the proposed technique is evaluated by considering a standard microgrid system shown in Fig. 2. It is a part of a distribution network, owned by Himmerlands Elforsyning, in Aalborg, Denmark. The system consists of three wind turbine generators and one combined heat and power plant unit. Generator data, line data, and grid data are considered from [20]. To test the efficiency of the proposed fault classification approach in the presence of various types of distributed generation units, the system is modified by replacing DG3 with photovoltaic (PV) system at bus 14. The nominal power generation of DFIG wind turbine generator and PV is

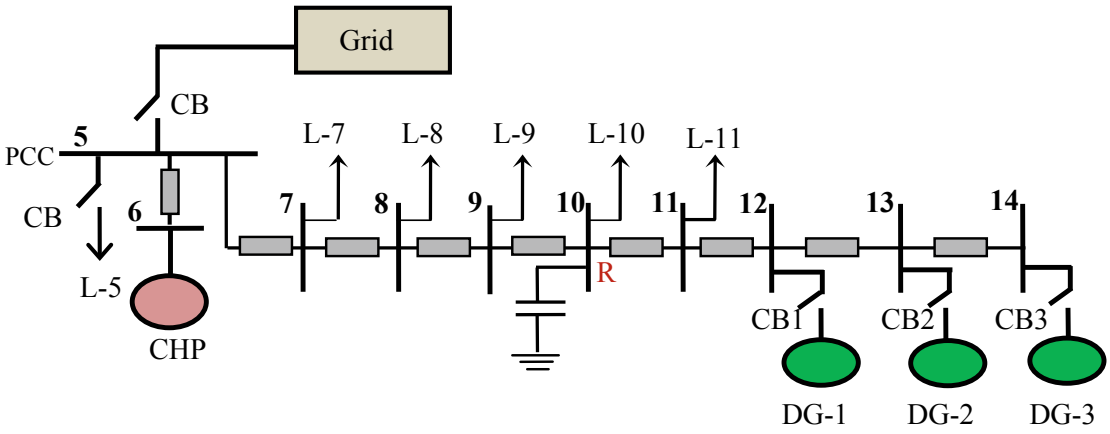

Fig. 2 Standard distribution network

2 MW and 630 kW, respectively. The simulation of the given network is performed in EMTDC/PSCAD. MATLAB software is used for logic development and the response of the technique is evaluated for different fault cases such as unsymmetrical and symmetrical faults, high resistance faults, close-in faults, nonlinear switching of load, and change in operating mode of microgrid system. The obtained results from each case are described below.

3.1 Single-Line-to-Ground Fault (LG)

In distribution system, LG faults are frequently occurring faults. To assess the potential of the proposed technique, a-g fault is simulated considering 5 Ω as the fault path resistance at 0.3 s in-between bus 10–11. The response of both fault detector unit and IMWAT are presented in Fig. 3. The computed absolute values of the average of one window current signal for each phase are shown in the figure. For phase-a, the measurement for three consecutive computed values is greater than the threshold, then the Counter (j) is set to 3. Hence, the output of FDU for all the three phases is [1, 0, 0] at 0.303 ms and is depicted in Fig. 3(b). So, the algorithm takes 3 ms to detect the fault using IMWAT. The proposed method further evaluates the value of i_g, MD, and MS as shown in Fig. 3. From the plots, it is noticed that $f1 \geq \beta_t$ AND minim ($f5$, $f6$, $f7$) = $f6$ AND minim ($f8$, $f9$, $f10$) = $f9$. Since all the conditions for a-g fault scenario are satisfied concurrently, the decision provided by relay is 1 which is correct.

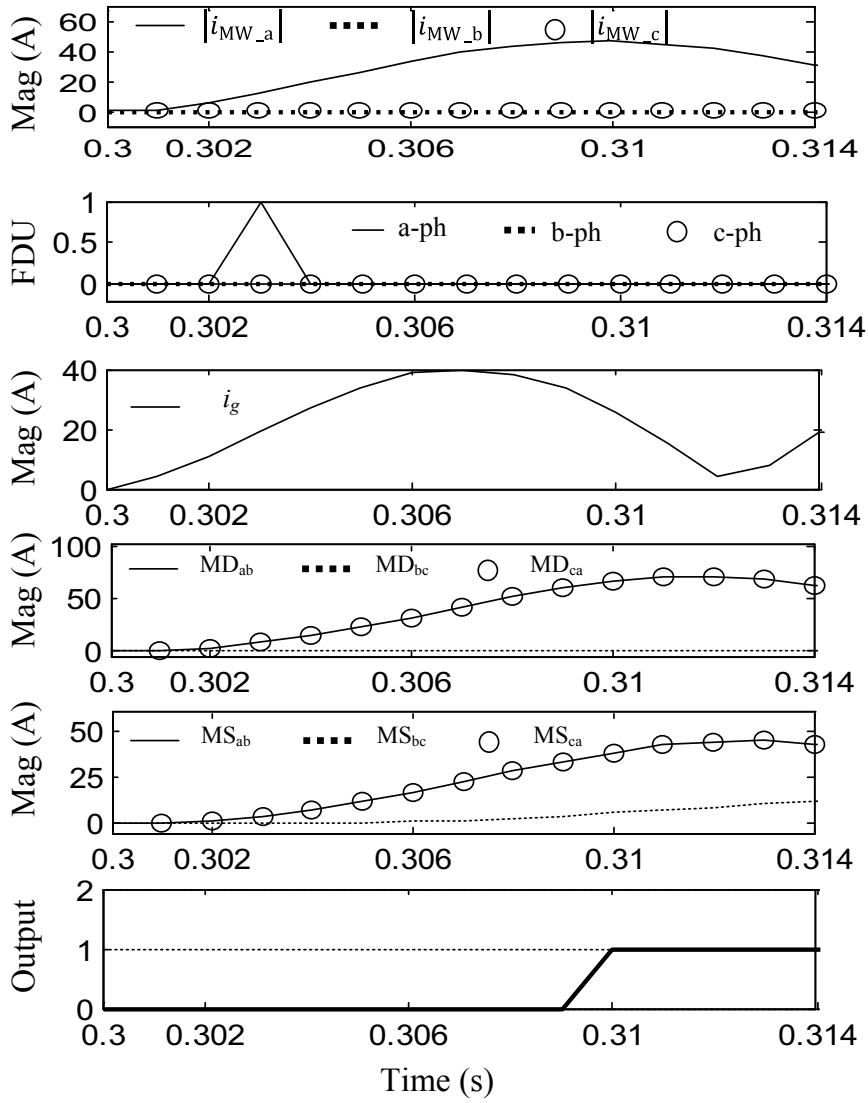

Fig. 3 Performance of FDU and proposed method during a–g fault

3.2 High Resistance Double-Line-to-Ground Fault

Next, to observe the response of proposed IMWAT technique for high resistance double-line-to-ground fault scenario, ab-g fault is created in-between bus 10–11 with a fault resistance of 150 Ohm. Fault is created at 0.3 s. The performance of relay for fault detector unit and proposed method is recorded and is depicted in Fig. 4. During far-end high resistance fault condition, the response of FDU for each phase is "1". As a consequence, the decision interpreted by the relay is incorrect. Hence, the information provided by moving window averaging approach is not adequate for correct faulty phase selection. In order to achieve the exact

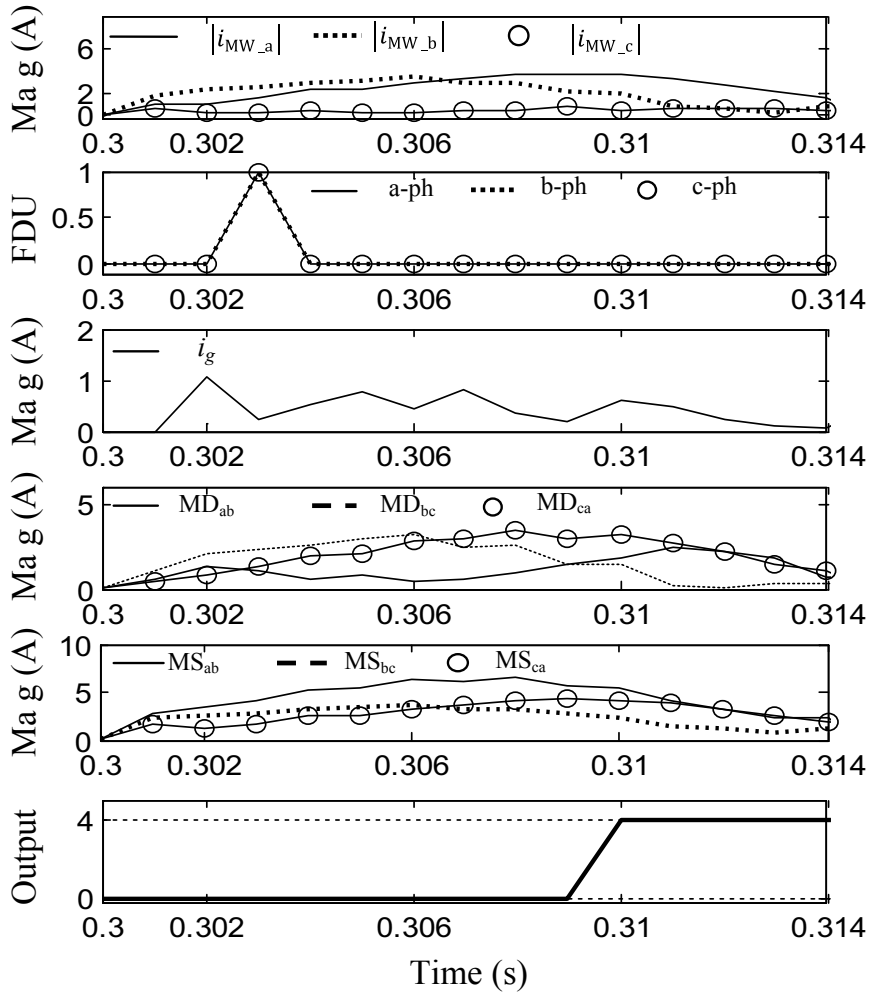

Fig. 4 Performance of FDU and proposed method during far-end high resistance a–b–g fault

classification of faults, the performance of moving window average-based FDU can be enhanced by employing the proposed IMWAT technique. So, by the integration of various proposed logics, the relay provides decision as "4", i.e., ab-g fault which is correct.

3.3 Double Line Fault

For the simulation of double line fault to observe the response of the proposed method, a b–c fault in-between bus 10–11 is created at 0.3 s. The fault resistance is considered as 5 Ohm. The response of the FDU and the proposed method are shown in Fig. 5. From the response of FDU it is cleared that, FDU only detects the

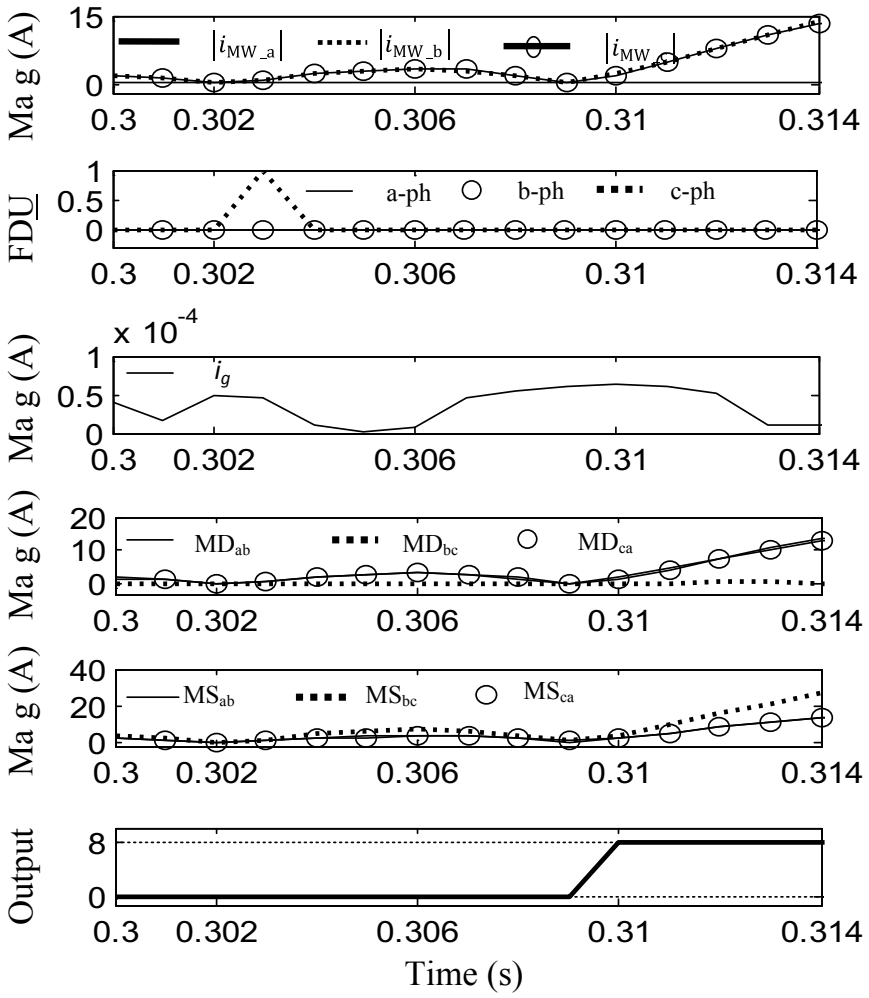

Fig. 5 Performance of FDU and proposed method during b–c fault

phase-c for b–c fault scenario. But the output of the proposed method is "8", which indicates the occurrence of b–c fault in microgrid system.

3.4 Close-in Fault

Close-in faults are more severe because the higher fault current magnitude deteriorates the performance of current transformer. So, relay finds more challenge during close-in fault. To simulate this condition, three-phase fault is simulated in-between bus 10–11 at 0.3 s. The fault resistance is 2 Ohm. By moving sum approach fault is detected at 0.303 s I all the three phases. The output of FDU for all the three phases will be [1]. From Fig. 6, $f1 \geq \beta_t$ AND $f2 \geq \beta_t$ AND $f3 \geq \beta_t$ AND $f4 \geq \beta_t$ this provides an output of 10, i.e., three-phase fault by IMWAT approach. Therefore,

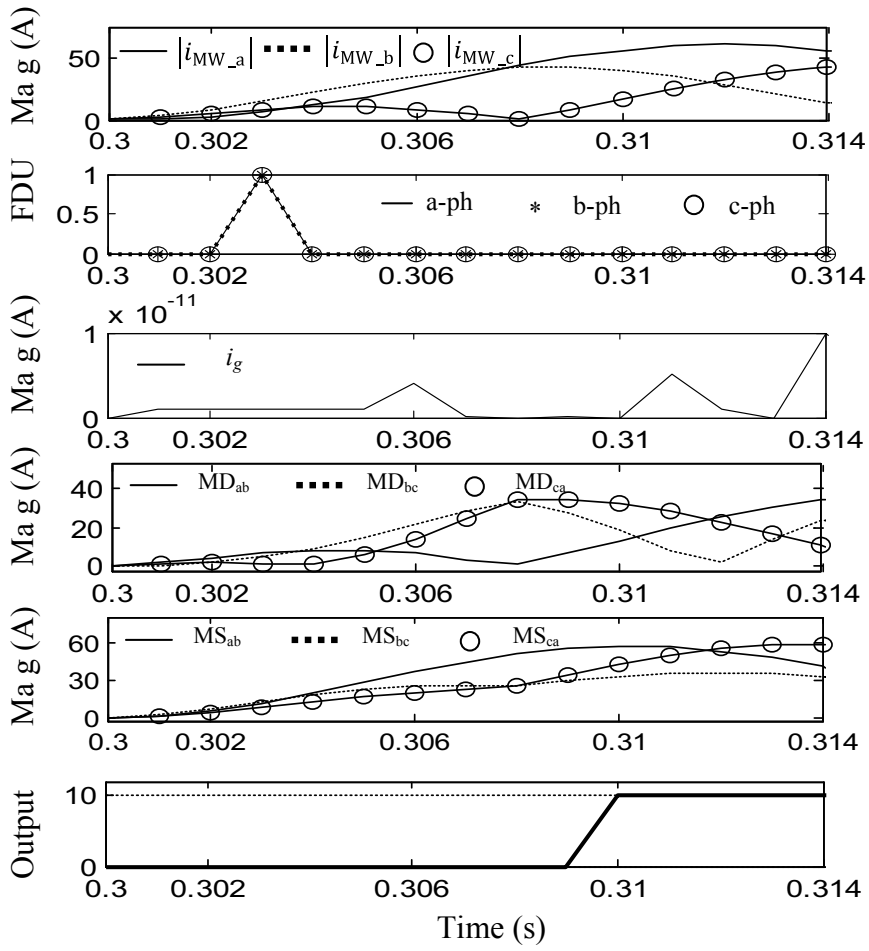

Fig. 6 Performance of FDU and proposed method during close-in three-phase fault

the algorithm can correctly classify close-in three-phase fault which is clear from the result.

3.5 Fault During Switching of Nonlinear Load

The application of electronic gadgets such as personal computer, laptop, printers, uninterrupted power supply, and music instruments, the generation of harmonics in distribution level is more. This may lead to false operation of fault classification algorithm. So, to verify the impact of the proposed method during switching of nonlinear loads, a 0.5 MW three-phase diode rectifier with resistive load is switched on at 0.3 s. At the same time, c-g fault is created in the line between bus 10–11.

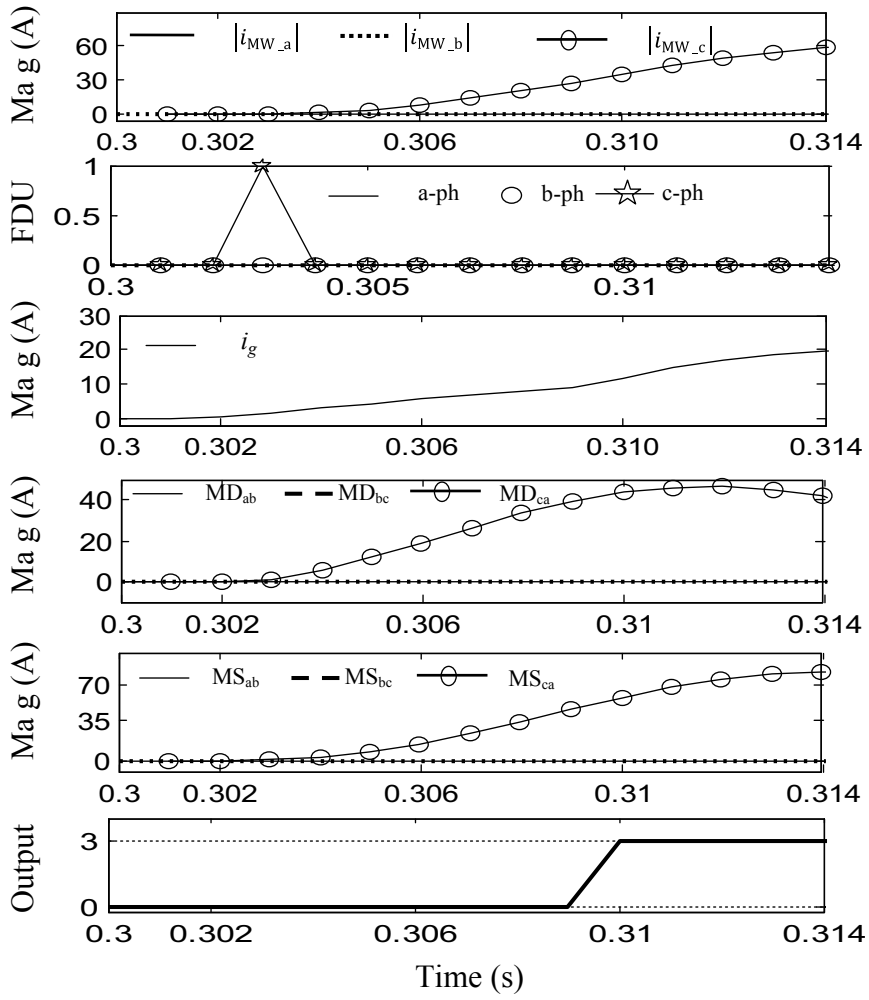

Fig. 7 Performance of FDU and proposed method during nonlinear load switching

As depicted from the output response of the proposed method shown in Fig. 7, the switching of nonlinear load has no significant effect on the proposed method.

3.6 Fault During Different Operating Modes

All the abovementioned results are provided for grid-connected mode. So, to verify the response of the proposed method during islanding mode, the PCC bus breaker, i.e., CB-4 is kept open. For this islanding case, an a–g fault is created at 0.305 s. The response of the proposed method for this case is shown in Fig. 8. From this figure, it is clear that the response of the method is also accurate for islanded mode as the final output by IMWAT technique is "1" which is correct.

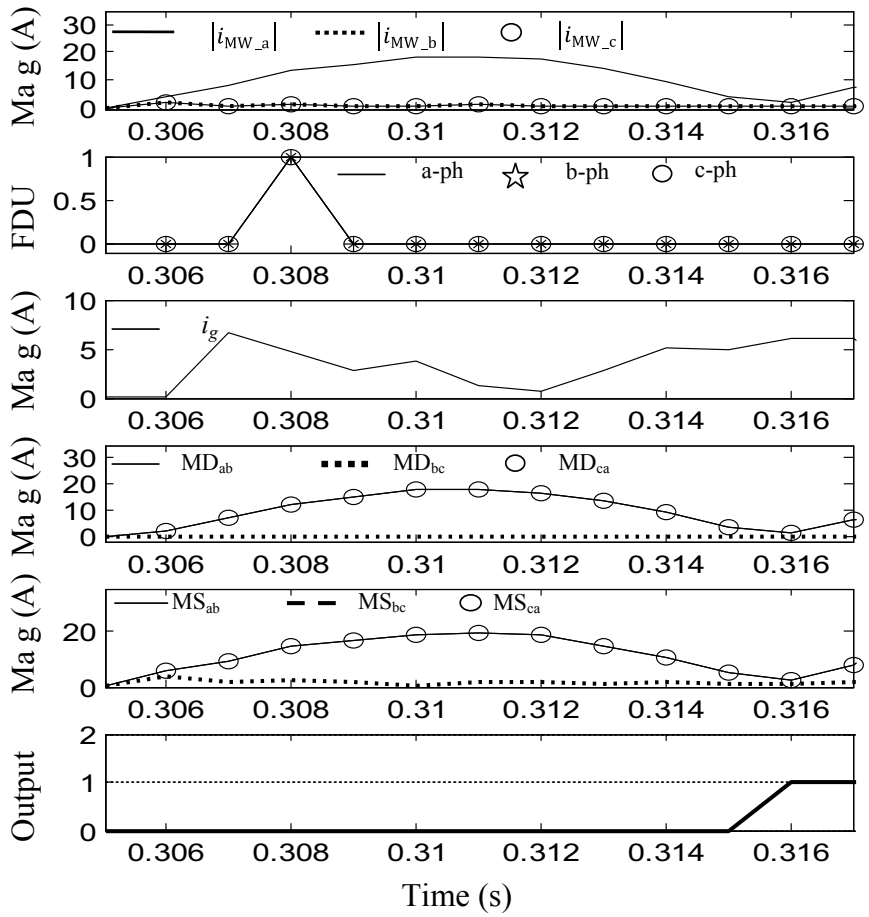

Fig. 8 Performance of FDU and proposed method for islanded mode of operation

So, the response of the method is verified for different critical cases and it is noticed that within one cycle time period accurate decision can be drawn irrespective of the critical operating conditions of fault and system.

4 Conclusion

Exact fault type selection is a challenging task in microgrid system due to the incorporation of renewable sources in the existing passive distribution network. The nonlinear operation of control devices, switching of nonlinear load ad changing mode of operation from grid-connected mode to islanded mode is the typical critical operating condition of microgrid system during which relay find challenges in discriminating the fault types. The other fault conditions such as close-in fault and high resistance fault may degrade the performance of existing protective relay

algorithms. To mitigate this technical and fault generated issues, a new integrated approach is proposed in this paper. In the integrated approach, the output of moving window averaging-based FDU is incorporated in the fault classification logic to obtain accurate decision. For ground fault detection residual current through ground s computed. Different indices are calculated for the fault class selection. The response of the proposed method is verified for various cases. It is observed from the results that within half-cycle time period exact fault type selection is possible in microgrid system.

Role of Data Analytics in Human Resource Management for Prediction of Attrition Using Job Satisfaction

Neerja Aswale and Kavya Mukul

Abstract The reputed management publications like Harvard Business Review (HBR) have started stressing upon the emergence of data-driven management decisions. The enhancing investments in data and analytics are underlining the aforementioned emergence. According to International Data Corporation, this investment is expected to grow up to $200 billion by 2020. In such a data lead management world collecting, managing, and analysing the human resources-related data becomes a key for any rather every organization. Human resource analytics is changing into necessary as strategic personnel designing is the need of the hour and helps organizations to investigate each side of HR metrics. HR analytics could be a holist approach. According to KPMG—India's Annual Compensation Trends Survey 2018–19 the average annual voluntary attrition across sectors is 13.1%. This is a considerably high percentage. Hence, antecedents leading to attrition are needed to be explored in order to propose appropriate HR policies, strategies, and practices. In relevance to these facts, this study focused on proposing a data-driven predictive approach that examines the relationship between the attrition (dependent variable) and other demographic and psychographic independent variables (Antecedents). The present study found that there is a strong relationship between job satisfaction and attrition. Further, there is a higher probability that the employees having work experience between 0–5 years may leave the organizations. Such data-based outcomes may offer help to HR managers in addressing the problems like attrition which intern may increase ROI. Thus, this paper underlines the emergence and relevance of analytics with special reference to human resource management domain.

1 Introduction

The emergence of technologies has changed the way the business domains used to be operated. Taking these developments into consideration it has become important to accept that the various business functions have started deploying the technological advancements. The human resources management is no longer an exception to this phenomenon. Therefore, the "Human resource analytics (HR analytics) is a vicinity in the subject of analytics. The HR analytics refers to application of analytic techniques to the functions of human resource department. The major emphasis of HR department is to achieve enhanced productivity by increasing individual performance of the employee. The increased individual performance will subsequently result into a higher return on investment." The modern philosophy of human resource management has shifted focus from Human resources to Human Capital. This has added roles and responsibilities of HR professionals. The modern HR professionals are suppose to predict futuristic standpoints to the organization using analytics. This shift demands proper exploration, examination, and evaluation of individual performances. This approach will further help for talent management practices that focuse on retention and acquisition of human resources. In such cases, the data-based evidence would help HR managers in designing the HR strategies. These evidence/trends can be analyzed using analytics that includes application modern business analytics techniques like data mining to human resources data. In continuation to this introductory insights the next section details about the need for using HR analytics for strategic HR decision-making. Further, it also informs about studies conducted in HR domain for understanding the application of HR analytics.

Being a multidisciplinary method, HR analytics combines methodology that improves the people-related selections to enhance person and company's performance. HR analytics is also known as people analytics, workforce analytics, and talent analytics. The HR analytics introduces high-end predictive modeling approaches that forecast the effect of changing the policies. Further, the HR analytics has become an integral part of human resources functions like recruitment, training, development, succession planning, compensation, benefits, retentions, and engagement. Traditionally, analytics is being used to focus on the rate of turnover and the cost of hiring. Using complex statistical analyses, HR analytics enables corporations to measure the business impact of people policies and predicts the future of the workforce. This allows managers to measure the relationship between financial performance of the organization and the human resource practices.

Muscalu and Serban [1] examined the relevance of HR analytics for strategic human resource management. The authors deployed HCM: 21 model to know the effectiveness of the department. Momin and Taruna [2] reported that the growing HR-related problems such as succession planning, recruitment, and employee retention. Sujeet et al. [3] mentioned that Human Resource Predictive Analytics (HRPA) was found useful for all HR functions. Bindu [4] conducted a review emphasizing on HR analytics skills and as a result of focus group discussions reported that bad records would lead to negative HR analytics, whereas business

analytics provides a multidimensional method toward constructing effective HR strategies [5]. Globcon Technologies Pvt. Ltd [6] reported that application of HR analytics has opened emerging niche areas in HR analytics as certain specific problems get addressed by means of HR analytics. Rajbhar et al. [7] concluded that HR analytics helps in improving workers overall performance in a team. This study also mentions that HR analytics can be used for increasing the productivity. Shweta [8] concluded that applying analytic procedures to the human resource data help in enhancing worker performance and consequently getting a higher return on investment.

2 Methodology

It was observed during literature review that the role of HR analytics is very well explored in developed countries and hardly explored for developing countries like India. Further, the practical relevance of HR analytics is hardly explored. Even though these study mentioned about relevance of HR analytics, a few studies have explored a specific phenomenon like attrition. This has created a scope for the present study that emphasized on attrition and explored the various factors related to this phenomenon. To have a systematic approach this study defined certain research objectives. These objectives are as follows:

(a) To study the factors affecting attrition.
(b) To predict the factors influence attrition.
(c) To identify factors affecting job satisfaction.
(d) To make recommendations for retention of employees on the basis of analysis.

H0: Attrition is directly co-related to job satisfaction.
H1: Attrition is not directly co-related to job satisfaction.

HR analytics is defined as "a method for evaluating and understanding the causal relationship between HR practices and overall performance results of organizations (such as client satisfaction, sales, or profit)". It also helps in supplying authentic and reliable foundations for human capital choices for integrating enterprise strategy and performance. This integration could be achieved using statistical strategies and experimental tactics based on various metrics of efficiency, effectiveness, and competitive advantage. Therefore, this section details the relevance of using data analytics for the HR functions. The prime advantages reported by the past researchers are as follows:

(a) HR analytics is affordable and provides the data-based evidence for both strategic and operational decisions.
(b) The enhanced technological advances also provided the access to big data related to human resource which makes use of HR analytics relevant.

(c) It also helps in tackling the global talent warfare by enhancing both talent acquisition and retention.

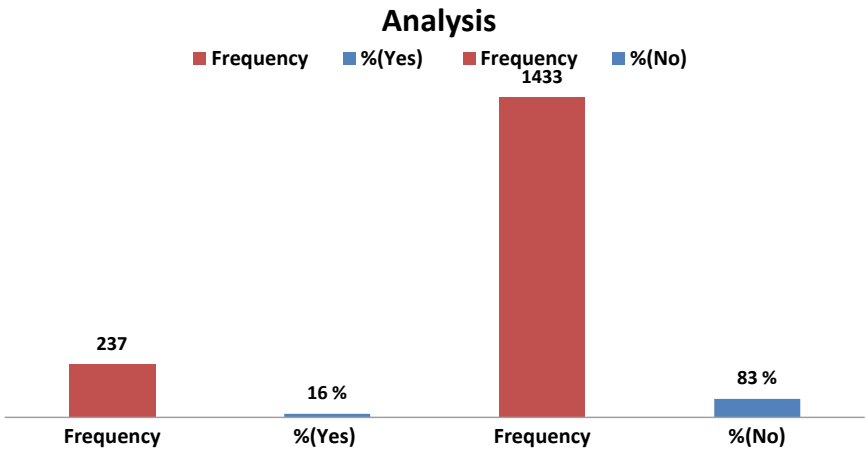
Further, there are three levels prominently used for analysis :

I. **Descriptive**: Descriptive HR analytics reveals and describes relationships. This type of analysis compares the present scenario with historical data patterns in order to generate insights. It consists of dashboards and score-cards; team of workers segmentation; statistics mining for main patterns; and periodic reports. Traditional HR metrics are mostly successful metrics (turnover rate, time to fill, value of hiring, volume employed and trained, etc.). The predominant center of attention is on cost reduction and process improvement.
II. **Predictive**: Predictive analysis covers an array of techniques (statistics, modeling, information mining) that use present day and historical facts to make predictions about the future policies, strategies, and practices. It deals with identifying probabilities and dealing with the elements of risk. The human capital (people) leverage intangible belongings to enhance employer performance, and hence the impact of various factors on human capital need to be explored. The predications related to such explorations may result in typical profiles and trends. These profiles and trends may be used for strategic human resources management decisions.
III. **Prescriptive**: Prescriptive analytics is used to analyze complicated facts to predict outcomes, provide resolution options, and exhibit desire impacts. The technique deals with reporting of HR metrics and prescriptive modeling of commercial organization practices. It involves in understanding the impact of knowledge of investments on the bottom line. Such kind of scenarios is rare in case of HR domain.

Taking the aforementioned logic into consideration this study used predictive approach in order to understand the relationship between attrition and job satisfactions in a better way. This study used a sizeable data set related to HR domain (fictional) created by IBM scientists.|The data set consist of 1470 data points and 35 variables. This data is specifically used for analysis of various HR-related attributes. The statistical tools like Statistical Package for Social Sciences (SPSS) and Microsoft Excel were used for analysis.

3 Data Analysis

The prime objective of this study was to identify the predictive indicators for identifying the typical profile of the employees who have left the organization. In order to develop these indicators, the data was divided into the employees left the organization (237) and still working in the organization (1433). This classification is presented as a Graph 1.



Graph 1 Classification of the employees

From the analyzed data it can be concluded that out of the total 1470 employees 16% employees have already left the organization. This number is 237 employees. The typical characteristics or behavioral pattern or the predictive indicators were identified on the basis of the employees who have left the organization.

Further, in order to identify the predictive indicators, the response or the characteristics of employees who left the organization were taken into consideration. The frequency analysis conducted for determining the predictive indicators is presented in Tables 1 and 2. Table 1 details about the factors related to an individual whereas Table 2 represents the prominent organizational factors identified by the researcher.

4 Individual Factors

The analysis presented in Table 1 indicates that the tendency to leave the organization is significantly higher among males, trainees, and unmarried employees. Further, it is moderate among sales representatives and people having life sciences as educational background. It is also there among lab technicians and people belonging to age group 31–35.

Similar kind of analysis is done for the organizational factors.

5 Organizational Factors

Researcher had observed that out of 20 factors, certain factors significantly influence the rate of attrition which are performance rating, years in current role, total years at company, years since last promotion, traveling in job, stock level, and percentage hike in salary. Further, the attrition may occur because of work–life

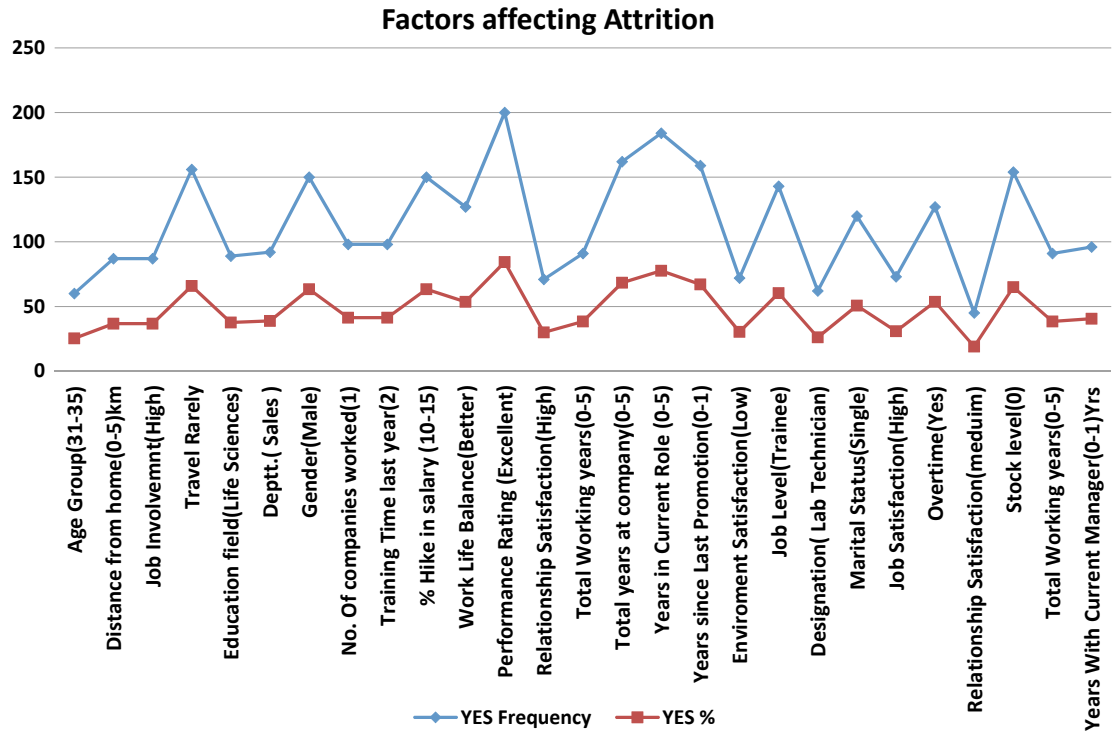
Table 1 Individual factors

Category	Frequency	Percentage
Gender (Male)	150	63
Job level (Trainee)	143	60
Marital status (Unmarried)	120	51
Department (Sales)	92	39
Education field (Life sciences)	89	38
Designation (Lab technician)	62	26
Age group (31–35)	60	25

balance, overtime, no. of companies worked, training time last year, years with current manager, total working experience, total working years, distance from home, job involvement, job satisfaction, environment satisfaction, and relationship satisfaction. Tables 1 and 2 are graphically represented as Graph 2.

Table 2 Organizational factors

Category	Frequency	Percentage
Performance rating (Excellent)	200	84
Years in current role (0–5)	184	78
Total years at company (0–5)	162	68
Years since last promotion (0–1)	159	67
Travelling in job (Rarely)	156	66
Stock level (0)	154	65
Percentage hike in salary (10–15)	150	63
Work life balance (Better)	127	54
Overtime (Yes)	127	54
No. Of companies worked (1)	98	41
Training time last year (2)	98	41
Years with current manager(0–1) yrs	96	41
Total working experience (0–5)	91	38
Total working years (0–5)	91	38
Distance from home (0–5) km	87	37
Job involvement (High)	87	37
Job satisfaction (High)	73	31
Environment satisfaction (Low)	72	30
Relationship satisfaction (High)	71	30
Relationship satisfaction (Medium)	45	19



Graph 2 Factors affecting attrition

Table 3 Results of hypothesis testing

	Attrition	Job Satisfaction
Attrition	1	
Job satisfaction	0.903481126	1

6 Hypothesis Testing

In order to test the hypotheses, correlation analysis is used. The results of hypothesis testing indicate that attrition and job satisfaction are strongly co-related. (Table 3)

Hence, from the above co-relation matrix, we can conclude that hence Ho Hypothesis is proved.

7 Multiple Regressions for Predictive Analysis

After confirming the impact of job satisfaction on attrition, the next step was to identify the parameters that impact the job satisfaction among the employees who left the organization. In order to identify these factors, the job satisfaction was

Table 4 Details of regression analysis

Regression statistics parameter	Details
Multiple R	0.339554231
R Square	0.115297076
Adjusted R Square	0.055249366
Standard error	1.086733162
Observations	237

Table 5 Results of ANOVA

ANOVA	*df*	SS	MS	*F*	Significance *F*
Regression	15	34.01409675	2.2676065	1.920091	0.022485206
Residual	221	260.9985615	1.180989		
Total	236	295.0126582			

treated as a dependent variable and 33 factors related to employees who left the organization as independent variables. The results of multiple regression are presented in Table 4.

In order to check the predictability of the factor, the multiple regression matrix was used. The threshold value for treading a factor as a predictive < 0.15 (Table 5).

From the above data, it is observed that four factors who have values less than or equal to 0.15 can be used to predict the job satisfaction. These factors are over time, stock option level, total working years, years at company, years with current manager. These predictors can be used for predicting the existing employee's tendency to leave the organization. Further, this will help the HR manager to design better strategies. The probability predications are presented in Table 6.

8 Probability Prediction for Attrition

From the above Table 7, it can be predicted that the employees who have been working for 0–5 years may leave the organization for growth, as the similar trend was observed with the employees who left the organization. This analogy can be applied for other factors like overtime years with current manager and total working experience.

Table 6 Predictors of job satisfactions

Stock option (0)	477	39
Over time(Yes)	289	23
Years with current manager(0–1) yrs	243	20
Total working experience (0–5)	225	18

9 Conclusion

Researchers have observed that there is a strong relationship between the job satisfaction and attrition and failing of which it may lead to attrition. The employees will be satisfied with the organization when the company offers an interesting job, good policies, benefits, compensation. Hence, the management need to have an appropriate HR mechanism to deal with this.

The practice of overtime may be perceived as the source of additional income and a factor that may lead to physical stress. Further, it may exhaust the employees and may inversely affect the efficiency. From the data, it is ascertained that 54% of employees have left the organization due to overtime as one of the factors and it could be predicted from the analysis that 23% of employees may leave the organization.

Employees own a share in the company's success with stock option plans offered them a sense of belongingness. Holding of a stock automatically makes employees a contributor to the profit and loss of the company. The researchers have noticed that 65% of the employees who resigned were not owning stocks of the organization. This tendency may influence 39% of existing staff.

It is observed that the company recruits fresh people and offers them experience, skill, knowledge, and train them for their future. This staff expects higher salaries and growth opportunities. Based on the analysis it may be considered that employee between 0 to 5 years of experience may leave the organization. This demands better policy-making. The researchers observed that the role of supervisor/reporting authority is one of the factors that need to be considered.

Hence, as a result of this study, the researcher proposes to use predictive analysis techniques for better HR policy and strategy making.

A Study of Business Performance Management in Special Reference to Automobile Industry

Gurinder Singh, Smiti Kashyap, Kanika Singh Tomar and Vikas Garg

Abstract In contemporary times, the automobile is one of the well-paid industries in the Indian market with an annual growth rate of 7.64% in the passenger-car market. The increasing disposable income of the people along with the ever-growing financial sector has led to this expendable growth. In accordance, there has been an increase in sales of passenger cars from 13.35% in –July 2018. This oligopoly market has fierce competition due to new entrants into the Indian markets. Thus, there emerges a need to grasp the knowledge to understand the ever-growing needs of the customers and dynamism in the technology-driven market. Every organization seeks to study consumer buying behavior and measure its business performance by analyzing customer perception toward the product. The understanding of customer's perception is an ongoing process to survive the cut throat competition. Taking this into consideration, the study provides insights about several attributes which drive a consumer behavior toward buying a product of a brand. The study has used theories and exploratory research design along with analytical tools to identify the major attributes of consumer buying behavior toward sedan cars within Delhi/NCR among high-end consumers. This knowledge helps the car manufacturers in market segmentation which enables the organization to plan the market strategies toward consumer retention and product upgradation.

Keywords Business performance management · Consumer buying behavior · Market segmentation · Factor analysis · Brand reputation · Purchase service · Physical appearance · Automotive techniques

1 Introduction

In India, the automobile is an industry which plays a major role in the growth of the Indian economy. The industry encompasses namely, passenger cars, two-wheelers, three-wheelers, commercial vehicles, multi-utility vehicles, and its components. The share of the Indian motorcycle manufacturers is the largest in the world, followed by other two-wheelers and tractor manufacturers. The Indian Commercial Vehicle manufacturers are the fifth largest across the global market and fourth largest in Asia. India has strength in manufacturing low-cost, fuel-efficient cars of various automobile companies namely, Maruti Suzuki, Volkswagen, Toyota, Hyundai, and Nissan.

Looking at the ever-growing share of the automobile industry in the growth, the government of India focuses on Research & Development to provide the infrastructure and world-class automotive testing to the industry. The paper throws light on the several determinants of consumer buying behavior of passenger cars which can be utilized by the industry for market segmentation, advertisement strategies, product differentiation in terms of technology upgradation, safety and user friendliness, and sales maximization.

1.1 Passenger Vehicles

A passenger vehicle is a four-wheeler vehicle used as a passenger carriage in which up to nine people including a driver can be seated. India is leading in the car market with a 9% growth rate. Japan is the only market which could come closer to this growth rate. China which is the largest market of passenger vehicles had registered a decline in the growth rate by 2.59% and the US market shrunk by 10%. The paper studies the consumer behavior of sedan cars in India. A sedan car is a 3-box configuration passenger-car with A: B: C pillars along with compartments for other things such as the engine of the car, its passenger, and cargo. The best sedan cars in India are Maruti Dzire, Honda Amaze, Honda City, Hyundai Verna, Maruti Ciaz, Toyota Yaris, Toyota Etios, Hyundai Xcent, Tata Tigor, C Class 2018, Sonata, Civic, A6 2019, A Class Sedan, etc.

1.2 Consumer Buying Behavior

The decision-making of a consumer, during a purchase is necessary to be understood to capture the market and tap the potential gains. The understanding is required in terms of what the dynamics of consumer preferences are.

Post this understanding, the automobile industry segments and works on the marketing strategies to improve business performance. In theory, there is a six-stages process of the consumer demand behavior which comprises:

- Exploratory research to understand the problem
- Assimilating the information for the research
- Evaluating the solutions and alternatives
- Decision-making
- The final purchase
- Post-purchase experience.

The decision-making of the consumer buying behavior can be studied at a psychological level, physiological level, financial level, and spatial level.

2 Literature Review

In the automobile industry, the factors which impact the buying pattern of new cars and second-hand cars have been studied extensively. It has been observed that the factors affecting the buying behavior of second-hand cars are very different from first-hand cars [20].

The purpose of studying the consumer buying behavior for new car entrants is to fill the gaps between customer expectations and the present products. This helps to depict the total quality management of the cars to tap the existing and potential buyers [12].

The question for managers in the service industries regarding consumer loyalty has been studied based on online or offline consumers. They have depicted the correspondence among customer satisfaction and loyalist in an online and offline environment. It shows that the consumer satisfaction level among online and offline customers is equal, however, the loyalty of the customer is more toward online service provider [16].

A pattern to study the pricing and advertisement expenditure using time series data has been made in 3D Innovation Diffusion Model with empirical evidence of sales to understand the growth pattern of sales [3].

The consumers have a bend toward sporting cars and speed cars as they consider it as the good of distinction. There are several constructs to these concepts. The variables like R&D by the technical fraternity, disposable income, and liberalization in terms of foreign exchange, high-end models and integration in automobiles pave way to the dynamic consumer behavior in the automobile industry as observed today [17].

The car segments in terms of easy finance availability of rural and urban sectors have been studied to understand the bend of consumer based on brand loyalty, which helps the existing companies to survive when new entrants come in the market. All market segments within the Indian market have been considered such as

value-for-money, safety and driving comforts, and brand image impacts on sales of passenger cars [5].

The logistic regression modeling has also been used to depict the protectionism adopted by the government of India to help the domestic car manufacturers to grow in the competitive world. The domestic car manufacturers use product differentiations, innovative products, and quality and reliability as the attributes to capture the market share. The companies such as Honda, Toyota, General Motors, Ford, and Hyundai used these strategies prior to liberalization and foreign direct transformation in the Indian market [14].

The increase in disposable income at the rate of 25% per annum and the changes in the sociocultural environment are the factors affecting consumer behavior in terms of luxury cars. Now, even middle-class people like to purchase luxury cars. So, the study shows how luxury cars now occupy the place in the daily life of the people within the Indian Economy [18].

Automotive Technology and Human Factor Research related to the past, present, and future is primarily driven in terms of the features of car control, display for the driver, driver workspace, driver's conditions, etc. [1].

The aim of this paper is to find the significant factors which influence the consumer buying behavior of sedan cars. Further, the paper provides recommendations to the automobile industry to upgrade their products, market segmentation, and advertisement strategies to maximize the sales and hence, capture the market.

3 Objectives

1. To evaluate the measures to improve the business performance of the sedan car industry to compete in the Indian metropolitan markets.
2. To determine the agents affecting the consumer buying behavior of sedan cars in Delhi/NCR.
3. To segment the market of sedan cars with reference to the consumer preferences.

4 Data Collection

This paper aims to evaluate the measures to improve business performance in the automobile industry. The business performance management is studied based on different perspectives namely, learning-growth perspective, financial perspective, customer perspective, and internalized business process [2].

This paper focuses on the learning and growth aspect of the automobile industry. The market segmentation is significant for the existing firms and new entrants to compete in the market [7]. With the review of the literature and pilot surveys among

the consumers of Delhi/NCR (30 consumers for the pilot survey were used), we have used the following variables which impact the consumer buying behavior in the sedan car market to do the market segmentation:

The demographic variables under study are age, sex, household income, and occupation.

Other factors:

4.1 Brand Reputation

This attribute influences consumer buying behavior. We have studied brand reputation using the following variables:

Brand image, its name, consistent and affordable pricing for high-end customers, and resale value are important in the decision-making process of the consumer [9].

4.1.1 Brand Name

It is the name given by the company to the product or a range of products. A consumer may associate themselves with a brand name or may build trust toward a specific brand name.

4.1.2 Price

It is the manufacturer suggested retail price of the car which influences the purchase of the product by the consumers given their income levels and preferences. This is also known as "Sticker Price".

4.1.3 Resale Value

It is a factor which is based on several attributes of the car which a customer keeps in mind while purchasing it. The customer likes to purchase a car with higher resale value.

4.2 Warranty

Sedan cars in India are sold by several companies such as Hyundai, Honda, Volkswagen, Maruti Suzuki, etc. The cars in the current era are more reliable and in cases of component failures, the companies provide for the replacement under the warranty period which is either in months/years or the kilometers driven from the date of delivery. A few companies even provide for extended warranty under the

name of "Forever yours" such as Maruti Suzuki. We have studied the warranty using the following variables:

4.2.1 Availability of Spare Parts

Availability of spare parts increases the longevity of the car and makes it economical.

4.2.2 Vehicle Availability

Availability of vehicle for use in the stipulated time of need.

4.3 Physical Appearance

The looks of a car play an important role in purchasing a car. We have studied physical appearance using the following variables:

4.3.1 Design and Exteriors

The design, shape, and surface are built by car manufacturers using upgraded technology which attracts the customer. The body of the car impacts the speed and safety of the car.

4.3.2 Comfort

It is a primary factor which influences consumer buying behavior. A comfortable vehicle with leg space, headroom, automatic starring are the definitive factors which a consumer investigates before buying the product.

4.4 Features

Apart from the looks, there are several other features which are kept into consideration while purchasing a car. We have used the following variables:

4.4.1 Interior Look

The well-defined body, neatly-cut lamp, installed lights, style, inside cabin, gearbox design, and several other interior designs are investigated by a consumer while purchasing a car.

4.4.2 Boot Space

The boot space ranges from 235 to 510 L in a sedan car which signifies how spacious a car is.

4.5 Technical Features

All the consumers look for an upgraded product along with user friendliness. We have used the following variables:

4.5.1 Technology

The sedan cars with high-tech features such as gadgets installed in the car, the automatic gear box, apple care play, compact hatch back, gas-electric hybrid technology, etc., are considered by the consumers prior to buying a car.

4.5.2 Engine

The cubic centimeters of the cylinder of the car engine are kept in mind by the consumer prior to purchase.

4.6 Value Addition

The additional services are provided by the car distribution channel to add value to the product. We have used the following variables:

4.6.1 Waiting Time

This is a time gap between the booking and delivery of the car.

4.6.2 Discount

The reduction in the price of the car makes the purchase attractive.

4.6.3 Safety

Several features in a car like airbag, crash rates, and platform, are important to a consumer and for auto-insurances.

4.6.4 Value for Money

If the utility received from the car is not in equilibrium with the pricing, the consumer tends to restrict the purchase.

4.7 Performance

The utility of the sedan car to a consumer can be studied using the following variables:

4.7.1 Mileage

The distance in kilometers covered by a car per liter of fuel is considered before purchase.

4.7.2 Fuel Economy

The fuel-efficiency of a car is amajor performance parameter.

5 Research Methodology

This is an exploratory research where we try to identify the major factors which determine the consumer buying behavior of sedan cars in Delhi/NCR. For the study, we have used high-end consumers under the income bracket of 7 Lac and above (per annum). The primary data was collected using the survey method [8].

We have built a questionnaire under several heads as per the variables. The responses to the questionnaire were collected from the consumers who were the potential buyers of sedan cars.

We have divided the Delhi/NCR majorly into four regions namely, north, south, west, and east to represent the consumers (with income of 7 Lac and above annually) of sedan cars. The information regarding the consumers was collected using the data available at the showrooms. We have used the sample size of 306 consumers from all the four regions to truly represent the target population and performed personalized interviews to collect the information.

6 Data Analysis

To identify the significant factors which affect consumer buying behavior, we have collected the data using the questionnaire method. Every question was analyzed to understand consumer preferences using bar graphs, pie charts, tables, and statistical tools.

6.1 Demographic Distribution of Consumers

6.1.1 On the Basis of Gender

The data collected shows that out of the sample, 20% of the consumers of sedan cars are females and 80% of the consumers are males (refer to Fig. 1). This interpretation helps the automobile industry to focus on the male counterpart of the society while designing the marketing strategies and features of the product.

The data collected shows that out of the sample size, 20% of the consumers are females and 80% are males.

6.1.2 On the Basis of Age

During the data analysis, it was found that sedan cars are purchased by consumers of different age groups. The maximum percentage of users, i.e., 50% of the users lie

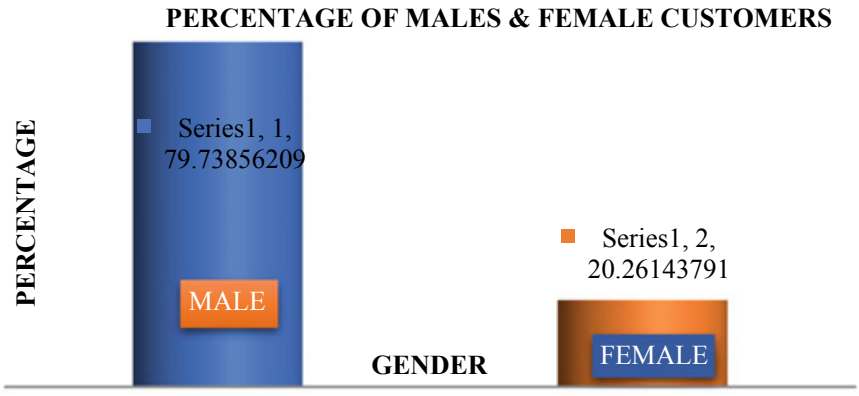

Fig. 1 Percentage of users of among males and females

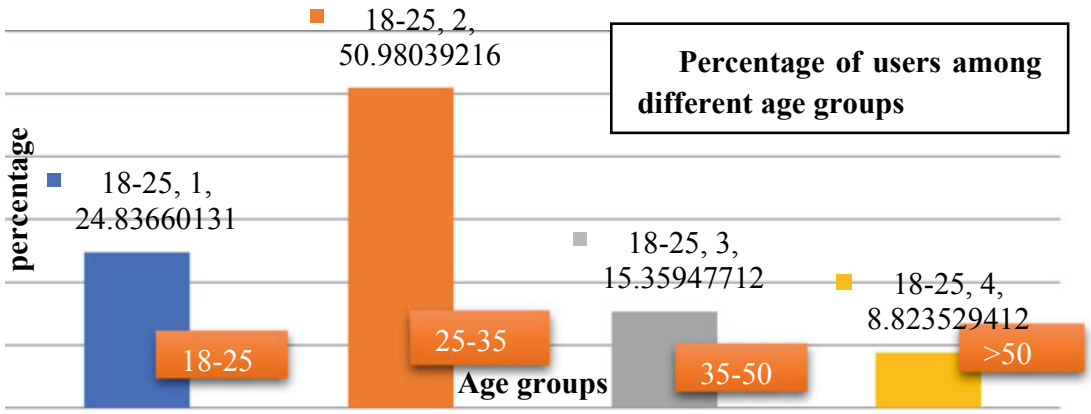

Fig. 2 Percentage of users among different age groups

in the age group of 25–35 years followed by the age group of 18–25 years constituting nearly 25% of the users (refer to Fig. 2). The rest 15% fall in the age group of 35–50 years and above. So, the companies should target the advertisements on the age group of 25–35 years to increase sales.

The consumers between 25–35 years are the people who demand 50% of the sedan cars in the market. The people between 35–50 years demand 15% of sedan cars in the market and 18–24 years demand 25% of the sedan cars in the market.

6.1.3 On the Basis of Occupation

The results show that the maximum users of sedan cars fall in the business class in terms of occupation constituting nearly 63%. The service class constitutes approximately 20% of the total users followed by students and others. (refer to Fig. 3). The automobile firms must focus on their marketing strategy on the business class.

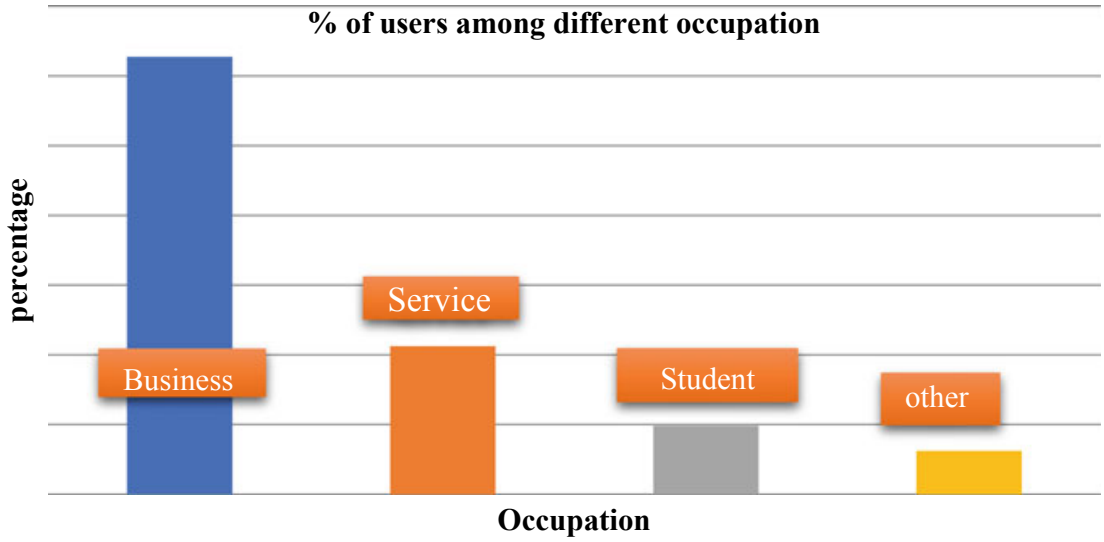

Fig. 3 Percentage of users among different occupation

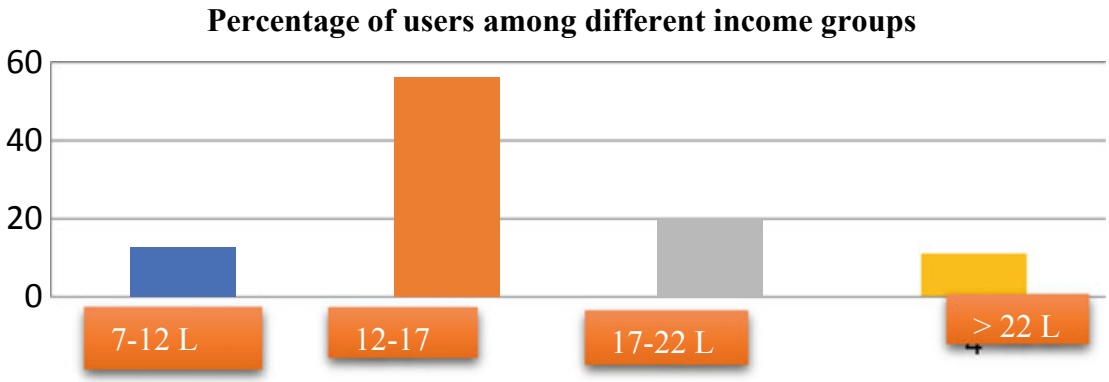

Fig. 4 Percentage of users among different income groups

Among the buyers, the maximum people are businessmen—approximately 63%. Nearly 20% are servicemen, 10% are students, and the rest 8% falls in the "others" category which includes self-employed people.

6.1.4 On the Basis of Income Groups

The data collected helps us to find that the maximum users lie in the income group of 12 to 17 Lacs constituting of up to 57%. 20% of the users fall in the income group of 17–22 Lacs and 12% of the users fall in the income group of 22 Lac and above and 11% fall in the income group of 7–12 Lacs (refer to Fig. 4). The companies' pricing, products, and marketing strategies must focus on users falling under the age group of 12 to 17 lacs.

According to my study, 57% of the buyers are of the income group 12–17 lacs per annum and 12% people of income above 22 lacs buy sedan cars, as people of this group would rather go for sedan cars.

6.2 Motivational Factors of Consumers

6.2.1 On the Basis of Daily Drive

The results show that on an average 30% of the consumers in Delhi/NCR drive under 50 kms, 25% of the consumers drive up to 50–80 kms, 34% the consumers drive up to 80–100 kms and rest 11% of the consumers drive above 100 kms (refer to Fig. 5). As on an average, maximum consumers drive between 80–100 kms, they would prefer more economical cars on roads such as diesel engine, good mileage along with luxury and comfort.

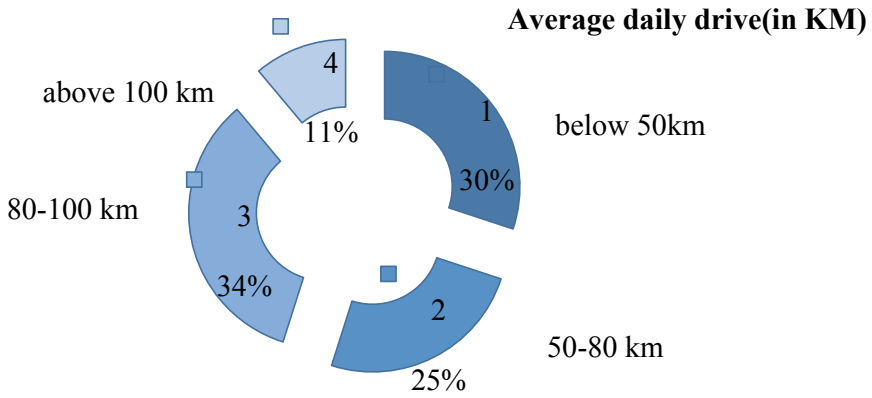

Fig. 5 The average daily drive of the consumers

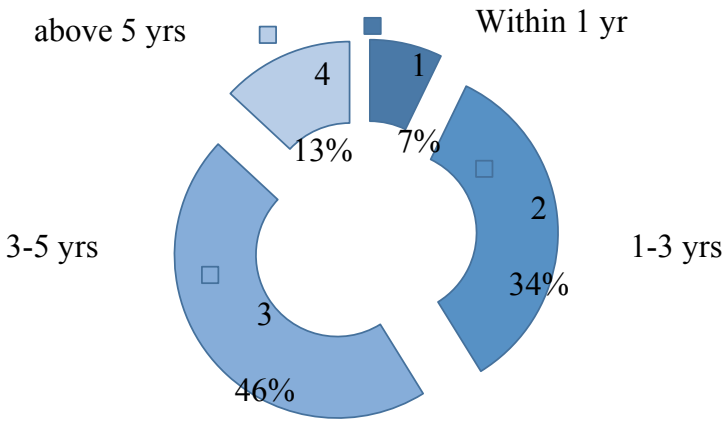
According to my survey, 34% of the buyers include people who drive 80–100 kms daily on an average and therefore they may be interested in a diesel engine sedan class car which would give them good mileage, luxury, and comfort.

6.2.2 On the Basis of Time Span Between Car Switch

The results show that on an average out of the total consumers of sedan cars in Delhi/NCR, 7% change their car within a time span of 1 year, 34% change it in 1 to 3 years, 46% change it in 3 to 5 years, and rest 13% change it in a span of above 5 years (refer to Fig. 6). The companies can use this data and intimate their consumers about the new releases within these time spans to retain the consumers.

According to my study, 46% people purchase/change their cars in 3–5 years. By keeping a track of such customers, who change their cars in every 3–5 years, the companies could send them invitations regarding their new releases and retain their customers.

Fig. 6 Time span in which the consumers change their cars



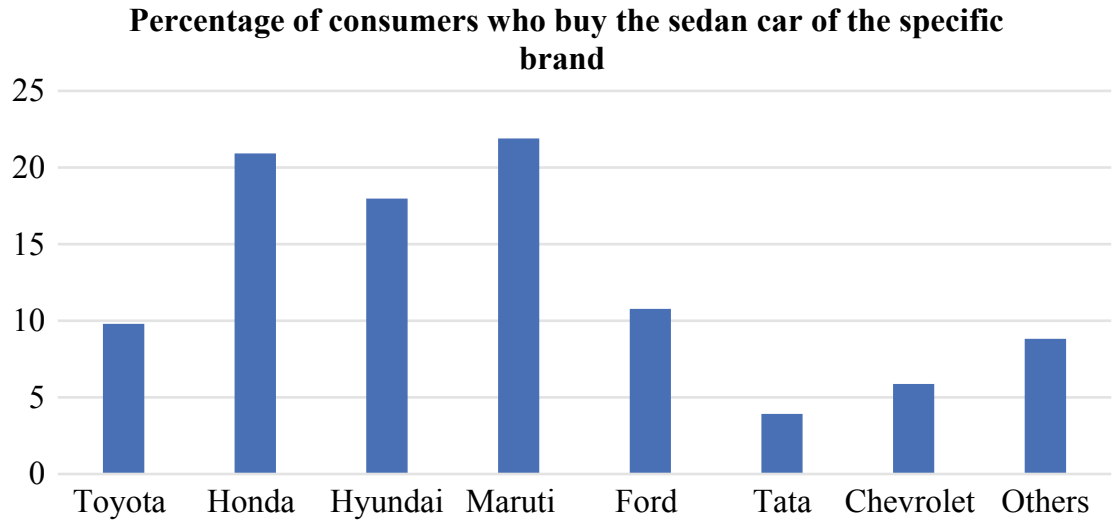


Fig. 7 The different brand sedan cars which consumers purchase

6.3 Preference of Consumers Toward Different Brands

The results show that in Delhi/NCR, 22% of the consumers buy Maruti sedan cars, 20% of the consumers buy Honda sedan cars, 18% of the consumers buy Hyundai sedan cars, 10% buy Ford, and the rest of the consumers prefer other brands like Toyota, Chevrolet, Tata, etc. (refer to Fig. 7). This shows the cut throat competition among the oligopolistic automobile industry.

According to the study, the consumers buy (cars) of other brands such as Honda, Hyundai, Maruti, and Ford which constitute 20, 18, 22, and 10%, respectively.

6.4 Consumer Preferences Based on Features of Sedan Cars

The study has used the 5-point Likert scale to analyze consumer preferences while buying a sedan car. The scale: 1 as Excellent, correspondingly 2 as Very-Good, followed by 3 as Satisfactory, 4 as Non-Satisfactory, and 5 as Poor. The study observes that when consumers purchase a sedan car, 20% is based on the comfort level of the car, 17% on the basis of engine strength, and 14% on the basis of luxury. Table 1 shows the weightage of different features while purchasing a sedan car.

Table 1 Frequency of consumer preference

Features	Frequency	Weightage (Percentage)
Comfort	64	20.91503
Luxury	43	14.05229
Engine	55	17.97386
Sunroof	36	11.76471
Cruise control	18	5.882353
Premium upholstery	24	7.843137
Push entry passive start (PEPS)	21	6.862745
Good mileage	39	12.7451
Others	6	1.960784

6.5 Factor Analysis

We have used the factor analysis technique using SPSS software. The factor analysis technique is used to extract the most significant variables from the list of several variables which influence the dependent variable. This tool calculates the maximum common variance of all variables to find the common score which determines the magnitude and direction of the impact of the independent variable on the dependent variable.

Factor analysis is a multivariate technique which is used to identify the underlying factors and then, eliminate the redundant variables [11].

We have calculated the eigenvalue which is used to consolidate the variance, characteristic roots, and latent values. Additionally, the scree plot of eigenvalue is used to find the significant variables of the study. All the variables on the scree plot before it becomes flat are taken into consideration [13]. An eigenvalue of either 1 or more than 1 is considered a good explanatory feature.

6.5.1 Descriptive Statistics

The data has been first analyzed to measure the central tendencies and dispersion using tools such as mean and standard deviation as depicted in Table 2. It is used to summarize the data set prior to applying factor analysis. The mean shows the influence of each factor on the consumer buying behavior of sedan cars. The weights which are closer to 0, hold no relevance while the larger the weights, larger is the influence on the dependent variable. The standard deviation shows the variation of these factors from the central tendencies. This data set is of total N (306) observations.

Table 2 Descriptive statistics

	Mean	Std. Deviation	Analysis N	Missing N
Technology	2.09	0.943	306	0

6.5.2 KMO and Bartlett's Test

The KMO and Bartlett's Tests were performed to check the adequacy of the data set for factor analysis. The value of Kaiser test lying between 0.5 and above can be considered as middling to perform factor analysis and hence, acceptable. Additionally, Bartlett's test is used to find how useful it is to apply the factor analysis on the data set. If the p value is less than 0.05, then it is considered suitable for further operations. The results in Table 3 show that the data set is suitable for factor analysis.

Table 3 KMO and Bartlett's test

Extraction method: Principal component analysis

6.5.3 Communalities

We have calculated communalities to find the proportion of the variance of the variable that can be explained by each factor. The Initial values indicate the estimates of variance on the account of all factors; it is always 1 for principal component extraction. The extraction value is the estimate of the variance of the variable by all components. A high extraction value indicates that all the variables are represented well. The corresponding results are shown in Table 4.

6.5.4 Total Variance Explained

The purpose is to extract the variables which explain the maximum variance of the dependent variable. To extract the total variance explained by the factors, we have run the factor analysis. The number of factors used for factor analysis is 19. The initial eigenvalue depicts the variance; the total values show the variance in each factor in descending order; the percentage of variance shows the total variance accounted by each factor and the cumulative percentage shows the variance accounted by the current and all the preceding factors. The result in Table 5 shows that the first seven variables explain approximately 70% of the total variance.

Table 5 Total variance explained

Component	Initial eigenvalues			Extraction sums of squared loadings			Rotation sums of squared loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	2.884	15.176	15.176	2.884	15.176	15.176	2.446	12.875	12.875

16	0.279	1.470	97.315						
17	0.202	1.062	98.376						
18	0.181	0.951	99.327						
19	0.128	0.673	100.000						

Extraction method: Principal component analysis

The extraction sum of squared loadings calculates the value of retained factors using common variance. This shows that a total of 7 factors are retained from a total of 19 factors. The rotation sums of squared loading are used to maximize the variance of each of the 7 factors in order to redistribute the total variance [19].

6.5.5 Scree Plot

The scree plot is the graph where the eigenvalue is plotted against the number of factors used for the study. The factors from where the line becomes flat show the magnitude of variance becoming smaller and smaller. Therefore, the graph shown in Fig. 8 depicts that the maximum variance is explained by the first seven variables. [15].

To further validate the extraction of the seven variables from the 19 variables of the study, we have calculated the correlation and covariance of each factor with these seven factors. The results show the high correlation and the appropriateness of the variables extracted. The Component Matrix (Table 6), Rotated Component Matrix (Table 7), Component Transformation Matrix (Table 8), Component Score Coefficients (Table 9), and Component score covariance matrix (Table 10) are shown in the appendix for reference.

6.5.6 Factor Loadings

The factors retained after performing factor analysis are brand reputation; purchase service, physical appearance, features, technical features, value additions, and

performance. Several attributes are studied under these variables. The factor loadings of these are shown using the component matrices [10].

The major results from the component matrices are summarized from Tables 11, 12, 13, 14, 15, 16, and 17:

Factor 1 comprises brand reputation provided by the company. Here price has maximum factor loading of .863 so it becomes an important factor.

Factor 2 comprises purchase services provided by the company. Here warranty has maximum factor loading of .812, so it becomes an important factor.

Factor 3 comprises physical appearance provided by company. Here design and exterior looks have maximum factor loading of .768, hence it becomes an important factor.

Here, factor 4 comprises features. Here, interiors have maximum factor loading of .754 so it becomes an important factor.

Factor 5 comprises technical features of the car provided by the company. As we can see, engine has maximum factor loading of .783, so it is an important factor.

Factor 6 comprises value addition. Here, waiting time has maximum factor loading of .783, so it becomes an important factor.

Factor 7 comprises performance provided by the company. Here, fuel economy has maximum factor loading of .863 which makes it an important factor.

Fuel economy	0.863	2.14

7 Conclusion

The understanding of customer's perception is an ongoing process to survive the cut throat competition. Taking this into consideration, the study provides insights about the several attributes which drive a customer's behavior toward buying a product of a brand. The study has used theories and exploratory research design along with analytical tools to identify the major attributes of consumer buying behavior toward sedan cars within Delhi/NCR among high-end consumers. This

knowledge helps car manufacturers in market segmentation which enables the organization to plan the market strategies toward consumer retention and product upgradation.

We have the output of factor analysis for this problem—the un-rotated factor matrix, the final statistics comprising the communality for all 19 variables, and the eigenvalues of all factors having eigenvalues of more than 1. The seven factors are extracted using factor analysis namely, brand reputation, physical appearance, features, purchase services, technical features, value addition, and performance. These variables capture approximately 70% of the total variance information content out of the 19 variables under study.

Under the Brand Reputation, price is the most influential factor having factor loading of .863, followed by warranty under Purchase Services having factor loading of .812, design and exterior looks under physical appearance with factor loading of .768, interior look under features with factor loading of .754, engine strength under technical features with factor loading of .783, value for money under value addition with factor loading of .863, and fuel economy under performance with factor loading of .863.

The automobile companies must focus on their male consumers falling under the age group of 25–35 years who lie in the business class within an income group of 12–17 lacs. The marketing strategy, advertisement, and price strategy should be specially designed for this segment of the consumers based on good mileage, luxury, comfort, and engine strength and fuel economy.

The automobile companies should also pay attention to additional factor, i.e., the time span of car switch among the customers to retain them. The customers upgrade their cars usually between a period of 3–5 years by either purchasing a new car of their trusted brand or switching the brand. So, to retain the customers, it is important that the companies keep a focus on R&D to develop new upgraded cars and intimating their existing customers from time to time.

Secure Online Voting System Using Biometric and Blockchain

Dipti Pawade, Avani Sakhapara, Aishwarya Badgujar, Divya Adepu and Melvita Andrade

Abstract Elections play an important role is democracy. If the election process is not transparent, secure and tamper proof then the reliability and authenticity of whole process is at stake. In this paper, we have discussed online voting system which fulfills all the above system requirements. We have addressed the issue of user authentication through iris recognition. We have used One Time Password (OTP) to have additional security check. We have also taken care that one valid user should not cast multiple votes. Use of Blockchain is the another security measure implemented in order to provide decentralized, tamper proof storage of data related to users biometric, personal details and votes casted by them. Thus we are not only focusing on user authenticity but also data security is also taken into consideration. The performance of the system has been tested for users from different age group and different background and its inference is presented.

Keywords Online voting · Blockchain · Sidechain · Iris recognition

1 Introduction

In democratic country like India, Election is considered as vital process. Right from choosing the Prime minister to the ward member, every election is carried out using voting system. Earlier, the ballot paper voting system was used in election process. Here people need to visit the appropriate Polling booth and need to show the voter ID card to prove their authenticity. Casting of vote is done by stamping on ballot paper secretly and then ballot paper is folded and deposited in ballot box. After the voting is done, the ballot boxes are sealed and moved to the counting center under security and counting of votes is carried out manually. But there were some incidences of manipulation with ballot boxes. Also this complete process took longer time for result declaration, required tremendous human resources and thus incurred high

costing. Because of all these reasons, Electronic Voting Machine (EVM) is introduced in 1982 in 70-Parur Assembly Constituency of Kerala on trial basis [1]. At mass level it is used in 1998 assembly elections in Madhya Pradesh, Rajasthan and the NCT of Delhi. After that, EVM is being used in all the elections conducted by Election Commission of India. EVMs are under purview of Election Commission of India only and cannot be used for other elections like university senate elections, society election or elections carried out in various organizations. Thus they are still using the traditional ballot paper base election process.

In this paper we have addressed to the various issues related to the university senate election, where electoral roll of graduate teachers is made electronically but still ballot paper is used for vote casting. It has been observed that percentage of votes casted is very low as compared to the total number of eligible voters. One of the reasons for this reluctance is that for casting vote one needs to travel to the particular place. Most effective solution to this is like preparing electoral list and conducting election through e-portal. But due to security concerns, this option is ruled out. Hence we are proposing the concept of online voting system where voter identification is done using biometric iris recognition. As biometric trait is the basic parameter under consideration to verify the genuine voter, security of iris template database is also our concern. For that purpose we are storing all the details of voter including iris feature on Blockchain, so that it cannot be tampered. The system takes care of the issue related to multiple votes casted by single voter. Once the pre-set time of election conduction is over the portal gets locked and result statistics are automatically emailed to the election candidates and concerned authority.

Further outline of the paper is as follows: Sect. 2 consists of related work in the area of applications of online elections and research in iris recognition system. In Sect. 3 overview of Blockchain and related technologies is given. In Sect. 4, the design and implementation of the proposed online voting system is discussed. In Sect. 5 results are presented and in Sect. 6 conclusion and future work is stated.

2 Related Work

2.1 Literature Survey on E-Voting Application

Khasawneh et al. [2] discussed the implementation of biometric based secure e-voting system. For voter identification, initially they have used official voter ID cards which need to insert in magnetic card reader to fetch the details of the voters from local or central database. If record is found then the individual's fingerprints are scanned and matched against the pre-stored database. Thus only authenticated person is allowed to vote and once voting is done then flag is set so that same person cannot do the voting again. Main concern of this approach is that the authentication is solely dependent on central Authentication server. If that server is down, whole voting system will be affected.

Petcu et al. [3] describes a mobile e-system consisting of various phases. Firstly one needs to enroll themselves by visiting physically to the authentication center. Here they need to provide some valid identity proof and if person is eligible to vote then his/her mobile number, voice and fingerprint samples are collected and key token is given to the voter. In authentication phase, the user has to access the web portal and has to provide the ID card details and key token provided at the time of enrolment. The system will then send a SMS key on successful collection of three voice samples and fingerprint samples for both the hands of a voter. Then one needs to provide the unique code, key token and SMS key which is verified by the authority and then vote access is given to that voter. Now voter can use e-voting module to cast the vote securely and vote counting is also done automatically. Here author have used so many key values which need to be provided, which make the system complicated to use.

Sridharan [4] considered the smart card, voter identification number (VID) and fingerprints to authorize and uniquely identify the individual. The complete system has four modules viz. Franchise Excising Terminal to recognize smart card, Authentication Terminal, the Distributed Databases and Central Controlling Server. Use of distributed database makes the system scalable. But still biometric data security concern exists.

Agarwal et al. [5] proposed the AADHAR ID based online authentication system where voter first needs to provide AADHAR ID which is being verified by authority and then password is mailed to the particular person. One needs to login into online voting system to cast the vote and it is accepted only if fingerprint matching is done successfully. Author has not given the insight to how templates for fingerprint matching are collected and how the fingerprint server database is maintained.

Table 1 gives the overview of the different parameters used in various e-voting applications for voter authentication.

Table 1 Overview of available e-voting application

S. No.	Author	Parameter used for authentication
1	Khasawneh et al. [2]	Specially designed magnetic tape based Voter ID card, fingerprints
2	Petcu et al. [3]	Physical Identity proof, Voice sample, fingerprint of both hands, key token, 4 digit key, SMSkey
3	Sridharan [4]	Smart card, VID and fingerprints
4	Agarwal et al. [5]	AADHAR ID, Password, fingerprints

2.2 Literature Survey on Iris Recognition System

Garagad et al. [6] proposed iris identification system which is claimed to be invariant to distance and eye tiltation. They have Performed segmentation to take out the region of interest. It involves low intensity region recognition in input image, detecting iris and boundary inference point (edge detection) followed by selective image cropping followed by pupil localization and normalization. For feature extraction first cartesian plane data of an image is obtained through signature code generation and then it is converted to a binary iris signature code to optimize the memory utilization and speed up the processing. Finally for iris matching binary signature code of input iris image and template image are compared using XOR bitwise operation. The author [6] concluded that, this approach is simple to implement and effective way of iris authentication in case of scale and tilt variance.

Neda et al. [7] have suggested hybrid approach for iris recognition model based on a multi-layer perceptron NN (MLPNN) and particle swarm optimization (PSO) algorithms. Here, to separate the sclera and pupil, iris localization is carried out using circular Hough transform algorithm [8, 9]. Then normalization is carried out to convert image from the space of the Cartesian coordinates to polar coordinates using rubber-sheet model of Daugman followed by image segmentation [10]. 2D gabor kernel method is applied to the pre-processed image to extract the features. For pattern matching author have proposed a hybrid approach based on ANN-based MLP and PSO algorithm and called it as MLPNN–PSO algorithm. This hybrid approach achieves 95.36% accuracy rate which is much better when these approaches are used separately.

Muthana et al. [11] discussed two methods of iris feature extraction viz. the Fourier descriptors (FD) and Principle Component Analysis (PCA). Before feature extraction, iris segmentation is carried out using pupil and iris localization. The pupil localization consists of following steps: smoothing using non-linear median filter, binarization, and noise removal using morphological operation and finding the iris center. While the iris localization is done by applying Canny masks which is used to locate iris boundary and circular Hough transform which is used to get complete circular shape. Next step in pre-processing is normalization using rubber sheet model. Then for feature extraction FD and PCA is used and their results are classified using Manhattan, Euclidean and Cosine distance. According to their result discussion accuracy rate of FD with Manhattan distance is highest i.e. 96%.

Table 2 gives the overall summary for different iris recognition system based on various parameters.

Table 2 Summary of iris recognition system

Database	Preprocessing	Feature extraction	Classifier	Recognition rate	Peculiarity
High-quality UPOL iris images captured in constrained environment [6]	Segmentation	Gray signature code generation and binary signature code generation	Bit to bit comparisons of binary signature codes using XOR operation	99.64 (for Normal Test input images) 90.698 (for tilt & scale variation)	Approach is invariant to distance and tilt variations
(CASIA)-iris V3 and UCI [7]	Circular Hough transform algorithm, rubber-sheet model	2D Gabor kernel method	Hybrid MLPNN–PSO algorithm	95.36%	MLPNN and PSO algorithm gives better
CASIA v1 [11]	Pupil and Iris localisation, iris normalization	Fourier descriptors (FD) and Principle Component Analysis (PCA)	Manhattan, Euclidean and Cosine distance	96%	FD is better than PCA and FD with Manhattan gives highest accuracy

3 Overview of Blockchain Technology

Database is considered as a very important component when we are talking about full stack application development. Traditional databases follow the client-server architecture, where client/user has a provision to perform CRUD operations (Create, Read, Update, and Delete) and data is stored on a centralized server. As all clients have the rights to modify or update the data, there is a database administrator who authorizes the client and makes sure that the data is not being compromised. But here as data is maintained in centralized database, the whole system gets hampered if database server crashes. Also the load on one server is more thus the overall computation speed is low. To address this problem the concept of distributed database was introduced. A distributed database is considered as a single logical database where nodes are physically distributed across several geographic locations and communicate with each other over a network. This kind of database is normally suited for an organization, where all trust each other. Here in case if any node fails the system continues to work with other node.

Blockchain is said to be a decentralized database where data integrity and transparency is considered as parameter for public verifiability [12]. Opposite to traditional database, Blockchain allows only read and write operations to be performed on the data. In read operation user can read/query the data on Blockchain

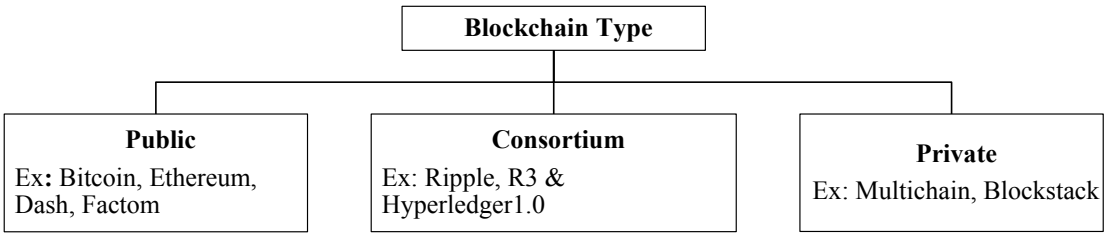

Fig. 1 Types of Blockchain

while write operation used to add the data on Blockchain. Whenever write operation is performed an additional block is appended in Blockchain. All previous data is available in block which cannot be altered. If it is being altered then it is added as new block and the original block data remains the same [13]. Thus it is considered as scam free, transparent system.

Figure 1 shows different types of Blockchain. Public Blockchain is also called as permissionless Blockchain, as there is no authority to sanction any Blockchain transaction. This means process of consensus building is public. Second type of Blockchain is consortium which is also known as public permissioned Blockchain. Here consensus process is monitored by a pre-selected group of nodes and for transaction verification minimum clearance is required. Private/private permissioned Blockchain is the third type of Blockchain where write operation rights are given to set of specific nodes while read rights can be public or restricted to specific nodes [14].

3.1 Sidechain

A sidechain is considered as separate blockchain that is attached to the blocks on the main blockchain. Main chain is also referred to as "Parent Blockchain" while sidechain is referred to as "childchain". The assets can be interchanged between the main chain and the sidechain at a predetermined rate. The major advantage of using sidechain is that one can easily develop and deploy a quickly scalable Blockchain solutions that too at lower cost and under high level of security [15].

3.2 Ethereum Platform

For our application development we are using Ethereum public Blockchain platform which allows the development of decentralized application (dapp). Ethereum platform has two building blocks viz. Ethereum Virtual Machine (EVM) and peer-to-peer network protocol. In order to get consensus for transaction, each node

in network runs the EVM and processes the instruction. In simple words EVM is a run time environment which converts the smart contract into EVM bytecode and deploys it onto Blockchain for execution. Here smart contracts are the basic building blocks of a program which consist of contract instructions which are simply set of instructions to be executed upon certain event. We have written our smart contract in solidity language [15].

3.3 Metamask

Earlier the biggest issue with using dapps was, using normal browsers it was not possible to write to the Blockchain. There were special Blockchain browsers like Mist but using it was very tricky and thus the whole development process became tedious. The solution to this issue is provided in the form of Metamask which is an Ethereum web browser extension. Metamask basically acts like a Ethereum wallet which stores Ethereum related data like private keys, public addresses etc. MetaMask is considered as the easiest way to interact with dapps in a browser. It allows you to connect to an Ethereum network without running a full node on the browser's machine [16].

4 Implementation Approach

As shown in Fig. 2, system has three main modules running on client side,

- Voter enrollment module using which user needs to enroll themselves as a authorized voter
- Election authority interface through which the election process is initiated and election result calculation command is triggered.
- Election interface, which verifies the identity of the user as valid voter and provides interface to cast the vote.

In order to connect our web user interface with the Ethereum Blockchain we have used Metamask. The overall system implementation is carried out as follows:

4.1 Working of Proposed System

As per the AICTE rules, every institute affiliated to the university needs to send the details of their employees to the university. These details include information like name, AADHAR ID number (UID), Email ID, PAN number, address etc. So before university election, name and Email ID and UID of eligible candidates are collected

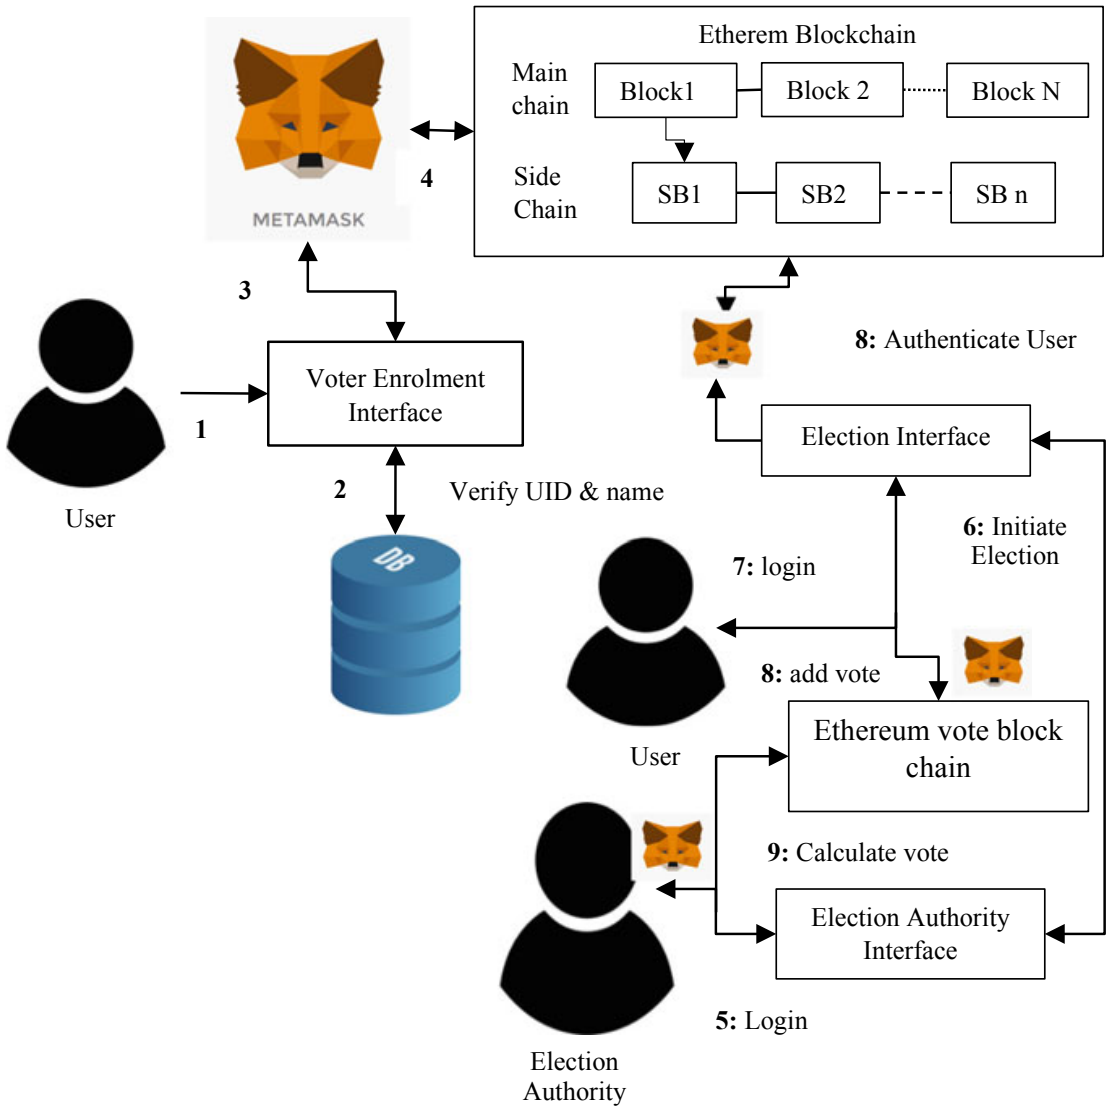

Fig. 2 Block diagram of proposed online voting system

from each institute and stored in database. A bot is designed to send auto-generated mail to notify eligible voters regarding voter enrollment deadline and guidelines. This bot will fetch the email IDs from the database and will send template mail to all specifying the link for registration and the description of the procedure to be followed.

Then the user needs to visit our election portal, for registration each user needs to provide basic information like name, address, valid mobile number and UID. This UID and name of the user is matched against the database for verification. If it gets matched then user has to choose unique username and password for them. This combination of username and password will be generated after successfully satisfying the required validation rules. For verification, link is sent on the respective Email Id. User needs to verify themselves by clicking on that link. Once verification is done, all the user data is pushed on Ethereum Blockchain through smart contract, then mining is carried out and genesis block is created [17].

The system will then ask the user to scan the iris. User can use webcam or front camera of mobile to take a picture of iris. The iris image is preprocessed and features are extracted. Preprocessing and feature extraction process is explained in Sect. 4.2. Once features are extracted, it is stored on associated sidechain along with other information like name, address, mobile number.

On the election day, the authorized person will instantiate the election portal. User have to login using the appropriate username and password which was generated during the enrollment phase. Then the user needs to provide his/her valid UID. System will then try to find the block on Blockchain with same UID. If the block is not found, then error message will be displayed otherwise system will scan the iris image through web-cam or front camera of mobile. Preprocessing and feature extraction is done using step in Sect. 4.2. These features are matched against the features stored on sidechain at the enrollment phase. If iris features do not match then the iris image is scanned again and matching is carried out. If match found, then One Time Password (OTP) is generated and sent to the mobile number stored on sidechain for that user. This OTP is valid for 40 s only. User needs to get verification done before that OTP expires. Because of some reason if OTP expires then the user can request for OTP again. Once OTP verification is done, e-ballot will appear on screen containing names and symbols of the candidates. In order to cast vote user needs to select the radio button in front of the particular candidate. Once voting is done flag is set for this user, so that same user should not cast the vote again. The vote casted by user is again pushed on Blockchain through smart contract and genesis block is created on voting Blockchain after mining is done.

The election authority person will disable the election portal once election period is over. On election authority console, calculate button is provided which will fetch all the votes from Blockchain, and calculate the number of votes gained by each candidate. Then the system will mail the result to the authorized members of election committee and the election candidates. Figure 3 depicts the flow of activities when user interacts with the election interface.

4.2 Iris Recognition System

Iris recognition system consists of following three steps:

- Preprocessing
- Feature Extraction
- Feature matching

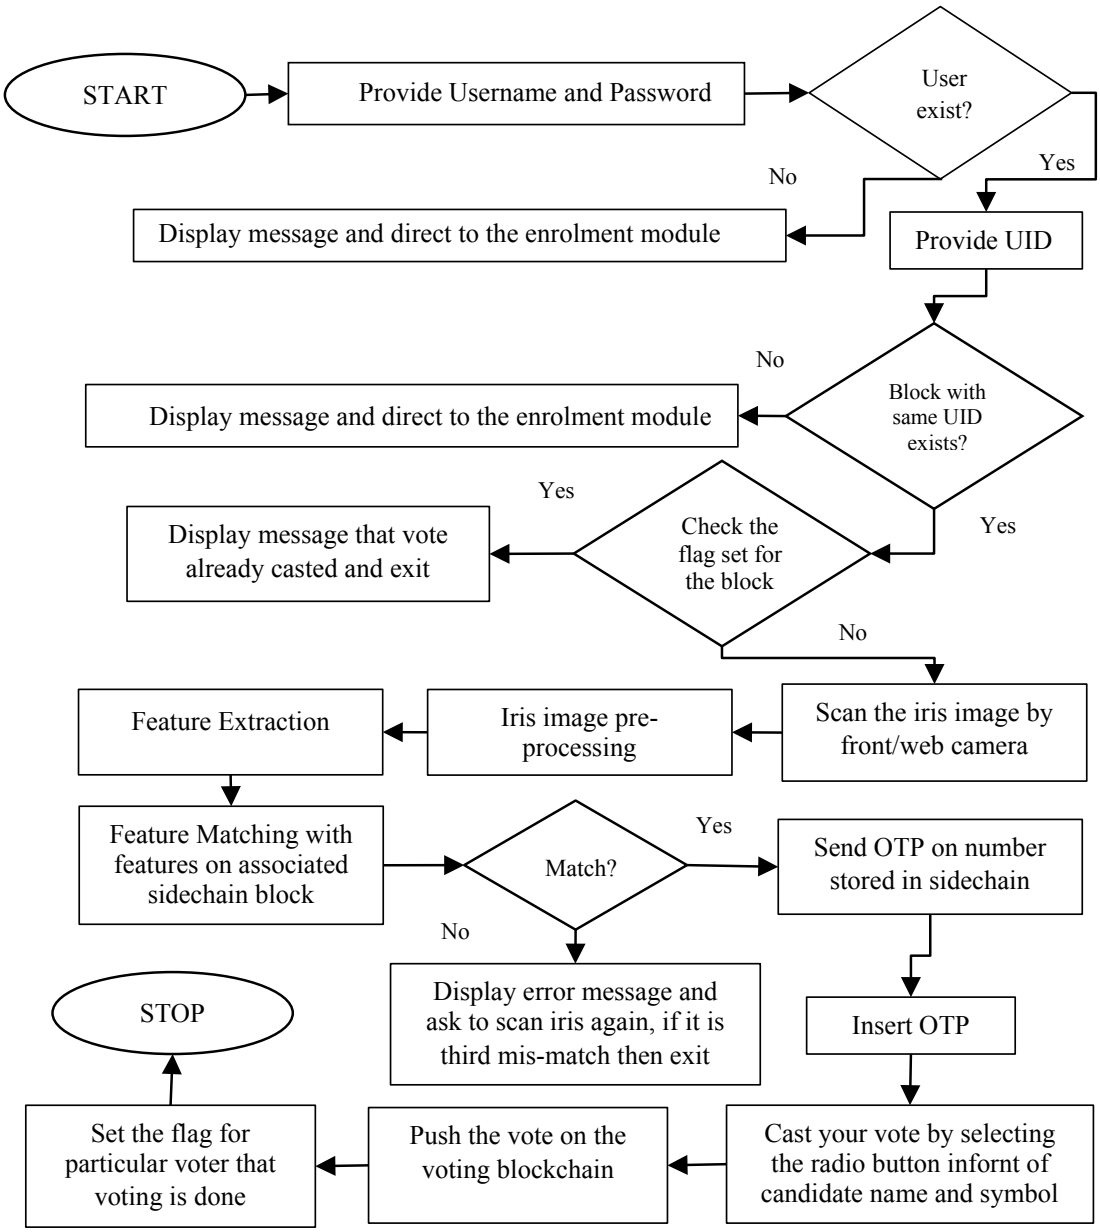

Fig. 3 Flowchart for online voting system for enrolled

4.2.1 Preprocessing

The first step is to convert the colored iris image to a greyscale image which contains only different shades of grey lying in the range of 0–255. This step is important because it reduces the unnecessary information in each pixel [18].

This grey color has the red, green and blue components in equal intensity in the RGB space. So henceforth, we only have one value in every pixel as compared to three values for every pixel of a colored image. Figure 4 depicts the process of color image conversion to greyscale image for any pixel at position (x, y) in colored image.

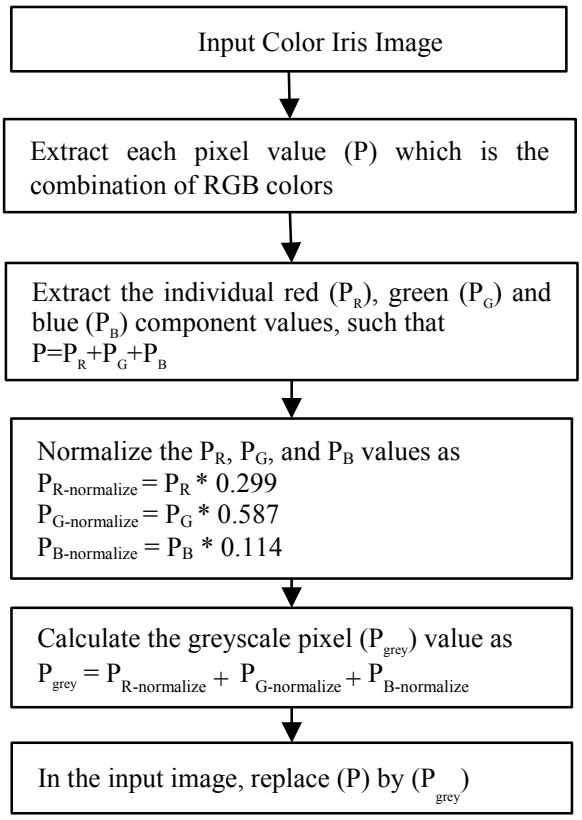

Fig. 4 Steps for color to greyscale Image conversion

The next step is to detect the edges of the iris and pupil. It works by detecting discontinuities in brightness. Sobel operator has been used for this purpose.

In sobel, we apply the derivative mask in horizontal and vertical direction to increase the edge intensity. The resultant is a faint boundary of the iris and pupil depending on the brightness of the image. It works by calculating the gradient of image intensity at each pixel within the image. It finds the rate of change of brightness.

The horizontal gradient Gx is the image that we get after applying the horizontal mask on the greyscale image (A) which is calculated as using the mask in Fig. 5a and the vertical gradient Gy is the image that we get after applying the vertical mask on the greyscale image (A) which is calculated by using mask in Fig. 5b. The masks contain positive and negative coefficients. This means the output image will also contain positive and negative values. The negative values are set to 0. The resultant image is the sum of the horizontal and vertical gradients.

(a)

$$G_x = \begin{bmatrix} +1 & 0 & -1 \\ +2 & 0 & -2 \\ +1 & 0 & -1 \end{bmatrix} * A$$

(b)

$$G_y = \begin{bmatrix} +1 & +2 & +1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix} * A$$

(c)

p4	p3	p2
p5	p	p1
p6	p7	p8

Fig. 5 **a** Sobel vertical mask, **b** Sobel horizontal mask, **c** CN mask

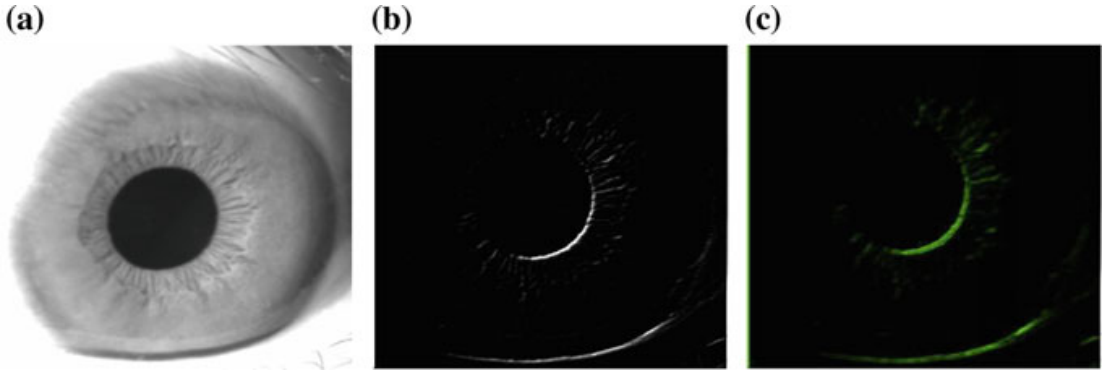

Fig. 6 **a** Sample input iris image, **b** after applying Gabor filter, **c** after applying CN mask

The next step is to use Gabor filter to analyze the texture of the iris. It basically does this by analyzing whether there is any specific frequency content in the iris in the localized region inside the iris circle. The image is convolved with a series of Gabor wavelets to perform a filtering operation. The buffered image is filtered and the resultant is produced as a rendered image [19, 20] (Fig. 6).

4.2.2 Feature Extraction

Minutiae representation is most widely used method of any biometric representation as it helps to determine uniqueness in an image. Minutiae or small details mark the regions of local discontinuity within a biometric image. For detecting minutiae points we have used Rutovitz's Cross Numbering technique.

This method extracts the minutiae points by identifying the bifurcation points (forking points) using a 3 × 3 mask on the local neighborhood pixels of the ridge pixel. These properties identify various properties (minutia) of iris like ridge endings, ridge bifurcations, etc. Figure 5c shows 3 × 3 Mask used for CN technique [21].

$$\mathrm{CN} = \frac{1}{2}\sum_{i=1}^{8} |P_i - P_{i+1}| \tag{1}$$

Using Eq. (1) we get iris feature vector. This output is then used for the matching algorithm.

4.2.3 Matching by Average Method

Step 1:
Here, each pixel is represented as 0xAARRGGBB (alpha, red, green, blue). By performing a bitwise-and with 0xFF, the individual RGB component is calculated as:

$$\begin{aligned} \text{red} &= (\text{rgbA} \gg 16) \,\&\, 0\text{xff} \\ \text{green} &= (\text{rgbA} \gg 8) \,\&\, 0\text{xff} \\ \text{blue} &= (\text{rgbA}) \,\&\, 0\text{xff} \end{aligned} \tag{2}$$

Step 2:
We calculate separate RGB values using Eq. (2) for both input and template iris images and calculate sum of difference between each of the values as

```
difference += Math.abs(redA − redB);
difference += Math.abs(greenA − greenB);
difference += Math.abs(blueA − blueB);
```

Step 3:
Then we calculate total number of pixels:
Number of pixels for each of the RGB component is calculated as given in Eq. (3) and then the summation of number of pixels for each RGB component is taken which gives the total number of pixels.

$$\text{Number of pixels for each RGB component} = \text{width} * \text{height} \tag{3}$$

Step 4:
For normalizing the value of different pixels and for accuracy we use average pixels per color component calculated as

```
average_different_pixels = difference/total_pixels
```

Step 5:
As there are 255 values of pixels(RGB) in total thus

```
Percentage = (average_different_pixels/255) * 100 * 10;
```

If percentage is greater than threshold value then it is iris mismatch otherwise it is considered as iris matched and the user is authenticated.

5 Results and Discussions

For the experimental purpose we have tested the system for 120 users. Now-a-days everyone has the basic knowledge of how to use the web based application. Still while using technology, comfort can be one of the key concerns in order to state the user friendliness of the application. Thus we have made 4 groups with 30 users in each group. Here users are the faculties of different age group and different background. The group details are as follows:

- Group A: contains users who are the faculties having age in between 27 and 42 years and belong to non-technical stream like Literature, Arts, Communication skill and Chemistry.
- Group B: contains users who are the faculties having age in between 27 and 42 years and belong to technical stream like Engineering, Polytechnic and Management.
- Group C: contains users who are the faculties having age in between 43 and 57 years and belong to non-technical stream like Literature, Arts, Communication skill and Chemistry.
- Group D: contains users who are the faculties having age in between 43 and 57 years and belong to technical stream like Engineering, Polytechnic and Management.

Table 3 shows the experimental results for users of different group based on age and their stream. For experimentation every group has used computer system and web camera of same configuration and same Internet speed. We have considered the standard environment with enough luminance and no tilt in iris image. Still it has been observed that there are few users whose iris matching is not done thus they

Table 3 Experimental results for users of different group based on age and their stream

Criteria	*A*	*B*	*C*	*D*
Average Time required for Enrollment (Sec)	4.38	3.89	5.99	4.46
Average Time required for Voting (Sec)	12.73	11.45	16.96	14.01
No. of user proceeding further with first OTP	24	25	19	25
No. of user not requesting OTP twice	02	02	03	00
No. of people not requesting OTP thrice or even more (max. 5 times)	00	00	01	01
No. of user for whom iris recognition is done in first attempt	16	21	10	18
No. of user for whom iris recognition is done in second attempt	08	06	07	03
No. of user for whom iris recognition is done in third attempt	02	00	06	05
No. of user for whom iris recognition is not done thus not casted the vote	04	03	07	04
No. of user casted the vote successfully	26	27	23	26

could not complete the voting process. We also found that technical expertise of the person and how well-versed the person is in dealing with web application and navigation has an impact on the total time required to complete the enrollment as well as voting process.

In second phase of experiment we have considered two groups viz. E and F each having 30 users. For group E, we asked the users to enroll during night with tilts and for group F enrollment is done during day time with tilts while voting for both the groups is carried out during day time. Here all the users are technically sound and between the age group of 27–48. For group E out of 30, only 19 users successfully casted the vote. For rest of the 11 users, biometric authentication failed. The reasons behind that is template iris features for this group is extracted and stored from image which is taken in night when luminance was poor. Thus the luminance plays an important role in the performance of system. For group F, out of 30, 23 people successfully did the iris authentication and casted vote. Thus even tilt in the iris image angle hampers the accuracy of the system.

Figure 7 gives the success and failure rate for all six groups. Same statistics can be considered for iris recognition accuracy and error rate of the system of the system. Thus the average accuracy of the system is 81.11% and average failure rate is 18.89%.

In Table 4, we have discussed the advantages of our proposed system over the existing system which are described in Sect. 2.1. In our system, we have completely eliminated the overhead of maintaining magnetic tape based voter ID cards or smart cards. This reduces the time as well as money required to complete the whole election process. Also there is no need for the voter to maintain these cards. We have also reduced the burden to generate and remember various security keys in order to use the system. Most of the researchers have used fingerprints for biometric

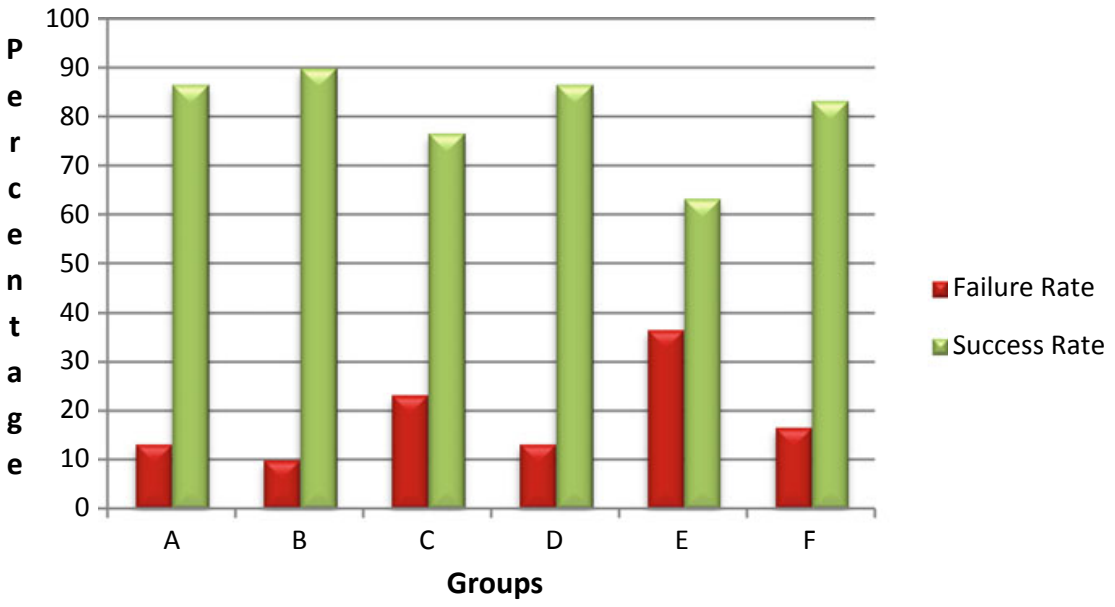

Fig. 7 Summary of success and failure rate for all five groups

Table 4 Advantage of proposed system over existing system

S. No.	Existing system discussed in Table 1	Advantage of proposed system over existing system
1	Khasawneh et al. [2]	No overhead of magnetic tape based Voter ID card, cost is low
2	Petcu et al. [3]	Easy to use as there is no need to generate and remember different keys
3	Sridharan [4]	Smart cards are not required to use the system
4	Agarwal et al. [5]	Biometric data storage is tamper proof and whole system is a decentralized, integrated and transparent

authentication in their system. Instead of fingerprints; we have used iris for biometric authentication as fingerprints are more vulnerable to attacks as compared to iris.

6 Conclusion and Future Work

This paper elaborates a technique of online voting empowered with biometric authentication and Blockchain Technology. By using iris recognition system, we make sure that only a verified person can cast the vote. Also as compared to the existing or proposed voting systems, our system does not store the captured iris image in the database. Instead, it extracts the features of the iris image and then removes the iris image from memory which makes the biometric data more secure. These extracted features along with all the other information of the user and the votes casted by them are stored on Blockchain. Thus system becomes transparent, decentralized and mishaps like information tampering or vote alternation can be easily detected. As now the average accuracy of the system is 81.11% and average failure rate is 18.89%. Accuracy rate is low because we have performed the experiment in low luminance and iris tilt variation. Thus capturing proper iris image with minimum noise is the prime requirement of the system. In future we are planning to improvise our iris recognition system, so that the overall system should work under non ideal condition without any constraint.

An Approach: Applicability of Existing Heterogeneous Multicore Real-Time Task Scheduling in Commercially Available Heterogeneous Multicore Systems

Kalyan Baital and Amlan Chakrabarti

Abstract Interest in design and use of heterogeneous multicore architectures has been increased in recent years due to the fact that the energy optimization and parallelization in heterogeneous multicore architecture are better than that of homogeneous multicore architecture. In heterogeneous multicore architectures, cores have similar Instruction Set Architecture (ISA) but the characteristics of the cores are different with respect to power and performance. Hence, heterogeneous architecture provides new prospects for energy-efficient computation and parallelization. Heterogeneous systems, furnished with different types of cores provide the mechanism to take actions with respect to irregular communication patterns, energy efficiency, high parallelism, load balancing, and unexpected behaviors. However, designing such heterogeneous systems for the different platforms like cloud, Internet of Things (IoT), Smart Devices, and Embedded Systems is still challenging. This paper studies the commercially available heterogeneous multicore architectures and finds out an approach or method to apply the existing work on heterogeneous multicore real-time task scheduling model to commercially available heterogeneous multicore architecture to achieve the parallelism, load balancing, and maximum throughput. The paper shows that the approach can be applied very efficiently to some of the commercially available heterogeneous systems to establish a generic heterogeneous model for the platforms like cloud, Internet of Things (IoT), Smart Devices, Embedded Systems, and other application areas.

1 Introduction

Heterogeneous multicore systems are increasing day by day in the field of embedded systems as well as cloud environments to improve system throughput, parallelization, load balancing, and energy efficiency. Heterogeneous multicore system includes cores with various types or/and complexities to address throughput and productivity for different applications. Different types of heterogeneous multicore systems based on different application areas are commercially available in the market to offer a high degree of parallelism and energy efficiency. Thus, there is an increasing motivation to design a generic heterogeneous model for different application domains including the following technological domains which are in high demand in the market today:

i. Cloud and IoT infrastructure which is high-performance and high-resource domain and offering a high degree of parallelism.
ii. Smart devices and embedded domain which is low-performance and low-resource domain but offering great energy efficiency.

Therefore, our focus is to find an approach to establish a generic heterogeneous model which can be utilized as high-performance and high-resource domain (i.e., cloud and IoT). The same generic model can also be used as energy efficient and low resource domain (i.e., smart devices and embedded systems) along with other common application areas.

Heterogeneous multicore system has achieved significant importance in the area of High-Performance Computing (HPC) which offers a higher degree of parallelization, and hence it has enormous potential for future use in data centers and cloud platforms. In this regard, heterogeneous architectures such as Intel Xeon Phi coprocessor and Graphics Processing Unit (GPU) have significant roles in HPC systems.

Recently, heterogeneous architecture is being used in the mobile technology such as ARM big.LITTLE octa-core architecture. The usage pattern for smartphones and tablets varies drastically, for example, high-processing usage likes mobile gaming and web browsing and low-processing usage likes texting, e-mail, and audio. Octa-core heterogeneous architecture such as ARM big.LITTLE fulfills the demand of these different performance requirements by combining two different types of cores.

Hence, in our proposed approach, we apply different architectural parameters of Intel Xeon Phi coprocessor in our proposed generic model such a way that the generic model can additionally be used as cloud and IoT platform along with several common application areas. Further, we apply different architectural parameters of octa-core (ARM big.LITTLE) in the proposed model for using it as smart devices and embedded systems.

The following significant contributions are explained in this paper:

1. To study the architecture of some of the commercially available heterogeneous multicore architecture such as Intel Xeon–Xeon Phi platform and big.LITTLE mobile octa-core platform.
2. To find an approach to apply the existing heterogeneous multicore real-time task scheduling model as per work [1] into the commercially available heterogeneous multicore systems (Intel Xeon–Xeon Phi platform and big.LITTLE mobile octa-core platform) to achieve the parallelism, load balancing and maximum throughput.
3. To provide the performance comparisons between commercially available heterogeneous multicore systems (Intel Xeon–Xeon Phi platform and big.LITTLE mobile octa-core platform) and existing heterogeneous multicore real-time system [1] to highlight the achievements.

The organization of this paper is as follows: Sect. 2 explains the review of literature for commercially available heterogeneous multicore architecture, namely, Intel Xeon–Xeon Phi platform and big.LITTLE mobile octa-core platform and related works. In this section, it has been shown that (i) Intel Xeon–Xeon Phi system is a good candidate to be used in cloud and IoT infrastructure besides other application domains and (ii) octa-core system is a good candidate to be used in smart devices and embedded systems domain. Section 3 introduces an approach for applicability of the existing work [1] to commercially available heterogeneous multicore architecture such as Intel Xeon–Xeon Phi platform and big.LITTLE mobile octa-core platform. The section explains how the existing model [1] has been established as a generalized platform, where it can be used as a Xeon–Xeon Phi cluster in the cloud and IoT infrastructure as well as big.LITTLE mobile octa-core model in smart devices and embedded system domain. Section 4 summarizes our contribution.

2 Literature Review of Commercially Available Heterogeneous Multicore Systems and Related Works

Several heterogeneous multicore systems are available commercially in the market, namely, Intel Xeon processor–Intel Xeon Phi coprocessor multicore system platform, mobile octa-core processor, GPU multicore processor, etc. They are designed to be operated at specific types of application areas. Some of them are best suited for high-performance areas, some of them are best suited for graphics and image processing areas, and some of them are best suited for providing energy efficiency.

However, we study two heterogeneous multicore architectures, namely, (A) Intel Xeon processor–Intel Xeon Phi coprocessor platform and (B) Mobile octa-core processor due to the demand in current market scenarios as explained in Sect. 1. The architectures of both the systems are described below.

2.1 Intel Xeon Processor–Intel Xeon Phi Coprocessor Platform

In recent development of computer architecture, multicore is inclined toward many-core in high-performance computing applications and Intel Many Integrated Core (MIC) coprocessor which is known as Xeon Phi coprocessor is rising as single-chip many-core processor for high-performance computation [2]. The scaling capability of Intel Xeon processor-based system is increased with the association of Intel Xeon Phi coprocessor which offers additional power efficient scaling, vector support, memory bandwidth and maintains programmability and support associated with Intel Xeon processor [3]. Hence, Intel Xeon and Xeon Phi are generally integrated into a single platform and generally used for highly parallel applications which reach the scaling limits on Intel Xeon processors. A typical block diagram of the platform as per work [3] is shown as Fig. 1.

As per the existing work [3, 4, 5, 6, 7] the following architecture of the platform consisting of Intel Xeon and Intel Xeon Phi may be summarized:

- A platform cannot have only coprocessors.
- A typical platform consist of (i) 1–2 Intel Xeon processors (with a certain numbers of cores) with high frequency for the execution of highly serial tasks and (ii) 1–8 Intel Xeon Phi coprocessors per host with low frequency for execution of highly parallel tasks.
- Each coprocessor has around 60 cores (4 hardware thread on each core).
- All the cores composed of two levels of caches (L1 and L2).
- The Xeon Phi is attached with a host CPU through Peripheral Component Interconnect (PCI) express just like a Graphics Processing Unit (GPU).
- Both the Intel Xeon processor and Intel Xeon Phi coprocessor can be utilized by the specific application to achieve a higher degree of performance and parallelization. However, Xeon Phi coprocessor and Xeon CPU are different in performance characteristics with each other. The coprocessor may contribute

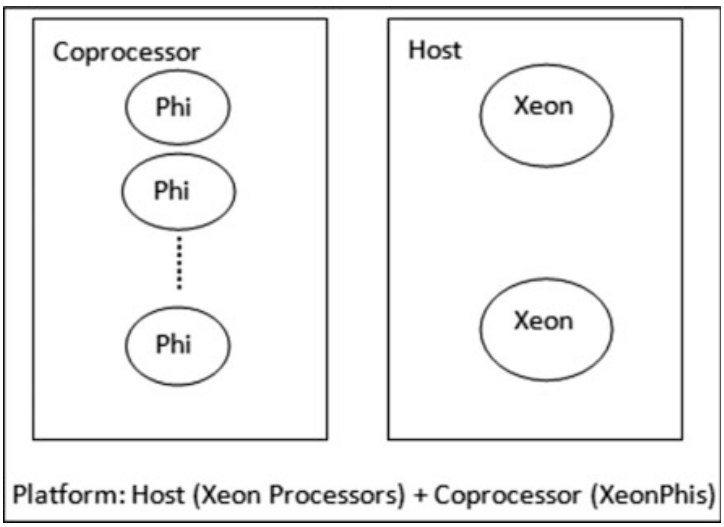

Fig. 1 A block diagram of platform consisting of Intel Xeon processor and Intel Xeon Phi coprocessor

considerably higher performance than the host processor for some applications, while the performance may be low for other applications.

- Preparing Intel Xeon Phi coprocessors should be done such a way that at first the performance of the Xeon Processor can be utilized fully for a given application. Additionally scaling of an application is very important to get the high performance and the application has to scale more than one hundred threads to achieve high parallelism.

Many research works are proposed to exploit the architecture of Xeon Phi to fit several applications. In paper [8], the authors presented new parallelization techniques that were used to search the biological sequence database in Xeon Phi-based architecture. The authors in paper [9] proposed a technique to enable the capabilities of Intel Xeon Phi for a virtual machine. In paper [10], the authors executed a well-known genomic aligner Burrows-Wheeler Aligner (BWA) in a heterogeneous system consisting of Xeon multicore processor and Xeon Phi manycore accelerator. More research work considering data analysis, performance, load balancing can be found in [11, 12, 13, 14].

From the above architecture on Intel Xeon–Xeon Phi system and all the existing research works based on the system, it may be concluded that Intel Xeon–Xeon Phi system is a good candidate to be used in cloud and IoT infrastructure besides other application domains for providing a high degree of parallelism and performance.

2.2 Mobile Octa-Core Processor

The functions of traditional desktop applications are steadily being taken over by mobile devices [15], and the end user uses it more closely than the Personal Computer (PC). Mobile devices have limited battery power and therefore, the thermal issue is more critical in mobile devices than the PC. More power is not required for a majority of tasks such as navigating through home screens, checking texts, and browsing the Web. However, power requirements become higher for tasks like HD video and gaming. Octa-core concept extends the battery life of modern handsets without compromising performance. Octa-core represents two separate operating setups of quad core integrated together on a single-chip for better energy efficiency. As per the work [16], it may be opinioned that ARM's big. LITTLE architecture is the basis of all octa-core mobile chips. As explained in the work [17], the architecture enables four (4) low-power Cortex-A7 cores (LITTLE cores) to operate with four (4) high-performance Cortex-A15 cores (big cores) and a simple block diagram as explained in the work [17] is shown as Fig. 2.

As per existing work [18, 19, 20] the following big.LITTLE architecture of ARM (mobile octa-core architecture) may be summarized:

- big.LITTLE octa-core architecture had been introduced to enhance the power optimization and performance simultaneously. big.LITTLE architecture consists

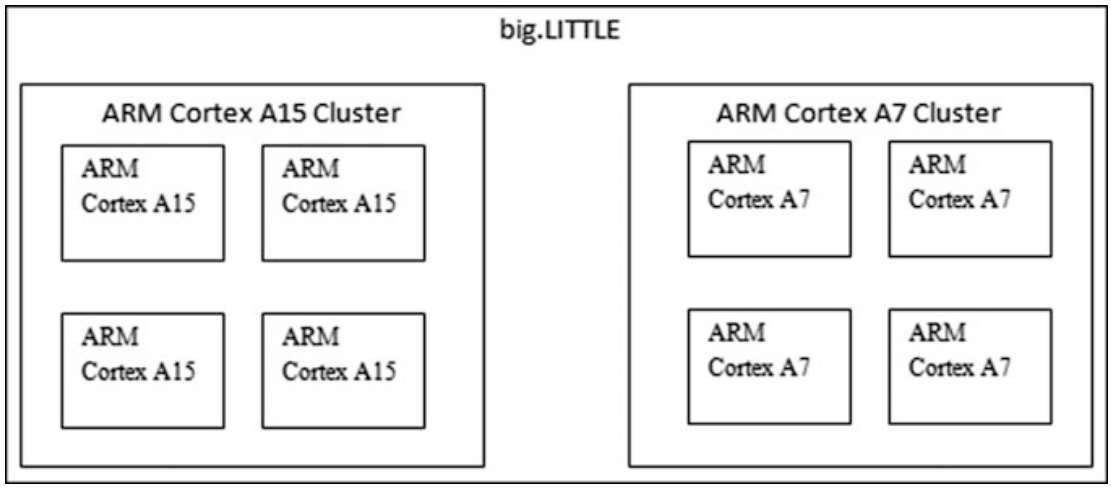

Fig. 2 Block diagram of big.LITTLE octa-core architecture of ARM

of performance-driven big core (but consumes more power) and power efficiency-driven LITTLE core (but delivers lower performance).

- Octa-core chips function as dual quad cores where tasks are balanced between them according to type. The low powered little set of cores is employed mostly while the faster big set of cores are used for advanced tasks. Different tasks have different performance and power requirements, and hence the tasks are required to be allocated to the correct processor according to their requirement.
- There are two major task scheduling techniques in big.LITTLE models as per below:

  (1) ***CPU Migration***: Here, each LITTLE core is paired with a big core and at any point of time, any single core in each pair is operational. The inactive core is powered off.

  (2) ***Global Task Scheduling***: The global scheduler is aware of the different capacities of big and LITTLE cores. The global scheduler keeps track of the performance requirement for each individual thread and decides which type of processor to utilize for each thread. Unused processors can be powered down. Global task scheduler is a flexible and popular model for all future development.

- Figure 3 shows power and performance and operating points of big (Cortex-A15) and LITTLE (Cortex-A7) processors [21]. As shown in *Fig.* 3, LITTLE core is more power efficiency than big core but performance is restricted than big core. Big core, on the other hand, provides high performance but with high power consumption. Altogether, big.LITTLE architecture in mobile environment can satisfy these two contradictory requirements—high performance with long battery life.

Many research works are found in the literature to use the big.LITTLE architecture in different applications. Paper [22] addressed the usage of low-power heterogeneous multicore such as ARM big.LITTLE architecture as micro servers

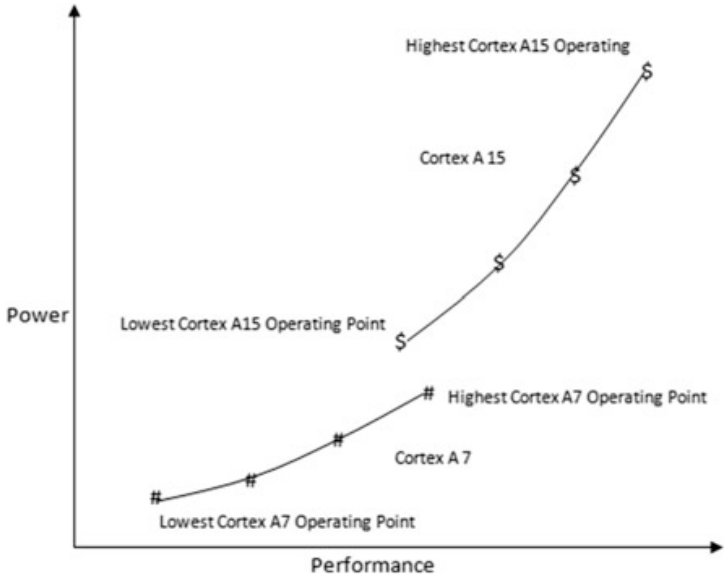

Fig. 3 Power and performance curve of ARM's big.LITTLE (Cortex-A15. Cortex-A7) architecture (from [21])

which were used as a web search application. The authors in [23] introduced hipster which is a method to merge heuristic and reinforcement learning to deal with latency critical workload using the ARM big.LITTLE architecture. More research work on big.LITTLE architecture considering the parameters of energy and performance can be found in [24, 25].

From the above architecture on octa-core system (big.LITTLE architecture) and all the existing research works based on the system, it may be concluded that octa-core system is a good candidate to be used in smart devices and embedded systems domain for providing greater energy efficiency with low resources.

From all the existing work on Xeon Phi as well as big.LITTLE octa-core architectures, it can be concluded that in near future there is a need to have a generalized heterogeneous multicore platform for execution of different applications in Xeon–Xeon Phi platform in the cloud and IoT infrastructure besides other application domains as well as mobile big.LITTLE octa-core architecture in the smart devices and embedded systems domain.

3 Applicability of Existing Work of Heterogeneous Multicore Real-Time Task Scheduling into Commercially Available Heterogeneous Multicore System

The objective of our work is to analyze the existing heterogeneous multicore scheduling model [1] and to establish the model as a generalized platform where it can be used as a Xeon–Xeon Phi cluster as well as big.LITTLE mobile octa-core model. The heterogeneous architecture of work [1] illustrated a dynamic real-time task scheduling model and the model as depicted in the work is shown as Fig. 4.

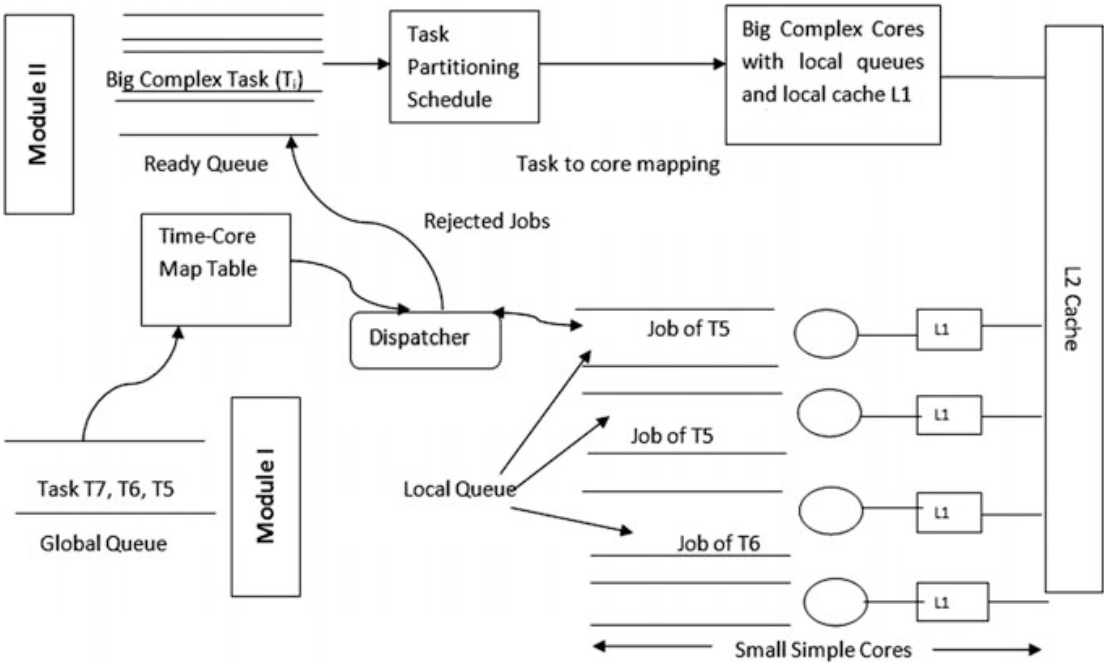

Fig. 4 Heterogeneous multicore real-time task scheduling model with different types of cores (from [1])

The heterogeneous architecture as explained in the work [1] may be summarized as per below:

- The architecture has two modules (module-I and module-II) along with a dispatcher to dispatch the matching or/and rejected job to/from particular core.
- The module-I is composed of low power small cores that are designed for the execution of low-power tasks to provide higher parallel system performance. The module-I is functional within a low-power range P (*where* $0 < P \leq P_l$ *and* P_l = *maximum power to activate the small cores*). The module has a global queue, where calculations of pseudo-release times of jobs (instances of low-power tasks) are completed and the time-core map table is searched with the calculated pseudo-release times. Consequently, run-time dispatcher forward the matching jobs to local queues of the corresponding cores. Subsequently, the jobs are assigned to cores from local queues meeting the deadline.
- The module-II is composed of high-power complex big cores that are incorporated for the execution of high-power tasks to provide higher serial system performance. The module-II is functional above a high power P (*where* $P_l < P \leq P_m$ *and* P_m = *maximum power to activate the cores*). The task instances (or jobs) of a big high-power task are stored in ready queue of particular big core. The rejected jobs from module-I are also accumulated in ready queues of module-II. Next task partitioning scheduling is used to forward all the task instances (or jobs) from ready queue to local queue and consequently into the corresponding big core.

- The model has C number of cores altogether, where $C = C_s + C_b$ (C_s = *Number of small cores;* C_b = *Number of big cores*). All the cores (small and big) consist of two levels of caches—L1 (own first level) and L2 (shared by all the cores). The work explained that low/high-power tasks are allocated to their corresponding small/big cores efficiently as per the requirements of serial and parallel performance.

We introduce an approach to apply this model [1] as Intel Xeon–XeonPhi cluster and mobile octa-core processors (big.LITTLE).

3.1 Applicability as Intel Xeon–Xeon Phi Multicore Platform

The high power big cores in module-II of work [1] are designed for highly serial tasks and can be treated Intel Xeon processors as the architecture of these cores are exactly similar to that of Xeon processors. The number of big cores of work [1] may be taken as n, i.e., $C_b = n$, *where* $n = i*j$; i = number of cores per Intel Xeon processor and j = number of Intel Xeon processor ($j \leq 2$).

Similarly, the low power small cores in module-I of work [1] are designed for highly parallel tasks and can be treated as Xeon Phi coprocessors as the architecture of these cores are exactly similar to that of Xeon Phi coprocessors. The number of small cores of work [1] may be taken as m, i.e., $C_s = m$, *where* $m = 60*k$; k = number of coprocessors ($k \leq 8$) and number of cores per Intel Xeon Phi coprocessor = 60.

Complete architecture of the model can act as a platform consisting of Intel Xeon processor and Intel Xeon Phi coprocessor that can be used in cloud and IoT infrastructure besides other application domains.

In the work [1] it has been shown that the task allocation percentage of the model is approximately near to 100% at a fixed time period. The model further shows that the CPU utilization% is very high (between 95 and 100%) when the number of cores is beyond four (4). Further, we compared the average utilization% of the model [1] with the average performance in terms of utilization of existing work [3] related to Xeon and Xeon Phi cluster. For the comparison, we considered average system utilization% with respect to a different number of cores which we get by varying the number of cores of the model [1] and by varying the number of threads and subsequently calculating the number of cores of the work [3]. The number of cores for the work [3] has been calculated from the assumption that each Xeon Phi core has been assigned four numbers of threads and each Xeon core has been assigned two numbers of threads as explained in the work [3].

We plotted the comparison result as shown in Fig. 5. From Fig. 5, we found that performance in terms of utilization for Xeon processor reached maximum (nearly 100%) when the number of cores was beyond eight (8) and for Xeon phi coprocessor utilization% reached high when the number of cores was beyond thirty-two

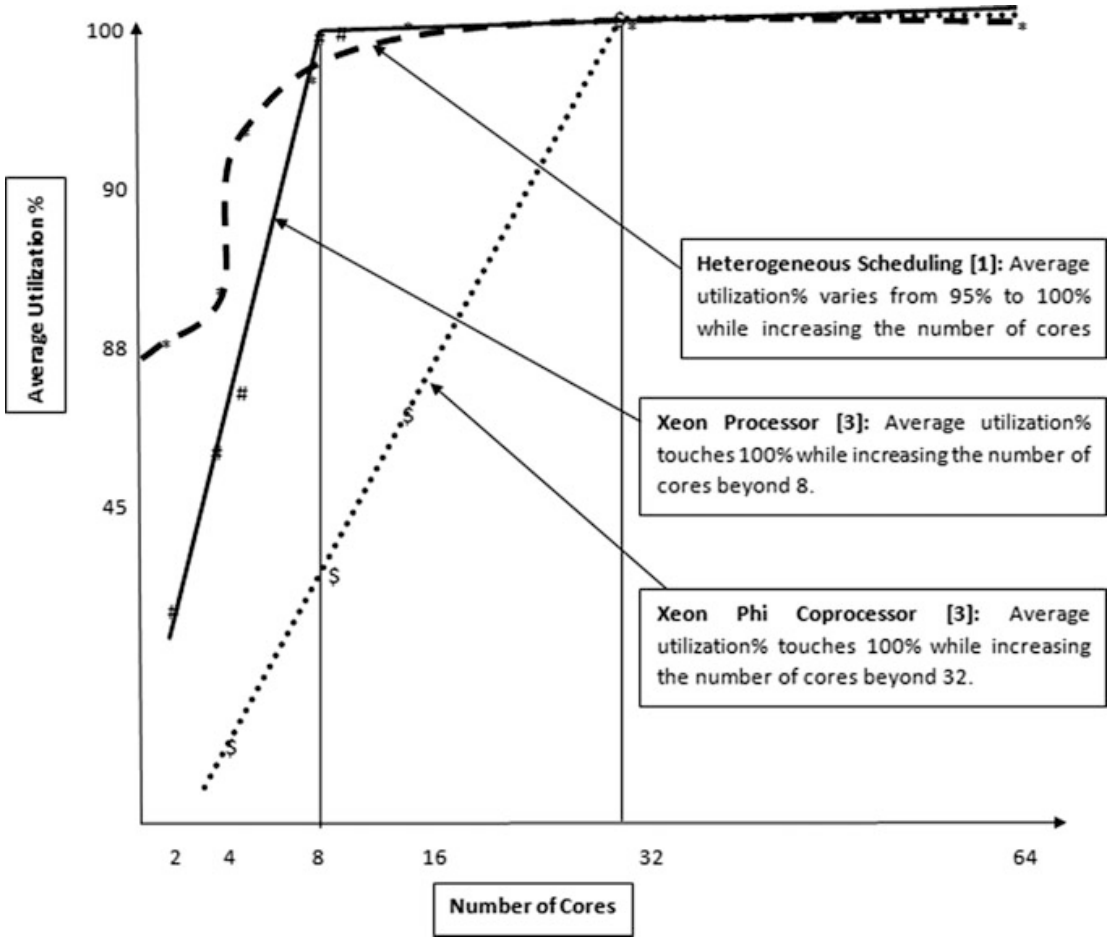

Fig. 5 Comparison of average system utilization: performance in terms of utilization for Xeon processor reached maximum (100%) when the number of cores was beyond eight and for Xeon phi coprocessor utilization% reached high when the number of cores was beyond 32. In the work [1], the average system utilization varied from 95% to 100% while increasing the number of cores beyond four. Hence, we can say that the model [1] can exactly fit into the system consisting of Intel Xeon processor and Intel Xeon Phi coprocessor

(32). Also, we found in the work [1], that the average system utilization varied from 95% to 100% while increasing the number of cores beyond four (4) only. Hence, we can say that the model [1] can exactly fit into the system consisting of Intel Xeon processor and Intel Xeon Phi coprocessor.

3.2 Applicability as Mobile Octa-Core Processor

The work of [1] exactly follows the architecture of ARM's big.LITTLE mobile octa-core architecture where each type of core is operational between certain power levels to optimize power and performance as explained in Fig. 3. The number of big cores (module-II) as well as small cores (module-I) of work [1] may be taken as four,

i.e., $C_s = C_b = 4$, so that the complete architecture of the model becomes the mobile octa-core processors that can be used in smart devices and embedded systems.

The work [1] followed the global task scheduling model of ARM's big.LITTLE architecture where a particular type of task including rejected task (small or big) was allocated to a particular type of core (small or big) through dispatcher maintaining constraints as explained previously.

The work [1] demonstrated that tasks of different types are allocated to cores of different types efficiently for optimization of power and performance maintaining very high task allocation percentage (100%) and CPU utilization percentage (varied from 95 to 100%). Further, we compared the job allocation% of the model [1] with the throughput in terms of job allocation% of existing work [26] related to mobile octa-core architecture (big.LITTLE). For comparison, we considered job allocation % with a fixed time period which we get by illustrating the variation in a number of jobs getting accommodated at a fixed time period.

We plotted the comparison result as shown in Fig. 6. From Fig. 6, we found that both the model accommodated 100% of the random task instances within a fixed time period. Hence, existing heterogeneous real-time task scheduling architecture [1] may be used as mobile octa-core architecture (big.LITTLE).

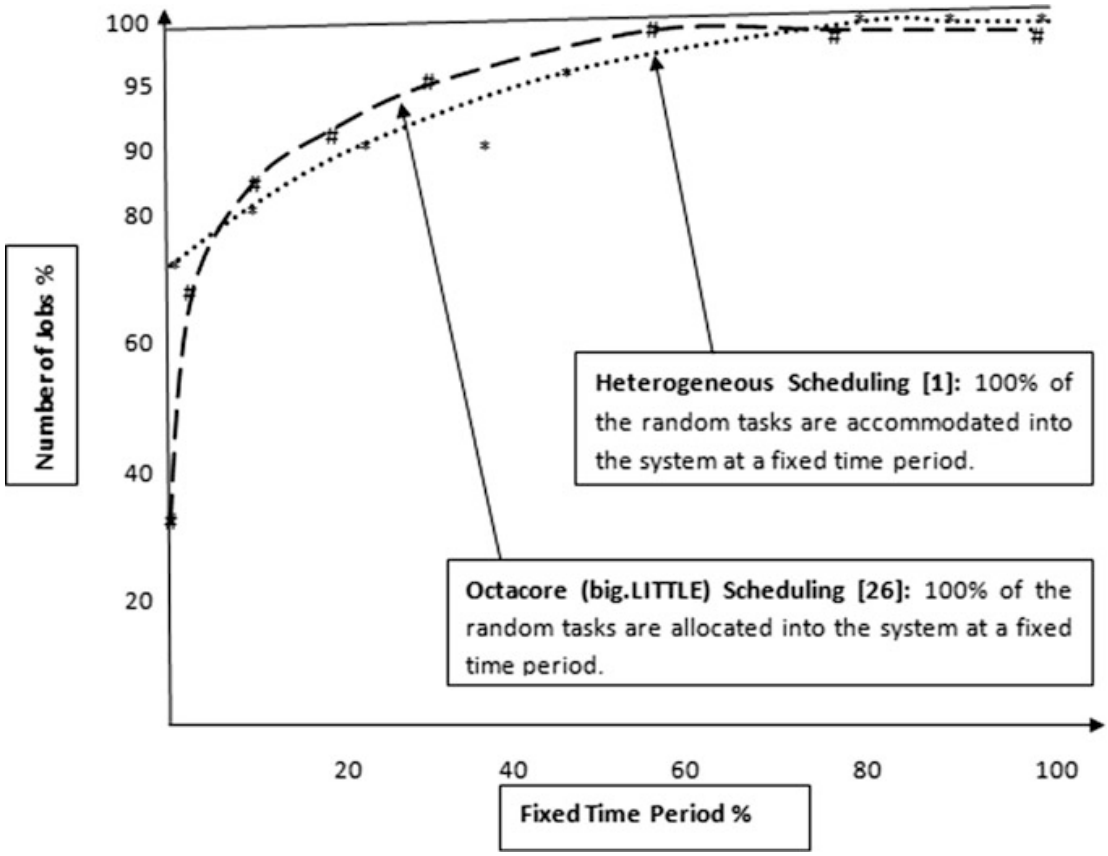

Fig. 6 Comparison of job allocation percentage between existing work [1] and mobile octa-core processor (big.LITTLE). The existing work explained that 100% of the random tasks are accommodated into the system at a fixed time period. As per work [26] 100% jobs are allocated in the ARM architecture of mobile octa-core

Therefore, from the above analysis considering the architectures of Xeon–Xeon Phi and big.LITTLE we can conclude that the existing heterogeneous multicore scheduling model [1] can be used as Intel Xeon–Xeon Phi platform in the cloud and IoT infrastructure besides other application domains as well as big.LITTLE mobile octa-core architecture in smart devices and embedded system domain maintaining the same power-performance benefit and parallelism.

4 Conclusion

This paper studies different parameters of commercially available heterogeneous multicore systems, namely, Intel Xeon–Xeon Phi cluster and mobile octa-core architecture. It also studies the scheduling algorithm for real-time tasks in existing heterogeneous multicore scheduling model [1]. It further finds out an approach or method to establish the existing heterogeneous system model [1] as a generic platform so that the generic model can be used as Intel Xeon–Xeon Phi processors and mobile octa-core processors as per requirements maintaining the same performance and parallelism.

The comparison results considering different parameters of existing model with Intel Xeon–Xeon Phi cluster and mobile octa-core architecture reveal that the existing model [1] can be applied as both the commercially available heterogeneous systems (Intel Xeon–Xeon Phi platform and mobile octa-core processors) for the use in cloud, IoT, smart devices, embedded systems, and other common application areas efficiently. Significant issues like resource sharing, energy enhancement, and dependency parameters will be incorporated in the existing model [1] to apply it as a more generic model.

Analyzing the Detectability of Harmful Postures for Patient with Hip Prosthesis Based on a Single Accelerometer in Mobile Phone

Kitti Naonueng, Opas Chutatape and Rong Phoophuangpairoj

Abstract This research studies the use of a single accelerometer inside a smartphone as a sensor to detect those postures that may be risks for patients with hip surgery to dislocate their joints. Various postures were analyzed using Euclidean distances to determine the feasibility to detect eight postures that were harmful. With the mobile phone attached to the affected upper leg, it was found that there was one harmful posture that could not be detected due to its close similarity with a normal posture. Meanwhile, the other two harmful postures, although indistinguishable based on their measured data, were still detectable with the suitably selected threshold. The distance measure analysis is useful as an indicator as to which posture will be near to missing out in the detection process. This will form a guideline for further design of a practical and more robust detecting system.

Keywords Accelerometer · Euclidean distance · Hip prosthesis dislocation · Smartphone

1 Introduction

In a total hip replacement, there are basically four components that are used to replace the hip joint of the affected patient as shown in Fig. 1(left). The components are merged into an implant (center) that fits into the hip (right). With a sufficient

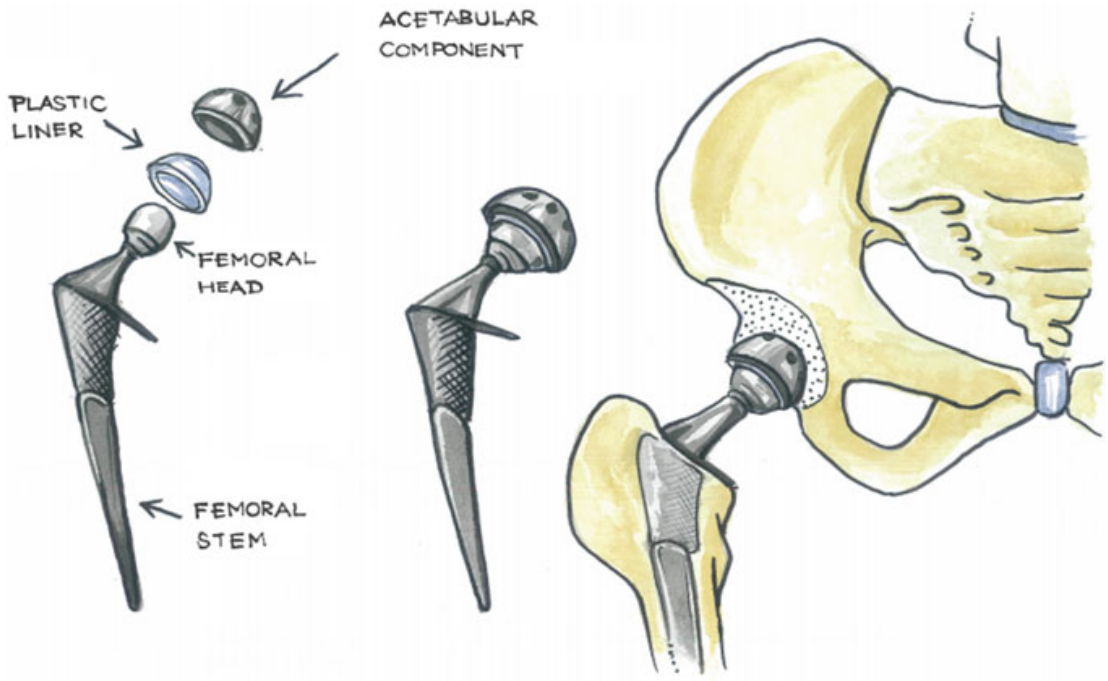

Fig. 1 Prosthetic components in total hip replacement

force from an inappropriate exercise or a repetitively unsuitable movement of the affected leg, the assembled joint can be dislocated.

For a patient who has undergone a hip replacement operation, during the recovery period which may last for a few months various postures and movements that are considered normal to ordinary people may be harmful to the person. These potentially harmful postures should be avoided to prevent possible dislocation of the joint that may lead to further complication and even require another surgery. Some of these forbidden postures or movements [1] are

- Cross the legs at the knees (during sitting, standing, or sleeping).
- Bring the knee up higher than the hip.
- Lean forward while sitting or as sitting down.
- Try to pick up something on the floor while sitting.
- Turn feet excessively inward or outward when bending down.
- Reach down to pull up blankets when lying in bed.
- Bend at the waist beyond 90°.

After being discharged from the hospital the person will need some help to get along with daily life at home. During this period a device that can help the person to stay more independently and safely will be most beneficial, and one such device, in this case, should be able to detect and give a warning against harmful movements or any postures that may cause a risk to the operated leg. Considering that the smartphone has already become an essential device for almost everybody's daily life and many applications are readily being built around its user-friendliness and myriad communication features, the next logical choice is to explore the

feasibility to incorporate these healthcare needs to it. Among various sensors embedded inside most smartphones are the most often used accelerometer in the form of a MEMS (Micro Electro Mechanical System) chip. The accelerometer is the sensor that is associated with the movement detection and therefore has applications in various core research areas such as gait analysis [2] human activity recognition [3–10], healthcare and fitness [11–17].

In this paper, the aim is to present the systematic approach to the collection of data and detection of improper postures based on a single accelerometer embedded in the smartphone, then to give the typical coordinate values of these harmful postures and of the relative distances that indicate the degree of detectability among themselves. This will simplify the remaining task of identifying the unrecommended postures and those that require further data collection to correctly identify them.

2 Related Work

Two major approaches have been used to detect and measure patterns of human motion in the three major research areas previously mentioned. One approach is based on the image processing techniques whereby video cameras were used to record 3D sequence of photographs of individual locomotion, which were then analyzed. Although the system is commercially available, highly accurate, and successfully implemented in a controlled environment, it is not publicly used and taken into everyday activities. Few main reasons are the relatively higher cost, the complexity of the procedures involved in the set-up, and the confinement to the controlled area to ensure proper operation. In another different approach, using accelerometers as movement and orientation sensors is more often the choice by most researchers. In recent research activities in the healthcare area, some new relevant initiatives have emerged. These are leg movement and hold detection for knee extension exercise [14], hip dislocation study [15], and upper arm posture and movement measurements [16]. According to the last report [16], an iPhone application was developed and validated against an optical tracking system (OTS). The small difference in comparison with the OTS indicated that the application which was based on sensors in a smartphone is a valid method. In another study, the method used to develop an Android-based mobile application which activated an alert signal and provided feedback in real time on the effectiveness of knee extension exercises was presented in [17]. Based on these reports it confirms that adopting a smartphone as a posture detecting device can give acceptable, valid and obviously more cost-effective results.

With a particular interest in the healthcare of the elderly, recent work on the detection of harmful postures leading to possible dislocation of the hip prosthesis was studied by using 3-axis accelerometer sensor present in any smartphone [15]. As far as the authors' knowledge, it was the first initiative to use a smartphone for the purpose of detecting (and further warning) the risky posture for hip-operated

patients. It was reported there that out of 14 postures understudy, there were three harmful postures that could not be classified correctly by using simply one smartphone. To give an insight into the details of these postures, this paper presents further study and report on the new analysis of the problem that could offer a better implementation.

3 Materials and Method

3.1 Instruments

The Android-based Sensor Fusion software set developed by Linköpins Universitet from Google Play Store was installed into Samsung Galaxy S6 smartphone and the application was used to record the sensor data. The smartphone was put into an extended armband and fastened to the thigh in the position as shown in Fig. 2.

For each typical posture selected as a reference, the 3-axis values of the accelerometer are recorded by the software. The deviation from this reference is measured using the Euclidean distance. To perform the detection analysis the application software was set to stream the data through the local area network to the program written in Microsoft Visual C# as shown in Fig. 3. This method is efficient and the data can be obtained in real time.

3.2 Proposed Method

For a smartphone testing, instead of using a traditional method that researchers have to develop an Android program, install and test it on a smartphone, this work used the publicly available software to read and send the sensor data and the PC-based program to study them. Changing a PC-based detection program is usually easier than changing the mobile program. It does not need to repeatedly load the written program to a smartphone installation and execution. Using this method an Android

Fig. 2 Position of the smartphone on the thigh

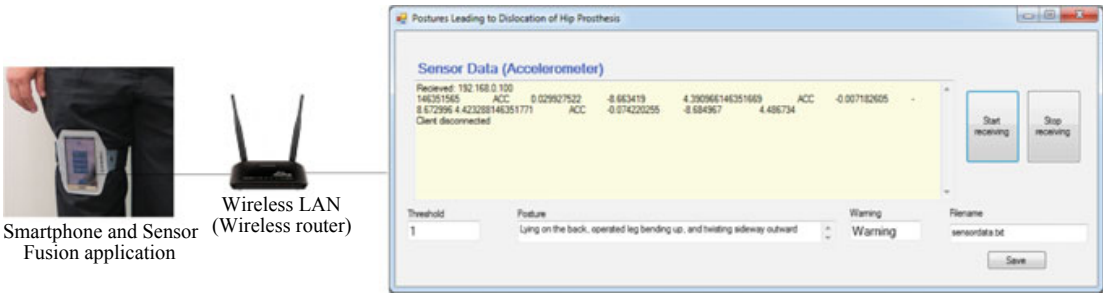

Fig. 3 Data collection of the test method

application to detect harmful postures can be developed after obtaining the desired test results.

The whole set-up worked as follows:

(1) Receive the accelerometer data from the installed application using the TCP socket communication.
(2) Extract the accelerometer *x*, *y,* and *z* values from the streaming data. Since the accelerometer values were received after the keyword "ACC", the program checked the keyword and then captured the string values of *x*, *y,* and *z*, respectively.
(3) Convert the string representation of the *x*, *y,* and *z* numbers to their equivalent real numbers.
(4) Compute the Euclidean distance between the receiving *x*, *y,* and *z* values and the selected values of each harmful posture.
(5) Detect harmful postures based on the Euclidean distance and a predefined threshold.

Steps 4–5 can be explained in details as follows:
Given that
P is the set of all detecting postures represented by

$$P = p_1, p_2, \ldots, p_i \quad 1 \leq i \leq N \tag{1}$$

N = the number of detecting postures,

p_i is selected accelerometer *x*, *y*, and *z* (reference) values for the *i*th posture represented by

$$p_i = (\mathrm{Ref}x_i, \mathrm{Ref}y_i, \mathrm{Ref}z_i), \quad 1 \leq i \leq N \tag{2}$$

O is an observation sequence (a sequence of accelerometer data) consisting of observations (o_t) at time 1 to time *T*.

$$O = (o_1\ o_2\ o_3 \ldots o_T) \tag{3}$$

$$o_t = (x_t, y_t, z_t) \quad 1 \leq t \leq T \tag{4}$$

(x_t, y_t, z_t) are accelerometer x, y, and z values occurring at time t. The Euclidean distance between two accelerometer data p_i and o_t is given by dist(p_i, o_t). The method to detect postures (DP*) at time t is described using the following equations:

$$\mathrm{DP}^* = \arg \min_{p_i \in P} \mathrm{dist}(p_i, o_t) \tag{5}$$

and

$$\mathrm{dist}(p_{\mathrm{DP}^*}, o_t) \leq \sigma \tag{6}$$

σ is a predefined detection threshold obtained from the experiments (e.g., 1).

By following the steps as indicated, manual intervention can be kept to a minimum and various results can be obtained for further analysis by using existing mathematical software packages.

4 Results

4.1 Standing, Walking, and Sitting

Figure 4 shows the accelerometer data x, y, z in the four scenarios, i.e., (1) straight standing, (2) walking, (3) sitting on a chair, and (4) sitting on a chair and slightly move the thigh up and down.

4.2 Reaching Down to Collect Object on the Floor or to Tie Shoestrings

Figure 5 shows the accelerometer data x, y, z when (1) sitting and bending up the leg to tie shoestrings, (2) sitting and stooping to collect an object on the floor or to tie shoestrings, and (3) stooping to collect object on the floor or to tie shoestrings with leg bending.

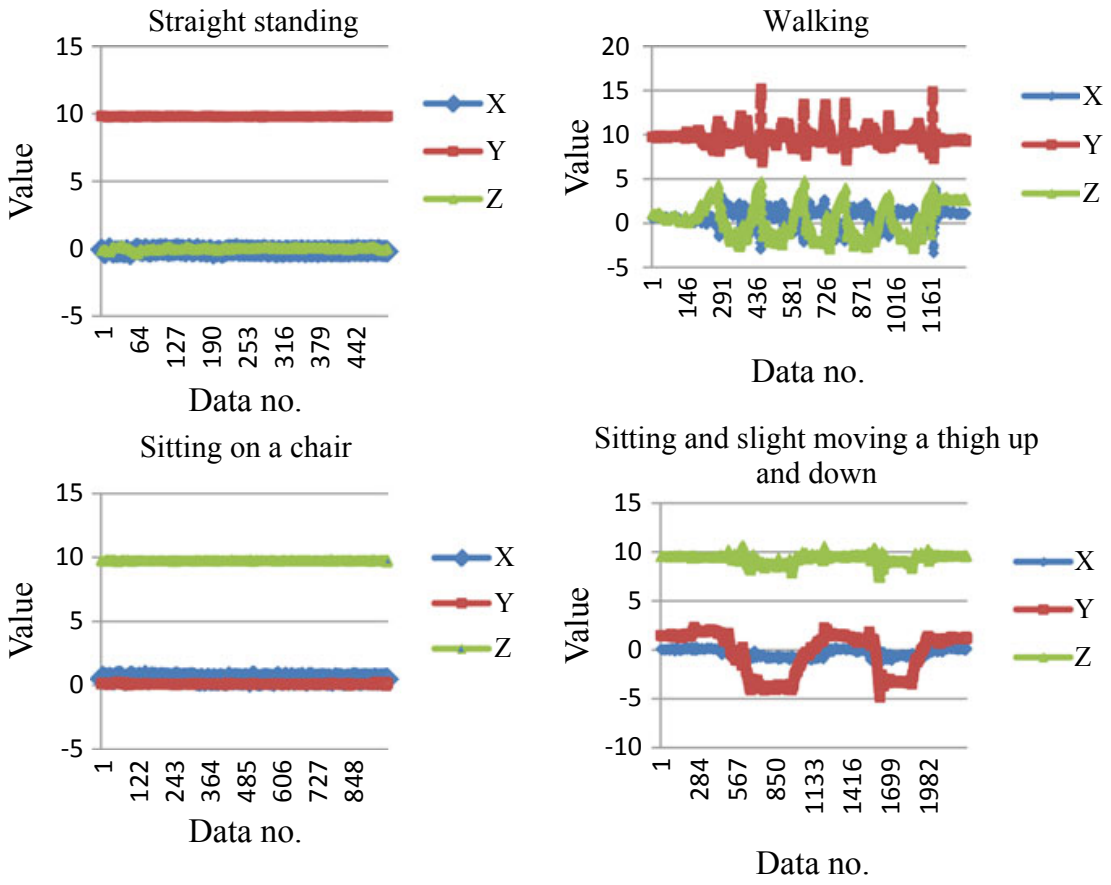

Fig. 4 Straight standing, walking, and sitting (with possibly a slight up-down thigh movement)

4.3 Lying on the Back

Figure 6 shows the accelerometer data *x*, *y*, *z* when (1) lying on the back, (2) lying on the back with the operated leg bent up and twisted sideways inward, and (3) lying on the back with the operated leg bent up and twisted sideways outward.

4.4 Twisting the Operated Leg Inward and Outward While Standing

Figure 7 shows the accelerometer data *x*, *y*, *z* when twisting an operated leg inward while standing, and outward while standing.

The next Fig. 8 shows the accelerometer data *x*, *y*, *z* when getting on a motorcycle.

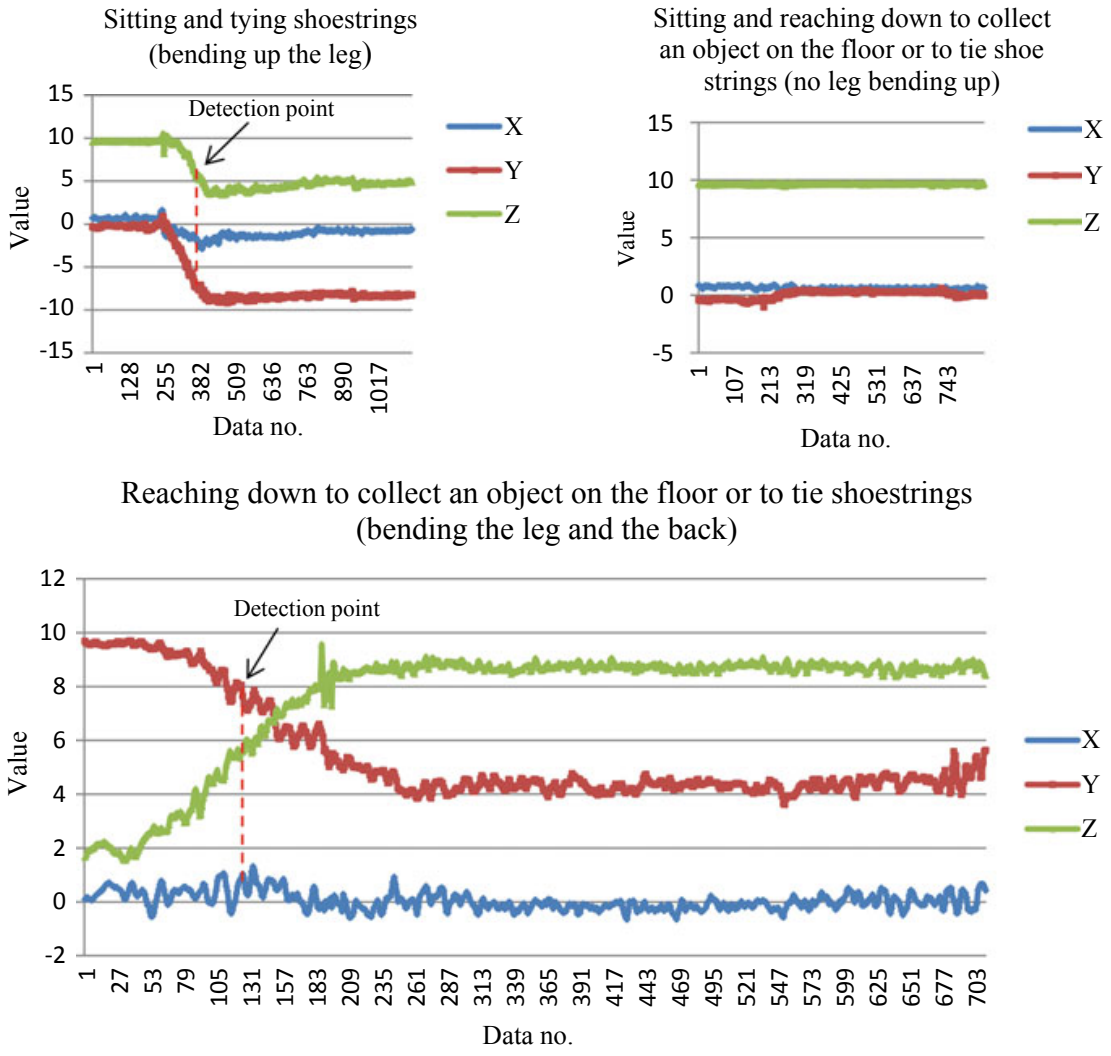

Fig. 5 Reaching down to collect object on the floor or to tie shoestrings

4.5 Accelerometer Outputs at Various Postures

The *x*–*y*–*z* values of the smartphone accelerometer at various different postures are shown in Table 1. In the last column, each posture is assigned either risk factor 0 (no risk), or 1 (with risk).

Euclidean distances between centroids are used to represent the relative differences among various postures as given in details in Table 2. Posture 2 (walking) and posture 3 (sitting) are two postures that have more different readings recorded. Notice that postures 1–4 are classified as "no risk" and postures 5–12 are classified as "at risk".

By setting the threshold of the Euclidean distance at unity, it was seen that most postures, particularly those considered being harmful, could be separated. These are cells with corresponding distance values more than one and displayed as empty cells as shown in Table 3. On the other hand, posture 5 and 8 could not be

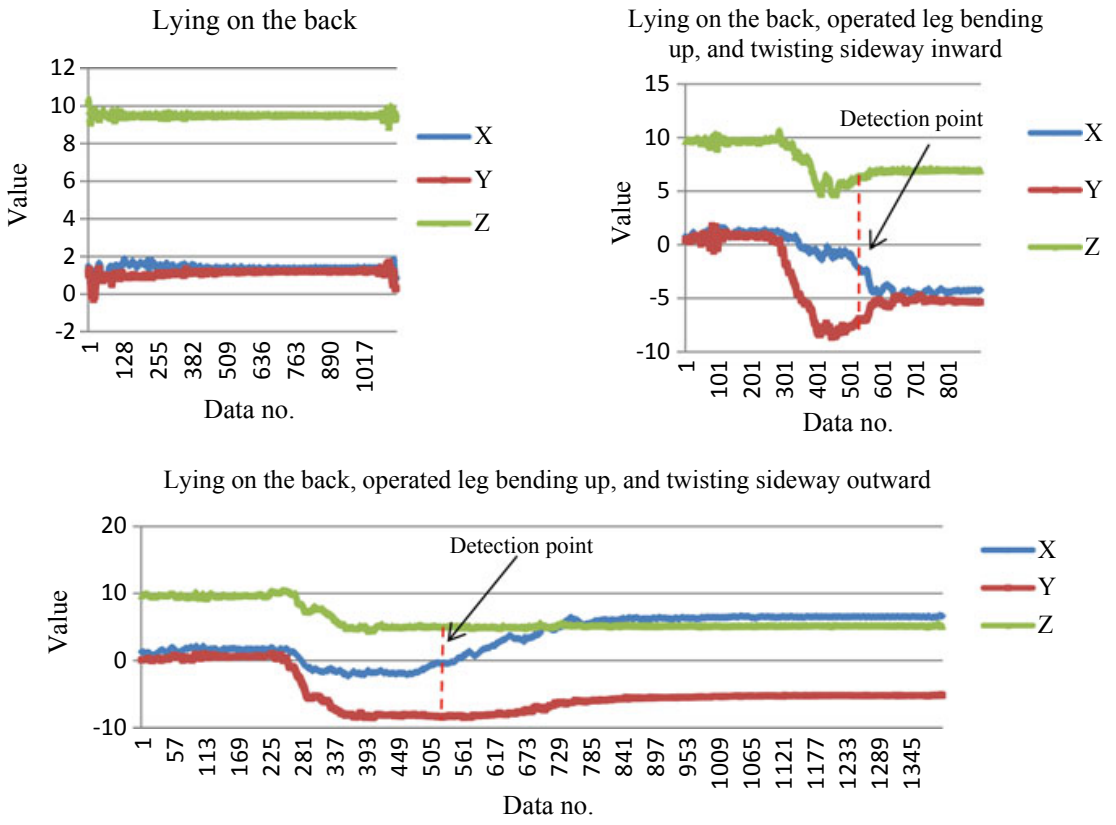

Fig. 6 Lying on the back posture

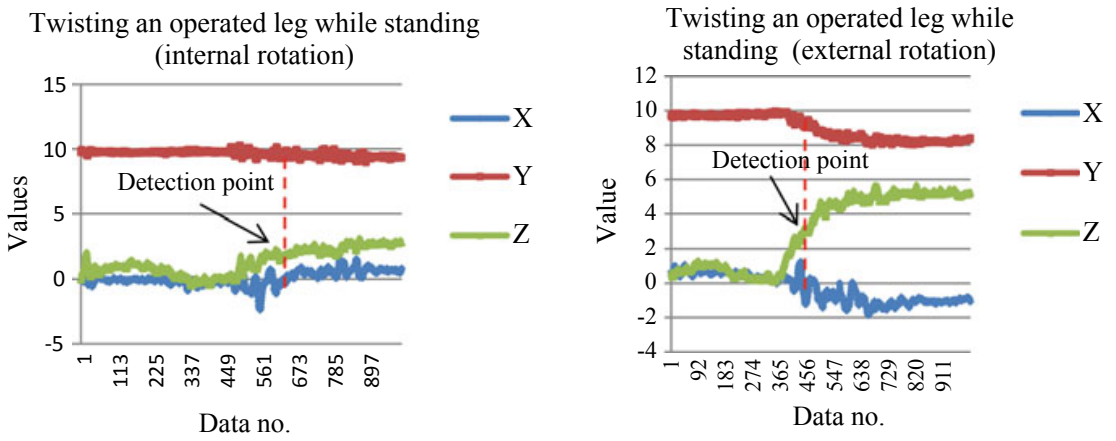

Fig. 7 Twisting an operated leg while standing (internal and external rotation)

distinguished from each other but they could be detected as harmful and give an alert signal since both were sufficiently at a far distance from the others. Posture 6 could not be recognized correctly because it was quite similar to posture 3 as far as the accelerometer values are concern. These cells in the table are labeled with the letter "N" which indicates that the two postures indicated by row and column could

not be distinguished from each other at the given threshold. For a higher threshold, more of such postures that are indistinguishable will surface up.

The Euclidean distance-based algorithm to identify harmful posture may be initiated by periodically reading the 3-axis accelerometer outputs from the mobile phone, then calculate the Euclidean distance between the sample posture and the known, selected values of the harmful postures in the database. If the distance is less than a chosen threshold value, then the sample posture is likely to close to the harmful one and the warning signal should be given.

There however remain certain postures that cannot be identified as normal or harmful, and these require further data from additional sensors to be attached at the other major parts of the body. One possibility is to attach a second sensor on the chest. This will give the information about the movement of the upper part of the body which can differentiate posture 5 from 8, and posture 6 from 3. Nevertheless, considering that each individual may not move exactly in the same pattern with the same range of movement for the same posture, and the position of the attached sensor can vary, the threshold value is an individual-dependent parameter that will require custom adjustment.

5 Conclusion

The analysis on the detectability of various harmful postures for hip-operated patient based on the use of a single accelerometer in the smartphone has been presented. This is the first initiative and a contribution made to the research area in addition to the proposed method for other similar developments. It was found that at the selected threshold, six out of eight harmful postures, including the major ones, could be detected and so the warning signal could be generated by the smartphone. In the future, the method to distinguish posture 3 (sitting) from posture 6 (sitting and reaching down to collect an object on the floor or to tie shoestrings) ought to be developed. This ambiguous posture could be solved by implementing an additional sensor to detect the movement of the upper part of the body. However, adding more sensors on the body is not the favorable option from a user convenience point of view, and therefore using a smartphone alone to detect all or as many of these harmful postures probably through better utilization of sensors and intelligent time series data analysis should be further investigated.

Acknowledgements We would like to thank Dr. Nathee Ruangthong of Ban Mi Hospital, Lop Buri, Thailand, for many of his valuable suggestions. One was that no real patient was required to participate as it might cause injuries and some difficulties. With this recommendation and to follow the ethical guideline for clinical trial, the participant who was a normal person in this trial was fully explained of the procedure and the use of the data collected and was later given a proper form of consent to sign voluntarily.

Software Development Process Evolution in Malaysian Companies

Rehan Akbar, Asif Riaz Khan and Kiran Adnan

Abstract GSD is a phenomenon mainly associated with the outsourcing of software development projects to some offshore company. Reduction in software development cost increased productivity and advantage of multisite development with respect to time are the main benefits that software development companies (SDCs) get from GSD. Besides benefits, a number of challenges associated with GSD are also observed. Consequently, the traditional processes to develop software are evolving and being replaced with a new set of processes which are lightweight and outcome-based. The process evolution has been deeply investigated in the context of companies mostly in Europe, Australia, USA and mainly other countries in those regions. In this regard, limited research has been carried out on Malaysian companies. The present research investigates the process evolution phenomenon in Malaysian companies. The current software development processes and the reasons for the evolution of software processes in Malaysian software companies have been identified. A qualitative approach using structured interviews has been followed for the collection of data collection and its analysis. The findings explain that software processes in most of the Malaysia companies are increasingly evolving or have been evolved. The companies are overwhelmingly adopting agile methods because of their support to GSD. Some of the companies are using ad hoc approaches for software development. The size of the company and project has been found as one of the main factors behind using ad hoc approaches. Mainly the small and medium-size companies and projects are involved in this practice.

1 Introduction

The Global Software Development (GSD) started in the late 1990's by mid-2000's it got an overwhelming response from the software companies [1]. GSD is a form of project outsourcing to offshore companies. GSD is carried out from different locations around the world that involved different teams for the development of software product [2, 3]. The availability of fast internet and latest communication tools are increasing the trend of developing software product from different locations [4]. GSD also developed the connections among different nations having different behaviors, social values, and different culture [5]. GSD helps the software companies to decrease the software development cost. Since, the GSD provides a number of benefits such as less development cost, development from different locations with respect to time, access to a large pool of experienced people and tax incentive [6–9]. Due to the GSD benefits, most of the SDCs have started the GSD to decrease the cost of software development and improve the software quality [10]. Moreover, GSD help to exchange the best expertise among teams [1, 8] and also provide access to skilled resources that would help the SDCs to increase their productivity and efficiency [1, 5, 8, 9]. In addition, the development of software with follow-the-sun (24/7) model also is an added advantage of GSD [8, 11].

Despite having advantages, a number of challenges are also associated with GSD [2, 5, 7, 12–16]. The main challenges being faced in GSD are related to communication and collaboration [5, 12, 13, 17–21], poor management [13, 22], project diversity and complexity,[12] and delayed response due to time zone difference [7, 12]. Although, the SDCs are using different communication applications like Skype, Instant Message (IM), Google chat, telephones, and emails [23, 24] to reduce these challenges. However, still, problems exist at certain levels and need to be addressed properly. To overcome the GSD challenges, many studies have proposed some strategies to meet the GSD challenges [6, 13, 25–28].

To deal with these challenges and to meet the market competition, software development processes have been evolving since the late 1990s and shifting towards new software development paradigms prominently agile methods [19]. The software project clients want to see the progress of the project on a weekly basis and also require to make necessary changes in requirements and deliverables anytime during the project. Consequently, to meet the client expectations the SDCs started following agile methods, as these approaches define procedures to provide an update to the client on a weekly basis [19, 29, 30]. According to Versionone survey [31] about 80% of the SDCs have been moved to the agile methodologies. The evolution in software development processes in companies operating in the UK, USA Australia, and other western countries have been investigated in different studies. However, limited work has been presented in the context of Malaysian companies. Most of the work presented on software development processes in Malaysian companies are very general and do not provide deep insight into process evolution and process paradigm shift. In the present research work, the aim is to check the trend of current software development processes in Malaysian companies

as a result of GSD. The evolution of software development processes, how the processes got affected and eventually changed in Malaysian companies, and reasons behind. The study also presents the expert views on the change in software development processes. In addition, some discussion on the software development practices in Malaysian companies has been made in the literature review section.

The section two of the paper presents the review of related literature while research methodology is presented in the third section. The results have been discussed in the fourth section and finally, conclusion has been summarized in section five followed by acknowledgment.

2 Related Work

A software process involves a set of procedures, tasks, and activities which are required to build a software [32]. The phenomenon to develop software from different locations is called GSD [19, 33]. Software development at different locations made the conventional software development process more difficult to implement. Consequently, most of the software development projects have been failed and over budget [34, 60, 61]. A number of factors behind the failure of GSD projects are misunderstanding of requirements, absence of face-to-face communication, absence of suitable software process, high coordination costs, lack of experience about distributed development, culture and languages problems, dependent modules in distributed development, and delay in responses due to time zone difference [4, 5, 7, 10, 12, 13, 32, 35, 36]. Numerous studies have suggested solutions and improvement to deal with these challenging factors [2, 6, 13, 25–28, 37–39].

The main purpose of using the software development process is delivering the project on time and within budget [32]. Therefore, software development companies need to follow a suitable software development process that helps to minimize these issues and deliver projects on time. The conventional approaches of software development have been deprecated because of less support to GSD and lightweight methodologies such as agile have appeared as popular practices by software development companies because of their support to frequent communication, short deliverables, and other disciplined practices [13, 18, 19, 26]. It is also observed that the application of agile methods in GSD environments has significantly reduced the failure rate of the projects [18, 26]. The existing studies describe that current software practices have been changed globally but are uncertain about Malaysian SDCs. As per our knowledge, there has not been carried out such study that investigates the current trends of software development in Malaysia as consequences of GSD. The research study presented in this paper accomplishes this research gap. Though a few studies have been conducted on Malaysian companies [40–46] but not in GSD perspective. Also, these studies insufficiently present the reasons behind the selection of the software development process as a result of GSD.

Almomani in a survey [41] investigated the difficulties in recent software processes improvement (SPI) practices in small and medium-size companies (SMEs) operating in Malaysia. The study has some limitations. Firstly, the study has been conducted through a questionnaire with small sample size, secondly, the target respondents are only those companies which are doing in-house development and are not involved in GSD. The study concludes that implementation of SPI is not very common in Malaysian SMEs because of inadequate knowledge, communication issues, and lack of resources. In addition, findings also show that many software development companies in Malaysia are using ad hoc approaches and agile methodologies. In 2005, Baharom [42] conducted a survey on software development practices in Malaysia. The survey has been conducted through a questionnaire and the findings of the survey explain that most of the software development companies are not following any software development process in their development environments. Moreover, software development companies have been facing problems in adopting standards and processes, software quality, over budget, and late delivery related issues.

In another research study [40], a survey using a questionnaire to observe the current practices of developing software in Malaysian companies has been conducted. The statistical analysis of the responses has been made to interpret the results. Findings show that the percentage usage of the methodology for managing the software project is still very low. Likewise, the use of the latest software development practices to develop software has also not been found satisfactory due to which the success rate of the projects is low. Another study conducted on "the adoption of software development methodologies among IT organization in Malaysia" has been found different from the present study in terms of (a) the study has been conducted on overall IT industry, not particularly on the companies involved in GSD, (b) the software development methodologies are defined and presented according to each phase of software development lifecycle (SDLC) such as requirements phase, design phase, development, and testing phase and (c) the focus of the study is too general [44]. Moreover, the results derived from these findings do not particularly list the names of software development processes rather it just generally discussed the software practices (without explicitly listing the software practices) being followed by Malaysian companies. However, it is found that few of the companies have developed their own processes while some of them are not following any software process. Furthermore, the author also proposed a framework with respect to each software development phase but sufficient discussion has not been made rather just discussed generally. The present study covers this gap and adequately investigates the most recent trends of software development practices in Malaysian companies as consequences of GSD and presents reason behind the process evolution.

3 Research Methodology

The research subject in present studies is software development companies operating in Malaysia which are practicing GSD in their software development environment. The qualitative research approach has been selected and data has been collected through structured interviews conducted face-to-face. Structured interviews are conducted to enhance the comparability of data [47]. Open-ended and pre-planned questions have been set for the interviews with the same replication in all the interviews [48]. The medium to conduct a structured interview could be face-to-face or online using the internet or via telephone. The interviews are divided into two sections such as (a) demographic data which is analyzed through statistical analysis and (b) open-ended structured questions which are analyzed qualitatively by using "general inductive approach" [49]. The general inductive approach is quite similar to grounded theory with the only difference is that it does not apply any coding technique for data analysis rather it analyzes the data more straight forward. [49] has discussed the general inductive approach in detail. The data from interviews have been managed and analyzed using qualitative data analysis software NVivo. Although, NVivo provides a platform to organize the qualitative data such as interviews and surveys at one place analysis of the data is totally dependent on the researcher that how he or she derived the result from it [50]. NVivo helps to reduce manual tasks and provide easy to manage, sort, and organize the qualitative data. The main features which NVivo provide are coding, querying text data, and representation of text with multiple charts and graphs in order to understand any particular phenomena. It is difficult to explain all the features of NVivo software, however, numbers of useful links are provided to understand the working of NVivo software in detail [51–57]. In NVivo, coding is performed in the 'Nodes' container. The information related to the particular question, theme or concept is stored under one node. In the present study, the answers of interviewees on current software development practices are stored in one node. It makes it easy to summarize the data and perform comparisons to derive the findings.

To conduct interviews for data collection, initially, 40 software development companies in Malaysia were selected. Only 25 software development companies agreed for the interviews out of which later 10 of companies refused to participate for interviews because of project deadlines and emergency meeting calls during the scheduled time. The privacy policies of the companies have been found as one of the big problems of low response rate as most of the companies also refused due to their company's privacy policy. Therefore, a total of 15 interviews could be conducted. During face-to-face interviews, it is ensured that all the questions have been clearly understood by the respondents in order to get proper answers. In face-to-face interviews, the researcher has the opportunity to clarify the confusion about the questions, if arise any.

Very few questions have been set for the interview. Mainly the questions asked were about the current software development practices in their company along with the follow-up question about reasons. The interviews have been conducted with

expert professionals such as project manager (PM), technical manager (TM), team leads, senior software engineers, senior system analysts, and software developers working in the Malaysian software companies.

4 Results and Discussion

The interviews have been divided into two sections as the first section is about demographic data comprising of name, email, company location, and respondent experience, and the second section is comprised of open-ended questions related to the current software development practices along with follow-up question on reasons to select the current practices.

In the first section, the questions have been asked to know the participants' qualification, experience level, and company profile. As shown in Table 1, 40% of the interviewees are senior software engineers, 33% software engineers, and 20% are project manager/technical manager. Only 7% were system analysts.

Most of the interviewees are quite experienced professionals in the software development industry as shown in Table 2. 20% respondents have experienced between 10 and 15 years while similarly, 20% of the respondents have more than 15 years of experience. 13.3% interviewees have experience of 3–5 years and 5–10 years. However, 33.4% of them have 1–3 year(s) of experience in software development.

As shown in Table 3, the response rate of companies with respect to their location. Kuala Lumpur, Penang, and Selangor are the main states in Malaysia where the big software development companies are operating their business [46, 58]. The majority of the respondents of the present study also belong to companies in Kuala Lumpur, Penang, and Selangor as given in Table 3. The data shows that 40% of the interviewee companies are from Penang, 26.7% from Selangor, and 13.3% companies are from Kuala Lumpur. 20% of the total companies are from Ipoh.

The size of the company has been estimated based on the number of employees (staff strength) in that company. As shown in Table 4, most of the respondents, i.e., overall 90% are from small and medium-sized companies. According to [41, 42, 59],

Table 1 Employee designation

Employee designation	Interviewees	Percentage (%)
Project Manager/Technical Manager	3	20
Project Team Lead	0	0
Senior Software Engineer	6	40
Software Engineer	5	33.3
System Analyst	1	6.7
Total	15	100

Table 2 Experience level in software development

Experience level	Interviewees	Percentage (%)
1–3 year(s)	5	33.4
3–5 years	2	13.3
5–10 years	2	13.3
10–15 years	3	20
More than 15 years	3	20
Total	15	100

Table 3 Locations of respondent companies

Company location	Interviewees	Percentage (%)
Kuala Lumpur	2	13.3
Selangor	4	26.7
Penang	6	40
Ipoh	3	20
Total	15	100

the majority of the software companies in Malaysia are small and medium-sized. Table 4 shows that 40% of the software companies have staff less than 20, while 26.7% companies have staff between 20 and 50. 20% of the companies have 50–100 employees while only 13.3% companies are enterprise-level big companies and have more than 200 employees.

In the second section, questions about the effect of GSD, changes in software development processes and reasons behind it have been asked. The analysis of the qualitative data shows that GSD has brought a significant change in Malaysian SDCs and it has also affected the software development paradigms. It is evident from the results that the majority of the SDCs operating in Malaysia have replaced their existing processes with lightweight processes predominantly agile methods. 6 out of 15 respondents particularly stated that their companies are using agile methods in their software development environment to deal with the challenges and problems faced due to GSD. According to a project manager, software development companies strive to launch their products early in the market and agile method provides support in terms of "better visibility and faster development." Another project manager added that the use of the agile method as "Managers can see the

Table 4 Company size w.r.t number of staff

Number of staff	Interviewees	Percentage (%)
Less than 20	6	40
Between 20 and 50	4	26.7
Between 50 and 100	3	20
Between 100 and 150	0	0
More than 200	2	13.3
Total	15	100

progress of projects and developers do the tasks with the given priority." Software engineers also believe that agile methods are the best software development practices to handle the GSD related issues such that "as far as agile is concerned, it helps this company. There are many potential benefits and issues that can arise from GSD. The most frequently cited issue is a communication problem, so agile helps to sort out the communication problem." A number of studies report that communication is the main issue in GSD [2, 4, 5, 12, 17, 20, 21]. The respondents of the current study also consider that communication is the main problem in GSD that can be overcome by following agile methods. Agile methods provide disciplined and best practices to develop the software product [19, 21, 26]. Among agile methods, Scrum is mostly being followed in the Malaysian SDCs because Scrum supports and defines processes for weekly updates and frequent communication among team members and clients [13, 18, 19, 26]. One of the software engineer respondents mentioned that "we use Scrum because we have daily meeting to discuss what we currently doing and possible problems we traced." Furthermore, a senior software engineer also supported using the Scrum as "we've been using Scrum in-house, and then we tried to use it in some outsourcing projects and it really works in terms of managing project resources and tracking project status." The analysis of the answers of the respondents shows that agile methods are suitable for the environments of software development companies and provide best practices to build the software as well as to manage the resources, tasks, and for better visibility of the project progress.

Subsequently, 3 out of 15 respondent companies have been found as following ad hoc approaches of software development. The small and medium-size of the companies has been found as the main reason for using ad hoc approaches in Malaysia [42]. Adding to this, one of the senior software engineers highlighted the reasons of using the ad hoc approaches in their software companies as "we don't use any process because we are a small and medium-size software company. That's why we don't use any process." Likewise, a project manager/technical manager also mentioned that "Because projects are not big usually 2 to 3 weeks long and this is the reason we don't follow any process because the use of the process is unnecessary."

Similarly, other studies conducted in Malaysia [40, 42–44] reports that most companies don't follow any software process; similar trends also found in the present study. Surprisingly, Malaysian SDCs are also following the software product line (SPL) due to GSD as 4 interview respondent companies are following the SPL. The common reason reported by the respondents is "to reuse the software components and for better management." According to [21], SPL and agile methods mostly share the common goals but achieved in different ways. However, few companies are still using traditional approaches of software development because the projects are at enterprise-level, as two of the participants are using the waterfall model and only one participant reported the ISO standards.

5 Conclusion

The research study presented in this paper successfully describes the trends of software development processes in Malaysian software development industry as well as the reasons from the experts. The findings show that GSD has brought a great evolution in Malaysian SDC and as a result software paradigm has been shifted. The findings also reveal that lightweight methodologies are the recent trends in the Malaysian SDCs. Agile and SPL methods are mostly being used as these provide fast development, better visibility of project progress, easy to manage resources and tasks as well as help to minimize the issues of GSD particularly related to communication and coordination. The small and medium-size of the companies as well as projects also urges them to follow ad hoc approaches. However, few of the respondent companies are still using traditional practices in their development environment as a result of GSD.

The results of the present study adequately explain the software development processes currently being used in Malaysian companies as a result of GSD. It also presents the views of IT experts in detail in order to know the reasons to adopt the current process and evolution in software development processes.

Automated Scheduling of Hostel Room Allocation Using Genetic Algorithm

Rayner Alfred and Hin Fuk Yu

Abstract Due to the rapid growth of the student population in tertiary institutions in many developing countries, hostel space has become one of the most important resources in university. Therefore, the decision of student selection and hostel room allocation is indeed a critical issue for university administration. This paper proposes a hierarchical heuristics approach to cope with hostel room allocation problem. The proposed approach involves selecting eligible students using rank based selection method and allocating selected students to the most suitable hostel room possible via the implementation of a genetic algorithm (GA). We also have examined the effects of using different weight associated with constraints on the performance of the GA. Results obtained from the experiments illustrate the feasibility of the suggested approach in solving the hostel room allocation problem.

Keywords Scheduling · Hostel space · Genetic algorithm

1 Introduction

A hostel management system is responsible for allocating students to available hostel spaces and managing students' resident and hostels information. The rapid rise in the student population of the tertiary institutions over the years in developing countries has become an inevitable challenge to university administration due to limited hostel spaces available in the university. Therefore, in order to cope with the issues above, optimization of the scheduling process for hostel room allocation is a must. Hostel room scheduling is the problem of allocating eligible students to hostel rooms while satisfying specified constraints and the scheduling process is

automated [2]. Automated scheduling is usually executed using a scheduling algorithm to generate a sequence of actions in order to achieve certain objectives. Some of the applications or problems which require automated scheduling are flow shop scheduling problem (FSSP) and job shop scheduling problem (JSSP) [1] including Hostel Space Allocation Problem [2]. Some examples of technique or method for dealing with scheduling problem are hybrid metaheuristic algorithm [3], relax and fix heuristics [4], and hierarchical heuristics approach [2]. The reason why these proposed techniques are advantageous is mainly because of the simplicity, flexibility, inexpensive computational cost, and derivation-free mechanism of heuristic or metaheuristic [5]. In this paper, a hierarchical heuristics approach will be proposed and implemented to optimize the scheduling process of hostel room allocation. Hierarchical heuristics approach is chosen because it is able to provide good results in dealing with multilevel allocation process of hostel space allocation problem [2].

The rest of the paper is organized as follow. Section 2 discusses related works with regard to implementation of GA-based heuristic in dealing with scheduling problems. Section 3 presents the design of the proposed hierarchical heuristics approach while the experimental setup is discussed in Sect. 4. This paper is concluded in Sect. 5.

2 Related Works

A large amount of research and study has been conducted in a variety of domains of scheduling problem such as JSSP [6], shelf space allocation problem (SSAP) [7], timetabling problem [8], knapsack problem [9], and bin-packing problem [10]. Yaqin et al. [6] studied on the job shop scheduling with multiobjectives-based on GA and according to the research, GA is relatively faster than other methods used for scheduling which are usually based on single point search as GA do multipoint searches on the whole population simultaneously. Their studies show that GA is feasible in optimizing NP-hard or combinatorial optimization problem. Castelli and Vanneschi [7] proposed a hybrid algorithm that combines GA and variable neighbor search (VNS) algorithm to increase the explorative ability of GA to prevent GA from being stuck in local optimum and results obtained from their experiments had shown the enhancement in explorative ability of GA. Yang et al. [9] introduced attribute reduction of rough sets into the crossover of GA to tackle multidimensional knapsack problem which is also known as the multi-constraints knapsack problem. The steps of the GA proposed by them are different than the steps in typical GA. If reduct is found in the genes of the parent chromosome, the particular genes in the reduct will be the points selected to crossover whereas in the event of no reduct is found, the single-point crossover is applied. Results obtained from their studies show that the likelihood of the proposed GA to reach a maximal solution is relatively higher than conventional GA. Other than that, Bennell et al. [10] proposed a multi-crossover genetic algorithm (MXGA) to solve

a new variant of the two-dimensional bin-packing problem where each rectangle is assigned a due date and each bin has a fixed processing time. Experiments conducted in their research shows that the MXGA performance better than the single crossover genetic algorithm in solving the bin-packing problem. One crucial similarity between the works reviewed above is such that GA is always a part of the proposed solution or method. Therefore, the motivation of our work is to implement GA in the proposed hierarchical heuristic approach in order to tackle the hostel room allocation problem. The hierarchical heuristics approach proposed in this work is different than the hierarchical heuristics approach proposed by Adewumi and Ali [2], in which instead of greedy-like heuristic, the rank based selection method is used in the selection stage. Moreover, the representation, as well as crossover and mutation mechanism of the GA, is different as well.

3 Hierarchical Heuristics Approach

This section explains the framework of the hierarchical heuristics approach. The main components of the approach, which are rank-based selection method and GA will be explained. The proposed hierarchical heuristics approach framework is shown in Fig. 1.

With respect to Fig. 1, necessary information of applicants, rooms and specified constraints will initially be provided to the framework. This information will be used during the selection stage; with the implementation of rank-based selection method, applicants will be ranked based on the weight they hold and higher ranker will be selected first. Weight hold by the applicant is determined via the degree in which the applicant satisfies the specified constraints and the order of priority of constraints will be shown in Sect. 4. A list of selected students or applicants will be produced at the end of the selection stage. During the allocation stage, the selected students will be allocated to the most suitable hostel room possible using GA-based on specified constraints. The constraints will be shown in Sect. 4.

3.1 Genetic Algorithm

A GA is a stochastic search algorithm which can be used to a variety of combinatorial optimization problems [11]. GA is also known as nature inspired algorithm for the reason that the steps in GA are based on the evolutionary process of biological organisms. GA evolves according to the principle “survival of the fittest”; this implies that offspring that carries best attributes genes will have higher chance to survive to the next generation. Generally, GA simulates the evolutionary process of biological organisms by generating individuals randomly that form up an initial population. Each individual is encoded into a string (chromosome) which represents a possible solution to a given problem. Fitness function is performed on

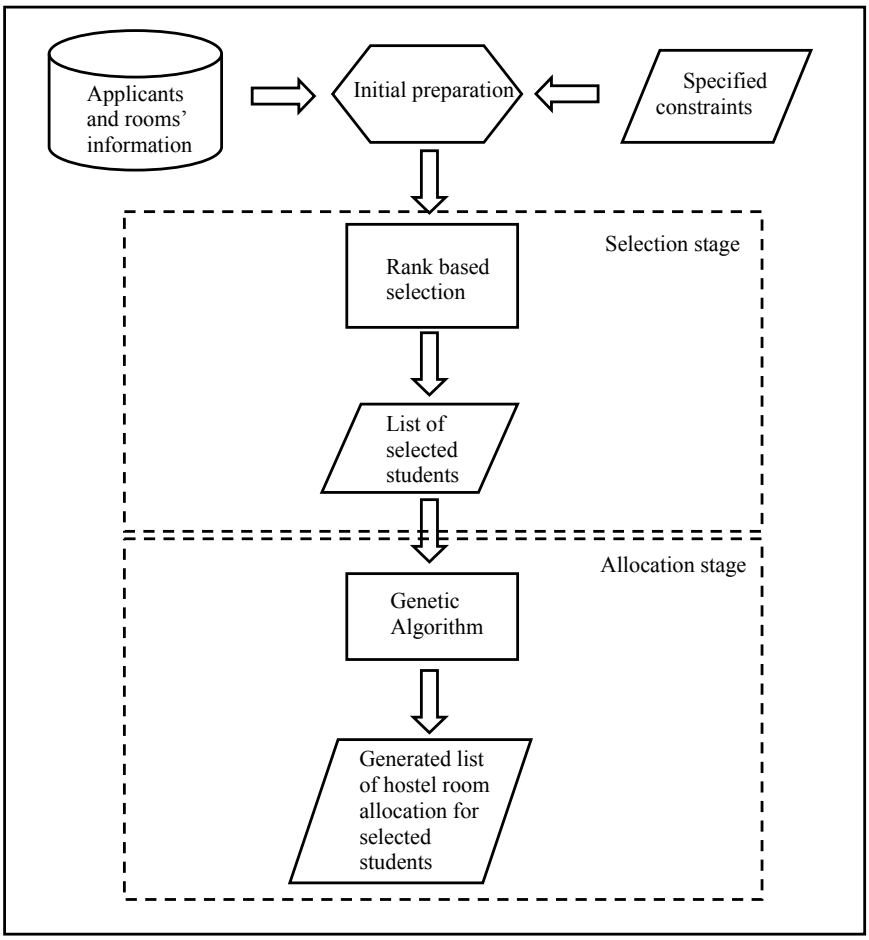

Fig. 1 Framework of hierarchical heuristics approach

each and every individual and each individual has its own fitness value. A probability of being selected during the selection process is assigned to each individual based on the individual's fitness value so as to ensure the characteristics of highly fit individuals or chromosomes are passed down to the next generation through a crossover procedure. The most general crossover method is called a one-point crossover; in which a single crossover point on both parents' chromosomes is selected first and then all information located beyond that single crossover point in either chromosome are swapped between these two parent chromosomes. The mutation is often applied to the offspring's chromosomes after crossover by altering some genes in the chromosomes, but with very low occurrence rate. In most of the case, less fit individuals will be replaced by the highly fit offspring and the new population will be reevaluated by the fitness function again. This sequence of processes will be repeated until a termination criterion is met.

3.2 Solution Encoding and Generic Operators

The encoding applied to represent candidate solutions for the GA used in the allocation stage as shown in Fig. 1 will be described in this section. The generic operators, which are crossover and mutation of the GA, will be described as well. Figure 2 illustrates how the candidate solutions are encoded. Based on Fig. 2, the integer values are the unique ID of selected students. The number of genes owned by each room varies with the types of room and as for this case, single room owns two genes while double room owns four genes. The length of the chromosome varies with the total number of rooms available. Figure 3 illustrates the process of crossover.

In Fig. 3, a self-crossover is used in order to ensure there is no repetition of integer values in the chromosome as the integer values are the unique ID of students. The crossover is done by randomly selects two portions with the same number of genes and swaps the genes of the selected portions in a random manner. The genes swapping phenomenon is controlled by a crossover rate of 0.45. On the other hand, the mutation process is almost the same as crossover process, in which the difference is that all the genes of the selected portions will be swapped completely in a random manner instead of controlled by a crossover rate of 0.45. The likelihood of the mutation process to happen is controlled by a mutation rate of 0.05.

3.3 Fitness Function

Fitness function, which is also known as evaluation function is used to evaluate individuals after initialization, crossover, and mutation steps to determine how fit the individuals are. In this work, the fitness of GA's individual will be evaluated based on the degree in which the constraints are satisfied. Each individual of the GA will have their own fitness value which is a set of real number in [0, 1]. A value of 0 indicates a complete violation of all given constraints while a value of 1 indicates no constraint is violated. The fitness of an individual, by referencing the fitness function in [2], is computed as:

$$f = \sum_{i=1}^{n} w_i u_i \in [0,\ 1] \tag{1}$$

where u_i in Eq. (1) is the utilization factor given as:

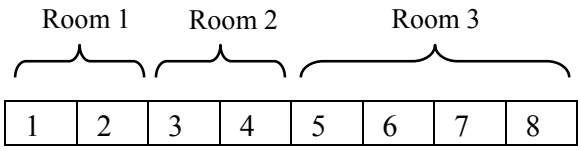

Fig. 2 Chromosome encoding of the GA in allocation stage

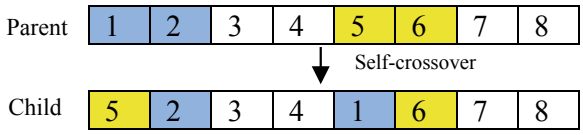

Fig. 3 Crossover process

$$u_i = \frac{1}{n} \tag{2}$$

w_i is the weight hold by gene i in a chromosome, n in Eqs. (1) and (2) is the total number of genes a chromosome has.

4 Experimental Setup

This section describes the experiments that are carried out in this work. The sample datasets for students (applicants) and rooms are shown in Tables 1, 2 and 3. The initial population of the GA will be randomly generated.

The main parameters for GA used are as follow 30 population size, 100 generations, crossover rate at 45% and mutation rate at 5%. The constraints applied to the selection and allocation process are as follow:

1. Selection:
   - Hard constraints
     - All first year students must be selected (FY).
     - Student representative must be selected (SR).
     - Uniformed units must be selected (SU).
     - Handicapped students must be selected (HS).
   - Soft constraints
     - Students with higher student development points are more likely to be selected (SD).
     - Students with higher CGPA are more likely to be selected (SC).

Table 1 Statistics of applicants per category

Category	Male	Female
First year	703	2635
Senior	297	1115
Student representative	4	8
Uniformed units	197	353
Handicapped	2	5
Food science and forestry	192	328
Others	605	3056

Table 2 Availability of rooms for male students

	Hostel				
Type	A/B	C/D	E	Angkasa	Usia
Single room capacity	52	52	52	52	
Double room capacity	148	148	148	148	0
Ground floor capacity	50	50	50	50	0

Table 3 Availability of rooms for female students

	Hostel				
Type	A/B	C/D	E	Angkasa	Usia
Single room capacity	140	140	140	140	140
Double room capacity	560	560	560	560	560
Ground floor capacity	150	150	150	150	150

2. Allocation:

- Hard constraints
  - Uniformed units must be allocated to hostel E (UH).
  - Handicapped students must be allocated to rooms situated on the ground floor (HG).
  - Single rooms are for senior students (SS).
- Soft constraints
  - Food Science (FS) and Forestry (FT) student should be allocated to hostel E (FE).
  - Students should be allocated to the hostel of their choices (SH).
  - First year students should be allocated to hostels inside the campus (SI).

Weights associated with selection and allocation constraints are shown in Tables 4 and 5. With respect to Table 4, weight associated to constraint FY is 0.51 and this is to make sure the sum of weights of other constraints is less than 0.51 as FY holds the highest priority in hard constraints. As for SR, SU, and HS, they have the same level of priority, in which fulfilling one or two or all of these constraints will give the student the same amount of weight, which is 0.25. This is to ensure the sum of weights for remaining soft selection constraints will not exceed 0.25. On the other hand, the four sets of weights' distribution for allocation constraints shown in Table 5 are used to examine the effect of weight associated constraints on the performance of the GA; during allocation stage, the results obtained from the rank

based selection are processed by the GA using these four sets of weights' distribution and the results obtained are used as a basis for optimizing the weights' distribution for allocation constraints. The optimization of weights' distribution for allocation constraints is done by simulating the GA 30 times using the same set of results obtained from rank-based selection but with 30 different sets of weights' distribution for allocation constraints which are randomly generated.

The results obtained from the rank-based selection during selection stage are shown in Table 6 where it shows the fulfillment of hard constraints as soft constraints of selection, which are SD and SC cannot be quantified. However, with the implementation of rank-based selection and normalization of student development point and CGPA, SD, and SC will always be optimized. The optimized weights' distribution for allocation constraints is shown in Table 7 while the allocation results obtained from simulating the GA using the four sets of weights' distribution and optimized weights' distribution are shown in Table 7. Based on Table 8, the performance of the GA is measured in term of constraints satisfaction in percentage

Table 4 Weights' distribution for selection constraints

Type	Constraints	Weight
Hard	FY	0.51

Total		7948	6602 (83.06%)	5981 (75.25%)	5401 (67.95%)	5049 (63.52%)	6331 (79.65%)

instead of average fitness value of GA's population. This is because fitness value is based on weights' distribution for allocation constraints and, therefore, it is not suitable for indicating the performance of the GA. The results obtained from both selection and allocation stages show the feasibility of the suggested approach in solving the hostel room allocation problem.

5 Conclusion

This paper proposed a hierarchical heuristics approach that includes the implementation of GA to cope with hostel room allocation problem. The effect of weights associated with constraints is examined by simulating GA with multiple sets of weights' distribution for allocation constraints. Optimized weights' distribution for allocation constraints is obtained during the simulation process. Results obtained from the experiments conducted show the feasibility of the proposed approach in dealing with the problem at hand. However, improvements can still be made in the

future to increase the overall performance of the proposed approach by tuning the GA components and parameters such as encoding method, crossover method, mutation method, crossover rate, mutation rate, population size, etc.

Evaluation of ASTER TIR Data-Based Lithological Indices in Parts of Madhya Pradesh and Chhattisgarh State, India

Himanshu Govil, Subhanil Guha, Prabhat Diwan, Neetu Gill and Anindita Dey

Abstract The present study was performed in some parts of Madhya Pradesh and Chhattisgarh State, India to compare the different quartz indices, feldspar indices and mafic indices according to Ninomiya (2005) and Guha (2016) using thermal infrared (TIR) bands (band 10, band 11, band 12, band 13, and band 14) of Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) data for detecting quartz, feldspar and mafic minerals. Results showed that these indices are equally useful for delineating quartz, feldspar or mafic minerals. It was noticed from the correlation coefficients that Guha's mafic index (GMI) and Ninomiya's mafic index (NMI) presented almost the same result. Guha's quartz index (GQI) was more powerful than Ninomiya's quartz index (NQI) in identifying quartz content in alkali granites and this GQI was also comparable with the Rockwall and Hofstra's quartz index (RHQI) in identifying quartz content in alkali granite.

Keywords ASTER · Feldspar · Mafic · Quartz · Thermal infrared

1 Introduction

The visible and near-infrared (VNIR) bands and the short wave infrared (SWIR) bands of satellite data are not so useful for detecting quartz and feldspar minerals [13] whereas thermal infrared (TIR) bands are useful for the delineation of the aforesaid minerals because of the vibration of Si–O bonds [7]. Lithological mapping is an important task of geological exploration. Earth observation techniques play an important role in lithological and mineralogical mapping. TIR region are

less studied than VNIR or SWIR regions for mineral identification due to the less availability of satellite sensors in the TIR domain.

Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) satellite sensor has three VNIR bands (band 1–3), six SWIR bands (band 4–9), and five TIR bands (band 10–14). ASTER VNIR and SWIR bands were used extensively in the mapping of clay, carbonate, aluminium hydroxide, and iron hydroxide [15].

In later studies, a different combination of ASTER TIR bands were frequently used in differentiating various types of rock [4, 8–10].

Ninomiya et al. [9] applied some selected lithological parameters to propose a series of ASTER TIR band based lithological indices for quartz, mafic, feldspar, and carbonate rock detection [1, 4, 9, 12]. High ratio of alkali feldspar is present in alkali feldspar rich granite while in granodiorite and tonalite this ratio becomes lower [2]. Granitoids are also characterized by a low amount of mafic mineral which is found in high amount in tonalite.

The present study tried to detect quartz, feldspar, and mafic mineral in various types of rocks using ASTER TIR bands. A number of geoscientists examined the utility of ASTER TIR bands in the formulation of rocks and mineral indices to identify the basic mineral content in the lithological variation [3–5, 9]. The published geological map was used as the reference map to get a reliable interpretation of the final results. Different lithological indices were compared to each other for enhancing the sub-variants of granitoids.

2 Study Area and Geology

The parts of Madhya Pradesh and Chhattisgarh State of east-central India were selected as the study area (Fig. 1) of the present research work. This entire region is composed of felsic and mafic rocks in significant amount. Granitoid or quartz enriched felsic rock has a combination of quartz, mafic and feldspar minerals. Geological map published from the Geological Survey of India with 1:250,000 scale was used as the reference map for analyzing the derived lithological indices.

3 Materials and Methods

Thermal bands specification of ASTER data was provided in Table 1. Emissivity values of quartz and feldspar minerals were analyzed and it was observed that the band 12 reflects the lowest emissivity value and band 10 and band 13 reflect the higher emissivity values for quartz mineral. ASTER band 11 has a lower emissivity than band 10 for feldspar mineral (Fig. 2). ASTER band 13 indicates the lowest emissivity and band 12 and band 14 have higher emissivity for mafic rocks and

minerals [14]. A significant reverse trend of emissivity values for TIR band 11 and band 12 was observed for quartz and feldspar minerals [14].

The lithological indices applied for detecting quartz, mafic and feldspar minerals were retrieved using TIR bands of ASTER sensor.

Guha's indices are described as follows [6]:

$$\text{Guha's quartz index (GQI)} = \frac{\text{band 10}}{\text{band 12}} \times \frac{\text{band 13}}{\text{band 12}} \tag{1}$$

$$\text{Guha's mafic index (GMI)} = \frac{\text{band 12}}{\text{band 13}} \times \frac{\text{band 14}}{\text{band 13}} \tag{2}$$

$$\text{Guha's feldspar index (GFI)} = \frac{\text{band 10}}{\text{band 11}} \times \frac{\text{band 12}}{\text{band 11}} \tag{3}$$

GQI, GMI and GFI were generally used to detect the rocks with high quartz content, high mafic minerals content, and high feldspar content, respectively. NQI and NMI were the two established lithological indices to detect quartz and mafic minerals, respectively [9]. Besides, Rockwall and Hofstra [11] proposed another index (RHQI) to detect quartz-rich rocks.

These indices are described as follows:

$$\text{Ninomiya's quartz index (NQI)} = \frac{\text{band 11} \times \text{band 11}}{\text{band 10} \times \text{band 12}} \tag{4}$$

$$\text{Ninomiya's mafic index (NMI)} = \frac{\text{band 12}}{\text{band 13}} \tag{5}$$

$$\text{Rockwall and Hofstra's quartz index (RHQI)} = \frac{\text{band 11}}{\text{band 10} + \text{band 12}} \times \frac{\text{band 13}}{\text{band 12}} \tag{6}$$

The present study compared GQI with respect to NQI in detecting quartz and GMI with respect to NMI in detecting mafic minerals. Applicability of RHQI and GQI was also examined.

4 Results

The study attempted to compare the lithological indices for identifying mafic, quartz and feldspar minerals. It was noticed that granite and quartz-rich granite were differentiated from mafic rich gneiss as yellow colour produced in the composite image of band 14 as red band, band 13 as green band and band 12 as blue band (Fig. 3a). Quartz particles were characterized with a red tint in the composite image of band 14 as red band, band 12 as green band and band 10 as blue band (Fig. 3c). NQI and NMI were the established rock bearing indices to distinguish quartz and mafic minerals in various types of lithological configurations. GQI provided a better result than NQI in the delineation of quartz content (Fig. 4a and b). Quartz enriched rocks were found as dark colour and bright colour in NQI and GQI images, respectively. This is because of the different emissivity values for quartz and feldspar in these TIR bands. GQI image was also compared to RHQI image. In RHQI image, the emittance value for quartz should be higher in band 11 [9]. Again, the emittance value for quartz was also high in band 13 compared to band 12 [6]. Thus, RHQI was used to delineate quartz content in granite and alkali granite (Fig. 4a and c). In GFI image, feldspar particles appeared as brighter in alkali granite (Fig. 4d). GMI and NMI built a strong correlation and thus these images were complementary to each other (Fig. 4e and f). It was found a relatively weak correlation (0.092) between GQI and NQI while GMI and NMI showed a strong (0.813) correlation (Table 2). However, GQI was comparable with RHQI in order to identify quartz enriched granitoids. GQI and RHQI built a very high correlation (0.808).

GFI and GQI had a very weak negative correlation (−0.090) because generally feldspar particle is increased slowly with the gradual decrease of quartz particle.

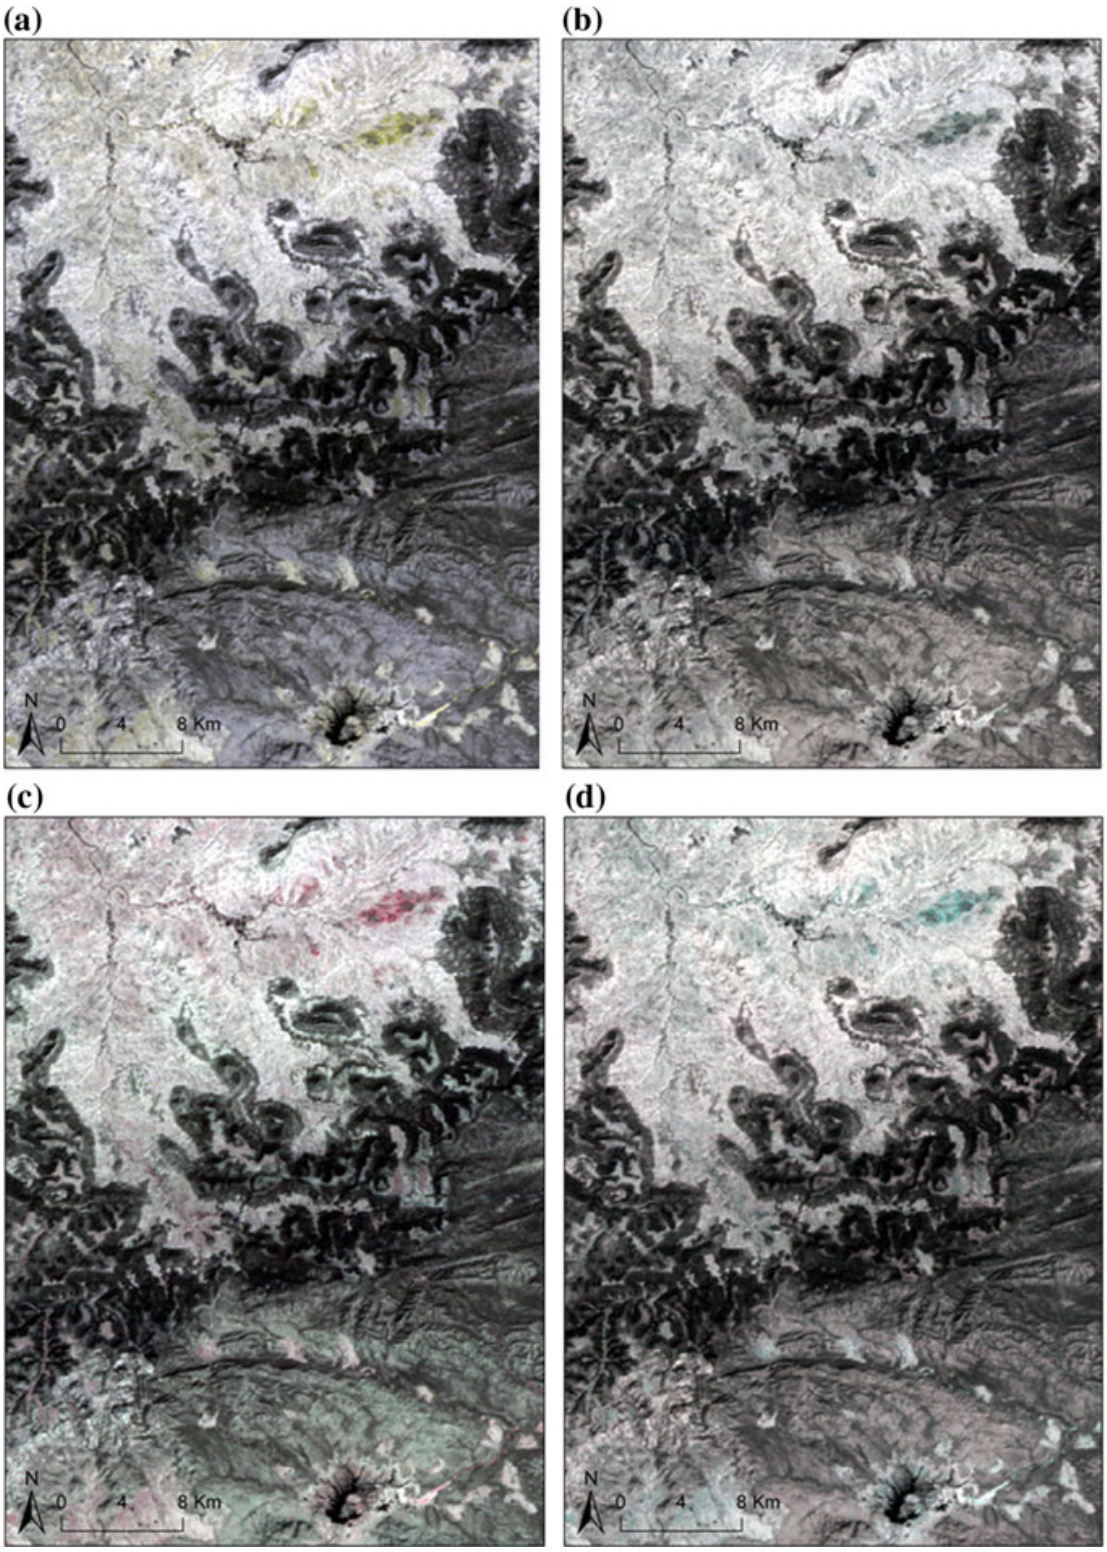

Fig. 3 ASTER TIR radiance composite images: **a** band 14 as red band, band 13 as green band, band 12 as blue band; **b** band 12 as red band, band 11 as green band, band 10 as blue band; **c** band 14 as red band, band 12 as green band, band 10 as blue band; **d** band 11 as red band, band 14 as green band, band 13 as blue band

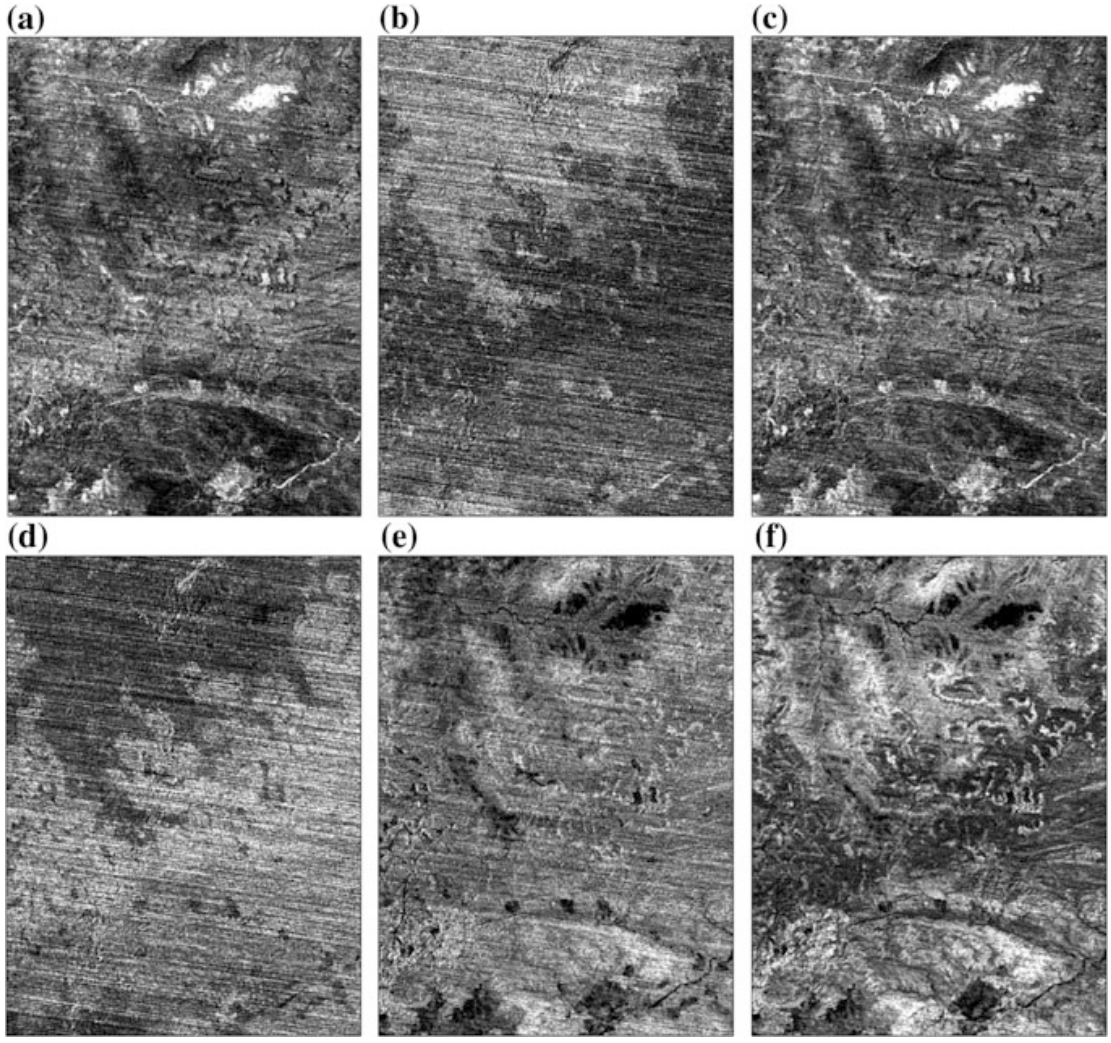

Fig. 4 **a** GQI image; **b** NQI image; **c** RHQI image; **d** GFI image; **e** GMI image; **f** NMI image

Table 2 Correlation Matrix of various lithological indices

	GQI	NQI	RHQI	GFI	GMI	NMI
GQI	1.00000	0.09179	0.80787	−0.09011	−0.80419	−0.88018
NQI	0.09179	1.00000	0.51516	−0.99992	−0.32162	−0.07198
RHQI	0.80787	0.51516	1.00000	−0.51341	−0.84916	−0.89145
GFI	−0.09011	−0.99992	−0.51341	1.00000	0.31993	0.06999
GMI	−0.80419	−0.32162	−0.84916	0.31993	1.00000	0.81306
NMI	−0.88018	−0.07198	−0.89145	0.06999	0.81306	1.00000

GMI and GFI were positively correlated with a regression value of 0.319 because feldspar particle is increased with the increase of mafic particle. GQI and GMI were negatively correlated with a very high regression value of −0.804 because quartz particle is increased rapidly with the decrease of mafic particle.

5 Discussions and Conclusions

The use of the lithological indices can be treated as a significant method for the delineation of quartz, mafic and feldspar minerals in granitoids. GQI was established as a more effective method compared to NQI (Fig. 4a and b). RHQI can retrieve quartz content almost as much as in GQI. GMI also provided a reliable comparison with NMI for delineation of mafic minerals (Fig. 4e and f). GMI and NMI were highly correlated (0.813) but the relationship became weak (0.091) between NQI and GQI (Table 2). GQI and QIRH also correlated with a high regression value (0.807) and hence can be used as important indices to determine quartz content in granite and alkali granite rocks. The results were significantly comparable to the published geological map. These indices can be evaluated in the different climatic and geologic environment to establish a more accurate conclusion.

Analyzing Linear Relationships of LST with NDVI and MNDISI Using Various Resolution Levels of Landsat 8 OLI and TIRS Data

Himanshu Govil, Subhanil Guha, Prabhat Diwan, Neetu Gill and Anindita Dey

Abstract The present study used the Normalized Difference Vegetation Index (NDVI) and the Modified Normalized Difference Impervious Surface Index (MNDISI) to determine the linear relationship between Land Surface Temperature (LST) distribution and these remote sensing indices under various spatial resolutions. Four multi-date Landsat 8 Operational Land Imager (OLI) and Thermal Infrared Sensor (TIRS) images of parts of Chhattisgarh State of India were used from four different seasons (spring, summer, autumn and winter). The results indicate that LST established moderate to strong negative correlations with NDVI and weak negative to moderate positive correlations with MNDISI at various spatial resolutions (30–960 m). Generally, the coarser resolutions (840–960 m) possess stronger correlation coefficient values due to more homogeneity. The autumn or post-monsoon image represents the strongest correlation for LST–NDVI and LST–MNDISI at any resolution levels. The image of winter season reveals the best predictability of LST distribution with the known NDVI and MNDISI values.

1 Introduction

Generally, the spatial and temporal resolution of satellite sensor should follow the nature of surface configurations [24]. In any urban area, the high value of Land Surface Temperature (LST) is generated mostly in the Impervious Surface Area (ISA) with lower vegetation intensity [18]. Therefore, most of the thermal remote sensing methods used the Normalized Difference Vegetation Index (NDVI) [5] and ISA [1] as the significant indicators of LST, and a number of studies based on the relationships of LST with NDVI [6–8, 19], and impervious surface fraction [22], were used to explore high LST. Some scholars applied fractal techniques for analyzing LST–NDVI relationship [19]. An adjusted stratified stepwise regression method was proposed to sharpen the LST within a high-density urban land and the adjacent areas [25]. An improved error estimation method was developed considering the scale difference [4]. The relationships of LST with NDVI and Modified Normalized Difference Impervious Surface Index (MNDISI) were recently investigated for a single date image at different resolutions [11] in which the relationships became strongest at 30 m resolution. In the present paper, a detailed examination was performed by using four cloudless Landsat 8 OLI (Operational Land Imager) and TIRS (Thermal Infrared Sensor) data taken from the four different seasons (spring, summer, autumn and winter) to evaluate the relationships of LST with NDVI and MNDISI at 30–960 m spatial resolutions. The main aim of the present study was to assess the LST–NDVI and LST–MNDISI relationships generated in the satellite images of different seasons at various spatial resolution using Landsat 8 data.

2 Study Area and Data

Part of Chhattisgarh State including the capital city of Raipur and its surroundings was selected for the entire research work. The total study area extends between 20°59′24″ N to 21°35′24″ N and 81°22′48″ E to 82°01′12″ E covers a total geographical area of 4356 km^2 (Fig. 1). The study area has an elevation ranging from 147 m to 370 m. Mahanadi River flows along the east of Raipur city and the elevated southern part is covered by forest. The study area is considered as tropical wet (Savannah) type of climate. Spring season exists for only one and half months (February–March) characterized by pleasant weather. Summer or pre-monsoon months (March–June) are hot and dry and dust storms occur frequently. July–September months are considered as monsoon or rainy season. October and November months are often considered as the autumn or post-monsoon season, characterized by an excellent climatic condition with comparatively low temperature and moderate moisture content in the air. The presence of high density of green vegetation really adds an extra flavour in Chhattisgarh during autumn. Winter months (December–January) experience a cool and dry climate. The average annual

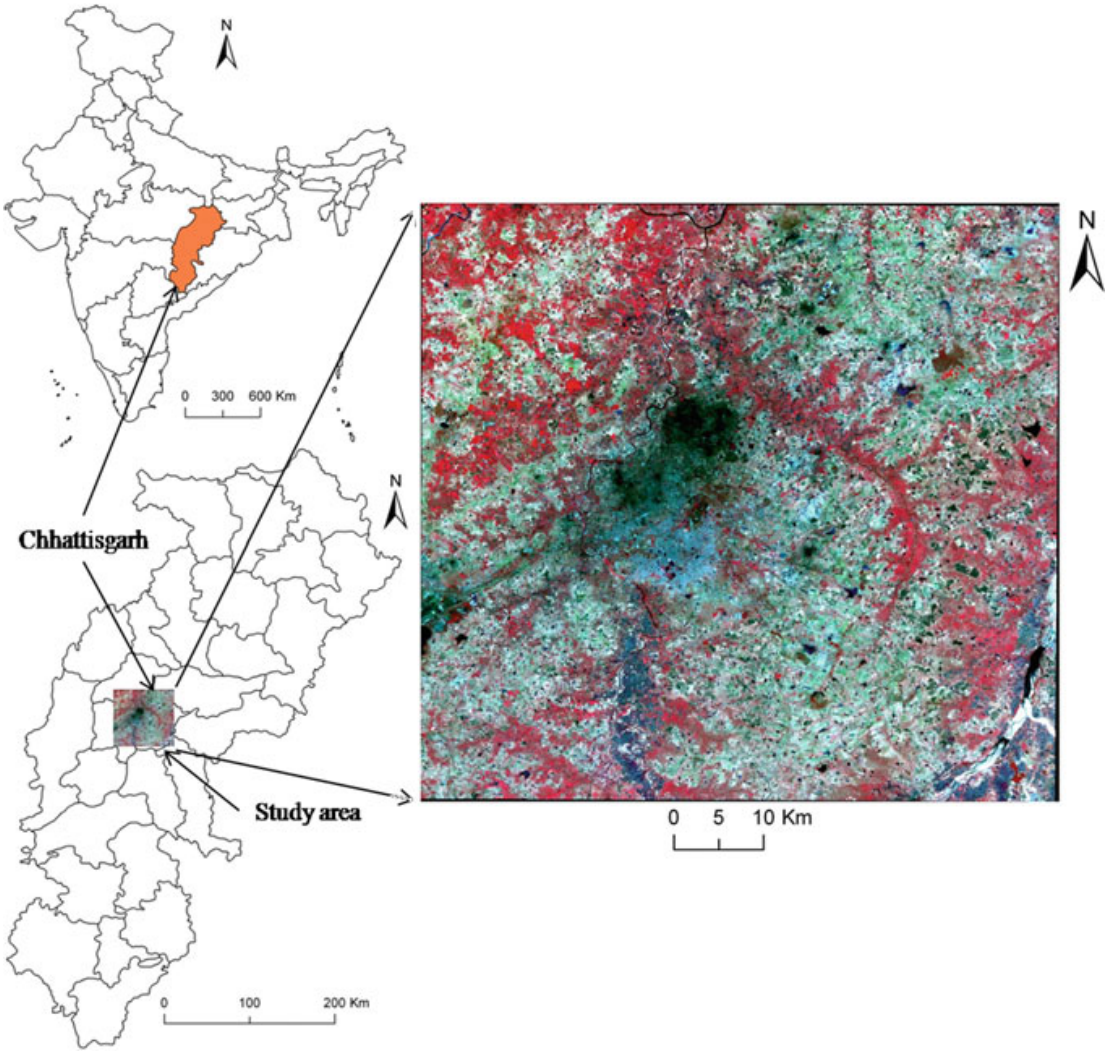

Fig. 1 Location of the study area

range of temperature is 20 °C–34 °C and average annual precipitation is 130 cm. An extensive bare land was observed throughout the study area including the capital city in the central part. The study area was also characterized by tropical mixed deciduous vegetation and red soil.

Four Landsat 8 OLI and TIRS data satellite images (Path/Row: 142/45) dated 3 February 2016, 23 April 2016, 16 October 2016 and 19 December 2016 were downloaded from the United States Geological Survey (USGS) Data Centre (Table 1) which were used as the representatives of the spring, summer or pre-monsoon, autumn or post-monsoon and winter seasons, prevails over the Chhattisgarh State of India, respectively. Landsat 8 TIRS dataset has two TIR bands (bands 10 and 11) in which band 11 has a larger calibration uncertainty. Thus, only TIR band 10 data was recommended in the present study. The TIR band 10 data was resampled to 30 m × 30 m pixel size of for all the satellite images.

Table 1 Specification of Landsat 8 OLI and TIRS satellite images

Data	Wavelength of Band 10 (μm)	Resolution of Band 10 (m)	Sun elevation (°)	Sun azimuth (°)	Cloud Cover (%)	Earth–Sun distance (astronomical unit-AU)	Path/ row	Coordinated Universal Time (UTC)	Date of acquisition

Table 2 Various indices used for the extraction of Land Use/Land Cover (LU-LC) features

Indices	Formula	Significance in LU-LC Identification	References
NDVI	(NIR–Red)/(NIR + Red)	Green vegetation extraction	[13]
MNDISI	[TIR–(MNDWI + NIR + SWIR1)/3]/ [TIR + (MNDWI + NIR + SWIR1)/3]	Impervious surface area extraction	[21]
MNDWI	(Green-SWIR1)/(Green + SWIR1)	Waterbody extraction	[23]

3 Methodology

3.1 Retrieving LST from Landsat 8 OLI Data

In this study, the mono-window algorithm was applied to retrieve LST from multi-temporal Landsat satellite image [6, 7, 14]. Ground emissivity, atmospheric transmittance and effective mean atmospheric temperature—these three parameters are needed to derive the LST using mono-window algorithm.

3.2 Extraction of NDVI and MNDISI

Various land surface biophysical parameters were applied to specify different types of land surface features [6, 7]. In this study, special emphasis was given on NDVI [9, 13] and MNDISI [10, 21] for determining the relationships with LST. NDVI was used as a vegetation index while MNDISI, based on modified normalized difference water index or MNDWI [23], acts as an index of impervious surface. These remote sensing indices were extracted by using the following formulas (Table 2).

4 Results and Discussion

4.1 Characteristics of LST, NDVI and MNDISI at Different Spatial Resolutions

There was a prominent variation of different time periods occurred in mean and Standard Deviation (STD) values of LST, NDVI and MNDISI under the different resolutions ranging from 30 to 960 m. The summer or pre-monsoon image had the maximum values of mean LST (44.26 °C) followed by spring image (27.37 °C), autumn or post-monsoon image (26.91 °C) and winter image (24.14 °C); and these

mean values were almost unaffected by the size of the pixel. But, Standard Deviation (STD) values of LST had been gradually decreasing with the increase of pixel size for each and every image. Again, the summer image had the maximum STD of LST (2.92 °C at 30 m resolution) followed by autumn image (2.09 °C at 30 m resolution), spring image (1.75 °C at 30 m resolution) and winter image (1.46 °C at 30 m resolution) and these STD values maintained a steady decreasing trend with the increase of pixel size, e.g., 2.24 °C, 1.64 °C, 1.34 °C and 1.02 °C, respectively for summer image, autumn image, spring image and winter image at 960 m resolution.

In the case of NDVI, the autumn image had the maximum value of mean NDVI (0.34) due to the abundance of green vegetation followed by winter image (0.14), summer image (0.14) and spring image (0.14) and these mean values remain almost unchanged at different spatial resolutions. But, STD values of NDVI was continuously decreasing as the spatial resolution becomes low and this phenomenon was noticed for the four multi-date images. The autumn image represented the maximum STD value of NDVI, both at 30 m resolution (0.10) and at 960 m resolution (0.07).

There was a very negligible variation in the multi-date images for mean MNDISI value at any particular spatial resolution. At 30 m resolution, the spring image (0.55) had the maximum values of mean MNDISI followed by winter image (0.54) because of the increase in imperviousness in soil due to lack of rainfall and vegetation. The summer image (0.53) had less value of mean MNDISI than spring image and winter image while it was least in the case of autumn image (0.52) because of the high percentage of soil moisture. STD values of MNDISI had a steady descending trend with the decrease of resolution or increase of pixel size and it was a common phenomenon for all the images. The winter image had the highest STD values of MNDISI at any resolution (0.05 at 30 m to 0.03 at 960 m resolution). But, for the rest of the three images, a dynamic effect was observed with the change of resolution. Up to 300 m resolution, the autumn image had greater STD values of MNDISI than summer and spring image while 360 m resolution onwards these STD values of MNDISI become lesser.

Figure 2 represented the spatial distribution pattern of LST, NDVI and MNDISI in the highest (30 m) resolution level for all the multi-date images. It was clear that in the spring image, the higher LST values generated over the western, central, northern and southern portions of the study area while these specific zones were simultaneously characterized by low NDVI and high MNDISI value. The figure also indicated that in the summer image, the lower LST values were found in the southern and the southeastern parts and the higher LST values were found in the northern portion of the study area. The NDVI values were normally inversely correlated with the LST values while MNDISI values were not very much significantly correlated to the LST values. In the autumn image, the central and western parts are characterized by high LST, low NDVI and high MNDISI values. The

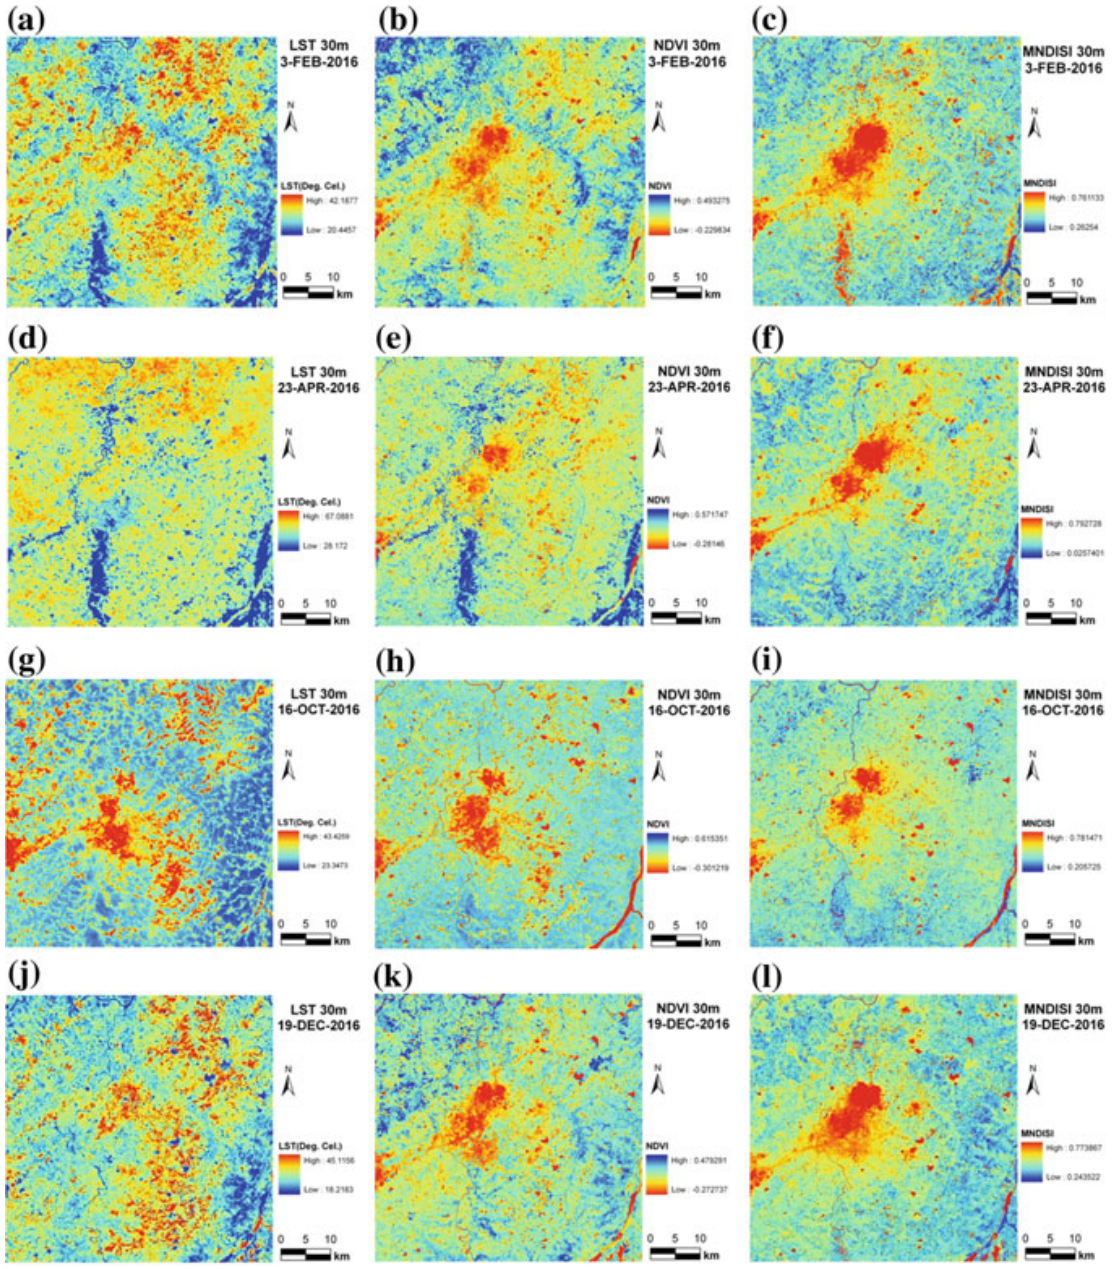

Fig. 2 Spatial distribution of LST, NDVI and MNDISI at 30 m resolution for spring image (**a**–**c**), summer image (**d**–**f**), autumn image (**g**–**i**) and winter image (**j**–**l**)

results remain almost similar at 30 m and 960 m resolution levels. In the winter image, no such evidence of significant changes was found due to the pixel size. The central part was characterized by high LST, low NDVI and high MNDISI values. Conversely, the northwest and the southeast portions had low LST, high NDVI and low MNDISI values.

4.2 Validation of Derived LST from Landsat 8 Data with Respect to MODIS Data

In the present study, MODIS data (MOD11A1 of 1 km resolution) was applied for the validation of LST retrieved from the aggregated Landsat 8 data of 960 m. Here, due to some missing pixels, MODIS data of exact corresponding date were not matched for LST validation process. MOD11A1 data (daily level 3 LST product) of the just preceding and the just following dates of Landsat 8 data were used in this study. The average MODIS LST values of the aforementioned two dates were taken for the final validation. No rainfall or strong winds occurred in between the acquisition of the Landsat 8 and MODIS imageries and almost similar weather conditions were noticed for the used Landsat 8 data and the corresponding MODIS data. Table 3 presented a strong correlation of retrieved LST from aggregated Landsat 8 data (960 m) and the corresponding MOD11A1 data (1 km) for multi-date satellite images.

4.3 Relationships Between LST–NDVI and LST–MNDISI Under Different Spatial Resolutions

The correlation coefficients between LST–NDVI and LST–MNDISI for various levels of spatial resolution (30–960 m) in four multi-date imageries were determined through pixel-by-pixel linear regression analysis. The 30 m LST, NDV, and MNDISI were aggregated to various resolution levels (60–960 m with 60 m intervals). The Pearson's correlation coefficients (significant at 0.001 level using one-tailed Student's *t* test) between LST–NDVI and between LST–MNDISI under different resolution levels and different dates were clearly understood from Table 4. The LST values had developed a negative correlation with the NDVI values at all resolution levels for all images. The three highest negative correlations were found in between 840 and 960 m resolution levels and the three lowest negative correlations were found in between 30 and 120 m resolution levels for all multi-date images. A steady and gradual increasing trend of negativity was observed in LST–NDVI correlation analysis with the decrease in resolution levels, i.e., weaker correlations developed at the higher or finer resolutions while stronger correlations developed at the lower or coarser resolutions and it appeared for all images. The

840	6241	−0.49	0.01	−0.67	0.16	−0.75	0.34	−0.35	0.05
900	5476	−0.49	0.01	−0.67	0.17	−0.75	0.34	−0.35	0.06
960	4761	−0.49	0.01	−0.67	0.17	−0.75	0.35	−0.35	0.06

strongest negative correlation (correlation coefficient values ranging from −0.59 to −0.75) was observed in the autumn image. The summer image also had a strong negative correlation (−0.50 to −0.67). A moderate negative correlation (−0.36 to −0.49) appeared in spring image while winter image experienced a low to moderate negative correlation (−0.16 to −0.35). The scenario became slightly different in LST–MNDISI correlation analysis (Table 4). The spring image (−0.12 to −0.01) revealed a very weak negative correlation between LST and MNDISI from 30 m to 780 m resolution while only the three coarser resolutions (840–960 m) had a very weak positive correlation. In the winter image (−0.14 to 0.06), up to 540 m spatial resolution, the correlation was very weak negative and it became very weak positive from 600 to 960 m resolutions. The summer image (−0.02 to 0.17) indicated very weak to weak positive correlation between LST and MNDISI except for 30 m and 60 m resolutions (very weak negative correlation). But, only the autumn image (0.12–0.35) holds a weak to moderate positive correlation between LST–MNDISI throughout the entire range of the resolution levels (30–960 m). The three highest positive correlations between LST and MNDISI were found between 840 m and 960 m resolution levels while the three lowest correlation values were found in between 30 and 120 m resolution levels for all the images. A constant increasing trend of positive correlation is observed between LST and MNDISI with the

decrease in resolution level and it occurs for each and every image (Table 4). Therefore, the correlations between LST–NDVI and between LST–MNDISI were best observed at 840–960 m resolution levels or at the coarser resolution levels due to the presence of more homogeneity in landscape features.

The stronger correlation between LST–NDVI and between LST–MNDISI at coarser resolution levels supports the relevance of linear correlation in determining LST with the known values of NDVI and MNDISI. The low density of vegetation and high density of impervious surface may together produce a high range of LST. The correlation graphs (significant at 0.05 levels) between LST–NDVI and between LST–MNDISI at various resolution levels and for all the images were presented in Fig. 3. Table 5 revealed the regression statistics of the correlation coefficients of LST–NDVI and LST–MNDISI relationship with respect to various resolution levels. In the correlation analysis between the correlation coefficients of LST–NDVI relationship and the various resolution levels, the values of coefficient of multiple

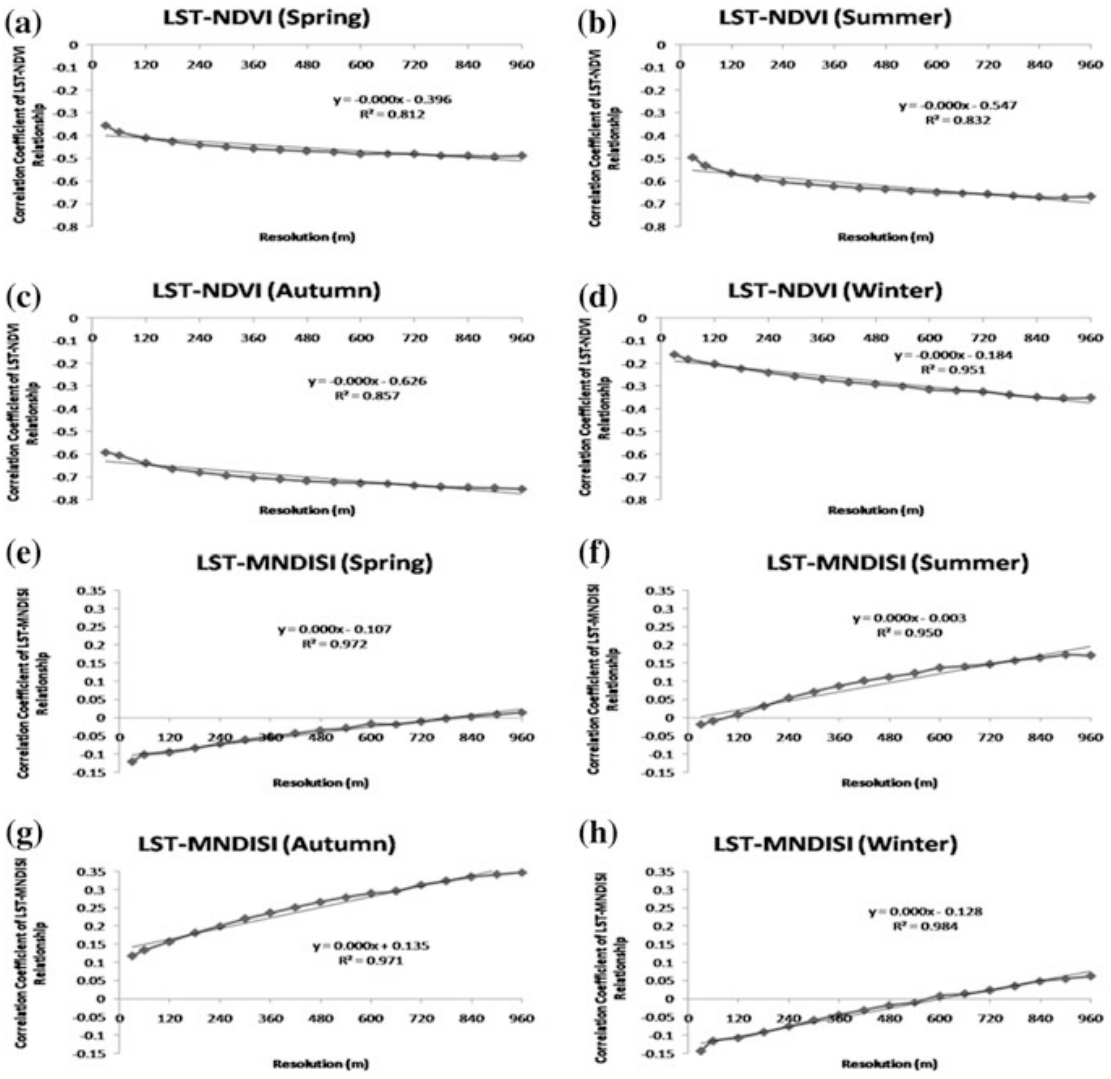

Fig. 3 Seasonal variation on LST–NDVI (**a**–**d**) and LST–MNDISI (**e**–**h**) correlation coefficients for various spatial resolutions

Table 5 Regression statistics of correlation coefficients of LST–NDVI and LST–MNDISI relationships with respect to different resolution levels for all images

	LST–NDVI correlation coefficients with various resolution levels (30–960 m)				LST–MNDISI correlation coefficients with various resolution levels (30–960 m)			
	Spring image	Summer image	Autumn image	Winter image	Spring image	Summer image	Autumn image	Winter image
Intercept	−0.40	−0.55	−0.63	−0.18	−0.11	−0.01	0.14	−0.13
Slope	−0.01	−0.01	−0.01	−0.01	0.01	0.01	0.01	0.01
Multiple R	−0.90	−0.91	−0.93	−0.98	0.99	0.98	0.99	0.99
R-squared	0.81	0.83	0.86	0.95	0.97	0.95	0.97	0.98
Adjusted R-squared	0.79	0.81	0.84	0.94	0.97	0.94	0.97	0.98
Standard error	0.02	0.02	0.02	0.01	0.01	0.01	0.01	0.01

determination or R-squared values are 0.81, 0.83, 0.86 and 0.95 for the spring image, summer image, autumn image and winter image, respectively while in the correlation analysis between the correlation coefficients of LST–MNDISI relationship and the various resolution levels, these R-squared values became 0.97, 0.95, 0.97 and 0.98 for the spring image, summer image, autumn image and winter image, respectively (Table 5). These R-squared values implicit a very strong correlation between the correlation coefficient values and the resolution levels for all the four multi-date satellite data. Hence, it can be concluded that 81.21%, 83.26%, 85.78% and 95.14% of the variance in the correlation coefficient values of LST–NDVI were predictable from the resolution levels for the images of the spring, summer, autumn and winter, respectively and 97.22%, 95.07%, 97.11% and 98.40% of the variance in the correlation coefficient values of LST–MNDISI were predictable from the resolution levels for the images of the spring, summer, autumn and winter, respectively. On the basis of multiple R, R-squared and adjusted R-squared values (Table 5), the winter image estimated the strongest correlation and may be considered as the best image under any possible resolution levels for the predictability of LST distribution with the known NDVI and MNDISI values. The overall results indicated that the NDVI and the MNDISI may be accepted as influential factors for LST distribution.

5 Conclusion

In this study, LST, NDVI and MNDISI were computed with 30–960 m resolutions for four multi-date imageries by using Landsat 8 OLI and TIRS data in parts of Chhattisgarh State, India. The linear relationships of LST–NDVI and LST–MNDISI varied with various resolution levels but yielded the higher correlation coefficient values around the coarser resolution (840–960 m) levels for all the four

images due to more homogeneity. For each data, the LST values tended to be negatively (weak to strong) correlated with the NDVI values and showed weak negative to moderate positive correlation with the MNDISI values. Autumn image (16 October 2016) reflected the strongest correlation followed by summer image while spring and winter images experienced weaker correlation for both the relationships. Moreover, a very strong negative correlation was also estimated between LST–NDVI correlation coefficients and various resolution levels. But, LST–MNDISI correlation coefficients and various resolution levels generated a very strong positive correlation. These strong relationships were sustained for all four different imageries. Amongst the four imageries, the winter image possessed the strongest correlation and ensured the best prediction level of LST distribution when NDVI and MNDISI values were known. NDVI and MNDISI may also be considered as significant variables for the prediction of LST distribution.

The study further recommends that these results may be investigated by the inclusion of other satellite imageries of low or high resolution and other LU-LC indices. Any nonlinear or nonparametric regression models may also be evaluated. A new study area may be selected with more homogeneous or heterogeneous landscape features. An important task of the present study was to observe the variation of correlation analysis for LST–NDVI and LST–MNDISI relationships in multi-date imageries. Hence, areas having extreme climatic conditions (hot, cold, wet or dry) may also be recommended for the future examination.

Automatic Robot Processing Using Speech Recognition System

S. Elavarasi and G. Suseendran

Abstract Nowadays, speech recognition is becoming a more useful technology in computer applications. Many interactive speech-aware applications exist in the field. In order to use this kind of easy way of communication technique into the computer field, speech recognition technique has to be evolved. The computer has to be programmed to accept the voice input and then process it to provide the required output, using various speech recognition software. Speech recognition is the process of converting speech signal to a sequence of words using appropriate algorithm. This provides an alternative and efficient way for the people who are not well educated or not having sufficient computer knowledge to access the systems and where typing becomes difficult. This speech recognition technique also reduces the manpower to accept and process the commands. In our research work, we have to implement this speech recognition technique in customer care center, where many queries have to be processed every day. Some of the queries are repeated often and the responses also seem to be the same. In such cases, we have to propose a methodology to automate the query-processing activities using this speech recognition technique. The ways of how to automate the system and how to process the queries automatically are explained in our methodology with suitable algorithm.

1 Introduction

In this decade, people want to make all the actions to be carried out in a much easier and faster way. In order to accomplish this, most of the things have to be modernized and computerized to perform the action efficiently. As the new trends emerge in each and every field, things have to be changed to accommodate the trend. In such a way, many new technologies have emerged in the computer field also. One such technology is *speech recognition* or *voice recognition.*

Speech recognition is a technology that has emerged in order to make easier the process of providing the requirements to the system by the user through speech rather than text. That is, speech recognition accepts the user's spoken words as input and then translates the words to appropriate text or commands to accomplish the task. It is also called as a software to accept and understand dictation to undertake the commands. While accepting the voice input, the system also gathers the information such as gender, expression or emotion and in some cases, the identity of the speaker. Thus, speech recognition converts the speech to text, and so it is also termed as *automatic speech recognition* or *ASR* or *speech to text.* This is also a potential for human–computer interaction.

Speech recognition is mostly used in many areas, since it is more useful for those who are not well educated or not having sufficient computer knowledge. The essential requirement for the user is to have sufficient language skills and proper pronunciation efficiency such that the user is able to process the commands. The major research challenges in this area are noise, speaker variation, language variation and vocabulary (Fig. 1).

While designing the speech recognition system, the researcher requires providing special attention toward the challenges:

- Speech module and illustration
- Speech pre-processing
- Feature extraction
- Database maintenance
- Performance evaluation.

In recent years, the enhancement and effective progress of speech recognition technology have been implemented in many areas to simplify the process of user requirements and to improve the performance. Some of the applications are:

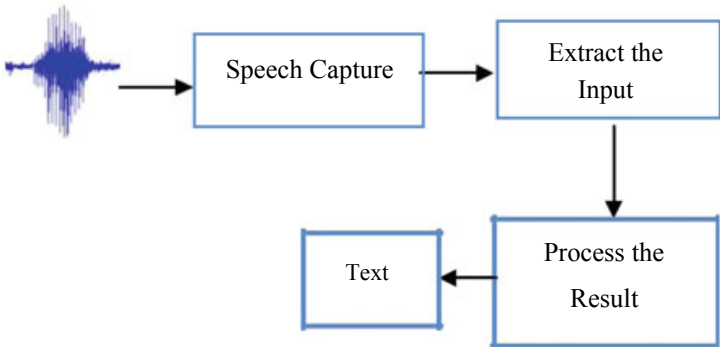

Fig. 1 Speech to text conversion

- Aerospace
- Automatic subtitling
- Hands-free computing
- Robotics
- Video games and so on.

In our research work, we have to implement the speech recognition technology in *customer care service* area to improve the customer satisfaction and experience some pre-defined operations with reduced manual efficiency. The major premise is to promote better customer service and to improve customer relationships.

Customer care service is the act of taking care of customer requirements by offering and delivering high-quality service in a short period of time. In order to provide such kind of response, more manual power has to be empowered. To avoid this dilemma, we have to provide suitable methodology to accomplish the process of responding the customer requirement through speech recognition technology automatically. This paper describes the development of an efficient speech recognition system over customer care service using various technologies.

Gupta et al. discussed that with development in the requirements for installed figuring and the interest for rising implanted stages, it is necessary that the discourse acknowledgment frameworks (SRS) are accessible on them as well. PDAs and other handheld gadgets are ending up increasingly ground-breaking and reasonable also. It has turned out to be conceivable to run interactive media on these gadgets. In that paper, different methods about discourse acknowledgment framework were discussed. Likewise, it displayed the rundown of procedure with their properties of feature extraction and feature coordinating. Through this audit paper, it is discovered that MFCC is generally used to include extraction and VQ is better over DTW [1].

Singh et al. expressed that using fake neural systems (ANNs), numerical models of the low-level circuits in the human mind, to enhance discourse acknowledgment execution, through a model known as the ANN-hidden Markov model (ANNHMM) have indicated guarantee for expansive vocabulary discourse acknowledgment frameworks. Accomplishing higher recognition precision, low word mistake rate, creating discourse corpus relying on the idea of dialect and tending to the issues of wellsprings of fluctuation through methodologies like missing data techniques and convolutive non-negative matrix factorization are the significant contemplations for building up an effective ASR. In this paper, an exertion has been gained to feature the ground made so far for ASRs of various dialects and the mechanical viewpoint of programmed discourse acknowledgment in nations like China, Russian, Portuguese, Spain, Saudi Arab, Vietnam, Japan, UK, Sri Lanka, Philippines, Algeria and India [2].

Arora et al. endeavored to portray a writing audit of automatic speech recognition. It talked about past years' propels gained in order to give ground that has been

refined here of research. One of the vital difficulties for scientists is ASR precision. The speech acknowledgment system centers around troubles with ASR, essential building squares of discourse preparing, highlight extraction, discourse acknowledgment and execution assessment. The primary target of the survey paper is to expose the advancement made in ASRs of various dialects and the mechanical perspective of ASR in various nations and to thoroughly analyze the procedures used in different phases of speech acknowledgment and recognize the examined subject in this testing field. They are not displaying comprehensive depictions of frameworks or numerical definitions, yet rather, they are introducing unmistakable and novel highlights of chosen frameworks and their relative benefits and demerits [3].

Rashmi conveyed a review of various calculations that can be used in discourse acknowledgment in light of the points of interest and disservices. Likewise, it helps in picking the better calculation in light of the examination done [4].

Gamit et al. depicted that speech acknowledgment is the procedure of consequently perceiving the talked expressions of individual in view of the data content in discourse flag. This paper presents a concise overview on automatic speech recognition and examines the different characterization procedures that have been refined in this wide region of discourse handling. The target of this survey paper is to outline a portion of the notable strategies that are broadly used in a few phases of discourse acknowledgment system [5].

Shaikh Naziya et al. examined about speech advances that are limitlessly used and have boundless employments. These advances empower machines to react accurately depending on human voices, and give helpful and profitable administrations. The paper gave a diagram of the discourse acknowledgment process, its fundamental model, its application and approaches, and furthermore, examined near investigation of various methodologies that are used for discourse acknowledgment framework. The paper additionally gives a review of various strategies of discourse acknowledgment framework and furthermore demonstrates the rundown portion of the notable techniques used in different phases of discourse acknowledgment system [6].

Navneet et al. introduced the programmed discourse acknowledgment framework and examined the significant subjects and advances made in the previous 60 long stretches of research, in order to give a mechanical point of view and energy about the principal advance that has been proficient in this vital region of discourse correspondence. Following quite a while of innovative work, the exactness of programmed discourse acknowledgment stays as one of the imperative research challenges. The outline of speech recognition framework requires watchful considerations to the accompanying: definition of different sorts of discourse classes, discourse acknowledgment process, ASR configuration issues and discourse acknowledgment strategies. The target of this audit paper is to outline and look at a portion of the notable techniques used in diverse periods of talk affirmation system and perceive an investigation on subject and applications which are at the front line of this stimulating and testing field [7].

Lawrence et al. looked into some of the significant features in the innovative work of programmed discourse acknowledgment amid the most recent couple of decades to give a mechanical point of view and a valuation for the principal advance that has been made in this imperative region of data and correspondence technology [8].

Prabhakar et al. gave a description of major inventive perspective and valuation for the vital progression of talk affirmation; gave graph technique made in each period of talk affirmation, besides condense; took a gander at changed talk affirmation systems; and perceived an investigation on subjects and applications which are at the front line of this stimulating and testing field [9].

Bhavneet Kaur gave a concise presentation of SRS portraying how the innovation functions, and after that, talks about the general engineering of SRS, strategies, benefits of using this framework, major mechanical point of view and valuation for the principal advancement of discourse acknowledgment. It gives a way to deal with the acknowledgment of discourse flag using recurrence ghastly data with Mel recurrence for the change of discourse that includes portrayal in a HMM-based acknowledgment approach, and furthermore, gives a review of strategies created in each phase of discourse acknowledgment alongside the momentum and explores future options on the same. This paper depicts the real difficulties for SRS framework which have been went over by clients' criticism and different examinations, which must be settled as quickly as time permits for better execution outcome [10].

Swati Atame et al. discussed that one of the technologies used in these fields is automatic singer identification, which is used to recognize from features of the audio signal, the singer of the song or who is the one who is singing, and the genuine singer [5]. This same area of singer identification and recognition can be used in the bioinformatics whereby the voice of the singer is used to gain access to a particular singer. The system would be very much useful to singers of the song who are actual singers and also to the common man who can store their speech and can later use this input signal to access the system. For the professional singers, there are many possibilities that the original singers' voice is get mimicked which may in this situation lead to pirated copies of the voice of the singer which are then sold into the market [11].

Hori et al. exhibited strategies for discourse-to-content and speech-to-discourse programmed synopsis in light of discourse unit extraction and connection. For the previous case, a two organized outline strategies comprising essential sentence extraction and word-based sentence compaction are examined. Sentence and word units which augment the weighted total of etymological probability, measure of data, certainty measure and linguistic probability of linked units are separated from the discourse acknowledgment results and connected for star ducing outlines. For the last case, sentences, words and between-filler units are researched as units to be removed from unique discourse.

Renals et al. portrayed the advancement of a framework to translate and outline voice messages. The consequences of the exploration introduced in this paper are two overlays. Initially, a cross-breed connectionist way to deal with the voicemail interpretation undertaking demonstrates that focused execution can be accomplished using a setting autonomous framework with less parameters than those in view of blends of Gaussian probabilities. Second, a successful and vigorous blend of factual with earlier learning hotspots for term weighting is used to remove data from the decoder's yield keeping in mind the end goal to convey rundowns to the message beneficiaries by means of a GSM short message service (SMS) entryway [12].

3 Proposed Methodology

3.1 Proposed Method

Speech recognition has been the most explored point since mid 1960s and is a standout among the most famous and dynamic territory of research. In speech recognition, there exists lot of fields for research such as:

- Speech recognition
- Speaker recognition
- Speech conversion
- Feature extraction
- Noise reduction.

Speech recognition is used in many applications since it does not need any syntax, procedure or coding to access the commands. It just simply accepts the spoken words as input and then translates it into appropriate text to perform the task. Thus speech recognition technology has unlimited users with exciting range of tasks. The main theme of the speech recognition technology is to "*listen*", "*identify*", "*understand*" and "*respond*" to the spoken information. It has the potential to act like an interface between the humans and computer, that is, human–computer interface.

In our research work, we choose this speech recognition technique to be implemented in a customer care organization in order to provide better performance in a short period of time. In customer care organization, they have the task of providing response for the queries submitted by the user. The queries may be of different types such as account details, server problem, server restart, password reset, account lock, account balance, account transaction and last transaction.

In some situations, the customer may submit the queries continuously, for which the executive provides response for it. Some of the queries may be repeated often that the executive must be processed every time. In this case, it requires huge manual power with 24 $\times$ 7 services and high cost.

In order to overcome these circumstances, we have to propose a methodology to automate the process of providing responses for the queries with some pre-defined activities. This has to be carried out by programming the customer care server with some set of instructions with appropriate keywords in the database. The methodology can be executed as follows:

When the customer calls for sending query, the server accepts the query as voice input and records it. Upon receiving the input, the server converts the voice input into text and then starts to search in the database for the keyword found in the text. As a result of this database search, the appropriate instructions for the query have been found from the database, and the response to it is sent to the customer. Thus, the query has been automatically processed by the speech recognition technology like ROBOT processing, and hence our methodology can also be termed as automatic ROBOT processing (ARP) (Fig. 2).

In case the customer needs to change his/her password means, it comes under the category "*Password Reset*". The customer first calls the customer care service and asks for password reset through voice command as: "*I Need Password Reset*". This command has been recorded by the server and then processed to convert into text. Then the server starts to search from the database for the keyword "*Password Reset*". In database, there exist several instructions for the password reset category that are to be programmed by the programmer to process the request in an appropriate manner.

In that database, if there exists as "*Please tell your Username*" and "*Please tell your Date of Birth*" for "password reset" category, then the server gets the instructions and converts it into speech and then transfers to the customer as to submit their username and date of birth through speech. Upon receiving the details from the customer, the server starts converting the details into text from speech and then validates the details. Only if the information provided by the customer matches with the database, the server allows the customer to reset their password. Otherwise, he/she has to be denied (Fig. 3).

Thus, the small pre-determined activities in the customer care service have been automated with the speech recognition technique to simplify the process and to reduce the manual power. It also reduces the cost of processing the pre-determined

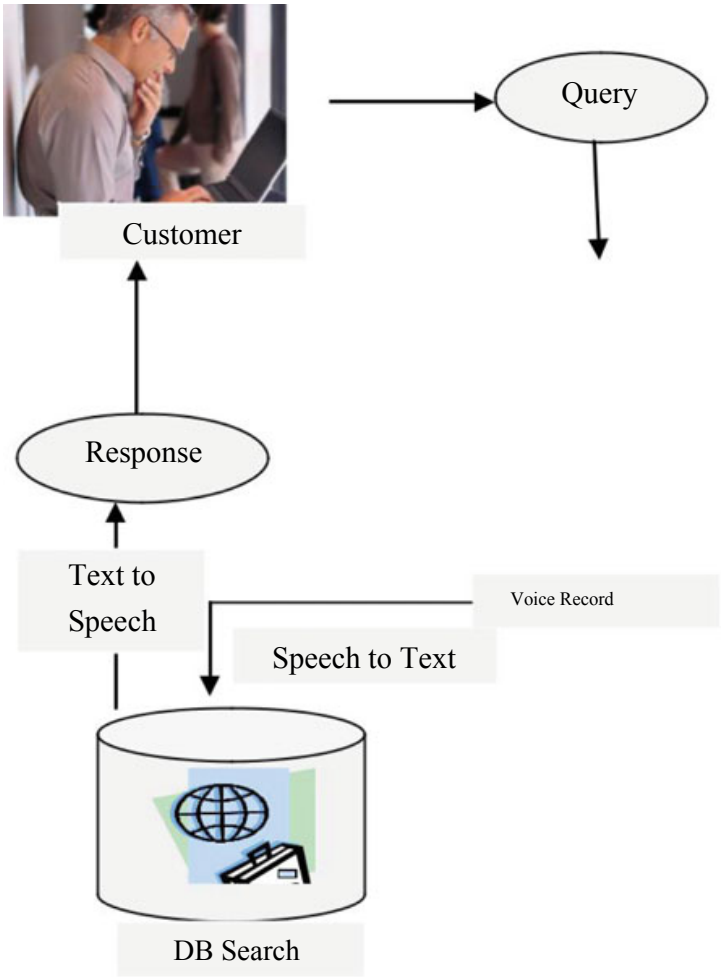

Fig. 2 Processing the customer query

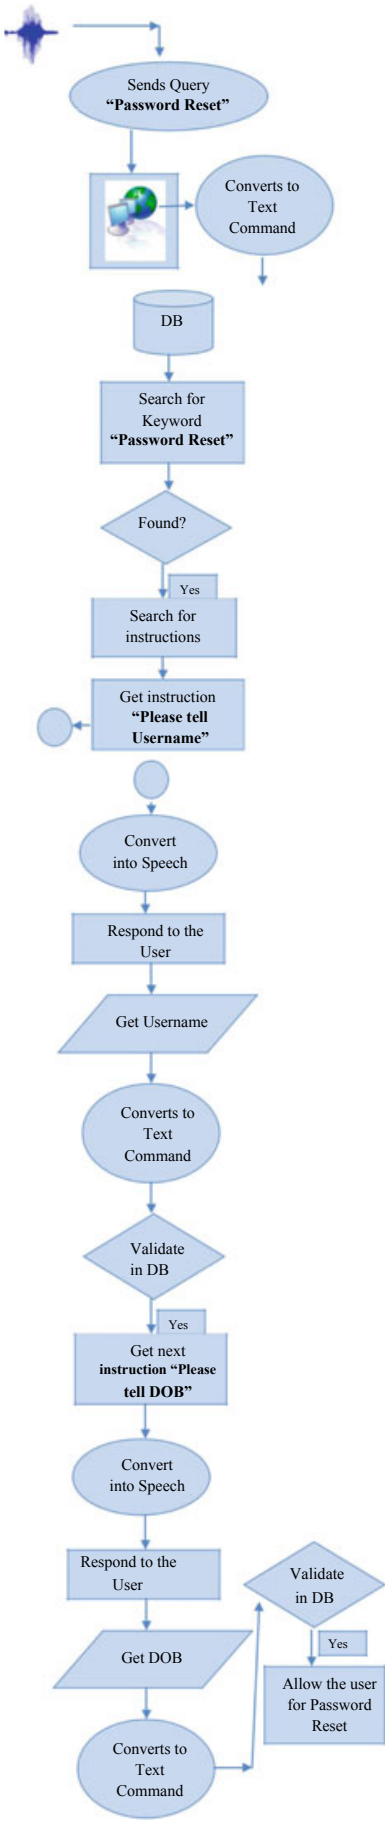

Fig. 3 Processing query for password reset

repetitive query processing. This kind of automatic processing the customer queries resembles ROBOT-type processing and thus we termed our methodology as ***automatic robot processing (ARP)***.

Along these lines, our proposed strategy acknowledges the voice information and follows the procedures to process the client inquiries effectively. The proposed strategy comprises a calculation to depict the stream of the procedure.

3.2 Algorithm-The Flow of Automatic Robot Processing (ARP)

B. Algorithm- The Flow of Automatic Robot Processing (ARP)

```
Begin
Load the server with Voice Recognition Software
 Load Database with instructions for Query Processing
If customer enters then
do
  Get the voice Command
  Translate the Voice Command to Text Command
  Search for relevant keywords
  Get appropriate instructions from the database
  Translate the instructions into speech commands
  Responds the customer with the speech command
until the query processing ends
End If
 End
```

4 Experimental Setup and Performance Metrics

We have to evaluate the performance of our proposed methodology in order to prove that our ARP query processing performs better than the existing techniques. This has to be carried out by taking some set of queries, and those queries have to be processed both manually and through our proposed ARP algorithm. The performance ratio is analyzed and the result has to be tabulated in order to prove that our ARP algorithm performs much better than the existing technique. While the

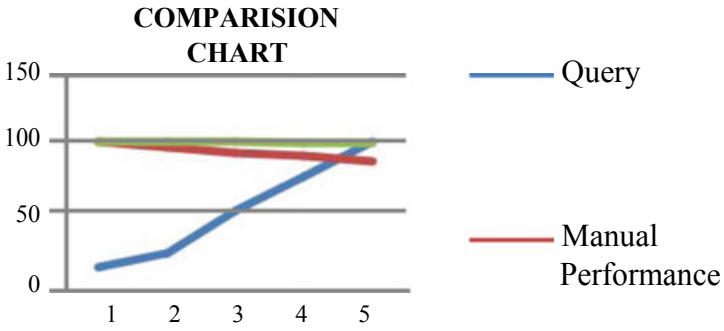

Fig. 4 Comparison chart

Table 1 Comparison results

Query	Manual performance	ARP performance
10	100	100
20	96	100
50	92	99.5
75	90	99
100	86	98

queries have to be processed manually, as the number of queries becomes increased, the ratio of performance seems low. However, when the queries have to be processed through our proposed algorithm, the performance becomes invariable. The results are tabulated and the comparison chart is shown below. With these results, it becomes clear that our ARP algorithm performs better and the queries are processed successfully (Fig. 4; Table 1).

5 Conclusions

Speech recognition is one of the most assimilating areas of artificial intelligence. This speech recognition technique helps the people who were uneducated or not having sufficient English knowledge or computer knowledge. After undertaking deep research, it has been proved that speech recognition has made a role for handling the speech-oriented activities and has been seen in many walks of life. In this computer world, various techniques are discussed about speech recognition system. This speech recognition is one of the most challenging problems to deal with. We have attempted in this paper to provide a solution to automate some pre-defined activities in the customer care organization. We also provide suitable algorithm to process this robot processing. In this case, it seems easy to access the queries in customer care center without any manual resources.

In future, our approach must be improved with much propelled route in order to handle more operations automatically with reduced manpower.

Banking and FinTech (Financial Technology) Embraced with IoT Device

G. Suseendran, E. Chandrasekaran, D. Akila and A. Sasi Kumar

Abstract In recent years the traditional financial industries have motivated for a new technology of financial technology (FinTech) clinch embraced with internet of things (IoT). The requirements of FinTech and IoT need to be integrated into new business environment. Several companies are affected because of the financial-level investments. So, there is a need to improve the next level of the business. FinTech can introduce a new service of tools and products for the emergent businesses through the internet of services which provide ideas linked in internet. Nowadays, increasing number of companies uses the IoT and creates new added values. The administrators of existing money-related organization in the direct society are dreadful by means of budgetary innovation. The social innovation is accomplished by new innovation. To make a powerful business plan and action, the FinTech and IoT are combined in order to create new innovative ideas based on the requirements.

1 Introduction

The current generation is surrounded by smart phones, which connect devices working from home, public places and office, colleges, schools and everywhere. The consumers use this opportunity to work smarter with the help of internet of things (IoT). Banking, finance and insurance companies are easily embraced with IoT devices. The banking and financial sectors create a new way of collecting the valuable information about the customer through IoT sensor devices using smart phones. FinTech is similar to electric vehicle innovation which works with capital valuation, trading, investment and asset valuation, and provides new improving accounting systems when compared to existing financial technology. Financial engineers handle hundreds of millions of datasets. It is not easy for them to maintain all the data. So FinTech is adapting to a larger field of the IoT and will transform all the customer information to cloud using IoT devices. Most of the banking and financial sectors can rapidly improve in e-commerce by connecting cloud business through the profitable offerings of business tactics, where the cloud is stored with a lot of customers' data. In recent years, all the banks are communicating with the customer through smart phones, social networks and any new sensors, in financial technology to create some new industries [1].

1.1 IoT-Aided Banking Services

The internet of things is a big approach in financial services. The IoT connected to the concerned bank through the internet will send and receive data that are stored in cloud. Figure 1 explains the details of the customer, bank and IoT transactions [2].

Around the world, billions of devices are connected with each other. These devices share the information on the cloud with the permission of the bank and allow the entire customers to view the account details and provide access power while using smart devices. It is the easiest way of communicating with the customer and also conveying the personal information through messages and alerts awaiting works.

1.2 Benefits of IoT in Banking Services

The most important benefit of IoT in banking services is providing the credit and debit cards for easy access of the services of the banks. Also, the bank can analyze the usage of ATMs in the specific area to increase and decrease the installations of ATMs. While using IoT device, all the customer information are stored in the devices. So, the bank uses this opportunity to help in identifying the customer's business needs, like supplier, retailer and distributors [3]. Figure 2 shows the details of the bank providing valuable services to a customer.

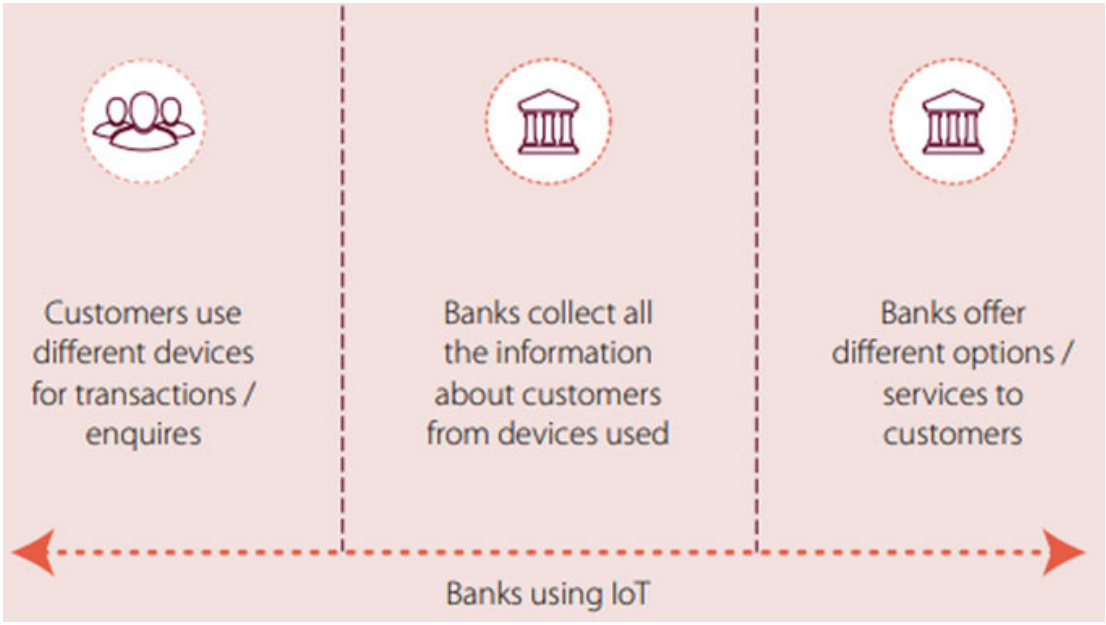

Fig. 1 How to connect customer, bank and IoT devices

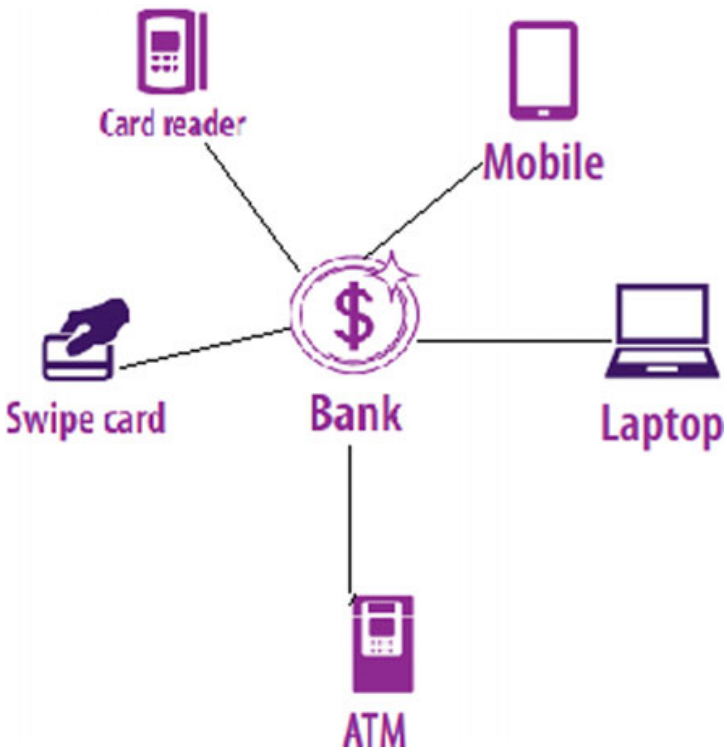

Fig. 2 Bank providing valuable services

2 Cyber Security in the Banking and FinTech on IoT

The banking and financial industry is the main target of cyber attacks. In this network world, personal data are easily accessed by the attacker. So, cybercrime is feared all around the world today. We will protect the cyber security in the banking and FinTech services industries. In Fig 3 IoT connects device through the internet and then connects to the FinTech, cloud, machine learning and industrial productivity.

Cyber Attack

Cyber attack is a careful mistreatment of a computer system, technology and networks. The hacker uses malicious code or software to alter the system and secrete code that can compromise the data to cybercrimes, such as health care documents, banking accounts details and hacking lock of the system.

As we are increasing the use of IoT connecting devices in the banking sector, the risk of cyber attacks also increases. The IoT connecting device communicates, analyzes and presents some new ways for technology. It is not only the data but other kinds of sensitive information are also shared through the IoT. Hence the risks are exponentially high [4].

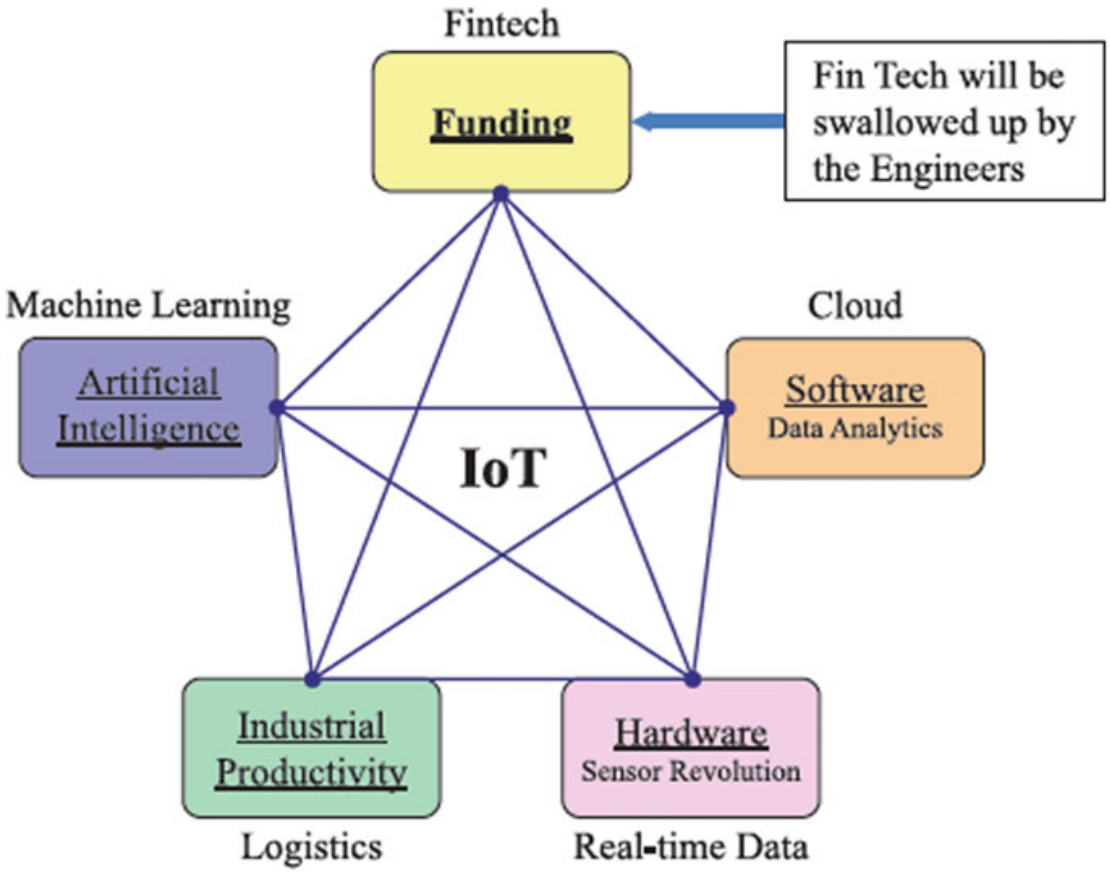

Fig. 3 Internet of things

Unencrypted Data
The data breach happens due to improper encryption, and the stolen data have immediate access.

Unprotected Third-Party Services
The internet services are an extremely worldwide connector; therefore, the cyber attacker can easily access the data of the targeted user, because third-party services are unprotected.

Unsecured Mobile Banking
In recent years, mobile banking users have increased. Using this opportunity, the mobile hacker accesses the data due to small computation time. For securing the data in mobile banking, a cryptography method of encryption and decryption is used.

A Constantly Changing Treat Landscape
In the past few years, cyber threat landscape has changed the financial services. Cybercriminals must change the low-value payment into high-value payment. So, a number of breaches affect the financial sector.

False-Positives
Anti-money laundering (AML) monitoring system is false-positive. The issue will point out the fake activity accessing time and calculated with the help of an analyst.

The Big Breach
The huge volume of financial data is increasing the risk on customers' security from hackers and cybercrime as it occurs at the night time. So beware of the breach in banking sectors.

These are major cyber security threats in banking and FinTech [5].

3 Challenges of Banking and Financial Institutions

Mainly four challenges are faced by banks and financial industries which respond consumer expectations, heavy competition on financial companies, regulatory pressure and not making enough money [6, 7].

i. **Not making enough money**
Many of the banks run on unprofitability because the financial industry is still not making enough return on investment.
ii. **Consumer expectation**
Many bank employees are feeling at most pressure because the expectations of the consumer are high. To maintain the standard they need to work hard which leads to the pressure.

iii. **Increased competition from financial technology companies**
FinTech companies is using the start up business to provide financial services to technologies. FinTech is a big challenge because of using a traditional banking system. They can change the modification and technical operation quickly, and another backup process is handled.

iv. **Regulatory pressure**
The bank requirements are continuously changing and because of that banks invest a lot of amount in some other business. So, the system processes to keep up with the higher goal requirements.

4 New Tools and Product for FinTech Sector

Traditional financial sectors are lacking because of some redundant files and were forced to move with the new tools and new products. With the advantages from new technologies, which are requirements, design and modeling, investments and delivery models are merged with IoT through the internet facilities. Table 1 lists out the new tools and products that are developed and developing in the financial sector. In 2018, 15 top Indian financial markets had radical transformation by technology and innovation in India. The FinTech sector in India with USD 1.2 billion in the year 2016 is expected to touch USD 2.4 billion in the year 2020. **MobiKwik**—Indian digital wallet company, **Capital Float**—digital financial company serving businesses, **Bank Bazaar**—online marketplace for bank loans, credit cards and insurance policies, **Incred**—web-based financial services, **PolicyBazaar**—online insurance aggregator, **Fino Payments Bank**—providing a

Table 1 New tools and product of FinTech company [9]

S. No.	FinTech sector	New tool	New products
1	Banking	Improved loan risk Monitoring Emp Debt Profit Analysis of SMS lending Financing failing applications	Record keeping with sensors Factoring and leasing Trade finance and energy finance Security for accounts Goolglization of accounts
2	Wealth management	Real-time IoT data for stocks IoT as main source for ideas IoT replaces bond derivatives	Telematics as a metric for start ups Link health monitor to wealth management Data to profit customer
3	Insurance	Insuring in high-risk areas Sensors data for smart payload Unbiased vehicle data	Pricing assets in risk-prone areas Accurate pricing product liability Weather detection reduces claims
4	Capital market	Leveraging IoT for crowd investing Block chain IPOs	New commodity data streams New banks for public access to capital

technology solutions for institutions like banks, governments and insurance companies, **CCAvenue**—popular payment gateway, **Razorpay**—a product suite that manages the entire payments lifecycle for all business are the topmost FinTech companies in India [8].

5 Use Cases of IoT—Digital Future

In banking, IoT is interconnected with connecting devices; the system that provides services does machine-to-machine (M2M) communications and is connected to lot of protocols, domains and applications. The IoT has impacted the traditional financial process such as trade financial, payments, personal financial management (PFM) and insurance [10]. There are many use cases that can be implemented in banking in the period ranging from small to long term (Fig. 4).

5.1 Account Management on Things

Biometrics (voice/touch) can make the accounts' access anywhere simpler through the digital channel. Using the new technology called Wet Ink, the customer can sign in remotely through any touch screen gadget and can be marked promptly onto physical paper with Wet Ink.

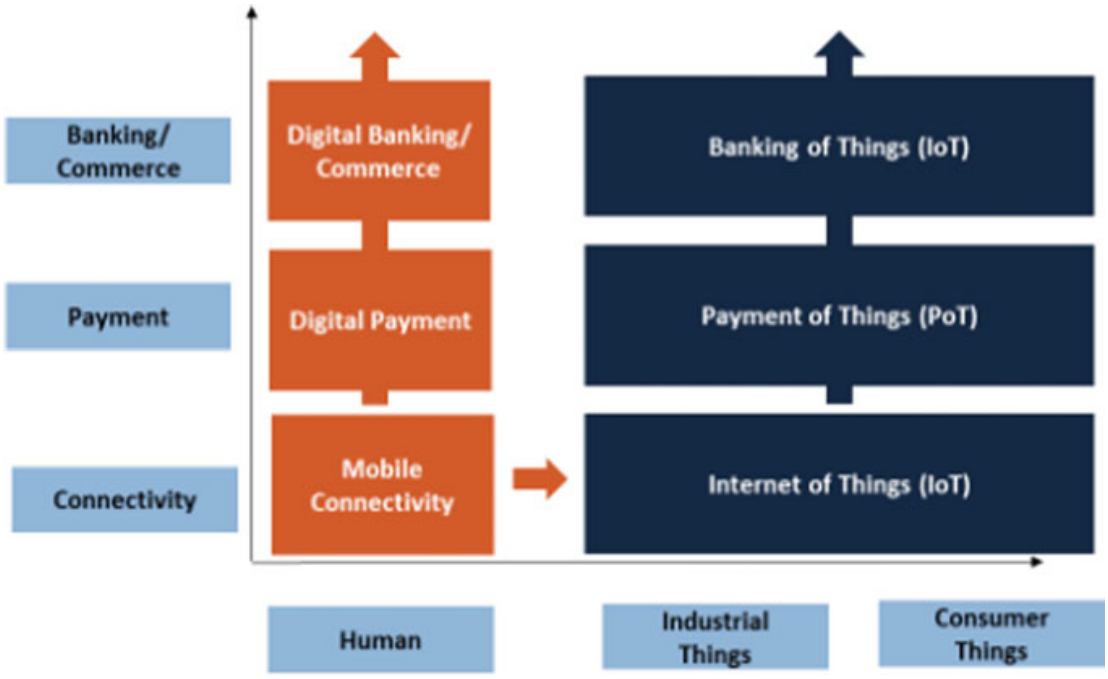

Fig. 4 IoT enabling banking of things in digital future

5.2 Leasing Finance Automation

New daily leasing models have enabled the digital assets worldwide and are effectively turning the traditional products and its services. For delineations, the rented resources could be bolted or debilitated remotely by the bank.

5.3 Smart Collaterals

An IoT device can empower the money-related banks to all the more likely command over client hypothecated resources, for example, observing their wellbeing, autos and home. Financial offerings such as manufacturing machinery, cars, building home loans as collaterals are provided in short term and can be done in a digital way automatically. For representations, in the event of EMIs are not paid, the motor can be impaired and the nature of security can be observed continuously.

5.4 Automated Payment Through Internet of Things

The traditional banking of payment transaction is automated and integrated of services. IoT can raise some conditions on security concerns and digital security in payments. So, the customer can do the payment transaction automatically like one bank to other bank or one bank to other companies.

5.5 Risk Mitigation in Trade Finance

High estimation of products are utilize the RFID monetary space. With the help of IoT the shipments including the delicate merchandise are monitored for example, restorative atoms. These executions of the hazard are relief and more educated choices at banks for including exchange back.

5.6 Wallet of Things

Wallet is associated with each device, where more devices have become digital and smart and that all banks have automated payments through IoT. For example, upkeep administrations utilizing wallet automatically can be stopping the payment transactions.

6 International Global Fintech Benchmark Report 2017

An international global FinTech benchmark report led an online review on FinTech chiefs from monetary establishments around the globe. An in-depth interview was conducted among senior executives from leading FinTech companies (Fig. 5).

FinTech technologies will come to emerging with Amazon, Google and business-based platforms by the next three years. From overview reacting investigation and huge information be arranged anticipated that would a large portion of consideration. 76% of back up plans, 65% of banks and 58% of advantage administration organizations are positioned the information examination as one of the best most FinTech advancements. Moreover, application programming interface advancements and mechanical autonomy and robo-guides are positioned in the high range of the world wide. Figure 6 shows the rising of FinTech with more enthusiasm in the upcoming next three years [7].

Insurance companies are more intent towards IoT because all valuable information and pricing are provided to the customer. The IoT connecting with the insurer person and his information from risk partners. On the off chance that any

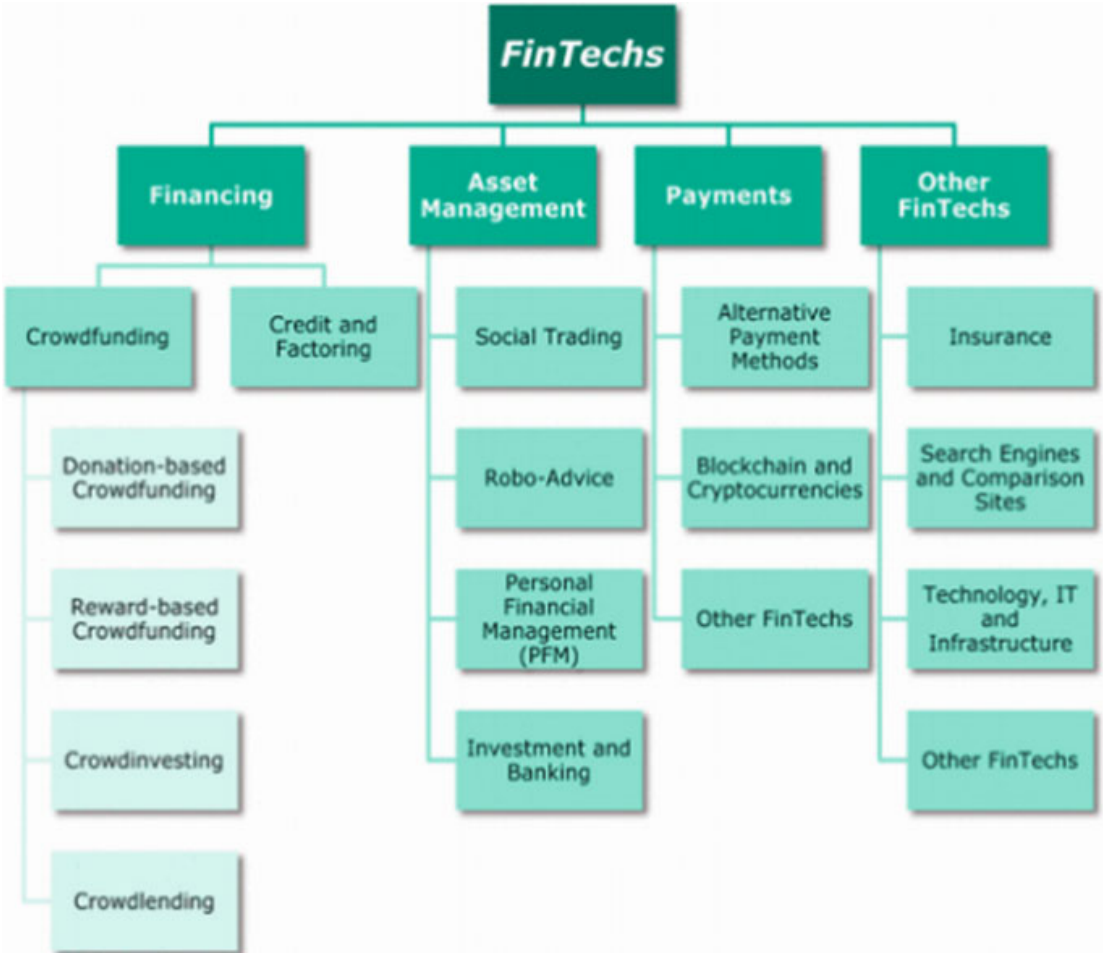

Fig. 5 Segments and elements of FinTech

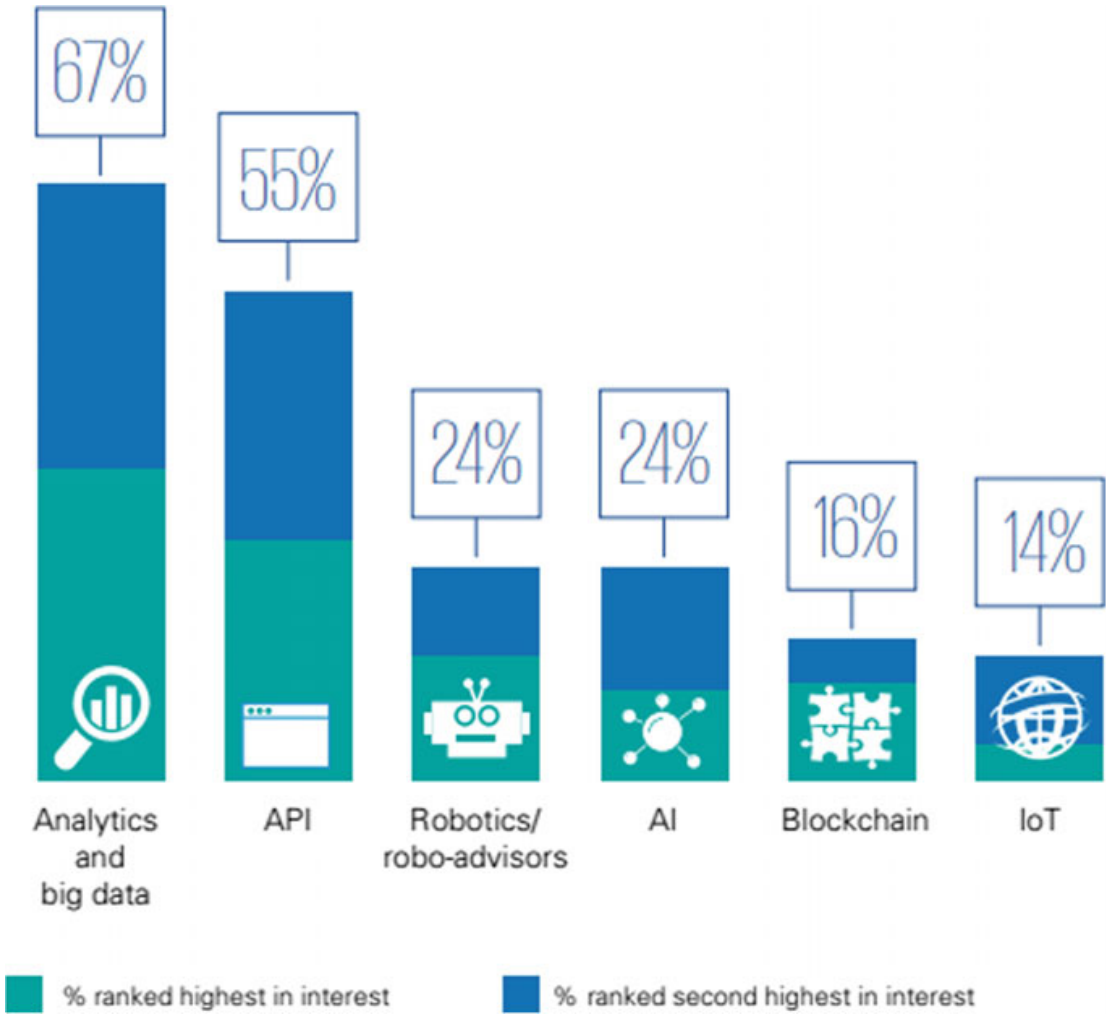

Fig. 6 Emerging FinTech in next three years in the field

mishaps to giving security after the occasion as a case. 36% resource administration organizations additionally positioned man-made consciousness as a best of advancements of intrigue. Safety net providers have more grounded enthusiasm for advances identified with IoT at that point banks or resource administration organizations.

In the course of recent months, the square chain has essential measurement of consideration. It was anticipating the high positioned organizations in the benefit administration. But, it was just 35% positioned zone intrigue.

7 Analysis and Discussion

For this part of work all information and data are collected from various research articles and magazines, and these data were discussed and investigated in this section. We divided the analyses into two categories: the first part is the status of

FinTech block chain and crypto currencies. EU, USA and India have how alternative payment methods and investment are to be demonstrated. Banking is providing positive characteristic as well as negative characteristic using FinTech global financial service sector elements [11].

7.1 FinTech Current Status and Positive Characteristics

FinTech is an imperative piece of open monetary administration segment. It gives information on monetary and keeping money of conventional individuals. The prospect getting diverse sorts of money related administrations. The fiasco and the wretchedness in all the three locales, for instance, the EU, USA and India, did negative effects and impacts on the advancement and interruption in the monetary administration sector [12].

The new FinTech companies are using block chain innovation that has given the opportunity and benefits for more money transaction related administrations. The term digital revolution was reported by Accenture in 2015.

According to Table 2, the Luxembourg is in the top position in digitalization index of 1.00 and USA has 0.92 in digitalization index, which means this is closing to reach the full potential value, and EU also has the average range digitalization value of 0.62, which means the EU member countries are positioned with different values. But India is lagging in digitalization world as it has the value 0.29 and positioned 83rd in the digitalization index.

The FinTech companies bid these services at a lower level price compared to traditional financial service sectors because fully automated technology accessing the operation and process work completely or partially. The motivation or main concept of FinTech service is to reduce the human errors and increase banking business transaction and accessing. In this system automatically applicable by India. India will reached the highest digitalization index ranking position when compared to EU and USA ranking level.

7.2 Fintech Current Status and Negative Characteristics

They are many positive characteristics identified by the people, which are block chain and crypto currencies, an alternative payment system and FinTech technology and banking solutions. Nevertheless, the treats related to the FinTech essentials are really negative effects in the FinTech financial service sectors. The negative elements are due to affecting the FinTech operations and that related process failed incompletely. That's why India is not able to develop it, while the EU and USA quickly increased the work regularly.

Table 2 BBVA digitalization index 2015 [13]

S. No.	Country	Index	S. No.	Country	Index
1	Luxembourg	1.00	44	Kazakhstan	0.47
2	United Kingdom	0.97	45	South Africa	0.47

41	Cyprus	0.48	84	Senegal	0.24
42	Hungary	0.48	85	Guatemala	0.22
43	Uruguay	0.47	86	Ukraine	0.21

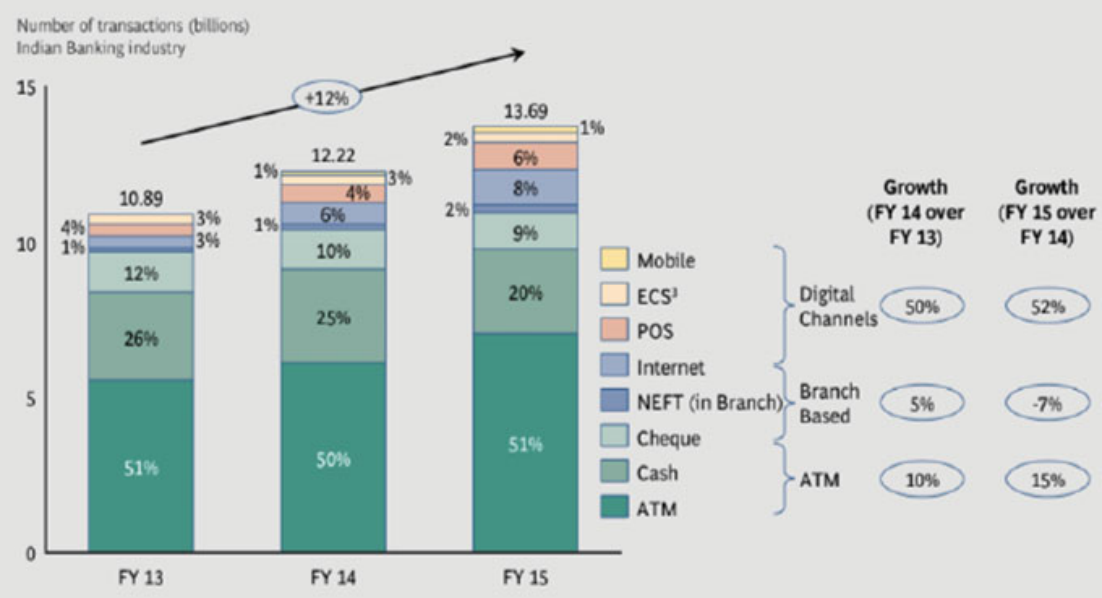

Fig. 7 Digitalization transaction of India in 2013–2015

According to the data, Fig. 7 displays the digitalization transaction in India's growth; however, the Billon Eco System (BCG) research in India that surveyed the ATM mobile transaction and withdrawal transaction at ATM, NEFT-based transaction in mobile, mobile internet and traditional transaction of cash and cheque and all our day-to-day our life usage showed 12% increase in the year 2013–2014 and also in 2014–2015; so, year by year as we increase FinTech operations, banking financial services also increased [14].

This is very a good example of block chain and crypto currencies method. The customer will need to safety for payment transaction because the hackers follow to your regular work. This cyber security and data privacy also comes from the USA and EU. The regularly EU, USA and India using the FinTech methods and block chain Methods for money transaction [15].

8 Conclusions

In this study the overall functions of financial advanced technologies, challenges of banking and financial industries, cyber security of banking while connecting IoT through the internet to store the all information's on cloud and benefits of the FinTech while connecting IoT device have been described. In addition, the use cases of FinTech on IoT in digital society in futures are mentioned in detailed. All banks, financial industry, insurance companies are moved to automated technology that reduces the workloads and easy to mingle the customer activities. From authors' point of view, the FinTech embraced with IoT in future will boom the society into the next generation.

Big Data Management

GRNN++: A Parallel and Distributed Version of GRNN Under Apache Spark for Big Data Regression

Sk. Kamaruddin and Vadlamani Ravi

Abstract Among the neural network architectures for prediction, multi-layer perceptron (MLP), radial basis function (RBF), wavelet neural network (WNN), general regression neural network (GRNN), and group method of data handling (GMDH) are popular. Out of these architectures, GRNN is preferable because it involves single-pass learning and produces reasonably good results. Although GRNN involves single-pass learning, it cannot handle big datasets because a pattern layer is required to store all the cluster centers after clustering all the samples. Therefore, this paper proposes a hybrid architecture, GRNN++, which makes GRNN scalable for big data by invoking a parallel distributed version of K-means++, namely, K-means‖, in the pattern layer of GRNN. The whole architecture is implemented in the distributed parallel computational architecture of Apache Spark with HDFS. The performance of the GRNN++ was measured on gas sensor dataset which has 613 MB of data under a ten-fold cross-validation setup. The proposed GRNN++ produces very low mean squared error (MSE). It is worthwhile to mention that the primary motivation of this article is to present a distributed and parallel version of the traditional GRNN.

1 Introduction

The term prediction is used for regression as well as classification. When the target variable is discrete the associated task belongs to classification and when the target variable is continuous the associated task is a regression. The regression or forecasting model takes the past data to predict the target variable. There are different neural network architectures used for regression, namely, MLP, RBF, WNN, GRNN, and GMDH.

MLP has been used for regression in several research works, namely, Kusakunniran et al. [1] presented a gait recognition system based on motion regression using MLP; Agirre-Basurko et al. [2] suggested MLP to forecast gas levels; Gaudart et al. [3] performed a regression for epidemiological data using MLP.

Similarly, RBF also has been used for regression, namely, Mignon and Jurie [4] proposed a face reconstruction algorithm, based on RBF regression in eigenspace; Hannan et al. [5] presented heart disease diagnosis using RBF; Taki et al. [6] used RBF for energy consumption prediction for wheat production.

WNN is used for regression models for forecasting reservoir inflow [7]. Vinaykumar et al. [8] implemented WNN for the estimation of cost of software development; Chauhan et al. [9] used DE-trained WNN for bankruptcy prediction in banks. Rajkiran and Ravi [10] used WNN for predicting reliability of software.

In addition, GMDH is used for regression, namely, Astakhov and Galitsky [11] presented tool life prediction in gundrilling; Elattar et al. [12] used GMDH for short-term load forecasting; Srinivasan [13] used GMDH for energy demand prediction; Ravisankar and Ravi [14] implemented GMDH for bankruptcy prediction in banks; Mohanty et al. [15] used GMDH for prediction of software reliability; Reddy and Ravi [16] proposed kernel GMDH for regression.

The ANN with its vast variants of architectures have been implemented in different application domains, namely, wireless networks [17], robot manipulator control [18], wind energy systems [19], cancer prediction in healthcare [20], crop production [21], and business [22].

Among these different architectural variants of ANN, the GRNN architecture is preferable as it uses a single pass for learning, and being non-parametric estimation produces a good result. In this article, we have proposed a hybrid version of GRNN for prediction. The motivation and contribution for the proposed method are introduced in Sect. 2.

The paper is structured in the following way: Motivation and contribution are presented in Sect. 2. A literature review is presented in Sect. 3. The proposed methodology is described in Sect. 4. The system setup for conducting experiments is discussed in Sect. 5, and the information about the dataset used in the experiment is described in Sect. 6. The results and discussion are presented in Sect. 7. Section 8 concludes the paper with future directions.

2 Motivation and Contribution

We have presented in the introduction section the different ANN architectures for regression. Among them, GRNN is an optimal choice for exploration being a one-pass trainer and non-parametric estimator. According to Specht [23], if a large dataset is involved, we should have a process of clustering to have neurons in the pattern layer. But, clustering of massive data is not efficient enough through any standard clustering approach. Even if we opt for the parallel version of K-means, it is not efficient enough with respect to optimal clustering. Again, we find there is no published work involving prediction of large-scale dataset using the GRNN. These shortcomings and adversaries are the strong cause of the motivation for the current research work.

In this proposed work GRNN is used for prediction of the large-scale dataset. Here, we have used a clustering approach using K-means‖ [24] which is a parallel version of K-means++ [25] to reduce the pattern layer neurons. It is a variant of K-means which has optimal initial seed selection approach. The K-means‖ is embedded into the architecture of GRNN for carrying out clustering before the pattern layer and implemented in a parallel distributed computing framework of Apache Spark which is henceforth called as GRNN++. The GRNN++ has shown very high accuracy in the form of mean squared error. The hybrid architecture has proved the implementation of the best features of two worlds, that is, of clustering and regression.

3 Literature Review

There are several variants of K-means proposed in the literature by the research community. Also, a large effort has been dedicated toward parallelization of K-means algorithm. Zhao et al. [26] have propounded a MapReduce framework for parallel K-means. Liao et al. [27] have presented an improved version of parallel K-means using MapReduce and a method for selecting the initial centroids. The K-means++ [25] is optimized by the process of selection of initial cluster centers, but it has a major drawback as being sequential. This limitation restricts its application to the massive dataset. It has to perform k-passes over the dataset to figure out k initial cluster centers. This drawback is addressed by K-means‖ [24]. Apart from K-means, evolving clustering method is another clustering approach which has been parallelized by Kamaruddin and Ravi [28].

The regression has always been the fascinating area of machine learning, and different approaches have been presented by the researchers. One of the efficient neural network architecture for regression is GRNN [23] which has the advantage of non-parametric estimation along with one-pass of training. These advantages enable the GRNN to be faster with better accuracy. There are several contributions by the researchers in different applications areas using GRNN, namely, Leung et al.

[29] have forecasted exchange rate using GRNN; Kayaer and Yildirim [30] implemented GRNN for medical diagnosis of diabetes; Li et al. [31] implemented GRNN for image quality assessment; Li et al. [32] implemented GRNN with fruit fly optimization algorithm for power load distribution prediction.

But the primary disadvantage of GRNN is that all the training data should be stored in the pattern layer, which requires more computational time. Thus, results in an inefficient architecture for the large-scale dataset.

Some researchers have presented hybrid architectures, and those are generally found to be more efficient. Ravi and Krishna [33] implemented generalized regression with auto-associative neural network (GRAANN) for imputing missing values. Similarly, the hybrid architecture of auto-associative extreme learning machine and multiple linear regression proposed by Tejasviram et al. [34] has shown better prediction capability. Kamaruddin and Ravi [35] presented a hybridization of particle swarm optimization and AANN for one-class classification and had applied it to credit card fraud detection which had demonstrated good performance.

From the study of the related literature, we found that GRNN has not been implemented in a parallel distributed environment and is not able to handle large-scale dataset. So the current research work addresses the issue.

4 Introduction to Proposed Methodology: GRNN++

GRNN is not able to handle large-sized dataset without efficient clustering. It will raise memory issues and increase the execution time. These drawbacks are due to the incapability of the standard clustering approach to handle large-sized dataset. In the proposed GRNN++ method this drawback has been addressed. The GRNN++ is implemented with Apache Spark and HDFS. It has two components, namely, (i) K-means‖ clustering, and (ii) GRNN for prediction. The two components are introduced in the following two subsections.

4.1 K-Means++: An Overview

The K-means clustering algorithm has an objective of minimal intra-cluster variance; that is, the sum of the squared distance of the points belonging to a cluster from their cluster center should be minimum. The K-means chooses random initial "K" cluster centers and updates the cluster centers with iterations until there is no further change in the cluster center, and thus finds reasonable solutions quickly. However, it suffers from at least two major drawbacks: (1) the algorithm has the worst-case execution time which is super-polynomial of input size; (2) the formed clusters may not be optimal with respect to the objective function.

The K-means++ [25] has addressed the deficiency of optimal clustering by the introduction of a method for cluster center initialization before execution of the iterations of K-means algorithm. The K-means++ clustering algorithm using an innovative method for initial cluster center selection or seed selection was proposed by Arthur and Vassilvitskii [25]. The algorithm has the following steps:

K-Means++ algorithm:

Let D be the dataset of p points in R^d and $x \in D$. Let $d(x)$ be the smallest distance from any given data point to its nearest cluster center which has been already selected.

1. Select first center C_1 uniformly at random from D.
2. For each data point $x \in D$, compute $d(x)$ and take a new center C_i, with probability $\frac{d(x)^2}{\sum_{x \in D} d(x)^2}$.
3. Repeat Step 2 until k centers have been selected altogether.
4. Proceed with the iterations of the K-means.

4.2 K-Means‖: An Overview

The K-means‖ is the parallel implementation of K-means++. Say, there are n number of samples, and k initial cluster centers are needed. The K-means++ performs k number of passes to sample one initial cluster center in each pass. But, K-means‖ samples first center uniformly at random. Then, the next centers will be chosen non-uniformly with a given probability which is stochastically biased by the already chosen centers. This happens in a parallel way across all partitions. Thus, the so-obtained $O(k \log n)$ points are finally re-clustered into k initial centers for the standard K-means iterations.

4.3 GRNN: An Overview

GRNN [23] is a feed forward neural network having roots in statistics. GRNN represents an advanced architecture in the neural networks that implements non-parametric regression with one-pass training.

The topology of GRNN is depicted in Fig. 1 and involves four layers of neurons, namely, input, pattern, summation, and the output.

The pattern layer comprises training neurons. The test sample is fed to the input layer. The distance, d_i, between the training samples presents as a neuron in the pattern layer, and the data point from the test set used for regression is used to figure out how well each training neuron in pattern layer can represent the feature space of the test sample, X. This probability density is calculated with Gaussian activation function. Thus, the summation of the product of target value and the result of activation function

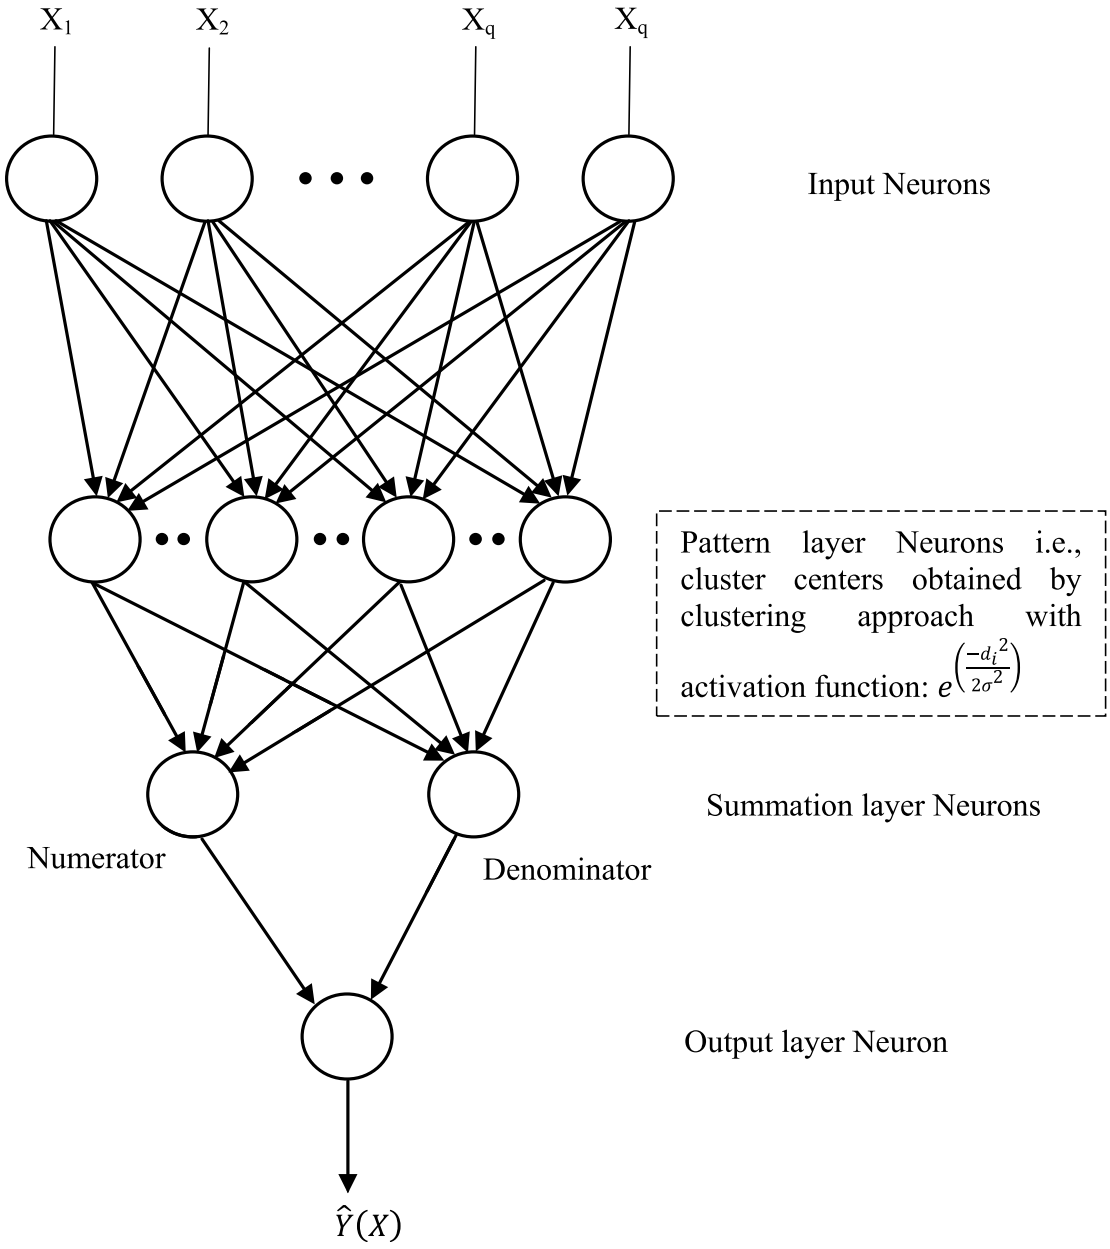

Fig. 1 Architecture of GRNN

for each neuron that is, $\sum_{i=1}^{n} Y_i * e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}$ forms the numerator term in the summation layer and the summation of the term $e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}$ that is, $\sum_{i=1}^{n} e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}$ forms the denominator term in the summation layer. Then, in the output layer, the prediction is calculated as $\widehat{Y}(X) = \frac{\sum_{i=1}^{n} Y_i * e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}}{\sum_{i=1}^{n} e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}}$. Here $d_i^2 = (X - X_i)^T * (X - X_i)$. X is a test sample and X_i is the neuron present in the pattern layer. For big datasets, the equations involved in

summation and output layer change to accommodate the information about the cluster centers. For further details please see the training algorithm presented in Sect. 4.4.

4.4 GRNN++: The Proposed Method

The training data is clustered with K-means‖. Thus, the cluster centers represent the data samples belonging to the cluster most effectively. Then the Dunn-like Index (a modified Dunn Index), a cluster validity index, is used for measuring the cluster validity.

The Dunn Index, proposed by Dunn [36], presents the approach for measuring the cluster quality so that the best clusters were selected based on the high compactness of clusters and high separation among them, that is, compact and well-separated clusters. The compactness with good separation is found by the ratio of minimum intra-cluster distance to the maximum inter-cluster distance. The Dunn Index can be presented as follows:

$$Dunn\,Index(D) = \min_{1 \le i \le M} \left\{ \min_{i+1 \le j \le M} \left(\frac{dist(c_i, c_j)}{\max_{1 \le l \le M} (diam(c_l))} \right) \right\}. \tag{1}$$

where M is the total number of clusters under consideration, $dist(c_i, c_j)$ is the inter-cluster distance and $diam(c_l)$ is the maximum intra-cluster distance or the largest diameter among all the clusters.

As the Dunn Index performs a calculation of maximum intra-cluster distance, that is, the diameter of a cluster under consideration, it is not suitable for large-scale dataset as it will involve large computational overhead. Also, it is affected by noisy data and outliers. So, we have used a Dunn-like Index [37] for cluster validity measurement. In this approach, the diameter, that is, the denominator of (1) is calculated by finding the radius using the distance from each sample present in the cluster to its cluster center, that is, $d\left(x, \overline{c_j}\right)$, where $x \in c_j$ cluster and $\overline{c_j}$ is its center. This Dunn-like Index is not affected by noise or outlier present in the data. The Dunn-like Index can be presented as:

$$Dunn-like\,Index(DL) = \min_{1 \le i \le M} \left\{ \min_{i+1 \le j \le M} \left(\frac{dist\left(c_i, c_j\right)}{\max_{1 \le l \le M} \left(2 * \frac{1}{|c_l|} \sum_{x \in c_l} d(x, \overline{c_l}) \right)} \right) \right\}. \tag{2}$$

The cluster centers form the clusters generated by the K-means‖ algorithm and validated by Dunn-like Index. They now represent the pattern nodes of GRNN++.

Then, each test sample is passed on to the neurons present in the pattern layer with a Gaussian probability density function resulting in higher value if the neuron has a strong similarity to the test sample. Now, the summation layer represents the numerator, denominator and the output layer presents the prediction as described in the overview of the GRNN section (refer to Sect. 4.3).

Training Algorithm for the proposed GRNN++

Step 1: Perform data normalization with the range [0,1].
Step 2: Divide the data to perform 10-Fold cross-validation.
Step 3: Take the training set and cluster them with K-Means|| with the k = 2 to 10.
Step 4: Compute Dunn-like Index by varying the value of k and find the k which produces optimal clustering.
Step 5: Consider the cluster centers represented by the optimal k as the neurons in the pattern layer of GRNN++ and pass the training or test data, as the case may be, to the pattern layer nodes with a Gaussian transfer function.
Step 6: The product of A_i, i.e., the sum of the output values of the samples present in the i^{th} cluster and the result of activation function for i^{th} neuron in the pattern layer $e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}$ i.e., $\sum_{i=1}^{n} A_i * e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}$ forms the numerator term in the summation layer (say *Num*).
Step 7: The product of B_i, i.e., count of the samples present in the i^{th} cluster and the result of activation function for i^{th} neuron in the pattern layer $e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}$ i.e., $\sum_{i=1}^{n} B_i * e^{\left(\frac{-d_i^2}{2\sigma^2}\right)}$ forms the denominator term in the summation layer (say *Denom*).
