PREFACE

This is the **Eighty Second** Issue of Current Awareness Bulletin started by Delhi Technological University, Central Library. The aim of the bulletin is to compile, preserve and disseminate information published by the faculty, students and alumni for mutual benefits. The bulletin also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **October, 2019**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A Hybrid Intelligent Approach for Solar Photovoltaic Power Forecasting: Impact of Aerosol Data, ***6.Astitva Kumar***, ***3.M. Rizwan*** and ***3.Uma Nangia***, Electrical, DTU

2. An ANFIS-based compatibility scorecard for IoT integration in websites, ***3.Akshi Kumar*** and ***6.Anshika Arora***, Computer Science, DTU

3. Analytical modeling for static and dynamic response of organic pseudo all-p inverter circuits, Neha Mishra, ***3.Poornima Mittal*** and Brijesh Kumar, ECE, DTU

4. Cross-Domain Ambiguity Detection using Linear Transformation of Word Embedding Spaces, ***8.Vaibhav Jain, 8.Sanskar Jain and 8.Nishant Tanwar***, CSE, DTU

5. Design, synthesis and evaluation of Coumarin-Phenylthiazole conjugates as cholinesterase inhibitors, ***6.Deepak Mishra***, ***6.Atiya Fatima***, ***3.Ram Singh***, Nupur S Munja, Vineet Mehta and Udayabanu Malairaman, Applied Chemistry, DTU

6. Do Women on Boards affect Firm's Financial Performance? Evidence from Indian IPO Firms, Amit Kumar Singh, ***8.Shubham Singhania*** and Varda Sardana, DTU

7. Edge detection based on type-1 fuzzy logic and guided smoothening, ***6.Sahil Raheja*** and ***3.Akshi Kumar***, IT and Computer, DTU

8. Efficient uorescence quenching of 5-aminoquinoline: ffi fl Silver ion recognition study, Nupur Pandey, ***3.Mohan Singh Mehata***, Nisha Fatma and Sanjay Pant, Applied Physics, DTU

9. ENHANCEMENT OF SURFACE INTEGRITY USING SPARK ASSISTED ABRASIVE FLOW MACHINING PROCESS, ***6.PARVESH ALI***, ***3.R. S. WALIA***, ***3.QASIM MURTAZA*** and ***3.RANGANATH M. S,*** DTU

10. Experimental and Computational Investigation on Mechanical Properties of Reinforced Additive Manufactured Component, ***6.Nagendra Kumar Maurya***, ***3.Vikas Rastogi*** and ***3.Pushpendra Singh***, Mechanical, DTU

11. Experimental investigation of joining of aluminum alloy 5083 by friction stir welding (FSW), ***3.R.S. Mishra*** and ***6.Preety Rani***, Mechanical, Production, Industrial and Automobiles, DTU

12. Experimentation and Modelling of CNT additive abrasive media for micro finishing, ***6.Parvesh Ali***, ***3.R S Walia***, ***3.Q Murtaza*** and ***3.Ranganath M.S***, Mechanical, DTU

13. Exploring Start-up Ecosystem and its Structural Impact : A Review, ***6.Surabhi Kapoor*** and ***3.Seema Singh***, Humanities, DTU

14. Fabrication and optimization of AA7075 matrix surface composites using Taguchi technique via friction stir processing (FSP), ***7.Ravi Butola*** , ***3.Ranganath M S*** and ***3.Qasim Murtaza***, Mechanical, DTU

15. Graphene as charge transport layers in lead free perovskite solar cell, Gagandeep, ***3.Mukhtiyar Singh***, Ramesh Kumar, and Vinamrita Singh, Applied Physics, DTU

16. High Diversity Gain Super-Wideband Single Band-Notch MIMO Antenna for Multiple Wireless Applications, ***6.Gaurav Saxena***, ***3.Priyanka Jain*** and Y K Awasthi, Electronics and Communication, DTU

17. Impedance Spectroscopy and Conduction Behavior in CoFe2O4-BaTiO3 Composites, ***6.S. SHANKAR***, O.P. THAKUR, and ***3.M. JAYASIMHADRI***, Applied Physics, DTU

18. Improving system reliability by optimal allocation of resources for discovering software vulnerabilities, Navneet Bhatt, Adarsh Anand and ***3.Deepti Aggrawal***, Management, DTU

19. Kinematic and Dynamic Analysis of an Industrial Six-Axis Robotic Manipulator, ***6.Ashwin Misra*** and ***8.Ghanvir Singh***, Mechanical, DTU

20. Managerial Paradox Toward Flexibility: Emergent Views Using Thematic Analysis of Literature, Sanjai Kumar Shukla, Sushil and ***3.Manoj Kumar Sharma,*** DTU

21. Modelling Of Viscoelastic Fluid In Finishing Processes, ***3.Krovvidi Srinivas***, ***3.Q. Murtaza***, ***3.A.K Agarwal***, Mechanical, DTU

22. New Failure Rate Model for Iterative Software Development Life Cycle Process, ***6.Sangeeta***, ***3.Kapil Sharma*** and Manju Bala, IT, DTU

23. On the Physical Layer Security over Beaulieu-Xie Fading Channel, Puspraj Singh Chauhana, ***6.1.Sandeep Kumar*** and Sanjay Kumar Sonia, Electronics and Communication, DTU

24. Performance and Emission Studies of a Variable Compression Ratio CI Engine using Bio Diesel Made from Waste Cooking Oil, Jatinder Kataria, S K Mohapatra, K Kundu and ***3.R Singh***, Mechanical, DTU

25. Preparation of Low Cost Magnetorheological Fluid and its Testing, ***3.R. C. Singh***, ***3.Ranganath M.S*** , ***8.1.Akshay Bhagat***, ***8.1.Kaushik K.***, ***8.1.Vaibhav Batra***, ***8.1.Shiven Mittal***, ***8.1.Gaurav Jain***, Mechanical and Production, DTU

26. Short-term PV power forecasting based on sky-conditions using intelligent modelling techniques, ***6.G. Perveen[1]***, ***3.M. Rizwan[2]*** and N. Goel, [1]Electronics and [2]Electrical, DTU

27. Sliding Mode Control with RBF Neural Network for Two Link Robot Manipulator, ***6.Ankita Yadav***, ***6.Ajit Kumar Sharma*** and ***3.Bharat Bhushan***, Electrical, DTU

28. Stability behavior of a nonlinear mathematical epidemic transmission model with time delay, ***6.Kanica Goel*** and ***3.Nilam***, Applied Mathematics, DTU

29. Thermodynamic analysis of Organic Rankine cycle driven by reversed absorber hybrid photovoltaic thermal compound parabolic concentrator system, Deepak Tiwari, Ahmad Faizan Sherwani, Deepali Atheaya, ***3.Anil Kumar*** and Nishant Kumar, Mechanical, DTU

Abstract
The penetration of solar photovoltaic (PV) power in distributed generating system is increasing rapidly. The increased level of PV penetration causes various issues like grid stability, reliable power generation and power quality; therefore, it becomes utmost important to forecast the PV power using the meteorological parameters. The proposed model is developed on the basis of meteorological data as input parameters, and the impacts of these parameters have been analyzed with respect to forecasted PV power. The main focus of this research is to explore the performance of optimization-based PV power forecasting models with varying aerosol particles and other meteorological parameters. A newly developed intelligent approach based on grey wolf optimization (GWO) using multilayer perceptron (MLP) has been used to forecast the PV power. The performance of the GWO-based MLP model is evaluated on the basis of statistical indicators such as normalized mean bias error (NMBE), normalized mean absolute error (NMAE), normalized root-mean-square error (NRMSE) and training error. The results of the developed model show the values of NMBE, NMAE and NRMSE as 2.267%, 4.681% and 6.67% respectively. To validate the results, a comparison has been made with particle swarm optimization, Levenberg–Marquardt algorithm and adaptive neuro-fuzzy approach. The performance of the model is found better as compared to other intelligent techniques. The obtained results may be used for demand response applications in smart grid environment.

Keywords Grey wolf optimization · Artificial neural network · Solar power forecasting · Solar PV · Distributed power generation

1 Introduction

The demand of electrical energy is increasing drastically because of increasing population, urbanization and increased comfort level. Due to greenhouse gases emission and depleting nature of conventional energy sources, the adoption of renewable energy sources such as solar, wind and biomass has been gaining momentum. Among the renewable energy sources, the adoption of solar photovoltaic is increasing day by day, because of various advantages such as clean, silent, availability and low running cost. However, the rapid development of solar PV system also brings many challenges in operation and control of solar PV-based power systems [1, 2]. Further, the high penetration of solar PV may cause the grid stability and reliability issues in smart grid environment. Therefore, the solar PV power forecasting is one of the key tools for this paradigm and plays a vital role in efficient integration of renewable power generation and reduction in volatility to distributed generation systems. Precise and accurate forecasting of PV power helps massively in planning and scheduling of power demand supply for the consumers as well as various distribution companies (DISCOMs). It further enhances system reliability and power quality issues due to uncertainty in PV power generation.

Further, the forecasting is an important tool for grid operators since they can schedule generation and distribution according to the load profile, and also define generation units to act as operating reserve generators [3, 4]. It is also an essential tool for creating a modern transactive energy framework in a grid-connected microgrid system [5–8]. PV power prediction not only reduces the number of units required in hot standby but also minimizes the operational costs. Therefore, prediction of PV power has become vital and very crucial for grid stability, optimal unit commitment and economical dispatch.

Published online: 12 October 2019

Recently, many studies have been performed to obtain accurate forecasts using different approaches such as mathematical modeling, regression models and intelligent technique-based approaches. There are two major approaches to predict solar PV output such as direct and indirect approach [9]. Direct approach is a technique where it directly calculates the power output of the PV system, whereas an indirect approach, firstly calculates the solar irradiation, and then calculates the PV power produced using a PV performance model of the plant. The indirect method is basically modeled using cloud imagery and numerical weather prediction techniques. Direct approach involves modeling using machine learning technique.

There are studies that have focused only on prediction of solar irradiation as it is the main element on which performance of the PV plant depends massively. Wan et al. [10] provided a comprehensive review for both the methods, direct and indirect, and also discussed the merits and demerits of various types of estimation methods. Antonanzas et al. presented an extensive review of solar PV power forecasting techniques focusing on the latest advancement and future trends. It is concluded that mostly forecasting horizon considered is day ahead, and statistical approach is superior in most occasions [11]. Chaturvedi et al. [12] also presented a review of solar forecasting based on various time horizon and classified as intra-hour, intra-day and day ahead. Figure 1 shows the different methodologies used for varying spatial and temporal resolutions, and Fig. 2 gives brief explanation about the different forecasting horizons (time horizons) and its various applications. Martinez-Anido et al. [13] discussed the impact of PV power forecasting

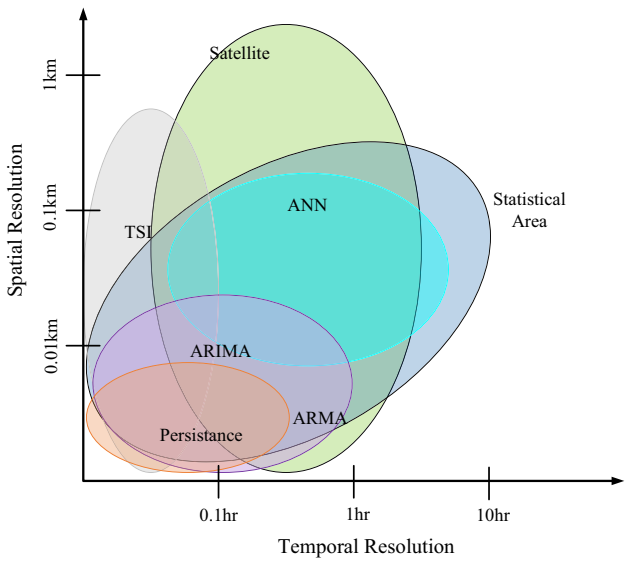

Fig. 1 Classification of short-term forecasting model

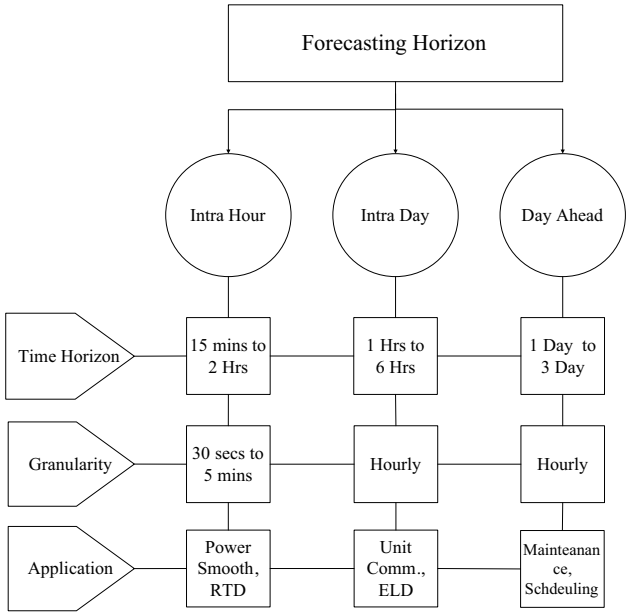

Fig. 2 Different forecasting horizons and their relation

in improving the power system operations and the cost of electricity generation.

Time horizon (t_h) of forecasted PV power output plays an important role in management of the PV systems and its control, for different locations like schools, hospitals, etc. Sanusi et al. performed a study considering clearness index (K_T) and diffuse ratio (D_R) for feasibility of solar energy utilization in tropical stations of Nigeria. In the study, 11-year data of solar radiation and maximum and minimum temperatures were collected and compared with monthly variations of K_T and D_R. The authors therefore suggested that the output of the solar PV system needs evaluation under different conditions, especially considering spatiotemporal variations, thus necessitating the need to monitor grid-connected PV plants by installers and investors [14]. Chu et al. [15] has proposed a PV power reforecasting model using ANN model based on three baseline model, namely ARMA, cloud tracking and kNN for 5, 10 and 15 min time horizons. The effect of aerosols over northern and eastern China was studied by Lia et al. [16]; their study showed that 1.5 kW h/m^2 per day was an annual reduction in solar radiation when compared with a pollution-free environment. The correlation between atmospheric aerosol and reduction of PV power is to be studied. Thus, there is a need for a solar PV power forecasting model that adapts to this change in the atmosphere.

To help in study of solar power output characteristics, authors have used multiple linear regression analysis with various weather data and solar irradiance data. Some other machine learning algorithms like *k*th nearest neighbor (kNN) regression algorithm, support vector machine (SVM), adaptive fuzzy algorithm, Markov chain, cluster evaluation are

present in different literatures for solar forecasting [17]. De Giorgi et al. designed Elmann ANN for the estimation of 960 kWp grid-connected PV plant. The performance indices considered were normalized error (NE), normalized mean absolute error (NMAE) and normalized root-mean-square error (NRMSE) [18]. In Ref. [19], authors have studied the prediction of global solar irradiance using relative humidity, temperature and modified sunshine duration factor. Amrouche et al. has proposed MLP-based ANN model to forecast global horizontal irradiance (GHI) for two different locations. Adaptability of the proposed ANN–MLP model by predicting GHI using unfamiliar data is highlighted by them [20]. Mellit et al. [21] discussed various artificial intelligent techniques for the sizing of various PV systems, PV–wind hybrid systems and also modeling of 24-h solar forecast system in Trieste, Italy. Ehsan et al. [22] proposed a 24-h ahead PV power forecasting model using MLP and discussed the use of different training algorithms and transfer function for different layers to map the input–output database. A fuzzy logic-based neural network model is designed in [23] to estimate solar radiation forecast using time-series data of radiation and temperature for different sky conditions. The mean absolute percentage error (MAPE) based on the fuzzy logic algorithm is between 13.87 and 20.22% for the solar radiation forecast. The MAPE of the neural network prediction model ranges from 10.85 to 20.33%. The results obtained from ARIMA models show MAPE is about 30% during the forecast studies of solar radiation [24]. NE ranges from [− 10%; 10%] for the various empirical and persistent models to estimate PV power; the use of optimized training algorithms along with MLP tool helps in further reducing it [25–27]. In Ref. [28], authors have proposed a new approach of ensemble tree learning algorithm to improve the SVM, ANN and DT techniques in predicting solar radiation with RMSE between 4.6 and 14.6%. Douiri modeled a self-tuning solar PV power model based on Takagi–Sugeno-type neuro-fuzzy technique. The model simulates the *I–V* characteristics to predict global maximum power point with 1.4% average error [29]. The above discussed models do not consider atmospheric aerosol content in modeling of the ANN or MLP forecasting models, and the errors range from 5 to 20%.

From the literature survey, it can be found that there is a need to find a new technique to forecast solar power for the growing smart grid environment with minimal error. The literature mainly focuses on solar energy or irradiance forecasting, and limited papers actually focused on PV power forecasting. The neural network techniques used in the previous PV power prediction model require large amount of dataset for training, but still are unable to predict accurately during hazy and high-pollution condition. The neural network-based prediction models with short-term time horizon were rarely found in the literature. The relationship between performance of PV forecasting models and aerosol attenuation in the atmosphere is rarely found in the literature. Authors of various literatures have tried to study the effect of rising pollution on the solar photovoltaics across different parts of the world and tried to develop a relation between aerosol particles and the solar energy. The paper develops a hybrid intelligent model to predict the solar PV power generation for varying aerosol content. A brief introduction about ANN and its various learning techniques, namely Levenberg–Marquardt (LM) and optimization-based (PSO and GWO) learning methods, have been discussed in the paper. In this paper, a hybrid direct solar PV power forecasting technique is proposed based on GWO approach. GWO is used to train weights of the feedforward ANN for mapping meteorological inputs and PV power as output. In this work, the solar irradiance (W/m^2) incident on the PV panel, cell temperature (^oC), Linke turbidity factor (τ_L) and wind speed (m/s) has been considered as input parameters and PV power as output of the model. The solar irradiance and cell temperature have been measured using solar system analyzer, and wind speed is collected from Global Forecast System (GFS) model. The highlights of the proposed model are use of GWO technique for training of the neural network. Study for selection of the various inputs and their relationship with solar PV power is performed, giving an insight of dependence of PV power generation on each input considered. The proposed model has been formulated considering the linear correlation factor of meteorological data to the PV power generation. The training and prediction of the solar PV power is done considering τ_L for varying aerosol content in the atmosphere. Extensive comparative analysis of the proposed model for hourly forecasting of PV power is presented using different performance indices for forecasting such as training error (TE), normalized root-mean-square error (NRSME), normalized mean bias error (NMBE), normalized mean absolute error (NMAE) and complexity and configuration of the system.

This paper is organized as follows. Section 2 presents a brief outline of the structure of the neural networks and MLP; the section also helps in explaining the learning techniques used to effectively train the artificial neural networks, techniques such as Levenberg–Marquardt, PSO and GWO. These techniques have been modeled using mathematical equations in Sect. 2. The effect of Linke turbidity and atmospheric aerosol variability on the solar irradiance is discussed in Sect. 3. The description of the site selected for data collection and testing along with the data processing is described in Sect. 4. Results and discussions of the hybrid intelligent model and its comparative study are provided in Sect. 5. A conclusion followed by the references is present in Sect. 6.

2 Artificial Neural Network

ANN can be described in general terms as a network to process information, and this network model is inspired by the architecture of a human brain. This is a parallel distributed type of architecture, comprising data processing elements called 'neurons.' ANN is generally characterized on the basis of three key factors such as architecture, training or learning algorithm and activation function. ANN is structured with input layers, hidden layers and output layers. Input layer is the data receiver; data are sent after computation through the output layer [30, 31]. Hidden layer is intermediate layer present between input and output layers; the number of hidden layers depends on convergence speed, generalization capability, neurons present in each layer and training data. These layers in the network are interconnected with help of communication links; these links are associated with specific weights that drive the amount of information passing from them. The transfer function in ANN is chosen according to the properties required. These can be linear or nonlinear to form an equivalent single-layer or multilayer network, respectively. Activation function is actuated when net_j exceeds the threshold to produce the output o_j. ANN working is divided into two steps: firstly, a training process, and secondly, network operating process. Schematic diagram of ANN architecture is shown in Fig. 3.

In this work, MLP model has been used because of various advantages such as functional approximation, fast learning capability to learn complex relationship for easy mapping of inputs to outputs. MLP is a layered feedforward ANN model that maps input to the output using historical data so that model can produce output when the desired output is unknown. Different training algorithms are employed on neural network model to update the weights of the layers; these training and updating of weights occur using pattern or batch [32]. The training cycle is completed when each training pattern is presented once to the MLP. Consider a two-layer MLP neural network as shown in Fig. 4.

The net input (n) of the unit i in layer $k+1$ is given by

$$n^{k+1}(i) = \sum_{j=1}^{sk} w^{k+1}(i,j)a^k(j) + b^{k+1}(i) \tag{1}$$

The output (a) of unit i will be

$$a^{k+1}(i) = f^{k+1}\left(n^{k+1}(i)\right) \tag{2}$$

For an M layer network, the system equations in matrix form are given by

$$a^{k+1}(i) = f^{k+1}\left(w^{k+1}a^k + b^{k+1}\right) \tag{3}$$

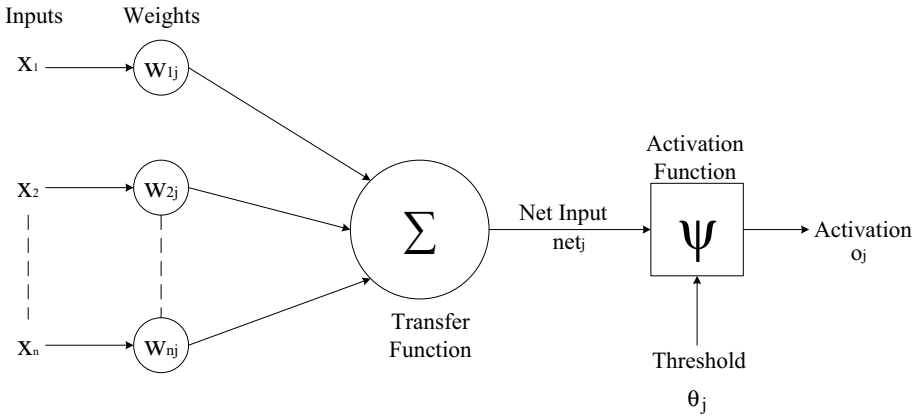

Fig. 3 Schematic diagram of ANN

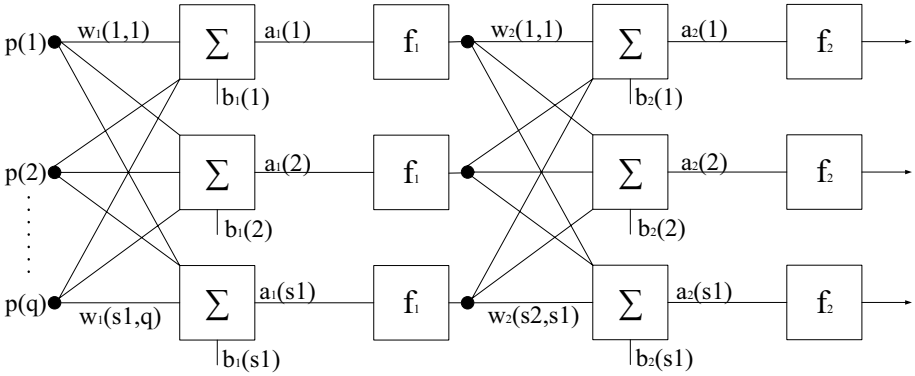

Fig. 4 Two-layer feedforward MLP neural network

Here, $k=0, 1, \ldots, M-1$, f^{k+1} is activation function of $(k+1)$th layer, w^{k+1} is the weight of $(k+1)$th layer and b^{k+1} is bias of $(k+1)$th layer.

From Fig. 4, it is observed that the task of the network is to learn associations between a specified pair of input and target pairs $\{(p_1,t_1),(p_2,t_2),\ldots,(p_q,t_q)\}$, so the performance index for the network is

$$V=\frac{1}{2}\sum_{q=1}^{Q}\left(t_q-a_q^M\right)^{\mathrm{T}}\left(t_q-a_q^M\right)=\frac{1}{2}\sum_{q=1}^{Q}e_q^{\mathrm{T}}e_q \tag{4}$$

where a_q^M is the output of the network when the p_q input is presented, and the error for the qth input is given by $e_q=t_q-a_q^M$. The performance index is approximated by

$$\hat{V}=\frac{1}{2}\sum_{q=1}^{Q}e_q^{\mathrm{T}}e_q \tag{5}$$

where the total sum of squares is replaced by squared errors for a single input/output pair.

2.1 Learning/Training Algorithms

Various learning techniques or training algorithms are used for modeling of the neural network-based MLP. These algorithms are namely gradient descent, Newton's method, conjugate gradient and Bayesian regularization. These learning methods help in creating a decision function for weight updation of the neural network. These techniques have few shortcomings of using large memory, high complexity and slow convergence. These learning methods define rules, and these rules imply a specific function to update the weights of the neurons after each epoch. The term gradient and BP can be used interchangeably; BP is a method where error between the network output and desired output is propagated backwardly. In the BP networks, data are fed forward, and there is no feedback. It is difficult to predict the result from various algorithms [33]. Optimization techniques can also be used for minimizing the cost function to define the weights of the MLP. The cost function depends on numerous parameters, so the optimization is single and multi-dimensional. Optimization helps in increasing the computational speed and enhances the convergence rate. In this paper, LM technique is used as the basis to formulate optimization-based neural network MLP. This paper proposes a new GWO-trained MLP and compares the proposed model with the models designed using LM technique and an intelligent optimization technique—PSO.

2.1.1 Levenberg–Marquardt Algorithm

LM algorithm is also known as damped least-square technique. This technique is designed to enhance the training performance without computing Hessian matrix [34]. This method is especially designed for functions relating to sum of squared error. The highlight of this algorithm is training speed, but limits the usage where large dataset for training is present. It also requires large computational memory. The cost function ($V(x)$) for LM is a sum of squares of error (e_i) (typically for feedforward networks) and is given by

$$V(x)=\sum_{i=1}^{N}e_i^2(x) \tag{6}$$

$$\nabla V(x)=J^{\mathrm{T}}(x)e_i(x) \tag{7}$$

$$\nabla^2 V(x)=J^{\mathrm{T}}(x)J(x)+S(x) \tag{8}$$

where $J(x)$ is the Jacobian matrix

$$J(x)=\begin{bmatrix}\frac{\partial e_1(x)}{\partial x_1} & \frac{\partial e_1(x)}{\partial x_2} & \cdots & \frac{\partial e_1(x)}{\partial x_n}\\ \frac{\partial e_2(x)}{\partial x_1} & \frac{\partial e_2(x)}{\partial x_2} & & \frac{\partial e_2(x)}{\partial x_n}\\ \vdots & \vdots\ddots & & \vdots\\ \frac{\partial e_N(x)}{\partial x_1} & \frac{\partial e_N(x)}{\partial x_2} & \cdots & \frac{\partial e_N(x)}{\partial x_n}\end{bmatrix} \tag{9}$$

and

$$S(x)=\sum_{i=1}^{N}e_i^2(x)\nabla^2 e_i^2(x) \tag{10}$$

Hessian matrix ($H(x)$) is approximated as

$$H(x)=\nabla^2 V(x)=J^{\mathrm{T}}(x)*J(x) \tag{11}$$

and gradient (g) is calculated as

$$g=J^{\mathrm{T}}(x)*e_i(x) \tag{12}$$

where $H(x)$ is the Hessian matrix, e_i is vector of network errors and $J(x)$ is the Jacobian matrix containing the first-order derivative of the network error with respect to the weights and biases. The key step in this method is computation of Jacobian matrix. This algorithm approximates the Hessian matrix using the following equation:

$$x_{i+1}=x_i-\left[J^{\mathrm{T}}(x)*J(x)+\mu I\right]^{-1}j^{\mathrm{T}}(x)e_i(x) \tag{13}$$

If μ is zero, then the equation is just Gauss–Newton methods, when μ is large, it becomes gradient descent with a small step size. This training algorithm approximates the error and discards second-order derivatives of the error.

2.1.2 Grey Wolf Optimization

Optimization algorithm in a neural network-based MLP has two phase cycles, namely propagation and weight update. The input data are propagated from input layer to the output layer.

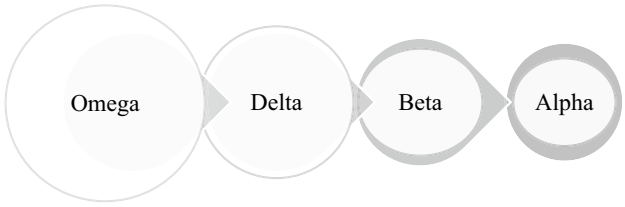

Fig. 5 Social hierarchy in grey wolves

The output from the output layer is compared with the target values, and a cost function is created in form of error. GWO algorithm mimics the properties of a grey wolf (Canis lupus). This algorithm outlines the mathematical model of the social hierarchy, tracking and hunting of grey wolves. In GWO, the fittest solution is considered as alpha (α), the second best is said to be beta (β), the third is called as delta (δ), and the rest are omega (ω). Figure 5 shows the social hierarchy among the pack of grey wolves. This complete is known as pack, in which α is the dominant factor to guide the hunting of the prey [35]. GWO is fast, requires less parameter definition and comparatively low computational memory. It focuses more on exploration, rather than exploitation, of a meta-heuristic technique. The below expressions show the behavior of grey wolves such as hunting and attacking.

$$\vec{D} = \left|\vec{C} \cdot \overrightarrow{X_{\mathrm{p}}}(t) - \vec{X}(t)\right| \tag{14}$$

$$\vec{X}(t+1) = \overrightarrow{X_{\mathrm{p}}}(t) - \vec{A} \cdot \vec{D} \tag{15}$$

where $\vec{D}$ defines the encircling behavior of the grey wolves, $\vec{X}$ indicates the position vector of grey wolf, $\overrightarrow{X_{\mathrm{p}}}$ is the position of the prey, $\vec{A}$, and $\vec{C}$ are coefficient vectors. The vectors $\vec{A}$ and $\vec{C}$ are calculated as follows:

$$\vec{A} = 2\vec{a} \cdot \vec{r_1} - \vec{a} \tag{16}$$

$$\vec{C} = 2 \cdot \vec{r_2} \tag{17}$$

where $\vec{a}$ are linearly decreased from 2 to 0 over the course of iterations, and r_1, r_2 are random vectors in [0, 1].

The following equation represents the hunting characteristics of the grey wolf.

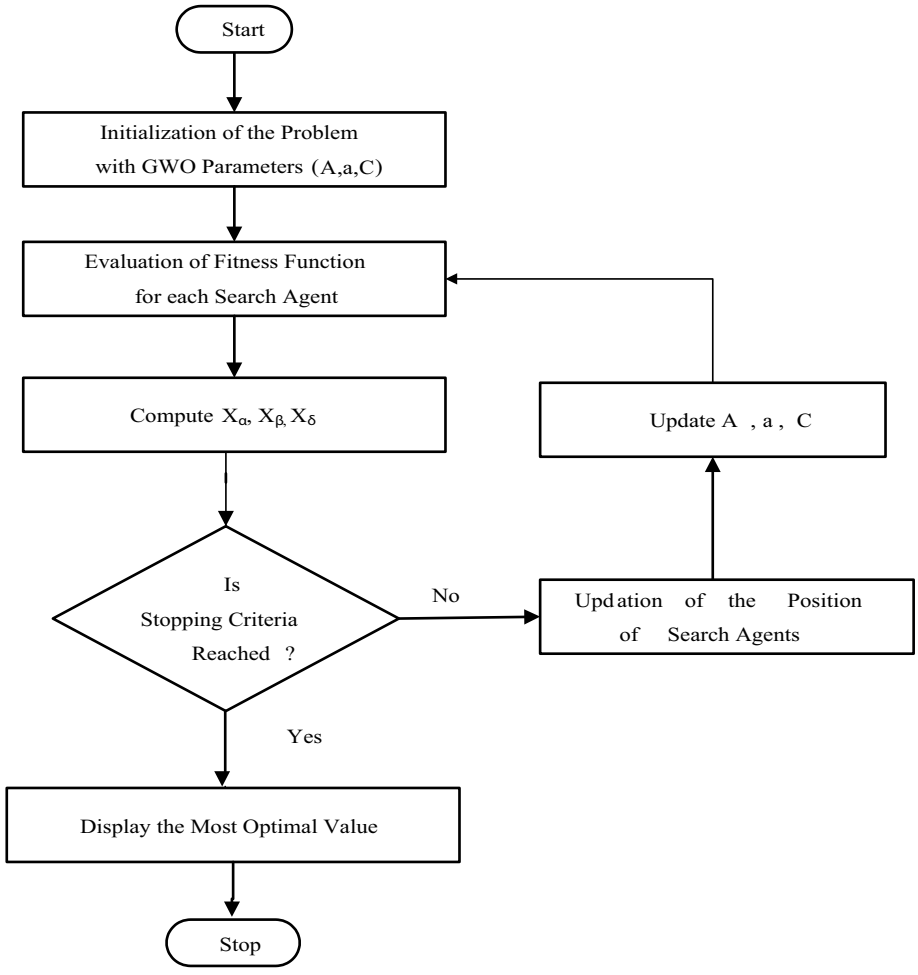

Fig. 6 Flowchart of GWO algorithm

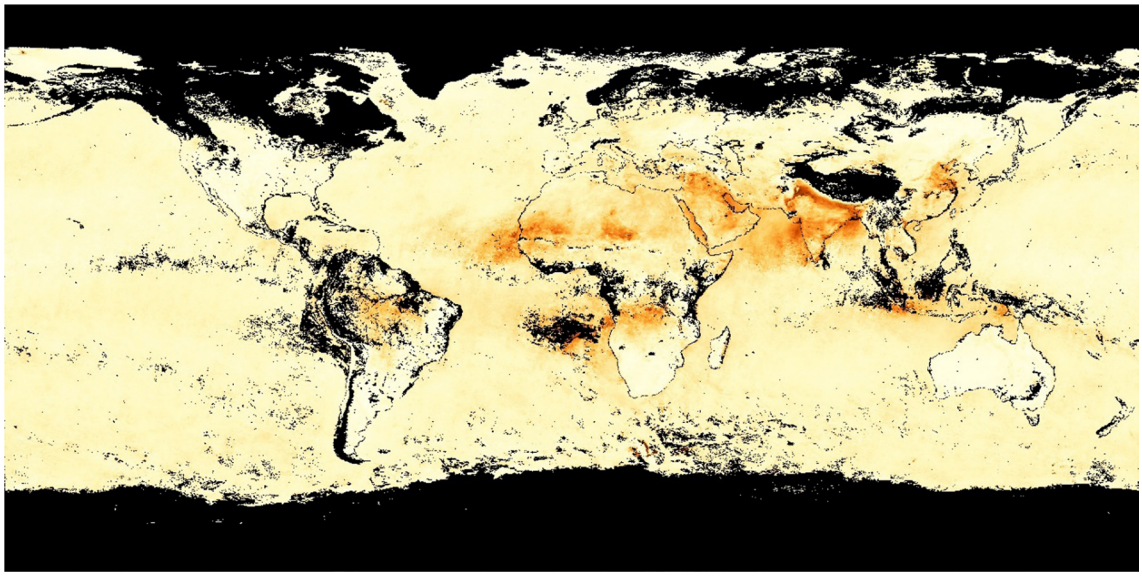

Fig. 7 Aerosol optical depth of the atmosphere for the month of October 2018 worldwide. *Source*: NASA Earth Observations (Terra/MODIS)

$$\begin{aligned}
&\overrightarrow{D_\alpha} = \left|\vec{C}\cdot\overrightarrow{X_\alpha} - \vec{X}(t)\right|; \quad \overrightarrow{D_\beta} = \left|\vec{C}\cdot\overrightarrow{X_\beta} - \vec{X}(t)\right|; \\
&\quad \overrightarrow{D_\delta} = \left|\vec{C}\cdot\overrightarrow{X_\delta} - \vec{X}(t)\right| \\
&\overrightarrow{X_1} = \overrightarrow{X_\alpha} - \vec{A}\cdot\overrightarrow{D_\alpha}; \quad \overrightarrow{X_2} = \overrightarrow{X_\beta} - \vec{A}\cdot\overrightarrow{D_\beta}; \\
&\quad \overrightarrow{X_3} = \overrightarrow{X_\delta} - \vec{A}\cdot\overrightarrow{D_\delta} \\
&\vec{X}(t+1) = \frac{\overrightarrow{X_1} + \overrightarrow{X_2} + \overrightarrow{X_3}}{3}
\end{aligned} \tag{18}$$

$\overrightarrow{X_\alpha}$, $\overrightarrow{X_\beta}$, $\overrightarrow{X_\delta}$ are the position vectors of alpha, beta and gamma, respectively. The GWO algorithm is applied to the practical problem of solar PV power forecasting using neural network MLP model. The steps involved in the development of GWO algorithm are given in flowchart and shown in Fig. 6. The stopping criterion used in the proposed technique is formulated by (i) tolerance error (tol_{err}), (ii) error is no longer decreasing or decreasing too slowly and (iii) maximum iteration is reached.

2.1.3 Particle Swarm Optimization

PSO algorithm is also a widely used technique to minimize or maximize a cost function. PSO is a population-based stochastic, meta-heuristic optimization method developed by Kennedy and Eberhart [36]. It mimics the social behavior of a flock of birds or a swarm of fishes [36]. They have discussed the use of PSO for multi-dimensional experiments such as training of weight in feedforward MLP neural network model. PSO is a technique that lies in between genetic algorithm and evolutionary programming. There are four parameters on

Table 1 τ_{L} and corresponding atmospheric conditions

Linke turbidity factor (τ_{L})	Sky conditions
$\tau_{\text{L}} = 1$	Dry and clean
$1 < \tau_{\text{L}} < 3$	Deep blue (high water vapor content)
$3 < \tau_{\text{L}} < 5$	Turbid atmosphere
$5 < \tau_{\text{L}} < 7$	Polluted atmosphere
$8 < \tau_{\text{L}}$	Hazardous

which performance of this optimization technique depends: personal best (p_{best}), global best (g_{best}), c_1 and c_2. The performance (search and exploit) of PSO is dependent on defining of parameters. The movement of the particles to the near global optimum position is described in the following equations

$$\begin{aligned}
v_{\text{id}}(t+1) = w_{\text{pso}}(t) * v_{\text{id}}(t) + c_1 * r_{\text{pso1}} * \left(p_{\text{best}} - x_{\text{id}}(t)\right) \\
+ c_2 * r_{\text{pso2}} * \left(g_{\text{best}} - x_{\text{id}}(t)\right)
\end{aligned} \tag{19}$$

$$x_{\text{id}}(t+1) = x_{\text{id}}(t) + v_{\text{id}}(t+1) \tag{20}$$

where $v_{\text{id}}(t+1)$ and $v_{\text{id}}(t)$ are the velocities of the particles at $(t+1)$ and t instances, respectively, $x_{\text{id}}(t+1)$ and $x_{\text{id}}(t)$ are the position of the particles at $(t+1)$ and t instances, respectively, c_1 and c_2 are exploitation and exploration coefficients, respectively, r_{pso1} and r_{pso2} are the random variables associated with exploitation and exploration coefficients, respectively, p_{best} and g_{best} are particle having personal best and global best values, $w_{\text{pso}}(t)$ is the weights of the particle that are given by Eq. (21)

$$w_{\mathrm{pso}}(t) = w_{\max} - \frac{\left(w_{\max} - w_{\min}\right)}{T} \times t \tag{21}$$

$w_{\max}$ is 0.9, $w_{\min}$ is 0.4, t is the current iteration, and T are the maximum number of iterations.

3 Impact of Aerosol Data on PV Power Forecasting

The air quality is measured using an air quality index (AQI). Atmospheric condition of a particular site in today's world not only considers the cloud and its movement but also the particulate matter of varying sizes. The movement of clouds and solar cycle has been considered as key factors modulating solar surface radiation. But, atmospheric aerosols and urban haze in cities are the growing problem for all the photovoltaic resources. Aerosols are the minute particles of dust, pollution, sea salts, etc., floating in the atmosphere. Aerosols have property to trap the ambient heat and increase the temperature; with an increase in aerosol content, the atmospheric condition changes and has a knock-on effect on the photovoltaics. Studies have been performed showing that 20% of the average solar dimming in China has been attributed due to increase in aerosols when wind speed is pretty low [37]. Studies have shown that that a large difference (≥ 25 W/m^2) is observed in Delhi, India, and 24.10% of aerosol optical depth from 2000 to 2011 has contributed to expansion of aerosol layer over 6 km [38]. The present estimates of the aerosols' forcing on global climate range from minus 0.6 watts per square meter to minus 4.0 watts per square meter, when combining both the direct and indirect effects of sulfate aerosols and biomass burning aerosols. Aerosol optical depth data from NASA observatory (Terra/MODIS) of the atmosphere for the month of October 2018 worldwide are shown in Fig. 7.

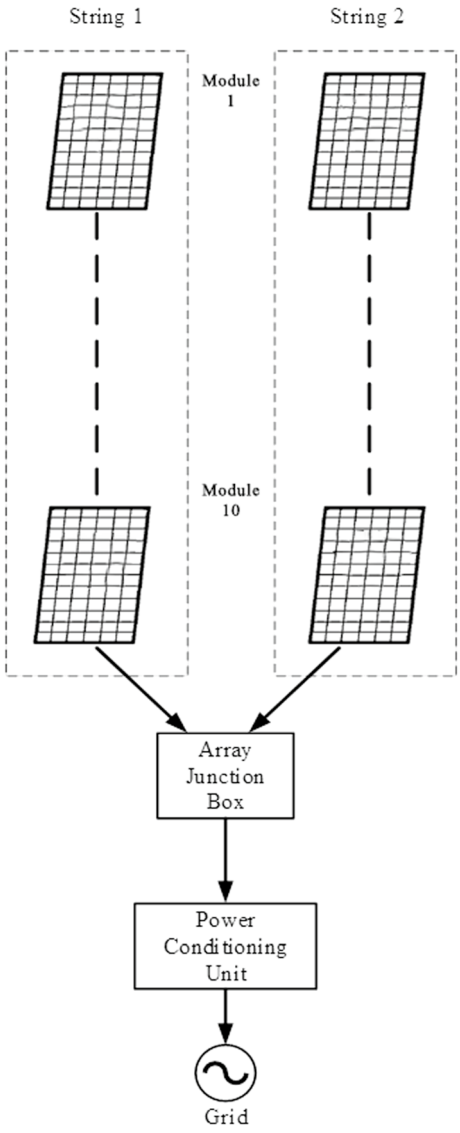

Fig. 8 Schematic single-line diagram of the PV system

Table 2 Specification of the solar PV system

Description	Value
Type	Polycrystalline
Maximum power of module	250 Wp
Open-circuit voltage (Voc) of module	37.05 V
Short-circuit current (Isc) of module	8.580 A
Maximum power voltage (Vpm) of module	30.74 V
Maximum power current (Ipm) module	8.15 A
Output tolerance of module	±2%
Total number of modules	20
Site layout	10×2
Exposure area of a module	1.640 m^2
Temperature coefficients of PV module	
α_{pv}	+0.058%/°C
β_{pv}	−0.330%/°C
γ_{pv}	−0.430%/°C

Aerosol index (AI) is the index that detects the presence of UV absorbing aerosols; this is given by TOMS and OMI AI from NASA Goddard Space Flight Centre [39], defined as

$$\mathrm{AI} = 100\left[\log_{10}\left(\frac{I_{360}}{I_{331}}\right)_{\mathrm{measured}} - \log_{10}\left(\frac{I_{360}}{I_{331}}\right)_{\mathrm{calculated}}\right] \tag{22}$$

The aerosol data can be adequately depicted by calculating the Linke turbidity (τ_{L}). The relationship between aerosols and Linke turbidity factor is discussed in the literature [40, 41]. τ_{L} describes the optical thickness of atmosphere due to various

aerosol particles and water vapor. It defines the absorption and scattering of solar radiation in different sky conditions. A high value of τ_L indicates higher number of aerosol particles in the atmosphere, and thus increasing the diffused radiation and reducing the direct radiation

$$\tau_L = \tau_{Lk}\left(\frac{\rho_{rk}}{\rho_{ra}}\right) \tag{23}$$

$$\tau_{Lk} = (0.9 + 9.4\sin(h)) \cdot \ln\left(\frac{I_0\varepsilon}{I_n}\right) \tag{24}$$

$$\rho_{rk} = 1/\left(9.4 + 0.9m_a\right) \tag{25}$$

$$\frac{1}{\rho_{ra}} = 6.5567 + 1.7513m_a - 0.1202m_a^2 + 0.0065m_a^3 - 0.00013m_a^4 \tag{26}$$

$$m_a = \frac{\text{Pressure}}{101{,}325}\left[\sin(h) + 0.15(h + 3.885)^{-1.253}\right]^{-1} \tag{27}$$

where τ_{Lk} is Linke turbidity factor under clear sky; according to Kasten, ρ_{rk} is Rayleigh integral optical thickness, and ρ_{ra} is integral optical thickness by Louche and modified by Kasten [42]. m_a is the atmospheric air mass, h is the sun elevation angle, and I_0 and I_n are sun constant and direct normal solar radiation. Table 1 shows the relation of varying sky conditions with respect to τ_L. The calculated τ_L is verified from the data along with the ranges given in Table 1 and was found to be accurately depicting the sky conditions.

4 Site Details and Data Processing

A 5 kW_p grid-connected PV system is installed at rooftop of the laboratory, and the data of the system are collected through Solar System Analyzer 9018BT during daytime for every 2 min. The inputs considered for the proposed PV forecasting model are solar irradiance (W/m^2) incident on the PV panel, cell temperature (°C), Linke turbidity (τ_L) and wind speed (m/s). A linear regression study was performed for selection of the various aforementioned inputs on the basis of 1-month historical data. The linear dependence of X and Y is studied using Pearson product moment correlation coefficient, to find the strength of linear dependence of nominal PV power generation output to the inputs. The negative correlation shows that larger values of τ_L and wind speed will result in smaller solar PV output. A large number of samples were collected for training of the neural network based on MLP model. The training dataset comprised of 80% of the time-series data, and 20% of the dataset was used for testing (10%) and validation (10%). The above selection of 80%, 10% and

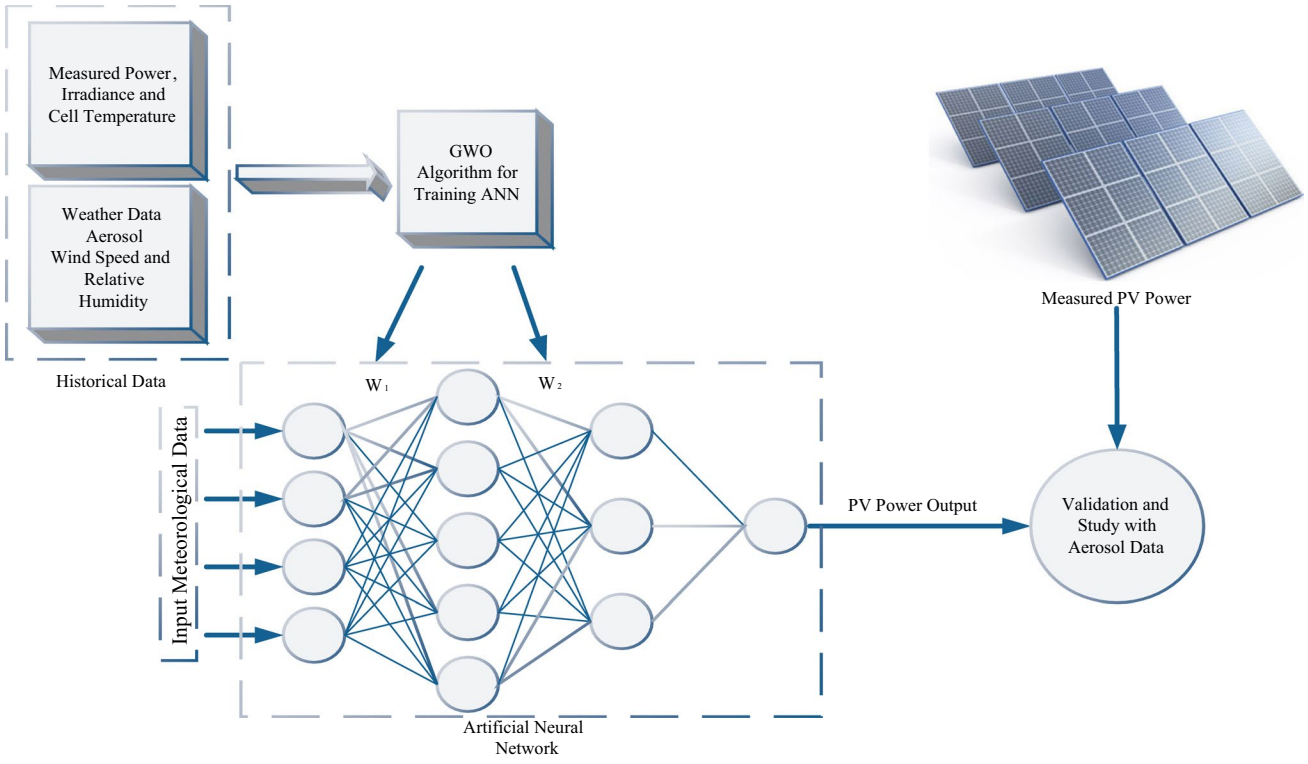

Fig. 9 Functional block diagram of the proposed hybrid intelligent model

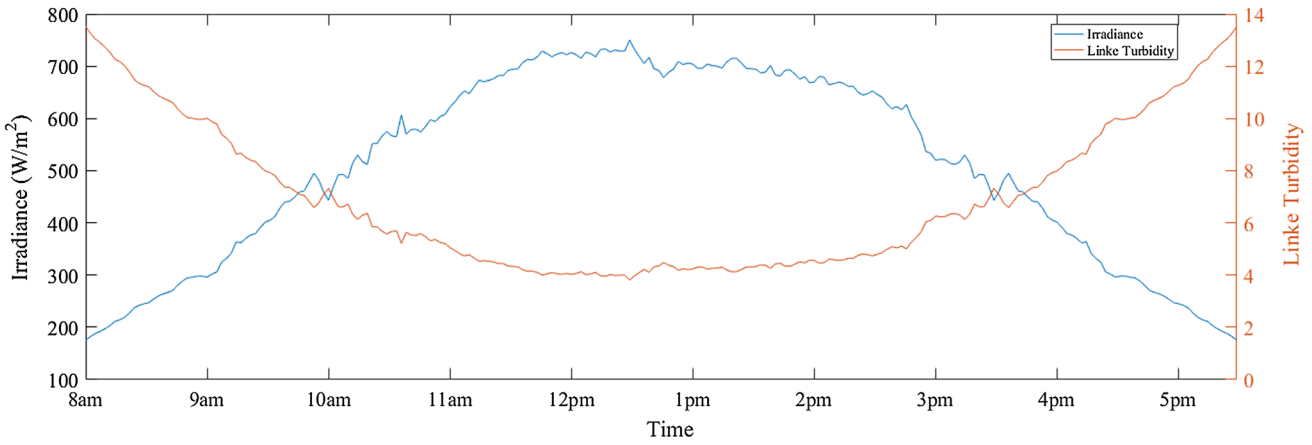

Fig. 10 Variation of irradiance and Linke turbidity for a highly polluted day

10% for different stages has been done using trial and error technique. The performance of the proposed model using above values is shown in Fig. 12. The measured data were verified with the data obtained from NREL and NOAA-GFS model for the last 10 years. The measured irradiance data were in the range of the irradiance obtained from the sources for the selected site. The schematic representation of the PV system considered is shown in Fig. 8, and the specifications of the solar PV system used in this study are provided in Table 2.

The ranges of each input vary in relation with the target values in ANN and other data mining techniques, so to prevent ill conditioning of the network normalization is required. Normalization also helps in having the same range values for different inputs. Normalization is preferred to reach a linear and robust relationship between nonlinear dataset. The inputs and the target values collected from 9018BT have been normalized using Eq. (28)

$$X^* = \frac{X_i - X_{\min}}{X_{\max} - X_{\min}} \tag{28}$$

where $0 \leq X^* \leq 1$, X_i is the current value of data X, $X_{\max}$ and $X_{\min}$ are the maximum and minimum value of the dataset X.

5 Results and Discussion

5.1 Statistical Indicators

The performance of the proposed hybrid intelligent forecasting model is analyzed using the statistical indices. The performance indicators used for proposed PV power forecasting model are normalized error (NE), normalized squared error (NSE) and training error (TE) or mean square error (MSE). The accuracy of the prediction is evaluated considering these metrics

$$\mathrm{NE} = \frac{P_{\text{out}} - P_{\text{e}}}{\mathrm{Max}_{i=1}^{M}\left(P_{\text{out}}\right)} \tag{29}$$

Here, P_{out} and P_{e} are actual PV power and estimated power output at every t_{h}, and M is the total number of samples

$$\mathrm{NSE} = (\mathrm{NE})^2. \tag{30}$$

NSE is calculated for easier calculation of normalized root-mean-square error (NRMSE)

$$\mathrm{NRMSE} = \sqrt{\frac{1}{M} \times \sum_{i=1}^{M} (\mathrm{NSE}) \times 100.} \tag{31}$$

Normalized mean bias error (NMBE) (%) and normalized mean absolute error (NMAE) (%) are also considered as performance indices

$$\mathrm{NMBE} = \frac{100}{M} \times \sum_{i=1}^{M} (\mathrm{NE}) \tag{32}$$

$$\mathrm{NMAE} = \frac{100}{M} \times \sum_{i=1}^{M} |\mathrm{NE}| \tag{33}$$

$$\mathrm{TE} = \mathrm{MSE} = \frac{1}{n}\left(\sum_{i=1}^{M} \left(x_i - \hat{x}_i\right)^2\right) \tag{34}$$

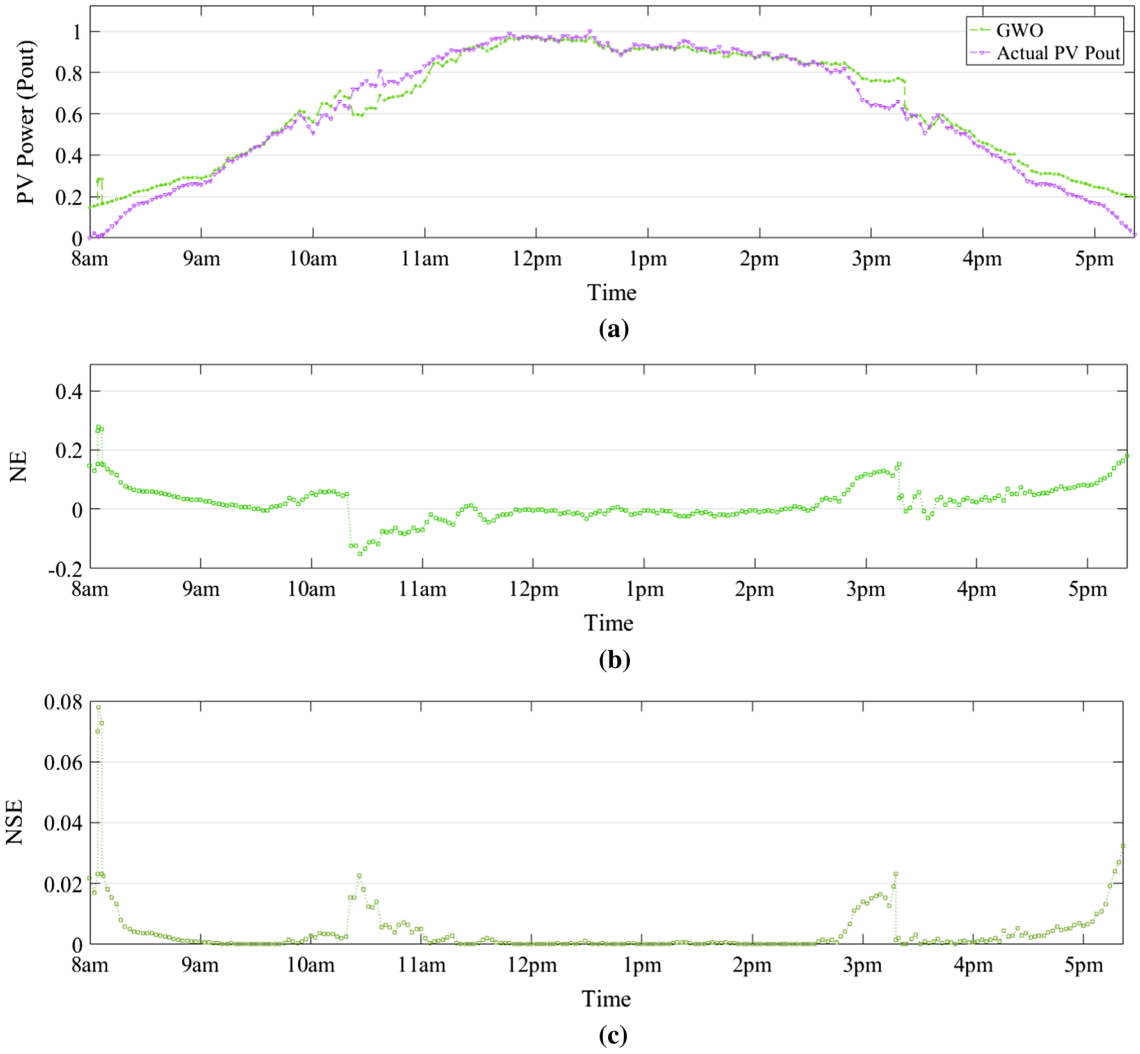

Fig. 11 **a** Performance of GWO model, **b** variation of NE for GWO model, **c** variation of NSE for GWO model

where x_i is the output of the trained model, $\hat{x}_i$ is target value, and M is the number of samples of data.

5.2 Performance of the Proposed Model

The proposed neural network model is trained using GWO algorithm considering four input parameters such as irradiance, cell temperature, wind speed and relative humidity. The training and validation stages of the proposed GWO-based ANN model, to predict the PV power, are shown in Fig. 9. The GWO algorithm acquires the previous data and assists in effective modeling of ANN network for forecasting the PV power. This meta-heuristic optimization algorithm is used to assign optimized weights to the layers of neural network by minimizing the cost function. The proposed hybrid intelligent model uses mean square error as its objective function for a maximum of 1000 iterations; the model comprises of four input nodes with five hidden layers and one output. The proposed method as defined in Eq. (23) accurately calculates the τ_L in accordance with the sky conditions and irradiance prevailing at the time, and it is given in Fig. 10. In this analysis, the effect of different parameters, such as irradiance, wind speed, cell temperature and aerosol data, is given in Table 6 of the appendix section. From Table 6, it is observed that the impact of τ_L on the PV power output is -38.2%; here, negative sign shows that as τ_L increases, the PV power generation decreases. The accuracy

Table 3 Performance indicators of different training algorithms during training state

Technique	Training error (TE)	Iterations/epochs	Regression coefficient (R)
GWO	3.23×10^{-4}	148	0.99720
PSO	4.33×10^{-4}	963	0.98575
LM	1.24×10^{-3}	89	0.98410
ANF	7.68×10^{-3}	678	NA

of the aerosol data and its effect on the PV power generation are studied in Fig. 18.

The performance of the proposed model has been assessed with changing air quality and is shown in Fig. 10. This figure shows the variation of irradiance and Linke turbidity for a highly polluted day. The mean τ_L for the day is calculated to be 8.5 (very polluted condition), and the density of aerosol particles during the morning and evening hours is very high and gradually decreases and is constant for the afternoon hours, for the selected site.

The forecasted PV power output from GWO–MLP model is also compared with the actual solar PV power measured using 9018BT Solar Analyzer. The measured PV power (P_{out}) and forecasted PV power using GWO model is shown in Fig. 11a. From Fig. 11a, it can be observed that the forecasted PV power is very close to the measured data during the afternoon (i.e., high sunshine hours). However, the performance of the proposed model is deteriorated in case of more diffuse solar irradiance. The NE for the designed model ranges from 0.27 to −0.12 as shown in Fig. 11b. GWO technique being more of an exploration-based computational

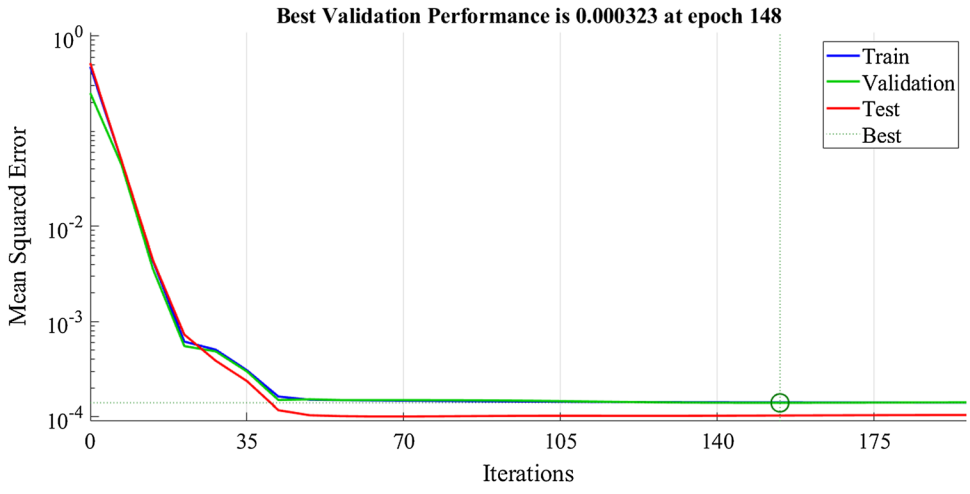

Fig. 12 MSE for testing, validation and training stages of the proposed model

technique, hence can readily forecast the variations of PV power. NRMSE, NMBE and NMAE of the proposed GWO model are 6.67%, 2.267% and 4.681%, respectively. As all the statistical indices have small values, it shows that the PV power output is accurately predicted for varying conditions that occur in a day.

A comparative analysis among the aforementioned algorithms is carried out on the basis of TE, iterations required for minimum TE and regression coefficient (R). The training error is said to be the error obtained when the trained model is again trained for target values. Regression coefficient (R) defines the associativity of the model output with its inputs. It defines the goodness of fitness function. It is a measure of how well the variation in the output is explained by the targets; the closer this coefficient is to 1, the better is the relation of inputs and outputs. Table 3 shows that the four training algorithms have been compared on the basis of TE, R and number of iterations required to reach minimum TE. The value of R using GWO-based MLP model is found to be 0.99832 with minimum number of iterations, i.e., highest computational speed training algorithm. From these results, it is revealed that the GWO-based model requires less computational time as compared to the other intelligent algorithms such as PSO. Further, the value of training error is also less for the proposed model which is 3.23×10^{-4}.

From Table 3, it can be concluded that GWO training technique is relatively better than the other training techniques. This technique has the minimum TE, and hence the associativity of inputs to output is also high, and the computational speed is faster than adaptive neuro-fuzzy (ANF) and PSO techniques. The training parameters for various algorithms are given in Table 4. The n_h value for the LM-based ANN model is 10 to reach a feasible TE of 10^{-3} order; this value of n_h is maximum in comparison with other techniques used; thus, the ANN model with LM approach is more complex than the GWO- and PSO-based models. Figure 12 clearly shows the performance of the GWO-based ANN solar PV forecasting model during different stages, i.e., training, validation and testing. The testing stage error is of the order 10^{-4}, i.e., very small, and the error for validation stage is similar to the training stage error.

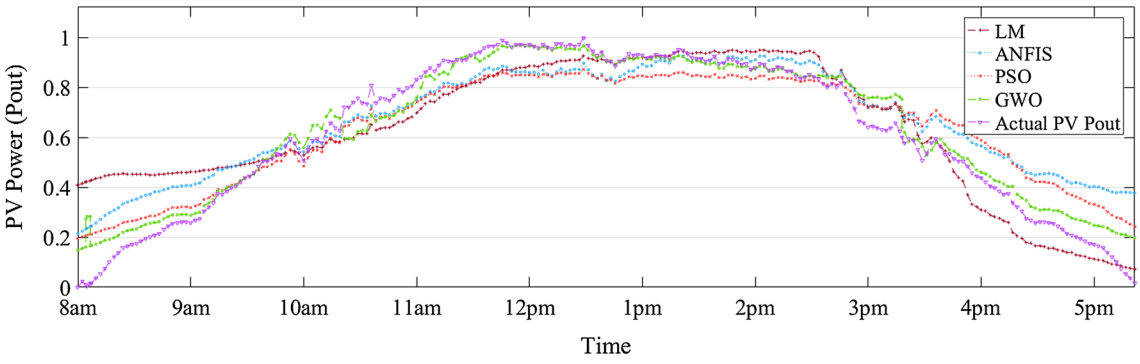

Fig. 13 PV power forecasting for high τ_L condition

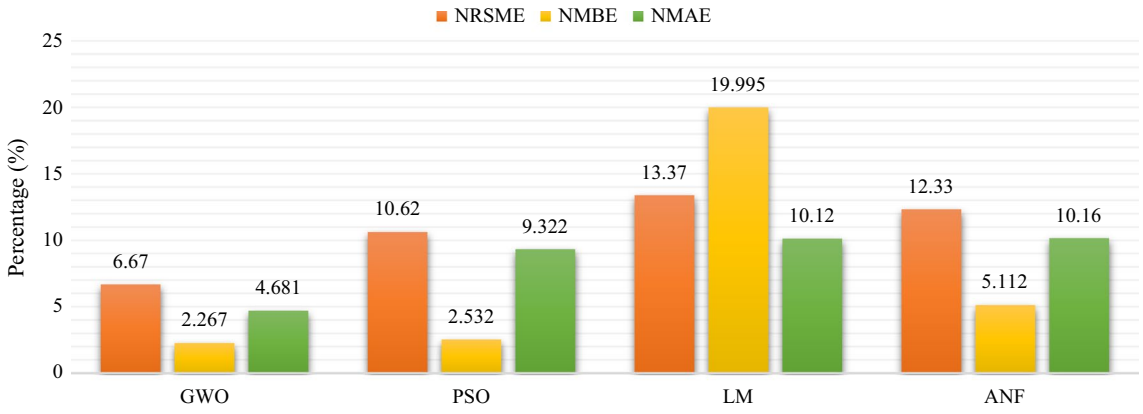

Fig. 14 Comparison of various forecasting model in terms of NRMSE, NMBE and NMAE

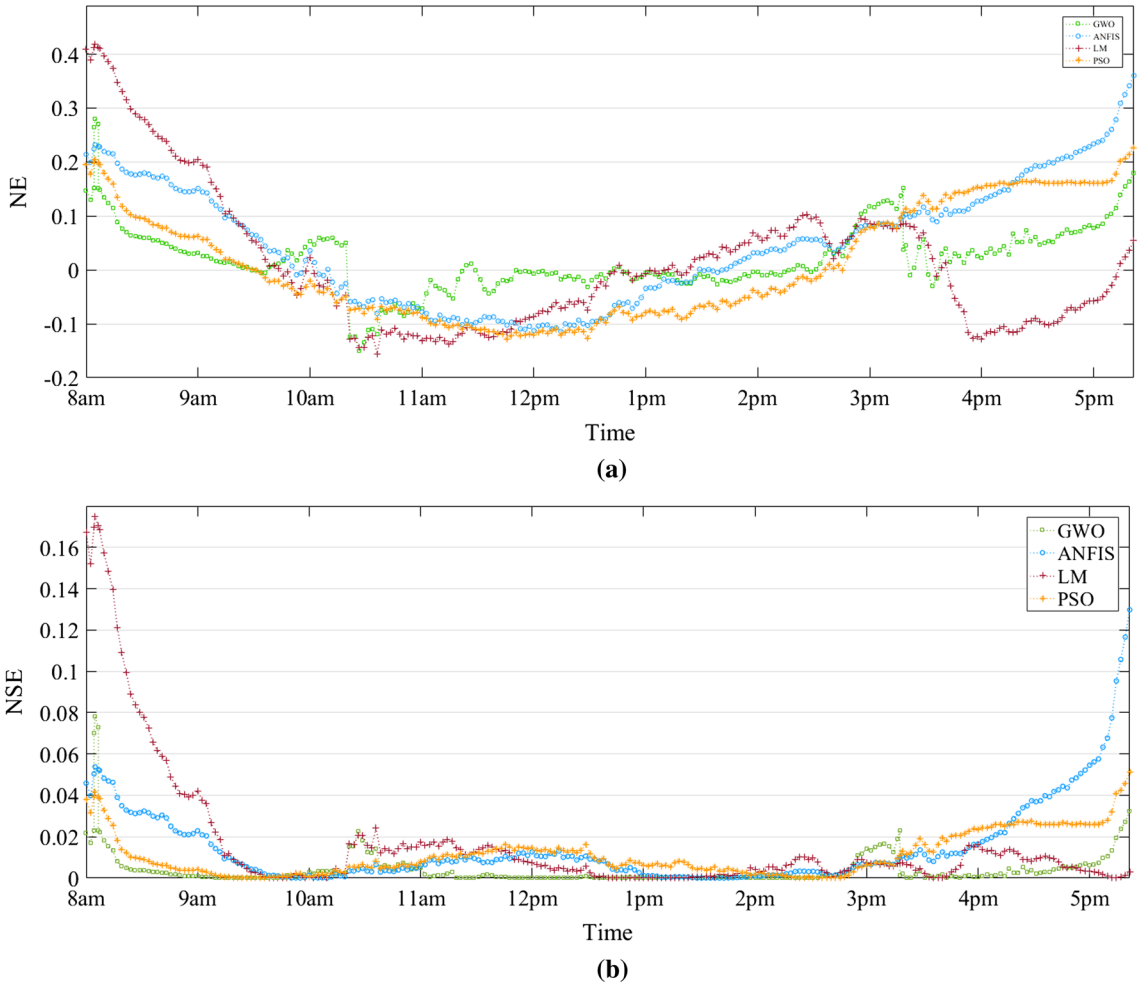

Fig. 15 **a** Variation of NE for different models, **b** variation of NSE for different models

The forecasted PV power output obtained from LM, ANFIS, PSO and GWO is compared with the measured data and shown in Fig. 13. The models forecast the PV power for every 2 min during sunshine hours. From Fig. 13, it is clearly seen that during morning hours, the PV power generation is low, and the power reaches maximum value in the noon hours, and then gradually decreases during the evening hours. However, the performance of the developed model is found satisfactory during sunshine hours. The performance indices are shown in Fig. 14 for different solar PV forecasting models. The normalized error (NE) and normalized squared error (NSE) of the predicted PV power for every sample are given in Fig. 15a, b, respectively. From Fig. 15a, b, it can be seen that NE and NSE are significantly large for the LM-based MLP model during morning and evening hours where the amount of diffuse irradiance is dominating as compared to the direct solar irradiance. When τ_L is very large, i.e., ≥ 9, diffuse irradiance increases significantly as the aerosol particle also increases the atmosphere. As τ_L is in the range of 5–7, the impact of aerosol particles do not affect the proposed PV power forecasting model as NE is small. However, the performance of the model has been improved significantly during noon hours. The summary of results obtained using Fig. 15a, b is also given in Table 5. The performance indicators such as NE, NRMSE, NMBE and NMAE for the different approaches are shown in Table 5. The value of statistical indicators used in this work is better for the proposed GWO model as compared to the other intelligent approaches.

Table 5 Performance comparison of the proposed models for prediction stage

Technique	NE	NRMSE	NMBE	NMAE
GWO	[0.27, −0.12]	6.67	2.267	4.681
PSO	[0.21, −0.10]	10.62	2.532	9.322
LM	[0.41, −0.15]	13.37	19.995	10.12
ANF	[0.38, −0.10]	12.33	5.112	10.16

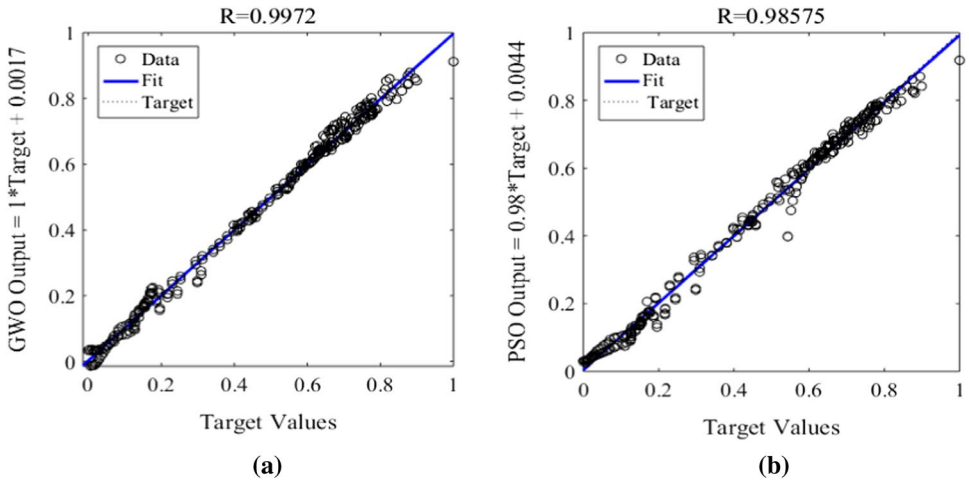

Fig. 16 **a** Regression plot of GWO in training state, **b** regression plot of PSO in training state

From the above figures and Table 5, it is concluded that the performance of the GWO-based approach is found better as compared to the other intelligent techniques. The obtained results from the proposed model may be used for various applications such as demand response, PV plant operation and control in smart grid environment. The regression coefficient plot for GWO- and PSO-based approach is also given in Fig. 16a, b, respectively.

6 Conclusion

In the proposed work, a new model based on GWO approach for solar PV power forecasting has been developed and presented for smart grid environment. The proposed model is developed on the basis of meteorological parameters to forecast the PV power output. The performance of the model is evaluated on the basis of statistical indicators and validated from the dataset obtained from 5 kWp PV system installed at the rooftop of the laboratory. The forecasted PV power model performance has also been analyzed with respect to changing air quality. This paper provides performance analysis of the proposed solar PV power forecasting model for varying air quality modeled using the Linke turbidity factor for the selected site. A comparative analysis of proposed GWO–MLP model with other intelligent techniques is also performed and was found better. The performance indicators such as TE, iterations and R were 3.23×10^{-4}, 148 and 0.99720, respectively, suggesting that the proposed hybrid intelligent model is better. The proposed model also offers relatively fast speed for training of the neurons and is comparatively less complex. The obtained results may be used for smart grid energy management and demand response applications and would be helpful in getting reliable, load smoothing and economical electrical energy to consumers.

The conference was possible with the financial support of UGC. I, on behalf of Kalindi College and entire staff of our Department of Computer Science, extend my gratitude to UGC for all their extended support and help. I would like to express my deepest gratitude to the Patron and Advisor of this conference, Principal Kalindi College, Dr. (Ms.) Anula Maurya, for providing all kind of administrative support while planning and execution of this conference. I thank all the invited keynote speakers for their enlightening talks. I sincerely owe my gratitude to all the Technical Programme Committee members for their timely review and comments on all the submissions. I sincerely thank all the teaching staff of Department of Computer Science, Kalindi College: Dr. Vandana Gupta, Ms. Shalini Sharma, Dr. Reena Jain, Ms. Anshula, Dr. Yogendra, Dr. Susheel, Ms. Ramya, Ms. Rajani, Mr. Harshvardhan; Computer lab staff Ms. Mamta Sachdeva, Ms. Asha Khantwal and Mr. Rajiv; and all the student team members for their support in successfully organizing this conference.

I am also thankful to Bloomsbury Publishing India Pvt. Ltd. for taking interest to publish this book. We are thankful to all the chapter contributors for providing their revised papers and supporting us whenever any information was required for completing the manuscript of the book. I wish all the readers a knowledge enhancing experience while reading this book.

Best wishes!

Nidhi Arora

Preface

Twenty first century has been defined by advancement in information technology and communication. It has become an integral part of our daily life and, has been the fastest growing area. The world has now become a global arena, with no virtual boundaries. Research is being conducted at a very fast pace, and practically every day there is addition to the existing sphere of knowledge with primary focal areas being Artificial Intelligence, Cloud Computing, Internet of Things, E-learning, Big Data Analytics and many more.

This book "Emerging Trends in Information Technology" is the outcome of the National Conference on Emerging Trends in Information Technology organised by Department of Computer Science, Kalindi College during 1st and 2nd August 2019. The conference was fully funded by University Grants Commission. The book consolidates some of the high quality original papers from the set of papers presented in the National Conference on Emerging Trends in Information Technology (NCETIT 2019). The main aim of the conference was to bring together experts from academic institutions, industries, leading engineers, students, scientists & scholars to facilitate close interaction for exchange of views & dissemination of knowledge with prime focus on the practical challenges encountered and the solutions adopted in all the fields related to Computers and Information Technology. Parallel invited talks on both days by experts from renowned Indian Universities attracted large number of audience from various colleges. Due to wider applicability of the conference theme, large number of abstracts and full papers were submitted and presented, out of which only sixteen high quality papers were selected to be published as chapters in this book after passing through peer review and plagiarism check though abstracts of all the presented papers were published in a souvenir booklet released during the conference.

Introduction

Nidhi Arora[1]

In today's fast growing highly connected world, where technology becomes obsolete even before reaching masses and data becomes big and diverse even before information could be fetched, there lays a tremendous pressure to keep technological growth pace in line with the issues of information and data handling. Each day brings new challenges in the field of emerging trends related to technological growth for efficient information handling.

There has become a direct relationship between a country's economy and its technological state of growth, since the technology has sweeped in almost every facet of life not even in urban brackets but also in rural setups. Hence, this is the prime research area in present world which makes it inevitable for researchers from all disciplines, ranging from humanities and pure sciences, to work in isolation leaving technology behind. Hence, technology and its applications is an interdisciplinary area where diverse research fields are centrally connected giving this field of research many dimensions and directions. Some hot topics one can see and identify are Big Data, Cyber Security, Social Media Analytics, Cloud Computing, Optimization, Artificial Intelligence, Machine Learning, Social Networks, Digital Image recognition and E-Services including E-Governance, E-Learning, E-Commerce and so on. The list mentioned is not consolidated but has many more sub fields which are independent and fascinate attention among masses.

To be truly able to apply and use any of these or all of these emerging technologies, one not only needs to fine tune its understanding regarding advantages but also the disadvantages of these technologies. Even though lot of knowledge is present on web portals, common physical platform of discussion, where mixed genres are facilitated to share their knowledge remains the necessity. This book provides a common medium of resource, where in each chapter presents a crucial discussion at length on a particular area of research in information technology field. The chapters

[1]Assistant Professor, Department of Computer Science, Kalindi College, University of Delhi
E-mail : nidhiarora@kalindi.du.ac.in

are a collection of papers presented in a National Conference on Emerging Trends in Information Technology wherein researchers and industry experts from all over India discussed these topics and facilitated peer community to enhance their knowledge about the state of the art in these fields.

Chapter 1 presents the current state of the art on classification methods of supervised machine learning for cyber security intrusion detection. The chapter enlisted approximately 40 related studies on cyber security for IDS that focusing on the architecture (single, hybrid or ensemble classifier), classifier algorithms using well-known public datasets for experiment, the classification algorithms based on supervised learning were evaluated using metrics (F1score, precision, false positive rate, false alarm rate, accuracy) and feature selection for supervised machine learning algorithms.

Chapter 2 focuses on in-depth analysis of two cryptographic techniques namely RSA and ECC in digital signature applications. It also compares the performance and security aspects of these techniques.

The epicenter of the study presented in **Chapter 3** deals with the role and impact of social media on Indian students. Parameters such as political mobilization, political influence, opinion, changing behaviour in youth are used to evaluate the role of social media. The methodology used in the research is mainly conducting (most of the data are collected using a questionnaire as a research tool).

Chapter 4 discusses sentiment analysis, a key research area among IT researchers. It discusses application of two different approaches are presented to extract the sentiment of the reviews at the sentence level. In the first approach, TextBlob library was used to calculate the polarity of the sentence whereas the second method follows a rule-based approach in which two Lexicons of polarised words (negative and positive) were used.

Chapter 5 presents various innovative frameworks to understand the transition of citizens' direct participation in Democracy to their e-participation in Digital Democracy. This study provides new insight into how different tools are used to engage citizen in governance through various e-participation models and what are challenges to enable the citizen to participate in the democratic process in India.

In-depth literature survey on the state of the art of Big Data paving its way to E-Business is discussed in **Chapter 6.** The survey focuses on the

different sorts of data held and its inverse usage for e-business along with different ways of providing security and safety for data corresponding to anonymity. It also highlights the issues in big data with respect to e-businesses and tries to trigger the maximum usage of big data applications effectively.

Chapter 7 revolves around the discussion on formulating an unconstrained nonlinear programming problem and determines the optimal solution using gradient search technique. Also the authors discuss the post optimality analysis by varying the coefficient of the objective function and the obtained optimal solution values respectively.

Chapter 8 authors beautifully discussed postmodern techno culture and the need for feminist intervention by use of mobile applications for women safety in India. The presented research explore the author's previous case study of "My Safetipin" mobile application from a fresh perspective of analysing female participation not as decision makers to look at possible reasons for failure of this e-participation platform.

Chapter 9 gives an overview on some significant works in the field of Recommender System on the basis of its three techniques namely collaborative filtering, content based filtering and hybrid filtering. The Chapter also includes various issues and application domains of Recommender System.

Chapter 10 investigates synchronization of two identical fractional order (FO) Chua's chaotic system with disturbance using the technique of Adaptive Sliding Mode. The introduced techniques has many applications in secure communication and neural network.

Chapter 11 presents a model developed for single server finite capacity Markovian queuing incorporating feedback of customers, encouraged arrivals and the concept of reverse reneging. In today's highly volatile uncertain environment, understanding customer behavior in advance is of utmost importance for any firm in order to stay ahead of competitors. Firms need to design effective operational strategies for overall functioning of the system.

Chapter 12 revolves around the discussion to absorb the ideas of Cyber Security alongside the unsafe impacts of Malicious Software and finding proper ways of protecting the system and simultaneously highlighting the cyber security on a global scale and especially in India. Malicious software, or Malware, is a Cyber Security threat that affects the user's computer system by exploiting the system's vulnerabilities.

Chapter 13 aims at assessing and benchmarking the operational efficiency of 12 scheduled (domestic and international) passenger airlines in India during the year 2016–17. Projections are discussed and improvements are mentioned which will help the decision makers to improve their companies performance.

Chapter 14 presents an in-depth survey on the applications of big data in real world. Use of Big data in all spheres of personal & professional lives be it agriculture, banking, travelling, healthcare, financial institutions, food industry, power sector, managing smart cities and homes is discussed at length.

Chapter 15 authors discussed hybrid projective combination synchronization (HPCS) between chaotic generalized three species Lotka-Volterra (GLV) biological system using adaptive control method. Lotka and Volterra introduced the well-known examples of basic biological models of two species predator and prey model. numerical simulations are performed to show the efficiency and accuracy of the suggested scheme using MATLAB.

Chapter 16 focusses on E-learning trends among students. One case study that provides a direct comparison of direct classroom teaching and teaching through E-Learning environment is presented to know whether there is any major difference in students learning and their performance when learning is through E-learning based approach and through classroom lecture based learning approach. In addition to this a survey was conducted in this study which allows the students to give their feedback and suggestions on both the learning approaches.

A Literature Survey on Cyber Security Intrusion Detection Based on Classification Methods of Supervised Machine Learning

Anu Yadav[1] and Ela Kumar[2]

ABSTRACT: *In the era of big data, with the rapid change in communication technology and the internet, the number of data features increasing and decreasing intrusion detection system performance in terms of accuracy. The growth of the Internet and its usage has risen a problem of network attacks; hence cyber security has become an important issue. The intrusion detection system (IDS) is used to classifying the patterns for attacks on the network and to identify unauthorized access due to cyber-attacks. In this literature survey paper enlisted approximately 40 related studies on cyber security for IDS that focusing on the architecture (single, hybrid or ensemble classifier), classifier algorithms using well-known public datasets for experiment, the classification algorithms based on supervised learning were evaluated using metrics (F1score, precision, false positive rate, false alarm rate, accuracy) and feature selection for supervised machine learning algorithms. This paper also included short descriptions of IDS and public dataset.*

Keywords: Machine Learning, KNN, SVM, LDA, Naïve Bayes.

1. INTRODUCTION

Today imagine our life without the Internet can't credible. There are lots of internet users who are regular user in cyberspace for various purposes such as educational, professional, commercial, and socialization. Internet increases users Tendencies to share their secret data and details, pictures and Opinions about the world. Hence it is an important aspect of

[1] PhD CSE Research Scholar, Department of Computer Science and Engineering IGDTUW, Delhi, India. E-mail: anuyadavcse@gmail.com

[2] Professor and HOD, Department of Computer Science and Engineering IGDTUW, Delhi, India. E-mail: ela_kumar@rediffmail.com

machine learning approaches to make a reliable model sooner that does not affect by cyber-attacks. This paper presents the outcome of a literature review of supervised machine learning (SML) for classification methods for cyber security. This paper enlisted more than 50 related studies which are published in the last few years and highly cited papers.

The ML (Machine learning) is a subfield of AI (Artificial Intelligence), which allows the machine to learn without programming. The ML is divided into four main categories based on the learning methods: supervised, unsupervised, semi-supervised and reinforcement.

The IDS (intrusion detection system) is used to discovered attacks on the cyber world by identifying unauthorized access, and modification of information for a particular machine learning system. The intrusion is divided into three main categories based on the detection for cyber analytics of IDS: First, the Misuse-based or Signature-based method, which detects the well-known type of attacks in the cyber world by using signatures of that particular attack by using frequent manual updates of the DB (database). Second, an anomaly-based method, which builds a network and system behaviour, and identifies anomalies. The last one is the Hybrid method which is a combination of misuse based and anomaly-based detection, they increased DR (detection rates) of known intrusions and decrease the FPR (false positive rate) for unknown attacks. The IDS is divided into two main categories based on the detection of intrusive behaviour: the host-based and network-based.

This literature paper focuses on SML Classification techniques for cyber security, the primary focus of our paper is to meet certain criteria for SML. The queries performed on IEEE, Springer, Google Scholar and Science Direct using machine learning, cyber security, KNN, SVM, LDA, Naïve Bayes and intrusion detection. The paper selected based on popular technique, the number of citations, UGC approved journal and publication year.

2. IDS PUBLIC DATASETS

The raw data is a basic component of research, which can be obtained directly or from existing public datasets. The dataset chosen should be perfect for machine learning approaches. The DARPA 1998/1999 intrusion detection dataset [1] which is used by most of the experiments conducted on IDS, it is collected and published by the CSTG (Cyber Systems and Technology Groups) of the MITLL (Massachusetts Institute of Technology Lincoln Laboratory).

The KDD cup99 dataset is more derived and contains 41 features/ attribute. Dataset aims to be freely available for survey/research and which is more realistic for IDS, a different version of this dataset provided by contest. The dataset has a connection which is labelled as normal or attack (DOS (Denial Of Service), R2L (Root 2 Local), U2R () and Probe) data.

The newly refined version of KDD Cup99 dataset is called as NSL-KDD, which introduced in KDDMT (Knowledge Discovery & Data Mining) Contest [39] to improve KDD Cup99 dataset. It identifies attribute is from intrusive or normal connections and contains 22 various attack types.

3. CLASSIFICATION METHOD FOR SML

3.1 *SVM*

SVM (Support Vector Machine) is most accurate and robust supervised learning model and construct hyperplane in the high dimensional feature space between two classes with maximum margin. As shown in figure line between support vector points is hyperplane and the closest vector points near separation hyperplane are support vector points [2].

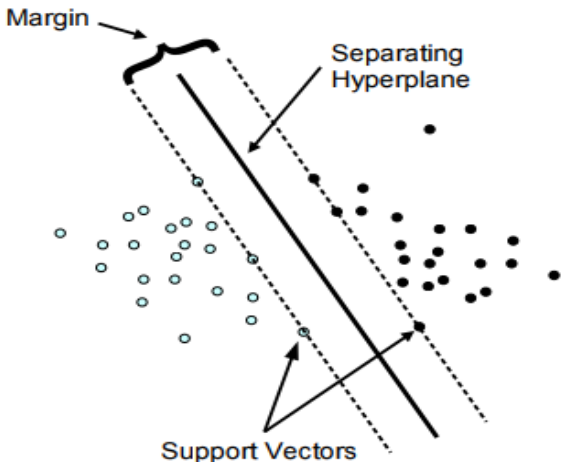

Fig. 1: Support Vectors, Hyperplane and Margin

[3] shows a combination of DBN (Deep belief network) as a DRA (dimensionality reduction algorithm), one-class SVM and anomaly detection technique for not labelled set of data.

[4] they used multi-class SVM and feature selection by chi-square for IDS model to decrease the FAR (false alarm rate) and increase the DR (detection rate) and classification accuracy (ACC) of network attacks on NSL-KDD dataset. In SVM use two parameters! (gamma) and C (over fitting constant) used in parameter tuning technique for RBF kernel (Radial Basis) optimization Function. They used 3 performance metrics and found that the PCA-GA-SVM, KPCA-GA-SVM, and SVM (single) methods have less time for training than N-KPCA-GA-SVM model.

[5] they explained a hyper-heuristic SVM configuration process as a bi-objective optimization problem for accuracy and complexity. The hyper-heuristic framework consists of high-level strategy (the search performance to control the selection) and low-level heuristics (to generate a new SVM configuration) with the Pareto set of SVM approach. Their framework evaluated Microsoft malware big data classification and anomaly intrusion detection cyber security problems.

[6] they use ELM and SVM in multi-level hybrid intrusion detection method for known and unknown attacks and obtained improved detecting efficiency. They used K-means to build a high-quality training dataset using KDD Cup 1999 for improving the performance of the classifiers and reduce the training time of classifiers. Their results show an accuracy of 95.75% with an improved detection rate of R2L, DoS, and U2R attacks.

[7] FWP-SVM-GA (Feature selection Weight Parameter optimization of SVM based on Genetic Algorithm) for human-centred IDS on KDD Cup 99 datasets. First, it optimizes mutation and crossover probability of GA based on the population evolution algebra search strategy and fitness function value that increases true positive rate, decreases the classification time and decreases the SVM error rate. The proposed model increases intrusion detection rate (96.61 and 100), true positive rate (0.9066%), and the accuracy rate (0.9975%) but it decreases FPR (3.39 and 0) and FNR (0.07%) for 10000 training set.

The K-means and multi-level SVM algorithm [8] for network IDS on NSL-KDD dataset which divides the data into different clusters by using Kmeans and mark the abnormal cluster using multi-level SVM for classification. The results show that increases the detection rate and reduce the false alarm rate by comparing the proposed model with SVM+CSOACN and C4.5+SVM. Experimental results showed that TPR and FPR for different attack types are DoS 98.64% (True Positive) 4.52%

(False Positive), Probe 97.81% (TP) 3.85% (FP), R2L 89.42% (TP) 20.21% (FP) and U2R 95.54% (TP) 6.97% (FP).

The problems due to a virus attacking the application layer network protocol, TCP communication protocol is analysed by IDS based on clustering and SVM [9]. Combination of unsupervised FCM and supervised SVM to calculate the distance between communication data and cluster centre. Experimental results show that improved accuracy and detection precision with the reduction in detection time and training time. The outcome of SVM detection accuracy of the test set is 94.8571% and time is 0.76647 sec where the outcome of FCM 96.8571% (accuracy), time is 0.56155 sec for test set and training set the accuracy is 97.3333% and the time is 0.49516 sec.

[10] used ADFALD dataset for host-based anomaly detection system with the one-class SVM algorithm. Their experiments show that model removed duplicate entries as well as achieve satisfactory performance and reduce the computational cost but the recognition rate will remain low.

[11] described the separation of control plane and data plane by using SDN (Software Defined Networking) controller for DDOS (Distributed Denial of Service) attacks. Among all algorithms, SVM classifier gives higher accuracy and less false positive rate.

[12] explained the SVM classifier method by combining feature selection and multiple class NSL-KDD CUP 99 intrusion detection dataset. The method best performance with an F1 score of 0.99 and worst performance F1 score of 0.77 which unable to detect intrusion in network. Their results show classification accuracy 91% using 3 features, 99% using 36 features, and 99% when 41 training features selected.

3.2 *KNN*

The KNN (K nearest neighbour) algorithm is simple, depends on accuracy as well as prediction and do not contain any learning phase hence called as a lazy learner but memorize the training data [13]. The KNN classifies the new data from the available dataset based on similarity measures using distance metrics (Euclidean distance, Mahalanobis or Hamming distance) to predict new unseen data point.

[14] The unbalanced normal data and intrusion data are obstacles which are solved by FCM (fuzzy C-means) and KNN algorithm to construct feature vectors in FCM based on clustering central point and fuzzy

matrix wherein KNN based on classifier on KDD-Cup 99 dataset. The FCM intrusion detection model is superior to the TANN (Triangle Area Based Nearest Neighbours) and CANN (combining cluster centres and nearest neighbours) models the accuracy of FCM+KNN is 98.73% where TANN is 98.47% and CANN is 96.07%, the detection rate of FCM+KNN is 96.23% where TANN is 94.5% and CANN is 86.05% and false alarm rate for FCM+KNN is 0.28%, TANN is 0.4% and CANN 0.75%.

[15] The fusion approach to detect intrusion that hybridises different classifiers of SVM, k-NN, and Primal-Dual PSO (Particle Swarm Optimisation) on the KDD99 dataset. There result shows that the highest accuracy of SVM, k-NN and pdAPSO is about 97%, 98% and 99.8% respectively, for R2L attack. This fusion approach generating accuracy of 98.55%.

[16] The intrusion detection using KNN-ACO (ant colony optimization) and SVM method performed on KDD1999 Cup dataset for improving classification accuracy and generates low false alarm rate. The overall accuracy rate for KNN-ACO is 94.17%, Back propagation neural network (BPNN) is 93% and SVM is 83%. The overall false alarm rate for KNN-ACO is 5.82%, BPNN is 6.90% and for SVM is 16.90%.

[17] Explained the CANN and KNN classifier performance by combining them with K-MEAN clustering on NSL-KDD dataset. To classify their data, they used the nearest neighbour (KNN) and the farthest neighbour (k-FN). The ten times comparison of CANN with k-FN CANN results shows improved accuracy and detection rate with reduces false alarm rate.

[18] To detect unknown attacks with insufficient training data by using Fuzzy C-Means algorithm, distance-weighted k-Nearest Neighbours classifier and Dempster Shafer Theory to assess the belief function and pignistic probabilities on KDD'99 datasets. The experimental result ofthe Fuzzy and DST recorded for DOS class 5.22% others 6.57% to 11.18%, Probe 3.90% others 6.21% to 12.07%, U2R 8.12% others 13.13% to 35.06%, R2L 9.98% others 10.29% to 24.60% and UA 11.25% others 40.68% to 47.94%.

[19] They proposed two-layer hybrid classification and detection process for network attacks detection on KDD99 dataset where first layer have GBDT classifier for identifying DoS attacks and second layer of KNN and stacking ensemble classifier which optimized by FOA (Fly Optimization Algorithm) to divide the non- DoS data from Normal, R2L,

Probe and U2L. Evaluation implemented by accuracy, precision rate and recall rate. The classification of DoS data with KNN on attacks like a smurf, neptune pod, back, and teardrop has high recall rate and precision rate of smurf and neptune is higher than 99% but back and the pod is higher than 60%. The higher accuracy SMOTE+GBDT+SEM method compared with SVM+ANN and SMOTE+GBDT methods.

[20] proposed KNN-TSA intrusion detection model based on TSA (tree-seed algorithm) reduces feature redundancy and extract feature for input and KNN is used for classification on KDD CUP 99 datasets to improve the accuracy and efficiency of network IDS. The experimental outcome shows Accuracy of KNN-PSO 83.65%, KNN-GA 78.78% and TSA-KNN 87.34%.

A hybrid approach of k-means clustering and KNN classification algorithm is presented in [21] to detect intrusion on the cloud system using NSL-KDD data set for evaluation of experiments. The experimental outcome proves the ability of the proposed model for detection of intrusion attacks.

3.3 *LDA*

The LDA (Linear Discriminant Analysis) is a simple, complex and robust classification method of SML proposed by RA fisher (1936), which provides accuracy based on linear combination of predictors/ variables for separating 2 classes/targets using Mahalanobis distance, coefficient vector, class probability, covariance matrix and score function.

[22] LDA- LR (Linear Discriminant Analysis and Logistic Regression) anomaly-based IDS model which performs well for binary class and multiclass classification problem. LDA – LR experiment on NSL-KDD dataset and comparison analysis between performances of other IDS based on Naive Bayes, C4.5 and SVM and LDA-LR. The Comparison of intrusion detection models on the binary class for 23 Features and measured accuracy (ACC) and DR in terms of percentage where SVM have 99.63% (ACC) 99.16% (DR), Naive Bayes 98.16% (ACC) 89.97% (DR), C4.5 have 99.85% (ACC) 90.95% (DR), LDA have 99.83% (ACC) 90.89% (DR), And LR have 98.27% (ACC) 91.59% (DR). The ACC and DR for LDA and LR models on the multi-class is 95.05% (ACC) &95.05% (DR) for LDA and 95.31% (ACC) & 98.74% (DR) for LR.

LDA feature extraction [23] method used to detect cyber-attacks and remove the useless information from original data by using truncated

mean to estimate the class mean vector. The experiments consist the 1000 training samples with the composition of 100 normal, 100 DOS, 100 R2L, 100 PROBE and 50 U2R for evaluation of truncated LDA (with different *P)* on KDD cup99 and NSLKDD dataset. Detection Rate and FPR of truncated LDA, LDA and median LDA compared and found that FP lower than 2.3%.

R1-PCA (Rotational Invariant L1-norm Principal Component Analysis) and median LDA (median Linear Discriminant Analysis) algorithm for Anomaly IDS [24]. The reduction dimension algorithms using L1-norm instead of the PCA Euclidean distance and LDA uses the class median vector to estimate the CMV (class mean vector) on KDDcup99 dataset. The experiments consist the 1000 training samples with the composition of 100 normal, 100 DOS, 100 R2L, 100 PROBE and 50 U2R for evaluation FPR and DR.

The ensemble of PCA-LDA (Principle Component Analysis -Linear Discriminant Analysis) feature extraction algorithms [25]. The experiment outcome shows that feature reduction, increased detection rate and accuracy. They compared PCA-SVM and LDA-SVM in terms of ACC, FP and FN. In PCA-SVM Overall-accuracy is 0.8902, False-positive is 0.0089 and False-negative is 0.1704 where In LDA-SVM ACC is 0.8993, FP is 0.0203, and FN is 0.1133.

The OPMCA (optimal mean PCA) with LDA [26] on KDDcup99 and NSL-KDD provide accuracy to improve defence from cyber-attacks and increase detection rate and decrease FPR. Dataset consists of 100 normal, 100 DOS, 100 R2L, 100 PROBE and 50 U2R with training data at 1000 samples. The outcome is compared with OMPCA+LDA to LDA and PCA datasets.

The classification algorithms LDA-PCA to identify Intrusion and anomaly on NSL-KDD dataset [27]. The PCA selecting eigenvectors and correlation matrix which obtained correlation between two variables count (94.4%).

D-LDA (Direct Linear Discriminant analysis) algorithm [28] proposed using work of PCA and two-stage PCA+LDA algorithms which eliminates singularity problem to enhance defence against cyber-attacks. The experiment performed on 10% KDD Cup 99 dataset and outcome is accuracy DR is 97.75%, false alarm rate 0.83% and DOS attack has the best classification which is 82%.

[29] GLDA-SVM (Genetic Linear Discriminant Analysis and Support Vector Machines) IDS is a hybrid feature selection approach of LDA, Genetic Algorithm and SVM Kernels as classifiers on NSL-KDD dataset. The experiment outcome shows that this efficient soft computing approach provides high DR and low false alarms, maintaining low cost and low detection time for the intrusion.

3.4 Naïve Bayes

The NB (Naïve Bayes) classification technique is a powerful predictive model but simply based on Bayes theorem and probabilistic classifiers with assumption between features. The NB used in SPAM filtering, diagnosis, new categories and weather prediction.

If irrelevant data is processed than computational power and resources are wasted hence to improve IDS more efficient the false positive rate must be reduced by combining SVM, Naïve Bayes, and decision trees [30]. The overall accuracy of this model is 99.62% and the false-positive rate of 1.57%.

[31] Explained IDS based on Bayesian network using the wrapper approach to eliminate irrelevant features and reduce time complexity and high accuracy. Used NSL-KDD datasets with WEKA and they obtained overall performance 98.2653 in terms of accuracy, 98.9 precision, 1.73 error rate, and 0.007 low false-positive rates.

The IDS based on Bayesian network and feature selection for network traffic data which is evaluated using Kyoto dataset [32]. The Experimental results show that approach has a high level of detection rate of 99.9%, high efficiency and low FAR (0.015%) in detecting network attack.

The two algorithms hybrid approach which consist PCA for feature extraction as well as reduces high dimensionality and Naive Bayes for classification on the KDD99 dataset [33]. The outcome indicates a high accuracy rate and lower FPR. The performance (accuracy) of the Naive Bayes for Attack types DOS is 87.47%, U2R is 95.76%, PROBE is 97.12%, and R2L is 72.16%. According to result as the number of features decreases accuracy, DR and FPR increases, i.e. for 41 number of feature DR is 79.461%, FPR 15.362% and ACC is 80.143%; for 35 number of features, DR is 82.131%, FPR 4.680% and ACC is 82. 312%; for 10 number of feature DR is 96. 52%, FPR 1.16% and ACC is 96.240%.

[34] IDS detect security problems, improves the detection rate and reduced the false alarm rate of TLMD (Two Layers of Multi-class

Detection) that performed on KDDcup99. TLMD method consists of the C5.0 and the Naive Bayes algorithm for adaptive network IDS, which handles imbalanced datasets, deal with a continuous attribute, and reduce noise in the dataset. The comparison of Average Accuracy of SVM is 83.97%, C5.0 is 92.77% and TLMD Method is 93.32%, which proved that TLMD has the highest accuracy among them.

[35] The k-means clustering and naïve Bayes classification hybrid method used to overcome issues of Misuse detection and anomaly detection mechanisms for IDS. The distance sum-based features (the distances from each sample to several centroids found) are used for classifier training and detection by using a clustering algorithm. The experiment result provides improved accuracy for Probe, R2L and U2R attacks on NSL-KDD dataset, but poor results for Normal and DoS attacks, the outcome is Normal 74.11%, DoS 86.05%, Probe 92.48%, R2L 32.02% and U2R 19.0%.

The Naive Bayesian network algorithm for IDS based on the PCA [36] which calculate the CV (characteristic value) of the data by network attack then extract the properties and principal components through the PCA. The experiment performed on KDD CUP 99 dataset which including 4 types of attacks Probe, DoS, U2L and R2L whose 41 attributes taken as extraction, the outcome showed that the algorithm reduces the data dimension and improve the detection rate.

[37] Developed an IDS using two techniques which are based on neural network, first PCA method for feature extraction and second technique is combination of Bayesian (for noise reduction) and KPCA (kernel principal component analysis for feature extraction). The experiment is implemented using java technology, learning rate value=0.7, Hidden unit=4 and performed on KDD Cup 99 dataset and its result gives high accuracy and low error rate. The experiment outcome produced based on two methods IDS based on neural network using PCA (ACC 90.13%, ERROR 9.87%, TIME 18874 ms, MEMORY 21735120 bytes) and IDS based on neural network using Bayesian and KPCA (ACC 92.07%, ERROR 7.93%, TIME 9010ms, MEMORY 38000136 bytes) results show that the accuracy%, error % and time are better.

The online Naïve Bayes (NB) classifier [38] detect normal or bad intrusion continuously and keep updating mean and standard deviations for features on KDD CUP 99 dataset. The approach is able to perform incremental update. The performance of different class problems (23-class problem, 5-class problem, and 2-class problem) are compared based on

F1 score and type of class. Then comparison between online NB and online KNN for *Normal* 0.2440% (NB) 0.2917% (KNN), *DoS* 0.8951% (NB) 0.8997% (KNN), *Probe* 0.0168% (NB) 0.0161% (KNN), *R2L* 0.0041% (NB) 0.0043% (KNN) and *U2R* 0.0422% (NB) 0.0506% (KNN). The *Accuracy* comparison of machine learning methods on 2class problem is0.93% for Online NB, Perceptron Learning *is* 0.87% and for Online k-NN 0.96%.

4. CONCLUSION

As cyber-attacks increasing due to easy internet usage and access, it is important to study a systematic survey on improved IDS and machine learning algorithms for cyber security concerns. This paper presents a literature review of supervised machine learning for classification methods security on the cyber world using different public Datasets. The paper focused on recent year's improvement in the performance of supervised machine learning in the area of IDS. It is not easy to choose the best effective approach because each method of classification for an IDS has its pros and cons, most of the paper provide comparisons between there proposed method with another approach.

In-depth Analysis of the Performance of RSA and ECC in Digital Signature Application

Arokia Ramya Terrance[1], Shalini Sharma[2], Anu Sharma[3], Kanika Tyagi[4], Nikita Shokeen[5] and Nitya Saini[6]

ABSTRACT: *After passing the Information Technology Act 2000, the digitally signed documents become legally valid in India. The digital signature is used to digitally sign the electronic documents. It is used in many applications like eTender, e-filing the Income-tax returns, etc. Around 20 million users are benefited by the eMudhra Digital Signature Certificate Company in India. The online transactions and e-authentication have witnessed tremendous growth in the digital world, hence cyber security has become a critical element for safe and secure operations. While transferring data files, it becomes ineluctable not only to authenticate the users but also to make sure that the original data has not tampered. The Digital signatures are used to uncover unauthorized alteration to data and provide cyber security to authenticate the identity. The Digital signature application makes use of cryptographic techniques in order to provide safe and secure information to the users. The paper presents an in-depth analysis of two cryptographic techniques namely RSA and ECC in the Digital Signature applications and compares the performance and security aspects of these techniques.*

Keywords: Cyber Security, Digital Signature, Cryptography, ECC, RSA.

1. INTRODUCTION

The digital signature is an electronic signature used to authenticate the digital file. The digital signature is necessary for safe and secure

communication in the digital world. It gives the recipient a very strong reason to believe that the message was sent by the claimed user and that message was not altered in transit. Similar to the hand-written signature perform the role in the traditional system to construct the authentication of the paper document, the digital signature performs the role of authenticating the digital document. The four main characteristics of the digital signature are as follows:

- ***Integrity:*** Integrity means that a digital signature ensures the originality of data sent that is the message or sent data is not modified or tampered while transferring.
- ***Confidentiality:*** Confidentiality means that digital signature confirms the privacy of the data sent, that is it attempts to make the content of the message secret.
- ***Authentication:*** Digital signature ensures proof of identity. It identifies the claimed sender and the receiver of the message correctly.
- ***Non-repudiation:*** Digital signature confirms that neither the sender nor the receiver can oppose to the fact that the message exists.

The Digital signatures are constructed with the help of public-key/ asymmetric cryptography. Asymmetric cryptography makes use of two distinct keys, named as the private key and public key, for the process of creation of the digital signature and verification of the digital signature. As shown in Figure 1, the sender's private key is used to generate a digital signature at the sender side, whereas his/her public key is used for digital signature verification at the receiver side.

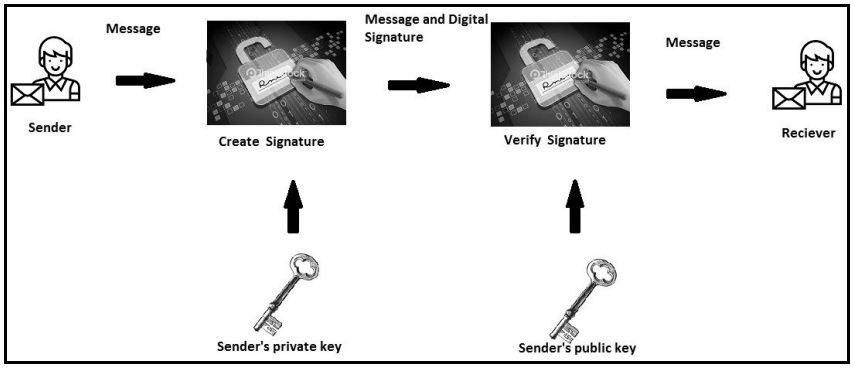

Fig. 1: Digital Signature

The applications of the digital signature include sending secure email, web-based monetary transactions, and code signing of any software developed

by any developer, e-Filing and e-tender. The digital signature is generated uniquely for every signer that is, no two different signers can have the same signature code. In India, the Digital Signature Certificate (DSC) authorized by the Controller of Certifying Agencies (CCA) helps different organizations or firms to have a smoother transaction of the Digital Signature application related to the Registrar of companies or Ministry of Corporate Affairs (MCA).

2. DIGITAL SIGNATURE PROCESS

The digital signature process is divided into the following three phases.

2.1 Key Generation

The process of key generation practices to produce the keys that are to be used in signing and verification process of digital signature. Whenever it executes, algorithm produces a key pair comprise of private (signing) key and an analogous public (verification) key. This process comprises of a random number generator and that will generate a unique key pair whenever it is used. SK stands for secret key because in the procedure the private key (signing key) is secret and PK stands for public key as the key is distributed to all users willing to verify the signature [1].

2.2 Digital Signature Creation

The creation of the Digital Signature involves the generation of the hash value for the given message, encrypting it, and transmitting it to the receiver, along with the original message and the process flow diagram is shown in Figure 2.

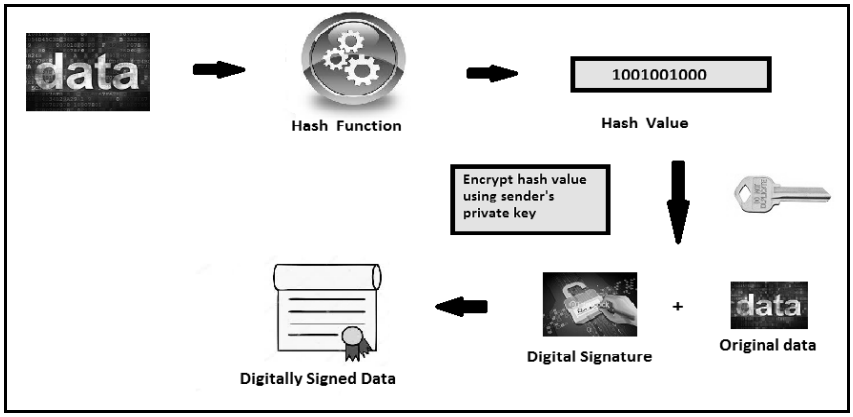

Fig. 2: Process Flow Diagram for the Creation of Digital Signature

Step 1: *Generating the Hash value*—The hash value of the original message is created, using one of the hash algorithms namely MD5, SHA-1, SHA-512.

Step 2: *Computing digital signature*—The created hash value should now be encrypted by the sender's private key, using any mathematical cryptographic encryption algorithm. The encrypted hash value is called as the digital signature

Step 3: *Transferring digital signature and original message*—The digital signature is obtained in the second step and the original message are transported to the recipient, who wants to verify the digital signature.

The above steps are illustrated in Figure 3, the Finite State Machine for signing the document by the sender.

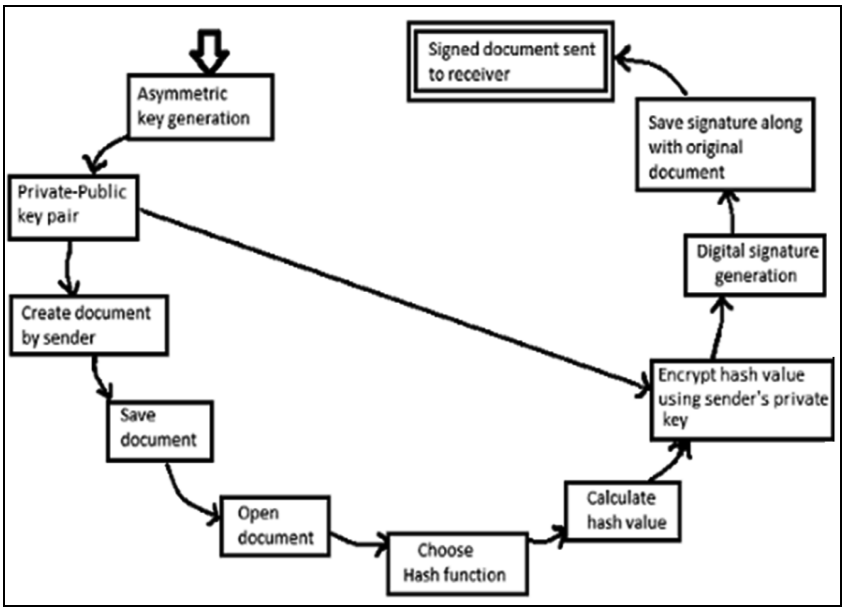

Fig. 3: Finite State Machine for Signing the Document by the Sender

2.3 Digital Signature Verification

The verification of the Digital Signature involves the computation of the hash value of the message and comparing it with the hash value obtained by decrypting the received digital signature and the process flow is shown in Figure 4.

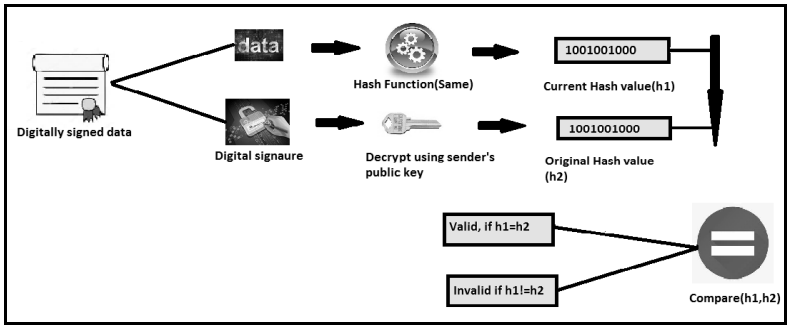

Fig. 4: Process Flow of the Verification of Digital Signature

Step 1: *Computing current hash value*—A Hash value for the message received by the recipient is computed using the same hashing algorithm used during the signing procedure. Let the resultant hash value be called as h1.

Step 2: *Obtaining hash value*—The digital signature received by the recipient is decrypted, using the same decryption algorithm corresponding to that which was used during the signing procedure. The decryption is done by the public key of the sender. Let the resultant hash value be called as h2.

Step 3: *Comparing hash values*—The hash value (h1) computed in the first step is compared with the hash value (h2) computed in the second step. If the values h1 and h2 are the same, then the verification process is fruitful and this proves that digital signature is valid. If the value of h1 and h2 is different, then the digital signature is invalid.

The above steps are illustrated in Figure 5, the Finite State Machine for verifying the document by the receiver.

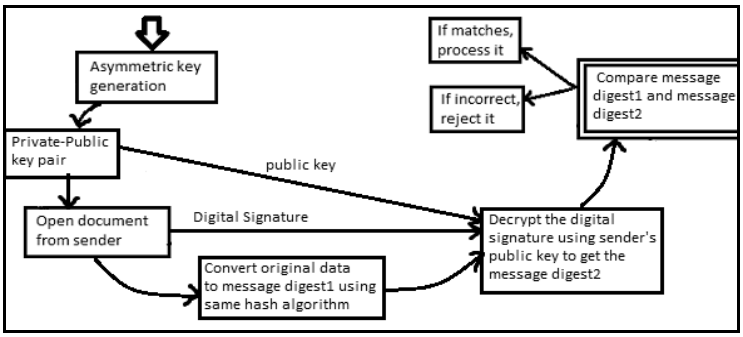

Fig. 5: Finite State Machine for Verifying the Document by a Receiver

The public key cryptosystem used to produce digital signatures can cause a sizeable difference in the performance of the digital signature process. The two most widely used algorithms in the digital signature are RSA and ECC. A brief analysis of these algorithms is done in this paper.

3. RSA

RSA is named after its devisers, Ron Rivest, Adi Shamir and Leonard Adleman [6]. RSA is a public-key cryptography that uses asymmetric key algorithms, where the key meant for encrypting a message is different from the key used for decrypting a message. RSA is the first algorithm that can be used both for encrypting the data and for generating digital signatures. RSA is most commonly used to establish truthfulness of data [7]. In the algorithm, two large prime numbers are used for creating the public key and the private key. RSA uses numbers e, d and n where (d, n) is known as the private key that must be kept secret and (e, n) is known as the public key that can be shared [3]. The number e is known as the public exponent, the number d is known as the private exponent, and n is known as the modulus. The key length of RSA is equal to the length of the modulus.

Key Generation

1. Choose two prime numbers p and q, where p and q should be distinct.
2. $n = pq$.
3. Let $\varphi(pq) = (p - 1)(q - 1)$ where φ is totient function.
4. Pick an integer e such that $1 < e < \varphi(pq)$, where e is an encryption key and $\gcd(e, \varphi(pq))=1$.
5. Calculate decryption key d such that, $d*e \bmod \varphi(pq) = 1$, where d is a secret key exponent.

Signature Creation

Let us consider the message being signed, m is in the range (1, 2, 3, ..., n–1). The Signature s is computed by encrypting the value of the hash function of the message h(m) where h is the hash function and m is the message sent from the sender end using the private key e.

$$s = h(m)^e \bmod n$$

Signature Verification

Signature is verified with the help of public-key d.

1. $h' = s^d \bmod n$, is computed.

2. If h' = h(m') mod n, then the signature is valid, and invalid otherwise where h is the hash function and m' is the message received at the receiver.

4. ECC

Elliptic Curve Cryptography, discovered by Miller and Kobiltz [5] is a cryptographic technique that makes use of public keys on elliptic curves over finite fields. ECC has been around since 1985. This type of system is most suitable for memory constraint devices such as Palmtop, Smartphone, Smartcards, [8]. For cryptographic use, the curve is considered over finite fields, not over real numbers. Here, we use an elliptic curve over prime fields, Z_p. An elliptic curve for all points (x, y) over Z_p is defined as follows:

$$y^2 = x^3 + ax + b \bmod p,$$

Where $p > 3$ and $a, b \in Z_p$, and the condition $4a^3 + 27b^2 \neq 0 \bmod p$ is satisfied.

The basic idea behind that the addition of two points P and Q, on an elliptic curve result in a third point, R on the curve, that is, P + Q = R. The addition is well defined only if there exists an identity element O, such that P + O = P. The inverse -P is defined as P + (-P) = O.

4.1 Elliptic Curve Digital Signature Algorithm

ECDSA is a revised version of Digital Signature Algorithm that uses elliptic curve cryptography. ECDSA was accepted as an American National Standards Institute (ANSI) in 1998 [4]. Here, we define our ECDSA standard for curves over prime fields Z_p.

Key Generation

1. Let us consider an elliptic curve E, of the general form described above, on which is a point A that generates a cyclic group whose order is q.
2. Choose an arbitrary integer t, and compute B = tA.
3. We now have the keys where,
   (a) k1 = (p, a, b, q, A, B), is the public key, and
   (b) k2 = (t), is the private key.

Signature Generation

The signature consists of a pair of integers (r, s). Both r and s are of the same bit length as q. Signature is generated as follows:

1. Choose an integer k_e with $0 < k_e < q$. Here, k_e is a key lasting for a short period of time.
2. Calculate $R = k_eA$.
3. Let r = x-coordinate of R.
4. Compute the value of the hash function of the message h(m) where h is the hash function and m is the message.
5. Compute signature, $s \equiv (h(m) + t.r)\ ke^{-1} \bmod q$,

Signature Verification

1. Compute value $v \equiv s \bmod q$.
2. Compute value $w_1 \equiv v.h(m) \bmod q$.
3. Compute value $w_2 \equiv v.r \bmod q$.
4. Compute $P = w_1A + w_2B$.
5. If $X_p = r \bmod q$, where X_p is the x-coordinate of point P, then the signature is valid and invalid otherwise.

5. COMPARISON BETWEEN ECDSA AND RSA

In this paper, we have implemented a digital signature application using a cryptographic technique named as RSA and ECC. We have executed the digital signature application on the original message of word count 268 using RSA with sample data inputs of 512, 768, 1024 and 2048 bits and ECDSA with sample data inputs of 192, 239 and 256 bits in CrypTool respectively and shown its impact in all the major phases namely Key Generation, Creation of the Signature and Verification of the Signature of the Digital Signature application. The hash function used is SHA-1 hash function. All the computations are performed using CrypTool 1.4.41 on a Microsoft Windows platform. CrypTool is an open-source project. The bit sizes are chosen as per its usage of these cryptographic techniques in most of the real-world devices.

5.1 Key Generation Phase

Table 1: Execution Time of Key Generation under Different Scenario

RSA		*ECC*	
RSA Modulus (Bits)	*Execution Time (Seconds)*	*Curve Parameter (Bits)*	*Execution Time (Seconds)*
512	0.1	192	0.027
768	0.13	239	0.018
1024	3.314	256	0.02
2048	4.086	Nil	Nil

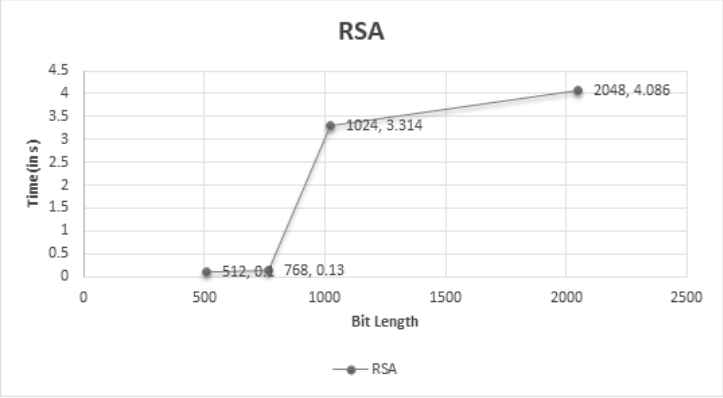

Fig. 6: Graph of the Execution Time for the RSA Key Generation Step for Distinct RSA Modulus

5.3 Signature Verification

Table 3: Execution Time of Signature Verification under Different Scenario

RSA		*ECC*	
RSA Modulus (Bits)	*Execution Time (Seconds)*	*Curve Parameter (Bits)*	*Execution Time (Seconds)*
512	0	192	0.002
768	0	239	0.006
1024	0	256	0.006
2048	0	Nil	Nil

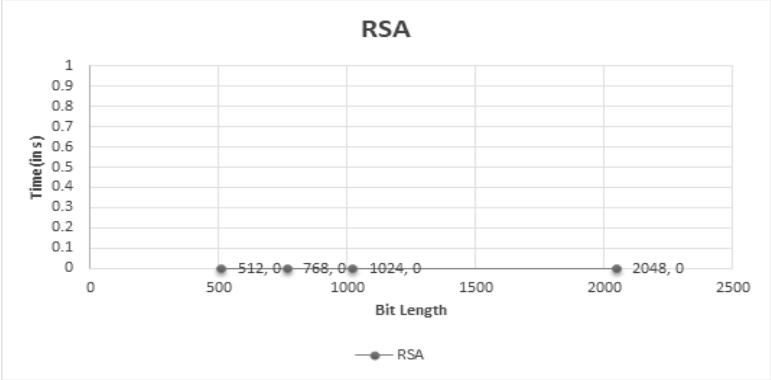

Fig. 10: Graph of the Execution Time of the RSA Signature Verification Phase for Different RSA Modulus

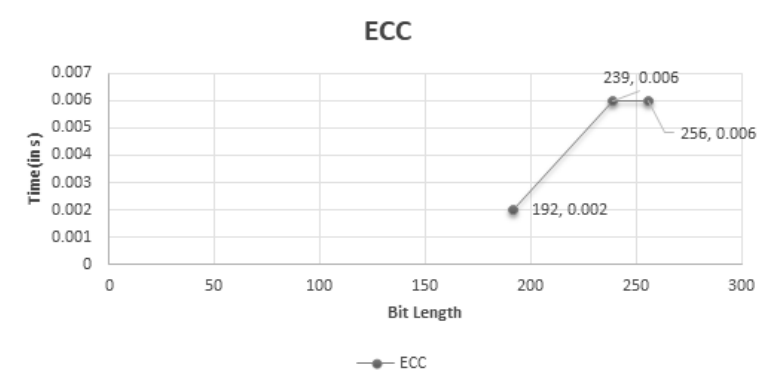

Fig. 11: Graph of the Execution Time of the ECC Signature Verification Phase for Different Curve Parameters

The above results show that the step for key generation of ECDSA is a lot swifter than that for RSA, whereas signature generation takes similar time and signature verification is faster for RSA, but not to a larger degree. Also, it is well-founded that Elliptic Curve point of a multiplication operation is found to be computationally more efficient than RSA exponentiation. [9]

Table 4: Comparison between ECDSA and RSA

Comparison Parameter	*RSA*	*ECDSA*
Encryption Time	Increases to a larger degree for all key sizes	Takes very less time to encrypt even very large keys
Decryption Time	Takes a lot more time than ECC to decrypt large messages	Takes more time than RSA to decrypt small messages but very less time to decrypt large messages
Key Generation Time	Slower, but quite comparable for smaller key sizes (e.g., 128 bits)	Outperforms RSA and is more efficient for bigger key sizes (e.g., 512 bits, 1024 bits, etc.)
Signature Generation Time	Slightly slower for smaller key sizes	Outperforms RSA and is evident for key sizes as large as 1024 bits
Signature Verification Time	Outperforms ECC even for very large key sizes	Takes more time than RSA

6. CONCLUSION

RSA cryptographic technique is comparatively easier to understand and implement than ECC. The main advantage of RSA over ECC, established from the research is that the operation like signature verification is faster in RSA, because of the smaller length of its public keys. In most of the practical scenarios, a message is generally signed only once and gets verified more than one time. It is a well-established fact that the computational power of the devices shows significant improvement with time. So, it will become relatively easier to detect the private key in the RSA signature scheme, as it requires factorizing the key into two primes. ECC, on the other hand, can be abused or we can say attacked if someone knows the ephemeral key, which is a slight advantage over RSA as it lasts

for a very short period of time. It is clear from the experiments conducted that ECC is able to provide almost a similar security level for digital signature operations as RSA, but for smaller bit lengths. In conclusion, ECC is an extremely appealing algorithm to be used in memory-constrained devices such as smartphones, tablets, etc.

Social Media—A Platform for Political Discourse: An Evaluation

Abhishek K. Singh[1]

ABSTRACT: *With the advent of media technologies, social media has gained eminence. Social media is becoming a very significant medium that communicate information through multimedia. Todays, social media is very powerful in disseminating messages and have become a very crucial part of political campaigns. The present study thus, evaluate how social media used to communicate and manage political discourse. In this study, researcher deals with the relation between politics and modern media tools that promotes the interaction between the politically influenced public and alternative sources of information. The focus of the research is around the issues of social networks which act both as a vehicle for social networking as well as a platform for political debate by incorporating various cases that suggests a polarization in the sources of information indicating the role of social media as an agent for polarization of opinion in social discourse in special contest to Indian youth. The epicenter of the study deals with the role and impact of social media on Indian students. Parameters such as political mobilization, political influence, opinion, changing behavior in youth are used to evaluate the role of social media. The methodology used in the research is mainly conducting (most of the data are collected using a questionnaire as a research tool)*

Keywords: Social Networking, Facebook, Political Discourse, New Media, Agenda Setting.

1. INTRODUCTION

The beginning of new media technologies has given a new platform for socio-political communication, including social media where common people can act react and interact with open, courageous and bold comments. Consequently, use of social media is very crucial as a public

[1]Academic Expert and Media Researcher, Ex-Faculty, Ministry of Higher Education, Sultanate of Oman. E-mail: asingh8319@gmail.com

sphere. The social media is not only a boon for social awareness, but it gives new astuteness to the political discourse as political mechanism. It is generally accepted that social media play a central role in information diffusion. As a result, many socio-political communities are taking it as the digital platform for political discussions (Chadwick, 2013). It provides important communication channel through which the political community or citizens, as ordinary contributor, can share information about its activities, publish its position on various topics, allocate information from multiple sources, as well as report on the issues surrounding them at a given time.

Social media is really a big demand because it gives new meanings to communication and information flow which greatly influences the way people think. Graham (1999) notes that present media technology certainly has an ability to create and support sociopolitical activities in the society as it directly influence the identity of individuals and shape their mindset towards specific outlines. Social media like Facebook, Twitter, YouTube and blogs have appeared, changing the feature and mechanism of modern communication. Social media enhances the link between social structure and public interactions for better peoples understanding towards the decision making process.

Media researchers have speculated that the use of social media influences citizen's political behavior (Gil de Zuniga, *et al.,* 2012). Many studies have shown that digital stands like social media have a deep penetration for social reform and if it is used suitably in an organized way, it has an ability to change public orientation. The social media are not the only source of information, identity and social relations, but it also used in the generation of a certain ideology and motivated people for political participation (Katz and Gurevich, 1974). As a result, social media is a very powerful tool that will spread, motivate, speed up information and give new meaning to political expressions.

"Political commitment and social media" has now become very smart and innovative approach in the field of contemporary social research. Specifically, in terms of Indian society, the social media is very popular and have a high range of reachability in its domain. In this research, the researcher has followed the social track to monitor the reactions related to political activity on social media. Social media are certainly contained very influential messages and have high impact on the sentiments of common users. In this paper, researcher has investigated the social media and its various provocative posts to understand the following questions :-

1. In what ways the young people are getting political information for political discourse on social media.
2. How do the general people show political sentiment in social media?
3. What forms of messages commonly used for political action in social media?
4. How do youngsters start involving themselves as a part of political discourse using political posts on social media.

2. LITERATURE REVIEW

Political discourses are mainly characterized by the different levels of issues and propagation of political, ideological based images and comments through digital media for communication and coordination. Social media like Facebook normally supports self expression and encourage social relations. Social media has a deep impact on the emotion of common users and it affects the diffusion of emotion. The social media accelerate the broader horizon of sentiments. Therefore, it can be pointed out here that SNS environment has wide converge than the traditional media networks (Brady, Wills, Jost, Tucker and van Bavel, 2017). Growing media use has been become a center of attraction of many researchers, especially, for political campaigns. Such as how social media is being used a tool for political agenda framing and how social media is being used to facilitate social sentiments politically (Zhang & Lee, 2018).

The Internet is growing and expanding like mushroom both vertically and horizontally due to the cheapening of technology. Especially among young people, internet is as essential as education. One research indicates that use of Twitter, Facebook, YouTube, Myspace is increasingly very common among younger age groups within the Arab world, especially the 20 to 30 year old age group, which uses the net more avidly compared to the rest of the population (Abdulla, 2006: p. 80).

Arab spring was the great example of social media used to unite social sentiments. In this respect, Egypt, the 90% (approx) population were active users of social media and very active in the political movements. In fact social media was the real driving force behind the Egypial revolution (Sahar Khamis & Katherine Vaughan, 2011). Some more studies say, new media revolution erupted in the Arab world after 1990, inspired by the introduction of both satellite television channels and the Internet (Khamis & Sisler, 2010), this situation is rapidly changing, since many Arab countries are currently striving to increase Internet penetration rates.

However, research is very limited in the field of social media as a platform to create emotional impact on political operation. Today's journalistic practices are used to create powerful and interesting news. Looking for something sensational, surprising or shocking to catch the public's attention is always been a motive of today's news makers to influence the public sentiments. Previous research has shown that the season of political operation strongly influences the quantity, style and (political) news about the actors (van Aelst & Swert, 2009). Different media deal with the same news in different ways. Moderators and serious newspapers and television news programs have most often used frameworks of responsibility and conflict in the presentation of news, while sensationalist media have most often used the framework of human interest (Semetko and Valkenburg, 2006).

3. OBJECTIVE OF THE STUDY

1. To analyze the social media as a catalyst to activate sentiments for political discourse.
2. To evaluate the usefulness of social media for news consumption, opinion, expression and provide a virtual space for political discourse.

As mentioned above, the research is analytical in nature as it sharply shows the power of social media in the promotion of political activity and how social media is used by political associations to motivate social elements for protest participation by influencing their online behavior and expressions. Furthermore, the issues highlighted in social media are certainly results, changes in expression and development of new political behavioral pattern in the social capitals.

4. RESEARCH METHODOLOGY

This study used a random sampling method to interpret the collected data. This study also takes into account some secondary data sources. Survey-based research conducted online and as emails. This was used with about 50 university students in Delhi-NCR. Information was also collected mainly by e-mail. The respondents were graduate students.

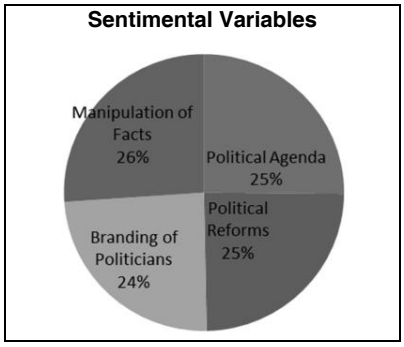
Respondents are mainly academic intellectuals of age group 20 to 30 years old. The data were collected on the basis of questionnaires based on the variables related to social media, political discussion and public opinion or sentiments, which is a main theme of the present research topic. The samples were consulted for their experience on social media and its role as a tool for political discourse.

5. ANALYSIS AND DISCUSSION

In this research the main focus area is the applications of social media and its related variables which play a very important role in the formation of the new culture of political discourse. Presently, online engagements have become a part of social civilization. Social media positively plays a very significant role in the political discourse and undoubtedly, it gives a new direction to the social perception and distress the political opinion. The present research pointed out how the social media affects the style of new communication systems to promote a specific agenda (mainly political). The research analysis was mainly focused on the political criteria of discussion on the social media which may have ability to change the entire political beliefs. The samples were asked questions keeping in mind the fact that social media surely have an powerful role in manipulating the political commitment to the society and it helps largely to polarize the users.

The present analysis was based on the following parameters:

1. ***Rationality and sentimental judgement:*** The respondents pointed out that the social media are very powerful and have intense ability to change the sentiment of users. Social media certainly emphasize the role of impression formation and allow political judgement. The rationality and its related factors play a very crucial role in the formation of agenda based mental image in the mind of users.

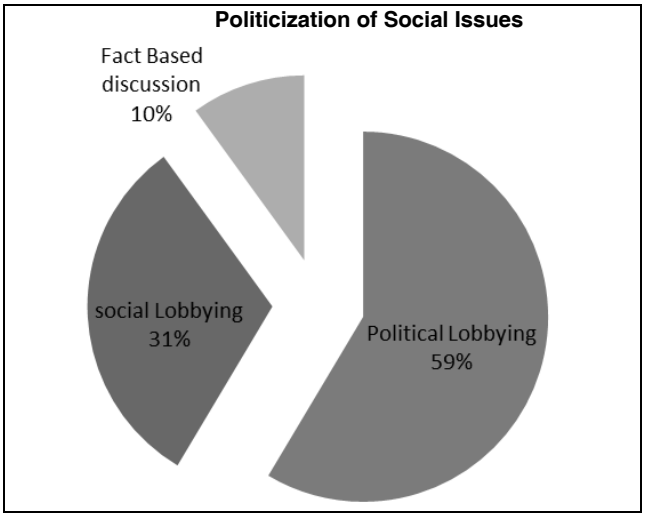


The present analysis indicated that the sentiment and the judgement for the comment shows the dialog for the news and updates are closely related to the emotional representation of online users. The user comments act as a catalyst, which shows the formation of the specific identity of participants. Thus, it may result, online activism

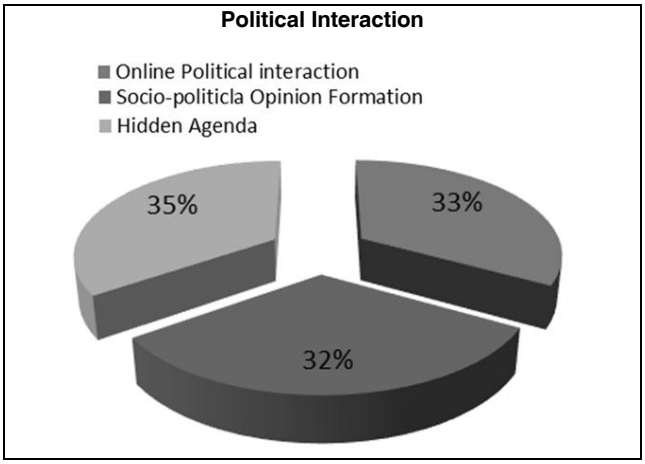
for political discourse. Here, it is also noteworthy that such online activism is very fundamentally growing as a political campaign as its power for sentimental penetration is very deep and highly influential in present social-technical public sphere.

2. ***Social Media as a political Public Sphere for political activism:*** The public sphere is a space of communication where common people discuss and analyze the information. Certainly, it creates a kind of public opinion and gives an issue based discourse on the social platform. Keeping in mind, this study mainly focuses on the three dimensions which usually conceptualize the online discussion constructively. These dimensions are:
   - ***Democratic rights, i.e. freedom of expression are used for Political Mobilization:*** The concepts of freedom of expression are used for the manipulation and diversion of the message. Thus, the response from the people are mentioned as:

   - ***Examine politicization of social issues for political lobbying:*** The general public have generally very limited reach of the content of political affairs. It's been noticed that the general people are using social media as a main source of information as its very easy and attractive medium where people easily participate and discuss with free space and opinion. It can be concluded here, the social issues are very much glamorized and politicized for political lobbying on social media. Political parties, activists and common groups are using social media as a political tool to reach maximum people of the society and to increase their members.



- ***Social understanding and interactive representation of specific ideology***: Social media as public spheres are mostly used for the social unification for presentation and representation of specific ideology. As per the responses for the respondents. The specific ideaology are most of the time have some hidden agenda and theme, which is usually political in nature. These kind of messages and compose in expression is used to spread some specific opinion and create a group of similar voice on online media. The responses are mentioned below:



This analysis based on all the considered factors pointed out the political utility of social networking sites, which indicate that social media such as Facebook, YouTube and Twitter is a legitimate place to discuss political issues and share political ideology. Under investigation in a conversation consists of participants with opposing views. Similarly, the research has apparently succeeded in overcoming the polarization of online discussion, which has penetrated online political debate in the social community. However, the representation of views within the various social media group was strongly biased in favor of discussions of like-minded participants with around 70% of all social media users. This shows that the unique construction of social networks, social networking sites can play a small role in facilitating the exposure of participants to different parties and the heterogeneity of online political discussions.

6. CONCLUSION

The results of this study are considerably pointed out the capacity of social media and social networking, which enable people from the dissimilar standpoint to incorporate and contribute in political discourse. In addition, people seek entertainment and use various platforms of social media and develop the capabilities of technologies to engage in political discussions and express their views on issues of interest to them. Even if the online political discussion existed long before the advent of social networks, the richness and the popularity of these technologies, and the reduction in the cost of Internet access, it may be that more people and new participants are attempting online political discourses. Besides, as this study pointed out, these sites can promote civility between different social groups in discussions and interactions. In these circumstances, we can conclude that growing citizens are dominantly using social media as a political tool. Social media regularly adding new creative users, who is encouraging such discussions at higher levels to reach maximum contributors. The study clearly stated all the research questions mentioned above. The social media, mainly points the youth and through various platform social media tried to reach and influence the youth for political discourse. Secondly, the social media, especially allows people to share political sentiments and get attached to the specific group as member for political discourse. The study startlingly stated that the social media is a kind of convenient media as it available in all possible languages with interactive text, picture, video and suitable use of multimedia, these new media features creates visual customization effect to attract and interact common users.

This study also gives rise to some optimism in the online political discourse. Social media, in the present era of information technology, certainly have a dominantly role in opinion formation by penetrating the social sentiments and criteria of political judgment. Social media is a major public sphere, where ordinary people gather to politely and rationally discuss perspectives and arrive at the best possible conclusion. Lastly, in my view point, social media were developed with the aim to connect and understand our society in a much better way, but how people are using it, is totally different as society is getting divided into different groups based on the specific political frame but isolated on humanitarian ground.

Feedback Ratings are Better Indicators of User Sentiments than Whole Review

Geeta Arneja[1] and Harmeet Kaur[2]

ABSTRACT: *Sentiment analysis is a field of NLP (Natural Language Processing) that is used to discover opinions from the textual data. These opinions have a great impact on customers to make decisions regarding online shopping and choosing products. With the advancement of digital technologies, a large amount of textual data is available in the form of customer reviews. Sentiment analysis systems are used to classify textual data on the basis of their polarity which can be positive, negative or neutral. In this paper, two different approaches were applied to extract the sentiment of the reviews at the sentence level. In the first approach, TextBlob library was used to calculate the polarity of the sentence whereas the second method follows a rule-based approach in which two Lexicons of polarised words (negative and positive) were used. In each of the approach, the value of sentiment was calculated both for the review and the summary provided in the dataset and ranked from 1-5. By performing statistical analysis on the relationship between reviews, summary and overall rating specified in the dataset, it becomes evident that the summary and ratings provide a much more accurate opinion of the reviewer. Since it is more time consuming to process textual data, ratings can be safely used for analysis of user sentiments*

Keywords: Sentiment Analysis, Rule-based Approach, TextBlob, Polarity, Lexicon.

1. INTRODUCTION

With the advancement in the field of opinion-rich resources like online review sites, it has become possible to use this information for

[1] Guest Faculty, Department of Computer Science, Rajdhani College, University of Delhi, Delhi, India. E-mail: arnejageeta@gmail.com

[2] Department of Computer Science, Hansraj College, University of Delhi, Delhi, India. E-mail: hkaur@hrc.du.ac.in

better understanding of people's opinions. Individuals rely on these reviews to make decisions related to online shopping, choosing events, products and entities. However, it would not be easy for an average human reader to detect relevant sites and mining the sentiment from the huge amount of unstructured text.

Sentiment analysis is the computational approach used to extract opinions, attitudes and assessments towards issues, products, services and events etc. An objective sentiment analysis system is needed that can automatically calculate the sentiment concealed within the unstructured text available on the Web. Sentiment analysis systems classify textual data on the basis of their polarity which can be positive, negative or neutral. It can be done at different levels like document level, sentence level and sub-sentence level. Different methods and algorithms have been devised to implement sentiment analysis. They can be classified as rule-based approaches, that are based on manually defined rules; automatic systems, that rely on machine learning techniques and hybrid systems which combine both of them.

In this paper, the dataset retrieved from Amazon beauty products was analyzed. It contains reviews of the customers about the beauty products sold by Amazon. Two different approaches were applied to extract the sentiment of the reviews at the sentence level:

1. TextBlob library was used to calculate the polarity of the sentence.
2. A rule-based approach in which two Lexicons of polarised words (negative and positive) were used.

In each of the approach, the value of sentiment was calculated both for the review and the summary provided in the dataset and ranked from 1–5. Correlation, a statistical measure, was then used to study the relationship between reviews, summaries and ratings for both the approaches. A formula based on the number of occurrences of positive and negative words, to compute the polarity of a review was devised and applied on the dataset. The polarity was modified if any positive or negative word was preceded either by negations (not, never etc.) or by emphasizers (highly, very etc.) accordingly.

The result sets derived from both the approaches were statistically analyzed against the overall ratings and against each other. Assuming that an average human expresses the precise opinion in summary, the results showed that the sentiments derived from summary data are much closer to the overall rating as compare to that of the whole review. Thus, in

order to make decisions, an individual can rely on feedback ratings instead of going through the whole reviews.

The structure of paper is as follows. Section 2 presents literature review. In section 3, we describe the research objective. Methodology is presented in section 4, which describes the approaches used and section 5 concludes the obtained results. The final section outlines the expansion possibilities in future.

2. LITERATURE SURVEY

Several researches have been made regarding sentiment analysis of data available on web in the form of reviews with focus on categorizing them as positive, negative and neutral. A huge amount of data is available on the web in the form of customers' reviews. Sentiment analysis of online customer reviews is under high demand from the perspective of customers and vendors. In [1] research problems based on the level of granularities have been discussed. In general, sentiment analysis has been investigated mainly at three levels: document level, sentence level and entity and aspect level.

Several researchers have worked on feature extraction and opinion-oriented words [2]. The task is performed by identifying the features of the product that customers have expressed opinions on (called opinion features) and ranking the features according to their frequencies that they appear in the reviews. Then, for each feature, the number of positive and negative customer reviews have been identified. The specific reviews are then attached to their corresponding features.

The machine learning approaches have also been used for sentiment analysis [3]. They use bag-of-words (BoW), Part-Of-Speech (POS) information and sentence position as features. They represent reviews as feature vectors that are sent as input to a learning device usually Naïve Bayes and SVM.

In [4], the sentiment analysis of unstructured reviews has been carried out. The authors identified the features present in the review and then classified them using Naïve Bayes classifier and calculated their positive, negative and neutral polarity distribution.

The problem of assigning a numerical score (one to five stars ranking) to a review is presented [5]. They described it as a multi-label classification problem, and presented it using two supervised learning approaches; Naïve Bayes (NB) and Support Vector Machines. Classification of movie

reviews is presented in [6] that used Support Vector Machine (SVM) algorithm with 'bag of words' (BoW), in which some of the special features are chosen. However, the constraint here is its main focus on adjectives and modifiers that express assessment. The researchers used sentiment analysis of user reviews, and proposed an effective method to classify the reviews into positive, negative, and neutral classes by including slangs using different types of lexicons [7]. The analysis of word dependency and structure of contextual information was incorporated with Rule based approaches for sentiment analysis [8, 9].

The lexicon-based approach proposed by [10] uses rule-based technique to classify the reviews. They classified the reviews using three steps, namely, (i) filtering, (ii) subjectivity classification, and (iii) sentiment scoring.

The foremost motivation of this work is presented by a lexicon-based method to sentiment classification [11]. The author used dictionaries of positive or negative words to for classifying reviews. A semantic calculator was proposed by incorporating intensifiers and negation words.

3. METHODOLOGY

In this paper, review data, summary and ratings provided in the dataset have been analysed and it was observed that feedback ratings are better indicators of customers' opinion in comparison to that of the whole review. Reviews, summary and overall rating from the dataset were extracted. Reviews and summaries, were then processed to calculate their sentiment value by using two different approaches; one is lexicon-based method [11] with a rule-based approach and second using TextBlob library.

The resultant sentiment values were then ranked from 1 to 5 based on proposed rule and finally a statistical comparison was done to show that feedback ratings are better indicator of sentiments.

3.1 Dataset

The dataset used in the current research has been downloaded from "Amazon Product Data" [12] that contains 1,98,502 records of review data related to beauty products from 2009 to 2014. With rapid growth of internet, the number of reviews available online is increasing every year. The review data of 2014 that contained maximum number of records (a total of 58,309) against previous years was extracted. So, 58,309 records were analysed for the experiment. The structure of each record is given in Table 1.

Table 1: Structure of Record

Field Name	*Description*
reviewerID	ID of the reviewer
asin	ID of the product
reviewerName	name of the reviewer
helpful	helpfulness rating of the review
reviewText	text of the review
overall	rating of the product
summary	summary of the review
unixReviewTime	time of the review (unix time)
reviewTime	time of the review (raw)

Out of the above mentioned 9 fields in Table 1, we extracted reviewText, overall and summary fields for our research.

3.2 Lexicon-Based Approach

Two different dictionaries have been used here in order to check the polarity of words [13]. One contains a list of 4784 negative words and other one contains a list of 2006 positive words. We also created two files; one for negative words (like not, never etc.) which when precedes some positive or negative word, flips its polarity and one for modifiers (like very, highly etc.) that adds onto addition weightage to the polarity when precedes any word. Python 3.2 is a versatile language and supports extremely stable libraries. It is used to implement the algorithms. For human language preprocessing, Natural language Toolkit (NLTK) was used. It provides an effective platform for building Python programs.

3.2.1 *Preprocessing*

A typical review contains word variations, negative words, modifiers (that adds on to the weightage of positive or negative words) etc. For implementing lexicon-based method, the reviews need to be preprocessed in order to normalize the text into a suitable form to extract the sentiments.

The preprocessing steps used are:

- Tokenization: Tokenization is a step that splits up longer strings of text into smaller pieces, called tokens, that retain all the essential data. Reviews were present in the form of sentences in the dataset which were tokenized using python's NLTK (Natural Language Toolkit) into a list of words. Further processing was performed after a review has been appropriately tokenized.
- Stop Words: A stop word is a commonly used word (such as "the", "a", "an", "in") that must be ignored as they are not supposed to take up unnecessary space and valuable processing time. For this, we removed them by updating the list of stop words provided by python's NLTK (Natural Language Toolkit) with more words that we consider to be included in stop words (such as ";", "!", "-").
- Lemmatization: It is the process of grouping together the varied inflected forms of a word so that they can be analysed as a single unit. It is basically the morphological analysis of words as it links words with similar meaning to one word. NLTK (Natural Language Toolkit) Word Netlemmatizer has been used for this.

3.2.2 *Sentiment Calculation*

Sentiment calculation is the total sum of the sentiment bearing positive or negative words of a review. The sentiment calculation is derived from established heuristics that are based on sentiment orientation of the words. Each word from the review is compared against positive and negative dictionary and its occurrence is recorded as count. If a match is found in negative dictionary the value of count is decremented and if it is found in positive dictionary the value is incremented. Whenever a match is found, the preceding word is checked against the list of negations (like "not", "never" etc.) and the value of count is accordingly flipped. If the preceding word is a modifier (like "very", "highly" etc.) then count is incremented/decremented by 50%. Finally, each review is assigned a rank from 1 to 5 using a set of heuristics.

The sentiment of summary data provided in the dataset is also processed in the same way. Both set of ranks, one derived from reviews and other from the summary data were then statistically compared with each other and against the overall rating provided in the dataset using coefficient correlation to show how reviews and summary data fare against the overall rating.

The sentiment calculation algorithm is shown in Algorithm 1.

Algorithm 1: Sentiment Calculation Using Lexicon-Based Method

```
Data: Pre-processed Amazon Review data
Result: Output: Reviews Ranked from 1 to 5
count as Sentiment value
rank as Rank value
For each Review in Review_set:
    For each word in the Review:
        If word in negative_dictionary then
                Decrement count
                If preceding word in negation then
                        Increment count by 2
                If preceding word in modifiers then
                        Subtract 0.5 from count
        If word in positive_dictionary then
                Increment count
                If preceding word in negation then
                        Decrement count by 2
                If preceding word in modifiers then
                        Add 0.5 to count
    If count <=-1 then
        rank=1
    Else if count >-1 And count<=-0.25 then
        rank=2
    Else if count > -0.25 And count <= 0.25 then
        rank=3
    Else if count > 0.25 And count <=1 then
        rank=4
    Else
        rank=5
    count=0
```

3.3 Sentiment Calculation Using TextBlob

In the second approach, TextBlob library of Python has been used to calculate sentiment value of reviews and summary data available in the dataset. *TextBlob* is a Python library for processing textual data. It provides an API for common natural language processing (NLP) tasks. Result sets were then ranked from 1 to 5 using a similar set of heuristics. The results are again statistically compared with each other and against the overall rating provided in the dataset.

4. RESULT AND DISCUSSION

The results obtained after statistical comparison are shown in Table 2. The value of Correlation Coefficient indicates a weak relationship

between review vs summary whereas a moderate relationship between review vs rating and summary *vs.* rating [14]. It shows a maximum value of 0.44 among summary and rating in Lexicon-based approach and 0.40 when TextBlob library is used.

Table 2: Correlation Coefficient among Review *vs.* Summary *vs.* Rating

Method Used	*Lexicon-Based Approach*	*Using TextBlob Library*
Review/Rating	0.35	0.37
Review/Summary	0.26	0.24
Summary/Rating	0.44	0.40

An average human reviewer provides a concise and accurate statement about a product in summary whereas a review may contain detailed information and a computational sentiment calculator may yield wrong results due to the overuse of positive words as compare to negative words in a negative review and vice versa. Such reviews belong to the category of thwarted expectations [15]. An example from dataset to illustrate this concept is hereunder:

> *"I am not knocking it as a product. The smell was nice and the exfoliation was gently, but it did nothing for my combination skin."*

This review has positive polarity throughout but flips in the end. In such cases, the sentiment calculated computationally may wrongly misinterpret a positive polarity whereas the summary of the review gives more precise result that matches the overall rating. The rating in the dataset corresponding to this review is 1 that represents a negative review and the summary is "this facial scrub did nothing for me ".

Thus, by analysing the relationship of reviews, summary and overall rating specified in the dataset, it becomes evident that the summary and ratings provides a much more accurate opinion of the reviewer. Since it is more time consuming to process textual data, ratings can be safely used for analysis of user sentiments.

5. CONCLUSION AND FUTURE SCOPE

We have shown the statistical comparison between summary data and review data against overall feedback rating data present in the dataset in order to validate that online customers can make use of overall rating to make decisions about any product as they are better indicators of

customers' opinion regarding a product as compare to whole review. We calculated the sentiment values of summary and review data using (i) Lexicon-based approach and (ii) TextBlob library and then sent them as inputs to the statistical comparison. The value of correlation coefficient indicates that summary data is comparatively closer to overall rating as compare to that of review data due to the presence of reviews that belong to the category of thwarted expectations. Both the approaches used above show similar results.

The proposed system can be extended to incorporate sentiment analysis at aspect level instead of sentence level. Other approaches based on machine learning or hybrid techniques can be used to calculate the sentiment that can be further analysed statistically against the results derived in the current work.

Digital Democracy and India: Study of Evolution in Citizen e-Participation Frameworks

Sharique Hassan Manazir[1] and Madhav Govind[2]

ABSTRACT: *Just like any other social system, democracy too needs regular innovation to respond to changing societal necessities and norms. The Internet and the corresponding rise of social media have provided scope for various innovative ways of engaging citizen and the democratic electorate on issues that matter for both as one nation. Many scholars have underlined the importance of citizen's participation in democracy and how ICT can play an important role in it. For instance, Gundogan (2010) believed that political participation is an essential component of democracy and consists of transferring citizens' ideas, opinions, feelings, desires, and critics to governing process at the stage of preparing policies, developing a solution and implementing the decisions. Hence, with the passage of time and post-advent of ICT, citizens' political participation has taken diverse forms both offline as well as online which gave rise to the concept of e-participation which acts as the backbone of Digital Democracy. The range and availability of citizen e-participation platforms provided by the government, non-government organizations as well as private players are increasing day by day as the idea of governance is shifting more and more from democracy to digital democracy. Various democratic governments are trying to define the future path of citizen participation in democratic decision through ICT based platform and thus with time various academic work with an innovative approach have come up. Although there are many frameworks to understand the pattern and motives of e- participation of people, yet none of them is adequate to capture the holistic view due to variations in the social context, digital inclusion, technological advancement, demographic changes etc.*

[2] Professor, Centre for Studies in Science Policy, JNU, New Delhi, India. E-mail: m_govind@mail.jnu.ac.in

In this study, we have analyzed the various innovative frameworks to understand the transition of citizens' direct participation in Democracy to their e-participation in Digital Democracy. This study provides new insight into how different tools are used to engage citizen in governance through various e-participation models and what are challenges to enable the citizen to participate in the democratic process in India.

Keywords: Digital Democracy, e-Participation, e-Governance, ICT, Digital Inclusion.

1. INTRODUCTION

Citizen Participation has always been an important aspect of any form of governance and becomes more important when we talk about democratically run governments. As per the available literature under democratic theories, there exists varying opinion upon citizen political participation. While scholars like Schumpeter limited idea of citizen political participation to voting only. (Shumpeter, 1946) Dahl accepted wide range of citizen action besides voting as political participation. (Bengtsson, 2008)

A well-planned citizen participation framework in governance can lead to informed citizen who would understand the technically difficult situations and would suggest a holistic, communitywide solutions. Conventionally in governance, there were different modes for ensuring citizen participation at different levels using different procedures, techniques and methods. They included electoral voting's, citizens juries, citizens panels, committees, consensus conferences, scenario workshops, deliberative polling, focus groups, multi-criteria mapping, public meetings, rapid and participatory rural appraisal etc. (Pimbert and Wakeford, 2001) Definition for political participation by (Vissers & Stolle, 2013) i.e. "political participation refers to all forms of involvement in which citizens express their political opinion and/or convey that opinion to political decision-makers," fits well into the online realm as well because it does not specifically mention whether these activities take place online or offline.

Lately, there has been various e-participation frameworks by scholars worldwide to understand and improve citizen e-participation. Though the definition of e-Participation is well understood, the study approach of "e-participation" has varied been worldwide which could be divided into five categories:

1. E-Governance Platform Analysis
2. Government Ministerial Website Content Analysis

3. Social media Platform Analysis
4. Citizen Enabled e-participation Platform Analysis
5. Government enabled e-participation Platform Analysis.

There has been enough research from the perspective of E-Governance projects evaluation. Most of the research have been done by the government department as part of its overall e-assessment strategy in collaboration with independent third parties such as IIT's, IIMs etc. (MCIT 2008; IIT and IIM-A, 2010). These studies have focused on broad parameters such as 'impact on outreach', 'cost of accessing services', 'quality of services' and "overall governance". The well-known scholars like Norris Pippa (2001) studied the e-participation in collaboration with United Nations, from the perspective of content analysis of 196 countries government websites and tried to understand how information provided on website is enabling citizen to interact with government. Scholars like Chun & Cho (2012) in their paper titled "E-Participation and transparent policy decision making" studied both the contents and the features of government websites as well as the social media platforms in Korea. Most of the research on e-participation has relied on "citizen enabled e-participation platforms". Macintosh et al are well-known name who have studied e-participation through that approach. Further similar approach and similar framework has been used by European Union too. (Lironi, 2016)

Table 1: Major form of Academic Work on E-participation

Sr. No	*Forms*	*Tools*	*Examples*	*Research*
1.	E-Governanc e Platforms	Services like feedback through email or discussion forum over dedicated e-governance scheme website	MCA21 Passport Income Tax	(MCIT, 2008); (DIT & IIM-A, 2010) etc.
2.	Ministry Website	Provision for policy feedback over specific policy draft; no formal feedback on acceptance or discussion over policy proposal or amendment.	TRAI	(Norris P., 2004)[UN World Public Sector Report Deepening Democracy via E-Governance]
3.	Social Media	Citizen share their issues and discuss with social media account of politicians, ministries etc.	Facebook, Twitter, Instagram	(Magro, 2012); (Effing, Hillegersberg, & Huibers, 2011);

Sr. No	*Forms*	*Tools*	*Examples*	*Research*
				(Bonsóna, Torresb, Royob, & Floresc, 2012); (Salamat & Hassan 2011) etc
4.	Government Enabled e-Participation Platforms	Citizen can participate in formal policy-making process through different tools.	My-Gov; Common Service Center etc	(Lamba, Yadav, & Lela, 2016) (Limited Conference Proceedings Only)
5.	Citizen Enabled e-Participation Platforms	Online Petitions, discussion forums	Change.org; gov2u.org etc	(Alathur, Ilavarasan, & M.P.Gupta, 2007); (Maciintosh, 2004)

Currently, there are various organizations engaged in the task of mapping citizen e-participation on the basis of different forms of parameters. (Heeks, 2006) Majority of research reports only focus upon e-government ranking, but UN E-Government Survey report comes up with e-participation index apart from E-Government index to evaluate yearly status of countries and rank them in order. UN derives e-Participation index by focusing on the government's use of online services for providing information to its citizens or "e-information sharing", interacting with stakeholders or "e-consultation" and engaging in decision-making processes or "e-decision-making" (UN, 2018) Below chart shows 2018 ranking of top 15 nations worldwide based upon their e-participation indices.

Table 2: e-Participation Ranking

E–Participation Index		
Sn No	*Country*	*Index*
1.	Republic of Korea	1
2.	Denmark	1
3.	Finland	1
4.	Netherlands	0.9888
5.	Japan	0.9831

E–Participation Index		
Sn No	*Country*	*Index*
6.	New Zealand	0.9831
7.	Australia	0.9831
8.	Spain	0.9831
9.	United Kingdom	0.9831
10.	United States of America	0.9831
11.	Norway	0.9775
12.	Brazil	0.9719
13.	France	0.9663
14.	Singapore	0.9663
15.	India	0.9551

2. EVOLUTION OF E-PARTICIPATION FRAMEWORK

Citizen political participation in governance decision making as well as public policy formulation through top-down approach (government or private entity initiated) or bottom-up approach (citizen-initiated) has been studied worldwide from various perspectives even before advent of Information Communication Technology.

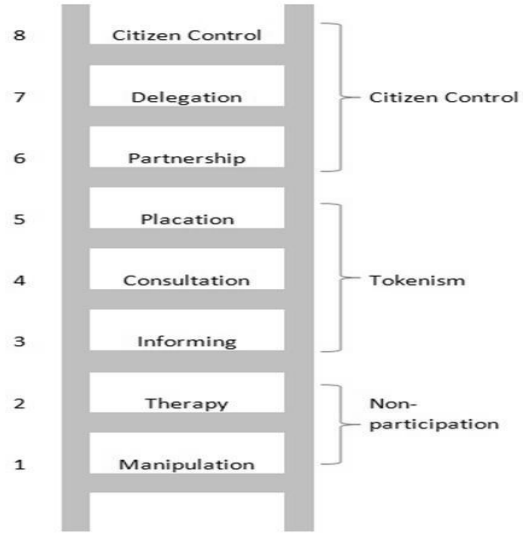

Fig. 1: Arnstein's Ladder of Citizen Participation (Arnstein S.R., 1969)

Before the advent of ICT way back in 1969, Arnstein's ladder of participation was the pioneer in study of citizen participation in governance and policymaking. She differentiated top-down approach into three layers namely Non-participation, tokenism and on top Citizen Power. (Cornwall, 2008). She characterized citizen participation as citizen power and defined it as "… the redistribution of power that enables the have-not citizens, presently excluded from the political and economic processes, to be deliberately included in the future". (Arnstein S. R., 1969) Later, Glass proposed citizen participation framework whose objectives included information exchange, education and support building, decision-making supplement and input probing. (Glass, 1979) After that, there were various theoretical model of citizen participation from various theoretical and academic perspectives which did not involved ICT or citizen participation in governance necessarily. Jule Pretty's "Typology of Participation" (1995), Sarah White's "Typology of Participation" (1996), Phil Tre Seder "Degree of Participation" (1998),

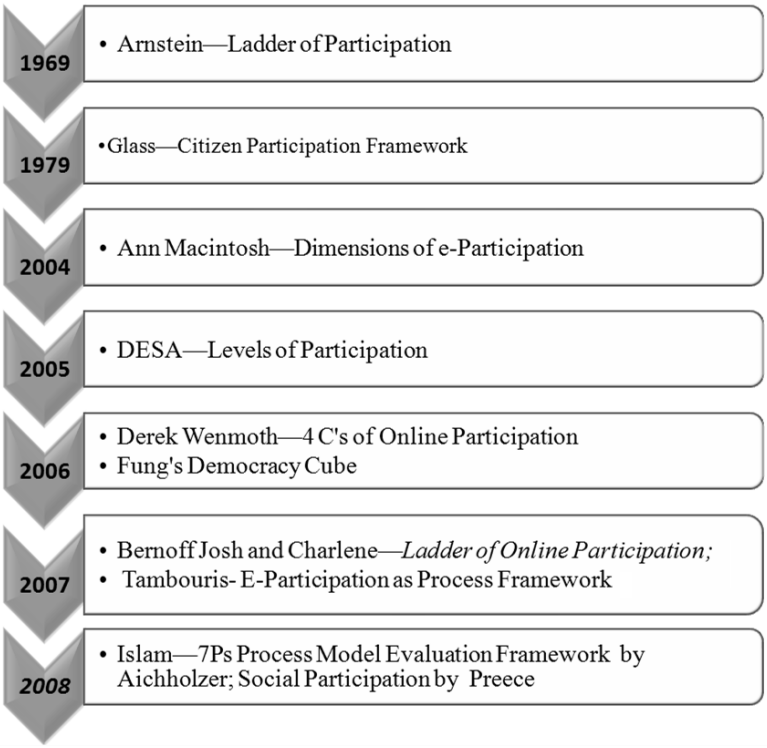

Fig. 2: Timeline for Evolution of e-Participation framework

Scott Davidson's "Wheel of Participation" (1998), OECD Active Participation Framework (2001), Herry Shier's "Pathways to Participation", UNICEF's "Strategic Approach to Participation" (2001), Jans & De Backer's "Triangle of Youth Participation (2002), IAP2's "Spectrum of Public Participation" (2007) and Diane Warbuton's "Engagement in the Policy Cycle" (2007) were worth mentioning such theoretical framework. It is an established fact that e-Participation from the perspective of e-governance and e-Democracy is still an evolving research area and thus there is very limited universally accepted framework catering all its aspects. (Kangere, 2002) First theoretical framework for citizen e-participation in public policy formulation was proposed by Ann Macintosh in the 2004. She identified e-enabling, e-engaging and e-empowering as major three dimensions of e-participation of citizen in a top-down approach for policymaking by government in consultation with citizen.

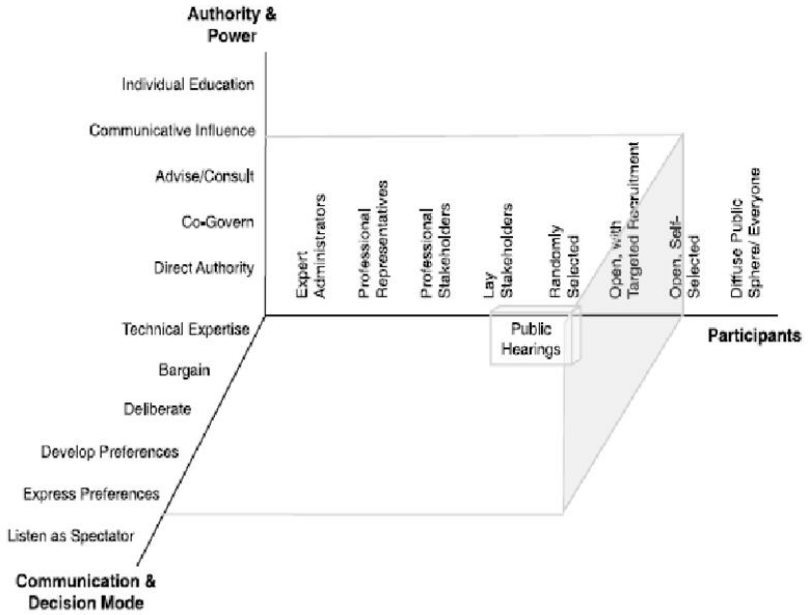

Fig. 3: Fung's Democracy Cube (Fung, 2006)

E-information, e-consultation and e-decision making are three-stage framework for explaining citizen participation in public policy formulation according to DESA approach. (DESA, 2005) Derek Wenmoth is the year 2006 developed 4C's of Citizen participation to

show how people participate in online communities in four different roles which were consumer, commentator, contributor and lastly commentator with all the four levels of participation with different set of motivation, behavior and end result of participation.. (Wenmoth, 2011) In 2006 Fung introduced "Democracy Cube" which has three dimensions: "the scope of participation", "the mode of communication and decision" among participants, and "the extent of the participants' authority". Participants could be inclusively or exclusively chosen to participate, under communication axis, six types of communication in citizen participation were identified: listening as a spectator, expressing preferences, developing preferences, aggregating and bargaining, deliberating and negotiating, and deploying expertise. Lastly, the authority axis was meant to measure the impact of public participation. (Fung, 2006)

On similar lines, Li and Bernoff came up with Ladder's of Online Participation in the year 2007 which basically dealt with user participation on different web portals with mainly six levels of user participation namely Inactive, Spectators, Joiners, Collectors, Critics and lastly Creators who create the online content. This theoretical framework too was limited for citizen participation on web portals and was not specifically dealing with public policy formulation. (Li & Bernoff, 2007)

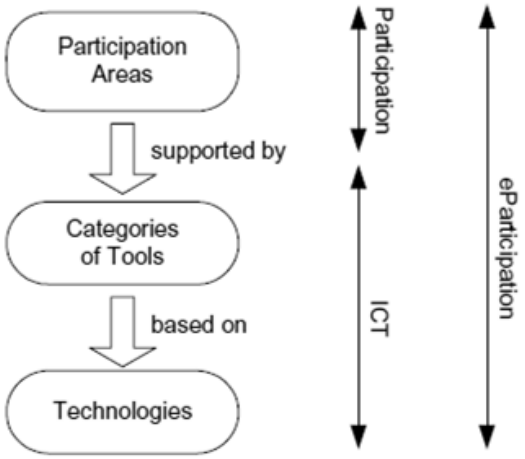

Fig. 4: Tambouris Framework of E-Participation (Efthimios TAMBOURIS, 2007)

In year 2007 Tabouris proposed framework for e-participation where he differentiated the whole process into five major levels namely Democratic processes, Participation areas, Participatory techniques, Categories of tools,

Technologies which could flow into two major directions i.e. the democratic processes which is top-down to the technologies or bottom-up technology-driven towards democratic processes. (Tambouris, 2007)

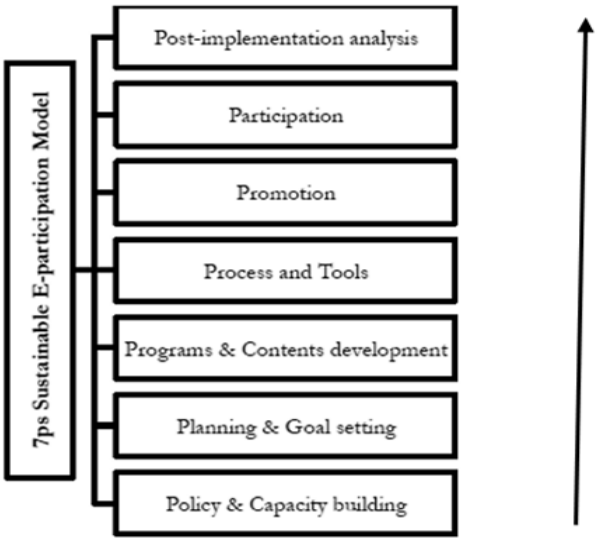

Fig. 5: Islam's 7P Sustainable E-Participation Model

Islam discussed in detail about universal applicability of e-Participation model since socio-economic, technological and digital inclusion issues vary from country to country. (Islam M. S., Towards a sustainable e-Participation implementation Process, 2008) Thus, he proposed 7Ps Sustainable e-Participation framework in year 2008 which has seven phases namely Post-implementation analysis, Participation, Promotion, Process and Tools, Programs and Contents development, Planning and Goal setting and lastly Policy and Capacity building in top-down manner.

3. INDIA AND E-PARTICIPATION FRAMEWORK POLICY

Recently Ministry of Communication and Information Technology, Government of India produced "Framework for Citizen Engagement in E-Governance" in 2012. For the first time, it defined Citizen participation, needs for ways i.e Information Sharing, Consultation, Joint Assessment and Shared Decision Making to share information and make citizens a partner in decision making. According to this framework citizen engagement in decision making would result in a better-informed decision. It defined Citizen Engagement as "an interactive two-way

process that encourages participation, exchange of ideas and flow of conversation."It conceptualized "information sharing, Consultation, Joint assessment, Shared decision-making and collaboration" as stages of an engaging citizen for participating in the governance. This framework was specifically meant for e-governance initiatives and not for e-participation platform meant for shared decision making. In the proposed framework citizen e-participation framework the question of outreach is dealt mostly from the perspective of Digital Divide i.e. accessibility while digital inclusion is given very less emphasis. While studies have found non-uniform access to ICT based on socioeconomic status, gender, age, race, geography, caste, language barrier etc scholars suggested that digital divide should must be studied as a phenomenon from the perspective of global, social as well as democratic divide. (Räsänen, 2006) According to IAMAI report based on census 2011, in Rural India only 20.25% population has access to Internet while in Urban India 65% has access to Internet. (UN, United Nations E-Government Survey 2018, 2018) In India use of internet is majorly male dominated in both rural as well as urban demography as per the latest reports. While 41% internet users in Urban India are female, only 36% of the total internet users in Rural India are females. (IAMAI, 2018) According to recent research reports, in India about 60 million people are disabled and 42.5% of them are women while 75% of people with disabilities come from rural areas. Thus, in India barriers to accessibility are all confluence when we talk about citizen political participation with governance using internet. India has total 780 official and nonofficial languages which is world's second-highest number of languages by any country.

4. FUTURE CHALLENGES

When we talk about citizen e-participation using Internet as a public sphere the question of outreach is dealt mostly from the perspective of Digital Divide while digital inclusion is given very less emphasis. (Helbig, Garcia, & Ferro, 2008) While some scholars still argue that issues pertaining to digital inclusion is always on a trajectory of being resolved with time as the new technology comes in and thus is resolved with time. (Compaine, 2001) Even according to UN E-Government Survey of 2018 in India finding content online in the local language is still a big challenge and despite progress, providing local, relevant and useful content, in addition to raising awareness about it, requires significant effort. (UN, 2018) Citizen E-Participation rights violation in form of abrupt internet access shutdown is another concern. Internet shutdowns is

not a new phenomenon but is indeed now a regular one in countries like, Syria, Nepal, Democratic Republic of Congo, Burundi, Ethiopia, Iraq, Kazakhstan, Pakistan, Sudan, Uzbekistan, Yemen, China, Zimbabwe, North Korea, Uganda, Bahrain, Bangladesh, Egypt, Turkey, Cameroon, Gambia, Myanmar, Egypt and India too. According to United Nations report shutting down internet with intention to disconnecting people even to quell political unrest is human rights violation. (Rue, 2011) Report states that "while internet blocking and filtering of internet denies users access to desired content, states even try to cut off access to the Internet completely. The Special Rapporteur considers cutting off users from internet access, regardless of the justification provided in violation of article 19, paragraph 3, of the International Covenant on Civil and Political Rights." According to recent research, India leads the world in the number of internet shutdowns, with over 100 reported incidents in 2018 alone. (Shahbaz, 2018) According to research reports by Boston Consulting Group's projection for 2016, internet contributes around 5.6% to India's total yearly GDP. In 2016 only India lost around US$968 million as total economic impact of internet disruptions, both in terms of number of days and total GDP lost. (Darrell West, 2016) Thus internet shutdowns not only are oppressive in nature but affects nations economy too since now entire economy is based on internet connectivity. Thus, we are not yet close to a robust citizen e-participation framework which caters to all the social, economic, political, demographical as well as technological issues of nations through uniform standard and hence there is immense scope of qualitative as well as quantitative research.

A Literature Analysis on Big Data Paving Its Way to E-Business

Suman Madan[1], Kirti Bhardwaj[2] and Shubhangi Gupta[3]

ABSTRACT: *Big data stands as a substantial buzzword considering the modern business management frontier today. A great outburst of interest occurred for big data analytics from various industries including academia and the e-business industry. E-businesses are constantly looking for ways to retain customers and improve the customer experience, not realizing that solution of this problem is right at their fingertips. Big data corresponds to exceedingly enormous datasets which are analyzed and scrutinized to reveal trends and subsequently, patterns in human behavior. The terminology of big data is not restricted or limited to data only, but it refers to using complex datasets to derive focus, direction, and for decision-making within an organization or firm. This outburst had forced e-business firms to use big data analytics in their value chain process for higher productivity. This survey paper focuses on the different sorts of data held and its inverse usage for e-business along with different ways of providing security and safety for data corresponding to anonymizations. It also highlights the issues in big data with respect to e-businesses and tries to trigger the maximum usage of big data applications effectively.*

Keywords: Big Data, E-business, Security, Models, Tools and Trends.

1. INTRODUCTION

The emerging web-based technologies are giving e-business firms metamorphic gains like real-time customer services, personalized offers, dynamic prices etc. [16]. The Big Data Analytics (BDA) is providing major help to e-business firms to use the available huge data more efficiently, improving the decision-making; converting one-time

[1] Asst. Prof., JIMS, Rohini, Delhi, India. E-mail: suman.madan@jimsindia.org
[2,3]Student, JIMS, Rohini, Delhi, India. E-mail: [2]archnabhardwaj1969@gmail.com; [3]shubhangig16@gmail.com

buyers to repeat customers, finding the lowest possible inventory level, bringing higher conversion rates etc. [1]. Big Data is thus proving that it is a game-changer when talked about retail and e-business. If businesses can successfully implement effective big data strategies, predict trends, optimise pricing and forecast demand then they will reap the rewards of better customer experiences and bigger profits. From the transaction cost aspect, BDA is benefitting the online businesses in terms of improving communication between buyers and sellers; reducing efforts of searching, bargaining and after sales monitoring while also increasing managerial efficiency and providing new recommendation algorithms.

Lots of researches have been done on this domain but the literature shows that it is largely informal, fragmented study only. This paper is result of research question: "How big data analytics can create more business value than traditional analytics for e-businesses?" To get more insights on this research issue, this paper focusses on providing an in-depth accumulative knowledge about big data and its types, along with tools that can be used to analyse it. The study aims to discuss and support both the qualitative and quantitative aspect of Big Data, its present and future scenarios focusing on its effect on e-business as an emerging and evolving technology. [4]

Figure 1 shows the journey of raw data to business intelligence (BI) helping organizations. BI cites the technology-driven process that analyses

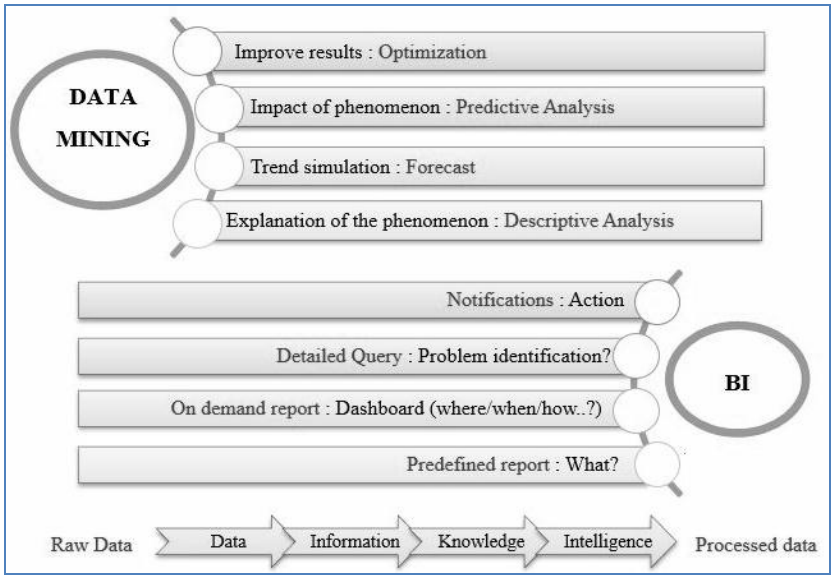

Fig 1: Process showing Conversion of Raw Data to Business Intelligence

data and produce appealable information for top management decision making task and thus in turn increasing market efficiency and lowering cost. BI is also helping e-businesses in predicting market trends, performing competitor analysis.

2. MOTIVATION

2.1 Literature Review

Ferreira, Pedrosa and Bernardino (2017) [6] proposed 4-level architecture for BI with e-business where in raw data of online business is transformed into knowledge by identifying purchase patterns of customers to improve CRM. The authors discussed cloud computing, big data and machine learning usage in data analytics, precisely. The issue raised by authors is organizational and related to user's data security and privacy, respectively.

Akter and Wamba (2016) [12] discussed good practices, nature of data and business value related to e-business based data for determining BDA. The authors highlighted few challenges in BDA like reaching directly to the business target along with internal changes in organization, identifying right and exact customer requirements to offer personalized offers, maintaining privacy of customer. But they didn't consider the security issue of customer's account details and need of skilled data analytical persons.

Aivalis, Boucouvalas and Gatziolis (2016) [12] proposed "log file analyser" application for accommodating technologies related to big data. The application allows the preloading of all e-business information along with customer information and then automatically posting advertisements in customer's social media accounts.

Chen and Laug (2016) [7] featured five V's corresponding to Big Data and e-business relationship and gave new research measurements that concentrate on real-time dynamic product pricing, analytics dependent on geographical constraints, customer behaviour and need of product managing and monitoring devices for taking care of mass requests. Sun, Strang and Zou (2015) [11] give the association between big data analytics and Business intelligence. Likewise, the authors propose how to improve business intelligence via big data analytics by giving new service based design or model.

2.2 Challenges

The aim of the paper is to understand the following [2]:

- To analyse big data characteristics and its need in E-Business
- Exploring the opportunities for E-Business by using Big Data Analytics
- Addressing the Big Data challenges
- To foresee future trends.

3. BIG DATA CHARACTERISTICS AND NEED IN E-BUSINESS

Since the markets both international and national are becoming customer-oriented, Big Data provides the benefits (Figure 2(a)) of time saving and less cumbersome buying, delivery and business, in general, especially for those who want to spend minimal time on regular chores like stocking groceries, etc.

This new data is characterized by what is commonly known as the 3Vs (Figure 2(b)):

- *V for Volume*: The growth rate of 50% a year, the volume of data available is growing exponentially with data cross-referencing being the key to determining the relevance of generated information.
- *V for Variety*: The various format types like text, photograph, etc, must now be added to a variety of internal and external providers; objects or people, while also encompassing the possible uses associated with raw data.
- *V for Velocity*: Given the rapid obsolescence of real-time data, its integration with other data to get a timely insight must be done rapidly.[2, 7]

These 3 V's of big data led to the addition of the following 2 V's:

- *V for Veracity*: Data obtained is limited in volume but controlled in terms of coherence and quality and so, its use hinges on the ability to neutralize these weaknesses without modifying the original information which leads to data reliability that has become an essential criterion as per the gigo13 principle application to Big Data.
- *V for Value*: Value assessment of a data item on the spot is difficult but one must be beware of falling into a restrictive pattern considering that a data source which may appear internally useless can have a monetizable value for another partner.[2, 7]

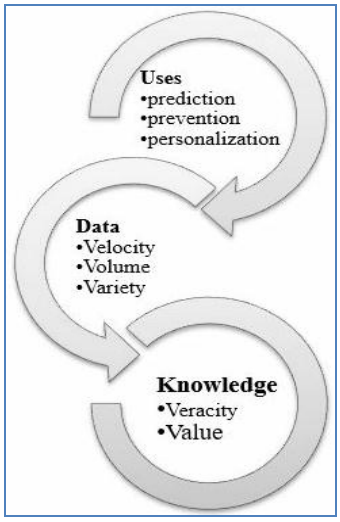

Fig. 2(a): Big Data and Advantages **Fig. 2(b):** Big Data Facilitating E-business

The knowledge thus derived is useful for the 3P's of any e-business:

- ***P for Prediction:*** Prediction is a huge part of big data uses as we need to anticipate the data to acquire adequate knowledge in order to predict problems, behaviours, tastes etc. Through big data we can collect and reconcile the data to apply analysis and predictive modelling [2, 7].
- ***P for Personalization:*** Personalising at the detailed level is the second category of uses. Big data basically helps us to create a solution for a specific group of people or an individual. For Example, creating a personalised website that is based on the information automatically builds the page and different processes are performed. The solution uses analysis and interactions for a customized contribution [2, 7].
- *P for Prevention:* The third use is for Prevention which implies that big data is used to identify the risks and dangers involved and prevent them [2, 7].

4. BIG DATA OPPORTUNITIES IN E-BUSINESS

In the current business scenario where data is considered as an asset worthy of monetary value, enterprises look for business transforming abilities from IT suppliers by embracing big data for:

1. *Risk Management:* This is a very important aspect as incorrect risk analysis can often lead to inadequate and unfit decision making and

higher expenses. Every risk needs to be identified with a systematic approach to prevent the company from threats due to data breaches. Analysis of big data can establish balance between opportunity and hazard. [3]

2. *Driving Research and Development*: R&D pertaining to Big Data is not so much about velocity as it is about viability, variety and sometimes even volume. Data analytics is used to visualize relationships and patterns. Genetic data mining helps in combining the real-world outcome of data with clinical data. It helps in recognising the research failures faster and design more efficient data with low costs.[3]
3. *Analysing Consumer Behaviour:* With the boom of World Wide Web, E-businesses and social media platforms have definitely revised the scene of accessible consumer behaviour data. E-commerce sites have now exchanged money registers and Point-of-Sale (POS) frameworks in a manner which enables recording of each and every move of the buyer, even when no purchase is being made. [3].

5. TYPES OF DATA

The different and clearly intricate, specialists from various fields like retail, finance, advertising and media describe data in three classes as indicated by securing focuses and proprietorship:

1. *First party:* It implies information possessed by the business, gathered about a business' clients, for instance, value-based information, statistic information gathered directly from clients by and large for business purposes, for either in-house investigation or deal to third parties. This information is shut. It isn't openly shared or uninhibitedly accessible. First party information can be viewed as a yield that may have an incentive in its very own privilege and can fill in as a reason for the restrictive upper hand. [15]
2. *Second party:* It means derived data where ownership is uncertain like data collected in collaboration with another company. This information is shared between organizations according to authoritative understanding indicating an extent of time and practices. Responsibility for information is dubious yet for the most part the organization gathering the information stores it. For instance, Google AdWords information, what number of site hits, what number of snaps, how often a specific inquiry term was entered. The nature of this data is also typically closed. [15]

3. *Third party:* It means data collected and owned by different parties. For example: government datasets, credit scores and audience ratings. This information incorporates open information just as information of a closed or business nature gathered from the web through web scratching or information gathered and prepared by information merchants. Third party information sellers bundle information as indicated by customer request, giving data on explicit objective gatherings. Third party information is a frequently expensive information. Plans of action at that point rotate around how to utilize such a contribution to make new items or improve business effectiveness in novel and imaginative ways [15].

6. BIG DATA BUSINESS MODELS

The business of big data allows many complexities as many organizations participate in various spectrums of gathering, handling, and selling of data. Rising in this market are "as a service" models in which organizations make available software, platforms, analytics, or consulting "as a service," to draw in their clients in different ways.

1. *Monetizing first party data:* In progressive firms, first party information is utilized to aid internal business choices on an incredibly fine grained scale. While the essential plan of action for these organizations is retail, first party data affects pretty much every critical choice. One clear approach to adapt restrictive first party data is to treat it like any market-worthy product and offer it to different sellers to whom this data may be directly or indirectly useful. Therefore, first party information is considered as a result or output in its own right.
2. *Data analytics as a 'Service':* The worth of data lies in the proceedings that are a result of its analysis and not in its intrinsic benefits. In this way, a typical business architecture model is made for organizations in the big data spectrum which is nothing but the provision of analytics as a service where data analytics is an integral part of the aforementioned model. Further, in this model, the analytics firm takes its own proprietary data, data supplied by its client or some third-party source of data as an input and generates data summary, analysis, insight, proposal, or some other product derived from that data, as an output. Analytics often result in reporting insights on a client's targeted audience segment based on aggregated behavioral data for particular groups. Since processing and analysis

of technology is being more affordable and the consumers have begun utilizing big data frequently, big data analytics is likewise being more accessible for individual use. Hence, a new variety of consumer facing analytics firms is emerging. For instance: Mappings, a portable application that empowers its customers to report their degrees of satisfaction and receive feedback, gathers individual personal information, examines it, and reports it in a usable structure to clients.

3. *Three distinct classes of big data business models.*
   (a) *Data users:* These are organizations that utilize data either in the process of business decisions, or as a contribution to different services and products. Such associations face problems like what data is to be generated, what data is required remotely, and by what means can this data be utilized to make an incentive inside the business? These organizations require tangible and human resources to exploit the information out of this data.
   (b) *Data suppliers:* These are organizations that either create data that is of native worth and therefore commercial or fulfill some sort of brokerage rule by providing access to an aggregation of first-party and third-party data. Such associations need not have any specialization in the supply of data as numerous associations are finding that they hold information that is of impressive worth when third parties put it to a use other than that for which it was really gathered. The key inquiries include – what data is accessible, what benefits the data might have and for whom, and by what means should data be conveyed to expand its worth?
   (c) *Data facilitators:* These organizations implement varied services including counsel on the best way to exploit big data, provision of physical architecture, and the arrangement of outsourced analytics services. These organizations have a significant job, currently, as many firms are redesigning to make data a key contributing element to their organizations.

7. BIG DATA AND SECURITY TECHNIQUES

Big data is gathered by all kinds of data and is, mostly, anonymous in nature, this process is called anonymisation. Anonymization is a privacy preserving technique that manipulates the information, make the data identification tough for anybody but the owners henceforth, making it different from that of data encryption. Anonymization of data eradicates

identifying features like social security numbers or names from the database. Since Different vulnerabilities can be linked with different types of anonymizations, there are various methods available to anonymize data, such as shuffling, encryption, substitution, date and number variance and nulling some fields. Some anonymization techniques are discussed for ambiguous data in database.

1. *Data Hiding:* It overrides a data value by swapping it with a value '0'. It is also known as Black marker anonymization. For example, while considering hospital database, an age of a patient might not be essential for processing, so it is swapped with constant '0'.
2. *Hash Calculation:* It can find a hash value either of a single field or several fields. It takes a variable input and produces fixed size hash of input. The SHA or MD5 can be used. For example, we can calculate hash of the first name and the last name.
3. *Shifting:* Shifting shifts a field or data value by specific value. It adds some offset to data value. Shift value is the only key to shift function, so that is kept secret. For example, an offset value 10 is added in age field.
4. *Data Truncation:* In this 'n' least significant bits are removed from numerical field. It conserves the info even if data at the last is lost. For example, the phone number of surgeons is truncated, and the first 4 digits are shown.
5. *Data Permutation:* It is a replacement technique. It swaps the original value with a new unique value. The selection of substitution value is random. They may result in non-collision. For example, first and last name are permuted.
6. *Data Enumeration:* It is also a replacement technique. It retains the sequential order of the events. It is beneficial for applications that require strict sequencing order. Example: salary field is enumerated along with preserving the execution order.
7. *IP Prefix-Preserving:* In this method the n-bit prefix of IP-address is preserved. Two anonymized IP addresses match on prefix of n-bits, iff two real IP addresses are same on prefix of n-bits. The IP address is prefix preserved here. Prefix preserving anonymization belongs to Typed Transformation, which uses single anonymized value for each unique value of original data. The tool TCPdPriv uses prefix preservation anonymization. Crypto PAN is an approach developed by Fan *et al.* for creating prefix preserving anonymized addresses without the use of prefix table. [8, 13].

8. TOOLS FOR ANALYSING BUSINESS

Following are certain data analytics tools that enterprises use to analyze their businesses based on their use cases:

1. *Apache Hadoop:* Hadoop tool is a collection of open-source software utilities that use a network of computers for forming racks of servers which are further used to solve problems involving big data via the MapReduce programming model. Moreover, NoSQL databases are mainstream tools for archiving data on these racks. Hadoop tasks or jobs are programmed in Java which requires a lot of complexity henceforth making it efficient yet complex to understated.[9, 10]
2. *Pentaho Business Analytics:* Pentaho is a software platform that started out as a report generating engine, in the beginning. It makes it easy to absorb information from new sources while having the facility to attach the tool to various NoSQL databases including MongoDB, Cassandra, etc. Once a connection is established, the information can be represented as if it was originally derived from SQL databases.[9, 10]
3. *Karmasphere Studio and Analyst:* Karmasphere Studio is an IDE that makes it simpler to make and run tasks in Hadoop. While setting up the work environment, the tools show the condition of test data at every single step making the client aware about how the temporary data will look like as it is sliced, analyzed and then reduced. [9, 10]
4. *Talend Open Studio:* Talend offers an Eclipse-based IDE for executing data processing tasks with Hadoop that are intended to help with data integrity, data quality and data management, all with subroutines tuned into these tasks. Talend Studio enables us to develop tasks by dragging and dropping little icons onto a canvas. It also has an added feature of adding proxy while getting a RSS, feed if required. [9, 10]
5. *Tableau Desktop and Server:* Tableau Desktop is a specialized visualization tool that simplifies viewing data in new innovative ways while slicing it. Tableau offers an interactive and dynamic mechanism so that we can slice data which makes it different from other such visualization tools.[9, 10]

9. ADDRESSING BIG DATA CHALLENGES

The following challenges apply to big data collection, cleansing and processing in the e-business domain:

1. *Guaranteeing the Authenticity and Accuracy of the acquired Data:* Today is the time of prescriptive investigation which like each other

innovation relies upon the legitimacy and precision of the information feed. One of the real challenges for most e-organizations is to comprehend which information is to be utilized for which examination like in Southeast Asia, where provincial dialects are numerous and various, making an interpretation of the gathered information into English is another hardship all alone.

2. *Detecting bots:* Due to the volume and type of traffic that they generate, Spiders and crawlers; collectively called bots which are automated programs visiting the websites including typical bots like web search engines (such as Google), site monitoring software, and price and email harvesters, are dramatically changing click-stream patterns at the website level.
3. *Lack of Talent:* Considering that Big Data is a comparatively new technology, determining the perfect fit and its successful implementation is often difficult.
4. *Security of the Data:* Some of the major Big Data security challenges include user authentication, restricted access or access constraints, meeting various compliance guidelines, appropriate encryption in data in-transit.

10. ADVANTAGES AND DISADVANTAGES OF BIG DATA

Advantages	*Disadvantages*
• Builds a better customer and customer gets an expertise opinion. • Predictive analytics results can be used to predict customer choice and his area of interest. • Big Data aids in personalising emails and increasing conversion rates. • Product Pricing can be updated in real-time so as to keep up with the competition. [10]	• This industry is limited by infrastructure specially for developing countries like India. The bandwidth available for usage restricts the type of content and services that can be accessible online. • While operational costs are minimal, setup costs are high, dedicated computer servers. • Highly talented and specialised workers are required for setup and maintenance • The inability to view products physically often means a lack of trust between buyer and seller • As this is still a comparatively new industry, regulations governing the industry are often ambiguous or simply not present. [10]

11. FUTURE BIG DATA TRENDS

The evident growth of e-business industry is resulting in companies focusing on new trends in e-business for sales to increase multi-fold by aligning e-business operations to customer expectations. Some of the trends wherein big data will prove to be a big promoter are [2, 5, 10]:

1. *Mobile Taking the Center Stage:* A responsive mobile site is the need of the hour as convenience and accessibility in terms of optimised checkout, content, site performance, content and online marketing are an integral part of the e-business technology trends leading to more visitors to the site inadvertently.
2. *Voice Search will be a Necessity:* According to estimates 50% of the searches will be voice search by 2020. The reason of which could be that people do not want to spend the time to type a query. Soon, businesses would have to focus on voice optimisation and not just text like the US-based outdoor gear and apparel brand which achieved a 24 percent increase in income by enabling voice-enabled search. Further, you could even optimise the local voice searches to cater to global markets. An essential element of this process would be the usage of structure and common language that reflects on the way people speak.
3. *Personalization Will Dominate Buying Cycles:* Personalization, another trend that would be on the surge in 2019, is based on the analysis of buying-behaviour history of buyers which helps in customer segregation and the examples of which are e-business companies like Amazon that uses user's browsing history to share recommendations which according to a recent report led to 35% increase in revenue for the Amazon recently.
4. *Payment Methods will Continue to Evolve:* This trend comprises emergence of specific payment methods and quantified categories of people like Kodak coin for photographers and musician for musicians since mobile payments, crypto currencies and digital wallets like Apple Pay, Google Pay, and Samsung Pay are leading the change in payment methodologies. Thus, not having adequate payments for your e-business portal will affect the shopping cart abandonment.
5. *Application of Augmented Reality:* A new way to display services and products can be augmented reality, that is expected to reach $ 133.78 billion by 2021 which provides a way to improve customer experience and can increase the sale profits at an extraordinary pace as the users get to explore and learn the different features of the product globally, as suggested by market research studies.

12. CONCLUSION

There's no uncertainty that Big Data has showed up as the new bleeding edge of development and rivalry in the field of e-business because of the difficulties and openings produced by the data upheaval and the outcomes that this information can create. Enormous Data really offers some incentive to e-organizations by utilizing the elements of individuals, procedures, and advancements to change information into experiences for money related ventures, basic leadership and reasonable answers for prior business issues.

This has turned into a thorough yet profitable methodology, managing information, sources, abilities, and frameworks so as to make an upper hand on the business front. Prominent e-business giants such as Amazon, Google, Facebook, and E-bay have already embraced Big Data Analytics at a time when it is most in demand.

Through the taxonomy and simplification of the key qualitative and quantitative aspects of Big Data Analytics, this study helps in presenting a valuable beginning stage for the use of Big Data in developing e-business explore, continuously. This study represents a unique way of encapsulating all the best tools and techniques like Hadoop that build and shape Big Data Analytics capabilities.

This position paper investigates Big information in e-business by drawing on a precise survey of the writing. The paper presents a system that investigates the definitional angles, unmistakable attributes, types, business worth and difficulties of Big Data in the field of e-business. Close by the above mentioned, the investigation impressions that once Big Data and its extension are all around characterized; explanatory strategies and kinds of huge information are surely known; and the difficulties relating to it are appropriately tended to, the Big Data application will amplify and show new plans of action that may change how we see commercialization in today.

A MATLAB Programming Applied in Gradient Search Method to Solve Quadratic Optimization Problem

L.N. Das[1] and Sanyam Gupta[2]

ABSTRACT: *In the applied Optimisation technique subject there are certain methods mentioned in Operations Research books to solve Quadratic optimisation problem. In this book chapter we formulate an unconstrained nonlinear programming problem and determine the optimal solution using gradient search technique. Also we discuss the post optimality analysis by varying the coefficient of the objective function and the obtained optimal solution values respectively. The solution process is determined with MATLAB Program coding and the post optimality discussion examples are also mentioned in this chapter.*

Keywords: Unconstraint Nonlinear Program, Gradient Search Method, Post Optimality Analysis.

1. INTRODUCTION

Optimization problem with objective or constraint function's variables having degree 2 is named quadratic programming problem. Unconstrained Quadratic programming is a special case of unconstrained nonlinear objective functioned optimization problem having many applications in mechanical production engineering, finance and economics. There are few discussions about the solution determining procedure of the quadratic programming is discussed in the optimization technique literature.

In the linear programming problem the objective function and constraint variables are of first degree. The iterative solution process for linear programing problem is obtained by using the simplex method. However, the optimization problem having either objective function or the constraint

[1,2]Department of Applied Mathematics, Delhi Technological University, Delhi.
E-mail: [1]lndas@dce.ac.in; [2]sanyam2804@gmail.com

function variables with the degree other than 1 is named nonlinear programming problem or NLP. Since a long time the researchers are investigating an effective iterative solution procedure for solving the NLP problem. The NLP problems are either constrained or unconstrained. The Karush-Kuhn-Tucker (KKT) constraint qualification algorithm [1] is one of the method for solving NLPP having objective function as well as constraint functions. The gradient search method is one among the methods for solving unconstraint NLPP. The algorithm of gradient search method is mentioned below.

1.1 Gradient Search Method

As per the definition of the book citation [1], we review the gradient search algorithm in this chapter as following manner.

Let $f(x,y)$: $S \times S \rightarrow R$ be a continuous nonlinear function defined in $S \times S$ where S ⊆ R. Select initial solution $x' = (x,y)$ & epsilon $(\varepsilon) > 0$ for given nonlinear function $f(x,y)$ and go for the following steps:

(a) Express $f(x' + h\nabla f(x'))$ as function of h by setting
$x_j = x_j' + h\left(\frac{\partial f}{\partial x_j}\right)_{x=x'}$, for $j = 1, 2, \ldots, n$ and h is real number name step length of the iteration
And substitute this expression in$f(x,y)$.

(b) Use calculus to find $h = h^*$ that maximizes $f(x' + h\nabla f(x'))$ over $h \geq 0$.

(c) Reset the value $x' = x' + h^*\nabla f(x')$.
Then go for stopping rule i.e.
Evaluate $\nabla f(x')$ at $x = x'$ and check if
$\left|\frac{\partial f}{\partial x_j}\right| \leq \varepsilon$ for all $j = 1, 2, \ldots, n$
If so, stop with the current x' as the desired approximation of an optimal solution x^*. Otherwise perform another iteration.

In this book Chapter we have solved the NLPP mentioned in Section 2 manually, and after the discussion of MATLAB coding in Section 3 we mention the MATLAB program to solve this problem with the help of computer having window operating system and we obtained the NLPP computerised solution. In Section 4 we discussed the post optimality analysis, where the parameters range and solution values are discussed in the screenshots as the program output. Finally, in the conclusion, we summarised the chapter's discussed topics.

2. PROBLEM FORMULATION

We assume the unconstrained NLPP maximize $f(x,y)$ subject to $x,y \in R^+ \cup \{0\}$ where,

$$f(x,y) = aXY + bY - cX^2 - dY^2 \quad \text{... (1)}$$

here a,b,c,d are parameters having real values. In order to apply gradient search method to solve the unconstrained NLPP we assume f is continuous function defined on $R^+ \cup \{0\} \times R^+ \cup \{0\} \to R$ with initial solution $x = 0, y = 0$ and epsilon is 0.1. Initially we assume that $a = 1, b = 1, c = 1, d = 1$ then the optimum value of the objective function is calculated as per the gradient search algorithm. Let us solve this problem manually and the solution procedure is mentioned below:

Maximize $f(x,y) = xy + y - x^2 - y^2$, with initial values $x' = (0,0)$ and $\varepsilon = 0.1$.

$$\frac{\partial f}{\partial x} = y - 2x$$

$$\frac{\partial f}{\partial y} = x + 1 - 2y$$

Gradient $\nabla f(x') = f(0,0) = (\frac{\partial f}{\partial X}, \frac{\partial f}{\partial Y})_{(0,0)} = (0,1)$

Begin the first iteration

$$x_1 = 0 + h.0 = 0$$

$$x_2 = 0 + h.1 = h$$

$$f\big(x' + h\nabla f(x')\big) = f\big((0,0) + h(0,1)\big) = f(0,h) = h - h^2$$

Since $f(0,h^*) = \max_{h \geq 0} f(0,h) = \max_{h \geq 0}\{h - h^2\}$

And assume $\frac{d}{dh}(h - h^2) = 1 - 2h = 0$

$$\Rightarrow h^* = \frac{1}{2}$$

$$x' = (0,0) + \frac{1}{2}(0,1) = (0,\frac{1}{2})$$

For this new value of x'

Gradient $\nabla f(x') = f\left(0,\frac{1}{2}\right) = (\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y})_{(0,\frac{1}{2})} = (\frac{1}{2}, 0)$

Begin the second iteration,

$$x_1 = 0 + h.\frac{1}{2} = \frac{h}{2}$$

$$x_2 = \frac{1}{2} + h.0 = \frac{1}{2}$$

$$f(x' + h\nabla f(x')) = f\left(\left(0, \frac{1}{2}\right) + h\left(\frac{1}{2}, 0\right)\right) = f\left(\frac{h}{2}, \frac{1}{2}\right) = \frac{1}{4}(h + 1 - h^2)$$

Since $f\left(\frac{h^*}{2}, \frac{1}{2}\right) = \max_{h \geq 0} f(\frac{h}{2}, \frac{1}{2}) = \max_{h \geq 0}\{\frac{1}{4}(h + 1 - h^2)\}$

And assume $\frac{d}{dh}\left(\frac{1}{4}(h + 1 - h^2)\right) = \frac{1}{4}(1 - 2h) = 0$ to determine the maximum value of h,

$$\Rightarrow h^* = \frac{1}{2}$$

$$x' = \left(0, \frac{1}{2}\right) + \frac{1}{2}\left(\frac{1}{2}, 0\right) = (\frac{1}{4}, \frac{1}{2})$$

Similarly we can do further iterations those are summarized in the following table.

Table 1

Iteration	x'	$\nabla f(x')$	$x' + h\nabla f(x')$	$f\left(x' + h\nabla f(x')\right)$	h^*	$x' + h^*\nabla f(x')$
1	(0, 0)	$(0, 1)$	$(0, h)$	$h - h^2$	$\frac{1}{2}$	$\left(0, \frac{1}{2}\right)$
2	$\left(0, \frac{1}{2}\right)$	$\left(\frac{1}{2}, 0\right)$	$\left(\frac{h}{2}, \frac{1}{2}\right)$	$\frac{1}{4}(h + 1 - h^2)$	$\frac{1}{2}$	$\left(\frac{1}{4}, \frac{1}{2}\right)$
3	$\left(\frac{1}{4}, \frac{1}{2}\right)$	$\left(0, \frac{1}{4}\right)$	$\left(\frac{1}{4}, \frac{1}{2} + \frac{h}{4}\right)$	$\frac{1}{16}(5 + h - h^2)$	$\frac{1}{2}$	$\left(\frac{1}{4}, \frac{5}{8}\right)$
4	$\left(\frac{1}{4}, \frac{5}{8}\right)$	$\left(\frac{1}{8}, 0\right)$	$\left(\frac{1}{4} + \frac{h}{8}, \frac{5}{8}\right)$	$\frac{1}{64}(21 + h - h^2)$	$\frac{1}{2}$	$\left(\frac{5}{16}, \frac{5}{8}\right)$
5	$\left(\frac{5}{16}, \frac{5}{8}\right)$	$\left(0, \frac{1}{16}\right)$	–	–	–	–

As $\nabla f(x') = \left(0, \frac{1}{16}\right) = (0, 0.0625)$

i.e. $|\frac{\partial f}{\partial x}|_{(0, \frac{1}{16})} = 0 < .01 = \varepsilon$

and $|\frac{\partial f}{\partial y}|_{(0, \frac{1}{16})} = 0.0625 < .01 = \varepsilon$

Therefore point of maximum is $\left(\frac{5}{16}, \frac{5}{8}\right) = (0.3125, 0.625)$ and hence the objective function maximum value is 0.

3. A MATLAB PROGRAM FOR SOLVINGUNCONSTRAINED NLPP USING GRADIENT SEARCH METHOD

We fit the problem solution algorithm in the MATLAB program to get the optimal solution.

```

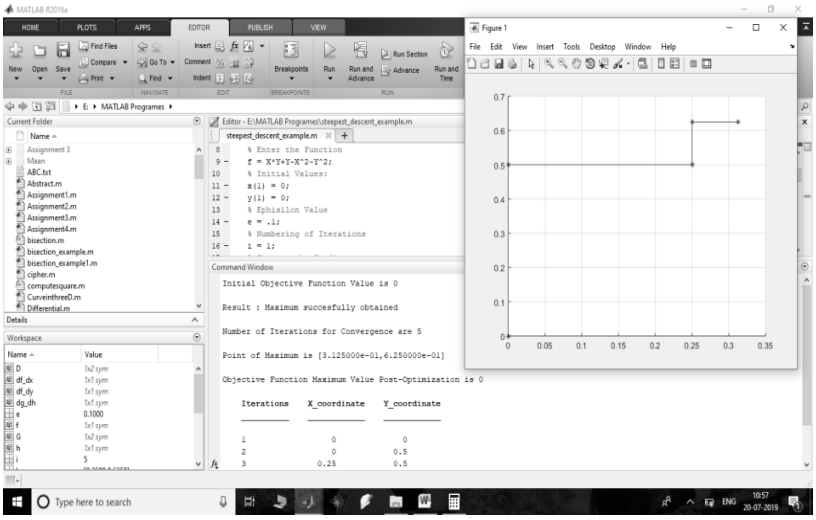

Fig. 1: Output when $a = 1, b = 1, c = 1, d = 1$

From the above screenshot we see outcome of the MATLAB program is $x = 3.125000e - 01$ and $y = 6.250000e - 01$ for the coefficients value $a = 1, b = 1, c = 1, d = 1$ with initial solution$x = 0$ & $y = 0$. The objective function value is 0. In the next section we study the range of a, b, c & d in different cases with the initial solution $x = 0, y = 0$ and epsilon $= 0.1$.

4. POST OPTIMALITY

In the above section we considered the function variables coefficients as $a = 1, b = 1, c = 1, d = 1$ for the optimization problem objective function defined in (1).

Case 1: Let us increase the variable coefficient a and keep $b = 1, c = 1, d = 1$ then up to $a = 1.42$ the result optimum value to the objective function is 0. Hence there is no change in the objective function value. At $a = 1.43, b = 1, c = 1, d = 1$ the objective function value is 1. In this manner, if we go on increasing value of $a = 1.82, b = 1, c = 1, d = 1$ the value of objective function is 1 for initial solution $(x = 0, y = 0)$ with value of epsilon 0.1 using the gradient search algorithm. If we set $a > 1.82, b = 1, c = 1, d = 1$, the objective function value changes. So the range of the coefficient a is (1.43, 1.82) for objective function value 1 with consideration $b = 1, c = 1, d = 1$ and the initial solution $(x = 0, y = 0)$ & value of epsilon 0.1.

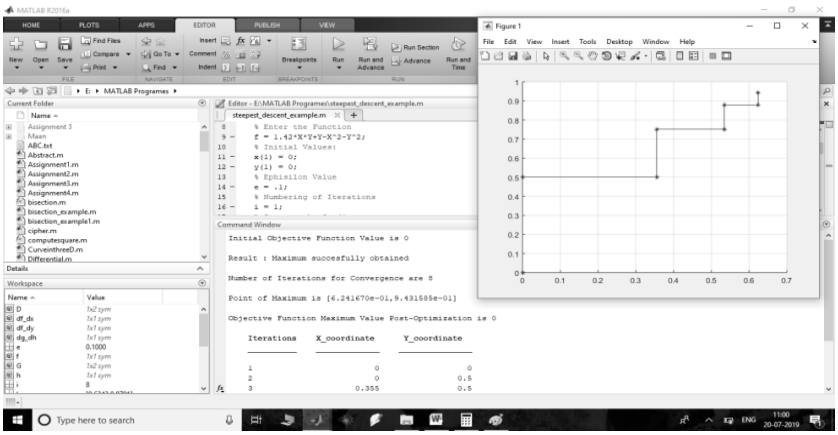

Fig. 2: Output when $a = 1.42, b = 1, c = 1, d = 1$

The above screenshot shows the optimal solution $x = 6.241670e - 01, y = 9.431585e - 01$ for the coefficients $a = 1.42, b = 1, c = 1$ & $d = 1$ with initial value $x = 0, y = 0$ and epsilon 0.1. The objective function value is 0.

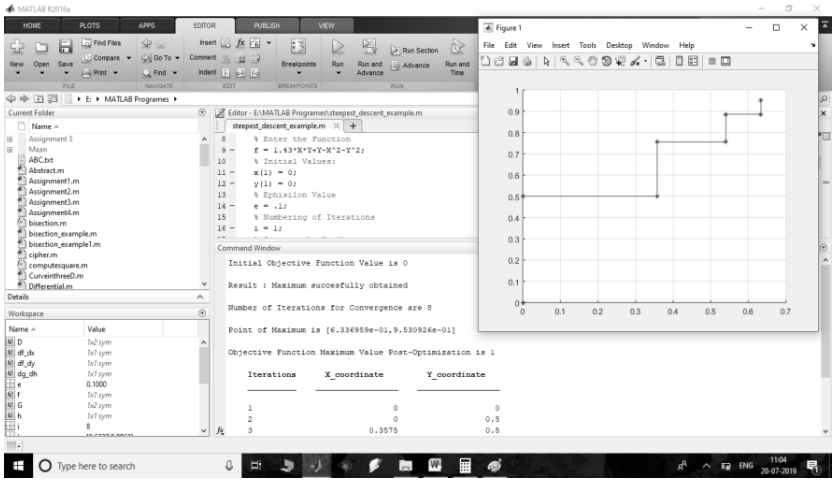

Fig. 3: Output when $a = 1.43, b = 1, c = 1, d = 1$

The above screenshot shows the optimal solution $x = 6.336959e - 01, y = 9.530926e - 01$ for the coefficients $a = 1.43, b = 1, c = 1$ & $d = 1$ with initial value $x = 0, y = 0$ and epsilon 0.1. The objective function value is 1.

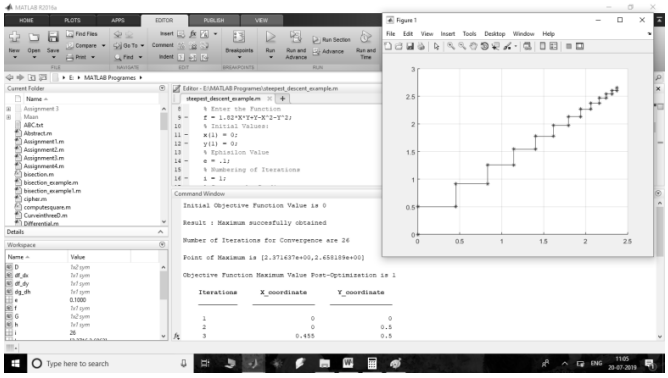

Fig. 4: Output when $a = 1.82, b = 1, c = 1, d = 1$

In the above screenshot the gradient search algorithm plotted graph has an ascent direction and explains the convergence of the solution search algorithm.

Case 2: Let us assume $a = 1, c = 1, d = 1$ and we have determine from the MATLAB program that the range of b is $(1.23, 2.12)$ for objective function value 1 with initial solution $(x = 0, y = 0)$ and value of epsilon 0.1.

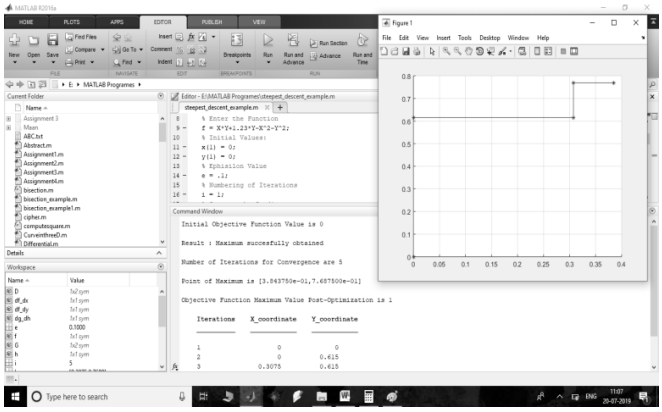

Fig. 5: Output when $a = 1, b = 1.23, c = 1, d = 1$

The screenshot explains the objective function value is 1 for $a = 1, b = 1.23, c = 1$ & $d = 1$with $x = 0, y = 0$ and epsilon 0.1. Further we observe $b = 1$ up to $b = 1.22$ the objective function value is 0 with the increment of 0.01 to the b value causes the value of the objective function different.

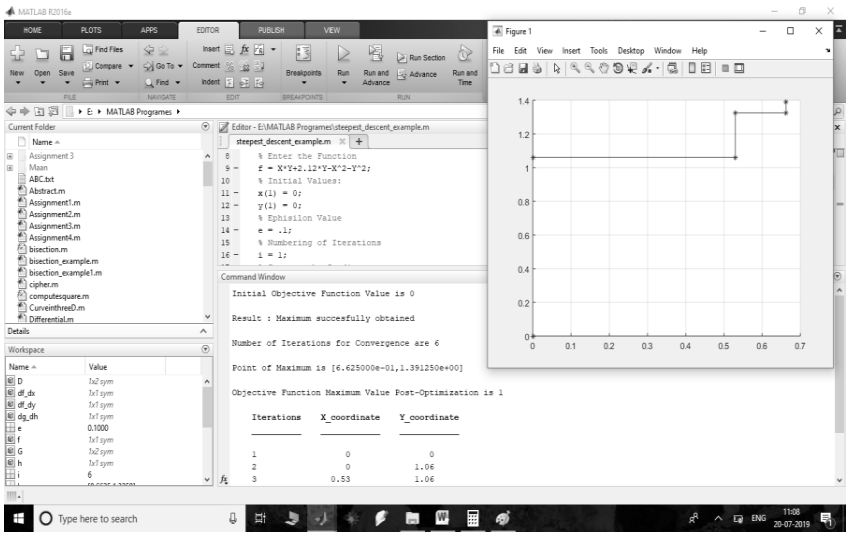

Fig. 6: Output when $a = 1, b = 2.12\ c = 1, d = 1$

In this screenshot we observe the objective function value is 1 and remains unchanged for $a = 1$, b belongs to (1.23, 2.12), $c = 1, d = 1$ for the initial solution $x = 0, y = 0$ and epsilon 0.1.

Case 3: When the parameter $\boldsymbol{a = 1.43}$ the range of $\boldsymbol{b}$ is within (1, 1.71) for $\boldsymbol{c = 1, d = 1}$, and objective function value is 1 with $\boldsymbol{x = 0, y = 0}$ and epsilon is 0.1. The screenshots are mentioned below

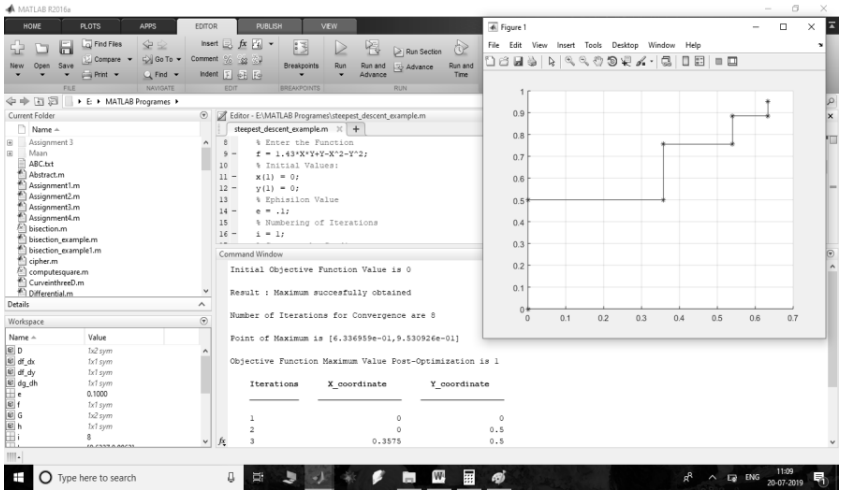

Fig. 7: Output when $a = 1.43, b = 1\ c = 1, d = 1$

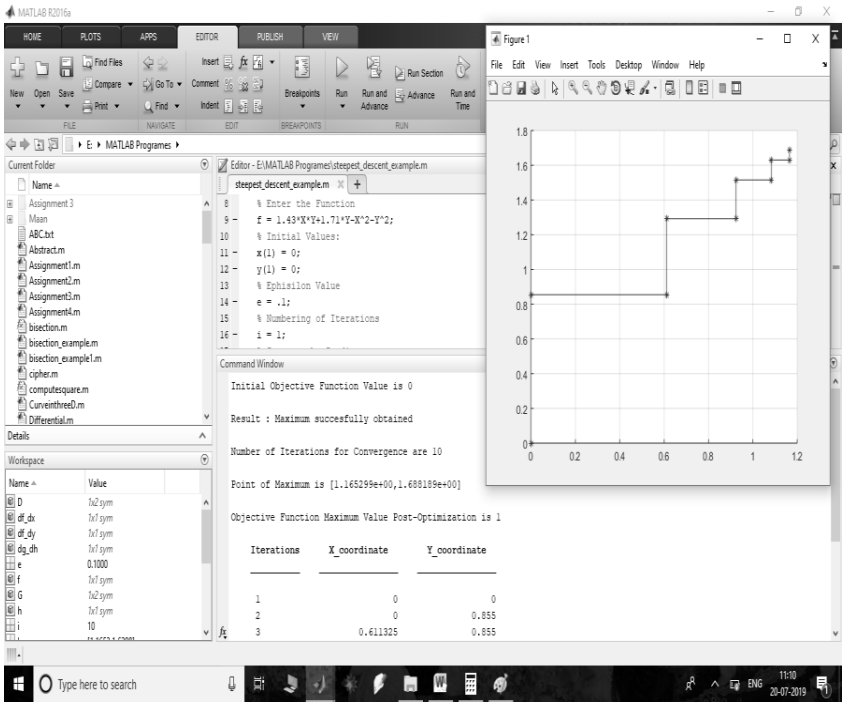

Fig. 8: Output when $a = 1.43, b = 1.71\ c = 1, d = 1$

Case 4: In this post optimality case, we observe if we change the value of c or d other than 1, and values of $a = 1, b = 1$ the objective functional value remain 0. If we assume $a = 1.43, b = 1.71$ and value of c or d is other than 1, the objective function value is 0 for initial solution $x = 0, y = 0$ and epsilon is 0.1.

5. CONCLUSION

The objective function mentioned in equation (1) is a general expression with coefficients a, b, c, d, where a, b, c, d are definite real numbers. We have observed the objective function value and optimal solution of the NLP problem are different, if we set suitable values to the parameter for obtaining the optimal solution by using gradient search algorithm with the initial solution $x = 0, y = 0$ and epsilon 0.1. Further if we assume x and y values are other than $(0, 0)$ the objective function value will be same but the gradient changes. For instance, if we assume $x = 1, y = 1, a = 1.43, b = 1, c = 1, d = 1$, then the optimal function value remains 1. This screenshot is mentioned below

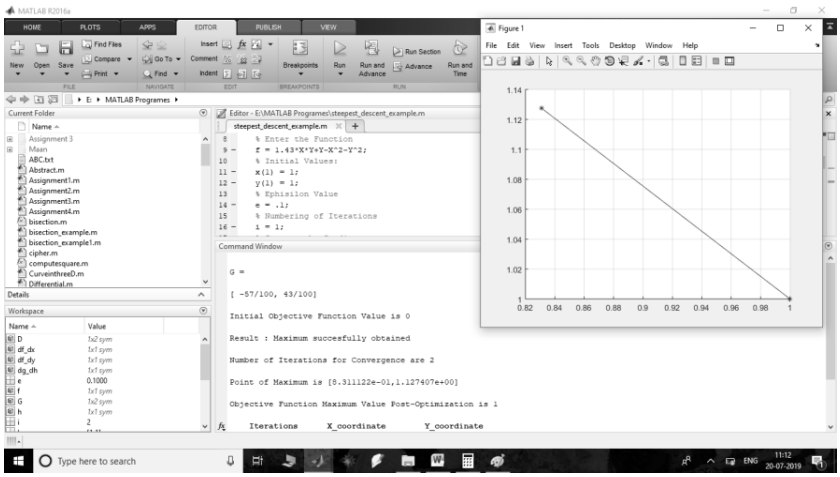

Fig. 9: Output when $x = 1, y = 1, a = 1.43, b = 1, c = 1, d = 1$

Postmodern Techno Culture and the Need for Feminist Intervention: Study of Mobile Applications for Women Safety in India

Rubina[*] and Madhav Govind[#]

ABSTRACT: *Women safety is a pressing issue especially in India and lately various innovators are trying to come up with ICT based solutions to empower women so that they can fight against this menace. Use of mobile phone-based applications for identifying rural and urban landscape on various safety parameters intended for women safety is one such digital system innovation. Though our previous research on similar mobile phone application "My Safetipin" shows that rather than helping the cause of women safety the mobile application was jeopardizing women safety in India. Feminist intervention in post-modern techno culture claims that more female participation not only as user of technological artifact but as decision maker at every stage of decision-making process can make the product better for females which in turns improve the society. Thus, this research tries to explore our previous case study of "My Safetipin" mobile application from a fresh perspective of analyzing female participation not from user perspective but as decision makers perspective to look at possible reasons for failure of this e-participation platform.*

Keywords: Feminist Technological Studies, Technological Determinism, Women Safety, Digital Exclusion, ICT.

1. INTRODUCTION

There exists missing perspective of technology into women's studies and at the same time theme of gender takes back seat in postmodern

[*] Research Scholar, Centre for Studies in Science Policy, JNU
E-mal: rubinaakhtar1612@gmail.com
[#] Professor, Centre for Studies in Science Policy, JNU.
E-mail: m_govind@mail.jnu.ac.in

techno-culture.[1] Techno culture tries to answer how technology pervade culture, both in terms of popular culture and gendered applications. Today we have the mobile phone, i.e., since it became a common occurrence, it is now the primary form of contact for most people, although originally only usable to make phone calls. It has become a vessel for many other parts of technology. Recent research on technology states the difference between 'Objective usability' and 'User experience', that is, what a computer can do and what the user can do with a computer, respectively. Use of android and I phone give user an amalgamation of features, combining many pieces of tech into one, and is designed for accessibility and ease of use, it becomes effectively part of both 'material' and popular culture in one swoop. Now 'digital' programs and applications have become a standard and recognizable medium to create work on par with traditional techniques.

The archetype thought is that women's use of technology is mostly viewed as dystopic. The emergent techno-feminism theory[2] defends a relationship in which technology is cause and the consequence of gender relations, at the same time. For years, feminists initiated a critique of the inherently patriarchal nature of technology and of technoscience. Socialist feminist tried to be more contextual in their work, pushing Marxist analysis beyond class to ask why and how modern technology became a male domain and to address the gendering impact of modern divisions of labor.[3] Even in a postmodern society, interaction between human and machines are studied as "man-machine system" making the whole technological academic discourse as a masculine discourse.[4]

Studies in past have showed that most of the problem that exist with technological solutions centered around women in India, are rooted in the fact that there is lack of involvement of female in the whole technology development cycle.[5] Even other previous academic work on gender politics raised concern regarding lack of female stakeholder presence in decision making process as far as technology implementation in society is concerned. It showed that technological determinism is not only non-neutral but at various instances forces female to bear most of the social

[1] Berg & Merete, 1995.
[2] Wajcman, 2004.
[3] Bray, 2012.
[4] Cockburn & Fiirst-Dilic, 1994.
[5] Manazir *et al*, 2019.

cost of technological advancement which leads to their own social oppression.[6] Since women safety is a pressing issue in India, we take technological solution in form of mobile phone applications for women safety as our theme of study. Taking further our previous study, for a robust policy level solution which can bring in feminist intervention for not only technological advancement but for social emancipation of society, without excluding females. Through this research we want to study the condition of female engagement at various stages of technological solution development cycle, barriers if any available in female intervention in decision making as well as possible solution beyond the technological determinism.

2. WHAT IS 'MY SAFETIPIN' MOBILE APPLICATION?

'My Safetipin' is a mobile application which was released on 9th March 2016 in India available on Android and Apple's Internetwork Operating System (iOS). It is basically meant to be a personal location guide of public places using Global Positioning System for the safety of females. It helps its user in taking a safer decision based on the safety score of an area thus notifying user how safe or unsafe any location is, to roam around. Also, user can notify their family and friends in case they are in an unsafe location and helps others to keep track of user. The application user can also rate an area based upon the nine parameters based upon their own understanding of these parameters thus scores are cumulative and could vary from user to user. In India, this mobile application is operational in 9 cities namely New Delhi, Gurgaon, Noida, Mumbai, Bengaluru, Chennai, Chandigarh, Guwahati, Karnal in English and Hindi languages. Thus "My Safetipin" currently is available to only 2.64% female population of India including those of rural and urban areas both.[7]

2.1 Research Question

1. What is the extent of women participation at conceptualization and development stages of technological solutions for women safety in form of mobile phone applications?

---

[6] Harding, 1995. [to curb unwanted pregnancy distribution of contraceptive devices for female as condition of aid by donor agency was favored, while neither male contraceptive nor women's education and social welfare was improved.]

[7] Manazir, Govind, & Rubina, 2019.

2. How does barrier at each developmental stage relate to the overall extent of women's participation with respect to such mobile phone-based applications?
3. How can female participation at various stages improve the development and implementation of women safety applications in India?

2.1.1 *Literature Review*

As per Marxian concept, it was accepted without much criticism that technological determinism is the most important influencer of cultural, political and economic aspects of any society.[8] Though it is true that technological determinism helps in development of technological artifacts but very less emphasis is given upon the fact that technology is not the sole factor of changes in society, but one of the many factors which should be seen in totality.[9]

Further women suffer with Digital Exclusion in India, where even the use of internet and mobile phones are majorly male dominated in both rural as well as urban demographics.[10] Female safety is an important issue today and even Sustainable Development Goals - 5 emphasizes "Women Equality and Empowerment", and mobile phones have emerged as a positive contributor towards women empowerment.[11] With advent of Information, Communication and Technology various forms of mobile phone applications have come up worldwide for women safety, and in India too they have large user base. These mobile phones based e-participation platforms aims at using available technologies to support active citizenship, enabling broader participation for reaching a wider audience and enabling more informed citizens' contributions through providing accessible and understandable information to target audience.[12] Technically e-participation platforms like "My Safetipin" mobile phone applications are nothing but forms of Digital System Innovation using advancement in technologies like GIS mapping, advanced internet connectivity technologies like 4G etc. But as far as technological solution's in form of e-participation platform for women safety are concerned, first we need to understand different stages where feminist intervention in decision making is not up to the mark.

---

8. Marx, 1959.
9. Berg & Merete, 1995.
10. IAMAI, 2017.
11. UN, 2018.
12. Manazir, Govind, & Rubina, 2019.

2.1.2 *Research Findings*

Epistemologically this study will be empiricist form of enquiry where we will follow mixed method including primary and secondary data research followed by case study of "My Safetipin" women safety application being used in India. Taking further our previous research on e-participation platform namely "My Safetipin"[13] where we analyzed the e-participation platform which claimed to resolve various issues related to women safety. We found that rather than resolving women safety concerns in rural and urban landscape mobile interface was not only not designed properly for the functions which it claimed to make moreover it was counterproductive to female users in case of distress and urgency.[14]

To understand level of involvement and skillset of all employees especially females in development of "My Safetipin" and taking leads from previous research which states more involvement of stakeholders like females in Digital System Innovation meant for women safety leads to better product[15] we conducted analysis of people involved with the product development as well as management and maintenance.

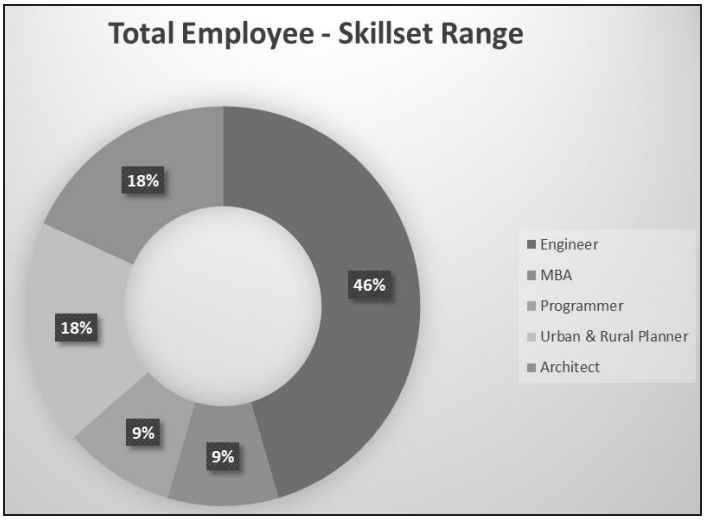

Fig. 1: Total Employee Differentiated based on their Skillset[16]

[13.] Manazir, Govind, & Rubina, 2019.
[14.] SafetiPin, 2019.
[15.] Vissers & Stolle, 2013.
[16.] SafetiPin, 2019.

We found that among total employees working with the organization in India, almost half of the total strength were engineers, followed by architect, urban and rural planners, MBA's and lastly programmers. Worth mentioning percentage of programmers and product development expert were least.

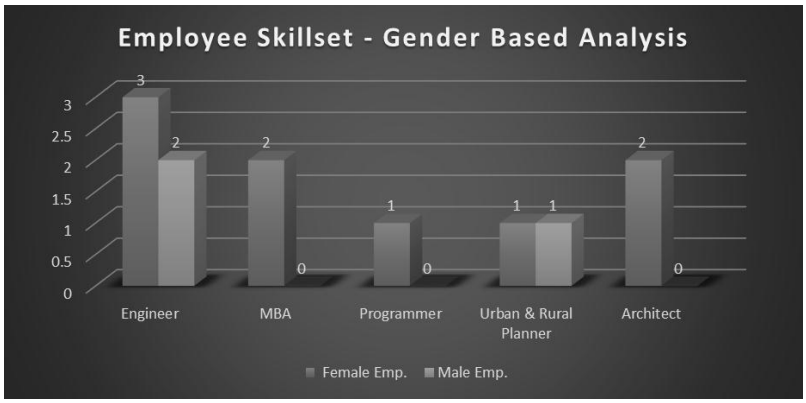

Fig. 2: Variation in Employees Skillset based on Gender[17]

Out of the total employee strength, females were most in every department and were in majority as far as Digital System Innovation development is concerned.

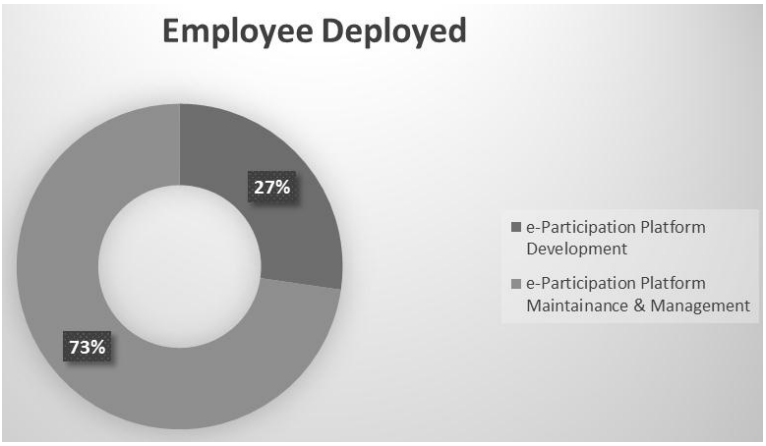

Fig. 3: Variation in Total Strength of Employees Deployed based on Major Roles Assigned

[17.] SafetiPin, 2019.

Also, while almost 3/4th of the employee strength was focused over e-Participation Platform maintenance and management only 1/4th of the total employee strength was meant for platform development and upgradation.

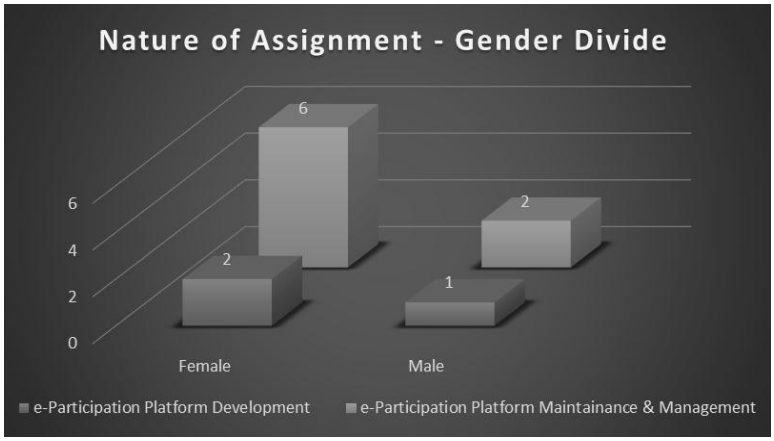

Fig. 4: Variations in Major Roles Assigned to Employees based on Gender[18]

On closer analysis we found that only 2 female staff are designated full time for e-participation platform development i.e. from Digital System Architecture development to final product launch along with only one male employee meant for managing GIS mapping, while remaining majority staff was meant for e-participation platform maintenance and management.

Thus, our two important findings were as follows:

1. Though majority of females were part of the organization as well as part of e-participation platform development team. Yet, there total strength especially of development was comparatively very low in comparison with the large female user base they want to serve to.
2. Majority of issues associated with the failure of functionality of e-participation platform is associated with poor Digital System Architecture designing process which shows all the stakeholders were not considered.
3. Digital Exclusion of females in India has not been considered which is visible by the fact that the mobile application has various issues and even after so much time of product launch there has been no upgradation in product glitches.

[18] SafetiPin, 2019.

3. CONCLUSION

This research aims to open academic debate regarding women participation in Science Technology and Society not only as a reader or observer but as a participant in decision making who can influence technology and in turn society for more inclusive and developed social system. Thus, our findings reveal that though it is true that female intervention is important in post-modern techno culture, but more than that involvement of females in decision making process i.e. Digital System Architecture Designing in case of e-participation platforms like 'My Safetipin' is very important. Also, corporations promoting such innovation should hire more and more females in decision making and product development roles.

Recommender System: Principles, Techniques and Application

Sushma Malik[1], Yukta Pandey[2] and Amanpreet Kaur[2]

ABSTRACT: *In today's internet era, human beings are fully dependent on the internet for their daily tasks. Internet is used to search everything and anything meaningful that the user requires. With the growth of internet, a number of business opportunities are created and are made available to the users easily. 24×7 online services of internet have generated large amount of choices, but users are now faced with the problem of information overload. To alleviate the problem of information overload, internet needs the filtering system that could help the user to discover the information or product which they search. Such kind of filtering systems are called the Recommender Systems. This kind of system acts as software that reduces the user's choices and provides them the most appropriate options as per user's requirements. Do you know how Amazon closely knows what kind of products the user need and display a number of options for the selection? Or how can Netflix know what kind of movies or series users are interested in watching? Or how does Facebook give the options of "people you may know". All of this objective can be achieved through the Recommender System that collect the user information, analyze it and produce an immersive user experience. We can say that the Recommender System helps the user in selection process which becomes easier and time saving. The major function of Recommender System is choosing the most appropriate recommendation for the user from abundant available options. A lot of extensive research is happening in this field which is tried to give more precise and relevant recommendations to a user. Recommender systems are employing in a variety of domains, and are most commonly used to generate the playlist for video and music for various sites like Netflix, YouTube and Spotify. Various E-Commerce sites like Amazon, Flipkart, and Paytm Mall etc are using the product recommenders system to recommend the products to users on their*

interest. Recommender System is also used for the content recommenders for social media platforms like Facebook and Twitter. This chapter gives review on some significant works in the field of Recommender System on the basis of its three techniques namely collaborative filtering, content based filtering and hybrid filtering. The present chapter also includes the various issues and application domains of Recommender System.

Keyword: Recommender System (RS), Collaborative Filtering (CF), Content based Filtering (CB), Cold Start Problem, E-governs, E-commerce.

1. INTRODUCTION

The World Wide Web or simply the internet has brought numerous changes in the way we are live and communicate with each other. The explosive growth in the amount of available digital information and the numbers of visitors to the internet have created potential challenges of information overload on the users who is searching the relevant and reliable information on the web. This situation increased the demand of Recommender systems more than ever before. RS has the ability to predict whether a particular user would prefer an item or not on the basis of user profile [1]. RS can be defined as a program which is used to recommend the most appropriate items (products or services) to the particular users by predicting a user's interest in an item based on related information about the items, the users and also the interaction between items and users.

The main objective of the RS is to minimize the information overload by retrieving the most relevant information and items and services from the huge amount of data and providing the personalized services to the users. The most important feature of RS is its ability to "guess" a use's preferences and interests by analyzing the behavior of that user and /or the behavior of other users to generate personalized recommendations [2].

2. PHASES OF RECOMMENDATION PROCESS

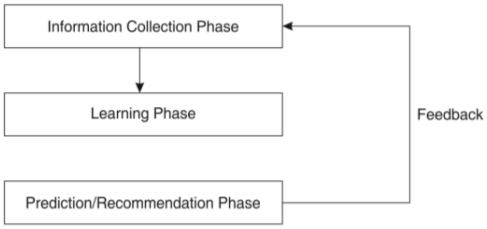

Fig. 1: Phases of Recommendation Process

2.1 Information Collection Phase

In this phase, relevant information of users are collect to create the user profile which include the user's attributes or content of the resources that user access on the web. For a good recommendation, user profile has been well designed. RS using the different types of inputs like explicit, implicit and hybrid feedback. The most convenient and high quality data collection method is explicit input method because in this data provided by the users regarding their interest in items or services. In implicit method, data collected indirectly through user behavior on the web and in hybrid method, data can be obtained through the combination of both explicit and implicit method.

2.2 Learning phase

In this phase, the learning algorithm is applied to filter and apply the user's features on the collected data from the information collection phase.

2.3 Prediction/Recommendation Phase

This phase recommends or predicts the items that user may prefer. This can be done either directly based on the dataset which are collected in information phase or through the system's observed activities of the user [1].

3. ISSUES IN RECOMMENDATION SYSTEM

This section is include the various issues related to the RS like:

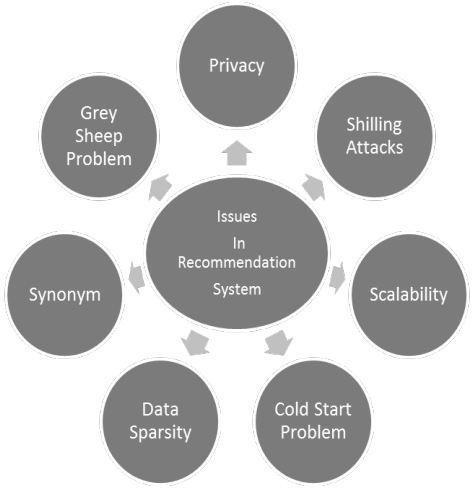

Fig. 2: Issues in Recommendation System

Cold Start Problem: The cold star problem arise when the new products are added into the catalogue or new user enter into the system. So the main reason for it is too little rating data is available in the initial state of the RS because neither new user taste can be predicted before its purchase nor the new items can be rated [2, 5, 7].

Synonym: This problem arise when same item is represented with more different names or having similar meanings. At that time RS cannot easily identify that the term symbolize different item or the same item. For example RS will treat "movie" and "film" differently. The excessive usage of synonym terms decrease the performance of the RS [7].

Shilling Attacks: what happens if number of users and competitor giving the false ratings to some products either to increase its popularity or to decrease into the RS? Such kind of situation break the user trust as well decreases the quality and performance of the RS [5].

Privacy: For the better recommendation to the user, RS need the personal information of the user but it may lead to issues of user data privacy and security. Users are unwillingly fill the personal data into the RS that suffers from the data privacy issues. Some time user feed the wrong data into the RS for that reason which affect the performance of the RS [5, 7].

Scalability: In many recommender techniques the problem of scalabilty arises when the number of users of items increases tremendously. Computation normally grows linearly with the number of users and items. Hence, the techniques which takes limited number of dataset fails here. A techniques that can increase the dataset as per the requirement is needed in a recommender system for it to perform efficiently [6, 7].

Grey Sheep Problem: Grey Sheep problem occur with people who do not completely agree or disagree with a group of people. This is some weird customer whose choices are out of the line. A user for instance may like first season of some web series but dislike the other seasons. Recommendation to such customers is difficult because their likes or dislikes are not certain [6].

Diversity: Primary factor on which most of the recommender system work upon is that similar user is likely to have similar taste. Many of the recommender system allows us to connect with social media and suggests us the shows or products that are brought by our friends on the social media platform or the similar type of products we have viewed before. It is not always necessary that we want to view the same kind of items that we have viewed before. This makes the recommendations monotonous.

Diversity is also important as say, a user has already brought TV set but now he does not want to buy that item again but many recommender system will keep showing the user different TV sets because he had bought it once [6].

Data Sparsity: This problem arises because the users generally rate only a limited number of products. There are thousands of products available most of which are generally not used by the users and hence, they are not rated by the users. Moreover, there are also users who buys a product but do not rate them or gives feedback. For instance, take your own example how many times have you watched a movie on an online platform and rated it? Or how many times have you brought a product online and rated it? There are rarely people who rate every product they see or buy. This leads to sparse user item matrix, inability to locate successful neighbours, and hence generation of weaker recommendation [5, 6].

4. RECOMMENDATION TECHNIQUES

The broad classifications of RS are including traditional methods such as collaborative filtering-based, content-based, knowledge-based, and hybrid methods and recently developed advanced methods, such as fuzzy set-based, social network-based, trust-based, context awareness-based, and group recommendation.

4.1 Collaborative Filtering

Due to human psychology, a user taking suggestions about something they own from their friends and family members which helps the user to take a decision. CF based technique help the user to take decision basede on the views of other users who have similar interest [6]. This technique can be divided into two categories like: user-based and item-based.

In the user-based CF approach, a user will obtain recommendations of items based on interest of the users having the similar taste. In the item-based CF approach, a user will receive recommendations of items that are similar to those they have loved in the past [1].

4.2 Content based Filtering

This technique using items features and interest of user to offer recommendations. Item features like keywords are used to describe items and user profile designate the items liked by the user. The recommendation engine, recommends the items that are similar with the items preferred in the past by the user [1, 6].

4.3 Hybrid Filtering

This technique is basically used to overcome the drabacks of traditional recommendation techniques like CF and CB techniques and to achive the higher performance. For that it combines the best features of two or more recommendation techniques. The most commonly used recommendation techniques for hybrid recommendation technique is CB and CF [6].

There are different possivble ways to combine the CB and CF for hybrid technique like:

1. CF and CB techniques are executed separately and after that combine their result.
2. Using the properties of CB in CF technique and vice a versa.
3. Design a combination model which combines both CB and CF features [4].

5. APPLICATION DOMAINS OF RECOMMENDER SYSTEMS

1. **e-Government:** e-Government initiative have been launched by almost all the governments across the globe. e-Government uses innovative system via information and communication technology to serve it's citizens by enhancing the management of the public sector. e-Government increases the transparency and accountability of government towards citizens. The major problem that hinders the services of e-Government is Information Overloading. Recommender System is an effective solution to this problem. It gives user the specific information and services they need rather than whole set of data [8].
   (a) **Government to citizen Services Recommendation:** It is provide citizens the access to information easily and quickly. It basically focuses on interaction between government and citizens. It enables citizens the services like tax payment, license registration, and other government services. It also gives citizens transparent information about various policies, government laws, and voting information helping an individual to make a decision.
   (b) **Government to Business Services Recommendation:** It is provides interaction between government and business enterprises, including profit and non-profit organizations. It enables the organizations to make contract bids, policies, and rules and regulations. Such services are useful for both the government and the business enterprises providing them with more business

benefits. It gives the organizations the opportunity to work with government with cost saving deals and effective results.

(c) **Government to Government Services Recommendation:** It focuses on interaction of government with agencies related to them to work efficiently for the betterment of it's citizens. Such services improves the transparency speed and consistency of the information.

2. **e-Business:** e-Business is any kind of business or commercial transaction that includes information sharing over internet. Internet has become that powerful tool that it has left behind the shop to shop walk in trend of buying items. Users now prefer sitting at home scrolling over the screen trend of shopping. But the problem with online shopping is that choosing and selecting your choice of product from such a large amount of item is a challenge in itself. To solve this problem Recommder System came into use. Recommender System filters the products according to many criteria depending on the algorithm of that particular recommender and shortlists the products according to the users taste, and thus saving their time. These products can be based on top sellers of that particular site, or analysis of the behavior of the customer through their past purchases. There are many sites like Amazon.com, ebay, flipkart, etc. that uses recommender system. Amazon and flipkart asks the user to check the specific category from a wide range of category to recommend products. Similarly, other sites uses many other different techniques to satisfy their customers needs [5, 8].
3. **e-Library:** e-Library is a collection of online database of digital objects that can include text, image audio or video. In simple words we can say that, it enables users to access digitalize data from anywhere across the world through internet. E-Library provides users with a wide range of information but at the same time the time cost and difficulty in finding proper information increases. Recommender System solves this hindrance by structuring the large content available in the database. Recommender System tends to reduce the information overload and retain the customer by recommending them the subset of data from the universal data according to their preference. This preference can be based on the past history of purchases, feedback given by the user to other books, or the books frequently visited. This recommendation acts like a filter saving users' time from traversing the whole set of data [5].

4. **E-tourism recommender systems:** Internet and mobile devices provide great opportunities to the tourists to access tourism information, but the impressive increase in the number of available tourism choices make it difficult for tourists to choose which option they prefer. This overload problem is solved by the E-tourism recommender systems which are designed to provide suggestions for tourists on the basis of their interest [5].
5. **E-learning recommender systems:** In today internet era, learning process is also changed from tradition method to E-learning method. E-learning RS have become more popular in educations institutions. The main objective of this kind of RS is to assist the users/learners to choose the courses, subjects and learning material as well as users learning activities [5, 7].

6. CONCLUSION

From the last few decades, RS open new oppertunities of retriving the personalized users information on the internet. RS have been used to solve the overload problem by suggesting related and relevant items and services to the users which are not readily available to the users on the system. This paper discuss the phases of RS process like, information collection phase, learning and predicting phase of the RS. It also discuss the traditional recommendation techniquies like Colllaborative, content based and hybrid techniques with several issues which are faced by the RS. This paper also discuss the various application domains of Recommender System like e-Government, e-Business, E-Tourism, E-Learning and many more. Several RS are designed that are based on CF, CB and Hybrid recommendation approches but each have some limitations which are the challenges for research work. Thus, the existing RS needs improvement for present and future requirments of improved recommendation qualities.

Adaptive Sliding Mode Disturbance Observer Control Base Synchronization in a Class of Fractional Order Chua's Chaotic System

Ayub Khan[1] and Uzma Nigar[2]

ABSTRACT: *In this paper, we have investigated synchronization of two identical fractional order (FO) Chua's chaotic system with disturbance using the technique of Adaptive Sliding Mode. Out of many control techniques, it is well observed that classical sliding mode control (SMC) technique has high precise tracking, low sensitivity to external disturbances, and predicated inaccuracy. However, in real applications, some disadvantage of SMC that may cause breakage in the system: chattering problem. To overcome this problem in SMC, some modification has been applied on SMC and proposed an adaptive SMC technique. A non-linear disturbance has many effects, such as increasing the instability and modeling inaccuracy. To resists this problem, a disturbance observer (DOB) is introduced. A DOB is used to estimate the parameter uncertainties, unmodeled dynamics, etc. In this paper firstly, we design, a non-linear FO DOB to tackle the unknown external bounded disturbances (BOD). Based on SMC, we design a sliding mode surface including the FO non-linear DOB for synchronization. Further, using the Lyapunov stability theory (LST), the design appropriate control method has been establishing that the state of master and slave chaotic system is synchronized with different initial conditions. FO Chua's chaotic system with external unknown BOD is synchronized via adaptive SMC for the first time. The introduced technique has many applications in secure communication and neural network.*

Keywords: FO Chua's Chaotic System, Adaptive SMC, FO Disturbance Observer, MATLAB.

1. INTRODUCTION

Henri Poincare, a French mathematician, which led to the theory of chaos [1]. A chaotic system is nonlinear dynamical systems that display complex and unpredictable behavior and highly sensitive to initial conditions. E.N. Lorenz, best known as the founder of modern chaos theory, gives the introduction of chaos phenomenon in the weather model in 1963 in [2]. In [3], Pecora and Carrol have first introduced the idea of chaos synchronization. Several types of synchronization have been introduced such as anti synchronization [4], complete synchronization [5], projective synchronization [6], hybrid synchronization [7], hybrid projective synchronization [6], etc.

Nowadays, various synchronization method have been applied to study the chaotic behaviour. These are active control [8], adaptive control [9], sliding mode control (SMC) [10], adaptive SMC [11], etc. SMC technique has a significant characteristic, and strong robustness against external disturbances and uncertainty. A nonlinear external disturbance has many effects, such as modeling inaccuracy and energy fluctuations, which can not be easily ignored. To overcome this problem, DOB has been designed. In [11] Shao firstly introduced the synchronization of FO chaotic system with unknown external BOD in 2016.

We present the adaptive SMC technique for the problem of synchronization in FO Chua's chaotic system with unknown external BOD based on Lyapunov stability theory. Hartley *et al.* [12] introduced fractional-order Chua's system. This paper is categorized as follows: Section 2, contains the preliminaries and some essential property of fractional calculus. Section 3, includes the system description of the FO Chua's system . Section 4, contains design methodology of the DOB of FO chaotic system . Section 5, contains an example of an adaptive sliding mode synchronizes of two identical FO Chua's chaotic system studied. Section 6 includes the numerical simulation. Section 7 consiste the application in secure communication, and Section 8 provides conclusions.

2. PRELIMINARIES

Definition 1: The Caputo's derivative of FO $'\alpha'$ of function $f(t)$ can be described as:

$$cD_{\omega}^{\alpha} f(\omega) = \frac{1}{\gamma(n-\alpha)} \int_{c}^{\omega} \frac{f^{n}(\Psi)}{(\omega - \Psi)^{\alpha - n + 1}} d\Psi$$

where $n-1<\alpha<n$ and $\gamma(\alpha)=\int_0^\infty \Psi^{\alpha-1}e^{-\Psi}d\Psi$ is the gamma function.

Property 1: If $\Psi(t)$ is a constant function and the order $q>0$, the Caputo FO derivative fulfill the given condition:

$$D^q\Psi(t)=0$$

Property 2: The Caputo fractional derivative satisfies the linear property:

$$D^\alpha[p_1\Psi_1(t)+p_2\Psi_2(t)]=p_1D^\alpha\Psi_1(t)+p_2D^\alpha\Psi_2(t)$$

Lemma 1: Suppose $\Psi(t)\in R$ be a continuous and derivable function. Then, we have: $\frac{1}{2}D^\alpha\Psi(t)^2\leq\Psi(t)D^\alpha\Psi(t)$, for any time $t\geq t_0$ and $0<\alpha<1$.

Lemma 2: Let the FO system satisfies $D^\alpha\Psi(t)\leq-p_0\Psi(t)+p_1$, then there exists a constant $t_1>0$ in which for all $t\in(t_1,\infty)$, we get $\|\Psi(t)\|\leq\frac{2p_1}{p_0}$.

Assumption: Let $\psi_i(t)$ be the unknown external disturbance for i = 1, 2, ..., n, then the Caputo's derivative of $\psi_i(t)$ is bounded, i.e., $|D^\alpha\psi_i(t)|\leq\xi_i$, where $\xi_i>0$ is an unknown constant.

3. SYSTEM DESCRIPTION

The FO Chua's chaotic system as a master system.

$$\begin{aligned}D^\alpha x_{11m}(t) &= a_1\Big[x_{12m}-x_{11m}-n_1x_{11m}\\ &\quad -\frac{1}{2}(n_0-n_1)(|x_{11m}+1|-|x_{11m}1|)\Big]\\ D^\alpha x_{12m}(t) &= x_{11m}-x_{12m}+x_{13m}\\ D^\alpha x_{13m}(t) &= -b_1x_{12m}-c_1x_{13m}\end{aligned}\quad\ldots(1)$$

where x_{11m},x_{12m},x_{13m} represent state vectors, a_1,b_1,c_1,n_0,n_1 is variable parameter, parameter values chosen as $a_1=10.1911,b_1=10.3035,c_1=0.1631,n_0=-1.1726$ and $n_1=-0.7872$.

Corresponding slave system can be written as:

$$\begin{aligned}D^\alpha y_{11s}(t) &= a_1[y_{12s}-y_{11s}-n_1y_{11s}-\frac{1}{2}(n_0-n_1)(|y_{11s}+1|\\ &\quad -|y_{11s}-1|)]+\psi_1+u_1\\ D^\alpha y_{12s}(t) &= y_{11s}-y_{12s}+y_{13s}+\psi_2+u_2\end{aligned}$$

$$D^{\alpha}y_{13s}(t) = -b_1 y_{12s} - c_1 y_{13s} + \psi_3 + u_3 \quad \ldots (2)$$

where, $\psi_1 = cost, \psi_2 = cos2t, \psi_3 = cos0.5t$ are the unknown bounded disturbances (BOD), and u_1, u_2, u_3 are the controllers. This paper is to estimate the unknown external disturbances $\psi_i(t)$.

4. FO DISTURBAN OBSERVER DESIGN

We create an FO nonlinear DOB as follows: [13]

$$\begin{aligned}\delta_1(t) &= \psi_1(t) - \sigma_1 y_{11s}(t)\\ \delta_2(t) &= \psi_2(t) - \sigma_2 y_{12s}(t)\\ \delta_3(t) &= \psi_3(t) - \sigma_3 y_{13s}(t)\end{aligned} \quad \ldots (3)$$

where, $\sigma_i > 0$ is constant. In (3), using Caputo's derivative and (2), we obtain,

$$\begin{aligned}D^{q_1}\delta_1(t) &= D^{q_1}\psi_1(t) - \sigma_1(a_1[y_{12s} - y_{11s} - n_1 y_{11s} - \frac{1}{2}(n_0 \\ &\quad - n_1)(|y_{11s} + 1| - \quad |y_{11s} - 1|)] + \delta_1 + \sigma_1 y_{11s}) \\ &\quad - \sigma_1 u_1\\ D^{q_2}\delta_2(t) &= D^{q_2}\psi_2(t) - \sigma_2(y_{11s} - y_{12s} + y_{13s} + \delta_2 + \sigma_2 y_{12s}) \\ &\quad - \sigma_2 u_2\\ D^{q_3}\delta_3(t) &= D^{q_3}\psi_3(t) - \sigma_3(-b_1 y_{12s} - c_1 y_{13s} + \delta_3 \\ &\quad + \sigma_3 y_{13s}(t)) - \sigma_3 u_3\end{aligned} \quad \ldots (4)$$

Estimate $\delta_i(t)$ to calculate the external disturbances written as:

$$\begin{aligned}D^{q_1}\hat{\delta}_1(t) &= -\sigma_1(a_1[y_{12s} - y_{11s} - n_1 y_{11s} - \frac{1}{2}(n_0 - n_1)(|y_{11s} \\ &\quad + 1| - |y_{11s} - 1|)] + \sigma_1 y_{11s}(t)) - \sigma_1\hat{\delta}_1(t) \\ &\quad - \sigma_1 u_1\\ D^{q_2}\hat{\delta}_2(t) &= -\sigma_2(y_{11s} - y_{12s} + y_{13s} + \sigma_2 y_{12s}(t)) - \sigma_2\hat{\delta}_2(t) \\ &\quad - \sigma_2 u_2\\ D^{q_3}\hat{\delta}_3(t) &= -\sigma_3\big(-b_1 y_{12s} - c_1 y_{13s} + \sigma_3 y_{13s}(t)\big) \\ &\quad - \sigma_3\hat{\delta}_3(t) - \sigma_3 u_3\end{aligned} \quad \ldots (5)$$

$\hat{\delta}_i(t)$ is the estimate of δ_i. Eq.(3), disturbance $\psi_i(t)$ can be estimated as:

$$\begin{aligned}\hat{\psi}_1(t) &= \hat{\delta}_1(t) + \sigma_1 y_{11s}(t)\\ \hat{\psi}_2(t) &= \hat{\delta}_2(t) + \sigma_2 y_{12s}(t)\\ \hat{\psi}_3(t) &= \hat{\delta}_3(t) + \sigma_3 y_{13s}(t)\end{aligned} \quad \ldots (6)$$

Define disturbance estimation error as:

$$\tilde{\psi}_1(t) = \psi_1 - \hat{\psi}_1, \tilde{\psi}_2(t) = \psi_2 - \hat{\psi}_2, \tilde{\psi}_3(t) = \psi_3 - \hat{\psi}_3$$

Using Eqs. (3) and (6), we get

$$\begin{aligned} \tilde{\delta}_1(t) &= \delta_1(t) - \hat{\delta}_1(t) = \psi_1(t) - \hat{\psi}_1(t) = \tilde{\psi}_1(t) \\ \tilde{\delta}_2(t) &= \delta_2(t) - \hat{\delta}_2(t) = \psi_2(t) - \hat{\psi}_2(t) = \tilde{\psi}_2(t) \\ \tilde{\delta}_3(t) &= \delta_3(t) - \hat{\delta}_3(t) = \psi_3(t) - \hat{\psi}_3(t) = \tilde{\psi}_3(t) \end{aligned} \quad \dots (7)$$

By subtracting Eqs. (5) from (4), the fractional derivatives $\tilde{\delta}_i$ are proposed as:

$$\begin{aligned} D^\alpha \tilde{\delta}_1(t) &= -\sigma_1 \tilde{\delta}_1(t) + D^\alpha \psi_1(t) \\ D^\alpha \tilde{\delta}_2(t) &= -\sigma_2 \tilde{\delta}_2(t) + D^\alpha \psi_2(t) \\ D^\alpha \tilde{\delta}_3(t) &= -\sigma_3 \tilde{\delta}_3(t) + D^\alpha \psi_3(t) \end{aligned} \quad \dots (8)$$

Lyapunov function can be chosen as:

$$V_{\psi_i}(t) = \frac{1}{2}\tilde{\psi}_i^{\,2}(t) = \frac{1}{2}\tilde{\delta}_i^{\,2}(t), \forall i = 1,2,3 \quad \dots (9)$$

Using the Caputo derivative in (9) and using Lemma 1, we have

$$D^\alpha V_{\psi_i(t)} < \tilde{\delta}_i(t) D^\alpha \tilde{\delta}_i(t) \quad \dots (10)$$

Substituting (8) into (10), it has

$$D^\alpha V_{\psi_i}(t) \le \tilde{\delta}_i(t)\left(-\sigma_i \tilde{\delta}_i(t) + D^\alpha \psi_i(t)\right) \le -\sigma_i \tilde{\delta}_i^{\,2}(t) + \tilde{\delta}_i(t) D^\alpha \psi_i(t) \quad \dots (11)$$

We observing that

$$(\tilde{\delta}_i(t) - D^\alpha \psi_i(t))^2 = \tilde{\delta}_i^2(t) + (D^\alpha \psi_i(t))^2 - 2\tilde{\delta}_i(t) D^\alpha \psi_i(t) > 0 \quad \dots (12)$$

$\tilde{\delta}_i(t) D^\alpha \psi_i(t) < \frac{1}{2}\tilde{\delta}_i^2(t) + \frac{1}{2}(D^\alpha \psi_i(t))^2$, from (11) and assumption 1 , we get

$$\begin{aligned} D^\alpha V_{\psi_i}(t) &\le -\sigma_i \tilde{\delta}_i^2(t) + \frac{1}{2}\tilde{\delta}_i^2(t) + \frac{1}{2}\xi_i^{\,2} \le -(\sigma_i - \frac{1}{2})\tilde{\delta}_i^2(t) + \frac{1}{2}\xi_i^{\,2} \\ &= \mu_0 V_{\Theta_i}(t) + \mu_1 \end{aligned} \quad \dots (13)$$

where $\mu_0 = 2\sigma_i - 1$ and $\mu_1 = 0.5\xi_i^2$. If $\sigma_i > 0.5$, This confirms that $\widetilde{\Theta}_i(t), \tilde{\psi}_i(t)$ are bounded using lemma 2 and equation (13), we achieve

$$|V_{\psi_i}(t)| \le \frac{\xi_i^{\,2}}{2(\sigma_i - 0.5)} \quad \dots (14)$$

which means

$$|\tilde{\psi}_i(t)| \leq \sqrt{\frac{{\xi_i}^2}{\sigma_i - 0.5}} \quad \ldots (15)$$

From (15). It indicate that $\tilde{\psi}_i(t)$ is bounded above, where $\tilde{\psi}_i(t)$ represents disturbance estimation error. $|\tilde{\psi}_i(t)|$ fulfill $|\tilde{\psi}_i(t)| \leq k_i$, where $k_i > 0$.

5. EXAMPLE OF ADAPTIVE SMCISTURBANCE OBSERVER

Error: $e_{11}(t) = y_{11s} - x_{11m}, e_{12}(t) = y_{12s} - x_{12m}, e_{13}(t) = y_{13s} - x_{13m}$

Applying Eqn. (1) and (2) in Eqn. (16), the error dynamics becomes:

$$\begin{aligned} D^{\alpha} e_{11}(t) = {} & a_1 e_{12} - a_1 e_{11} + 0.7872 a_1 e_{11} + 0.1927 a_1 [(|y_{11s} \\ & + 1| - |y_{11s} - \quad 1|) - (|x_{11m} + 1| - |x_{11m} \\ & - 1|)] + cost + u_1 \end{aligned}$$

$$\begin{aligned} D^{\alpha} e_{12}(t) &= e_{11} - e_{12} + e_{13} + cos2t + u_2 \quad \ldots (16) \\ D^{\alpha} e_{13}(t) &= -b_1 e_{12} - c_1 e_{13} + cos0.5t + u_3 \end{aligned}$$

To achieve FO error system, the sliding surface $s_i(t)$ is considered as:

$$s_i(t) = e_{1i}(t), i = 1, 2, 3 \quad \ldots (17)$$

Applying the Caputo derivative in (17), we have:

$$D^{\alpha} s_i(t) = D^{\alpha} e_{1i}(t), i = 1, 2, 3 \quad \ldots (18)$$

By using the adaptive SMC method, the desired controller is composed as:

$$\begin{aligned} u_1(t) = {} & -a_1 e_{12} + a_1 e_{11} - 0.7872 a_1 e_{11} - 0.1927 a_1 [(|y_{11s} + 1| \\ & - |y_{11s} - 1|) \ - (|x_{11m} + 1| - |x_{11m} - 1|)] \\ & - \eta_1 s_1 - \hat{k}_1 sign(s_1(t)) - \hat{\psi}_1 \\ u_2(t) = {} & -e_{11} + e_{12} - e_{13} - \eta_2 s_2 - \hat{K}_2 sign(s_2(t)) - \hat{\psi}_2 \quad \ldots (19) \\ u_3(t) = {} & b_1 e_{12} + c_1 e_{13} - \eta_3 s_3 - \hat{k}_3 sign(s_3(t)) - \hat{\psi}_3 \end{aligned}$$

where $\text{sign}(s) = \frac{|s|}{s}$ and $\eta_i > 0$ are constants. $\hat{k}_i$ is estimated value of $k_i$is:

$$\begin{aligned} D^{\alpha} \hat{k}_1 &= \gamma_1 (|s_1(t)| - \hat{k}_1) \\ D^{\alpha} \hat{k}_2 &= \gamma_2 (|s_2(t)| - \hat{k}_2) \quad \ldots (20) \\ D^{\alpha} \hat{k}_3 &= \gamma_3 (|s_3(t)| - \hat{k}_3) \end{aligned}$$

where $\gamma_i > 0, i = 1,\ 2,\ 3$. Using (19) in (16), The error dynamics can be written as:

$$\begin{aligned} D^{\alpha}e_{11}(t) &= -\eta_1 s_1 - \hat{k}_1 sign(s_1(t)) + \psi_1 - \hat{\psi}_1 \\ D^{\alpha}e_{12}(t) &= -\eta_2 s_2 - \hat{k}_2 sign(s_2(t)) + \psi_2 - \hat{\psi}_2 \\ D^{\alpha}e_{13}(t) &= -\eta_3 s_3 - \hat{k}_3 sign(s_3(t)) + \psi_3 - \hat{\psi}_3 \end{aligned} \quad \ldots (21)$$

If the control input is constructed as (19) for error dynamics (16), then the $s_i(t)$ is bounded and stable, and is given in the form of:

$$|s_i(t)| \leq \tau, \text{where } \tau > 0 \quad \ldots (22)$$

Using equation (17) and (22), we obtain

$$e_{1i}(t) \leq \tau \quad \ldots (23)$$

According to the above discussions, it is clear that if the $s_i(t)$ is bounded, then the error $e_{1i}(t)$ is also bounded.

Theorem 1: For the synchronization error system (16) with $0 < \alpha < 1$, the sliding surface is designed according to (17). The unknown BOD is estimated by using the scheme FO non-linear DOB (5) and (6). Then, $e(t)$ is eventually bounded and stable under the adaptive SMC technique as (19) and (20).

Proof: The Lyapunov functional V(t) is selected as:

$$V(t) = \sum_{i=1}^{3} \frac{1}{2} s_i(t)^2 + \sum_{i=1}^{3} \frac{1}{2} \tilde{\psi}_i(t)^2 + \sum_{i=1}^{3} \frac{1}{2} \left(\frac{1}{\sqrt{\gamma_i}} (\hat{k}_i - k_i)\right)^2 \quad \ldots (24)$$

Using property 2 in equation (24), one achieves

$$D^{\alpha}V(t) = \frac{1}{2}\left(\sum_{i=1}^{3} D^{\alpha}s_i(t)^2 + \sum_{i=1}^{3} D^{\alpha}\tilde{\psi}_i(t)^2 + \sum_{i=1}^{3} D^{\alpha}\left(\frac{1}{\sqrt{\gamma_i}}(\hat{k}_i - k_i)\right)^2\right) \quad \ldots (25)$$

using $\tilde{k}_i = \hat{k}_i - k_i$ and Lemma 1 in equation (25) can be written as:

$$D^{\alpha}V(t) \leq \sum_{i=1}^{3} s_i(t) D^{\alpha}s_i(t) + \sum_{i=1}^{3} \frac{1}{2} D^{\alpha}\tilde{\psi}_i^2(t) + \sum_{i=1}^{3} \frac{1}{\sqrt{\gamma_i}} \tilde{k}_i D^{\alpha}\left(\frac{1}{\sqrt{\gamma_i}} \tilde{k}_i\right) \quad \ldots (26)$$

On applying property 2 in equation (26), we obtain

$$D^{\alpha}V(t) \leq \sum_{i=1}^{3} s_i(t)D^{\alpha}s_i(t) + \sum_{i=1}^{3} \frac{1}{2}D^{\alpha}\tilde{\psi}_i(t)^2 + \sum_{i=1}^{3} \gamma_i^{-1}\tilde{K}_i D^{\alpha}\tilde{K}_i \quad \ldots (27)$$

Using (18) and substituting (21) into (27), we achieve

$$D^{\alpha}V(t) \leq \sum_{i=1}^{3} s_i(t)\left(-\eta_i s_i + \tilde{\psi}_i(t) - \hat{k}_i sign\left(s_i(t)\right)\right) + \sum_{i=1}^{3} \frac{1}{2}D^{\alpha}\tilde{\psi}_i^2(t) + \sum_{i=1}^{3} \gamma_i^{-1}\tilde{k}_i D^{\alpha}\tilde{k}_i \quad \ldots (28)$$

Using property 1 and $\tilde{k}_i = \hat{k}_i - k_i$, we get

$$D^{\alpha}\tilde{k}_i = D^{\alpha}\hat{k}_i \quad \ldots (29)$$

where K_i is a constant parameter

In view of equations (20) and (28), one can achieve

$$\sum_{i=1}^{3} \gamma_i^{-1}\tilde{k}_i D^{\alpha_i}\tilde{k}_i = \sum_{i=1}^{3} \tilde{k}_i\left(|s_i(t)| - \hat{k}_i\right) \leq \sum_{i=1}^{3} \tilde{k}_i|s_i(t)| - \frac{1}{2}\sum_{i=1}^{3} \tilde{k}_i^2 + \frac{1}{2}\sum_{i=1}^{3} {k_i}^2 \quad \ldots (30)$$

After substituting the above inequality in (28), we get

$$D^{\alpha}V(t) \leq \sum_{i=1}^{3} s_i(t)\left(-\eta_i s_i(t) + \tilde{\psi}_i(t) - \hat{k}_i sign\left(s_i(t)\right)\right) + \frac{1}{2}\sum_{i=1}^{3} D^{\alpha}\tilde{\psi}_i^2(t) + \sum_{i=1}^{3} \tilde{k}_i|s_i(t)| - \frac{1}{2}\sum_{i=1}^{3} \tilde{k}_i^2 + \frac{1}{2}\sum_{i=1}^{3} {k_i}^2 \quad \ldots (31)$$

We notice that (31) can be rewritten as:

$$D^{\alpha}V(t) \leq -\sum_{i=1}^{3} \eta_i s_i^2(t) + \sum_{i=1}^{3} |s_i(t)|\tilde{\psi}_i| + \sum_{i=1}^{3} \tilde{k}_i|s_i(t)| - \sum_{i=1}^{3} \frac{1}{2}\tilde{k}_i^2 + \sum_{i=1}^{3} \frac{1}{2}{k_i}^2 - \sum_{i=1}^{3} \hat{k}_i|s_i(t)| + \sum_{i=1}^{3} \frac{1}{2}D^{\alpha}\tilde{\psi}_i^2(t) \quad \ldots (32)$$

Using the condition $|\tilde{\psi}_i(t)| < k_i$ and $\sum_{i=1}^{3} \tilde{k}_i|s_i(t)| - \sum_{i=1}^{3} \hat{k}_i|s_i(t)| = -\sum_{i=1}^{3} k_i|s_i(t)|$. Furthermore, (32) can be obtained as

$$D^{\alpha}V(t) \leq -\sum_{i=1}^{3} \eta_i s_i^2(t) - \sum_{i=1}^{3} \frac{1}{2}\tilde{k}_i^2 + \sum_{i=1}^{3} \frac{1}{2}k_i^2 + \sum_{i=1}^{3} \frac{1}{2}D^{\alpha}\tilde{\psi}_i^2(t) \quad \ldots (33)$$

Considering equation (11) and (33), we get

$$D^{\alpha}V(t) \leq -\sum_{i=1}^{3} \eta_i s_i^2(t) - \sum_{i=1}^{3} \frac{1}{2}\tilde{k}_i{}^2 + \sum_{i=1}^{3} \frac{1}{2}k_i^2 + \sum_{i=1}^{3} -(\sigma_i - \frac{1}{2})\tilde{\psi}_i{}^2(t) + \sum_{i=1}^{3} \frac{1}{2}\xi_i^2 \leq -p_2V(t) + p_3 \quad \ldots (34)$$

where $p_2 = min(2\eta_i, 1, 2\eta_i - 1)$ and $p_3 = \sum_{i=1}^{3} \frac{1}{2}\xi_i^2 + \sum_{i=1}^{3} \frac{1}{2}k_i^2$. On selected the value of parameters $\eta_i > 0$ and $\sigma_i > 0.5$, the error is bounded. Using Lemma 2 in (34), we achieve

$$|V(t)| \leq \frac{2p_3}{p_2} = \frac{\sum_{i=1}^{3} \xi_i^2 + \sum_{i=1}^{3} k_i^2}{p_2} \quad \ldots (35)$$

Which implies that

$$\| s(t) \| \leq \sqrt{\frac{2(\sum_{i=1}^{3} \xi_i^2 + \sum_{i=1}^{3} k_i^2)}{p_2}} \quad \ldots (36)$$

From the inequality (36), when $t \to \infty$, the synchronization error $e(t)$ and $s(t)$ are bounded. Thus, error dynamics (16) is stable and bounded from Lemma 2. Hence, bounded synchronization between two identical FO Chua's chaotic system is achieved successfully.

6. NUMERICAL SIMULATION

Numerical simulations are performed in the MATLAB software with $h = 0.001$. The initial states of the master system and slave system are considered as $(x_{11m}, x_{12m}, x_{13m}) = (1,\ 1,\ 1)$, $(y_{11s},\ y_{12s},\ y_{13s}) = (1.4,\ 0.4,\ 0.3)$. The initial states for the error systems are $(e_{11}, e_{12}, e_{13}) = (2.2,\ 3.1, -2.1)$ and $\hat{\delta}_1(0)$, $\widehat{\delta}_2(0)$, $\widehat{\delta}_3(0)) = (.1,\ .1,\ .1)$ and $(\hat{k}_1(0)$, $\hat{k}_2(0), \hat{k}_3(0)) = (.5, .5, .5)$, the designed parameters $(\sigma_1,\ \sigma_2,\ \sigma_3) = (50,\ 50,\ 50), (\gamma_1,\ \gamma_2,\ \gamma_3) = (.1,\ .1,\ .1), (\eta_1,\ \eta_2,\ \eta_3) = (50,\ 50,\ 50)$.

Disturbance assumed as $\psi_1 = cost, \psi_2 = cos2t,\ \psi_3 = cos0.5t$. Phase portrait of Chua's chaotic system in 3-D is shown in Figure 1(a). Synchronization of master system and slave system is illustrated in Fig 1(b-d). Errors $e_{11}(t)$, $e_{12}(t), e_{13}(t)$ are converging to zero as displayed in Figure 1(e). Time trajectories of the BOD ψ_i and disturbance estimation $\hat{\psi}_i$ are depicted in Figure 1(f-h).

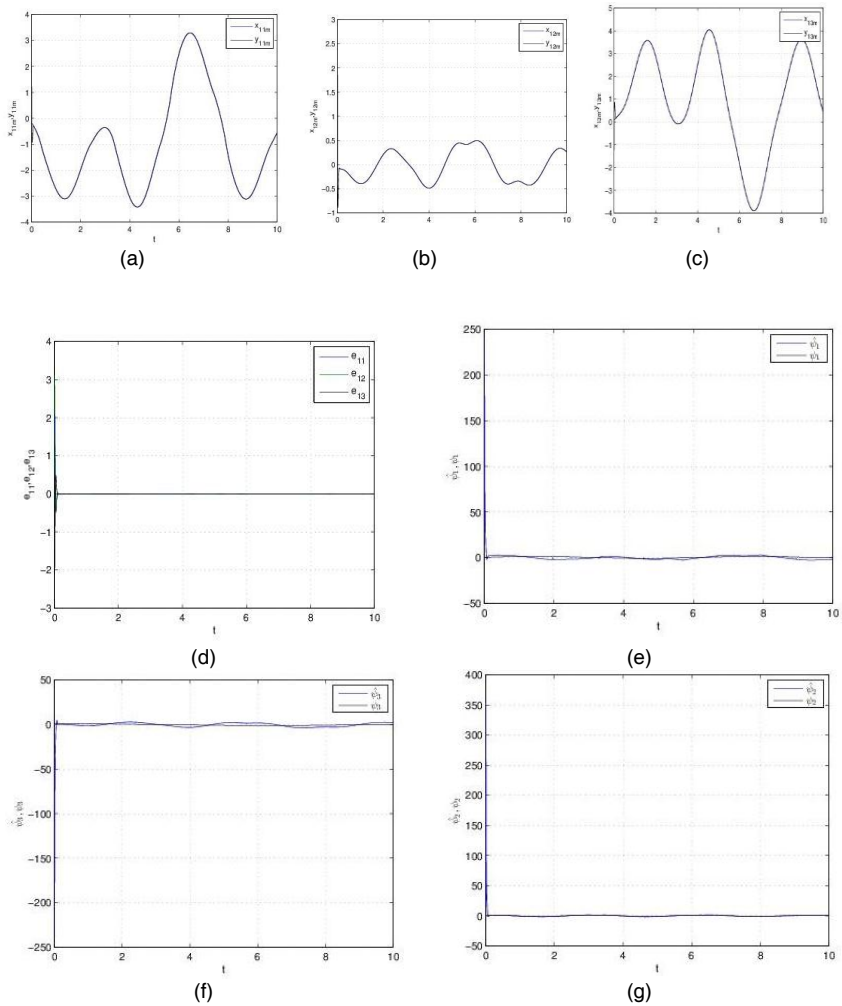

Fig. 1: (a) Synchronization of State Variable between $x_{11m}(t)$ and y_{11s}; **(b)** Synchronization of State Variable between $x_{12m}(t)$ and $y_{12s}(t)$; **(c)** synchronization of state variable between $x_{13m}(t)$ and $y_{13s}(t)$; **(d)** $\hat{\psi}_1(t)$ and $\psi_1(t)$; **(e)** $\hat{\psi}_2(t)$ and $\psi_2(t)$; **(f)** $\hat{\psi}_3(t)$ and $\psi_3(t)$.

7. APPLICATION IN SECURE COMMUNICATION

Across the last two decades, chaotic systems have noticed much application in science and engineering, especially in the area of secure communication. For secure transmission in chaos, the master system is fixed at the transmitter and a slave at the receiver. The central purpose is to protect the information signal masking it with the chaotic signals and transfer to be recovered later only by the approved receiver after taking out the requisite synchronization. In a signal masking method, the message signal $M(t)$ is added to the chaotic master signal, and at the receiver, the transmitted signal is of the form $S(t) = x_{12m}(t) + M(t)$ is assigned to a chaotic slave signal. The recovered message signal $\widehat{M}(t)$ is obtain when the transmitted signal is subtracted from the chaotic signal y_{12s} ie. $\widehat{M}(t) = S(t) - y_{12s}$. For the numerical simulation, we select the $M(t) = 5cos4t$.

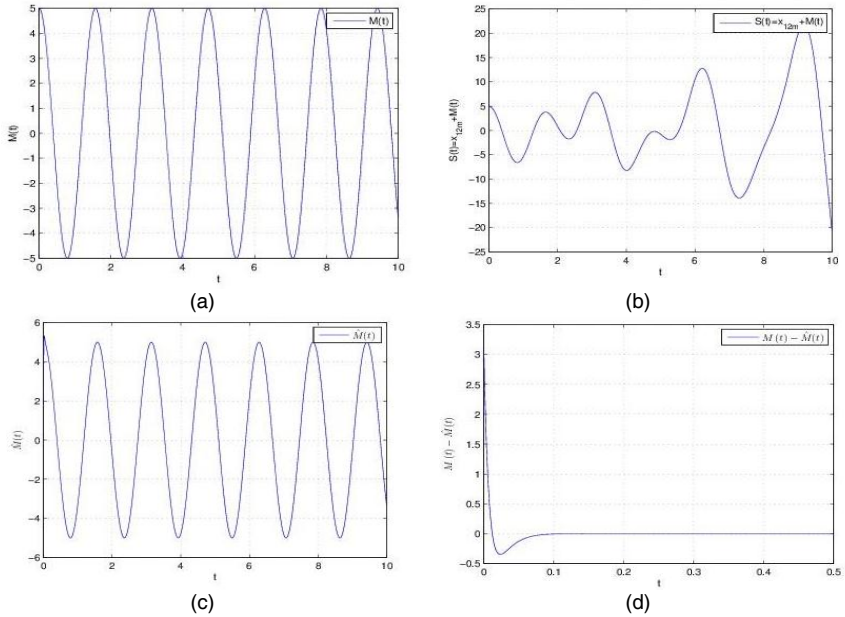

Fig. 2: (a) The Original Message Signal M(T); **(b)** Transmitted Message Signal S(t) **(c)** Recovered Signal $\widehat{M}(t)$; **(d)** Error Message Signal $M(t) - \widehat{M}(t)$

8. CONCLUSION

This work proposes a FO non-linear DOB based adaptive SMC synchronization for the identical FO Chua's chaotic system with unknown external BOD. A non-linear DOB has been applied to approximate the

external disturbance. The sliding surface based on SMC technique is performed to achieving the synchronization among two identical FO Chua's chaotic system had different initial values. It is shown that synchronization error is stable and bounded under the adaptive SMC technique.

A Single Server Finite Capacity Markovian Feedback Queuing System with Encouraged Arrivals and Reverse Reneging

Bhupender Kumar Som[1] and Sunny Seth[2]

ABSTRACT: *In today's highly volatile uncertain environment, understanding customer behaviour in advance is of utmost importance for any firm in order to stay ahead of competitors. Firms need to design effective operational strategies for overall functioning of the system. Stochastic queuing model can be formulated for such systems by taking into consideration various contemporary challenges being faced by firms and these models then can be solved to derive performance measure of the system so as to give an overview of various characteristics involved in the model. The model developed in this paper is single server finite capacity Markovian queuing model incorporating feedback customers, encouraged arrivals and the concept of reverse reneging.*

Keywords: Encouraged Arrivals, Queuing Model, Reverse Reneging, Feedback Customers.

1. INTRODUCTION AND LITERATURE SURVEY

As it can be observed in the current scenario that in order to attract customers firms often announce sale which encourages more and more customers to join the system (let it be online or offline). Such customers are termed as *encouraged arrivals*. Encouraged arrival can be understood as a concept contrary to the concept of discouraged arrival existing in queuing literature, where arriving customer gets discouraged in joining the queue looking at more customers present in the system. Encouraged arrivals at times become a challenging issue if firm is not

[1] Professor, JIMS Rohini, Sector-5, New Delhi, India. E-mail: bksoam@live.com

ready and well prepared in advance to entertain the large customer base. In queuing literature, a customer behaviour termed as *reneging* is defined for customers who join the system but leave without availing service after waiting for a time exceeding their threshold limit of patience. Chances of a customer getting impatient and leaving the queue are high in reneging. But in case of encouraged arrivals it has been observed that the patience level of customers is very high and customers are willing to wait for a very longer period of time to avail service, so in this case the concept opposite to reneging prevails and is termed as reverse reneging. Also due to encouraged arrivals as well as reverse reneging customer base of the system grows bigger and puts service facility under pressure and forces servers to service at a little fast pace. This at times leads to some sort of dissatisfaction amongst customers and certain dissatisfied customers may re-join the queue again for availing satisfactory service. Such customers are known as feedback customers. With all these challenges which firms often face these days, it is necessary for firms to understand the functioning of the system well in advance before they announce sale so that efficient strategies and policies can be formed. If firms don't consider such approaches in taking preventive measures in advance they may face chaotic situations which then may hamper their business to a greater extent. As now-a-days with social media in hand, customers don't hesitate to put any bad experience immediately on various social media platforms which hampers not only business but also deteriorate the brand image of the firm.

In [13] Som and Seth introduced the concept of encouraged arrivals and studied single server finite capacity queuing model. They also discussed economic analysis of the model and extended the work in [14] by studying reneging in the model for managing business effectively. They further studied two server heterogeneous model in [15] by incorporating reneging and retention in the model and derived various performance measures of the system and performed sensitivity analysis of the model. In [16] they studied finite capacity multi-server queuing model with encouraged arrivals along with the reneging, retention and feedback and discussed various special cases of the model. In [17] they extended the work by studying infinite capacity multi-server feedback queuing model and discussed encouraged arrivals in non-preemptive priority queuing model in [18] for managing healthcare facility.

Natvig [9] studied queues in which arriving customers gets discouraged by more customers present in queue and Reynolds [10] discussed multi-server queues with discouragement and studied steady state solution of

the model. Haight [6] studied queuing model with reneging and derived steady state distributions of number of customers in the system. Ancker and Gafarian [1, 2] studied queuing model with balking in which customer refuses to join the system and reneging in which customer joins the system but leaves if service does not begin by certain time which is random with negative exponential distribution. They also derived customer loss rate, mean time in queue for reneging and non-reneging customers and also discussed special case of no reneging. Later many authors studied reneging [11, 3, 4]. Wang *et al*. [22] reviewed of queuing models with customer impatience including balking and reneging behaviour of customers and also discussed research tendencies of models.

Takacs [20] studied single server queuing model with feedback customers in steady stage and derived distribution of queue length and also discussed Laplace-Stieltjes transform. Davignon and Disney [5] studied M/G/1 queuing model with feedback customers in steady state and derived busy period distribution. Santhakumaran and Thangaraj [12] studied single server queuing model with impatience and feedback customers. They derived the stationary distribution of arrival process and also discussed no feedback case.

Kumar and Som [7] introduced the concept of reverse reneging and studied queuing model in steady state, derived various measures of the model and further in [8] studied reverse reneging model with reverse balking. Reverse balking is a concept in which probability of a customer joining the system increases with more number of customers present in the system. Thangarajan and Sasikala [21] studied queuing model with controlling the arrival rates at faster and slower rate with reverse reneging. They derived system probabilities with faster and slower rate of arrivals and discussed the characteristics of the model with numerical illustrations. Recently Som and Seth [19] studied model with encouraged arrivals and reverse reneging and extended the work in this paper by incorporating the concept of feedback customers along with encouraged arrivals and reverse reneging in finite capacity single server queuing model.

2. MATHEMATICAL MODEL FORMULATION

It is assumed that Poisson arrivals occur with parameter $\lambda(1+\eta)$, where 'η' represents the percentage increase in number of customers. Service times are exponential with parameter μ. Reverse reneging rate is {N−(n−1)} ξ, where N is the capacity of the system, n is number of customers present in the system and ξ is exponentially distributed reneging

parameter. A feedback customer may re-join the queue with probability $q = 1 - p$and service discipline is FCFS.

Under the assumptions discussed above, following model is formulated:

$$\frac{d}{dt}P_0 = -\lambda(1+\eta)P_0(t) + (\mu p + N\xi)P_1(t)\,; n = 0 \quad \ldots (1)$$

$$\frac{d}{dt}P_n = \lambda(1+\eta)P_{n-1}(t) - \{\lambda(1+\eta) + \mu p + [N-(n-1)]\xi\}P_n(t) + \{\mu p + [N-n]\xi\}P_{n+1}(t)\,; 1 \le n < N \quad \ldots (2)$$

$$\frac{d}{dt}P_N = \lambda(1+\eta)P_{N-1}(t) - (\mu p + \xi)P_N(t)\,; n = N \quad \ldots (3)$$

Validity of the model is tested using Laplace transform and the model developed here is found to be valid.

In Steady-state, taking$P_n(t) = P_n$ and $\frac{d}{dt}P_n(t) = 0\ as\ t \to \infty$, model becomes:

$$0 = -\lambda(1+\eta)P_0 + (\mu p + N\xi)P_1\,; n = 0 \quad \ldots (4)$$

$$0 = \lambda(1+\eta)P_{n-1} - \{\lambda(1+\eta) + \mu p + [N-(n-1)]\xi\}P_n + \{\mu p + [N-n]\xi\}P_{n+1}\,; 1 \le n < N. \quad \ldots (5)$$

$$0 = \lambda(1+\eta)P_{N-1} - (\mu p + \xi)P_N\,; n = N \quad \ldots (6)$$

3. STEADY-STATE SOLUTION

Recursively solving model equations, we get;

$$P_n = \Pr\{n \text{ customers in the system}\} = \prod_{i=1}^{n}\frac{\lambda(1+\eta)}{\mu p + [N-(i-1)]\xi}P_0,;\ 1 \le n\ \le N \quad \ldots (7)$$

Using condition of normality $\sum_{n=0}^{N} P_n = 1$

$$P_0 = Pr\{\text{system is empty}\} = \left\{1 + \sum_{n=1}^{N}\left[\prod_{i=1}^{n}\frac{\lambda(1+\eta)}{\mu p + [N-(i-1)]\xi}\right]\right\}^{-1} \quad \ldots (8)$$

4. MEASURES OF PERFORMANCE

Having calculated probabilistic measures, various performance measures can be derived as follows:

1. Expected system length (L_S)

$$L_s = \sum_{n=1}^{N} nP_n$$

$$L_s = \sum_{n=1}^{N} n \left\{ \prod_{i=1}^{n} \frac{\lambda(1+\eta)}{\mu p + [N-(i-1)]\xi} \right\} P_0 \quad \ldots (9)$$

2. Expected system waiting time (W_S)

$$W_s = \frac{L_s}{\lambda(1+\eta)}$$

$$W_s = \frac{1}{\lambda(1+\eta)} \sum_{n=1}^{N} n \left\{ \prod_{i=1}^{n} \frac{\lambda(1+\eta)}{\mu p + [N-(i-1)]\xi} \right\} P_0 \quad \ldots (10)$$

3. Expected queue waiting time (W_q)

$$W_q = W_s - \frac{1}{\mu}$$

$$W_q = \frac{1}{\lambda(1+\eta)} \sum_{n=1}^{N} n \left\{ \prod_{i=1}^{n} \frac{\lambda(1+\eta)}{\mu p + [N-(i-1)]\xi} \right\} P_0 - \frac{1}{\mu} \quad \ldots (11)$$

4. Expected queue length (L_q)

$$L_q = \lambda(1+\eta) W_q$$

$$L_q = \sum_{n=1}^{N} n \left\{ \prod_{i=1}^{n} \frac{\lambda(1+\eta)}{\mu p + [N-(i-1)]\xi} \right\} P_0 - \frac{\lambda(1+\eta)}{\mu} \quad \ldots (12)$$

5. NUMERICAL ILLUSTRATION

The results of probabilistic measures and measures of performance can be translated in MS Excel and simulated results can be obtained by varying particular parameters. These simulated results can help the firm understand its functioning in advance. Firm can decide by looking at these simulated results that at which service rate firm should provide service for varying arrival rates so as to maintain the smooth and efficient operations in the system and keeping the average length of the system and/or average waiting time of customers in control.

Table 1: Variations in Various Performance Measures with Respect to Arrival Rate Taking μ = 6, ξ = 0.2, η = 0.5 and p = 0.7, N = 10

λ	*Ls*	*Lq*	*Ws*	*Wq*
2	1.078634	0.578634	0.359545	0.192878
2.1	1.209730	0.684730	0.384041	0.217375
2.2	1.357475	0.807475	0.411356	0.244689
2.3	1.523695	0.948695	0.441651	0.274984
2.4	1.710026	1.110026	0.475007	0.308341
2.5	1.917754	1.292754	0.511401	0.344734

λ	*Ls*	*Lq*	*Ws*	*Wq*
2.6	2.147634	1.497634	0.550675	0.384009
2.7	2.399716	1.724716	0.592522	0.425856
2.8	2.673202	1.973202	0.636477	0.469810
2.9	2.966361	2.241361	0.681922	0.515255
3	3.276523	2.526523	0.728116	0.561450
3.1	3.600175	2.825175	0.774231	0.607565
3.2	3.933144	3.133144	0.819405	0.652738
3.3	4.270853	3.445853	0.862799	0.696132
3.4	4.608619	3.758619	0.903651	0.736984
3.5	4.941944	4.066944	0.941323	0.774656

*Simulated data.

The table above shows how various performance measures vary with varying arrival rate of customers. As the arrival rate increases all performance measures increases as expected.

Table 2: Variations in Various Performance Measures with Respect to Service Rate Taking λ = 3, ξ = 0.2, η = 0.5 and p = 0.7, N = 10

μ	*Ls*	*Lq*	*Ws*	*Wq*
4.6	5.564117	4.585856	1.23647	1.019079
4.7	5.37134	4.413893	1.193631	0.980865
4.8	5.181184	4.243684	1.151374	0.943041
4.9	4.994341	4.075974	1.109854	0.905772
5	4.811427	3.911427	1.069206	0.869206
5.1	4.632976	3.750623	1.02955	0.833472

5.3	4.291182	3.442125	0.953596	0.764917
5.4	4.128493	3.295159	0.917443	0.732258
5.5	3.971583	3.153401	0.882574	0.700756
5.6	3.820592	3.01702	0.84902	0.670449
5.7	3.675596	2.886122	0.816799	0.641361
5.8	3.536614	2.760752	0.785914	0.6135
5.9	3.403614	2.640903	0.756359	0.586867
6	3.276523	2.526523	0.728116	0.56145

*Simulated data.

The table above shows how various performance measures vary with varying service rate of customers. As the service rate increases, all the performance measures decreases.

6. CONCLUSION AND FUTURE SCOPE

In this paper we developed a queuing model incorporating all the contemporary challenges being faced by firms in current scenario and then solved this queuing model for deriving various probabilistic measures and performance measures theoretically. These theoretical results are of great use for the firm encountering these issues. These results can be translated in MS Excel for generating simulations to give firms a fair idea about various parameters involved in the model. This paper provides any firm facing issues as discussed above with an insight to look into the future performance and decide the level of various operating parameters in advance so as to be prepared with any kind of situation which may arise in future by making use of the results of simulated results as presented in the numerical illustration section. And effective operational strategies then can be devised in advance for smooth functioning of such systems and situations of chaos can be controlled.

Further economic analysis of the above model can be performed and model can also be studied in transient state. Optimization of the model can be carried out for parameters like service rate, system capacity, etc.

Study on Cyber Security and Malware Protection

Tripti Lamba[1] and Shivani Kandwal[2]

ABSTRACT: *Cyber Security deals with protecting digital information and information systems. It underlines on protecting limitless data kept up on the frameworks from opponents who might need to get to, degenerate, harm, pulverize or deny access to the equivalent. Hence, it is an important part of the IT field. The target of this paper is to absorb the ideas of Cyber Security alongside the unsafe impacts of Malicious Software and finding proper ways of protecting the system and simultaneously highlighting the cyber security on a global scale and especially in India. Malicious software, or Malware, is a Cyber Security threat that affects the user's computer system by exploiting the system's vulnerabilities. It is another primary threat to the security of information stored in the computer systems. Therefore, there is a need for malware protection. Although, the current security measures and solutions generally protect the computer system against known risks, yet they are attackable to unknown risks. Normally it is hard to predict how anti-malware software would react to new (unknown) malicious software. And for that reason, malware protection remains in the continuous development phase.*

Keywords: Cyber Security, Protection, Attack, Vulnerabilities Crime, Malware.

1. INTRODUCTION

Cybersecurity is the activity of defending frameworks, systems, and projects from advanced attacks. Normally these cyber-attacks targets accessing, manipulating, or destroying susceptible information [17]. Significance of the field is growing due to increasing dependence on computer systems, the Internet and wireless networks and because of the populous increase of "smart" devices. It is also one of the primary

[1] Associate Professor, IITM, Delhi, India. E-mail: triptigautam@yahoo.co.in
[2] IITM, Delhi, India. E-mail: ishivanikandwal@gmail.com

challenges of the modern world [22]. Cyber Security is needed because there are threats to the cyber world. One of the key contestants in that section is Malware. Malware is probably the greatest risk in PC security [5]. Malware protection is more important today than ever since cybersecurity malware threats like viruses and trojans are on a sky-rocketing high.

This paper is divided into various sections. Section 1 gives a brief introduction to the need for cybersecurity and malware protection. The literature review has been discussed in section 2. Section 3 describes the significance of cybersecurity. Cybersecurity objective is discussed in section 4.Major challenges to security measures like IoT threats; AI expansion etc. has been discussed in section 5. Application of Cybersecurity has been discussed in Section 6. Cybersecurity in the world has been explained in section 7. Section 8explains about malware, which is a major concern that is mainly spreading through the internet. Section 9 gives the conclusion of the paper.

2. LITERATURE REVIEW

It's the 21st century or as it is more famously known as the age of electronics. Everything from the most complex of tasks to the basic of works is now digital in nature, and because of that particular fact, day-to-day tasks are easy and convenient to perform. But not everything is all good; this digital age has its own drawbacks. As with the added benefits of digitization of data, come the threats of the digital world.

Cyber Crime is almost an integral part of this world and Cyber Security, a well thought and needed counter measure [1]. Cyber Security deals with safeguarding digital information and information systems technological solutions for shielding personal data and computer networks are essential but not sufficient to ensure security [2]. Cyber-Security, Cyber-Safety, and Cyber-Ethics should be integrated for a better approach. As of late Cybersecurity has emerged as a dug in subject for PC frameworks and foundation with a main issue of defending delicate data on the frameworks from opponents who might need to get to, degenerate, harm, wreck or disallow access to the equivalent. E-commerce, mobile and cloud computing and social networking are becoming prominent trends of cyber security by adopting new technologies [3].

Also, there are some challenges that are caused due to lack of coordination between security agencies and the critical IT infrastructure [2]. Going to

the opposite side of the coin, Malware is one of the essential security dangers looked by the Cyber Community. Malware, or Malicious Software, Exploits the framework's vulnerabilities to overrun itself in the framework and after that damage the information put away in the framework by the client [4].

Typically, it is difficult to anticipate how hostile to malware programming would respond to new (obscure) malevolent programming. What's more, hence, malware security stays in the ceaseless advancement stage so as to have the option to identify new malware or new variations of existing malware, unexpectedly, so is Malware [5].

In May 2019 the Facebook auxiliary said "a progressed digital entertainer" misused a security imperfection and introduced the malware by focusing on clients' cell phones through WhatsApp's call work, conceivably enabling programmers to get to private messages, area information and other data. As a preventive measure and prompt refreshed rendition of the application was discharged and clients were approached to refresh their application.[33]

3. THE SIGNIFICANCE OF CYBER SECURITY

Organizations send susceptible data across different networks and to other devices in the span of commerce, and cybersecurity explain the subject devoted to protecting the same information and the systems used to treat or save it [20].

In today's associated world, everyone gets the profit from exceptional cyber defense affairs. At an individual level, a cybersecurity attack can lead to everything from identity theft, to blackmail attempts, to the destruction of valuable data like family pictures. [10] Everyone relies on vital areas alike financial service companies, hospitals, power plants etc. Ensuring all these and other organizations is essential to keep our society functioning, hospitals, and financial service companies [9].

4. CYBER SECURITY OBJECTIVES

Security comprehensively has four objectives: confidentiality, availability, integrity, and non-repudiation. The first and foremost objective is confidentiality that is keeping information away from people who should not possess the same [27].

After privacy there comes accessibility which means guaranteeing that information spared in the system can be come to by the individuals who

ought to have it. Accessibility is a wide point moving toward things, for example, shortcoming toleration to shield against access control and forswearing of administration to guarantee that information is accessible to those qualified for access it.

In basic words, honesty means verifying that the data spared in the system can never be polluted or modified in a manner that isn't significant. Both classification and accessibility add to uprightness. Security is a huge enough errand simply attempting to meet the classification respectability accessibility goals. Non-renouncement (NR) implies the assurance that somebody can't expel the lawfulness of something.

5. CHALLENGES TO CYBER SECURITY MEASURES

The most troublesome test in cybersecurity is the regularly developing kind of security dangers. [8] Traditionally, associations and the administration have thought the greater part of their cybersecurity assets on outskirt security [32] to shield just their most fundamental framework components and safe-prepare for known dangers.

Today, this methodology is insufficient, since the dangers are abnormal state and change more all of a sudden than associations can stay aware of [21]. Accordingly, counseling associations energize increasingly proactive and versatile procedures to digital security [11].

5.1 Ransomware Evolution

Ransomware is the most despicable aspect of cybersecurity, IT, information experts, and administrators. Sensibly nothing is riskier than a developing infection that snaps onto client and business data that must be evacuated in the event that you satisfy the cybercriminal's unfortunate needs

5.2 A.I. Expansion

Artificial Intelligence might be capable of improve shield against incoming cyber-attacks. The record of present AI applications is already abundant and expanding as shown in Fig. 1. More racing and more reliable account scoring for banks, enhanced disease examination and treatment community for health care organizations are just a few samples. But it's not all genuine, the Artificial Intelligence, if configured, could do more impairment than good.

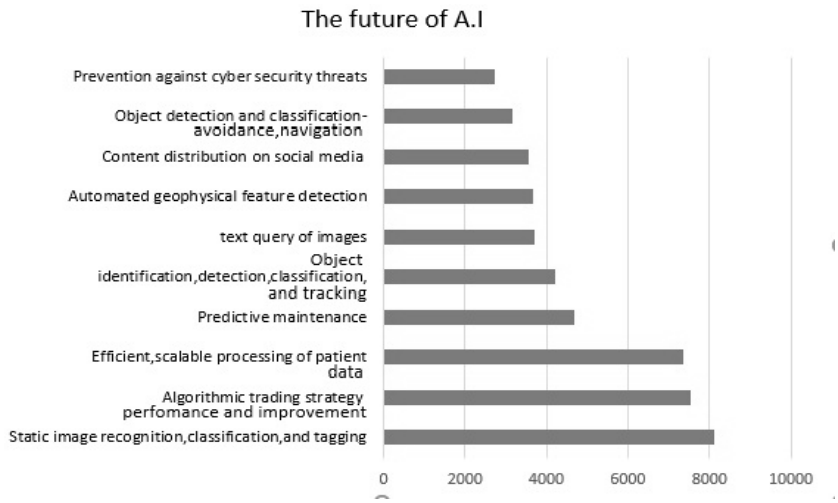

Fig. 1: Forecasted Cumulative Global AI Revenue (2016–2025) by Use Case (U.S dollar)

Source: https://www.statista.com/chart/6810/the-future-of-ai [35]

5.3 Serverless App Vulnerability

Serverless applications can welcome digital assaults. Client information is particularly in risk when clients get your accreditations off-server or locally on their gadget. Unfortunately, with the majority of the weakness that serverless applications speak to, they don't appear to go anyplace in the years to come. Current usage of Serverless Apps is shown in Figure 2.

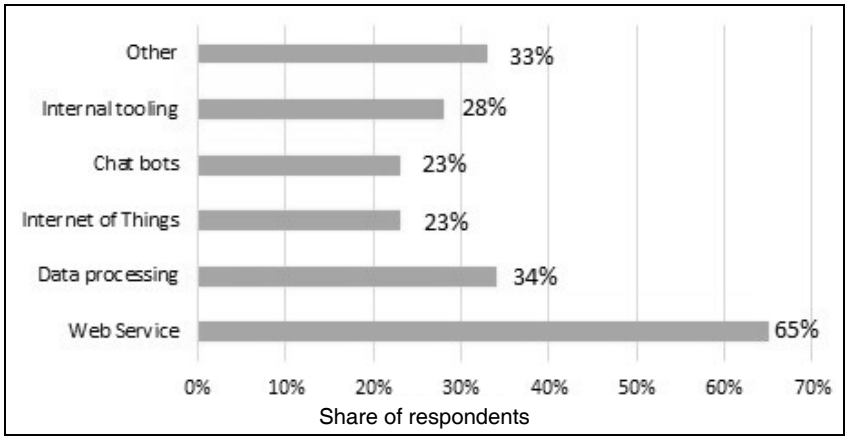

Fig. 2: Uses of Serverless Architecture Worldwide, as of 2016

Source: https://www.statista.com/statistics/658570/worldwide-serverless-architecture-survey-uses [36]

5.4 IoT Threats

Many people are constantly connected. Web of Things is ensuring that each and every gadget you possess is associated with the same. Obviously, the majority of that association conveys with it monstrous advantages, which is the thing that makes it so engaging in any case. The obstruction is that the majority of that interconnectedness makes clients exceptionally delicate to digital assaults. A considerable lot of the gadgets have extreme vulnerabilities.

6. APPLICATIONS OF CYBER SECURITY

- *Filtered Communication:* Include a firewall, against infection, hostile to spam, remote security, and online substance filtration.
- *Protection:* Cybersecurity arrangements give advanced security to your information that will guarantee your workers aren't in danger from potential dangers
- *Increased Productivity:* Viruses can hinder PCs to a slither, and making work for all intents and purposes unthinkable. Successful cybersecurity disposes of this probability, amplifying the potential yield.
- *Denies Spyware:* Spyware is a sort of digital pollution which is planned to observe on your PC activities and convey that information back to the digital lawbreaker.

7. CYBER SECURITY IN THE WORLD

Global Telecommunication Union (ITU) is the UN's specific organization for data and correspondence innovation. ITU's drive Global Cybersecurity Index (GCI) which is an index produced, analyzed and published by the union itself, measures the engagement of countries to cybersecurity to raise cybersecurity consciousness. Country's commitment evaluation is based on five pillars. These are (i) legal, (ii) technical, (iii) organizational, (iv) capacity building, and (v) cooperation [26]. The index holds value for each participating country with respect to the five pillars. A normalized score is generated with respect to the scores of five pillars. On the basis of the normalized score rank of the country is depicted in Figure 3.

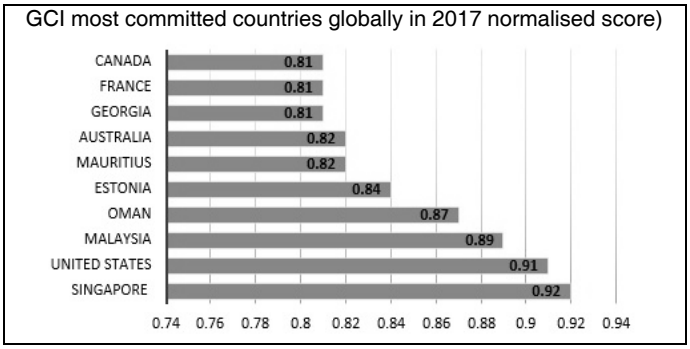

Fig. 3: Top Ten Most Committed Countries Towards Cyber Security, GCI (normalized score) 2017

Source: ITU-GCI 2017. [26]

7.1 Cybersecurity in India

India has been ranked 23rd out of 165 nations and has been mentioned under the maturing category of the index (2017) [27]. However, here lies an utmost concern as well: why India does not have a higher commitment towards cybersecurity? The answer to the question can be answered on the basis of the following four points:

- Lack of awareness among the masses: Despite various efforts from the government' people are still unaware [31].
- National level architecture for Cybersecurity: National level architecture that unifies the efforts of different sectors of the country
- Separation: Boundaries in cyberspace that make activities vulnerable to cyber attacks.
- Lack of uniformity in devices used for internet access: Devices with higher security norms are used by a smaller percentage of the population.

7.2 Measures for Cybersecurity in India

The Government of India legislative, technical and institutional measures for addressing issues related to cybersecurity. Some specific measures are listed below:

- Introduction to the "Digital Swachhta Kendra" (Cleaning of Botnet and examination of Malware) [30]
- National Cyber Security Coordinator (NCSC) under National Security Council Secretariat (NSCS) synchronizes with various offices for digital security related issues at the na-tional level.

- Information Technology Act, 2000: IT act has control arrangements to deal with digital dangers and assaults [28].
- The Indian Computer Emergency Response Team (CERT-In) the national nodal firm for responding to PC security occasions [29].
- National Critical Information Infrastructure Protection Center (NCIIPC) has been accus-tomed for insurance of basic data framework in the country.
- National Cyber Coordination Center (NCCC) has been worked to make essential situational consciousness of subsisting and potential cybersecurity dangers and encourage opportune information sharing for proactive, defensive and preventive activities
- All the new government sites and applications are inspected continuing to their facilitating and on normal premise succeeding facilitating.

8. INTRODUCTION TO MALWARE

Malware is one of the primary dangerous phenomena spreading over the internet. It is a document or code, ordinarily conveyed over a system, that taints, investigates, takes or directs for all intents and purposes any conduct an assailant need. It shifts in sort and abilities [16]. Actually, most Internet issues, for example, spam messages and forswearing of administration assaults have malware as their fundamental reason. With the expanding noteworthiness of malware in Internet assaults, much research was focused on creating systems to gather, study, and relieve malignant code. Thusly, so as to shield our frameworks from a dangerous demonstration of malware, it is important to gather and study malware found on the Internet.Objectives of a Malware Program are as follows:

- *Give Remote Control to an Attacker for utilization of the sullied Machine:* The malware looks at a framework through a far-off system association, things like this are not known to the injured individual [24].
- *Send Spam from the Infected Machine to Innocent Targets:* Negotiated applications are the most famous conveyance framework utilized by programmers to ship malware to clients' gadgets. Malware administrators will more often than not incline toward prominent applications to repackage or ruin, improving the prob-capacity that unfortunate casualties will download their maverick articulation.
- *Review the Infected User's Local Network:* Inserting malware into certifiable online promotion systems to focus on a wide range of end-clients. The promotions appear to be consummately typical and appear on an expansive scope of applications and website pages.

- *Steal Sensible Data:* Malware uncovers casualties of private and prohibitive data with the expectation of adapting held onto information through direct use or underground dispersion.

8.1 Different Types of Malware

- *Viruses:* Programs that imitate themselves all through a PC or system. At the very least, infections can debase or erase information, utilize the client's email to spread, or erase everything on a hard plate. [24]
- *Worms:* Self-duplicating infections that abuse security vulnerabilities to consequently in-wrinkle themselves crosswise over PCs and systems. Not at all like numerous infections, worms don't connect to existing projects or change documents. They normally go incon-spicuous until replication arrives at a scale that uses noteworthy framework assets or system transmission capacity [6].
- *Trojans:* Malware covered up in what gives off an impression of being certified programming. When actuated, Trojans will convey whatever activity they have been customized to take out. Dissimilar to infections and worms, Trojans don't imitate or duplicate through pollution [7].
- *Rootkits:* Programs that give special (root-level) access to a PC. Rootkits change and cover up in the working framework [23].
- *Remote Administration Tools (RATs):* Software that empowers a remote driver to control a framework. These instruments were essentially worked for real use, yet are currently utilized by danger on-screen characters. They are difficult to identify.
- *Spyware:* Malware that assembles data about the use of the tainted PC and conveys it back to the aggressor [18].
- *Botnets:* Short for "robot arrange," these are systems of tainted PCs under the specialist of single assaulting gatherings rehearsing order and-control servers [13].

8.2 Propagation Techniques

- *Web Browsing:* The most straightforward method for getting tainted is through drive-by-download. Using this strategy, malware engineers don't have any objective other than to contaminate whatever number mama chines as would be prudent [15]. Current programs like Chromium (a similar open-source venture on which Google created Chrome) incorporate two components which are structured remembering security [14].

- *USB Thumb Drives:* Thumb drives (or USB drives) are additionally used to develop malignant programming. The technique utilizes the Autorun highlight to begin malware when the capacity gadget is associated by the working system [12].
- *Email Spear Phishing:* Spear phishing is an email parodying trick exertion that objectives a standard particular association which is looking for unapproved access to classified information [16]. Lance phishing endeavors are not begun by discretionary assailants but rather are bound to be directed by culprits out for monetary increase, exchange confidences or military information [9]. Like email data utilized in ordinary phishing efforts, skewer phishing data seem to originate from a submitted source. Here falsehoods the disadvantage of information science (information mining) too [19].

8.3 Malware Protection

Malware security protection gives the essential layer of assurance for a PC or system [26]. The extended need for malware protection has to do with the widespread availability today of exceptional tools originally intended for cyber spying and cyber warfare [25]. Different ways of protecting users from Malware shown in Figure 4.

- *Access Control and Password Security:* The possibility of client name and secret phrase has been a significant method for protecting our data. This can be one of the main measures with respect to cybersecurity and assurance.
- *Authentication of Data:* The records that we get must be confirmed be before downloading that is it ought to be checked if the equivalent has been gone before from a trusted and a dependable source and that they are not altered. [6]
- *Malware Scanners:* This product more often than not checks every one of the records and archives that are available in the framework for vindictive code or damaging infections. Infections, worms, and Trojan steeds are instances of malignant programming.
- *Firewalls:* It a product program or bit of equipment that hides out programmers, infection es, and worms that endeavor to arrive at the machine over the Internet. All messages getting to the Internet go through the firewall present, which looks at each message and deters the individuals who don't coordinate the predetermined security criteria.

- *Anti-Virus Software:* Antivirus programming is a machine program that recognizes, anticipates, and requires exertion to square or take out malevolent programming programs, for example, infections and worms.

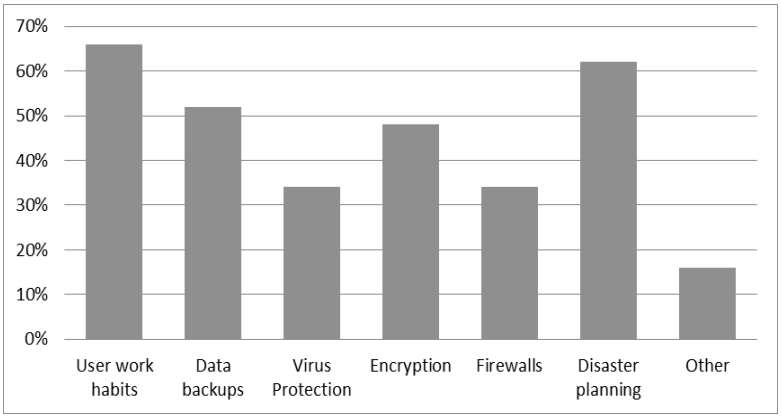

Fig. 4: Ways of Protection from Malware

9. CONCLUSION

Cybersecurity is a huge field that is ending up progressively significant in light of the fact that the world is ending up thickly interconnected as systems being utilized to do unsafe exchanges. This additionally results in malware being spread like out of control fire. Accordingly, Cyber-wrongdoing keeps on leaving behind various ways. Accordingly, so as to accomplish in general security, one should trust however check and realize that assurance is a significant part.

Despite the fact that, the present safety efforts and arrangements for the most part secure the PC framework against known dangers, yet they are attackable to obscure dangers. The most recent and troublesome advancements, alongside the new digital apparatuses and dangers that become known every day, are testing associations with learning of realizing how to verify their foundation as well as, which new stages and knowledge they require to do as such.

There is no perfect or durable answer for digital wrongdoing; it continues advancing as different violations do. In any case, the capacity to have a go at taking an absolute best to limit them is the security that stands in the middle of to guarantee a protected and secure future in the internet.

Efficiency Evaluation and Benchmarking of Air Carriers in India for the Year 2016–17 Using Data Envelopment Analysis (DEA)

Bharti Seth[1], Punita Saxena[2] and Shalini Arora[3]

ABSTRACT: *Paper aims at assessing and benchmarking the operational efficiency of 12 scheduled (domestic and international) passenger airlines in India during the year 2016–17. Efficiency scores (technical, pure technical and scale) are calculated using input-orientation data envelopment analysis models. Super-efficiency and cross-efficiency ranking methods under variable returns-to-scale are implemented to rank the airlines based on their performance to remove the biased nature of standard DEA models. Air India Express and Spice Jet are serving as benchmarks in Indian Airline Industry for inefficient airlines. Projections are discussed and improvements are mentioned which will help the decision makers to improve their companies performance.*

Keywords: Airline Efficiency, Data Envelopment Analysis, Super-Efficiency, Cross-Efficiency.

1. INTRODUCTION

Indian Air transportation started in the year 1911 and was one of the expensive modes of transport in India for the majority of Indian population. But, nowadays air transport is becoming affordable and hence demand in the market has increased. Aviation industry has become competitive and hence efficiency evaluation is necessary. Since 1911, the civil aviation industry of India has witnessed many revolutionary changes

and has emerged as one of the rapidly growing industries in the country. India has moved from an underdeveloped to a developing economy and for continual growth of the industry, proprietors of the industry are responsible to implement the efficient decisions of policy makers which are in best interest of population. This paper will provide insight to the decision makers to tackle the challenges prevailing in the market.

It has been accepted world-wide that DEA is a cogent technique to assess the operational efficiencies of airlines. Efficiencies estimated are relative to the best performing airline. Best performing airline is assigned an efficiency score of unity and efficiency of other airlines vary between zero and one. This paper mainly focuses on assessing and benchmarking the performance of airlines operating in India. Techniques of DEA are used to obtain the ranks of 12 scheduled airlines operating in India based on their performance scores.

Rest of the paper is organised as follows. Section 2 presents the contribution of DEA in assessing the performance of airlines; Section 3 presents the models used in the study; Section 4 presents the data and explains the variables used for measuring the performance; Section 5 discusses the findings obtain; Section 6 comprises of concluding remarks.

2. LITERATURE REVIEW: DEA IN AVIATION INDUSTRY

This section agglomerates the work done globally by the researchers in the context of evaluating the performance of operational airlines using the non-parametric technique of DEA.

The term DEA was introduced by Charnes *et al*. [3]. They developed the mathematical programming technique to examine the technical efficiency of a set of homologous decision making units (DMUs) that was later extended by Banker *et al*. [2].

In last four decades (1978–2018), DEA has been applied in the transport sector (land, air and water) and there exists a voluminous literature in this sector. The research efforts related to the evaluation of airlines performance using the techniques of DEA are discussed below.

Precisely, Schefczyk [18] for the first time discovered that DEA is a robust tool for benchmarking of operational performance of airlines using non-financial data. Study analyzed the efficiency of 15 large international airlines for the year 1990 using DEA technique and regression analysis. Good, Roller and Sickles [9] assessed the performance of largest European and American airlines during the year 1976–1986 using two techniques

namely the stochastic frontier model based on regression analysis and full frontier model based on linear programming methods (DEA). The study suggested that European airline industry will be benefitted by deregulation and privatization but the pace of restructuring and reorganization of the industry should be gradual. Tofallis [23] ascertained that Input Efficiency Profiling (IEP) model is more powerful than conventional DEA models while deriving input-specific efficiency ratings. IEP model is applied on the data set of 14 major airlines and results are compared to conventional models of DEA. Fethi *et al*. [8] applied the stochastic DEA on a panel of 17 European Airlines. They used the Land, Lovell and Thore [13] model to find the effect of liberalisation on the efficiency of airlines. After allowing the stochastic error, they concluded that larger airline companies were efficient in 1995 and they resembled those who were efficient in 1993 but not those in 1991. Scheraga [19] studied the sample of 38 large international airlines for the years 1995 and 2000. As both the years were dynamic years in the history of airlines, therefore author investigated whether the operational airlines efficiency implies the financial mobility. He used the non-oriented and oriented DEA models to calculate the efficiency scores and concluded that in a dynamic environment, airlines must have some process of greater capabilities which can allow developing a fund flow so that an airline can operate smoothly. Michaelides *et al*. in [17] estimated the technical efficiency of a panel of 24 largest network airlines over the period 1991–2000. They observed that airlines were technically efficient with scores ranging from 51% to 97% approximately and following the constant returns-to-scale. They compared the approaches of DEA and Stochastic Frontier Analysis (SFA) and concluded the results obtained from both the approaches were approximately similar. Lee and Worthington [14] investigated the efficiency scores of 53 domestic, international and budget airlines in the year 2006 using the conventional DEA models. Study reveals that the exclusion of budget airlines impinged the relative efficiency scores. Efficiency scores of airlines are not much affected by relaxing the input variable of non-flight assets. Zhu in [26] measured the airline performance using a two-stage process. Study applied the centralized model of Liang, Cook and Zhu [15] to a set of 21 airlines and concluded that centralized model is more powerful than standard DEA models. Wen-Min Lu *et al*. studied the relationship between the corporate governance and operating efficiency of 30 airlines operating in US in [16]. They found that low cost airlines are more efficient then the full–service ones but less efficient marketers. Their findings demonstrated that corporate governance has

significantly influenced airline performance. Joo and Fowler in [11] measured the relative efficiency of 80 airlines in Asia, Europe and North America. They found that airlines in Europe are less efficient than airlines in other two regions. Also the efficiency differences between the airlines in Europe and the airlines in other two regions are statistically significantly in terms of technical and purely-technical efficiency scores but not significant between the airlines in Asia and North America. Kottas and Madas in [12] employed the techniques of DEA in assessing the effect of alliance group membership on 30 major international airlines for the period 2012–16. They concluded mainly three facts. Firstly an alliance group membership is not associated with efficient airline. Secondly high freight traffic revenue sharing airlines are more efficient than the airlines with lower freight traffic revenue share and finally the mean efficiency difference regarding air carriers operating in Asian and European continent are statistically significant over the air carriers operating in America. There are other researchers also who have worked in the aviation sector in evaluating the operational efficiency of airlines using the techniques of DEA.

However, the research is still at an infancy stage when we talk about the operational efficiency of an Indian Airlines using the DEA techniques. The efficiency scores of all airlines operating in India during 2006–2010 were studied in [10]. Authors applied variable returns-to-scale and IEP models of DEA over the data and found that budget and low cost airlines were more efficient when compared to the full service airlines in the private sector. Further, private low-cost airlines and all public sector airlines were efficient. They found that greater inefficiency is associated with the input of operating cost. Selvan *et al*. in [21] analysed the performance of airlines operating in India for the period of 2010 to 2014. They used two-stage DEA to evaluate the overall efficiency and applied the super-efficiency DEA model to rank the airlines. They found that production efficiency has higher impact on the overall efficiency than marketing efficiency. They also suggested that airlines in India must emulate the LCC model to be highly efficient.

From the available literature it is justifiable that DEA is an efficient tool in evaluating the operational efficiency of airlines operating in India. This paper aims at:

- Evaluating the technical, pure technical and scale efficiencies of airlines operating in India.

- Ranking the airlines under study by computing super and cross efficiencies.
- Providing the benchmarks for the decision makers of inefficient airline companies to improve.

3. MODELS

3.1 Conventional Models

Conventional models are the standard DEA models, also known as the radial-measures of efficiency. They can be either input oriented or output oriented. Charnes, Cooper and Rhodes (CCR) model is at head when we list down all the models in DEA literature. It was proposed in [3] and was named after the three authors (Charnes, Cooper and Rhodes). While the Banker, Charnes and Cooper (BCC) model was proposed in [2] and it is an extension of the CCR model. CCR model follows the assumption of constant returns-to-scale (CRS) while the production frontier of BCC model is the set spanned by the convex hull of organisational units under study which leads to variable returns-to-scale. Let there be 'n' DMUs whose efficiencies have to be compared. Let $X = \{x_{ir}\}$ and $Y = \{y_{jr}\}$ be $m \times n$ and $s \times n$ input and output matrix respectively. Let $v_i, i = 1, 2, \dots, m$ be input weights and $u_j, j = 1, 2, \dots, s$ be output weights. A DMU whose efficiency is being evaluated is called as **target DMU** and designated as$DMU_o, o = 1, 2, \dots, n$. The efficiency is calculated by CCR model as follows:

$$\max_{v,u} \theta = \frac{u_1 y_{1o} + u_2 y_{2o} + \cdots + u_s y_{so}}{v_1 x_{1o} + v_2 x_{2o} + \cdots + v_m x_{mo}}$$

$$\text{subject to } \frac{u_1 y_{1r} + u_2 y_{2r} + \cdots + u_s y_{sr}}{v_1 x_{1r} + v_2 x_{2r} + \cdots + v_m x_{mr}} \leq 1 \ (\mathrm{r} = 1, 2, \dots, \mathrm{n})$$

$$u_1, u_2, \dots, u_s \geq \epsilon > 0$$

$$v_1, v_2, \dots, v_m \geq \epsilon > 0$$

Here, ϵ is a non-Archimedean constant.

Objective is to obtain the weights v_i and u_j that maximize the efficiency of target DMU. Constraints indicate that efficiency of any other DMU should not exceed 1. Constraints also signify that optimal objective value is at most 1.

The BCC model for calculating the efficiency of D_o is formulated below.

$$\max_{v,u,u_o} \theta = u_1 y_{1o} + u_2 y_{2o} + \cdots + u_s y_{so} - u_o$$

subject to $\frac{u_1 y_{1r} + u_2 y_{2r} + \cdots + u_s y_{sr} - u_o}{v_1 x_{1r} + v_2 x_{2r} + \cdots + v_m x_{mr}} \leq 1$ (r $= 1, 2, \ldots,$ n)

$$v_1 x_{1o} + v_2 x_{2o} + \cdots + v_m x_{mo} = 1$$

u_o unrestricted

$$u_1, u_2, \ldots, u_s \geq 0$$

$$v_1, v_2, \ldots, v_m \geq 0$$

The BCC model differs from CCR model only in the adjunction of the convexity constraint. CCR efficiency will always be less than the BCC efficiency as the feasible region of BCC model is the subset of the feasible region of CCR model.

3.2 SBM Model

Slack-Based Measure (SBM) of efficiency model which was introduced in [24] is a measure of efficiency which is unit-invariant and also it is monotonically decreasing in each input and output slacks. The SBM model is represented as follows:

$$\min_{\lambda, s^-, s^+} \rho = \frac{1 - \frac{1}{m}\sum_{i=1}^{m} \frac{s_i^-}{x_{io}}}{1 + \frac{1}{s}\sum_{r=1}^{s} \frac{s_r^+}{y_{ro}}}$$

Subject to

$$x_o = X\lambda + s^-$$

$$y_o = Y\lambda - s^+$$

$$\lambda \geq 0, s^- \geq 0, s^+ \geq 0$$

Here $s^-$and s^+ are the slacks associated with input and output respectively. The SBM efficiency ρ^* will be equal to 1 only if the slacks are zero in all inputs and outputs. The objective of the model is to minimize the ratio of mean input and output mix inefficiencies. The model is also congruent with the standard DEA model.

3.3 Cross Efficiency Model

This model was first proposed in [22] and then later on in 1994, Doyle and Green re-examined this model in [6]. In this model we calculate the efficiency of each DMU using the weights of inputs and outputs chosen by other DMUs. Thus, cross-efficiency score of a particular DMU reflects that how it is rated by other existing DMUs. Mathematically, cross-

efficiency of DMU_k as measured by DMU_o is defined as the ratio of weighted output and weighted input, where the weights of input and output of DMU_o and levels of input and output of DMU_k are used. Mathematically, it can be expressed as follows:

$$E_{ok} = \frac{\sum_{r=1}^{s} u_{ro} y_{rk}}{\sum_{i=1}^{m} v_{io} x_{ik}}$$

A cross-efficiency matrix is a square matrix of order n and E_{ok} is the entry in row-o and column-k. Diagonal entries of this matrix are called the self-rated efficiencies and this score represents how highly the DMU can rate itself. Entries along any o-row represent the score of all the DMUs when optimal weights of DMU_o are used, that is, how DMU_o rates the other DMUs. Along the k-column the entries represent how DMU_k is rated by all other DMUs. All theses scores help us in ranking the DMUs under study.

3.4 Super Efficiency Model

The foundation of this model was laid in [1]. The model was examined further and infeasibilities and modified version of this model are discussed in [25, 20, 4]. Super-efficiency DEA model calculates the efficiency score while excluding the DMU under study from the reference set. This model helps in ranking even those DMUs which are fully efficient according to most of the DEA models. Super-efficiency model can be applied using the radial and non-radial measures of efficiency. In our study we have used the non-radial slack-based measure of efficiency [25] for calculating the super-efficiency score of efficient DMUs.

4. DATA

Our data set consists of a group of 12 Indian airlines national and private namely: Air India, Air India Express, Alliance Air, Air Asia, Go Air, Indigo, Jet Airways, Jet Lite, Spice Jet, True Jet, Vistara and Zoom Air. Data related to efficiency indicators of scheduled Indian airlines of both service types: domestic and international for the year 2016–17 has been collected from the website which is maintained by the office of Directorate General of Civil Aviation (DGCA). From this source, we identified three input variables and four output variables. It is found that negative correlation prevails among selected input and output variables. Table 1 presents the statistics on input and output variables for the year 2016–17 of selected Indian airlines. Definitions of the selected variables based on handbook on civil aviation statistics for the year 2016–17 available at the website of DGCA are defined below.

Table 1: Descriptive for Input and Output Variables of Airlines under Study

	CASK	*EASK*	*FASK*	*LF*	*FS*	*RPK*	*PR*
Max	10.795	15.909	5.277	91.59	131	46288.31	182434
Min	2.389	0.183	1.528	68.8	1	3.883	14
Average	4.726	1.858	2.465	79.82	40.5	14125.92	56388.21
SD	2.336	4.251	1.118	6.55	45.19	17170.4	68998.15

4.1 Input Variables

Cost per available seat kilometres (CASKs): It is calculated as the ratio of operating expense for the year and available seat kilometres. It is chosen as an input variable as lower CASK implies higher efficiency of an airline.

$$\text{CASK} = \frac{\text{Operating Expense (In Million)}}{\text{ASK (In Million)}}$$

Expenditure on personnel per available seat kilometres (EASKs): It is calculated by dividing the total amount on personnel an airline is spending including their salaries, wages, bonuses and other allowances by the available seat kilometres. This factor is considered as an input variable because lower EASK signifies how efficiently airline company personnel are working.

$$\text{EASK} = \frac{\text{Expenditure on personnel (In Million)}}{\text{ASK (In Million)}}$$

Flight operation Expense per available seat kilometres (FASKs): Lower expense on flight operations implies the lower expenditure on flight movements which indicates a more efficient aircraft. FASK is calculated by dividing the flight operation expense by available seat kilometres. Flight operation expense includes the expenditure on repairing, hiring, insurance and other movements of aircraft.

$$\text{FASK} = \frac{\text{Flight Operation Expense (In Million)}}{\text{ASK (In Million)}}$$

4.2 Output Variables

Revenue Passenger Kilometre (RPK): It is calculated as the sum of the products obtained by multiplying the number of revenue passengers carried on each flight by the flight stage distance. Higher RPK value indicates the higher sale of available seats and therefore it can be considered as an output variable while evaluating the efficiency of an airline.

Load Factor (LF): Load factor indicates that how successful an airline is in selling its available seats. It is calculated by dividing the RPK value by

the available seat kilometres. However higher load factor does not indicate that airline escalating towards efficient frontier. An airline has to maintain a break-even load factor to surmount over all the expenditures in providing the services

Fleet Size (FS): As mentioned in [26], FS can be taken as an output variable and is equal to the total number of aircrafts an airline company owns or leases. Higher fleet size indicates the more seat capacity to meet the market demands.

Passenger Revenue (PR): It is the revenue collected from the sale of tickets and ex-baggage charges. This factor plays a valuable role because an efficient airline has to generate more revenue for its survival.

5. RESULTS AND DISCUSSIONS

5.1 Efficiency Analysis

Efficiency score of the CCR model is called the technical efficiency (TE) and that of the BCC model is called the purely technical efficiency (PTE). TE and PTE scores are also called the CCR score and BCC score respectively. Nature of TE and PTE is global and local respectively. Scale efficiency (SE) is defined as the ratio of CCR score and BCC score. Table 2 shows the efficiency scores in input-orientation and returns-to-scale of 12 scheduled airlines for the year 2016–17. Five airlines namely Air India, Air India Express, Indigo, Jet Airways and Spice Jet are fully efficient according to CCR and BCC model as their TE, PTE and SE scores are all equal to unity so they needs to be further investigated to obtain the ranks. There is one airline namely Go Air which is locally efficient but not globally as it follows the decreasing returns-to-scale. According to SE scores, all the airlines are above average and this may mean that the inefficiencies of airlines (Alliance Air, Jet Lite, True Jet, Vistara and Zoom Air) are mainly due to their inefficient management.

5.2 Benchmarks

Table 2 shows that according to the input-oriented CCR model, Spice Jet and Air India Express are serving as benchmarks for inefficient units Alliance Air and Zoom Air respectively. For other inefficient units (Air Asia, Go Air, True Jet, Vistara and Jet Lite) Spice Jet and Air India Express both are in reference set.

Input-oriented BCC Model identifies that Air India Express is only serving as a benchmark for both of the inefficient units namely Alliance Air and

Zoom Air. Spice Jet and Air India Express are in reference set for other inefficient units. Further it is found that Air India, Indigo, Go Air and Jet Airways are although efficient units but they are not in the reference set of any inefficient unit.

Table 2: Efficiencies and Returns-to-Scale of Airlines in India for the Year 2016–17

S. No.	*DMU*	*CCR Scores*		*BCC Scores*			*SE*
		TE	*Reference*	*PTE*	*Reference*	*RTS*	
1.	Air India	1	Air India	1	Air India	Constant	1
2.	Air India Express	1	Air India Express	1	Air India Express	Constant	1
3.	Alliance Air	0.537196	Spice Jet	0.631661	Air India Express		0.85044
4.	Air Asia	0.825325	Air India Express, Spice Jet	0.931174	Air India Express, Spice Jet		0.886326
5.	Go Air	0.867612	Air India Express, Spice Jet	1	Go Air	Decreasing	0.867612
6.	Indigo	1	Indigo	1	Indigo	Constant	1
7.	Jet Airways	1	Jet Airways	1	Jet Airways	Constant	1
8.	Jet Lite	0.655842	Air India Express, Spice Jet	0.659082	Air India Express, Spice Jet		0.99508
9.	Spice Jet	1	Spice Jet	1	Spice Jet	Constant	1
10.	True Jet	0.295379	Air India Express, Spice Jet	0.298401	Air India Express, Spice Jet		0.98988
11.	Vistara	0.647246	Air India Express, Spice Jet	0.669106	Air India Express, Spice Jet		0.96733
12.	Zoom Air	0.493715	Air India Express	0.53435	Air India Express		0.92396

5.3 Rankings

Cross-efficiency and super-efficiency methods are applied to the panel of data and Table 3 shows the efficiency scores with ranks. Cross-efficiency scores under variable returns-to-scale are calculated and super-efficiency scores using slack-based measure of efficiency under variable returns-to-scale are calculated. In Table 2 almost half of the airlines under evaluation

are fully efficient but we can now analyse these fully efficient airlines further through cross-efficiency and super-efficiency scores. Air India Express is maintaining the first position throughout in all the scores. Although True Jet is efficient with respect to SE (0.98988) but its low PTE score forces it to be inefficient with lowest cross-efficiency and SBM scores. According to both the ranking methods, it is found that Air India is ranked low among all the efficient airlines which signifies its absence from the reference sets of inefficient units.

Table 3: Cross-Efficiency and Super-Efficiency Scores with Ranks

S. No.	*DMU*	*SBM Super Efficiency*	*Ranking*	*BCC Cross Efficiency*	*Ranking*
1.	Air India	1.017453	5	0.832369682	7
2.	Air India Express	1.5329	1	1.19209462	1
3.	Alliance Air	1	10	0.333709007	11
4.	Air Asia	1	7	0.903502888	5
5.	Go Air	1.005183	6	0.953641339	4
6.	Indigo	1.317317	2	1.017452027	3
7.	Jet Airways	1.043206	3	0.844982037	6
8.	Jet Lite	1	9	0.673950726	8
9.	Spice Jet	1.028995	4	1.018600658	2
10	True Jet	1	12	0.319217574	12
11.	Vistara	1	8	0.652377606	9
12.	Zoom Air	1	11	0.383297825	10

5.4 Correlation of Ranks

Ranks for airlines are obtained using the cross-efficiency method under variable returns-to-scale and super-efficiency method using slack-based measure under variable returns-to-scale. We need to find out that the ranks obtained from both the methods are independent of each other or not. Spearman's Rank Correlation coefficient (ρ) was computed and was observed to have a p-value of 1 at 5% level of significance. This justifies that the two ranking structures are independent of each other.

5.5 Slacks and Projections

Table 4(a, b, c) represents the input excess and output shortfalls obtained from CCR model with projections. LF row in Table 4(a, b, c) implies that every airline is successful in selling their seats. According to the results, no airline needs to improve this LF output variable. However, it is ironical that Alliance Air and True Jet airlines are capable of selling their available seats while maintaining the break-even load factor but still have very high projection percentage. Inefficient airlines need to reduce CASK in the range (13%–75%), EASK in the range (13%–98%), FASK in the range (13%–70%). It is found that Go Air is the one that needs a minimum reduction of approx 13% in all the input variables. The projection percentage of EASK for Zoom Air is very high (99%) as they got very small time-window to business in the market. It is found that True Jet and Alliance Air are spending more on their employees.

Table 5(a, b, c) represents the input excess and output shortfalls obtained from BCC model with projections. According to BCC model, the reduction percentage range of CASK, EASK and FASK are (7%–78%), (19%–99%) and (20%–71%) respectively. It is found that Air Asia requires least reduction in all the three input variables. BCC model also suggest that Alliance Air and Zoom Air are spending more on their employees. True Jet is the one which is spending more on flight operations. Further it is found in contrast with CCR results that Alliance Air needs to improve its load factor by 10% approx. In future this can be further investigated.

6. CONCLUSIONS

The present paper has targeted the 12 scheduled passenger airlines operating in India. Airlines of both service-type domestic and international are considered for evaluating their operational efficiencies. TE, PTE and SE scores are obtained in Table 2 using input-orientation CCR and BCC models. It is found that five fully efficient airlines are lying in the most productive scale size region, region where constant returns-to-scale property dominates. SE scores suggest that airlines are globally inefficient because of their inefficient management or operations. Therefore the airlines executives need to strategise their managerial policies in order to become an efficient airline.

It is also found that efficient airlines not present in the reference sets are holding a low rank according to ranking methods. Super-efficiency and cross-efficiency scores in Table 3 justify that Air India Express is the most efficient airline among all the efficient airlines. Ranks obtained from super-efficiency and cross-efficiency methods are independent.

Results in Tables 4 and 5 showed that Alliance Air and True Jet need to curb the expenditure on their personnel for their survival. As mentioned in section 5 that LF is the variable which needs no improvement according to CCR model but BCC model suggested that Alliance Air needs to increase its load factor by 10%. In this direction, future research work can be done to investigate the relation between the load factor and other output variables related to revenue. Also, sensitivity analysis can be done in relation to the effect on operational efficiency of airlines on deletion of any input and output variables under study. In addition airline companies should strategize their future policies in a holistic way which is propitious for both customers and personnel.

Big Data Applications in Real-World

Shalini Sharma[1], Naresh Kumar[2] and Kuldeep Singh Kaswan[3]

ABSTRACT: *This paper presents the application of big data in real world. Nowadays Big data is used in all spheres of personal and professional lives be it agriculture, banking, travelling, healthcare, financial institutions, food industry, power sector, managing smart cities and homes. The goal of big data is to analyse the vast amount of data at the disposal of varied sectors and help them in taking better decisions regarding management, security, sales etc. in order to perform better in this competitive world. Although Big data is used in various fields we usually consider only a few real world applications which impact the general population and provide support and comfort to commoners in tremendous ways. Using qualified and skilled analyst to analyze large amount of complex data collected from various resources like sensors, smart phones, digital devices, Internet of Things, customers feedback, social media, cloud computing and data mining, big data is helping companies to make better informed decisions to secure business growth.*

Keywords: Internet of Things, Big Data Analytics, Data Visualization, Integration, Cloud Computing, Machine Learning.

1. INTRODUCTION

Big data is a term used to refer to data sets that are too large or complex for traditional data-processing application software to adequately deal with.

The definition of Big Data, given by Gartner is, "Big Data is high-volume, and high-velocity and/or high-variety information assets that demand cost-effective, innovative forms of information processing that enable enhanced insight, decision making, and process automation" [1]. As the name suggests data that is big in amount or we can say that big data is collection of large amount of data collected from diverse fields in real

[1,2,3] School of Computing Science and Engineering, Galgotias University, Greater Noida, UP, India. E-mail: [1]shalini.sharma@rediffmail.com; [2]Naresh.dhull@gmail.com; [3]kaswankuldeep@gmail.com

world i.e. it can be from social networking sites, or medical data, data related to climate, or it can be your mobile data, transactional data etc.

The data collected could be of different variety and format, they might be structured, semi-structured or non-structured depending upon the areas from where it was collected. The data collected in such manner will be generated and logged at very high speed making it impossible for a single machine to store or process. Big data is something that can be used to analyse insights which can lead to better decisions and strategic business moves According to a study by Boyd & Crawford [2] it "rests on the interplay of:

(a) *Technology:* Maximizing computation power and algorithmic accuracy to gather, analyze, link and compare large data sets.
(b) *Analysis:* Drawing on large data sets to identify patterns in order to make economic, social, technical, and legal claims.
(c) *Mythology:* The widespread belief that large data setsoffer a higher form of intelligence and knowledge that can generate insights that were previously impossible, with the aura of truth, objectivity, and accuracy."

The data collected is of no use unless it is analysed and a useful outcome is produced for decision making. In today's world enormous amount of data is at the disposal of decision makers. Big data is formally defined as 4V's which refers to the datasets high in volume, variety, velocity and veracity, where veracity means availability and accountability.

IBM Scientists Mention that *Big Data* has Four-Dimensions: Volume, Velocity, Variety, and Veracity [7]. Because of these characteristics of big data it is difficult to handle them using traditional tools and techniques. Furthermore these data sets need to be studied and solutions must be provided in order to extract value and information from these datasets. Decision makers can gain valuable insights from solutions provided after analysing the varied and rapidly changing data using big data analytics.

2. BIG DATA ANALYTICS

Big Data gives us a new technology that provides insights available in real-time. Business, governments and even NGOs are benefited with the insights offered by big data analysis. Nowadays data is available in abundance and so is its access like search on Google or interaction on Facebook through status updates likes or dislikes pictures and videos. All such things are data or information of varying nature thus it can be analysed, and utilised for numerous applications.

By analysing social media data, user preferences can be known while shopping, destinations that they like to travel, type of hotels they prefer to stay at, mode of travel etc. The shop keepers can identify which items are on demand and at what time which thing is best selling. Similarly travel agents can monitor the data looked by customers for preferred destination and can customise their packages according to the prevalent demand. This technique is known as data analytics, and it is one of the biggest trends of 2018.

Now with everything smart be it watches, glasses, television, mobiles and even smart clothes the world is poised to become a huge data collection mechanism. Big Data analytics can help organizations to better understand the information contained within the data and can also help identify the data which is most important to the business and future business decisions. Analysts working with Big Data typically want the knowledge that comes from analyzing the data [6].

3. APPLICATIONS OF BIG DATA

Agriculture, Healthcare industries, educational sector, banking sector, insurance service, industrialization, transportation services all have the use of big data analysis and are tremendously growing.

3.1 Agriculture

India is an agricultural based country and plays an important role in the socio-economic fabric of India. Climate and economy are two major factors on which the production of crop is dependant. An important issue for agricultural is the accurate yield estimation for the various crops involved in the planning. Condition of climate, soil, fertilizers to be used, and commodity prices all these information helps a farmer to make decisions regarding farming. Accurate information regarding the crop yield and risks plays a significant role in the production scheduling of supply chain decision for companies that uses agricultural products as raw materials, food, animal feed, fertilizers, livestock, pesticides, seed and paper.

3.2 Business

Business houses are using big data to lead the competitive landscape by taking advantage of marketing product and services according to the customers need. In order to achieve the desired goal, customer feedback collected using mobile apps, smart phones, e-commerce sites or POS

systems is analysed by which businesses are in position to identify what works, what doesn't and why. Businesses that make strategies to improve productivity or performance depending upon the analysis done on customer experience further help boost revenue growth and customer loyalty. On the other hand if they choose to neglect the indication they not only lose their customers but also have to deal with more data savvy competitor.

To get the desired quality and optimized service process improvements, we need to focus on efficiency gains, optimising the workforce, increasing revenue, savings cost, improving operations and speeding time to manufacture company's product. Understanding Big Data and its advantages will eventually help in transforming a major business process by analysing the data using appropriate analytical tools.

3.3 Healthcare

Cost of healthcare is increasing with the advancement of technology. Big data is a great helping hand in the field of medicine and healthcare. Record of patient's history is required by every physician for accurate diagnosis whereas the after patients successful treatment his history will be stored in the database forever which can only be accessed by his physician or himself. Doctor whenever wants can view a patient's history stored in database either for reference purpose or for further treatment of the said patient. Since large number of medical equipments are data oriented so it is possible for a doctor to prescribes medicine without even visiting patient only by looking into patients history and data provided by remote devices (heart, temperature, BP monitoring watches) attached with the patient at a remote location.

For accurate diagnosis doctors rely on patients clinical record which means collection of vast amount of data from different patients and also from different sources like billing, Electronic medical Records (EMR), path-labs etc., which cannot be done with the old storing techniques of data. Since the data that is being collected is large in variety, from various sources and in different format therefore there is a need for Big Data approach to handle all this.

Thus with the use of big data analytics, the patients outcome can be improved while lowering the cost. Data generated by hospital information system (HIS) is growing at tremendous rate which marks the era of Big data in healthcare and is being used by the healthcare industry for workflow management, in taking good care of patients, in scientific

research and education in medical field. If we timely and appropriately utilize the characteristics of big medical data then it can bring huge benefits in terms of cost, improved quality and better productivity. Because of highly interdisciplinary distributed and complex characteristic of medical data new and efficient technologies like semantic web, cloud computing and data mining are becoming necessary to share, obtain and utilize the information and knowledge imparted by these medical Big data. The ultimate goal of analysis of Big data is to present the result to the user using some visualization tools, but traditional visualization tools such as bar graph, scatter plot and histogram can not reflect the complexity of the results of Big data analysis. Therefore for powerful visual explanation of big data analysis result network steam graph, 3D scatter plot and multi dimensional heat map has been introduced.

3.4 Education

In higher education data is captured and generated in large amount from various sources and in different format. It can be termed big as it contain volume, velocity and variety. The data so generated can be from student's interaction, learning activities and materials, syllabus, result, evaluation, administrative data and other type of data required for innovative teaching methods and procedures for quality improvement. Size and type of the educational data in higher education reflects the requirement for special techniques to be applied in order to gain better insight into student's domain. The techniques are used to improve learning approaches, student's performance and quality of education. Big data analytics also affect the decision making in administrative work and in better utilisation of organizational resources. With the help of Big data analysis of previous years result data and current continuous assessments data we can find out the weak students and can take the measurements in the form of extra coaching classes or guidance to prevent the student from failing in that particular subject. Major part of big data is applicable for investigation into probable improvement in the content of course curriculum.

Big data usage in Students Performance

Student's performance can be measured after analysing the data collected regarding students activities by placing various sensors inside the campus. For students to perform well an assessment of their personal life like time spent in eating, sleeping, studying, environment at home is required for sentiment analysis. Sentiment along with conduct plays a vital role in

shaping students academic life and affecting his grades. To get the desired result of improved student's grade and to reduced fail rate we need to combine the analysis of large student's data sets and IOT technology.

Efficient Teaching

Teachers are require to enhance learning experience by incorporating various innovative teaching methods, thus forcing them to keep pace with the current technologies, new tools and enabling them to be equipped and qualified enough to perform the analysis on vast students data for desired results. To determine student's requirement, learning curve and performance, instantaneous feedback regarding teaching methods, student's social and economic sentiments, effectiveness of course material will help a teacher to take corrective measures teaching methodologies. Analysis of student's data helps a teacher to identify the students which require special attention in academic field as well as personal field. Teacher can employ various methods to boost their morale through appreciation and rewards.

Educational institutions are yet to utilize the full potential of Big data because of lack of computational tools and human resources .Need for students privacy and security of highly confidential data also attributed to slow pace of education institutes in utilizing Big data techniques.

3.5 Banking and Fraud Detection

Comprehensive Analytics

It is required by banks and other financial institutions to build a strong fraud detection strategy.

- Banks detect suspicious patterns after analysing the bank data with the help of necessary analytical tools, notify the customer quickly about fraud incident and place themselves in better position for settlement.
- Analytics look for pattern in data that helps detect fraud. Customers usually have same pattern for deposits, withdraws, using debit and credit cards and personal loan accounts, which analytic algorithm can combine and look for any fraud indicators. Deviation from the usual pattern or withdrawing large amount must be confirmed from the user to avoid any fraud activity. Keeping track of number of bounced cheques, average balances and other customer characteristics for deep analysis helps a bank to detect any potential cheque fraud. Thus in banking sector Big data is implemented and hugely used to find

out any fraud activity. Big data detects the misuse of debit or credit cards, detects unusual patterns in customer statics, detect any credit, debit or other transactional hazard.

- As the technology advances so does the fraudulent attacks although the financial institutions are investing in preventing and capturing the fraud attacks but the nature and extent of fraud keep evolving and changing with the time. Eliminating the current fraud is not an ultimate practical goal of the financial sector, what they need is to change the way fraudulent attackers are dealt with by including real-time detection and behaviour analysis techniques to give new perspective to fraud detection and prevention.
- Analytics allow banks or financial institutions to derive patterns, keep track of any unusual activities and timely locate unusual transactions helpful in preventing any fraudulent activity. Financial institutions are finally waking up to the new ways of fighting fraud with the help of Big data analytics. Big data help financial institution to deal with fraud in different manner and possible get different results too.

Identify Suspicious Activities

Suspicious behaviour is monitored by banks to spot fraudulent activities by analysing real time data. For example, banks usually get notified about the use of card from a device first time, if bank receives multiple notification from a first time usage of device for credit card payment placed at different locations bank confirm about the same from the client and block the card and online transactions in case of fraud usage.

Banks can access data related to customer from various sources such as social sites, call centres conversation, on-line transaction logs which help them in identifying unusual activities. For example -suppose a customer who is credit card holder of a particular bank is on vacation, thus after analysing the data from social networking site, online banking transactions and credit card transaction any attempt on credit card or debit card transaction during the time he is travelling in plane must be blocked

Identify Possible Fraud Attempts

Insurance companies access vast amount of data from various resources like social media, medical record, past claims, phone records and criminal records to examine the claim when received. If something suspicious is being detected the claim is flagged and forwarded for further investigation.

3.6 Traffic Management

Government is planning to incorporate Big data solutions in implementing co-ordinated traffic signals and other variables to improve traffic flow, congestion and fuel consumption and to reduce accidents and passengers safety using new age algorithms and real-time information. Growing focus on the use of big data analytics and development of intelligent networks result in reduced road block, traffic congestion, pollution and assist in managing smooth traffic with fewer safety hazards.

Use of GPS and advanced sensors are designed to help in traffic management and forward alerts to traffic officials for a possible roadblock or any traffic violation. Sensors are usually installed in the vehicles like trucks, ships, planes and provide real time data regarding driver's capabilities and traffic.

GPS signals are used to predict the flow and condition of traffic like estimated delay due to congestion, alternate route suggestion, estimated time to reach the destination etc.

Transport industry handles bulks of data. It has number of equipment's and numerous control models of applications. If anything goes wrong or accident happens, this will put the system in inefficient state and the entire system will shut down.

3.7 Travelling Sector

Predictive analysis is nothing but applying appropriate statistical model to vast amount of data, collected from different sources, to find hidden patterns for prediction and gain insight from the information at our disposal.

- This predictive analysis is used by the travel agencies, airlines, airports etc. to predict the customer behaviour and unlock possibilities for traveller using predictive model.
- Tourism portals, Social networks along with tourist's collaboration are becoming main reference point while planning a trip. We search everything while planning a trip: the type of destination, staying in a hotel, which flight is best to choose etc.
- Predictive analysis helps to find a match between users need and requirements to product and services available in the market. Recommender systems are also used to recommend types of destinations one can visit on his own. Tourism industry now a day's take advantage of technology provided by Big data to continue

expanding and improving services. Today most airlines make use of the Big data to access information about a customer's preference for seat, food and type of disease or constraint they might be suffering in order to serve them better. Because of the maximum adaptability to customers need and improvement in services depending upon the feedback provided Big data is the best ally of Tourism companies.

In today's time, travellers leave digital footprints on the web, social media, post reviews of every hotel stay, every airline reservation and every rental car reservation during their trip also travel companies have lots of data regarding each step of journey planned for customer from flight plans to check-ins. This information can be used by the travelling companies to provide better services so that customers feel appreciated and choose recommend travelling agency which results in more income and profits.

Big data is very powerful and has a very strong positive effect in travel and hospitality industry, consumers expected to see these positive developments in travel industry too.

3.8 Food Industry

It is very difficult for food industry to personalize the food according to the desire of customers as their tastes might vary depending upon their background and age**.** So it's a Big challenge for food industry to utilize data to better serve and understand the need of customers. Use of mobile phones and social media for food safety is an example how Big data is changing the food industry. Restaurants, retailers and food producers everyone is using big data to better understand customer's requirements and unravel market trends related to food. To better understand what customers needs, Big data is helping one of the world's largest business sector, by using sophisticated methods and analytical. Restaurants owners now realizing the importance of Big data and analytics in competitive market, they are optimizing their menu by including revised prices, adding new dishes, modifying the old once according to data collected from customer.

4. SUMMARIZATION

Big Data technology has made insights available in real-time. Agriculture, Healthcare, Education, Financial institutions, Business, Government and even NGOs can benefit by utilizing the insights offered by big data analysis. Big data technology is the new challenge it needs new architecture, techniques, algorithms for its implementation. Also technical

skills are required to analyze the data. So experts are needed to execute Data Mining tools and techniques. Big data presents more opportunities, creates much interest for research and reference in technical progress. Major concern is ensuring big data security and integrity. When collecting data, all measures for security practices must be followed; keeping in mind the complexity and huge size of Big Data.

Table 1: Comparative Analysis of Research Done in Different Fields Using Big Data

S.No.	*Domain*	*Author*	*Brief*	*References*
1.	Agriculture	Jharna Majumdar, Sneha Naraseeyappa and Shilpa Ankalaki	Analysis is done to obtain best yield of wheat product by using various data mining techniques like PAM, CLARA and DBSCAN V to obtain optimum climatic conditions (best temperature, worst temperature and rainfall) for higher production. Out of the three the DBSCAN gives the best analyses of clustering quality metrics.	[18]
2.	Agriculture	Sukhpal Singh Gill, Inderveer Chana, Rajkumar Buyya	Author proposed a Cloud-based automatic information system (AaaS) for agriculture services. The system is used to collect and manage various types of agriculture-related data based on different domains through different sources and classify them using K-NN (k-Nearest Neighbour) classification mechanism in usable clusters of agriculture data.	[26]
3.	Agriculture	Andreas Kamilaris, Andreas Kartakoullis, and Francesc X	Emphasis is given on smart farming which is nothing but use of combination of technologies (IOT, cloud computing, remote sensing) to increase the yield by handling the agricultural challenges in terms of productivity, food security, environmental affect and sustainability. The survey paper provide us with a comparison table informing the reader about how big data is collected from various sources and how its characteristics are being used, which type of	[28]

S.No.	*Domain*	*Author*	*Brief*	*References*
			applications in agriculture are currently using big data and what techniques are employed for analysis. Various problems have been identified along with certain barriers and solutions for these problems were addressed with justification for barriers.	
4.	Agriculture	Iuliia Protopop and Aleksan Shanoyanb	This paper provides the utilization of big data applications and ICT adoption for the potential growth of agriculture in the developing countries. The case studies suggest that with the advancement of technologies (like mobile phones and cloud) provide an infrastructure for data collection and aggregation for development of big data applications.	[27]
5.	Agriculture	Alfons Weersink, Evan Fraser, David Pannell, Emily Duncan and Sarah Rotz	Paper emphasise that at present use of GPS technologies enable us to produce data more rapidly than we can analyze it, since generating data didn't require any specific skills set whereas adoption of variable technologies requires both new skills and decision-making models.	[29]
6.	Agriculture	Bellon-Maurel, Pascal Neveu, Alexandre Termier and Frédérick Garcia	Several barriers exist that are keeping stakeholders from adopting usage of ICT and big data in the agricultural sector. Beyond these barriers there are also certain risks involved from the development of technology in agriculture, such as farmers losing their autonomy, as the control is centralized in the hands of some global firms.	[30]
7.	Business	O.Liu, W.K. Chong, K.L. Man, and C.O. Chan	This paper discussed the application of big data analytics in various business situations and challenges. These business applications not only changed our everyday life but also bring problems related to security and privacy.	[7]

S.No.	*Domain*	*Author*	*Brief*	*References*
8.	Business	Ya Chuan YAO, Qiang HAN, Hong Ying YANG, Xu Yao ZHANG	This paper analysed the different parameters involving large amount of data in production of industry and design a micro cloud based distributed processing system and studies a storage scheme based on cloud computing.	[31]
9.	Banking	Elaheh Radmehr, Mohammad Bazmara	To achieve better and flawless decision making, depending upon the sheer volume of data, available through social or economical aspect of a financial organization, a bank requires strong and effective decision making tools. Business intelligence tools provide the past, present and future perspective in achieving better resource planning and customer relations.	[32]
10.	Education	Christos Vaitsis, Vasilis Hervatis and Nabil Zary	The goal of this chapter is to familiarise the user with the concept of educational data, scientific analytical techniques for data manipulation and how they can be utilized in health education system to exploit big data	[33]
11.	Education	ARCHANA RAO PN, KISHORE BAGLODI	This paper emphasise the use of big data in three main sections of education students, teachers and Institution. Every aspect of the education sector can be harnessed with suitable data mining technologies to predict and understand the relevant sentiments [9]	[20]
12.	Medical	Jing-Song Li, Yi-Fan Zhang and Yu Tian	This paper target the use of data generated from hospital information system (HIS). This data hold great value to patient care and treatment, the workflow management, scientific research, and education in healthcare industry. To improve the predictability of CP this study shows that combining traditional statistical and advanced semantic methods	[21]

S.No.	Domain	Author	Brief	References
			enables timely decision with final goal of improving healthcare quality	
13.	Transportation	Gang Zeng	Architecture of transportation system is proposed based on big data platform, challenges discussed and advantages of big data in transportation were outlined. At last the key technology in ITS is discussed emphasising on the advantages in the future.	[23]
14.	Transportation	Gavin Kemp, Genoveva Vargas-Solar, Catarina Ferreira da Silva, Parisa	This paper propose a service oriented architecture based on the usage of big data and cloud computing in transport applications, hosting several services to be composed to produce a DSS	[34]

This table reveals big data is used everywhere as agriculture, business, banking, education, medical etc. A number of architecture prototypes have been proposed by different researchers to improve big data process.

5. CONCLUSION

This paper includes the applications of big data in such fields of real world which influence the life of a common man for good. There is a growing use of Big data in basic utilities sector like power and water which requires to be explored further to provide better affordable solutions.

Moreover researcher can also focus on the use of big data in improving basic amenities of public and improving the standard of living in developing countries by focusing the use of Big data in fighting diseases. Also the technologies like mobile networking, data mining, multimedia, cloud computing, experts system can be enhanced by the use of big data.

Adaptive Control and Hybrid Projective Combination Synchronization of Chaos Generated by Generalized Lotka-Volterra Biological Systems

Ayub Khan[1] and Harindri Chaudhary[2]

ABSTRACT: *In this manuscript, we study hybrid projective combination synchronization (HPCS) between chaotic generalized three species Lotka-Volterra (GLV) biological system using adaptive control method. Lotka and Volterra introduced the well-known examples of basic biological models of two species predator and prey model. This system explains the interaction between two species predator-prey model and it contains a system of ordinary differential equations. Though it is a very famous model, it has many drawbacks, for instance, it avoids numerous essential characteristics such as interplay among another species of the similar ecosystem, connection with the environment and so on. Samardzija and Greller studied the dynamics and the chaotic analysis of GLV for the first time in the year 1988. Ever since the area of biological control in various biological systems existing in nature has been an active field for researchers and biologists. Here, we consider two predators and one prey population present in the biological system. Initially, this paper exhibits the phase portraits of GLV system, which is a 3-D chaotic system. The adaptive biological control law for attaining global and asymptotic hybrid projective chaos synchronization of the state variables of the system with uncertain parameters has been derived using Lyapunov stability theory (LST). Also, it is noted that both complete synchronization and anti-synchronization coexist in hybrid projective combination synchronization. Furthermore, numerical simulations are performed to show the efficiency and accuracy of the suggested scheme using MATLAB. Significantly, the analytical results are in*

excellent agreement with computational results. The considered approach has many applications in the field of secure communication and image encryption.

Keywords: Chaotic System, Hybrid Projective Synchronization, Combination Synchronization Lotka-Volterra System, Adaptive Control.

1. INTRODUCTION

Chaos theory is defined as the qualitative analysis of extremely complex nonlinear dynamical systems found in natural environment possessing inherent properties such as infinite recurrence, boundedness and high sensitivity to initial conditions. Chaos theory has a variety of applications in numerous fields of engineering and applied sciences, for instance, biomedical engineering [1], neural networks [2], weather models [3], ecological models [4], jerk systems [5], encryption [6], etc.

E.N. Lorenz [7] firstly discovered the most famous 3-D chaotic system in 1963 while studying a weather model for atmospheric convention. Consequently, Rossler [8] found an algebraically much simplified 3-D chaotic system other than the Lorenz system in 1976. These classical systems were ensued by the origination of several 3-D chaotic systems, for instance, Chen system, Sprott system, Lu-Chen system, Cai system, etc.

Generalized Lotka-Voltera (GLV) three-species model is the most prominent among all the existing biological models. Arnedo *et al*. [9] have demonstrated that three species can possess chaotic behavior in an ecosystem. Samardzija and Greller [10] studied GLV three species biological model in detail.

Pecora and carroll [11] firstly introduced the synchronization of chaotic dynamical systems in 1990 by applying master-slave configuration. Chaos synchronization is described as a procedure of adjusting identical or non-identical chaotic systems in such a way that both depict the same behavior owing to coupling to achieve stability. Till date, various types of synchronization techniques for chaotic systems have been developed such as complete synchronization [12], anti-synchronization [13], hybrid synchronization [14], hybrid projective synchronization [15], lag synchronization [16], phase synchronization [17] etc.

Up to now, numerous schemes have been introduced in control theory to stabilize the chaos including the active control [18], adaptive control [19], backstepping design [20], feedback control [21],sliding mode control [22],

etc. In the available literature, for an integer order dynamical system to be chaotic, the dimension of the state equations should be at least three and at least one Lyapunov exponent must be positive.

Chaos synchronization and control among chaotic systems using adaptive control scheme was firstly advocated by Hubler in 1989. [23]. Mainieri and Rehacek [24] in 1999 introduced the concept of projective synchronization for synchronizing the chaotic systems. In [25], synchronization of a modified Chua's circuit system using adaptive control method has been studied. Moreover, projective synchronization and chaos in secure communication are studied in [26]. Also, in [27], adaptive backstepping technique for synchronizing chaotic systems has been investigated. In [28] and [29], ACM is discussed to synchronize the generalized three species Lotka-Volterra biological system.

Considering the above mentioned discussions, this paper aims to investigate a hybrid projective combination synchronization (HPCS) between three identical GLV systems by using ACM. Adaptive control technique is very important to estimate the parameters between master and slave systems. Also, based on LST, we examime in detail an adaptive control law together with an estimated parameter update laws.

The description of the present paper is as follows: Section 2 deals with the preliminaries containing some notations and essential terminology to be used in the upcoming sections. Section 3 contains the basic structured properties of the considered GLV system. Section 4 investigates the ACM along with a parameter estimation update laws to stabilize asymptotically and globally the given GLV system. Section 5 contains the numerical simulations illustrating the effectiveness and feasibility of the considered HPCS approach. Lastly, Section 6 concludes the paper.

2. PRELIMINARIES

In this section, we describe the methodology to achieve combination synchronization according to master-slave configuration among three identical integer order chaotic systems with two master systems and one slave system which are requisites for the upcoming sections.

Two master systems and one slave system are considered as:

$$\dot{w}_1 = g_1(w_1)\eta_1 + G_1(w_1) \quad \ldots (1)$$

$$\dot{w}_2 = g_2(w_2)\eta_2 + G_2(w_2) \quad \ldots (2)$$

$$\dot{z}_1 = h_1(z_1)\theta_1 + H_1(z_1) + u_1 \quad \ldots (3)$$

where $w_1 = (w_{11}, w_{12}, \ldots, w_{1n})^T \in R^n$, $w_2 = (w_{21}, w_{22}, \ldots, w_{2n})^T \in R^n$, $z_1 = (z_{11}, z_{12}, \ldots, z_{1n})^T \in R^n$ are the state vectors of master and slave systems (1), (2) and (3) respectively, $G_1, G_2, H_1 : R^n \to R^n$ are three nonlinear continuous functions, $\eta_1 = (\eta_{11}, \eta_{12}, \ldots, \eta_{1p_1})^T$ is a $p_1 \times 1$ unknown parameter vector of the first master system (1), $\eta_2 = (\eta_{21}, \eta_{22}, \ldots, \eta_{2p_2})^T$ is a $p_2 \times 1$ unknown parameter vector of the second master system (2), $\theta_1 = (\theta_{11}, \theta_{12}, \ldots, \theta_{1p_3})^T$ is a $p_3 \times 1$ unknown parameter vector of the slave system (3), $g_1 : R^n \to R^{n \times p_1}$, $g_2 : R^n \to R^{n \times p_2}$, $h_1 : R^n \to R^{n \times p_3}$, $u_1 = (u_{11}, u_{12}, \ldots, u_{1n}) \in R^n$ is the appropriate controller which is to be designed.

Definition 1: If there exist three constant matrices $P, Q, R \in R^n \times R^n$ and $R \neq 0$ such that:

$$lim_{t \to \infty} \| E \| = lim_{t \to \infty} \| (Pw_1 + Qw_2 - Rz_1) \| = 0$$

the combination of two master systems (1) and (2) is said to perform combination synchronization with one slave system (3) and $\|.\|$ denotes matrix norm.

Remark 2.1: The constant matrices P, Q and R are called the scaling matrices. Moreover,P, Q and R can be extended as matrices of functions of state variables w_1, w_2 and z_1.

Remark 2.2: The problem of combination synchronization will be converted into the chaos control issue for $P = Q = 0$.

Remark 2.3: If $R = -I$ and $P = Q = -\beta I$, for $\beta = 1$ it turns into combination completes synchronization and for $\beta = -1$ it will be reduced to combination anti-synchronization. Combination of complete and anti- synchronization makes hybrid projective combination synchronization (HPCS). Thus the HPCS error takes the form :

$$E = z_1 - \beta(w_1 + w_2), \quad \ldots (4)$$

where $\beta = \text{diag}(\beta_1, \beta_2, \ldots, \beta_n)$.

Remark 2.4: Definition 1 displays that the combination of master systems and slave systems may be expanded to more systems. Further, master systems and slave systems of the combination synchronization scheme can be identical or non-identical.

3. DESCRIPTION OF 3-D GLV CHAOTIC SYSTEM

Introduced by Samardzija *et al*. [10] in 1988, the considered chaotic system famously known as Generalized Lotka-Volterra (GLV) three species biological system is described as:

$$\begin{cases} \dot{x}_{11} = & x_{11} - x_{11}y_{11} + n_1 x_{11}^2 - l_1 x_{11}^2 z_{11} \\ \dot{y}_{11} = & -y_{11} + x_{11}y_{11} \\ \dot{z}_{11} = & m_1 z_{11} + l_1 x_{11}^2 z_{11} \end{cases} \quad \ldots (5)$$

where $(x_{11}, y_{11}, z_{11})^T \in R^3$ is the state vector and l_1,m_1 and n_1 are positive parameters. Also, in (5), x_{11} represents the prey population and y_{11}, z_{11} denote the predator populations. For $l_1 = 2.9851$, $m_1 = 3$ and $m_1 = 3$ and $n_1 = 2$,the system (5) depicts chaotic behaviour. Also, Figure 1(a-d) display the phase plots of (5). Moreover, the detailed theoretical study and numerical simulation results for (5) can be found in [10].

4. ILLUSRATIVE EXAMPLE

In this section, we discuss HPCS scheme to obtain the laws in order to estimate parameters together with adaptive laws in such a way that all the state variables x_{11}, y_{11} and z_{11} tend to equilibrium points as t approaches infinity.

Here, the two master systems and the corresponding slave system with controllers can be defined as:

$$\begin{cases} \dot{x}_{11} = & x_{11} - x_{11}y_{11} + n_1 x_{11}^2 - l_1 x_{11}^2 z_{11} \\ \dot{y}_{11} = & -y_{11} + x_{11}y_{11} \\ \dot{z}_{11} = & m_1 z_{11} + l_1 x_{11}^2 z_{11} \end{cases} \quad \ldots (6)$$

$$\begin{cases} \dot{x}_{21} = & x_{21} - x_{21}y_{21} + n_1 x_{21}^2 - l_1 x_{21}^2 z_{21} \\ \dot{y}_{21} = & -y_{21} + x_{21}y_{21} \\ \dot{z}_{21} = & m_1 z_{21} + l_1 x_{21}^2 z_{21} \end{cases} \quad \ldots (7)$$

$$\begin{cases} \dot{x}_{31} = & x_{31} - x_{31}y_{31} + n_1 x_{31}^2 - l_1 x_{31}^2 z_{31} + u_{11} \\ \dot{y}_{31} = & -y_{31} + x_{31}y_{31} + u_{12} \\ \dot{z}_{31} = & m_1 z_{31} + l_1 x_{31}^2 z_{31} + u_{13}, \end{cases} \quad \ldots (8)$$

where u_{11},u_{12} and u_{13} are adaptive controllers to be designed in such a manner that HPCS between three identical chaotic systems will be obtained.

Define now the state errors as

$$\begin{cases} E_{11} = & x_{31} - \beta_1(x_{11} + x_{21}) \\ E_{12} = & y_{31} - \beta_2(y_{11} + y_{21}) \\ E_{13} = & z_{31} - \beta_3(z_{11} + z_{21}) \end{cases} \quad \ldots (9)$$

The main goal of this paper is to introduce controllers $u_{1i}, (i = 1,2,3)$ so that the state errors defined in (9) satisfy

$$lim_{t\to\infty} E_{1i}(t) = 0 \; for \; (i = 1,2,3).$$

The consequent error dynamics is transformed as:

$$\begin{cases} \dot{E}_{11} = & E_{11} - x_{31}y_{31} + n_1x_{31}^2 - l_1x_{31}^2z_{31} - \beta_1(x_{21}y_{21} + n_1x_{21}^2 \\ & -l_1x_{21}^2z_{21} - x_{11}y_{11} + n_1x_{31}^2 - l_1x_{11}^2z_{11}) + u_{11} \\ \dot{E}_{12} = & -E_{12} + x_{31}y_{31} - \beta_2(x_{11}y_{11} + x_{21}y_{21}) + u_{12} \\ \dot{E}_{13} = & -m_1E_{13} + l_1x_{31}^2z_{31} - \beta_3(l_1x_{21}^2z_{21} + l_1x_{11}^2z_{11}) + u_{13} \end{cases} \quad \ldots (10)$$

Now, we define the adaptive controllers as:

$$\begin{cases} u_{11} = & -E_{11} + x_{31}y_{31} - \hat{n}_1x_{31}^2 + \hat{l}_1x_{31}^2z_{31} + \beta_1(x_{21}y_{21} + \hat{n}_1x_{21}^2 \\ & -\hat{l}_1x_{21}^2z_{21} - x_{11}y_{11} + \hat{n}_1x_{31}^2 - \hat{l}_1x_{11}^2z11) - K_1E_{11} \\ u_{12} = & E_{12} - x_{31}y_{31} + \beta_2(x_{11}y_{11} + x_{21}y_{21}) - K_2E_{12} \\ u_{13} = & \hat{m}_1E_{13} - \hat{l}_1x_{31}^2z_{31} + \beta_3(\hat{l}_1x_{21}^2z_{21} + \hat{l}_1x_{11}^2z_{11}) - K_3E_{13} \end{cases} \quad \ldots (11)$$

where K_1, K_2 and K_3 are positive gain constants

By substituting the values of controllers (11) in error dynamics (10), we get

$$\begin{cases} \dot{E}_{11} = & (n_1 - \hat{n}_1)x_{31}^2 - (l_1 - \hat{l}_1)x_{31}^2z_{31} - \beta_1\,[(n_1 - \hat{n}_1)x_{21}^2 \\ & -(l_1 - \hat{l}_1)x_{21}^2z_{21} + (n_1 - \hat{n}_1)x_{11}^2 - (l_1 - \hat{l}_1)x_{11}^2z_{11}] - K_1E_{11} \\ \dot{E}_{12} = & -K_2E_{12} \\ \dot{E}_{13} = & -(m_1 - \hat{m}_1)z_{31} + (l_1 - \hat{l}_1)x_{31}^2z_{31} + \beta_3\,[(m_1 - \hat{m}_1)z_{11} \\ & -(l_1 - \hat{l}_1)x_{21}^2z_{21} + (m_1 - \hat{m}_1)z_{11} - (l_1 - \hat{l}_1)x_{11}^2z_{31}] - K_3E_{13} \end{cases} \quad \ldots (12)$$

where $\hat{l}_1$, $\hat{m}_1$ and $\hat{n}_1$ are estimated values of unknown parameter l_1, m_1 and n_1 respectively.

Now defining parameter estimation error as:

$$\tilde{l}_1 = l_1 - \hat{l}_1, \tilde{m}_1 = m_1 - \hat{m}_1, \tilde{n}_1 = n_1 - \hat{n}_1, \quad \ldots (13)$$

Applying (13), the error dynamics (12) simplifies as:

$$\begin{cases} \dot{E}_{11} = & \tilde{n}_1(x_{31}^2 - \beta_1 x_{21}^2 _ \beta_1 x_{11}^2) - \tilde{l}_1(x_{31}^2 z_{31} - \beta_1 x_{21}^2 z_{21} - \beta_1 y_{11} z_{11}) - K_1 E_{11} \\ \dot{E}_{12} = & -K_2 E_{12} \\ \dot{E}_{13} = & -\tilde{m}_1 E_{13} + \tilde{l}_1(x_{31}^2 z_{31} - \beta_3 x_{21}^2 z_{21} - \beta_3 x_{11}^2 z_{11}] - K_3 E_{13} \end{cases}$$

The derivative of the parameter estimation error (13), we get

$$\dot{\tilde{l}}_1 = -\dot{\tilde{l}}_1, \dot{\tilde{m}}_1 = -\dot{\tilde{m}}_1, \dot{\tilde{n}}_1 = -\dot{\tilde{n}}_1 \quad \ldots (14)$$

The Lyapunov function is constructed as

$$V(E(t)) = \frac{1}{2}\left[E_{11}^2 + E_{12}^2 + E_{13}^2 + \tilde{l}_1{}^2 + \tilde{m}_1{}^2 + \tilde{n}_1{}^2\right] \quad \ldots (15)$$

which implies that $V(E(t))$ is positive definite .

Derivative of the Lyapunov function $V(E(t))$ is given by

$$\dot{V}(E(t)) = E_{11}\dot{E}_{11} + E_{12}\dot{E}_{12} + E_{13}\dot{E}_{13} - \tilde{l}_1\dot{\tilde{l}}_1 - \tilde{m}_1\dot{\tilde{m}}_1 - \tilde{n}_1\dot{\tilde{n}}_1 \quad \ldots (16)$$

Keeping (16) in view, we describe the parameter estimates laws by the following rule:

$$\begin{cases} \dot{\tilde{l}}_1 = & -(x_{31}^2 z_{31} - \beta_1 x_{21}^2 z_{21} - \beta_1 x_{11}^2 z_{11})E_{11} + (x_{31}^2 z_{31} - \beta_3 x_{21}^2 z_{21} \\ & -\beta_3 x_{11}^2 z_{11})E_{13} + K_4 \tilde{l}_1 \\ \dot{\tilde{m}}_1 = & -E_{13} + K_5 \tilde{m}_1 \\ \dot{\tilde{n}}_1 = & x_{31}^2 - \beta_1 x_{11}^2 - \beta_1 x_{21}^2 + K_6 \tilde{n}_1, \end{cases} \quad \ldots (17)$$

where K_4, K_5 and K_6 are positive gain constants.

Theorem 1: The chaotic systems (6)-(8) are globally and asymptotically hybrid projective combination synchronized for each initial states $(x_{11}(0), y_{11}(0), z_{11}(0)) \in R^3$ by the adaptive controller (11) and the parameter update law (17).

Proof: The Lyapunov function $V(E(t))$ as defined in (15) is a positive definite function in R^6. On simplifying equations (16) and (17),we have

$$\dot{V}(E(t)) = -K_1 e_{11}^2 - K_2 e_{12}^2 - K_3 e_{13}^2 - K_4 \tilde{l}_1{}^2 - K_5 \tilde{m}_1{}^2 - K_6 \tilde{n}_1{}^2 < 0$$

which establishes that $\dot{V}(E(t))$ is negative definite.

Hence, by using LST, we deduce that the HPCS errror $E(t) \to 0$ asymptotically as $t \to \infty$ for each initial conditions $E(0) \in R^3$. This ends the proof.

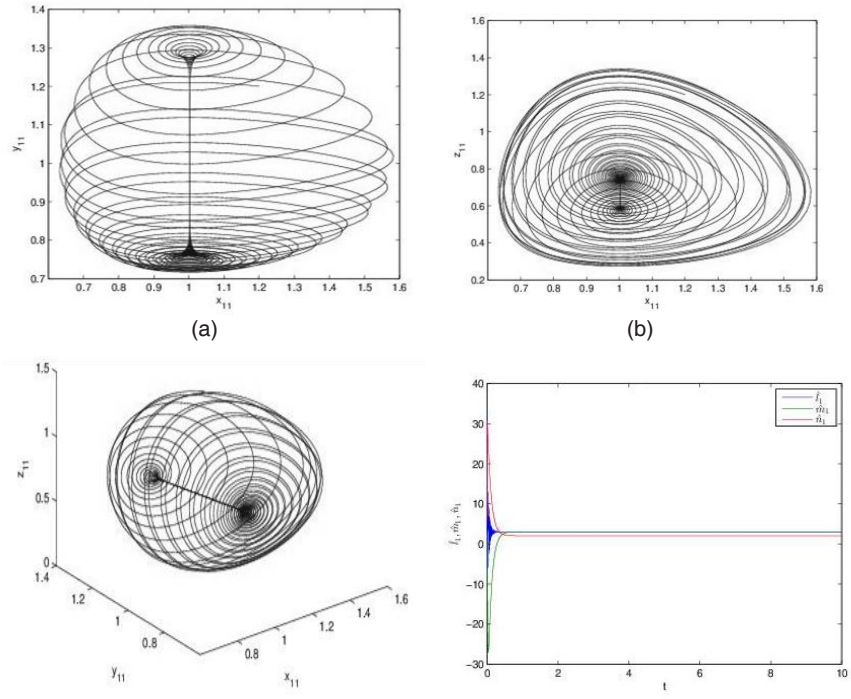

Fig. 1: Phase Plots of 3-D GLV Chaotic System in (a) $x_{11} - y_{11}$ Plane, (b) $y_{11} - z_{11}$ Plane, (c) $x_{11} -$ y11-z11 Space, (d) Parameter Estimation

5. NUMERICAL SIMULATION

In this section, we present some simulation experiments to illustrate the effectiveness and feasibility of the proposed HPCS scheme using ACM. To achieve this, we use the fourth-order Runge-Kutta method to solve systems of ordinary differential equations. The parameters of the given system are taken as $l_1 = 2.9851$, $m_1 = 3$ and $n_1 = 2$ to show that the system behaves chaotically in the absence of control inputs. The initial states of the master and slave systems are $(x_{11}(0) = 27.5, y_{11}(0) = 23.1, z_{11}(0) = 11.4$, $(x_{21}(0) = 1.2, y_{21}(0) = 1.2, z_{21}(0) = 1.2$ and $(x_{31}(0) = 2.9, y_{31}(0) = 12.8, z_{31}(0) = 20.3$ respectively.

We achieve hybrid projective synchronization between master and slave systems by choosing the scaling matrix β with $\beta_1 = 2, \beta_2 = -4, \beta_3 = 3$. Here, the control gains are taken as $K_i = 6$ for $i = 1, 2, 3$. The numerical simulations are exhibited in Fig. 2(a-c) which display the state trajectories of master and slave systems. The synchronization errors $(e_{11}, e_{12}, e_{13}) =$

$(-54.5,110,-17.5)$ approaches zero as t approaches infinity in Figure 2(d). Moreover, Figure 1(d) depicts that estimated values $(\hat{l}_1, \hat{m}_1, \hat{n}_1$ of unknown parameters converge respectively to their original values asymptotically with time. Therefore, the proposed HPCS scheme between master and slave system is verified computationally.

6. CONCLUSION

In this paper, we have investigated the proposed HPCS scheme between identical chaotic GLV system via adaptive control technique. By designing proper control inputs based on LST, the considered HPCS technique is achieved. The particular cases of anti-synchronization, complete synchronization, and chaos control problem are also discussed. The effectivity and feasibility of the theoretical results are justified in simulations by using MATLAB. Remarkably, the theoretical analysis and the numerical results both are in complete agreement. In fact, the considered HPCS scheme has potential and advantages as it has various applications in encryption and secure communication. In our investigation, the time taken by the synchronization error converging to zero is less in comparison with other related published work. We noticed that our discussed technique is basic yet theoretically rigorous. Moreover, we understand that the investigated HPCS scheme may be generalized by using other control techniques.

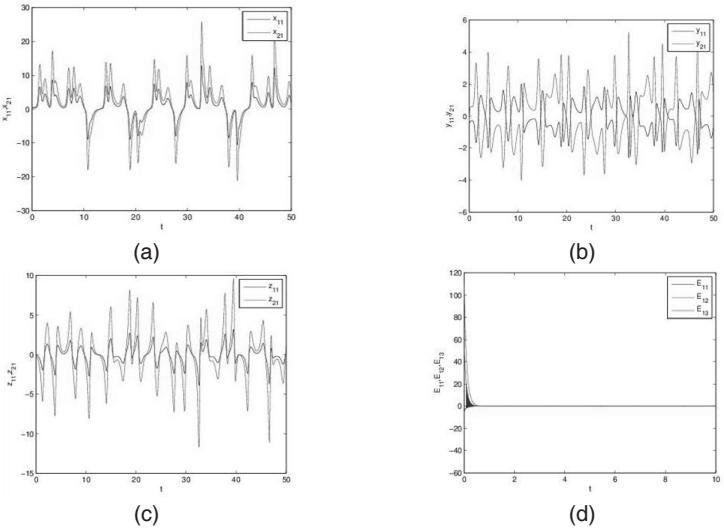

Fig. 2: HPCS Trajectories of GLV System (a) between $x_{11}(t) - x_{21}(t)$, (b) between $y_{11}(t) - y_{21}(t)$, (c) between $z_{11}(t) - z_{21}(t)$, (d) HPCS Synchronization Error

E-Leaning:
Emerging Trend in Learning

Diksha Grover[1] and Shweta Paradkar[2]

ABSTRACT: *In a fast developing nation like India where the majority of the population comprises of young adults, a strong education system is must for the overall growth and development of the nation. Unfortunately, our educational planners and policy makers have not succeed in providing quality education and the required infrastructure to the remote locations, thus depriving the youth of the country the basic education. Thus our educational planners are in the view that E-learning can overcome this problem through effective utilization of the resources in a cost effective manner. E-learning has a larger outreach and thus can have a larger audience. Today, integration of digital technology in all areas of businesses and technology is changing how enterprises offering corporate training. As digital transformation has made the enterprises to think how employees should be trained. Today the enterprises are gradually moving from the traditional classroom-based training approach to technology-enabled eLearning instead. The percentage of on line learning is increasing day by day as E-Learning is becoming very popular at different places of work. Whether E-Learning is the solution for all the businesses so in this regard we have discussed that enterprises providing corporate training should consider the advantages and disadvantages of eLearning when seeking out a solution to meet the challenges of business world. This paper review one case study that provides a direct comparison of direct classroom teaching and teaching through E-Learning environment. The study was conducted to know whether there is any major difference in students learning and their performance when learning is through E-learning based approach and through classroom lecture based learning approach. In addition*

1. INTRODUCTION TO E-LEARNING

E-Learning a platform to provide skills and knowledge with the help of technology enablers i.e. computer, smart devices and internet networks. E-Learning consists of applications and processes that includes internet based learning, computer based learning and training, virtual learning prospects and digital collaboration. E-Learning Content can be self paced or instructor controlled and it can be in the form of text, audio, image, streaming video and audio. E-Learning can be used by a wide range of people who have difficulty in attending conventional classroom training due to many reasons such as geographically dispersed with limited time and resources, restricted from participating in classroom sessions because of cultural and religious beliefs, located in conflict and post conflict areas.

1.1 Techniques and "Tools of E-Learning"

1. **Smart Class Room:** Smart classroom an E-learning tool, aims at developing the students learning ability and in order to grow academically teacher can use different methods of teaching and learning are necessary to inculcate deeper level of growth and conceptual development. It is a step to the future of education. Teachers can choose variety of technologies including slide presentation, Audio and video conferencing, Application sharing, Shared whiteboard etc.
2. **Use of Technology in Education in Rural and Isolated Communities:** The increased availability of low cost video cameras those in mobile phones helps teachers to take short videos of their peers and then jointly review and discuss pedagogical approaches and specially difficult topics to teach in informal way as a part of their professional development. Lack of resources (including textbooks and other teaching materials), promoting more use of mobile phones helping teachers in small but meaningful ways by providing access to education content. Generally the places where Internet connectivity is unreliable innovative approaches to caching and distributing digital content can enable off-line access to vast numbers of online resources enabling the students to access and read on their small devices.

E-Shalas provide education to children in rural areas, mostly in areas where power supply doesn't exist and literacy levels are low. High school students sit in a smart classroom and learn their lessons on an entirely latest solar-powered LED projector. The syllabus of e-Shalas is available in both Kannada and English, with a voice-over making the lessons self-explanatory. The visual instruction encapsulate the content knowledge and can be accessed via devices such as Android mini-PCs, tablets and mobile phones. The teachers are given a tablet loaded with the same content, so they are well-versed with the lessons before they run it in the classroom. This unique projector has an android mini-computer, speakers, power supply panel and remote mouse fitted to it, which makes it energy-efficient. As against the normal LED projector's power consumption of 250-watt, this projector consumes only 25 watts. The solar panel on the building terrace is a single 75-watt power panel and the entire system costs less than INR 1,00,000 (one-time investment).

Fig. 1: e-Shala Solar Powered Classes in Addagal Rural School (Karnataka)

3. **Computer Based Training Tools:** In today's digital world, we need CBT Tools to upload or create learning materials for effective students learning and can also provide corporate training to your employees by providing training material or by creating your own training site. For example **iSpring Learn** is a cloud-based LMS. In iSpring Learn, you can upload an unlimited number of training materials (presentations, text documents, video and audio files, as well as SCORMcourses).

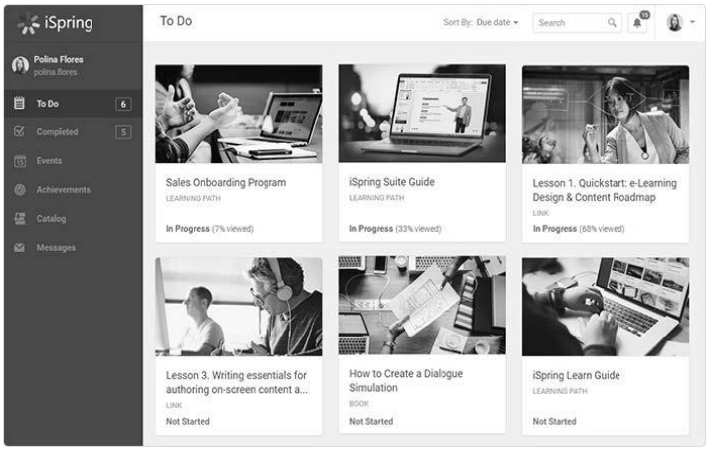

Fig. 2: Ispring (a cloud based LMS)

Learn Cube is a **virtual classroom learning tool** that offers live video and Audio support, various classroom communication tools, class scheduling, and media sharing. During online classes, teachers can interact with learners via video and text chat, use a whiteboard for explaining the learning material, and share content including PDFs, audio files, videos, and measure their performance using online quizzes and tests.

2. E-LEARNING—A DIGITAL TRAINING PLATFORM FOR CORPORATES

Integration of digital technology in all areas of businesses and technology is also changing how enterprises offering corporate training. As digital transformation has made the enterprises to think how employees should be trained and organizations have recognized the training an employee is much easier and less expensive than replacing them. Today the enterprises are gradually moving from the traditional classroom-based training approach to technology-enabled eLearning instead. The percentage of on line learning is increasing day by day as E-Learning is becoming very popular at different places of work.

- The main advantage of providing training to the employs using **E-Learning** as compared to traditional methods of training it can be delivered fast and employee can learn anywhere and at anytime regardless of geography and time zones.
- **Training through E-learning** is less expensive as compared to the traditional tainting that must be developed in house in a classroom

style format where a dedicated staff, room and devices are required whereas E-Learning can be instituted immediately.

- **E-Learning** is tailor-made as it ensures that each employee learns the skills that should matched with the business needs of the organization.
- **E-Learning** can easily be scale as we have one employee to provide training, a dozen or even a hundred, eLearning will work for all of them.
- In some situations **E-Learning** is not a complete solution as some of us learn better when we can discuss our knowledge and ideas with others in these situations one can go for blended learning –mix of online and instructor-led courses.
- **Training to employees through E-Learning** fails to offer the hands-on experience that helps people to retain new knowledge and skills, so one should look for the E-Learning techniques that offer hands-on projects to learn new skills and virtual labs for software development classes.

There are a number of **Web Based Authoring Software's** that helps us to provide online training to employees and to create own training site. One of the example of such tools T**ovuti** (https://www.tovuti.io) is web-based training software that allows you to buildyour own online training site and add thelearning content in the form of videos, power points, PDF's, SCORM files etc. This authoring tool offers more than50 different types of training activities and assignments that can be used to builde-courses.

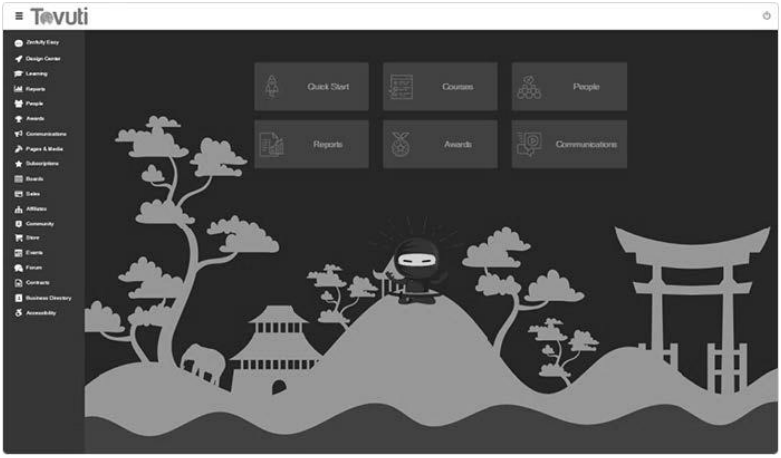

Fig. 3: Tovuti (a web based authoring tool)

3. E-LEARNING AND RURAL INDIA

India has witnessed the education divide in terms of equality and accessibility for decades now. It is expected that the population of the country will touch 1.5 B by 2030 and 1.7B by 2050; hence, the existing physical infrastructure will fall short of meeting the learning needs of this ever-growing population. Being enormously diverse nation, along with infrastructure being the major hurdle, language and content also pose problems. It is very difficult to provide quality teachers in every remote part of the country or even in the semi urban and urban areas.

Over 60% of students up to the age of ten in the rural India, lack basic reading skills. There has been a considerable improvement in the Pupil Teacher Ratio in the past decade, yet the single teacher schools in rural parts accounting 8.8 percent of the total schools in India, is the major concern of the education system. These are the main factors contributing towards degrading quality of education and high school dropout rates by the age of fourteen.

Thus, the importance of e-learning cannot be over emphasized providing best learning resources to the student's right at the comfort of their home and convenience. India provides one of the cheapest internet facilities across the world making it even more convenient for the users to access these resources rather than spending hundreds of rupees on the books."E-Kranti", an initiative undertaken by the government with collaborations various telecom companies for providing basic internet services in the most remote locations of the country under the Digital India campaign. The barriers faced by the teachers in the rural areas can be listed as limited training in the use of digital tools, no prior experience in using latest technologies or tools. This problem can be overcome by training the trainers, initiated by several government and non-government organizations (NGO's) on using various digital tools such as LCD screens, smart boards etc, to teach different concerts through these learning aids. A single teacher can address a larger audience located across remote areas along with overcoming the problem of shortage of teachers.

The union budget of 2018–19 has allocated a sum of Rs. 456 cr towards the development and deployment of the infrastructure across the rural locations in order to bring about a sea change in the style of learning. The NGO's play a very significant role in spreading e-learning across the villages and rural area in the country. 'PRATHAM" is one such program in collaboration with Vodafone, who have inducted digital classroom called "Learn, out of the box" to enrich and enhance the quality of

education. The teachers have the freedom to design the content and curriculum as per the need of the students depending upon the area and location under the following pointers:

- The content should have a sense of purpose that is achievable.
- Due consideration given to time and space constraints, yet involve a complete participation.
- Discovering individual talents.
- Learning outcome closely linked with the practical application.

Fig. 4: A School in Amravati District Using Alexa for E-learning

4. E-LEARNING AND WOMEN

Women have always been considered the weaker sex in the society through generation across the globe. They had to face restriction, cultural and societal pressures and were always considered a handicap. However, being one of the fastest growing economies in the world, socio-economic development of women is a key pillar that holds the development of the entire nation. Empowerment of women being with providing them basic education so that they understand their fundamental rights and duties. In rural India, women are not given the opportunities to complete their primary education, where there is still a gender divide when it comes to empower women. For women who are not allowed to go to school, or drop out at the primary level, or are not able to complete their education due to either family, financial pressure or distance being hindrance in their progress, e-learning can offer a life changing solution, create social and legal awareness and overall upliftment of the society, confront the patriarchal forces. E-learning offers a viable solution to the barriers related to the women education. E-learning can:

- Help raise the self esteem.
- Help complete the education at any level.
- Give the liberty to study at their own pace, time and place.
- Increase career opportunities, earn income, become financially independent.
- Help women look after their families and yet have a career.
- Help women contribute to society and have an analytical approach.

Thus, e-learning serves as a very powerful tool for women to empower themselves as well as society in general.

5. E-LEARNING AND EMPLOYABILITY

Employment opportunities are one of the major concerns of students pursuing online courses and they still have a long way to go as compared to regular campus based courses or degrees. But the future prospects for online courses are on an upward trend. Currently, India is only second to USA in the number of e-learners and is expected to grow leaps and bounds by the year 2025. The online education market stands USD 247 million that will grow to about USD 1.96 billion by the year 2021. The students mainly opt for online courses for pursuing PG courses, mostly in tier 1 cities, whereas in tier 2cities they go for online course that provide lucrative job opportunities.

Several online courses offer different programs to improve skill set of an individual for promotion and appraisal chances. The working professional can enroll in such courses in the comfort of their homes and improve upon their knowledge base. An added degree or a certificate course can do wonders to the resume of a student or professional. Many universities in India offer many such courses that everyone can take advantage.

Some online course offer preparatory programs for clearing competitive examinations specially in the tier 2and 3 cities, where exam specific mobile app helps prepare for these examination in lack of quality teachers through mock tests, videos, counseling, and webinar. MOOC's (Massive Open Online Courses) has been revolutionary in e-learning globally and offers many lectures even helpful for the educators .

E-learning has created massive impact on the way education can reach all irrespective of age, sex, caste and creed. Factors that make e-learning a preferred choice:

- E-learning comes with low cost as compared to regular courses. Even the lectures recorded once can be used any number of times anywhere.

- It offers complete flexibility in terms of choice of place, time and pace, which suits the busy schedule of an individual.
- Learn on the move. We can access contents from anywhere and do not have dependency of going and sitting in a classroom.
- The whole concept of e leaning is to make education more available and interesting.

However, there are areas where e-learning can have few disadvantages:

- Computer proficiency is a very important prerequisite of e-learning and some user may find it very tedious affair as not everyone is comfortable in front of a machine ad prefer traditional classrooms.
- Dependency on good internet connection, which can be a major hindrance sometimes.
- Learners may lose interest or motivation since there are no fixed schedules.
- Lack of proper assessment and evaluation, as students might not be honest while answering.

6. A REVIEW OF CASE STUDIES OF E-LEARNING PROJECTS CARRIED OUT IN THE FIELDS OF BANKING, FINANCE AND INSURANCE SECTORS

E-Learning has been successfully integrated into the corporate world and various companies for educating, informing and spreading awareness among both employees and customers. A learning management system forms the basis for training, educating, assessing and delivering content.

We review the case study of Enhance System Private Limited, a company based in Delhi that specializes in providing e solutions to various banking and financial firms for over 12 years. In the review we discuss how Enhance System has helped ICICI bank, one of the largest banks in India, develop customized content, e-learning software and training management systems.

6.1 Enhance Assists the Bank in Training the Employees to Better Understand Their Product and Sell Them

The Enhance System developed a module that provided the required information about the products being offered by the bank, also effectively train its employees to understand the products thoroughly and hence be able to sort out the customer queries. The features of each product were explained through the intense use of graphics and quizzes. The executives were exposed to interactive real life scenarios between the bank and

customer. A feedback mechanism was provided to have a comprehensive leaning of the module. This module is currently live and the employees are trained using the same.

6.2 Enhance Provides E-solutions with Design Mechanism for Instructional Strategies for Its Banking Clients

For managing the instructional design strategies, Enhance Systems partitioned each objective into smaller topics, which then underwent treatment on levels of interactivity from being empirical to simple knowledge, creating real life scenarios with the use of graphics. Later in the stage role plays, case studies, and stories were inducted. Modules were successfully accepted by the bank.

6.3 Enhance Develops Simulations for Managing Sales for ICICI Bank

For the purpose of absorption through campuses across India, ICICI bank felt a requirement of providing information on banking and finance through e-learning. Enhance provided a LMS to prepare students in banking field for absorption. For this Enhance integrated its own LMS with other LMs already into the system and with success. It was the first time that such concept was introduced in educational institutes. The LMS was hosted on temporary servers and was able to handle service calls from students. It resulted in ICICI bank getting favorable response from the colleges.

6.4 Enhance Uses Simulation Method for Counseling for ICICI Bank

ICICI bank is one of the biggest recruiters in India and their young recruits face the task of leading the teams very early in their careers and face the heat. For this they needed counseling. Enhance developed a simulations for the users to go through real life situations. A counselee would be there in front and data would be supplied from the background on which the users willinteract with the simulation and answer accordingly. Additional support through a mentor was provided that could be called upon at any stage for guidance. An audit is provided to user at the end of the session on his performance with a constructive feedback.

6.5 Enhance Distributes Learning Material on CD's

Enhance distributes course content on CD's which were also made available via LMS of the Enhance. This helped the employees to study

these courses at their leisure if the internet facilities were down. These could be viewed offline as well as updated versions using LMS.

From the above case study, the importance e-learning is shown across various applications in which e-learning can be helpful for acquiring additional skill.

7. CONCLUSION

E-learning has made a very strong impact on the learning and teaching in general. Looking at the current trends in India it is very safe to say that the markets are expected to grow considerably in the next five years. Many universities and institutes have adopted e-learning to increase the trainers and students access to information. It is improving the literacy rate across the country at a very fast pace. It has help to address and overcome a majority of problems related to higher education and bridge the gap between the rural and urban parts of the country. E-Learning has helped the employees in corporate sector to learn and master new skills in order to meet the challenges in changing technology at such a rapid pace. E-learning has raised the level of literacy and economic development in countries where technical education is costly, opportunities are limited and economic disparities exist.

An ANFIS-based compatibility scorecard for IoT integration in websites

Akshi Kumar[1] · **Anshika Arora**[1]

© Springer Science+Business Media, LLC, part of Springer Nature 2019

Abstract

Cyber-physical systems and Internet of Things (IoT) form two different levels of the vertical digital integration. Integration of websites with IoT-connected devices has compelled creation of new web design and development strategies where websites are designed keeping in mind the permutations of smart devices. The design should be seamless across different devices and the website design company or web designer should be well informed and aware of the different considerations for design with IoT interactions. In this work, we expound the effectiveness of IoT integration in website design. To realize an IoT-powered IT ecosystem as an essential technology for improving customer experience, a strength–weakness–opportunity–threat analysis is done. Further, with an intent to apprehend the integration support that an existing GUI front end may provide to a smart device, an ANFIS model is proposed to determine the compatibility of an e-commerce website for integration with IoT devices. A dataset of 600 e-commerce websites from .com domain is used to train and test the learning model. Seven features (page loading speed, broken links, browser compatibility, resolution, total size, privacy and security, and interface and typography) which impact the compatibility of IoT integration in websites have been used. Evaluation criteria for assigning score to each feature has been identified. Finally, the compatibility score, the $\text{IoTScore}_{\text{site}}$ which evaluates the websites' integration capabilities and support to IoT devices is generated by adding all the feature scores. The preliminary results generated using the prediction model clearly determine the worthiness of website for IoT integration.

Keywords IoT integration · Website design · Cyber-physical systems · ANFIS · Machine learning

1 Introduction

An IoT is a network of objects embedded with electronics, software, network connectivity and sensors [1]. It is about connecting numerous heterogeneous cyber-physical devices or things that sense, monitor, analyse and adapt stochastic events gathered without human origination to create value from autonomic agents that process data, to create granular knowledge and wisdom for both machines or humans to make smarter decisions and actions [2]. It merges the virtual and physical worlds, creating a smart environment such that when these devices share and analyse data, they have the capability to transform our lives in innumerable ways. Figure 1 explains how IoT and cyber-physical systems (CPS) are connected.

A generic IoT system involves three key components:

1. *Embedded systems* Consists of heterogeneous sensors responsible for providing information about the physical entity.
2. *Middleware* Is responsible for data aggregation, acquisition control and network connectivity.
3. *Cloud services* Provides comprehensive storage, computation, analytics, application hosting and management mechanisms.

IoT is a biggest frontier which can improve our lives in many aspects. This cutting-edge technology not only affects the consumers but also the providers of IoT solutions. With the ubiquitous internet connectivity and bandwidth in abundance along with reduced cost of wearables and smart devices, the impact of the Internet of Things (IoT) and technology in our lives is manifold and profound. IoT devices are

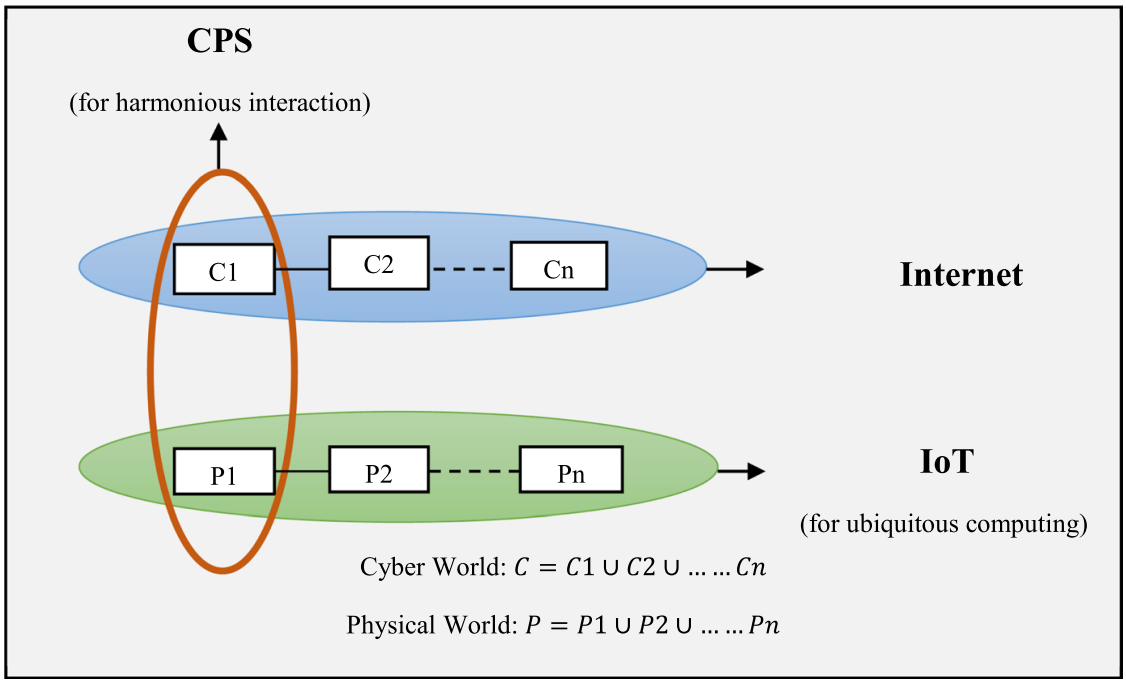

Fig. 1 Interconnection between IoT and CPS

becoming a part of the mainstream electronics culture [3]. According to Statista,[1] the IoT market is expected to reach $457 billion by 2020. This is a phenomenal increase from just $194 billion in 2017.

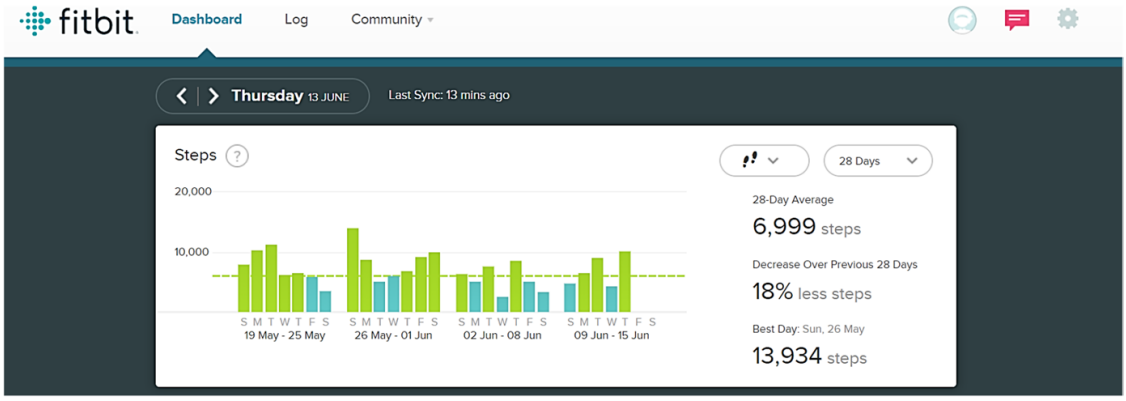
As the IoT solutions define the new paradigm for customer-oriented digital experience, they are inevitably getting more complex and dynamic. The network-connected cyber-physical devices can communicate via standard protocols and share data in different environments via the intermediate gateway nodes like modems, routers, switches and cellular base stations. To build a single communication platform which acts seamlessly for devices and applications to talk to each other, regardless of how they are physically connected is a challenging task [4]. Developing a completely new platform of communication where all devices are digitally augmented is expensive and time-consuming. A better solution is to reuse the established World Wide Web ecosystem and leverage the capabilities of its readily available application layer protocol, thus typifying the concept of Web of Things (WoT). WoT complements the existing IoT ecosystem, reduces costs and creates value by combining multiple devices and information services [5, 6]. More specifically, while IoT is all about creating a network of things, objects, people, applications and systems, WoT makes their integration to web. Integration aids capturing data from smart devices and making the data move into business applications with the intent of automating processes, supporting real-time monitoring and applying analytics for understandings. Recently there have been many web-enabled IoT applications such as smart homes, smart cities, smart industry, smart agriculture and smart healthcare which play a significant role in our lives. Though organizations and businesses are eager to develop applications that support these devices, exploiting IoT device interfaces to integrate applications with those devices can be complex. Further, deriving meaningful information is another crucial aspect.

Web-enabled IoT application development is a lot more intricate than a customary web development. This is primarily owing to the voluminous data, dynamic user interfaces, intense communications and security and reliability problems pertaining to the IoT applications [7]. These peculiarities influence the current generation of website design and development. Web design can be broken into two key categories [8]:

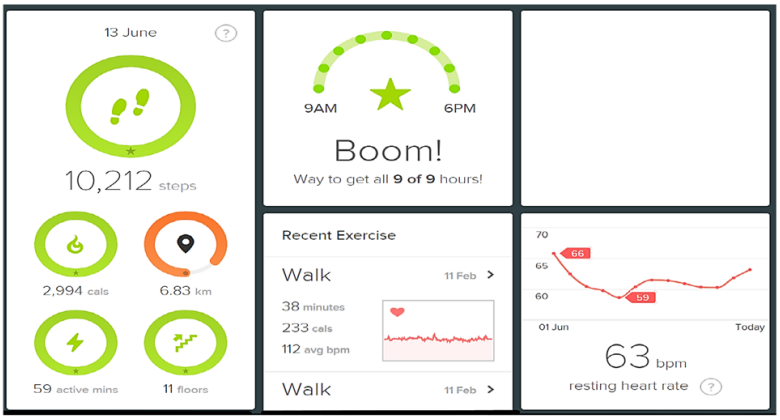
1. Front end: Graphical User Interface (GUI) which can be related to User Experience (UX) [9].
2. Back end: Database storage, data manipulation and data processing [10].

The front-end interface is used by the users to connect and communicate with IoT devices like cameras, sensors, etc. For example, the wearable technology, fitbit uses a bluetooth connectivity to track user's physical activity including the number of steps taken, distance traversed and calories burned, etc. [11] and integrates with software that logs this personal activity data (Fig. 2). A clean interface is needed for an easy communication with smart devices. The design should be tractable and

[1] www.Statista.com.



(a)



(b)

Fig. 2 fitbit dashboard on "fitbit.com"; **a** user's physical activity tracked, **b** personal activity log

must adapt itself according to various IoT-connected devices. Concurrently, numerous websites may also require the multifaceted capabilities to communicate with the back-end databases which store personalized data obtained from IoT devices [12, 13].

The design should be seamless across different devices and the website design company or web designer should be aware and well-informed of the different considerations for design with IoT interactions. Thus, many challenges ascend for web designers in terms of both back-end and front-end design to make a website worth for IoT integration. Some design considerations required to successfully develop website designs with IoT interactions include [14]:

- *Strong back-end* It is important that communication between users and IoT devices is very clear. This can be attained establishing a robust back-end design architecture. Each of the devices has several capabilities, data and commands that operate just according to the inclinations of users. A fine back-end receives and transmits data, and it helps the users in communicating with the device in a seamless way.
- *Intuitive user interface* For an IoT application, it is vital to have a clean, fast and an interactive layout. A web designer must work on latest web design practices but ensure that design inclusions are meaningful and support a rational

workflow. Also, the major concern is that the new IoT-based design should be mobile compatible so that smart users can benefit from it. User interface further requires to work on two aspects as given next:

1. *Easier front-end interaction* JavaScript is the most efficient language which has the potential to make a smart device interactive. It is an event-driven language and has capability of executing commands simultaneously with the interaction with smart devices and capturing data in the database. Moreover, it has the capability of multi-tasking where multiple tasks can run at the same time. JavaScript must be targeted by all web developers as it has an extensive set of plugins and libraries.
2. *Mobile user-experience* Mobile interfaces are the need of today. Simple designs are better for understanding and are easier to load on mobile. Web developers are expected to produce designs that are capable of adapting itself across many smartphone screens irrespective of the feature and size for the smart device.

- *Speed measurability* Conventional page requests are directly analysed by the web server. However, in the case of contemporary IoT-integrated websites, there are two hardware components, namely the IoT device and web server using an internet cloud service, thus increasing the chances of slow user response and more latency. Thus, design strategies for slow connections must be adopted. Simple and lighter themes make the pages load faster. Following are some of the steps that can improve page load speed:

  1. Create accelerated mobile pages (AMP) pages that are capable of loading faster on mobile devices.
  2. Use browser caching.
  3. Minimize the number of CSS and JS files.
  4. Reduce the number of redirects.
  5. Minimize the number of images.
  6. Hotlinking of images should be disabled.
  7. Reduce the server load with the use of CDN.
  8. Fix the broken links.
  9. Use caching plugins and clean the database.

- *Power management* Most of the IoT devices are battery-powered and wireless. For this, fully fledged power management is essential. Heavy programmes running in the back end, do drain the battery and this leads to less user communication. This is why the new layout must be designed for minimizing excess power use.
- *Security and privacy* One common drawback of IoT or the associated solutions is that they offer a way to hackers. If one could unlock a web-connected front door, a hacker potentially could do the same and help himself to the contents of the home. Though device designers are responsible for privacy and

security, but there is a need of a third-party web designer who must make security the main design consideration.
- *Testing considerations* Testing of IoT integrated website is complicated than the conventional websites.

IoT has made a significant impact on e-commerce businesses. IoT-enabled devices exchange data with each other through the internet, helping retail and e-commerce businesses to carry on their operations efficiently. As more devices get connected and gain smart features, more data are gathered, and consumer experience is improved. With the penetration of IoT, the e-commerce industry is expected to see a growth in revenue, a better supply chain management and inventory management and an improved customer service. This integration of websites with IoT devices has fostered the need to upgrade web design and development strategies where websites are designed keeping in mind the permutations of smart devices. Flexible, clean and user-friendly interface is the need of the hour where the information has to be displayed using lesser content.

Motivated by this, in this work, we expound the effectiveness of IoT integration in website design and propose an adaptive neuro-fuzzy inference system (ANFIS) to determine the compatibility of an e-commerce website with IoT devices. The ANFIS combines the learning capabilities of neural networks with the abilities of fuzzy logic to model uncertainty in expressiveness. It incorporates the benefits of adaptive control technique, artificial neural network and the fuzzy inference system [15]. The intent is to apprehend the integration support that an existing GUI front-end may provide to a smart device using a prediction model. A dataset of 600 e-commerce websites from .com domain is used to train and test the learning model. Seven features (page loading speed, broken links, browser compatibility, resolution, total size, privacy and security, and interface and typography) which impact the compatibility of IoT integration in website are used. These features are derived from the design considerations for successful IoT interactions with website [14]. Evaluation criteria for assigning score to each feature is identified. The sum of all the feature scores generates the compatibility score, the $\text{IoTScore}_{\text{site}}$. This compatibility score is finally used to evaluate the websites integration capabilities and support to IoT devices. Thus, the primary contributions of this research are:

1. A strength–weakness–opportunity–threat (SWOT) analysis to demonstrate the effectiveness of IoT integration in website design.
2. A novel ANFIS model to determine the compatibility of an e-commerce website for integration with IoT devices.

The proposed prediction model will facilitate to realize an IoT-powered IT ecosystem as an essential technology for improving customer experience. The paper is organized as follows: Review of related literature work is given in Sect. 2 followed by Sect. 3 which expounds the SWOT analysis of IoT integration in website design. Section 4 describes the concepts used in proposed model and Sect. 5

presents the proposed ANFIS model. Section 6 discusses the results and finally, the conclusion and future scope of the research is presented in Sect. 7.

2 Related work

Various studies have been reported in the domain of IoT. Gubbi et al. [2] presented an implementation of IoT based on cloud vision and also discussed the application domains and technologies that were likely to drive IoT research in future. They also presented an implementation using Aneka, which considered the interaction of private and public clouds. Lee et al. [16] presented five major IoT technologies which were important for the deployment of IoT-based products and services. The authors discussed three categories of IoT for enterprise applications used to enhance customer value and also described five technical and managerial challenges. Gigli et al. [17] introduced four categories of services which can be used to build an IoT application. Many applications of IoT have been reported in the field of healthcare and medical science [13, 18], agriculture [19], across fog and cloud [20], etc.

Software architectures originated from Web service research mainly for Web service interoperation to Web resources management for IoT have been proposed. Castellani et al. [21] worked on web services for IoT and concentrated on the communication technology for IoT devices and its implementation adopting the Representational State Transfer (REST) approach. The REST relied on GET and POST methods of HTTP and data were exchanged using standard XML. Xu et al. [13] proposed an IoT-based model for emergency medical services. They described the data collection, data integration and data interoperation methods in case of medical emergencies. They proposed a global data accessing method (UDA-IoT) to handle heterogeneous IoT data in medical service using RESTful architecture. Doukas et al. [18] discussed how IoT features web applications which can be accessed globally, were scalable, and were able to provide communication interfaces to peripheral applications. They discussed how appropriate interfaces enable the data dissemination to external applications. They also discussed how web apps provided the indispensable data real-time monitoring and management. The authors also explained that device and location independence enabled users to operate the systems via web browser and illustrated various websites which managed IoT sensors data. Yu et al. [22] argued that interactivity of a website is essential in IoT computer-mediated communications as it is considered as one of the key advantages of the medium. They also stated that interactivity is a vital part of the IoT service and influences customers' online experience in a positive way.

Researchers have proposed models which facilitate evaluation and assessment of websites based on various design features of the website. Kumar and Gupta [9] discussed the shift from software quality models to web-based quality models eventually proposing a π model where the horizontal line of the π signified the backbone of quality models with quality assessment parameters common to both kind of software, whereas the two vertical pillars of the π depicted the quality attributes specific to the software type. Loiacono et al. [23] proposed WebQual model which evaluated website quality based on a number of dimensions,

and the model was evaluated on three samples. Hartmann et al. [24] focused on user experience exploring some of the contextual features that impact user experience. Contextual evidence facilitates digging out User-centric information [25]. Sobecki et al. [26] demonstrated website usability assessment models and discuss about website interface quality. They also present models for organizing data in frames further to be used in an expert system. Schubert and Selz [27, 28] developed Web Assessment Tool considering the three phases of a transaction on a website, namely information, agreement and settlement and named this tool as WA. Extended Web Assessment Model (EWAM) was an extended model of WA which contained fundamentals of TAM and social influence proposed by Schubert et al. [29]. In our previous work [30], we identified website quality features which were necessary to predict the quality of website and introduced a website quality model using filter-wrapper-based feature selection algorithms.

None of the above-mentioned website quality models consider integration with IoT to evaluate website quality. This research is the first reported study to effectively capture and measure the IoT integration in websites qualitatively. We propose a prediction model to calculate an IoT integration compatibility scorecard for e-commerce websites. The study substantiates the need of IoT integration to collect data from smart devices to be utilized by the business applications to automate processes, support real-time monitoring and apply analytics for insights. Thus, the proposed model is superlative as compared to other website assessment models [23, 24, 26–29]. We propose an Adaptive Neuro-Fuzzy Inference System (ANFIS)-based model to validate the compatibility of IoT within a website. ANFIS has previously been applied in other areas of predictive learning which include image processing, face detection systems, etc. [31–33].

3 SWOT analysis

A SWOT analysis framework is generally used by business organizations as a strategic planning technique for analysing relevant internal and external factors making an impact over people, process, product, projects, initiatives, objectives and outcome of a system. It is a fundamental model used to evaluate the organizations internal strengths and weaknesses, as well as external opportunities and threats. It also acts as a vigorous mechanism for decision making [34].

Integrating websites with IoT-connected devices brings the opportunity to adopt new front-end design strategies of websites. Sophisticated, flexible and a clean user interface is imperative. To examine how IoT integration with websites has affected the website design, a SWOT analysis is done. The strengths, weaknesses, opportunities and threats of IoT integration in website design are as follows:

- *Strengths* Strengths determine the internal, positive attributes of integrating websites with IoT devices.

- Innovative front-end web designs allow many IoT devices to display web data searched via browsers on the device's screen.
- Interactive user interface help users to interact with the websites on various IoT-connected devices.
- New front-end web designs are mobile compatible that are used across various smartphone screens.
- New designs are being used which adapt themselves according to the varied screen sizes of IoT-connected devices having different display types.
- New designs are capable of integrating with multiple web browsers which may be used to search web data on most of the IoT devices.

- *Weaknesses* Weaknesses are negative factors that detract from the strengths discussed.
  - A single design may not be easy to adopt across different devices that are connected through IoT.
  - New website designs require the complex capability to communicate with back-end databases that are able to store personalized data obtained from IoT devices.
  - Due to communication and data transfer taking place through cloud slow user responses are experienced.
  - Heavy programmes running in the back end, use enough battery which leads to less user communication.
  - Testing IoT-integrated websites are complicated than conventional websites.
- *Opportunities* Opportunities are external factors that are likely to contribute to the success of the proposed model.
  - Avoid loss of productivity and loss of product.
  - Improved customer experience and engagement.
  - Increased competitiveness.
  - New revenue streams.
- *Threats* Threats are external factors that cannot be controlled.
  - Designs for extremely small screen sizes are potentially difficult to be made.
  - As small screen sizes require web content without images which may not give desired e-satisfaction to users of websites.
  - Multi-device interaction mostly implies recurring authentications, gateway processes that differs with devices.
  - Security and privacy may be breached when websites are integrated with IoT-connected devices.

Quite clearly, creating a standardized setting for normal and seamless interactions between a user and a system is challenging. Adopting an IoT solution requires cross-functional coordination between business, operations and security verticals. Thus, based on the identified need to create efficient user experience for IoT products, in this research, we assess the effectiveness of IoT integration in website design and propose an ANFIS to determine the compatibility of an e-commerce website with

IoT devices. The ANFIS is trained using key features derived from the core design components supporting IoT integration with websites, namely interactive interface, speed measurability, privacy and security and power management. The following sections discuss the details.

4 Background concepts

Sections 4.1–4.3 discuss the concepts and techniques used in this work.

4.1 Artificial neural networks (ANN)

ANNs imitates the human nervous system where number of nodes in ANN represents the neurons in brain [35]. The nodes are connected to each other by links which have weights associated with them. The nodes take data as input to perform basic operations on it and then pass the output to other nodes through connecting links. This output is known as activation value. The learning in ANNs takes place by updating weights of links whenever needed. Whether to alter the weight or not depends on the output predictions. In order to get accurate outputs, activation functions are applied on inputs. The most commonly used activation function in ANN is sigmoid function [36]. The way of modification of connection weights can be categorized as follows [37]:

- *Supervised learning* The ANN is given a dataset. The output of ANN is compared with the desired output present in the dataset. Based on the difference between predicted and actual values, the weights are updated. This process repeats until ANN gives the desired output.
- *Unsupervised learning* This way of training is independent. During training, ANN clusters the same kind of input data into clusters. For a new input data, ANN categorizes it into one of the clusters. No feedback on results is provided in this case.
- *Reinforcement learning* It is similar to supervised learning as in this case ANN gets feedback for its outputs. The difference is that here the feedback is evaluative instead of instructive. The weights are adjusted on the basis of these feedbacks.

There are two types of ANN topologies: feedback (feedback loops present) and feed-forward (unidirectional information flow no feedback loops).

4.2 Fuzzy inference system (FIS)

'A fuzzy Inference System abbreviated as FIS is a system that uses fuzzy set theory to map inputs to outputs'. If intended to do fuzzy classification, the inputs are features and the outputs are the classes [38]. The process of fuzzy inference involves *membership functions, fuzzy logic operators* and *IF–THEN rules* [39, 40].

4.2.1 Membership functions

Membership functions characterize fuzziness or the degree of truth in fuzzy logic. It represents a curve that describes the mapping between the points in the input space and membership values which are also called degree of membership. The value of degree of membership lies between the range of 0 and 1. The Fuzzy Logic Toolbox comprises of 11 types of built-in membership functions. These functions are built from some basic functions as:

1. piecewise linear functions,
2. quadratic and cubic polynomial curve,
3. sigmoid curve,
4. Gaussian distribution functions.

4.2.2 Fuzzy logic operators

Fuzzy logical reasoning is related to standard Boolean logic. Standard logical operations will hold when the fuzzy values are kept at boundaries like 0 (completely false) and 1 (completely true). In fuzzy logic, AND operator is implemented with minimum, OR operator is implemented using maximum and NOT as negation, i.e.

$$A \text{ AND } B = \text{Min}(A, B) \tag{1}$$

$$A \text{ OR } B = \text{Max}(A, B) \tag{2}$$

$$\text{NOT } A = 1 - A \tag{3}$$

4.2.3 IF–THEN rules

Usually the knowledge involved in fuzzy reasoning is expressed as rules. A fuzzy IF–THEN rule is of the form as given in Eq. 4.

$$\text{IF Input}_1 \text{ is } A_1 \text{ AND Input}_2 \text{ is } A_2 \ldots \text{AND Input}_n \text{ is } A_n \text{ THEN } Z = B \tag{4}$$

where Input_i and Z are fuzzy variables and A_i and B are fuzzy terms (fuzzy sets). The 'IF' part is known as antecedent or premise, whereas the 'THEN' part is termed as a consequence or conclusion. The inputs are connected via fuzzy logical connectives such as 'AND' and 'OR'.

4.3 Adaptive neuro-fuzzy inference system (ANFIS)

ANFIS combines the best features of neural network and fuzzy inference system [41]. It is defined as a multilayer feed-forward architecture where each neuron executes its function for arriving signals. It maps input features to input membership functions. Mapping is done between the input membership functions and the if–then rules. These rules are further mapped to a set of output features. Finally, the output features are mapped to output membership functions which are further

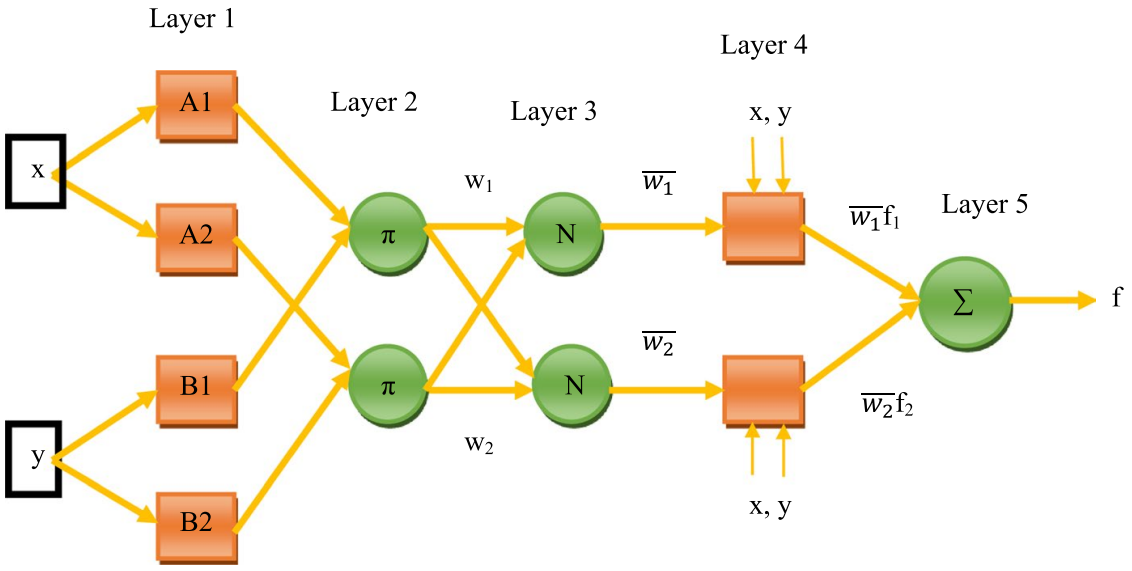


Fig. 3 ANFIS architecture

mapped to the decision which is associated with the output. ANFIS is an effective soft computing technique with easy implementation and easy incorporation of both numeric and linguistic knowledge for solving a problem. Figure 3 shows the architecture of an ANFIS.

Each layer in ANFIS contributes in calculating the parameters with the help of the respective functions present in them. The working of each layer is briefly described as follows:

1. *Layer 1* Every node in layer 1 is an adaptive node. In this layer, the output of each node is fuzzy membership grade of the inputs. Here, the parameters are known as premise parameters. During the process of learning, different parameters are used for the specification and tuning of membership functions. The membership function can be represented in Eq. 5.

$$\mu_{Ai}(x) = \frac{1}{1 + \left|\frac{x - c_i}{a_i}\right|^{2b}} \tag{5}$$

   where $\mu_{Ai}(x)$ lies between 0 and 1; a_i, b, c_i are parameter set.
2. *Layer 2* Each node is a fixed node in this layer. Product of input signals is the output of the nodes in this layer which can be written as given in Eq. 6.

$$O_{2,i} = w = \mu_{Ai}(x) \cdot \mu_{Bi}(x) \tag{6}$$

3. *Layer 3* All nodes in this layer are fixed nodes. They calculate the ratio of the ith rule's firing strength relative to the sum of all rule's firing strengths. The normalized firing strength is the output which can be written as given in Eq. 7.

$$O_{2,i} = \bar{w} \times w_1 / (w_1 + w_2) \tag{7}$$

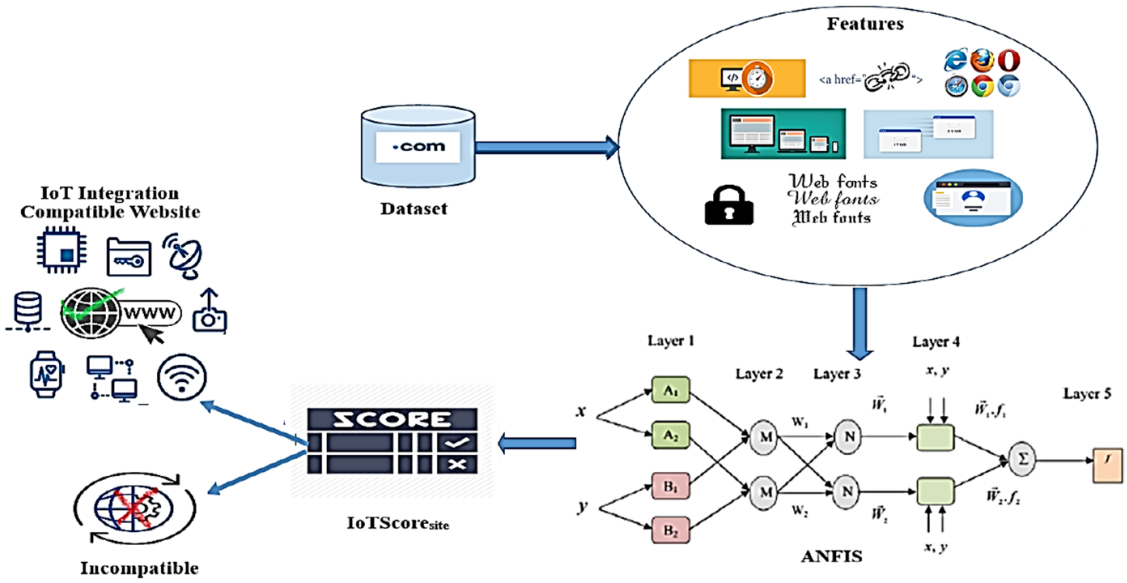

Fig. 4 Graphical illustration of the proposed model

4. *Layer 4* Each node in layer 4 is an adaptive node. The output of these nodes can be defined as given in Eq. 8.

$$O_{4,i} = \overline{w}_i f_i = \overline{w}_i (p_i x + q_i y + r_i) \tag{8}$$

where $\{p_i, q_i, r_i\}$ is the parameter referred to as consequent parameters.

5. *Layer 5* In this layer, all nodes are fixed nodes. Their job is to sum all arriving signals and output that as total output. The total output can be defined as given in Eq. 9.

$$O_{5,i} = \sum \overline{w}_i f_i \tag{9}$$

ANFIS identifies the rules on its own and tunes the membership function parameters accordingly. In order to develop an efficient model, some choices should be made carefully, for example, setting the optimization methods, types of output MFs and the number of epochs.

5 ANFIS-based compatibility model for IoT-integrated websites

Interacting with things via websites demands distinctive design considerations to eventually enhance the user experience. It is thus imperative to investigate the worthiness of a website for IoT integration. In this work, we propose an ANFIS model for evaluating the compatibility of website design and IoT device integration. Various e-commerce websites have been collected (with the domain.com) and seven website design features have been identified which typify the compatibility of website with IoT devices. An ANFIS model has been trained with these seven features and tested for the testing data. The ANFIS output as $\text{IoTScore}_{\text{site}}$ has been observed for the sample websites. Figure 4 depicts the architecture of the proposed model.

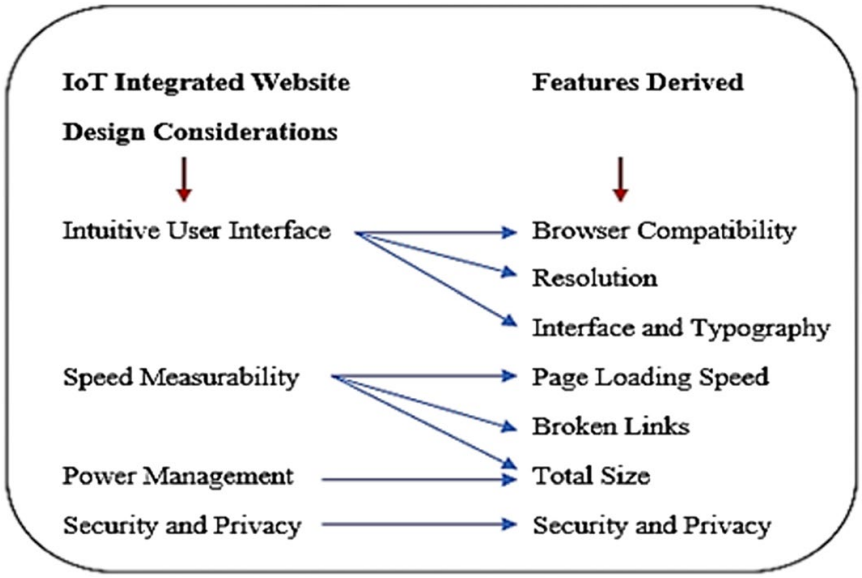

Fig. 5 Derived features for IoT integrated website design

5.1 Dataset preparation

A top-level domain recognizes a certain element regarding the associated website type, such as its objective (business, government and education), its owner or the geographical area from which it belongs. Examples of some of the popular top-level domains include .com, .org, .net, .gov, .biz and .edu. Since this work is to propose a model for the evaluation of business websites compatibility with IoT integrated devices we consider only the.com websites. In this work, 600 e-commerce websites (with the *.com* domain) have been evaluated for compatibility with IoT devices using an adaptive neuro-fuzzy inference system. Also, we have identified seven features of website design which impact the compatibility of website with IoT devices and are imperative to predict the IoTScore of a website. These features are as follows:

- Page loading speed.
- Broken links.
- Browser compatibility.
- Resolution.
- Total size.
- Privacy and security.
- Interface and typography.

The features have been derived from the design considerations for successful IoT interactions with website [14]. Figure 5 illustrates the mapping between the aforementioned website design considerations for IoT-integrated websites and website design features used in this study.

The following sub-sections describe these features and their evaluation criteria.

Table 1 Evaluation criteria based on percentage of broken links

Percentage of broken links	Score
0	10
0–0.010	9
0.010–0.020	8
0.020–0.030	7
0.030–0.040	6
0.040–0.050	5
0.050–0.080	4
0.080–0.100	3
0.100–0.200	2
0.200–0.500	1
> 0.500	0

5.1.1 Page loading speed

Page loading speed is defined as the 'speed by which a web page loads' [30]. It is inversely proportional to page loading time which is, the time taken by a web page to load completely.

Evaluation criteria An online tool 'GTMETRIX[2]' has been used to determine the loading speed. It gives the percentage value for a page's speed. In this study we have converted the percentage to score out of 10. For example: 81–90% has been scored as 9.

5.1.2 Broken links

Broken Links are 'links that don't work and send visitors to a webpage that no longer exists' [42]. It occurs due to variety of reasons such as:

- Non-availability of webpage.
- Movement of webpage without a redirect being added.
- Change in the URL structure of website.

Evaluation criteria Another online tool 'DEADLINKCHECKER'[3] has been used in this study which crawls through the website to identify presence of broken links. The evaluation criteria are based on the percentage of broken links found, and the score have been assigned as given in Table 1.

[2] www.gtmetrix.com.

[3] www.deadlinkchecker.com/.

Table 2 Scoring criteria based on total size of a website

Web page size (in MB)	Score
> 50 MB	0
25–50 MB	1
15–25 MB	2
13–15 MB	3
11–13 MB	4
9–11 MB	5
7–9 MB	6
5–7 MB	7
3–5 MB	8
1–3 MB	9
< 1 MB (in KB)	10

5.1.3 Browser compatibility

Browser compatibility is defined as the 'capability or flexibility of a website to function on different web browsers [30].

Evaluation criteria The websites have been browsed via various browsers, namely Google Chrome, Internet Explorer, Mozilla Firefox and Microsoft Edge. Websites show varied behaviours with these browsers. Some websites are not compatible with all the browsers. Scores in the range of 1–10 have been given to websites assigning 2.5 for compatibility with each browser.

5.1.4 Resolution

Resolution is defined as 'the number of pixels present on a display screen where a pixel represents an individual point of colour. The resolution is generally expressed in terms of the number of pixels on the horizontal axis and the number on the vertical axis'. The resolution feature is used to evaluate the appearance of website with different screen sizes.

Evaluation criteria The website either showed same or varied behaviour with different screen sizes. Scores in the range of 1 to 10 have been given in accordance to the ability of websites to adapt with different screen sizes, where a value of '1' corresponds to the websites which are unable to adjust effectively to different screen sizes and a value of 10 indicates the website is able to adapt itself to various screen sizes. Websites which are able to adjust with different screen sizes have been given higher scores and websites which show distorted content when evaluated on small screen sizes have been given lower scores.

5.1.5 Total size

Web page size is an integral feature which determines the speed of page loading as the bigger a page is, the longer it takes to load the required resources to display it. Total Size is the size of web page in MB.

Evaluation criteria For evaluating the size of webpage, an online tool *'GTMETRIX'* has been used in this study. Table 2 gives the scoring criteria of websites based on its total size.

5.1.6 Privacy and security

Privacy and security determine the steps taken while website design to secure the information and prevent websites from hackers and malwares.

Evaluation criteria For assessment of website privacy and security, an online tool '*Qualys SSL Labs*[4]' has been used. It grades the website as A+, A, B+, B, C and D based on Cipher Suits and Strength, SSL/TLS version, Key Exchange, Handshake simulation, Protocol Support and Details, BEAST and much more. A score of 10 has been given to the websites evaluated with A+ grade, 8 to A grade websites, 6 to websites with B+ grade, 4 and 2 to C and D grade websites, respectively.

5.1.7 Interface and typography

Intuitive Interface is defined as the extent of ease by which a website can be used and understood. Typography & Font is based on font size, font style and readability of website's content [30].

Evaluation criteria In this work interface of a website is evaluated using crowded sourcing and websites are scored in the range of 1–10 depending on its ease of usage. Also, typography and font have been evaluated and weighted average of interface score and font score has been used to determine overall score of this feature. Highest score has been given to 12-point Arial font because of its legibility and sharpness. It is also considered as the most preferred font by websites users [43]. Lower to it is scored 12-point Times New Roman as it is considered as the fastest to read font by users [43]. The other fonts lagging behind in the queue are 12-point anti-aliased Arial, 10-point Arial, 12-point anti-aliased Times New Roman and 10-point times New Roman which have been scored with decreasing values. Other fonts sizes and styles have been scored as per their readability.

Intuitive interface and typography score has been calculated using Eq. 10:

$$\frac{\alpha.\mathrm{IS} + \beta.\mathrm{TFS}}{100} \tag{10}$$

where IS is the Interface Score attained by crowd sourcing, TFS is the Typography and Font Score, α and β are the coefficients where $\alpha = 100$ and $\beta = 10$..

[4] www.ssllabs.com.

Table 3 $\text{IoTScore}_{\text{Site}}$ evaluation

Sum of features score	$\text{IoTScore}_{\text{site}}$	Compatibility
≥ 50	2	Website design is *highly compatible* with IoT devices
≥ 30	1	Website design has *medium compatibility* with IoT devices
< 30	0	Website design is *not compatible* with IoT devices

The websites in the dataset are labelled with the $\text{IoTScore}_{\text{site}}$ based on the sum of all the feature scores. This cumulative score, $\text{IoTScore}_{\text{Site}}$ finally characterizes the compatibility score of the website to IoT devices. The generated scorecard depicts the integration support that these websites have. The compatibility thresholds for integration support are as given in Table 3.

5.2 ANFIS implementation

The ANFIS implementation contains two processes: that is, the ANFIS system training and the model testing. The following sub-sections describe the details.

5.2.1 ANFIS system training

A typical ANFIS training process has been depicted in Fig. 6 [44]. The first step is to obtain training and checking data sets. Training data set must have an output vector which contains the output for every set of inputs. The premise parameters for MFs are set by using training data set. A threshold error value is determined. Least squares method is used to find consequent parameters. The premise parameters are updated using the gradient decent method if error is greater than threshold. Once the error comes out to be lesser than the threshold value, the process terminates. The role of checking data set is to compare the predicted values to actual values [44]. Hybrid learning is used by ANFIS for learning while training. Hybrid learning is an integration of the gradient descent and the least squares method. The first step of ANFIS training in MATLAB is to create training data set. The data set must be in the form of a matrix where the output should be in the last column. The number of columns depends on the numner of inputs and the rows denote the existing data points. There are 2 commands in the MATLAB to generate FIS using the training data set, namely GENFIS1 and GENFIS2. However, these two commands differ in a way that GENFIS1 produces grid partitioning of the input space to generate the FIS and thus it is more likely to have the problem of the ``curse of dimensionality'', while GENFIS2 uses subtractive clustering (SUBCLUST) to produce scattering partition. Due to this reason in this study, we have used the GENFIS2 command for generating the FIS. After setting the number of epochs matlab system training begins.

Once the training process terminates, we get the final membership functions and training. ANFIS functions well with one training data set, but if checking data set is also provided, then the chances are more that system will understand the model

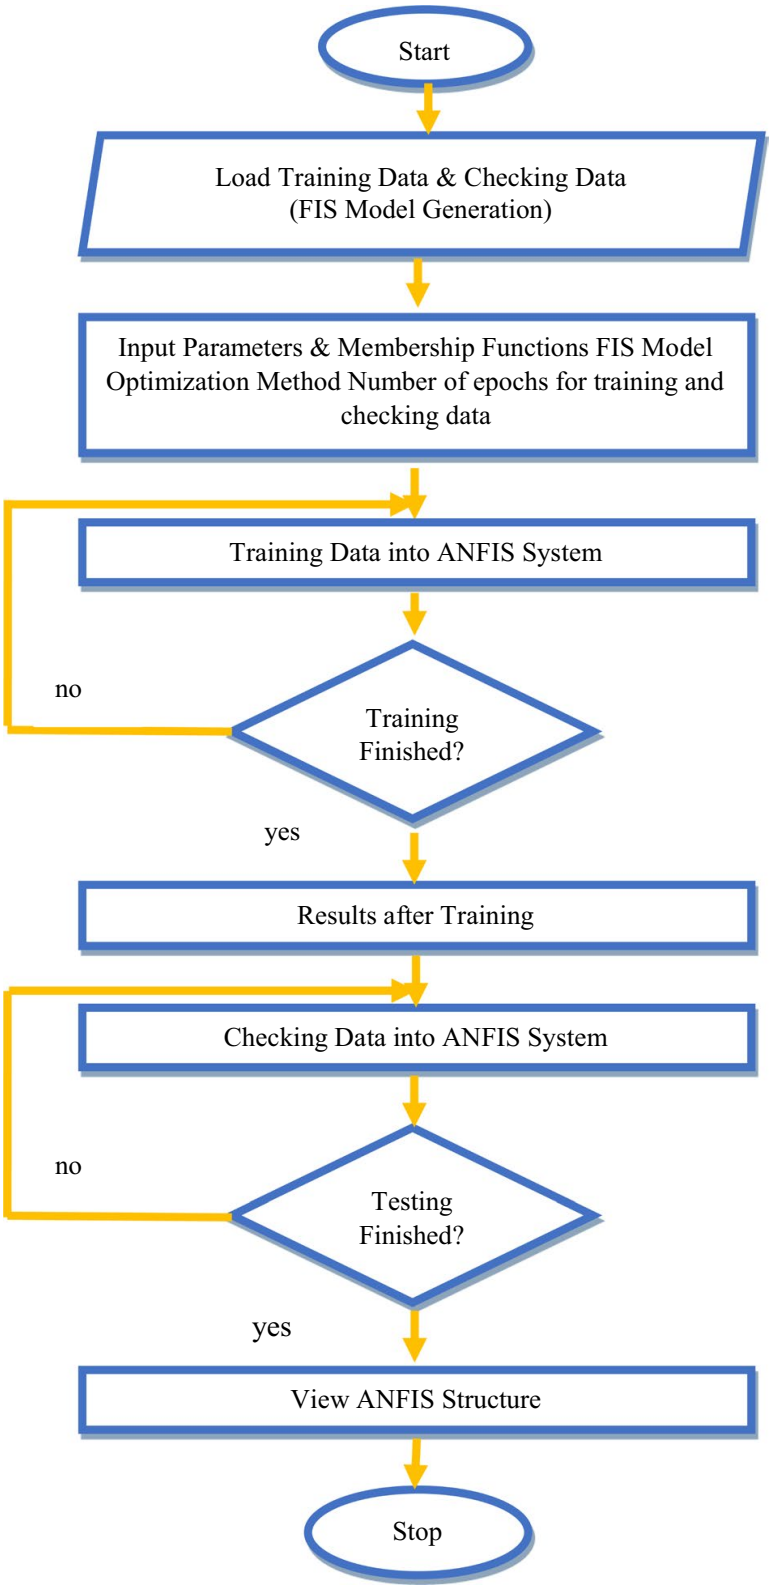

Fig. 6 ANFIS training process

more accurately. Using evalfis function, system performance can be evaluated. That is, the trained model is tested for different sets of inputs in order check its performance. Here, we used the dataset created in the previous section.

Table 4 Parameter setting

Parameter	Value
Range of influence	0.5
Accept ratio	0.5
Reject ratio	0.15
Squash factor	1.25

Table 5 Generated FIS

No. of inputs	7
No. of outputs	1
No. of MFs	38 38 38 38 38 38 38

5.2.2 ANFIS model testing

ANFIS model testing is done to validate the model which is a process by which the input vectors on which the FIS model was not trained are given to the trained FIS. It is done to check the ability of the FIS model to predict the output values corresponding to the given input vectors and to check its generalization capability [45]. Validation of the model is done after the FIS is trained using a testing data which is different from the data set used for training of FIS.

6 Results and discussion

In this research, ANFIS model is implemented to evaluate the IoT compatibility of website designs. Section 6.1 describes the ANFIS model training process. Section 6.2 describes the result of model testing. Section 6.3 gives the ANFIS output for a sample website based on the rules generated.

6.1 Training ANFIS

The parameters selected to generate the FIS are given in Table 4.

The ANFIS model has 7 inputs and 1 output. In this study, we choose the sub-clustering method to generate the FIS. The sub-clustering method generates a FIS with following details as given in Table 5.

Figure 7 illustrates the FIS generated with 7 inputs represented as initial black discs, 38 clusters for each input represented as white discs, 38 rules as blue discs, 38 output MFs as the next white discs, one aggregated output and one final output.

The Epoch 1 error was observed to be 0.2048. We trained the FIS with epoch 100 and epoch 150. It was observed that the training error was decreased as the

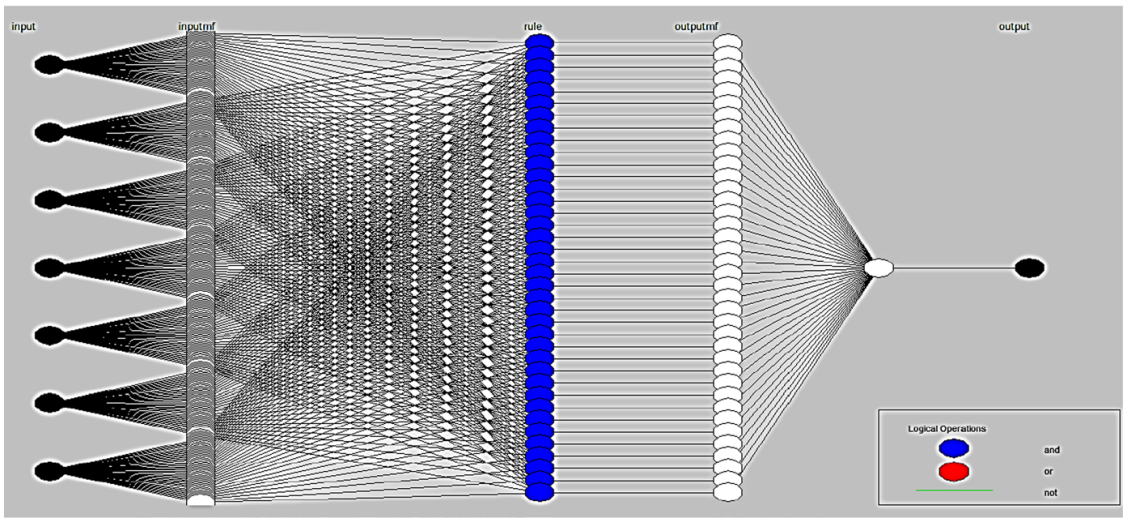

Fig. 7 Structure of generated FIS

Table 6 Training and checking error with varying epochs

Epoch	Training error	Checking error
100	0.1467	0.6001
150	0.1414	0.6731

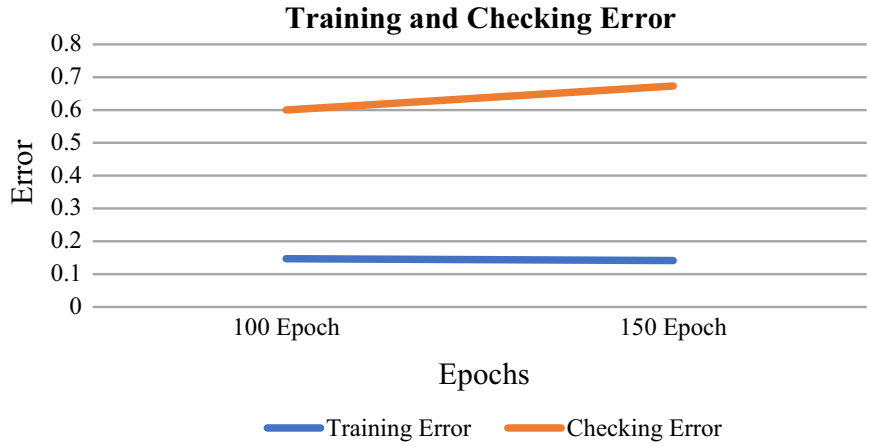

Fig. 8 Training and checking error w.r.t epochs

number of epochs increased but the checking error increased. Table 6 represents the training and checking error with epoch 100 and epoch 150.

Figure 8 shows the trends of training and checking error with respect to number of epochs.

As the checking error increases with no. of epochs we chose 100 epochs for training the FIS and build the final model. Figure 9 represents the graph for training data with which the FIS was trained and Fig. 10 represents graph for checking data.

The total number of parameters and fuzzy rules for ANFIS were 836 and 38, respectively, as shown in Table 7.

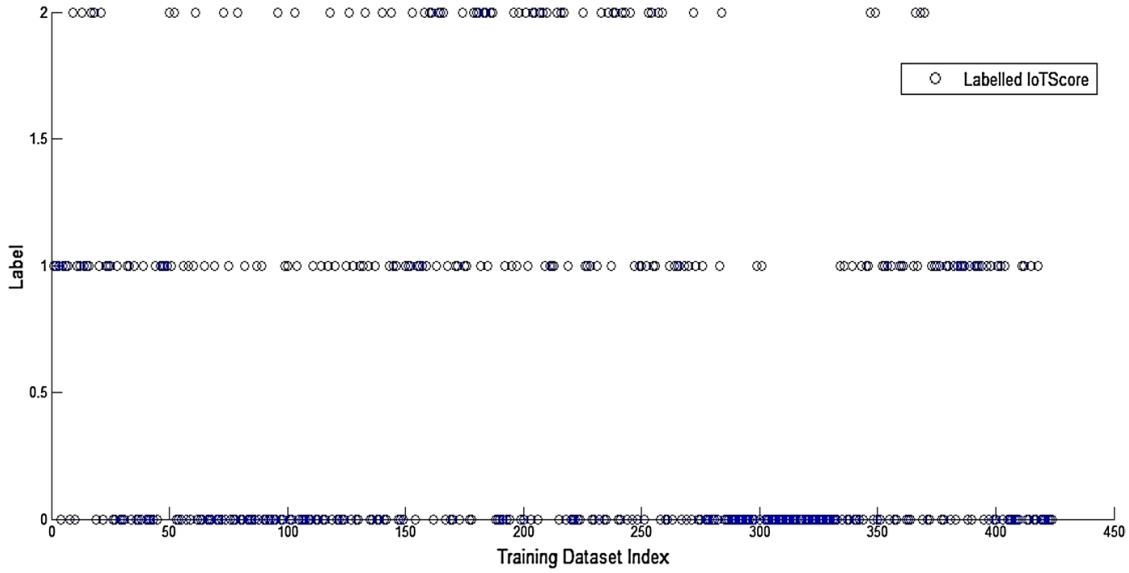

Fig. 9 Training data distribution

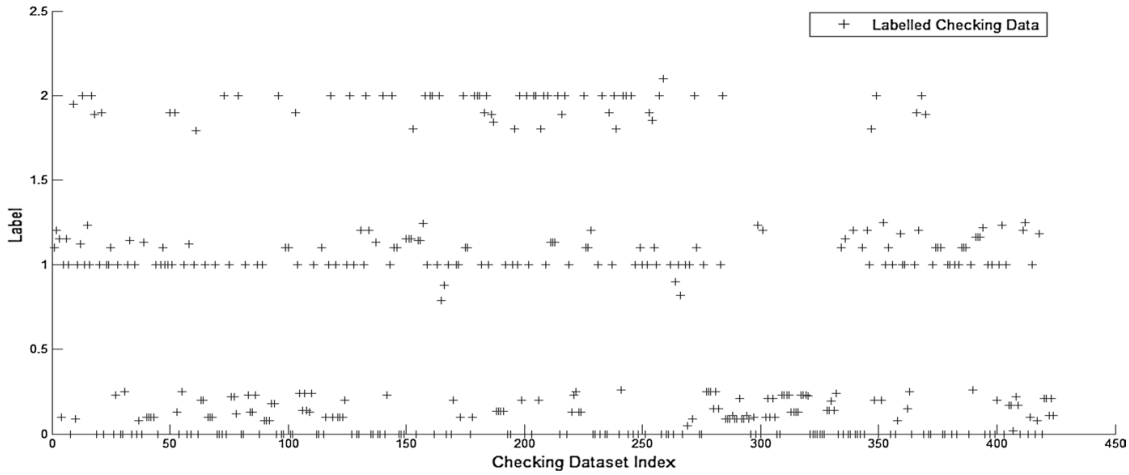

Fig. 10 Checking data distribution

Table 7 ANFIS information

ANFIS item	Value
Number of nodes	618
Number of non-linear parameters	532
Number of linear parameters	304
Number of total parameters	836
Number of training data pairs	424
Number of checking data pairs	424
Number of fuzzy rules	38

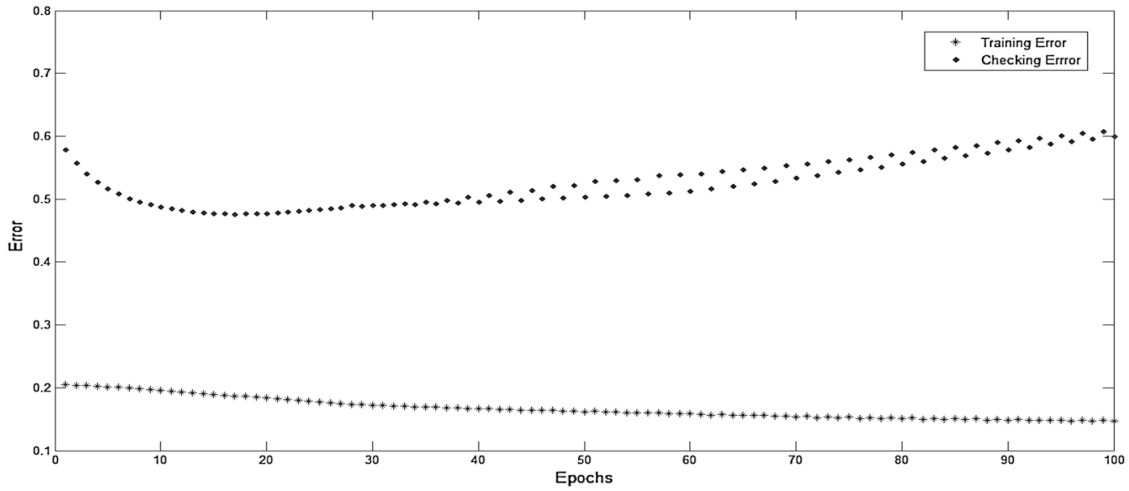

Fig. 11 Training and checking error

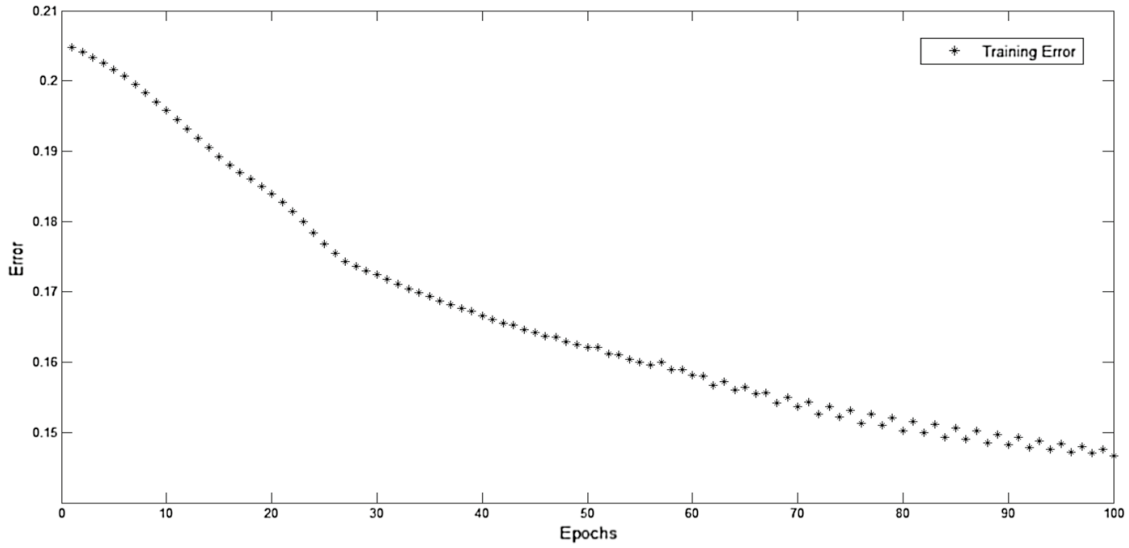

Fig. 12 Training error w.r.t epochs

The error tolerance was set to zero and model optimization was chosen to be *hybrid*. The hybrid optimization method is a combination of least squares and back propagation gradient descent method [46]. After training of ANFIS, the training data errors and checking errors were plotted against the number of epochs as shown in Fig. 11.

The checking error rises up after a certain point till where it decreases which is the point of model overfitting. ANFIS automatically selects its parameters allied with the minimum checking error (just prior to this jump point).

At epoch 100, the training error and the checking error were observed to be 0.1467 and 0.6001, respectively. Figure 12 represents the fall of training error as the number of epochs increases.

Figure 13 shows the result of testing the checking data against the trained FIS. The average testing error in this case came out to be 0.6001.

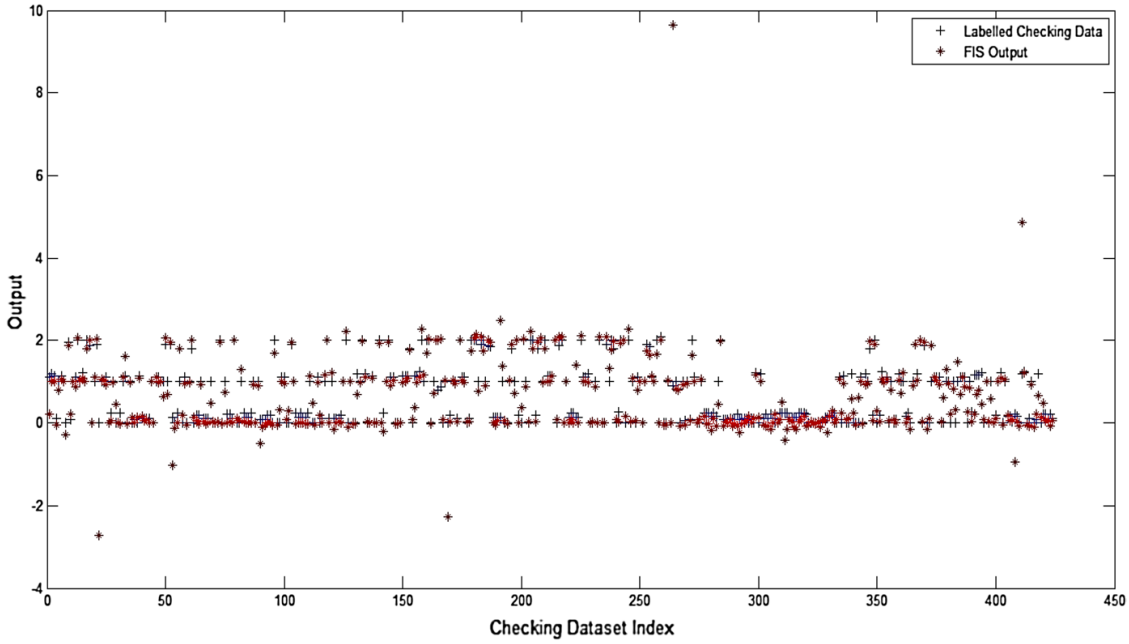

Fig. 13 Testing checking data against the trained FIS

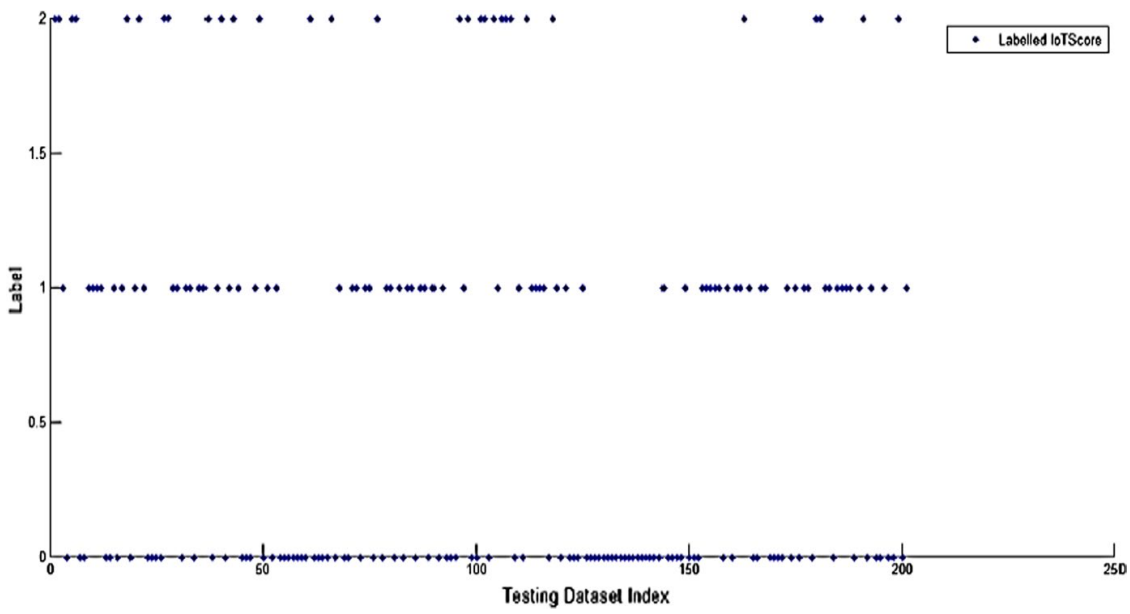

Fig. 14 Test data distribution

6.2 Testing the model

Figure 14 represents testing data points graphically. The number of test data pairs is observed to be 201.

Figure 15 shows the result of testing the model against training data itself. The average testing error in this case came out to be 0.1467.

The performance of the proposed model is shown in Fig. 16 which shows the plot of actual and predicted values of website quality for testing data. The average testing error came out to be 5.0941.

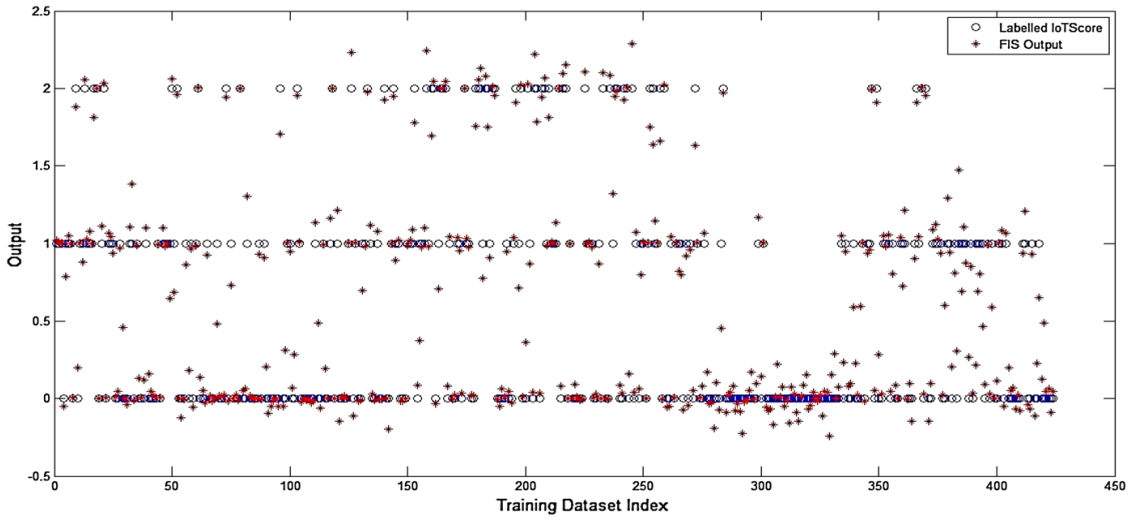

Fig. 15 Training data points and FIS output

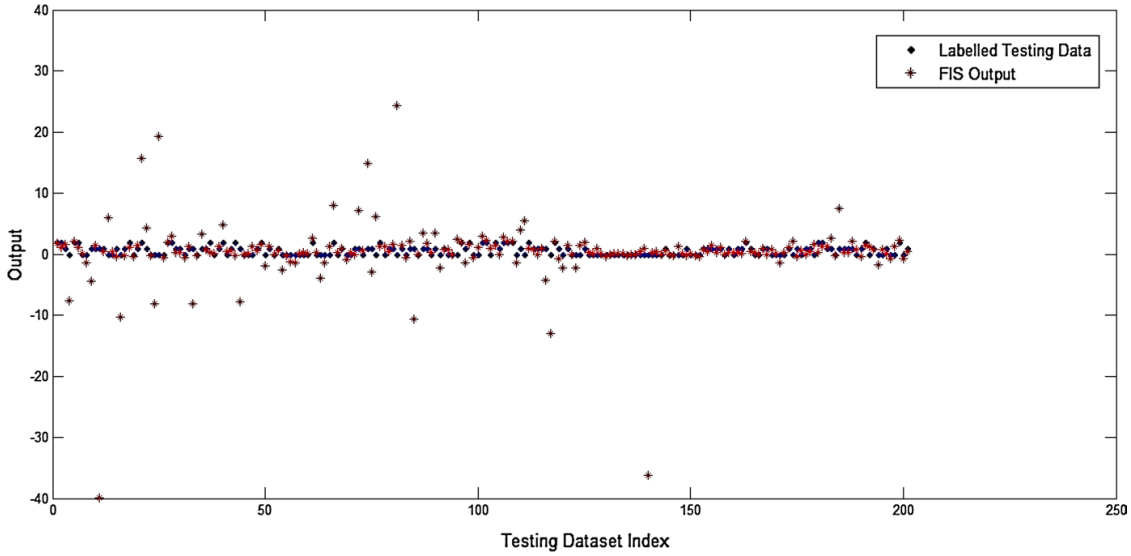

Fig. 16 Testing data points and FIS output

Table 8 Summary of ANFIS model

Epoch	Training error	Average testing error
100	0.1467	5.0941

Table 8 represents the summary of training and testing ANFIS model for evaluating $\text{IotScore}_{\text{site}}$ for the training and testing data.

6.3 ANFIS output

The example of IoT compatibility has been illustrated below for a sample website. Inputs for the sample website are given in Table 9.

Table 9 Feature input values

Input no.	Input value
Input 1	6
Input 2	5
Input 3	7
Input 4	9
Input 5	5
Input 6	5
Input 7	9.5

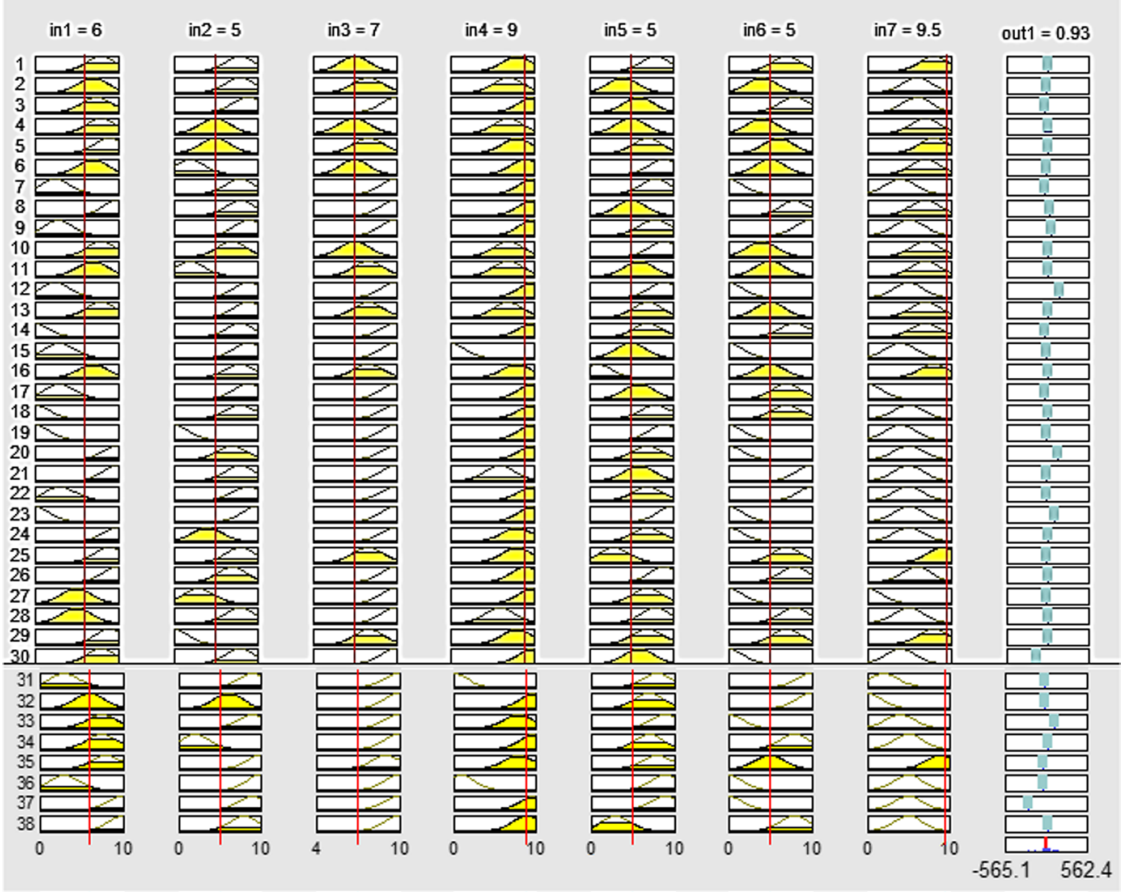

Fig. 17 Rule base and evaluation of $\text{IoTScore}_{\text{site}}$ for sample website

Figure 17 illustrates the rule base and evaluation of IoT scorecard for the sample website with the above input values.

The output $\text{IoTScore}_{\text{site}}$ for the sample website is 0.93. The value of $\text{IoTScore}_{\text{site}}$ lies between 0 and 1 and closer to 1 which implies that the website has medium compatibility when integrated with IoT devices.

On evaluating all 600 websites, it was observed that more than 60% websites show low compatibility with IoT integrated devices with the value of $\text{IoTSite}_{\text{score}}$ closer to 0. Only 10% websites show a value closer to 2 and can be considered as IoT compatible websites. This creates an alarming situation for e-commerce websites

and indicates that current business websites require major design changes and need to adopt new development strategies.

7 Conclusion

It is evident that at the heart of IoT systems are the User Interface (UI) which comprises the visual elements of a page and the User Experience (UX) which focuses on site navigation, search engine optimization and research and analytics. Web designers are the architects of these elements and are responsible to build sites that communicate with back-end databases that have collected information from IoT devices and create front-end interfaces, allowing users to interact with numerous devices that frequently have different screen sizes or run on different platforms. This study evaluates the websites integration capabilities and support to IoT devices and depicts that most of the samples in the show low or medium IoT integration compatibility instigating new challenges for web developers in terms of both back- and front-end design to make a website worth for IoT integration. The proposed ANFIS generates a compatibility score $\text{IoTScore}_{\text{Site}}$ to comprehend the interconnected development, new devices and web development methodologies which create new business opportunities.

IoT is *not* the end product and customers do not buy IoT. It is not simply an iPhone, a networking application or a wearable device. It requires a technology-aware approach to product experience which includes upgrades, adapting to other products, personalization and big data [47–51]. As a future direction, ensemble machine learning methods [52], deep learning models such as recurrent neural networks and convolution neural networks can be implemented to evaluate the compatibility of website design with IoT integrated devices. Also, compatibility studies with respect to integrating IoT to applications, cloud service, big data and semantic web technologies need investigation.

Abstract
This paper presents the performance analysis of an all-*p*-organic pseudo-inverter circuit using dual gate organic thin film transistors. The proposed inverter design has shown significantly high performance in terms of noise margin, gain and propagation delay, leading to the design of more robust digital circuits that, too, exhibit augmented performance. The parameters of the all-*p*-organic pseudo-inverter are compared with those of zero-V_{gs} load logic (ZVLL) and dynamic load logic based conventional inverters, and a substantial improvement is found for the novel combination of a dual gate flexible TFT with a pseudo-design. Performance parameters were deeply analyzed, and we observed that the noise margin is improved by 42.8% as compared to ZVLL based conventional inverters. A bootstrap technique was implemented to further improve the performance and reduce the threshold voltage drop. The performance parameters were analyzed mathematically and compared with simulated values. The static as well as dynamic characteristics of organic pseudo-all-*p* inverter, with and without bootstrap technique, were observed. Static power consumption of the organic pseudo-all-*p* inverter was estimated. In this way, improvement of noise margin by the bootstrap circuit of the organic pseudo-inverter is characterized. The reduced threshold voltage applied to design of low power circuits enables longer power backup for various applications.

1 Introduction

The field of flexible electronics has achieved remarkable developments in recent years. Organic semiconductors (OSCs) are inexpensive substitutes for low cost large–area electronics. However, in conventional semiconductors, production cost and flexibility are obvious constraints. Universal logic gates and inverters are essential for applications of organic thin film transistors (OTFTs), but only a few logic designs have been reported to date [1–6]. The performance of an organic inverter is affected by the process of fabrication. Uniformity in deposition of the layers is highly desirable for better performance of organic inverters. The different reasons for degradation in the transistor performance include its geometry defects, oxide breakdown, electro migration, hot carrier injection DIBL and ESD. These defects cause deflation in the performance of the transistor and the circuit. The external disturbances mentioned above include noise, overvoltage and overcurrent that affect the circuit. It will be possible in the future to use disposable organic circuits, for example by printing them on paper, cloth; glass etc., because of their economically viable fabrication processes at low temperature [3–7]. Of two different structures based on the position of the gate, i.e. single gate and dual gate, the dual gate configuration is superior in its performance as compared to single gate. The presence of two gates provides a higher charge injection area, hence better charge accumulation over the single gate thin film transistor. Dual gate organic transistors (DG-OTFTs) operate on the principle of accumulation rather than inversion, unlike MOSFET devices [1, 4]. The charge transport in the transistors occurs due to a hopping mechanism, which explains the movement of charge particles (holes and electrons) from HOMO and LUMO levels. For conduction to occur, the holes (or electrons) must

have an energy level which is higher than the band gap energy (E_g). In the organic semiconductor, proper overlapping of orbitals is also important; the commonly preferred overlapping among orbitals is sp^2 hybridized orbitals [3].

This paper comprises six sections. Section 1 is the introduction, Sect. 2 includes the structures and electrical properties of the single and dual gate based organic transistors. In Sect. 3, dual gate based inverters, along with new organic pseudo-all-p structure, are presented. Sections 4 and 5 give the performance improvement techniques and power consumption of the inverter along with mathematical extraction of parameters. Finally, Sect. 6 highlights the important outcomes, limitations and challenges of dual gate-based inverters.

2 Dual gate versus single organic thin film transistors

The single gate OTFT comprises a gate (preferably at the bottom) passivated by high-k dielectric material. A commonly used gate material is aluminum (Al), which exhibits a work function somewhere in the range of 3.5 to 3.9. In production, the OSC layer is placed over the dielectric [3, 7]. Depending upon the relative position of source and drain electrodes with respect to the OSC, devices are described as bottom contact or top contact devices. In bottom contact structures, the source and drain are sandwiched between the OSC and the dielectric; in top contact devices, the source and drain are positioned above the OSC layer, as shown in Fig. 1. Bottom contact-based devices can be fabricated using various techniques such as spin coating, solution processing and sample printing [3].

Single gate-based devices and circuits are less performant than dual gate-based circuits [1], due to low mobility and presence of a single channel that reduces the charge injection area. In contrast, the charge injection area gets doubled in a dual gate transistor in the presence of two separate channels at top and bottom. Another reason for the reduced performance of the single gate design is its higher threshold voltage as compared to the dual gate design. The presence of two channels in DG-OTFTs provides significant reduction in threshold voltage. Higher threshold voltage has a negative effect on OTFT performance, giving rise to structural defects in the device. These defects affect the parameters such as trans-conductance, mobility and sub-threshold slope (SS). Sub-threshold slope should be as low as possible. Patterning of layers in the device is an important concern which is used to estimate structural disorders. If the grain particles are not aligned uniformly, the device will consume a higher amount of voltage, raising the threshold voltage of the device and thereby increasing the sub-threshold slope. In describing device performance, there are numerous

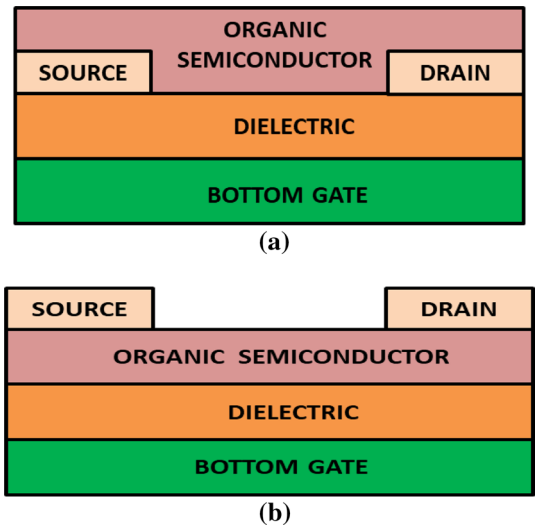

Fig. 1 Single gate based **a** bottom contact and **b** top contact OTFT structures

parameters that play a significant role in predicting OTFT device behaviour. These include current I_{ON}/I_{OFF} ratio, sub-threshold slope (SS), trans-conductance (g_m), threshold voltage (V_T) and mobility (μ).

2.1 Simulation setup and parameters extraction of DG-OTFT

The dual gate based organic thin film transistor was analyzed using a Silvaco Atlas 2-D simulator. The structure of the device and its input and output characteristics are shown in Figs. 2 and 3, respectively. Here, the channel was formed within the pentacene; a p-type material. The dimensions of the device are summarized in Table 1. The mobility was analyzed using a Poole–Frenkel mobility model, which is given as [8],

$$\mu = \left(\frac{\Delta}{kT} - 1\right) - \left(\frac{\beta}{kT} - \gamma\right), \tag{1}$$

where μ is the field dependent mobility, μ_o is the zero field mobility and E is the electric field. Activation energy and Poole–Frenkel constant (for a p-type) are specified by Δ and β, respectively. The values of Δ and β are given by 1.792×10^{-2} eV and 7.758×10^{-5} eV, respectively [3]. The iterations were carried out using the Newton–Raphson (N–R) algorithm. The analysis was performed on both the steady and transient inputs. The N–R algorithm was used under the mixed mode simulation for steady state analysis and transient state analysis. In this work, the Atlas device was used with full and modified Newton algorithms for steady state simulation.

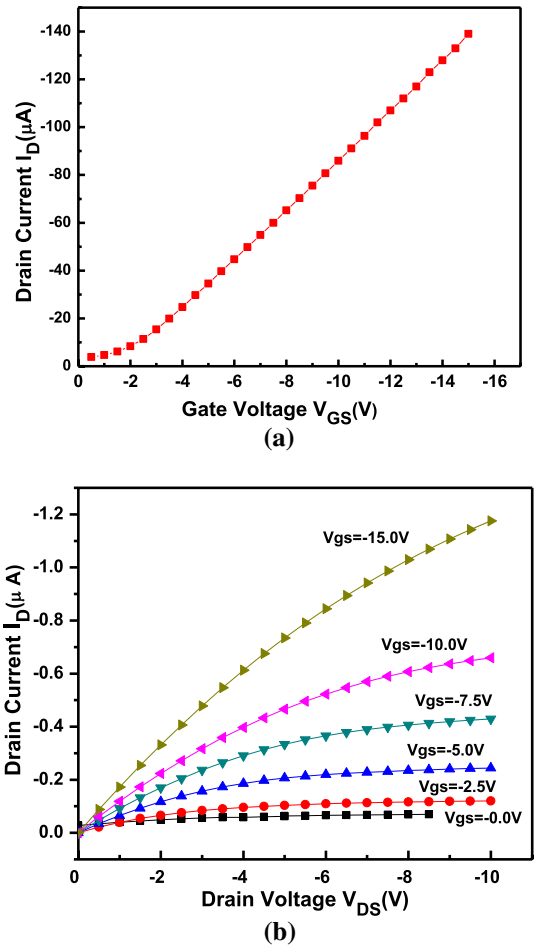

Fig. 2 Characteristics plots of DG-OTFT **a** transfer curve (I_D–V_{GS}) and **b** output curve (I_D–V_{DS})

The pseudo-inverter consists of a cascaded structure in which the output of the first inverter is fed to the second inverter. There is more than one Atlas device in the structure, so each device is simulated under mixed mode simulation in which structures are combined internally. The resulting solution file is a single file which contains both the structures. Extraction of mixed mode log files requires re-initialization of Atlas.

The electrical features of the dual gate organic transistor include the input (I_D–V_{GS}) and output (I_D–V_{DS}) characteristics shown in Fig. 2. The electrical parameters include the threshold voltage, sub-threshold slope, drain current, trans-conductance, mobility, I_{ON}/I_{OFF} ratio and trap density.

Threshold voltage (V_T) is an important factor that governs the morphology of the device. If the size of the grain particles is not uniform, then trap density increases, consuming a considerable amount of power and resulting in higher threshold voltage. Sub-threshold slope is used to reveal defects, interface states and trap density. SS is a measure of switching behavior of the transistor, which depends on the thickness of the insulating layer [3–6]. With an insulating layer thickness of 100 nm for a bottom contact device, the sub-threshold slope is measured as 5.85 V/dec. Mobility of an organic transistor gives insight into the movement of charge carriers in the device. In this work, the *p*-type material (pentacene) we used has a hole mobility of 0.62 cm^2/V s.

Drain current flows in the OTFT from source to drain due to accumulation of charges in the channel. Drain current decreases with increase in channel length '*L*' due to increased charge density from source to drain. When the depth of the layer is increased, the concentration of the holes is increased in the active layer. As a result, the charge density in the channel is increased, leading to an increase in the drain current. Trans-conductance is used to estimate the variation in the drain current due to change in gate voltage; it should be as high as possible and is determined graphically from the slope of the transfer curve. In this work the trans-conductance was obtained as 2.12×10^{-7} μS.

I_{ON}/I_{OFF} is the ratio of the current in the accumulation mode to the current in the depletion mode. A higher I_{ON}/I_{OFF} ratio indicates higher utility in switching applications. In this paper I_{ON}/I_{OFF} ratio was observed to be on the order of 10^7.

2.2 Dual gate organic thin film transistor

The dual gate based OTFT exhibits superior performance compared to its single gate counterpart. Pentacene is the preferred material due to its higher mobility as compared to other organic materials, such as CuPc, P_3HT and C_{60} [4]. Organic transistors can be further as *p*-type or *n*-type, based on the polarity (positive or negative) of the channel formed between source and drain electrodes. The main difference between *p*-type and *n*-type materials is of the mobility of respective charge carriers, which is an important parameter when integrating these transistors into a specific application (Fig. 3). Mobility of the *p*-type material is reported as higher than that of the *n*-type material. In this work, a dual gate pseudo-all-*p* inverter was realized using devices with *p*-type materials only. A pseudo-all-*p* inverter is used to improve the noise margin and propagation delay, which in turn increases the circuit robustness. The organic conventional inverter circuit and the proposed pseudo-all-*p* inverter are discussed in Sects. 3 and 4, respectively.

3 Organic conventional inverter circuit

Organic inverters may also be designed using a pair of *p* and *n*-type transistors, similar to the CMOS inverter. In this section, the dual gate-based inverter circuit is analysed. Depending on the connections between the source, gate and drain terminals, the inverter design may consist of zero-V_{gs}

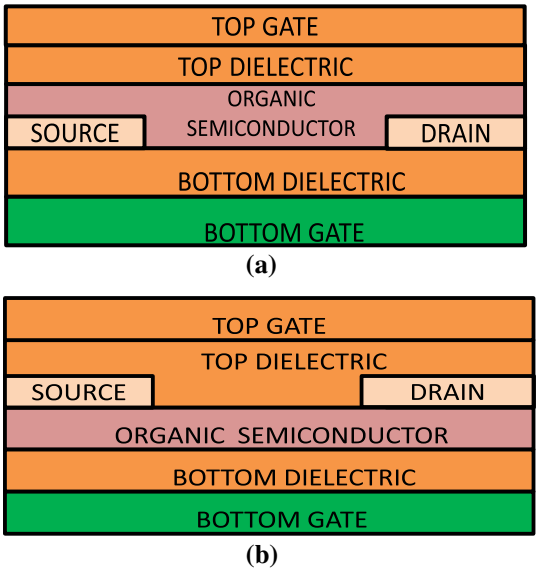

Fig. 3 Structure of DG-OTFT **a** bottom contact and **b** top contact

Table 1 Structural dimensions and materials of DG-OTFT

Thin film	Material	Dimension (nm)
Bottom gate	Ag	150

Top dielectric	Al_2O_3	300
Top gate	Ag	150

load logic (ZVLL) or diode load logic (DLL) [3, 9, 10]. These configurations are different in terms of their outcomes and are suitable for specific purposes. DLL is preferred for higher switching applications, whereas, ZVLL is a better choice for robustness against external noise. The DG-OTFT based ZVLL and DLL inverters are given in Fig. 4.

In ZVLL configuration, the gate and source terminals are shorted with each other to form a constant current source from V_{DD} to ground. This topology gives an advantage of higher noise margin and voltage swing, which helps to increase the robustness of the circuit. The driver transistor operates in enhancement mode and the load transistor operates in depletion mode.

At lower V_{IN}, the channel resistance of the driver transistor is much smaller than its load, causing to the driver to be in the 'ON' state, and thus V_{OUT} is obtained as near to V_{DD}. On the other side, at higher V_{IN}, comparatively a larger aspect ratio (*W*/*L*) is required for pull down action. At higher V_{IN} both the driver and load transistor form a zero-gate to source and are in the ON state. Therefore, the *W*/*L* ratio of the load transistor is around five times higher than that of the driver transistor.

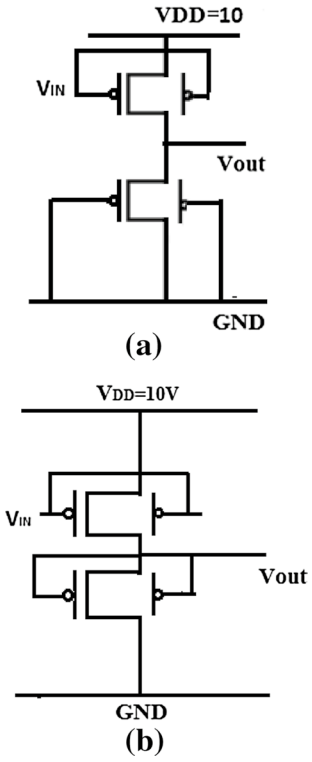

Fig. 4 DG-OTFT based inverter configuration **a** DLL and **b** ZVLL

In a DLL inverter, the drain and source terminals are connected to ground. In this configuration, both driver and load transistors operate in enhancement mode. They are compatible with both enhancement and depletion type load transistors. They are proven as the faster circuits, as compared to the ZVLL based inverter.

The *W*/*L* ratio is an important factor when selecting and designing the inverter configuration. It maximizes the noise margin (NM) and allows the capacitive load to charge and discharge in equal times by providing identical current to source and sink capabilities. If the *W*/*L* ratio is varied, then the steepness of the transfer characteristics is increased. If the aspect ratio is greater than 1, then the inverter is known as a HI-skewed inverter, and if the ratio is less than 1 it is known as a LO-skewed inverter. A HI-skewed inverter gives a better noise margin as compared to a LO-skewed inverter. To achieve more robustness in the inverter performance, a pseudo-all-*p* inverter is proposed and described in the subsequent section.

3.1 Proposed dual gate organic pseudo-all-*p* inverter

The organic pseudo-all-*p* inverter circuit topology is vital to achieving better inverter performance. It is designed to enhance the noise margin of the inverter. As observed from the literature, the circuit structure involves two configurations: pseudo-D and pseudo-E. It is a two stage inverter

structure in which the output of the first inverter is connected as the input to the second inverter. The left configuration can be either pseudo-D or pseudo-E, and the connection on the right is a level shifter. V_{DD} is the supply voltage and output is expected to attain maximum swing between V_{DD} and GND. There is a significant difference between the ZVLL, DLL and organic pseudo-all-*p* based circuit. The two stage structure keeps the higher voltage V_{OH} constant and provides a reduction in V_{OL} that is absent in the zero-V_{gs} logic circuit. This is an important influencing factor for the design of the pseudo-all-*p* inverter. Zhao et al. [10] reported the single gate based organic pseudo-CMOS inverter shown in Fig. 5.

3.1.1 Operation of pseudo-all-*p* inverter

The structure shown in Fig. 6 is the circuit for the pseudo-all-*p* inverter. It consists of four transistors: TFT1, TFT2, TFT3 and TFT4 respectively. When the input V_{IN} applied at the TFT1 is logic LOW, the TFT1 operates in linear region, while TFT2 is in saturation region. Subsequently, TFT3 and TFT4 operate in the cut-off and linear regions, respectively. With TFT1 in the linear region, the source V_{DD} appears at the output terminal; V_{01} is used as input for second stage, comprising TFT3 and TFT4. With TFT3 in cut-off and TFT4 in linear region, the output is forced to logic HIGH, which is an expected voltage transfer characteristic (VTC). When the input is HIGH, both TFT1 and TFT2 are in the linear region, while TFT3 and TFT4 are in the linear and saturation regions, respectively. With TFT

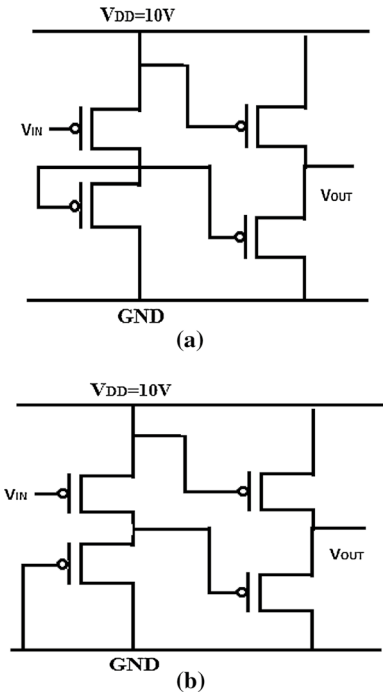

Fig. 5 SG-OTFT based pseudo-all-*p* inverter **a** ZVLL and **b** DLL configurations

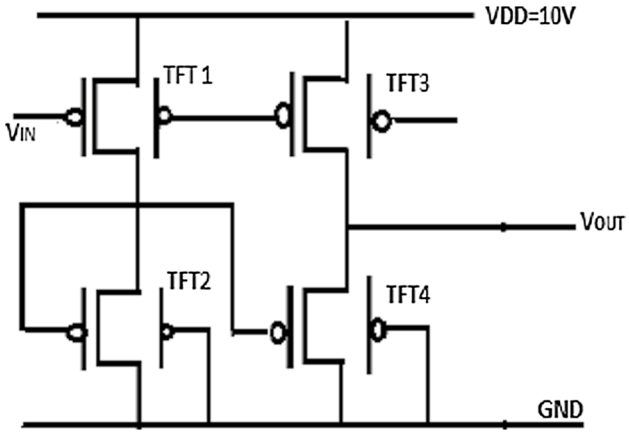

Fig. 6 Circuit schematic of dual gate based pseudo-all-*p* inverter

4 in saturation, it drains the current from V_{DD} , leading to an output voltage equal to '0'. The pseudo-all-*p* inverter is illustrated in Fig. 6.

Voltage transfer characteristics and voltage gain of dual gate based organic pseudo-all-*p* inverter are shown in Figs. 7 and 8, respectively. From the VTC of the inverter, various performance parameters, including noise margin (NM), voltage swing, gain and power consumption, were extracted and further analyzed in Sect. 4 and 5, respectively.

The noise margin of the circuit is explained as the maximum noise that can be tolerated by the input without any disturbance in the output.

$$NM_H = V_{OH} - V_{IH} \text{ and } NM_L = V_{IL} - V_{OL}$$

The noise margin of the circuit should be high for better performance of the circuit. In this work the value of NM_L is higher than the value of NM_H. The lower value for

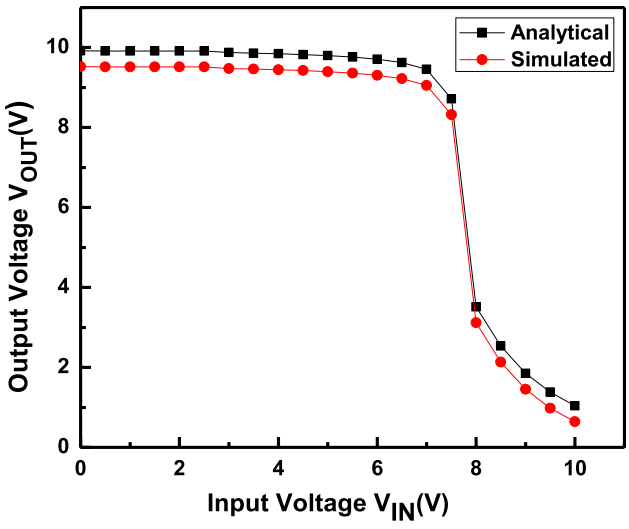

Fig. 7 Voltage transfer characteristics (VTC) of dual gate organic all-*p* pseudo-inverter circuit

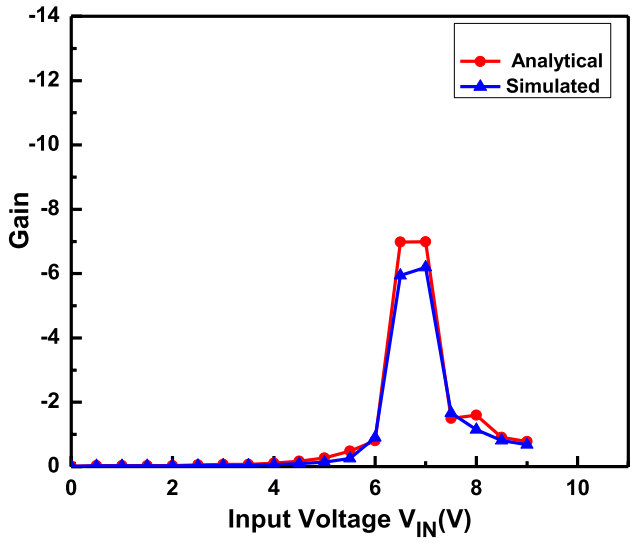

Fig. 8 Voltage gain plot of dual gate organic all-*p* pseudo-inverter in ZVLL configuration

NM_H is due to the presence of a weak pull down transistor (*p*-type). The voltage gain is depicted in Fig. 8.

The magnitude of V_{OH} must be high and close to V_{DD} to achieve high noise margin. The maximum value attained by V_{OH} is limited to (V_{DD}–V_T) owing to the threshold voltage drop of the device. The minimum pull down that can be achieved by *p*-MOS is equal to V_T , always. In order to achieve better performance threshold, voltage drop should be minimized. The dynamic behaviour of the dual gate based pseudo-all-*p* inverter is demonstrated in Fig. 9. The V_{OUT} exhibits some spikes with magnitude between 10 and 11 V at the beginning of the pull-down action. When the input is changed instantaneously from 0 to V_{DD}, the voltage over gate-drain capacitor has to change from V_{DD} to 0 V. This could happen only if an infinite amount of current flows through the capacitor [11, 12]. Due to the low *K* of the organic *p*-type pull-down transistor, it may not able perform a fast draining action, and for some instances the V_{OUT} may retain a value between V_{DD} to 2* V_{DD} unless the pull-down transistor comes completely under good conducting mode.

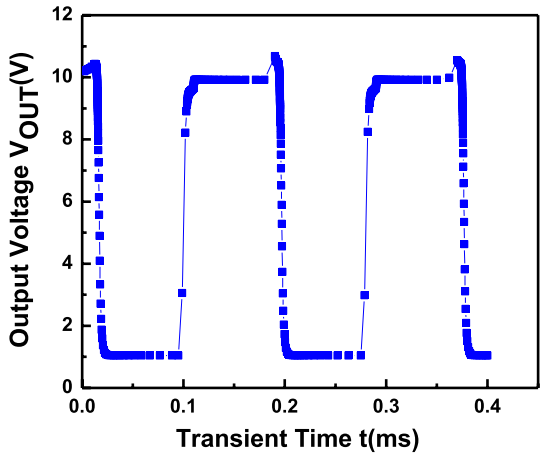

Fig. 9 Transient characteristics of dual gate organic all-*p* pseudo-inverter in ZVLL configuration

To analyse the transient characteristics, a square pulse was applied with a magnitude of 10 V and frequency of 1 kHz. From the transient characteristics, the propagation time delays are calculated. The high-to-low (τ_{PHL}) and low-to-high (τ_{PLH}) transition can be defined as the time taken by the capacitor to charge and discharge, respectively. Output rise time and fall time are calculated from the transient characteristic.

4 Parameter extraction of all-*p* organic pseudo-inverter using analytical models

In this section, the mathematic models behind extraction of pseudo-inverter parameters are analyzed to understand the circuit behaviour in depth. The extraction of critical voltage levels, noise margins, propagation delay, power consumption are described in the following subsections.

4.1 Analysis and extraction of static parameters

Critical performance parameters such as V_{OH}, V_{OL}, V_{IH}, V_{IL} and V_{TH} are extracted from the VTC plot, as demonstrated in Fig. 7.

(a) V_{OH} extraction

The value of V_{OH} is extracted on applying a zero input, wherein TFT1 operates is in linear region and TFT2 is in cut-off. The TFT1 is working as a driver transistor, whereas TFT2 is working as a load transistor. The output of the load transistor is connected as the input for TFT4. Since the transistors are placed in series, the drain current in steady state is equal. As the load transistor is in cut-off region, the drain current is zero and $V_{OUT}=V_{OH}=V_{DD}=10$ V.

(b) V_{OL} extraction

For extraction of V_{OL} the input voltage is equal to the supply voltage V_{DD}. The operating status of different transistors is summarized in the Table 2. The transistors TFT3 and TFT4 are connected in cascade. As both the transistors (TFT3 and TFT4) are acting as the buffer, thus current is same at the steady state and equal to zero. Now, the modified equation may be expressed as:

$$\mu C_{OX}\frac{W}{L}\left(\frac{\left(V_{GS}-V_{TH}\right)^2}{2}\right)=0 \tag{2}$$

On simplifying, the magnitude for V_{OL} is obtained as 2 V.

(c) V_{IL} extraction

As per the status of the transistor mentioned in Table 2 on V_{IL} input, the KCL is applied at the output node, wherein the current at the steady state are set equal and expressed as:

$$K_n\left(\frac{W}{L}\right)\left(\left(V_{GS}-V_{TH}\right)V_{DS}\frac{V_{DS}^2}{2}\right)=K_n\left(\frac{W}{L}\right)\times\left(\frac{\left(V_{GS}-V_{TH}\right)^2}{2}\right) \tag{3}$$

Using the above conditions as input to TFT4, we have:

$$\left(V_{IN}-8\right)\times\left(V_{OUT}-10\right)-\frac{1}{2}\left(V_{OUT}-10\right)^2=\frac{1}{2}\left(V_{IN}+8-V_{OUT}\right)^2 \tag{4}$$

Differentiating with regard to 'V_{IN}' on both sides and using the condition from the VTC, we get:

$$\left(V_{IN}-8\right)\times\frac{dV_{OUT}}{dV_{IN}}+\left(V_{OUT}-10\right)-\frac{1}{2}\times2\times\left(V_{OUT}-10\right)\times\frac{dV_{OUT}}{dV_{IN}}=\frac{1}{2}\times2\times\left(\left(V_{IN}+8-V_{OUT}\right)\times\left(\frac{1}{2}-\frac{dV_{OUT}}{dV_{IN}}\right)\right) \tag{5}$$

Setting $V_{IN}=V_{IL}$ we get $V_{IL}=6.28$ V.

(d) V_{IH} extraction

Similar to V_{IL}, the V_{IH} is extracted as:

$$K_n\left(\frac{W}{L}\right)\left(\frac{\left(V_{GS}-V_{TH}\right)^2}{2}\right)=K_n\left(\frac{W}{L}\right)\left(\frac{\left(V_{GS}-V_{TH}\right)^2}{2}\right) \tag{6}$$

Putting the values we get:

$$K_n\left(\frac{800}{90}\right)\left(V_{IN}-8\right)^2=2 \tag{7}$$

Differentiating with regard to V_{IN} on both sides we get 8 V. The remaining two transistors, TFT 3 and TFT4, are acting as a buffer, so the current remains same in both the transistors at the steady state.

$$K_n\left(\frac{W}{L}\right)\left(\frac{\left(V_{GS}-V_{TH}\right)^2}{2}\right)=K_n\left(\frac{W}{L}\right)\left(\frac{\left(V_{GS}-V_{TH}\right)^2}{2}\right) \tag{8}$$

$$K_n\left(\frac{800}{90}\right)\times\frac{1}{2}\left(V_{IN}-8\right)^2=K_n\left(\frac{800}{90}\right)\times\frac{1}{2}\times\left(V_{O1}+2-V_{OUT}\right)^2 \tag{9}$$

Differentiating with regard to 'V_{IN}' on both sides we get:

$$V_{IN}-8=2-V_{OUT} \tag{10}$$

Setting $V_{IN}=V_{IH}$ and $V_{OUT}=V_{OL}=2.0$,V we get $V_{IH}=8.0$ V.

4.2 Analysis and extraction of dynamic parameters

From the VTC characteristics of the inverter, it can be seen that the transition occurs for quite a narrow duration. In this region, the inverter works as an amplifier, as the gain is higher than unity only for this region. The analytical value of the gain is calculated from the earlier measured values of the critical voltages and discussed as:

Width of the transition region $=(V_{IH}-V_{IL})$ V
Height of the transition region $=-(V_{OH}-V_{OL})$ V
Gain 'A_v' $=-(V_{IH}-V_{IL})/(V_{OH}-V_{OL})=-4.65$
$NM_H=(V_{OH}-V_{IH})=(9.91–8)=1.91$ V
$NM_L=(V_{IL}-V_{OL})\ V=(6.28-2.0)=4.28$ V

It can be observed from Table 3 that the performance of the dual gate pseudo-all-*p* inverter is higher than that of conventional inverter configurations.

The gain is augmented by factors of 2 and 1.5 compared to DLL and ZVLL configurations, respectively. Additionally, the output voltage swing is increased by 25% and 19% for the pseudo-inverter compared to DLL and ZVLL, respectively. This is due to the presence of the cascaded logic design of the pseudo-all-*p* inverter, which enhances the values of the V_{OH} and V_{OL}. The static performance parameters calculated through analytics are compared with the values extracted from simulation and are listed in Table 4. The parameters show a close match with reasonable validation.

Table 2 Static parameters and mode of transistor organic all-*p* pseudo-inverter circuit

Static parameter	Mode of operation	Transistors in 'ON' state
V_{OH}	Linear and cut-off	TFT1
V_{OL}	Cut-off and saturation	TFT2
V_{IL}	Linear and saturation	TFT1 and TFT2
V_{IH}	Both in saturation	TFT1 and TFT2

Table 3 Comparison of performance parameters of proposed dual gate pseudo-all-*p* inverter with conventional inverter

Parameters	Static performance parameter extraction			Dynamic performance parameter extraction

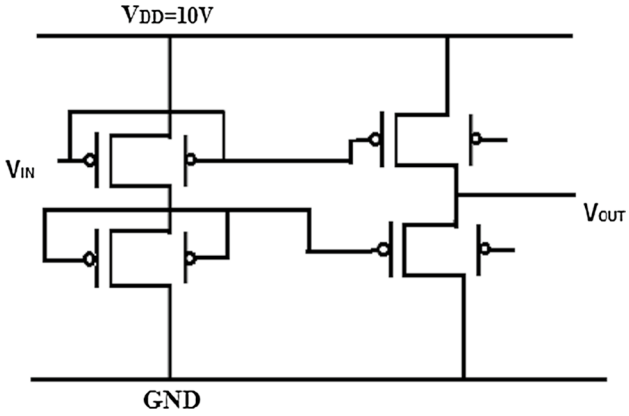

Fig. 10 Back gate biasing in DG-OTFT organic pseudo-all-*p* inverter

5 Performance improvement techniques of organic dual gate pseudo-all-*p* inverters

One of the performance limiting factors is the threshold voltage drop occurring in the circuits. To improve performance, this threshold voltage drop should be minimized. There are different techniques for improving the performance. In this work, two techniques are employed:back gate biasing and bootstrapping.

5.1 Back gate biasing in organic pseudo-all-*p* inverters without bootstrap technique

Reliable as well as robust operation of organic circuits is directly linked with the noise margin, which should be considerably high to ensure stable characteristics [13]. Threshold voltage can be limited by applying a fixed bias at the back gate, while a higher positive value of fixed gate bias is applied at the back gate of the driver [13]. Furthermore, front and back gate are coupled together for the load transistor to improve the noise margin and gain of the inverter.

By applying a fixed bias, the transistor operates in the linear region. Back gate V_{TH} control is used to limitat the performance degradation of the circuit and shift it towards $V_{DD}/2$, which is expected for the ideal behaviour of the inverter. The organic pseudo-inverter with back gate biasing is shown in Fig. 10; it has proven to be an efficient technique for enhancing the noise margin and robustness of the circuit.

5.2 Organic pseudo-all-*p* inverter with bootstrap technique

Bootstrapping is used to reduce the threshold voltage drop in the circuit [3, 12]. The circuit structure consists of a body capacitor (CB) that is used in the feedback loop between the output node and the input node. The charge stored on the capacitor is added to the voltage available at its input node, resulting in voltage boosting at its output terminal.

As a result, the threshold voltage drop is compensated and the noise margin is enhanced. The dual gate based pseudo-inverter with bootstrapping is shown in Fig. 11. All transistors are operating in sub-threshold operation using the bootstrap technique. The voltage transfer characteristic with bootstrapping is shown in Fig. 12. Bootstrapping is more efficient in reducing the leakage power and enhancing the speed of the logic circuits. It provides voltage levels above supply voltage and below the ground potential. This phenomenon leads the devices into the super cut-off region-which minimizes the leakage power dissipation.

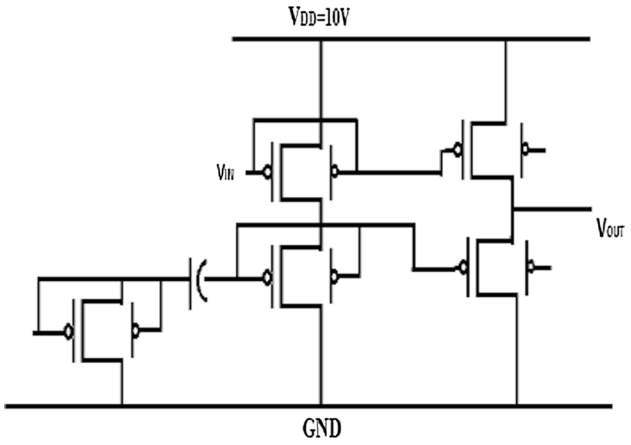

Fig. 11 Dual gate organic pseudo-all-*p* inverter with bootstrap technique

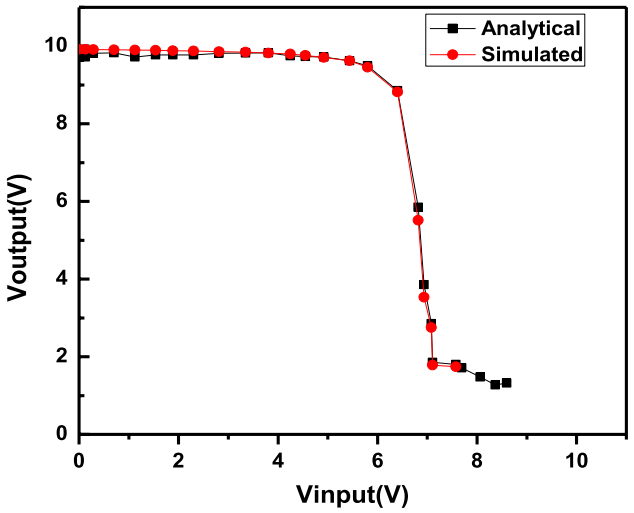

Fig. 12 VTC plot of analytical and simulated results for organic pseudo-inverter with bootstrap technique

Table 5 Comparison of extracted values of the dynamic performance parameters with and without bootstrap technique

Parameter	Extracted parameter without bootstrap technique	Extracted parameter with bootstrap technique
τ_{PHL} (μs)	77	79
τ_{PLH} (μs)	12	84
τ_{p} (μs)	44	82
P_S (μW)	22.2	31.1

Comparison of extracted values of the dynamic performance parameters with and without bootstrapping is summarized in Table 5. The output voltage level is held to a minimum value by its body transistor, which is boosted with a body capacitor. The main purpose of the body capacitor is to reduce threshold voltage (V_{TH}) sensitivity. The gain of the inverter using bootstrapping is improved by 48.47%. Voltage gain of a organic pseudo-all-*p* inverter with and without bootstrap techniques in ZVLL configuration is depicted in Fig. 13. A comparison between noise margin of organic pseudo-all-*p* inverter with and without bootstrap technique is given in Table 6, which shows that the higher value of noise margin (NM_H) improved by 25% with the bootstrap inverter.

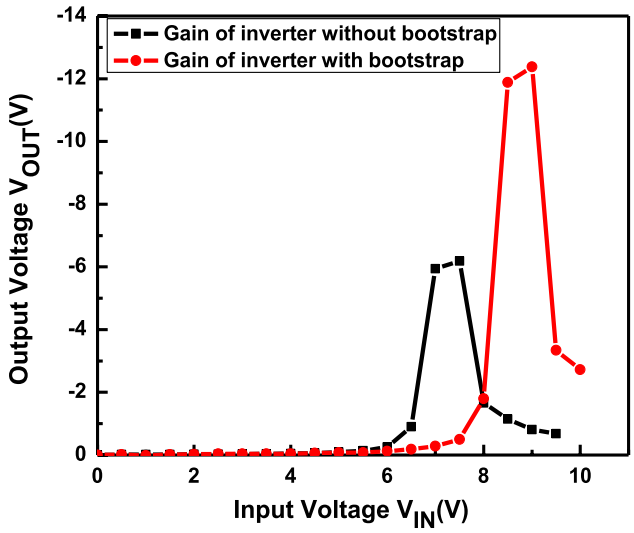

Fig. 13 Voltage gain of organic pseudo-all-*p* inverter with and without bootstrap techniques in ZVLL configuration

Table 6 Comparison of extracted parameters of DG-OTFT based pseudo-all-*p* inverter with and without bootstrap technique

Parameter	Without bootstrap (V)	With bootstrap (V)
V_{OH}	9.91	9.96
V_{TH}	7.35	7.21
V_{OL}	1.05	0.92
NM_H	1.93	1.96
NM_L	5.45	2.64

From the dynamic characteristics, it is observed that the propagation delay is increased in the organic pseudo-all-*p* inverter with bootstrap technique, as shown in Fig. 14, due to the weak pull down (*p*-type) transistor in the structure that may be increased using a high aspect ratio for the pull down transistor.

The power consumed should be estimated for the device, as it is an important parameter used to predict the reliability of the device for long term use. If the device consumes less power, it is more reliable for intended use. The power consumed by the inverter is discussed in Sect. 6.

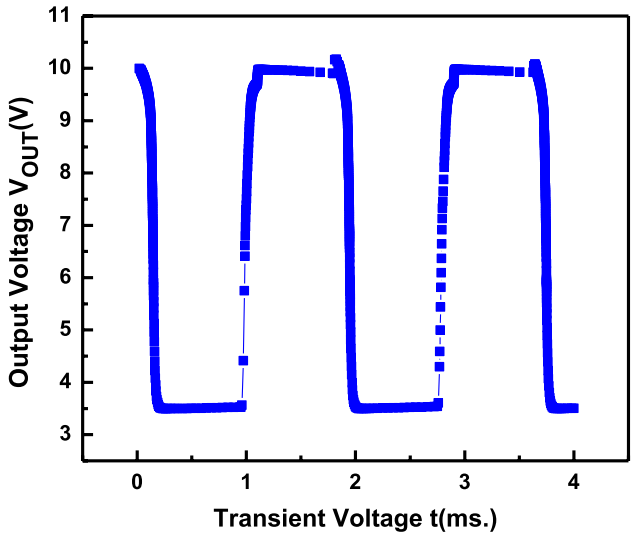

Fig. 14 Transient characteristics of organic pseudo-all-*p* inverter with bootstrap technique in ZVLL configuration

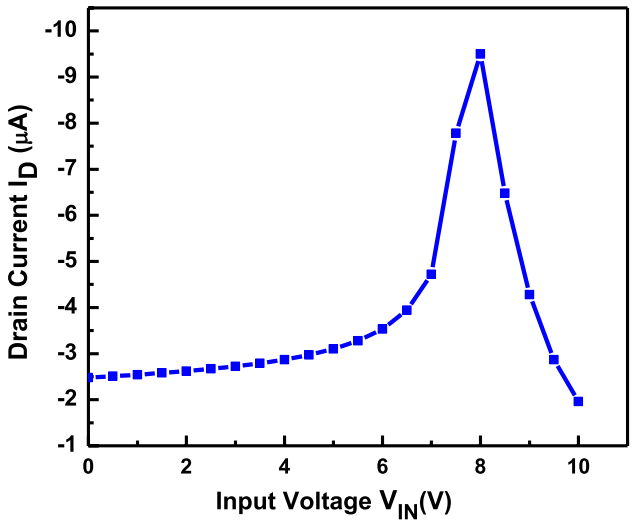

Fig. 15 Power supply current of organic pseudo-all-*p* inverter

6 Estimation of propagation delay, power consumption and area in dual gate organic pseudo-all-*p* inverter

The power consumed by a pseudo-all-*p* inverter is dependent on the amount of current flowing through the inverter. The current consumed I_S is the peak value of the current flowing through the driver transistor during the ON state. In MOSFET based devices there is considerable power consumption due to leakage, the current flowing through the inverter when it is in the OFF state.

To overcome this leakage power, the bootstrap technique is employed. Applying an input voltage above the supply but below the ground potential is said to be in the super cut-off region. As the device is operating in super-cut-off region the leakage power is minimised. The power consumed by the inverter is optimized when both the TFT3 and TFT4 are in the saturation region, as shown in Fig. 15, and compared with ZVLL and DLL based inverters in Table 7. The area consumed by the design is higher, as compared to conventional inverter, due to the presence of cascaded logic in the inverter, which results in a four transistor array.

The power consumed is given by Eqs. 11, 12 and 13.

$$P_S = I_S \times V_{DD} \tag{11}$$

$$P_L = I_L \times V_{DD} \tag{12}$$

$$\text{PDP} = P \times \tau_P \tag{13}$$

From the above equations it is observed that the power consumption of a dual gate based pseudo-all-*p* inverter is lower than that of conventional inverters. It is reduced by 84% for pseudo-all-*p* inverter without bootstrapping as compared to DLL conventional configuration, as shown in Table 7. Consequently, the power delay product (PDP) with bootstrapping is higher as compared to that without bootstrapping, due to the weak pull down transistor and higher propagation delay. Likewise, the static and transient performances of the dual gate design differ from those of the single gate design due to the difference in structure, transconductance and I_{ON}/I_{OFF} ratio.

There is a significant increase of 30% in the voltage gain of the organic pseudo-all-*p* inverter in comparison to the ZVLL (DG) of conventional inverter, as observed in Table 8. Similarly, the output swing is improved by 16.85% and 32.58% in comparison to the dual gate based ZVLL and DLL inverters, respectively.

Likewise, the propagation delay of dual gate pseudo-all-*p* inverter is reduced by 59.09% with regard to the ZVLL inverter, as depicted in Table 8. Similarly, there is improvement in the value of V_{OH} by 18.59% and 24.77% in the value of NM_H compared to conventional organic inverter, as shown in Table 9.

Table 7 Comparison of performance in terms of propagation delay power, area and PDP of pseudo-all-*p* inverter with conventional inverter

Parameter	τ_p (μs)	Power P_S (μW)	PDP = $P_S \times \tau_p$ (ps)	Area (μm^2)
DLL (DG)	25	139	3475	40,000
ZVLL (DG)	70	22	1540	40,000
DG-organic pseudo-all-*p* inverter	44	22.2	888	80,000

Table 8 Performance comparison of dual gate based circuit with single gate

Parameter	Static performance parameter extraction				Dynamic performance parameter extraction		
	V_{OH}	V_{OL}	A_v	Output swing	τ_p (µs)	τ_{PHL} (µs)	τ_{PLH} (µs)
DLL (DG)	8.1	2.1	2.2	6.0	25	54	21
DLL (SG)	7.9	2.9	1.9	5.0	93	154	32
ZVLL (DG)	9.0	1.6	3.1	7.4	70	146	38
ZVLL (SG)	9.0	2.1	2.6	6.9	159	277	40
Pseudo-all-p inverter, ZVLL (DG)	9.95	1.05	4.65	8.9	44	77	12

Table 9 Performance comparison of dual gate organic pseudo-all-*p* inverter with conventional inverter in terms of area and static parameters

Parameters	V_{OH} (V)	V_{OL} (V)	NM_L (V)	NM_H (V)	Area (µm^2)
Conventional organic inverter	8.1	2.1	5.1	4.1	40,000
Proposed dual gate pseudo-all-*p* inverter	9.95	1.05	1.93	5.45	80,000

7 Conclusion

This research paper has presented a dual gate based organic pseudo-all-*p* inverter with and without bootstrap technique. The static and transient characteristics of the inverter were observed and transition time was extracted. DG based transistors have shown better performance mainly in terms of mobility, drain current, trans-conductance, thereby improving the performance of entire circuits. These transistors have better control over the threshold voltage due to the possibility of biasing at both the gates. Significant increases of 16.85% and 32.58%, respectively, were obtained for the voltage swing of the proposed inverter over the conventional DLL and ZVLL configurations. Propagation delay and power consumption were greatly reduced as well. The extracted value of propagation delay of dual gate pseudo-all-*p* inverter was reduced by 59.09% with regard to the ZVLL inverter. Additionally, bootstrapping and back gate biasing techniques were applied. The higher value of noise margin (NM_H) was improved by 25% with the bootstrap inverter technique. Also, the gain of the inverter using bootstrapping was improved by 48.47%. Thus, the bootstrap inverter technique was proven as a significant stepping stone towards achieving high-performance flexible digital circuits.

"Lecture Notes on Multidisciplinary Industrial Engineering" publishes special volumes of conferences, workshops and symposia in interdisciplinary topics of interest. Disciplines such as materials science, nanosciences, sustainability science, management sciences, computational sciences, mechanical engineering, industrial engineering, manufacturing, mechatronics, electrical engineering, environmental and civil engineering, chemical engineering, systems engineering and biomedical engineering are covered. Selected and peer-reviewed papers from events in these fields can be considered for publication in this series.

Preface

Manufacturing is the backbone of the economy of a nation. It is one of the oldest activities of the human civilization. In the twenty-first century, the emphasis is on enhancing the efficacy and efficiency of manufacturing processes and systems by using the computational power. Industry 4.0 aims to make use of digital manufacturing, cloud computing and manufacturing, Internet of things, and big data analytics. It is essential to understand the manufacturing processes scientifically, develop models, and optimize them. In December 2011, the 1st International Conference on Computational Methods in Manufacturing (ICCMM 2011) was organized at the Indian Institute of Technology Guwahati. The conference was a huge success with encouraging participation from industry and academia. After a gap of 8 years, the 2nd International Conference on Computational Methods in Manufacturing (ICCMM 2019) was organized on March 8–9, 2019.

The objective of this conference was to promote the use of computational techniques in manufacturing by providing a platform for sharing ideas and expertise. We wanted to bring practicing engineers, experimentalists, and computational experts together. We received contributed papers from the researchers covering all major areas of computational manufacturing and allied fields. A total of 125 full papers were received, which were peer-reviewed. The authors have revised their papers based on the review comments. Finally, 90 papers were selected for inclusion in the book of proceedings.

This book of proceedings covers the following broad topics: material forming, joining and welding, casting, additive manufacturing, material fabrication, subtractive manufacturing, process modeling, simulation, analysis, optimization, and design. Although the focus of the conference is on computational techniques, most of the authors have invariably included experimental results as experiments are the inseparable part of modeling of manufacturing.

We hope that the book of proceedings will be a valuable document for the delegates, scientists, engineers, and research scholars. Springer has taken the responsibility of publishing and distributing it to a wider audience. We wish to

thank Ms. Swati Meherishi, Ms. Avni, and other staff members of Springer. We acknowledge the support provided by the reviewers, members of advisory and organizing committees, and colleagues at IIT Guwahati. Any feedback to the editors regarding this collection will be highly appreciated.

About the Editors

R. Ganesh Narayanan is an Associate Professor at the Department of Mechanical Engineering, Indian Institute of Technology (IIT) Guwahati, India. He received his Ph.D. from the IIT Bombay, India. His research areas include metal forming and joining. He has contributed many research articles in reputed journals and international conferences. He has edited few books including 'Sustainable Material Forming and Joining' published by CRC Press USA, 'Strengthening and Joining by Plastic Deformation' published by Springer Singapore, 'Advances in Material Forming and Joining' published by Springer India, and 'Metal Forming Technology and Process Modeling' published by McGraw Hill Education, India. He has also edited special issues of journals including 'Advances in Computational Methods in Manufacturing' in the International Journal of Mechatronics and Manufacturing Systems, and 'Numerical Simulations in Manufacturing' in the Journal of Machining and Forming Technologies. He has organized three international conferences at IIT Guwahati namely International Conference on Computational Methods in Manufacturing (ICCMM) in 2011, the 5th International and 26th All India Manufacturing Technology, Design and Research (AIMTDR) Conference in 2014, and International Conference on Computational Methods in Manufacturing (ICCMM) in 2019. He has also organized a GIAN course on 'Green Material Forming and Joining' at IIT Guwahati in 2016.

Shrikrishna N. Joshi is an Associate Professor in the Department of Mechanical Engineering, Indian Institute of Technology Guwahati, India, where he joined after completing his doctoral studies from IIT Bombay in 2010. His research interests include laser based manufacturing, ultraprecision machining, computer aided design and manufacturing (CAD/CAM) and, manufacturing process modeling & optimization. He has authored/co-authored about 50 research articles in international journals/conferences and six book chapters. He has also co-edited 2 books on "Laser based manufacturing" with Springer.

Uday Shanker Dixit is a Professor in the Department of Mechanical Engineering, Indian Institute of Technology Guwahati. He completed his BE in Mechanical Engineering from the University of Roorkee (now the Indian Institute of Technology Roorkee) in 1987, and his MTech and PhD in Mechanical Engineering from the Indian Institute of Technology Kanpur (IIT Kanpur) in 1993 and 1998, respectively. Professor Dixit has previously worked on designing machines for industry, and as the Officiating Director of the Central Institute of Technology, Kokrajhar. Professor Dixit has been actively engaged in research in various areas of design and manufacturing for the last 25 years. He has authored/co-authored more than 200 research papers, 27 book chapters and 7 books on mechanical engineering. He has also co-edited 7 books on manufacturing. Presently, he is an associate editor of the Journal of the Institution of Engineers (India), Series C and Vice-President of the AIMTDR conference.

Material Forming

Chapter 1
Numerical Simulation of Micro Forming of Bio-Absorbable AZ80 Magnesium Alloy

D. Rajenthirakumar, N. Srinivasan and R. Sridhar

Abstract The characteristics of grains during the micro forming process are unpredictable. It reflects in the material behavior, interfacial friction and surface finish due to size effects. This paper describes the numerical analysis of size effects and frictional effects during the plastic deformation of magnesium AZ80 alloy in the micro extrusion process. On the basis of true stress–strain curve, the material model is used for numerical investigation. The results reveal that the flow stress increases with decreasing grain size due to increasing interfacial friction. The results are then validated with the micro extrusion experiments conducted. Further, the friction generation and load prediction can be achieved through numerical simulation is the primary criteria.

Keywords Micro forming · Extrusion · Finite element method · Size effect

1.1 Introduction

Miniaturization technology has transformed the very risky assignment into a smart task not only in electronic field but also in medical devices such as pacemakers, implantable defibrillators, catheters, stents, and neuromodulator device. The metals and glasses are replacing the polymers due to its higher strength in minimum grain size. During the transformation from macro scale to micro scale the phenomena called size effect governs the micro plastic deformation of material and its behavior [1]. When scaling down the characteristics of grains are unpredictable pertaining to material behavior. During the micro forming process, surface to volume ratio increases considerably and grain size effect ruins the flow stress of the material [2]. Hence, different methods of experiments and numerical analysis are conducted by

researchers worldwide. The primary focus of the research is to control the size effect and minimize the interfacial friction.

Piwnik and Mogielnicki simulated the influence of container roughness on material flow process in micro extrusion. They concluded the significant impact of a wave roughness on material flow in the process [3]. The authors also simulated the interfacial friction towards the improvement of surface roughness [4]. The strategies to estimate grain properties and model grain size effect are developed and the grain size effect on deformation behavior and the scatter of flow stress are modeled. The results are then validated with experiments [5]. So to eliminate the time taken and expenses for experimenting, numerical simulation is employed to predict the behavior in several aspects during the experiments.

In this work, a numerical simulation of AZ80 Mg alloy is performed and the results obtained are then validated with physical experiments. The AZ80 Mg has a huge application in biomedical field [6]. The paper mainly focuses on the numerical analysis of micro extrusion by which the prediction of size effects and friction at interfaces has been achieved. Initially, the material model is obtained by micro compressions test, which is given as input for numerical simulation. The second stage is the FEM simulation. The last stage is the validation of numerical analysis with experiments.

1.2 Micro Compression Test and Size Effects

The material for the micro compression experiment is AZ80 Mg alloy of different grain sizes such as 20, 36, and 84 µm in quasi-static condition. The strain rate is 0.1 mm/s which is kept constant. Figure 1.1 shows the true stress–strain curves for

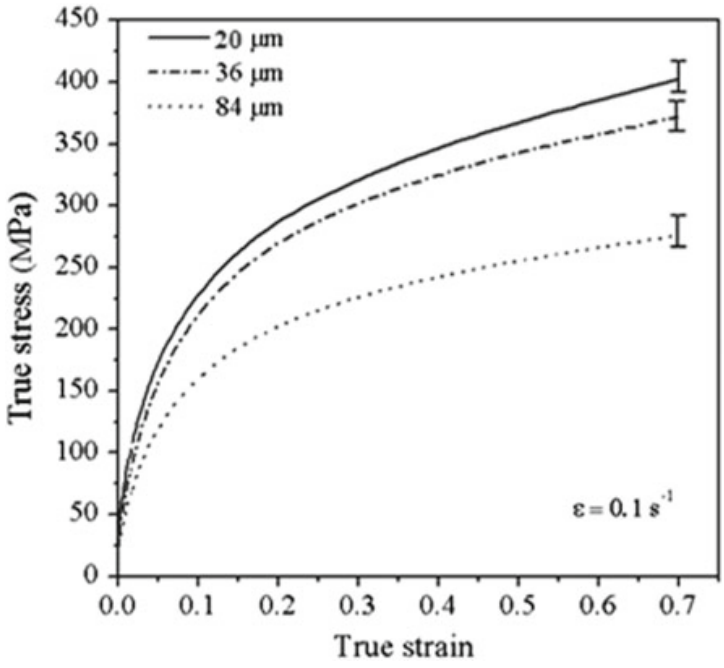

Fig. 1.1 True stress–strain curve

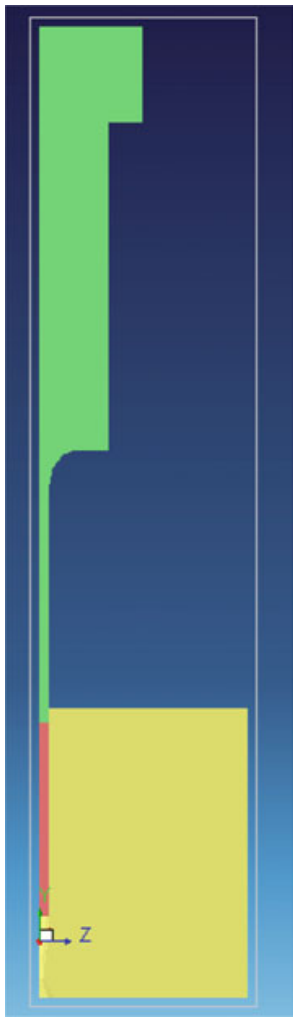

Fig. 1.2 FEM—2D axisymmetric Model

specimens in 1.2 mm diameter and three different grain sizes. The curves illustrate that the flow stress increases with decrease in grain size.

The effects of scaling down with decreasing flow stress are discussed through so-called surface model [7]. The resistance to deformation gets varied from surface layer to inner grains of the material. The difference is due to the hardness variation in surface layer to inner grains of the material. The occurrence of interfacial friction effect can be seen in flow stress curves. The existence of larger grains count possesses maximum resistance to plastic deformation. As a result, the smaller the grains, the larger the friction generated in tool-billet interfaces can be noticeable.

1.3 FEM Model

AFDEX is a metal forming simulator, meets the requirements for bulk metal-forming and simulation. The AFDEX_V17R00 is utilized for predicting the nonlinear behavior of material in 2D and 3D. Based on the previous results in literature [8], 0.3 µm is selected as coefficient of friction as it is a dry condition, as

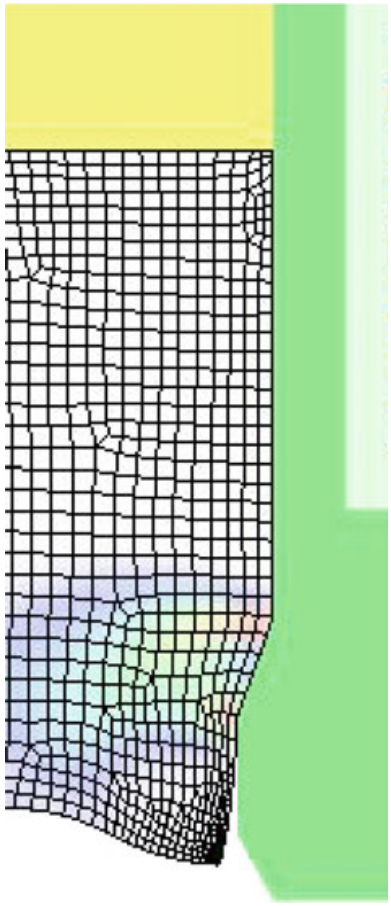

Fig. 1.3 Meshed model

an assumption to compare the frictional effect on forming load. The micro extrusion tooling system is modeled as rigid bodies while the forming material (micro pin) is an elastoplastic body. Simulations are performed with the most widely used von Mises yield criterion as it gives equal weight to all principal stresses. Considering the symmetry in both geometry and loading conditions, a single half experimental setup is modeled (see Fig. 1.2). The meshing in Fig. 1.3 is done with 8200 four nodes 2D axisymmetric quadrilateral element. These elements have maintained the accuracy in stress analysis. The adaptive meshing technique is selected to retain the mesh quality. To obtain a suitable mesh, a local element size has to be applied. This requires some trial and error method.

1.4 Physical Experiment

In order to show the effects of grain size and investigate the interfacial friction, an experimental setup is designed and micro extrusion tests with AZ80 magnesium billets of different grain sizes have been performed. Figure 1.4 shows the exploded view of micro extrusion die assembly and Fig. 1.5 shows the schematic view of micro extrusion die assembly.

Fig. 1.4 Micro extrusion—die assembly

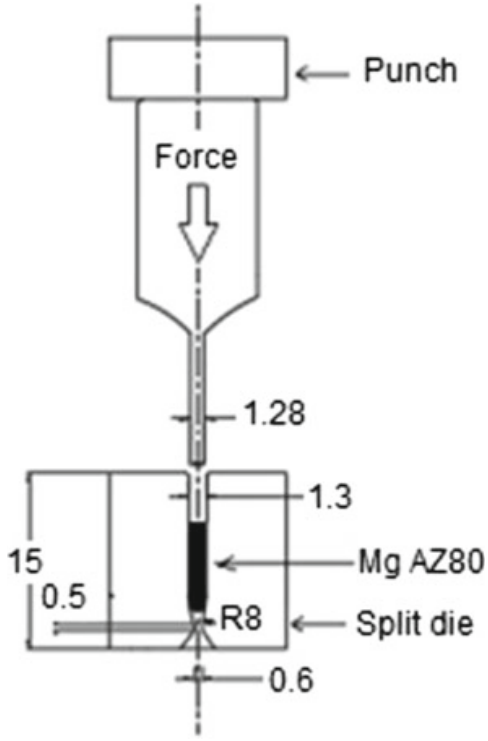

Fig. 1.5 Schematic view of microextrusion assembly

1.5 Results and Discussion

The numerical simulation of micro forward extrusion is performed to evaluate the interfacial friction. The 20 μm grain size is selected for simulations it possesses high grains count per unit volume. The Von-Mises stress distribution and strain distribution of the micro forward extrusion are shown in Figs. 1.6 and 1.7, respectively. The material undergoes the severe shear deformation at the die-billet contact surfaces. The differences in friction coefficient are observed in stress and strain distribution. The interfacial friction observed during the simulation (see Fig. 1.8) is reduced with coefficient of friction.

The experimental results are then compared with numerical simulation for validation purpose. The micro extruded parts are shown in Fig. 1.9. The billet-die interfaces are exposed to friction which increases with the decrease of specimen size. This is due to the increase of the fraction of contact area and so, the peak is observed initially in forming load. It started decreasing due to increase in proper

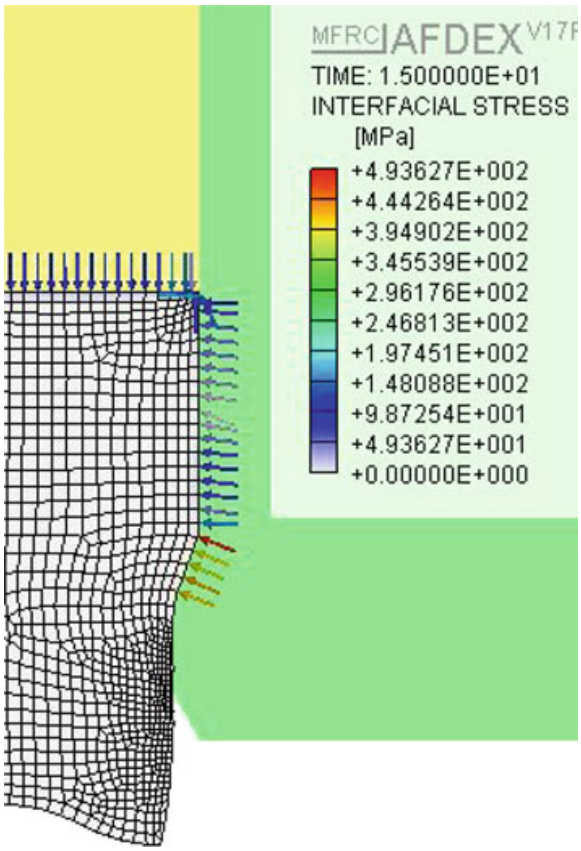

Fig. 1.8 Interfacial stress (20 μm)

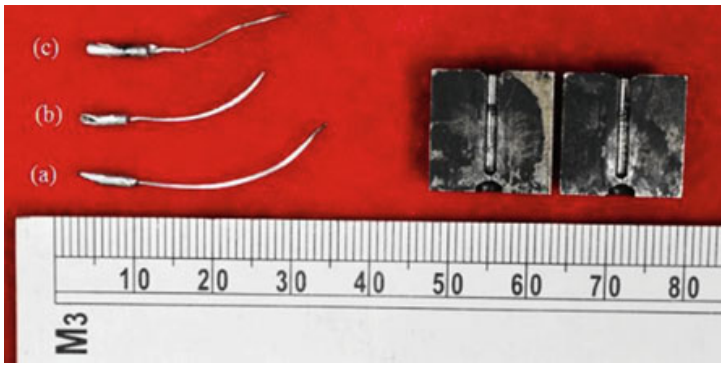

Fig. 1.9 Micro extruded parts, **a** 20 µm, **b** 36 µm and **c** 84 µm

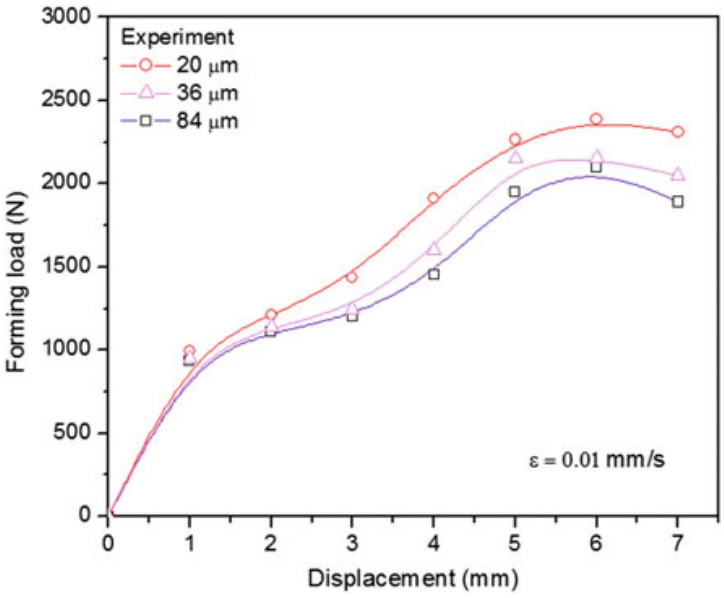

Fig. 1.10 Load versus displacement curve of AZ80 Mg

material plastic flow. The numerical simulation of the micro forward extrusion performed with 0.3 µm. The load–displacement response obtained from experiments is shown in Fig. 1.10. The maximum load consumed by 20 µm is due to high grains count per unit volume which possesses high strain resistance to deformation.

1.6 Conclusions

The numerical simulation and experimental validation has been conducted for biological grade Mg alloy AZ80 and the following conclusions are made:

- The interfacial friction increases with decrease of grain size. It is proved by observing high interfacial stress of 20 µm than the deformation of other grain size Mg AZ80 alloy.
- The flow stress of AZ80 Mg alloy increases with reduction in grain size.
- The deformation load increases with reduction in grain size.

- The numerical simulation results with AFDEX shows the in-depth friction condition effects in the micro forward extrusion process. When the friction coefficient increases the deformation load increases correspondingly.

The numerical simulation has concealed significant benefits such as load prediction for several friction conditions, existence of interfacial friction and minimizing the time and number of experiments. Even though the numerical analysis shows some deviation with experiments, it is likely to be considered for prediction.

Chapter 2
Investigation on Tensile Testing of Tailor Welded Blanks (TWBs)—A Simulation Study

Shalin Marathe and Harit Raval

Abstract The goal of better fuel economy can be fulfilled by the use of technology like TWBs (Tailor Welded Blanks). TWB is a product of joining two or more than two materials before any forming operation. The limitations associated with TWBs are the weld line movement and reduced formability. The formability reduction of TWB is due to the thin/weak material involved in it and therefore the tensile study of the TWBs becomes an important aspect. In the present study, investigation of tensile testing of Similar Material Dissimilar Gauge TWB and Dissimilar Material Similar Gauge TWB has been done numerically. For the simulation purpose, ABAQUS/Explicit has been used. The results indicate that the thin/weak material governs the strength of the TWB because the failure or necking is observed in that particular side only. Also, it has been observed that the failure locations are found to be at the boundary of thin/weak base material and weld zone.

Keywords Tailor welded blanks (TWBs) · Friction stir welding (FSW) · ABAQUS/explicit · Simulation · Tensile testing

2.1 Introduction

Nowadays, automobile, aerospace, transportation, and shipbuilding industries are aiming at weight reduction of the components without compromising the strength and Tailor Welded Blanks (TWBs) have been found to fulfill these requirements. TWB is a product of joining two or more than two material prior to any forming operation. TWB involves joining of two or more than two materials having different properties, thicknesses and/or coatings by any of the conventional joining processes. As it involves joining of materials having different densities the overall weight of the product decreases [1]. Also, TWBs are subjected to forming after the

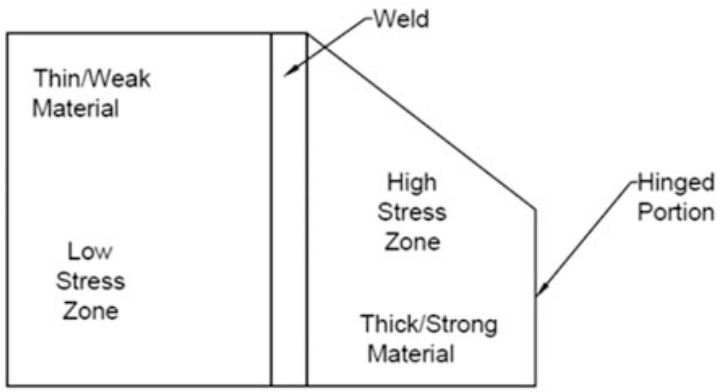

Fig. 2.1 Schematic representation of TWB used at inner door panel of an automobile body

joining has been done and because of that the number of dies required for the forming decreases [1] which also leads to decrease the product lead time and cost as well. Figure 2.1 indicates the schematic of TWB which is used at the inner door panel of an automobile body.

Despite of such tremendous advantages, the application of TWBs has been not up to the mark as limitations like formability reduction [2] and weld line movement [3] are associated with TWBs. In TWBs, as there is a presence of weld between the two parent metals, the whole product becomes inhomogeneous and when TWBs are subjected to forming operations these inhomogeneities result in uneven strain [2] and hardness distribution [2, 4, 5] across the weld. This uneven distribution of hardness and strain leads to failure of the TWBs resulting in the low formability of the component. A lot of research has been done to investigate the formability behavior of TWBs during the conventional forming [2] operations and it has been observed that the formability of TWBs is found to be decreasing in comparison to the parent metal participating in it. Now in order to improve the formability of the TWBs lots of efforts have been done by researchers.

TWBs are generally developed from the materials like steel [6–8], aluminum and its alloys [4, 9] and titanium as more application is found in automobile, ship-building, aerospace and transportation industries. The application of steel to develop TWBs has been reduced as the aluminum material gives a higher amount of weight saving [10]. TWBs involving steel as parent material are generally developed using the laser welding [6, 9, 11–13] processes and if aluminum and its alloys are used as parent material than solid-state welding processes like FSW [9, 14–16] is found more suitable. As aluminum has low laser absorption capacity and it is very reflective in nature, it is quite difficult to weld using laser welding and other conventional welding techniques.

In order to decide the quality of the TWBs, there are many testing methods available and tensile testing is one of them. So, in this present work tensile testing of TWBs has been performed using a simulation tool ABAQUS/Explicit. The simulation methods save important resource like time, material and cost. So in present work, testing of TWBs made from similar material having different thickness/gauge and dissimilar materials having similar thickness/gauge are investigated using a simulation tool. In this work, TWB is considered to be made

from FSW process which is known as Friction Stir Tailor Welded Blank (FSTWB). Results like plastic strain, Von-misses stresses, Load versus Displacement diagram, Stress–Strain behavior and True strain distribution across the weld are extracted from the simulation and compared with published literatures.

2.2 Numerical Conditions

In this present study, all the simulations are carried out using ABAQUS/Explicit [17]. This study has been divided into two sections. First section contains the simulation study on similar material dissimilar gauge TWBs made from FSW process and second section contains the same investigation for dissimilar material similar gauge TWBs. For all the simulations "Weld Zone" approach is adopted to define the weld properties in the tensile test specimen.

2.2.1 Section-I (Similar Material Dissimilar Gauge TWBs)

In this section, as a Base Material AA 5754 of 1.06 and 1.66 mm is used. The different material properties used during the simulation for the mentioned material is given in Table 2.1.

The material has been modeled as 3 dimensional deformable. The dimensions of the tensile test specimen and the cross-section of the welded joint are shown in Fig. 2.2a, b, respectively. It was assumed that the base metal and weld metal were following the power-law equation.

Figure 2.3a indicates the cross-section (isometric view) and Fig. 2.3b indicates dissimilar gauge tensile test specimen (isometric view) modeled in the ABAQUS environment. The entire simulation was completed in total two steps namely Initial and step-1. In the initial step of the simulation one end of the specimen was encastre

(All DOF (Degree of Freedom) constrained) and in step-1 another end was given the displacement in the X direction only (transverse to the weld).

As shown in Fig. 2.4 thin base metal was given encastre boundary condition and thick base metal was given displacement in the X-direction. Meshing was done using linear tetrahedral elements. Table 2.2 indicates the meshing details used during the simulations.

2.2.2 Section-II (Similar Gauge Dissimilar Material TWBs)

In this section, tensile testing of TWB made from dissimilar material having similar gauge is performed using the ABAQUS/Explicit tool. Figure 2.5 indicates the tensile specimen modeled in the ABAQUS environment. The tensile testing was done as per the ASTM-E8 standards using a sub-sized tensile test specimen. For this section, the material properties were used as per Table 2.3.

In this investigation, one end of specimen was given encastre boundary conditions and another was given the displacement. The meshing details used for the simulation purpose are tabulated in Table 2.4. Figure 2.6 indicates the meshed model of tensile test specimen in the ABAQUS environment. Similar to case-I, this simulation was also completed using total 2 number of steps and materials were assumed to follow the Power law equation.

2.3 Results and Discussions

In the upcoming sub-sections, the results extracted from the simulation study have been discussed and compared with the same of available literatures. Responses like stress–strain curve, load versus displacement curve, failure location in the specimen and strain developed in the tensile test specimen are compared.

2.3.1 Section-I (Similar Material Dissimilar Gauge TWBs)

For the given boundary conditions, load versus displacement graph was extracted from the simulation and plotted as shown in Fig. 2.7 which also compares it with the published literature.

It can be observed that the natures of both the mentioned results are in good agreement with each other which indirectly authenticates the methodology adopted for the simulation purpose. From the simulations, results of plastic strain were also extracted as indicated in Fig. 2.8.

The maximum plastic strain was observed in the thin material as indicated in Fig. 2.8 and it was found at the boundary region of the thin base material and the weld zone. The value of maximum plastic strain predicted by the present study of simulation was 0.2519 and it was 0.2004 by the published study [18] which seems to be in very good agreement with each other.

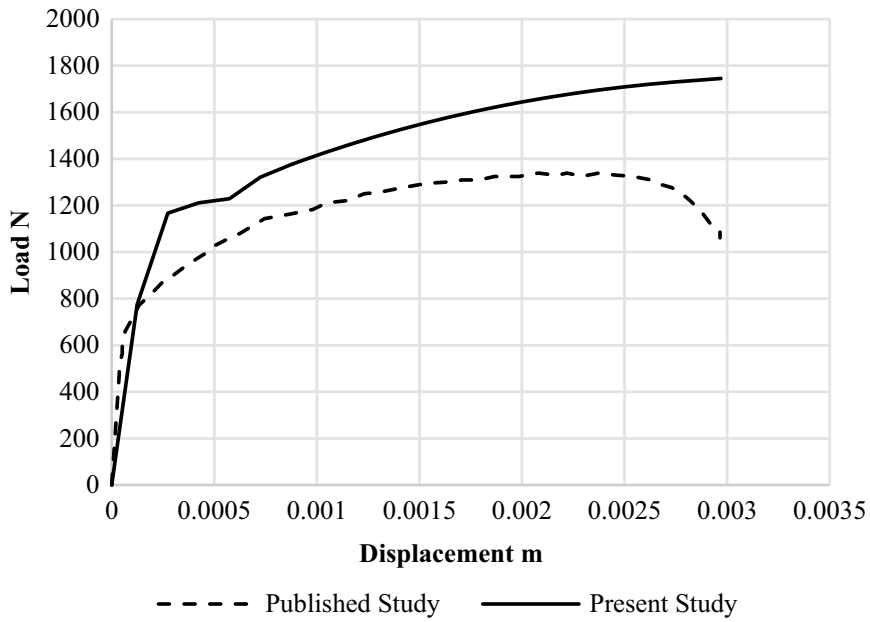

Fig. 2.7 Comparison of load versus displacement graph between published [18] and present study

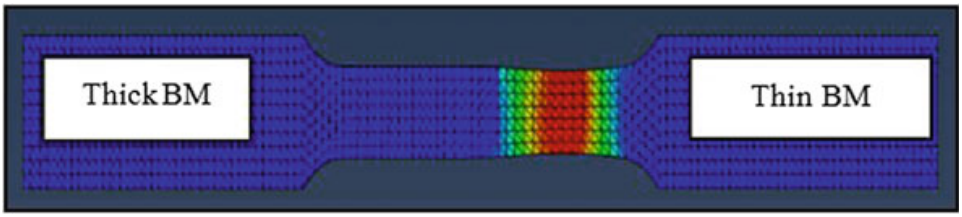

Fig. 2.8 Plastic strain (in X direction only) PE11 for present study

2.3.2 Section-II (Dissimilar Material Similar Gauge TWBs)

From the given boundary conditions in the section-II, the results like failure/necking locations, strain distributions across the weld and stress–strain behavior of TWB were extracted and compared with the published literature. Figure 2.9 indicates the present simulation result for necking location in the tensile test specimen. The failure location from weld center was observed at 11 mm in experimental study of published literature [2] and that was observed at 13 mm for the present simulation study. So, it can be stated that the results were in reasonably good agreement with each other.

The engineering stress–strain behavior of TWB was also plotted and compared with the published results as indicated in Fig. 2.10. From Fig. 2.10, it can be seen that the yield point predicted by present study and published study are in good agreement but for the plastic deformation part of the graph, a slight mismatch is found. This disagreement can be reduced by providing more appropriate boundary conditions and material properties during the simulations.

One more result of strain distribution across the weld was extracted from the simulation and compared with the published results as indicated in Fig. 2.11. The maximum strain value is observed at 13 mm from weld center for the present simulation study and that is the failure/necking point in the tensile test specimen of TWB. There was a disagreement between the present and published study regarding strain distribution which can be resolved using better boundary conditions and material properties.

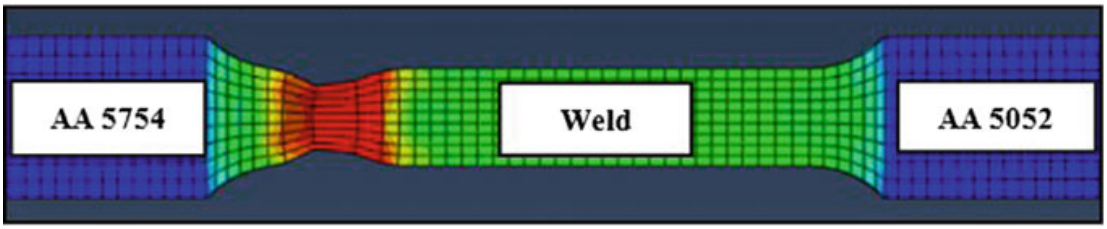

Fig. 2.9 Thinning/necking location for present simulation study (at 13 mm from weld centre)

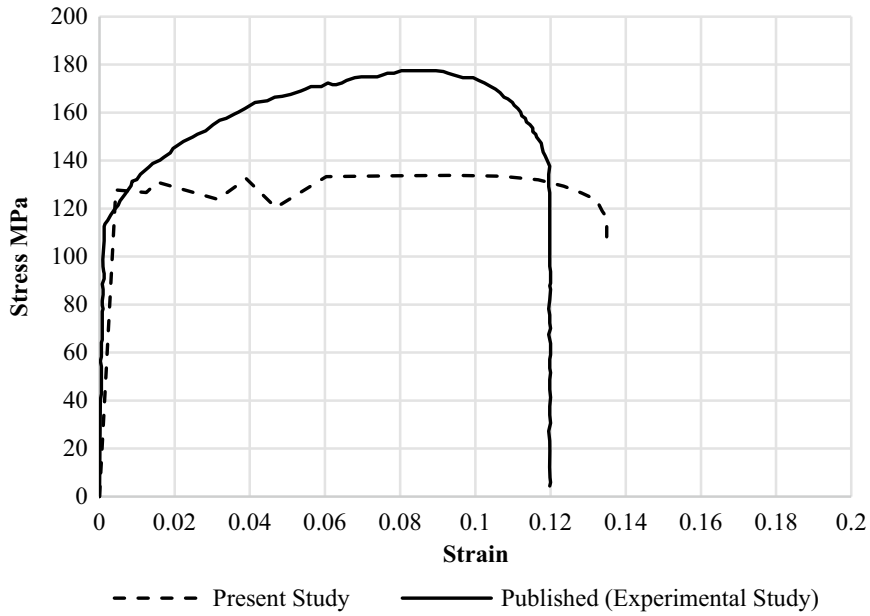

Fig. 2.10 Comparison of engineering stress–strain curve between present (simulation) and published [2] experimental results

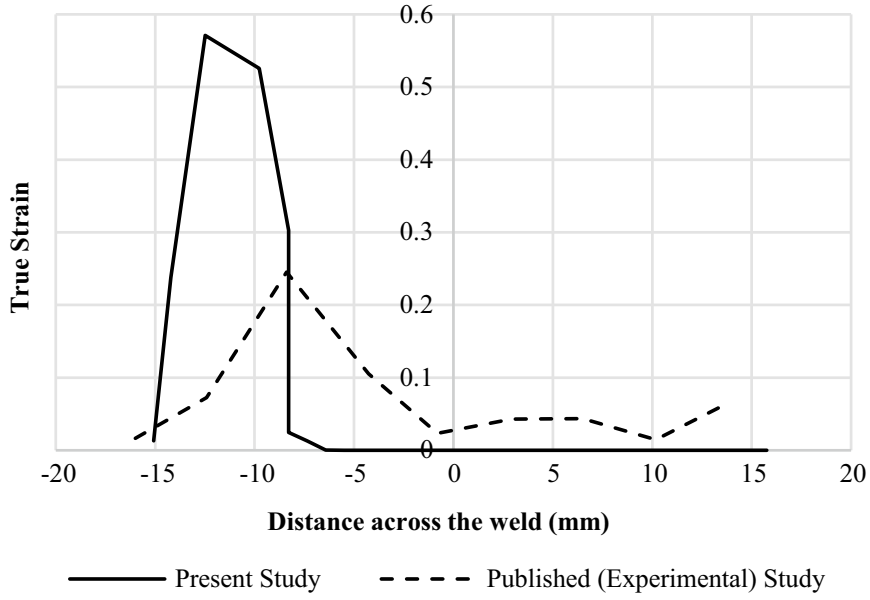

Fig. 2.11 Comparison of strain distribution across the weld for published [2] and present study

2.4 Conclusions

In the present research work, study of tensile behavior of the TWBs through FE analysis has been carried out. Following points can be concluded from the reported study:

- The "Weld Zone" approach used to define the weld properties during the simulation gives reasonably good results.
- The strength of the TWBs depends upon the weak/thin base material participating in it.
- To improve the strength and quality of the TWBs, strain distribution across the weld should be as even as possible.
- The boundary region between the weld zone and the base material is found to be the weakest.
- The simulation methodology not only saves the time, cost and resources but it also leads to reasonably good results for material behavior. The only limitation associated with the simulation methodology is that it demands for the accurate and proper input data in terms of boundary conditions and material properties.
- It is not necessarily required to perform the experimental/physical testing for accurate results. As represented in results of section-II, accurate results can be obtained to predict the material behavior during any deformation process by adopting appropriate approach for the simulation which is "Weld Zone" in this case.

Formability Evaluation of EN-10149-2 (S700mc) Steel Under In-Plane Plane Stretching Condition

Dereje H/Georgis, Perumalla Janaki Ramulu and Habtamu Beri

Abstract The current effort is intended to evaluate the forming behavior of the EN-10149-2 (S700mc) steel of 2.42 mm thickness under in-plane plane-stretching (IPPS) condition at ambient conditions. EN-10149-2 (S700mc) steel has good mechanical properties and lightweight that increase the application in automotive, aerospace, and industrial structural design compared to other metals. For which, the tensile and plain stretching test samples were prepared in three rolling directions 0°, 45°, and 90°. The mechanical properties such as the yield strength, tensile strength, uniform elongation, total elongation, hardening exponent (*n*-value), material strength coefficient (*K*) and plastic strain ratio (*R*-value) of EN-10149-2 (S700mc) steel are evaluated from the tensile testing. The microstructure and hardness of the material were also evaluated. IPPS evaluation test has been carried out by stamping circular grids at the middle of the specimen by which measured the manor and major strain using thickness gradient necking criterion (TGNC). The obtained results from experiments found that the maximum limit strain is appeared for the rolling direction of 45° and followed by 90° and 0°. This indicates that the maximum formability is in 45° rolling direction during the IPPS test.

3.1 Introduction

Basically, metalworking processes are grouped into two classes, namely, bulk-forming and sheet metal forming. The sheet metal blank is plastically deformed into a three-dimensional shape without any critical changes in the thickness of the sheet materials. In other deformation cases, elastic recapturing or springback may be significant because the amounts of plastic and elastic deformations are equivalent. Some of the important sheet metals forming processes are deep drawing, stretching, bending and rubber pad forming [1]. Moreover, numerous car businesses vehicles composed under the thought of lightweight, crash execution, vitality sparing, and ecological perspective are of unique intrigue which is much essential to drive the vehicles' material selection process. Among all the materials existed in the market, steel material has a significant impact on many automotive parts where strength is more important. In this needy, steel industries are developing new grades of advanced high strength steels (AHSS) with high strength to weight ratio as lightweight structures [2]. Likewise, EN-10149-2 (S700mc) steel sheet has many application areas in modern manufacturing industries. It has also good mechanical properties and lightweight that increases the application in automotive, aerospace, and industrial structural design compared to other metals [3, 4]. In-plane tensile tests were conducted to produce strain paths from uniaxial tension to plane strain in mild steel and high strength steel. An in-plane forming limit test that was independent of tooling geometry and friction was created. Results showed that a wide sample with a wide but short gauge section needed to produce forming limit strains close to plane strain. The sample had sufficient area for clamping to avoid fracture outside the plane strain region in the center of the sample was suggested [5]. There were other studies on the in-plane plane-stretching behavior of different materials and their limiting strains were evaluated [6–11].

Although many studies have been investigated the formability of high strength steel low alloy (HSLA) both experimentally and numerically, the formability prediction of HSLA under the in-plane plane stretching condition not been studied much. Researchers published so far described the formability prediction based on the strain path diagrams, yield criteria. The detailed description of the formability of EN-10149-2 (S700mc) steel with 2.42 mm thickness under in-plane plane-stretching (IPPS) condition has not discussed. Based on the applications of the EN-10149-2 (S700mc) steel at different level industries, the present work generates the data for forming characteristics of this particular material which can be used directly without further formability tests.

3.2 Materials and Methodologies

3.2.1 Materials

The material selected for this study was high strength low alloy or micro-alloyed steel, EN 10149-2 steel sheet which has 2.42 mm thickness. Chemical composition of material is shown in Table 3.1.

3.2.2 Methodologies

Mechanical Properties and Micro-Structure Evaluation of EN-10149-2

The microstructure of EN-10149-2 steel sheet was studied by optical microscope of model Huvitz HR-300 series. Hardness was measured using Vickers's hardness testing machine. The mechanical properties of EN-10149-2 steel sheet were measured using tensile tests as per ASTM- B557 M by cutting sheet in different rolling directions such as 0°, 45°, and 90° and evaluated the mechanical properties and plastic strain ratio (R) as per ASTM- E517 through tensile tests. Tensile tests were performed at a nominal cross-head speed of 1 mm/min, at room temperature. On an ISO 68982-1 universal testing machine and repeated thrice for each set to check the reproducibility. Failure from grip or slippage during testing was not observed. Figure 3.1 shows the base metal tensile specimen. The mechanical properties like yield strength, ultimate tensile strength, uniform elongation, strain hardening coefficient (n) and strength coefficient (K) were evaluated as per the standard procedure after testing the samples till failure. The load-stroke behavior obtained during testing and converted into engineering stress–strain and true stress–strain

plot for evaluating the mechanical properties. The plastic strain ratios at different rolling directions were obtained after testing the base material to 10% plastic strain.

Plane–Strain Tension Testing

In this study, plane stretching testing samples were prepared based on the width constraints method. Figures 3.2 and 3.3 show the schematic and original in-plane plane-stretching test specimens with circular grids of 3 mm in diameters on experiment specimen.

3.3 Results and Discussion

3.3.1 Mechanical Properties of Sheet Metal

Figures 3.4 and 3.5 are shown the material EN-10149-2 steel uniaxial tensile test specimen before and after the testing, respectively. Figure 3.5 representing the tested specimen at different rolling direction 0°, 45°, and 90°.

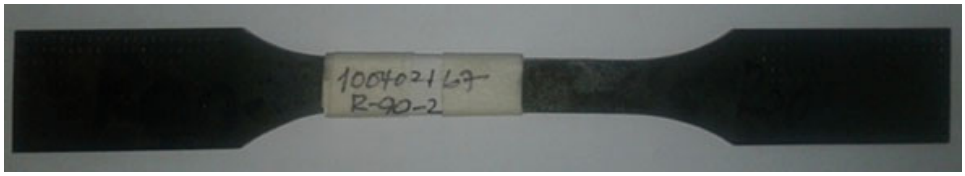

Fig. 3.4 EN-10149-2 specimen before tensile test

Fig. 3.5 EN-10149-2 specimen after tensile test

The mechanical properties of the EN-10149-2 sheet metal are evaluated from the uniaxial tensile tests tabulated in Table 3.2. The evaluated mechanical properties like yield stress, uniform elongation, tensile stress, material strength coefficient (K) and strain hardening coefficient (n). The base material engineering stress–strain behavior in different rolling directions is shown in Fig. 3.6. Table 3.2 shows the tensile properties of all three reputations and Table 3.3 summarizes the mechanical properties of EN-10149-2 base material. The yield strength and ultimate tensile strength are found to be within 972–1020 MPa and 1018–1054 MPa, respectively. The uniform elongation and strain hardening exponent are about 6.8% and 0.22 respectively.

Table 3.4 indicates summarized mechanical properties of EN-10149-2 (S700mc) sheet steel. The mechanical properties and anisotropy value are shown in Table 3.4.

3.3.2 Microstructure of EN-10149-2

Metallographic investigations were carried out on the sample of base metal. Etching with Nital 2% for 10 s; this etchant was used to reveal the banded structure, and the grain boundaries and carbide containing phases. A typical microstructure of EN-10149-2 is shown in Fig. 3.7.

From the microstructure of base metal in Fig. 3.7 indicates the ferrite, pearlite structures along with carbon content. Ferrite and pearlite structure is responsible for the better mechanical properties.

3.3.3 Evaluation of Hardness

Hardness was measured using Vickers hardness (VH) testing machine at five different locations with 10 kg load. The average hardness number of the sample is noted as 124.94 VHN.

Table 3.4 Mechanical property and Plastic Anisotropy (r-value) of EN-10149-2 sheet metal

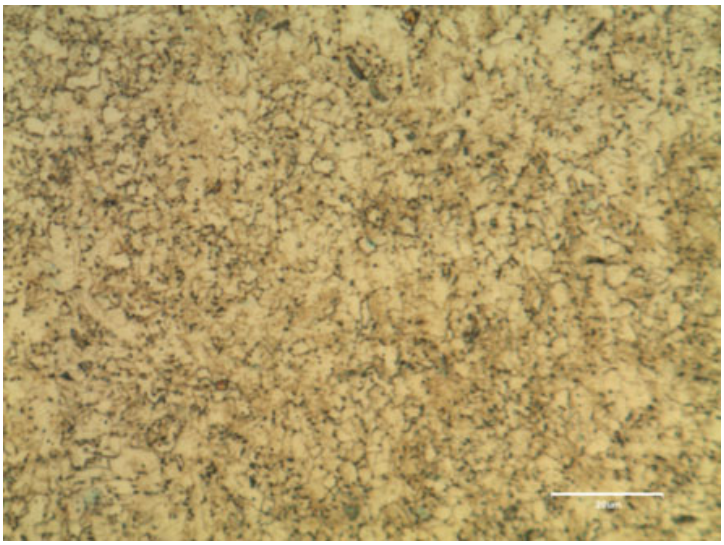

Fig. 3.7 Microstructure of EN-10149-2 at room temperature

3.3.4 In-Plane Plane Stretching (IPPS) Test

The samples were prepared in three rolling directions namely, 0°, 45° and 90° in number two per each rolling direction. The limit strains are evaluated by measuring the length of the major and minor axes of deformed circular grids at the failure region of EN-10149-2 sheet blanks. Figure 3.8 shows circular grids printed on the surface of base materials before deformation and Fig. 3.9 grids elongation after deformation, during IPPS formability tests. The digitized caliper two digits decimal was used to measure the circular grids before and after deformation of base materials for evaluating true major and minor limit strains.

Failure Criteria used for Limit Strains Evaluation

Thickness gradient-based necking criterion (TGNC)

Thickness gradient-based necking criterion is used to obtain forming limit strains of EN-10149-2 sheet blanks [12–15]. Necking can be understood as a thinning phenomenon in any sheet metal during the deformation process. It mostly distinguishes necking as a localized thinning phenomenon, i.e., a localized region within the deforming sheet where a steep gradient in thickness develops. A local critical

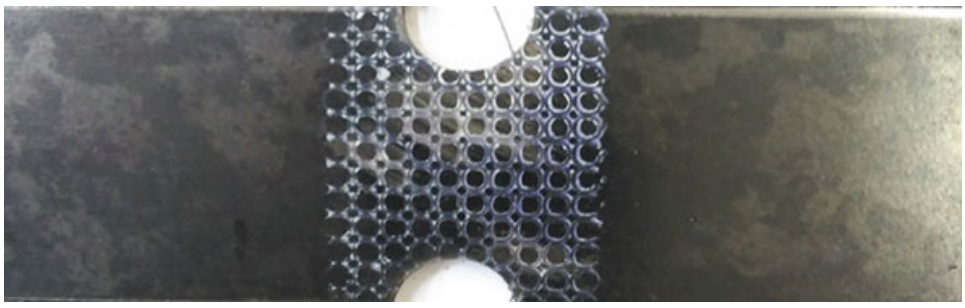

Fig. 3.8 Method of grid measurement before deformation

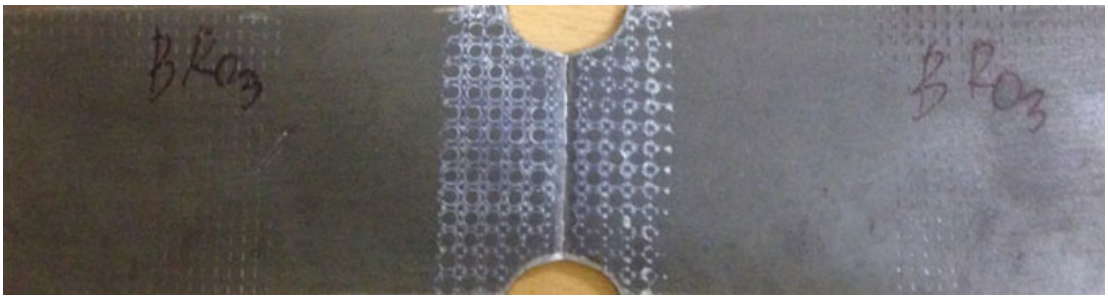

Fig. 3.9 Method of grid measurement after deformation

thickness gradient (Rc) must exist at the onset of a locally visible neck. The maximum major and minor strain in the thinner element is then reported as the forming limit strain. It is found from the earlier experiments that necking occurs in the sheet metal when the thickness gradient (ratio of the thickness of neighboring elements or circles) falls below 0.92 [12–15].

$$R_{\text{thickness gradient}} = \frac{\text{thickness}_{\text{Necking element}}}{\text{thickness}_{\text{Neighboring element}}} = \frac{t_n}{t_{n-1}} \text{or} \frac{t_n}{t_{n+1}} \leq R_{\text{Cri}} \Rightarrow \text{material failure or necking}$$

$$R_{\text{Critical}} = 0.92$$

Table 3.5 shows the limit strain results using TGNC from in-plane plane-stretching tested samples in three different rolling directions. Figure 3.10

Table 3.5 Limit strains results using TGNC from in-plane plane-stretching tested

Orientations	Trials	Measured circle diameter (mm)	Measured value- original diameter (mm)	$R_{\text{thickness gradient}}$	Major strain	Minor strain
0°	1	3.124	0.124	0.9193	0.124	0.104
		3.114	0.114			
	2	3.231	0.231	0.9166	0.252	0.114
		3.252	0.252

		3.525	0.525			
	2	3.424	0.424	0.91973	0.464	0.192
		3.461	0.464			
90°	1	3.451	0.451	0.92011	0.451	0.353
		3.416	0.416			
	2	3.294	0.294	0.91588	0.321	0.264
		3.321	0.321			

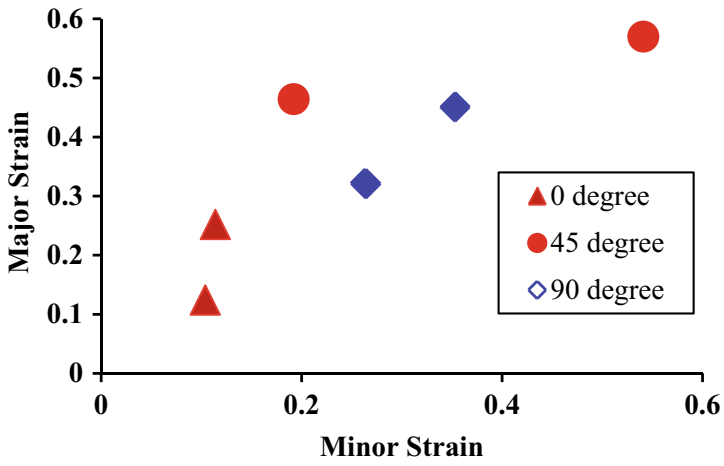

Fig. 3.10 Comparison of limit strain of in-plane plane-stretching test on three rolling directions with two reputations

shows the limit strain comparison of three (0°, 45°, 90°) different rolling direction with two reputations. Limit strain is evaluated using the TGNC after the experiment on three rolling directions. The maximum limit strain is appeared for the rolling direction of 45° and followed by 90° and 0°. This indicates that the maximum formability is in 45° rolling direction during the in-plane plane-stretching test.

3.4 Conclusions

In this work, in-plane plane stretching (IPPS) test is conducted in order to determine limit strains of the EN-10149-02 steel material. From the results, the following conclusions are drawn as follows:

- EN-10149-02 steel material had the highest yield and tensile strength in the transverse direction (90°) and a diagonal direction (45°). The strain handing exponent and total elongation is more at 0° and decreases in the diagonal direction (45°).
- The microstructure result shows that the material constitutes more pearlite matrix grain structure with small carbide boundaries which leads to material more ductile and formable. Vickers's hardness of EN-10149-02 steel material value is 122.24 VHN.
- In-plane plane stretching experimental tests the limit strain evaluated using the TGNC after the experiment on three rolling directions. The maximum limit strain is appeared for the rolling direction of 45° and followed by 90° and 0°. This indicates that the maximum formability is in 45° rolling direction during the in-plane plane-stretching test.

Chapter 4
Stretch Formability Prediction of AA6023-T6 Alloy Sheet Under Two Different Heating Conditions

Manaye Mathewos Handiso, Perumalla Janaki Ramulu and G. Somasundaram

Abstract Sheet metal forming is a process widely used in the manufacturing industry. There are several sheet metals forming processes are existing including stretch forming process. In the present work, stretch formability of AA6023-T6 sheet of 2 mm thickness at room temperature and annealed sheet at 400 °C has been performed. For which mechanical properties were evaluated through tensile test for all the conditions. For stretching operations, simulations were performed using limit dome height (LDH) test using PAM STAMP 2G software. During LDH test, the maximum value of LDH for annealed sheets of AA6023-T6 at 400 °C and minimum value for sheets at room temperature is observed. Uniform thickness distribution for annealed blanks at 400 °C is observed compared to room temperature. The room temperature stretch formability of AA6023-T6 alloy sheet has 39.5 maximum dome height and annealed sheet at 400 °C has 43 maximum dome heights. By which, annealed AA6023-T6 sheet has good stretch formability compared to room temperature stretch formability.

4.1 Introduction

Sheet metal forming is one of the most used processes in the manufacturing industry. There are many sheet metals forming processes including stretch forming process. In stretch forming process the sheet metal is clamped around its edge and stretched over a die or forming block, which moves upward, downward or sideways, depend up on the machine used. Stretch forming is applicable to produce aircraft-wing skin panel, automotive doors panel and window frames etc. The design of components needs the analysis of instability and determining of possible deformation of sheet metal. The determination of possible forming limits and analysis of instability of sheet metal was predicted from forming limit diagrams (FLDs) [1]. The applied load on sheet metal causes the plastic deformation when it was greater than yield strength of the metal. The stress induced during the process was greater than yield strength, but less than fracture strength of the material [2]. Another important factor which has influence on sheet metal forming is anisotropy. It is the directional variation of mechanical properties. In other words, the reaction of materials to applied stress at different direction has different reaction to the applied stress. The strength and formability of the materials are the main properties which are very important for industrial applications of sheet metals [3]. The forming behavior of a certain sheet metals always depends up on the forming temperature during forming process. For instance, aluminum series of 6xxx alloys had quite less level of formability at room temperature than aluminum series of 5xxx alloys [4, 5]. The amount of strain hardening in the material decided the formability of the materials. The tensile test was one of the mechanical properties' evaluation process in which the strain hardening exponent of the sheet metal evaluated. If the tensile tests of the sheet metal had maximum percentage of elongations, it can be predicted as the sheet metal with a good formability [6]. Forming temperature had significant influence on formability. Many researches were developed on the effect of temperature on the formability of different sheet metals. For example, Nolan et al. [7] studied the formability of a 7000 series alloy under different forming temperature. They performed the tensile tests and deep drawing tests to evaluate the forming behavior. The experiment was taken at both elevated and room temperature. In the drawing process of the metal, the formability of the given sheet metal increased with the increase of forming temperature. This warm forming behavior of the sheet metal indicated that the condition of formability of the alloy improved with that of the forming temperature. For the warm forming condition of 7000 series alloy in general the forming temperature observed in the range of 200–600 °C. The forming condition of stretch flange has a good formability at warm forming condition than cold forming process. Tokita et al. (2017) [8] studied the forming conditions of the stretch formability of two different high strength steels. The forming was preferred on warm forming by spherical stretch forming tests at various forming temperature including room temperature up to 600 °C. Their experiment showed the suitable forming temperature for stretch formability of steels. The observations from the experiments indicated the value of

maximum dome height related to the maximum formability indications. There was maximum dome height for test of steel at elevate temperature and minimum dome height at room temperature forming process. High initial forming temperature was one of the affecting factors which causes the loss of quality in the forming process and also the coefficient of friction has a significant influence on the forming behavior of the alloy. Ali and Jumah [2] investigated the forming behavior of annealed aluminum alloy at different forming temperature. The formability of alloy increased with the increasing of the forming temperature. When temperature was at maximum level, the formability was significantly good but the drawback at this forming temperature was the excessive ductility. In this case, the application of alloy limited to its strength. In general, elongation increased, with increase of temperature of AA6061-T6 alloy during tension test. Moreover, at elevated temperature greater or equal to 280 °C, the elongation increases with decreasing strain rate. With spreading of the deformation area, the deformation was more uniform than that at high strain rate; elongation increase gradually [9]. The increase or reduction of strain and plastic anisotropies related to texture intensity and texture distribution should be the main factors for good stretch formability. Refining strain (ductility) of the materials also influence the stretch formability [10, 11]. Forming limit diagram (FLD) was used to predict the materials formability behavior under different forming condition. It played a great role in industries, because it was also the most applicable method to evaluate the formability of sheet metals [12–15]. The value for these parameters calculated with respect to the specimen just before fracture. Forming limit diagrams (FLDs) are a suitable and often used mechanism for classification of the formability and investigation of sheet metal forming process. Forming limit diagram (FLD) also used to indicate the forming limit of a given sheet metals at different state of deformation. For different materials the upper limit curve (ULC) of the forming limit diagram provides breaking, and they calculated with respect to specimens just before breaking. The increase in local necking causes the increase in deformation of a certain specimen at stress concentration area. While the local necking increased further there was no change in stress to the rest of part of the specimen which was not subjected to the necking [16]. The effects of punch and die temperature on the formability of a cup shaped AA3003 aluminum alloy sheet. The formability improves as the temperature difference between the punch and the die increases. Also, the forming speed does not affect localized necking for the given punch velocities in the study. The simulations were captured for both punch force and failure location. The important parameters to control the thickness reduction in the blank were identified as friction and blank holder force. The finite element analysis model was validated with the selected experimental cases. Stretch formability of sheet metals depends on temperature of sheets. Increase in sheet metals temperature increase the stretch formability, but ductility of sheet metals was observed at elevated sheet temperature from the existing literature. To overcome the excessive ductility of sheet metal, annealing in between elevated temperature and room temperature was needed [17]. Based on the above observations, the present study objective is to predict the stretch formability of AA6023-T6 sheet of 2 mm thickness at room temperature and annealed at 400 °C.

4.2 Materials and Methodologies

4.2.1 Base Material

The Material selected for this study was AA6023-T6 alloy sheet which has 2 mm thickness. AA6023-T6 alloy sheet. Table 4.1 shows the nominal chemical composition of this material.

4.2.2 Tensile Test

The mechanical properties of base metal were measured using tensile tests as per ASTM- B557 M. The base metal was cut in different rolling directions like 0°, 45° and 90° and the mechanical properties and plastic strain ratio (R) were evaluated through tensile tests as per ASTM- E517. Tensile tests were performed at a nominal cross-head speed of 1 mm/min, at room temperature and annealed at 400 °C specimens on an ISO 68982-1 universal testing machine tensile testing machine and repeated thrice for each set to check the reproducibility. Failure from grip or slippage during testing was not observed. Figure 4.1 shows base metal tensile specimen. The mechanical properties of base material like yield strength, ultimate tensile strength, total elongation, uniform elongation, strain hardening coefficient (n) and strength coefficient (K) were evaluated as per the standard procedure after testing the samples till failure. The load-stroke behavior obtained during testing was converted into engineering stress–strain and true stress–strain plot for evaluating the mechanical properties. The plastic strain ratios at different rolling directions were obtained after testing the base material to 10% plastic strain.

4.2.3 Simulation Details

Finite element method was used for numerical analysis of sheet metal forming operations. The numerical analysis of stretch forming process was done by PAM STAMP 2G software. The input model consists of die, blank, blank holder, draw and punch were constructed in pre-processor. The punch, die and blank holder had considered as rigid body. The fine meshing was done on the surface of die, blank holder and punch, since, the blank has been considered as a deformable body. In limit dome height (LDH) test, the blank with 2 mm thickness is deformed by a hemispherical punch (diameter: 101.6 mm) inside opening of a die with 105.9 mm diameter. For simulations process, five tests with different size of blanks (100 mm × 200 mm, 125 mm × 200 mm, 150 mm × 200 mm, 175 mm × 200 mm, and 200 mm × 200 mm) were used for each (0°, 45° and 90°) orientation of samples. The tools required for LDH test, punch, die, blank holder, draw bead, and blank generated in solid works, a CAD packages, and meshed using delta mesh facility in PAM STAMP 2G. Both Hollomon's strain hardening law and Hill's 1948 isotropic hardening yield criterion was used as the plasticity model. The base material comprised quadrilateral shell elements of Belytschko–Tsay formulation with five through-thickness integration points. A uniform mesh size of 1 mm was used for all the simulations. The friction coefficient m was assumed to be 0.12 and is kept constant throughout the study. The blank was as the active body and the punch force used was 80 kN to avoid the drawing and tearing near draw beads during forming prediction. For prediction, the forming limit strain thickness gradient necking criterion (TGNC) was used [18–21].

4.3 Results and Discussion

4.3.1 Mechanical Properties of Base Material

The base material true stress–strain behavior at different rolling directions of two different heating conditions are shown in Figs. 4.2 and 4.3. Tables 4.2 and 4.3 summarize the mechanical properties of AA 6061 base material obtained in the present work. The yield strength and ultimate tensile strength are found to be within 180–200 MPa and 193–206 Mpa, respectively.

Heat treatment of the aluminum alloys causes change in mechanical and anisotropy values. Table 4.3 indicates the value of mechanical properties and plastic anisotropy of AA6023-T6 alloy sheet after annealing at 400 °C with one and half hours soaking time.

4.3.2 Evaluation of Forming Limit Diagram

The forming limit diagram indicates the stretch formability characteristics of the sheet metal. The forming limit diagram is also the forming limit curve, which is one of necessary value during practical assessment of sheet stretch forming process. Figures 4.4 and 4.5 show the comparison between the form limit curves of AA6023-T6 alloy sheets at room temperature and annealed alloy sheets and Table 4.4 indicate major and minor strain obtained by thickness gradient-based necking criterion at LDH.

Figure 4.4 shows the form limit curves of a sheet that predicts the stretch formability of AA6023-T6 alloy sheet at room temperature. The distribution of the curves of blanks with different dimension to the upper limit curve (ULC) is scattered. There are some blanks lie above the upper limit curve ULC which indicates fracture before the necking. The stretch formability of these blanks which have fracture earlier than the forming limit is not acceptable. The earlier formation of fracture caused due to the cold forming condition. The maximum limit dome height LDH observed in the stretch formability of blanks under room temperature forming

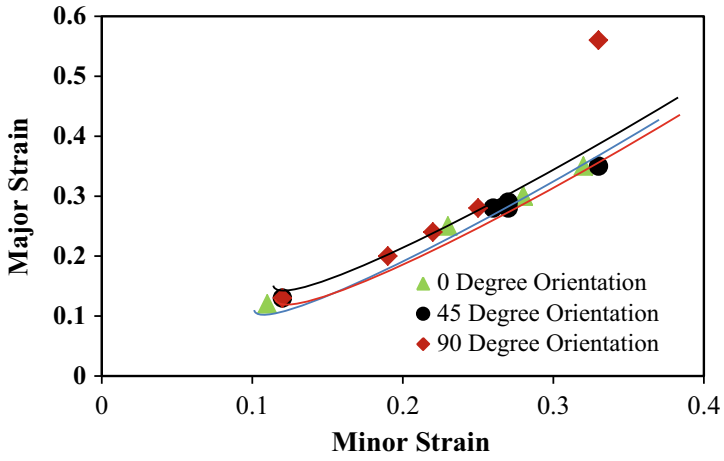

Fig. 4.4 Form limit curve of AA6023-T6 alloy sheet at room temperature forming condition

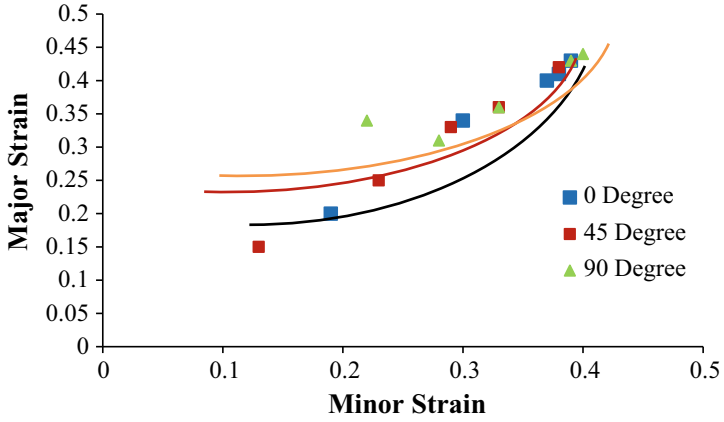

Fig. 4.5 Form limit curve of AA6023-T6 alloy sheet after annealing condition

Table 4.4 Major and minor strain at LDH for room temperature blanks

	0° oriented					45° oriented					90° oriented				
Blanks	1	2	3	4	5	1	2	3	4	5	1	2	3	4	5
Major strain	0.12	0.25	0.30	0.30	0.35	0.13	0.29	0.35	0.28	0.28	0.13	0.24	0.56	0.20	0.28
Minor strain	0.11	0.23	0.28	0.28	0.32	0.12	0.27	0.33	0.27	0.26	0.12	0.22	0.33	0.19	0.25
LDH	26	37.2	39	39	39	29.5	38.5	39	39.5	39.5	32	39	39.5	39.5	39

condition for blanks with dimension of 150 mm × 200 mm, 175 mm × 200 mm and 200 mm × 200 mm is 39.5 mm. From the value of maximum limit dome height LDH, these blanks have good formability compared to the others blanks with minimum value of limit dome height. Table 4.5 indicates major and minor strain obtained by thickness gradient-based necking criterion at LDH for annealed blanks.

Figure 4.5 shows the form limit curves of sheet that predicts the stretch formability of annealed AA6023-T6 alloy sheet. The distribution of the curves of blanks with different dimension to the upper limit curve is scattered. The distribution of the curves of the blanks is under limit of the upper forming limit diagram. This indicates there is no earlier fracture occurred before necking. The stretch formability of these blanks which are scattered blow the upper forming limit curve and near to the upper limit curve is recommended blanks for attaining a good formability. The maximum limit dome height LDH observed in the stretch formability of blank which are formed after annealing condition with dimension of 150 mm × 200 mm, 175 mm × 200 mm and 200 mm × 200 mm is 43 mm. From the value of maximum limit dome height LDH, these blanks have good formability compared to the others blanks with minimum value of limit dome height. The comparison between the maximum limit dome heights of the blanks at room temperature annealed alloy sheet shows the stretch formability of AA6023-T6 alloy sheets. The average maximum limit dome height LDH for room temperature forming condition of the blanks is 39.5 mm and the average maximum limit dome height LDH is 43 mm. Therefore, annealed AA6023-T6 alloy sheet has a good formability at annealing temperature of 400 °C and 90 min soaking time than sheet at room temperature.

Table 4.5 Major and minor strain at LDH for annealed blanks

	0° oriented					45° oriented					90° oriented				
Blanks	1	2	3	4	5	1	2	3	4	5	1	2	3	4	5

LDH	31	40.5	41.5	42	41.5	32	42.5	43	43	43	30.5	41.5	43	43	43

4.4 Conclusions

From the present work, the following conclusions are drawn.

- LDH from simulation justified the stretch formability behavior of AA6023-T6 alloy sheet. A blank at room temperature with dimensions of 150 mm × 200 mm, 175 mm × 200 mm and 200 mm × 200 mm have 39.5 mm maximum dome height and blank with dimension of 100 mm × 200 mm and 125 mm 200 mm at room temperature have 26 mm minimum dome height.
- Annealed blanks at 400 °C with 150 mm × 200 mm, 175 mm × 200 mm and 200 × 200 dimensions have maximum dome height compared to 100 mm 200 mm and 125 mm × 200 mm blanks at room temperature. The maximum dome height observed in simulation is 43 mm and minimum 31 mm. By which, the blanks with dimension of 150 mm × 200 mm, 175 mm × 200 mm and 200 mm × 200 mm have good stretch formability compared to blanks with dimension of 100 mm × 200 mm and 125 mm × 200 mm at room temperature.
- The comparison between stretch formability of AA6023-T6 alloy sheet at room temperature and annealed sheet at 400 °C shows, AA6023-T6 alloy sheet at room temperature has 39.5 mm maximum dome height and annealed sheet at 400 °C has 43 mm maximum LDH, therefore, annealed sheet has good stretch formability.

Chapter 5
FE Analysis of Single Point Incremental Forming (SPIF) for Tailor Welded Blanks (TWBs)

Shalin Marathe and Harit Raval

Abstract Fuel economy along with cost reduction is the ultimate target of the automobile industries and in order to achieve that, reduction in weight of the automobile body parts should be done. The homogeneous blanks are replaced by Tailor Welded Blanks (TWBs) while manufacturing the components of an automobile vehicle in order to reduce the weight and cost of the components. TWB is the outcome of joining two or more than two materials having different properties. Despite of having extremely important advantages, technology of TWB is associated with the limitation of weld line shift and formability reduction during the forming process. During the conventional forming process, formability of the TWBs is found to be decreasing and weld line shift is observed to be on higher side. In order to improve the formability of homogeneous blanks, Single point incremental forming process (SPIF) is found to be the excellent solution. However, the combination of SPIF and TWBs technology is not much explored by the researchers. In this present work, simulation of SPIF process for TWBs has been attempted. Effect of different tool initial position on the responses like weld line shift, Plastic Equivalent strain (PEEQ) is investigated. It has been found that the tool dragging effect and deformation of weak material is responsible for the weld line shift during the SPIF process. Particularly for SPIF process, nature and magnitude of weld line shift is affected by the tool initial position.

5.1 Introduction

The automobile industries are aiming at vehicles with more fuel economy along with reduction in the cost of manufacturing the automobile body parts. Reduction in weight without compromising the strength of the component is possible by adopting technology like TWBs. TWB is a product of joining of two or more than two material having different properties which are subjected to forming operations. The joining of material with different densities will lead to the reduction in the overall weight of the component. A schematic representation of TWB used in inner door panel of a car body is shown in Fig. 5.1.

Automobile, aerospace, transportation, and shipbuilding industries are aiming at weight reduction of the components without compromising the strength and TWBs have been found to fulfill these requirements. TWB is a product of joining two or more than two materials prior to any forming operation. TWB involves joining of two or more than two materials having different properties, thicknesses and/or coatings by any of the conventional joining processes. As it involves joining of materials having different densities the overall weight of the product decreases [1]. Also, TWBs are subjected to forming after the joining has been done and because of that the number of dies required for the forming decreases [1] which also leads to decrease the product lead time as well. Figure 5.1 indicates the typical example of TWB.

In conventional technologies, forming of two different materials was done separately and then joining was performed. In the case of TWBs, joining is followed by forming of welded blank using a single die setup and that leads to the manufacturing cost reduction [1, 2]. The joining method adopted for development of TWB depends upon the parent material involved in it. As the application of aluminum instead of steel leads to the 20% reduction of weight [3], use of aluminum is increasing in the automobile applications. For welding of aluminum, friction stir welding process is found to be producing sound and defect-free welds [4].

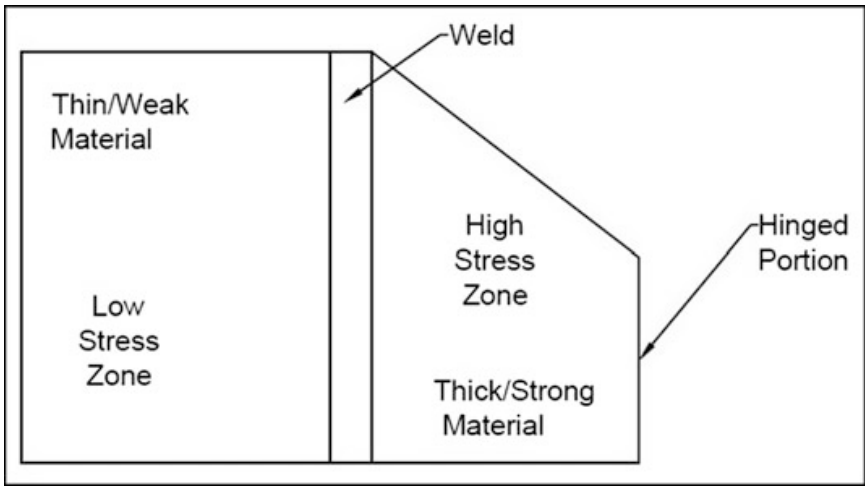

Fig. 5.1 Schematic representation of TWB used in inner door panel of a car body

Despite of having such tremendous advantages, the application of TWBs is limited as they are associated with the limitation of formability reduction [5, 6] and weld line shift [7, 8] during the forming process. In order to improve the forming behavior of TWBs during forming process, many efforts have been made. Such effort was made by Suresh et al. [8] in which the selective heating method was used to heat the strong/thick material to reduce the weld line shift during the stamping process. During the conventional forming process like deep drawing, the weld line shift is observed towards thick/strong material side [5] and formability of TWBs is found to be decreasing [5] than the same of parent material participating in it. However, for homogeneous blank, SPIF results in the better formability compared to the conventional forming processes [9]. So, the combination of SPIF and TWBs technology should be explored which is done by very few researchers.

So, in this present simulation study, FE analysis of SPIF process is carried out for the TWBs developed from the friction stir welding process. The effect of different initial position of tool on the responses like weld line shift, Plastic Equivalent Strain (PEEQ) and formed geometry is investigated.

5.2 Simulation Strategy

5.2.1 Challenges in Simulation of TWBs

For the simulation of TWBs, the major challenge is the consideration of the weld metal properties. During simulation, if the properties of the weld metal are not considered then results of simulation and experimental work are found to be deviating from each other [6, 7, 10]. In order to consider the weld metal properties, testing of welded joint is required to be performed and from that, different properties are extracted and used during the simulation. Rule of Mixture (ROM) can also be adopted to determine the weld metal properties [11]. During simulation of TWBs, if the appropriate properties of the weld metal are considered than actual behavior of the TWBs during that particular process can be predicted [12–14]. In order to consider the weld metal properties during simulation, an approach called "Weld Zone" is used [15]. In this approach, a different zone for weld metal is modeled and separate properties are assigned to it (see Fig. 5.2). In present simulation study, weld zone approach is used during the simulation in order to define the weld zone properties.

FSW results into the different zones in the welded blanks like WN (Weld Nugget), HAZ (Heat Affected Zone), TMAZ (Thermo Mechanically Affected Zone) and Base Metal. In the present simulation WN, HAZ and TMAZ are combined and considered as Weld Metal/Weld Nugget/Weld Zone. The properties of all

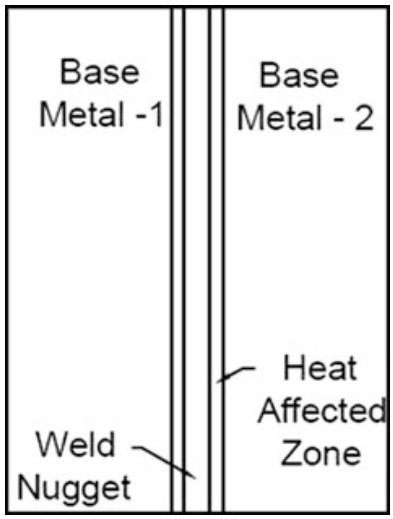

Fig. 5.2 Schematic representation of weld and heat affected zones

the mentioned welding zones can be considered during simulations but for that mechanical testing is required. However, consideration of such properties will lead to more accurate results.

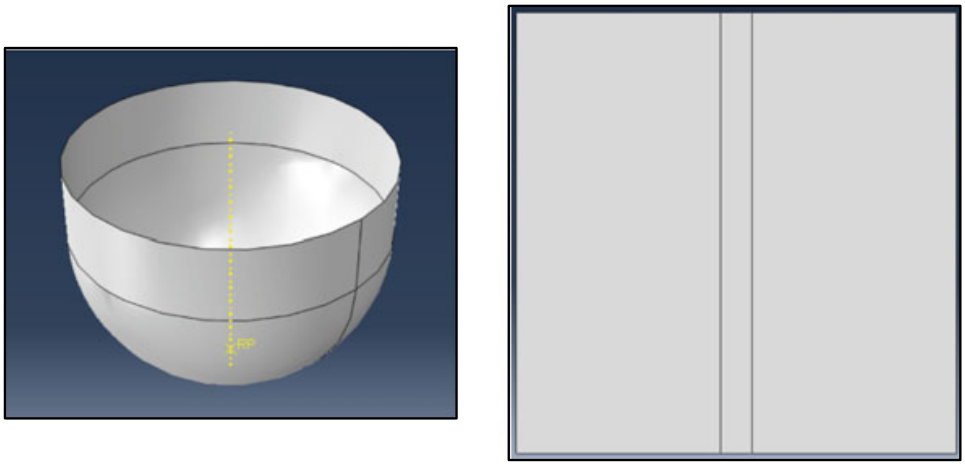
5.2.2 Simulation Methodology

In this work, ABAQUS/Explicit is used for the simulation purpose. In the modeling module, two instances are modeled namely blank and tool. In this present work, it is assumed that two blanks are welded using FSW process in order to develop a TWB. TWB is having dimensions of 70 × 70 mm^2 and 2 mm of thickness. The width of weld zone is assumed to be of 5 mm. Particularly, for FSW, the range of welding zones depends upon the diameter of the FSW tool shoulder. However, this present study is focused on the forming parameters and its effect of the weld line movement. In order to weld the plate of 2 mm thickness, FSW tool having 2 mm pin diameter is required. Considering that, shoulder diameter will be in the range of 4–6 mm [16]. So, the HAZ produced after welding will be in the same range. So, in present simulation study, 5 mm width of weld zone/material is considered.

The tool is considered as analytical rigid body and the blank is considered as shell type deformable body (see Fig. 5.3). The blank material is considered as isotropic in nature for the ease of simulation. However anisotropic properties can be considered and accuracy of results can be further improved.

The material properties used during simulations are represented in Table 5.1. The properties of the weld metal were assumed. The TWB is considered to be fabricated from AA 5754 H22 and AA 5052 H32 using the FSW process. Now onwards AA 5754 H22 and AA 5052 H32 is considered as weak base metal/weak material and strong base metal/strong material respectively.

The material having high value of yield strength is considered as strong material and material having low value of yield strength is considered as weak material.



(a) Hemispherical tool (rigid body, 6 mm radius)

(b) TWB – shell deformable body (70*70 mm^2,2 mm thick)

Fig. 5.3 Instances modeled in ABAQUS/explicit

Table 5.1 Properties used during simulation [5]

Property	AA 5754 H22	AA 5052 H32	Weld
Density[a] (ρ) (kg/m^3)	2670	2680	2670
Young's modulus[a] G (N/m^2)	70.3×10^9	70.3×10^9	70.3×10^9
Yield stress (σ_y) (N/m^2)	122×10^6	140×10^6	131×10^6
Poisson's ratio[a] (μ)	0.33	0.33	0.33

Strain Hardening index (n)	0.112	0.125	0.1185

[a]Indicates assumed properties

During simulation, material of TWB is assumed to follow the Power-Law equation as indicated below.

$$\sigma = K\varepsilon^n \tag{1}$$

In Eq. 1, σ and ε indicates true stress and true strain respectively. After the modeling, assembly of the SPIF tool and the blank is done. After assembly, interaction between SPIF tool and blank is provided in terms of friction. A surface to surface contact is defined between tool and blank and friction coefficient of 0.1 [17] is defined in order to consider the effect of friction (see Fig. 5.4).

The flat TWB is deformed using SPIF process and converted on to the target geometry frustum of pyramid. The dimensions of the pyramid are presented in Table 5.2.

During the simulation, the edges of the blank were fixed by defining encastre boundary (see Fig. 5.5) condition. The encastre boundary condition ensures pure stretching of the blank during forming operation and it eliminates the chance of drawing of material.

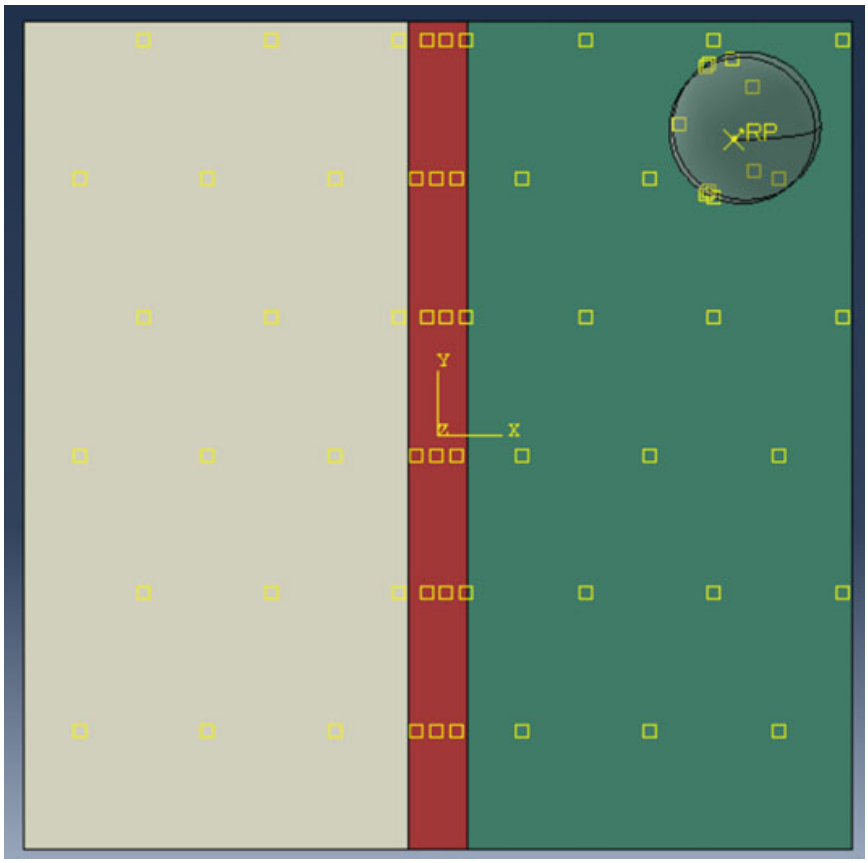

Fig. 5.4 Assembly of tool and blank and interaction between tool and blank

Table 5.2 Dimensions of the target geometry/frustum of pyramid

S. No.	Particular	Unit	Magnitude
1	Wall angle	Degree	45
2	Height of the pyramid	mm	20
3	Top dimensions	mm^2	50 × 50
4	Bottom/base dimensions	mm^2	10 × 10

The tool was given boundary condition in terms of movement in order to produce the target geometry (see Fig. 5.5). Tool starts the movement and goes through the path 1–2–3–4 and then it deforms the blank in the direction of thickness (perpendicular to plane of this paper) by 0.5 mm in step 5. The magnitude of movement of tool in step 5 depends upon the wall angle of target geometry. This cycle is repeated till the desired geometry is produced. Total 205 different boundary conditions were defined along with total 43 different amplitudes for the tool in order to produce the target geometry. The values of SPIF parameters adopted during the simulation are represented in Table 5.3.

After successful implementation of boundary conditions, meshing of blank is done with the help of S4R shell elements by keeping mesh size of 0.5 mm. For the present simulation study, mesh sensitivity analysis was carried out and based on

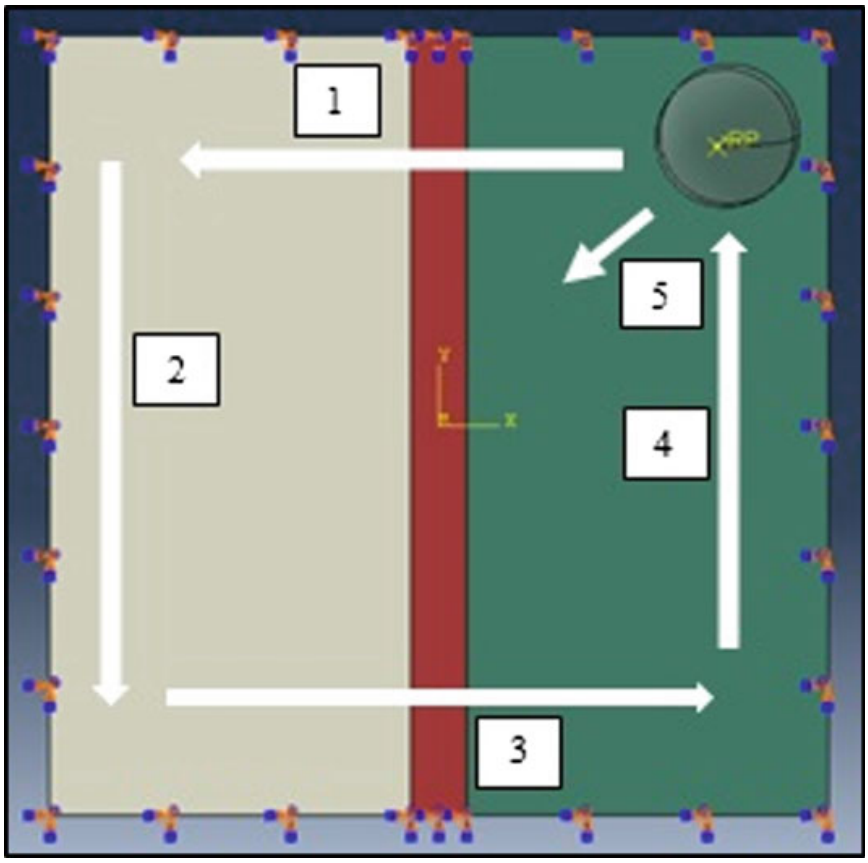

Fig. 5.5 Encastre boundary condition to the edges of the blank and direction of tool movement

Table 5.3 Constant SPIF process parameters for present work

S. No.	Particular	Unit	Magnitude

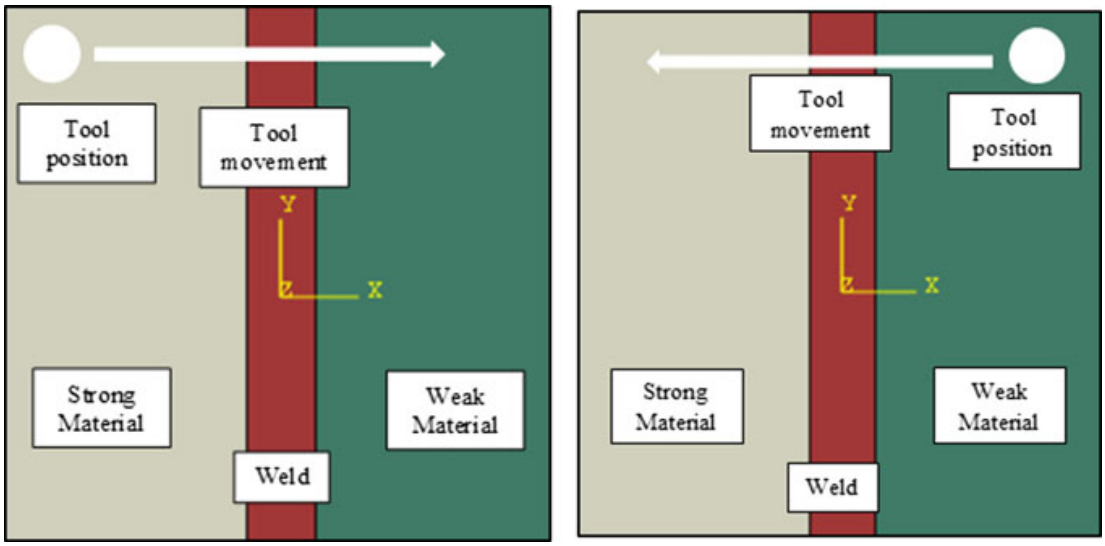
4	Tool radius compensation	mm	Not considered
5	Incremental depth	mm	0.5

computational time for one complete simulation and considering the available computational resources 0.5 of mesh size was selected. The meshing process is followed by the submission of job for the analysis.

The main aim of the present simulation study is to check the effect of different tool starting position on weld line shift during forming. In order to study this, two starting position of tools are considered as indicated in Fig. 5.6.

If the tool is starting its movement from strong material it will be considered as SFS condition (see Fig. 5.6a) and if it is starting from weak material it will be



(a) Starting From Strong (SFS) material

(b) Starting From Weak material (SFW)

Fig. 5.6 Two different starting position of SPIF tool

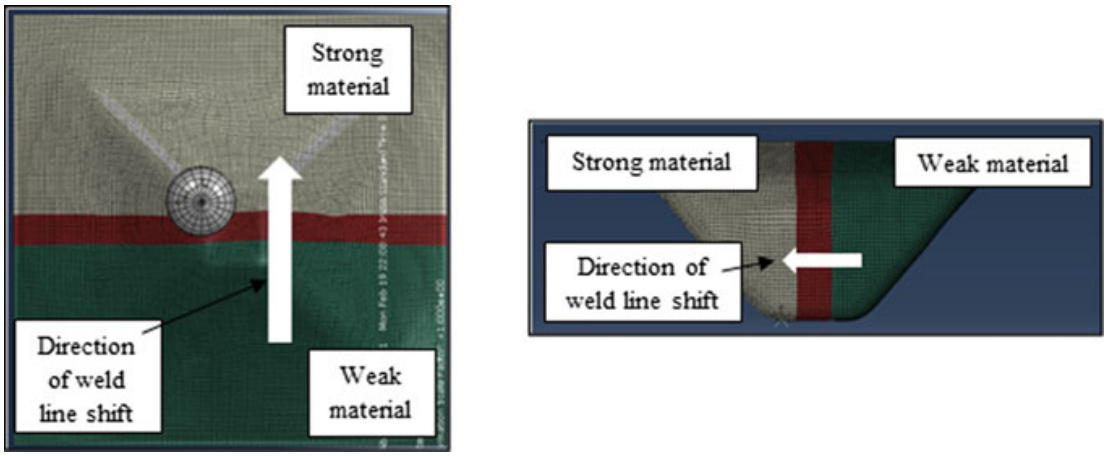
considered as SFW condition (see Fig. 5.6b). In the next sections, the effect of tool starting position on different responses is discussed in detail.

5.3 Results and Discussion

After the successful completion of simulations, results like weld line shift, PEEQ and formed geometry are studied and discussed below.

5.3.1 Formed Component

The formed component is analyzed for the weld line shift. Figure 5.7a, b indicates the top view and side view of the component formed using the SPIF process respectively. It can be observed from Fig. 5.7 that the weld line is shifted towards strong material by marginal amount. In order to investigate the weld line shift in detail, a node path was generated on the weld line and displacement of each node was recorded.



(a) Top view (b) Side view

Fig. 5.7 Formed component—frustum of pyramid

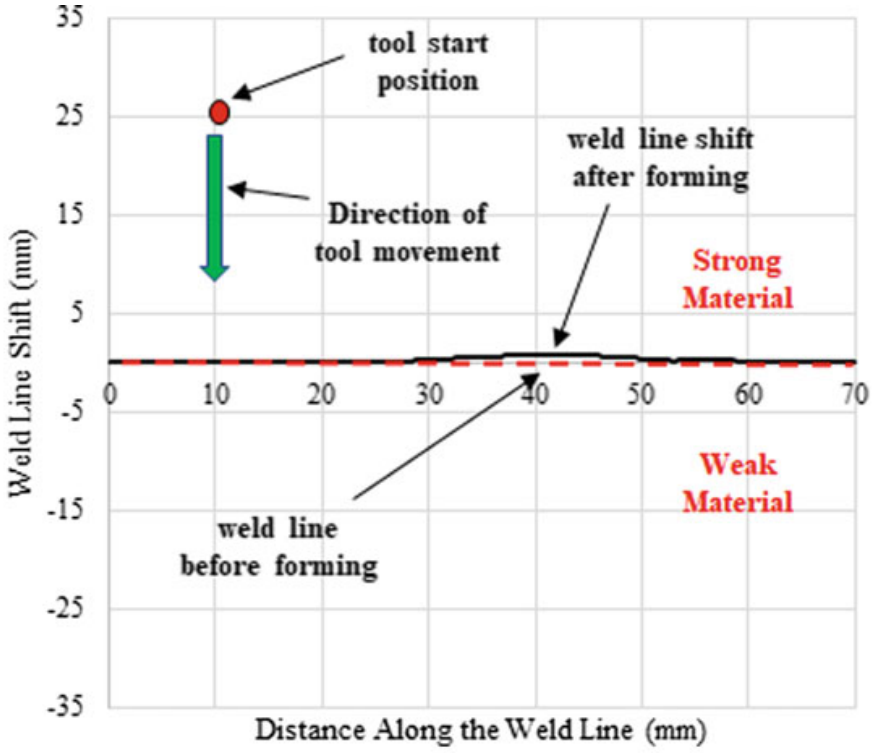
5.3.2 Weld Line Shift

During any forming process, same amount of deformation is applied by tool on strong, weak and weld material. As the deformation resistance capacity of the weak material is less compared to strong material, more deformation is experienced by the weak material compared to strong material. Due to this, weld line shifts towards strong material during any forming operation.

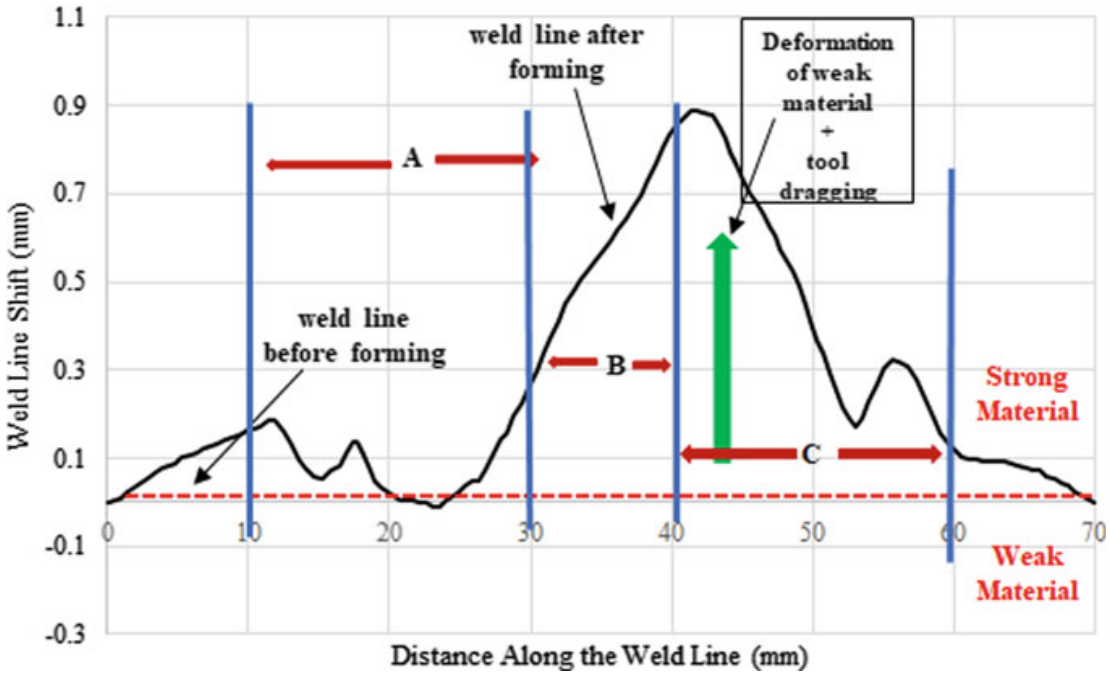
As the SPIF process involves local deformation of material due to tool movement, the weld line shift depends upon the initial position of tool. In order to understand the mechanism of weld line shift particularly for SPIF process, consider Fig. 5.8.

Figure 5.8a represents the overall view of the blank and position of weld line shift before and after forming process for SFS case. Figure 5.8b represent the magnified view with different sections. Section B can be called as untouched section, as there is no interaction between tool and blank in it. Section A and C represent the weld line shift in the wall of the pyramid. It should be observed that the weld line shift in section A is less compared to the same in section C. In SFS case, the strong material is above the mean line and weak material below the mean line. When the tool comes from section B to section C, deformation of weak material is supported by the tool dragging effect. Due to which more weld line shift is observed in section C. Now, in section A, deformation of weak material is opposed by the tool dragging and because of that the amount of weld line shift observed in section A is less. The weld line shift observed in section B is only due to section A and C.

Figure 5.9 represents the magnified view of the weld line shift observed for the case SFW. The sections represented in the figure are same as Fig. 5.8. The nature and magnitude of weld line shift of SFW case are different from the same of SFS case. It clearly indicates that the magnitude and nature of weld line shift depends



(a) Weld line shift overall view



(b) Magnified view of weld line shift

Fig. 5.8 Weld line shift (max. 0.88 towards strong side) for case SFS (Starting From Strong)

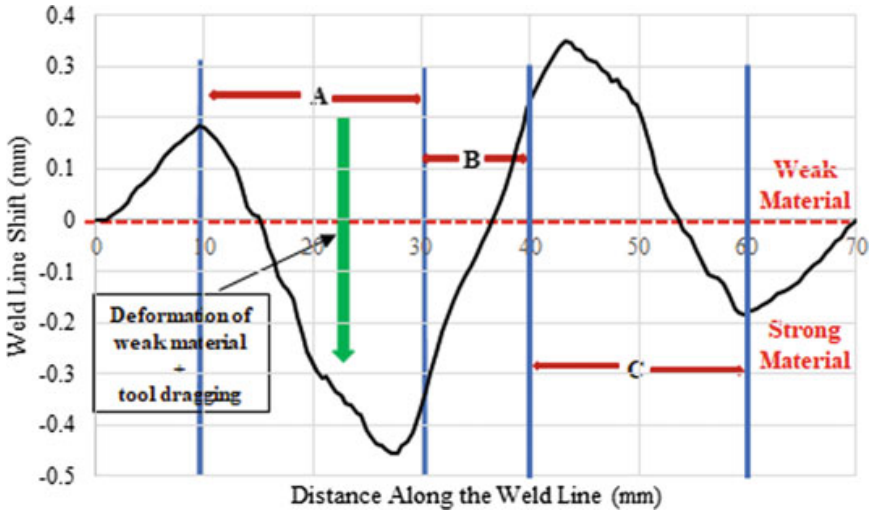


Fig. 5.9 Weld line shift (max. 0.45 towards strong side) for case SFW (starting from weak)—magnified view

upon on the initial position of the tool particularly for the SPIF process. In Fig. 5.9, on comparison of section A and C, it can be observed that the magnitude of weld line shift in section A is higher than the same of section C. For SFW case, the weak material is above the mean line and strong material is below the mean line. In section A, weld line shift is supported by the tool dragging effect and in section C same is opposed by the tool dragging, due to that, section A is experiencing more weld line shift.

In SPIF process, the deformation of the blank is localized unlike other conventional forming processes. Due to this localized deformation mechanism, the weld line shift of TWB during the SPIF process depends upon the initial position of the forming tool.

5.3.3 Plastic Equivalent Strain (PEEQ)

PEEQ result represents the permanent strain present in the body after the forming has been completed. Figure 5.10a, b represent the results of PEEQ for the case SFS and SFW, respectively. These results are based on the von-mises stress criteria.

For the SFS case, more plastic strain is observed in weak material compared to strong material. Due to this, for SFS case, weld line shift is observed only on one side (see Fig. 5.8). More strain leads to excessive thinning and that may lead to the failure of the blank during the forming. Due to in-homogeneity near the weld material, more value of PEEQ is observed there as well.

For the SFW case, value of PEEQ on strong and weak side is observed to have nearly same value. In Fig. 5.10b, two sections are highlighted which are responsible for the weld line shift in section A and C. Due to that, the nature of weld line shift is found to be sinusoidal in nature for SFW case (see Fig. 5.9).

(a) SFS – Max. 4.96 (b) SFW – Max. 6.58

Fig. 5.10 PEEQ in the formed component

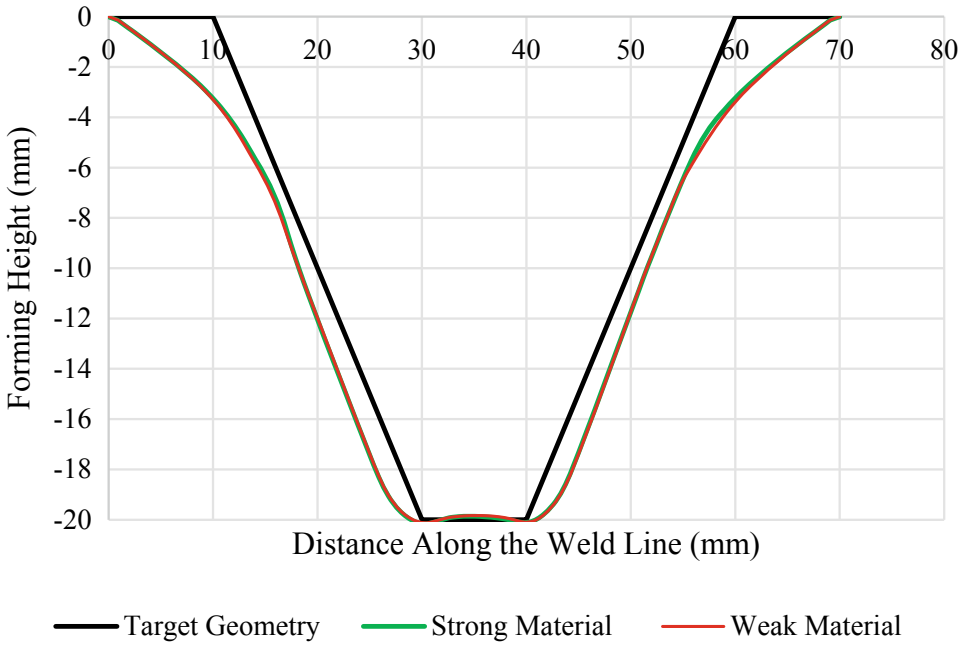
5.3.4 Comparison with the Target Geometry

The formed geometry is compared with the target geometry for SFS and SFW case in Fig. 5.11a, b, respectively. It can be observed that the formed geometry is deviating from the target geometry. In order to resolve this effect, proper tool radius compensation should be considered. For both SFS and SFW case, it should be noted that strong material is experiencing more spring back compared to the weak material because strong material is having high yield strength compared to weak material.

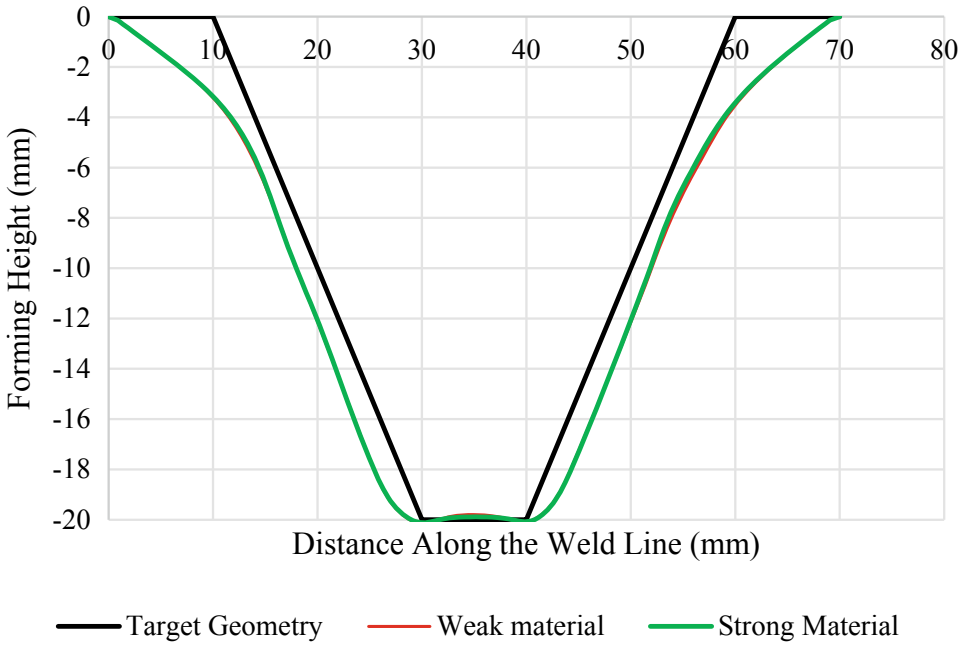
5.4 Conclusions

In the present research work, FE analysis of SPIF process is attempted for the TWBs. The effect of two different initial positions of tool on weld line shift, PEEQ and target geometry has been investigated. From the reported simulation study, the following points can be concluded:

- FE analysis can be adopted to study the forming behavior of the TWBs during SPIF process.
- Other than process parameters, weld line shift is affected by the initial position of the tool for the SPIF process. Initial position of tool affects the nature and magnitude of the weld line shift during the SPIF process.
- For the presented simulation conditions SFW results into the less weld line shift compared to the SFS case.



(a) For SFS case



(b) For SFW case

Fig. 5.11 Comparison with target geometry

- More weld line shift is observed in the wall section of the pyramid and that is due to the high amount of strain produced in it.
- If the deformation of weak material is supported by the tool dragging during the forming process, it leads to the maximum weld line shift.

- Formed geometry is nearly matching with the target geometry. However, the gap between them can be reduced by adopting proper tool radius compensation during forming.

Chapter 6
Joining Concentric Tubes by End Forming: A Finite Element Simulation Study

E. Premananda and R. Ganesh Narayanan

Abstract Concentric tubes are used in heat exchangers, chemical and bioreactors, air conditioners, etc. for transmitting fluid from one location to another. Butt joining of tubes is generally performed and this is accomplished by welding and mechanical fastening. The joining of concentric tubes is mostly performed by fusion welding processes. In the present work, an alternative approach to join two concentric tubes using end forming is proposed. A die groove is designed using finite element (FE) analyses to optimize the process parameters for successful joining. FE code ABAQUS/CAE is used for the FE simulations. The tubes are joined by end forming within the die groove. Such FE simulations helped in practical demonstration of the joining process as well.

Keywords Tube joining · End forming · Finite element simulation

6.1 Introduction

Tubes form an integral part of automotive industries, chemical factories, air conditioning system, railway structures, food processing sectors, construction and shipbuilding industries. Concentric tubes are used in heat exchangers, chemical and bioreactors, air conditioners, etc. for transmitting fluid from one location to another. They act as a structural member and hence they are joined and supported suitably to form a mechanical system. Butt joining of tubes is generally performed to take care of length requirements and this is accomplished by welding and mechanical fastening. The joining of concentric tubes is seen in certain applications, in which the ends are joined for sealing and supporting purposes. This is mostly done by

fusion welding processes viz., arc welding and flame welding. Green and sustainable manufacturing and fabrication of parts, as a theme and at a process level, plays a vital role in the development of new materials and processes. One can quote many examples for this. Such a development is meant for cleaner manufacturing and healthy environment. Some examples in which 'welding' is replaced by 'forming or plastic deformation' to accomplish the joining operation are discussed below.

Agrawal and Narayanan [1] proposed a method to join a steel to a thin sheet by end forming of tube. FE simulations were conducted to optimize the parameters. Some criteria were suggested to select the successful joints for fabrication and testing. Alves et al. [2] proposed a method of joining a tube to a sheet using end forming of tube. The forming component involves two localized bends in the tube between which the sheet is placed. FE simulations were conducted to check the possibility of the joining method. A practical example of joining a lever to a fulcrum in an automotive braking system has been demonstrated using the proposed method. A similar method of localized bending of tubes to join two tubes was presented by Alves et al. [3]. In this, joining of carbon steel welded tube (n = 0.06; k = 616.4 MPa) with Aluminium 6060T6 tube was demonstrated. The slenderness ratio and angle of inclination of chamfered edges are optimized to yield a successful product. Silva et al. [4] presented an environmental friendly joining of tubes involving localized bending of tubes. This is similar to tubular lap joints that have a significant overlay with the counterfacing surfaces of the coupling tubes to be joined. The proposal has been demonstrated experimentally and through numerical simulations. The joints performed well in tensile, bending, torsion, and water tightness destructive tests. A new method of fabricating gas and liquid storage reservoirs using nosing of a tubular preform has been demonstrated by Alves et al. [5]. The cases with and without mandrel have been compared. The case in which a mandrel is used for fabrication has been successful. Zhang et al. [6] had used rotary swaging technology for joining two tubes, in which a concave arc region has been formed to take care of the joint efficiency. The ratio of tensile load of the joined tubes to the maximum tensile load of the single tube can reach up to 68% for the inner tube and 47% for the outer tube, depicting the acceptable strength of the joint for practical applications. In separate work, Zhang et al. [7] demonstrated that copper and aluminium tubes can be joined by rotary swaging. The length of the overlapped region plays a vital role in deciding the joint strength. Many such examples can be quoted in the context.

From the discussion, it is imperative that the end forming of tubes is either used to fabricate tubular components or used to join tubes or to join tubes to sheets. By adopting these processes, usage of filler materials, shielding gases, flux in fusion welding processes are ruled out. Thus, joining by end forming can be categorized under green and sustainable joining processes.

In this context, the main objective of the present work is to propose and analyze a simple manufacturing method for joining of concentric tubes having dissimilar properties using end forming. An experimental setup having a die groove has been designed using FE simulations in Abaqus/CAE, FE code. The tubes undergo plastic deformation at their ends in the die groove and get mechanically interlocked to form a joint at the tube end. The influence of three important parameters is studied through FE simulations and suggestions on the sensitivity of those parameters are delivered in the article. Such parameters are optimized within chosen range for practical demonstration.

6.2 Proposed Joining Method

Figure 6.1 shows the proposed method of joining concentric tubes. The tubes of dissimilar qualities are located just above the die groove. The punch is given downward displacement such that the tubes move along the die groove and plastically deform through end curling. During tube end curling, the ends get mechanically interlocked to form a joint at the ends. The joining of concentric tubes by end forming is studied with the inner tube of length 70 mm, internal diameter 37.8 mm, and thickness 1.64 mm, and an outer tube of internal diameter 42.8 mm, and thickness 1.92 mm. The study is carried out to verify process feasibility as a function of gap between the tubes 'd', ratio of length of tubes 'h_1/h_2', and Coulomb's friction coefficient, μ. The input parameters are given in Table 6.1. The range for these parameters was selected after several FE simulation trials.

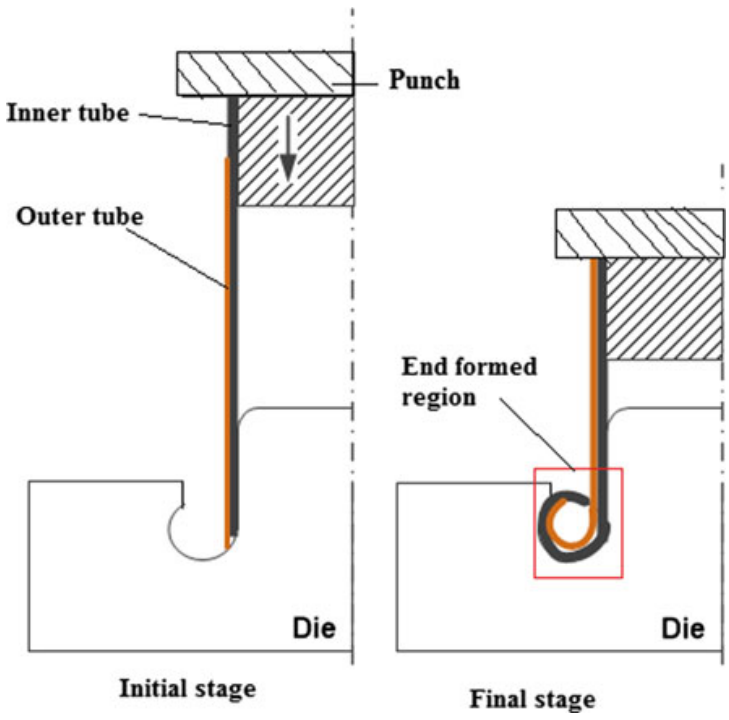

Fig. 6.1 Schematic of joining of concentric tubes by end forming

Table 6.1 List of varying input parameters for concentric tubes joining

Coulomb's friction coefficient (μ)	Ratio of length of tubes (h_1/h_2)	Gap between the tubes (d) in mm
0.05	70/44	0.10
0.08	70/46	0.50
0.10	70/48	0.86
0.15	70/50	1.00
0.20	70/52	1.50

h_1 = length of internal tube referred to as tube1
h_2 = length of external tube referred to as tube2

6.3 FE Simulation and Experiment Trial

The numerical simulation of joining of concentric tubes by end forming is carried out by using the FE code Abaqus/CAE, version 6.7. The selected mesh size for punch and tube is 4 mm and for die is 3.5 mm. The element type of die and punch (rigid bodies) are C3D4 and tube (deformable) is C3D8R. The element size has been chosen after sensitivity analyses and for minimum computational time. The objective of this study is to join the concentric tubes by end forming process. By using the simple die which is used in case of single tube, the locking of tubes did not take place. So a die having groove is designed to fabricate the joint. The entire process can be divided into three stages, i.e., stage 1, stage 2 and stage 3.

Stage 1: As both the tubes are of different length, i.e., internal tube is larger than the external tube, when axial compression takes place the internal tube starts to deform at the die surface. Since there is no contact between the punch and external tube, it rests at the bottom portion without having any deformation which is shown in Fig. 6.2.

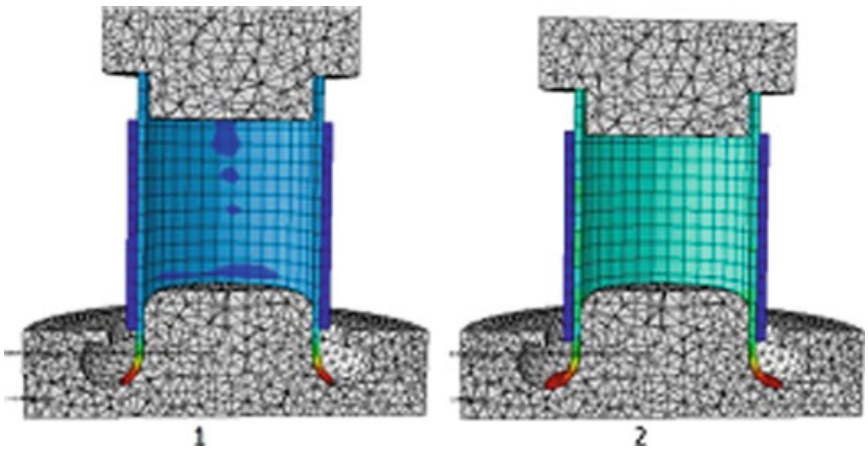

Fig. 6.2 Stage 1 of the proposed joining method

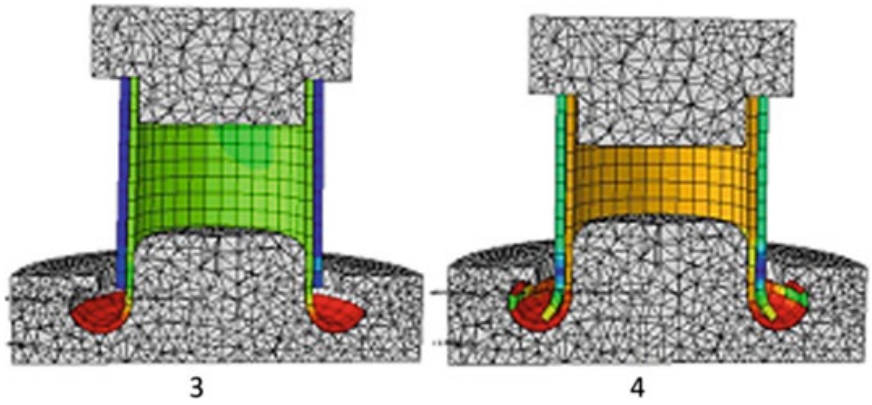

Fig. 6.3 Stage 2 of the proposed joining method

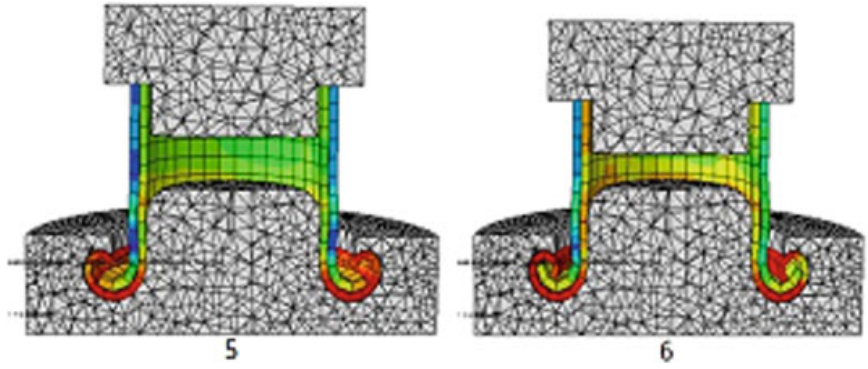

Fig. 6.4 Stage 3 of the proposed joining method

Stage 2: In this stage, the external tube comes in contact with the punch and it also starts deforming above the internal tube. By the time, the internal tube keeps on deforming and acquires the shape of groove of the die. The process of stage 2 is shown in Fig. 6.3.
Stage 3: As the upper portion of the die groove is heading inward, the leading edge of internal tube starts deforming in the inward direction. After a particular stage, the tubes get mechanically locked as shown in Fig. 6.4.

Some experimental trials were conducted to demonstrate the joining method at lab scale. Figure 6.5 shows the experimental setup clamped in a universal testing machine. The tubes were displaced in the downward direction at a uniform cross-head speed of 1 mm/min.

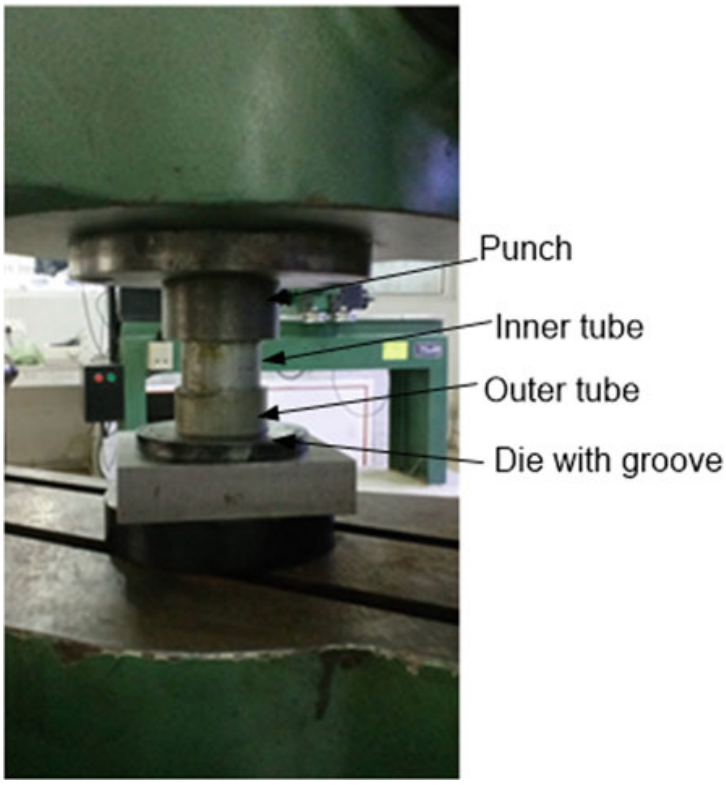

Fig. 6.5 Experimental setup for the proposed joining method

6.4 Material Properties Evaluation

The uniaxial tensile experimental tests were performed in order to study the mechanical properties of the tubes by means of universal testing machine. The specimen used as internal tube is mild steel tube of internal diameter 37.8 mm and thickness of 1.64 mm, the outer tube is of internal diameter 42.8 mm and thickness is 1.92 mm. The mechanical properties obtained for both the tubes from the tensile test are presented in Table 6.2. The internal tube is referred to as tube 1 and the outer tube is referred to as tube 2. The other material properties assumed are density = 7850 kg/m^3, Poisson's ratio = 0.303. These were obtained from tensile tests. The true stress-strain data which is used in the simulation process was fit to the Hollomon's power hardening law defined as, $\sigma = K\varepsilon^n$, where K and n are the strength coefficient and the strain hardening exponent, respectively. For FE simulations, the tubes are considered isotropic, and von-Mises yield function is followed.

Table 6.2 Mechanical properties of the tubes

Tube	Elastic modulus (GPa)	Yield stress (MPa)	Ultimate tensile strength (MPa)	Uniform elongation (%)	n	K (MPa)
Tube 1	84.6	339	406	12.3	0.15	646
Tube 2	106.3	305	342	9.9	0.14	526

6.5 Results and Discussion

Length ratio of both tubes plays a major role in the locking of both the tubes. When the simulation was carried out for tubes having equal length the external tube started to buckle in the mid-region when they were forced to deform along die groove region. Therefore, tubes having different length were introduced in order to get the desired locking of concentric tubes. The length of internal tube is kept fixed and the length of external tube was changed. Figure 6.6 shows the load-displacement curve for different length ratios. The curves have been fit to the data by a polynomial.

It can be seen that for higher and lower length ratios the process is unsuccessful. As the length of external tube increases, the load required for the joint formation also increases. The result of the process for different length ratios, whether it is successful or unsuccessful, is listed in Table 6.3. In case 1, the locking of tubes was not proper. The internal tube strikes the external tube before it moves inside. In cases 2, 3 and 4 the locking was good. In case 5, both the tubes start to buckle before joining.

In forming processes friction plays a key role. The friction between the internal tube and die is considered as frictionless and the friction between both the tubes is

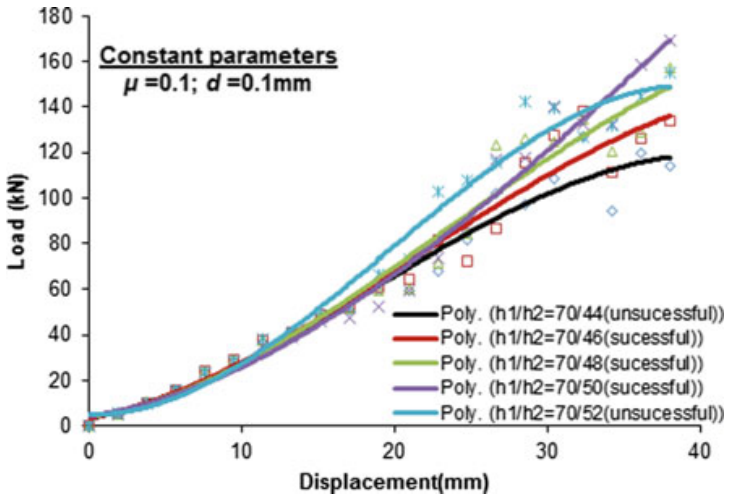

Fig. 6.6 Load evolution for various tubes length ratios

Table 6.3 Effect of length ratio of tubes in concentric tube joining

Cases	h_1/h_2	Results
Case 1	70/44	Unsuccessful
Case 2	70/46	Successful
Case 3	70/48	Successful
Case 4	70/50	Successful
Case 5	70/52	Unsuccessful

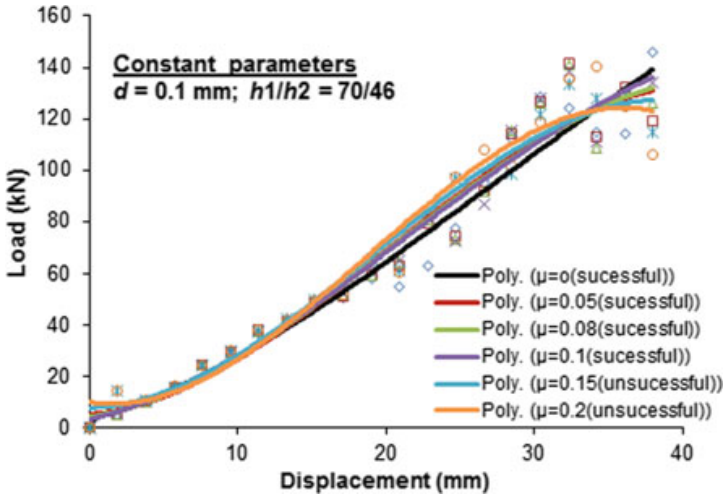

Fig. 6.7 Load evolution for various Coulomb's friction coefficient

Table 6.4 Effect of Coulomb's friction coefficient in concentric tube joining

Cases	μ	Results
Case 1	0	Successful
Case 2	0.05	Successful
Case 3	0.08	Successful
Case 4	0.10	Successful
Case 5	0.15	Unsuccessful
Case 6	0.20	Unsuccessful

varied to observe the effect. As the friction coefficient increases, the load required for the process also increases (Fig. 6.7). For very high value of friction coefficient, the process is unsuccessful. The results for different μ values are listed in Table 6.4. The locking of tubes was acceptable for cases 1–4. In case 5 and 6, tubes started to buckle from the upper portion.

The gap between the tubes was varied in order to evaluate its effect on the forming process. It is observed that for no gap or 0.1 mm gap the process is feasible. For all values other than 0.1 mm, the process is unsuccessful. For all the unsuccessful cases, the load drops when the tubes start buckling (Fig. 6.8). Moreover, in all the unsuccessful cases, the tube buckled when the external tube made contact with the internal tube at die groove region.

Some experimental attempts were made as shown in Fig. 6.9 to join concentric tubes. Though tubes underwent forming in the die groove as observed in simulations, the inner tubes failed before joining is fully accomplished. Such a failure pattern was not observed in FE simulations as instability criterion was not implemented.

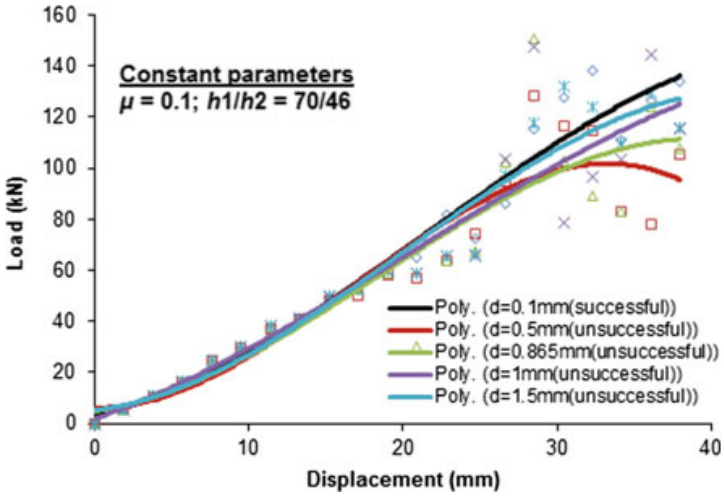

Fig. 6.8 Load evolution for different tube gaps

Fig. 6.9 Joints made by end forming

6.6 Conclusions

An attempt has been made to join concentric tubes by means of end forming operation. The input parameters such as length ratio of tubes, Coulomb's friction coefficient and gap between the tubes have significant effects on the feasibility of the process. The entire analyses have been carried out by FE simulations. The parameters are optimized and experimental demonstration is partially successful. During experimentation, the inner tubes failed due to circumferential stretching before joint formation occurred.

Chapter 7
Optimization of the Forming Parameters in U-Bending for Punch Force and Springback Using Taguchi Method

P. Venkateshwar Reddy, D. Mohana Krishnudu, U. Pranavi and P. Janaki Ramulu

Abstract Springback is a crucial factor that influences the feature of sheet metal in the sheet metal forming (SMF). In SMF operations, springback of the component during unloading mostly determines whether the component confirms to the design dimensions and tolerances. The aim of the current work is to analyze the importance of forming parameters on the responses: punch force and springback in U-Bending of SS 304. Strip length, punch speed and lubricant with three levels each have been considered in the current work as the forming parameters. The effects of different process parameters on U-bending of sheet metal have been investigated by conducting experiments on SS 304. Experiments have been conducted as per Taguchi's L_9 orthogonal array. The optimum conditions have been determined based on their effect on punch force and springback of the sheet metal.

Keywords Springback · U-bending · Optimization · Taguchi · Forming

7.1 Introduction

The sheet metal forming method includes a mixture of elastic–plastic bending and stretch deformation of the sheet. These deformations might prompt a lot of springback of the formed sheet metal part. Springback represents a challenge for

manufacturers who desires to meet specific dimensions. It is wanted to anticipate and diminish springback with the goal that the last part dimensions can be controlled however much as could reasonably be expected. Significance of the springback calculation is noteworthy from the economical point [1]. Ayres [2] proposed the utilization of various advance procedure to diminish springback in stamping tasks. Liu [3] proposed to shift the holding pressure amid the forming procedure in the way of giving tensile pre-loading to lessen the springback in the formed component. Chou and Hung [4] considered the impact of process factors of the strategies utilized to lessen springback by an optimization procedure for U channel parts. Chan et al. [5] investigated on the springback effect on sheet metal bending by considering various die-punch parameters like punch angle, punch corner radius and die-shoulder radius by performing FEM analysis. Reche et al. [6] studied on air bending tests by considering the effect of bending angle, sheet thickness and loading conditions on spring back. A lot of efforts have been carried out to eliminate the springback, most of them mainly focused on the optimization technique by considering draw-beads, bend curvature radius, punch forces and blank holder force [7, 8]. Maia et al. [9] investigated the U-rail to compare various optimization techniques and prediction tools, with an aim of finding capable strategies for springback compensation. Kakandikar and Nandedkar [10] investigated the process parameters which influences the springback by using optimization technique on automotive component. Vasudevan et al. [11] investigated on the springback of electrogalvanised steel sheet by considering many process parameters and also coating of the materials along with its geometrical parameters and concluded that the punch speed, die opening along with sheet orientation has high influence on the springback. Buang et al. [12] investigated on the stainless steel sheet by considering the effect of the die and punch radii on the springback of V-die bending process and concluded that the springback decreased by decreasing the die and punch radii. Maske and Sawale [13] studied the optimized parameters on the springback effect on aluminum sheet considering the effect of temperature and gauge of the sheet and concluded that the temperature affects the springback phenomenon and their optimized condition is found out. Gautam et al. [14] compared both the numerical and experimental results of springback in 3 ply cladded sheet metal by considering orientation of the sheet metal and concluded that the specimens oriented along the transverse direction have a greater springback when compared to the perpendicular direction.

Only very few of the earlier works have focused on the optimization of forming parameters in sheet metal U-Bending of SS 304. Thus, the aim of the current work is to optimize the forming parameters so as to minimize the punch force and springback using Taguchi Method.

7.2 Materials and Method

7.2.1 Tool and Workpiece Material

Strips made up of SS 304 with thickness of 1 mm were used for the current study. Tables 7.1 and 7.2 shows the chemical composition and mechanical properties of SS 304 respectively. Tools such as punch and die are made of tool steel and their dimensions are shown in Table 7.3. The schematic illustration of tools used in the present study is shown in Fig. 7.1. The fabricated experimental setup is attached to the Universal Testing Machine (UTM) is as shown in Fig. 7.2. Figure 7.3 represents the deformed images of the sheet metal after measuring of springback angle.

7.2.2 Design of Experiments Using Taguchi Method

Taguchi method is used for various problems with multiple parameters due to its practicality and robustness [15, 16]. In Taguchi method, optimization refers to the purpose of best levels of control factors; these best levels are that which maximizes the Signal-to-Noise (S/N) ratios. In this method, the experiments are conducted based on Orthogonal Arrays to conclude the best levels. Strip length, punch speed, and lubricant are the three factors were considered for the experimental outline.

Table 7.1 Chemical composition of SS 304 in wt%

Fig. 7.2 Experimental setup for U-bending

Each factor has three levels. So L_9 Orthogonal Array (OA) was shaped in light of the three factors three-level design. The decision of a suitable OA relies upon the measure of control parameters and its levels. To appraise the principle parameter impacts, the design should be Orthogonal and Balanced. Taguchi has arranged some orthogonal arrays that fulfills the over two properties for various number of parameter-level combinations [17]. Inferable from cost and other test confinements, in the present case, a fractional factorial plan with nine runs has been chosen out of

Fig. 7.3 Deformed images after forming the sheet metal

Table 7.4 Considered parameters and their levels

Parameters	Level 1	Level 2	Level 3

the full factorial design, $3^3 = 27$ runs. The combination of factors and their levels are recorded in Table 7.4. The recorded methodology of the Taguchi appears in Fig. 7.4. However, this technique helps in deciding the feasible combinations of factors and recognizing the best combination. This, in turn, implies that the resources (materials and time) required for the experiments are also minimum.

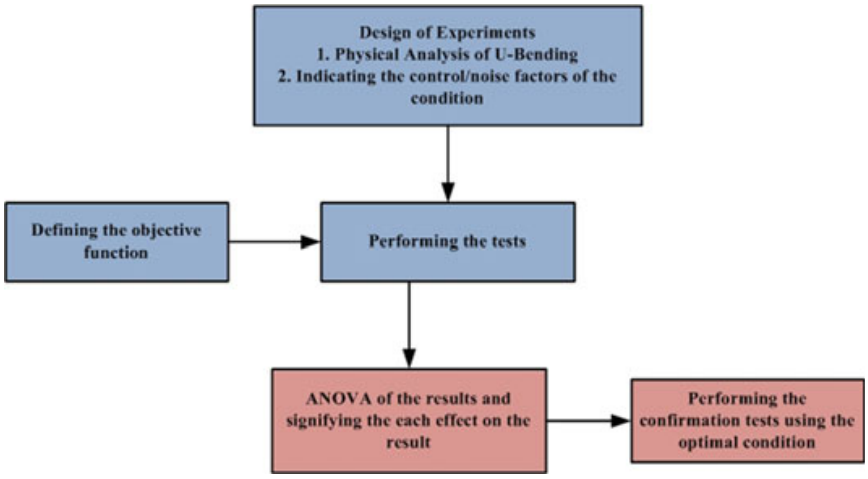

Fig. 7.4 Robust design flowchart for Taguchi method

7.3 Results and Discussion

The main aim of the present study is to optimize the forming parameters like strip length, punch speed and lubricant to achieve low punch force and springback. U-Bending test is analyzed to get a better combination of forming parameters using Taguchi technique for a different set of combinations. Table 7.5 shows the experimental test conditions and its responses.

7.3.1 Effect of Forming Parameters on Punch Force

The influence of forming parameters on Punch force is shown in Fig. 7.5. The punch force increases with increase in strip length since the punch has to travel more distance along with strip into the die. For both punch and die the contact area is increased as the length of the strip increased, thereby the punch force increased as the length of the strip increased. Whereas there is only a minute variation with punch speed and lubrication on punch force. Similar results were observed from the literature work carried out by the authors [18]. In their work lubricant does not affect much on the punch force as the same results were observed in the present study.

Table 7.6 represents the response for mean of means on punch force and it is observed that the most influencing factor on the punch force is the strip length followed by the punch speed and the lubricant. Since the punch travel is more for longer strip length with more contact time between the tools, so the punch force required is more for longer strips. Works carried out by different authors in the literature obtained almost the same results.

Table 7.5 Experimental test conditions and their response values

Test No.	Strip length	Punch speed	Lubricant	Punch force (kN)	Springback angle
1	75	5	Engine oil	10.5	4.6
2	75	10	Mineral oil	11.5	4.5
3	75	15	Grease	10.9	4.9
4	95	5	Mineral oil	17.5	5.1
5	95	10	Grease	16.9	5.5
6	95	15	Engine oil	18.2	5.2
7	115	5	Grease	21.6	5.4
8	115	10	Engine oil	20.6	5.1
9	115	15	Mineral oil	22.1	4.8

Delta	10.47	0.73	0.60
Rank	1	2	3

Table 7.7 represents the ANOVA results for punch force. It is observed that the strip length is the most influencing factor that affects the punch force and the percentage of contribution is about 99%. Meanwhile, the percentage contribution of punch speed and lubricant together is 1%.

7.3.2 *Effect of Forming Parameters on Springback*

The influence of forming parameters on springback is shown in Fig. 7.6. The springback increases with increase in strip length (18.5%) upon a length of 95 mm and then decreases a little (7.2%) for a strip length of 115 mm. Whereas there is only a minute variation with punch speed and also there are some interesting facts observed with the lubricants on springback with variations for different lubricants. Similar results have been observed by the authors in the literature [18]. Lubricants of different viscosity had an impact on the springback in their work similarly same results observed in the present work. The effect of punch speed on springback is not much observed by the literature studies also [19]. Only a minute variation of springback is observed in the present study also similar to the literature study.

Table 7.8 represents the response for mean of means on Springback and it is observed that the most influencing factor on the springback is the strip length and lubricant and only a minute influence by punch speed is observed. Similar results were also observed by the literature studies.

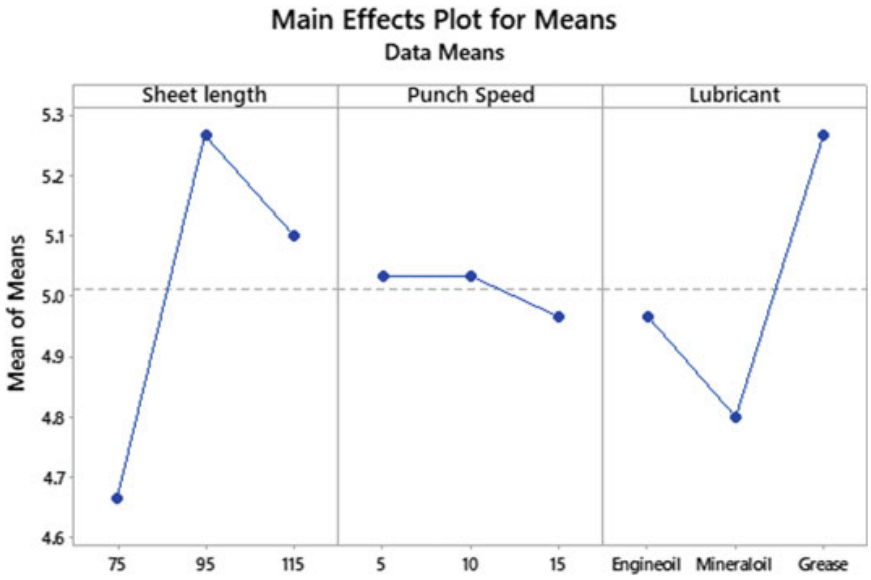

Fig. 7.6 Parameters affect plot on springback

Table 7.8 Response for mean of means on springback

Level	Strip length	Punch speed	Lubricant
1	4.667	5.033	4.967

0.0666667	99.04%	96.17%	80.62%		

Table 7.9 represents the ANOVA results for springback. It is observed that the strip length and lubricant are the most influencing factors that affect the springback and the percentage of contributions is about 62.5 and 36.4% respectively. Similar results were observed with the literature studies, all the obtained results are validated with the works carried out by different authors in their works.

7.4 Conclusions

Sheet metal U-Bending was conducted on SS 304 and the forming parameters were analyzed in terms of punch force and springback by varying the strip length, punch speed, and lubricant. Using Taguchi method its optimum machining conditions were determined. Using ANOVA significance parameters were defined. From the present work, the following conclusions were drawn.

- From the statistical analysis, it is observed that strip length is the most influencing parameter that affects both punch force and springback.
- From Taguchi, the optimum forming parameters for punch force were identified as Strip length of 75 mm, Punch speed of 10 mm/min and engine oil as lubricant and are validated by the experiment. The punch force for the optimum conditions is observed as 10.4 kN.
- From Taguchi, the optimum forming parameters for springback were identified as Strip length of 75 mm, Punch speed of 15 mm/min and mineral oil as lubricant and are validated by the experiment. The springback angle for the optimum conditions is observed as 4.5°.
- Obtained results of both punch force and springback are compared to the literature works and a good agreement among the results is observed.

Chapter 8
Experimental Analysis on Springback of JIS 3302 Grade Steel Sheet Material Under Various Heat-Treated Conditions

Kemal Ramato, Perumalla Janaki Ramulu and N. R. R. Anbusagar

Abstract JIS 3302 grade steel sheet material has a wide range of applications in automotive industries. Any kind of sheet metal has to undergo different forming test before a real-time application. There are many forming processes are existed to check the formability of sheet materials. Among all the forming process, bending process is one of the formability tests had a drawback interms of springback. The springback behavior is a measurable quantity for any material after the test. Based on the springback nature of sheet material end product shape finalization will be done. This has a dictum for the present work on springback effect analysis of JIS 3302 steel sheet material is focused. And also, the effect of various heat treatments on springback characteristics of JIS 3302 steel sheet metal studied using experimental and numerical analysis. For the experimental work, sheet was cut with the dimensions of specimen 150 mm × 40 mm × 2 mm in three different rolling directions such as 0°, 45°, and 90° and bending test conducted on V-bending die with 90°. For the tensile testing specimens were cut as per ASTM standard in three rolling directions. The results showed that before heat treatment, the workpiece has taken more load for bending and recorded higher value of springback, whereas, the annealed workpiece has the lowest load consumption to bend and lower springback value.

8.1 Introduction

Plastic deformation is concerning about metal forming process which has huge applications in various industries. Their main attribute is high efficiency, repeatability, and economy; simultaneously keeping the proper surface condition in mass production. The most frequently used techniques for sheet metal forming are bending, stretching and stamping [1]. Bending is one of the most commonly used methods beyond the sheet metal forming process. The common products obtained with the aid of bending are automobile panels, supermarket shelves, automotive component, aerospace vehicles, pressure vessels, medical equipment, electrical component, drums and housing utensils, etc. [2]. During the forming process force applied when the force is removed, the metal tries to coming back to its original shape and results in a phenomenon named "springback". This is due to the elastic deflection that occurs in the material after the bending process takes place [3]. Ramulu et al. [4] studied springback analysis on AA 6061 Aluminum alloy sheets with seven different rolling directions of sheet with the combination of U and V die shape. In order to make bending at a desired angle the process parameters considered were different load, displacement, and die angle. Finally, concluded that, the effect of rolling direction on springback effects was very sharp and prominent. Main factors that change the springback effect were indicated as sheet thickness, material properties and tool geometry [5–12]. Based on these literatures, the present work aimed to investigate the effect of springback on JIS 3302 steel sheet metal of 2 mm thickness by experimental and numerical work with different heat-treating conditions of the sheet.

8.2 Methodology and Materials

8.2.1 Materials

JIS 3302 grade steel sheet of 2 mm thickness material was used for the present work. This grade material has a wide-ranging of applications and economic considerations in the industries. Table 8.1 shows the chemical composition of JIS 3302 steel material before heat treatment.

Table 8.1 JIS 3302 grade steel chemical composition (in wt%)

C	Si	Mn	P	S	Cr	Mo	Ni	Cu	W	Fe
0.05	0.0065	0.19	0.078	0.035	0.041	0.003	0.014	0.02	0.04	99.5

8.2.2 Experiment: Bending Process

The specimens were prepared in the form strips at different rolling directions (0°, 45°, and 90°) of sheet. This specimen was cut by hydraulic shearing machine from 1000 mm × 2500 mm × 2 mm sheet metal with specimen dimensions of 150 mm × 40 mm × 2 mm as shown in Fig. 8.1. In total, 9 experiments were planned in which 3 tests at ambient condition, 3 tests at full annealing condition and other three tests at normalizing condition in three rolling directions. In a whole, 27 specimens were prepared for three repetitions for each. The full annealing and normalizing heat treatment methods were performed at 900 °C. This 900 °C temperature was considered due to virtually near to recrystallization temperature where phase changes. When phage changes, change in mechanical properties is inevitable.

The V-bending process was used for the bending tests. The experiment set-up was composed of a punch, a die and guide pins which are given in Fig. 8.2. This experiment was performed on hydraulic press brakes machine. The movement of the punch was hydraulically powered and applied enough force on the blank. Experimental setup was not disturbed for all experiments and the tests were conducted under the same operating conditions. The punch stroke was fixed and not moved up to the bottom of the die. A gap of 2 mm, which was equal to sheet thickness was maintained between the final position of punch and the die to avoid crushing of the sheet material at the bending profile. The angle of the die was 90°.

8.2.3 Tensile Test Procedure

The tensile specimens were made from sheet at rolling direction of 0°, 45° and 90° as per ASTM standard E-8 M as shown in Fig. 8.3. Tensile tests were performed at

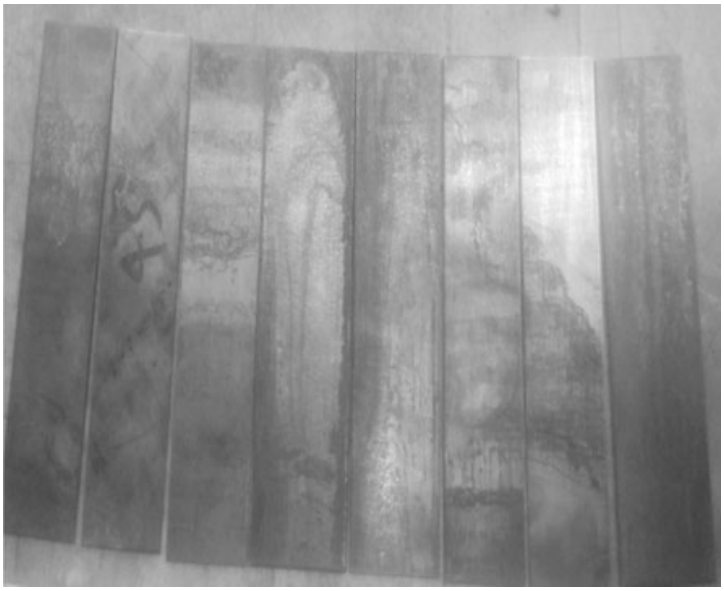

Fig. 8.1 Specimen for bending test with 150 mm × 40 mm × 2 mm dimensions

Fig. 8.2 Experimental setup for V-bending

Fig. 8.3 Specimen prepared for tensile test

a nominal cross-head speed of 1 mm/min, of samples at room temperature and annealed at 900 °C conditions on an ISO 68982-1 universal testing machine. Tests were repeated three times for each condition. The mechanical properties of JIS 3302 grade steel sheet material like yield strength, ultimate tensile strength, total elongation, uniform elongation, strain hardening coefficient (n) and strength coefficient (K) were evaluated as per the standard procedure after testing the samples till failure. The obtained load-stroke behavior during testing was converted into engineering stress–strain and true stress–strain plot for evaluating the mechanical properties. The plastic strain ratios at different rolling directions were obtained after testing the base material to 10% plastic strain.

8.3 Results and Discussion

8.3.1 Tensile Test Result

The results of tensile tests are shown in Table 8.2 such as ultimate stress (Tensile stress), yield stress, total elongation, strain hardening coefficient (n) and material strength (K). The ultimate stress and yielding stress for annealed specimens are the lowest when it is compared with the results from normalized and before heat treating specimen as presented in Table 8.2.

8.3.2 Springback Results from the Experiments

The experiments are conducted on JIS 3302 grade steel sheet of 2 mm thickness with different rolling directions. For illustration few of the deformed sheets are shown in Fig. 8.4. For each test, three repetitions are followed. In each repetition, springback angles are measured with equal time interval. All the experimental data is tabulated in Table 8.3. Among all the specimens, the major springback has seen without heat-treated specimen as 3.5° in 90° rolling direction and minimum is in annealed sample as 0.5° in 0° rolling direction (Fig. 8.5).

The effect of springback and resulting properties of mechanically formed steel plates have been presented and discussed. It is found that the 2 mm V-bended sheet metal exhibited the largest value of springback 3.060 for experimental. Due to the springback errors, the desired angle of 90° was not achieved. From this of point, it can be concluded that springback causes geometric inaccuracies in sheet metal bending.

Table 8.2 Mechanical properties of JIS 3302 grade steel sheet material

8.4 Conclusions

In this study, several bending tests are conducted to determine the effect of heat treatment on the springback. For this work, two different types of heat treatment were applied to the JIS 3302 grade steel and the amount of springback is determined under three circumstances. Moreover, the effect of rolling angle to the springback is also studied individually. Hence, the general conclusions attained in this study are as follows:

- The specimen used have the highest yield strength without heat treatment condition compared to annealing and normalizing and it also observed that higher springback obtained in the specimen compared to others.
- It observed that when rolling direction increase the elongation of specimen is decreases.
- In heat treatment condition, required punch force to bend the sheet metal was higher than the material in normalizing condition where the lowest in annealing condition.

Experimental and Numerical Assessment of Residual Stresses in AA6061 After Surface Treatment by Deep Cold Rolling

Rakesh Kumar, Gulshan Kumar, Vijay Gautam and Subhajit Konar

Abstract Deep cold rolling is a mechanical method of surface treatment used to adapt the desired surface properties in machine components for aerospace industries. In this process, localized plastic deformation is rendered on the surface by rolling a form tool wheel on the specimen to condense high dislocation density which imparts high compressive residual stresses resulting in increased tensile and fatigue strength. The main focus of the present study is to characterize the distribution of residual stresses on the surface and subsurface of an 8-mm-thick plate made of an aluminium alloy AA6061-O, after deep cold rolling operation to different depths of 0.5, 1, 1.5 and 2.0 mm. The observed residual stresses are correlated with the microstructural features in the deformed depths of the specimens. The residual stress and grain size in the deformed specimens are examined by using grazing incidence X-ray diffraction and electron backscatter diffraction technique, respectively. It is observed that deep cold rolling leads to significant grain refinement, resulting in high values of residual stresses through thickness. The compressive residual stresses are found to be higher on the surface of the specimen and reduce gradually with the penetration depth. The experimental results are compared with the results obtained by FE analysis using ABAQUS. A good agreement is observed between the experimental and the simulated values of residual stresses and the trends of stress distribution pattern.

9.1 Introduction

Residual stresses are the stresses preserved in a material in the absence of any external force. These stresses can originate from phase transformation, thermal origin and defects like vacancies, dislocation, voids, cracks, etc. [1]. Residual stresses are mainly categorized into micro and macro stresses. Micro stresses are developed in grains due to existence of inclusions, dislocations, faults, etc. The macro stress is the average of stresses generated in each grain [2]. The stresses, compressive in nature, are beneficial in fatigue designing of components under dynamic load, whereas the tensile residual stresses are detrimental for the components subjected to fatigue and must be avoided. Undesirable residual stresses can lead to increased chances of crack propagation, distortion and premature failures in the components [3]. There are several methods to impart useful compressive residual stresses like deep cold rolling (DCR), shot peening, burnishing, surface hardening, etc. on the surface of the component to improve its fatigue strength [4]. Although shot peening is generally adopted for most components subjected to fatigue, DCR extends several benefits over the shot peening process. DCR imparts a deeper layer of compressive residual stress with remarkably good surface finish, but this process has a limitation in applying it for different geometrical profiles of the components [5]. This technique is widely used in automotive parts (e.g. crankshafts and shaft fillets), turbine blades, wheel flange, turbine disk, rotors, compressor fan blade, railway axles, etc. [6].

Subsequent paragraphs, however, are indented. DCR improves the fatigue strength, wear resistance and surface finish and decreases crack propagation and stress corrosion cracking by inducing a compressive residual stress on the surface [7]. This process is carried out using a roller shape or a ball-type deforming tool. As the rigid blunt roller or ball tool deforms the material underneath to a predetermined depth, a longitudinal groove is created along the length of the tool path resulting in an elasto-plastic zone. On removal of the deforming forces, the recovery of elastic region develops a zone of large compressive residual stress on the surface [5].

Wong et al. [5] explored the feasibility of DCR on titanium test specimens using three different cold rolling tool designs. The effects of process variables and design variables on yielding depth and residual stresses set-up were investigated. It was concluded that the rolling pressure affects the residual stress profile the most. Bozdana et al. [8] developed a new ultrasonic-assisted DCR, using static and dynamic forces of ultrasonic vibrations and investigated the effects of process parameters on titanium alloy test coupons. The process proved to be advantageous in reduced deforming pressure treating thin components without deteriorating the shape and a magnitude of 900 MPa of residual stress could be set-up at a depth of 0.2 mm. Zhu et al. [9] investigated the fatigue strength of titanium alloy specimens treated and untreated by ultrasonic-assisted DCR. Scanning electron microscopy of

the fractured specimens was also done. It was concluded that the new process was able to generate a deep layer of residual stress with high surface finish and resulted in enhanced fatigue strength of the fatigue test specimens. Xie et al. [14] studied the effects of ultrasonic-aided DCR process on microstructure of 30CrMnSiNi2A steel using nano-hardness tester, x-ray diffraction (XRD), scanning electron microscope (SEM), electron backscatter diffraction (EBSD) and transmission electron microscope (TEM). It was observed that severe plastic deformation by ultrasonic-aided DCR produced nano-crystallization, grain refinement, strain-induced martensite transformation, shear bands, intense shear texture and rolling texture in the surface and subsurface of the test specimens. Liu et al. [10] studied the mechanical properties of the surface prepared by ultrasonic surface rolling process, and nano-indentation tests were adopted to evaluate the force and depth of penetration. The magnitude of yield strength and strain hardening exponent were evaluated and the results were compared with the results obtained by FE simulations and found to be in good agreement. Juijerm et al. [11], surface treated the aluminium alloys AA5083 and 6110 using deep rolling at room temperature. It was observed that deep rolling enhanced the fatigue strength of aluminium alloys as compared to the polished condition due to near surface compressive residual stresses as well as work hardening and increased hardness induced by deep rolling.

Aluminium alloys due to its light weight, non-magnetic in nature, resistance to corrosion, high specific strength and better ductility are widely used in various industrial applications (aerospace, automotive, marine, building structure, etc.) [12], and offer lot of potentials to be surface treated by DCR. The development of a surface with high magnitude of compressive residual stress in high strength aluminium alloys depends on many factors like feed rate, roller speed, roller feed, applying force by roller, etc. Feed of roller affects the upper surface of the component, but does not affect the depth of penetration. The optimum combination of rolling force and rolling feed affects the surface hardness the most, whereas, if rolling force is maximum and feed is minimum then maximum surface hardness is achieved. The set-up for the DCR can be easily installed with conventional milling and lathe machines [13].

In the present work, the feasibility study of DCR on aluminium alloy AA6061 is carried out. The main focus of the study is to characterize the distribution of residual stresses on the surface and subsurface of 8-mm-thick plate made of an aluminium alloy AA6061-O after deep cold rolling operation to different depths of 0.5, 1, 1.5 and 2.0 mm. The observed residual stresses are correlated with the microstructural features in the deformed depths of the specimens. The residual stress and grain size in the deformed specimens are examined by using grazing incidence X-ray diffraction and electron backscatter diffraction technique, respectively.

9.2 Methodology

9.2.1 Experimental Work

Material Selection. In the present study, a wrought aluminium alloy AA6061 in annealed state is selected on the basis of its wide applications and high potential to be worked at room temperature by DCR. AA6061 is a precipitation hardening alloy, containing magnesium and silicon as its major alloying elements. The alloying elements enable the material to possess excellent tensile strength coupled with ductility and corrosion resistance and offer high resistance to fracture toughness. Some of the typical examples of applications of this alloy are heavy duty structures, marine structures, rail road, pipe lines, etc. The material is procured in the form of a plate with dimension 300 mm × 100 mm × 8 mm. The chemical composition of the alloy obtained by spark-based spectrometer is given in Table 9.1.

Tensile Properties. The tensile samples are prepared as per the ASTM standard by wire-cut electric discharge machining (WEDM) as shown in Fig. 9.1. A minimum of four samples of AA6061 is tested to obtain the scatter in results. The tensile specimens are tested on a 50 kN UTM, and load versus elongation data are procured using a dedicated Horizon software. The engineering stress–engineering strain curves are plotted to obtain the various tensile properties of the material. The engineering stress–strain plots are converted into true stress–true strain data and ln true stress versus ln true strain data between yield strength and UTS is used to determine the strain hardening exponent and strength coefficients.

Experimental set-up for DCR and sample preparation. Deep rolling set-up is installed on a horizontal milling machine and shown in Fig. 9.2. The milling cutter is replaced with a properly designed roller wheel of 75 mm in diameter, 5 mm thick

Table 9.1 Chemical composition of AA6061 in wt%

AA6061	Mg	Si	Cu	Cr	Fe	Ti	Zn	Co
	0.98	0.61	0.23	0.18	0.21	0.15	0.02	0.15

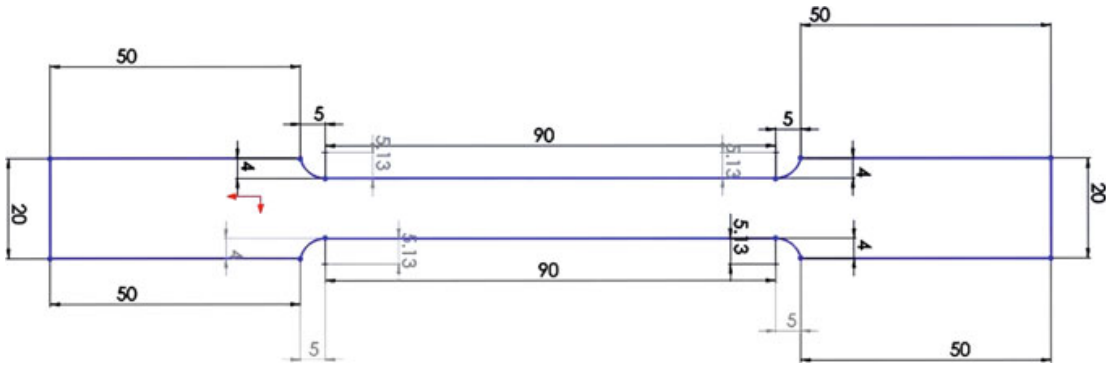

Fig. 9.1 Tensile sample details as per ASTM-E8M (all dimensions are in mm)

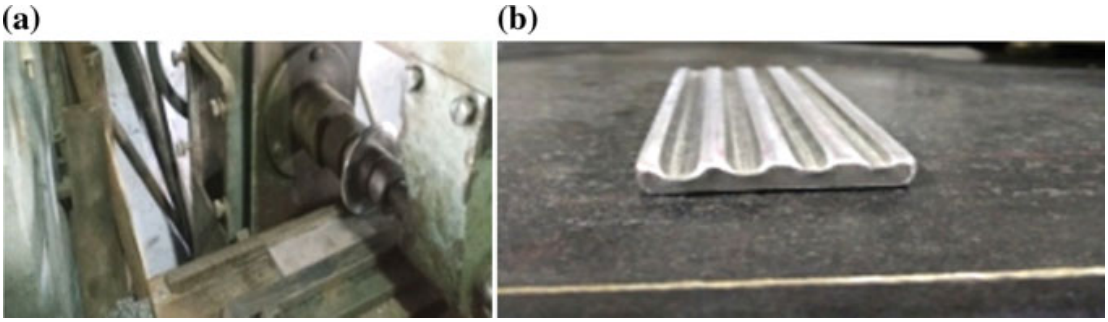

Fig. 9.2 **a** Deep rolling set-up on a milling machine (*Courtesy* Thapar University, Patiala) and **b** Deep cold-rolled aluminium specimen

and a nose radius of 2.5 mm made of D2 steel, hardened and tempered to deep roll the aluminium alloy at room temperature. The deep rolling process is carried out on the samples rigidly secured to the table using a fixture and the spindle is rotated at 10RPM to achieve the desired plastic deformation to different depths of 0.5, 1.0, 1.5 and 2 mm.

DCR-processed samples are carefully partitioned longitudinally by a diamond abrasive wheel cutter and polished in different stages from finishing with sub-micron SiC 1200 mesh to electropolishing to perform the microstructure characterization of different depth-rolled samples. The electropolishing is done on prepared samples so as to remove dust and scratches and to get a mirror surface grove of the samples. Electropolishing is done with perchloric acid 20% and methanol 80% at 27 V and 4.5 A current for a soaking time of 10 s.

Electron back scatter diffraction (EBSD), as shown in Fig. 9.3, is performed to measure the grain orientation, texture, grain size and grain boundary in plastically deformed regions of the processed samples to correlate the microstructure with residual stress.

Grazing Incidence X-ray diffraction. The grazing incidence X-ray diffraction (XRD) is a rapid Panalytical make, non-destructive system for analysing a large range of alloys, including metals, polymers and semiconductors as shown in Fig. 9.4. This technique is used to determine the residual stresses on a surface at an omega angle. In this case, the longitudinal stress is measured (σ_{11}) which is residual stress. Residual stress measurements on four samples processed by DCR to different depths of 0.5, 1.0, 1.5 and 2 mm are diagnosed on the surfaces at an omega angle of 0.1°, 0.5° and 0.8°.

9.2.2 Finite Element Modelling (FEM)

A three-dimensional, elasto-plastic finite element model is developed for DCR. The FE simulations were conducted using ABAQUS 6.13-1 software. In the simulations, an elastic plastic deformable rectangular aluminium alloy (Al6061) plate

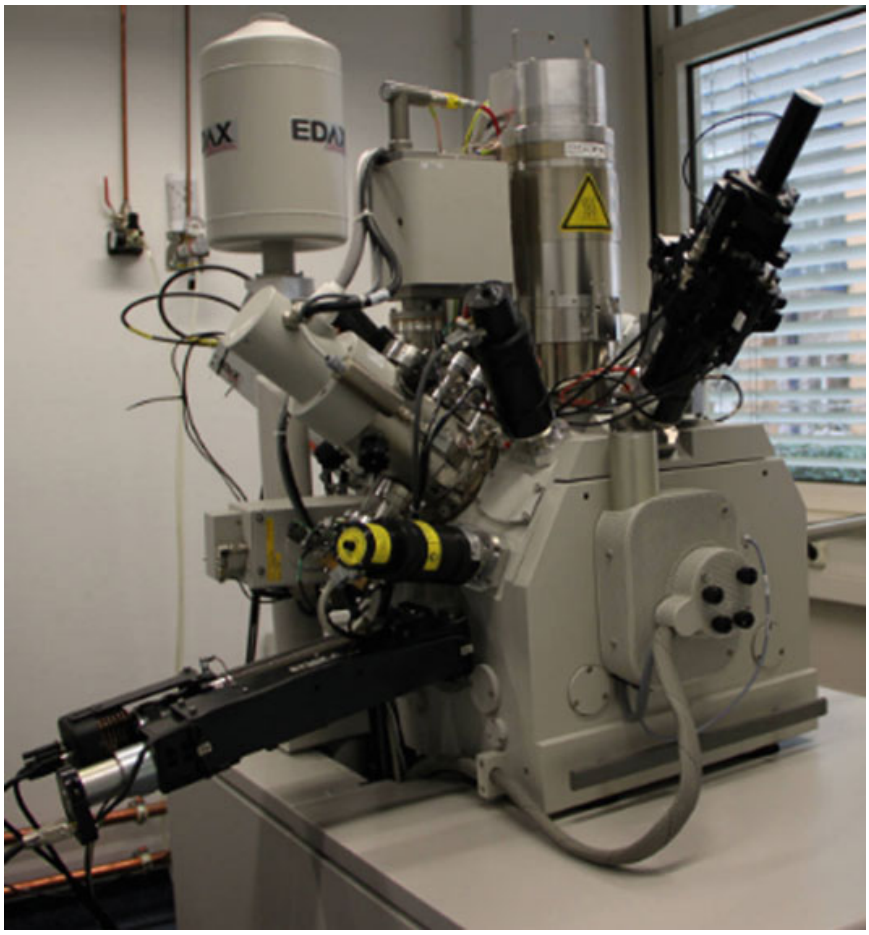

Fig. 9.3 Electron backscatter diffraction instrument to characterize grain structure (*Courtesy* IIT, Bombay)

of dimension 150 mm in length, 100 mm in width and 8 mm thickness is modelled and encastered along the edges to restrict the movement in any direction. The material model is designed to be isotropic in nature with modulus of elasticity (E) and Poisson's ratio (v) as 68.9 GPa and 0.33, respectively. The plastic data between 0.2% offset yield strength and ultimate tensile strength are selected from true stress–true strain plots to simulate the annealed behaviour of the material. The geometric model is using continuum stress/displacement and 8-nodded linear brick C3D8R elements. Element size plays an important role in attaining accurate results. A large number of elements can increase the computational time and a very small number of elements can lead to the inaccurate results. A structured mesh is used in this model. ABAQUS/Explicit has three different options for C3D8R elements, i.e. average strain kinematic, orthogonal and centroid formulations. The average strain kinematic formulation has been used in this study. Though, average strain kinematic formulation required more computational time compared to other two formulation techniques. The Lagrangian approach has been used in the present paper. In this approach, the initial configuration for the time $t = 0$ and the final state for the time $t + \Delta t$ are considered. Dynamic explicit method is used for the simulations.

Fig. 9.4 GIXRD Panalytical^{TM} set-up (*Courtesy* IIT, Bombay)

Mesh density is a significant metric used to control accuracy and a high-density mesh will produce results with high accuracy. However, if a mesh is too dense, it will require a large amount of computer memory and long runtimes, especially for multiple-iteration runs that are typical of nonlinear analyses. The basic fundamental and accurate method for evaluating mesh quality is to refine the mesh until von Mises stress value doesn't change significantly with each refinement.

In this study, 56,250 elements and 58,420 nodes with 15 elements in thickness direction and 250 elements are used in the width direction. To save the time, a biased mesh is generated in the deformation region using double biasing with a bias ratio of 3.

A roller wheel with 75 mm in diameter, 5 mm in thickness, 2.5 mm as nose radius is modelled as discrete rigid. The wheel is provided to have a uniform rotational speed of 10RPM. The simulations were conducted for penetration depths of 0.5, 1.0, 1.5 and 2.0 mm to deform the material longitudinally along the length of the specimen as shown in Fig. 9.5.

Coulomb friction was given to the contact surfaces and it is important to note that adequate friction is required to contact between the sheet and deep roller. Frictional forces at the interface of the roller and the sheet are responsible for pulling the sheet through the roller. A residual stress gradient has been observed at the surface of the deep-rolled sheet.

Boundary conditions are divided into two steps: an initial step and the analysis step. In the initial step, the sheet was given an initial velocity of 10 mm/s in

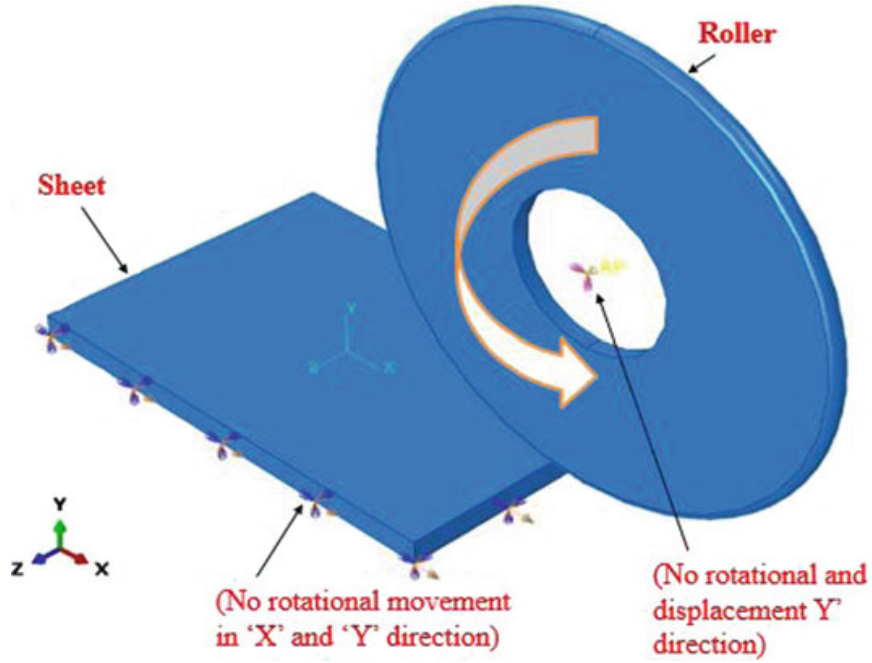

Fig. 9.5 A 3D finite element model DCR

'*x*'-direction. The interaction between the roller and the upper surface of the sheet is defined in this step. A displacement/rotation boundary condition is defined to constrain the motion of the sheet. The side faces of the sheet are made zero in '*y*'- and '*z*'-direction. Similarly, the boundary condition of the roller was made such that the roller could rotate only about their respective axis of rotation. All other translational and rotational degrees of freedom were constrained in '*x*'- and '*z*'-directions. In the analysis step, the rollers were given with an equal and opposite angular velocity. The friction model used in this study, allows the relative motion between the two contact surfaces. On the basis of literature survey on DCR, a frictional coefficient value of 0.2 is used in all the simulations.

9.3 Result and Discussion

9.3.1 Tensile Properties

The results obtained from the uniaxial tension tests conducted at room temperature are plotted and depicted in Fig. 9.6a and ln(true stress) versus ln(true strain) are shown in Fig. 9.6b. It is observed that the yield strength of annealed aluminium alloy AA6061 is 69 MPa and tensile strength is 132 MPa. The ductility of the alloy is excellent and found to be 42%. The strain hardening exponent is 0.3 on an average basis indicating good uniform stretchability.

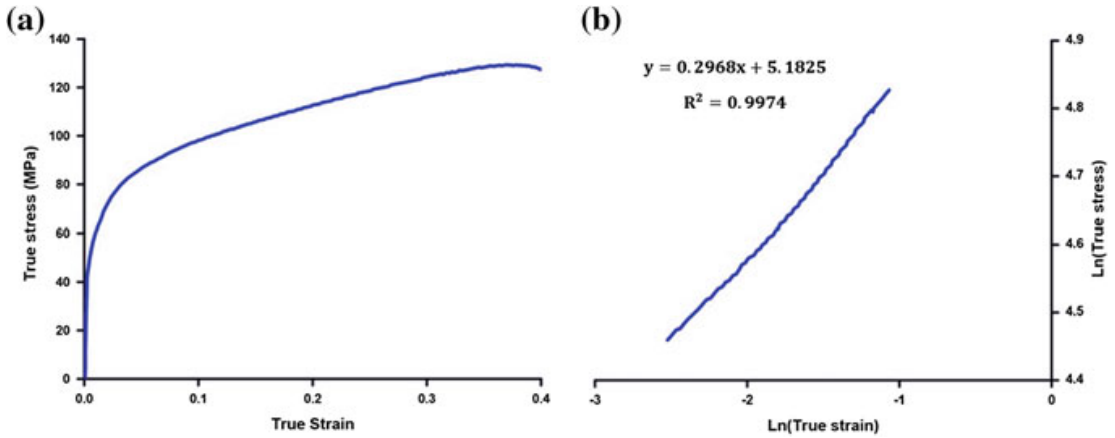

Fig. 9.6 **a** True stress versus true strain plot, **b** ln (true stress) versus ln (true strain) plot for tested tensile specimens of AA6061

9.3.2 Microstructure Characterization

Electron backscatter diffraction (EBSD) is used to characterize the microstructure of the deformed zones of AA6061 specimens. EBSD analysis revealed elongated grains in as-received parent material with a coarse grain size of 135.89 µm as shown in Fig. 9.7a. The various results of EBSD scan obtained at different DCR depths of 0.5, 1.0, 1.5 and 2.0 mm are shown in Fig. 9.7b–e, respectively. It is observed that the grain size with a deformation depth of 0.5 mm is 3.12 µm but the fine grains are segregated in a zigzag manner as shown in Fig. 9.7b. A fairly homogeneous ultrafine-grained microstructure is revealed at a deformation depth of 1.0 mm and the grain size is 1.95 µm. A similar ultrafine homogeneous grain size and distribution is observed with penetration depth of 1.5 and 2.0 mm without any remarkable difference in the average grain size.

9.3.3 Residual Stresses by Experiments and Simulations

The GIXRD method is used to determine the residual stress generated by DCR at the surface and subsurface of the specimens and the results obtained are plotted and shown in Fig. 9.8. It is interesting to find that the specimens of AA6061-O as procured has the range of residual stress ranging from −160 MPa(compressive) to 20 MPa (tensile) at the surface and at a depth of 0.6 mm below surface, respectively. After the first surface treatment by DCR with a tool penetration depth of 0.5 mm, there is a drastic increase in the values of residual stresses ranging from −230 to −160 MPa at surface and 0.6 mm below surface, respectively. All the generated residual stresses are compressive in nature. The similar trend is observed with tool penetration depth of 1, 1.5 and 2.0 mm but the magnitude of residual

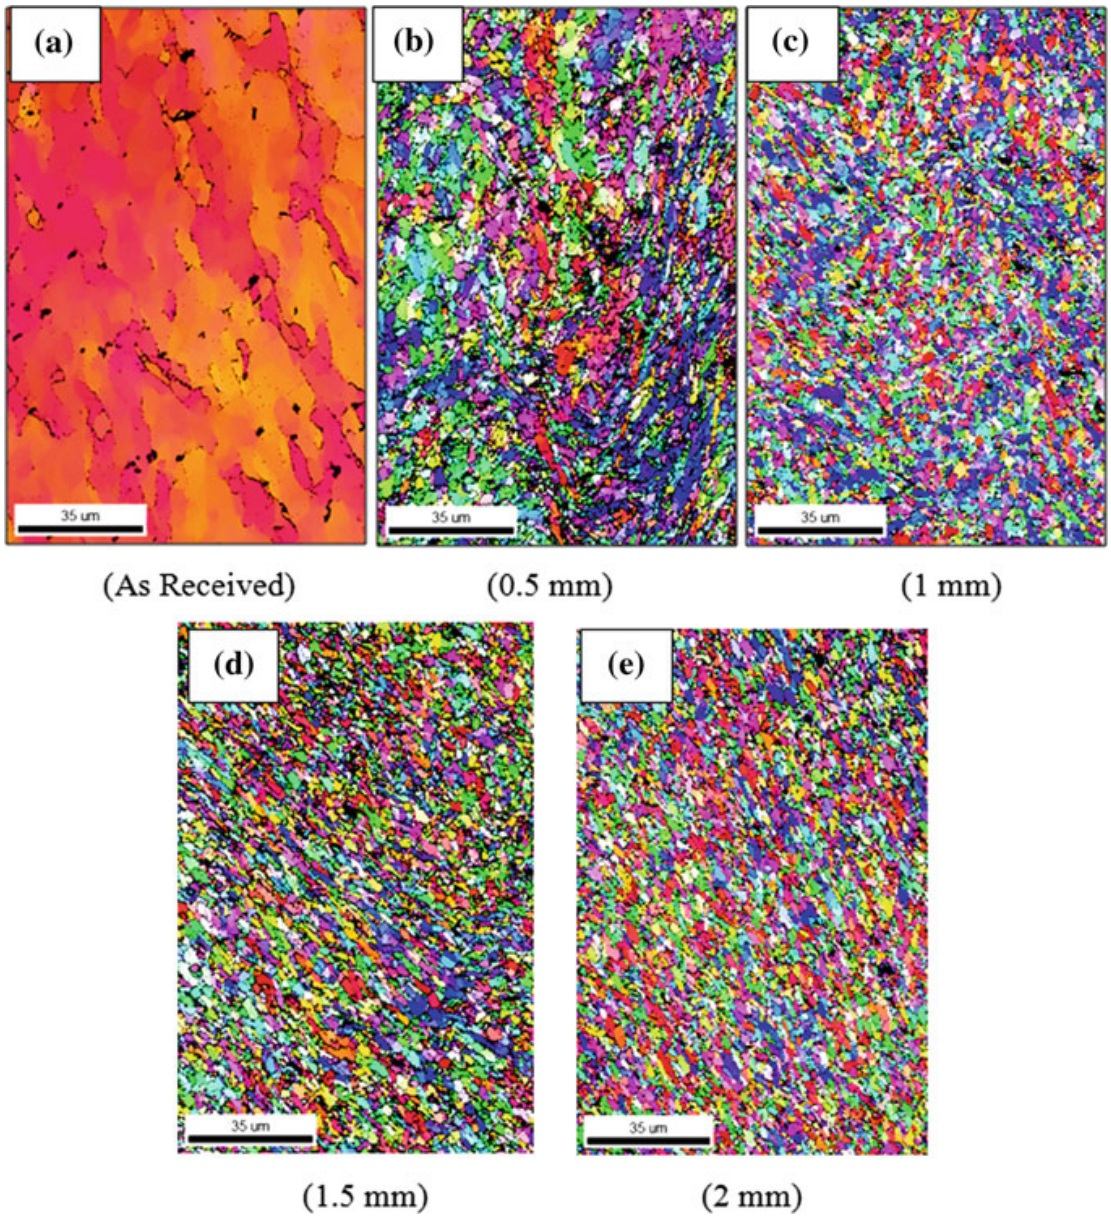

Fig. 9.7 EBSD scans after surface treatment by DCR

stresses is highest with higher depth of penetration by DCR. The values of residual stress on the surface of the material deformed is comparatively higher than the values generated over the subsurface, and the values of compressive residual stress is a function of depth of penetration by DCR, i.e. the stresses are higher on the surface and starts decreasing with increasing distance in depth. This could be attributed to the higher localized deformation at the surface directly under tool and lower concentration of deformation underneath the surface.

The results of residual stresses obtained by FE simulations are captured and plotted between longitudinal stress versus penetration depth for different tool depths of 0.5, 1.0, 1.5 and 2.0 mm and are shown in Fig. 9.9. It is clearly observed that the FE simulation results are in good agreement with the results obtained by

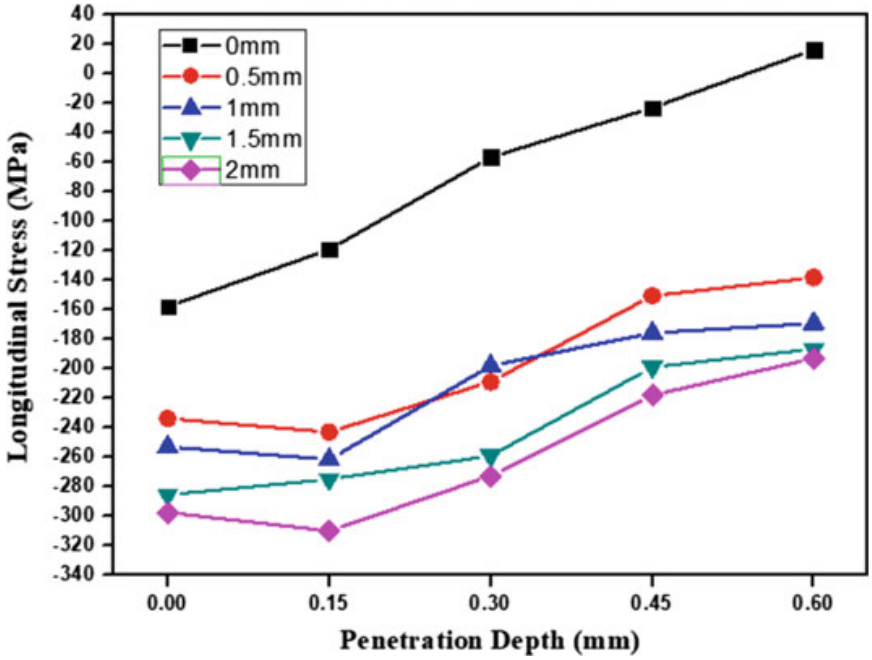

Fig. 9.8 Experimental results of residual stress versus penetration depth

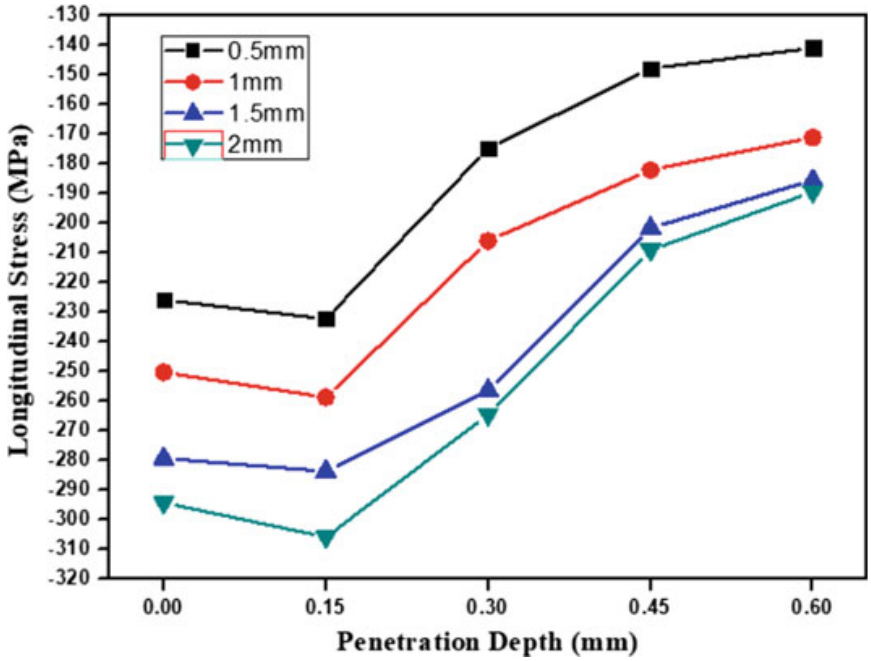

Fig. 9.9 FE simulation results of residual stress gradient in longitudinal direction (LD)

experiments. It is depicted from Table 9.2 that the percentage error in all cases between experimental and simulation for various DCR depth surfaces with their respective penetration depth are below 5%.

It is also observed that up to the depth of 0.15 mm, the values of residual stress increase and then reduce gradually with increasing distance beneath the surface.

Table 9.2 Chemical composition of AA6061 in wt%

DCR depth (mm)	% error				
	Penetration depth (mm)				
	0.00 (%)	0.15 (%)	0.30 (%)	0.45 (%)	0.60 (%)
0.50	3.29	4.36	4.98	1.72	2.10
1.00	1.02	1.03	4.04	3.70	1.20
1.50	2.13	3.20	1.00	1.46	0.48
2.00	1.07	1.29	2.93	3.99	1.76

This could be attributed to the higher plastic deformation resulting in higher dislocation density at a distance of 0.15 mm below the surface, and the material is getting plasticised between the tool and the material itself due to resistance to deformation from the strength offered by the material below the subsurface. A similar trend in the results of residual stresses is observed with different tool penetration depths by DCR of 0.5, 1.0, 1.5 and 2.0 mm. The contour of longitudinal residual stress obtained from simulations is shown in Fig. 9.10. It is found that the stresses on the surface of the specimens in the un-deformed region are tensile in nature whereas the stresses on the deformed region are compressive. This could be attributed to self-equilibrating nature of residual stress, i.e. the net sum of residual stress is zero.

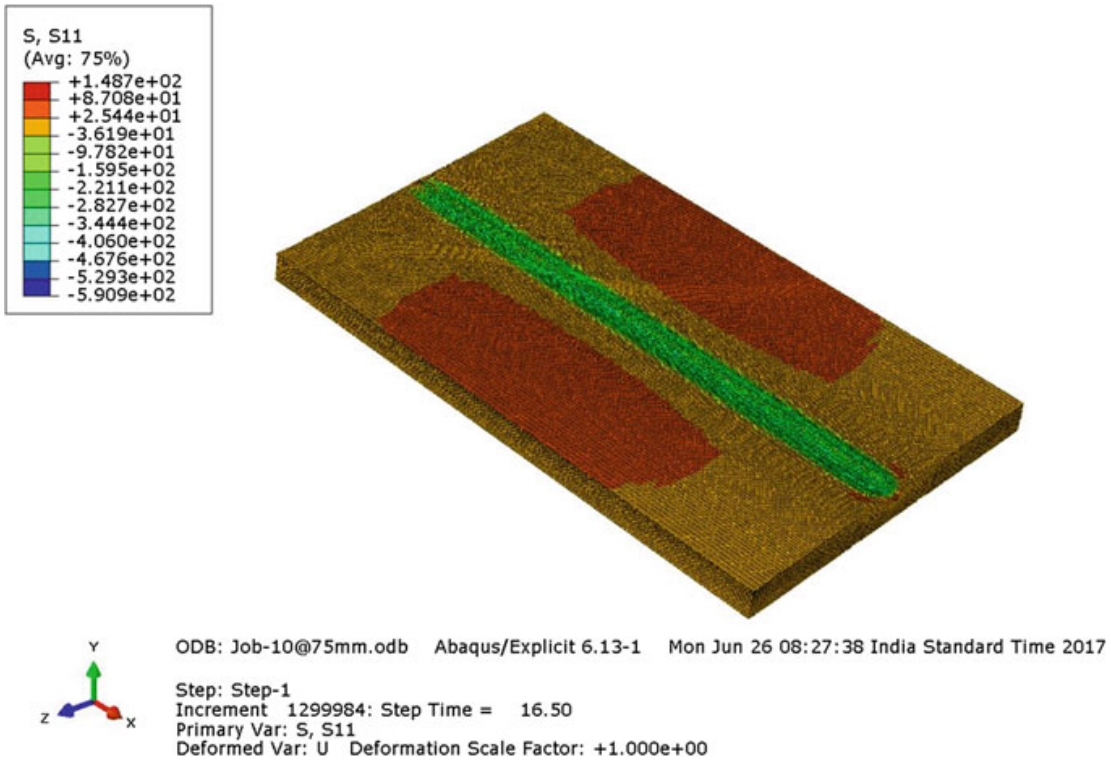

Fig. 9.10 FE simulation results of residual stress by DCR to 0.5 mm tool depth

9.4 Conclusions

Aluminium plate of AA6061 with 8 mm thickness is deep-rolled to different depths of 0.5, 1.0, 1.5 and 2.0 mm. On the basis of experimental work and FE simulations, the following conclusions can be drawn:

- The yield strength of aluminium alloy AA6061 in annealed state is 69 MPa and tensile strength is 132 MPa. The ductility of the alloy is excellent and found to be 42%.
- EBSD analysis revealed elongated grains in as-received parent material with a coarse grain size of 135.89 µm. The grain size with a deformation depth of 0.5 mm is 3.12 µm but the fine grains are segregated in a zigzag manner. A fairly homogeneous ultrafine-grained microstructure is revealed at a deformation depth of 1.0 mm and the grain size is 1.95 µm. A similar ultrafine homogeneous grain size and distribution are observed with penetration depth of 1.5 and 2.0 mm without any remarkable difference in the average grain size.
- The values of residual stress on the surface of the material deformed are comparatively higher than the values generated over the subsurface and is a function of depth of penetration by DCR, i.e. the stresses are higher on the surface and starts decreasing with increasing distance in depth. This could be attributed to the higher localized deformation at the surface directly under tool and lower concentration of deformation underneath the surface.
- The FE simulation results are in good agreement with the results obtained by experiments.

Chapter 10
Analysis of Hot Workability of Inconel Alloys Using Processing Maps

Gauri Mahalle, Nitin Kotkunde, Amit Kumar Gupta and Swadesh Kumar Singh

Abstract Understanding deformation behavior and workability is key prerequisite to optimize process parameters to improve the material processing conditions and confirming safe performance during forming. The deformation characteristics of Inconel 718 and 625 alloys have been investigated using hot tensile tests at temperature range (room temperature to 973 K) at interval of 100 K and at quasi-static strain rate of 0.0001, 0.001, and 0.01 s^{-1}. The experimental findings confirmed that tensile flow stresses are considerably subtle to strain deformation temperature and strain rate. From tensile flow stress behavior, processing maps have been developed using dynamic material model approach at different value of strains. It was observed that the temperature range ($T < 550$ K) for Inconel 718 and 600–900 K for Inconel 625 for lower strain rate (0.0001 s^{-1}) efficiency were maximum at different considered strain values. The optimum working parameters for both the alloys have been identified.

mechanical properties like high yield (700–1250 MPa) and ultimate tensile strengths (950–1650 MPa), good creep and rupture strengths, and high resistance to fatigue and corrosion at elevated temperature. This results in broad applicability in aerospace, nuclear, marine, and chemical industries [2, 3]. Because of constricted forming temperature assortment, more deformation resistance and intricate microstructures, extensive investigation of flow behavior at high temperature of Inconel alloy is very important [4, 5]. Moreover, Inconel alloys are difficult to machine to aimed shape due to extreme toughness, poor thermal conductivity, work hardening characteristics, and presence of hard abrasive carbide at elevated temperature [6].

Understanding deformation behavior is key necessity to optimize process parameters for improving the material processing conditions and confirming safe performance during various manufacturing process. Significant investigations attempted to improve constitutive expression to define complex deformation characteristics by strain, temperature, and strain-rate effects [7, 8]. Tan et al. [9] examined the deformation characteristics for Inconel 718 superalloy tested in hot compression experiments and fitted Arrhenius constitutive equation. Further, optimal processing parameters were determined. Cai et al. [10] stated that strain does not influence the processing map in the test temperature (1050–1180 °C) and developed the deformation equation to describe necessity of peak stress on tested temperature and strain rate. Zhang et al. [11, 12] observed the flow behavior, microstructure evolution, and dislocation behavior with processing maps of the Ni-based superalloy. Peak efficiency in the process of deformation is highly influenced by dislocation density in instability domain with low DRX. Authors investigated effect of the early aging time and microstructure on the processing map of precipitation-hardenable Ni-based superalloy [13, 14]. Though, no substantial effort has been reported in studied literature on the processing plots of Inconel alloys at warm temperatures and quasi-static range strain rates. This paper focuses on the processing map for Inconel alloys at warm temperatures and quasi-static strain rate.

10.2 Materials and Experimental Procedures

In present experimental work, Inconel 718 and 625 alloy sheets, of thickness 1 mm with nominal composition (wt%) as mentioned in Table 10.1, are used. Sub-sized *ASTM E08/E8M-11* standard dimensions are used as flat tensile test specimens, as shown in Fig. 10.1a. Normally, strain-rate scale of the static tension test, either with screw driven or hydraulic machine, is measured in the middle of 10^{-5} and 10^{-1} s^{-1} [15]. It is valuable for studying hot forming performed at lower strain rates as Inconel alloys are strain-rate sensitive [16]. Tensile tests are conducted on a UTM with maximum weight carrying capacity of 50 kN. Two-zone split furnace is having heating capacity up to 1500 K with ±3 K accuracy. Tensile experiments are accomplished from RT to 973 K intervals of 100 K and at 0.01, 0.001, and

Table 10.1 Chemical composition (wt%) of received Inconel 718 and 625 alloy sheet

Element	Ni	Fe	Mo	Cr	Nb	Al	Mn	Ti	Si	Others
For Inconel 718	51.463	20.44	2.871	18.279	5.012	0.561	0.062	1.092	0.051	0.169
For Inconel 625	61.495	3.304	9.479	21.739	3.271	0.067	0.123	0.166	0.101	0.104

0.0001 s^{-1} quasi-static strain rates. First, samples are heated at 20 °C/min to their deformation temperature and then heat preservation time is 10 min to achieve uniform temperature. The Experimental procedure for Quasi-static isothermal hot tensile tests is shown in Fig. 10.1b.

Figure 10.2a–d gives representative true stress–strain curves of alloys measured along rolling direction with different temperatures. Decrease in the flow stress and increased fracture strain show that flow stresses are significantly influenced by test temperature and strain rates. First, flow stress rises linearly to yield stress value for small strain values, due to effect of strain hardening. Noticeable observation from true stress–strain curve at lower strain rate is the serrated yielding phenomenon reported over the temperature range 673–973 K. The serration behavior is described by the Portevin-Le Chatelier effect specially, when homogeneous deformation occurs. The serration observed in Inconel alloys is combination of type A and B, the rise in strain rate and test temperature, according to Rodriguez classification of serrated flow [17]. Similar observations were reported previous studies [18, 19]. Differently, confirming the serrated yielding phenomena is by strain-rate sensitivity (m) parameter. The negative m value confirms claim of PLC or DSA effect in alloys.

10.3 Processing Map

Processing map is basically combination of the power dissipation efficiency plot and flow instability plot for various temperatures and strain rates. It shows occurrences of damage as a function of processing variable (temperature, strain and strain-rate sensitivity). Processing map is very useful for the selection of deformation processing conditions. Fracture boundaries in processing map are very sensitive to prior thermomechanical history, microstructure, composition of metal, and numerous material parameters (like diffusivity).

At constant temperature and strain, the test metal piece has been considered as energy dissipation system. Considering material as energy dissipation, total input power (P) is [20]

$$P = \sigma\dot{\varepsilon} = G + J = \int_0^{\dot{\varepsilon}} \sigma \, \mathrm{d}\dot{\varepsilon} + \int_0^{\sigma} \dot{\varepsilon} \, \mathrm{d}\sigma \tag{10.1}$$

where σ and $\dot{\varepsilon}$ are flow stress and strain rate. G content defines the heat dissipation during plastic deformation and J co-content defines internal energy variation because of the microstructural evolution. While in plastic deformation process, heat dissipated mostly by G content (due to temperature rise) and less amount by J co-content (due to microstructural evolution). Strain-rate sensitivity (m) from flow stress expression is used to determine the power distribution among G content and J co-content. For plastically deforming materials, power law can be represented as

$$\sigma = k(T, \varepsilon, \dot{\varepsilon})\dot{\varepsilon}^{m(T,\varepsilon,\dot{\epsilon})} \tag{10.2}$$

when strain and deformation temperature are considered as constants. The flow stress expression is given as [20, 21]

$$\sigma = k\dot{\varepsilon}^{m} \tag{10.3}$$

where K is strain hardening constant and m is the strain-rate sensitivity, calculated as [20, 21]

$$m = \frac{\partial J}{\partial \sigma} = \frac{\dot{\varepsilon}\mathrm{d}\sigma}{\sigma \mathrm{d}\dot{\varepsilon}} = \frac{\partial(\ln \sigma)}{\partial(\ln \dot{\varepsilon})} \tag{10.4}$$

Figure 10.3 plotted with ln σ and ln $\dot{\varepsilon}$ values for tested temperatures and fitted with polynomial quadratic fit. m values are determined from slope of these lines. This value varies from 0 to 1 (m = 0 represents no power dissipation, m = 1 represents ideal linear dissipator, and $m > 0$ represents material with positive strain-rate sensitive).

Diversions of m at 0.15 strain with respect to strain rate and deformation temperature are plotted in Fig. 10.4. From the figures, m value first drops and then rises as deformation temperature increases. It is because of microstructure evolution which needs more heat dissipation for particular test temperature. Even when m is

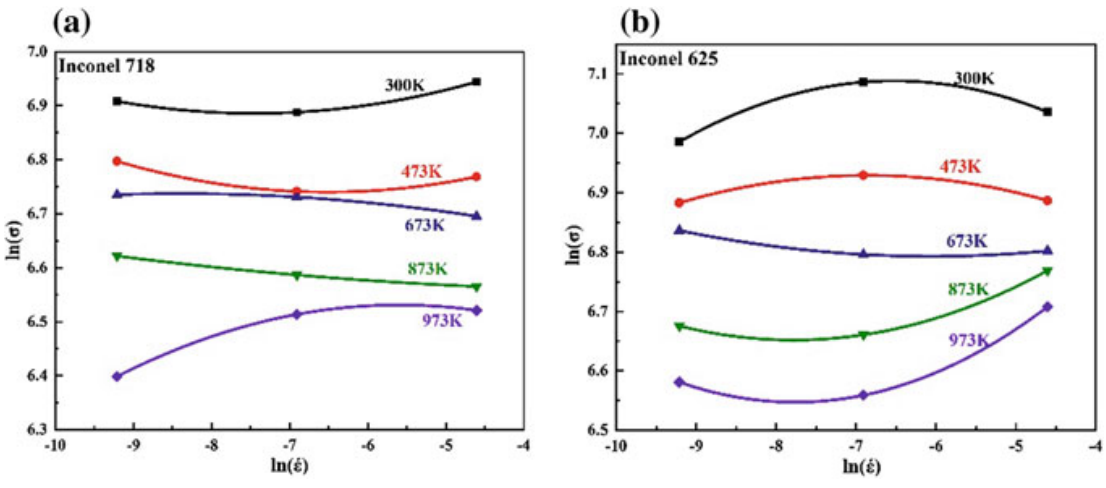

Fig. 10.3 Correlation between the flow stress and strain rate at 0.15 strain of Inconel alloys (**a**, **b**)

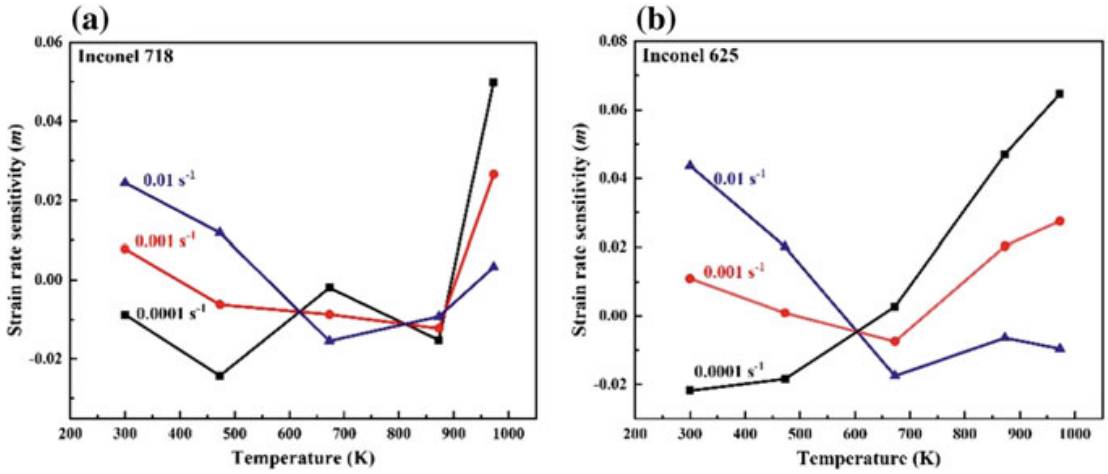

Fig. 10.4 Changes in strain-rate sensitivity (m) exponent at 0.15 strain with temperature for various strain rates of Inconel alloy (**a**, **b**)

negative or zero then also microstructural evolution can occur, this must be evaluated by joined analysis of both efficiency plot and instability plot.

Power dissipation map is one of the representations of the power dissipation efficiency (η) in the microstructural evolution. Dissipation efficiency (η) is expressed as

$$\eta = \frac{J}{J_{\max}} = \frac{2m}{m+1} \tag{10.5}$$

Here,

$$J = \int_0^{\sigma} \dot{\varepsilon} \mathrm{d}\sigma = \frac{m}{m+1}\sigma\dot{\varepsilon}$$
$$J_{\max} = \frac{\sigma\dot{\varepsilon}}{2} \tag{10.6}$$

and $J_{\max}$ represents the ideal linear dissipation (m = 1).

During deformation process, to identify the microstructural instability, number of flow instability criterion has to be reported by researchers [22, 23]. Most commonly used criteria for creation of the processing maps are Prasad instability criterion. Researchers have reported that Prasad instability criterion is more conventional to use than other [24, 25]. Therefore, Conventional Prasad's criterion is centered on maximum rate of entropy creation in the metallurgical system and considered to trace instable regions in processing map. It is represents as

$$\xi = \frac{\partial \ln[m/(m+1)]}{\partial \ln \dot{\varepsilon}} + m \tag{10.7}$$

here, ξ is the dimensionless instability parameter.

Instability plot is divided generally into two regions by instability parameter ξ: region with $\xi < 0$ considered as the instability domain, whereas $\xi > 0$ considered as the stable domain. Contour plot constructed to conclude difference of η at various strain rate and deformation temperature with a fixed strain value. Figure 10.5 signifies contour plot viewing changes of η value considered for Inconel alloys at different strain rate and deformation temperature at strain of 0.15. This plot is called as power dissipation plot. Contour value represents efficiency of the material's power dissipation. From this figure, it is noted that the η value rises with a drop in the strain rate at low test temperature as well as in high test temperature region. Highest for Inconel 718 alloy is 38%, which occurs at a temperature range of 300–480 K and lower stress rate (0.0001 s^{-1}). While the highest η around 35% for Inconel 625 alloy is occurring at 650–700 K temperature range also at lower strain rate of 0.0001 s^{-1}. Generally, except few unpredictable variations (such as unpredictable fracture), high power dissipation efficiency defines better workability of the material [24]. Hence, it is necessary to consider the other aspects (unreliable variations) while deciding the experimental processing conditions of material. The goal of microstructural optimization is not sufficient only on the basis of the highest efficiency [24, 25].

Figure 10.6 represents processing plots by superimposing efficiency plots on instability plots at 0.07, 0.15, and 0.20 strain. The shaded gray region represents the instability ($\xi < 0$). For Inconel 718 alloy, it is perceived that the instability takes place in lower temperature ($T > 600$ K) for strain rates of 0.0001 s^{-1}. This indicates that Inconel 718 alloy possess very poor workability in this range of temperature and strain rates. Whereas for Inconel 625 alloy, instability occurs in high temperature ($T > 700$ K) for all stain rates. The reason for the stability of Inconel 718 alloy is might be due to the formation of precipitate at test temperature which strengthen the alloy. For both the alloys, higher η values are detected in lower strain rates (0.0001 s^{-1}) region. Further, it can be detected that the influence of strain on unstable region is considerable. The total area of the unstable region increases with increase in strain as almost instability is noticed in high strain rate and low-temperature regions. The highest efficiency in the stable region for 0.15 and

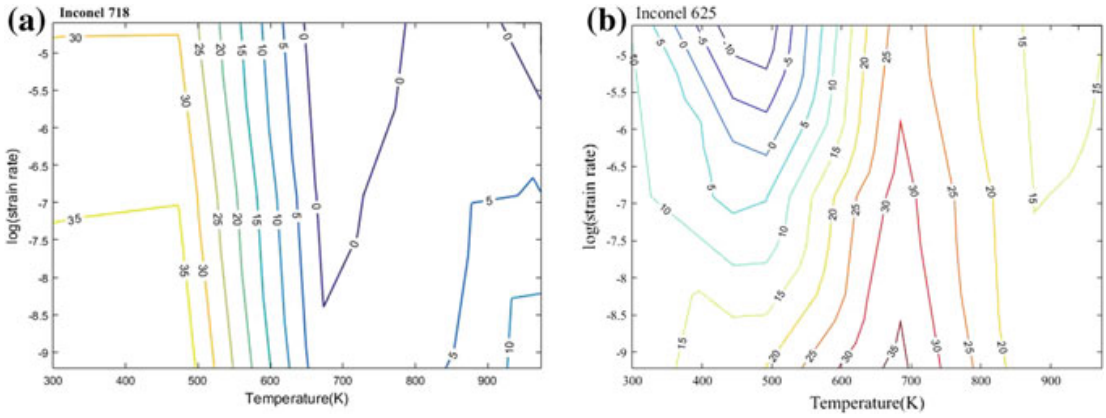

Fig. 10.5 Power dissipation efficiency plot for Inconel alloys (**a**, **b**) at 0.15 strain

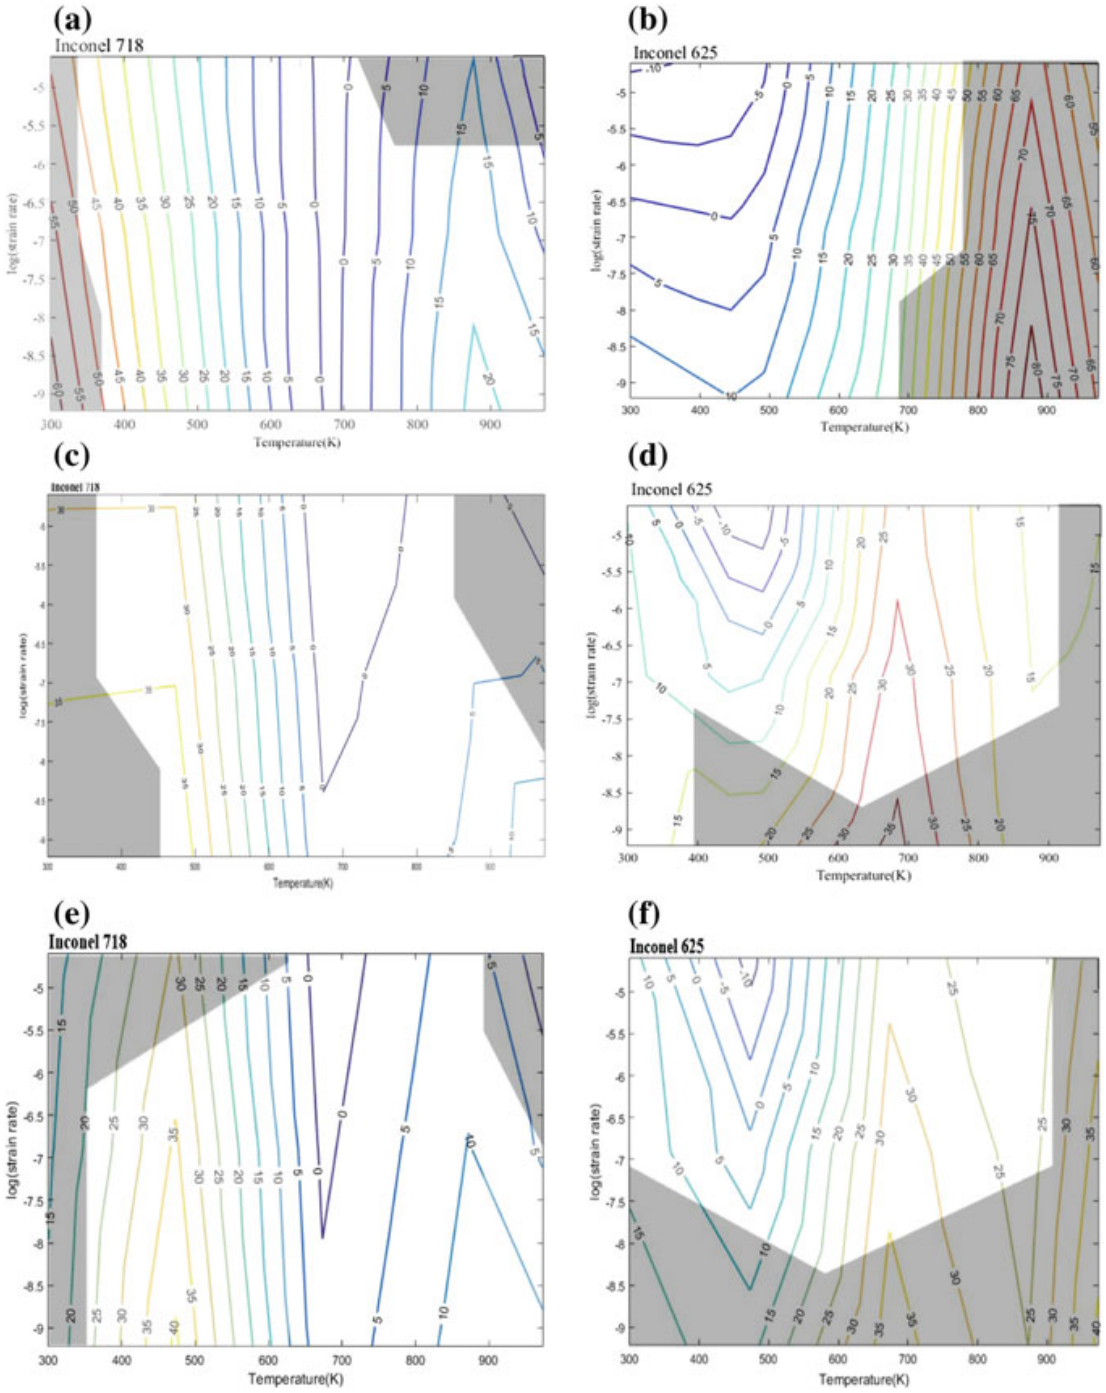

Fig. 10.6 Processing plots for Inconel alloys at **a**, **b** 0.07, **c**, **d** 0.15, and **c** 0.20 strain

0.20 strains is 35 and 38–40%, which is lower than the efficiency at 0.06 strain, i.e. 80 and 60% for Inconel 625 alloy and 718 alloy, respectively. Based on considerations, for the processing of Inconel alloys, 0.06 strain was selected as the optimal parameter condition.

10.4 Conclusions

This study involves workability analysis of Inconel alloy, namely 625 and 718, by processing plots for temperature range of 300–973 K at the strain rates of 0.01, 0.001, and 0.0001 s^{-1}. Following conclusions can be made from the analysis:

- The flow stress and strain hardening behaviors are considerably affected by strain rates and test temperatures in Inconel alloys. The reduction in yield strength observed approx. 31% (From 499.7 to 343.58 MPa) and ultimate strength by approx. 19.8% (from 951.14 to 762.14 MPa), happens with improvement in % elongation from 41.8 to 51.6% from RT to 973 K.
- Processing plots have been established for Inconel alloys at 0.06, 0.15, and 0.20 strains. It is noticed that temperature range ($T < 550$ K) for Inconel 718 and 600–900 K for Inconel 625 for lower strain rate (0.0001 s^{-1}) efficiency were maximum at different considered strain values. Therefore, this condition is considered as optimal parameter processing for the deformation process for Inconel alloys. Further, influence of strain on the instable region is noticed.

Future work includes integration of these established processing plots in finite element analysis of deformation processes of Inconel alloy.

Chapter 11
Investigation on Metallographic Analysis of Electron Beam Ti6Al4V Alloy Welds

Sohini Chowdhury, Yadaiah Nirsanametla and Manapuram Muralidhar

Abstract Electron beam weld quality is evaluated by careful selection of weld parameters and by control of the temporal distribution of electron beam on surface of work piece. Moreover, the integral effect of the electron beam current and weld velocity on weld joint is significant during electron beam welding (EBW) process. In the present work, bead-on-plate EBW of Ti6Al4V alloy plates of 5 mm thickness is carried out to examine the influences of various process parameters with respect to microstructure evolution and weld bead shapes and dimensions. Also, a relationship among input thermal energy, macro- and microstructural characteristics of electron beam Ti6Al4V alloy weldments is established. The experiments were carried out with beam current ranging from 15 to 30 mA and welding velocity from 1200 to 1400 mm min^{-1}. Moreover, a constant focus current and accelerating voltage of 2030 mA and 60 kV are considered. Furthermore, welding modes such as melt-in and keyhole modes are examined with respect to the linear energy and welding process efficiency along with microstructure evolution. In addition, the magnitude of temperature in the heat-affected zone of electron beam welded Ti6Al4V alloy samples is determined using Rosenthal's analytical model at distinct weld regimes. Furthermore, Marangoni and Fourier numbers are employed to investigate weld pool characteristics at distinct weld regimes. Based upon the results, it is observed that electron beam power has a significant influence on weldment profile and penetration level while the welding speed has a noteworthy impact on the solidified structure of fusion zone. Also, three weld regimes were identified under the specified welding conditions. Keyhole mode welding is achieved for linear energy above 77 J mm^{-1}, and melt-in mode welding is attained when linear energy is below 45 J mm^{-1}. Moreover, transition mode welding is identified when the linear energy is in between 56.57 and 75 J mm^{-1}. Furthermore, the efficiency of welding process was assessed by relating electron beam power with fusion zone area. It was recognised that a higher linear energy promoted a higher process efficiency comparative to a lower linear energy. A lower linear

11.1 Introduction

The necessity for lightweight materials has substantially escalated in the fabrication industries on account of critical service aspects. Specifically, titanium alloys are currently implemented in all ranges of applications such as automotive, aerospace and nuclear applications. However, the extensive employment of titanium alloys in critical manufacturing domain can be attributed to excellent properties at high temperature, superior fatigue behaviour, corrosion resistance features and high specific strength [1–3]. In addition, the usage of titanium alloys has now been extended to bio-medical devices because of high bio-compatibility property [4]. α-β two-phase Ti6Al4V alloy is the most commonly used titanium-based alloys and is widely implemented in major domain of manufacturing sector. Earlier, several researchers attempted to join titanium assemblies with numerous joining techniques including fusion welding and solid state joining [5–10]. However, an elemental issue of joining titanium and its alloys is its reaction with atmospheric gases at an elevated temperature which results into embrittlement in the welded specimen [11]. Therefore, the EBW process is the most desirable welding technique to join titanium metal assemblies as it provides a controlled atmosphere to operate. Moreover, EBW offers production of wide span of complicated weld geometries along with an enhanced quality level, flexibility and processing capability. Besides, high energy density electron beam produces welds with minimum heat-affected zone (HAZ) and deep penetration which accounts for low level of distortion in weldments. However, the deep penetration mechanism is associated with vapour cavity formation also referred to as keyhole which is enclosed by high-temperature molten weld pool.

Although, the output of welding operation is prominently established upon keyhole characteristics whose integrity is governed by an equilibrium between recoil pressure in the vapour cavity and surface tension of the weld pool. Hence, weld penetration and weld defects are directly related to keyhole stability that implies; if keyhole collapses, a lower penetration is attained. Besides, weld defects in the form of porosities, spiking defects and several others are generated due to keyhole instability and fluctuations. Moreover, several experimental efforts also provided a qualitative understanding of keyhole dynamics as a function of time [12–14]. Also, the keyhole stability is based on optimisation of weld parameters. Akman et al. demonstrated that control of laser output parameters can efficiently control weld penetration and weld bead width in laser welding process

[15]. Squillace et al. [16] reported that the under fill defects in Ti6Al4V alloy laser welds depends on a definite heat input. The authors also determined that the under fill defect is maximum in keyhole mode welds as compared to conduction mode welds. Li et al. studied the influence of electron beam weld parameters on weld profile and weld distortion of titanium-based Ti2AlNb alloy plates [17]. Liu et al. conducted experiments to determine the welding stresses induced after electron beam welding and milling operations from a thick titanium metal plate of 50 mm thickness [18]. Also, Junaid et al. studied the effect of beam parameters on titanium-based Ti5Al2.5Sn alloy sheets with respect to weld bead width and mechanical characteristics. However, from the esteemed reports, it is recognised that EBW of Ti6Al4V alloy is limited. Thus, a comprehensive analysis of EBW of Ti6Al4V alloy can lay a good contribution to the prevailing approaches.

In this work, electron beam welding experiments were performed on 5 mm thick Ti6Al4V alloy plates and weld seams are evaluated in terms of weld geometry and microstructure. The aim of the present work is to establish a relationship between input thermal energy, weld morphology and microstructural characteristics for electron beam welded Ti6Al4V alloy at distinct weld regimes. Moreover, different weld regimes are characterised for Ti6Al4V alloy samples under different welding conditions corresponding to Marangoni number and Fourier numbers. Also, the temperature distribution in HAZ of Ti6Al4V alloy is determined by employing Rosenthal's analytical model.

11.2 Experimental Investigation

In the present work, Ti6Al4V alloy in annealing condition is considered for experimental investigation. The electron beam bead-on-plate welds were conducted on 5 mm thick Ti6Al4V alloy, and the plate dimension (length × width) is 100 mm 50 mm. Prior to welding operations, all the sample surfaces were properly cleaned with acetone and clamped carefully by fixtures to prevent distortion during welding operation. However, to ensure high thermal transfer rate during joining process, the backing plate in fixture is assembled with copper material.

The weld tests were carried out for a suitable combination of weld speed and electron beam power where a stable weld seam is acquired. The different welding conditions that were adapted during EBW of Ti6Al4V alloy are listed in Table 11.1. The experiments were conducted by varying weld speed and electron beam current at fixed accelerating voltage and focusing condition. The accelerating voltage level was maintained constant at 60 kV for all the samples, while the beam current was varied between 15 and 30 mA and weld speed was ranged between 1200 and 1400 mm/min. Furthermore, for evaluation of weld properties, the metallographic examination was conducted. The specimens were sectioned at middle segment across the weld length, grounded and chemically etched with Keller's reagent solution. Thereafter, the weld cross sections and microstructure of the polished weld specimen were acquired with optical microscope.

Table 11.1 Electron beam welding conditions of Ti6Al4V alloy

Weld sample	Accelerating voltage (kV)	Beam current (mA)	Focus current (mA)	Weld speed (mm/min)
1	60	15	2030	1400
2	60	15	2030	1200
3	60	22	2030	1400
4	60	22	2030	1200
5	60	25	2030	1400
6	60	25	2030	1200
7	60	30	2030	1400
8	60	30	2030	1200

To characterise the weld geometry and distinguish weld regimes of Ti6Al4V alloy weldment, linear energy is considered. The linear energy (L_e) which is the ratio of power transferred to the weld speed is represented as

$$L_E = VI/u \tag{11.1}$$

where V, I and u indicate accelerating voltage (kV), electron beam current (mA) and weld speed (mm/s), respectively. Moreover, the process efficiency is quantified by fundamental welding process efficiency (W_E) parameter which correlates the transmitted beam power with fusion zone area. It takes into account the energy required for creating the joining or welding phenomena in the material. Hence, the parameter is represented as

$$W_E = A/L_e \tag{11.2}$$

where A indicates area of the fusion zone (mm^2).

In order to demonstrate thermal and fluid flow characteristics of Ti6Al4V alloy welds, Marangoni number and Fourier numbers are employed. Marangoni number is represented as a ratio of surface tension force to viscous force, and it is mathematically represented as

$$M_a = \frac{d\gamma}{dT} \times \frac{w\Delta T}{\mu\alpha} \tag{11.3}$$

Fourier numbers is defined as a ratio of thermal transmission rate to thermal storage rate and mathematically given as

$$F_o = \frac{\alpha}{ul} \tag{11.4}$$

where $d\gamma/dT$, w, μ, α, ΔT represent surface tension gradient (N m^{-1} K^{-1}), width of molten pool (mm), viscosity (kg m^{-1} s^{-1}), thermal diffusivity (m^2 s^{-1}), temperature gradient (K).

11.3 Results and Discussion

In this section, the macro- and microstructural characteristics of Ti6Al4V alloy weld joint are characterised for a wide range of linear energy varying from 38.57 to 90 J mm^{-1}. The estimation of temperature is also carried out using Rosenthal's analytical model. Moreover, weld pool behaviour is identified by Fourier numbers and Marangoni number at distinct weld regimes.

The effect of process variables such as beam current and welding speed on weld morphology and microstructural characteristics is examined. Figure 11.1 demonstrates the appearance of bead-on-plate Ti6Al4V alloy weld joint corresponding to weld sample #1 at 38.57 J/mm linear energy. It is observed that a smooth, bright, clean weld bead is formed with no oxide formation which indicates the effectiveness of electron beam welding process.

Moreover, the seam morphology of Ti6Al4V alloy weldments corresponding to weld sample #2 and #8 at a constant welding velocity of 1200 mm min^{-1} is presented in Fig. 11.2. Different weld profiles and weld regimes are identified under different linear energy values. The macrograph displays an elliptical profile at linear energy of 45 J/mm (Fig. 11.2a) while a nail head profile (Fig. 11.2b) is attained at linear energy of 90 J/mm. The transition from an elliptical profile to nail head profile is attributed to an increase in linear energy which increases the weld

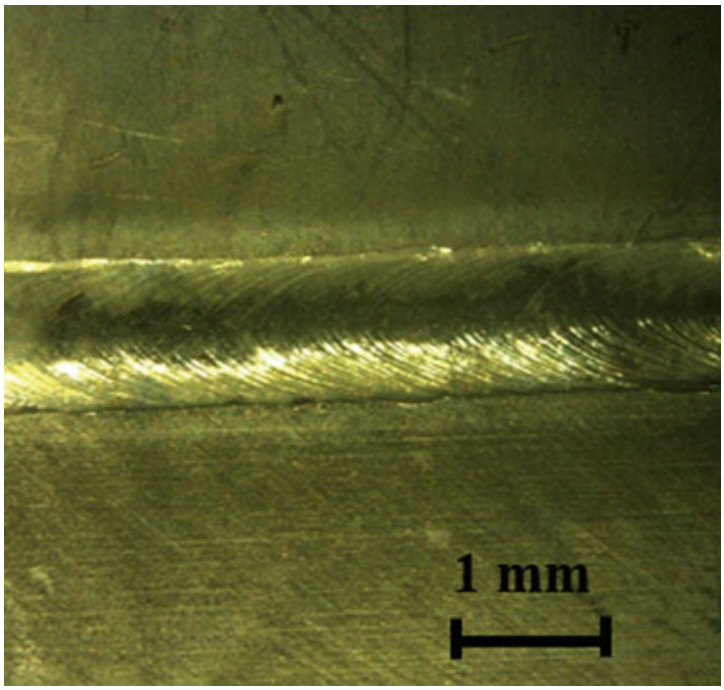

Fig. 11.1 Appearance of the weld surface at linear energy 38.57 J/mm

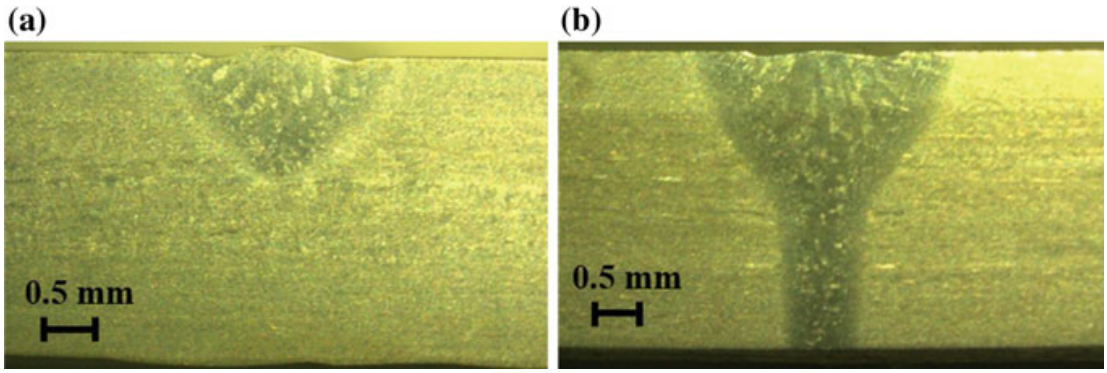

Fig. 11.2 Cross section of weld samples **a** #2 and **b** #8 at constant weld speed of 1200 mm/min

penetration considerably. Also, the cross-sectional macrograph of Ti6Al4V alloy weldments displays a conduction mode welding (Fig. 11.2a) at 45 J/mm and a keyhole mode welding (Fig. 11.2b) at 90 J/mm. This indicates that conduction mode welding is attained for linear energy values at or below 45 J/mm, and keyhole mode welding is attained for linear energy values at or above 77 J/mm. In addition, transition mode welds are also observed between linear energy values of 56.57 and 75 J/mm. Besides, full penetration welds are desirable in most applications due to high joint strength acquired. Moreover, the macrograph reveals no major weld defects such as porosity and spiking defects.

Table 11.2 depicts fusion zone area, linear energy and welding process efficiency values of weld samples. Weld sample 2 reveals a higher welding efficiency than weld sample 1. This is probably due to the fact that the energy spent in the form of heat conduction loss and overheating is higher than energy spent to increase fusion zone area of weld sample 1. Conversely, for weld sample 1, more energy is spent on increase in fusion zone area than thermal losses. Therefore, it can be concluded that lower weld speed or higher linear energy promotes higher process efficiency than higher weld speed or lower linear energy at a constant electron beam power. Figure 11.3 illustrates the cross-sectional macrographs of weld samples under varying linear energy conditions. Figure 11.3a, b corresponds to weld sample

Table 11.2 Efficiency parameters of electron beam welded Ti6Al4V alloy

Weld sample	Weld area (mm^2)	Linear energy ($J\ mm^{-1}$)	Welding process efficiency ($mm^3\ J^{-1}$)
1	3.53	38.57	0.078
2	5.972	45	0.154
3	8.58	56.57	0.135
4	9.43	66	0.166
5	10.422	64.28	0.138
6	11.2	75.75	0.174
7	12.541	77.14	0.139
8	14.25	90	0.184

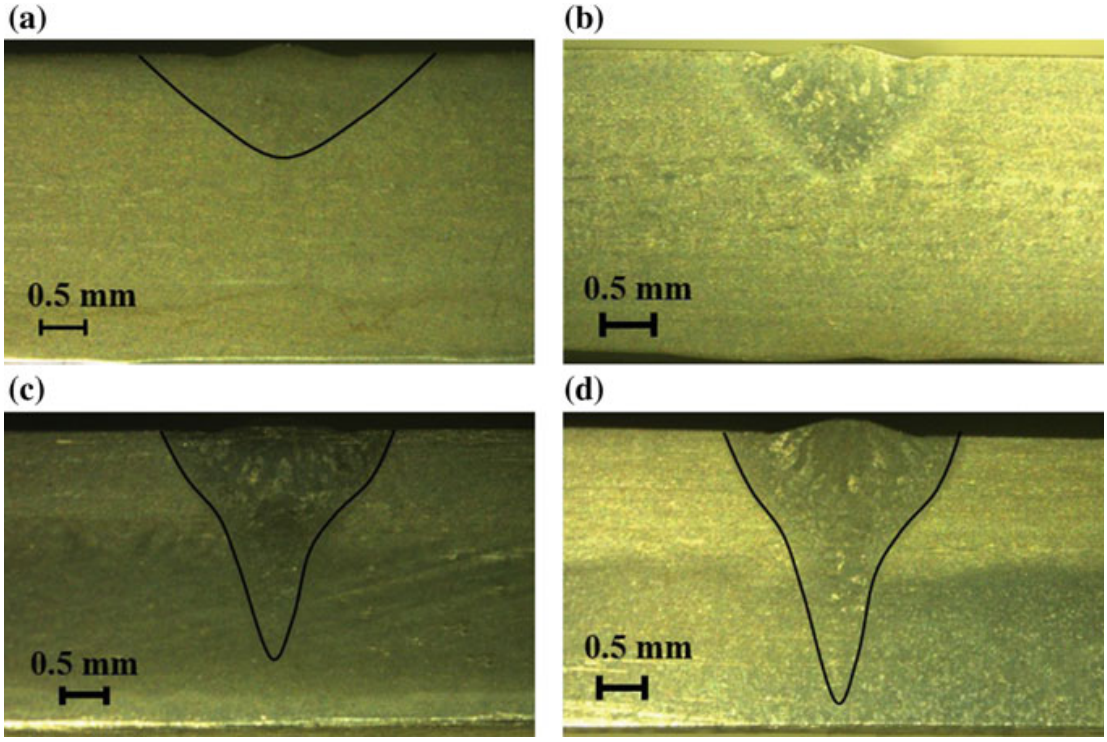

Fig. 11.3 Cross-sectional macrographs of weld samples corresponding to linear energy, **a** 38.57 J mm^{-1}, **b** 45 J mm^{-1}, **c** 75.75 J mm^{-1} and **d** 64.28 J mm^{-1}

1 and 2, respectively, which refers to a decrease in weld speed from 1400 to 1200 mm/min at constant beam current of 15 mA. Similarly, Fig. 11.3c, d corresponds to weld sample 5 and 6, respectively, which refers to a decrease in weld speed from 1400 to 1200 mm/min at a constant beam current of 25 mA. The reduction in weld penetration and an increase in weld width are identified at higher weld speed. Moreover, with an increase in beam current, penetration level in weldment is increased remarkably.

The heat transfer mode and material flow characteristics in the molten metal during welding operation determine the weld joint quality. Moreover, the prediction of temperature using experimental methods is critical during the welding process since molten weld pool width is quite small and there is a possibility of plasma formation. Hence, an analytical model is employed in the present work for estimation of the temperature field in the HAZ analytically. Also, with the purpose of addressing the issue of heat transfer mode in electron beam weldments, Marangoni number [19] and Fourier numbers [20] are employed.

In the present work, Rosenthal's analytical model is employed, since it takes into account the integral effect of processing parameters and thermal properties of Ti6Al4V alloy for prediction of temperature analytically [21, 22]. The positions for estimation of peak temperature in transverse direction of welding line are shown in Fig. 11.4a. The estimated temperature values corresponding to welding conditions are given in Table 11.1 and presented in Fig. 11.4b. It can be identified that the magnitude of temperature in HAZ of weld plates is much lower than liquidus

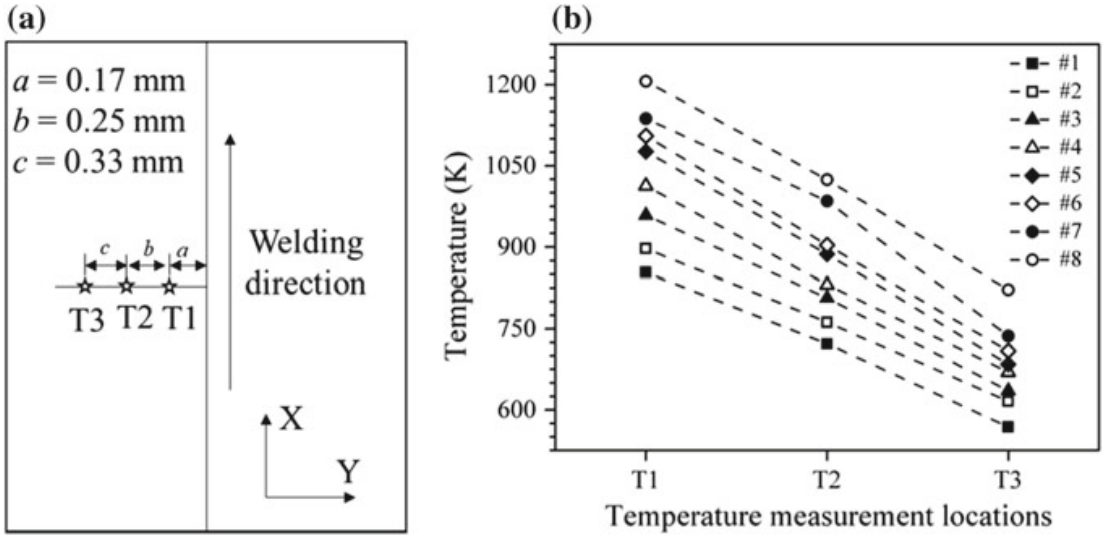

Fig. 11.4 **a** Temperature measurement locations along the welding line and **b** estimated temperature values corresponding to processing conditions of Table 11.2

temperature. Also, temperature at location '*T*1' is determined to be higher than '*T*2' and '*T*3' locations. Since '*T*1' corresponds to a location near FZ while, '*T*2' and '*T*3' correspond to the locations away from the melt zone. Moreover, it is determined that conduction weld (#2) exhibited a lower temperature value when compared with keyhole weld (#7). Furthermore, it is determined that the percentage difference in magnitude of temperature at '*T*1' location for conduction and keyhole mode is 26.0.

Figure 11.5 presents the variation of Marangoni number (Ma) and Fourier numbers as a function of linear energy corresponding to electron beam Ti6Al4V alloy welds. It is observed that *Ma* and *Fo* increases and reduces linearly with increases in magnitude of linear energy, respectively. Moreover, three distinct weld regimes are separated with respect to *Ma* and *Fo* values. Fundamentally, higher *Ma* value indicates higher molten metal velocity at the surface and convective heat

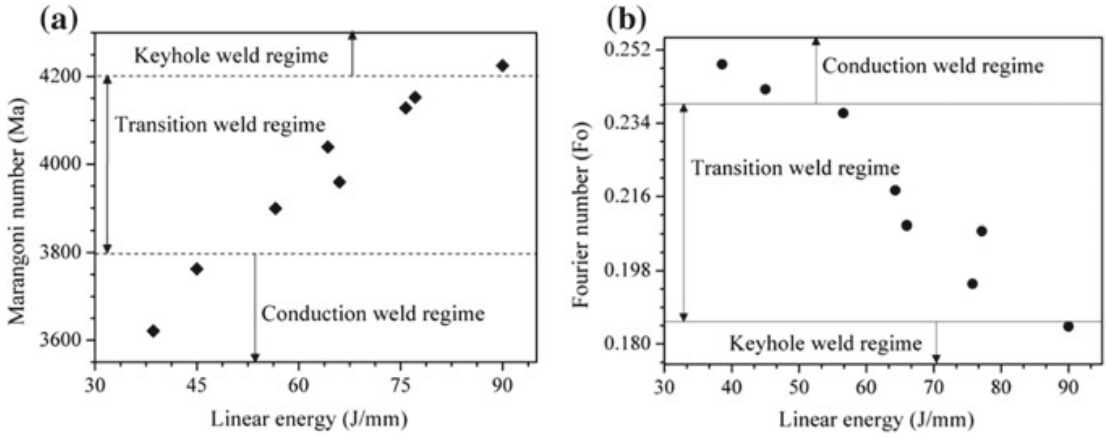

Fig. 11.5 Influence of linear energy on **a** Marangoni number and **b** Fourier number

transmission in the weld pool dictates the process. From Fig. 11.5a, it can be observed that the conduction weld regime exhibits lower Marangoni number when compared with transition and keyhole weld regime. This reflects that conduction welds are subjected to low molten metal velocity at the surface and produces a more stable weld bead with lower aspect ratio. The Fourier numbers is associated with solidification rate of crystals at the FZ which eventually accounts for thermo-mechanical damage in the material. Higher Fourier numbers is always preferable in weldments, since it indicates lower thermal storage rate and lower characteristics length of the molten pool on account of high solidification rate. From Fig. 11.5b, it is observed that conduction weld regime exhibited higher Fourier numbers than transition and keyhole welds. Thus, conduction welds are subjected to high solidification rate and low thermo-mechanical damage relative to transition and keyhole welds.

The microstructure of parent metal of Ti6Al4V alloy primarily consists of body-centred cubic (BCC) β phase distributed in an area of hexagonal close-packed α phases. However, during welding operation, due to rapid heating and cooling process, transformation from α to β phase and decomposition of β to α phase occurs at the fusion zone, respectively, in a short duration of time. This entire heating and cooling operation depends on heating and cooling rate of Ti6Al4V alloy. In case cooling rate is greater than critical cooling rate of Ti6Al4V alloy (around 623 K/s), then microstructure evolution from β to α^1 martensite structure is promoted in the weld zone. Similarly, at lower cooling rate, secondary lamella growth is promoted due to diffusion-controlled nucleation [23]. However, β phases can be traced out in the fusion zone irrespective of cooling rate of Ti6Al4V alloy weldments. The microstructure of fusion zone region of weld samples #1 (Fig. 11.6a) and #8 (Fig. 11.7a) displays similar microstructure at the weld zone comprising of

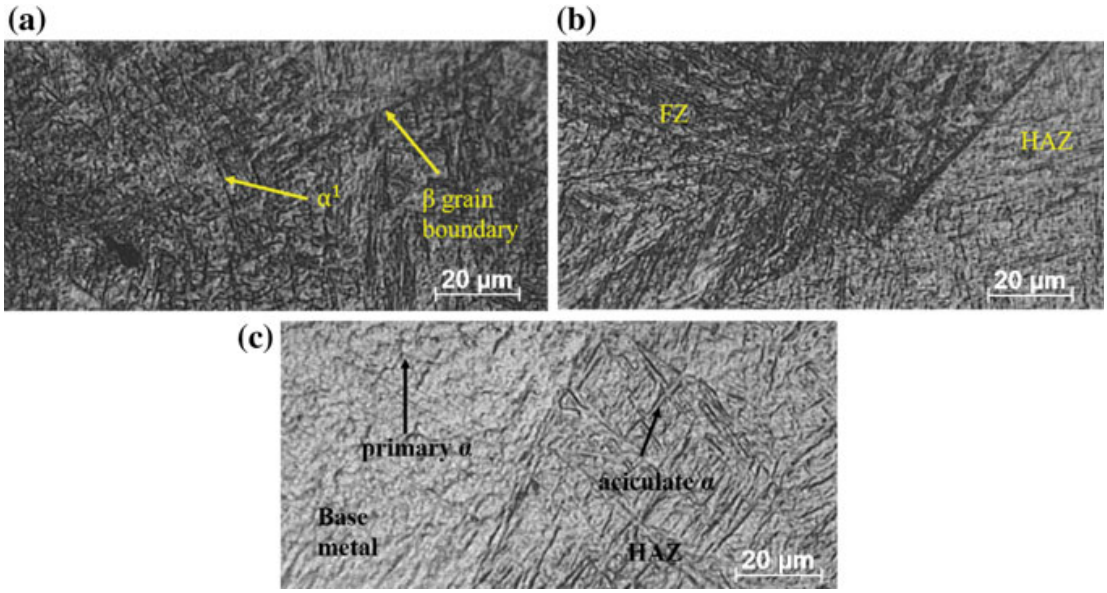

Fig. 11.6 Illustartion of microstructure at different zones for Ti6Al4V alloy weldment at 38.57 J/mm

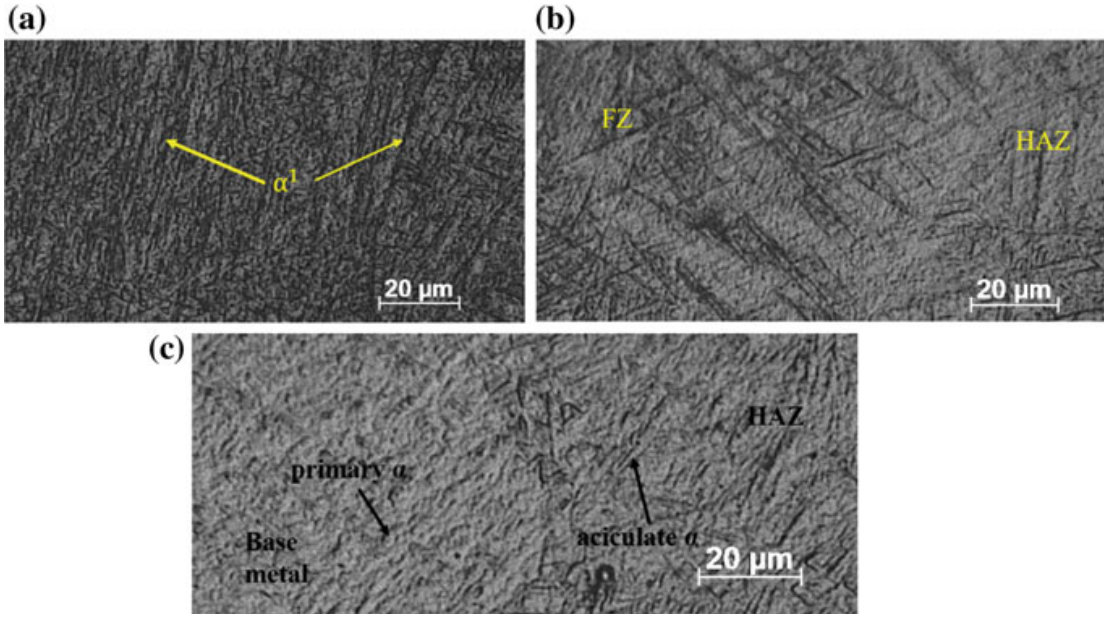

Fig. 11.7 Illustartion of microstructure at different zones for Ti6Al4V alloy weldment at 90 J/mm

martensitic α^1 solidified structure within the β grains. The solidified microstructure α^1 is evolved when β phase is quenched above beta transus temperature at a cooling rate above the critical cooling rate of Ti6Al4V alloy [24]. Moreover, the length and distribution of martensitic structures in the FZ vary in accordance with the solidification rate. It has been determined that the size of α^1 grains is higher in keyhole weld regime relative to the conduction weld regime. However, the percentage content of martensitic structure reduces with increase in linear energy. Therefore, it can be inferred that the fusion zone of weld samples #1 and #8 does not differ much by cooling rate. Although, the amount, distribution and size of acicular α^1 solidified structure at each weld zone differ comparatively corresponding to weld speed. Also, the cooling rate of Ti6Al4V alloy weldment is comparatively enhanced due to implementation of copper as backing plate in fixture [25].

Figures 11.6c and 11.7c display the different weld zones of Ti6Al4V alloy corresponding to weld samples #1 and #8 at 1400 mm/min and 1200 mm/min weld speed, respectively. The heat-affected zone (HAZ) displays a much more complex microstructure as it consists of primary α grains, martensitic α^1 and β grains. Moreover, due to temperature gradient in the Ti6Al4V alloy specimen, the microstructure in the HAZ varied from a rich α^1 (near fusion zone) to a poor α^1 (far from fusion zone) [26]. However, the microstructure in distinct weld zones is directly proportional to the linear energy. A higher linear energy leads to lower cooling rate which induces diffusion-controlled phase transformation. Conversely, a lower linear energy promotes a rich domain of acicular α^1 solidified structure in the fusion zone.

11.4 Conclusion

This paper has presented detailed experimental results of electron beam welding process of 5 mm thick Ti6Al4V alloy specimen. Based on the present investigation, the following conclusions are derived.

- The linear energy which is expressed as power transmitted to weld speed is an influential parameter to determine weld profiles and weld regimes of Ti6Al4V alloy specimen.
- A lower weld speed promotes higher process efficiency than higher weld speed.
- The temperature distribution in HAZ of Ti6Al4V alloy weldments is lower in conduction weld regime than keyhole weld regime.
- The fusion zone of electron beam Ti6Al4V alloy weldments primarily consists of martensitic α^1 structures with small amount of β grains.
- The distribution, amount and size of martensitic α^1 and β grains are influenced by heat input and cooling rate.
- Also, a higher linear energy leads to lower cooling rate which induces diffusion-controlled phase transformation.
- The conduction weld regime exhibited lower martensitic size than keyhole weld regime. However, the density of martensitic structures in the FZ is determined to be more in the conduction weld regime.
- The magnitude of *Ma* number is determined to be lower in conduction weld regime. However, *Fo* number value is relatively higher in conduction weld regime than keyhole weld regime.

Chapter 12
Multi-objective Optimization of FSW Process Variables of Aluminium Matrix Composites Using Taguchi-Based Grey Relational Analysis

Subramanya R. B. Prabhu, Arun Kumar Shettigar, Mervin A. Herbert and Shrikantha S. Rao

Abstract Successful joining of aluminium alloys using friction stir welding (FSW) opens a new window research in extending this technique to join aluminium matrix composites (AMCs). Current research is focused on optimization of process variables for multiple responses simultaneously. Experiments were performed using tool pin profile, rotational speed (RS) and welding speed (WS) as ideal process variables for multi-objective optimization in FSW of AMCs. Tensile strength, macro-hardness and elongation are considered as multi-response behaviour. Grey relational grade for the chosen multiple responses are obtained using grey analysis. Analysis of variance was utilized to understand the influence of process variables on the grey relational grade. Analysis reveals that RS and WS were the most influencing process variables on the output responses. Confirmation experiments were performed at optimized process variables to validate the present study. Predicted values were in good agreement with the experimental results.

12.1 Introduction

FSW is a novel technique invented by The Welding Institute (TWI, UK) in 1991 to join difficult to weld materials like aluminium and its alloys [1]. FSW is a solid-state welding process where materials are joined by plasticizing and forging action rather than melting and recasting [2]. FSW offers several benefits over conventional fusion welding process. A non-consuming rotating tool alters the material flow and creates a defect-free weld during FSW. The nature of material flow is affected by the tool pin profile as well as process variables [3]. Cavaliere et al. [4] performed FSW of AA6082 alloys and studied the effect of process variables on microstructure and mechanical properties. Rajakumar et al. [5] analysed the influence of process variables such as rotational speed (RS), welding speed (WS), axial load, tool pin profiles and hardness of tool on the mechanical properties of FS-welded AA 7075 alloy. Malopheyev et al. [6] worked on optimization of FSW of 6061-T6 aluminium alloy processing variables and stated that increasing the welding speed hindered precipitation coarsening which improved after ageing. Literature study reveals that most of the study focused on the influence of tool profile and process variables on microstructure and tensile properties. Studies indicate that the quality of the weld mainly depends on various process variables such as shoulder diameter, axial load, RS and WS. To predict the mechanical properties of FS-welded AA 6061, Elangovan et al. [7] created a mathematical model by utilizing process variables like WS, RS, tool geometry and axial load. Murugan and Ashok Kumar [8] also developed similar model to predict tensile strength of friction stir welded stir cast AA6061-T6/AlNp composite incorporating RS, WS, axial load and tool profile as process variables. Artificial neural network (ANN) was used by Ukuyucu et al. [9] to get correlation among mechanical properties of FS-welded aluminium plates and FSW process variables. Subramanya et al. [10] studied multi-response optimization of friction stir welding process variables, using TOPSIS approach to optimize FSW of aluminium matrix composites. Multi-response base on orthogonal array (OA) coupled with grey relational analysis was used by Vijayan et al. [11] to optimize the FSW process variables to join aluminium alloy AA5083 by FSW. Deepandurai and Parameshwaran [12] performed multi-response optimization of FSW variable for AA7075/SiCp using response surface methodology and fuzzy-based grey relational analysis. Comprehensive literature findings indicate that most of the reports allied to the optimization of FSW variables have utilized one response at a time. However, meagre study had been performed on the influence of variables on the multiple responses simultaneously. The present work is focused on optimization of variables while FSW of AMCs for macro-hardness, tensile strength and % elongation using grey relational analysis.

12.2 Experiments

12.2.1 Process Variables Selection

FSW was performed on a conventional vertical milling machine (Make: Bharat Fritz Werner). The material used in this study was AA6061-4.5(wt%) Cu-5(wt%) SiC composite. These composites were prepared by stir casting technique. Composite plates having size of 100 × 50 × 6 mm were prepared from the stir cast composite by machining. FSW tool was prepared using M2 steel with a hardness of 60 HRC. Three types of tool geometries were used in the present study, namely square (SQ), threaded cylindrical (TC) and combined threaded cylindrical and square (CTS). Tool pin geometries are shown in Fig. 12.1.

Set-up used for FSW process is shown in Fig. 12.2. Process was carried out by altering the process variable values. RS, WS and tool pin geometries are chosen as process variables to optimize the FSW of AMCs. Other variables such as tool shoulder diameter of 18 mm and tool tilt angle of 2.50 are maintained constant in order to limit the study. Working range of process variables is fixed by conducting the trial experiments which gives defectless joints. It has been observed that process variables outside the working range yields defects in the joints, such as crack and tunnel hole. The number of experiments for the present study was considered based on Taguchi's design of experiment method. As per Taguchi's method, the degree of

A	Tool geometry	TC	SQ	CTS
B	Rotational speed (RS)	700	1000	1300
C	Traverse speed (WS)	60	70	80

freedom (DOF) of selected OA must be equal to or higher than the total DOF required for the experiment. In the present work, L9 OA was used to carry out the experiments. Process variables used in the present study and their three levels were shown in Table 12.1.

12.2.2 Evaluation of FSW Performances

Specimens for tensile tests were prepared as per ASTM E8 standard from both welded and the base material. Specimens were cut from the workpiece in a direction normal to the weld path. Three specimens were prepared from each of the welded parts and average of these values was considered as parametric values. Ultimate tensile strength and % elongation values were measured by performing test on universal testing machine.

The hardness test was performed across the weld at the middle region at 3 mm gap on both sides of the weld path. Test was performed on Vickers macro-hardness tester by choosing load of indentation of 5 kg for 15 s. Table 12.2 lists the FSW process variables used in the study and corresponding output responses.

Table 12.2 FSW process variable values and output responses

Expt. No.	Process variables			Output responses		
	Tool profile	RS (RPM)	WS (mm/min)	UTS (MPa)	Vickers hardness (Hv)	% Elongation
1	TC	700	60	118	102	8.6
2	TC	1000	70	158	118	7.4

7	CTS	700	80	145	116	8.4
8	CTS	1000	60	150	118	8.2
9	CTS	1300	70	146	126	8.6

12.3 Grey Relational Analysis

The Taguchi method is an important tool for enhancing the productivity and quality during research and development. Taguchi offers meticulous way of design and analysis of experiment to improve the productivity. Most of the Taguchi techniques were on optimization of single responses. However, combining grey relational analysis (GRA) with the Taguchi methods enables the optimization of process variables for two or more than two responses simultaneously [13]. In GRA, grey relational coefficients for various responses are computed and average of these are called grey relational grade (GRG). These GRGs are considered as single-output response for the Taguchi experiment. In the present study, GRA-based Taguchi method is used to optimize the FSW variables for the output responses namely macro-hardness, tensile strength and % elongation.

12.3.1 Response Pre-processing

Since the unit and range of one response differ from the others, pre-processing of responses were necessary in GRA. When the scatter range of response is too large or when target direction of the response is different, then also response pre-processing is to be carried out in GRA. Response pre-processing is a process of converting original responses into comparable values. Responses are to be normalized in the range of zero to one to make them comparable values. In the present study, all the three responses namely tensile strength, macro-hardness and % elongation, 'larger the better' criteria were selected, as quality of the weld was represented by higher values of these responses. The original values of responses were normalized as follows for the 'larger the better' criteria.

$$p_i^*(k) = \frac{p_i(k) - \min p_i(k)}{\max p_i(k) - \min p_i(k)} \tag{12.1}$$

where $p_i(k)$ and $p_i^*(k)$ are the values before and after response pre-processing, where i represents the experiment number and k represents the response. Normalized values after pre-processing were listed in Table 12.3.

Further, $\Delta_{oi}(k)$ represents the deviation of the normalized value $p_i^*(k)$ from the reference value $p_0^*(k)$. Calculation was done for all the experiments and responses and listed in Table 12.4.

$$\Delta_{oi}(k) = \left|p_0^*(k) - p_i^*(k)\right| \tag{12.2}$$

Table 12.3 Normalized value of responses after pre-processing

12.3.2 Calculating Grey Relational Coefficient (GRC) and Grey Relational Grade (GRG)

A grey relational coefficient (GRC) was calculated using the values obtained after response pre-processing. GRC formulates the relationship among the actual normalized response values with the ideal values. The GRC can be calculated as follows.

$$\delta_i(k) = \frac{\Delta_{\min} + \delta \cdot \Delta_{\max}}{\Delta_{oi}(k) + \delta \cdot \Delta_{\max}} \tag{12.3}$$

where $\Delta_{oi}(k)$ is the deviation of the normalized value $p_i^*(k)$, and from the reference value $p_0^*(k)$, δ is a coefficient of identification. The value of δ is taken as 0.33 by considering the equal preference for all the variables. The GRG for each experiment were calculated and tabulated in Table 12.5.

After calculating GRC, grey relational grade was obtained by taking the average of GRC corresponding to each experiment. The multiple response optimization of the process variables are based on the GRG.

$$\beta_i = \frac{1}{n}\sum_{k=1}^{n} \delta_i(k) \tag{12.4}$$

where $\delta_i(k)$ is the GRG for the *i*th experiment which vary from 1 to 9 and n is the number of responses. Table 12.4 lists the GRG for each experiment. The experiment which is nearer to the ideal normalized value shows higher GRG. From the Table 12.4, Experiment 5 has best multi-response value, since it has the highest GRG. From the present work, it could be inferred that the optimization of multiple responses of FSW of AMCs can be done by converting multiple responses into a grey relational grade.

Table 12.5 Grey relational coefficient (GRC) and grey relational grade (GRG)

Expt. No.	Grey relational coefficient (GRC)			Grey relational grade (GRG)
	UTS	Vickers hardness	Elongation

Table 12.6 Grey relational grade (GRG) response table

Factors	Process variable	Grey relational grade			Main effect
		Level 1	Level 2	Level 3	
A	Tool profile	0.3882	0.5673[a]	0.5185	0.1791
B	Rotational speed (RS)	0.4233	0.5370[a]	0.5137	0.1137
C	Welding speed (WS)	0.4442	0.5387[a]	0.4911	0.0945

Total mean value of the GRG = 0.4913
[a]Optimum GRG levels

The orthogonal experimental design enables to separate out the influence of each process variables on the GRG at different level. For instance, the hardness at levels 1, 2 and 3 can be computed by averaging the GRG for the Experiments 1–3, 4–6 and 7–9, respectively. The average of GRG for each level of the other responses namely tensile strength and elongation were calculated and listed in Table 12.6. The average of GRG for the nine experiments was computed and shown in Table 12.6. When the GRG is larger, the quality of the product will be nearer to the ideal value. Hence, higher GRG is required for optimum performance.

Based on higher GRG, the optimal process variables for better hardness, tensile strength and % elongation is Level 2 of each process variables as given in Table 12.6.

From the analysis, the optimal process variables are RS of 1000 RPM, WS of 70 mm/min and tool pin profile at Level 2, i.e. square pin profiled tool.

12.3.3 Validation Test

To confirm the enhancement of output responses while FS welding of aluminium composite, validation test was performed. Validation experiments were performed by choosing the process variables at optimum levels. Composites were welded using tool with square profiled pin, choosing RS as 1000RPM and WS as 70 mm/min. Welded samples were tested for tensile strength, macro-hardness and % elongation. Samples show better mechanical properties as given in Table 12.7 in comparison with the sample obtained from 5th experiment which has higher GRG. This implies that Taguchi-based GRA can be successfully employed for optimization of multiple responses simultaneously.

Table 12.7 Comparison of responses for experiment No. 5 and experiment with optimum process variables

Expt. No.	Process variables			Output responses		
	Tool profile	RS (RPM)	WS (mm/min)	UTS (MPa)	Vickers hardness (Hv)	% Elongation
5	SQ	1000	80	166	123	7.9
Optimum variables	SQ	1000	70	170	126	8.4

12.4 Result and Discussion

Amount of heat generated at this region depends on the RS, WS and type of tool, which controls the plasticization and flow of material. Frictional heat generated at the weld region and stirring action of the FSW tool influences the recrystallization of the grain, grain growth and grain orientation. All these factors control the mechanical properties of the joint [14–20]. From the microstructural study, it is found that SiC particles distributed within the matrix dendrites with no definite grain orientations as reported in literature [14]. Figure 12.3 depicts the various zones of weld area. Based on the grain size, the weld area is classified into four zones. (a) Stir zone (SZ) is a dynamically recrystallized zone due to the severe stirring action of the tool. The frictional heat produced at the tool workpiece interface is sufficient to plasticize the material and develops a new set of fine equiaxed grains. (b) Thermo-mechanically affected zone (TMAZ), next to SZ, is not in direct contact with the FSW tool. The heat produced at the SZ and the stirring action of the tool in the SZ alters the size of the grain and its orientation in this region. Material plastically deforms due to the shear stress resulted from the material flow. The grins are elongated and inclined in the direction of shear stress.

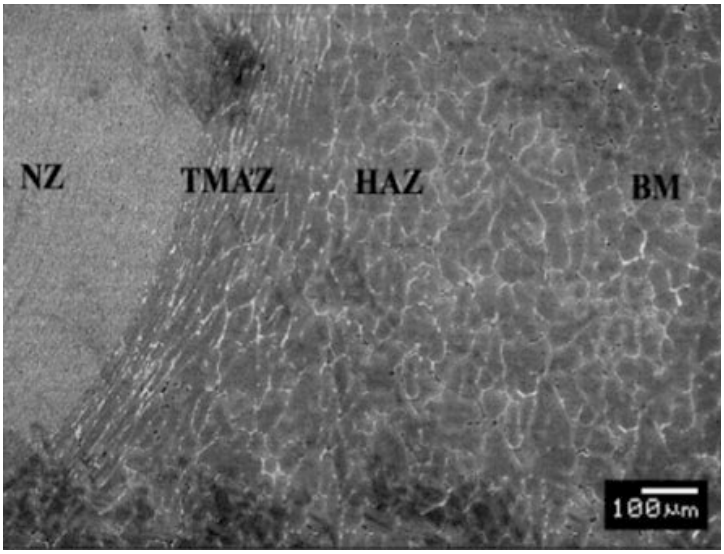

Fig. 12.3 Various zones of friction stir welded joint

(c) Heat affected zone (HAZ), is a zone next to TMAZ, does not undergo plastic deformation but, heavily influenced by the thermal cycle. The heat generated at the weld zone is sufficient to growth of the grains at HAZ. The grain structure at the HAZ is similar to the base material but of bigger size due to grain growth. (d) Base material (BM), region which is neither affected by the thermal cycle nor with the mechanical action of the tool.

Plasticization of material and the material flow in the weld region largely depends on the heat generated at the tool–workpiece interface and the amount of heat supplied to the weld region. Amount of heat generated at the tool–workpiece interface was dependent on the RS and heat supplied to workpiece was on WS [14–16]. As the RS increases, the quantity of heat generates at the weld region increases. So, at low speed, the heat generated at the region is less which affects the plasticization of material which in terms affects the weld quality. RS higher than the optimum speed generates more heat at the weld region, thereby creating turbulent material flow in the region [17]. Optimum heat generation is must for plasticization and proper material flow in the weld region. WS controls the transfer of generated heat at tool–workpiece to the workpiece [18]. Lower WS leads to higher heat input and results in the grain growth and larger heat-affected zone (HAZ). This phenomenon reduces the tensile strength and hardness. Higher WS leads to lower heat input to the weld region, thereby affecting the plasticization of material. Also, higher WS increases the cooling rate which affects the solidification of the plasticized materials in the weld region. Optimum WS is necessary to control the cooling rate which in term controls the grain growth in the weld region [19]. Mechanical properties of the welded samples were dependent on the grain structure and thus optimum RS and WS are necessary to obtain better mechanical properties.

Material flow around the tool pin is affected by the type of pin profile [15, 21]. The factor which varies with different type of tools was the ratio of swept volume to static volume. Conventional unthreaded cylindrical tool has this ratio as one, where both volumes are equal. Presence of thread on the cylindrical pin slightly increases this ratio and it has value of 1.02 in the present study. Polygon-shaped tools have higher swept volume compared to the static volume, results in higher ratio values. Square-shaped pin used in the present study has ratio of 1.57 and combined threaded cylindrical and square pin has ratio of 1.30. As the ratio increases, the pulsating effect of the tool also increases which results in improved material flow around the pin. Proper flow of material results in uniform distribution of particles, finer grain structure, thereby improving the mechanical properties of the welded parts. The present study supports the above phenomenon, indicating FSW with square profiled pin exhibits better mechanical properties.

12.5 Conclusions

The GRA has been used successfully to optimize the FSW process variables in joining AMCs for multiple responses namely macro-hardness, tensile strength and % elongation. Taguchi's L9 orthogonal array has been utilized for the experimental work. The FSW process variables are optimized for multiple responses, namely macro-hardness, tensile strength and % elongation. The present study indicates that complicated multiple response optimizations simultaneously can be significantly simplified by the Taguchi and GRA approach. From the study, it is inferred that to obtain better responses simultaneously, the optimum level of process variables to weld AMCs are square profiled pin with rotational speed of 1000 rpm and WS of 70 mm/min.

Chapter 13
Tool Durability and Weldability in Hybrid Friction Stir Welding of High-Strength Materials

Amit Chaudhary, Chiranthan Ramesh, Viswanath Chinthapenta and Murshid Imam

Abstract Challenges that prevent broad industry adoption for friction stir welding of high-strength materials are (i) premature tool failure, (ii) selection of tool material and design, and (iii) weldability. To address these typical issues, a finite element-based study for laser-assisted friction stir welding process is carried out in ABAQUS, commercially available FE software. Experimentally, it has been shown that for welding of thick plate, laser assistance ahead of the tool is sought to be beneficial. However, the introduction of laser heating adds another complexity in modeling aspects. It is carried out in twofold. Firstly, the laser preheating is modeled to obtain the thermal map on the sample. Next, the regular FSW process is carried out on the already preheated sample. The important findings achieved are improving weld productivity and satisfactory tool life.

Keywords Friction stir welding · High-strength material · Laser heating · Thermal diffusivity · Finite element modeling

13.1 Introduction

Friction stir welding is a solid-state joining process which is developed by W. M. Thomas from TWI, Cambridge, England in 1991 [1]. This process was particularly used for the material which was unweldable by traditional welding technologies. In FSW, a specially designed rotating tool plunged into the abutting edges of the sheet to be welded and then transverse along the joint line. In this process, heat is generated by friction and severe plastic deformation allowing strong metallurgical bonds at the abutting interface. As compared to fusion welding technologies, there is no liquid weld pool formation, and hence excellent metallurgical

properties such as fine microstructures, elimination of cracks in the weld zone, high depth of penetration is , comparatively less energy requirements, no requirement of shielding gas, and absence of consumable electrode [2]. As the capability of the FSW process expands, its demand in joining high-strength material also increases.

During welding of high-strength material, it is observed that the toolpin bend or deform due to high bending and torsional stresses. To overcome this problem, laser preheating of the sheet/plate is carried out ahead of the tool. Laser preheating softens the material so that bending and torsional stresses acting on the tool can be decreased. The present work aims to develop a finite element model for the laser-assisted FSW process. The proposed finite element has the two important industrial applications: (i) it helps to widen the process window by improving the weldability and (ii) improving tool durability by reducing the stresses, especially when FSW of high-strength material with larger sheet thickness needs to be conducted. A passively 3D FE coupled thermo-mechanical model has been developed by considering the thermal and mechanical aspects in ABAQUS/Explicit and to control the heavy distortion, arbitrary Lagrangian-Eulerian (ALE) formulation has been used. For incorporating the moving body heat source, DFLUX user-defined subroutine code was used.

13.2 Finite Element Method

A three-dimensional coupled Eulerian-Lagrangian thermo-mechanical FSW model is developed in ABAQUS/Explicit. The whole simulation is carried out in a dynamic, temp-displacement, explicit step. Stable time increment estimator is used for time marching. In the Lagrangian model, as the material deforms, mesh also deforms with it. In the Eulerian model, the mesh does not change as the material deforms. A large amount of heat is generated due to large plastic deformation and friction. The governing and material constitutive equations are given in Fig. 13.1. The workpiece material used in the present is 2024-T3 aluminum alloy. The dimensions and mesh density of the workpiece are shown in Fig. 13.1b, c. The mechanical and thermal properties are chosen in the simulation is based on the reported work by Mandal et al. [3]. The workpiece is modeled as three-dimensional deformable bodies, reference point and inertia are provided to the tool. Due to large deformation and mesh distortion, arbitrary Lagrangian-Eulerian (ALE) meshing has been considered in the simulation. A C3D8RT element has been chosen, which is a multi-material thermally coupled 8-noded element. Tool–workpiece interaction is defined by using the surface-to-surface contact formulation with tangential force on penalty basis.

Laser beam heating is solved in coupled temperature displacements, a pre-step to plunge. The Gaussian distribution is used to explain the shape of the laser beam heat source. The double-ellipsoidal heat source describes the shape of the body heat source. The laser beam intensity exponentially changes with a penetration depth of

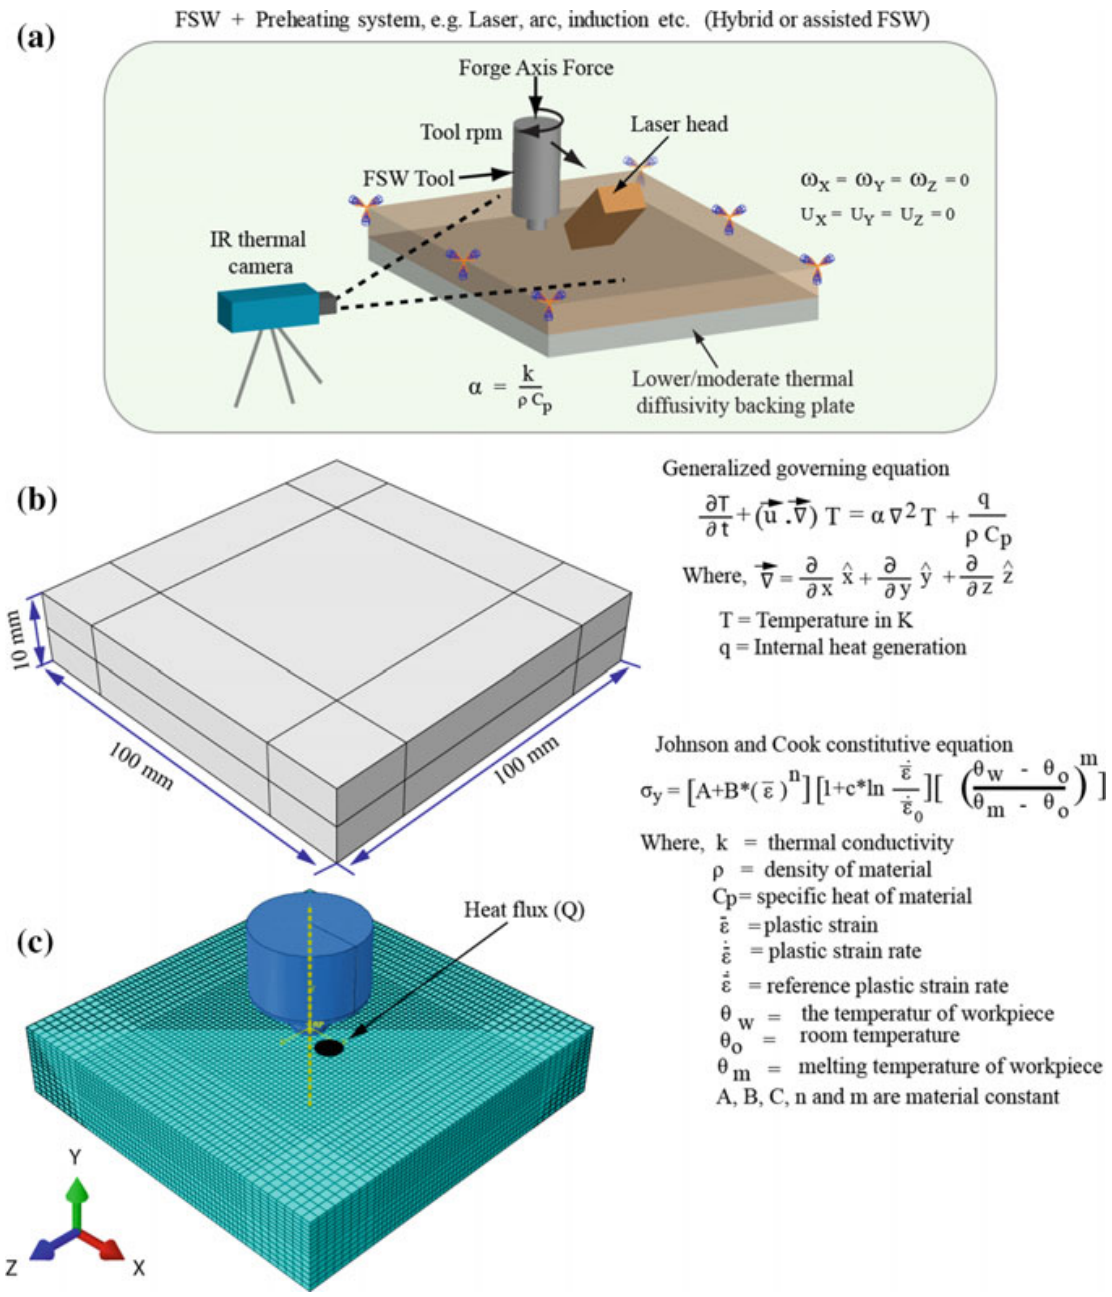

Fig. 13.1 **a** Schematic diagram of FSW with the preheating system, **b** dimensions of the deformable workpiece, and **c** FEA model with laser heat flux and governing equation of material model and heat transfer

welded element. The moving heat source parameters are controlled by changing DFLUX user-subroutine code which is written in FORTRAN programming language. The plunge stage of the tool is modeled in the next step based on the temperature-dependent properties from the laser pre-heating with dynamic, time–temperature explicit analysis. In the present work, FEM formulation is done by using ABAQUS commercial package. Goldak's model is used for simulating the laser heat source. Figure 13.2 shows the schematic of double ellipsoid Goldak heat source model. Double-ellipsoidal heat source Goldak's model was used to preheat

$$q_1(x,y,z) = \frac{6\sqrt{3}\, f_1 Q}{abc_1\pi\sqrt{\pi}} \exp\left(-3\frac{x^2}{a^2} - \frac{y^2}{b^2} - 3\frac{z^2}{C_1^2}\right)$$

$$q_2(x,y,z) = \frac{6\sqrt{3}\, f_2 Q}{abc_1\pi\sqrt{\pi}} \exp\left(-3\frac{x^2}{a^2} - \frac{y^2}{b^2} - 3\frac{z^2}{C_2^2}\right)$$

the workpiece. Two-half ellipses are connected to single semi-axis. Power distribution of this double-ellipsoidal model heat source is given by the equations as shown in Fig. 13.2. Note that the resultant distribution of heat source is given by $q(x, y, z) = q_1(x, y, z) + q_2(x, y, z)$.

13.3 Results and Discussion

Figure 13.3a shows the relationship between welding parameters and a shift in weld productivity. Note that in this figure, the data for selection of control process parameters for plate thickness >19 mm are compared with the process window of 4-mm-thick sheet [4–8]. It can be cleary seen from this figure that there is a shift in weld productivity of FSW of thicker plate when compared with the smaller sheet thicknesses (<4 mm). The reason for the shift in the weld productivity can be understood as follows: (i) selection of process control parameters requires a more physical/scientific understanding of the process for welding thicker plates. To weld thicker plate, higher heat energy per unit length is needed. The control heat input parameters are tool rotational speed, axial force, and welding speed. In the case of thicker plate, large magnitude of axial force is required to ensure the optimum material mixing along the weld plate thickness. Therefore, the coupling of the tool rotational speed and axial force needs to be adjusted in such a way that it avoids the overheating of the material at the tool shoulder/workpiece interface. Otherwise, the higher degree of thermal softening will make the process unstable and the excess flash formation, (ii) the present industrial practice to avoid such a situation is the

weld-flip-weld approach. The first weld pass is made with the shorter tool probe length and then workpiece is flipped for welding from the other side. This approach involves cleaning of the bead obtained after the first weld pass, the additional time for the readjustment of the fixtures and requirement of large clamping forces for the adjustment of the workpiece with the fixtures because of the distortion of the workpiece after the first weld pass. In addition, the tool probe experiences the larger bending and shear stress in the case of thicker plates. The intricate tool probe profile design is detrimental for the tool life. To achieve better welding condition, the tool has been provided with probe surface which acts as a notch and the tool became weaker at that section and may lead to failure. Therefore, the tool material must be strong enough to withstand the large bending and torsion stresses acting on the tool when the welding speed is high. In this context, Laser pre-heating ahead of the tool has been found to be beneficial to solve such problems for welding of thicker plates and for welding of high-strength alloys. From Fig. 13.3b, it can be observed that for the high-strength material (mild- and high-strength steels) the yield strength does

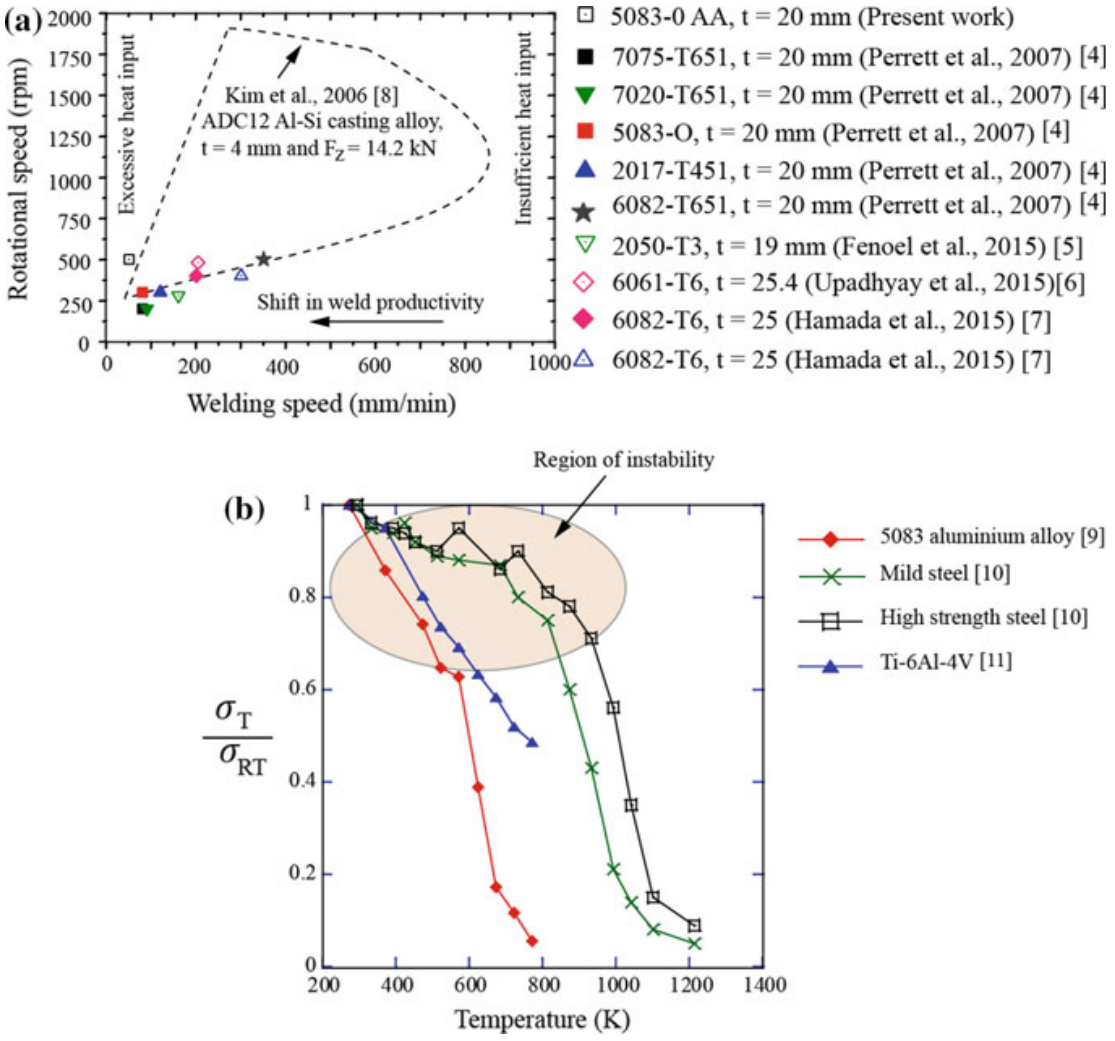

Fig. 13.3 **a** Process map for weld productivity in thick aluminum welds and **b** instability region for carrying out friction stir welding of high-strength materials

not vary significantly for the temperature range from 300 to 800 K (for details see the Fig. 13.3b). Note that σ_T/σ_{RT} is the ratio of the yield strength of the materials at elevated temperatures and room temperature, respectively. At the time of tool plunging, the temperature is not sufficiently high to cause the thermal softening of the work material and thereby leads to the tool failure. Adding the laser heating helps to solve this problem. The finite element simulation with laser pre heating has been carried out to compare the results and benefits of pre-heating over without pre-heating. From the predicted model, it can be observed that stress developed on the tool has been decreased significantly.

Figure 13.4a shows the comparisons of maximum principal stress values at three different locations during the plunging stage. Here, the maximum principal stress values are compared for both the cases (with and without preheating). The three locations (location 1, location 2, and location 3) shown here is for the tool plunging

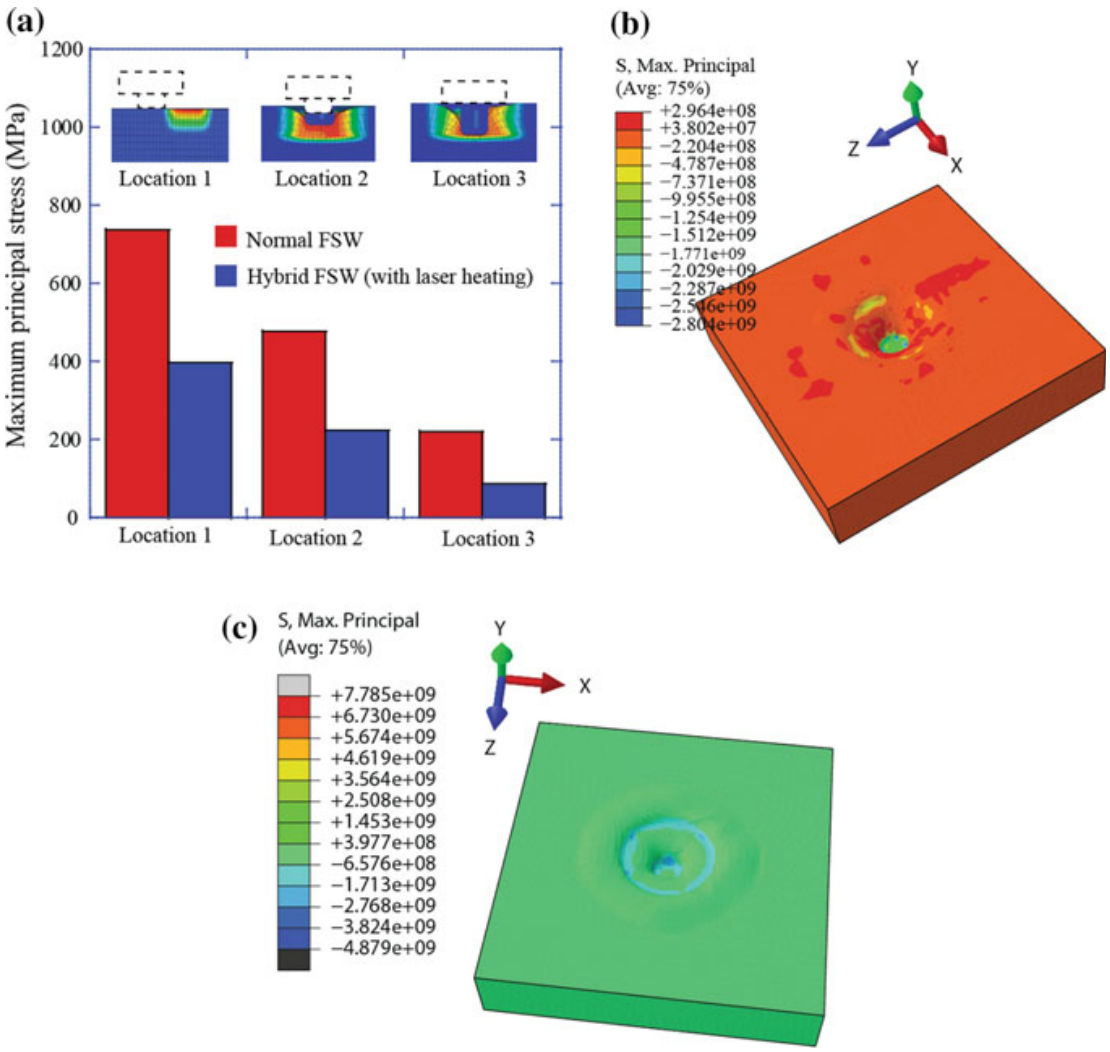

Fig. 13.4 **a** Comparisons of stress values at plunging locations 1, 2, and 3, respectively, **b** finite element simulation result showing the maximum principal stress value for normal FSW process at location 3, and **c** finite element simulation result showing the maximum principle stress value for Hybrid FSW process at location 2

distance of 0.6, 6, and 12 mm, respectively. Note that Fig. 13.4 b, c shows the predicted maximum principal stress on the workpiece at location 3 and location 2 for the case of normal FSW process and laser-assisted FSW. The stresses generated on the tool can be reduced in a very much amount in the case of laser heating as compared to the normal FSW process. Thus, it can be clearly understood that the laser heating is beneficial for causing the thermal softening of the material, particularly during the plunging. On similar lines, Yaduwanshi et al. [9] and Fei et al. [10] pointed out that the laser preheating is beneficial for the welding of dissimilar materials, particularly when aluminum and other high-strength materials (Steel, Titanium, etc.) are involved [11–13].

13.4 Conclusion

Laser-assisted friction stir welding has a potential to lower the stresses acting on the FSW tool by causing the thermal softening of the workpiece material. The finite element model suggests that the tool durability can be greatly improved. The addition of laser heating can also widen the process window, and hence better productivity can be achieved. The development of hybrid FSW system paves the way to establish this inexpensive and simple technique in heavy metal industries where metallurgical problems are still the main challenges to overcome.

Chapter 14
Swarm-Intelligence-Based Computation for Parametric Optimization of Electron Beam Fabrication

Sanjib Jaypuria, Amit Kumar Das and Dilip Kumar Pratihar

Abstract In the present paper, two recently developed intelligent swarm optimization algorithms were used for optimization of input variables in the electron beam welding process. The computational intelligence-based optimization algorithms used in this study were bonobo optimizer (BO) and cricket algorithm (CA), which are swarm-intelligence-based algorithms developed by mimicking self-organization, co-evolution, and learning of multiple agents in that particular swarm of the population. Bead-on-plate welding of CuCrZr alloy plate was carried out by electron beam. The welding runs were designed according to central composite design, and regression analysis was conducted to establish input–output dependency. Accelerating voltage, beam current, scanning speed, and focusing distance were considered as input variables of the process, whereas bead geometry parameters and microhardness of weld zone were regarded as the responses of the electron beam welding process. An optimization problem was formulated with an aim to minimize the weldment area without sacrificing the bead penetration and microhardness of the fusion zone. Penalty function approach was also used in this study to optimize the unconstrained problem. Three optimization algorithms were used in this study to solve the optimization constrained problem designed to optimize the input variables of the process yielding proper responses of the weld region. The performances of proposed approaches were evaluated based on percent deviation from that of the experimental result. Bonobo optimizer outperformed cricket algorithm and genetic algorithm for optimizing the process.

14.1 Introduction

Manufacturing processes are always associated with trial and error method prior to the actual experimentation. It is always not beneficial to conduct these trial experiments due to the wastage of resources and time. Therefore, these days' industries are shifting toward the automation of manufacturing processes, which will reduce the lead time and consumption of resources [1]. In addition to input–output modeling, manufacturing industries also require optimization tools to enhance productivity by ensuring quality-based products. Most of the manufacturing processes deal with multi-input–output systems with complex interdependency of the variables; so, optimization is needed to get a suitable set of input parameters, which ensure a high-quality product. Electron beam welding is such a fusion welding process, where multiple process parameters are involved along with a certain degree of automation of the process. Electron beam welding has gained diverse applications in the fields like nuclear, energy, aerospace, and automotive in the recent era. The wide application of this process is because of low heat input, high aspect ratio, a minimal area of heat-affected zone and capability to weld reactive and reflective metals [2]. Here, electron beam acts as a heat source and fuses the joint by providing intense heat energy, which is being converted from the high-speed electron beam's kinetic energy. The quality of the joint is also decided by the vacuum environment of the welding [3].

Computational intelligence is a part of soft computing tools or metaheuristic algorithms, which are promising tools for modeling, optimization, and prediction of response in material and manufacturing engineering [4]. The most frequently used tools include artificial neural network (ANN), genetic algorithm (GA), fuzzy logic (FL), particle swarm optimization (PSO), and others. A few researchers studied the applicability of metaheuristic algorithms in the different manufacturing process and welding methods.

Benyounis and Olabi [5] reviewed linear regression, response surface method, artificial neural network (ANN), Taguchi method, and design of experiment (DoE) techniques used in welding process for optimization and modeling. It had been concluded from their work that GA and other metaheuristic algorithms are powerful optimization tools, especially in the irregular experimental region. The ability of these evolutionary approaches to operate in a vast set of search points to find optimal point was well appreciated in this work. Sathiya et al. [6] performed a laser welding of AISI 904L and investigated the relationship between laser input parameters and laser-welded joint characteristics. They first established the input–output relationships by artificial neural network and then, the developed model was used for optimization of responses using genetic algorithm. Jha et al. [7] modeled electron beam welding of reactive zircaloy by artificial neural network. The developed neural networks were optimized by GA, PSO, and BP algorithm. These developed bidirectional models had shown good prediction capability of the model. BPNN had proved the better performance as compared to the other two approaches. Park and Rhee [8] performed experiments on the laser welding of automotive grade

AA5182 aluminum alloy and studied the tensile strength of the welded joints. A neural network model tuned by genetic algorithm was proposed to predict the tensile strength using the experimental data. Dey et al. [9] conducted electron beam welding of stainless steel and experiments were designed according to central composite design (CCD). The objective of their study was to minimize the weld area without hampering the maximum bead penetration. Penalty function approach was used to obtain the suitable process parameters of the electron beam welding process. Kanigalpula et al. [10] studied the spiking behavior of partially penetrated ETP copper plates welded using electron beam. The constrained optimization problem for achieving the minimum standard deviation of penetration was solved using genetic algorithm, particle swarm optimization, and desirability function approach. The predicted results with various proposed approaches were verified with that of real experiments and a good agreement between them was achieved. In addition to this, there were a very few available literatures, where swarm-intelligence-based optimization algorithms were implemented on the manufacturing process and system for optimization and modeling.

It is observed from the literature that metaheuristic approaches are mostly used in the optimization of many manufacturing processes in addition to traditional tools because of their flexibility and accuracy. In addition to this, the modeling tool like neural network is also fine-tuned with these evolutionary approaches for the better efficiency of the developed neural network architecture. In most of the available literature, optimization tools like genetic algorithm and particle swarm optimization are used for optimization and modeling of the manufacturing process. It is also found from the research that there are only a few available works of literature, where swarm-intelligence-based approaches were used for optimization of electron beam fabrication.

Therefore, here, two recently developed, swarm-intelligence-based algorithms, e.g., Bonobo optimizer (BO) and cricket algorithm (CA), were used to optimize the process parameters of electron beam welding. The approaches were intended to minimize the weldment area and maximize the bead penetration and weld zone microhardness. The performance comparison and working principle were discussed in this work. In addition to this, genetic algorithm (GA), which is a bio-inspired tool, was also used to optimize the constrained problem. The performances of these developed models were evaluated in terms of absolute percentage deviation and convergence rate.

14.2 Experimentation and Data Collection

Precipitation hardened CuCrZr alloy plates of dimension 100 mm × 65 mm × 10 mm were used for electron beam welding in bead-on-plate configuration. The procured metal had 0.80 wt% Cr, 0.06 wt% Zr, and 0.13% impurities and remaining as copper. The primary input parameters of electron beam welding, namely accelerating voltage (V), beam current (I), welding speed (S), and focusing distance

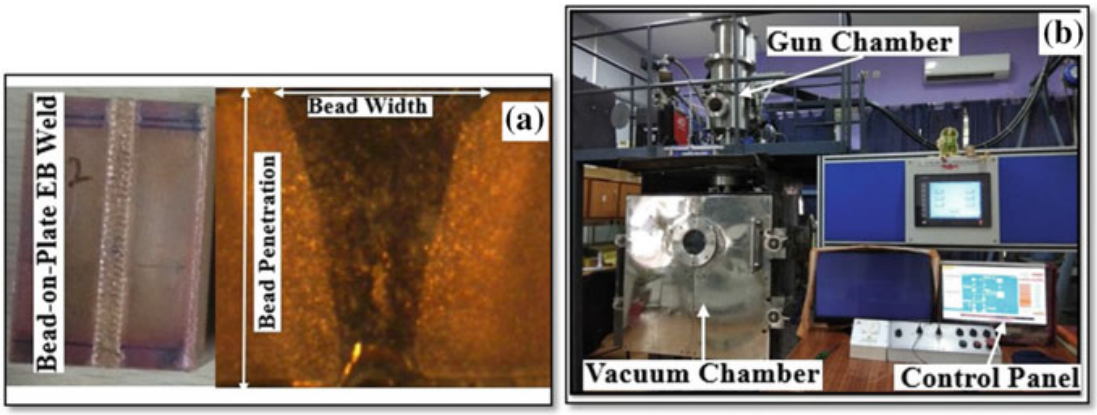

Fig. 14.1 Photograph of **a** weld bead geometry and **b** electron beam welding setup

(B) were taken as process variables, whereas microhardness of fusion zone and bead geometrical parameters, like bead penetration (BP), bead width (BW), microhardness of fusion zone (μ_{FZ}), was considered as the responses to be measured. Figure 14.1a indicates various geometrical features of the weld bead. The photograph of electron beam welding setup along with their principal components is given in Fig. 14.1b. A few trial runs were conducted to select the ranges of input variables. The actual experiments for this study were prepared by considering the method of central composite design (CCD) with three central points. A total of 27 combinations of input parameters were generated, and 81 experiments were conducted by considering three replicates of the original CCD [11]. The actual and test cases experimental data were taken from [11]. A section of the weld (15 × 10 10 mm) was cut from the obtained weld for measuring the weld responses. The polished and etched samples were examined using optical macroscope to measure bead penetration and width. Microhardness of fusion zone (FZ) was measured for each sample in Vickers microhardness tester at an applied load of 50-gf and dwell time of 15 s.

14.3 Method of Analysis: Proposed Approaches

The mathematical relationships between the inputs and output were established by nonlinear regression before solving the optimization problem. The proposed metaheuristic approaches, which were used as optimization algorithms in the developed problem, were briefly discussed below.

14.3.1 Regression Analysis

A nonlinear statistical regression analysis was conducted using Minitab15 software to establish input–output relationships of the process, as given below in Eq. (14.1).

$$y = \beta_0 + \sum_{i=1}^{k} \beta_i x_i + \sum_{i=1}^{k} \beta_{ii} x_i^2 + \sum_{i=1}^{k} \sum_{i<j}^{k} \beta_{ij} x_i x_j + \varepsilon \tag{14.1}$$

where y is the response parameter; $\beta_0, \beta_i, \beta_{ii}$ are the coefficients to be computed using the least squares method. Here, ε denotes the error in fitting. The nonlinear regression equations for the responses were determined, as shown in Eqs. (14.2)–(14.4).

$$\begin{aligned} \text{BW} = & -172.103 + 2.16103\,V + 0.827001\,I - 0.0522837\,S \\ & + 0.479534\,B + 0.0104345\,V^2 - 0.00000530401\,I^2 \\ & - 0.00000157596\,S^2 + 0.000117136\,B^2 - 0.00057152\,VI \\ & - 0.0000567146\,VS - 0.00867625\,VB - 0.0000572391\,IS \\ & - 0.00193298\,IB + 0.000171340\,SB \end{aligned} \tag{14.2}$$

$$\begin{aligned} \text{BP} = & 5857.98 + 8.02798\,V + 0.0920434\,I + 0.0623438\,S \\ & - 33.0775\,B - 0.0313765\,V^2 - 0.00146853\,I^2 \\ & + 0.00000207134\,S^2 + 0.0456195\,B^2 \\ & + 0.0000113958\,VI - 0.0002530645\,VS \\ & - 0.0113766\,VB - 0.000145435\,IS \\ & + 0.00100352\,IB - 0.000114410\,SB \end{aligned} \tag{14.3}$$

$$\begin{aligned} \mu_{\text{FZ}} = & 435.876 + 41.1517\,V - 6.48847\,I - 0.289883\,S \\ & - 6.03015\,B - 0.285728\,V^2 + 0.00680864\,I^2 \\ & + 0.000101836\,S^2 + 0.00893827\,B^2 \\ & + 0.00541667\,VI + 0.000987500\,VS - 0.0291667\,VB \\ & + 0.000322917\,IS + 0.013\,IB + 0.000104167\,SB \end{aligned} \tag{14.4}$$

14.3.2 Problem Formulation

A constrained optimization problem was formulated to maximize the weld penetration and microhardness of the weld zone without increasing the weld area.

Minimize

$$A = 0.5 \times (\text{BW} \times \text{BP}) \tag{14.5}$$

subject to

$$\begin{aligned} &\mathrm{BP} \geq 0.7 \times t, \\ &|\mu_{\mathrm{PM}} - \mu_{\mathrm{FZ}}| \leq 59.0 \end{aligned}$$

and

$$\begin{aligned} &50 \leq V \leq 60 \\ &70 \leq I \leq 110 \\ &600 \leq S \leq 1000 \\ &365 \leq B \leq 375 \\ &\mu_{\mathrm{PM}} = 153 \\ &t = 10 \end{aligned}$$

Here, t and μ_{PM} indicate the thickness of the specimen in mm and microhardness of base or parent metal in VHN, respectively. A denotes the weldment area, which had to be minimized for the reduction of bead width and large heat-affected area. Therefore, the constrained optimization problem was designed to minimize weld area without scarifying the bead penetration and microhardness of the fusion zone. The above functional constraint was set by observing the microhardness of FZ for different combinations of input parameters lying within their respective ranges.

14.3.3 Genetic Algorithm (GA)

Genetic algorithm (GA) is a bio-inspired metaheuristic algorithm working based on Darwin's principle of natural selection and evolution. Therefore, concisely, a GA initiates the operation by selecting a random population of solutions and then improves the fitness level through iterative utilization of selection, crossover, and mutation operators. This iterative process stops when the stopping criterion is reached. Interested readers may refer to Pratihar [12] for a detailed discussion of the working principle of GA. The results of GA had been obtained from the literature for comparison purpose [11]. The working flowchart is given in Fig. 14.2a.

14.3.4 Bonobo Optimizer (BO)

Very recently, a new metaheuristic algorithm, named as bonobo optimizer, has been developed [13]. This newly proposed optimization algorithm imitates the social behavior and reproductive strategies of the bonobos. Generally, bonobos have been found to adopt a fusion–fission social practice, and moreover, they have four types of reproductive strategies, like promiscuous, restrictive, consortship, and extra-group mating. Furthermore, in the algorithm, two-phase conditions, namely

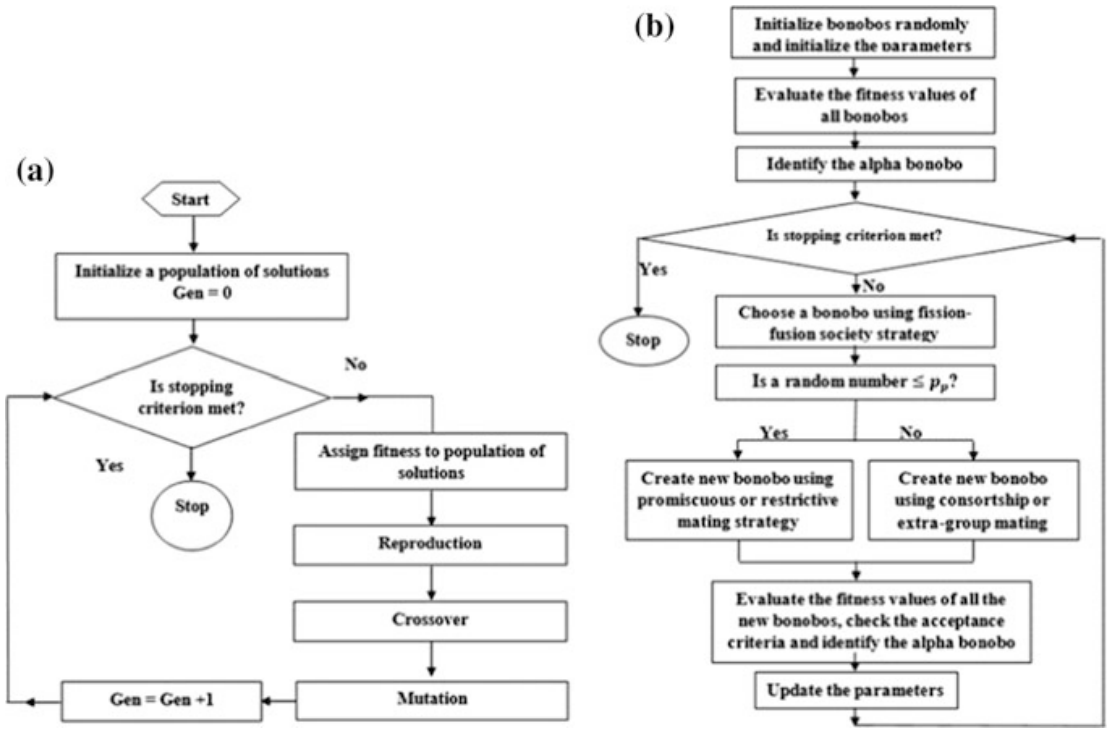

Fig. 14.2 Flowcharts of **a** genetic algorithm and **b** bonobo optimizer

positive phase and negative phase, have been considered and depending upon the phase, its associated phase probability (p_p), either exploitation or exploration phenomenon, is promoted. These strategies have been artificially modeled in the developed BO to make a more efficient optimization technique. Nevertheless, the parameters of the BO have been made adaptive to reach the globally optimum solution with the faster convergence rate. The flowchart of this BO has been shown in Fig. 14.2b.

14.3.5 Cricket Algorithm (CA)

Motivated from the nature and characteristics of an insect, namely cricket, a novel cricket algorithm had been proposed in recent time [14]. This algorithm was developed considering the functional aspects of some swarm-intelligence-based optimization methods, like bat algorithm, firefly algorithm, particle swarm optimization (PSO), etc. Also, a few peculiar characteristics of the crickets, such as forecasting the weather by courtesy of the number of fluttering of crickets and the sound frequency in the temperature, are artificially modeled to solve the optimization problems [15]. It had been applied to solve several standard benchmark functions and various real-world optimization problems. In those experiments, CA had shown its supremacy in performance compared to a few other optimization algorithms.

14.4 Results and Discussion

Sixteen test cases were used to validate this mathematical model. Figure 14.3 shows the absolute percentage deviation in the prediction of responses. The mean absolute percent error (MAPE) in the prediction of BW, BP, and μ_{FZ} were found to be 2.44, 4.84, and 1.14%, respectively. Similarly, the root mean squared error in prediction of BW, BP, and μ_{FZ} were found to be equal to 0.58, 1.03, and 4.47, respectively. In addition to this, *R*-squared value for each response in the regression model was also determined to check the closeness of data points to a fitted regression line. The values were found to be 97.95, 76.15, and 97.77% for BW, BP, and μ_{FZ}, respectively.

A real-coded genetic algorithm was utilized to solve the optimization problem in MATLAB 2015b environment. The minimum value of the fitness function (here the weldment area) was the objective of the study. A penalty function approach was adopted to handle constrained optimization problem, where infeasible solutions were penalized for being removed from the population of solutions. As the performance of the GA is dependent on its parameters, the parametric study was carried out to decide the set of optimal GA parameters by varying one parameter at a time and keeping the others unaltered [12]. The best fitness was obtained for the following GA parameters: $P_c = 0.9$; $P_m = 0.009$; $N = 100$, and $G_{max} = 150$. The GA could yield the optimal solution as follows: $V = 56.08$ kV; $I = 88.6$ mA; $S = 600$ mm/min, and $B = 365$ mm. The optimized value of the area of the weldment, as obtained by the GA, was 12.14 mm^2. A detailed comparison of various algorithms suggested results and is given in Table 14.1.

The common parameters, such as population size ($N = 100$) and maximum number of iterations ($iter_{max} = 150$), are taken the same for each of the optimization

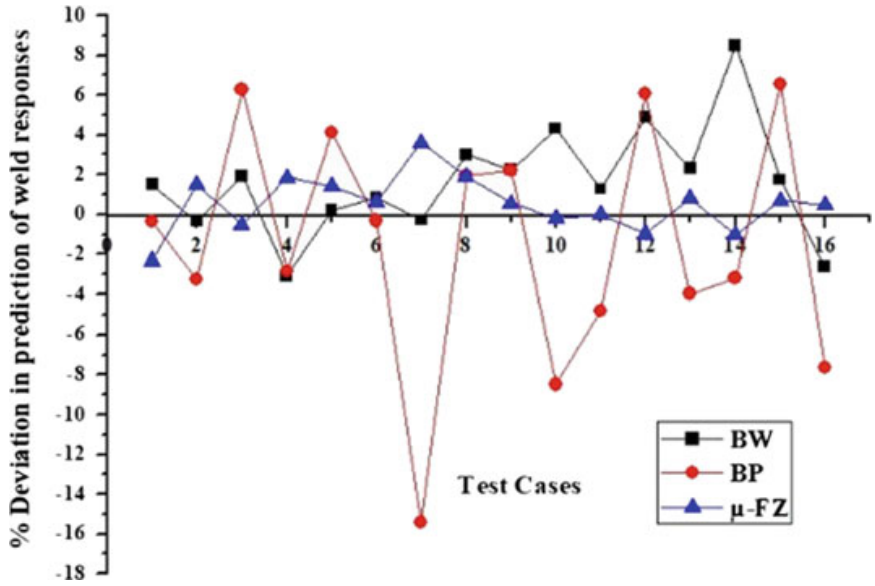

Fig. 14.3 Deviation (%) in the prediction

Table 14.1 Comparison of algorithm suggested results and experimental results

Proposed approaches	V (kW)	I (mA)	S (mm/min)	B (mm)	Area (mm^2)	BW (mm)	BP (mm)	μ_{FZ} (VHN)
CA	57	84	620	375	12.10	3.46	7.00	99.19
EXP	57	84	620	375	11.74	3.40	6.91	100.26
% error					3.093	1.70	1.36	1.066
BO	56	84	607	375	11.99	3.43	7.00	100.76
EXP	56	84	607	375	11.84	3.34	7.09	100.33
% error					1.544	2.54	0.97	0.428
GA [11]	56.08	88.6	600	365	12.14	3.45	7.04	99.66
EXP	56	88	600	365	12.65	3.61	7.01	96.87
% error					4.031	4.43	0.42	2.880

techniques. In addition, the algorithm-specific parameters used for BO are as follows: Initial probability for extra-group mating, $p_{\text{xgm_initial}} = 0.03$; sharing coefficient for alpha bonobo and the selected bonobo are found to be equal to 1.3 and 1.4, respectively; rate of change of phase probability, rcpp = 0.0036; maximum value for the temporary subgroup size factor, $\text{tsgs}_{\text{factor_max}} = 0.02$. The BO obtained the optimal solution as follows: V = 56 kV; I = 84 mA; S = 607 mm/min; and B = 375 mm. The optimized value of area of weldment as obtained by the BO was 11.99 mm^2. For CA algorithm, the following parameters were taken while it is running: minimum frequency, $Q_{\min} = 0$; $\beta_{\min} = 0.2$. The CA predicted the optimal solution as V = 57 kV; I = 84 mA; S = 620 mm/min; and B = 375 mm. The optimized value of area of weldment as obtained by the CA was 12.10 mm^2.

From Table 14.1, it is observed that BO could yield the best result compared to others for this optimization problem. Therefore, it can be concluded that BO could outperform GA and CA in this study.

The convergence plots of BO and CA algorithms are given in Fig. 14.4. The graph indicates that BO could yield a better solution with faster convergence rate

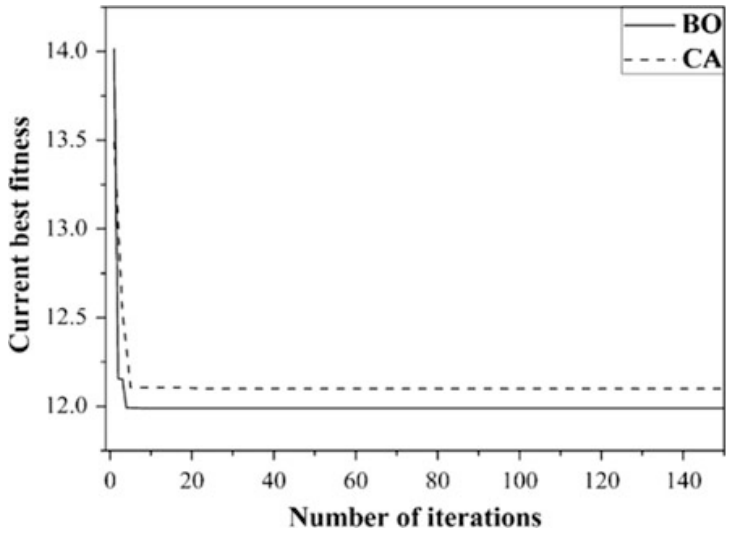

Fig. 14.4 Convergence plot for BO and CA

compared to CA. It can be inferred from the result of absolute percentage deviation and the result of the convergence rate that BO emerges as the winner for the optimization problem attempted in this study. In BO, the parameters of the algorithm are found to be adaptive in nature. According to the need of the situation, either exploitation or exploration phenomenon is promoted, or a proper balance between these two is maintained. In the case of a positive phase, the solutions are updated either using a promiscuous or restrictive type of reproductive strategy, and in this phase, the searching agents are observed to follow the current best solution. On the other hand, a more diversified search is found using either a consortship or extra-group mating strategy during a negative phase. Furthermore, the selection procedure of the mating partner based on the fission–fusion social behavior of the bonobos is also responsible for maintaining a right balance between the selection pressure and population diversity. Due to these reasons, BO is found to have an efficient searching mechanism to reach the globally optimum solution and hence, it has better performance compared to others.

14.5 Conclusion

A constrained optimization problem was formulated to yield minimum weld area without violating the requirement of high penetration and microhardness of the fusion zone. Mathematical relationship among input–output was established using regression, and the obtained equation was validated with experimental results. The following conclusions can be made from the present work.

- The formulated optimization problem was solved using BO and CA, which are swarm intelligence-based algorithm. In addition to this, the solution obtained using the evolutionary genetic algorithm was also taken from available literature for comparison of results among various approaches. The optimal results from different approaches were validated with that of real experiments. The maximum absolute percentage deviation in the prediction of optimal input parameters in all algorithms were found to be less than 4%, which indicates a closer match between algorithms suggested results and experimental results. The absolute percent deviation for all responses was within 2%, and the convergence rate was also faster in BO as compared to that of other approaches. Therefore, it could be concluded that BO performs better than GA and CA based on convergence and accuracy.
- It is advisable to maintain mid-level of voltage and current, a minimum level of welding speed and maximum level of focusing distance to achieve the minimum weld cross section along with a desirable level of penetration and microhardness in weld zone during the electron beam welding of copper alloy.

Chapter 15
Effect of Pulsation on Temperature Distribution of Laser-Welded Dissimilar Joint of Thin Sheet

Bikash Kumar and Swarup Bag

Abstract Dissimilar joints are characterized by microstructural change and compositional gradient which evolve large variation in physical and mechanical properties across the welded joints. The combination of dissimilar material is challenging goal for development of parts with locally optimized parameter especially for Ti-SS joints. Due to high cost (like Ti-alloy), joining of dissimilar material (Ti-SS) helps to reduce the cost incurred by eliminating the otherwise unavoidable usage of costly and rare metal. The present study includes the pulsed laser welding of dissimilar joint of Ti-alloy and AISI 304. EDX analysis is performed on welded specimen for investigation of morphology attained by different zone. It is reported that fusion zone of dissimilar joint contains very fine-grained morphology because grains are not allowed to grow more at high heat input for shorter time span (pulsation). EDX analysis conveys the presence of intermetallic compounds which is majorly composed of Fe, Ti, and Cr. Cooling rate plays important role to determine microstructural variation. But it is difficult to measure it experimentally, so three-dimensional thermal model has been developed and validated with experimental result. Furthermore, average cooling rate is estimated for Ti and SS at different locations across the weld zone. Significant difference in thermo-physical properties like specific heat capacity and conductivity are major parameter due to which large difference has been found in the estimated cooling rate between Ti-alloy and stainless steel alloy at same location at same instant of time.

15.1 Introduction

Owning to massive difference in chemical and physical characteristics, welding of dissimilar metal configuration is, however, a challenging task. In order to seize the privilege of certain attributes of each component to enhance the potential of product, dissimilar welding is accomplished. Particularly, dissimilar joints of Ti-alloy and stainless steel are used in petrochemical, chemical, electronics, nuclear and power generation industries [1]. The application of different alloy and metal for components provides greater flexibility to the designer and production engineer and often results in economic and technical advantage over products manufactured from single material. Costly metal (i.e. Ti-alloy) with eminent properties (i.e. low density, high strength, corrosion resistance and lightweight) can be used in critical location with relatively cheaper material (i.e. steel alloy) in order to improve productivity, production flexibility, weld quality and manufacturing opportunity.

In agreement with Fe–Ti diagram, the solubility of iron (Fe) in titanium is very low at room temperature beyond which intermetallic phases (i.e. Fe_2Ti, FeTi) are accounted [2]. These intermetallic morphologies are brittle in nature and leads to spontaneous crack formation during conventional fusion-welded joint. Mismatching of stress generated by thermal cycle (i.e. thermal stress) between parent metal resembles crack formation. To resolve and minimize the undesirable issue arises due to application of conventional process, low energy input process i.e. laser welding process can be efficiently utilized. Rapid heating and cooling cycle, accurate weld bead position, precise and localized beam, process flexibility, low residual stress and distortion generation are its principle features. Therefore, laser beam process is effective tool to control the brittle intermetallic formation at some magnitude.

Unlike continuous, pulse mode welding is characterized by a series of overlapping spot weld. The resulting pulsed weld is one where subtle variations in the pulsing parameters can lead to dramatic differences in quality of weld [3]. However, continuous waved welding process is accomplished of quasi-steady-state temperature distribution during fusion. Modern Nd: YAG laser process has capacity to shape the flux profile for each pulse at wide range of frequency and introduction of several additional parameters like pulse shaping, pulse energy, pulse duration, average power, etc. Owing to its good coupling efficiency, more flexible beam delivery, particularly pulsed mode Nd: YAG laser is a more convenient process for thin sheet welding as compared to continuous mode of CO_2 laser [4]. A precise amount of beam power can be applied for a short period of time causing small heat-affected zone (HAZ) and low distortion is possible. For the same average power, pulsed Nd: YAG laser can provide comparatively much higher penetration than continuous mode.

Matsunawa et al. [5] reported that Ti-alloy is susceptible towards pore formation due to impingement of hydrogen and other gases in melt pool. To overcome this issue, researcher implemented overlapping factor in pulse mode welding process.

Besides, it is shown that the number of porosity can be minimized with increasing overlapping factor, and even defect-free weld joint could be possible for more than 75% overlapping factor [6]. Few literatures have been found which demonstrate and characterize dissimilar joint of Ti-SS alloy. Hiraga et al. [7] investigated lap welding of Ti and AISI 304 of thickness 0.5 mm with a pulsed Nd: YAG laser to produce vacuum container used as thermo bottles. It revealed that when AISI 304 is used as upper sheet, then joint could be produced within a narrow range of welding condition; however, when Ti is used as upper sheet, joint had been found within wide range. Chen et al. [8] examined the dissimilar joint of Ti-alloy and stainless steel (SS304) of thickness 1 mm by using CO_2 laser and characterized the impact of laser beam offset on the microstructural morphology and mechanical properties of joints. Offsetting of laser beam towards steel results more durable joint having intermetallic compounds like FeTi + α-Ti, FeTi + Fe_2Ti + $Ti_5Fe_{17}Cr_5$ but when laser beam was offset towards Ti-alloy, spontaneous fracture happened. It is also reported that tensile strength of joint was higher when laser beam was offset towards SS304. However, characterization of bead geometry found for dissimilar joint based on EDX analysis is still hazy.

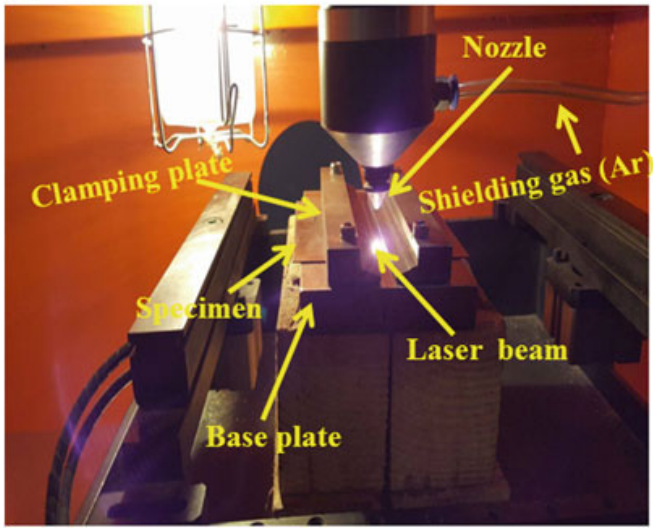
A number of FEM-based numerical models have been developed and investigated by different researcher for the simulation of temperature distribution [9, 10]. To determine the temperature distribution numerically by considering temperature-dependent domain properties and, latent heat of fusion and solidification, author has developed quasi-steady-state heat transfer model [11] for GTA welding. Moreover, the influence of welding velocity on double-ellipsoidal volumetric model has been suggested by another researcher [12]. However, effect of pulsation on the temperature distribution of dissimilar joint for thin sheet (thickness: 1 mm) by implementing volumetric heat source model is not focused so far.

The present study focuses on the primary investigation of experimentally observed macrostructural morphology and EDX analysis for dissimilar joint of Ti–6Al–4V alloy and AISI 304 alloy. Weld zone observed from experimental investigation has been compared with FEM-based 3D thermal (numerical) model. The influence of pulse-on temperature distribution during welding has been considered in the present analysis. Cooling rate plays important role for prediction of mechanical properties and evaluation of microstructure for laser welding process. So, based on numerically extracted temperature–time data, average cooling rate for different zones of each component (Ti-alloy and SS304) for post-welded samples have also been estimated. Furthermore, relation is established between microstructure evolved and cooling rate.

15.2 Experimental Investigation

The plate of 304 grade of stainless steel (60 × 50 × 1 mm^3) and Ti–6Al–4V alloy (60 × 50 × 1 mm^3) is chosen as specimen for pulsed Nd: YAG laser welding (capacity: 500 W) in butt joint configuration. Figure 15.1a depicts the welding

(a)



(b)

Process variable (optimized)	value
Peak power (kW)	1.8
Average power (W)	360
Pulse energy (J)	7.25
Heat input (J/mm)	80
Frequency (Hz)	50
Pulse width (ms)	4
Flow rate (L/min)	8
Weld speed (mm/s)	4.5
Offset distance (mm)	5

Fig. 15.1 **a** Schematic diagram of pulsed Nd: YAG laser welding set-up; **b** optimized parameter for dissimilar weld

set-up which is used to perform experiments. It is composed of fixed laser source, while the specimen along with fixture moves at a constant speed with auto-guided work table. The surfaces of specimens (i.e. Ti-alloy, SS304) are carefully pre-processed or polished to remove oxidized or coating layer and then clamped in fixture. As stable welding exists within a narrow range of parameter so heat input is considered as controlling parameter for present analysis to identify optimum process variables. Specimen is welded at an average power of 360 W with weld velocity of 4.5 mm/s (optimized parameter shown in Fig. 15.1b) for a constant pulse repetition rate of 50 Hz.

Welded specimens are cut across the welding line for metallographic analysis by using wire-electrodischarge machine (W-EDM) to avoid alteration of residual stress during cutting. Macro-graph of weld bead geometry is observed under upright optical microscope (*LEICA-S6D*). In order to investigate the morphology of joint and elemental composition, scanning electron microscope (SEM) outfitted with an energy dispersive X-ray spectroscopy (EDX) is used.

15.3 Theoretical Background

15.3.1 Thermal Analysis

A finite element (FE)-based three-dimensional heat transfer model for dissimilar laser welding has been developed by using ABAQUS commercial software. Temperature-dependent thermo-physical properties such as specific heat capacity, conductivity and constant density, latent heat of fusion are considered for the

simulation. A full-axisymmetric geometrical domain has been considered in which half geometry is assumed as Ti–6Al–4V alloy, whereas another half geometry is considered as stainless steel (304). Due to coherent and collimate nature of laser beam (spot dia. ~1 mm), the weld line is so narrow that suitably fine mesh is necessary to capture steep temperature. Thermal effects due to solidification of melt pool are simulated by considering the latent heat of fusion for both the material (Ti-alloy and SS). The temporal and spatial diversification of pulsed moving heat source is implemented through DFLUX user subroutine. The Gaussian form of heat flux is assumed over volume in such a way that flux density decreases in thickness (depth) direction and pulse attribute is also included over time domain. Double-ellipsoidal volumetric heat source model is considered for the real representation of laser beam [12]. For the inclusion of pulse characteristics, the temporal variation of flux intensity is assumed as 1 for pulse-on time and considered as 0 for pulse-off time. The average absorptivity of Ti-alloy and SS 304 are taken as 0.34 [13] and 0.17 [14], respectively. The nonlinear heat conduction equation based on energy conservation principle is given by

$$\rho_m C_p \left(\frac{\partial T}{\partial t} - V \frac{\partial T}{\partial x_1} \right) = \frac{\partial}{\partial x_i} \left(k_{ij} \frac{\partial T}{\partial x_j} \right) + h_g \tag{15.1}$$

where x_i for $i = 1, 2, 3$ represents x-, y- and z-axis, ρ_m is the density for Ti-alloy and stainless steel, T is the temperature, C_p is the specific heat, h_g is the internal heat generation or power generation under controlled volume, k_{ij} is the component of thermal conductivity and V is the welding velocity along x-axis. The boundary interaction associated with heat transfer between substrate and surrounding environment during fusion welding are implemented for the solution of conduction equation (shown in Fig. 15.2a).

a. Dirichlet boundary interaction, at time

$$t = 0, T(x, y, z, 0) = T_i \, 300 \text{ K} \tag{15.2}$$

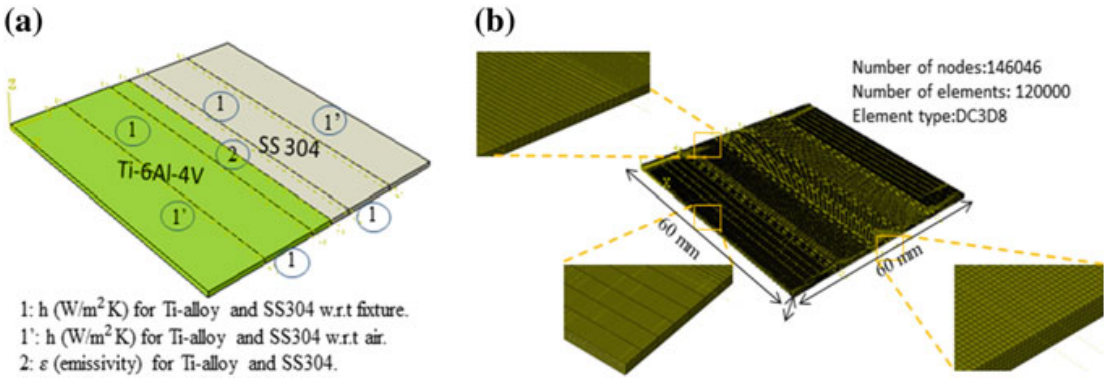


Fig. 15.2 **a** Thermal constraints for dissimilar modelling; **b** meshed geometrical configuration of thermal model

b. Neumann boundary condition; mathematically, heat interactions at all the surfaces can be expressed as

$$k_t \frac{\partial T}{\partial n} - q_f + \varepsilon_r \sigma_r \left(T^4 - T_i^4\right) + h_t (T - T_i) = 0 \tag{15.3}$$

where T_i is ambient temperature, k_t is isotropic thermal conductivity of the material, q_f is Gaussian distributed heat flux impinges on substrate, ε_r is the emissivity, σ_r denoted as Stefan–Boltzman constant (5.67×10^{-8} $\mathrm{Jm^{-2}\ s^{-1}\ K^{-4}}$), h_t is the convective heat transfer coefficient between workpiece and ambient surrounding.

The geometrical configuration of dissimilar welded joints with optimum uniform mesh discretization at fusion zone (FZ) and non-uniform meshing at far away distance for each component is shown in Fig. 15.2b.

15.4 Result and Discussions

15.4.1 EDS Analysis

Energy dispersive X-ray (EDX) spectroscopic analysis is performed to determine the elemental distribution and EDX-based scanning electron microscopic (SEM) investigation is carried to understand morphology attained by dissimilar joint of Ti-SS component. Figure 15.3 shows SEM images of different zones of welded specimen. Figure 15.3a depicts the fusion zone (FZ) which is composed of very fine-grained morphology and its grain boundary. Several small pores are also visible on the surface of grain is due to inclusion of hydrogen gas entrapment at high temperature in Ti-alloy. However, basic microstructure of austenitic stainless (304) is consists of equiaxed, austenitic twinned structure as shown in Fig. 15.3b. The austenitic structure completely transformed into delta ferrite upon heating. During welding, the liquid phase is nucleated at triple networks and grain boundary depending upon interface energy at solidus temperature. Upon further heating, the liquid phase is distributed along the grain boundary and generates a continuous junction along the grain edge as clearly visible in Fig. 15.3a.

Due to pulse phenomena, components experience higher temperature for very small interval of time due to which weld pool lasts for short duration at fusion zone. As time spent by the substrate at high temperature domain decreases, grains are not allowed to grow more during cooling which resembles very fine-grained microstructure in FZ. EDS analysis as spectrum 12 (as shown in Fig. 15.4) confirms that fusion zone is majorly composed of elements like Fe (55%), Cr (15%), C (12%), Ti (6%) and Ni (6%). There is possibility that these elements form intermetallic compound like FeTi + Fe_2Ti + $Ti_5Fe_{17}Cr_5$ + Ni_3Ti and some form of

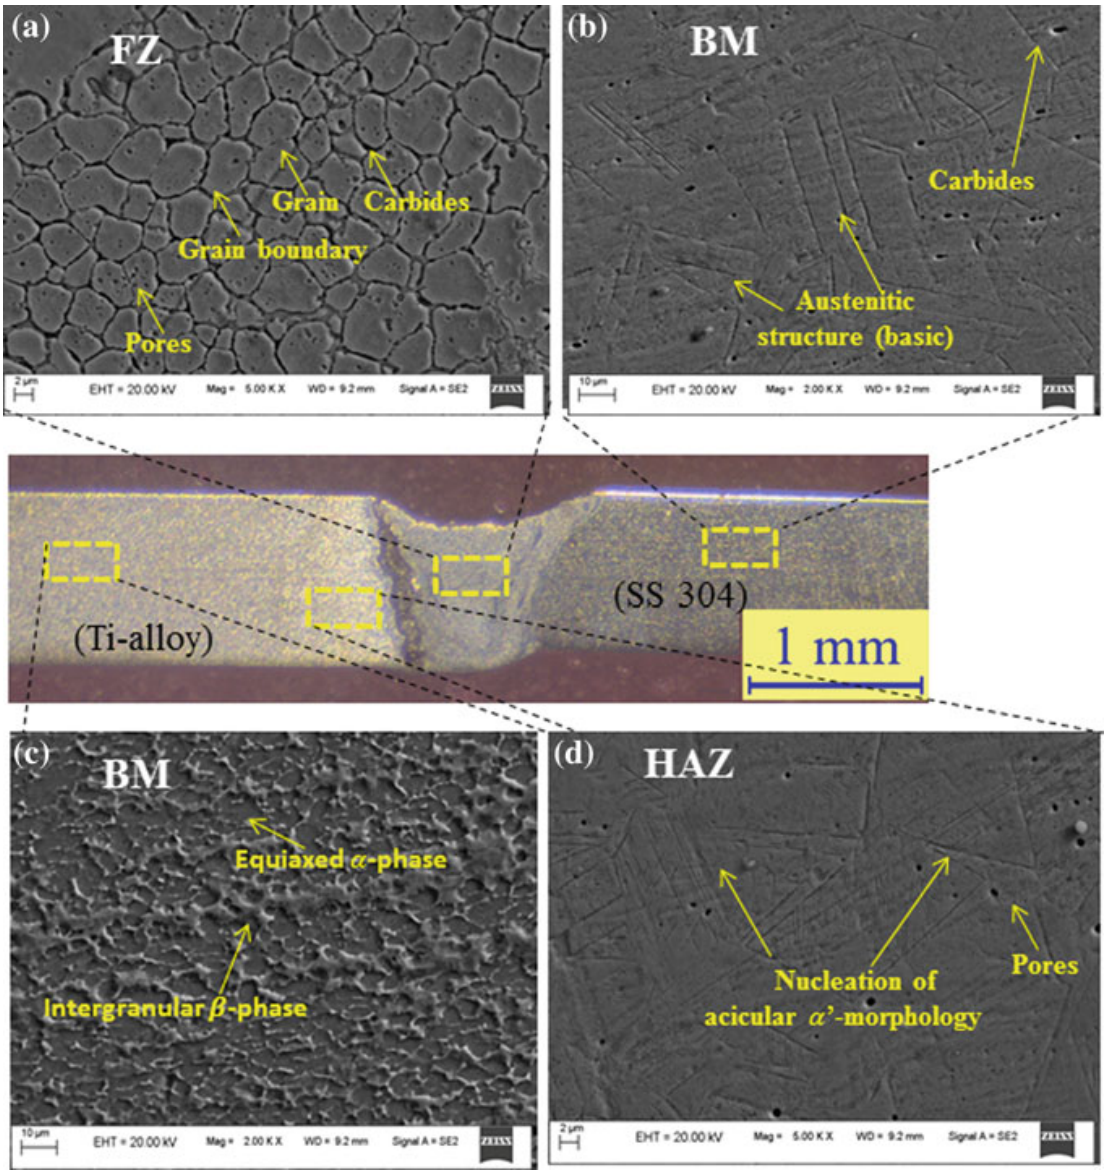

Fig. 15.3 SEM image of **a** FZ; **b** base material (stainless steel); **c** base material (Ti-alloy); **d** HAZ (Ti-alloy)

carbides due to diffusion of Ti-alloy with SS 304 at elevated temperature. Figure 15.3c depicts the basic microstructure of Ti–6Al–4V, consists of equiaxed α-phase (dark region) and line-like white region (light region) as intergranular β-phase. Figure 15.3d signifies the heat-affected zone at the verge of molten zone at Ti-side which clarifies the nucleation of acicular type α' brittle martensitic microstructure.

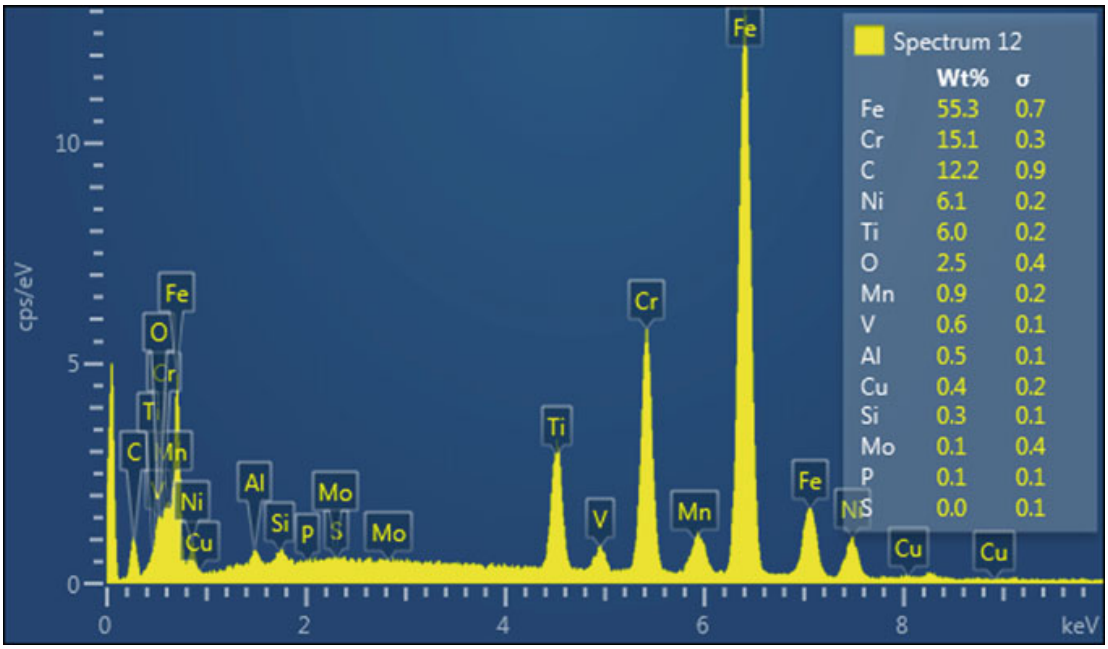

Fig. 15.4 EDS-based spectrum for fusion zone (FZ) of dissimilar weld joint

15.4.2 Numerical Result

FEM-based three-dimensional thermal modelling is undertaken to predict weld bead geometry and to study variation in nodal temperature in both components of dissimilar weld during pulsed laser welding. The numerical simulation of temperature distribution is carried out corresponding to welding speed 4.5 mm/s and average power of 360 W for the heat input of 80 J/mm. Figure 15.5a manifests the comparison between experimental and numerical weld bead profile for dissimilar joint of Ti-alloy and AISI 304. It reveals that macrostructural characteristics (weld bead profile, HAZ) of simulated domain are of similar pattern as anticipated by experimental result. Heat affected a zone which manifests solid-state phase transformation represented by region between blue and yellow colour band, mushy zones are characterized by liquidus (Ti-alloy $\sim$ 1933 K; SS $\sim$ 1723 K) and solidus temperature (Ti-alloy $\sim$ 1877 K; SS $\sim$ 1673 K) is designated as yellow band, whereas FZ is represented by red colour layer for both components. The contour plot of spatial and temporal movement of heat flux in pulsed off and on condition is expressed in Fig. 15.5b. It shows that the red colour band is only visible in pulse-on condition due to attainment of higher temperature for short period which is attributed to entrapment of direct laser beam on the substrate. Experimentally obtained bead profile reveals that the evaporation phenomena also involved for the present optimized process parameter. However, numerical result did not exhibit evaporation occurrence since the maximum temperature attained here is well below of boiling temperature (3500 K). Therefore, it can conclude that conduction mode of welding is prevailing over keyhole model for developed thermal model.

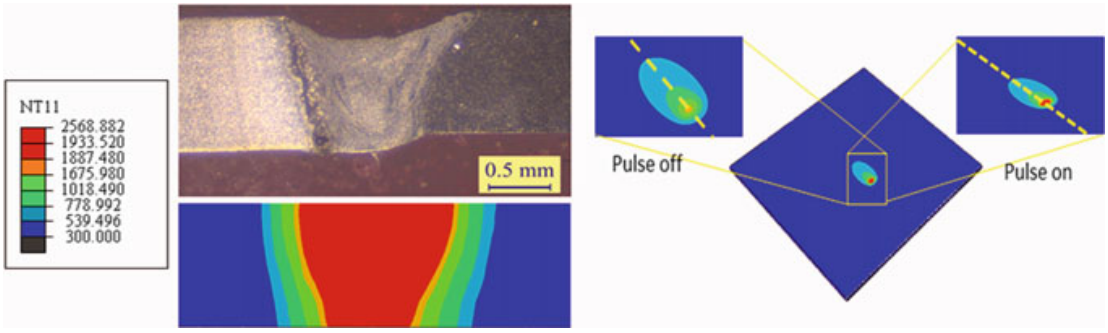

Fig. 15.5 **a** Comparison of experimental and numerical weld bead profile; **b** contour plot of spatial movement of laser bear at pulse-on condition and pulse-off condition

Figure 15.6 depicts the temperature–time variation in Ti-alloy and stainless steel part during pulsed welding. It shows the needle-type structure at peak temperature for both materials. Pulse-on and pulse-off appearances lead to instantaneous temperature gradient at weld line or at closer distance from weld line which is attributed to formation of peak and valley for very short time duration. It is obvious from the figure that peak and valley existence gradually decreases away from the weld line for both the material. Figure 15.6a reveals the attained temperature across the weld line for Ti-alloy side while on stainless steel side is shown in Fig. 15.6b. For both cases, achieved temperature is gradually decreasing as the distance increases from the weld line, and this is due to the fact that at weld line, substrate is in direct contact with laser beam; however, as the distance increases, less amount of heat conduction occurs across the molten zone.

The temperature attained by Ti-alloy is about 2350 K at 0.5 mm distance of weld line, whereas SS 304 achieved 2000 K at same distance across the weld line. The higher diffusive heat transfer coefficient and absorptivity of Ti-alloy as compared with SS304 resemble higher amount of heat diffusion throughout the surface unlike stainless steel. Figure 15.7a conveys that temperature distribution in the

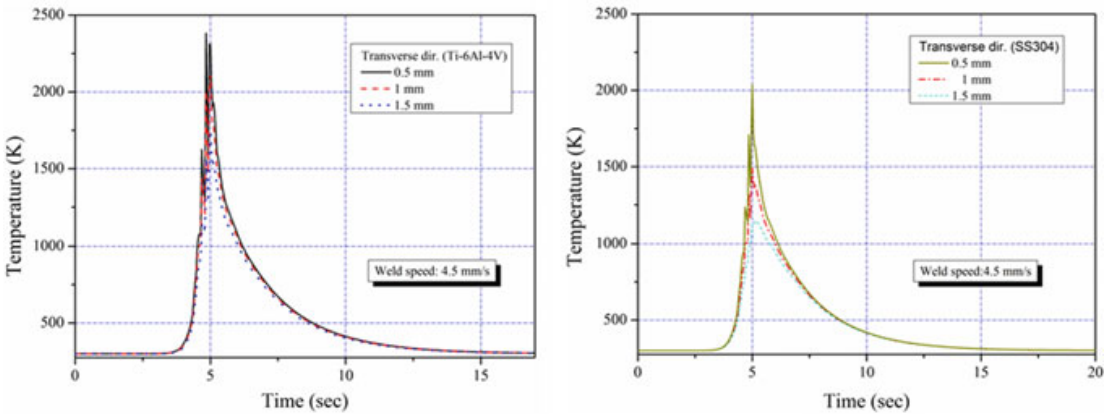

Fig. 15.6 Temperature distribution at different location across the weld zone, **a** Ti–6Al–4V alloy; **b** SS 304

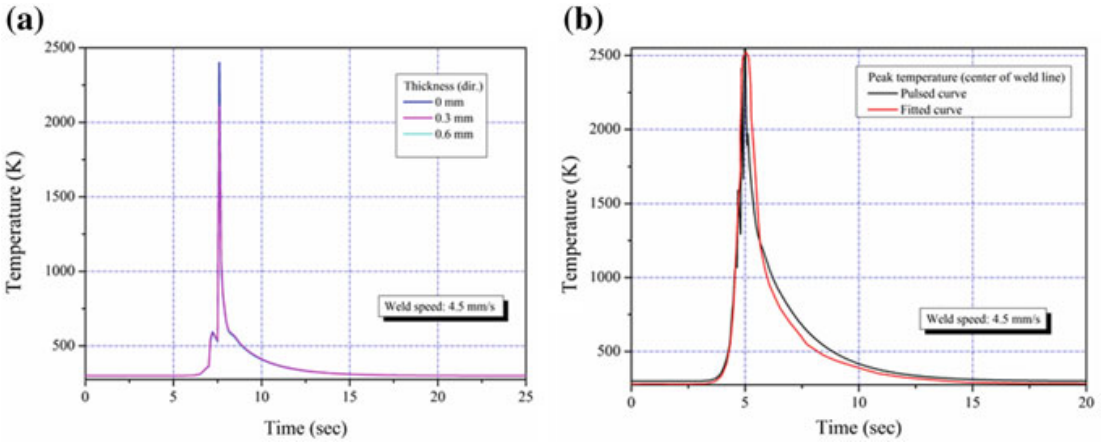

Fig. 15.7 **a** Temperature profile in thickness direction at weld line; **b** temperature profile obtained at mid of weld line in pulsed condition and fitted curve by Gaussian function

component in thickness direction at centre point of weld pool. At the top of the surface, attained temperature is the same as that of peak temperature ($\sim$2500 K). Drop of the temperature throughout the thickness is very low up to 0.5 mm thereafter it increases but not so much because of the thinness of the weldments.

15.4.3 Cooling Rate Estimation

Researchers have already described that cooling rate corresponding to laser welding of thin sheet plays significant role for the prediction of different microstructures attained by weldments and its associated mechanical properties. Senkov et al. [15] investigated the effect of controlled cooling rate on the morphology and mechanical properties of Ti-alloy. The weld thermal cycle mainly consists of continuous heating and followed by cooling it up to ambient environment. It is unsuitable or crucial to determine the attained temperature–time history during welding at fusion zone due to involvement of melting phenomena. Hence, simulation-based time–temperature data are implemented for the estimation of cooling rate at different location of both components of weldments.

In the present work, pulsed mode of welding is considered for the investigation so the temperature profile exhibits instantaneous temperature variation with respect to time at higher temperature. For the sake of simplicity, the achieved temperature profile at weld zone is curve fitted by using Gaussian basic function which provided satisfactory continuous curve. Fitted continuous curve is implemented for the calculation of cooling rate in the present study as depicted in Fig. 15.7b. The temperature at which remarkable phase transformation occurs during cooling cycle is considered for the estimation of cooling rate here. Kumar et al. [16] reported the alpha-dissolution and beta-transus temperature for the dual-phase Ti-alloy as 940 and 1275 K. Mathematical formulation for the estimation of cooling rate is also

revealed in the literature. The phase transformation temperature range for stainless steel is assumed as 773 and 1073 K.

Figure 15.8 shows the temperature distribution at different location across the weld line within assumed phase transformation temperature range for Ti–6Al–4V and steel alloy. These curves reveal that temperature profile within this range is approximately linear for both components. Therefore, it is obvious that slope of these curve can predict fairly accurate average cooling rate. Figure 15.8a depicts that the time spent for the attainment of phase transformation temperature at a distance of 0.5 mm (closer to weld line) is comparatively more than (i.e. 1.4 s) that of 1 mm or 1.5 mm across the weld line for steel alloy. Due to direct contact of weld line with heat flux, nearby region of fusion zone experiences high heat input which sustain weld pool for comparatively longer period of time. Therefore, it takes higher solidification time. Hence, average cooling rate is lower (i.e. 220 K/s) at this location, and at 1 and 1.5 mm location, cooling rate are 258 and 277 K/s, respectively.

Figure 15.8b conveys the temperature distribution within alpha-dissolution temperature and beta-transus temperature range for Ti-alloy. It shows that 0.84 s of total time is elapsed for the attainment of phase transformation temperature at the location of 0.5 mm across the weld centre while somewhat less time is taken at the location of 1 and 1.5 mm across the weld line. So, the estimated cooling rate at closer (weld line) distance is comparatively less (i.e. 398 K/s), whereas cooling rate attained at 1 and 1.5 mm distance are 420, 424 K/s, respectively.

It is observed that the estimated cooling rate at same location of two different materials is having remarkable difference, i.e. 220 K/s for stainless steel and 398 K/s for Ti–6Al–4V at 0.5 mm distance from weld centre. Because, cooling rate eminently associated with the thermal behaviour of material. Accomplishment of temperature depends upon the thermo-physical properties like specific heat, diffusion coefficient, thermal conductivity, etc. So, it can deduce that significant difference in these properties of Ti-alloy and SS 304 is responsible for great difference in cooling rate.

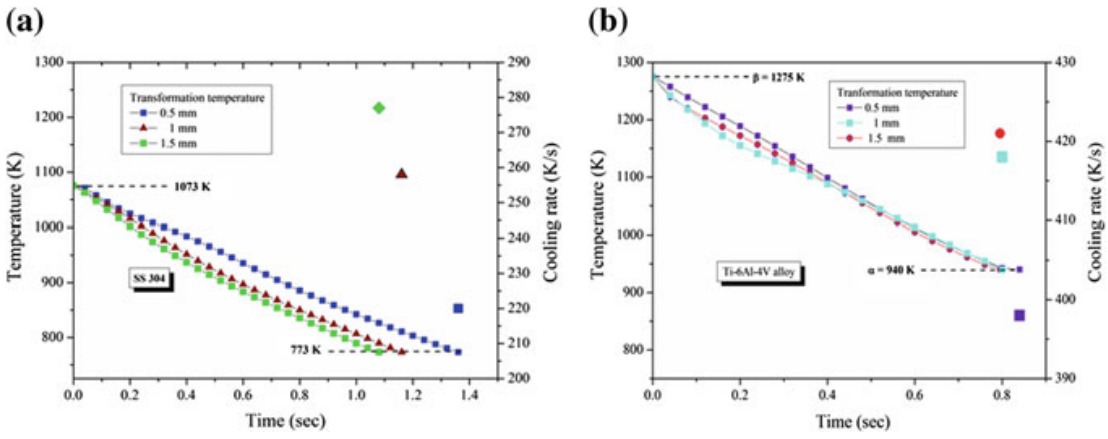

Fig. 15.8 Temperature profile within the range of phase transformation and cooling rate, **a** stainless Steel 304; **b** Ti–6Al–4V alloy

It is already reported in the literature that microstructural evolution can be determined with the help of appropriate cooling rate calculation. It is well established fact that 400 K/s is critical cooling rate for dual-phase Ti-alloy, up to which massive diffusional nucleated secondary lamellar structure can be obtained and beyond which hexagonal acicular α' martensitic structure is possible. Widmanstatten weave-basket-like morphology can be produced at very low cooling rate in dual-phase Ti-alloy. EDS analysis reveals that the nucleation of acicular α' martensitic structure (Fig. 15.3d) has been found at heat-affected zone (nearby region of fusion zone) and it is also observed that the estimated cooling rate at HAZ location is approximately 420 K/s which is well higher that critical cooling rate as reported in the literature. Therefore, it can be concluded that the estimated average cooling rate based on numerical model is fair and accurate and showing good agreement with experimentally observed morphology in the present study.

15.5 Conclusion

Pulsed laser butt welding of titanium alloy to stainless steel has been performed at optimized process variable. EDS-based morphological study and FEM-based temperature distribution have been studied in the present work. Based on this study, conclusions are summarized as following:

- After solidification of weld zone, fine-grained morphology is revealed. Because, due to pulsation effect, high temperature attained at weld zone is only for small period of time that lasts weld pool for shorter period. So, nucleated grain during re-solidification from liquid to solid phase is not allowed to grow more, whereas nucleated acicular α' martensitic structure is observed in HAZ of Ti-alloy side.
- Energy dispersive X-ray (EDX) spectroscopic analysis confirms that FZ majorly contains Fe, Cr, C and Ti elements that resemble formation of intermetallic compound like FeTi + Fe_2Ti + $Ti_5Fe_{17}Cr_5$ + Ni_3Ti during fusion of both components (Ti-alloy and SS 304) at high temperature.
- Good agreement has been observed between experimentally and numerically welds bead profile. However, evaporation of material at top surface is clearly shown in experimental result but attained maximum temperature of weld zone is well below the boiling temperature so an evaporation phenomenon is neglected in 3D modelling.
- The maximum temperature attained at Ti-side is higher than that of stainless steel side. Significant difference in diffusion coefficient and absorptivity is the possible reason for the same.
- As it is difficult to measure temperature–time data at weld zone experimentally, so cooling rate is estimated at different location (i.e. at a distance of 0.5, 1 and 1.5 mm across the weld line) by using numerical simulated result. Maximum cooling rate has been found at 1.5 mm distance for both of the components of weldments, i.e. 424 K/s for Ti-alloy and 277 K/s for stainless steel.

- It is revealed that remarkable difference in thermo-physical properties such as specific heat capacity, conductivity, diffusivity, etc. are the feasible reason for the large difference in cooling rate of both of the material at the same location.
- Estimated average cooling rate for HAZ of Ti-alloy has predicted similar type of morphology as observed in experimental investigation and also reported by the other researchers.

Chapter 16
Activated TIG Welding of AISI 321 Austenitic Stainless Steel for Predicting Parametric Influences on Weld Strength of Tensile Test—Experimental and Finite Element Method Approach

S. Mohan Kumar, N. Siva Shanmugam and K. Sankaranarayanasamy

Abstract Tungsten inert gas (TIG) welding is the most common manufacturing process used to join materials like stainless steel, titanium and aluminium alloys due to their high-quality and inexpensive welds. Furthermore, the difficulty in welding plates having a thickness of 4 mm or more is overcome by employing activated TIG (A-TIG) welding process which uses an activating flux for high depth of penetration in a single pass. Uni-axial tensile test is conducted to assess the tensile strength of the material by experimentation. In this study, a uni-axial tensile test of base metal (BM) and weld metal (WM) samples are simulated using ABAQUS to evaluate the accuracy of finite element (FE) simulation results with the experimental results for predicting the tensile strength. The results show that the stress–strain values predicted by the FE analysis agree with experimental results. Also, the fracture behaviour of experimentation and FE simulation is identical with ductile mode of fracture. The fracture location of the sample in FE analysis is found very similar to experimental fractured samples. The results of ferrite measurement indicate that concentration of delta-ferrite in the WM (5.9 FN) is higher than BM (1.2 FN) content and show better mechanical behaviour in the A-TIG weldments. Also, scanning electron microscope (SEM) shows that the failure of BM and WM resembled to ductile mode-type fracture.

16.1 Introduction

AISI 321 material has excellent resistance to corrosion [1]. Widely used in automotive industries, jet aircraft components, welded pressure vessels in the defence sector and high-speed impact on firewalls, the encounter of static and dynamics loads on AISI 321 is a common problem. The demand for the controlled weld shape and deeper penetration in TIG welding led to the novel modification of the well-known TIG process, called as A-TIG welding. A-TIG welding was introduced during the 1960s by the E.O. Paton Institute of Electric Welding [2]. The A-TIG joining process uses a thin layer of flux which is spread over the welding region before welding [3]. Tensile testing provides engineers with a wealth of data about the mechanical behaviour of the metals, elastic modulus, tensile strength, yield strength, the percentage of elongation and the stress–strain relationship of the materials. Hence, it is essential to understand the mechanical behaviour and metallurgical aspects that affect the results of the tensile test [4]. Reisgen et al. [5] conducted an FE analysis of uni-axial tensile test to evaluate the tensile strength of laser-welded TRIP700 steel sheet. Garcia-Garino et al. [6] carried out an FE simulation of tensile test for a metal specimen and found good agreement with the analytical and experimental results. Patel et al. [7] studied the effect of activated fluxes like SiO_2 and TiO_2 on the mechanical behaviour of AISI 321 using the TIG welding. However, research works related to FE simulation of tensile test of A-TIG-welded samples are few. Hence, in the present study, tensile test was carried out on base- and A-TIG-welded butt joint of AISI 321 and compared with the experimental and FE analysis results for validation.

16.2 Experimentation Procedure

Bead on plate trials is performed to choose optimum welding parameter. Selection of perfect welding current, arc length and welding speed defines the requirement of the good weld bead. The material selection in the present study is commercially available type AISI 321 austenitic stainless steel. Tables 16.1 and 16.2 show the chemical composition and the physical properties of AISI 321, respectively. Welding equipment model Fronius MagicWave 4000 is used for joining AISI 321 with experimental set-up shown in Fig. 16.1. Particularly during A-TIG joining process, a very thin film of activating flux is painted to the material top surface

before joining so as to increase the depth of penetration (DOP). Based on our previous study [8], the commercial Edison Welding Institute (EWI) flux is used in this work, and corresponding ingredients of activated flux are shown in Table 16.3. This increase in DOP is attributed to the mechanisms of arc constriction and Marangoni reversal flow. Before joining the AISI 321 plate of 6 mm thickness was cut into strips of 100 × 100 mm and roughly polished with sheets of silicon carbide to remove the impurities in surface and further scrubbed with acetone. The input weld parameters selected after examinations from the trials of the bead on the plate are shown in Table 16.4. Figure 16.2 represents the welded plate with butt joint configuration. Further, Fig. 16.2b shows the macrostructure of the butt joint with achieved full depth of penetration. The sample for the tensile test is cut from the plate specimen following ASTM E8/E8M-16a standard as shown in Fig. 16.2c.

16.3 Results and Discussion

16.3.1 Experimental and FE Simulation of the Tensile Test

The AISI 321 tensile specimens of BM and WM were prepared as per standard. The wire-cut EDM process was used to section the specimens. Tensile tests were carried out using Tinius Olsen 50 KN load cell at room temperature with a loading rate of 1 mm/min until failure.

FE analysis of tensile test was performed using ABAQUS—a commercial available FE analysis software. Brief illustration of FEM procedure is shown in Fig. 16.3. The part was modelled in ABAQUS, and physical material properties such as density, Young's modulus and Poisson's ratio assigned are 8090 kg/m^3,

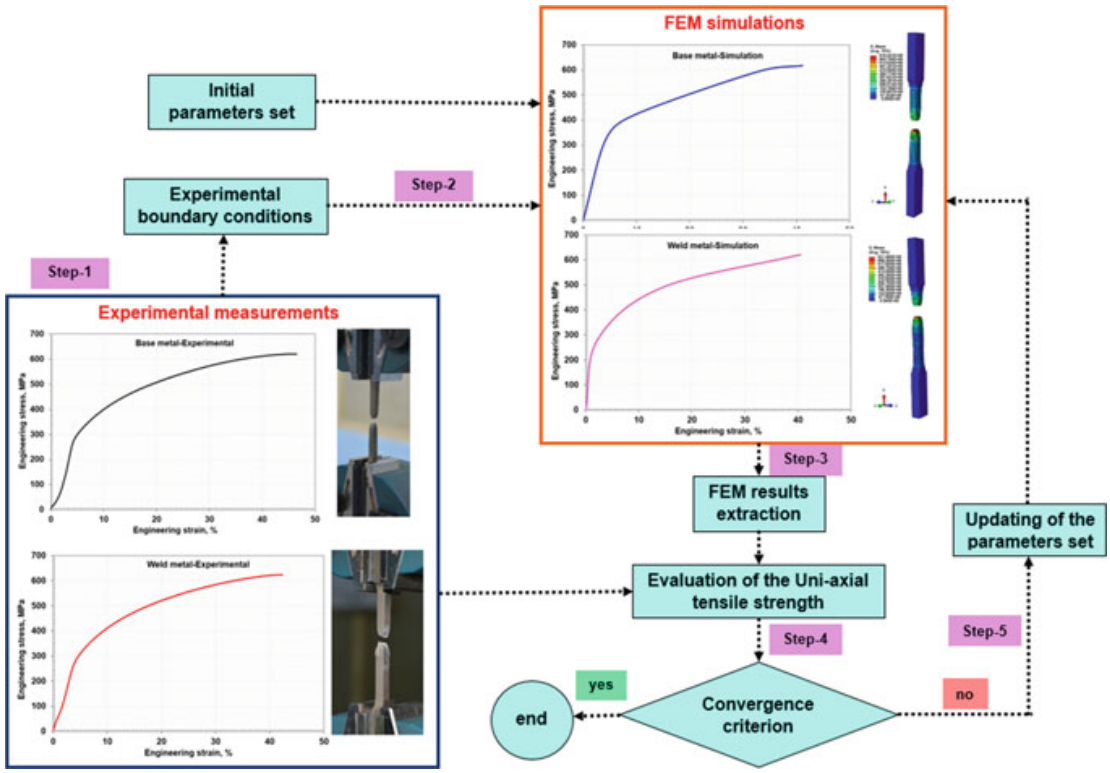

Fig. 16.3 Flow chart of FE method for uni-axial tensile test

Table 16.5 Tensile properties of AISI 321

Part	Yield stress (MPa)	Yield strain (%)	Tensile stress (MPa)	Tensile strain (%)
BM	213	3.536	621	46.56
WM	215	3.088	624	42.4

193 GPa and 0.3, respectively. From uni-axial tensile test, mechanical properties obtained for BM and WM specimens are assigned for plasticity as shown in Table 16.5.

The dynamic explicit analysis was conducted in consideration of nonlinear geometry. Suitable damage material model is necessary to initiate fracture and subsequent failure in the FE model. It is assumed that the material behaviour is isotropic. Hence, the Johnson–Cook model is utilized for analysing the failure. Johnson–Cook (JC) material model is one such model used in the present analysis for material failure, considering the effects of pressure, temperature, equivalent stress and strain rate. JC model's damage parameters assigned for ductile damage in AISI 321 are shown in Table 16.8 [9]. Based on the critical literature review, it is understood that the behaviour of both AISI 316L and AISI 321 austenitic grade stainless steels is almost same. For confirming the similarity in mechanical properties, a uni-axial tensile test has been conducted for both AISI 316L and AISI 321. From the uni-axial tensile test results (Fig. 16.4), the following data are extracted,

Table 16.6 Uni-axial tensile test results of AISI 321 and AISI 316L

Material name	Yield stress (MPa)	Tensile stress (MPa)	Tensile strain (%)
AISI 321	213	621	46.56
AISI 316L	208	594	40.96

Table 16.7 Physical properties

Material name	Density (kg/m^3)	Young's modulus (GPa)
AISI 321	8090	193
AISI 316L	8000	193

Table 16.8 JC damage parameters assigned for AISI 321

D1	D2	D3	D4	D5
0.05	3.44	2.12	0.002	0.61

and the same have been presented in Table 16.6. The density and Young's modulus are also similar in nature (refer Table 16.7).

Owing to the similarities between the two grades of ASS, the JC damage parameters of AISI 316L material are utilized in the present study for performing the tensile test simulation of AISI 321.

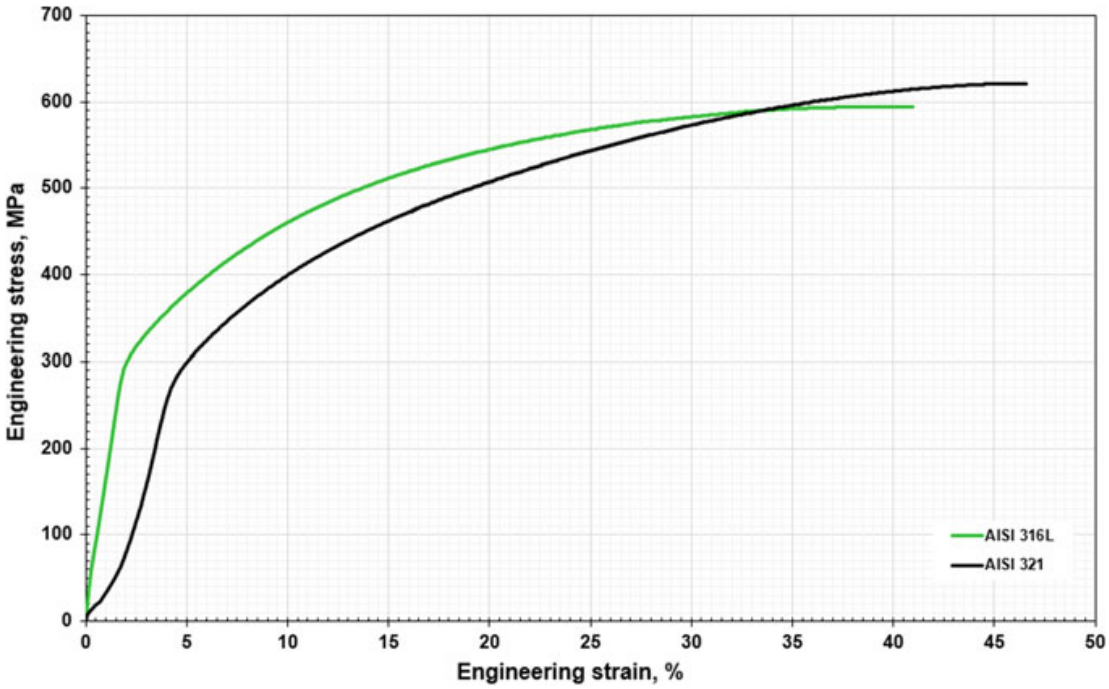

Fig. 16.4 Stress-versus-strain plot for AISI 321 and AISI 316L

The predicted results from the simulation of the uni-axial tensile test also confirm with an error % of 0.51 and 0.48 for BM and WM of AISI 321 steel in comparison with experimental tensile test. JC material model is mathematically expressed by Eqs. 16.1 and 16.2.

The failure is expected when parameter $D = 1$

$$D = \sum \frac{\Delta\varepsilon}{\varepsilon_f} \tag{16.1}$$

$$\bar{\varepsilon}_f = [D_1 + D_2 \exp D_3\sigma^*][1 + D_4 \ln \dot{\varepsilon}^*][1 + D_5 T^*] \tag{16.2}$$

where

$\Delta\varepsilon$ is the increment of effective plastic strain during an increment in loading.
$\bar{\varepsilon}_f$ is the equivalent strain to fracture.
$\dot{\varepsilon}^*$ is the dimensionless strain rate.
T^* is the homologous temperature.
σ^* is the average of the three normal stresses to the von Mises equivalent stress assumed $\sigma^* \leq 1.5$.
D_1, D_2, D_3, D_4 and D_5 are material-dependent constants.

The experimental setting provides boundary conditions for the tensile specimen. One end of the specimen is ENCASTERED (U1 = U2 = U3 = UR1 = UR2 = UR3 = 0), where movement is restricted in all degrees of freedom, while another end is allowed to move in the X-direction for BM and WM (refer Fig. 16.5a, b).

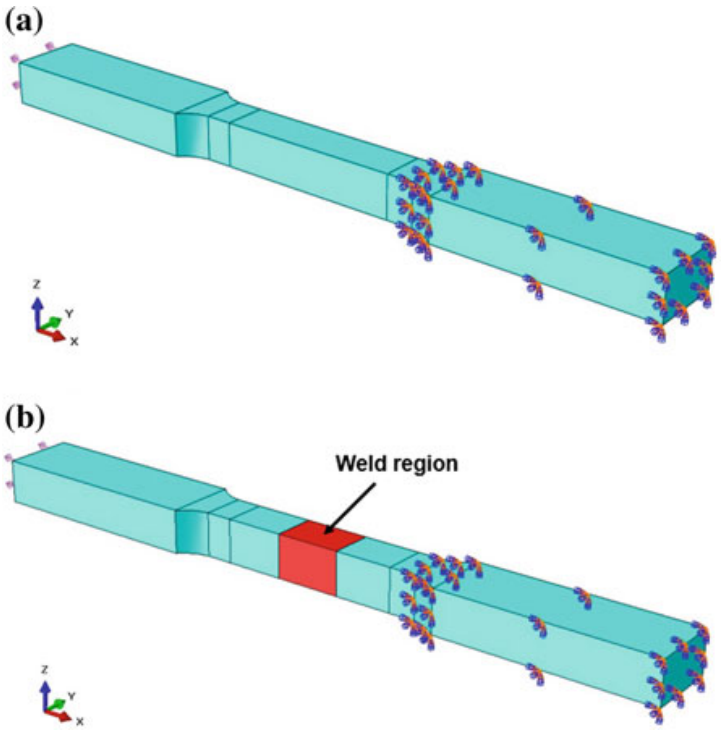

Fig. 16.5 Boundary conditions for the modelled tensile test specimens, **a** BM and **b** WM

Table 16.9 Meshing parameters used for uni-axial tensile test simulation

Part	Shape of element	Meshing technique	Elements generated	Element type
BM and WM	Hexagonal	Structured	6672	C3D8R (an eight-node linear brick, reduced integration with hourglass control)

The meshing of the model is conducted by employing fine mesh at the gauge length section and coarse mesh at the gripping section (to reduce the computational time) as results are expected only at gauge length section. The parameters used for meshing in FE analysis are shown in Table 16.9. Further, the meshed tensile test model of BM and WM is described in Fig. 16.6a, b separately.

Figure 16.7a shows the experimental tensile test depicting the fracture behaviour of the BM. Similarly, a tensile test conducted using the FE model is shown in Fig. 16.7b with a subsequent fracture. A good match can be observed in fracture at the centre of the specimen in both the analyses. Also, the fracture behaviour of the BM and WM samples was observed with the ductile mode of fracture and found similar with FE analysis as shown in Figs. 16.8 and 16.10. Likewise, for WM, the fracture region obtained after performing experimental and FE analysis is shown in Fig. 16.9a, b, respectively. From our earlier investigations [8], the mechanical properties of HAZ were better than the BM using A-TIG process. From the results

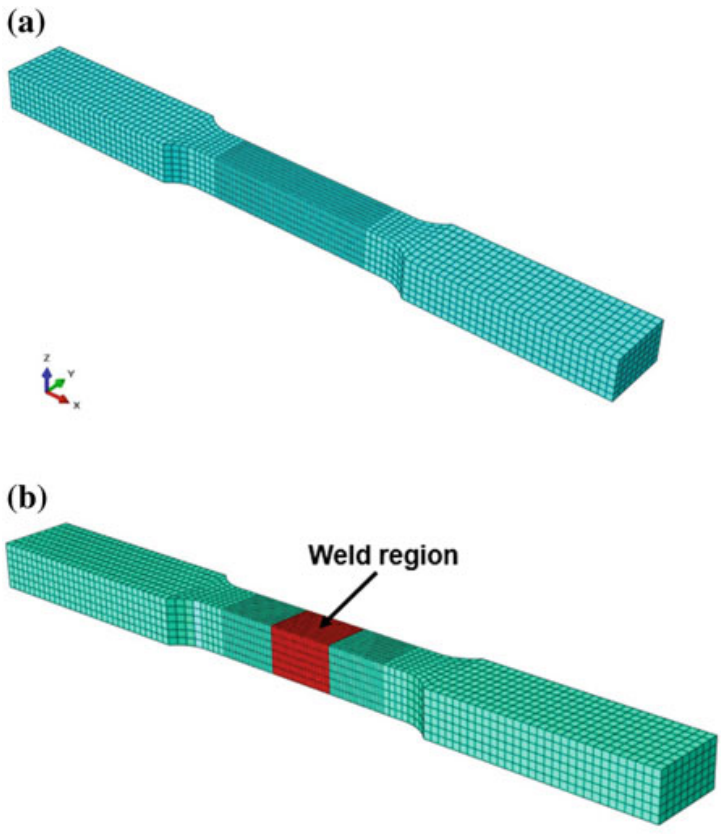

Fig. 16.6 Modelled tensile test specimens with mesh, **a** BM and **b** WM

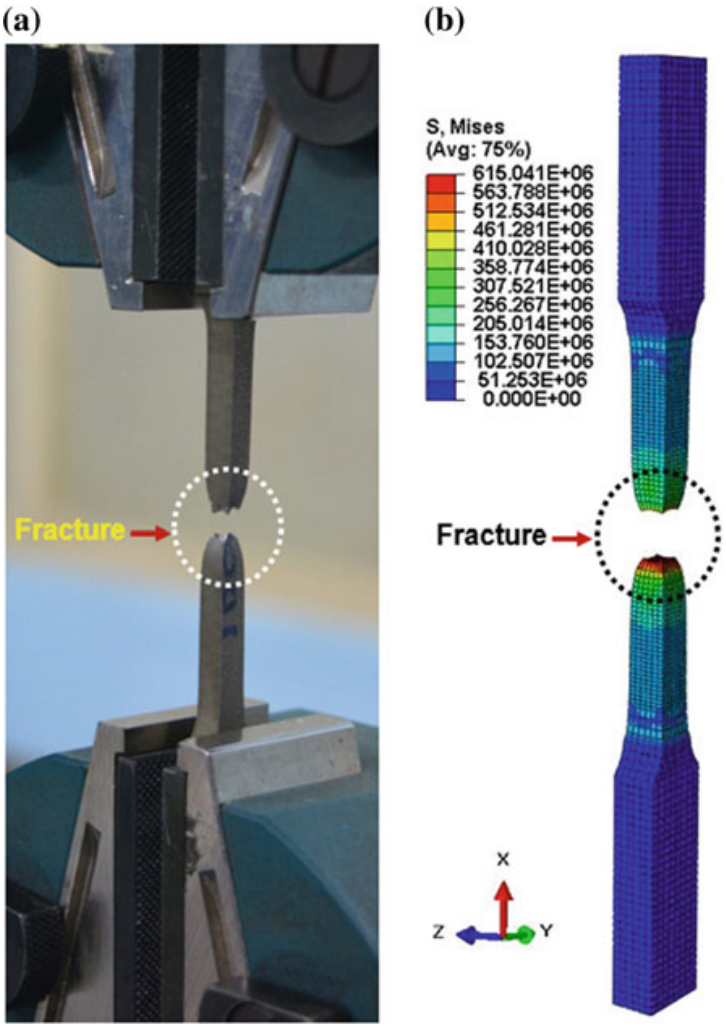

Fig. 16.7 Comparison of the BM tensile test between experimental (**a**) and FE analysis (**b**)

of uni-axial tensile test on both BM and WM, it is evident that the fracture occurred in the BM regions. Hence, the effect of heat-affected zone in the FE simulation is not considered. Excellent agreement is revealed through visual comparison as fracture occurred always in the BM, i.e. ductile mode of failure as shown in Fig. 16.10 between experimental and FE analysis.

The stress–strain curves determined from the tensile test are shown in Fig. 16.11. The tensile strength for the BM and WM tested experimentally at 621 and 624 MPa, respectively, while the FE simulation tensile strength for the BM and WM is 617.8 and 621 MPa, respectively. Table 16.10 presents the tensile strength and the crack position for BM and WM specimens. It was observed that welded specimen has slightly higher tensile strength compared to base, and percentage of elongation of weld specimen decreased considerably when compared to the BM specimen in experimental and FE analysis. From Table 16.10, it is evident that excellent result is obtained in terms of tensile strength for base and weld metal with the percentage of error 0.51 and 0.48%, respectively. Results of ferrite measurement (Fischer FERITSCOPE FMP30) in BM and WM zones of AISI 321 are 1.2 and 5.9 FN, respectively. It is confirmed that the increase in tensile strength and decrease in

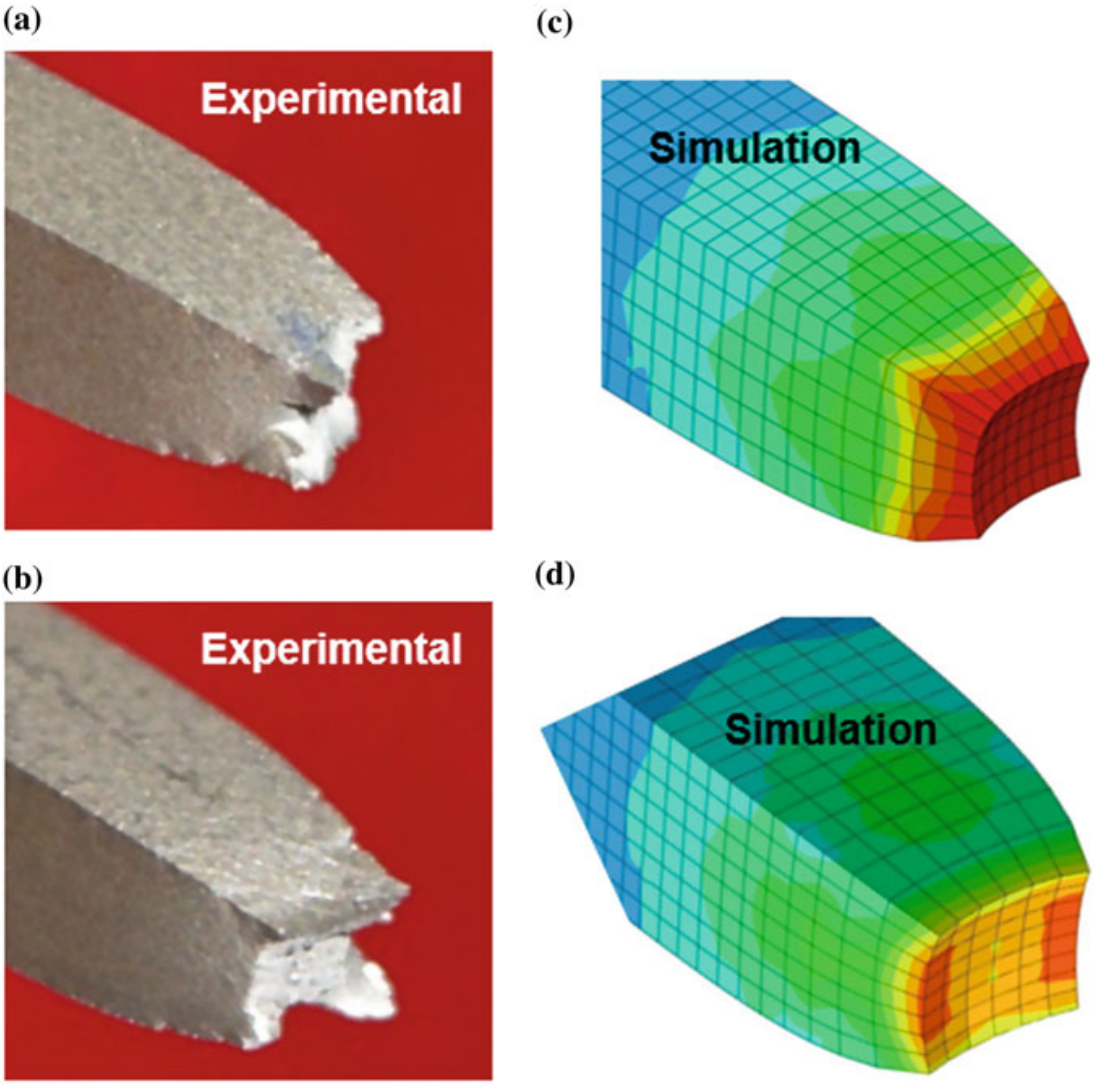

Fig. 16.8 Comparison of BM tensile test fracture surface mode between experimental (**a** and **b**) and FE analysis (**c** and **d**)

ductility are attributed to the hike in the delta-ferrite content. The tensile test results can corroborate that the A-TIG WM tensile strength is better than BM [10]. The experimental and FE simulation joint efficiency of the WM is 101.1 and 100.51%, respectively. The fractured specimens also showed a ductile fracture.

16.3.2 Fractography Examination

The fractured tensile specimen is cleaned ultrasonically and examined using SEM [11]. The tensile strength of the WM is higher than that of the BM only due to the influence of the welding heat input leading to rearrangement of the molecular orientation. Further, as is clear from Figs. 16.12 and 16.13, it has characteristics

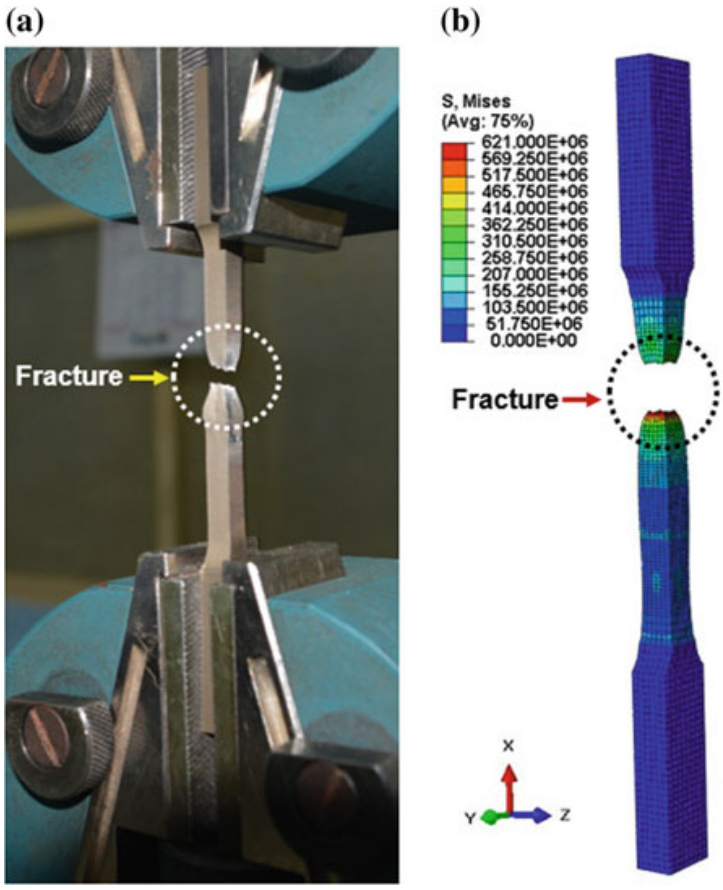

Fig. 16.9 Comparison of the WM tensile test between experimental (**a**) and FE analysis (**b**)

similar to those of the BM and the WM. It is understood from the fracture surface of the WM sample that there are microvoids and fine dimples as compared with the BM and such fine dimples contribute to the improvement of the load-carrying capacity of the WM. Also, on the fractured surface of the WM and the BM, it has similar characteristics, that is, the evolution of a honeycomb structure with voids and dimples confirming the ductile failure.

16.4 Conclusions

The following most important inferences are summarized from the current study.

- A-TIG welding was performed on AISI 321 with optimal input parameters achieving good depth of penetration and bead width for butt joint configuration.
- Experimental tests performed on BM and WM were evaluated for mechanical strength. The uni-axial tensile test showed higher strength for WM—624 MPa compared to BM—621 MPa. The increase in weld strength and reduction in ductility are due to the increase in the delta-ferrite content.
- The prediction by FE analysis was observed with a tensile strength of 621 and 617.8 MPa for WM and BM, respectively.

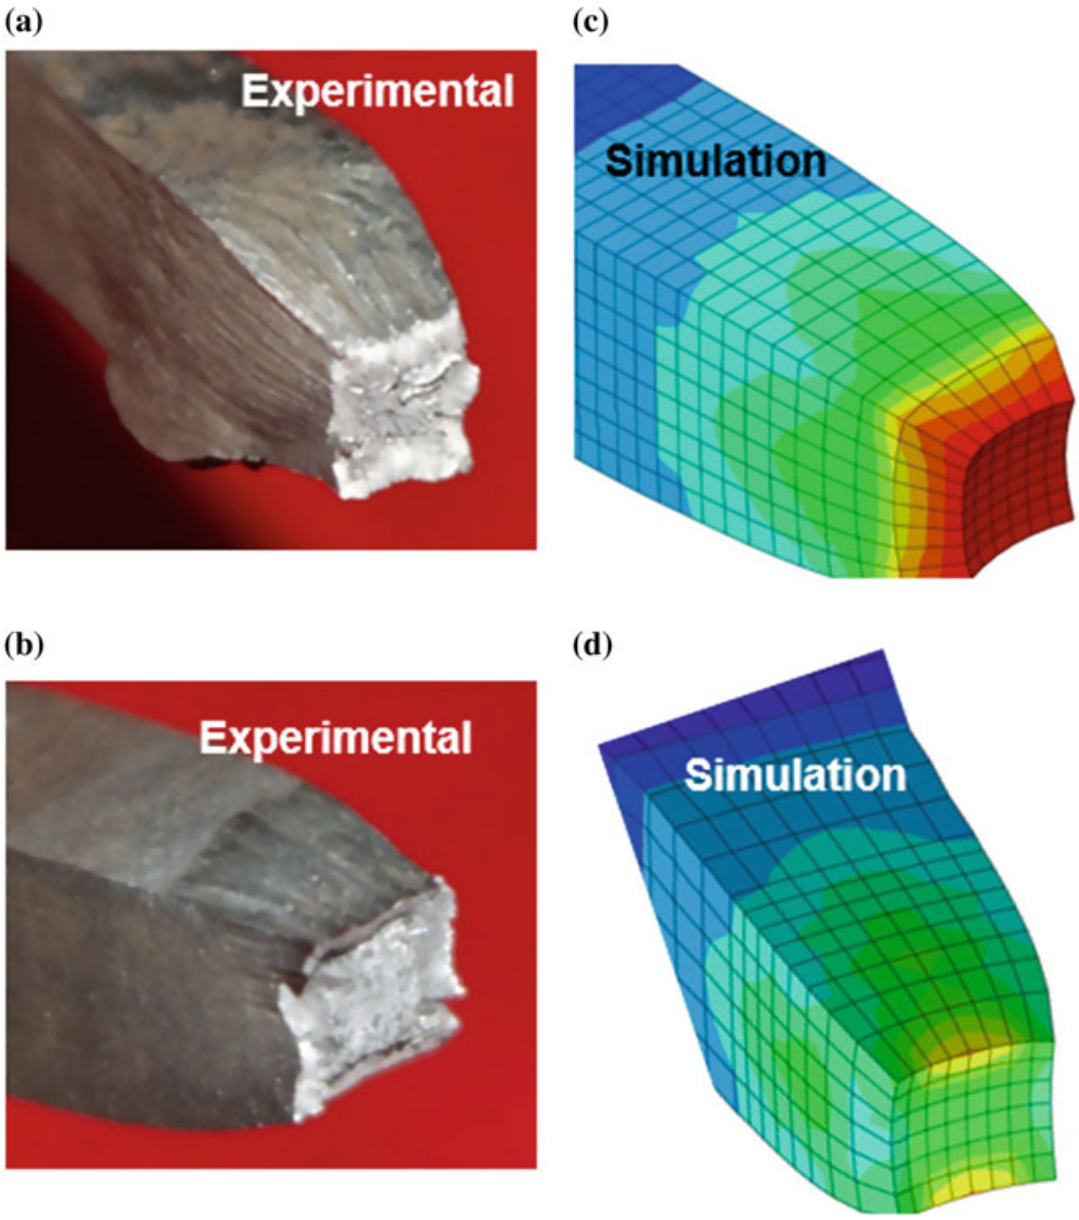

Fig. 16.10 Comparison of WM tensile test fracture surface mode between experimental (**a** and **b**) and FE analysis (**c** and **d**)

- The fracture position of the FE analysis tensile test is found very similar to fractured samples.
- The proper validation by calculating the percentage of error for the tensile test with an error is less than 1%.
- The observation of fractography reveals that voids and dimples are found in the fractured area of the tensile test sample and confirms ductile mode of failure.

Chapter 17
Design Optimization of Welding Parameters for Multi-response Optimization in TIG Welding Using RSM-Based Grey Relational Analysis

S. C. Moi, R. Rudrapati, A. Bandyopadhyay and P. K. Pal

Abstract This paper presents a research work on optimization of input process parameters using response surface methodology (RSM) along with grey relational analysis to enhance the weldment quality responses in tungsten inert gas welding of 316L austenitic stainless steels. The process control parameters selected for the investigation are welding current, welding speed, and gas flow rate. The experiments have been performed using Box–Behnken design of RSM with three factors, three levels each. Experiments have been performed and output responses: ultimate tensile strength (UTS) and weld width (WW) have also been measured. Grey relational analysis technique has been applied on experimental data to convert multi-output problem into single-response problem. Mathematical model has been developed correlating the process parameters with grey relational grade. The effects of welding input parameters on multi-performance characteristics have been studied graphical contour plots which made from the developed mathematical model. Optimal process parametric has been obtained at higher grey relational grade value. The results of ANOVA and contour plots indicating that output responses, UTS and WW, are significantly influenced by welding input parameters. The concluding remarks have been drawn from the study.

17.1 Introduction

The selection of the material for any industrial application is based on its mechanical properties like strength, ductility resistance to oxidation and/corrosion, sensitization, etc. Variety of austenitic stainless steel materials which are used for many industrial purposes, type 316L is usually considered over other austenitic steel materials as a structural material, because, of its higher corrosion resistance and excellent mechanical properties both at low and high temperature [1]. Austenitic stainless steel (type 316L) is one of the most consumable materials in orthopedic implants [2], and it is considered as a major structural part for sodium cooled fast reactor applications [3], etc. TIG welding is very useful for similar or dissimilar welding of metals compared to laser welding, because, of high welding quality, high stability in welding of variety of industrial applications. Tungsten inert gas (TIG) welding with and without use of filler material is generally applied welding methods for joining of stainless steels for the industrial applications like pipe, automotive exhaust gas system, chemical industry-based equipment, power plants [3], etc. Welding of 316L austenitic stainless steel (ASS) is important area of research [4] due to corrosion and crack formation resistance [5].

In TIG welding, correct selection of welding process parametric setting is very important to decide the quality of the weld specimen. The quality levels of weldments is highly depending on many interactive input variables such as, the gap maintained between the joined parts, evaporation of parts, torch angle, quantity of the shielding gases present, pulse frequencies and the electrode tip angle selected, etc. when conduction of welding operation. It is very important to select the optimal welding process parametric combination to obtain required weld performances [6]. The systematic analysis and optimization approaches are required to produce desired quality welding and to enhance the quality responses of joining parts [7] but it required to study and understand the welding process extensively because many factors control the welding process [8].

The experimental analysis and optimization of any welding process are difficult job due to many interlinked parameters involved while solving it. The experimental analysis of welding is often a very costly as well as time-consuming process [9]. With a view to achieving the desired quality characteristics in TIG welding of 316L austenitic stainless steels, statistically designed experiments based on the Box–Behnken design of RSM have been used to conduct experimental study. The Box–Behnken experimental design-based RSM is very useful to study system or process effectively to obtain the required information about the direct and interaction effects of input process variables on performance measures with only fifteen number of experimental runs. The input parameters considered in the present work are current, speed, and gas flow rate. The welding performance characteristics measured after the experimentation are ultimate tensile strength (UTS) and weld width. Solving the multi-performance characteristics is not an easy task. Ghosh et al. [10], Wahule and Wasankar [11], and Bahar et al. [12] stated that grey relational analysis (GRA) is efficient for solving multi-objective problems. In the present research investigation,

GRA is utilized to solve the multi-responses by converting multi-output parameters into single response. RSM has been used to make mathematical equation between the input factors and grey relational grade. Two-dimensional contour plots have been made RSM to analyze the factor effects on output response(s).

17.1.1 Literature Survey

Recently, some papers reported in literature to establish a new experimental optimization approach using Taguchi method to analyze TIG welding with minimum number experimental runs.

Durgutlu [13] had investigated the microstructure, penetration, and mechanical properties of 316L ASS in TIG welding operation. They tested the effects of shielding gas (i.e., hydrogen in argon) while welding of 316L ASS. They found highest tensile strength of sample at 1.5% H_2-Ar from their study. Soltani and Tayebi [5] had conducted a comparative analysis of welding of 304L and 316L stainless steels using laser and TIG welding operations. They considered yield strength, elongation, hardness, and weld width as output responses. Authors stated from their study that TIG welding has produced better weld results compared to laser welding. Thomas et al. [4] had been investigated the fatigue crack growth rate in stainless steel (type 316LN) sheets joined by using traditional multi-pass TIG and activated TIG welding processes. Researchers had been found that better results while welding of multi-pass welding of 316LN stainless steel compared to activated TIG welding. Cheng et al. [14] studied the significances of TIG flux on the quality responses of dissimilar welds between mild steel G3131 and austenitic stainless steel 316L. The experimental runs were performed to investigate the effects of CaO, Fe_2O_3, Cr_2O_3, and SiO_2. They found residual slag on TIG weld surface due to oxide flux. Improvements in weld joint penetration and increased weld depth to width ratio were obtained by using SiO_2 powder. Reddy [15] conducted experiments to weld AISI 4140 and AISI 316 with and without using filler metal in TIG welding. The quality responses were evaluated from the study.

Ghosh et al. [10] made an investigation to visualize the welding factor effects on multi-performance characteristics of weld joint in metal inert gas (MIG) welding of ferritic stainless steel to austenitic stainless steel with the use of grey relational analysis and Taguchi method. Authors mentioned that welding responses were highly depend on the proper selection input parametric combination. Researchers had also been stated that grey relational analysis is efficient to deal with multi-responses problems. Wahule and Wasankar [11] had been carried out experimental research work to optimize the multi-outputs such as tensile strength (TS) and % elongation (PE) in TIG welding of SS304 and Fe-410 materials. They considered grey relational analysis technique to solve multi-objective problem (TS and PE) into single objective problem. Researchers used analysis of variance tool to study the significances of input parameters on both the output responses. They stated from their work that input welding parameters are significantly affecting the mechanical properties of welded

joint. They optimized multi-objectives: TS and PE simultaneously by using grey relational analysis. Bahar et al. [12] had conducted analysis on TIG welding of SS316 and MS1020 materials to enhance the welding performance. Authors selected current, welding speed, and gas flow rate as input parameters and hardness, percentage elongation, and UTS as output responses. GRA had been used to optimize the multi-output variables. Factor effects on all the responses were analyzed by analysis of variance and graphical main effect plots. Optimum input combination had been obtained by grey based Taguchi method. Authors had stated that GRA was very useful to optimize multi-objectives simultaneously.

From the literature review, one can identify that various aspects of TIG welding had been investigated by the researchers. These aspects include parametric studies related to enhance the welded joint quality characteristics as well. However, research is still being continued. This indicates the need for further research. The effects of weld process parameters on weld joint quality characteristics like UTS and weld width though studied by some investigators, conclusive relationship between process parameters, and quality characteristics—explaining the effects will only emerge through more extensive research.

17.2 Response Surface Methodology (RSM) and Grey Relational Analysis (GRA)

RSM is used to determine the relationships between output response(s) and a set of quantitative input parameters. RSM is very useful to predict the improved product quality over the quality achieved. In the present work, RSM's Box–Behnken experimental table with three factors, three levels each, and fifteen runs (Table 17.1) are chosen. The mathematical equation is then postulated that illustrates the relationship between the input process variables and response characteristic. The quantitative form of a mathematical model to postulate the relationships between input and output variables is given as follows:

$$Y = f(\text{current, speed, gas flow rate}) \tag{17.1}$$

where Y is the output response. Here, it is assumed that the independent control variables are continuous and controllable by experiments with negligible errors. The complete explanation of the process behavior can be obtained through second-order polynomial equation is given below.

$$\begin{aligned} Y = {} & \beta_0 + \beta_1(\text{current}) + \beta_2(\text{speed}) + \beta_3(\text{gas flow rate}) + \beta_{11}(\text{current} * \text{current}) \\ & + \beta_{22}(\text{speed} * \text{speed}) + \beta_{33}(\text{gas flow rate} * \text{gas flow rate}) + \beta_{12}(\text{current} * \text{speed}) \\ & + \beta_{13}(\text{current} * \text{gas flow rate}) + \beta_{23}(\text{speed} * \text{gas flow rate}) \end{aligned} \tag{17.2}$$

Table 17.1 Box–Behnken design, output responses, and grey relational grade and ordering

Run	Input parameters			Output responses		Grey relational analysis	
	Current (A)	Speed (cm/min)	GFR (l/min)	UTS (MPa)	Weld width (mm)	Grey relational grade	Grey relational order
1	100	12	9	612.13	7.61	0.418719	13
2	150	12	9	616.42	6.78	0.542807	11
3	100	18	9	608.48	6.22	0.711446	7
4	150	18	9	630.37	6.35	0.76222	5
5	100	15	6	621.26	6.81	0.561772	9
6	150	15	6	612.91	6.64	0.559544	10
7	100	15	12	580.61	7.37	0.354331	15
8	150	15	12	607.69	6.82	0.498924	12
9	125	12	6	624.15	6.83	0.575156	8
10	125	18	6	616.24	6.18	0.770095	4
11	125	12	12	592.42	7.44	0.371909	14
12	125	18	12	615.88	6.24	0.729702	6
13	125	15	9	639.42	6.55	0.782465	3
14	125	15	9	642.64	6.54	0.832558	1
15	125	15	9	639.67	6.56	0.782788	2

where Y = output response and the betas are coefficients of linear, quadratic, and interaction of welding process parameters. The term β_0 is the intercept term; β_1, β_2, and β_3 are the linear terms; β_{11}, β_{22}, and β_{33} are the squared terms; and β_{12}, β_{13}, and β_{23} are the interactions between the input factors. This empirical mathematical model is helpful to identify the optimum welding parametric setting to obtain desired weld performance.

GRA is mainly utilized to solve the multi-attribute decision-making problems. It considers multi-objectives simultaneously to identify the best alternative. Data preprocessing steps of GRA can be expressed as:

Step 1: In the GRA, first step is to preprocess the experimental data because the factor goals and directions may be different in each other. The preprocessing of the data is called grey relational generation. The equations for calculating higher-the-better and lower-the-better are given in Eqs. 17.3 and 17.4, respectively. Higher-the-better:

$$X_i(k) = \frac{Y_i(k) - \min Y_i(k)}{\max Y_i(k) - \min Y_i(k)} \tag{17.3}$$

where $X_i(k)$ is the value after grey relational generation while min $Y_i(k)$ and max $Y_i(k)$ are, respectively, the smallest and largest values of $Y_i(k)$ for the kth response. Lower-the-better:

$$x_i(k) = \frac{\max y_i(k) - y_i(k)}{\max y_i(k) - \min y_i(k)} \tag{17.4}$$

where $x_i(k)$ is grey relational generation; min $y_i(k)$ and max $y_i(k)$ are the smallest and largest values of $y_i(k)$ for the kth response.
Step 2: Grey relation coefficient
By normalizing, grey relational coefficient (GRC) is calculated by using Eq. 17.5 which is given below

$$\xi_i(k) = \frac{\Delta \min + r\Delta \max}{\Delta o_i k + r\Delta \max} \tag{17.5}$$

where $\Delta o_i = \| x_0(k) _ x_i(k) \|$ is variance of the absolute value between $x_0(k)$ and $x_i(k)$ and here "r" is distinguishing coefficient used to adjust the difference of the relational coefficients; Δ min and Δ max are minimum and maximum values of Δo_i for the kth response; "r" is within the set {0, 1}. $\xi_i(k)$ is grey relation coefficient.
Step 3: Determination of the grey relational grade (GRG) for each experiment combination

$$\alpha_i = \sum_{k=1}^{n} \xi_i(k)/n \tag{17.6}$$

where "n" is the number of performance characteristics; $\xi_i(k)$ = grey relation coefficient of each response; α_i is grey relational grade.
Step 4: Grey relational ordering: In GRA, final step is to provide the grades of GRG an ascending order to all factor combinations. Optimal parametric setting can be obtained at which parametric combination possess highest grade value.

17.3 Experimental Procedure

As already mentioned, that present work is planned to obtain the better weld qualities on 316L austenitic stainless steel material in TIG welding operation by using RSM and grey relational analysis. The selected dimensions of base material, i.e., 316L austenitic stainless steel are: 50 mm × 80 mm × 3 mm, and 1.6 mm diameter of ER316L austenitic stainless steel filler rod has been selected for the work. Juang and Tarng [16] and Ugur et al. [17] had mentioned that correct selection of process parameters had highest influence on the weld pool geometry as well as mechanical properties of welded joint in TIG welding operation. The important process parameters: welding current, gas flow rate, and welding speed have been selected for the present experimentation investigation. The selected input parametric settings and their levels are current = 100, 125, and 150 A; speed = 12, 15, and 18 cm/min; and gas flow rate = 6, 9, and 12 l/min. The experiments have been performed as per

Fig. 17.1 Experimental setup

Box–Behnken design of response surface methodology. Figure 17.1 shows the photographic view of a semi-automatic TIG welding machine (Model-SUPERGEN320, M/C SR. No-12111097670 and Make-Ador Welding Ltd.). Box–Behnken design matrix has been shown in Table 17.1. After TIG welding operation, visual and X-ray radiographic tests have been conducted on welded specimen to check the defects in it. However, visual and X-ray radiographic test results have not been discussed in the present paper. Output responses, ultimate tensile strength (UTS) and weld width (WW), have been measured and given in Table 17.1.

17.4 Converting Multi-response into Single-Response Problem

Grey relational analysis has been conducted on experimental data to translate multi-responses into single objective problem by following the steps mentioned above. Present work, UTS and WW, must be maximized to enhance the mechanical properties and WW needs to be minimized to reduce the material requirement. As mentioned above, in GRA, first step is to preprocess the data. Here, Eqs. 17.3 and 17.4 have been used to preprocess the data of UTS and WW, respectively. Equation 17.5 has been used to calculate the grey relational coefficient. Finally, Eq. 17.6 has been used to determine the grey relational grade (GRG) by averaging the grey relational coefficients (GRC) of both the responses, UTS and WW. Grey relational ordering has been made to grey relational grade values. The GRG values and ordering are given in Table 17.1.

17.5 Results and Analysis

The experiments have been made and output responses are measured and shown in Table 17.1. GRA is used to translate multi-objectives, i.e., UTS and WW into single response, grey relational grade (Table 17.1). RSM is applied on grey relational grade to postulate the relationships between welding factors: current, speed and gas flow rate, and grey relational grade. Contour plots have been made from developed mathematical equation by using RSM application. Optimum welding condition obtained highest grey relational grade.

17.5.1 Mathematical Modeling and Contour Plots

Developing mathematical model from the experimental data can create a more scope to study and analyze the experimental results. In the present investigation, RSM has been utilized to develop the mathematical relationships between the welding process parameters and grey relational grade (GRG) as given in Table 17.1. Here, GRG is developed from the output responses: UTS and PE as already mentioned above. RSM is one of the empirical mathematical modeling tools used to carry out to develop mathematical relationships between input and output parameters. General polynomial quadratic model of is already given in Eq. 17.2. The constant values of β_0, β_1, β_2, β_3, β_{11}, β_{22}, β_{33}, β_{12}, $\beta_{13,}$ and β_{23} as given in Eq. 17.3 are calculated from experimental data (i.e., GRG in the present case) as shown in Table 17.1 using least square. The developed models are shown in Eq. 17.7.

$$\begin{aligned} Y = & -6.33747 + 0.0486566 * \text{current} + 0.404600 * \text{speed} \\ & + 0.212709 * \text{gas flow rate} - 1.98029\text{E} - 04 * \text{current} * \text{current} \\ & - 0.0127831 * \text{speed} * \text{speed} - 0.0103304 * \text{gas flow rate} * \text{gas flow rate} \\ & + 2.32751\text{E} - 05 * \text{current} * \text{speed} + 5.16623\text{E} - 05 * \text{current} * \text{gas flow rate} \\ & - 0.00207718 * \text{speed} * \text{gas flow rate} \end{aligned} \tag{17.7}$$

where Y is output response.

The contour plots are two-dimensional plots which are very useful to study the main and interaction effects of two factors on outcome in a single plot [18]. In the present work, contour plots have been drawn from the developed mathematical model (Eq. 17.7) of grey relational grade (GRG) by RSM application from the MINITAB 16.1 software. The relationship between GRG with the welding input parameters has been demonstrated graphically by these plots. Each line in the contour plots is a constant—response line. The contour lines in a plot, comparatively straighter lines, indicate lesser or no interaction effect on the output variable.

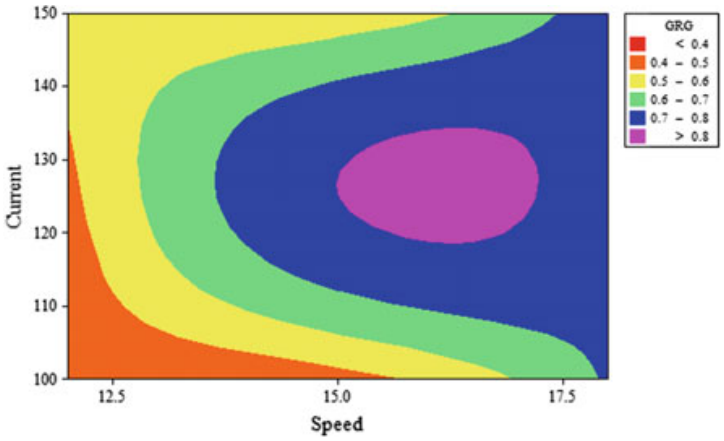

Fig. 17.2 Contour plot showing combined effects of current and speed on GRG

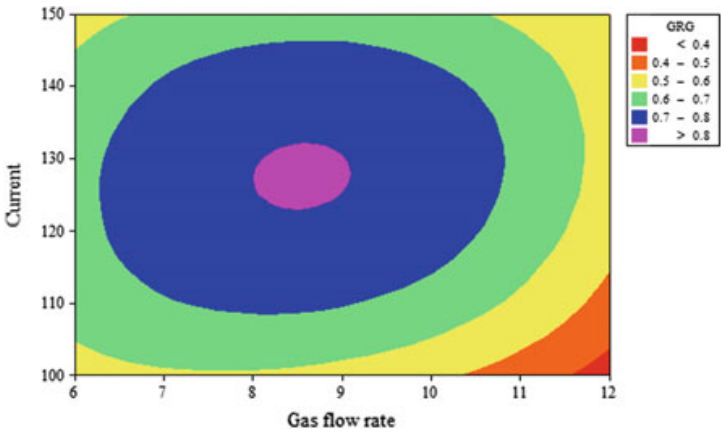

Fig. 17.3 Contour plot showing combined effects of current and gas flow rate GRG

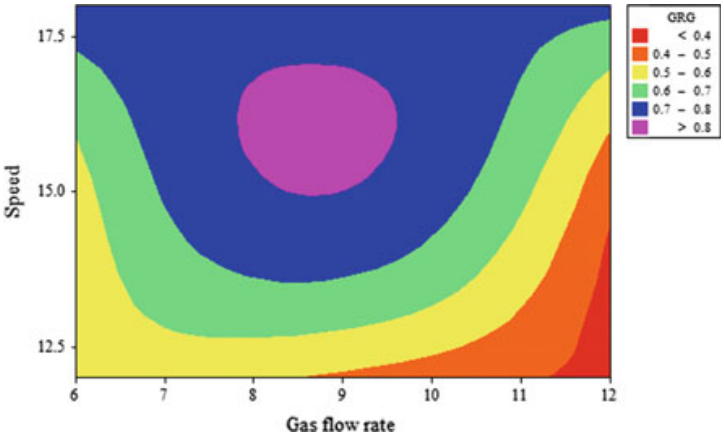

Fig. 17.4 Contour plot showing combined effects of speed and gas flow rate on GRG

The elliptical nature or bent/circular contours in a plot shows that input parameters are significant on the response. The contour plots for GRG is shown in Figs. 17.2, 17.3, and 17.4.

From contour plots of grey relational grade (GRG) as given in Figs. 17.2, 17.3, and 17.4, it is noted that all the welding input variables are most significant for UTS and weld width. From the contour plots, one can identify the optimum parametric setting where better outcome obtained. In a contour plot, each shade has set of two

input parameters which projecting certain output values. From the all contour plots shown in Figs. 17.2, 17.3 and 17.4, it is observed that input parameters current = 125 A, speed = 15 cm/min and gas flow rate = 9 l/min, is one of optimum parametric setting which produces higher grey relational grade. Same parametric setting has also been suggested by grey relational analysis (Table 17.1) for predicting multi-response characteristics combinedly.

17.6 Conclusions

The experiments have been conducted to study, model, and optimize the weld responses: ultimate tensile strength (UTS) and weld width (WW) combinedly in TIG welding on 316L austenitic stainless steel plates. Following are the conclusions drawn from the present research investigation:

1. Multi-objective problem (UTS and WW) is converted into single-response problem (i.e., grey relational grade) by GRA approach
2. Mathematical relationships between welding parameters and grey relational grade by response surface methodology (RSM)
3. Contour plots are drawn using RSM application
4. The effects of welding parameters on both the responses are studied from contour plots
5. Input welding parameters are most significant for both the responses
6. Optimum welding condition: current = 125 A, speed = 15 cm/min, and gas flow rate = 9 l/min is obtained by GRA
7. RSM and GRA are very useful to optimize the welding conditions of TIG welding 316L austenitic stainless steel.

Chapter 18
Subjective Factors Consideration in the Selection of Welding Technique for Welded Tube Manufacturing

Ravindra S. Saluja and Varinder Singh

Abstract In choosing the right welding process for an application like welded tube manufacturing, the manufacturing engineers have to take into account a large number of selection criteria. Choosing the right welding process for any application is difficult not only due to multiple factors affecting the decision but also due to a number of emerging new welding techniques becoming available as alternatives. Some of the alternative welding processes for manufacturing tubes have been Fretz-Moon process (FM), low-frequency (LF) as well as high-frequency (HF) alternating current resistance welding, direct current (DC)-based resistance welding in addition to gas metal arc welding (GMAW), and submerged arc welding (SAW) in some specific applications. A systematic examination of the decision situation may lead us to an appropriate choice rather than basing the decision on one factor or the other in stand-alone manner. This paper presents an analytic hierarchy process (AHP)- based decision analysis for the selection of welding process in a case of manufacturing small diameter steel tubes.

Keywords Steel tubes · Welding process · Decision analysis · AHP

18.1 Introduction

Tube manufacturing is one of the major industries supporting almost all other sectors dealing with engineering products. Most of the tubes are manufactured by a technique involving roll bending a sheet or strip and welding the ends in a continuous operation to give it a tube shape. This type of manufacturing technique is preferred one in comparison to seamless tube manufacturing as it offers significant

advantages on economics and production front. Tubes manufactured by this technique are commonly called welded tubes and are able to satisfy general quality requirements. By subjecting such products to post-processing operations such as cold drawing and some other operations, even stringent quality requirements are met easily. The choice of welding technique plays a major role in defining the cost and quality of such tubes. In general, the techniques of welding deployed for manufacturing different tubes are decided based on stand-alone technical considerations. In the past, many researchers [1–4] have pointed out the inadequacies of such approach while deciding welding techniques for different applications. The application of multiple criteria decision tools for systematic consideration of varied factors has been a topic of active research in the recent past wherein such investigations have resulted in well thought out selection processes for applications as trivial as butt joints for aluminum parts to hard facing of carbon steels by welding harder material.

For commercially important tube manufacturing industry, no systematic treatment is yet reported in literature for consideration of multiple alternatives available and the multiple attributes affecting the decision. An appropriate choice of welding for a mass scale industry of tube manufacturing may make a significant difference in the competitiveness of the industry in terms of cost and quality in addition to the some benefits even for general society in terms of resource sustainability. In the modern times, a vast amount of technological research is resulting in the advent of newer techniques in welding technology. The present research may also pave way for consideration of newer alternatives which may result in fruitful and commercially exploitable innovations. Thus, a systematic decision-making process is very much needed that can take the multiple attributes as well as multiple alternatives into consideration for selection of the most appropriate welding technique for welded tube manufacturing. Different multi-attribute decision-making (MADM) tools may be used for analyzing this decision. Analytic hierarchy process (AHP) is one of the popular ones used by a number of researchers for decision making in different applications [5]. Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) is another multi-attribute method that has been used to deal with a number of multi-attribute decision problems [1, 6–8]. A hybrid AHP-TOPSIS approach has also been in use to provide decision support in many applications. Similarly, there are many more MADM tools, all with the aim of resolving the multi-attribute decision situation in a systematic manner while following different algorithms. On the other hand, the fuzzy scales have also been adopted by a number of researchers within AHP, TOPSIS, and different other MADM methodologies [9–11]. Researchers [11] have also discussed that the use of different MADM tools do not create significant difference in results and the choice of the tool may be based on minimizing the computational load. AHP in its basic form also holds significant promise and is widely used to address decision situations involving subjective judgments in pairwise comparison of attributes as well as alternatives in the domain of the chosen attributes of decision making.

The present paper investigates the choice of welding technique for small diameter tube manufacturing considering multiple subjective attributes. AHP

method is employed as it offers a simple way to systematically arrive at the user preference to meet the goal of selection process.

18.2 Methodology and Implementation

The overall methodology used in this paper for investigating decision making in welding process selection for small diameter tube manufacturing while considering subjective factor is graphically presented in Fig. 18.1.

18.2.1 AHP Model

For calculating the weights and user preference scores based on the subjective factors, AHP method is used. The general steps in AHP are described below which are based on established literature sources [3–5].

(a) Index the welding processes that engineers can take into consideration for potential pick.
(b) Find the attributes with measurable values that could be used in decision making.

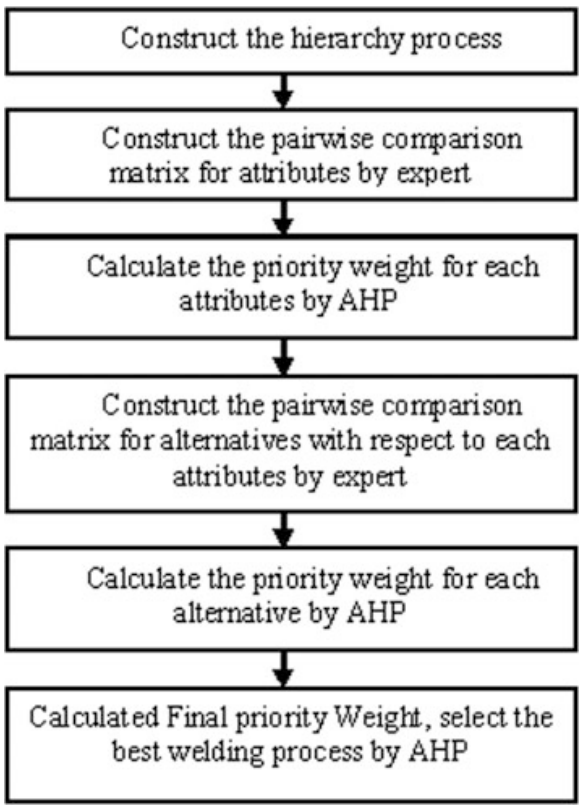

Fig. 18.1 Welding process selection based on the subjective factor by using an AHP methodology for tube manufacturing

(c) Next, the pairwise comparison matrix of set of attributes is completed by capturing relative importance as per expert views.
(d) Once the pairwise comparison has been captured in a matrix for attributes, the normalized values are estimated. The values of each column are normalized by dividing each value in column by the sum of the values in the same column. Then, the average of each row is calculated to provide priorities weights (PW) of the criteria.
(e) Similar to steps (c and d), the pairwise comparisons of all the alternatives is used to obtain priority weights (PW) of each alternative with respect to different attributes.
(f) Also, before weights are calculated in steps (c, d, and e), it is necessary to check the pairwise comparisons are consistent. For that purpose, a measure known as consistency ratio (CR) is obtained as below.

$$\mathrm{CR} = \mathrm{CI}/\mathrm{RI}, \tag{18.1}$$

where consistency index,

$$(\mathrm{CI}) = (\lambda_{\max} - n)/(n-1) \tag{18.2}$$

$\lambda_{\max}$ = Maximum eigen value
n = Dimension of matrix.
And RI is a random index based on a table in reference [5].
So as long as CR < 0.1, the evaluations arrived at are considered consistent.
(g) For AHP-based selection, the weighted normalized decision matrix is calculated by summations of the products of attribute weights and alternative weights to obtain the final rankings.
(h) Compute the weighted priority scores for each alternative.
(i) In the end, the ranks are assigned to alternatives having the highest weighted priority score.

18.2.2 Implementation of Decision-Making Model

The case of manufacturing welded tube with the following design specifications has been considered for this study.

Material: Low carbon steel.
Diameter: 15 mm
Thickness: 2 mm

Based on the design specifications and the guidelines of the Society of Manufacturing Engineering [12, 13], four welding processes have been shortlisted for this case for further study namely Fretz-Moon method (FM), direct current

electric resistance welding (DC), low-frequency electric resistance welding (LF), and high-frequency electric resistance welding (HF). Many research papers [1–4] dealing with selection of welding processes for different applications use many different attributes.

The hierarchical structure of the decision problem is presented in Fig. 18.2 where the top level indicates the overall goal, which is to bring the best welding process available for tube manufacturing on mass scale. As the attributes important for the current decision making, namely setup time requirement (SR), worker skill requirement (WSR), occupational factor (OF), ease of automation (EA), and quality (QY), are explained in Table 18.1, at the second level, such attributes and their relative importance toward achievement of the goal of selecting the best alternative are analyzed through pairwise comparison. At the next level, the four potential alternatives, namely Fretz-Moon process (FM), direct current electric resistance welding (DC), low-frequency electric resistance welding (LF), and high-frequency electric resistance welding (HF), are considered for pairwise comparison in the direct of each attribute.

For pairwise comparison of different attributes as well as alternatives, the scale of comparison is presented in Table 18.2. It is used to fill the pairwise comparison elements for each attribute in Table 18.3. It is also used to fill pairwise comparison for each alternative with respect to all considered attribute in Table 18.4.

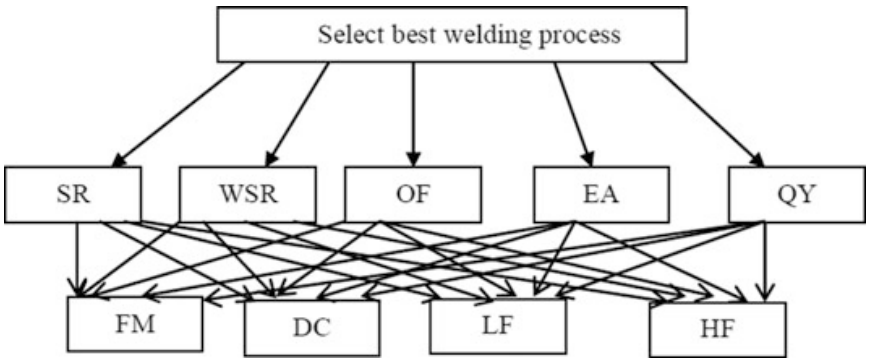

Fig. 18.2 Schematic diagram of analytic hierarchy process

Table 18.1 Description of attributes considered [3, 4]

S. No.	Subjective attributes	Description
1	Setup time requirement (SR)	Welding parameters setting, cleaning the base metal, and clamping joint in fixtures
2	Worker skill requirement (WSR)	Refer to the skill level of worker required
3	Occupational factor (OF)	Arc glare, smoke, and fumes
4	Ease of automation (EA)	Manual, semi-automatic, and fully automatic
5	Quality (QY)	Weld bead appearance and surface finish

Table 18.2 Strength of preference for pairwise comparison [3–5]

Strength of importance	Verbal judgement
1	Equally preferable
3	Moderately preferable
5	Strongly preferable
7	Very strongly preferable
9	Extremely strongly preferable
2, 4, 6, 8	Intermediate values
1/2, 1/3, 1/4 etc.	Reciprocal of above values

18.3 Results and Discussion

The pairwise comparison of attributes for this case of tube manufacturing is presented in Table 18.3. As evident from the priority weight scores in Table 18.3, the quality of the welding process is considered as the most important attributes followed by occupational factor and so on.

Similar way, the pairwise comparison of welding processes with regard to each of the considered attributes and values of priority weights (PW) is presented in Table 18.4. It may be noted that the calculated consistency ratio by using Eq. (18.1) in Tables 18.3 and 18.4 is found to be less than 0.1 as per the requirement of AHP procedures.

The results of Table 18.4 are summarized in Table 18.5 and overall composite priority weights of alternatives are calculated according to step (f) and step (g) as mentioned in Sect. 18.2.1 and are reported in Table 18.6. From the overall priority weights for different alternatives as available in Table 18.6, the highest value for direct current (DC) resistance welding is observed.

18.3.1 Discussion

It may be observed that DC resistance welding is standing high in the order of preference. The reason for this outcome is that the quality of weld in terms of clean

DC	0.006	0.023	0.054	0.043	0.260	0.39	1
LF	0.006	0.023	0.054	0.043	0.048	0.17	3
HF	0.016	0.023	0.133	0.043	0.103	0.32	2

weld is of highest importance in the present case of small diameter tube manufacturing on mass scale, as the post weld flash removal is extremely difficult. The DC resistance welding is otherwise a poorer choice in comparison to a more popular alternative of high-frequency alternating current resistance welding as is evident from Table 18.4. For medium diameter tubes, the cleaner quality weld may acquire lesser importance and the choice may tilt toward high-frequency alternating current resistance welding as flash removal is easier owing to larger diameter. The utility of such decision analysis is that it considers different practical aspects and uses the provided information systematically, which help the design engineer and manufacturing engineer to choose the most appropriate process considering several attributes simultaneously.

18.4 Conclusions and Future Scope

In this work, the AHP model has been used for investigating the issue of selecting appropriate welding process for a case of small diameter tube manufacturing on mass scale while considering multiple attributes, namely setup time requirement, worker skill requirement, occupational factor, ease of automation, and quality of weld. The conclusions drawn from the study and the future scope are presented below:

i. For the case of manufacturing a welded tube with the following design specifications: material—carbon steel, diameter—15 mm and thickness—2 mm, the direct current (DC)-based resistance welding is found to be the most appropriate process while considering multiple attributes.
ii. AHP-based analysis is found to be simple for adaptation by experts while systematically collecting expert opinion on different factors in the otherwise complex problem of selection involving multiple attribute and choices as well.
iii. In future, there is scope to consider emerging welding processes for multiple attribute-based analysis before actual commercial deployment. Also, there is scope to consider multiple MADM methods as well as fuzzy approach due to subjective judgments involved.

Chapter 19
GMAW Investigation of AISI 201 Stainless Steel and Industry Need Optimization Using Genetic Algorithm

Krity Lata, M. Chandrasekaran, S. K. Tamang, R. Ramesh and N. K. Rana

Abstract In this work, the welding investigation of AISI 201-grade stainless steel (120 mm × 60 mm with 4 mm thickness) using gas metal arc welding (GMAW) has been carried out. Four weld parameters, viz. wire feed rate, welding voltage, nozzle-to-plate distance and welding speed, are used to investigate different weld bead characteristics [i.e. penetration (*P*), bead width (*W*) and bead height (*H*)]. The welding experiments are performed using Taguchi L9 experimental design, and each run is completed in a single pass. The predictive models are developed to predict weld bead geometry, and the performance of the model is validated. The increase in wire feed rate and voltage increases penetration and bead width, while an increase in nozzle-to-plate distance decreases the value of penetration and bead width. The welding parameters are optimized using genetic algorithm to determine the optimal combinations of welding parameters for better quality of component having maximum *P* with minimum *W* and *H* at which the maximum weld quality be achieved.

Keywords AISI 201-grade stainless steel · GMAW · Weld bead · Genetic algorithm

19.1 Introduction

Nitrogen-strengthened austenitic stainless steel (200 series) has found more applications in modern industries compared to conventional AISI 300 series of stainless steel components [1]. The price of nickel is relatively higher compared to other austenite formation elements such as manganese, and changing so, it becomes

necessary to increase such a material like AISI 201, as an option, with the same weight of chromium 18%, and instead of nickel, 7 wt% of manganese is added to stabilize the austenitic phase, and weight of nickel is decreased from 8 to 3 wt% in stainless steel of AISI 201 grade [2]. Hence, AISI 201 SS is a high Cr–Mn–N stainless steel which is free of nickel. This material is useful in manufacturing of battle tanks in defence applications possessing low cost, better corrosion resistance and excellent mechanical properties. This material can be used for conventional construction applications such as nuclear reactors, thermal power plants, civil construction, vessels and heat exchangers and for multiple industrial applications such as food and dairy processing equipment and kitchen equipment for consumer use.

Gas metal arc welding (GMAW) is a renowned soldering process used for various ferrous and non-ferrous materials. This is a cheaper and cost-effective process, without flaws, without faults, with proper appearance and with easy mechanizing [3]. In this process of welding, an arc is struck between a continuous consumable wire electrode and the workpiece metal. To provide a good-quality weld having economic production of desired weld bead geometry, optimum selection of welding parameters is important. A number of researches were conducted on welding investigation and parametric optimization in different welding processes on joining various materials. Choudhury and Chandrasekaran [4] reviewed previous research works published in the areas of welding investigation and optimization on aerospace materials. In gas tungsten arc welding (GTAW), Juang and Tarng [5] studied the selection of optimal process parameters to obtain optimum welding bead geometry. The effects of hardness and penetration depth were investigated by Ibrahim et al. [6] on various MIG welding process parameters. The optimum parameter combination was assessed by Datta et al. [7], using the Taguchi approach and the Grey relational analysis, in order to reach an optimum penetration depth and minimum bead height, bead height and depth of the welds. They concluded that Taguchi–Grey method adopted achieves an improved weld quality. The effect of weld speed on microstructure, mechanical characteristics and corrosion studies of AISI 201 GTA welded stainless steel sheets was studied by Chuaiphan and Srijaroenpramong [2]. Kim et al. [8] studied gas metal arc welding process parameters modelling and optimizing with GA and RSM. Sathiya et al. [9] have examined laser welding processes of the AISI 904L super austenitic stainless steel materials' assemblies and process parameters for optimization with the help of soft computing methods such as ANN and GA. The author has attempted to investigate the effect of various weld parameters on weld bead characteristics during the AISI 201 SS GMAW process on beads on plates in the present investigation. The experimental results are analysed and weld parameters are optimized using GA to get better penetration with minimum bead width and bead height. The result provides important guidelines for the selection of weld parameters for particular application in fabrication industries.

19.2 GMAW Experimentation Procedure

The experiments designed were based on Taguchi L9 OA having 4 factors and 3 levels. The welding parameters were chosen as wire feed rate (*W*), welding voltage (*V*), nozzle-to-plate distance (*N*) and welding speed (WS), and response parameters were chosen as penetration (*P*), bead width (*W*) and bead height (*H*). Experiments were done on bead on plate (AISI 201 stainless steel of size 120 mm × 60 mm, 4 mm thick) as per design matrix using TransPuls Synergic 3200 MIG welding machine. The experimental set-up was prepared as shown in Fig. 19.1. GMAW machine was connected to shielding gas (98% Ar + 2% O_2) cylinder, and gas flow rate was controlled electronically using this machine. AISI 316L wire rod having diameter 1.2 mm was selected as welding electrode and was attached to the welding torch which was further connected to the set-up table and fixed at a torch angle of 90°. DCEP electrical polarity was used as it concentrated more heat on melting the filler material in the welding area. The variations in welding voltage automatically changed the current in this experimental set-up. Before welding, the workpiece was cleaned, degreased and clamped in the experimental set-up. After the complete configuration, the tests were performed randomly using the design matrix so that any systemic error was avoided. By conducting test runs, the working range of all the selected factors was determined by changing one factor while the remaining factor was kept as constant values. Thus, when inspecting the weld bead for a smooth appearance, no visible defects such as undercut and surface porosity were obtained in various test experiments and given in Table 19.1, and the range of parameters of process variables was defined.

Figure 19.2 shows welded specimens. After welding, the specimen was cut and grinded in a grinder disc and polished using nylon polishing cloth with levigated polishing alumina solution. The specimen was etched with etchant solution (15% HCL + 10% HNO_3 + 2–3 drop glycerine) and then washed with alcohol solution.

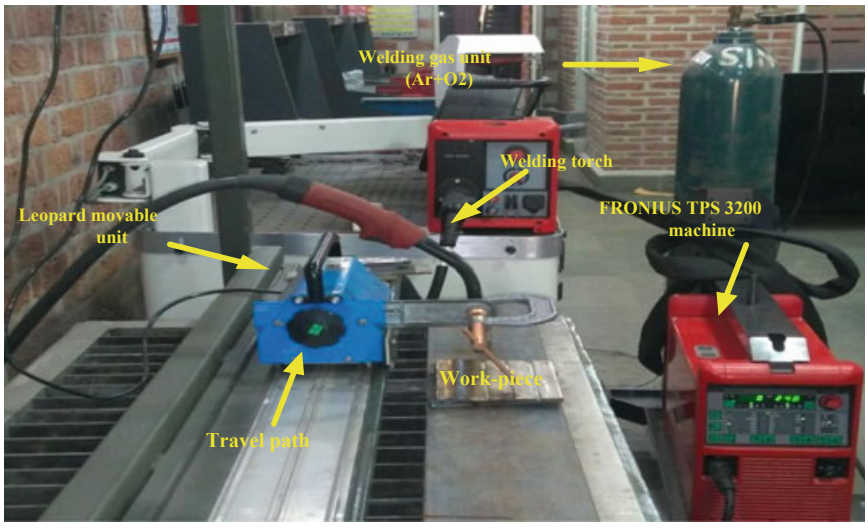

Fig. 19.1 GMAW experimental set-up

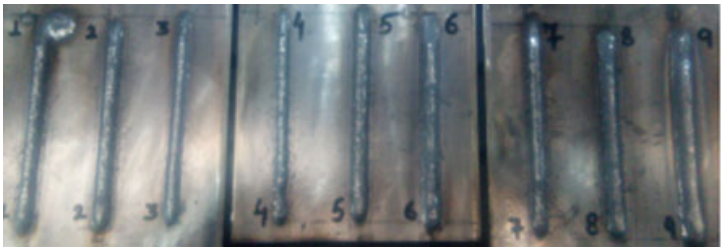
Table 19.1 GMAW parameters and their levels

Parameter	Unit	Symbol	Level 1	Level 2	Level 3
Wire feed rate	m/min	WFR	6	7	8
Welding voltage	V	*V*	20	22	24
Nozzle-to-plate distance	mm	*N*	16	20	24
Welding speed	mm/min	WS	220	260	300

Fig. 19.2 Weld runs

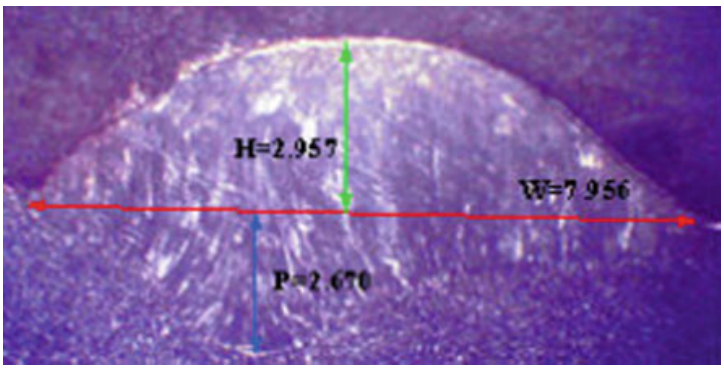


The bead profile parameters such as penetration, bead width and bead height were measured using 'stereo microscope' to get bead profile of experiments. The measured weld profiles are shown in Fig. 19.3.

19.2.1 Effect of Welding Parameters On the Performance Measures

The experimental results obtained from GMAW experiments were analysed through graphical figure. It shows and studies the effects of each parameter on responses. The effect of wire feed rate (WFR) on different geometries of weld beads, such as penetration, bead width and bead height, is shown in Fig. 19.4. The increase in wire feed rate, penetration and bead width is observed. For all wire feed values, bead height is constant.

Fig. 19.3 Microstructure measurement of a weld bead profile



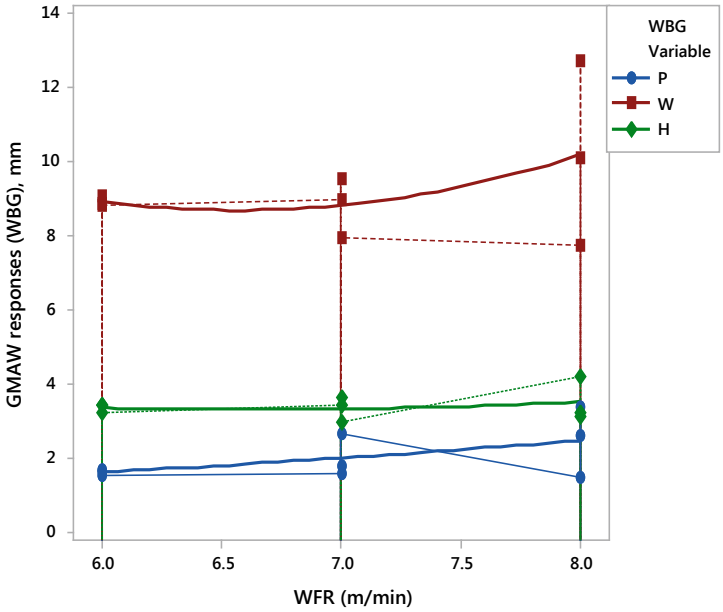


Fig. 19.4 Effect of wire feed rate on P, W and H

Similarly, the effect of other weld parameters is studied. It is observed that increase in welding voltage increases penetration and bead width, whereas bead height decreases very slightly. The increase in the value of the nozzle-to-plate distance lowers the penetration value and the width of the bead.

19.3 Development of RSM Modelling

The experimental results are used to develop predictive modelling of different weld characteristics using response surface methodology (RSM). RSM is statistical and empirical method being widely used for the development of predictive models. Three different models are developed for predicting P, W and H characteristics of weld bead geometry.

In this work, functional correlation between different weld bead characteristics and process parameters is found using regression analysis. The linear models with interaction terms show better correlation. In general, linear model with interaction terms is given in Eq. 19.1.

$$y = \beta_0 + \sum_{i=1}^{k} \beta_i x_i + \sum_{j=i+1}^{k} \sum_{i=0}^{k} \beta_{ij} x_i x_j + \varepsilon, \tag{19.1}$$

where y is the response and x_i (1, 2, …, k) is the level of k variable. β_0 is constant, β's are model coefficients, and ε is modelling error, respectively. The regression model is developed using statistical software Minitab 17®. The predictive model equations obtained for P, W and H are given in Eqs. 19.2, 19.3 and 19.4,

respectively. The correlation coefficient (R^2) values of each model equation are above 95%.

$$P = 34.11 - 5.093\,\text{WFR} - 1.358\,V - 0.427\,N + 0.00254\,\text{WS} + 0.2176\,\text{WFR} \times V + 0.0379\,\text{WFR} \times N + 0.0057\,V \times N, \quad (19.2)$$

(R^2 = 99.96%, R^2 = 99.67%)

$$W = 187.6 - 23.6\,\text{WFR} - 9.24\,V - 0.58\,N + 0.0124\,\text{WS} + 1.180\,\text{WFR} \times V - 0.074\,\text{WFR} \times N + 0.062\,V \times N, \quad (19.3)$$

(R^2 = 95.03%, R^2 = 60.23%)

$$H = -14.6 + 3.46\,\text{WFR} + 0.896\,V - 0.185\,N - 0.00489\,\text{WS} - 0.163\,\text{WFR} \times V + 0.112\,\text{WFR} \times N + 0.0057 \times N, \quad (19.4)$$

(R^2 = 97.15%, R = 77.23)

Table 19.2 presents predictive performance of the model comparing with the experimental results, and it shows an average error of 0.621, 4.780 and 1.89% for P, W and H, respectively. Also, the maximum error percentage is well within 5.5%, except one data set for W. The established models can be used with considerable accuracy to determine penetration, bead width and bead height.

Table 19.2 Model predictions

S. No.	Experimental results			Model prediction			% Error		
	P	W	H	P	W	H	P	W	H
1	1.686	8.863	3.427	1.693	8.984	3.383	0.42	1.360	1.280
2	1.600	9.105	3.415	1.575	8.504	3.236	1.58	1.600	5.240

Average percentage error (APE)							0.621	4.780	1.890

19.4 Parametric Analysis

The effect of weld parameters on various weld measures is analysed through contour figures. Three weld bead characteristics, viz. penetration, bead width and bead height, are studied over the range of parameters under consideration. The effect of responses is investigated by two different parameters, while other parameters are kept constant at middle level. As the wire feed rate and voltage increase, the penetration and bead width increase, while the value of penetration and bead width decreases with increase in the value of nozzle-to-plate distance. In this contour figures, you can better understand how weld parameters interact with various weld bead responses.

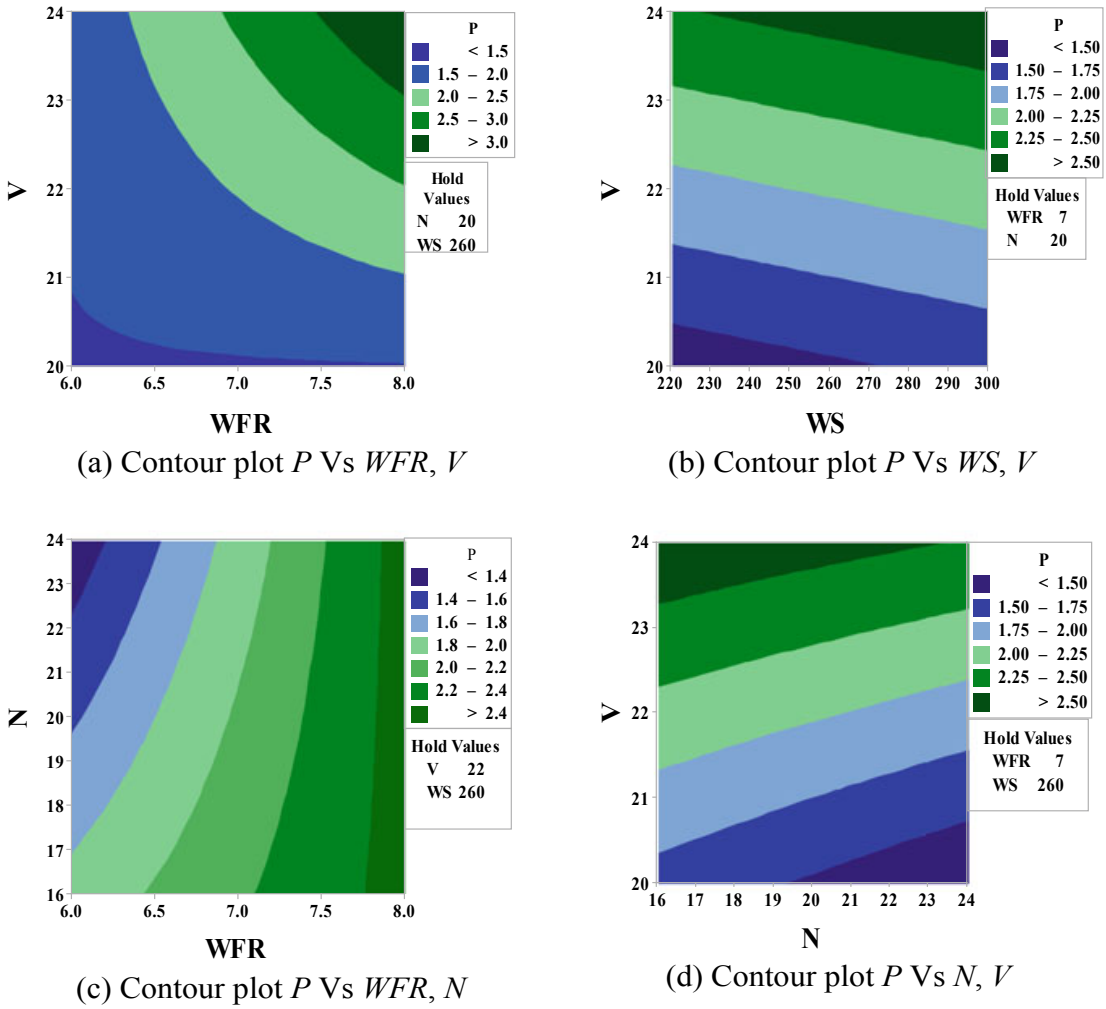
19.4.1 Contour Figures for Penetration (P)

From the results, it is clear that the welding voltage (V), interaction terms WFR $\times$ V and wire feed rate (WFR) are the most significant parameters that affect the penetration. Four figures, viz. P versus WFR and V, WS and V, WFR and N, and V and N, are figured, and it is shown in Fig. 19.5. The dark green colour indicates maximum penetration, and dark blue colour indicates minimum penetration.

The variation in V and WFR on P is shown in Fig. 19.5a. It shows that V and WFR bears a direct relationship with penetration. Increased value of V and WFR increases P in a range of 1.5–3 mm. The Fig. 19.5b also shows that V and N direct variation in P, and Fig. 19.5c shows that as the value of WFR increases, the value of P increases. A minimal effect of N is observed in case of penetration. Figure 19.5d shows the variation of P with N and V that shows direct relationship. The deeper penetration needs high values of input factors.

19.4.2 Contour Figures for Bead Width (W)

Figure 19.6 shows the contour figures for bead width (W) versus WFR and V, WFR and N, V and WS, *and* V and N. From the Fig. 19.6a, it is observed that WFR and N holds a direct relationship with bead width, and as WFR and N increases, the value W also increases. Figure 19.6b shows that with an increase in V, the value of W decreases. From the Fig. 19.6c, W increases with increase in the value of N and WS, and in Fig. 19.6d, low value of N shows minimum W, and W slightly increases with increase in N. W is almost unaffected with an increase in V.



(a) Contour plot *P* Vs *WFR*, *V*

(b) Contour plot *P* Vs *WS*, *V*

(c) Contour plot *P* Vs *WFR*, *N*

(d) Contour plot *P* Vs *N*, *V*

Fig. 19.5 Contour figures for penetration

19.4.3 Contour Figures for Bead Height (H)

Contour figures of *H* versus WFR and *V*, WFR and WS, *and V* and *N* shown in Fig. 19.7 provide better understanding of weld parameter on *H*. From the Fig. 19.7a, it is observed that the value of height (*H*) increases with increase in wire feed rate (*W*) and remains unaffected by *V* value. From Fig. 19.7b, it is also observed that with an increase in WFR, bead height increases and *H* decreases with an increase in welding speed (WS). From the Fig. 19.7c, *H* is maximum at low value of *V* and minimum when the welding voltage (*V*) increases and *H* increases with increase in nozzle-to-plate distance (*N*).

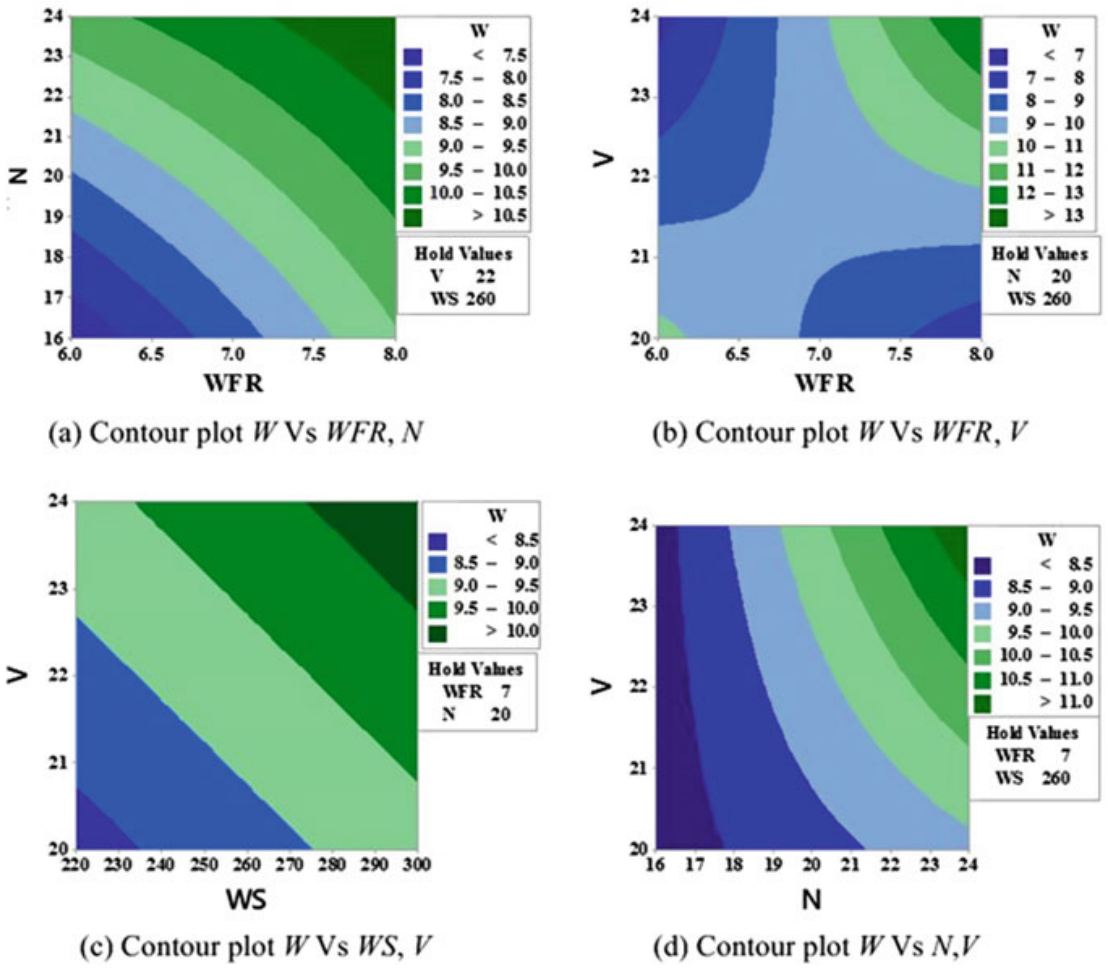


Fig. 19.6 Contour figures for bead width

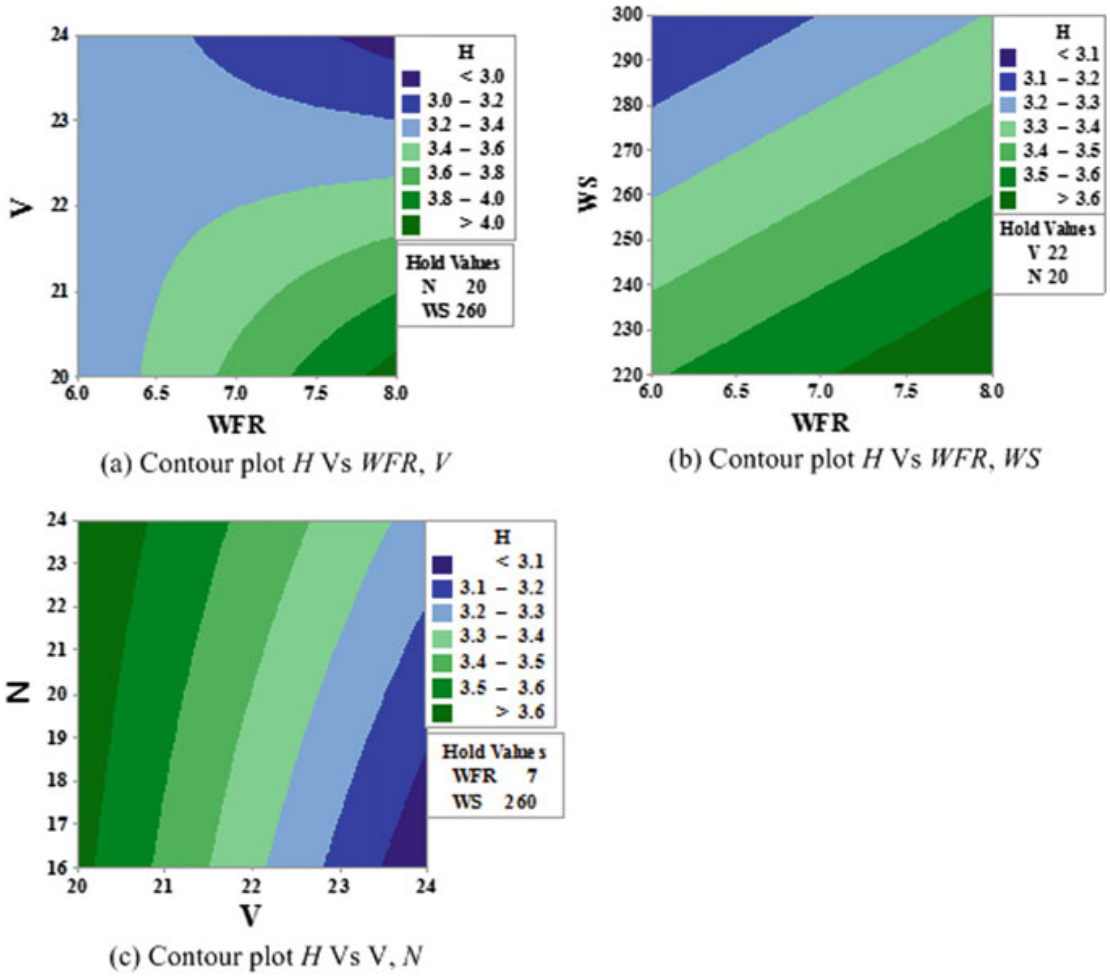
19.5 Optimization of GMAW Welding

19.5.1 Single-Objective Optimization Using GA

In single-objective optimization, optimum process parameters are obtained to maximize penetration and minimize bead width and bead height individually. The optimization problem is formulated with fitness function derived from regression model equations and is optimized using GA toolbox available in MATLAB 14. The function P (penetration) is maximized and function W (bead width) and H (bead height) are minimized subjected to variable bounds of the factors. The range of the level of each factor decides the upper and lower bounds of the variables. The GA optimization is carried out for both single and multiple objectives. The problem is formulated for single-objective optimization as follows:



(a) Contour plot *H* Vs *WFR*, *V*

(b) Contour plot *H* Vs *WFR*, *WS*

(c) Contour plot *H* Vs V, *N*

Fig. 19.7 Contour figures for bead height

Objective 1

$$\textbf{Maximize } \boldsymbol{P}(\boldsymbol{WFR}, \boldsymbol{V}, \boldsymbol{N}, \boldsymbol{WS}) = -(34.11 - 5.093\,\text{WFR} - 1.358\,V - 0.427\,N + 0.00254\,\text{WS} + 0.2176\,\text{WFR} \times V + 0.0379\,\text{WFR} \times N + 0.00570\,V \times N) \tag{19.5}$$

Objective 2

$$\textbf{Minimize } \boldsymbol{W}(\boldsymbol{WFR}, \boldsymbol{V}, \boldsymbol{N}, \boldsymbol{WS}) = 187.6 - 23.6\,\text{WFR} - 9.24V - 0.58N + 0.0124\,\text{WS} + 1.180\,\text{WFR} \times V - 0.074\,\text{WFR} \times N + 0.062\,V \times N \tag{19.6}$$

Objective 3

$$\textbf{Minimize } \boldsymbol{H}(\boldsymbol{WFR}, \boldsymbol{V}, \boldsymbol{N}, \boldsymbol{WS}) = -14.6 + 3.46\,\text{WFR} + 0.896\,V - 0.185\,N - 0.00489\,\text{WS} - 0.163\,\text{WFR} \times V + 0.0112\,\text{WFR} \times N + 0.0057\,V \times N \tag{19.7}$$

Table 19.3 GA results for single-objective optimization

S. No.	Optimization objective	No. of iterations	Optimum process parameters				Results obtained (mm)
			WFR (m/min)	V (V)	N (mm)	WS (mm/min)	
1	Maximize P	121	8	24	20	258	3.468
2	Minimize W	134	6	24	16	220	4.312
3	Minimize H	109	8	24	16	300	2.483

The variable process is bounded by its lower bound (LB) and upper bound (UB). The LB and UB are given as $6 \leq \text{WFR} \leq 8$; $20 \leq V \leq 24$; $16 \leq N \leq 24$; $220 \leq \text{WS} \leq 300$. The problem can be optimized with the MATLAB 14 GA toolbox. Table 19.3 shows GA results for single optimization.

19.5.2 Simultaneous Optimization

In this work, multi-optimization is performed for two different optimization problems. Each optimization problem provides 18 Pareto-optimal fronts that provide different values of optimum parameters. Each combination of optimum parameter provides the corresponding value of maximum penetration (P), minimum bead width (W) and minimum bead height (H) obtained in the weld bead geometry. The problem is formulated as follows:

Multi-optimization objective 1

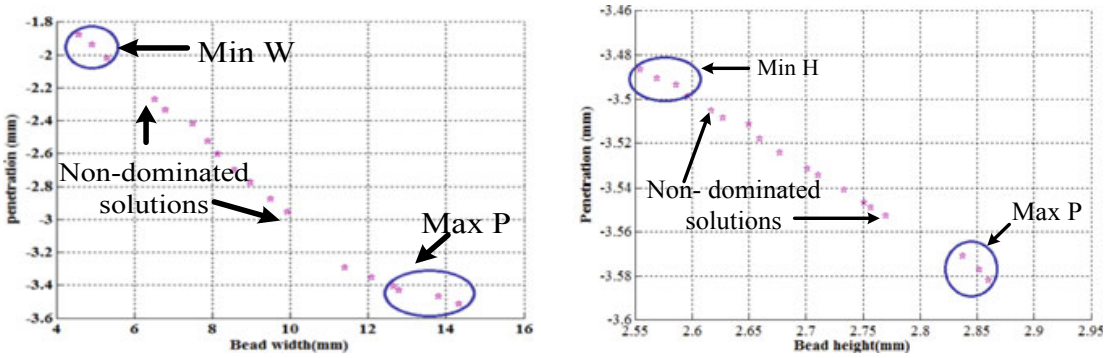
$$\textbf{Maximize } \boldsymbol{P} \textbf{ and minimize } \boldsymbol{W}(\boldsymbol{WFR}, \boldsymbol{V}, \boldsymbol{N}, \boldsymbol{WS}) \tag{19.8}$$

Multi-optimization objective 2

$$\textbf{Maximize } \boldsymbol{P} \textbf{ and minimize } \boldsymbol{H}(\boldsymbol{WFR}, \boldsymbol{V}, \boldsymbol{N}, \boldsymbol{WS}) \tag{19.9}$$

subjected to $6 \leq \text{WFR} \leq 8; 20 \leq V \leq 24; 16 \leq N \leq 24; 220 \leq \text{WS} \leq 300$.

The above multi-objective optimization problem of GMAW of AISI 201 SS is carried out using GA toolbox in MATLAB 14. Figure 19.8 shows the non-dominated Pareto front figure being a number of optimal solutions for objectives 1 and 2, respectively.



(a) For *P* and *W* (b) For *P* and *H*

Fig. 19.8 Pareto-optimal solutions

19.6 Industrial Application Optimization

Manufacturing industries require production of better quality of components having maximum penetration (*P*) with minimum bead width (*W*) and bead height (*H*) for economic production of quality components. In reference to optimization problem 1, GA solutions are given in Table 19.4. For the industrial use of this optimization

18	7.999	23.982	20.669	286.882	3.541	13.661

results, the value of penetration P is arranged in ascending order. Considering optimum parameters to be obtained for a weld design having $P \geq 2$, the GA provides 14 possible optimal solutions (i.e. S. No. 5–18). For minimum bead width, S. No. 5 is found to be optimum providing minimum bead width W satisfying the penetration (P) in the desired level. If $P \geq 3$, GA provides 8 possible optimal solutions (i.e. S. No. 11–18) and S. No. 11 is the optimal solution providing minimum bead width (W) satisfying penetration (P).

Similarly, in reference to optimization problem 2, GA solutions are given in Table 19.5. Considering optimum parameters to be obtained for a weld design having $P \leq 3.5$, the GA provides 5 possible optimal solutions (i.e. S. No. 1–5). For minimum bead height, S. No. 1 is found to be optimum providing minimum H satisfying the P in the desired level. If $P \geq 3.5$, GA provides 13 possible optimal solutions (i.e. S. No. 6–18) and S. No. 6 is the optimal solution providing minimum H satisfying P.

19.7 Conclusion

This study investigates the influence of process parameters of gas metal arc welding (GMAW) like wire feed rate, welding voltage, nozzle-to-plate distance and welding speed on weld bead geometry such as penetration, bead width and bead height during the welding process of stainless steel of AISI 201 grade. Parametric analysis and development of predictive model are carried out. The most important parameters for the geometry of weld beads are welding voltage and wire feed rates. The increase in wire feed rates and voltage increases penetration and bead width, while increasing the distance between nozzles decreases the penetration value and bead width. The deeper penetration needs high values of input factors. The developed model having R^2 value greater than 95% and predictive performance with an average error of less than 5% confirms the effectiveness of the model. The single optimization using GA provides maximum P of 3.468 mm, minimum W of 4.312 mm and minimum H of 2.483 mm corresponding to different combinations of weld parameters. The simultaneous optimization of both (i) penetration (P) and bead width (W); (ii) penetration (P) and bead height (H) using GA gives 18 combinations of Pareto-optimal solutions. Optimized results can be used as guidelines for manufacturing industry to select optimum welding parameters to produce desired penetration value (P) with either minimum width or height of weld bead. The approach is found to be an effective and have minimum effort.

Finite Element Modelling and Experimental Verification of Dissimilar Joining Between Inconel 718 and SS 316L by Micro-plasma Arc Welding

Ajit Kumar Sahu and Swarup Bag

Abstract In the present research work, an attempt is made to successfully weld Inconel 718, a nickel-based superalloy with SS 316L, an austenitic stainless steel in autogenous mode by using constant current micro-plasma welding process. A finite element method (FEM)-based, three-dimensional (3D) thermal model is developed for butt welding configuration between the selected bimetallic combinations by using a double-ellipsoidal volumetric heat source model. A good consistency is found between the numerically obtained and experimentally obtained weld bead measurements. The numerical model is further used to extract peak temperatures, time–temperature profiles along with average cooling rates of the welding processes. Obtained cooling rates are correlated with the weld micro-structures and mechanical properties. Micro-structural study by SEM analysis has shown coarse columnar dendritic structure in the weld interior for the higher heat input welding case, whereas lower heat input during welding leads to fine weld micro-structure due to high cooling rate. An improvement in the tensile strength and hardness value is observed with increase in weld cooling rate and low heat input during the joining process.

20.1 Introduction

Welding of dissimilar materials is always a challenging task due to the differences in material composition and physical properties which need several trials to optimize successful welding parameters. Dissimilar material welding has been in demand for various industries to reduce material cost and to improve flexibility in design. It not only satisfies the service condition but also reduces component cost by reducing the amount of high-cost materials in a component [1]. Inconel 718 is a nickel–chromium-based precipitation hardened superalloy which is strengthened mostly by γ'' (Ni_3Nb) precipitates [2]. Excellent corrosion and oxidation resistance along with extensive mechanical properties at elevated temperature makes Inconel 718 suitable for various critical condition applications. Higher resistance to strain age cracking during the welding makes it one of the most successful high temperatures nickel–chromium alloy ever designed. It is widely used to make hot section components of aero engine, liquid rocket cryogenic engines, and gas turbines blades. It is also widely used in chemical industries, process industries, and nuclear reactors in various severe working conditions [3]. Similarly, austenitic steels are widely used in petrochemical, aerospace, and power generating sector in the form of plates, coils, sheets, bars, and tubing. AISI 316L contains lower amount of carbon which makes this austenitic steel immune to the sensitization at elevated temperatures [4]. AISI 316L exhibits higher creep and tensile strength as compared to other nickel–chromium austenitic steels over a wide temperature range. It also possesses excellent toughness even at the cryogenic temperature which makes it distinct from other chromium–nickel austenitic stainless steels.

The aforesaid features of Inconel 718 and AISI 316L make them suitable to use in the form of bimetallic joint for various engineering applications to make various components in aerospace engine and gas turbine engine. This bimetallic combination is used by ALSTOM Power Sweden for making compressor rotor where high pressure compressor stages are made by Inconel 718 and low pressure stages are made of austenitic based stainless steel [5]. Fusion welding is one of the most preferred joining techniques for this bimetallic combination to establish a good metallurgical bond between the mating surfaces. Although fusion welding of Inconel 718 is not utterly free from welding defects, it can be minimized by taking required precautions during welding process. Defects like solidification cracking and micro-fissuring in the fusion zone (FZ) and heat affected zone (HAZ) are major problem associated with the Inconel 718 and AISI 316L [6]. The generation of intermetallic Laves phase by segregation of niobium (Nb) in the interdendritic region during weld metal solidification is the main cause of above welding defects in Inconel 718 [7], whereas formation of 3–9% of δ ferrite reduces tendency of hot cracking, but higher percentage of ferrite content reduces creep life along with corrosion resistance of the AISI 316L joint [8]. A higher weld cooling rate has resulted in minimization of these defects which can be achieved by using a heat source of higher power density [9]. Thavamani et al. [10] have used gas tungsten arc welding (GTAW) process for welding Inconel 718 at three different heat input

of 530, 670 and 800 J/mm and reported the size of dendrites and crack sensitivity of the weld increasing with increase in heat input. Lower value of heat input improves the weld cooling rate, whereas higher value slows down the weld cooling rate which leads to segregation of various useful alloying element into the interdendritic regions, leading to deterioration of mechanical properties of the welded component. Bansal et al. [11] have used microwave welding to join Inconel 718 and AISI316L with Inconel 718 powder as interfacing layer between the two surfaces and reported good joint strength for the bimetallic welded joint. Ramkumar et al. [12] have used multi-pass GTAW process to weld this bimetallic combination of material and reported superior mechanical properties for the joint as compared to the AISI 316L base material. Ramkumar et al. [13] inspected the dissimilar welding of Inconel 718 and SS 316L with the help of constant and pulsed current mode GTAW process. They found weld prepared by pulsed current mode has superior tensile, hardness and toughness properties as compared to constant current mode weld which is mainly due to the control of Laves phase formation due to higher cooling rate, obtained during pulsed current mode of welding. Kumar et al. [4] also employed CCGTAW and PCGTAW to weld Inconel 625 and AISI 316L and stated presence of various secondary phases in the HAZ are minimal for PCGTAW condition. From the above literature review, it can be concluded that the scope and application of joining this bimetallic combination are wider and required through investigation in terms of joint performance at ambient temperature. The selection of proper welding techniques and process condition is an important aspect of welding dissimilar materials. By using advanced welding techniques, full penetration can be achieved comparatively at a lower heat input; as a result, the weld cooing rate can be enhanced and formation of various deleterious secondary phases can be constricted [14]. From the open literature, it was evident most of the reported work were limited to GTAW process for joining this bimetallic combination. Hence, in the present study, micro-plasma arc welding technique which has higher power intensity among all the arc welding processes is used to join this bimetallic combination [15]. μ-PAW also possesses good arc stability even at very low range of current as compared to GTAW which makes this process more suitable for joining thin sheets. The present study is mainly focused on weldability, mechanical and metallurgical analysis of these bimetallic joints obtained at different condition of continuous current μ-PAW process. Another objective of the present study is to correlate the effect of heat input/cooling rate on fusion zone micro-structure and Laves phase formation by different welding condition.

Direct experimental investigations during welding are extremely expensive and often impossible because of the complexity of the process and presence of high temperature arc. Hence, a three-dimensional finite element (FE)-based numerical model was developed using ABAQUS to obtain the temperature isotherm in the fusion zone along with time–temperature history of μ-PAW welding process. The conductive heat transfer-based numerical modelling is done by using a moving double-ellipsoidal heat source that is accountable for complex physical phenomena like conduction, convection along with radiation heat transfer from the joining surfaces to the ambient. The double-ellipsoidal heat source is used in the current

study due to its unique capability to incorporate steep gradient of temperature in the front of heat source and a gentle gradient in the trailing edge of weld pool [16]. Temperature-based physical properties of the materials were considered in the model. Thereafter, the time–temperature profile of the fusion zone from the numerical model is accounted for estimation of the cooling rate. The influence of weld cooling rate/solidification rate on weld micro-structure and corresponding outcome on mechanical properties are reported in the present study.

20.2 Experimental Procedure

As received Inconel 718 and AISI 316L stainless steel sheets of thickness 0.7 mm were sheared into 100 × 60 mm coupons with welding direction normal to the rolling direction, the chemical composition of the base materials were analysed by energy dispersive X-ray (EDX) technique and results are shown in Fig. 20.1. Based on EDX analysis, the resulted composition (wt%) of Inconel 718 and AISI 316L are given in Table 20.1.

The welding surfaces were cleaned with acetone prior to the welding process for removing oxides and other foreign impurities. Sheets were clamped in a restrain fixture made up of copper to achieve high cooling rate. The welding torch of micro-plasma set-up is kept fixed and the workpiece is allowed to move at a constant velocity. Commercially available argon gas (99% pure) is used as plasma gas as well as used as a shielding gas for the protection of weld pool. Butt configuration weld joints were prepared by constant current (CC) mode using micro-plasma arc welding set-up with a DC current range of 0.05–50 A. The plasma gas and shielding gas flow rate are maintained at 0.5 and 5 L/min, respectively, with a nozzle standoff distance of 2 mm. The other welding parameters employed for making defect free welds are depicted in Table 20.2 which is obtained by a wide range of welding trials.

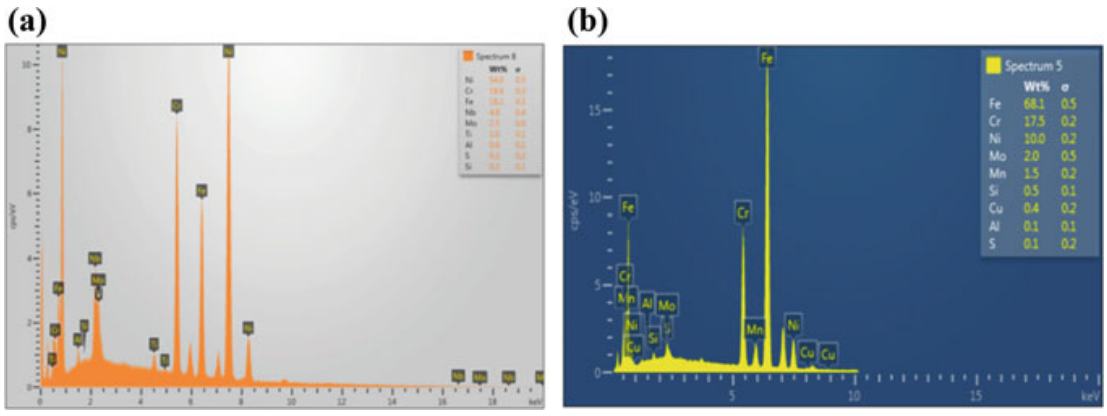

Fig. 20.1 EDX elemental analysis of **a** Inconel 718 and **b** AISI 316L base material

Table 20.1 Chemical composition (wt%) of Inconel 718 and AISI 316L

Elements	Ni	Cr	Nb	Mo	Ti	Al	Si	S	Fe
Inconel 718	54.0	18.6	4.8	2.5	1.0	0.6	0.2	0.2	Bal.
Elements	Ni	Cr	Mo	Mn	Si	Cu	Al	S	Fe
AISI 316L	10.0	17.5	2.0	1.5	0.5	0.4	0.1	0.1	Bal.

Table 20.2 Process parameters for μ-PAW of Inconel 718 and SS 316L weldments

Sample	Current (A)	Voltage (V)	Welding speed (mm/s)	Heat input (J/mm)
S1	14	24	3.4	99
S2	15	24	3.2	112

The welded samples were sheared normal to the welding direction and polished for macro-structural analysis. Then, the mirror polished samples were etched in a mixture of HCl, HF and CH_3COOH in the ratio of 1.5:1:1, respectively, for the micro-structural analysis. The micro-structural analyses were done by the help of optical microscope and scanning electron microscope. Vickers's micro-hardness measurements were done across the weld bead for each specimen to analyse the hardness behaviour. Tensile test of the welded specimens and base materials are conducted at room temperature to analyse the yield strength, ultimate tensile strength and percentage elongation. For each condition, two sub-size transverse specimens were prepared according to ASTM E8 M standard with a gauge length of 25 mm. The tests were conducted by a computer controlled servo-hydraulic universal tensile testing machine with a cross-head speed of 1 mm/min.

20.3 Numerical Model

Experimental investigations have certain limitations due the involvement of high temperature heat source during the welding process. Hence, a finite element-based conduction heat transfer model is developed for the micro-plasma arc welding process to obtain temperature distribution of the entire weldment. The moving heat source is incorporated in the model by using a DFLUX subroutine with the numerical model. To approximate the influence of convective transport of heat in weld pool, a Gaussian distributed double-ellipsoidal volumetric heat source is used to distribute the heat flux into the joining surfaces. Temperature-based thermo-physical properties for SS 316L and Inconel 718 were considered in the present analysis [17, 18]. For simplification, following assumptions were considered in the model: Top surface of the fusion zone is assumed as flat and neglecting the effect of plasma arc and shielding gas. The initial temperature of workpiece was taken as uniform ambient temperature (T_0) of 300 K. The latent heat of melting and

cooling is incorporated, whereas material evaporation from the fusion zone is neglected. The surface of the base plates which is exposed to heat flux and other surfaces is subjected to heat losses due to convection and radiation. The surfaces which are directly exposed to air were assigned a convective heat transfer coefficient (h) of 35 W/m^2 K [16]. However, surfaces which are in direct contact with the copper fixture and backing plate, which have high thermal conductivity, are assigned with a high heat transfer coefficient of 1000 W/m^2 K [19]. The fundamental governing equation of heat transfer or conservation of energy in 3D Cartesian coordinate is expressed as

$$\rho C\left(\frac{\partial T}{\partial t}-v\frac{\partial T}{\partial x}\right)=\frac{\partial}{\partial x}\left(k\frac{\partial T}{\partial x}\right)+\frac{\partial}{\partial y}\left(k\frac{\partial T}{\partial y}\right)+\frac{\partial}{\partial z}\left(k\frac{\partial T}{\partial z}\right)+\dot{q} \qquad (20.1)$$

where (x, y, z) is the coordinate system associated with the moving heat source. ρ, k and C refer to density, thermal conductivity and specific heat of the base material, respectively. T and t represents temperature and time variable, respectively. $\dot{q}$ is the internal heat generation per unit time and per unit volume and 'v' is considered as the velocity of the plasma arc in welding direction (x-axis) or moving coordinate axis. The meshing arrangement of base plate is shown in Fig. 20.2. Very fine meshing is provided in the fusion zone area to capture thermal history precisely as it is exposed to a very concentric heat source where the temperature gradient becomes steep. While coarser meshing was generated in the area far from the heat flux to reduce computational cost, Continuum solid eight nodded brick elements (DC3D8 type) were selected in the thermal analysis for diffusive heat transfer.

The double-ellipsoidal parameters like width (b) and depth (c) of the double-ellipsoidal heat source were directly taken from the experimental results. The length of front (c_f) and rear (c_r) quadrant were estimated as a function of velocity [20]. In dissimilar welding, the fusion zone becomes a mixture of both base materials which will produce various intermetallic compounds during the

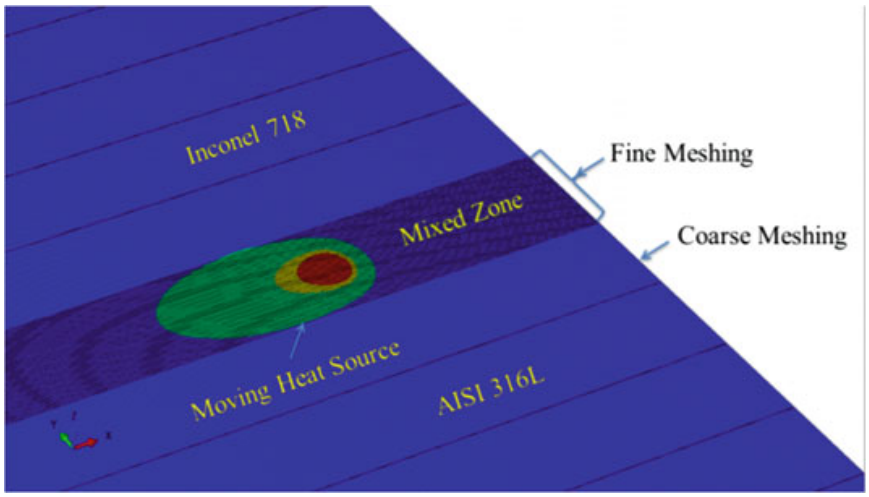

Fig. 20.2 Finite element meshing of solution domain

solidification and will have an impact the joint efficiency. Therefore, to correlate the weld cooling rate with intermetallic phase formation precisely, the temperature dependent thermo-physical properties of fusion zone were considered as the average of both base materials which is named as mixed zone as shown in Fig. 20.2.

20.4 Results and Discussion

20.4.1 Temperature Field Characteristics

Temperature distribution corresponding to S1 welding condition along with the moving heat source is shown in Fig. 20.3. A peak temperature of 2169 K is achieved at the weld centre line. The fusion zone (FZ) is defined by 1730 K which is the liquidus temperature of AISI 316L, i.e. maximum between the base materials [1]. And the heat affected zone (HAZ) was defined below 1547 K which is the solidus temperature of Inconel 718, i.e. minimum between the base materials [21]. The region between these two isotherm contours is considered as mushy zone where liquid and solid phase coexists together.

The comparison between simulated and experimentally estimated weld macrographs in transverse cross section for both welding conditions is shown in Fig. 20.4, where FZ, mushy zone, and HAZ are well defined. The shape and size of the numerically simulated outcomes were found to be in good agreement with the experimentally obtained weld macrographs. With increase in welding heat input per unit length, the size of weld bead increases and the fusion zone becomes wider. The weld cross section of S2 welding condition is little bit of straight type as compared

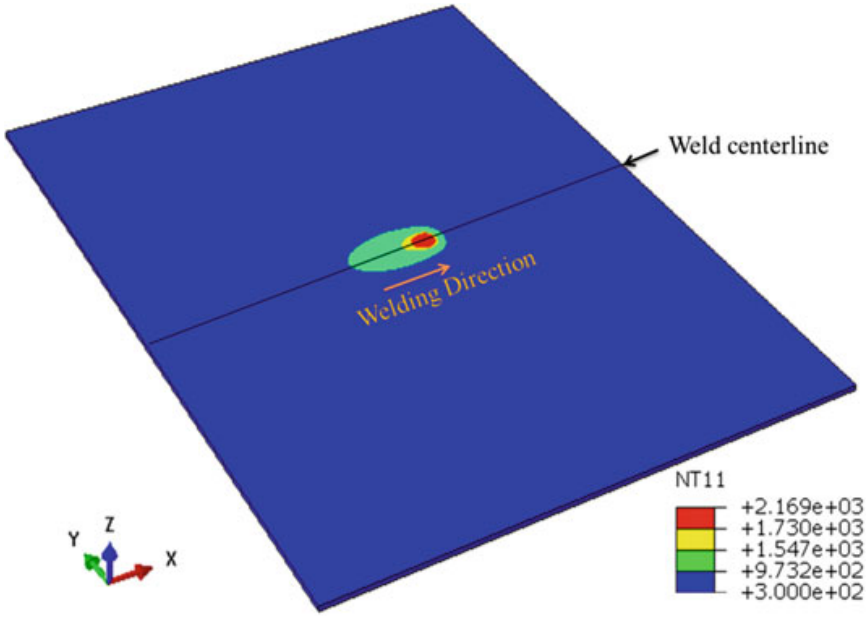

Fig. 20.3 Temperature distribution for S1 welding condition

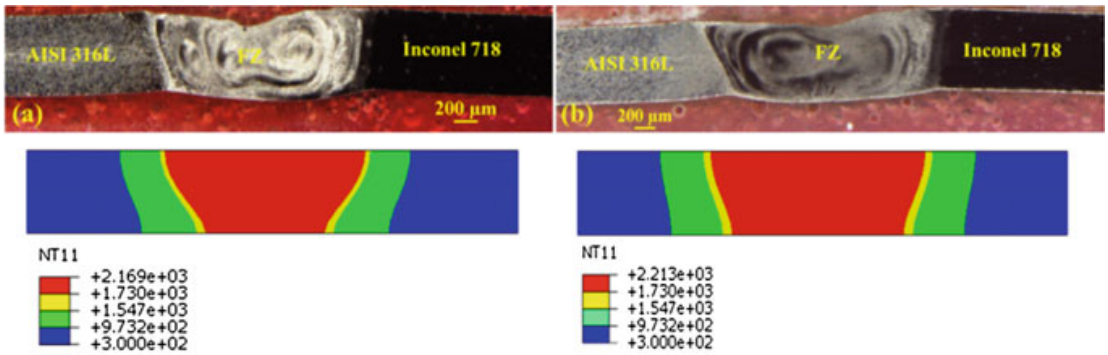

Fig. 20.4 Comparison of weld macrograph for **a** S1 and **b** S2 welding condition

to S1 welding condition which is due to higher heat input during welding process. The maximum error found to be 6% in the weld bead width comparison at the cap and root between experimentally and numerically measured value (Table 20.3).

Figure 20.5 shows the time–temperature profiles of S1 and S2 welding condition at weld centre along with the average weld cooling rate. The temperature rises rapidly as the heat source approaches and drops steadily to ambient temperature when the heat source passes away from the node. The quality of weld is greatly dependent on heat input per unit length during the welding process, peak

Table 20.3 Weld bead dimensions at different location

Location	S1		S2	
	Experimental	Numerical	Experimental	Numerical
Weld cap (mm)	2.46	2.38	2.6	2.44
Weld root (mm)	1.91	1.8	1.96	1.94

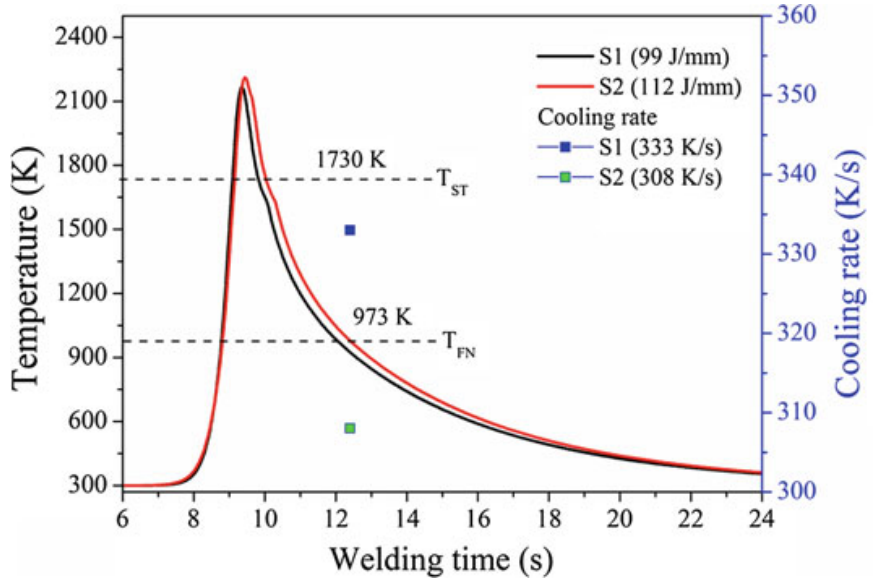

Fig. 20.5 Time–temperature profile and average cooling rate of S1 and S2 welding conditions

temperature, and cooling rate. The peak temperature of S1 and S2 welding conditions were found to be 2169 and 2213 K, respectively. Higher peak temperature for S2 welding condition is attributed to the higher heat input during welding process. The average weld cooling rate was calculated by taking the slope of time–temperature curve between transformation start (T_{ST}) and finish temperature (T_{FN}). Higher liquidus temperature among Inconel 718 and SS 316L was considered as T_{ST} as below this temperature phase transformation initiated. Minimum value of solid phase transformation end temperature among the bimetallic is taken as T_{FN} as below this temperature phase transformation does not occurs. The calculated average cooling rate for S1 and S2 welding condition were 333 and 308 K/s. When the weld peak temperature increases, weld pool lasts for longer period of time resulted in lower average cooling rate.

20.4.2 Effect of Cooling Rate on Weld Micro-structure and Mechanical Properties

Formation of various intermetallic phases during weld cooling period is the major challenge of fusion welding process. Segregation of Mo and Nb in the interdendritic region leads to formation of deleterious Laves phases in Inconel 718 which promotes liquation cracks and micro-fissuring in the FZ and HAZ [14]. In AISI 316L, formation of higher percentage of δ ferrite in interdendritic region has deleterious effect on mechanical properties and corrosion resistance of the joint. The scale of solidification structure is dominated by the cooling rate; higher cooling rate will produce finer dendrites, whereas lower value will produce coarse dendrites. In Fig. 20.6, higher magnification SEM micro-structure of weld interior for both the welding conditions is shown. Higher cooling rate of S1 weld condition (333 K/s) leads to fine micro-structure as compared to S2 weld condition (308 K/s). Coarse columnar dendrites were observed in the weld interior for S2 welding condition, whereas fine interconnected equiaxed type of micro-structure was observed in S1 welding condition.

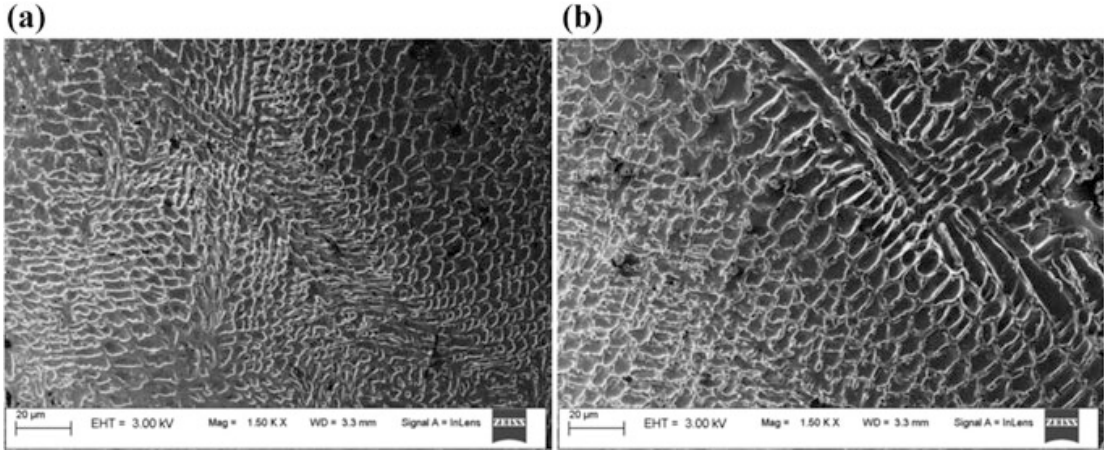

Fig. 20.6 Fusion zone micro-structure of **a** S1 and **b** S2 welding condition

Table 20.4 Results of tensile test

	Inconel 718 (base material)	AISI 316L (base material)	S1 (weld joint)	S2 (weld joint)
YS (MPa)	594	408	389	337
UTS (MPa)	878	679	653	596
Elongation (%)	23	39	26	21

The weld cooling rate plays a crucial role in controlling interdendritic segregation and formation of various intermetallic phases in the fusion zone. Lower heat input assures a higher cooling rate during the solidification that hinders the segregational tendency of solutes in the interdendritic regions, resulting in a fined micro-structure in the fusion zone. Formation of various intermetallic phases consumes a notable amount of beneficial alloying elements from the base material which results deterioration of weld quality. Hence, control of intermetallic Laves and δ-ferrite phases in the solidified zones improves mechanical properties of the joint. The tensile properties of both base and welded materials are given in Table 20.4. S1 welded samples were failed in the AISI 316L base material sides, whereas S2 welded samples were failed in the fusion zone as shown in Fig. 20.7. The tensile strength of S1 weld metal were found superior to the S2 weld material which is mainly due to the fined micro-structure of the fusion zone that reduces segregation and formation of intermetallic in the grain boundary. S1 welded sample has a tensile strength of 96% to that of the AISI 316L base material and a tensile strength of 74% to that of Inconel 718. The improvement in tensile strength of S1 welded condition is mainly attributed to the fine weld micro-structure which is mainly due to the higher cooling rate achieved during the welding process.

Cross-weld micro-hardness profile of the S1 and S2 weldments are shown in Fig. 20.8. The average micro-hardness values of base material are 219 HV and 134 HV for Inconel 718 and AISI 316L, respectively. Fusion zone of S1 welding condition has an average micro-hardness value of 154 HV, whereas for S2 welding condition, it has a lower value of 148 HV. Higher hardness of S1 fusion zone is mainly due to the fine micro-structure because of higher cooling rate. The hardness is found to be less in the HAZ region as compared to the FZ and BM, which is mainly attributed to the grain coarsening from FZ towards BM.

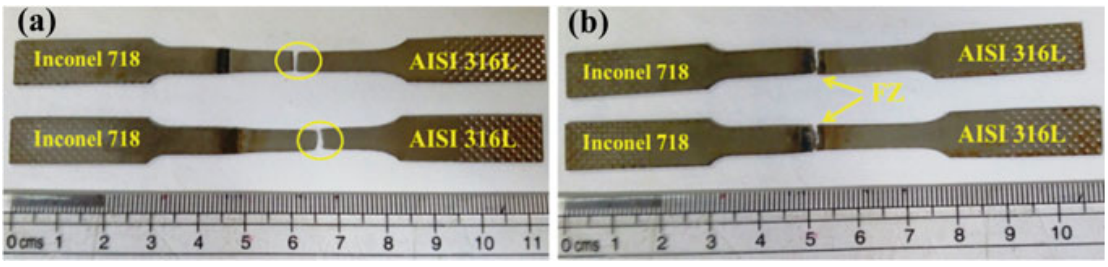

Fig. 20.7 Location of tensile fracture for **a** S1 and **b** S2 welding conditions

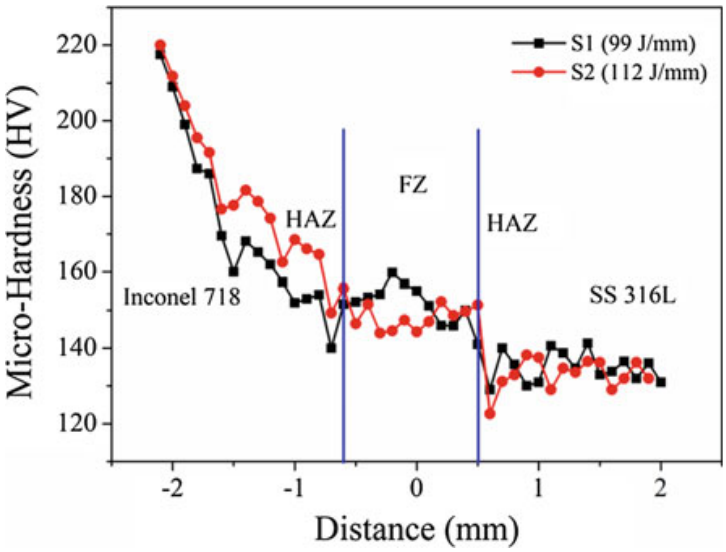

Fig. 20.8 Cross-weld micro-hardness distribution

20.5 Conclusion

In the present study micro-plasma arc welding between Inconel 718 with AISI 316L sheet materials with butt joint configuration has been undertaken. A three-dimensional FE-based thermal model is developed to investigate the thermal cycle during the welding process. The following conclusions were drawn from the current study

- A good agreement was obtained between the shape and size of computed and experimentally obtained weld bead.
- Full weld penetration for the bimetallic combination was achieved at a heat input of 99 J/mm.
- A maximum cooling rate of 333 K/s was calculated from the numerical model for the low heat input of 99 J/mm.
- Refinement in weld micro-structure is observed at 333 K/s cooling rate as compared to 308 K/s which results in improved joint efficiency (96.17% of AISI 316L base material) and ductility (26%) of the welded joint.
- A maximum micro-hardness difference of 6 HV is reported between the FZ of 99 and 112 J/mm welding condition.

Chapter 21
Numerical Simulation and Experimental Validation of A-TIG Welding of 2.25Cr–1Mo Steel

A. R. Pavan, B. Arivazhagan, S. Arun Kumar, M. Vasudevan and S. Mahadevan

Abstract Localized heating and cooling during welding introduces residual stress in the weld joints due to the thermal gradients. The microstructure formation in 2.25Cr–1Mo steel is very much sensitive to the rate of cooling and eventually, the austenite may transform to pearlite/bainite/martensite. A variant of Tungsten Inert Gas (TIG) welding called Activated-TIG (A-TIG) welding was made use of in this study. Here, we have tried to develop a numerical model based on the finite element method to predict the thermo-mechanical behavior of 6 mm thick 2.25Cr–1Mo steel weld joints, with accounting solid-state phase transformation. The heat energy supplied to the workpiece is determined and calibrated in the heat source model. Simulated thermal cycle showed a peak temperature of 1377 °C at 8 mm distance away from the weld centerline, whereas, the experimental result showed 1371 °C. A *k*-type thermocouple was used to measure the temperature distribution during welding. The simulated thermal distributions were sequentially coupled to mechanical analysis. The evolution of stress and ultimately the locked-in residual stresses were determined. X-ray diffraction studies showed the peak residual stress near heat affected zone of 592 MPa and the vertical height gauge was used to measure the distortion before and after welding. The predicted residual stresses and distortion showed good agreement with the experimental measurements.

21.1 Introduction

A higher level of welding residual stress or locked-in stress in the weld joint is a life-limiting factor under service conditions. Steep thermal gradient and shrinkage of sizeable molten metal volume generate tensile stress near the weld joint and is inevitable. This, in turn, leads to stress corrosion cracking, causes brittle fracture and premature failure of engineering components [1]. But, compressive residual stresses are beneficial in certain circumstances [2]. Therefore, by knowing the magnitude of residual stress, one can estimate the remaining life of weld joints with safety measures. However, the locked-in stresses can be controlled and reduced by proper choice of the welding process and use of restraints. Thus, the safety of the structure and design can be increased.

The 2.25Cr–1Mo steel has been most widely used in petrochemical, modern power generation industry in the form of boilers, heaters, heat exchangers, reactors, and hydrocrackers usually built as heavy wall pressure vessels in very high temperature range of 350–550 °C because of its excellent strength at elevated temperatures [3, 4]. The excellent resistance to creep and corrosion, high toughness and good weldability makes it as a candidate material in service conditions. Alongside, these materials have good physical properties such as a low thermal expansion coefficient and a high thermal conductivity. Hence, Cr–Mo steels are promising to operate at high temperatures and under low stresses. Moreover, the integrity of the weld joint decides the performance of any components. Further, the mechanical properties of 2.25Cr–1Mo steel depend on the microstructure, which is sensitive to the cooling rate which in turn depends on heat input during welding [5]. Normally air-cooled steel forms bainitic microstructure at room temperature. This type of steel is usually air cooled after austenitization for service in power plant applications [6]. For 2.25Cr–1Mo joint fabrication, Shielded Metal Arc Welding (SMAW) and TIG welding have been widely adopted [7]. Moreover, TIG has lower productivity while joining the thick (>3 mm) components due to a large number of weld passes utilized to create a joint which eventually introduces high tensile residual stress near the joint with very high distortion. Recently, the variant of TIG welding known as A-TIG welding is widely applied due to its higher productivity [7], low cost, lower micro inclusion, low residual stress and distortion and also because of autogenous welding. An activating flux containing multi-component oxides, applied on the joint alters the surface tension of the weld pool and controls the arc constriction during TIG welding and eventually enhances the depth of penetration up to 300% compared to conventional TIG welding process [8].

However, experimentally assessing the evolution of welding residual stress and optimizing the welding parameters to achieve better weld geometry is time-consuming and costly. Thus, a computational approach is utilized to envisage the thermo-mechanical behavior of the weld joint. The welding thermal cycle, residual stress and distortion could be determined by simulation and appropriate measures or changes in the welding process and conditions could be adopted during

the fabrication to reduce the level of residual stresses and distortion in the actual component.

The computational simulation tool has been used from the past few decades to understand the evolution of welding residual stress and distortion in the welded structures. The commonly used approach is one way coupled approach, viz. sequential coupling of thermal history to mechanical analysis. Various studies [9–13] are available on the prediction of welding residual stress and distortion. Further, the complexity in the numerical model is, to consider the solid-state phase transformations during welding. Many studies have successfully incorporated phase transformation in the numerical model [6, 14, 15]. In addition, very few literatures predicted the welding residual stress and distortion in 2.25Cr–1Mo steel [16–18]. However, there is a limited number of literatures on understanding the evolution of welding residual stress and distortion in A-TIG welded 2.25Cr–1Mo steel joints. Therefore, the motivation of this research work is to predict welding residual stress and distortion by considering solid-state phase transformation in 2.25Cr–1Mo steel weld joint fabricated by autogenous A-TIG welding process by numerical simulation.

21.2 Finite Element Modeling

The dimension of 2.25Cr–1Mo steel plate is 300 × 120 × 6 mm^3. Straight-sided square butt joint configuration was used for A-TIG welding process. Numerical simulations were performed using commercially available SYSWELD software. The optimized meshing is necessary to resemble the exact experimental result in the numerical model. Hence, optimization of mesh size, with the right choice of mesh dimensions is required for improving the accuracy of the simulation. In this work, around 30 mm near to the weld line, fine mesh to a size of 1 mm × 0.8 mm (quadrilateral) was chosen, since the effect of the temperature gradient is more near the weld region and heat affected zone as shown in Fig. 21.1.

Goldak double ellipsoidal heat source model was used for defining a heat source [19]. The thermomechanical analysis is done by sequential coupling of thermal and mechanical analysis. Here the thermal and phase transformation strains are coupled

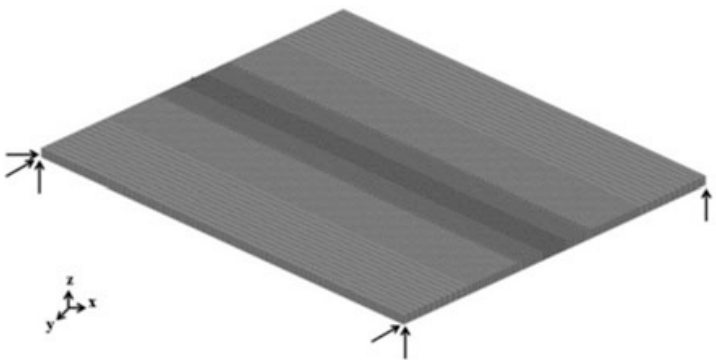

Fig. 21.1 Weld pad model

with non-linear mechanical analysis to understand the evolution of stress and distortion in the weld joint. It was assumed that there is no influence of any structural changes on the thermal analysis part.

21.2.1 Material Properties

The residual stresses and the dimensional change in the weld joint originate owing to the changes in thermo-physical, mechanical properties and microstructural characteristics of materials. Therefore, to get good accuracy in the model, it is necessary to choose appropriate material properties. For 2.25Cr–1Mo steel, the material database was taken from the literature and SYSWELD database [16] as shown in Fig. 21.2. Heat transfer due to convective flow in molten metal is considered in the model by increasing the thermal conductivity value by 2–3 times above the melting temperature.

The heat source fitting tool is used to calibrate the double ellipsoidal heat source and compared with the experimental weld bead macrograph. In addition, the experimental and predicted thermal profiles were compared to know significant heat supply into the material. Further, the obtained thermal stains are sequentially coupled to the mechanical analysis.

21.2.2 Governing Equations

Welding introduces significant heat energy in a localized region. Thus, the heat transfer during welding is primarily due to conduction mode. Heat conduction can be described as shown in the following Eq. (21.1).

$$\nabla(k\nabla T) + Q = \rho C(\partial T/\partial t) \tag{21.1}$$

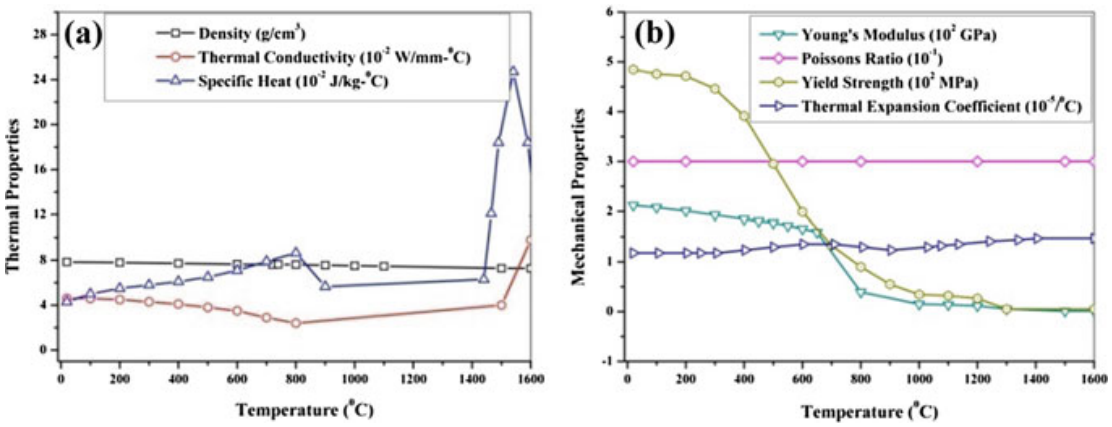

Fig. 21.2 2.25Cr–1Mo steel material properties **a** thermal physical and **b** mechanical properties

where k is the thermal conductivity (W/m °C), Q is the volumetric heat flux (W/m^3), ρ is the density (kg/m^3), and C is the specific heat (J/kg °C).

After welding, the heated material starts to cool to ambient temperature due to convection and radiation. The rate of convection heat transfer is governed by Newton's law of cooling as Eq. (21.2).

$$Q_c - h_c(T_S - T_0) = 0 \tag{21.2}$$

From, Stefan–Boltzmann law the radiation heat transfer is expressed as Eq. (21.3),

$$Q_r - \varepsilon\sigma(T_S^4 - T_0^4) = 0 \tag{21.3}$$

where h_c is the film coefficient for convection [$\sim$25 W/(m^2 K)], T_S is the surface temperature (K), T_0 is the ambient temperature (K), ε is the emissivity (0.8), and σ is the Stefan–Boltzmann constant (5.67 $\times$ 10^{-8} W/m^2 K^4). The total heat transfer can be written as,

$$Q_t = Q_c + Q_r \tag{21.4}$$

$$Q_t = h_c(T_S - T_0) + \varepsilon\sigma\,(T_S^4 - T_0^4) \tag{21.5}$$

By solving Eq. (21.5)

$$\left.\begin{aligned} Q_t &= h_c(T_S - T_0) + \varepsilon\sigma(T_S - T_0)(T_S + T_0)(T_S^2 + T_0^2) \\ Q_t &= [h_c + \varepsilon\sigma(T_S + T_0)(T_S^2 + T_0^2)](T_S - T_0) \end{aligned}\right\}$$

$$h_{eq} = h_c + \varepsilon\sigma(T_S + T_0)\,(T_S^2 + T_0^2) \tag{21.6}$$

$$Q_t = h_{eq}(T_S - T_0) \tag{21.7}$$

where Q_t is the total surface heat transfer and h_{eq} is the overall heat transfer coefficient. To account the phase transformation from parent phase to austenite and austenite to bainite phase transformation in the analysis, Leblond's equation and Johnson–Mehl–Avrami (JMA) were used (Eqs. 21.8 and 21.9).

$$dz/dt = \big(z_{eq}(T) - z/\tau(T)\big)f(\dot{T}) \tag{21.8}$$

$$p = 1 - \exp(-kt^n) \tag{21.9}$$

where z_{eq} refers to austenite proportion at phase equilibrium, z is austenite proportion, p is the fraction of bainite, k and n are kinetic parameters and t is time. The parameters of the JMA equation should be obtained from the Continuous Cooling Transformation (CCT) diagram. Here, we have assumed in the model that there is no formation of martensite upon cooling in the weld metal.

In addition, after the completion of the thermal analysis, by solving Eqs. (21.1) and (21.7) the obtained temperature distributions are coupled to a mechanical analysis by using Eqs. (21.10) and (21.11). In simple terms, the thermal analysis is sequentially coupled to mechanical analysis. Hence, the possible total strain induced on the material during welding is by elastic, thermal, plastic and due to phase transformation as shown in Eq. (21.10).

$$\Delta\varepsilon^{\text{total}} = \Delta\varepsilon^{\text{elastic}} + \Delta\varepsilon^{\text{thermal}} + \Delta\varepsilon^{\text{plastic}} + \Delta\varepsilon^{\text{phase}} \tag{21.10}$$

For, mechanical analysis, the force equilibrium is given as Eq. (21.11)

$$\sigma_{ij} + p_j = 0 \tag{21.11}$$

where σ_{ij} is stress tensor and p_j is body force at any point within the boundary. For the finite element formulation, the basic equilibrium equation can be used to achieve the virtual induced strain and displacement.

21.2.3 Boundary Condition

During the experiment, the weld joint was clamped to avoid vertical movement. Therefore, to match with experimental conditions, the apt external constraints were provided in the model. The rigid clamps were made use of to avoid rotational motion and translational motion of the weld joint. The elastic clamp with a finite stiffness of 10,000 N/mm is used to achieve the proper deformation. Isotropic hardening model was used to consider elastic-plastic material behavior.

21.3 Experimental

As received 2.25Cr–1Mo plates with normalized at 950 °C for 20 min and tempered at 730 °C for 60 min was used with dimension 300 mm × 120 mm × 6 mm having a straight square but joint configuration. Weld plate is fabricated by using A-TIG welding with heat input 2.38 kJ/mm. The transient temperature during the welding process was captured by Chromel-Alumel thermocouples placed 8 mm away from the center of the weld as shown in Fig. 21.3. Vertical height gauge was used to obtain the difference in height of the plate before and after welding (least count 0.006 mm) to estimate the level of distortion.

X-ray diffraction was utilized to estimate the magnitude of welding residual stress with Cr–Kα radiation. The $\sin^2\psi$ method was performed to evaluate the magnitude of residual strain and later strain is converted into stress. Initially, the

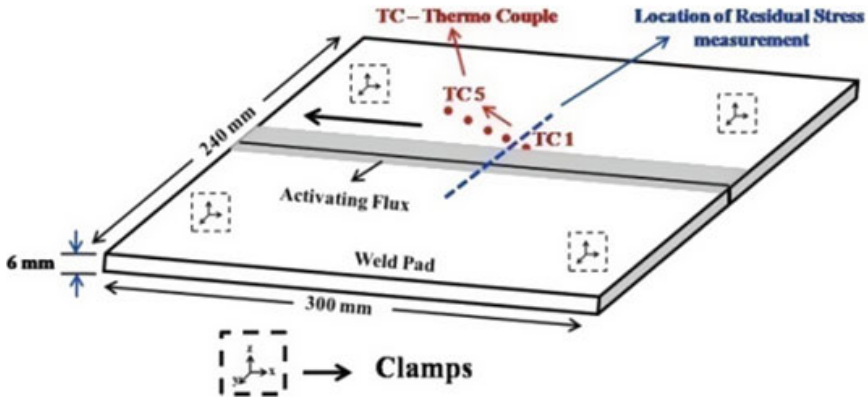

Fig. 21.3 Weld pad configuration

change in d-spacing is characterized at different ψ angles. The slope of a linear plot of d-spacing versus $\sin^2\psi$ gives the residual strain in the material, where, d represents the lattice spacing and ψ is the angle between the surface normal and the bisector of the incident and diffracted beam which is normally varied in the angular range of 0° to 45°.

21.4 Results and Discussion

21.4.1 Thermal Analysis

The thermo-mechanical simulation was carried out by utilizing FEM based SYSWELD software. The heat source fitting tool is employed to calibrate the heat source by comparing with the experimental weld macrograph to ensure the significant amount of heat energy supplied into the material (Fig. 21.4). Initially, heat energy supplied into the weld joint was calibrated using double ellipsoidal heat

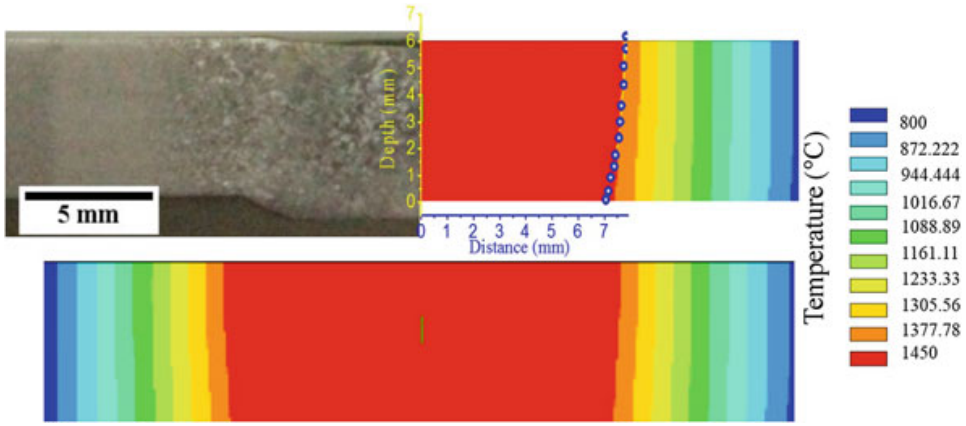

Fig. 21.4 Heat source fitting

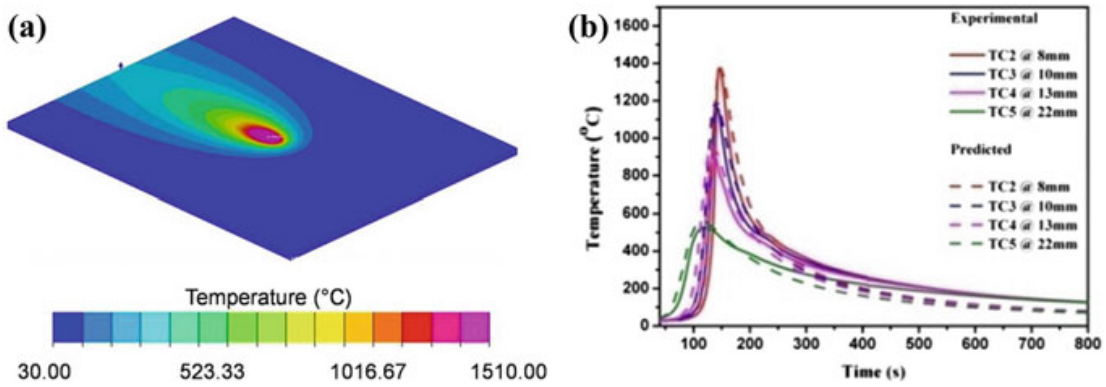

Fig. 21.5 **a** Thermal analysis of weld plate **b** thermal cycles near the weld center

source function parameters as shown in Eqs. (21.12) and (21.13) and fitted with the experimental result as shown in Fig. 21.5b.

Heat input, $Q = \left(\frac{I \times V \times \eta}{v}\right)$

$$q_f(x,y,z,t) = \frac{6\sqrt{3}f_r Q}{a_f bc\pi\sqrt{\pi}} e^{-3x^2/a_f^2} e^{-3y^2/b^2} e^{-3[z+v(\tau-t)]^2/c^2} \tag{21.12}$$

$$q_r(x,y,z,t) = \frac{6\sqrt{3}f_r Q}{a_r bc\pi\sqrt{\pi}} e^{-3x^2/a_r^2} e^{-3y^2/b^2} e^{-3[z+v(\tau-t)]^2/c^2} \tag{21.13}$$

I is the current, V is voltage, η is the efficiency of the welding process and v is the torch velocity in m/s. Efficiency is assumed to be 80% for A-TIG welding. Where a_f and a_r is the front and rear length of the weld pool, respectively, c is the weld penetration depth and b is half width of the weld bead. f_f and f_r ($f_r + f_f = 2$) is the front and rear fractions of the double ellipsoidal heat source, which is considered as 0.4 and 1.6 respectively. q_r and q_f are power densities in W/m^3. The first thermocouple fixed near (8 mm) to the weld bead shows highest peak temperature of 1371 °C and the fifth thermocouple is fixed away (22 mm) from the center of the weld showed lowest peak temperature of 520 °C. This change in peak temperature shows the Gaussian heat distribution, where, the heat flux density is high at the center and gradually decreases away from the center.

During the welding of 2.25Cr–1Mo steel, the microstructures in the weld zone and near the heat affected zone alters according to the applied heat input and mainly due to cooling rate. It is well known that phase transformation affects the magnitude of residual stress due to volume change (body-centered cubic structure to face-centered cubic structure). However, the magnitude of residual stress depends on the yield strength of the material and in turn, yield strength, directly depends on the microstructure of the weld material. Hence it is important to consider yield strength and phase transformation effect on the numerical model for good accuracy. Figure 21.6 shows the granular bainitic microstructure of base metal and bainitic lath structure of as-welded sample; this displayed the typical characteristics of the

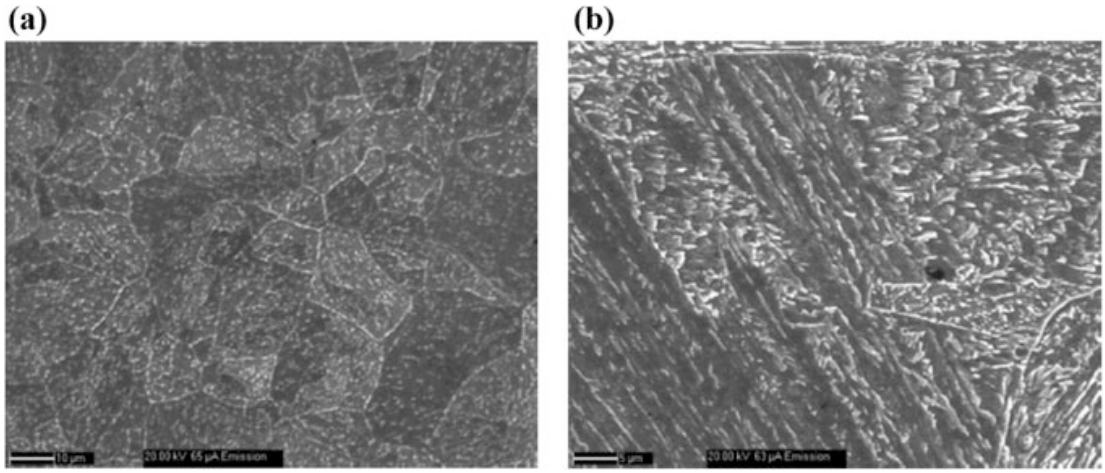

Fig. 21.6 Microstructure **a** base metal **b** weld metal

bainitic microstructure. To consider ferrite/bainite to austenite and austenite to bainite phase transformation, Eqs. (21.4) and (21.5) were used in the model respectively.

21.4.2 Mechanical Analysis

The temperature histories were then sequentially coupled for the mechanical analysis to determine the level of welding residual stress, shrinkage effect and distortion. The strains produced by the thermal energy are coupled to mechanical analysis. The thermal strains, plastic and elastic strains along with volume strains produced due to solid-state phase transformation effect, induce stress in the material. To consider all these factors in the numerical model, temperature dependent material properties must be incorporated, that is, Young's modulus and Poisson's ratio was taken into account for elastic strains. The coefficient of thermal expansion was used for achieving thermal strains. For plastic and phase transformation induced strains, temperature dependent stain hardening and change in volume viz., phase transformation properties were considered in the material database, respectively. A dip in the residual stress distribution across the fusion zone indicates volume relaxation of the weld metal due to phase transformation effect as shown in the contours (Fig. 21.7a, b) of longitudinal residual stress in 2.25Cr–1Mo weld joints.

Figure 21.7 shows the comparison of measured and predicted longitudinal welding residual stress profiles at the mid-cross-section of the weld joint. Measured peak tensile residual stress is 592 MPa while the predicted value was 568 MPa. The weld-induced residual stress has high magnitude at heat affected zone (HAZ) and at the weld center; there was a relaxation in the stress value. This is mainly due to localized heating and cooling, the only a small area near the joint is affected by the

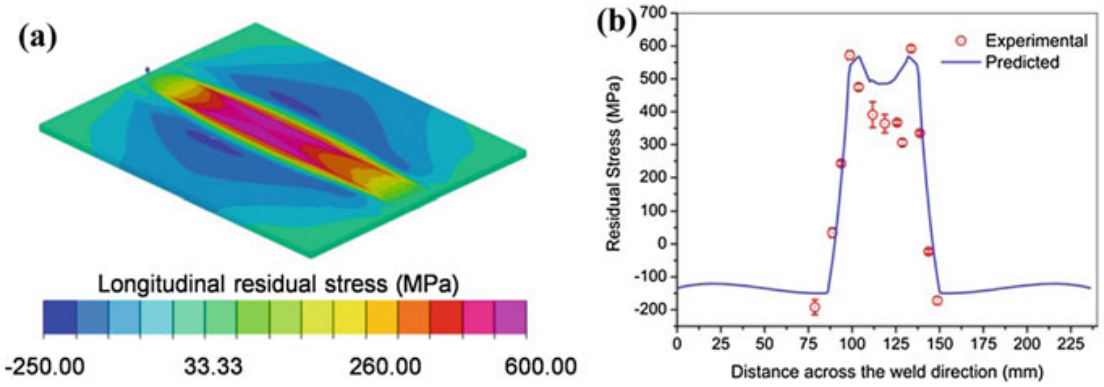

Fig. 21.7 Longitudinal residual stress **a** contour image **b** validation

intense heat source which leads to the steep thermal gradient. Hence, the contraction of the molten metal pool is hindered by the cooler region. Therefore, usually in a weld metal peak tensile stress near the interface (heat affected zone) can be found (Fig. 21.7b). Further, volume change during phase transformation relieves the built-up stress and eventually leads to the stress relaxation at the weld center. The predicted and measured tensile residual stresses near the vicinity of the joint are of the order of yield strength of the material. Thus, the excess generation of stress will drive the deformation in the structure, called distortion (Fig. 21.8a, b).

The formation of stress and eventually the residual stress during heating and cooling cycles at a spot can be understood from Fig. 21.9a, b. As the heating starts, compressive stress increases to a peak value and the stress is limited to materials yield strength. Further, compressive stress starts to decrease as the metal starts to soften. Eventually drops down to zero at the melting point of the material. During cooling, tensile stress starts to build slowly due to thermal strains and at the bainitic start temperature (Bs (T)) there was small stress relieving effect due to the phase transformation from austenite to bainite and also due to change in yield strength. For 2.25Cr–1Mo steel, the Bs (T) varies from 490 to 520 °C. Also, it can be predicted by using the below equation [7].

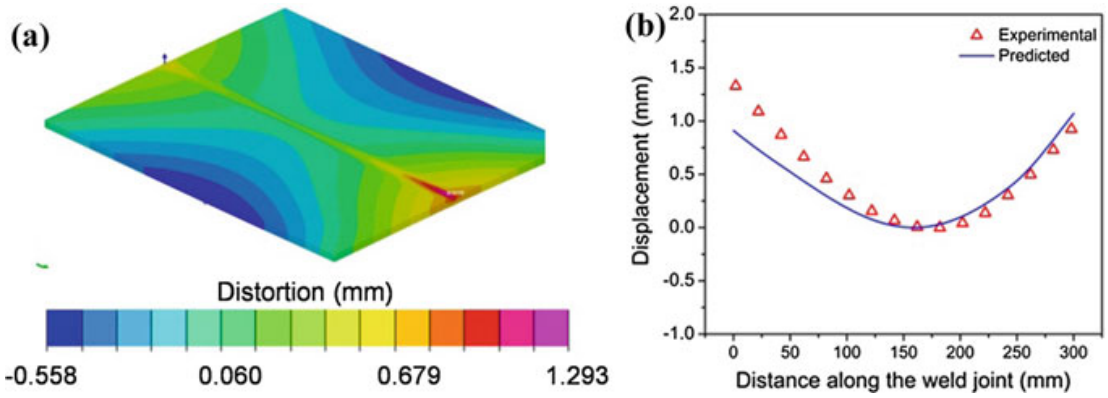

Fig. 21.8 Distortion **a** contour image **b** validation

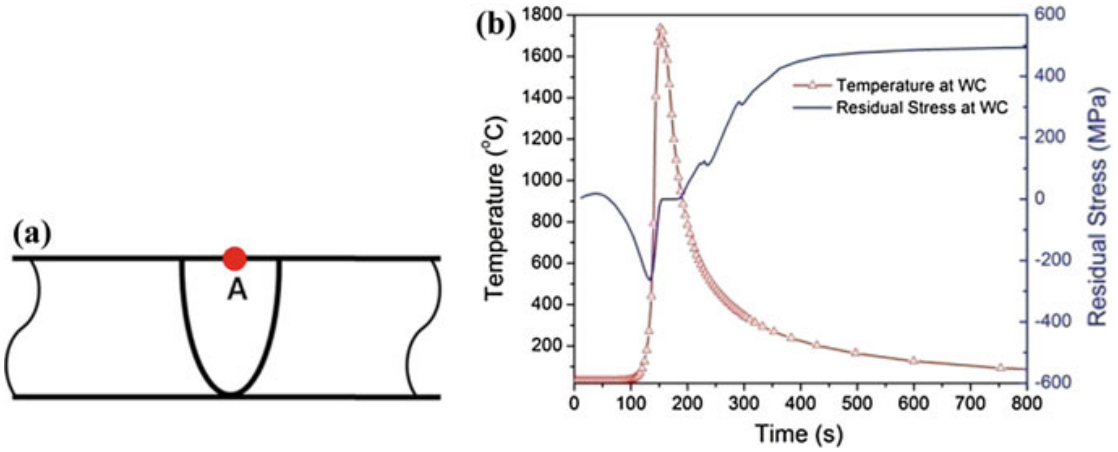

Fig. 21.9 **a** Schematic sketch showing the location of a spot for predicting stress evolution. **b** Evolution of stress during welding thermal cycle at a spot

$$\mathrm{Bs}(^{\circ}\mathrm{C}) = 630 - 45\,\mathrm{Mn} - 40\,\mathrm{V} - 35\,\mathrm{Si} - 30\,\mathrm{Cr} - 25\,\mathrm{Mo} - 20\,\mathrm{Ni} - 15\,\mathrm{W}. \tag{21.14}$$

Meanwhile, cooling beyond bainitic start temperature causes the generation of very high tensile stress because of the dominating effect of thermal strains over volume strain. Eventually, the tensile stress reaches the maximum value of the order of yield strength of base/weld metal.

21.5 Conclusions

Thermo-Mechanical analysis of A-TIG welding of 2.25Cr–1Mo steel has been successfully carried out by the numerical model. The predictions of the numerical model are validated by experimental tools. The following conclusions are drawn from this study:

1. The peak temperature at 8 mm distance was measured as 1371 °C using thermocouples and the thermal cycle exhibited a sharp temperature gradient. Numerical prediction showed 1377 °C at the same spot and therefore, there was good agreement between the predicted and measured temperatures.
2. The predicted and the measured peak tensile residual stress were found to be 592 and 568 MPa respectively near the heat affected region. The welding residual stress profile across the weld joint displayed a typical “M” shape curve which implied that austenite to bainitic phase transformation had an influence on the final residual stress.

3. The observed microstructure at room temperature showed typical bainitic microstructure. Also, the model successfully predicted the distortion with good accuracy. The predicted thermal cycle, residual stress and distortion showed good agreement with the experimentally measured values.

Chapter 22
Finite Element Modeling of Hybrid Laser-TIG Welding of Type 316L(N) Stainless Steel

M. Ragavendran, M. Vasudevan and M. Menaka

Abstract In the present study, thermomechanical analysis of autogenous hybrid laser-TIG welding of type 316L(N) austenitic stainless steel has been carried out. It has been realized that the residual stress due to welding plays a vital role in the mechanical properties of the joint and its performance during service. Therefore, it is important to study the residual stress of type 316L(N) stainless steel weld joint produced by hybrid welding process. First, the thermal analysis was carried using a hybrid heat source consisting of conical and double ellipsoidal models. The heat source was calibrated by comparing the simulated weld bead profile with that of the experimentally obtained weld bead profile. Then, the obtained temperature distribution was sequentially coupled to the mechanical analysis. The simulated thermal cycle was validated by temperature measurements using noncontact real-time IR thermography. The simulated residual profile was validated by an ultrasonic technique employing critically refracted longitudinal waves. The ferrite content of the weld metal was measured using ferrite scope. Distortion in the weld joint is measured using digital vertical height gauge. Optical microscopy is employed for microstructural characterization of the weld joint. The weld metal exhibited a peak tensile residual stress value of 320 MPa. The predicted distortion values were very low. There was a good agreement found between the predicted and experimentally measured thermal cycles, residual stresses, and distortion.

22.1 Introduction

Type 316L(N) austenitic stainless steel is the main structural material used in the construction of nuclear reactors. It is the preferred nuclear grade structural material for reactor due to its good mechanical properties, corrosion, and irradiation resistance [1]. Welding is the predominant fabrication method employed during their construction. Therefore, the utilization of an advanced welding process for welding of type 316L(N) stainless steel is of high importance. Laser welding has high-energy density and the advantages are lower residual stress and distortion that are due to low heat input, high welding speeds, and ease of automation. But for welding high-thickness plates using a laser, keyhole instability occurs which produces a lot of porosity in the welds. Arc welding is most widely used, but it has a lot of limitations namely high residual stress and distortion due to high heat input. Slow welding speed and need of groove preparation limit the productivity.

For welding, heavier components, an advanced welding process such as hybrid laser-TIG welding process could be used. In our earlier study, hybrid laser-TIG welding process parameters were optimized for welding of type 316L(N) austenitic stainless steel using RSM and GA [2, 3]. The advantages of hybrid welding are good gap bridging ability and enhanced productivity; high penetration capability with faster welding speeds due to more energy delivered into the material [4]. The process improves the weld quality with reduction of porosity and cracks due to slow cooling rate and enhances ductility [5]. The accurate measurement of temperature during hybrid welding is difficult using conventional thermocouples. It cannot measure the weld pool temperature; it will measure only the nearby base metal temperature. Therefore, in this study, these limitations will be overcome by using noncontact real-time IR thermography for precise measurement of temperature. It is also employed for authenticating, fine-tuning, and validating the FEM model.

The novelty in this investigation was the use of IR thermography to measure the temperature distribution in the weld pool and its surroundings to validate the FEM predictions. Further, the thermal model was sequentially coupled to the mechanical analysis for determination of residual stress. The predictions of the numerical analysis presented in this investigation on the temperature distribution, residual stress, and distortion were confirmed by measurements by the use of an experimental tool.

22.2 Experimental

The 316L(N) plates of size 300 mm × 125 mm × 5.6 mm were used in straight square butt joint configuration. The setup is given in Fig. 22.1. The laser-TIG hybrid welding was carried out with the determined optimal parameters with a heat input of 0.466 kJ/mm. Weld joint was made autogenously. After the weld joint was fabricated, the residual stress studies were made by utilizing an ultrasonic technique

22.3 Numerical Modeling

The thermal analysis of hybrid laser-TIG welding simulation was executed using commercially available SYSWELD software which is exclusively used for the modeling and simulation of fusion welding processes. The hybrid heat source model consisting of double ellipsoid for the arc welding and three-dimensional conical for the laser welding is used in the analysis. The geometrical parameters of the heat source models are taken from the experimental weld bead. Figure 22.3 schematically represents the combined heat source model employed in this study.

22.3.1 Governing Equations

The heat transfer due to confined heating while welding is mainly due to conduction mode. The amount of heat conduction relies on the materials thermophysical properties, the amount of weld metal volume produced, and weld morphology. Heat conduction defined by finding the solution for the following equation.

$$\nabla(k\nabla T) + Q(x, y, z, t) = \rho \mathrm{Cp}(\partial T/\partial t) \tag{22.1}$$

where Q = Heat flux volume (W m^{-3}), k = Thermal conductivity (W m^{-1} °C^{-1}), ρ = Density (kg m^{-3}), Cp = Specific heat capacity (J kg^{-1} °C^{-1}), and T = Transient temperature (°C), t = time (s). The heat loss due to radiation and conduction throughout the welding is given by Stefan–Boltzmann relation and Newton's law of cooling.

22.3.2 Boundary Condition

The hybrid laser-TIG hybrid was conducted using various welding parameters. The initial temperature was 30 °C. All the heat losses namely radiation heat loss which is predominant in the weld pool, convective and conductive heat losses that are prevalent away from the weld pool are taken into account. In the model, convective and radiative losses were considered on all its surfaces except the symmetry plane. Similar to the experimental conditions, the plates to be welded are clamped appropriately to avoid the translational and rotational movements.

22.3.3 Finite Element Modeling

The dimension of the weld plate used in finite element modeling was 300 × 125 × 5.6 mm. The butt joint configuration with a square edge preparation, without a groove, was used for welding. To improve the precision and effectiveness of the simulation, optimum mesh size should be used. The effect of heat input due to welding will be more in the weld center and heat-affected zone (HAZ). So to get the accurate weld bead morphology, finer mesh size was used in these zones and the other regions are given little coarser mesh to reduce the computation time. The heat source moves in Y-axis. The model was formulated such as the welding direction was along the Y-axis and the model was about the XY plane. The thermophysical properties of the type 316L(N) austenitic stainless steel were considered from room temperature to melting point are taken from IGCAR databook [6].

22.4 Results and Discussion

22.4.1 Temperature Distribution and Weld Bead Comparison

Temperature distribution in the transverse direction is plotted from the weld centerline. The induced peak temperature is almost the same near the regions next to the weldment. The distance far away from the weldment is not affected by two heat sources. The peak temperature changes if the heat source traverses in its path throughout the welding. All the nodes are heated till its peak temperature because the heat source strikes a corresponding node and it begins to cool when it travels further. The profiles are obtained in the quasi-state condition. The weld bead produced by the hybrid welding process is perfectly matching with the predicted finite element model using SYSWELD. If the predicted weld bead geometry is matching well with experiments, then the results given by the predicted model are reliable and almost accurate. Figure 22.4 shows the weld macrograph which is compared with the FEM model.

The thermal heat source profiles of IR thermography are compared with FEM model. Temperature profile matches well in the quasi-state condition. There was a good agreement found within the measurements and the predicted temperature using the model. The peak temperature measured also almost found equal to that of the predicted by the model. The variations seen may be due to assumptions during the material modeling beyond the melting point of the material and experimental constraints. These deviations are reduced by improving the numerical modeling analysis. Figure 22.5 shows the IR temperature distribution profile which is compared with that of the FEM model. Figure 22.6a presents the numerical modeling results, in which the induced peak temperature due to welding which keeps on

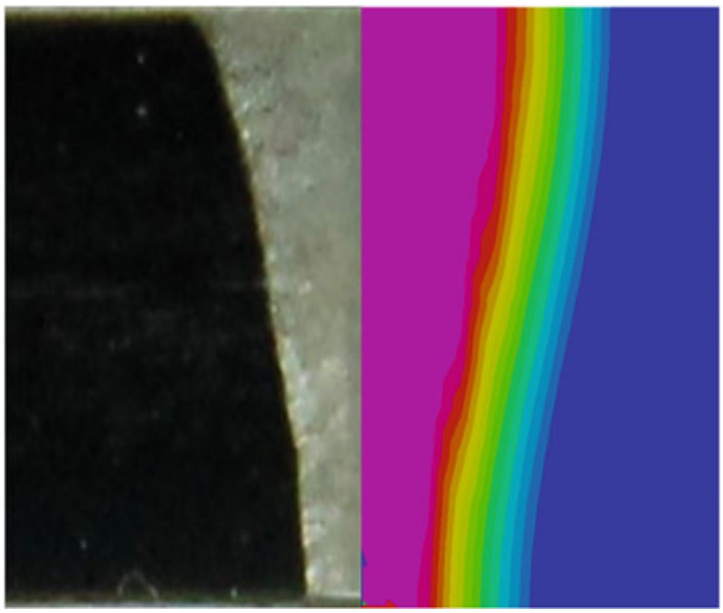

Fig. 22.4 Weld macrograph compared with FEM model

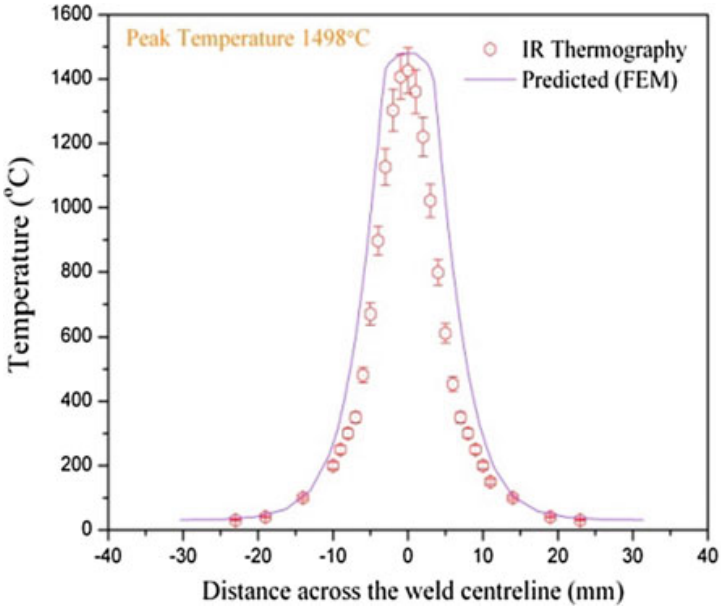

Fig. 22.5 Temperature measured by IR thermography compared with FEM at 50 s

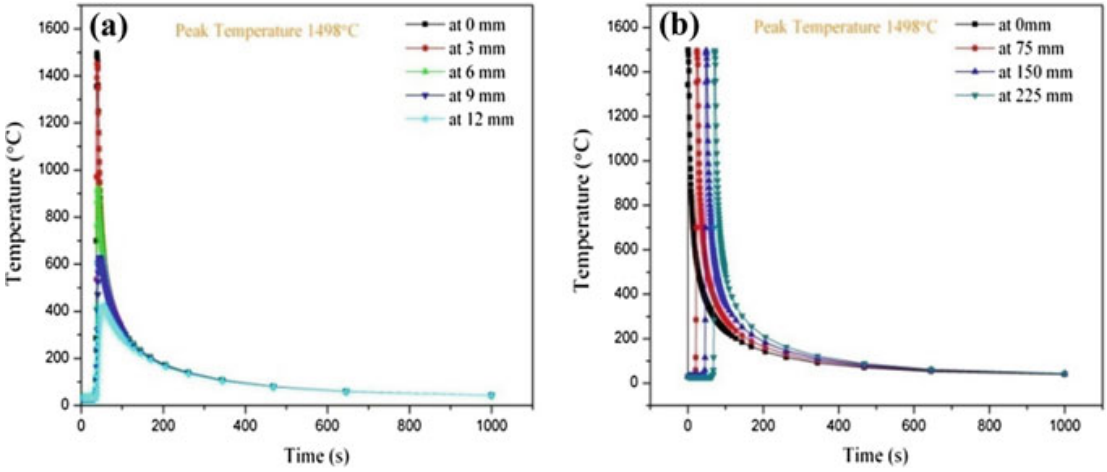

Fig. 22.6 Thermal cycle from welding centerline: **a** transverse direction **b** longitudinal direction

decreasing in the transverse direction. Thermal cycle along the weld center line for various locations is shown in Fig. 22.6b.

22.4.2 Residual Stress Analysis

The residual stress measurement was conducted by employing ultrasonic testing. The predicted residual stress profiles were confirmed by longitudinal residual stress measurements taken at the center of the weld joints. The residual stress values evaluated are compared with the model and it is presented in Fig. 22.7a.

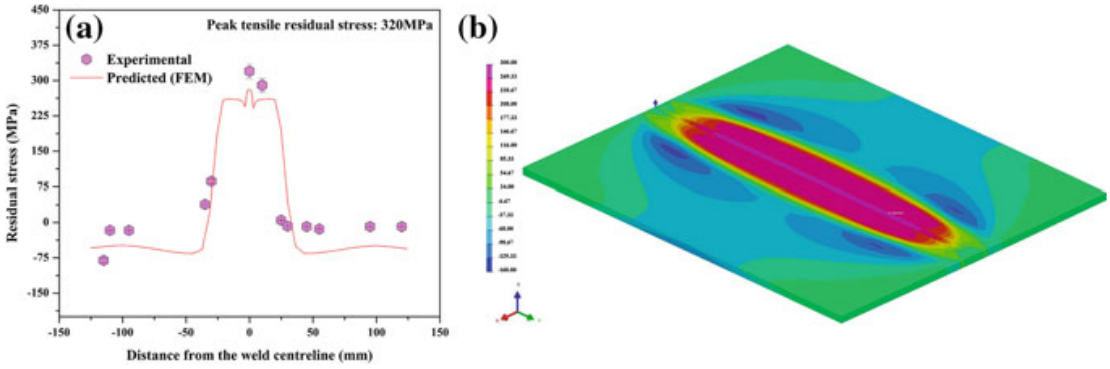

Fig. 22.7 Residual stress **a** comparison of FEM versus ultrasonic testing **b** distribution in welded plate

Figure 22.7b shows the residual stress distribution in the welded plate. The peak tensile stress is at the weld center and the value is around 280 MPa as predicted by the model. The maximum tensile stress measured by the ultrasonic technique is 320 MPa. The flat region observed next to the peak tensile residual stress is due to the autogenous hybrid heat sources. That is, if the filler wire is used, heat input will be utilized for melting the filler wire. But in the case of autogenous welding, the heat input is spread over a more area next to weld metal. Moreover, the type 316L (N) austenitic stainless steel has low thermal conductivity, so it retains high temperature over a more extended period due to which the residual stress profile is flat near to the weldment. There was a good agreement found within the predicted model and the experimentally calculated residual stress.

The evolution of stress and finally the residual stress during heating and cooling cycles due to welding can be explained by spot analysis given in Fig. 22.8a, b as a function of time. When welding starts, compressive stress rises to a peak value and the stress is restricted to materials yield strength. Then, the compressive stress begins to decline as the metal commences softening. Finally, stress falls to zero at the melting point of the base metal. During cooling, the tensile stress rises to

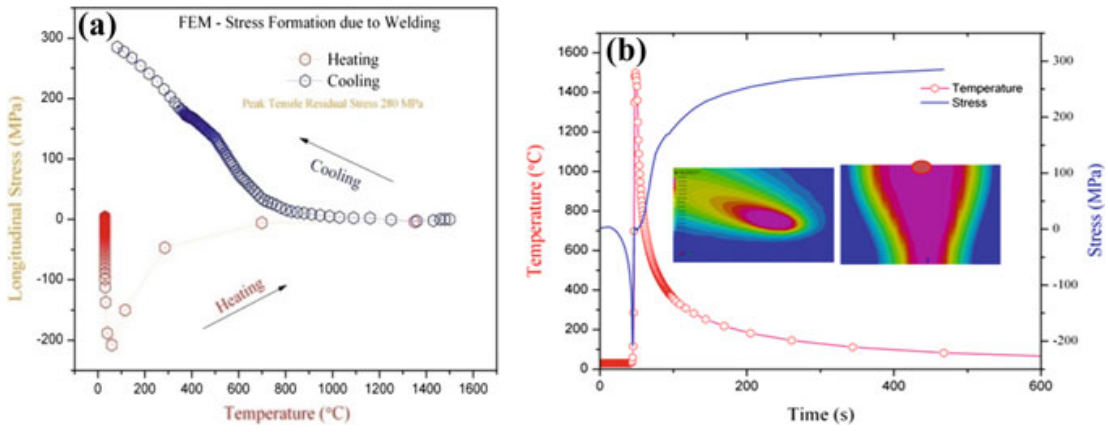

Fig. 22.8 **a** Stress evolution during welding—spot analysis **b** stress evolution as a function of time

develop slowly due to the thermal strains. Due to welding, there is no phase transformation effect in austenitic stainless steel. Henceforth, no signature dips or stress relaxation changes in the temperature versus stress plot on cooling side.

22.4.3 Distortion Analysis

The distortion in weld joints is caused by the heat input amount and the associated weld metal volume. Since the welding parameters are employed in such a way to produce low weld metal volume with full penetration without any defects, the distortion is less in the joint fabricated by the hybrid welding process. The heating and melting efficiency are improved in hybrid welding which results in lower weld metal volume. Therefore, low distortion is accompanied with lower heat input. Distortion is too low because of the weld metal volume produced by the two heat sources is limited when compared with arc welding alone which is possessing a higher heat input. The predicted model values are found to agree with the experimental values. Figure 22.9a exhibits the distortion comparison of the FEM model with the experimental data. Figure 22.9b shows the distortion in the welded plate.

22.4.4 Microstructure

The weld joint produced by hybrid laser-TIG welding process shows a primary austenitic solidification mode. Weld metal consists of the fewer amount of delta ferrite (0.9FN) and austenite phases. The hybrid welding process has higher welding speed which increases the cooling rate that results in primary austenitic solidification mode with the low ferrite number [7]. Figure 22.10a shows the weld macrostructure and Fig. 22.10b shows microstructure of the weld. The weld macrostructure exhibited a typical wine glass shape. Because the TIG heat source

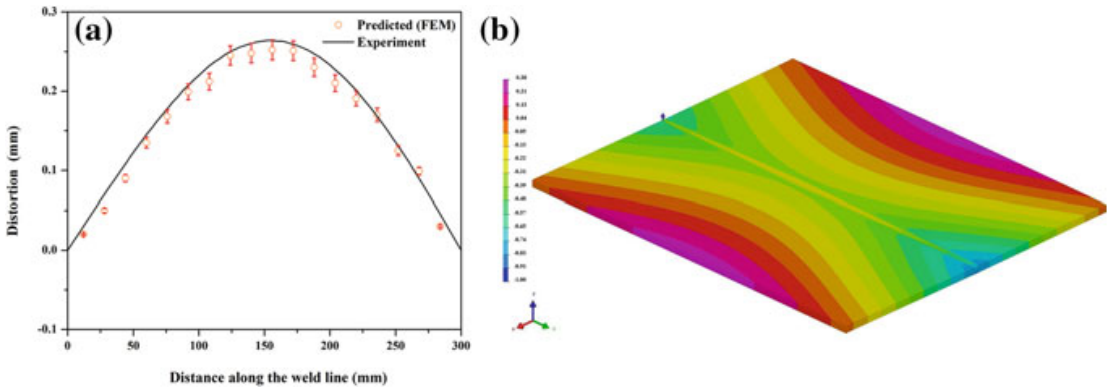

Fig. 22.9 Distortion **a** comparison of FEM with experiment **b** weld plate—FEM

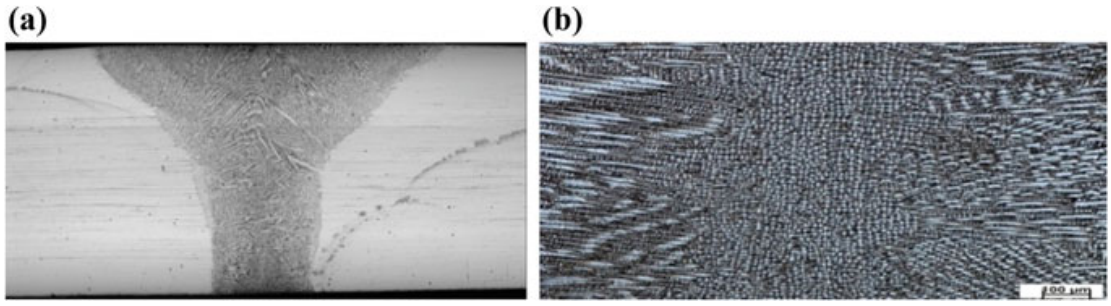

Fig. 22.10 Hybrid laser-TIG **a** weld macrograph and **b** microstructure

acts on the upper part of the weld and widens the bead width. The laser acts on the bottom part of the weld pool through the keyhole mode. This synergistic action of the combined heat sources gives the wine cup-shaped weld bead [8]. All through the entire weld, the central equiaxed grains were sandwiched between columnar dendrites.

22.5 Conclusions

In this paper, the thermomechanical analysis of hybrid laser-TIG welding of type 316L(N) austenitic stainless steel is done and validated by the experiments. The conclusions are given below.

- The calibration of the heat source was done on the basis of the weld bead morphology obtained by welding. The weld macrograph matches perfectly with the model reflecting the accuracy of the heat source chosen.
- The thermal cycle observed using FEM and IR thermography is almost equal and the variations are due to experimental limitations while capturing the thermal data.
- The maximum tensile residual stress predicted is 280 MPa and the experimentally measured is 320 MPa. The residual stress predictions are found to be in a good agreement with the predicted finite element model using SYSWELD.
- The distortion prediction is also in correspondence with validated experiments.

Numerical Study on Electromagnetic Crimping of Aluminum Tube and Steel Profiled Rod

Getu Tilahun Areda and Sachin Dnyandeo Kore

Abstract Electromagnetic crimping (EMC) is one of the advanced manufacturing technologies used to join lightweight material including metals with metallurgical and thermal property differences. This paper investigates EMC process numerically to deform aluminum tube (Al6061-T6) to the steel profiled rod using the electromagnetic (EM) module of LS-DYNA^{TM}. Electromagnetic crimping methods can join multiple material systems without melting. A longitudinal groove was designed on steel rod for mechanical interlocking to resist the torsional load. Groove geometrical parameters like groove length, depth, edge radius, and width were kept constant. Effects of voltage on an effective plastic strain, resultant impact velocity, resultant displacement, and temperature were studied in detail. Moreover, the simulation was carried out also to analyze the effect of capacitance on process parameters, and results are discussed in detail. The developed model is validated and found in a good agreement with experiment. Based on the results found, it is possible to predict essential process parameters for enhanced joint strength.

Keywords Electromagnetic crimping (EMC) · Numerical modeling · Groove geometrical parameters · Maxwell's equation · LS-DYNA^{TM} · Johnson-Cook

23.1 Introduction

A new era of a manufacturing process is looking for developing advanced techniques for joining lightweight materials that can overcome problems associated with the conventional approach. Joining methods like fusion welding has several

limitations like the creation of intermetallic compound, crack, voids, etc. that needs to be addressed. An advanced technological solution like solid-state joining becomes best options to overcome the existed limitations. Joining metals which have high aspect ratio for lightweight applications requires a method which can provide enhanced joint strength without being affected by thermal property differences between the mating parts. EMC process is a punchless, an environmentally friendly, green, and able to complete the work within a microsecond. This method becomes best suited to resolve defects associated with a thermal-based joining technique like arc welding. Automotive and space frame industries are exceedingly demanding the advantage of this process.

Thermal, mechanical, and electromagnetic are phenomenon's which needed to be addressed using numerical analysis in case of an electromagnetic forming (EMF) process. LSTC^{TM} has introduced an electromagnetic module to simulate the EMF process [1]. In the electromagnetic module of LS-DYNA^{TM}, magnetic field, Lorentz force, current in the conductor, etc. are calculated. The mechanical solver deals with the structural analysis of the deformation. The electromagnetic module solves Maxwell's equations. The thermal solver calculates internal energy, generation of heat and its flow. As the process involves high strain rates, it has all advantages of high velocity forming like improved FLD, minimized spring back, and less wrinkling [2]. Metal forming is one of the LS-DYNA^{TM} main applications with capabilities that allow one to simulate conventional and high-speed forming process [3].

In this chapter, the electromagnetic crimping of an aluminum tube on profiled steel rod was modeled and simulated with 3D finite element method. Simulations are carried out using LS-DYNA^{TM}. Effects of voltage and capacitance on process parameters of electromagnetic crimping were studied. Resultant velocity, resultant displacement, effective plastic strain, and temperature are predicted, and the effect of high voltage on deformation was analyzed using the EM module of LS-DYNA^{TM} software. The compression of the aluminum tube on profiled carbon steel rod has been predicted with 3D finite element simulation at various voltage and capacitance levels.

Capacitor bank in an electromagnetic forming machine is used to store the required amount of energy that will be discharged into the coil, while the high current switch is closed. Induced current starts to flow on the surface of the tube which is caused by a current in the coil. The magnetic field generated due to primary and induced current results radial force known as the Lorentz force used to launch the workpiece away from the coil. The impact that produced due to high speed will make the workpieces to deform beyond its elastic limit for different EMF applications like joining, cutting, welding, and shearing. The total duration of the process takes no longer than 100 microseconds. Electromagnetic crimping process has several applications such that medical (pharmaceutical glass bottles), automotive, space frame structures, wire crimping, double seaming, hemming, and clinching [4, 5]. Capacitors, resistors, and inductors are the main components of the EMF system as shown in Fig. 23.1. The electrical properties of the considered workpieces are exceedingly significant in increasing or decreasing deformation

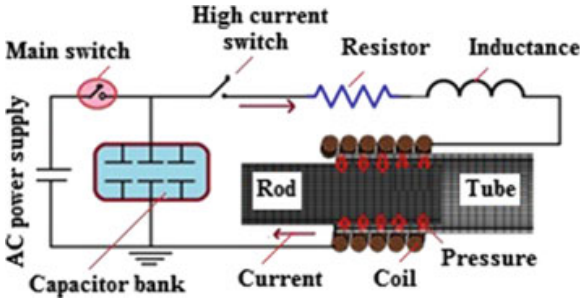

Fig. 23.1 Circuit diagram of EMC process

levels. Direct application of electromagnetic energy can deform metals like magnesium and aluminum which has low formability in the conventional forming process. Applying magnetic energy directly to deform lower electrically conductive metals like stainless steel is too difficult.

23.2 Governing Equations of EMF Process

The required electrical energy which is stored in the bank of the capacitor is given by Eq. 23.1, and the resulting current $I(t)$ by Eq. 23.2.

$$E_c(t) = \frac{1}{2} CV^2(t) \tag{23.1}$$

$$I(t) = V_0 \sin(wt)\mathrm{e}^{-\beta t} \tag{23.2}$$

where $V(t)$ voltage across the capacitor, C capacitance, ω frequency, β damping coefficient, and t time. Set of Maxwell's equations form the basis of numerical computation in any FEM software. The generation of magnetic pressure due to the interaction of two opposite magnetic field is computed using Maxwell's equations. The resultant Lorentz force which is a function of current density and magnetic field density also calculated in the same approach. Differential forms of Maxwell's equations (Eqs. 23.3–23.6) are shown below.

$$\nabla \times B = \mu_0 (J + \varepsilon_0 \partial E / \partial t) \tag{23.3}$$

$$\nabla \times E = -\partial B / \partial t \tag{23.4}$$

$$\nabla \cdot E = \rho / \varepsilon_0 \tag{23.5}$$

$$\nabla \cdot B = 0 \tag{23.6}$$

where E electric flux intensity, B magnetic field density, μ_0 magnetic permeability, J current density, ρ net charge density, ε_0 permittivity of vacuum, and t is for time.

23.3 Geometrical Dimensions of Workpiece and Material Properties

Geometrical dimensions tube, copper coil, and steel profiled rod are shown in Fig. 23.2a–c. Total of four longitudinal grooves was designed, and its geometrical parameters kept constant for all simulation. Axisymmetric coil with dimension and shape as shown in Fig. 23.2b was used.

Table 23.1 shows the properties of the aluminum tube, copper oil, and steel rod used in this study.

23.4 3D Finite Element Modeling

Simulations were carried out for different voltages levels using identical coil geometry which is modeled as a rigid body to make it simple for calculation in the boundary element method. Hence, deformation was analyzed only on the tube at the joining zone. The ranges of voltage were varied from 1.5 to 4 kV with an increasing rate of 0.5 kV. The arrangement of workpieces and tool coil for simulation is shown in Fig. 23.3. The model parts have meshed with 3290, 6580, and 2394 number of elements for the coil, rod, and tube, respectively.

Electromagnetic crimping is a high-speed joining process using a magnetic pulse, and the material model which take care of strain rate hardening and softening due to temperature rise is Johnson cook (JC). In order to evaluate the constitutive response of the tube, the flow stress which is determined as a function of the plastic

Parameters of JC strength model for Al6061-T6 and steel and parameters for linear polynomial EOS for Al6061-T6 are shown in Tables 23.2 and 23.3.

23.5 Results and Discussion

Numerical results are discussed and analyzed in detail as follows. Effects of voltage and capacitance on other process parameters were explained based on the selected element in the joining zone. Moreover, the transient magnetic field is determined for different values of capacitance.

23.5.1 Effect of Voltage on Effective Plastic Strain

Effective plastic strain result at different voltage levels is shown in Fig. 23.4. Maximum of 1.038 and minimum of 0.0127 effective plastic strain were obtained using 4.0 and 1.5 kV for an element (H-24494) which is found in the deformation zone. These results were obtained from the element found at maximum deformation which is parallel to the groove surface. There were rebounding effects when we considered voltage more than 4 kV that leads to having minimum radial displacement and effective plastic strain.

23.5.2 Effect of Voltage on Resultant Displacement and Velocity

Figure 23.5a shows the resultant displacement of an element (H-24494) at different voltage levels. Keep increasing voltage levels causes the resultant displacement to reach its maximum due to increasing discharge energies. Increasing voltage to 4.0 kV leads an element to displace by 2.29 and 0.085 mm was found while using 1.5 kV voltage. Resultant displacement reaches a peak at a different time for each voltage level but almost equal to for more than 2.5 kV with small variations. If we go beyond 4.0 kV, radial displacements will significantly decrease due to rebounding effect. Measuring parameters like a radial or resultant displacement during an experiment is a challenging task due to the involving speed, but it is possible to predict using 3D simulation as shown in Fig. 23.5a. Besides that, resultant velocity is one of the critical process parameters needs to be determined by the electromagnetic crimping process. Increasing voltage from 1.5 to 4.0 kV causes the velocity to rise from 15.075 to 438.44 m/s. The percentage of increment of

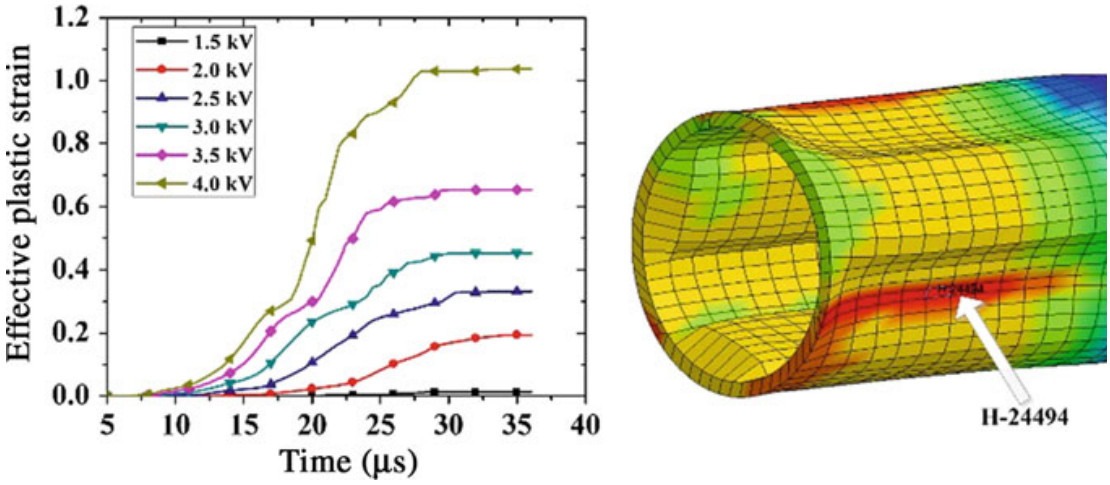

Fig. 23.4 Effect of voltage on effective plastic strain

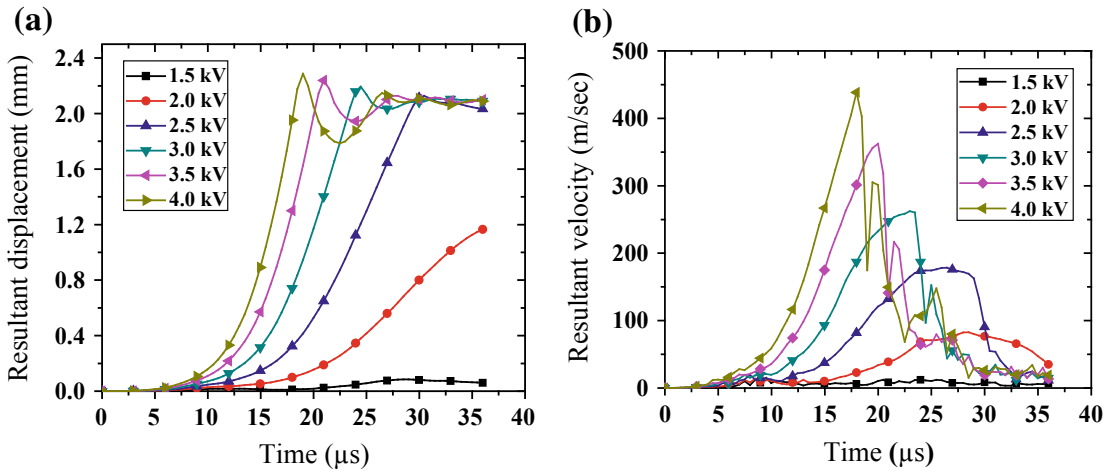

Fig. 23.5 Effect of voltage on **a** resultant displacement and **b** resultant velocity

velocity compared to variation in voltage shows some difference, but it has direct influence as shown in Fig. 23.5b. Minimum velocity of 15.075 m/s was found while applying a voltage of 1.5 kV.

23.5.3 Effect of Voltage on Temperature and Current

As a solid-state process, increments of temperature up to a melting point of any of the metal under consideration were not expected. The rising of temperature in electromagnetic crimping process is not sufficient to cause phase change during deformation, but it may soften the joining zone. Maximum of temperature 568.19 K was obtained using 4.0 kV as shown in Fig. 23.6a. The result shows an apparent variation of temperature caused by different voltage level. Minimum increment of 27.15 K from room temperature was found while using 1.5 kV compared to

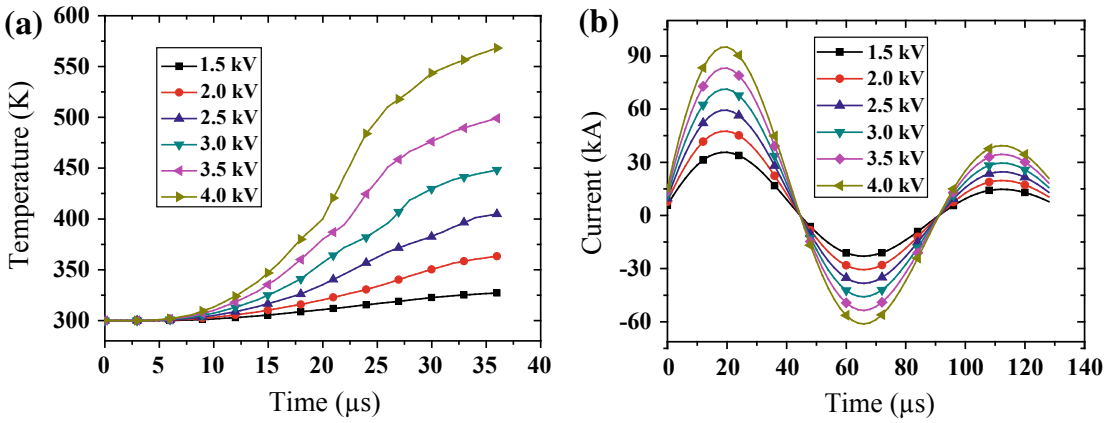

Fig. 23.6 Effect of voltage on **a** temperature and **b** current

different voltage levels. Variations of current at different voltage levels for identical RLC circuit are shown in Fig. 23.6b. The amplitude of the current curve for all voltage levels reaches a maximum at 20 microseconds. Maximum current was achieved while using 4.0 kV that is 95 kA, and a minimum of 35.6 kA was found while using 1.5 kV. The direct proportionality between voltage and current obtains the pattern as shown in Fig. 23.6b for different voltage levels. Current tends to increase as voltage increases, and variation of 0.5 kV has a significant effect on increasing or decreasing its amplitude.

23.5.4 *Effect of Capacitance on Process Parameters (V and ε)*

Simulation result obtained using 3.0 kV was referred to analyze the effect of capacitance on resultant velocity and effective plastic strain. Increasing 22.68% of capacitance from 426 to 551 μF leads to an increment of a 10.66% resultant velocity. This increment is depicted graphically in Fig. 23.7a. It is required to have a significant difference in capacitance to obtain great variation in resultant velocity. Stored energy will be high if the capacitance is increased and that leads to having an increased effective plastic strain as shown in Fig. 23.7b.

An element (H-24494) on the outside surface of the tube and at the middle of the coil was selected to measure the strain. The effective plastic strain was found uniformly increased as capacitance varies from 426 to 551 μF. Maximum and minimum effective plastic strain of 0.530 and 0.454 were obtained while rising values of capacitance from 426 to 551 μF. It is essential to increase capacitance significantly to attain a meaningful variation in resultant velocity and plastic strain.

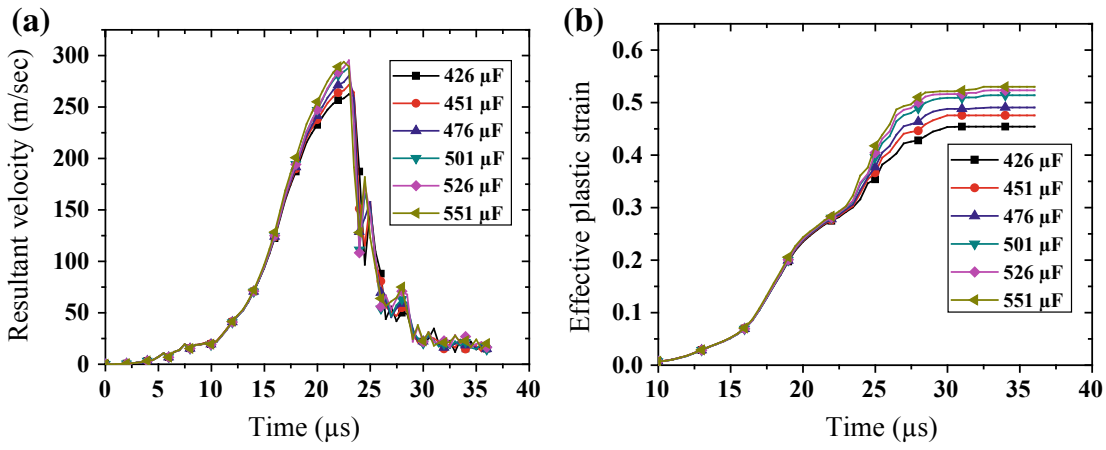

Fig. 23.7 Effect of capacitance on **a** resultant velocity and **b** effective plastic strain

23.5.5 Effect of Capacitance on Resultant Displacement and Temperature

Increasing capacitance by 22.6% leads the resultant displacement to increase only by 3.22% as demonstrated in Fig. 23.8a. The proportional variation between capacitance and resultant displacement shows great differences. Beside that Fig. 23.8b shows how temperature varies due to different levels of capacitance where inductance, resistance, and voltage kept constant. A temperature increment of 4.9% was obtained by comparing the maximum and the minimum result found for increasing capacitance by 22.6%. Room temperature was considered as simulation condition which is 300 K.

23.5.6 Effect of Capacitance on Magnetic Field

Magnetic field increases as capacitance increases by keeping other circuit parameters constant. The minimum magnetic field of 10.7 T was found using 426 µF, and a maximum of 14.62 T obtained using 551 µF capacitance. Lorentz force which is a function of the magnetic field also increases accordingly. The result revealed that increasing the capacitance by 29.34% leads to increasing the magnetic field by 36.6%. It is vital to add capacitance of the EMF (electromagnetic forming) system based on the required level of deformation, which gives a significant difference in the resulted magnetic field.

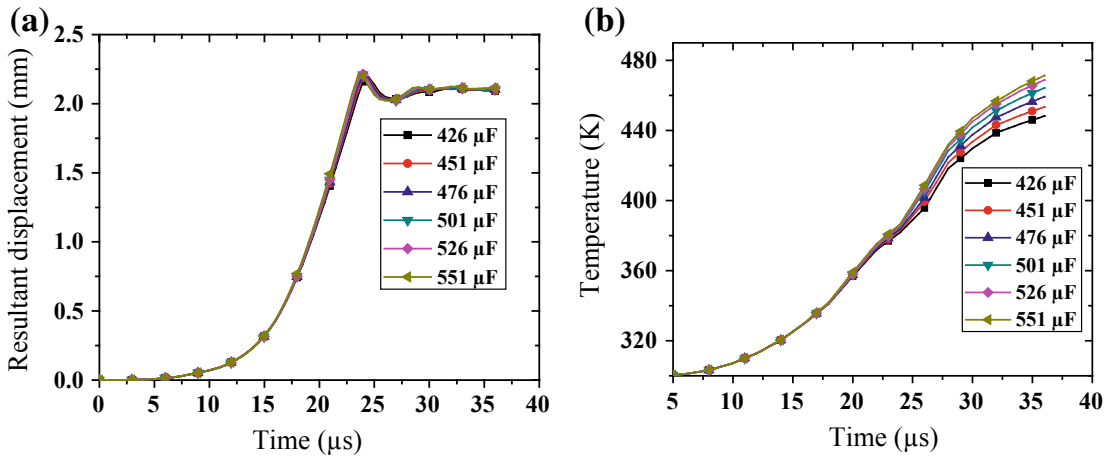

Fig. 23.8 Effect of capacitance on **a** resultant displacement and **b** temperature

23.5.7 Failure Prediction

Figure 23.9 shows von Mises stress distribution on the joining zone at a different time value using 4 kV. The magnitude of stress is found maximum at groove edge that possibly leads to generate necking and thinning which cause joint failure. One of the critical geometrical parameters which can directly affect the joint strength by acting as a cutting edge is the groove edge radius which is 0.5 mm in this study. Moreover, Fig. 23.10 confirms the failure region by showing where shear strain, von Mises stress, and shear stress become maximum.

Results are taken at the end of 36 microseconds for different energy levels. A minimum and maximum von Mises stress of 341.6 and 382.6 MPa were found at the various voltage levels. A better groove filling is observed while using 4 kV that leads to resist higher torque load. Therefore, 4 kV is found optimum voltage for the given material system and geometrical parameters.

23.5.8 Experimental Work

The experiment is carried out using a setup shown in Fig. 23.11 which has a similar geometrical parameter to the FE model. The same geometrical and process parameters are used to conduct the experiment. Discharge energy generated using

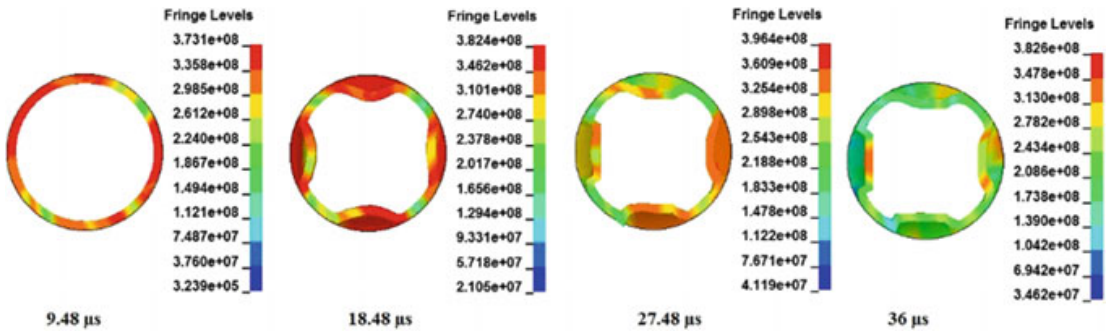

Fig. 23.9 Distribution of von Mises stress on joining zone for 4 kV at the different time value

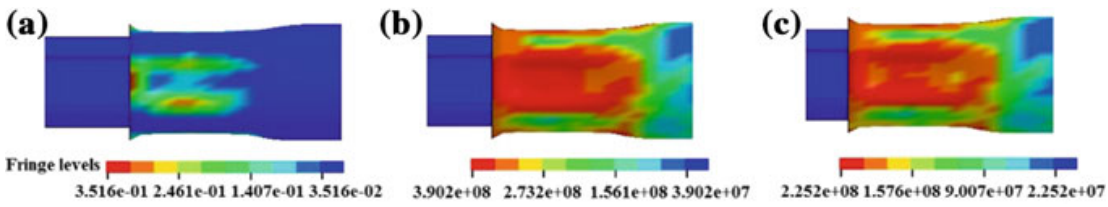

Fig. 23.10 Contours of **a** maximum shear strain **b** von Mises stress, and **c** Tresca (maximum shear stress)

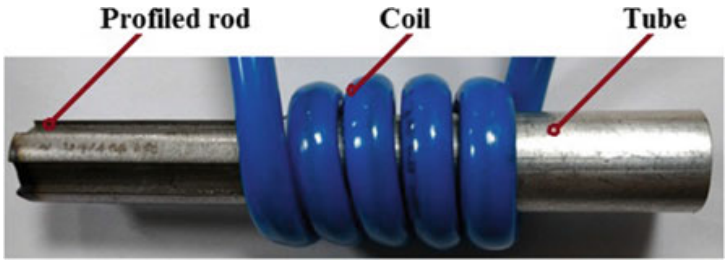

Fig. 23.11 Experimental setup

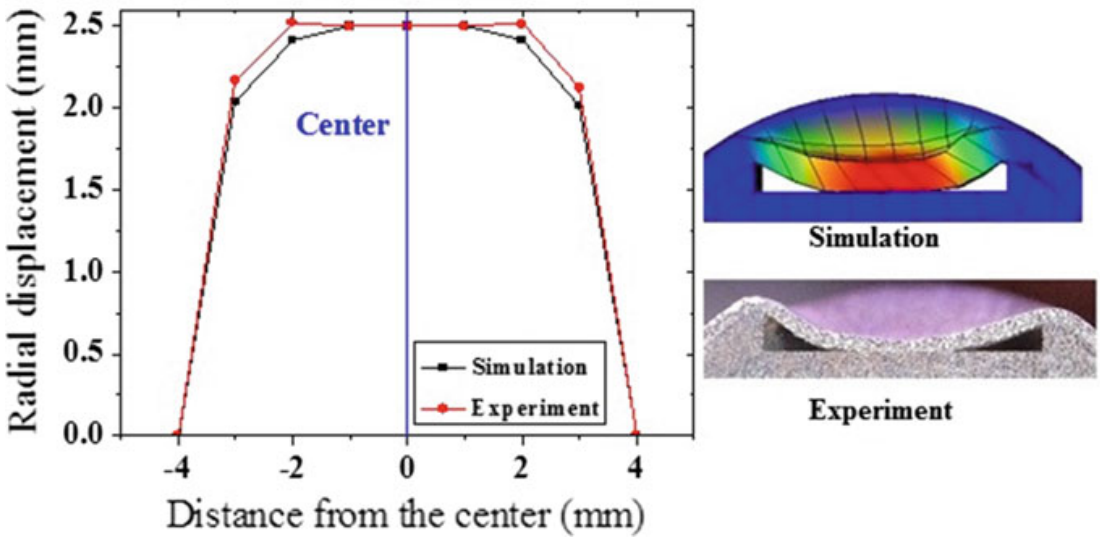

Fig. 23.12 Radial displacement in simulation and experiment

4 kV is applied, and the radial displacement is measured to compare with the simulation.

The radial displacement was measured using cross section of crimped sample and compared with simulation as depicted in Fig. 23.12. Measured gap between the tube and groove surface at the deformation zone was found in good agreement with the simulation. The deformation at the center of the coil is higher that leads to having the maximum radial displacement. The radial displacement was measured with 1 mm gap starting from the center to ends of the groove.

23.6 Conclusions

In this study, numerical modeling and simulations of electromagnetic crimping for transferring torsional load were demonstrated. The aluminum tube gets crimped on the groove of the steel rod successfully, while electromagnetic energy is applied. Process parameters which are difficult to measure and the possible failure region during the experiment were predicted successfully using the EM module of

LS-DYNA™. The increasing voltage causes the effective plastic strain, radial displacement, resultant velocity, temperature, and output current to increase accordingly. Moreover, the effects of increasing capacitance on resultant velocity, effective plastic strain, radial displacement, temperature, and magnetic field were found less significant. The result revealed that increasing the capacitance by 29.34% leads to increasing the magnetic field by 36.6%. Further, the resultant displacement is getting decreased as voltage increases beyond 4 kV due to re-bouncing effect. Therefore, 4 kV is found optimum voltage for the given material system and geometrical parameters. A mean percentage error which is less than 7% was found while comparing radial displacement obtained from simulation and experiment. The developed model was validated and shows a good agreement with experiment.

Chapter 24
Temperature Prediction During Self-pierce Riveting of Sheets by FEA-ANN Hybrid Model

Deepak Mylavarapu, R. Ganesh Narayanan and Manas Das

Abstract Nowadays, the automobile industries are more concerned about reducing automobile weight for improving fuel efficiency and reduced vehicle emission. Hence, there is a need for relatively lighter weight materials like aluminium alloy replacing steel parts for automobiles. However, joining of these lightweight materials is very difficult using conventional spot welding technique, which is a slow process also. In the present study, an alternative high-speed advanced mechanical fastening technique, namely self-pierce riveting is used for joining of these lightweight sheets of different materials. In this process, a semi-tubular rivet is pressed by a punch into two or more sheets which are supported on a die. Due to the special design of die shape, the rivet flares inside bottom sheet to form a mechanical interlock. Experimental measurement of temperature inside the sheets during the process is a difficult task, as the process takes place for a fraction of a second within a span of 10 mm. In the present study, the temperature rise during SPR process is predicted by finite element simulation using Abaqus® for any combination of sheet materials, process conditions and tool dimensions to understand the process. In addition, an ANN model is developed to predict the temperature rise during joint formation in sheets for any combination of process parameters. The ANN model accurately predicted the temperature evolution during the process. Hence, with the hybrid ANN-FEM strategy one can design and optimize the process, tool and material conditions, efficiently, which otherwise will be time and resource-intensive.

24.1 Introduction

The overall weight of an automobile governs the fuel efficiency and vehicle emissions. Polmear [1] pointed out that the fuel consumption can be reduced by 5.5% for each 10% reduction in weight. This is possible when lightweight structures and lightweight materials are used in automotive sectors. Use of aluminium alloys in place of steel is one of the possible solutions. Hirsch [2] highlighted that, as part of Super Light Car project, about 53% of the parts contribution is from Aluminium alloy in the form of sheet panels, extrusion in front rails, bumper, crash parts, in the rear underbody rail, and in wheelhouse structure as high-pressure die-cast. The formability of Aluminium sheets is also acceptable and can be improved by materials processing. Joining of lightweight sheets including Aluminium alloys is sometimes difficult with traditional welding processes. In this context, friction stir welding, adhesive bonding, mechanical clinching, laser welding and some hybrid joining methods are used successfully with support from numerical simulations and parametric optimization [3].

Self-pierce riveting (SPR) is a high-speed cold joining method used for joining similar and dissimilar materials including non-metals and metals. In SPR, a rivet is made to deform the sheets arranged in lap configuration above a die with groove. A punch is used to displace the rivet downwards. Depending on the die design, the sheets are mechanically locked. In the process of joining, the upper sheet is pierced and the rivet is flared, while the lower sheet is just deformed.

The stages in SPR along with the schematic of load evolution are shown in Fig. 24.1. During clamping, the rivet is pushed by a punch perpendicular to the sheet surface. In this stage, the rivet clamps the sheets. In piercing stage, the rivet causes severe plastic deformation of the upper sheet resulting in sheet piercing. The lower end of the rivet flares in the third stage and follows the contours of the die. Sheet overlap and interlock distance that are responsible for the required mechanical resistance are achieved during the stage. In the compression stage, the punch continues to push the rivet inside the sheets to be joined. The punch movement stops

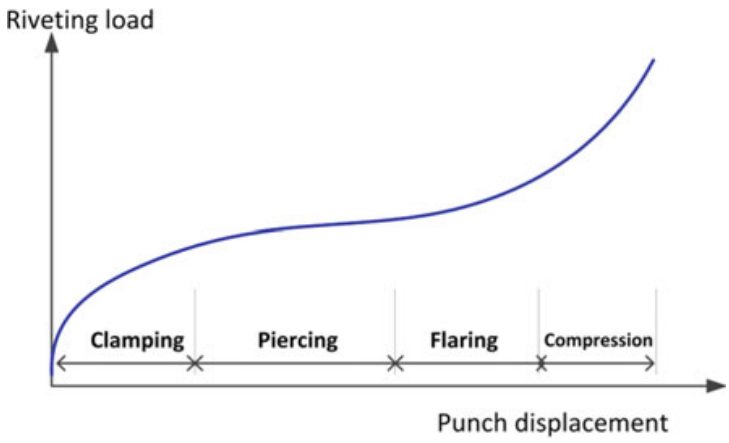

Fig. 24.1 Load evolution in SPR

when it reaches a predetermined load or displacement. The rivet head surface is levelled with the sheet surface at this stage.

Some important contributions in SPR of variety of materials including those involving modelling is presented here. Xu [4] studied the influence of three important factors, namely die type (height of projected region is varied), rivet length and sheet combination on the SPR quality indices like bottom sheet thickness, undercut and rivet spread. The relation between SPR variables and outputs is not unique. The die requirements change with the outputs monitored. The rivet length has negative effect on bottom thickness, but positive effect on undercut and spread. Some of these parameters have interaction effect as well. The experimental analyses by Sun et al. [5] showed superiority of SPR joints (made of aluminium and steel grade sheets) as compared to resistance spot welded joints. The adhesive bonding also improved the static and fatigue behaviour, specifically in lap shear mode. In a similar attempt by Mori et al., it has been observed that the static and fatigue strengths of SPR joints are better than that of clinched joints and resistance spot welded joints. There exists a slight slip at the joint interface in the case of SPR and clinched joints that have improved the fatigue behaviour as compared to resistance spot welding [6]. Johnson et al. [7] attempted to evaluate the joint quality by computer image processing method. With this system, one can identify the number of rivets present in the machine jaw and the material thickness after joining. A comparative analysis of SPR joints made by steel rivet and aluminium rivet by mechanical testing revealed that the rivet material has no influence on the initial stiffness of the mechanical response [8]. But the maximum force and the displacement at maximum force get affected significantly. It is also observed that the SPR joint made by steel rivet can tolerate larger normalized maximum load as compared to the one made by aluminium rivet at varying loading angle.

Several authors have attempted to study the SPR process through numerical simulations. Mori et al. [9] through finite element analyses (FEA) optimized the die shape to produce a successful SPR joint made of multi-layered steel-Al sheets. Porcaro et al. [10] performed numerical simulations using a 2D axisymmetric model in LS-DYNA for joining two sheets using rivet and tools. The effect of mesh size, adaptive time interval, friction and material failure on the joint prediction is studied. Bouchard et al. [11] investigated the SPR process using Forge 2005, an FE code. A Lemaitre-coupled damage model has been applied to predict failure during the process. In the same manner, Casalino et al. [12] implemented fracture conditions through plastic strain threshold during SPR numerical simulations to understand the piercing of rivet leg into the sheets. He et al. [13] through numerical simulations and experiments showed that the SPR joints and hybrid SPR joints (SPR + adhesive bonded) performed better than adhesive bonded joints. The article on recent developments in FE simulations of SPR process presented by He et al. [14] is noteworthy. Mylavarapu et al. [15] predicted critical thinning during SPR through FE simulations. They proposed a strain mapping method to evaluate the thinning of sheets. Later, they used a trained artificial neural network (ANN) model for which FE simulations were conducted to predict the temperature evolution during SPR. The friction coefficient, upper sheet materials properties and lower

sheet material properties like strain hardening exponent and strength coefficient are the input parameters for temperature prediction [16]. The present work is an extension of the previous attempt made by the authors.

The main aim of the present work is to predict the temperature evolution during SPR by FEA-ANN hybrid model. For this case, ten different SPR parameters are considered for temperature prediction. SPR process is modelled and simulated using a FE code ABAQUS® using explicit-temperature-displacement module. Temperature prediction during SPR is not attempted until now. Such analyses will help in selecting the materials and process conditions appropriately during SPR.

24.2 FE Simulation of SPR

FE simulation of SPR is performed using a 2D-axisymmetric model that is generated in ABAQUS® using explicit-temperature-displacement module. Four-node 2D elements with four Gauss points and hourglass control are selected for modelling. An average element size of 0.5 mm × 0.5 mm is used for meshing. The element type of CPS4RT, which is a four-node plane-strain quadrilateral element with reduced integration along with temperature DOF, is used. Reduced integration corresponds to lowering of the order of integration as compared to that of full integration. The meshing in the sheets and the blank holder is done in structured form, but the meshing of the rivet, die and the punch are done in free meshing form. This causes the rivet to have varying element dimensions. The FE model contains a rivet, bottom plate, top plate, punch, blank holder and die. Among this, the punch, blank holder and die are assumed as rigid parts. The rivet and sheets are considered plastically deformable during riveting process and are modelled as elastic–plastic materials. The rivet geometry is assumed to have a nominal diameter of 5 mm and is made of high-strength steel. The punch is of 5 mm diameter with 2 mm as its corner radius. The blank holder has inner radius of 10 mm and outer radius of 20 mm and is modelled as an annular ring. The die geometry has a projection at the centre that controls the rivet flaring. The blank holder and punch geometries are modelled such that sufficient clearance is provided between the surfaces. The dimensions are based on standards available practically. Figure 24.2 shows the FE model for SPR analyses and one of the simulated cases.

The sheet material properties represent a 5xxx Al alloy, and the stress–strain behaviour of the material is shown in Fig. 24.3. The stress–strain curve was obtained from uniaxial tensile tests following standard procedure. The rivet material was considered much stronger than the sheet. Since its material properties were not evaluated, a multiplying factor was considered with respect to the sheet to obtain its stress–strain behaviour. However, both are modelled as elasto–plastic materials. The other tools (die, punch and the blank holder) were modelled as rigid by considering properties of tool steel which has very high elastic modulus. The other material properties required to simulate the FE explicit-temperature-displacement model are given in Table 24.1.

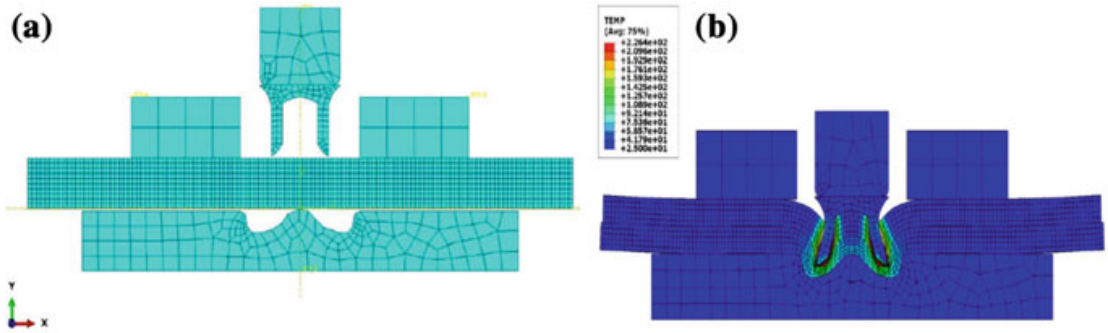

Fig. 24.2 FE model of SPR **a** initial stage for 0.21 tip height, **b** FE simulation of an SPR case

Fig. 24.3 True stress–strain behaviour of 5xxx Al sheet

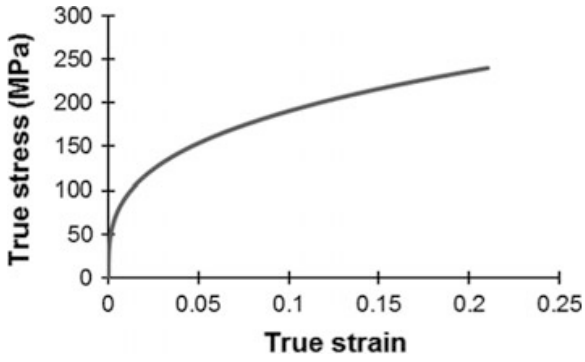

Table 24.1 Material properties used for FE simulations

Material	Properties					
	Density (kg/m^3)	Specific heat (J/kg K)	Thermal conductivity (W/m K)	Inelastic heat factor	Elasticity (GPa)	Poisson's ratio
5xxx sheet	2700	900	205	0.9	68	0.33
Rivet	7830	490	50.2	0.9	180	0.3
Tool	7830	490	50.2	0.9	210	0.3

In the FE model, the interactions are created between the rivet and the sheets, the upper and the lower sheets, the blank holder and the upper sheet, the rivet and the punch, and the die and the lower sheet. The contact was modelled using surface-to-surface penalty formulation. Constant Coulomb's friction coefficient was set as per the levels decided (given later). The sheets are clamped between the die and the blank holder with a holding force of about 5 kN. The die and the blank holder are fixed during SPR simulations. The punch is provided with a prescribed displacement of 6.5 mm to push the rivet through the sheets for joint formation. The rate of punch movement is fixed such that the total displacement occurs in 1 s in real practice. After the completion of each simulation, temperature at an element that is in contact with the rivet tip was evaluated with respect to punch displacement.

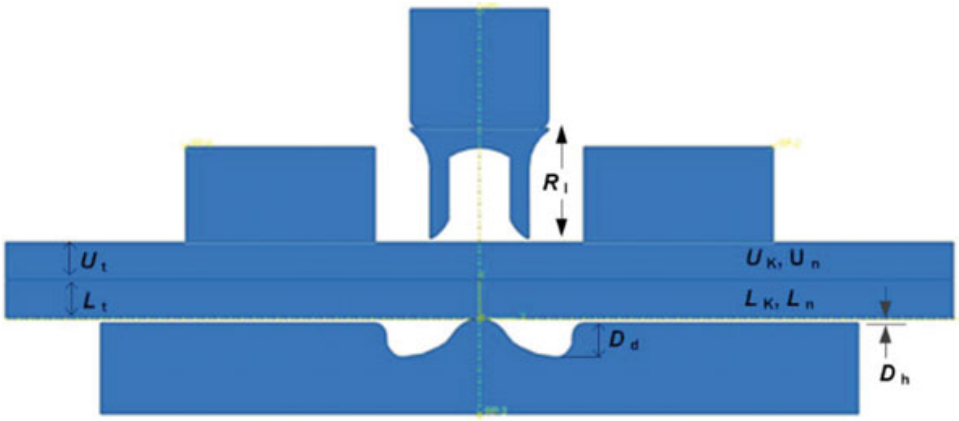

Fig. 24.4 Definition of SPR parameters

24.3 SPR Parameters

The SPR parameters considered for the ANN modelling are Coulomb's coefficience of friction (μ), die tip height (D_h), die depth (D_d), rivet length (R_l), upper sheet thickness (U_t), lower sheet thickness (L_t), upper sheet K (U_K), upper sheet n (U_n), lower sheet K (L_K), lower sheet n (L_n). Here, K and n are the strength coefficient and strain hardening exponent of the sheet materials. The parameters are defined in Fig. 24.4. The levels for these parameters (shown in Table 24.2) were selected based on available SPR data and material properties. The range was chosen to satisfy the practical range available for these parameters.

24.4 ANN Model

In the present work, ANN model was developed to predict the temperature evolution during SPR. A total of 440 FE simulations were carried out for ten parameters (Table 24.2) with several levels for each parameter. To predict the temperature evolution during SPR, the temperature-displacement curves from FE simulations were divided into segments at equal intervals. For example, in Fig. 24.5, the plot for four combinations out of 440 combinations is shown with the segments made at different displacements. Here, for 6-mm-punch displacement, 10 segments are considered. Hence, for every 0.6 mm a partition line is drawn. For one partition line, the curves intersect at four different points. These four temperatures are considered as output for a particular displacement at four different SPR conditions. Similar exercise has been followed for all the segments resulting in large data set for temperature evolution. A sample table for four combinations at one partition line is given in Table 24.3. The eleven different temperature values for a condition will be trained to generate an ANN model.

The ANN model was trained by using back-propagation algorithm using an in-house C++ code. The algorithm is based on the error-correction learning rule. In the current application, the objective is to use the network to learn mapping between input and output patterns. The components of the input pattern consist of the control variables of the SPR operation (Table 24.2), whereas the output pattern components represent the temperature rise during the process. The nodes in the hidden layer are necessary to implement the nonlinear mapping between the input and output patterns. Each neuron is connected to all the other neurons in the adjacent layer through the weighted connections. In the forward pass, the synaptic weights remain unaltered throughout the network and the function signals of the network are computed on a neuron-by-neuron basis.

Training and prediction are performed separately for each output temperature, i.e., for each partition line. Thus, the eleven outputs are trained separately, generating eleven ANN architectures. The final ANN architecture contains five input neurons, one hidden layer with ten neurons, and one output neuron corresponding to temperature at each displacement. The final architecture has been decided based on numerous trial exercises. For the first eight displacement levels, tan-sigmoid transfer function has been used between input and hidden layer, while log-sigmoid between hidden layer and output layer. However, for the last three displacement levels, tan-sigmoid transfer function has been used between input and hidden layer and hidden layer and output layer. The coefficient of transfer function between the

input and hidden neurons and the coefficient of transfer function between the hidden neurons and output, learning constant, momentum constant are decided based on trial and error and accuracy of the network. The trained ANN has been validated with the FE simulation results at 44 intermediate levels (Table 24.4) for checking the adequacy of the ANN model.

24.5 ANN Prediction

The trained ANN model has been validated for 44 intermediate cases (given in Table 24.4) that were not part of the training set. Out of these, validation for ten cases, namely case 4, case 7, case 12, case 13, case 19, case 28, case 33, case 38, case 41, case 43 (indicated in Table 24.4), is shown in Fig. 24.6. It is observed that the temperature evolution predictions from ANN agree well with that of from FE simulations. There is about 5% deviation. Similar accuracy levels are observed in all other cases as well. Figure 24.6k shows the accurate ANN predictions for all 44 SPR cases. With the FEA-ANN hybrid model, one can design and optimize the SPR process, tool and material conditions, efficiently, which otherwise will be time and resource intensive.

24.6 Conclusions

The temperature measurement during SPR is challenging and difficult task to perform in shop floor. The temperature has to be monitored in the deforming region of the sheet which is inside the die with a diameter of about 10 mm and the process occurs for a small duration. The present work demonstrates that the temperature rise

during SPR process can be predicted using a robust FEA-ANN strategy for any combination of sheet materials, process conditions and tool dimensions. The ANN model is sufficiently accurate to predict the temperature evolution during SPR and hence can be used as a 'virtual machine' for analyses.

Chapter 25
Determination of Optimal Cutting and Tool Geometry Parameters for Better Surface Integrity of Hard Turned AISI 52100 Steel-Hybrid GRA-PCA

P. Umamaheswarrao, D. Ranga Raju, K. N. S. Suman and B. Ravi Sankar

Abstract In the present work, AISI 52100 steel hard turning has been performed using PCBN tools. Cutting speed, feed, depth of cut, nose radius and negative rake angle are the input parameters, and the measured responses are surface roughness and workpiece surface temperature. Experiments are planned as per central composite rotatable design (CCD) of response surface methodology (RSM). The effect of input parameters and their interactions are discussed with main effects plot and response surface plots. Further, the multi-objective optimization scheme is proposed by adopting grey relational analysis (GRA) coupled with the principal component analysis (PCA). Results demonstrated that responses considerably affected by speed followed by nose radius, feed, depth of cut and negative rake angle. Cutting speed 1000 rpm, feed 0.04 mm/rev, depth of cut 0.4 mm, nose radius 1 mm and negative rake angle 15° are the obtained optimum cutting parameters.

25.1 Introduction

Optimum machining parameter's determination in manufacturing industry leads to the reduction in production cost and time, increases the production rate, improves the product quality and reduces environment impact which in turn leads to productivity enhancement [1, 2]. The comparison of conventional machining versus hard turning is shown in Fig. 25.1. [3]. Higher material removal rate, less machining time, less set-up time and greater flexibility are the merits in hard machining in contrast to grinding. Complex part fabrication using hard turning saves 30% manufacturing costs [4]. During AISI 52100 steel hard turning with PCBN tool, feed rate has a significant influence on the surface finish, while cutting speed and depth of cut had marginal effect [5, 6]. Ravi Sankar et al. [7] revealed surface roughness greatly influenced by the speed and nose radius in AISI 52100 hard turning with PCBN tools.

Suhail Adeel et al. [8, 9] obtained better surface roughness at higher the workpiece surface temperature for AISI 1020 steel. The cutting performance could be effectively sensed and controlled by the workpiece surface temperature, while AISI D2 steel hard turning cutting speed, depth of cut followed by feed were the major contributors to workpiece surface temperature development [10]. During turning of EN-9 steel, the workpiece surface temperature was considerably affected by feed subsequently cutting speed and depth of cut [11]. Multi-objective

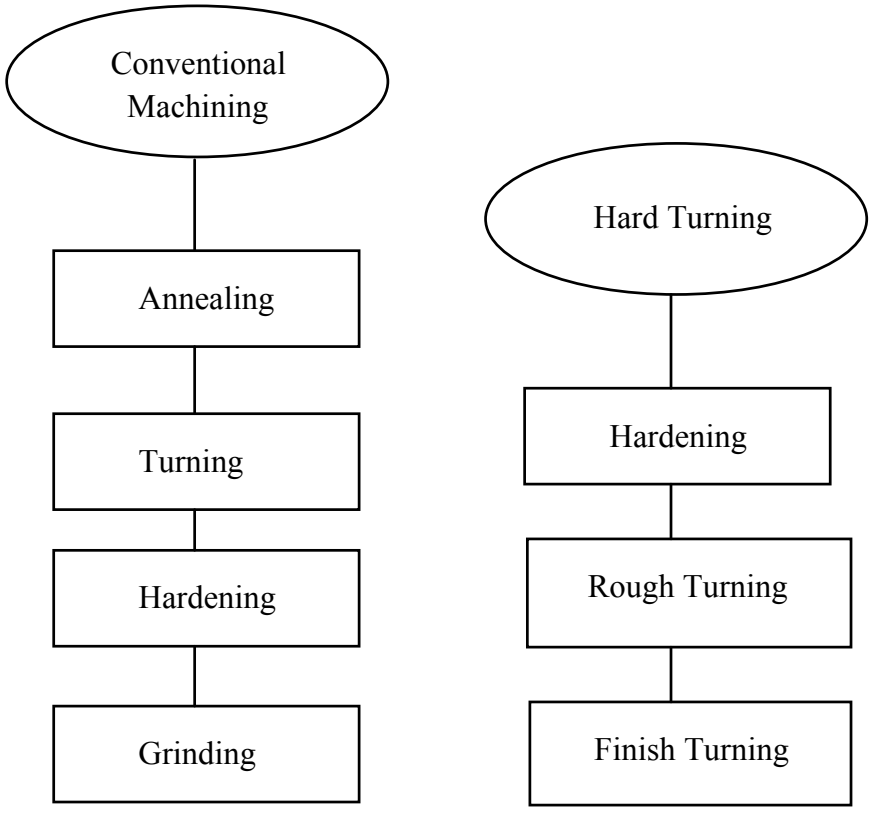

Fig. 25.1 Conventional machining and hard turning comparison [4]

optimization of parameters was performed by deploying GRA coupled with PCA and gained wider accomplishment [12–14].

From the literature, it was elucidated that hard turning was the best alternative to grinding owing to its merits. Much emphasis was made on AISI 52100 steel hard tuning by several researchers due to its applications in various parts of the industry. The past studies made a large amount of interest to investigate the effect of cutting parameters on the responses. Scanty literature was available on the effect of tool parameters on the output responses, and the much interest was focused on nose radius. Most of the studies focused on the machining forces developed and surface roughness during hard turning.

However, the workpiece surface temperature reported to be the sensible and controlling factor for turning performance. Hence, the present study was aimed to conduct hard turning of AISI 52100 steel using PCBN tools with cutting speed, feed rate and depth of cut as cutting conditions whereas nose radius and negative rake angle as tool geometry parameters. Surface roughness and workpiece surface temperature (also termed as surface temperature) were considered as responses. Further, multi-objective optimization was performed deploying GRA coupled with PCA for optimum cutting conditions.

25.2 Experimental Work

Experiments are designed using central composite rotatable design (CCD) of second order which is found to be the most efficient tool in response surface method (RSM). Five input parameters were varied at five levels throughout the experiment, and their influences on responses like surface roughness and workpiece surface temperature were examined. Levels and their factors are depicted in Table 25.1.

Experiments were conducted using variable speed and feed drive lathe in dry condition. Experimental set-up is depicted in Fig. 25.2. Round bars of 48 mm diameter and 500 mm length made of AISI 52100 steel were used for the experiment with a hardness of 57 HRC. Machining length and diameter of workpiece

5	Negative rake angle		α	−5	−15	−25	−35	−45

Fig. 25.2 Experimental set-up

were fixed at 30 and 48 mm respectively for every experimental run. In the present work, PCBN inserts were used with different nose radii such as r = 0.4, 0.6, 0.8, 1 and 1.2 mm with different rake angles (−5, −15, −25, −35 and −45). Inserts are mounted on a tool holder of ISO Designation PSBNR2525 M12.

Mitutoyo make surface roughness tester (SJ-210) was used to measure the surface roughness of the turned samples. Workpiece surface temperature was measured using an infrared thermometer manufactured by AMPROBE (range: −50 to 1550 °C, Model: IR 750). Experimental matrix with results is depicted in Table 25.2.

25.3 Methodology Adopted

Hybrid GRA-PCA

Hybrid GRA-PCA is adopted to obtain optimum parametric combinations, and the methodology is shown in Fig. 25.3.

25.4 Results and Discussion

The experiments were conducted as per the CCD plan of response surface method. The experimental runs with rank, GRC and GRG are depicted in Table 25.3.

Better multiple performance characteristics are obtained at larger GRG. A larger delta value indicates the higher significance of the parameter in controlling the response.

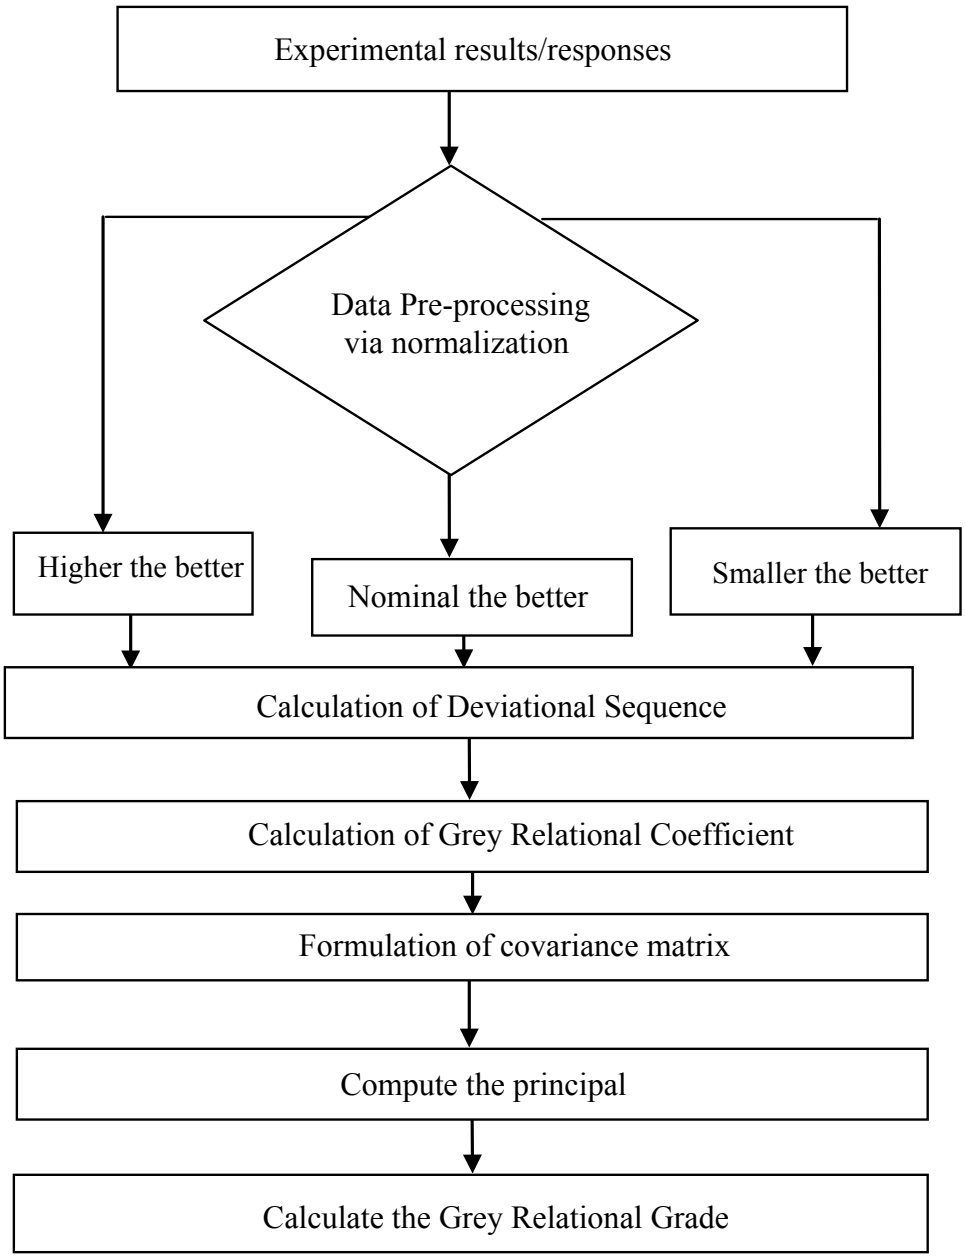

Fig. 25.3 Methodology for hybrid GRA-PCA

ANOVA is used to estimate each machining parameters percentage of contribution on multi-objective optimization. From the ANOVA analysis, it is clear that speed contribution is highest followed by nose radius, feed, depth of cut and negative rake angle as depicted in Table 25.4.

Quadratic equation for GRG after eliminating insignificant terms for 95% confidence level is given below

From the main effects plot (Fig. 25.4) shows that grey relational grade increases significantly with an increase in speed which indexes the occurrence of optimum surface roughness and workpiece surface temperature. This is due to more thermal softening of material with an increase in speed [15, 16]. As feed increases, grey relational grade reduces due to the more feed marks which lead to higher surface

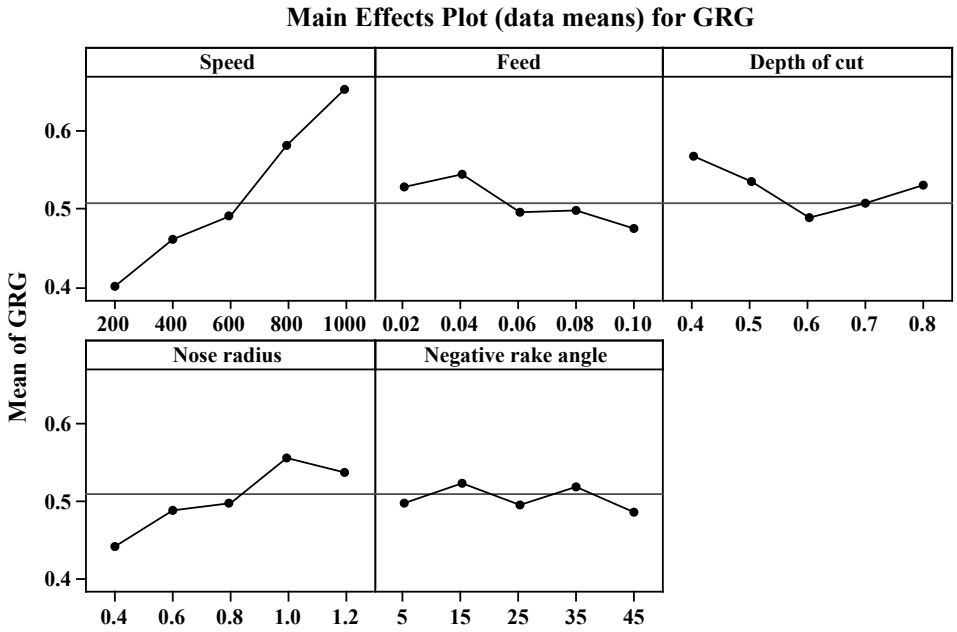

Fig. 25.4 Main effects plot for GRG

roughness and ploughing effect [17]. As the depth of cut increases, grey relational grade decreases and then increases. This is attributed to the increased cutting resistance and cutting force since chipping does not take place at nose radius which has a notable influence on the surface roughness as well as workpiece surface temperature [18]. Grey relational grade increases with an increase in nose radius. This is attributed to the increased nose radius leads to a reduction in surface roughness from general principles of metal cutting. Grey relational grade varies marginally with an increase in negative rake angle. This is due to the increased edge strength of the tool with an increase in negative rake angle causing ease in machining [18, 19]

From the main effect plot (Fig. 25.4), it is observed that the optimistic overall grey relational grade can be achieved with speed = 1000 rpm, feed = 0.04 mm/rev, depth of cut = 0.4 mm, nose radius = 1 mm and negative rake angle = 15°, respectively. GRG for the obtained optimum combination of parameters was 0.80887 estimated from Eq. 25.2 and was 5.24% more than the highest GRG in Table 25.3. Hence, the obtained values were optimum.

$$\gamma = \gamma_m + \sum_{i=1}^{q} (\overline{\gamma_j} - \gamma_m) \tag{25.2}$$

The interaction among the parameters is discussed with the help of response surface plots shown in Fig. 25.5. The optimum grey relational grade is noticed at the combinations of upper limits of speed due to thermal softening [15, 16], lower limits of feed due to less feed marks and upper limits of nose radius due to more

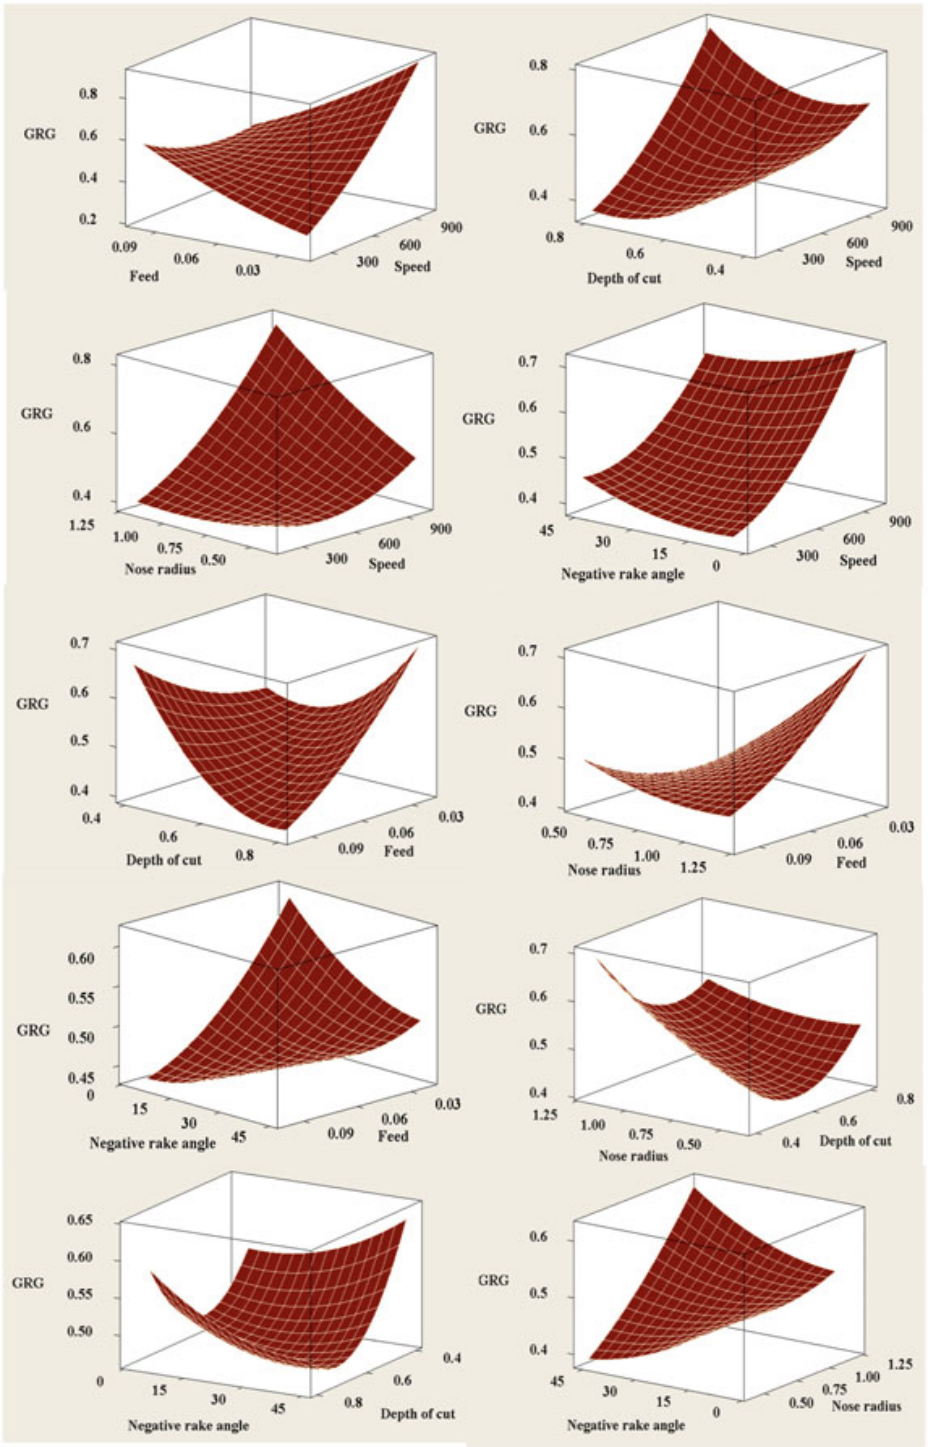

Fig. 25.5 Response surface plots [hold values were speed 600 rpm, feed 0.06, depth of cut 0.6, nose radius 0.8 and negative rake angle 25]

ploughing energy [20]. However, the interaction of depth of cut and negative rake angle with other parameters is observed to be significant, due to the variation of the developed cutting resistance and edge strength.

25.5 Conclusions

Multi-objective optimization for AISI 52100 hardened steel was performed using hybrid GRA-PCA

- The obtained optimum combination of parameters and their levels were A5B2C1D4E2, i.e. (speed = 1000 rpm, feed = 0.04 mm/rev, depth of cut = 0.4 mm, nose radius = 1 mm and negative rake angle = 15°).
- Responses were notably affected by speed followed by nose radius, feed, depth of cut and negative rake angle.
- Higher GRG is noticed during the interaction at upper limits of speed, lower limits of feed and higher limits of nose radius. However, the depth of cut and negative rake angle exhibit considerable interaction with other parameters.
- An increase in the value of predicted weighted GRG from 0.768536 to 0.80887 confirms the improvement in the performance of hard turning.

Chapter 26
Study of Cutting Edge Radius Effect on the Cutting Forces and Temperature During Machining of Ti6Al4V

Siddharam Mane, Shyamprasad Karagadde and Suhas S. Joshi

Abstract The cutting-edge radius of the tool has significant effects on the machining process, as it influences the cutting forces, stresses, and temperature at the tool–chip interface. These parameters ultimately affect the tool life and surface integrity of the finished workpiece. The presence of cutting-edge radius in the tools protects them from easily chipping off during the cutting process. A finite element based ABAQUS™ model is used to evaluate the effect of cutting-edge radius for 20, 40, and 60 μm on the cutting forces for orthogonal cutting of Ti6Al4V alloy at different cutting parameters. It was observed that the cutting-edge radius influences both the cutting and thrust forces. An increase of 4–8% and 12–14% in the cutting force and thrust force was observed when the cutting-edge radius changes from 20 to 60 μm. The temperature in the tool was increased with increasing cutting-edge radius.

Keywords Machining · Ti6Al4V · Cutting-edge radius · Finite element modeling

26.1 Introduction

In any machining process, a cutting tool with rounded cutting edges provides an enhanced tool life. The optimum cutting-edge radius for a machining process depends on the work material, tool material, and machining process parameters. Tool-edge geometry has significant effects on the cutting process, as it affects cutting forces, stresses, temperatures, the coefficient of friction, and tool–chip contact length. Nasr et al. [1] showed increasing cutting-edge radius increases both the residual stresses and temperature in the workpiece for AISI 316L steels. Liu and Melkote [2] have studied the tool-edge radius effect on the microstructure of the hard turned of AISI 52100 steel. They observed that large edge honed tools produce substantial subsurface

plastic flow. Wyen and Wegener [3] conducted the experimental study for orthogonal turning on Ti6Al4V with different cutting-edge radii. They found that the coefficient of friction is influenced by the cutting-edge radius of the tool.

Kim et al. [4] carried out numerical and experimental analysis considering the effect of the tool edge on the cutting process. They confirmed that a major cause for the size effect is the tool-edge radius and increase in the tool-edge radius that causes a change in the temperature distribution in the tool and changes the location of maximum temperature. Endres and Kountanya [5] showed that increasing the cutting-edge radius reduces the flank wear of the tool. Increasing cutting-edge radius increases mechanical stability, but the increasing contact length on the flank face due to the increase in cutting edge results in different thermo-mechanical loads on the cutting edge [6]. Zhao et al. [7] experimentally carried out hard turning of AISI 52100 steel under the cutting-edge radius of 20, 30, and 40. They found that the flank wear decreases with increasing radius.

Use of the cutting tool with some radius protects the edge from chipping off during machining, hence increases tool life. Considering the effect of cutting edge on the cutting forces, temperature profile, the coefficient of friction and contact length, an attempt is made to understand the effect of cutting-edge radius on the cutting forces and temperature in the machining of difficult to machine alloy like Ti6Al4V. This is done by developing a numerical model for two cutting-edge radii of 20 and 40, and 60 μm for different cutting speeds.

26.2 Numerical Modeling

A finite element model using ABAQUS™ is used for modeling and simulation of the tool and the workpiece. A 2D dynamic coupled temperature displacement model is used for simulating orthogonal cutting as shown in Fig. 26.1.

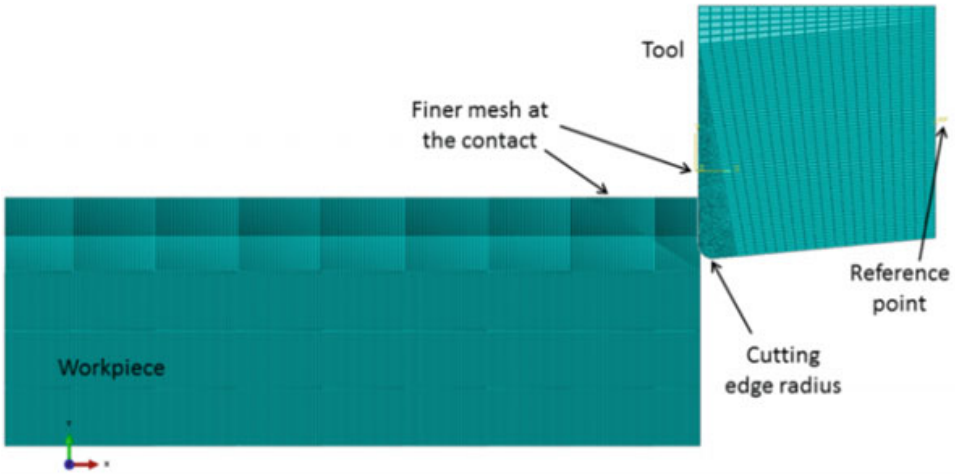

Fig. 26.1 Numerical modeling of orthogonal cutting

Table 26.1 Numerical model cutting parameters

Parameters	Value
Workpiece	Ti6Al4V
Tool	Tungsten carbide

Cutting speed (m/min)	30, 50, 70, 90
Depth of cut (mm)	0.1
Rake angle	0
Cutting-edge radius (μm)	20, 40, 60

Table 26.2 Thermophysical properties of the workpiece and tool [8, 9]

Parameter	Workpiece	Tool
Specific heat (J/kg k)	670	178
Thermal conductivity (W/m k)	6.6	24
Density (kg/m^3)	4430	15700
Young's modulus (GPa)	110	705
Poisson's ratio	0.33	0.23

Table 26.3 Johnson–Cook parameter for Ti6Al4V alloy [10]

A (MPa)	B (MPa)	n	C	m	T_m	T_0
1098	1092	0.93	0.014	1.1	1630	20

The element type used for both the tool and workpiece refers to CPE4RT elements. The tool is assumed to be a rigid body since there will not be any deformation in the tool. A reference point is located at the tip of the tool for providing velocity to the tool. 20, 40, and 60 μm are the three different cutting-edge radii of the tool used in the simulation. The workpiece used is a rectangular block of 3 × 5 × 15 mm. Finer mesh size is used near the tool–workpiece contact region, as shown in Fig. 26.1. A total number of elements in the tool and the workpiece are 2392 and 39140, respectively. The cutting parameters for the modeling are listed in Table 26.1. The thermophysical properties of the tool and the workpiece are listed in Table 26.2.

Since machining is a dynamic process, there will be high strains, strain rate, and temperature involved. To accommodate this, a Johnson–Cook flow stress model was used for Ti alloy shown in Table 26.3. The Johnson–Cook fracture model is given in Table 26.4. The thermoplastic behavior of titanium alloy by Johnson–Cook model is given by,

Table 26.4 Johnson–Cook fracture model parameters for Ti6Al4V alloy [10]

D_1	D_2	D_3	D_4	D_5	ε_0
−0.09	0.25	−0.5	0.014	3.87	1

$$\sigma = [A + B\varepsilon^n]\left[1 + C\ln\frac{\dot{\varepsilon}}{\varepsilon_0}\right]\left[1 - \left(\frac{T - T_0}{T - T_m}\right)^m\right] \tag{26.1}$$

where σ is the equivalent stress, ε is the equivalent plastic strain, $\dot{\varepsilon}$ is the equivalent strain rate, and ε_0 is the reference strain rate. T, T_0, and T_m are the current temperature, room temperature, and melting temperature of the workpiece, respectively. The parameters A, B, n, C, and m are material constants, and they refer to initial yield stress, hardening modulus, strain hardening coefficient, strain rate dependency coefficient, and thermal softening coefficient, respectively.

26.3 Results and Discussion

Figure 26.2 shows an example of simulation at a cutting speed of 90 m/min. The stresses observed in the model are in the range of 1.7–1.9 GPa, which is generally observed in machining conditions.

26.3.1 Forces Evaluation

Forces generated in machining plays an important role in the heat flow and effectively the temperature distribution along the rake face of the tool. Hence, the estimation of cutting forces is important in order to understand the heat flow and temperature.

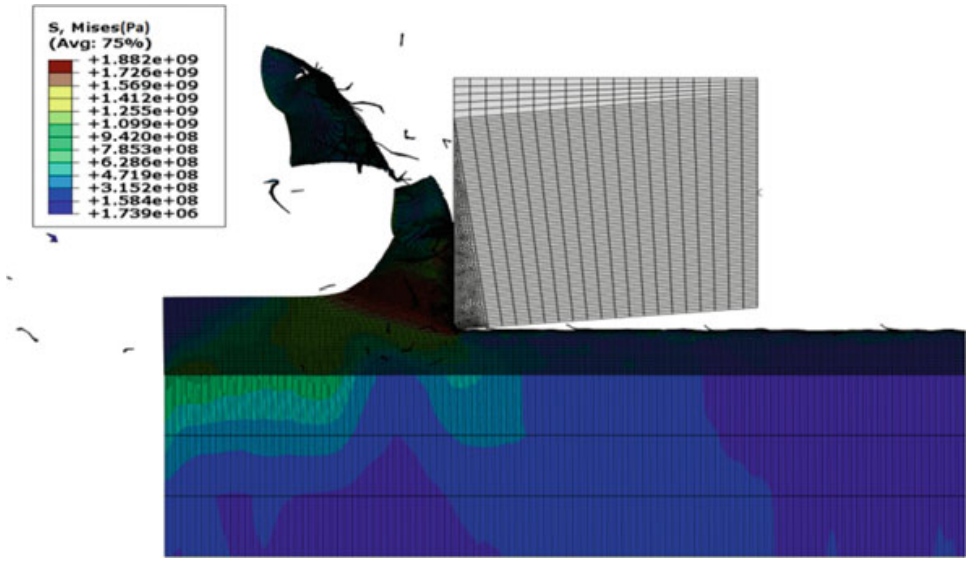

Fig. 26.2 Stresses (Pa) obtained in the finite element model

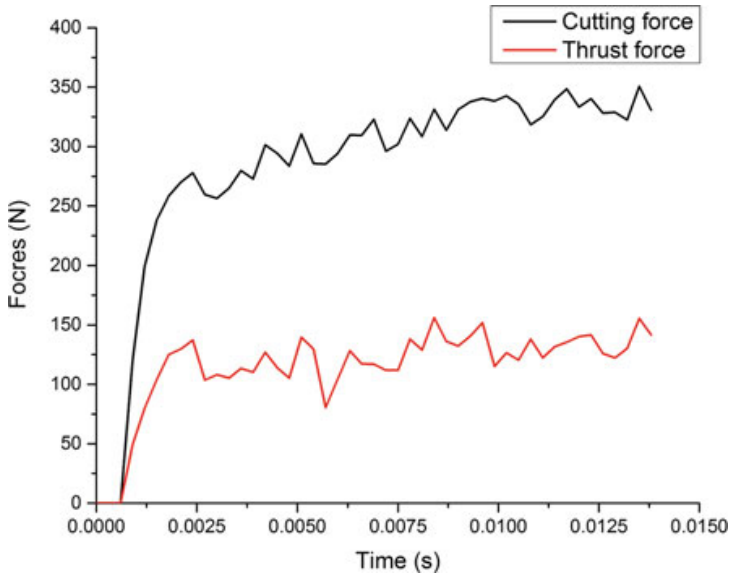

Fig. 26.3 Variation in the cutting and thrust forces with time

Figure 26.3 shows the variation in the cutting and thrust force with time. The cutting forces are large as compared to the thrust forces. These forces are evaluated for all four cutting speeds and three cutting-edge radii, as shown in Table 26.1.

The average cutting forces for cutting conditions are plotted in Fig. 26.4. As can be seen, with the change in cutting speed, change in the cutting force is around 4–5% only, whereas changing cutting edge from 20 to 60 µm changes cutting force and feed force on an average by 4–8 and 12–14%, respectively. For a radius of 20 µm, the cutting forces and thrust force are in the range of 250 and 80 N, respectively. However, for a larger radius of 40 µm, the cutting force shows some variation with cutting speeds, but the thrust force remains more ever in the range of 70–80 N. Overall, changing cutting edge influences the forces more as compared to the cutting force. The contact area at the tip of the tool is more in case of 60 µm as compared to the 20 µm. This increase in contact area increases the resistance the tool tip, and hence, the cutting forces observed in the case of 60 µm are higher.

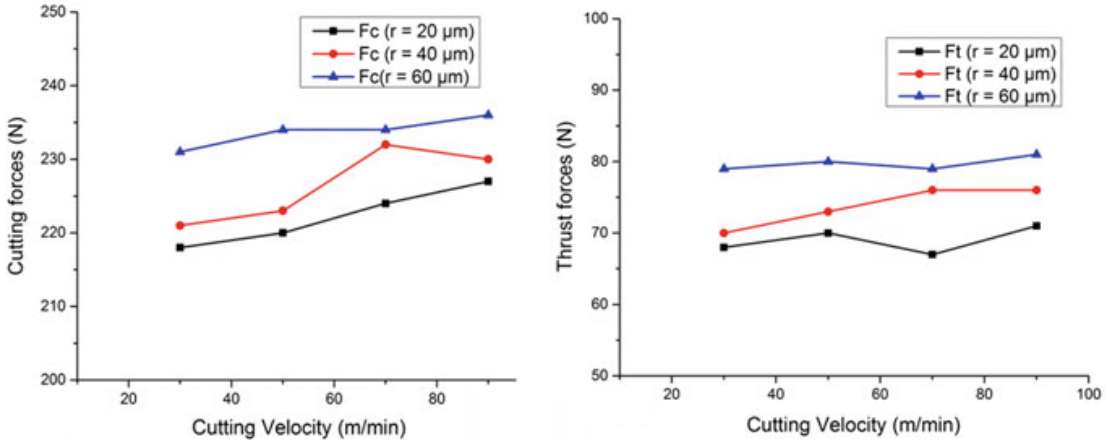

Fig. 26.4 Cutting and thrust forces for $f = 0.1$ mm/rev

26.3.2 Maximum Temperature in the Tool

Figure 26.5 shows the location of the maximum temperature developed around the tool tip. For a smaller cutting-edge radius of 20 µm, the maximum temperature location was away from the tool tip at all cutting speeds except 90 m/min where the maximum temperature was observed at the tool tip. In the case of 40 µm radius, two peaks of temperature are observed at all cutting speeds. These peaks are at the tool tip and around 1.2–1.8 mm from the tip of the tool, see Fig. 26.5b. The reason for observing the second peak on the rake face is due to the friction at the tool–chip interface. It is observed that for a larger radius of 60 µm, the maximum temperature location shifts away from the tool tip which is more toward the flank side of the tool, such a trend is observed because, in the case of larger cutting edge, the contact between the flank face of the tool and workpiece is more, can be seen in Fig. 26.5c. This causes more friction between the tool and workpiece away from the tool causing shifting of the maximum temperature location away from the tool tip. Whereas, in the case of 20 µm cutting-edge radius, the contact area was less, hence, less temperature around tool tip (Fig. 26.5a).

The temperature developed for the cutting process in the case of all the three cutting-edge radii is plotted in Fig. 26.6. The maximum temperature is observed away from the tool tip in the case of low edge radius (Fig. 26.6a), whereas, for an intermediate radius of the tool, i.e., 40 µm, the temperature obtained at the tool tip are higher as compared to 20 µm cutting radius. The maximum temperature obtained in the simulation is around 450 and 500°C for 20 and 40 µm at a cutting speed of 90 m/min, respectively. Also, the spread of the temperature is observed to be more in case of 40 and 60 µm as compared to the 20 µm cutting edge because of the large contact area available between the tool and workpiece for 40 and 60 µm edges. The maximum temperature of 550 °C was observed in the case of 60 µm

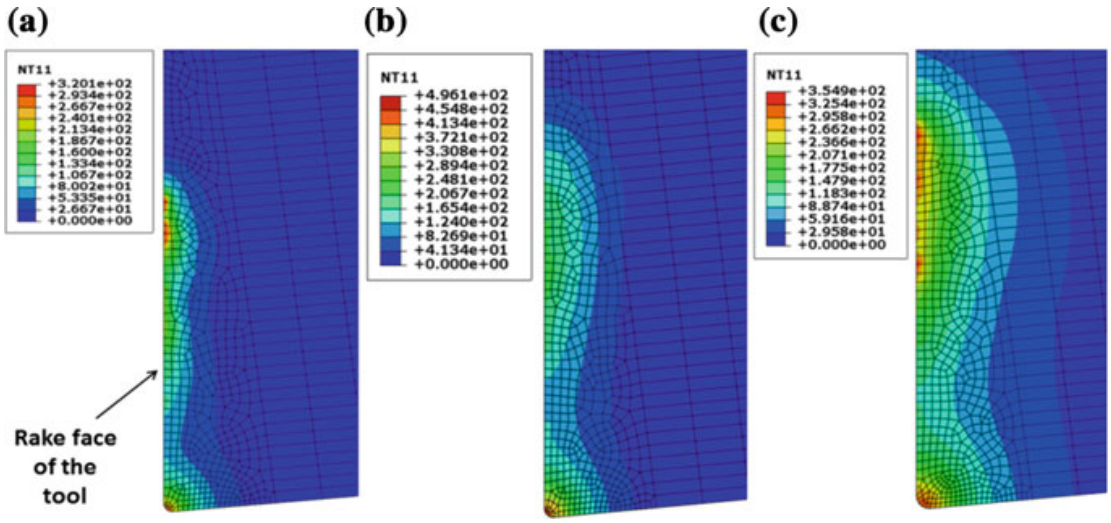

Fig. 26.5 Location of the maximum temperature generated along the rake face of the tool, **a** r = 20 µm, **b** r = 40 µm, **c** r = 60 µm

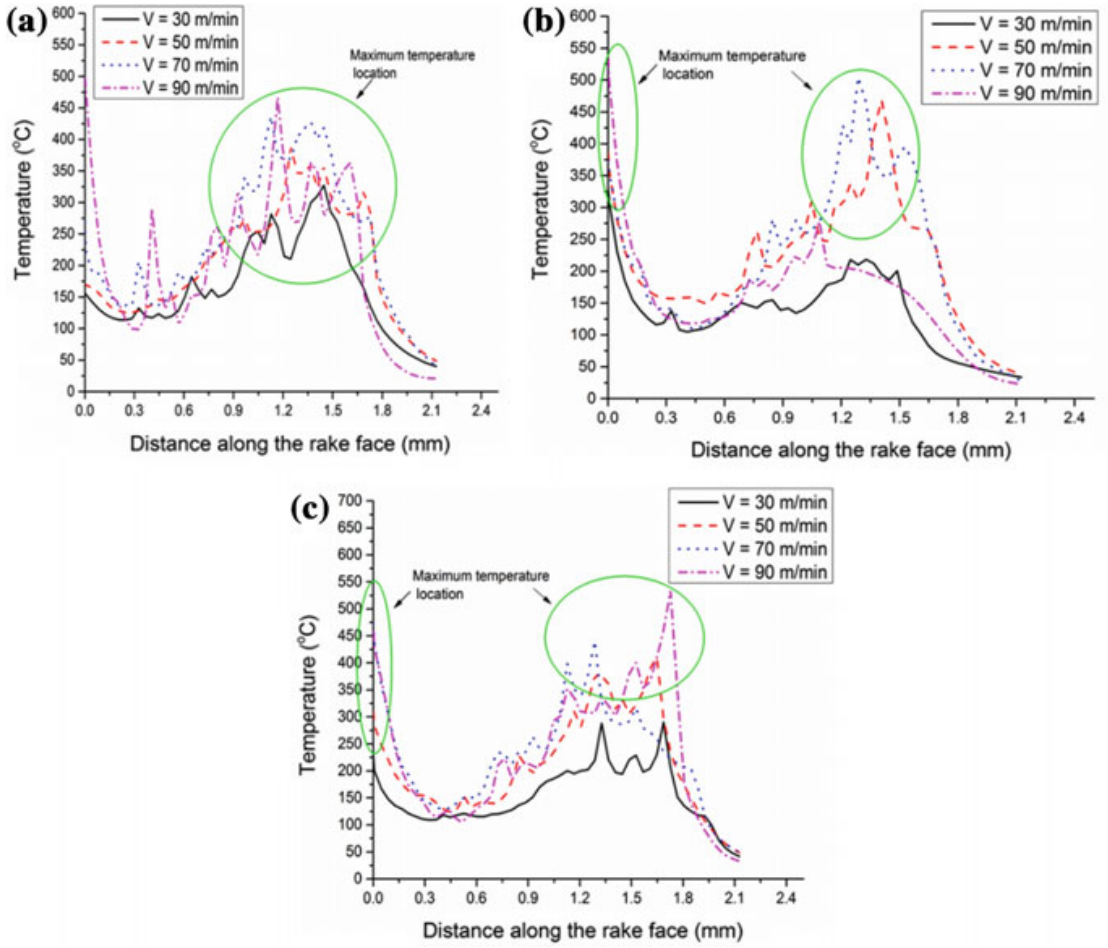

Fig. 26.6 Temperature along the rake face of the tool in the case of **a** r = 20 μm, **b** r = 40 μm, **c** r = 60 μm

cutting-edge radius at a speed of 90 m/min. Hence, the cutting-edge radius has an influence on not only the maximum induced temperature but also over the zone of temperature.

26.4 Conclusions

A FEM-based model is developed for predicting the cutting forces and temperature in the machining of Ti6Al4V alloy. It is seen that the cutting edge of the tool plays a major role in the induced temperature of machining and cutting forces. The cutting force and thrust force are seen to be increased by 4–8 and 12–14%, for a cutting-edge radius of 20 and 60 μm, respectively. The obtained temperature contours show that the maximum temperature location changes along the rake face of the tool as the cutting-edge radius changes. Although the effect of changing tool-edge radius on the forces is small, its effect on the tool temperature influences

significantly. Selecting a suitable cutting edge according to cutting conditions and material properties should be selected to improve the surface integrity and enhancing the cutting tool life.

Chapter 27
Comparative Study on Effect of Inclusions and Machinability Aspects of Alloy Steels

V. Krishnaraj, K. Thillairajan and R. Rajeshshyam

Abstract In recent decades, the noticeable amount of research has been carried out in the role of non-metallic inclusions and their relationship to the machinability of various steels. This paper compares the performances of EN alloy steels for varied machinability aspects throughout the machining under dry cutting condition. Cutting speed, feed, and depth of cut were the major ruling parameters affecting the machinability of materials. The present works review the machining of different alloy steels and the role of non-metallic inclusions in them. More precisely, the effects of composition and morphology of inclusions on machinability factors such as cutting force and chip size and shape are discussed and summarized. EN 1A Pb&Te alloy steel provides lower cutting force, and good curl or breakdown chips thus provides the better machinability.

Keywords Alloy steel · Non-metallic inclusions · Machinability · Chip morphology

27.1 Introduction

Several alloy steels, which can be machined at higher cutting speeds and show longer tool life by adding additives, have been developed and used for making the screws, fasteners, and many automobile components. The performance of steels is becoming increasingly stringent. Consumer's expectation is high on the quality and performance of alloy steels. Microstructure, composition, segregation, and cleanliness are the dominant criteria in determining the properties of steel. At present, most of the steel manufacturers are unable to attain completely pure steel without any non-metallic inclusions. These are present in steel greater or lesser according to their mixture and conditions of production. Usually, these non-metallic inclusions

are the foreign substances; they affect the homogeneity of the structure and influence the machinability. Inclusions are compound materials, embedded inside the steel at the time of the manufacturing process, and it has a distinctive chemical composition and properties. Non-metallic inclusions influence the properties of steels like machinability, formability, and toughness and corrosion resistance.

In general, machinability can be represented as an optimal combination of the following factors that are low cutting forces, high metal removal rates, low tool wear rates, excellent surface finish, and good curl or breakdown of the chip. Tanaka et al. [1] investigated the machinability study of BN free-machined steel. They identified that BN free-machining steel exhibits slightly lower cutting temperature and smaller cutting forces. Jiang et al. [2] studied titanium diboride particles on machinability and machining criteria optimization during machining of TiB_2/Al MMCs. They revealed that TiB_2 particles influence on machining force, residual stress, and surface roughness. Lalbondre et al. [3] experimented the machinability of AISI 51100 and AISI 52100. They revealed that machinability of AISI 51100 is superior to AISI 52100. Anmark et al. [4] proposed that machinability of clean steels is significantly improved by resulfurization. The better machinability of the standard steel grade R is partly linked to its high content of sulphur (0.028 wt% S) which results in higher amount of MnS inclusion in the steel matrix. This MnS inclusion acts as stress risers in the primary shear region during machining. They concluded that MnS particles improved the chip formation process and prolong the cutting life. Alizadeh [5] examined the influence on the machinability of sintered steels and reported that addition of 0.3 MnS resulted in higher machinability. Joseph [6] revealed the effects of inclusions in carbon and alloy steels in their mechanical properties and cause of failure. Addition to that, inclusions, such as oxides and manganese sulphides, affect the anisotropy of these materials with respect to rolling condition. MnS particles particularly resist the anisotropy because of its elongated morphology after hot rolling.

Gupta et al. [7] quantified the micro-scale effects of inclusions on the steel sheets. They identified that the size, properties (hard and soft), and shape of the inclusions have a substantial effect on stress concentration and peak stress in a steel sheet in which inclusions are ingrained. Das et al. [8] described the comparative study on machinability of alloy steel using uncoated carbide and coated cermet inserts during hard turning. They experienced coated cermets attained a lower cutting force, minor flank wear, and reduced workpiece surface temperature. The revealed the depth of cut was the influential parameter for feed force and radial force.

The objective of the present work is on the comparative analysis of three different alloy steels. The machining operation was conducted in a dry environment based on Box–Behnken design using three factors and three levels. The machinability of the workpiece is investigated based on the output reacts like machining force and chip morphology.

27.2 Experimental Details

A complete testing procedure was carried out to examine the effect of inclusions on machinability of alloy steels when turning at several cutting conditions without coolant supply. The work materials were EN 8M free-machining steel, EN 1A alloy, and EN 1A Pb&Te alloy steel. Figure 27.1 represents the cylindrical bars of 28 mm diameter and 440 mm length made of different alloying elements which are used for the experiments.

Three parameters such as cutting speed, feed, and depth of cut are discrete at three levels during the experiments and their influences on output parameters such as cutting force and chip morphology are examined. The experimental runs are designed using Box–Behnken design without compromising the accuracy of results. Before getting into the actual machining, the rough layers were removed from the specimens.

27.2.1 Chemical Composition

A portion of the workpiece was cut using the parting tool and was polished using different grades of abrasive sheets and was subjected to the spectroscopy tests. The chemical composition obtained and major constitutions are summarized in Table 27.1.

27.2.2 Hardness and Microstructure

Hardness was determined by tests conducted using Vickers hardness testing machine wherein a square-based pyramid-shaped diamond indenter was used at 300 g load for 10 s. The diagonal of the indentation was measured and Vickers

Fig. 27.1 Workpiece material

Table 27.1 Chemical composition of alloy steels (in weight %)

Element (in mass%)	EN 8M steel	EN 1A steel	EN 1A Pb&Te
C	0.37	0.07	0.077

Mn	1.27	1.28	1.25
S	0.14	0.23	0.24
Cr	0.06	0.038	0.04
Pb	–	–	>0.38
Te	–	–	0.001

Table 27.2 Vickers hardness of the alloy steels

Specimens	EN 8M steel	EN 1A steel	EN 1A Pb&Te
Vickers hardness	193	168	161

hardness was determined. The hardness values of the three steels are listed in Table 27.2.

The piece was then observed under an optical microscope after application of natal etchant. EN 8M has medium carbon steel 40% ferrite and 60% pearlite formation, EN 1A has low carbon steel with 70–75% ferrite and 25–30% pearlite, and EN 1A Pb&Te has almost ferrite structure with pearlite of 5–10%.

27.2.3 Inclusions

Inclusions are non-metallic compounds embedded in steel during the manufacturing process. It has a different chemical origin and gives different mechanical properties to steel. Inclusions have domination on several properties of steel, such as formability, toughness, and machinability and corrosion resistance. The workpieces were then observed under an optical microscope to study the distribution of inclusions on the surface as shown in Figs. 27.2, 27.3 and 27.4.

The above image indicates the Type B alumina inclusions. Literature has shown that the existence of non-metallic inclusions [particularly the hard ones such as alumina (Al_2O_3)] and complex oxides and voids has adverse effects on mechanical properties of steels. The inclusions are distributed in a particular area, and it looks like a clustered formation as shown in Fig. 27.2a. Clusters of inclusions are also unfavourable since they may result in a local drop of mechanical properties such as toughness and fatigue strength. These inclusions tend to increase the hardness of the workpiece while simultaneously increasing strength to a particular limit. This increase in hardness makes it difficult to machine.

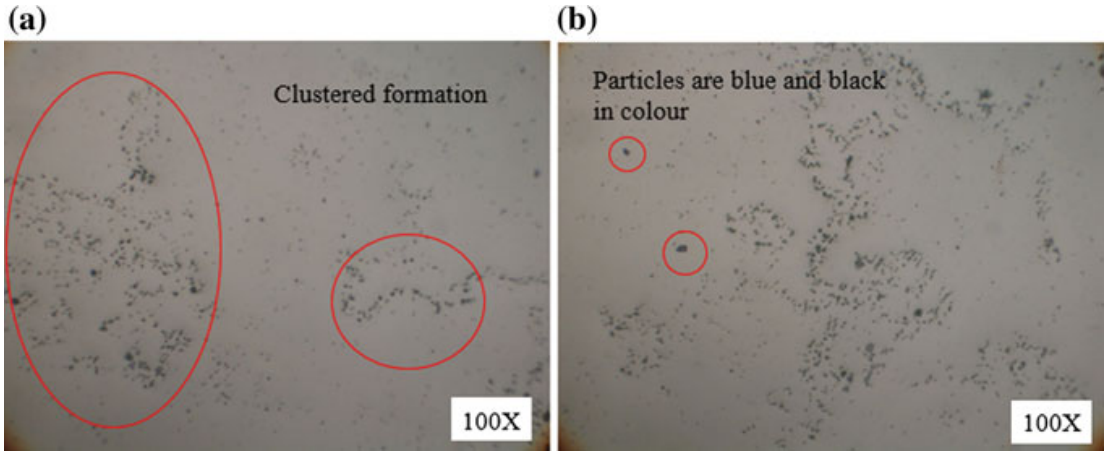

Fig. 27.2 **a** Type B–alumina type thin series 2.5 (fine size 2–9 μm). **b** Type B alumina thin series 1.5 inclusions in EN 8M free-machining steel

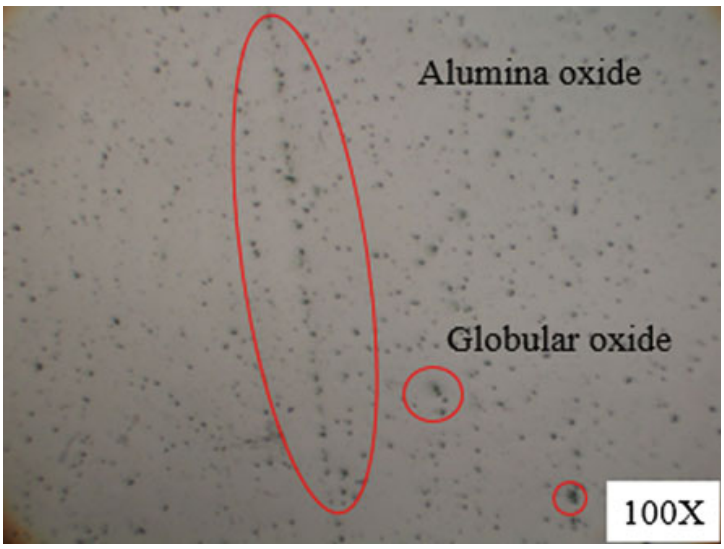

Fig. 27.3 Type D globular oxide thin series 3 (size 3–8 μm) inclusions in EN 1A steel

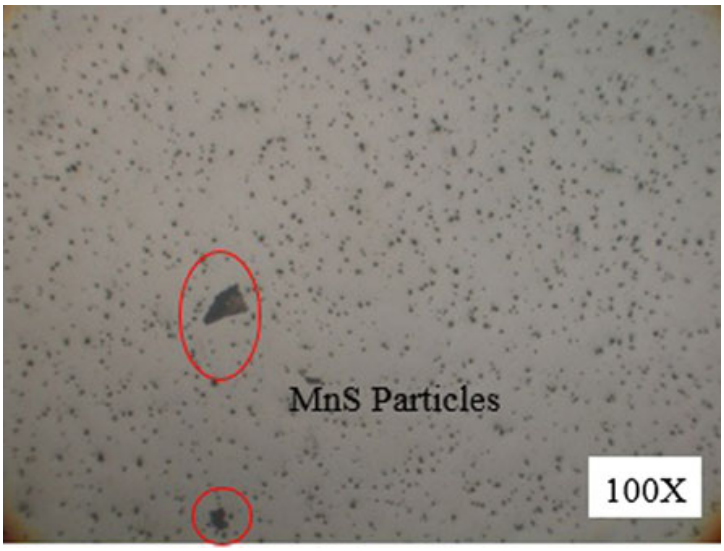

Fig. 27.4 Type D globular oxide thin series 3 inclusions in EN 1A Pb&Te steel

Figure 27.3 shows the type of inclusions formed in EN 1A Alloy steel. Globular shape of inclusions is desirable since their effect on the mechanical properties of steel is moderate. The spherical shape of globular inclusions has shown their formation in a liquid state at low content of aluminium, as indicated in Fig. 27.3. Examples of globular inclusions are manganese sulphide and oxysulphide formed during solidification in the spaces between the dendrite arms, iron aluminates, and silicates.

The MnS inclusions marked are shown in Fig. 27.4. MnS inclusions have a positive influence on the machinability, as they are soft in comparison with steel matrix and act as voids. As a result, the chips are smaller in length which leads to easier removal and declines the total power consumption during the machining.

27.2.4 Experimentation

In the present work, the multilayer CVD-coated inserts are used. The insert grade of CNMG 120408 MT TT5100 was procured from Taegu Tec. The ISO Range is (P20-P35) and shape of the insert is square (90° point angle) without any specific type of chip breaker geometry. This insert is mounted on a tool holder of ISO designation ECLNR-2020K12 as shown in Fig. 27.5. The inserts utilized in these experiments contain multilayer coatings (TiCN–Al_2O_3–TiN). Titanium nitride coatings were given at outer layer, alumina oxide, and titanium carbon nitride are as an intermediate and bottom layer of the insert.

The various control parameters adopted during the experiment are shown in Table 27.3.

Figure 27.6a, b shows the experimental setup. The turning operation was executed on a lathe of Pinacho SC 200x750 with spindle power of 4 kW and speed range of 40–2800 rpm. For measuring the cutting force, three-dimensional Kistler tool dynamometer was used.

Fig. 27.5 Cutting inserts and tool holder

Table 27.3 Control parameters and their levels for Box–Behnken design

S. No	Parameter	Unit	Symbol	Low level	Medium level	High Level
1	Cutting speed	m/min	*v*	125	162.5	200
2	Feed	mm/rev	*f*	0.1	0.15	0.2
3	Depth of cut	mm	*d*	0.5	0.75	1

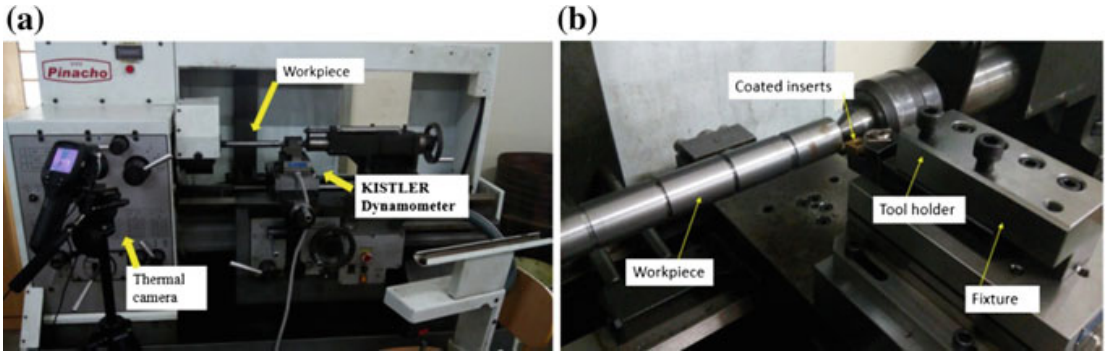

Fig. 27.6 Experimental setup

27.3 Result and Discussion

From Fig. 27.7, it was observed that the resultant cutting force of EN 8M steel was higher when compared to other two materials. When comparing to these three steels, EN 1A Pb&Te steel, accomplished the lower cutting forces at all cutting conditions owing to their low hardness and effects of lead and tellurium content in the steel.

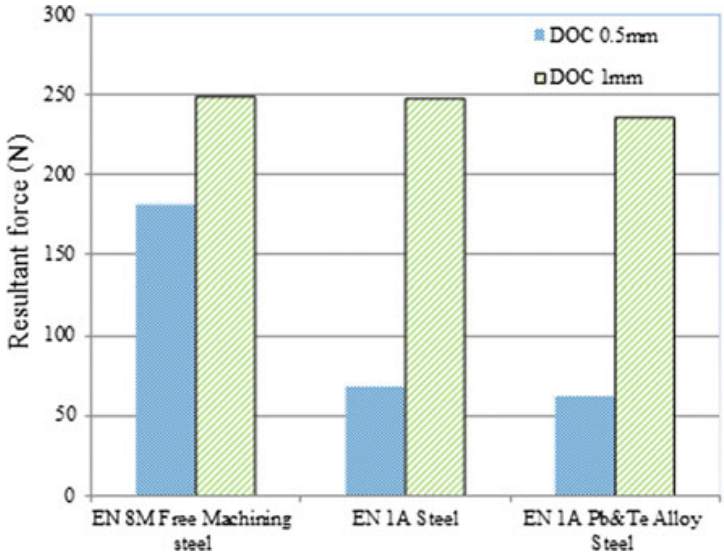

Fig. 27.7 Comparison of resultant forces for three different steels (when cutting speed 162.5 m/min, feed–0.1 mm/rev)

27.3.1 Chip Morphology

All cases which occur in a material during machining are depicted in the chip character, for example, in shape and density of chip morphology. Machining of EN 8M free machining steel obtained helical and continuous chips at higher cutting speed. On the other hand, chips were obtained blue in colour because of carbon content, which is 0.37%. During machining, an adequate amount of heat is expelled from the workpiece. Figure 27.8 shows the chips generated during machining of EN 8M steel. EN 1A alloy steel has produced the chips with light golden in colour and helical continuous one at higher cutting speed as shown in Fig. 27.9. The Lead and Tellurium alloy steel obtained small and discontinuous chips in all cutting conditions. The high content of sulphur (0.24%) results in an increased amount of MnS inclusions in the steel matrix. It is due to the effect of MnS inclusions and leads which predominantly improves the machinability. MnS inclusions act as a stress raiser in the primary shear region during the machining. As a result, they improve the chip formation process as shown in Fig. 27.10.

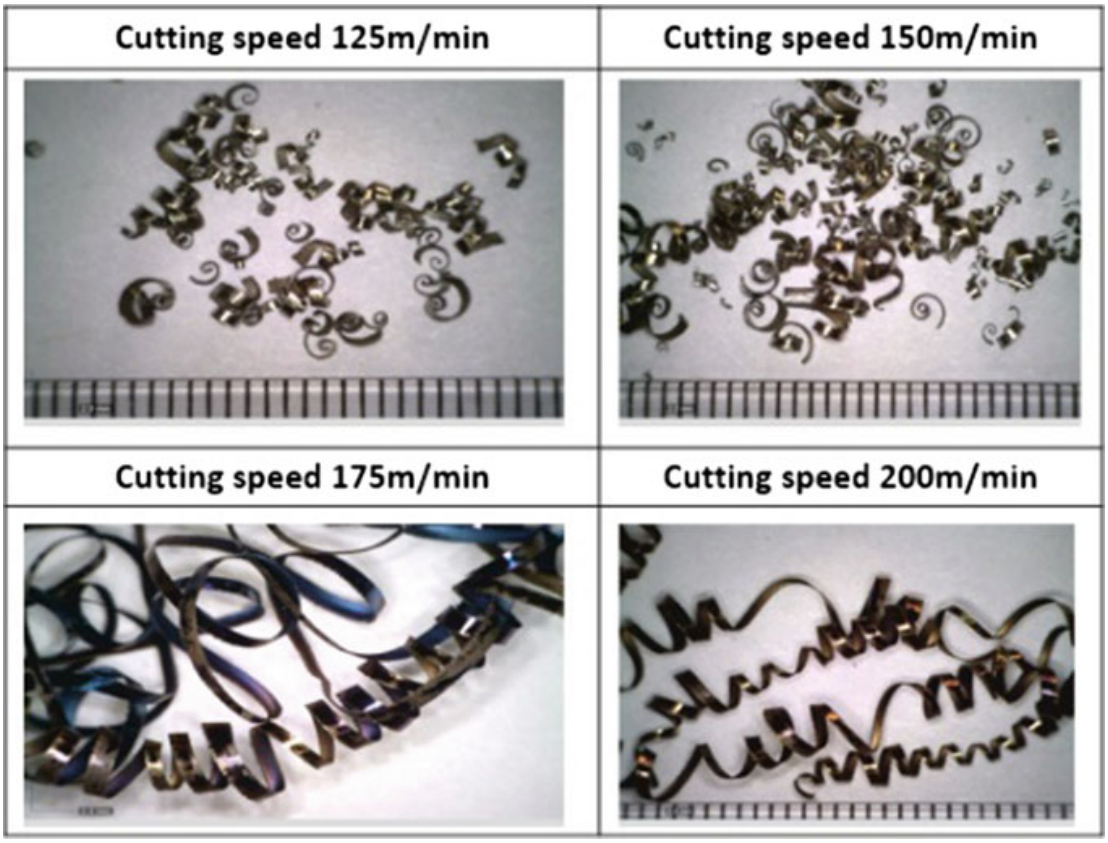

Fig. 27.8 Chips formation of EN 8M free-machining steel

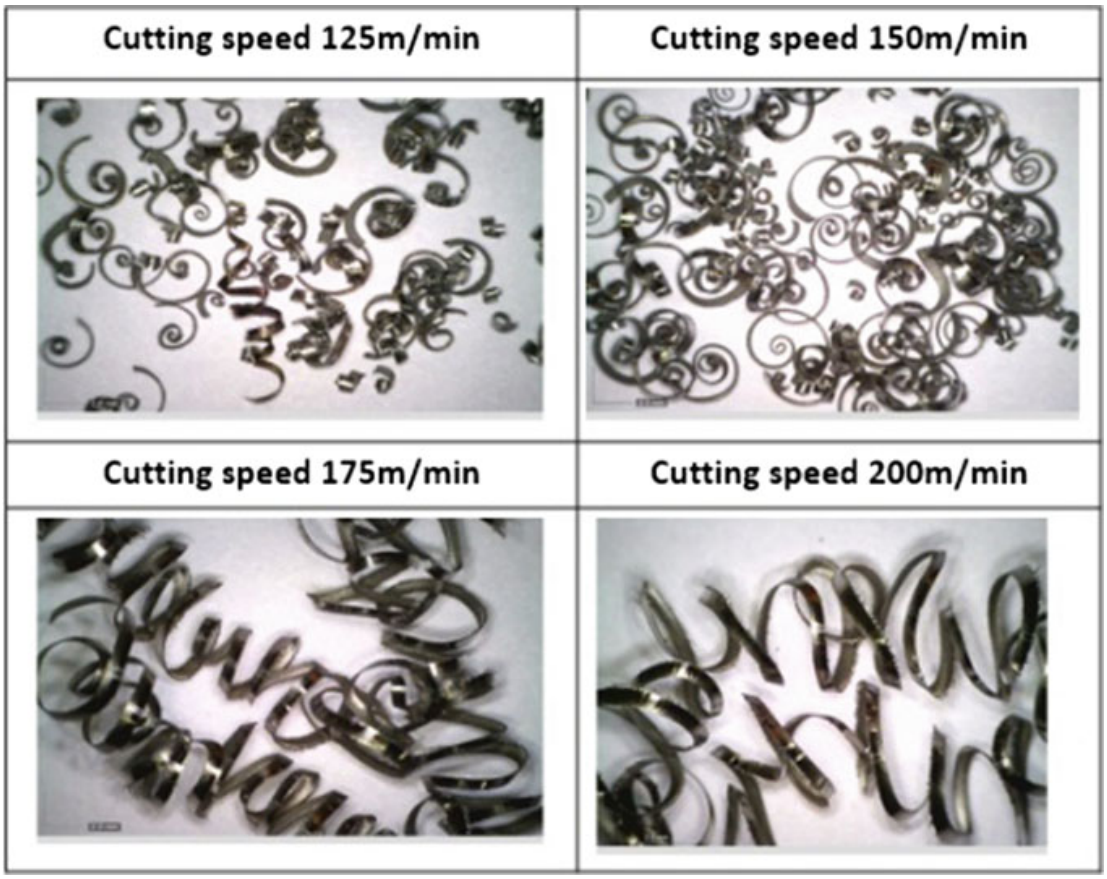

Fig. 27.9 Chip formation of EN 1A alloy steel

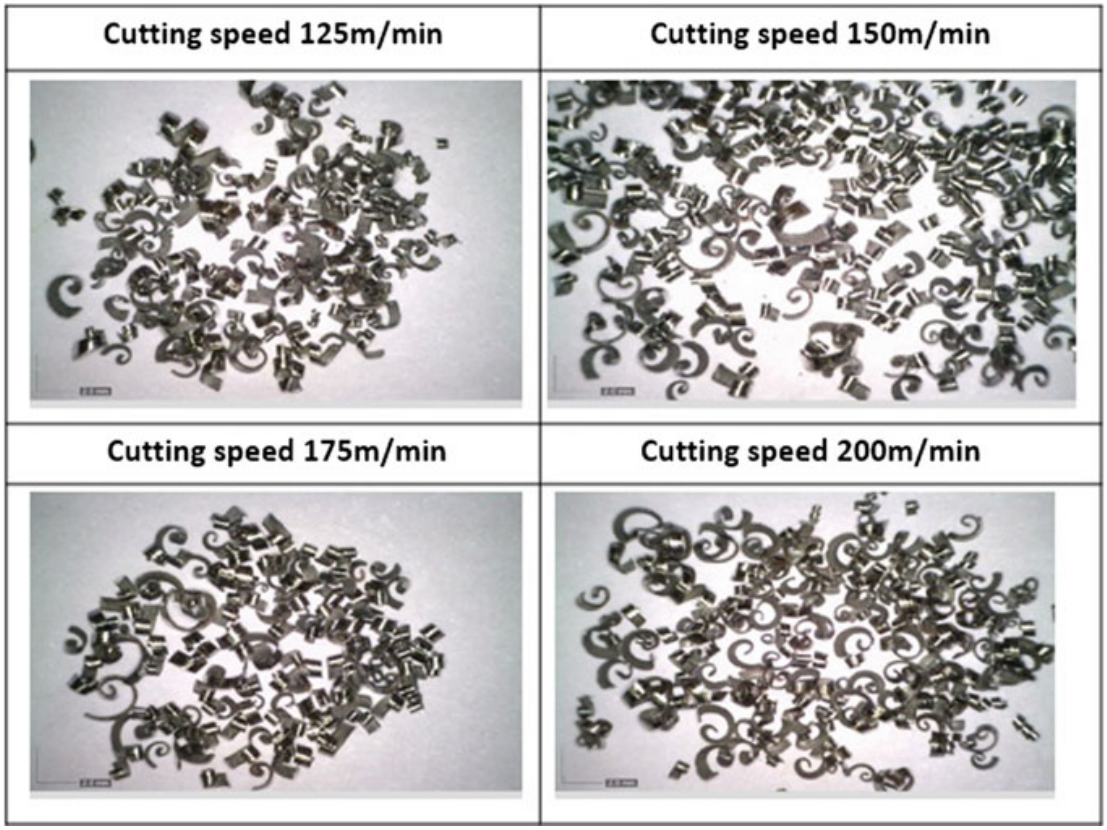

Fig. 27.10 Chip formation of EN 1A Pb&Te alloy steel

27.3.2 Discussion

In this overall experimentation, dynamic cutting forces under different cutting speeds and chip morphology were measured during dry machining of different alloy steels. Due to the chemical composition and effect of inclusions, the results were significantly varied. EN 8M free-machining steel is the hardest one because it has 40% ferrite and 60% pearlite, so it generated the highest cutting forces. The chips were segmented associated with low cutting speed, and it is lengthy and continuous at higher cutting speed.

EN 1A has a significant amount of manganese and sulphur, due to this effect, it has a lower level of cutting forces were observed. Chips were discontinuous at lower cutting speed, and it was longer and continuous at higher cutting speed.

EN 1A Pb&Te alloy has an almost ferrite structure and only 5–10% pearlite structure with large amount of inclusions (MnS Particles). Hence, it has generated the least amount of cutting forces; moreover, it has Pb content of >0.38% and Mn 1.25 with S 0.24. These three elements improve machinability. It has produced discontinuous chips in all cutting conditions when compared to other alloy steels.

27.4 Conclusion

The following outcomes are drawn out from the results gained from the current work.

- An influence of carbon content in EN 8M free-machining steel has experienced higher cutting force and obtained long and continues chips at higher cutting speeds.
- Manganese combined with sulphur (MnS) provides better machinability. The tendency of MnS inclusions in EN 1A alloy steel has generated cutting forces moderately and chips were seen curled and continues at higher cutting speed.
- As manganese, sulphur, and lead contents are increased, cutting forces were significantly decreased. Particularly in EN 1A Pb&Te alloy, lower cutting force was seen and discontinuous chips were found. This provides better machinability.

Chapter 28
Process Parameters Optimization of Electrical Discharge Machining of Al7075/SiC/WS2 by Using MCDM

Rakesh Kumar Patel and M. K. Pradhan

Abstract This paper determines the optimum process parameters of the non-conventional electrical discharge machining. The performance of the EDM machine depends upon the process parameter used. In this analysis, weight percentage, pulse current (I_p), discharge voltage (V), and pulse duration (T_{on}) are used as process parameters. The optimized output parameters are MRR, TWR, surface roughness, and radial overcut. By using face-centered composite design, nine trials were conducted on the workpiece which is made up of Al7075/SiC/WS2 hybrid composite. The trial results obtained were used in decision-making method correlation coefficient and standard deviation (CCSD) integrated approach. These results give useful information on how to control the machining parameters and accuracy of the components produced from EDM. Decision-making method used is simple, and results obtained are confirmed by conducting confirmation experiments.

Keywords Electrical discharge machining (EDM) · Material removal rate (MRR) · Tool wear rate (TWR) · Correlation coefficient and standard deviation (CCSD)

28.1 Introduction

In this article, investigation has been done on the effect of EDM parameters on machining characteristics of EDM machine for Al7075/SiC/WS_2 hybrid composite and the Multi-criteria decision-making (MCDM) method, Correlation coefficient and standard deviation (CCSD) integrated approach used for determining the weights of attributes. CCSD can be used in a multi-objective problem in various fields. EDM is a non-conventional manufacturing process, which is widely used to

make more precise, accurate, and attractive components in modern manufacturing industries. In this study, the main focus was to increase material removal rate and minimize surface roughness, tool wear rate, and radial overcut for composite. The Al7075/SiC/WS_2 hybrid composite has been selected to analyze this optimization method. The various EDM input parameters such as discharge voltage (V), discharge current (I_p), pulse-on time (T_{on}), and wt% of reinforcement materials have applied to machining of a composite. The machining of particulate metal matrix composites presents a significant challenge since a number of reinforcement materials are significantly harder than the commonly used high-speed steel (HSS) and carbide tools. The reinforcement phase causes rapid abrasive tool wear, and therefore, the widespread usage of particulate metal matrix composites is significantly impeded by their poor machinability and high machining costs. Although often categorized as difficult to machine, MMCs are actually readily machinable. They form short cutting chips and require moderate cutting forces, and the range of machining parameters at which they can be machined is quite wide. However, MMCs are highly abrasive, and tools can wear rapidly.

To avoid these problems, EDM was used due to its non-contact machining characteristic. More optimum machining parameters in EDM machine are optimized to get a desirable magnitude of EDM responses on particulate metal matrix composites.

Even many attempts have been made by the experimenters for the enhancement of the MRR and improvement in accuracy, but association of CCSD method for obtaining optimal setting on EDM of Al7075/SiC/WS_2 hybrid composite has never been attempted; thus, in this research, the aforesaid unique combination has been attempted.

28.2 Literature Review

A significant number of research papers are reviewed to know the approach of yielding optimal EDM performance measures of high MRR, low TWR, and acceptable ROC. This section provides a study of each of the performance measures and the scheme for their enhancement. Roy et al. [1] used dielectric fluid mixed with Al powder and conducted experiment in EDM machine, and to analyze the experimental results, response surface methodology (RSM) is used. The input process parameters used are pulse current, pulse-on time, and concentration of Al powder on kerosene dielectric and found that due to increase in Al powder on dielectric fluid reduced the MRR and increases surface finish. Pradhan and Biswas [2] have implemented successfully by employing RSM and investigated the individual effect of the input parameters on the responses like MRR and surface roughness (R_a). Further, Pradhan and Biswas [3] have explored the effects of I_p, T_{on}, duty cycle (T_{au}), and V on various response parameters using two neuro-fuzzy and one neural network model. Mandal et al. [4] used an artificial neural network model and multi-objective optimization approach for obtaining the best process parametric

combinations for a better productivity and fine surface finish. Dvivedi et al. [5] used Al6063 SiCp metal matrix composite to check machineability in EDM. They investigated the optimum value of MRR and TWR by considering the input variables T_{on}, T_{off}, and I_p. Kanagarajan et al. [6] had investigated the EDM performance of tungsten carbide/cobalt cemented carbide by considering the input parameters such as electrode rotation, I_p, T_{on}, and flushing pressure. Jaharah et al. [7] found that on machining of tool steel on EDM, MRR increases and TWR decreases with increase in the I_p and T_{on}. Dhar et al. [8, 9] used Al–4Cu–6Si alloy—10 wt% SiCp composites on EDM machine—to find the effect of I_p, T_{on}, and V on MRR, TWR, and gap on EDM. To develop the relationship between the machining parameters used a second-order nonlinear mathematical model and found that MRR, TWR, and gap on EDM increase with increase in I_p and T_{on}.

In past, substantial efforts are carried out to increase output parameters such as MRR, TWR, and accuracy of EDM process. The important issue is to pick the process parameters such as I_p, T_{au}, T_{on}, V, flushing pressure, dielectric fluid, and polarity in such a way that increases MRR and accuracy, and simultaneously ROC, TWR, and surface roughness should diminish.

28.3 Description of the Experiments

The experiments were conducted under various parameter settings of discharge current, pulse-on time, and discharge voltage. The Minitab 18 software was used for Taguchi's method to modeling alternatives and attributes of EDM parameters. Finally, the soft computing techniques were employed for modeling of MRR, TWR, radial overcut, and R_a.

Calculate the responses of EDM machine

$$\text{MRR}\left(\frac{\text{mm}^3}{\text{min}}\right) = \frac{\text{Weight Loss (gm)} \times 60}{\text{Density of Sample}\left(\frac{\text{gm}}{\text{mm}^3}\right) \times \text{Machining Time (s)}}$$

$$\text{TWR}\left(\text{mm}^3/\text{min}\right) = \frac{\text{Weight Loss(gm)} \times 60}{\text{Density of Tool(gm/mm}^3) \times \text{Machining Time (s)}}$$

$$\text{Radial Over Cut (ROC)} = \frac{D_1 - D_2}{2}$$

where D_1 = right side reading on digital micrometer and D = left side reading on digital micrometer. The Toolmaker microscope was used to calculate ROC. The digital surface roughness meter is used to calculate surface roughness of surface of cavity on composite surface generated by EDM machine (Table 28.1), where 0.75, 1, and 1.5 represent the wt% of WS_2 in composite with constant 10 wt% of SiC (Fig. 28.1).

Table 28.1 Experimental results

28.4 Analysis Method

Wang et al. [10] used CCSD multi-criteria decision making method. Suppose there are n decision alternatives A_1, …, A_n to be evaluated in terms of m attributes $O_1, O_2, \ldots, O_m$, it forms a decision matrix which can be represented as $X = (x_{ij})$ $n \times m$ where x_{ij} is the performance value of A_i with respect to O_j. The m attributes

can be categorized into two groups: beneficial and non-beneficial. The beneficial attributes are those whose values are always larger the better. The non-beneficial attributes are those whose values are smaller the better. Due to the attributes in different units, the decision matrix $X = (x_{ij})n \times m$ needs to be normalized to eliminate its dimensional units. The commonly used normalization method is:

for beneficial attributes

$$z_{ij} = \frac{x_{ij} - x_j^{\min}}{x_j^{\max} - x_j^{\min}} \tag{28.1}$$

for non-beneficial attributes

$$z_{ij} = \frac{x_j^{\max} - x_{ij}}{x_j^{\max} - x_j^{\min}} \tag{28.2}$$

z_{ij} Normalized value of output parameter.

Now remove attribute O_j one by one from the set of attributes one at a time, and see its impact on decision making. When O_j is removed, the overall assessment value of each alternative can be calculated as

$$d_{ij} = \sum_{k=1,k\neq j}^{m} z_{ik} w_k \quad i = 1, 2, \ldots, n$$

The correlation coefficient between the attributes and the score values can be expressed as

$$R_j = \frac{\sum_{i=1}^{n} \left(z_{ij} - p_j\right)\left(d_{ij} - q_j\right)}{\sqrt{\sum_{i=1}^{n} \left(z_{ij} - p_j\right)^2 \left(d_{ij} - q_j\right)^2}}$$

where

$$p_j = \frac{1}{n}\sum_{i=1}^{n} z_{ij}, \quad q_j = \frac{1}{n}\sum_{i=1}^{n} d_{ij}$$

The attribute given more weightage which have bigger standard deviation value and smaller weightage which have lower standard deviation value in comparison.

From the above calculations, the weights of attributes can be determined as

$$w_j = \frac{\sigma_j \sqrt{1 - R_j}}{\sum_{j=1}^{m} \sigma_j \sqrt{1 - R_j}} \quad j = 1, 2, \ldots, n \tag{28.3}$$

R_j Correlation coefficient between the values of O_j.
σ_j Standard deviation of the values of O_j.

The score of each decision alternative can be determined by

$$d_{ij} = \sum_{j=1}^{m} z_{ij} w_j \quad i = 1, 2, \ldots, n \tag{28.4}$$

28.5 Results and Discussion

To get the optimum result of the machining parameters and to reduce the manufacturing cost of composite product, the CCSD method was used to optimization of EDM parameters for machining of hybrid composite (Al7075 + SiC + WS2) and find the rank of alternatives. According to the CCSD integrated approach, the weight of the attributes is 0.2528, 0.2518, 0.2118, and 0.2737 for the attribute MRR, TWR, ROC, and R_a, respectively, which was calculated by using Eq. (28.3).

The overall assessment value of each decision alternative can be computed by

$$d_i = \sum_{j=1}^{m} z_{ij} w_j, \quad i = 1, 2, \ldots, n$$

From Table 28.2, values shown are normalized value which was calculated by using Eq. (28.1) for beneficial and Eq. (28.2) for non-beneficial attribute, and score was calculated by using above Eq. (28.4) (Fig. 28.2).

From the above graph, alternative 9 has highest score, so it is best suitable alternative according to MCDM. EDM of hybrid composite Al7075/SiC/WS2 with input value of alternative 9 gives optimum value of output parameters.

Table 28.2 Overall score assessment and ranking

Alternatives	MRR (mm^3/min)	TWR (mm^3/min)	ROC (mm)	R_a (μm)	Score	Rank
1	0.5320	0.7013	0.4784	1	0.6913	2

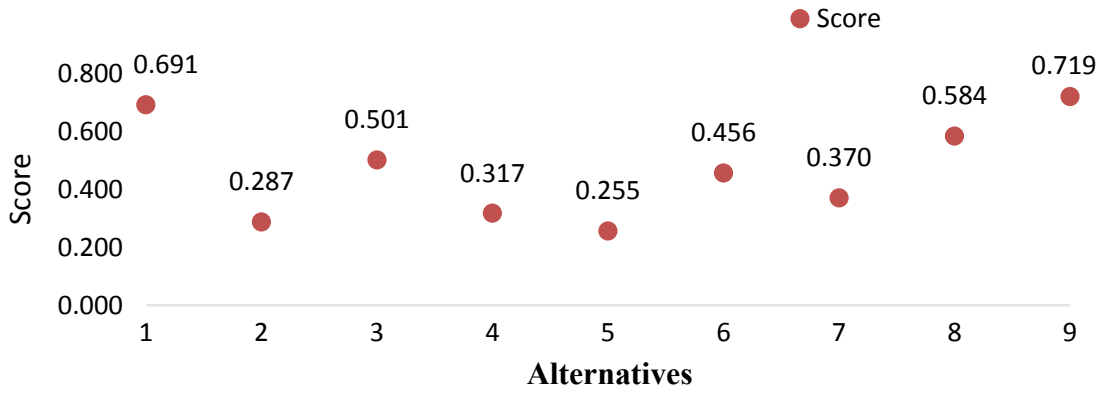

Fig. 28.2 Score of the alternatives

28.6 Conclusion

This study proposes optimization of the EDM input process parameters. CCSD method shows that the alternative 9 is the best alternative. The optimal condition out of the given alternatives determined by the CCSD methods is as follows: pulse current 12 A, pulse-on time 100 µs, weight percentage 1.5, and discharge voltage 100 V. These results will help in reducing the machining cost, error, and time consumption in the machining process and also enhance the surface quality and efficiency. This study gives the optimum input process parameter of EDM to achieve desired MRR, TWR, surface roughness, and radial overcut, in the die sinking of Al7075/SiC/WS2 hybrid composite.

Chapter 29
CNC Turning and Simulation of Residual Stress Measurement on H13 Tool Steel

Ravi Butola, Qasim Murtaza and Ranganath M. Singari

Abstract This paper deals with the measurement of residual stress produced during turning operation. CNC turning is a machining process to remove unwanted material from the workpiece to produce desired rotational parts. Turning is a widely used cutting process in the manufacturing industry, and thus, continuous research is going on to optimize it because of cutting high-performance dynamics, workpiece materials, and cutting tools. Turning operation was performed on H13 tool steel workpiece dimensions 110 × Ø22 mm on CNC Lathe machine tools. H13 tool steel is used for manufacturing of friction stir welding and processing tool. The main aim of the current study is to determine the residual stress using PulsetecμX-360n portable stress analyzer setup, and Abaqus 6.14 software was used to simulate the turning process. Experimental tests were performed on H13 tool steel materials which are in form of FSW/FSP tool, which consists of different pin profiles. The experimental outcomes are then compared with the outcomes obtained from the simulation. Experimental results validate the simulation results for both the tool pin profiles which are lying within the acceptable range.

29.1 Introduction

Turning operation was performed on H13 tool steel workpiece on CNC Turning Center Lathe. The dimension of workpiece was 110-mm-long cylinder with 22 mm diameter. The cutting tool insert used was uncoated tungsten carbide CNMG 120404–THM for turning operation, and it was a dry turning since no cutting fluid was used. In turning processes, large plastic deformation takes place; the prediction and control of the material fracture is a critical issue. In order to surface finish and integrity of the new component, the damage and fracture of the materials should be predicted. H13 tool steel is used for manufacturing of friction stir welding and processing tool which are used for making welding joints and surface composite. Friction stir processing, a development based on friction stir welding (FSW), is a solid-state processing technique for microstructure modification [1]. FSW/FSP tool consists of shoulder and different pin profiles, i.e., cylindrical and taper cylindrical pin profiles have been used to process the aluminum-based surface composite at different tool rotation and tool traveling speeds. Cylinder pin profile is simplest in construction considering the machining operations performed in making the cylindrical pin profile. The parameters considered for the tool design are shoulder diameter, pin diameter, and length of the pin. Huang et al. [2] studied the impact of residual stress at the initial stage and turning-induced stresses after deformation of aluminum and found that turning-induced residual stresses are the primary cause of distortion. Plate deformation is increased by coupling of compressive residual stress and machining-induced residual stress while deformation is decreased by the coupling action of tensile initial residual stress and machining-induced residual stress. Wang et al. [3] carried out a study on residual stress in machined surface of monocrystalline silicon based on molecular dynamics simulation. They found that on the increasing depth of cut, the maximum tensile residual stress decreases while compressive residual stress increases underneath the surface and same happened when the tool rake angle changed from positive to negative. Fergani et al. [4] predicted the residual stress in multi-pass milling machining using thermomechanical stress model using Neumann–Duhamel law. A regeneration algorithm was proposed that considers the combination of initial stresses and material cyclic hardening in residual stress calculations. Sharma and Butola [5] reviewed Taguchi's technique, response surface methodology, and gray fuzzy algorithm for optimal values of machining parameters in the CNC process of turning. They found that material removal rate increased with increase in feed rate and depth of cut, while the increase in cutting speed decreased it. Huang et al. [6] investigated the influence of residual stress on the monolithic component deformation using FEM as well as experimental work and found that initial residual stress in the blank was the main factor of deformation for three-frame monolithic beam and deformation is increased by coupling of initial and turning residual stresses. Johnson and Cook [7] have been developed that the flow stress is defined as a function of strain, strain rate, and temperature. Pres et al. [8] have been reported a measurement, simulation, and the comparison between the cutting force and geometrical feature of the chip. Wang

et al. [9] have been presented the frequency and cutting force for Ti6Al4V after that they compare their simulation and experimental result, and they found good agreement between them. Umbrello et al. [10] develop a hardness flow stress simulation model of turning processes based on Johnson–Cook equation. Chaudhary et al. [11] have reviewed that different FSP tool pin is used at different parameter. FSP can be widely used in metals such as Al alloy that is lightweight and can be used extensively in various applications. The significance of this research will have a major and robust impact on the manufacturing industry. The prediction of residual stresses by using Abaqus software could become an opportunity to undertake by the tool manufacturers by changing or improving the cutting tool design prior to manufacturing and same supported by experimental data using PulsetecμX-360n portable stress analyzer setup.

The objective of this research is to the measurement of residual stress using PulsetecμX-360n portable stress analyzer setup. After CNC turning, the process on H13 tool steel materials which are in form of FSW/FSP tool has manufactured two different tool profiles, i.e., cylindrical and taper cylindrical pin and shoulder. To simulate the turning of H13 tool steel workpiece and determine stresses, Abaqus 6.14 software was used.

29.2 Experimental Method

29.2.1 Selection of Tool Materials

Each material is characterized by a unique set of physical, mechanical, and chemical properties which can be treated as attributes of a specific material. The selection of material is primarily dictated by the specific attributes that are required for manufacturing friction stir processing tool. H13 tool steel is used for manufacturing of friction stir welding and processing tool which are used for making welding joints and surface composite. The tool requisite for friction stir processing must resist thermal fatigue cracking under hot working operations. H13 tool steel is versatile chromium–molybdenum hot work steel that is widely used in manufacturing of friction stir welding and processing tool. The workpiece in form H13 tool steel rod of diameter 22 mm and length 110 mm, processed by Mahindra and Mahindra Steel, was used in this investigation. The chemical composition of these materials in weight percentage as supplied by the producer is given in Table 29.1.

Table 29.1 Chemical composition of tool material-H13 tool steel

C	Mn	Si	Cr	Mo	V
0.40	0.40	1.00	5.25	1.35	1.00

29.2.2 Machining Methodology

Machining methodology consists of machining techniques and equipment used for machining or shaping the tools. In this research, two workpieces were made with different pin profiles like cylindrical and taper cylindrical. For machining the tool material into the desired tool pin profile, CNC Lathe machine tool was used. Primarily, turning was used for making the shoulder of the tool. For a cylindrical pin, the further turning operation was performed. In the first step, turning reduced the diameter from 22 to 19.95 mm for the entire length of the tool because 19.95 mm diameter is the maximum diameter that can accommodate the FSW machine in our laboratory. In the second step, turning reduced the diameter from 19.65 to 7.22 mm for pin length of 3.50 mm. The taper cylindrical pin has generated a taper of length 3.50 mm with diameter linearly varying from 7.22 to 3.50 mm, and tool pin length depends upon the thickness of the workpiece to be processed (Fig. 29.1; Table 29.2).

29.2.3 Measurement Condition of H13 Tool Steel

Measurement of residual stress in cylindrical pin and taper cylindrical pin was performed on the following conditions: pitch 50 µm, X-ray irradiation time (setup) 30 s, X-ray irradiation time (Meas.) 30 s, X-ray irradiation time (Max) 101 s, X-ray

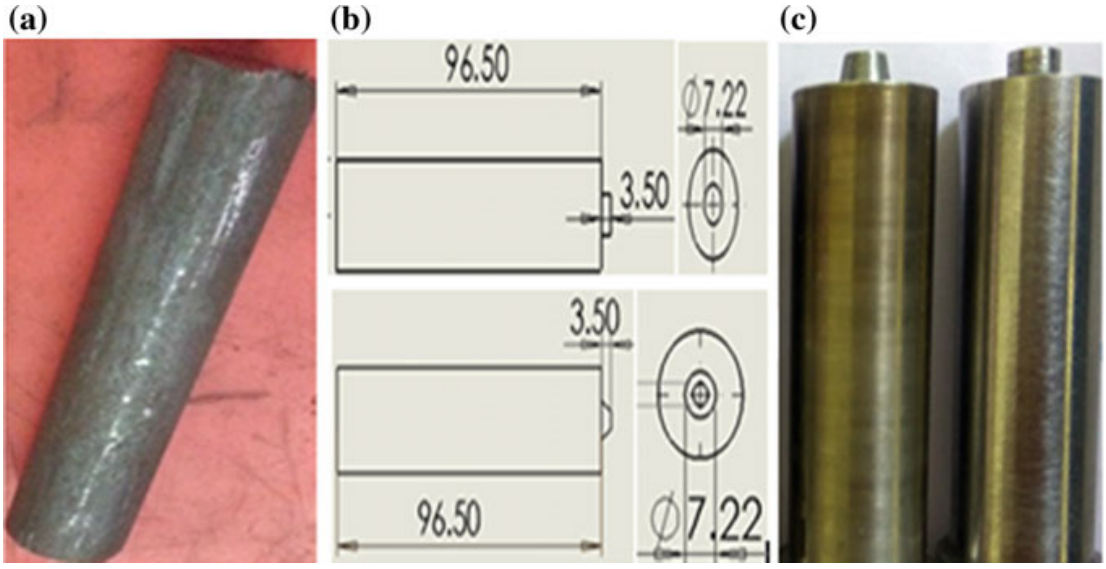

Fig. 29.1 **a** H13 tool steel rod, **b** dimension of tool, and **c** after turning

Table 29.2 Input machining parameter

Cutting speed (S)	Feed rate (F)	Depth of cut
1500 (Rpm)	0.10 (mm/rev)	1 (mm)

tube current 1.00 mA, X-ray tube voltage 30.00 kV, X-ray incidence angle 35.0°, offset of alpha angle 0°, X-ray wavelength (K-Alpha) 2.29093 A (Cr), X-ray wavelength (K-Beta) 2.08480 A (Cr), total measurement count 6631, oscillation count 7, detection sensitivity 26.1% (224,879), peak strength (Ave) 209 k, and temperature 31.56 °C.

29.2.3.1 Sample Information

The basic idea was to measure residual stresses on the machined workpieces of H13 tool steel as follows: wavelength K-Alpha, diffraction angle (2θ) = 156.396°, diffraction lattice angle (2η) = 23.604°, interplanar spacing (d) = 1.170, diffraction plane (h, k, l) = 2, 1, 1, crystal structure BCC, Young's modulus (E) = 224.000 GPa, Poisson's ratio (v) = 0.280, sigma (x) stress constant (K) = −465.097 GPa, tau (xy) stress constant (K) 380.985 GPa, and sigma (y) stress constant (K) = −2091.661 GPa.

29.2.3.2 Measurement of Residual Stresses

Residual stress measurement was performed in Precision Manufacturing Lab at Delhi Technological University. After turning operation of H13 tool steel, the next step is to the measurement of residual stress has been done on the specimen using PulsetecμX-360n portable stress analyzer setup. Two specimens were performed for measurement of residual stress, i.e., cylindrical and taper cylindrical profiles. Mechanical residual stresses are generally produced because of the plastic deformation in the non-uniform manner caused during manufacturing operations. Residual stresses can be made naturally during the operation or may be produced in order to generate the desired stress profile in the component [12] (Fig. 29.2).

29.3 Modeling of Cylindrical and Taper Cylindrical Tool

The following steps will illustrate in different stages involved in the FEA of the turning process to create a cylindrical and taper cylindrical tool profile discussed below

- Standard and explicit model was selected upon opening the Abaqus 6.14 package. This allows for explicit integration scheme to solve highly nonlinear systems with many complex contacts under transient loads.
- In the Part module, a 3-D deformable part with solid extrusion feature is chosen. This part is the H13 tool steel workpiece.
- Figure 29.3a shows a circular sketch of 22 mm radius which is drawn. This was the raw dimension of the workpiece. Figure 29.3b shows the part is extruded to

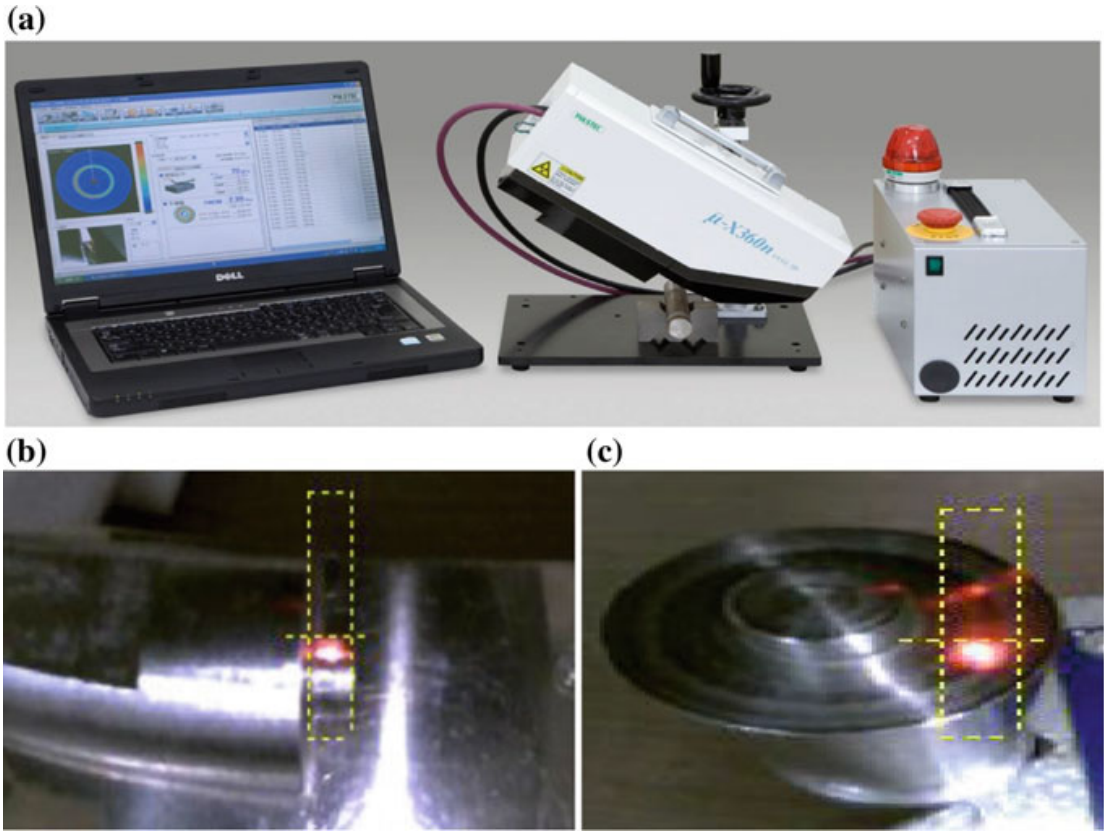

Fig. 29.2 **a** PulsetecμX-360n portable stress analyzer set up, **b**, **c** image captured by stress analyzer

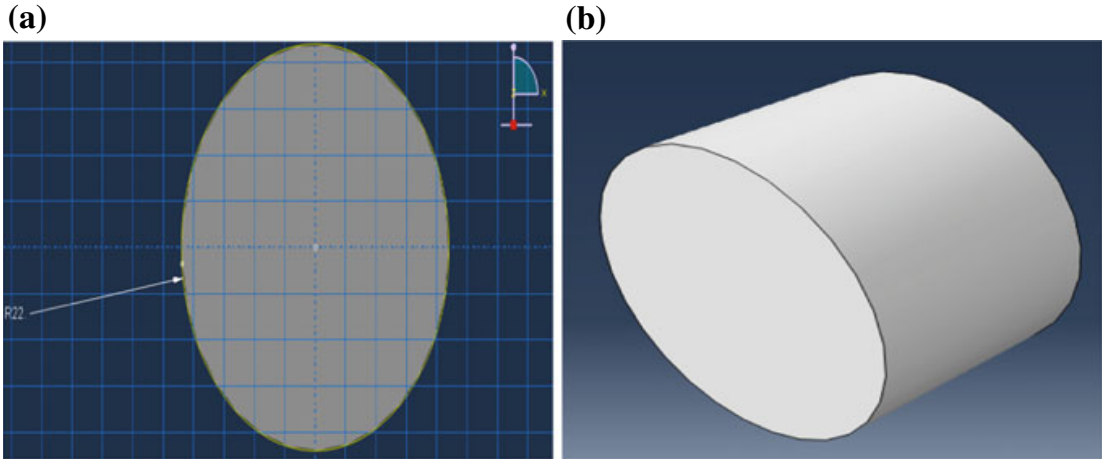

Fig. 29.3 **a** Geometry for workpiece with R 22 mm and **b** shown 30-mm-extruded cylindrical workpiece

30 mm depth. Note that it is shorter than the actual length of the workpiece. This is because we are only interested in the region most affected by the turning process.

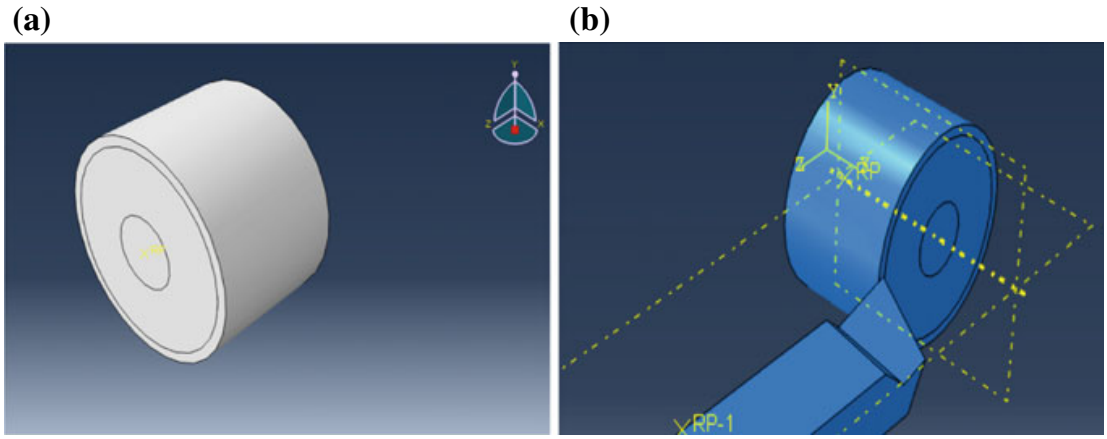

Fig. 29.4 **a** Partitioned regions in the workpiece and **b** assembly

- Figure 29.4a shows the part is partitioned into three different regions. It will help in improving the mesh generation. Since there is step cutting involved, different regions can be meshed to be of finer/coarser quality.
- In the Materials module, the material is defined by entering the properties of H13 tool steel under the *Material Behaviors* section. Properties like conductivity, ductile damage, shear damage with damage evolution, density, elastic, expansion, and plastic behavior are defined. Johnson-Cook damage criterion was followed.
- Figure 29.5a shows the Mesh module, 3D stress family of explicit, and linear geometric order, and Hex element type is assigned to the workpiece. Element deletion is chosen since we are not interested in chip flow and only the stresses on the workpiece surface. In the interaction module, friction contact with the coefficient of 0.4 is used. In the load module, boundary conditions are added. Here, the angular velocity to the workpiece, the depth of cut, and feed rate are given to the tool.

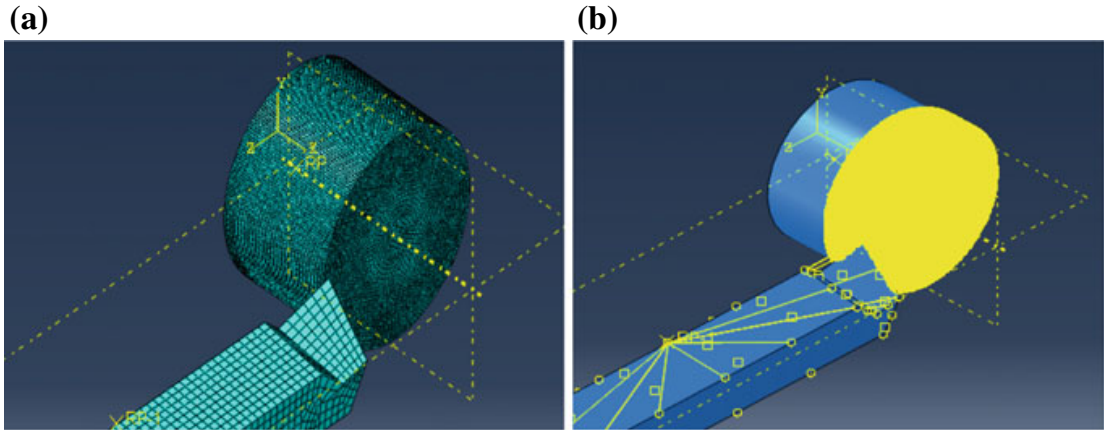

Fig. 29.5 **a** Meshing and **b** constraints added to the workpiece and tool

The procedure followed for the stress analysis of the cylindrical tool pin was similar to the procedure described in the previous section. The only exception lies in the load module, where the boundary conditions are modified so that the tool travels in a straight path parallel to the workpiece axis.

29.4 Results and Discussion

As these stresses play a very important role in the working performance of the component, it becomes quite necessary to examine the magnitude and nature of the residual stresses contained in the component. Stresses present can be tensile or compressive in nature but generally tensile nature of residual stresses is undesired as it can because quench cracking, stress-induced corrosion cracking, and fatigue failure. Compressive nature is desired one as it gives opposite effect of the tensile stresses on the component.

The developed FE analysis model was validated by comparing the simulation of the turning process with the experimental data. Figures 29.5 and 29.6 show the simulation of turning process by using Abaqus 6.14 software. Due to advancement in technology and new methodology, now residual stresses due to turning operation can be visualized using computer simulation. Experiments have done by using PulsetecμX-360n portable stress analyzer machine. Residual stress name is given to the stress which is left in the component after removal of the load. It remains almost in every rigid structure generated due to every operation performed on it such as metallurgical, thermal, and mechanical during manufacturing. Simulation of residual stress is an important process when H13 tool steel is used for CNC turning operation. Measurement of residual stresses due to CNC turning can now be visualized via computer simulations due to advancements in technology.

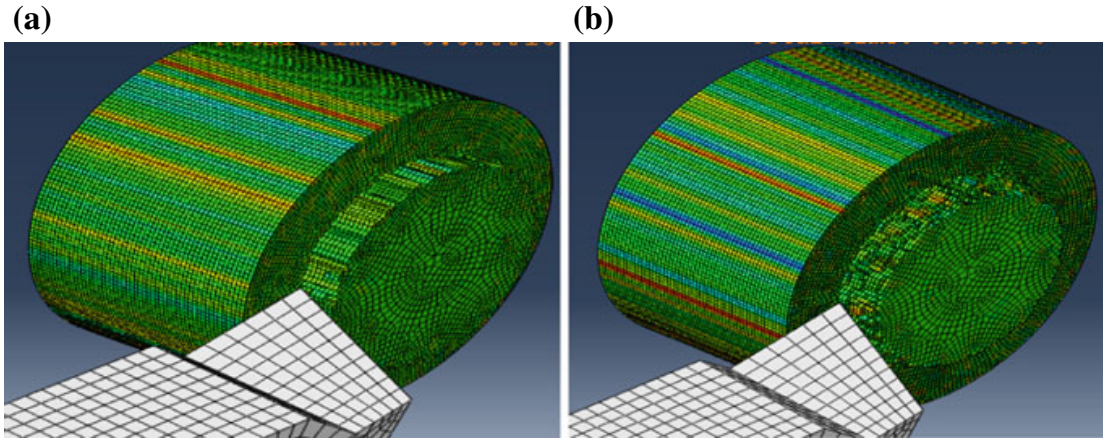

Fig. 29.6 **a** Stress contours of cylindrical tool pin and **b** stress contours of taper cylindrical tool pin

Unfortunately, turning processes have not yet been simulated to perfection in software due to a large number of deformations and variables involved. To overcome this problem, FE analysis is carried out in Abaqus/CAE 6.14. Experimental data is obtained from by using a PulsetecμX-360n portable stress analyzer setup. Experimental and simulation results show the percentage error lying within the acceptable range for both the cylindrical and taper cylindrical tool of H13 tool steel (Figs. 29.7, 29.8, 29.9 and 29.10; Tables 29.3 and 29.4).

The outcome of the residual stress on the periphery of a cylindrical pin and shoulder was observed to be compressive 166 and 280 MPa, respectively. The standard deviation was 16, 19 MPa, respectively. The outcome of the residual stress on the periphery of the taper cylindrical pin and shoulder was observed to be compressive 301 and 444 MPa, respectively. The standard deviation was 17 and 18 MPa, respectively.

After the measurement of residual stress, an experimental data and simulation data for cylindrical tool pin were found to be compressive 223 MPa and compressive 240 MPa, respectively, so the percentage error was observed that 7.62%. For taper cylindrical tool pin, an experimental data and simulation data were found to be compressive 372 MPa and compressive 398 MPa, respectively, so the percentage error observed was 6.98%.

Table 29.3 Measurement of residual stress in different tool pin and shoulder

S. No.	Pin profile	Residual stress [MPa] (Absolute)	Average stress [MPa] (Absolute)
1	Cylindrical pin	166	223
2	Cylindrical shoulder	280	
3	Tapered cylindrical pin	301	372
4	Tapered cylindrical shoulder	444	

Table 29.4 Summary of results and error %

S. No.	Tool pin profile	Residual stress [MPa] (Absolute) from simulation	Average stress [MPa] (Absolute) from experiment	Error %
1	Cylindrical pin	240	223	7.62
2	Tapered cylindrical pin	398	372	6.98

29.5 Conclusions

In the current research, the study was carried out on simulation of residual stresses stimulated by turning of H13 tool steel. Two different tool pin profiles, i.e., cylindrical and taper cylindrical is used.

After analyzing the result of an experimental data and simulation data, the percentage error was observed that 7.62% for cylindrical tool profile and 6.98% for taper cylindrical tool profile and the percentage error can be rectified with the help by improving the mesh size quality that could be helpful for production of new material. Experimental results validate the simulation results for both the tool pin profiles which are lying within the acceptable range.

Chapter 30
Small-Scale Machining Simulations

Anuj Bisht, Anish Roy, Uday S. Dixit, Satyam Suwas and Vadim V. Silberschmidt

Abstract Molecular dynamics (MD) and single-crystal plasticity finite-element method (CP FEM) are approaches used to simulate the micro-machining process. At such small-length scales, anisotropic behaviour of material becomes important; the two methods can essentially capture it. Therefore, it is important to understand the fundamental principle behind these methods as well as their capabilities and limitations in order to select the scheme to simulate the micro-machining process. In this paper, the fundamentals of MD and CP FEM are introduced in brief. The applicability of the respective method is further illustrated with the help of examples from the literature. Thereafter, the two methods are compared and discussed in terms of their various aspects and capabilities. This discussion should enrich the reader and assist their choice of an appropriate simulation method.

Keywords Micromachining · CP FEM simulation · Molecular dynamics

30.1 Introduction

There is a push for miniaturization of devices with improved performance in electronic and sensor industry. Precision micromachining in such components is unavoidable often to facilitate assembly of parts. The behaviour of such devices under the process of micro-machining is not completely understood. This is primarily due to the change in behaviour of material at lower length scales, which in turn depends on intrinsic and extrinsic material parameters. Firstly, grain size is the most important intrinsic material parameter, which influences the materials

behaviour. The strength of the material increases with the decrease in grain size from micron to submicron and nanometre regime, known as "Hall–Petch (HP) effect" [1, 2]. The increase in strength upon grain size reduction is mainly attributed to the increase in grain boundary area, which acts as barrier for dislocation motion [3]. Secondly, the size of the sample is an extrinsic material factor, and the strength of the material increases in decreasing the sample dimension to micron and submicron scale [4–6], an effect similar to the HP effect. This phenomenon is mainly attributed to the starvation of dislocation (plasticity carriers) on reducing the sample dimension. Apart from the mentioned phenomena, material is observed to drift from the conventional behaviour when it is machined at micron and nanoscale. Similar behaviour is also observed under indentation at various length scales, known as "indentation size effect (ISP)" [7–9]. Due to the unconventional behaviour of material showing scale effects, there is a need to study the process to better understand the phenomenon occurring during micro-machining process.

Experimental studies are instrumental in reflecting the actual events. However, due to the limitations of method involved in experiments, the phenomena can be studied only after its completion and the evolution of defects in the material is speculated based on the findings. In this regard, simulation methods are quite instrumental to study the evolution of material. Finite-element methods are used conventionally to simulate various material processes [10–12], which includes deformation behaviour, using bulk phenomenological-based models. They are good in simulating phenomenon where the scales are larger compared to the inherent dislocation slip phenomena. Johnson–Cook model is a popular model used and is for isotropic material. However, materials are crystalline and, hence, inherently anisotropic in nature [13]. The anisotropic nature becomes prominent under the event of limited small-scale deformation process, where the deformation length scale becomes comparable to deformation features like slip bands due to dislocation slip activity. To account for the crystal anisotropy, there are two simulation methods adopted for simulating the micro-machining processes, namely single-crystal plasticity (CP) finite-element method (FEM) [14–16] and molecular dynamics (MD) [17–19]. The two mentioned simulation methods are based on different principles.

The CP FEM modelling takes into account the anisotropy in material in a FEM framework. On the other hand, MD is an atomic-level simulation and is primarily based on Newton's second law of motion to describe the trajectory of atoms with time. Atomic potential function is used to describe the interatomic interaction between atoms. This essentially means the scale of the two simulations is very different.

The aim of the present paper is to introduce to the reader the two methods used for simulation of micro-machining process. They are described using two examples from the literature. The principle behind the two methods is introduced in brief in their respective section. The example also focuses on the information, which can be extracted from the respective simulation.

30.2 Simulation Techniques

Here, we discuss the basics of the two simulation methods, namely molecular dynamics (MD) simulation and finite-element (FE)-based crystal plasticity (CP) numerical models. In this section, we briefly discuss the two techniques, which are commonly used to predict machining outcomes in the small-length scales.

30.2.1 Molecular Dynamics Simulation

Molecular dynamics (MD) is a versatile simulation technique, which finds applications in the simulation of material behaviour at very small-length scales (scale of molecules). In MD, the behaviour of an ensemble of molecules of the material is studied when subjected to an externally imposed thermo-mechanical load. It proceeds by solving the many body problem involving atoms at each time step. The principle relation in MD is based on Newton's second law of motion. Newton's equation of motion for an atom i in the system is given by

$$f_i = m_i a_i, \tag{30.1}$$

where f_i is the net force exerted on the atom i, m_i is its mass and a_i is the acceleration of atom i. The net force f_i on atom i is the summation of individual forces (f_{ij}) exerted by atoms j on atom i.

The net force f_i is given by the gradient of the potential energy (V):

$$f_i = -\nabla_i V. \tag{30.2}$$

Potential functions are used to describe the interacting forces (f_{ij}) among the atoms i and j. Lennard-Jones (LJ) potential [20, 21], analytical bond-order potential (ABOP) [22], embedded atom method (EAM) [23] and Tersoff potential [24] are important potential functions to name a few. Specific potential functions were developed for specific bond types including ionic bond, metallic bond, covalent bond, valence bond and others. The choice of an appropriate potential function depends on the material and problem at hand [25]. For example, the EAM potential is useful for describing the interaction among interacting metallic atoms, while ABOP is trustable for describing covalent materials.

Once the force is obtained at the current time step t, the position (r_i) and velocity (v_i) of atom i can be obtained for the next time step $t + \delta t$ by time integration step. Various time integration schemes are available to march ahead in time. Velocity Verlet integrator [26] and rRESPA multi-timescale integrator [25] are popular time integration schemes. The position (r_i) and velocity (v_i) of atom i at time step $t + \delta t$ as given be Velocity Verlet algorithm are

$$x_i(t+\delta t) = x_i(t) + v_i(t)\Delta t + \frac{1}{2}a_i(t)\delta t^2, \tag{30.3}$$

$$v_i(t+\delta t) = v_i(t) + \frac{a_i(t) + a_i(t+\delta t)}{2}\delta t. \tag{30.4}$$

30.2.2 Crystal Plasticity Finite-Element Simulation

The classical crystal plasticity theory is discussed in the present section. When a material is deformed plastically, it experiences both elastic and plastic strain. A deformation gradient ($\boldsymbol{F}$), in a continuum sense, can be decomposed into an elastic part ($\boldsymbol{F}_e$) and plastic part ($\boldsymbol{F}_p$):

$$\boldsymbol{F} = \boldsymbol{F}_e\boldsymbol{F}_p. \tag{30.5}$$

On differentiating the deformation gradient ($\boldsymbol{F}$), we get:

$$\dot{\boldsymbol{F}} = \dot{\boldsymbol{F}}_e\boldsymbol{F}_p + \boldsymbol{F}_e\dot{\boldsymbol{F}}_p. \tag{30.6}$$

Now, the velocity gradient ($\boldsymbol{L}$) is defined as

$$\boldsymbol{L} = \dot{\boldsymbol{F}}\boldsymbol{F}^{-1} \tag{30.7}$$

and, thus, $\boldsymbol{L}$ can be decomposed into

$$\boldsymbol{L} = \dot{\boldsymbol{F}}_e\boldsymbol{F}_e^{-1} + \boldsymbol{F}_e\left(\dot{\boldsymbol{F}}_p\boldsymbol{F}_p^{-1}\right)\boldsymbol{F}_e^{-1} = \boldsymbol{L}_e + \boldsymbol{L}_p. \tag{30.8}$$

Plastic deformation in metals is attributed to the cumulative motion of individual dislocations on their respective slip planes, which leads to shear deformation along the slip planes in a crystal. Following this, the plastic velocity gradient ($\boldsymbol{L}_p$) is defined as the sum of shear rates due on all slip systems:

$$\boldsymbol{L}_p = \sum_{i=1}^{N} \dot{\gamma}^{\alpha}\boldsymbol{s}^{\alpha} \otimes \boldsymbol{m}^{\alpha}, \tag{30.9}$$

where $\dot{\gamma}^{\alpha}$ is the shear slip rate on slip system α; unit vectors $\boldsymbol{s}^{\alpha}$ and $\boldsymbol{m}^{\alpha}$ define the slip direction and slip plane; and N is the total number of slip systems. The velocity gradient can further be decomposed in terms of rate of stretching $\boldsymbol{D}$ and rate of spin $\boldsymbol{W}$, for both elastic and plastic component. From Eqs. (30.8) and (30.9), the elastic and plastic part of velocity gradient $\boldsymbol{L}$ is expressed as

$$\boldsymbol{L}_e = \boldsymbol{D}_e + \boldsymbol{W}_e = \dot{\boldsymbol{F}}_e \boldsymbol{F}_e^{-1}, \quad \boldsymbol{L}_p = \boldsymbol{D}_p + \boldsymbol{W}_p = \sum_{i=1}^{N} \dot{\gamma}^{\alpha} \boldsymbol{s}^{\boldsymbol{\alpha}} \otimes \boldsymbol{m}^{\boldsymbol{\alpha}}. \tag{30.10}$$

The relationship between the elastic part of the rate of stretching ($\boldsymbol{D}_e$) and the Jaumann rate of Cauchy stress ($\boldsymbol{\Sigma}$) as a constitutive law is given by Huang [27] as:

$$\overset{\nabla}{\boldsymbol{\Sigma}} + \boldsymbol{\Sigma}(\boldsymbol{I} : \boldsymbol{D}_e) = \boldsymbol{C} : (\boldsymbol{D} - \boldsymbol{D}_p) \tag{30.11}$$

where $\boldsymbol{C}$ is the fourth-order elastic stiffness tensor and $\boldsymbol{I}$ is the second-order unit tensor. The Jaumann rate of stress evolution is

$$\overset{\nabla}{\boldsymbol{\Sigma}} = \dot{\boldsymbol{\Sigma}} - \boldsymbol{W}_e \boldsymbol{\Sigma} + \boldsymbol{\Sigma} \boldsymbol{W}_e. \tag{30.12}$$

The calculation of plastic velocity gradient $\boldsymbol{L}_p$ is based on the shear strain rate $\dot{\gamma}^{\alpha}$ experienced by individual slip system α and is typically expressed as a power law [28] in terms of resolved shear stress τ^{α} as

$$\dot{\gamma}^{\alpha} = \dot{\gamma}_0 \left| \frac{\tau^{\alpha}}{g^{\alpha}} \right|^{n} \operatorname{sgn}(\tau^{\alpha}), \tag{30.13}$$

where $\dot{\gamma}_0$ is the reference shear strain rate, τ^{α} is the strain rate sensitivity and g^{α} is the slip resistance of the slip system α. The resolved shear stress τ^{α} on a slip system α is obtained using Schmid's law

$$\tau^{\alpha} = \operatorname{sym}(\boldsymbol{s}^{\alpha} \otimes \boldsymbol{m}^{\alpha}) : \boldsymbol{\Sigma}. \tag{30.14}$$

and the slip resistance $\dot{g}^{\alpha}$ is given by

$$\dot{g}^{\alpha} = \sum_{i=1}^{N} h_{\alpha\beta} \left| \dot{\gamma}^{\beta} \right|, \tag{30.15}$$

where $h_{\alpha\beta}$ is the hardening modulus. The hardening in a slip system α can be due to dislocation present on the same slip system α (given by $h_{\alpha\alpha}$) or due to the presence of dislocation on other slip system β (given by $h_{\alpha\beta}$). Modified version of the hardening relation proposed by Asaro [29] is used in the case studied [14] and is given by,

$$h_{\alpha\alpha} = (h_0 - h_s) \operatorname{sech}^2 \left(\frac{(h_0 - h_s)\gamma}{\tau_0 - \tau_s} \right) + h_s,$$

$$h_{\alpha\beta} = q h_{\alpha\alpha} (\alpha\beta), \qquad \gamma = \sum_{\alpha} \int_0^t |\dot{\gamma}^{\alpha}| dt, \tag{30.16}$$

where τ is the shear stress, h is the hardening modulus and q is the latent hardening ratio. The subscripts "0" and "s" represent the initial and saturated condition. γ is the accumulative shear strain over all the slip systems.

The CP formulation is implemented in a general purpose finite-element software ABAQUS/Explicit via a material subroutine (VUMAT). Details of the implementation are available elsewhere [14]. Material removal in a single crystal is non-trivial. To this end, a new approach was proposed, which has capability in accounting for shear deformation in individual slip systems. This is given by [14].

$$\max\left(\gamma - \gamma_{cr},\, \gamma_{sl,min} - \gamma_{sl,cr}\right) \geq 0, \tag{30.17}$$

$$\gamma = \min(\gamma^{\alpha}),\ \alpha = 1, 2, \ldots N, \tag{30.18}$$

where subscripts "sl, cr" and "cr" correspond to a critical value for a single slip system and for all slip systems, respectively. The criterion accounts for the total slip (from all slip systems) at a spatial location as well as the induced slip from individual slip systems. Once the mentioned criteria were satisfied, the element was either deleted or converted into smoothed-particle hydrodynamics (SPH) particles.

30.3 Case Studies

In this section, we illustrate two case studies for simulation of machining processes at lower length scales, each for MD and CP FEM. For MD, we refer to the recent work of Goel et al. [19] on the cutting behaviour of silicon (Si). For CP FEM, the work of Liu et al. [14] on the micromachining of single-crystal metal is referred.

30.3.1 MD: Influence of Microstructure on Cutting Behaviour of Silicon [19]

Goel et al. [19] carried out the MD simulation of nanometric cutting of silicon in order to study the difference in the cutting behaviour of single crystalline (SC) and polycrystalline (PC) Si. The MD simulation was performed using a large-scale atomic/molecular massively parallel simulator (LAMMPS) [30]. The simulation set-up at the start of cutting simulation after equilibration is shown in Fig. 30.1. The atoms in the workpiece (Si) and diamond cutting tools (C) were categorized into three zones according to their functions. The Newton atoms are atoms in the region, which were directly involved in the tool–workpiece interaction. The thermostatic atoms are a thin boundary layer of atoms, which were subjected to a thermostat in order to mimic the heat dissipation in the cutting region due to coolant during the machining operation. The boundary atoms were subjected to rigid boundary condition. A sharp cutting edge was used to ensure the brittle-regime machining in

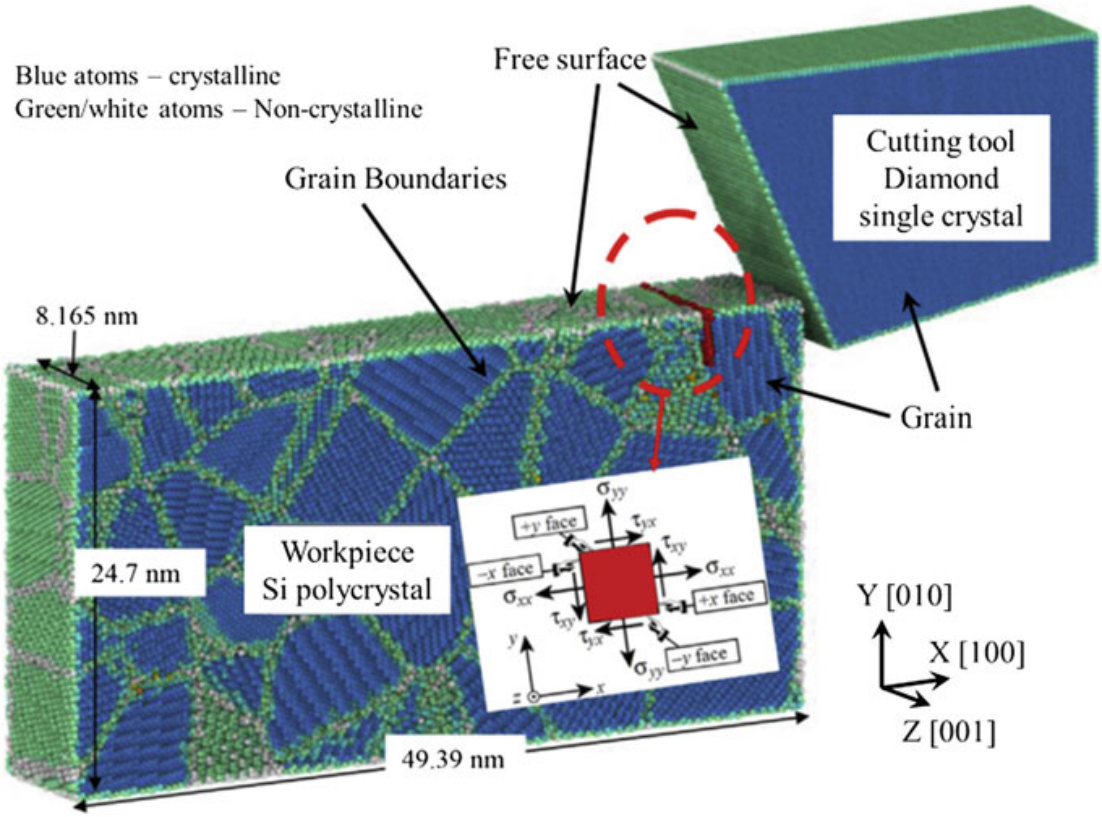

Fig. 30.1 A schematic diagram of the MD simulation model of nanometric cutting of polycrystalline silicon. The blue atoms are diamond atoms while white and green atoms are atoms at grain boundaries and free surface [19]

order to study such a process. To simulate the atomic interactions, ABOP potential was found to be suitable and advantageous as it describes the interaction between carbon and silicon.

The SC silicon required a larger cutting force during machining when compared to PC silicon. The chip for machining SC silicon was more curled (Fig. 30.2a) than the chip obtained from machining PC silicon (Fig. 30.2b). The chip formation in PC silicon takes place with plastic deformation concentrated along the grain boundaries via amorphization of the grain boundaries (Fig. 30.2d). Chunks of grains are pulled off as chips with no defect activity (Fig. 30.2f), indicating minimal plastic activity within the grains. The grain boundaries had large residual stresses (Fig. 30.2b) which help to reduce the critical stress to activate plastic deformation mediated along grain boundary, and, thus, resulting in lower cutting force for PC silicon.

An interesting observation in machining of SC silicon is the periodic occurrence of nano-grooves on the machined surface (Fig. 30.2c). The nano-grooves are regions of amorphous silicon indicating brittle cracking. Such nano-grooves were also observed in experimental studies of nanomachined silicon [25] (inset in Fig. 30.2c). These grooves form along (010) orientation and were inclined 45°–55° to the cutting direction.

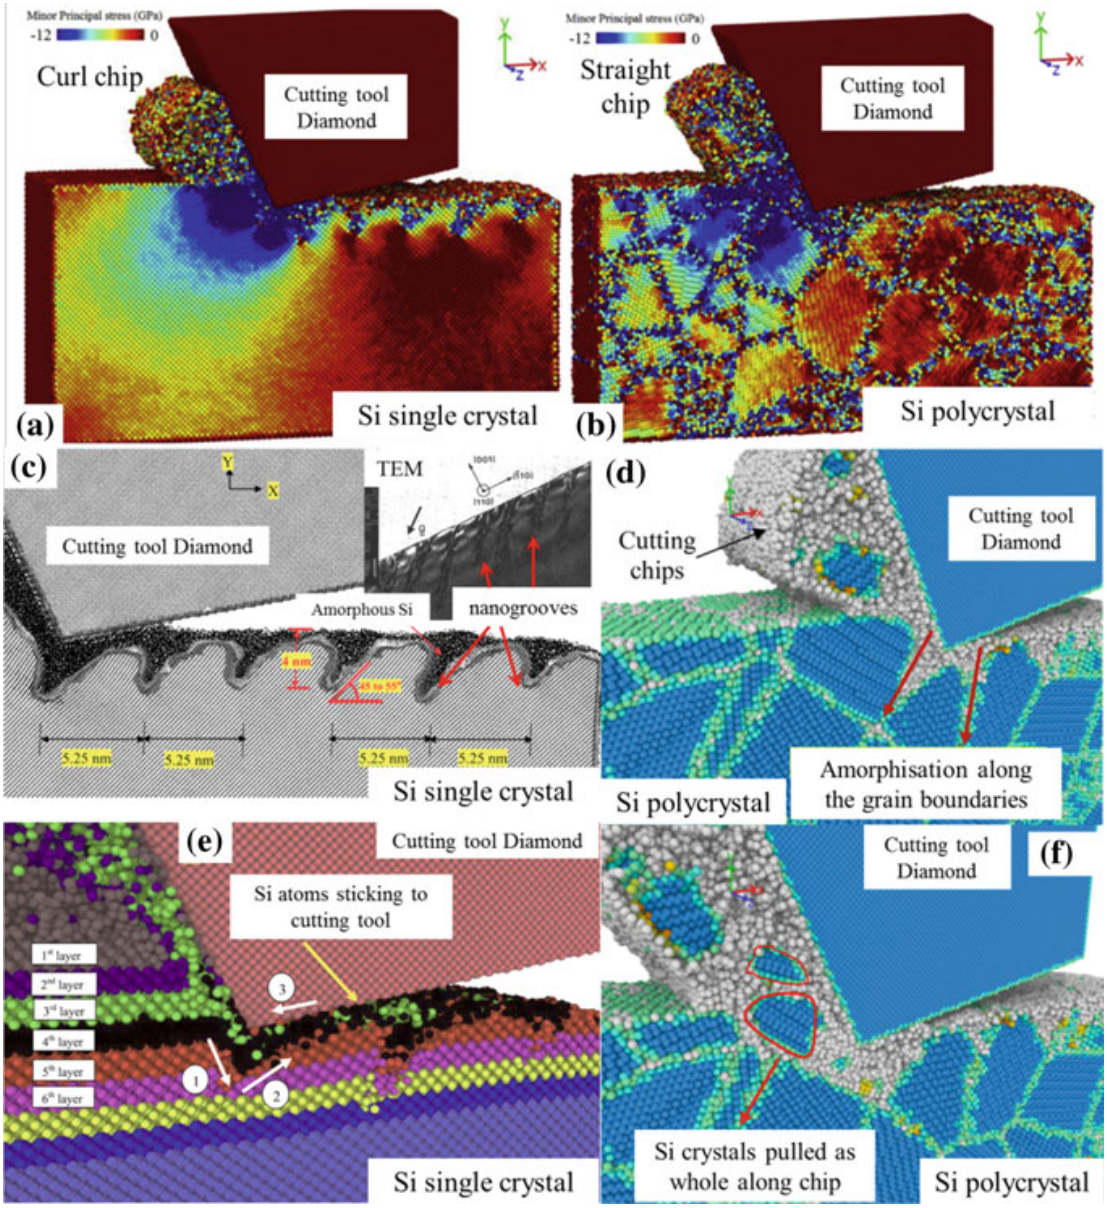

Fig. 30.2 Variation in the minor principal stress (compressive) during cutting of single-crystal (**a**) and polycrystalline (**b**) silicon [19]. (**c**) Formation of nano-grooves in the cutting zone. The inset in (**c**) is TEM image of diamond-turned specimen along (010) orientation [25]. (**e**) The path of vorticity as observed from displacement of atoms from different coloured layers [19]. Images (**d**) and (**f**) are the snapshot at various stages of cutting showing amorphization and grain pulled-outs along the chip [19]

The authors further investigated the grooving mechanism by visualization. For this, the layers of atoms of 0.54 nm thickness before machining are coloured differently. A snapshot of the machined SC silicon shows the grooving process (Fig. 30.2e). On machining, the material layer above the point of stagnation (layer 4 black Fig. 30.2e) was sheared and eventually separated from the workpiece as chips, while the layer beneath was under pure compression and slipped under the bottom the tool face. This process of flow of silicon under the tool creates a vortex.

This vorticity phenomenon leads to the flow of material (black layer) below the cutting tool and downwards in the wake of the cutting edge [19]. Sites formed by such process have abundant amorphous silicon.

One surprising finding in this study as reported by the authors [19] was the more or less absence of dislocation formation upon cutting. A burst of dislocations are normally observed under nanoindentation simulations [31]. Only a few ¼ <111> partial dislocations were observed in a selective case in the sub-surface after machining. Plasticity was mainly via amorphization and flow of silicon and was responsible for the ductile behaviour [19].

30.4 Crystal Plasticity Simulation of Micromachining of Single-Crystal Metal: Methodology and Analysis [14]

A finite-element model for single-crystal copper (FCC structure) was used to study micro-scratching (Fig. 30.3a) [14]. The micro-scratching was performed in two stages using a rigid frictionless cutting tool with 60° wedge angle and 6.25° clearance angle. The two-stage micro-scratching consisted of a linearly increasing cutting depth up to 18 µm (engagement stage) followed by a constant cutting depth of 18 µm (full-engagement stage), as shown in Fig. 30.3b. A cutting velocity of 10 mm/min was used. The model was meshed using eight-node brick elements with reduced integration (C3D8R), and a finer mesh was employed near the cutting zone for better accuracy. The copper single-crystal model is oriented such that (110) plane is parallel to the cutting plane. In the study, the cut was performed along [1–10] direction (0°) (symmetric) and at 45° to [1–10] direction (asymmetric).

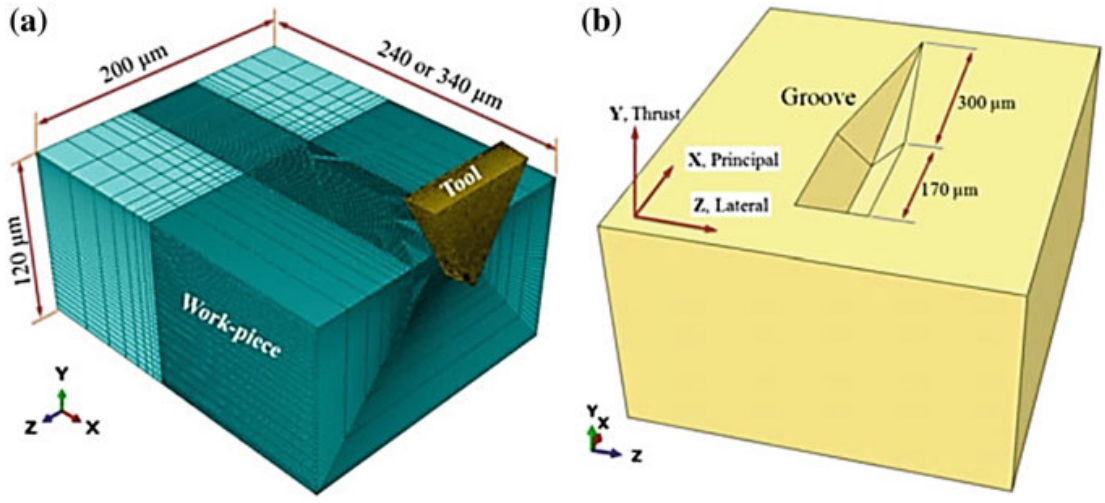

Fig. 30.3 **a** Finite-element model for micro-scratching simulation. **b** Schematic of the two-step micro-scratching experiment [14]

Different material removal models (element deletion, ALE and SPH) adopted resulted in similar cutting and reaction force in the full-engagement stage. However, the time for simulation was significantly different for the three methods. The element deletion was the most computationally efficient. ALE and SPH had higher computational costs, around 7 and 10 times that of element deletion, respectively. Thus, in the study, all further simulations were performed using element deletion.

The cutting forces during the two-step micro-scratching process for 0° and 45° direction are shown in Fig. 30.4a and b, respectively. The principal force matches well with the experimental results. The principal force for the 45° direction was 40% higher than that for 0° direction and shows the anisotropy in the material. In comparison, the predictions for thrust forces are relatively poor. It was observed to be not significantly dependent on the cutting direction.

The chip morphology for 0° direction and 45° direction from simulations (Fig. 30.5a and c) and experiments (Fig. 30.5b and d) is shown in Fig. 30.5. The simulations are capable of capturing the chip morphology and compare well with experiments. For 0° direction, the chip is symmetric, while for 45° direction, it is asymmetric. This is due to the crystal symmetry/asymmetry along the cutting direction. The crystal possesses a twofold symmetry along [1–10] direction (0° direction); hence, activated slip systems were symmetrical with respect to the cutting direction 0°. This results in a symmetrical chip formation (Fig. 30.5a) and stress field. However, no crystal symmetry exists along the cutting 45° direction, which explains the asymmetrical chip (Fig. 30.5c).

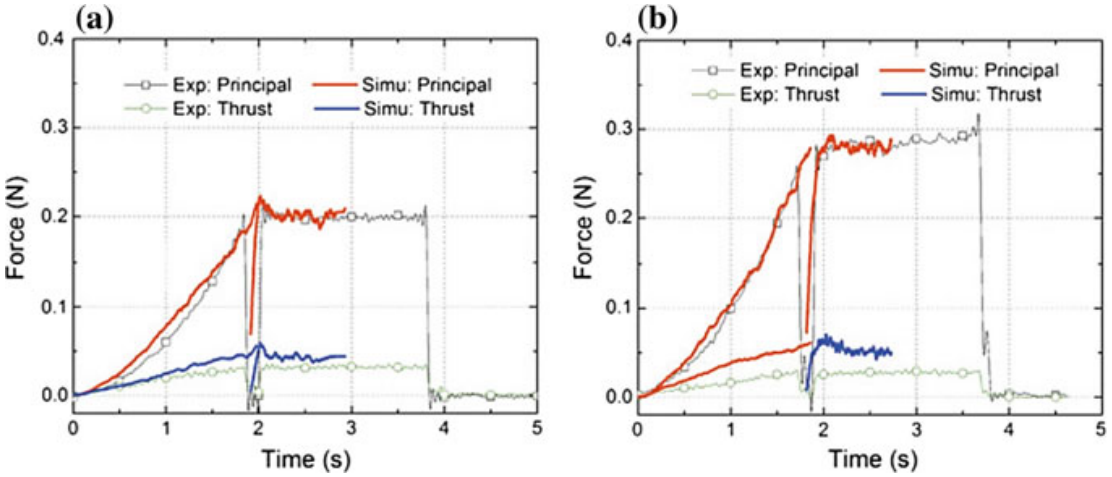

Fig. 30.4 Comparison of cutting force for FE simulations and experimental data in micro-scratching of single-crystal copper along 0° (**a**) and 45° (**b**) direction [14]

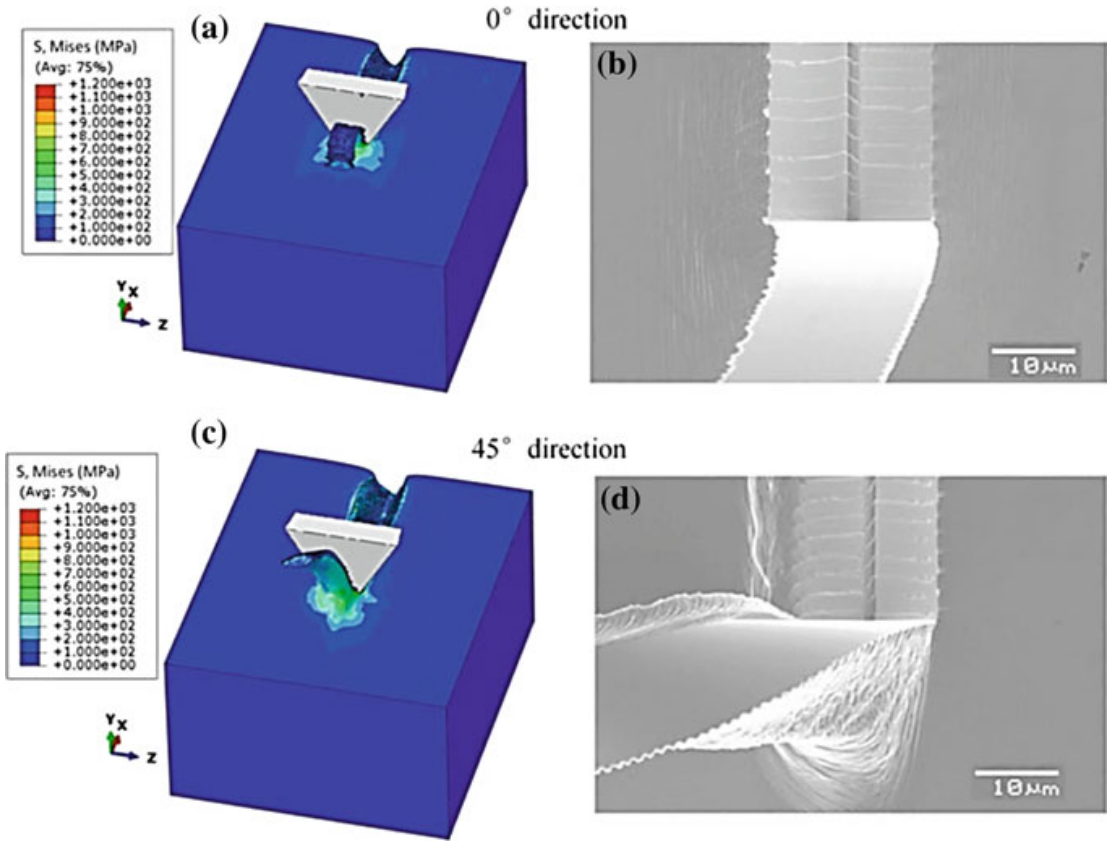

Fig. 30.5 Comparison of chip morphology on micro-scratching of single-crystal copper simulation (**a**) and experiment along 0° (**b**) direction; (**c**) simulation along 45° direction; (**d**) experiment along 45° direction [14]

30.5 Comparison of the Two Methods

The two methods for simulating micromachining processes, namely MD and CP FEM, are versatile techniques with several advantages and disadvantages. A right choice of simulation technique depends on several factors including the workpiece material, processing condition, size of machining cut to name a few.

Molecular dynamics (MD) is very helpful in situations when the underlying deformation mechanism is not well understood. Since potential function is the only necessary information needed to run a simulation. The results obtained provide fundamental insight into the nuances of the deformation processes. Depending on the boundary conditions and interaction among atoms, the system evolves in time. No prior knowledge of how the system will evolve is required. However, we note that the results obtained are dependent on an accurate potential function being defined for the material of interest. This is because a wide variety of interactions, such as ionic, metallic and covalent, are possible among atoms. This particularly becomes important as the number of interacting atom types increases in the system, which leads to an increase in the complexity of the potential and simulation computational cost. Nevertheless, a great depth of information ranging from

vacancy cluster, dislocation type, surface defects to phase transformation can be extracted from the simulation. Timescale and domain size are other factors, which often limit the applicability of MD simulations. With an increase in size, the computational cost increases exponentially. Even with the advances in computational facility available today, the simulation length scale for an MD simulation is limited to a few hundreds of nanometre. MD usually needs a time step of a few fem to seconds for numerical convergence. This again limits the time available for the simulation to a few nanoseconds. Due to this limitation, MD simulations generally involve a very high strain rate, typically 10^8 s^{-1} and above. These strain rates are unrealistic for real-world applications and merely provide an insight into the nuances of deformation processes.

Single-crystal plasticity-based FEM (CP FEM) uses phenomenological constitutive material laws to account for the anisotropic material deformation mechanisms. From a practical standpoint, CP FEM is computationally efficient and possesses the capability of modelling reasonable spatial domains. Various deformation modes including slip systems [14, 32] and twin systems [33] can be incorporated in the CP FEM model. The choice of deformation modes to be considered for CP FEM simulation is principally based on the active dominant mechanisms. Slip-based gradient plasticity is dominant in FCC materials, especially those having high stacking fault energy like Al and Ni. The twin-induced plasticity is dominant primarily in FCC materials with low stacking fault energy (brass and silver) and in HCP materials (Mg, Ti, Zr). By incorporating multiple modes in simulation, the activity of each system during the deformation can be studied via CP FEM simulations. Moreover, the deformation modes changes with sample size and temperature. Such dependency of deformation modes on size [32] and temperature [33] can be incorporated with the help of experimental data, which widens the applicability of CP FEM modelling to a large-scale scenario. Furthermore, the effect of individual deformation mode can be investigated via CP FEM by only considering a particular mode during the simulation, which helps in better understanding the role of individual deformation system. Nevertheless, it should be noted that CP FEM simulation is based on phenomenological constitutive material laws and, thus, for new materials initial experimental investigation for identification of deformation modes and calibration of material model is required.

30.6 Conclusion

In this paper, two methods, namely molecular dynamics (MD) and single-crystal plasticity (CP) FEM, used for simulation of micro-machining process are described in brief with the help of two examples from the literature. Both methods capture the anisotropic behaviour of the material. The basics of the two methods along with their capability are illustrated. Various aspects of the two methods are compared to give the reader a better understanding of respective advantages and deficiencies. MD is more suitable when the underlying deformation mechanisms are not well

understood. On the other hand, CP FEM is apt for realistic simulations and can be executed for a wide range of loading conditions. It is clear that even the type of data obtained from the two simulation methods is very different. Thus, the appropriate choice of simulation method depends primarily on the investigation at hand.

Chapter 31
Process Parameters Optimization of Cylindrical Grinding Machining Using Taguchi Method

T. Nancharaiah and M. Subramanyam

Abstract The main objective of this work is to study the effect of material hardness, workpiece speed and depth of cut on surface finish and material removal rate in cylindrical grinding process. For three process parameters at three different levels, L9 orthogonal array (OA) is selected. Experiments were conducted, and roughness values and material removal rates are calculated. S/N ratio is performed to get the optimal process parameters for surface roughness and material removal rate. ANOVA is carried out, and the percentage of contribution of each selected parameter was found.

Keywords Cylindrical grinding · Surface roughness · Material removal rate

31.1 Introduction

Machining involves removing materials using cutting tools for getting rid of unwanted materials from workpiece and converting into the desired shape. There are four movements in cylindrical grinding. They are the work must revolve, the wheel must revolve, the work must pass the wheel and wheel must pass work. Surface finish is the important output parameter in cylindrical grinding. Many researchers worked in this area, a few are cited here for references.

Athreya and Venkatesh [1] illustrated the parameter design of the Taguchi method and optimizing the process parameters. Rupesh [2] applied Taguchi method to decide the optimal process parameter for surface roughness. Prasad [3] measured the vibration and temperature rise. Habrat [4] revealed that grinding with the use of resin bond grinding wheel provides significantly lower grinding force components

during the process. Mohite et al. [5] focused on the ability of a grinding wheel measured in terms of surface of workpiece during the subsequent grinding operation.

31.2 Experimentation

31.2.1 Grinding Machine Specifications

See (Table 31.1).

31.2.2 En Alloy Steels

Mild steel of different compositions is considered for analysis. EN 19, EN 24 and EN 31 of different grades of the mild steels are turned on a lathe and then cylindrical grinding operation is performed as per L9 orthogonal array. The chemical composition of EN 19, EN 24 and EN3 1 is as shown in Tables 31.2, 31.3 and 31.4, respectively.

Table 31.1 Specifications of grinding machine

Model	DEVCO UC-150
Center distance	160 mm
Center height	102 mm
Angle of swiveling	±9 °C
Speed of transverse	140-260-370-700 mm/min
In feed of hand wheel	0.01 Division
Grinding wheel size	250*25*76.2 mm
Grinding wheel speed	2300 rpm
Work head single spindle speed	90-210-360 rpm
Spindle in taper	MT-3
Total power required	3.5HP (MAX)

Table 31.2 Chemical composition of EN 19 steel

Carbon	0.36–0.44%
Silicon	0.10–0.35%
Manganese	0.45–0.70%
Sulfur	0.040 Max
Phosphorus	0.035 Max
Chromium	1.00–1.40%
Molybdenum	0.20–0.35%

Phosphorus	0.040%
Chromium	1.00–1.60%

31.2.3 Input Process Parameters and Output Variables

The aim of grinding process is to get a better surface finish and higher rate of production. Currently there is a need for precise and accurate components in every field, so grinding operation is used to achieve this goal.

31.2.3.1 Process Parameters

In this study, the process parameters at their levels are given in Table 31.5.

31.2.3.2 Output Parameters

The material removal rate (MRR) and surface roughness of the workpiece have been measured from machined surfaces. To have minimum MRR and minimum roughness value, the optimal process parameters should be chosen.

Table 31.5 Selection of different levels of input process parameters

Parameter	Level 1	Level 2	Level 3
Hardness	40	47	55
Speed (rpm)	100	214	340
Depth of cut (microns)	10	20	30

31.2.4 Experimental Setup

The experiments were performed on DEVCO UC-150 cylindrical grinding machine. Depth of cut (D), speed (N) and hardness (H) is set at different levels, and the effects of these parameters on material removal rate and surface roughness are studied using Taguchi method. Surface roughness values are measured using SURFTEST SJ301.

For better surface roughness, smaller is better S/N ratio was used in this study and is calculated using the formula given below.

$$\mathbf{S/N\ ratio} = -\mathbf{10log}\ (\mathbf{Ra}^2)$$

In the Taguchi method of the smaller the better method, the smallest S/N value which is calculated is the best optimized running in the system. Smallest S/N ratio has highest surface finishing (Tables 31.6, 31.7, 31.8, 31.9, 31.10 and 31.11).

From the above Ra values, the signal to noise ratio is calculated using the below formula

Table 31.6 Surface roughness values as per L9 orthogonal array

S. No. (microns) (Ra)	Hardness roughness	Speed (rpm)	Depth of cut	Roughness (Ra)
1	40	100	10	0.81
2	40	214	20	0.78
3	40	340	30	1.25
4	47	100	20	1.06
5	47	214	30	1.08
6	47	340	10	1.20

7	30	340	47	246
8	30	100	55	224
9	30	214	40	282

Table 31.9 S/N values for machining the EN 19, 24, 31 workpieces

S. No.	Depth (microns)	Speed (rpm)	Hardness	Metal removal rate (MRR) (mm^3/min)	S/N ratio
1	10	100	40	152	−20.81
2	10	214	47	163	−19.89
3	10	340	55	158	−20.52
4	20	214	55	169	−19.42
5	20	340	40	176	−18.53
6	20	100	47	171	−18.86
7	30	340	47	246	−16.18
8	30	100	55	224	−17.27
9	30	214	40	282	−15.36

Table 31.10 ANOVA table for surface roughness

Parameter	Dof	SS	SS_m	% of contribution	F-test
Hardness	2	0.3066	0.1533	47.52	37.85
Speed	2	0.1983	0.0945	30.74	22.59
Depth of cut	2	0.1322	0.0661	20.49	16.32
Error	2	0.0081	0.00405	1.25	–
Total	8	0.6452	–	–	–

$$\mathbf{S/N\ ratio} = -\mathbf{10log}\ (\mathbf{Ra^2})$$

Lower S/N ratio indicates better surface finish.

From the above MRR values, the signal to noise ratio is calculated using the below formula

Table 31.11 ANOVA table for MRR

Parameter	Dof	SS	SS_m	% of contribution	F-test
Depth of cut	2	15042.8	7521.43	89.30	31.82
Speed	2	748.223	391.11	4.44	1.65
Hardness	2	580.223	280.11	3.44	1.22
Error	2	472.69	236.349	2.806	–
Total	8	16844	–	–	–

$$\mathrm{SN} = -10x\log\left[\frac{1}{n}\sum_{i}^{n} y_i^2\right]$$

Higher S/N ratio indicates that maximum MRR value.

31.3 Results and Discussions

31.3.1 Discussions

From Fig. 31.1, it was observed that surface roughness value increases if the depth of cut and speed increases and decreases if hardness increases.

It was observed from Fig. 31.2 that material removal rate increases if depth of cut increases and decreases if hardness and speed increases.

From the ANOVA, it was found that hardness effects on surface roughness are 47.52%, speed are 30.74% and depth of cut are 20.49%, and hardness effects on MRR are 3.44%, speed are 4.44% and depth of cut are 89.30%.

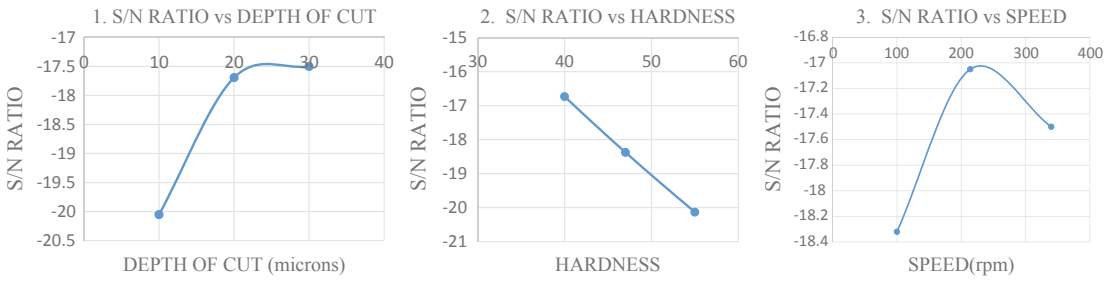

Fig. 31.1 Mean effective plots for surface roughness

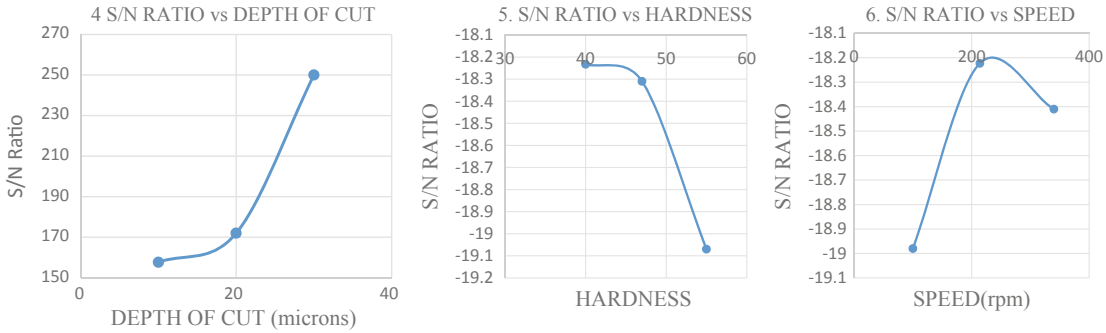

Fig. 31.2 Mean effective plots for material removal rate

31.4 Conclusions

Based on Taguchi method, experiments were conducted using EN alloy steels by varying depth of cut, hardness and speed parameters on cylindrical grinding machine, and the following conclusions were drawn.

(a) Higher depth of cut results MRR increases and surface finish decreases
(b) Increase in hardness, MRR decreases and surface finish increases
(c) Increase in speed, MRR increases and then decreases, surface finish decreases and then increases

From ANOVA, it concludes that hardness is more effective on surface roughness, and depth of cut is more effective on MRR.

Chapter 32
Effect of Sequential Drilling Process on In-situ Bone Temperature

Varatharajan Prasannavenkadesan and Ponnusamy Pandithevan

Abstract In orthopedic surgery, sequential drilling is the process of making multiple holes to facilitate the implant fixation. During the bone drilling process, the generated heat will cause thermal damage that affects the implant fixation strength because of "osteonecrosis," a permanent death of the tissues around the drilling site. In this work, an attempt was made to identify the effects of sequential drilling of cadaveric human femur bone on the heat accumulation. To perform the sequential drilling process, the rotational speed of 1500 rpm and 80 mm/min feed rate was considered with the 4 mm deep holes. Thermal images were captured using Sonel® infrared thermography during the drilling process. It was identified that the accumulated heat increased as the number of sequential holes increased. It was also observed that the distance between the drilled holes influenced the amount of temperature rise. The number of sequential holes drilled and the distance between the holes greatly influenced the temperature rise. This study showed the accumulation of heat during sequential drilling and its consequences in the temperature rise. It is recommended to the surgeons to increase the field of a drilling site in such a way to increase the distance between the subsequent holes to avoid thermal damage to the bone to prevent from further complications.

Keywords Orthopedic surgery · Sequential drilling · Femur bone · In-situ temperature · Osteonecrosis

32.1 Introduction

Bone drilling procedure is one of the most commonly employed surgical procedures in orthopedics, during joint replacement and implant fixations. During the drilling of bone, the interaction between tool and bone; and the contact between the chip

and the drill bore, creates friction which in turn induces heat [1]. When the generated temperature exceeded the threshold will lead to a condition called "thermal necrosis," a permanent death of the bone cells and because of that, the strength of the bone will reduce [2]. The phenomenon of necrosis will lead the bone to loss its healing capability and this will become more common in case of drilling, especially in multi-pass or sequential drilling [3]. This kind of thermal damage increases with increase in temperature and also with respect to the exposure time [4]. Apart from the threshold value that causes the thermal necrosis, the time being exposed also decides the severity of the damage. It has been reported in the literature that the necrosis condition will occur if the temperature is at 47 °C for 1 min and if the temperature increased to 53 °C, then the time to cause the failure will be less than a second [5, 6]. Based on the literature, it was identified that the temperature which is greater than or at 70 °C will result in a sudden state of thermal injury, and also even a lesser temperature with prolonged exposure time will provide the same adverse effects. Other than time, the significant parameters that increase the temperature rise include the thickness of the bone considered and also depth of the holes drilled [7]. Even though the temperature generated during drilling can be reduced with the help of irrigation, it is not recommended in some actual clinical cases [4]. Because of the low thermal conductivity of bone as reported in the literature, the dissipation of heat will be difficult and the build-up heat due to the multi-pass drilling will be more [8]. The main objective of this work was to identify the effect of heat accumulation in the sequential drilling with respect to the distance between the drilling sites, as the severity due to the temperature is large when compared with the single-hole drilling of femoral cortical bone. Based on this work, necessary recommendations can be provided to the surgeons to aid the drilling process in clinical trials.

32.2 Materials and Methods

Sequential drilling was performed in a vertical CNC milling machine (MTAB Maxmill®). Sonel® KT-160A infrared thermal imaging camera was used to capture the temperature data and processed with the Sonel ThermoAnalyze® software. Figure 32.1 shows the experimental setup considered. The surgical drill bit of 3.2 mm diameter was used in this study. Sequential drilling was performed at a rotational speed of 1500 rpm and feed rate of 80 mm/min with 4 mm deep holes to study the accumulation of heat.

The most commonly used parameter range for orthopedic surgery was identified through the literature and from surgeon guidance. The combination of rotational speed and feed rate that provides the higher temperature rise was identified through trial experiments. Based on that, the parameters were selected for this work. To facilitate the process of drilling, the femur bone was cut into pieces and mount into polymethylmethacrylate (PMMA). In order to replicate the clinical case, the dwell time of 1 s was provided between each pass. The accumulation of heat during the sequential drilling is due to the adjacent holes. In general, the thermocouple is

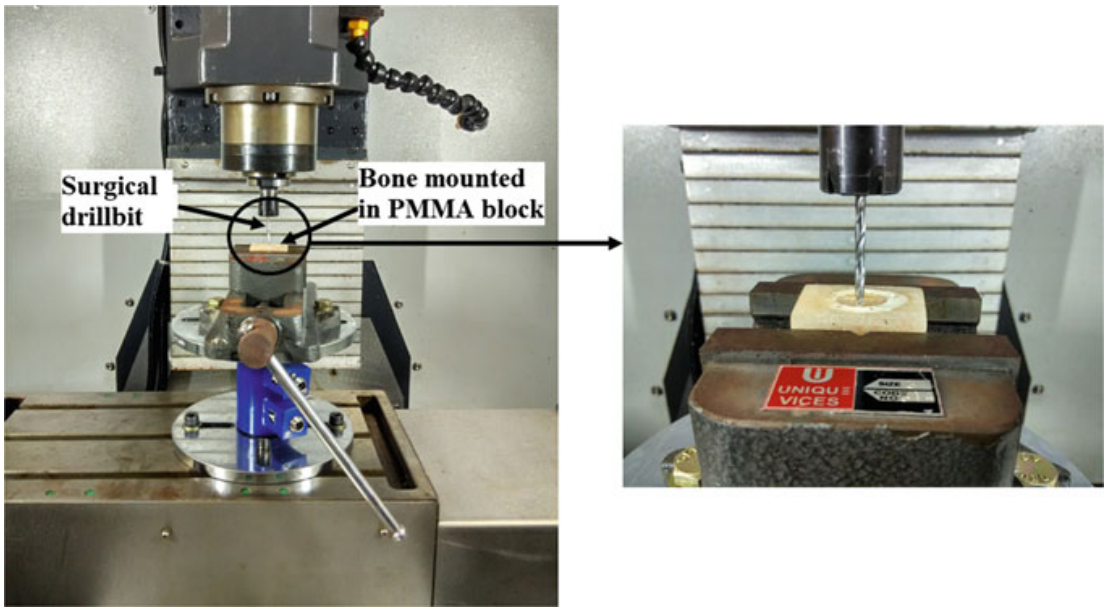

Fig. 32.1 Experimental setup used to conduct the sequential drilling in bone

employed to capture the data during single-hole drilling. But, in the case of sequential hole drilling, the multiple placements of thermocouple require several holes to house the thermocouples, which affects the integrity of the bone [9]. Because of this, the thermocouple is not employed in this study. A 2 × 3-hole array was considered and its schematic representation is shown in Fig. 32.2. The scheme considered for the sequential drilling is based on the distance from margin to margin (4 mm) of the drilled hole. Two points A and B were selected to study the accumulation of heat with respect to the drilling (Fig. 32.2). Six holes were drilled and two reference points "A" and "B" were considered as an analyzing region to identify the heat accumulation phenomenon.

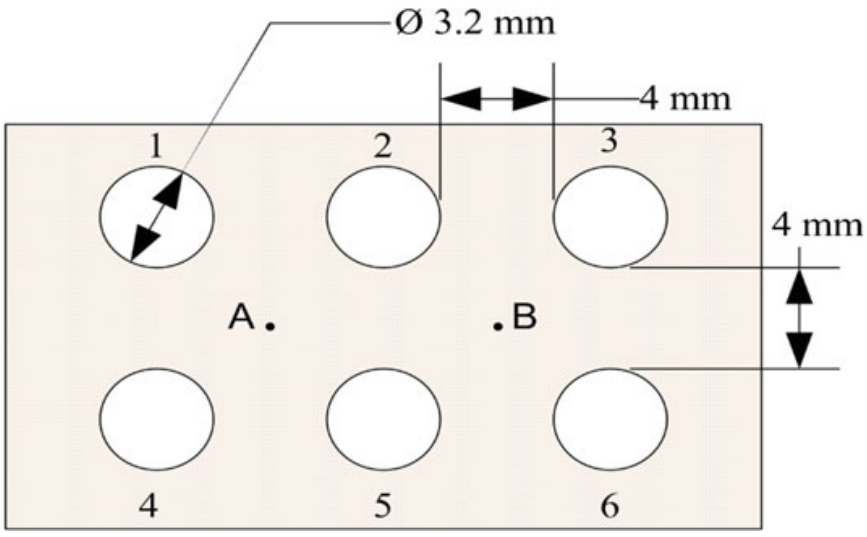

Fig. 32.2 Drilling sequence considered in this work with the reference points A and B

32.3 Results and Discussion

The variation in temperature (T) with respect to the time (t) for each drilling action is shown in Fig. 32.3. A representative thermal image and the corresponding thermal profile (Temperature, T vs. Distance, d) captured are shown in Fig. 32.4 for illustrative purpose. Based on the considered feed rate (80 mm/min), to achieve the full depth (4 mm), 3 s was taken. The dwell period provided was 1 s and thus a total time period of 4 s was taken to complete a single hole. The upright line, shown in Fig. 32.3 represents the hole number and the corresponding abscissa provides the time (t).

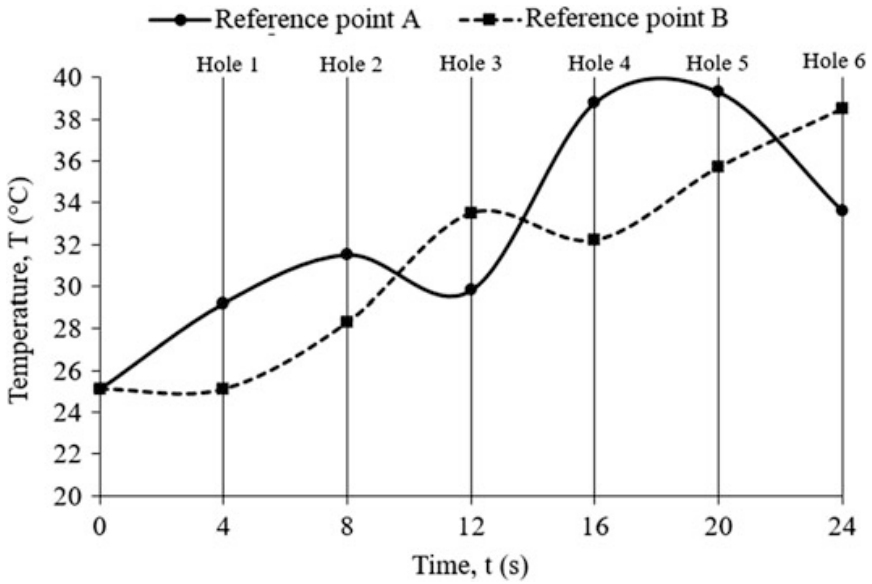

Fig. 32.3 Captured temperature data with respect to the time during sequential drilling

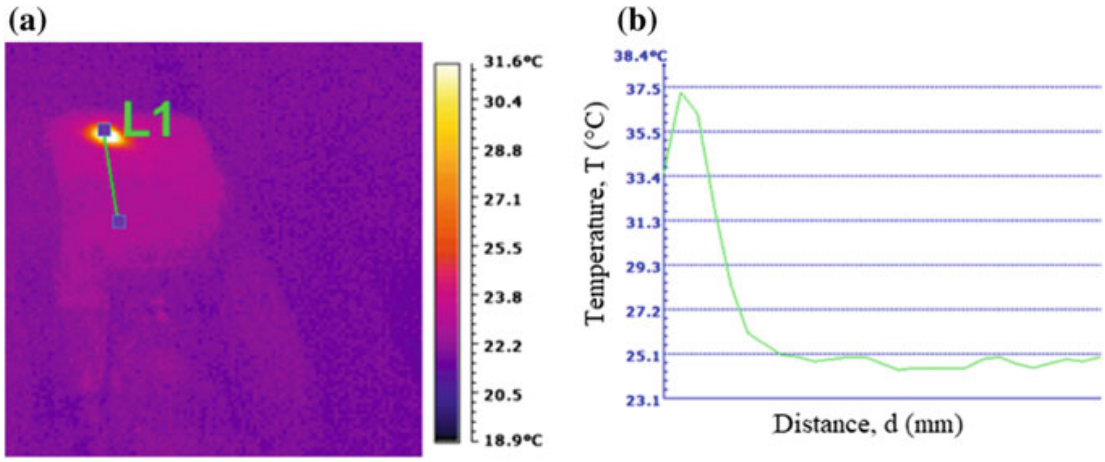

Fig. 32.4 Representative temperature data, **a** thermal image captured during the drilling with its temperature contour and **b** temperature profile of the processed thermal image

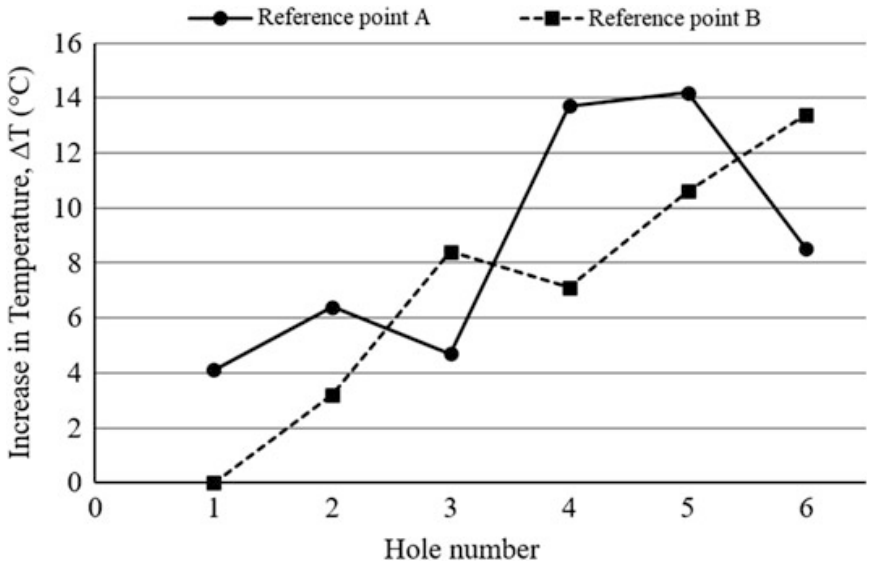

Fig. 32.5 Temperature rise during drilling with respect to the hole number

As the sequential drilling procedure starts, the reference point A (RP_A) responds first and then the reference point B (RP_B). This can be identified through Fig. 32.5, which shows the relation between the increase in temperature rise (ΔT) during the drilling and the hole number.

When drilling was made at the position of the hole number 1, the temperature information was obtained through RP_A and at this particular instance, the absence of heat was observed at RP_B. As the sequential drilling process proceeded through the subsequent passes, the accumulation of heat was clearly visible. The temperature rise was decreased substantially as the position of RP_A was far from the hole number 3. When the drilling site is in proximal (hole number 4) to the RP_A, again the temperature was increased drastically, which may be due to the accumulation of heat. Hole number 6 also showed the same trend as that of hole number 3. In the case of RP_A, it may be reported as the heat accumulation was increased for the drilling sites which are proximal to RP and gets decreased when the drilling site was farther. In the case of RP_B, it is noticed from the obtained data (Fig. 32.5) that there was not an initial rise in temperature when drilling was performed at hole number 1. A similar trend was obtained in the case of RP_B, in such a way that the heat accumulation was greater when the RP_B is at nearer to the drill site. Also, it can be noticed from Fig. 32.5 that the temperature rise at RP_A and RP_B follows the opposite trend. It may be due to the reason that the considered reference points A and B are at opposite to each other. Due to this, at a particular instance, for a considered drilled hole higher temperature rise or heat accumulation was observed at the reference point which is nearer to the drilled hole. Thus, the RP_A responds in a greater way to the sites 1, 2, 4, and 5; the RP_B provides the temperature information for the sites 2, 3, 5, and 6. The farther distance might be the reason for the RP_B for not providing any information about hole number 1 at the initial time. As the sequential drilling is involved in the drilling of more than a hole, the heat gets

accumulated and gets transferred to the next drilling site. Due to this, more chance for the osteonecrosis condition when the temperature reaches 47 °C. So to avoid that in sequential drilling, the surgeons are advised to select the drilling site farther from the previously drilled hole. In this present work, even though, the sequence of the holes to be drilled is changed since the distance between the drilling sites were maintained at the same distance, the temperature profile will not vary. As a preliminary work, those effects were not included in this study. Based on the conducted experiments, it may be concluded that the temperature rise during multi-pass drilling can be reasonably reduced by increasing the dwell time, and this discussion is in good agreement with the numerical study reported earlier [10]. By increasing the dwell period or the time interval between the passes, more time to disintegrate the heat generated can be obtained so that the accumulation can be reduced.

32.4 Conclusion

In this work, an attempt was made to investigate the accumulation of temperature in the cadaveric human femur bone during sequential drilling with a 3.2 mm surgical drill bit for orthopedic applications. Temperature is higher at the margin of the drilled holes, but the accumulation of heat was analyzed at the considered reference points A and B. Accumulation of heat was found to be increased during the subsequent passes of the drilling. From the investigation made, it may be concluded that the distance which is considered as a datum for comparison has a significant impact over the captured temperature information. Because of this kind of heat accumulation due to the sequential drilling, the thermal damage occurred during the orthopedic surgery will be more. By this preliminary study, it was identified that by increasing the margin to margin distance between the drilled holes, the thermal damage can be decreased through the decrease in the heat accumulation or temperature rise. The main limitation of this work is that the observations provided were based on the very limited experimental study. So more follow-up experiments are need to be conducted to have better repeatability and understanding about the effects of sequential drilling. The postoperative success of the drilling process in orthopedic surgery not only depends on the reduction of temperature rise through the identification of optimal distance or optimal parameters but also the geometry of drill bit design, which reduces the efforts in the process of surgery. The authors tend to travel in further directions of this work in such a way to explore the effects of exposure time and the distance between the holes to the thermal damage caused, to implement this phenomenon in the virtual orthopedic surgery protocol. As the temperature generation is more at the proximity of the drill site, and it is also necessary to optimize the way in which the sequential drills can be made to avoid heat accumulation. So the association between the personnel from engineering and physicians is required to develop the surgical protocol for the automated surgeries.

Chapter 33
FE-Based Heat Transfer Analysis of Laser Additive Manufacturing on Ti–6Al–4V Alloy

Sapam Ningthemba Singh, Sohini Chowdhury, Md. S. Mujaheed Khan, Manapuram Muralidhar and Yadaiah Nirsanametla

Abstract A thorough understanding of laser-based additive manufacturing process and effect of various process variables such as scanning velocity and laser beam power on melt-pool dimensions and temperature variation is a promising task in design and manufacture of an able product. The present work is focused on comprehending the thermal and melt-pool behavior of a high layer thickness five-layer laser additive manufacturing of Ti–6Al–4V alloy quantitatively. A three-dimensional (3D) nonlinear transient thermal model is developed based on a finite element procedure to simulate single- and multi-layer of Ti–6Al–4V alloy and to estimate melt-pool dimensions and thermal cycles. In this work, temperature-dependent material properties and Gaussian distributed 'disk' heat source model are implemented along with actual process boundary and initial conditions. Also, the influence of laser beam power and laser scanning velocity was examined with respect to melt-pool characteristics and thermal cycles. The laser scanning velocity ranges from 200 to 500 mm s^{-1} and laser beam power from 100 to 400 W are examined. It is observed that the temperature rises for successive layers as the laser power supply continues on consecutive layers. Also, it is obvious that with the rise in temperature, melt-pool dimensions also increase. Furthermore, the melt-pool dimensions increase as the number of deposited layers increases. Time–temperature history and melt-pool evolution in different layers with respect to laser beam power and laser scanning velocity are presented. To verify the effectiveness of the developed model, simulated results are compared with experimentally measured melt-pool profiles and dimensions. A fair agreement between experimental results and computed values is achieved.

33.1 Introduction

Laser-based additive manufacturing (AM) is an advanced manufacturing technique in which an object is fabricated in a layer-wise manner directly from a CAD file. Moreover, it is quite different from conventional machining processes where parent material undergoes subtractive operations to acquire the desired final product [1]. Hence, it gains some significant advantages over conventional machining processes in terms of design freedom, manufacturing flexibility, the ability to manufacture complex and customized shapes. Also, a variety of materials ranging from polymers, metals, alloys to ceramics can be utilized to manufacture desired products either in powder form or the form of the wire material. The main applications of laser-based additive manufacturing processes are in the field of aerospace, automotive, prototyping and healthcare—dental and medical. Ti–6Al–4V alloy is mainly used in the aerospace, automotive and healthcare industries where high strength, high corrosion resistance and light materials are of main necessity [2–4]. Hence, it is of prime interest to investigate and to have good knowledge of laser additive manufacturing of Ti–6Al–4V which will help to predict the nature of the interaction of the laser with the substrate, melt-pool formation and temperature variations during and after manufacturing operation. Data from such analysis can be used to further study mechanical and microstructural properties. This, in turn, will help in designing an efficient process, optimized machines for specific jobs.

Owing to the importance of additive manufacturing of Ti–6Al–4V alloy in different industrial domains, several researchers have carried out experimental investigations to understand the thermo-physics and its effect on final microstructural and mechanical characteristics of the built product. Yadroitsev et al. [5] reported selective laser melting (SLM) of Ti–6Al–4V alloy for single-layer and single-track application to monitor temperature and microstructural changes during the process. The authors implemented a CCD camera to determine temperature distribution and melt-pool dimensions. It was found that the depth and width of melt pool increase with a continuous supply of laser power. Presence of foreign particles or the addition of extra elements in material results in a drastic change in surface tension and shape of the deposited layer during the LAM process. Traces of rare earth elements such as lanthanum hexaboride and boron in the Ti–6Al–4V and slow cooling rate result in very large Ti particles and improved strength. However, the final structure of the material is more hardened due to the presence of these elements [6]. It is possible to maintain constant energy density by adjusting laser intensity, scanning speed, layer thickness, cooling rate, etc. However, changing the process parameters will result in varying shapes and mechanical properties for constant energy density. Bartolomeu et al. [7] examined the influence of heat source (laser power) and scanning velocity on hardness, density and shear strength of Ti–6Al–4V material during a SLM process. Further studies were carried out on the influence of process variables on microstructure. However, they ignored heat transfer and interaction during the whole process. In experimental research on single-track SLM of Ti–6Al–4V material, it is asserted that the process variables

can be varied to control melt-pool dimensions. Controlling melt-pool dimensions is necessary to adjust the final microstructure of the object. However, single-track experiments cannot provide complete information on a multi-layer built object. Contrary to the theoretical concept, when layer thickness varies from 20 to 60 μm, it is found that there is a negligible effect on the melt-pool depth and width when the scanning speed and laser power are kept constant [8].

Chandrakanth et al. [9] compared the effects on the melt-pool characteristics of Ti–6Al–4V with respect to laser power and scanning velocity during the SLM process considering when the material is in powder state and no powder state [9].

Conducting experiments corresponding to every AM criterions is not desirable in terms of resources and expenditure. Hence, it is preferable to simulate AM process using available tools and methods to examine the effect of input factors on the final built object. Numerical simulations can be used to compute melt-pool dimensions and time–temperature distribution in the laser additive manufacturing process. Qingcheng et al. [10] developed a finite element model to determine the thermo-mechanical behavior of Ti–6Al–4V alloy for laser engineered net shaping (LENS) process using ellipsoidal heat source model. The computed results were determined to be in good agreement with the experimental data [10]. Over the past few years, several thermal models have been developed to simulate AM processes to examine the thermal and mechanical effects with respect to process variables. A computational model of 40 layers of the Ti–6Al–4V alloy was studied by Xufei et al. [11] during the solid forming process using generic heat source model. However, performing finite element analysis for 40 layers will increase computational cost. They determined that the initial temperature of the substrate and the cooling rate after the fabrication process are significant factors. The SLM model developed by Ali et al. [12] considered absorptivity, laser spot area and laser power for effective evaluation of optical penetration of laser beam. They also found that there is no or little noticeable increase in the maximum temperature after the fourth layer. Hence, taking more number of the layer to study the thermal analysis and melt-pool formation is not required. Kurian et al. [13] carried out a detailed comparison of FEM result with experimental data during the SLM process for single-track and single-layer stainless steel 316L material [13]. Moreover, the computational model yielded good results when compared with experimental data, and it is within an acceptable range. Similarly, Jun et al. [14] developed a FEM model to analyze the distortion and residual stresses in electron beam-based additive manufacturing of Ti–6Al–4V alloy. In their work, the authors have implemented a uniform distribution heat source model to simulate the AM process. It was found that the distortion level increases initially for 2–3 layers and then decreases as the layers accumulate [14]. However, the heat source in the real world is not uniform. Thermal distribution along the layer can be applied for determining minimum scanning velocity. A minimum energy density should be maintained to avoid incomplete melting and to prevent balling effect [15]. Jihong et al. [16] analyzed that the heat-affected zone (HAZ) is a significant output parameter in the SLM process [16]. However, several investigators neglected HAZ in their analysis [17–22].

The aim of the present work is to develop a FE model for a five-layer thin-walled Ti–6Al–4V alloy during the laser additive manufacturing process to study the effect of laser power and scan velocity. Using the developed model, five different layers are examined with respect to time–temperature history and melt-pool formation using moving Gaussian distributed disk heat source model. To verify the correctness of the developed model, predicted results are compared with experimental values and found in good agreement.

33.2 Theoretical Background

A transient finite element-based model is developed for five-layer SLM process of Ti–6Al–4V to determine the nonlinear, time–temperature history and melt-pool dimensions at each point of the five layers. SLM setup consists of a laser source, a powder feeding mechanism, a base or a building platform, roller scrapper and other auxiliary parts [16]. The transient heat conduction equation for a three-dimensional heat flux can be represented as

$$\boldsymbol{k}\left(\frac{\partial^2 \boldsymbol{T}}{\partial \boldsymbol{x}^2}+\frac{\partial^2 \boldsymbol{T}}{\partial \boldsymbol{y}^2}+\frac{\partial^2 \boldsymbol{T}}{\partial \boldsymbol{z}^2}\right)+\dot{\boldsymbol{Q}}=\boldsymbol{\rho c_p}\left(\frac{\partial \boldsymbol{T}}{\partial \boldsymbol{t}}+\boldsymbol{v}\frac{\partial \boldsymbol{T}}{\partial \boldsymbol{y}}\right), \tag{33.1}$$

where ρ, c_p, T, v, k and $\dot{Q}$ are the density of the material, specific heat, velocity vector, temperature variable, thermal conductivity and heat generation rate (internal) per unit volume. The first term represents the heat conduction process in Cartesian coordinates system along with internal heat generation rate in the substrate. The initial temperature distribution at time $t = 0$ is given by

$$T(x,y,z)|_{t=0}=T_0, \tag{33.2}$$

where T_0 is the ambient temperature and is assumed to be 298 K.

The thermal transfer within the melt pool is largely due to the latent heat of conduction. Heat is dissipated from the layers as well from the substrate to the atmosphere by convection and radiation modes. The necessary boundary conditions are expressed by Newtonian convection (Newton's Law of Cooling) and gray-surface body behavior [23–29], and mathematically represented as

$$k\frac{\partial T}{\partial n}-q+q_{\mathrm{c}}+q_{\mathrm{r}}=0, \tag{33.3}$$

where q_{c} and q_{r} are heat loss due to convection and radiation mode, and q is the rate of heat influx. The basic equation of convection heat loss and radiation heat loss is

$$q_c = h(T - T_0), \tag{33.4}$$

$$q_r = \sigma\epsilon\left(T^4 - T_0^4\right), \tag{33.5}$$

where $h\sigma$ is the coefficient of convective heat transfer, is the Stephan–Boltzmann constant (5.67 J/m^2 s K^4) and ϵ is melt-pool emissivity, T_0 is initial temperature and T is the instantaneous temperature.

The Gaussian distributed disk heat source model that is utilized in the present analysis is given by [30].

$$q = \frac{3\eta P}{\pi r^2}\exp\left(\frac{-3(x^2+y^2)}{r^2}\right), \tag{33.6}$$

where q is the heat flux, η is the laser absorption coefficient, P is the laser power, r is the effective laser beam radius, and x and y are the respective position of the laser beam at a given time.

A computational model was developed using FE-based ANSYS 14.5 software. The dimensions of the substrate are 10 mm × 31 mm × 4 mm and five layers with layer thickness 1 mm as shown in Fig. 33.1. Also, temperature-dependent material properties such as thermal conductivity, density and specific heat are used [31]. The scanning pattern of the laser on successive layers is shown in Fig. 33.2. The process variables used in the present work are given in Table 33.1. Six different data sets are utilized to simulate laser additive manufacturing process and to analyze melt-pool dimensions and temperature distribution.

The deposition of layers is simulated using the element birth and death technique in ANSYS APDL. When the first layer is exposed to the laser, the elements in the other four layers are classified as death elements. After the first layer, the second layer is activated using element birth feature while keeping the last three layers deactivated, and this process is repeated till the fifth layer.

33.3 Results and Discussions

In this section, the influence of laser beam power and scanning velocity on the melt-pool profile and time–temperature distribution at selected points on each layer is presented along with the validation of model predictions with experimental results. Variation of melt-pool dimensions as well as the effect of laser power variation on peak temperature magnitude and overall temperature values is presented. Also, the effect of scanning velocity at constant laser power is also analyzed. To verify the effectiveness of the model, it is calibrated and compared with the experimental data.

For validation of the numerical model results, experimental work is considered from the literature [8]. An SLM experiment was conducted by Yang et al. (2016) which consists of IPG YLR-500 fiber laser, a powder delivery system, a support and building platform along with a process control computer system using Ti–6Al–4V alloy powder with a range of 30–50 μm in an inert environment of Argon. Table 2 depicts the process parameters used in the experimental investigation. From the experimental investigation, it is observed that the melt-pool width ($\sim$70 μm to $\sim$160 μm) and depth ($\sim$10 μm to $\sim$200 μm) increase as the power is increased from 100 to 500 W keeping the other parameters unchanged. But the melt pool decreases when the scanning speed increases from 100 to 1000 mm s^{-1} keeping the laser power and layer thickness constant.

A finite element-based heat transfer model is developed to examine the melt-pool formation and thermal cycles. To confirm the viability of the developed model, the single-layer FEM model is developed initially of 1 mm layer thickness. The single-layer model is compared and validated with the experimental data from literature [8]. The melt-pool depth corresponding to the computed value and the experimental result of data set #3 of Table 33.1 are determined to 0.12 and

0.13 mm. Moreover, a percentage difference in melt-pool depth is estimated to be 5.38% for all processing conditions of Table 33.1 and which is under acceptable range. Comparison of computed (left) and experimental (right) melt-pool shape corresponding to data set #3 of Table 33.1 is presented in Fig. 33.3, and the red color zone represents the melt zone.

With the application of laser power, a sudden rise in temperature is observed with a high-temperature gradient. Figure 33.4 shows the 3D transient temperature distribution at different positions and at different layers corresponding to process variables given in Table 33.1. Figure 33.4a shows the location of the laser source

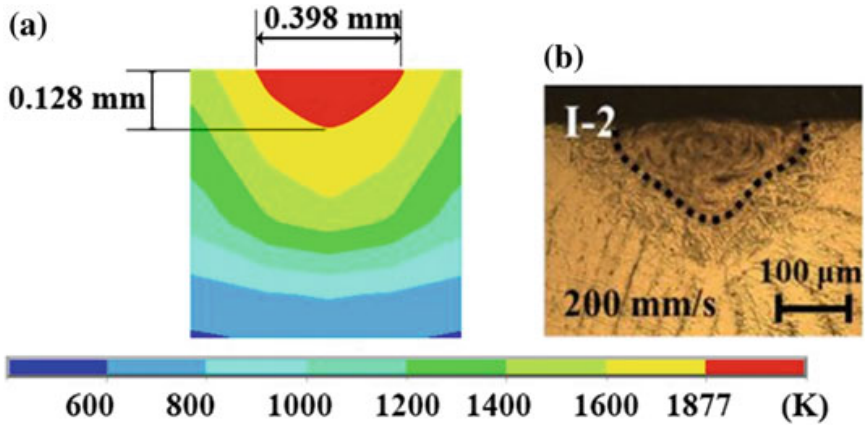

Fig. 33.3 Comparison of computed (left) and experimental (right) melt-pool shape and size corresponding to data set #3 of Table 33.1 of for a single-layer laser additive manufacturing

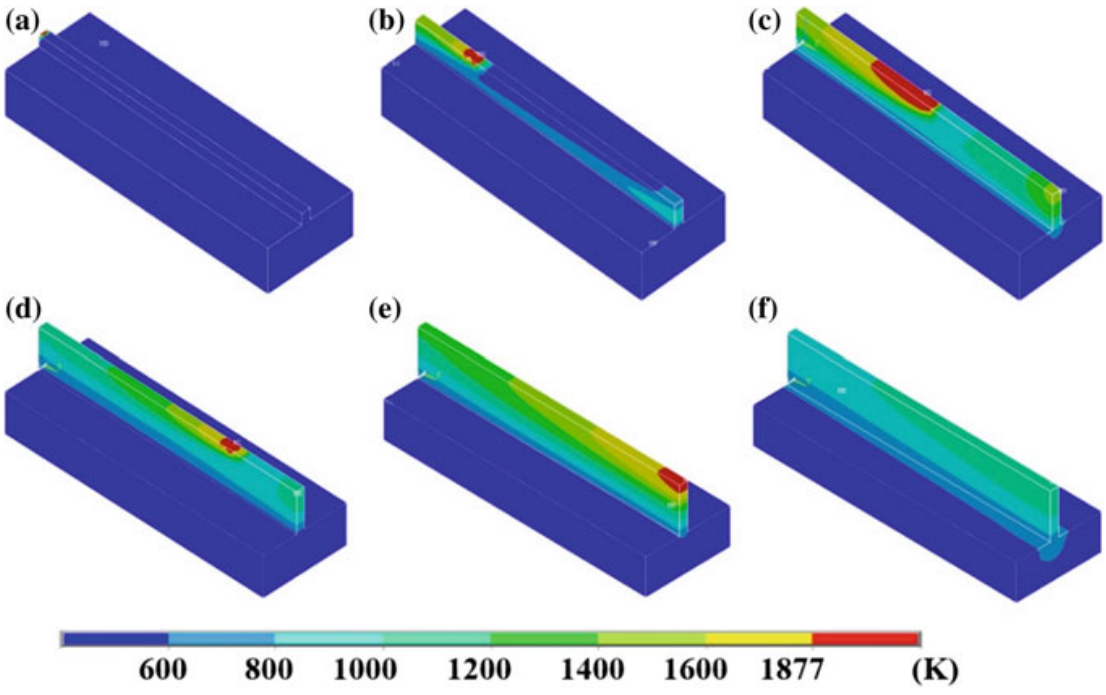

Fig. 33.4 3D transient temperature distribution at different positions and different layers during five-layer laser additive manufacturing of Ti–6Al–4V alloy

which is at the beginning of the first layer corresponding to data set #6. Figure 33.4 (b) represents the location of the laser source which is at a distance of 7.75 mm along the scanning direction of the second layer corresponding to data set #5. Similarly, Fig. 33.4c demonstrates the location of the laser source which is at the center of the third layer corresponding to the data set #4. Figure 33.4d represents the location of the laser source which is at a distance of 23.25 mm along the scanning direction of the fourth layer corresponding to data set #3. Figure 33.4e shows the location of the laser source at the end of the fifth layer corresponding to data set #2. Figure 33.4f represents the cooling nature of laser additive manufacturing of Ti–6Al–4V alloy. It is observed from Fig. 33.4c, d that the melt zone and heat-affected zone are wider for high laser beam power and low scanning velocity.

Figure 33.5 depicts the time–temperature history of each layer at a distance of 7.75 mm along the scanning direction. This figure shows a rapid rise in temperature followed by a gradual decrease in temperature. The sudden rise in temperature is due to sudden impingement of laser power at a point, and a gradual decrease is because of laser source moving away from that specific point. Theoretically, there should be five different peaks for the first layer, four for the second layer and three for the third layer and likewise. This is because laser power passes above a specific point for five, four, three times during the whole process. However, the graph reveals only three visible peaks. It shows that for a point below three layers where the laser is striking, there is little effect of laser power on that point for specific data set. However, other data set represents five peaks during the whole process. This reflects that high laser power affects the temperature at a point, even though layers are away from it. However, the overall temperature of the point still increases as the number of layers increases. After the manufacturing process, there is a rapid decrease in the temperature due to cooling up to 2.5 s, after that the cooling takes place slowly. This is due to the temperature difference between the ambient and builds parts decreases, and heat transfer due to convection decreases sharply.

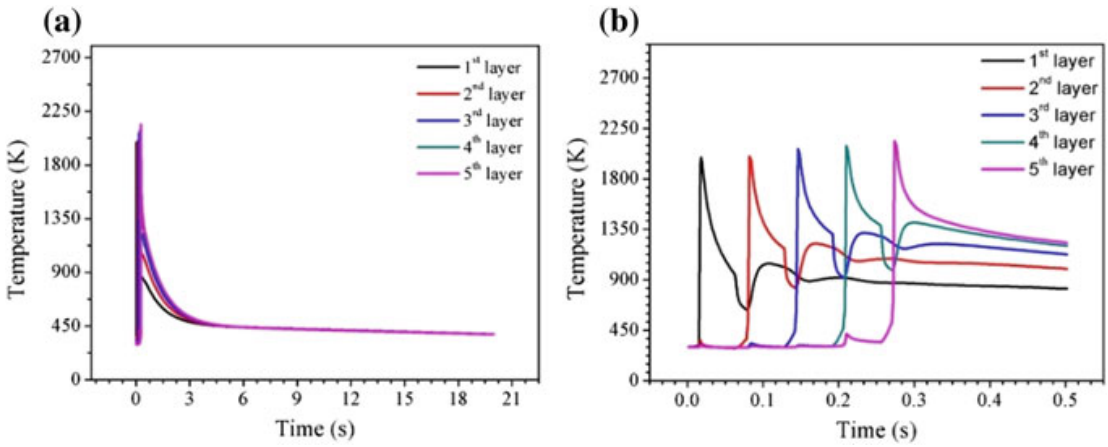

Fig. 33.5 Time–temperature history of each layer during a five-layer laser additive manufacturing of Ti–6Al–4V alloy for data set # 6 of Table 33.1

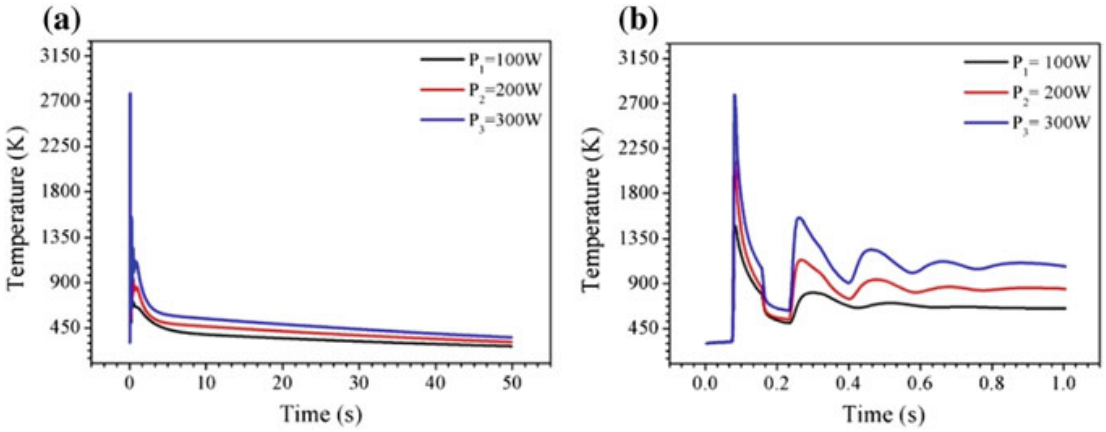

Fig. 33.6 Thermal cycles at constant scanning velocity of 200 mm s^{-1} and different laser beam power: **a** full view and **b** magnified view

The effect of laser power on the time–temperature history of Ti-alloy material is graphically represented in Fig. 33.6. For constant laser scanning velocity of 200 mm s^{-1}, the laser power is varied from 100 to 300 W. Correspondingly, the peak temperatures are 1484, 2113 and 2788 K at the top of the first layer and a distance of 23.25 mm along the scanning direction corresponding to the laser power 100, 200 and 300 W, respectively. There are five peaks for 300 and 200 W laser power; however, for 100 W there are only three peaks. Figure 33.7 shows the increased melt-pool dimensions when laser power varies from 100 to 200 W at constant scanning velocity. It can be identified that there is an incomplete melting and sintered which is represented by the yellow and light green region. This results in a change of microstructure and mechanical properties in the final product.

Figure 33.8 depicts the temperature variation at constant laser power and increasing laser scanning velocity. At constant laser power of 200 W (Fig. 33.8a) and an increasing scanning velocity from 200 to 300 mm s^{-1}, the temperature reduces from 2113 to 1738 K at the top of the first layer and a distance of 23.25 mm along the scanning path. A similar trend is observed when power is

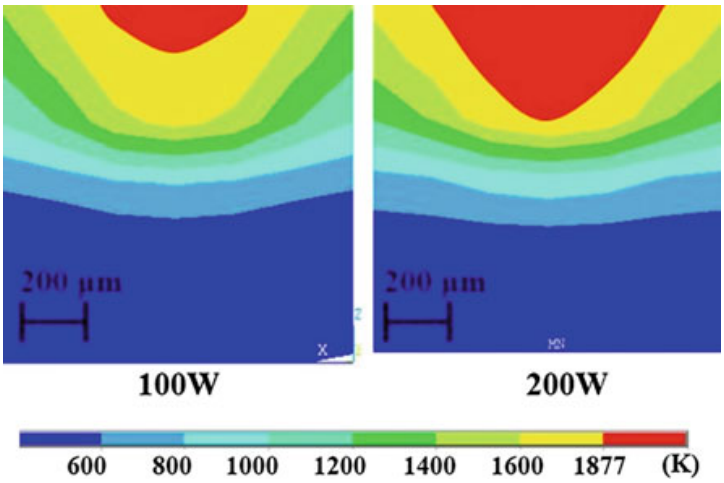

Fig. 33.7 Effect of laser power on the melt-pool formation at a constant scanning velocity of 200 mm s^{-1} in Ti–6Al–4V alloy during laser additive manufacturing

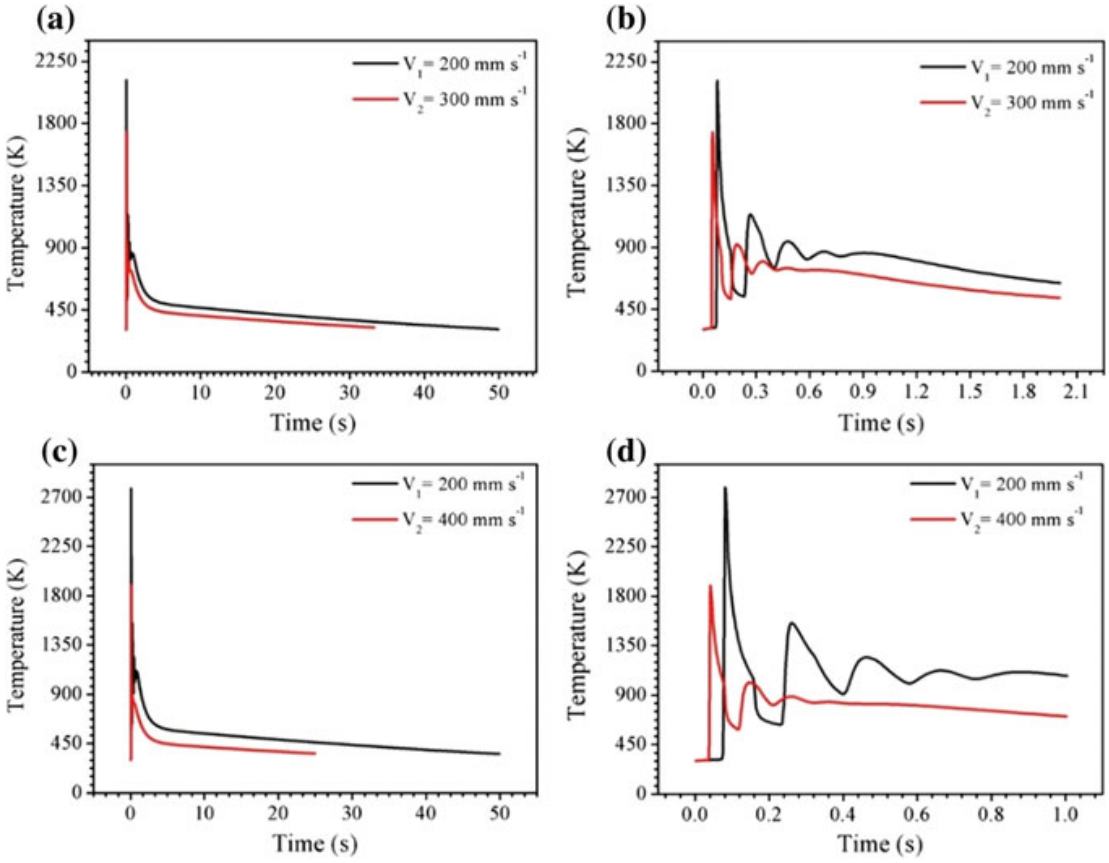

Fig. 33.8 Effect of scanning speed at constant laser beam power **a**, **b** 200 W and **c**, **d** 300 W

300 W (Fig. 33.8c) and scanning velocity is increased from 200 to 400 mm s^{-1}, and temperature decreases from 2788 to 1895 K. The temperature distribution and peak temperatures were estimated using developed model along with melt-pool formation.

33.4 Conclusion

In the present work, a 3D transient FE model of a large layer thickness five-layer laser-based additive manufacturing is developed to understand the complex evolution of melt-pool shape and dimensions as well as transient temperature distribution. The developed model results are validated with the experimentally measured values to verify the effectiveness of the process model. The model is determined to be in good accordance with the experimental data.

The influence of laser beam power and scanning velocity examined five-layer laser additive manufacturing process using a developed model. It is observed that the temperature of subsequent layers rises with an increase in layer number. In the first layer, the substrate played an important part in conducting the heat away from the layers. The results also showed that for low power or high speed, there is the

negligible effect of temperature on the first layer when the laser source passes through the fourth layer. However, if the laser power is high and the scanning speed is low, it is still a significant influencing factor for the first layer even when the laser source passes on the fifth layer. It is also found that the temperature increases up to 2788 from 1484 K when laser beam power increases from 100 to 300 W at the top of the first layer for the same scanning velocity, 200 mm s^{-1}. Moreover, the temperature decreases from 2788 to 1895 K when the laser power is 300 W, and scanning velocity is changed from 200 to 400 mm s^{-1}. The future scope of the present work is the development of a mechanical model to estimate the residual stresses and mechanical properties using the present thermal model. Also, this model will provide a base to develop a process model for a multi-layer, multi-tracks during additive manufacturing.

Chapter 34
Material Perspective and Deformation Pattern of Micro-Sized Metallic Particle Using Cold Gas Dynamic Spray

Abdul Faheem, Faisal Hasan and Qasim Murtaza

Abstract The cold gas dynamic spray is a solid powder deposition phenomenon of coating and repairing with a broad materials range. This deposition technology gained attention not only in institutions but also in industrial aspects. This coating technology is a surface engineering technology which is presently replacing electron, laser beam type of technologies for additive manufacturing. This study provides the pattern of deformation of both particle and substrate under the impact of high particle velocity. An ABAQUS/Explicit, a finite element methodology was used to forecast the coating behaviour of different engineering materials. A FEM approach was used for the simulation of the metallic impact of substrate and particle. A wide range of impact velocities was used to finding the threshold or critical velocity for the proper deposition, phenomenon of rebounding and also to divulge the mechanism of governance, i.e. adiabatic shear instability (ASI). This study focused and revealed how engineering materials that are commonly used in aerospace engineering behaved under different impact conditions using kinetic spray coating technology.

Keywords Cold gas dynamic spray · Numerical simulation · Critical velocity · Finite element methodology

34.1 Introduction

Cold gas dynamic spray or cold spray (CS) or kinetic spray is a new material deposition technology which is procuring attention of surface engineering. This is a newly gaining noticed coating process used for a wide range of materials, i.e. ductile, brittle, ceramics and composite materials, etc., [1] without noteworthy heating of micro- or

nano-solid particles. A kinetic spray, firstly, at the Russian's Institute of Applied and Theoretical Mechanics of Science was discovered more than two decades ago and the first patent on it done in 1994 [2]. In CS, adhesion between the particle and substrate occurs due to the impact of the high velocity of micro- or nano-size of particles [3]. This high velocity not only effects the deformation of both of it but also equated a large amount of plastic deformation [4]. The acceleration of particles is obtained by the convergent–divergent nozzle under high pressure with a Mach number in the range of 3 for the impact phenomenon [5]. Apart from heating, the dimension instability and surface protection also be done by alternate technology, i.e. kinetic spray [6]. This metal joining process is similar to cladding in which the fusion of parts occurs to fasten the dissimilar metals [7, 8] (Fig. 34.1).

The major disadvantage of high-pressure cold spray system is the erosion at the throat of the nozzle due to erosion particle which not only affects the working of the nozzle but also the deposition quality [9]. (2) Low-pressure cold spray is a system in which powder is fed at that point in the nozzle where the gas expanded the least pressure. This system is commonly used for metal alloys and ceramics. LPCS systems are generally portable and smaller and also workable on a limited range of velocity (300–600 m/s). Due to the portability of LPCS, it does not need pressurizer feeder (Fig. 34.2).

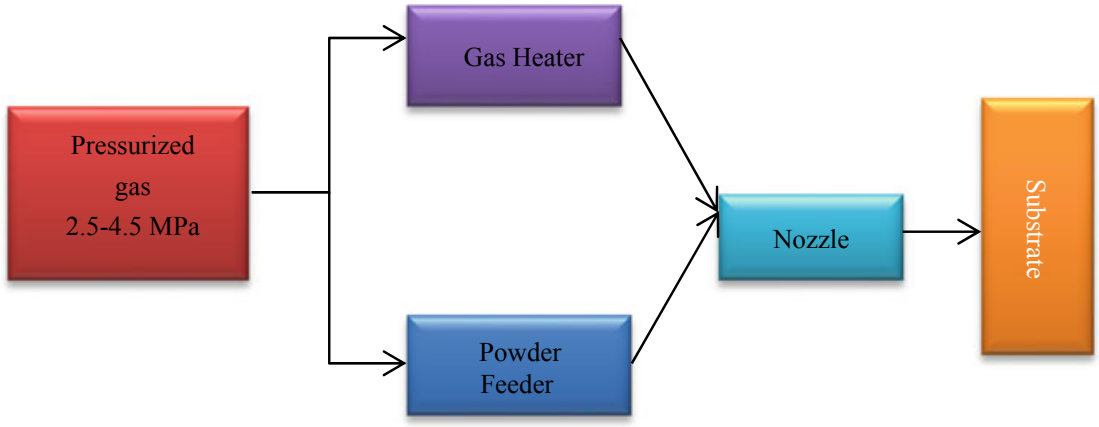

Fig. 34.1 High-pressure cold gas dynamic spray system

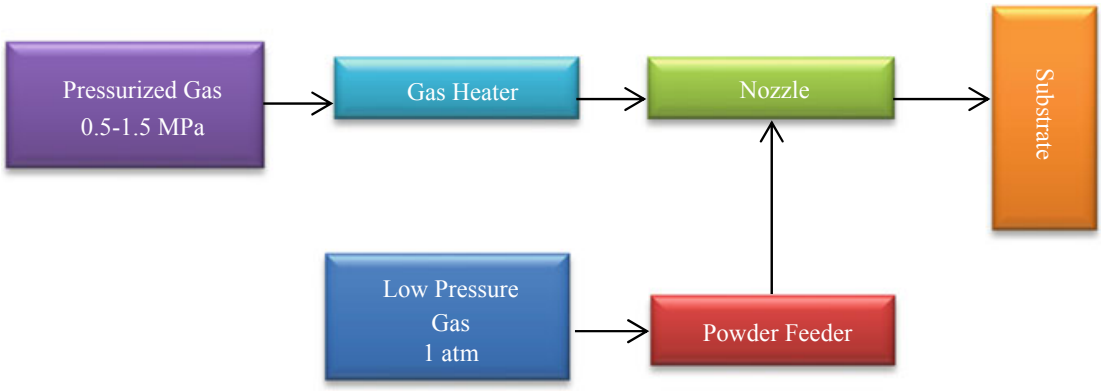

Fig. 34.2 Low-pressure cold gas dynamic spray system

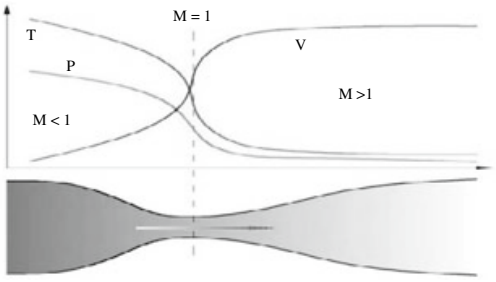

Fig. 34.3 Pressure, velocity and temperature variation in convergent–divergent nozzle

Generally, the pressure of working gas is between 0.5 and 1 MPa, and the flow rate is about 0.5–2 m^3/min. In LPCS, the design of the nozzle at exit is limited to Mach number less than 3, and inlet pressure is also less 1 MPa. If it exceeds, then atmospheric pressure is not able to supply powder particles into the nozzle. Due to this restriction, only low velocities particle reached into the nozzle. There are different variants of the standard apparatus of cold spray like kinetic metallization, pulsed gas dynamic spraying and vacuum cold spray.

KM is a variant of cold gas dynamic spraying that uses a convergent nozzle to achieve Mach number 1 at the exit of the gas velocity and small divergence for the compensation of friction impact. The deposition efficiency of micro- or nano-sized particles either preheated or at normal temperature solely depends on the mechanical and thermal properties of the engineering materials [10] (Fig. 34.3).

34.2 Numerical Methodology

Modelling of high velocity has been done by ABAQUS/Explicit using the code of finite element analysis (FEM). FEM has been commonly adopted for impact analysis in the kinetic spray. Adiabatic condition has been assumed for all kind of impact phenomenon. Particle is in range of 10–20 μm with the axis-symmetric condition for the impacting single particle on the substrate. Aluminium, copper and titanium have been used for the high-velocity impact simulation. Both the particle and substrate have not been preheated, and the impact problem was assumed to be adiabatic. Elements for the geometries are four-node bilinear quad elements and also with reduced integration and hourglass control (CAX4R) [11]. Reference strain rate for all the materials is taken as 1. Johnson–Cook (J-K) plasticity approach has been used which deals with thermal softening, strain and strain rate hardening. The elasticity response assumed to be linear for both the materials. Considerations of gravity, friction and rebounding force have been neglected in this study. The

damage parameters are not considered in this study. For the J-K approach, the values of equivalent plastic strain (PEEQ) solely depend at the integration points. An isotropic condition has been assumed for both thermal and mechanical properties of the material. The boundary conditions for constraining the substrate and particle motion have been shown in Fig. 34.4. For both the particle and substrate, axis-symmetric boundary condition has been used. Fixed boundary condition is used for the right side of the substrate's surface. J-K plasticity approach has been used for the plastic deformation of the particle as well as the substrate. This model gives the rate dependency of material during plastic deformation. Thermal softening, strain hardening and strain rate sensitivity are also defined for the model. The equivalent flow stress is given by as

$$\sigma_e = \left(A + B\epsilon_p^n\right)(1 + C\ln\epsilon^*)(1 - (T^*)^m) \tag{34.1}$$

where A and B are yield stress and work hardening parameter of the material. T^* is the homologous temperature. Different boundary conditions were used from ABAQUS/Explicit, i.e. symmetry about a plane where X is constant (XSYMM) and ENCASTRE where $U1 = U2 = U3 = 0$ (Table 34.1).

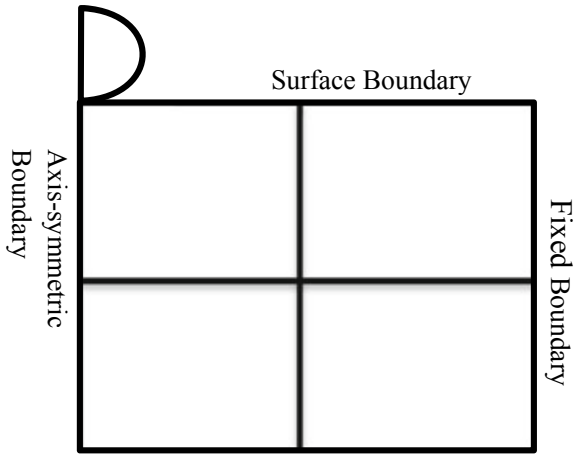

Fig. 34.4 Boundary conditions for the axis-symmetric single particle impact

Table 34.1 Properties of different materials

Material	Cu	Al	Ti
Density (kg/m^3)	8960	2700	7870

(a) Mesh Distribution in axis-symmetry Single particle impact. Number of elements and nodes are 12840 and 13075 respectively for 20 micrometer copper particle.

(b) Magnified view of Mesh at the contact zone of particle and substrate.

Fig. 34.5 Meshing of axis-symmetric impact behaviour of cold spray

Meshing plays a very crucial role in every computational problem. It also plays a vital role in the estimation of computational cost. Different meshing has been used like the diameter of particle (d_p)/32, d_p/35 and d_p/40. It was found that after d_p/40, there were no improvements in the results occurred. So, d_p/40 meshing size as shown in Fig. 34.5 has been used for all the computational impact problem in cold gas dynamic spray.

34.3 Results and Discussion

Copper particle having a diameter of 10 μm at a diameter of particle (d_p)/40 meshing at different velocities and also different values of equivalent plastic strain (PEEQ), compression ratio and flattening ratio, etc., were found for checking the adequate bonding between them. Figures 34.6 and 34.7 show that the flattening ratio and compression ratio are totally depended on the velocities and mechanical properties. Figure 34.8 also shows that values of PEEQ solely depend on the velocity of particle and substrate materials. Thermal properties also play a very important role for the deformation of the particle, i.e. if the specific heat of the material is low, then the particle will plastically deform at low velocity.

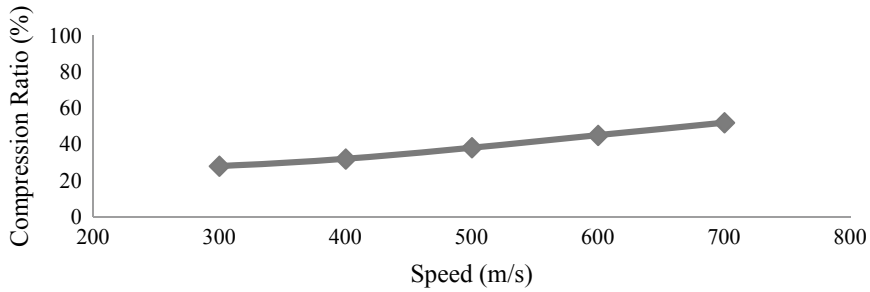

Fig. 34.6 Variation of compression ratio vs increasing the speed of 10 µm copper particle with meshing size $d_p/40$ using the lagrangian approach

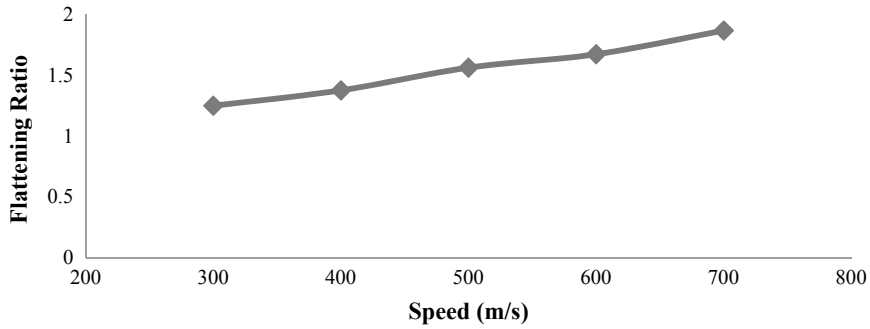

Fig. 34.7 Variation of flattening ratio by increasing the speed of 10 µm copper particle with meshing size $d_p/40$ using the lagrangian approach

34.3.1 Deformation Behaviour of Soft Particle on Hard Substrate

It has been seen from Fig. 34.9 that the deformation behaviour of a soft particle like aluminium when impacted on the hard substrate than splattering phenomenon occured. When micro-sized particle impacts at a certain angle like 30°, 45° and 60° especially when the particle made of soft material, splattering of the particle occurs on the surface of substrate with minute crater.

Formation of the jet by the deformation of the particle also been seen that removes the oxide layer from the surface. As shown in Fig. 34.9, when 20 µm aluminium particle is impacted at a different angle, then deformation behaviour is totally different from the perpendicular impact.

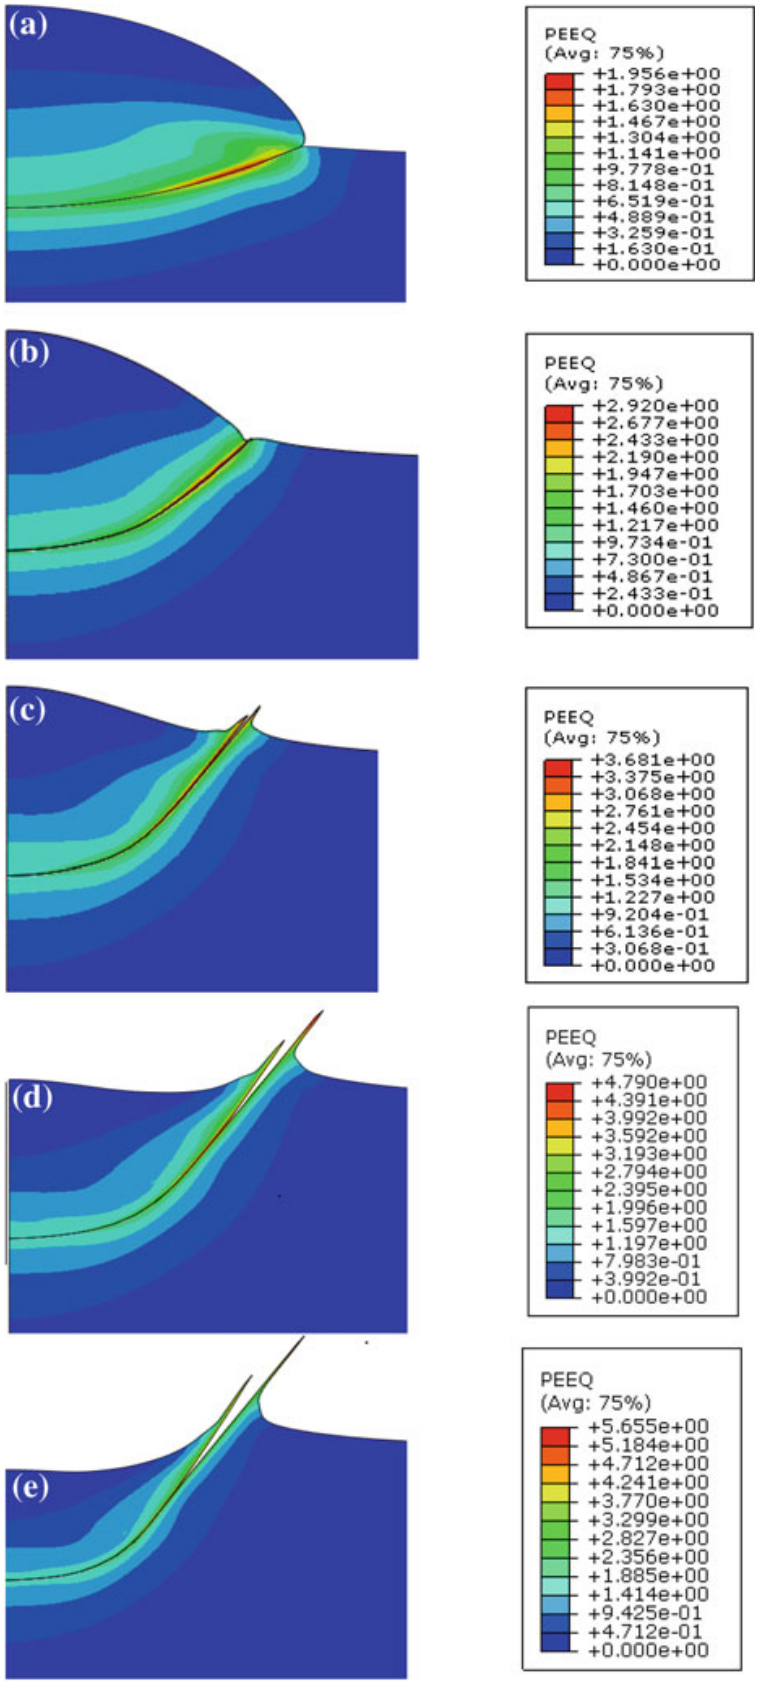

Fig. 34.8 Contour of 10 µm diameter of the copper particle with copper substrate and PEEQ at different velocities **a** 300, **b** 400, **c** 500, **d** 600 and **e** 700 m/s respectively

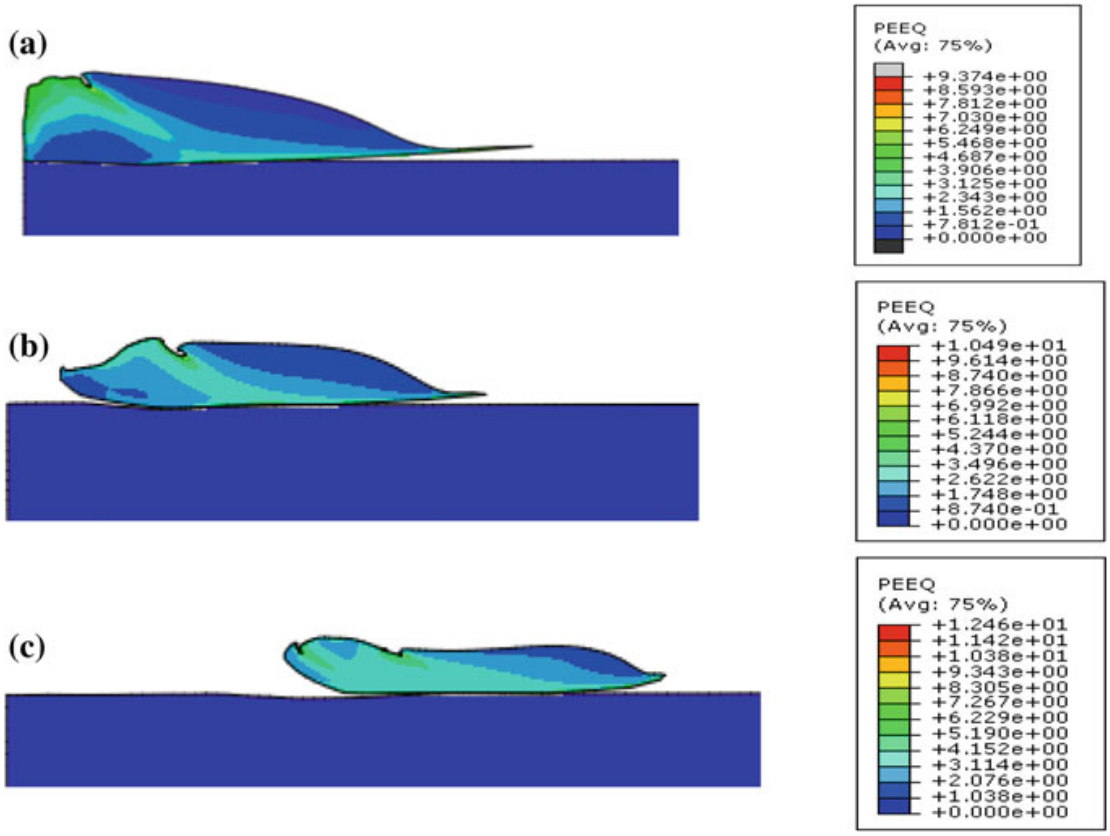

Fig. 34.9 Contour and values of PEEQ for 20 μm aluminium particle on titanium substrate at an angle of **a** 30°, **b** 45° and **c** 60° at 750 m/s, respectively

34.4 Conclusion

Different ranges of micro-sized particles have been probed during the plastic deformation process using kinetic spray technology. It has been investigated that for same particle and substrate, the critical velocity which is required for proper bonding, contour and crater formation and also for the adequate penetration is in the range of 500–560 m/s. Critical velocity has been very important for the adequate metal coating on the substrate by cold gas dynamic spray.

On the contrary, using soft particle and impacting on the hard substrate, it has been probed that huge amount of increment in the critical velocity or adequate penetration requires more particle velocity as compared to same particle/substrate. In this impact condition, homogeneity and uniformity of metal coating have occurred which indicates better coating. Lastly, the inclination angle also played a crucial role in the splattering and uniformity in metal coating using cold spray.

Chapter 35
Towards an Improved Understanding of Stereolithography Process—A Computational Study

Usharani Rath and Pulak M. Pandey

Abstract Amongst various futuristic manufacturing technologies, additive manufacturing is fast emerging from the lap of laboratory-scale testing to full-scale commercial applications. Stereolithography of polymeric materials has the potential to offer cost-effective and accurate solutions for many industrial sectors such as automotive, aerospace and electronics. However, the process of understanding and comprehending the underlying physics of the liquid additive manufacturing process is still in its infantile stage. In the present work, an attempt was made to computationally model the laser beam and the photosensitive resin interaction in the stereolithography process. The laser source was considered as a Gaussian heat source, and the liquid vat was considered as a homogenous isotropic fluid domain. Finite element modelling approach was utilized to evaluate the thermal changes occurring during the photo-initiated curing process. The resultant process quality indicators such as transient temperature distribution across the liquid vat, conductive and radiative heat flux, laser intensity on the liquid layer and its diminishing impact across the layer thickness were computed and compared. Maximum local temperature as high as 390 K was found on the irradiated location which cools down rapidly due to heat conduction and diffusion. However, the temperature reduces exponentially with the height of resin vat, and it takes around 4 s for the irradiated point to cool down to the ambient temperature and gets cured. Approximately 1.1×10^6 W/m^2 of laser intensity is produced on the bottom surface of laser. Some selected results were validated with contemporary literature and found to be satisfactorily consistent.

35.1 Introduction

3D printing technology has been a watershed across the manufacturing industry in the last two decades. Some distinct features, such as ability to produce any complex three-dimensional geometries from a CAD file employing a layer-by-layer approach, zero material wastage, nearly net shape production of parts and enhanced automation leading to improved process capability, make these set of additive technologies futuristic and transformational. This solid free-form fabrication technique uses layer-by-layer approach to obtain physical objects from a CAD model by generating material deposition path or laser scanning path.

Stereolithography is one of the pioneers and widely used 3D printing technique utilizing photosensitive liquid resin as the feedstock. The pre-programmed laser cures the liquid resin vat in a layer-by-layer approach resulting from the chemical crosslinking of the monomer resin to produce solid 3D polymeric components as designed by the input CAD model. It produces physical 3D objects with highest precision and accuracy as compared to other commercially available 3D printers such as selective laser sintering or fused deposition modelling.

A good number of research expeditions are reported on stereolithography process and its capabilities. However, the process modelling and analysis of underlying physics of stereolithography process are still in its early stages, and very few research contributions are reported on the same. Huang et al. [1] generated dynamic finite element code for evaluating the shrinkage effects in constrained-surface stereolithography process. They suggested that the surface tension of liquid resin

and shape of physical model may give rise to the inaccuracies of 3D-printed parts. Lee et al. [2] utilized artificial neural network to build up a model that can predict the effects of process parameters on the build accuracy of stereolithography process. They also mentioned that understanding the process physics can improve the process performance of the photo-curing process. They concluded that reduced layer thickness and increased hatch spacing improved the part performance. Bartolo [3] compared the phenomenological approach with the mechanistic approach for the stereolithography process. They suggested that the photo-curing process is an exothermic reaction increasing the local temperature of the irradiated region which gradually diminishes through conduction, convection and diffusion. Furthermore, they also implied that the fraction variation contour has similar resemblance as that of laser intensity which is conical. It was also explained that the local temperature and light intensity can lead to increased curing reaction and reduced printing time. Jiang et al. [4] utilized a dynamic finite element-based method to anatomize the shrinkage effects occurred during conventional stereolithography and mask-based stereolithography processes. They could also investigate the presence of residual stresses during the stereolithography process. Emami et al. [5] developed an analytical model for scanning-projection stereolithography process. They evaluated and compared the total laser energy intensity received by projection stereolithography and scanning-projection stereolithography processes during curing of each layer. They also indicated that SPSL process produces better accuracy than the PSL process. Liravi et al. [6] adopted cohesive zone model and conducted finite element simulation to predict the separation force existing between the cured part and the resin tray. Bae et al. [7] proposed a segregation model to determine optimum process parameters for direct ceramic stereolithography. The model was developed from the degree of segregation and the time constants such as writing time and settling time. Bikas et al. [8] recommended that the major cause of poor quality and inaccurate parts in additive manufacturing lies in the limited available modelling and optimization approaches.

In the light of the literature survey, it was realized that the quantum of research on the modelling and simulation of stereolithography process is scanty. However, from the research contributions by Bartolo [3] and Jiang et al. [4], it has been established that modelling of the stereolithography process can lead to better understanding of the underlying physics and improve the process performance. However, none of the research papers reported the transient temperature distribution along the resin surface and along the depth. Furthermore, findings regarding the laser intensity variation along the depth of resin are also very few.

Thus, in the wake of the aforementioned literature explorations, the objective of the present research investigation was formulated to vindicate some of the underlying physics of the stereolithography process. In the present study, the finite element analysis of the bottom-up stereolithography process was carried out for a single-layer curing of resin vat. As an outcome, the transient temperature distribution, laser intensity variation, conductive and convective flux contours, transient residual stress distribution and variation on the resin surface were evaluated and analysed for improved part quality and better process performance.

35.2 Process Modelling

A finite element-based commercial multi-physics software package, COMSOL, which operated under Windows 64-bit operating system, was used for the simulation study. The physical model of the present study primarily consists of a methyl methacrylate resin vat of 10 cm length, 5 cm width and 3 mm height. The fluid properties of resin and specifications of laser used in bottom-up stereolithography set-up are presented in Tables 35.1 and 35.2. The UV laser was considered as a moving heat source which travels across the bottom surface of resin vat. The X-coordinate of laser beam follows a ramp function with a slope of 1/50, so that the laser moves 10 cm distance along X-direction in 5 s.

35.2.1 Assumptions

There are broadly five assumptions considered in the present modelling expedition in line with the spirit of some of the reviewed literature [3, 4] and the contemporary understanding of stereolithography process.

1. The model was considered as a homogenous and isotropic fluid domain.
2. The effect of optical scattering was not considered.
3. Convection effects were taken as negligible as air is quiescent inside the stereolithography chamber.
4. The heat generation was considered to be only due to heat of polymerization as the stereolithography process is governed by photo-curing reaction.
5. The absorption of UV laser intensity was considered to be governed by Beer–Lambert's law.

Table 35.1 Resin fluid properties

Serial number	Properties	Value
01	Density (g/cm^3)	1.12
02	Dynamic viscosity (Pa s)	890
03	Thermal conductivity (W/mK)	0.25
04	Specific heat (J/kgK)	1500
05	Ambient temperature (K)	298.15
06	Emissivity	0.9

Table 35.2 Laser specifications

Serial number	Specifications	Value
01	Power (mW)	120
02	Wavelength (nm)	405
03	Spot size (mm)	0.155
04	Radiation	Ultraviolet

35.2.2 Governing Equations

A set of governing equations were used in the current study to model the physics of heat transfer due to laser radiation. There are two equations governing the three-dimensional transient energy equation and absorption of UV radiation (Beer–Lambert's law) by the liquid resin vat, given by Eqs. 35.1, 35.2 and 35.3, respectively. The governing Equation 35.1 is solved considering the heat source 'Q' as a Gaussian heat source.

$$\rho C_{\mathrm{p}} \frac{\partial T}{\partial t} + \rho C_{\mathrm{p}} u \nabla T + \nabla \cdot (-K \nabla T) = Q \tag{35.1}$$

$$I_{\mathrm{s}} = I_0 \exp[-2 \times (s/w)^2] \tag{35.2}$$

$$I_Z = I_0 \exp\left(\frac{-z}{D_{\mathrm{P}}}\right) \tag{35.3}$$

where ρ, C_{p} and K are the density, specific heat capacity and thermal conductivity of liquid resin used, respectively. Q is the heat generated from the photo-curing exothermic reaction. I_{s} and I_0 are the laser intensity at the resin bottom surface and the original laser intensity, respectively. s and w are the coordinate of irradiated point and laser spot width, respectively. I_Z is the laser intensity at a height z from the bottom surface of resin vat. D_{P} is a material property of the photo-polymeric resin, known as penetration depth.

35.2.3 Beer–Lambert's Law

Beer–Lambert's law is utilized to establish a relation between the depth of penetration of a light source in a material and the attenuation coefficient of the material. The attenuation coefficient of the material is inversely proportional to the material property $(D_{\mathrm{P}})$of the medium through which the material is travelling. A material or medium with higher attenuation coefficient is supposed to have reduced depth of penetration of light source travelling through it. Equations 35.2 and 35.3 govern the Beer–Lambert' law at the resin vat bottom surface and at a specific height from the bottom surface.

35.2.4 Domain and Boundary Conditions

Various boundary and initial conditions were applied in the present model for the UV radiation and subsequent phenomena such as transient heat conduction,

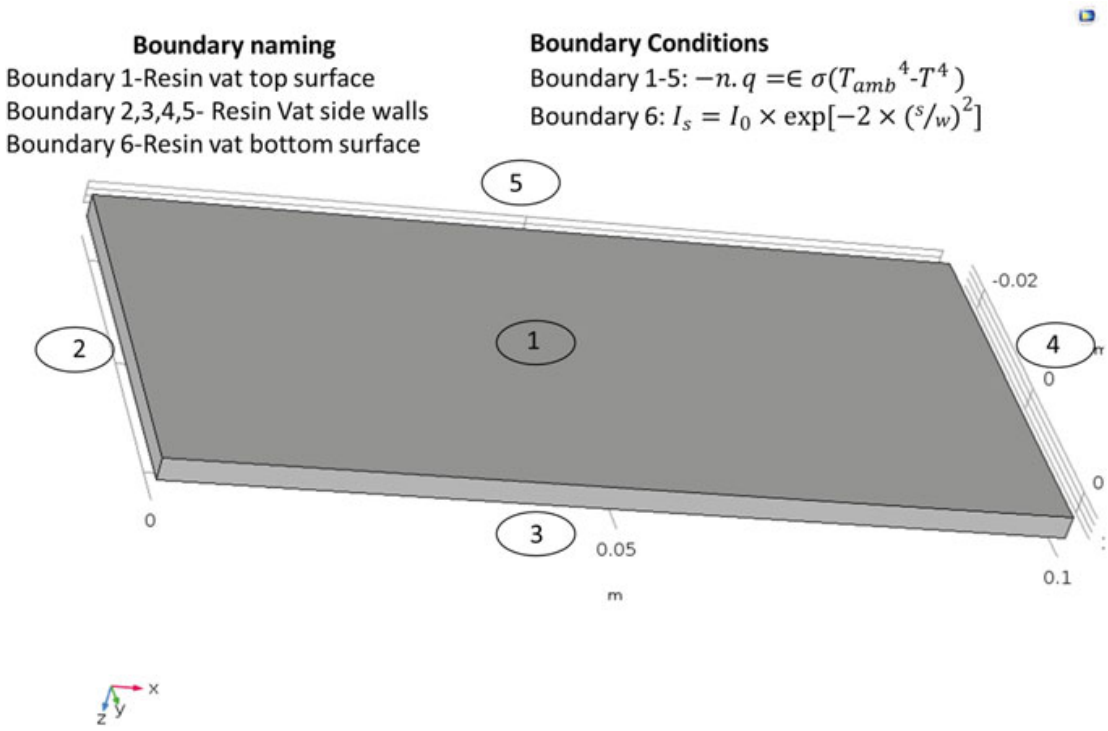

Fig. 35.1 Geometric model with boundary and initial conditions

convection and diffusion to happen. The boundary and initial conditions are clearly depicted from Fig. 35.1. A single rectangular fluid domain was considered for the simplicity of the model with six boundaries. Boundary 1 was considered as the top surface of the resin vat, and boundaries 2, 3, 4 and 5 were modelled as the side surfaces of the resin vat. Boundary 6 was considered as the bottom surface of the resin vat, on which the laser light was irradiated.

35.2.5 Meshing

A customized meshing chronology was used to discretize the three-dimensional geometric model of resin vat. Tetrahedral meshing was done with a maximum element size as 0.001 mm for the entire domain for the convergence of the solution. A total of 536,841 numbers of elements were generated. The model generation and succeeding analysis were done using COMSOL commercial software package. The simulation was performed for an irradiation time of 5 s with 0.1 as the time step and 0.001 as the relative tolerance of the simulation study.

35.3 Results and Discussion

The dynamic temperature variation on the bottom surface of resin vat is represented in Fig. 35.2. The maximum local temperature obtained during the curing process at the point of irradiation was predicted to be 390 K, which diminishes to ambient temperature by heat conduction and diffusion in a very short span of time. Furthermore, it can also be clearly visualized that the temperature rise due to irradiation at each irradiated point is maximum and reduces radially as per the Gaussian distribution. The variation of temperature with the height from the bottom surface of resin vat at a particular irradiated point is represented in Fig. 35.3. The decrease in temperature with height signifies that the absorption of UV radiation on resin vat is according to the Beer–Lambert's principle. Nonetheless, further slight increase in temperature might be caused due to the diminished conduction and diffusion as compared to the bottom surface. The variation of temperature with time at a particular irradiated point (boundary 2) on the resin bottom surface is also shown in Fig. 35.4. The curing profile of the photo-polymeric resin is in accordance with the star-weave build structure, which resembles a conical shape [9]. The laser intensity distribution follows a conical pattern as presented in Fig. 35.5, validating the work done by Bartolo [3]. Moreover, the laser intensity reduces from the bottom to top surface of resin vat in accordance with the Beer–Lambert's principle as represented in Eq. 35.3 and cures the resin irradiated beyond the critical laser intensity. The value of critical laser intensity varies depending on the resin and

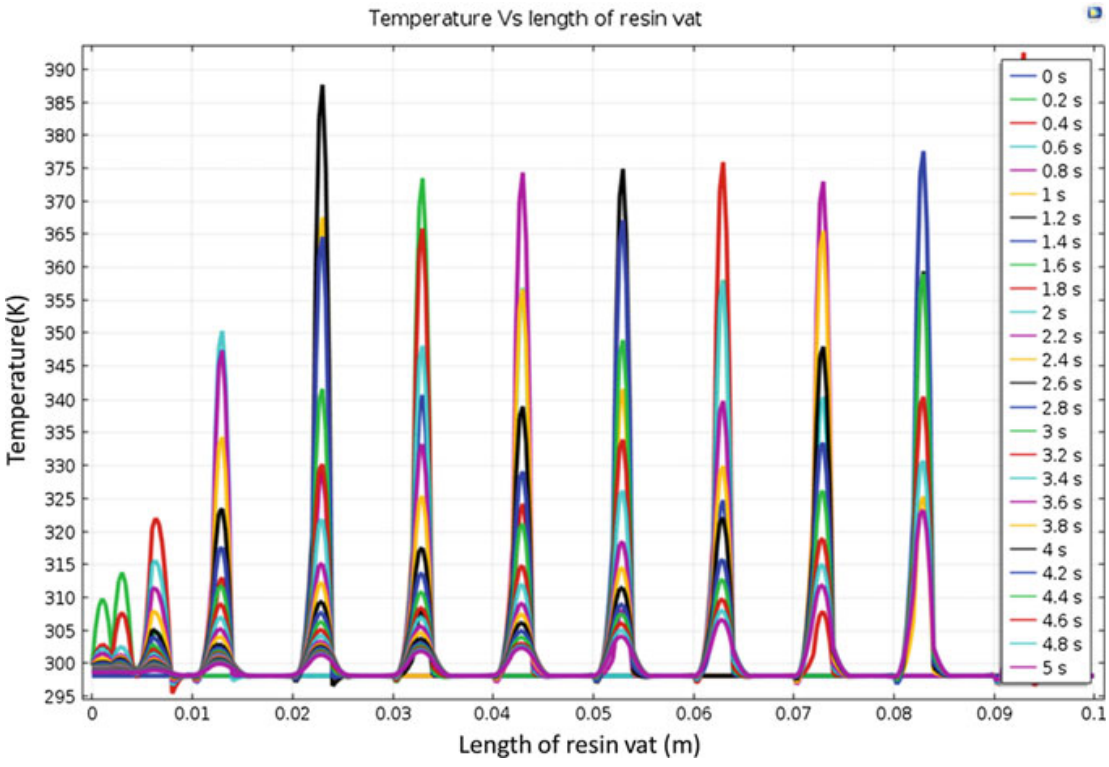

Fig. 35.2 Temperature variation on the bottom surface of resin vat

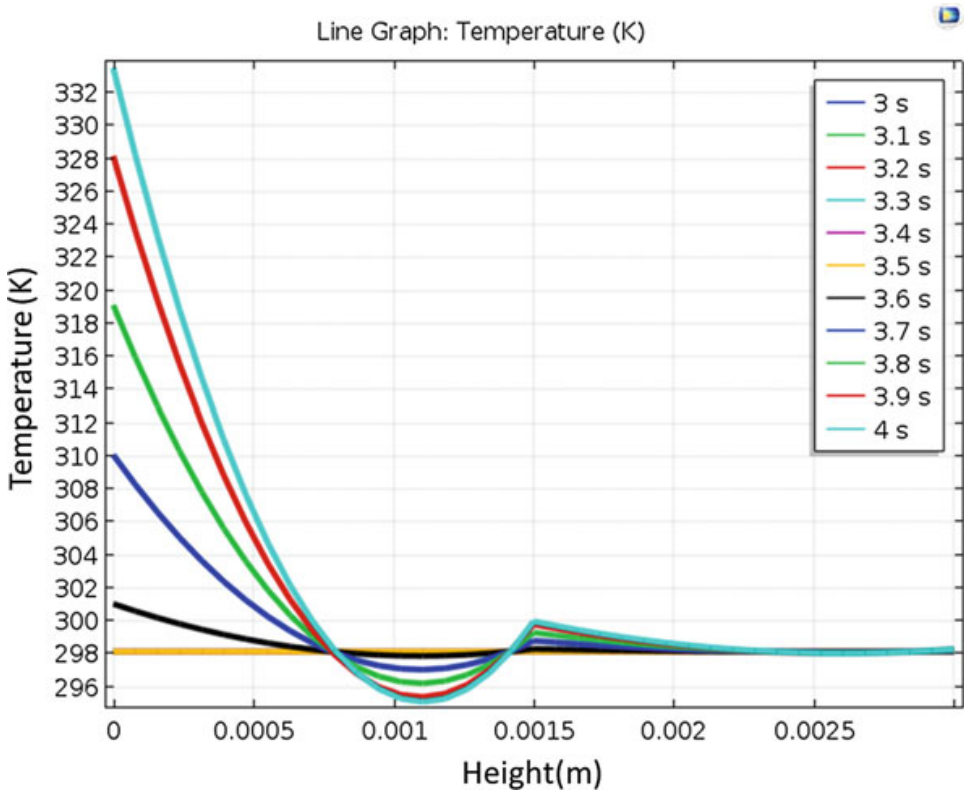

Fig. 35.3 Temperature variation with height of resin vat

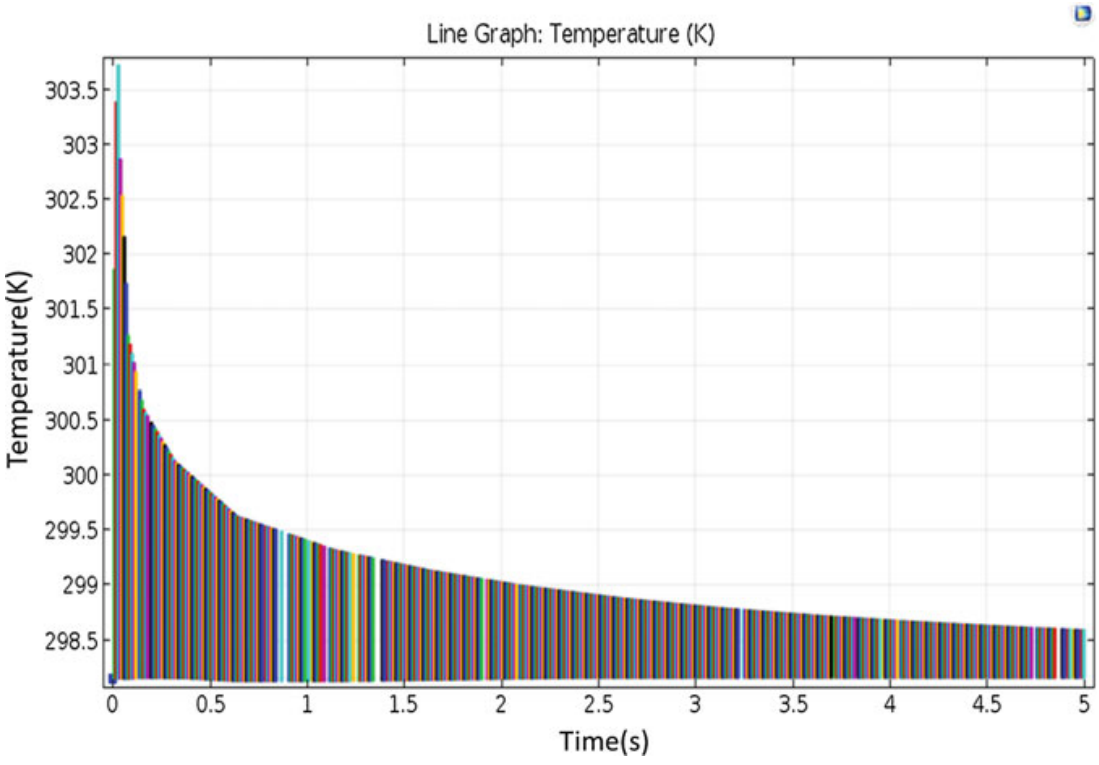

Fig. 35.4 Temperature variation with time

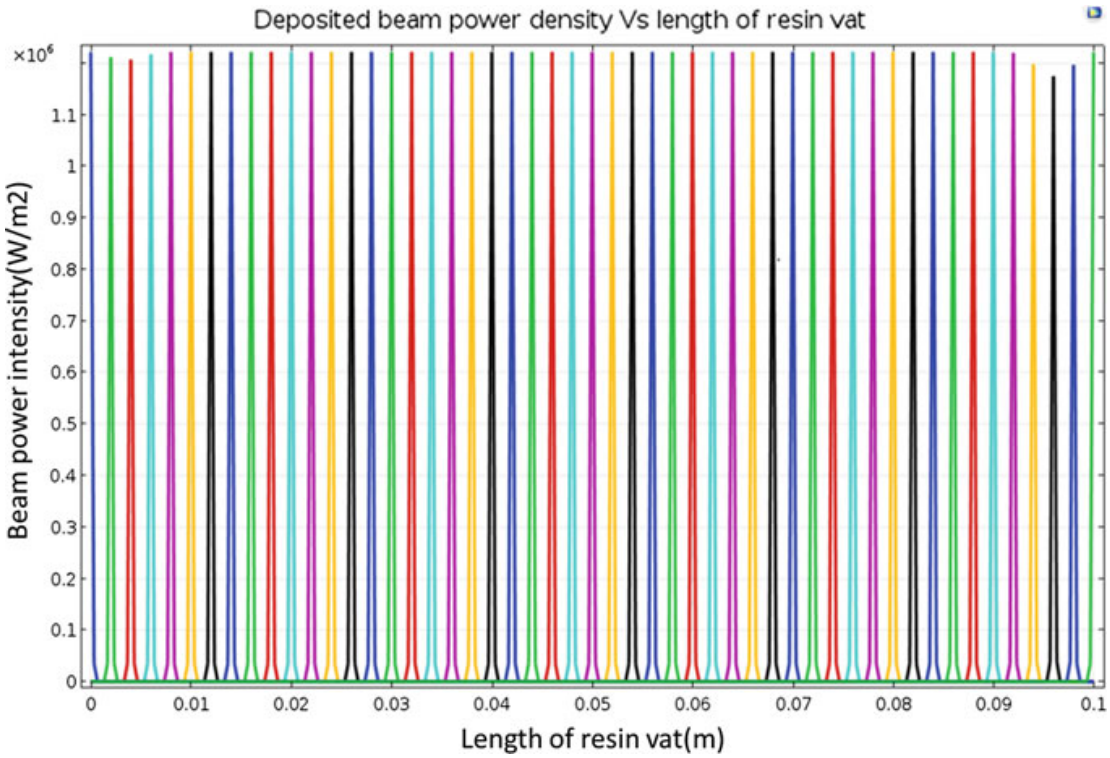

Fig. 35.5 Laser intensity variation on the bottom surface of resin vat

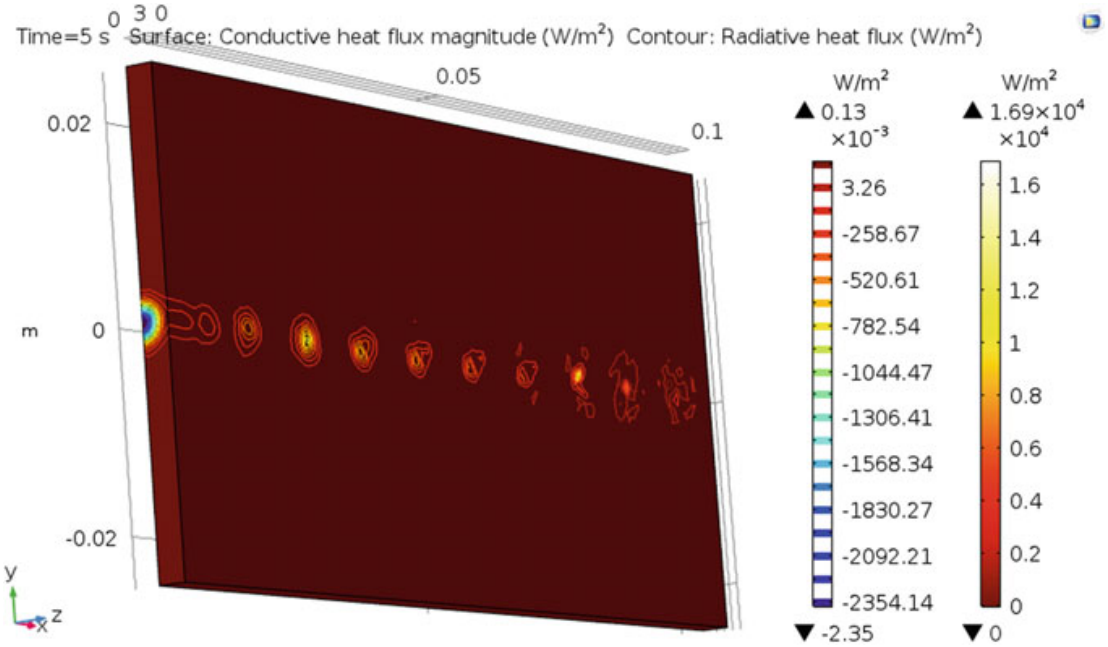

Fig. 35.6 Conductive heat flux contour

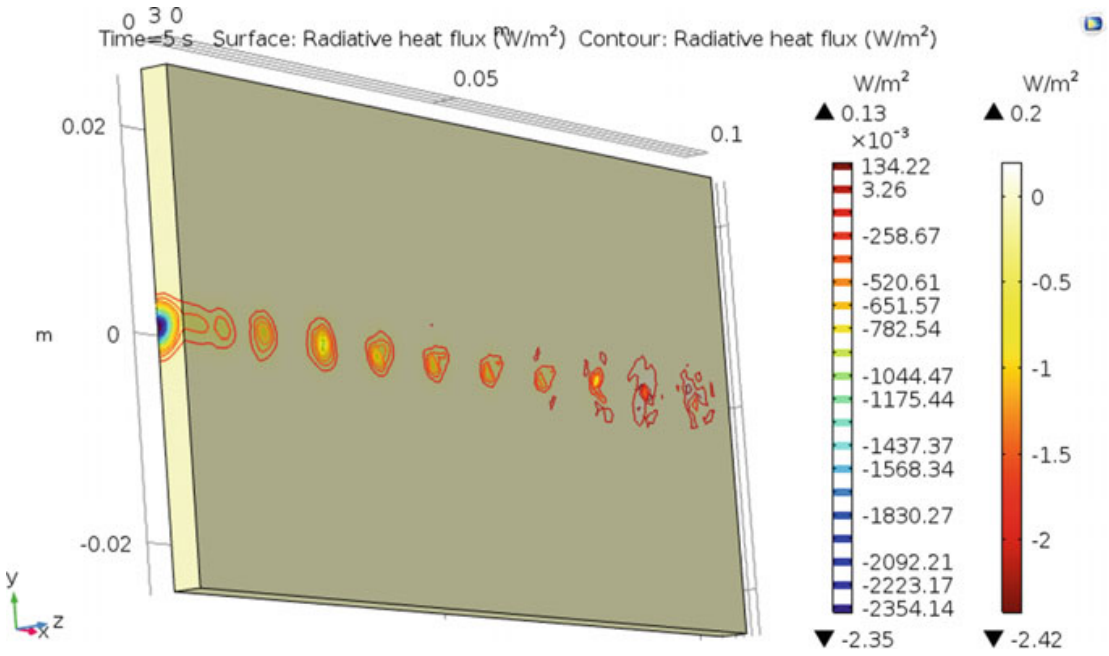

Fig. 35.7 Radiative heat flux contour

machine specifications. It can be evaluated by conducting a good number of experiments and plotting the semi-logarithmic graph between cure depth and logarithm of maximum exposed laser energy. The local heat generation and subsequent temperature rise due to exothermic photo-curing reaction decline expeditiously by heat conduction and diffusion. The conductive heat flux and radiative heat flux contours are depicted from Figs. 35.6 and 35.7, respectively.

35.4 Conclusions

A macroscopic model established by finite element method using the governing equations for the physical changes occurring during the stereolithography process was proposed. The following inferences can be deduced from the research work.

1. The transient temperature history on the surface and along the depth of the liquid resin irradiated by ultraviolet laser light with 405 nm wavelength was analysed.
2. Irradiated zone of resin undergoes a local increase in temperature as high as 390 K, which reduces quickly due to the advent of conduction and diffusion.
3. Laser intensity cures the laser across the depth in a conical manner, resulting in the prediction of fractional conversion contour of liquid resin to the green-state/semi-solid resin as conical [3]. The bottom surface of resin vat was irradiated with a laser intensity of 1.1×10^6 W/m^2.

The simulation approach can be improved further by considering the chemical kinetics of the photo-curing reaction, which involves the monomer and photo-initiator concentration in the liquid resin.

Chapter 36
Experimental Investigations for Effects of Raster Orientation and Infill Design on Mechanical Properties in Additive Manufacturing by Fused Deposition Modelling

Pushpendra Yadav, Ankit Sahai and Rahul Swarup Sharma

Abstract Manufacturing and designing of various functional components in the fields of engineering, automobile and aerospace are being done by additive manufacturing (AM) technology. These activities must be supported by the knowledge of process parameters that may influence mechanical properties of industrial products. Fused deposition modelling (FDM) is one of the most popular AM technologies in which the quality of part depends on selection of process variables. The present work focuses on two input process parameters, i.e. raster orientation and infill density and its effect on the mechanical properties of 3D-printed samples. The PLA samples were prepared in *XY* and *XZ* orientation with infill density of 20, 40, 60, 80 and 100%. The tensile testing is conducted to evaluate the effects of these process parameters on tensile strength, ultimate strength, etc. Further, fractography was performed and it is concluded that dimple size and distribution on fractured surface were affected by the infill density. Printing time was also checked and compared for specimens printed for different parameters, which shows printing time is least for *XY* orientation and maximum for *XZ* orientation. Printing time increases as the infill density increases from 20 to 100%.

36.1 Introduction

3D printing is considered as the future of the technology in the world and is a manufacturing phenomenon that will revolutionize industries, factories and mass production in the coming years. With the advent of Industry 4.0, 3D printing has become a buzzword in almost all industrial sectors. Although 3D printing technologies took birth in the 1980s, mainly by the name of rapid prototyping, they got a fresh impetus in this century and have been growing at an exponential rate in last few years [1]. This technology allows designers to quickly and inexpensively produce prototypes without tooling or machining which act as catalysts to students, researchers, scientists and innovators to rapidly produce prototypes based on their imagination and thus 3D printing is helping users across all age groups to enhance product manufacturing by simplification in working. Some economists have considered this a third industrial revolution following mechanization and assembly line production [2]. This industry has grown quickly in recent years to an annual value of over $5 billion. Sales of 3D desktop printers were 160,000 in 2014 and grew to nearly 300,000 in 2015 [3]. Some predictions have shown that the 3D printing total market revenue will be between $7 and $23 billion per year by 2020. Because of this massive expansion and growing significance, FDM 3D printing is being studied in the areas of medical, aerospace, building equipment, materials, preparation techniques, etc. and is still the subject of research [4–8]. 3D printing is far different from traditional manufacturing processes and saves lots of build time, production waste and can be easily worked by ordinary workers as compared to skilled machining, forging, casting, etc. where skilled workers are required to complete the job. But with any manufacturing process, it is important to focus on resource saving and environmental issues and with the new technologies coming up in 3D printing, it is necessary to pay more attention to its sustainability in context to the present scenario before we integrate 3D printing with industrial set-up. The sustainability studies will also help scientists, researchers and other decision makers to understand the 3D printing process and its implications in different applications or products [7]. Therefore, it is extremely important to understand the influence of process variables or parameters on product development. These variables can be classified in: material properties, build specifications, part positioning and orientation and environment [8]. A similar study was developed by Ziemian et al. [9] in which the group evaluated the effect of raster orientation in the direction of the strain and developed the optimal levels for improving the strength of the specimen. The most studied parameters, in a static situation, have been build orientation, raster angle, raster width, raster-to-raster air gap and nozzle diameter or slice height [10, 11]. Some researchers have also analysed the effect of 3D printing in Engineering education which is suitable for classrooms and public spaces and encourages action-based learning, exploration and innovation, to accelerate the acceptance and involvement of 3D printing technologies in the manufacturing sector [12, 13].

Not many people have focused the research on the effect of infill density on the mechanical properties of PLA materials for different raster orientations. Therefore, the present work focuses on the effect of infill density on mechanical properties in *XY* and *XZ* orientation and its fractography analysis using scanning electron microscopy (SEM).

36.2 Fused Deposition Modelling Process

One of the most exciting and widely used additive manufacturing technologies is fused deposition modelling (Fig. 36.1) which is based on the material extrusion process. In FDM process, the polymer filament is fed to the liquefier chamber where it gets heated to a particular temperature depending upon the melting point of the material used for printing. Once the material is heated, it gets softens and melts and after that molten material is pushed through the nozzle from the liquefier with some suitable velocity. The extruded material in molten form is deposited on the platform layer by layer which slowly gets cooled at room temperature. The layer thickness and other parameters depend upon the G-code generated by the slicing software.

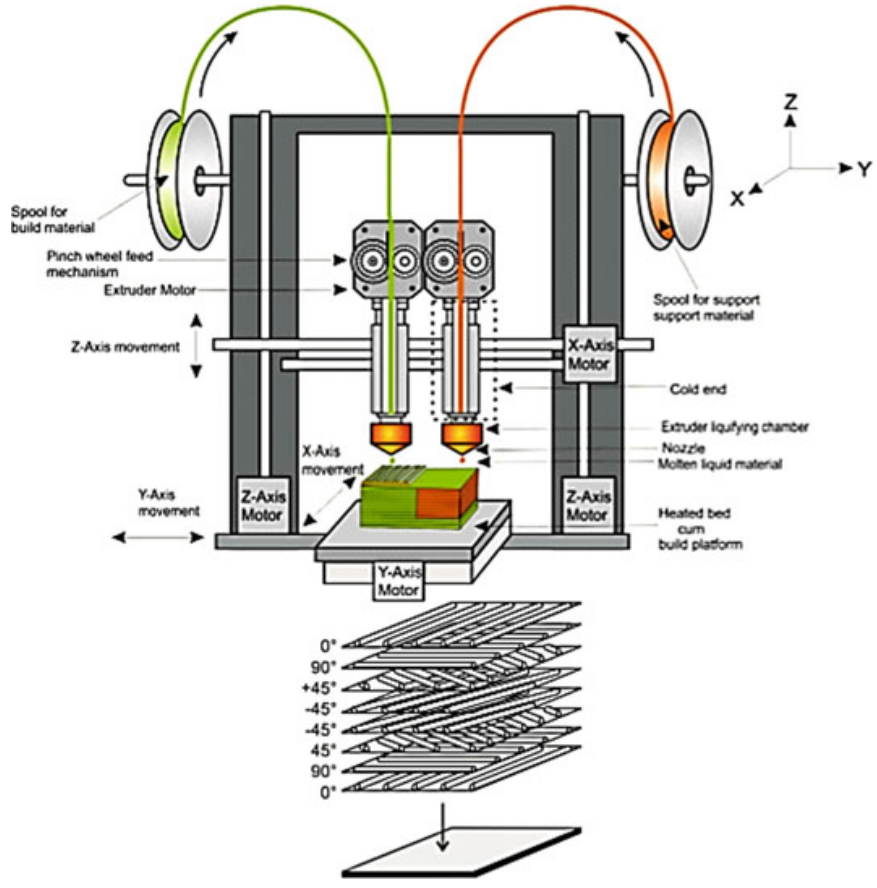

Fig. 36.1 Complete process of FDM process machine set-up

These 3D printers working in FDM technology are easy to design, build and quick to work upon. The students, researchers and even normal household users can easily install and work to produce the desired products using the different parameter combinations and of different shapes and sizes. These printers can be a great learning experience as the users can visualize, model and print in quick succession to get the rapid prototype of the specimen or product.

36.3 Experimental Details

In the present work, raster orientation and infill density are input parameters and based on their different combinations, mechanical properties like tensile strength and yield strength are calculated. The tensile test specimens were prepared based on ASTM D638, standard dimensions are used corresponding to Type-1 specimen in Fig. 36.2, and each sample set consisted of five specimens, Fig. 36.3. The geometry of the 3D-printed specimens was modelled using SolidWorks software exported as an STL file and imported to the 3D printing software. A 50 KN universal testing machine was used for tensile testing with speed of 5 mm/min, and fractography was performed using scanning electron microscope (SEM). The material used for current experiment is PLA.

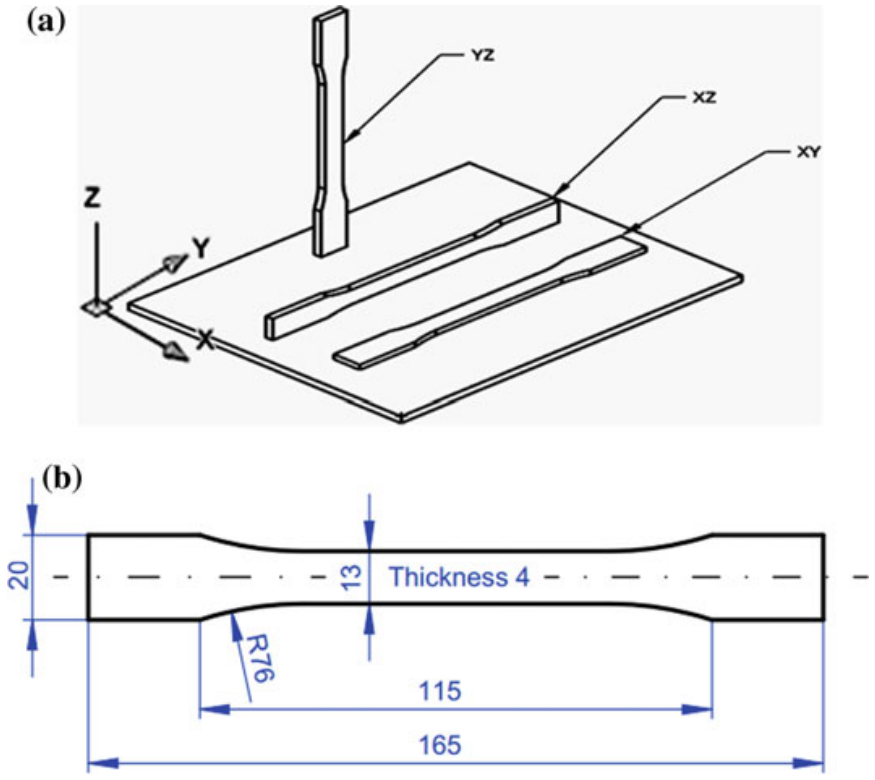

Fig. 36.2 Different raster orientations *XY*, *XZ*, *YZ* and ASTM D638 Type-1 tensile test specimen

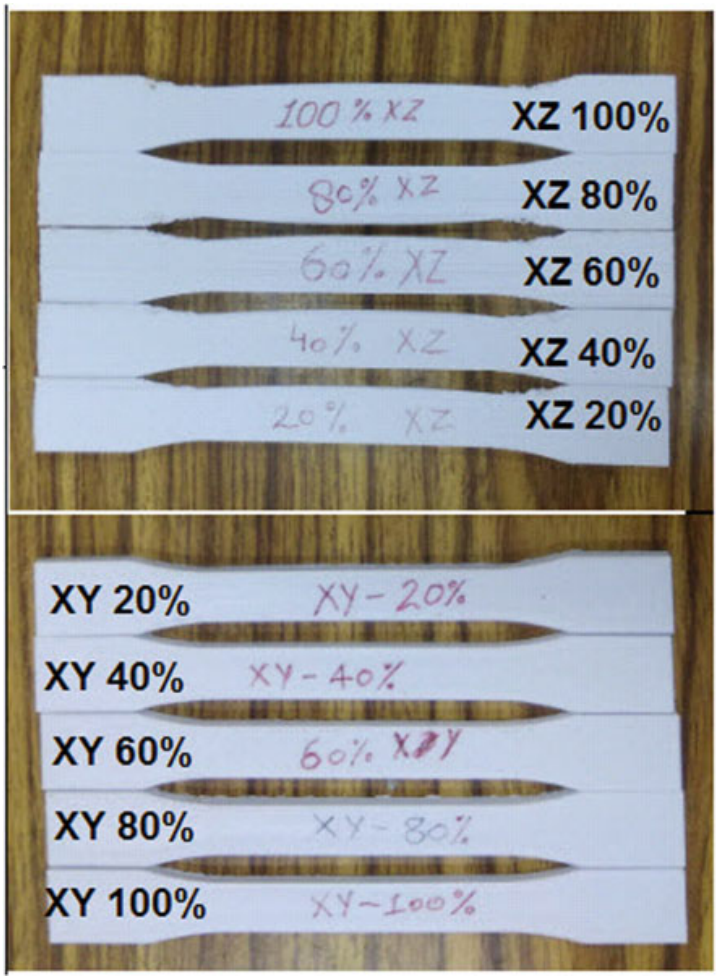

Fig. 36.3 Printed specimens in each orientation of *XY*-and *XZ*-directions

Before performing fractography, tensile tested samples were cut and gold (75%) and palladium (25%) coating was done for better image analysis. During experimentation, mechanical properties were evaluated for raster orientation *XY* and *XZ* as mentioned in Tables 36.1, 36.2 based on certain fixed parameters such as infill pattern, layer thickness, temperature and air gap while infill density and raster orientation were changed, Table 36.3.

Bed temperature	60 °C		*XY*

36.4 Results and Discussion

The experimentation was mainly focussed on the evaluation of mechanical properties with the variation in raster orientation and infill density. The stress–strain curve in Fig. 36.4 indicates that PLA-printed specimen in *XY* plane exhibits the maximum tensile stress 45.09 MPa and elongation as 14.68%. In *XZ* orientation,

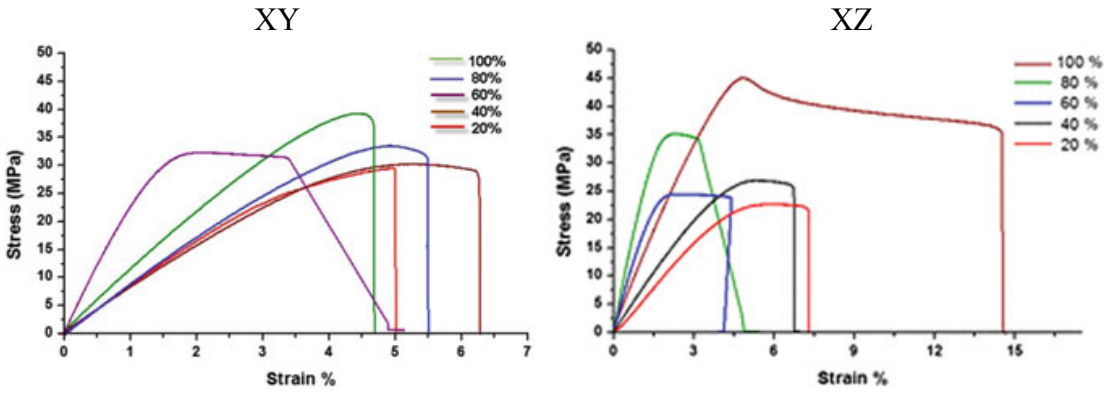

Fig. 36.4 Stress–strain curve for different infill densities in *XY* and *XZ*-raster orientations

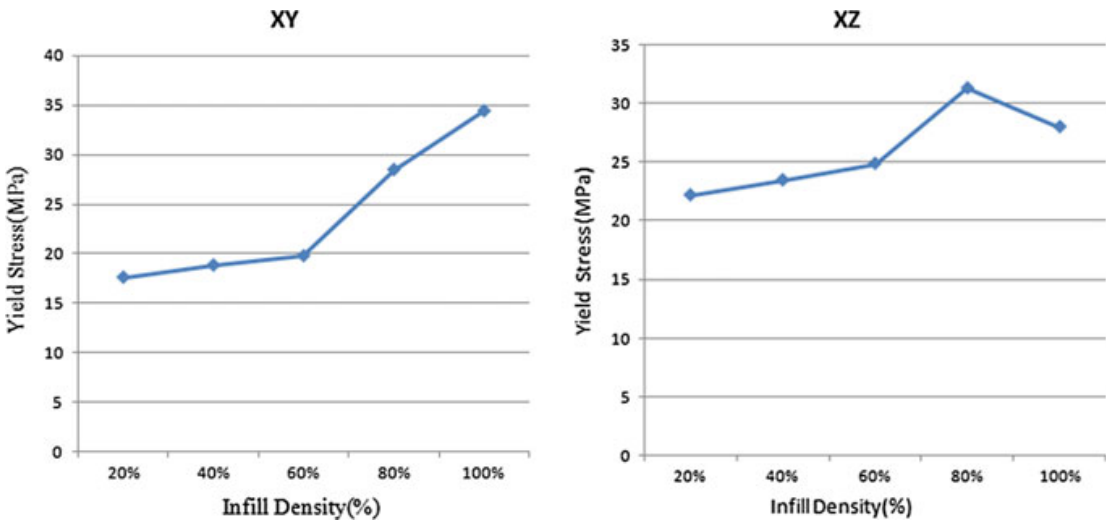

Fig. 36.5 Variation of yield stress for different infill densities and raster orientations

maximum tensile strength is 39.25 MPa for 100% infill density while maximum elongation is 6.3% for 40% infill density. The graph clearly indicates that the value of tensile strength in *XZ* for all infill densities are close to each other while in *XY* orientation the trend is completely different and the values range from 21 to 45 MPa. Figure 36.5 displays the variation of yield strength for *XY* and *XZ* orientation with different infill densities.

36.5 Fractography

In product design and manufacturing, failure analysis is an important part and, therefore, in this work the fractured surface of PLA specimens is also analysed using SEM for different raster orientations and infill densities, Fig. 36.6. It is depicted that ductile fracture is observed in *XZ* orientation as fibre is deformed in different planes leading to trans-layer tensile failure. The fracture gets transferred from one layer to another in *XZ*-direction. Specimens with *XY* orientation displayed intermediate brittle-ductile fracture behaviour. Failure is generally caused by raster pulling and rupturing as clearly depicted in Fig. 36.6. The fractured surface exhibits different fracture modes indicating hairline and major cracks marked with arrows at different location of fractured surface. In *XY* orientation, yield stress and elongation at break are more as compared to *XZ*, thereby exhibiting prolonged necking while applying tensile load as depicted in Tables 36.1 and 36.2. The strain (%) is more in *XY* orientation compared with *XZ* orientation. *XY* orientation shows brittle and ductile fracture which can be attributed to cooling rate behaviour during the solidification of material. The *XZ* orientation displays ductile fracture with dimples visible at different locations of fractured surface.

Figure 36.7 displays the printing time for different infill densities and raster orientations for PLA material. The printing time and number of layers for the tensile

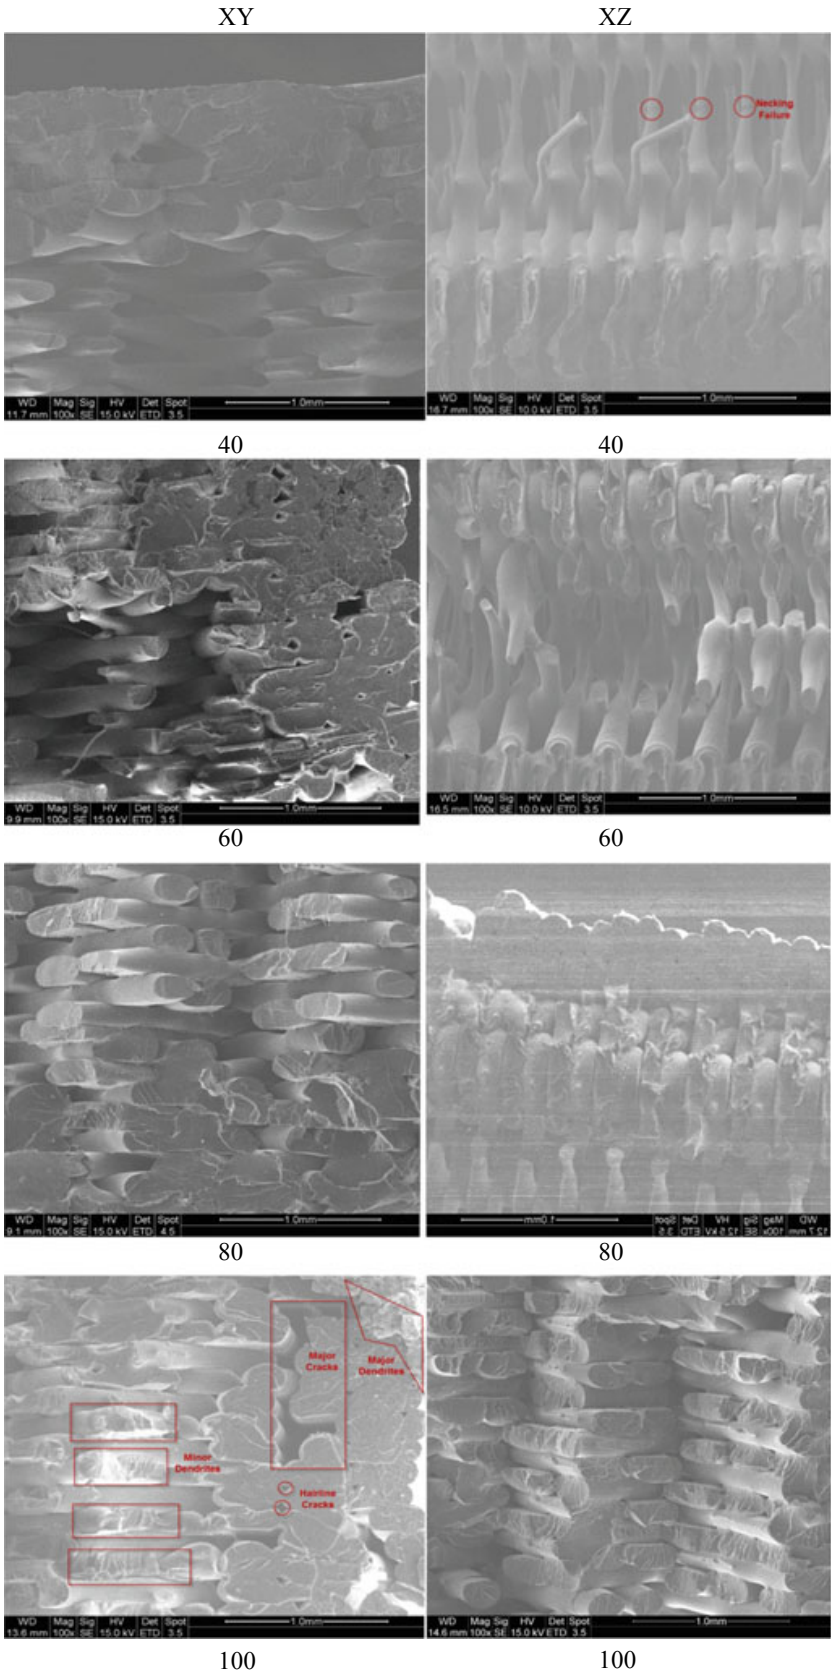

Fig. 36.6 SEM image fractured surface of *XY* and *XZ*-raster orientation and different infill density

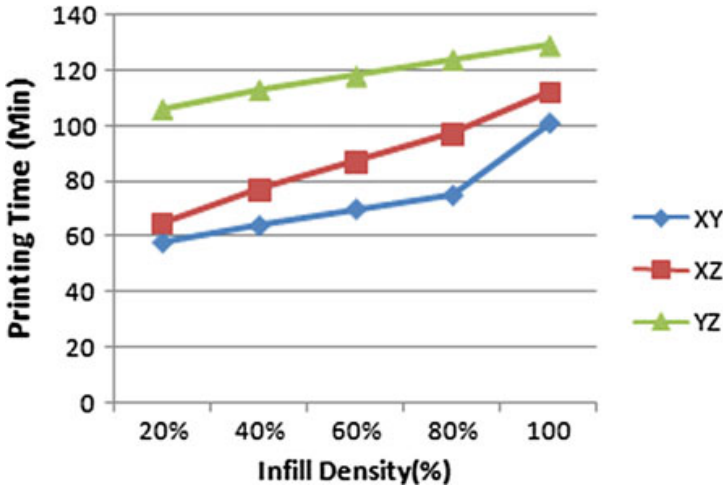

Fig. 36.7 Variation of printing time for various infill densities and raster orientations

samples depend upon the various process parameters such as raster orientation, layer thickness and feed rate. Also, the printing time is directly related to manufacturing cost [9]. Raster orientation *YZ* exhibited the longest printing time as compared to *XY* samples which have the shortest time. Printing time also decreases as feed rate is increased for *XY* orientation. In case of the *YZ* orientation, printing time remained almost constant for high feed rate values.

36.6 Conclusion

The research outlines the following conclusions:

- The maximum tensile stress in *XY* orientation is 45.09 MPa for 100% infill density with elongation as 14.68%, and similarly for the *XZ* orientation maximum tensile stress 39.256 MPa for 80% and elongation as 6.422% for 40% infill density.
- In *XY*-raster orientation, yield stress goes on increasing at different infill densities from 20 to 100% in step of 20. The maximum rate of change of yield stress is **0.958** with reference to 20% infill density. Similarly, in *XZ*-raster orientation, yield stress is increasing but at a smaller rate of change is **0.2618** with reference to 20% infill density. This clearly indicates that from yield stress point of view *XY* orientation is stronger than *XZ* orientation. This is also supported from Tables 36.1 and 36.2 that yield load is more at *XY* orientation as compared to *XZ* orientation.
- *XY* orientation has least printing time as compared to *XZ* and *YZ* orientation, with *YZ* taking maximum printing time.
- Fracture morphologies are affected by the raster orientation direction and infill density with *XY* orientation displayed intermediate brittle-ductile fracture behaviour while *XZ* displayed ductile fracture.
- Failure after tensile loading exhibits hairline and major cracks in *XY* orientation.

Acknowledgements The authors acknowledge the help from ACMS, IIT Kanpur for allowing to perform tensile testing and fractography. Support from TEQIP-III, Faculty of Engineering, DEI and MHRD NMEICT is highly appreciated.

Chapter 37
Development of Methods for Machine Intelligence Quotient Measurement for Piston Casting by Die Casting Machines: A Study

Rupshree Ozah and Muralidhar Manapuram

Abstract Pistons are the most important parts of an automobile engine. Pistons are manufactured by various die casting processes like sand casting, gravity die casting, pressure die casting and automatic die casting. Manufacturing assets and processes have different intelligent attributes based on embedded intelligent systems. Not much of work seems to be available for measurement and quantification of machine intelligent quotient (MIQ) for metal casting manufacturing machines. To assess the intelligence of die casting machines, three methods are developed. High MIQ indicates the lower interaction between human and die casting machine, i.e., the machine can take comparatively higher percentage of decisions in machine operations. In the present work, an attempt has been made to develop a stepwise procedure for MIQ measurement by three methods, i.e., human–machine cooperative system, geometric polytope method and multiple perspective analysis methods. MIQ for three die casting machines is computed based on human–machine cooperative method, and it has been found that automatic die casting machine has the highest MIQ (109.31) followed by pressure die casting machine (59.69) and gravity die casting machine (26.44) the lowest.

37.1 Introduction

Automobile industry is the fast growing and technology-intensive industry. India is the second-largest casting producing country in the world. Globalization has led to increase the pressure on engineers and technologists to increase the efficiency of casting manufacturing processes and assets to edge-over other manufacturing processes and cost effectiveness. With the advent of computers, Internet, intelligent techniques, Industry 4.0 and cyber physical system's decision-making attributes of machines have been increased significantly. But there are no systematic methods to measure MIQ of machines. Moreover, efforts of researchers to embed human intelligent attributes by various software programs and hardware devices enable to enhance MIQ. Various tools [1] used to communicate or to transfer intelligence to the machine are fuzzy logic, genetic algorithm, vision system, charge couple device (CCD) cameras, sensors and actuators.

Intelligence is always studied in humans but has been observed in both non-human animals and plants. Intelligence in the machine is also called as artificial intelligence. Engineers and scientists are trying to impart human intelligence attributes to machines to improve machine intelligence [2, 3]. Not of much work seems to be available for measurement of MIQ. Hence in this paper, a stepwise procedure is developed to measure the machine intelligence quotient. MIQ for three types of die casting machines (gravity die casting machine, pressure die casting machine and automatic die casting machine) for the manufacture of piston casting is also considered by human–machine cooperative system. In addition, two more methods for measuring MIQ have been considered and discussed in brief.

37.2 Machine Intelligent Quotient and Its Sub-systems

Intelligence is always a hard topic to express and there is no clear definition for it. It may be defined as the ability to respond rapidly and successfully to a new situation. Intelligence requires the ability to sense the environment, make decisions and control action [4]. Various attributes of intelligence are adaptability, self-maintenance, communication, autonomy, learning, self-improvement, anticipation, goal seeking, inference and creativity. Intelligent machine is a machine that learns and can solve problems by reasoning and inference. Intelligent controller is any control system that can deliver a degree of human-like response to stimuli. Nowadays, intelligent factories have been evolving with intelligent machine systems along with intelligent human–machine interfaces.

Intelligent systems can be broadly classified into four types viz. biological intelligence, artificial intelligence, machine intelligence and computational intelligence. Intelligent quotient is developed in human beings in the form of intelligence quotient (IQ) which can be defined as the ratio of mental age and chronological age multiplied by hundred.

Machine intelligence is another term used to measure the intelligence of the machine, i.e., theory and development of the computer systems facilitating to perform the tasks normally which requires human intelligence.

Machine intelligence is the process of analyzing, organizing and converting data into knowledge, where (machine) knowledge is defined as the structured information acquired and applied to remove ignorance and uncertainty about a specific task pertaining to the intelligent machine [5]. Machine intelligence consists of two components, i.e., control intelligence and interface intelligence. Interface intelligence indicates the degree of intelligence of human–computer interaction that may be human to machine interaction and vice versa. Machine intelligence quotient can be considered as a union of machine control intelligence and machine interface intelligence [6]. High machine intelligent quotient indicates the number of decisions taken by machines is more than human, i.e., machine to human interaction is more than human to machine interaction. Nowadays, machines are taking complex decisions without any interaction of human in fully automatic process. The taxonomy of intelligence and its meaning and the paradigms are presented in Table 37.1.

Intelligence attributes consist of activity attributes (cognition, memory, logical thinking, creative thinking and evaluation), material attributes (images, symbols, non-verbal perceptions), product attributes (classes, relations, systems, unitary items, transformations and implications) and their combinations. There is a continuous effort by the engineers and the technologies to impart human intelligent attributes to machines and industrial shop-floor systems [7, 8].

The human intelligence has been gradually increasing linearly with time, but the machine intelligence has not been significant during 1950–2000 [9]. In Fig. 37.1, human intelligence and machine intelligence with time are shown. With the advent of computer, artificial intelligence, sensors, actuators, neural networks, the intellectual power of machines has been steeply increased. The point where the machine

Table 37.1 Taxonomy of intelligence and its paradigms

Types of intelligence	Literal meaning	Paradigms of intelligence
Biological intelligence	Naturally grown organism, human knowledge plus sensory input	Human and other developed species brain
Artificial intelligence	Cognitive inspired artificial models, knowledge tidbits and sensor data	Intelligent systems, knowledge systems, decision-making systems

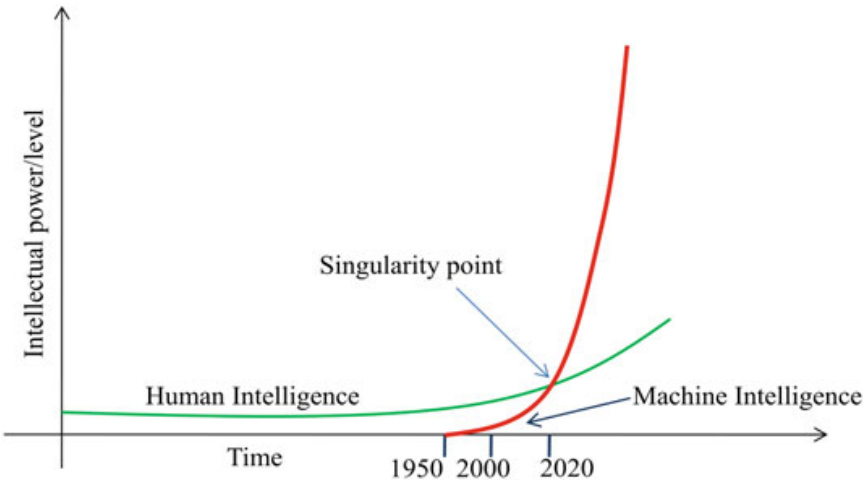

Fig. 37.1 Evolution of human and machine intelligence

intelligence outperforms the human intelligence is termed as singularity. In this century, machine intelligence is likely to supersede human intelligence.

37.3 Die Casting Machines for Piston Manufacturing

Pistons are the short piece of metal that moves up and down under pressure inside a cylinder of an engine and are made gas tight by piston rings. Pistons are usually made of Al–Si alloy and manufactured by different types of die casting machines viz. gravity, pressure and automatic based on the quantity, quality and lead times. The number of automobiles manufactured [10, 11] and the number of pistons required are quantified during 2008–2016 and presented in Table 37.2. The numbers of automobiles and pistons produced during a decade period are 157.1 million and 238.2 million, respectively. The annual requirement of pistons for automobile industry is around 60.12 million.

Al–Si pistons are generally manufactured by die casting processes, i.e., gravity die casting, pressure die casting and automatic die casting process. In die casting machine, molten metal enters the mold cavity under gravity [12]. Pressure die casting is characterized by forcing molten metal under high pressure into a mold cavity. Gravity die casting (GDC) is preferred in medium to large volumes and of a heavier section thickness than high pressure die casting, but thinner sections than sand casting. It has very good dimensional accuracy and also good cast surface finish. Pressure die casting cycle time is less, reliable and cost-effective manufacturing process for the production of high volumes and cast components that are near net-shaped having tight tolerances. In automatic die casting, more operations castings are performed by machines like automatic die coating, automatic pouring and ejection without any human interaction. The tasks of die casting machine,

sequence of operations, task performed by human or machine for gravity, pressure die and automatic die casting machines are presented in Table 37.3.

37.4 Methods for MIQ Measurement for Die Casting Machines

In the present research, three methods for computation of MIQ of die casting machines have been considered. These include machine–human cooperative system, geometric polytope method and multiple perspective analysis method.

37.4.1 Method for MIQ Measurement for Die Casting Machines by Human–Machine Cooperative System

This system basically estimates the mental workload and data quantity and their interface complexity. Stepwise procedure to estimate MIQ is as follows:

Step 1: To find out the input and output variables of the target machine, i.e., the die casting machines and decide the task performed by either machine or human.
Step 2: To define the die casting intelligent task set,

$$T = \{T_1, T_2, T_3, T_4, T_5, T_6, T_7, T_8\} \tag{37.1}$$

where $T_1, T_2, T_3, T_4, T_5, T_6, T_7, T_8$ are the intelligent tasks of die casting machine performed by machine and human. These are the set of tasks required to control and operate the event.

Step 3: To determine the intelligent task cost,

$$t = \{t_1, t_2, t_3, t_4, t_5, t_6, t_7, t_8\} \tag{37.2}$$

where $t_1, t_2, t_3, t_4, t_5, t_6, t_7, t_8$ are the task intelligent costs. Task intelligent costs t_i are intelligence required to execute the task T_j which is varying from 6 to 22 for the tasks 1–8.

Step 4: To prepare data transfer matrix $D = d_{ij}$, for transferring data from task T_i to T_j.

$$D = d_{ij} = \begin{bmatrix} d11 & d12 & d13 & d14 & d15 & d16 & d17 & d18 \\ d21 & d22 & d23 & d24 & d25 & d26 & d27 & d28 \\ d31 & d32 & d33 & d34 & d35 & d36 & d37 & d38 \\ d41 & d42 & d43 & d44 & d45 & d46 & d47 & d48 \\ d51 & d52 & d53 & d54 & d55 & d56 & d57 & d58 \\ d61 & d62 & d63 & d64 & d65 & d66 & d67 & d68 \\ d71 & d72 & d73 & d74 & d75 & d76 & d77 & d78 \\ d81 & d82 & d83 & d84 & d85 & d86 & d87 & d88 \end{bmatrix} \tag{37.3}$$

Step 5: To prepare the task allocation matrix for gravity die casting machine, pressure die casting and automatic die casting machines. The element of this type of matrix can only have binary numbers, i.e., 0 or 1. If the machine performs a task T_i then a_{i1} is 1, and if human performs the task a_{i2} will be 1. If the task T_i is neither assigned by the machine nor human, then it will be 0. Hence, $a_{i1} + a_{i2} + a_{i3} = 1$ for all $1 \leq i \leq n$ task allocation matrix will be $3 \times n$.

$$A = \begin{pmatrix} a_{i1} & a_{j1} & 0 \\ \vdots & \ddots & \vdots \\ a_{i8} & a_{j8} & 0 \end{pmatrix} \tag{37.4}$$

Step 6: To prepare the task allocation matrix considering the task performed by machine or human. To prepare task allocation table considering the task performed by either human or machine, let us consider the machine–human interface (C_{mh}) and human–machine interface complexity (C_{hm}). The values can be from 0.01 to 0.09 depending on the human–machine interaction. Higher values are assigned where more human interaction is required and vice versa. The interface complexities are to be considered for three die casting machines.

Step 7: To prepare the task allocation graph by considering the set of tasks and their interactions like machine to machine, human to machine and machine to human.

Step 8: To compute the machine control intelligent quotient C, i.e., the sum of all intelligent task costs [10].

$$C = \sum_{i=1}^{n} a_{i1} t_i + \sum_{i=1}^{n} a_{i2} t_i \tag{37.5}$$

where C is the control intelligence quotient (CIQ) of the overall control system containing the human and machine. C is the sum of all task intelligence costs (both machine and human).

$$C = t_1 + t_2 + t_3 + t_4 + t_5 + t_6 + t_7 + t_8 \tag{37.6}$$

Step 9: To compute the human intelligence quotient (H). It is the sum of task intelligence costs allocated to the human and interface intelligence costs. We can obtain MIQ by subtracting H from C.

$$H = \sum_{i=1}^{n} a_{i2} t_i + C_{\text{mh}} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{i1} a_{j2} d_{ij} + C_{\text{hm}} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{i2} a_{j1} d_{ij} \tag{37.7}$$

Step 10: MIQ is divided into two components, i.e., machine control intelligence and interface intelligence.

$$M = M_{\text{i}} + M_{\text{c}} \tag{37.8}$$

$$M_{\text{i}} = -\left\{ C_{\text{mh}} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{i1} a_{j2} d_{ij} + C_{\text{hm}} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{i2} a_{j1} d_{ij} \right\} \tag{37.9}$$

$$M_{\text{c}} = \sum_{i=1}^{n} a_{i1} t_i \tag{37.10}$$

M_{i} values are either negative or zero. It implies that if M_{i} is zero, then it will not have any effect on MIQ. If M_{i} is negative, it means the interface overhead deteriorates the machine intelligence quotient.
Step 11: To compute MIQ, subtract H from C;

$$M = C - H \tag{37.11}$$

37.4.2 Estimation of MIQ by Geometric Polytope Method

This method is used to estimate a relative means of determining how to contrast across different machines for comparative intelligence or autonomy. A stepwise procedure for MIQ measurement or estimation is as follows:

Step 1: To define the axes of the geometric polytope to be relevant to that performance of the attribute (goal) under consideration.
Step 2: To define the scales of each axis of the geometric polytope to be relevant to the attribute or goal of interest.
Step 3: To plot the attribute values (productivity, cost, cycle time, etc.) for different machines (die casting) on the same axis.
Step 4: To consider polytope area resulting will provide a relative comparison of the efficiency of a particular machine to perform certain attributes.
Step 5: To use the relative measures of machine intelligence, the effectiveness to perform specific attributes or goal under various conditions can be determined. It is difficult to get an absolute value of MIQ but the comparison is made based on the area of polytope. Higher the area of polytope, then higher is the MIQ of machine.

37.4.3 Estimation of MIQ by Multiple Perspective Analysis

In this method, three filters are used, i.e., technical filter (T), organizational filter (O), personal filter (P). Technical filter includes

Step 1: To define linguistic variables to take values on the interval between zero and one for measuring machine intelligence.
Step 2: To consider three filters, i.e., technical, organizational and personal and their attributes.
Step 3: To normalize the micro and macroeconomic measures (attributes) like productivity, cost and cycle time, etc., for three die casting machines.
Step 4: To correlate the fuzzified values {T-O-P} to MIQ.

For example, three die machines have {0.4, 0.3, 0.2} for gravity die casting, {0.5, 0.4, 0.3} for pressure die casting and {0.7, 0.6, 0.5} for automatic die casting. Then, automatic die casting machine has got the higher MIQ of {0.7, 0.6, 0.5} on linguistics scale which reflects 0.7 for technical, 0.6 for organizational and 0.5 for personal filter.

37.5 Computation of MIQ by Machine–Human Cooperative System for Die Casting Machines

Computation of MIQ for three die casting machines is given below considering intelligent tasks and costs.

Step 1: To find out the input–output variables of the die casting machines and decide the performance performed by either machine or human.
Step 2: To define die casting machine intelligent task set.

$$T = \{T_1, T_2, T_3, T_4, T_5, T_6, T_7, T_8\}$$

Step 3: To determine intelligent task cost,

$$t_i = \{6, 10, 15, 19, 22, 18, 16, 14\}$$

Step 4: To prepare data transfer matrix,

$$\begin{aligned}
D &= d_{ij} = d_{8\times 8} \\
D_1 &= \{d_{14}, d_{16}, d_{24}, d_{26}, d_{34}, d_{36}, d_{45}, d_{46}, d_{47}, d_{56}, d_{67}, d_{68}\} \\
&= \{25, 25, 15, 17, 19, 15, 30, 12, 20, 20, 20, 22\} \\
D_2 &= \{d_{13}, d_{14}, d_{16}, d_{17}, d_{23}, d_{24}, d_{26}, d_{27}, d_{34}, d_{35}, d_{38}, d_{45}, d_{48}, d_{56}, d_{57}, d_{67}, d_{68}, d_{78}\} \\
&= \{20, 22, 12, 14, 15, 24, 17, 15, 12, 30, 12, 32, 14, 28, 24, 15, 19, 22\} \\
D_3 &= \{d_{12}, d_{13}, d_{14}, d_{15}, d_{17}, d_{23}, d_{28}, d_{34}, d_{38}, d_{45}, d_{48}, d_{56}, d_{58}, d_{67}, d_{68}, d_{78}\} \\
&= \{14, 18, 28, 30, 26, 19, 12, 20, 16, 12, 24, 22, 22, 30, 20, 28, 26\}
\end{aligned}$$

Step 5: Task allocation matrix

$$\begin{bmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{bmatrix}$$

Gravity die casting machine

$$\begin{bmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$$

Pressure die casting machine

$$\begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}$$

Automatic die casting machine

Step 6: To prepare task allocation table considering the task performed by either human or machine, let us consider the machine–human interface (C_{mh}) and human–machine interface complexity (C_{hm}). The values considered are from 0.02 to 0.05.
Step 7: Task allocation shows the task performed by human, machine and events of three die casting machines. Tasks allocations are shown in task allocation matrices (step 5).
Step 8: To determine the control intelligence quotient for three die casting machines,

$$C_1 = 120,\ C_2 = 120, C_3 = 120$$

(Eq. 37.6)
Step 9: To compute the human intelligent quotient (Eq. 37.7) for three die casting machines,

$$H_1 = 83 + (0.04 \times 94) + (0.05 \times 136) = 93.56;$$
$$H_2 = 52 + (0.03 \times 129) + (0.04 \times 111) = 60.31;$$
$$H_3 = 6 + (0.025 \times 138) + (0.02 \times 62) = 10.69$$

Step 10: To compute die casting machine control intelligence (Eq. 37.10) and interface intelligence (Eq. 37.9),

$$M_{c1} = 37,\ M_{c2} = 68,\ M_{c3} = 114;$$
$$M_{i1} = -10.56,\ M_{i2} = -8.31,\ M_{i3} = -4.69$$

Step 11: To compute MIQ (using Eq. 37.11),

$$M_1 = C_1 - H_1 = 120 - 93.56 = 26.44;$$
$$M_2 = C_2 - H_2 = 120 - 60.31 = 59.69;$$
$$M_3 = C_3 - H_3 = 120 - 10.69 = 109.31$$

The total intelligent costs have been considered 120 for all eight tasks for die casting machines and considered the task costs from 6 to 22 according to the task complexity, and it is shown in Table 37.4. The interface intelligence for all of the casting processes is negative due to the fact that the interface overhead deteriorates the MIQ. The control intelligence stayed top for the automatic die casting machine as this machine has controlled the more intelligence task than other two methods. The computed MIQ values are presented in Table 37.5.

Table 37.4 Task description, tasks intelligent costs

Task element	Task description	Intelligent task description	Task intelligent cost	Task intelligent cost
T_1	Machine on/off	Detect	t_1	6
T_2	Die lubrication	Identify	t_2	10
T_3	Core insertion	Observe	t_3	15

T_8	Extraction of the casting	Evaluate	t_8	14
			Total	120

Table 37.5 Estimation of die casting machines intelligence quotient

Description	Gravity die casting machine	Pressure die casting machine	Automatic die casting machine
Total intelligent cost ($C = H + M$)	120	120	120
Human intelligence quotient (H)	93.56	60.31	10.69
Control intelligence (M_c)	37	68	114
Interface intelligence (M_i)	−10.56	−8.31	−4.69
Machine intelligence quotient (M)	26.44	59.69	109.31

37.6 Conclusions

In the present paper, MIQ and its sub-systems are defined and formulated for computation of machine intelligence. Three methods for measuring MIQ were formulated, and MIQ was calculated by human–machine cooperative process for gravity die casting, pressure die casting and automatic die casting machines. Human–machine cooperative system is more suitable for estimation of die casting machines for the manufacture of pistons. MIQ of automatic die casting machine has the highest and gravity die casting machine lowest. It is also useful for comparison of different machines with different intelligent attributes manufactured by original equipment manufacturers. From the MIQ computation, it was found that automatic die casting machine has the highest MIQ of 109.31 followed by pressure die casting machine (56.69) and gravity die casting machine (26.44).

Chapter 38
Optimization of Porosity in Cast Aluminium Foams

R. Kumar, G. Avinash and Neha Gupta

Abstract Closed-cell ultra-light aluminium foams are often used as structural materials in aerospace, railways and automobile sectors as they provide good strength to weight ratio with high impact strength and corrosion resistance. Melt - based metal foams can be casted using indirect foaming techniques, wherein gas bubbles are created inside the melt which has been pre-treated in a suitable way. The properties of these metal foams are directly affected by nature of porosity, which is difficult to measure and control experimentally. Therefore, theoretical solutions have to be developed to control this porous structure. In the present work, a aluminium foam, prepared using foaming method using blowing agents with porosity $\sim$86%, is used, where the effect of melt viscosity and solidification time on gas bubble size and its rising velocity inside melt have been theoretically studied. The calculations showed that rising velocity of hydrogen gas bubbles, aluminium melt viscosity and solidification time are responsible for motion of bubbles in the aluminium melt. Control of this movement of bubbles can result in optimum porosity in the solidified foam. A relationship has been established for viscosity enhancement due to the addition of additives like Ca, Al_2O_3, SiC, TiB_2, SiO_2, BN and their influence on bubble size and its rising velocity during solidification of this foam. Overall, the study suggested amount of additives that are required to be added in a given volume of aluminium melt, to increase melt viscosity and to maximize bubble entrapment. The results also showed that a cooling time of $\sim$8 s leads to efficient bubble entrapment with uniform pore structure and hence properties of aluminium foam.

38.1 Introduction

In recent years, light-weight metal foams have gained a lot of attraction both for the scientific research and industrial applications. Amongst metal foams, aluminium alloys are commercially the most exploited ones due to their high strength to density ratio, good corrosion resistance and competitive cost [1]. The application potential of these materials has already being explored for different fields, namely construction, energy absorption, thermal or sound insulation, etc. where improvement in safety is needed. Several processing methods can be used to produce these structures as casting, powder metallurgy, metal deposition, additive manufacturing and many more [2]. Closed-cell metallic foams can be economically obtained by solidifying melt containing well-dispersed gas bubbles, also known as indirect gas foaming technique. Such foams are commonly used for structural applications as they exhibit properties as enhanced energy absorption with high stiffness to weight ratio [3], thereby offering significant performance gains.

Most of the properties, such as strength, sound insulation, impact energy absorption, etc. of these foams are extremely sensitive and are directly affected by its final pore size and its distribution [1–3]. Hence, a well-controlled closed-cell pore structure is often desired in order to obtain high-quality metal foams, so as to meet the requirements of specific applications. Therefore, it is very much required to have good pore distribution and its control during processing. However, it is a tedious task to experimentally control porosity using foaming techniques due to the complex nature of foaming process which often leads to non-homogeneous distribution of gas bubbles. Pore size, shape and its distribution depend on melt viscosity, bubble size and rising velocity, solidification time, surface tension, fluid buoyancy and drag velocity. Therefore, it is extremely important to control these parameters during foaming process. Only few studies have been reported on theoretical optimization studies related to pores formation in metal foams [4–8]. It is known that low melt viscosity and high bubble rise velocity tends to drain the melt faster leading to rapid escape of gas bubbles before foaming [5]. This leads to fabrication of imperfect foam having lower porosity. Therefore, melt with sufficient viscosity and optimal bubble rise velocity has to be prepared to efficiently stabilize the liquid foam and fabricate structurally sound aluminium foams [6, 7]. Talaria discussed and predicted terminal bubble velocity in a given liquid [5]. His viscosity expression can be easily used to relate with a given bubble and it's rising velocity. Studies by Banhart showed the importance of studies, to understand stabilization mechanisms for metal foams [6]. Akiyama et al. have prepared closed-cell aluminium foams through indirect gas foaming technique which used titanium hydride (TiH_2) as foaming agent and calcium as additive to enhance the viscosity of the melt so as to adjust its foaming properties [7].

In this work, a closed-cell aluminium foam was prepared using similar technique as by Akiyama et al. by adding TiH_2 as foaming agent to create hydrogen bubbles [7]. These bubbles resulted in inhomogeneous pore development in aluminium foam upon solidification. Here, the effect of melt viscosity and cooling conditions

on pore formation in aluminium foam has been investigated theoretically. Further, the effect of different additives (Ca, Al_2O_3, TiB_2, SiO_2, SiC and BN) on melt viscosity and its influence on bubble diameter and hence its rising velocity during solidification of this foam was analysed. A relationship has been developed for melt viscosity, solidification time, bubble size and bubble rising velocity for efficient pore entrapment and thereby uniform distribution in aluminium foam.

38.2 Materials and Methods

Aluminium alloy was heated at 720 °C in a Heat Treat Electric furnace for 1.5 h, to which 1.8 wt% additive (calcium) was added as thickening agent under continuous stirring to adjust the melt viscosity. Thereafter, 1.5 wt% TiH_2 was added as blowing agent to this melt to form hydrogen gas bubbles. Continuous stirring (total time = 150 s, speed = 1000 rpm) of the melt resulted in a homogeneous distribution of additive, and blowing agent inside melt till cooling helped to obtain a foam with porosity of $\sim$86%.

Under these well-controlled experimental conditions, a porous structure with uniform pore size and spherical shape was expected. However, a non-uniform porous structure was observed as illustrated in Fig. 38.1, despite taking precautions in the process, which resulted in decrement of foam properties (strength, stiffness, etc.) when compared to theoretical values, as was also observed by Suresh et al. [9]. Efficient control of porosity in the foam is a solution to this. Also, it is known that bubble rising velocity and melt viscosity in the aluminium melt affects the porosity in foam [1–3]. For study, a mould with dimensions 15 × 15 × 15 cm^3 with 20 cm sprue length and 2 cm sprue diameter was used. Here, an effort has been done to solve and study for the in situ pore size and its distribution with respect to melt viscosity during solidification using theoretical calculations.

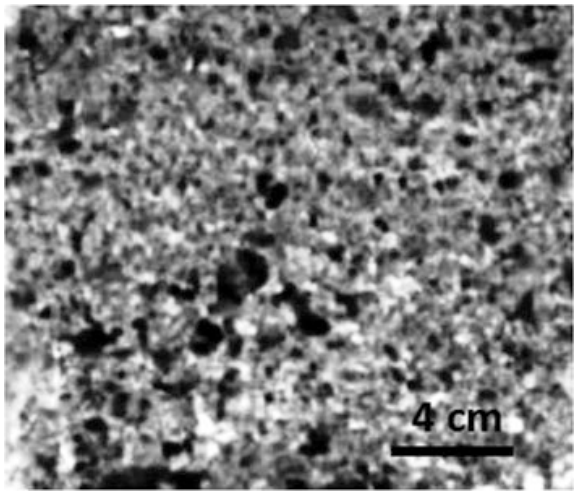

Fig. 38.1 Microstructure of foam showing non-uniform porosity

38.3 Results and Discussion

In continuation of our earlier works [4], we know that pore size can be controlled by controlling the diameter of hydrogen bubble generated inside the aluminium melt. Also, pore size distribution of foam can be controlled by controlling the rising velocity of these hydrogen bubbles. Here, a relationship between bubble size with pore size and bubble rising velocity with pore distribution inside the aluminium foam during solidification have been developed. Using Stokes equation [4, 10], hydrogen gas bubble rising velocity can be calculated, which indicates the movement of bubbles inside aluminium melt leading to pore distribution inside foam upon solidification. It was calculated that the small isolated gas bubbles rose in melt at 720 °C with rising velocity of 0.038 m/s. For this rising velocity, the distance covered by bubbles at solidification start (~615 °C, 30 s) [11] is 1.1241 m. This bubble displacement was too high compared to the height of the mould used; therefore, the gas bubbles get easily escaped resulting in undesired low porosity foam structure. The bubble rising velocity has to be therefore decreased by increasing the melt viscosity so that gas bubbles stay in the melt for longer time, thus resulting in a structurally sound porous structure. The same was confirmed by Akiyama et al., who used calcium as thickening agent to increase the melt viscosity [7].

This velocity is strongly dependant on the aluminium melt viscosity. The relative viscosity (μ_{rel}) due to the addition of additives is [4, 11]:

$$\mu_{rel} = \frac{\mu_{sus}}{\mu_{liq}} \tag{38.1}$$

μ_{sus} Dynamic viscosity of the suspension
μ_{liq} Dynamic viscosity of the aluminium melt (1.38 MPa) [12].

Using Eq. (38.1), it was calculated that after the addition of 1.8 wt% additive, the viscosity of aluminium melt increased from 1.38 to 7.4 MPa and was high enough to hold gas bubbles inside the melt for longer times. This increase in viscosity decreased the bubble rise velocity from 0.038 to 0.007 m/s, which helped in efficient entrapment of gas bubbles in the melt to achieve desired pore structure.

Table 38.1 Volume percentage of different additives that can be used

Additives	Volume %
Ca	2.79
Al_2O_3	7.11
TiB_2	8.14
SiO_2	4.77
SiC	5.78
BN	3.16

Different additives can be used to obtain such increment in melt viscosity. Table 38.1 reports the calculated volume percentages of some of these additives.

However, when TiH_2 was added to the melt, it decomposed and resulted in formation of gas bubbles. These bubbles further expanded as they rose in the melt. The increase in bubble diameter w.r.t. solidification time can be given as [13]:

$$d(t) = 2\left[\frac{K}{\sqrt{D} \pm \sqrt{\frac{K^2}{D} + 2(0.9253K)}}\right] t^{\frac{1}{2}} \tag{38.2}$$

where,

$d(t)$	Bubble diameter (mm)
$K = \sqrt{\frac{3}{\pi}} \times \frac{D(C-C_w)}{\rho_g}$	1.22×10^{-6} m^2/s
C	Gas concentration in the liquid (0.14×10^{-3} kg/m^3)
C_w	Gas concentration within the pore (0.055×10^{-3} kg/m^3)
ρ_g	Bubble density (0.17×10^{-3} kg/m^3)
D	Diffusion coefficient of hydrogen in the Al-melt (2.5×10^{-6} m^2/s)
t	Solidification time (s).

Equation (38.2) showed that gas expansion leads to bubble growth, which further influences its rising velocity. These changes were calculated using Stokes equation and Eq. (38.2) and are reported in Table 38.2. Table 38.2 shows that with increase in solidification time, bubble growth occurs, which also enhances their rising velocities due to expansion. This increase in bubble growth during solidification can lead to increased pore size.

Overall, the study concludes that for a foam size of 15 cm × 15 cm × 15 cm, to have hydrogen gas bubble being effectively entrapped inside aluminium melt, a reduction in solidification time has to be done. As per calculations, the solidification time should be less than 8 s so as to get uniform porosity in foam. Therefore, for

Table 38.2 Influence of solidification time and bubble size on bubble rising velocity

t (sec)	d (mm)	U_∞ (mm/s)
1	0.74	2.33
2	1.05	4.71
3	1.29	7.05
4	1.49	9.40
5	1.67	11.72
6	1.83	14.11
7	1.97	16.46
8	2.11	18.8
9	2.24	21.15
10	2.36	23.52

parameters chosen, along with improvement in melt viscosity by adding 1.8 wt% additives, fast cooling of the melt are required so that an optimal uniform pore size and distribution can be achieved.

38.4 Conclusion

This work was performed to have a better understanding and control over pore size and its distribution in aluminium foam to have better property control. It was observed that the melt viscosity increased on the addition of 1.8 wt% additives like Ca, Al_2O_3, TiB_2, SiO_2, SiC and BN, which helped in holding bubbles in the melt. The viscosity enhanced from 1.38 to 7.4 MPa. This increased melt viscosity helped in entrapping the bubbles in the melt by decreasing bubble rise velocity from 0.038 to 0.007 m/s.

It was also observed that with increment in solidification time, bubble growth occurs due to gas expansion, which affects their rising velocity. This leads to increase in pore size, which is sometimes undesirable. Calculations suggested that reducing solidification time from 30 s to less than 8 s, improved the entrapment of gas bubbles inside the aluminium melt, thereby creating effective porosity in the foam.

Overall, using calculations discussed here, it is expected that a researcher can optimize his/her parameters used to fabricate foams as mould size, melt used, melt viscosity, amount of additives and solidification time to obtain uniform porosity in the metal foam and hence it's properties. This study can help in better designing of the experiments used for development of metal foams by indirect foaming method.

Chapter 39
To Predict Surface Roughness and Linear Shrinkage of Die Casting Process by Using of Fuzzy Algorithm Model

Narendra Krishania and Anil Kumar Birru

Abstract This research paper narrates a manually constructed Mamdani based on fuzzy algorithm model for envisaging surface roughness and linear shrinkage of die casting, so that defects can be refrained from the casting in terms of surface finish and dimensions. A set of rules established by the help of mathematical model have been used to derive two fuzzy controllers which are being used in this process. With the help of this fuzzy algorithm, high production rate and high quality of products can be obtained by controlling process parameters. Confirmation experiments reveal that these fuzzy logics are able to attain optimum grouping of the process parameters. Hence, the quality of casted products in die casting process can be improved to a greater extent by this approach. The predicted surface roughness and linear shrinkage by this model had an error of only 3.55 and 6.02%, respectively, which was confirmed by checking the validity of the model developed by performing confirmation experiments. This proposed model can be reasonably utilized by the industries involved in die casting around the world to increase the overall effectiveness of the process and product.

Keywords Fuzzy logic · Orthogonal array · Surface roughness · Linear shrinkage

39.1 Introduction

Metal casting is a vital part of industrial production. It is generally used to develop near net shape component. Nowadays, the theory of direct/net shape manufacturing is attaining great importance in terms of lead time and cost reduction [1].

The die casting is an economical and efficient method offering a wide range of shapes than any other process. During manufacturing a metal part, the shapes of the

metals depend upon the injection temperature and liquid level. Die casting parameters like injection temperature, moisture level, injection pressure, and liquid level by using embedded controller. In the conventional system, the die casting parameters are measured by manual. The process of die casting involves five main stages which are clamping, injection, cooling, ejection, trimming. Basically, non-ferrous alloys are die casted like alloys of aluminium, alloys of copper, alloys of magnesium, and alloys of zinc. Die casting machines used are of two types—one is hot chamber machine (alloys with low melting temperature are die casted like zinc) and cold chamber machine (alloys with high melting temperature are die casted, like aluminium). Several engine components and pump components are manufactured using die casting.

Accuracy of die casting is affected by many factors like injection pressure too high, injection temperature too high, cooling time too short, low pouring temperature, clamp force too low, ejection force too high, non-uniform cooling rate.

To recognize the significant controllable process parameters which influence the quality of the casted products, it is essential to understand and find out the relationship among these controllable process parameters and quality of the casted products. The selection of the suitable process parameters for making qualitative casted products is one of the primary challenges in casting industry. It is very difficult to set appropriate process parameters with consideration of multiple performance characteristics and to depend on large amount of experimental operations. Therefore, it is important to effectively obtain the optimal process parameters to reduce trial and error time and consuming cost in the casting process [2].

Fuzzy reasoning is one of the prevailing tools which is used for modelling and governing undefined multi-criterion conclusion-making problems. It is grounded on the notion to obtain a set of association between inputs and outputs describing a procedure. So, the technique of fuzzy modelling conveys a nonlinear course better than several existing process [3]. Fuzzy logic techniques have been implemented by a number of researchers in their conclusion-making glitches. A fuzzy logic controller for forecasting the level regulator of molten steel in strip casting methods was created by Park and Cho [4]. With the aid of orthogonal array fuzzy linguistic approach, a general optimization system was implemented in the CNC turning operation for surface by Lan [5]. With the help of fuzzy-based Taguchi technique, Hsiang et al. [6] discovered the optimal process parameters that were maximizing the multiple performance characteristic index (MPCI) for hot extrusion of AZ31 and AZ61 magnesium alloy bicycle carriers [7, 8]. So, in the present study an effort has been made to create fuzzy logic controllers for estimation of quality of casting products with some provided set of process parameters like injection temperature, injection pressure, and time. It was originated that the predicted and measured values are in close proximity [9–12]. The closeness of results implies that the fuzzy modelling technique is efficient to estimate the quality of the patterns used for die casting.

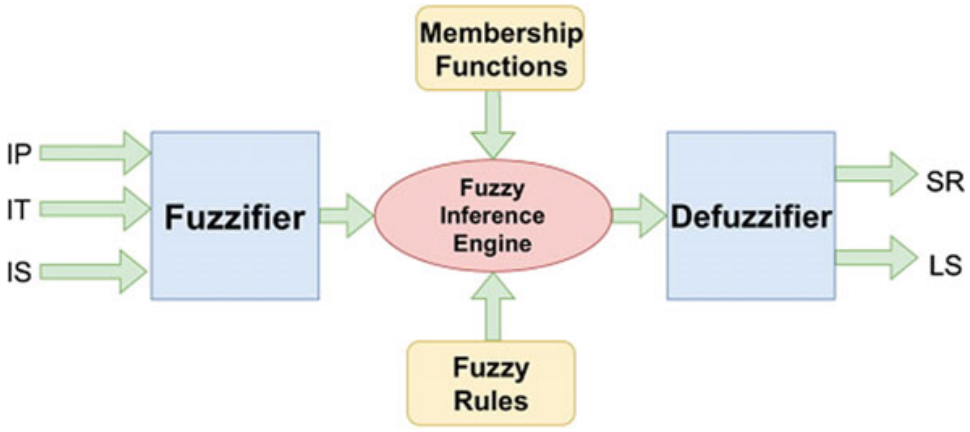

Fig. 39.1 Structure of three inputs two outputs' fuzzy logic

39.1.1 Fuzzy Logic Overview

Mamdani method is the most used fuzzy inference. Initially, one of the first fuzzy processes to regulate a steam engine and boiler was developed by Mamdani and Assilia in [13–15]. A fuzzy logic arrangement consisting of three inputs and two outputs is developed for this study which is shown in Fig. 39.1 [16]. Following steps are followed to execute Mamdani fuzzy inference:

(a) fuzzification of the input variables,
(b) rule output are evaluated and aggregated, and
(c) defuzzification.

Mamdani fuzzy rule is described as:

$$\text{Rule 1: If } y_1 \text{ is } M_1,\ y_2 \text{ is } N_1 \text{ and } y_3 \text{ is } O_1 \text{ then } z_1 \text{ is } P_1 \text{ and } z_2 \text{ is } Q_1 \text{ else}$$
$$\text{Rule 2: If } y_1 \text{ is } M_2,\ y_2 \text{ is } N_2 \text{ and } y_3 \text{ is } O_2 \text{ then } z_1 \text{ is } P_2 \text{ and } z_2 \text{ is } Q_2 \text{ else}$$
$$\text{Rule } n\text{: If } y_1 \text{ is } M_n,\ y_2 \text{ is } N_n \text{ and } y_3 \text{ is } O_n \text{ then } z_1 \text{ is } P_n \text{ and } z_2 \text{ is } Q_n \text{ else}$$

where M_i, N_i, O_i, P_i, and Q_i are termed as fuzzy subsets which are described by the analogous membership function [17–20].

39.2 Experimental Work

By performing the experiment with single variable at a time approach, the span of the particular process parameters is determined. The designed symbols and ranges of the process parameters are provided in Table 39.1. In the present study, the response parameters considered are surface roughness (SR) in µm and linear shrinkage (LS) in percentage.

Table 39.1 Factors and levels used in the experiments

Factor	Description	Unit	Range	Level 1	Level 2	Level 3
A	Pouring temperature	°C	650–750	650	700	750
B	Injector pressure	Bar	120–240	120	180	240
C	Plunger velocity	m/s	1.2–3.8	1.2	2.5	3.8

Table 39.2 L_9 orthogonal array used in the primary experiments

Experiment no.	A	B	C	SR	LS
1	650	120	1.2	48.5541	1.412
2	650	180	2.5	55.8354	1.384
3	650	240	3.8	63.0352	1.204
4	700	120	1.2	58.2841	2.974
5	700	180	2.5	65.3251	2.575
6	700	240	3.8	73.7327	2.045
7	750	120	1.2	61.0512	3.715
8	750	180	2.5	66.0263	3.315
9	750	240	3.8	75.1121	3.012

The primary experiments were conducted using nine test trials; these nine test trials were designed on the basis of L_9 orthogonal array. The reason of choosing L_9 orthogonal array is that shorter arrays are not capable of producing ample data to appropriately analyse the method since they are too simple and longer arrays would create complexity for the trial method. The response of assigned L_9 orthogonal array is shown in Table 39.2. In order to consider the three unlike performance characteristics in Taguchi method, corresponding values of the surface roughness (SR) and linear shrinkage (LS) are processed by the fuzzy logic unit.

39.2.1 Fuzzy Logic Modelling

In this work, three inputs and two outputs are used to evolve a fuzzy controller. Pouring temperature (PT), injector pressure (IP), and plunger velocity (PV) are three input variables, and surface roughness (SR) and linear shrinkage (LS) are two output variables. To make the fuzzy rule base, Mamdani fuzzy "If-Then" declarations for 27 rules has been considered, and to execute inference of max–min operation, Mamdani implication method has been adopted. To change fuzzy data to crisp response values, the centre of gravity method has been used by the defuzzifier. By acquiring triangular membership function, fuzzy division of input and output variables is carried out. Block diagram of fuzzy controller is shown in Fig. 39.2. This has been developed by MATLAB.

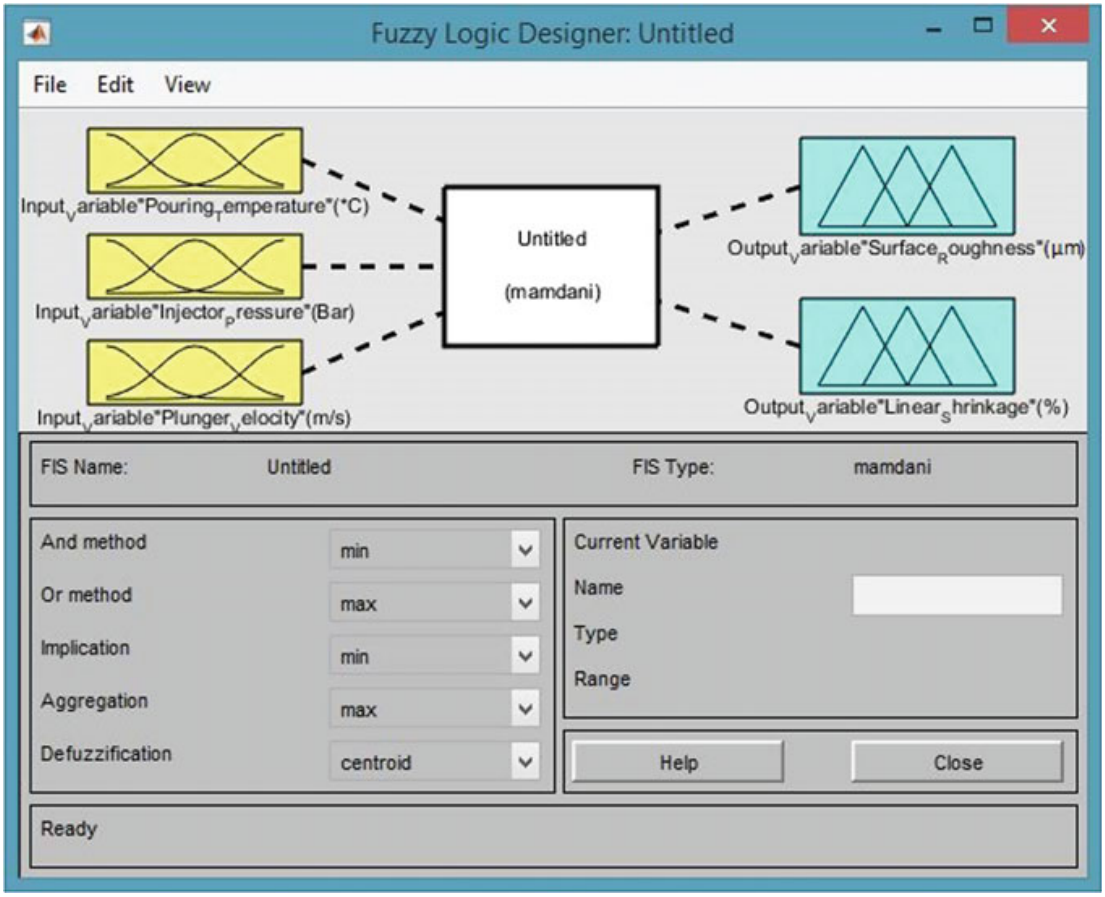

Fig. 39.2 Block diagram of fuzzy controller

Membership functions of the three inputs are small (S), medium (M), and large (L), and membership functions of the two outputs are very small (VS), small (S), medium (M), large (L), and very large (VL). Input and output functions are shown in Figs. 39.3 and 39.4. Table 39.3 shows the fuzzy intervals for input and output for forecasting the response, namely surface roughness (SR) and linear shrinkage (LS) of the casted products in die casting process. By taking into account the max–min combinational operation and with provided set of inputs, experimental results are originated on which these fuzzy rules are established. A non-fuzzy output is provided by the fuzzy reasoning of these rules as shown in Fig. 39.5.

Validation of Fuzzy Model Prediction

Three experiments were performed with different combination of the input process parameters which were not incorporated in the training set (randomly chosen). In Table 39.4, the corresponding experimental responses are measured and listed. From the fuzzy controller, the response values are again acquired for the same set of input process parameters. Then, to find out the extent by which the fuzzy controller is working, the percentage of error was calculated. The experimental and the predicted result obtained from the Mamdani fuzzy model has been plotted on graph as shown in Fig. 39.6. Also, bar graph has been drawn between experimental and fuzzy predicted data as shown in Fig. 39.7.

39.3 Discussion

In this work, to predict the quality characteristics, namely surface roughness and linear shrinkage of casted product in die casting process, a fuzzy logic controller using Taguchi orthogonal array design has been developed. Prediction results show that Mamdani inference was on the basis of maximum error calculated. So, for

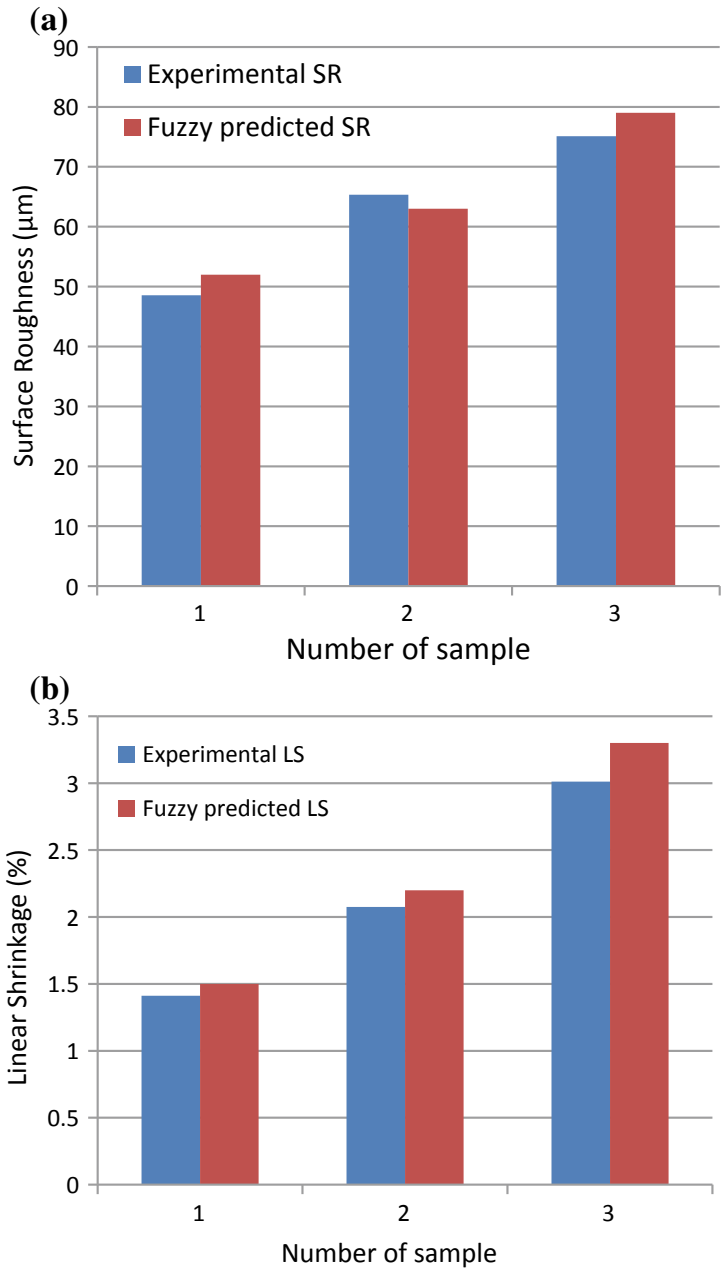

Fig. 39.7 Prediction of **a** surface roughness and **b** linear shrinkage

improving the quality and reliability of the entire process, it has proved to be an effective and powerful tool. By enhancing the number of experiments, the anticipated values of fuzzy output can be further precisely predicted. It is also very useful and can also be used for the optimization of multiple performance quality process parameters and casted product material, to test the ability of the expert systems in prediction of the outputs.

39.4 Conclusion

From the present study, resulting conclusions are summarized as follows:

- The capability of generalization and prediction of pattern characteristics within the range of experimental data such as surface roughness and linear shrinkage of casted product in die casting process have been shown with the help of Mamdani fuzzy inference.
- Industries which are using the experience of skilled workers can use a set of fuzzy rules which further result in improvement in forecasting ability of the process.
- For automation of the process, this methodology seems to be beneficial.

Prediction of Hot Spot and Hot Tear of the Al–Cu Cast Alloy by Casting Simulation Software

Kumara Swamy Pulisheru and Anil Kumar Birru

Abstract The process of casting in foundry is complex and involves large process to get the required part, and such process needs simulation before manufacturing. Casting simulation may save material and gives optimal process of casting in foundry. The defect minimization or prevention is challenging and plays significantly in enhancing the productivity of the foundry. The aim of the present study is to compute hot spots and hot tearing in Al–Cu cast alloy. The originating points of the feed paths represent the hot spots that lead to a shrinkage defect. Some studies have been carried out on hot tear. It was observed that the location of hot tear is at inter-junction of mold cavity to the gate. The developed model is used as bench mark to predict the location of hot spot and hot tear of Al–Cu cast alloy by green sand casting method with casting simulation software.

Keywords Hot spot · Hot tear · Sand casting · Al–Cu cast alloy · Simulation

40.1 Introduction

Poor quality and low yield are major issues for foundries which will increase the rejection rate. Additional melting of molten metal, which directly reflects the quality of the casting and casting yield, highly depend upon solidification of molten metal in the cavity. The direction of molten metal referred to as a feed path which is automatically generated using the vector element method (VEM). The volumetric contraction during solidification compensated from adjacent hotter regions of molten metal. Solidification of casting progressively takes place from the mold boundary which isolates last solidifying points in the mold cavity said to be a 'hot spot' which are the most probable locations for shrinkage related defects. Computer-aided design and simulation have been playing vital role from the last two decades. Casting simulation is to improve the quality and casting yield in

K. S. Pulisheru · A. K. Birru (✉)

R. G. Narayanan et al. (eds.), *Advances in Computational Methods in Manufacturing*, Lecture Notes on Multidisciplinary Industrial Engineering,
https://doi.org/10.1007/978-981-32-9072-3_40

shorter time in shop floor trial-and-error approach. The effect of feeder location, shape, size, and feed aids might give tangible information by casting simulation software. The minimization of defects may be performed by an appropriate feeding system to ensure directional solidification from thin to thick sections of the casted produced. Sutaria et al. [1] observed that computed feed path and hot spot by combining level set method were the last solidified region in casting by vector notation method. Computed feed paths during solidification represent the mass-less particles along the liquid–solid interface. Sutaria et al. [2] investigated with the application of gradient vector method (GVM) and found that directional solidification and hot spot in the casting observed by pouring three layouts of a multi-junction casting. Sutaria et al. [3] investigated the optimization of casting feeders by vector element method (VEM) using feed paths.VEM resulted in terms of hot spot locations correlated with FEM.

Choudhari et al. [4] it was observed that the optimizing feeder dimensions and increasing feeding efficiency of casting by minimizing of the casting defect. Casting simulation enables visualization of progressive freezing regions inside the casting to locate the hot spot. Choudhari et al. [5] studied that the defect minimization in casting to improve the casting yield was compared with its experimental validation. Similarly, applied simulation-based gradient vector method is used to identify the location of shrinkage porosity.

Jain et al. [6] comparative study was made on sand casting and investment casting to minimize the tooling cost for reduction of production cost. It was found that the tooling cost was more in case of sand casting due to additional allowances to get defect-free casting which gives more errors in dimensional allowances, whereas in case of investment casting get more surface finishing. Hodbe et al. [7] studied the manual design, fabrication of tools, and trial-and-error in process to minimize the defects, said process was repeated to get defect-free casting in foundry industries. The defect-free casting increases the casting yield. Simulation-based trials save the time, loss of material, and other industrial expenditure. Rabindra et al. [8] investigated the solidification behavior and detection of hotspots in aluminum alloy castings: Computer-aided analysis by AutoCAST and compared with experimental validation. Birru and Benny Karunakar [9] investigated minimization of hot tear by adding the grain refiners with different levels of composition Al–2.5, Ti–0.5C and Al–3.5, Ti–1.5C with the variation of pouring temperatures as 700, 750, and 780 °C. Gajbhiye et al. [10] investigated the reducing shrinkage porosity in a sand casting process by simulation in AutoCAST-X software with experimental validation by destructive testing. Hence, much work is not emphasized to compute hot spots and hot tearing in Al–Cu cast alloy, and especially in sand casting, authors made an attempt to predict the hot tearing and hot spots.

40.2 Methodology

40.2.1 Problem Definition

The objective of the study is to identify the defects in Al–Cu cast alloy casting such as hot spot and hot tear by AutoCAST simulation software. By optimizing the defects in casting enables to improve the casting yield and quality of the casting part.

40.2.2 Process Design

The entire study has been divided as section, viz. design of model, numerical simulation using AutoCAST software, and analyzing the results. The entire process of simulation is as shown in Fig. 40.1. Casting material is used as Al–Cu alloy and mold is taken as green sand as per aimed work for the sand casting foundry requirements. The CAD model is developed in Creo software. Design parameters are taken from the design calculation as depicted in Table 40.1. The material properties are mentioned in Table 40.2, restricted to simulation software which is considered as boundary conditions to casting simulation.

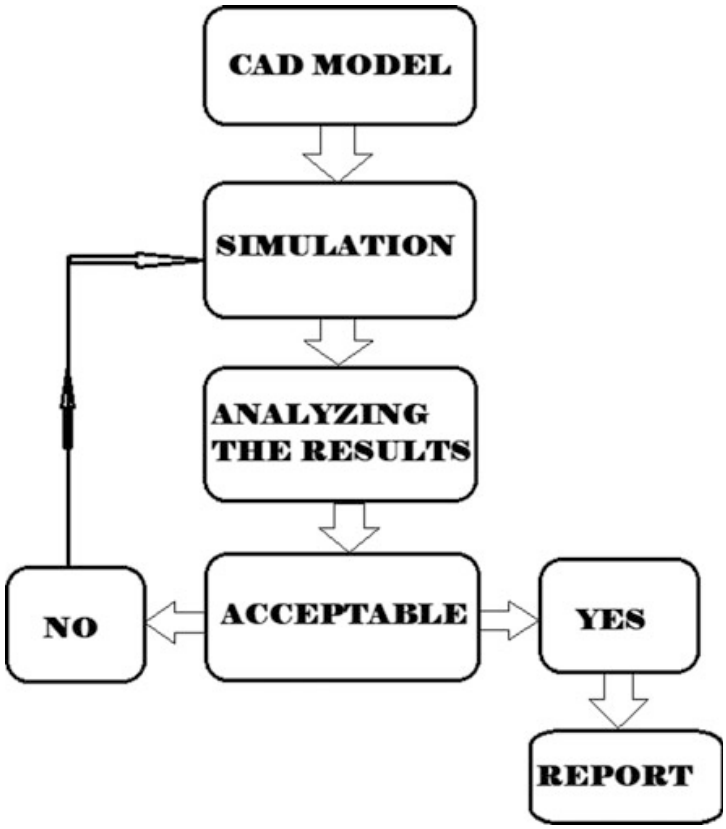

Fig. 40.1 Flow chart for the casting simulation in foundry

Table 40.1 Design parameters

S. N.	Design parameters	Value (mm)	Cross section
1	Pouring basin, height, length, and width	8, 20, 15	Rectangular
2	Diameter of sprue at top, bottom, and sprue length	10, 8, 23.5	Cylindrical
3	Sprue well diameter and height	10, 5	Cylindrical
4	Ingate dimensions, width, height, and length	8, 4, 52	Rectangular

Table 40.2 Material properties

S. N.	Description	Designated value	Units
1	Density	2800	Kg/m^3
2	Thermal conductivity	121	W/m-K
3	Specific heat	920	J/Kg-K
4	Solidus temperature	570	°C
5	Liquidus temperature	650	°C

The design of pattern helps to obtain the acceptable design mold which leads to get good quality casting in foundry industries. The design of part consists of various elements such as pouring basin, sprue, sprue well, and ingates, and they act as a channel to molten metal to flow into the mold cavity to get the desired shape of the mold cavity.

40.2.3 Numerical Simulation

Numerical simulation describes the applications of AutoCAST software for method design and optimization of casting process to enable to get defect-free casting. In the present investigation, simulation process of the selected CAD part was modeled in (.stl file), imported into AutoCAST for simulation. The mold box dimensions have been considered as 200 × 100 × 80 mm as shown in Fig. 40.2. The simulation was carried out by choosing the green sand casting process with aluminum-based alloy. The mold is subdivided into cubic elements with the element size of 1 mm for internal computation for uniform solidification and mold filling. The pouring temperature is considered 700 °C in casting simulation. It was observed from Fig. 40.3 that the Al–Cu alloys were much prone at TC-1 region and TC-2 region.

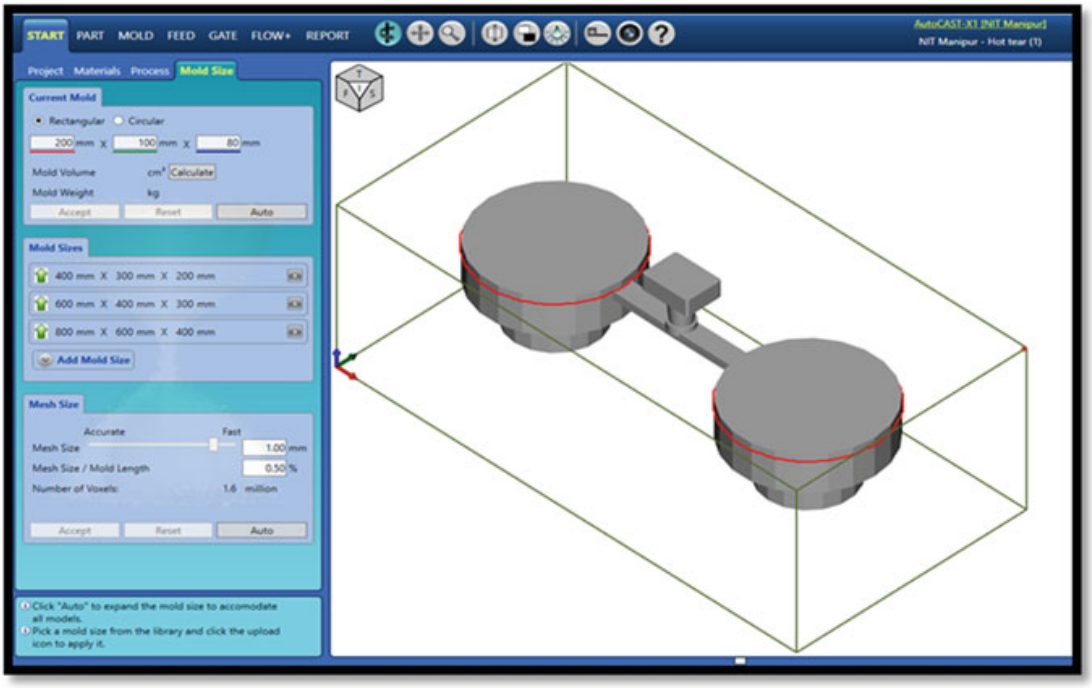

Fig. 40.2 Mold box dimensions for the present investigations

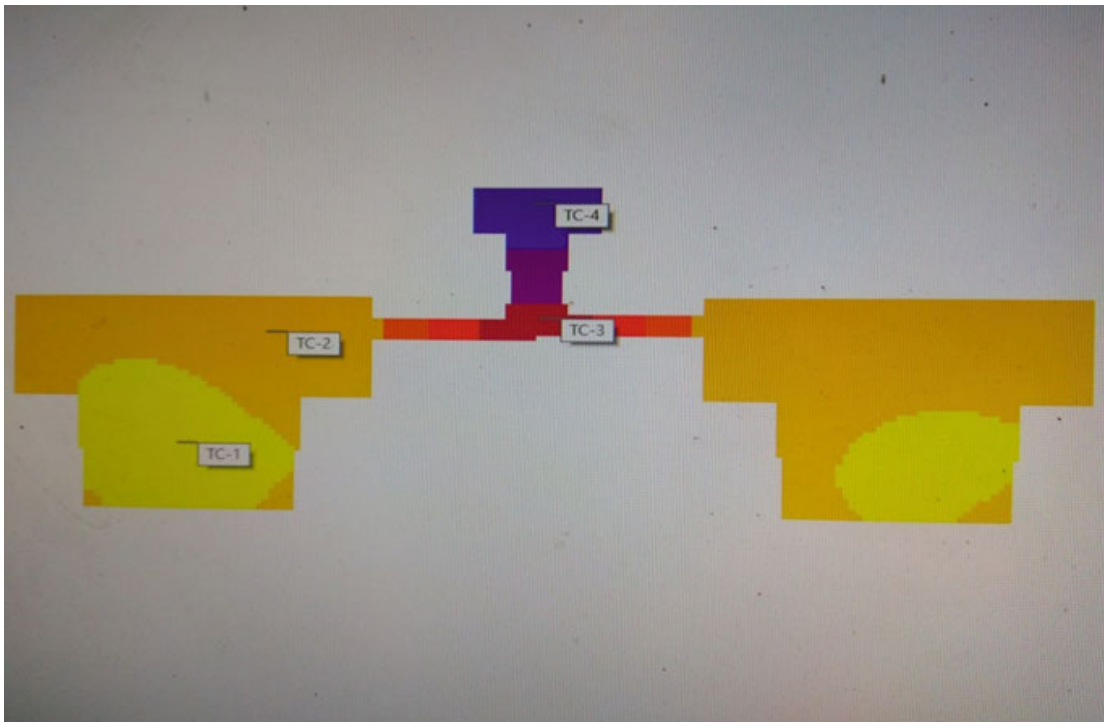

Fig. 40.3 Temperature at TC-1 to TC-4 regions in the casted part

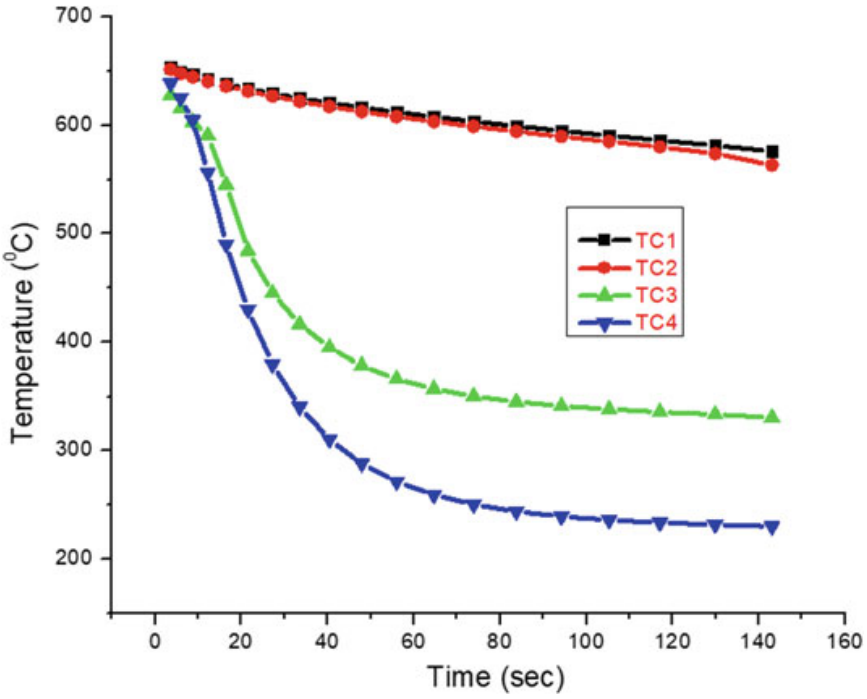

Fig. 40.4 Effect of pouring temperature on different zones in Al–Cu cast alloy

Hot tear was shown at the left end of the casted product, similarity index at the right side of the casted product was observed, TC-3 region the molten metal was distributed at both the sides uniformly, and TC-4 was observed as hard zone of the Al–Cu alloy casted product.

The solidification of molten metal has been compared with the time Vs temperature as shown in Fig. 40.4. An average of four K type thermo-couples at different regions in casting solidification process was observed. TC-1, TC-2 was hot sport and hot tear zones, respectively TC-3 is junction zone were the molten Al–Cu alloy flows, and TC-4 is the hard zone.

40.3 Results and Discussion

In Fig. 40.5, it was observed that the feed metal paths show the solidification direction of Al–Cu alloy casting in 2D and 3D sectioned casting with feed path vector notation as mentioned below

- Progressive Solidification-Cooling
- Directional Solidification-Feed metal paths.

The progressive solidification is represented by isothermal maps (at equal temperature). The directional solidification is represented by feed paths (with temperature gradients).

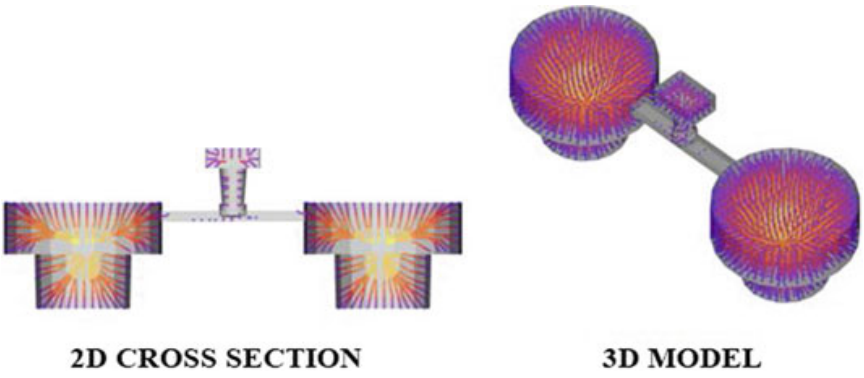

Fig. 40.5 Feed paths by vector notation method of 2D cross section and 3D model

The last solidified region in casting called the hot spot which leads to volumetric shrinkage of the molten metal in the process of solidification. In casting process to compensate the volumetric shrinkage of the molten metal in solidification process the feeder has facilitate to overcome the shrinkage porosity in the casting part. The casting simulation enables to identify the hot spot region to facilitating the feeder for getting the quality casting in foundry.

Figures 40.6 and 40.7 it shows the hot tear occurs where the weakest zone in cavity while in solidification process due to sudden cooling of the molten metal from high temperature to low temperature. Casting simulation enables to identify the weaker zone in mold cavity for the redesign of mold cavity to overcome the hot tears in casting hence, to get the good quality casting part in foundry.

The hot spot and hot tear zones were correlated with Figs. 40.6 and 40.7 for TC-1 to TC-4, the significance of pouring temperature with respect to the solidification time has effect on the Al–Cu cast alloy. In the process of solidification noticed that the TC-3 conditions as the temperature decrease with respect to the time, the flow of material decreased as the time increased and it was also noted that drastically drop down in the temperature was observed at 20–40 s. Similarly, hard zone at TC-4 condition, the temperature drastically drops down at 15–35 s. Hence, it leads to the hot tearing defect in casting solidification. Similarly, for TC1-TC2, the hot spot was observed at the verge of solidification, i.e., TC-1, respectively,

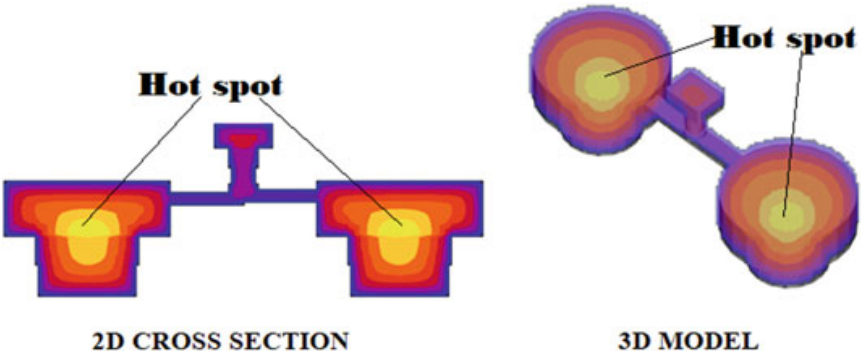

Fig. 40.6 Hot spot region of Al–Cu cast alloy: 2D-cross-sectional view and 3D-isometric view

Fig. 40.7 Hot tear region of Al–Cu cast alloy: 2D-top view and 3D-model

before the formation of the hot spot, the ending of the hot tear starts in Al–Cu cast alloy, and it was further scope to the authors that the grain refinement may also consider for aforesaid alloy.

40.4 Conclusion

Casting simulation was implemented for Al–Cu alloy with green sand mold which enables to predict the problems in casting process in foundry industries. With a motive to minimize the defects in casting especially for green sand molds to acquire the quality of the castings

1. The present study enabled to identify the hot spot and hot tears in casting part by casting simulation.
2. It facilitated optimization of design and casting yield for the preceding process to overcome the hot spot and hot tears by providing feed aids and redesign of the mold cavity.
3. It was concluded that casting simulation enables for trial-and-error to get the accuracy in casting by optimizing the defects in casting, which saves the time and loss of material in foundry which ultimately impacts to enhance the productivity of the industry.
4. It was observed that the Al–Cu alloy in the green sand mold system, the hot tearing and hot spot occurred in the range of 600–700 °C as the solidification time increases at 120–140 s with a minor variation in the hot tearing and hot spot hence, it was concluded that the hot spot increases, respectively, as hot tearing increases vice versa.

Acknowledgements Authors are much thankful for the TEQUIP-III, NPIU-New Delhi, for financial support for purchase of AutoCAST software to carry out the simulation of designed casting.

Chapter 41
Influence of Pouring Temperature on Fluidity of Al–Cu Cast Alloy: Analyses Using Casting Simulation Software

Kumara Swamy Pulisheru and Anil Kumar Birru

Abstract The fluidity of molten metal plays a vital role in the casting process when we are confined in manufacturing thinner sections. The aim of the present study is to determine the effect of pouring temperature on the fluidity of Al–Cu cast alloy. The simulation was performed by AutoCAST-X software with altered pouring temperatures of 700, 750, and 800 °C. It was observed that the fluidity was enhanced when the pouring temperature at 800 °C for the aforesaid cast alloy. Similarly, it was found that the volume of fill increased with the increasing pouring temperature and also strong agreement was observed with the solidification time and fill time.

Keywords Sand casting · Fluidity · Al–Cu cast alloy · Pouring temperature · Simulation

41.1 Introduction

In the manufacturing process, casting is one of the most economical processes among all the available process even in the twenty-first century with respect to the volume of the production. Aluminum alloys are one of the most widely used materials from the past few decades and versatile raw material found in the common foundry metal. The ratio of the cast to wrought aluminum alloy products is increasing in a number of castings being used in automotive, aerospace industries, and domestic goods. The advantage of aluminum alloys mainly from their low density, moderate castability, and excellent mechanical properties.

In manufacturing industry, computer-aided design and simulation play a vital role in forecasting the problems in the manufacturing process for improving of production and quality of the product. The application of casting simulation is increasing in the foundry as it essentially replaces or minimizes the shop-floor trials to achieve the desired internal quality at the highest possible time. Casting solidification simulation is now widely used to visualize the effect of feeder location, shape, size, and feedaids (such as feeder sleeves and mold chills) on the solidification sequence, temperatures, and cooling rates. Based on the earlier researchers, the feeding system design is iteratively modified and simulated until an optimal design the smallest number and volume of feeders to prevent casting shrinkage defects is achieved. In a casting process, the term "fluidity" indicates the distance of the molten metal can flow in a mold at a constant cross-sectional area before it solidifies [1]. The fluidity in casting enhances the casting yield. Over the decades, a considerable amount of experimental and numerical work has been carried out to understand casting solidification and feeding mechanism. Mohan Krishna et al. [2] investigated understanding of the fluidity behavior of narrow and wide freezing range aluminum alloys, respectively (47,100, and 51,300), then extended to cast superalloy CMSX4 and ductile cast iron (GJS-400-18) product. It was found that spiral and complex shaped sand and mullite molds with molten alloys having varied superheats of 25, 50, and 100 °C over the liquid temperatures were simulated using finite element method-based software. Birru et al. [1] investigated the fluidity of Al–Zn alloys, such as the standard A713 alloy with and without scrap addition. Fluidity measurements were performed with a double spiral fluidity test consisting of gravity casting of double spirals in green sand molds with good reproducibility. The influence of recycled alloy on fluidity has been compared with that of the virgin alloy, and the results showed that the fluidity decreased with the increase in recycled alloy at minimum pouring temperatures. Joshi et al. [3] investigated the analytical hierarchy process to the determination of relative weights of various criteria for castability evaluation. The criteria are categorized in a three-level hierarchy, with the middle level comprising mold, feeding, and gating groups. The methodology is illustrated by modifying the product and tooling design of a gray iron bracket casting and estimating the improvement in manufacturability. Manoj et al. [4] studied on casting simulation of a virtual process which ensures casting without defects. It involves computer-aided modeling, pattern design, simulation, and optimization. Fluidity of molten metal plays an important role in producing sound complex castings. The objective of the analysis study is to identify the factors affecting casting fluidity by changing sprue height, pouring temperature, and flow rate on the fluidity of aluminum alloy (AlSi-13).

Ravi et al. [5] studied the desired quality at the least cost without shop-floor trials, with design, process simulation, and quality evaluation and cost estimation carried out. It was found that simulation results are evaluated using three quality indices, moldability, fillability, and feedability. Sutaria et al. [6] investigated the volumetric contraction accompanying solidification of molten metal manifests in

defects like shrinkage cavity, porosity, centerline shrinkage, corner shrinkage, and sink. These defects may be minimized by designing an appropriate feeding system to ensure directional solidification from thin to thick sections in the casting, leading to feeders. Ravi et al. [7] identified the location of a feeder, calculating to minimum size creating its solid model, attaching the feeder model to the casting, carrying out solidification simulation, predicting quality and estimating the yield. Naveen et al. [8] studied the castings that serve these specific applications have to achieve the quality requirements of superior mechanical properties and zero porosity. To achieve these objectives within a limited time frame in a product development process, CAD technologies combined with process simulation tools are increased to optimize the form filling and solidification of the cast parts. Hence, the newly developed simulation of flywheel component that was prototyped via sand casting route. Results of casting trials showed a high level of confidence in the simulation tools.

41.2 Methodology

41.2.1 Problem Definition

The objective of the present study on the fluidity of Al–Cu cast alloy with altered pouring temperature by choosing the method of green sand mould process. In which effect of pouring temperature on the casted part is being analyzed to optimize the defects in the casting process by choosing an appropriate method design. The optimization of method design is carried out by casting simulation.

41.2.2 Process Design

The entire study has been divided into sections, viz. design of the model, numerical simulation using AutoCAST software, and lastly analyzing the results. The entire process is as shown in flowchart as in Fig. 41.1. The entire process shows the method design in the foundry.

To study the fluidity of Al–Cu cast alloy with altered pouring temperatures such as 700, 750, and 800 °C considered the model as a rectangular plate with the size of 220 × 140 × 5 mm by Cre-O software as shown in Fig. 41.2 and converted it into **.stl** file to import it into an AutoCAST software for simulation.

Casting material is used as A206 [9], the chemical composition is as shown in Table 41.1, and mold material is taken as green sand with the dimensions of 300 × 100 × 160 as shown in Fig. 41.3, as per the foundry requirement. The design of the gating system consists of various elements like pouring basin, sprue,

3	Specific heat	920	J/Kg-K
4	Solidus temperature	570	°C
5	Liquidus temperature	650	°C

and sprue well, runner, and ingates. They act as passageways for the flow of molten metal from the ladle to various portions of the mold cavity. Design dimensions are obtained for gating system, and the feeder is mentioned in Table 41.2. The material properties, as mentioned in Table 41.3, restricted to simulation software which is considered as boundary conditions to casting simulation.

41.2.3 Numerical Simulation Using AutoCAST Software

Simulation has been performed in AutoCAST environment according to the design dimensions obtained for a pattern with allowances and gating system. Casting simulation enables to check the part-process compatibility, parting plane and moldability index, and feed metal paths–directional solidification (thin to thicker regions) and to predict the location of shrinkage defects such as porosity and cracks.

Simulation-based trials do not involve wastage of material, energy, and labor and do not hold up regular production. Computer simulation provides a clear understanding of the casting phenomena to identify the location and extent of internal defects, ensuring defect-free castings. Thus, numerical simulation of casting can be considered as an important method to make casting technique change from experience test to science guidance. It requires a standard **.stl** file of the methods layout. However, the application of proper boundary conditions leads to accurate results of the simulation.

Part and Mold box

The prerequisite of this software is to create the part model in CAD software and save it as a standard **.stl** file for importing in AutoCAST. The mold box dimensions have been taken as 300 × 100 × 160 mm as shown in Fig. 41.3. The entire mold containing the casting is automatically subdivided into cubic elements for internal computations such as thickness, solidification, and mold filling. The element size mesh was considered as 3.5 mm.

Simulation with different pouring temperatures

The simulation at different pouring temperatures of 700, 750, and 800 °C was performed. It was observed that the fill time and solidification time increased with respect to the increasing temperature, and the volume of fill is high at higher pouring temperature. Casting simulation between Figs. 41.4 and 41.12 indicates the fill time, solidification time, and percentage of the volume of fill with respect to the altered pouring temperatures, i.e., 700, 750, and 800 °C. In this process, molten metal flow may be visualized at different cross sections of the mold cavity. It enables to visualize the flow of molten metal regions and solidification regions in the casting process (Figs. 41.4, 41.5, 41.6, 41.7, 41.8, 41.9, 41.10, 41.11, and 41.12).

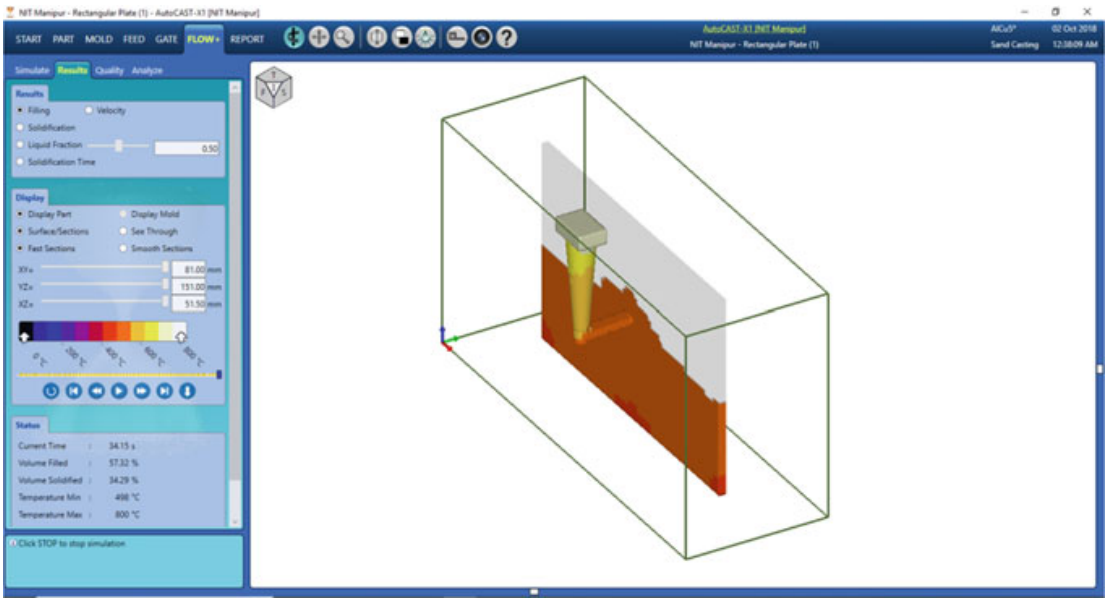

Fig. 41.12 Volume of fill with the pouring temperature of 800 °C

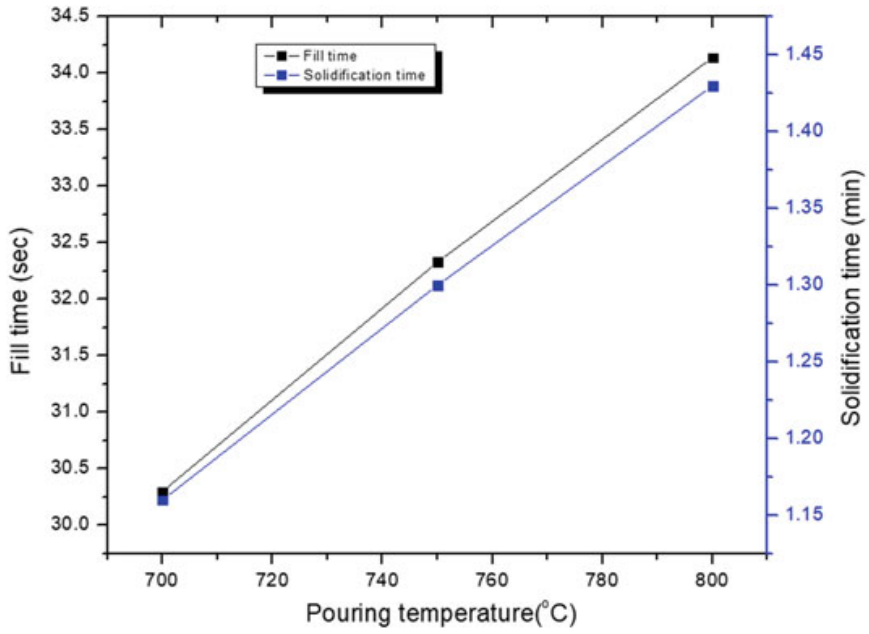

Fig. 41.13 Fill time and solidification time with altered pouring temperatures

41.3 Results and Discussion

Casting simulation enhanced the fluidity of the molten metal with altered pouring temperatures. In Fig. 41.13, it was observed that with the increasing pouring temperature, the fill time and solidification time were increased. In Fig. 41.14, it was observed that when the fill time increased, then the percentage of the volume of fill in the cavity increased. In Fig. 41.15, it was observed that the percentage of the

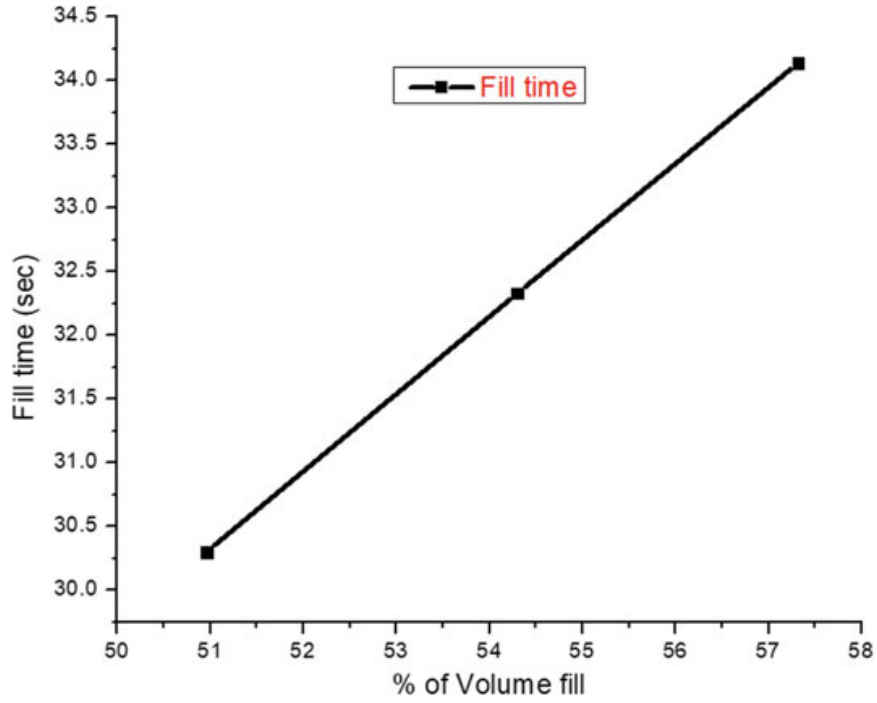

Fig. 41.14 Percentage of volume of fill with respect to fill time

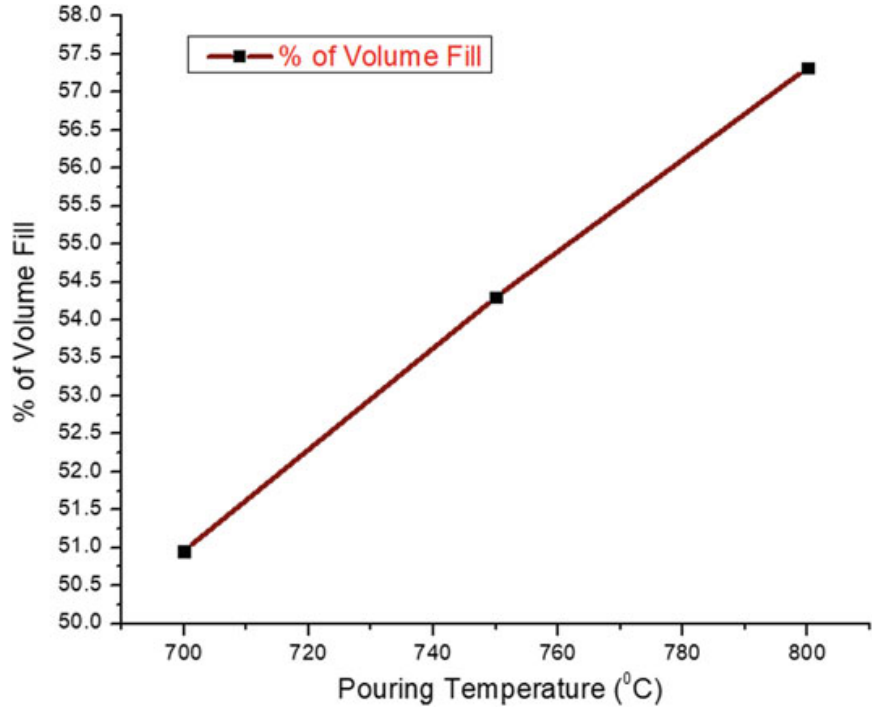

Fig. 41.15 Percentage of volume fill with the altered pouring temperatures

volume of fill increased with the increased pouring temperature. Hence, it was observed that the fluidity increased with the increasing temperature and fill time according as shown in Figs. 41.13, 41.14, and 41.15. Hence, it was observed that fluidity increased with increased pouring temperature.

41.4 Conclusion

In this present investigation, it was observed that solidification simulation enables visualization of freezing inside a casting and identification of the last freezing regions.

1. The effect of pouring temperature enabled the filling time and solidification time; it was observed at with the increasing pouring temperatures, i.e., 700 to 800 °C, the fill time and solidification time were increased.
2. It was observed that the volume of fill increased with increasing temperature and with the increased pouring temperature, the fill time and percentage of the volume of fill increased.
3. In casting simulation, it was observed that the effect of pouring temperature on the fluidity of the Al–Cu cast alloy was increased with the increasing temperature. It was found that the volume of fill increased with the increasing pouring temperature and also strong agreement was observed with the solidification time and fill time.
4. It was concluded that fluidity of Al–Cu cast alloy might be increased with increasing temperature. Hence, it was recommended that the industries have might implement the simulation before manufacturing to economize the product to reach all the levels of the customers.

Chapter 42
Analysis and Optimization of Tool Wear Rate in Magnetic Field-Assisted Powder-Mixed Electrical Discharge Machining of Al6061 Alloy Using TLBO

Arun Kumar Rouniyar and Pragya Shandilya

Abstract This paper presents the optimization and analysis of machining parameters on machining of Al6061 alloy using magnetic field-assisted powder-mixed electrical discharge machining (MFAPM-EDM) process. For performance analysis, peak current (I_P), spark on time (S_{ON}), spark off time (S_{OFF}), powder concentration (PC), and magnetic field (MF) are considered as machining parameters and tool wear rate (TWR) as performance measures. The experimental design based on Box Behnken Design is used for conducting the experiments and single objective optimization is performed using teaching–learning-based optimization (TLBO) algorithm. Peak current is observed as the most significant parameters followed by spark on time, magnetic field, and powder concentration. Model to predict TWR is developed in terms of machining parameters. The optimum set of machining parameters for minimum TWR using TLBO algorithm is obtained at I_P-1 *A*, S_{ON}-30 µs, S_{OFF}-51 µs, PC-10 g/l, and MF-0.45 T.

Keywords MFAPM-EDM · Al6061 alloy · Tool wear rate · TLBO

42.1 Introduction

Aluminum 6061 alloy is light and medium strength alloy with magnesium and silicon as principal element other than aluminum. Al6061 alloy is used in the field of aerospace, automobile, marine industries, and architectural and structural applications. This is mainly due to specific properties such as lightweight, hard, strong and toughness, high corrosion resistance, better machinability and

formability [1, 2]. Conventional machining of Al6061 possesses severe difficulties such as built of edge formation, adhesion between tool and workpiece, poor surface quality, dimensional inaccuracy and burr formation [3, 4]. Thus, to mitigate the above difficulties, the researchers have opted for the non-conventional machining process.

Among non-convectional machining process, electrical discharge machining (EDM) was found suitable for machining intricate profiles on difficult to machine materials irrespective of material hardness with high degree of automation [2, 5]. Material removal mechanism in EDM mainly occurs by melting and evaporation. EDM process was mainly used for tool and die making but at the current scenario, applications are extended to aerospace, military, automobile, and surgical industries. However, the machining with EDM at large scale has certain limitations such as low machining efficiency, poor surface finish, prone to heat and residual stress generated on workpiece material during machining [6–8]. Thus to overcome such problem, hybrid machining process known as magnetic field-assisted powder-mixed EDM (MFAPM-EDM) was developed which can machine complex profiles of conductive materials with higher efficiency and better surface quality. In this process, removal of material from the surface of the workpiece is assisted by powder particle mixed in a dielectric fluid in the presence of magnetic field. The material removal occurs by multiple discharges due to bridging of powder particle under the sparking area instead of single spark combined with Lorentz force developed due to the magnetic field-coupled electric field which assists in removing material. The Lorentz force changes the path of electrolytic ions by reducing the mean free path shifting of debris from the workpiece and tool in the discharge zone as well as accounts for increasing the electron density. Thus, this Lorentz force has a significant impact on the plasma channel which effectively expelling the debris particles leading to increase erosion volume and maintaining uniform discharge waves by gap causing improvement in the MRR, TWR, and better surface integrity [9, 10]. For example, Bhatt et al. [9] machined AISI D3, H13, and AISI D3 steel with tungsten and titanium powder mixed in EDM oil under the influence of magnetic field to examine the effect of process parameters on MRR, overcut, surface roughness, TWR, and microhardness. Krishna Kant [11] used *U*-shaped copper tool to machine EN-19 steel with graphite powder in the dielectric fluid in assisted with a magnetic field to study the effect of process parameters on overcut, MRR and surface roughness. Bains et al. [10] carried out machining of Al–Si MMCs with silicon carbide powder-mixed dielectric fluid under the influence of fixed magnetic field in EDM. Under the influence of the magnetic field at high spark energy, increase in material erosion rate and decrease in recast layer thickness, surface roughness, and microhardness were observed. Hienz et al. [12] performed machining on Ti-6Al-4V alloy under the influence of magnetic field to study the influence on erosion efficiency, plasma temperature, and debris field characterization.

After epitomized scrutiny of literature review, most of the literatures are available in magnetic assisted EDM or powder-mixed EDM process. Few literatures available on machining the difficult to cut conductive materials using

MFAPM-EDM process were improvement in MRR, TWR, and surface integrity was observed. In this present experimental work, MFAPM-EDM process was used to machine Al6061 alloy with aluminum powder mixed in EDM oil under the influence of magnetic field. The effect of machining parameters, namely peak current (I_P), spark on time (S_{ON}), spark off time (S_{OFF}), powder concentration (PC), and magnetic field (MF) on tool wear rate (TWR) were studied. Response surface model to predict TWR was developed, and single objective optimization was performed using teaching–learning-based optimization (TLBO) to determine the optimum machining parameters.

42.2 Experimental Setup and Methods

The experiments were performed on modified conventional die-sinking machine (EMS 5030, Elektra) with fabricated attachment equipped to it as shown in Fig. 42.1. The machine is supplied with ELECTRONIA PRS-20 which can operate peak current up to 35 A. Proper stirring system is designed to solve the problem of powder settling, and a magnetic system is attached for the quick removal of debris for the machining area. Al6061 alloy of dimension 40 mm × 40 mm × 10 mm was machined using 12-mm-diameter electrolytic copper as a tool, aluminum powder (mesh size-200), grade 5 EDM oil as dielectric fluid, and neodymium ring magnet. The machining parameters considered for the experimental work were peak current, spark on time, spark off time, powder concentration, and magnetic field. Box Behnken design (BBD)-based response surface methodology (RSM) was used for designing the experiments [13]. The level and range of machining parameters were decided based on literature review, one parameter at a time and specifications of machine setup. Table 42.1 shows the range and level of experimental machining conditions. For TWR, measurement of the weight of tool before and after

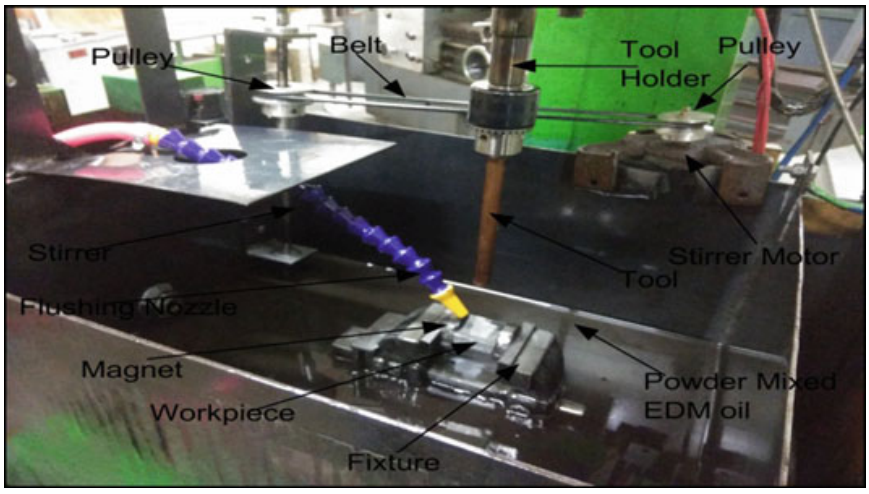

Fig. 42.1 Pictorial view of experimental setup for MFAPM-EDM

Table 42.1 Range and levels of experimental machining conditions

Sl. no.	Machining Parameters	Symbol	Levels		
			1	2	3
1	Peak current (A)	I_P	1	4	7
2	Spark on time (μs)	S_{ON}	30	50	70

4	Powder concentration (g/l)	PC	6	8	10
5	Magnetic field (T)	MF	0.15	0.30	0.45

machining was measured using digital precision pan balance (Model- SI-215D, Denver Instruments) with a maximum capacity of 210 grams. TWR was calculated using Eq. (42.1) [14]. The magnetic field was measured using digital gauss meter.

$$\text{TWR}\,(\text{g/min}) = \frac{T_{\text{bm}} - T_{\text{am}}}{t} \tag{42.1}$$

where

T_{bm} Tool weight before machining (g)
T_{am} Tool weight after machining (g)
t Machining time = 10 min.

42.3 Optimization Using TLBO

For this experimental work, teaching–learning-based optimization (TLBO) was employed. TLBO is a single as well as multi-objective optimizing algorithm to obtain solutions for discrete and continuous data problem. TLBO was coined by R. V. Rao for higher consistency which defines the teaching–learning capability of teachers and learners in the given classroom. Two basic modes, i.e., teacher phase and learner phase, are present in this TLBO algorithm. During teacher phase, the teacher tries to give knowledge to the learners and tries to improve the mean results of the classroom. While during learner phase, they try to interact among themselves to increase the knowledge [15]. The following steps are involved to find the optimum solution using TLBO algorithm.

(a) Design variables and its range, objective function, population size, and the number of iterations are defined.
(b) A table containing design variables value, objective function with population size are prepared and mean of all design variables are calculated.
(c) Based on objective function value, the teacher values are calculated.
(d) Other variable values are updated based on the teacher values.

(e) Comparison between new values and corresponding old values of an objective function are performed and the table is updated.
(f) Random values are selected and compared among the learners to improve the values.
(g) Comparison between new values and previous old values of the objective function are performed and the table is updated.
(h) Iterations are performed up to termination criteria.

42.4 Results and Discussion

The BBD design along with experimental results of TWR is shown in Table 42.2. Forty six different experimental combinations run are performed on machining of an Al6061 alloy by the MFAPM-EDM process.

42.4.1 Analysis of Tool Wear Rate

The calculated TWR for different experimental conditions was considered for the analysis. Table 42.3 describes the analysis of variance (ANOVA) for TWR carried out using design expert *V* 9.0.5 at 95% confidence level to determine the significant parameters. From Table 42.3, the *F*-value of a model was observed to be 64.36 implying the significance of the model. Likewise, I_P, S_{ON}, S_{OFF}, PC, and MF passed the significant test as $p < 0.05$ was observed. I_P was most influential machining parameters followed by S_{ON}, PC, and MF, while the effect of S_{OFF} was least. However, S_{ON}-PC and PC-MF among interactions and for quadratic terms I_P, S_{ON}, and PC was observed to be significant.

The effect of machining parameters depicted in main effect plot is shown in Fig. 42.2a–e. With increase in peak current from 1 to 7 A, increase in TWR was observed from Fig. 42.2a. This is mainly because of the increment in electrical power which melts the material from tool electrode due to high spark energy which is proportional to peak current. However, increase in TWR was observed with

increase in S_{ON} from 30 to 70 µs as shown in Fig. 42.2b; this is due to an increase in pulse duration for machining that produces high spark energy which causes melting and evaporation of material from tool surface. Also, decrease in TWR was observed from Fig. 42.2c with increase in spark off time from 35 to 51 µs. It is because of less time the spark gets to be in contact with the workpiece material resulting in the decrease in TWR. From Fig. 42.2d, the decrease in TWR was observed with an increase in powder concentration from 6 to 10 g/l. This was a result of the formation of a narrow channel which transfers the heat to the workpiece materials rather than tool after the addition of powder in EDM oil causing low TWR. From Fig. 42.2e, the decrease in TWR, with an increase in MF from 0.15 to 0.45 T, was attributed to the diamagnetic behavior of electrolytic copper which opposed the magnetic field when increased and the debris particles were repelled away causing low TWR.

42.4.2 Response Surface Modeling

A second-order model was developed in terms of significant machining parameters to predict the TWR. The regression coefficient of the model was obtained using experimental data at 95% confidence level. The second-order model for TWR in coded factors is stated in Eq. (42.2).

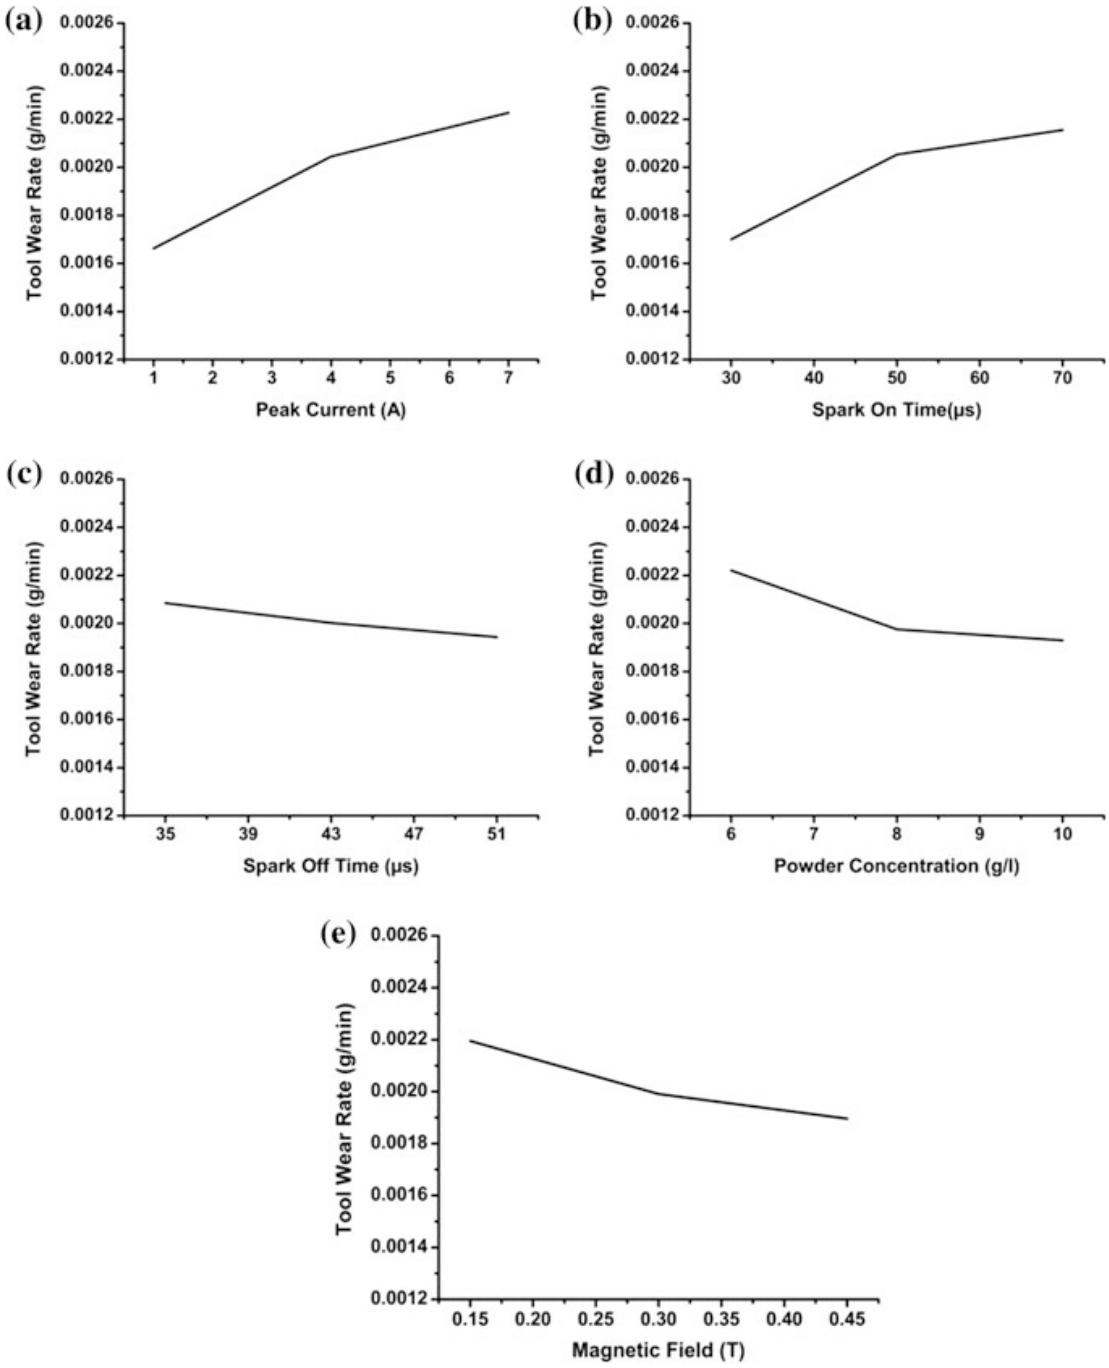

Fig. 42.2 Main effect plot of machining parameters **a** peak current **b** spark on time **c** spark off time **d** powder concentration **e** magnetic field on TWR

$$\begin{aligned}\text{TWR} = &+2.073\times10^{-3}+2.830\times10^{-4}\times A+2.278\times10^{-4}\times B-8.167\times10^{-5}\times C\\ &-1.454\times10^{-4}\times D-1.496\times10^{-4}\times E+1.171\times10^{-4}\times B\times E-7.450\times10^{-5}\times D\times E\\ &-1.108\times10^{-4}\times A^2-1.334\times10^{-4}\times B^2+6.274\times10^{-5}\times D^2\end{aligned} \tag{42.2}$$

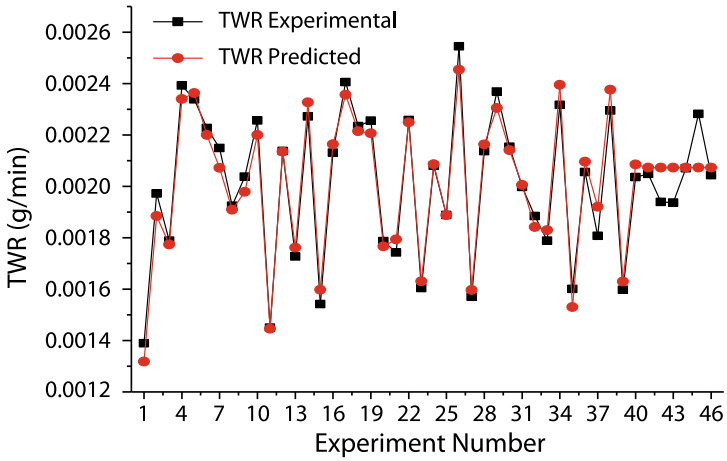

Fig. 42.3 Experimental and predicted TWR against experimental runs

Predicted *R*-Sq. value of 0.9199 for TWR was in reasonable agreement with the adjusted *R*-Sq. value of 0.9337. The second-order model developed was found to be congruent with the experimental data as shown in Fig. 42.3.

42.4.3 Optimization Using TLBO

Response surface model developed and experimental data were used in teacher–learner phase for optimizing the machining parameters. Single objective optimization was carried out to determine the optimum set of machining parameters for TWR. For optimization, the computer code was developed with population size = 46 and number of iterations = 20 using MATLAB R2016a. The optimal solution of machining parameters for TWR with the number of iterations is shown in Fig. 42.4, and convergence graph shows the decreasing curve for TWR with increasing the successive iterations. The optimized value of TWR was obtained at eighth iterations, and the optimum set of machining parameters for minimum TWR (0.000813 gm/min) was obtained at I_P-1 A, S_{ON}-30 µs, S_{OFF}-51 µs, PC-10 g/l, and MF-0.45 T, respectively.

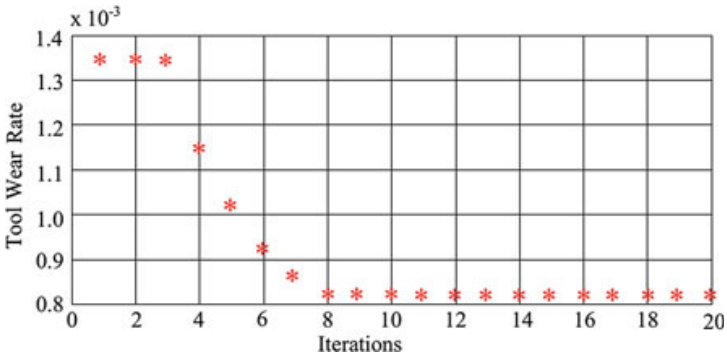

Fig. 42.4 TWR with number of iterations

Table 42.4 Confirmation results for TWR

Input machining parameters					TWR (g/min)	
I_P (A)	S_{ON} (µs)	S_{OFF} (µs)	PC (g/l)	MF (T)	Optimized	Experimental
1	30	51	10	0.45	0.000813	0.000894

42.4.4 Confirmation Test

Once the optimum machining parameters were identified using TLBO algorithm for minimum TWR, the same combination of machining parameters was used for the validation by performing the experiments in MFAPM-EDM process. The results obtained with TLBO and experiments for optimum machining parameters are shown in Table 42.4.

42.5 Conclusions

In this paper, magnetic field-assisted powder-mixed EDM was successfully used for machining Al6061 alloy with aluminum powder mixed in EDM oil. The experimental design was based on BBD, and ANOVA was carried out at 95% confidence level to determine the influential machining parameters for TWR. Modeling in terms of coded machining parameters was carried out using response surface modeling, and the optimized set of machining parameters was obtained using TLBO algorithm. The following conclusions were obtained from this work.

1. Peak current was most influential machining parameters followed by spark on time, magnetic field, and powder concentration while spark off time has least effect.
2. Second-order model to predict the TWR was developed using response surface and was found to be congruent with the experimental results.
3. Using TLBO, optimized set of machining parameters was obtained at eighth iteration for I_P-1 A, S_{ON}-30 µs, S_{OFF}-51 µs, PC-10 g/l, and MF-0.45 T for minimum TWR.

Chapter 43
ANFIS-Based Subtractive Clustering Algorithm for Prediction of Response Parameters in WEDM of EN-31

Kunal Chopra, Aishwarya Payla, Guneet Kaur and Eswara Krishna Mussada

Abstract Wire electrode discharge machining (WEDM) is an accurate but an expensive and time-consuming process. In order to establish a stable connection between input and output variables, implementation of soft computing techniques can be useful. Therefore, the current study focuses on comparing adaptive neuro-fuzzy inference system (ANFIS)-based subtractive clustering algorithm with numerous input combinations as well as multivariate regression models in order to simulate and map the output variables with the process parameters used during experimentations, namely pulse-on time (T_{on}), servo voltage (S_v), wire feed (W_f), and wire tension (W_t). Results show that ANFIS models have the ability to estimate the edge roughness (E_r) and kerf width (K_w) more accurately with 96.2 and 97.3% accuracy. ANFIS model is more reliable, accurate, and productive as it uses the learning of neural networks to predict. Also, the developed model has been used to study and explain the effect of various input variables upon the quality of machining. High pulse-on time directly decreases the quality increasing the edge roughness and kerf width which are both undesirable. Low wire feed has shown to decrease both the response parameters regardless of other input parameters. Wire tension has shown much less significant effect as compared to the other three variables.

43.1 Introduction

Manufacturing industry all around the world is focusing on improving quality even for intricate geometries but not at the expense of high cost. The issue of high forces generated in traditional machining processes has been overcome by the advent of non-conventional machining processes which removed the contact between the tool and workpiece and hence reducing contact and frictional stresses. Wire electrode discharge machining (WEDM) is one of the advanced machining process which uses electro-thermal process for machining conductive materials. A thin metal wire as the electrode removes the material by melting and vaporization of workpiece material [1]. Continuously flowing dielectric fluid ensures the flushing of debris thus formed from the workpiece surface. The spark erosion process used for material removal in WEDM makes it possible to machine even the hard materials. Since there is no contact between tool and workpiece surfaces, friction does not come into play and hence residual stresses generated at the cutting zone are low.

Mahapatra et al. [2] through the study of different input variables including pulse-on time (T_{on}), pulse frequency, discharge current, wire speed, wire tension (W_t) and dielectric flow on the surface finish, and kerf width (K_w) found discharge current, pulse duration, and dielectric flow rate to be the most influential parameters for minimization of surface roughness and kerf width in rough cutting operations. Kumar et al. [3] found I_P (peak current), T_{on}, T_{off}, and W_f to have effect on the surface finish in that order while WEDM of high-speed steel (HSS) through zinc-coated wire. Sharma et al. [4] did the experimental study followed by parameter optimization on WEDM and found out that T_{on} majorly affects the response parameters such as surface roughness (S_r) and C_r. Experimental investigation done by Garg et al. [5] focused on machining Al/10% $ZrO_{2(P)}$ metal matric composite by WEDM. They studied the effect of the input parameters on surface roughness (S_r) and cutting velocity (CV). Machining parameters such as pulse width, short time pulse and time between pulses were found to affect both the response parameters most. Servo control mean reference voltage was observed to have similar significance on affecting the response parameters. Fard et al. [6] machined AlSiC metal matrix composite to study the effect of T_{on}, T_{off}, W_f, W_t, S_v, and discharge current on S_r and cutting speed by applying ANOVA to the experimental results. In his study, T_{on} and discharge current were found to be the most significant factors influencing the studied targets while W_t had the least impact. Parmanik et al. [7] processed duplex stainless steel in WEDM and observed that increasing T_{on} did not have a linear effect on K_w and craters along with resolidified molten were noticed on the machined surface. Tosun et al. [8] analyzed the crater sizes formed due to 0.25 mm diameter brass wire under different cutting parameters. It was concluded that pulse duration and open-circuit voltage have adverse effect on crater [8]. Chopra et al. [9] found low T_{on} and S_v to be the important parameters to minimize edge roughness (E_r) while machining EN-31 through WEDM.

Regression is a statistical approach to establish a relationship between two sets of variables, dependent variables and the independent variables. Regression can further be multivariate regression or multiple regression. Multivariate regression refers to estimating more than one output variable using single regression model and when multivariate regression consists of more than one predictor variable it refers to multivariate multiple regression. Majumder et al. [10] studied the impact of pulse-on time, pulse-off time and wire feed on kerf width (K_w), S_r, and material removal rate (MRR). They developed general regression neural network (GRNN) and multiple regression models for prediction and comparison of studied key machinability aspects. Maher et al. [11] performed experiments to study the impact on CNC WEDM response parameters like cutting speed, surface roughness, and white layer thickness while machining titanium alloy grade 5(Ti6Al4V). Their study involves development of a regression model to study the effect of performance index on the machinability aspects studied. In order to increase the productivity and accuracy of the machining of super alloy, Udimet-L605 done by WEDM, Nain et al. [12] developed linear regression model to understand the relation between input and output parameters followed by application of particle swarm optimization (PSO), concluding T_{on} to be the most impacting factor on C_r.

Artificial neural networks were introduced to simulate the neural structure similar to brain by establishing a relationship between I/O data during training phase which could be recalled during the verification or optimization process [13]. In ANN algorithms, each processing element or neurons can reproduce the biological NN having numerous inputs and a single output considering certain assumptions and constraints. ANN is an effective technique which can approximate with high precision even nonlinear functions [14] but the efficiency is constrained to problem under consideration [15]. Ramakrishnan et al. [16] designed an ANN model using back-propagation algorithm to predict the characteristic parameters, namely MRR and S_r, of CNC WEDM while machining Inconel 718. Optimization was done using multi-response signal-to-noise ratio (MRSN) and analysis of variance (ANOVA) was applied to determine the level of impact of the response parameters.

Adaptive neuro-fuzzy inference system (ANFIS) combines ANN with fuzzy modeling thus capturing benefits of both techniques in one framework only. It provides a means to map the input–output data relations. Yilmaz et al. [17] developed a fuzzy model that allowed precise selection of EDM parameters using if-then. Fuzzification was done by triangular membership function while defuzzification process was then carried out by centroid area method in order to obtain minimum electrode wear and better surface quality. Maher et al. [18] applied ANFIS to predict the value of white layer thickness (WLT) in WEDM and obtained an accuracy of 97.39%. Maher et al. [19] successfully designed ANFIS model for the selection of optimum machining parameters with the objective of achieving higher productivity at the highest possible surface quality and sustainable development at minimum cost.

Present study is conducted with the objective of investigating the effect of four input parameters, pulse-on time, servo voltage, wire tension, and wire feed on the machining performance of die steel EN-31 and to develop both multivariate regression and ANFIS model to predict and improve the output parameters, viz. edge roughness (E_r) and kerf width (K_w). EN-31 alloy steel has a number of applications in manufacturing industry due to its outstanding wear resistance and high load-carrying capacity. There is limited literature available on the prediction and optimization of K_w; however, no study has been carried out for prediction of E_r while machining through WEDM.

43.2 Experimental Work

The experiments were conducted on "Electronica Wire-cut Electric Discharge Machine" which can cut with speeds upto 230 mm^2/min and workpiece of heights up to 250 mm can be held in its clamp. Out of many wires available for cutting operation, brass wire having a diameter of 250 μm was used which provides better integrity of surface while conducting current. Deionized water is a proven dielectric to provide a good conducting sphere of influence while machining and hence was used in our experimentations.

Four machining parameters, namely pulse-on time (T_{on}), servo voltage (S_v), wire tension (W_t), and wire feed (W_f), were selected in this study for investigating the effect on edge roughness and kerf width. These parameters were identified on the basis of literature survey and pilot experimentation to maintain the appropriate spark gap. T_{on} and S_v were scrutinized at three levels while W_f and W_t were scrutinized at two levels on the basis of economic impact of changing the parameters. Duty factor for the machine was kept at 0.7. A general full-factorial design for experimentation was used for studying the effect of each parameter on performance. Table 43.1 shows the control parameters and their levels along with the other parameters that were kept constant throughout the machining operation.

The crests and troughs formed along the edge were the result of craters and irregularities formed due to the rapid melting and re-solidification of material. The accuracy of machined component is a direct measure of kerf width and edge roughness which were measured at several locations along the machined edge by "Olympus optical microscope" as shown in Fig. 43.1 and averaged over all the readings for each experiment. Each machined specimen was cleaned with acetone before observing under the optical microscope.

Table 43.1 Control and constant parameters

Parameters	Level-1 (low)	Level-2 (medium)	Level-3 (high)
T_{on} (µs)	100	110	120
S_v (V)	20	40	60
W_f (m/min)	5	8	–
W_t (g)	660 g	1140 g	–
Wire diameter	250 µm	–	–
Constant machining parameters			
Wire material		Standard brass	
Peak current		12 (fine pulse and 2 power pulses ON)	
Peak voltage		11	
Cutting speed override		25%	
Duty cycle		0.70	
Servo feed		10 mm/min	
Dielectric fluid		De-ionized water	

43.3 Modeling Approach

Regression analysis has been used to map the input and output variables in order to obtain a function which could predict the response measures on the basis of given input values. Since the ranges of our parameters are not consistent and hence weights were required, instead, techniques like feature scaling, normalization, and polynomial feature scaling were applied as a part of data preprocessing step. It is usually done using Min-Max scaling method, which is the simplest method of all and consists of rescaling the range of features in range of [−1, 1]. Equation (43.1) shows the formula used. Platform used for this project is Jupyter Notebook and programming language was Python. Scikit-learn is a popular open-source library used to implement machine learning and perform statistical analysis in Python. It features various classification, regression, and clustering algorithms and is designed to interoperate with the Python numerical and scientific libraries NumPy, SciPy, and Pandas.

$$x' = \frac{x - \min(x)}{\max(x) - \min(x)} \tag{43.1}$$

After that, polynomial feature transformation was applied for both degree 2 polynomial and degree 3 polynomial. It helped find relationship between different dependent variables and their impact on independent variables, E_r and K_w. Cubic polynomial regression helped improve the R score from 67 to 94% for both of our response variables which is more accurate than linear regression. The function obtained for K_w and E_r are depicted in Eqs. (43.2) and (43.3).

$$\begin{aligned} k_w = {} & (-2.50e-10) + (-192.45)x1 + (-2165.67)x2 + (554.52)x3 + (-7.49)x4 \\ & + (-48.36)x1^2 + (6677.44)x1x2 + (-1715.03)x1x3 + (79.42)x1x4 \\ & + (-754.35)x2^2 + (-725.72)x2x3 + (-233.69)x2x4 + (554.52)x3^2 \\ & + (-159.07)x3x4 + (-7.49)x4^2 + (94.92)x1^3 + (-3708.53)x1^2x2 \\ & + (2081.60)x1^2x3 + (-222.51)x1^2x4 + (-125.49)x1x2^2 + (575.63)x1x2x3 \\ & + (-854.05)x1x2x4 + (-1950.18)x1x3^2 + (895.14)x1x3x4 \\ & + (115.820)x1x4^2 + (439.84)x2^3 + (118.36)x2^2x3 + (-11.80)x2^2x4 \\ & + (-35.93)x2x3^2 + (213.71)x2x3x4 + (605.77)x2x4^2 \\ & + (554.52)x3^3 + (-210.62)x3^2x4 + (-355.05)x3x4^2 + (-7.49)x4^3 \end{aligned} \tag{43.2}$$

$$\begin{aligned} E_r = {} & (6.68409772e-13) + (44.15)x1 + (95.005)x2 + (47.19)x3 + (-10.25)x4 \\ & + (-2.44)x1^2 + (-310.30)x1x2 + (-165.98)x1x3 + (62.73)x1x4 + (36.996)x2^2 \\ & + (59.24)x2x3 + (8.78)x2x4 + (47.19)x3^2 + (-33.66)x3x4 + (-10.25)x4^2 \\ & + (-48.77)x1^3 + (236.87)x1^2x2 + (207.42)x1^2x3 + (-156.19)x1^2x4 \\ & + (-34.74)x1x2^2 + (-127.937)x1x2x3 + (34.075)x1x2x4 \\ & + (-198.43)x1x3^2 + (216.10)x1x3x4 + (65.22)x1x4^2 + (-12.088)x2^3 \\ & + (8.95)x2^2x3 + (13.79)x2^2x4 + (42.10)x2x3^2 + (-21.76)x2x3x4 \\ & + (-28.67)x2x4^2 + (47.19)x3^3 + (-41.62)x3^2x4 + (-55.87)x3x4^2 + (-10.25)x4^3 \end{aligned} \tag{43.3}$$

where $x1$, $x2$, $x3$, and $x4$ are the independent variables (T_{on}, S_v, $W_{f,}$ and $W_{t,}$ respectively) along with the regression coefficients.

ANFIS model exploits the capability of learning by neural network in order to establish a relationship between input–output parameters which uses fuzzy rules. Due to high variability in the input variables, subtractive clustering algorithm was used for fuzzy rule determination process which checks each and every data point for potential cluster center and the point with highest density in its vicinity is considered as the cluster center with readings outside the range of influence of that center being excluded and are again checked for potential of being a cluster center. It is an iterative process that runs until all points lie within the range of influence of a cluster center. Subtractive clustering approximates the function as a generalized bell curve and determine the number of rules and membership functions. Since the number of centers to be created for the distribution of data was not clear, automated algorithm of subtractive clustering and fuzzy rules were used. Similar to feature scaling, the data were first normalized as ranges for our variables are not same. In normalization, mean is involved when standardizing the data as shown in the equation below:

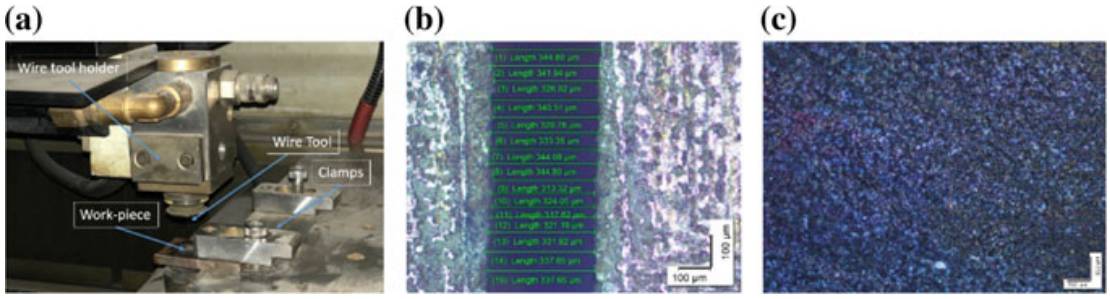

Fig. 43.1 **a** Experimental setup, **b** kerf width measurement, and **c** microscopic image of machined surface at T_{on} = 110 µs, S_v = 60 V

Table 43.2 Information of the trained ANFIS model

Number of nodes	307
Number of linear parameters	150
Number of nonlinear parameters	240
Number of training data pairs (membership functions)	30
Number of fuzzy rules	30

$$x' = \frac{x - \text{average}(x)}{\text{stdev}(x)}. \tag{43.4}$$

The data were then trained using the MATLAB's ANFIS toolkit using subtractive clustering as an FIS technique having 0.5 s the range of influence using the hybrid training algorithm. The structure with four input and single output parameters formed a structure containing 30 input membership functions and fuzzy rules as shown in Fig. 43.1. The membership functions and parameters obtained are shown in Table 43.2. Training error for E_r and K_w came out to be 2.16e–7 and 1.51e–7, respectively. The trained model was used to test the data and predict for randomly selected readings as mentioned in Sect. 43.4.

43.4 Results and Discussion

Effect of machining parameters on E_r and K_w is shown in Figs. 43.2 and 43.3. With the rise in S_v and T_{on} values roughness is found to be increasing. While wire tension at higher S_v values and wire feed has negligible effect on the roughness. Higher values of wire tension reduce the vibration in the wire thus maintaining the spark gap required for the machining process. The reduced vibrations give more interaction time to electrode with the workpiece thus utilizing the energy available for material removal and forming larger number of craters on the surface. At higher gap, voltage energy density is more resulting in more rapid vaporization and hence localized material removal takes place at the cutting edge which leads to higher

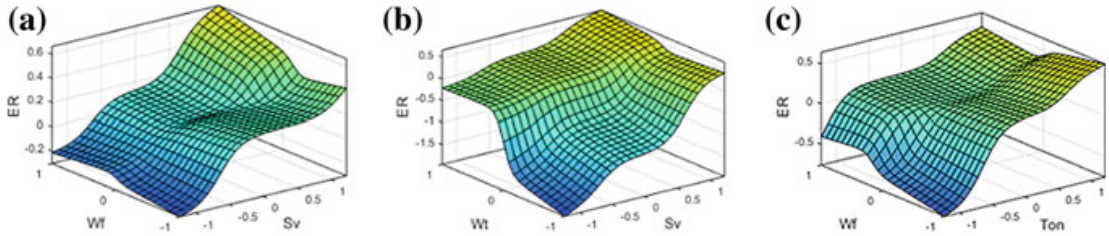

Fig. 43.2 Modeled edge roughness by ANFIS w.r.t **a** wire feed and servo voltage, **b** wire tension and servo voltage, and **c** wire feed and pulse-on time

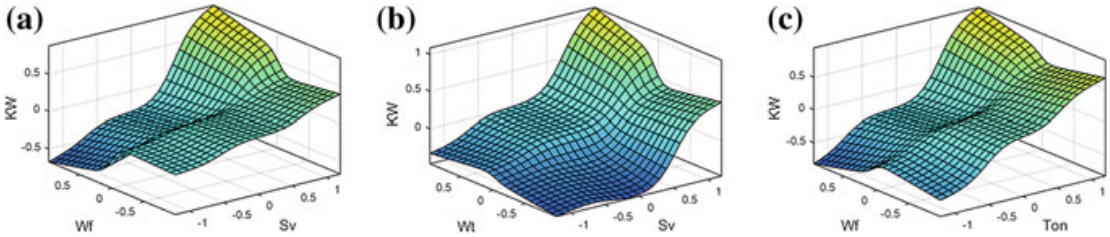

Fig. 43.3 Modeled kerf width by ANFIS in w.r.t. **a** wire feed and servo voltage, **b** wire tension and servo voltage, and **c** wire feed and pulse-on time

roughness. As the pulse duration increases, discharge energy around the wire intensifies. Due to more energy available at the spark zone, deep craters are formed which contribute to the roughness of the cutting edge.

Kerf width depends on the radius of effective spark gap. With the rise in S_v spark energy increases, this increases accounts for a wider spark gap and hence higher kerf width values. Kerf width was found to be increase with T_{on}. As at higher T_{on} values, more electrons from the wire comes in contact with the neutral particles of dielectric fluid. This interaction magnifies the ionization effect which causes more material to vaporize. While wire tension is not affecting the kerf much, wire feed at lower S_v and T_{on} values decreases the kerf. This can be accounted to the inability of wire to maintain least required spark gap for conduction when the vibrations in the wire are more at higher feed. When more discharge energy is available, increase in vibrations results in widening the gap further.

43.5 Model Verification

Six random readings were selected to test the models generated by both the methods. First, they were put into the relation obtained from multivariate regression and each output value was compared with experimental value and a prediction error was calculated for both E_r and K_w as shown in Tables 43.3 and 43.4. Average error, E_{avg} was measured by the following formula:

Table 43.3 Comparison of experimental and predicted responses of E_r for test data

Machining parameters				Response parameters			Predictive error	
T_{on}	S_v	W_f	W_t	Experimental	ANFIS	Regression	ANFIS	Regression
100	40	8	1140	8.09	8.44	6.91	0.043	0.147
100	60	8	660	11.61	10.97	15.09	0.054	0.301
110	40	5	660	10.49	10.79	11.22	0.028	0.069
110	60	5	1140	10.81	10.63	11.43	0.017	0.057
120	20	8	1140	10.12	9.82	10.98	0.030	0.084
120	20	5	1140	9.38	9.90	7.04	0.055	0.249
						E_{avg}	0.038	0.151

Table 43.4 Comparison of experimental and predicted responses of K_w for test data

Machining parameters				Response parameters			Error	
T_{on}	S_v	W_f	W_t	Experimental	ANFIS	Regression	ANFIS	Regression
100	40	8	1140	302.689	299.811	302.689	0.009	0.055
100	60	8	660	292.041	297.377	292.041	0.018	0.002
110	40	5	660	271.998	288.615	271.998	0.057	0.129
110	60	5	1140	325.289	316.444	325.289	0.027	0.033
120	20	8	1140	331.386	325.799	331.386	0.016	0.003
120	20	5	1140	311.654	322.612	311.654	0.035	0.095
						E_{avg}	0.027	0.053

$$E_{\text{avg}} = \frac{1}{m}\sum_{i=1}^{m} Ei. \tag{43.5}$$

where E_i = error of sample number i an m is the total number of samples.

$$E_i = \left|\frac{\text{Experimental} - \text{Predicted}}{\text{Experimental}}\right| \tag{43.6}$$

The errors in multivariate regression model came out to be 15.1 and 5.3% for E_r, and $K_{w,}$ respectively. The same six readings were then predicted with the ANFIS model and again a prediction error was measured. ANFIS model predicted the output with an error of 3.8 and 2.7% for E_r and $K_{w,}$ respectively. Figure 43.4 shows the comparison of measured and predicted values of test data in ANFIS model. These low values of average error show that the ANFIS model developed is adequate to predict the studied response parameters, E_r and K_w. However, the average prediction error obtained through multivariate regression model for E_r and K_w are quite high when compared with ANFIS model and is thus, not capable of predicting the machinability aspects accurately.

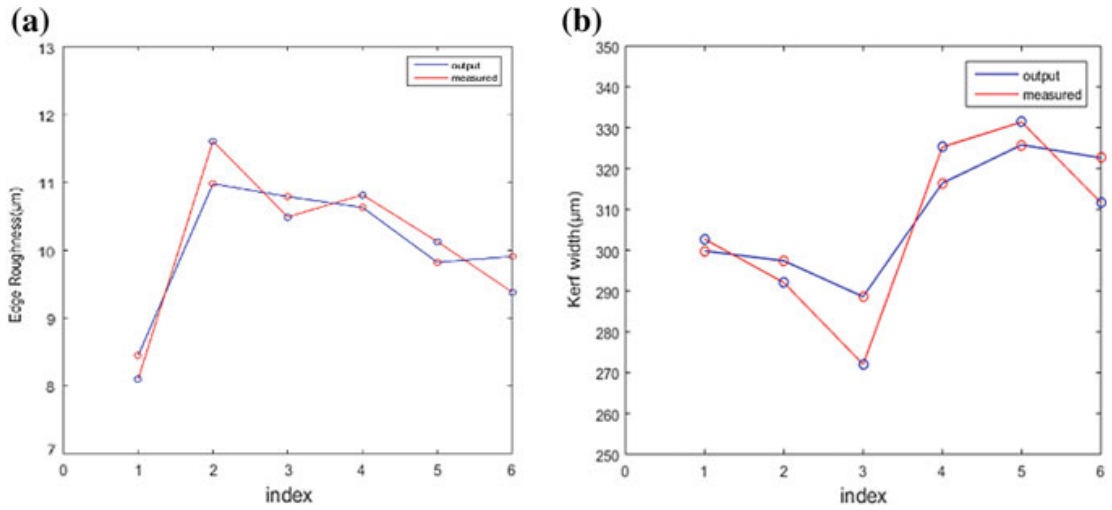

Fig. 43.4 Measured vs. predicted values for **a** edge roughness and **b** kerf width

43.5.1 Analysis of Machining Variables

Analysis of variance (ANOVA) was performed to determine significance of each machining parameters on both the responses. E_r is most influenced by servo voltage followed by W_t, W_f, and T_{on} as can be seen from Table 43.5 below, whereas Table 43.6 shows that T_{on} and W_f are the most and least important parameters, respectively, for affecting the kerf.

Main effects plots for the mean of E_r and K_w were also plotted using MiniTab software. Figure 43.5a shows the relation of E_r with the various machining parameters. Roughness is increasing with the increase in W_t, S_v, and T_{on} but is inversely dependent on the W_f, while K_w is seen to be directly dependent on all the input parameters.

Table 43.5 ANOVA table for mean w.r.t. E_r

Source	DF	Adj SS	Adj MS	*F*-value	*P*-value
T_{on}	2	2.565	1.282	0.3	0.745
S_v	2	56.17	28.087	10.39	0
W_f	1	14.83	14.827	3.86	0.058
W_t	1	1.489	1.489	0.35	0.557

Table 43.6 ANOVA table for mean w.r.t. K_w

Source	DF	Adj SS	Adj MS	*F*-value	*P*-value
T_{on}	2	7344	3671.9	16.83	0
S_v	2	2023	1011.6	2.67	0.084
W_f	1	267.3	267.3	0.64	0.43

43.6 Conclusion

Manufacturing Industry has a socio-economic responsibility in providing quality products keeping the costs incurred as low as possible. This has driven many researchers to look for best set of machining conditions. A full-factorial design has been used for experimentations upon which predictive models were built through multivariate regression and ANFIS. ANFIS model was able to predict with an accuracy of 96.2 and 97.3% for E_r and $K_{w,}$ respectively, which is higher than that obtained by regression model. Surface plots from ANFIS show that high T_{on} values increase the E_r significantly. High W_t also increased the roughness on edges. Similarly, increasing T_{on} and S_v increased the K_w. Lower wire feed value was able to decrease the K_w even at high S_v and T_{on}. These inputs cannot be kept too low as productivity is again a matter to be considered while production and hence a trade-off is necessary while deciding the input variables for any machining process. Further work can include finding the most optimum input variables which could give highly efficient process.

Chapter 44
On Estimation of Scallop Height from CNC Part Programs

A. Kukreja and S. S. Pande

Abstract Today, complex freeform surfaces are widely used on parts in automobile, aerospace, and die– mold industries. Multi-axis computer numerical control (CNC) machines are used to manufacture such parts as they need tighter tolerances and high surface finish to meet functional and aesthetic requirements. Scallop height is primarily used to measure and assess the surface quality of such products. The inspection methods used in practice are expensive and need experienced personnel. No simulation techniques exist, as of now, to estimate the part quality apriori. This paper reports the development of an algorithm to estimate the scallop heights for freeform surface machining from the CNC part programs. The developed system takes STL file of the simulated machined component from the VERICUT and slices it along the specified planes. Points so generated are analyzed to estimate scallop heights at various regions on the surface using numerical curve-fitting techniques. The developed system has been validated with the case studies. The system provides a robust and accurate estimation of the part quality.

Keywords Scallop height estimation · Surface topography · CNC machining

44.1 Introduction

Today freeform surfaces are widely used on parts in automobile, aerospace, and die–mold industries. To suit various functional and aesthetic requirements, these parts need to be manufactured with tighter tolerances and good surface quality.

Multi-axes (3–5 axis) CNC machines are mainly used to manufacture such complex freeform surface parts [1]. They need a robust, error-free part program to drive the tool for machining.

The literature documents a focused research effort to develop various toolpath planning strategies (iso-planar, iso-scallop, etc.) [2–4] during the past two decades. In the commercial domain, several CAM systems exist which provide facilities for part modeling, toolpath planning, and CNC code simulation to generate and validate CNC part programs. CNC simulators provide the graphical simulation of toolpath and provide an estimation of machining time and code length. However, there is no facility in any CAM software/simulator to estimate the part scallop height which forms a primary measure of the part quality. VERICUT is one such software that provides the simulation of machining and gives the user a tool to measure scallop height at particular points [5]. The "manual" measurement system allows the measurement of scallops one point at a time which is cumbersome, error-prone, and could even leave some of the areas unobserved.

Literature reports very scant work focused on the prediction of surface roughness during milling. Ralph and Loftus [6] proposed a mathematical model for the average height, area, and volume of the scallops in freeform surface machining. However, it agreed poorly with machining trials. Bedi et al. [7] made a comparison of toroidal, ball end, and flat end mill in terms of surface roughness quantified as scallop heights and feed marks. A comprehensive review of the inspection techniques for machined freeform surfaces was presented by Li and Gu [8]. They pointed out that the inspection techniques are costly, complex, and time-consuming. The CNC part programs are thus required to be generated in a sequential design–plan–machine–inspect route which increases the cycle time. No system has been developed that can predict scallop height variation directly from part programs in the simulation. A need, thus, exists to develop an accurate procedure to estimate a priori part quality (scallop height) from the CNC part program during simulation. This paper is an attempt in this direction.

Rest of the paper is organized as follows. Section 44.2 explains the modular diagram and data flow of the system developed. The case studies are discussed in Sect. 44.3, and the conclusion is presented in Sect. 44.4.

44.2 Modular Diagram of the System

Figure 44.1 shows the modular diagram of the system. The developed system takes NC codes as input. It is simulated in VERICUT 8.0 to generate a CAD model of the machined surface in the STL format. The STL model file is exported, and is, in effect, processed by our system. The CAD model (STL file) is sliced by the inspection planes perpendicular to the lay direction of the machined surface. The inter-planar distance is definable by the user to decide a number of slicing planes. The intersection of the inspection (slicing) plane and STL machined model generates the surface profile in the form of points. A curve is fitted to these intersection

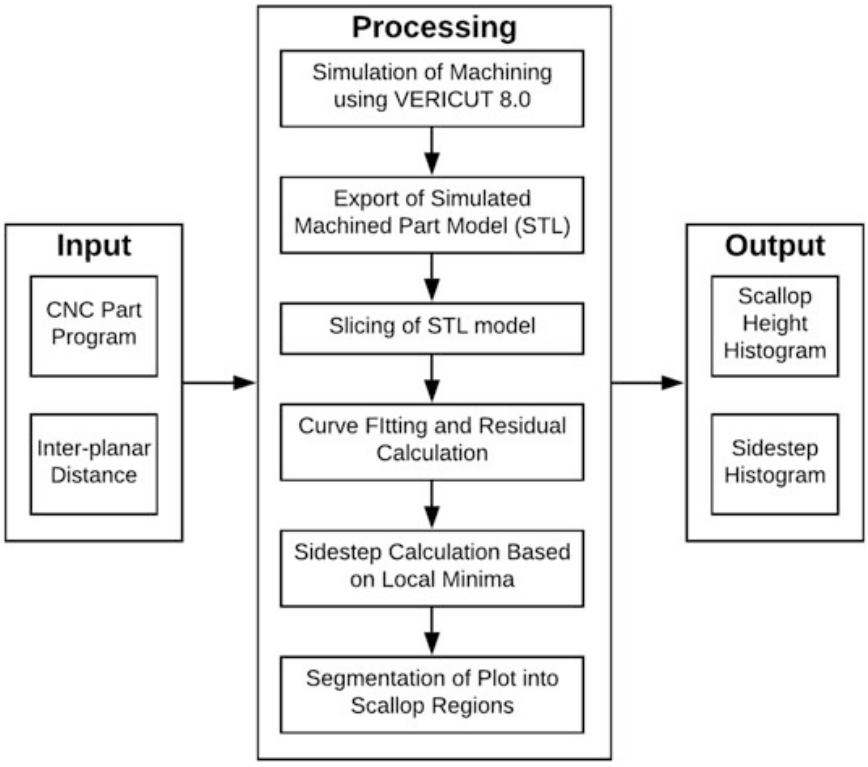

Fig. 44.1 Modular design of the system

points to generate a surface profile in the evaluation plane. Scallop height is computed from the curve by the residual calculation and segmentation at several points throughout the surface. Scallop height and step size estimated are plotted as histograms. In what follows, various system modules are explained.

44.2.1 Slicing of CAD Model

The machined part model (STL) model generated in VERICUT is sliced using parallel planes that are perpendicular to the lay direction (Fig. 44.2a). The intersection of the slicing planes and STL model would give points that form the surface topology pattern with superimposed waviness and roughness profiles (Fig. 44.2b).

Due to the direct slicing of STL facets, the scallop curve therefrom is well defined with less noise. A MATLAB function file "stl_slice_and_plot" was used [9]. The function first finds the triangles that intersect with the slicing plane. The lines created on the triangle face by the intersection plane are identified and processed further. The distance between the slicing planes is user definable, and hence, the user can control the areas to be evaluated and generate data on the desired surface topography.

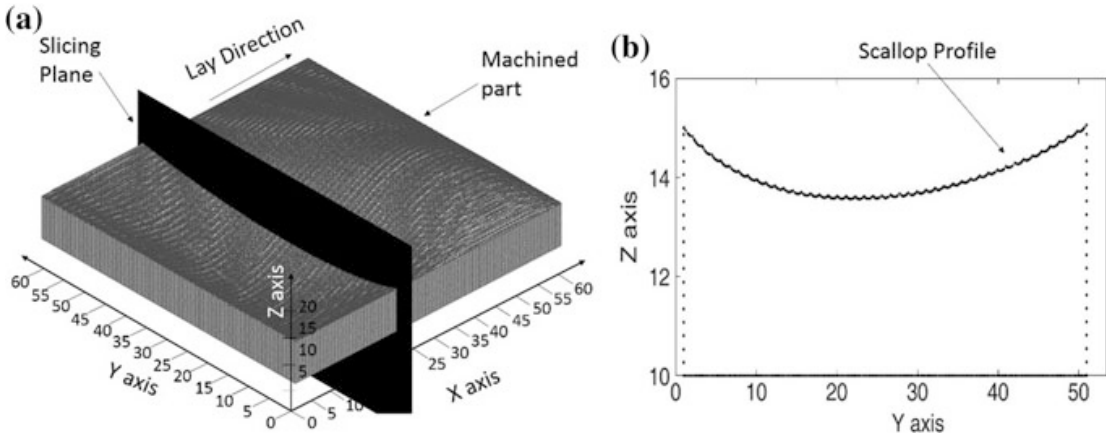

Fig. 44.2 **a** Slicing of the STL model and **b** points generated after slicing

44.2.2 Curve Fitting and Residual Calculation

After getting the point data, the next task was to remove waviness from the profile and calculate scallop heights based on the surface roughness profile. The waviness is removed by fitting a curve and then calculating the residuals of all data points. Residual gives the measure of skewness of the scallop data. Several curve-fitting methods were tried out [10]. For a large dataset, using "Gaussian fitting" and "third-degree polynomial fitting" resulted in poor fitting as the residual values were coming out to be large and were skewed on either side of the curve. After several trials, the ninth-degree polynomial fitting was found to be giving best approximation with residual variation within the desired level. Hence, in the present work, ninth-degree polynomial curve fitting approach has been used. The main advantages of polynomial fits include reasonable flexibility for data that is linear and not too complicated. This makes the fitting process fast, accurate, and computationally simple [11]. Equation (44.1) shows the polynomial model for curve fitting used in this work.

$$z = \sum_{k=0}^{n} p_i y^{n+1-i} \tag{44.1}$$

where $n + 1$ is the order and n is the degree of the polynomial ($1 \leq n \leq 9$). The order gives the number of coefficients to be fitted, and the degree gives the highest power of the predictor variable. The minimum distance (residual) of all the scallop points from the curve points are calculated based on Eq. (44.2).

$$\text{R(i)} = \min\left(\sqrt{\left(z_{1i} - z_{2j}\right)^2 + \left(y_{1i} - y_{2j}\right)^2} \quad \forall\, j\epsilon[1,m]\right) \;\forall\, i\epsilon[1,k] \tag{44.2}$$

where R = minimum distance of scallop point "i" from the fitted curve; m is the total number of points taken on the fitted curve; y_1, z_1 signifies the scallop points; k is the total number of scallop points; y_2, z_2 signifies the sample points taken on the fitted curve.

44.2.3 Segmentation and Scallop Height Calculation

Scallop pattern can be clearly seen on the profile after the residual calculation (Fig. 44.3b). The generated residual curve is then segmented based on the sidestep while generating the CNC toolpath. The sidesteps are identified by searching for consecutive local minima or local maxima points. The local minima are found by comparing the z-values of the preceding and succeeding points with the current point.

The distance of two consecutive local minima (the difference between y-values) gives the sidestep variation in the slicing plane, that, in turn, facilitate calculation of scallops. The plot shown in Fig. 44.4 is then segmented as per calculated sidesteps.

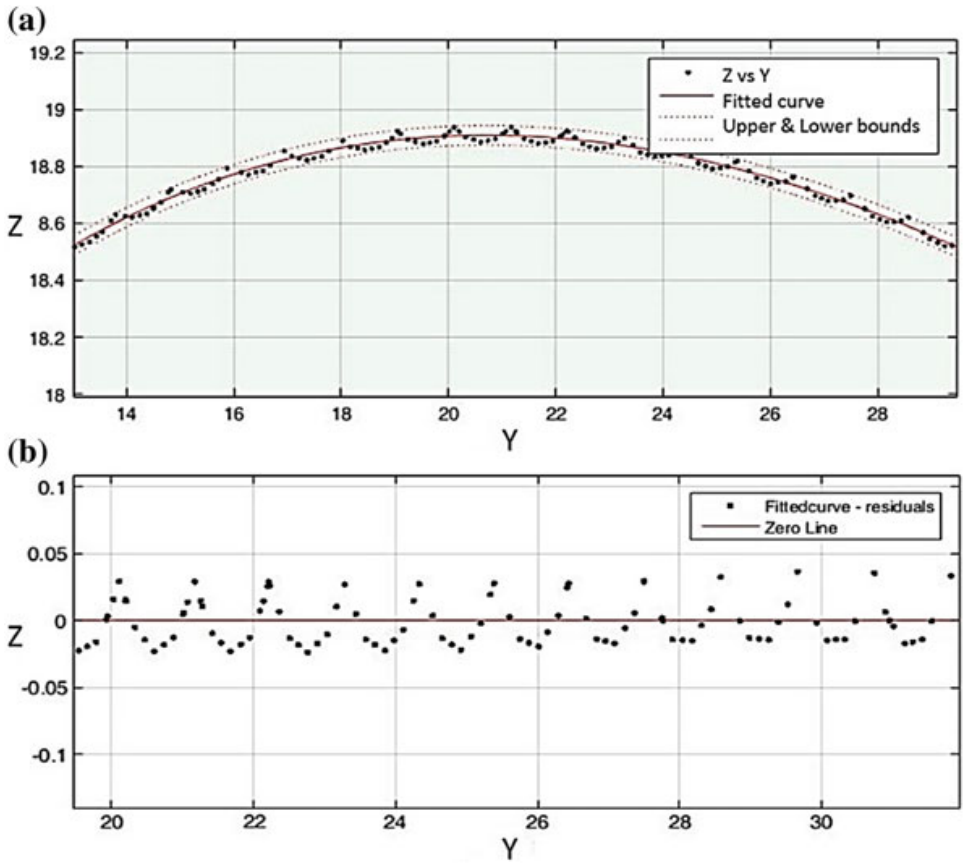

Fig. 44.3 **a** Curve fitting and **b** residual plot

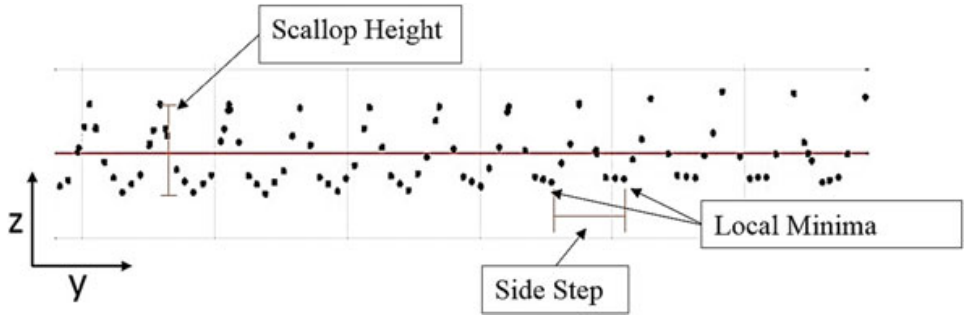

Fig. 44.4 Segmentation and scallop height calculation

The highest and lowest points (z) in the segments give scallop height for each sidestep (Eq. 44.3).

$$\check{S} = \max(z_i) - \min(z_i) \tag{44.3}$$

where $\check{S}$ is scallop height and z_i is the z-coordinate of scallop points. The case studies have been presented in the next section.

44.3 Results and Discussions

The algorithm for scallop estimation was implemented using MATLAB R2015b on Windows 10 platform, Intel Core i5, and 4 Gb RAM. The simulation software VERICUT 8.0 was used to generate a CAD model of the part (in the STL format) produced by the input CNC part program. The validation of the developed system was done using Mastercam X5-based iso-planar toolpath planning strategy. This was followed by extensive testing of the system on different kinds of surfaces produced with CNC programs with various toolpath strategies, like iso-parametric, iso-scallop, and adaptive planar [12].

The following case studies show the results and validation of the approach. The case study 1 refers to a relatively simple geometry with known values of scallops while case study 2 explores a complex bicubic Bezier surface with adaptive sidesteps generated using algorithm proposed by Dhanda and Pande [12] for three-axis CNC machining.

44.3.1 Case Study 1

In this case, the CNC part program was generated using Mastercam X5. The model has concave and convex portions (Fig. 44.5a). The scallop height was set to be 0.05 mm on a flat surface with sidestep 1.091 mm. It can go up to 0.1 mm at 45° to the lay direction.

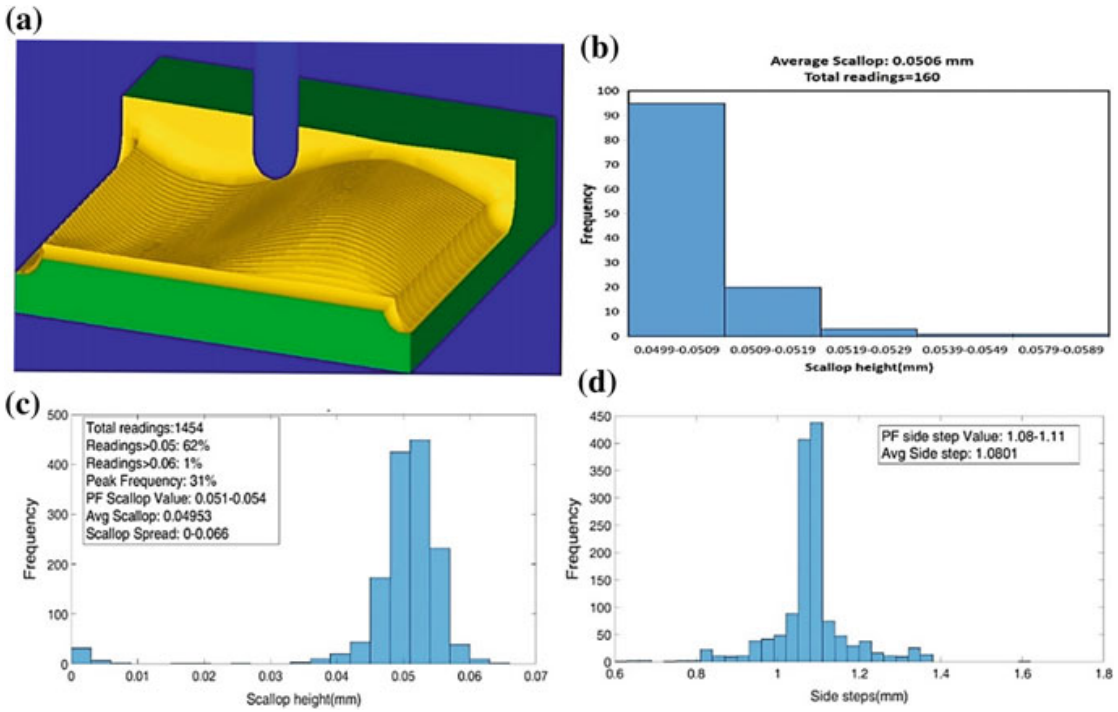

Fig. 44.5 Case 1; **a** Mastercam generated tool paths; **b** scallop estimation using VERICUT; **c** scallop estimation using developed system; and **d** sidestep variation

The scallop option in the VERICUT X-Caliper was used to measure the scallop height formed by two parallel intersecting cylinders chosen manually. It then identifies the cylinders being measured by displaying intersecting circles on the machined part model [5]. Figure 44.5b shows the generated histogram of the values estimated by the VERICUT (Range: 0.0499–0.058 mm). The scallop heights were estimated on 160 points (15 planes) throughout the surface using the X-Caliper tool of VERICUT. The average scallop was found to be 0.0506 mm. It is a known fact that the concave region has larger scallop heights and convex region has smaller scallop heights than the flatter region for the same sidesteps. The values estimated using VERICUT does not show this trend. This is because it does not consider the curvature of the surface while estimating scallops. The measurement/estimation is very approximate with limited points and sometimes unable to cover the whole machined surface.

Figure 44.5c shows the scallop height values estimated using the developed system (Range: 0.04–0.06 mm). The values below 0.05 mm indicate the convex regions and the values above 0.05 mm indicates concave regions. The scallop heights are calculated based on the sidesteps that are found using the method explained in Sect. 44.2.3. A similar trend is seen for the sidestep (Fig. 44.5d). In both the Fig. 44.5c and d, there is a spread but it is quite small. It is seen that the scallop frequency histogram from our system (Fig. 44.5c) has a well-defined symmetric peak around the expected scallop value (0.05 mm).

The spread in the sidestep values is due to the approximation in generating STL model of the machined stock, and the slicing of the STL model which may induce

errors (in calculating local minima) as the plane (facet) and curve intersection was solved using numerical methods in the developed system. This error in sidestep values directly affects the scallop height estimation and therefore some values of scallop height (Fig. 44.5c) are outside the tolerance band (0.04–0.06 mm).

44.3.2 Case Study 2

In this case, a complex bicubic Bezier surface was designed (Fig. 44.6a) and a CNC part program was generated using an adaptive planar strategy [12]. The maximum permissible sidesteps in various regions were automatically calculated by the algorithm reported in [12] based on surface curvature while maintaining the surface finish (i.e., tolerance <0.05 mm). The sidesteps were found to be in the range of 0.75–1.5 mm to maintain the required surface quality [12].

Figure 44.6(b) shows the scallop heights frequency histogram estimated using VERICUT (Range: 0.0235–0.0485 mm). The scallop height was estimated at 120 points (9 planes). The average scallop was found to be 0.0372 mm. Similar to case study 1, it is seen that the VERICUT values are not considering the effect of surface curvature. The scallop values are under tolerance but its range is much wider than desired. The developed system shows that most of the values of scallop height are in the range of 0.04–0.05 mm (Fig. 44.6c). About 83% of values were found to be

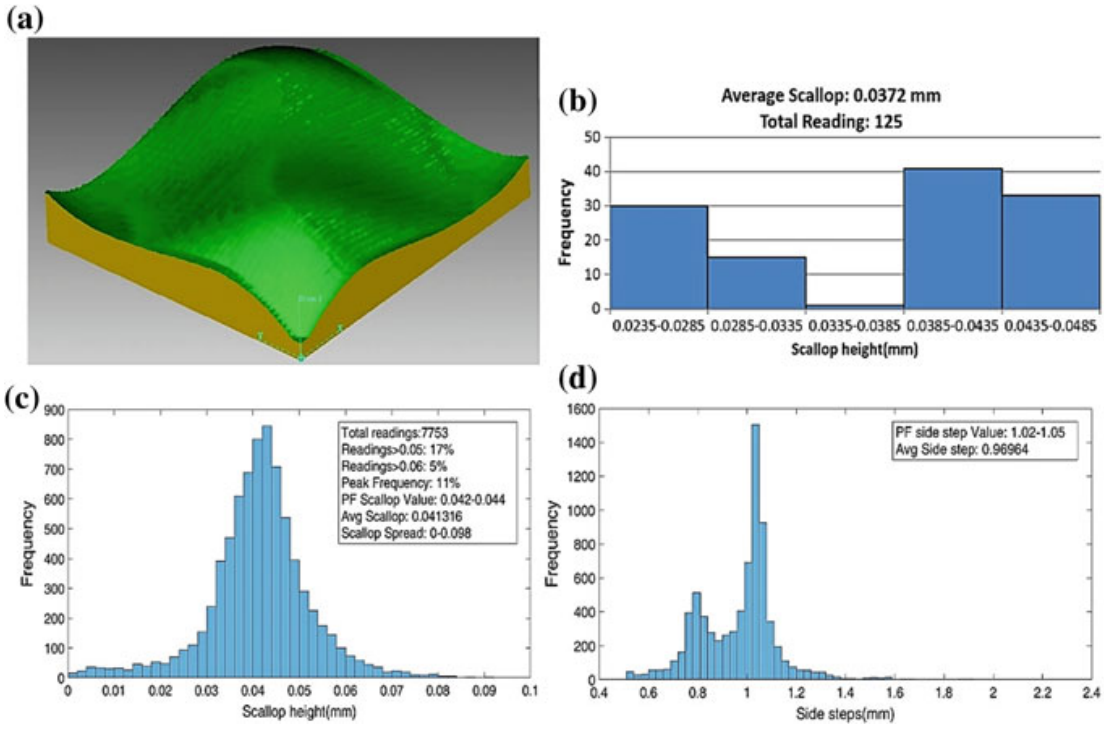

Fig. 44.6 Case 2; **a** Mastercam generated tool paths; **b** scallop estimation using VERICUT; **c** scallop estimation using developed system; **d** sidestep variation

below 0.05 mm with the average scallop of 0.041 mm. Hence, it agrees well with the desired values. According to the adaptive strategy reported in [12], the sidesteps for the concave regions were below 1.091 mm and for convex regions above 1.091 mm, a similar trend can be seen in Fig. 44.6d. The scallop heights were calculated based on these sidesteps values. The out-of-bound values seen in Fig. 44.6d may be again due to inherent error in the approximation done during STL generation and slicing algorithm.

As seen in case studies, the system is robust enough to estimate scallop for any kind of machined surface. The developed system could also be applied to five-axis machined parts. VERICUT cannot analyze these, and it fits the circle on the machined surface to find scallop heights but the surface generated in five-axis machines using flat end mill forms elliptical scallops. In essence, the developed system gives an accurate, fast, and robust estimation of scallop values from the simulation of a CNC part program without performing the actual cutting. It will thus help in significantly reducing product development lead time.

44.4 Conclusions

Despite a lot of research on CNC toolpath planning and simulation, no system exists that can estimate part quality (scallop height) directly from CNC part programs for the entire surface. Simulation software like VERICUT provides a very approximate tool. The system developed in this paper precisely caters to these requirements. The work proposes an algorithm for scallop height estimation from the simulation of machining using CNC part programs. In essence, it analyzes the simulated 3D machined surface, develops a mathematical model for the surface topography, and estimates the scallop and wavelength parameters. The system has been extensively tested for a variety of CNC part programs and surface topographies. It provides an accurate, fast, and robust estimate of part quality from the CNC part programs apriori.

Chapter 45
Influence of Guides on Critical Speeds of Circular Saws

S. Singhania, P. Kumar, S. K. Gupta and M. Law

Abstract This paper investigates the influence of guides on the critical speeds of circular saws. Guides constrain the out-of-plane lateral motion of these rotating saws and have a stabilizing effect by increasing the critical speeds, below which the rotating saw is stable. We present expanded analytical formulations in which guides are modelled as multiple discrete spring-damper elements approximating the distributed nature of the guide pad and saw interactions. We observe that for a given guide pad area, convergence analysis is necessary to understand how many discrete spring-damper elements are actually necessary to approximate the distributed nature of the guide pad and saw interactions. Curiously, we observe that damping in the guides has no significant influence on the critical speed and that it only changes the nature of frequency-speed characteristics of the rotating saw. We also find that critical speeds are sensitive to guides modelled with a distribution of discrete spring elements along the radial and/or circumferential directions. These observations suggest that more generalized formulations that model the guide pads as distributed spring-damper systems, rather than multiple discrete spring-damper elements, are necessary. We expect our findings to instruct and advise the placement of guides on rotating circular saws, such that a preferential increase in critical speeds can be obtained to make possible high speed and productivity circular sawing operations in the wood-working and metal-cutting industries concerned with circular sawing processes.

45.1 Introduction

Circular sawing is a common cutting operation across the wood-working and metal-cutting industries. It involves feeding a rotating circular saw into the work-piece to cut logs, bars, and tubes to lengths of desired sections. To meet the demands on high productivity in these industries, circular saws are desired to be operated at high speeds allowing more material to be removed per unit time. However, when the saw is rotating, forward- and backward-travelling waves are generated. The natural frequencies of the backward-travelling waves decrease with an increase in saw rotation speed, and the speed at which a natural frequency corresponding to a backward wave becomes zero is known as the critical speed [1]. When rotation speeds correspond to the critical speed, large amplitude vibrations appear, which can destroy the saw, the work material being cut, and the machine tool system. It is hence necessary to understand the factors governing critical speed instability, which is the focus of this paper.

Significant research attention across industries and academia has been paid on characterizing, predicting, and avoiding critical speeds. In some early seminal work, Mote and Nieh [2], and Szymani and Mote [3] studied the vibrations and critical speeds of rotating circular saws. Contemporarily, as a means of increasing the critical speeds of saws, Iwan and Moeller [4] presented formulations for saws constrained by guides. Guides constrain the out-of-plane lateral motion of rotating flexible saws and increase their critical speeds. Since these guides offer resistance to motion and act as a transverse load, Schajer [1], Hutton et al. [5], and Lehmann and Hutton [6], all investigated the influence of guided saws, with guides modelled as lumped spring elements. Hutton [5] observed that multiple guides were necessary to increase the critical speed. Though their [1, 5, 6] formulations allowed for the possibility of incorporating multiple guides, they ignored the influence of damping, if any, offered by guides. Damping in guides was investigated by Mote [7], and he observed that, if not favourably positioned, guides promote instability. However, his analysis was for the case of a stationary saw subjected to a moving load, and not the case we are interested in—a rotating, and constrained saw.

Since guides are actually pads distributed over a sector area constraining the lateral out-of-plane motion of the rotating saw, they need to be modelled as distributed systems. However, all the earlier reported work [1, 5–7] modelled the guide as a spring lumped at the geometric centre of the guide pad. Mohammadpanah and Hutton [8] were the first to investigate the distributed pad–saw interaction by modelling the guide as 16 linear springs distributed equally over the area of the guide pad. However, the effect of distributed damping in the guide was ignored. They also did not report on how many springs are sufficient to describe the distributed guide area, i.e. no convergence analysis of critical speeds to an increase in number of springs was presented.

This paper addresses the above two issues, i.e. understanding through systematic convergence studies, how many spring-damper systems are actually necessary to approximate the distributed pad–saw interaction, and understanding the role of

damping in guides on the critical speeds of circular saws. To do so, we systematically modify the formulations for guided rotating circular saws, to include the possibility of incorporating multiple spring-damper systems. These modified formulations are presented in Sect. 45.2. Models are first numerically verified in Sect. 45.3 with results from a commercially available circular sawing stability code, CSAW® [9]. Verification is only provided for the undamped guide modelled as a single spring. Numerically verified models are then subjected to convergence analysis in Sect. 45.4, which includes discussions on the influence of damping on critical speeds, as well as discussion about the influence of modelling discrete spring-damper elements distributed radially, and circumferentially. The paper is concluded in Sect. 45.5.

45.2 Mathematical Model for the Critical Speed of Circular Saws

A circular saw, laterally constrained by a guide pad, is modelled as a flexible disc with a clamped inner radius, r_i, outer radius, r_0, rotating with an angular velocity of Ω in the clockwise direction as shown in Fig. 45.1. Ignoring any external load, the governing equation of motion of the circular saw in the stationary frame of reference with a guide pad modelled as multiple spring-damper systems, distributed equally over the area of guide pad, is modified from [5] to become:

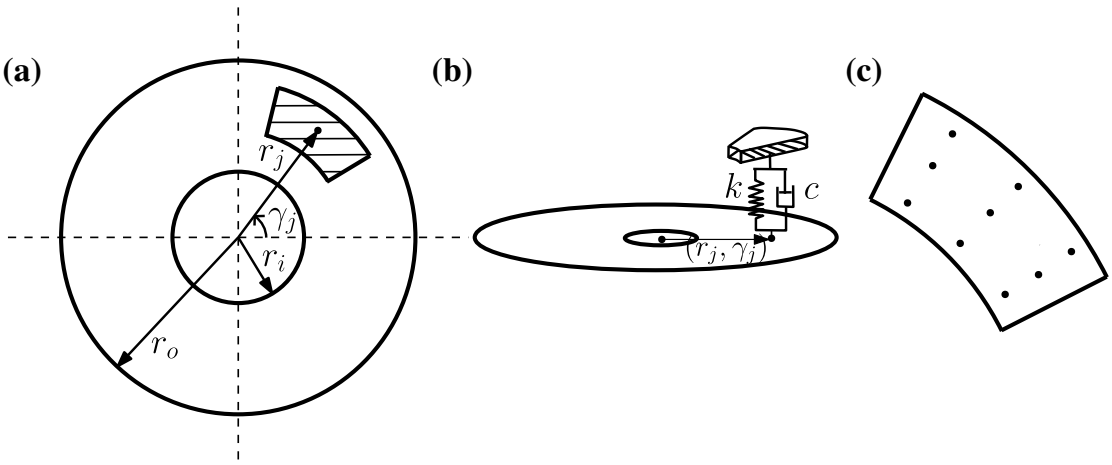

Fig. 45.1 Schematic of **a** circular saw and guide pad **b** the interaction between the guide pad and circular saw and **c** distribution of discrete spring-damper elements over the guide pad

$$D\nabla^4 u + \rho h\left(\frac{\partial^2 u}{\partial t^2} + 2\Omega\frac{\partial^2 u}{\partial t\partial\gamma} + \Omega^2\frac{\partial^2 u}{\partial\gamma^2}\right) - h\left[\left(\frac{1}{r}\right)\left(\frac{\partial}{\partial r}\right)\left(r\sigma_r\frac{\partial u}{\partial r}\right) + \left(\frac{1}{r^2}\right)\left(\frac{\partial}{\partial\gamma}\right)\left(\sigma_\gamma\frac{\partial u}{\partial\gamma}\right)\right] + \sum_{j=1}^{J} k_j u\left(\frac{1}{r}\right)\delta(r-r_j)\delta(\gamma-\gamma_j) + \sum_{j=1}^{J} c_j\frac{\partial u}{\partial t}\left(\frac{1}{r}\right)\delta(r-r_j)\delta(\gamma-\gamma_j) = 0 \tag{45.1}$$

wherein the first term represents bending stiffness, the second term represents inertial stress, the third term represents in-plane rotational stress, and the fourth and fifth terms represent stiffness and damping due to the interaction between the guide and circular saw, respectively, at the location of r_j, γ_j.

In Eq. (45.1), D is the flexural rigidity $(= Eh^3/12(1-\nu^2))$, E is the Young's modulus, h is circular saw thickness, ν is the Poisson ratio, ρ is the density of circular saw; $\nabla^4\left(= \left[\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \left(\frac{1}{r^2}\right)\left(\frac{\partial^2}{\partial\gamma^2}\right)\right]^2\right)$ is a bi-harmonic operator; $\delta(\cdot)$ is the Dirac delta function, k and c represent the stiffness and damping of the guide pad; J is the number of spring-damper elements; $u(r,\gamma,t)$ is the transverse displacement of the circular saw, and r, γ represent the radial and angular coordinates with respect to a fixed frame of reference.

Equation (45.1) is a fourth-order partial differential equation, and since it is difficult to solve it analytically, we use the Galerkin projection method to solve it [5]. To represent the deflection of circular saw due to bending, the transverse displacement $u(r,\gamma,t)$ can be written by a modal expansion. Therefore, the solution of Eq. (45.1) is assumed in the following form [5, 10]:

$$u(r,\gamma,t) = \sum_{m=0}^{m}\sum_{n=0}^{n}[C_{mn}(t)\cos(n\gamma) + S_{mn}(t)\sin(n\gamma)]R_{mn}(r) \tag{45.2}$$

wherein $C_{mn}(t)$ and $S_{mn}(t)$ are the unknown functions (modal coordinates), m and n represent the number of nodal circles and nodal diameters, respectively, and $R_{mn}(r)$ are radial functions chosen to satisfy the inner and outer boundary conditions of the circular saw. These $R_{mn}(r)$ can be approximated by polynomial functions as [5]:

$$R_{mn}(r) = \sum_{i=0}^{4} E_{mni} r^{m+i}, \tag{45.3}$$

wherein E_{mni} are unknown coefficients determined from the out-of-plane boundary conditions given by Eq. (45.4) and additional normalizing conditions, $R_{mn}(r_o) = 1$. Since the circular saw is clamped at its inner radius and is free at its outer radius, displacement and the slope at the inner radius will be zero, whereas bending

moment and shear force at the outer radius will be zero. Therefore, the boundary condition at the inner and outer radius in terms of transverse displacement can be written as:

$$\left.\begin{array}{c} u(r_i,\gamma,t)=0, \frac{\partial}{\partial r}u(r_i,\gamma,t)=0, \\ M_{rr}(r_o,\gamma,t)=0, Q_r(r_o,\gamma,t)-\frac{1}{r_o}\left(\frac{\partial}{\partial\gamma}\right)M_{r\gamma}(r_o,\gamma,t)=0, \end{array}\right\} \tag{45.4}$$

wherein M_{rr} and $M_{r\gamma}$ are bending moments, and Q_r is the shear force [5].

Equation (45.1) can be rewritten with brevity, in terms of a differential operator (L) as:

$$L(u)=0, \tag{45.5}$$

wherein

$$L=D\nabla^4+\rho h\left(\frac{\partial^2}{\partial t^2}+2\Omega\frac{\partial^2}{\partial t\partial\gamma}+\Omega^2\frac{\partial^2}{\partial\gamma^2}\right)-h\left[\left(\frac{1}{r}\right)\left(\frac{\partial}{\partial r}\right)\left(r\sigma_r\frac{\partial}{\partial r}\right)+\left(\frac{1}{r^2}\right)\left(\frac{\partial}{\partial\gamma}\right)\left(\sigma_\gamma\frac{\partial}{\partial\gamma}\right)\right]$$
$$+\sum_{j=1}^{J}k_j\left(\frac{1}{r}\right)\delta(r-r_j)\delta(\gamma-\gamma_j)+\sum_{j=1}^{J}c_j\frac{\partial}{\partial t}\left(\frac{1}{r}\right)\delta(r-r_j)\delta(\gamma-\gamma_j).$$

Since the assumed form of the solution does not satisfy the equation of motion exactly, the residue can be minimized using the Galerkin projection approach, resulting in:

$$\int_0^{2\pi}\int_{r_i}^{r_o}L(u)(R_{ql}\cos(l\gamma))rdrd\gamma=0, \tag{45.6}$$

$$\int_0^{2\pi}\int_{r_i}^{r_o}L(u)(R_{ql}\sin(l\gamma))rdrd\gamma=0, \tag{45.7}$$

wherein $q=0,1,\ldots,m$, $l=0,1,\ldots n$. Solving and simplifying Eqs. (45.6) and (45.7), we get:

$$\sum_{m=0}^{m}\alpha_1\left[\delta^{(1)}_{qml}\frac{d^2C_{ml}}{dt^2}+\delta^{(2)}_{qml}\frac{dS_{ml}}{dt}+\delta^{(3)}_{qml}C_{ml}\right]+\sum_{m=0}^{m}\left[N^{(1)}_{qml}C_{ml}+N^{(2)}_{qml}S_{ml}\right]=0, \tag{45.8}$$

$$\sum_{m=0}^{m}\beta_1\left[\delta^{(1)}_{qml}\frac{d^2S_{ml}}{dt^2}-\delta^{(2)}_{qml}\frac{dC_{ml}}{dt}+\delta^{(3)}_{qml}S_{ml}\right]+\sum_{m=0}^{m}\left[N^{(3)}_{qml}C_{ml}+N^{(4)}_{qml}S_{ml}\right]=0, \tag{45.9}$$

$$\alpha_1=\left\{\begin{array}{ll}\pi, & l\neq 0\\ 2\pi, & l=0\end{array}\right\},\beta_1=\left\{\begin{array}{ll}\pi, & l\neq 0\\ 2\pi, & l=0\end{array}\right\}.$$

For the sake of brevity, $\delta^{(1)}_{qml}$, $N^{(1)}_{qml}$, $N^{(2)}_{qml}$, $N^{(3)}_{qml}$, $N^{(4)}_{qml}\delta^{(2)}_{qml}$, $\delta^{(3)}_{qml}$ are not defined here, and the reader is directed to [5] for details. The above Eqs. (45.8) and (45.9) can be rewritten in a compact form as:

$$[A]\{\ddot{x}\} + [B]\{\dot{x}\} + [C]\{x\} = 0 \tag{45.10}$$

where the vector $\{x\}$ is an array of $\{C_{0,0}, C_{0,1},\ldots, C_{1,0}, C_{1,1},\ldots, C_{m,n}, S_{0,1}, S_{0,2},\ldots, S_{1,1}, S_{1,2}, \ldots, S_{m,,n}\}$. In Eq. (45.10), $[A]$ is the mass matrix, $[B]$ is the gyroscopic matrix, and $[C]$ is the stiffness matrix. Since $[B]$ and $[C]$ depend on the rotational speed of circular saw, dynamics of circular saw depends on rotational speed. As Eq. (45.10) is a second-order linear differential equation, the solution of the equation can be assumed in the form of $x(t) = \{X\}e^{\lambda t}$. On substituting the assumed form of the solution, Eq. (45.10) forms an eigenvalue problem which can be solved for every combination of rotational speed and other parameters. The imaginary part of the eigenvalue, λ of this eigenvalue problem, corresponds to a natural frequency of the circular saw. To reduce the effective number of parameters, we non-dimensionalize Eq. (45.10) as:

$$\Omega_0 = \left[\frac{\rho h r_o^4}{D}\right]^{\frac{1}{2}}\Omega, \zeta = k\left(\frac{r_o^2}{D}\right), \phi = \left[\frac{\rho h r_o^4}{D}\right]^{\frac{1}{2}}\omega, c_1 = \frac{c r_o^2}{\sqrt{\rho h r_o^4 D}}$$

wherein c_1 is the non-dimensional damping, ζ is the non-dimensional stiffness, ω is the natural frequency, ϕ is the non-dimensional natural frequency, and Ω_0 is the non-dimensional rotational speed.

We solve the above set of equations and, at first, verify the formulations against results from CSAW®, as discussed next, in Sect. 45.3, followed by convergence testing and investigations with damping in Sect. 45.4.

45.3 Numerical Verification of Critical Speed Model

As a preliminary check of our proposed formulations, we first verify our results with those obtained from a commercially available circular sawing stability code, CSAW®. Comparisons are made with frequency-speed diagrams, known as the Campbell diagram. We limit our numerical checks for the case of an unguided saw, and for the case of a guided saw, with the guide modelled as an undamped point spring—since CSAW® does not have the facility of including damping. We limit our comparisons for the number of nodal circles, m as 1, and the number of nodal diameters, n as 4. The saw, assumed to be made of steel, is clamped at its inner radius, $r_i = 42.5$ mm and has a free outer radius, $r_o = 142.5$ mm.

Campbell diagrams for the unguided case are compared in Fig. 45.2. As is evident, the critical speed obtained from the proposed analytical model (Fig. 45.2a) occurs at 8497 rpm, whereas the critical speed obtained from CSAW® (Fig. 45.2b)

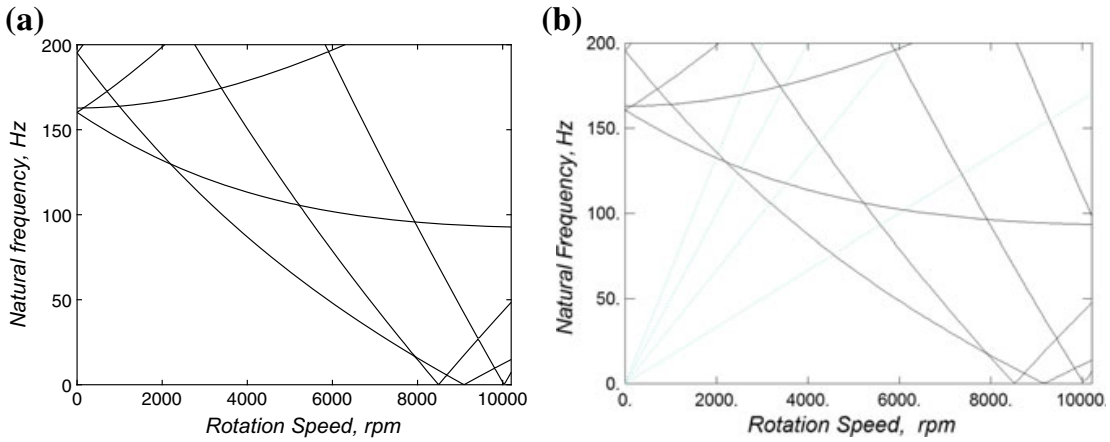

Fig. 45.2 Campbell diagram for unguided circular saw obtained **a** using analytical model and **b** using CSAW®

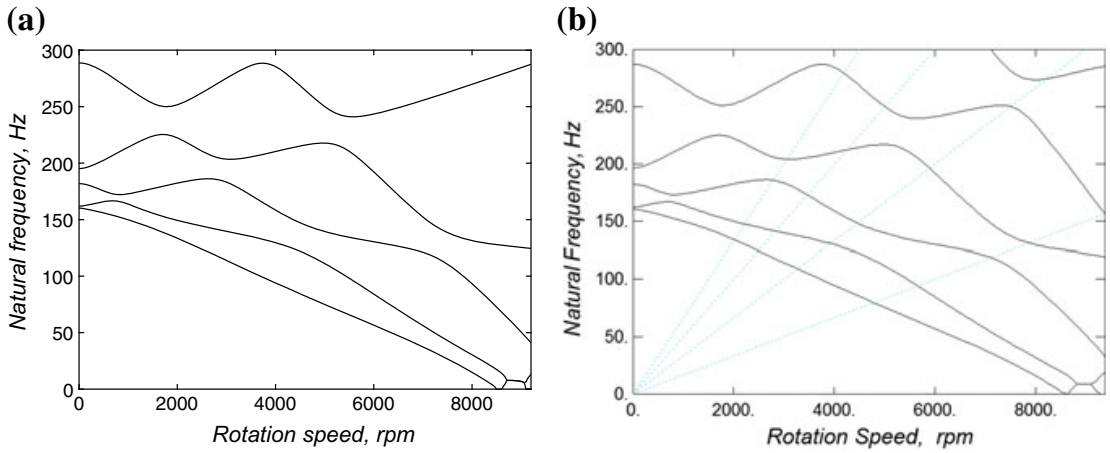

Fig. 45.3 Campbell diagram for guided circular saw obtained **a** using analytical model and **b** using CSAW®

occurs at 8519 rpm, which is approximately same as our analytical model. In the Campbell diagram obtained from CSAW®, there appear four straight lines from the origin. These represent the first four engine order (EO) lines and correspond to imperfections or unbalance in the rotating parts of the system. These faults generate harmonic and sub-harmonic levels of vibrations [8] as shown in Fig. 45.2b.

Campbell diagrams for the guided case are compared in Fig. 45.3. The guide pad has been modelled as a sector of a circular disc with orientation of inner and outer angle as 5° and 36°, respectively, whereas, inner and outer radii of the guide pad are 57 and 142.5 mm, respectively. The spring element, located at the geometric centre of the pad, has a stiffness 7.5×10^8 N/m. We observe that the analytical model predicted response (Fig. 45.3a) is consistent with the results from CSAW® (Fig. 45.3b), and that there is no change in the critical speed with a single guide. This observation is consistent with those reported earlier in [5].

Having numerically verified the analytical model, we use the analytical model to understand how many spring-damper systems are actually necessary to approximate distributed guide and saw interactions, and to understand the role of damping in guides on the critical speeds of circular saws, as is discussed next, in Sect. 45.4.

45.4 Results and Discussion

In this section, we first present convergence analysis for understanding how many spring-damper systems are actually necessary to approximate distributed guide and saw interactions, for a given guide area, followed by analysis for damped guides, followed by analysis on the influence of modelling multiple spring-damper systems radially and circumferentially. Guide pad area for all results presented herein is 4614 mm^2. Guide location is the same as described in Sect. 45.3. All combinations of the spring-damper elements approximating the guide pad are distributed uniformly over the guide pad area. All results presented herein are for the mode corresponding to the first critical speed. All results are presented in the non-dimensional form of the Campbell diagrams.

45.4.1 Convergence Analysis of Discrete Multiple Spring Elements to Model the Guide Pad

For a given guide area, and location, it is, in general, difficult to a prior establish the required number of discrete spring elements, necessary to capture the saw and guide interactions. We neglect the damping in the guide presently, influence of which is discussed separately in Sect. 4.2. We analyse sensitivity of the first critical speed with five combinations of spring elements approximating the same guide area, i.e. with J as 1, 4, 9, 16, and 25. Overall effective stiffness k_j in each case was taken to be as 7.5×10^8 N/m. Results for all cases are shown in Fig. 45.4.

As is evident from Fig. 45.4, an increase in number of springs increases the critical speed. However, beyond 16 springs, the critical speed does not appear to change, suggesting that 16 springs are sufficient to describe the size and location of the guide pad under consideration. Interestingly, we observe that with four discrete springs, the critical speed increases, which is not consistent with the findings reported in [5], in which they found that to increase the critical speed, at least eight discrete uniformly distributed guides modelled as a discrete point spring elements are necessary. This suggests that it is indeed necessary to model the pad–saw interaction as multiple discrete spring elements.

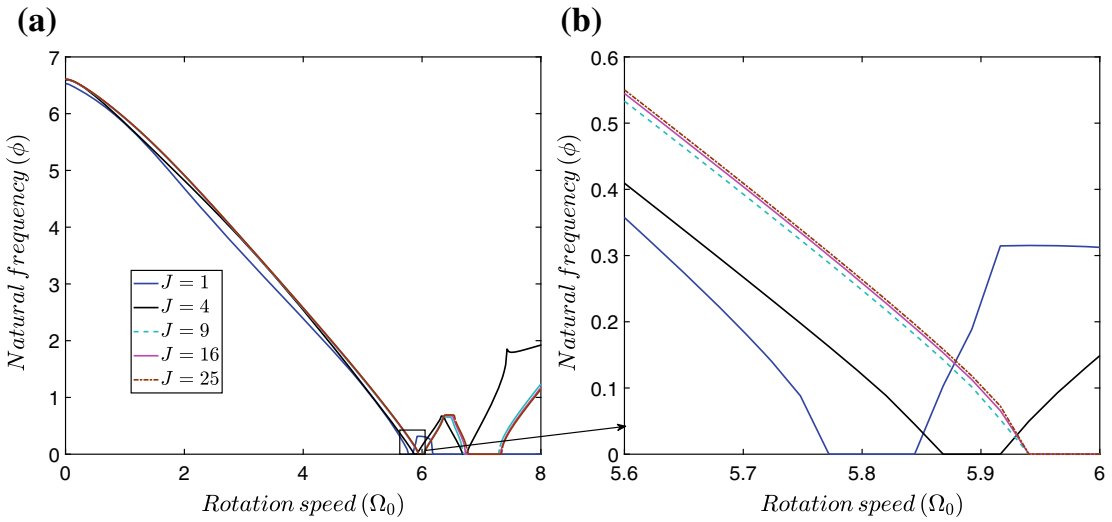

Fig. 45.4 Campbell diagram for multiple discrete spring elements distributed equally over the guide pad corresponding to the lowest mode

45.4.2 Influence of Damping on the Critical Speed

Since guides offer not just stiffness, but also damping, influence of damping on the critical speed is reported herein. To delineate the influence of damping, i.e. without stiffness, we present results for a guide with only damping in Fig. 45.5a and for a guide with stiffness and damping in Fig. 45.5b. For the case of a guide with damping only, we model the guide to have an overall effective damping of $c_j = 17.2\,\mathrm{N/m/s}$, for equivalent 16 damping elements. For the case of a guide modelled with discrete spring-damper elements, we take the number of elements to be 16, with an equivalent overall stiffness and damping of $7.5 \times 10^8\,\mathrm{N/m}$ and $17.2\,\mathrm{N/m/s}$, respectively.

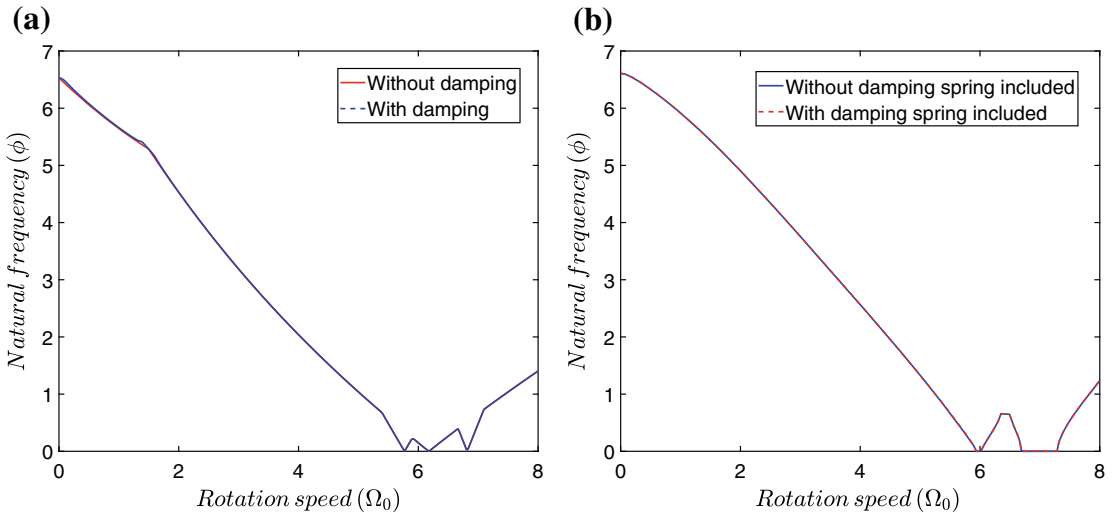

Fig. 45.5 Campbell diagram for circular saw with pad–saw interaction modelled as **a** discrete damper elements **b** discrete spring-damper elements corresponds to the lowest mode

As is evident from Fig. 45.5a, saws with guides with damping only, i.e. without springs, do not influence the critical speed and behave like unguided saws, which are curious. We also observe that damping only affects the frequency-speed characteristics. Furthermore, even for the case of guides modelled with multiple discrete spring-damper systems, the critical speed does not change when compared to the critical speed for the case of guides modelled only as springs, as is evident from Fig. 45.5b. These observations suggest that damping has no influence on the critical speeds of saws for the given guide pad configuration (mentioned in Sect. 45.3), which is unusual and unexpected and needs further investigations.

45.4.3 *Influence of Circumferential and Radial Distribution of Spring Elements on the Critical Speed*

In this section, we present the influence of orientation of the distribution of discrete spring elements that are to approximate a given guide pad area, on the critical speed. We present results for the guide pad approximated by different number of discrete spring elements, distributed uniformly in the circumferential and radial directions for a given area. Results for a uniform distribution of discrete spring elements along the circumferential direction (with fixed radial location at 99.75 mm) are shown in Fig. 45.6, and results for uniform distribution of discrete spring elements along the radial direction (with fixed circumferential location at 20.5°) are shown in Fig. 45.7. Since damping was shown to not influence the critical speed, we neglect it herein. As before, the overall effective stiffness in each case is taken to be 7.5×10^8 N/m. As is evident from Fig. 45.6, as the number of discrete spring elements increases along the circumferential direction, the critical speed increases and becomes constant after $J = 8$. However, as is evident from Fig. 45.7, for the case of different discrete spring elements along the radial direction

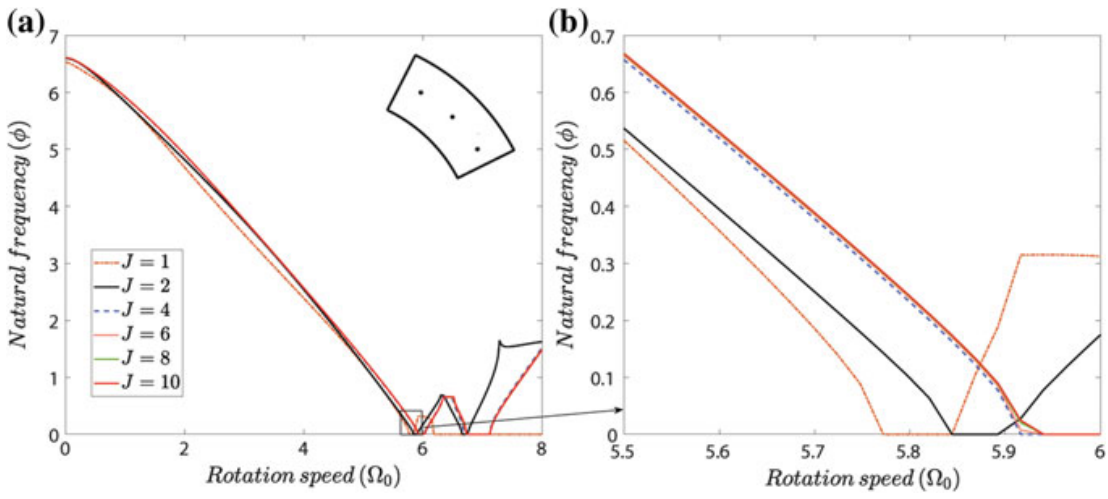

Fig. 45.6 Influence of multiple spring element over the guide pad in circumferential direction

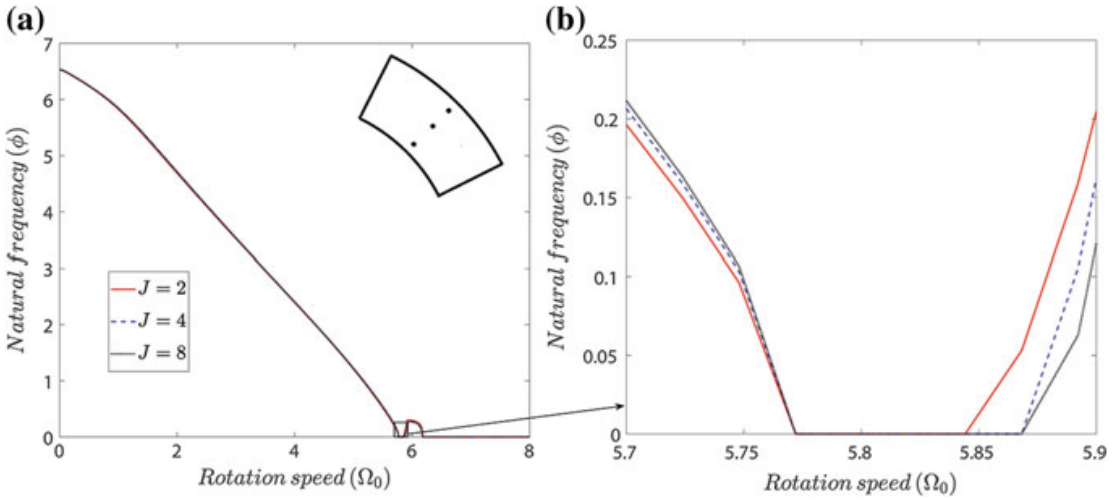

Fig. 45.7 Influence of multiple spring element over the guide pad in radial direction

at a fixed orientation, there is no observable change (increase) in critical speed with an increase in the discrete spring elements. We can hence conclude that for a given guide pad area modelled as discrete springs, an increase in discrete spring elements distributed along the circumferential direction leads to an increase in critical speed, whereas an increase in discrete spring elements distributed along the radial direction does not have any influence on critical speed.

These observations, which are different than those observed in the convergence analysis in Sect. 44.4.1, where we observed the critical speed to not change beyond 16 discrete spring elements approximating the same guide area, suggests that the approach to distributing discrete springs to approximate the guide area has a large bearing on the critical speed. Furthermore, we suspect that these results are not generalizable but need to be investigated separately for each guide pad area, and location, pointing to the need for a more generalized formulation that models the guide pads as distributed spring-damper systems, rather than multiple discrete spring-damper elements. Further investigations are also necessary to understand how these findings might change for the case of a saw with multiple guides.

45.5 Conclusion

This paper reports on the influence of guides on the critical speed of rotating saws. Since guides are known to improve critical speeds, understanding how they are modelled is essential to advise guide placement. Using numerically verified analytical models that include guides modelled as multiple discrete spring-damper elements, we observe that damping has no influence on critical speed, which is confounding, and needs further investigations. We also observe that for guides approximated with multiple discrete spring elements, the number, orientation, and location of the springs govern the increase in the critical speed, if any. We observe

that for a given guide area, it is necessary to carry out convergence analysis to understand how many discrete spring elements are actually necessary to approximate distributed guide and saw interactions. We also observe that critical speeds are very sensitive to guides modelled with a distribution of discrete spring elements along the radial direction and/or circumferential direction. These observations suggest that a more generalized formulation that models the guide pads as distributed spring-damper systems, rather than multiple discrete spring-damper elements are necessary. Experimental validation is also necessary and is planned.

Chapter 46
Investigations on the Influence of Radial Run-Out on Cutting Forces for Serrated Cutters

P. Bari, M. Law and P. Wahi

Abstract Serrated cutters with their complex local tool geometries result in continuously changing chip thickness and engagement conditions due to a change in local radius along the serration height. This change in geometry results in a reduction of cutting forces, and hence these cutters are favoured in the rough cutting of difficult-to-cut materials. The change in local radius of the cutter is also influenced by the radial run-out on the tool. Run-out, though undesirable, is inevitable. How this run-out influences the local radius, chip thickness, and forces is not entirely understood for serrated cutters. This paper fills that gap, by presenting a model that factors in the influence of radial run-out on cutting forces for serrated cutters. Investigations with different sets of cutting parameters show that for cutting with a low feed, and high axial and radial depths of cut, the influence of run-out on the cutting forces is negligible. For the case of cutting with high feeds however, we find that run-out adversely impacts cutting forces for any combination of axial and radial depths of cut. We also observe that with certain combinations of cutting parameters and run-outs, serrated cutters lose their advantage over regular end mills with similar levels of run-outs. Our findings suggest that serrated cutters may be used even with high levels of run-outs when the feed is low, and that their use should be avoided for any level of run-out when cutting with high feed rates.

reduction of cutting forces, and hence these cutters are favoured in the rough cutting of difficult-to-cut materials. The change in local radius of the cutter is also influenced by the radial run-out on the tool. Run-out is characterized as the difference in the geometrical axis of the tool from the spindle's rotational axis. Run-out, though undesirable, is inevitable due to how the tool is clamped in the tool holder and also due to manufacturing tolerances and errors. How this run-out influences the local radius, chip thickness, and forces is not entirely understood for serrated cutters. The main focus of this paper is hence to incorporate run-out in predictive force models for serrated cutters and present systematic investigations on how different levels of run-out influence cutting forces for serrated cutters for different combinations of cutting parameters.

Since run-out changes the nature of cutting forces, contributes to surface roughness errors on machined workpieces, and also contributes to premature tool wear and potential breakage of the tool, a lot of research attention has been paid on modelling and understanding the influence of run-out for milling cutters. Early seminal work by Martellotti [1, 2] reported on the influence of run-out in milling processes. Later, Kline and DeVor [3] presented mathematical models incorporating the influence of run-out on force prediction for regular end mills. Zheng et al. [4] reported on face milling force profile changes with run-outs. Wan et al. [5] proposed new techniques to calibrate cutting force coefficients and run-out parameters in peripheral milling. The effect of run-out on cutting force variation and surface roughness generation was also studied by Krüger and Denkena [6], in which they identified run-out parameters from measured process forces using model-based run-out identification methods. Schmitz et al. [7] explored the effect of milling cutter run-out on surface topography, surface location error, and stability in end milling operations. More recently, Li et al. [8] addressed the issue of run-out in five-axis milling processes. Most literature addressing the influence of run-out in milling has focused only on regular end mills, and even though run-out is an important factor for end mills with serrations, the reported research on serrated end mills has focused more on modelling the serration geometry and its influences than on run-out.

Some classical early work on straight fluted serrated end mills was presented by Tlusty et al. [9], in which it was shown that due to the reduced contact between the tool and the workpiece on account of serrations, cutting forces reduce. Merdol and Altintas [10, 11], and Dombovari et al. [12] reported modelling of cylindrical and tapered serrated end mills with a generalized representation of serration profiles using cubic splines without considering the effect of run-out. Later, Campomanes [13] presented a detailed mechanics-based model that included the influence of helix with sinusoidal serrations, and used an approximate chip thickness model. He also made passing reference to how run-out does not have a significant effect on the cutting forces for serrated end mills at lower feed rates. His work, however, or the work of others before, and/or after him, does not support the claim based on model-based systematic investigations. Since serrated cutters preferentially reduce cutting forces, the influence of run-out on cutting forces, if any, and if run-out negates the positive influence of serrations in reducing forces, needs to be

understood comprehensively based on systematic model-based investigations and is the main motivation of the present work.

We present an expanded geometric model for serrated cutters that includes the influence of radial run-out, in Sect. 46.2. We limit our discussions in this paper to serrations only of the sinusoidal kind. We ignore axial run-out presently. We also assume that run-out is measurable on serrated tools. Measuring run-out on regular end mills is possible and has been reported on elsewhere; see, for example, [14–16]. However, measuring run-out on serrated cutters due to constantly changing radius along the serration wavelength is non-trivial and needs to be addressed separately. Assuming run-out to be measurable, we systematically investigate its influence on force profiles for different combinations of cutting parameters in Sect. 46.3. We systematically discuss the influence of run-out for different levels of feed, and axial and radial depths of cut. This is followed by the main conclusions in Sect. 46.4.

46.2 Geometric Model of Serrated Cutter with Run-Out

This section describes the geometry of serrated cutters considering the influence of radial run-out. Models described in this section build on the classical work done by Merdol and Altintas [11], and by Dombovari et al. [12], and also on our own earlier reported work [17], by including the influences of run-out.

46.2.1 Modelling of Serration Profile

A schematic and a cross-sectional view of a sinusoidal serrated cutter with run-out is shown in Fig. 46.1. Due to the run-out, cutter geometrical centre, denoted by O_g, deviates from spindle rotation centre O_r, by a constant radial deviation, ρ.. The run-out angle between direction of radial offset (deviation) and the nearest tooth at the bottom of the tool is denoted by δ. We assume that there is no axial run-out or any cutter geometric axis tilt; i.e. ρ is constant along the cutter height. Due to the run-out, since the whole system rotates about the spindle axis through O_r, it is convenient to model all things with respect to O_r, and hence the xyz coordinate frame is attached to O_r as shown.

The cutter can have N number of flutes (teeth), but as an example, only three (ith, $(i+1)$th, and $(i+l)$th) flutes are shown in Fig. 46.1. As there is a wavy surface along the flute of the serrated cutter, the local geometrical radius changes along the flute and the height. The local geometrical radius which is measured with respect to geometrical axis (dotted line through O_g shown in Fig. 46.1a) which is parallel to z-axis for the ith flute at the height z is defined as:

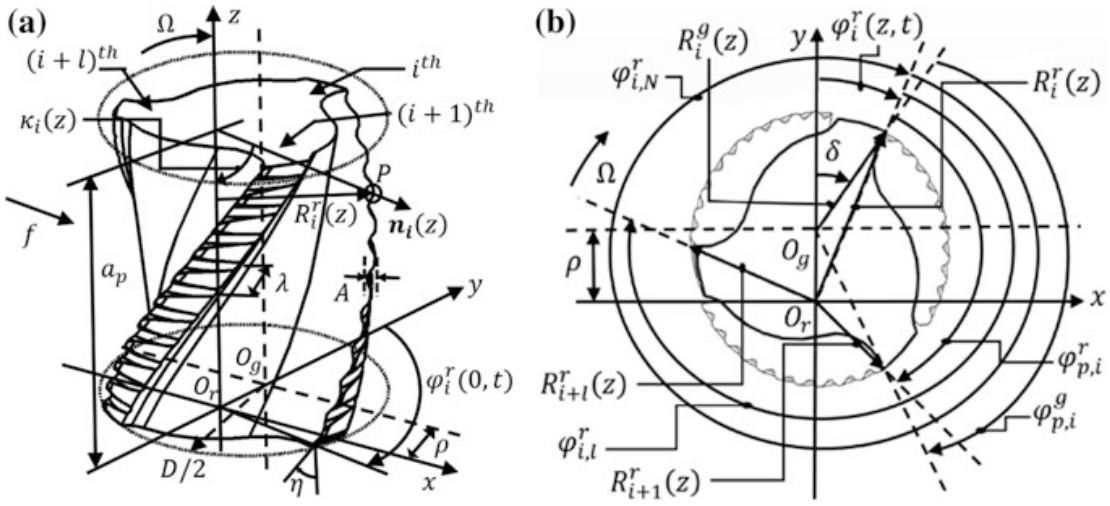

Fig. 46.1 **a** Geometry of the serrated cutter with run-out. Figure is adapted and modified from [17]. **b** Cross-sectional view at height z with run-out

$$R_i^g(z) = \frac{D}{2} - \Delta R_i^g(z) \tag{46.1}$$

where D is shank diameter (nominal diameter) of the cutter, and $\Delta R_i^g(z)$ is the variation in local geometrical radius for the sinusoidal serration profile:

$$\Delta R_i^g(z) = \frac{A}{2} - \frac{A}{2}\sin\left(\frac{2\pi z}{\lambda \cos\eta} - \psi_i + \frac{\pi}{2}\right) \tag{46.2}$$

where A is the serration amplitude, which is half of the peak-to-peak serration height; λ is the wavelength; η is the helix angle; and ψ_i is the phase shift due of the serrations on different flutes, explained in [17]. All geometries are measured with respect to spindle rotational axis which do not align with cutter geometrical axis due to eccentricity between them caused by the run-out. Due to the run-out, we define another local radius called the rotational radius with respect to the z-axis through O_r as follows:

$$\begin{aligned} R_i^r(z) = \Bigg[& \left(\rho + R_i^g(z)\cos\left(\delta - \sum_{k=1}^{i-1}\varphi_{p,k}^g - \frac{2z\tan\eta}{D}\right)\right)^2 \\ & + \left(R_i^g(z)\sin\left(\delta - \sum_{k=1}^{i-1}\varphi_{p,k}^g - \frac{2z\tan\eta}{D}\right)\right)^2 \Bigg]^{0.5} \end{aligned} \tag{46.3}$$

The local geometrical radius $R_i^g(z)$ for a representative four-fluted sinusoidal serrated cutter without and with run-out is shown in Fig. 46.2a and b, respectively. Cutter parameters are as follows: shank diameter D = 16 mm, serration amplitude

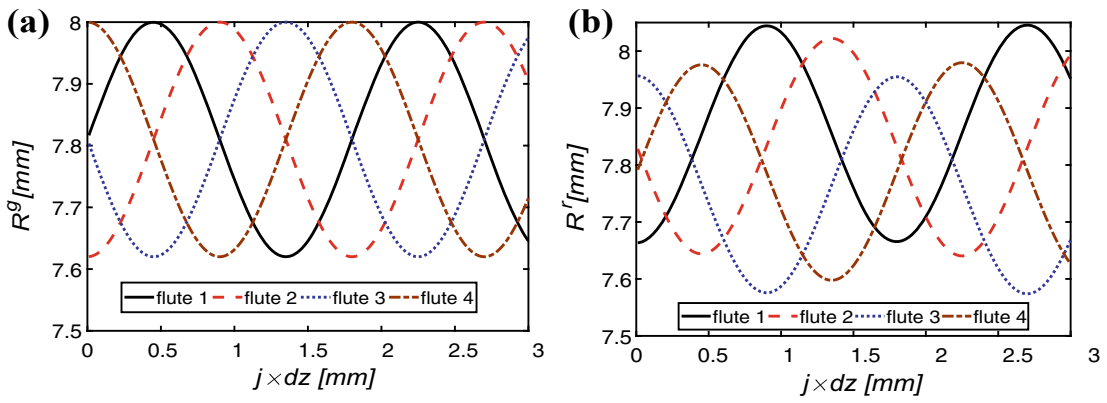

Fig. 46.2 **a** Variation of local geometrical radius, R^g, along height without run-out. **b** Variation of local rotational radius, R^r, along height with run-out: $\rho = 50\,\mu m, \delta = 30^\circ$

and wavelength $A = 0.38$ mm and $\lambda = 1.8$ mm; and, helix angle $\eta = 20^\circ$. Run-out is assumed as $\rho = 50\,\mu$m and $\delta = 30$. Comparing Fig. 46.2a and b, we see that run-out makes the radius irregular.

In addition to causing a change in the local radius, run-out also changes the instantaneous radial immersion angle. The angular position for the ith flute at height z, measured from the y-axis in a clockwise direction considering the run-out, called the instantaneous radial immersion angle, is calculated as follows

$$\varphi_i^r(z,t) = \Omega t + \sum_{k=1}^{i-1} \varphi_{p,k}^r - \frac{2z\tan\eta}{D} \tag{46.4}$$

where Ω is the clockwise spindle speed (rad/sec) and $\varphi_{p,k}^r$ is new pitch angle with respect to O_r due to the run-out. The relationship between the new pitch angle $\varphi_{p,k}^r$ with respect to O_r and the old geometrical pitch angle $\varphi_{p,k}^g$ with respect to O_g is shown in Fig. 46.3a. From Fig. 46.3a, using the cosine triangle formula, $\varphi_{p,k}^r$ is calculated as follows:

$$\varphi_{p,k}^r = \cos^{-1}\frac{\left(R_i^r(z)\right)^2 + \left(R_{i+1}^r(z)\right)^2 - \left(L_i^r(z)\right)^2}{2R_i^r(z)R_{i+1}^r(z)} \tag{46.5}$$

where

$$L_i^r(z) = \sqrt{\left(R_i^g(z)\right)^2 + \left(R_{i+1}^g(z)\right)^2 - 2R_i^g(z)R_{i+1}^g(z)\cos\varphi_{p,k}^g}$$

In addition to a change in the instantaneous radial immersion angle and pitch angles, run-out also changes the axial immersion angle, and that is calculated as detailed in [17]. Furthermore, the changed pitch angle, due to run-out, may result in a delay between formation of the current surface being generated and the previous

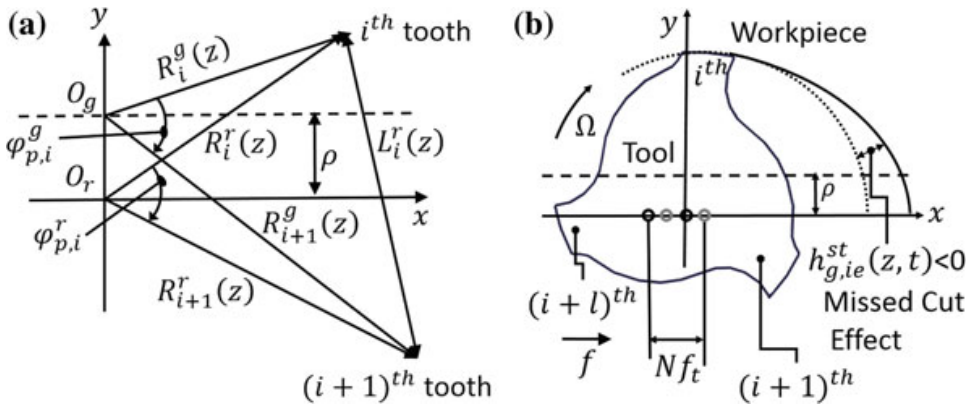

Fig. 46.3 **a** Calculation of the new rotational pitch angle, $\varphi_{p,k}^r$, due to the run-out on serrated cutters. **b** Missed cut effect with run-out for serrated cutter

surface generated, due to which redistribution of multiple delays may occur, and this can be factored in as discussed in [17] and as discussed next in Sect. 2.2.

46.2.2 Local Chip Thickness

Elemental physical static chip thickness is defined as the local distance between previous and current cut surfaces in the direction of normal vector $\boldsymbol{n}_i(z)$ of the flute considering run-out with circular tool path approximation as:

$$h_i^{st}(z,t) = g_i(z,t) \min_{l=1}^{N} \left[\left(R_i^r(z) - R_{i+l}^r(z) \right) + f_{i,l}(z,t) \sin\varphi_i^r(z,t) \right] \sin\kappa_i(z) \qquad (46.6)$$

where $f_{i,l}(z,t)$ is the corresponding feed motion during delay time $\tau_{i,l}$, $\kappa_i(z)$ is the axial immersion angle, $g_i(z,t)$ is the screening function due to radial immersion and missed cut (Ref. Fig. 46.3b) effect, explained in [17], and $R_i^r(z)$ is calculated from Eq. (46.3). The missed cut effect considering the run-out creates a non-uniform chip thickness profile as shown schematically in Fig. 46.3(b).

Variation in the chip thickness profile for a four-fluted sinusoidal serrated cutter considering zero run-out is shown in Fig. 46.4a, and considering run-out ($\rho = 50\,\mu\text{m}, \delta = 30^\circ$) is shown in Fig. 46.4b. The cutting conditions chosen are: depth of cut, $a_p = 3\,\text{mm}$; feed, $f_t = 0.25\,\text{mm/tooth}$; and speed, 5000 rpm, for slotting, i.e. 100% immersion. Comparing Fig. 46.4a and b, we see that due to the run-out, the flute chip thickness for the first and second flutes increases by 150%, and for the other two flutes, it decreases by 5%. Since chip thickness is different with run-outs, cutting forces which depend on chip thickness are also expected to be different.

The force model presented in [17] is used incorporating Eq. (46.6) to investigate the influence of run-out on force profiles, as discussed next, in Sect. 46.3. Furthermore, since the chip thickness also depends on the instantaneous entry and

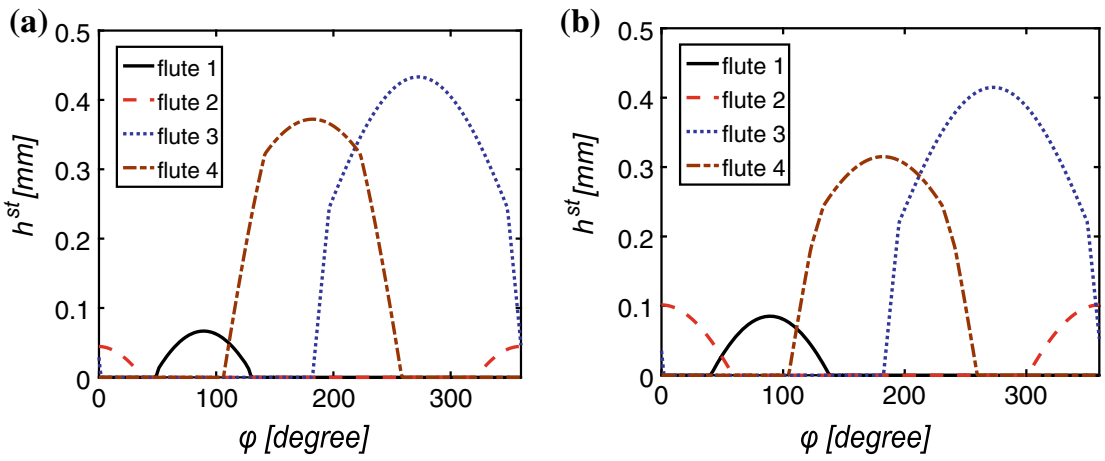

Fig. 46.4 Chip thickness (hst) distribution at tool tip ($z = 0$ mm) **a** without run-out and **b** with run-out: $\rho = 50\,\mu$m, $\delta = 30^\circ$

exit angles, these too will change with run-out, and they will also result in the force model being updated. However, for brevity, those formulations are not reported herein, since we observed that even without the updated entry and exit angle formulations, the force profiles do not change much.

46.3 Effect of Run-Out for Serrated Cutter at Different Operating Conditions

In this section, we discuss the influence of run-out on cutting forces for different combinations of cutting parameters. Our serrated cutting force model without run-out was numerically verified against other reported results and was also experimentally validated in our earlier reported work in [17]. We have also numerically verified our run-out model, albeit for the regular end mill case (i.e. by putting $A = 0$ in force model), using a commercially available advanced machining process simulation software, CutPRO [18], but have not reported those results here for brevity. Herein, we only present numerical investigations for our serrated model with run-out.

Although serrated cutters are more effective at reducing forces with low feeds than at high feeds, the effect of run-out is investigated for all possible operating conditions. Two types of feeds, one low (0.02 mm/tooth) and the other high (0.25 mm/tooth), are chosen. We present results with a low feed in Sect. 3.1 and present a subset of results with a high feed in Sect. 3.2. At each feed, two levels of engagement conditions, one low (10% up milling) and the other high immersion (100% slotting), are taken. Again, for each engagement condition, two levels of depths of cut, one low ($a_p = 3$ mm) and the other high ($a_p = 8$ mm), are chosen. Other cutting conditions for all cases are as follows: run-out angle $\delta = 30^\circ$, 5000 rpm, helix $\eta = 20^\circ$. For each case, cutting force is compared for zero run-out,

small run-out (5 μm), and large run-out (50 μm), as discussed in subsequent sub-sections. To also understand, how/if run-out on serrated cutters can potentially negate the positive influence of serrations, which is to otherwise reduce force, we also discuss in Sect. 46.3.3 results for regular end mills with run-outs.

46.3.1 *Influence of Run-Out at Low Feed (0.02 mm/tooth) Rates*

Effect of run-out on serrated cutting forces (F_x) at low feed (0.02 mm/tooth) rates is shown in Fig. 46.5. From Fig. 46.5, we observe that the ratio of maximum to average force increases with an increase in run-out. Maximum difference occurs between zero run-out and large run-out force profiles. For 10% up milling, at a low depth of cut ($a_p = 3$ mm) (Fig. 46.5a), the increase of the peak amplitude of up to 25% from the case of zero run-out is observed, and at a high depth of cut ($a_p = 8$ mm) (Fig. 46.5b), the increase of the peak amplitude of up to 12% is observed.

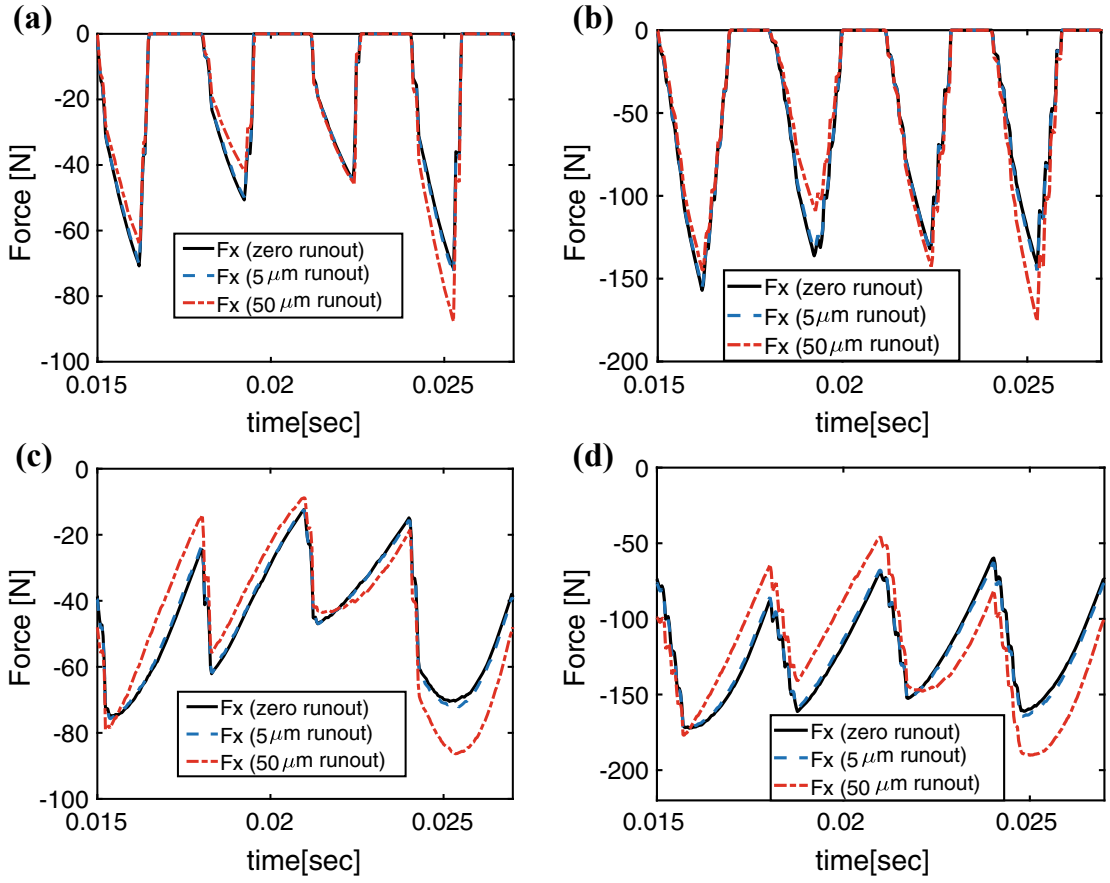

Fig. 46.5 Influence of run-out on cutting force (F_x) for a sinusoidal serrated end mill for low feed rates: **a** $a_p = 3$ mm, at 10% up milling; **b** $a_p = 8$ mm, at 10% up milling; **c** $a_p = 3$ mm, at 100% milling (slotting); and **d** $a_p = 8$ mm, at 100% milling (slotting)

For 100% milling (slotting) at a low depth of cut ($a_p = 3\,\text{mm}$) (Fig. 46.5c), the increase of the peak amplitude of up to 13% is observed, and at a high depth of cut ($a_p = 8\,\text{mm}$) (Fig. 46.5d), the increase of the peak amplitude of up to 10% is observed.

From these investigations, we can conclude that at low feeds, there is no substantial increase in the maximum force, or a significant change in the force profile, even with large values of run-out. This is interesting and is consistent with the insightful observations made in passing by Campomanes [13]. We also see that for the cases investigated, there is no significant change in the mean value of the forces, even with large run-outs on serrated cutters. These observations suggest that serrated end mills may be used even with large run-outs on them at low feeds, and potentially any combination of axial and radial depths of cuts, without resulting in any potentially significant damage to the tool, or the surface profile.

46.3.2 *Influence of Run-Out at High Feed (0.25 mm/tooth) Rates*

Effect of run-out on serrated cutting forces (F_x) at high feed (0.25 mm/tooth) rates is shown in Fig. 46.6. Here, we report on only a subset of the cutting combinations reported on in Sect. 46.3.1. As before, in this case too, we observe that the ratio of maximum to average force increases with an increase in run-out. For 10% up milling at low depth of cut ($a_p = 3\,\text{mm}$) (Fig. 46.6a), the increase of the peak amplitude of up to 35% is observed. For the 100% milling (slotting) at high depth of cut ($a_p = 8\,\text{mm}$) (Fig. 46.6b), the increase of the peak amplitude of up to 25% is observed.

Contrasting the results for high immersion with those of the low immersion case, we see that with high feed rates and for low immersion cutting, run-out appears to

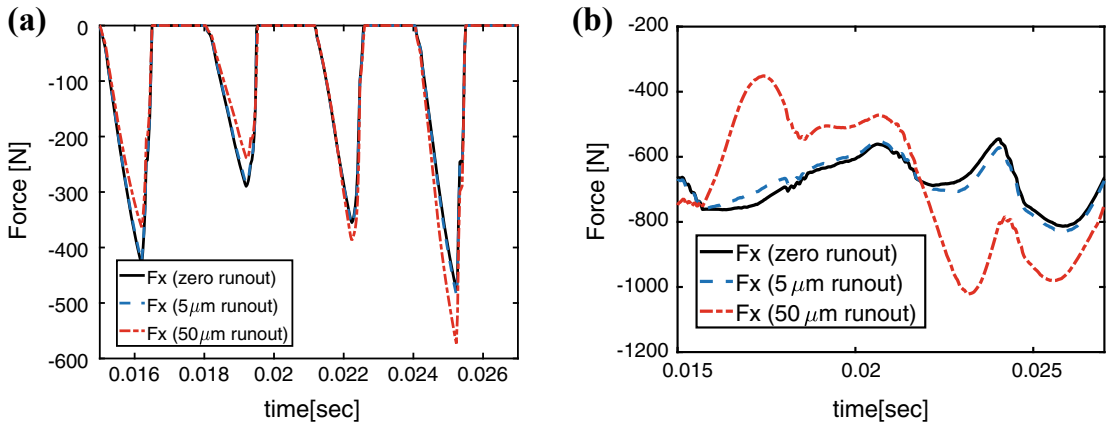

Fig. 46.6 Influence of run-out on cutting force (F_x) for sinusoidal serrated end mill for high feed rates: **a** $a_p = 3\,\text{mm}$, at 10% up milling, and **b** $a_p = 8\,\text{mm}$, at 100% milling (slotting)

have a more severe effect than at the high feed and high immersion case. Moreover, for the high feed and high axial and radial depths of cut, there is also a significant change in the force profile for high levels of run-out as compared to the case of zero run-out. These observations suggest that if serrated cutters have high levels of run-out, they best be avoided to be used with high feed rates. A sudden increase in forces, may cause impact loading on the cutter, which may cause it to prematurely break.

Seeing that serrated cutters with high run-outs are not advisable to use with high feed rates, to understand if/how run-out on serrated cutters used at high feed rates can potentially negate the positive influence of serrations, which is to otherwise reduce forces, we discuss results for regular end mills with run-outs next in Sect. 3.3 and contrast those findings with those observed here.

46.3.3 *Influence of Run-Out at High Feed (0.25 mm/tooth) Rates for Regular End Mills*

Effect of run-out on regular end mill cutting forces (F_x) at high feed (0.25 mm/tooth) rates is shown in Fig. 46.7. Here too, we report on only a subset of the cutting combinations reported on in Sect. 3.1. Results herein are obtained by setting $A = 0$ in the force model, i.e. essentially making it a regular end mill. All other geometries are the same as for the serrated end mill. As observed for serrated end mills, we observe that the ratio of maximum to average force increases with an increase in run-out. As evident in Fig. 46.7, for 10% up milling at a low depth of cut $(a_p = 3\,\text{mm})$ (Fig. 46.7a), the increase of peak amplitude of up to 37% is observed, whereas for 100% milling (slotting) at a high depth of cut $(a_p = 8\,\text{mm})$ (Fig. 46.7b), difference of the peak amplitude up to 46.5% is observed. These observations, as before, suggest that if regular end mills have high levels of run-out, they best be avoided to be used with high feed rates.

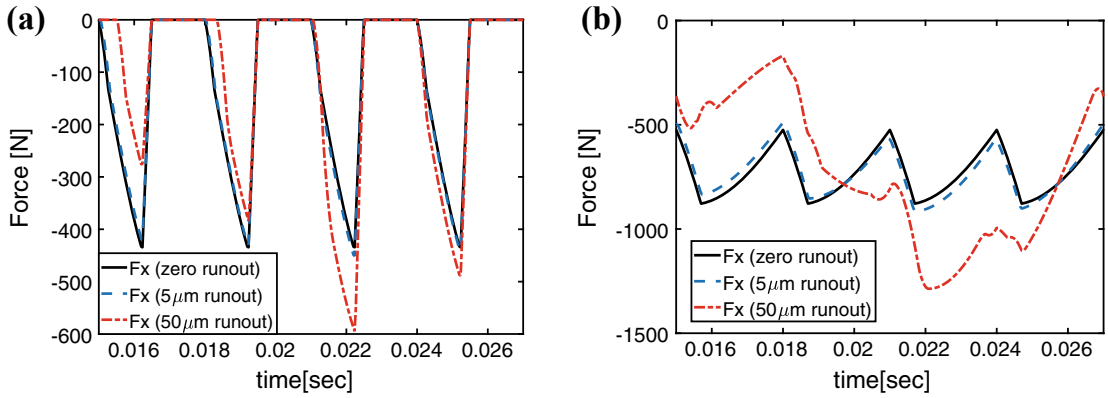

Fig. 46.7 Influence of run-out on cutting forces (F_x) for regular end mill at high feed rates: **a** $a_p = 3\,\text{mm}$, at 10% up milling, and **b** $a_p = 8\,\text{mm}$, at 100% milling (slotting)

Comparing the results for serrated cutters with run-out and with cutting at high feed and low immersion in Fig. 46.6a with those in Fig. 46.7a for regular end mills with run-out and high feed, with also low immersion, it is clear that even in the case of no run-out, the maximum force for the serrated end mill considered is 11% higher than regular end mills, which suggests that serrated cutters are ineffective at high feed rates, since there is no preferential reduction in cutting forces. The trend, however, reverses for the case with large run-out, which is strange, and needs to be investigated further. For the case of serrated end mill cutting with high feed and high immersion (axial, and radial), the peak force from Fig. 46.6b is lower than the case of regular end mills from Fig. 46.7b, without and with large run-outs. These observations are interesting and suggest that at certain combination of cutting and run-out parameters, serrated end mills retain their advantage over regular end mills, while at certain other combinations of cutting and run-out parameters, serrated cutters lose their advantage over regular end mills.

46.4 Conclusions

This paper discussed the influence of run-out on serrated cutters. We expanded the geometric force model for sinusoidal serrated cutters by including the effect of run-out. We systematically investigated how the run-out influences local chip thickness distribution, and how that in turn can potentially change the force profile for serrated cutters with run-out. Comprehensive investigations on the influence of run-out on forces were presented for a combination of feed rates, and axial and radial depths of cut. We observed that high levels of run-out increase the ratio of maximum to average forces and also change the nature of the cutting force profile. Interestingly, we observed that at low feeds, and large axial and radial depths of cut, run-out had no significant effect on the serrated force profiles, suggesting that even for large levels of run-outs, serrated cutters may still be used with low feed and high axial and radial depths of cuts, without worrying too much about if run-out may damage the workpiece quality or cause tool breakage. For cutting with high feed rates however, we observed that run-out adversely impacts cutting forces for any combination of axial and radial depths of cut. We also observed that with certain combinations of cutting parameters and run-outs, serrated cutters lose their advantage over regular end mills with similar levels of run-outs, and hence their use in such cases should be avoided.

Our findings were only for the case of sinusoidal serrations and having neglecting axial run-out. How run-out potentially influences force profiles for other serration types needs to be also investigated. Furthermore, numerical investigations presented herein need experimental validation, which will also include actually measuring run-out on serrated cutters, and these form part of our planned future investigations.

Chapter 47
Modeling and Optimization of WEDM Parameters Using Design of Experiments

P. Bharathi, G. Srinivasarao and P. G. Krishnaiah

Abstract In the current work, modeling and optimization of input parameters in wirecut electric discharge machine (WCEDM) of titanium [Ti-6A-4V] (Grade 5) were attempted. WCEDM working variables such as pulse-on-time (T_{ON}), pulse-off-time (T_{OFF}), servo-voltage (SV), peak-current (IP), and wire feed were considered to study the responses of cutting speed or speed of cut (CS) and wire wear ratio (WWR). Each input parameter was set at three levels. Experiments were conducted as per central composite face (CCF)-centered design. Based upon the runs' data, model equations for CS and WWR were developed using multiple linear regression. Optimization of practice parameters had been performed with the help of level mean analysis, response graphs, and model equations. From the analysis, it was observed that pulse-on-time was the substantial considerable input variable followed by servo-voltage, peak-current, and pulse-off-time.

Keywords WCEDM · Modeling · Optimization · Cutting speed · Wire wear ratio

47.1 Introduction

The WCEDM is a non-classical thermoelectric machining practice used for cutting newer, harder materials like titanium, composites, and ceramics. Titanium and its alloy are winning materials owing to their unique amalgamation of properties like high hardness and chemical wear resistance to substantial environments and tendency to form a stable, tightly adherent, protective surface film [1]. Due to the excellent properties of titanium alloys, the usage is being increased in applications

like aerospace, chemical processing, surgical implants, and missile component [2]. Titanium and its alloys are the popular choice for fixation devices and are used to make artificial hips and knee replacement surgeries and other biological implants [3]. [Ti-6A-4V] is an alpha–beta alloy group, in which α-stabilizer possesses excellent creep resistance and β-stabilizers exhibit high hardenability and a higher density [4]. It is a substantial suitable process for machining very complex profiles of conductive hard materials where the high degree of precision and surface finish is the crucial factor. In WCEDM, material removal mechanism is very complex with a series of electric sparks generating the tremendous amount of heat between workpiece material and conductive tool which melts and evaporates minute amount of the workpiece and electrode material. The dielectric medium apart from providing the necessary dielectric strength continuously flushes away the solidified debris and also dissipates the heat from the machining zone. The tool wire (usually less than 0.3 mm diameter) is continuously fed from a supply spool, and the tool electrode is controlled and monitored by the CNC system. Researchers have focused on the input variables, pulse-on-time, pulse-off-time, servo-voltage, and peak-current, to avoid severe problems like the short-circuit of wire, wire fracture, and work exterior surface spoil leading to decrease in the overall efficiency of the process. Ghodsiyeh et al. [5] studied the effect of cutting parameters counting pulse-on-time, pulse-off-time, and peak-current on exterior surface roughness, sparking gap, and material removal rate of titanium (Ti-6Al-4V) alloy. Statistically the optimization model is the best manufacturing tool. Kaojy et al. [6] conducted the input variables' optimization of electric liberation cutting process of Ti-6Al-4V alloy considering multiple recital attribute wire wear ratio, material removal rate [MRR], and exterior surface coarseness using the Taguchi technique and gray relational coefficient grades. The process parameters chosen in this revision are discharge current, open voltage, pulse duration, and duty factor. The optimized process parameters prove an improved electrode wear ratio of 0.15, MRR of 0.12, and surface roughness of 0.19. Krishna et al. [7] built a hybrid replica by artificial neural networks [ANN] and applied genetic algorithm technique to optimize the exterior surface coarseness in electric discharge cutting of [Ti-6Al-4V] alloy by allowing for the concurrent effect of peak-current and voltage.

Xess et al. [8] performed concurrent optimization of the practice accomplishment material removal rate, surface roughness with aid of gray Taguchi's technique for cutting of titanium [Ti-6A-4V] alloy in EDM. Jabbaripour et al. [9] investigated the response distinctiveness of material removal rate [MRR], ratio of tool rapture [TWR], and diverse aspects of integrity of surface for Ti-6Al-4V on electrical discharge machining (EDM) specimens like topography of cutting surface, crack initiation, white layer (recast layer) height, and microhardness. Here, three process machining variables including pulse-current, pulse-on-time, and open-circuit voltage were altered through EDM runs. The effects of MRR and TWR versus process cutting variables were carried out based on foremost and combine outcome plots and too confirmed by analysis of variance results. The practical values exposed that broad aspects of exterior surface reliability for machined specimens are substantially exaggerated by pulse-current and pulse-on-time. Spedding and Wang et al.

[10] developed models through RSM and ANN to characterize the responses in WCEDM ultimate performance obtained by two techniques. Susanta et al. [11] applied weighted principal component [WPC] procedure to optimize the numerous outputs of the WCEDM process. The outcome offered good improvement in overall quality level by the WPC rather than other approaches. Rupesh et al. [12] had conducted studies on pure titanium with input variables such as pulse-on-time, pulse-off-time, peak-current, wire feed, wire tension, and servo-voltage. Dual-response optimization was performed on performance characteristics like cutting speed and surface coarseness. Anish-Kumar et al. [13] investigated on WCEDM using RSM with pure titanium as source material and copper alloy brass electrode. The responses of material removal rate, surface coarseness, dimensional deviation, and wire wear ratio were optimized by using multi-output optimization through desirability approach. Nayak et al. [14] calculated the optimal combination of variables for maximum MRR, minimum SR, and kerf width. Amitesh et al. [15] carried out studies on surface integrity, material removal rate, and wire wear ratio in WCEDM of Nimonic 80 alloys. Pulse-on-time and pulse-off-time were identified as considerable parameters. Further, single- and multi-response optimization were compared and validated. Advanced microscope, i.e., SEM analysis, concluded that the effect of the higher pulse-on-time causes height of recast layer. Sanjeev et al. [16] used the desirability function approach to optimize surface coarseness and velocity of cut while cutting alloys of composite (MMC). It was identified that the pulse width (PW), the time among pulses, small pulse time, and servo manage to mean reference voltage have the individual and interactive influence on the response variables. Srinivasarao et al. [17] conducted experiments on AISI 52100 steel using a CCF design and studied the effect of the input variables like pulse-on-time, pulse-off-time, de-ionized water pressure, and wire feed on surface roughness. Srinivasarao et al. [18] run the titanium Grade 5 material with CCF design with input variables like pulse-on-time, pulse-off-time, peak-current (IP), servo-voltage (SV), and wire feed (WF). Mathematical models were formulated for material subtraction rate and surface coarseness, and multi-objective optimization has been performed using desirability approach. Bharathi et al. [19] focused on some cutting limits T_{ON}, T_{OFF}, WF, and voltage while machining SS304 material for high MRR, lower SR, and kerf width using multi-objective optimization. Nihat et al. [20] investigated on wire wear ratio in WCEDM with the practice parameters like pulse duration, open-circuit voltage, wire speed, dielectric flushing pressure on 'AISI-4140' steel (work material), and brass wire (tool). From this study, it was observed that WWR increased by amplifying pulse duration and open-circuit voltage, while it is decreased by wire speed and non-conductive flushing pressure.

47.1.1 Materials and Processes

The work material used for experimentation is Ti-6A-4V. The annealed brass wire was used as a cutting tool with a diameter 0.25 mm and 1000 MPa tensile strength

Table 47.1 Element composition of the specimen

Element	N	C	Fe	O	Al	V	Ti
Composition	0.1	0.1	0.3	0.2	6.8	4.5	88.08

to manufacture very excellent, exact, and spotless cuts. The chemical composition of the workpiece is shown in Table 47.1 [21]. Workpieces in the form of the rectangle plate are considered for conducting the runs.

The speed of the cutting determined by dividing the cutting length by time is taken for each experiment. Wire wear ratio was determined as follows:

$$\text{wire wear ratio} = \left[\frac{\text{IWW} - \text{FWW}}{\text{IWW}}\right]$$

IWW = wire weight before machining
FWW = wire weight after machining

The tool electrode was weighted before and after the machining, and the weight reduction was determined to get the output response, i.e., WWR. An electronic weighing scale with 0.001 g accuracy was taken for weight dimension. The mean value was used to minimize the error in weighing.

47.1.2 Design of Experiments

Five input variables, specifically pulse-on-time, pulse-off-time, servo-voltage, peak-current, and wire feed, were accounted to revise the responses cutting speed (CS) and wire wear ratio [WWR]. Each input variables was located as three levels which are shown in Table 47.2. Experiments run using CCF design for five factors, and the CCF layout includes 28 experiments in which there are 16 fractional points, 10 axial points, and 2 center-points. All the experiments are carried out in random order in order to avoid bias. The runs along with responses, i.e., cutting speed and wire wear ratio, are shown in Table 47.3.

Table 47.2 Factors and corresponding levels

Factor	Factors	Level 1 (−1)	Level 2 (0)	Level 3 (+1)
T_{ON} (μs)	Pulse-on-time	107	113	119

47.2 Examination of Data and Analysis of the Outcome

The foremost objective of this work is to examine the influence of variables on the response by means of response tables, response plots, and mathematical modeling. The main effects are studied from the factorial segment of the CCF layout which consists of the experiments from 1 to 16. One-factor-at-a-time analysis has been made using the experiments from 17 to 28. The performance of each control variable on the output assumed, i.e., cutting speed has been executed with level mean analysis. A level mean of a factor is the average of the cutting speed value of experiments in which the factor is at a particular level. For the factorial portion of CCF design, the mean value of the cutting speed for the T_{ON} at level '−1' and '+1'

can be determined by a mean response for runs 1–8 and 9–16, respectively. The average of the response for every level of the cutting variables can be computed in a similar manner. The control variable with the strongest influence is calculated by the difference between the average values of the factor at large and small levels. For one-factor-at-a-time analysis, the level means' values of T_{ON} are obtained by considering the experimental values for experiments 17, an average of 27 and 28, and 18 (i.e., 0.531, the average value of 1.1 and 1.11, 1.50). For T_{OFF}, the level means' values are obtained by considering the experimental values for experiments 19, an average of 27 and 28, and 20 (i.e., 2.865, the average value of 1.1 and 1.11, 1.151). From one-factor-at-a-time analysis, the change in each parameter is observed when the factor is changing from level '−1' to level '0' and to level '+1'. The level averages obtained from the fractional factorial part of CCF layout and one-factor-at-a-time analysis for cutting speed and wire wear ratio are represented in Tables 47.4, 47.5, 47.6, and 47.7 respectively.

Table 47.4 Level means: The factorial segment of [CCF] layout

Level	T_{ON}	T_{OFF}	IP	SV	WF
−1	0.8082	1.608	0.891	1.633	1.298

Rank	1	3	3	2	4

47.2.1 Cutting Speed (CS)

The level means from Table 47.4 show that the T_{ON} is the substantial considerable parameters followed by servo-voltage, peak-current, and pulse-off-time. The wire feed rate is observed as not considerable. The same behavior was observed in the case of single-factor simultaneous analysis, but the pulse-off-time is identified as substantial considerable instead of the pulse-on-time. This might be due to the existence of combined effects (Fig. 47.1).

47.2.2 Wire Wear Ratio (WWR)

The level means from Table 47.6 shows that the T_{ON} is the considerable parameters followed by peak-current, servo-voltage, pulse-off-time, and wire feed rate. From Table 47.7, it can be observed from the single-factor simultaneous analysis that the pulse-on-time is identified as substantial considerable and remaining all factors are having more or less the similar effect. The reverse trend in case of pulse-off-time and peak-current has been identified, i.e., in the factorial portion if the pulse-off-time is escalating from level '−1' to level '+1', the wire wear ratio is increasing, whereas in one-factor-at-a-time analysis, if the pulse-off-time is escalating from level '−1' to level '+1' the wire wear ratio is decreasing. The similar trend can also be observed in the case of peak-current. From factorial portion when the peak-current is growing from starting level '−1' to end level '+1', the wire wear ratio is decreasing, whereas in one-factor-at-a-time analysis, if the peak-current is increasing from level '−1' to level '+1', the wire wear ratio is increasing. This is due to the existence of combined effects. The combined effects are studied by means of model equations and surface graphs.

47.2.3 Development of Mathematical Models

Based upon the experimental data, second-order models are developed for cutting speed and wire wear ratio. The data is given in the coded appearance of factors,

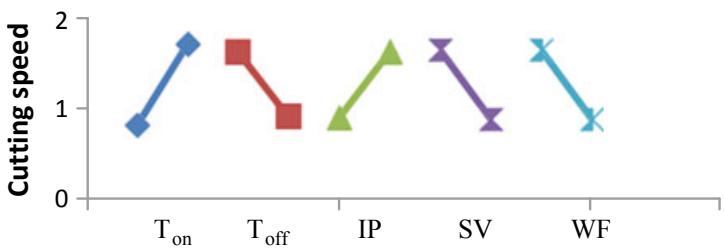

Fig. 47.1 Response plot for fractional factorial of CCF design for CS

i.e., minus one to plus one to SPSS software to estimate the model equation. The model equation for cutting speed is shown below:

$$\begin{aligned} \mathrm{CS} &= 1.425 + 0.45T_{\mathrm{ON}} - 0.41T_{\mathrm{OFF}} + 0.347\mathrm{IP} - 0.3795\mathrm{SV} \\ &\quad - 0.482(T_{\mathrm{ON}})^2 + 0.511(T_{\mathrm{OFF}})^2 - 0.491(\mathrm{IP})^2 \\ &\quad + 0.302(\mathrm{WF})^2 + 0.187T_{\mathrm{ON}}\mathrm{IP} - 0.121\mathrm{IPSV} \\ R^2 &= 0.928 \end{aligned}$$

The R^2, the value of 0.928, exhibits that variability in cutting speed is 92.8%, described by the model.

Based on the model, the response of the CS decreases as an increase in the T_{OFF} and SV and increases with an increase in T_{ON} and IP. The combination of IP with T_{ON} and SV is also identified as considerable. Further, the presence of square terms of the pulse-on-time, pulse-off-time, peak-current, and wire feed indicates the quadratic nature in output.

Combined effects mean the dual effect of two input variables on the response. The combined effect of pulse-on-time and peak-current on speed of cut gives that CS goes to a maximum value 1.436 mm/minute at larger value of pulse-on-time as well as peak-current at the same time as it reaches minimum value 0.158 mm/minute, where pulse-on-time is smaller level and peak-current is also smaller level as shown in Fig. 47.2. The combined effect of peak-current with servo-voltage on cutting speed gives that cutting speed of maximum value 1.781 mm/minute at the larger level of peak-current and smaller level of servo-voltage, while it reaches the least amount value of 0.845 mm/minute at the smaller level of peak-current and smaller level of servo-voltage. Decreasing SV decreases the gap between the electrode and work material that results in high ionization of dielectric medium and hence generates high discharge energy.

47.2.3.1 Optimum Values of Speed of Cut

The optimum values corresponding to the utmost cutting speed of 3.3719 mm/minute are the pulse-on-time 119 ms µs, pulse-off-time 51 ms µs, peak-current 12 A, servo-voltage 30 V, and wire feed 3 m/minute (Figs. 47.3 and 47.4).

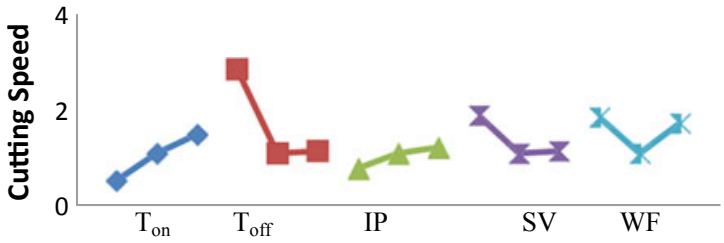

Fig. 47.2 Response plot for one-factor-at-a-time analysis for CS

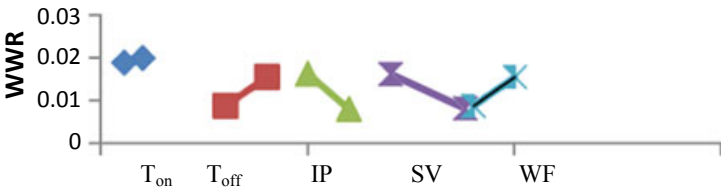

Fig. 47.3 Response plot for factorial of CCF design (WWR)

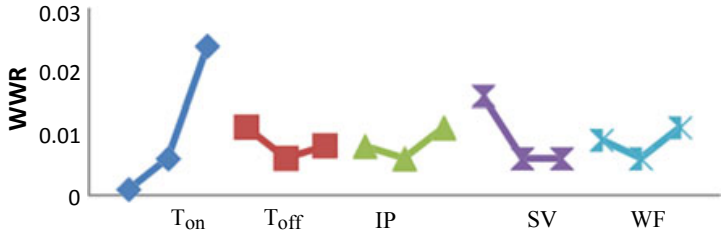

Fig. 47.4 Response plot for one-factor-at-a-time analysis (WWR)

The model equation for wire wear ratio is shown below:

$$\begin{aligned}\text{WWR} = {} & (0.01) + 0.004\,T_{\text{ON}} + 0.003\,T_{\text{OFF}} - 0.003\,\text{IP} - 0.004\,\text{SV} \\ & + 0.003\,\text{WF} + 0.003(T_{\text{ON}})^2 + 0.005\,T_{\text{ON}}\,T_{\text{OFF}} - 0.0\,T_{\text{ON}}\text{IP} - 0.003T_{\text{ON}}\text{SV} + 0.002T_{\text{ON}}\text{WF} \\ & - 0.005T_{\text{OFF}}\text{IP} - 0.005\,T_{\text{OFF}}\text{SV} + 0.005\,T_{\text{OFF}}\text{WF} + 0.005\,\text{IP}\,\text{SV} - 0.004\,\text{IP}\,\text{WF} \\ & - 0.006\,\text{SV}\,\text{WF} - (R^2 - 0.963)\end{aligned}$$

The R^2 value 0.963 implies that 96.3% of the variability in wire wear ratio is described by the model as given in the above equation (Figs. 47.5 and 47.6).

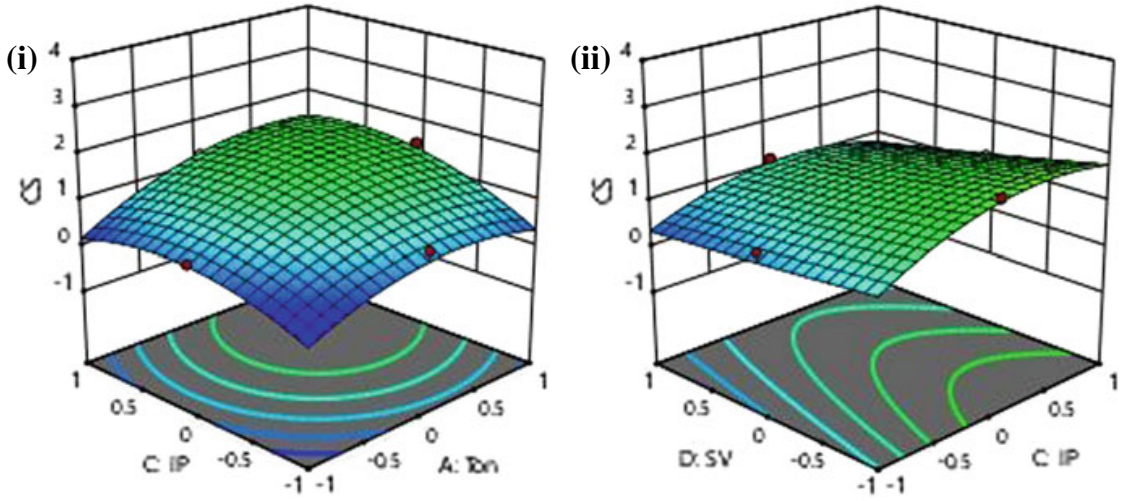

Fig. 47.5 (i) Effect of IP and T_{ON} on cutting speed (T_{OFF} = 0, SV = 0, WF = 0) and (ii) effect of IP and SV on cutting speed (T_{ON} = 0, T_{OFF} = 0, WF = 0)

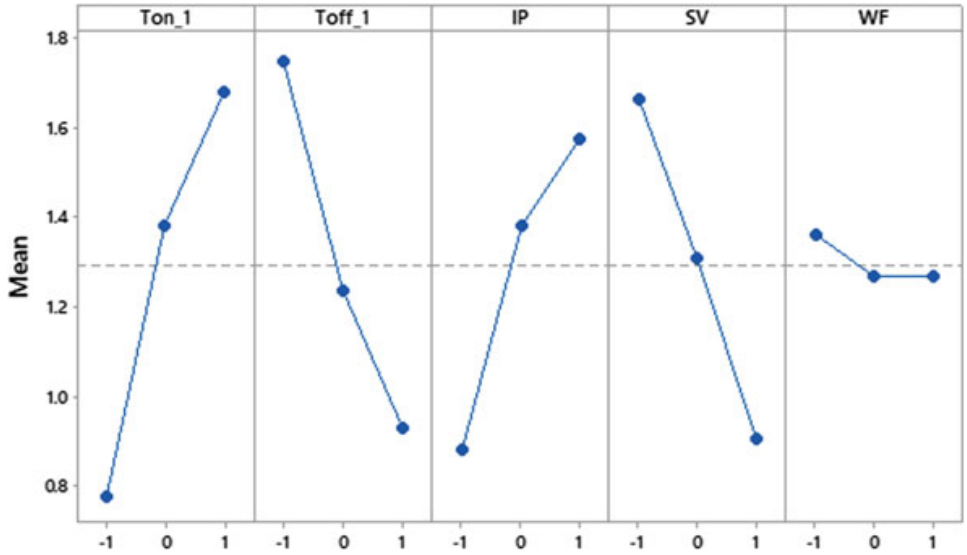

Fig. 47.6 Main effect plots for cutting speed

The combined effect of the pulse-on-time and pulse-off-time on WWR during their interaction gives that WWR goes to a maximum value of 0.028 at the higher value of pulse-on-time same as pulse-off-time, while it reaches the minimum value of 0.008, where the pulse-on-time and pulse-off-time were at lower level. The combined effect of pulse-off-time with peak-current on WWR shows that WWR's maximum value is 0.012 at the higher level of pulse-off-time and lower level of peak-current while it reaches minimum value 0.005 at the smaller level of pulse-off-time as well as lower level of peak-current. The optimum input variables equivalent to the minimum WWR 0.0099 were the pulse-on-time = 107 microseconds; pulse-off-time = 63 microseconds, peak-current = 12 A, servo-voltage = 30 V, and wire feed rate = 3 m/minute (Figs. 47.7 and 47.8).

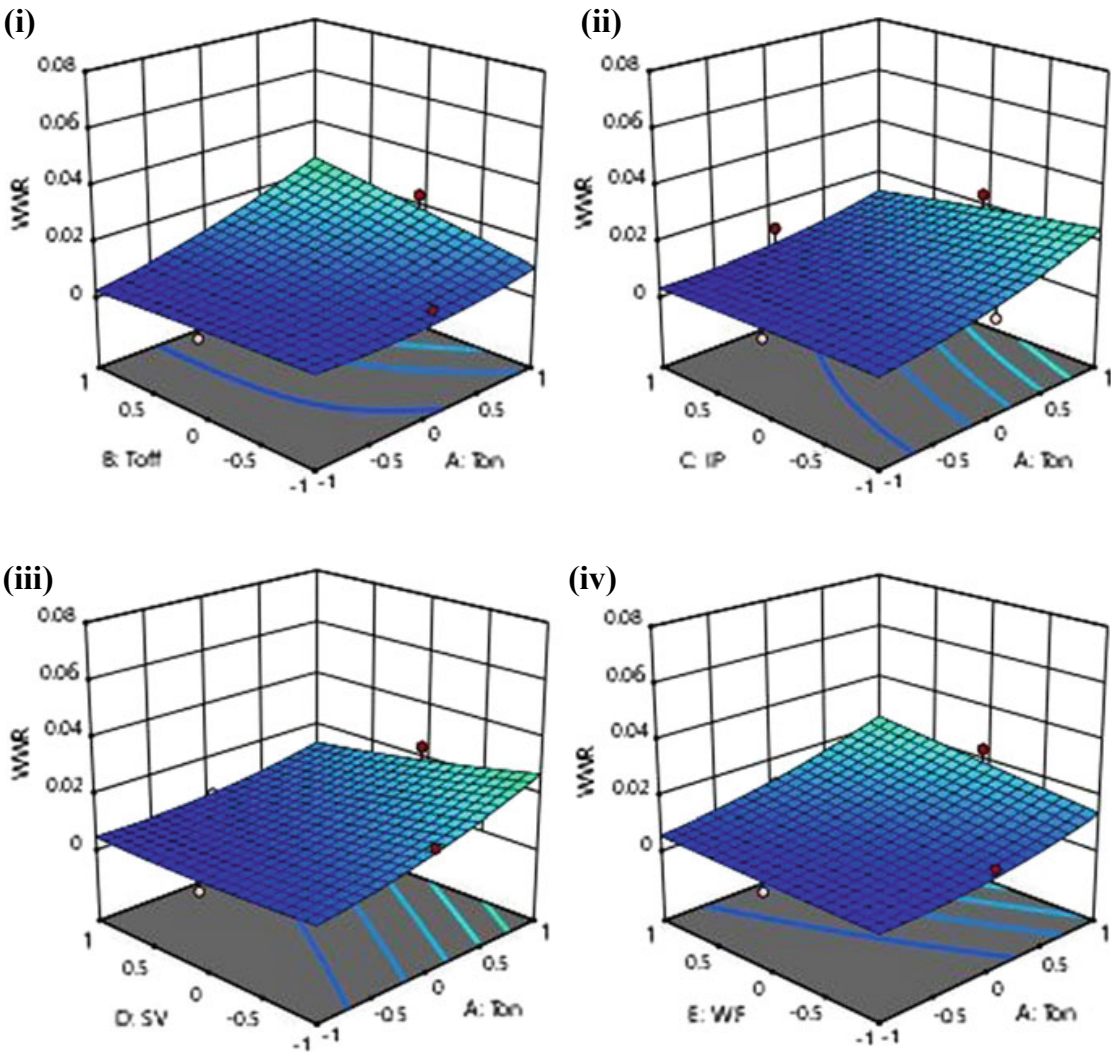

Fig. 47.7 (i) Effect of T_{OFF} and T_{ON} on WWR, (ii) effect of IP and T_{ON} on WWR, (iii) effect of SV and T_{ON} on WWR, and (iv) effect of WF and T_{ON} on WWR

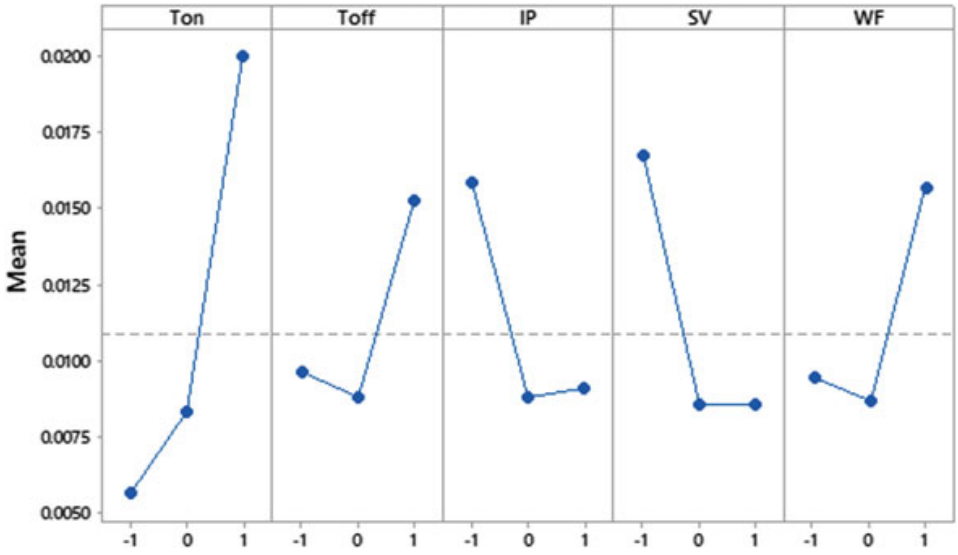

Fig. 47.8 Major outcome plots for wire wear ratio

47.3 Conclusions

Modeling and optimization of input variables have been performed in WCEDM of titanium [Ti-6A-4V] material with annealed brass wire as the electrode. The following observations are made:

1. All input variables having a considerable effect on cutting speed and wire wear ratio.
2. The factors pulse-on-time and peak-current have a positive effect, whereas pulse-off-time and servo-voltage have a negative effect on cutting speed.
3. The factors pulse-on-time, pulse-off-time, and wire feed have a positive outcome, whereas peak-current and servo-voltage have a negative effect on WWR.
4. The importance of interaction and second-order terms which shows the quadratic nature of the response is also observed on both responses.
5. The optimum values corresponding to the high cutting speed of 3.3719 mm/minute are the pulse-on-time 119 µs, pulse-off-time 51 µs, peak-current 12A, servo-voltage 30 V, and wire feed 3 m/minute.
6. The optimum values related to the minimum WWR 0.0099 were pulse-on-time = 107 µs; pulse-off-time = 63 µs, peak-current = 12 A, servo-voltage = 30 V, and wire feed rate = 3 m/minute

Analysis on Thermal Characteristics of Micro-Drilled Glass Using Microwave Energy at 2.45 GHz

Gaurav Kumar and Apurbba Kumar Sharma

Abstract Use of microwave energy at 2.45 GHz for micromachining offers promising nontraditional machining technique for brittle materials like glass. However, process is yet to be analyzed for better understanding of the process mechanism to minimize the defects associated with the thermal damages in the machined materials. In the present paper, the process was studied using the finite element method, and a 3D model of the microwave drilling setup was developed using COMSOL Multiphysics v5.2 software. Simulation was carried out to study the thermal characteristics of the materials with time while irradiated during the process. The main affecting parameters were analyzed to find out the possible reasons for the defect associated with this process. Simulation of the microwave drilling process was carried out for a combination of graphite concentrator (diameter = 500 μm) and borosilicate glass (thickness = 1.2 mm) at 700 W. Simulation results revealed that the electric field intensity near the concentrator tip was higher (approximately 8.99×10^6 V/m) enough to ionize the air dielectric media which causes the generation of plasma around the tip of concentrator. The maximum temperature in the machining zone was observed approximately 1100 °C in 6 s. The rapid rise in temperature in the specimen induces a very high thermal stress (approximately 85 MPa) which reaches beyond the fracture strength of the borosilicate glass. The experimental investigation of the same concentrator-specimen combination demonstrated the similar pattern of fracture while drilling in the air using the same processing parameters.

48.1 Introduction

Microwave drilling is a thermal energy-based advanced machining method in which electromagnetic energy concentrated at the tip of the concentrator is used to ablate/melt the material from the workpiece just beneath the concentrator. Microwave drilling was reported successfully for the first time by Jerby et al. in the year 2002. An extendable monopole antenna was used to concentrate the microwave into a small hot spot with the help of a coaxial waveguide. Due to the creation of hot spot, material became soft and antenna was made to penetrate inside the softened material to create a hole [1–3]. Later on, they reported that microwave drilling takes place due to thermal run-away effect at the tip of metallic drill. Theoretical analysis of thermal run-away effect was done by coupling the Maxwell's and heat equations to understand the temperature variation of hot spot with respect to time. It was reported that temperature of hot spot rises very rapidly [4]. In the year 2015, Lautre et al. performed drilling on various materials using microwave energy in a domestic microwave applicator using gravity feed. Drilling on various materials like polymer, glass, etc. was reported [5, 6]. But, a significant amount of thermal damage was present around the hole. To understand the mechanism, the process was simulated using COMSOL Multiphysics. It was reported that the jamming of the concentrator was taking place due to solidification of glass melt as the upper plasma sphere was relatively cooler. The high temperature of the plasma sphere around the concentrator tip caused it to melt and get blunt. So, as the cylindricity or conicity of the concentrator tip is lost, plasma formation at concentrator tip stops [7]. Later on, precursors were used to reduce thermal shock on the glass specimen but problems of concentrator jamming and blunting were still present [8]. In the year 2018, Kumar and Sharma used dielectrics to reduce thermal damage and avoid problem of concentrator melting and jamming while drilling glass [9].

Finite element-based modeling has been used for predicting the liquid and solid-state material transformation, the transient temperature distribution, and residual stresses induced in the workpiece during thermal energy-based machining processes [10–12]. Dhanik and Joshi studied the effect of inter-electrode gap on plasma temperature. It was found that temperature lies within 8100 ± 1750 K with a change in the inter-electrode gap [11]. Jiao and Wang simulated the laser cutting of glass plate to study the temperature and thermal stress distribution using ANSYS. It was reported that a dual-laser beam method where a laser beam was focused to machine the undesired material from the glass and an off-focused CO_2-laser beam was used to preheat the glass sample helped in reducing the thermal gradients. Due to reduced thermal gradient, the thermal stress became less than the critical fracture strength of the glass [12]. Krötz et al. simulated the single discharge of electrochemical arc machining for analyzing the heat-affected zone. It was found that duration of discharge and heat transfer from discharge to workpiece governs the diameter of heat-affected zone rather than the arc spot diameter [13].

Therefore, the objective of the present study is to simulate the microwave drilling process to understand the mechanism of the process and to find out the reason behind thermal damage induced in the workpiece during machining.

48.2 Modeling and Simulation

Figure 48.1 shows the experimental setup of microwave drilling. The pin vice is made up of structural steel and is used to hold concentrator. The material of the concentrator is also of structural steel. Microwave drilling is achieved by concentrating electric field at the tip of a metallic concentrator which rests just above the top surface of the workpiece (borosilicate glass) with the help of pin vice. As the electric field strength around concentrator tip reaches above the ionization potential of the medium around it, plasma is formed at the concentrator tip as shown in Fig. 48.2. The plasma formed ablates/melts the material from the workpiece just beneath it and the concentrator penetrates inside the workpiece to create a hole. But, it is very difficult to have a clear understanding of the process mechanism of microwave drilling due to the limitation in experimental assessment of distribution of electric field inside the cavity, temperature, and thermal stress along the surface of the workpiece, etc. So, the software tool like COMSOL Multiphysics can help in having a better understanding of the process mechanism.

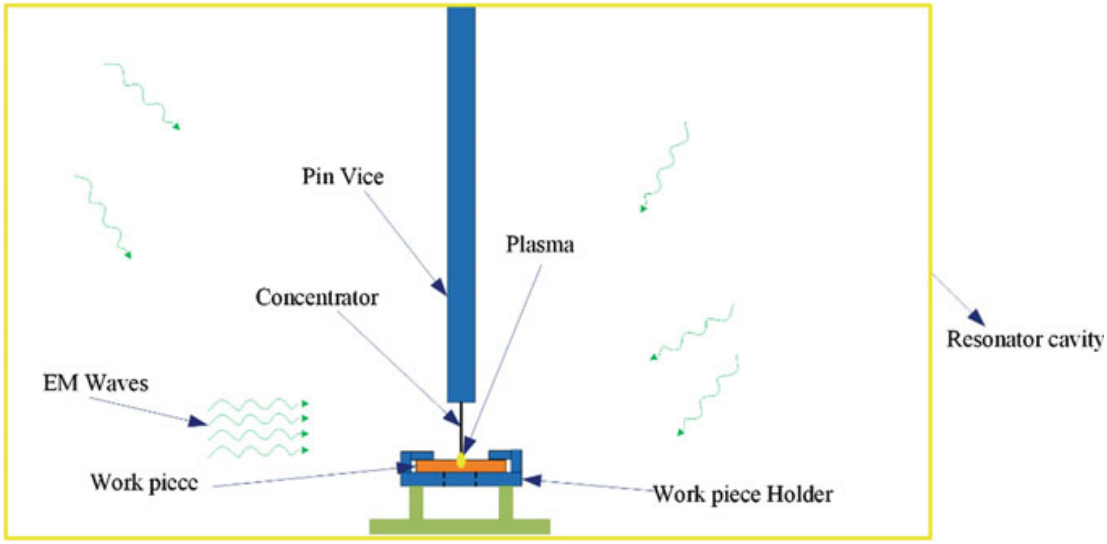

Fig. 48.1 Schematic diagram of the microwave drilling experimental setup

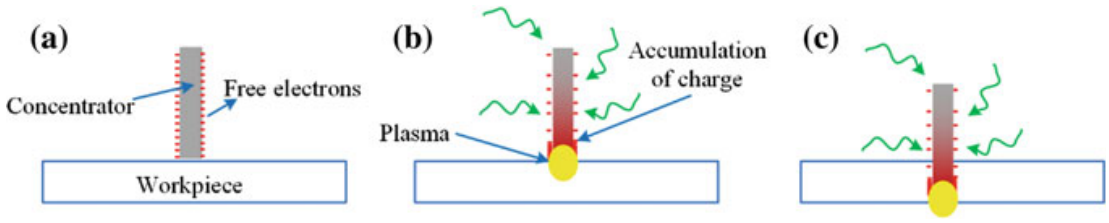

Fig. 48.2 Schematic of: **a** concentrator resting just above workpiece, **b** plasma formation after the microwave oven is switched on, and **c** concentrator penetrating inside the workpiece

48.2.1 Model Development

A 3D model of the experimental setup of microwave drilling as shown in Fig. 48.3 was developed using COMSOL Multiphysics 5.2 software to analyze the process and the behavior of workpiece while machining. The dimensions of the above model are shown in Table 48.1.

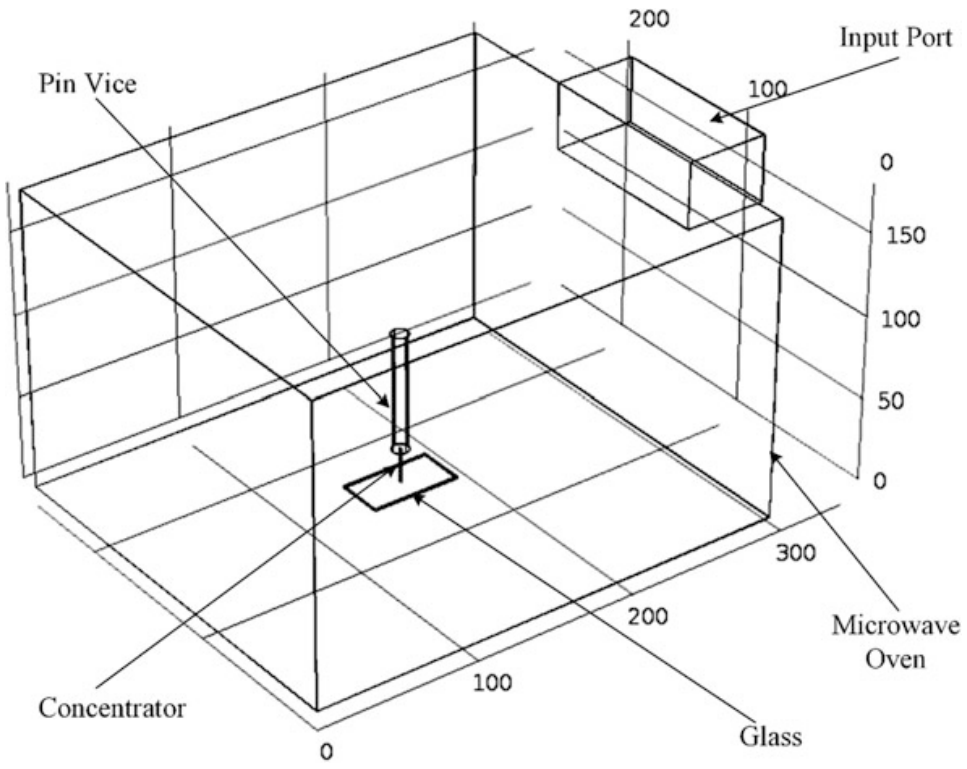

Fig. 48.3 Schematic of the 3D model of the microwave drilling

Table 48.1 Dimensions of the component used to generate the 3D model

Component	Oven	Waveguide	Pin vice	Concentrator	Workpiece
Dimensions (mm)	292 × 256 × 180	110 × 40 × 50	70 × 4.2(ϕ)	20 * 0.5(ϕ)	53 × 28 × 1.2

48.2.2 Meshing

Physics-controlled meshing is used to mesh the 3D model of the microwave drilling. Figure 48.4 shows the meshed 3D model. Fine meshing has been used to mesh the cavity (Fig. 48.4a), and extremely fine meshing has been used to mesh the concentrator and workpiece (Fig. 48.4b). The number of vertex elements, edge elements, triangular elements, and tetrahedral elements is 40, 557, 4504, and 45,401, respectively. The degrees of freedom solved for are 292,505. Figure 48.4c shows the plot of element quality of meshed geometry. The domain element statistics are as follows: average element quality = 0.653; element volume ratio = 1.924×10^{-7}; mesh volume = 1.368 × 107; average growth rate: 2.077.

48.2.3 Assumptions

The phenomenon of microwave drilling is governed by the formation of plasma at the tip of the concentrator and its subsequent interaction with the workpiece material. The formation of plasma depends upon the coupling of electromagnetic waves with the material of workpiece and concentrator. Besides it, shape of concentrator and its absorption behavior also influence the intensity of plasma formed. Therefore, following assumption has been made in order to simplify the model: (a) The workpiece, concentrator, and concentrator holder material used in the study are homogeneous and isotropic. (b) The atmosphere temperature inside the system is considered to be 27 °C, initially. (c) The air domain and jigs used are not

Table 48.2 Property of the material of different component of experimental setup

Property	Materials		
	glass	Steel	Copper
Density (kg/m^3)	2210	7850	8960
Thermal Conductivity (W/(m × K))	1.4	44.5	400
Heat Capacity at constant pressure (J/(kg × K))	730	475	385
Relative permeability	1	1	1
Relative permittivity	4.2	1	1
Electrical conductivity (S/m)	1×10^{-14}	4.032×10^{6}	5.998×10^{7}
Young's modulus (N/m^2)	70×10^{9}	200×10^{9}	110×10^{9}
Poisson's ratio	0.22	0.30	0.35
Coefficient of thermal expansion(1/K)	3.3	12.3×10^{-6}	17×10^{-6}

considered for thermal analysis as they have zero dielectric losses. (d) The walls of the cavity and waveguide are considered to be made up of copper. (e) The port is excited by a transverse electromagnetic standing wave fields in the Z direction. The property of the material of the different component of the experimental setup is shown in Table 48.2 which has been taken from the material library of the software.

48.2.4 Governing Equations

COMSOL Multiphysics (version 5.2), a finite element-based software has been used to solve the governing equations. The phenomenon of interaction of microwave with the concentrator and glass can be explained with the help of Maxwell's equations. The following equation based on standard Maxwell's EM equations with the stipulated excitation at the rectangular port is solved for electric field ($\boldsymbol{E}$) inside the waveguide and oven:

$$\nabla \times \left(\mu_r^{-1} \nabla \times \boldsymbol{E}\right) - k_0^2 \left(\varepsilon_r - \frac{j\sigma}{\omega \varepsilon_0}\right) \boldsymbol{E} = \boldsymbol{0} \tag{48.1}$$

where μ_r = relative permeability, k_0 = wave number in the free space, ε_r = relative permittivity, j = imaginary unit, ω = angular frequency, σ = conductivity, and ε_0 = permittivity of free space.

Due to the externally applied electromagnetic field, a very intense electric field ($\sim 10^6$ V/m) around the tip of the concentrator gets developed. This high electric field propagates through dielectric materials by ionizing it and creating a hot spot just beneath the tool tip. The heat generation in the concentrator, at the interface of concentrator and workpiece and in the dielectric media, can be expressed by the heat transfer equation as:

$$\rho C_p \frac{\partial T}{\partial t} = \nabla.(k\nabla T) + P(r,T) - P_{\text{Loss}}(T_S) \tag{48.2}$$

where t = time (s), ρ = material density (kg m^{-3}), C_p = specific heat capacity (J kg^{-1} K^{-1}), and k = thermal conductivity (Wm^{-1} K^{-1}), $P(r,T)$ = power absorbed by the dielectric, $P_{\text{Loss}}(T_S)$ = power lost to the surrounding due to convection and radiation respectively.

Due to the creation of hot spot on the surface of the tool tip, a thermal gradient is developed on the surface of workpiece. Due to this thermal gradient, a thermal stress is induced inside the surface of workpiece which is expressed using the following equation:

$$\sigma_{\text{th}} = \frac{E\alpha}{1-\vartheta}(\Delta T) \tag{48.3}$$

where σ_{th} = residual thermal stress (MPa), E = Young's modulus, ϑ = Poisson's ratio and α = coefficient of temperature expansion, ΔT = temperature differential on the surface of the workpiece.

48.2.5 Validation

The result obtained after simulating the above experimental condition was validated experimentally. Figure 48.5a shows the optical image of a hole drilled in air. It is evident from the figure that circular and radial cracks are present around the hole. These cracks originate from the critically stressed zone and propagate through the materials around it. It is evident from the figure that an area of $\sim$4.09 mm^2 is critically stressed. Figure 48.5b shows the simulated result of the distribution of around the hole created. It is evident that an area of 3.878 mm^2 is having Von

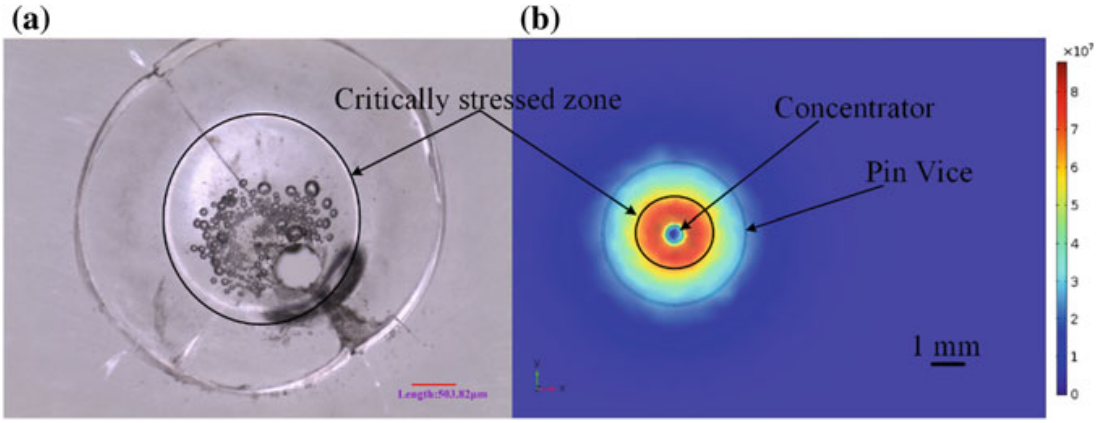

Fig. 48.5 **a** Optical image of the workpiece drilled in air and **b** Top view of the simulated stressed zone around the hole drilled on the borosilicate glass

Mises stress value greater than 60 MPa (critical stress limit for fracture of glass) which is called critically stressed zone. Both the experimental and simulated results are almost close to each other. Thus, the above-proposed model can be used for further study.

48.3 Results and Discussion

Figure 48.6 shows the distribution of electric field around concentrator tip. It can be observed from the zoomed view of electric field distribution around corners of concentrator tip that electric field strength is more than 10^6 V/m. Due to the high strength of electric field around concentrator tip, medium around the concentrator tip is ionized and plasma formation takes place. Consequently, maximum temperature in the surface of the workpiece just beneath the concentrator tip and concentrator rises rapidly up to 1100 °C and 950 °C in 6 s, respectively as shown in Fig. 48.7. It is also evident that maximum temperature in workpiece is higher as compared to the concentrator. This shows that core of the plasma formed, i.e., the zone of maximum temperature is around the surface of the workpiece. This is also evident from Fig. 48.8. It takes around 2 s to reach the softening temperature of borosilicate glass (~820 °C). As the glass melts, the concentrator starts to penetrate inside the workpiece. But, after few seconds, when the temperature is around 1100 °C, phenomena of ablation also takes place. Figure 48.8 shows the distribution of temperature along the different direction of the surface. It can be observed from Fig. 48.8 that temperature drops rapidly along the surface away from concentrator. The temperature just beneath the concentrator is around 950 °C and increases to around 1100 °C up to a distance of 0.4 mm. But after 0.4 mm, temperature decreases rapidly, and after 0.8 mm, the temperature comes below 800 °C. Due to this, the material removal takes place only up to a radial distance of 0.4 mm.

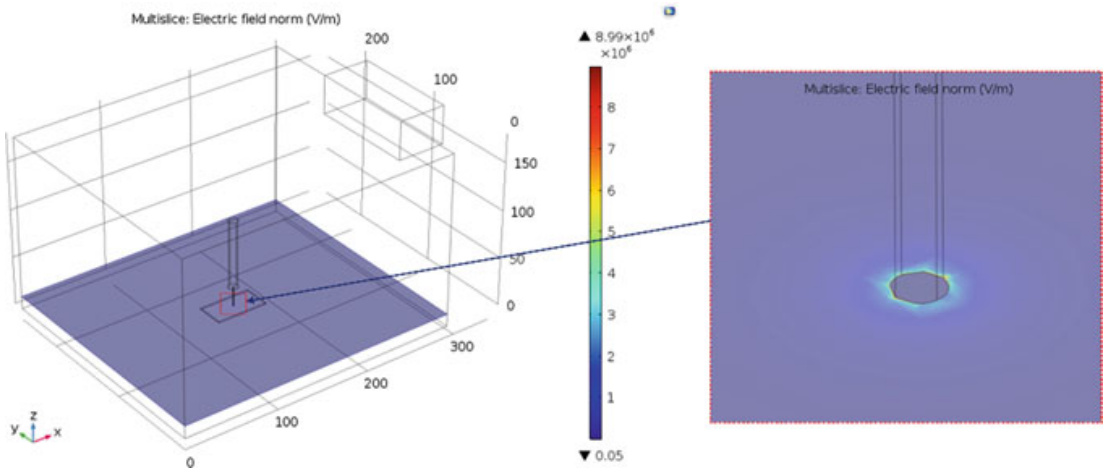

Fig. 48.6 Distribution of electric field around concentrator (inset: zoomed view of electric field distribution around concentrator tip)

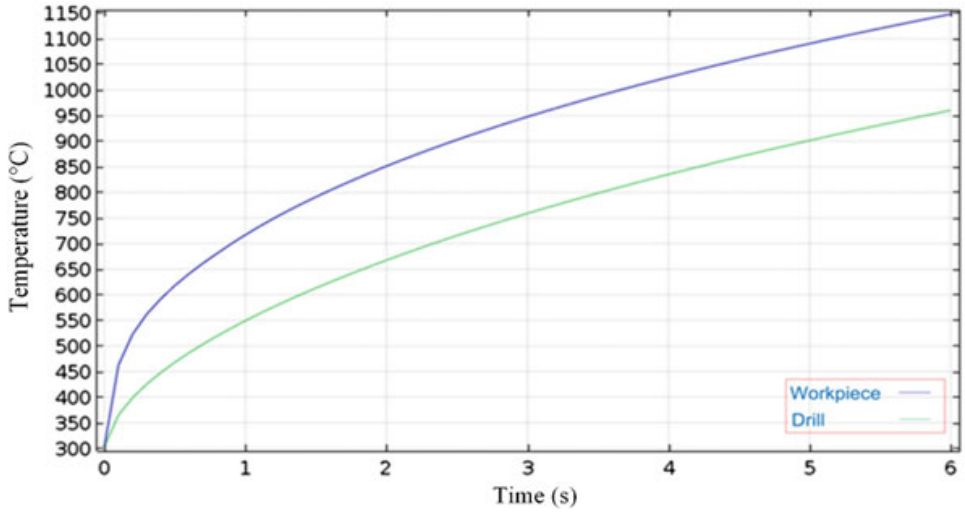

Fig. 48.7 Distribution of maximum temperature in concentrator and workpiece with respect to time

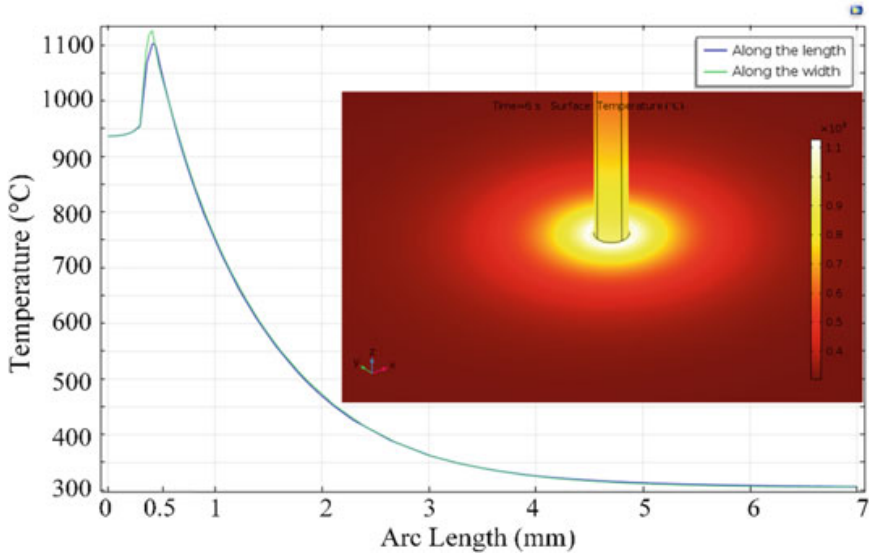

Fig. 48.8 Distribution of temperature along the surface with respect to arc length in different direction

The area after radial distance of 0.4 mm is heat-affected zone and highly stressed. Due to the high thermal gradient after 0.4 mm, the value of Von Mises stress rises above the critical stress limit for fracture of glass (60 MPa) as shown in Fig. 48.9. The region up to a radial distance of $\sim$1.3 mm is highly stressed zone. Crack initiates in this zone and propagates radially up to certain distance on the surface of the workpiece and after that circumferentially around the hole as shown in Fig. 48.5a. Due to the high thermal stress, glass often cracks while drilling in air. The hole drilled in glass in air at a controlled feed rate of 1.2 mm/s is shown in

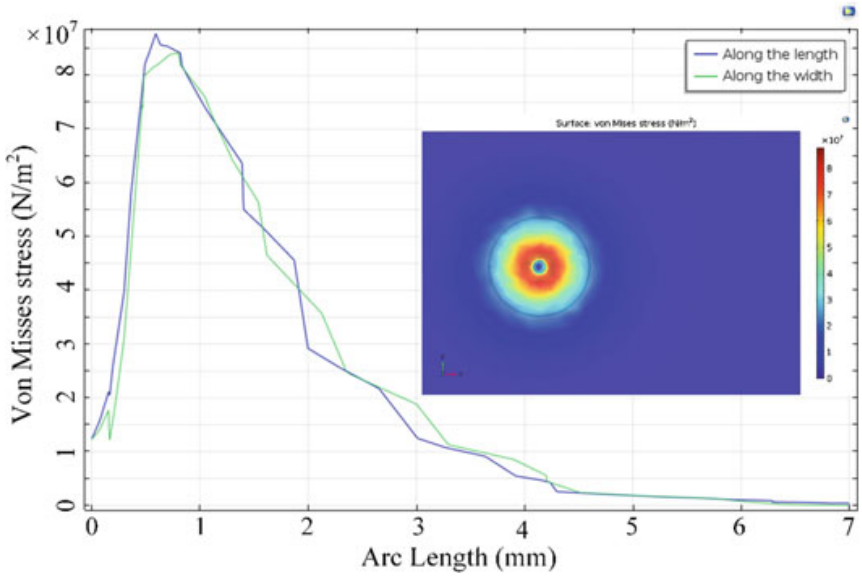

Fig. 48.9 Stress distribution along the surface just below the tip of the concentrator

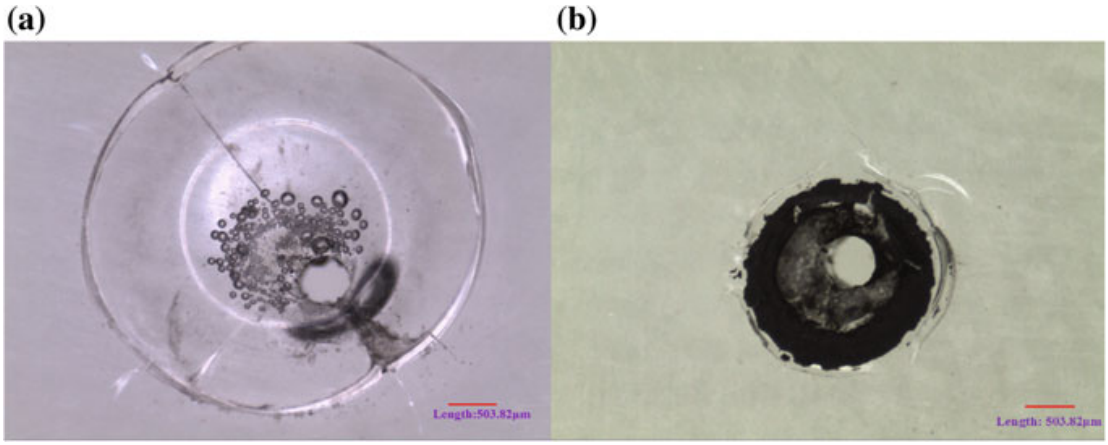

Fig. 48.10 Optical image of the hole drilled in (**a**) air (**b**) dielectric at a feed rate of 1.2 mm/s

Fig. 48.10a. It can be observed that significant amount of cracks is present around hole drilled. But as the medium around the concentrator tip is changed by a dielectric like transformer oil, the cracks and heat-affected zone are reduced significantly as shown in Fig. 48.10b. Dielectrics help in reducing the thermal gradient due to which cracks around the hole are reduced. Dielectric also helps in confining the shape of the plasma which ultimately reduces the thermal damage area as shown in Fig. 48.10b. But, a significant amount of carbon deposit is seen around the hole.

48.4 Conclusion

COMSOL Multiphysics 5.2 was used to simulate the microwave drilling process. Followings are the conclusions based on the simulation study:

- High electric field strength around the concentrator tip ($\sim 8.99 \times 10^6$ V/m) which is more than dielectric breakdown strength of air ionizes the medium around it to produce plasma.
- The maximum temperature on the surface of workpiece just beneath the concentrator tip is ~ 1100 °C which is higher than the ablation temperature of the borosilicate glass.
- The mechanism of material removal from the target area consists of combined action of ablation and melting.
- A very high thermal stress (~ 85 MPa) around the concentrator tip is induced in the surface of the workpiece which is the prime reason behind the crack generation while drilling.
- Dielectric helps in reducing the thermal gradient which ultimately lessens the crack and thermal damage around the hole.

Chapter 49
A Study on the Effect of Polarity Change on Various Parameters on Ti6Al4V in Powder-Mixed Micro-EDM Using Multi-objective Grey Fuzzy Optimization

Deepak Sharma, Anusha Roohi Siddique, Vishnu Kumar, Shalini Mohanty and Alok Kumar Das

Abstract The study emphasizes on the effect of polarity change while conducting experiments using tungsten disulphide in powder-suspended micro-EDM process on Ti6Al4V alloy workpiece with brass tool electrode. For design of experiment, Taguchi method with L9 orthogonal array has been adopted. For each set of experiments, three levels of factors such as voltage, duty factor and machining time are considered. The responses such as MRR (higher the better) and SR (lower the better) are calculated, and a grey fuzzy logic model is built for optimization of the parameters. ANOVA table shows that the voltage plays the most significant role when machining in straight polarity followed by machining time and duty factor, whereas for reverse polarity machining time is the most significant one followed by voltage and duty factor. In case of straight polarity, confirmatory tests were performed at $V = 25$, DF = 55 and $T = 8$ and in reverse polarity at $V = 25$, DF = 45 and $T = 8$ and GFRG in case of straight polarity was found to increase by 0.216 and increased by 0.182 for the reverse polarity.

49.1 Introduction

With the everyday advancement in the field of engineering and technology, one gets to witness novel methods of machining at every step. Now is the time when the researchers and industries are moving towards the non-traditional machining and hybrid machining at a very fast rate. With growing requirements of precision, tolerances and other high aspect ratio micro-features, micro-EDM has served as a very important technique to achieve the former. Micro-EDM is nothing but just an evolution of the process of EDM where the size of the tool and movement of the axis of resolution are small to the level of microns and the discharge energy which is released is very less as compared to the conventional EDM [1].

Various parameters are considered for carrying out experiments in micro-EDM, but polarity change has been a challenging parameter by researchers. The difference in polarities of the workpiece and electrode and comparing them help in comprehending the results better. Generally, the aim of a machining process is to provide better surface finish with optimized parameters. Polarity of the process holds great significance in such a case. To this aspect, Schluze [2] studied that EDM with reverse polarities (tool positive) proves to be important when small material is required to be removed during finishing operations. It can also be used to remove oxide layers on the surface when used in hybrid processes with ECM. Parshuramalu et al. [3] have provided with a methodology for testing and finding out how the different tools and workpiece can be used with alteration of polarity. It is clear that if the polarity is not chosen properly, serious effects on wear and stability can occur. The experiments were carried out on a steel workpiece in a sinking EDM with copper electrode. From the results, it was found that the removal of steel was greatly affected by the polarity and the current settings. Researchers have been trying to improve the EDM process for a long time now. From changing the electrode to improving the dielectric, everything is tried to increase the efficiency of this process. Kumar et al. [4] mixed nanopowder of Al_2O_3 in dielectric. In this process, reverse polarity was used and it was found out that there was a reduction in micro-cracks with enhanced surface finish. Tyagi et al. [5] produced green sintered electrodes along with copper powder in die-sinking EDM. They performed EDC in straight polarity. As a consequence, coating with enhanced thickness and better surface properties were formed. It is evident that research progress with reference to the polarity change has not been much prevalent and hence, in the present work, an effort is done to study the effect of different parameters of the machining process on surface roughness of Ti6Al4V workpiece when machined with mixing powder in dielectric in micro-EDM.

Whenever machining is done, it is very necessary that the parameters at which it is done are optimum. It is an arduous work to ensure that the process parameters are best. Hence, certain optimization methods like principal component analysis, Taguchi methodology and GRA are used and have proved to be of great importance for obtaining desirable results. Various researchers have used GRA for optimization of the performance parameters while experimenting. Gopal and Chakradhar [6]

optimized the parametric settings of feed rate, voltage applied and the concentration of the electrolyte for an ECM process. Durairaj et al. [7] made use of the GRA method in WEDM for finding out the vital process parameters which affected the optimal values of kerf width, and SR. Kumar and Kumar [8] determined optimal values of different parameters like pulse on duration (Ton), discharge current and gap voltage for an EDM process using GRA method considering MRR, electrode wear, SR as response values. Natarajan and Arunachalam [9] used Taguchi system and GRA to improve the EDM machining inputs by many regular attributes. Gopalakannan et al. [10] conducted experiments by selecting process parameters like gap voltage, pulse current, pulse on and off duration and used Taguchi-based GRA for EDM process with several outputs like EWR, MRR and SR. They decided that current and pulse on duration were the parameters of highest significance. Dewangan et al. [11] conducted experiments by means of RSM on composites with wire EDM and applied grey fuzzy method. Optimum values of process parameters were acquired, and consequent values of the MRR and SR were established. Ramanan and Shanavas [12] applied Taguchi and grey fuzzy logic to improve parameters of performance in turning of the AISI D2, while Soepangkat et al. [13] used the same for optimization in submerged arc welding.

Though a lot of researchers have used the above-mentioned methodology for optimizing difficult parameters of various non-traditional machining processes and electrical discharge machining in general [14], a optimization of parameters specifically for a micro-EDM has not been done. The purpose of the present study is to highlight the multi-objective optimization of powder-mixed micro-EDM under different polarities using grey fuzzy technique.

49.2 Methodology

49.2.1 Grey Relational Generation

In grey method, some interrelated information is well known and other is unknown. These multiple interrelated performance characteristics can be solved by grey relational analysis. In this analysis by using certain formulas, experimental data (MRR and SR) was normalized in the range of 0 and 1 and these values were used in generating grey relational coefficient which will direct the connection among the desired and actual experimental numbers. According to the type of normalized data required, GRA is of three types, namely lower the better, higher the better and nominal the better. To get normalized higher-the-better MRR values, the following equation was used:

$$X_a(b) = \frac{y_a(b) - \min y_a(b)}{\max y_a(b) - \min y_a(b)} \tag{49.1}$$

Similarly, normalized smaller-the-better SR values can be obtained by:

$$Y_a(b) = \frac{\max y_a(b) - y_a(b)}{\max y_a(b) - \min y_a(b)} \tag{49.2}$$

where $a = 1, 2, 3, \ldots k$ and $b = 1, 2, 3, \ldots q$; k is the number of experimental data; q is the number of factors; $y_a(b)$ is the actual sequence; $y_a(b)$ is the value post-grey relational generation; min $y_a(b)$ and max $y_a(b)$ are the smallest and largest values of $y_a(b)$, respectively.

Grey relational coefficient (GRC)

$$\epsilon_a(b) = \frac{\Delta\min + \omega\Delta\max}{\Delta oi(k) + \omega\Delta\max} \tag{49.3}$$

where $\epsilon_a(b)$ is the grey relational coefficient; Δ_{oa} is difference among $y_o(b)$ and $y_a(b)$; $y_o(b)$ is the best sequence; Δmax is uppermost value of $\Delta_{oa}(b)$; Δmin is smallest value of $\Delta_{oa}(b)$; ω is the distinctive coefficient which is in the range of $0 \leq \omega \leq 1$. To get the results closer to optimal normalized value, highest value of grey relational coefficient has been used.

Grey Relation Grade (GRG)

The average of GRC value corresponding to each criterion is the GRG value.

$$\Gamma_a = \frac{1}{n}\sum_{b=1}^{n} \epsilon_a(b) \tag{49.4}$$

where n is no. of characteristics; greater the value of GRC, more will be its priority. The greater value of GRC suggests that corresponding process parameter is close to the optimal parameter.

49.2.2 Fuzzy Logic

Fuzzy logic is a scheme where the perceptive analysis of certain data by a human brain is represented. Fuzzy logic helps in making certain deductions which are similar to the results from a certain scheme of proposals which show considerable similarity with the initial data. A fuzzy logic division comprises of membership functions, fuzzifier, a fuzzy rule base, the inference engine (Mamdani) and a defuzzifier. The fuzzy interface engine (Mamdani) is shown in Fig. 49.1. Membership functions are fed to the fuzzifier which generates the grey relational coefficients. The membership function of MRR and SR is shown in Fig. 49.2, and membership function of GFRG is shown in Fig. 49.3. The fuzzifier interface engine converts these values to fuzzy values, and at end, defuzzifier alters fuzzy values in the form of grey fuzzy reasoning grade.

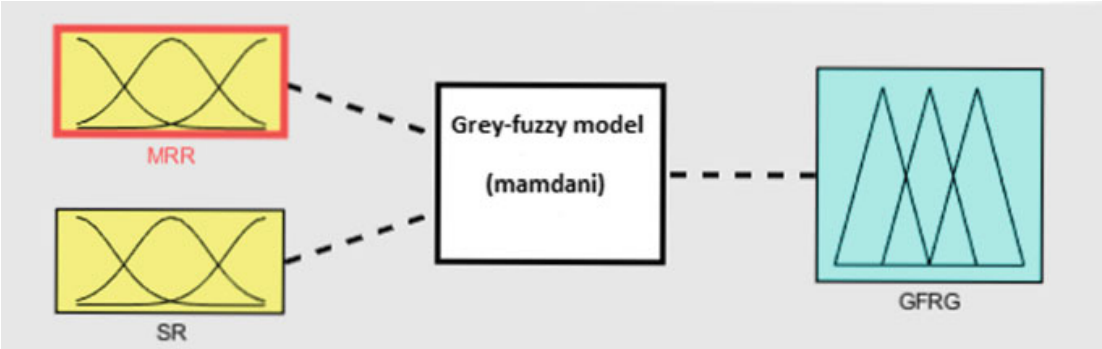

Fig. 49.1 Fuzzy logic model for process responses

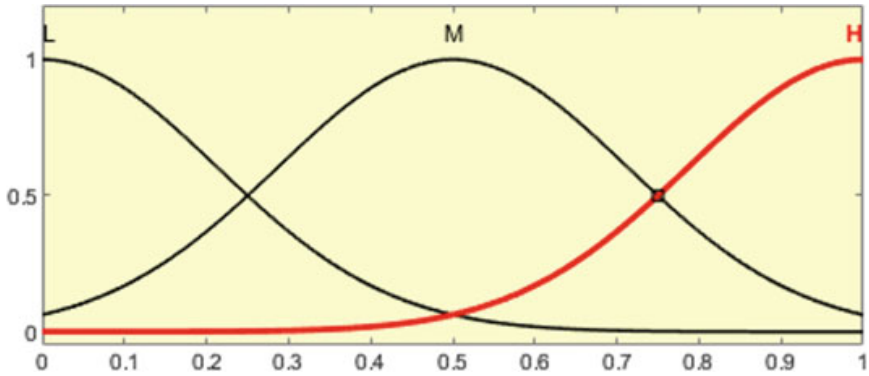

Fig. 49.2 Membership function for MRR and SR

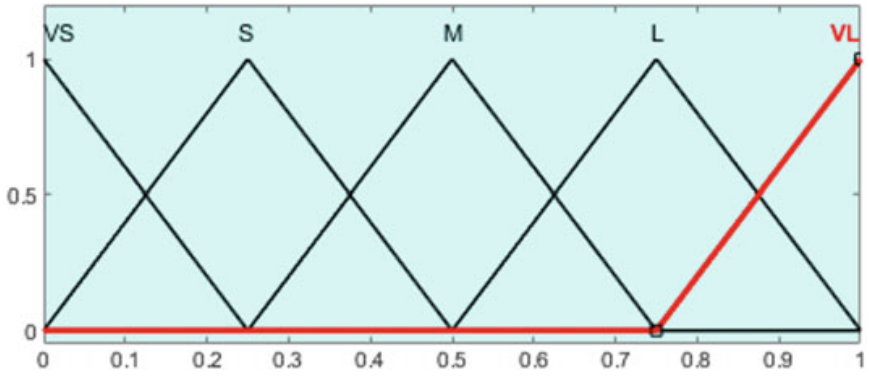

Fig. 49.3 Membership function for grey fuzzy reasoning grade

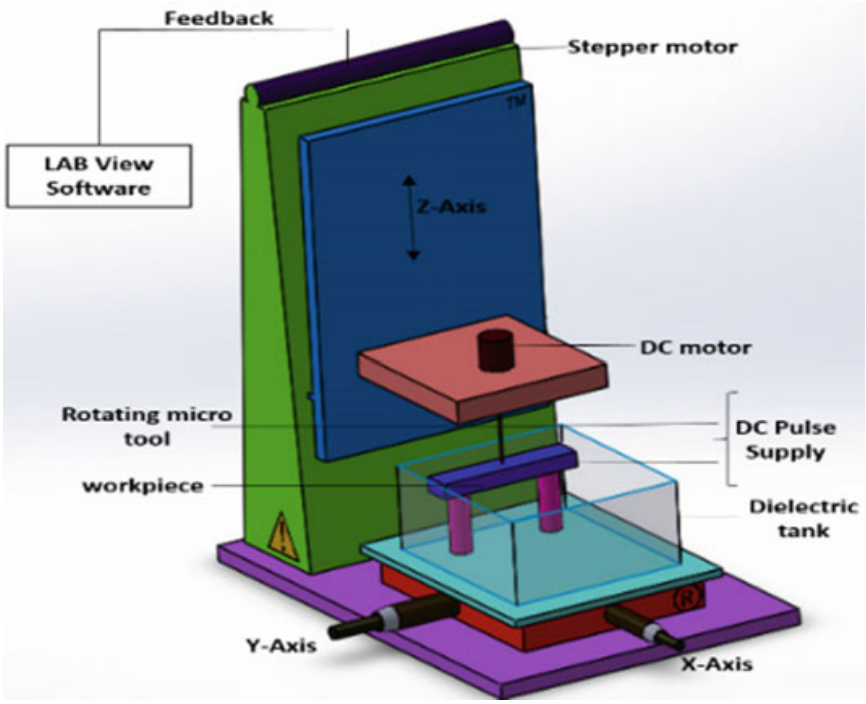

Fig. 49.4 Three-dimensional figure of micro-EDM system

49.3 The Experimental Set-Up and Procedure

Experiment was conducted on Ti6Al4V workpiece of dimensions 10 × 10 × 1.5-mm thickness with brass tool of 1-mm diameter and 30-mm length. De-ionized water was used as dielectric medium and tungsten disulphide as suspended powder particles. To conduct the experiments, a three-axis system fitted out with the micro-EDM set-up is used as shown in Fig. 49.5. XY-stage is used to provide longitudinal and transverse motion to the workpiece. A DC motor is used to impart rotational motion to the tool, and the workpiece is submerged in the dielectric with proper clamping. Another motor is devoted to the set-up to provide vertical motion to the tool. The 3D model of micro-EDM set-up is presented in Fig. 49.4. Transistor-based power supply was used, and LabVIEW software allows the z-axis motion.

A total of 9 × 2 experiments were directed (for reverse and straight polarities) by choosing L9 Taguchi DOE as shown in Table 49.2. The uncontrolled input parameters are voltage (V), duty factor (%) and machining time (min). Tool is fixed to be positive and the workpiece is connected to negative terminal for reverse polarity, and tool is negative and workpiece is positive for straight polarity. Trial experiments were conducted to decide different levels of parameter values, and it was observed that as the difference between the values of parameters for consecutive levels was small it was difficult to differentiate between the performance parameter values so middle-range parameters with sufficient difference were nominated for the experiments as shown in Table 49.1. The performance of

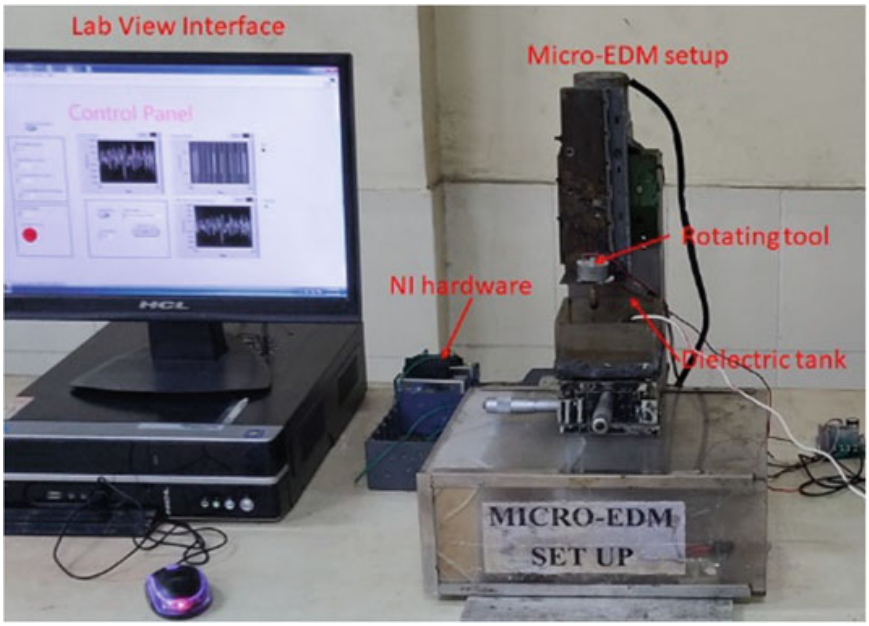

Fig. 49.5 Micro-EDM set-up

Table 49.1 Parameters of the process and their levels

Factors	Parameters	Level 1	Level 2	Level 3
A	Voltage, *V*	25	40	55
B	Duty factor, DF	35	45	55
C	Machining time, *T* (min)	6	8	10

experiments was measured by MRR and SR. Each of these values is considered at once to get GFRG which yield the optimum MRR and SR. Design of experiment is generated by L9 Taguchi array system.

The flow chart shown in Fig. 49.6 gives a concise idea about how the grey fuzzy logic works. It starts with the construction of design of experiment with the help of Taguchi L9 design. Experimental data was then converted to normalized data with the help of formulas. This normalized data was used to calculate grey relational coefficients for both MRR and SR, and the GRCs for both straight and reverse polarities are then fed to the fuzzifier as input membership functions. With the help of certain "if and then" rules, fuzzy interface engine (Mamdani) converts these values to fuzzy values and then the defuzzifier converts them into grey fuzzy reasoning grades. GFRG values decide the optimal solution, and then confirmatory tests were done to verify the optimal solution.

49.4 Results and Discussion

49.4.1 The Grey Reasoning Coefficient

For each performance parameter, normalized values were calculated. Table 49.3 displays the calculated normalized value of each quality characteristic, grey relational coefficients and grey relational grade.

Table 49.3 Normalized and GRC table

Exp no.	Normalized value of		Normalized value of		Grey relational coefficient of		Grey relational coefficient of		GRG_{st}	GRG_{rev}

49.4.2 The Grey Fuzzy Reasoning Analysis

MRR and surface roughness are two inputs, and GFRG is one output of fuzzy logic method. The GRC for MRR and surface roughness are considered as the inputs to the fuzzy logic method. To establish the fuzzy if and then rule as shown in Table 49.4, the language-based membership operators L, M and H were used to indicate the grey relational coefficient of the entered variables. Similarly, the output grey relational grade has been signified through the member functions VS, S, M, L, VL on triangular shape membership function.

The common methods for defuzzification are centre of maximum (COM) and centre of area (COA). The relationship between two inputs and output is developed by certain "if-then" rules that are:

Rule 1: If $m1$ is $V1$ and $n2$ is $W1$ and $p3$ is $X1$ and $q4$ is $Y1$, then output (G) is $Z1$.
Rule 2: If $m1$ is $V2$ and $n2$ is $W2$ and $p3$ is $X2$ and $q4$ is $Y2$, then output (G) is $Z2$.
Rule n: If $m1$ is Vn and $n2$ is Wn and $p3$ is Xn and $q4$ is Yn, then output (G) is Zn.

where Vi, Wi, Xi and Yi are the fuzzy subsections distinct by the equivalent member functions, i.e. μVi, μWi, μXi and μYi, respectively. The inference engine (Mamdani) does fuzzy reasoning on rules defined by fuzzy system while considering max and min inference for generating a specific fuzzy value, $\mu c_o(G)$.

$$\begin{aligned}\mu c_o(G) = &(\mu V_1(m_1) \wedge \mu W_1(n_2) \wedge \mu X_1(p_3) \wedge \mu Y_1(q_4) \wedge \mu Z_1(G)) \\ &\vee (\mu V_1(m_1) \wedge \mu W_2(n_1) \wedge \mu X_2(p_2) \wedge \mu Y_2(q_3) \wedge \mu Z_2(G)) \\ &\vee (\mu V_n(m_1) \wedge \mu W_n(n_2) \wedge \mu X_n(p_3) \wedge \mu Y_n(q_3) \wedge \mu Z_n(G)).\end{aligned}$$

where $\vee$ is the maximum operator and $\wedge$ is the minimum operator. The process of defuzzification has been used to convert the fuzzy interface output into exact value of GFRG(G_o).

Table 49.4 Fuzzy if and then rule

I/C criteria	Input (if)		MPCI (then)
	Individual desirability values of MRR	Individual desirability values of SR	
1	L	L	VS
2	L	M	S
3	L	H	M
4	M	L	S
5	M	M	M
6	M	H	L
7	H	L	M
8	H	M	L
9	H	H	VL

$$G_o = \frac{\sum G\mu c_o(G)}{\sum \mu c_o(G)} \tag{49.5}$$

Graphical illustration of fuzzy logic reasoning is shown in Fig. 49.7 (straight polarity) and Fig. 49.8 (reverse polarity). The nine rows represent rules, and three columns represent MRR, SR and GFRG, respectively. Both the graphs are taken at optimal parameters, and in Fig. 49.7 the input values of grey relational coefficient of SR and MRR are 0.39 and 1, respectively, and defuzzified output is 0.666 which shows the combined effect of both the input values. Similarly, in Fig. 49.8 the input values are 0.403 and 1 and corresponding output value is 0.671. The GFRG values with their respective ranks are shown in Table 49.5.

The response analysis in Tables 49.6 and 49.7 determined that for straight polarity the parameter combination $V = 25$, DF = 55 and $T = 8$ gives the optimal value and for reverse polarity the parameter combination $V = 25$, DF = 45 and $T = 8$ gives the optimal value of MRR and SR. Figures 49.9 and 49.10 show the mean of mean, response graph of GFRG for straight and reverse polarities, respectively.

49.4.3 Analysis of Variance

ANOVA is formulated for both straight and reverse polarities using GFRG values to calculate the percentage by which each parameter is affecting the process. The results of ANOVA for straight polarity are given in Table 49.8 and for reverse polarity in Table 49.9. From ANOVA tables, it is justified that in case of straight polarity voltage (27.19%) influences more on alloying process followed by

49.4.4 Theoretical Prediction and Confirmation of Experiments

After obtaining optimal level of design parameters in case of straight and reverse polarities, the last step is to forecast and settle the upgradation of performance features. Table 49.10 shows the contrast of original process parameters and optimal process parameters in case of straight polarity, and as noted the MRR improved from 0.00347 to 0.009225 g/min, surface roughness (SR) decreased from 1.856 to 1.83 μm, and GFRG is improved by 0.216. Similarly, Table 49.11 shows the comparison for reverse polarity, and as noted MRR increased from the value of 0.00034 to 0.00035 g/min and GFRG is improved by 0.182. It is clearly revealed that multiple performance parameters are improved using grey fuzzy optimization technique. MRR is calculated by the formula as given in Eq. 49.6.

$$\text{MRR} = \frac{W_\text{i} - W_\text{f}}{t} \tag{49.6}$$

where W_i and W_f are the weights before and after the experiments and t is the time of machining in seconds.

FESEM images of both straight and reverse polarities at 40 V, 35% duty factor and 8 min machining time are shown in Figs. 49.11 and 49.12, respectively. It is found that the recast layer is more uneven in case of straight polarity whereas a

GFRG	0.501	0.704	0.717
Improvement of GFRG		0.203	0.216

Table 49.11 Results of process performance by means of the original and optimal factors for reverse polarity

	The initial process parameters	The optimal process parameters	
		Prediction	Experiment
Level	A1B3C3	A1B2C2	A1B2C2
MRR	0.00032	0.00034	0.00035
Surface roughness	0.379	0.15	0.177
GFRG	0.604	0.767	0.786
Improvement of GFRG		0.163	0.182

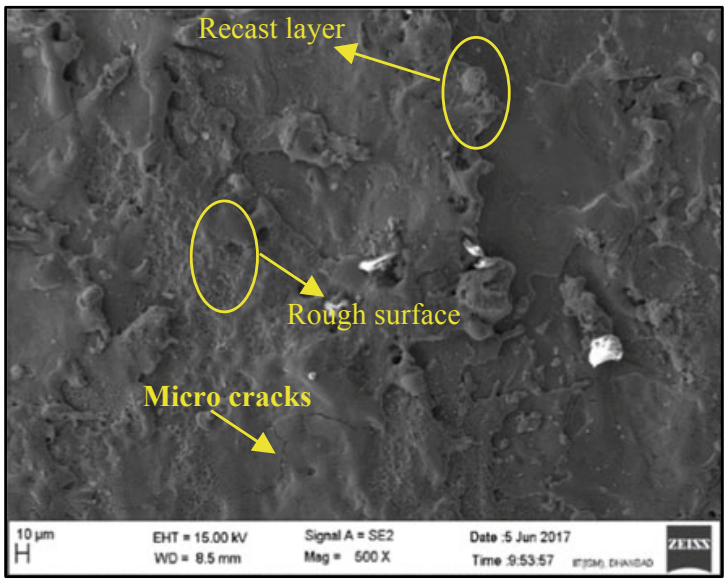

Fig. 49.11 FESEM for straight polarity

comparatively lower surface roughness is seen in reverse polarity. This may be due to less discharge energy available at workpiece in case of reverse polarity as compared to straight polarity. In addition to that, WS_2 is a solid lubricating powder; thus, it plays an important role to improve surface properties of workpiece.

49.5 Conclusions

The combination of optimization method and grey fuzzy logic is used in current research work for concurrently optimizing the numerous performance characteristics like MRR and SR both in straight and reverse polarities. After summarizing the key attributes of this experimental investigation, the following conclusions were drawn:

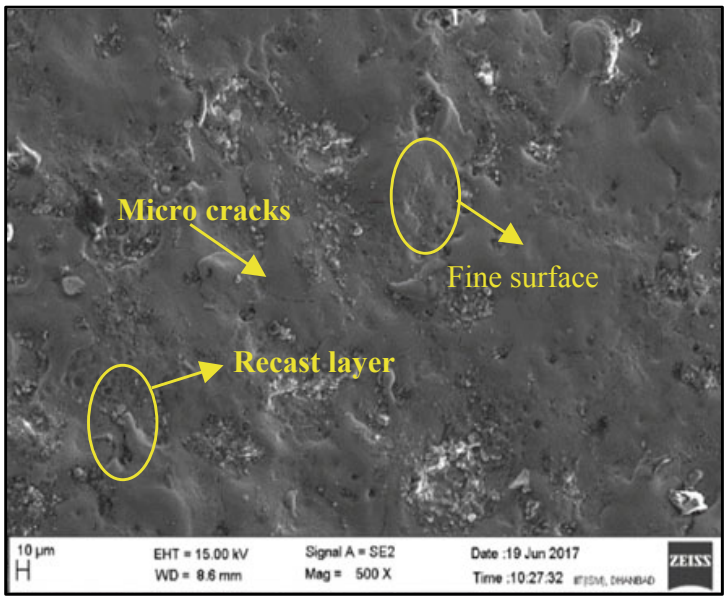

Fig. 49.12 FESEM for reverse polarity

1. The optimal parametric combination in straight polarity is $V = 25$, DF = 55 and $T = 8$ and in reverse polarity is $V = 25$, DF = 45 and $T = 8$ determined by grey fuzzy logic.
2. The ANOVA results determine that in case of straight polarity voltage (27.19%) influences more and in case of reverse polarity machining time (33.63%) affects more.
3. It has been concluded from the results that the lower surface roughness was obtained in case of reverse polarity as compared to what obtained in straight polarity as the craters formed in case of straight polarity were of comparatively greater size due to the direction of current which in turn resulted in high energy flow to the workpiece.
4. It is indeed complicated to convert multiple parametric optimizations into a single GFRG. So, an amalgamated technique like grey fuzzy logic method along with orthogonal array system provides an efficient way for optimizing the process parameters in micro-EDM.

Chapter 50
Multi-output Response Optimization for Overall Enhancement of Mechanical Characteristics Using Utility Approach for AISI 316L Austenitic Stainless Steel Using Microplasma Arc Welding

Srikant Prasad, Dibakor Boruah and Pintu Thakur

Abstract This paper presents multi-output advancement for microplasma arc welding (MPAW) process using utility methodology. It is an advanced unconventional welding process in which very thin (usually less than 1 mm) metal surfaces are joined using plasma arc. A successful trial has been made to weld 0.5-mm-thick 316L stainless steel sheet. An attempt has been made to optimize the MPAW parameters for a desired equal-weighted multi-output such as ultimate tensile strength, yield strength, percentage elongation, Young's modulus, and weld hardness at fusion zone and heat-affected zone. The design of experiments L_{27} orthogonal matrix was conducted using levels of several visually successful trials. An analytical tool analysis of variance and interaction has been clubbed with utility approach to get desired aim of experimentation. As per different work application, the different preferable weight can be incorporated into the output. The confirmation test correlated with the best-desired aim of the output parameter. It was observed that overall utility for all mechanical properties and corresponding S/N ratio is enhanced with 0.28 and 0.42 values, respectively. It was found that welding speed with 49.01% and pulse time with 13.21% are the most significant parameters.

The enhancement in the responses confirmed the approach of the feasibility of utility analysis which can help to enhance the product reliability for an industrial application.

Keywords MPAW · Optimization · Overall utility · ANOVA

50.1 Introduction

Microplasma arc welding (MPAW) was invented first by Robert Gage in 1957, which was introduced in 1964 to the welding industry for better control of the arc-welding process in lower current ranges. The plasma gas (the fourth state of matter) is used to generate arc with the help of argon gas. An ionization potential of plasma gas is 15.6 eV [1]. It takes very low currents to generate plasma arc. The argon gas is preferred as plasma gas because its low ionization potential ensures reliable starting and dependable pilot arc [2]. This arc is utilized to weld very thin plates even less than 0.5 mm. Low-alloy stainless steel sheet 316L is the useful engineering materials for industrial applications since they enriched with an excellent combination of properties like high strength-to-weight ratio, corrosion resistance, good toughness, fatigue life, which make it attractive for different applications through advanced joining process like MPAW. During welding, several input parameters which influence the welding properties need to be optimized for the better performance in the field application. The welding input parameters influence weld joint quality during the welding process. Therefore, it can be considered as a multi-input and multi-output process. Recently, a few researchers have reported optimization of 304L and Inconel considering effect of grain size, bead geometry, hardness, and ultimate tensile strength (UTS) using pulse microplasma [3]. The pulsed current microplasma arc-welding parameters were optimized to maximize UTS for AISI 304L sheets material using response surface method [4] and Hooke and Jeeves Algorithm by Shiv Prasad et al. [5]. The latest research work on the optimization of hydroxyapatite synthesis and microplasma spraying of porous coatings onto titanium implants has been reported by Alontsevadalontseva et al. [6]. According to the authors best of knowledge, no literature reported optimization of AISI 316L austenitic stainless steel sheet of using pulse MPAW. The various tests have been conducted to evaluate mechanical properties like tensile test, hardness, and weld bead geometry. As a multi-output response ultimate tensile strength (UTS), yield strength (YS), percentage elongation (%E), young modulus (YM), hardness of fusion zone (H_{FZ}) and hardness of heat-affected zone (H_{HAZ}) were used to study the optimization process using utility approach which helped to quantify the integrated performance of the MPAW. The confirmation experiment was conducted to validate the optimized parameters of the process. The predicted parameters have been correlated with the experimental result of the optimized parameters. The optimal welding conditions help to increase the productivity, minimize the total operating cost and strengthening of weld joint.

50.2 Experimental Work

The welding experiments were conducted using Aircraft plasma MP-50. The stainless steel 316L sheet of size (100 mm × 150 mm), thickness 0.5 mm was welded without filler material. The experiment had been designed as per design of experiment (DOE), using orthogonal array L27 Taguchi fractional factorial design method. The Argon gas was used as an orifice gas and shielding gas. The shielding gas prevents the weld from oxidation during welding and welds remain shiny. The coupling of orifice and shielding gas made with help of "T" joint attached at the end of cylinder exit pipe. The transferred arc mode in which the torch is brought in close to the workpiece, welding current is initiated, and the arc is transferred from the electrode to the workpiece which produces excess temperature up to 1700 °C to meet the welding requirement, then it cooled down to permissible temperature by means of circulating water through the nozzle. The complete experimental setup and welding fixture have been developed at IIT Guwahati central workshop. The setup has been shown in Fig. 50.1.

50.2.1 Weld Direction Determination for Rolled Sheet

To enhance percentage elongation, the weld direction has been determined with special light scattering technique which always shines in the direction perpendicular to the rolling direction. Due to rolling, grains are elongated in the direction of rolling resulting in less percentage elongation and hardness in the rolling direction. Therefore, care has been taken during the experiment and welding direction has been proposed normal to the light scattering direction [2]. Figure 50.2a illustrates the weld direction and rolling direction with the help of light scattering direction.

The yellow arrow shows the rolling direction, and the blue arrow shows the welding direction.

The welding setup, fixture, and standoff distance adjustment features for MPAW setup were fabricated at IIT Guwahati central workshop for accuracy of weld quality, which has been shown in Fig. 50.2b, a welded sample was shown in Fig. 50.2c. The weld fixture was also designed as per dimension of weld sheet and less arc deflection. The interface gap between two weld plates, which is not permissible was ensured properly before welding. The chemical composition of the weld material used in these experiments has shown in Table 50.1. The significant six parameters in three levels which have an impact on weld quality, taken into consideration and shown in Table 50.2.

During post-weld process, tensile samples were cut through CO_2 laser-cutting machine, make: model no: LVD Orion3015, power rated 2.5 kW. The hardness samples (5 mm × 5 mm) and tensile samples as per the dimension of standard

ASTM–B557M-10 were extracted. Figure 50.3a shows the extraction of tensile, hardness, and microstructure sample, and Fig. 50.3b shows the tested tensile sample.

The material properties considered in the present investigation are: UTS, YS, YM, %E, $H_{FZ,}$ and H_{HAZ}. The bead geometry is the mirror of the mechanical properties of a weld which depends upon reinforcement height and bead width [5]. The proper reinforcement height is required to get good strength of the welding [6]. All the mechanical output properties have been shown in Table 50.3.

50.3 Result and Discussion

50.3.1 Optimization Using Utility Approach

Multi-response optimization is the most prominent area in the research for the welding industries to meet satisfaction, reliability, and cost reduction. Nowadays, unconventional welding process like MPAW is a very successful welding technology to weld materials with a very low thickness. Very precise control on parameters is required for its utility. Various process parameters need to be optimized to meet several demandable responses from the customer to manufacturer. The optimization of weld parameters is necessary to get optimal response for all quality characteristics. The multi-output characteristic is needed to scale for a single-output characteristic on a single composite scale index to get a single optimal setting of MPAW parameters [7–9]. The multi-response optimization is a need of today for industrial application where more than one response is coupled simultaneously using utility analysis. Several analytical techniques were explored to

handle the need for multi-optimization problem. Previously, some work has been reported for optimization is gray relation analysis, response surface methodology (RSM), and Taguchi methods. A research paper has been published on gray-based Taguchi method for parameters optimization of submerged arc bead on plate-welding process. Till now, no publication has been reported on multi-optimization using utility tool for MPAW process. For single output response Taguchi and RSM methodology are reliable optimization, but for multi-output welding process Taguchi analysis is not feasible [10–13]. Very few works are presented in literature for multi-response optimization problems [14, 15]. In comparison with utility approach, the desirability approach is not efficient up to a level. In the desirability approach, individual desirability is scaled into single composite index, for overall multi-response. Due to the complexity of computational aspects, several desirability values appear with zero value during the calculation which is difficult to analyze with ANOVA. Few publications on multi-output optimization have been reported on bead on plate welding. However, during the experiment, it was observed that the responses of real-welding process are different than the bead on plate welding [16]. Datta et al., have reported on submerged arc bead on plate welding using gray-based Taguchi technique. This research paper has been focused on overall enhancement of weighted mechanical properties for MPAW [17]. The mechanical property of a MPAW has been shown in Table 50.3.

50.3.2 Utility Concept Approach

The utility alludes to the fulfillment of customer; it contrasts from individual to individual, time to time and place, as defined by Prof. Hobson, "Utility is the capacity of a decent to fulfill a need". The business analyst estimated the utility in cardinal (numerical terms), yet there was no standard unit for estimating utility. In this way, the financial analysts utilized a fanciful measure, known as ('Util'). The costumers assess the item based on handiness. Taguchi configuration cannot deal with multi-output responses since every execution trademark have distinctive unit [18]. The general utility is the composite record of all quality as indicated by their value, which is appointed through the weight of the particular responses. A few research papers have been reported on Taguchi-constructed utility approach in light of various welding processes like Laser, EBM, and SAW process. However, no work has been accounted for on 0.5-mm-thin plate Austenitic steel 316L sheet welding through MPAW process. Subsequently, an effort has been made to represent the enhancement using utility-based Taguchi approach for multi-objective MPAW process for a thin austenitic steel sheet of 316L. This method was utilized to decide the ideal and best mix of process parameters for this process specifically welding pulse current, welding speed, pulse width, pulse frequency, plasma gas flow rate and stand of distance to maximize UTS, YS, %E, and hardness of the weld with the weight priority index to meet customer requirement.

50.3.3 Determination of Utility Value

All the output data has been converted into overall utility index to determine the utility for quality characteristics. In this approach, a preference scale has to construct using weight and composite numbers which is called overall utility. There are several preference scales, namely (i) exponential, (ii) logarithmic, and (iii) linear, but in the present research, investigation logarithmic approach has been considered as a preference scale index.

It is the evaluation of diverse quality characteristics in a rational choice by combining to make a composite index which represents the utility of a product. The overall utility index of a weld output is a sum of utilities of individual's quality characteristics.

$$U(X_1, X_2, \ldots\ldots\ldots\ldots, X_n) = \sum_{i=1}^{n} U_n(X_i) \tag{50.1}$$

$$P_i = A \times \log\left(\frac{X_{i,}}{X_{i,}}\right) \tag{50.2}$$

$$A = \frac{9}{\log\left(\frac{X_i^*}{X_{i,}}\right)} \tag{50.3}$$

50.3.3.1 Steps in Calculation of Utility

Step 1: In the utility analysis, the minimum acceptable quality is set numeric index 0 and the best acceptable quality level is set 9. Among the several scales mentioned above, the log scale has been chosen to find the preference number (P_i). The following equation is followed to find the constant value (A).

Step 2: For finding the value (A) using (P_i) value 9 in Eq. (50.3), we have to use (X_i*) as optimal pridicted output, and (X_i,), as minimum characteristic output among all.

Step 3: We have to find preference number (P_i) using Eq. (50.4). At this stage, we have to incorporate index (A) value and (X_i) individual present output carectersitic value, and (X_i), as minimum charectersitic output among all. The chart repersented below has been prepared using above Eq. 50.4 for all mechanical responcees like UTS-P, YS-P, YM-P, %E-P, $H_{FZ\text{-}P}$, and $H_{HAZ\text{-}P}$, respectively. The equal weightage has been considered for all outputs for predicted mechanical properties which are shown in Table 50.4. Depending on the customer requirements, the attributes to preference weightage may be given priority among all property. The property can be adjusted by incorporating weight (W) into individual utility index. Sum of all weights should not more than 1.

Table 50.4 Overall utility of data processing for predicted properties after assigning weights

Exp. no.	UTS-P W	YS-P W	YM-P W	%E-P W	$H_{FZ\text{-}P}$ W	$H_{HAZ\text{-}P}$ W

27	0.06	1.7	0.93	0.94	0.1	0.1

$$U(X_1, X_2, \ldots\ldots\ldots\ldots, X_n) = \sum_{i=1}^{n} W_i U_n(X_i) \tag{50.4}$$

A methodology of combining Taguchi and utility concept was introduced for predicting the optimal parameter settings of the combined responses. The six quality characteristics, namely UTS, YS, YM, %E, H_{FZ}, H_{HAZ}, during the experimental observation ratio of top width to top reinforcement were considered in this study for best output. The response parameters were individually optimized using Taguchi's technique to obtain the optimal input settings for response characteristics of MPAW, and using corresponding value, the mean for responses was predicted. These results are tabulated in Table 50.5.

Table 50.5 Optimal parameter setting for individual response characteristics

Response characteristics	Optimal level of process parameters	Predicted optimal value quality characteristics
UTS	$IP_2 + WS_2 + PGFR_1 + PT_2 + PF_3 + SOD_1$	919.99
YS	$IP_1 + WS_1 + PGFR_2 + PT_1 + PF_1 + SOD_1$	450.65
YM	$IP_3 + WS_2 + PGFR_3 + PT_2 + PF_3 + SOD_1$	111,895.1
%E	$IP_1 + WS_1 + PGFR_4 + PT_1 + PF_2 + SOD_1$	0.66
H_{FZ}	$IP_3 + WS_2 + PGFR_5 + PT_2 + PF_1 + SOD_3$	242.48
H_{HAZ}	$IP_3 + WS_1 + PGFR_6 + PT_2 + PF_1 + SOD_3$	232.88

Analysis of utility data for optimal parameter settings: the response graphs of overall utility and corresponding S/N ratio graphs plotted are shown below in Fig. 50.4.

The iteration between parameters (WS × SOD) and (PT × SOD) has been considered in the present study. The result reveals that third level of peak current (I_{P3}), first level of welding speed (WS_1), plasma gas flow rate (PGF_1), pulse time (PT_2), and third level of pulse frequency (PF_3) are expected to produce maximum values of utility and S/N ratio within the boundaries experimental zone. The ANOVA of utility data and S/N ratio are given in following Tables 50.6.

Analysis of Variance for mean of overall utility.

Where, SSQ = Sum of squares, MSS = Mean sum of square, DOF = Degrees of freedom, F = Fisher's ratio (the test statistic).

The utility approach reveals that welding speed (49.01%), pulse time (13.21%), and interaction of WS × SOD (12.11%), PT × SOD (11%) and standoff distance (9.57%). Interaction effect of welding speed and stand of distance are high

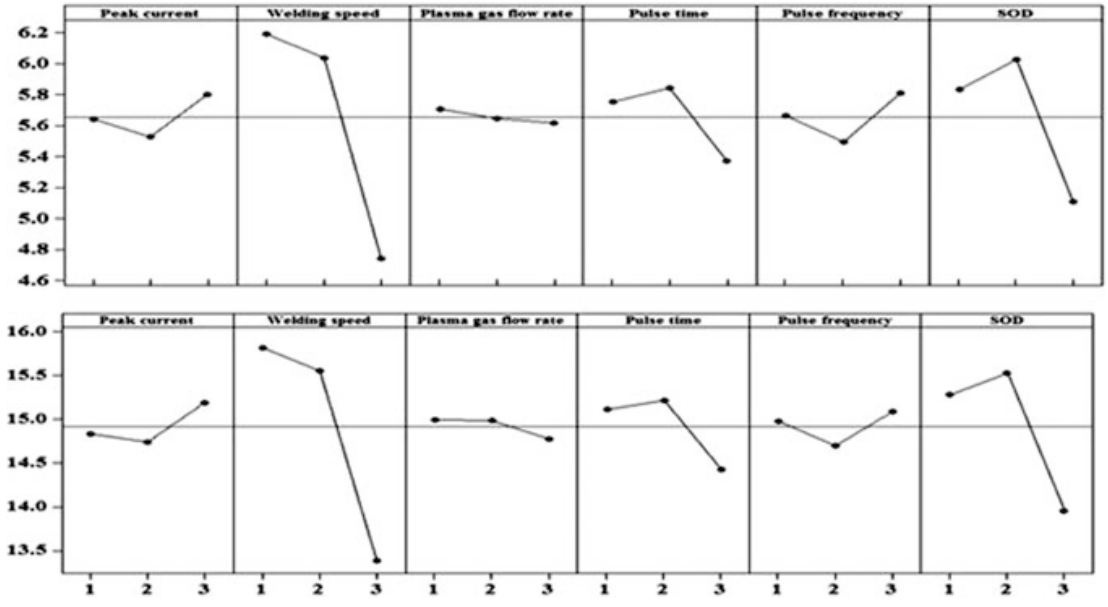

Fig. 50.4 Response graph of overall utility and S/N ratio

compared with that of other input parameters even though other parameters such as peak current, plasma gas flow rate, and pulse frequency also contribute to the overall enhancement of the response characteristics. The percentage contribution of the input variables on the response characteristics is depicted by means of the pie chart Fig. 50.5.

The variation of overall utility with experiments is given in Table 50.7. It can be observed from the below table that experiment 9 and 17 have the lowest utility value, and experiment 13 and 24 have the highest utility value. The utility values are nearly uniform for experiments 1, 3, 5. From this variation, it can be inferred that the welding process is highly unpredictable. The predicted mean for overall utility has been tabulated based on Eq. (50.5) for the optimal parameter setting, where T_u is the total average of overall utility and μ_m is the predicted mean value.

$$\mu_m = \mathrm{IP}_3 + \mathrm{WS}_1 + \mathrm{PGFR}_2 + \mathrm{PT}_2 + \mathrm{FP}_3 + \mathrm{SOD}_2 - 5T_u \tag{50.5}$$

The predicted value of mean for overall utility obtained from the above formula is 5.6682 and corresponding S/N ratio is 15.0689.

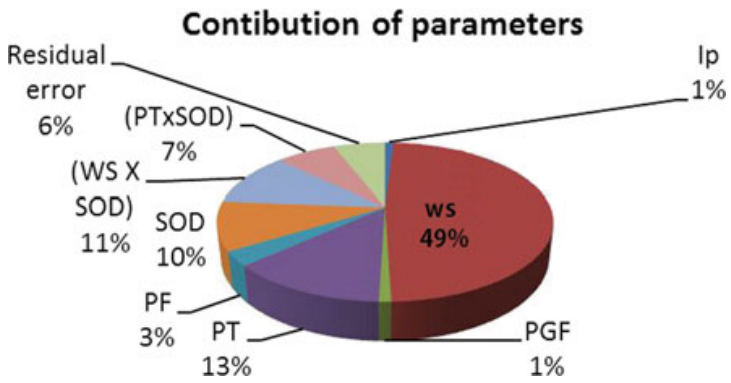

Fig. 50.5 Pie chart showing the relative contribution of process parameters

Table 50.7 Overall utility and their corresponding S/N ratio

Exp. no.	Overall utility	S/N	Exp. no.	Overall utility	S/N

14	4.951167	13.89415			

Maximum Overall utility and S/N ratio are 5.6682 and 15.06897

The obtained values of overall utility and S/N ratios for L_{27} are given in Table 50.7.

50.3.4 Confirmation Experiment

The confirmation experiment was performed using predicted value which was calculated from optimization using overall utility approach analysis. The best experiment was considered on the basis of maximum overall utility, not on the basis of particular single properties. The stress–strain curve obtained by this confirmation test which is target aim considering optimization using utility approach, as shown in Fig. 50.6.

The observed values of quality characteristics were correlated with experimental confirmation test results in the given Table 50.8.

The results ensure the existence and reliability of optimization coupling with utility approach for MPAW. It ensures that it is a cost-effective way to minimize the production cost and quality welds. It was observed from the analysis that enhancement in the overall utility is 0.28 and S/N ratio is 0.42, compared with the initial best setting. For the general requirements, UTS is considered dominant properties among all, so UTS properties have been highlighted in Table 50.9.

Hence, the model developed based on overall utility approach using Taguchi is well applicable and reliable to get desired weighted output for all properties of MPAW process.

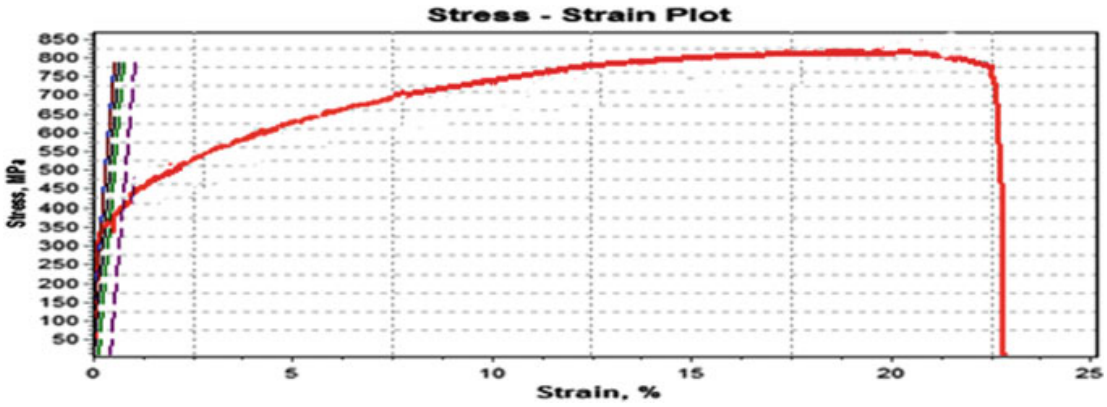

Fig. 50.6 Stress–strain curve of confirmation test

Table 50.8 Observed values of response characteristics for confirmation experiment

Response characteristics	Best factor setting for overall utility (Exp. 13)	Optimal process condition	
	IP_2, WS_2, $PG_{f/r3,}$ PT_1, PF_1, SOD_2	Prediction with optimum setting considering interactions (WS × SOD), (PT × SOD)	Confirmation experiment with optimal condition
UTS (MPa)	756.22	IP_3 WS_2 $PGFR_2$ PT_2 PF_1 SOD_1 (Based on mean responce graph)	823.00
YS (MPa)	360.67		552.93

H_{HAZ}	210		212
Initial S/N ratio	15.06897 (Max)	15.9438	15.48
Overall utility for best setting	5.668243 (Max)	5.91000	5.94
Improvement in overall utility = (5.94 − 5.66) = 0.28 Improvement in S/N ratio = 15.48 − 15.06 = 0.42			

Table 50.9 UTS of confirmation test and some highlighted experiments

Sample name	UTS (MPa)
(a) Exp. 25	395.75 MPa (lowest value)
(b) Exp. 6	803.54 MPa (highest value for UTS)
(c) Exp. 13	756.21 MPa (UTS is moderate but overall utility as multi-output has highest significant value)
(c) Base metal	725 MPa (reference value)
(d) The enhanced value	823 MPa (enhanced UTS using utility approach)

50.4 Conclusion

1. The recognition of rolling direction of sheet to choose welding direction has a vital importance in welding, and it improves weld quality such as % elongation.
2. It was observed that enhancement in the overall utility is 0.28 and S/N ratio is 0.42 compared with the initial best setting. Hence, the model developed based on overall utility optimization approach is well applicable to get desired weighted output for the UTS, YS, %E, YM, $H_{FZ,}$ and H_{HAZ} properties of MPAW process.
3. ANOVA coupled with utility approach was performed to determine the significant parameters in this study, and it was found that welding speed with 49.01% and pulse time with 13.21% were most influential factors affecting the weld quality. Even though the contribution of other parameters was minimal but cannot be ignored in the study.
4. The confirmation test projects an enhancement in UTS which is 823 MPa. It is showing improvement in UTS from Exp. 6 and Exp. 13.
5. The optimization work using utility approach helps to enhance the productivity, reliability, quality, and cost reduction for an industrial application of the MPAW process.

Chapter 51
Characterization of Geometrical Features of Ultra-Short Pulse Laser-drilled Microholes Using Computed Tomography

K. Kiran Kumar, G. L. Samuel and M. S. Shunmugam

Abstract High-aspect-ratio high-quality microholes are required in turbine blades to improve cooling performance. These cooling holes are drilled by pulsed laser and hence dimensional as well as geometrical tolerances like circularity and cylindricity are important. The measurement of geometrical features of the microholes is a very challenging task without destroying the components. In the present work, the microholes are produced on Ti6Al4V alloy by ultra-short pulse laser. The geometrical features of microholes are then captured using a non-destructive technique, namely computed tomography. CT-scanned 3D data is directly used for geometrical analysis using open-source software, GOM Inspect. Since algorithms used in the GOM Inspect are proprietary in nature, the extracted coordinate data are also analyzed using the computational methods developed by the authors based on least squares technique. The dimension, circularity, and cylindricity of microholes are compared with the results obtained from GOM Inspect software and a close match is found.

Keywords Microholes · Ultra-short pulse laser · Computed tomography · Geometrical analysis · Least squares technique

51.1 Introduction

The high-aspect-ratio microholes with tight tolerances are in high demand in automotive, aerospace, electronic, and biomedical industries. Specific applications include fuel injection nozzle, turbine blade and printed circuit board (PCB), inkjet printer nozzle and microneedles. The microholes for film cooling are drilled on turbine blade having complex geometry by ultra-short pulse laser. Unlike tool-based machining in which the geometry and axis of the hole are controlled by

the tool and its movement, the geometry of hole and its axis are determined by the ablation process in the laser drilling. Therefore, selection of parameters for proper control of laser ablation process is important to produce high-quality holes. It is imperative that the dimensional and form errors of hole produced by laser drilling are measured and characterized. Measurement of the dimensional and geometrical errors of microholes is a difficult task. The geometrical deviations of microhole are characterized as 2D and 3D errors, namely circularity and cylindricity. Different approaches have been reported in the literature to measure the dimensional and geometrical accuracy of microholes. The conventional methods reported in the literature mostly involve sectioning and polishing. These techniques require accurate axis alignment and they are also time-consuming.

It is important to characterize the microholes without destroying the machined holes. Kao and Shih [1] have investigated the form measurements of microholes using coordinate measuring machine (CMM) with a combination of optical and contact sensors. Non-destructive testing method based on optical system has been used for the inspection of cooling holes in turbine blade in aero-engine application [2]. Computed tomography (CT) is the only technology capable of measuring inner and outer geometry of components without destroying the machined surface. CT is able to detect pores or small delaminations within composites and measure small and hidden coolant bores of turbine blade [3]. CT technique has been used for industrial applications in the field of dimensional metrology [4]. Zhang et al., have reported measurement of features of the laser-drilled microholes using micro-CT [5]. 3D geometrical measurements of ablated crater such as volume, depth, and width and cone angle have been reported by Galmed et al. [6]. The characterization of geometrical features of microholes without destroying the holes still remains as a very big challenge.

In order to avoid destruction of machined component, non-destructive technique based on computed tomography is employed in the present work. CT is used to scan an array of 3×3 microholes drilled by ultra-short pulse laser micromachining. Further, the CT-scanned volume data is analyzed by using GOM Inspect available as open-source software. Dimensional and geometrical errors of laser-drilled microholes are also evaluated using computation technique developed by the authors based on least squares technique. The results are compared with those obtained from GOM Inspect software and discussed.

51.2 Microhole Drilling

The microhole drilling experiments are conducted by using ultra-short pulse laser. The Yb-doped fiber laser (make: Amplitude Systems; model: Satsuma HP2) operates at a central wavelength of 1030 nm with pulse duration in the range of 350 fs to 10 ps. The maximum average power is 20 W and pulse energy of 40 μJ is

delivered at a repetition rate of 200 kHz. The laser system is integrated with the ALPhNOV machine and laser beam is guided with trepanning head of GFH GmbH. Trepanning drilling technique is used to machine an array of 3 × 3 microholes in 1.5-mm-thick Ti6Al4V alloy plate.

51.3 Characterization of Microholes

The characterization of microholes is very challenging task. The conventional methods using sectioning and polishing are time-consuming and inaccurate due to axis misalignment. In order to overcome these problems, non-destructive technique like computed tomography (CT) is used. CT technology is capable of measuring the internal and external geometric features of complex-shaped components.

51.3.1 Computed Tomography

X-ray-based computed tomography technique is used for dimensional metrology of industrial components. The radiation emitted by a point-source X-ray passes through the measured object to a flat detector (sensor) and several 2D images are taken at various angular positions with the help of a rotating stage. 3D data reconstruction generates a 3D voxel model. Post-processing of voxel data using image processing technique detects the edges of the component for further analysis. The schematic diagram of computed tomography technique is shown in Fig. 51.1.

For precise measurement using CT, a high-quality tomogram is extracted from the detected surface. The CT scan image quality is mainly dependent on voxel size and focal spot size. The sharper images can be obtained with smaller X-ray spot size of high-power nanofocus tube. In the present work, nanotomphoenix|x-ray (make: GE, Germany) available at Centre for Non-destructive Evaluation (CNDE), Mechanical Engineering Department, IIT Madras, shown in Fig. 51.2 is used. The nanotom CT works at a tube voltage of 110 kV and current of 80 μA, with a minimum voxel size of <500 nm. The array of 3 × 3 microholes is scanned, and the scanning time is approximately 45 min.

From the generated volume data file, volume graphics (VG viewer) open-source software creates 3D and 2D images for visualization [7]. The 2D and 3D views of the component are shown in Fig. 51.3. In the present work, GOM Inspect open-source software [8] is used in the next step to generate the geometric model as shown in Fig. 51.4.

Computed tomography volume data (.vgl format) file is directly imported in GOM Inspect software, without converting into STL format. This is an easy

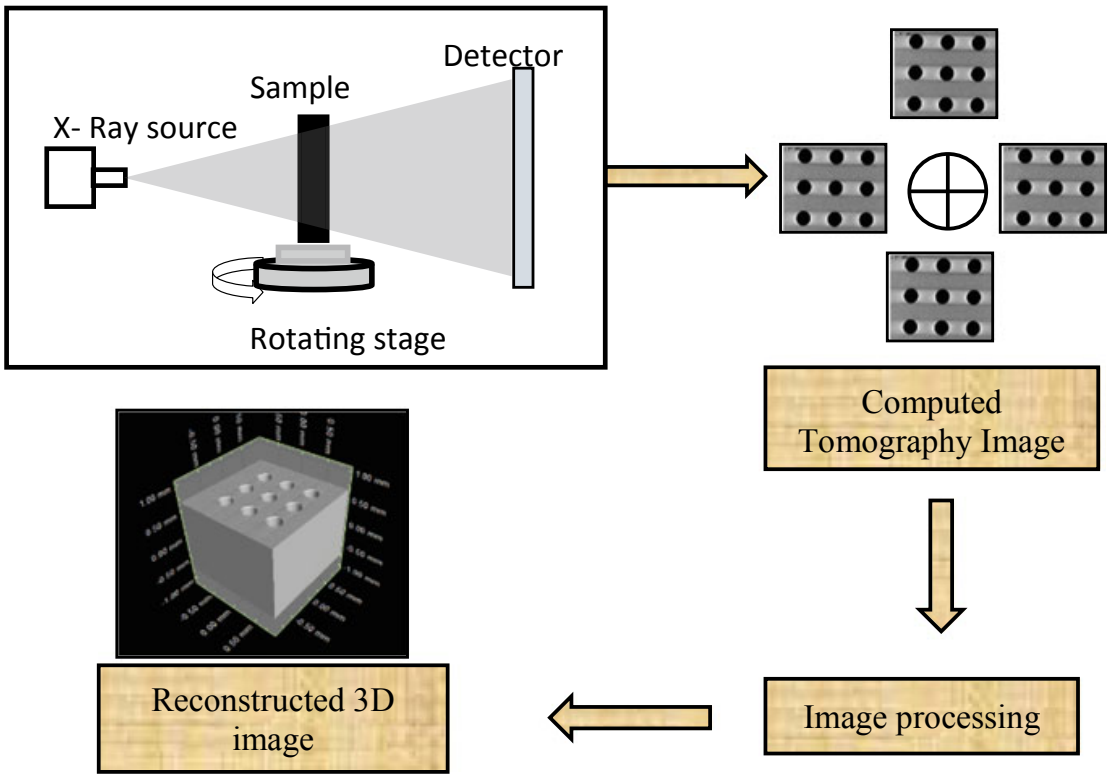

Fig. 51.1 Schematic diagram of computed tomography technique

Fig. 51.2 Computed tomography (CT) system at CNDE, IIT Madras

approach for the dimension analysis of CT-scanned complex shape and size. After importing CT volume data in GOM inspect software, it converts into mesh elements. Cylinder surfaces are constructed by selecting the holes. The coordinate transformation is done by using axis alignment with respect to z-axis in vertical direction. From the geometric model, dimensional and form errors of microholes are assessed as outlined in Sect. 51.4.

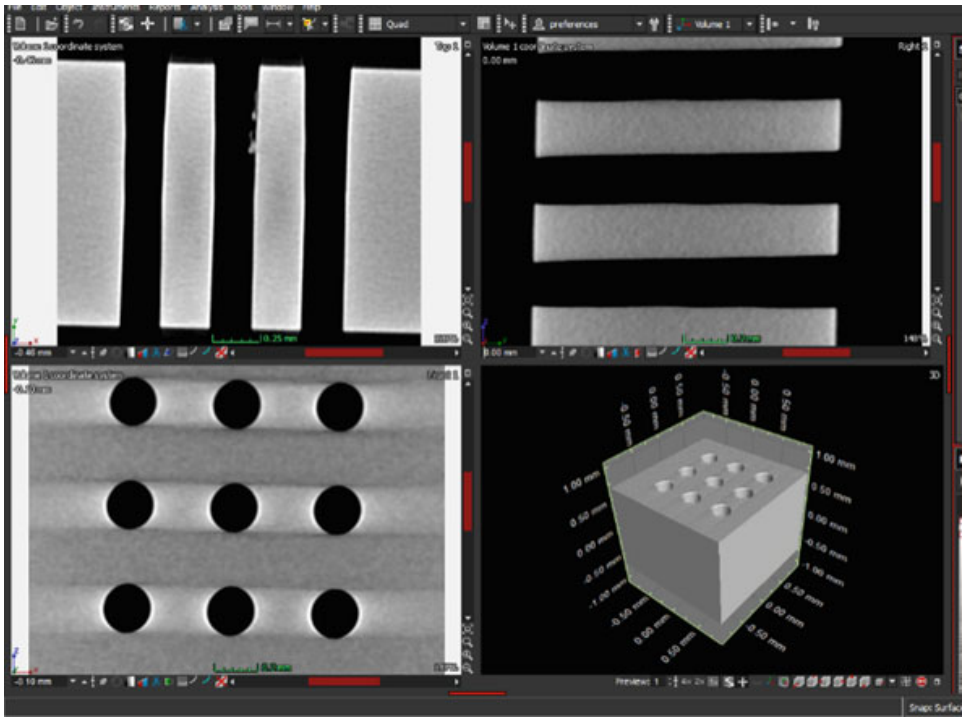

Fig. 51.3 Screenshot of reconstruction of CT-scanned images using volume graphics module

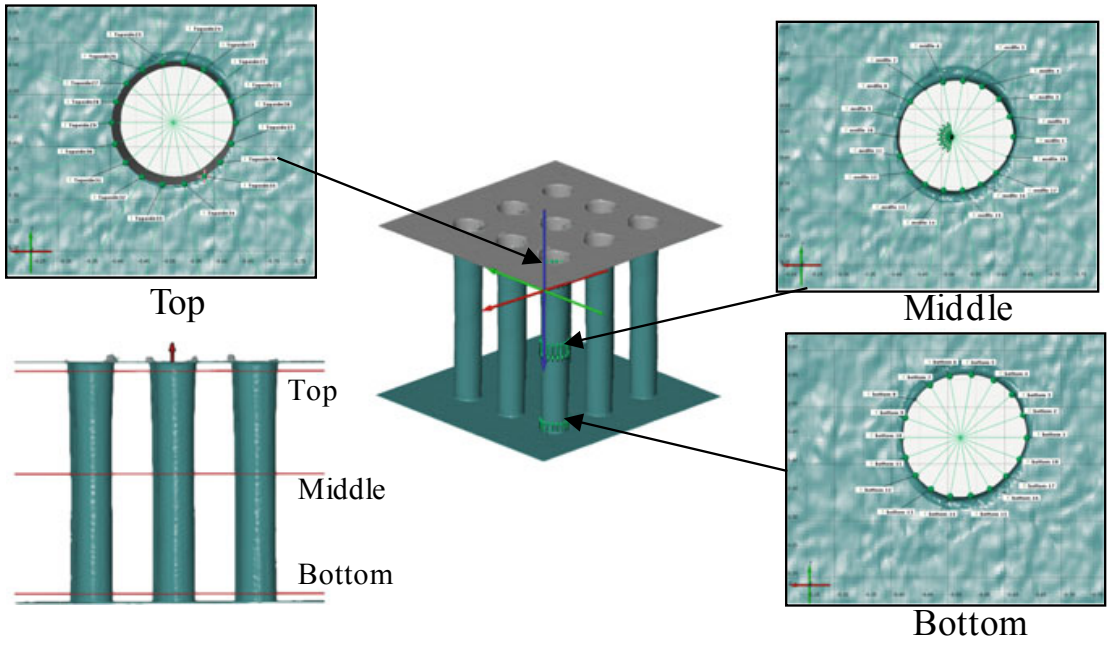

Fig. 51.4 Extracting the xyz coordinates from CAD geometry at three sections (top, middle, and bottom)

51.4 Computational Methods

To compare with the results obtained from GOM Inspect software, least squares technique developed by the authors is used for evaluation of form errors. The coordinates of microholes are extracted using GOM Inspect at selected sections as shown in Fig. 51.4. The *xyz* coordinates are extracted at top, middle, and bottom sections, respectively. The *xyz* coordinates at top surface of one microhole are given in Table 51.1.

The extracted coordinate data of microholes contains both size and form information, and a suitable method has to be implemented to separate the form data and size information. Samuel and Shunmugam [9] have proposed a transformation technique for evaluation of form error from the coordinate data. Accordingly, a reference circle is chosen passing through three selected points and the deviations are computed using Eq. (51.1).

$$d_i = \left[(x_i - x_R)^2 + (y_i - y_R)^2\right]^{1/2} - r_R \tag{51.1}$$

Points for establishing reference circle (1, 4, 7) at all three sections

where; (x_i, y_i) are coordinates of extracted data. (x_R, y_R) is center of reference circle and r_R is its radius. The form data in the form of (r_i, θ_i) is computed as

$$r_i = d_i - d_{\min} + d_o \tag{51.2}$$

$$\theta_i = \tan^{-1}\left[\frac{(y_i - y_R)}{(x_i - x_R)}\right] \tag{51.3}$$

where; $d_{\min}$ is minimum value of d_i and d_o is taken as 0.001 mm.

In the present work, transformation approach is implemented for evaluating circularity and cylindricity of microholes and the results are discussed in Sect. 51.5. 2D and 3D form errors (circularity, cylindricity) of the microholes are evaluated by using least squares technique [10]. The deviations from the limacon and limacon cylinder are expressed in the linear form as follows.

$$e_i = r_i - (R_o + x_o \cos\theta_i + y_o \sin\theta_i) \tag{51.4}$$

$$e_i = r_i - [R_o + (x_o + l_o z_i)\cos\theta_i + (y_o + m_o z_i)\sin\theta_i] \tag{51.5}$$

where; e_i is linear deviation at ith point, R_o is estimated radius for limacon/limacon cylinder, (r_i, θ_i) are polar coordinates at ith point, (x_o, y_o) are estimated center coordinates and (l_o, m_o) are estimated slope values for limacon cylinder.

The least squares parameter for the limacon and limacon cylinder are estimated from the following equations.

$$\begin{bmatrix} \sum\cos^2\theta_i & \sum\sin\theta_i\cos\theta_i & \sum\cos\theta_i \\ \sum\sin\theta_i\cos\theta & \sum\sin^2\theta_i & \sum\sin\theta_i \\ \sum\cos\theta_i & \sum\sin\theta_i & \sum 1 \end{bmatrix} \begin{bmatrix} x_o \\ y_o \\ R_o \end{bmatrix} = \begin{bmatrix} \sum r_i\cos\theta_i \\ \sum r_i\sin\theta_i \\ \sum r_i \end{bmatrix} \tag{51.6}$$

$$\begin{bmatrix} \sum\cos^2\theta_i & \sum\sin\theta_i\cos\theta_i & \sum z_i\cos^2\theta_i & \sum z_i\sin\theta_i\cos\theta_i & \sum\cos\theta_i \\ \sum\sin\theta_i\cos\theta & \sum\sin^2\theta_i & \sum z_i\sin\theta_i\cos\theta & \sum z_i\sin^2\theta_i & \sum\sin\theta_i \\ \sum z_i\cos^2\theta_i & \sum z_i\sin\theta_i\cos\theta_i & \sum z_i^2\cos^2\theta_i & \sum z_i^2\sin\theta_i\cos\theta_i & \sum z_i\sin\theta_i \\ \sum z_i\sin\theta_i\cos\theta_i & \sum z_i\sin^2\theta_i & \sum z_i^2\sin\theta_i\cos\theta_i & \sum z_i^2\sin\theta_i & \sum z_i\sin\theta_i \\ \sum\cos\theta_i & \sum\sin\theta_i & \sum z_i\cos\theta_i & \sum z_i\sin\theta_i & \sum 1 \end{bmatrix}$$
$$\begin{bmatrix} x_o \\ y_o \\ l_o \\ m_o \\ R_o \end{bmatrix} = \begin{bmatrix} \sum r_i\cos\theta_i \\ \sum r_i\sin\theta_i \\ \sum r_i z_i\cos\theta_i \\ \sum r_i z_i\sin\theta_i \\ \sum r_i \end{bmatrix} \tag{51.7}$$

51.5 Results and Discussion

The microhole's dimensions are measured at top, middle, and bottom sections by fitting three-point circle at the respective sections in the GOM software. The diameters of microhole are obtained as 240, 220, and 220 μm at top, middle, and bottom sections, respectively, with height of 0.056, 0.681, and 1.306 mm, respectively, as shown in Fig. 51.5. If the practice of quantifying taper based on entry (top) and exit (bottom) diameters is followed, there is a general taper in the microhole with the size narrowing with the depth.

Similarly, the cylindricity error of microhole is measured as 11.2 μm by using Gaussian fit method, which is available in GOM Inspect software.

51.5.1 Comparison of Results with Least Squares Limacon Technique

The microhole geometrical xyz coordinate data given Table 51.1 is transformed to polar coordinates with respect to a reference circle. The reference circle is established by using a circle fitted through three selected points from given data. For example, center coordinates and radius of reference of circle passing through points 1, 4, and 7 are obtained as $x_R = -0.522$ mm; $y_R = 0.443$ mm and radius $r_R = 0.120$ mm, respectively. The deviations of each point with respect to reference circle are computed using Eq. (51.1). From the form data (r_i, θ_i), the form errors are evaluated with reference to a limacon. This is because, the center (x_R, y_R) chosen for transformation is different from the actual center of the circular feature. It has been shown in the literature that, it has been shown that the offset introduces certain distortion in the transformed profile and hence a limacon must be used as a reference for evaluating the circularity error form from data [11].

The transformed data (r_i, θ_i) is not listed in this paper due to space limitation. The data exhibits nonuniform angular spacing, and hence the general solution given by Eq. (51.6) is used to arrive at the limacon parameters. The results are plotted for top, middle, and bottom sections in polar chart as shown in Fig. 51.6. The parameters are given in Table 51.2, along with circularity errors and diameters. The circularity error is obtained as 3.182, 5.670, and 7.699 μm at top, middle, and bottom sections, respectively. From the above results, it observed that the quality of laser-drilled microhole changes with respect to depth. There is a good match between the diameter values obtained.

The cylindricity of microhole is evaluated by considering the height (z-coordinates). The xyz coordinates are extracted from geometric model for top, middle, and bottom sections as shown in Fig. 51.5. Table 51.3 gives value parameters obtained in the cylindricity evaluation. The cylindricity error of microhole is evaluated as

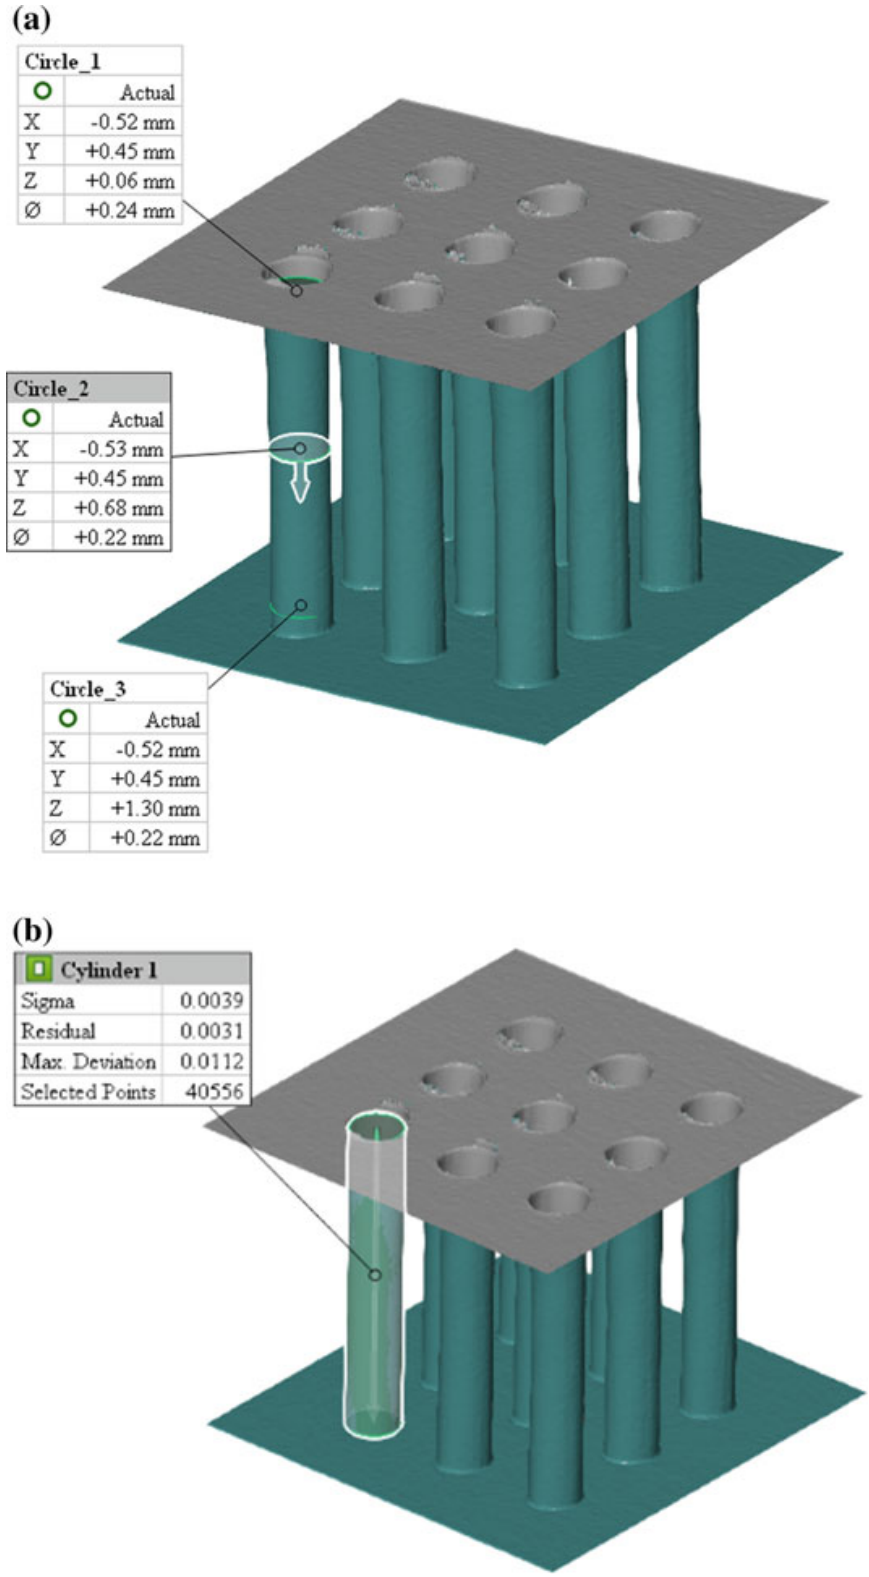

Fig. 51.5 Screen shot of microhole geometry measurement **a** diameter, **b** cylindricity

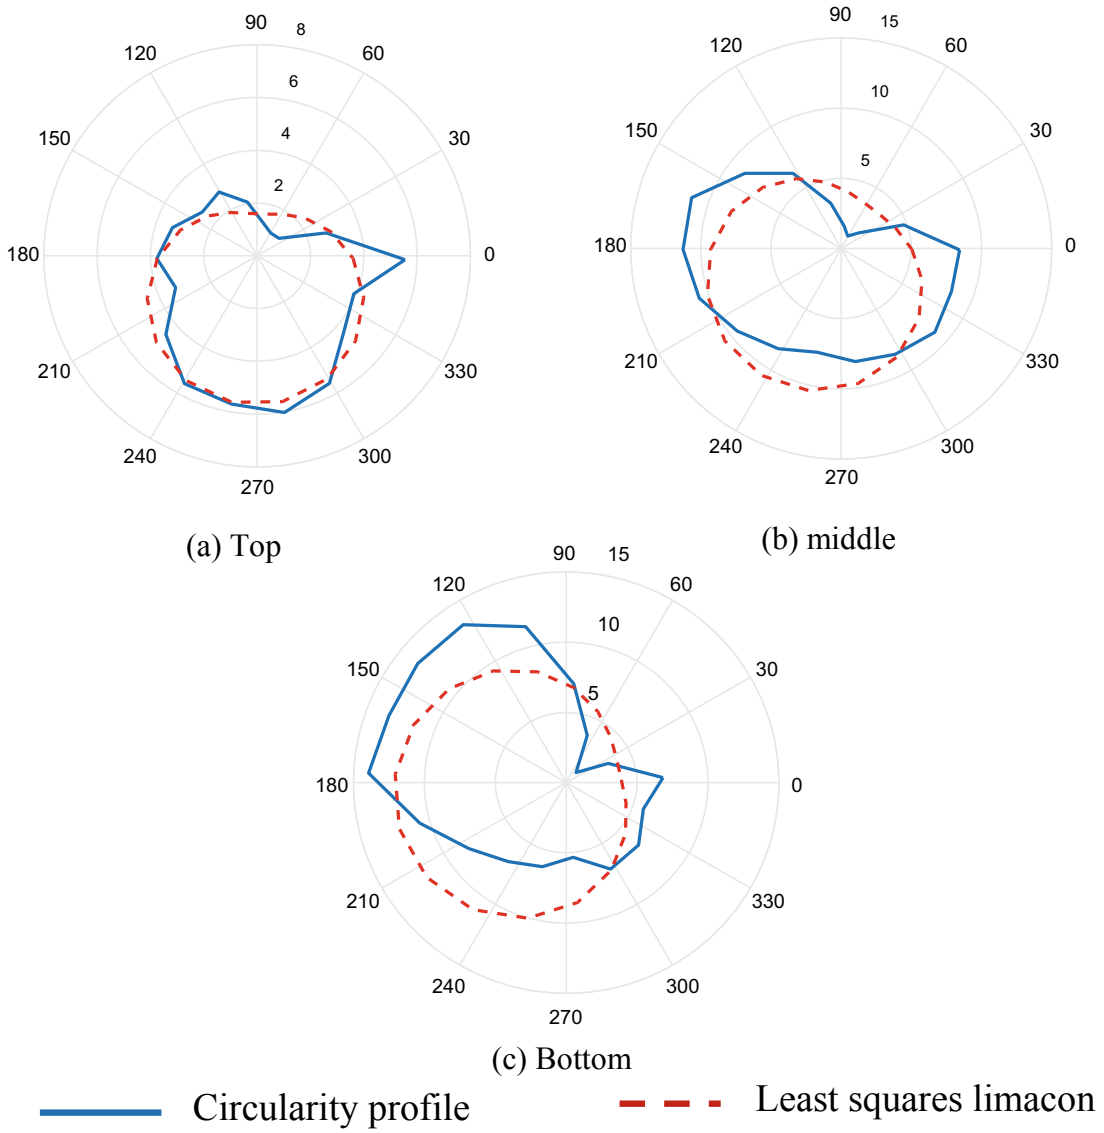

Fig. 51.6 Circularity profile along with least squares limacon at different sections

16.317 µm by using least squares technique. The cylindricity value of 11.2 µm is obtained from Gaussian fit method in GOM Inspect software. The value is lower than that computed from least squares limacon technique. Without the details of Gaussian fit method used in GOM Inspect, it is difficult to give reasons for the difference in the cylindricity errors. Interestingly, the diameter values agree with each other well.

In the above table, subscripts R and o refer to reference cylinder and limacon cylinder, respectively, while x, y represent the intersection of axis with top plane; l, m are the slope of axis; r is the radius of the cylinder.

51.6 Conclusion

New approach is established in the present work to characterize the geometrical features of the ultra-short pulse laser-drilled microholes. Using computed tomography, it is feasible to characterize the laser-drilled microholes without destroying the sample. The dimensional accuracy of computed tomography volume data is directly analyzed in GOM Inspect software. The diameters of microhole are 240,

220, and 220 µm at top, middle, and bottom sections, respectively, showing a taper in the microhole.

The form errors of microholes are established by least squares limacon technique. The circularity errors are 3.188, 5.670, and 7.699 µm at top, middle, and bottom sections, respectively. Cylindricity of microhole is evaluated as 16.317 µm using least squares limacon technique, which is higher than the result obtained from Gaussian fit in GOM Inspect software. Future work will be extended to evaluate the conicity error of microholes using computational technique.

Investigation on Rotary Electrical Discharge Machining (EDM) of EN-25 Material Using Copper Electrode for Improving Geometrical Errors

L. Selvarajan, R. Rajavel, F. Leo Princely, R. Aravind and T. P. Habeeb Masood

Abstract In this analysis, an investigation and testing work were carried out on the spark EDM of EN-25 material using copper electrodes. Considering the machining parameters such as pulse on time, pulse off time, current, dielectric pressure for machining the effect of these following input parameters on output characteristics like metal removal rate (MRR), tool wear rate (EWR), wear ratio (WR), cylindricity (CYL), circularity (CIR), and perpendicularity (PER). The investigation was carried on with L_9 orthogonal array. The effect of each machining parameters on response characteristics was studied independently using trend analysis. From results, circularity has been minimized to decrease of current and increase of dielectric pressure. Cylindricity has been minimized to decrease of current and increase of dielectric pressure. Perpendicularity has been minimized to increase of current and decrease of dielectric pressure.

52.1 Introduction

As the world of manufacturing is growing at an exponential rate, the focus on surface finish and accuracy of parts produced is becoming highly important. This importance to finish and accuracy is evolving due to modern unconventional machining processes such as electric discharge machining. The shift to nontraditional machining is due to the exogenous nature of machining in case of conventional machining process. Owing to these current industry trends, an experimental study on the EDM of EN-25 is mandatory rather than that of a choice. It is used in automobile components and aerospace components. It is used for Adapters, Axles, Die Holders, Connecting Rods, Ejector Rods and Drill Shanks. Thus, in this investigation, EN-25 steel was used as the workpiece. The experiments were performed with EDM oil as dielectric fluid and 2-mm-copper tool. The input factors considered are current (A), pulse off time (μs) and pulse on time (μs) and dielectric fluid (kg/cm^2). This experimental investigation will increase the depth of knowledge of EDM and hence increase the propensity to success in terms of accuracy and surface finish.

52.2 Literature Review

Selvarajan et al. [1] in this work deal with the review of various papers related to optimization of EDM process. The electrode is chosen from regularly used Cu, CuW, and AgW as copper, which is based on the study by Muttamara et al. [2]. Uno et al. [3] spark EDM has emerged as an outstanding approach for cutting conductive metals that are otherwise highly difficult to machine. Lin et al. [4] in research introduce the multiresponse performance index is used to solve the spark EDM process with multiple responses or output characteristics. The machining parameters (the workpiece polarity, duty factor, pulse on time, and current, dielectric fluid and discharge voltage) are optimized with examinations of the multiple performance characteristics (electrode wear ratio and metal removal rate). Luis et al. [5] in this work, a comparative study of the spark EDM of various conductive ceramics had been carried out. Based on the experience acquired in the field of EDM for other materials, as, when the pulse time is reduced, which is equivalent to improving duty cycle, the MRR value tends to gradually increase. Arivazhaghan and Rajaduri [6] in this paper, illustration of the influence of input machining parameters on the metal removal rate is determined along with performance measurement analysis. The objective of this paper is to study the influence of operating technique parameters of copper electrode on the metal removal rate of EN-19 material followed by optimization. Soni and Chakraverti [7] in this paper describe optimum parameters for Titanium Grade (Ti-6Al-4V) using rotary spark machining process. The response of volume metal removal rate (MRR) and surface roughness (Ra) is considered for enhancing or increasing the machining efficiency.

Selvarajan et al. [8] EN-19 is tensile strength steel so it is widely used in different machinery parts such as shafts, racks, studs, bolts, nuts, rollers, etc. Wire EDM seems a good choice for machining the irregular shapes on medium steel Material. In the research, optimization of EDM parameters to improve geometrical errors by Selvarajan et al. [9] and the various methods to improve tolerance in $MoSi_2$–SiC was done. In another study by Selvarajan et al. [10], the optimization of machining parameters for improving circularity of Si_3N_4–TiN composite was done. Optimization of spark EDM Parameters in machining of $MoSi_2$–SiC composites for enhancing geometrical error was done by Selvarajan et al. [11]. It is evident that in all the above research studies conducted on either different materials or with different parameters. There is a noticeable research gap in terms of research on analyzing the machining of input parameters on geometrical output characteristics such as circularity, cylindricity, and perpendicularity. Thus, the research objective was chosen to be analyzing the individual impact of input parameters on each of these geometrical characteristics. The output parameters such as perpendicularity, cylindricity, and circularity are measured by using CMM, they are found applications in high accuracy.

52.3 Research Plan

Figure 52.1 shows that the research plan at EN-25 material with copper electrode.

52.4 Experimental Methodology

The experimental setup of EDM drilling machine is shown in Fig. 52.2. The workpiece material is shown in Fig. 52.3. The chemical composition of EN-25 steel was shown in Table 52.1

The properties of EN-25 steel are furnished in Tables 52.2 and 52.3 determine the working condition of the EDM drilling used for machining EN-25 steel.

The number of experiments to be conducted is nine and thus the L_9 orthogonal array was found to be suitable as instead of conducting 81 experiments based on factorial setup; this orthogonal array helps to finish the study within nine experiments. The values for each factor at various levels are shown below (Table 52.4).

This is the Taguchi's L_9 orthogonal array table where the experiment is done according to this procedure. The outputs are measured using a CMM whose image is provided in Fig. 52.4.

52.4.1 MRR and TWR Formula

Measurement of metal rmoval rate:

- MRR = Machined workpiece weight loss (g)/machining time (min)

Fig. 52.4 CMM testing machine

Measurement of tool wear rate:

- TWR = Electrode weight loss (g)/machining time (min)

Measurement of percentage wear rate:

- Wear ratio is defined as the ratio of the tool wear rate to the material removal rate.
  %WR = EWR/MRR

52.5 Results and Discussion

Table 52.5 depicts the input parameters, namely current, pulse on time, pulse off time, and dielectric pressure. The weight of the electrode and workpiece before and after machining is taken to calculate MRR and EWR as per formula in Sect. 52.4.1

The machining time, material removal rate, electrode wear rate, wear ratio, circularity, perpendicularity, and cylindricity are shown in Table 52.6.

Now, the relationship between output parameters and each input parameter can be deeply studied. Firstly relationship with respect to current is studied in Fig. 52.5a–c.

The material and electrode wear rate are increased with increasing current. The geometrical tolerances like circularity, perpendicularity, and cylindricity increase with respect to current at a very gradual manner. We can also observe that the wear ratio is decreasing with current, and thus by decreasing current we can decrease wear ratio. Maximum metal removal rate (0.743 g/min) is obtained on the condition of current 7 A, pulse on time 30 µs, pulse off time 5 µs, and dielectric pressure 24 kg/cm^2.

The relationship of performance characteristics with respect to pulse on time is shown in Fig. 52.6a–c.

The material and electrode wear rate are high when pulse on time is high and they are at maximum pulse on time of 30 µs. Cylindricity is decreasing with pulse on time, but there is only negligible change in perpendicularity and circularity with pulse on time. The wear ratio of the whole shows an increasing trend with respect to pulse on time. Minimum EWR (0.030 g/min) is acquired at the condition of current 4 A, pulse on time 20 µs, pulse off time 4 µs, and dielectric pressure 24 kg/cm^2.

The relationship between output characteristics and pulse off time is shown in Fig. 52.7a–c.

The material removal rate is showing a decreasing trend with pulse off time, and electrode wear rate has a negligible variation with respect to pulse off time. All geometrical characteristics, namely perpendicularity, cylindricity, and circularity

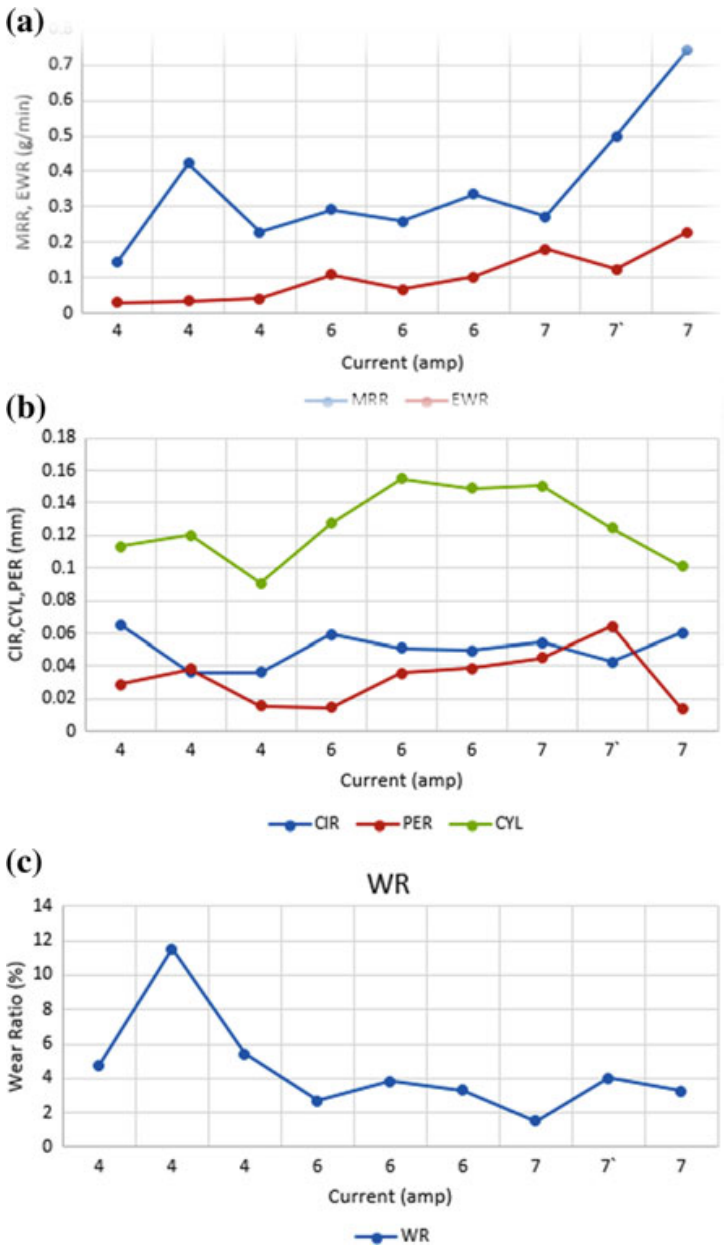

Fig. 52.5 **a** Relationship between current and MRR and EWR. **b** Relationship between current and CIR, PER, and CYL. **c** Relationship between current and wear ratio

show only a negligible change with respect to pulse off time. Whereas a gradual increasing trend is observed with wear ratio and pulse off time. Minimum circularity 0.0361 mm is acquired at the condition of current 4 A, pulse on time 25 µs, pulse off time 5 µs, and dielectric pressure 26 kg/cm^2. Minimum perpendicularity 0.0140 mm is acquired at the condition of current 7 A, pulse on time 30 µs, pulse off time 5 µs, and dielectric pressure 24 kg/cm^2. Minimum cylindricity 0.0907 mm is acquired at the condition of current 4 A, pulse on time 30 µs, pulse off time 6 µs, and dielectric pressure 28 kg/cm^2.

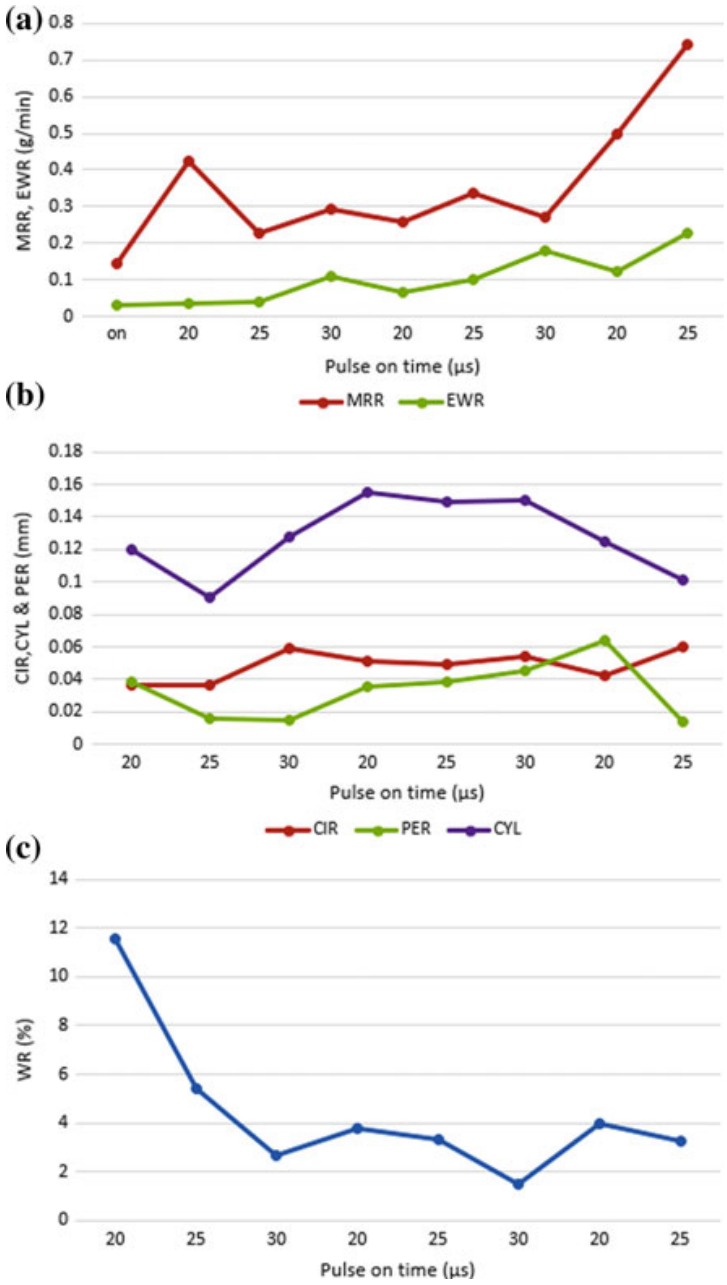

Fig. 52.6 **a** Relationship between pulse on time and MRR and EWR. **b** Relationship between pulse on time and CIR, PER, and CYL. **c** Relationship between pulse on time and wear ratio

The relationship of output characteristics with dielectric pressure is expressed in Fig. 52.8a–c.

There is only negligible change in both MRR and EWR, but at minimum dielectric pressure of (24 kg/cm^2), both are at their maximum. Cylindricity shows the gradual decrease with respect to dielectric pressure, circularity, and perpendicularity have not witnessed only negligible change with respect to dielectric pressure. There is a gradual decrease in wear ratio with respect to dielectric pressure. Minimum wear ratio 8.53% is obtained on the effect of current 4 A, pulse on time 25 µs, pulse off time 5 µs, and dielectric pressure 26 kg/cm^2.

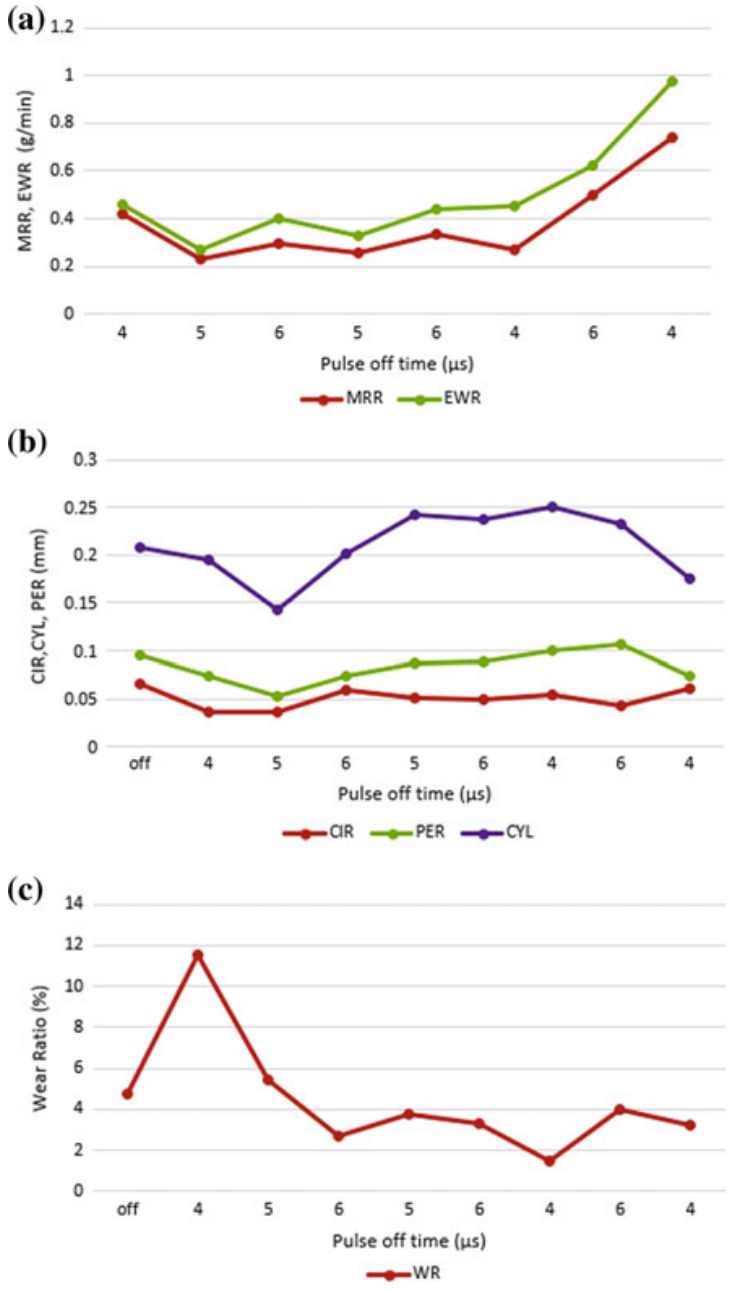

Fig. 52.7 **a** Relationship between pulse off time to MRR and EWR. **b** Relationship between pulse off time to CIR, PER, and CYL. **c** Relationship between pulse off time and wear ratio

52.6 Conclusions

- The three significant factors influencing the value of the MRR are the current (A), pulse on time (µs), and the pulse off time (µs). From results, MRR has been increased with increase current (A), pulse on time (µs), and decrease of pulse off time (µs). Metal removal enhancing increases with increase of pulse off time up to 6 µs then it's tended to decreases.
- The three main outstanding factors affecting the value of the EWR are the current (A), pulse on time, and the pulse off time. From results, EWR has been decreasing with decrease current (A), dielectric pressure (kg/cm^2). The value of

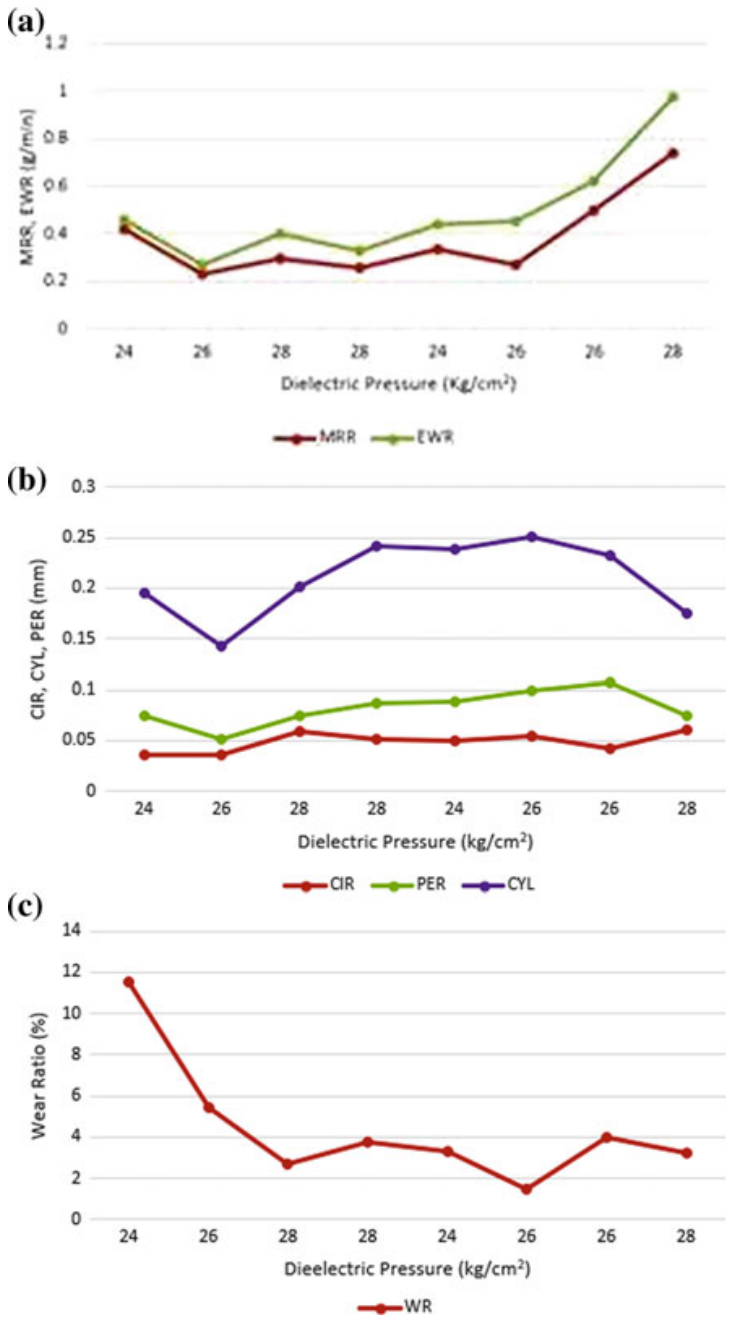

Fig. 52.8 **a** Relationship between dielectric pressure to MRR and EWR. **b** Relationship between dielectric pressure to CIR, PER, and CYL. **c** Relationship between dielectric pressure to wear ratio

EWR decreases with the decrease of pulse on time. However, EWR decreases with increase the pulse off time up to 6 μs.

- The two main notable factors affecting the geometric tolerance of circularity are the current (A) and dielectric pressure (kg/cm^2). From results, circularity has been minimized with decrease of current (A) and increase of dielectric pressure (kg/cm^2).
- The two main important factors affecting the geometric tolerance of perpendicularity are the current (A) and dielectric pressure (kg/cm^2). From results, perpendicularity has been minimized with increase of current (A) and decrease of dielectric pressure (kg/cm^2).

- The two main notable factors affecting the geometric tolerance of cylindricity are the current (A) and dielectric pressure (kg/cm^2). From results, cylindricity has been minimized with decrease of current (A) and increase of dielectric pressure (kg/cm^2).
- From the results of response table and response graph, the optimal level setting of four machining parameters is *A*, *B*, *C,* and *D* for minimizing the electrode wear rate and maximizing material removal rate among the nine experiments by using the Taguchi L_9 orthogonal array.
- The most important factors affecting the EWR and MRR of the spark EDM process have been identified as factor *A* (current), factor *B* (spark on time), factor *C* (spark off time), and factor *D* (dielectric pressure).

Chapter 53
Computation of End-Cutting-Edge Wear of Single-Point Cutting Tool Using Image Processing

Vishal K. Singh and Shrikrishna N. Joshi

Abstract This paper presents a simple and efficient method for computation of cutting-edge wear of a single-point cutting tool in a plain turning operation. It comprises development of an efficient and accurate image processing-based computer algorithm which compares two images of the cutting tool, i.e., before and after its use in the machining operation. The first image has been used as the reference image. Location of the tool in the image was found out using the developed image processing algorithm. Vertical and horizontal magnifications of the tool image were adjusted such that both the images of the tool have same tool width in terms of pixels. The portion of the images containing tools was extracted and used for the wear computation. The performance of the algorithm was tested by conducting systematic experiments and it was found to be efficient and stable. Only 28 s was noted for the computation of tool wear based on the images captured by a simple digital camera. The algorithm efficiently removes the noise present in the images of worn-out cutting tool used in real-life conditions.

53.1 Introduction

In the rapidly changing global marketplace, cost-cutting and boosting up productivity are the main goals of the manufacturing industry. With the introduction of manufacturing concepts like JIT, high-speed machining and precision manufacturing have gained more importance. Predicting exact tool life has been a challenge for manufacturing engineers for a long time. Thus, the tool rooms prefer preventive maintenance of the machine tools and cutting tools. However, often the capacity of

R. G. Narayanan et al. (eds.), *Advances in Computational Methods in Manufacturing*, Lecture Notes on Multidisciplinary Industrial Engineering,
https://doi.org/10.1007/978-981-32-9072-3_53

the tool remains unused and thus increases the cost of production. Therefore, predicting tool life with a fair degree of accuracy is essential to carry out an efficient metal cutting process. Further, the realization of unattended machining processes is a prerequisite for ensuring successful operation of intelligent manufacturing systems (IMSs), flexible manufacturing systems (FMSs), and flexible manufacturing cells (FMCs) [1].

To analyze the performance of cutting tool life, dimensional tool life can be used as a parameter. Astakhov [2] defined the term 'dimensional tool life' as the time period within which the cutting tool assures the required dimensional tolerance and required surface integrity of the workpiece. Authors derived the mathematical equations based on the tribology of metal cutting. Literature reports eminent attempts on development of multisensor models to predict the tool failure [3–7]. Most of them are based on the indirect approach of measurement/monitoring and predict the time of catastrophic failures only [4]. Use of multisensor models is expensive and costly for being employed in real-world daily machining work. On the importance scale, computation of gradual wear ranks higher than catastrophic failure, as it controls the dimensional tolerance of the tool. Direct methods of measurement, particularly computer vision are by nature more suitable for monitoring gradual wear of the tool; but tedious [8]. Therefore, researchers worldwide focused their attention on measuring tool wear between the machining cycles and *ex situ* tool wear measurement.

Use of image processing in the field of tool wear monitoring dates back to the early 90s. Kurada and Bradley in their work proposed a tool wear monitoring system to measure the flank wear. This system was dependent on a He–Ne laser source for illumination [9]. Fadare and Oni proposed a system, which uses two light sources inclined at 45° to horizontal. In addition, two perpendicular views of the tool are captured [10]. Shahabi and Ratnam used workpiece roughness profile, obtained using computer vision for assessment of flank wear and nose radius wear [11].

Recent work in the field of tool wear computation and prediction involves computer vision; use of high-quality charge-coupled device (CCD) sensors and artificial neural network (ANN). ANN accounts for the unknown variables and parameters involved. Most of these research works have been focused on measurement of flank wear and crater wear. Flank wear is the major criterion for measurement of tool life but capturing images during machining is quite a challenging task; a lot of noise in form of chips, dirt, and cutting fluid is present in the background [8]. Tan et al. in their work used sensor placement and optimum fusion of sensors for real-time machine condition monitoring [12].

In the present work, a simple and efficient method for computation of cutting-edge wear of the single-point cutting tool in a plain turning operation is developed. It comprises of development of an efficient and accurate image processing-based computer algorithm which compares two images of the cutting tool, i.e., before and after its use in the machining operation. In what follows, the details of development of algorithm and its experimental validation are presented in the following sections.

53.2 Methodology

A true-color digital image is a 3-dimensional matrix arrangement of primary color pixels with different intensities, whereas a grayscale image is a 2-dimensional arrangement of pixel intensities. Since every digital image or video (series of images varying with time) is a matrix; therefore, two images can be differentiated using the contents of their matrix using mathematical operations. This is the basic idea behind using image processing to determine the tool wear. Use of computer algorithms to detect, improve, or compute features of the image, or the objects in the image is known as image processing. Feature extraction from image requires various steps to be followed which are presented in Fig. 53.1.

53.2.1 Image Acquisition

It is the first step of image processing. It comprises of camera calibration and image capturing.

Camera Calibration. In this step, the parameters of camera's lens and image sensor are estimated. These parameters help to correct the lens distortion, to measure the size of an object in world units, and to determine the location of the camera in the scene. Camera parameters include intrinsic, extrinsic, and distortion coefficients. To estimate the camera parameters, 3-D world points and their corresponding 2-D image points are required. Multiple images of a calibration pattern such as a checkerboard are used. Using the correspondences, camera parameters are estimated. After calibration of the camera, the accuracy of the estimated parameters could be evaluated using reprojection errors and parameter estimation errors. Figure 53.2 shows the developed image acquisition setup for capturing the images of worn-out cutting tool.

Image Capturing Setup. Image capturing step comprises of a click-type camera and LED light source (a set of three numbers of 10 W LED bulbs) placed at the bottom of a transparent and hollow box-shaped tool holder. A white paper sheet placed

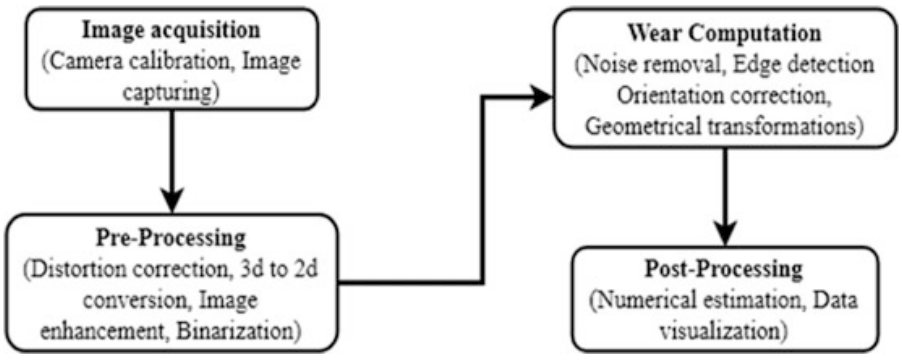

Fig. 53.1 Image processing flow diagram

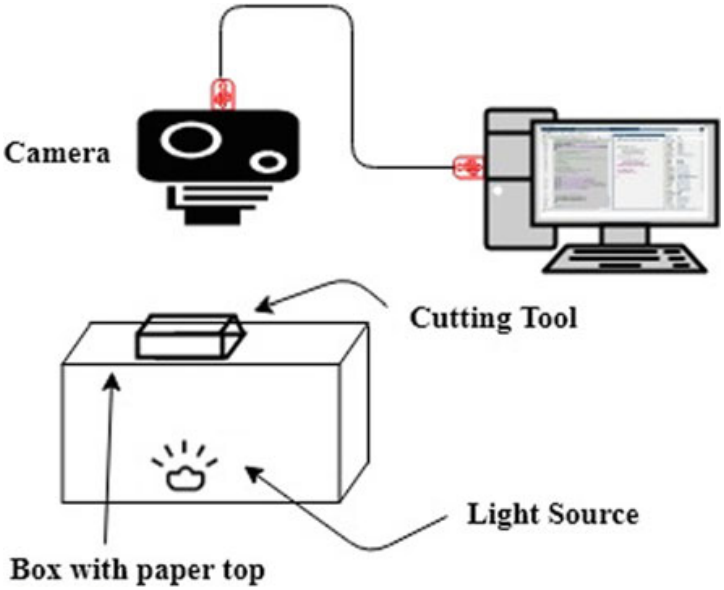

Fig. 53.2 Image acquisition setup

between the tool holder and tool produces a diffused light effect. The diffused light effect helps to minimize the light blobs appearing in the captured images due to the unbalanced distribution of the light from the illumination source. The cutting tool is placed on the marked space on tool holder. An image is captured on the camera which is placed directly above the tool holder. Two images of the tool are captured —one before the start of a machining run carried out for a chosen set of process conditions, and the second image captured after completion of the machining run. The Sony DSC-W570 camera captures a true-color image of size 4608 × 3456 and then, the images are imported into MATLAB™-based image processing utility.

53.2.2 Preprocessing

Distortion Correction. The environmental factors, namely temperature and humidity, affect the quality of images. This causes faulty representation of real-world objects in the image world, which reduces the precision in the measurement of parameters of an image. All the regions in an image cannot be assigned a proportionate number of pixels per world unit.

This problem was solved by using MATLAB™ undistorting function. It was used during camera calibration. Figure 53.3 shows the possible radial camera distortions.

3D to 2D Conversion. In this work, the true-color image [stacking of red (*R*), green (*G*), and blue (*B*) intensity distribution] is converted to a grayscale image. Equation (53.1) is used for conversion of true-color image to grayscale image, *I*.

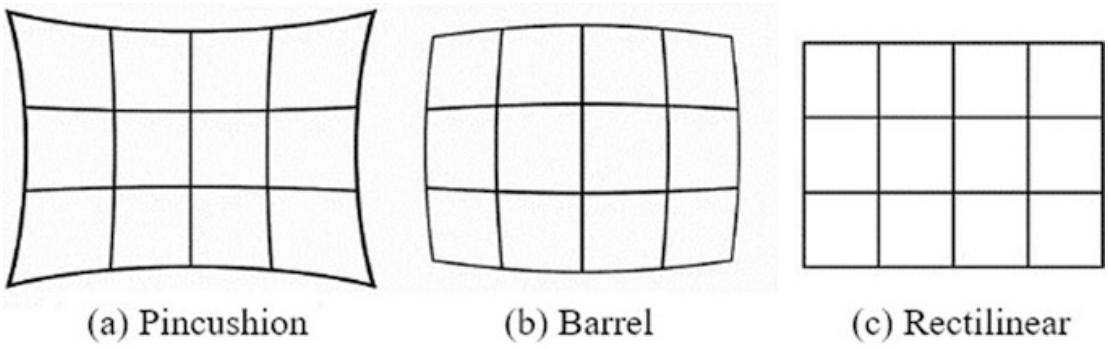

Fig. 53.3 Types of camera distortion

$$I = 0.2989 \times R + 0.5870 \times G + 0.1140 \times B \tag{53.1}$$

Image filtering. Some of the captured images have inherited noise, namely Gaussian noise and salt and pepper noise. These noises are removed by Gaussian filter and median filter, respectively. Gaussian filtering is achieved by convolving the 2-D Gaussian distribution function with the image matrix.

$$G(x, y) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{x^2 + y^2}{2\sigma^2}\right) \tag{53.2}$$

where G is the output of Gaussian operation on the image; x and y are the directions in which the function is operating. The standard deviation σ is the most important of all; it controls the amount of blurring, and its higher value causes more blurring and might lead to the loss or distortion of image features. A median filter is more effective than convolution as it reduces the noise and preserves the edges. Use of smoothening filters causes blurred edges. For proper detection of features and edges, unsharp masking (subtraction of a blurred version of the image from itself) sharpens the images. Image taken has poor contrast between the region of interest (ROI) and background; to tackle this problem 'imadjust,' a MATLAB™ function is employed. It uses the histogram stretching/shrinking to increase or decrease the contrast.

Binarization. The operations performed on the image are combinations of addition, subtraction, multiplication, and matrix inversion. It is convenient to perform these operations on matrix ones (1s) and zeros (0s). Binarization is the conversion of pixel intensities to ones and zeros. Pixels above the threshold are assigned ones and those below the threshold are assigned zeros. Threshold calculated using Otsu's method is more suitable for separation of classes in gray level [11]. In the current work, the effectiveness of the threshold varied from 0.9348 to one during the experiments. If the binarization assigns ones to the background, then inversion (reversing assigned values to pixels) of the image is required to increase the efficiency of computation.

53.2.3 Wear Computation

Noise Removal. Noise occurring in the images is of two types, namely disconnected noise and connected noise. Figure 53.4 shows the various types of noise that can be associated with a camera image. Disconnected noise is present in the image but stays at a distance apart from ROI. Connected noise is attached to ROI or in the vicinity of ROI. In addition, due to their random nature, connected noise cannot be separated using predefined steps. Connected noise occurs due to the shade of the tool as well. The width of such noise happens to be constant if the image acquisition setup does not change, and thus, making it possible to clear them. When the image is binarized, all the disconnected noises are present; there is no difference in the noise blocks and tool in terms of pixels. In the present algorithm, the binarized image was labeled, i.e., provided pixel numbers to each object in the image. Figure 53.5 shows typical binary image matrices. The camera was placed in such a manner that tool gets the maximum area in captured images. This helps in detecting the objects related to cut-chips, as the size of disconnected noise can be in the form of chips, which will not be larger than the tool itself. Then, the identity of the largest object is detected, and the rest of the objects in the image are discarded (Fig. 53.5).

Edge Detection. Orientation correction of the image is resource-consuming operation; it works faster with the edge image of the tool. The Canny operator is more suitable to find the edges in the image by using the local maxima of the image gradient. This method uses two thresholds to detect strong edges (high magnitude

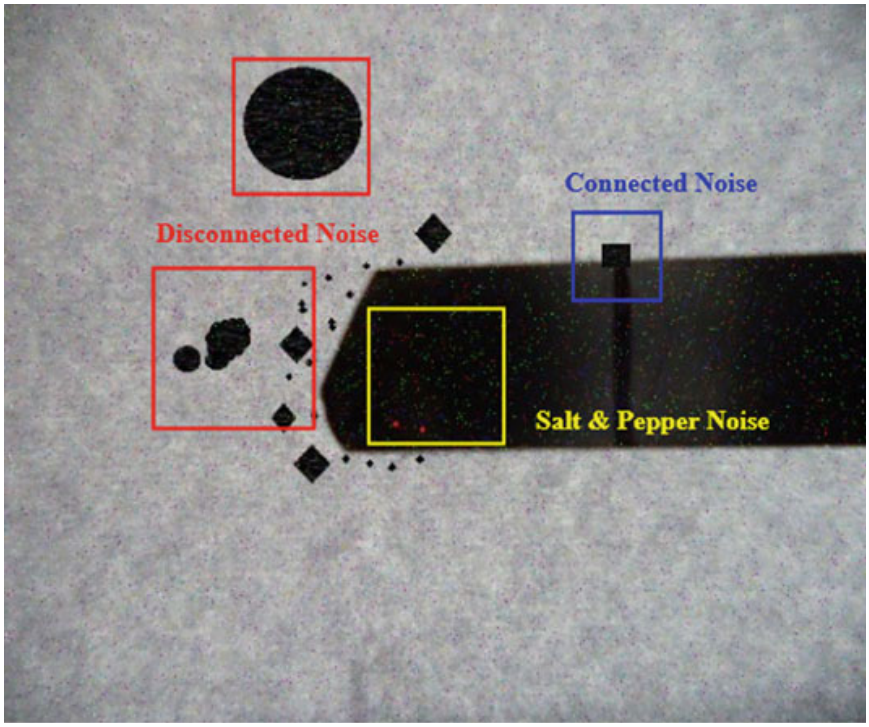

Fig. 53.4 Types of noise, disconnected noise, connected noise, and salt and pepper noise

of gradient) and weak edges (low magnitude of gradient) while preserving the weak edges connected to strong edges. However, the use of two thresholds makes the Canny method less susceptible to noise and helps in faster detection of true weak edges.

Use of automatic anisotropic Gaussian filters has shown improved results for edge detection process which removes the inherent deficiency of missing edges due to nonmaxima suppression associated with the Canny's algorithm [13].

Orientation Correction. The tool images were captured after removing the cutting tool from the lathe machine; and therefore, they are vulnerable to a slight deviation in tool orientation in the horizontal plane. In addition, the amount of deviation is different for any two images. This leads to false area detection. The orientation of images is corrected using Radon transform and is given by

$$\acute{f} = Rf = \int_L f(x, y)\mathrm{d}s \tag{53.3}$$

$$x = p\,\cos\phi - s\,\sin\phi \tag{53.4}$$

$$y = p\,\sin\phi + s\,\cos\phi \tag{53.5}$$

where ds is the increment in length along L (Eq. 53.3), With reference to the image, the Radon transform is the projection of the image intensity along a radial line oriented at a specific angle, ϕ; and ϕ varies from $\pi/2$ to $\pi/2$. If ϕ is a scalar, $\acute{f}$ is a column vector containing the Radon transform for theta degrees. The angle ϕ corresponding to the maximum value of Radon transform is the orientation angle β for the object in the image. In addition, the accuracy of orientation angle can be tuned to suit the need.

Geometrical Transformations. The cutting tool shown in Fig. 53.4 can have four possible orientations, horizontal with tool base on left or right, vertical with base on top or bottom. By using the geometrical properties, the tip, and the base of the tool are identified. After obtaining the orientation angle of the tool in an image, the image is rotated in a manner (i.e., using rotation angle as $\pm\beta$ or $90° \pm \beta$ or $180° \pm \beta$) that every tool image has the same orientation. Rotation of the image matrix in MATLAB^{TM} increases its size. It is due to image padding (addition of ones and zeros based on user's choice) action of rotation function. In addition, an increase in the size of an image is different for different angles of rotation. To subtract one image from another, the sizes of two images must be same. Therefore, the image cropping accompanied translation is necessary. Figure 53.6 shows the captured images of a typical cutting tool and their corresponding binary images. The centroid of binary image of the worn tool is aligned to the centroid of healthy tool. Then, the subtraction operation is performed to obtain the worn-out area, as shown in Fig. 53.7.

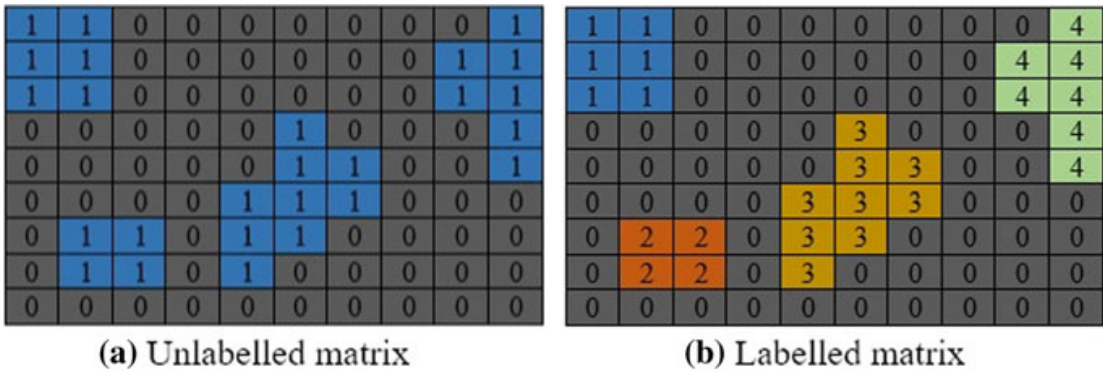

Fig. 53.5 Binary image matrices

Numerical Estimation. Tool wear data is computed in terms of pixels, and size of pixel is a function of camera's intrinsic properties, standoff distance between camera and objects. Therefore, this data is converted to world units, millimeters. It may happen that worn tool image and healthy tool image are assigned different number of pixels for same actual width. This discrepancy is taken care by resizing both the images such that 700 pixels are assigned to the width of the tool in each image; the number of pixels assigned to tool width for the experimental setup varied around 700.

53.3 Experimental Setup

To validate the performance of the developed algorithm, in-house experiments on plain turning operation were carried out on cylindrical workpiece made up of H13 steel, measuring 25 mm in diameter and 110 mm length. The experiments were performed on 11 kW, high-speed precision lathe, HMT NH26. At start, an image of the cutting tool was captured just after it was ground and the second image was captured after its failure. Machining parameters used for this experiment are listed in Table 53.1. The image for cutting tool was taken in the lab in presence of proper illumination source and away from machining noises like chips, dirt, cutting fluid,

Table 53.1 Machining parameters

Sr. no.	Parameter	Value
1	Tool material	High-speed steel (HSS) (*Miranda Tools make*)
2	Tool dimension	1/4″ × 4″
3	Work material	H13 steel (cylindrical)
4	Spindle speed	598 rpm
5	Feed	0.058 mm/rev
6	Depth of cut	0.5 mm
7	Machining time	2.1 min (stopped due to tool failure)

etc. The details regarding the image acquisition setup are already presented in Sect. 53.2.1. A schematic representation of image acquisition setup is shown in Fig. 53.2.

53.4 Results and Discussion

53.4.1 Image processing

Figure 53.6a, c shows the input true-color images and Fig. 53.6b, d shows the noise removed in corresponding binary images with scale factor one. Tables 53.2 and 53.3 show the properties of tools in corresponding binary images. Table 53.4 shows the numerical value of wear area.

The number of pixels assigned for tools in the image is 687 for the healthy tool and 731 for the worn tool image. Both the images were resized to bring the tool width to 700 pixels. Table 53.2 shows the properties of both the images.

Properties	Values in pixels	Values in world units
Area	24,739	2.03 mm^2
Perimeter	815.57	7.39 mm
Equivalent diameter	177.48	1.41 mm

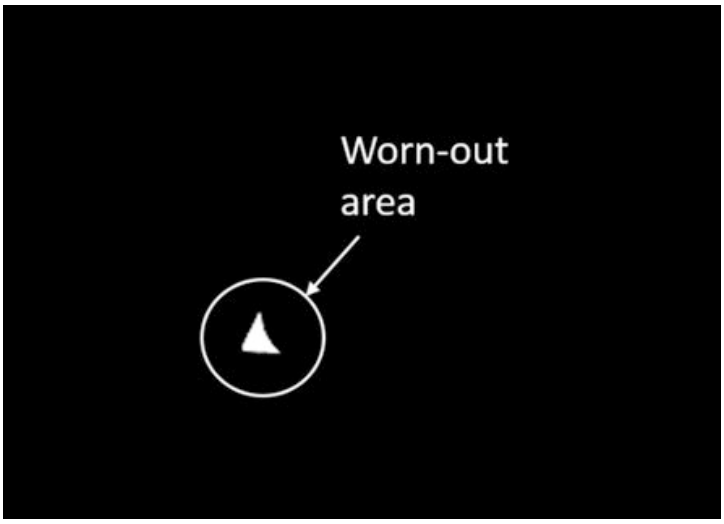

Fig. 53.7 Worn-out area image

Area mentioned in Table 53.2 is in terms of number of pixels. It can clearly be noted that there is reduction in the area of captured image after the machining run. Equivalent diameters were computed by treating the area to be equal to the area of a circle. A difference in centroid coordinates of both images occurs because of two reasons; first, actual position of tool while image capturing and second, due to wear of a portion of the tool.

Figure 53.7 shows the worn-out area image. The original worn-out area image contains some disconnected noise. This disconnected noise occurs, as the alignment of the image tools is not exactly 100%, but very close to it. The size of noise is very small and can be removed by using disconnected noise removal method as mentioned in Sect. 53.2.3.

The width of the tool is 6.35 mm and 700 in terms of pixels. Based on this, the conversion scale was computed as 0.0091 mm/pixel. Since the pixels are square of the data obtained using the current experimental setup, it was assumed that area conversion scale is square of conversion scale. It is equal to 8.23×10^{-5} mm^2/ area in terms of pixels. Table 53.4 shows the worn-out area in terms of pixels and in world units.

In this work, image processing toolbox available in MATLAB™ is used. It has a plethora of predefined functions, some of which can be customized to suit the need of the work. In addition, MATLAB™ provides a seamless integration of its various predeveloped modules which found to be very helpful during the development of algorithm of the present work.

Fig. 53.8 Variation of time and percentage error with different scale factors

53.4.2 Speed Test Results

During the algorithm development, it was noticed that a trial on a large size image, i.e., 4608 × 3456 (original image) consumed a considerable amount of time, 87 s; therefore, a speed test was conducted to test the response of the developed algorithm. In this test, the dimensions of the original image were scaled and the effect of reduction in size of the image was studied. The reduction in size of the image was performed manually using Windows Paint application. The time for single run of the developed algorithm was collected from MATLAB™ profiler. First, the scale factor (by what factor the image size has been reduced) was varied from 1 to 2.304. Then, the errors in wear areas were determined. It was noted that by using the scaled images, the speed and accuracy of the computation were improved. Figure 53.8 shows that a scale factor (reduction) of two performed well and can be used for the further computations.

Overall, this work demonstrates a simple and easy method to compute the tool wear, in which only a simple digital camera is sufficient for computation of tool wear. Camera can be mounted in CNC machines, which captures the images in intervals when tool is not interacting with workpiece. By computing the end-cutting-edge wear, dimensional accuracy of workpiece could easily be improved by applying in-process tool compensation. The present work may also help in monitoring the in-process tool wear.

53.5 Conclusion

In the present work, a simple and efficient image processing algorithm has been developed for computation of wear in cutting edges of single-point cutting tool used in plain turning operation. An in-house image acquisition setup has been developed to capture the images of cutting tools (before and after machining). The captured images were preprocessed using various advanced image processing functions such as distortion correction, conversion from 3D to 2D, filtering using Gaussian and

median filters, and binarization. Canny operator was used to properly orient the captured images. The orientation of the images was corrected using Radon transform. Finally, the worn-out area was computed in terms of pixels by using the geometric transformations of captured images. The size of pixel is a function of camera's intrinsic properties, standoff distance between camera and objects. The performance of the developed algorithm has been validated by conducting in-house experiments on plain turning operation, and it was found satisfactory. During the speed test, it was noticed that processing of the original image (4608 × 3456) consumed a considerable amount of time, 87 s. However, the scaled image with reduction factor of two improved the speed of computation as well as accuracy.

The work presented hereby is useful for tool monitoring process and for tool change decision-making process. The presented algorithm has potential and flexibility of being used with fully automatic tool changing process. The whole process involves use of a simple digital camera, which reduces the cost of the operation. This work would be useful for all tool rooms, machine tool manufacturers, and small-scale industry. However, reduction in computation time would further enhance the potential of this work. Integration of artificial neural networks (ANN) would reduce the frequency of image acquisition required for the process.

Chapter 54
Modelling and Analysis of Multi-agent Approach for an IoT-Enabled Autonomous Manufacturing System

K. B. Badri Narayanan and M. Sreekumar

Abstract Industrial Internet of Things (IIoT) is a digital platform to perform machine-to-machine communication, acquire sensor data, analyse, and deliver comprehensive information and also facilitate the manufacturing system to implement smart decisions faster. This paper presents modelling and analysis of an IoT-enabled autonomous manufacturing system based on the performance metrics. Multi-agent interaction has been defined through a generalised control architecture, considering as an autonomous manufacturing system. The number of jobs entering and leaving the machines computes time-dependent performance metrics such as cycle time and work in process using Little's law. The mean arrival rate of each machine is calculated by evaluating the amount of work and a utilisation factor. The squared coefficient of inter-arrival rates based on successive substitution of job flow from machine x to machine y has also been obtained. This is preliminary work in the process of designing an IoT-enabled autonomous manufacturing system capable of self-learning and executing accurate decision faster.

54.1 Introduction

According to Moore's law, the exponential growth of technology is forcing constant up-gradation in manufacturing the environment. Current manufacturing scenario lacks in adopting the changes, so an intelligent manufacturing system with a decentralised multi-agent approach shall be of a solution. In manufacturing systems, downtime can happen due to various disorders such as tool failure, workstation

failure, the breakdown of material handling devices like a robot, conveyor, and transfers system. This downtime issue generally increases the lead time and production cost. Immediate rescheduling of the process flow of the respective workpiece offers a solution for reducing systems downtime wisely and efficiently [1]. Also, reconfiguration changes the structure of the manufacturing layout that requires new scheduling [2–4]. Even state-of-the-art modern manufacturing facilities cannot be able to provide a complete solution for machine downtime.

For agent breakdown cases, present automation systems use a defined protocol. Hence for defining a new protocol, the system should be interrupted in the middle. This aspect increases the rigidness of the system. This can be avoided by using the machine-to-machine communication protocol called Process Field Net (PROFINET). Similarly, a cognitive approach can be implemented to adopt rapid changes in the manufacturing systems environment. Several unique paradigms of Intelligent Manufacturing Systems (IMS) such as holonomic systems [5, 6], cognitive systems [7], biological systems [8, 9], and reconfigurable manufacturing systems [10, 11] have already been established.

A manufacturing Petri Net (MPN)-based scheduling model for IoT-enabled hybrid flow shop manufacturing is discussed in [12]. IoT in the manufacturing system digitises the real-time production system and provides a faster smart decision. In the present work, an IoT enabled autonomous manufacturing system, as shown in Fig. 54.1, is designed by considering every machine as agents. Jobs are considered as encapsulated with radio-frequency identification (RFID) tags and represented as stable, smart objects (SSO). Every machine is attached with RFID readers and represented as dynamic smart objects (DSO). Similarly, every worker is

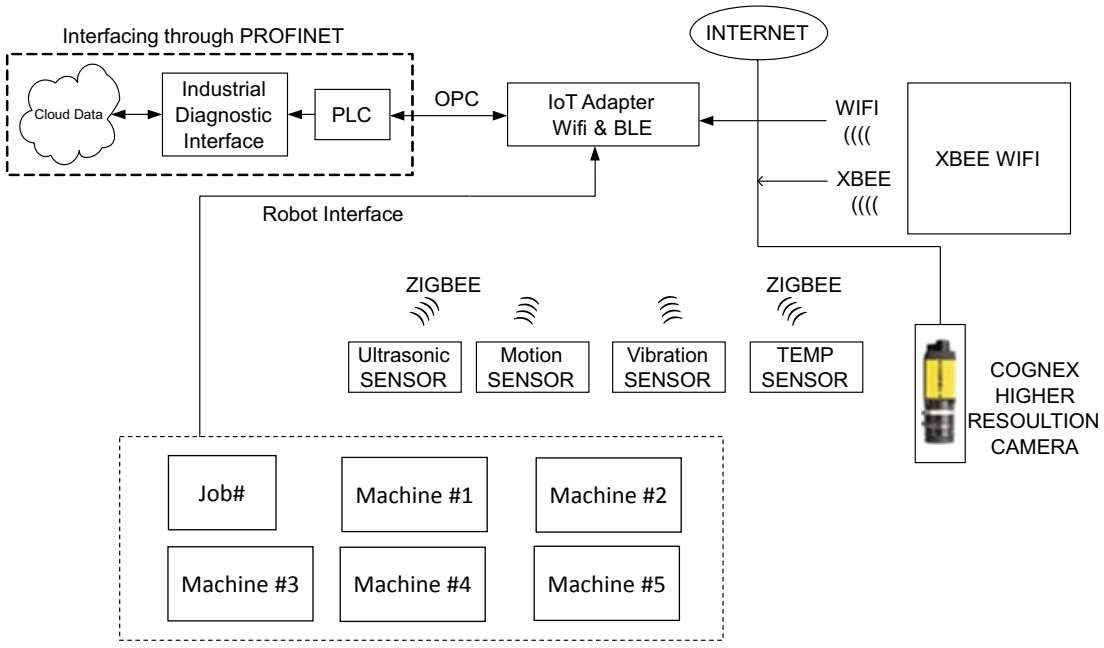

Fig. 54.1 Schematic arrangement of wireless communication in an IoT-enabled manufacturing system

provided with RFID smart ID card. Machining and buffering are recorded in the database by interactions between SSO, DSO, and smart ID card.

The rest of this article is constructed as follows. Section 54.2 discusses the core technologies such as swarm intelligence and control architecture of autonomous manufacturing systems. Section 54.3 is focused on modelling and analysis of the performance metrics of manufacturing systems. The conclusion is drawn in Sect. 54.4, followed by references.

54.2 Core Technologies

54.2.1 Swarm Intelligence

Swarm intelligence is a bio-inspired technique that mimics the localised interaction behaviour that exists amongst various species such as ant, insects, and other animals. Ant colony optimisation (ACO) is a swarm technique which mimics the food searching behaviour of ants. The interaction between ants is carried out basically by deposition of pheromone by a preceding ant. ACO can be implemented in manufacturing systems by considering machines as a group of autonomous and cooperative agents like ants. Such systems could be self-organised by a local interaction between SSO, DSO, and smart ID card. Every machine can calculate its pheromone value for a particular process. During machine failure, the agent interaction can be defined by comparing the machine specification and process information that are available in the database. The formulation of pheromone value can be accomplished by

$$P_X = \left[\alpha_{\mathrm{WIP}}(\mathrm{WIP}_O/\mathrm{WIP}) + \alpha_{\mathrm{CT}}(\mathrm{CT}_O/\mathrm{CT}) + \alpha_S\left(\frac{C_{SO}^2}{C_S^2}\right) + \alpha_I\left(\frac{C_{AO}^2}{C_A^2}\right) + \alpha_A\left(\frac{\delta_{xo}}{\delta_x}\right)\right]^{-1} \tag{54.1}$$

where P_X—pheromone value, WIP_O—maximum work in process, CT_O—maximum cycle time, C_{SO}^2 represents the maximum squared coefficient of variation for service time, C_{AO}^2—maximum squared coefficient of variation for the inter-arrival rate of jobs, δ_{xo}—maximum arrival rate of jobs to machine x. The factors $\alpha_{\mathrm{WIP}}, \alpha_{\mathrm{CT}}, \alpha_S, \alpha_I$ and α_A represent the weight of WIP, CT, C_{SO}^2, C_{AO}^2 and δ_{xo}, respectively. After generating the pheromone values of each process for all machines, the machine failures can be identified with the following cases

Case 1: If $\forall P_X < 0.2$
Then send a message from MES to Employee staff RFID /*all machines are good*/

Case 2: If $\exists! P_X \geq 0.2$
Then send a message from MES to Employee staff RFID /*the machine x is selected for rectifying the failure*/
Case 3: If there are more than one $P_X \geq 0.2$
Then send a message from MES to Employee staff RFID /*the machine which is having the highest pheromone value selected for rectifying the first and followed by the subsequent highest value*/
Case 4: If $\forall P_X \geq 0.2$
Then

(i) send a message from MES to staff RFID /*All machines had pheromone value above 0.2*/
(ii) In response to the above message, send a message from staff to MES /*requesting the MES for rescheduling*/.

54.2.2 Control Architecture

The generalised control architecture of autonomous manufacturing systems is shown in Fig. 54.2. The core elements of the control architecture are agent interaction, agent behaviour, and database. The interaction between agents and manufacturing execution system (MES) occurs through Extensible Markup Language (XML). XML provides readable formats to both humans and machines. The industrial control system protocol Open Platform Communication (OPC) interfaces the machine with Programmable Logic Controller (PLC) and connects the physical devices like sensors integrated with machining centres. The database stores the information like job address, machine address, process details about jobs, sensor data, and tool failures. The agent cooperation is incorporated by calculating the pheromone value of each agent. Then the agents compare the pheromone value by interacting with nearest agents and finally, the agent which has the highest pheromone value is chosen to rectify the failure.

54.3 Performance Metrics

The mean of performance metrics considered for modelling and analysis of an IoT-enabled autonomous manufacturing system is cycle time CT, work in process WIP, arrival rate, squared coefficient of variation for inter-arrival, and service time. Using Little's law, the probability of seven different jobs flow across the manufacturing systems is formulated by equating the number of jobs entering and leaving the machine. This also computes the time-dependent variables such as cycle time and work in process. The mean arrival rate of each machine is calculated by

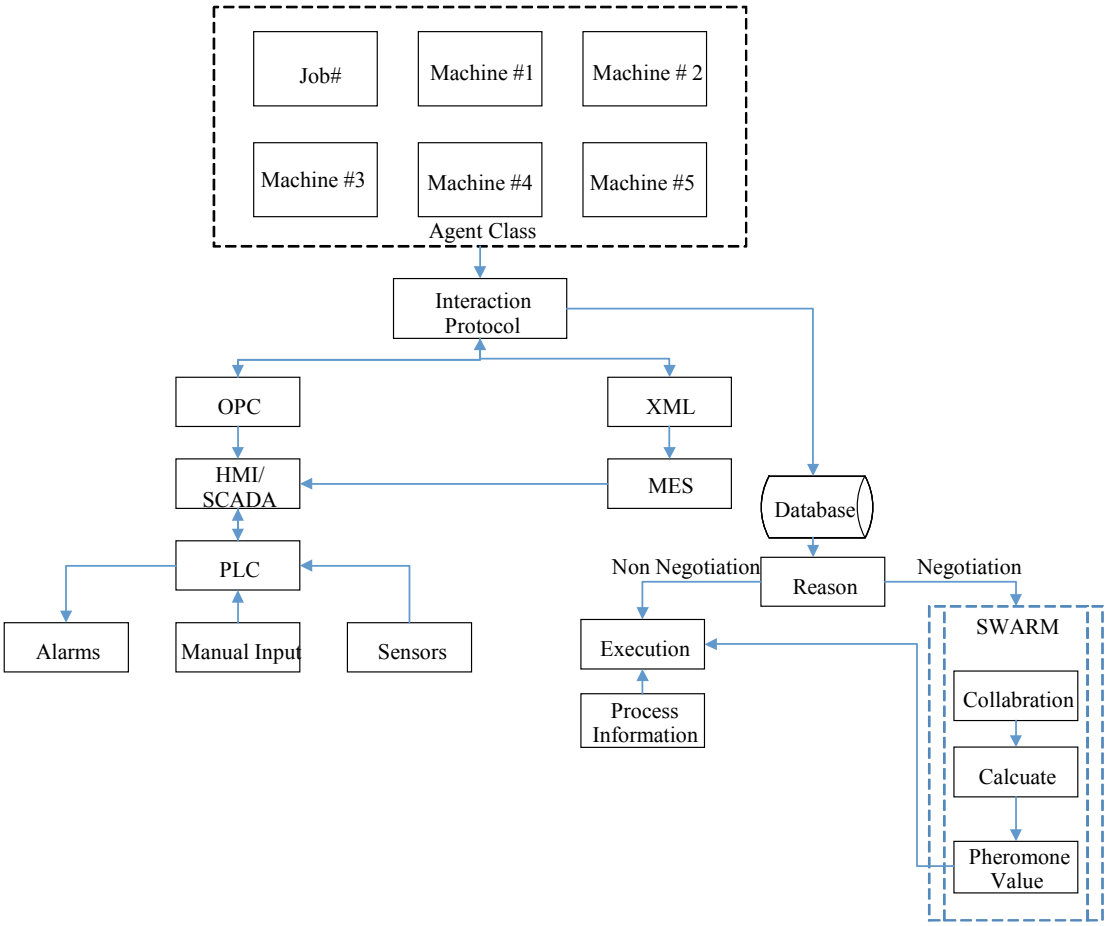

Fig. 54.2 A generalised control architecture of an autonomous manufacturing system

evaluating the amount of work and a utilisation factor. The squared coefficient of inter-arrival rates is obtained by successive substitution of job flow from machine x to machine y.

54.3.1 Workflow Modelling

A discrete workflow network, defining the arrival rate, is more complicated than the continuous systems. Consider machines, as shown in Fig. 54.3, the job is entering from an external source into the first machine with a mean rate of o. However, machine 1 also got rejected job with probability d. Hence, the flow into the machine 1 is not clear. Sequentially, the probability for machine 2 is also not clear since the job arrives from machine 1 has a mean rate of p_1. This quandary is a regular due to the discrete movement of jobs. These situations demand to calculate flow rates concurrently. For example, δ_x for $x = 1, 2 \ldots n$ is used to indicate the total arrival of jobs for machine x. The mean flow rates are modelled mathematically using steady-state conditions as

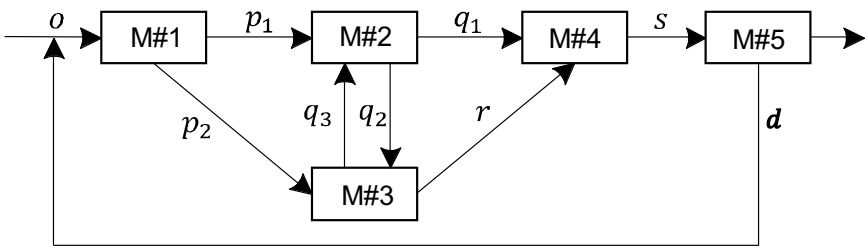

Fig. 54.3 Autonomous manufacturing system topology

$$\left.\begin{aligned}\delta_1 &= o + d\delta_5\\ \delta_2 &= p_1\delta_1\\ \delta_3 &= p_2\delta_1 + q_1\delta_2\\ \delta_4 &= \delta_3 + q_2\delta_2\\ \delta_5 &= s\delta_4\end{aligned}\right\} \tag{54.2}$$

The steps involved in the evaluation of autonomous manufacturing systems are detailed below.

Step 1. Compute the amount of work for each machine by considering n machines in a manufacturing system with i type jobs and each type flows is defined by transmitting matrix R_i and by assuming that summation of any row should be less than one. Let o_i denote mean arrival rate of type i jobs, and now the vector δ_i is given by [13]

$$\delta_i = \left[I - (R_i)^T\right]^{-1} o_i \tag{54.3}$$

Amount of work for each machine is calculated by

$$\mathrm{AW}_x = \sum_{i=1}^{m} \delta_{i,x} E[T_s(i,x)] \tag{54.4}$$

where m—maximum number of products,
$\delta_{i,x}$—the rate of product type i entering into machine x as shown in Table 54.1 and $E[T_s(i,x)]$ is mean service time of type i job at machine x.

The utilisation factor u_x, for machine x, is,

$$u_x = \frac{\mathrm{AW}_x}{c_x} = \frac{\sum_{i=1}^{m} E[T_s(i,x)]}{c_x} \tag{54.5}$$

Table 54.1 Arrival rate of each machine

Arrival rate of each machine x	Job types						
	J# 1	J# 2	J# 3	J# 4	J# 5	J# 6	J# 7
$\delta 1$	5.0813	5.4585	5.102	5.4348	5.102	5.0201	5.004
$\delta 2$	4.065	4.3668	0	0	0	0.2008	0.2002
$\delta 3$	0	3.7118	1.0204	0	1.0204	1.004	1.0008
$\delta 4$	0.813	4.5852	1.0204	4.3478	0	0	0.04
$\delta 5$	0.813	4.5852	1.0204	4.3478	1.0204	0.2008	0.04

Step 2. The meantime, squared coefficient of variation for the service time, and squared coefficient of variation for the arrival times at machine x are calculated by

$$E[(T_s(x)] = \sum_{i=1}^{m} \frac{\delta_{ix}}{\delta_x} E[T_s(i,x)] = \frac{\mathrm{AW}_x}{\delta_x} \tag{54.6}$$

$$C_s^2(x) = \frac{\left\{\sum_{i=1}^{m} \frac{\delta_{i,x}}{\delta_x} E[T_s(i,x)]^2 [1 + C_s^2(i,x)]\right\}}{\left\{\sum_{i=1}^{m} \left(\frac{\delta_{i,x}}{\delta_x}\right) E[T_s(i,x)]\right\}^2} - 1 \tag{54.7}$$

Step 3. The combined transmitting matrix $R = (r_{x,y})$ gives the transferring possibilities of a subjective job and is determined by

$$r_{x,y} = \frac{\sum_{i=1}^{m} \delta_{ix} r_{x,y}^{i}}{\delta_x} \quad \text{for } x, y = 1, \ldots, n \tag{54.8}$$

The flow of jobs from machine x that are routed directly to machine y will be called as x to y stream and the squared coefficient of variation of inter-arrival times to y from x is obtained by

$$C_a^2(y) = \frac{o_y}{\delta_y} C_a^2(0,y) + \sum_{x=1}^{n} \frac{\delta_x r_{x,y}}{\delta_y} \begin{bmatrix} r_{x,y}(1 - u_x^2) C_a^2(x) \\ + r_{x,y} u_x^2 \left(\frac{C_s^2(x) + \sqrt{c_x} - 1}{\sqrt{c_x}}\right) + 1 - r_{x,y} \end{bmatrix} \tag{54.9}$$

Then, the mean cycle time spent within the manufacturing system by a type i job is given by

$$CT^i = \frac{\sum_{i=1}^{m} \delta_{i,x}\{CT_q(x) + E[T_s(i,x)]\}}{\sum_{y=1}^{n} o_{iy}} \tag{54.10}$$

54.3.2 Performance Analytics

The flow sequence of each product is shown in Table 54.2, and the processing time is shown in Table 54.3. The flow rate of each machine is assumed as [13] $o = 5$, $p_1 = 0.8$, $p_2 = 0.2$, $q_1 = 0.6$, $q_2 = 0.2$, $q_3 = 0.2$, $r = 1$, $s = 1$ and $d = 0.1$. The amount of work done is calculated by Eq. (54.4). The meantime and squared coefficient of variation for the service time at machine x can be calculated using the Eqs. (54.6) and (54.7).

Table 54.2 Sequence of each product type

Job sequence J	Job Types						
	J#1	J#2	J#3	J#4	J#5	J#6	J#7
Sequence 1	M# 1	M# 1	M# 1	M# 1	M# 1	M# 1	M# 1

The multiple job study problems now shrink to a single job study. The transferring possibilities of a subjective job and is determined by Eq. (54.8). The mean time spent with the manufacturing system by a type i job is calculated using Eq. (54.10). The shop floor parameters like cycle time CT, work in process WIP, arrival rate, squared coefficient of variation for inter-arrival, and service time are shown in Fig. 54.4.

In Fig. 54.4, the performance metrics of each machine is monitored remotely. The database provides dynamics of real-time data for intelligent decision-making. Pheromone value of each machine is evaluated based on real-time data of performance metrics. Each machine has a different threshold value for different performance metrics. When the performance metrics getting deviated beyond the threshold value, messages are sent to employee's smart ID to overcome the deviation. The significance of this paper provides a solution to overcome the downtime of each machine using the cognitive ability of agents. Swarm intelligence improves the

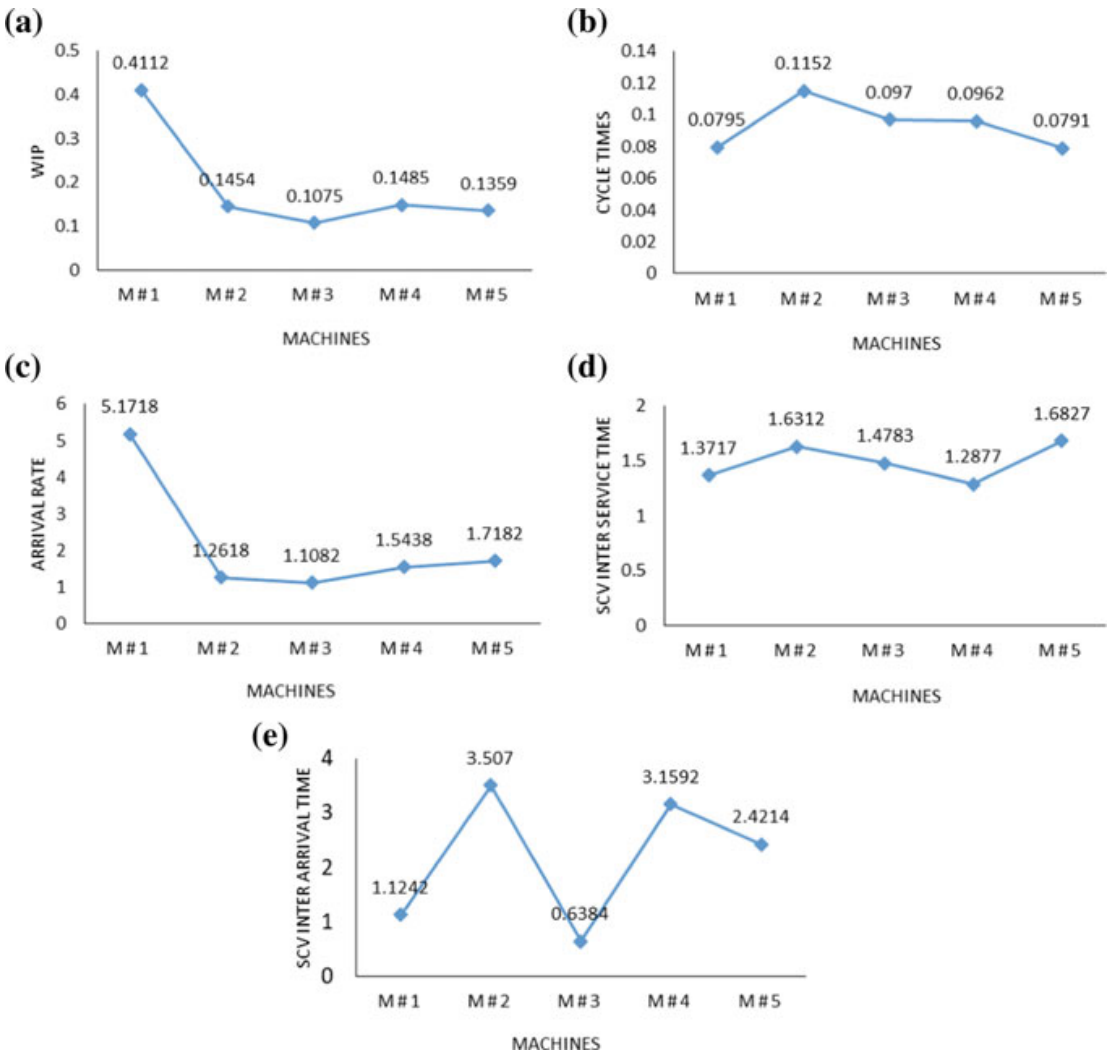

Fig. 54.4 Performance parameters **a** cycle time, **b** work in process, **c** arrival rate, **d** SCV inter-arrival time, and **e** SCV service time

autonomous behaviour of each agent to defend the disturbances without any upper-level aid and enhances the reliability of the system. The dashboard is transparently showing the dynamic status of machine health and the solution based on pheromone value priorities and addresses the failure immediately.

54.4 Conclusion

In this work, an attempt has been made to derive mathematical model and analyse a manufacturing system integrated with IoT based on the mean of performance metrics such as cycle time, work in process, arrival rate, squared coefficient of variation for service time, and inter-arrival rate. This model reflects the real-time operations of machining and buffering in a smart manufacturing system. The swarm intelligence of machining agents improves system robustness to face machine failures by multi-agent interaction, adaptable to changes, and reliable in product quality. The manufacturing system becomes rigid by decentralised control and autonomous behaviour in decision-making. The simulation results of all performance metrics provide dynamic states of each machine. The results also provide continual process adjustment in the manufacturing system to avoid failure of machines by evaluating the pheromone value. The manufacturing systems become intelligent to handle the disturbances in priority sequence using pheromone value and to reduce the downtime of the machine. Future research line extends to the development of the finite state of a machine for more precise modelling.

Estimation of Distortion for CFRP Antenna Reflector During Autoclave Processing

Shrey Patel, Dhaval Shah, Shashikant Joshi and Kaushik Patel

Abstract Carbon fibre-reinforced polymer (CFRP) composites are broadly utilized in space applications due to their very high specific properties over typical metals and alloys. Autoclave curing is one of the finest composite producing techniques to achieve great dimensional accuracy of the advanced shaped component. The cure shrinkage, which is commonly referred to as warpage or spring-back distortion, is induced as a result of material thermo-elastic anisotropy during composite laminates manufacturing. In this paper, the distortion of CFRP reflectors is estimated using experimental and numerical approaches for autoclave processing. The antenna reflectors have been fabricated using HCU200/A45 prepreg and stainless steel AISI 430 as a part and tool material, respectively. The geometric modelling and finite element analysis (FEA) have been performed for parabolic reflectors using ABAQUS software along with COMPRO plug-in. Thermochemical and stress-deformation analysis has been performed to obtain the deformed shape of the antenna reflectors. The laminate thickness has been considered as a process parameter. The experimental and numerical results have been compared and located in sensible agreement with one another.

55.1 Introduction

The use of CFRP prepreg composites in aerospace, automotive, and defence industries is growing mainly due to their high strength and stiffness to weight ratios. Although there is a wide scope of application of these materials, still there is a limited use because of quality reliability issues, high raw material, manufacturing cost, and lengthy manufacturing cycle. Autoclave process is the most popular for getting high-quality composites components compared to other composite manufacturing processes. This manufacturing process gives the minimum void content in manufactured composite components as compared with other vacuum infusion process, resin transfer moulding process, filament winding process, and hand layup process. The antenna reflectors used for transmitting the radio frequency signals between two devices in space applications, and therefore, the profile of the reflectors should be accurate. The COMPRO, a special purpose subroutine, can be used for simulation of autoclave manufacturing process along with ABAQUS software. The COMPRO plug-in consists of the material database for prepreg, fibre and resin system, and tool materials. The thermochemical, flow-compaction, and stress-deformation analysis modules are available for the simulation of composites.

Many researchers worked on the prediction of warpage and spring-back deformations for composite components. During the process of curing, Hahn and Pagano [1] found out that some stresses which developed during that process varied with respect to temperature development. Darrow and Smith [2] established three process parameters, i.e., mould expansion, thickness cure shrinkage, and fibre volume fraction gradients that effects on spring-in deformations. Twigg et al. [3] predicted warpage of flat laminates with considering the part length, tool–part interaction, the effect of release film, and release agent as process parameters. Stefniak et al. [4] performed experimental work to quantify the various mechanisms, i.e., property gradient mechanism, stress gradient mechanisms with respect to their relative contribution to composite part distortions. Kaushik et al. [5] studied the result of various process parameters, i.e., pressure, ramp rate, and the degree of cure on the coefficient of friction in the autoclave process. Fernlund and Poursartip [6] demonstrated the effect of the cure cycle and tool surface condition on spring-back deformation. Zeng and Raghavan [7] implemented three-dimensional process model through user subroutine interfaced with finite element software. Abusafieh et al. [8] described the effect of temperature and degree of cure by using experimental setup and FEA. Dong [9] derived the mathematical formula to calculate spring-in of flat laminates using the effective coefficient of thermal expansion. Mezeix et al. [10] simulated spring-back deformation of unidirectional carbon/epoxy flat laminates manufactured through the autoclave process.

In this research paper, experimental and numerical approaches have been used to estimate distortion for CFRP antenna reflectors. The stainless steel AISI 430 and HCU200/A45 prepreg tape have been identified as a tool and part material, respectively. The laminate thickness, i.e., 0.8, 1.6, 2, and 2.4 mm has been considered as a process parameter. In the experimental approach, CFRP antenna

reflectors have been fabricated using the autoclave process. The geometrical modelling as well as FE analysis has been performed with the help of COMPRO plug-in using ABAQUS software. The thermochemical and stress-deformation analysis has been carried out for CFRP antenna reflectors to predict distortion. The comparison of distortions for fabricated reflectors using autoclave process and simulation has been carried out.

55.2 Experimental Approach

55.2.1 Material Selection

The AISI 430 grade of stainless steel has been selected as a tool material due to the ease of availability and machinability by comparing other grades of steel. The HCU200/A45 prepreg tape (tensile strength = 3450 MPa, fibre density = 1.8 g/cm^3) has been identified, which consists of excellent surface finish and mechanical properties. The consolidation materials, i.e., release agent, vacuum bag, peel ply, and breather cloth have been required in the manufacturing of composite parts using the autoclave process. These consolidation materials have been sustained temperature up to 200 °C. The laboratory-scale autoclave machine of overall diameter 900 mm and length of 1000 mm has been used for the manufacturing process.

55.2.2 Fabrication of Antenna Reflectors

The 300 × 300 × 70 mm size block of stainless steel AISI 430 material has been procured. The 3D CAD model has been prepared using solid modelling software for paraboloid profile with a circumferential diameter of 240 mm at one face with the depth of 50 mm. The machining of stainless steel tool has been performed using NC code in the 5-axis VMC machine with the great surface finish as shown in Fig. 55.1. The three coats of release agent have been applied on the parabolic tool surface. The numbers of prepreg layers as per the required thickness of reflector have been cut into the circular shape of 300 mm diameter. Peel ply, breather cloth, and vacuum bag have been kept on layers of prepreg. The sealant tape has been applied over the entire assembly to prevent leakage of air and resin from the assembly. The vacuum valve has been placed at the centre of a vacuum bag to maintain pressure. The one end of the vacuum hose has been connected to a valve whereas another end at the outlet of the vacuum pump. The entire setup has been kept in the autoclave for curing as shown in Fig. 55.2. The manufacturer recommended curing cycle has been given to the autoclave. The demoulding process has been performed at atmospheric condition after the completion of the curing process. The finish cured and demoulded reflector is shown in Fig. 55.3.

Fig. 55.1 Stainless steel AISI 430

Fig. 55.2 Autoclave machine

Fig. 55.3 Manufactured CFRP antenna reflector

55.3 Numerical Approach

The geometry of the tool and part has been created as per actual dimensions in ABAQUS software. The thermochemical and stress-deformation analysis has been performed with the help of COMPRO plug-in for antenna reflectors to predict distortion [11]. The methodology followed in the numerical approach has been described as a flow chart as shown in Fig. 55.4.

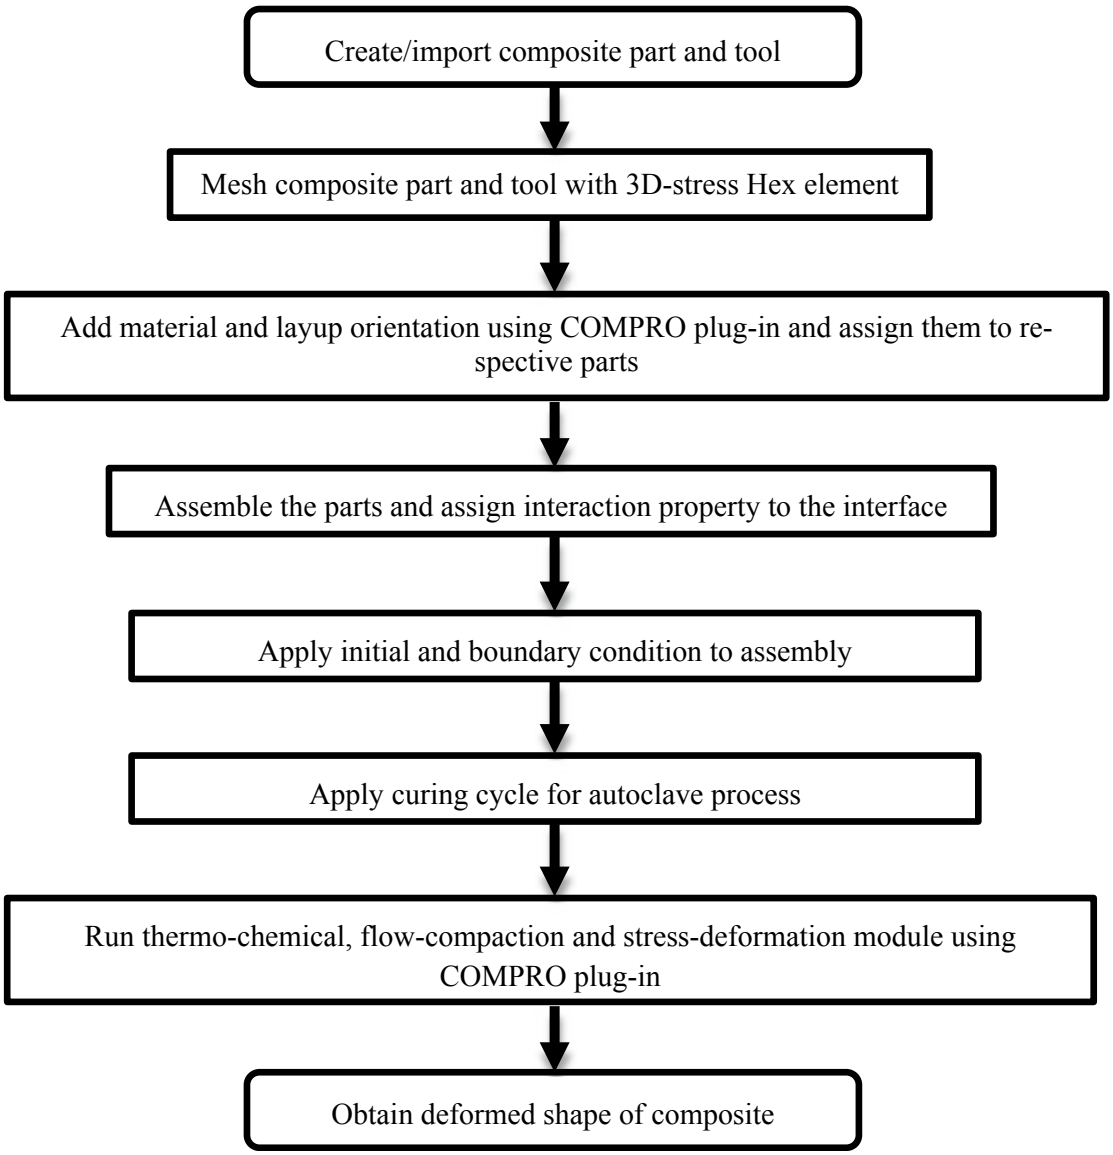

Fig. 55.4 Methodology for numerical simulation using ABAQUS with COMPRO plug-in

55.3.1 Simulation Procedure

The curing process of CFRP reflector has been simulated using ABAQUS along with COMPRO plug-in [12]. The paraboloid shape tool and reflector have been modelled using solid modelling software and imported in ABAQUS. The tool has been partitioned along two perpendicular planes passing through the centre of the model. The total of eight partitions has been created for the reflector in ABAQUS modeller. Each edge has been divided into five segments at a radius of 25, 50, 75, and 100 mm for the reflector. This will be facilitated for node generation at each junction and is further used to measure distortion at these locations. The thickness of the reflector should be modelled according to a number of prepreg layers as per thickness of each layer. The tool and reflector have been discretized using 3D Stress

20 node quadratic C3D20 elements. The meshed model for tool and reflector is shown in Fig. 55.5a, b, respectively. The stainless steel and carbon fibre prepreg material have been assigned for tool and reflector, respectively. These both materials have been imported using COMPRO plug-in. The through-thickness direction and in-plane direction has been assigned to the reflector as per stacking direction and fiber orientation to perform simulation using COMPRO. Assembly of tool and reflector has been performed by creating individual instances in the assembly module in ABAQUS. Frictional properties have been assigned to the interaction surfaces of tool and reflector. The tool top and reflector bottom surface have been selected as master and slave surface, respectively. The friction coefficient and limiting shear stress have been considered as 0.15 and 140,000 $N/mm^{2,}$ respectively. Assembly of tool and reflector has been assigned an initial temperature of 20 °C. The fix boundary constraints have been applied for tool and reflector to restrict their free expansion during the cure cycle in *X*-, *Y*-, and *Z*-directions.

Thermochemical analysis has been performed using COMPRO plug-in. The heat transfer coefficient of 80 W/m^2k has been applied on all exterior surfaces of reflector and tool. The manufacturer recommended cure cycle has been given as temperature-time data for autoclave processing. The temperature profile and degree of cure plot have been obtained as a result of thermochemical analysis. The demoulding step has been defined to get the deformed shape of the reflector. The tool has been deactivated using model change command in the interaction module in tool removal step. The proper boundary conditions have been applied to the reflector during tool removal step. The residual stress profile and deformed shape have been obtained as a result of the stress-deformation analysis.

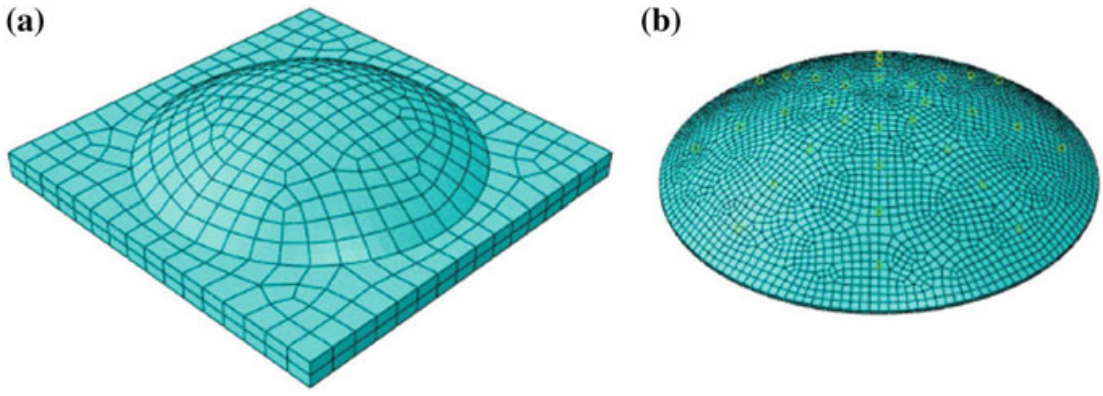

Fig. 55.5 Meshed mould and reflector

55.4 Results and Discussion

55.4.1 Distortion Measurement in Experimental Approach

The measurement of the specified coordinate points on the reflector surface has been performed using 3D scanning to confirm the accuracy of the parabolic shape obtained after curing. This has been accomplished by comparing the theoretical CAD model with 3D scan data. The 200 coordinate points have been obtained by projecting circles of diameter 50, 100, 150, 200, and 240 mm on the parabolic surface of the reflector. The deviation for scan data of reflector and CAD model has been measured for each coordinate point, and the same has been shown as a contour plot in Fig. 55.6. The distortion for each fabricated reflector has been calculated using root mean square (RMS) of deviations for all coordinate points. The predefined coordinate points on the CAD model and scanned data points on reflector along with deviation are given in Table 55.1. The final distortion, i.e., RMS value has been obtained as 0.37 mm.

55.4.2 Distortion Measurement in Numerical Approach

The deformation for total 41 coordinate points at the junction of division and partition on edge has been obtained as shown in Fig. 55.7. The original and deformed shape after demoulding for reflector is shown in Fig. 55.8. The deviation between coordinate points of original and deformed shape reflector are given in Table 55.2. The distortion for each fabricated reflector has been calculated using root mean square (RMS) of deviations for all coordinate points. The final distortion, i.e., RMS value has been obtained as 0.43 mm.

55.4.3 Comparison of Experimental and Numerical Results

Distortion of CFRP antenna reflectors has been determined using experimental and numerical approaches as given in Tables 55.1 and 55.2, respectively. Numerical results also compare quite well with experimental results. It has been shown that the difference between them in the range of 5–14%. The similar procedure has been repeated for different laminate thicknesses, i.e., 0.8, 1.6, 2, and 2.4 mm using both

approaches. The measured deformation using experimental and numerical approaches has been found as a good agreement with each other. However, for lower thickness components, the percentage difference is higher compared to high thickness components. The distortion for the corresponding reflector has been determined and compared with each other as shown in Fig. 55.9. The distortion decreases as laminate thickness increases due to the transverse contraction in the composite part. The close examination of the predicted final reflectors shape reveals that non-uniform thermal and cure shrinkage strains due to the coefficient of thermal expansion and coefficient of cure shrinkage anisotropies would result in changes in the shape of geometry. A sensitivity analysis revealed that the part thickness variation is the most important source of the predicted distortion.

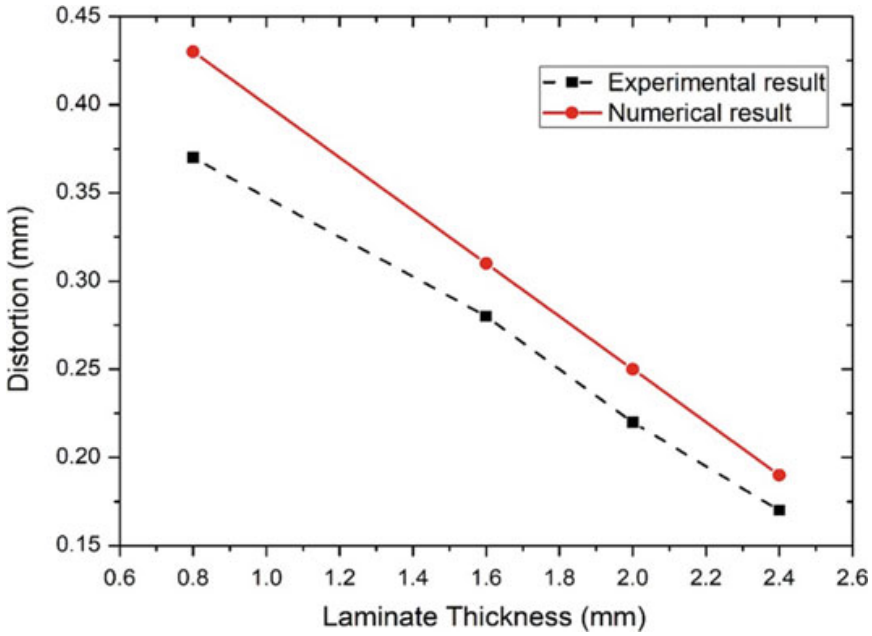

Fig. 55.9 Comparison of distortion for experimental and numerical result

55.5 Conclusions

Carbon fibre-reinforced polymer (CFRP) antenna reflectors have been fabricated using autoclave processing. The HCU200/A45 prepreg and stainless steel AISI 430 as a part and tool material, respectively, have been used in this study. The deviation in reflectors has been measured using 3D scanning technique. The geometric modelling and finite element simulation have been performed using ABAQUS software along with COMPRO plug-in. Thermochemical and stress-deformation analysis has been executed to obtain the distortion of the antenna reflectors. The distortion for reflectors has been determined using both approaches. The laminate thickness has been considered as a process parameter. The distortion decreases as laminate thickness increases. The measured deformation using experimental and numerical approach has been compared and found within 5–15% range.

Chapter 56
Comparative Study of Hydroxyapatite Nanocomposites Reinforced with Zirconia and Titania Produced by Using HEBM

Vemulapalli Ajay Kumar, Penmetsa Rama Murty Raju, Nallu Ramanaiah and Siriyala Rajesh

Abstract Hydroxyapatite ($Ca_{10}(PO_4)_6(OH)_2$–HAp) conglomerate with various weight fractions (5, 10, 15, 20 and 25 wt%) is fabricated by reinforcing TiO_2 and ZrO_2 + TiO_2 nanoparticles (20–40 nm). In order to obtain homogeneous mixing of HAp, particles are reinforced using high-energy ball milling (HEBM) at 300 rpm for 1 h, compacted at 100 bar with holding time of 150 s and sintered at 1200 °C. X-ray diffraction (XRD) analysis, energy-dispersive spectroscopy (EDX) and microstructural analysis using field emission scanning electron microscopy (FESEM) have been carried out on the obtained samples. The mechanical characterization of the composites has been evaluated through flexural strength, compression strength, hardness, young modulus and fracture toughness. The mechanical properties are found to be improved with increasing content of TiO_2; however, with increasing content of TiO_2 + ZrO_2, mechanical properties are found to be improved significantly up to the addition of 20 wt % of reinforcement content. When 25 wt% of TiO_2 + ZrO_2 reinforcement is added to HAp, the mechanical properties are found to be decreased. The reduction could be due to the increase in dominant smaller particles of ZrO_2 and grain size. The improved mechanical properties are correlated with the observed microstructural features.

56.1 Introduction

The chemical composition or the structure similar to human hard tissues such as bone and teeth exhibits biocompatibility and bioactivity of hydroxyapatite (HAp). HAp, after implantation into human body as artificial material, can provide scaffolds for the formation of new bone tissues. It plays a role of osteoconduction because its calcium and phosphorous can be free from the material surface and absorption of the new tissues. In the field of medical sciences, it is considered to be a vital aspect with respect to human health, and the bioactive ceramics such as HAp are attractive candidates for body's hard tissues replacement [1–4] among different categories. The application of HAp has excellent biocompatibility properties, but the application is limited due to its low strength and brittle nature, but it has excellent biocompatibility [5]. Prokopiev et al. [6] reported microstructure and mechanical properties of sintered HAp on the sintering temperature at fixed compaction pressure (20 MPa) and also observed that Young's modulus and shear modulus (isotropic) increase with sintering temperature between 1200 and 1280 °C. Lee et al. [7] studied about Al_2O_3 and ZrO_2. Due to their excellent oxidation resistance, good biocompatibility and wear resistance, they are considered as a matrix as well as reinforcement phases. Que et al. [8] reported the major effect on the HAp structure and enhanced HAp properties on addition of titania to HAp. Due to the introduction of secondary phases, the phase changes in the composites at higher sintering temperatures are observed. Viswanath and Ravi Shankar [9] studied the interfacial reactions in hydroxyapatite/alumina nanocomposite in which alumina reacted completely with hydroxyapatite. Xihua et al. [10] reported the fabricating of hydroxyapatite matrix ceramic composites with low cost; alumina is introduced in hydroxyapatite.

Yu et al. [11] reported the implication of nano-ZrO_2 on the mechanical properties of reinforced HAp bone cement. Hongbo et al. [12] investigated first of its kind the fabrication of laminated and functionally graded HAp/Y-TZP composites by means of the spark plasma sintering (SPS). The functionally graded HAp/Y-TZP and laminated HAp/Y-TZP are designed strong Y-TZP core-bioactive HAp layer structure, a non-symmetric Y-TZP layer to HAp later structure or a bioactive HAp core-strong Y-TZ player structure. Aminzare et al. [13] studied the nanocomposite by HEBM in order to obtain highly dense objects with desired mechanical properties. The phase decomposition and mechanical properties have been investigated with the effects of alumina and titanianoparticles on microstructure. Ahmed et al. [14] reported that the titanianano/hydroxyapatite composites produced by HEBM. The effect of addition of titania, sintering temperature, formed phases time and their influence regarding compressive strength of HAp were investigated. Khalil et al. [15] studied the mechanical and microstructure properties of hydroxyapatite and hydroxyapatite-yttria stabilized zirconia (3YSZ) with 20 vol%-(ZrO_2 + 3 mol% Y_2O_3) nanopowders developed by High Frequency Induction Heat Sintering (HFIHS) at different temperatures. The main objective of their study is to synthesize and then sinter the HAp–3YSZ powders with higher hardness, higher toughness,

grain size in fine scale and constituent distribution homogeneously. Oktar [16] observed the influence of sintering process of the composite materials, made of hydroxyapatite, that were derived from the bovine bone, with 5 and 10 wt% of TiO_2, on their mechanical properties. The mechanical properties of the produced composite materials revealed the developed microstructure and the phases formed during sintering effecting the densification. Mobasherpour et al. [17] adopted a precipitation method to synthesize nanocrystalline HAp and investigated the effects of ZrO_2–Al_2O_3 on mechanical properties of nanocrystalline HAp powder. Improved bending and the tensile strength of HAp by using La_2O_3, ZrO_2, and TiO_2 as binders have been observed by Shin-Ike et al. [18].

In the present study, the application of HEBM technique is to produce HAp/TiO_2 and HAp/ZrO_2 + TiO_2 nanocomposites and the effect of the addition of TiO_2 and ZrO_2 + TiO_2 to HAp on the microstructure and mechanical strength of the composites was investigated. The correlation between the mechanical and microstructural properties was systematically established.

56.2 Materials and Methods

56.2.1 Sample Preparation

Hydroxyapatite (HAp) and its composite powders of particle size 20–40 nm with various wt% of TiO_2 and ZrO_2 + TiO_2 (0, 5, 10, 15, 20 and 25 wt%) were combined with HAp by HEBM. Powders were milled under dry condition using tungsten carbide hardened steel balls for 1 h with rotational speed 300 rpm. The balls to powders ratio considered were 20:1. The milling powder samples were compacted under pressure of 100 bar at room temperature for dwell time 150 s. The equipment used for compacting has two channels which can operate from 0.005 to 200 bars and can go from room temperature to 500 °C. These compacted powders are made into cylindrical specimens (compression strength, hardness) which comprises of 20 mm diameter and 5 mm height and a plain specimen (flexural strength and fracture toughness) about 40 mm length, 10 mm width and 3 mm thickness. To sum, sintering was performed in normal atmosphere using electric resistance box furnace at 1200 °C and the heating time 1 h. The specimens were fed into the furnace and heated up to desired temperature. The heating time was calculated from the point at which the desired temperature has been reached. All the sintered samples were furnace cooled.

56.2.2 Experimental Procedure

X-ray diffractometer (XRD) equipped with Cu–K_α radiation (wavelength λ = 1.5406 Å°) is used to distinguish HAp and its composites. This test is operated between 6 and 90° using a step size of 0.01° which follows the width (β) of their

diffraction pattern; the average crystallite size (D) was estimated using Scherer's formula [14]. The microstructural information was known by field emission scanning electron microscopy (FESEM). The compositions of the elements Ca, P, O and Zr are evaluated using energy-dispersive analysis of X-rays (EDAX) attached with FESEM. The compressive strength of the nanocomposite ceramics of size 20 mm (diameter) and 5 mm (height) was conducted on UTM. The density of sinter samples was measured using distilled water by the Archimedes' method (relative density). This test was executed under a quasi-static loading range, where the initial strain rate (ε*) is fixed at 0.001 s^{-1}; i.e., the machine crosshead speed ($\vartheta = \varepsilon * h_o$) is 0.005 mm/s. And h_o is the specimen's initial height, where the test is conducted on specimens which are loaded up to fracture [14].

Hardness test (Knoop hardness indenter) is evaluated on the basis of polished HAp composites which were analyzed using the Shimadzu HMV-2000 microhardness tester. The load on the specimen 4.905 N and holding time of 15 s are used in the measurements as per ASTM E384. The width-to-length ratio of the indenter is 1:7.11. The concavity or indention depth is around (1/30)th of the longer dimension, and its face angle for the rectilinear edge is 172° and for the breadth is 130°.

Knoop hardness '*H*' can be determined by Eq. (56.1) as below [12]:

$$H = 14229 \frac{L}{d^2} \tag{56.1}$$

The load refers to '*L*' (Newton), and the longer diagonal of the indentation refers to '*d*' (mm).

Young's modulus along the composites was determined through the following Eq. (56.2) as given below [12]:

$$\frac{B'}{A'} = \frac{B}{A} - \alpha \frac{E}{H} \tag{56.2}$$

(B^1/A^1) gives the indent diagonal ratio, and (B/A) gives the ratio of the indenter dimensions. The term 'α' relates to a constant of a value of 0.45.

The three-point bending test is used to determine the flexural strength of the nanocomposite. The HAp composite specimens (40 mm length, 10 mm width and 3 mm thickness) were first prepared and refined to smooth out surface flaws before setting them on a three-point bending testing setup. The load (frame crosshead speed of 0.05 mm/min) was put from the top at middle of the bar. Through the indentation technique, the fracture toughness K_c (Eq. 56.3) was calculated, and the values were confirmed through the equation below [15]:

$$K_C = \xi \left[\frac{E}{H}\right]^{2/5} \frac{P}{d \times l^{1/2}} \tag{56.3}$$

'K_c' gives fracture toughness, 'E' refers Young's modulus (GPa), and 'H' gives the hardness (GPa). 'P' gives the applied load (N); 'ξ' shows the constant which is based on the geometry of the indenter ($\xi = 0.008$).

56.3 Results and Discussion

56.3.1 Microscopic Analysis

The morphologies of HAp and its composites are observed by a FESEM. HAp forms a crosslink with one and other during the growth process. This provides a conducive condition for the adhesion and growth of biological tissues. Figure 56.1 gives the XRD patterns of HAp and standard HAp (PdF card no. 74-0566). The diffraction pattern of HAp powder used for the current study is in good agreement with standard HAp pattern, and it is also observed that there are no reflections from impurities.

XRD patterns were used for the analysis of specimens which had undergone the process of pressing and then sintering at a temperature of 1200 °C. Figure 56.2 shows XRD patterns of HAp and its composites (HAp/TiO_2). When the TiO_2 powder was added, stronger peaks are detected along with HAp and TiO_2 when the compacting and the sintering processes were carried out under the same condition. With increase in TiO_2 (indicated with '$') content along with the HAp (indicated with '#'), TiO_2 phase reflections are present. Using Scherer's formula, all the XRD

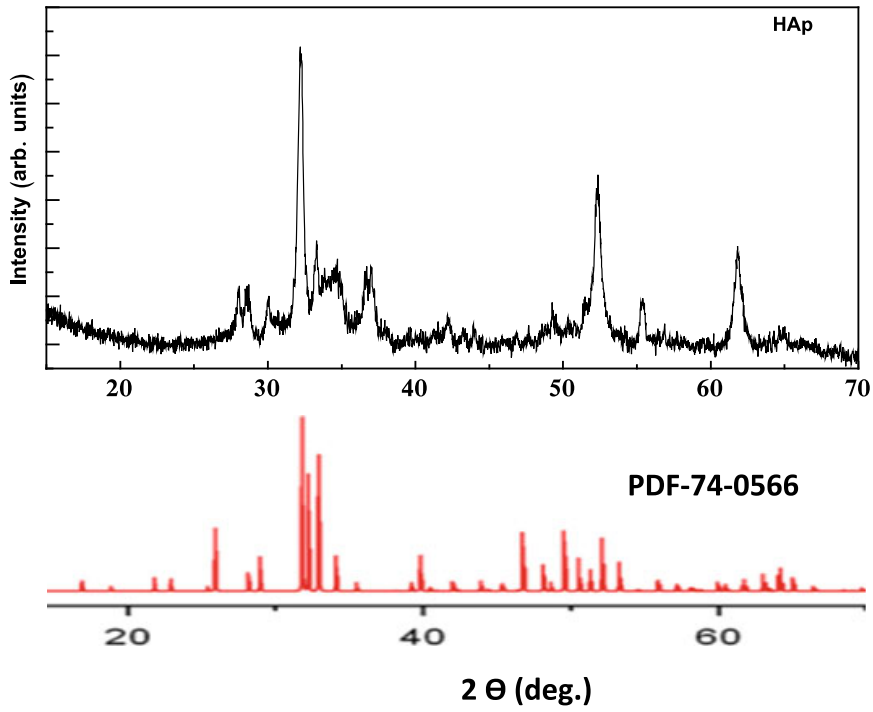

Fig. 56.1 XRD pattern of HAp sample and standard HAp

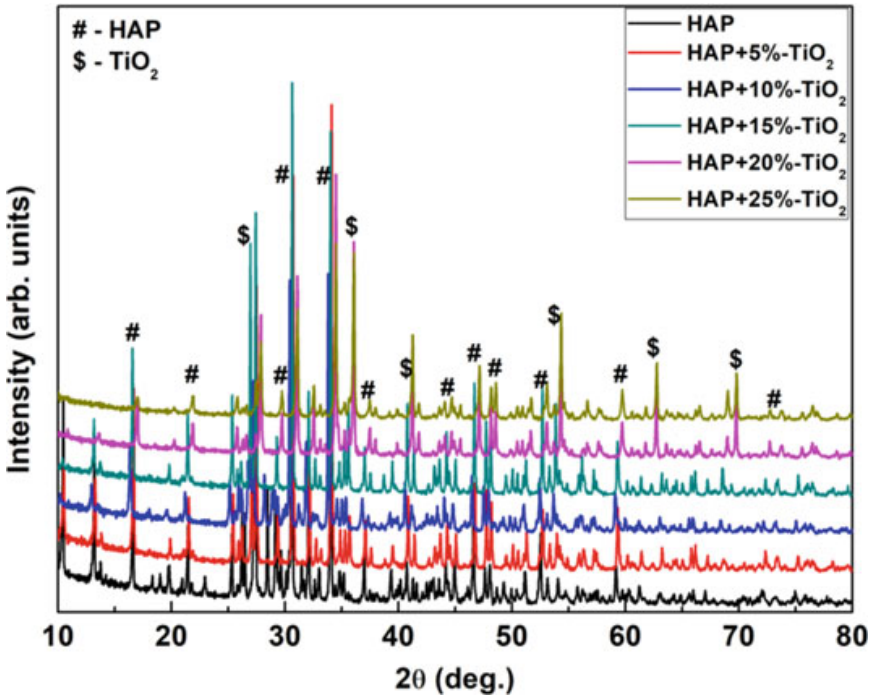

Fig. 56.2 XRD patterns of HAP/ZrO_2 composites after sintering

patterns crystallite sizes are calculated and observed, and they are in the range of 40.01–16.11 nm and 47.39–42.39 nm for HAp/TiO_2 and HAp/(TiO_2 + ZrO_2) composites, respectively. This shows clearly that there is a gradual decrease in the crystallite size when there is addition of TiO_2 in the process. It is analyzed with the increase of TiO_2 content; there will be increase in the reflections of TiO_2 phase. TiO_2 structural stability was studied with the improved TiO_2 content which in turn increased by intensities of diffraction patterns. There were no additional reflections due to the impurities.

Figure 56.3 depicts XRD patterns of HAp and its composites (TiO_2 + ZrO_2). The reflections observed were matched with the parent phase (HAp-marked with '#') and its composites (TiO_2 marked with '$' + ZrO_2 marked with '@'). It is observed that due to the impurities, there were no additional reflections. It is observed that ZrO_2 + TiO_2 attained more structural stability with increase in the diffraction patterns intensities due to the increasing of ZrO_2 + TiO_2 content. At 25 wt% of composite (TiO_2 + ZrO_2), strong tricalcium phosphate (TCP) peaks are detected along with zirconia and HAp. This formation of TCP may be attributed due to excessive reaction between the HAp and ZrO_2 with the improved wt% of ZrO_2 particles. The TCP structure is a typical biomaterial with excellent biocompatibility and osteoconductivity, by which the formation of new bone tissue is accelerated when these materials are implanted into the body which is observed by the Colon et al. [19]. TCP is fragile bioceramic and consequently cannot be used on their own as major load-bearing implants in the human body. From the identified phases as shown in Fig. 56.3, it can be seen that ZrO_2 has shown a dominant phase

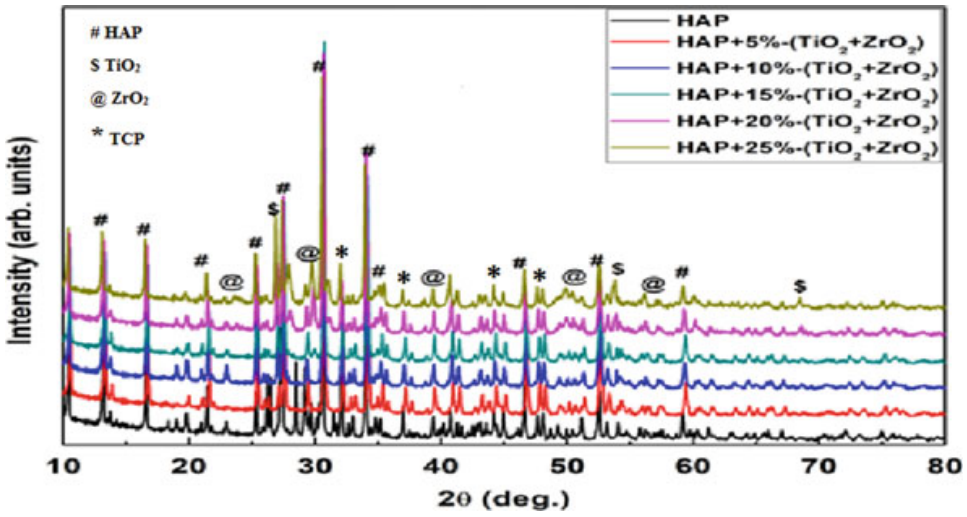

Fig. 56.3 XRD patterns of HAp/ZrO_2 + TiO_2 composites after sintering

over TiO_2 on addition of ZrO_2 + TiO_2 which is in good agreement with the studies conducted by Miao et al. [20].

Field emission scanning electron microscopy (FESEM) is used to analyze the morphology of the powders (HAp/5, 10, 15, 20 and 25 wt% TiO_2 and TiO_2 + ZrO_2) after HEBM. The morphology of the initial large particles is significantly changed due to fracture and de-agglomeration processes. After 1 h of HEB milling of the HAp/TiO_2 powders, sporadic-shaped morphologies are observed. These small particles were also observed after the cold welding phenomenon during ball milling.

FESEM micrographs of the HAp/TiO_2 composites which had undergone compacting and sintering at a temperature of 1200 °C with different wt% are shown in Fig. 56.4a–e. Based on the micrographs, it is observed that there is a considerable change in morphology due to the addition of TiO_2. This addition of different wt% may induce the nucleation which tends to the formation of leaf-like structures. The average size of leaf-like structure is observed around 18 μm, whereas a needle- and irregular shaped morphology of TiO_2 is observed for 25 wt% HAp/TiO_2 composite. Hence, it may be concluded that as the wt% of TiO_2 increases in the composite, the agglomerated irregular shape morphology is observed.

FESEM micrographs of the HAp/TiO_2 + ZrO_2 composites with different wt% are shown in Fig. 56.5a–e. A unique growth of rounded particle with small in size was exhibited by the composites with ZrO_2 + TiO_2 contents at various wt%. In Fig. 56.5a–e, the matrix is shown with smaller particles of ZrO_2 + TiO_2. From the micrographs, it is evident that there may be alteration in the composites microstructural properties due to the increase of ZrO_2 + TiO_2 content and homogeneous distribution of particles inside the grains which enhances mechanical properties. This may be attributed due to the interlocking of particles with the grain boundaries uniformly which can be observed from Fig. 56.5d and e.

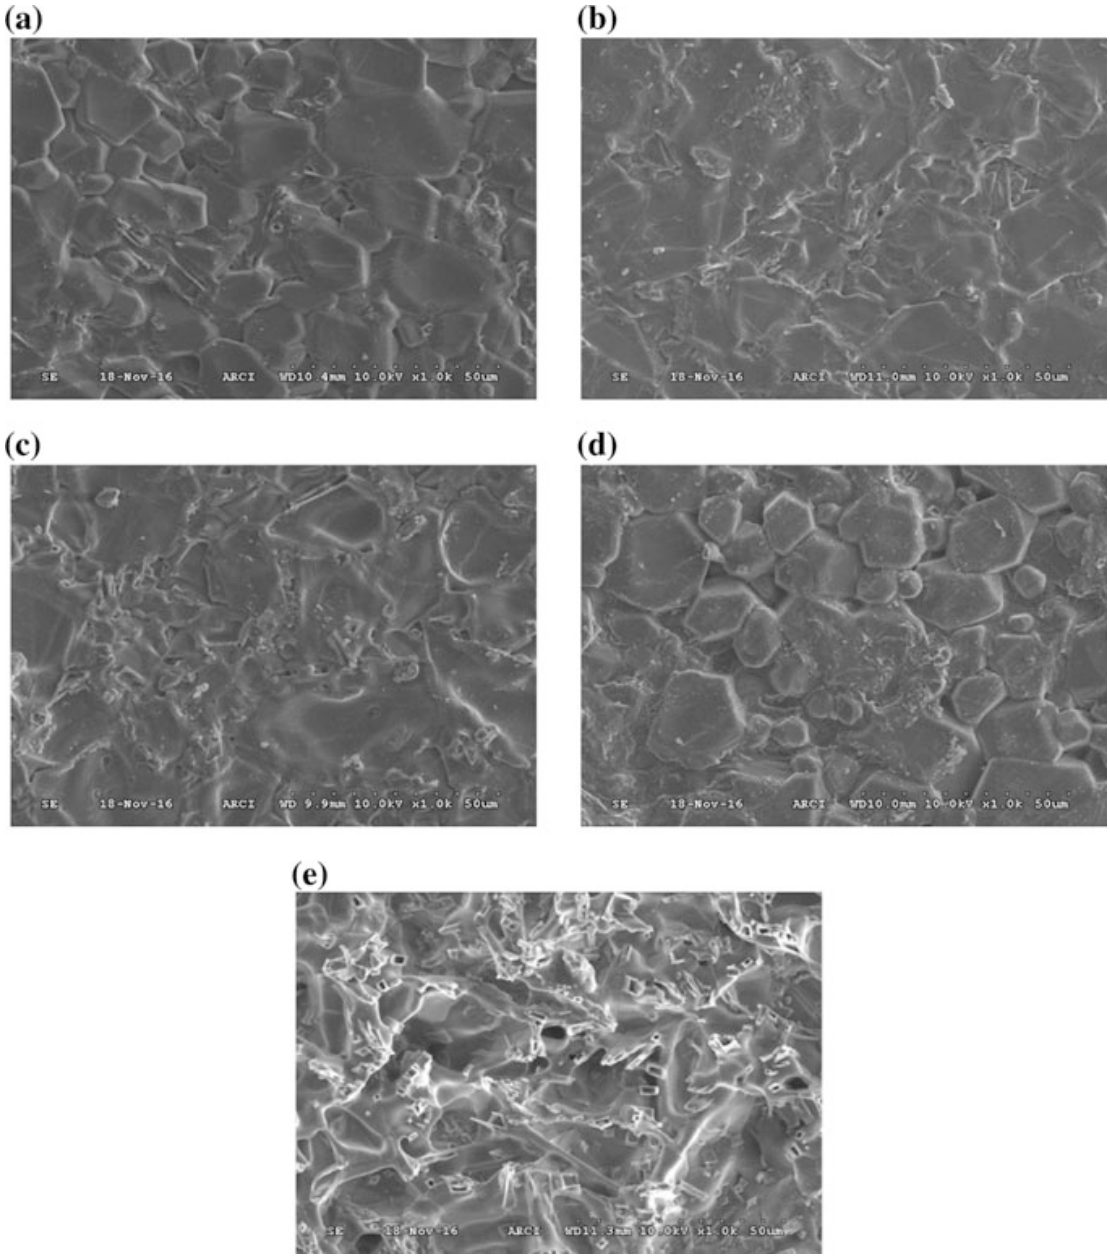

Fig. 56.4 FESEM micrographs of HAp/TiO_2 composites: **a** 5 wt%, **b** 10 wt%, **c** 15 wt%, **d** 20 wt% and **e** 25 wt%

Figure 56.6a shows energy-dispersive X-ray spectroscopy (EDX) analysis of HAp/TiO_2 composite. The presence Ca, P and Ti can be seen from the figure. Figure 56.6b shows the EDX analysis of HAp/TiO_2 + ZrO_2 composite. The EDX shows that Ca, P, Zr and Ti can be seen from Fig. 56.6b, whereas background grains exhibited strong Zr intensity but weak Ti intensity. The EDX results show that samples were free of metallic contaminants. However, contaminants could be found in very little percentages which are lower than the accuracy of the applied instrument.

Figure 56.7. shows the grain size of the HAp composites estimated from the ASTM line method [21] The grain size HAp/TiO_2 composite is observed to decrease gradually from 52 nm (5 wt% of TiO_2) to 20.1 nm with increase in TiO_2 content up to 25 wt%, whereas in HAp/ZrO_2 + TiO_2 composites, it is observed that the grain size is in the range of 42.1–19.09 nm.

56.3.2 Mechanical Properties

Based on the structural and morphological analysis, an attempt has been made to understand the formation mechanism of the composites TiO_2 and ZrO_2 + TiO_2. The measured density of HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites is shown in Fig. 56.8.

Calculated densities of HAp/TiO_2 and HAp/TiO_2 + ZrO_2 (5, 10, 15, 20 and 25 wt%) samples sintered at 1200 °C for 1 h are in close agreement with theoretical density. The density is found to be increasing gradually with TiO_2 content. With increase in TiO_2 content, it can be attributed that the grain size of HAp/TiO_2 composites decreases. The maximum density for HAp/TiO_2 + ZrO_2 composites has been obtained at 20 wt% reinforcement content. When 25 wt% of reinforcement is added to HAp, the density is found to be decreased, due to the background grains with strong Zr intensity but weak Ti intensity [20] of HAp nanocomposites, Fig. 56.5. Khalil et al. [15] has observed HAp and HAp-20 vol% 3YSZ composites at different sintered temperatures by HFIHS process.

Figure 56.9 shows the variation of hardness with reference to wt% of HAp composites. The effect of reinforcement on hardness of HAp composites can be studied as a function of density and grain size.

The increment of hardness is observed from 6.01 to 10.03 GPa. With the improvement in the TiO_2 content, the hardness of the HAp composites has been increased; at that time, grain size was observed a gradual decrease, whereas the density and the hardness increased. Among all the HAp composites (5, 10, 15, 20 and 25 wt%), maximum hardness value is 10.03 GPa, observed for the 25 wt% TiO_2 content. However, for HAp/ZrO_2 + TiO_2 composites, the hardness is increased from 5.56 to 14.01 GPa, with increasing content of ZrO_2 + TiO_2 from 5 to 20 wt%. The highest hardness (14.01 GPa) has been observed at 20 wt% ZrO_2 + TiO_2 content. Interestingly, a drop in hardness (9.98 GPa) has been observed for 25 wt% ZrO_2 + TiO_2 content. The similar work was conducted by Guo et al. [12] is observed to be in good agreement with Knoop hardness values (7.5 GPa at 20 wt% of Y-TZP) observed.

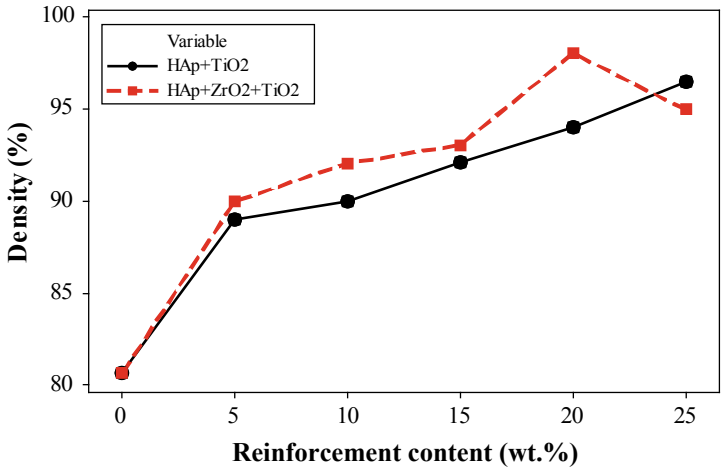

Fig. 56.8 Variation of density in HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites

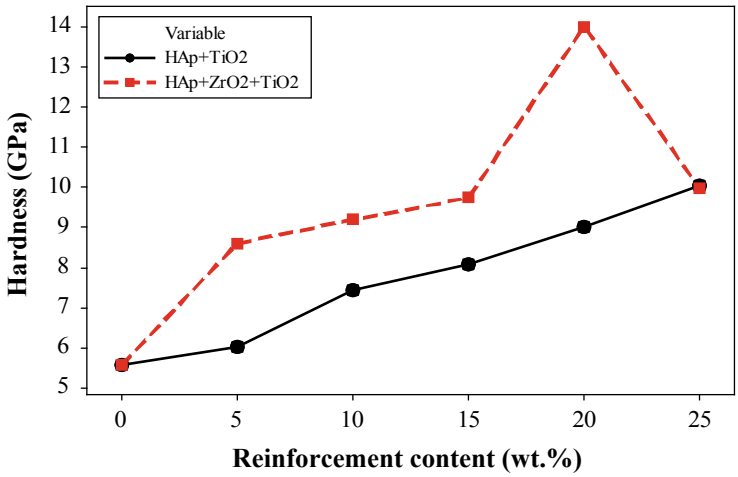

Fig. 56.9 Variation of hardness in HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites

Figure 56.10 shows Young's modulus of HAp/TiO_2 and HAp/ZrO_2 + TiO_2 sintered composite samples. With increase in wt% of TiO_2 content, Young's modulus of the HAp/TiO_2 composites is increasing from 91.2 to 128.5 GPa. The highest value of Young's modulus of 128.5 GPa has been obtained for 25 wt% of TiO_2 composite, whereas for HAP/ZrO_2 + TiO_2 composites, Young's modulus of the HAp composites was found to be increasing from 89.09 to 328.08 GPa. Young's modulus of sintered HAp composites samples increases with increasing ZrO_2 + TiO_2 content. For the HAP/ZrO_2 + TiO_2 composites, Young's modulus reaches a maximum at 20 wt%, reinforcement content followed by a slight decrease for 25 wt% composite. With increase in reinforcement content, grain size decreases and density increases; as a result, hardness is improved. The effect of the ceramic as additives is to improve the density and young's modulus values [8]. Due to the same reason, Young's modulus has also been improved with increase in reinforcement content.

Figure 56.11 shows the fracture toughness trend for HAp/TiO_2 and HAp/ZrO_2 + TiO_2 sintered composites with varying wt% of reinforcement. The fracture toughness is found to be varying from 0.742 to 3.05 MPa $m^{1/2}$. The highest value of fracture toughness of 3.05 MPa $m^{1/2}$ has been obtained for 25 wt% of TiO_2

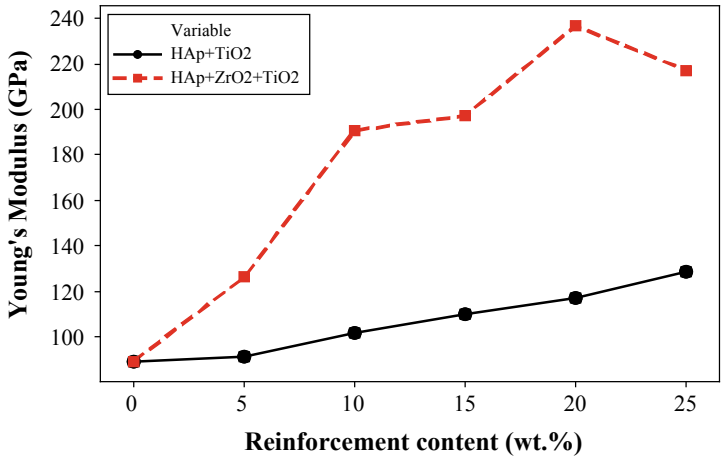

Fig. 56.10 Variation of Young's modulus in HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites

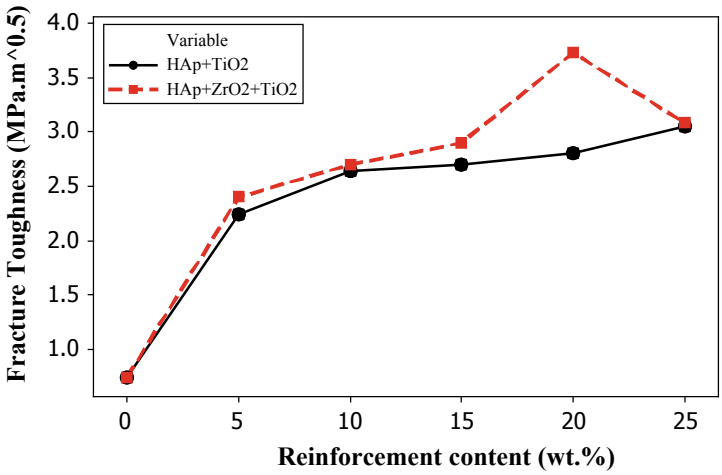

Fig. 56.11 Variation of fracture toughness in HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites

composite, whereas for HAp/ZrO_2 + TiO_2 composite, the values vary from 0.742 to 3.73 MPa $m^{1/2}$ and maximum fracture toughness 3.73 MPa $m^{1/2}$ has been obtained at 20 wt% of composite. Upon further addition of reinforcement content, i.e. 25 wt%, there is a drop in fracture toughness. It is true that hardness and Young's modulus depend on the density and grain size of composite. Further, it can also be concluded that fracture toughness in turn depends on hardness and Young's modulus.

Figure 56.12 shows the flexural strength of HAp/TiO_2 and HAp/TiO_2 + TiO_2 composites. With increasing wt% of TiO_2, the flexural strength varies from 50–206 MPa for HAp/TiO_2 composite. The highest value of fracture toughness of 206 MPa has been obtained for 25 wt% of TiO_2 composite, whereas for HAp/ZrO_2 + TiO_2 composites, the flexural strength varies from 50 to 236.8 MPa, and the maximum flexural strength is observed at 20 wt% of HAp/ZrO_2 + TiO_2 composite after which there is a dropin flexural strength for 25 wt% of reinforcement. The sintered samples with higher density improved mechanical properties, flexural strength, compression strength and hardness. Oktar [16] observed same results for bending and hardness at different temperatures, strength 86.2 MPa and hardness 143.5 HV (HAp-TiO_2 5 wt% at 1200 °C).

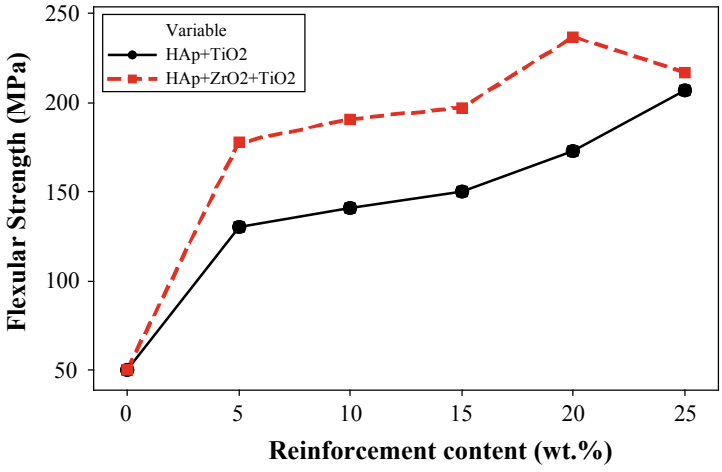

Fig. 56.12 Variation of flexural strength HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites

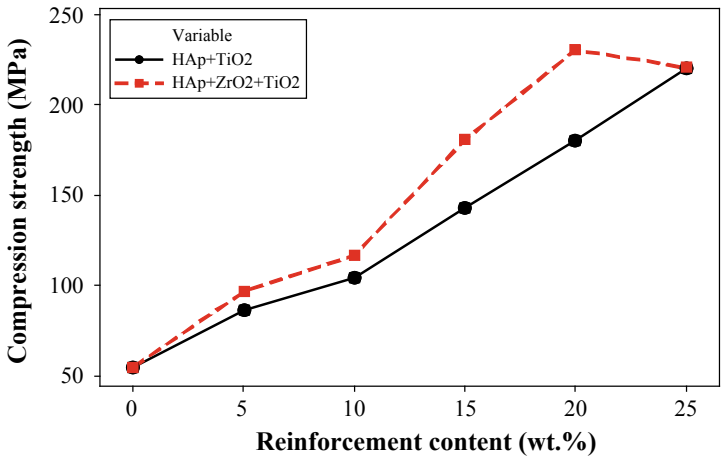

Fig. 56.13 Variation of compressive strength for HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites

Figure 56.13 can be observed that for HAp/TiO_2 composite, the compression strength varies from 50 to 220.06 MPa with increasing wt% of TiO_2. The maximum compression strength of 220.6 MPa is obtained at 25 wt% TiO_2, whereas the HAp/(ZrO_2 + TiO_2) composite has compression strength values in the range of 50–230.67 MPa. The maximum compressive strength of 230.67 MPa was obtained for 20 wt%, after which it shows a drop in compression strength. The reason can be attributed to the increase in the dispersion of reinforcement particles in the matrix phase, Figs. 56.4 and 56.5. Que et al. [8] observed the hardness and young's modulus of the pure HAp samples and the HAp/TiO_2 (10 mol%) composites as a function of the sintering temperature. The highest hardness and Young's modulus, which are 2.81 and 45.33 GPa, respectively, are obtained at the sintering temperature of 1100 °C. Salman et al. [22] presented the fabrication and characterization of composite materials of hydroxyapatite and Ti. Hydroxyapatite (HA) powder was obtained from bovine bones (BHA) and human enamel (EHA) via calcination technique. Powder-compacts were sintered at different temperatures between 1000 and 1300 °C. The best mechanical properties for BHA–Ti composites were obtained after sintering in the range of 1200–1300 °C and for EHA–Ti composites in the range of 1100–1300 °C.

56.4 Conclusions

The HAp/TiO_2 and HAp/ZrO_2 + TiO_2 composites are successfully prepared using HEBM. All the mechanical properties are investigated with HAp and its composites. It is observed that with increase in reinforced content wt% of composite the mechanical properties are found to be improved.

The following major observations can be drawn from the present investigation:

i. All the composites of HAp and TiO_2 possess hardness values of 5.56–10.3 GPa, and the hardness values of HAp/ZrO_2 + TiO_2 composites lie in the range of 5.56–14.01 GPa.

ii. Young's modulus of the sintered HAp/TiO_2 composites varied from 89.09 to 128.5 GPa. Young's modulus of the sintered HAp/ZrO_2 + TiO_2 composites varied from 89.09 to 328.08 GPa which are high compared to the pure HAp.
iii. The composites of HAp and TiO_2 fracture toughness are found to be in the range of 0.742–3.05 MPa $m^{1/2}$, and HAp/ZrO_2 + TiO_2 composites fracture toughness was found to be in the range of 0.742–3.73 MPa $m^{1/2}$. Comparing the hardness, young's modulus and toughness of pure HAp, HAp/TiO_2 and HAp/(ZrO_2 + TiO_2), composites with 20 wt% are found to yield better.
iv. The flexural strength of HAp/TiO_2 composites increased from 50 to 206 MPa, whereas the flexural strength of HAp/ZrO_2 + TiO_2 composites was found to increase from 50 to 236.8 MPa.
v. The compressive strength of HAp/TiO_2 composites for 25 wt% addition is 220.67 MPa significantly higher than pure HAp, whereas the compressive strength of the 20 wt% HAp/ZrO_2 + TiO_2 composites is 230.67 MPa which is higher than pure HAp.
vi. By adding ZrO_2 + TiO_2, all the mechanical properties have been enhanced. HAp/ZrO_2 + TiO_2 composites had better mechanical properties than that HAp/TiO_2. The investigated biocomposite materials can be used for implant applications.

Parametric Optimization of Corrosion Resistance of Electroless Ni–Co–P Coating

Subhasish Sarkar, Rishav Kumar Baranwal, Ishita Koley, Rupam Mandal, Tapendu Mandal and Gautam Majumdar

Abstract This research paper investigates the effect of cobalt on the corrosion resistance of electroless Ni–P coating by forming a ternary alloy with Ni–P. The corrosion resistance offered by the ternary coating was measured for coating formed by varying the composition of the bath. The varying bath parameters were the concentration of cobalt source (cobalt sulphate) (A), concentration of reducing agent (sodium hypophosphite) (B) and the temperature (C) of the bath. The corrosion resistance was measured using electrochemical impedance spectroscopy (EIS). Taguchi's method has been applied with corrosion resistance as response operator to find the optimum resistance to corrosion and the optimum bath parameters, and along with it, ANOVA is done to find significant interactions between factors. The scanning electron microscopy (SEM) and energy-dispersive X-ray spectroscopy (EDAX) were performed to find the surface morphology and surface composition of the optimized coating.

Keywords Taguchi · Corrosion resistance · ANOVA · Surface morphology

57.1 Introduction

Coatings in the recent time have gathered attention of many researchers as they enhance and introduce different surface properties. Their increased application in the industry [1] is one of the main reasons for it. Coatings can be done by various techniques like electrodeposition, physical vapour deposition, chemical vapour deposition and electroless coating. We have used the electroless technique as it is advantageous. Ni–P coatings are better known for their corrosion resistance [2]. The mechanical and tribological properties can be improved with the help of various heat

treatment techniques. However, this can also be achieved with the help of using different elements and complexes. Corrosion is such a phenomenon which degrades the life of metals and causes unpredictable failure in various applications of such metals. Hence, it is very essential to improve the corrosion resistance of the metals or superimpose a coating which has ameliorated anticorrosion properties. This coating has a sacrificial nature. So, in order to increase the corrosion resistance, the introduction of a third element/complex has been preferred [3–5]. The use of cobalt in binary coatings has provided better microhardness compared to the binary coatings [12]. Cobalt introduces a new property of electromagnetic shielding [6, 7] in Ni–P coatings while increasing the corrosion resistance of the coating at the same time.

A number of optimization techniques have been used in the past to optimize the coating [8–11]. We have applied the Taguchi L_{27} orthogonal array design to optimize the corrosion resistance. The Taguchi analysis showed that the level 3 of A, level 3 of B and level 1 of C were the optimized parameters. Analysis of variance (ANOVA) has been applied to find the significant factors and the significant interactions which affect the corrosion resistance. It has been found that all the interactions between the factors are significant for the corrosion resistances. The corrosion resistance of the coatings was measured using EIS. The optimized corrosion resistances were 24.525 and 476.17 Ω cm^2. The EDAX analysis showed the weight percentage of cobalt at 10.90% which is just enough to improve the hardness and induce electromagnetic shielding. The nodular grains present in the coatings were shown by SEM analysis.

57.2 Experimental Methods

The coating took place over copper substrates of thickness 0.1 mm and dimensions 2 × 1.5 mm^2. The pre-treatment of the substrate surface was done by acid cleaning process in 25% HCl for 90 s. The surface of the substrate was activated by using palladium chloride solution at 55 °C for 10 s. It was then rinsed with distilled water, and then, it was immersed in the electroless bath.

The electroless bath consisted of nickel sulphate hexahydrate, cobalt sulphate, sodium hypophosphate, tri-sodium citrate dehydrate and ammonium sulphate. Their respective concentrations are given in Table 57.1.

Table 57.1 Bath composition

Bath constituents	Reagents	(g/L)
Nickel source	Nickel sulphate hexahydrate	5
Cobalt source	Cobalt sulphate	10/15/20
Reducing agent	Sodium hypophosphate	20/25/30
Complexing agent	Tri-sodium citrate dehydrate	15
Buffering agent	Ammonium sulphate	10

The temperature of the bath was varied between 80, 85 and 90 °C. The bath volume was 200 ml, and the deposition time was 60 min.

Cobalt sulphate and sodium hypophosphate control the percentage of cobalt and phosphorus in the coating, respectively, while temperature controls the rate of deposition of the coating.

To study the electrochemical behaviour or corrosion behaviour, standard electrochemical potentiodynamic polarization tests of the above specimens were performed using three electrode corrosion cells in 3.5% Na Cl solution (3.5 g of NaCl in 100 ml double-distilled water). Polarization experiments were carried out as per ASTM standard methods (ASTM G5: Potentiostatic and Potentiodynamic Anodic Polarization Measurements and ASTM G59: Polarization Resistance Measurements) using OrigaLys Potentiostat (software: OrigaMaster 5) with a voltage range from −900 to +600 mV and a scan rate of 1 mV/sec. Electrochemical impedance spectroscopy (EIS) was done to know the surface morphology of the effected region after potentiocyclic voltammetry testing. The frequency range for EIS was from 100 kHz to 100 Hz with initial voltage of 10 mV. The corrosion resistances of each coating are shown in Table 57.2. The corrosion resistance was calculated using the Randles circuit, which forms a double-layer capacitance at the interaction of the coatings'

27	20	30	90	344.27

surface and the corroding medium. The two layers are formed due to charge transfer across the two different phases at the interaction point.

Design of experiments is an effective tool to determine the optimum conditions. The Taguchi method uses 'larger the better' technique in the present case to optimize the coatings' response. The varying parameters in the bath are called factors, while the different values of a parameter are called levels. We used three factors, and each factor had three levels. The Taguchi method uses the signal-to-noise ratio for finding the optimum conditions for optimum resistance. More positive value of S/N ratio means lesser noise which in turn indicates the best level in that factor. With the help of ANOVA, we can identify the significant parameters and the significant interactions. This is done by interpreting the interaction plots between AxB, BxC and AxC.

The surface morphology and its composition were determined by SEM and EDAX, respectively.

57.3 Results

Taguchi Analysis:

The larger the better uses the following formula for calculating the S/N ratio:

$$\frac{\mathrm{S}}{\mathrm{N}} = -10\log_{10}\left[1/n\left[\sum\frac{1}{y^2}\right]\right]$$

The S/N ratio is the ratio of the desired signal to the undesired noise, which is calculated using the above-mentioned formula. If for a particular level of a factor, signal is high with lower noise; it will indicate a higher S/N ratio which is desired.

Using this concept, the plots of S/N ratio for different levels of each factor are shown in Fig. 57.1.

The average S/N ratio for each factor is shown by the dotted lines in Fig. 57.1.

From Fig. 57.1, we can see the most positive values are achieved for level 3 of A (cobalt sulphate), level 3 for B (sodium hypophosphate) and level 1 for C (temperature of bath). Thus, the optimized coating is A3B3C1, which is the 24th experiment having resistance as 233.98 Ω cm^2.

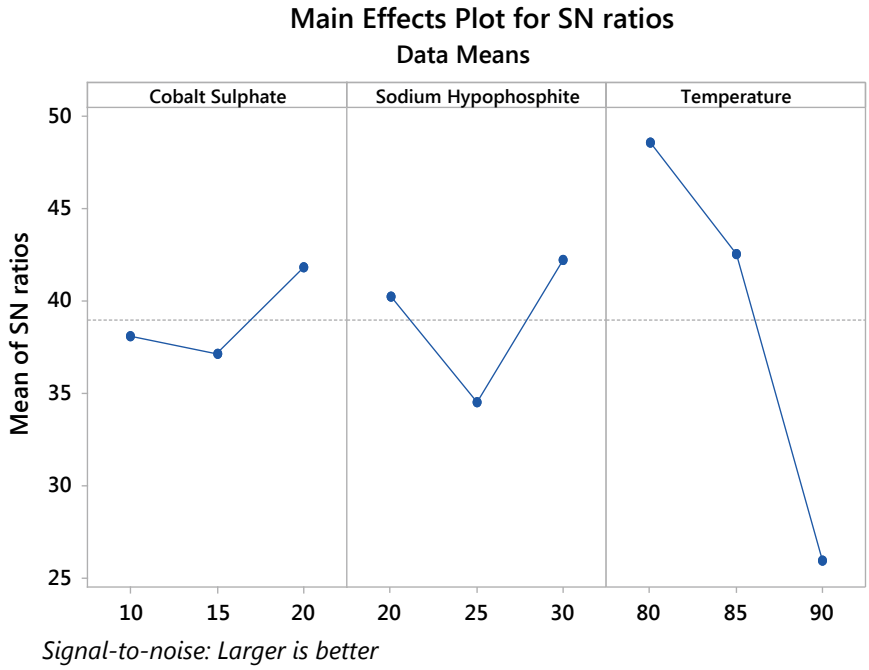

Fig. 57.1 S/N ratio of three levels of each parameter

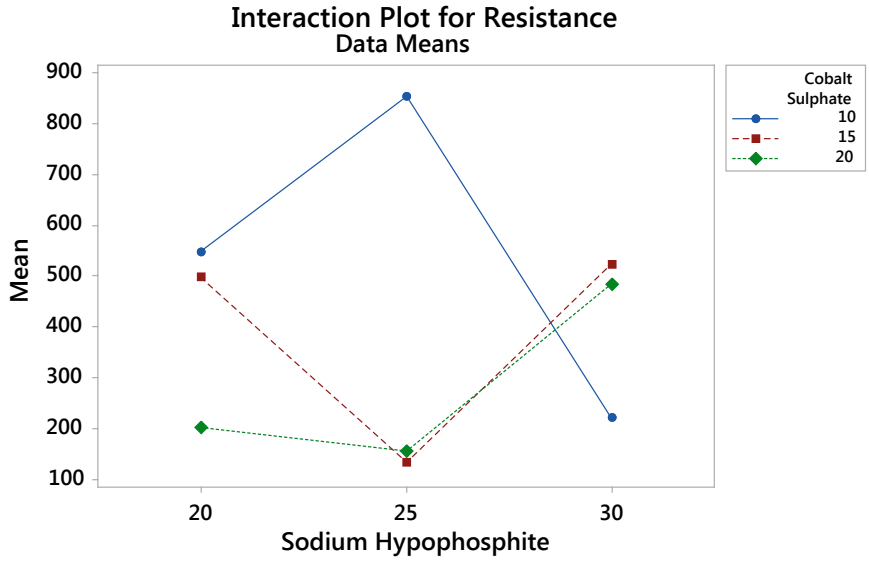

Fig. 57.2 Interactions between cobalt sulphate and sodium hypophosphite

The ANOVA results for R1 and R2 can be interpreted from Figs. 57.2, 57.3 and 57.4.

The blue, red and green lines represent the levels 1, 2 and 3, respectively, of the factors. If these lines remain horizontal or parallel to each other, then insignificant interactions between the factors have taken place. On the other hand, if the lines are inclined to each other and intersect at many points then good interactions have taken place between the factors. So for resistance offered to corrosion, we can say clearly, by observing the graphs that good interactions exist between A, B and C.

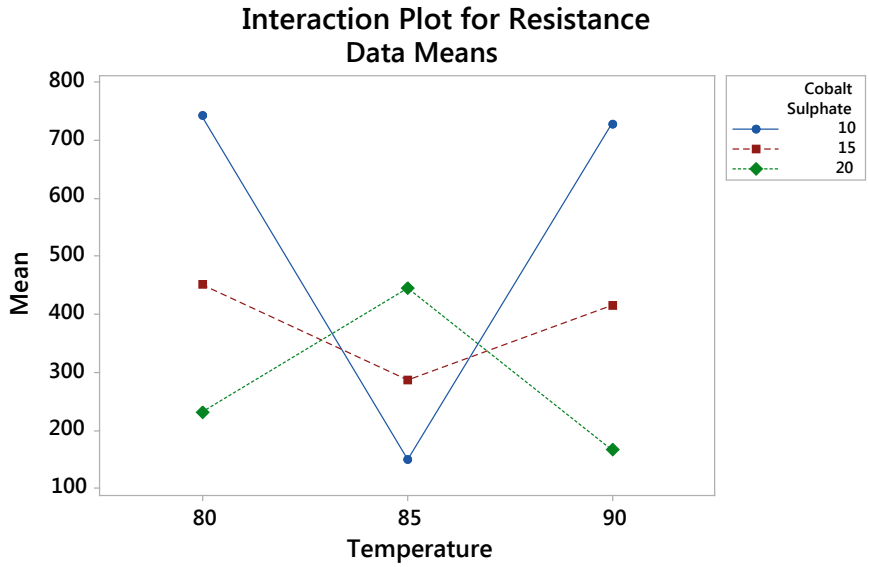

Fig. 57.3 Interactions between cobalt sulphate and temperature

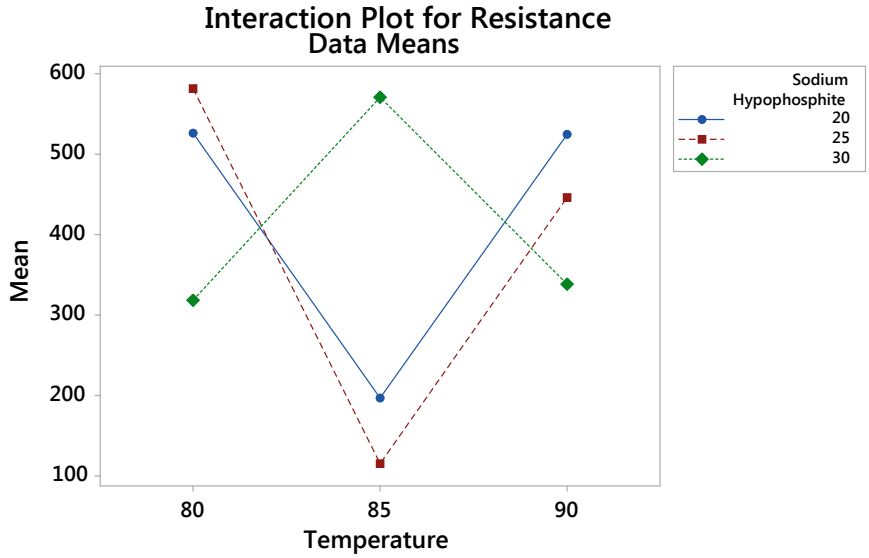

Fig. 57.4 Interactions between temperature and sodium hypophosphite

The energy-dispersive X-ray analysis shows the percentage of different elements on the surface of the coatings (Fig. 57.5). Its results are shown in Table 57.3. The cobalt % is 10.9% which is very influential in improving the various properties [12] and in this case corrosion resistance.

The composition is as shown.

Scanning electron microscopy was done to study the deposition on the surface of copper. Figure 57.6 shows the homogeneous deposition with very small agglomerated materials as globules. Since the surface is fully intact with coating. Hence, the porosity of the coating is very low. With low porosity, the corrosion agents which when gets deposited on the surface are unable to penetrate the surface of the coating which allows the coating to have higher corrosion resistance.

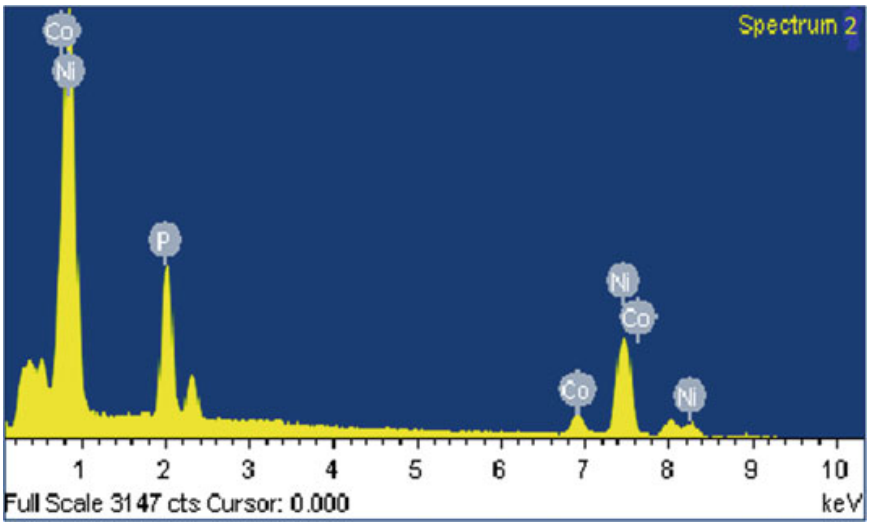

Fig. 57.5 EDAX image of the optimized sample

Table 57.3 EDAX result

Element	Weight %	Atomic %
Ni	76.89	69.34
Co	10.90	9.79
P	12.21	20.87

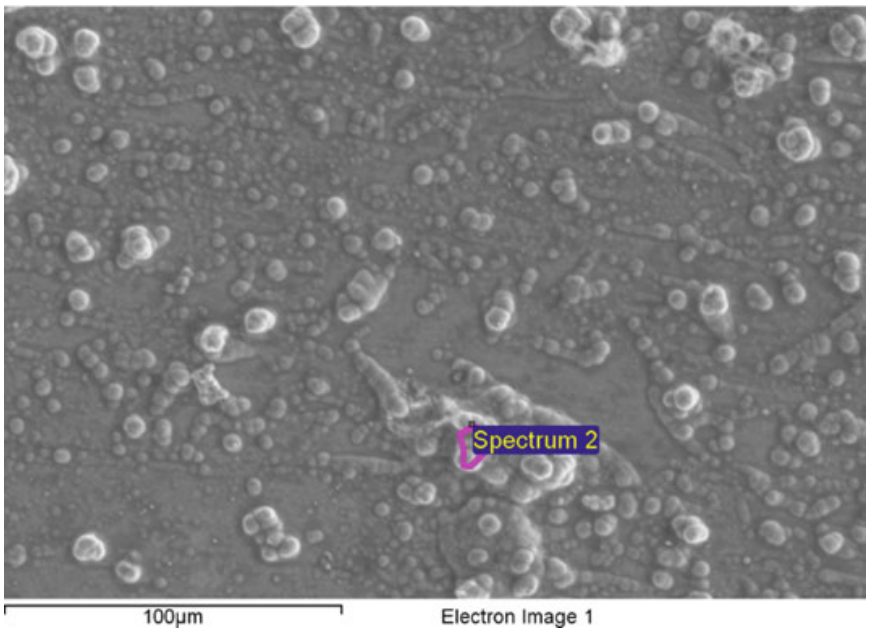

Fig. 57.6 SEM image of the coating

57.4 Conclusion

The electroless coating was optimized using Taguchi's method, and the optimized conditions are as follows: cobalt sulphate—10 g/L, sodium hypophosphite—30 g/L and temperature of bath at 80 °C. The increased resistance of the coating will have sacrificial behaviour. ANOVA results show that the interactions between each level (3 levels) of different factors (cobalt sulphate, nickel sulphate and temperature) are significant in determining the corrosion resistance of the coating. SEM results reveal intact coating taking place which allows the corrosion resistance to increase by hindering the movement of corroding materials into the substrate. The EDAX results show the weight percentage of cobalt at 10.9% which is enough to increase the corrosion resistance of the substrate material.

Acknowledgements We would like to thank Professor Deb Dulal Das of IIEST Shibpur, for the SEM and EDAX analysis.

Chapter 58
Investigation on Dimensional Accuracy for CFRP Antenna Reflectors Using Autoclave and VARTM Processes

Tushar Gajjar, Dhaval Shah, Shashikant Joshi and Kaushik Patel

Abstract The carbon fibre reinforcement polymer (CFRP) is widely used in space applications, automobile industries, aerospace and sports equipment because of good specific properties over conventional metals and alloys. Autoclave processing is one of the best manufacturing techniques to achieve high-dimensional accuracy for complex-shaped component. But, due to high initial and processing cost, vacuum-assisted resin transfer moulding (VARTM) is the alternative manufacturing method. In this research paper, CFRP antenna reflectors have been manufactured using autoclave process and VARTM manufacturing process to evaluate dimensional accuracy. The part thickness of laminate and layup orientation has been considered as a processing parameter in reflector manufacturing. The dimensions of the inner surface of the manufactured reflectors have been measured using 3D scanning techniques at the different locations. The deviation between theoretical CAD model and reflector dimensions at each location provides dimensional inaccuracy for the fabricated reflectors. The investigation on the dimensional inaccuracy of cured reflectors manufactured using the autoclave and VARTM manufacturing techniques has been carried out and the percentage difference has been found within the acceptable limit.

58.1 Introduction

The composite material is a combination of two or more materials which are widely used in aerospace industries, space applications, automobiles and sports industries due to its high strength-to-weight ratio [1]. A prepreg is a pre-impregnated fibre and available as unidirectional, bi-directional and twill fabric tape [2]. The autoclave curing process is widely used for making complex-shaped composite components because of high-dimensional accuracy. But, due to high capital as well as processing cost, VARTM process is the alternative manufacturing method. The variation between cured laminated composite part dimensions and theoretical dimension is usually referred as spring-back deformation or warpage depending on the shape of components.

Many researchers worked on the prediction of the spring-back deformation and warpage for the composite products. Darrow and Smith [3] occupied three process parameters—thicknesses cure shrinkage, fibre volume fraction gradients and mould expansion that effects on spring-back deformation. Fernlund and Poursartip [4] exhibited the effect of the cure cycle and tool surface condition on spring-back deformation. Kaushik et al. [5] calculated the effectiveness of various parameters like pressure, degree of cure and ramp rate on the coefficient of friction in the autoclave process. Kappel et al. [6] measured the effect of crucial parameters such as part thickness, layup, part radius and scattering of occurring distortion during the autoclave manufacturing process. Correia et al. [7] developed an analytical formulation of governing equation for incompressible flow and this model successively used to measure the effect of process parameters such as inlet and outlet pressure, fibre architecture and layup orientation. Govignon et al. [8] performed experimentation on thickness variation during compaction to replicate reinforcement behaviour while pre-filling, filling and post-filling stage. Hammami et al. [9] studied the effects of the processing variables in vacuum infusion moulding process by developing the one-dimesional model. The compaction test was conducted with the maximum compaction pressure not beyond 0.1 MPa. It was established that for low compaction pressures (≤ 0.1 MPa), the number of layers did not have a significant effect on the compaction behaviour of the preform. Arulappan et al. [10] performed experiments on CFRP material with flat plate, *L*-shaped plate and the flat plate with a central circular hole. The pressure was varried for different shape. The flow of resin depends on flow medium. For large structure, high permeability medium (HPM) was selected for getting high flow rate and reduced filing time. Song et al. [11] developed an experimental model for incorporating resin flow through the preform as well as relaxation of the preform because resin pressure and part thickness variation were parameters in VARTM which play a vital role in manufacturing component.

In this research paper, autoclave and VARTM manufacturing processes have been used to predict dimensional accuracy of CFRP antenna reflectors. The AISI 430 grade stainless steel material has been chosen for manufacturing of parabolic mould. The thickness of the laminate and layup orientation has been considered as

process parameters. The Hinpreg A45 CFRP prepreg is used in autoclave process, whereas carbon fibre dry fabric along with epoxy resin 520 and D-type hardener is used in the VARTM process. The parabolic-shaped reflectors have been cured using autoclave and VARTM processes. The dimensions at the inner surface of manufactured CFRP reflectors have been measured using 3D scanning techniques at different 200 locations. The deviation between the theoretical CAD model and reflector dimensions at each location gives dimensional inaccuracy or spring-back deformation for the manufactured CFRP reflectors. The comparison of spring-back deformation of cured reflectors manufactured using autoclave and VARTM manufacturing techniques has been carried out. The reflectors with different thickness and layup sequences have been fabricated using both manufacturing techniques, and dimensional accuracy has been matched.

58.2 Experimental Preparation

The stainless steel AISI 430 grade has been identified as mould material with 300 × 300 × 70 mm size. The 3D model of the parabolic mould has been prepared using solid modelling software. The dimension of the parabolic profile at one side is 240 mm circumferential diameter with 50 mm depth. The stainless steel mould block has been machined using NC code in 5–axis vertical milling centre with very high surface finish as shown in Fig. 58.1.

58.2.1 Reflectors Manufacturing Using Autoclave Process

The Hinpreg A45 unidirectional prepreg tape has been selected for the autoclave experimental process. Layers of prepreg are cut into the round shape of 300 mm diameter depending upon the required number of laminates and thickness as shown in Fig. 58.2. The consolidation materials like release agent, peel ply, breather cloth, vacuum bagging, etc. have been used in the autoclave process. In the autoclave process, the entire release agent has been applied on the parabolic mould surface.

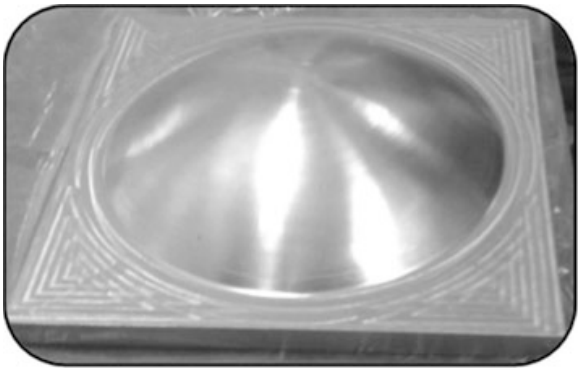

Fig. 58.1 Manufactured stainless steel mould

Fig. 58.2 Unidirectional cut prepreg

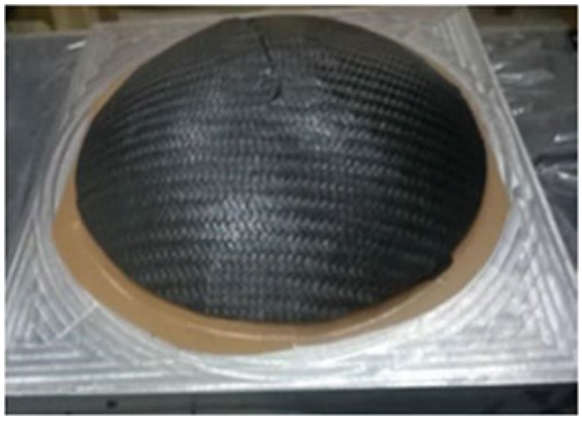

Fig. 58.3 Layers of CFRP prepreg on steel mould

The arrangement of prepreg layers with proper orientation is shown in Fig. 58.3. Peel ply permits free passage of volatiles and excess matrix while curing. To apply the vacuum and guide the removal of air and volatiles from the assembly, the breather fabric has been provided. Thicker breathers are required during great autoclave pressures. Sealant tape and vacuum bag are used for sealing the entire assembly. The whole set-up has been vacuum bagged with the help of vacuum film, vacuum valve and hose pipe as shown in Fig. 58.4.

Fig. 58.4 Vacuum bagging and air suction process

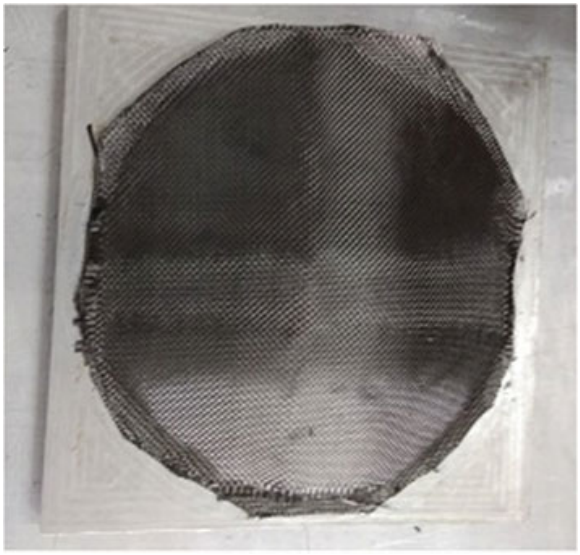

Fig. 58.5 Four layers of carbon fibre

58.2.2 Reflectors Manufacturing Using VARTM Process

The parabolic shape reflectors are also manufactured using the VARTM process. The dry carbon fabric has been selected as a reinforcement and epoxy resin 520 and D-type hardener as a matrix material in the VARTM experimental process. The epoxy resin 520 having mix viscosity at 27 °C of 650 ± 100 MPas, the specific gravity of 1.15–1.18 g/cm^3 and pot life at 27 °C of 1.5–2 h has been considered. Similarly, D-type hardener consists of tensile strength of 70 MPa, the flexural strength of 120 MPa and impact strength of 80 N/m is mixed with one-fourth of resin ratio. The vacuum pump, infusion mesh, purported plastic, catch pot, etc. have been used for VARTM process. The layer of the release agent is applied on the paraboloid surface of the mould for ease of demoulding. The four layers of carbon fibre have been arranged on the mould surface in the proper sequence as shown in Fig. 58.5. Similarly, peel ply, purported plastic and infusion mesh are placed on fibre layers simultaneously and the whole assembly is sealed using sealant tape and vacuum bag as shown in Fig. 58.6. The PVC hose pipe is attached at resin inlet and another side for obtaining vacuum pressure. The resin is sucked into the system because of vacuum pressure as shown in Fig. 58.7.

58.2.3 Curing of CFRP Reflectors

In the autoclave process, the entire set-up—mould, composite prepreg along with consolidation materials, is kept in autoclave machine for curing purpose as shown in Fig. 58.8. The mould along with consolidate material has been cured for twenty-four hours at an atmospheric temperature in the VARTM process as shown in Fig. 58.9. The atmospheric pressure of 1 bar in VARTM, whereas 5 bar pressure in autoclave is retained machine throughout the curing cycle.

Fig. 58.6 Vacuum bag along with sealant tape

Fig. 58.7 Resin inlet hose and vacuum hose

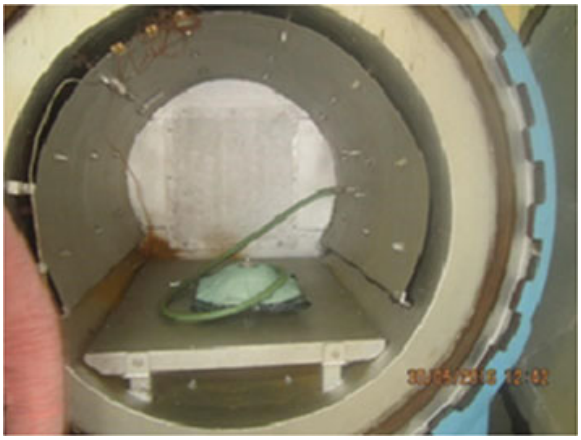

Fig. 58.8 Curing in autoclave machine

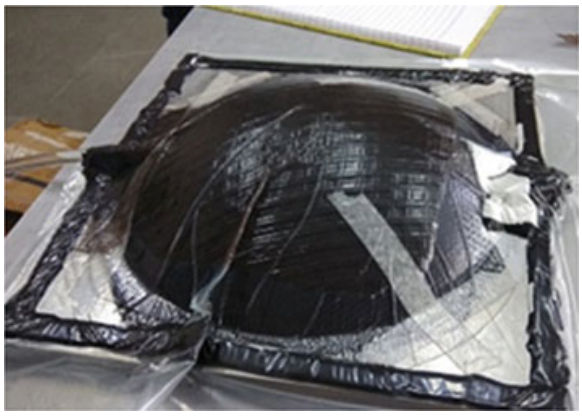

Fig. 58.9 Curing in VARTM process

Fig. 58.10 Autoclave demoulding process and cured reflector

Fig. 58.11 VARTM demoulding process and cured reflector

The entire assembly is taken out from the autoclave machine after the curing process and consolidation materials are detached from the assembly at room temperature as shown in Fig. 58.10. The sequence of demoulding process for VARTM process and final cured reflector is shown in Fig. 58.11.

58.3 Dimensional Measurement Using 3D Scanning

The inner surface of reflectors is selected for dimension measurement and 200 number of coordinate points are identified on this surface. These points are obtained projecting circles of diameter 50, 100, 150 and 240 mm on parabolic surface of the reflector. Measurement of specified points is performed to ensure the accuracy of the parabolic reflector using the 3D scanner. This scanned model of the composite reflector is superimposed with the theoretical CAD model for the same to achieve deviation on each prescribed coordinate points. The deviation at each coordinate point is given using contour plot as shown in Fig. 58.12. The root means square of all 200 points deviations is referred as spring-back deformation for that reflector. The theoretical X, Y and Z coordinates and scanned X, Y and Z coordinates are given in Table 58.1 for autoclave curing, whereas Table 58.2 for VARTM curing process.

The spring-back deformation for the reflector manufactured using autoclave manufacturing process is 0.37 mm, whereas for the reflector manufactured using VARTM process is 0.35 mm. This value has been obtained for the same configuration reflector in each case. The difference between the autoclave manufacturing process and VARTM manufacturing process is around 5%. The different antenna reflectors have been manufactured with different laminate thickness and layup orientations. The 4, 8 and 12 number of layers and unidirectional, cross- and quasi-isotropic layup orientations have been considered. The deviation, i.e. dimensional inaccuracy, is observed and root mean square value is compared from VARTM and autoclave curing process for each case.

58.4 Conclusions

The CFRP antenna reflectors have been manufactured using autoclave and VARTM manufacturing processes with stainless steel AISI 430 mould. Hinpreg A45 uni-directional prepreg tape is used in the autoclave and bi-axial dry fabric with epoxy 520 resin along with hardener D has been used in the VARTM process. The dimension at the inner surface of CFRP manufactured reflectors has been measured

using 3D scanning techniques at 200 different locations. The comparison of spring-back deformation of cured reflectors manufactured using autoclave manufacturing techniques and VARTM process has been carried out. The percentage deviations in spring-back deformation have been found within 5% range so the VARTM process gives more dimensional accuracy compared to autoclave process and VARTM is the cheapest process compare to autoclave process. The effect of laminate thickness and layup orientation has been considered as a process parameter. As laminate thickness increases, the spring-back deformation decreases. The quasi-isotropic layup orientation has minimum spring-back deformation.

Chapter 59
On Finite Element Analysis of Melting of Metallic Powders Using Microwave Energy at 2.45 GHz

Mohit Kumar, Gaurav Kumar and Vikas Kukshal

Abstract Use of microwave energy for processing of materials is gaining vast popularity due to its inherent superior characteristics like reduced processing time, better control on microstructure and enhanced mechanical properties. In this paper, the interaction of the microwave with metallic powder is analyzed using COMSOL Multiphysics software. Further, the effect of particle size on microwave absorption is also been analyzed. Microwave hybrid heating (MHH) technique is used to heat the metallic powder. Initially, metallic powder gets heated conventionally, i.e., through the heat transfer with separator plate and susceptor material. Once the metallic powder reaches the critical temperature, metallic powder starts to absorb the microwave and volumetric heating takes place. Also, the effects of input power on electric field strength and melting time of charge were analyzed. Further, it was found that as the size of the metallic powder particle is reduced, the time required for melting and casting of metallic powder reduces.

59.1 Introduction

The casting process is used to produce products with a wide range of variety in terms of complex shape, size and order quantity [1]. It is the most efficient manufacturing process to overcome complexity. Nowadays, cost, power and time saving are critical issues in the casting process. Microwave heating is a novel process which has a wide range of application in manufacturing processes like sintering, surface modification, casting, joining, drilling and cladding [2–7]. The past studies focused on the heating of metal powder [8, 9], melting [9] and composite casting with graphite mold [10] using microwave energy at 2.45 GHz. It is not possible to heat bulk metal directly using the microwave as bulk metal acts as a reflector to microwave at low temperature. But a recent study has shown that microwave hybrid heating (MHH) can be used to heat bulk metal and consequently, bulk metal can be melted and further cast in graphite mold [4].

Roy et al. [2] reported the microwave sintering process of metal powders (Fe–Ni and Fe–Cu) at a 2.45 GHz frequency and compared MW processed results with

conventionally processed results. Properties like modulus of rupture (MOR), Rockwell hardness and sintered density of MW processed samples are substantially greater than conventional samples. It was reported that similar heating occurred with or without using susceptor, but the presence of susceptor provided rapid heating. Ghosh et al. [3] examined the characterization of microwave-heated aluminum powder (average particle size 25–30 μm with 99.7% purity) by XRD, SEM, TEM, EDX analysis and Fourier transform infrared (FTIR) spectroscopy. EDX analysis and FTIR studied revealed that Al powder transformed into Al–Al_2O_3 core–shell composite powder after the microwave heating process. SEM indicated that the morphology of microwave-processed Al powder was largely different from unprocessed Al powder [3]. Gupta and Sharma [7] developed nickel-based powder (EWAC, the average particle size of 40 μm) cladding on austenitic stainless steel (SS-316) substrate by using a domestic microwave system (1 kW and 2.45 GHz). The cladding was done successfully with an exposure time of 360 s. It was found that average Viker's micro-indentation hardness (304 ± 48 HV) of microwave clad is twice that of the SS-316 substrate (175 HV).

Chandrasekaran et al. [9] investigated the experimental and theoretical results of microwave melting of metals (Pb, Sn, Al and Cu) at 2.45 GHz and different power levels (520, 910 and 1300 W). Also, they compared the results with conventional heating and found that the energy required in microwave heating was half of the conventional heating (muffle furnace) and also processing time was very less as compared to the conventional heating. Singh et al. [10] reported the microwave melting and casting of metallic powders (EWAC or Ni-based powder + SiC) at 900 W and 2.45 GHz through MHH. It was observed that sample of EWAC + 10% SiC metal–ceramic composite casting is approximately 2.64 times harder than the sample of pure EWAC casting. Mishra and Sharma [4] reported the microwave casting of bulk aluminum alloy (AA-7039) by MHH at 1400 W and 2.45 GHz. The whole process was carried out inside the microwave oven cavity, and a new mechanism of in situ microwave casting was proposed. Four different temperature-dependent phases were also found during the study of time–temperature characteristics. Further, it was reported that the mode of heating in each phase was different. The time–temperature plot was validated using simulated data obtained from COMSOL Multiphysics software [11]. It was also reported that AA-7039 cast developed using in situ microwave casting through MHH showed superior property in the cast with less than 2% porosity and ultimate tensile strength of 148.46 ± 10 MPa [12].

The basic objective of the present work-study is to investigate the simulation result of the melting and casting of AA-7039 powder using MHH. The electromagnetic wave, frequency domain and heat transfer in solids were studied in COMSOL Multiphysics 5.2a software tool. The electric field distribution, temperature distribution and time–temperature profile of metallic powder were determined. The effect of input power on the electric field norm inside the microwave oven and melting time of charged or metallic powder were also discussed. In addition, the results showing the effect of particle size on melting time are also reported.

59.2 Modeling and Simulation

59.2.1 Model Development

A three-dimensional model of microwave (MW) casting of aluminum alloy 7039 powder was developed using COMSOL Multiphysics 5.2a software tool. The dimensions of the developed 3-D model of the microwave oven were taken from commercially available LG domestic microwave, and it operates at a power of 900 W with 2.45 GHz frequency source of a rectangular waveguide working in TE_{10} mode. The microwave oven cavity with dimensions of 335 × 335 × 215 mm^3 (W × D × H) and rectangular waveguide with dimensions of 50 × 43 86 mm^3 (W × D × H) were modeled to simulate the casting process. The powder material (particle radius 0.44 mm) was cast into a graphite mold cavity with dimensions of 24 × 45 × 10 mm^3 (W × D × H), and ceramic brick was used as a base of the setup. In the simulation, the MHH technique was used by taking SiC plate as a separator and SiC powder as a susceptor with a 4-mm thickness of both. The chemical composition of aluminum alloy (AA) 7039 used is shown in Table 59.1, and material properties used in the simulation analysis are shown in Table 59.2.

A simplified 3-D model of MW casting of metallic powder is shown in Fig. 59.1. The inset shows the zoomed view of metallic powder. A single sphere particle was generated with a preferred dimension, and an array operation was performed on the sphere particle. A number of particles were added in three dimensions (*X*-, *Y*- and *Z*-axes) by giving offset distance according to the mold dimensions using array operation.

59.2.2 Assumptions

In order to overcome the complexity and to simplify the model, the following assumptions were made:

(a) The ambient temperature and pressure of the system were assumed to be 27 °C and 1 atm, respectively.
(b) The oxidation of powder material and other chemical changes were not considered.
(c) Susceptor powder was taken as bulk metal (plate) to simplify the study.

Table 59.1 Chemical composition of AA 7039 [13]

Element	Zn	Mg	Mn	Fe	Cr	Si	Cu	Al
% weight	4.12	2.88	0.28	0.22	0.22	0.14	0.01	Balance

Table 59.2 Material properties used in the simulation study [11]

Materials	Density (kg m^{-3})	Specific heat at constant pressure (J kg^{-1} K^{-1})	Thermal conductivity (W m^{-1} K^{-1})	Electric conductivity (S m^{-1})	Permittivity	Magnetic permeability	Emissivity
AA-7039 (powder)	2700	$741.56 + 0.5071 \times T$	$238/(0.000011 \times T^{2.30} + (0.124/T))$	$3.774 \times 10^7/(1 + 0.0043 \times (300.15))$	1	1	0.19

(d) The wall of the microwave oven and waveguide were considered as copper metal.
(e) The ceramic bricks and air domain were not considered in the thermal analysis.
(f) The rectangular port was excited by transverse electric (TE_{10}) field in *Z*-direction only.

59.2.3 Governing Equations

A Hewlett-Packard (HP) work system (16 GB RAM) was used for simulation. Finite element-based COMSOL Multiphysics software was used to solve the current problem. The software couples the physics of electromagnetic wave in the frequency domain and heat transfer in the transient domain. Maxwell's equations were used to solve the electromagnetic wave of propagation. The electric field (E) inside the microwave oven is given by Eq. (59.1) [11]:

$$\nabla \times \mu_r^{-1}(\nabla \times E) - k_0^2\left(\varepsilon_r - \frac{j\sigma}{\omega\varepsilon_0}\right)E = 0 \tag{59.1}$$

where μ_r is the relative permeability, E is the time-harmonic electric field ($V\,m^{-1}$), ε_r is the relative permittivity, $j = \sqrt{(-1)}$, σ is the electrical conductivity, ω is angular frequency, ε_0 is the permittivity of vacuum, i.e., 8.85×10^{-12} ($F\,m^{-1}$), and k_0 is the wave number in free space which can be formulated in Eq. (59.2) [11]:

$$k_0 = \omega\sqrt{\varepsilon_0\mu_0} = \frac{\omega}{c_0} \tag{59.2}$$

where c_0 is the speed of light in vacuum. The expression of complex electric permittivity (ε^*) of dielectric material is given by Eq. (59.3) [11]:

$$\varepsilon^* = \varepsilon' - j\varepsilon'' \tag{59.3}$$

where ε' is the dielectric constant $(\mathrm{F\,m^{-1}})$ and ε'' is the dielectric loss factor $(\mathrm{F\,m^{-1}})$. The complex electric permittivity $\left(\varepsilon^*_{\mathrm{m}}\right)$ for metallic material can be expressed as in Eq. (59.4) [14]:

$$\varepsilon^*_{\mathrm{m}} = 1 - \frac{4\pi\sigma_{\mathrm{m}}}{\gamma\left[\left(\frac{\omega^2}{\gamma^2}\right)+1\right]} + j\frac{4\pi\sigma_{\mathrm{m}}}{\omega\left[\left(\frac{\omega^2}{\gamma^2}\right)+1\right]} \tag{59.4}$$

where σ_{m} is the static electrical conductivity of metals, its range for well-conducting metals is $10^{13} - 10^{14}\,\mathrm{s^{-1}}$, and γ is the collision frequency of electrons, $\gamma = 8.5 \times 10^{14}\,\mathrm{s^{-1}}$ (for solid aluminum at room temperature) [15]. In Eq. (59.4), $\left(\frac{\omega^2}{\gamma^2}\right) \ll 1$; therefore, the second term approaches zero for the real part of $\varepsilon^*_{\mathrm{m}} \to 1$. For aluminum, Eq. (59.4) can be expressed as:

$$\varepsilon^*_{\mathrm{m}} = 1 + j\frac{4\pi\sigma_{\mathrm{m}}}{\omega} \tag{59.5}$$

As from the above equation, it is clear that heat dissipated (dielectric loss) in the metallic material depends on σ_{m}. Thus, the dependence of static electrical conductivity of metal (σ_{m}) on temperature (T) is as follows:

$$\sigma_{\mathrm{m}}(T) = \frac{\sigma_0}{1 + \beta(T - T_0)} \tag{59.6}$$

where β is the temperature coefficient of metal and σ_0 is the electrical conductivity of metal at a temperature T_0.

Fourier's energy balance Eq. (59.7) can be used to estimate the microwave (MW) energy dissipation as heat inside the powder material at the time of microwave exposure as [16, 17]:

$$\rho C_P \frac{\partial T}{\partial t} + Q_{\mathrm{Loss}} = Q(r,T) + \nabla.(k\nabla T) \tag{59.7}$$

where C_P is the specific heat capacity $\left(\mathrm{J\,kg^{-1}\,K^{-1}}\right)$, ρ is the density $(\mathrm{kg\,m^{-3}})$, k is the thermal conductivity $\left(\mathrm{W\ m^{-2}\,K^{-1}}\right)$, Q_{Loss} is the heat losses from material inside the microwave, and $Q(r,T)$ is the heat source or microwave (MW) energy

absorbed by the powder material. For metal, it can be expressed as in Eq. (59.8) [16, 17]:

$$Q(r,T)=\frac{1}{2}\left[\omega\varepsilon''_{\mathrm{m}}(r,T)|E(r,T)|^2+\omega\mu''_{\mathrm{m}}(r,T)|H(r,T)|^2+\sigma_{\mathrm{m}}|E(r,T)|^2+\sigma_{\mathrm{i}}|E(r,T)|^2\right] \tag{59.8}$$

where $H(r,T)$ and $E(r,T)$ are the local electromagnetic field vectors at point r and temperature T in (K), μ''_{m} is magnetic loss factor $(\mathrm{H\ m^{-1}})$, $\varepsilon''_{\mathrm{m}}$ is dielectric loss factor $(\mathrm{F\ m^{-1}})$ of metallic materials, and σ_{i} is ionic conductivity of metallic ions in the metal lattice.

59.2.4 Boundary Conditions

Boundary conditions used to approach the real experimental conditions are as follows:

- The impedance boundary condition was used to define the minimum penetration depth of microwave on the wall of the microwave oven and waveguide. This boundary condition is shown in Fig. 59.2a and can be expressed by Eq. (59.9) [11]:

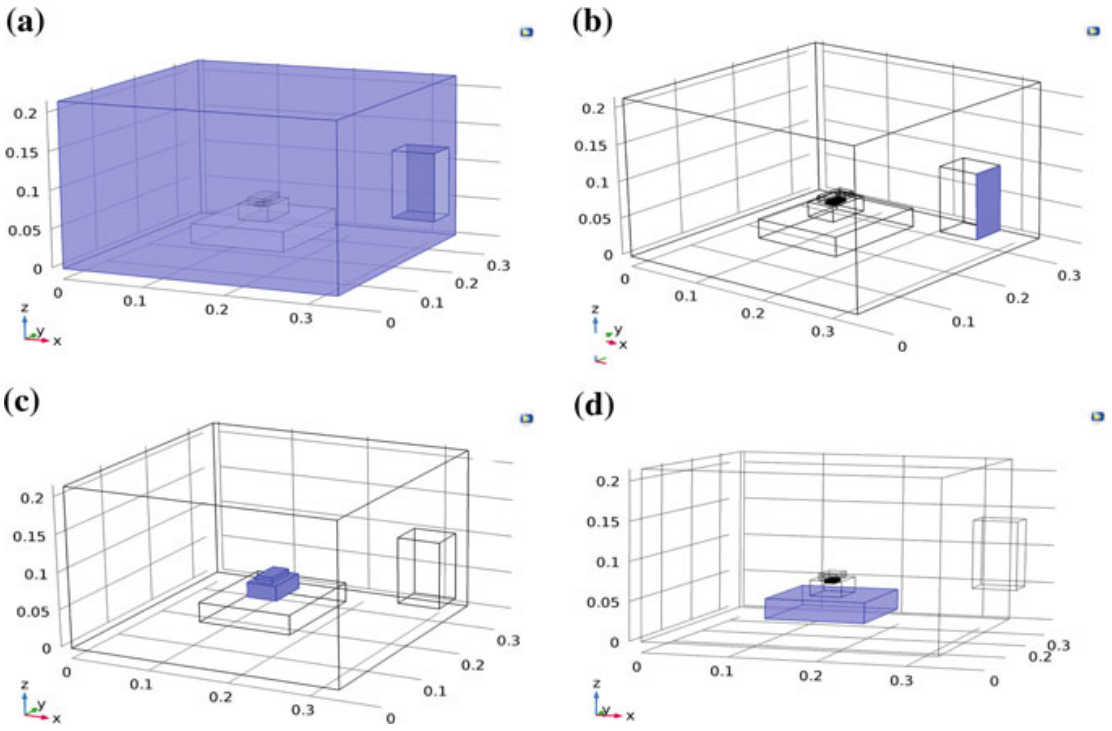

Fig. 59.2 Boundary conditions used in simulation: **a** impedance boundary condition, **b** port boundary condition, **c** heat transfer in solid and **d** thermal insulation

$$\sqrt{\frac{\mu_0\mu_r}{\varepsilon_0\varepsilon_r - j\frac{\sigma}{\omega}}}n \times H + E - (n.E)n = (n.E_s)n - E_S \tag{59.9}$$

where μ_0 is the permeability of vacuum, n is a unit vector which is perpendicular to the surface of the metal boundary, and E_S is the electric field component along the surface.

- A rectangular port boundary was used for wave excitation as the transverse electric (TE_{10}) field. The port boundary condition is shown in Fig. 59.2b. The port boundary condition at a small volume $\partial\Omega$ of edge element (S) is expressed by Eq. (59.10) [11]:

$$S = \frac{\int (E - E_1).E_1\partial\Omega}{\int E_1.E_1\partial\Omega} \tag{59.10}$$

- The heat transfer in solid condition is applied to the powder charge, mold, separator and susceptor as shown in Fig. 59.2c. The thermal insulation boundary condition (i.e., heat flux is zero) is shown in Fig. 59.2d and governed by Eq. (59.11) [11]:

$$-n \times (-k\nabla T) = 0 \tag{59.11}$$

- The heat flux and diffuse surface boundary conditions are applied on the surface of mold, separator and susceptor, which can be expressed by Eqs. (59.12, 59.13) [11]:

$$-n \times (-k\nabla T) = h(T_0 - T) \tag{59.12}$$

$$-n \times (-k\nabla T) = \varepsilon_{rad}\sigma_m\left(T_0^4 - T^4\right) \tag{59.13}$$

where h is the convective heat transfer coefficient and ε_{rad} is emissivity of the radiative surfaces.

59.2.5 Meshed Model

For simulating the above 3-D model, user-controlled mesh was used for meshing. Different types of free tetrahedral mesh like a finer, extra fine and extremely fine were used according to the suitable element size. Figure 59.3 shows mesh quality statistics (the average element quality and average growth rate) of 'finer' (Fig. 59.3a), 'extra fine' (Fig. 59.3b) and 'extremely fine' (Fig. 59.3c) mesh element sizes. The average element quality was good in case of extremely fined mesh with a low growth rate. The meshed model of microwave casting is shown in Fig. 59.4.

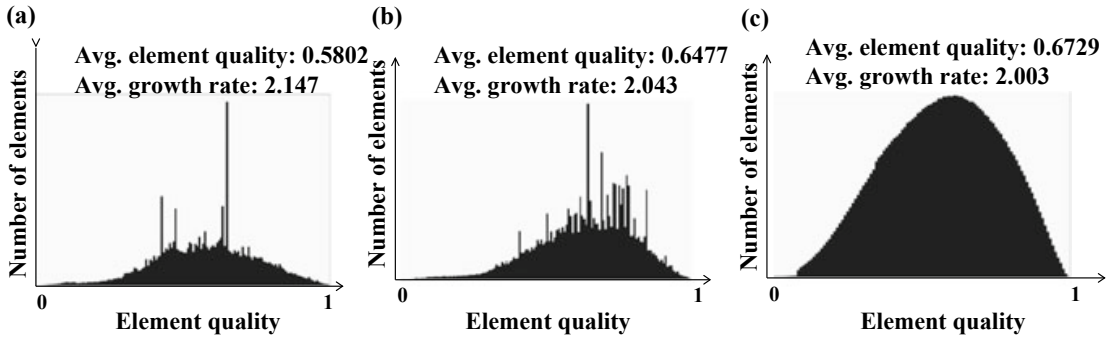

Fig. 59.3 Element quality comparison of **a** finer, **b** extra fine and **c** extremely fine element size

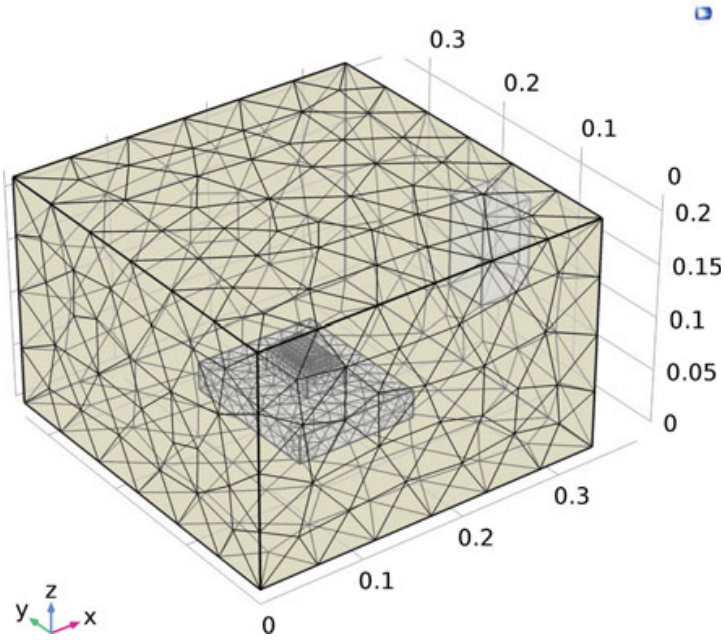
Fig. 59.4 Meshing of the experimental model



59.3 Results and Discussion

59.3.1 Electric Field Distribution and Temperature Distribution

The electric field distribution inside the microwave oven is shown in Fig. 59.5a. The energy is transmitted to the cavity at a power of 900 W and a frequency of 2.45 GHz. The distribution of the electric field is non-uniform inside the cavity because of the node and antinode formations due to the fluctuation of the electric field. So, the experimental setup should be kept precisely at a dense area of the electric field as it may affect the microwave absorption and hence, the energy required to melt the charged particle may be different.

As the electric field travels through dielectric materials like SiC plate and SiC powder, dielectric material starts to absorb it. This results in heating of dielectric

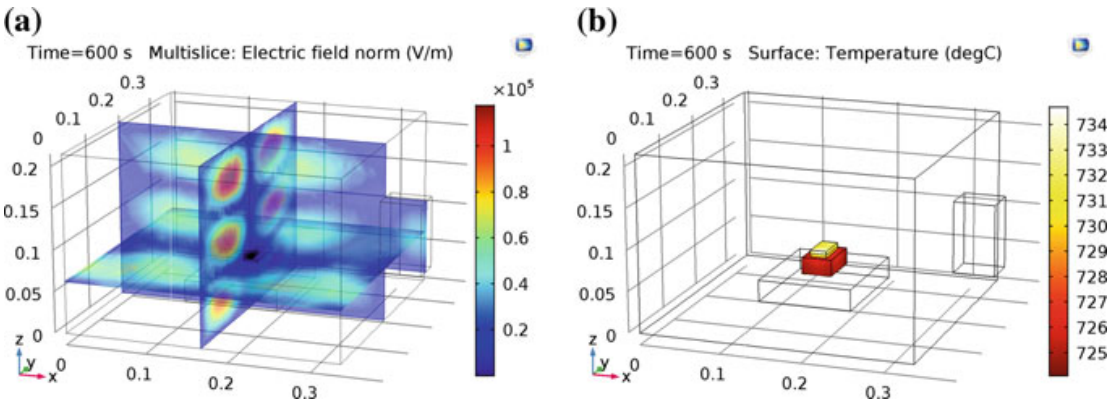


Fig. 59.5 **a** Electric field distribution inside the microwave oven and **b** temperature distribution

material. Initially, SiC powder couples with microwave radiation, starts heating up and transfers heat to SiC plate. SiC plate and graphite mold also start absorbing microwave and get heated rapidly, but charged powder absorbs very less microwave. Initially, the charged powder gets heated by conventional mode of heat transfer through SiC plate, susceptor and graphite mold. Once, the temperature of charged powder reaches up to a critical point, powder particles start absorbing microwave radiation and get heated by both conventional heating and microwave heating. The temperature increases rapidly with respect to the time, and melting of charged particles takes place. This heating phenomenon is known as microwave hybrid heating (MHH). This melted material is solidified and cast in a graphite mold.

The surface temperature distribution of heat transfer in the solid domain is shown in Fig. 59.5b. It is evident from the temperature distribution that temperature rise of SiC powder (susceptor) and SiC plate (separator) is more as compared to the metallic powder and graphite mold. This is due to the high dielectric constant, i.e., relative permittivity of SiC as compared to the metal as shown in Table 59.2. The time–temperature graph of charged powder is shown in Fig. 59.6. Initially, the heating rate of the charged powder is high but after reaching the melting point heating rate decreases. The melting of charged powder starts within 400 s, and after that temperature becomes constant. It can also be seen from Fig. 59.6 that slope of curve, i.e., rate of heating, increases after a certain time duration. This is the time duration after which powder particles start to absorb microwave radiation.

59.3.2 Effect of Input Power

The variation in input power affects the electric field norm inside the microwave oven and consequently affects the melting time of charged powder as shown in Fig. 59.7. The input power was varied 700–1300 W with step size 200 W with an exposure time of 600 s. It is observed from the figure that the maximum electric

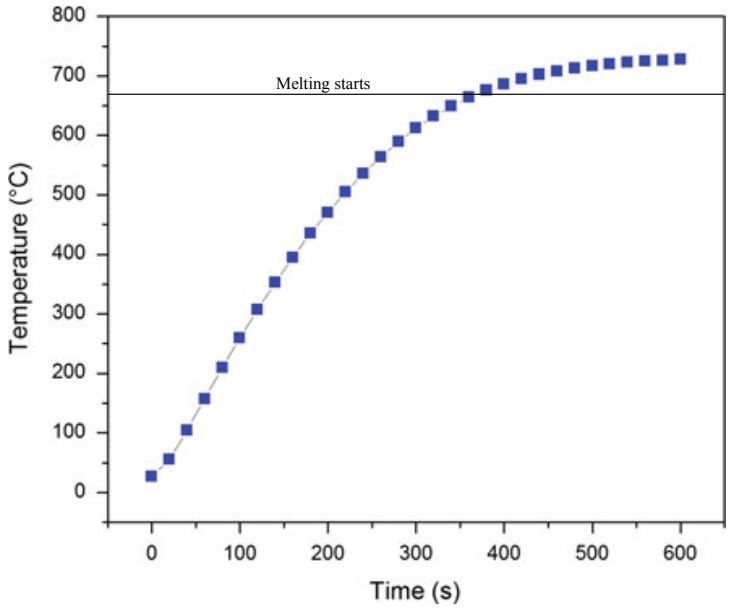

Fig. 59.6 Time–temperature graph at 900 W

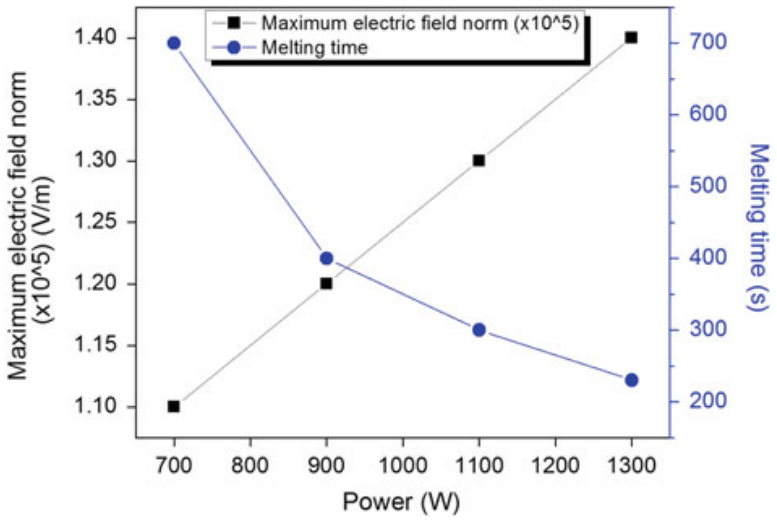

Fig. 59.7 Effect of power on electric field norm inside and the maximum temperature inside the charge

field norm inside the microwave increases linearly with input power. This happens because power absorbed inside the material is directly proportional to the electric field strength (Eq. 59.8). Also, the melting time of charged powder decreases with an increase in input power. The maximum electric field norm value varies from 1.1×10^5 to 1.4×10^5 V/m, and melting time decreased from 700 to 230 s by rising the input power from 700 to 1300 W, respectively.

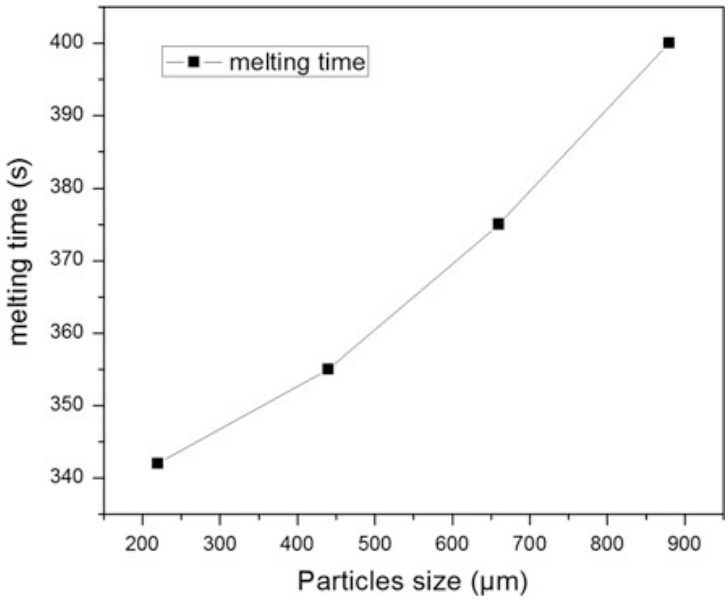

Fig. 59.8 Effect of powder particles in terms of melting time

59.3.3 Effect of Size of Powder Particles

Figure 59.8 shows the variation in melting time of charged powder with variation in particle size at 900 W. As the AA 7039 powder size reduces, the melting time of the charged powder reduces. Thus, it indicates that smaller-sized particles have higher microwave absorption capacity [18]. Microwave gets absorbed inside the material up to a particular depth called skin depth. As the particle size is reduced, the effective surface area which interacts with microwave increases and consequently, factors like Joule loss increase which increase the microwave absorption capacity [12, 19].

59.4 Conclusion

A 3-D microwave oven setup was modeled to find the precise location of experimental setup inside the cavity. COMSOL Multiphysics software tool was used successfully to simulate the microwave hybrid heating (MHH) of AA 7039 powder at a rated power of 900 W and 2.45 GHz frequency. Following are the conclusions based on the above study:

- It was observed that the experimental setup should be placed at the high magnitude or dense area of the electric field.
- It was found that the melting of the metallic powder achieved within 400 s and temperature rises to −730 °C in 600 s at the power of 900 W.
- It was observed that higher is the input power, more is the electric field norm, consequently reducing the melting time of charged powder.

- From the simulation results obtained, it can be concluded that decreasing the powder particle size results in more absorption of microwave energy and hence the time required for melting and casting of metallic powder reduces.

Acknowledgements The authors would like to express sincere gratitude to Prof. Apurbba Kumar Sharma for allowing and doing the simulation work using COMSOL Multiphysics in Microwave Material Processing Laboratory, IIT Roorkee.

Chapter 60
Tribological Behaviour of Nylon 6 Composites and Optimization of Process Parameters Using Hybrid Taguchi-GRA and CSA

Sudhir Kumar, Barnik Saha Roy and K. Panneerselvam

Abstract Friction and wear are the main causes observed by manufacturing industries which lead to the replacement of components. The objective of the present work is to investigate the tribological behaviours of Nylon 6 and glass-filled (GF) Nylon 6 composites using a pin-on-disc configuration. Pin materials were fabricated by injection moulding machine and tested for friction and wear against 320 grit size silicon carbide (SiC) sandpaper. The effect of the different load (N), glass-filled content (wt%) and sliding distance (m) were studied for the coefficient of friction (COF) and specific wear rate (SWR). Analysis of variance (ANOVA) procedure was used to find out the percentage contribution of process parameters (load, sliding distance and varying glass-filled content) with the COF and SWR. Process parameters were optimized by hybrid Taguchi-grey relational analysis (GRA) and cuckoo search algorithm (CSA). There is a close relationship between COF and SWR with wear mechanisms.

60.1 Introduction

Polymer matrix composites (PMCs) are replacing traditional metals and unfilled polymers due to their superior properties such as intrinsic lubrication property and wear resistance with low processing cost [1]. The application of polymer composites is mostly in sliding components in the food and chemical industry like gears and cams. This may be mainly attributed to the Nylon having inherent lubrication behaviour which avoided the use of oil lubrication [2]. Ramesh and Suresh carried out friction and wear test of polymer composites and observed grit size dominant factors followed by applied load and sliding distance [3]. Grey relational analysis (GRA) may be used to convert multiple objective optimization problems to a single objective problem [4–6]. Yang and Deb [7] investigated a new evolutionary and population-based algorithm cuckoo search for optimizing process parameters. Cuckoo search is based on the breeding behaviour of cuckoo birds. The study on hybrid Taguchi-GRA and CSA for multi-criteria optimization in tribological process parameters is very rare. The aim of present work is to investigate the friction and wear characteristic of Nylon 6 and glass-filled Nylon 6 composites against the abrasive paper. There is a close relationship between COF and SWR with wear mechanisms.

60.2 Materials and Methods

The material selected in this investigation for pin specimens was glass-filled Nylon 6 (0, 10, 20 and 30 wt%) in the form of granules as shown in Fig. 60.1. Injection moulding machine was used to fabricate the Nylon 6 composite specimens for mechanical (UTS, impact strength and hardness) and tribological test. The mould temperature was maintained at 240 °C. The size of stationary GF Nylon 6 pin specimen was 6 mm-diameter and 31 mm-length according to ASTM G99-05. Schematic illustration of the pin-on-disc set-up is shown in Fig. 60.2. Track diameter of the disc (320 grit size sandpaper) was 40 mm. The Taguchi technique is a powerful tool to optimize process parameters. The process parameters used for the experiment are presented in Table 60.1. Grey relational analysis is used to convert multi-objective (COF and SWR) into a single response optimization problem.

Cuckoo search (CS) is an evolutionary and population-based approach that mimics the breeding behaviour of cuckoo birds. The preliminary experiments show the promising results of this approach in the field of search and optimization. The idealized steps of CS can be stated as follows:

(1) Every cuckoo bird lays an egg on the randomly selected nest.
(2) The number of nests (agents) and eggs (individuals) in each nest is fixed.
(3) Nest with the high quality of eggs (elite members) is passed on to the next generation.

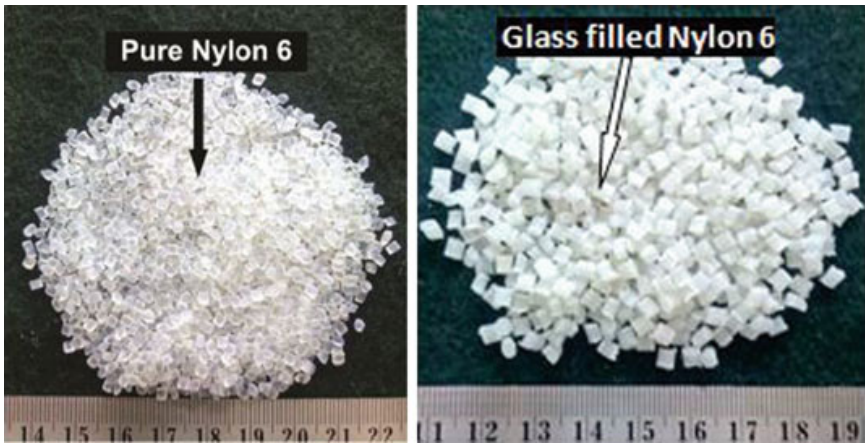

Fig. 60.1 Pure Nylon 6 and GF Nylon 6 (granule form) [1]

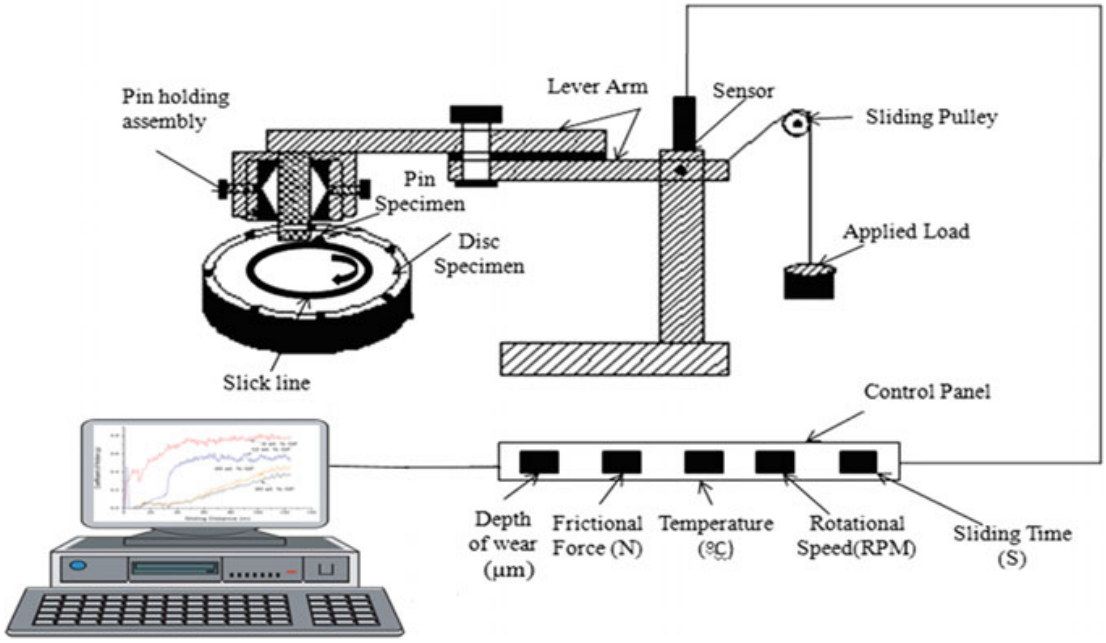

Fig. 60.2 Experimental set-up of pin-on-disc [8]

Table 60.1 Process parameters and their levels

Factor symbol	Control factors	Levels			
		1	2	3	4
A	Glass filled (wt%)	0	10	20	30
B	Load (N)	5	10	15	20
C	Sliding distance (m)	125	250	375	500

(4) If the host bird discovers an alien egg based on the external characteristics of an egg such as colour and spots, then host bird either throws the alien egg away or builds an entirely new nest at the new location.

For feature selection, the host nest n is defined as an agent containing multiple eggs (or individuals) called population. Each egg is represented as a binary string, with a 1 for inclusion of feature (or attribute) and a 0 for the exclusion of feature. Step 4 is implemented by maintaining the index of the worst nest and replacing it with better individuals. Levy flight is a random walk and named after French Mathematician Paul Levy, in which steps are defined in terms of step length having a probability distribution that is heavy-tailed. The direction of the steps in Levy flights can be isotropic or random. Various studies demonstrated the flight behaviour of many insects and animals based on Levy flights. In the past decade, these behaviours have been applied in optimization and optimal search and found to yield promising results [5–7].

60.3 Results and Discussion

The mechanical characterization includes evaluation of impact strength, UTS and hardness of the composites that are presented in Table 60.2. The UTS increased as to increase the GF wt% presented in Table 60.2. This may be attributed to the better distribution of GF and superior adhesion among the Nylon and GF. The hardness (shore D) increased as to increase the GF wt% as shown in Table 60.2. This may be attributed to brittleness character of GF. Nylon 6 material has high impact strength due to ductile nature and flexibility of the interface molecular chain resulting in absorbing more energy presented in Table 60.2. The impact strength increased as to increase the GF wt%. The improvement in impact strength of composites is due to good bonding strength between matrix and reinforcement. The experiments were conducted using L_{16} orthogonal array details which are shown in Table 60.3.

60.3.1 Effect of GF Content, Load and Sliding Distance on COF

The variation of COF w.r.t different sliding distances is depicted in Fig. 60.3. The load shared by both glass filled and Nylon 6 during sliding as depicted in Fig. 60.4, the major part of the load supported by GF resulting COF decreased. In the case of pure Nylon 6, the COF was observed more; however, further increase in glass-filled COF decreased due to rubbing of glass filled on the abrasive paper as shown in Fig. 60.5.

The COF of the Nylon 6 composites decreases as to increase load. This may be mainly due to the increase in heat generation of the surface of the specimen and contact zone of pin specimen. At 5 N load, the thermal motion of molecules of polymer observed weak, this may be because the heat generation at contact zone was low, then plastic deformation of polymer molecule cannot respond to load, and thus COF is relatively high. At 9.8 N loads, as the heat generation increases molecular segment of polymer movement gradually increases, then plastic deformation of polymer molecule can respond to load, and thus the corresponding COF gradually decreases. At 15 N loads, the heat generation increases molecular segments likely to move freely, the plastic deformed polymeric material at contact zone of pin and disc forms a low shear strength interfacial film which acts like as lubricant, and thus COF again decreases as shown in Fig. 60.5. The COF decreases

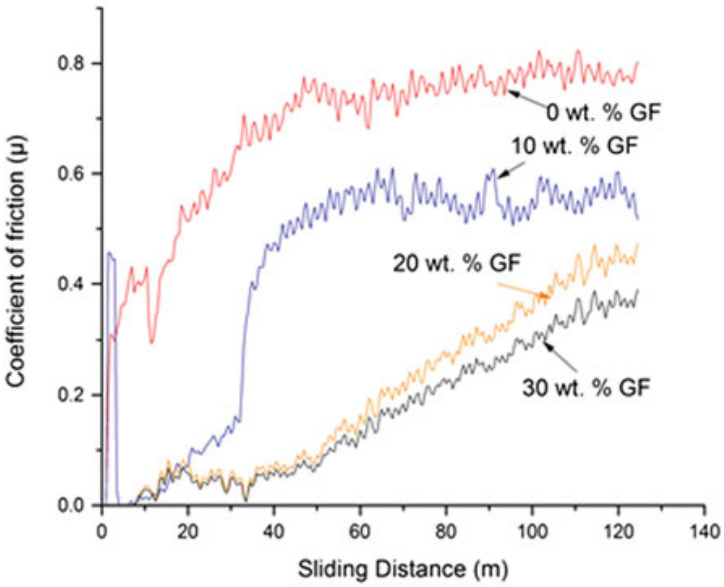

Fig. 60.3 Relation between sliding distance and coefficient of friction irrespective of load

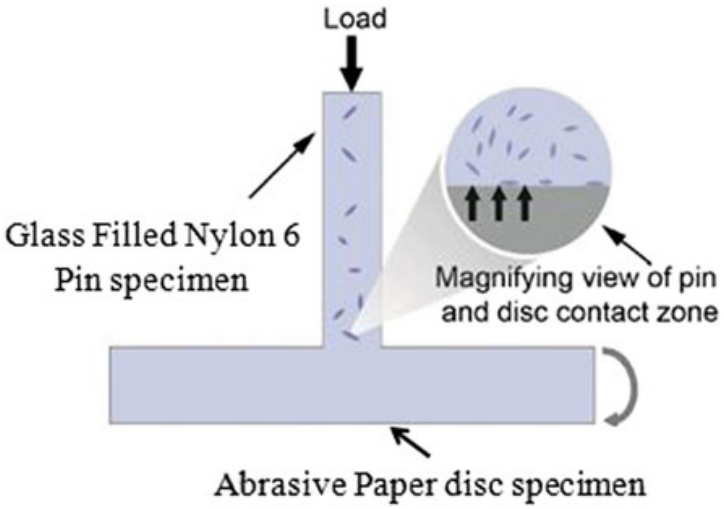

Fig. 60.4 Schematic representation of load sharing between GF and Nylon 6 [8]

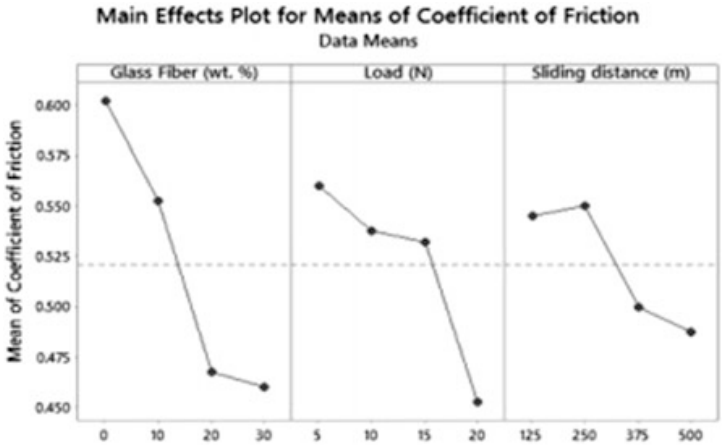

Fig. 60.5 Relation between process parameters and COF

with an increase in sliding distance for Nylon 6 composites. This may be mainly attributed to pin specimen slides over the same wear track, thus resulting in less effect of abrasiveness. Similar trends are found by other researchers [8, 9].

60.3.2 *Effect of GF Content, Load and Sliding Distance on SWR*

The values of SWR are observed from 0.0161 mm^3/Nm to 0.1189 mm^3/Nm. In the case of Nylon 6, SWR was very high and when glass filled increased then SWR decreased. When glass filled increases hardness and strength increases, so wear resistance improved. During sliding, load shared by glass filled and Nylon 6 is depicted in Fig. 60.4. This may be mainly attributed to improved wear resistance. The SWR decreases as an increase in load for Nylon 6 composites as shown in Fig. 60.6. Similar trends were found by other researchers [8, 9].

The variation of SWR w.r.t different sliding distances at a different GF is depicted in Fig. 60.8. The SWR of Nylon 6 composites decreased as an increase in the sliding distance. This may be mainly attributed to the repetition of the pin on same wear track gap on emery paper filled by debris.

60.3.3 *Grey Relational Analysis and Implementation of Cuckoo Search Algorithm*

The grey relational analysis results are shown in Table 60.3. The optimum parameter combination for minimum COF and SWR is shown in Fig. 60.7. ANOVA was done for grey relational grades, and the results are presented in Table 60.4. It was observed that glass filled has the dominant factor followed by load and sliding distance.

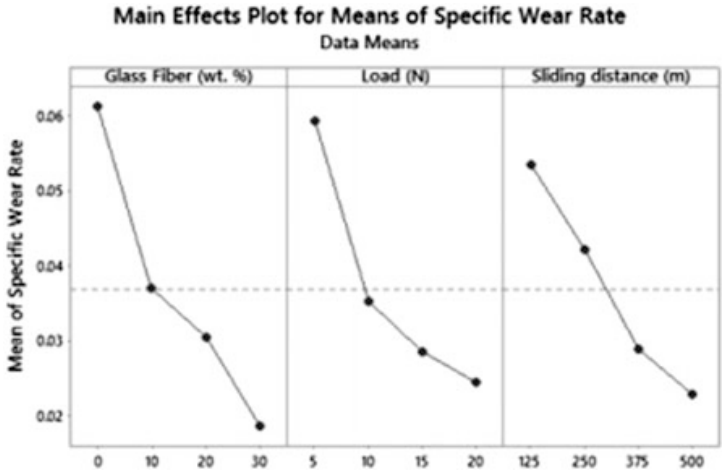

Fig. 60.6 Relation between process parameters and SWR

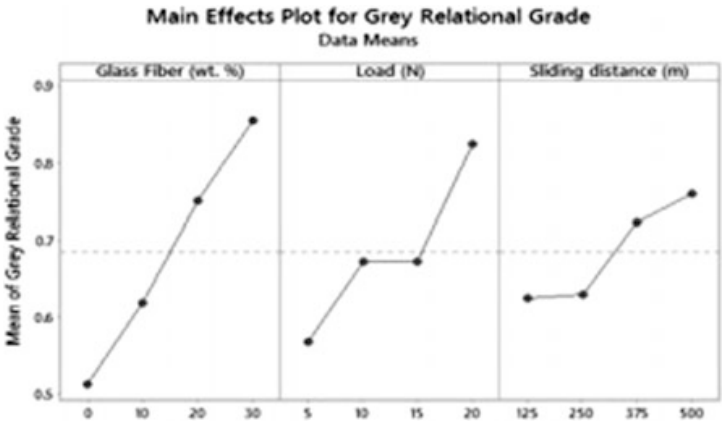

Fig. 60.7 Effect of control factors with their levels for GRG

Table 60.4 Analysis of variance of grey relational analysis

Source	DOF	Adj. SS	Adj. MS	F-cal.	P-value	% contribution
Glass filled (wt%)	3	0.26	0.08	129.85	0.000	57.92
Load (N)	3	0.13	0.04	65.07	0.000	29.02
Sliding distance (m)	3	0.05	0.01	27.25	0.001	11.74
Residual error	6	0.00	0.00	–	–	1.32
Total	15	0.46	–	–	–	–

Lower and upper limits of the parametric constraints are $0 \leq$ glass filled (wt%) ≤ 30, $125 \leq$ sliding distance (m) ≤ 500, $5 \leq$ load (N) ≤ 20. The cuckoo search parameter values are the number of nests $n = 25$, discover rate = 0.25, number of iteration = 100. Figure 60.8 shows the objective obtained during minimization for all iterations. It was revealed that firstly, the value of the objective function is at a higher value and as the iteration progresses, the objective function

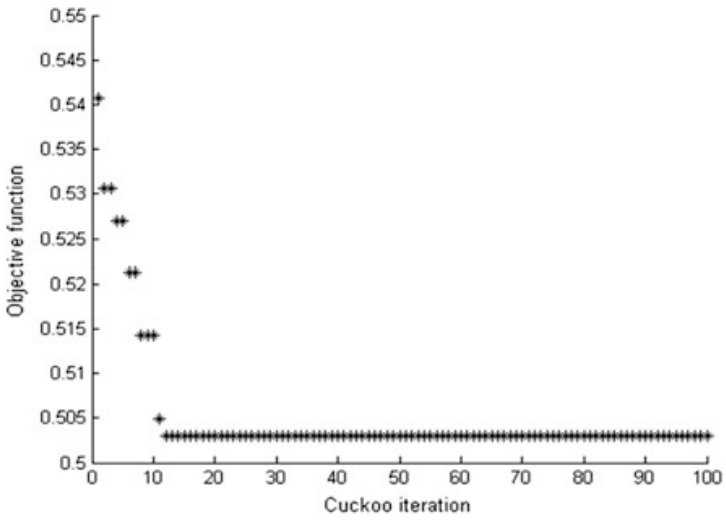

Fig. 60.8 Variation of objective function with iterations

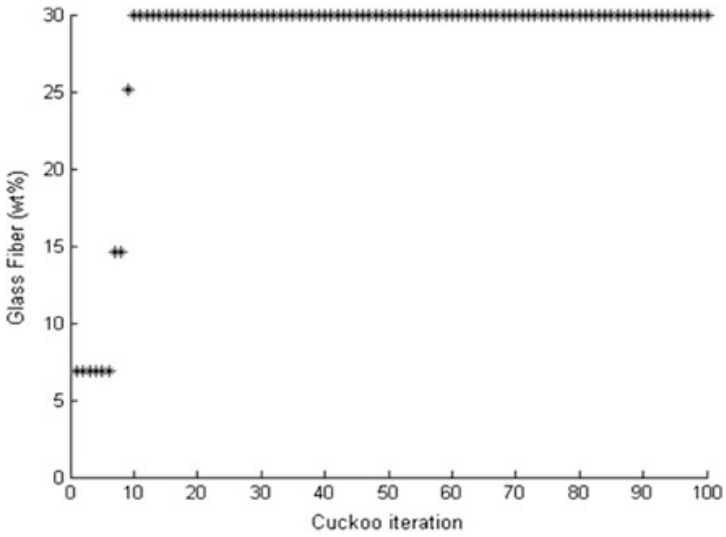

Fig. 60.9 Variation of glass filled with iterations

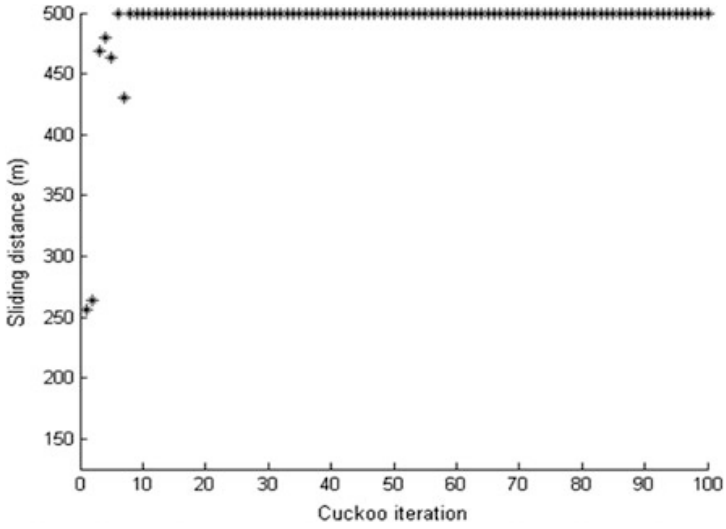

Fig. 60.10 Variation of sliding distance with iterations

values converge quickly. The best solution obtained is the objective function value of 0.5030 for glass-filled content of 30 wt%, sliding distance 500 m and load of 20 N for lower COF and SWR as shown in Figs. 60.9, 60.10 and 60.11.

60.3.4 Confirmation Tests for CSA

With the identified optimal process parameters of glass-filled content of 30 wt%, sliding distance of 500 m and load of 20 N, a confirmation experiment was conducted as shown in Table 60.5.

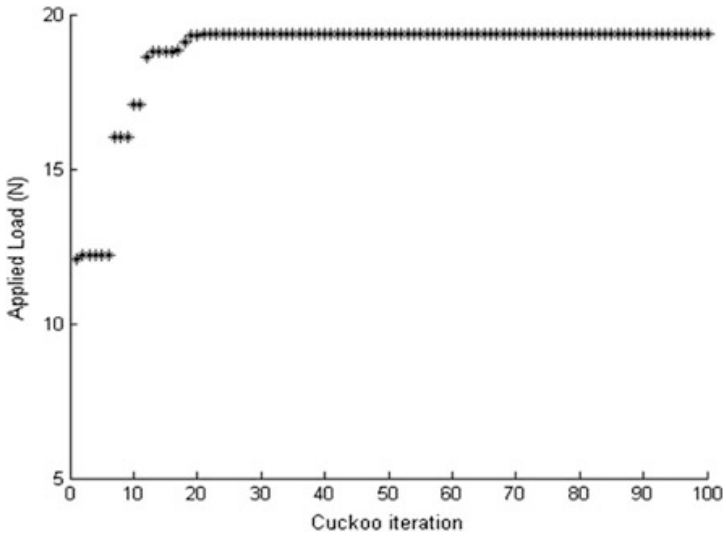

Fig. 60.11 Variation of load with iterations

Table 60.5 Measured responses of confirmation experiment for cuckoo search

	Optimal parameters	
	Prediction	Experiment
Parameter levels	$A_4B_4C_4$	$A_4B_4C_4$
COF (μ)		0.43
SWR (mm^3/Nm)		0.010
Grey relational grade (GRG)	0.988	0.967
Objective function = 1/(1 + GRG)	0.5030	0.5083

60.3.5 Worn Surface Morphology

Figure 60.12 shows a schematic illustration of abrasive wear mechanism. Figure 60.13a shows typical micrograph of unabraded counter-face of 320 grit size SiC abrasive paper. In case of low sliding distance, repetition of the pin over the wear track is less so clogging of abrasive wear debris is observed low as shown in Fig. 60.14a. However, in the case of 500-m sliding distance repetition of the pin over the wear track is more resulting in less effect of abrasiveness as shown in Figs. 60.13b and 60.14b. Consequently, decrease COF and SWR. Plastic deformation, micro-cracking and micro-cutting are the dominant wear mechanisms found in case of pure Nylon 6. This may be mainly attributed to more frictional heat generated at contact zone as shown in Fig. 60.15a. However, in the case of glass-filled Nylon 6, polymer softening decreased as depicted in Fig. 60.15b. This may be mainly attributed to the load shared by glass filled and Nylon 6 as shown in Fig. 60.4. Typical micrograph of 30 wt% GF Nylon 6 at 20 N shows more damage worn surface which results in de-bonding of the glass filled from the matrix. Consequently at 5 N, worn surface observed mild wear. Wear mechanism shows a good correlation with the trend of COF and SWR (Fig. 60.16).

60.4 Conclusions

From the experimental investigation, the following conclusions have been drawn:

- The present study demonstrated successful fabrication of glass-filled Nylon 6 composites using injection moulding.
- Glass-filled Nylon 6 improves the mechanical (hardness and tensile strength) and tribological properties (COF, weight loss and SWR).
- The weight loss of Nylon 6 composites increases as load increases; however, the addition of glass filled decreases the weight loss.
- The COF and SWR of glass filled Nylon 6 composites decreases as increase glass filled content and least achieved at 30 wt%.

- On the basis of ANOVA, glass filled content 57.92%, sliding distance 11.74% and load 29.02% exerts a significance influence on multiple responses.
- Cuckoo search shows that 30 wt% glass-filled content, 20 N load and 500 m sliding distance combinations of factor give the best solution.
- In case of Nylon 6 plastic deformation, micro-cracking and micro-cutting are dominant wear mechanisms; however, glass-filled Nylon 6 reduces these defects. The worn surface is characterized by the direction of abrasion.

Chapter 61
Fabrication of Hexagonal Bar from Aluminum Alloy AA6063 Scrap by Frictional Stir Back Extrusion on Milling Machine

Gizaw Yohannes, Habtamu Beri and Perumalla Janaki Ramulu

Abstract Friction stir back extrusion (FSBE) is a novel and an efficient method of manufacturing sounded products by using specialized tool in one step (without melting of scrap). It can be saved about 40% of material, 26–31% of energy consumption, and 16–60% of labor costs compared with conventional extrusion. The main aim of this study is fabrication of hexagonal bar from aluminum alloy scrap by FSBE. The material used for this study is AA6063 as a scrap and H-13 tool steel as a die. Considered parameters were chamber rotational speed and vertical die transverse speed as major parameter on conventional milling machine. This work has proved the feasibility to extrude hexagonal-shaped bar by using FSBE by fixed die and rotates chamber. So far, none of the researchers carried out experiment by fixed die and rotate chamber in FSBE, and also no one applied FSBE to produce other than circular shape. Aluminum hexagonal-shaped bar is used as a supporter in medical and marine industry, as a raw material to the mass production of hexagonal head aluminum nut and bolt, Allen wrenches, etc. Extruded bar was defect-free, non-blurred grain boundary, and clear surface than the base material. The result showed that the compression strength of extruded sample was higher than the base material. The optimum rotational speed of chamber to produce hexagonal bar with the minimum twist angle is 250 rpm and transverse speed 6.25 mm/min. If the rotational speed increases, twist angle also increased.

61.1 Introduction

Friction stir extrusion (FE) was developed by The Welding Institute (Cambridge, UK) in the early 1990s. It was derived from friction stir processing as a process of forming or reforming ceramic/metal composite material. Over the past two decades, significant amount of work had done on multiple aspect of friction stir process. Along with the rapid development of automotive, aerospace, and manufacturing industry in recent years, novel technologies like near-net shape manufacturing, additive manufacturing, solar energy jet, and fuel cell battery plays a critical role in producing safe, economical, and durable products. Friction stir extrusion process can meet this need as an innovative and economical material processing method as it directly converts metal wastes without melting to useful products. Compared with traditional manufacturing processes, it has more efficient, green, energy saving, and environmentally friendly technologies [1]. Friction stir extrusion relies on extensive plastic deformation and basic frictional heating, consolidates, and extrudes the small block, chips, and scrap directly into functional form. For example, direct recycling aluminum can save about 40% of material, 26–31% of energy consumption, and 16–60% of labor costs. The friction extrusion process falls into the category of direct recycling methods and it has all the advantages [2].

Aluminum and its alloys had received much attention in aerospace, automobile, and construction industries; due to their high strength-to-weight ratio, good formability, excellent corrosion resistance, low maintenance, good toughness, and high strength-to-weight ratio [3]. Tang and Reynolds [4] applied friction stir extrusion (FSE) technology and produced fully consolidated wires from aluminum alloy AA2050 and AA2195 machining chips. The fully equiaxed recrystallized microstructure in extruded wire was observed by optical microscopy. But, neither the trend of compression properties nor hardness test has been discovered. Abu-Farha [5] applied the derivative of FE which is called frictional stir back extrusion to produce sounded, defect-free aluminum alloy AA6063-T52 tube. A rotating tool is plunged into aluminum round bar specimens at a selected feed rate, forcing the processed material radially outward and thus forming tubes. Khorrami and Movahedi [6] fabricated the aluminum tubes by using a novel process of friction stir back extrusion and also investigated in detail the microstructural evolution as well as the mechanical properties of the formed tube. Behnagh et al. (2014), produced fully consolidated wires from aluminum alloy AA7277 machining chips by the friction stir extrusion. Components were stationary cartridge and a rotating plunger with a scroll-faced head. Hangai et al. [7] fabricated the AA1050 tubes filled with ADC12 foam by frictional stir back extrusion and foam able precursor was coated on the surface of the inner wall of the fabricated tube.

Babu et al. [8] carried out the hardness properties of friction stir processed AZ31 magnesium alloy wire at different processing conditions. The parameters were studied at the three different traveling speeds: 20, 30, and 40 mm/min with two different rotation speeds 600 and 800 rpm. The smallest precipitate size is obtained at spindle speed and feed rate combination of 800 rpm and 40 mm/min. Mechanical characterization and manufacturing of square bar was made of aluminum scraps through friction stir back extrusion process using a conventional lathe machine [9]. Baffari et al. [10] investigated the effect of process parameters and initial temper of the base metal on the wire quality by frictional stir extrusion. They considered rotational speed and vertical applied force. Extrusions were carried out with varying rotational speed (100, 200, and 300 rpm) and extrusion force (26.7, 35.6, 44.5, and 53.4 kN). Die and tool machined from H-13 tool steel and billet AA2050 chip and best sounded wire fabricated by 35.9 kN and 100 rpm are optimum. Although many researchers have done on frictional stir welding, frictional stir extrusion and channeling, some researchers experimentally proved frictional stir back extrusion by rotating the die and fixed chamber to produce tube, wire, rod, and c-channel. But no one applied frictional stir back extrusion to produce hexagonal-shaped bar which was proposed in this work. No work has been reported in the area of studying mechanical properties like hardness and compression strength of aluminum alloy AA6063 friction extruded bar, which was carried out in the present work.

61.2 Materials and Methodologies

The materials used to perform this work are as follows

- H-13 tool steel die and chamber
- Aluminum alloy billet
- 210 mm length M16 × 2 bolts
- Three-jaw chuck
- Rotary table
- T-headed bolt

The equipment to facilitate the friction stir back extrusion (FSBE) to produce hexagonal bar were adjustable wrench, chuck jaw Allen key, file and silicon carbide paper, small hammer, and box wrench. Table 61.1 shows the equipment and their specification used for the FSBE.

Universal Milling Machine

In the below Table 61.2, the maximum and minimum torque of milling machine was calculated by keeping other parameters constant. The specification of the milling machine was as indicated in Table 61.2.

Table 61.1 Machinery used for experiment and sample test

61.2.1 Design and Fabrication of Die and Chamber

Geometrical Design of Die and Chamber
The 3D modeling was made before manufacturing die and chamber. Figure 61.1a, b shows the surface of chamber and scroll-faced die with hexagonal-shaped center hole.

Chemical Composition of Aluminum Alloy Billet
The chemical composition of aluminum alloy billet was tested using spectrometer instrument. The obtained chemical composition of billet is shown in Table 61.3 and identified as AA 6063 alloy.

Figure 61.2 shows the scrap of aluminum alloy which was used for the FSBE to produce the hexagonal bars.

61.2.2 Process Parameters of Milling Machine to Fabricate Hexagonal-Shaped Bar

The process parameter like die rotational speed and plunge rate were varied by keeping die, chamber, plunge diameters, and contact land length of die parameters constant. The selected rotational speed was 200, 250, 315, 400, 500, and 630 rpm and with transverse speed 12.5 mm/min as shown Table 61.4. The range of rotational speed and plunge rate were considered based on previous research work [2]. The process parameters of frictional stir extrusion were optimized and decided the

Table 61.4 Friction stir back extrusion process parameters

Test number	Die rotational speed (rpm)	Transverse speed of milling table (mm/min)
1	200	6.25
2	250	6.25
3	315	6.25
4	400	6.25
5	500	6.25
6	630	6.25

plunge rate 14 mm/min, hole size 5 mm, and initial contact land length was 2 mm to produced sounded wire [7].

Within the above given rotational speed and transverse speed, the experiment was performed.

61.2.3 Consolidation and Extrusion Period of Time

Friction consolidation is the period of time that compacted the scrap material with in cavities of chamber and maximized density of chips and scrap. The combination of high temperature and plastic deformation to be made the scrap material highly compacted. Friction extrusion is the whole process that includes consolidation, stirring, and extrusion by using scroll- or spiral-shaped die feed to the center plasticized material. The local temperature of extruded material increased up to 0.6–0.9 T_m [11]. In this experiment, the transverse feed was given by manually up to consolidate aluminum alloy scrap by above 0.6 T_m and engaged automatic feed

after consolidate of material. The extrusion period was taken 1.28 min to each sample using automatic feed.

61.2.4 Fabrication of Hexagonal Bar

Specimen Fabrication Procedure

To produce sample bar, the prepared scrap was compacted within cavities of chamber using small-sized ball pen hammer. This pre-compact process was used to increase the length of output hexagonal bar. Then the compacted chips and scrap were taped by a circular disc 40 mm diameter and 5 mm thickness. The taper disc was made from the same aluminum alloy the chips made of to hold the scrap and increases friction between scroll-faced die up to consolidate. It was turned by lathe machine at high-speed steel cutter. To produce hexagonal sample bars, the compacted chamber with scrap was installed on the spindle of milling machine and also die was fixed milling machine table with proper alignment as indicated in Fig. 61.3. The consolidation time depends on rotational speed of chamber. Then after chips are plasticized automatic transverse gear engaged. In this process the machine table moved up 6.25 mm distance per one minute. Then after the sample bar extruded, the die was removed by engaging the clash downward to change feed direction.

61.3 Results and Discussion

61.3.1 The Fabricated Die and Chamber

The scroll-faced die and one side cavity chamber are the basic equipment in friction stir back extrusion (FSBE). The function of this die and chamber is to consolidate, stir, and extrude aluminum scrap. To resist wear occurrence in the process of stirring and hexagonal-shaped sample bar production, it should be heat treated. The color looks like black after heat treatment as Fig. 61.4.

61.3.2 Extruded Samples at Different Speeds and Discussion

Figure 61.5 shows the samples fabricated at different rotational speed and their shapes at each rotational speed. For example, sample one is extruded at 630 rpm and 6.25 mm/min, sample two 500 rpm and 6.25 mm/min, etc.

Figure 61.5 shows the possibilities of FSBE to fabricate hexagonal-shaped bar and other shapes from aluminum alloy scrap. Most of extrudes twisted and circular shapes. The reason of twist is, in FSBE die shape, machine power and extruded material properties affects the shape, length, and mechanical properties of extrudes. Sample one is performed at the rotational speed of 630 rpm and transverse speed of 6.25 mm/min. In this process parameter, the extruded product is resulted with large twisting angle almost like a circular rod shaped. This sample is longer than the other and is about 280 mm in length and circular in shape due to higher rotational speed. The rotational speed played an important role and contributed 71.6% to the overall extrusion parameters. If the rotational speed increases, the possibility of consolidated aluminum to be changed into liquid form is high. In this time, the die land length must be done longer than the other because it takes few second to solidify for melted aluminum. To this work, the die center hole depth (hexagonal shape former) was 2 mm. the much-plasticized aluminum extrude out immediately by not formed hexagonal shape. It made circular shape due to high rotational speed and shortage of depth of hexagonal shape formed hole.

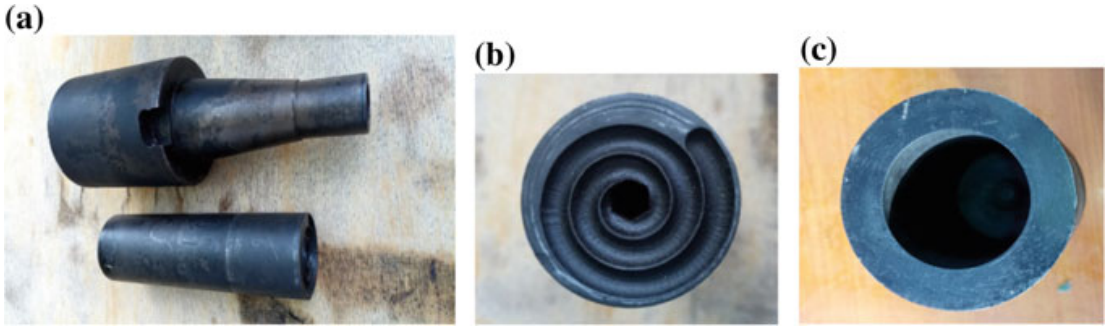

Fig. 61.4 Surface of die and chamber (**a**), spiral face of die, (**b**) and cavities of chamber (**c**)

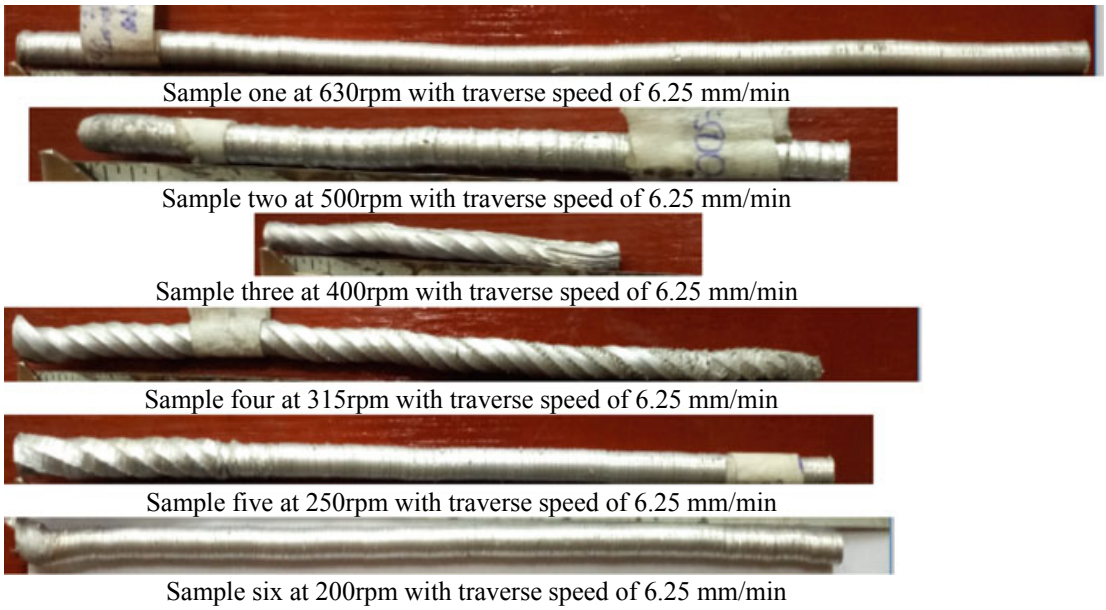

Fig. 61.5 Samples extruded by FSBE at different rotational speed

Sample two also almost the same shape to sample one, it is some hexagonal form related with sample one. It has been performed by rotational speed of 500 rpm and constant transverse speed 6.25 mm/min. The consolidate time took 5 min and extrusion time 1.28 min and the result is shown in Fig. 61.5 as 10.5 mm length and 6 mm diameter extrudes by friction stir extrusion. As explained above in sample one, rotational speed changed also resulted in shape change of the extruded products. The solution to this problem is design and manufacture die by deepened on each rotational speed of chamber. And also die center shape formed hole depth varied (means above 2 mm). Similarly, the other samples are manufactured at different process parameters as shown in Table 61.4.

Conclude to all the above discussion, the optimum rotational speed was 250 rotational speed and 6.25 mm/min transverse speed. In the case of surface smoothness, the optimum rotational speed was 325 rpm and the consolidation time also affects the physical properties of sample or hexa-bar (Table 61.5).

Table 61.5 Duration of scrap consolidation and extrusion time at each rotational speed

Sample No.	Rotational speed	Transverse speed (mm/min)	Consolidation time (min)	Extrusion period (min)
1.	630	6.25	5	1.28
2.	500	6.25	7	1.28
3.	400	6.25	7	1.28
4.	315	6.25	8	1.28
5.	250	6.25	9	1.28
6.	200	6.25	10	1.28

61.4 Conclusions

Defect-free sounded hexagonal-shaped bar has been fabricated by using FSBE process from aluminum alloy 6063 scrap. The considered process parameters are constant transverse speed 6.25 mm/min and variable rotational speed (200, 250, 315, 400, 500, and 630 rpm) of milling machine FU-281. From this interval of rotational speed, the accurate hexagonal-shaped bar obtained at 250, 315, and 400 rpm and all others are completely circle.
